- Comments were received from the DTSC on the May 2014 Final FS on 24 June 2014 and a response was issued 1 July 2014.

A summary table of comments received through September 2012 from the DTSC and their responses is included as Appendix A. Subsequent comments and responses after September 2012 are also provided in Appendix A.

This report was prepared by Ms. Rebecca Flynn Oliver, P.E., of Geosyntec and reviewed by Mr. Gregory Corcoran, P.E., of Geosyntec, in accordance with Geosyntec's peer review policy.

1.2 Description of Feasibility Study Process

The Remedial Investigation (RI) for the Site comprises three separate reports: the *Revised Draft Remedial Investigation Report* (Stantec, 2008); the *Draft Memorandum – Data Gap Analysis* (Stantec, 2010a); *Draft Human Health Risk Assessment* (HHRA) (Geosyntec, 2010); and the *Addendum to the August 22, 2008 Revised Draft 2006 Remedial Investigation Report* (Stantec, 2010c). This FS Report includes the following information and evaluations in general accordance with *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (USEPA, 1988):

- Background information on the Site, including a summary of investigative and remedial work performed to date;

- Future use of the Site, future risk exposure pathways, and receptors that may be at risk;
- Remedial Action Objectives (RAOs) and cleanup criteria;
- Identification of remedial technologies that potentially can be employed to remediate the Site contaminants;
- Screening of the remedial technologies to identify those that can realistically remediate or isolate wastes at the Site;
- Development of a range of potential remedial technologies to address impacted soil, soil gas, and groundwater, and remedial alternatives, which are combinations of remedial technologies that can address impacted media at the Site;
- Screening of the remedial alternatives to identify those that can realistically address conditions at the Site;
- Analysis of remedial alternatives using United States Environmental Protection Agency (USEPA) criteria; and
- Comparative analysis of remedial alternatives that will result in identification of the preferred remedial alternative for the Site.

1.3 Organization

This document is organized into the following sections:

- Section 2 – "Site Background," describes the history and physical characteristics of the Site, including hydrogeology;
- Section 3 – "Remedial Investigation Summary," summarizes the results of the remedial investigation;
- Section 4 – "Remedial Action Objectives and Cleanup Criteria," summarizes the findings of the draft HHRA and identifies the potential future use of the Site, future risk exposure pathways, and potential receptors that may be at risk. The RAOs also are identified, along with cleanup criteria selected to achieve those objectives;
- Section 5 – "Identification and Screening of Technologies," identifies potential remedial technologies. The remedial technologies are then screened based on their effectiveness, implementability, and cost to address human health risks and ecological risks associated with these media;
- Section 6 – "Development of Remedial Alternatives," uses the retained technologies from Section 5 to compile remedial alternatives that address a range of potential response actions and technical approaches for the Site.

Remedial alternatives are further screened, evaluated and ranked in terms of effectiveness, implementability, and cost to identify the final set of remedial alternatives for detailed analysis;

- Section 7 – "Detailed Analysis of Alternatives," presents a nine-criteria analysis of the final set of remedial alternatives;
- Section 8 – "Comparative Analysis of Alternatives," uses the nine-criteria analysis results to compare the alternatives to assess which alternative provides the best balance of the nine criteria, and is, therefore, the recommended alternative; and
- Section 9 – "References," presents the FS Report references.

Tables, figures, and appendices are included at the end of this FS Report. Appendices attached to this FS Report include the following:

- Appendix A contains the responses to regulatory comments. Comments up to September 2012 are provided in Table A-1; copies of subsequent response to comment letters are also provided in Appendix A;
- Appendix B contains the Treatability Study prepared by Stantec and provided in the Remedial Investigation (Stantec, 2008);
- Appendix C contains the derivation of the risk-based concentrations;
- Appendix D contains calculation packages for the high-strength geotextile and anchor trenches;
- Appendix E contains estimated construction schedules for Alternatives 2A through 4; and
- Appendix F contains the Conceptual Design of the Alternative 2A with the Optional Alternative 2A cover.

2. SITE BACKGROUND

2.1 General

This section includes the following background information on the Site:

- Site location and description;
- Site history;
- Geology; and
- Hydrogeology

The information presented in this section generally has been excerpted from the *Revised Draft RI* (Stantec, 2008).

2.2 Site Location and Description

The Site is located in the southwest corner of the Artesia Boulevard and Normandie Avenue intersection in the City of Gardena, Los Angeles County, California (Figure1-1). Generally, the area surrounding Site is bordered to the south by the Los Angeles County Department of Public Works (LACDPW) Dominguez Flood Channel, to the east by the Southern Pacific Railroad right-of-way, to the west by the western Haack property line, and to the north by Artesia Boulevard, although a small portion of Artesia Boulevard is included within the Site. Commercial and residential properties are currently located to the north, east, and west of the Site (Figure 1-2) (Stantec, 2008). For the purpose of this report, the Site is comprised of the Cooper, Haack, and four (4) residential properties as shown on Figure 1-2.

The Site is greater than 5.6 acres of mixed-use development and primarily consists of two properties, the Cooper property and the Haack property. The Cooper property is approximately 3.0 acres, approximately 90 percent of which is comprised of two large sumps (referred to as the "Cooper North" and "Cooper South" sumps) containing primarily petroleum refining wastes. The Haack property is approximately 2.6 acres, contains one modified sump (referred to as the "Haack sump") and the "Haack Rework Area", which is a reworked and mixed soil-sludge area south of the Haack sump. The Haack Rework Area encroaches onto the extreme northern portions of the two easternmost residential lots. In this FS Report, the wastes in the sumps will be referred to as "sludge" for ease of reference. This FS Report will address the three sumps and the Haack Rework Area, constituting the areas of concern (Figure 1-2) (Stantec, 2008).

2.3 Site History

The *Revised Draft RI* documents the site history and presents historic aerial photographs. The following section summarizes the site history and evaluation of the photographs presented by Stantec (Stantec, 2008).

Early topographic maps show that the eastern (Cooper property area) and southern (southern Haack and residential areas) portions of the Site were elevated, which suggests that some amount of clay material could have been extracted from excavations into the elevated bluff.

During the 1920's, the Moneta Brick Company leased the Site. By 1928 the area of the two Cooper sumps had been excavated to a lower surface elevation than the current LACDPW land to the south and most of the Haack and residential properties. The railroad tracks east of the Cooper property were elevated above the land surface of the current Cooper property, and clay mining at the Cooper property had been completed by this time. Clay mining operations were occurring on the northern Haack property in 1928 and 1929. By 1929 the southern portion of the Haack property (present Haack Rework Area) had an elevated scoured slope. This elevated area sloped eastward towards the land surface of the current southern Cooper property. Boring logs from RB-2 and RB-3 indicate that fill material (including brick and concrete debris and glass) extended to elevations of approximately 8 feet above mean sea level (amsl) (depths of 17 to 20 feet below the scoured slope surface) in portions of the Haack Rework Area. An aerial photograph from May 1938 documents that creation of the disposal sumps at the Site had not yet begun. Denys Goddard purchased the land consisting of the current Haack, Cooper, and residential properties in May 1939.

Newspaper reports indicate that sludge disposal had commenced by March 1940. The Haack Sump, Cooper South Sump, and the Haack Rework Area had been constructed and contained sludge by March 1941. The Cooper North Sump had not yet been constructed. By early December 1941 the eastern and northern berms of the Cooper North Sump had been constructed and initiation of sludge disposal into this sump had commenced. Sludge deposition at the Site had occurred at the Haack Sump, the Haack Rework Area, a small pit between these two locations (constructed after March 1941), and the Cooper South Sump by this time.

By September 1946, the Haack and two Cooper sumps were filled with sludge, and vegetation had reclaimed the small pit and the Haack Rework Area. Some excavation of soil had occurred into the bluffs west and south of the western portion of the Haack Sump, but there had been no further development of the Haack and Cooper properties. Denys Goddard sold the future Haack and Cooper property parcels to Wendell and

Golda Hopkins in March 1947, but maintained ownership of the residential lots. The Hopkins' sold their property to S&L Manufacturing in January 1948.

By December 1951, the western portion of the Haack Sump had been covered with dirt and was converted to a parking lot. The eastern portion of the Haack Sump does not appear to have been altered. A significant portion of the bluff south and southwest of the Haack Sump had been excavated. This excavation activity removed the small sludge pit that was located between the Haack Sump and the Haack Rework Area. Two structures had been constructed in the northwestern portion of the Haack property. The Haack Rework Area remained vegetated and the two easternmost residential lots (on the Goddard property) had structures on them.

On October 1, 1952, S&L Manufacturing sold the northern-most strip of their property to the State of California for a highway easement. By early 1956, Artesia Blvd (Highway 91) had been constructed with the southern portion of the roadway encroaching into the Haack Sump northern berm.

By January 1958, the Dominguez Channel had been reconstructed and extended eastward south of the Site. A third structure (the "administrative building") had been constructed on the Haack property at the southern edge of the parking lot. The Cooper property had not significantly changed since 1951. The two westernmost residential lots had structures on them by this time. In May 1958, S&L Manufacturing sold the current Haack and Cooper properties to Charles Warfel. Warfel then sold the current Cooper property to William Ward in January 1959 and the Haack property to Clarence and Genevieve Haack in May 1960. In late 1960, the City of Gardena annexed the area of the Site from the County of Los Angeles.

By November 1962 significant changes had occurred at the Haack property. The bluff immediately south of the "administrative building" had been excavated back to the present day cut-bank (located west of boring HPB11). This excavation expanded the parking lot south of the "administrative building." The parking lot on the Haack property appeared to have been paved, although the eastern portion of the Haack property remains a vegetated area immediately west of the Cooper North Sump. The Haack Rework Area appeared altered and may have received soil cover from the excavation activities that occurred immediately north of the Haack Rework Area. The future Cooper property was unchanged. William Ward sold his property to Thomas Cooper in December 1977.

The two Cooper sumps currently are capped by a geosynthetic liner that was installed by OHM Corporation (OHM) in July 1993 as part of the DTSC's environmental program at the Site. A second geosynthetic liner was installed above the 1993 liner by ARC in August 2013 (Stantec, 2014). The Haack Sump has been covered by asphalt

and a concrete slab. Currently the Haack property is leased to various tenants who operate small businesses, including a U-Haul rental agency, a metal fabricating, sand blasting and painting company, and an auto body repair shop. Three buildings and numerous small trailer-type storage structures are present on the Haack property.

2.4 Geology

The following discussion is based on California Department of Water Resources (CalDWR) Bulletin No. 104, Planned Utilization of the Ground-water Basins of the Coastal Plain of Los Angeles County, Appendix A — Ground Water Geology, dated June 1961, reprinted April 1988 (CalDWR, 1961) and discussions contained in reports from previous investigations (CalEPA 1994, URS 1994, and Stantec, 2008).

The Site is located in the Los Angeles Coastal Plain and is underlain by a thick sequence of marine and continental sediments that were deposited in a broad synclinal depression. This depression is generally referred to as the Los Angeles Basin. The Los Angeles Basin is bisected by the northwest trending Newport-Inglewood uplift, which divides the Coastal Plain into two smaller synclinal troughs. The Site is located in the West Coast Basin, which constitutes the southwest portion of the Los Angeles Basin.

The Site is located near the junction of the Torrance Plain and the Dominguez Erosion Gap. The Torrance Plain runs west of and parallel to the hills of the Newport-Inglewood uplift from the Ballona Gap southeast to the Dominguez Gap. The Plain is a broad featureless area only slightly dissected locally by the Dominguez Creek (Dominguez Channel).

According to boring logs in the Ecology and Environmental, Inc. (EEI) (1986), Metcalf and Eddy (1992), CalEPA (1994) and URS (1994) reports, sediments underlying the Site, to the maximum explored depth of 92 feet below ground surface (bgs), consist primarily of a mixture of clays and silts with interbeds of sand. Copies of the available boring logs from these previous studies are provided in Appendix F and summarized in Table 13 of the *Revised Draft RI* (Stantec, 2008). This stratigraphy correlates in general with the observed conditions in borings completed in conjunction with the *Revised Draft RI* (Stantec 2008), which reached a maximum depth of 100 feet bgs.

2.5 Hydrogeology

The following discussion is based on CalDWR *Bulletin No. 104, Planned Utilization of the Ground-water Basins of the Coastal Plain of Los Angeles County, Appendix A - Ground Water Geology*, dated June 1961, reprinted April 1988 (CalDWR, 1961) and discussions contained in reports from previous investigations (CalEPA 1994, URS 1994, Stantec, 2008).

The Site is located in what is known as the West Coast Groundwater Basin. The West Coast Groundwater Basin has existing beneficial uses for municipal and domestic supply wells, agricultural supply, industrial process supply, industrial service supply, and aquaculture (LARWQCB, 1994). This basin is hydraulically isolated from other, larger groundwater basins in the Coastal Plain by the regional Newport-Inglewood Fault. The Site is underlain by Holocene and late-Pleistocene Age alluvial and marine deposits, which include the Bellflower Aquiclude at the ground surface, and the Gardena and/or Gage Aquifers of the Lakewood Formation beneath the aquiclude. Major underlying aquifers (beneath the Lakewood Formation) are the Lynwood and the Silverado Aquifers of the San Pedro Formation.

The uppermost defined unit within the basin, and the unit that the Site is located within, is the Bellflower Aquiclude. Regionally, the Bellflower Aquiclude contains interfingered zones of permeable and less permeable sediments. The zones with modest to relatively high hydraulic conductivity consist of fine to coarse sand with gravel and silty sand. These coarser grained sediments vary in thickness from 10 to 60 feet and are not laterally continuous. However, in some areas, these permeable zones can contain significant amounts of water. Little beneficial use is made of water in these shallow, discontinuous hydraulic zones because well yields tend to be low and water quality generally poor (CalDWR, 1961).

The Gardena/Gage, Silverado, and Lynwood Aquifers are all capable of storing or conveying groundwater in significant quantities and constitute major sources of groundwater in the West Coast Groundwater Basin. The Lynwood and Silverado Aquifers are primary sources for domestic water supply, while the Gardena and Gage Aquifers are a secondary domestic water supply source. Neither the Gardena nor Gage Aquifers are currently pumped for domestic use. The intervening finer-grained aquitards have not been named. These aquitards, including those that separate the Gardena and Gage Aquifers from the Lynwood Aquifer and the Lynwood Aquifer from the Silverado Aquifer, are discontinuous in nature and absent in some areas.

Immediately beneath the Site, there are two hydraulic groundwater zones within the Bellflower Aquiclude: Zone A (upper) and Zone B (lower), which are approximately 15 to 25 and 75 to 80 ft bgs, respectively. Site groundwater monitoring wells are screened within these two zones. General groundwater chemistry analyses were performed at the Site to evaluate if a hydraulic interconnection exists between Zone A and Zone B due to the existence of a downward vertical gradient between the two zones. The groundwater chemistry analysis indicated that the two zones are characterized by different groundwater geochemistry. The concrete lined Dominguez Channel influences the flow direction of the shallow Zone A groundwater southward while the deeper Zone B groundwater has a flow direction to the east – southeast. Groundwater monitoring at the

Site over the past seven years indicates that COCs are not migrating vertically or laterally over any significant distance from the locations of the waste material.

The area surrounding the Site is urbanized, with surface waters that drain via storm drains into the Dominguez Channel. The Dominguez Channel is a concrete-lined flood-control structure immediately south of the Site. The upstream portion of the modern day Dominguez Channel originates several miles west-northwest of the Site, and it drains surface water to the southeast where it discharges to the Cerritos Channel of the Los Angeles Harbor. Surface water at the Site generally drains towards the north and east following site topography, and is intercepted by a flood control storm drain located at the northeast corner of the Site adjacent to the intersection of Artesia Boulevard and Normandie Avenue.

Historically, the Dominguez Channel flowed along a natural channel bed located approximately several hundred feet west and north of the Site where it flowed eastward into Laguna Dominguez. Presently the shallow groundwater beneath the Site is influenced by the concrete lined Dominguez Channel and flows southward.

3. REMEDIAL INVESTIGATION SUMMARY

3.1 General

The nature and extent of hydrocarbon and metal impacts at and surrounding the Site have been evaluated through several investigation programs conducted since 1982. Sludge, soil, surface water, groundwater, and soil vapor have been investigated. The following sections provide a summary of findings for each of these media. Details of the investigations and findings can be found in the *Revised Draft RI* (Stantec, 2008) and the *Addendum to the Revised Draft RI* (Stantec, 2010c).

3.2 Nature and Extent of Contamination

3.2.1 Soil/Sludge

As part of the RI investigation, Stantec collected over 300 subsurface soil and sludge samples from beneath and surrounding the sumps and rework area to delineate the vertical and horizontal extents of continuous (nonreworked) sludge and sludge-induced impacts to the adjacent soil. The samples were analyzed for organic and inorganic constituents. In addition, pH was measured to determine the effects of the sludge on the soil pH near the sumps and adjacent berms. Organic constituents analyzed were: volatile fuel hydrocarbons (VFHs), total extractable hydrocarbons (TEHs), volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), and polynuclear aromatic hydrocarbons (PAHs). Inorganic constituents analyzed were: Title 22 metals, mercury, and hexavalent chromium.

Sludge constituents are as follows (Stantec, 2008):

- **VFH and TEH**: Heavier hydrocarbon compounds predominate in the sludge.
- **VOCs**: Most commonly detected include ethylbenzene, p-isopropyltoluene, naphthalene, toluene, 1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, and m-, o-, p-xylene compounds.
- **Non-PAH SVOCs**: Not typically detected in sludge samples due to the dilution factor necessary to analyze the sludge samples.
- **PAHs**: The most predominant PAH compounds include benzo(a)-pyrene, benzo(b)-fluoranthene, chrysene, fluoranthene, phenanthrene, and pyrene.
- **Title 22 Metals**: Background, offsite soil, onsite non-reworked soil, and sludge samples were collected during the RI. Antimony, barium, cadmium, vanadium, and zinc were all reportedly lower in the sludge when compared with background soil, while lead and molybdenum were higher in the sludge when compared to background soil. Arsenic and thallium concentrations were similar

in the sludge and background soil while copper had a wider range (higher and lower) of concentrations in sludge compared to background soil. During the 2006 RI field investigation, arsenic was detected in background soil on the LADPW property at 82 milligrams per kilogram (mg/kg). Sampling was performed during the subsequent 2009 RI field investigation at this location and immediate vicinity and resulted in arsenic concentrations of less than 5.5 mg/kg; therefore, the 82 mg/kg concentration could not be confirmed (Stantec, 2010a). Isolated areas on the Haack property had significantly higher concentrations of antimony, arsenic, chromium, copper, molybdenum, nickel, and zinc than typically found at the Site (Stantec, 2010c).

- **Chromium VI**: Analytical results for hexavalent chromium and total chromium in sludge ranged from <0.026 to 0.73 mg/kg and 0.55 to 4.7mg/kg, respectively. Analytical results for hexavalent chromium and total chromium in background soil ranged from <0.026 to 1.3 mg/kg and 6.0 to 28 mg/kg, respectively. One background 2006 soil sample was suspect for hexavalent chromium, having hexavalent chromium and total chromium values of 100 mg/kg and 33 mg/kg respectively (Stantec, 2008; Geosyntec, 2010). Subsequent resampling of this location resulted in hexavalent chromium and total chromium values of <1.0 mg/kg and 17 mg/kg respectively; therefore, the 2006 hexavalent chromium test result of 100 mg/kg is suspect (Geosyntec, 2010).
- **pH**: The pH of the sludge samples ranged from 0.39 to 9.05 while pH of the background soil averaged 6.57 (Stantec, 2008). The 2009 RI activities included an assessment of pH in soil adjacent to the sludge. Results of testing indicate pH ranges from 5.2 to 10.3 in soil adjacent to the sludge (Stantec, 2010a).

During the RI, four areas of sludge disposal were investigated: the Cooper South Sump, the Cooper North Sump, the Haack Sump, and the Haack Rework Area. The delineation of nonreworked sludge is shown on Figure 1-2 and illustrates the lateral extent of congruent sludge having any thickness. Below is a summary of the results of the delineation (Stantec, 2008):

- **Cooper South Sump**: The Cooper South Sump has an identified maximum thickness of 13.5 feet. Figure 10A of the *Revised Draft RI* (Stantec, 2008) illustrates the general vertical profile of this sump. Vertical attenuation of sludge impacts in soil typically ranged from 1.5 to 3 feet beneath the sludge; lateral impacts of sludge in soil are negligible. Approximately 6,700 cubic yards (CY) of sludge was calculated by Stantec to be in the Cooper South Sump (Stantec, 2010c). Approximately 8,000 CY of sludge containing soil interbeds was calculated by Stantec to be in the Cooper South Sump (Stantec, 2008).
- **Cooper North Sump**: The Cooper North Sump has an identified maximum thickness of 17.5 feet. Figure 10A of the *Revised Draft RI* (Stantec, 2008)

illustrates the general vertical profile of this sump. Vertical attenuation of sludge impacts in soil typically ranged from 5 to 7.5 feet beneath the sludge, with the exception of one boring where chrysene was detected up to 11 feet beneath the sludge. Some TEH and PAH constituents were detected approximately 6 feet laterally from this sump in depths up to 15 feet bgs indicating some lateral migration in soil to the north; however, other borings indicated lateral impacts of sludge in soil is negligible. Stantec calculated approximately 7,000 CY of sludge is in the Cooper North Sump (Stantec, 2010c). Approximately 9,300 CY of sludge containing soil interbeds was calculated by Stantec to be in the Cooper North Sump (Stantec, 2008).

- **Haack Sump**: The Haack sump consists of several discontinuous layers of sludge varying in thickness from 0.5 to 3.0 feet to a depth up to 14.6 feet bgs. Boring logs indicated the western and central areas of the sump had been reworked, possibly during site development in the late 1940's. Figure 10B of the *Revised Draft RI* (Stantec 2008) illustrates the general vertical profile of this sump. Stantec calculated approximately 2,250 CY of sludge is in the Haack Sump (Stantec, 2010c). Approximately 2,900 CY of sludge containing soil interbeds was calculated by Stantec to be in the Haack Sump (Stantec, 2008).
- **Haack Rework Area**: The Haack rework area consists of deposited sludge, soil, and debris in discontinuous and mixed layers beneath a soil cover with thickness varying from less than 1 foot to 10 feet. The thickness of sludge in the western portion of the Haack Rework Area is thinner and occurs at a higher elevation than at the eastern edge of the Haack Rework Area. Figures 10E and 10F of the *Revised Draft RI* (Stantec, 2008) illustrate the general vertical profile of this area. Stantec calculated approximately 670 CY of sludge material is in the Haack Rework Area (Stantec, 2010c). Approximately 1,200 CY of sludge containing soil interbeds (soil-sludge material) was calculated by Stantec to be in Haack Rework Area (Stantec, 2008).

Delineation borings were conducted at several specific areas of the Site. The results of the sampling are provided in the *Revised Draft RI* (Stantec, 2008) and summarized below:

- **Eastern LACDPW Easement**: Borings were performed to determine if sludge had migrated offsite onto the LACDPW property east of the Cooper property. The 2006 delineation borings encountered sludge within 6 inches bgs in all five delineation borings (Stantec, 2008). Subsequent delineation borings were performed in 2009 east of the 2006 delineation borings which delineated the extent of the continuous sludge shown on Figure 1-2 (borings DPW116 through DPW121 and GWP102) (Stantec, 2010a).

- **East-Central Haack Property (Former Drum Storage Area)**: Sampling of the former drum storage area on the Haack property was performed in 2006 to determine if metal concentrations in soil were elevated when compared to background soil concentrations. Elevated lead concentrations were detected at a depth of 1.5 feet in all four borings, but lead concentrations were in the range of background at a depth of 5 feet. Elevated concentrations of antimony, arsenic, copper, and molybdenum were detected in one boring at a depth of 1.5 feet. One hexavalent chromium concentration above background was detected at 5 feet bgs.
- **Sludge Surface Samples**: Sludge surface samples were collected to determine if analytical interference resulted in high arsenic, antimony, and thallium concentrations during the 1982 investigation. With the exception of the low level of antimony detected in one boring, antimony, arsenic, and thallium were not detected in the samples; therefore, it suggests the 1982 data is not valid.
- **Sump Perimeter**: Borings were performed around the perimeters of the sumps to assess the lateral extent of continuous sludge during both the 2006 and 2009 RI activities. Continuous sludge is a sludge-only deposit and excludes soil mixed with sludge. The results of the step-out borings indicate the extent of the continuous sludge, which is illustrated on Figure 1-2.
- **Offsite Adjacent Residential Properties**: Borings were advanced in the residential properties in the southern portion of the site during the 2006 and 2009 RI activities to investigate the presence of sludge. The results of these borings indicate that the extent of the sludge has been delineated as illustrated on Figure 1-2.

3.2.2 Surface Water

Surface water samples were collected upstream and downstream of the Site from the Dominguez Channel in 2006 and 2008. During both sampling events, the samples had gasoline range organics (GRO) concentrations of 58 µg/L and 50 µg/L in 2006 and 2008, respectively. No SVOCs were observed. Two VOCs, tetrachlorothene and trichloroethene, were observed during both events; upstream samples had higher concentrations of both VOCs than the downstream samples. Barium was found in surface water at concentrations approximately double what was detected in the soil and sludge samples. Copper, lead, and vanadium were detected at levels below background for the Site (Stantec, 2008).

Analytical data from surface water samples collected from the inner channel of the Dominguez Channel indicated elevated concentrations of GRO and VOC analytes in contrast to the non-detections for those analytes in groundwater monitored at the Site. Based on the organic chemical parameters, the Site is not impacting surface water

quality in the channel. Overall, the observed concentrations of metals in surface water adjacent to the Site support the same conclusion, that the Site groundwater conditions are not impacting surface water quality. Both upstream and downstream surface water samples have at least twice the concentration of antimony, molybdenum, nickel, barium, lead, and copper compared to shallow groundwater at the southern boundary of the Site (Stantec, 2010b).

3.2.3 Soil Gas

The soil gas investigation activities evaluated the subsurface concentrations of VOCs, hydrogen sulfide, and methane at various locations across the Site for use in the baseline HHRA. Constituent concentrations reported above the detection limit for targeted VOCs include benzene, toluene, ethylbenzene, m-,p-,o-xylenes, 1,3,5-trimethylbenzene, and Freon 113. Concentrations ranged from non-detect to 2.2 µg/L-vapor (toluene) (Stantec, 2008).

During the 2006 RI activities, benzene concentrations in the soil gas samples ranged from non-detect to 0.3 µg/L-vapor by Method 8260B and from non-detect to 0.260 µg/L-vapor by Method TO-15. Hydrogen sulfide concentrations in the soil vapor samples ranged from non-detect to 5.1 parts per million by volume (ppmv) except for one sample location with results of greater than 50 ppmv. Methane concentrations in the soil gas samples ranged from non-detect to 220 ppmv (Stantec, 2008).

During the 2009 RI activities, additional samples were collected from 22 semi-permanent direct-push soil gas probes. Samples collected near the Haack administrative building showed no VOCs greater than California Human Health Screening Levels (CHHSLs). On the residential properties, benzene from the sample collected from the former corral was the only constituent reported higher than the specific constituent CHHSL value. The results elsewhere at the Site during the 2009 RI activities generally confirmed the results of the 2006 RI (Stantec, 2010a).

3.2.4 Soil Vapor Flux

An Air Pathway Analysis (APA) was performed during the 2006 investigation to evaluate the exposure pathway of outdoor inhalation of vapors. The surfaces evaluated included:

- exposed, undisturbed sludge on the Cooper property;
- exposed, disturbed sludge on the Cooper property;
- soil on both the Cooper and Haack properties; and
- asphalt and concrete-slab covered soil on the Haack property.

The results of the APA are provided in the *Revised Draft RI* (Stantec, 2008) and are summarized below:

- **Ambient Air**: Methane and select VOCs were reported above the quality control (QC) criteria and/or reporting limit in the four ambient air samples collected. Detected methane levels are typical of global, outdoor, ambient air. Detections of VOCs on the Haack property are most likely related to industrial activities on the property and not from undisturbed surface emissions from the nearby sumps. The VOCs detected on the Cooper property may be related to the presence of sludge in the sumps.
- **Undisturbed**: Twenty (20) open (undisturbed) soil flux samples of 61 collected were reported to have specific compounds above the QC criteria and/or reporting limit. The undisturbed sludge had low to moderate emissions and, in general, more compounds were detected at Cooper property locations than Haack property locations. Higher emissions and more detectable compounds were detected at Cooper Sump locations overlying sludge.
- **Disturbed**: All nine (9) disturbed flux samples collected were reported to have specific compounds above the QC criteria and/or reporting limit. The disturbed condition can be generally characterized as having moderate to high area source emissions as compared to the undisturbed sludge condition. In addition, more compounds were detected in the emissions from the disturbed sludge condition than from the undisturbed sludge condition. Odor analyses confirmed the potential for sulfuric compounds from disturbed sludge to create nuisance odors to people in the area or downwind of the disturbed sludge.
- **Infiltration**: Specific compounds were detected above the QC criteria and/or reporting limits for each of the infiltration flux samples. The flux chamber was used to test the air emissions through seams and cracks in the concrete and asphalt. Compounds having the maximum detections represent a different mixture of sulfur and hydrocarbon compounds as detected in the undisturbed sludge condition, indicating that the individual compound emissions are greatly affected by the surface coverings and slab.

3.2.5 Groundwater

3.2.5.1 Summary of Groundwater Monitoring

Well clusters MW-01A/B, MW-02A/B, and MW-03A/B were periodically sampled from 1994 through 2002. Analytical results of these samples supported the findings of earlier investigators, with trace amounts of volatile organic compounds (VOCs) detected in 1994 samples immediately after installation, and no VOC detections in the

next ten years of sampling. Detections in 1994 were likely the result of cross-contamination during well installation (Stantec, 2008).

Groundwater samples obtained on February 28, 2002, contained detectable concentrations of antimony, lead, and thallium that were above the maximum concentration level (MCL), as defined in Title 22 CCR §64431. With a very few exceptions, prior to the 2002 sampling event, analytes tested in groundwater samples were either not detected or found below the laboratory reporting limit. Quarterly groundwater monitoring and sampling of MW-01A/B, MW-02A/B, MW-03A/B, and G-4 was agreed to as part of a Consent Decree entered into between DTSC and Atlantic Richfield Company, which became effective November 4, 2004 (§VIIC, paragraph 2, lines 2-3). Wells MW-4A, MW-4B and MW-5A have been installed during Atlantic Richfield Company's RI investigation of the Site.

The following summary is abstracted from the *First Quarter 2010 Groundwater Monitoring Report* (Stantec, 2010b):

The depth to Site groundwater in the A-zone ranges between 10.5 and 18 feet below the ground surface. The groundwater in the A-zone flows southward with an approximate velocity of 0.04 feet per day. The depth to Site groundwater in the B-zone ranges between 15.5 and 22 feet below the ground surface. The groundwater in the B-zone flows east-southeast with an approximate velocity of 0.18 feet per day.

Nine of the ten groundwater monitoring wells showed no detectable concentrations of GRO, VOCs, or PAHs above the RL during the first quarter 2010 sampling event. Samples from the recently installed MW-05A well indicated a GRO detection of 390 µg/L. VOCs detected above the reporting limit in well MW-05A included benzene (0.73 µg/L), naphthalene (3.4 µg/L), m-,p-xylenes (1.5 µg/L), 1,2,4-trimethylbenzene (2.8 µg/L), and 1,3,5-trimethylbenzene (23 µg/L). Total xylene levels in MW-05A were 1.7 µg/L.

Wells with SVOCs detected included well MW-01A with acenaphthylene (5.6 µg/L), bis(2-ethylhexyl)phthalate (3.2 J[1] µg/L; detected below the reporting limit), and naphthalene (3.2 J µg/L; detected below the reporting limit); MW-01B had bis(2-ethylhexyl)phthalate (3.9 µg/L); MW-02A had acenaphthylene (2.1 µg/L), bis(2-ethylhexyl)phthalate (10 µg/L), 2-methylphenol 2.3 µg/L, naphthalene (2.6 µg/L), and phenol (1.2 µg/L); and MW-02B had acenaphthylene (0.75 µg/L).

[1] J = Analyte was detected between the method detection limit and reporting limit; reported value is estimated.

The groundwater pH levels have remained relatively constant since project sampling began in the first quarter of 2006. The anomalously high pH levels reported during the 1994 and 2002 sampling events have not been observed recently. Generally, groundwater samples from onsite wells (with the exception of MW-5A) have a pH ranging between 6.0 and 8.0. Recently installed well MW-05A has had groundwater pH readings ranging from 4.5 to 5.8.

For each groundwater sampling event since the year 2000, both dissolved (starting in 2006) and non-dissolved phase barium have been detected above the RL in all wells. The highest concentration of barium continues to be detected up-gradient and off site in well MW-01B.

During the second quarter 2010 sampling event, reportable trace amounts of arsenic were detected in both non-dissolved phase (total metals) in wells MW-01A, MW-02A, MW-02B, MW-03A, MW-05A, and G-4 and in the dissolved phase in wells MW-02A, MW-02B, MW-03A, and MW-05A. Well MW-04B showed the highest levels of arsenic in both dissolved and non-dissolved phases (4.4 and 4.4 µg/L, respectively).

Well MW-05A had elevated non-dissolved levels of cobalt (140 µg/L), copper (62 µg/L), nickel (190 µg/L), and zinc (3,800 µg/L) (total metals), and elevated dissolved levels of cobalt (190 µg/L), copper (74 µg/L), nickel (240 µg/L), and zinc (4,400 µg/L) compared to the other site monitoring wells.

3.2.5.2 Summary of Hydropunch Sampling

During the 2009 RI activities, additional groundwater assessment was performed using hydropunch sampling. Groundwater samples were collected in the A and B horizons, respectively to test for VOCs, SVOCs, PAHs, metals, and pH. No VOCs, SVOCs, or PAHs were detected above MCLs. Dissolved metal concentrations of beryllium, cadmium, and nickel were reported in one sample (GWP-100) from the A horizon. pH ranged from 6.74 to 7.44 in the A horizon with the exception of a 4.74 pH value from GWP-100. pH was not measured in the B horizon (Stantec, 2010a).

3.2.6 Perched Groundwater

Ten temporary groundwater wells were installed during the 2009 RI activities to investigate suspected perched groundwater. The results of the investigation are discussed in the *Data Gaps Memorandum* (Stantec, 2010a). In summary, benzene was detected at 1.6 µg/L, and some SVOCs were detected above the detection limit but below the reporting limit (J-flag). Lab pH ranged from 3.82 to 6.93, and PAHs were not detected in concentrations greater than 5 µg/L. Total metals above primary and/or secondary MCLs included: antimony, arsenic, beryllium, cadmium, chromium, copper,

nickel, selenium, and zinc. Dissolved metals above primary and/or secondary MCLs included: nickel and zinc.

3.3 Fate and Transport

Based on the results from previous investigations and the extensive field work performed as part of the *Revised Draft RI* (Stantec, 2008), the current Conceptual Site Model (CSM) suggests that:

- The undisturbed sludge at the Site does not pose a threat to surface water and does not pose a threat to shallow (A-horizon) or deeper (B-horizon) groundwater quality throughout much of the Site. Shallow groundwater is impacted (lower pH, total & dissolved metals) south of the Haack sump; however, these impacts are not detected in samples collected downgradient of the sumps.
- The undisturbed sludge at the Site does not pose a substantive threat to the air quality in the immediate vicinity of the Site. However, isolation of the sludge from temperature fluctuations above approximately 100 degrees would further minimize this potential impact; and
- The undisturbed sludge does not pose a threat to further contamination of soil surrounding the sludge by leaching of constituents of potential concern (COPCs) from the sludge (Stantec, 2008).

The transport mechanisms identified during the HHRA are discussed further in Section 4.2 but in summary are: wind erosion and dust, volatilization to indoor and ambient air, and leaching to groundwater.

3.4 Treatability Studies Conducted

3.4.1 General

A treatability study was conducted by Stantec to define and evaluate the physical and chemical characteristics of the sludge and evaluate neutralization/stabilization options. The following sections summarize the results of the treatability study found in Appendix J of the *Revised Draft RI* (Stantec, 2008) and included as Appendix B of this FS Report.

3.4.2 Acidity

The testing showed that the acidity of the sludge ranged from 6.1 to 20.8 percent by weight. The Cooper South Sump had the highest acidity, with an average value of 19 percent by weight (Stantec, 2008).

3.4.3 Wet Density

Wet densities of the sludge samples were determined from samples collected using a Fann Model 140 mud balance. The densities for the samples ranged from 63 lb/ft^3 to 79 lb/ft^3. The average density of the sludge collected from the Cooper North Sump was 65.7 lb/ft^3, and the average density of the sludge from the Cooper South Sump was denser at 72.8 lb/ft^3. The sludge collected in the Haack Rework Area had an average density of 74.9 lb/ft^3 (Stantec, 2008).

3.4.4 Moisture

The average moisture of the sludge ranged from 9.8 to 22.3 percent on a wet basis. The moisture of the soil below the sludge sumps ranged from 12.1 to 25.6 percent on a wet basis. The soil below the Cooper North Sump was noted to have higher moisture content (24.2 percent) when compared to the soil below the Haack Rework Area, which averaged 14 and 16.9 percent moisture, respectively (Stantec, 2008).

3.4.5 Viscosity

The viscosities of sludge samples were tested at different temperatures to determine material viscosity as a function of temperature. This data was plotted as semi-log graphs to generate trend lines for modeling the viscosity as a function of temperature in accordance with ASTM Method D 2493. The sludge is highly viscous, ranging from 1.7×10^6 to 2.5×10^6 centipoises (cP) at a reference temperature of 140ºF. The results of the testing show that the sludge in the Cooper North Sump had a slightly lower viscosity than the sludge in the Cooper South Sump. The sludge in the Cooper North Sump had an average viscosity of 1.7×10^6 cP at 140ºF while the viscosity of sludge in the Cooper South Sump averaged 2.5×10^6 cP at 140ºF. Sludge collected from the Haack property in the Haack Rework Area was heated to 220ºF, but it was still too viscous to test for viscosity, thus indicating the sludge may contain other solids from disruption during development activities in that area (Stantec, 2008).

3.4.6 Softening Point

The softening point of the sludge was evaluated by the softening point test defined in ASTM Method D36. The results of the testing show that the softening point of the sludge samples from the Cooper property ranged from 158ºF to 185ºF. The sludge in the Cooper North Sump had a slightly lower softening point than the sludge in the Cooper South Sump. The sludge in the Cooper North Sump had an average softening point of 159ºF while the average softening point for the sludge in the Cooper South Sump was 180ºF. The softening point of the sludge collected in the Haack Rework Area was greater than 210ºF (Stantec, 2008).

3.4.7 Neutralization and Stabilization Testing

Five different reagent mixes were tested with the sludge to evaluate their neutralization/stabilization ability. The five mixes included: calcium oxide (CaO), 50/50 (w/w) mix of CaO and calcium carbonate ($CaCO_3$), calcium hydroxide ($Ca(OH)_2$), a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$, and Portland cement (Stantec, 2008).

Testing indicated that the sludge can be neutralized by treatment using 25 percent treatment reagent addition by weight where the treatment reagent is comprised of 50 percent hydrated lime ($Ca(OH)_2$) and 50 percent $CaCO_3$ fines. Approximately 10 percent water addition was also required to help activate the lime and carbonate reactions. The addition of 50 percent soil by weight during this mixing will also effectively solidify the waste so it is no longer susceptible to viscoelastic deformation. This treatment also effectively fixates lead, as demonstrated through long-term leaching tests, and neutralizes acid gases such as hydrogen sulfide (H_2S) and sulfur dioxide (SO_2) (Stantec, 2008).

3.4.8 Vapor Evolution

Stantec also evaluated the potential rates of off-gas evolution during full-scale mixing operations as a function of temperature. Headspace analyses were performed on the sludge samples at temperatures of 60ºF, 100ºF, 140ºF, 180ºF, and 212ºF (Stantec, 2008).

3.4.8.1 VOC and TPH Headspace Results

The analyses indicated no benzene was emitted from the sludge samples at temperatures ranging from 60 to 212ºF. Toluene was not detected at 60ºF; however, detected concentrations increased as temperature increased. Similarly, ethylbenzene and xylenes were near detection limits at 60ºF, and detected concentrations increased as temperatures increased. Detected concentrations of toluene, ethylbenzene, and xylenes did not exceed the Occupational Safety and Health Administration (OSHA) permissible exposure limits (PELs) (Stantec, 2008).

Total petroleum hydrocarbons (TPH) was monitored in the vapor headspace as a function of temperature, where TPH represents the total concentration of VOCs detected for GRO and diesel range organics (DRO). Initial concentrations of TPH in the vapor headspace were below 12.5 ppmv in the Cooper North and Cooper South Sump samples at 60ºF. However, TPH concentrations increased exponentially with increasing temperature. At 212ºF, the concentrations of TPH in the vapor headspace of samples from the Cooper North and Cooper South Sump were 259 ppmv and 223 ppmv, respectively. These data indicate that TPH (as petroleum distillates) will not

present a health and safety issue with respect to construction work since the concentrations are less than the OSHA PEL of 500 ppmv for petroleum distillates (Stantec, 2008).

Samples collected from the Haack Rework Area did not have detectable concentrations of benzene, toluene, ethylbenzene, and xylenes (BTEX) and TPH, with the exception of toluene and xylenes. These compounds were only detected when temperatures were increased to 212ºF. TPH was below detection limits at 60ºF, and detected concentrations rose to a maximum at 212ºF (Stantec, 2008).

3.4.8.2 H_2S and SO_2 Headspace Results

H_2S and SO_2 were monitored in the headspace of sludge samples at various temperatures. The results showed that these sulfurous gases were readily emitted from disturbed and heated sludge samples in the Cooper North and Cooper South Sumps. The vapor concentrations of SO_2 in equilibrium with sludge samples from both sumps exceeded 150 ppmv at 60ºF. The vapor concentration of H_2S was 408 ppmv for the Cooper North Sump and 471 ppmv for the Cooper South Sump at 60ºF, but at higher temperatures it exceeded 500 ppmv for both sumps. These data show that H_2S and SO_2 will both be present at an exposure risk to workers and the community if the sludge is disturbed for neutralization and stabilization treatment, as the OSHA PELs for H_2S and SO_2 are 10 ppmv and 2 ppmv, respectively (Stantec, 2008).

The sludge samples collected from the Haack Rework Area had substantially lower concentrations of H_2S and SO_2 in the vapor headspace. The vapor concentrations of SO_2 in equilibrium with sludge samples ranged from 8 to 71 ppmv. The vapor concentration of H_2S ranged from 2 to 50 ppmv. These data show that H_2S and SO_2 emissions from sludge on the Haack property could present an exposure risk to workers and the community if the sludge is disturbed for neutralization and stabilization (Stantec, 2008).

3.4.9 Metal and Organic Mobilization

Treated and untreated composite samples of sludge from the Cooper North and Cooper South Sumps were analyzed for total RCRA metals, VOCs, SVOCs, and PAHs and for analyses of leachable RCRA metals and organics by both the toxic characteristic leaching procedure (TCLP) and synthetic precipitation leaching procedure (SPLP) (Stantec, 2008).

3.4.9.1 Untreated Sludge Leaching

Analyses showed that the composite sludge sample contained 22.4 mg/kg lead and 1.2 mg/kg barium. The TCLP extract contained 0.24 mg/L lead and 0.06 mg/L barium, thus indicating that the sludge would not be characterized as a hazardous waste under the definitions and exclusions given in 40 CFR Part 21 for lead or barium, even in a final TCLP extract of pH 3.97. The SPLP extract contained 0.31 mg/L lead and less than 0.01 mg/L barium at a final SPLP extract pH of 2.15. This indicates that the SPLP will be more likely to produce leaching effects in laboratory analyses than the TCLP (Stantec, 2008).

The analyses for total SVOCs, PAHs and VOCs identified the following constituents in the sludge:

- Benzo(a)anthracene 70,000 µg/kg;
- Chrysene 160,000 µg/kg;
- 2-Methylnaphthalene 30,000 µg/kg;
- Phenanthrene 200,000 µg/kg;
- Pyrene 60,000 µg/kg;
- Ethylbenzene 200 µg/kg;
- Toluene 400 µg/kg;
- Xylenes 1,000 µg/kg;
- 2-Methylnapthalene 1,900 µg/kg;
- 1,2,4-Trimethylbenezene 700 µg/kg;
- 1,3,5-Trimethylbenzene 500 µg/kg; and
- 1,2,3-Trimethylbenzene 1,100 µg/kg.

Despite the presence of these compounds within the sludge itself, no PAHs or SVOCs were identified in the SPLP extract for the untreated sludge above the detection limit of 5 µg/L. This indicates that the SVOCs and PAHs within the sludge are largely immobile. Toluene was detected in the SPLP extract of the untreated sludge at 7 µg/L, and 1,2,3-trimethylbenzere was detected in the SPLP extract at 1 µg/L (Stantec, 2008).

Analysis of the sludge for TPH as GRO and DRO showed that the sludge contained 70 mg/kg GRO and 39,000 DRO. This shows that only 3.9 percent of the sludge is comprised of organics in the C6 to C28 hydrocarbon range, thus showing that the majority of organics in the sludge have a very high molecular weight in excess of 400 (Stantec, 2008).

3.4.9.2 Treated Sludge Leaching

Samples of composite sludge treated with a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$ at dosage rates of 22, 24, 26, and 28 percent reagent by weight with respect to the original mass of untreated sludge were subjected to SPLP testing. The results showed that the treatment produced non-detectable concentrations of RCRA metals and SVOCs in each of the SPLP extracts, with the exception of barium which was detected at 0.01 mg/L. This shows that the treatment reduced the concentration of leachable lead by the SPLP to less than 0.03 mg/L (Stantec, 2008).

3.4.10 Long-Term Leaching Analysis

A long-term leaching test was performed on a composite sludge sample from the Cooper North and Cooper South Sumps that was treated at a dosage of 25 percent of the 50/50 (w/w) $Ca(OH)_2$ and $CaCO_3$ reagent mix. The sample was subjected to the SPLP extraction procedure daily, with new extract water being added to the sample after each SPLP extraction to evaluate the long-term leaching effects after multiple extractions. The leachate from every other extraction was filtered and sent for analyses of PNAs, RCRA metals, and VOCs. The extracts were also tested in the laboratory for pH and alkalinity (Stantec, 2008).

Testing indicated lead did not leach from the sludge even after ten sequential SPLP extractions, indicative that treatment of the sludge with $Ca(OH)_2$ and $CaCO_3$ provides long-term stability for lead. Trace concentrations of barium, ethylbenzene, toluene and xylenes leached from the treated sludge, but the concentrations were well below the primary drinking water standards. Additionally, trace concentrations of trimethylbenzene isomers, 2-methylnapthalene, and acetone leached from the treated sludge, but there are no primary or secondary drinking water standards for these compounds. Minimal alkalinity was removed from the sludge during the ten sequential extractions, thus indicating that many more extractions could have been performed while still maintaining alkaline stability in the treated material (Stantec, 2008).

3.4.11 Permeability

Composite samples of untreated and treated sludge from the Cooper North and Cooper South Sumps were tested for permeability by modified American Society for Testing and Materials (ASTM) D5084, Method C. The treated samples consisted of composite sludge samples treated with 15 percent calcium hydroxide and 15 percent $CaCO_3$ fines by weight. Stantec reported that the untreated sludge exhibited permeability less than $1x10^{-8}$ centimeters per second (cm/s), while the treated sludge exhibited permeability of approximately $9x10^{-3}$ cm/s (Stantec, 2008).

3.4.12 Evaluation of Soil Additive

Four composite samples of sludge were treated with 25 percent reagent comprised of a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$. Prior to adding the reagent, the samples were amended with 0, 25, 50, and 75 percent soil, by weight (Stantec, 2008).

The testing showed that the addition of soil to the neutralized sludge improved the density of the treated material and maintained high strength. Because the sludge at the Site is so viscous, it was difficult to assess how the soil additive worked as a stabilization material for bituminous stabilization at ambient temperatures. Therefore, samples of neutralized sludge treated with 0, 25, 50, and 75 percent soil were compacted into cores using a Harvard compaction apparatus, and the cores were placed into a convection oven at 220ºF to test the stability of the sludge. The testing showed that the neutralized samples containing no soil exhibited viscoelastic flow at 220ºF. The samples containing 25 percent soil exhibited minor viscoelastic properties, and the samples containing 50 and 75 percent soil by weight exhibited no viscoelastic properties. These test results show that the addition of 50 percent soil to neutralized sludge by weight converts the sludge into a stable solid material, even at elevated temperatures that exceed the softening point of the sludge (Stantec, 2008).

3.4.13 Evaluation of Thermal Treatment

Although the sludge was found to contain approximately 4 percent diesel-range organics, the majority of hydrocarbon in the sludge was comprised of very large chain hydrocarbons having a molecular weight greater than 400. When the sludge was tested for BTU value, it was found to have a very high heating value of 13,000 BTUs per pound. This confirms that the sludge is comprised primarily of organics. However, the sludge also had an elevated sulfur content of approximately 7 percent. This high sulfur content suggests that incineration or fuel combustion of the sludge is not a viable treatment alternative due to the large amount of SO_2 gas that would be emitted during combustion. Stantec has estimated over 1,800 cubic feet (280 pounds) of SO_2 gas could be emitted for each ton of sludge incinerated or combusted. Site-wide, the total mass of SO_2 generated by thermal treatment of the sludge would exceed 2,600 tons (Stantec, 2008).

3.4.14 Evaluation of Moisture/Density Relationship for Treated Sludge

Four samples of sludge treated with 25 percent of a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$ were tested for moisture/density relationship to determine optimal dry density and moisture content for compaction after treatment. Testing was performed on a sample without soil amendment and on three samples amended with 25, 50, and

75 percent soil by weight with respect to the initial weight of untreated sludge (Stantec, 2008).

The test results showed that the neutralized sludge without soil amendment had a very low maximum dry density of 52.3 lb/ft^3 and high optimum moisture content of 46.7 percent. When the neutralized sludge was amended with 25 percent soil, the maximum dry density increased to 64.1 lb/ft^3 and the optimum moisture content decreased to a more reasonable value of 29.5 percent. The neutralized sludge sample amended with 50 percent soil had a maximum dry density of 68.8 lb/ft^3 and an optimum moisture content of 25.7 percent, and the sample amended with 75 percent soil had a maximum dry density of 71.6 lb/ft^3 and an optimum moisture content of 24.4 percent. Based on Table 13, stabilized sludge amended with 12 percent $CaCO_3$ and 12 percent $Ca(OH)_2$ has a density of 81 lb/ft^3 (Stantec, 2008).

3.4.15 Testing for Asphaltic Qualities

Testing of the sludge indicated that it will have low marketability as recycled asphalt, even when neutralized, for the following reasons:

- The sludge is a brittle, glass-like material with little to no ductility;
- The viscosity of the sludge is too high for use as asphalt cement in road construction;
- The sludge contains a high concentration of impurities and suspended solids which causes it to fail to meet the test for asphalt solubility for both asphalt cement and roofing asphalt;
- The sludge has a negative American Petroleum Institute (API) gravity;
- The softening point falls into acceptable ranges for a Type II roofing asphalt, but the sludge fails to meet most of the remaining specifications for Type II roofing asphalt; and
- Penetration values for the sludge were too low for use as asphalt cement but meet the specifications for Type IV roofing asphalt.

Although the sludge shares the softening point specifications for Type II roofing asphalt and the penetration specifications for Type IV roofing asphalt, it fails to meet the ductility requirements for either of these asphalt grades. The brittle nature of the material gives it undesirable properties because the material is easily cracked and sheared, thus making it unsuitable for roofing or pavement construction applications (Stantec, 2008).

Section VII.C. of the Consent Decree requires the evaluation of the proposal of Mr. Thomas Cooper for recycling the sludge as one of the alternatives in the FS. The

Cooper Sumps sludge, in a non-neutralized state, releases significant quantities of H_2S and SO_2 gas when disturbed. The release of these gases from the sludge as well as the physical characteristics of the sludge, makes the sludge unacceptable for recycled asphalt application. The sludge recycling alternative is not evaluated further in this FS.

4. REMEDIAL ACTION OBJECTIVES AND CLEANUP CRITERIA

4.1 General

This section describes the development of remedial action objectives (RAOs) and target cleanup levels for the Site. The development of RAOs is required by RI/FS guidance as part of the FS. The process of developing the RAOs depends upon the assessment of risk to identified receptors at the Site and in the Site vicinity. A discussion of the risk assessment (RA) at the Site follows.

4.2 Chemicals of Potential Concern

The chemicals of potential concern (COPCs) for the Site were developed and discussed in the hazard identification section of the *Draft Human Health Risk Assessment* (HHRA) (Geosyntec, 2010). USEPA guidance states that the list of chemicals should include all chemicals that were:

- Positively detected in at least one sample;
- Detected above levels of the same chemicals found in associated blank samples;
- Tentatively identified, but may be associated with the Site based on historical information;
- Transformation products of detected chemicals; and
- Detected above naturally occurring levels (background).

During the RA, those contaminants posing a potential risk to receptors at the Site were identified as COPCs and can be found in Table 4-1 for soil, soil gas, and groundwater.

4.3 Human Health Risk Assessment

4.3.1 Approach

The draft HHRA included an evaluation of health risks to potentially exposed receptor populations consisting of: commercial/industrial workers, construction workers, hypothetical future residents, and trespassers. Potential exposures were evaluated for these populations assuming existing physical site conditions (without the existence of the protective caps on the Cooper and Haack properties and prior to any future remediation efforts at the Site). In addition, a current residential scenario has been included for the immediate adjacent offsite residential area (Geosyntec, 2010).

Future development of the Site and the immediate adjacent offsite residential area would be commercial as designated in the City of Gardena's report titled *Artesia Corridor Specific Plan* (TPC, 2006). To conservatively evaluate the potential risks

under an unrestricted land use scenario, a more conservative hypothetical future residential scenario was included in the HHRA to evaluate potential risks under an unrestricted land use scenario. Additionally, the conservative construction worker, shallow groundwater to outdoor vapor inhalation and dermal contact scenario was evaluated to represent groundwater in an open excavation (Geosyntec, 2010).

To evaluate the spatial distribution of risk driving chemicals, two types of comparison criteria were developed for each chemical identified in the risk characterization: (1) those based on background; and (2) risk-based values (RBCs) or target risk concentrations which are based on each receptor group and assuming site-specific soil characteristics and a target risk goal. For worker exposures (commercial/industrial and construction worker) a target risk goal of 1 in 100,000 (1×10^{-5}) was used. For residential and trespasser scenarios a 1 in 1,000,000 (1×10^{-6}) target risk goal was used. For those chemicals in which the risk-based concentrations are below background, the background concentration is used as the comparison criteria. This is the case for arsenic and residential and commercial/industrial worker scenarios, and benzo(a)pyrene toxicity equivalent (BaP-eq) for the residential scenarios (Geosyntec, 2010).

4.3.2 Results

The results of the HHRA indicate that exposures to onsite soils may potentially exceed target risk goals for all potential receptor scenarios evaluated: commercial/industrial worker, construction worker, hypothetical future onsite/current offsite resident, and trespasser. The primary contributors to the risk estimates were arsenic, hexavalent chromium, naphthalene, and predominantly the carcinogenic PAHs as represented by the BaP-eq concentration. The majority of locations where concentrations of these chemicals were elevated occurred within areas of known sludge material which are currently covered by the existing geomembrane cap, soil, concrete, and/or asphalt (Geosyntec, 2010).

4.4 Chemicals of Concern

Following completion of the HHRA, primary risk driving chemicals were identified from the list of COPCs (see Section 4.2) as chemicals of concern (COCs). These chemicals were identified as primary risk drivers because they are the most ubiquitous chemicals throughout the Site and because they are co-located with a majority of the COPCs (i.e., the risk associated with the COCs would encompass the COPCs). Based on the HHRA, the primary COCs at the Site are:

- **Soil**: arsenic, hexavalent chromium, naphthalene, and the BaP-eq
- **Air**: benzene, hydrogen sulfide
- **Groundwater**: dibenz(a,h)anthracene

These COCs are present in the Cooper and Haack Sumps as well as in the Haack rework area. Methane has been detected at low concentrations around the site but was not identified as a COC based on the HHRA. Due to the potential explosive risk associate with methane, it has been included with as a Remedial Action Objective.

4.5 Remedial Action Objectives

RAOs are goals specific to various media and apply to those media that have been identified as posing an unacceptable risk based on the HHRA work performed for the Site. The RAOs for onsite soils, soil gas, and groundwater are:

- Prevent ingestion/direct contact with sludge and/or soil having 10^{-5} to 10^{-6} excess cancer risk from carcinogenic constituents as represented by arsenic, hexavalent chromium, naphthalene, and the BaP-eq concentration;
- Prevent dermal contact with shallow groundwater having 10^{-5} excess cancer risk from carcinogenic polycyclic aromatic hydrocarbons (PAHs) as represented by dibenz(a,h)anthracene;
- Prevent dermal contact with low pH, PAH containing sludge;
- Prevent inhalation of volatile organic compounds (VOCs), as represented by benzene, posing excess cancer risk levels of 10^{-5} to 10^{-6}; and
- Prevent explosive risks associated with methane.

4.6 Applicable or Relevant and Appropriate Requirements

The Applicable or Relevant and Appropriate Requirements (ARARs), as defined by 40 CFR 300.5, presented in this section were identified for the remedial actions presented in this document to comply with Federal environmental law or more stringent standards promulgated under State environmental law. Federal and State environmental laws are evaluated to determine if they are either applicable or relevant and appropriate.

"To Be Considered" (TBC) criteria have also been identified to cover Federal and State nonpromulgated standards, policies, or guidance documents and local requirements for constituents which do not have developed preliminary remedial goals or ARARs.

The ARARs are divided up into the following three categories according to the type of CERCLA action they govern: chemical-specific, location-specific, and action-specific requirements. ARARs and TBC criteria are presented in Table 4-2.

4.6.1 Potential Chemical-Specific Requirements

At the Site, chemical-specific requirements include RCRA provisions defining hazardous waste, maximum contaminant levels (MCLs) derived from the Safe Drinking

Water Act, and primary and secondary national standards for ambient air quality. The Draft HHRA identifies the site-specific, risk-based cleanup levels (Geosyntec, 2010).

4.6.2 Potential Location-Specific Requirements

No location-specific ARARS were identified since the Site is not located in any sensitive or protected area.

4.6.3 Potential Action-Specific Requirements

The potential action-specific requirements for the Site include:

- **Porter-Cologne Water Quality Control Act**: Set on a case by case basis by the Regional Water Quality Control Board (RWQCB), water emission standards are applied to waste water, groundwater, and stormwater runoff from the Site.
- **South Coast Air Quality Management District (SCAQMD)**: Emissions of gases, particulate matter, and fugitive dust are set by the SCAQMD and may apply if they are part of the State Implementation Plan pursuant to the Clean Air Act.
- **National Pollution Discharge Elimination System (NPDES)**: Requires the elimination of most non-stormwater discharges, Stormwater Pollution Prevention Plan (SWPPP) preparation, and stormwater discharge monitoring.
- California Civil Code and California Health and Safety Code governing land use restrictions.
- DTSC hazardous constituent regulations as outlined in 22 CCR Division 4.5.

4.7 Future Site Use

The Site is currently used for residential and commercial/industrial applications. The DTSC has requested the following three future land use scenarios be evaluated for the Site:

- Current land use will continue; residential properties would remain and Cooper and Haack areas would remain commercial/industrial;
- Use the Site for residential only; and
- Use the Site for commercial/industrial only.

As a conservative approach to meet the DTSC request, the residential cleanup goals will be used, which are the most stringent.

The City of Gardena has developed the City of Gardena Master Plan (TPC, 2006) which indicates the Site would be developed in the future as commercial property with a mix

of commercial buildings and parking. To accommodate this development plan and constraints of the Site, ARC requested the remedial design be compatible with a parking lot or open space end use incorporating curbs, gutters, light poles, and utilities.

4.8 Target Cleanup Levels

The target cleanup levels for the Site were developed with consideration given to the following factors:

- Hypothetical future use scenario;
- Remedial action objectives; and
- Potential site health risk.

The cleanup levels shown in Tables 4-3, 4-4, and 4-5 were developed for each of the COCs identified in Section 4.3. Cleanup criteria either are numeric goals to be achieved through remediation or are non-numeric, performance-based criteria. The cleanup levels shown in Tables 4-3, 4-4, and 4-5 will be used subsequently in this FS Report to guide the selection and screening of remedial technologies and the development and detailed analysis of remedial alternatives. A discussion of the development of cleanup criteria follows.

4.8.1 Site-Specific Action Levels

Soil cleanup criteria are based on the derivation of risk-based concentrations (RBCs) for site COCs. RBCs were developed for each chemical identified as a COC or "risk driver" in the risk characterization of the HHRA (Geosyntec, 2010) based on each receptor group and assuming site-specific soil characteristics as presented in Appendix C. RBCs were derived for arsenic, BaP-eq, hexavalent chromium, benzene, and naphthalene in soil (Table 4-3); benzene in soil gas (Table 4-4); and dibenz(a,h)anthracene in groundwater (Table 4-5). The derivation of these concentrations is provided in Appendix C. RBCs are presented for both cancer and noncancer effects; cancer effects generally produce lower RBCs. The selected site-specific action levels (SSALs), considering background concentrations, are presented in the last column for each receptor group.

For arsenic in soil, the DTSC screening level of 12 mg/kg, which is considered background for southern California sites (Cal-EPA DTSC, 2007), was used as the SSAL for residential receptors.

For BaP-eq in soil, a concentration of 0.9 mg/kg, considered representative of background PAH concentrations in southern California soils, was used as the SSAL for residential receptors.

The SSALs for the residential, commercial/industrial, and trespasser scenarios were compared to soil, soil gas, and groundwater sample results collected during the RI. The results of the comparisons are provided on Figures 4-1 through 4-5.

5. IDENTIFICATION AND SCREENING OF TECHNOLOGIES

5.1 Introduction

General response actions (GRAs) describe remedial actions that would address RAOs and achieve cleanup criteria for hypothetical future receptors that may be exposed to soil, soil gas, and groundwater contaminants. This section provides a discussion of GRAs and also provides identification of potential remedial technology types and specific technologies. A screening analysis was conducted to reduce the number of potentially applicable technologies to those that were determined to be potentially able to achieve the RAO for the COCs.

5.2 General Response Actions

Specific GRAs identified for onsite impacts include the following:

- No action;
- Remediate or remove soils that present potential ingestion and/or dermal contact risk;
- Containment;
- Reduce concentrations of COCs that present a potential inhalation risk;
- Gas monitoring and treatment;
- Monitor groundwater; and
- Implement institutional controls to restrict access to sludge and to control and manage risk associated with future mixed-use redevelopment.

5.3 Technology Identification and Screening

In accordance with USEPA guidance, potential remedial technology types and specific technologies that can be used to implement the GRAs were identified and then screened to assess their effectiveness, implementability, and cost. This section provides a screening of technologies to identify those that will be combined into remedial alternatives in Section 6 of this FS Report. The following technologies have been identified for remediation and are listed in Table 5-1:

- No action;
- Institutional controls;
- Treatment;
- Stabilization/neutralization;

- Thermal treatment;
- Sludge recycling;
- Containment;
- Excavation and removal for offsite disposal;
- Engineered controls;
- Vapor and gas control systems; and
- Groundwater monitoring.

In accordance with US EPA Feasibility Study guidance, Table 5-1 presents the screening of each technology based on its relative effectiveness, implementability, and cost. This screening provides the rationale behind the decision to retain or eliminate each technology type. Therefore, based on the screening, the following technology types were retained for further evaluation:

- No action (as required by USEPA guidance);
- Institutional controls;
- Treatment;
- Stabilization/neutralization;
- Containment;
- Excavation;
- Engineering Controls;
- Gas control systems; and
- Groundwater Monitoring.

A summary of technologies retained is presented in Table 5-2. Each retained technology will be integrated into one or more remedial alternatives, described in Section 6.

6. DEVELOPMENT OF REMEDIAL ALTERNATIVES

In this section, remedial alternatives for the Site are assembled from those technologies that remain after the initial screening in Section 5. Each remedial alternative includes a remedial approach that accommodates the hypothetical future use scenario described in Section 4 and assumes that Site features are removed prior to remedy implementation. Each remedial alternative listed in Table 6-1 is designed to address each impacted media at the Site.

6.1 Remedial Alternatives

Table 6-1 presents the four remedial alternatives that were retained for evaluation:

- Alternative 1 – No action;
- Alternative 2A – Capping with selective excavation;
- Alternative 3 – Capping with selective excavation and stabilization/neutralization; and
- Alternative 4 – Excavation with offsite disposal.

Alternatives 2A and 3 include institutional controls, gas control and monitoring, and groundwater monitoring. All four alternatives are described below.

Alternatives 2A through 4 are depicted on Figures 6-1 through 6-16. Details shown are conceptual for estimating and comparison purposes only, and do not represent the results of full engineering design and analysis.

6.1.1 Alternative 1 – No Action

This alternative consists of performing no work now or in the future to attempt to mitigate an existing condition. The current geomembrane cover would remain and no deed restrictions would be placed on the property.

For No Action to be considered an acceptable alternative, the concentrations of COCs would have to be below RAOs. This alternative would provide no exposure pathway reductions. There would be no controls to prevent future site development or site access. Groundwater contamination would not be known since monitoring would not be performed. Future site development would be hindered due to the instability of the sludge material. The No Action Alternative is required by USEPA FS guidance.

6.1.2 Alternative 2A – Capping with Selective Excavation

Alternative 2 was originally presented in the Draft FS dated February 2011. Alternative 2A replaced Alternative 2 in the Draft FS Addendum dated 29 September 2011.Alternative 2A is consistent with the former Alternative 2 in that capping and selective excavation of the sludge in the Haack Rework area are evaluated. However, the evaluated cap proposed in Alternative 2A is significantly lower in overall height than the cap of former Alternative 2. Additionally, different disposal scenarios for the Haack Rework material are proposed in Alternative 2A. The lower profile cap and different Haack Rework material disposal alternative presented in this FS Report is in response to comments received from the City of Gardena during the 10 May 2011 meeting. In addition to the layout and cap profile presented herein, the Optional Alternative 2A Cover which eliminates the retaining wall adjacent to Artesia Blvd. is summarized in Section 6.1.2.3 below and provided in greater detail in Appendix F.

6.1.2.1 General Overview

The Site is generally divided into three areas: the Cooper North and South Sumps on the Cooper Property, the Haack Sump and the Haack Rework Area located primarily within the Haack property, four residential properties, land owned by Los Angeles County and a small area of land beneath the Artesia Boulevard right-of-way. Because these areas of the Site are divided among different property owners, the properties may not all be available for remedial construction at one time. The following sections describe, in general, the proposed Alternative 2A approach for each area. Section 6.1.2.2 describes the remedial implementation approach for the entire Site in greater detail.

As described previously, the sludge material beneath the Artesia Boulevard South sidewalk and Artesia Boulevard are below road base material and asphalt or sidewalk concrete. The concrete and asphalt surface prevent ingestion and direct contact with the sludge as well as reduce its mobility by containing the sludge. This sludge material is considered to be already capped.

Future access from current and/or future utility and/or construction workers will be addressed in the Risk Management Plan (RMP). The RMP will describe contaminants remaining onsite, known locations of impacts, contact information, and minimum, recommended personal protective equipment for current and future utility and/or construction workers. Institutional controls will include requirements that the City of Gardena and/or Caltrans provide notice of potential subsurface hazardous materials in the area of Artesia Boulevard where sludge is potentially located, prior to issuing work permits. Institutional controls will also include requirements related to Site development and cap loading restrictions.

Cooper North and South Sumps

The existing geomembranes will remain in place with the cap installed above. The geomembrane will provide a construction surface and preliminary support during installation of the overlying materials. Furthermore, the existing surfaces minimize the dermal contact and gas inhalation exposure risks to the construction workers during installation of the cap.

The sludge and overlying geomembranes in the Cooper North and South Sumps will be capped, from bottom to top, with the following materials: (1) high-strength geotextile; (2) between 0 and 4.5 feet (ft) of foundation layer material; (3) a horizontal gas collection system: gas collection geostrips and gas collection geocomposite; (4) geosynthetic clay liner (GCL); (5) high-density polyethylene (HDPE) geomembrane; (6) drainage geocomposite; and (7) up to 12-inches (in.) of Class II aggregate base.

Haack Sump

The existing asphalt and concrete will remain in place with the cap installed above. The asphalt and concrete will provide a construction surface and preliminary support during installation of the overlying materials. Furthermore, the existing surfaces minimize the dermal contact and gas inhalation exposure risks to the construction workers during installation of the cap. In areas where sludge has migrated to the surface, asphalt repair will be performed prior to installation of the cap.

The sludge in the Haack Sump will be capped, from bottom to top, with the following materials: (1) between 0 and 4.5 ft of foundation layer material; (2) a horizontal gas collection system made up of gas collection geostrips and gas collection geocomposite; (3) geosynthetic clay liner (GCL); (4) HDPE geomembrane; (5) drainage geocomposite; and (6) up to 12 in. of Class II aggregate base.

Haack Rework Area

The Haack Rework area is composed of soil-sludge material and soil overburden. The Haack Rework overburden material will be disposed of as foundation material beneath the Cooper North and/or South sumps cap. Approximately 2,670 CY of Haack Rework soil-sludge material and 2,450 CY Haack Rework overburden are anticipated to be relocated during construction activities. Disposal of the Haack Rework material will be dependent on the material properties of the soil-sludge and availability of staging areas within the property during construction, as described in greater detail in Section 6.1.2.2.

6.1.2.2 Detailed Alternative 2A Components

Alternative 2A includes the following major elements:

- Existing surface preservation;
- High-strength geotextile installation;
- Select excavation of impacted material (Haack Rework material);
- Containment of sludge along Artesia Boulevard;
- Installation of gas control and monitoring system;
- Capping of the sumps;
- Institutional controls;
- Groundwater monitoring; and
- Optional Alternative 2A Cover.

The approximate area of Alternative 2A is depicted on Figures 6-1 and 6-2. The construction and cap components are discussed further in the following sections.

Existing Surface Preservation

The existing geomembrane surface on the Cooper Property and concrete and asphalt surfaces above the Haack Sump will remain in place and the cap will be installed above these surfaces. New asphalt will be placed above the existing, degraded areas of asphalt surface over the Haack Sump prior to the initiation of cap construction on the Haack property. The geomembrane, asphalt, and concrete surfaces will provide a barrier to minimize worker dermal exposure to sludge contact as well as gas generation and release. Additionally, the concrete and asphalt surfaces will provide strength to the cap on the Haack Sump, eliminating the need for the high-strength geotextile described below.

High-Strength Geotextile Installation

A polypropylene high-strength geotextile will be placed above the existing geomembrane surface in the Cooper North and South sump areas; no polypropylene high-strength geotextile is proposed above the Haack sump area. The geotextile will be used to provide reinforcement during installation of the foundation soil to support both the weight of the soil and construction equipment. The polypropylene high-strength geotextile will be anchored around the perimeter of the two Cooper sumps with an anchor trench and/or secured to sheet piling along Artesia Boulevard. The minimum tensile strength and anchorage of the high-strength geotextile have been evaluated and are included in Appendix D. A typical anchor trench is shown as Detail 7 on Figure 6-14.

Haack Rework Material Excavation and Disposal

The Haack Rework area is comprised of approximately 2,670 CY of sludge and a soil-sludge material beneath approximately 2,450 CY of soil overburden; therefore, a total of approximately 5,120 CY of material is anticipated to be relocated during construction activities. Haack rework material excavation will be performed using standard construction equipment. A contingency plan will be developed which establishes gas concentration thresholds and corresponding actions such as odor suppression, soil replacement, and/or evacuation. Odor suppressant equipment (foaming units) will be present during excavation to control odors and gas emissions, if necessary. South Coast Air Quality Management District (AQMD) Rule 1166 and applicable California Occupational Safety and Health (Cal-OSHA) exposure limits will be followed during excavation and handling of the Haack Rework material.

As previously described, the Haack Rework soil-sludge material will be removed and disposed of offsite. The Haack Rework area overburden soil will be used as foundation material beneath the Cooper or Haack Sumps caps.

The Haack Rework soil-sludge material would be excavated and disposed of at a commercial, non-RCRA hazardous landfill (assumed to be the Buttonwillow Facility). Assuming all 2,670 CY of soil-sludge material is disposed of offsite and assuming 16 CY capacity end-dump trucks are used, approximately 164 truckloads would be necessary to transport the material an estimated 150 miles one-way to the Buttonwillow Facility. An estimated 18 trucks[2] per day could be loaded and transported to the Buttonwillow Facility, resulting in approximately 10 days of hauling from the Site (Appendix E).

The Haack Rework area will be excavated no deeper than an elevation of approximately 20 ft above mean sea level (amsl) as shown on Figure 6-5. Following excavation of material from the Haack Rework area using visual means to guide the limits of the excavation, confirmation sampling to determine the absence of sludge and COCs at 5 ft intervals to a depth of 10 ft below the planned excavation grade would be performed to confirm the material was removed. Confirmation sample results will be compared to risk-based cleanup goals described in Section 4.8. Where testing indicates concentrations in excess of cleanup goals, additional material would be excavated, hauled, disposed of offsite or reused as foundation material, and additional confirmation testing would be performed.

[2] Assumptions: (1) 3 trucks are loaded per hour between 7 am and 1 pm, such that trucks can get to the disposal facility prior to closing

Upon completion of excavation, confirmation sampling, and receipt of test results indicating that the samples are below risk-based cleanup goals, the area will be backfilled with clean on- or off-site soil and graded to drain. The slope from the southern residential properties resulting from the excavation of the Haack Rework area will be contoured to a 3 ft horizontal to 1 ft vertical (3H:1V) grade while portions of the excavations lower than the surrounding land will be backfilled and graded to drain (Figures 6-1 and 6-2).

Vapor Control During Construction

Health and safety controls will be implemented during construction, specifically during the excavation of the Haack Rework material. The Treatability Study performed by Stantec (Stantec, 2007) indicated the Haack Rework soil-sludge material is significantly degraded; however, detectable concentrations of hydrogen sulfide and sulfur dioxide are still produced when the sludge material is disturbed. Therefore, during construction activities, vapor suppressing foams can be used and workers will be provided health and safety monitoring devices such as hydrogen sulfide and sulfur dioxide indicator badges. The badges alert workers when the permissible exposure limit (PEL, 10 parts per million [ppm] and 2 ppm for hydrogen sulfide and sulfur dioxide, respectively) is nearing so the worker can exit the work area or change practices. Additionally, fixed monitoring will be performed around the perimeter of the Site to alert workers when the PEL is detected so work activities can pause and/or be altered to minimize impacts to off-site receptors.

At the completion of excavation activities each day, a vapor suppressing foam or soil cover will be used to cover the exposed excavation and stockpiles to minimize release of vapors.

6.1.2.3 Capping of the Sumps

The proposed, conceptual Haack and Cooper cap grades of Alternative 2A are shown on Figure 6-2 with cross sections shown on Figures 6-3 and 6-4. This preliminary cap design is in accordance with 22 CCR §66264.228. In accordance with 22 CCR, the cap consists of a foundation layer, low-hydraulic conductivity layer, and erosion-resistance layer. The Alternative 2A cap is illustrated on Figure 6-13, in Details 1-A and 1-B, and would consist of the layers described below. An alternative cap design is described in the Section *Optional Final Cover Configuration (No Retaining Wall),* below, which eliminates the retaining wall adjacent to Artesia Blvd. The Optional Alternative 2A cover is described in greater detail in Appendix F.

Foundation and Gas Collection Layers

The foundation soil and gas collection layers would be placed above the high-strength geotextile and asphalt and concrete for the Cooper and Haack Sumps, respectively, and consist of, from bottom to top, minimum 1 ft of foundation soil, gas collection geostrips, and a gas collection geocomposite. The minimum 1 ft foundation and gas collection layer will support the low-hydraulic conductivity layer and erosion resistance layer in accordance with 22 CCR §66264.228(e)(4). The foundation soil would consist of Haack Rework overburden soil, on-site soils and/or imported fill material. Approximately 13,000 CY of foundation material will be required for the Cooper Sumps and Haack Sump.

The foundation material would initially be placed using the "finger fill soil placement technique," which incorporates the use of parallel, narrow berms over the polypropylene high-strength geotextile. Approximately 3,900 CY of material would be placed using the "finger fill soil placement technique." The initial, 1-ft berms will then gradually be expanded across the sumps until the entire sump surface is covered with one foot of foundation soil.

During finger fill placement of soil above the polypropylene high-strength geotextile, movement of the sludge will be minimized and contained by the existing berms and the anchor trenches securing the polypropylene high strength geotextile and existing geomembrane. Where available space onsite limits traditional anchor trenches, the high-strength geotextile may be secured with concrete anchors or attached to sheet piles with battens.

After the initial 1-ft placement of soil across the sump, an additional 9,100 CY of foundation soil will be placed in lifts until final foundation grades are met (1 ft below the final cover grades shown on Figures 6-1 and 6-2). The slopes will be a minimum of 2 percent (%) to reduce impacts on drainage due to settlement of the foundation material and/or sludge.

Rows of gas collection geostrips will be placed at the surface of the foundation layer. The geostrips are 6 to 12 in. wide and consist of a geosynthetic filter fabric surrounding a molded polyethylene core (US Fabrics, 2011a). The molded polyethylene core provides a pathway for the gas to travel, while the filter fabric prevents soil intrusion and clogging. A polyethylene core and polypropylene geotextile, which are more resistant to acidic environments, will be required in the technical specifications. The gas collection geocomposite will be placed above the geostrip rows and the foundation layer (Details 1-A and 1-B, Figure 6-13). The gas collection and control system is described in greater detail below.

Low-Hydraulic Conductivity Layer

The low-hydraulic conductivity layer would be placed above the foundation soil and gas collection geostrips and geocomposite and would consist of a geosynthetic clay liner (GCL) overlain by a 60-mil HDPE geomembrane (Details 1-A and 1-B, Figure 6-13). In accordance with 22 CCR §66264.228(e)(5), the low-hydraulic conductivity layer would reduce the downward migration of precipitation and the upward migration of gas. The low-hydraulic conductivity layers would be secured within an anchor trench around the perimeter of the sumps as described below.

Anchor Trenches

The existing geomembrane (located above the two Cooper Sumps), the high strength geotextile, and the low-hydraulic conductivity layer (60-mil HDPE geomembrane overlying a GCL) are or will be anchored above the sumps using separate anchor trenches. The existing geomembrane is secured above the sumps using a 2 ft by 2 ft anchor trench (OHM, 1994). These anchor trenches act similarly to shallow, vertical barriers by minimizing the opportunity for lateral "overspilling" of surface sludge. Lateral migration of the sludge at depth has not been shown to occur through the soil based on soil borings outside the immediate areas of the sumps.

The high strength woven geotextile will be secured in a separate 2 ft by 2 ft anchor trench located outside the limits of the Cooper Sumps. During excavation of the anchor trenches, a Contingency Plan will be implemented with gas levels and corresponding corrective actions to be taken. Corrective actions will include but not be limited to odor suppression, soil replacement, and/or evacuation.

The GCL and HDPE geomembrane will be secured by an additional anchor trench around the perimeter of the Haack and Cooper Sumps. The anchor trench will vary in configuration depending on the termination condition. On the eastern, southern, and portions of the northern and western perimeters, the anchor trench will consist of a vee-trench filled with concrete to form a surface water drainage ditch (Detail 6 on Figure 6-14). On portions of the northern and western perimeters, the anchor trench will consist of a 1 ft deep by 2 ft wide anchor trench (Detail 7 on Figure 6-14). Where sheet piles are located on the northern edge of the site and space is limited, the geosynthetic materials will be secured to the sheet piles using battens.

Erosion Resistance Layer

The erosion resistance layer is comprised of a drainage geocomposite overlain by 1 ft of Class II aggregate base, in accordance with 22 CCR §66264.228(e)(10). The drainage geocomposite minimizes hydrostatic head buildup above the hydraulic barrier and

provides a means to drain precipitation that has infiltrated the overlying Class II aggregate base toward the outside of the cap and perimeter drainage channels. The Class II aggregate base will be resistant to foreseeable erosion effects caused by wind-scour, raindrop impact, and runoff prior to site development.

Sheet Pile Cut-Off Wall

Along a portion of the northern Site boundary, limited space is available to allow for grading to install the cap system. As a result, sheet piles would be installed to allow for the vertical rise of the cap without altering the Artesia Boulevard right-of-way. The sheet piles would be installed to a maximum depth of 18 feet bgs, consistent with the deepest known sludge in the Cooper North and Haack Sumps, and extend upwards to approximately 3 feet from the ground surface to accommodate the cap. The sheet piles would be coated to minimize corrosion of the steel due to the low pH and high hydrogen sulfide environment. A decorative exterior wall will cover the exposed portion of the sheet piles along Artesia Boulevard. The sheet pile cut-off wall will provide a barrier between the Haack sump sludge and Artesia Blvd and its adjacent sidewalk.

Final Cap Topography

The final cap surface is shown on Figures 6-1 and 6-2. Cross sections of the final cap topography are provided on Figures 6-3 and 6-4. Drainage channels are shown on the exterior of the sumps to the north, south, east, and west as well as bisecting the Cooper North and South sumps. The channels drain with a 0.5% slope to the northeast and northwest corners of the Cooper North and Haack sumps, respectively. The cap slopes up from the drainage channels with a minimum 2% slope to a maximum elevation of 25.7, 24.8, and 25.6 ft amsl on the Haack, Cooper North, and Cooper South sumps, respectively. Along Artesia Boulevard, the approximate height of the cap will be 22 to 23 ft amsl which includes the maximum 3 ft wall to support the final cover and an additional 6-inch curb to direct stormwater runoff to the perimeter drainage channels. The Haack Rework area will be backfilled and graded to drain as shown on Figures 6-1 and 6-2.

Optional Final Cover Configuration (No Retaining Wall)

An optional final cover configuration was identified which eliminated the retaining wall described in the *Sheet Pile Cut-off Wall* section, above. The grading in the area affected by the elimination of the retaining wall was revised to accommodate a minimum 5 percent (%) slope draining to the north and terminating at a 6 to 9 inch (in.) concrete curb immediately adjacent to the Artesia Boulevard (Blvd.) sidewalk (Optional Alternative 2A). The minimum foundation layer thickness is reduced to 0 ft adjacent to the curb to accommodate the lower cap height. The curb will deter unintended light

traffic across the slope, act as a water-stop for drainage from the slope, and accommodate the slight variations in the existing Haack Sump concrete slab surface elevation.

The high-strength geotextile will be protected by the overlying geocomposite and geomembrane. Landscaping in the form of decorative rock, artificial turf, or planter box-type vegetation structures will limit maintenance and potential impacts to the geomembrane. If necessary, cushion geotextiles may be used above the geomembrane where geocomposite is not present to prevent damage from installed landscaping.

The modifications necessary to eliminate the retaining wall and allow for the Optional Alternative 2A Cover will require waivers of some requirements in California Code of Regulations, Title 22 (22 CCR). A complete description of the alternative cover configuration is provided in Appendix F.

6.1.2.4 Gas Control and Monitoring System

The gas control system would be comprised of perimeter vertical gas migration control wells and a below-cap horizontal gas collection system. The proposed layouts of the vertical and horizontal gas collection systems are shown on Figures 6-6 and 6-7, respectively.

Vertical Gas Migration Wells

The system of gas migration control wells is designed to be a passive system that, as a contingency, can be converted readily to an active system. The system will operate actively for a period of two weeks following completion of the remedial action construction at the Site. Based on the concentrations of constituents detected during the two-week startup period, the system will remain active or switch to passive operation with the option for active control in the future. The system may be converted to passive operation with written prior approval from the DTSC. The decision to make the system active again would be based upon future gas monitoring at the Site.

A series of alternating air inlet and gas extraction piping would be placed approximately every 80 ft along the perimeter of the cap, except where sheet piles are installed as shown on Figure 6-6. The wells would be installed to approximately 2 ft above the groundwater "A" horizon ("A" horizon approximate elevation between 5.85 and 11.55 ft amsl [Stantec, 2011]). The air inlet and gas extracting wells act to create a "curtain" of air surrounding the sumps, minimizing the horizontal migration of gas without extracting gas from the sludge.

During active gas extraction, a vacuum will be applied to the gas extraction wells, thus extracting gases from these wells, which will be conveyed to a treatment system for

treatment prior to discharge to the atmosphere. The location of the system is shown on Figures 6-6 and 6-7. The vacuum pressure in the gas extraction wells imparts a vacuum on the soils surrounding each gas extraction well. With the air inlet wells equally spaced between the gas extraction wells, the air inlet forces a "short-circuiting" of the flow into the gas extraction wells. The "short circuiting" effect creates a preferential flow path between the air inlet and gas extraction wells, thereby allowing the system to "sweep" or "flush" gases migrating from the sludge material laterally without extracting gases from within the sludge (Figure 6-8).

During passive gas extraction, subsurface gas movement is non-existent or very small, allowing barometric pumping and diffusion to vent subsurface gases from the vertical gas migration control wells.

Below-Cap Horizontal Gas Collection System

A horizontal gas collection system (utilizing geostrips) would be placed within the foundation layer of the cap, as discussed above. Similar to the vertical gas migration control wells around the perimeter of the cap, the horizontal gas collection system is designed to initially operate as an active system, during a start-up period of two weeks. The system would then be operated as a passive system, but is designed as a contingent measure to be readily converted to active, if necessary. As a passive system, it would be vented to the atmosphere and rely on barometric pumping and diffusion to vent subsurface gases from the system. The decision to make the system active would be based upon post-cap construction gas monitoring at the Site as described in *Gas Treatment System*, below.

The design of the gas collection system incorporates gas collection geostrips and air inlet geostrips, both connected to separate gas collection and air inlet piping. Piping is connected to the treatment compound where actively extracted gases can be treated prior to discharge to the atmosphere and fresh air can be pulled into the system through the air inlet piping. Gases fluxing out of the sludge and vertically rising to the base of the hydraulic barrier component of the cap will be collected in the continuous gas collection geocomposite layer. Parallel geostrips will allow collected gases to be "flushed" or "swept" from the gas extraction geocomposite to the gas extraction geostrips by allowing fresh air into the air inlet geostrips. Geostrips will convey the collected gases to the gas extraction piping and the treatment compound.

Gas Treatment System

The gas extracted from the control system would be treated using specialized granular activated carbon (GAC). Specialized Granular Activated Carbon (GAC) products have been manufactured to include hydrogen sulfide and sulfur dioxide oxidation.

Specifically, Calgon Carbon has a number of specialized GAC products for hydrogen sulfide and sulfur dioxide environments.

The gas system will be operated actively for a period of time defined in a future Operations, Maintenance, and Monitoring (OMM) Plan. During initial operation, soil gas data, including constituents extracted and their concentrations, will be collected. The need for active gas collection will be based on the extracted soil gas COC concentrations and associated, calculated health risk goals. If start-up data indicates that COC concentrations are below risk-based trigger concentrations, and therefore, active gas collection is not needed, the system may be converted to a passive system which vents to the atmosphere or is turned off with no venting.

Soil gas samples will be collected from the treatment system and perimeter soil gas probes on a regularly basis to evaluate the operation of the system and/or migration of soil gas. Sample results will be compared to risk-based trigger concentrations developed with the OMM Plan for each COC. Development of the risk-based trigger concentrations will assume soil gas will cause outdoor air to become impacted with COCs; however, the outdoor air concentration used to develop the trigger concentration will be low enough to not result in adverse health effects. Based on the assumed conditions at the Site, if soil gas trigger concentrations are not exceeded, outdoor air concentrations will remain below human-health risk based concentrations. If soil gas concentrations are triggered, the gas collection and treatment system may be activated.

Gas Monitoring System

Multi-level gas migration probes would be placed outside of the perimeter of the cap. The probes are designed to be outside of the vertical gas migration control wells.

The gas probes are shown on Figure 6-7. A total of nine probes were selected based on the average distance between probes of 300 ft to provide multiple locations to detect potential gas migration, if any. Each monitoring location will consist of three nested probes with 1 ft screen lengths at 5 ft intervals for discrete sample collection. The rationale for the location was based on a location outside of the radius of influence of the vertical gas migration control wells and within the property boundary and/or in a location accessible for monitoring which increased or decreased some distances between the probes. For example, probes were placed within the median of Artesia Boulevard rather than in the street to provide a safer location for monitoring. With further refinement of design, the location and number of probes may change with adjustments to the radius of influence of the vertical gas migration control wells and the locations of buildings and utilities for future site development.

Regular monitoring of gas concentrations at the probe locations would be performed before, during, and after system operation. The decision to convert the gas collection

systems to an active system would be partially based upon the results of the probe monitoring activities and threshold contaminant concentrations developed in the Operations, Maintenance, and Monitoring (OMM) Plan as described in the *Gas Treatment System* section, above.

6.1.2.5 Institutional Controls

The anticipated institutional controls for the Site would consist of governmental controls, such as zoning and building permit restrictions, proprietary controls that restrict property use, and informational controls. Governmental controls would restrict the zoning of the Site to commercial (as identified in the Artesia Corridor Specific Plan) and prohibit sensitive land uses (i.e., residential, hospitals, schools, or child-care centers), specify building construction requirements (i.e., inclusion of gas control system beneath new structures). Environmental land use restrictions may also be applicable. Proprietary controls would place use restrictions on the Site properties. Restrictions would include future land use, the prevention of excavation or drilling within certain areas of the Site (i.e., within the capped areas), controlled traffic loads over the caps, prohibit onsite groundwater extraction for municipal and domestic use (i.e., drinking water purposes), industrial, and agricultural (i.e., irrigation) use, future building location restrictions, provide for potential easements (i.e., for O&M activities) and conveyance of proprietary control restrictions to future property owners (i.e., restrictions "run with the land"). Informational controls would include deed notices on the Site property titles and ensure inclusion of the Site on a California registry of contaminated sites. Land use covenants (LUCs) to place deed restrictions on the site will be filed with the Los Angeles County Recorder's Office and annual LUC restriction inspections will be conducted by DTSC to ensure compliance. The asphalt cap above the sludge within Artesia Boulevard will have increased maintenance to repair cracking and normal wear that increase the permeability.

Furthermore, a Health and Safety Plan (HASP) and Construction Quality Assurance (CQA) Plan would be required to establish minimum health and safety protocol during construction, and provide documentation of proper excavation, cap, and gas control system construction. A Risk Management Plan (RMP) would be developed for the Site to reduce the risk of future construction worker exposure to groundwater if the Site is developed. The RMP would discuss the hazards at the Site, minimum PPE requirements, and notification requirements.

6.1.2.6 Groundwater Monitoring

Eight of the existing ten groundwater monitoring wells would be properly abandoned prior to commencement of the remedial action. Upgradient wells MW-1A and MW-1B would not be abandoned. During the remedial action activities, an appropriate

groundwater monitoring network would be agreed upon with input from the DTSC. After the completion of the remedial action, the future groundwater monitoring wells would be installed. Groundwater monitoring would continue to be performed on a semi-annual basis. A typical groundwater monitor well is shown as Detail 3 on Figure 6-13.

The future development plans of the Site, which are currently unknown, would control where future monitoring wells would be installed. The well locations of the future monitoring well network would be agreed upon in consultation with the DTSC prior to completion of the remedial action. It is anticipated that the new monitoring wells would be installed shortly after completion of the remedial action.

6.1.2.7 Future Site Development

Following completion of the cap construction, the resulting Site conditions will facilitate the construction of a parking lot and an ingress/egress road to accommodate future commercial development at the Site. The 12-in. thick Class II aggregate base will provide a working surface for construction equipment used for parking lot construction, prevent the accumulation of free water within or below the pavement structure, and affect the rate of load distribution on the cap (Caltrans, 2008). Final landscape development designed in conjunction with the future parking lot above the cap will require the use of above grade planters to prevent biological intrusion into the cap.

The grades and final elevation of the cap have been reduced to allow for a flatter surface on which to construct a parking lot and be a less prominent feature along Artesia Boulevard. As described in Section 6.1.2.3, the maximum elevation of the cap will be 25.7 ft amsl and the slopes will vary between 2H:1V and 2 percent. During commercial development of the Site, the slopes of the parking lot can be further reduced by adding fill above the lower portions of the cap, provided drainage from the geocomposite is maintained. Selective fill would allow for a flatter surface and ramp features to facilitate car movement. The cap has been shown to support construction loads at the surface (Appendix D). During final design of the cap, traffic load restrictions will be developed and incorporated into the institutional controls.

6.1.3 Alternative 3 – Capping with Selective Excavation and Stabilization/ Neutralization

Alternative 3 includes the following major elements (Figures 6-9 and 6-10):

- Existing surface removal;
- Consolidation of material;
- Stabilization/neutralization of the current upper 3 feet of sludge in the Cooper Sumps;

- Capping of sludge remaining onsite;
- Installation of gas control and monitoring system;
- Institutional controls; and
- Groundwater monitoring.

Some of these elements were discussed in Section 6.1.2; therefore, the installation of the gas control and monitoring system (Section 6.1.2.4), institutional controls (Section 6.1.2.5), and groundwater monitoring (Section 6.1.2.6) will not be repeated herein. Existing surface removal, the consolidation of material, sludge stabilization/neutralization, and capping are discussed further in the following sections.

6.1.3.1 Existing Surface Removal

A geomembrane liner is currently above the Cooper North and South Sumps. Prior to initiating neutralization and stabilization activities, the existing geomembranes will be removed to permit access to the sludge. The reinforced concrete and asphalt covers above the Haack Sump will remain in place.

6.1.3.2 Consolidation of Material

In general, the sludge is contained in the three sumps: Cooper North and South, and Haack. As previously discussed in Section 3.2.1, approximately 2,670 CY of a soil-sludge material is located outside of the sumps in the Haack Rework area. To excavate the soil-sludge material, approximately 2,450 CY of overburden will need to be excavated. Additionally, along the eastern property line, a thin layer of sludge exists which appears to be the result of spillage or overflow from the sumps.

The Haack Rework and eastern overflow areas would be consolidated into one of the three sumps prior to capping, and used as fill beneath the cap low-hydraulic conductivity layer (to be discussed in Section 6.1.3.4). The Haack Reworked material will be tracked during placement and will not be placed where it will be in contact with the gas collection system. Approximately 5,380 CY of Haack Rework (2,670 CY), Haack Rework overburden (2,450 CY), and eastern overflow (260 CY) are anticipated to be placed above the sumps.

Following visual excavation of material from the Haack Rework and eastern overflow, confirmation sampling would be performed to confirm the material was removed. Confirmation sample results would be compared to cleanup goals. Where testing indicates concentrations in excess of cleanup goals, additional material would be removed and consolidated above the sumps. Haack Rework and eastern overflow excavations will be backfilled using soils obtained from nonimpacted areas of the site.

6.1.3.3 Stabilization/Neutralization of Cooper North and South Sludge

Stabilization/neutralization of the sludge material would be performed to the top 3 feet of the sludge to solidify the sludge for support of the proposed overlying cap. From the treatability studies performed by Stantec, it was determined that the addition of a 50/50 weight for weight (w/w) mix of calcium hydroxide ($Ca(OH)_2$) and calcium carbonate ($CaCO_3$) at a dosage rate of 20 to 30 percent reagent to sludge mix and 10 percent water neutralizes the sludge material. The addition of 50 percent soil (by weight) to this mix would effectively solidify the waste such that it is no longer susceptible to viscoelastic deformation (Stantec, 2008).

In-situ mixing would be performed through use of an excavator. The sludge on the edges of the sump would be mixed first to establish a foundation for equipment to move inward. Mixing would be performed to the minimum depth to support equipment, which is estimated at 3 feet. Due to the difficulty segregating the sludge and interbedded soil layers, it is assumed both the sludge and soil materials within the top 3 feet would be mixed as sludge. Therefore, the sludge volume used to calculate the reagent volume was the 2008 sludge volume in the top 3 feet, or 13,500 CY (Stantec, 2008).

Mixing with the reagents and soil would cause bulking of the materials. According to the Treatability Study performed by Stantec, the sumps are expected to bulk 69 percent, based on the mix design specified (Appendix B, Stantec, 2008). Therefore, the bulked materials are anticipated to increase the height of the sumps by approximately 2 feet, resulting in a total treated sludge thickness of approximately 5 feet.

Respirators (or if warranted by conditions, more stringent personal protective equipment such as Self-Contained Breathing Apparatus [SCBA]), engineering controls (potentially tenting over the excavation), and air monitoring may be required to address potential emissions of sulfurous gases from the sludge generated during mixing (Stantec, 2008).

6.1.3.4 Capping of the Sumps

Similar to Alternative 2A, the Alternative 3 cap would consist of foundation, gas collection, barrier, drainage, and protective layers covering the Cooper North and South, and Haack sumps contiguously within the Site boundary; however, the gas collection layer, erosion protection layer, and sheet piling proposed for Alternative 3 are different than Alternative 2A, as described below. As discussed in Section 6.1.2.1, the portion of the Haack sump outside of the Site boundary beneath the sidewalk and Artesia Blvd. is considered to be already capped in this Alternative (Stantec, 2010a).

The proposed final grades are shown on Figure 6-10. The Alternative 3 cap is depicted on Figure 6-15 in Details 1-C and 1-D.

Foundation and Gas Collection Layers

The foundation soil and gas collection layers would be placed above the stabilized sludge layer and consist of, from bottom to top, minimum 1 foot of foundation soil, gas collection piping, and a gas collection geocomposite. The minimum 1 ft foundation and gas collection layer will support the low-hydraulic conductivity layer and erosion resistance layer in accordance 22 CCR §66264.228(e)(4). The foundation soil would consist of onsite, impacted soil and Haack Rework material where available. Impacted foundation layer material would be supplemented with soil material imported from offsite. Impacted soil and Haack Rework material will be tracked during placement and placed such that it is not in contact with the gas collection system. Horizontal gas collection pipes surrounded by gas collection aggregate would be embedded in the foundation layer. Nonwoven geotextile would surround the aggregate to prevent clogging of the aggregate due to fines intrusion. The foundation layer would be graded with 3 percent slopes to accommodate drainage.

Low-Hydraulic Conductivity Layer

The low-hydraulic conductivity layer would be placed above the foundation and gas collection layers and would consist of a geosynthetic clay liner (GCL) and a 60-mil high density polyethylene (HDPE) geomembrane. In accordance with 22 CCR §66264.228(e)(5), the low-hydraulic conductivity layer would reduce the downward migration of precipitation and the upward migration of sludge and gas.

Erosion Resistance Layer

The erosion resistance layer is comprised of a drainage geocomposite and 2 feet of vegetated cover soil. In accordance with 22 CCR §66264.228(e)(10), the drainage geocomposite would prevent hydrostatic head buildup and drain precipitation that has infiltrated the overlying vegetated cover soil toward the outside of the cap and perimeter drainage channels while the vegetative cover soil will be resistant to foreseeable erosion effects by wind-scour, raindrop impact, and runoff.

Along the northern property boundary, limited space is available to allow for grading to install the cap system. As a result, sheet piles would be installed to allow for the vertical rise of the cap without altering Artesia Boulevard or the railroad property. The sheet piles would be installed to an average depth of 18 feet bgs and extend between 4 and 10 feet from the ground surface to accommodate the cap.

Final Cap Topography

The final cover grades are shown on Figure 6-10. The minimum thickness of the cover is 6 feet which accounts for the 3-foot stabilization layer (with bulking, 3 ft sludge layer increases to a total thickness of 5 feet), 1-foot (minimum) foundation layer, and 2-foot erosion resistance layer. The maximum cover thickness would be approximately 12.5 feet due to increasing the foundation layer to 9.5 feet to create a cover surface with 3 percent (%) slopes.

The maximum elevation of the cover for Alternative 3 is 35 feet amsl. Artesia Boulevard north of the Haack property has an elevation of approximately 20 feet amsl. Along Artesia Boulevard, the Alternative 3 cap elevation varies from approximately 26 feet amsl to 29 feet amsl resulting in a retaining wall height along Artesia Boulevard between 4 and 10 feet high.

Gas Monitoring System

The gas control and monitoring system is shown on Figures 6-11 and 6-12. The design of the Alternative 3 system is the same Alternative 2A; however, Alternative 3 will incorporate 3-inch solid and perforated polyvinyl chloride (PVC) pipes rather than geostrips. Pipes are proposed for Alternative 3 because the thicker foundation layer can accommodate the pipes and filter material.

6.1.3.5 Future Site Development

The resulting Site conditions following cap construction will facilitate an open-space end use; however, use as a parking lot may be difficult due to steep slopes around the cap edges. The maximum height of the cap is approximately 34.5 ft amsl or approximately 14.5 ft above the surrounding area (Figure 6-10). Areas around the site are available for future development such as the residential properties to the south.

6.1.4 Alternative 4 – Excavation with Offsite Disposal

Excavation and offsite disposal of the sludge would involve excavating the sludge materials to depths between 0.5 and 17.5 feet bgs (Figure 6-16). Shoring would be required in areas to support the sump walls in locations shown on Figure 6-16, at a minimum. Active dewatering would be required to remove perched groundwater and shallow groundwater when excavation and backfill are below the water table. Additionally, dewatering would be necessary to remove ponded misting agents. Respirators (or if warranted by conditions, more stringent personal protective equipment such as Self-Contained Breathing Apparatus [SCBA]), engineering controls (potentially tenting over the excavation), and air monitoring may be required to address potential emissions of sulfurous gases from the sludge generated during excavation (Stantec, 2008). Alternative 4 includes the following major elements:

- Concrete and asphalt removal;
- Excavation of sludge material from the Cooper North and South and Haack Sumps;
- Excavation of soil-sludge material from the Haack Rework Area;
- Transportation to a disposal facility;
- Confirmation sampling;
- Backfill of sumps; and
- Groundwater monitoring.

Groundwater monitoring was discussed in Section 6.1.2.6, and will not be repeated herein. Surface covering material removal, sludge stabilization/neutralization, and capping are discussed further in the following sections. These elements are discussed further in the following sections.

6.1.4.1 Concrete and Asphalt Removal

In order to access the Haack sump, the existing 6-inch reinforced concrete slab and 8-inch asphalt pavement would need to be removed. Since the underside of the concrete slab is in contact with the sludge material, after the concrete is demolished, it would be stockpiled onsite to allow for characterization sampling. Representative concrete samples should be collected and analyzed for metals, PAHs, and VOCs. Concrete found to contain metals, PAHs, or metals at concentrations exceeding hazardous waste classification thresholds would require disposal at an offsite hazardous waste facility. If materials are found to be nonhazardous, they may be recycled or disposed of at a nonhazardous facility.

6.1.4.2 Excavation of Sumps

The sumps would be excavated to the maximum depth of sludge as reported during the RI. Based on the boring logs, sludge depth varies between 0.5 and 17.5 ft bgs (Figure 6-16) (Stantec, 2008). Where significant overburden is present, such as on the Haack Sump, the overburden may be stockpiled separately, sampled, and used as backfill if testing indicates concentrations of constituents are below cleanup objectives. Using an excavator, sludge and interbedded soil would be mixed with the $Ca(H)_2/CaCO_3$ reagent and loaded directly into trucks for transport to the disposal facility. Due to the difficulty segregating the sludge and interbedded soil layers, it is assumed both the sludge and soil materials would be excavated and managed as sludge. Because of the acid gas generation during mixing, a tent would be necessary around the excavator and working surface to capture and treat the gas during mixing. As discussed in Section 6.1.3.3, the addition of the reagent would result in bulking of the material. With only the addition of

the reagent, it is anticipated bulking of the sludge would be approximately 25% and assuming 15% over-excavation, resulting in a total disposal volume of approximately 45,923 CY or 50,200 tons (based on a bulk density assumption of 81 lb/cy [Stantec, 2008]). It is assumed that the sludge containing 25% admixture will be acceptable as-is for disposal at a landfill permitted to accept non-RCRA hazardous waste such as the Buttonwillow Facility.

During excavation below the groundwater table or within the perched water zones, some dewatering may be necessary. The area where this is most likely is in the Haack Sump near the northern border of the Site. In this region, groundwater entering the excavation would be pumped to a tank where it would be sampled prior to disposal.

6.1.4.3 Excavation of Haack Rework Area

The Haack Rework area would be excavated without the addition of the reagent. Based on the Treatability Study, the rework material is significantly degraded indicating stabilization/neutralization is likely not necessary. Furthermore, the Treatability Study demonstrated that significant quantities of gas are not likely to be produced when the Haack Rework material is disturbed; therefore, a tent system with gas treatment is not necessary (Stantec, 2008).

The Haack Rework overburden would be excavated and stockpiled separately. Similar to the Haack overburden, the overburden material would be sampled and used as backfill if testing indicates concentrations of constituents are below cleanup objectives. Using an excavator, the Haack Rework sludge material would be loaded directly into trucks for transport to the disposal facility.

6.1.4.4 Confirmation Sampling

Following excavation of the sumps and Rework area, confirmation samples would be collected and analyzed for the COCs. Where confirmation sampling indicates sludge material remains, additional material would be excavated in the area represented by the confirmation sample. When confirmation sampling indicates sludge material has been removed, the removal would be considered complete and backfill would be initiated.

6.1.4.5 Backfill of Sumps

Following removal completion, the sumps would be backfilled with non-impacted, imported soil. The sumps would be backfilled to pre-excavation grades.

6.1.4.6 Transportation to Disposal Facility

The neutralized sludge material would be transported to the Buttonwillow Facility in covered trucks. This disposal facility was selected because it accepts non-RCRA hazardous wastes containing petroleum. The total volume estimated for disposal includes the sludge volume with interbedded soil calculated by Stantec in 2008, 0.5 foot over-excavation at the base of the sumps, and reagent volume for a total disposal volume of 45,923 CY and the total disposal weight of 50,200 tons. Based on testing performed by Stantec during the treatability study, the neutralized sludge would be disposed at a non-hazardous facility (Appendix B, Stantec, 2008); however, due to avoid potential future disposal liability, a non-RCRA hazardous waste facility, the Buttonwillow Facility, was selected for this Alternative analysis.

7. DETAILED ANALYSIS OF ALTERNATIVES

7.1 General

This section includes a detailed analysis of the final remedial alternatives for the Site. An overview of the nine criteria used for the detailed analysis is presented below.

7.2 Detailed Analysis Criteria

The CERCLA guidance document explains the nine criteria that are used to evaluate each remedial alternative [USEPA, 1988]. The first two criteria relate directly to findings that must be made in the Record of Decision (ROD) for the Site. These are categorized as threshold criteria that a selected remedy must meet.

1. **Overall Protection of Human Health and the Environment** – This criterion requires evaluation of how the alternative achieves and maintains protection of human health and the environment. The overall assessment of protectiveness draws on the assessments conducted under other evaluation criteria, especially long-term effectiveness and permanence, short-term effectiveness, and compliance with ARARs. Evaluation of the overall protectiveness of an alternative focuses on whether an alternative achieves adequate protection and describes how risks posed through each pathway are eliminated, reduced, or controlled through treatment, engineered controls or institutional controls. This evaluation also considers whether an alternative poses any unacceptable short-term or cross-media impacts.
2. **Compliance with ARARs** – This criterion requires an evaluation of how the alternative complies with identified ARARs and applicable advisories or guidance that are "to be considered." ARARs are generally categorized as action-specific, location-specific, or chemical-specific Federal or state-promulgated requirements. A list of potential Federal and state action-specific, location-specific, or chemical-specific ARARs have been identified for the Site and are included in Table 4-2.

The following seven criteria are "balancing" criteria. They represent the primary criteria upon which the detailed analysis is based and that are used to distinguish among alternatives that meet the threshold requirements above. The alternative that strikes the best balance among these seven criteria and that meets the threshold criteria generally is the preferred alternative.

3. **Long-term Effectiveness and Permanence** – Requires evaluation of the long-term effectiveness of the remedial alternative in maintaining protection

of human health and the environment following implementation of the alternative.

4. **Reduction of Toxicity, Mobility, and Volume Through Treatment** – The assessment against this criterion evaluates the anticipated performance of the treatment technologies that the alternative comprises, and assesses their ability to reduce the toxicity, mobility and volume of contaminated materials through the use of treatment.
5. **Short-term Effectiveness** – Requires an assessment of the protection of human health and the environment during construction and implementation of the remedial alternative until RAOs are met. The following factors are addressed as appropriate for each alternative: protection of the community during remedial actions; protection of workers during remedial actions; environmental impacts; and time until remedial response objectives are achieved.
6. **Implementability** – This criterion requires an assessment of the technical and administrative feasibility of an alternative, including the availability of required services and materials to execute the alternative. How each alternative is impacted by the property ownership (i.e., one, large, single property or seven individual properties) will also be discussed.
7. **Cost –** Requires evaluation of the anticipated capital costs and operation and maintenance (O&M) costs of an alternative. For this FS Report, O&M costs are presented in 2012 dollars using a 2 percent discount rate per EPA Guidance (EPA, 2000).
8. **State Acceptance** – Allows for consideration of preferences or apparent concerns by the State of California Department of Toxic Substances Control (DTSC).
9. **Community Acceptance** – Allows for consideration of the community's preferences or concerns regarding remedial alternatives. DTSC formally considers the community's preferences or concerns after this FS Report and proposed plan are prepared.

7.3 Final Remedial Alternatives – Detailed Analysis

7.3.1 General

This section includes the detailed analysis of the four final remedial alternatives presented in Section 6.1 and in Table 6-1. Each alternative is analyzed separately according to the nine criteria listed above. The common elements of the final remedial alternatives are not evaluated as they are the same for each alternative.

7.3.2 Final Remedial Alternative 1– No Action

7.3.2.1 Overall Protection of Human Health and the Environment

The no action alternative does not effectively mitigate potential future risks associated with the ingestion, inhalation, or direct contact of Site soils or soil gas. It does not provide any means for source zone mass removal or containment and would not be protective of human health under the hypothetical future scenario use. Because the no action alternative does not meet the threshold requirement of providing overall protection of human health and the environment, no further analysis of this alternative is performed.

7.3.3 Alternative 2A – Capping with Selective Excavation

7.3.3.1 Overall Protection of Human Health and the Environment

Overall protection of human health and the environment is moderate to high with this remedial alternative. The exposure routes for receptors as identified in the HHRA are dermal contact with sludge, ingestion of sludge, and inhalation of soil gas. Selective excavation would remove the Haack Rework area sludge material that is associated with potential gas risks. The sludge in the three sumps would be capped, reducing the risk associated with dermal contact and ingestion. Additionally, a gas control and monitoring system would be installed beneath the cap to control gas which may be generated by the sludge. High overall protection is not achieved with this method due to the source remaining onsite.

7.3.3.2 Compliance with ARARs

Compliance with ARARS is moderate with this remedial alternative. ARARs potentially applicable to Site remedial actions are provided in Table 4-2. Precautions would be required to ensure that short-term community and worker exposures to dust, noise, truck traffic, and VOC emissions are limited to acceptable levels during soil excavation and handling, per AQMD standards. This remedial alternative is compliant with the Groundwater ARARs by implementing institutional controls limiting onsite extraction of groundwater. Groundwater data has indicated that the sumps are not contributing to offsite impacts; therefore, institutional controls limiting onsite extraction are sufficient for groundwater ARAR compliance.

At some locations of the Site groundwater in the A-zone may encounter the waste material where excavations are the deepest. Waste impacted groundwater has been documented at Well MW-5A which is located immediately down gradient of the Haack Sump. Where these impacts occur the groundwater is characterized by a lower pH, occurrence of gasoline range hydrocarbons, the occurrence of some volatile organic

compounds in the low ppb range, elevated concentrations of some metals and modifications to its inorganic groundwater chemistry. However these impacts are attenuated over a short lateral distance down-gradient of the waste as documented in wells MW-3A and MW-4A which are located within or downgradient of the Site's sumps. Impacts to deeper water bearing zones have not been confirmed as the groundwater impacts observed in Well MW-5A are not observed in the B-zone monitoring wells at the Site and the geochemistry of the two water bearing zones are noticeably different suggesting limited hydraulic communication.

The Bellflower Aquiclude groundwater in the vicinity of the Site is naturally degrade as evidence by the Total Dissolved Solids (TDS) concentrations in the A-zone and the TDS and chloride concentrations in the B-zone which exceed the recommended secondary MCL values as documented in the up-gradient, background wells (wells MW-1A and MW-1B). During development of the Site's existing monitoring wells prior to reinstituting the groundwater monitoring program in 2006, some wells were pumped dry and development operations were halted to allow for recharge. This observation suggests that the two hydraulic zones immediately beneath the Site have limited yield that cannot be sustained over time. The naturally degraded groundwater quality and limited yield of the Bellflower Aquiclude at the Site indicates that human use of the groundwater beneath the Site is not likely.

The California Regional Boards are required to assure that the beneficial uses of municipal and domestic supply are designated for protection wherever those uses are presently being attained. This ARAR requirement may not be applicable to the Site because the groundwater upgradient of the Site is naturally degraded and the beneficial uses requirement is not presently being attained . Institutional controls preventing onsite extraction or use of groundwater should be sufficient for groundwater ARAR compliance.

7.3.3.3 Long-Term Effectiveness and Permanence

Long-term effectiveness and permanence is moderate to high for this remedial alternative. The permanent cap with the below-cap and perimeter passive gas control system provides long-term effectiveness. To maintain the long-term integrity of the cap and related remedial measure components, maintenance and monitoring would be provided. If the Site is developed, the parking lot surface above the cap should be maintained by the future property owner(s) to prevent cracking and/or ponding of surface water. If gas monitoring indicates concentrations in excess of acceptable values, the below-cap and perimeter vertical gas migration control wells can be made active, which adds to long-term effectiveness in controlling the migration of gas to the environment.

Based on its location, the Site is potentially at risk for high ground shaking and liquefaction during an earthquake. High ground shaking would minimally affect this alternative because its planned future use is a parking lot. Liquefaction may result in differential settlement of the cap; however, the differential settlement can be corrected with maintenance of the cap. High ground shaking would minimally affect this alternative because its planned future use is a parking lot; however, veneer stability may be compromised. Damage due to a loss of veneer stability may be repaired with maintenance.

High long-term effectiveness and permanence is not achieved with this method due to maintenance requirements.

7.3.3.4 Reduction of Toxicity, Mobility, or Volume through Treatment

Reduction in toxicity, mobility, or volume through treatment is moderate with this remedial alternative. The cap design would include a gas collection system that can be connected to a treatment system during start-up and continued use, if necessary, based upon start-up monitoring results. If the gases are treated, some reduction in toxicity would be realized. The cap and site drainage improvements would provide a reduction in mobility of the waste as infiltration of water would be mitigated. Waste volume would be reduced with the removal of the Haack Rework material; however, the sludge contained in the Cooper and Haack sumps would not be reduced.

Mobility of the sludge would be reduced with this Alternative. On the Haack Sump, there is evidence of sludge movement from beneath the cap at the edges of the concrete and asphalt cover. The installation of low-hydraulic conductivity layer, associated anchor trench, along with existing soil containment, will minimize the lateral migration of sludge.

Gas transport at the Site occurs as a result of diffusion; therefore, the rate of lateral migration of gas constituents is very low. If necessary, the perimeter vertical gas migration control wells can be activated to collect potentially migrating gases and/or remove in-place gases from subsurface soils. The collected gas can be treated if necessary, which results in reduction of the toxicity of the waste.

7.3.3.5 Short-Term Effectiveness

The short-term effectiveness of Alternative 2A is moderate to high. Cap construction would be performed above the existing surfaces on the Cooper and Haack sumps reducing gas generation, gas migration, and dermal contact risks from the exposed sludge. The Cooper sumps currently have an exposed geomembrane covering the sludge which minimizes dermal contact and gas migration. The high-strength geotextile will be installed above the existing geomembrane in a manner that minimizes damage to the

existing liner surface (e.g., hand placement). Prior to the installation of the high-strength geotextile, only limited foot traffic will be permitted above the sumps.

The existing concrete and asphalt surfaces will be maintained above the Haack Sump. The geosynthetic cap components (geostrips, gas extraction geocomposite, GCL, HDPE geomembrane, and drainage geocomposite) will be installed directly above the foundation soil overlying the concrete and asphalt surfaces and anchored outside of the perimeter of the sumps as identified in the RI, between the Cooper North and Haack Sumps, or to the sheet pile along Artesia Boulevard. The sludge between the Cooper North and Haack Sumps is discontinuous and degraded, and occurs deeper than the proposed anchor trench depth of 3 ft bgs, as identified in the RI. Therefore gas generation due to the construction of the anchor trench between the Cooper North and Haack Sumps is anticipated to be minimal to non-existent. By maintaining the current concrete and asphalt surfaces, the dermal contact and gas migration risks are minimized during construction.

The short-term effectiveness of Alternative 2A is not high due to the excavation and offsite transport of the Haack Rework material. If the Haack Rework soil material were used as fill beneath the cap, a reduced construction time is achievable as less imported material would be needed. Additionally, there would be a reduced risk of exposure to the public during transport to the final disposal facility.

In addition, based on borings CPB28, CPB29, and CPB30 performed during the Remedial Investigation (RI) between the Haack and Cooper North sumps, degraded soil-sludge was encountered intermittently between the ground surface and 7 to 8 feet below the ground surface (ft bgs). As a result, degraded soil-sludge may be encountered during both anchor trench excavations in this area. Degraded soil-sludge will be removed as necessary during anchor trench construction and anchor trenches will be backfilled with non-impacted soil. Degraded soil-sludge handling and potential gas generation will be managed in accordance with the Contingency Plan.

The cap construction would provide immediate short-term effectiveness since worker risk is low and impacts on environment are minor (grading operations). Liquid infiltration, gas migration, and physical contact would remain controlled due to limited disturbance of the existing surfaces. Because the disturbance to the sludge would be limited, hazardous gas generation would be minimal.

The duration of Alternative 2A, not including preliminary startup of the gas control system, is estimated at approximately 129 calendar days. The estimated construction breakdown schedule is provided in Appendix E.

7.3.3.6 Implementability

Technical implementation of Alternative 2A is relatively easy; however, construction implementation due to the urban setting of the Site, as well as Site size constraints and property owner agreements, create implementation challenges as discussed below.

Urban Setting

Due to the urban setting of the Site, traffic and close proximity to sensitive receptors affect the implementability of Alternative 2A. Traffic will increase the length of time to haul impacted material to an offsite disposal facility and the time to import material such as fill for the foundation layer. Alternative work hours may be proposed to reduce the effects of traffic on construction activities. Close proximity to sensitive receptors concerns are mitigated by leaving the existing surfaces on the sumps in place and by providing continuous monitoring during excavation of the Haack Rework area. The technologies for continuous monitoring are readily available and can easily be deployed at the Site during construction.

Site Size

The majority of the Cooper property contains sludge within the North and South sumps, while approximately one quarter of the Haack property contains the Haack Sump. Of the Haack property not containing the sump, approximately half is sloped and elevated leaving the one quarter available for construction staging and storage. As a result, easements and/or leases may be necessary on the southern Los Angeles Department of Public Works (LADPW) property to provide additional space and additional site ingress/egress. Furthermore, due to the eastern sludge boundary corresponding to the Cooper property boundary, the eastern drainage channel and anchor trench will be located within the LADPW property and will require fill to be placed to maintain and control drainage of that parcel. Additional agreements with the LADPW will be required in order to construct the cap.

By leaving the existing surfaces in place, material may be staged above the Haack Sump while construction is occurring on the Cooper Sumps. Additionally, the reduced fill needed for Alternative 2A requires less imported material and material stockpiling. The lower ground pressure equipment which will be used to place the fill above the high strength geotextile is generally smaller than traditional equipment, thereby requiring less storage space than larger, heavier equipment. As a result, while Alternative 2A has implementation challenges due to the Site size and location, the design of the Alternative 2A cap reduces the effect of the challenges.

7.3.3.7 Cost

The estimated capital cost of Alternative 2A is $5,844,150 based on 2012 estimates. However, a cost savings of approximately $314,500 may be achieved by using the Haack Rework soil-sludge material onsite as foundation soil. The estimated net present value of operating and maintenance costs assuming quarterly groundwater and soil vapor probe monitoring for 30 years is $4,882,500 based on 2012 estimates. Therefore, the total present value cost of Alternative 2A is $10,726,650 based on 2012 estimates. Table 7-1 presents a cost breakdown of Alternative 2A.

7.3.3.8 State Acceptance

State acceptance is high for Alternative 2A including the Optional Alternative 2A Cover. The health and environmental risks during implementation of the remedy are low, the overall cap height is minimal, and it achieves the City's redevelopment goals.

7.3.3.9 Community Acceptance

During the May 10, 2011 meeting between the DTSC and City of Gardena (City), the City expressed concerns regarding the appearance of Alternative 2 (since removed) being similar to a "landfill," and the height of the cap being too high. The City expressed the desire that the final remedial alternative be consistent with the vision and goal of future development for the Site.

Alternative 2A is a lower cap option for the Site. The maximum height of the cap is approximately 25.5 ft amsl near the center of the Site. This elevation is approximately 5.5 ft higher than Artesia Boulevard north of the Haack Property. Immediately adjacent to Artesia Boulevard, the maximum height of the cap and associated retaining wall is 23 ft amsl, or 3 ft higher than Artesia Boulevard. The Optional Alternative 2A Cover removes the retaining wall along Artesia Boulevard, further achieving the City vision and goal of future site development.

The elevation of the cap on the Cooper Property is similar to the elevation of the railroad grade immediately east of the Cooper Property. The final cap surface will consist of Class II aggregate base to support construction of a parking lot consistent with the future commercial development of the Site. Additionally, the cap structure has been designed to support loading associated with traffic and parking. Lower areas of the cap such as drainage channels may be filled to provide a more level surface on which to construct a future parking lot, provided the functionality of the cap is not compromised. As a result, Alternative 2A with the Optional Alternative 2A cover achieves medium to high community acceptance.

7.3.4 Alternative 3 – Capping with Neutralization/Stabilization and Selective Excavation

7.3.4.1 Overall Protection of Human Health and the Environment

Capping of the partially stabilized/neutralized sludge, combined with selective excavation, would provide moderate overall protection of human health and the environment. The exposure routes for receptors as identified in the HHRA are dermal contact with sludge, ingestion of sludge, and inhalation of soil gas. Neutralization/stabilization of the sludge would further improve the pH, neutralize acid gases, fixate lead, and provide long-term strength (Stantec, 2008). This Alternative is not ranked higher because the neutralization/stabilization process would require substantial mixing of the sludges, releasing hazardous gases and odors, thereby requiring a tent and gas treatment system to control gas emissions during construction. Selective excavation and consolidation within the sumps would remove the eastern overflow and Haack Rework area with the associated gas risks. Further, this Alternative does not address localized groundwater impacts at the Site. The sumps would be capped, reducing the risk associated with dermal contact and ingestion. Additionally, a gas control and monitoring system would be installed beneath the cap to control gas which may be generated by the sludge.

7.3.4.2 Compliance With ARARs

ARARs potentially applicable to Site remedial actions are shown in Table 4-2. Alternative 3 would provide moderate compliance with ARARs. Precautions would be required to ensure that short-term community and worker exposures to dust, noise, truck traffic, and VOC emissions are limited to acceptable levels during soil mixing and handling, per ambient air quality health standards.

This remedial alternative is compliant with the Groundwater ARARs by implementing institutional controls limiting onsite extraction of groundwater. Groundwater data has indicated that the sumps are not contributing to offsite impacts; therefore, institutional controls limiting onsite extraction are sufficient for groundwater ARAR compliance. This Alternative does not remediate the groundwater; therefore, this Alternative is not given a "high" ARAR compliance rating.

7.3.4.3 Long-Term Effectiveness and Permanence

The permanent cap with stabilization/neutralization and the below-cap and perimeter passive gas control system provide moderate to high long-term effectiveness. Routine maintenance and monitoring would be provided and would positively contribute to the long-term effectiveness of the remedial measure. If gas monitoring indicates impacts in excess of acceptable values, the below-cap and perimeter vertical gas migration control

wells can be made active, which adds to long-term effectiveness in controlling the migration of gas to the environment.

Based on its location, the Site is potentially at risk for high ground shaking and liquefaction during an earthquake. High ground shaking would minimally affect this alternative because its planned future use is open space; however, veneer stability may be compromised. Damage due to a loss of veneer stability may be repaired with maintenance. Liquefaction may result in differential settlement of the cap; however, the differential settlement can be corrected with maintenance of the cap.

7.3.4.4 Reduction of Toxicity, Mobility, and Volume Through Treatment

Reduction of toxicity, mobility, and volume through treatment is Moderate for Alternative 3. The toxicity of the sludge would be reduced through stabilization/neutralization by improving the pH, neutralizing acid gases, fixating lead, and providing long-term strength (Stantec, 2008). The cap design would include a gas collection system that can be connected to a treatment system during start-up and continued use, if necessary, based upon start-up monitoring results. If the gases are treated, some reduction in toxicity would be realized. The cap and Site drainage improvements would provide a reduction in mobility of the waste as infiltration of water would be mitigated; hence, migration of liquids from waste would be reduced. An increase in waste volume through bulking would be realized with the remedial measure.

Gas transport at the Site occurs as a result of diffusion; therefore, the rate of lateral migration of gas constituents is very low. If necessary, the perimeter vertical gas migration control wells can be activated to collect potentially migrating gases and/or remove in-place gases from subsurface soils. The collected gas can be treated if necessary, which results in reduction of the toxicity of the waste.

7.3.4.5 Short-Term Effectiveness

Short-term effectiveness of Alternative 3 is low to moderate. Stabilization/neutralization would require the mixing of the top 3 feet of sludge with $Ca(OH)_2/CaCO_3$. In order to mix the top 3 feet of sludge, the existing cover on the Cooper Sumps would require removal, temporarily increasing the risks associated with the sumps and decreasing the effectiveness of this Alternative. During the exposed period, stormwater could come into contact with the sludge, increasing the volume of materials requiring treatment. While fencing around the Site would be continuously maintained to prevent trespasser entry, animals, such as birds, may enter the Site and either become entrapped in the sludge or potential spread sludge to off-site areas. Additionally, during sludge mixing, significant quantities of acid gases would be released. Therefore, there may be an

increased, short-term risk during mixing activities which would require mitigation through treatment of the acidic gases. The cap construction would provide short-term effectiveness as liquid infiltration, gas migration, and physical contact would be controlled upon cap placement.

7.3.4.6 Implementability

Implementability of Alternative 3 is low. Alternative 3 may be difficult to implement due to the mixing of $Ca(OH)_2/CaCO_3$ compounded with the urban setting of the Site and the Site size. During mixing operations, significant quantities of acid gases would be released which would require treatment. Uncontrolled reactions have been known to occur when neutralizing acid sludges which require constant supervision to prevent the uncontrolled release of hydrogen sulfide gas. A tent would be necessary to contain the gases for treatment prior to discharge to the atmosphere. Due to the size of the sumps, a tent large enough to span the sumps to locations where stable foundations can be achieved may be difficult or impossible to engineer or construct. Similarly to Alternative 2A, the urban setting of the Site increases the impacts the construction would have on area traffic and the proximity to sensitive receptors. Business operations near the Site operate 24-hours a day meaning limiting mixing activities to night-time work only would still affect the public. Significant quantities of neutralizing material as well as soil would need to be imported and stored at the Site; the importing of material could significantly impact traffic as large trucks are forced to enter the Site off Artesia Blvd. Storage at the Site is limited due to the sumps and topography with staging, office, and storage areas limited to the eastern portion of the Haack Property. Stormwater controls or treatment systems, such as retention basins, would be limited by the amount of space at the site.

7.3.4.7 Cost

The estimated capital cost of Alternative 3 ranges between $11, 219,880 and $12,646,280 based on 2012 estimates. This range is due to the variable cost of neutralization admixture, $CaCO_3$ and $CaOH_2$. The costs are highly variable based where the material is sourced from, shipping costs, and construction activities. The high cost variability adds to the low cost rating of this Alternative due to the uncertainty of prices during construction. The estimated net present value of operating and maintenance costs assuming quarterly groundwater and soil vapor probe monitoring for 30 years is $4,882,500 based on 2012 estimates. Therefore, the total present value cost of Alternative 3 ranges from $16,102,380 to $17,528,780 based on 2012 estimates. Table 7-2 presents a cost breakdown of Alternative 3.

7.3.4.8 State Acceptance

State acceptance of Alternative 3 is low due to the health risks associated with neutralizing the sludge as well as the overall height of the cap..

7.3.4.9 Community Acceptance

As discussed in Section 7.3.3.9, the City of Gardena expressed concerns regarding the appearance of Alternative 3 and the desire for a final remedial alternative to be consistent with future development plans. As a result, Alternative 3 has low community acceptance.

7.3.5 Alternative 4 – Excavation with Offsite Disposal

7.3.5.1 Overall Protection of Human Health and the Environment

Alternative 4 would provide moderate to high protection of human and health and the environment by removing the sludge and rework material from the Site. The risk to human health through dermal contact, inhalation, or ingestion would be eliminated because the sludge and rework material would be removed and disposed of offsite. During construction activities and transport of the material, risk to human health and the environment would be increased as significant quantities of acid gases would be released when the sludge is disturbed. Furthermore, there is an increased risk to human health during transport of the material as it would require hauling to a facility where transport would potentially expose many more individuals to the sludge than if it were to remain onsite.

7.3.5.2 Compliance With ARARs

ARARs potentially applicable to Site remedial actions are shown in Table 4-2. Alternative 4 would provide high compliance with ARARs. Excavation and offsite disposal of sludge can be difficult or impossible to perform in compliance with applicable emissions, disposal, and transportation regulations. Precautions would be required to ensure that short-term community and worker exposures to dust, noise, truck traffic, and VOC emissions are limited to acceptable levels during soil excavation and handling, per ambient air quality health standards. Poor groundwater quality (as documented in MW-05A immediately adjacent) may be improved as the suspected sludge source is removed.

7.3.5.3 Long-Term Effectiveness and Permanence

Alternative 4 would provide high long-term effectiveness and permanence since the impacted material would be removed from the Site.

7.3.5.4 Reduction of Toxicity, Mobility, and Volume Through Treatment

Alternative 4 would provide low to moderate reduction of toxicity, mobility, and volume of the sludge or rework material through treatment. This alternative creates a large amount of waste compared to the other alternatives presented and discussed. This waste should be taken into consideration for evaluating these criteria. Alternative 4 will not reduce the toxicity or volume of the sludge or rework material. The mobility of the sludge would be temporarily increased due to transportation of the sludge, then reduced since it would be disposed of in an appropriate facility with a bottom liner system. The migration of sludge constituents is further reduced by the admixture prior to transport which was shown to reduce leaching and gas generation during the Treatability Study (Appendix B, Stantec, 2008). The volume of the sludge would increase approximately 20 to 40 percent following admixture. Other wastes that would be produced during treatment include impacted groundwater, vapor treatment associated liquid and solid wastes, and decontamination wastes. Taking these wastes into consideration, Alternative 4 would provide low to moderate reduction of toxicity, mobility, and volume of sludge and associated wastes through treatment.

7.3.5.5 Short-Term Effectiveness

Alternative 4 would provide moderate short-term effectiveness by removing the sludge and rework material from the Site; however, in order to neutralize the sludge for off-site disposal, risks associated with the sludge are temporarily increased. Neutralization of the sludge requires deep mixing of the sludge with $Ca(OH)_2/CaCO_3$. In order to mix the sludge, the existing sump covers would require removal, temporarily increasing the risks associated with the sumps and decreasing the effectiveness of this Alternative. During the exposed period, stormwater could come into contact with the sludge, increasing the volume of materials requiring treatment. While fencing around the Site would be continuously maintained to prevent trespasser entry, animals, such as birds, may enter the Site and either become entrapped in the sludge or potentially spread sludge to off-site areas. Additionally, during sludge mixing, significant large quantities of acid gases, when compared to the other alternatives presented and discussed, would be released. Therefore, there may be an increased, short-term risk during mixing activities which would require mitigation through treatment of the acidic gases.

7.3.5.6 Implementability

Implementability of Alternative 4 would be low due to the sludge depth, site proximity to sensitive receptors, site size, and site access issues. The majority of the sludge to be excavated is previously undisturbed sludge, which has a less viscous consistency than the degraded soil-sludge material that is proposed to be removed in Alternative 2A and Alternative 3. As an area is excavated, sludge would flow to the newly excavated

portion of the sump. The depth of the excavation would be between 0.5 and 17.5 ft bgs, depending on the sump, and due to the size of the Site there would not be enough room to slope the sides of the excavation. Therefore, shoring would be required, which would limit the ability to "chase" impacted materials laterally during excavation and obtain side wall conformance samples. During mixing of the reagent and sludge, acid gas containment and treatment would be necessary. A tent would be necessary to contain the gases for treatment prior to discharge to the atmosphere. Due to the size of the sumps, a tent large enough to span the sumps to locations where stable foundations may be achieved would be difficult to implement. An equipment hood may provide the necessary containment; however, the working area is limited by the size of the hood.

Similarly to Alternatives 2A and 3, the urban setting of the Site increases the impacts the construction would have on area traffic and the proximity to sensitive receptors. Business operations near the Site operate 24-hours a day meaning limiting mixing activities to night-time work only would still affect the public. Significant quantities of neutralizing material as well as soil would need to be imported and stored at the Site; the importing of material could significantly impact traffic as large trucks are forced to enter the Site off Artesia Blvd. Storage at the Site is limited due to the sumps and topography with staging, office, and storage areas limited to the eastern portion of the Haack Property. Stormwater controls or treatment systems, such as retention basins, would be limited by the amount of space at the site.

7.3.5.7 Cost

The estimated capital cost of Alternative 4 is high compared to the alternatives presented and discussed, and ranges between $26,217,950 and $28,991,650 based on 2012 estimates. The costs are highly variable based where the admixture material is sourced from, shipping costs, and construction activities. The high cost variability adds to the low cost rating of this Alternative due to the uncertainty of prices during construction. The estimated net present value of groundwater monitoring costs over 30 years is $113,200 based on 2012 estimates. Therefore, the total present value cost of Alternative 4 is between $26,331,150 and $29,104,850 based on 2012 estimates. Table 7-3 presents a cost breakdown of Alternative 4.

7.3.5.8 State Acceptance

State acceptance of Alternative 4 is low due to constructability challenges.

7.3.5.9 Community Acceptance

During the 10 May 2011 meeting with the DTSC and City of Gardena, the City felt Alternative 4 best achieved their future development goals; therefore, this Alternative receives a moderate to high ranking for community acceptance.

8. COMPARATIVE ANALYSIS OF ALTERNATIVES

8.1 General

In this section, the final remedial alternatives are compared by using the detailed analysis criteria. The purpose of this comparative analysis is to identify the relative advantages and disadvantages of each final remedial alternative and to provide a basis for identifying the preferred remedial alternative.

8.2 Final Remedial Alternatives

8.2.1 General

In Table 8-1, each final remedial alternative is assigned a ranking for each detailed analysis criterion. These rankings range from "low" to "high" and are accompanied by a numeric ranking from 1 to 5 (Note 3, below). At the conclusion of the comparative analysis, the preferred remedial alternative is identified.

8.2.2 Overall Protection of Human Health and the Environment

Alternative 1, No Action, does not provide adequate protection of human health and the environment. No further assessment or comparison with this alternative is provided. Alternative 2A performs better than Alternatives 3 and 4 due to disturbance of only the degraded Haack Rework sludge material. As demonstrated in the Treatability Study and Surface Flux Testing (Stantec, 2007), disturbing the non-degraded sludge results in the generation of significant quantities of hydrogen sulfide and sulfur dioxide. Significant mechanical disturbance of the non-degraded sludge occurs in Alternatives 3 and 4. Both Alternatives 2A and 3 would leave the majority of the sludge onsite, which reduces their overall protection of human health and the environment; however, Alternative 4 excavates the sludge from the Site and transports the sludge along public streets and highways en route to final disposal at the Buttonwillow Facility. During transport, the public may become potentially exposed to the sludge due to traffic accidents resulting in a sludge release or gas release from the truck. The same transport risks are not anticipated with transport of the Haack Rework soil-sludge material as proposed in Alternative 2A due to the degraded nature of this sludge and the significantly reduced volume of sludge to be transported.

---

(3) A numeric ranking of "1" is lowest, or worst; "5" is highest, or best. With respect to cost, "1" is most expensive; "5" is least expensive.

8.2.3 Compliance With ARARs

Alternative 4 would perform the best with respect to ARARs due to the removal of the sludge and source for potential onsite groundwater impacts. All Alternatives perform well with respect to ARAR compliance; however, Alternatives 2A and 3 are ranked lower because a potential source for onsite groundwater impacts remains in place.

8.2.4 Long-Term Effectiveness and Permanence

Alternative 4 is ranked the highest for long-term effectiveness and permanence because the sludge is removed from the site and disposed of offsite. Alternative 3 is ranked higher than Alternative 2A with respect to long-term effectiveness and permanence. Both alternatives would be effective and permanent over the long term with maintenance; however, because Alternative 3 neutralizes some of the sludge, the treatment is likely more permanent.

Based on its location, the Site is at risk for high ground shaking and liquefaction during an earthquake regardless of the remedial alternative. High ground shaking would minimally affect Alternatives 2A and 3 because of their planned future use as a parking lot or open space, respectively. High ground shaking on Alternatives 2A and 3 slopes may result in veneer failure and liquefaction may result in differential settlement of the cap. Both the veneer failure and differential settlement can be corrected with maintenance of the cap. Alternative 4 provides the greatest long-term effectiveness and permanence since the sludge is removed from the site and disposed of offsite.

8.2.5 Reduction of Toxicity, Mobility, and Volume through Treatment

Alternatives 2A and 3 would reduce mobility of the sludge by limiting infiltration and wind erosion. Alternative 3 would slightly reduce toxicity and mobility through partial in-situ treatment of the source zone; however, toxicity would increase as gases are released during mixing of the sludge for treatment. The volume of material within the sumps would increase due to bulking during neutralization and increase the cap height by a minimum of 3 ft. In Alternative 3, the net toxic material (non-stabilized sludge) would be reduced. The volume of sludge material in the sumps would remain the same with Alternative 2A. Treatment of sludge with Alternative 4 would increase the volume of waste material to be disposed of by 20 to 40 percent due to neutralization as well as generate more waste from decontamination water, spent vapor treatment carbon, and ponded dust and emissions control liquid. Alternative 4 would reduce the mobility of the sludge after offsite disposal since the disposal landfill would be equipped with a liner system to collect leachate; however, transport of the material would temporarily increase the potential mobility.

8.2.6 Short-Term Effectiveness

Alternative 2A would perform the best with respect to short-term effectiveness. Unlike Alternatives 3 and 4, Alternative 2A does not significantly disturb the sludge, thereby minimizing the release of gas. The existing surfaces, which have been shown to reduce the migration of gas, will remain in place during construction resulting in limited sludge disturbance and therefore, gas generation. Alternatives 2A and 3 incorporate a cap into the final design which would provide a reduction in risk due to inhalation, dermal exposure, and ingestion.

Alternatives 3 and 4 significantly disturb the sludge, which has been demonstrated to generate significant quantities of hydrogen sulfide and sulfur dioxide gas requiring tenting and gas control systems during mixing and excavation operations. The gas control system, incorporating a tent, blower, and treatment system, would significantly increase the amount of time to remediate the Site due to the limited operating space within the enclosed facility. Additionally, waste materials from the treatment system components, such as a scrubber, could generate additional waste, which could increase the total volume of hazardous materials at the Site. The length of time would be increased due to the use of smaller equipment as well as down time during treatment system maintenance.

Alternative 4 would provide a reduction in risk after the sludge was transported offsite; however, risk is temporarily increased in the short-term during sludge disturbance and transport. Given that the weight of material estimated for offsite disposal is approximately 45,900 CY and a typical end dump truck capacity is 16 CY, approximately 2,870 truck loads are anticipated for Alternative 4. Smaller, 16 CY trucks are proposed for Site work due to the limited space available onsite for staging and operating larger trucks. Additionally, using the estimated 20 trucks per day discussed in Section 6.1.2.2, trucks transport of the sludge would require a minimum of 160 days for transport, which does not include additional delays due to limitations from tenting and gas control during excavation.

Due to the nature of the sludge disposal within the sumps, Alternative 4 would require the excavated sumps to be exposed for periods of time during confirmation sampling. Temporary backfill of sludge in the interim would generate the potential for non-impacted material to become impacted through contact, thereby increasing the amount of material excavated and the time to remediate.

The durations of the Alternatives are estimated at 129, 235, and 301 calendar days for Alternatives 2A, 3, and 4, respectively. The construction duration of Alternative 2A is approximately half of Alternative 3 and 4 times less than Alternative 4, meaning the potential exposure time of sludge hazards to workers is significantly reduced.

Additionally, the construction impacts on the community including truck traffic and visual distractions are significantly reduced with Alternative 2A. The estimated construction schedules are provided in Appendix E.

8.2.7 Implementability

All Alternatives are difficult to implement due to the site location and size; however, the design of Alternative 2A limits the effects of these challenges on construction. These challenges are discussed in further detail below:

Urban Setting

Due to the urban setting of the Site, traffic and close-proximity to sensitive receptors affect the implementability of all Alternatives. Traffic will increase the length of time to haul impacted material to an offsite disposal facility and the time to import construction materials such as fill.

Alterative 2A requires the least amount of imported and exported material, thus reducing overall truck traffic on Artesia Boulevard. Both Alternatives 3 and 4 require significant truck traffic to import stabilization material as well as, in the case of Alternative 4, export sludge offsite. As discussed previously in Section 6.1.4.2, 3,565 truck loads are estimated for transport of excavated sludge to an offsite facility, which could negatively affect the traffic flows in the vicinity of the Site.

Site Size

The majority of the Cooper property contains sludge in the North and South sumps, while approximately one quarter of the Haack property contains the Haack Sump. The portion of the Haack property not containing the sump is split into a sloped and elevated portion and a flatter portion that could be available for construction staging and material storage. Furthermore, easements and/or leases may be necessary on the Los Angeles Department of Public Works (LADPW) property for grading and fill placement to provide for surface water flow and collection, as well as providing additional space and additional site ingress/egress.

Alternatives 3 and 4 require stockpiling of stabilization material; therefore, the time for stabilization is directly proportional to how much material is available onsite to mix. If only limited quantities of material are available onsite due to storage area constraints, the length of time to implement Alternatives 3 and 4 will increase.

Site Proximity to Sensitive Receptors

Alternatives 3 and 4 pose significant implementation issues due to the gas generation during mixing and excavation of the sludge and the potential impacts to neighboring

sensitive receptors. Gas control and treatment would be necessary during mixing and excavation of the sludge. Construction of a tent to contain the gases would be difficult to perform due to low bearing capacity of the sludge and the area the tent would need to span (minimum of the Cooper North sump). Gases captured by the tent would need treatment prior to discharge. In addition, the size of the tent and treatment system would further reduce the space available on the Site to stage construction including equipment storage, stockpiling of fill material, and construction facilities.

Implementation of Alternative 2A has fewer engineering and health and safety complications. By maintaining the existing surfaces, gas generation from the sumps would be minimized and continuous monitoring with readily available vapor suppression equipment will provide a means to minimize potential effects of gas generation during excavation in the Haack Rework area. In addition, Alternative 2A requires less imported material and material stockpiling, thus reducing the effects of traffic and the reduced Site size on construction. As a result, while Alternative 2A has implementation challenges due to the Site size and location, the design of the Alternative 2A cap reduces the effect of the challenges.

8.2.8 Cost

Alternative 2A has the lowest capital cost of approximately $5.8 million, with Alternatives 3 and 4 having low-range capital costs of approximately $11.2 million and $26.2 million, respectively and high-range costs of approximately $12.6 and $29.1 million. Alternatives 2A and 3 have identical net present value 30 year O&M costs of approximately $4.9 million based on 2012 estimates. Alternative 4 has the lowest net present value O&M cost of approximately $113,200. Alternative 2A has the lowest combined remedial cost and is not dependent on the highly variable neutralization admixture cost which may vary from as low as $300/ton to as high as $750/ton or more. All costs are based on 2012 estimates.

8.2.9 State Acceptance

The DTSC has identified Alternative 2A with the Optional Alternative 2A Cover to be the preferred remedial approach.

8.2.10 Community Acceptance

In accordance with USEPA guidance, this criterion will be addressed when DTSC is making its final remedial decision and the ROD is being prepared.

During the 10 May 2011 meeting between the DTSC and the City, the City expressed concerns regarding the appearance of the former Alternative 2 being similar to a “landfill,” and the height of the cap being too high. The City expressed the desire that

the final remedial Alternative be consistent with the vision and goal of future development for the Site.

Alternative 2A provides a reduced cap thickness, and accounts for future use as a parking lot subgrade consistent with the City's vision for commercial development. Alternative 3 proposes a cap sloping upward to a maximum elevation of 35 ft amsl, which makes parking lot construction more difficult above the high grades and slopes of the Site. Alternative 4 proposes the Site is excavated and filled. Alternative 4 best incorporates the City's vision for commercial development; however, given the potential health risks associated with implementation, short-term effectiveness, and cost challenges, Alternative 2A with the Optional Alternative 2A Cover provides the best compromise to meet the City's development vision.

8.3 Preferred Remedial Alternative

Based on the comparative analysis of the remedial alternatives, the alternative that meets the RAOs and ranks the highest is Alternative 2A, capping with selective excavation. The elements of Alternative 2A are:

- Prepare a construction HASP and CQA Plan;
- Prepare a Risk Management Plan;
- High-strength geotextile installation;
- Select excavation of impacted material;
- Containment of sludge along Artesia Boulevard;
- Capping of sludge;
- Installation of gas control and monitoring system;
- Institutional controls;
- Perform semi-annual groundwater monitoring; and
- Complete a formal review of cap effectiveness after five years.

This remedial alternative effectively mitigates the risk from ingestion, inhalation, and dermal contact with onsite soils for future non-residential occupants of buildings onsite, and future landscapers and utility workers. This alternative also effectively mitigates the risk from dermal contact with Site groundwater through the cap and institutional controls including the Health and Safety Plan and Risk Management Plan.

Alternative 2A readily meets the criteria of overall protection of human health and the environment and satisfies ARARs. When evaluated against the balancing criteria, Alternative 2A provides short-term effectiveness as well as long-term effectiveness and

permanence. It is implementable and presents an effective balance of cost against the other criteria. Alternative 2A also would accommodate future potential redevelopment of the Site.

Figures 1 through 8 in Appendix F demonstrate the conceptual design of Alternative 2A with the Optional Alternative 2A Cover. The design for Alternative 2A with Optional Alternative 2A Cover will be presented in the Remedial Action Plan.

TABLES

TABLE 4-1
CONSTITUENTS OF POTENTIAL CONCERN
Gardena Sumps, Gardena, California

Geosyntec consultants

Soil		
1,1,1,2-Tetrachloroethane	Chlorobenzene	Methylene chloride
1,2,3-Trichlorobenzene	Chloroethane	Molybdenum
1,2,4-Trimethylbenzene	Chromium	Naphthalene
1,3,5-Trimethylbenzene	Chromium VI	n-Butylbenzene
1,3-Dichlorobenzene	Chrysene	Nickel
Acenaphthene	Cobalt	n-Propylbenzene
Acenaphthylene	Copper	Oil range organics (C29-C40)
Aluminum	Dibenz(a,h)anthracene	o-Xylene
Anthracene	Dibromochloromethane	Phenanthrene
Antimony	Diethyl phthalate	p-Isopropyltoluene
Arsenic	Diesel range organics (C13 - C28)	Pyrene
Barium	Extractable fuel hydrocarbons (C10 - C40)	sec-Butylbenzene
Benzene	Extractable fuel hydrocarbons (C13 - C40)	sec-Butylbenzene
Benzo(a)anthracene	Extractable fuel hydrocarbons (C8 - C40)	Selenium
Benzo(a)pyrene	Ethylbenzene	Silver
Benzo(b)fluoranthene	Fluoranthene	Styrene
Benzo(g,h,i)perylene	Fluorene	tert-Butylbenzene
Benzo(k)fluoranthene	Gasoline range organics (C4 - C12)	Thallium
Benzoic acid	Indeno(1,2,3-cd)pyrene	Toluene
Beryllium	Iron	trans-1,3-Dichloropropene
Bis(2-ethylhexyl)phthalate	Isopropylbenzene	Vanadium
Bromobenzene	Lead	Volatile fuel hydrocarbons (C4-C12)
Butyl benzyl phthalate	m,p-Xylenes	Zinc
Cadmium	Mercury	
Soil Gas		
1,1-Difluoroethane (LCC)	Chloroethane	
1,2,4-Trimethylbenzene	Chloroform	
1,2-Dichloro-1,1,2,2-tetrafluoroethane	Chloromethane	
1,2-Dichloroethane	Cyclohexane	
1,3,5-Trimethylbenzene	Dichlorodifluoromethane	
1,3-Butadiene	Ethylbenzene	
1,4-Dioxane	Freon 113	
2,2,4-Trimethylpentane (Isoctane)	Heptane	
2-Butanone	Hexane	
4-Ethyltoluene	m,p-Xylene	
4-Methyl-2-pentanone	Methylene chloride	
Acetone	Naphthalene	
Benzene	o-Xylene	
Bromodichloromethane	Propylene	
Bromoform	Styrene	
Carbon disulfide	Tetrachloroethene	
Carbon tetrachloride	Toluene	
Chlorobenzene	Trichloroethene	
Chloroethane	Trichlorofluoromethane

Groundwater		
1,2,4-Trimethylbenzene	Chloride	Mercury
1,2-Dichlorobenzene	Chloroethane	Methylene chloride
1,2-Diphenylhydrazine/Azobenzene	Chloromethane	Molybdenum
1,3,5-Trimethylbenzene	Chromium	Naphthalene
1,4-Dichlorobenzene	Chromium VI	Nickel
2,4-Dimethylphenol	Chrysene	Nitrate-N
2-Methylnaphthalene	Cobalt	Oil range organics (C29-C40)
2-Methylphenol	Copper	o-Xylene
Acenaphthylene	Dibenz(a,h)anthracene	Phenanthrene
Antimony	Diethyl phthalate	Phenol
Arsenic	Di-n-butyl phthalate	Potassium
Barium	Di-n-octyl phthalate	Pyrene
Benzene	Diesel range organics (C13 - C28)	Selenium
Benzo(a)anthracene	Extractable fuel hydrocarbons (C13 - C40)	Silver
Benzo(b)fluoranthene	Ethylbenzene	Sodium
Benzo(g,h,i)perylene	Fluorene	Sulfate
Benzo(k)fluoranthene	Gasoline range organics (C4 - C12)	Sulfide
Benzoic acid	Indeno(1,2,3-cd)pyrene	Thallium
Benzyl alcohol	Iron	Toluene
Beryllium	Isophorone	Vanadium
Bis(2-ethylhexyl)phthalate	Lead	Xylenes, total
Butyl benzyl phthalate	m,p-Xylenes	Zinc
Cadmium	Magnesium	
Calcium	Manganese	

TABLE 4-2
APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS
Gardena Sumps, Gardena, California

Geosyntec consultants

Requirement	Prerequisites	Citation	ARAR Determination (A, RA, or TBC)	Comments
CHEMICAL-SPECIFIC APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS				
Clean Air Act (42 USC 7401-7671) Regulated by the SCAQMD				
Primary and secondary national standards for ambient air quality to protect public health and welfare (including standards for particulate matter and lead)	Air contamination affecting public health and welfare	40 CFR 50.4-50.12	A	SCQAMD standards from State Implementation Plan and California Air Resources Board are more restrictive
Resources Conservation and Recovery Act (42 USC 6901-6991[i]) Regulated by the CalEPA, DTSC				
Defines RCRA hazardous waste. A solid waste is toxic, based on the TCLP, if the waste exceeds the TCLP maximum concentrations.	Waste	22 CCR 66261.21-66261.24, 66261.100	A	Applicable for material disposed of offsite
Definition of "non-RCRA hazardous waste"	Waste	22 CCR 66261.22, 66261.24, 66261.101, 66261.3	A	Applicable for determining whether a waste is non-RCRA hazardous waste.
Safe Drinking Water Act (42 USC 300(f-j) - 26) Regulated by the SWRCB				
Maximum contaminant levels (MCLs) for organic and inorganic chemicals of concern in drinking water.	Public water system	40 CFR 141.61 (a,b), 141.62(b), & 141.11	RA	Leachate from the sumps may impact groundwater that has a designated beneficial use as municipal water. The Lynwood, Silverado, Gardena, and Gage aquifers have designated domestic water supply use.
Non-zero maximum contaminant level goals (MCLGs) for organic and inorganic chemicals of concern in drinking water	Public water system	40 CFR 141.50 & 141.51	RA	Leachate from the sumps may impact groundwater that has a designated beneficial use as municipal water. The Lynwood, Silverado, Gardena, and Gage aquifers have designated domestic water supply use.
California Safe Drinking Water and Toxic Enforcement Act (California Health and Safety Code 25249.5 - 25249.13) Regulated by the SWRCB				
Primary MCLs for inorganic chemicals of concern in drinking water	Drinking water source	22 CCR 64431 and 64449	RA	Leachate from the sumps may impact groundwater that has a designated beneficial use as municipal water. The Lynwood, Silverado, Gardena, and Gage aquifers have designated domestic water supply use.
Public health goals for inorganic chemicals in drinking water	Drinking water source	Health and Safety Code 116365	TBC	Guidelines established by the Office of Environmental Health Hazard assessment based on health considerations; HHRA was performed with site-specific conditions and acceptable risk was identified
LOCATION-SPECIFIC APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS				
No location-specific ARARs were identified for the Gardena Sumps Site. The site is not located in a sensitive or protected area	----	----	----	----
ACTION-SPECIFIC APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS				
Porter-Cologne Water Quality Control Act (California Water Code, Division 7) Regulated by the SWRCB				
Any activitiy that could affect water quality must not result in water quality parameters exceeding appropriate beneficial use water quality objectives	Contaminants affecting waters of the state	Los Angeles Basin Water Quality Control Plan	A	Groundwater protection standards are set at levels consistent with identified beneficial use for the area
State antidegradation policy applicable to both surface and ground water requiring that discharges to waters of the state be regulated to achieve the "highest water quality consistent with maximum benefit to the people of the State."	Contaminants affecting waters of the state	Los Angeles Basin Water Quality Control Plan	A	Groundwater protection standards are set at levels consistent with identified beneficial use for the area
Requires that quality of the waters of the state that is better than needed to protect all beneficial uses be maintained unless certain findings are made. Discharges to high-quality waters must be treated using best practicable treatement or control necessary to prevent pollution or nuisance and to maintain the highest quality water. Requires cleanup to background water quality or to lowest concetrations technically and economically feasible to achieve. Beneficial uses must, at least, be protected	Contaminants affecting waters of the state	SWRCB Res. 68-16	A	Groundwater protection standards are set at levels consistent with identified beneficial use for the area
California Hazardous Waste Control Laws Regulated by the Cal EPA, DTSC				
Person who generates waste shall determine if that waste is hazardous waste.	Waste	22 CCR 66262.10 & 66262.11	A	Materials in sumps are hazardous due to H_2S emissions in excess of 500 ppm_v. After neutralization, the gases are fixed indicating the material is no longer hazardous.

TABLE 4-2
APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS
Gardena Sumps, Gardena, California

Geosyntec consultants

Requirement	Prerequisites	Citation	ARAR Determination (A, RA, or TBC)	Comments
California Hazardous Waste Control Laws Regulated by the Cal EPA, DTSC (cont.)				
Owners and operators of a RCRA surface impoundment, waste pile, land treatment unit, or landfill shall conduct a monitoring and response program for each regulated unit	Unit which has waste which may pose a threat to human health or the environment	22 CCR 66264.91	NA	----
Requirements for monitoring groundwater, surface water, and the vadose zone	Hazardous waste unit	22 CCR 66264.97	NA	----
Design and construction requirements for the foundation, earth-barrier, and vegetation-support layers of the final cover	Discharge of hazardous waste to land after 7/18/97 for treatment, storage, or disposal	22 CCR 66264.228	NA	----
Requires that hazardous wastes be covered by a low-permeability cover of specific properties. The cover will prevent the downward entry of water to the closed unit for at least 100 years. Provides for post-closure care and maintenance of the cover and related components. Toxic or flammable gas or vapor must be controlled for as long as it is emitted from the site	Discharge of hazardous waste to land after 7/18/97 for treatment, storage, or disposal	22 CCR 66264.310	NA	----
Solid Waste Disposal Regulatory Reform Act Regualted by the SWRCB and CalRecycle				
Waste discharges are responsible for accurate characterization of waste. Defines designated nonhazardous solid waste and inert waste	Discharge of nonhazardous waste to land after 7/18/97 for treatment, storage, or disposal	27 CCR 20220 (b,c,d) and 20230 (b)	A	----
Requires detection monitoring. Once a significant release has occurred, evaluation or corrective action monitoring is required	Discharge of water to land after 7.18.1997	27 CCR 20385 (a) (1) and (2)	A	Water quality monitoring required for closed units, unless they are clean-closed.
Defines water quality protection standards that apply during closure and post-closure maintenance periods	Discharge of water to land after 7.18.1997	27 CCR 20390, 20395, and 20400	A	Water quality protection standards in WDRs must be met as demonstrated in detection monitoring program
Establishes requirements for gas monitoring and controls as related to closure and post-closure of units	Discharge of water to land after 7.18.1997	27 CCR 20921 to 20937	A	Gas monitoring required for closed units
Defines point of compliance as hydraulically downgradient from the unit and requires soil, surface water, and groundwater monitoring with RAOs for 3 years after cleanup.	Discharge of water to land after 7.18.1997	27 CCR 20405, 20410, and 20415	A	WDRs will specify monitoring locations
Closure and postclosure maintainence submittal requirement showing that the unit will meet performance standards and will comply with waste containment and precipitation and drainage control	Discharge of water to land after 7.18.1997	27 CCR 20950	A	Relevant to site closure
Requirements for final cover slopes, foundation layer, low-hydraulic conductivity layer, and erosion-resistance layer and mandates cover maintenance plan and annual cost estimates.	Discharge of water to land after 7.18.1997	27 CCR 21090	A	Relevant to site closure
Requires access control, site protection, and signage during closure and postclosure	Discharge of water to land after 7.18.1997	27 CCR 21135	A	Relevant to site closure
Sets design criteria for final covers of units	Discharge of water to land after 7.18.1997	27 CCR 21140	A	Relevant to site closure
Requires monitoring and analysis of differential settlement during the postclosure period	Discharge of water to land after 7.18.1997	27 CCR 21142	A	Relevant to site closure
Requires minimum of 1.5 factor of safety for static and seismic stability of final unit face	Discharge of water to land after 7.18.1997	27 CCR 21145 and 21750	A	Relevant to site closure
Requires postclosure maintenance of final cover and control systems for no less than 30 years.	Discharge of water to land after 7.18.1997	26 CCR 21180	A	Relevant to site closure
Requires that postclosure land uses shall protect public health and safety, prevent damage to the unit, and prevent public contact with waste	Discharge of water to land after 7.18.1997	26 CCR 221190 (a)	A	Relevant to site closure

TABLE 4-2
APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS
Gardena Sumps, Gardena, California

Geosyntec consultants

Requirement	Prerequisites	Citation	ARAR Determination (A, RA, or TBC)	Comments
Clean Air Act (42 USC 7401-7671) Regulated by the SCAQMD				
Limits visible emissions from a single source	Air emissions	SCAQMD Rule 401	A	Applicable for construction activities
Prohibits discharge of materials that cause injury, detriment, nuisance, or annoyance to the public; endanger the comfort, repose, health, or safety of the public; or cause or have tendency to cause injury or damage to business or property	Air emissions	SCAQMD Rule 402	A	Applicable for construction activities
Shall not cause or allow emissions of fugitive dust such that the presence of dust remains visible in the atmosphere beyond the property line of the emission source and shall not allow PM10 levels to exceed 50 mg/m^3	Generation of fugitive dust	SCAQMD Rule 403	A	Applicable for construction activities
Prohibits discharge into the atmosphere of particulate matter in excess of specified concentrations	Generation of particulates	SCAQMD Rule 404	A	Applicable for construction activities
Limits equipment from discharging particulate emissions in excess of 0.99 to 30 lbs/hr, based on a given process weight	Generation of particulates	SCAQMD Rule 405	A	Applicable for construction activities
Limits cabon monoxide and sulfur dioxide from any equipment other than that used for mobile equipment propulsion or stationary equipment engines	Air contaminant sources except mobile equipment or stationary engines	SCAQMD Rule 407	A	Applicable for construction activities
Prohibits building or using equipment which reduces or conceals an emission otherwise consituting a violation	Air emissions	SCAQMD Rule 408	A	Applicable for construction activities
Limits particulate emissions from the exhaust of a combustion source (other than an internal combustion engine) to 0.23 g/m^3 at 12% CO_2 averaged over 15 minutes	Combustion sources except internal combustion engines	SCAQMD Rule 409	A	Applicable for construction activities
Limits emissions of sulfur compounds from gaseous fuels to no more than 40 parts per million, 0.05 percent by weight (liquid fuels), and 0.56 pounds of sulfur per million BTUs (solid fossil fuels)	Combustion sources using liquid or solid fossil fuels	SCAQMD Rules 431.1, 431.2, 431.3	A	Applicable for construction activities
Limits concentrations of oxides of nitrogen from any non-mobile sources fuel-burning equipment, averaged over 15-minutes, to a rage of 125 to 300 ppm (gaseous fuels) and 225 to 400 ppm depending on equipment size	Non-mobile equipment using gaseous, liquid, or solid fuels	SCAQMD Rule 474	A	Applicable for construction activities
Specifies emissions testing, monitoring procedures, or handling or hazardous pollutants such as beryllium, benzene, mercury, vinyl chloride, and asbestos	Hazardous air pollution	SCAQMD Reg. X NESHAPS	A	Applicable for construction activities
Sets emissions standards for nitrous oxides, voliatile organic compounds, and carbon monoxide from gaseous and liquid fuels portable engines	Portable engines used on construction site	SCAQMD Rule 1110-2	A	Applicable for construction activities
Requires person excavating a landfill to identifiy mitigation measures to enure that a public nuisance does not occur.	Excavation of inactive landfill	SCAQMD Rule 1150	A	Applicable for construction activities
Limits volatile organic compound emissions from contaminated soil to less than 50 ppm. For higher emissions an approved mitigation plan, describing removal methods and mitigations measures must be obtained.	Volatile organic compounds in soil being excavated	SCAQMD Rule 1166	A	Applicable for construction activities
All new sources of air pollution that may result in a net emission increase of any nonattainment air contaminant or any halogenated hydrocarbon are to employ Best Available Control Technology. Limits emissions of nonmethane organic compounds to less than 1 lb/day	Nonattainment contaminant or halogenated hydrocarbon	SCAQMD Rule 1303	A	Applicable for construction activities
Requires equipment to be constructed with Best Available Control Technology. Non-attainment emission increases must be offset and substantianted with modeling that the equipment will not significantly increase concentrations of non-attainment emissions.	New/modified equipment which may cause issuance of a non-attainment contaminant	SCAQMD Reg XII New Source Review	A	Applicable for construction activities
Defines health risk assessment methodology; exempts nonmethane organic compounds from controls if the health risk is less than 1 in 1 million.	nonmethane organic compounds	SCAQMD Rule 1401	A	----

TABLE 4-2
APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS
Gardena Sumps, Gardena, California

Geosyntec consultants

Requirement	Prerequisites	Citation	ARAR Determination (A, RA, or TBC)	Comments
Clean Water Act (33 USC 1251-1387) and Porter-Cologne Water Quality Control Act (California Water Code, Division 7) Regulated by the SWCRB and Los Angeles RWQCB				
Waste Management Units undergoing final closure, with 1 acre of disturbance or more, must comply with substantive requirements for eliminating most nonstormwater discharges, developing and implementing a stormwater pollution prevention plan, and monitoring stormwater discharges	Construction activity on site larger than 1 acre	SWRCB Order 99-08-DWQ; SWRCB Res. 2001-046	A	Site exceeds 1 acre
Requires incorporation of permanent Best Management Practices to control storm water runoff pullution after completion of the project. Requires monitoring, sampling, and analysis of stormwater discharges under specified circumstances.	Long-term operation and maintenance of site	SWRCB Order R8-2002-0012	A	Stormwater pollution controls required for long-term maintenance
Miscellaneous State Provisions for Institutional Controls				
Provides conditions under which land-use restrictions apply to successive owners of land	Transfer site to new owner	Ca. Civil Code 1471	A	Institutional controls apply to future site use
Prohibits certain uses of land containing hazardous waste without a specific variance.	Hazardous waste property	California Health and Safety Code 25232 (b)(1)(A-E)	RA	Materials in the sumps are hazardous waste due to H_2S concentrations; however closed conditions are similar to conditions of a closed hazardous landfill.
OSWER Directive – Air Stripper Control Guidance (9355.8-28)				
Guidance regarding the use of emission controls at CERCLA sites. Will be used to develop air emissions controls if necessary.	----	----	----	----
Air Toxic "Hot Spot" Act (California Health and Safety Code § 44300 et seq.) as implemented by the SCAQMD and overseen by the Air Resources Board under CCR, Title 17, Section 93300 et seq.				
This statute and its regulations require operators of regulated facilities to prepare and submit inventory emission plans and reports and, in some cases, the preparation of health risk assessments. Only applicable if facility uses or releases a "listed" substance and releases more than 25 tons/year of total organic gases, particulate matter, nitrogen oxides or sulfur oxides.	----	----	TBC	The risk assessment required under the "Hot Spot" Act is more stringent than that performed under the FS because the FS risk assessment calculated risks due to exposure to soil and groundwater at the Site, not risks attributable to treatment processes from the remedial alternatives.

NOTES:

A - Applicable requirement (cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under Federal or State environmental or facility citing laws that specifically address a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance found at a CERCLA site)

RA - Relevant and appropriate requirement (cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under Federal environmental or State environmental or facility siting laws that, while not applicable to a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance at a CERCLA site, address problems or situations sufficiently similar to those encountered at the CERCLA site that their use is well suited to the particular site)

TBC - To be considered (Federal and State nonpromulgated standards, policies, or guidance documents and local requirements)
NA - Not applicable

CalEPA - California Environmental Protection Agency
CCR - California Code of Regulations
CFR - Code of Federal Regulations
DTSC - California Department of Toxic Substances Control
DWQ - Division of Water Quality
MCL - Maximum contaminant level
MCLG - Maximum contaminant level goal
RCRA - Resources Conservation and Recovery Act
RWQCB - Regional Water Quality Control Board
SCAQMD - South Coast Air Quality Management District
SWRCB - California State Water Resources Control Board
TCLP - Toxic characteristic leaching procedure
USC - United States Code

lbs/hr - pounds per hour
g/m^3 - grams per cubic meter
mg/m^3 - milligrams per cubic meter
ppm - parts per million

TABLE 4-3
SUMMARY OF SITE-SPECIFIC ACTION LEVELS FOR SOIL
Gardena Sumps, Gardena, California

Notes:

BaP-eq: benzo(a)pyrene toxicity equivalent

mg/kg: milligram per kilogram

RBCc: risk-based concentration based on cancer effects

RBCnc: risk-based concentration based on noncancer effects

SSAL: site-specific action level

Selected SSALs are the lowest between RBCc and RBCnc, or the background concentration for chemicals in which the RBCs were below background (e.g., arsenic and BaP-eq for the residential scenario).

(1) For arsenic, the DTSC screening level of 12 mg/kg (Cal-EPA DTSC, 2007), considered representative of background in southern California soils, was selected as the SSAL.

(2) For benzo(a)pyrene, a concentration of 0.9 mg/kg, considered representative of background PAH concentrations in southern California soils, was selected as the SSAL.

	Site-Specific RBCnc	Site-Specific RBCc	Selected SSAL
Polyaromatic Hydrocarbons			
Dibenz[a,h]anthracene	--	2.0E+00	2.0E+00

Notes:

" -- " not applicable

RBCc: risk-based concentration based on cancer effects

RBCnc: risk-based concentration based on noncancer effects

SSAL: site-specific action level

µg/L: micrograms per liter

Selected SSAL is the lowest between RBCc and RBCnc

TABLE 5-1
PRELIMINARY TECHNOLOGY SCREENING
Gardena Sumps, Gardena, California

Geosyntec consultants

Technology Type	Technology	Description	Screening Criteria			Comments
			Effectiveness	Implementability	Cost	
No Action	No Action	No work is performed, now or in the future, to attempt to mitigate existing conditions.	Minimal. Existing cap systems mitigate potential exposure to impacted materials; however, without maintenance, caps could degrade over time	Implementable.	Minimal cost	Retained as required by the RI/FS Guidance
Institutional Controls	Deed Restriction	Prohibit sensitive land uses.	Effective. Exposure mitigation depends on level of restriction	Implementable with owner cooperation and agency approval. Must meet legal requirements. May be implemented in combination with other technologies.	Minimal cost	Retained.
	Plans	Health and Safety and Risk Management Plans.	Effective. Requires minimum safety standards and site information to reduce exposure risks	Implementable.	Minimal cost.	Retained.
Treatment	Solidification/Neutralization	Chemically treat sludges to bind contaminants into a soil-like matrix.	Effective. Increases strength of sludge, neutralizes acidity of sludge	Implementable. Would require sludge handling and create significant on-site management issues such as emissions	High capital, minimal O&M	Retained.
	Thermal	Excavate impacted sludge and soil and treat by heating to volatalize contaminants.	Effective.	Implementable. Would require caustic scrubber system to capture sulfur dioxide and hydrogen sulfide as well as combustion units or afterburners.	High capital and high O&M	Eliminated due to large amounts of sulfur dioxide and hydrogen sulfide generation
	Recycling	Excavate impacted sludge and transport offsite for use in road construction or roofing.	Not effective. Sludge has high viscocity, high solids content, and no ductility.	Implementable. Would require sludge handling and create significant on-site management issues such as emissions	High capital, minimal O&M	Eliminated due to ineffectiveness of sludge recycling
Containment	Low permeability clay liner	Horizontal cap installed to mitigate contact with impacted sludge and soil, rainwater infiltration, and reduce vapor migration to surface by constructing a low permeability clay barrier, a geosynthetic membrane, and an erosion protection layer over sludge and impacted soils.	Effective. Mitigates downward migration of liquid.	Implementable. May require restriction on future land use.	Moderate capital, low O&M.	Retained.
	Geosynthetic membrane		Effective. Mitigates downward migration of liquid, vertical migration of gases, and dermal exposure.	Implementable. May require restriction on future land use.	Moderate capital, low O&M.	Retained.
	Erosion protection layer		Effective. Mitigates erosion of impacted soil and/or damage to underlying layers due to erosion.	Implementable. May require restriction on future land use.	Moderate capital, low O&M.	Retained.
Excavation	Excavation	Excavate sludge and/or impacted soil. Backfill excavation with imported soil. Dispose of sludge and impacted soil in Class I landfill, non-hazardous landfill, or TSCA cell, depending upon waste classification.	Effective. Impacted materials are removed from the Site.	Implementable. Potential major difficulties due to traffic and air emissions.	High capital, no O&M	Retained.
Engineered Controls	Vapor control systems	Install subsurface barriers and vapor control systems to mitigate soil vapor migration.	Effective. Migration of constituents is reduced or eliminated.	Implementable. May be implemented in combination with other technologies	Moderate capital, moderate O&M	Retained.
	Groundwater Monitoring	Monitor natural attenuation of consituents once source of constituents is isolated, treated, and/or removed.	Effective. Migration of constituents is identified prior to offsite transport and/or public exposure	Implementable. Currently ongoing at the site	Minimal capital, moderate O&M.	Retained.

TABLE 5-2
SUMMARY OF RETAINED TECHNOLOGIES
Gardena Sumps, Gardena, California

Geosyntec consultants

Technology Type	Technology
No Action	None.
Institutional Controls	Deed restriction on type of future development and use of the Gardena Sumps Site. Groundwater monitoring of natural attenuation. Health and safety plans and risk management plan for construction and future site use.
Treatment	Neutralization/Stabilization
Containment	Cap
Excavation	Excavation of sludge, excavation of impacted soil
Engineered Controls	Vapor control system
	Groundwater Monitoring

TABLE 6-1

REMEDIAL ALTERNATIVE TECHNOLOGIES

Gardena Sumps, Gardena, California

Geosyntec consultants

Technology Type	Technology	Remedial Alternatives			
		1	2A	3	4
No Action	No Action	X			
Containment	Cap		X	X	
Excavation	Excavation of sludge				X
Excavation	Excavation of impacted soils - on-site management			X	
Excavation	Excavation of impacted soils - off-site disposal		X		X
Treatment	Neutralization/ Stabilization			X	
Institutional Controls	Deed restriction		X	X	
Engineered Controls	Gas Control System		X	X	
	Groundwater Monitoring		X	X	X

Preliminary Remedial Alternatives

1 No Action

2A Capping with selective excavation

3 Capping with stabilization/neutralization and selective excavation

4 Excavation with offsite disposal

TABLE 8-1
COMPARATIVE ANALYSIS OF ALTERNATIVES
Gardena Sumps, Gardena, California

Geosyntec consultants

Alternative	Description	Overall Protection of Human Health and the Environment	Compliance with ARARs	Long-term effectiveness and permanence	Reduction of toxicity, mobility, or volume	Short-term effectiveness	Implementability	Cost	Total
Alternative 1	Score:	1	1	1	1	2	5	5	16
	No Action: no ongoing maintenance of geomembrane, asphalt, or concrete covers or fencing.	Low: Current geomembrane cover provides limited protection of human health and the environment. Asphalt and concrete caps provide protection of human health and the environment. Without on-going maintenance of caps which is not included with the alternative, protection of human health and the environment is limited.	Low: Does not provide compliance with ARARs.	Low: Caps are not effective over long-term without on-going maintenance.	Low: Toxicity, mobility, and/or volume are not reduced with this option.	Low to moderate: The caps and fenced conditions provide some short-term effectiveness as contact with the sludge is reduced through the clean cover (Haack Rework), geomembrane (Cooper Sumps), and concrete (Haack Sump).	High: Easy to implement	Low: No associated cost	
Alternative 2A	Score:	4	3	4	3	4	4	3	25
	Capping with selective excavation: Excavate Haack Rework and dispose offsite	Moderate to high: Exposure routes would be eliminated through capping; however, source would remain onsite. Gas would not be generated during implementation of this Alternative.	Moderate: complies with ARARS but requires additional monitoring and treatment to do so.	Moderate to high: With maintenance, will provide long-term protection.	Moderate: Reduces mobility of sludge by limited surface water infiltration and wind erosion. Gas treatment will reduce the toxicity of the waste. Onsite volume will be reduced.	Moderate to High: Excavation of Haack Rework reduces short-term effectiveness	Moderate to high: Technical implementation is relatively easy.	Moderate	
Alternative 3	Score:	3	3	4	3	2	1	2	18
	Capping with partial stabilization/neutralization and selective excavation: Partially stabilize/neutralize sludge, excavate Haack Rework and consolidate beneath composite cap system above sumps.	Moderate: Exposure routes would be eliminated through capping; however, source would remain onsite and gas generation would be high during mixing and stabilization	Moderate: complies with ARARS but requires additional monitoring and treatment to do so.	Moderate to high: With maintenance, will provide long-term protection, some sludge is neutralizaed reducing long-term concerns with untreated sludge remaining.	Moderate: Reduces mobility of sludge by neutralization, limited infiltration and wind erosion. Gas treatment and partial neutralization will reduce the toxicity of the waste. Overall volume will increase but toxicity will be reduced.	Low to moderate: Mixing of materials will release significant quantities of gas; however cap will provide immediate short-term effectiveness.	Low: Difficult to implement due to gas generation and mixing	Moderate to high: Costs associated with partial neutralization/stabilization and gas treatment	
Alternative 4	Score:	4	5	5	2	3	1	1	21
	Excavate impacted materials and dispose with off-site.	Moderate to High:Sludge and rework material would be disposed of offsite eliminating the exposure routes; however, excavation and transport of material temporarily increases risk with gas generation and public exposure.	High: Complies with ARARS	High: Very effective as material is removed from the Site.	Low to moderate: The toxicity is reduced but volume is doubled. Mobility is significantly increased when material is exposed, excavated, and hauled on public roads for final disposal.	Moderate: Removal will result in immediate effectiveness; however, excavation will generate significant gas and transport will expose public to hazards.	Low: Difficult to implement due to material properties and gas generation	High: Costs associated with partial neutralization/stabilization, gas treatment, transport, and disposal	

Notes:
ARARs - Applicable or Relevant and Appropriate Requirements
State Acceptance and Community Acceptance criteria will be assessed during comment periods and are not presented in this table.
Ranking - A numeric ranking of "1" is lowest, or worst; "5" is highest, or best. With respect to cost, "1" is most expensive; "5" is lease expensive

APPENDIX A

Responses to Comments

Geosyntec consultants

Revised Final Draft FS Report Section No.	Original FS Report Section No.	Addendum Section No.	Comment Date	Comment No.	DTSC Comments	Geosyntec Response
ES; 3.2.6	ES; 3.2.6		3/30/2011	Greg Sweel -7	Remove the speculative statement regarding perched water being related to leaking utilities and note that perched water has also been detected at several areas beneath the site.	The statement regarding perched water being related to leaking utilities has been removed. The Draft FS pages ES-5 and 18 errata sheets are included with Attachment 1.
ES-11; 7.3.3.9; 7.3.4.9; 7.3.5.9; 8.2.10	ES-11; 7.3.3.9; 7.3.4.9; 7.3.5.9; 8.2.10	5.9	6/9/2011	Greg Holmes - 7	p. 49, "Community Acceptance": The U.S. EPA RI/FS guidance states: "The modifying criteria are formally assessed after the public comment period. However, state or community views are considered during the feasibility study to the extent they are known." Since ARC and DTSC have met with the City of Gardena (the City) and now know its views, community views should be addressed in the feasibility study. In the meeting on May 10, 2011 between DTSC, the City of Gardena and ARC, the following was discussed:	The Addendum addresses the “Community Acceptance” concerns of the City of Gardena presented in Comment 7a below.
ES-11; 8.2.10	ES-11; 8.2.10	5.9	6/9/2011	Greg Holmes -3	p. ES-11, "Community Acceptance": This criterion should be addressed at the present time. See specific comment No.7 below.	A general discussion of community acceptance for Alternatives 1, 2, 3, and 4 is discussed in Section 5.9 of the Addendum. The City of Gardena desires to have a commercial structure(s) located at the Site. Alternative 2A has been conceptually designed to minimize the height of the containment cap and provide support for a future parking lot consisting of automobile and light truck traffic on the Cooper property. The removal of sludge from the Haack Rework Area will allow for the construction of a commercial structure on that portion of the Site.
ES-12; 8.3	ES-12; 8.3	6	6/9/2011	Greg Holmes -5	p. ES-12, last sentence: The statement "Alternative 2 would also best accommodate future potential redevelopment of the Site" is not supported. Please provide text to support this statement, or remove it.	The Addendum removes this statement.
ES-8; 6.1.2.5	ES-8; 6.1.2.5	3.3.7	6/9/2011	Greg Holmes -1	p. ES-8, second bullet: A health and safety plan, construction quality assurance plan, and risk management plan are not institutional controls. See EPA 540-F-00-005 for examples of institutional controls. An institutional control that should be included is a land use covenant to place a deed restriction on the site.	Land use restrictions were discussed in Section 6.1.2.5 of the Draft FS and are discussed in Section 3.3.7 of the Addendum. Specific institutional controls for Alternative 2A are zoning restrictions, groundwater use restrictions, land use covenants, and conservation easements in accordance with EPA 540-F-00-005. Appropriate institutional controls are being evaluated and will include a land use covenant.
ES-8; 6.1.2.5	ES-8; 6.1.2.5	3.3.7	6/9/2011	Greg Holmes -2	p. ES-8, third bullet: Same comment as above.	See response to Comment 1. (Greg Holmes -1)
2.4	2.4		3/30/2011	Greg Sweel -15	Replace the word "board" with "broad" in Section 2.4.	This replacement has been made. The Draft FS page 7 errata sheet is included with Attachment 1.
2.5	2.5		3/30/2011	Greg Sweel -3	Include a discussion of the listed beneficial uses for groundwater beneath the site as described in the Regional Water Quality Control Board Basin Plan	The site is located within the West Coast Basin of the Los Angeles Groundwater Basin. Based on the Basin Plan for the Coastal Watersheds of Los Angeles and Ventura Counties, the West Coast Basin has existing beneficial uses for Municipal and Domestic Supply Wells, Agricultural Supply, Industrial Process Supply, Industrial Service Supply, and Aquaculture (LARWQCB, 1994).
4.4	4.4	2.1	6/6/2011	Efrem Neuwirth -2	Section 4.5: Remedial Action Objectives: HERO recommends modifying the RAO for vapor intrusion risks to include potential health risks from hydrogen sulfide and explosive risks from methane. While the proposed remedies may accomplish this goal, achieving the narrative goal should be explicitly stated. Benzene in soil-gas within one area in the sump was the only chemical in soil gas identified in the HHRA which individually was found in any location to contribute to risks above 1 x 10^{-6} or a hazard of 1.0. However hydrogen sulfide which is the main soil gas health risk was not included in the HHRA. Methane was present at some locations although at relatively low levels. However HERO still recommends that the remedial action as well as the proposed mitigation consider methane to insure that this status does not change in the future.	The Addendum includes a section that addresses the potential health risks of hydrogen sulfide and methane for the FS alternatives.
4.4	4.4	2.1	6/6/2011	Efrem Neuwirth - Conclusions and Recommendations	HERO recommends making modest changes to the remedial action objectives for vapors and gases including modification of the RBC for benzene, adding an RBC for hydrogen sulfide, and monitoring for methane.	The risk-based concentrations were based on reasonable and protective input parameters used in the approved baseline risk assessment for current and future commercial and residential receptors. Therefore, we believe that no further modification is needed. Potential hazards to H_2S and methane from sludge material is addressed as a part of the remedial alternatives discussion in the Addendum to the FS.
4.5	4.5	2.2	10/31/2011	Greg Sweel -1	Include prevention of dermal contact with the low pH sludge, in addition to PAHs, as one of the listed remedial objectives.	Prevention of dermal contact with the low pH sludge will be included with remedial objectives.
4.5	4.5	2.2	11/11/2011	Efrem Neuwirth -1	HERO appreciates that the remedy alternatives address contact with the sludge to deal with the chronic risks from the PAHs and other COPCs, however HERO still recommends that the remedial objectives state that acute risks from direct physical contact should also be addressed by the remedy.	Prevention of dermal contact with the sludge will be included with remedial objectives.
4.5	4.5	2.2	3/30/2011	Greg Sweel -9	Include prevention of dermal contact with low pH sludge on the list of remedial action objectives.	Section 2.2 of the Addendum lists the prevention of dermal contact as one of the remedial objectives.
4.5	4.5	2.2	3/30/2011	Greg Sweel -10	Replace "benzene" with "volatile organic compounds" on the list of remedial action objectives.	The word “benzene” has been replaced with “volatile organic compounds” in Section 2.2 of the Addendum.

Revised Final Draft FS Report Section No.	Original FS Report Section No.	Addendum Section No.	Comment Date	Comment No.	DTSC Comments	Geosyntec Response
4.5	4.5	2.2	6/6/2011	Efrem Neuwirth -1	Section 4.5: Remedial Action Objectives: HERO recommends an addition to the remedial action objectives for the site which incorporate the numerical RBCs. HERO recommends adding a narrative objective of preventing all future direct contact with the sludge material to prevent potential acute dermal toxicity from the complex PAH mixture and acids in the sludge. The proposed remedies may accomplish this goal; however, achieving this goal should be explicitly stated.	The Risk Based Concentrations (RBCs) are generally incorporated into the remedial action objectives (RAOs) in the discussion of prevention of ingestion, inhalation, and dermal contact with sludge or soil in excess of the 10^{-5} to 10^{-6} cancer risk as represented by arsenic, hexavalent chromium, naphthalene, benzo(a)pyrene equivalence (BaP-eq), dibenz(a,h)anthracene, and VOCs (Section 4.5 of the Draft FS, Section 2.2 of the Addedum). The RBCs are specifically incorporated into the site-specific action levels discussed in Section 4.8.1 of the Draft FS. The Addendum includes a section that addresses the prevention of future direct contact with the sludge.
8		5	5/2/2011	Tizita Bekele -General	Four remedial alternatives including no action are considered for the site. The description of the alternatives is not detailed enough for proper evaluation. The detailed analysis of the alternatives is lacking in demonstrating why the preferred alternative, alternative 2, is superior over the rejected alternatives, specifically alternative 4, excavation and off-site disposal. Although the difference in the estimated cost of alternative 2 and 4 is significant, other factors, such as implementability and compatibility with future land use, should be discussed in detail for the cost/benefit evaluation of each alternative.	A detailed design of the chosen alternative will be presented following the submittal of the Remedial Action Plan, as part of the Remedial Design document. Additional details for the comparative analysis have been added to Section 5 of the Addendum.
6.1.2.2			9/6/2012	Perry Myers -3	The proposed high strength geotextile will be placed above the existing geomembrane which appears to have experienced minor tears and punctures in the past. This could lead to exposure of the high strength geotextile to the low pH sludge. The performance of the existing geomembrane and the high strength geotextile and the expected useful life in contact with the low pH sludge should be evaluated as an aid in choosing a feasible remedy and account for future replacement costs.	ARC, in response to the existing tears and minor punctures within the existing geomembrane, is in the process of overlaying the existing geomembrane with a fabric reinforced 45 mil thick polypropylene ethylene copolymer (PEC) geomembrane designed and manufactured nearly identical to the existing geomembrane. The proposed high-strength geotextile will be manufactured from polypropylene. Polypropylene has been shown to be compatible with low pH environments (SI Geosolutions, 1997). A statement that a polypropylene geotextile will be utilized has been included in the Revised Final Draft FS in Section 6.1.2.2.
6.1.2.2			9/6/2012	Perry Myers -4	In the April 4, 2012 response to DTSC comments from Steven Hariri, it was indicated that the actual design of the parking lot on top of the proposed cap would be deferred to the developer. However, it is our opinion that it would be in order to address any possible traffic or other load limitations/restrictions, based on typical traffic expected in a commercial/retail development, that are related to the cap design in the FS.	The preliminary loading used in the evaluation of the high strength geotextile was the weight of the dozer and "finger fill" soil during construction corresponding to a pressure at the surface of the geotextile of 720 pounds per square foot. This is the design pressure for the selection of geotextile strength needed to support the construction loading. Once the first foot of soil is placed above the geotextile, the bearing capacity is higher (accounting for strength of the soil layer over the geotextile and sludge) and the ability of the cap to support additional surface loads gets better with additional material thickness. Therefore, the traffic loading is expected to not affect the geotextile design. Final design will account for a 200 psf traffic loading on the completed surface.
3.2.1	3.2.1		3/30/2011	Greg Sweel -8	Include the range of pH values detected from the sludge in Section 3.2.1.	The range of pH values has been included in Section 3.2.1. The Draft FS page 8 errata sheet is included with Attachment 1.
					HERO disputes that the input parameters under discussion (site-specific soil properties, including building height) utilized in calculating the risk based concentrations were all agreed to in previous meetings and/or memorandum. HERO refers the reader to the letter/memorandum dated February 12, 2009 (after the referenced phone call) from Kyle Christie representing ARCO to Joseph Cully, DTSC Project Manager. What is agreed to in the response to comment 1 in that memorandum is the use of the US EPA default values for loam (following future GSU approval of that soil type classification) for the HHRA and use of the measured site-specific properties (soil moisture content included) in the uncertainty section. Hero was unable to find any documentation of the review of the soil type, however, HERO will accept the loam classification since the effects on the modeled vapor intrusion risks are likely to be within an acceptable range. However, the soil moisture content offered for use of 0.244 is not well within the expected values for loam material. It is in fact, the upper bound of the range of moisture for that soil type (0.061-0.24 v/v, see Table 10 in the USER'S GUIDE FOR EVALUATING SUBSURFACE VAPOR INTRUSION INTO BUILDINGS, available at http://www.epa.gov/oswer/riskassessment/airmodel/pdf/2004_0222_3phase_users_guide.pdf.	Soil physical property data were collected as part of the original investigation work for the Remedial Investigation for the site. Eight samples were collected from a depth of 5 feet and 15 feet below ground surface (bgs) from 4 locations. This data was summarized and used in the risk assessment. Subsequent to the original data, additional moisture content data was collected in July 2009 to evaluate whether the moisture content of 0.244 is a reasonable assumption to use in the modeling. This data was transmitted to DTSC November 2010 (Stantec, 2010). Moisture content data provided in the Revised Draft Remedial Investigation Addendum was collected at many locations across the site with a total of 32 samples collected at depths up to 10 feet bgs. When reviewing the data from the top 10 feet, the average moisture content by dry weight is 15.2 percent. This value is very similar to and actually slightly higher than the average moisture content used in the risk assessment of 14.9 percent

Revised Final Draft FS Report Section No.	Original FS Report Section No.	Addendum Section No.	Comment Date	Comment No.	DTSC Comments	Geosyntec Response
4.8.1; Table 4-4	4.8.1; Table 4-4		11/11/2011	Efrem Neuwirth -3	HERO still recommends utilizing the default soil properties for the generic soil type at this time. If site-specific properties including moisture content are to be used in calculating risk based concentrations for soil-gas, then a sufficient amount of samples representative of the soil on-site need to have been collected and analyzed to determine if they are representative of all site soils and do not vary to a significant extent. This is especially true in regards to locations adjacent to sludge where the future monitoring system and buildings will be located, in comparison with soil locations above or below layers of the sludge. HERO is unaware of such an analysis having been performed. Please provide this information with all appropriate documentation so the site-specific properties can be evaluated. HERO also notes that the samples are not applicable to new imported soils in the Haack Rework area. Information will need to be provided to demonstrate that imported soil has the same site-specific physical properties as the pre-existing soil if the risk based concentrations are to be applicable to soil-gas in the proposed Haack removal area. HERO accepts the use of 12-ft ceiling height for this Site in calculating the commercial/industrial risk based concentrations. HERO notes that the increased volume from 12-ft ceiling height has only a minor effect on the risk evaluation.	(0.244 volumetric moisture content). Due to the large number of samples collected across the site the moisture content has been well defined and the value of 0.244 is considered appropriate for use in the modeling. It is acknowledged that information will need to be provided to document that any new import soil brought onto the site is of the same soil type and has similar soil-physical properties as what was assumed in the modeling. This will be addressed through the construction specifications which will require a certain type of soil and gradation.
6.1.2.2		3.3.1	10/31/2011	Greg Sweel -2	Sludge beneath portions of the Haack sump have been observed to daylight through the asphalt surface and beyond the concrete adjacent to the sidewalk along Artesia Boulevard. Portions of the existing asphalt surface have been compromised and these conditions should be addressed in the FS.	ARC has also noticed that sludge daylights through areas of the Haack parking lot asphalt and in one area beneath the edge of the concrete cap over the Haack sump adjacent to the Artesia Boulevard sidewalk. ARC and DTSC personnel also observed, during a December 2011 Site visit, that the integrity of portions of the Haack asphalt was significantly degraded. ARC informed the DTSC that areas of degraded asphalt would be overlain by new asphalt prior to commencing with the installation of the Haack Sump cap foundation layer. A sheet pile wall will be installed adjacent to the sidewalk and Artesia Boulevard along the north side of the Haack sump. This will contain sludge within the Haack sump minimize sludge from daylighting along Artesia Boulevard and the sidewalk. Section 3.3.1 of the FS Addendum is revised as follows: The existing geomembrane surface on the Cooper Property and concrete and asphalt surfaces above the Haack Sump will remain in place and the cap will be installed above these surfaces. New asphalt will be placed above the existing, degraded areas of asphalt surface over the Haack Sump prior to the initiation of cap construction on the Haack property. The geomembrane, asphalt, and concrete surfaces will provide a barrier to minimize worker dermal exposure to sludge contact as well as gas generation and release. Additionally, the concrete and asphalt surfaces will provide strength to the cap on the Haack Sump, eliminating the need for the high-strength geotextile described in Section 3.3.2.
6.1.2.2		3.3.3	10/31/2011	Greg Sweel -8	Confirm that excavation to 20 feet above mean sea level will remove the sludge and sludge impacted materials from the Haack Rework area. Include or provide a plan to collect confirmation samples.	Confirmation sampling to determine the presence of sludge below an elevation of 20 feet mean sea level will be performed following excavation of the Haack Rework area to its planned excavation grade. A Confirmation Sampling Plan will be prepared in the Remedial Action Plan.
6.1.2.2		3.3.4	5/2/2011	Tizita Bekele -1	The potential for release of hydrogen sulfide and sulfur dioxide during the excavation and consolidation of the sludge/soil and sludge material in Haack Rework area and the eastern edge of the sumps should be discussed in detail.	Section 3.3.4 of the Addendum discusses measures to minimize the release of hazardous vapors during excavation of the Haack Rework Area sludge.
6.1.2.2		3.3.1	5/2/2011	Tizita Bekele -4	In addition to displacement, there is a potential for hydrogen sulfide and sulfur dioxide release as the sludge would be disturbed during placement of stabilization material. A detailed assessment of the potential toxic gas releases and mitigation measures to curb the impact should be included.	The preservation of the existing surface materials (asphalt and concrete over the Haack sump and the geomembrane liner over the Cooper sumps) above the three sumps in Alternative 2A (see section 3.3.1 of the Addendum) minimizes disturbance of the sludge and generation of toxic gas releases during placement of the geotextile and foundation layer above the sludge. Vapor control during construction is addressed in Section 3.3.4 of the Addendum.
6.1.2.2	6.1.2.2	3.3.3	6/6/2011	Efrem Neuwirth -4	Following possible removals of sludge, HERO recommends sampling soil-gas for VOCs, hydrogen sulfide and methane to insure that the residual risks are acceptable.	Sludge will be removed from the Haack Rework Area based on visual criteria. There are no plans to perform soil-gas sampling after the removal of the sludge since the source of the VOCs, hydrogen sulfide, and methane will have been removed.
6.1.2.2	6.1.2.2	3.3.3	6/6/2011	Efrem Neuwirth -7	Please describe in greater detail the proposed removal of soil from the HAACK rework area and what if any reworked soil may be left behind. What would be the elevation of the land relative to the adjacent sumps and the homes following the removal? Would there be a need to import fill material? Conceivably, RBCs or future· action objectives for soil gases might need adjusting if the characteristics of the soil are significantly changed.	A detailed description of sludge removal from the Haack Rework Area and land surface elevations is included in the Addendum, Section 3.3.3. It is not anticipated that the soil characteristics will be significantly different as fill material will consist of onsite material and/or fill material meeting a specific grain size distribution and compaction requirements dictated in construction specifications (to be developed during Remedial Design).

Revised Final Draft FS Report Section No.	Original FS Report Section No.	Addendum Section No.	Comment Date	Comment No.	DTSC Comments	Geosyntec Response
6.1.2.2		3.3.4	6/9/2011	Greg Holmes -General	A proposed new alternative, as discussed below, should include excavation of sludge from the "rework" area and shipment offsite for disposal. This new alternative should also include measures to prevent the release of hazardous vapors.	The Addendum to the Gardena Sumps Draft FS presents Alternative 2A. Alternative 2A was requested by the DTSC during a meeting between the DTSC, the City of Gardena, and ARC on 10 May 2011 and includes a modification of the containment cap alternative presented in the Draft FS. Alternative 2A includes the excavation of sludge from the Haack Rework Area. This sludge will be transported offsite for disposal. Haack Rework soil-sludge material may be placed under the containment cap in the Cooper Sumps portion of the site as part of the foundation soil necessary to achieve drainage design criteria. Reworked soil overburden currently above the sludge may be utilized as part of the foundation layer of the containment cap as described in Section 3.3.3 of the Addendum. Section 3.3.4 of the Addendum discusses measures to minimize the release of hazardous vapors during excavation of the Haack Rework Area sludge.
6.1.2.2		3.3.3	6/9/2011	Greg Holmes -7b	The City and the DTSC representatives requested that the FS consider off-site disposal of impacted soil to be excavated as part of the recommended remedial alternative rather than incorporation of such soil below the cap.	The Addendum addresses offsite disposal of impacted material such as the Haack Rework material (Section 3.3.3); however, the elevation concerns will not be alleviated by offsite disposal of this material. As described in the response to Comment 6, above, the height of the cap presented in Alternatives 2 and 3 is the result of meeting stability and drainage requirements of 22 CCR and 27 CCR. The estimated 6,500 cubic yards (CY) of impacted material is only 17% of the 39,200 CY of soil necessary to create the final cover grades for Alternatives 2 and 3. Alternative 2A will incorporate a thinner cap which will require less fill than Alternative 2. The Haack Rework soil-sludge material may be used as part of Alternative 2A's foundation layer, beneath the low-hydraulic conductivity layer; however, the description of its use and the cost estimates are based on off-site disposal.
					It is stated that the material below Artesia Boulevard and the adjacent sidewalk is considered capped and will be left in place. Given that a permanent cap is proposed as a remedy for the onsite sludge please clarify the basis of the assumption that this material is capped and provide analysis showing that the cover on this material would provide the same level of protection and for the same duration as the proposed onsite cap.	An explanation of the mapped boundaries of sludge as depicted in Figure 2AS and other figures in the December 2010 'Addendum to the August 22, 2008 Revised Draft 2006 Remedial Investigation Report' and Figure 3-2 (clarification sheet 17) of the April 2012 Revised Feasibility Study is required to clarify the statement that the sludge material beneath Artesia Boulevard is capped. In early 2009 the DTSC staff and ARC agreed that future revised maps illustrating the lateral distribution of sludge would address sludge of any thickness or at any depth encountered and exclude mixtures of soil-sludge material. Boring AB-101, drilled within Artesia Boulevard, was located to the north of the location of the northern Haack Sump berm and encountered asphalt, roadbase and constructed fill to 2.8 feet bgs. A sludge layer having an apparent thickness of approximately 0.5 to 0.75 feet was encountered at 5.5 feet bgs and was overlain and underlain by deposits of reworked soil-sludge material, indicating that this sludge layer had also been re-worked and was not a continuation of the Haack Sump. Borings AB-102 and AB-103, drilled near AB-101, encountered asphalt, roadbase and constructed fill to a depth of 6 feet bgs but no sludge material. The 2009 mapping agreement results in the extension of mapped sludge into Artesia Boulevard. However, it is interpreted that the sludge encountered in AB-101 is a large fragment of sludge displaced from the Haack Sump during the significant widening and reconstruction of Artesia Boulevard in the mid-1950s. The occurrence of reworked soil-sludge material (including larger fragments of sludge) with a thickness of approximately 3.75 feet lies beneath a small portion of Artesia Boulevard. This reworked soil-sludge material is capped by approximately 2.75 feet of asphalt, roadbase, and fill material that meets Cal Trans standards for state highway construction. This soil-sludge mixture is contained to the west by approximately 2.5 feet of asphalt and roadbase material underlain by approximately 4.25 feet of reworked clay and silt (boring AB-100) and contained to the north and east by approximately 2.5 feet of asphalt and roadbase material underlain by approximately 3.5 feet of reworked silty sand and sandy silt (borings AB-102 and AB-103). The soil-sludge mixture would be contained to the south by the proposed sheet pile cut-off wall.

Revised Final Draft FS Report Section No.	Original FS Report Section No.	Addendum Section No.	Comment Date	Comment No.	DTSC Comments	Geosyntec Response
6.1.2.2			9/6/2012	Perry Myers -9		Code of Federal Regulations (CFR) Title 40, Part 264.310 designates the requirements for a hazardous waste landfill cover which includes: provide long-term minimization of migration of liquids through the closed landfill, function with minimum maintenance, promote drainage and minimize erosion or abrasion of the cover; accommodate settling and subsidence so that the integrity is maintained, and have a permeability less than or equal to the permeability of any bottom liner system or natural subsoils present. The concrete and asphalt "caps" currently over the sludge deposits have not shown evidence of settlement since their installation. They provide a relatively impermeable surface to minimize infiltration into the sludge deposits. The permeability of the current asphalt is unknown but asphalt with permeabilities as low as 10^{-7} cm/s can be achieved. Furthermore, the City of Gardena maintains the roadway such that the asphalt surface remains in good condition. The area of Artesia Boulevard that overlays the soil-sludge material shows no evidence of differential settlement, even with heavy truck traffic. As part of the institutional controls, the requirement for a low-permeability asphaltic concrete paving will be included when Caltrans repaves the portion of Artesia Blvd covering the sludge material.
6.1.2.2			9/6/2012	Perry Myers -10	Alternative 2A proposes to use the Haack Rework Area material as part of the foundation layer beneath the Haack, Cooper North or Cooper South Sumps or off haul it for disposal. However, about half (2670 CY) is indicated to be sludge and a soil-sludge mixture and would appear to be unsuitable for use as foundation material. The FS should further justify use of the sludge/soil as foundation material.	It is proposed to only use the Haack overburden soil as foundation material. The text has been revised to reflect this.
6.1.2.2			9/6/2012	Perry Myers -11	Figure 3-1 of the FS Addendum depicts the sludge in the area between the Haack and Cooper North Sumps as continuous, requiring the anchor trench for the high strength geotextile to be constructed in the sludge. The FS should discuss how contact with this low pH material affects the performance and life expectancy of the geotextile, whether the proposed anchor trench in this area will need modifying to provide adequate bearing capacity and lateral resistance, and gas mitigation measures that will be necessary due to disturbing the sludge.	The 2009 mapping agreement resulted in the Haack Sump – North Cooper Sump berm being illustrated as a continuous sludge deposit. ARC believes that the Haack and Cooper North Sump are not one contiguous sump at depth. Borings CPB28, CPB29 and CPB30 were drilled to investigate if these two sumps were contiguous. All three of these borings encountered one to two discrete, thin sludge layers (<1.0 feet thick) within the upper 5.0 feet of the ground surface. These discontinuous sludge layers are interbedded with reworked fill which consists of a mixture of silt, brick debris and sludge fragments. ARC's interpretation is that the discontinuous sludge layers represented surficial overflow deposits which were then buried with reworked fill materials as the height of the berm was increased. The December 1941 aerial photograph (Figure C-7 of the 2008 revised draft RI report) and the September 1946 aerial photograph (Figure C-8 of the 2008 revised draft RI report) show the Haack Sump – North Cooper Sump berm where the anchor trench is proposed to be located. The high strength geotextile will not be negatively impacted by small amounts of sludge which may be present within the anchor trench, as described in response to comment No. 6. Material excavated from the anchor trench containing sludge will not be used to backfill the trench and will be used as foundation material beneath the capor disposed of offsite depending on the properties of the material. The cost estimate conservatively assumes the material will be disposed of offsite.
6.1.2.3		3.2.1, 3.2.2, 3.2.3	2/10/2012	Steven Hariri -3	ESPO recommends a minimum of two feet of foundation layer as required by 27CCR§21090(a)(1).	In order to accommodate the City of Gardena's request for a reduced cap height, a minimum 1 foot foundation layer thickness was designed. The 1 foot thickness is a minimum and will generally occur along the perimeter of the cap. The foundation thickness increases with the 2 percent graded slope to a maximum of approximately 3.5 feet. During design of the final cap, an evaluation will be provided which demonstrates that the differential settlement of waste and ultimate land use will not affect the structural integrity of the final cover in accordance with 27CCR§21090(a)(1).
6.1.2.3		3.3.5.4	2/10/2012	Steven Hariri -5	The one foot of base above the geomembrane may not be protective of the geomembrane from heavy construction equipment required for development. Therefore, ESPO recommends a total cover over the cap of a minimum of eighteen inches to two feet comprised of infiltration and erosion layers (27CCR§21140(b) and 40CFR258.60(a)) unless an equivalent is demonstrated. The total cover can include the full structural section of base with asphaltic concrete (AC) or portland concrete cement (PCC) surface layer.	During design of the final cap, the puncture resistance of the geomembrane will be evaluated for construction and longer term loading (as understood at the time of final design). Final design will evaluate the loading conditions (construction and long term), adjacent material particle sizes, and drainage composite nonwoven geotextile mass per unit area to appropriately protect the underlying geomembrane hydraulic barrier. Results of the engineering calculations will be used to prepare technical specifications that may limit the size of construction equipment operating on the aggregate base and prepare minimum requirements for material index properties (e.g. aggregate maximum particle size, minimum mass per unit area of geotextile, etc.).

Geosyntec consultants

Revised Final Draft FS Report Section No.	Original FS Report Section No.	Addendum Section No.	Comment Date	Comment No.	DTSC Comments	Geosyntec Response
6.1.2.3		3.2.1, 3.2.2, 3.2.3	2/10/2012	Steven Hariri -6	ESPO recommends the consideration of other membranes such as linear low-density polyethylene (LLDPE) or polyvinyl chloride (PVC) geomembrane in lieu of HDPE to mitigate future differential settlement and longevity of the geomembrane.	The high density polyethylene (HDPE) liner was primarily selected due to its chemical resistance, particularly with respect to the acidic materials found in the sumps. The basis of this selection was determined during the McColl Superfund design where HDPE geomembrane was tested in contact with the acidic waste (similar to the Gardena Sumps waste) and found to be suitable for the final cover application. Linear Low Density Polyethylene (LLDPE) and Polyvinyl Chloride (PVC) are generally regarded as more flexible than HDPE with significant elongation prior to breaking; however, both are not recommended due to chemical resistance less than that of HDPE. Given past experience with using HDPE geomembranes for final cover hydraulic barriers at the McColl, Del Amo, and Thomas Ranch site remediation projects, HDPE is the desired geomembrane for the Gardena Sumps site.
6.1.2.3		3.3.5.6	3/30/2011	Greg Sweel -2	Describe the current site topography and explain how the proposed remedial option may affect these features	A detailed description of the current site topography is found in Section 5.1.1 of the Addendum to the 22 August 2008 Revised Draft 2006 Remedial Investigation Report (RI Addendum). Site topography is illustrated in Figures 9A, 9AS, 17AS through 17KS of the RI Addendum report. A detailed description of anticipated land surface elevations is included in Alternative 2A of the Addendum.
6.1.2.3		3.3.5	3/30/2011	Greg Sweel -12	Extend the sheet piling around all sump perimeters to prevent lateral spread.	Lateral spread of sludge has been shown to be contained at depth by the existing berms and excavation sidewalls; therefore sheet piles around the sump perimeters are not needed. Additionally, the geosynthetic liner components of the cap will be secured using an anchor trench around the perimeter of the sumps. The anchor trench will further minimize the lateral spread of the sludge as the liner will be anchored two feet deep along the perimeter of the sumps thereby acting as a vertical cut-off barrier at the top of the sludge sumps. The anchor trenches are further discussed in Section 3.3.5 of the FS Addendum. Sheet piles will be utilized at the northern boundary of the Haack and Cooper properties along portions of Artesia Boulevard to provide an above grade retaining wall approximately 3-feet high.. The top of the sheet piles that are exposed above Artesia Boulevard will have a decorative facing.
6.1.2.3		3.3	5/2/2011	Tizita Bekele -3	Adding the stabilization material would displace the sludge that could result in overflow of waste material to the surrounding areas and possibly spread to unimpacted areas in the subsurface. A detailed description of how the stabilization material will be placed, and how overflow and possible subsurface spread of sludge material will-be prevented, should be included.	A detailed description of site preparation, high-strength geotextile installation, and foundation layer placement for Alternative 2A is provided in Section 3.3 of the Addendum. The geotextile and foundation layer will utilize anchor trenches located beyond the perimeter of the sludge to secure them above the sludge. This design will minimize the opportunity for the overflow and spread of the sludge to areas outside of the detected sludge limits.
6.1.2.3	8.3	3.3.5.1	5/2/2011	Tizita Bekele -9	Section 8.3-The basis and assumptions for a 3.5 foot stabilization layer across the sumps should be provided.	The 3.5-foot stabilization layer across the sump is based on preliminary evaluations of necessary stability for construction activities and supporting construction loading. The stabilization material was shown to provide adequate support for similar sludge and low strength soil capping construction projects. The basis and assumptions for Alternative 2A are provided in the Addendum.
6.1.2.3	6.1.2.3	3.3.5.6	6/9/2011	Greg Holmes -6	p. 38, "Erosion Resistance Layer": Please describe the change in topography that would result from construction of this layer, particularly the final elevation above street level in various portions of the cap.	The erosion resistance layer for Alternatives 2 and 3 contributes to 2 feet of the total cover thickness per California Code of Regulation, Title 22 (22 CCR), Section 66264.228(e)(14). The minimum thickness of the cover is 6.5 feet which accounts for the 3.5-foot stabilization layer, 1-foot (minimum) foundation layer, and 2-foot erosion resistance layer. The maximum cover thickness would be approximately 12.5 feet due to increasing the foundation layer to 9.5 feet to create a cover surface with 3 percent (%) slopes. The maximum elevation of the cover for Alternatives 2 and 3 is 35 feet amsl. Artesia Boulevard north of the Haack property has an elevation of approximately 20 feet amsl. Along Artesia Boulevard, the Alternatives 2 and 3 cap elevation varies from approximately 26 feet amsl to 29 feet amsl resulting in a retaining wall height along Artesia Boulevard between 6 and 9 feet high. A discussion concerning the containment cap's topography that will be generated by Alternative 2A is included in the Addendum. A minimum 1-foot foundation layer will be placed on top of a high-strength geotextile. The erosion resistance layer for Alternative 2A will be comprised of 1-foot of Class II aggregate base, in accordance with 22 CCR, Section 66264.228(e)(10). Therefore, the minimum thickness of the cover for Alternative 2A is 2 feet and the maximum thickness would be 4.5 feet to achieve a 2% slope and maintain perimeter drainage. The maximum elevations of the covers for Alternative 2A are 25.7, 24.8, and 25.6 feet amsl on the Haack, Cooper North, and Cooper South sumps, respectively, or approximately 4.5 to 6 ft higher than the Artesia Blvd elevation of 20 ft asml. Along Artesia Boulevard, the cap elevation varies from approximately 20 feet amsl to 22.5 feet amsl. Above the retaining wall, a 0.5 ft curb will be constructed to direct stormwater to the stormwater channels. The cover retaining wall and curb result in a retaining wall height along Artesia Boulevard no greater than 3 feet high.

Geosyntec consultants

Revised Final Draft FS Report Section No.	Original FS Report Section No.	Addendum Section No.	Comment Date	Comment No.	DTSC Comments	Geosyntec Response
6.1.2.3	6.1.2.3	3.3.5.6	6/9/2011	Greg Holmes -7a	The City's representatives expressed their concerns that the recommended remedial alternative would be a "landfill", their concerns over the height of the proposed soil and cap, and the proposed construction of a retaining wall. They indicated that this alternative proposes an incompatible solution to the vision and goal of the community of Gardena which is to move toward future development of the site.	The Addendum presents Alternative 2A which is similar to the cap presented in Alternatives 2 and 3 from the FS, but has been re-engineered to have a lower overall height.
6.1.2.3			9/6/2012	Perry Myers -2	The functioning of the high strength geotextile as presented in the Cover Evaluation Calculation Packages dated February 1, 2012 appears to depend on the placement of a stabilizing berm outside of the sludge footprint prior to placement of intermediate (finger fill) berms. However, the existing sludge footprint would appear to extend to or beyond the property lines along the east and north portions of the site. In addition, sheet piling is proposed along portions of the north property boundary. It appears that the absence of space for placement of a stabilizing layer either beyond the south and north, or east and west margins of the sludge footprint would significantly impact the feasibility/constructability of the proposed cap.	Along the eastern portion of the Site, the high strength geotextile would be anchored within the Los Angeles Department of Public Works (LADPW) property. North of the Haack Sump, geosynthetics would be secured to the sheet pile walls utilizing battens. If necessary, concrete anchors with battens may be utilized in portions of the site with limited access to reduce the size of the geotextile anchors.
6.1.2.3			9/6/2012	Perry Myers -7	The proposed sheet piling along the north margin of the Cooper and Hack Sumps are likely to be in sludge or soil-sludge materials with pH ranging from less than one to more than nine. The FS should discuss the long term effects of the variable pH material on the sheet piling and any effects on the expected life in this setting. An effective life of the sheet piling should be estimated and a cost for replacement included in the cost estimate.	Steel can corrode when exposed to low pH and/or hydrogen sulphide environments. This is a typical environment in the petroleum industry and, as a result, many coatings have been developed to protect the steel from these environments. A coating, such as the Wasser Polyflex 204, will be used on the sheet piles to minimize corrosion of the steel sheet piles. The sheet pile unit price for Alternatives 2 and 3 includes the cost for the protective coating.
6.1.2.3			9/6/2012	Perry Myers -8	The easterly margin of the sludge material appears to coincide with the easterly site property line. This would appear to preclude room for an anchor trench within nonsludge soil materials. Please discuss how the anchor trench along this portion of the site would be configured.	Please see the response to 9/6/12 ESPO comment #2. (Perry Meyers - 2)
6.1.2.3; Table 8-1		3.3.5; Table 4-1	5/2/2011	Tizita Bekele -2	An estimation of the amount of stabilization material for Alternative 2 should be included.	The amount of stabilization material for Alternative 2 was provided in the attached cost estimate tables. The estimated volume was 8,100 CY of gravel, 4,100 CY of sand, and an additional 2,100 CY of sand to be used as geocell fill. The amount of foundation material for Alternative 2A is provided in Section 3.3.5 as well as Table 4-1.
6.1.2.4		3.3.6	2/10/2012	Steven Hariri -9	Please discuss the methods used to prevent fugitive emissions via air inlets or passive vents off gassing into the atmosphere. Furthermore, the proposed vapor probes, passive operation of vertical and horizontal gas extraction system with air inlets to comply with SCAQMD Rule 1150.1 requirements.	The gas control wells will be operated as an active system until it is demonstrated they can be operated passively based on permit limitations on total organic carbon (TOC) concentrations in soil gas and risk-based concentrations developed for Site constituents of concern (COCs). Passive operation will occur if emissions via the air inlet or gas outlet wells are below permit limitations. For additional operational details, please see the response to Comment 5 (3/7/12) received from Greg Holmes.
6.1.2.4	6.1.2.4	3.3.6.3	3/7/2012	Greg Holmes -5	HERO is also concerned about the response to comment #3 because it is not yet clear what the decision-making process will be for determining whether the future vapor mitigation system will be run as active or passive, as well as design issues such as the lateral distance of future buildings to the sumps. As mentioned above, HERO prefers beginning with a more protective risk-based number developed using the default properties for loam. When developing an Operation and Maintenance plan for the future vapor mitigation system, HERO recommends considering other relevant information such as spatial and temporal variability of measurements at monitoring points and the magnitude in concentration changes, instead of a simple comparison with risk-based concentrations, in the decision-making process.	As stated in response 3, the soil-gas risk based concentrations (RBCs) have been re-evaluated with default loam soil properties. The vapor mitigation system will be operated actively for a period of time defined in a future Operations, Maintenance, and Monitoring (OMM) Plan. During initial operation, soil gas data, including constituents extracted and their concentrations, will be collected. The need for active gas collection will be based on the extracted soil gas COC concentrations and associated, calculated health risk goals. If start-up data indicates that COC concentrations are below risk-based trigger concentrations, and therefore, active gas collection is not needed, the system may be converted to a passive system which vents to the atmosphere. Soil gas samples will be collected from the treatment system and perimeter soil gas probes on a regularly basis to evaluate the operation of the system and/or migration of soil gas. Sample results will be compared to risk-based trigger concentrations developed with the OMM Plan for each COC. Development of the risk-based trigger concentrations will assume soil gas will cause outdoor air to become impacted with COCs; however, the outdoor air concentration used to develop the trigger concentration will be low enough to not result in adverse health effects. Based on the assumed conditions at the Site, if soil gas trigger concentrations are not exceeded, outdoor air concentrations will remain below human-health risk based concentrations. If soil gas concentrations are triggered, the gas collection and treatment system may be activated.

Geosyntec consultants

Revised Final Draft FS Report Section No.	Original FS Report Section No.	Addendum Section No.	Comment Date	Comment No.	DTSC Comments	Geosyntec Response
6.1.2.4		3.3.6.3	10/31/2011	Greg Sweel -9	Include the rational for the number and location of the proposed gas probes as depicted on Figure 3-6.	The gas probes are shown on Figure 3-7. A total of nine probes were selected, based on an average distance between probes of 300 ft, to provide multiple locations to detect potential gas migration, if any. The rationale for the location was based on a location outside of the radius of influence of the vertical gas migration control wells and within the property boundary and/or in a location accessible for monitoring, which increased or decreased some distances between the probes. For example, probes were placed within the median of Artesia Boulevard rather than in the street to provide a safer location for monitoring. With further refinement of design, the location and number of probes may change with adjustments to the radius of influence of the vertical gas migration control wells and the locations of buildings and utilities for future site development.
6.1.2.4	6.1.2.4	3.3.6.3	3/30/2011	Greg Sweel -18	Additional gas monitoring probes will be necessary to evaluate radius of influence and effectiveness of the proposed gas control system.	Additional gas monitoring probes have been included with the gas monitoring system. A total of nine multi-level probes are proposed for Alternative 2A.
6.1.2.4		3.3.6.3	6/6/2011	Efrem Neuwirth -5	Following possible consolidation of the sludge, HERO recommends that action objectives be developed for soil-gas to demonstrate that soil-vapor is being contained at acceptable levels. HERO recommends consulting the DTSC Vapor intrusion Mitigation Advisory (VIMA), available at www.dtsc.ca.gov.	As a part of the post-closure plan for the remedy, an operations, maintenance and monitoring plan (OMMP) will be prepared. As a part of the OMMP, monitoring and action objectives will be developed, based on results of the HHRA, to monitor the containment system.
6.1.2.4			9/6/2012	Perry Myers -6	The FS indicates that the existing geomembrane and asphalt surfaces will be left in place over the sumps. However, for the proposed gas collection to be effective, communication with the sludge will be necessary. This would likely require cutting perforations or removal of portions of the geomembrane. The FS should discuss how this would be implemented, ramifications of perforating the existing membrane for installation of the proposed cap and any effects it may have on the performance of the proposed high strength geotextile.	Gas which may be generated and released from the surface of the cap will either travel to the edges of the cap where it will be collected by the vertical gas collection wells or exit through pathways through the existing geomembrane and asphalt surfaces (such as punctures and cracks). It is anticipated that some damage will occur to the existing geomembrane surface during construction which may allow gas to escape and be collected through the horizontal gas collection system. The existing geomembrane is beneficial during initial construction activities to act as a barrier for workers installing the high strength geotextile. The polypropylene high-strength geotextile is compatible with low pH environments; therefore, contact with the sludge will not affect its performance (SI Geosolutions, 1997).
6.1.2.4			9/6/2012	Perry Myers-12	The type of treatment system for the below-cap gas collection system is not specified in section 3.3.6.2 but the cost line item in the associated cost estimates indicates granulated activated carbon (GAC) will be used. GAC may not be appropriate for treatment of high concentrations of hydrogen sulfide and sulfur dioxide gas. An alternative treatment system that includes a thermal component and acid scrubber-to remove these gases should be evaluated and the cost estimate should be adjusted accordingly.	Gas quantity is expected to be very low and, as such, a thermal destruction unit is not appropriate or efficient. The current plan is to use permanganate impregnated granular activated carbon (GAC) (hydrosol) to remove sulfur compounds. Specialized blends of granular activated carbon are designed to treat hydrogen sulfide such as Calgon's Centaur 4x6. The Alternative 2A and 3 granular activated carbon costs account for the increased price of the specialty carbon. Significant quantities of hydrogen sulfide are not anticipated during construction of Alternative 2A or following capping of Alternatives 2A and 3 based on the results of flux chamber testing performed during the Revised Remedial Investigation. During Alternative 3 or 4 neutralization, a thermal oxidizer, or other high concentration, high flow system will be implemented for treatment of vapors.
6.1.2.5		3.3.5.1	2/10/2012	Steven Hariri -4	Please provide the full conceptual pavement structural section and design of the proposed parking lot cap in addition to the one-foot of Class II aggregate base presented in figures.	The traffic loading scenarios are unknown for the developed Site; therefore, a future Site developer will be responsible for the design and construction of the paved surface for the parking lot.
6.1.2.5			2/10/2012	Steven Hariri -11	Please reevaluate the calculations of the high-strength geotextile and anchor trenches with the full structural pavement section weight and overlying vehicles to include H-20 loading.	The final pavement section and loading conditions will be determined by the Site developer (see response to Comment 4). If the proposed capping alternative is selected as the preferred remedial alternative by the DTSC, a detailed design will consider maximum loading conditions for the cap based on the anticipated development of the Site.
6.1.2.5	6.1.2.5		3/7/2012	Greg Holmes -1	Institutional Controls, under the proposed Alternative 2A, disposal of excess sludge to an off-site disposal facility and placement of a cap over remaining sludge without stabilization, should state that a land use covenant (LUC) to place a deed restriction on the Site will be filed with the Los Angeles County Recorder's Office, and annual LUC restriction inspections will be conducted by DTSC to ensure compliance.	Noted. Clarification Sheets 5 and 12 are provided which revise Section 6.1.2.5 of the Draft FS and Section 3.3.7 of the FS Addendum, respectively related to Institutional Controls.
6.1.2.5		3.2	10/31/2011	Greg Sweel -7	Sludge containing materials beneath Artesia Boulevard and the southern sidewalk should be addressed by restricting access from current and/or future utility and/or construction workers.	Future access from current and/or future utility and/or construction workers will be addressed in the Risk Management Plan (RMP). The RMP will describe contaminants remaining onsite, known locations of impacts, contact information, and minimum, recommended personal protective equipment for current and future utility and/or construction workers. Institutional controls will include that the City of Gardena and/or Caltrans provide notice of potential subsurface hazardous materials in the area of Artesia Boulevard where sludge is potentially located when issuing work permits.
6.1.2.6		3.3.8	3/7/2012	Greg Holmes -2	DTSC's geologist notes that the response to the last comment in the Draft FS Response to Comments does not address the request to remove the sentence regarding a "period of 5 years".	The statement regarding a "period of 5 years" has been removed from Section 3.3.8 of the FS Addendum. This section has been included as Clarification Sheet 13.
6.1.2.6	6.1.2.6	3.3.8	10/31/2011	Greg Sweel -4	Include replacement of groundwater monitoring wells following cap construction in the draft FS.	Groundwater monitoring well replacement is discussed in Section 6.1.2.6 in the draft FS and Section 3.3.8 in the FS Addendum presenting Alternative 2A.

Geosyntec consultants

Revised Final Draft FS Report Section No.	Original FS Report Section No.	Addendum Section No.	Comment Date	Comment No.	DTSC Comments	Geosyntec Response
6.1.2.6		3.3.8	10/31/2011	Greg Sweel -6	Recognize that abandonment of monitoring wells MW-01A and MW-01B will eliminate data from upgradient of the site. If these wells are removed, then describe how comparison to background water quality will be determined.	Replacement of groundwater monitoring wells is discussed in Section 3.3.8 of the FS Addendum. The DTSC makes a good observation. Section 3.3.8 of the FS Addendum is revised as follows: Eight of the existing ten groundwater monitoring wells would be properly abandoned prior to commencement of the remedial action. Upgradient wells MW-1A and MW-1B would not be abandoned. During the remedial action activities an appropriate groundwater monitoring network would be agreed upon with input from the DTSC. After the completion of the remedial action, the future groundwater monitoring wells would be installed. Groundwater monitoring would continue to be performed on a semi-annual basis. A typical groundwater monitor well is shown as Detail 3 on Figure 6-9 in the draft FS (Geosyntec, 2011).
6.1.2.6		3.3.8	10/31/2011	Greg Sweel -10	It is not clear why the installation of a groundwater monitoring network is not included as part of the draft FS. Also, future groundwater monitoring would be performed until such time a time as DTSC approves cessation. Remove the sentence regarding a "period of 5 years."	The future development plans of the Site, which is currently unknown, would control where future monitoring wells would be installed. The well locations of the future monitoring well network would be agreed upon in consultation with the DTSC prior to completion of the remedial action. It is anticipated that the new monitoring wells would be installed shortly after completion of the remedial action.
6.1.2.6	6.1.2.6		3/30/2011	Greg Sweel -13	Additional groundwater monitoring wells will be necessary to replace the properly abandoned wells. Section 6.1.2.6 indicates that 6 existing wells would be replaced by only 2 wells.	It is anticipated that current monitoring wells MW-2A, MW-2B, MW-4A, MW-4B, and MW-5A will be abandoned prior to implementation of the remedial action. Future groundwater monitoring wells to replace the abandoned wells will be installed after completion of the remedial action and in consultation with the DTSC. Wells MW-1A and MW-1B will be properly abandoned and not replaced.
6.1.2.6			9/6/2012	Perry Myers-13	Section 3.3.8 , Groundwater Monitoring. Paragraph one states that ten groundwater monitoring wells will be abandoned while the second paragraph states eight wells. The inconsistency should be eliminated.	The Gardena Sumps groundwater network consists of ten wells. Two off-Site wells (MW-1A and MW-1B) are upgradient wells that will not be abandoned. The remaining eight wells (MW-2A, MW-2B, MW-3A, MW-3B, MW-4A, MW-4B, MW-5A and G-4) are located in the footprint of the proposed cap and will be abandoned prior to construction of an engineered cap. Future monitoring wells constructed outside the footprint of the engineered cap will be installed for future groundwater monitoring after completion of the engineered cap.
6.1.2.7		3.4	3/30/2011	Greg Sweel -14	Describe the ability of the Alternative 2 cap to support future potential redevelopment of the site.	Alternative 2 was preliminarily designed to support traffic loads resulting from the construction of a parking lot above the sumps based on the similar design of the Thomas Ranch Site in Corona, California (Geosyntec, 2005). The discussion on future potential redevelopment of the Site is discussed in Section 3.4 of the Addendum.
6.1.2.7		3.4	3/30/2011	Greg Sweel -16	Explain how the placement of a two foot thick vegetated soil cover will facilitate a parking lot on the cap.	The two foot thick vegetated soil cover was incorporated into Alternative 2 per California Code of Regulations Title 27 (27 CCR) Section 21090(a)(3)(A) requiring a minimum 1 foot vegetated soil layer containing no waste, placed above the low-hydraulic-conductivity layer, is capable of sustaining plant growth, and is initially planted. Two feet the erosion resistance layer was proposed to support the installation of shallow conduit piping. A discussion addressing the uppermost cap material to facilitate a parking lot is included in Section 3.4 of the Addendum.
6.1.4			9/6/2012	Perry Myers-15	Section 6.1.4 of the FS states the excavation will extend to depths between .5 and 23.5 feet bgs and references figure 6-8. The descriptions of the sumps included in the FS indicate the thickest area of sludge is in the Cooper North Sump at 17.5 feet. These descriptions appear to be inconsistent and should be reconciled. If there is six feet of overburden on top of the sludge in the Cooper North Sump (to create a depth of 23.5' bgs) this should be noted in the FS and accounted for in the determination of soil volumes for disposal.	The excavation was evaluated at a depth to 23.5 ft bgs due to the lithological information provided for boring HPB09. The deepest reported sludge layer was encountered at a depth of approximately 8 ft bgs; however, tar clasts and hydrocarbon odors were reported to a depth of 23.5 ft bgs in that boring. Excavation in this area has been revised to reflect the 8 ft bgs sludge depth and the quantities for disposal have been updated. Confirmation sampling in this area during excavation may result in removal of additional material not accounted for in the cost estimate.
6.1.4.2			9/6/2012	Perry Myers-16	Section 6.1.4.3 states 52,000 CY (or 49,900 tons) of material will need to be disposed of due to bulking caused by the neutralization process. ESPO tabulated a total of 22,870 CY of sludge with interbedded soil for the four areas to be excavated (sec. 3.2.1). Applying a 25% bulking factor does not equal 52,000 CY. The FS should provide additional detail on how the total for disposal was calculated.	The estimated disposal volume of 52,000 cubic yards (cy) was based on the approximately 33,250 cy of sludge with soil interbeds and 3,750 cy of Haack rework excavation volumes. The sludge volume is increased by 25 percent for admixture bulking and 15 percent for over-excavation contingency. The excavation volume has been revised to 30,895 cy (subject to 25% admixture bulking and 15% overexcavation) and it is assumed the 2,670 cy of Haack Rework area sludge will not require neutralization; therefore, the treated sludge volume for disposal is revised to approximately 45,900 cy (50,500 tons based on a density of 81 pounds per cubic foot [Stantec, 2008]).
7.3.3.2, 7.3.4.2, 7.3.5.2, 8.2.3			9/6/2012	Perry Myers-14	The FS does not adequately consider threats posed by the waste to groundwater quality when developing and evaluating alternatives. Protection of water quality is included in the applicable or relevant and appropriate requirements (ARARs). Sections 3.2.1 and 3.2.6 of the FS indicate that perched groundwater is in contact with the sludge in some areas and past sampling results indicate impacts have occurred. The FS should evaluate all alternatives for compliance with water quality ARARs and should, at a minimum, specifically discuss how alternative 2A will be protective of groundwater.	A discussion of groundwater ARARs has been added to Sections 7.3.3.2, 7.3.4.2, 7.4.5.2, and 8.2.3 of the Revised Draft FS.

Revised Final Draft FS Report Section No.	Original FS Report Section No.	Addendum Section No.	Comment Date	Comment No.	DTSC Comments	Geosyntec Response
7.3.3.3, 7.3.4.3, 7.3.5.3			9/6/2012	Perry Myers -1	The Site is located in an area of high seismic activity; however seismicity does not appear to have been considered in the remedial alternatives presented. In addition, the area around Artesia Boulevard and the Dominguez Flood Control Channel corridor, including the Site, is within a zone mapped as susceptible to seismic induced liquefaction by the California Geological Survey (CGS). The effects of seismicity on the performance of all remedies under consideration should be included, at least on a preliminary level during remedy evaluation in the FS. In addition, the consequences of remedy failure due to seismic-induced loading as well as mitigation measures required to repair any failures should be considered.	The seismic hazard discussion for each remedy has been included in long-term protection of human health and the environment (Sections 7.3.3.3, 7.3.4.3, 7.3.5.3).
7.3.3.5; 7.3.4.5; 7.3.5.5; 8.2.6	7.3.3.5; 7.3.4.5; 7.3.5.5	4.3.5	5/2/2011	Tizita Bekele -6	Short term effectiveness for all the alternatives considered should include a detailed assessment of possible adverse impacts on workers, community and the environment during remedy implementation, as well as, the mitigation measures that would be applied to minimize adverse impacts. There would be potential releases of toxic gases, VOC emissions, dust, noise, truck traffic, etc. during construction and all potential impacts should be addressed.	Additional details have been incorporated for the evaluation of short-term effectiveness for Alternative 2A in Section 4.3.5 of the Addendum and for each alternative in Section 5.2.6 of the Addendum.
7.3.3.6; 7.3.4.6; 7.3.5.6; 8.2.7	7.3.3.6; 7.3.4.6; 7.3.5.6; 8.2.7	4.3.6; 5.2.7	5/2/2011	Tizita Bekele -8	Section 7.3.3.6-Although the technologies in Alternative 2 are conventional, the site specific conditions are not. Given the urban setting of the project site, being located at the intersection of major streets with the potential releases of toxic gases during implementation, the assessment of the implementability provided in the document is severely inadequate and unacceptable. Safe implementation of the remedy is key in assessing the feasibility of the alternative at this site and sufficient detail should be provided.	Additional details relating to the urban setting of the project have been addressed in Sections 4.3.6 and 5.2.7 of the Addendum.
Figure 4-4; Table 4-4	Figure 4-4; Table 4-4		3/7/2012	Greg Holmes -3	Regarding the response to DTSC's Human and Ecological Risk Office (HERO) comment #3, HERO does not concur with taking an average measurement of the soil properties to use for calculating soil-gas risk based concentrations. The moisture content is highly variable and some of the points were from soil underneath the sludge which may not be representative of the soil between the sumps and future buildings.	The soil-gas risk based concentrations (RBCs) have been re-evaluated with default loam soil properties. The benzene in soil gas concentrations using default loam soil properties are included in the revised Appendix B of the Draft FS (Attachment 3). The following soil vapor locations were in excess of the residential soil gas RBCs for benzene: SV119 at 6 and 10 feet below ground surface (ft bgs), SV127 at 5 ft bgs, SV19 at 5 ft bgs, SV118 at 5 ft bgs, and SV11 at 5 ft bgs. These locations are shown on the revised Figure 4-4 of the Draft FS included as Clarification Sheet 16.
Figure 4-4; Table 4-4	Figure 4-4; Table 4-4		3/7/2012	Greg Holmes -4	Regarding the response to the comment #3, HERO recommends revising the risk-based concentration for benzene using the default properties for loam. When developing risk-based concentrations or action levels for soil-gas for other chemicals of concern which were not included in the Human Health Risk Assessment (for example, sulfide gases), default properties should be utilized.	The RBCs for soil-gas have been revised using the default loam properties, see response to Comment 3. Sulfide gases were evaluated during the risk assessment and subsequent generation of RBCs. Carbon disulfide concentrations were not found to pose a risk in excess of criteria presented in the Human Health Risk Assessment (Geosyntec, 2011). Detections of hydrogen sulfide were only encountered in the sludge; therefore, hydrogen sulfide does not appear to migrate from the sludge.
Figure 6-14	Figure 6-6		3/30/2011	Greg Sweel -20	Portions of the Haack sump are currently paved with degraded asphalt. Removal and replacement of the asphalt with concrete will be required, as depicted on Figure 6-6.	The existing surface of the Haack Sump will be maintained and the cap will be installed above the existing asphalt or concrete material depending on the locations in the sump. Concrete is not a more suitable material for construction of the final cap as both the asphalt and concrete will provide a construction surface and preliminary support during installation of the overlying materials. Furthermore, the existing surfaces minimize the dermal contact and gas inhalation exposure risks to the construction workers during installation of the cap and removing the asphalt to place concrete could expose the workers to unnecessary risk. The revised Figure 6-6 is provided with the errata sheets in Attachment 1.
Figure 6-14	Figure 6-6	Figure 3-9	5/2/2011	Tizita Bekele -13	A multi-level gas monitoring probe with a 1 foot screen length at 5 ft interval across the entire thickness of the waste is recommended. The proposed 15 ft screen is too long to collect discrete samples.	This detail has been revised on Figure 3-9 of the Addendum.
Figure 6-15		Figure 3-10	2/10/2012	Steven Hariri -10	Please address the disposition of the surface drainage of the geocomposite of Detail 6.	Detail 6 illustrates the conceptual layout of the geosynthetics in relation to the slopes and incorrectly shows the drainage geocomposite day-lighting without a perimeter channel. The revised Figures are included as Clarification Sheets 17, 18, and 19.
Figure 6-3 and 6-4		Figure 3-3 and 3-4	5/2/2011	Tizita Bekele -12	Figure 6-6-Cross-section detail for the Normandie Avenue side should be provided.	Cross-sections for Alternative 2A in the Addendum are provided as Figures 3-3 and 3-4.
Figure 6-7; Figure 6-12	Figure 6-4	Figure 3-7	5/2/2011	Tizita Bekele -10	Figure 6-4 -Five gas probes are proposed for monitoring gas migration. It appears that the probes are located within the vertical gas migration control wells area of influence. It is recommended to place additional gas probes between the outside of the vertical wells area of influence and potential receptors, such as the residences and commercial buildings. These additional probes may be necessary to adequately monitor gas migration towards those receptors.	The probes currently shown for Alternatives 2 and 3 are located as close to the sumps as possible for detecting gas migration when the gas control system is not in operation. Additional probes will be included for detecting gas migration when the gas control system is in operation as shown on Figure 3-7 of the Addendum.

Revised Final Draft FS Report Section No.	Original FS Report Section No.	Addendum Section No.	Comment Date	Comment No.	DTSC Comments	Geosyntec Response
Appendix C	Appendix B		6/6/2011	Efrem Neuwirth -3	HERO does not concur with the use of the measured soil properties in developing soil-gas risk based concentrations as was done for benzene since it is not clear if these values are representative of the whole Site. HERO recommends using the Johnson and Ettinger (J&E) recommended soil:-properties for the generic soil type entered. HERO also does not concur with assuming that a future office will have a vertical height of 12-ft (366 cm). HERO recommends using a more protective 8-ft (244 cm). In addition, the J&E spread sheets provided for a commercial/industrial worker do not follow the exposure parameters (exposure duration, exposure frequency, and averaging time for non-carcinogens) provided in Table 1; HERO recommends correcting the spreadsheets for the above-mentioned exposure parameters.	The DTSC letter to Kyle Christie, dated 30 October 2008, concerning the risk assessment approach included a 24 October 2008 memo from Bryan Eya of HERD (now HERO) to Joe Cully. HERD recommended that the Geological Services Unit (GSU) of DTSC make a determination whether the soil type (loam) are appropriate for use in the vapor intrusion model. GSU required 49 additional soil gradation curves be obtained at the soil vapor sampling depths during the 2009 field activities to verify that site specific soil data would be appropriate for use in the vapor intrusion modeling. Mean particle size distribution was 25 samples silt, 23 samples sand and one sample gravel. Particle percentage of silt and clay >50% occurred in 39 samples while particle percentage of silt and clay <50% occurred in 10 samples. The soil particle characteristics are that of loam. The GSU approved the use of site soil characteristics for the vapor intrusion model because the site soils were characteristic of loam. The site-specific input parameters used in the derivation of RBCs are well within expected values for loam material. The building dimensions for the vapor intrusion modeling were discussed with Bryan Eya and DTSC during a 25 September 2008 teleconference. HERD and DTSC did not object to the use of the building height dimensions for residential (8-feet or 244 centimeters (cm)) and commercial/industrial (12-feet or 366 cm) for current and future buildings. Therefore these building dimension values were used in the approved baseline risk assessment and in the development of risk-based goals for the FS. The J&E spreadsheets were used only for developing a unit modeled indoor air concentration that was then used in separate spreadsheets presented in Attachment A to calculate a risk-based concentration. This approach is consistent with what was done in the baseline risk assessment. Therefore the exposure parameters depicted in the J&E spreadsheet were not used and do not impact the RBC derivation.
Appendix E		Appendix B	5/2/2011	Tizita Bekele -7	Duration of the project should be provided in the short term effectiveness analysis.	The anticipated duration of the project has been added to the Addendum.
N/A			2/10/2012	Steven Hariri -1	Please affix a professional engineer stamp to the final version of the Final Feasibility Study Report, Attachment, and Calculations	The Final Feasibility Study with attachments and, if applicable, calculations, will be stamped by a California professional engineer.
N/A		3	2/10/2012	Steven Hariri -2	ESPO recommends an analysis of the maximum credible earthquake for evaluation of damage to the foundation or structures which control leachate, surface drainage, erosion or gas as required by 23CCR§2547 and 22CCR§66264.228(a)(2)(C)(6).	The cap surface drainage and erosion systems, as well as the gas migration control system, will be evaluated for damage due to the maximum credible earthquake during final design of the cap, if the capping alternative is selected as the preferred remedial alternative by the DTSC. A detailed design will be completed as part of a future Remedial Design submittal.
N/A			10/31/2011	Greg Sweel -5	Please check the last sentence of this response on page 4.	This sentence contained a typo and should read as follows: “The two foot erosion resistance layer was proposed to support the installation of shallow conduit piping”.
N/A			11/11/2011	Efrem Neuwirth -2	HERO accepts the proposal to deal with vapors and gases in the future operations, maintenance and monitoring plan (OMMP; see comment 5).	Acknowledged
N/A			11/11/2011	Efrem Neuwirth -4	HERO finds this approach acceptable for removals of sludge in the Haack rework area due to the unique nature and distribution of the source material.	Acknowledged
N/A			11/11/2011	Efrem Neuwirth -5	HERO acknowledges the response and the future submittal of an OMPP to address action objectives for soil-gases and vapors. However, HERO does not concur with only using the results of the HHRA which does not deal with the explosives risks and acute health risks from a variety of compounds or chronic risks from hydrogen sulfide. As notedin HEROs response to comment 2, HERO accepts dealing with all these issues in the OMPP.	Acknowledged

However, HERO does not concur with only using the results of the HHRA which does not deal with the explosives risks and acute health risks from a variety of compounds or chronic risks from hydrogen sulfide. As notedin HEROs response to comment 2, HERO accepts dealing with all these issues in the OMPP.	Acknowledged
N/A			3/30/2011	Greg Sweel -4	Confirm the statement in Section 2.5 that shallow groundwater beneath the site is influenced by the adjacent concrete-lined Dominguez Channel.	A discussion of the influence of the Dominguez Channel (engineered weep holes in the channel) on the flow direction of the shallow (A-horizon) is discussed in Sections 3.10.5 and 5.1.2 of the Addendum to the August 22, 2008 Revised Draft 2006 Remedial Investigation Report and illustrated in Figures 10As and 18S of Appendix D (design drawings of the Dominguez Channel).
N/A			3/30/2011	Greg Sweel -5	Discuss the presence, and identify the location, of nearby groundwater production wells.	The closest active public supply well, the "Dalton Well", is located approximately 1,000 feet northwest of the Site. The Dalton Well is upgradient of the Site and is screened at depths several hundred feet deeper than the screen intervals of the Site monitoring wells. The Dalton Well hydraulic study (Section 3.9 of the Addendum to the August 22, 2008 Revised Draft 2006 Remedial Investigation Report) documented that water production from the Dalton Well does not influence shallow groundwater beneath the Site. The next closest groundwater production well is located approximately 1-mile east of the Site.
N/A			3/30/2011	Greg Sweel -6	Acknowledge and identify which constituents of concern detected in groundwater exceed the maximum contaminant levels (MCLs).	ARC has been performing quarterly groundwater monitoring at the Site for five and a half years (through second quarter 2011). Detections commonly exceeding groundwater MCLs at the Site are: total dissolved solids (TDS) in wells MW-1A, MW-1B, MW-2A, MW-2B, MW-3A, MW-3B, MW-4A, MW-4B, MW-5A, and G-4; chloride in wells MW-1B, MW-2B, MW-3B, MW-4B and G-4; sulfate in wells MW-2B, MW-3B, MW-4A, MW-4B, MW-5A and G-4; and iron in wells MW-2B, MW-3B, MW-4B, MW-5A and G-4. Benzene, beryllium, and nickel were detected in MW-5 at concentrations exceeding their MCL.
N/A			3/30/2011	Greg Sweel -11	Explain the rationale for why the top three feet of sludge in the Cooper North and South sumps was selected for mixing/stabilization/neutralization. Also, include the sludge in the Haack sump in Alternative A3.	The top 3 feet of sludge in the Cooper North and South sumps was selected to create a stabilized "crust" in which to operate equipment and place the overlying cap materials. Three feet was selected to mimic the 3.5-foot stabilization layer identified for Alternative 2. The sludge in the Haack sump was not identified for stabilization because the existing concrete and asphalt surface has shown to be supportive of overlying vehicles and traffic and therefore does not require a stabilized surface for construction.
N/A			3/30/2011	Greg Sweel -19	Explain the need for air inlet wells as part of the gas control system.	Air inlet wells are proposed for the gas control system to facilitate the "curtain" effect of the system as demonstrated on Figure 6-5 in the Draft FS and as shown on Figure 3-8 in the Addendum. The gas control system will not be designed to extract gas from the sludge; rather it will be designed to collect gases migrating laterally from the sludge.
N/A			3/30/2011	Greg Sweel -21	Depict and describe the future use of groundwater monitoring well cluster MW-01A and MW-01B on Figure 6-2.	Figure 6-2 shows the locations of groundwater monitoring wells located at the Site and the conceptual final cover elevations for Site Alternatives 2 and 3. Wells MW-01A and MW-01B are located approximately 470 feet northwest of the northwest corner of the Site. Depicting Wells MW-01A and MW-01B in Figure 6-2 would have decreased the scale to illustrate the conceptual Site final cover elevations and thereby result in a less than useful figure. ARC will request that wells MW-01A and MW-01B be abandoned as the two wells have provided useful information during the remedial investigation but are no longer required to monitor the groundwater at the Site.
N/A			5/2/2011	Tizita Bekele -5	Section 7.3.3.4-The document states that no reduction in waste volume would be realized by alternative 2, but there would be an increase in the waste volume from the addition of the stabilization material. The estimated increase in volume should be discussed along with how the increased volume would alter the topography, aesthetic, and compatibility with future planned land use.	The volume of "waste" will not be increased in Alternatives 2 and 2A since clean fill, sand, and gravel would be imported and used as the stabilization materials above the sludge. Also, see the response to Comments 6 and 7b in the "Response to Comments from Greg Homes, DTSC (9 June 2011)" section above.
N/A			5/2/2011	Tizita Bekele -11	Level of methane gas should be assessed before use of air inlet during gas extraction from the vertical gas control wells.	The air inlet piping will be vented to the atmosphere and used to create a "curtain" to minimize lateral migration and is not anticipated to contain methane quantities any greater than surrounding outdoor air concentrations. Air entering the air inlet piping is anticipated to travel through pore spaces within the soil to the gas extraction system where it will be treated prior to discharging back to the atmosphere.

Revised Final Draft FS Report Section No.	Original FS Report Section No.	Addendum Section No.	Comment Date	Comment No.	DTSC Comments	Geosyntec Response
N/A			6/6/2011	Efrem Neuwirth -General	Risk based concentrations are calculated for a 1×10^{-5} risk level for commercial/industrial and construction worker receptors, while 1×10^{-6} RBCs are calculated for residents and trespassers. In addition, for arsenic and the carcinogenic polycyclic aromatic hydrocarbons (PAHs), comparisons are also made to the regional background levels which are often used by the DTSC as remedial goals (12 mg/kg and 0.9 mg/kg, respectively). These RBCs are incorporated into the remedial objectives for the site. The large majority of material above the various RBCs are in the sludge including the Haack rework soil. There are also numerous petroleum related VOCs which were measured in the shallow groundwater (12-ft bgs) or in soil-gas proximal to the sludge. Most of these VOCs have low toxicity and low concentrations. It is likely that the large majority of VOCs are trapped in the sludge and only slowly migrate out into the surrounding environmental media making it difficult to accurately evaluate possible vapor intrusion risks. The proposed remedial actions deal with potential uncertainties by removing the sludge material and/or consolidation and capping the material and providing a vapor intrusion mitigation system to insure that what may migrate out of the material in the future does not pose potential health risks.	Comment noted
N/A			6/6/2011	Efrem Neuwirth -6	In the future, HERO recommends using the OEHHA toxicity values for arsenic to determine if clean up levels for various land reuse scenarios may be higher than 12 mg/kg. HERO does not recommend altering the arsenic RBCs for the site since there is only a single location identified on the Site with concentrations greater than 12 mg/kg (42 mg/kg).	Comment noted
N/A	ES-11; 6.1.2.3		6/9/2011	Greg Holmes -4	p. ES-11, "Remedy Selection", third bullet: Please describe "geocell".	A geocell, also referred to as a Cellular Confinement System (CCS), typically consists of high density polyethylene (HDPE) strips expanded to form a honeycomb-like structure filled with sand to stabilize low bearing capacity soils. The three dimensional structure of the geocell reduces the vertical settlement and improves the load-bearing capacity of surfaces such as roadways. The geocell is effective by preventing the lateral movement of fill materials and distributing the loads to a larger area (Geoproducts, 2011).
N/A			6/9/2011	Greg Holmes -7c	ARC was requested by DTSC to prepare a new FS alternative which would include a sufficient level of detail as to be considered implementable and consistent with the future Remedial Action Plan.	The Addendum presents Alternative 2A and includes a conceptual grading plan. Preliminary design calculations were performed to evaluate the stability of the cap and evaluate its effectiveness for a future use as a parking lot. A detailed design will be completed following submittal of the Remedial Action Plan, as part of the Remedial Design submittal.
N/A			6/9/2011	Greg Holmes -7d	The ARC representative indicated that he would speak to Ms. Tizita Bekele, DTSC senior engineer, to identify requirements that would be applicable to the construction of a cap and include the level of detail requested by DTSC in the design of the new remedial alternative.	A meeting with Ms. Tizita Bekele will be held following the submission of this response and Addendum.
N/A			6/9/2011	Greg Holmes -7e	The ARC representative agreed to provide a draft of a new remedial alternative to the City and the DTSC representatives for review prior to finalizing the FS report, and that ARC would submit the revised FS report to DTSC and the City after receiving their comments.	The Addendum with Alternative 2A is enclosed with this Response to Comments.
N/A			9/6/2012	Joseph Cully - 1	For the proposed Alternative 2A, how long will the cap last before it needs to be replaced? What will be cost of replacing this cap?	Studies have shown high-density polyethylene (HDPE) liners lifetimes are at least several hundred years (Rowe and Sangam, 2002). In an EPA-sponsored study conducted by Bonaparte et al. (2002) on the performance of waste containment systems, the overall service life of HDPE geomembranes was estimated to be on the order of 1,000 years. If the cap requires replacement due to unforeseen incidents or catastrophic events, the cost to replace the cap is estimated as approximately $3.45M. This assumes the gas treatment system, vertical gas wells, and sheet piles remain intact after the catastrophic events. This is based off the initial installation costs included with Table 7-1 of the Revised Draft FS.
N/A			9/6/2012	Joseph Cully - 2	Health and Safety Code section 25355.2 requires that responsible parties demonstrate to DTSC and maintain financial assurance to cover the cost of maintaining and replacing the cap. Please address the mechanisms that will be in place to show that the parties will be financially responsible for maintaining, and, should the need arise, removing and replacing the cap in the future.	As referenced in Health and Safety Code section 25355.2, Section 66265.143 of Title 22 provides for five or more financial assurance mechanisms that responsible parties to be named in a possible future Site corrective action consent decree could use to satisfy their financial assurance obligations. At this time it is not known which of these financial assurance mechanisms will be utilized.

Geosyntec consultants

Revised Final Draft FS Report Section No.	Original FS Report Section No.	Addendum Section No.	Comment Date	Comment No.	DTSC Comments	Geosyntec Response
N/A			9/6/2012	Perry Myers/ Recommendations -1	The comments/recommendations presented in this memorandum regarding the remedy alternatives and the associated cost estimates should be adequately addressed.	Noted.
N/A			9/6/2012	Perry Myers/ Recommendations -2	A single document incorporating all revisions, addendums, additional figures and tables should be created and submitted for approval. The current system of original document, addendum, errata and clarification sheets creates confusion and makes a comprehensive review difficult and time consuming.	The Revised Final Draft Feasibility Study has been created which incorporates the Addendums, Clarification Sheets, and Comments received on the Draft Feasibility Study and Feasibility Study Addendum.
N/A			9/6/2012	Perry Myers/ Recommendations -3	The FS should explore transportation options for disposal other than 14 or 16 CY dump trucks. Larger trucks or use of the adjacent rail line should be considered to reduce impacts and costs.	Larger trucks are not recommended due to the small size of the site limiting the truck turning radius and staging areas as well as the difficulting entering/exiting the site onto Artesia Boulevard. Utilizing the adjacent railroad is not feasible due to the limited space availability for construction of a rail spur and the small quantity of rail cars that would be able to be loaded at the site.
N/A			9/6/2012	Perry Myers/ Recommendations -4	The MatCon final surface for Alternative 2A discussed by E&E should be considered. ESPO has had favorable experience with this product and believes it should be considered as a viable alternative for use as the low hydraulic conductivity layer.	The use of MatCon would not limit the height of the cap any further due to the required ground improvements needed to install MatCon as well as provide the strength for the final parking lot.
N/A			9/7/2012	Perry Myers/ Recommendations -5	Consideration should be given to conducting an excavation pilot study at the Site. Goals for the pilot study could include; more accurately assessing gas generation from disturbing the sludge, evaluating whether a tent is necessary or whether products such as Odex andlor Hydroseal can adequately control hydrogen sulphide and sulfur dioxide gases, and mixing techniques for neutralization.	An excavation pilot study is not proposed at this time due to the risks associated with uncontrolled reactions of neutralizing agents and the sludge, exposure of the sludge, and proximity to sensitive receptors. Furthermore, boring logs and test data have indicated the variability of sludge within the sumps; therefore, a small scale pilot study will not be representative of excavation conditions and may lead to a "false sense of security" with inadequate controls, such as lack of vapor system, during full-scale implementation.
N/A		3.3.5	2/10/2012	Steven Hariri -7	ESPO recommends the slopes steeper than a horizontal to vertical ratio of three to one, or having a geosynthetic component (27CCR§21090(a)) be evaluated with slope stability calculations (27CCR§21750(f)(5)).	A detailed design will be completed as part of a Remedial Design submittal if the capping alternative is selected as the preferred remedial alternative by the DTSC. Slope stability evaluations will be performed during design of the final cap.
N/A		3.3.5.6	2/10/2012	Steven Hariri -8	ESPO recommends that the final cover slopes less than three percent (27CCR§21090(6)(b)(1)(A)) be evaluated for storm intensity (27CCR§21090(6)(b)(1)(B)).	Similar to responses to Comments 2 and 7, a detailed design will be completed as part of a Remedial Design submittal if the capping alternative is selected as the preferred remedial alternative by the DTSC. During design of the final cap system, the final cover slopes will be evaluated for the referenced storm intensity.
N/A			10/31/2011	Greg Sweel -3	Provide the evidence cited which has shown that lateral spread of the sludge is contained at depth by the existing berms. The intent of the original comment was not necessarily directed to current conditions, rather to those conditions post cap construction when the weight of the overlying constructed cap and vehicular parking may increase the potential for the lateral spread of sludge.	Outer sump berms that have not had their integrity disrupted after 1945 are the northern North Cooper Sump berm and the southern South Cooper Sump berm. Borings CPB-04, CPB-23, CPB-24, SV-26, SV-124 and SV-126 drilled through the northern North Cooper Sump berm did not reveal the presence of sludge. Borings CPB-19, CPB-20, CPB-21 and CPB-22 drilled through the southern South Cooper Sump berm did not reveal the presence of sludge within the berm although surficial sludge above the berm was noted in borings CPB-19 and CPB-20. The viscosity of the sludge material is such that it does not flow within the soil at the site, as evidenced by the lack of subsurface, non-man-induced, migration of the sludge materials over the 60+ years it has been in place. Additional loading associated with the proposed final cover system is not anticipated to change the physical characteristics of the sludge. Therefore, the proposed cover loading will not create a lateral spreading of the sludge material. Final design of the cover system, to be prepared during the remedial design phase of the project will further evaluate and fine tune the cover system design.
N/A			3/30/2011	Greg Sweel -1	DTSC's Engineering Services Unit should evaluate the analysis of proposed alternatives, treatment options, containment, and engineering controls.	Comment noted
N/A			3/30/2011	Greg Sweel -17	DTSC's Human and Ecological Risk Office should evaluate the proposed target cleanup and action levels.	Comment noted
Table 7-1			9/6/2012	Perry Myers -5	The sludge material is of low shear strength and is likely to undergo both settlement and creep movement under load. In addition, due to the viscous nature of the material and the expected softening during high temperature periods in the summer season the settlement and creep movement could lead to surface expressions of the sludge as has been observed in the past. The FS should discuss the effects of both total and differential settlement on the performance of the cap and their effects on the operations and maintenance (O&M) activities as these have a direct bearing on the efficacy of the remedy and the costs associated with it.	Settlement and creep of the cap is anticipated to be negligible. Settlement is driven by consolidation of soils through deformation of soil particles, relocation or reorientation of soil particles, and expulsion of liquids (water and/or air) from the soil matrix. The tarry sludge material found within is of such a high viscosity that the material does not readily flow into the adjacent soil matrix. Therefore, the sludge material will not exhibit settlement from expolsion of liquids. Furthermore, the solid particles found within the sludge matrix are enveloped in fluid like, high viscosity materials that allow relocation and reorientation of solid particles bu the volume of the overall sludge matrix is not changed significantly. This is evident in the fact that the Haack Sump concrete pavement has not settled over the past 14 years. Concrete cracking is evident, but likely related to durability and shrinkage rather than settlement. Last, previous capping projects like McColl, Del Amo, and Thomas Ranch sites containing similar sludge materials have not indicated significant settlement. Settlement and creep that occurs can be corrected with minor maintenance during the life of the cap. Upon completion of the closure construction, the sludge material will be insulated from direct sunlight and ambient temperature increases; therefore, the softening of the sludge will cease to be a problem once the cap is in place. The costs associated with the creep and settlement maintenance are included with the maintenance costs.

Revised Final Draft FS Report Section No.	Original FS Report Section No.	Addendum Section No.	Comment Date	Comment No.	DTSC Comments	Geosyntec Response
Tables 7-1 through 7-3			9/6/2012	Perry Myers/Cost Estimate Review -1	According to the note on the Unit Price page for Mobilization/Demobilization, this cost should be 10% of the total construction cost ($454,491 instead of $297,300). ESPO notes this guidance does not appear to have been used for any of the alternatives. The estimate for Alternative 2 (no longer in consideration) notes the listed cost is 1 0% of the construction subtotal without markup costs which is a hidden row, but the Unit Price page indicates that markups are not applied (factor is= 1). It is not clear what the Mobilization/Demobilization cost is based on. The 10% approach appears valid since the cost of Mobilization/Demobilization should increase as the scope of the project gets larger. This issue should be revisited and the cost estimates or the notes revised as necessary.	The cost estimates have been revised to reflect a mobilization/demobilization of 10 percent for all alternatives.
Tables 7-1 through 7-3			9/6/2012	Perry Myers/Cost Estimate Review -2	7 acres for clearing and grubbing appears to be an error since the entire Site is 5.6 acres. ESPO notes this item is a minor cost.	The acreage for clearing and grubbing is 7 acres because areas beyond the Cooper and Haack Properties will require clearing and grubbing for laydown, staging, roadways, and office areas.
Tables 7-1 through 7-3			9/6/2012	Perry Myers/Cost Estimate Review -3	The FS calls for destroying 8 current groundwater monitoring wells, not 3. This change adds $50,000 to the estimate	The cost estimate tables are revised to reflect the destruction of 8 groundwater monitoring wells.
Tables 7-1 through 7-3			9/6/2012	Perry Myers/Cost Estimate Review -4	The unit cost for the sheet piling appears low. The RACER unit cost for permanent sheet piling was $24.65/SF. See comment 11 for Alternative 4 below.	The unit cost for sheet piles have been revised to approximately $29 per square foot based on preliminary quotes received from vendors and including a protective coating for the Site conditions. The temporary sheet piling price was revised to approximately $25 per square foot based on prelimary quotes, assuming a 1-month rental period, protective coating, and decontamination of the sheets.
Tables 7-1 through 7-3			9/6/2012	Perry Myers/Cost Estimate Review -5	The FS lists 2,670 CY of sludge/soil and 2,450 CY of soil overburden for the Haack Rework area and uses a density of .9 tons/CY to calculate the weight of the material. The cost estimate appears to assume all of the Haack Rework material is disposed off-site (scenario 3) and lists 4,600 tons for disposal. The unit cost of $80/ton for transportation and disposal appears low.	The cost for disposal has been revised to $120/ton. This is based of a quote received to transport and dispose of the non-hazardous material at the Buttonwillow Facility, a non-RCRA hazardous waste facility.
Tables 7-1 through 7-3			9/6/2012	Perry Myers/Cost Estimate Review -6	The square footage of high strength geotextile appears to include covering the Haack Sump, which over estimates the amount of material needed by -24,000 SF.	The high strength geotextile will not cover the Haack Sump; the costs have been revised to reflect this.
Tables 7-1 through 7-3			9/6/2012	Perry Myers/Cost Estimate Review -7	It is not clear if the 3,900 CY quantity listed for fingerfill soil placement in the foundation layer is imported soil or sourced onsite. The only source available onsite is the Haack Rework area and under scenario 3 none of the material would be available. This cost should be re-visited.	The finger fill soil material is assumed to be imported.
Tables 7-1 through 7-3			9/6/2012	Perry Myers/Cost Estimate Review -8	The treatment system for the gas collection system uses granular activated carbon, which may be inappropriate for the concentrations of hydrogen sulfide expected. A treatment system based on a thermal oxidizer with an acid air scrubber should also be evaluated and associated cost estimate prepared.	Please see the response to comment Perry Myers-12.
Tables 7-1 through 7-3			9/6/2012	Perry Myers/Cost Estimate Review -9	The FS states vertical gas migration wells will be installed every 20 feet around the perimeter, with the exception of the area along Artesia Boulevard where a sheet piling retaining wall will be installed. Using the supplied figures in the FS, ESPO calculated a total of 71 wells were needed. ESPO agrees with this spacing due to the type of soil. The cost estimate only includes 20 wells for this element of the remedy. The cost estimate should be revised to include 71 wells.	The text has been revised to state vertical gas migration wells will be installed every 80 feet around the perimeter. The costs have not been revised.
Tables 7-1 through 7-3			9/6/2012	Perry Myers/Cost Estimate Review -10	ESPO included construction of 7 new groundwater monitoring wells in its cost estimate after consulting with Mr. Paul Pongetti, P.G. of the geological services unit, who has previously worked on this Site. The Geosyntec cost estimate includes 3 new wells and should be revised.	The number and location of future groundwater monitoring wells to be installed will be determined in consultation with the DTSC. A minimum of three new wells is likely and this number was used for cost estimation purposes.
Tables 7-1 through 7-3			9/6/2012	Perry Myers/Cost Estimate Review -11	ESPO notes the unit price to install temporary sheet piling is almost double the cost to install the permanent sheet piling in Alternative 2A. The cost should be reviewed and revised as necessary. See comment 3 for Alternative 2A.	This cost has been revised to approximately $25 per square foot. The costs were previously assumed higher than the permanent costs due to decontamination of the sheet piling and management of the wastes from decontamination.

Revised Final Draft FS Report Section No.	Original FS Report Section No.	Addendum Section No.	Comment Date	Comment No.	DTSC Comments	Geosyntec Response
Tables 7-1 through 7-3			9/6/2012	Perry Myers/Cost Estimate Review -12	1tem #13 of the Quantities page of the original cost estimate indicates that 28,556 CY of net clean cut will be generated to make 1% grades. After bulking this volume increases to 37,123 CY. Under Alternative 4 this material is listed as Fill (Place and Grade Excavated Site Soil) and is combined with 4,000 CY of imported fill to backfill the excavated sumps (total of 41 ,200 CY). ESPO could not find a discussion of this 37,123 CY of net clean cut material in the text of the FS nor is excavation and use/disposal of this material included in the cost estimate for Alternative 2A. If this material is an artifact of the original FS that will no longer be generated the cost estimate for Alternative 4 should be revised to include sufficient imported fill to backfill the excavated sumps to the planned grades. If this material will be generated to meet planned grades across the Site, it should be discussed in the text and the cost estimate for Alternative 2A should be revised accordingly.	Grading of the site outside of the sump areas and areas immediately around the sump has been removed from the Feasibility Study. The quantities of imported fill have been revised to reflect the need for increased import to achieve proposed grades.
Tables 7-1 through 7-3			9/6/2012	Perry Myers/Cost Estimate Review -13	The unit cost for the amendment to neutralize sludge prior to disposal is prohibitively high, $6,000/ton. Based on experience, ESPO believes the quotes of $402/ton for CaOH2 and $198.87/ton for CaC03 from E&E (material + shipping) are more accurate. Based on the quantities included, using these unit costs results in a reduction of $28,172,950 to the cost estimate.	The costs have been revised to reflect recent quotes from manufacturers. It is noted that the price of these materials can be very volatile with ranges quoted from $160 per ton up to $750 per ton (CaOH2) and between $145 and $160 per ton (CaCO3).
Tables 7-1 through 7-3			9/6/2012	Perry Myers/Cost Estimate Review -14	The 49,900 tons used to calculate disposal costs should be revisited (see comment 16 under Task 1). The unit price of $50/ton for transportation and disposal appears low and needs adjustment unless a written quote supporting this price is provided.	Please see the response to Perry Myer/Cost Estimate Review - 5.
Tables 7-1 through 7-3			9/6/2012	Perry Myers/Cost Estimate Review -15	The long term monitoring costs include groundwater and soil gas monitoring. ESPO believes soil gas monitoring will not be necessary post excavation. Additionally, the a·nalyses needed to monitor groundwater should be fewer than if the waste is left in place since the source has been removed. The total time for monitoring will also likely be less.	The monitoring costs have been revised to reflect 5 years of post-excavation monitoring for Alternative 4.

Transmittal: **Response to Comments on the Revised Final Draft Feasibility Study Report**
Gardena Sumps Site
Southwest Corner of Artesia Boulevard and Normandie Avenue
Gardena, California
DTSC Site No. 400067

Dear Mr. Cully:

Geosyntec Consultants (Geosyntec), on behalf of the Atlantic Richfield Company (ARC), is pleased to provide this response to Department of Toxic Substances Control's (DTSC) comments on the Revised Final Draft Feasibility Study Report (Revised Final Draft FS). These responses were prepared to address the DTSC comments dated 27 December 2013 and 9 January 2013, received 17 January 2013. The DTSC comments are provided below in *italics* with ARC's response following. Errata sheets are provided as attachments as noted in the response.

Response to Comments

ESPO Comments

1. *The Report should include an acronym list after the table of contents.*

Acknowledged. An acronym list has been included after the table of contents (Attachment 1).

2. *Section 2.5 Hydrogeology. The executive summary includes a discussion of the two hydraulic zones within the Bellflower Aquiclude (Zone A and B) which should also be presented in this section. Additionally, this section should discuss the connectivity between these shallow A and B groundwater zones and the underlying water bearing zones that have beneficial uses and the*

potential, or lack thereof, for contaminants of concern (COCs) to migrate vertically and laterally.

Section 2.5 of the text has been revised to address this comment (Attachment 1).

3. *Section 3.2.5.1 Summary of Groundwater Monitoring. The discussion should include the predominant groundwater flow direction, depth to groundwater, and average velocity. Figure 3-3 should include an arrow denoting groundwater flow direction.*

Section 3.2.5.1 of the text has been revised to address this comment. Groundwater flow directions (present and historic) at the Site are illustrated in the quarterly groundwater monitoring reports that can be accessed in Envirostor (http://www.envirostor.dtsc.ca.gov/public/profile_report.asp?global_id=19490135).

4. *Section 3.4.8 Vapor Evolution. ESPO notes the completed Treatability Study provided data regarding gas generation but this data cannot be used to directly calculate volumes or concentrations of gases that might be produced during construction for the purpose of evaluating health risks. ESPO disagrees with Geosyntec's response to comments dated 11/6/12 and believes an excavation pilot study should be conducted at the Site. Goals for the pilot study should include; more accurately assessing gas generation from disturbing the sludge, evaluating whether a tent or shroud is necessary or whether products such as Odex and/or Hydroseal can adequately control hydrogen sulfide and sulfur dioxide gases, and in-situ mixing techniques for neutralization that incorporate a hood.*

A Pilot Study to evaluate the gas generation, mitigation, and mixing techniques is not warranted at this time. Results of the neutralization study were used to qualitatively evaluate the amount of gas generated during sludge neutralization for stabilization or excavation (Alternatives 3 and 4, respectively).

During the Remedial Investigation, surface vapor flux testing was performed on undisturbed and disturbed sludge samples. Results indicated that sludge disturbed by moderate surface agitation released concentrations of sulfur dioxide up to 26,000 $\mu g/m^2$, min^{-1} (STANTEC, 2008). The disturbed sludge vapor flux testing results provide sufficient evidence that the disturbance of sludge results in the release of sulfur dioxide. The Treatability Study results further support the generation of sulfur dioxide and hydrogen sulfide during the sludge neutralization process.

5. *Section 4.6.3 Potential Action-Specific Requirements. The text for the Porter Cologne Water Quality Control Act should also include groundwater.*

Noted, groundwater has been added to the text for the Porter Cologne Water Quality Control Act.

6. *Section 6.1.2.1 Alternative 2A General Overview. Included in this Alternative is repaving an area of Artesia Boulevard, where sludge material is located below the roadway, with low-permeability asphaltic concrete and requiring increased maintenance of this area. The Alternative also includes institutional controls to restrict loading on the proposed cap over the sludge in the sumps. The text should include a discussion of whether the area of Artesia Boulevard that includes sludge material has incurred increased maintenance in the past and whether or not load restrictions for the roadway are necessary.*

The sludge beneath Artesia Boulevard has not detrimentally impacted the roadway, as indicated by the lack of specific pavement repairs above the sludge. Given that the sludge beneath Artesia Boulevard is very thin, is covered by approximately 5 ft of soil and structural pavement section, and that over 50 years of continuous traffic loading have not induced sludge related detriment to the roadway, no load restrictions in addition to those already established by the City and State, will be required.

7. *Section 6.1.2.2 Haack Rework Material Excavation and Disposal. The fourth paragraph appears to have been added to this section in error. It presents a discussion about finger berm construction, which is only proposed for the Cooper sumps.*

Acknowledged, this paragraph was added to this section in error and has been removed (Attachment 1).

8. *Section 6.1.2.2 Vapor Control During Construction. The proposed monitoring and work practices must also consider off-site receptors to avoid unacceptable exposures to the public.*

As described in the Section 6.1.2.2 Vapor Control During Construction, fixed monitoring will be performed around the perimeter of the work area during construction and when the PEL, or a percentage of the PEL, is reached, work activities will pause and/or be altered to minimize impacts to off-site receptors.

9. *Section 6.1.2.3 Capping of the Sumps. ESPO notes the sheet piling and high strength geotextile will be in contact with the sludge and these critical elements of the cap have a finite life. This section should include the life expectancy of the high strength geotextile and the sheet piling so replacement of these features can be scheduled in the Operations and Maintenance Plan, should this Alternative be selected for implementation.*

Sheet piles will be coated to minimize corrosion (i.e. Wasser Polyflex 304) and are expected to have a lifetime in excess of 50 years. The high-strength polypropylene geotextile is not needed after construction of the overlying cover materials; therefore, replacement of the high-strength geotextile will not be included in the Operations and Maintenance Plan.

10. *Section 6.1.2.4 Gas Treatment System. The text should be modified to note the system may be converted to passive operation only with written prior approval from DTSC.*

Acknowledged. The text has been revised to reflect this (Attachment 1).

11. *Section 6.1.2.4 Gas Monitoring System. The first paragraph refers to Figure 3-6 but ESPO could not find this figure in the Report. Please correct the reference.*

The text refers to figure 6-6, the “3-6” is struck out from the previous draft feasibility study and is no longer applicable.

12. *Section 6.1.3.2 Consolidation of Material. Section 3.2.1 states the Haack Rework Area contains 650 cubic yards (CY) of material (without describing the composition of the material, leaving the reader to assume it is sludge only) and 1200 CY of sludge with soil interbeds. Since the description used here is "of a sludge/soil mixture" it would appear the estimate of 1200 CY is appropriate, not 650 CY. Please eliminate the apparent inconsistency and revise the text as necessary.*

The Haack Rework area is estimated to contain 2,670 CY of soil-sludge and 2,450 CY of overburden soil. The text has been revised to reflect this (Attachment 1).

13. *Section 6.1.3.2 Consolidation of Material. The second sentence of the second paragraph is confusing and should be revised to provide a clear summary of the total volume that will be placed above the sumps. The volumes listed for the Haack Rework (assumed to be the sludge with interbedded soils) and Haack Rework overburden are inconsistent with the volumes listed previously in the Report. The sum of the volumes listed here total 5380 CY, not 5120 CY.*

The volumes indicated in the text have been changed to be consistent with the volumes stated in the previous paragraph. The Haack Rework (2,670 CY), Haack Rework overburden (2,450 CY), and eastern overflow (260 CY) will total 5,380 CY (Attachment 1).

14. *Section 6.1.3.4 Capping of the Sumps. It should be clarified that impacted material to be used as foundation soil will be treated, the same as the top three feet of the sumps, to prevent corrosion issues with the materials used to construct the gas control and protective layers of the proposed cap and to help prevent gas and odor generation during construction.*

Impacted material used as foundation soil will consist of soil-like material from the Haack Rework area which will not be treated. The Haack Rework material is degraded and will not be placed in contact with gas collection features. Odor and gas generation will be controlled with odor suppressant equipment.

15. *Section 6.1.3.4 Final Cap Topography. The minimum thickness of the cover was deleted from the second sentence as part of the RTC, but a revised thickness was not inserted. The text should be revised to include the new thickness.*

The revised value of 6 feet is provided in the report and is located directly after the deleted value.

16. *Section 6.1.4 Alternative 4. The text states that active dewatering would be required for the duration of excavation. This statement is incorrect and should be revised. Dewatering will only be necessary where the excavation approaches or is within the water table.*

The text has been clarified to indicate active dewatering would be required to remove perched groundwater and shallow groundwater when excavation and backfill are below the water table, and would be necessary to remove ponded misting agents (Attachment 1).

17. *Section 6.1.4 Alternative 4. Third bullet in the list associated with the first paragraph. The Haack Rework Area contains sludge with interbedded soils that cannot be separated and has been described as distinctly different than the sludge material. The text should be revised.*

The text has been revised to refer to the material excavated from the Haack Rework Area as soil-sludge (Attachment 1).

18. *Section 6.1.4.2 Excavation of Sumps. The first sentence should be revised to clarify whether the depth listed is below ground surface (bgs) or some other reference.*

The depth listed is below ground surface (bgs) and the text has been revised (Attachment 1).

19. *Section 6.1.4.2 Excavation of Sumps. In addition to using an excavator to perform mixing of the sludge with the admixture for neutralization, the use of a drill rig equipped with an auger and hood should be evaluated.*

Use of drill rigs for mixing thick sludge layers is difficult due to the lack of structural support available for the drill rig. Prior to neutralization, the sludge is soft and will not support the drill rig without specific structural elements put into place. Drill rig operation can be staged to work on top of previously neutralized sludge, thereby giving some support; however, the drilling operation will always be at the edge of treatment and highly susceptible to bearing capacity failure. Due to the safety concerns, the use of a drill rig with a hood is not considered further.

20. *Section 7.3 Final Remedial Alternatives- Detailed Analysis. The evaluation of the Alternative is biased towards the preferred alternative throughout this section. The benefits of Alternative 2A are routinely overemphasized while the impacts and negatives are minimized. Conversely for Alternatives 3 and 4, the impacts and negatives are stressed and the benefits (especially long term for Alternative 4) are minimized. The analysis should be redone without bias. Each alternative has major advantages and disadvantages that should be presented in a balanced manner. As written, the Detailed Analysis calls the conclusions of the Report into question.*

The detailed analysis of Alternatives discusses each Alternative with respect to the nine criteria. The benefits and impacts are discussed equally for all Alternatives.

21. *Section 7.3.3.2 Compliance with ARARs. This section should include a more detailed discussion of the potential for contaminated groundwater at the Site to impact other water bearing zones. The included discussion is insufficient. ESPO notes that if it is determined contaminated groundwater in the A Zone can impact deeper zones or the A zone qualifies as a unit with beneficial uses, the rating for this section will change to low. See Comment 2 also.*

Section 7.3.3.2 of the text has been revised to address this comment (Attachment 1).

22. *Section 7 .3.3.3 Long-Term Effectiveness and Permanence. The text in the second paragraph states that high ground shaking is only expected to have minimal effects because a parking lot is planned on the remediated site. However, no data or analysis of high seismic ground shaking effects such as liquefaction, settlement/subsidence, or lateral spreading and any surface expressions of the underlying sludge is included in the Report to justify this statement. While it is*

likely that ground shaking could have minimal effects, a preliminary evaluation of ground shaking effects should be included in the Report to provide a basis supporting any conclusions that are made about ground shaking effects.

A preliminary evaluation of ground shaking was performed for the site and liquefaction was identified as a potential site response. Settlement and subsidence was shown to be minimal due to the thickness of the liquefiable layer and residual material strength. Sand boils would not occur through the sludge due to the low permeability of the sludge and relatively high permeability of the soil around the sumps. Lateral spreading to the south of the engineered cap caused by liquefaction-induced soil displacement at the Dominguez channel was identified as a possibility during the seismic analysis.

23. *Section 7.3.3.3 Long-Term Effectiveness and Permanence. An analysis of what would be necessary to repair a failure in the high strength geotextile should be part of the Report and the results included here. If repairs require removal of the cap above the geotextile this alternative would have low long term effectiveness and could create unacceptable health risks if sludge is exposed during a seismic event. See Comment 22 also.*

The high-strength geotextile provides support during construction of the overlying cover materials at which time the bearing capacity of the sludge is improved. If a failure were to occur in the high-strength geotextile, it would be during construction of the cover, at which time it could be repaired. Following installation of the soil cover system, the high-strength geotextile provides no additional support or necessary function for the cover.

24. *Section 7.3.3.4 Reduction of Toxicity, Mobility, or Volume through Treatment. The Alternative should be rated low for this evaluation. Treatment will not be performed, toxicity is not reduced, and volume is minimally reduced in the least impacted area only. The argument for mobility reduction seems to contradict other sections of the Report. See comment for RTC (Perry Myers 5) below.*

This Alternative is rated moderate because the mobility and volume of the sludge is reduced. The cap will reduce upward and displacement-induced mobility of the sludge. The gas system will further reduce mobility by preventing gas migration, if any. The volume of the sludge onsite will be reduced by relocating the Haack Rework material.

25. *Section 7.3.3.5 Short-Term Effectiveness. The text states cap construction would be performed above the existing surfaces, reducing gas generation. ESPO notes the anchor trench*

for the high strength geotextile runs, in part, between the Cooper North and Haack sumps, creating the potential for disturbing sludge that was shown to generate gases in the Treatability Study. This section should discuss the potential for excavating gas generating sludge material, the required actions to prevent unacceptable exposures, and how this may affect the short term effectiveness and implementability of Alternative 2A.

Gas generation is not anticipated during the construction of the anchor trench. The depth of the anchor trenches (3 feet) is anticipated to be above the sludge reported in the area. Additionally, the sludge which runs between the Cooper North and Haack sumps is similar to the Haack rework material in that it is discontinuous and degraded and therefore gas generated from the disturbance of this sludge in anticipated to be minimal.

26. *Section 7.3.3.6 Site Size. Since implementation of this Alternative requires construction on the Los Angeles Department of Public Works (LADPW) property along the eastern margin of the Site, discussions should be initiated with the LADPW to verify access can be obtained. See comment for RTC (Perry Myers 2) below.*

An access agreement with the LADPW currently exists and is renewed on a periodic basis. Additionally, the presence of sludge on the LADPW property east of the Cooper property may result in the listing of the LADPW as a potential responsible party as previously identified by the DTSC in a 1992 Imminent and Substantial Endangerment Order. It is not believed that the LADPW future actions or use of the property would be adversarial to the implementation of this Alternative.

27. *Section 7.3.4.1 Overall Protection of Human Health and the Environment. ESPO notes that similar to Alternative 2A, Alternative 3 may not adequately address protection of groundwater and that the evaluation of Alternative 3 may need revision depending on the additional information regarding hydrogeology that will be added to the Report. See Comments 2 and 21 also.*

Alternative 3 would not address current impacts to groundwater. This has been included in the discussion in Section 7.3.4.1 (Attachment 1).

28. *Section 7.3.4.3 Long-Term Effectiveness and Permanence. Similar to the evaluation for Alternative 2A, the text should discuss the potential for surface expressions of sludge during a seismic event and the potential health risks should this occur. See comment for RTC (Steven Hariri 2) below and Comment 23 also.*

Preliminary analyses of the site behavior during a seismic event do not indicate the potential for a surface release of sludge.

29. *Section 7.3.5 Alternative 4- Excavation with Offsite Disposal. The individual sections of the Alternative 4 evaluation were not rated low to high as were the evaluations for the other alternatives. The rating should be included for each subsection. ESPO's opinion on the ratings for Alternative 4 is as follows:*

7 .3.5.1 high -moderate

7.3.5.2 high -moderate

7.3.5.3 high -high

7.3.5.4 high –low to moderate

7.3.5.5 low -moderate

7.3.5.6 low -low

7.3.5.7 low –high costs, low ranking

7.3.5.8 moderate to high –not evaluated yet

7.3.5.9 moderate to high (based on statements from the city) –low to high

Noted. The sections have been rated based on the ratings provided in revised Table 8-1. The ratings for Alternative 4 are as follows:

7 .3.5.1 Moderate to high

7.3.5.2 High

7.3.5.3 High

7.3.5.4 Low to moderate

7.3.5.5 Moderate

7.3.5.6 Low

7.3.5.7 High

7.3.5.8 Not assessed yet

7.3.5.9 Moderate to high.

See Attachments 1 [Report Text] and 2 [Table 8-1]for revised rankings.30. *Section 7.3.5.2 Compliance with ARARs. This alternative complies with all ARARS and should be rated high. The statement that implementing this alternative will be impossible to perform in compliance with applicable emissions, disposal, and transportation regulations is not supported by the rest of the Report. Engineering controls can be used to meet emissions, treatment of the sludge will meet disposal requirements, and transportation requirements can be met. All will likely increase costs, perhaps significantly, but this section is to evaluate the alternative's ability to comply with ARARS, no other criteria. See Comment 20 also.*

The text and Table 8-1 have been revised to reflect high compliance of ARARs for Alternative 4 (Attachments 1 [Report Text] and 2 [Table 8-1]).

31. *Section 7.3.5.2 Compliance with ARARs. ESPO does not recall seeing this upgradient source argument previously in the Report. This statement should be removed unless additional information is provided in the Report to justify it.*

The Bellflower Aquiclude groundwater in the vicinity of the Site is naturally degraded as evidence by the Total Dissolved Solids (TDS) concentrations in the A-zone and the TDS and chloride concentrations in the B-zone which exceed the recommended secondary MCL values as documented in the up-gradient, background wells (wells MW-1A and MW-1B). Similar TDS and chloride concentrations also exist in groundwater obtained from the on-Site monitoring wells that are not impacted by waste.

32. *Section 7.3.5.5 Reduction of Toxicity. Mobility. and Volume Through Treatment. This analysis should be done from the perspective of the Site. Toxicity, mobility, and volume would all be significantly reduced and this section should be rated high for this alternative.*

While we agree that the long term toxicity, mobility, and volume would be significantly reduced upon completion of the remedy, the short term toxicity, mobility, and volume during

construction of the remedy actually increases. Alternative 4 would provide moderate reduction of toxicity, mobility, and volume of the sludge or rework material through treatment. This alternative creates a large amount of waste compared to the other alternatives presented and discussed. This larger volume of waste, which will be handled and shipped off site, is taken into consideration for evaluating these criteria. The volume of the sludge would double after admixture and would require disposal off site. Other wastes that would be produced include impacted groundwater, equipment decontamination wastes, and vapor treatment liquid and solid wastes. The mobility of the sludge impacts would be increased during this option as gas is generated during excavation and mixing activities. The mobility of the sludge would be temporarily increased due to trucking to an offsite disposal facility.

33. *Section 7.3.5.5 Short-Term Effectiveness. The fifth sentence should be revised to state " .. acid gases may be generated", not "would". As the Treatability Study was qualitative for construction activities, the assertion that significant quantities of acid gases would be generated is not currently supported by the Report. If additional information supporting this assertion is generated through implementation of an onsite pilot study, or other approved study/source, then the text can remain unchanged. See Comment 4 and Comment* [sic] *and Comment 20.*

The text has been revised to refer to the amount of acid gas produced with Alternative 4 in relative terms to the amount of acid gas that would be produced by the other alternatives presented and discussed (Attachment 1). As previously discussed in the responses to Comments 4 and 20, there is sufficient evidence from the Remedial Investigation Flux Chamber testing, the Treatability Study, and Sites with similar sludge materials, such as McColl, to support the potential for gas generation.

34. *Section 7.3.5.5 Short-Term Effectiveness. The last sentence refers to a cap, which is not part of this Alternative, and should be revised/removed. See comment for RTC (Perry Myers 5) also.*

Noted. The last sentence has been removed from the text (Attachment 1).

35. *Section 8 Comparative Analysis of Alternatives. This entire section, and the associated table(s), should be reviewed and revised as necessary once changes are made to the Report to address all comments made by DTSC on this document. ESPO may have additional comments on Section 8 once it is revised.*

Section 8 is revised to discuss the comparative rankings of the Alternatives.

36. *Section 7.3.5.6 lmplementability. Previous sections describe the sludge properties as soil like and rely on this characterization to design the cap in Alternative 2A and evaluate that alternative's performance during a seismic event. If the sludge is more viscous than previously described, the entire Report should be reviewed and revised as necessary to accurately reflect the material properties of the existing waste.*

The majority of the sludge to be excavated in Alternative 4 is previously undisturbed sludge, which has a less viscous consistency than the degraded soil-sludge material located in the Haack Rework area, eastern overflow, within berms, and within Artesia Blvd. Previously undisturbed sludge is not proposed to be removed in Alternative 2A and Alternative 3.

37. *Appendix A Response to Comments (RTC Summary Table (Perry Myers/Cost Estimate Review 1 0). Given the regulatory agency providing oversight for the cleanup has provided guidance on the number of groundwater monitoring wells likely to be required, using three new wells for cost estimating purposes instead of the recommended number would under estimate the Operations and Maintenance costs for Alternatives 2A and 3 related to long term monitoring. Installation of three new wells is likely acceptable for the Alternative 4 cost estimate due to the included source removal. The cost estimates for Alternatives 2A and 3 should be revised to include installation and monitoring of at least eight new groundwater wells (see comments on the Report from Greg Sweel of DTSC's Geological Services Unit for more detailed guidance). Analysis should include all COCs on a quarterly basis.*

] The addition of five groundwater wells creates a small, uniform, $40,000 construction cost increase to Alternatives 2A and 3 which will not affect the outcome of the relative cost difference of the three Alternatives. Increasing monitoring to quarterly from semi-annually, and the addition of 5 groundwater wells increases the O&M costs for Alternatives 2A and 3 from approximately $1.12M to approximately $3.18M. These costs are believed to be conservatively high for the 30-year period as soil vapor monitoring will likely decrease to semi-annually or annually or eliminated as occurred at sites similar to Gardena Sumps (Thomas Ranch, McColl). Further, groundwater monitoring will likely decrease to semi-annually or annually. While the O&M cost increase is significant, the costs of each alternative compared to one another remains the same, low (Alternative 2A), medium (Alternative 3), and high (Alternative 4). The revised cost tables are provided in Attachment 2.

38. *Appendix A Response to Comments (RTC) Summary Table (Perry Myers/Cost Estimate Review 9). The response to comments indicates Geosyntec is relying on a zone of influence (ZOI) of 40 feet for each of the gas migration wells to control gases generated from the sludge. A detailed discussion should be included in the Report that justifies the ROI and demonstrates the proposed gas collection system is adequate.*

The Zone of Influence (ZOI) is assumed from published, typical values for silty to fine sand. Typical ZOI values for those materials range from 20 ft – 40 ft (Silt) to 60 - 100 ft (fine sand) (Wong, 1997). The material at the site is generally silty sand; therefore, a 40-ft ZOI is appropriate for Feasibility Study-level planning and cost estimating purposes.

39. *Appendix A RTC (Perry Myers 2). The response to comment states that the high strength geotextile will be anchored within the Los Angeles Department of Public Works (LADPW) property along the eastern margin of the site. This may be acceptable as long as unhindered access for both installation and future maintenance is secured and guaranteed. Discussion should be initiated with the LADPW to verify access can be obtained. In addition, costs for concrete anchors and associated battens should be included in the remedy cost estimate.*

An access agreement with the LADPW currently exists and is renewed on a periodic basis. Additionally, the presence of sludge on the LADPW property east of the Cooper property may result in the listing of the LADPW as a potential responsible party as previously identified by the DTSC in a 1992 Imminent and Substantial Endangerment Order. It is not believed that the LADPW future actions or use of the property would be adversarial to the implementation of this Alternative and long term maintenance. The cost for anchor trenches is included in the cost of material under high strength geotextile located in Table 7-1. An additional cost of $15 per linear foot of sheet piling has been included for the battens. (Attachment 2)

40. *Appendix A RTC (Perry Myers 4). The response to comment states that the "final design will account for a 200 psf traffic loading on the completed surface". This level of loading would appear to preclude most light trucks and SUVs which would typically be expected in a retail or office parking lot and raises serious questions about the viability of a parking lot on the remediated site. Please clarify the vehicle size/weight limitations that are likely to be imposed on an onsite parking lot, or the feasibility of construction adjustments needed to accommodate such vehicles.*

We evaluated the cover for H20 loading of 80 psi (11,520 psf) at the cap surface and found it to be acceptable. H20 loading is greater than SUV and light truck loading and therefore inclusive of those loads.

41. *Appendix A RTC (Perry Myers 5). The response to comment states that settlement and creep of the cap is expected to be negligible and that the tarry sludge is of such high viscosity that it will not exhibit settlement from expulsion of liquids. This would appear to contradict the statement in the second paragraph of Section 7.3.3.4 of the Report which states that there is evidence of sludge movement from beneath the cap at the edges of the concrete and asphalt cover on the Haack Sump and Section 7.3.5.6 that states as an area is excavated the sludge would flow to the newly excavated portion of the sump. The observed sludge movement likely will be exacerbated by application of additional load from the proposed cover/cap. In addition, data from the 2008 Treatability Study by Stantec (Appendix B Treatability Study, Section 3.1.3 Moisture, of the current Report) indicates that the sludge has moisture contents varying from 9.8 to 22.3%. Given these moisture content levels in the sludge, it is likely that the sludge will undergo settlement (by expulsion of water) under load.*

Experience with similar sludge materials at the McColl, Del Amo, and Thomas Ranch sites indicates that the surficial sludge materials are highly susceptible to temperature. The surficial sludge materials are warmed by the sun and hotter summer temperatures, making them less viscous and prone to movement. This is seen in the current asphalt and concrete capped areas of the site where the sludge near the surface is warmed and repeated traffic loading compresses the flexible pavement and underlying sludge, thereby allowing it to migrate upwards through cracks in the pavement.

When a thicker final cover, which will provide more thermal insulation from the sun and hotter temperatures, is constructed, the sludge will exhibit more viscous characteristics and be less susceptible to migration. Furthermore, the installation of the cap components (soil, geotextile, geomembrane, etc.) will further impede the movement of the sludge material as the porosity of these cap materials, where the sludge would move, will be much smaller than the current pavement cracks that provide a pathway for sludge to migrate to the surface.

The presence of moisture in a fine grained material, such as the sludge at the site, does not necessarily relate to the ability of the material to compress. Expulsion of water is driven by the microstructure of the sludge and the hydraulic conductivity of the sludge. The microstructure of the sludge provides a certain amount of porosity, which can be reduced with reorientation of the

microstructure. If the microstructure does change and the porosity is reduced, the liquid contents of the porosity will be expelled. Expelled liquids are hindered by the hydraulic conductivity of the adjacent materials and the liquid travel distance to get out of the sludge. In this case, the sludge, which has a very low hydraulic conductivity of 1×10^{-8} cm/sec, will limit the expulsion of the liquid.

These factors have been exhibited by similar sludge materials found at the McColl, Del Amo, and Thomas Ranch sites. Six years of settlement monitoring of the Thomas Ranch site Pond 2, which contains 15 feet of low viscosity and soft sludge material, indicates that a maximum settlement of 6.84 inches has occurred in the middle of Pond 2. This settlement occurred within the first three years after completion of construction and is attributed to the large aggregate, with large open pores, that was placed over the sludge during construction. The sludge migrated into the aggregate pores allowing the final cover to settle slightly. This settlement has now ceased, indicating that liquid expulsion driven compression of the sludge is not occurring.

42. *Appendix A RTC (Steven Hariri 2). While it is appropriate to complete a detailed evaluation of damage to the cap surface drainage and erosion systems, as well as the gas migration control system, during the remedial design phase, it would be prudent to perform a preliminary evaluation at the feasibility study stage to provide data and information for use in remedy selection. We would strongly suggest a preliminary evaluation of seismic induced liquefaction, lateral spreading, subsidence, and other effects be considered at this stage.*

A preliminary evaluation of ground shaking was performed for the site and liquefaction was identified as a potential site response. Settlement and subsidence was shown to be minimal due to the thickness of the liquefiable layer and residual material strength. Sand boils would not occur through the sludge due to the low permeability of the sludge and relatively high permeability of the soil around the sumps. Lateral spreading to the south of the engineered cap caused by the liquefaction-induced soil displacement at the Dominguez channel was identified as a possibility during the seismic analysis.

<u>Efrem Neuwirth Comments</u>

1. *HERO appreciates the changes which were made to the soil-vapor risk based concentrations (Table 4-4) for benzene based upon modeling utilizing the default soil physical properties for loam (in Appendix C) rather than the previously utilized site specific properties. HERO also appreciates that the response to comments indicated that possible future fill material will not be*

more permissive to soil-vapor migration than those used in the modeling for evaluating vapor intrusion risks.

Despite the aforementioned changes, the response to comments still argues that the site specific moisture content is reasonable. However in HEROs opinion, it is not appropriate to use an average value from across the site for modeling vapor migration when there is considerable variability as was the case in the data collected for the moisture content (% weight). In addition, the bulk soil density was not measured in the majority of the samples, such that the volumetric water content cannot be determined.

Acknowledged.

Greg Sweel Comments

1. *Appendix A (Response to Comments)*

I generally concur with the RTCs and the proposed revisions and defer to the Engineering and Special Projects Office (ESPO) regarding concerns related to areas of their expertise.

There are a few RTCs which need some additional clarification. Specifically, page 7 of 15 (Greg Sweel – 9) mentions that the location and number of proposed soil gas probes may change. I would recommend that any changes in number and location be made after consultation and agreement with DTSC. Also, there remains conflict between several RTCs (Greg Sweel – 6, Greg Sweel – 13, Greg Sweel – 21, and Perry Myers – 13) regarding the number of groundwater monitoring wells which are proposed for abandonment.

Noted. The exact locations and number of proposed soil gas probes will be decided in consultation with the DTSC.

2. *Section 3.3 (Fate and Transport)*

Some areas of sludge may be in direct contact with groundwater resulting in ongoing contamination. The subject document should integrate removal of the source areas and protection of groundwater resources as a remedial alternative.

The document evaluates the feasibility of removing the sludge and the potential source of localized groundwater impacts in Alternative 4. Groundwater impacts which may be attributed to

the sludge are localized and not impacting offsite areas as evidence by the lack of downgradient impacts; therefore, the incorporation of institutional controls preventing the use of onsite groundwater as well as notification of excavation and other activities where groundwater may be encountered, are sufficient for protection with Alternatives 2A and 3.

3. *Section 6.1.2.6 (Groundwater Monitoring)*

We note that Tables 7-1 through 7-3 only estimate costs for the installation of three (3) replacement groundwater monitoring wells. These tables should be revised to include at least eight (8) new wells (4 well clusters each consisting of a Zone A and a B completion). Also, Figure 6-13 should include a schematic for deep (Zone B) monitoring wells along with shallow (Zone A) wells.

The addition of five groundwater wells creates a small, uniform, $40,000 construction cost increase to Alternatives 2A and 3 which does not affect the outcome of the relative cost difference of the three Alternatives. Increasing monitoring to quarterly from semi-annually, and the addition of 5 groundwater wells increases the O&M costs for Alternatives 2A and 3 from approximately $1.12M to approximately $3.18M. These costs are believed to be conservatively high for the 30-year period as soil vapor monitoring will likely decrease to semi-annually, annually, or eliminated altogether as occurred at sites similar to Gardena Sumps (Thomas Ranch, McColl). Further, it groundwater monitoring will likely decrease to semi-annually or annually. While the O&M cost increase is significant, the costs of each alternative to one another remains the same, low (Alternative 2A), medium (Alternative 3), and high (Alternative 4). The revised cost tables are provided in Attachment 2.

The typical well shown in Figure 6-13 is provided for demonstration purposes only and is not intended to serve as construction guidance for future onsite wells. Additional wells and their schematics, if necessary, will be included in the RAP and subsequent design reports.

4. *Section 7.3.5.2 (Compliance with ARARs)*

The newly added text mentions that groundwater beneath the site has been impacted from upgradient sources. We believe this statement is not accurate and should be removed.

The Bellflower Aquiclude groundwater in the vicinity of the Site is naturally degrade as evidence by the Total Dissolved Solids (TDS) concentrations in the A-zone and the TDS and chloride concentrations in the B-zone which exceed the recommended secondary MCL values as documented

in the up-gradient, background wells (wells MW-1A and MW-1B). Similar TDS and chloride concentrations also exist in groundwater obtained from the on-Site monitoring wells that are not impacted by waste. Impacted was a poor choice of words, degraded should have been used in place of impacted.

If you have questions or require additional information about the enclosed report, please contact Mr. Kyle Christie with ARC at 714-670-5303.

Sincerely,

Gregory T. Corcoran, P.E.

EXECUTIVE SUMMARY

This Revised Final Draft (RTC, 11/6/12) Feasibility Study (FS) Report was prepared for the Gardena Sumps Site (Site) in Gardena, California. This FS Report was prepared for submittal to the California Environmental Protection Agency (CalEPA), Department of Toxic Substances Control (DTSC) in accordance with the California Health and Safety Code. The FS Report is a requirement of Consent Decree CV04-7882-AHM (JTLx), (Consent Decree). This Revised Final Draft FS incorporates the comments and requests made by the DTSC on the original draft FS dated February 2011 and the Draft Feasibility Study Addendum – Alternative 2A (Addendum). Revisions to the original Draft FS resulting from the Addendum and comments are shown as either strike out (deletions) or underline (additions) with the corresponding comment package date at the end. (RTC, 11/6/12)

Background

The Site is located in the southwest corner of the Artesia Boulevard and Normandie Avenue intersection in the City of Gardena, Los Angeles County, California. Generally, the area surrounding the Site is bordered to the south by the Los Angeles County Department of Public Works (LACDPW) Dominguez Flood Channel, to the east by the Southern Pacific Railroad right-of-way, to the west by the western Haack property line, and to the north by Artesia Boulevard, although a small portion of Artesia Boulevard is included within the Site. Commercial and residential properties are currently located to the north, east, and west of the Site (Stantec, 2008).

The site was developed as a clay mine during the 1920s by the Moneta Brick Company. Clay mining resulted excavations that were ~~in what are known as the Haack, Cooper South, and Cooper North sumps and Haack Rework Area~~ reportedly used for sludge disposal beginning in approximately ~~at the Site. These sumps were reportedly used for sludge disposal beginning in March~~ (RTC, 11/6/12) 1940. By September 1946, the Haack, Cooper South and Cooper North Sumps had been ~~and two Cooper sumps were~~ (RTC, 11/6/12) filled with sludge, and vegetation had reclaimed ~~the small pit and~~ (RTC, 11/6/12) the Haack Rework Area (Stantec, 2008).

By December 1951, the western portion of the Haack Sump had been covered with dirt and was converted into a parking lot. On October 1, 1952, the northern-most strip of the Site ~~Haack~~ (RTC, 11/6/12) property was sold to the State of California for a highway easement. By early 1956, Artesia Boulevard (Highway 91) had been constructed, with the southern portion of the roadway encroaching into the Haack Sump northern berm. By January 1958, the Dominguez Channel had been reconstructed and extended eastward south of the Site (Stantec, 2008).

By November 1962, the bluff on the Haack Property (RTC, 11/6/12) had been excavated to expand the Haack ~~paved~~(RTC, 11/6/12) parking lot, although the eastern portion of the Haack property contained sludge ~~remained a vegetated area~~ (RTC, 11/6/12) immediately west of the Cooper North Sump. The Haack Rework Area appeared altered and may have received soil cover from excavation activities that occurred immediately north of the Haack Rework Area. The future Cooper property was unchanged even after it was sold to Thomas Cooper in December 1977 (Stantec, 2008).

Currently, the two Cooper sumps are capped by a geosynthetic material that was installed by OHM Corporation (OHM) in July 1993 as part of the DTSC's environmental program at the Site. The Haack Sump has been covered by asphalt and a concrete slab. Currently the Haack property is leased to various tenants who operate small businesses, including a U-Haul rental agency, a metal fabricating, sand blasting and painting company, and an auto body repair shop. Three buildings and numerous small trailer-type storage structures are present on the Haack property (Stantec 2008).

Geology and Hydrogeology

The Site is located in the Los Angeles Coastal Plain and is underlain by a thick sequence of marine and continental sediments that were deposited in a broad synclinal depression generally referred to as the Los Angeles Basin. The Los Angeles Basin is bisected by the northwest trending Newport-Inglewood uplift, which divides the Coastal Plain into two smaller synclinal troughs. The Site is located in the West Coast Basin, which constitutes the southwest portion of the Los Angeles Basin (Stantec, 2008).

The Site is located near the junction of the Torrance Plain and the Dominguez Erosion Gap. The Torrance Plain runs west of and parallel to the hills of the Newport-Inglewood uplift from the Ballona Gap southeast to the Dominguez Gap. The Plain is a broad featureless area only slightly dissected locally by the Dominguez Creek (Dominguez Channel) (Stantec, 2008).

According to boring logs in the Ecology and Environmental, Inc. (EEI) (1986), Metcalf and Eddy (1992), CalEPA (1994) and URS (1994) reports, sediments underlying the Site, to the maximum explored depth of 92 feet below ground surface (ft bgs), consist primarily of a mixture of clays and silts with interbeds of sand (Stantec, 2008).

The Site is underlain by the Bellflower Aquiclude at the ground surface, and beneath that, the Gardena and/or Gage Aquifers of the Lakewood Formation within the larger, West Coast Groundwater Basin. Regionally, the Bellflower Aquiclude contains interfingered zones of permeable and less permeable sediments with modest to relatively high hydraulic conductivity. Little beneficial use is made of water in these

shallow, discontinuous hydraulic zones because well yields tend to be low and water quality generally poor (CalDWR, 1961).

Immediately beneath the site, there are two hydraulic zones within the Bellflower Aquiclude: Zone A (upper) and Zone B (lower), which are approximately 15 to 25 and 75 to 80 ft bgs, respectively. Site groundwater monitoring wells are screened within these two zones (Stantec, 2008). Presently the shallow groundwater beneath the Site is influenced by the concrete lined Dominguez Channel and flows southward (Stantec, 2010c).

Beneath the Lakewood Formation are the Lynwood and the Silverado Aquifers, which are capable of storing or conveying groundwater in significant quantities and constitute major sources of groundwater in the West Coast Groundwater Basin. While these aquifers are designated as primary and secondary sources of domestic water supply, neither the Gardena nor Gage Aquifers are currently pumped for domestic use (Stantec, 2008).

The area surrounding the Site is urbanized, with surface waters that drain via storm drains into the Dominguez Channel. The upstream portion of the modern day Dominguez Channel originates several miles west-northwest of the Site, and it drains surface water to the southeast where it discharges to the Cerritos Channel of the Los Angeles Harbor. Historically, the Dominguez Channel flowed along a natural channel bed located approximately several hundred feet west and north of the Site, where it flowed eastward into Laguna Dominguez. Surface water at the Site generally drains towards the north and east following site topography, and is intercepted by a flood control storm drain located at the northeast corner of the Site adjacent to the intersection of Artesia Boulevard and Normandie Avenue (Stantec, 2008).

Contaminant Distribution

During the 2006, 2008, and 2009 Remedial Investigation (RI) activities, Stantec collected subsurface soil, sludge, surface water, groundwater, perched groundwater, soil gas, and soil vapor flux samples to identify the nature and extent of contamination. Results of the sampling activities are summarized in the following paragraphs.

Sludge

The Cooper North and South Sumps have a maximum thickness of 17.5 ft and 13.5 ft, respectively, while the Haack Sump varies in thickness from 0.5 to 3 ft to depths up to 14.6 ft bgs. Based on analytical results, attenuation of sludge was typically 1 to 7.5 ft below the bottom of the sludge (Stantec, 2008). The sludge volumes in the sumps are

6,700 cubic yards (cy), 7,000 cy, and 2,250 cy in the Cooper South, Cooper North, and Haack Sumps, respectively (Stantec, 2010c).

The Haack rework area consists of deposited sludge, soil, and debris in discontinuous and mixed layers beneath a soil cover with thickness varying from less than 1 foot to 10 feet. Stantec calculated approximately 650 cy of material is in the Haack Rework Area (Stantec, 2010c).

Constituents identified in the sludge included volatile fuel hydrocarbons (VFHs), total extractable hydrocarbons (TEHs), volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), polynuclear aromatic hydrocarbons (PAHs), Title 22 metals, mercury, and hexavalent chromium.

Surface Water

Surface water samples were collected upstream and downstream of the Site from the Dominguez Channel in 2006 and 2008. Analytical data from surface water samples indicated elevated concentrations of gasoline range organics (GRO) and VOC analytes in contrast to the non-detections for those analytes in groundwater monitored at the Site. Based on the organic chemical parameters, the Site is not impacting surface water quality in the channel.

Soil Gas

The soil gas investigation activities evaluated the subsurface concentrations of VOCs, hydrogen sulfide, and methane at various locations across the Site for use in the baseline human health risk assessment (HHRA). Constituent concentrations reported above the detection limit for targeted VOCs include benzene, toluene, ethylbenzene, m-,p-,o-xylenes, 1,3,5-trimethylbenzene, and Freon 113. Methane and hydrogen sulfide were also detected in samples collected during the 2006 RI activities.

Soil Vapor Flux

Air pathway analysis (APA) was performed on ambient air samples, exposed disturbed and undisturbed sludge on the Cooper property, soil on both the Cooper and Haack properties, and asphalt and concrete slab-covered soil on the Haack property. Results of the APA indicated methane and select VOCs were present in ambient air likely due to industrial activities on the Haack property and sludge on the Cooper property. The undisturbed sludge had low to moderate emissions, while the disturbed condition can be generally characterized as having moderate to high area source emissions. Odor analyses confirmed the potential for sulfuric compounds from disturbed sludge to create nuisance odors to people in the area or downwind of the disturbed sludge. The infiltration analysis in locations above cracks and seams in the asphalt and concrete

indicated that the individual compound emissions are greatly affected by the surface coverings and slab.

Groundwater

The *First Quarter 2010 Groundwater Monitoring Report* identified nine of ten groundwater monitoring wells as having no detectable concentrations of GRO, VOCs, or PAHs above the Reporting Limit (RL). Samples from MW-05A had detections of GRO and VOCs above the RL. SVOCs were reported in wells MW-01A, MW-01B, and MW-02A. Generally, groundwater samples from onsite wells have a pH ranging between 4.5 and 8.0. Metals detected in samples collected from the groundwater wells included barium, arsenic, cobalt, copper, nickel, and zinc.

Perched Groundwater

~~Perched groundwater in the Haack Sump area is suspected to be the result of leaking utilities.~~ (RTC, 9/29/11) Perched groundwater has been detected at several locations beneath the Site. Total metals detected above primary and/or secondary MCLs included: antimony, arsenic, beryllium, cadmium, chromium, copper, nickel, selenium, and zinc. Dissolved metals above primary and/or secondary MCLs included: nickel and zinc. Benzene was detected in a perched groundwater sample below the MCL, and some SVOCs were detected above the detection limit but below the RL.

Treatability Study

A treatability study was conducted by Stantec to define and evaluate the physical and chemical characteristics of the sludge and evaluate neutralization/stabilization options. Acidity, wet density, moisture, viscosity, softening point, and leaching were evaluated on untreated sludge samples. Different reagent mixes were tested with the sludge to evaluate their neutralization/stabilization ability. Thermal treatment and asphaltic recycling were also evaluated during the treatability study.

The treatability study indicated the following:

- The acidity of the sludge ranged from 6.1 to 20.8 percent by weight;
- The densities for the samples ranged from 63 lb/ft^3 to 79 lb/ft^3;
- The average moisture of the sludge ranged from 9.8 to 22.3 percent on a wet basis;
- The sludge is highly viscous, ranging from 1.7×10^6 to 2.5×10^6 centipoises (cP) at a reference temperature of 140ºF;

- The softening point of the sludge varied from 158ºF for samples collected from the Cooper property to over 210 ºF for samples collected from the Haack Rework area;
- A mixture of 50 percent hydrated lime ($Ca(OH)_2$) and 50 percent calcium carbonate fines ($CaCO_3$) with the addition of 10 percent water and 50 percent soil by weight effectively solidifies the sludge, fixates lead, and neutralizes acid gases such as hydrogen sulfide (H_2S) and sulfur dioxide (SO_2);
- Disrupting or heating the sludge will result in the release of H_2S and SO_2 gases, but the release of VOCs from the sludge should be minimal unless the sludge is heated;
- The SPLP extracts for untreated sludge contained detectable lead, but lead was below the detection limits in SPLP extracts for treated sludge;
- The permeability of the untreated sludge was less than $1x10^{-8}$ cm/sec due to the monolithic, asphaltic properties of the untreated sludge, but the permeability of the material increased to $9x10^{-3}$ cm/sec after treatment;
- The sludge has a high BTU value of 13,000 BTUs/lb, but the high sulfur content of the sludge (7 percent sulfur) would make incineration or use of the sludge as a fuel prohibitively expensive due to sulfur-removal and vapor treatment requirements; and
- Testing for asphaltic qualities of the sludge indicates that it will be unsuitable for use as recycled asphalt for road construction or roofing since it has no ductility, high viscosity, and high solids content.

Feasibility Study Process

The Feasibility Study (FS) process is specified by the USEPA. The purpose of the FS process is to provide sufficient information on potential remedial options so that informative treatment decisions can be made. The FS process consists of developing remedial alternatives, screening those alternatives, and then performing a detailed analysis of the most applicable alternatives. The steps to this process include:

- Developing Remedial Action Objectives (RAOs) based on the results of the RI, HHRA, and future site use;
- Identifying and selecting applicable remedial technologies for soil based on effectiveness, implementability, and cost;
- Developing alternatives from the retained remedial technologies that satisfy the RAOs;

- Screening the alternatives and performing a detailed analysis of each of the final alternatives; and
- Performing a comparative analysis of the final alternatives sufficient to provide the information necessary to select an appropriate remedy for the site.

Remedial Action Objectives and Cleanup Criteria

RAOs are goals specific to various media and apply to those media that have been identified as posing an unacceptable risk based on the HHRA work performed for the Site. The RAOs for onsite soils, soil gas, and groundwater are:

- Prevent ingestion/direct contact with sludge and/or soil having 10^{-5} to 10^{-6} excess cancer risk from carcinogenic constituents as represented by arsenic, hexavalent chromium, naphthalene, and the BaP-eq concentration;
- Prevent dermal contact with shallow groundwater having 10^{-5} excess cancer risk from carcinogenic polycyclic aromatic hydrocarbons (PAHs) as represented by dibenz(a,h)anthracene;
- Prevent dermal contact with low pH, PAH containing sludge (RTC, 2/10/12);
- ~~Prevent inhalation of benzene posing excess cancer risk levels of 10^{-5} to 10^{-6}~~ (RTC, 9/29/11);
- Prevent inhalation of volatile organic compounds (VOCs), as represented by benzene, posing excess cancer risk levels of 10^{-5} to 10^{-6} (RTC, 9/29/11); and
- Prevent explosive risks associated with methane. (RTC, 9/29/11)

Applicable Remedial Technologies

Potentially applicable technologies for soil remediation were screened based on effectiveness, implementability, and cost. The remedial technologies determined to be most applicable to the Site are:

- No action;
- Institutional controls;
- Treatment:
  - Stabilization/neutralization
- Containment;
- Excavation and removal for offsite disposal; and
- Engineered controls:
  - Vapor and gas control systems; and

- Groundwater monitoring.

Other technologies identified but eliminated from further consideration are:

- Treatment:
  - Thermal treatment and
  - Sludge recycling

These technologies were eliminated primarily due to their ineffectiveness as identified during the treatability study.

Development of Remedial Alternatives

Four alternatives were developed from the retained remedial technologies:

- Alternative (A) 1 – No action: This consists of no remedial actions or institutional controls to address soils above target cleanup levels;
- ~~A 2 – Capping with selective excavation: This alternative consists of excavating the Haack Rework area and a portion of sludge overflow along the eastern Cooper sump and consolidating the materials above the Cooper North and South Sumps. A cap consisting of a stabilization layer, foundation layer, low-hydraulic conductivity layer, and erosion resistance layer would be constructed above the sumps. A gas control and monitoring system would be installed beneath the cap and around the sumps, and groundwater monitoring would remain ongoing. Institutional controls consisting of a Health and Safety Plan (HASP), Construction Quality Assurance (CQA) Plan, and Risk Management Plan (RMP) would be implemented.~~ (RTC, 9/29/11)
- A 2A – Capping with selective excavation: This alternative consists of excavating the Haack Rework area and disposing of the sludge (RTC, 11/6/12) material offsite. A cap consisting of a high strength geotextile, foundation layer, low-hydraulic conductivity layer, and erosion resistance layer would be constructed above the sumps. A gas control and monitoring system would be installed beneath the cap and around the sumps, and groundwater monitoring would remain ongoing. Institutional controls consisting of a Health and Safety Plan (HASP), land use covenants (LUCs), Construction Quality Assurance (CQA) Plan, and Risk Management Plan (RMP) would be implemented. (RTC, 9/29/11)
- A 3 – Capping with selective excavation and stabilization/neutralization: This alternative includes mixing the top three feet of sludge in the Cooper North and South Sumps with reagent to stabilize/neutralize the sludge. The Haack Rework area and a portion of sludge overflow along the eastern Cooper sump would be

mixed with the stabilized/neutralized material. A cap consisting of a foundation layer, low-hydraulic conductivity layer, and erosion resistance layer would be constructed above the Cooper North and South and Haack Sumps. A gas control and monitoring system would be installed beneath the cap and around the sumps, and groundwater monitoring would remain ongoing. Institutional controls consisting of a Health and Safety Plan (HASP), Construction Quality Assurance (CQA) Plan, and Risk Management Plan (RMP) would be implemented.

- A 4 – Excavation with offsite disposal: This alternative includes excavation of sludge with disposal offsite. The sludge would be mixed with the neutralizing agent and loaded into trucks for disposal offsite. Major components of this alternative include concrete and asphalt removal, excavation and mixing of sludge, transportation to the disposal facility, confirmation sampling, sump backfill, and groundwater monitoring.

Detailed Analysis of Alternatives

The CERCLA guidance document explains the nine criteria that are used to evaluate each remedial alternative [USEPA, 1988]. The first two criteria are categorized as threshold criteria that a selected remedy must meet:

- Overall Protection of Human Health and the Environment; and
- Compliance with ARARs.

The following seven criteria are “balancing” criteria. They represent the primary criteria upon which the detailed analysis is based and that are used to distinguish among alternatives that meet the threshold requirements above:

- Long-term Effectiveness and Permanence;
- Reduction of Toxicity, Mobility, and Volume Through Treatment;
- Short-term Effectiveness;
- Implementability;
- Cost;
- State Acceptance; and
- Community Acceptance.

State and community acceptance are evaluated following public comment on the FS Report.

Overall Protection of Human Health and the Environment

Alternative 1, No Action, does not provide adequate protection of human health and the environment. No further assessment or comparison with this alternative is provided. Alternative ~~2~~ 2A (RTC, 9/29/11) would perform better than Alternative 3. While Alternative 3 stabilizes/neutralizes a portion of the sludge, the mixing of the reagent releases potentially hazardous amounts of hydrogen sulfide and sulfuric acid gas. Alternative 4 would provide very good protection of human health and the environment with the removal of the impacted materials; however, because of the risks associated with hazardous gas generation during excavation and transportation of the material, the overall protection is deemed moderate.

Compliance with ARARs

Alternative ~~2~~ 2A (RTC, 9/29/11) would perform better with respect to ARARs due to the reduction of gas emissions when compared to Alternatives 3 and 4.

Long-term Effectiveness and Permanence

Alternative 3 is ranked higher than ~~2~~ 2A (RTC, 9/29/11) with respect to long-term effectiveness and permanence. Both alternatives would be effective and permanent over the long-term with maintenance; however, because Alternative 3 neutralizes a portion of the sludge, the treatment is likely more permanent. Alternative 4 provides the greatest long-term effectiveness and permanence since the sludge is removed from the site and disposed offsite.

Reduction of Toxicity, Mobility, and Volume Through Treatment

Alternative 3 would slightly reduce toxicity and mobility through partial in-situ treatment of the source zone; however, toxicity would increase as acid gases are released during mixing of the sludge for treatment. Alternatives ~~2~~ 2A (RTC, 9/29/11) and 3 would reduce mobility of the sludge by limiting infiltration and wind erosion. Alternative 4 would reduce the mobility of the sludge after offsite disposal since the disposal landfill would be equipped with a liner system to collect leachate; however, transport of the material would temporarily increase the potential mobility.

Short-term Effectiveness

Alternative ~~2~~ 2A (RTC, 9/29/11) would perform the best with respect to short-term effectiveness. Unlike Alternatives 3 and 4, Alternative ~~2~~ 2A (RTC, 9/29/11) does not significantly disturb the sludge, thereby minimizing the release of acid gas. Both Alternatives ~~2~~ 2A (RTC, 9/29/11) and 3 incorporate a cap into the final design which would provide an immediate reduction in risk due to inhalation, dermal exposure, and

ingestion. Alternative 4 would provide a reduction in risk after the sludge was transported offsite; however, risk is temporarily increased in the short-term during sludge disturbance and transport.

Implementability

Alternatives 3 and 4 pose significant implementation issues due to the gas generation during mixing and excavation of the sludge. Gas control and treatment would be necessary during mixing and excavation of the sludge. Construction of a tent to contain the gases would be difficult to perform due to low bearing capacity of the sludge and the area the tent would need to span (minimum of the Cooper North sump). Gases captured by the tent would need treatment prior to discharge.

Alternative ~~2~~ 2A (RTC, 9/29/11) is relatively easy to implement. A stabilization layer on the Cooper sumps would be placed first to provide a surface in which to install the foundation and gas collection, barrier, and cover layers. Disturbance of the sludge would be limited to the eastern overflow and Haack Rework Area, which are significantly degraded and would release significantly less acid gas than the sludge in the Haack and Cooper Sumps (Appendix A, Stantec, 2008). The materials necessary for construction are available and do not require admixtures or special equipment.

All Alternatives are difficult to implement due to the Site's urban setting, size, and proximity to sensitive receptors; however, the design of Alternative 2A limits the effects of these challenges on construction. The urban setting with high traffic flows will be impacted with the significant truck traffic entering and exiting the site with imported soil and exported waste. Alternative 2A limits the traffic by only exporting Haack Rework material and importing minimal soil for backfill and foundation. The size of the Site is limited due to the extent of the sumps leaving little space available for storage, staging, and construction activities. Alternative 2A is not as affected by the space limitations because neutralization materials will not be required, and as such, storage area for these materials is not required for this Alternative. (RTC, 9/29/11)

Alternatives 3 and 4 pose significant implementation issues due to the gas generation during mixing and excavation of the sludge and the potential impacts to neighboring sensitive receptors. Limiting work to night-time only would not reduce the risks to near-by businesses which operate 24-hours a day. Implementation of Alternative 2A has fewer engineering and health and safety complications since the sludge is not fully disturbed, thus limiting the release of hazardous gas. (RTC, 9/29/11)

While Alternative 2A has implementation challenges due to the Site size and location, the design of the Alternative 2A cap results in the most implementable remedial alternative. (RTC, 9/29/11)

Cost

Alternative ~~2~~ 2A (RTC, 9/29/11) has the lowest capital cost of approximately ~~$5,206,314~~ $5,774,550 ~~with Alternatives 3 and 4 having comparable capital costs of $35,402,274 and $54,067,350, respectively~~. (RTC, 11/6/12) Alternative 3 has a capital cost highly dependent on neutralization admixture costs ranging from $11,144,880 to $12,566,880. Similarly to Alternative 3, Alternative 4 has a cost highly dependent on the admixture price ranging from a low of $26,217,950 to a high of $28,991,650. (RTC, 11/6/12)Alternatives ~~2~~ 2A (RTC, 9/29/11) and 3 have identical net present value O&M costs of approximately ~~$1,563,800~~ $2,822,100.00 (RTC, 11/6/12). Alternative 4 has the lowest net present value O&M cost of approximately ~~$620,500~~ $113,200 (RTC, 11/6/12). Alternative 2A has the lowest combined remedial cost. (RTC, 9/29/11)

State Acceptance

In accordance with USEPA guidance, this criterion will be addressed when DTSC is making its final remedial decision and the ROD is being prepared.

Community Acceptance

In accordance with USEPA guidance, this criterion will be addressed when DTSC is making its final remedial decision and the ROD is being prepared. During the May 10, 2011 meeting between the DTSC and the City, the City expressed concerns regarding the appearance of the former Alternative 2 being similar to a "landfill," and the height of the cap being too high. The City expressed the desire that the final remedial Alternative be consistent with the vision and goal of future development for the Site. (RTC, 9/29/11)

Alternative 2A provides a reduced cap thickness, and accounts for future use as a parking lot subgrade consistent with the City's vision for commercial development. Alternative 3 proposes a cap sloping upward to a maximum elevation of 35 ft amsl, which makes parking lot construction more difficult above the high grades and slopes of the Site. Alternative 4 proposes the Site is excavated and filled. Alternative 4 best incorporates the City's vision for commercial development; however, given the implementation, short-term effectiveness, and cost challenges, Alternative 2A provides the best compromise to meet the City's development vision. (RTC, 9/29/11)

Remedy Selection

~~Based on the comparative analysis of the remedial alternatives, the alternative that meets the RAOs and ranks the highest is Alternative 2,capping with selective excavation. The elements of Alternative 2 are:~~ (RTC, 9/29/11)

- ~~Prepare a construction Health and Safety Plan and Construction Quality Assurance Plan;~~ (RTC, 9/29/11)
- ~~Place a 3.5-foot stabilization layer across the Cooper North and South sumps consisting of gravel, sand, and geocell;~~ (RTC, 9/29/11)
- ~~Excavate the Haack Rework area, segregating the overburden soil from the sludge/soil mixture;~~ (RTC, 9/29/11)
- ~~Install retaining wall (sheet pile) along northern perimeter (Artesia Blvd);~~ (RTC, 9/29/11)
- ~~Place the Haack Rework material and other site soils as the foundation layer above the stabilization layer with horizontal gas collection pipes embedded. The foundation layer would increase in thickness and would be graded such that the final surface would drain at 3 percent to the cap perimeters;~~ (RTC, 9/29/11)
- ~~Install vertical gas migration control wells;~~ (RTC, 9/29/11)
- ~~Install geosynthetic layers consisting of, from bottom to top, a gas collection geocomposite, GCL, 60-mil HDPE geomembrane, and drainage geocomposite;~~ (RTC, 9/29/11)
- ~~Place 2 feet of cover soil above the geosynthetics;~~ (RTC, 9/29/11)
- ~~Install groundwater monitoring wells;~~ (RTC, 9/29/11)
- ~~Operate the below-cap gas collection system and the perimeter vertical gas migration control well system as active systems for a period of at least 2 weeks. Following the start-up period, operate the below-cap gas collection system and vertical gas migration control well system passively. During passive operation, monitor the performance of the proposed alternative remedial measure with a system of perimeter gas migration sentry wells outside the limit of the perimeter vertical gas migration control wells. If the monitoring data indicate significant gas migration from the waste, convert the system to active gas control and, if required, include gas treatment;~~ (RTC, 9/29/11)
- ~~Prepare a Risk Management Plan;~~ (RTC, 9/29/11)
- ~~Perform semi-annual groundwater monitoring; and~~(RTC, 9/29/11)

- ~~Complete a formal review of remediation effectiveness after five years.~~ (RTC, 9/29/11)

~~This remedial alternative effectively mitigates the risk from ingestion, inhalation, and dermal contact with onsite soils for both future non-residential and residential occupants of buildings on site, and future landscapers and utility workers. This alternative also effectively mitigates the risk from dermal contact with site groundwater through the cap and institutional controls including the Health and Safety Plan and Risk Management Plan.~~ (RTC, 9/29/11)

~~Alternative 2 readily meets the criteria of overall protection of human health and the environment and satisfies ARARs. When evaluated against the balancing criteria, Alternative 2 provides short-term effectiveness as well as long-term effectiveness and permanence. It is readily implementable and presents an effective balance of cost against the other criteria. Alternative 2 also would best accommodate future potential redevelopment of the Site.~~ (RTC, 9/29/11)

Based on the comparative analysis of the remedial alternatives, the alternative that meets the RAOs and ranks the highest is Alternative 2A, capping with selective excavation. The elements of Alternative 2A are: (RTC, 9/29/11)

- Prepare a construction HASP and CQA Plan;
- Prepare a Risk Management Plan;
- High-strength geotextile installation;
- Select excavation of impacted material;
- Containment of sludge along Artesia Boulevard;
- Capping of sludge;
- Installation of gas control and monitoring system;
- Institutional controls;
- Perform semi-annual groundwater monitoring; and
- Complete a formal review of cap effectiveness after five years. (RTC, 9/29/11)

This remedial alternative effectively mitigates the risk from ingestion, inhalation, and dermal contact with onsite soils for future non-residential occupants of buildings onsite, and future landscapers and utility workers. This alternative also effectively mitigates the risk from dermal contact with Site groundwater through the cap and institutional controls including the Health and Safety Plan and Risk Management Plan. (RTC, 9/29/11)

Alternative 2A readily meets the criteria of overall protection of human health and the environment and satisfies ARARs. When evaluated against the balancing criteria, Alternative 2A provides short-term effectiveness as well as long-term effectiveness and permanence. It is implementable and presents an effective balance of cost against the other criteria. Alternative 2A could also accommodate future potential redevelopment of the Site as a parking lot to support a commercial operation. (RTC, 9/29/11)

1. INTRODUCTION

1.1 Terms of Reference

This document presents the Revised Final Draft (RTC, 11/6/12) Feasibility Study (Revised Final Draft FS) Report for the Gardena Sumps Site (Site) in Gardena, California. The FS Report is a requirement of Consent Decree CV04-7882-AHM (JTLx), (Consent Decree). The original draft (RTC, 11/6/12) FS Report (Draft FS) was prepared for submittal to the California Environmental Protection Agency (CalEPA), Department of Toxic Substances Control (DTSC) in accordance with the California Health and Safety Code on 11 February 2011. After submittal of the Draft FS, the following timeline of correspondence and revisions occurred:

- A meeting with the DTSC and City of Gardena on 2 May 2011 and receipt of comments from the DTSC 6 June 2011 and 9 June 2011.

- Responses to comments including the Draft Feasibility Study Addendum – Alternative 2A (FS Addendum) were prepared by Geosyntec Consultants, Inc. (Geosyntec) and submitted to the DTSC on 29 September 2011.

- Comments on the FS Addendum were received from the DTSC on 31 October 2011 and 11 November 2011.

- Calculations supporting the preliminary cap design were requested by the DTSC 28 January 2012. The calculations were subsequently transmitted to the DTSC on 1 February 2012.

- A letter in response to DTSC comments received 31 October 2011 and 11 November 2011 was issued by Geosyntec on 7 February 2012.

- Additional DTSC comments on the Addendum and 10 February 2012 response to comments package were received on 7 March 2012 and 30 March 2012.

- A response to comments package was submitted to DTSC by Geosyntec on 4 April 2012 as the Revised Draft Feasibility Study (Revised FS) which included clarification sheets for the Draft FS and FS Addendum.

- Comments were received from the DTSC on the Draft FS, comment responses, and Revised FS on 6 September 2012. (RTC, 11/6/12)

This document represents the Revised Final Draft FS following a recommendation in the 6 September 2012 comment package to revise the documents to form one, comprehensive Feasibility Study. This package addresses the comments and concerns

which were presented in the letters received from DTSC. This draft represents revisions to the original, Draft FS with the changes identified in the following manner:

- Text deleted from the report is ~~struck-out~~ with the corresponding comments package date at the end (RTC, [Date]).
- Text added to the report is underlined with the corresponding comments package date at the end (RTC, [Date]).
- Text removed from a revised text section is ~~struck-out and underlined~~ with the corresponding comments package date at the end (RTC, [Date]).
- Text added to a revised text section is double underlined with the corresponding comments package date at the end (RTC, [Date]).

A summary table of all comments received from the DTSC and their responses is included as Appendix A.

This report was prepared by Ms. Rebecca Flynn, P.E., of Geosyntec and reviewed by Mr. Gregory Corcoran, P.E., both of Geosyntec, in accordance with Geosyntec's peer review policy.

1.2 Description of Feasibility Study Process

The Remedial Investigation (RI) for the Site comprises three separate reports: the *Revised Draft Remedial Investigation Report* (Stantec, 2008); the *Draft Memorandum – Data Gap Analysis* (Stantec, 2010a); *Draft Human Health Risk Assessment* (HHRA) (Geosyntec, 2010); and the *Addendum to the August 22, 2008 Revised Draft 2006 Remedial Investigation Report* (Stantec, 2010c). This FS Report includes the following information and evaluations in general accordance with *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (USEPA, 1988):

- Background information on the Site, including a summary of investigative and remedial work performed to date;
- Future use of the Site, future risk exposure pathways, and receptors that may be at risk;
- Remedial Action Objectives (RAOs) and cleanup criteria;
- Identification of remedial technologies that potentially can be employed to remediate the Site contaminants;
- Screening of the remedial technologies to identify those that can realistically remediate or isolate wastes at the Site;

- Development of a range of potential remedial technologies to address impacted soil, soil gas, and groundwater, and remedial alternatives, which are combinations of remedial technologies that can address impacted media at the Site;
- Screening of the remedial alternatives to identify those that can realistically address conditions at the Site;
- Analysis of remedial alternatives using United States Environmental Protection Agency (USEPA) criteria; and
- Comparative analysis of remedial alternatives that will result in identification of the preferred remedial alternative for the Site.

1.3 Organization

This document is organized into the following sections:

- Section 2 – "Site Background," describes the history and physical characteristics of the Site, including hydrogeology;
- Section 3 – "Remedial Investigation Summary," summarizes the results of the remedial investigation;
- Section 4 – "Remedial Action Objectives and Cleanup Criteria," summarizes the findings of the draft HHRA and identifies the potential future use of the Site, future risk exposure pathways, and potential receptors that may be at risk. The RAOs also are identified, along with cleanup criteria selected to achieve those objectives;
- Section 5 – "Identification and Screening of Technologies," identifies potential remedial technologies. The remedial technologies are then screened based on their effectiveness, implementability, and cost to address human health risks and ecological risks associated with these media;
- Section 6 – "Development of Remedial Alternatives," uses the retained technologies from Section 5 to compile remedial alternatives that address a range of potential response actions and technical approaches for the Site. Remedial alternatives are further screened, evaluated and ranked in terms of effectiveness, implementability, and cost to identify the final set of remedial alternatives for detailed analysis;
- Section 7 – "Detailed Analysis of Alternatives," presents a nine-criteria analysis of the final set of remedial alternatives;
- Section 8 – "Comparative Analysis of Alternatives," uses the nine-criteria analysis results to compare the alternatives to assess which alternative

provides the best balance of the nine criteria, and is, therefore, the recommended alternative; and

- Section 9 – "References," presents the FS Report references.

Tables, figures, and appendices are included at the end of this FS Report.

2. SITE BACKGROUND

2.1 General

This section includes the following background information on the Site:

- Site location and description;
- Site history;
- Geology; and
- Hydrogeology

The information presented in this section generally has been excerpted from the *Revised Draft RI* (Stantec, 2008).

2.2 Site Location and Description

The Site is located in the southwest corner of the Artesia Boulevard and Normandie Avenue intersection in the City of Gardena, Los Angeles County, California (Figure1-1). Generally, the area surrounding Site is bordered to the south by the Los Angeles County Department of Public Works (LACDPW) Dominguez Flood Channel, to the east by the Southern Pacific Railroad right-of-way, to the west by the western Haack property line, and to the north by Artesia Boulevard, although a small portion of Artesia Boulevard is included within the Site. Commercial and residential properties are currently located to the north, east, and west of the Site (Figure 1-2) (Stantec, 2008). For the purpose of this report, the Site is comprised of the Cooper, Haack, and four (4) residential properties as shown on Figure 1-2.

The Site is greater than 5.6 acres of mixed-use development and primarily consists of two properties, the Cooper property and the Haack property. The Cooper property is approximately 3.0 acres, approximately 90 percent of which is comprised of two large sumps (referred to as the "Cooper North" and "Cooper South" sumps) containing primarily petroleum refining wastes. The Haack property is approximately 2.6 acres, contains one modified sump (referred to as the "Haack sump") and the "Haack Rework Area", which is a reworked and mixed sludge/soil area south of the Haack sump. The Haack Rework Area encroaches onto the extreme northern portions of the two easternmost residential lots. In this FS Report, the wastes in the sumps will be referred to as "sludge" for ease of reference. This FS Report will address the three sumps and the Haack Rework Area, constituting the areas of concern (Figure 1-2) (Stantec, 2008).

2.3 Site History

The *Revised Draft RI* documents the site history and presents historic aerial photographs. The following section summarizes the site history and evaluation of the photographs presented by Stantec (Stantec, 2008).

Early topographic maps show that the eastern (Cooper property area) and southern (southern Haack and residential areas) portions of the Site were elevated, which suggests that some amount of clay material could have been extracted from excavations into the elevated bluff.

During the 1920's, the Moneta Brick Company leased the Site. By 1928 the area of the two Cooper sumps had been excavated to a lower surface elevation than the current LACDPW land to the south and most of the Haack and residential properties. The railroad tracks east of the Cooper property were elevated above the land surface of the current Cooper property, and clay mining at the Cooper property had been completed by this time. Clay mining operations were occurring on the northern Haack property in 1928 and 1929. By 1929 the southern portion of the Haack property (present Haack Rework Area) had an elevated scoured slope. This elevated area sloped eastward towards the land surface of the current southern Cooper property. Boring logs from RB-2 and RB-3 indicate that fill material (including brick and concrete debris and glass) extended to elevations of approximately 8 feet above mean sea level (amsl) (depths of 17 to 20 feet below the scoured slope surface) in portions of the Haack Rework Area. An aerial photograph from May 1938 documents that creation of the disposal sumps at the Site had not yet begun. Denys Goddard purchased the land consisting of the current Haack, Cooper, and residential properties in May 1939.

Newspaper reports indicate that sludge disposal had commenced by March 1940. The Haack Sump, Cooper South Sump, and the Haack Rework Area had been constructed and contained sludge by March 1941. The Cooper North Sump had not yet been constructed. By early December 1941 the eastern and northern berms of the Cooper North Sump had been constructed and initiation of sludge disposal into this sump had commenced. Sludge deposition at the Site had occurred at the Haack Sump, the Haack Rework Area, a small pit between these two locations (constructed after March 1941), and the Cooper South Sump by this time.

By September 1946, the Haack and two Cooper sumps were filled with sludge, and vegetation had reclaimed the small pit and the Haack Rework Area. Some excavation of soil had occurred into the bluffs west and south of the western portion of the Haack Sump, but there had been no further development of the Haack and Cooper properties. Denys Goddard sold the future Haack and Cooper property parcels to Wendell and

Golda Hopkins in March 1947, but maintained ownership of the residential lots. The Hopkins' sold their property to S&L Manufacturing in January 1948.

By December 1951, the western portion of the Haack Sump had been covered with dirt and was converted to a parking lot. The eastern portion of the Haack Sump does not appear to have been altered. A significant portion of the bluff south and southwest of the Haack Sump had been excavated. This excavation activity removed the small sludge pit that was located between the Haack Sump and the Haack Rework Area. Two structures had been constructed in the northwestern portion of the Haack property. The Haack Rework Area remained vegetated and the two easternmost residential lots (on the Goddard property) had structures on them.

On October 1, 1952, S&L Manufacturing sold the northern-most strip of their property to the State of California for a highway easement. By early 1956, Artesia Blvd (Highway 91) had been constructed with the southern portion of the roadway encroaching into the Haack Sump northern berm.

By January 1958, the Dominguez Channel had been reconstructed and extended eastward south of the Site. A third structure (the "administrative building") had been constructed on the Haack property at the southern edge of the parking lot. The Cooper property had not significantly changed since 1951. The two westernmost residential lots had structures on them by this time. In May 1958, S&L Manufacturing sold the current Haack and Cooper properties to Charles Warfel. Warfel then sold the current Cooper property to William Ward in January 1959 and the Haack property to Clarence and Genevieve Haack in May 1960. In late 1960, the City of Gardena annexed the area of the Site from the County of Los Angeles.

By November 1962 significant changes had occurred at the Haack property. The bluff immediately south of the "administrative building" had been excavated back to the present day cut-bank (located west of boring HPB11). This excavation expanded the parking lot south of the "administrative building." The parking lot on the Haack property appeared to have been paved, although the eastern portion of the Haack property remains a vegetated area immediately west of the Cooper North Sump. The Haack Rework Area appeared altered and may have received soil cover from the excavation activities that occurred immediately north of the Haack Rework Area. The future Cooper property was unchanged. William Ward sold his property to Thomas Cooper in December 1977.

The two Cooper sumps currently are capped by a geosynthetic material that was installed by OHM Corporation (OHM) in July 1993 as part of the DTSC's environmental program at the Site. The Haack Sump has been covered by asphalt and a concrete slab. Currently the Haack property is leased to various tenants who operate

small businesses, including a U-Haul rental agency, a metal fabricating, sand blasting and painting company, and an auto body repair shop. Three buildings and numerous small trailer-type storage structures are present on the Haack property.

2.4 Geology

The following discussion is based on California Department of Water Resources (CalDWR) Bulletin No. 104, Planned Utilization of the Ground-water Basins of the Coastal Plain of Los Angeles County, Appendix A — Ground Water Geology, dated June 1961, reprinted April 1988 (CalDWR, 1961) and discussions contained in reports from previous investigations (CalEPA 1994, URS 1994, and Stantec, 2008).

The Site is located in the Los Angeles Coastal Plain and is underlain by a thick sequence of marine and continental sediments that were deposited in a ~~board~~ broad (RTC, 9/29/11) synclinal depression. This depression is generally referred to as the Los Angeles Basin. The Los Angeles Basin is bisected by the northwest trending Newport-Inglewood uplift, which divides the Coastal Plain into two smaller synclinal troughs. The Site is located in the West Coast Basin, which constitutes the southwest portion of the Los Angeles Basin.

The Site is located near the junction of the Torrance Plain and the Dominguez Erosion Gap. The Torrance Plain runs west of and parallel to the hills of the Newport-Inglewood uplift from the Ballona Gap southeast to the Dominguez Gap. The Plain is a broad featureless area only slightly dissected locally by the Dominguez Creek (Dominguez Channel).

According to boring logs in the Ecology and Environmental, Inc. (EEI) (1986), Metcalf and Eddy (1992), CalEPA (1994) and URS (1994) reports, sediments underlying the Site, to the maximum explored depth of 92 feet below ground surface (bgs), consist primarily of a mixture of clays and silts with interbeds of sand. Copies of the available boring logs from these previous studies are provided in Appendix F and summarized in Table 13 of the *Revised Draft RI* (Stantec, 2008). This stratigraphy correlates in general with the observed conditions in borings completed in conjunction with the *Revised Draft RI* (Stantec 2008), which reached a maximum depth of 100 feet bgs.

2.5 Hydrogeology

The following discussion is based on CalDWR *Bulletin No. 104, Planned Utilization of the Ground-water Basins of the Coastal Plain of Los Angeles County, Appendix A - Ground Water Geology*, dated June 1961, reprinted April 1988 (CalDWR, 1961) and discussions contained in reports from previous investigations (CalEPA 1994, URS 1994, Stantec, 2008).

The Site is located in what is known as the West Coast Groundwater Basin. The West Coast Groundwater Basin has existing beneficial uses for municipal and domestic supply wells, agricultural supply, industrial process supply, industrial service supply, and aquaculture (LARWQCB, 1994). (RTC, 9/29/11) This basin is hydraulically isolated from other, larger groundwater basins in the Coastal Plain by the regional Newport-Inglewood Fault. The Site is underlain by Holocene and late-Pleistocene Age alluvial and marine deposits, which include the Bellflower Aquiclude at the ground surface, and the Gardena and/or Gage Aquifers of the Lakewood Formation beneath the aquiclude. Major underlying aquifers (beneath the Lakewood Formation) are the Lynwood and the Silverado Aquifers of the San Pedro Formation.

The uppermost defined unit within the basin, and the unit that the Site is located within, is the Bellflower Aquiclude. Regionally, the Bellflower Aquiclude contains interfingered zones of permeable and less permeable sediments. The zones with modest to relatively high hydraulic conductivity consist of fine to coarse sand with gravel and silty sand. These coarser grained sediments vary in thickness from 10 to 60 feet and are not laterally continuous. However, in some areas, these permeable zones can contain significant amounts of water. Little beneficial use is made of water in these shallow, discontinuous hydraulic zones because well yields tend to be low and water quality generally poor (CalDWR, 1961).

The Gardena/Gage, Silverado, and Lynwood Aquifers are all capable of storing or conveying groundwater in significant quantities and constitute major sources of groundwater in the West Coast Groundwater Basin. The Lynwood and Silverado Aquifers are primary sources for domestic water supply, while the Gardena and Gage Aquifers are a secondary domestic water supply source. Neither the Gardena nor Gage Aquifers are currently pumped for domestic use. The intervening finer-grained aquitards have not been named. These aquitards, including those that separate the Gardena and Gage Aquifers from the Lynwood Aquifer and the Lynwood Aquifer from the Silverado Aquifer, are discontinuous in nature and absent in some areas.

Immediately beneath the Site, there are two hydraulic groundwater zones within the Bellflower Aquiclude: Zone A (upper) and Zone B (lower), which are approximately 15 to 25 and 75 to 80 ft bgs, respectively. Site groundwater monitoring wells are screened within these two zones. General groundwater chemistry analyses were performed at the Site to evaluate if a hydraulic interconnection exists between Zone A and Zone B due to the existence of a downward vertical gradient between the two zones. The groundwater chemistry analysis indicated that the two zones are characterized by different groundwater geochemistry. The concrete lined Dominguez Channel influences the flow direction of the shallow Zone A groundwater southward while the deeper Zone B groundwater has a flow direction to the east – southeast. Groundwater monitoring at the

Site over the past seven years indicates that COCs are not migrating vertically or laterally over any significant distance from the locations of the waste material. (RTC, 1/9/2013)

The area surrounding the Site is urbanized, with surface waters that drain via storm drains into the Dominguez Channel. The Dominguez Channel is a concrete-lined flood-control structure immediately south of the Site. The upstream portion of the modern day Dominguez Channel originates several miles west-northwest of the Site, and it drains surface water to the southeast where it discharges to the Cerritos Channel of the Los Angeles Harbor. Surface water at the Site generally drains towards the north and east following site topography, and is intercepted by a flood control storm drain located at the northeast corner of the Site adjacent to the intersection of Artesia Boulevard and Normandie Avenue.

Historically, the Dominguez Channel flowed along a natural channel bed located approximately several hundred feet west and north of the Site where it flowed eastward into Laguna Dominguez. Presently the shallow groundwater beneath the Site is influenced by the concrete lined Dominguez Channel and flows southward.

3. REMEDIAL INVESTIGATION SUMMARY

3.1 General

The nature and extent of hydrocarbon and metal impacts at and surrounding the Site have been evaluated through several investigation programs conducted since 1982. Sludge, soil, surface water, groundwater, and soil vapor have been investigated. The following sections provide a summary of findings for each of these media. Details of the investigations and findings can be found in the *Revised Draft RI* (Stantec, 2008) and the *Addendum to the Revised Draft RI* (Stantec, 2010c).

3.2 Nature and Extent of Contamination

3.2.1 Soil/Sludge

As part of the RI investigation, Stantec collected over 300 subsurface soil and sludge samples from beneath and surrounding the sumps and rework area to delineate the vertical and horizontal extents of continuous (nonreworked) sludge and sludge-induced impacts to the adjacent soil (Figure 3-1). The samples were analyzed for organic and inorganic constituents. In addition, pH was measured to determine the effects of the sludge on the soil pH near the sumps and adjacent berms. Organic constituents analyzed were: volatile fuel hydrocarbons (VFHs), total extractable hydrocarbons (TEHs), volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), and polynuclear aromatic hydrocarbons (PAHs). Inorganic constituents analyzed were: Title 22 metals, mercury, and hexavalent chromium.

Sludge constituents are as follows (Stantec, 2008):

- **VFH and TEH**: Heavier hydrocarbon compounds predominate in the sludge.
- **VOCs**: Most commonly detected include ethylbenzene, p-isopropyltoluene, naphthalene, toluene, 1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, and m-, o-, p-xylene compounds.
- **Non-PAH SVOCs**: Not typically detected in sludge samples due to the dilution factor necessary to analyze the sludge samples.
- **PAHs**: The most predominant PAH compounds include benzo(a)-pyrene, benzo(b)-fluoranthene, chrysene, fluoranthene, phenanthrene, and pyrene.
- **Title 22 Metals**: Background, offsite soil, onsite non-reworked soil, and sludge samples were collected during the RI. Antimony, barium, cadmium, vanadium, and zinc were all reportedly lower in the sludge when compared with background soil, while lead and molybdenum were higher in the sludge when compared to background soil. Arsenic and thallium concentrations were

similar in the sludge and background soil while copper had a wider range (higher and lower) of concentrations in sludge compared to background soil. During the 2006 RI field investigation, arsenic was detected in background soil on the LADPW property at 82 milligrams per kilogram (mg/kg). Sampling was performed during the subsequent 2009 RI field investigation at this location and immediate vicinity and resulted in arsenic concentrations of less than 5.5 mg/kg; therefore, the 82 mg/kg concentration could not be confirmed (Stantec, 2010a). Isolated areas on the Haack property had significantly higher concentrations of antimony, arsenic, chromium, copper, molybdenum, nickel, and zinc than typically found at the Site (Stantec, 2010c).

- **Chromium VI**: Analytical results for hexavalent chromium and total chromium in sludge ranged from <0.026 to 0.73 mg/kg and 0.55 to 4.7mg/kg, respectively. Analytical results for hexavalent chromium and total chromium in background soil ranged from <0.026 to 1.3 mg/kg and 6.0 to 28 mg/kg, respectively. One background 2006 soil sample was suspect for hexavalent chromium, having hexavalent chromium and total chromium values of 100 mg/kg and 33 mg/kg respectively (Stantec, 2008; Geosyntec, 2010). Subsequent resampling of this location resulted in hexavalent chromium and total chromium values of <1.0 mg/kg and 17 mg/kg respectively; therefore, the 2006 hexavalent chromium test result of 100 mg/kg is suspect (Geosyntec, 2010).
- **pH**: ~~The pH of the sludge samples averaged 2.22~~ <u>The pH of the sludge samples ranged from 0.39 to 9.05</u> (RTC, 9/29/11) while pH of the background soil averaged 6.57 (Stantec, 2008). The 2009 RI activities included an assessment of pH in soil adjacent to the sludge. Results of testing indicate pH ranges from 5.2 to 10.3 in soil adjacent to the sludge (Stantec, 2010a).

During the RI, four areas of sludge disposal were investigated: the Cooper South Sump, the Cooper North Sump, the Haack Sump, and the Haack Rework Area. The delineation of nonreworked sludge is shown on Figure 1-2 and illustrates the lateral extent of congruent sludge having any thickness. Below is a summary of the results of the delineation (Stantec, 2008):

- **Cooper South Sump**: The Cooper South Sump has an identified maximum thickness of 13.5 feet. Figure 10A of the *Revised Draft RI* (Stantec, 2008) illustrates the general vertical profile of this sump. Vertical attenuation of sludge impacts in soil typically ranged from 1.5 to 3 feet beneath the sludge; lateral impacts of sludge in soil is negligible. Approximately 6,700 cubic yards (CY) of sludge was calculated by Stantec to be in the Cooper South Sump (Stantec, 2010c). Approximately 8,000 CY of sludge containing soil

interbeds was calculated by Stantec to be in the Cooper South Sump (Stantec, 2008).

- **Cooper North Sump**: The Cooper North Sump has an identified maximum thickness of 17.5 feet. Figure 10A of the *Revised Draft RI* (Stantec, 2008) illustrates the general vertical profile of this sump. Vertical attenuation of sludge impacts in soil typically ranged from 5 to 7.5 feet beneath the sludge, with the exception of one boring where chrysene was detected up to 11 feet beneath the sludge. Some TEH and PAH constituents were detected approximately 6 feet laterally from this sump in depths up to 15 feet bgs indicating some lateral migration in soil to the north; however, other borings indicated lateral impacts of sludge in soil is negligible. Stantec calculated approximately 7,000 CY of sludge is in the Cooper North Sump (Stantec, 2010c). Approximately 9,300 CY of sludge containing soil interbeds was calculated by Stantec to be in the Cooper North Sump (Stantec, 2008).
- **Haack Sump**: The Haack sump consists of several discontinuous layers of sludge varying in thickness from 0.5 to 3.0 feet to a depth up to 14.6 feet bgs. Boring logs indicated the western and central areas of the sump had been reworked, possibly during site development in the late 1940's. Figure 10B of the *Revised Draft RI* (Stantec 2008) illustrates the general vertical profile of this sump. Stantec calculated approximately 2,250 CY of sludge is in the Haack Sump (Stantec, 2010c). Approximately 2,900 CY of sludge containing soil interbeds was calculated by Stantec to be in the Haack Sump (Stantec, 2008).
- **Haack Rework Area**: The Haack rework area consists of deposited sludge, soil, and debris in discontinuous and mixed layers beneath a soil cover with thickness varying from less than 1 foot to 10 feet. The thickness of sludge in the western portion of the Haack Rework Area is thinner and occurs at a higher elevation than at the eastern edge of the Haack Rework Area. Figures 10E and 10F of the *Revised Draft RI* (Stantec, 2008) illustrate the general vertical profile of this area. Stantec calculated approximately 650 CY of material is in the Haack Rework Area (Stantec, 2010c). Approximately 1,200 CY of sludge containing soil interbeds was calculated by Stantec to be in Haack Rework Area (Stantec, 2008).

Delineation borings were conducted at several specific areas of the Site. The results of the sampling are provided in the *Revised Draft RI* (Stantec, 2008) and summarized below:

- **Eastern LACDPW Easement**: Borings were performed to determine if sludge had migrated offsite onto the LACDPW property east of the Cooper property. The 2006 delineation borings encountered sludge within 6 inches

bgs in all five delineation borings (Stantec, 2008). Subsequent delineation borings were performed in 2009 east of the 2006 delineation borings which delineated the extent of the continuous sludge shown on Figure 1-2 (borings DPW116 through DPW121 and GWP102) (Stantec, 2010a).

- **East-Central Haack Property (Former Drum Storage Area)**: Sampling of the former drum storage area on the Haack property was performed in 2006 to determine if metal concentrations in soil were elevated when compared to background soil concentrations. Elevated lead concentrations were detected at a depth of 1.5 feet in all four borings, but lead concentrations were in the range of background at a depth of 5 feet. Elevated concentrations of antimony, arsenic, copper, and molybdenum were detected in one boring at a depth of 1.5 feet. One hexavalent chromium concentration above background was detected at 5 feet bgs.
- **Sludge Surface Samples**: Sludge surface samples were collected to determine if analytical interference resulted in high arsenic, antimony, and thallium concentrations during the 1982 investigation. With the exception of the low level of antimony detected in one boring, antimony, arsenic, and thallium were not detected in the samples; therefore, it suggests the 1982 data is not valid.
- **Sump Perimeter**: Borings were performed around the perimeters of the sumps to assess the lateral extent of continuous sludge during both the 2006 and 2009 RI activities. Continuous sludge is a sludge-only deposit and excludes soil mixed with sludge. The results of the step-out borings indicate the extent of the continuous sludge, which is illustrated on Figure 1-2.
- **Offsite Adjacent Residential Properties**: Borings were advanced in the residential properties in the southern portion of the site during the 2006 and 2009 RI activities to investigate the presence of sludge. The results of these borings indicate that the extent of the sludge has been delineated as illustrated on Figure 1-2.

3.2.2 Surface Water

Surface water samples were collected upstream and downstream of the Site from the Dominguez Channel in 2006 and 2008. During both sampling events, the samples had gasoline range organics (GRO) concentrations of 58 µg/L and 50 µg/L in 2006 and 2008, respectively. No SVOCs were observed. Two VOCs, tetrachlorothene and trichloroethene, were observed during both events; upstream samples had higher concentrations of both VOCs than the downstream samples. Barium was found in surface water at concentrations approximately double what was detected in the soil and

sludge samples. Copper, lead, and vanadium were detected at levels below background for the Site (Stantec, 2008).

Analytical data from surface water samples collected from the inner channel of the Dominguez Channel indicated elevated concentrations of GRO and VOC analytes in contrast to the non-detections for those analytes in groundwater monitored at the Site. Based on the organic chemical parameters, the Site is not impacting surface water quality in the channel. Overall, the observed concentrations of metals in surface water adjacent to the Site support the same conclusion, that the Site groundwater conditions are not impacting surface water quality. Both upstream and downstream surface water samples have at least twice the concentration of antimony, molybdenum, nickel, barium, lead, and copper compared to shallow groundwater at the southern boundary of the Site (Stantec, 2010b).

3.2.3 Soil Gas

The soil gas investigation activities evaluated the subsurface concentrations of VOCs, hydrogen sulfide, and methane at various locations across the Site for use in the baseline HHRA. Soil gas samples were collected in the locations indicated on Figure 3-2. Constituent concentrations reported above the detection limit for targeted VOCs include benzene, toluene, ethylbenzene, m-,p-,o-xylenes, 1,3,5-trimethylbenzene, and Freon 113. Concentrations ranged from non-detect to 2.2 µg/L-vapor (toluene) (Stantec, 2008).

During the 2006 RI activities, benzene concentrations in the soil gas samples ranged from non-detect to 0.3 µg/L-vapor by Method 8260B and from non-detect to 0.260 µg/L-vapor by Method TO-15. Hydrogen sulfide concentrations in the soil vapor samples ranged from non-detect to 5.1 parts per million by volume (ppmv) except for one sample location with results of greater than 50 ppmv. Methane concentrations in the soil gas samples ranged from non-detect to 220 ppmv (Stantec, 2008).

During the 2009 RI activities, additional samples were collected from 22 semi-permanent direct-push soil gas probes. Samples collected near the Haack administrative building showed no VOCs greater than California Human Health Screening Levels (CHHSLs). On the residential properties, benzene from the sample collected from the former corral was the only constituent reported higher than the specific constituent CHHSL value. The results elsewhere at the Site during the 2009 RI activities generally confirmed the results of the 2006 RI (Stantec, 2010a).

3.2.4 Soil Vapor Flux

An Air Pathway Analysis (APA) was performed during the 2006 investigation to evaluate the exposure pathway of outdoor inhalation of vapors. The surfaces evaluated included:

- exposed, undisturbed sludge on the Cooper property;
- exposed, disturbed sludge on the Cooper property;
- soil on both the Cooper and Haack properties; and
- asphalt and concrete-slab covered soil on the Haack property.

The results of the APA are provided in the *Revised Draft RI* (Stantec, 2008) and are summarized below:

- **Ambient Air**: Methane and select VOCs were reported above the quality control (QC) criteria and/or reporting limit in the four ambient air samples collected. Detected methane levels are typical of global, outdoor, ambient air. Detections of VOCs on the Haack property are most likely related to industrial activities on the property and not from undisturbed surface emissions from the nearby sumps. The VOCs detected on the Cooper property may be related to the presence of sludge in the sumps.
- **Undisturbed**: Twenty (20) open (undisturbed) soil flux samples of 61 collected were reported to have specific compounds above the QC criteria and/or reporting limit. The undisturbed sludge had low to moderate emissions and, in general, more compounds were detected at Cooper property locations than Haack property locations. Higher emissions and more detectable compounds were detected at Cooper Sump locations overlying sludge.
- **Disturbed**: All nine (9) disturbed flux samples collected were reported to have specific compounds above the QC criteria and/or reporting limit. The disturbed condition can be generally characterized as having moderate to high area source emissions as compared to the undisturbed sludge condition. In addition, more compounds were detected in the emissions from the disturbed sludge condition than from the undisturbed sludge condition. Odor analyses confirmed the potential for sulfuric compounds from disturbed sludge to create nuisance odors to people in the area or downwind of the disturbed sludge.
- **Infiltration**: Specific compounds were detected above the QC criteria and/or reporting limit for each of the infiltration flux samples. The flux chamber was used to test the air emissions through seams and cracks in the concrete and asphalt. Compounds having the maximum detections represent a different mixture of sulfur and hydrocarbon compounds as detected in the undisturbed

sludge condition, indicating that the individual compound emissions are greatly affected by the surface coverings and slab.

3.2.5 Groundwater

3.2.5.1 Summary of Groundwater Monitoring

Well clusters MW-01A/B, MW-02A/B, and MW-03A/B were periodically sampled from 1994 through 2002. Analytical results of these samples supported the findings of earlier investigators, with trace amounts of volatile organic compounds (VOCs) detected in 1994 samples immediately after installation, and no VOC detections in the next ten years of sampling. Detections in 1994 were likely the result of cross-contamination during well installation (Stantec, 2008).

Groundwater samples obtained on February 28, 2002, contained detectable concentrations of antimony, lead, and thallium that were above the maximum concentration level (MCL), as defined in Title 22 CCR §64431. With a very few exceptions, prior to the 2002 sampling event, analytes tested in groundwater samples were either not detected or found below the laboratory reporting limit. Quarterly groundwater monitoring and sampling of MW-01A/B, MW-02A/B, MW-03A/B, and G-4 was agreed to as part of a Consent Decree entered into between DTSC and Atlantic Richfield Company, which became effective November 4, 2004 (§VIIC, paragraph 2, lines 2-3). Wells MW-4A, MW-4B and MW-5A have been installed during Atlantic Richfield Company's RI investigation of the Site.

The following summary is abstracted from the *First Quarter 2010 Groundwater Monitoring Report* (Stantec, 2010b):

The depth to Site groundwater in the A-zone ranges between 10.5 and 18 feet below the ground surface. The groundwater in the A-zone flows southward with an approximate velocity of 0.04 feet per day. The depth to Site groundwater in the B-zone ranges between 15.5 and 22 feet below the ground surface. The groundwater in the B-zone flows east-southeast with an approximate velocity of 0.18 feet per day. (RTC, 1/9/2013)

Nine of the ten groundwater monitoring wells showed no detectable concentrations of GRO, VOCs, or PAHs above the RL during the first quarter 2010 sampling event. Samples from the recently installed MW-05A well indicated a GRO detection of 390 µg/L. VOCs detected above the reporting limit in well MW-05A included benzene (0.73 µg/L), naphthalene (3.4 µg/L), m-,p-xylenes (1.5 µg/L), 1,2,4-trimethylbenzene (2.8 µg/L), and 1,3,5-trimethylbenzene (23 µg/L). Total xylene levels in MW-05A were 1.7 µg/L.

Wells with SVOCs detected included well MW-01A with acenaphthylene (5.6 µg/L), bis(2-ethylhexyl)phthalate (3.2 J[1] µg/L; detected below the reporting limit), and naphthalene (3.2 J µg/L; detected below the reporting limit); MW-01B had bis(2-ethylhexyl)phthalate (3.9 µg/L); MW-02A had acenaphthylene (2.1 µg/L), bis(2-ethylhexyl)phthalate (10 µg/L), 2-methylphenol 2.3 µg/L, naphthalene (2.6 µg/L), and phenol (1.2 µg/L); and MW-02B had acenaphthylene (0.75 µg/L).

The groundwater pH levels have remained relatively constant since project sampling began in the first quarter of 2006. The anomalously high pH levels reported during the 1994 and 2002 sampling events have not been observed recently. Generally, groundwater samples from onsite wells (with the exception of MW-5A) have a pH ranging between 6.0 and 8.0. Recently installed well MW-05A has had groundwater pH readings ranging from 4.5 to 5.8.

For each groundwater sampling event since the year 2000, both dissolved (starting in 2006) and non-dissolved phase barium have been detected above the RL in all wells. The highest concentration of barium continues to be detected up-gradient and off site in well MW-01B.

During the second quarter 2010 sampling event, reportable trace amounts of arsenic were detected in both non-dissolved phase (total metals) in wells MW-01A, MW-02A, MW-02B, MW-03A, MW-05A, and G-4 and in the dissolved phase in wells MW-02A, MW-02B, MW-03A, and MW-05A. Well MW-04B showed the highest levels of arsenic in both dissolved and non-dissolved phases (4.4 and 4.4 µg/L, respectively).

Well MW-05A had elevated non-dissolved levels of cobalt (140 µg/L), copper (62 µg/L), nickel (190 µg/L), and zinc (3,800 µg/L) (total metals), and elevated dissolved levels of cobalt (190 µg/L), copper (74 µg/L), nickel (240 µg/L), and zinc (4,400 µg/L) compared to the other site monitoring wells.

3.2.5.2 Summary of Hydropunch Sampling

During the 2009 RI activities, additional groundwater assessment was performed using hydropunch sampling. Groundwater samples were collected in the A and B horizons, respectively to test for VOCs, SVOCs, PAHs, metals, and pH. No VOCs, SVOCs, or PAHs were detected above MCLs. Dissolved metal concentrations of beryllium, cadmium, and nickel were reported in one sample (GWP-100) from the A horizon. pH ranged from 6.74 to 7.44 in the A horizon with the exception of a 4.74 pH value from GWP-100. pH was not measured in the B horizon (Stantec, 2010a).

[1] J = Analyte was detected between the method detection limit and reporting limit; reported value is estimated.

3.2.6 Perched Groundwater

Ten temporary groundwater wells were installed during the 2009 RI activities to investigate suspected perched groundwater. The results of the investigation are discussed in the *Data Gaps Memorandum* (Stantec, 2010a). In summary, benzene was detected at 1.6 µg/L, and some SVOCs were detected above the detection limit but below the reporting limit (J-flag). Lab pH ranged from 3.82 to 6.93, and PAHs were not detected in concentrations greater than 5 µg/L. Total metals above primary and/or secondary MCLs included: antimony, arsenic, beryllium, cadmium, chromium, copper, nickel, selenium, and zinc. Dissolved metals above primary and/or secondary MCLs included: nickel and zinc. ~~Perched groundwater in the Haack Sump area is suspected to be the result of leaking utilities.~~ (RTC, 9/29/11)

3.3 Fate and Transport

Based on the results from previous investigations and the extensive field work performed as part of the *Revised Draft RI* (Stantec, 2008), the current Conceptual Site Model (CSM) suggests that:

- The undisturbed sludge at the Site does not pose a threat to surface water and does not pose a threat to shallow (A-horizon) or deeper (B-horizon) groundwater quality throughout much of the Site. Shallow groundwater is impacted (lower pH, total & dissolved metals) south of the Haack sump; however, these impacts are not detected in samples collected downgradient of the sumps. (RTC, 1/9/2013)
- The undisturbed sludge at the Site does not pose a substantive threat to the air quality in the immediate vicinity of the Site. However, isolation of the sludge from temperature fluctuations above approximately 100 degrees would further minimize this potential impact; and
- The undisturbed sludge does not pose a threat to further contamination of soil surrounding the sludge by leaching of constituents of potential concern (COPCs) from the sludge (Stantec, 2008).

The transport mechanisms identified during the HHRA are discussed further in Section 4.2 but in summary are: wind erosion and dust, volatilization to indoor and ambient air, and leaching to groundwater.

3.4 Treatability Studies Conducted

3.4.1 General

A treatability study was conducted by Stantec to define and evaluate the physical and chemical characteristics of the sludge and evaluate neutralization/stabilization options. The following sections summarize the results of the treatability study found in Appendix J of the *Revised Draft RI* (Stantec, 2008) and included as Appendix B of this Revised Final Draft FS.

3.4.2 Acidity

The testing showed that the acidity of the sludge ranged from 6.1 to 20.8 percent by weight. The Cooper South Sump had the highest acidity, with an average value of 19 percent by weight (Stantec, 2008).

3.4.3 Wet Density

Wet densities of the sludge samples were determined from samples collected using a Fann Model 140 mud balance. The densities for the samples ranged from 63 lb/ft^3 to 79 lb/ft^3. The average density of the sludge collected from the Cooper North Sump was 65.7 lb/ft^3, and the average density of the sludge from the Cooper South Sump was denser at 72.8 lb/ft^3. The sludge collected in the Haack Rework Area had an average density of 74.9 lb/ft^3 (Stantec, 2008).

3.4.4 Moisture

The average moisture of the sludge ranged from 9.8 to 22.3 percent on a wet basis. The moisture of the soil below the sludge sumps ranged from 12.1 to 25.6 percent on a wet basis. The soil below the Cooper North Sump was noted to have higher moisture content (24.2 percent) when compared to the soil below the Haack Rework Area, which averaged 14 and 16.9 percent moisture, respectively (Stantec, 2008).

3.4.5 Viscosity

The viscosities of sludge samples were tested at different temperatures to determine material viscosity as a function of temperature. This data was plotted as semi-log graphs to generate trend lines for modeling the viscosity as a function of temperature in accordance with ASTM Method D 2493. The sludge is highly viscous, ranging from 1.7×10^6 to 2.5×10^6 centipoises (cP) at a reference temperature of 140ºF. The results of the testing show that the sludge in the Cooper North Sump had a slightly lower viscosity than the sludge in the Cooper South Sump. The sludge in the Cooper North Sump had an average viscosity of 1.7×10^6 cP at 140ºF while the viscosity of sludge in

the Cooper South Sump averaged 2.5 $\times 10^6$ cP at 140ºF. Sludge collected from the Haack property in the Haack Rework Area was heated to 220ºF, but it was still too viscous to test for viscosity, thus indicating the sludge may contain other solids from disruption during development activities in that area (Stantec, 2008).

3.4.6 Softening Point

The softening point of the sludge was evaluated by the softening point test defined in ASTM Method D36. The results of the testing show that the softening point of the sludge samples from the Cooper property ranged from 158ºF to 185ºF. The sludge in the Cooper North Sump had a slightly lower softening point than the sludge in the Cooper South Sump. The sludge in the Cooper North Sump had an average softening point of 159ºF while the average softening point for the sludge in the Cooper South Sump was 180ºF. The softening point of the sludge collected in the Haack Rework Area was greater than 210ºF (Stantec, 2008).

3.4.7 Neutralization and Stabilization Testing

Five different reagent mixes were tested with the sludge to evaluate their neutralization/stabilization ability. The five mixes included: calcium oxide (CaO), 50/50 (w/w) mix of CaO and calcium carbonate ($CaCO_3$), calcium hydroxide ($Ca(OH)_2$), a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$, and Portland cement (Stantec, 2008).

Testing indicated that the sludge can be neutralized by treatment using 25 percent treatment reagent addition by weight where the treatment reagent is comprised of 50 percent hydrated lime ($Ca(OH)_2$) and 50 percent $CaCO_3$ fines. Approximately 10 percent water addition was also required to help activate the lime and carbonate reactions. The addition of 50 percent soil by weight during this mixing will also effectively solidify the waste so it is no longer susceptible to viscoelastic deformation. This treatment also effectively fixates lead, as demonstrated through long-term leaching tests, and neutralizes acid gases such as hydrogen sulfide (H_2S) and sulfur dioxide (SO_2) (Stantec, 2008).

3.4.8 Vapor Evolution

Stantec also evaluated the potential rates of off-gas evolution during full-scale mixing operations as a function of temperature. Headspace analyses were performed on the sludge samples at temperatures of 60ºF, 100ºF, 140ºF, 180ºF, and 212ºF (Stantec, 2008).

3.4.8.1 VOC and TPH Headspace Results

The analyses indicated no benzene was emitted from the sludge samples at temperatures ranging from 60 to 212ºF. Toluene was not detected at 60ºF; however, detected concentrations increased as temperature increased. Similarly, ethylbenzene and xylenes were near detection limits at 60ºF, and detected concentrations increased as temperatures increased. Detected concentrations of toluene, ethylbenzene, and xylenes did not exceed the Occupational Safety and Health Administration (OSHA) permissible exposure limits (PELs) (Stantec, 2008).

Total petroleum hydrocarbons (TPH) was monitored in the vapor headspace as a function of temperature, where TPH represents the total concentration of VOCs detected for GRO and diesel range organics (DRO). Initial concentrations of TPH in the vapor headspace were below 12.5 ppmv in the Cooper North and Cooper South Sump samples at 60ºF. However, TPH concentrations increased exponentially with increasing temperature. At 212ºF, the concentrations of TPH in the vapor headspace of samples from the Cooper North and Cooper South Sump were 259 ppmv and 223 ppmv, respectively. These data indicate that TPH (as petroleum distillates) will not present a health and safety issue with respect to construction work since the concentrations are less than the OSHA PEL of 500 ppmv for petroleum distillates (Stantec, 2008).

Samples collected from the Haack Rework Area did not have detectable concentrations of benzene, toluene, ethylbenzene, and xylenes (BTEX) and TPH, with the exception of toluene and xylenes. These compounds were only detected when temperatures were increased to 212ºF. TPH was below detection limits at 60ºF, and detected concentrations rose to a maximum at 212ºF (Stantec, 2008).

3.4.8.2 H_2S and SO_2 Headspace Results

H_2S and SO_2 were monitored in the headspace of sludge samples at various temperatures. The results showed that these sulfurous gases were readily emitted from disturbed and heated sludge samples in the Cooper North and Cooper South Sumps. The vapor concentrations of SO_2 in equilibrium with sludge samples from both sumps exceeded 150 ppmv at 60ºF. The vapor concentration of H_2S was 408 ppmv for the Cooper North Sump and 471 ppmv for the Cooper South Sump at 60ºF, but at higher temperatures it exceeded 500 ppmv for both sumps. These data show that H_2S and SO_2 will both be present at an exposure risk to workers and the community if the sludge is disturbed for neutralization and stabilization treatment, as the OSHA PELs for H_2S and SO_2 are 10 ppmv and 2 ppmv, respectively (Stantec, 2008).

The sludge samples collected from the Haack Rework Area had substantially lower concentrations of H_2S and SO_2 in the vapor headspace. The vapor concentrations of SO_2 in equilibrium with sludge samples ranged from 8 to 71 ppmv. The vapor concentration of H_2S ranged from 2 to 50 ppmv. These data show that H_2S and SO_2 emissions from sludge on the Haack property could present an exposure risk to workers and the community if the sludge is disturbed for neutralization and stabilization (Stantec, 2008).

3.4.9 Metal and Organic Mobilization

Treated and untreated composite samples of sludge from the Cooper North and Cooper South Sumps were analyzed for total RCRA metals, VOCs, SVOCs, and PAHs and for analyses of leachable RCRA metals and organics by both the toxic characteristic leaching procedure (TCLP) and synthetic precipitation leaching procedure (SPLP) (Stantec, 2008).

3.4.9.1 Untreated Sludge Leaching

Analyses showed that the composite sludge sample contained 22.4 mg/kg lead and 1.2 mg/kg barium. The TCLP extract contained 0.24 mg/L lead and 0.06 mg/L barium, thus indicating that the sludge would not be characterized as a hazardous waste under the definitions and exclusions given in 40 CFR Part 21 for lead or barium, even in a final TCLP extract of pH 3.97. The SPLP extract contained 0.31 mg/L lead and less than 0.01 mg/L barium at a final SPLP extract pH of 2.15. This indicates that the SPLP will be more likely to produce leaching effects in laboratory analyses than the TCLP (Stantec, 2008).

The analyses for total SVOCs, PAHs and VOCs identified the following constituents in the sludge:

- Benzo(a)anthracene 70,000 µg/kg;
- Chrysene 160,000 µg/kg;
- 2-Methylnaphthalene 30,000 µg/kg;
- Phenanthrene 200,000 µg/kg;
- Pyrene 60,000 µg/kg;
- Ethylbenzene 200 µg/kg;
- Toluene 400 µg/kg;
- Xylenes 1,000 µg/kg;
- 2-Methylnapthalene 1,900 µg/kg;

- 1,2,4-Trimethylbenezene 700 µg/kg;
- 1,3,5-Trimethylbenzene 500 µg/kg; and
- 1,2,3-Trimethylbenzene 1,100 µg/kg.

Despite the presence of these compounds within the sludge itself, no PAHs or SVOCs were identified in the SPLP extract for the untreated sludge above the detection limit of 5 µg/L. This indicates that the SVOCs and PAHs within the sludge are largely immobile. Toluene was detected in the SPLP extract of the untreated sludge at 7 µg/L, and 1,2,3-trimethylbenzere was detected in the SPLP extract at 1 µg/L (Stantec, 2008).

Analysis of the sludge for TPH as GRO and DRO showed that the sludge contained 70 mg/kg GRO and 39,000 DRO. This shows that only 3.9 percent of the sludge is comprised of organics in the C6 to C28 hydrocarbon range, thus showing that the majority of organics in the sludge have a very high molecular weight in excess of 400 (Stantec, 2008).

3.4.9.2 Treated Sludge Leaching

Samples of composite sludge treated with a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$ at dosage rates of 22, 24, 26, and 28 percent reagent by weight with respect to the original mass of untreated sludge were subjected to SPLP testing. The results showed that the treatment produced non-detectable concentrations of RCRA metals and SVOCs in each of the SPLP extracts, with the exception of barium which was detected at 0.01 mg/L. This shows that the treatment reduced the concentration of leachable lead by the SPLP to less than 0.03 mg/L (Stantec, 2008).

3.4.10 Long-Term Leaching Analysis

A long-term leaching test was performed on a composite sludge sample from the Cooper North and Cooper South Sumps that was treated at a dosage of 25 percent of the 50/50 (w/w) $Ca(OH)_2$ and $CaCO_3$ reagent mix. The sample was subjected to the SPLP extraction procedure daily, with new extract water being added to the sample after each SPLP extraction to evaluate the long-term leaching effects after multiple extractions. The leachate from every other extraction was filtered and sent for analyses of PNAs, RCRA metals, and VOCs. The extracts were also tested in the laboratory for pH and alkalinity (Stantec, 2008).

Testing indicated lead did not leach from the sludge even after ten sequential SPLP extractions, indicative that treatment of the sludge with $Ca(OH)_2$ and $CaCO_3$ provides long-term stability for lead. Trace concentrations of barium, ethylbenzene, toluene and xylenes leached from the treated sludge, but the concentrations were well below the primary drinking water standards. Additionally, trace concentrations of

trimethylbenzene isomers, 2-methylnapthalene, and acetone leached from the treated sludge, but there are no primary or secondary drinking water standards for these compounds. Minimal alkalinity was removed from the sludge during the ten sequential extractions, thus indicating that many more extractions could have been performed while still maintaining alkaline stability in the treated material (Stantec, 2008).

3.4.11 Permeability

Composite samples of untreated and treated sludge from the Cooper North and Cooper South Sumps were tested for permeability by modified American Society for Testing and Materials (ASTM) D5084, Method C. The treated samples consisted of composite sludge samples treated with 15 percent calcium hydroxide and 15 percent $CaCO_3$ fines by weight. Stantec reported that the untreated sludge exhibited permeability less than $1x10^{-8}$ centimeters per second (cm/s), while the treated sludge exhibited permeability of approximately $9x10^{-3}$ cm/s (Stantec, 2008).

3.4.12 Evaluation of Soil Additive

Four composite samples of sludge were treated with 25 percent reagent comprised of a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$. Prior to adding the reagent, the samples were amended with 0, 25, 50, and 75 percent soil, by weight (Stantec, 2008).

The testing showed that the addition of soil to the neutralized sludge improved the density of the treated material and maintained high strength. Because the sludge at the Site is so viscous, it was difficult to assess how the soil additive worked as a stabilization material for bituminous stabilization at ambient temperatures. Therefore, samples of neutralized sludge treated with 0, 25, 50, and 75 percent soil were compacted into cores using a Harvard compaction apparatus, and the cores were placed into a convection oven at 220ºF to test the stability of the sludge. The testing showed that the neutralized samples containing no soil exhibited viscoelastic flow at 220ºF. The samples containing 25 percent soil exhibited minor viscoelastic properties, and the samples containing 50 and 75 percent soil by weight exhibited no viscoelastic properties. These test results show that the addition of 50 percent soil to neutralized sludge by weight converts the sludge into a stable solid material, even at elevated temperatures that exceed the softening point of the sludge (Stantec, 2008).

3.4.13 Evaluation of Thermal Treatment

Although the sludge was found to contain approximately 4 percent diesel-range organics, the majority of hydrocarbon in the sludge was comprised of very large chain hydrocarbons having a molecular weight greater than 400. When the sludge was tested for BTU value, it was found to have a very high heating value of 13,000 BTUs per pound. This confirms that the sludge is comprised primarily of organics. However, the

sludge also had an elevated sulfur content of approximately 7 percent. This high sulfur content suggests that incineration or fuel combustion of the sludge is not a viable treatment alternative due to the large amount of SO_2 gas that would be emitted during combustion. Stantec has estimated over 1,800 cubic feet (280 pounds) of SO_2 gas could be emitted for each ton of sludge incinerated or combusted. Sitewide, the total mass of SO_2 generated by thermal treatment of the sludge would exceed 2,600 tons (Stantec, 2008).

3.4.14 Evaluation of Moisture/Density Relationship for Treated Sludge

Four samples of sludge treated with 25 percent of a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$ were tested for moisture/density relationship to determine optimal dry density and moisture content for compaction after treatment. Testing was performed on a sample without soil amendment and on three samples amended with 25, 50, and 75 percent soil by weight with respect to the initial weight of untreated sludge (Stantec, 2008).

The test results showed that the neutralized sludge without soil amendment had a very low maximum dry density of 52.3 lb/ft^3 and high optimum moisture content of 46.7 percent. When the neutralized sludge was amended with 25 percent soil, the maximum dry density increased to 64.1 lb/ft^3 and the optimum moisture content decreased to a more reasonable value of 29.5 percent. The neutralized sludge sample amended with 50 percent soil had a maximum dry density of 68.8 lb/ft^3 and an optimum moisture content of 25.7 percent, and the sample amended with 75 percent soil had a maximum dry density of 71.6 lb/ft^3 and an optimum moisture content of 24.4 percent. Based on Table 13, stabilized sludge amended with 12 percent $CaCO_3$ and 12 percent $Ca(OH)_2$ has a density of 81 lb/ft^3 (RTC, 11/6/12) (Stantec, 2008).

3.4.15 Testing for Asphaltic Qualities

Testing of the sludge indicated that it will have low marketability as recycled asphalt, even when neutralized, for the following reasons:

- The sludge is a brittle, glass-like material with little to no ductility;
- The viscosity of the sludge is too high for use as asphalt cement in road construction;
- The sludge contains a high concentration of impurities and suspended solids which causes it to fail to meet the test for asphalt solubility for both asphalt cement and roofing asphalt;
- The sludge has a negative American Petroleum Institute (API) gravity;

- The softening point falls into acceptable ranges for a Type II roofing asphalt, but the sludge fails to meet most of the remaining specifications for Type II roofing asphalt; and
- Penetration values for the sludge were too low for use as asphalt cement but meet the specifications for Type IV roofing asphalt.

Although the sludge shares the softening point specifications for Type II roofing asphalt and the penetration specifications for Type IV roofing asphalt, it fails to meet the ductility requirements for either of these asphalt grades. The brittle nature of the material gives it undesirable properties because the material is easily cracked and sheared, thus making it unsuitable for roofing or pavement construction applications (Stantec, 2008).

Section VII.C. of the Consent Decree requires the evaluation of the proposal of Mr. Thomas Cooper for recycling the sludge as one of the alternatives in the FS. The Cooper Sumps sludge, in a non-neutralized state, releases significant quantities of H_2S and SO_2 gas when disturbed. The release of these gases from the sludge as well as the physical characteristics of the sludge, makes the sludge unacceptable for recycled asphalt application. The sludge recycling alternative is not evaluated further in this FS.

4. REMEDIAL ACTION OBJECTIVES AND CLEANUP CRITERIA

4.1 General

This section describes the development of remedial action objectives (RAOs) and target cleanup levels for the Site. The development of RAOs is required by RI/FS guidance as part of the FS. The process of developing the RAOs depends upon the assessment of risk to identified receptors at the Site and in the Site vicinity. A discussion of the risk assessment (RA) at the Site follows.

4.2 Chemicals of Potential Concern

The chemicals of potential concern (COPCs) for the Site were developed and discussed in the hazard identification section of the *Draft Human Health Risk Assessment* (HHRA) (Geosyntec, 2010). USEPA guidance states that the list of chemicals should include all chemicals that were:

- Positively detected in at least one sample;
- Detected above levels of the same chemicals found in associated blank samples;
- Tentatively identified, but may be associated with the Site based on historical information;
- Transformation products of detected chemicals; and
- Detected above naturally occurring levels (background).

During the RA, those contaminants posing a potential risk to receptors at the Site were identified as COPCs and can be found in Table 4-1 for soil, soil gas, and groundwater.

4.3 Human Health Risk Assessment

4.3.1 Approach

The draft HHRA included an evaluation of health risks to potentially exposed receptor populations consisting of: commercial/industrial workers, construction workers, hypothetical future residents, and trespassers. Potential exposures were evaluated for these populations assuming existing physical site conditions (without the existence of the protective caps on the Cooper and Haack properties and prior to any future remediation efforts at the Site). In addition, a current residential scenario has been included for the immediate adjacent offsite residential area (Geosyntec, 2010).

Future development of the Site and the immediate adjacent offsite residential area would be commercial as designated in the City of Gardena's report titled *Artesia*

Corridor Specific Plan (TPC, 2006). To conservatively evaluate the potential risks under an unrestricted land use scenario, a more conservative hypothetical future residential scenario was included in the HHRA to evaluate potential risks under an unrestricted land use scenario. Additionally, the conservative construction worker, shallow groundwater to outdoor vapor inhalation and dermal contact scenario was evaluated to represent groundwater in an open excavation (Geosyntec, 2010).

To evaluate the spatial distribution of risk driving chemicals, two types of comparison criteria were developed for each chemical identified in the risk characterization: (1) those based on background; and (2) risk-based values (RBCs) or target risk concentrations which are based on each receptor group and assuming site-specific soil characteristics and a target risk goal. For worker exposures (commercial/industrial and construction worker) a target risk goal of 1 in 100,000 (1×10^{-5}) was used. For residential and trespasser scenarios a 1 in 1,000,000 (1×10^{-6}) target risk goal was used. For those chemicals in which the risk-based concentrations are below background, the background concentration is used as the comparison criteria. This is the case for arsenic and residential and commercial/industrial worker scenarios, and benzo(a)pyrene toxicity equivalent (BaP-eq) for the residential scenarios (Geosyntec, 2010).

4.3.2 Results

The results of the HHRA indicate that exposures to onsite soils may potentially exceed target risk goals for all potential receptor scenarios evaluated: commercial/industrial worker, construction worker, hypothetical future onsite/current offsite resident, and trespasser. The primary contributors to the risk estimates were arsenic, hexavalent chromium, naphthalene, and predominantly the carcinogenic PAHs as represented by the BaP-eq concentration. The majority of locations where concentrations of these chemicals were elevated occurred within areas of known sludge material which are currently covered by the existing geomembrane cap, soil, concrete, and/or asphalt (Geosyntec, 2010).

4.4 Chemicals of Concern

Following completion of the HHRA, primary risk driving chemicals were identified from the list of COPCs (see Section 4.2) as chemicals of concern (COCs). These chemicals were identified as primary risk drivers because they are the most ubiquitous chemicals throughout the Site and because they are co-located with a majority of the COPCs (i.e., the risk associated with the COCs would encompass the COPCs). Based on the HHRA, the primary COCs at the Site are:

- **Soil**: arsenic, hexavalent chromium, naphthalene, and the BaP-eq
- **Air**: benzene, hydrogen sulfide

- **Groundwater**: dibenz(a,h)anthracene

These COCs are present in the Cooper and Haack Sumps as well as in the Haack rework area. Methane has been detected at low concentrations around the site but was not identified as a COC based on the HHRA. Due to the potential explosive risk associate with methane, it has been included with as a Remedial Action Objective. (RTC, 9/29/11)

4.5 Remedial Action Objectives

RAOs are goals specific to various media and apply to those media that have been identified as posing an unacceptable risk based on the HHRA work performed for the Site. The RAOs for onsite soils, soil gas, and groundwater are:

- Prevent ingestion/direct contact with sludge and/or soil having 10^{-5} to 10^{-6} excess cancer risk from carcinogenic constituents as represented by arsenic, hexavalent chromium, naphthalene, and the BaP-eq concentration;
- Prevent dermal contact with shallow groundwater having 10^{-5} excess cancer risk from carcinogenic polycyclic aromatic hydrocarbons (PAHs) as represented by dibenz(a,h)anthracene;
- Prevent dermal contact with low pH, PAH containing sludge (RTC, 2/10/12);
- ~~Prevent inhalation of benzene posing excess cancer risk levels of 10^{-5} to 10^{-6}~~ (RTC, 9/29/11);
- Prevent inhalation of volatile organic compounds (VOCs), as represented by benzene, posing excess cancer risk levels of 10^{-5} to 10^{-6}(RTC, 9/29/11); and
- Prevent explosive risks associated with methane. (RTC, 9/29/11)

4.6 Applicable or Relevant and Appropriate Requirements

The Applicable or Relevant and Appropriate Requirements (ARARs), as defined by 40 CFR 300.5, presented in this section were identified for the remedial actions presented in this document to comply with Federal environmental law or more stringent standards promulgated under State environmental law. Federal and State environmental laws are evaluated to determine if they are either applicable or relevant and appropriate.

"To Be Considered" (TBC) criteria have also been identified to cover Federal and State nonpromulgated standards, policies, or guidance documents and local requirements for constituents which do not have developed preliminary remedial goals or ARARs.

The ARARs are divided up into the following three categories according to the type of CERCLA action they govern: chemical-specific, location-specific, and action-specific requirements. ARARs and TBC criteria are presented in Table 4-2.

4.6.1 Potential Chemical-Specific Requirements

At the Site, chemical-specific requirements include RCRA provisions defining hazardous waste, maximum contaminant levels (MCLs) derived from the Safe Drinking Water Act, and primary and secondary national standards for ambient air quality. The Draft HHRA identifies the site-specific, risk-based cleanup levels (Geosyntec, 2010).

4.6.2 Potential Location-Specific Requirements

No location-specific ARARS were identified since the Site is not located in any sensitive or protected area.

4.6.3 Potential Action-Specific Requirements

The potential action-specific requirements for the Site include:

- **Porter-Cologne Water Quality Control Act**: Set on a case by case basis by the Regional Water Quality Control Board (RWQCB), water emission standards are applied to waste water, groundwater, (RTC, 1/9/2013) and stormwater runoff from the Site.
- **South Coast Air Quality Management District (SCAQMD)**: Emissions of gases, particulate matter, and fugitive dust are set by the SCAQMD and may apply if they are part of the State Implementation Plan pursuant to the Clean Air Act.
- **National Pollution Discharge Elimination System (NPDES)**: Requires the elimination of most non-stormwater discharges, Stormwater Pollution Prevention Plan (SWPPP) preparation, and stormwater discharge monitoring.
- California Civil Code and California Health and Safety Code governing land use restrictions.
- DTSC hazardous constituent regulations as outlined in 22 CCR Division 4.5.

4.7 Future Site Use

The Site is currently used for residential and commercial/industrial applications. The DTSC has requested the following three future land use scenarios be evaluated for the Site:

- Current land use will continue; residential properties would remain and Cooper and Haack areas would remain commercial/industrial;
- Use the Site for residential only; and
- Use the Site for commercial/industrial only.

As a conservative approach to meet the DTSC request, the residential cleanup goals will be used, which are the most stringent.

The City of Gardena has developed the City of Gardena Master Plan (TPC, 2006) which indicates the Site would be developed in the future as commercial property with a mix of commercial buildings and parking. To accommodate this development plan and constraints of the Site, ARC requested the remedial design be compatible with a parking lot or open space end use incorporating curbs, gutters, light poles, and utilities.

4.8 Target Cleanup Levels

The target cleanup levels for the Site were developed with consideration given to the following factors:

- Hypothetical future use scenario;
- Remedial action objectives; and
- Potential site health risk.

The cleanup levels shown in Tables 4-3, 4-4, and 4-5 were developed for each of the COCs identified in Section 4.3. Cleanup criteria either are numeric goals to be achieved through remediation or are non-numeric, performance-based criteria. The cleanup levels shown in Tables 4-3, 4-4, and 4-5 will be used subsequently in this FS Report to guide the selection and screening of remedial technologies and the development and detailed analysis of remedial alternatives. A discussion of the development of cleanup criteria follows.

4.8.1 Site-Specific Action Levels

Soil cleanup criteria are based on the derivation of risk-based concentrations (RBCs) for site COCs. RBCs were developed for each chemical identified as a COC or "risk driver" in the risk characterization of the HHRA (Geosyntec, 2010) based on each receptor group and assuming site-specific soil characteristics as presented in Appendix C. (RTC, 4/4/12) RBCs were derived for arsenic, BaP-eq, hexavalent chromium, benzene, and naphthalene in soil (Table 4-3); benzene in soil gas (Table 4-4); and dibenz(a,h)anthracene in groundwater (Table 4-5). The derivation of these concentrations is provided in Appendix B. RBCs are presented for both cancer and noncancer effects; cancer effects generally produce lower RBCs. The selected site-specific action levels (SSALs), considering background concentrations, are presented in the last column for each receptor group.

For arsenic in soil, the DTSC screening level of 12 mg/kg, which is considered background for southern California sites (Cal-EPA DTSC, 2007), was used as the SSAL for residential receptors.

For BaP-eq in soil, a concentration of 0.9 mg/kg, considered representative of background PAH concentrations in southern California soils, was used as the SSAL for residential receptors.

5. IDENTIFICATION AND SCREENING OF TECHNOLOGIES

5.1 Introduction

General response actions (GRAs) describe remedial actions that would address RAOs and achieve cleanup criteria for hypothetical future receptors that may be exposed to soil, soil gas, and groundwater contaminants. This section provides a discussion of GRAs and also provides identification of potential remedial technology types and specific technologies. A screening analysis was conducted to reduce the number of potentially applicable technologies to those that were determined to be potentially able to achieve the RAO for the COCs.

5.2 General Response Actions

Specific GRAs identified for onsite impacts include the following:

- No action;
- Remediate or remove soils that present potential ingestion and/or dermal contact risk;
- Containment;
- Reduce concentrations of COCs that present a potential inhalation risk;
- Gas monitoring and treatment;
- Monitor groundwater; and
- Implement institutional controls to restrict access to sludge and to control and manage risk associated with future mixed-use redevelopment.

5.3 Technology Identification and Screening

In accordance with USEPA guidance, potential remedial technology types and specific technologies that can be used to implement the GRAs were identified and then screened to assess their effectiveness, implementability, and cost. This section provides a screening of technologies to identify those that will be combined into remedial alternatives in Section 6 of this FS Report. The following technologies have been identified for remediation and are listed in Table 5-1:

- No action;
- Institutional controls;
- Treatment:
    - Stabilization/neutralization

    - Thermal treatment and
    - Sludge recycling
- Containment;
- Excavation and removal for offsite disposal; and
- Engineered controls:
    - Vapor and gas control systems; and
    - Groundwater monitoring.

In accordance with US EPA Feasibility Study guidance, Table 5-1 presents the screening of each technology based on its relative effectiveness, implementability, and cost. This screening provides the rationale behind the decision to retain or eliminate each technology type. Therefore, based on the screening, the following technology types were retained for further evaluation:

- No action (as required by USEPA guidance);
- Institutional controls;
- Treatment:
    - Stabilization/neutralization
- Containment;
- Excavation; and
- Engineering Controls:
    - Gas control systems; and
    - Groundwater Monitoring.

A summary of technologies retained is presented in Table 5-2. Each retained technology will be integrated into one or more remedial alternatives, described in Section 6.

6. DEVELOPMENT OF REMEDIAL ALTERNATIVES

In this section, remedial alternatives for the Site are assembled from those technologies that remain after the initial screening in Section 5. Each remedial alternative includes a remedial approach that accommodates the hypothetical future use scenario described in Section 4 and assumes that Site features are removed prior to remedy implementation. Each remedial alternative listed in Table 6-1 is designed to address each impacted media at the Site.

6.1 Remedial Alternatives

Table 6-1 presents the four remedial alternatives that were retained for evaluation:

- Alternative (A) 1 – No action;
- ~~A 2 – Capping with selective excavation~~ (RTC, 9/29/11)~~;~~
- A 2A – Capping with selective excavation (RTC, 9/29/11);
- A 3 – Capping with selective excavation and stabilization/neutralization; and
- A 4 – Excavation with offsite disposal.

Alternatives ~~2~~ 2A (RTC, 9/29/11) and 3 include institutional controls, gas control and monitoring, and groundwater monitoring. All four alternatives are described below.

Alternatives ~~2~~ 2A (RTC, 9/29/11) through 4 are depicted on Figures 6-1 through 6-16. Details shown are conceptual for estimating and comparison purposes only, and do not represent the results of full engineering design and analysis.

6.1.1 Alternative 1 – No Action

This alternative consists of performing no work now or in the future to attempt to mitigate an existing condition. The current geomembrane cover would remain and no deed restrictions would be placed on the property.

For No Action to be considered an acceptable alternative, the concentrations of COCs would have to be below RAOs. This alternative would provide no exposure pathway reductions. There would be no controls to prevent future site development or site access. Groundwater contamination would not be known since monitoring would not be performed. Future site development would be hindered due to the instability of the sludge material. The No Action Alternative is required by USEPA FS guidance.

~~6.1.2 Alternative 2 – Capping with Selective Excavation~~

~~Alternative 2 includes the following major elements:~~ (RTC, 9/29/11)

- ~~Existing surface removal;~~
- ~~Consolidation and capping of impacted material;~~
- ~~Capping of sludge;~~
- ~~Installation of gas control and monitoring system;~~
- ~~Institutional controls; and~~
- ~~Groundwater monitoring.~~

~~This alternative is depicted on Figures 6-1 and 6-2. The cap surface shown in Figure 6-2 is for comparative purposes in this Feasibility Study only and does not represent the final cap surface. Each component is discussed further in the following sections.~~ (RTC, 9/29/11)

~~*6.1.2.1 Existing Surface Removal*~~

~~A geomembrane is currently above the Cooper North and South Sumps. Prior to initiating consolidation activities, the existing geomembrane will be cut to allow sludge to permeate through and prevent the potential for gas build up. The geomembrane will remain in place and Haack Rework and Eastern Overflow material would be consolidated above it.~~ (RTC, 9/29/11)

~~*6.1.2.2 Consolidation of Material*~~

~~In general, the sludge is contained in the three sumps: Cooper North and South, and Haack. As previously discussed in Section 3.2.1, approximately 650 CY of a sludge/soil mixture is located outside of the sumps in the Haack Rework area. To excavate the sludge/soil mixture, approximately 3,550 CY of overburden will need to be excavated. Additionally, along the eastern property line, a thin layer of sludge exists which appears to be the result of spillage or overflow from the sumps. Also, as shown on Figure 6-1, some sludge material is outside of the Site boundary beneath the sidewalk and Artesia Blvd. This sludge material is considered to be already capped with asphalt, concrete, and a minimum of 18 inches of sand and/or silty sand above the first detected sludge deposits (Stantec, 2010a).~~ (RTC, 9/29/11)

~~The Haack Rework and eastern overflow areas would be consolidated into one of the three sumps prior to capping, and used as fill beneath the cap low-hydraulic conductivity layer (to be discussed in Section 6.1.2.2). Approximately 4,460 CY of Haack Rework (650 CY), Haack Rework overburden (3,550 CY), and eastern overflow (260 CY) are anticipated to be placed above the sumps.~~ (RTC, 9/29/11)

~~Following visual excavation of material from the Haack Rework and eastern overflow, confirmation sampling would be performed to confirm the material was removed.~~

~~Confirmation sample results would be compared to cleanup goals. Where testing indicates concentrations in excess of cleanup goals, additional material would be removed and consolidated above the sumps. Haack Rework and eastern overflow excavations will be backfilled using soils obtained from unimpacted areas of the site.~~ (RTC, 9/29/11)

~~*6.1.2.3 Capping of the Sumps*~~

~~The Cooper North and South and Haack Sumps would remain in place. Human health and the environment would be protected through use of a cap which would act as a barrier to prevent both dermal contact and gas exposure. The proposed, conceptual Haack and Cooper cap grades are shown on Figure 6-2. This preliminary cap design is in accordance with California Code of Regulations Title 22 (22 CCR) §66264.228. The grades show on Figure 6-2 incorporate minimum slopes to maintain cover integrity in the event of settling and/or subsidence per 22 CCR §66264.228(a)(2)(C)(4). The final design of the cap may have flatter slopes if analyses are performed to show ponding will be prevented. In accordance with 22 CCR, the cap consists of a foundation layer, low-hydraulic conductivity, and erosion-resistance layer. The Alternative 2 cap is illustrated on Figure 6-6, in Detail 1-A, and would consist of the following layers:~~ (RTC, 9/29/11)

~~*Stabilization Layer*~~

~~The stabilization layer is intended for use over the sludge material in the Cooper North and South sumps (Detail 1-A, Figure 6-6). The Haack Sump is currently overlaid by a 6-inch reinforced concrete pad which would act as the stabilization layer (Detail 1-C, Figure 6-6). Prior to placement of the stabilization layer over the Cooper Sumps, the geomembrane material will be cut to allow sludge to seep through and mix with the gravel layer. The stabilization layer on the Cooper North and South sumps will consist of, from bottom to top, 2 feet of gravel, 1 foot of sand, high-strength woven geotextile, and a 6-inch geocell filled with sand. The bottom gravel layer placed above the cut geomembrane is intended to partially sink into the sludge material to provide stabilization during construction of the overlying materials. The high-strength woven geotextile would provide separation reinforcement and, along with the geocell reinforcement, would "bridge" the soft sludge areas and provide the strength needed to support the cap.~~ (RTC, 9/29/11)

~~*Foundation and Gas Collection Layers*~~

~~The foundation soil and gas collection layers would be placed above the stabilization layers and consist of, from bottom to top, minimum 1 foot of foundation soil, gas collection piping, and a gas collection geocomposite. The minimum 1 ft foundation and gas collection layer will support the low-hydraulic conductivity layer and erosion~~

resistance layer in accordance 22 CCR §66264.228(e)(4). The foundation soil would consist of onsite, impacted soil and Haack Rework material where available. Impacted foundation layer material would be supplemented with soil material obtained from unimpacted areas of the site. Horizontal gas collection pipes surrounded by gas collection aggregate would be embedded in the foundation layer. Nonwoven geotextile would surround the aggregate to prevent clogging of the aggregate due to fines intrusion. (RTC, 9/29/11)

Low-Hydraulic Conductivity Layer

The low-hydraulic conductivity layer would be placed above the foundation and gas collection layers and would consist of a geosynthetic clay liner (GCL) and a 60-mil high density polyethylene (HDPE) geomembrane. In accordance with 22 CCR §66264.228(e)(5), the low-hydraulic conductivity layer would reduce the downward migration of precipitation and the upward migration of sludge and gas. (RTC, 9/29/11)

Erosion Resistance Layer

The erosion resistance layer is comprised of a drainage geocomposite and 2 feet of vegetated cover soil. In accordance with 22 CCR §66264.228(e)(10). the drainage geocomposite would prevent hydrostatic head buildup and drain precipitation that has infiltrated the overlying vegetated cover soil toward the outside of the cap and perimeter drainage channels while the vegetative cover soil will be resistant to foreseeable erosion effects by wind scour, raindrop impact, and runoff. (RTC, 9/29/11)

Along the northern property boundary, limited space is available to allow for grading to install the cap system. As a result, sheet piles would be installed to allow for the vertical rise of the cap without altering Artesia Boulevard or the railroad property. Furthermore, the installation of sheet piles would prevent lateral migration of the sludge material from beneath the cap due to the new weight of the cap. The sheet piles would be installed to an average depth of 20 feet bgs and extend between 4 and 10 feet from the ground surface to accommodate the cap. (RTC, 9/29/11)

6.1.2.4 Gas Control and Monitoring System

The gas control system would be comprised of perimeter vertical gas migration control wells and a below-cap horizontal gas collection system. The proposed layouts of the vertical and horizontal gas collection systems are shown on Figures 6-3 and 6-4, respectively. (RTC, 9/29/11)

Vertical Gas Migration Control Wells

The system of gas migration control wells is designed to be a passive system that, as a contingency, can be converted readily to an active system. The system will operate

actively for a period of 2 weeks following remedial action at the site. Based on the concentrations of constituents detected during the 2-week startup period, the system will remain active or switch to passive operation with the option for active control in the future. The decision to make the system active again would be based upon future gas monitoring at the Site. (RTC, 9/29/11)

As a passive system, the wells are designed to intercept gases that may migrate laterally from the sumps; the gases are then vented to the atmosphere or to a treatment system. Barometric pumping would help "flush" the wells. As an active system, alternate wells would serve as air inlet and gas extraction wells. In this way, a "curtain" of air would be created that would intercept gases that may potentially migrate from the sumps as depicted on Figure 6-5. The extracted gases would then be vented to the atmosphere or to a treatment system. The wells would be installed to the approximately 2 ft above the groundwater "A" horizon. (RTC, 9/29/11)

Below-Cap Horizontal Gas Collection System

A horizontal gas collection system would be placed within the foundation layer of the cap, as discussed above. Similar to the vertical gas migration control wells around the perimeter of the cap, the gas collection system is designed to initially operate as an active system, during a start-up period of approximately two weeks. The system would then be operated as a passive system, but is designed as a contingent measure to be readily converted to active. As a passive system, it would be vented to the atmosphere and rely on barometric pumping to flush the system. The decision to make the system active would be based upon post-remediation gas monitoring at the Site. (RTC, 9/29/11)

The design of the gas collection system incorporates two separate gas collection pipes near the perimeter of the cap. A gas transport pathway between the gas collection pipes is established by the geocomposite component of the cap. As a passive system, gas entering the geocomposite would transmit to either of the gas collection pipes and would vent to the atmosphere or gas treatment system. As an active system, one of the pipes would be an air inlet pipe and the other pipe would be an extraction pipe. A flow of air and gas from the air inlet pipe to the extraction pipe would be created across the width of the caps and would remove gas that may accumulate below the barrier component of the cap. (RTC, 9/29/11)

Gas Monitoring System

Gas migration sentry probes would be placed near the perimeter of the cap. The proposed locations of the probes are shown on Figure 6-4. The sentry probes are designed to be outside of the vertical gas migration control wells. Regular monitoring of gas concentrations at the probe locations would be performed before, during, and after system operation. The decision to convert the gas collection systems to an active

~~system would be partially based upon the results of the sentry probe monitoring activities, and threshold contaminant concentrations developed in the Operations, Maintenance, and Monitoring (OM&M) Plan.~~ (RTC, 9/29/11)

~~*6.1.2.5 Institutional Controls*~~

~~The anticipated institutional controls for the Site would prohibit sensitive land uses (i.e., single family residence, hospitals, schools, or child care centers), specify new building construction (i.e., first floor non-residential, upper floor residential, and inclusion of gas control system), and prohibit onsite groundwater extraction for municipal (i.e., drinking water purposes), industrial, and agricultural (i.e., irrigation) use. Furthermore, a Health and Safety Plan (HASP) and Construction Quality Assurance (CQA) Plan would be required to establish minimum health and safety protocol during construction, and provide documentation of proper excavation, cap, and gas control system construction. A Risk Management Plan (RMP) would be developed for the Site to reduce the risk of future construction worker exposure to groundwater if the Site is developed. The RMP would discuss the hazards at the site, minimum PPE requirements, and notification requirements. Land use covenants (LUCs) to place deed restrictions on the site will be filled with the Los Angeles County Recorder's Office and annual LUC restriction inspections will be conducted by DTSC to ensure compliance (RTC, 4/4/12)~~ (RTC, 9/29/11)

~~*6.1.2.6 Groundwater Monitoring*~~

~~Groundwater monitoring would continue to be performed on a semi-annual basis for a period of 5 years after the remedial controls have been implemented. During construction, three sets of wells would be destroyed to accommodate construction of the cap. Following construction, two wells would be installed to represent the upgradient and downgradient conditions with the remaining well network.~~ (RTC, 9/29/11)

6.1.2 Alternative 2A – Capping with Selective Excavation

Alternative 2A replaced Alternative 2 in the Draft FS dated February 2011. Alternative 2A is consistent with the former Alternative 2 in that capping and selective excavation of the sludge in the Haack Rework area are evaluated. However, the evaluated cap proposed in Alternative 2A is significantly lower in overall height than the cap of former Alternative 2. Additionally, different disposal scenarios for the Haack Rework material are proposed in Alternative 2A. The lower profile cap and different Haack Rework material disposal alternative presented in this Final Revised Draft FS is in response to comments received from the City of Gardena during the 10 May 2011 meeting. (RTC, 9/29/11)

6.1.2.1 General Overview

The Site is generally divided into three areas: the Cooper North and South Sumps on the Cooper Property, the Haack Sump and the Haack Rework Area located primarily within the Haack property, four residential properties, land owned by Los Angeles County and a small area of land beneath the Artesia Boulevard right-of-way. Because these areas of the Site are divided among different property owners, the properties may not all be available for remedial construction at one time. The following sections describe, in general, the proposed Alternative 2A approach for each area. Section ~~3.3~~ 6.1.2.2 (RTC, 11/6/12) describes the remedial implementation approach for the entire Site in greater detail. (RTC, 9/29/11)

As described ~~in the Draft FS (Geosyntec, 2011),~~ previously (RTC, 11/6/12), the sludge material beneath the Artesia Boulevard South sidewalk and Artesia Boulevard are below road base material and asphalt or sidewalk concrete. The concrete and asphalt surface prevent ingestion and direct contact with the sludge as well as reduce its mobility by containing the sludge. (RTC, 11/6/12) This sludge material is considered to be already capped; however, institutional controls will include a requirement for repaving the area with "low-permeability asphaltic concrete" and increased maintenance of the asphalt surface in this area. ~~and therefore was not addressed in the Draft FS and will not addressed in Alternative 2A.~~ (RTC, 11/6/12)

Future access from current and/or future utility and/or construction workers will be addressed in the Risk Management Plan (RMP). The RMP will describe contaminants remaining onsite, known locations of impacts, contact information, and minimum, recommended personal protective equipment for current and future utility and/or construction workers. Institutional controls will include requirements (RTC, 11/6/12) that the City of Gardena and/or Caltrans provide notice of potential subsurface hazardous materials in the area of Artesia Boulevard where sludge is potentially located, prior to (RTC, 11/6/12) issuing work permits. (RTC, 2/10/12) Institutional controls will also include requirements related to Site development and cap loading restrictions. (RTC, 11/6/12)

Cooper North and South Sumps

The existing geomembrane will remain in place with the cap installed above. The geomembrane will provide a construction surface and preliminary support during installation of the overlying materials. Furthermore, the existing surfaces minimize the dermal contact and gas inhalation exposure risks to the construction workers during installation of the cap. (RTC, 11/6/12)

The sludge in the Cooper North and South Sumps will be capped, from bottom to top, with the following materials: (1) high-strength geotextile; (2) between 1 and 4.5 feet (ft) of foundation layer material; (3) a horizontal gas collection system: gas collection geostrips and gas collection geocomposite; (4) geosynthetic clay liner (GCL); (5) high-density polyethylene (HDPE) geomembrane; (6) drainage geocomposite; and (7) 12-inches (in.) of Class II aggregate base. (RTC, 9/29/11)

Haack Sump

The existing asphalt and concrete will remain in place with the cap installed above. The asphalt and concrete will provide a construction surface and preliminary support during installation of the overlying materials. Furthermore, the existing surfaces minimize the dermal contact and gas inhalation exposure risks to the construction workers during installation of the cap. (RTC, 9/29/11) In areas where sludge has migrated to the surface, asphalt repair will be performed prior to installation of the cap. (RTC, 11/6/12)

The sludge in the Haack Sump will be capped, from bottom to top, with the following materials: (1) between 0.5 and 4.5 ft of foundation layer material; (2) a horizontal gas collection system made up of gas collection geostrips and gas collection geocomposite; (3) geosynthetic clay liner (GCL); (4) HDPE geomembrane; (5) drainage geocomposite; and (6) 12 in. of Class II aggregate base. (RTC, 9/29/11)

Haack Rework Area

The Haack Rework area is composed of soil-sludge material and soil overburden. The Haack Rework overburden material will be disposed of as foundation material beneath the Cooper North and/or South sumps cap. ~~These materials will be removed and relocated or disposed of in three possible scenarios or a combination of the following three scenarios: (1) beneath the Cooper North and/or South Sumps cap as foundation layer material; (2) beneath the Haack Sump cap as foundation layer material; and (3) offsite disposal.~~ (RTC, 11/6/12) Approximately 2,670 CY of Haack Rework soil-sludge material and 2,450 CY Haack Rework overburden are anticipated to be relocated during construction activities. Disposal of the Haack Rework material will be dependent on the material properties of the soil-sludge and (RTC, 11/6/12) ~~property~~ availability of staging areas within the property (RTC, 11/6/12) during construction, as described in greater detail in Section ~~3.3.3~~ 6.1.2.2. (RTC, 11/6/12)

6.1.2.2 Detailed Alternative 2A Components

Alternative 2A includes the following major elements:

- Existing surface preservation;
- High-strength geotextile installation;

- Select excavation of impacted material (Haack Rework material);
- Containment of sludge along Artesia Boulevard;
- Installation of gas control and monitoring system;
- Capping of the sumps;
- Institutional controls; and
- Groundwater monitoring.

The approximate area of Alternative 2A is depicted on Figures ~~3-1~~ 6-1 and ~~3-2~~ 6-2. (RTC, 11/6/12) The construction and cap components are discussed further in the following sections.

Existing Surface Preservation

The existing geomembrane surface on the Cooper Property and concrete and asphalt surfaces above the Haack Sump will remain in place and the cap will be installed above these surfaces. New asphalt will be placed above the existing, degraded areas of asphalt surface over the Haack Sump prior to the initiation of cap construction on the Haack property. (RTC, 2/10/12) The geomembrane, asphalt, and concrete surfaces will provide a barrier to minimize worker dermal exposure to sludge contact as well as gas generation and release. Additionally, the concrete and asphalt surfaces will provide strength to the cap on the Haack Sump, eliminating the need for the high-strength geotextile described ~~in Section 3.3.2.~~ below. (RTC, 11/6/12)

High-Strength Geotextile Installation

A polypropylene (RTC, 11/6/12) high-strength geotextile will be placed above the existing geomembrane surface in the Cooper North and South sump areas; no polypropylene (RTC, 11/6/12) high-strength geotextile is proposed above the Haack sump area. The geotextile will be used to provide reinforcement during installation of the foundation soil to support both the weight of the soil and construction equipment. The polypropylene (RTC, 11/6/12) high-strength geotextile will be anchored around the perimeter of the two Cooper sumps with an anchor trench and/or secured to sheet piling along Artesia Boulevard. The minimum tensile strength and anchorage of the high-strength geotextile have been evaluated and are included in Appendix D. (RTC, 2/1/12) A typical anchor trench is shown as Detail 7 on Figure ~~3-10~~ 6-14.

Haack Rework Material Excavation and Disposal

The Haack Rework area is comprised of approximately 2,670 CY of sludge and a soil-sludge mixture beneath approximately 2,450 CY of soil overburden; therefore, a total of approximately 5,120 CY of material is anticipated to be relocated during construction activities. Haack rework material excavation will be performed using standard

construction equipment. Odor suppressant equipment (foaming units) will be present during excavation to control odors and gas emissions, if necessary. South Coast Air Quality Management District (AQMD) Rule 1166 and applicable California Occupational Safety and Health (Cal-OSHA) exposure limits will be followed during excavation and handling of the Haack Rework material.

As previously described, the Haack Rework soil-sludge material will be removed and disposed of offsite ~~relocated by three possible scenarios: (1) beneath the Cooper North and/or South Sumps cap; (2) beneath the Haack Sump cap; and/or (3) offsite disposal.~~ (RTC, 11/6/12) The Haack Rework area overburden soil will be used as foundation material beneath the Cooper or Haack Sumps caps.

~~Scenarios 1 and 2 are dependent on the phasing of the construction. For example, if all parcels are available for cap construction at one time, the Haack Rework soil-sludge material can be placed within the Cooper North and South cap; however, if only the Haack Sump and Residential Properties are available for cap construction, the Haack Rework soil-sludge material will be placed within the Haack Sump cap. Material will only be placed as foundation material if it meets the requirements for engineered fill as defined in the future construction specifications.~~ (RTC, 11/6/12) ~~In Scenarios 1 and 2, the Haack Rework soil-sludge mixture material would be excavated and placed as foundation material above the high strength geotextile or 6-inch reinforced concrete or asphalt on the Cooper North and South Sumps or Haack Sump, respectively. The material would be used as foundation material to support the overlying geosynthetics and erosion resistant layer, provide fill to generate the minimum grades for drainage, and support the gas collection strip composite (geostrip), gas collection piping, and gas collection geocomposite.~~ (RTC, 11/6/12)

~~The construction schedule for Scenarios 1 and 2 is estimated to require approximately 14 days to relocate the material from the Haack Rework area to the sump(s).~~ (RTC, 11/6/12)

The Haack Rework soil-sludge material would be excavated and disposed of at a commercial, non-RCRA hazardous landfill (assumed to be the Buttonwillow Facility). Assuming all 2,670 CY of soil-sludge material is disposed of offsite and assuming 16 CY capacity end-dump trucks are used, approximately 164 truckloads would be necessary to transport the material an estimated 150 miles one-way to the Buttonwillow Facility. An estimated 18 trucks[2] per day could be loaded and transported to the Buttonwillow Facility, resulting in approximately 10 days of hauling from the Site

[2] Assumptions: (1) 3 trucks are loaded per hour between 7 am and 1 pm, such that trucks can get to the disposal facility prior to closing

(Appendix E [RTC, 9/29/11]). ~~Scenario 3 has been included in the cost estimation, Table 3-1, and detailed and comparative analyses, Sections 4 and 5, respectively. A potential cost savings of $314,500 may be achieved if Scenarios 1 or 2 are implemented.~~(RTC, 11/6/12)

~~Initial finger berm construction as described in Section 3.3.5.1 6.1.2.3 (RTC 11/6/12) is estimated to require 8 days, assuming approximately 500 CY per day of material can be relocated. After the initial lift is placed, an additional 9 days would be required to place the additional 9,100 CY of foundation material, assuming an increased placement efficiency of 1,000 CY per day. The increase in efficiency after the initial lift is due to the less selective and restrictive nature of the placement after the working surface becomes more supportive. A preliminary schedule is provided in Appendix E. (RTC, 9/29/11)~~ (RTC, 1/9/2013)

The Haack Rework area will be excavated no deeper than an elevation of approximately 20 ft above mean sea level (amsl) as shown on Figure ~~3-5~~ 6-5. (RTC, 11/6/12) Following excavation of material from the Haack Rework area using visual means to guide the limits of the excavation, confirmation sampling to determine the absence of sludge and (RTC, 2/10/12) COCs at 5 ft intervals to a depth of 10 ft below the planned excavation grade (RTC, 2/10/12) would be performed to confirm the material was removed. Confirmation sample results will be compared to risk-based cleanup goals ~~provided in the Draft FS~~ described in Section 4.8. (RTC, 11/6/12) Where testing indicates concentrations in excess of cleanup goals, additional material would be excavated, hauled, disposed of offsite or reused as foundation material, and additional confirmation testing would be performed.

Upon completion of excavation, confirmation sampling, and receipt of test results indicating that the samples are below risk-based cleanup goals, the area will be backfilled with clean on- or off-site soil and graded to drain. The slope from the southern residential properties resulting from the excavation of the Haack Rework area will be contoured to a 3 ft horizontal to 1 ft vertical (3H:1V) grade while portions of the excavations lower than the surrounding land will be backfilled and graded to drain (Figures ~~3-1~~ 6-1 and ~~3-2~~ 6-2). (RTC, 11/6/12)

Vapor Control During Construction

Health and safety controls will be implemented during construction, specifically during ~~including~~ (RTC, 11/6/12) the excavation of the Haack Rework material. The Treatability Study performed by Stantec (Stantec, 2007) indicated the Haack Rework soil-sludge material is significantly degraded; however, detectable concentrations of hydrogen sulfide and sulfur dioxide are still produced when the sludge material is disturbed. Therefore, during construction activities, vapor suppressing foams can be

used and workers will be provided health and safety monitoring devices such as hydrogen sulfide and sulfur dioxide indicator badges. The badges alert workers when the permissible exposure limit (PEL, 10 parts per million [ppm] and 2 ppm for hydrogen sulfide and sulfur dioxide, respectively) is nearing so the worker can exit the work area or change practices. Additionally, fixed monitoring will be performed around the perimeter of the Site to alert workers when the PEL is detected so work activities can pause and/or be altered to prevent additional releases.

At the completion of excavation activities each day, a vapor suppressing foam or soil cover will be used to cover the exposed excavation and stockpiles to minimize ~~prevent additional~~ (RTC, 11/6/12) release of vapors.

6.1.2.3 Capping of the Sumps

The proposed, conceptual Haack and Cooper cap grades of Alternative 2A are shown on Figure ~~3-1~~ 6-2 with cross sections shown on Figures 6-3 and 6-4. (RTC, 11/6/12) This preliminary cap design is in accordance with 22 CCR §66264.228. In accordance with 22 CCR, the cap consists of a foundation layer, low-hydraulic conductivity layer, and erosion-resistance layer. The Alternative 2A cap is illustrated on Figure ~~3-9~~ 6-13 (RTC, 11/6/12), in Details 1-A and 1-B, and would consist of the layers described below.

Foundation and Gas Collection Layers

The foundation soil and gas collection layers would be placed above the high-strength geotextile and asphalt and concrete for the Cooper and Haack Sumps, respectively, and consist of, from bottom to top, minimum 1 ft of foundation soil, gas collection geostrips, and a gas collection geocomposite. The minimum 1 ft foundation and gas collection layer will support the low-hydraulic conductivity layer and erosion resistance layer in accordance with 22 CCR §66264.228(e)(4). The foundation soil would consist of ~~Haack Rework soil-sludge material,~~ (RTC, 11/6/12) Haack Rework overburden soil, on-site soils and/or imported fill material. Approximately 13,000 CY of foundation material will be required for the Cooper Sumps and Haack Sump. (RTC, 9/29/11)

The foundation material would initially be placed using the "finger fill soil placement technique," which incorporates the use of parallel, narrow berms over the polypropylene (RTC, 11/6/12) high-strength geotextile. Approximately 3,900 CY of material would be placed using the "finger fill soil placement technique." The initial, 1-ft berms will then gradually be expanded across the sumps until the entire sump surface is covered with one foot of foundation soil. (RTC, 9/29/11)

During finger fill placement of soil above the polypropylene (RTC, 11/6/12) high-strength geotextile, movement of the sludge will be minimized and contained by the existing berms and the anchor trenches securing the polypropylene (RTC, 11/6/12) high

strength geotextile and existing geomembrane. (RTC, 9/29/11) Where available space onsite limits traditional anchor trenches, the high-strength geotextile may be secured with concrete anchors or attached to sheet piles with battens. (RTC, 11/6/12)

After the initial 1-ft placement of soil across the sump, an additional 9,100 CY of foundation soil will be placed in lifts until final foundation grades are met (1 ft below the final cover grades shown on Figures ~~3-1~~ 6-1 and ~~3-2~~ 6-2). (RTC, 11/6/12) The slopes will be a minimum of 2 percent (%) to reduce impacts on drainage due to settlement of the foundation material and/or sludge. (RTC, 9/29/11)

Rows of gas collection geostrips will be placed at the surface of the foundation layer. The geostrips are 6 to 12 in. wide and consist of a geosynthetic filter fabric surrounding a molded polyethylene core (US Fabrics, 2011a). The molded polyethylene core provides a pathway for the gas to travel, while the filter fabric prevents soil intrusion and clogging. A polyethylene core and polypropylene geotextile, which are more resistant to acidic environments, will be required in the technical specifications. (RTC, 11/6/12) The gas collection geocomposite will be placed above the geostrip rows and the foundation layer (Details 1-A and 1-B, Figure ~~3-9~~ 6-13). (RTC, 11/6/12) The gas collection and control system is described in greater detail (RTC, 9/29/11) ~~in Section 3.3.6~~ below. (RTC, 11/6/12)

Low-Hydraulic Conductivity Layer

The low-hydraulic conductivity layer would be placed above the foundation soil and gas collection geostrips and geocomposite and would consist of a geosynthetic clay liner (GCL) overlain by a 60-mil HDPE geomembrane (Details 1-A and 1-B, Figure ~~3-9~~ 6-13). (RTC, 11/6/12) In accordance with 22 CCR §66264.228(e)(5), the low-hydraulic conductivity layer would reduce the downward migration of precipitation and the upward migration of gas. The low-hydraulic conductivity layers would be secured within an anchor trench around the perimeter of the sumps as described below. (RTC, 9/29/11)

Anchor Trenches

The existing geomembrane (located above the two Cooper Sumps), the high strength geotextile, and the low-hydraulic conductivity layer (60-mil HDPE geomembrane overlying a GCL) are or will be anchored above the sumps using separate anchor trenches. The existing geomembrane is secured above the sumps using a 2 ft by 2 ft anchor trench (OHM, 1994). These anchor trenches act similarly to shallow, vertical barriers by minimizing the opportunity for lateral "overspilling" of surface sludge. Lateral migration of the sludge at depth has not been shown to occur through the soil based on soil borings outside the immediate areas of the sumps. (RTC, 9/29/11)

The high strength woven geotextile will be secured in a separate 2 ft by 2 ft anchor trench located outside the limits of the Cooper Sumps. (RTC, 9/29/11)

The GCL and HDPE geomembrane will be secured by an additional anchor trench around the perimeter of the Haack and Cooper Sumps. The anchor trench will vary in configuration depending on the termination condition. On the eastern, southern, and portions of the northern and western perimeters, the anchor trench will consist of a vee-trench filled with concrete to form a surface water drainage ditch (Detail 6 on Figure ~~3-10~~ 6-14). (RTC, 11/6/12) On portions of the northern and western perimeters, the anchor trench will consist of a 1 ft deep by 2 ft wide anchor trench (RTC, 9/29/11) (Detail 7 on Figure ~~3-10~~ 6-14). (RTC, 11/6/12) Where sheet piles are located on the northern edge of the site, the geosynthetic materials will be secured to the sheet piles using battens. (RTC, 11/6/12)

Erosion Resistance Layer

The erosion resistance layer is comprised of a drainage geocomposite overlain by 1 ft of Class II aggregate base, in accordance with 22 CCR §66264.228(e)(10). The drainage geocomposite minimizes hydrostatic head buildup above the hydraulic barrier and provides a means to drain precipitation that has infiltrated the overlying Class II aggregate base toward the outside of the cap and perimeter drainage channels. The Class II aggregate base will be resistant to foreseeable erosion effects caused by wind-scour, raindrop impact, and runoff prior to site development. (RTC, 9/29/11)

Sheet Pile Cut-Off Wall

Along a portion of the northern Site boundary, limited space is available to allow for grading to install the cap system. As a result, sheet piles would be installed to allow for the vertical rise of the cap without altering the Artesia Boulevard right-of-way. The sheet piles would be installed to a maximum depth of 18 feet bgs, consistent with the deepest known sludge in the Cooper North and Haack Sumps, and extend upwards to approximately 3 feet from the ground surface to accommodate the cap. The sheet piles would be coated to minimize corrosion of the steel due to the low pH and high hydrogen sulfide environment. (RTC, 11/6/12) A decorative exterior wall will cover the exposed portion of the sheet piles along Artesia Boulevard. (RTC, 9/29/11) The sheet pile cut-off wall will provide a barrier between the Haack sump sludge and Artesia Blvd and its adjacent sidewalk. (RTC, 2/10/12)

Final Cap Topography

The final cap surface is shown on Figures ~~3-1~~ 6-1 and ~~3-2~~ 6-2. (RTC, 11/6/12) Cross sections of the final cap topography are provided on Figures ~~3-3~~ 6-3 and ~~3-4~~ 6-4. (RTC, 11/6/12) Drainage channels are shown on the exterior of the sumps to the north, south, east, and west as well as bisecting the Cooper North and South sumps. The channels

drain with a 0.5% slope to the northeast and northwest corners of the Cooper North and Haack sumps, respectively. The cap slopes up from the drainage channels with a minimum 2% slope to a maximum elevation of 25.7, 24.8, and 25.6 ft amsl on the Haack, Cooper North, and Cooper South sumps, respectively. Along Artesia Boulevard, the approximate height of the cap will be 22 to 23 ft amsl which includes the maximum 3 ft wall to support the final cover and an additional 6-inch curb to direct stormwater runoff to the perimeter drainage channels. The Haack Rework area will be backfilled and graded to drain as shown on Figures ~~3-1~~ 6-1 and ~~3-2~~ (RTC, 9/29/11) 6-2. (RTC, 11/6/12)

6.1.2.4 Gas Control and Monitoring System

The gas control system would be comprised of perimeter vertical gas migration control wells and a below-cap horizontal gas collection system. The proposed layouts of the vertical and horizontal gas collection systems are shown on Figures ~~3-6~~ 6-6 and ~~3-7~~ 6-7 (RTC, 11/6/12), respectively. (RTC, 9/29/11)

Vertical Gas Migration Wells

The system of gas migration control wells is designed to be a passive system that, as a contingency, can be converted readily to an active system. The system will operate actively for a period of two weeks following completion of the remedial action construction at the Site. Based on the concentrations of constituents detected during the two-week startup period, the system will remain active or switch to passive operation with the option for active control in the future. The system may be converted to passive operation with written prior approval from the DTSC. (RTC, 1/9/2013) The decision to make the system active again would be based upon future gas monitoring at the Site. (RTC, 9/29/11)

A series of alternating air inlet and gas extraction piping would be placed approximately every ~~20~~ 80 ft (RTC, 11/6/12) along the perimeter of the cap, except where sheet piles are installed as shown on Figure 3-6. The wells would be installed to approximately 2 ft above the groundwater "A" horizon ("A" horizon approximate elevation between 5.85 and 11.55 ft msl [Stantec, 2011]). The air inlet and gas extracting wells act to create a "curtain" of air surrounding the sumps, minimizing the horizontal migration of gas without extracting gas from the sludge. (RTC, 9/29/11)

During active gas extraction, a vacuum will be applied to the gas extraction wells, thus extracting gases from these wells, which will be conveyed to a treatment system for treatment prior to discharge to the atmosphere. The location of the system is shown on Figures ~~3-6~~ 6-6 and ~~3-7~~ 6-7. (RTC, 11/6/12) The vacuum pressure in the gas extraction wells imparts a vacuum on the soils surrounding each gas extraction well. With the air inlet wells equally spaced between the gas extraction wells, the air inlet forces a "short-

circuiting" of the flow into the gas extraction wells. The "short circuiting" effect creates a preferential flow path between the air inlet and gas extraction wells, thereby allowing the system to "sweep" or "flush" gases migrating from the sludge material laterally without extracting gases from within the sludge (RTC, 9/29/11) (Figure ~~3-8~~ 6-8). (RTC, 11/6/12)

During passive gas extraction, subsurface gas movement is non-existent or very small, allowing barometric pumping and diffusion to vent subsurface gases from the vertical gas migration control wells. (RTC, 9/29/11)

Below-Cap Horizontal Gas Collection System

A horizontal gas collection system (utilizing geostrips) would be placed within the foundation layer of the cap, as discussed above. ~~in Section 3.3.5.1.~~ (RTC, 11/6/12) Similar to the vertical gas migration control wells around the perimeter of the cap, the horizontal gas collection system is designed to initially operate as an active system, during a start-up period of two weeks. The system would then be operated as a passive system, but is designed as a contingent measure to be readily converted to active, if necessary. As a passive system, it would be vented to the atmosphere and rely on barometric pumping and diffusion to vent subsurface gases from the system. The decision to make the system active would be based upon post-cap construction gas monitoring at the Site (RTC, 9/29/11) as described in *Gas Treatment System*, below. (RTC, 11/6/12)

The design of the gas collection system incorporates gas collection geostrips and air inlet geostrips, both connected to separate gas collection and air inlet piping. Piping is connected to the treatment compound where actively extracted gases can be treated prior to discharge to the atmosphere and fresh air can be pulled into the system through the air inlet piping. Gases fluxing out of the sludge and vertically rising to the base of the hydraulic barrier component of the cap will be collected in the continuous gas collection geocomposite layer. Parallel geostrips will allow collected gases to be "flushed" or "swept" from the gas extraction geocomposite to the gas extraction geostrips by allowing fresh air into the air inlet geostrips. Geostrips will convey the collected gases to the gas extraction piping and the treatment compound. (RTC, 9/29/11)

*Gas Treatment System (*RTC, 11/6/12)

The gas extracted from the control system would be treated using specialized granular activated carbon (GAC). Specialized Granular Activated Carbon (GAC) products have been manufactured to include hydrogen sulfide and sulfur dioxide oxidation. Specifically, Calgon Carbon has a number of specialized GAC products for hydrogen sulfide and sulfur dioxide environments. (RTC, 11/6/12)

The gas system will be operated actively for a period of time defined in a future Operations, Maintenance, and Monitoring (OMM) Plan. During initial operation, soil gas data, including constituents extracted and their concentrations, will be collected. The need for active gas collection will be based on the extracted soil gas COC concentrations and associated, calculated health risk goals. If start-up data indicates that COC concentrations are below risk-based trigger concentrations, and therefore, active gas collection is not needed, the system may be converted to a passive system which vents to the atmosphere or is turned off with no venting. (RTC, 4/4/12)

Soil gas samples will be collected from the treatment system and perimeter soil gas probes on a regularly basis to evaluate the operation of the system and/or migration of soil gas. Sample results will be compared to risk-based trigger concentrations developed with the OMM Plan for each COC. Development of the risk-based trigger concentrations will assume soil gas will cause outdoor air to become impacted with COCs; however, the outdoor air concentration used to develop the trigger concentration will be low enough to not result in adverse health effects. Based on the assumed conditions at the Site, if soil gas trigger concentrations are not exceeded, outdoor air concentrations will remain below human-health risk based concentrations. If soil gas concentrations are triggered, the gas collection and treatment system may be activated. (RTC, 4/4/12)

Gas Monitoring System

Multi-level gas migration probes would be placed outside of the perimeter of the cap. The proposed locations of the nine probes are shown on Figure 3-6. The probes are designed to be outside of the vertical gas migration control wells. (RTC, 9/29/11)

The gas probes are shown on Figure ~~3-7~~ 6-7. (RTC, 11/6/12) A total of nine probes were selected based on the average distance between probes of 300 ft to provide multiple locations to detect potential gas migration, if any. (RTC, 2/10/12) Each monitoring location will consist of three nested probes with 1 ft screen lengths at 5 ft intervals for discrete sample collection.(RTC, 9/29/11) The rationale for the location was based on a location outside of the radius of influence of the vertical gas migration control wells and within the property boundary and/or in a location accessible for monitoring which increased or decreased some distances between the probes. For example, probes were placed within the median of Artesia Boulevard rather than in the street to provide a safer location for monitoring. With further refinement of design, the location and number of probes may change with adjustments to the radius of influence of the vertical gas migration control wells and the locations of buildings and utilities for future site development. (RTC, 2/10/12)

Regular monitoring of gas concentrations at the probe locations would be performed before, during, and after system operation. The decision to convert the gas collection systems to an active system would be partially based upon the results of the probe monitoring activities and threshold contaminant concentrations developed in the Operations, Maintenance, and Monitoring (OMM) Plan (RTC, 2/10/12) as described in the *Gas Treatment System* section, above. (RTC, 11/6/12)

6.1.2.5 Institutional Controls

The anticipated institutional controls for the Site would consist of governmental controls, such as zoning and building permit restrictions, proprietary controls that restrict property use, and informational controls. Governmental controls would restrict the zoning of the Site to commercial (as identified in the Artesia Corridor Specific Plan) and prohibit sensitive land uses (i.e., residential, hospitals, schools, or child-care centers), specify building construction requirements (i.e., inclusion of gas control system beneath new structures). Environmental land use restrictions may also be applicable. Proprietary controls would place use restrictions on the Site properties. Restrictions would include future land use, the prevention of excavation or drilling within certain areas of the Site (i.e., within the capped areas), (RTC, 9/29/11) controlled traffic loads over the caps (RTC, 11/6/12), prohibit onsite groundwater extraction for municipal and domestic use (i.e., drinking water purposes), industrial, and agricultural (i.e., irrigation) use, future building location restrictions, provide for potential easements (i.e., for O&M activities) and conveyance of proprietary control restrictions to future property owners (i.e., restrictions "run with the land"). Informational controls would include deed notices on the Site property titles and ensure inclusion of the Site on a California registry of contaminated sites. (RTC, 9/29/11) Land use covenants (LUCs) to place deed restrictions on the site will be filed with the Los Angeles County Recorder's Office and annual LUC restriction inspections will be conducted by DTSC to ensure compliance. (RTC, 4/4/12) The asphalt cap above the sludge within Artesia Boulevard will have increased maintenance to repair cracking and normal wear that increase the permeability. (RTC, 11/6/12)

Furthermore, a Health and Safety Plan (HASP) and Construction Quality Assurance (CQA) Plan would be required to establish minimum health and safety protocol during construction, and provide documentation of proper excavation, cap, and gas control system construction. A Risk Management Plan (RMP) would be developed for the Site to reduce the risk of future construction worker exposure to groundwater if the Site is developed. The RMP would discuss the hazards at the Site, minimum PPE requirements, and notification requirements. (RTC, 9/29/11)

6.1.2.6 Groundwater Monitoring

~~The existing ten groundwater monitoring wells would be properly abandoned prior to commencement of the remedial action. During the remedial action activities an appropriate groundwater monitoring network would be agreed upon with input from the DTSC. After the completion of the remedial action, the future groundwater monitoring wells would be installed. Groundwater monitoring would continue to be performed on a semi-annual basis for a period of 5 years (RTC, 2/7/12)after the remedial controls have been implemented. A typical groundwater monitor well is shown as Detail 3 on Figure 6-9 in the Draft FS (Geosyntec,2011).~~ (RTC, 4/4/12)

Eight of the existing ten groundwater monitoring wells would be properly abandoned prior to commencement of the remedial action. Upgradient wells MW-1A and MW-1B would not be abandoned. (RTC, 4/4/12) During the remedial action activities, an appropriate groundwater monitoring network would be agreed upon with input from the DTSC. After the completion of the remedial action, the future groundwater monitoring wells would be installed. Groundwater monitoring would continue to be performed on a semi-annual basis. A typical groundwater monitor well is shown as Detail 3 on Figure ~~6-9 in the draft FS (Geosyntec, 2011)~~ 6-13.(RTC, 11/6/12)

The future development plans of the Site, which are currently unknown, would control where future monitoring wells would be installed. The well locations of the future monitoring well network would be agreed upon in consultation with the DTSC prior to completion of the remedial action. It is anticipated that the new monitoring wells would be installed shortly after completion of the remedial action. (RTC, 4/4/12)

6.1.2.7 Future Site Development

Following completion of the cap construction, the resulting Site conditions will facilitate the construction of a parking lot and an ingress/egress road to accommodate future commercial development at the Site. The 12-in. thick Class II aggregate base will provide a working surface for construction equipment used for parking lot construction, prevent the accumulation of free water within or below the pavement structure, and affect the rate of load distribution on the cap (Caltrans, 2008). Final landscape development designed in conjunction with the future parking lot above the cap will require the use of above grade planters to prevent biological intrusion into the cap. (RTC, 9/29/11)

The grades and final elevation of the cap have been reduced to allow for a flatter surface on which to construct a parking lot and be a less prominent feature along Artesia Boulevard. As described in Section ~~3.3.5~~ 6.1.2.3 (RTC, 11/6/12), the maximum elevation of the cap will be 25.7 ft amsl and the slopes will vary between 2H:1V and 2

percent. During commercial development of the Site, the slopes of the parking lot can be further reduced by adding fill above the lower portions of the cap, provided drainage from the geocomposite is maintained. Selective fill would allow for a flatter surface and ramp features to facilitate car movement. (RTC, 9/29/11) The cap has been shown to support construction loads at the surface (Appendix D). During final design of the cap, traffic load restrictions will be developed and incorporated into the institutional controls. (RTC, 11/6/12)

6.1.3 Alternative 3 – Capping with Selective Excavation and Stabilization/ Neutralization

Alternative 3 includes the following major elements (Figures ~~6-2~~ 6-9 and ~~6-7~~ 6-10): (RTC, 11/6/12)

- Existing surface removal;
- Consolidation of material;
- Stabilization/neutralization of the current upper 3 feet of sludge in the Cooper Sumps;
- Capping of sludge remaining onsite;
- Installation of gas control and monitoring system;
- Institutional controls; and
- Groundwater monitoring.

Some of these elements were discussed in Section 6.1.2; therefore, ~~the existing surface removal (Section 6.1.2.1), the consolidation of material (Section 6.1.2.2),~~ (RTC, 11/6/12) the installation of the gas control and monitoring system (Section 6.1.2.4), institutional controls (Section 6.1.2.5), and groundwater monitoring (Section 6.1.2.6) will not be repeated herein. Existing surface removal, the consolidation of material, ~~surface covering material removal,~~ (RTC, 11/6/12) sludge stabilization/neutralization, and capping are discussed further in the following sections.

6.1.3.1 Existing Surface Removal

A geomembrane is currently above the Cooper North and South Sumps. Prior to initiating neutralization and stabilization activities, the existing geomembrane will be removed to permit access to the sludge. The reinforced concrete and asphalt covers above the Haack Sump will remain in place. (RTC, 11/6/12)

6.1.3.2 Consolidation of Material

In general, the sludge is contained in the three sumps: Cooper North and South, and Haack. As previously discussed in Section 3.2.1, approximately ~~650~~2,670 (RTC, 1/9/2013) CY of a sludge/soil mixture is located outside of the sumps in the Haack Rework area. To excavate the sludge/soil mixture, approximately ~~3,550~~ 2,450 (RTC, 1/9/2013) CY of overburden will need to be excavated. Additionally, along the eastern property line, a thin layer of sludge exists which appears to be the result of spillage or overflow from the sumps. (RTC, 11/6/12)

The Haack Rework and eastern overflow areas would be consolidated into one of the three sumps prior to capping, and used as fill beneath the cap low-hydraulic conductivity layer (to be discussed in Section 6.1.3.4). Approximately ~~5,120~~5,470 CY (RTC, 1/9/2013) of Haack Rework ~~(2,670 CY)~~(2,670 CY) (RTC, 1/9/2013), Haack Rework overburden ~~(2,450 CY)~~(2,450 CY) (RTC, 1/9/2013), and eastern overflow (260 CY) are anticipated to be placed above the sumps. (RTC, 11/6/12)

Following visual excavation of material from the Haack Rework and eastern overflow, confirmation sampling would be performed to confirm the material was removed. Confirmation sample results would be compared to cleanup goals. Where testing indicates concentrations in excess of cleanup goals, additional material would be removed and consolidated above the sumps. Haack Rework and eastern overflow excavations will be backfilled using soils obtained from unimpacted areas of the site. (RTC, 11/6/12)

6.1.3.3 Stabilization/Neutralization of Cooper North and South Sludge

Stabilization/neutralization of the sludge material would be performed to the top 3 feet of the sludge to solidify the sludge for support of the proposed overlying cap. From the treatability studies performed by Stantec, it was determined that the addition of a 50/50 weight for weight (w/w) mix of calcium hydroxide ($Ca(OH)_2$) and calcium carbonate ($CaCO_3$) at a dosage rate of 20 to 30 percent reagent to sludge mix and 10 percent water neutralizes the sludge material. The addition of 50 percent soil (by weight) to this mix would effectively solidify the waste such that it is no longer susceptible to viscoelastic deformation (Stantec, 2008).

In-situ mixing would be performed through use of an excavator. The sludge on the edges of the sump would be mixed first to establish a foundation for equipment to move inward. Mixing would be performed to the minimum depth to support equipment, which is estimated at 3 feet. Due to the difficulty segregating the sludge and interbedded soil layers, it is assumed both the sludge and soil materials within the top 3 feet would be mixed as sludge. Therefore, the sludge volume used to calculate the

reagent volume was the 2008 sludge volume in the top 3 feet, or 13,500 CY (Stantec, 2008).

Mixing with the reagents and soil (RTC, 11/6/12) would cause bulking of the materials. According to the Treatability Study performed by Stantec, the sumps are expected to bulk 69 percent, based on the mix design specified (Appendix A, Stantec, 2008). Therefore, the bulked materials are anticipated to increase the height of the sumps by approximately 2 feet, resulting in a total treated sludge thickness of approximately 5 feet.

Respirators (or if warranted by conditions, more stringent personal protective equipment such as Self-Contained Breathing Apparatus [SCBA]), engineering controls (potentially tenting over the excavation), and air monitoring may be required to address potential emissions of sulfurous gases from the sludge generated during mixing (Stantec, 2008).

6.1.3.4 Capping of the Sumps

Similar to Alternative 2A, the Alternative 3 cap would consist of foundation, gas collection, barrier, drainage, and protective layers covering the Cooper North and South, and Haack sumps contiguously within the Site boundary; however, the gas collection layer, erosion protection layer, and sheet piling proposed for Alternative 3 are different than Alternative 2A, as described below. As discussed in Section 6.1.2.1, (RTC, 11/6/12) the portion of the Haack sump outside of the Site boundary beneath the sidewalk and Artesia Blvd. is considered to be already capped in this Alternative (Stantec, 2010a). The proposed final grades are shown on Figure ~~6-2~~ 6-10. (RTC, 11/6/12) The Alternative 3 cap is depicted on Figure ~~6-6~~ 6-15 in Details 1-C and 1-D. (RTC, 11/6/12)

Foundation and Gas Collection Layers

The foundation soil and gas collection layers would be placed above the stabilized sludge layer and consist of, from bottom to top, minimum 1 foot of foundation soil, gas collection piping, and a gas collection geocomposite. The minimum 1 ft foundation and gas collection layer will support the low-hydraulic conductivity layer and erosion resistance layer in accordance 22 CCR §66264.228(e)(4). The foundation soil would consist of onsite, impacted soil and Haack Rework material where available. Impacted foundation layer material would be supplemented with soil material imported from offsite. Horizontal gas collection pipes surrounded by gas collection aggregate would be embedded in the foundation layer. Nonwoven geotextile would surround the aggregate to prevent clogging of the aggregate due to fines intrusion. The foundation layer would be graded with 3 percent slopes to accommodate drainage. (RTC, 11/6/12)

Low-Hydraulic Conductivity Layer

The low-hydraulic conductivity layer would be placed above the foundation and gas collection layers and would consist of a geosynthetic clay liner (GCL) and a 60-mil high density polyethylene (HDPE) geomembrane. In accordance with 22 CCR §66264.228(e)(5), the low-hydraulic conductivity layer would reduce the downward migration of precipitation and the upward migration of sludge and gas. (RTC, 11/6/12)

Erosion Resistance Layer

The erosion resistance layer is comprised of a drainage geocomposite and 2 feet of vegetated cover soil. In accordance with 22 CCR §66264.228(e)(10), the drainage geocomposite would prevent hydrostatic head buildup and drain precipitation that has infiltrated the overlying vegetated cover soil toward the outside of the cap and perimeter drainage channels while the vegetative cover soil will be resistant to foreseeable erosion effects by wind-scour, raindrop impact, and runoff. (RTC, 11/6/12)

Along the northern property boundary, limited space is available to allow for grading to install the cap system. As a result, sheet piles would be installed to allow for the vertical rise of the cap without altering Artesia Boulevard or the railroad property. The sheet piles would be installed to an average depth of 18 feet bgs and extend between 4 and 10 feet from the ground surface to accommodate the cap. (RTC, 11/6/12)

Final Cap Topography

The final cover grades are shown on Figure 6-10. The minimum thickness of the cover is ~~6.5~~ 6(RTC, 11/6/12) feet which accounts for the ~~3.5~~ 3-foot stabilization layer (with bulking, 3 ft sludge layer increases to a total thickness of 5 feet) (RTC, 11/6/12), 1-foot (minimum) foundation layer, and 2-foot erosion resistance layer. The maximum cover thickness would be approximately 12.5 feet due to increasing the foundation layer to 9.5 feet to create a cover surface with 3 percent (%) slopes. (RTC, 9/29/11)

The maximum elevation of the cover for Alternative 3 is 35 feet amsl. Artesia Boulevard north of the Haack property has an elevation of approximately 20 feet amsl. Along Artesia Boulevard, the Alternative 3 cap elevation varies from approximately 26 feet amsl to 29 feet amsl resulting in a retaining wall height along Artesia Boulevard between 4 and 10 feet high. (RTC, 9/29/11)

Gas Monitoring System

The gas control and monitoring system is shown on Figures 6-11 and 6-12. The design of the Alternative 3 system is the same Alternative 2A; however, Alternative 3 will incorporate 3-inch solid and perforated polyvinyl chloride (PVC) pipes rather than

geostrips. Pipes are proposed for Alternative 3 because the thicker foundation layer can accommodate the pipes and filter material. (RTC, 11/6/12)

6.1.3.5 Future Site Development

The resulting Site conditions following cap construction will facilitate an open-space end use; however, use as a parking lot may be difficult due to steep slopes around the cap edges. The maximum height of the cap is approximately 34.5 ft amsl or approximately 14.5 ft above the surrounding area (Figure 6-10). Areas around the site are available for future development such as the residential properties to the south. (RTC, 11/6/12)

6.1.4 Alternative 4 – Excavation with Offsite Disposal

Excavation and offsite disposal of the sludge would involve excavating the sludge materials to depths between 0.5 and ~~23.5~~ 17.5(RTC, 11/6/12) feet bgs (Figure ~~6-8~~ 6-16 [RTC, 11/6/12]). Shoring would be required in areas to support the sump walls in locations shown on Figure ~~6-8~~ 6-16, (RTC, 11/6/12) at a minimum. ~~Active dewatering for the duration of excavation would be required to remove perched water and groundwater from the excavation.~~ Active dewatering would be required to remove perched groundwater and shallow groundwater when excavation and backfill are below the water table. Additionally, dewatering would be necessary to remove ponded misting agents. (RTC 1/9/2013) Respirators (or if warranted by conditions, more stringent personal protective equipment such as Self-Contained Breathing Apparatus [SCBA]), engineering controls (potentially tenting over the excavation), and air monitoring may be required to address potential emissions of sulfurous gases from the sludge generated during excavation (Stantec, 2008). Alternative 4 includes the following major elements:

- Concrete and asphalt removal;
- Excavation of sludge material from the (RTC, 11/6/12) Cooper North and South and Haack Sumps;
- Excavation of soil-sludge material from the (RTC, 1/9/2013) (RTC, 11/6/12) Haack Rework Area;
- Transportation to a disposal facility;
- Confirmation sampling;
- Backfill of sumps; and
- Groundwater monitoring.

Groundwater monitoring was discussed in Section ~~6.1.2.5~~ 6.1.2.6, (RTC, 11/6/12) and will not be repeated herein. Surface covering material removal, sludge

stabilization/neutralization, and capping are discussed further in the following sections. These elements are discussed further in the following sections.

6.1.4.1 Concrete and Asphalt Removal

In order to access the Haack sump, the existing 6-inch reinforced concrete slab and 8-inch asphalt pavement would need to be removed. Since the underside of the concrete slab is in contact with the sludge material, after the concrete is demolished, it would be stockpiled onsite to allow for characterization sampling. Representative concrete samples should be collected and analyzed for metals, PAHs, and VOCs. Concrete found to contain metals, PAHs, or metals at concentrations exceeding hazardous waste classification thresholds would require disposal at an offsite hazardous waste facility. If materials are found to be nonhazardous, they may be recycled or disposed of at a nonhazardous facility.

6.1.4.2 Excavation of Sumps

The sumps would be excavated to the maximum depth of sludge as reported during the RI. Based on the boring logs, sludge depth varies between 0.5 ~~foot~~ and ~~23.5~~ 17.5 (RTC, 11/6/12) ~~feet~~ft bgs (RTC, 1/9/2013) (Figure ~~6-8~~ 6-16 [RTC, 11/6/12]) (Stantec, 2008). Where significant overburden is present, such as on the Haack Sump, the overburden may be stockpiled separately, sampled, and used as backfill if testing indicates concentrations of constituents are below cleanup objectives. Using an excavator, sludge and interbedded soil would be mixed with the $Ca(H)_2/CaCO_3$ reagent and loaded directly into trucks for transport to the disposal facility. Due to the difficulty segregating the sludge and interbedded soil layers, it is assumed both the sludge and soil materials would be excavated and managed as sludge. Because of the acid gas generation during mixing, a tent would be necessary around the excavator and working surface to capture and treat the gas during mixing. As discussed in Section ~~6.1.3.2~~ 6.1.3.3 (RTC, 11/6/12), the addition of the reagent would result in bulking of the material. With only the addition of the reagent, it is anticipated bulking of the sludge would be approximately 25% and assuming 15% over-excavation, resulting in a total disposal volume of approximately ~~52,000~~ 45,923 CY or ~~49,900~~ 50,200 (RTC, 11/6/12) tons (based on a bulk density assumption of 81 lb/cy [Stantec, 2008]). It is assumed that the sludge containing 25% admixture will be acceptable as-is for disposal at a landfill permitted to accept non-RCRA hazardous waste such as the Buttonwillow Facility.

During excavation below the groundwater table or within the perched water zones, some dewatering may be necessary. The area where this is most likely is in the Haack Sump near the northern border of the Site. In this region, groundwater entering the excavation would be pumped to a tank where it would be sampled prior to disposal.

6.1.4.3 Excavation of Haack Rework Area

The Haack Rework area would be excavated without the addition of the reagent. Based on the Treatability Study, the rework material is significantly degraded indicating stabilization/neutralization is likely not necessary. Furthermore, the Treatability Study demonstrated that significant quantities of gas are not likely to be produced when the Haack Rework material is disturbed; therefore, a tent system with gas treatment is not necessary (Stantec, 2008).

The Haack Rework overburden would be excavated and stockpiled separately. Similar to the Haack overburden, the overburden material would be sampled and used as backfill if testing indicates concentrations of constituents are below cleanup objectives. Using an excavator, the Haack Rework sludge material would be loaded directly into trucks for transport to the disposal facility.

6.1.4.4 Confirmation Sampling

Following excavation of the sumps and Rework area, confirmation samples would be collected and analyzed for the COCs. Where confirmation sampling indicates ~~impacted~~ sludge (RTC, 11/6/12) material remains, additional material would be excavated in the area represented by the confirmation sample. When confirmation sampling indicates ~~impacted~~ sludge (RTC, 11/6/12) material has been removed, the removal would be considered complete and backfill would be initiated.

6.1.4.5 Backfill of Sumps

Following removal completion, the sumps would be backfilled with ~~onsite material outside of the impacted areas where available.~~ (RTC, 11/6/12) non-impacted, imported soil ~~would be placed if additional material is required~~. (RTC, 11/6/12) The sumps would be backfilled to pre-excavation grades.

6.1.4.6 Transportation to Disposal Facility

The neutralized sludge material would be transported to the Button Willow Facility ~~a disposal facility~~ (RTC, 11/6/12) in covered trucks. This disposal facility was selected because it accepts non-RCRA hazardous wastes containing petroleum. (RTC, 11/6/12) The total volume estimated for disposal includes the sludge volume with interbedded soil calculated by Stantec in 2008, 0.5 foot over-excavation at the base of the sumps, and reagent volume for a total disposal volume of ~~49,900~~ 45,923 CY and the total disposal weight of 50,200 tons. (RTC, 11/6/12) Based on testing performed by Stantec during the treatability study, the neutralized sludge would be disposed at a non-hazardous facility (Appendix ~~A~~ B [RTC, 11/6/12], Stantec, 2008); however, due to avoid potential future disposal liability (RTC, 11/6/12), a non-RCRA hazardous waste

facility, the Buttonwillow Facility, was selected for this Alternative analysis. (RTC, 11/6/12)

7. DETAILED ANALYSIS OF ALTERNATIVES

7.1 General

This section includes a detailed analysis of the final remedial alternatives for the Site. An overview of the nine criteria used for the detailed analysis is presented below.

7.2 Detailed Analysis Criteria

The CERCLA guidance document explains the nine criteria that are used to evaluate each remedial alternative [USEPA, 1988]. The first two criteria relate directly to findings that must be made in the Record of Decision (ROD) for the Site. These are categorized as threshold criteria that a selected remedy must meet.

1. **Overall Protection of Human Health and the Environment** – This criterion requires evaluation of how the alternative achieves and maintains protection of human health and the environment. The overall assessment of protectiveness draws on the assessments conducted under other evaluation criteria, especially long-term effectiveness and permanence, short-term effectiveness, and compliance with ARARs. Evaluation of the overall protectiveness of an alternative focuses on whether an alternative achieves adequate protection and describes how risks posed through each pathway are eliminated, reduced, or controlled through treatment, engineered controls or institutional controls. This evaluation also considers whether an alternative poses any unacceptable short-term or cross-media impacts.
2. **Compliance with ARARs** – This criterion requires an evaluation of how the alternative complies with identified ARARs and applicable advisories or guidance that are "to be considered." ARARs are generally categorized as action-specific, location-specific, or chemical-specific Federal or state-promulgated requirements. A list of potential Federal and state action-specific, location-specific, or chemical-specific ARARs have been identified for the Site and are included in Table 4-2.

The following seven criteria are "balancing" criteria. They represent the primary criteria upon which the detailed analysis is based and that are used to distinguish among alternatives that meet the threshold requirements above. The alternative that strikes the best balance among these seven criteria and that meets the threshold criteria generally is the preferred alternative.

3. **Long-term Effectiveness and Permanence** – Requires evaluation of the long-term effectiveness of the remedial alternative in maintaining protection

of human health and the environment following implementation of the alternative.

4. **Reduction of Toxicity, Mobility, and Volume Through Treatment** – The assessment against this criterion evaluates the anticipated performance of the treatment technologies that the alternative comprises, and assesses their ability to reduce the toxicity, mobility and volume of contaminated materials through the use of treatment.
5. **Short-term Effectiveness** – Requires an assessment of the protection of human health and the environment during construction and implementation of the remedial alternative until RAOs are met. The following factors are addressed as appropriate for each alternative: protection of the community during remedial actions; protection of workers during remedial actions; environmental impacts; and time until remedial response objectives are achieved.
6. **Implementability** – This criterion requires an assessment of the technical and administrative feasibility of an alternative, including the availability of required services and materials to execute the alternative. How each alternative is impacted by the property ownership (i.e., one, large, single property or seven individual properties) will also be discussed.
7. **Cost –** Requires evaluation of the anticipated capital costs and operation and maintenance (O&M) costs of an alternative. For this FS Report, O&M costs are presented in ~~2011~~ 2012 (RTC, 11/6/12) dollars using a ~~7~~ 2 (RTC, 11/6/12) percent discount rate per EPA Guidance (EPA, 2000).
8. **State Acceptance** – Allows for consideration of preferences or apparent concerns by the State of California Department of Toxic Substances Control (DTSC).
9. **Community Acceptance** – Allows for consideration of the community's preferences or concerns regarding remedial alternatives. DTSC formally considers the community's preferences or concerns after this FS Report and proposed plan are prepared.

7.3 Final Remedial Alternatives – Detailed Analysis

7.3.1 General

This section includes the detailed analysis of the four final remedial alternatives presented in Section 6.1 and in Table 6-1. Each alternative is analyzed separately according to the nine criteria listed above. The common elements of the final remedial alternatives are not evaluated as they are the same for each alternative.

7.3.2 Final Remedial Alternative 1– No Action

7.3.2.1 Overall Protection of Human Health and the Environment

The no action alternative does not effectively mitigate potential future risks associated with the ingestion, inhalation, or direct contact of Site soils or soil gas. It does not provide any means for source zone mass removal or containment and would not be protective of human health under the hypothetical future scenario use. Because the no action alternative does not meet the threshold requirement of providing overall protection of human health and the environment, no further analysis of this alternative is performed.

~~7.3.3 Final Remedial Alternative 2 – Capping with Selective Excavation~~

~~*7.3.3.1 Overall Protection of Human Health and the Environment*~~

~~Capping with selective excavation would provide moderate to high overall protection of human health and the environment. The exposure routes for receptors as identified in the HHRA are dermal contact with sludge, ingestion of sludge, and inhalation of soil gas. Selective excavation and consolidation within the sumps would remove the eastern overflow and Haack Rework area with the associated gas risks. The sumps would be capped reducing the risk associated with dermal contact and ingestion. Additionally, a gas control and monitoring system would be installed beneath the cap to control gas which may be generated by the sludge. High overall protection is not achieved with the method due to the source remaining onsite.~~ (RTC, 9/29/11)

~~*7.3.3.2 Compliance with ARARs*~~

~~ARARs potentially applicable to Site remedial actions are shown in Table 4-2. Precautions would be required to ensure that short-term community and worker exposures to dust, noise, truck traffic, and VOC emissions are limited to acceptable levels during soil excavation and handling, per ambient air quality health standards.~~ (RTC, 9/29/11)

~~*7.3.3.3 Long-Term Effectiveness and Permanence*~~

~~The permanent cap with the below-cap and perimeter passive gas control system provides long-term effectiveness. To maintain the long-term integrity of the cap and related remedial measure components, maintenance and monitoring would be provided. If gas monitoring indicates concentrations in excess of acceptable values, the below-cap and perimeter vertical gas migration control wells can be made active, which adds to long-term effectiveness in controlling the migration of gas to the environment.~~ (RTC, 9/29/11)

~~*7.3.3.4 Reduction in Toxicity, Mobility, or Volume Through Treatment*~~

~~The cap design would include a gas collection system that can be connected to a treatment system during start-up and continued use, if necessary, based upon start-up monitoring results. If the gases are treated, some reduction in toxicity would be realized. The cap and Site drainage improvements would provide a reduction in mobility of the waste as infiltration of water would be mitigated. No reduction in waste volume would be realized with the remedial measure~~. (RTC, 9/29/11)

~~Gas transport at the Site occurs as a result of diffusion; therefore, the rate of lateral migration of gas constituents is very low. If necessary, the perimeter vertical gas migration control wells can be activated to collect potentially migrating gases and/or remove in-place gases from subsurface soils. The collected gas can be treated if necessary, which results in reduction of the toxicity of the waste~~. (RTC, 9/29/11)

~~*7.3.3.5 Short-Term Effectiveness*~~

~~The cap construction would provide immediate short-term effectiveness since worker risk is low and impacts on environment are minor (grading operations). Liquid infiltration, gas migration, and physical contact would be controlled upon cap placement. Because the disturbance to the sludge would be limited, hazardous gas generation would be minimal.~~ (RTC, 9/29/11)

~~*7.3.3.6 Implementability*~~

~~Technical implementation of Alternative 2 is relatively easy. The alternative uses conventional construction technologies~~. (RTC, 9/29/11)

~~*7.3.3.7 Cost*~~

~~The estimated capital cost of Alternative 2 is $5,206,314. The estimated net present value of operating and maintenance costs is $1,563,800. Therefore, the total present value cost of Alternative 2 is $6,770,114. Table 7-1 presents a cost breakdown of Alternative 2.~~ (RTC, 9/29/11)

~~*7.3.3.8 State Acceptance*~~

~~State acceptance of Alternative 2 will be assessed during the public comment period.~~ (RTC, 9/29/11)

~~*7.3.3.9 Community Acceptance*~~

~~Community acceptance of Alternative 2 will be assessed during the public comment period~~. (RTC, 9/29/11)

7.3.3 Alternative 2A – Capping with Selective Excavation

7.3.3.1 Overall Protection of Human Health and the Environment

Overall protection of human health and the environment is moderate to high with this remedial alternative. The exposure routes for receptors as identified in the HHRA are dermal contact with sludge, ingestion of sludge, and inhalation of soil gas. Selective excavation would remove the Haack Rework area sludge material that is associated with potential gas risks. The sludge in the three sumps would be capped, reducing the risk associated with dermal contact and ingestion. Additionally, a gas control and monitoring system would be installed beneath the cap to control gas which may be generated by the sludge. High overall protection is not achieved with this method due to the source remaining onsite. (RTC, 9/29/11)

7.3.3.2 Compliance with ARARs

Compliance with ARARS is ~~high~~ moderated (RTC, 1/9/13) with this remedial alternative. ARARs potentially applicable to Site remedial actions are provided in Table 4-2. Precautions would be required to ensure that short-term community and worker exposures to dust, noise, truck traffic, and VOC emissions are limited to acceptable levels during soil excavation and handling, per AQMD standards.(RTC, 9/29/11) This remedial alternative is compliant with the Groundwater ARARs by implementing institutional controls limiting onsite extraction of groundwater. Groundwater data has indicated that the sumps are not contributing to offsite impacts; therefore, institutional controls limiting onsite extraction are sufficient for groundwater ARAR compliance. (RTC, 11/6/12)

At some locations of the Site groundwater in the A-zone may encounter the waste material where excavations are the deepest. Waste impacted groundwater has been documented at Well MW-5A which is located immediately down gradient of the Haack Sump. Where these impacts occur the groundwater is characterized by a lower pH, occurrence of gasoline range hydrocarbons, the occurrence of some volatile organic compounds in the low ppb range, elevated concentrations of some metals and modifications to its inorganic groundwater chemistry. However these impacts are attenuated over a short lateral distance down-gradient of the waste as documented in wells MW-3A and MW-4A which are located within or downgradient of the Site's sumps. Impacts to deeper water bearing zones have not been confirmed as the groundwater impacts observed in Well MW-5A are not observed in the B-zone monitoring wells at the Site and the geochemistry of the two water bearing zones are noticeably different suggesting limited hydraulic communication. (RTC, 1/9/13)

The Bellflower Aquiclude groundwater in the vicinity of the Site is naturally degrade as evidence by the Total Dissolved Solids (TDS) concentrations in the A-zone and the TDS and chloride concentrations in the B-zone which exceed the recommended secondary MCL values as documented in the up-gradient, background wells (wells MW-1A and MW-1B). During development of the Site's existing monitoring wells prior to reinstituting the groundwater monitoring program in 2006, some wells were pumped dry and development operations were halted to allow for recharge. This observation suggests that the two hydraulic zones immediately beneath the Site have limited yield that cannot be sustained over time. The naturally degraded groundwater quality and limited yield of the Bellflower Aquiclude at the Site indicates that human use of the groundwater beneath the Site is not likely. (RTC, 1/9/13)

The California Regional Boards are required to assure that the beneficial uses of municipal and domestic supply are designated for protection wherever those uses are presently being attained. This ARAR requirement may not be applicable to the Site because the groundwater upgradient of the Site is naturally degraded and the beneficial uses requirement is not presently being attained . Institutional controls preventing onsite extraction or use of groundwater should be sufficient for groundwater ARAR compliance. (RTC, 1/9/13)

7.3.3.3 Long-Term Effectiveness and Permanence

Long-term effectiveness and permanence is moderate to high for this remedial alternative. The permanent cap with the below-cap and perimeter passive gas control system provides long-term effectiveness. To maintain the long-term integrity of the cap and related remedial measure components, maintenance and monitoring would be provided. If the Site is developed, the parking lot surface above the cap should be maintained by the future property owner(s) to prevent cracking and/or ponding of surface water. If gas monitoring indicates concentrations in excess of acceptable values, the below-cap and perimeter vertical gas migration control wells can be made active, which adds to long-term effectiveness in controlling the migration of gas to the environment. (RTC, 9/29/11)

Based on its location, the Site is potentially at risk for high ground shaking and liquefaction during an earthquake. High ground shaking would minimally affect this alternative because its planned future use is a parking lot. Liquefaction may result in differential settlement of the cap; however, the differential settlement can be corrected with maintenance of the cap. High ground shaking would minimally affect this alternative because its planned future use is a parking lot; however, veneer stability may be compromised. Damage due to a loss of veneer stability may be repaired with maintenance. (RTC, 11/6/12)

High long-term effectiveness and permanence is not achieved with this method due to maintenance requirements. (RTC, 9/29/11)

7.3.3.4 Reduction of Toxicity, Mobility, or Volume through Treatment

Reduction in toxicity, mobility, or volume through treatment is moderate ~~to high~~ (RTC 1/9/13) with this remedial alternative. The cap design would include a gas collection system that can be connected to a treatment system during start-up and continued use, if necessary, based upon start-up monitoring results. If the gases are treated, some reduction in toxicity would be realized. The cap and site drainage improvements would provide a reduction in mobility of the waste as infiltration of water would be mitigated. (RTC, 9/29/11) ~~No reduction in waste volume would be realized with this remedial measure~~. Waste volume would be reduced with the removal of the Haack Rework material; however, the sludge contained in the Cooper and Haack sumps would not be reduced. (RTC, 1/9/13)

Mobility of the sludge would be reduced with this Alternative. On the Haack Sump, there is evidence of sludge movement from beneath the cap at the edges of the concrete and asphalt cover. The installation of low-hydraulic conductivity layer, associated anchor trench, along with existing soil containment, will minimize the lateral migration of sludge. (RTC, 9/29/11)

Gas transport at the Site occurs as a result of diffusion; therefore, the rate of lateral migration of gas constituents is very low. If necessary, the perimeter vertical gas migration control wells can be activated to collect potentially migrating gases and/or remove in-place gases from subsurface soils. The collected gas can be treated if necessary, which results in reduction of the toxicity of the waste. (RTC, 9/29/11)

7.3.3.5 Short-Term Effectiveness

The short-term effectiveness of Alternative 2A is moderate to high. Cap construction would be performed above the existing surfaces on the Cooper and Haack sumps reducing gas generation, gas migration, and dermal contact risks from the exposed sludge. The Cooper sumps currently have an exposed geomembrane covering the sludge which minimizes dermal contact and gas migration. The high-strength geotextile will be installed above the existing geomembrane in a manner that minimizes damage to the existing liner surface (e.g., hand placement). Prior to the installation of the high-strength geotextile, only limited foot traffic will be permitted above the sumps. (RTC, 9/29/11)

The existing concrete and asphalt surfaces will be maintained above the Haack Sump. The geosynthetic cap components (geostrips, gas extraction geocomposite, GCL, HDPE geomembrane, and drainage geocomposite) will be installed directly above the foundation soil overlying the concrete and asphalt surfaces and anchored outside of the

perimeter of the sumps as identified in the RI, between the Cooper North and Haack Sumps (RTC, 1/9/2013), or to the sheetpile along Artesia Boulevard. The sludge between the Cooper North and Haack Sumps is discontinuous and degraded, and occurs deeper than the proposed anchor trench depth of 3 ft bgs, as identified in the RI. Therefore gas generation due to the construction of the anchor trench between the Cooper North and Haack Sumps is anticipated to be minimal to non-existent. (RTC, 1/9/2013) By maintaining the current concrete and asphalt surfaces, the dermal contact and gas migration risks are minimized during construction. (RTC, 9/29/11)

The short-term effectiveness of Alternative 2A is not high due to the excavation and offsite transport of the Haack Rework material. If the Haack Rework soil material were used as fill beneath the cap, a reduced construction time is achievable as less imported material would be needed. Additionally, there would be a reduced risk of exposure to the public during transport to the final disposal facility. (RTC, 9/29/11)

The cap construction would provide immediate short-term effectiveness since worker risk is low and impacts on environment are minor (grading operations). Liquid infiltration, gas migration, and physical contact would remain controlled due to limited disturbance of the existing surfaces. Because the disturbance to the sludge would be limited, hazardous gas generation would be minimal. (RTC, 9/29/11)

The duration of Alternative 2A, not including preliminary startup of the gas control system, is estimated at approximately 129 calendar days. The estimated construction breakdown schedule is provided in Appendix A. (RTC, 9/29/11)

7.3.3.6 Implementability

Technical implementation of Alternative 2A is relatively easy; however, construction implementation due to the urban setting of the Site, as well as Site size constraints and property owner agreements, create implementation challenges as discussed below. (RTC, 9/29/11)

Urban Setting

Due to the urban setting of the Site, traffic and close proximity to sensitive receptors affect the implementability of Alternative 2A. Traffic will increase the length of time to haul impacted material to an offsite disposal facility and the time to import material such as fill for the foundation layer. Alternative work hours may be proposed to reduce the effects of traffic on construction activities. Close proximity to sensitive receptors concerns are mitigated by leaving the existing surfaces on the sumps in place and by providing continuous monitoring during excavation of the Haack Rework area. The technologies for continuous monitoring are readily available and can easily be deployed at the Site during construction. (RTC, 9/29/11)

Site Size

The majority of the Cooper property contains sludge within the North and South sumps, while approximately one quarter of the Haack property contains the Haack Sump. Of the Haack property not containing the sump, approximately half is sloped and elevated leaving the one quarter available for construction staging and storage. As a result, easements and/or leases may be necessary on the southern Los Angeles Department of Public Works (LADPW) property to provide additional space and additional site ingress/egress. Furthermore, due to the eastern sludge boundary corresponding to the Cooper property boundary, the eastern drainage channel and anchor trench will be located within the LADPW property and will require fill to be placed to maintain and control drainage of that parcel. Additional agreements with the LADPW will be required in order to construct the cap. (RTC, 9/29/11)

By leaving the existing surfaces in place, material may be staged above the Haack Sump while construction is occurring on the Cooper Sumps. Additionally, the reduced fill needed for Alternative 2A requires less imported material and material stockpiling. The lower ground pressure equipment which will be used to place the fill above the high strength geotextile is generally smaller than traditional equipment, thereby requiring less storage space than larger, heavier equipment. As a result, while Alternative 2A has implementation challenges due to the Site size and location, the design of the Alternative 2A cap reduces the effect of the challenges. (RTC, 9/29/11)

7.3.3.7 Cost

The estimated capital cost of Alternative 2A is ~~$4,544,913 $5,774,550,.(RTC, 11/6/12)~~ $5,844,150. (RTC, 1/9/13) However, a cost savings of approximately $314,500 may be achieved by using the Haack Rework soil-sludge material onsite as foundation soil. (RTC, 11/6/12) The estimated net present value of operation and maintenance costs is ~~$1,563,800~~ ~~$2,822,100. (RTC, 11/6/12)~~ $4,882,500 (RTC, 1/9/2013). Therefore, the total present value cost of Alternative 2A is ~~$6,108,713 $8,596,650. (RTC, 11/6/12)~~ $10,726,650. (RTC, 1/9/13) Table 7-1 presents a cost breakdown of Alternative 2A. (RTC, 9/29/11)

7.3.3.8 State Acceptance

State acceptance of Alternative 2A will be assessed during the public comment period. (RTC, 9/29/11)

7.3.3.9 Community Acceptance

During the May 10, 2011 meeting between the DTSC and City of Gardena (City), the City expressed concerns regarding the appearance of Alternative 2 (since removed

[RTC, 9/29/11]) being similar to a "landfill," and the height of the cap being too high. The City expressed the desire that the final remedial alternative be consistent with the vision and goal of future development for the Site. (RTC, 9/29/11)

Alternative 2A is a lower cap option for the Site. The maximum height of the cap is approximately 25.5 ft amsl near the center of the Site. This elevation is approximately 5.5 ft higher than Artesia Boulevard north of the Haack Property. Immediately adjacent to Artesia Boulevard, the maximum height of the cap and associated retaining wall is 23 ft amsl, or 3 ft higher than Artesia Boulevard. The elevation of the cap on the Cooper Property is similar to the elevation of the railroad grade immediately east of the Cooper Property. The final cap surface will consist of Class II aggregate base to support construction of a parking lot consistent with the future commercial development of the Site. Additionally, the cap structure has been designed to support loading associated with traffic and parking. Lower areas of the cap such as drainage channels may be filled to provide a more level surface on which to construct a future parking lot, provided the functionality of the cap is not compromised. (RTC, 9/29/11)

7.3.4 Alternative 3 – Capping with Neutralization/Stabilization and Selective Excavation

7.3.4.1 Overall Protection of Human Health and the Environment

Capping of the partially stabilized/neutralized sludge, combined with selective excavation, would provide moderate ~~to high~~ (RTC 1/9/13) overall protection of human health and the environment. The exposure routes for receptors as identified in the HHRA are dermal contact with sludge, ingestion of sludge, and inhalation of soil gas. Neutralization/stabilization of the sludge would further improve the pH, neutralize acid gases, fixate lead, and provide long-term strength (Stantec, 2008). This Alternative is not ranked higher because (RTC, 1/9/13) the neutralization/stabilization process would require substantial mixing of the sludges, releasing hazardous gases and odors, thereby requiring a tent and gas treatment system to control gas emissions during construction. Selective excavation and consolidation within the sumps would remove the eastern overflow and Haack Rework area with the associated gas risks. Further, this Alternative does not address localized groundwater impacts at the Site (RTC, 1/9/13). The sumps would be capped, reducing the risk associated with dermal contact and ingestion. Additionally, a gas control and monitoring system would be installed beneath the cap to control gas which may be generated by the sludge.

7.3.4.2 Compliance With ARARs

ARARs potentially applicable to Site remedial actions are shown in Table 4-2. Alternative 3 would provide moderate compliance with ARARs. (RTC, 1/9/2013).

Precautions would be required to ensure that short-term community and worker exposures to dust, noise, truck traffic, and VOC emissions are limited to acceptable levels during soil mixing and handling, per ambient air quality health standards.

This remedial alternative is compliant with the Groundwater ARARs by implementing institutional controls limiting onsite extraction of groundwater. Groundwater data has indicated that the sumps are not contributing to offsite impacts; therefore, institutional controls limiting onsite extraction are sufficient for groundwater ARAR compliance. (RTC, 11/6/12) This Alternative does not remediate the groundwater; therefore, this Alternative is not given a "high" ARAR compliance rating. (RTC, 1/9/13)

7.3.4.3 Long-Term Effectiveness and Permanence

The permanent cap with stabilization/neutralization and the below-cap and perimeter passive gas control system provide moderate to high (RTC, 11/6/12) long-term effectiveness. Routine maintenance and monitoring would be provided and would positively contribute to the long-term effectiveness of the remedial measure. If gas monitoring indicates impacts in excess of acceptable values, the below-cap and perimeter vertical gas migration control wells can be made active, which adds to long-term effectiveness in controlling the migration of gas to the environment.

Based on its location, the Site is potentially at risk for high ground shaking and liquefaction during an earthquake. High ground shaking would minimally affect this alternative because its planned future use is open space; however, veneer stability may be compromised. Damage due to a loss of veneer stability may be repaired with maintenance. Liquefaction may result in differential settlement of the cap; however, the differential settlement can be corrected with maintenance of the cap. (RTC, 11/6/12)

7.3.4.4 Reduction of Toxicity, Mobility, and Volume Through Treatment

The toxicity of the sludge would be reduced through stabilization/neutralization by improving the pH, neutralizing acid gases, fixating lead, and providing long-term strength (Stantec, 2008). The cap design would include a gas collection system that can be connected to a treatment system during start-up and continued use, if necessary, based upon start-up monitoring results. If the gases are treated, some reduction in toxicity would be realized. The cap and Site drainage improvements would provide a reduction in mobility of the waste as infiltration of water would be mitigated; hence, migration of liquids from waste would be reduced. An increase in waste volume through bulking would be realized with the remedial measure.

Gas transport at the Site occurs as a result of diffusion; therefore, the rate of lateral migration of gas constituents is very low. If necessary, the perimeter vertical gas migration control wells can be activated to collect potentially migrating gases and/or

remove in-place gases from subsurface soils. The collected gas can be treated if necessary, which results in reduction of the toxicity of the waste.

7.3.4.5 Short-Term Effectiveness

Stabilization/neutralization would require the mixing of the top 3 feet of sludge with $Ca(OH)_2/CaCO_3$. In order to mix the top 3 feet of sludge, the existing cover on the Cooper Sumps would require removal, temporarily increasing the risks associated with the sumps and decreasing the effectiveness of this Alternative. During the exposed period, stormwater could come into contact with the sludge, increasing the volume of materials requiring treatment. While fencing around the Site would be continuously maintained to prevent trespasser entry, animals, such as birds, may enter the Site and either become entrapped in the sludge or potential spread sludge to off-site areas. Additionally, during sludge mixing, ~~As a result,~~ (RTC, 11/6/12)significant quantities of acid gases would be released. Therefore, there may be an increased, short-term risk during mixing activities which would require mitigation through treatment of the acidic gases. The cap construction would provide short-term effectiveness as liquid infiltration, gas migration, and physical contact would be controlled upon cap placement.

7.3.4.6 Implementability

Alternative 3 may be difficult to implement due to the mixing of $Ca(OH)_2/CaCO_3$ compounded with the urban setting of the Site and the Site size. (RTC, 11/6/12) During mixing operations, significant quantities of acid gases would be released which would require treatment. Uncontrolled reactions have been known to occur when neutralizing acid sludges which require constant supervision to prevent the uncontrolled release of hydrogen sulfide gas. (RTC, 11/6/12) A tent would be necessary to contain the gases for treatment prior to discharge to the atmosphere. Due to the size of the sumps, a tent large enough to span the sumps to locations where stable foundations can be achieved may be difficult or impossible to engineer or construct. Similarly to Alternative 2A, the urban setting of the Site increases the impacts the construction would have on area traffic and the proximity to sensitive receptors. Business operations near the Site operate 24-hours a day meaning limiting mixing activities to night-time work only would still affect the public. Significant quantities of neutralizing material as well as soil would need to be imported and stored at the Site; the importing of material could significantly impact traffic as large trucks are forced to enter the Site off Artesia Blvd. Storage at the Site is limited due to the sumps and topography with staging, office, and storage areas limited to the eastern portion of the Haack Property. Stormwater controls or treatment systems, such as retention basins, would be limited by the amount of space at the site. (RTC, 11/6/12)

7.3.4.7 Cost

The estimated capital cost of Alternative 3 ~~is~~ ranges between ~~$11,144,880~~ $11,219,880(1/9/13) and ~~$35,402,274~~ ~~$12,566,880~~ $12,646,280 (1/9/13). This range is due to the variable cost of neutralization admixture, $CaCO_3$ and $CaOH_2$. The costs are highly variable based where the material is sourced from, shipping costs, and construction activities. The high cost variability adds to the low cost rating of this Alternative due to the uncertainty of prices during construction. (RTC, 11/6/12) The estimated net present value of operating and maintenance costs assuming quarterly groundwater and soil vapor probe monitoring for 30 years (RTC, 1/9/2013) is ~~$1,563,800~~ ~~$2,822,100. (RTC, 11/6/12)~~ $4,882,500 (RTC, 1/9/2013). Therefore, the total present value cost of Alternative 3 ~~is $36,966,074~~ ranges from ~~$13,996,980 to $15,388,980. (RTC, 11/6/12)~~ $16,102,380 to $17,528,780 (RTC, 1/9/13). Table 7-2 presents a cost breakdown of Alternative 3.

7.3.4.8 State Acceptance

State acceptance of Alternative 3 will be assessed during the public comment period.

7.3.4.9 Community Acceptance

As discussed in Section 7.3.3.9, the City of Gardena expressed concerns regarding the appearance of Alternative 3 and the desire for a final remedial alternative to be consistent with future development plans. As a result, Alternative 3 has low community acceptance. ~~Community acceptance of Alternative 3 will be assessed during the public comment period.~~ (RTC, 11/6/12)

7.3.5 Alternative 4 – Excavation with Offsite Disposal

7.3.5.1 Overall Protection of Human Health and the Environment

Alternative 4 would provide moderate to high (RTC, 1/9/2013) protection of human and health and the environment by removing the sludge and rework material from the Site. The risk to human health through dermal contact, inhalation, or ingestion would be eliminated because the sludge and rework material would be removed and disposed of offsite. During construction activities and transport of the material, risk to human health and the environment would be increased as significant quantities of acid gases would be released when the sludge is disturbed. Furthermore, there is an increased risk to human health during transport of the material as it would require hauling to a facility where transport would potentially expose many more individuals to the sludge than if it were to remain onsite.

7.3.5.2 Compliance With ARARs

ARARs potentially applicable to Site remedial actions are shown in Table 4-2. Alternative 4 would provide high compliance with ARARs. (RTC, 1/9/2013) ~~Excavation and offsite disposal of sludge can be difficult or impossible to perform in compliance with applicable emissions, disposal, and transportation regulations.~~ (RTC, 1/9/2013) Precautions would be required to ensure that short-term community and worker exposures to dust, noise, truck traffic, and VOC emissions are limited to acceptable levels during soil excavation and handling, per ambient air quality health standards. Poor groundwater quality (as documented in MW-05A immediately adjacent) may be improved as the suspected sludge source is removed. (RTC, 11/6/12)

7.3.5.3 Long-Term Effectiveness and Permanence

Alternative 4 would provide high long-term effectiveness and permanence ~~is effective and permanent~~ (RTC, 1/9/2013) since the impacted material would be removed from the Site.

7.3.5.4 Reduction of Toxicity, Mobility, and Volume Through Treatment

Alternative 4 would provide low to moderate reduction of toxicity, mobility, and volume of the sludge or rework material through treatment. This alternative creates a large amount of waste compared to the other alternatives presented and discussed. This waste should be taken into consideration for evaluating these criteria. (RTC, 1/9/2013) Alternative 4 will ~~not~~ (RTC, 1/9/2013) reduce the toxicity ~~or volume~~ (RTC, 1/9/2013) of the sludge or rework material. The mobility of the sludge would be temporarily increased due to transportation of the sludge, then (RTC, 1/9/2013) reduced since it would be disposed of in an appropriate facility with a bottom liner system. The migration of sludge constituents is further reduced by the admixture prior to transport which was shown to reduce leaching and gas generation during the Treatability Study (Appendix A, Stantec, 2008). The volume of the sludge would double following admixture. Other wastes that would be produced during treatment include impacted groundwater, vapor treatment associated liquid and solid wastes, and decontamination wastes. Taking these wastes into consideration, Alternative 4 would provide low to moderate reduction of toxicity, mobility, and volume of sludge and associated wastes through treatment. (RTC, 1/9/2013)

7.3.5.5 Short-Term Effectiveness

Alternative 4 would provide moderate short-term effectiveness ~~is effective in the short term~~ (RTC, 1/9/2013) by removing the sludge and rework material from the Site; however, in order to neutralize the sludge for off-site disposal, risks associated with the sludge are temporarily increased. Neutralization of the sludge requires deep mixing of

the sludge with $Ca(OH)_2/CaCO_3$. In order to mix the sludge, the existing sump covers would require removal, temporarily increasing the risks associated with the sumps and decreasing the effectiveness of this Alternative. During the exposed period, stormwater could come into contact with the sludge, increasing the volume of materials requiring treatment. While fencing around the Site would be continuously maintained to prevent trespasser entry, animals, such as birds, may enter the Site and either become entrapped in the sludge or potentially spread sludge to off-site areas. Additionally, during sludge mixing, ~~significant~~ large quantities of acid gases, when compared to the other alternatives presented and discussed, (RTC, 1/9/2013) would be released. Therefore, there may be an increased, short-term risk during mixing activities which would require mitigation through treatment of the acidic gases. ~~The cap construction would provide short-term effectiveness as liquid infiltration, gas migration, and physical contact would be controlled upon cap placement. (RTC, 11/6/12~~) (RTC, 1/9/2013)

7.3.5.6 Implementability

Implementability ~~Implementation~~ of Alternative 4 would be low~~challenged~~ (RTC, 1/9/2013) due to the sludge depth, site proximity to sensitive receptors, site size, (RTC, 11/6/12) and site access issues. The majority of the sludge to be excavated is previously undisturbed sludge, which has a less viscous consistency than the degraded soil-sludge material that is proposed to be removed in Alternative 2A and Alternative 3. (RTC, 1/9/2013) As an area is excavated, sludge would flow to the newly excavated portion of the sump. The depth of the excavation would be between 0.5 and ~~23.5~~ 17.5 (RTC, 11/6/12) ~~feet~~ ft bgs (RTC, 1/9/13), depending on the sump, and due to the size of the Site there would not be enough room to slope the sides of the excavation. Therefore, shoring would be required, which would limit the ability to "chase" impacted materials laterally during excavation and obtain side wall conformance samples. Shoring may be used, but due to the discontinuity of sludge material, during mixing of the reagent and sludge, acid gas containment and treatment would be necessary. A tent would be necessary to contain the gases for treatment prior to discharge to the atmosphere. Due to the size of the sumps, a tent large enough to span the sumps to locations where stable foundations may be achieved would be difficult to implement. An equipment hood may provide the necessary containment; however, the working area is limited by the size of the hood.

Similarly to Alternatives 2A and 3, the urban setting of the Site increases the impacts the construction would have on area traffic and the proximity to sensitive receptors. Business operations near the Site operate 24-hours a day meaning limiting mixing activities to night-time work only would still affect the public. Significant quantities of neutralizing material as well as soil would need to be imported and stored at the Site; the importing of material could significantly impact traffic as large trucks are forced to enter the Site off Artesia Blvd. Storage at the Site is limited due to the sumps and

topography with staging, office, and storage areas limited to the eastern portion of the Haack Property. Stormwater controls or treatment systems, such as retention basins, would be limited by the amount of space at the site. (RTC, 11/6/12)

7.3.5.7 Cost

The estimated capital cost of Alternative 4 is high compared to the alternatives presented and discussed, and (RTC, 1/9/2013) ~~is $54,067,350~~ ranges between $26,217,950 and $28,991,650. The costs are highly variable based where the admixture material is sourced from, shipping costs, and construction activities. The high cost variability adds to the low cost rating of this Alternative due to the uncertainty of prices during construction. (RTC, 11/6/12) The estimated net present value of groundwater monitoring costs is ~~$620,500~~ $113,200. (RTC, 11/6/12) Therefore, the total present value cost of Alternative 4 is ~~$54,687,850~~ between $26,331,150 and $29,104850. (RTC, 11/6/12) Table 7-3 presents a cost breakdown of Alternative 4.

7.3.5.8 State Acceptance

State acceptance of Alternative 4 will be assessed during the public comment period.

7.3.5.9 Community Acceptance

~~Community acceptance of Alternative 4 will be assessed during the public comment period.~~ (RTC 9/29/11) During the 10 May 2011 meeting with the DTSC and City of Gardena, the City felt Alternative 4 best achieved their future development goals (RTC, 11/6/12); therefore, this Alternative receives a moderate to high ranking for community acceptance (1/9/2013).

8. COMPARATIVE ANALYSIS OF ALTERNATIVES

8.1 General

In this section, the final remedial alternatives are compared by using the detailed analysis criteria. The purpose of this comparative analysis is to identify the relative advantages and disadvantages of each final remedial alternative and to provide a basis for identifying the preferred remedial alternative.

8.2 Final Remedial Alternatives

8.2.1 General

In Table 8-1, each final remedial alternative is assigned a ranking for each detailed analysis criterion. These rankings range from "low" to "high" and are accompanied by a numeric ranking from 1 to 5 (Note 3, below). At the conclusion of the comparative analysis, the preferred remedial alternative is identified.

8.2.2 Overall Protection of Human Health and the Environment

~~Alternative 1, No Action, does not provide adequate protection of human health and the environment. No further assessment or comparison with this alternative is provided. Alternative 2 would perform better than Alternative 3. While Alternative 3 stabilizes/neutralizes a portion of the sludge, the mixing of the reagent releases hazardous amounts of hydrogen sulfide and sulfuric acid gas. Alternative 4 would provide very good protection of human health and the environment with the removal of the impacted materials; however, because of the risks associated with hazardous gas generation during excavation and transportation of the material, the overall protection is deemed moderate~~. (RTC, 9/29/11)

Alternative 1, No Action, does not provide adequate protection of human health and the environment. No further assessment or comparison with this alternative is provided. Alternative 2A performs better than Alternatives 3 and 4 due to disturbance of only the degraded Haack Rework sludge material. As demonstrated in the Treatability Study and Surface Flux Testing (RTC, 1/9/13) (Stantec, 2007), disturbing the non-degraded sludge results in the generation of significant quantities of hydrogen sulfide and sulfur dioxide. Significant mechanical disturbance of the non-degraded sludge occurs in Alternatives 3 and 4. Both Alternatives 2A and 3 would leave the majority of the sludge onsite, which reduces their overall protection of human health and the environment; however,

---

(3) A numeric ranking of "1" is lowest, or worst; "5" is highest, or best. With respect to cost, "1" is most expensive; "5" is least expensive.

Alternative 4 excavates the sludge from the Site and transports the sludge along public streets and highways en route to final disposal at the Buttonwillow Facility. During transport, the public may become potentially exposed to the sludge due to traffic accidents resulting in a sludge release or gas release from the truck. The same transport risks are not anticipated with transport of the Haack Rework soil-sludge material as proposed in Alternative 2A due to the degraded nature of this sludge and the significantly reduced volume of sludge to be transported. (RTC, 9/29/11)

8.2.3 Compliance With ARARs

~~Alternative 2 would perform better with respect to ARARs due to the reduction of gas emissions when compared to Alternatives 3 and 4.~~ (RTC, 9/29/11)

~~Alternative 2A would perform with respect to ARARs due to the minimal gas emissions, reduced truck traffic, and lack of sludge exposed to air and possible stormwater when compared to Alternatives 3 and 4. (RTC, 9/29/11)~~ (RTC, 1/9/13)

Alternative 4 would perform the best with respect to ARARs due to the removal of the sludge and source for potential onsite groundwater impacts. All Alternatives perform well with respect to ARAR compliance; however, Alternatives 2A and 3 are ranked lower because a potential source for onsite groundwater impacts remains in place. (RTC, 1/9/13)

8.2.4 Long-Term Effectiveness and Permanence

~~Alternative 3 is ranked higher than Alternative 2 with respect to long-term effectiveness and permanence. Both alternatives would be effective and permanent over the long-term with maintenance; however, because Alternative 3 neutralizes the sludge, the treatment is likely more permanent. Alternative 4 provides the greatest long-term effectiveness and permanence since the sludge is removed from the site and disposed of offsite.~~ (RTC, 9/29/11)

Alternative 4 is ranked the highest for long-term effectiveness and permanence because the sludge is removed from the site and disposed of offsite. (RTC, 1/9/13) Alternative 3 is ranked higher than Alternative 2A with respect to long-term effectiveness and permanence. Both alternatives would be effective and permanent over the long term with maintenance; however, because Alternative 3 neutralizes some of (RTC, 11/6/12) the sludge, the treatment is likely more permanent. (RTC, 9/29/11)

Based on its location, the Site is at risk for high ground shaking and liquefaction during an earthquake regardless of the remedial alternative. High ground shaking would minimally affect Alternatives 2A and 3 because of their planned future use as a parking lot or open space, respectively. High ground shaking on Alternatives 2A and 3 slopes

may result in veneer failure and liquefaction may result in differential settlement of the cap. Both the veneer failure and differential settlement can be corrected with maintenance of the cap. (RTC, 11/6/12) Alternative 4 provides the greatest long-term effectiveness and permanence since the sludge is removed from the site and disposed of offsite. (RTC, 9/29/11)

8.2.5 Reduction of Toxicity, Mobility, and Volume through Treatment

~~Alternative 3 would slightly reduce toxicity and mobility through partial in-situ treatment of the source zone; however, toxicity would increase as acid gases are released during mixing of the sludge for treatment. Alternatives 2 and 3 would reduce mobility of the sludge by limiting infiltration and wind erosion. Alternative 4 would reduce the mobility of the sludge after offsite disposal since the disposal landfill would be equipped with a liner system to collect leachate; however, transport of the material would temporarily increase the potential mobility.~~ (RTC, 9/29/11)

Alternatives 2A and 3 would reduce mobility of the sludge by limiting infiltration and wind erosion. Alternative 3 would slightly reduce toxicity and mobility through partial in-situ treatment of the source zone; however, toxicity would increase as gases are released during mixing of the sludge for treatment. The volume of material within the sumps would increase due to bulking during neutralization and increase the cap height by a minimum of 3 ft. In Alternative 3, the net toxic material (non-stabilized sludge) would be reduced. The volume of sludge material in the sumps would remain the same with Alternative 2A. Treatment of sludge with Alternative 4 would double the volume of waste material to be disposed of as well as generate more waste from decontamination water, spent vapor treatment carbon, and ponded dust and emissions control liquid. (RTC, 1/9/13) Alternative 4 would reduce the mobility of the sludge after offsite disposal since the disposal landfill would be equipped with a liner system to collect leachate; however, transport of the material would temporarily increase the potential mobility. (RTC, 9/29/11)

8.2.6 Short-Term Effectiveness

~~Alternative 2 would perform the best with respect to short-term effectiveness. Unlike Alternatives 3 and 4, Alternative 2 does not significantly disturb the sludge thereby minimizing the release of acid gas. Both Alternatives 2 and 3 incorporate a cap into the final design which would provide an immediate reduction in risk due to inhalation, dermal exposure, and ingestion. Alternative 4 would provide a reduction in risk after the sludge was transported offsite; however, risk is temporarily increased in the short-term during sludge disturbance and transport.~~ (RTC, 9/29/11)

Alternative 2A would perform the best with respect to short-term effectiveness. Unlike Alternatives 3 and 4, Alternative 2A does not significantly disturb the sludge, thereby minimizing the release of gas. The existing surfaces, which have been shown to reduce the migration of gas, will remain in place during construction resulting in limited sludge disturbance and therefore, gas generation. Alternatives 2A and 3 incorporate a cap into the final design which would provide a reduction in risk due to inhalation, dermal exposure, and ingestion. (RTC, 9/29/11)

Alternatives 3 and 4 significantly disturb the sludge, which has been demonstrated to generate significant quantities of hydrogen sulfide and sulfur dioxide gas requiring tenting and gas control systems during mixing and excavation operations. The gas control system, incorporating a tent, blower, and treatment system, would significantly increase the amount of time to remediate the Site due to the limited operating space within the enclosed facility. Additionally, waste materials from the treatment system components, such as a scrubber, could generate additional waste, which could increase the total volume of hazardous materials at the Site. (RTC, 11/6/12) The length of time would be increased due to the use of smaller equipment as well as down time during treatment system maintenance. (RTC, 9/29/11)

Alternative 4 would provide a reduction in risk after the sludge was transported offsite; however, risk is temporarily increased in the short-term during sludge disturbance and transport. Given that the weight of material estimated for offsite disposal is approximately ~~49,900 tons and a typical end dump truck capacity is 14 tons, approximately 3,565 truck loads are anticipated for Alternative 4~~ 45,900 CY and a typical end dump truck capacity is 16 CY(RTC, 11/6/12, approximately ~~3,565~~ 2,870 (RTC, 11/6/12 truck loads are anticipated for Alternative 4. Smaller, 16 CY trucks are proposed for Site work due to the limited space available onsite for staging and operating larger trucks (RTC, 11/6/12) Additionally, using the estimated 20 trucks per day discussed in Section ~~3.3.3~~ 6.1.2.2, trucks (RTC, 11/6/12) transport of the sludge would require a minimum of ~~179~~ 160 (RTC, 11/6/12) days for transport, which does not include additional delays due to limitations from tenting and gas control during excavation. (RTC, 9/29/11)

Due to the nature of the sludge disposal within the sumps, Alternative 4 would require the excavated sumps to be exposed for periods of time during confirmation sampling. Temporary backfill of sludge in the interim would generate the potential for non-impacted material to become impacted through contact, thereby increasing the amount of material excavated and the time to remediate. (RTC, 9/29/11)

The durations of the Alternatives are estimated at 129, 235, and 301 calendar days for Alternatives 2A, 3, and 4, respectively. The construction duration of Alternative 2A is approximately half of Alternative 3 and 4 times less than Alternative 4, meaning the

potential exposure time of sludge hazards to workers is significantly reduced. Additionally, the construction impacts on the community including truck traffic and visual distractions are significantly reduced with Alternative 2A. The estimated construction schedules are provided in Appendix ~~A~~ (RTC, 9/29/11) E.(RTC, 11/6/12)

8.2.7 Implementability

~~Alternatives 3 and 4 pose significant implementation issues due to the gas generation during mixing and excavation of the sludge. Gas control and treatment would be necessary during mixing and excavation of the sludge. Construction of a tent to contain the gases would be difficult to perform due to low bearing capacity of the sludge and the area the tent would need to span (minimum of the Cooper North sump). Gases captured by the tent would need treatment prior to discharge. (RTC, 9/29/11)~~

~~Alternative 2 is relatively easy to implement. A stabilization layer on the Cooper sumps would be placed first to provide a surface in which to install the foundation and gas collection, barrier, and cover layers. Disturbance of the sludge would be limited to the eastern overflow and Haack Rework, which are significantly degraded and would release significantly less acid gas than the sludge in the Haack and Cooper Sumps (Appendix A, Stantec, 2008). The materials necessary for construction are available and do not require admixtures or special equipment.~~ (RTC, 9/29/11)

All Alternatives are difficult to implement due to the site location and size; however, the design of Alternative 2A limits the effects of these challenges on construction. These challenges are discussed in further detail below: (RTC, 9/29/11)

Urban Setting

Due to the urban setting of the Site, traffic and close-proximity to sensitive receptors affect the implementability of all Alternatives. Traffic will increase the length of time to haul impacted material to an offsite disposal facility and the time to import construction materials such as fill. (RTC, 9/29/11)

Alterative 2A requires the least amount of imported and exported material, thus reducing overall truck traffic on Artesia Boulevard. Both Alternatives 3 and 4 require significant truck traffic to import stabilization material as well as, in the case of Alternative 4, export sludge offsite. As discussed previously in Section 6.1.4.2, 3,565 truck loads are estimated for transport of excavated sludge to an offsite facility, which could negatively affect the traffic flows in the vicinity of the Site. (RTC, 9/29/11)

Site Size

The majority of the Cooper property contains sludge in the North and South sumps, while approximately one quarter of the Haack property contains the Haack Sump. The

portion of the Haack property not containing the sump is split into a sloped and elevated portion and a flatter portion that could be available for construction staging and material storage. Furthermore, easements and/or leases may be necessary on the Los Angeles Department of Public Works (LADPW) property for grading and fill placement to provide for surface water flow and collection, as well as providing additional space and additional site ingress/egress. (RTC, 9/29/11)

Alternatives 3 and 4 require stockpiling of stabilization material; therefore, the time for stabilization is directly proportional to how much material is available onsite to mix. If only limited quantities of material are available onsite due to storage area constraints, the length of time to implement Alternatives 3 and 4 will increase. (RTC, 9/29/11)

Site Proximity to Sensitive Receptors

Alternatives 3 and 4 pose significant implementation issues due to the gas generation during mixing and excavation of the sludge and the potential impacts to neighboring sensitive receptors. Gas control and treatment would be necessary during mixing and excavation of the sludge. Construction of a tent to contain the gases would be difficult to perform due to low bearing capacity of the sludge and the area the tent would need to span (minimum of the Cooper North sump). Gases captured by the tent would need treatment prior to discharge. In addition, the size of the tent and treatment system would further reduce the space available on the Site to stage construction including equipment storage, stockpiling of fill material, and construction facilities. (RTC, 9/29/11)

Implementation of Alternative 2A has fewer engineering and health and safety complications. By maintaining the existing surfaces, gas generation from the sumps would be minimized and continuous monitoring with readily available vapor suppression equipment will provide a means to minimize potential effects of gas generation during excavation in the Haack Rework area. In addition, Alternative 2A requires less imported material and material stockpiling, thus reducing the effects of traffic and the reduced Site size on construction. As a result, while Alternative 2A has implementation challenges due to the Site size and location, the design of the Alternative 2A cap reduces the effect of the challenges. (RTC, 9/29/11)

8.2.8 Cost

~~Alternative 2 has the lowest capital of approximately $5,206,314 and O&M cost, with Alternatives 3 and 4 having comparable capital costs of $35,402,274 and $54,067,350, respectively. Alternatives 2 and 3 have identical net present value O&M costs of approximately $1,563,800. Alternative 4 has the lowest net present value O&M cost of approximately $620,500. Alternative 2 has the lowest combined remedial cost.~~ (RTC, 9/29/11)

Alternative 2A has the lowest capital cost of approximately ~~$4.5~~ $5.8 million, with Alternatives 3 and 4 having ~~having comparable~~ low-range capital costs of approximately ~~$35.4~~ $11.1 million and ~~$54.1~~ $26.2 million, respectively and high-range costs of approximately $12.6 and $29.1 million. (RTC, 11/6/12) Alternatives 2A and 3 have identical net present value O&M costs of approximately ~~$1.6~~ $2.8 million. (RTC, 11/6/12) Alternative 4 has the lowest net present value O&M cost of approximately ~~$0.6 million~~ $113,200. Alternative 2A has the lowest combined remedial cost and is not dependent on the highly variable neutralization admixture cost which may vary from as low as $300/ton to as high as $750/ton or more. (RTC, 11/6/12)

8.2.9 State Acceptance

In accordance with USEPA guidance, this criterion will be addressed when DTSC is making its final remedial decision and the ROD is being prepared.

8.2.10 Community Acceptance

~~In accordance with USEPA guidance, this criterion will be addressed when DTSC is making its final remedial decision and the ROD is being prepared.~~ (RTC, 9/29/11)

During the May 10, 2011 meeting between the DTSC and the City, the City expressed concerns regarding the appearance of the former (RTC, 11/6/12) Alternative 2 being similar to a "landfill," and the height of the cap being too high. The City expressed the desire that the final remedial Alternative be consistent with the vision and goal of future development for the Site. (RTC, 9/29/11)

Alternative 2A provides a reduced cap thickness, and accounts for future use as a parking lot subgrade consistent with the City's vision for commercial development. Alternative 3 proposes a cap sloping upward to a maximum elevation of 35 ft amsl, which makes parking lot construction more difficult above the high grades and slopes of the Site. Alternative 4 proposes the Site is excavated and filled. Alternative 4 best incorporates the City's vision for commercial development; however, given the potential health risks associated with implementation, short-term effectiveness, and cost challenges, Alternative 2A provides the best compromise to meet the City's development vision. (RTC, 9/29/11)

8.3 Preferred Remedial Alternative

~~Based on the comparative analysis of the remedial alternatives, the alternative that meets the RAOs and ranks the highest is Alternative 2, capping with selective excavation. The elements of Alternative 2 are~~: (RTC, 9/29/11)

- ~~Prepare a construction Health and Safety Plan and Construction Quality Assurance Plan;~~ (RTC, 9/29/11)
- ~~Place a 3.5-foot stabilization layer across the Cooper North and South sumps consisting of gravel, sand, and geocell; (RTC, 9/29/11)~~
- ~~Excavate the Haack Rework area, segregating the overburden soil from the sludge/soil mixture;~~ (RTC, 9/29/11)
- ~~Install retaining wall (sheet pile) along northern perimeter (Artesia Blvd);~~ (RTC, 9/29/11)
- ~~Place the Haack Rework material and other site soils as the foundation layer above the stabilization layer with horizontal gas collection pipes embedded. The foundation layer would increase in thickness and would be graded such that the final surface would drain at 3 percent to the cap perimeters;~~ (RTC, 9/29/11)
- ~~Install vertical gas migration control wells;~~ (RTC, 9/29/11)
- ~~Install geosynthetic layers consisting of, from bottom to top, a gas collection geocomposite, GCL, 60-mil HDPE geomembrane, and drainage geocomposite~~; (RTC, 9/29/11)
- ~~Place 2 feet of cover soil above the geosynthetics;~~ (RTC, 9/29/11)
- ~~Install groundwater monitoring wells;~~ (RTC, 9/29/11)
- ~~Operate the below-cap gas collection system and the perimeter vertical gas migration control well system as active systems for a period of at least 2 weeks. Following the start-up period, operate the below-cap gas collection system and vertical gas migration control well system passively. During passive operation, monitor the performance of the proposed alternative remedial measure with a system of perimeter gas migration sentry wells outside the limit of the perimeter vertical gas migration control wells. If the monitoring data indicate significant gas migration from the waste, convert the system to active gas control and, if required, include gas treatment;~~ (RTC, 9/29/11)
- ~~Prepare a Risk Management Plan;~~ (RTC, 9/29/11)
- ~~Perform semi-annual groundwater monitoring; and~~ (RTC, 9/29/11)
- ~~Complete a formal review of remediation effectiveness after five years.~~ (RTC, 9/29/11)

~~This remedial alternative effectively mitigates the risk from ingestion, inhalation, and dermal contact with onsite soils for both future non-residential and residential occupants of buildings on site, and future landscapers and utility workers. This alternative also~~

~~effectively mitigates the risk from dermal contact with site groundwater through the cap and institutional controls including the Health and Safety Plan and Risk Management Plan.~~ (RTC, 9/29/11)

~~Alternative 2 readily meets the criteria of overall protection of human health and the environment and satisfies ARARs. When evaluated against the balancing criteria, Alternative 2 provides short-term effectiveness as well as long-term effectiveness and permanence. It is readily implementable and presents an effective balance of cost against the other criteria. Alternative 2 also would accommodate future potential redevelopment of the Site~~. (RTC, 9/29/11)

~~Figures 6-2 through 6-7 demonstrate the conceptual design of Alternative 2 and are for the purposes of evaluating costs in this Feasibility Study. The overall height of the cap may be reduced by alternatives such as flatter final cap slopes and a narrower stabilization layer which will be evaluated and presented in the Remedial Action Plan (RAP). The final design for Alternative 2 will be presented in the RAP~~. (RTC, 9/29/11)

Based on the comparative analysis of the remedial alternatives, the alternative that meets the RAOs and ranks the highest is Alternative 2A, capping with selective excavation. The elements of Alternative 2A are (RTC, 9/29/11):

- Prepare a construction HASP and CQA Plan;
- Prepare a Risk Management Plan;
- High-strength geotextile installation;
- Select excavation of impacted material;
- Containment of sludge along Artesia Boulevard;
- Capping of sludge;
- Installation of gas control and monitoring system;
- Institutional controls;
- Perform semi-annual groundwater monitoring; and
- Complete a formal review of cap effectiveness after five years. (RTC, 9/29/11)

This remedial alternative effectively mitigates the risk from ingestion, inhalation, and dermal contact with onsite soils for future non-residential occupants of buildings onsite, and future landscapers and utility workers. This alternative also effectively mitigates the risk from dermal contact with Site groundwater through the cap and institutional controls including the Health and Safety Plan and Risk Management Plan. (RTC, 9/29/11)

Alternative 2A readily meets the criteria of overall protection of human health and the environment and satisfies ARARs. When evaluated against the balancing criteria, Alternative 2A provides short-term effectiveness as well as long-term effectiveness and permanence. It is implementable and presents an effective balance of cost against the other criteria. Alternative 2A also would accommodate future potential redevelopment of the Site. (RTC, 9/29/11)

Figures ~~3-1~~ 6-1 through ~~3-10~~ 6-8, 6-13, and 6-15 (RTC, 11/6/12) demonstrate the conceptual design of Alternative 2A and were prepared for the purposes of evaluating costs in this Addendum. The design for Alternative 2A will be presented in the Remedial Action Plan. (RTC, 9/29/11)

TABLE 8-1
COMPARATIVE ANALYSIS OF ALTERNATIVES
Gardena Sumps, Gardena, California

Geosyntec consultants

Alternative	Description	Overall Protection of Human Health and the Environment	Compliance with ARARs	Long-term effectiveness and permanence	Reduction of toxicity, mobility, or volume	Short-term effectiveness	Implementability	Cost	Total
Alternative 1	Score:	1	1	1	1	2	5	5	16
	No Action: no ongoing maintenance of geomembrane, asphalt, or concrete covers or fencing.	Low: Current geomembrane cover provides limited protection of human health and the environment. Asphalt and concrete caps provide protection of human health and the environment. Without on-going maintenance of caps which is not included with the alternative, protection of human health and the environment is limited.	Low: Does not provide compliance with ARARs.	Low: Caps are not effective over long-term without on-going maintenance.	Low: Toxicity, mobility, and/or volume are not reduced with this option.	Low to moderate: The caps and fenced conditions provide some short-term effectiveness as contact with the sludge is reduced through the clean cover (Haack Rework), geomembrane (Cooper Sumps), and concrete (Haack Sump).	High: Easy to implement	Low: No associated cost	
~~Alternative 2~~	~~Score:~~	~~4~~	~~5~~	~~4~~	~~3~~	~~5~~	~~4~~	~~3~~	~~28~~
	~~Capping with selective excavation: Excavated Haack Rework and consolidated beneath composite cap system above sumps.~~	~~Moderate to high: Exposure routes would be eliminated through capping; however, source would remain onsite.~~	~~High: complies with ARARS.~~	~~Moderate to high: With maintenance, will provide long-term protection.~~	~~Moderate: Reduces mobility of sludge by limited infiltration and wind erosion. Gas treatment will reduce the toxicity of the waste. Volume will not be reduced.~~	~~High: Immediate short-term effectiveness with little gas generation.~~	~~Moderate to high: Technical implementation is relatively easy.~~	~~Moderate~~	
Alternative 2A (RTC, 9/29/11)	Score:	4	~~5~~ 3 (RTC, 1/9/13)	4	3	5	4	3	26
	Capping with selective excavation: Excavate Haack Rework and dispose offsite (RTC, 9/29/11)	Moderate to high: Exposure routes would be eliminated through capping; however, source would remain onsite. (RTC, 9/29/11) Gas would not be generated during implementation of this Alternative. (RTC 1/9/13)	~~High: complies with ARARS. (RTC, 9/29/11)~~ Moderate: complies with ARARS but requires additional monitoring and treatment to do so.(RTC, 1/9/13)	Moderate to high: With maintenance, will provide long-term protection. (RTC, 9/29/11)	Moderate: Reduces mobility of sludge by limited surface water infiltration and wind erosion. Gas treatment will reduce the toxicity of the waste. Onsite volume will be reduced. (RTC, 9/29/11)	High: Immediate short-term effectiveness with little gas generation. (RTC, 9/29/11)	Moderate to high: Technical implementation is relatively easy. (RTC, 9/29/11)	Moderate (RTC, 9/29/11)	
Alternative 3	Score:	~~4~~ 3 (RTC, 1/9/13)	3	4	3	2	1	2	18
	Capping with partial stabilization/neutralization and selective excavation: Partially stabilize/neutralize sludge, excavate Haack Rework and consolidate beneath composite cap system above sumps.	Moderate ~~to high~~ (RTC, 1/9/13): Exposure routes would be eliminated through capping; however, source would remain onsite and gas generation would be high during mixing and stabilization (RTC, 1/9/13)	Moderate: complies with ARARS but requires additional monitoring and treatment to do so.	Moderate to high: With maintenance, will provide long-term protection, some sludge is neutralizaed reducing long-term concerns with untreated sludge remaining.	Moderate: Reduces mobility of sludge by neutralization, limited infiltration and wind erosion. Gas treatment and partial neutralization will reduce the toxicity of the waste. Overall volume will increase but toxicity will be reduced.	Low to moderate: Mixing of materials will release significant quantities of gas; however cap will provide immediate short-term effectiveness.	Low: Difficult to implement due to gas generation and mixing	Moderate to high: Costs associated with partial neutralization/stabilization and gas treatment	
Alternative 4	Score:	~~3~~ 4 (RTC, 1/9/13)	~~3~~ 5 (RTC, 1/9/13)	5	2	3	1	1	21
	Excavate impacted materials and dispose with off-site.	~~Moderate~~ Moderate to High (RTC, 1/9/13):Sludge and rework material would be disposed of offsite eliminating the exposure routes; however, excavation and transport of material temporarily increases risk with gas generation and public exposure.	~~Moderate: complies with ARARS but requires additional monitoring and treatment to do so.~~ High: Complies with ARARS (RTC, 1/9/13)	High: Very effective as material is removed from the Site.	Low to moderate: ~~The toxicity and/or volume are not reduced; however, the mobility is reduced.~~ The toxicity is reduced but volume is doubled. Mobility is significantly increased when material is exposed, excavated, and hauled on public roads for final disposal. (RTC, 1/9/13)	Moderate: Removal will result in immediate effectiveness; however, excavation will generate significant gas and transport will expose public to hazards.	Low: Difficult to implement due to material properties and gas generation	High: Costs associated with partial neutralization/stabilization, gas treatment, transport, and disposal	

Notes:
ARARs - Applicable or Relevant and Appropriate Requirements
State Acceptance and Community Acceptance criteria will be assessed during comment periods and are not presented in this table.
Ranking - A numeric ranking of "1" is lowest, or worst; "5" is highest, or best. With respect to cost, "1" is most expensive; "5" is lease expensive

Transmittal: **Response to Comments on the Revised Final Draft Feasibility Study Report**
Gardena Sumps Site
Southwest Corner of Artesia Boulevard and Normandie Avenue
Gardena, California
DTSC Site No. 400067

Dear Mr. Cully:

Geosyntec Consultants (Geosyntec), on behalf of the Atlantic Richfield Company (ARC), is pleased to provide this response to Department of Toxic Substances Control's (DTSC) comments on the Revised Final Draft Feasibility Study Report (Revised Final Draft FS). These responses were prepared to address the DTSC comments dated 23 May 2013 and received 3 October 2013. The DTSC comments are provided below in *italics* with ARC's response following. The updated text of the Revised Final Draft Feasibility Study Report is provided as Attachment 1.

COMMENTS

1. No further comment.

2. No further comment.

3. No further comment.

4. ESPO still believes there is significant value in conducting an excavation pilot study before the final remedy is selected, as the volume and concentrations of hydrogen sulfide and sulfur dioxide generated by various construction activities has major implications for each of the

alternatives reviewed. Alternative 2A relies on not disturbing sludge, thereby not generating gases, to prevent unacceptable exposures during construction. If some of the assumptions underlying Alternative 2A are found to be in error, unacceptable volumes of gases could be generated quickly. The contingency plan that will be required for the implementation phase will have to account for this possibility and include measures to contain gases and protect the public. The more uncertainty there is with gas generation and effective containment measures the more conservative the contingency plan must be, possibly including personnel and equipment kept onsite for immediate response should monitoring action levels be exceeded (see HERO response to DTSC 1/9/13 comment 8). Testing of different containment/mitigation measures would be part of the pilot study. Alternatives 3 and 4 assume gases will be generated, and therefore contain additional measures not included in Alternative 2A, but would also benefit from a pilot study.

A discussion of a gas contingency plan has been included in the Alternative 2A Haack Rework Excavation description. The initial excavation of the Haack Rework area would provide the same information that would be generated from a pilot study. During initial excavation, odor suppressants and PPE would be present, as identified in the Contingency Plan. Continued excavation would be modified as necessary based on gas generation experienced during initial excavation.

5. No further comment.

6. The response to comment states that over 50 years of traffic loading have not induced sludge related detriment to the roadway as indicated by the lack of specific pavement repairs above the sludge. Please provide the rationale for requiring low permeability asphaltic concrete in the roadway.

The low permeability asphaltic concrete is included in response to a comment posed by ESPO in September 2012. The comment, which related specifically to the off-site sludge beneath the adjacent roadway pavement, was “Given that a permanent cap is proposed as a remedy for the onsite sludge please clarify the basis of the assumption that this material is capped and provide analysis showing that the cover on this material would provide the same level of protection and for the same duration as the proposed onsite cap.” (Geosyntec, 2013, Appendix A) A low-permeability asphalt could be incorporated into the Institutional Control requirements to provide similar protection as the onsite cap. Current asphalt paving may remain in place until the next scheduled pavement maintenance.

7. No further comment.

8. ESPO will defer to HERO as their comment on the response adequately expresses our continued concerns.

Noted.

9. It appears that with a six-foot thick cover, the high strength geotextile would only be needed during construction. This is acceptable provided a minimum cover thickness to support future parking lot loads (H20 loading is indicated) is maintained. We could not find much information on the Wasser Polyflex 304 product suggested for use in sheet pile corrosion protection. Please include information on this product indicating its corrosion protection performance and expected life in a low pH environment such as exists at Gardena Sumps (this information may be appended to the document). (Gathungu)

The six-foot thick cover is part of Alternative 3 while the high-strength geotextile is included for Alternative 2A. Alternative 2A will support H-20 loading as demonstrated in the calculation package included in Attachment 2. Information on the Wasser Polyflex 304 is included as Attachment 3.

10. No further comment.

11. No further comment.

12. No further comment.

13.The individual volumes in the second paragraph total 5,380 CY (as stated in the RTC), not 5,470. The text should be corrected.

The text has been revised to reflect 5,380 CY.

14. The response is satisfactory with respect to corrosion and gas generation but may be difficult to implement. The text should be revised to indicate the placement of the Haack material in the sumps will be tracked (and documented) and procedures/requirements will be implemented during construction to ensure the material is not placed in areas where the gas collection system will be constructed. If Alternative 3 is chosen as the preferred remedy, details of the tracking and other construction requirements will need to be submitted to DTSC for approval/concurrence.

Section 6.1.3.2 has been revised to include a statement that Haack Rework and overflow material placement above the sumps will be tracked and documented to demonstrate the material is not in contact with the gas collection layer.

21. No further comment.

22. The text states that a preliminary evaluation of ground shaking was performed and liquefaction was identified as a potential site response. The text further states that settlement and subsidence was shown to be minimal. Please include a numerical value, or range, for the calculated settlement and subsidence. The text states that sand boils would not occur through the sludge due to the low permeability of the sludge and relatively high permeability of the soil around the sumps. However, the critical condition would be occurrence of "sludge boils" rather than sand boils. Please discuss the potential for "sludge boils" to occur. The text further states that lateral spreading to the south of the engineered cap caused by liquefaction-induced soil displacement at the Dominguez Channel was identified as a possibility. Please discuss any measures that should be taken to address this condition and include costs of implementing these measures in the cost estimates. (Gathungu)

Based on recommendations in Idriss and Boulanger (2008), typical liquefaction-induced volumetric strain (or settlement) is on the order of 5% or less. Conservatively assuming the upper bound of anticipated strain and a liquefiable layer thickness ranging from approximately 15 to 23 feet, calculated liquefaction-induced settlement is on the order of 9 to 14 inches. Based on a review of available subsurface explorations, the presence of potentially liquefiable material at depth at the site is relatively uniform and differential settlement resulting from liquefaction is expected to be significantly less than total liquefaction induced settlement. Based on a review of

the liquefiable zone thickness in individual cone penetration test (CPT) borings and the distance between the borings, differential settlement will result in post-settlement grades less than 2 percent; however, reverse grades resulting in ponding are unlikely at the Site.

Development of sand boils occurs when water flows upward to relieve excess pore pressures developed at depth during rapid loading conditions. Sand boils are most likely to develop in liquefied areas where inhomogeneity in soil type and permeability are present (e.g, low permeability confining layers promote buildup of excess pore pressures which may be locally relieved through an isolated higher permeability zone). The low permeability and low viscosity of the Cooper Sumps sludge at the Site (permeability of less than 1.0×10^{-8} cm/sec, viscosity approximately 20,000 poise at 60F [Stantec, 2008]) reduces the potential for development of sludge boils within the waste footprint. Potential pore pressure buildup in the liquefiable zone beneath the sludge would likely be relieved through the higher permeability zones outside of the sludge footprint rather than through the low permeability sludge. Based on the viscous nature of the sludge material (similar to a tar) at the Site, the potential for liquefaction of the sludge material at the site is considered low.

While lateral spreading to the south toward the Dominguez Channel was identified as a possibility for the site, the likelihood of this affecting the integrity of the engineered cap is considered low due to the distance between the cap and the north side of the channel and the geometric limitations of the Dominquez Channel to accommodate soil movement. Mitigation of impacts due to potential lateral spreading will be evaluated during overall site development as its potential effect on the caps is minor relative to the effect on buildings developed near the channel.

23. No further comment.

24. ESPO disagrees with the response and believes reduction of toxicity, mobility, or volume through treatment should be rated low, as originally stated. ESPO notes this issue is minor in the overall context of the feasibility study and can be revisited at a later time if necessary.

Noted. The ranking remains as moderate due to the removal of the Haack Rework and reduced mobility of the sludge and soil gas.

25. ESPO could not find a figure that provides the location of the high-strength geotextile anchor trench. Please provide a figure (similar to 6-2) that depicts the high-strength geotextile anchor trench location in detail sufficient to allow us to evaluate its elevation above the sludge on

Section A of Figure 6-3, or inform us which existing figure contains this information, so we may complete our review. Also, the response states an anchor trench depth of three feet while section 6.1.2.3 states this anchor trench will be two-foot by two-foot. Please clarify and revise the response or report as necessary.

The high strength geotextile anchor trench is a minimum of 2 feet deep and is shown on Detail 7 on Figure 6-14.

26. No further comment.

27. No further comment.

28. The text states that preliminary analyses of the site during a seismic event do not indicate the potential of surface release of sludge. Please expand this response to indicate the seismic parameters (magnitude, fault system, acceleration, etc.) used in the analyses. (Gathungu)

To develop seismic parameters for the site, Geosyntec performed a probabilistic seismic hazard analysis (PSHA) using the 2008 beta version of the United States Geological Survey (USGS) software and fault parameter database. An average shear wave velocity for the upper 30 meters of soil of 520 meters per second was used based on a review of subsurface explorations presented in the Revised Draft Remedial Investigation (Stantec, 2008). The PSHA for a 10 percent probably of exceedance in 50 years (475-year return period) indicated a peak ground acceleration of 0.34g representing a modal magnitude 7.4 event. The PSHA used does not identify a single fault that will cause a seismic event at the site, but rather incorporates all of the potential seismic sources that could contribute to ground shaking at the site.

29. The restatement of ESPO's original comment has errors in the rankings for the individual sections that should be corrected for clarity.

Noted. The ranking should have been:

7 .3.5.1 high

7.3.5.2 high

7.3.5.3 high

7.3.5.4 high

7.3.5.5 low

7.3.5.6 low

7.3.5.7 low

7.3.5.8 moderate to high

7.3.5.9 moderate to high (based on statements from the city)

30. No further comment.

31. No further comment.

32. ESPO still believes a rating of high is appropriate for this section. The revised text in section 7.3.5.4 states the volume of the sludge would double following admixture. Per section 6.1.4.2, bulking of the sludge due to addition of the reagent is expected to be 25 percent, not 100 percent. The text in section 7.3.5.4 should be revised to be consistent with section 6.1.4.2. The increased volume will result in additional disposal costs but overall the site will see a reduction in volume from this alternative. The revisions to the text regarding a temporary increase in mobility are more appropriate for section 7.3.5.5, and have already been made, and should be deleted from this section.

The volume of waste would increase by a minimum of 25 percent due to the admixture addition; an additional 15 percent over-excavation is anticipated during sludge and admixture removal. A ranking of moderate has been given to this Alternative due to the additional waste streams that would be created during implementation. During implementation, air treatment systems would be necessary for treatment of vapors being generated during neutralization and waste handling. The air treatment systems would incorporate a scrubber system which would routinely require change-outs resulting in an additional waste material requiring disposal. Further, odor suppression systems typically include spray-applied foams, which will add a minor amount to the waste disposal volume. During excavation, groundwater would be encountered. Groundwater would be removed from the excavation and disposed of in accordance with applicable regulations. Further, soil and sludge below the groundwater surface would need to be dewatered onsite to remove excess liquid before hauling and disposing of the material at a landfill; the water removed from the soil and sludge would require solidification or collection and treatment before disposal. As a result, more waste is generated with Alternative 4 from: waste bulking, air

scrubber systems, odor suppressants, and groundwater dewatering. We have updated the text in Sections 7.3.5.4 and 8.2.5 to reflect an anticipated 25% to 40% increase in waste volumes.

33. No further comment.

34. No further comment.

35. No further comment.

36. The response refers to "degraded soil-sludge" material and "previously undisturbed sludge". This would appear to imply that degradation of sludge/soil-sludge materials has occurred. While sludge materials may have been mixed with soil in some areas, it is not clear that degradation of the sludge-soil has occurred. In addition, Alternative 3 involves stabilization of the upper three feet of sludge beneath the existing temporary cover/membrane which likely is previously undisturbed, and therefore would generate gas similar to excavation in Alternative 4. (Gathungu)

The Haack Rework Area contains both sludge and mixtures of sludge-soil material. Physical testing of the sludge from the North Cooper Sump, South Cooper Sump and Haack Rework Area was performed during the treatability testing of the sludge material as part of the Remedial Investigation. The sludge samples from the Haack Rework Area were shown to be previously disturbed and thus degraded as evidenced by their higher moisture content, lower acidity and greater viscosity than the sludge samples from the two Cooper Sumps. Further evidence of this degradation was shown by the vapor evolution tests where the sulphur dioxide and hydrogen sulfide gas emitted from agitated Haack Rework Area sludge was reduced by more than 95% compared to emissions from agitated Cooper Sumps sludge. Neutralization and stabilization of the sludge presented in Alternative 3 would generate significant quantities of hydrogen sulfide and sulfur dioxide gas.

37. No further comment.

38. ESPO believes the estimate of 40 feet for the zone of influence is optimistic but has no further comments regarding this issue for the feasibility study.

Noted.

39. No further comment.

40.The text states that the cover was evaluated for H20 loading of 80 psi at the cap surface and found to be acceptable. The load capacity of the cover is dependent on cover thickness. We note that the proposed minimum cover thickness is on the order of two feet for Alternative 2A. Please include the minimum cover thickness used in the evaluation as well as the applicable factor of safety. In addition, if the total cover thickness required to support the indicated loading will require a parking lot structural pavement section thicker than would otherwise be required, the report should indicate the minimum structural pavement section that will be required along with the feasibility of final cover/pavement grade elevations that may be required. (Gathungu)

The calculation package that demonstrates the cover can support H20 loading is included as Attachment 2.

41. Given the level of settlement experienced at other sites (Del Amo, McColl, and Thomas Ranch) with similar materials, the text should include an estimate of the expected settlement at the Gardena Sumps site and discuss expected effects on the proposed cap and the proposed parking Jot pavements. The associated repair/maintenance costs should be included in the cost estimates. (Gathungu)

The settlement at the Thomas Ranch Site was a maximum of 6.84 inches in the middle of Pond 2 as provided in the Response to Comments dated 12 April 2013 (Geosyntec, 2013). This settlement was the result of porous gravel layer settling into the sludge and sludge subsequently filling the gravel pore spaces within the first three years (some of this settlement occurred during construction). This settlement does not represent the anticipated settlement at the Gardena Sumps Site because the proposed cap does not have a gravel layer above the sludge. The Del Amo Site has seen between -0.10 and 0.08 feet of elevation change over a five year period (2000 to 2005) (EPA, 2005). McColl has experienced no significant settlement (USACE, 2007).

Settlement and creep was questioned by Perry Myers in his comments dated 6 September 2012. Our response was as follows:

> "Settlement and creep of the cap is anticipated to be negligible. Settlement is driven by consolidation of soils through deformation of soil particles, relocation or reorientation of soil particles, and expulsion of liquids (water and/or air) from the soil matrix. The tarry sludge material found within is of such a high viscosity that the material does not readily flow into the adjacent soil matrix. Therefore, the sludge material will not exhibit settlement from expolsion of liquids. Furthermore, the solid particles found within the sludge matrix are

> enveloped in fluid like, high viscosity materials that allow relocation and reorientation of solid particles but the volume of the overall sludge matrix is not changed significantly. This is evident in the fact that the Haack Sump concrete pavement has not settled over the past 14 years. Concrete cracking is evident, but likely related to durability and shrinkage rather than settlement. Last, previous capping projects like McColl, Del Amo, and Thomas Ranch sites containing similar sludge materials have not indicated significant settlement. Settlement and creep that occurs can be corrected with minor maintenance during the life of the cap. Upon completion of the closure construction, the sludge material will be insulated from direct sunlight and ambient temperature increases; therefore, the softening of the sludge will cease to be a problem once the cap is in place. The costs associated with the creep and settlement maintenance are included with the maintenance costs." (Geosyntec, 2013)

42. See response to comment #22.

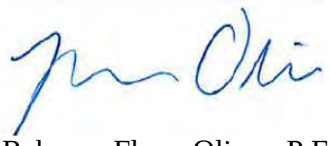
New ESPO comments

43. Section 8.2.5 Reduction of Toxicity, Mobility, and Volume through Treatment. The text states the volume of waste material to be disposed of would double with Alternative 4. Per section 6.1.4.2, bulking of the sludge due to addition of the reagent is expected to be 25 percent, not 100 percent. The text should be revised to be consistent with section 6.1.4.2.

The text has been revised to reflect an expected bulking of between 25 and 40 percent.

44. Section 8.2.8 Cost. The operations and maintenance costs for alternatives 2A and 3 have not been updated to reflect the new cost estimates included in Attachment 2. The text should be revised.

The text has been revised.



OPTIONAL ALTERNATIVE 2A COVER

In addition to incorporating the DTSC's comments as noted above, the Revised Final Draft Feasibility Study has also been updated to include the Optional Alternative 2A Cover design. The Addendum to the Revised Final Draft Feasibility Study for the Gardena Sumps Site: Optional Alternative 2A Cover (Addendum) was prepared in response to concerns with the height and appearance of the proposed retaining wall along the northern edge of the Haack Sump and a portion of the Cooper North Sump. The retaining wall was eliminated and grading in the

area affected by the elimination of the retaining wall (the "Optional Alternative 2A Cover") was revised to accommodate a minimum 5 percent (%) slope draining to the north and terminating at a 6 to 9 inch (in.) concrete curb immediately adjacent to the Artesia Boulevard (Blvd.) sidewalk (Revised Alternative 2A). The curb will deter unintended light traffic across the slope, act as a water-stop for drainage from the slope, and accommodate the slight variations in the existing Haack Sump concrete slab surface elevation. The Addendum will be included as Appendix F to the Updated Revised Final Draft FS and is included as Attachment 4 to this response to comments.

If you have questions or require additional information about the enclosed report, please contact Mr. Kyle Christie with ARC at 714-670-5303.

EXECUTIVE SUMMARY

This Revised Final Draft (RTC, 11/6/12) Feasibility Study (FS) Report was prepared for the Gardena Sumps Site (Site) in Gardena, California. This FS Report was prepared for submittal to the California Environmental Protection Agency (CalEPA), Department of Toxic Substances Control (DTSC) in accordance with the California Health and Safety Code. The FS Report is a requirement of Consent Decree CV04-7882-AHM (JTLx), (Consent Decree). This Revised Final Draft FS incorporates the comments and requests made by the DTSC on the original draft FS dated February 2011 and the Draft Feasibility Study Addendum – Alternative 2A (Addendum). Revisions to the original Draft FS resulting from the Addendum and comments are shown as either strike out (deletions) or underline (additions) with the corresponding comment package date at the end. (RTC, 11/6/12)

Background

The Site is located in the southwest corner of the Artesia Boulevard and Normandie Avenue intersection in the City of Gardena, Los Angeles County, California. Generally, the area surrounding the Site is bordered to the south by the Los Angeles County Department of Public Works (LACDPW) Dominguez Flood Channel, to the east by the Southern Pacific Railroad right-of-way, to the west by the western Haack property line, and to the north by Artesia Boulevard, although a small portion of Artesia Boulevard is included within the Site. Commercial and residential properties are currently located to the north, east, and west of the Site (Stantec, 2008).

The site was developed as a clay mine during the 1920s by the Moneta Brick Company. Clay mining resulted excavations that were ~~in what are known as the Haack, Cooper South, and Cooper North sumps and Haack Rework Area~~ reportedly used for sludge disposal beginning in approximately ~~at the Site. These sumps were reportedly used for sludge disposal beginning in March~~ (RTC, 11/6/12) 1940. By September 1946, the Haack, Cooper South and Cooper North Sumps had been ~~and two Cooper sumps were~~ (RTC, 11/6/12) filled with sludge, and vegetation had reclaimed ~~the small pit and~~ (RTC, 11/6/12) the Haack Rework Area (Stantec, 2008).

By December 1951, the western portion of the Haack Sump had been covered with dirt and was converted into a parking lot. On October 1, 1952, the northern-most strip of the Site ~~Haack~~ (RTC, 11/6/12) property was sold to the State of California for a highway easement. By early 1956, Artesia Boulevard (Highway 91) had been constructed, with the southern portion of the roadway encroaching into the Haack Sump northern berm. By January 1958, the Dominguez Channel had been reconstructed and extended eastward south of the Site (Stantec, 2008).

By November 1962, the bluff on the Haack Property (RTC, 11/6/12) had been excavated to expand the Haack ~~paved~~(RTC, 11/6/12) parking lot, although the eastern portion of the Haack property contained sludge ~~remained a vegetated area~~ (RTC, 11/6/12) immediately west of the Cooper North Sump. The Haack Rework Area appeared altered and may have received soil cover from excavation activities that occurred immediately north of the Haack Rework Area. The future Cooper property was unchanged even after it was sold to Thomas Cooper in December 1977 (Stantec, 2008).

Currently, the two Cooper sumps are capped by a geosynthetic material that was installed by OHM Corporation (OHM) in July 1993 as part of the DTSC's environmental program at the Site. The Haack Sump has been covered by asphalt and a concrete slab. Currently the Haack property is leased to various tenants who operate small businesses, including a U-Haul rental agency, a metal fabricating, sand blasting and painting company, and an auto body repair shop. Three buildings and numerous small trailer-type storage structures are present on the Haack property (Stantec 2008).

Geology and Hydrogeology

The Site is located in the Los Angeles Coastal Plain and is underlain by a thick sequence of marine and continental sediments that were deposited in a broad synclinal depression generally referred to as the Los Angeles Basin. The Los Angeles Basin is bisected by the northwest trending Newport-Inglewood uplift, which divides the Coastal Plain into two smaller synclinal troughs. The Site is located in the West Coast Basin, which constitutes the southwest portion of the Los Angeles Basin (Stantec, 2008).

The Site is located near the junction of the Torrance Plain and the Dominguez Erosion Gap. The Torrance Plain runs west of and parallel to the hills of the Newport-Inglewood uplift from the Ballona Gap southeast to the Dominguez Gap. The Plain is a broad featureless area only slightly dissected locally by the Dominguez Creek (Dominguez Channel) (Stantec, 2008).

According to boring logs in the Ecology and Environmental, Inc. (EEI) (1986), Metcalf and Eddy (1992), CalEPA (1994) and URS (1994) reports, sediments underlying the Site, to the maximum explored depth of 92 feet below ground surface (ft bgs), consist primarily of a mixture of clays and silts with interbeds of sand (Stantec, 2008).

The Site is underlain by the Bellflower Aquiclude at the ground surface, and beneath that, the Gardena and/or Gage Aquifers of the Lakewood Formation within the larger, West Coast Groundwater Basin. Regionally, the Bellflower Aquiclude contains interfingered zones of permeable and less permeable sediments with modest to relatively high hydraulic conductivity. Little beneficial use is made of water in these

shallow, discontinuous hydraulic zones because well yields tend to be low and water quality generally poor (CalDWR, 1961).

Immediately beneath the site, there are two hydraulic zones within the Bellflower Aquiclude: Zone A (upper) and Zone B (lower), which are approximately 15 to 25 and 75 to 80 ft bgs, respectively. Site groundwater monitoring wells are screened within these two zones (Stantec, 2008). Presently the shallow groundwater beneath the Site is influenced by the concrete lined Dominguez Channel and flows southward (Stantec, 2010c).

Beneath the Lakewood Formation are the Lynwood and the Silverado Aquifers, which are capable of storing or conveying groundwater in significant quantities and constitute major sources of groundwater in the West Coast Groundwater Basin. While these aquifers are designated as primary and secondary sources of domestic water supply, neither the Gardena nor Gage Aquifers are currently pumped for domestic use (Stantec, 2008).

The area surrounding the Site is urbanized, with surface waters that drain via storm drains into the Dominguez Channel. The upstream portion of the modern day Dominguez Channel originates several miles west-northwest of the Site, and it drains surface water to the southeast where it discharges to the Cerritos Channel of the Los Angeles Harbor. Historically, the Dominguez Channel flowed along a natural channel bed located approximately several hundred feet west and north of the Site, where it flowed eastward into Laguna Dominguez. Surface water at the Site generally drains towards the north and east following site topography, and is intercepted by a flood control storm drain located at the northeast corner of the Site adjacent to the intersection of Artesia Boulevard and Normandie Avenue (Stantec, 2008).

Contaminant Distribution

During the 2006, 2008, and 2009 Remedial Investigation (RI) activities, Stantec collected subsurface soil, sludge, surface water, groundwater, perched groundwater, soil gas, and soil vapor flux samples to identify the nature and extent of contamination. Results of the sampling activities are summarized in the following paragraphs.

Sludge

The Cooper North and South Sumps have a maximum thickness of 17.5 ft and 13.5 ft, respectively, while the Haack Sump varies in thickness from 0.5 to 3 ft to depths up to 14.6 ft bgs. Based on analytical results, attenuation of sludge was typically 1 to 7.5 ft below the bottom of the sludge (Stantec, 2008). The sludge volumes in the sumps are

6,700 cubic yards (cy), 7,000 cy, and 2,250 cy in the Cooper South, Cooper North, and Haack Sumps, respectively (Stantec, 2010c).

The Haack rework area consists of deposited sludge, soil, and debris in discontinuous and mixed layers beneath a soil cover with thickness varying from less than 1 foot to 10 feet. Stantec calculated approximately 650 cy of material is in the Haack Rework Area (Stantec, 2010c).

Constituents identified in the sludge included volatile fuel hydrocarbons (VFHs), total extractable hydrocarbons (TEHs), volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), polynuclear aromatic hydrocarbons (PAHs), Title 22 metals, mercury, and hexavalent chromium.

Surface Water

Surface water samples were collected upstream and downstream of the Site from the Dominguez Channel in 2006 and 2008. Analytical data from surface water samples indicated elevated concentrations of gasoline range organics (GRO) and VOC analytes in contrast to the non-detections for those analytes in groundwater monitored at the Site. Based on the organic chemical parameters, the Site is not impacting surface water quality in the channel.

Soil Gas

The soil gas investigation activities evaluated the subsurface concentrations of VOCs, hydrogen sulfide, and methane at various locations across the Site for use in the baseline human health risk assessment (HHRA). Constituent concentrations reported above the detection limit for targeted VOCs include benzene, toluene, ethylbenzene, m-,p-,o-xylenes, 1,3,5-trimethylbenzene, and Freon 113. Methane and hydrogen sulfide were also detected in samples collected during the 2006 RI activities.

Soil Vapor Flux

Air pathway analysis (APA) was performed on ambient air samples, exposed disturbed and undisturbed sludge on the Cooper property, soil on both the Cooper and Haack properties, and asphalt and concrete slab-covered soil on the Haack property. Results of the APA indicated methane and select VOCs were present in ambient air likely due to industrial activities on the Haack property and sludge on the Cooper property. The undisturbed sludge had low to moderate emissions, while the disturbed condition can be generally characterized as having moderate to high area source emissions. Odor analyses confirmed the potential for sulfuric compounds from disturbed sludge to create nuisance odors to people in the area or downwind of the disturbed sludge. The infiltration analysis in locations above cracks and seams in the asphalt and concrete

indicated that the individual compound emissions are greatly affected by the surface coverings and slab.

Groundwater

The *First Quarter 2010 Groundwater Monitoring Report* identified nine of ten groundwater monitoring wells as having no detectable concentrations of GRO, VOCs, or PAHs above the Reporting Limit (RL). Samples from MW-05A had detections of GRO and VOCs above the RL. SVOCs were reported in wells MW-01A, MW-01B, and MW-02A. Generally, groundwater samples from onsite wells have a pH ranging between 4.5 and 8.0. Metals detected in samples collected from the groundwater wells included barium, arsenic, cobalt, copper, nickel, and zinc.

Perched Groundwater

~~Perched groundwater in the Haack Sump area is suspected to be the result of leaking utilities.~~ (RTC, 9/29/11) Perched groundwater has been detected at several locations beneath the Site. Total metals detected above primary and/or secondary MCLs included: antimony, arsenic, beryllium, cadmium, chromium, copper, nickel, selenium, and zinc. Dissolved metals above primary and/or secondary MCLs included: nickel and zinc. Benzene was detected in a perched groundwater sample below the MCL, and some SVOCs were detected above the detection limit but below the RL.

Treatability Study

A treatability study was conducted by Stantec to define and evaluate the physical and chemical characteristics of the sludge and evaluate neutralization/stabilization options. Acidity, wet density, moisture, viscosity, softening point, and leaching were evaluated on untreated sludge samples. Different reagent mixes were tested with the sludge to evaluate their neutralization/stabilization ability. Thermal treatment and asphaltic recycling were also evaluated during the treatability study.

The treatability study indicated the following:

- The acidity of the sludge ranged from 6.1 to 20.8 percent by weight;
- The densities for the samples ranged from 63 lb/ft^3 to 79 lb/ft^3;
- The average moisture of the sludge ranged from 9.8 to 22.3 percent on a wet basis;
- The sludge is highly viscous, ranging from 1.7×10^6 to 2.5×10^6 centipoises (cP) at a reference temperature of 140ºF;

- The softening point of the sludge varied from 158ºF for samples collected from the Cooper property to over 210 ºF for samples collected from the Haack Rework area;
- A mixture of 50 percent hydrated lime ($Ca(OH)_2$) and 50 percent calcium carbonate fines ($CaCO_3$) with the addition of 10 percent water and 50 percent soil by weight effectively solidifies the sludge, fixates lead, and neutralizes acid gases such as hydrogen sulfide (H_2S) and sulfur dioxide (SO_2);
- Disrupting or heating the sludge will result in the release of H_2S and SO_2 gases, but the release of VOCs from the sludge should be minimal unless the sludge is heated;
- The SPLP extracts for untreated sludge contained detectable lead, but lead was below the detection limits in SPLP extracts for treated sludge;
- The permeability of the untreated sludge was less than $1x10^{-8}$ cm/sec due to the monolithic, asphaltic properties of the untreated sludge, but the permeability of the material increased to $9x10^{-3}$ cm/sec after treatment;
- The sludge has a high BTU value of 13,000 BTUs/lb, but the high sulfur content of the sludge (7 percent sulfur) would make incineration or use of the sludge as a fuel prohibitively expensive due to sulfur-removal and vapor treatment requirements; and
- Testing for asphaltic qualities of the sludge indicates that it will be unsuitable for use as recycled asphalt for road construction or roofing since it has no ductility, high viscosity, and high solids content.

Feasibility Study Process

The Feasibility Study (FS) process is specified by the USEPA. The purpose of the FS process is to provide sufficient information on potential remedial options so that informative treatment decisions can be made. The FS process consists of developing remedial alternatives, screening those alternatives, and then performing a detailed analysis of the most applicable alternatives. The steps to this process include:

- Developing Remedial Action Objectives (RAOs) based on the results of the RI, HHRA, and future site use;
- Identifying and selecting applicable remedial technologies for soil based on effectiveness, implementability, and cost;
- Developing alternatives from the retained remedial technologies that satisfy the RAOs;

- Screening the alternatives and performing a detailed analysis of each of the final alternatives; and
- Performing a comparative analysis of the final alternatives sufficient to provide the information necessary to select an appropriate remedy for the site.

Remedial Action Objectives and Cleanup Criteria

RAOs are goals specific to various media and apply to those media that have been identified as posing an unacceptable risk based on the HHRA work performed for the Site. The RAOs for onsite soils, soil gas, and groundwater are:

- Prevent ingestion/direct contact with sludge and/or soil having 10^{-5} to 10^{-6} excess cancer risk from carcinogenic constituents as represented by arsenic, hexavalent chromium, naphthalene, and the BaP-eq concentration;
- Prevent dermal contact with shallow groundwater having 10^{-5} excess cancer risk from carcinogenic polycyclic aromatic hydrocarbons (PAHs) as represented by dibenz(a,h)anthracene;
- Prevent dermal contact with low pH, PAH containing sludge (RTC, 2/10/12);
- ~~Prevent inhalation of benzene posing excess cancer risk levels of 10^{-5} to 10^{-6}~~ (RTC, 9/29/11);
- Prevent inhalation of volatile organic compounds (VOCs), as represented by benzene, posing excess cancer risk levels of 10^{-5} to 10^{-6} (RTC, 9/29/11); and
- Prevent explosive risks associated with methane. (RTC, 9/29/11)

Applicable Remedial Technologies

Potentially applicable technologies for soil remediation were screened based on effectiveness, implementability, and cost. The remedial technologies determined to be most applicable to the Site are:

- No action;
- Institutional controls;
- Treatment:
    - Stabilization/neutralization
- Containment;
- Excavation and removal for offsite disposal; and
- Engineered controls:
    - Vapor and gas control systems; and

- Groundwater monitoring.

Other technologies identified but eliminated from further consideration are:

- Treatment:
  - Thermal treatment and
  - Sludge recycling

These technologies were eliminated primarily due to their ineffectiveness as identified during the treatability study.

Development of Remedial Alternatives

Four alternatives were developed from the retained remedial technologies:

- Alternative (A) 1 – No action: This consists of no remedial actions or institutional controls to address soils above target cleanup levels;
- ~~A 2 – Capping with selective excavation: This alternative consists of excavating the Haack Rework area and a portion of sludge overflow along the eastern Cooper sump and consolidating the materials above the Cooper North and South Sumps. A cap consisting of a stabilization layer, foundation layer, low-hydraulic conductivity layer, and erosion resistance layer would be constructed above the sumps. A gas control and monitoring system would be installed beneath the cap and around the sumps, and groundwater monitoring would remain ongoing. Institutional controls consisting of a Health and Safety Plan (HASP), Construction Quality Assurance (CQA) Plan, and Risk Management Plan (RMP) would be implemented.~~ (RTC, 9/29/11)
- A 2A – Capping with selective excavation: This alternative consists of excavating the Haack Rework area and disposing of the sludge (RTC, 11/6/12) material offsite. A cap consisting of a high strength geotextile, foundation layer, low-hydraulic conductivity layer, and erosion resistance layer would be constructed above the sumps. A gas control and monitoring system would be installed beneath the cap and around the sumps, and groundwater monitoring would remain ongoing. Institutional controls consisting of a Health and Safety Plan (HASP), land use covenants (LUCs), Construction Quality Assurance (CQA) Plan, and Risk Management Plan (RMP) would be implemented. (RTC, 9/29/11)
- A 3 – Capping with selective excavation and stabilization/neutralization: This alternative includes mixing the top three feet of sludge in the Cooper North and South Sumps with reagent to stabilize/neutralize the sludge. The Haack Rework area and a portion of sludge overflow along the eastern Cooper sump would be

mixed with the stabilized/neutralized material. A cap consisting of a foundation layer, low-hydraulic conductivity layer, and erosion resistance layer would be constructed above the Cooper North and South and Haack Sumps. A gas control and monitoring system would be installed beneath the cap and around the sumps, and groundwater monitoring would remain ongoing. Institutional controls consisting of a Health and Safety Plan (HASP), Construction Quality Assurance (CQA) Plan, and Risk Management Plan (RMP) would be implemented.

- A 4 – Excavation with offsite disposal: This alternative includes excavation of sludge with disposal offsite. The sludge would be mixed with the neutralizing agent and loaded into trucks for disposal offsite. Major components of this alternative include concrete and asphalt removal, excavation and mixing of sludge, transportation to the disposal facility, confirmation sampling, sump backfill, and groundwater monitoring.

Detailed Analysis of Alternatives

The CERCLA guidance document explains the nine criteria that are used to evaluate each remedial alternative [USEPA, 1988]. The first two criteria are categorized as threshold criteria that a selected remedy must meet:

- Overall Protection of Human Health and the Environment; and
- Compliance with ARARs.

The following seven criteria are “balancing” criteria. They represent the primary criteria upon which the detailed analysis is based and that are used to distinguish among alternatives that meet the threshold requirements above:

- Long-term Effectiveness and Permanence;
- Reduction of Toxicity, Mobility, and Volume Through Treatment;
- Short-term Effectiveness;
- Implementability;
- Cost;
- State Acceptance; and
- Community Acceptance.

State and community acceptance are evaluated following public comment on the FS Report.

Overall Protection of Human Health and the Environment

Alternative 1, No Action, does not provide adequate protection of human health and the environment. No further assessment or comparison with this alternative is provided. Alternative ~~2~~ 2A (RTC, 9/29/11) would perform better than Alternative 3. While Alternative 3 stabilizes/neutralizes a portion of the sludge, the mixing of the reagent releases potentially hazardous amounts of hydrogen sulfide and sulfuric acid gas. Alternative 4 would provide very good protection of human health and the environment with the removal of the impacted materials; however, because of the risks associated with hazardous gas generation during excavation and transportation of the material, the overall protection is deemed moderate.

Compliance with ARARs

Alternative ~~2~~ 2A (RTC, 9/29/11) would perform better with respect to ARARs due to the reduction of gas emissions when compared to Alternatives 3 and 4.

Long-term Effectiveness and Permanence

Alternative 3 is ranked higher than ~~2~~ 2A (RTC, 9/29/11) with respect to long-term effectiveness and permanence. Both alternatives would be effective and permanent over the long-term with maintenance; however, because Alternative 3 neutralizes a portion of the sludge, the treatment is likely more permanent. Alternative 4 provides the greatest long-term effectiveness and permanence since the sludge is removed from the site and disposed offsite.

Reduction of Toxicity, Mobility, and Volume Through Treatment

Alternative 3 would slightly reduce toxicity and mobility through partial in-situ treatment of the source zone; however, toxicity would increase as acid gases are released during mixing of the sludge for treatment. Alternatives ~~2~~ 2A (RTC, 9/29/11) and 3 would reduce mobility of the sludge by limiting infiltration and wind erosion. Alternative 4 would reduce the mobility of the sludge after offsite disposal since the disposal landfill would be equipped with a liner system to collect leachate; however, transport of the material would temporarily increase the potential mobility.

Short-term Effectiveness

Alternative ~~2~~ 2A (RTC, 9/29/11) would perform the best with respect to short-term effectiveness. Unlike Alternatives 3 and 4, Alternative ~~2~~ 2A (RTC, 9/29/11) does not significantly disturb the sludge, thereby minimizing the release of acid gas. Both Alternatives ~~2~~ 2A (RTC, 9/29/11) and 3 incorporate a cap into the final design which would provide an immediate reduction in risk due to inhalation, dermal exposure, and

ingestion. Alternative 4 would provide a reduction in risk after the sludge was transported offsite; however, risk is temporarily increased in the short-term during sludge disturbance and transport.

Implementability

Alternatives 3 and 4 pose significant implementation issues due to the gas generation during mixing and excavation of the sludge. Gas control and treatment would be necessary during mixing and excavation of the sludge. Construction of a tent to contain the gases would be difficult to perform due to low bearing capacity of the sludge and the area the tent would need to span (minimum of the Cooper North sump). Gases captured by the tent would need treatment prior to discharge.

Alternative ~~2~~ 2A (RTC, 9/29/11) is relatively easy to implement. A stabilization layer on the Cooper sumps would be placed first to provide a surface in which to install the foundation and gas collection, barrier, and cover layers. Disturbance of the sludge would be limited to the eastern overflow and Haack Rework Area, which are significantly degraded and would release significantly less acid gas than the sludge in the Haack and Cooper Sumps (Appendix A, Stantec, 2008). The materials necessary for construction are available and do not require admixtures or special equipment.

All Alternatives are difficult to implement due to the Site's urban setting, size, and proximity to sensitive receptors; however, the design of Alternative 2A limits the effects of these challenges on construction. The urban setting with high traffic flows will be impacted with the significant truck traffic entering and exiting the site with imported soil and exported waste. Alternative 2A limits the traffic by only exporting Haack Rework material and importing minimal soil for backfill and foundation. The size of the Site is limited due to the extent of the sumps leaving little space available for storage, staging, and construction activities. Alternative 2A is not as affected by the space limitations because neutralization materials will not be required, and as such, storage area for these materials is not required for this Alternative. (RTC, 9/29/11)

Alternatives 3 and 4 pose significant implementation issues due to the gas generation during mixing and excavation of the sludge and the potential impacts to neighboring sensitive receptors. Limiting work to night-time only would not reduce the risks to near-by businesses which operate 24-hours a day. Implementation of Alternative 2A has fewer engineering and health and safety complications since the sludge is not fully disturbed, thus limiting the release of hazardous gas. (RTC, 9/29/11)

While Alternative 2A has implementation challenges due to the Site size and location, the design of the Alternative 2A cap results in the most implementable remedial alternative. (RTC, 9/29/11)

Cost

Alternative ~~2~~ 2A (RTC, 9/29/11) has the lowest capital cost of approximately ~~$5,206,314~~ $5,774,550 ~~with Alternatives 3 and 4 having comparable capital costs of $35,402,274 and $54,067,350, respectively~~. (RTC, 11/6/12) Alternative 3 has a capital cost highly dependent on neutralization admixture costs ranging from $11,144,880 to $12,566,880. Similarly to Alternative 3, Alternative 4 has a cost highly dependent on the admixture price ranging from a low of $26,217,950 to a high of $28,991,650. (RTC, 11/6/12)Alternatives ~~2~~ 2A (RTC, 9/29/11) and 3 have identical net present value O&M costs of approximately ~~$1,563,800~~ ~~$2,822,100.00 (RTC, 11/6/12)~~ $4,882,500 (RTC, 11/12/13). Alternative 4 has the lowest net present value O&M cost of approximately ~~$620,500~~ $113,200 (RTC, 11/6/12). Alternative 2A has the lowest combined remedial cost. (RTC, 9/29/11)

State Acceptance

In accordance with USEPA guidance, this criterion will be addressed when DTSC is making its final remedial decision and the ROD is being prepared.

Community Acceptance

In accordance with USEPA guidance, this criterion will be addressed when DTSC is making its final remedial decision and the ROD is being prepared. During the May 10, 2011 meeting between the DTSC and the City, the City expressed concerns regarding the appearance of the former Alternative 2 being similar to a "landfill," and the height of the cap being too high. The City expressed the desire that the final remedial Alternative be consistent with the vision and goal of future development for the Site. (RTC, 9/29/11)

Alternative 2A provides a reduced cap thickness, and accounts for future use as a parking lot subgrade consistent with the City's vision for commercial development. Alternative 3 proposes a cap sloping upward to a maximum elevation of 35 ft amsl, which makes parking lot construction more difficult above the high grades and slopes of the Site. Alternative 4 proposes the Site is excavated and filled. Alternative 4 best incorporates the City's vision for commercial development; however, given the implementation, short-term effectiveness, and cost challenges, Alternative 2A provides the best compromise to meet the City's development vision. (RTC, 9/29/11)

Remedy Selection

~~Based on the comparative analysis of the remedial alternatives, the alternative that meets the RAOs and ranks the highest is Alternative 2,capping with selective excavation. The elements of Alternative 2 are:~~ (RTC, 9/29/11)

- ~~Prepare a construction Health and Safety Plan and Construction Quality Assurance Plan;~~ (RTC, 9/29/11)
- ~~Place a 3.5-foot stabilization layer across the Cooper North and South sumps consisting of gravel, sand, and geocell;~~ (RTC, 9/29/11)
- ~~Excavate the Haack Rework area, segregating the overburden soil from the sludge/soil mixture;~~ (RTC, 9/29/11)
- ~~Install retaining wall (sheet pile) along northern perimeter (Artesia Blvd);~~ (RTC, 9/29/11)
- ~~Place the Haack Rework material and other site soils as the foundation layer above the stabilization layer with horizontal gas collection pipes embedded. The foundation layer would increase in thickness and would be graded such that the final surface would drain at 3 percent to the cap perimeters;~~ (RTC, 9/29/11)
- ~~Install vertical gas migration control wells;~~ (RTC, 9/29/11)
- ~~Install geosynthetic layers consisting of, from bottom to top, a gas collection geocomposite, GCL, 60-mil HDPE geomembrane, and drainage geocomposite;~~ (RTC, 9/29/11)
- ~~Place 2 feet of cover soil above the geosynthetics;~~ (RTC, 9/29/11)
- ~~Install groundwater monitoring wells;~~ (RTC, 9/29/11)
- ~~Operate the below-cap gas collection system and the perimeter vertical gas migration control well system as active systems for a period of at least 2 weeks. Following the start-up period, operate the below-cap gas collection system and vertical gas migration control well system passively. During passive operation, monitor the performance of the proposed alternative remedial measure with a system of perimeter gas migration sentry wells outside the limit of the perimeter vertical gas migration control wells. If the monitoring data indicate significant gas migration from the waste, convert the system to active gas control and, if required, include gas treatment;~~ (RTC, 9/29/11)
- ~~Prepare a Risk Management Plan;~~ (RTC, 9/29/11)
- ~~Perform semi-annual groundwater monitoring; and~~(RTC, 9/29/11)

- ~~Complete a formal review of remediation effectiveness after five years.~~ (RTC, 9/29/11)

~~This remedial alternative effectively mitigates the risk from ingestion, inhalation, and dermal contact with onsite soils for both future non-residential and residential occupants of buildings on site, and future landscapers and utility workers. This alternative also effectively mitigates the risk from dermal contact with site groundwater through the cap and institutional controls including the Health and Safety Plan and Risk Management Plan.~~ (RTC, 9/29/11)

~~Alternative 2 readily meets the criteria of overall protection of human health and the environment and satisfies ARARs. When evaluated against the balancing criteria, Alternative 2 provides short-term effectiveness as well as long-term effectiveness and permanence. It is readily implementable and presents an effective balance of cost against the other criteria. Alternative 2 also would best accommodate future potential redevelopment of the Site.~~ (RTC, 9/29/11)

Based on the comparative analysis of the remedial alternatives, the alternative that meets the RAOs and ranks the highest is Alternative 2A, capping with selective excavation. The elements of Alternative 2A are: (RTC, 9/29/11)

- Prepare a construction HASP and CQA Plan;
- Prepare a Risk Management Plan;
- High-strength geotextile installation;
- Select excavation of impacted material;
- Containment of sludge along Artesia Boulevard;
- Capping of sludge;
- Installation of gas control and monitoring system;
- Institutional controls;
- Perform semi-annual groundwater monitoring; and
- Complete a formal review of cap effectiveness after five years. (RTC, 9/29/11)

This remedial alternative effectively mitigates the risk from ingestion, inhalation, and dermal contact with onsite soils for future non-residential occupants of buildings onsite, and future landscapers and utility workers. This alternative also effectively mitigates the risk from dermal contact with Site groundwater through the cap and institutional controls including the Health and Safety Plan and Risk Management Plan. (RTC, 9/29/11)

Alternative 2A readily meets the criteria of overall protection of human health and the environment and satisfies ARARs. When evaluated against the balancing criteria, Alternative 2A provides short-term effectiveness as well as long-term effectiveness and permanence. It is implementable and presents an effective balance of cost against the other criteria. Alternative 2A could also accommodate future potential redevelopment of the Site as a parking lot to support a commercial operation. (RTC, 9/29/11)

1. INTRODUCTION

1.1 Terms of Reference

This document presents the Revised Final Draft (RTC, 11/6/12) Feasibility Study (Revised Final Draft FS) Report for the Gardena Sumps Site (Site) in Gardena, California. The FS Report is a requirement of Consent Decree CV04-7882-AHM (JTLx), (Consent Decree). The original draft (RTC, 11/6/12) FS Report (Draft FS) was prepared for submittal to the California Environmental Protection Agency (CalEPA), Department of Toxic Substances Control (DTSC) in accordance with the California Health and Safety Code on 11 February 2011. After submittal of the Draft FS, the following timeline of correspondence and revisions occurred:

- A meeting with the DTSC and City of Gardena on 2 May 2011 and receipt of comments from the DTSC 6 June 2011 and 9 June 2011.

- Responses to comments including the Draft Feasibility Study Addendum – Alternative 2A (FS Addendum) were prepared by Geosyntec Consultants, Inc. (Geosyntec) and submitted to the DTSC on 29 September 2011.

- Comments on the FS Addendum were received from the DTSC on 31 October 2011 and 11 November 2011.

- Calculations supporting the preliminary cap design were requested by the DTSC 28 January 2012. The calculations were subsequently transmitted to the DTSC on 1 February 2012.

- A letter in response to DTSC comments received 31 October 2011 and 11 November 2011 was issued by Geosyntec on 7 February 2012.

- Additional DTSC comments on the Addendum and 10 February 2012 response to comments package were received on 7 March 2012 and 30 March 2012.

- A response to comments package was submitted to DTSC by Geosyntec on 4 April 2012 as the Revised Draft Feasibility Study (Revised FS) which included clarification sheets for the Draft FS and FS Addendum.

- Comments were received from the DTSC on the Draft FS, comment responses, and Revised FS on 6 September 2012. (RTC, 11/6/12)

- Comments were received from the City of Gardena through the DTSC during meetings on 11 July, 30 August 2013, and 5 September. Appendix F, Alternative 2A Cover Option is the response to those comments. (RTC, 11/12/13)

- Comments were received from DTSC on the Revised Final Draft FS on 3 October 2013 and a response was issued 13 November 2013. (RTC, 11/12/13)

This document represents the Updated (RTC, 11/12/13) Revised Final Draft FS following a recommendation in the 6 September 2012 comment package to revise the documents to form one, comprehensive Feasibility Study. This package addresses the comments and concerns which were presented in the letters received from DTSC. This draft represents revisions to the original, Draft FS with the changes identified in the following manner:

- Text deleted from the report is ~~struck-out~~ with the corresponding comments package date at the end (RTC, [Date]).

- Text added to the report is underlined with the corresponding comments package date at the end (RTC, [Date]).

- Text removed from a revised text section is ~~struck-out and underlined~~ with the corresponding comments package date at the end (RTC, [Date]).

- Text added to a revised text section is double underlined with the corresponding comments package date at the end (RTC, [Date]).

A summary table of all comments received from the DTSC and their responses is included as Appendix A.

This report was prepared by Ms. Rebecca Flynn **Oliver**, P.E., of Geosyntec and reviewed by Mr. Gregory Corcoran, P.E., both of Geosyntec, in accordance with Geosyntec's peer review policy.

1.2 Description of Feasibility Study Process

The Remedial Investigation (RI) for the Site comprises three separate reports: the *Revised Draft Remedial Investigation Report* (Stantec, 2008); the *Draft Memorandum – Data Gap Analysis* (Stantec, 2010a); *Draft Human Health Risk Assessment* (HHRA) (Geosyntec, 2010); and the *Addendum to the August 22, 2008 Revised Draft 2006 Remedial Investigation Report* (Stantec, 2010c). This FS Report includes the following information and evaluations in general accordance with *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (USEPA, 1988):

- Background information on the Site, including a summary of investigative and remedial work performed to date;

- Future use of the Site, future risk exposure pathways, and receptors that may be at risk;
- Remedial Action Objectives (RAOs) and cleanup criteria;
- Identification of remedial technologies that potentially can be employed to remediate the Site contaminants;
- Screening of the remedial technologies to identify those that can realistically remediate or isolate wastes at the Site;
- Development of a range of potential remedial technologies to address impacted soil, soil gas, and groundwater, and remedial alternatives, which are combinations of remedial technologies that can address impacted media at the Site;
- Screening of the remedial alternatives to identify those that can realistically address conditions at the Site;
- Analysis of remedial alternatives using United States Environmental Protection Agency (USEPA) criteria; and
- Comparative analysis of remedial alternatives that will result in identification of the preferred remedial alternative for the Site.

1.3 Organization

This document is organized into the following sections:

- Section 2 – "Site Background," describes the history and physical characteristics of the Site, including hydrogeology;
- Section 3 – "Remedial Investigation Summary," summarizes the results of the remedial investigation;
- Section 4 – "Remedial Action Objectives and Cleanup Criteria," summarizes the findings of the draft HHRA and identifies the potential future use of the Site, future risk exposure pathways, and potential receptors that may be at risk. The RAOs also are identified, along with cleanup criteria selected to achieve those objectives;
- Section 5 – "Identification and Screening of Technologies," identifies potential remedial technologies. The remedial technologies are then screened based on their effectiveness, implementability, and cost to address human health risks and ecological risks associated with these media;
- Section 6 – "Development of Remedial Alternatives," uses the retained technologies from Section 5 to compile remedial alternatives that address a range of potential response actions and technical approaches for the Site.

Remedial alternatives are further screened, evaluated and ranked in terms of effectiveness, implementability, and cost to identify the final set of remedial alternatives for detailed analysis;

- Section 7 – "Detailed Analysis of Alternatives," presents a nine-criteria analysis of the final set of remedial alternatives;
- Section 8 – "Comparative Analysis of Alternatives," uses the nine-criteria analysis results to compare the alternatives to assess which alternative provides the best balance of the nine criteria, and is, therefore, the recommended alternative; and
- Section 9 – "References," presents the FS Report references.

Tables, figures, and appendices are included at the end of this FS Report.

2. SITE BACKGROUND

2.1 General

This section includes the following background information on the Site:

- Site location and description;
- Site history;
- Geology; and
- Hydrogeology

The information presented in this section generally has been excerpted from the *Revised Draft RI* (Stantec, 2008).

2.2 Site Location and Description

The Site is located in the southwest corner of the Artesia Boulevard and Normandie Avenue intersection in the City of Gardena, Los Angeles County, California (Figure1-1). Generally, the area surrounding Site is bordered to the south by the Los Angeles County Department of Public Works (LACDPW) Dominguez Flood Channel, to the east by the Southern Pacific Railroad right-of-way, to the west by the western Haack property line, and to the north by Artesia Boulevard, although a small portion of Artesia Boulevard is included within the Site. Commercial and residential properties are currently located to the north, east, and west of the Site (Figure 1-2) (Stantec, 2008). For the purpose of this report, the Site is comprised of the Cooper, Haack, and four (4) residential properties as shown on Figure 1-2.

The Site is greater than 5.6 acres of mixed-use development and primarily consists of two properties, the Cooper property and the Haack property. The Cooper property is approximately 3.0 acres, approximately 90 percent of which is comprised of two large sumps (referred to as the "Cooper North" and "Cooper South" sumps) containing primarily petroleum refining wastes. The Haack property is approximately 2.6 acres, contains one modified sump (referred to as the "Haack sump") and the "Haack Rework Area", which is a reworked and mixed sludge/soil area south of the Haack sump. The Haack Rework Area encroaches onto the extreme northern portions of the two easternmost residential lots. In this FS Report, the wastes in the sumps will be referred to as "sludge" for ease of reference. This FS Report will address the three sumps and the Haack Rework Area, constituting the areas of concern (Figure 1-2) (Stantec, 2008).

2.3 Site History

The *Revised Draft RI* documents the site history and presents historic aerial photographs. The following section summarizes the site history and evaluation of the photographs presented by Stantec (Stantec, 2008).

Early topographic maps show that the eastern (Cooper property area) and southern (southern Haack and residential areas) portions of the Site were elevated, which suggests that some amount of clay material could have been extracted from excavations into the elevated bluff.

During the 1920's, the Moneta Brick Company leased the Site. By 1928 the area of the two Cooper sumps had been excavated to a lower surface elevation than the current LACDPW land to the south and most of the Haack and residential properties. The railroad tracks east of the Cooper property were elevated above the land surface of the current Cooper property, and clay mining at the Cooper property had been completed by this time. Clay mining operations were occurring on the northern Haack property in 1928 and 1929. By 1929 the southern portion of the Haack property (present Haack Rework Area) had an elevated scoured slope. This elevated area sloped eastward towards the land surface of the current southern Cooper property. Boring logs from RB-2 and RB-3 indicate that fill material (including brick and concrete debris and glass) extended to elevations of approximately 8 feet above mean sea level (amsl) (depths of 17 to 20 feet below the scoured slope surface) in portions of the Haack Rework Area. An aerial photograph from May 1938 documents that creation of the disposal sumps at the Site had not yet begun. Denys Goddard purchased the land consisting of the current Haack, Cooper, and residential properties in May 1939.

Newspaper reports indicate that sludge disposal had commenced by March 1940. The Haack Sump, Cooper South Sump, and the Haack Rework Area had been constructed and contained sludge by March 1941. The Cooper North Sump had not yet been constructed. By early December 1941 the eastern and northern berms of the Cooper North Sump had been constructed and initiation of sludge disposal into this sump had commenced. Sludge deposition at the Site had occurred at the Haack Sump, the Haack Rework Area, a small pit between these two locations (constructed after March 1941), and the Cooper South Sump by this time.

By September 1946, the Haack and two Cooper sumps were filled with sludge, and vegetation had reclaimed the small pit and the Haack Rework Area. Some excavation of soil had occurred into the bluffs west and south of the western portion of the Haack Sump, but there had been no further development of the Haack and Cooper properties. Denys Goddard sold the future Haack and Cooper property parcels to Wendell and

Golda Hopkins in March 1947, but maintained ownership of the residential lots. The Hopkins' sold their property to S&L Manufacturing in January 1948.

By December 1951, the western portion of the Haack Sump had been covered with dirt and was converted to a parking lot. The eastern portion of the Haack Sump does not appear to have been altered. A significant portion of the bluff south and southwest of the Haack Sump had been excavated. This excavation activity removed the small sludge pit that was located between the Haack Sump and the Haack Rework Area. Two structures had been constructed in the northwestern portion of the Haack property. The Haack Rework Area remained vegetated and the two easternmost residential lots (on the Goddard property) had structures on them.

On October 1, 1952, S&L Manufacturing sold the northern-most strip of their property to the State of California for a highway easement. By early 1956, Artesia Blvd (Highway 91) had been constructed with the southern portion of the roadway encroaching into the Haack Sump northern berm.

By January 1958, the Dominguez Channel had been reconstructed and extended eastward south of the Site. A third structure (the "administrative building") had been constructed on the Haack property at the southern edge of the parking lot. The Cooper property had not significantly changed since 1951. The two westernmost residential lots had structures on them by this time. In May 1958, S&L Manufacturing sold the current Haack and Cooper properties to Charles Warfel. Warfel then sold the current Cooper property to William Ward in January 1959 and the Haack property to Clarence and Genevieve Haack in May 1960. In late 1960, the City of Gardena annexed the area of the Site from the County of Los Angeles.

By November 1962 significant changes had occurred at the Haack property. The bluff immediately south of the "administrative building" had been excavated back to the present day cut-bank (located west of boring HPB11). This excavation expanded the parking lot south of the "administrative building." The parking lot on the Haack property appeared to have been paved, although the eastern portion of the Haack property remains a vegetated area immediately west of the Cooper North Sump. The Haack Rework Area appeared altered and may have received soil cover from the excavation activities that occurred immediately north of the Haack Rework Area. The future Cooper property was unchanged. William Ward sold his property to Thomas Cooper in December 1977.

The two Cooper sumps currently are capped by a geosynthetic material that was installed by OHM Corporation (OHM) in July 1993 as part of the DTSC's environmental program at the Site. The Haack Sump has been covered by asphalt and a concrete slab. Currently the Haack property is leased to various tenants who operate

small businesses, including a U-Haul rental agency, a metal fabricating, sand blasting and painting company, and an auto body repair shop. Three buildings and numerous small trailer-type storage structures are present on the Haack property.

2.4 Geology

The following discussion is based on California Department of Water Resources (CalDWR) Bulletin No. 104, Planned Utilization of the Ground-water Basins of the Coastal Plain of Los Angeles County, Appendix A — Ground Water Geology, dated June 1961, reprinted April 1988 (CalDWR, 1961) and discussions contained in reports from previous investigations (CalEPA 1994, URS 1994, and Stantec, 2008).

The Site is located in the Los Angeles Coastal Plain and is underlain by a thick sequence of marine and continental sediments that were deposited in a ~~board~~ broad (RTC, 9/29/11) synclinal depression. This depression is generally referred to as the Los Angeles Basin. The Los Angeles Basin is bisected by the northwest trending Newport-Inglewood uplift, which divides the Coastal Plain into two smaller synclinal troughs. The Site is located in the West Coast Basin, which constitutes the southwest portion of the Los Angeles Basin.

The Site is located near the junction of the Torrance Plain and the Dominguez Erosion Gap. The Torrance Plain runs west of and parallel to the hills of the Newport-Inglewood uplift from the Ballona Gap southeast to the Dominguez Gap. The Plain is a broad featureless area only slightly dissected locally by the Dominguez Creek (Dominguez Channel).

According to boring logs in the Ecology and Environmental, Inc. (EEI) (1986), Metcalf and Eddy (1992), CalEPA (1994) and URS (1994) reports, sediments underlying the Site, to the maximum explored depth of 92 feet below ground surface (bgs), consist primarily of a mixture of clays and silts with interbeds of sand. Copies of the available boring logs from these previous studies are provided in Appendix F and summarized in Table 13 of the *Revised Draft RI* (Stantec, 2008). This stratigraphy correlates in general with the observed conditions in borings completed in conjunction with the *Revised Draft RI* (Stantec 2008), which reached a maximum depth of 100 feet bgs.

2.5 Hydrogeology

The following discussion is based on CalDWR *Bulletin No. 104, Planned Utilization of the Ground-water Basins of the Coastal Plain of Los Angeles County, Appendix A - Ground Water Geology*, dated June 1961, reprinted April 1988 (CalDWR, 1961) and discussions contained in reports from previous investigations (CalEPA 1994, URS 1994, Stantec, 2008).

The Site is located in what is known as the West Coast Groundwater Basin. The West Coast Groundwater Basin has existing beneficial uses for municipal and domestic supply wells, agricultural supply, industrial process supply, industrial service supply, and aquaculture (LARWQCB, 1994). (RTC, 9/29/11) This basin is hydraulically isolated from other, larger groundwater basins in the Coastal Plain by the regional Newport-Inglewood Fault. The Site is underlain by Holocene and late-Pleistocene Age alluvial and marine deposits, which include the Bellflower Aquiclude at the ground surface, and the Gardena and/or Gage Aquifers of the Lakewood Formation beneath the aquiclude. Major underlying aquifers (beneath the Lakewood Formation) are the Lynwood and the Silverado Aquifers of the San Pedro Formation.

The uppermost defined unit within the basin, and the unit that the Site is located within, is the Bellflower Aquiclude. Regionally, the Bellflower Aquiclude contains interfingered zones of permeable and less permeable sediments. The zones with modest to relatively high hydraulic conductivity consist of fine to coarse sand with gravel and silty sand. These coarser grained sediments vary in thickness from 10 to 60 feet and are not laterally continuous. However, in some areas, these permeable zones can contain significant amounts of water. Little beneficial use is made of water in these shallow, discontinuous hydraulic zones because well yields tend to be low and water quality generally poor (CalDWR, 1961).

The Gardena/Gage, Silverado, and Lynwood Aquifers are all capable of storing or conveying groundwater in significant quantities and constitute major sources of groundwater in the West Coast Groundwater Basin. The Lynwood and Silverado Aquifers are primary sources for domestic water supply, while the Gardena and Gage Aquifers are a secondary domestic water supply source. Neither the Gardena nor Gage Aquifers are currently pumped for domestic use. The intervening finer-grained aquitards have not been named. These aquitards, including those that separate the Gardena and Gage Aquifers from the Lynwood Aquifer and the Lynwood Aquifer from the Silverado Aquifer, are discontinuous in nature and absent in some areas.

Immediately beneath the Site, there are two hydraulic groundwater zones within the Bellflower Aquiclude: Zone A (upper) and Zone B (lower), which are approximately 15 to 25 and 75 to 80 ft bgs, respectively. Site groundwater monitoring wells are screened within these two zones. General groundwater chemistry analyses were performed at the Site to evaluate if a hydraulic interconnection exists between Zone A and Zone B due to the existence of a downward vertical gradient between the two zones. The groundwater chemistry analysis indicated that the two zones are characterized by different groundwater geochemistry. The concrete lined Dominguez Channel influences the flow direction of the shallow Zone A groundwater southward while the deeper Zone B groundwater has a flow direction to the east – southeast. Groundwater monitoring at the

Site over the past seven years indicates that COCs are not migrating vertically or laterally over any significant distance from the locations of the waste material. (RTC, 1/9/2013)

The area surrounding the Site is urbanized, with surface waters that drain via storm drains into the Dominguez Channel. The Dominguez Channel is a concrete-lined flood-control structure immediately south of the Site. The upstream portion of the modern day Dominguez Channel originates several miles west-northwest of the Site, and it drains surface water to the southeast where it discharges to the Cerritos Channel of the Los Angeles Harbor. Surface water at the Site generally drains towards the north and east following site topography, and is intercepted by a flood control storm drain located at the northeast corner of the Site adjacent to the intersection of Artesia Boulevard and Normandie Avenue.

Historically, the Dominguez Channel flowed along a natural channel bed located approximately several hundred feet west and north of the Site where it flowed eastward into Laguna Dominguez. Presently the shallow groundwater beneath the Site is influenced by the concrete lined Dominguez Channel and flows southward.

3. REMEDIAL INVESTIGATION SUMMARY

3.1 General

The nature and extent of hydrocarbon and metal impacts at and surrounding the Site have been evaluated through several investigation programs conducted since 1982. Sludge, soil, surface water, groundwater, and soil vapor have been investigated. The following sections provide a summary of findings for each of these media. Details of the investigations and findings can be found in the *Revised Draft RI* (Stantec, 2008) and the *Addendum to the Revised Draft RI* (Stantec, 2010c).

3.2 Nature and Extent of Contamination

3.2.1 Soil/Sludge

As part of the RI investigation, Stantec collected over 300 subsurface soil and sludge samples from beneath and surrounding the sumps and rework area to delineate the vertical and horizontal extents of continuous (nonreworked) sludge and sludge-induced impacts to the adjacent soil (Figure 3-1). The samples were analyzed for organic and inorganic constituents. In addition, pH was measured to determine the effects of the sludge on the soil pH near the sumps and adjacent berms. Organic constituents analyzed were: volatile fuel hydrocarbons (VFHs), total extractable hydrocarbons (TEHs), volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), and polynuclear aromatic hydrocarbons (PAHs). Inorganic constituents analyzed were: Title 22 metals, mercury, and hexavalent chromium.

Sludge constituents are as follows (Stantec, 2008):

- **VFH and TEH**: Heavier hydrocarbon compounds predominate in the sludge.
- **VOCs**: Most commonly detected include ethylbenzene, p-isopropyltoluene, naphthalene, toluene, 1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, and m-, o-, p-xylene compounds.
- **Non-PAH SVOCs**: Not typically detected in sludge samples due to the dilution factor necessary to analyze the sludge samples.
- **PAHs**: The most predominant PAH compounds include benzo(a)-pyrene, benzo(b)-fluoranthene, chrysene, fluoranthene, phenanthrene, and pyrene.
- **Title 22 Metals**: Background, offsite soil, onsite non-reworked soil, and sludge samples were collected during the RI. Antimony, barium, cadmium, vanadium, and zinc were all reportedly lower in the sludge when compared with background soil, while lead and molybdenum were higher in the sludge when compared to background soil. Arsenic and thallium concentrations were

similar in the sludge and background soil while copper had a wider range (higher and lower) of concentrations in sludge compared to background soil. During the 2006 RI field investigation, arsenic was detected in background soil on the LADPW property at 82 milligrams per kilogram (mg/kg). Sampling was performed during the subsequent 2009 RI field investigation at this location and immediate vicinity and resulted in arsenic concentrations of less than 5.5 mg/kg; therefore, the 82 mg/kg concentration could not be confirmed (Stantec, 2010a). Isolated areas on the Haack property had significantly higher concentrations of antimony, arsenic, chromium, copper, molybdenum, nickel, and zinc than typically found at the Site (Stantec, 2010c).

- **Chromium VI**: Analytical results for hexavalent chromium and total chromium in sludge ranged from <0.026 to 0.73 mg/kg and 0.55 to 4.7mg/kg, respectively. Analytical results for hexavalent chromium and total chromium in background soil ranged from <0.026 to 1.3 mg/kg and 6.0 to 28 mg/kg, respectively. One background 2006 soil sample was suspect for hexavalent chromium, having hexavalent chromium and total chromium values of 100 mg/kg and 33 mg/kg respectively (Stantec, 2008; Geosyntec, 2010). Subsequent resampling of this location resulted in hexavalent chromium and total chromium values of <1.0 mg/kg and 17 mg/kg respectively; therefore, the 2006 hexavalent chromium test result of 100 mg/kg is suspect (Geosyntec, 2010).
- **pH**: ~~The pH of the sludge samples averaged 2.22~~ <u>The pH of the sludge samples ranged from 0.39 to 9.05</u> (RTC, 9/29/11) while pH of the background soil averaged 6.57 (Stantec, 2008). The 2009 RI activities included an assessment of pH in soil adjacent to the sludge. Results of testing indicate pH ranges from 5.2 to 10.3 in soil adjacent to the sludge (Stantec, 2010a).

During the RI, four areas of sludge disposal were investigated: the Cooper South Sump, the Cooper North Sump, the Haack Sump, and the Haack Rework Area. The delineation of nonreworked sludge is shown on Figure 1-2 and illustrates the lateral extent of congruent sludge having any thickness. Below is a summary of the results of the delineation (Stantec, 2008):

- **Cooper South Sump**: The Cooper South Sump has an identified maximum thickness of 13.5 feet. Figure 10A of the *Revised Draft RI* (Stantec, 2008) illustrates the general vertical profile of this sump. Vertical attenuation of sludge impacts in soil typically ranged from 1.5 to 3 feet beneath the sludge; lateral impacts of sludge in soil is negligible. Approximately 6,700 cubic yards (CY) of sludge was calculated by Stantec to be in the Cooper South Sump (Stantec, 2010c). Approximately 8,000 CY of sludge containing soil

interbeds was calculated by Stantec to be in the Cooper South Sump (Stantec, 2008).

- **Cooper North Sump**: The Cooper North Sump has an identified maximum thickness of 17.5 feet. Figure 10A of the *Revised Draft RI* (Stantec, 2008) illustrates the general vertical profile of this sump. Vertical attenuation of sludge impacts in soil typically ranged from 5 to 7.5 feet beneath the sludge, with the exception of one boring where chrysene was detected up to 11 feet beneath the sludge. Some TEH and PAH constituents were detected approximately 6 feet laterally from this sump in depths up to 15 feet bgs indicating some lateral migration in soil to the north; however, other borings indicated lateral impacts of sludge in soil is negligible. Stantec calculated approximately 7,000 CY of sludge is in the Cooper North Sump (Stantec, 2010c). Approximately 9,300 CY of sludge containing soil interbeds was calculated by Stantec to be in the Cooper North Sump (Stantec, 2008).
- **Haack Sump**: The Haack sump consists of several discontinuous layers of sludge varying in thickness from 0.5 to 3.0 feet to a depth up to 14.6 feet bgs. Boring logs indicated the western and central areas of the sump had been reworked, possibly during site development in the late 1940's. Figure 10B of the *Revised Draft RI* (Stantec 2008) illustrates the general vertical profile of this sump. Stantec calculated approximately 2,250 CY of sludge is in the Haack Sump (Stantec, 2010c). Approximately 2,900 CY of sludge containing soil interbeds was calculated by Stantec to be in the Haack Sump (Stantec, 2008).
- **Haack Rework Area**: The Haack rework area consists of deposited sludge, soil, and debris in discontinuous and mixed layers beneath a soil cover with thickness varying from less than 1 foot to 10 feet. The thickness of sludge in the western portion of the Haack Rework Area is thinner and occurs at a higher elevation than at the eastern edge of the Haack Rework Area. Figures 10E and 10F of the *Revised Draft RI* (Stantec, 2008) illustrate the general vertical profile of this area. Stantec calculated approximately 650 CY of material is in the Haack Rework Area (Stantec, 2010c). Approximately 1,200 CY of sludge containing soil interbeds was calculated by Stantec to be in Haack Rework Area (Stantec, 2008).

Delineation borings were conducted at several specific areas of the Site. The results of the sampling are provided in the *Revised Draft RI* (Stantec, 2008) and summarized below:

- **Eastern LACDPW Easement**: Borings were performed to determine if sludge had migrated offsite onto the LACDPW property east of the Cooper property. The 2006 delineation borings encountered sludge within 6 inches

bgs in all five delineation borings (Stantec, 2008). Subsequent delineation borings were performed in 2009 east of the 2006 delineation borings which delineated the extent of the continuous sludge shown on Figure 1-2 (borings DPW116 through DPW121 and GWP102) (Stantec, 2010a).

- **East-Central Haack Property (Former Drum Storage Area)**: Sampling of the former drum storage area on the Haack property was performed in 2006 to determine if metal concentrations in soil were elevated when compared to background soil concentrations. Elevated lead concentrations were detected at a depth of 1.5 feet in all four borings, but lead concentrations were in the range of background at a depth of 5 feet. Elevated concentrations of antimony, arsenic, copper, and molybdenum were detected in one boring at a depth of 1.5 feet. One hexavalent chromium concentration above background was detected at 5 feet bgs.
- **Sludge Surface Samples**: Sludge surface samples were collected to determine if analytical interference resulted in high arsenic, antimony, and thallium concentrations during the 1982 investigation. With the exception of the low level of antimony detected in one boring, antimony, arsenic, and thallium were not detected in the samples; therefore, it suggests the 1982 data is not valid.
- **Sump Perimeter**: Borings were performed around the perimeters of the sumps to assess the lateral extent of continuous sludge during both the 2006 and 2009 RI activities. Continuous sludge is a sludge-only deposit and excludes soil mixed with sludge. The results of the step-out borings indicate the extent of the continuous sludge, which is illustrated on Figure 1-2.
- **Offsite Adjacent Residential Properties**: Borings were advanced in the residential properties in the southern portion of the site during the 2006 and 2009 RI activities to investigate the presence of sludge. The results of these borings indicate that the extent of the sludge has been delineated as illustrated on Figure 1-2.

3.2.2 Surface Water

Surface water samples were collected upstream and downstream of the Site from the Dominguez Channel in 2006 and 2008. During both sampling events, the samples had gasoline range organics (GRO) concentrations of 58 µg/L and 50 µg/L in 2006 and 2008, respectively. No SVOCs were observed. Two VOCs, tetrachlorothene and trichloroethene, were observed during both events; upstream samples had higher concentrations of both VOCs than the downstream samples. Barium was found in surface water at concentrations approximately double what was detected in the soil and

sludge samples. Copper, lead, and vanadium were detected at levels below background for the Site (Stantec, 2008).

Analytical data from surface water samples collected from the inner channel of the Dominguez Channel indicated elevated concentrations of GRO and VOC analytes in contrast to the non-detections for those analytes in groundwater monitored at the Site. Based on the organic chemical parameters, the Site is not impacting surface water quality in the channel. Overall, the observed concentrations of metals in surface water adjacent to the Site support the same conclusion, that the Site groundwater conditions are not impacting surface water quality. Both upstream and downstream surface water samples have at least twice the concentration of antimony, molybdenum, nickel, barium, lead, and copper compared to shallow groundwater at the southern boundary of the Site (Stantec, 2010b).

3.2.3 Soil Gas

The soil gas investigation activities evaluated the subsurface concentrations of VOCs, hydrogen sulfide, and methane at various locations across the Site for use in the baseline HHRA. Soil gas samples were collected in the locations indicated on Figure 3-2. Constituent concentrations reported above the detection limit for targeted VOCs include benzene, toluene, ethylbenzene, m-,p-,o-xylenes, 1,3,5-trimethylbenzene, and Freon 113. Concentrations ranged from non-detect to 2.2 µg/L-vapor (toluene) (Stantec, 2008).

During the 2006 RI activities, benzene concentrations in the soil gas samples ranged from non-detect to 0.3 µg/L-vapor by Method 8260B and from non-detect to 0.260 µg/L-vapor by Method TO-15. Hydrogen sulfide concentrations in the soil vapor samples ranged from non-detect to 5.1 parts per million by volume (ppmv) except for one sample location with results of greater than 50 ppmv. Methane concentrations in the soil gas samples ranged from non-detect to 220 ppmv (Stantec, 2008).

During the 2009 RI activities, additional samples were collected from 22 semi-permanent direct-push soil gas probes. Samples collected near the Haack administrative building showed no VOCs greater than California Human Health Screening Levels (CHHSLs). On the residential properties, benzene from the sample collected from the former corral was the only constituent reported higher than the specific constituent CHHSL value. The results elsewhere at the Site during the 2009 RI activities generally confirmed the results of the 2006 RI (Stantec, 2010a).

3.2.4 Soil Vapor Flux

An Air Pathway Analysis (APA) was performed during the 2006 investigation to evaluate the exposure pathway of outdoor inhalation of vapors. The surfaces evaluated included:

- exposed, undisturbed sludge on the Cooper property;
- exposed, disturbed sludge on the Cooper property;
- soil on both the Cooper and Haack properties; and
- asphalt and concrete-slab covered soil on the Haack property.

The results of the APA are provided in the *Revised Draft RI* (Stantec, 2008) and are summarized below:

- **Ambient Air**: Methane and select VOCs were reported above the quality control (QC) criteria and/or reporting limit in the four ambient air samples collected. Detected methane levels are typical of global, outdoor, ambient air. Detections of VOCs on the Haack property are most likely related to industrial activities on the property and not from undisturbed surface emissions from the nearby sumps. The VOCs detected on the Cooper property may be related to the presence of sludge in the sumps.
- **Undisturbed**: Twenty (20) open (undisturbed) soil flux samples of 61 collected were reported to have specific compounds above the QC criteria and/or reporting limit. The undisturbed sludge had low to moderate emissions and, in general, more compounds were detected at Cooper property locations than Haack property locations. Higher emissions and more detectable compounds were detected at Cooper Sump locations overlying sludge.
- **Disturbed**: All nine (9) disturbed flux samples collected were reported to have specific compounds above the QC criteria and/or reporting limit. The disturbed condition can be generally characterized as having moderate to high area source emissions as compared to the undisturbed sludge condition. In addition, more compounds were detected in the emissions from the disturbed sludge condition than from the undisturbed sludge condition. Odor analyses confirmed the potential for sulfuric compounds from disturbed sludge to create nuisance odors to people in the area or downwind of the disturbed sludge.
- **Infiltration**: Specific compounds were detected above the QC criteria and/or reporting limit for each of the infiltration flux samples. The flux chamber was used to test the air emissions through seams and cracks in the concrete and asphalt. Compounds having the maximum detections represent a different mixture of sulfur and hydrocarbon compounds as detected in the undisturbed

sludge condition, indicating that the individual compound emissions are greatly affected by the surface coverings and slab.

3.2.5 Groundwater

3.2.5.1 Summary of Groundwater Monitoring

Well clusters MW-01A/B, MW-02A/B, and MW-03A/B were periodically sampled from 1994 through 2002. Analytical results of these samples supported the findings of earlier investigators, with trace amounts of volatile organic compounds (VOCs) detected in 1994 samples immediately after installation, and no VOC detections in the next ten years of sampling. Detections in 1994 were likely the result of cross-contamination during well installation (Stantec, 2008).

Groundwater samples obtained on February 28, 2002, contained detectable concentrations of antimony, lead, and thallium that were above the maximum concentration level (MCL), as defined in Title 22 CCR §64431. With a very few exceptions, prior to the 2002 sampling event, analytes tested in groundwater samples were either not detected or found below the laboratory reporting limit. Quarterly groundwater monitoring and sampling of MW-01A/B, MW-02A/B, MW-03A/B, and G-4 was agreed to as part of a Consent Decree entered into between DTSC and Atlantic Richfield Company, which became effective November 4, 2004 (§VIIC, paragraph 2, lines 2-3). Wells MW-4A, MW-4B and MW-5A have been installed during Atlantic Richfield Company's RI investigation of the Site.

The following summary is abstracted from the *First Quarter 2010 Groundwater Monitoring Report* (Stantec, 2010b):

The depth to Site groundwater in the A-zone ranges between 10.5 and 18 feet below the ground surface. The groundwater in the A-zone flows southward with an approximate velocity of 0.04 feet per day. The depth to Site groundwater in the B-zone ranges between 15.5 and 22 feet below the ground surface. The groundwater in the B-zone flows east-southeast with an approximate velocity of 0.18 feet per day. (RTC, 1/9/2013)

Nine of the ten groundwater monitoring wells showed no detectable concentrations of GRO, VOCs, or PAHs above the RL during the first quarter 2010 sampling event. Samples from the recently installed MW-05A well indicated a GRO detection of 390 µg/L. VOCs detected above the reporting limit in well MW-05A included benzene (0.73 µg/L), naphthalene (3.4 µg/L), m-,p-xylenes (1.5 µg/L), 1,2,4-trimethylbenzene (2.8 µg/L), and 1,3,5-trimethylbenzene (23 µg/L). Total xylene levels in MW-05A were 1.7 µg/L.

Wells with SVOCs detected included well MW-01A with acenaphthylene (5.6 µg/L), bis(2-ethylhexyl)phthalate (3.2 J[1] µg/L; detected below the reporting limit), and naphthalene (3.2 J µg/L; detected below the reporting limit); MW-01B had bis(2-ethylhexyl)phthalate (3.9 µg/L); MW-02A had acenaphthylene (2.1 µg/L), bis(2-ethylhexyl)phthalate (10 µg/L), 2-methylphenol 2.3 µg/L, naphthalene (2.6 µg/L), and phenol (1.2 µg/L); and MW-02B had acenaphthylene (0.75 µg/L).

The groundwater pH levels have remained relatively constant since project sampling began in the first quarter of 2006. The anomalously high pH levels reported during the 1994 and 2002 sampling events have not been observed recently. Generally, groundwater samples from onsite wells (with the exception of MW-5A) have a pH ranging between 6.0 and 8.0. Recently installed well MW-05A has had groundwater pH readings ranging from 4.5 to 5.8.

For each groundwater sampling event since the year 2000, both dissolved (starting in 2006) and non-dissolved phase barium have been detected above the RL in all wells. The highest concentration of barium continues to be detected up-gradient and off site in well MW-01B.

During the second quarter 2010 sampling event, reportable trace amounts of arsenic were detected in both non-dissolved phase (total metals) in wells MW-01A, MW-02A, MW-02B, MW-03A, MW-05A, and G-4 and in the dissolved phase in wells MW-02A, MW-02B, MW-03A, and MW-05A. Well MW-04B showed the highest levels of arsenic in both dissolved and non-dissolved phases (4.4 and 4.4 µg/L, respectively).

Well MW-05A had elevated non-dissolved levels of cobalt (140 µg/L), copper (62 µg/L), nickel (190 µg/L), and zinc (3,800 µg/L) (total metals), and elevated dissolved levels of cobalt (190 µg/L), copper (74 µg/L), nickel (240 µg/L), and zinc (4,400 µg/L) compared to the other site monitoring wells.

3.2.5.2 Summary of Hydropunch Sampling

During the 2009 RI activities, additional groundwater assessment was performed using hydropunch sampling. Groundwater samples were collected in the A and B horizons, respectively to test for VOCs, SVOCs, PAHs, metals, and pH. No VOCs, SVOCs, or PAHs were detected above MCLs. Dissolved metal concentrations of beryllium, cadmium, and nickel were reported in one sample (GWP-100) from the A horizon. pH ranged from 6.74 to 7.44 in the A horizon with the exception of a 4.74 pH value from GWP-100. pH was not measured in the B horizon (Stantec, 2010a).

[1] J = Analyte was detected between the method detection limit and reporting limit; reported value is estimated.

3.2.6 Perched Groundwater

Ten temporary groundwater wells were installed during the 2009 RI activities to investigate suspected perched groundwater. The results of the investigation are discussed in the *Data Gaps Memorandum* (Stantec, 2010a). In summary, benzene was detected at 1.6 µg/L, and some SVOCs were detected above the detection limit but below the reporting limit (J-flag). Lab pH ranged from 3.82 to 6.93, and PAHs were not detected in concentrations greater than 5 µg/L. Total metals above primary and/or secondary MCLs included: antimony, arsenic, beryllium, cadmium, chromium, copper, nickel, selenium, and zinc. Dissolved metals above primary and/or secondary MCLs included: nickel and zinc. ~~Perched groundwater in the Haack Sump area is suspected to be the result of leaking utilities.~~ (RTC, 9/29/11)

3.3 Fate and Transport

Based on the results from previous investigations and the extensive field work performed as part of the *Revised Draft RI* (Stantec, 2008), the current Conceptual Site Model (CSM) suggests that:

- The undisturbed sludge at the Site does not pose a threat to surface water and does not pose a threat to shallow (A-horizon) or deeper (B-horizon) groundwater quality throughout much of the Site. Shallow groundwater is impacted (lower pH, total & dissolved metals) south of the Haack sump; however, these impacts are not detected in samples collected downgradient of the sumps. (RTC, 1/9/2013)
- The undisturbed sludge at the Site does not pose a substantive threat to the air quality in the immediate vicinity of the Site. However, isolation of the sludge from temperature fluctuations above approximately 100 degrees would further minimize this potential impact; and
- The undisturbed sludge does not pose a threat to further contamination of soil surrounding the sludge by leaching of constituents of potential concern (COPCs) from the sludge (Stantec, 2008).

The transport mechanisms identified during the HHRA are discussed further in Section 4.2 but in summary are: wind erosion and dust, volatilization to indoor and ambient air, and leaching to groundwater.

3.4 Treatability Studies Conducted

3.4.1 General

A treatability study was conducted by Stantec to define and evaluate the physical and chemical characteristics of the sludge and evaluate neutralization/stabilization options. The following sections summarize the results of the treatability study found in Appendix J of the *Revised Draft RI* (Stantec, 2008) and included as Appendix B of this Revised Final Draft FS.

3.4.2 Acidity

The testing showed that the acidity of the sludge ranged from 6.1 to 20.8 percent by weight. The Cooper South Sump had the highest acidity, with an average value of 19 percent by weight (Stantec, 2008).

3.4.3 Wet Density

Wet densities of the sludge samples were determined from samples collected using a Fann Model 140 mud balance. The densities for the samples ranged from 63 lb/ft^3 to 79 lb/ft^3. The average density of the sludge collected from the Cooper North Sump was 65.7 lb/ft^3, and the average density of the sludge from the Cooper South Sump was denser at 72.8 lb/ft^3. The sludge collected in the Haack Rework Area had an average density of 74.9 lb/ft^3 (Stantec, 2008).

3.4.4 Moisture

The average moisture of the sludge ranged from 9.8 to 22.3 percent on a wet basis. The moisture of the soil below the sludge sumps ranged from 12.1 to 25.6 percent on a wet basis. The soil below the Cooper North Sump was noted to have higher moisture content (24.2 percent) when compared to the soil below the Haack Rework Area, which averaged 14 and 16.9 percent moisture, respectively (Stantec, 2008).

3.4.5 Viscosity

The viscosities of sludge samples were tested at different temperatures to determine material viscosity as a function of temperature. This data was plotted as semi-log graphs to generate trend lines for modeling the viscosity as a function of temperature in accordance with ASTM Method D 2493. The sludge is highly viscous, ranging from 1.7×10^6 to 2.5×10^6 centipoises (cP) at a reference temperature of 140ºF. The results of the testing show that the sludge in the Cooper North Sump had a slightly lower viscosity than the sludge in the Cooper South Sump. The sludge in the Cooper North Sump had an average viscosity of 1.7×10^6 cP at 140ºF while the viscosity of sludge in

the Cooper South Sump averaged 2.5 $\times 10^6$ cP at 140ºF. Sludge collected from the Haack property in the Haack Rework Area was heated to 220ºF, but it was still too viscous to test for viscosity, thus indicating the sludge may contain other solids from disruption during development activities in that area (Stantec, 2008).

3.4.6 Softening Point

The softening point of the sludge was evaluated by the softening point test defined in ASTM Method D36. The results of the testing show that the softening point of the sludge samples from the Cooper property ranged from 158ºF to 185ºF. The sludge in the Cooper North Sump had a slightly lower softening point than the sludge in the Cooper South Sump. The sludge in the Cooper North Sump had an average softening point of 159ºF while the average softening point for the sludge in the Cooper South Sump was 180ºF. The softening point of the sludge collected in the Haack Rework Area was greater than 210ºF (Stantec, 2008).

3.4.7 Neutralization and Stabilization Testing

Five different reagent mixes were tested with the sludge to evaluate their neutralization/stabilization ability. The five mixes included: calcium oxide (CaO), 50/50 (w/w) mix of CaO and calcium carbonate ($CaCO_3$), calcium hydroxide ($Ca(OH)_2$), a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$, and Portland cement (Stantec, 2008).

Testing indicated that the sludge can be neutralized by treatment using 25 percent treatment reagent addition by weight where the treatment reagent is comprised of 50 percent hydrated lime ($Ca(OH)_2$) and 50 percent $CaCO_3$ fines. Approximately 10 percent water addition was also required to help activate the lime and carbonate reactions. The addition of 50 percent soil by weight during this mixing will also effectively solidify the waste so it is no longer susceptible to viscoelastic deformation. This treatment also effectively fixates lead, as demonstrated through long-term leaching tests, and neutralizes acid gases such as hydrogen sulfide (H_2S) and sulfur dioxide (SO_2) (Stantec, 2008).

3.4.8 Vapor Evolution

Stantec also evaluated the potential rates of off-gas evolution during full-scale mixing operations as a function of temperature. Headspace analyses were performed on the sludge samples at temperatures of 60ºF, 100ºF, 140ºF, 180ºF, and 212ºF (Stantec, 2008).

3.4.8.1 VOC and TPH Headspace Results

The analyses indicated no benzene was emitted from the sludge samples at temperatures ranging from 60 to 212ºF. Toluene was not detected at 60ºF; however, detected concentrations increased as temperature increased. Similarly, ethylbenzene and xylenes were near detection limits at 60ºF, and detected concentrations increased as temperatures increased. Detected concentrations of toluene, ethylbenzene, and xylenes did not exceed the Occupational Safety and Health Administration (OSHA) permissible exposure limits (PELs) (Stantec, 2008).

Total petroleum hydrocarbons (TPH) was monitored in the vapor headspace as a function of temperature, where TPH represents the total concentration of VOCs detected for GRO and diesel range organics (DRO). Initial concentrations of TPH in the vapor headspace were below 12.5 ppmv in the Cooper North and Cooper South Sump samples at 60ºF. However, TPH concentrations increased exponentially with increasing temperature. At 212ºF, the concentrations of TPH in the vapor headspace of samples from the Cooper North and Cooper South Sump were 259 ppmv and 223 ppmv, respectively. These data indicate that TPH (as petroleum distillates) will not present a health and safety issue with respect to construction work since the concentrations are less than the OSHA PEL of 500 ppmv for petroleum distillates (Stantec, 2008).

Samples collected from the Haack Rework Area did not have detectable concentrations of benzene, toluene, ethylbenzene, and xylenes (BTEX) and TPH, with the exception of toluene and xylenes. These compounds were only detected when temperatures were increased to 212ºF. TPH was below detection limits at 60ºF, and detected concentrations rose to a maximum at 212ºF (Stantec, 2008).

3.4.8.2 H_2S and SO_2 Headspace Results

H_2S and SO_2 were monitored in the headspace of sludge samples at various temperatures. The results showed that these sulfurous gases were readily emitted from disturbed and heated sludge samples in the Cooper North and Cooper South Sumps. The vapor concentrations of SO_2 in equilibrium with sludge samples from both sumps exceeded 150 ppmv at 60ºF. The vapor concentration of H_2S was 408 ppmv for the Cooper North Sump and 471 ppmv for the Cooper South Sump at 60ºF, but at higher temperatures it exceeded 500 ppmv for both sumps. These data show that H_2S and SO_2 will both be present at an exposure risk to workers and the community if the sludge is disturbed for neutralization and stabilization treatment, as the OSHA PELs for H_2S and SO_2 are 10 ppmv and 2 ppmv, respectively (Stantec, 2008).

The sludge samples collected from the Haack Rework Area had substantially lower concentrations of H_2S and SO_2 in the vapor headspace. The vapor concentrations of SO_2 in equilibrium with sludge samples ranged from 8 to 71 ppmv. The vapor concentration of H_2S ranged from 2 to 50 ppmv. These data show that H_2S and SO_2 emissions from sludge on the Haack property could present an exposure risk to workers and the community if the sludge is disturbed for neutralization and stabilization (Stantec, 2008).

3.4.9 Metal and Organic Mobilization

Treated and untreated composite samples of sludge from the Cooper North and Cooper South Sumps were analyzed for total RCRA metals, VOCs, SVOCs, and PAHs and for analyses of leachable RCRA metals and organics by both the toxic characteristic leaching procedure (TCLP) and synthetic precipitation leaching procedure (SPLP) (Stantec, 2008).

3.4.9.1 Untreated Sludge Leaching

Analyses showed that the composite sludge sample contained 22.4 mg/kg lead and 1.2 mg/kg barium. The TCLP extract contained 0.24 mg/L lead and 0.06 mg/L barium, thus indicating that the sludge would not be characterized as a hazardous waste under the definitions and exclusions given in 40 CFR Part 21 for lead or barium, even in a final TCLP extract of pH 3.97. The SPLP extract contained 0.31 mg/L lead and less than 0.01 mg/L barium at a final SPLP extract pH of 2.15. This indicates that the SPLP will be more likely to produce leaching effects in laboratory analyses than the TCLP (Stantec, 2008).

The analyses for total SVOCs, PAHs and VOCs identified the following constituents in the sludge:

- Benzo(a)anthracene 70,000 µg/kg;
- Chrysene 160,000 µg/kg;
- 2-Methylnaphthalene 30,000 µg/kg;
- Phenanthrene 200,000 µg/kg;
- Pyrene 60,000 µg/kg;
- Ethylbenzene 200 µg/kg;
- Toluene 400 µg/kg;
- Xylenes 1,000 µg/kg;
- 2-Methylnapthalene 1,900 µg/kg;

- 1,2,4-Trimethylbenezene 700 µg/kg;
- 1,3,5-Trimethylbenzene 500 µg/kg; and
- 1,2,3-Trimethylbenzene 1,100 µg/kg.

Despite the presence of these compounds within the sludge itself, no PAHs or SVOCs were identified in the SPLP extract for the untreated sludge above the detection limit of 5 µg/L. This indicates that the SVOCs and PAHs within the sludge are largely immobile. Toluene was detected in the SPLP extract of the untreated sludge at 7 µg/L, and 1,2,3-trimethylbenzere was detected in the SPLP extract at 1 µg/L (Stantec, 2008).

Analysis of the sludge for TPH as GRO and DRO showed that the sludge contained 70 mg/kg GRO and 39,000 DRO. This shows that only 3.9 percent of the sludge is comprised of organics in the C6 to C28 hydrocarbon range, thus showing that the majority of organics in the sludge have a very high molecular weight in excess of 400 (Stantec, 2008).

3.4.9.2 Treated Sludge Leaching

Samples of composite sludge treated with a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$ at dosage rates of 22, 24, 26, and 28 percent reagent by weight with respect to the original mass of untreated sludge were subjected to SPLP testing. The results showed that the treatment produced non-detectable concentrations of RCRA metals and SVOCs in each of the SPLP extracts, with the exception of barium which was detected at 0.01 mg/L. This shows that the treatment reduced the concentration of leachable lead by the SPLP to less than 0.03 mg/L (Stantec, 2008).

3.4.10 Long-Term Leaching Analysis

A long-term leaching test was performed on a composite sludge sample from the Cooper North and Cooper South Sumps that was treated at a dosage of 25 percent of the 50/50 (w/w) $Ca(OH)_2$ and $CaCO_3$ reagent mix. The sample was subjected to the SPLP extraction procedure daily, with new extract water being added to the sample after each SPLP extraction to evaluate the long-term leaching effects after multiple extractions. The leachate from every other extraction was filtered and sent for analyses of PNAs, RCRA metals, and VOCs. The extracts were also tested in the laboratory for pH and alkalinity (Stantec, 2008).

Testing indicated lead did not leach from the sludge even after ten sequential SPLP extractions, indicative that treatment of the sludge with $Ca(OH)_2$ and $CaCO_3$ provides long-term stability for lead. Trace concentrations of barium, ethylbenzene, toluene and xylenes leached from the treated sludge, but the concentrations were well below the primary drinking water standards. Additionally, trace concentrations of

trimethylbenzene isomers, 2-methylnapthalene, and acetone leached from the treated sludge, but there are no primary or secondary drinking water standards for these compounds. Minimal alkalinity was removed from the sludge during the ten sequential extractions, thus indicating that many more extractions could have been performed while still maintaining alkaline stability in the treated material (Stantec, 2008).

3.4.11 Permeability

Composite samples of untreated and treated sludge from the Cooper North and Cooper South Sumps were tested for permeability by modified American Society for Testing and Materials (ASTM) D5084, Method C. The treated samples consisted of composite sludge samples treated with 15 percent calcium hydroxide and 15 percent $CaCO_3$ fines by weight. Stantec reported that the untreated sludge exhibited permeability less than $1x10^{-8}$ centimeters per second (cm/s), while the treated sludge exhibited permeability of approximately $9x10^{-3}$ cm/s (Stantec, 2008).

3.4.12 Evaluation of Soil Additive

Four composite samples of sludge were treated with 25 percent reagent comprised of a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$. Prior to adding the reagent, the samples were amended with 0, 25, 50, and 75 percent soil, by weight (Stantec, 2008).

The testing showed that the addition of soil to the neutralized sludge improved the density of the treated material and maintained high strength. Because the sludge at the Site is so viscous, it was difficult to assess how the soil additive worked as a stabilization material for bituminous stabilization at ambient temperatures. Therefore, samples of neutralized sludge treated with 0, 25, 50, and 75 percent soil were compacted into cores using a Harvard compaction apparatus, and the cores were placed into a convection oven at 220ºF to test the stability of the sludge. The testing showed that the neutralized samples containing no soil exhibited viscoelastic flow at 220ºF. The samples containing 25 percent soil exhibited minor viscoelastic properties, and the samples containing 50 and 75 percent soil by weight exhibited no viscoelastic properties. These test results show that the addition of 50 percent soil to neutralized sludge by weight converts the sludge into a stable solid material, even at elevated temperatures that exceed the softening point of the sludge (Stantec, 2008).

3.4.13 Evaluation of Thermal Treatment

Although the sludge was found to contain approximately 4 percent diesel-range organics, the majority of hydrocarbon in the sludge was comprised of very large chain hydrocarbons having a molecular weight greater than 400. When the sludge was tested for BTU value, it was found to have a very high heating value of 13,000 BTUs per pound. This confirms that the sludge is comprised primarily of organics. However, the

sludge also had an elevated sulfur content of approximately 7 percent. This high sulfur content suggests that incineration or fuel combustion of the sludge is not a viable treatment alternative due to the large amount of SO_2 gas that would be emitted during combustion. Stantec has estimated over 1,800 cubic feet (280 pounds) of SO_2 gas could be emitted for each ton of sludge incinerated or combusted. Sitewide, the total mass of SO_2 generated by thermal treatment of the sludge would exceed 2,600 tons (Stantec, 2008).

3.4.14 Evaluation of Moisture/Density Relationship for Treated Sludge

Four samples of sludge treated with 25 percent of a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$ were tested for moisture/density relationship to determine optimal dry density and moisture content for compaction after treatment. Testing was performed on a sample without soil amendment and on three samples amended with 25, 50, and 75 percent soil by weight with respect to the initial weight of untreated sludge (Stantec, 2008).

The test results showed that the neutralized sludge without soil amendment had a very low maximum dry density of 52.3 lb/ft^3 and high optimum moisture content of 46.7 percent. When the neutralized sludge was amended with 25 percent soil, the maximum dry density increased to 64.1 lb/ft^3 and the optimum moisture content decreased to a more reasonable value of 29.5 percent. The neutralized sludge sample amended with 50 percent soil had a maximum dry density of 68.8 lb/ft^3 and an optimum moisture content of 25.7 percent, and the sample amended with 75 percent soil had a maximum dry density of 71.6 lb/ft^3 and an optimum moisture content of 24.4 percent. Based on Table 13, stabilized sludge amended with 12 percent $CaCO_3$ and 12 percent $Ca(OH)_2$ has a density of 81 lb/ft^3 (RTC, 11/6/12) (Stantec, 2008).

3.4.15 Testing for Asphaltic Qualities

Testing of the sludge indicated that it will have low marketability as recycled asphalt, even when neutralized, for the following reasons:

- The sludge is a brittle, glass-like material with little to no ductility;
- The viscosity of the sludge is too high for use as asphalt cement in road construction;
- The sludge contains a high concentration of impurities and suspended solids which causes it to fail to meet the test for asphalt solubility for both asphalt cement and roofing asphalt;
- The sludge has a negative American Petroleum Institute (API) gravity;

- The softening point falls into acceptable ranges for a Type II roofing asphalt, but the sludge fails to meet most of the remaining specifications for Type II roofing asphalt; and
- Penetration values for the sludge were too low for use as asphalt cement but meet the specifications for Type IV roofing asphalt.

Although the sludge shares the softening point specifications for Type II roofing asphalt and the penetration specifications for Type IV roofing asphalt, it fails to meet the ductility requirements for either of these asphalt grades. The brittle nature of the material gives it undesirable properties because the material is easily cracked and sheared, thus making it unsuitable for roofing or pavement construction applications (Stantec, 2008).

Section VII.C. of the Consent Decree requires the evaluation of the proposal of Mr. Thomas Cooper for recycling the sludge as one of the alternatives in the FS. The Cooper Sumps sludge, in a non-neutralized state, releases significant quantities of H_2S and SO_2 gas when disturbed. The release of these gases from the sludge as well as the physical characteristics of the sludge, makes the sludge unacceptable for recycled asphalt application. The sludge recycling alternative is not evaluated further in this FS.

4. REMEDIAL ACTION OBJECTIVES AND CLEANUP CRITERIA

4.1 General

This section describes the development of remedial action objectives (RAOs) and target cleanup levels for the Site. The development of RAOs is required by RI/FS guidance as part of the FS. The process of developing the RAOs depends upon the assessment of risk to identified receptors at the Site and in the Site vicinity. A discussion of the risk assessment (RA) at the Site follows.

4.2 Chemicals of Potential Concern

The chemicals of potential concern (COPCs) for the Site were developed and discussed in the hazard identification section of the *Draft Human Health Risk Assessment* (HHRA) (Geosyntec, 2010). USEPA guidance states that the list of chemicals should include all chemicals that were:

- Positively detected in at least one sample;
- Detected above levels of the same chemicals found in associated blank samples;
- Tentatively identified, but may be associated with the Site based on historical information;
- Transformation products of detected chemicals; and
- Detected above naturally occurring levels (background).

During the RA, those contaminants posing a potential risk to receptors at the Site were identified as COPCs and can be found in Table 4-1 for soil, soil gas, and groundwater.

4.3 Human Health Risk Assessment

4.3.1 Approach

The draft HHRA included an evaluation of health risks to potentially exposed receptor populations consisting of: commercial/industrial workers, construction workers, hypothetical future residents, and trespassers. Potential exposures were evaluated for these populations assuming existing physical site conditions (without the existence of the protective caps on the Cooper and Haack properties and prior to any future remediation efforts at the Site). In addition, a current residential scenario has been included for the immediate adjacent offsite residential area (Geosyntec, 2010).

Future development of the Site and the immediate adjacent offsite residential area would be commercial as designated in the City of Gardena's report titled *Artesia*

Corridor Specific Plan (TPC, 2006). To conservatively evaluate the potential risks under an unrestricted land use scenario, a more conservative hypothetical future residential scenario was included in the HHRA to evaluate potential risks under an unrestricted land use scenario. Additionally, the conservative construction worker, shallow groundwater to outdoor vapor inhalation and dermal contact scenario was evaluated to represent groundwater in an open excavation (Geosyntec, 2010).

To evaluate the spatial distribution of risk driving chemicals, two types of comparison criteria were developed for each chemical identified in the risk characterization: (1) those based on background; and (2) risk-based values (RBCs) or target risk concentrations which are based on each receptor group and assuming site-specific soil characteristics and a target risk goal. For worker exposures (commercial/industrial and construction worker) a target risk goal of 1 in 100,000 (1×10^{-5}) was used. For residential and trespasser scenarios a 1 in 1,000,000 (1×10^{-6}) target risk goal was used. For those chemicals in which the risk-based concentrations are below background, the background concentration is used as the comparison criteria. This is the case for arsenic and residential and commercial/industrial worker scenarios, and benzo(a)pyrene toxicity equivalent (BaP-eq) for the residential scenarios (Geosyntec, 2010).

4.3.2 Results

The results of the HHRA indicate that exposures to onsite soils may potentially exceed target risk goals for all potential receptor scenarios evaluated: commercial/industrial worker, construction worker, hypothetical future onsite/current offsite resident, and trespasser. The primary contributors to the risk estimates were arsenic, hexavalent chromium, naphthalene, and predominantly the carcinogenic PAHs as represented by the BaP-eq concentration. The majority of locations where concentrations of these chemicals were elevated occurred within areas of known sludge material which are currently covered by the existing geomembrane cap, soil, concrete, and/or asphalt (Geosyntec, 2010).

4.4 Chemicals of Concern

Following completion of the HHRA, primary risk driving chemicals were identified from the list of COPCs (see Section 4.2) as chemicals of concern (COCs). These chemicals were identified as primary risk drivers because they are the most ubiquitous chemicals throughout the Site and because they are co-located with a majority of the COPCs (i.e., the risk associated with the COCs would encompass the COPCs). Based on the HHRA, the primary COCs at the Site are:

- **Soil**: arsenic, hexavalent chromium, naphthalene, and the BaP-eq
- **Air**: benzene, hydrogen sulfide

- **Groundwater**: dibenz(a,h)anthracene

These COCs are present in the Cooper and Haack Sumps as well as in the Haack rework area. Methane has been detected at low concentrations around the site but was not identified as a COC based on the HHRA. Due to the potential explosive risk associate with methane, it has been included with as a Remedial Action Objective. (RTC, 9/29/11)

4.5 Remedial Action Objectives

RAOs are goals specific to various media and apply to those media that have been identified as posing an unacceptable risk based on the HHRA work performed for the Site. The RAOs for onsite soils, soil gas, and groundwater are:

- Prevent ingestion/direct contact with sludge and/or soil having 10^{-5} to 10^{-6} excess cancer risk from carcinogenic constituents as represented by arsenic, hexavalent chromium, naphthalene, and the BaP-eq concentration;
- Prevent dermal contact with shallow groundwater having 10^{-5} excess cancer risk from carcinogenic polycyclic aromatic hydrocarbons (PAHs) as represented by dibenz(a,h)anthracene;
- Prevent dermal contact with low pH, PAH containing sludge (RTC, 2/10/12);
- ~~Prevent inhalation of benzene posing excess cancer risk levels of 10^{-5} to 10^{-6}~~ (RTC, 9/29/11);
- Prevent inhalation of volatile organic compounds (VOCs), as represented by benzene, posing excess cancer risk levels of 10^{-5} to 10^{-6}(RTC, 9/29/11); and
- Prevent explosive risks associated with methane. (RTC, 9/29/11)

4.6 Applicable or Relevant and Appropriate Requirements

The Applicable or Relevant and Appropriate Requirements (ARARs), as defined by 40 CFR 300.5, presented in this section were identified for the remedial actions presented in this document to comply with Federal environmental law or more stringent standards promulgated under State environmental law. Federal and State environmental laws are evaluated to determine if they are either applicable or relevant and appropriate.

"To Be Considered" (TBC) criteria have also been identified to cover Federal and State nonpromulgated standards, policies, or guidance documents and local requirements for constituents which do not have developed preliminary remedial goals or ARARs.

The ARARs are divided up into the following three categories according to the type of CERCLA action they govern: chemical-specific, location-specific, and action-specific requirements. ARARs and TBC criteria are presented in Table 4-2.

4.6.1 Potential Chemical-Specific Requirements

At the Site, chemical-specific requirements include RCRA provisions defining hazardous waste, maximum contaminant levels (MCLs) derived from the Safe Drinking Water Act, and primary and secondary national standards for ambient air quality. The Draft HHRA identifies the site-specific, risk-based cleanup levels (Geosyntec, 2010).

4.6.2 Potential Location-Specific Requirements

No location-specific ARARS were identified since the Site is not located in any sensitive or protected area.

4.6.3 Potential Action-Specific Requirements

The potential action-specific requirements for the Site include:

- **Porter-Cologne Water Quality Control Act**: Set on a case by case basis by the Regional Water Quality Control Board (RWQCB), water emission standards are applied to waste water, groundwater, (RTC, 1/9/2013) and stormwater runoff from the Site.
- **South Coast Air Quality Management District (SCAQMD)**: Emissions of gases, particulate matter, and fugitive dust are set by the SCAQMD and may apply if they are part of the State Implementation Plan pursuant to the Clean Air Act.
- **National Pollution Discharge Elimination System (NPDES)**: Requires the elimination of most non-stormwater discharges, Stormwater Pollution Prevention Plan (SWPPP) preparation, and stormwater discharge monitoring.
- California Civil Code and California Health and Safety Code governing land use restrictions.
- DTSC hazardous constituent regulations as outlined in 22 CCR Division 4.5.

4.7 Future Site Use

The Site is currently used for residential and commercial/industrial applications. The DTSC has requested the following three future land use scenarios be evaluated for the Site:

- Current land use will continue; residential properties would remain and Cooper and Haack areas would remain commercial/industrial;
- Use the Site for residential only; and
- Use the Site for commercial/industrial only.

As a conservative approach to meet the DTSC request, the residential cleanup goals will be used, which are the most stringent.

The City of Gardena has developed the City of Gardena Master Plan (TPC, 2006) which indicates the Site would be developed in the future as commercial property with a mix of commercial buildings and parking. To accommodate this development plan and constraints of the Site, ARC requested the remedial design be compatible with a parking lot or open space end use incorporating curbs, gutters, light poles, and utilities.

4.8 Target Cleanup Levels

The target cleanup levels for the Site were developed with consideration given to the following factors:

- Hypothetical future use scenario;
- Remedial action objectives; and
- Potential site health risk.

The cleanup levels shown in Tables 4-3, 4-4, and 4-5 were developed for each of the COCs identified in Section 4.3. Cleanup criteria either are numeric goals to be achieved through remediation or are non-numeric, performance-based criteria. The cleanup levels shown in Tables 4-3, 4-4, and 4-5 will be used subsequently in this FS Report to guide the selection and screening of remedial technologies and the development and detailed analysis of remedial alternatives. A discussion of the development of cleanup criteria follows.

4.8.1 Site-Specific Action Levels

Soil cleanup criteria are based on the derivation of risk-based concentrations (RBCs) for site COCs. RBCs were developed for each chemical identified as a COC or "risk driver" in the risk characterization of the HHRA (Geosyntec, 2010) based on each receptor group and assuming site-specific soil characteristics as presented in Appendix C. (RTC, 4/4/12) RBCs were derived for arsenic, BaP-eq, hexavalent chromium, benzene, and naphthalene in soil (Table 4-3); benzene in soil gas (Table 4-4); and dibenz(a,h)anthracene in groundwater (Table 4-5). The derivation of these concentrations is provided in Appendix B. RBCs are presented for both cancer and noncancer effects; cancer effects generally produce lower RBCs. The selected site-specific action levels (SSALs), considering background concentrations, are presented in the last column for each receptor group.

For arsenic in soil, the DTSC screening level of 12 mg/kg, which is considered background for southern California sites (Cal-EPA DTSC, 2007), was used as the SSAL for residential receptors.

For BaP-eq in soil, a concentration of 0.9 mg/kg, considered representative of background PAH concentrations in southern California soils, was used as the SSAL for residential receptors.

5. IDENTIFICATION AND SCREENING OF TECHNOLOGIES

5.1 Introduction

General response actions (GRAs) describe remedial actions that would address RAOs and achieve cleanup criteria for hypothetical future receptors that may be exposed to soil, soil gas, and groundwater contaminants. This section provides a discussion of GRAs and also provides identification of potential remedial technology types and specific technologies. A screening analysis was conducted to reduce the number of potentially applicable technologies to those that were determined to be potentially able to achieve the RAO for the COCs.

5.2 General Response Actions

Specific GRAs identified for onsite impacts include the following:

- No action;
- Remediate or remove soils that present potential ingestion and/or dermal contact risk;
- Containment;
- Reduce concentrations of COCs that present a potential inhalation risk;
- Gas monitoring and treatment;
- Monitor groundwater; and
- Implement institutional controls to restrict access to sludge and to control and manage risk associated with future mixed-use redevelopment.

5.3 Technology Identification and Screening

In accordance with USEPA guidance, potential remedial technology types and specific technologies that can be used to implement the GRAs were identified and then screened to assess their effectiveness, implementability, and cost. This section provides a screening of technologies to identify those that will be combined into remedial alternatives in Section 6 of this FS Report. The following technologies have been identified for remediation and are listed in Table 5-1:

- No action;
- Institutional controls;
- Treatment:
    - Stabilization/neutralization

    - Thermal treatment and
    - Sludge recycling
- Containment;
- Excavation and removal for offsite disposal; and
- Engineered controls:
    - Vapor and gas control systems; and
    - Groundwater monitoring.

In accordance with US EPA Feasibility Study guidance, Table 5-1 presents the screening of each technology based on its relative effectiveness, implementability, and cost. This screening provides the rationale behind the decision to retain or eliminate each technology type. Therefore, based on the screening, the following technology types were retained for further evaluation:

- No action (as required by USEPA guidance);
- Institutional controls;
- Treatment:
    - Stabilization/neutralization
- Containment;
- Excavation; and
- Engineering Controls:
    - Gas control systems; and
    - Groundwater Monitoring.

A summary of technologies retained is presented in Table 5-2. Each retained technology will be integrated into one or more remedial alternatives, described in Section 6.

6. DEVELOPMENT OF REMEDIAL ALTERNATIVES

In this section, remedial alternatives for the Site are assembled from those technologies that remain after the initial screening in Section 5. Each remedial alternative includes a remedial approach that accommodates the hypothetical future use scenario described in Section 4 and assumes that Site features are removed prior to remedy implementation. Each remedial alternative listed in Table 6-1 is designed to address each impacted media at the Site.

6.1 Remedial Alternatives

Table 6-1 presents the four remedial alternatives that were retained for evaluation:

- Alternative (A) 1 – No action;
- ~~A 2 – Capping with selective excavation~~ (RTC, 9/29/11)~~;~~
- A 2A – Capping with selective excavation (RTC, 9/29/11);
- A 3 – Capping with selective excavation and stabilization/neutralization; and
- A 4 – Excavation with offsite disposal.

Alternatives ~~2~~ 2A (RTC, 9/29/11) and 3 include institutional controls, gas control and monitoring, and groundwater monitoring. All four alternatives are described below.

Alternatives ~~2~~ 2A (RTC, 9/29/11) through 4 are depicted on Figures 6-1 through 6-16. Details shown are conceptual for estimating and comparison purposes only, and do not represent the results of full engineering design and analysis.

6.1.1 Alternative 1 – No Action

This alternative consists of performing no work now or in the future to attempt to mitigate an existing condition. The current geomembrane cover would remain and no deed restrictions would be placed on the property.

For No Action to be considered an acceptable alternative, the concentrations of COCs would have to be below RAOs. This alternative would provide no exposure pathway reductions. There would be no controls to prevent future site development or site access. Groundwater contamination would not be known since monitoring would not be performed. Future site development would be hindered due to the instability of the sludge material. The No Action Alternative is required by USEPA FS guidance.

~~6.1.2 Alternative 2 – Capping with Selective Excavation~~

~~Alternative 2 includes the following major elements:~~ (RTC, 9/29/11)

- ~~Existing surface removal;~~
- ~~Consolidation and capping of impacted material;~~
- ~~Capping of sludge;~~
- ~~Installation of gas control and monitoring system;~~
- ~~Institutional controls; and~~
- ~~Groundwater monitoring.~~

~~This alternative is depicted on Figures 6-1 and 6-2. The cap surface shown in Figure 6-2 is for comparative purposes in this Feasibility Study only and does not represent the final cap surface. Each component is discussed further in the following sections.~~ (RTC, 9/29/11)

~~*6.1.2.1 Existing Surface Removal*~~

~~A geomembrane is currently above the Cooper North and South Sumps. Prior to initiating consolidation activities, the existing geomembrane will be cut to allow sludge to permeate through and prevent the potential for gas build up. The geomembrane will remain in place and Haack Rework and Eastern Overflow material would be consolidated above it.~~ (RTC, 9/29/11)

~~*6.1.2.2 Consolidation of Material*~~

~~In general, the sludge is contained in the three sumps: Cooper North and South, and Haack. As previously discussed in Section 3.2.1, approximately 650 CY of a sludge/soil mixture is located outside of the sumps in the Haack Rework area. To excavate the sludge/soil mixture, approximately 3,550 CY of overburden will need to be excavated. Additionally, along the eastern property line, a thin layer of sludge exists which appears to be the result of spillage or overflow from the sumps. Also, as shown on Figure 6-1, some sludge material is outside of the Site boundary beneath the sidewalk and Artesia Blvd. This sludge material is considered to be already capped with asphalt, concrete, and a minimum of 18 inches of sand and/or silty sand above the first detected sludge deposits (Stantec, 2010a).~~ (RTC, 9/29/11)

~~The Haack Rework and eastern overflow areas would be consolidated into one of the three sumps prior to capping, and used as fill beneath the cap low-hydraulic conductivity layer (to be discussed in Section 6.1.2.2). Approximately 4,460 CY of Haack Rework (650 CY), Haack Rework overburden (3,550 CY), and eastern overflow (260 CY) are anticipated to be placed above the sumps.~~ (RTC, 9/29/11)

~~Following visual excavation of material from the Haack Rework and eastern overflow, confirmation sampling would be performed to confirm the material was removed.~~

~~Confirmation sample results would be compared to cleanup goals. Where testing indicates concentrations in excess of cleanup goals, additional material would be removed and consolidated above the sumps. Haack Rework and eastern overflow excavations will be backfilled using soils obtained from unimpacted areas of the site.~~ (RTC, 9/29/11)

~~*6.1.2.3 Capping of the Sumps*~~

~~The Cooper North and South and Haack Sumps would remain in place. Human health and the environment would be protected through use of a cap which would act as a barrier to prevent both dermal contact and gas exposure. The proposed, conceptual Haack and Cooper cap grades are shown on Figure 6-2. This preliminary cap design is in accordance with California Code of Regulations Title 22 (22 CCR) §66264.228. The grades show on Figure 6-2 incorporate minimum slopes to maintain cover integrity in the event of settling and/or subsidence per 22 CCR §66264.228(a)(2)(C)(4). The final design of the cap may have flatter slopes if analyses are performed to show ponding will be prevented. In accordance with 22 CCR, the cap consists of a foundation layer, low-hydraulic conductivity, and erosion-resistance layer. The Alternative 2 cap is illustrated on Figure 6-6, in Detail 1-A, and would consist of the following layers:~~ (RTC, 9/29/11)

~~*Stabilization Layer*~~

~~The stabilization layer is intended for use over the sludge material in the Cooper North and South sumps (Detail 1-A, Figure 6-6). The Haack Sump is currently overlaid by a 6-inch reinforced concrete pad which would act as the stabilization layer (Detail 1-C, Figure 6-6). Prior to placement of the stabilization layer over the Cooper Sumps, the geomembrane material will be cut to allow sludge to seep through and mix with the gravel layer. The stabilization layer on the Cooper North and South sumps will consist of, from bottom to top, 2 feet of gravel, 1 foot of sand, high-strength woven geotextile, and a 6-inch geocell filled with sand. The bottom gravel layer placed above the cut geomembrane is intended to partially sink into the sludge material to provide stabilization during construction of the overlying materials. The high-strength woven geotextile would provide separation reinforcement and, along with the geocell reinforcement, would "bridge" the soft sludge areas and provide the strength needed to support the cap.~~ (RTC, 9/29/11)

~~*Foundation and Gas Collection Layers*~~

~~The foundation soil and gas collection layers would be placed above the stabilization layers and consist of, from bottom to top, minimum 1 foot of foundation soil, gas collection piping, and a gas collection geocomposite. The minimum 1 ft foundation and gas collection layer will support the low-hydraulic conductivity layer and erosion~~

resistance layer in accordance 22 CCR §66264.228(e)(4). The foundation soil would consist of onsite, impacted soil and Haack Rework material where available. Impacted foundation layer material would be supplemented with soil material obtained from unimpacted areas of the site. Horizontal gas collection pipes surrounded by gas collection aggregate would be embedded in the foundation layer. Nonwoven geotextile would surround the aggregate to prevent clogging of the aggregate due to fines intrusion. (RTC, 9/29/11)

Low-Hydraulic Conductivity Layer

The low-hydraulic conductivity layer would be placed above the foundation and gas collection layers and would consist of a geosynthetic clay liner (GCL) and a 60-mil high density polyethylene (HDPE) geomembrane. In accordance with 22 CCR §66264.228(e)(5), the low-hydraulic conductivity layer would reduce the downward migration of precipitation and the upward migration of sludge and gas. (RTC, 9/29/11)

Erosion Resistance Layer

The erosion resistance layer is comprised of a drainage geocomposite and 2 feet of vegetated cover soil. In accordance with 22 CCR §66264.228(e)(10). the drainage geocomposite would prevent hydrostatic head buildup and drain precipitation that has infiltrated the overlying vegetated cover soil toward the outside of the cap and perimeter drainage channels while the vegetative cover soil will be resistant to foreseeable erosion effects by wind scour, raindrop impact, and runoff. (RTC, 9/29/11)

Along the northern property boundary, limited space is available to allow for grading to install the cap system. As a result, sheet piles would be installed to allow for the vertical rise of the cap without altering Artesia Boulevard or the railroad property. Furthermore, the installation of sheet piles would prevent lateral migration of the sludge material from beneath the cap due to the new weight of the cap. The sheet piles would be installed to an average depth of 20 feet bgs and extend between 4 and 10 feet from the ground surface to accommodate the cap. (RTC, 9/29/11)

6.1.2.4 Gas Control and Monitoring System

The gas control system would be comprised of perimeter vertical gas migration control wells and a below-cap horizontal gas collection system. The proposed layouts of the vertical and horizontal gas collection systems are shown on Figures 6-3 and 6-4, respectively. (RTC, 9/29/11)

Vertical Gas Migration Control Wells

The system of gas migration control wells is designed to be a passive system that, as a contingency, can be converted readily to an active system. The system will operate

actively for a period of 2 weeks following remedial action at the site. Based on the concentrations of constituents detected during the 2-week startup period, the system will remain active or switch to passive operation with the option for active control in the future. The decision to make the system active again would be based upon future gas monitoring at the Site. (RTC, 9/29/11)

As a passive system, the wells are designed to intercept gases that may migrate laterally from the sumps; the gases are then vented to the atmosphere or to a treatment system. Barometric pumping would help "flush" the wells. As an active system, alternate wells would serve as air inlet and gas extraction wells. In this way, a "curtain" of air would be created that would intercept gases that may potentially migrate from the sumps as depicted on Figure 6-5. The extracted gases would then be vented to the atmosphere or to a treatment system. The wells would be installed to the approximately 2 ft above the groundwater "A" horizon. (RTC, 9/29/11)

Below-Cap Horizontal Gas Collection System

A horizontal gas collection system would be placed within the foundation layer of the cap, as discussed above. Similar to the vertical gas migration control wells around the perimeter of the cap, the gas collection system is designed to initially operate as an active system, during a start-up period of approximately two weeks. The system would then be operated as a passive system, but is designed as a contingent measure to be readily converted to active. As a passive system, it would be vented to the atmosphere and rely on barometric pumping to flush the system. The decision to make the system active would be based upon post-remediation gas monitoring at the Site. (RTC, 9/29/11)

The design of the gas collection system incorporates two separate gas collection pipes near the perimeter of the cap. A gas transport pathway between the gas collection pipes is established by the geocomposite component of the cap. As a passive system, gas entering the geocomposite would transmit to either of the gas collection pipes and would vent to the atmosphere or gas treatment system. As an active system, one of the pipes would be an air inlet pipe and the other pipe would be an extraction pipe. A flow of air and gas from the air inlet pipe to the extraction pipe would be created across the width of the caps and would remove gas that may accumulate below the barrier component of the cap. (RTC, 9/29/11)

Gas Monitoring System

Gas migration sentry probes would be placed near the perimeter of the cap. The proposed locations of the probes are shown on Figure 6-4. The sentry probes are designed to be outside of the vertical gas migration control wells. Regular monitoring of gas concentrations at the probe locations would be performed before, during, and after system operation. The decision to convert the gas collection systems to an active

~~system would be partially based upon the results of the sentry probe monitoring activities, and threshold contaminant concentrations developed in the Operations, Maintenance, and Monitoring (OM&M) Plan.~~ (RTC, 9/29/11)

~~*6.1.2.5 Institutional Controls*~~

~~The anticipated institutional controls for the Site would prohibit sensitive land uses (i.e., single family residence, hospitals, schools, or child care centers), specify new building construction (i.e., first floor non-residential, upper floor residential, and inclusion of gas control system), and prohibit onsite groundwater extraction for municipal (i.e., drinking water purposes), industrial, and agricultural (i.e., irrigation) use. Furthermore, a Health and Safety Plan (HASP) and Construction Quality Assurance (CQA) Plan would be required to establish minimum health and safety protocol during construction, and provide documentation of proper excavation, cap, and gas control system construction. A Risk Management Plan (RMP) would be developed for the Site to reduce the risk of future construction worker exposure to groundwater if the Site is developed. The RMP would discuss the hazards at the site, minimum PPE requirements, and notification requirements. Land use covenants (LUCs) to place deed restrictions on the site will be filled with the Los Angeles County Recorder's Office and annual LUC restriction inspections will be conducted by DTSC to ensure compliance (RTC, 4/4/12)~~ (RTC, 9/29/11)

~~*6.1.2.6 Groundwater Monitoring*~~

~~Groundwater monitoring would continue to be performed on a semi-annual basis for a period of 5 years after the remedial controls have been implemented. During construction, three sets of wells would be destroyed to accommodate construction of the cap. Following construction, two wells would be installed to represent the upgradient and downgradient conditions with the remaining well network.~~ (RTC, 9/29/11)

6.1.2 Alternative 2A – Capping with Selective Excavation

Alternative 2A replaced Alternative 2 in the Draft FS dated February 2011. Alternative 2A is consistent with the former Alternative 2 in that capping and selective excavation of the sludge in the Haack Rework area are evaluated. However, the evaluated cap proposed in Alternative 2A is significantly lower in overall height than the cap of former Alternative 2. Additionally, different disposal scenarios for the Haack Rework material are proposed in Alternative 2A. The lower profile cap and different Haack Rework material disposal alternative presented in this Final Revised Draft FS is in response to comments received from the City of Gardena during the 10 May 2011 meeting. (RTC, 9/29/11)

6.1.2.1 General Overview

The Site is generally divided into three areas: the Cooper North and South Sumps on the Cooper Property, the Haack Sump and the Haack Rework Area located primarily within the Haack property, four residential properties, land owned by Los Angeles County and a small area of land beneath the Artesia Boulevard right-of-way. Because these areas of the Site are divided among different property owners, the properties may not all be available for remedial construction at one time. The following sections describe, in general, the proposed Alternative 2A approach for each area. Section ~~3.3~~ 6.1.2.2 (RTC, 11/6/12) describes the remedial implementation approach for the entire Site in greater detail. (RTC, 9/29/11)

As described ~~in the Draft FS (Geosyntec, 2011),~~ previously (RTC, 11/6/12), the sludge material beneath the Artesia Boulevard South sidewalk and Artesia Boulevard are below road base material and asphalt or sidewalk concrete. The concrete and asphalt surface prevent ingestion and direct contact with the sludge as well as reduce its mobility by containing the sludge. (RTC, 11/6/12) This sludge material is considered to be already capped; however, institutional controls will include a requirement for repaving the area with "low-permeability asphaltic concrete" and increased maintenance of the asphalt surface in this area. ~~and therefore was not addressed in the Draft FS and will not addressed in Alternative 2A.~~ (RTC, 11/6/12)

Future access from current and/or future utility and/or construction workers will be addressed in the Risk Management Plan (RMP). The RMP will describe contaminants remaining onsite, known locations of impacts, contact information, and minimum, recommended personal protective equipment for current and future utility and/or construction workers. Institutional controls will include requirements (RTC, 11/6/12) that the City of Gardena and/or Caltrans provide notice of potential subsurface hazardous materials in the area of Artesia Boulevard where sludge is potentially located, prior to (RTC, 11/6/12) issuing work permits. (RTC, 2/10/12) Institutional controls will also include requirements related to Site development and cap loading restrictions. (RTC, 11/6/12)

Cooper North and South Sumps

The existing geomembrane will remain in place with the cap installed above. The geomembrane will provide a construction surface and preliminary support during installation of the overlying materials. Furthermore, the existing surfaces minimize the dermal contact and gas inhalation exposure risks to the construction workers during installation of the cap. (RTC, 11/6/12)

The sludge in the Cooper North and South Sumps will be capped, from bottom to top, with the following materials: (1) high-strength geotextile; (2) between 1 and 4.5 feet (ft) of foundation layer material; (3) a horizontal gas collection system: gas collection geostrips and gas collection geocomposite; (4) geosynthetic clay liner (GCL); (5) high-density polyethylene (HDPE) geomembrane; (6) drainage geocomposite; and (7) 12-inches (in.) of Class II aggregate base. (RTC, 9/29/11)

Haack Sump

The existing asphalt and concrete will remain in place with the cap installed above. The asphalt and concrete will provide a construction surface and preliminary support during installation of the overlying materials. Furthermore, the existing surfaces minimize the dermal contact and gas inhalation exposure risks to the construction workers during installation of the cap. (RTC, 9/29/11) In areas where sludge has migrated to the surface, asphalt repair will be performed prior to installation of the cap. (RTC, 11/6/12)

The sludge in the Haack Sump will be capped, from bottom to top, with the following materials: (1) between 0.5 and 4.5 ft of foundation layer material; (2) a horizontal gas collection system made up of gas collection geostrips and gas collection geocomposite; (3) geosynthetic clay liner (GCL); (4) HDPE geomembrane; (5) drainage geocomposite; and (6) 12 in. of Class II aggregate base. (RTC, 9/29/11)

Haack Rework Area

The Haack Rework area is composed of soil-sludge material and soil overburden. The Haack Rework overburden material will be disposed of as foundation material beneath the Cooper North and/or South sumps cap. ~~These materials will be removed and relocated or disposed of in three possible scenarios or a combination of the following three scenarios: (1) beneath the Cooper North and/or South Sumps cap as foundation layer material; (2) beneath the Haack Sump cap as foundation layer material; and (3) offsite disposal.~~ (RTC, 11/6/12) Approximately 2,670 CY of Haack Rework soil-sludge material and 2,450 CY Haack Rework overburden are anticipated to be relocated during construction activities. Disposal of the Haack Rework material will be dependent on the material properties of the soil-sludge and (RTC, 11/6/12) ~~property~~ availability of staging areas within the property (RTC, 11/6/12) during construction, as described in greater detail in Section ~~3.3.3~~ 6.1.2.2. (RTC, 11/6/12)

6.1.2.2 Detailed Alternative 2A Components

Alternative 2A includes the following major elements:

- Existing surface preservation;
- High-strength geotextile installation;

- Select excavation of impacted material (Haack Rework material);
- Containment of sludge along Artesia Boulevard;
- Installation of gas control and monitoring system;
- Capping of the sumps;
- Institutional controls; and
- Groundwater monitoring.

The approximate area of Alternative 2A is depicted on Figures ~~3-1~~ 6-1 and ~~3-2~~ 6-2. (RTC, 11/6/12) The construction and cap components are discussed further in the following sections.

Existing Surface Preservation

The existing geomembrane surface on the Cooper Property and concrete and asphalt surfaces above the Haack Sump will remain in place and the cap will be installed above these surfaces. New asphalt will be placed above the existing, degraded areas of asphalt surface over the Haack Sump prior to the initiation of cap construction on the Haack property. (RTC, 2/10/12) The geomembrane, asphalt, and concrete surfaces will provide a barrier to minimize worker dermal exposure to sludge contact as well as gas generation and release. Additionally, the concrete and asphalt surfaces will provide strength to the cap on the Haack Sump, eliminating the need for the high-strength geotextile described ~~in Section 3.3.2.~~ below. (RTC, 11/6/12)

High-Strength Geotextile Installation

A polypropylene (RTC, 11/6/12) high-strength geotextile will be placed above the existing geomembrane surface in the Cooper North and South sump areas; no polypropylene (RTC, 11/6/12) high-strength geotextile is proposed above the Haack sump area. The geotextile will be used to provide reinforcement during installation of the foundation soil to support both the weight of the soil and construction equipment. The polypropylene (RTC, 11/6/12) high-strength geotextile will be anchored around the perimeter of the two Cooper sumps with an anchor trench and/or secured to sheet piling along Artesia Boulevard. The minimum tensile strength and anchorage of the high-strength geotextile have been evaluated and are included in Appendix D. (RTC, 2/1/12) A typical anchor trench is shown as Detail 7 on Figure ~~3-10~~ 6-14.

Haack Rework Material Excavation and Disposal

The Haack Rework area is comprised of approximately 2,670 CY of sludge and a soil-sludge mixture beneath approximately 2,450 CY of soil overburden; therefore, a total of approximately 5,120 CY of material is anticipated to be relocated during construction activities. Haack rework material excavation will be performed using standard

construction equipment. (RTC, 11/6/12) A contingency plan will be developed which establishes gas concentration thresholds and corresponding actions such as odor suppression, soil replacement, and/or evacuation (RTC, 11/12/13) Odor suppressant equipment (foaming units) will be present during excavation to control odors and gas emissions, if necessary. South Coast Air Quality Management District (AQMD) Rule 1166 and applicable California Occupational Safety and Health (Cal-OSHA) exposure limits will be followed during excavation and handling of the Haack Rework material. (RTC, 11/6/12)

As previously described, the Haack Rework soil-sludge material will be removed and disposed of offsite ~~relocated by three possible scenarios: (1) beneath the Cooper North and/or South Sumps cap; (2) beneath the Haack Sump cap; and/or (3) offsite disposal.~~ (RTC, 11/6/12) The Haack Rework area overburden soil will be used as foundation material beneath the Cooper or Haack Sumps caps.

~~Scenarios 1 and 2 are dependent on the phasing of the construction. For example, if all parcels are available for cap construction at one time, the Haack Rework soil-sludge material can be placed within the Cooper North and South cap; however, if only the Haack Sump and Residential Properties are available for cap construction, the Haack Rework soil-sludge material will be placed within the Haack Sump cap. Material will only be placed as foundation material if it meets the requirements for engineered fill as defined in the future construction specifications.~~ (RTC, 11/6/12) ~~In Scenarios 1 and 2, the Haack Rework soil-sludge mixture material would be excavated and placed as foundation material above the high strength geotextile or 6-inch reinforced concrete or asphalt on the Cooper North and South Sumps or Haack Sump, respectively. The material would be used as foundation material to support the overlying geosynthetics and erosion resistant layer, provide fill to generate the minimum grades for drainage, and support the gas collection strip composite (geostrip), gas collection piping, and gas collection geocomposite.~~ (RTC, 11/6/12)

~~The construction schedule for Scenarios 1 and 2 is estimated to require approximately 14 days to relocate the material from the Haack Rework area to the sump(s).~~ (RTC, 11/6/12)

The Haack Rework soil-sludge material would be excavated and disposed of at a commercial, non-RCRA hazardous landfill (assumed to be the Buttonwillow Facility). Assuming all 2,670 CY of soil-sludge material is disposed of offsite and assuming 16 CY capacity end-dump trucks are used, approximately 164 truckloads would be necessary to transport the material an estimated 150 miles one-way to the Buttonwillow

Facility. An estimated 18 trucks[2] per day could be loaded and transported to the Buttonwillow Facility, resulting in approximately 10 days of hauling from the Site (Appendix E [RTC, 9/29/11]). ~~Scenario 3 has been included in the cost estimation, Table 3-1, and detailed and comparative analyses, Sections 4 and 5, respectively. A potential cost savings of $314,500 may be achieved if Scenarios 1 or 2 are implemented.~~(RTC, 11/6/12)

~~Initial finger berm construction as described in Section 3.3.5.1 6.1.2.3 (RTC 11/6/12) is estimated to require 8 days, assuming approximately 500 CY per day of material can be relocated. After the initial lift is placed, an additional 9 days would be required to place the additional 9,100 CY of foundation material, assuming an increased placement efficiency of 1,000 CY per day. The increase in efficiency after the initial lift is due to the less selective and restrictive nature of the placement after the working surface becomes more supportive. A preliminary schedule is provided in Appendix E. (RTC, 9/29/11)~~ (RTC, 1/9/2013)

The Haack Rework area will be excavated no deeper than an elevation of approximately 20 ft above mean sea level (amsl) as shown on Figure ~~3-5~~ 6-5. (RTC, 11/6/12) Following excavation of material from the Haack Rework area using visual means to guide the limits of the excavation, confirmation sampling to determine the absence of sludge and (RTC, 2/10/12) COCs at 5 ft intervals to a depth of 10 ft below the planned excavation grade (RTC, 2/10/12) would be performed to confirm the material was removed. Confirmation sample results will be compared to risk-based cleanup goals ~~provided in the Draft FS~~ described in Section 4.8. (RTC, 11/6/12) Where testing indicates concentrations in excess of cleanup goals, additional material would be excavated, hauled, disposed of offsite or reused as foundation material, and additional confirmation testing would be performed.

Upon completion of excavation, confirmation sampling, and receipt of test results indicating that the samples are below risk-based cleanup goals, the area will be backfilled with clean on- or off-site soil and graded to drain. The slope from the southern residential properties resulting from the excavation of the Haack Rework area will be contoured to a 3 ft horizontal to 1 ft vertical (3H:1V) grade while portions of the excavations lower than the surrounding land will be backfilled and graded to drain (Figures ~~3-1~~ 6-1 and ~~3-2~~ 6-2). (RTC, 11/6/12)

[2] Assumptions: (1) 3 trucks are loaded per hour between 7 am and 1 pm, such that trucks can get to the disposal facility prior to closing

Vapor Control During Construction

Health and safety controls will be implemented during construction, specifically during ~~including~~ (RTC, 11/6/12) the excavation of the Haack Rework material. The Treatability Study performed by Stantec (Stantec, 2007) indicated the Haack Rework soil-sludge material is significantly degraded; however, detectable concentrations of hydrogen sulfide and sulfur dioxide are still produced when the sludge material is disturbed. Therefore, during construction activities, vapor suppressing foams can be used and workers will be provided health and safety monitoring devices such as hydrogen sulfide and sulfur dioxide indicator badges. The badges alert workers when the permissible exposure limit (PEL, 10 parts per million [ppm] and 2 ppm for hydrogen sulfide and sulfur dioxide, respectively) is nearing so the worker can exit the work area or change practices. Additionally, fixed monitoring will be performed around the perimeter of the Site to alert workers when the PEL is detected so work activities can pause and/or be altered to prevent additional releases.

At the completion of excavation activities each day, a vapor suppressing foam or soil cover will be used to cover the exposed excavation and stockpiles to minimize ~~prevent additional~~ (RTC, 11/6/12) release of vapors.

6.1.2.3 Capping of the Sumps

The proposed, conceptual Haack and Cooper cap grades of Alternative 2A are shown on Figure ~~3-1~~ 6-2 with cross sections shown on Figures 6-3 and 6-4. (RTC, 11/6/12) This preliminary cap design is in accordance with 22 CCR §66264.228. In accordance with 22 CCR, the cap consists of a foundation layer, low-hydraulic conductivity layer, and erosion-resistance layer. The Alternative 2A cap is illustrated on Figure ~~3-9~~ 6-13 (RTC, 11/6/12), in Details 1-A and 1-B, and would consist of the layers described below.

Foundation and Gas Collection Layers

The foundation soil and gas collection layers would be placed above the high-strength geotextile and asphalt and concrete for the Cooper and Haack Sumps, respectively, and consist of, from bottom to top, minimum 1 ft of foundation soil, gas collection geostrips, and a gas collection geocomposite. The minimum 1 ft foundation and gas collection layer will support the low-hydraulic conductivity layer and erosion resistance layer in accordance with 22 CCR §66264.228(e)(4). The foundation soil would consist of ~~Haack Rework soil-sludge material,~~ (RTC, 11/6/12) Haack Rework overburden soil, on-site soils and/or imported fill material. Approximately 13,000 CY of foundation material will be required for the Cooper Sumps and Haack Sump. (RTC, 9/29/11)

The foundation material would initially be placed using the "finger fill soil placement technique," which incorporates the use of parallel, narrow berms over the

polypropylene (RTC, 11/6/12) high-strength geotextile. Approximately 3,900 CY of material would be placed using the "finger fill soil placement technique." The initial, 1-ft berms will then gradually be expanded across the sumps until the entire sump surface is covered with one foot of foundation soil. (RTC, 9/29/11)

During finger fill placement of soil above the polypropylene (RTC, 11/6/12) high-strength geotextile, movement of the sludge will be minimized and contained by the existing berms and the anchor trenches securing the polypropylene (RTC, 11/6/12) high strength geotextile and existing geomembrane. (RTC, 9/29/11) Where available space onsite limits traditional anchor trenches, the high-strength geotextile may be secured with concrete anchors or attached to sheet piles with battens. (RTC, 11/6/12)

After the initial 1-ft placement of soil across the sump, an additional 9,100 CY of foundation soil will be placed in lifts until final foundation grades are met (1 ft below the final cover grades shown on Figures ~~3-1~~ 6-1 and ~~3-2~~ 6-2). (RTC, 11/6/12) The slopes will be a minimum of 2 percent (%) to reduce impacts on drainage due to settlement of the foundation material and/or sludge. (RTC, 9/29/11)

Rows of gas collection geostrips will be placed at the surface of the foundation layer. The geostrips are 6 to 12 in. wide and consist of a geosynthetic filter fabric surrounding a molded polyethylene core (US Fabrics, 2011a). The molded polyethylene core provides a pathway for the gas to travel, while the filter fabric prevents soil intrusion and clogging. A polyethylene core and polypropylene geotextile, which are more resistant to acidic environments, will be required in the technical specifications. (RTC, 11/6/12) The gas collection geocomposite will be placed above the geostrip rows and the foundation layer (Details 1-A and 1-B, Figure ~~3-9~~ 6-13). (RTC, 11/6/12) The gas collection and control system is described in greater detail (RTC, 9/29/11) ~~in Section 3.3.6~~ below. (RTC, 11/6/12)

Low-Hydraulic Conductivity Layer

The low-hydraulic conductivity layer would be placed above the foundation soil and gas collection geostrips and geocomposite and would consist of a geosynthetic clay liner (GCL) overlain by a 60-mil HDPE geomembrane (Details 1-A and 1-B, Figure ~~3-9~~ 6-13). (RTC, 11/6/12) In accordance with 22 CCR §66264.228(e)(5), the low-hydraulic conductivity layer would reduce the downward migration of precipitation and the upward migration of gas. The low-hydraulic conductivity layers would be secured within an anchor trench around the perimeter of the sumps as described below. (RTC, 9/29/11)

Anchor Trenches

The existing geomembrane (located above the two Cooper Sumps), the high strength geotextile, and the low-hydraulic conductivity layer (60-mil HDPE geomembrane overlying a GCL) are or will be anchored above the sumps using separate anchor trenches. The existing geomembrane is secured above the sumps using a 2 ft by 2 ft anchor trench (OHM, 1994). These anchor trenches act similarly to shallow, vertical barriers by minimizing the opportunity for lateral "overspilling" of surface sludge. Lateral migration of the sludge at depth has not been shown to occur through the soil based on soil borings outside the immediate areas of the sumps. (RTC, 9/29/11)

The high strength woven geotextile will be secured in a separate 2 ft by 2 ft anchor trench located outside the limits of the Cooper Sumps. (RTC, 9/29/11) During excavation of the anchor trenches, a Contingency Plan will be implemented with gas levels and corresponding corrective actions to be taken. Corrective actions will include but not be limited to odor suppression, soil replacement, and/or evacuation (RTC, 11/12/13).

The GCL and HDPE geomembrane will be secured by an additional anchor trench around the perimeter of the Haack and Cooper Sumps. The anchor trench will vary in configuration depending on the termination condition. On the eastern, southern, and portions of the northern and western perimeters, the anchor trench will consist of a vee-trench filled with concrete to form a surface water drainage ditch (Detail 6 on Figure ~~3-10~~ 6-14). (RTC, 11/6/12) On portions of the northern and western perimeters, the anchor trench will consist of a 1 ft deep by 2 ft wide anchor trench (RTC, 9/29/11) (Detail 7 on Figure ~~3-10~~ 6-14). (RTC, 11/6/12) Where sheet piles are located on the northern edge of the site, the geosynthetic materials will be secured to the sheet piles using battens. (RTC, 11/6/12)

Erosion Resistance Layer

The erosion resistance layer is comprised of a drainage geocomposite overlain by 1 ft of Class II aggregate base, in accordance with 22 CCR §66264.228(e)(10). The drainage geocomposite minimizes hydrostatic head buildup above the hydraulic barrier and provides a means to drain precipitation that has infiltrated the overlying Class II aggregate base toward the outside of the cap and perimeter drainage channels. The Class II aggregate base will be resistant to foreseeable erosion effects caused by wind-scour, raindrop impact, and runoff prior to site development. (RTC, 9/29/11)

Sheet Pile Cut-Off Wall

Along a portion of the northern Site boundary, limited space is available to allow for grading to install the cap system. As a result, sheet piles would be installed to allow for the vertical rise of the cap without altering the Artesia Boulevard right-of-way. The

sheet piles would be installed to a maximum depth of 18 feet bgs, consistent with the deepest known sludge in the Cooper North and Haack Sumps, and extend upwards to approximately 3 feet from the ground surface to accommodate the cap. The sheet piles would be coated to minimize corrosion of the steel due to the low pH and high hydrogen sulfide environment. (RTC, 11/6/12) A decorative exterior wall will cover the exposed portion of the sheet piles along Artesia Boulevard. (RTC, 9/29/11) The sheet pile cut-off wall will provide a barrier between the Haack sump sludge and Artesia Blvd and its adjacent sidewalk. (RTC, 2/10/12)

Final Cap Topography

The final cap surface is shown on Figures ~~3-1~~ 6-1 and ~~3-2~~ 6-2. (RTC, 11/6/12) Cross sections of the final cap topography are provided on Figures ~~3-3~~ 6-3 and ~~3-4~~ 6-4. (RTC, 11/6/12) Drainage channels are shown on the exterior of the sumps to the north, south, east, and west as well as bisecting the Cooper North and South sumps. The channels drain with a 0.5% slope to the northeast and northwest corners of the Cooper North and Haack sumps, respectively. The cap slopes up from the drainage channels with a minimum 2% slope to a maximum elevation of 25.7, 24.8, and 25.6 ft amsl on the Haack, Cooper North, and Cooper South sumps, respectively. Along Artesia Boulevard, the approximate height of the cap will be 22 to 23 ft amsl which includes the maximum 3 ft wall to support the final cover and an additional 6-inch curb to direct stormwater runoff to the perimeter drainage channels. The Haack Rework area will be backfilled and graded to drain as shown on Figures ~~3-1~~ 6-1 and ~~3-2~~ (RTC, 9/29/11) 6-2. (RTC, 11/6/12)

Optional Final Cover Configuration

An optional final cover configuration was identified which eliminated the retaining wall described in the *Sheet Pile Cut-off Wall* section, above. The grading in the area affected by the elimination of the retaining wall was revised to accommodate a minimum 5 percent (%) slope draining to the north and terminating at a 6 to 9 inch (in.) concrete curb immediately adjacent to the Artesia Boulevard (Blvd.) sidewalk (Optional Alternative 2A). The curb will deter unintended light traffic across the slope, act as a water-stop for drainage from the slope, and accommodate the slight variations in the existing Haack Sump concrete slab surface elevation. The modifications necessary to eliminate the retaining wall and allow for the Optional Alternative 2A Cover will require waivers of some requirements in California Code of Regulations, Title 22 (22 CCR). A complete description of the alternative cover configuration is provided in Appendix F. (RTC, 11/12/13)

6.1.2.4 Gas Control and Monitoring System

The gas control system would be comprised of perimeter vertical gas migration control wells and a below-cap horizontal gas collection system. The proposed layouts of the vertical and horizontal gas collection systems are shown on Figures ~~3-6~~ 6-6 and ~~3-7~~ 6-7 (RTC, 11/6/12), respectively. (RTC, 9/29/11)

Vertical Gas Migration Wells

The system of gas migration control wells is designed to be a passive system that, as a contingency, can be converted readily to an active system. The system will operate actively for a period of two weeks following completion of the remedial action construction at the Site. Based on the concentrations of constituents detected during the two-week startup period, the system will remain active or switch to passive operation with the option for active control in the future. The system may be converted to passive operation with written prior approval from the DTSC. (RTC, 1/9/2013) The decision to make the system active again would be based upon future gas monitoring at the Site. (RTC, 9/29/11)

A series of alternating air inlet and gas extraction piping would be placed approximately every ~~20~~ 80 ft (RTC, 11/6/12) along the perimeter of the cap, except where sheet piles are installed as shown on Figure 3-6. The wells would be installed to approximately 2 ft above the groundwater "A" horizon ("A" horizon approximate elevation between 5.85 and 11.55 ft msl [Stantec, 2011]). The air inlet and gas extracting wells act to create a "curtain" of air surrounding the sumps, minimizing the horizontal migration of gas without extracting gas from the sludge. (RTC, 9/29/11)

During active gas extraction, a vacuum will be applied to the gas extraction wells, thus extracting gases from these wells, which will be conveyed to a treatment system for treatment prior to discharge to the atmosphere. The location of the system is shown on Figures ~~3-6~~ 6-6 and ~~3-7~~ 6-7. (RTC, 11/6/12) The vacuum pressure in the gas extraction wells imparts a vacuum on the soils surrounding each gas extraction well. With the air inlet wells equally spaced between the gas extraction wells, the air inlet forces a "short-circuiting" of the flow into the gas extraction wells. The "short circuiting" effect creates a preferential flow path between the air inlet and gas extraction wells, thereby allowing the system to "sweep" or "flush" gases migrating from the sludge material laterally without extracting gases from within the sludge (RTC, 9/29/11) (Figure ~~3-8~~ 6-8). (RTC, 11/6/12)

During passive gas extraction, subsurface gas movement is non-existent or very small, allowing barometric pumping and diffusion to vent subsurface gases from the vertical gas migration control wells. (RTC, 9/29/11)

Below-Cap Horizontal Gas Collection System

A horizontal gas collection system (utilizing geostrips) would be placed within the foundation layer of the cap, as discussed above. ~~in Section 3.3.5.1.~~ (RTC, 11/6/12) Similar to the vertical gas migration control wells around the perimeter of the cap, the horizontal gas collection system is designed to initially operate as an active system, during a start-up period of two weeks. The system would then be operated as a passive system, but is designed as a contingent measure to be readily converted to active, if necessary. As a passive system, it would be vented to the atmosphere and rely on barometric pumping and diffusion to vent subsurface gases from the system. The decision to make the system active would be based upon post-cap construction gas monitoring at the Site (RTC, 9/29/11) as described in *Gas Treatment System*, below. (RTC, 11/6/12)

The design of the gas collection system incorporates gas collection geostrips and air inlet geostrips, both connected to separate gas collection and air inlet piping. Piping is connected to the treatment compound where actively extracted gases can be treated prior to discharge to the atmosphere and fresh air can be pulled into the system through the air inlet piping. Gases fluxing out of the sludge and vertically rising to the base of the hydraulic barrier component of the cap will be collected in the continuous gas collection geocomposite layer. Parallel geostrips will allow collected gases to be "flushed" or "swept" from the gas extraction geocomposite to the gas extraction geostrips by allowing fresh air into the air inlet geostrips. Geostrips will convey the collected gases to the gas extraction piping and the treatment compound. (RTC, 9/29/11)

*Gas Treatment System (*RTC, 11/6/12)

The gas extracted from the control system would be treated using specialized granular activated carbon (GAC). Specialized Granular Activated Carbon (GAC) products have been manufactured to include hydrogen sulfide and sulfur dioxide oxidation. Specifically, Calgon Carbon has a number of specialized GAC products for hydrogen sulfide and sulfur dioxide environments. (RTC, 11/6/12)

The gas system will be operated actively for a period of time defined in a future Operations, Maintenance, and Monitoring (OMM) Plan. During initial operation, soil gas data, including constituents extracted and their concentrations, will be collected. The need for active gas collection will be based on the extracted soil gas COC concentrations and associated, calculated health risk goals. If start-up data indicates that COC concentrations are below risk-based trigger concentrations, and therefore, active gas collection is not needed, the system may be converted to a passive system which vents to the atmosphere or is turned off with no venting. (RTC, 4/4/12)

Soil gas samples will be collected from the treatment system and perimeter soil gas probes on a regularly basis to evaluate the operation of the system and/or migration of soil gas. Sample results will be compared to risk-based trigger concentrations developed with the OMM Plan for each COC. Development of the risk-based trigger concentrations will assume soil gas will cause outdoor air to become impacted with COCs; however, the outdoor air concentration used to develop the trigger concentration will be low enough to not result in adverse health effects. Based on the assumed conditions at the Site, if soil gas trigger concentrations are not exceeded, outdoor air concentrations will remain below human-health risk based concentrations. If soil gas concentrations are triggered, the gas collection and treatment system may be activated. (RTC, 4/4/12)

Gas Monitoring System

Multi-level gas migration probes would be placed outside of the perimeter of the cap. The proposed locations of the nine probes are shown on Figure 3-6. The probes are designed to be outside of the vertical gas migration control wells. (RTC, 9/29/11)

The gas probes are shown on Figure ~~3-7~~ 6-7. (RTC, 11/6/12) A total of nine probes were selected based on the average distance between probes of 300 ft to provide multiple locations to detect potential gas migration, if any. (RTC, 2/10/12) Each monitoring location will consist of three nested probes with 1 ft screen lengths at 5 ft intervals for discrete sample collection.(RTC, 9/29/11) The rationale for the location was based on a location outside of the radius of influence of the vertical gas migration control wells and within the property boundary and/or in a location accessible for monitoring which increased or decreased some distances between the probes. For example, probes were placed within the median of Artesia Boulevard rather than in the street to provide a safer location for monitoring. With further refinement of design, the location and number of probes may change with adjustments to the radius of influence of the vertical gas migration control wells and the locations of buildings and utilities for future site development. (RTC, 2/10/12)

Regular monitoring of gas concentrations at the probe locations would be performed before, during, and after system operation. The decision to convert the gas collection systems to an active system would be partially based upon the results of the probe monitoring activities and threshold contaminant concentrations developed in the Operations, Maintenance, and Monitoring (OMM) Plan (RTC, 2/10/12) as described in the *Gas Treatment System* section, above. (RTC, 11/6/12)

6.1.2.5 Institutional Controls

The anticipated institutional controls for the Site would consist of governmental controls, such as zoning and building permit restrictions, proprietary controls that

restrict property use, and informational controls. Governmental controls would restrict the zoning of the Site to commercial (as identified in the Artesia Corridor Specific Plan) and prohibit sensitive land uses (i.e., residential, hospitals, schools, or child-care centers), specify building construction requirements (i.e., inclusion of gas control system beneath new structures). Environmental land use restrictions may also be applicable. Proprietary controls would place use restrictions on the Site properties. Restrictions would include future land use, the prevention of excavation or drilling within certain areas of the Site (i.e., within the capped areas), (RTC, 9/29/11) controlled traffic loads over the caps (RTC, 11/6/12), prohibit onsite groundwater extraction for municipal and domestic use (i.e., drinking water purposes), industrial, and agricultural (i.e., irrigation) use, future building location restrictions, provide for potential easements (i.e., for O&M activities) and conveyance of proprietary control restrictions to future property owners (i.e., restrictions "run with the land"). Informational controls would include deed notices on the Site property titles and ensure inclusion of the Site on a California registry of contaminated sites. (RTC, 9/29/11) Land use covenants (LUCs) to place deed restrictions on the site will be filed with the Los Angeles County Recorder's Office and annual LUC restriction inspections will be conducted by DTSC to ensure compliance. (RTC, 4/4/12) The asphalt cap above the sludge within Artesia Boulevard will have increased maintenance to repair cracking and normal wear that increase the permeability. (RTC, 11/6/12)

Furthermore, a Health and Safety Plan (HASP) and Construction Quality Assurance (CQA) Plan would be required to establish minimum health and safety protocol during construction, and provide documentation of proper excavation, cap, and gas control system construction. A Risk Management Plan (RMP) would be developed for the Site to reduce the risk of future construction worker exposure to groundwater if the Site is developed. The RMP would discuss the hazards at the Site, minimum PPE requirements, and notification requirements. (RTC, 9/29/11)

6.1.2.6 Groundwater Monitoring

~~The existing ten groundwater monitoring wells would be properly abandoned prior to commencement of the remedial action. During the remedial action activities an appropriate groundwater monitoring network would be agreed upon with input from the DTSC. After the completion of the remedial action, the future groundwater monitoring wells would be installed. Groundwater monitoring would continue to be performed on a semi-annual basis for a period of 5 years (RTC, 2/7/12)after the remedial controls have been implemented. A typical groundwater monitor well is shown as Detail 3 on Figure 6-9 in the Draft FS (Geosyntec,2011).~~ (RTC, 4/4/12)

Eight of the existing ten groundwater monitoring wells would be properly abandoned prior to commencement of the remedial action. Upgradient wells MW-1A and MW-1B

would not be abandoned. (RTC, 4/4/12) During the remedial action activities, an appropriate groundwater monitoring network would be agreed upon with input from the DTSC. After the completion of the remedial action, the future groundwater monitoring wells would be installed. Groundwater monitoring would continue to be performed on a semi-annual basis. A typical groundwater monitor well is shown as Detail 3 on Figure ~~6-9 in the draft FS (Geosyntec, 2011)~~ 6-13.(RTC, 11/6/12)

The future development plans of the Site, which are currently unknown, would control where future monitoring wells would be installed. The well locations of the future monitoring well network would be agreed upon in consultation with the DTSC prior to completion of the remedial action. It is anticipated that the new monitoring wells would be installed shortly after completion of the remedial action. (RTC, 4/4/12)

6.1.2.7 Future Site Development

Following completion of the cap construction, the resulting Site conditions will facilitate the construction of a parking lot and an ingress/egress road to accommodate future commercial development at the Site. The 12-in. thick Class II aggregate base will provide a working surface for construction equipment used for parking lot construction, prevent the accumulation of free water within or below the pavement structure, and affect the rate of load distribution on the cap (Caltrans, 2008). Final landscape development designed in conjunction with the future parking lot above the cap will require the use of above grade planters to prevent biological intrusion into the cap. (RTC, 9/29/11)

The grades and final elevation of the cap have been reduced to allow for a flatter surface on which to construct a parking lot and be a less prominent feature along Artesia Boulevard. As described in Section ~~3.3.5~~ 6.1.2.3 (RTC, 11/6/12), the maximum elevation of the cap will be 25.7 ft amsl and the slopes will vary between 2H:1V and 2 percent. During commercial development of the Site, the slopes of the parking lot can be further reduced by adding fill above the lower portions of the cap, provided drainage from the geocomposite is maintained. Selective fill would allow for a flatter surface and ramp features to facilitate car movement. (RTC, 9/29/11) The cap has been shown to support construction loads at the surface (Appendix D). During final design of the cap, traffic load restrictions will be developed and incorporated into the institutional controls. (RTC, 11/6/12)

6.1.3 Alternative 3 – Capping with Selective Excavation and Stabilization/ Neutralization

Alternative 3 includes the following major elements (Figures ~~6-2~~ 6-9 and ~~6-7~~ 6-10): (RTC, 11/6/12)

- Existing surface removal;
- Consolidation of material;
- Stabilization/neutralization of the current upper 3 feet of sludge in the Cooper Sumps;
- Capping of sludge remaining onsite;
- Installation of gas control and monitoring system;
- Institutional controls; and
- Groundwater monitoring.

Some of these elements were discussed in Section 6.1.2; therefore, ~~the existing surface removal (Section 6.1.2.1), the consolidation of material (Section 6.1.2.2),~~ (RTC, 11/6/12) the installation of the gas control and monitoring system (Section 6.1.2.4), institutional controls (Section 6.1.2.5), and groundwater monitoring (Section 6.1.2.6) will not be repeated herein. Existing surface removal, the consolidation of material, ~~surface covering material removal,~~ (RTC, 11/6/12) sludge stabilization/neutralization, and capping are discussed further in the following sections.

6.1.3.1 Existing Surface Removal

A geomembrane is currently above the Cooper North and South Sumps. Prior to initiating neutralization and stabilization activities, the existing geomembrane will be removed to permit access to the sludge. The reinforced concrete and asphalt covers above the Haack Sump will remain in place. (RTC, 11/6/12)

6.1.3.2 Consolidation of Material

In general, the sludge is contained in the three sumps: Cooper North and South, and Haack. As previously discussed in Section 3.2.1, approximately ~~650~~2,670 (RTC, 1/9/2013) CY of a sludge/soil mixture is located outside of the sumps in the Haack Rework area. To excavate the sludge/soil mixture, approximately ~~3,550~~ 2,450 (RTC, 1/9/2013) CY of overburden will need to be excavated. Additionally, along the eastern property line, a thin layer of sludge exists which appears to be the result of spillage or overflow from the sumps. (RTC, 11/6/12)

The Haack Rework and eastern overflow areas would be consolidated into one of the three sumps prior to capping, and used as fill beneath the cap low-hydraulic conductivity layer (to be discussed in Section 6.1.3.4). The Haack Reworked material will be tracked during placement and will not be placed where it will be in contact with the gas collection system (RTC, 11/12/13). Approximately ~~5,120~~5,470 ~~-~~ 5,380 (RTC 11/12/13) CY (RTC, 1/9/2013) of Haack Rework ~~(2,670 CY)~~(2,670 CY) (RTC,

1/9/2013), Haack Rework overburden ~~(2,450 CY)~~(2,450 CY) (RTC, 1/9/2013), and eastern overflow (260 CY) are anticipated to be placed above the sumps. (RTC, 11/6/12)

Following visual excavation of material from the Haack Rework and eastern overflow, confirmation sampling would be performed to confirm the material was removed. Confirmation sample results would be compared to cleanup goals. Where testing indicates concentrations in excess of cleanup goals, additional material would be removed and consolidated above the sumps. Haack Rework and eastern overflow excavations will be backfilled using soils obtained from unimpacted areas of the site. (RTC, 11/6/12)

6.1.3.3 Stabilization/Neutralization of Cooper North and South Sludge

Stabilization/neutralization of the sludge material would be performed to the top 3 feet of the sludge to solidify the sludge for support of the proposed overlying cap. From the treatability studies performed by Stantec, it was determined that the addition of a 50/50 weight for weight (w/w) mix of calcium hydroxide ($Ca(OH)_2$) and calcium carbonate ($CaCO_3$) at a dosage rate of 20 to 30 percent reagent to sludge mix and 10 percent water neutralizes the sludge material. The addition of 50 percent soil (by weight) to this mix would effectively solidify the waste such that it is no longer susceptible to viscoelastic deformation (Stantec, 2008).

In-situ mixing would be performed through use of an excavator. The sludge on the edges of the sump would be mixed first to establish a foundation for equipment to move inward. Mixing would be performed to the minimum depth to support equipment, which is estimated at 3 feet. Due to the difficulty segregating the sludge and interbedded soil layers, it is assumed both the sludge and soil materials within the top 3 feet would be mixed as sludge. Therefore, the sludge volume used to calculate the reagent volume was the 2008 sludge volume in the top 3 feet, or 13,500 CY (Stantec, 2008).

Mixing with the reagents and soil (RTC, 11/6/12) would cause bulking of the materials. According to the Treatability Study performed by Stantec, the sumps are expected to bulk 69 percent, based on the mix design specified (Appendix A, Stantec, 2008). Therefore, the bulked materials are anticipated to increase the height of the sumps by approximately 2 feet, resulting in a total treated sludge thickness of approximately 5 feet.

Respirators (or if warranted by conditions, more stringent personal protective equipment such as Self-Contained Breathing Apparatus [SCBA]), engineering controls (potentially tenting over the excavation), and air monitoring may be required to address

potential emissions of sulfurous gases from the sludge generated during mixing (Stantec, 2008).

6.1.3.4 Capping of the Sumps

Similar to Alternative 2A, the Alternative 3 cap would consist of foundation, gas collection, barrier, drainage, and protective layers covering the Cooper North and South, and Haack sumps contiguously within the Site boundary; however, the gas collection layer, erosion protection layer, and sheet piling proposed for Alternative 3 are different than Alternative 2A, as described below. As discussed in Section 6.1.2.1, (RTC, 11/6/12) the portion of the Haack sump outside of the Site boundary beneath the sidewalk and Artesia Blvd. is considered to be already capped in this Alternative (Stantec, 2010a). The proposed final grades are shown on Figure ~~6-2~~ 6-10. (RTC, 11/6/12) The Alternative 3 cap is depicted on Figure ~~6-6~~ 6-15 in Details 1-C and 1-D. (RTC, 11/6/12)

Foundation and Gas Collection Layers

The foundation soil and gas collection layers would be placed above the stabilized sludge layer and consist of, from bottom to top, minimum 1 foot of foundation soil, gas collection piping, and a gas collection geocomposite. The minimum 1 ft foundation and gas collection layer will support the low-hydraulic conductivity layer and erosion resistance layer in accordance 22 CCR §66264.228(e)(4). The foundation soil would consist of onsite, impacted soil and Haack Rework material where available. Impacted foundation layer material would be supplemented with soil material imported from offsite. Impacted soil and Haack Rework material will be tracked during placement and placed such that it is not in contact with the gas collection system. (RTC, 11/12/13) Horizontal gas collection pipes surrounded by gas collection aggregate would be embedded in the foundation layer. Nonwoven geotextile would surround the aggregate to prevent clogging of the aggregate due to fines intrusion. The foundation layer would be graded with 3 percent slopes to accommodate drainage. (RTC, 11/6/12)

Low-Hydraulic Conductivity Layer

The low-hydraulic conductivity layer would be placed above the foundation and gas collection layers and would consist of a geosynthetic clay liner (GCL) and a 60-mil high density polyethylene (HDPE) geomembrane. In accordance with 22 CCR §66264.228(e)(5), the low-hydraulic conductivity layer would reduce the downward migration of precipitation and the upward migration of sludge and gas. (RTC, 11/6/12)

Erosion Resistance Layer

The erosion resistance layer is comprised of a drainage geocomposite and 2 feet of vegetated cover soil. In accordance with 22 CCR §66264.228(e)(10), the drainage

geocomposite would prevent hydrostatic head buildup and drain precipitation that has infiltrated the overlying vegetated cover soil toward the outside of the cap and perimeter drainage channels while the vegetative cover soil will be resistant to foreseeable erosion effects by wind-scour, raindrop impact, and runoff. (RTC, 11/6/12)

Along the northern property boundary, limited space is available to allow for grading to install the cap system. As a result, sheet piles would be installed to allow for the vertical rise of the cap without altering Artesia Boulevard or the railroad property. The sheet piles would be installed to an average depth of 18 feet bgs and extend between 4 and 10 feet from the ground surface to accommodate the cap. (RTC, 11/6/12)

Final Cap Topography

The final cover grades are shown on Figure 6-10. The minimum thickness of the cover is ~~6.5~~ 6(RTC, 11/6/12) feet which accounts for the ~~3.5~~ 3-foot stabilization layer (with bulking, 3 ft sludge layer increases to a total thickness of 5 feet) (RTC, 11/6/12), 1-foot (minimum) foundation layer, and 2-foot erosion resistance layer. The maximum cover thickness would be approximately 12.5 feet due to increasing the foundation layer to 9.5 feet to create a cover surface with 3 percent (%) slopes. (RTC, 9/29/11)

The maximum elevation of the cover for Alternative 3 is 35 feet amsl. Artesia Boulevard north of the Haack property has an elevation of approximately 20 feet amsl. Along Artesia Boulevard, the Alternative 3 cap elevation varies from approximately 26 feet amsl to 29 feet amsl resulting in a retaining wall height along Artesia Boulevard between 4 and 10 feet high. (RTC, 9/29/11)

Gas Monitoring System

The gas control and monitoring system is shown on Figures 6-11 and 6-12. The design of the Alternative 3 system is the same Alternative 2A; however, Alternative 3 will incorporate 3-inch solid and perforated polyvinyl chloride (PVC) pipes rather than geostrips. Pipes are proposed for Alternative 3 because the thicker foundation layer can accommodate the pipes and filter material. (RTC, 11/6/12)

6.1.3.5 Future Site Development

The resulting Site conditions following cap construction will facilitate an open-space end use; however, use as a parking lot may be difficult due to steep slopes around the cap edges. The maximum height of the cap is approximately 34.5 ft amsl or approximately 14.5 ft above the surrounding area (Figure 6-10). Areas around the site are available for future development such as the residential properties to the south. (RTC, 11/6/12)

6.1.4 Alternative 4 – Excavation with Offsite Disposal

Excavation and offsite disposal of the sludge would involve excavating the sludge materials to depths between 0.5 and ~~23.5~~ 17.5(RTC, 11/6/12) feet bgs (Figure ~~6-8~~ 6-16 [RTC, 11/6/12]). Shoring would be required in areas to support the sump walls in locations shown on Figure ~~6-8~~ 6-16, (RTC, 11/6/12) at a minimum. ~~Active dewatering for the duration of excavation would be required to remove perched water and groundwater from the excavation.~~ Active dewatering would be required to remove perched groundwater and shallow groundwater when excavation and backfill are below the water table. Additionally, dewatering would be necessary to remove ponded misting agents. (RTC 1/9/2013) Respirators (or if warranted by conditions, more stringent personal protective equipment such as Self-Contained Breathing Apparatus [SCBA]), engineering controls (potentially tenting over the excavation), and air monitoring may be required to address potential emissions of sulfurous gases from the sludge generated during excavation (Stantec, 2008). Alternative 4 includes the following major elements:

- Concrete and asphalt removal;
- Excavation of sludge material from the (RTC, 11/6/12) Cooper North and South and Haack Sumps;
- Excavation of soil-sludge material from the (RTC, 1/9/2013) (RTC, 11/6/12) Haack Rework Area;
- Transportation to a disposal facility;
- Confirmation sampling;
- Backfill of sumps; and
- Groundwater monitoring.

Groundwater monitoring was discussed in Section ~~6.1.2.5~~ 6.1.2.6, (RTC, 11/6/12) and will not be repeated herein. Surface covering material removal, sludge stabilization/neutralization, and capping are discussed further in the following sections. These elements are discussed further in the following sections.

6.1.4.1 Concrete and Asphalt Removal

In order to access the Haack sump, the existing 6-inch reinforced concrete slab and 8-inch asphalt pavement would need to be removed. Since the underside of the concrete slab is in contact with the sludge material, after the concrete is demolished, it would be stockpiled onsite to allow for characterization sampling. Representative concrete samples should be collected and analyzed for metals, PAHs, and VOCs. Concrete found to contain metals, PAHs, or metals at concentrations exceeding hazardous waste classification thresholds would require disposal at an offsite hazardous

waste facility. If materials are found to be nonhazardous, they may be recycled or disposed of at a nonhazardous facility.

6.1.4.2 Excavation of Sumps

The sumps would be excavated to the maximum depth of sludge as reported during the RI. Based on the boring logs, sludge depth varies between 0.5 ~~foot~~ and ~~23.5~~ 17.5 (RTC, 11/6/12) ~~feet~~ft bgs (RTC, 1/9/2013) (Figure ~~6-8~~ 6-16 [RTC, 11/6/12]) (Stantec, 2008). Where significant overburden is present, such as on the Haack Sump, the overburden may be stockpiled separately, sampled, and used as backfill if testing indicates concentrations of constituents are below cleanup objectives. Using an excavator, sludge and interbedded soil would be mixed with the $Ca(H)_2/CaCO_3$ reagent and loaded directly into trucks for transport to the disposal facility. Due to the difficulty segregating the sludge and interbedded soil layers, it is assumed both the sludge and soil materials would be excavated and managed as sludge. Because of the acid gas generation during mixing, a tent would be necessary around the excavator and working surface to capture and treat the gas during mixing. As discussed in Section ~~6.1.3.2~~ 6.1.3.3 (RTC, 11/6/12), the addition of the reagent would result in bulking of the material. With only the addition of the reagent, it is anticipated bulking of the sludge would be approximately 25% and assuming 15% over-excavation, resulting in a total disposal volume of approximately ~~52,000~~ 45,923 CY or ~~49,900~~ 50,200 (RTC, 11/6/12) tons (based on a bulk density assumption of 81 lb/cy [Stantec, 2008]). It is assumed that the sludge containing 25% admixture will be acceptable as-is for disposal at a landfill permitted to accept non-RCRA hazardous waste such as the Buttonwillow Facility.

During excavation below the groundwater table or within the perched water zones, some dewatering may be necessary. The area where this is most likely is in the Haack Sump near the northern border of the Site. In this region, groundwater entering the excavation would be pumped to a tank where it would be sampled prior to disposal.

6.1.4.3 Excavation of Haack Rework Area

The Haack Rework area would be excavated without the addition of the reagent. Based on the Treatability Study, the rework material is significantly degraded indicating stabilization/neutralization is likely not necessary. Furthermore, the Treatability Study demonstrated that significant quantities of gas are not likely to be produced when the Haack Rework material is disturbed; therefore, a tent system with gas treatment is not necessary (Stantec, 2008).

The Haack Rework overburden would be excavated and stockpiled separately. Similar to the Haack overburden, the overburden material would be sampled and used as backfill if testing indicates concentrations of constituents are below cleanup objectives.

Using an excavator, the Haack Rework sludge material would be loaded directly into trucks for transport to the disposal facility.

6.1.4.4 Confirmation Sampling

Following excavation of the sumps and Rework area, confirmation samples would be collected and analyzed for the COCs. Where confirmation sampling indicates ~~impacted~~ sludge (RTC, 11/6/12) material remains, additional material would be excavated in the area represented by the confirmation sample. When confirmation sampling indicates ~~impacted~~ sludge (RTC, 11/6/12) material has been removed, the removal would be considered complete and backfill would be initiated.

6.1.4.5 Backfill of Sumps

Following removal completion, the sumps would be backfilled with ~~onsite material outside of the impacted areas where available.~~ (RTC, 11/6/12) non-impacted, imported soil ~~would be placed if additional material is required~~. (RTC, 11/6/12) The sumps would be backfilled to pre-excavation grades.

6.1.4.6 Transportation to Disposal Facility

The neutralized sludge material would be transported to the Button Willow Facility ~~a disposal facility~~ (RTC, 11/6/12) in covered trucks. This disposal facility was selected because it accepts non-RCRA hazardous wastes containing petroleum. (RTC, 11/6/12) The total volume estimated for disposal includes the sludge volume with interbedded soil calculated by Stantec in 2008, 0.5 foot over-excavation at the base of the sumps, and reagent volume for a total disposal volume of ~~49,900~~ 45,923 CY and the total disposal weight of 50,200 tons. (RTC, 11/6/12) Based on testing performed by Stantec during the treatability study, the neutralized sludge would be disposed at a non-hazardous facility (Appendix ~~A~~ B [RTC, 11/6/12], Stantec, 2008); however, due to avoid potential future disposal liability (RTC, 11/6/12), a non-RCRA hazardous waste facility, the Buttonwillow Facility, was selected for this Alternative analysis. (RTC, 11/6/12)

7. DETAILED ANALYSIS OF ALTERNATIVES

7.1 General

This section includes a detailed analysis of the final remedial alternatives for the Site. An overview of the nine criteria used for the detailed analysis is presented below.

7.2 Detailed Analysis Criteria

The CERCLA guidance document explains the nine criteria that are used to evaluate each remedial alternative [USEPA, 1988]. The first two criteria relate directly to findings that must be made in the Record of Decision (ROD) for the Site. These are categorized as threshold criteria that a selected remedy must meet.

1. **Overall Protection of Human Health and the Environment** – This criterion requires evaluation of how the alternative achieves and maintains protection of human health and the environment. The overall assessment of protectiveness draws on the assessments conducted under other evaluation criteria, especially long-term effectiveness and permanence, short-term effectiveness, and compliance with ARARs. Evaluation of the overall protectiveness of an alternative focuses on whether an alternative achieves adequate protection and describes how risks posed through each pathway are eliminated, reduced, or controlled through treatment, engineered controls or institutional controls. This evaluation also considers whether an alternative poses any unacceptable short-term or cross-media impacts.
2. **Compliance with ARARs** – This criterion requires an evaluation of how the alternative complies with identified ARARs and applicable advisories or guidance that are "to be considered." ARARs are generally categorized as action-specific, location-specific, or chemical-specific Federal or state-promulgated requirements. A list of potential Federal and state action-specific, location-specific, or chemical-specific ARARs have been identified for the Site and are included in Table 4-2.

The following seven criteria are "balancing" criteria. They represent the primary criteria upon which the detailed analysis is based and that are used to distinguish among alternatives that meet the threshold requirements above. The alternative that strikes the best balance among these seven criteria and that meets the threshold criteria generally is the preferred alternative.

3. **Long-term Effectiveness and Permanence** – Requires evaluation of the long-term effectiveness of the remedial alternative in maintaining protection

of human health and the environment following implementation of the alternative.

4. **Reduction of Toxicity, Mobility, and Volume Through Treatment** – The assessment against this criterion evaluates the anticipated performance of the treatment technologies that the alternative comprises, and assesses their ability to reduce the toxicity, mobility and volume of contaminated materials through the use of treatment.
5. **Short-term Effectiveness** – Requires an assessment of the protection of human health and the environment during construction and implementation of the remedial alternative until RAOs are met. The following factors are addressed as appropriate for each alternative: protection of the community during remedial actions; protection of workers during remedial actions; environmental impacts; and time until remedial response objectives are achieved.
6. **Implementability** – This criterion requires an assessment of the technical and administrative feasibility of an alternative, including the availability of required services and materials to execute the alternative. How each alternative is impacted by the property ownership (i.e., one, large, single property or seven individual properties) will also be discussed.
7. **Cost –** Requires evaluation of the anticipated capital costs and operation and maintenance (O&M) costs of an alternative. For this FS Report, O&M costs are presented in ~~2011~~ 2012 (RTC, 11/6/12) dollars using a ~~7~~ 2 (RTC, 11/6/12) percent discount rate per EPA Guidance (EPA, 2000).
8. **State Acceptance** – Allows for consideration of preferences or apparent concerns by the State of California Department of Toxic Substances Control (DTSC).
9. **Community Acceptance** – Allows for consideration of the community's preferences or concerns regarding remedial alternatives. DTSC formally considers the community's preferences or concerns after this FS Report and proposed plan are prepared.

7.3 Final Remedial Alternatives – Detailed Analysis

7.3.1 General

This section includes the detailed analysis of the four final remedial alternatives presented in Section 6.1 and in Table 6-1. Each alternative is analyzed separately according to the nine criteria listed above. The common elements of the final remedial alternatives are not evaluated as they are the same for each alternative.

7.3.2 Final Remedial Alternative 1– No Action

7.3.2.1 Overall Protection of Human Health and the Environment

The no action alternative does not effectively mitigate potential future risks associated with the ingestion, inhalation, or direct contact of Site soils or soil gas. It does not provide any means for source zone mass removal or containment and would not be protective of human health under the hypothetical future scenario use. Because the no action alternative does not meet the threshold requirement of providing overall protection of human health and the environment, no further analysis of this alternative is performed.

~~7.3.3 Final Remedial Alternative 2 – Capping with Selective Excavation~~

~~*7.3.3.1 Overall Protection of Human Health and the Environment*~~

~~Capping with selective excavation would provide moderate to high overall protection of human health and the environment. The exposure routes for receptors as identified in the HHRA are dermal contact with sludge, ingestion of sludge, and inhalation of soil gas. Selective excavation and consolidation within the sumps would remove the eastern overflow and Haack Rework area with the associated gas risks. The sumps would be capped reducing the risk associated with dermal contact and ingestion. Additionally, a gas control and monitoring system would be installed beneath the cap to control gas which may be generated by the sludge. High overall protection is not achieved with the method due to the source remaining onsite.~~ (RTC, 9/29/11)

~~*7.3.3.2 Compliance with ARARs*~~

~~ARARs potentially applicable to Site remedial actions are shown in Table 4-2. Precautions would be required to ensure that short-term community and worker exposures to dust, noise, truck traffic, and VOC emissions are limited to acceptable levels during soil excavation and handling, per ambient air quality health standards.~~ (RTC, 9/29/11)

~~*7.3.3.3 Long-Term Effectiveness and Permanence*~~

~~The permanent cap with the below-cap and perimeter passive gas control system provides long-term effectiveness. To maintain the long-term integrity of the cap and related remedial measure components, maintenance and monitoring would be provided. If gas monitoring indicates concentrations in excess of acceptable values, the below-cap and perimeter vertical gas migration control wells can be made active, which adds to long-term effectiveness in controlling the migration of gas to the environment.~~ (RTC, 9/29/11)

~~*7.3.3.4 Reduction in Toxicity, Mobility, or Volume Through Treatment*~~

~~The cap design would include a gas collection system that can be connected to a treatment system during start-up and continued use, if necessary, based upon start-up monitoring results. If the gases are treated, some reduction in toxicity would be realized. The cap and Site drainage improvements would provide a reduction in mobility of the waste as infiltration of water would be mitigated. No reduction in waste volume would be realized with the remedial measure~~. (RTC, 9/29/11)

~~Gas transport at the Site occurs as a result of diffusion; therefore, the rate of lateral migration of gas constituents is very low. If necessary, the perimeter vertical gas migration control wells can be activated to collect potentially migrating gases and/or remove in-place gases from subsurface soils. The collected gas can be treated if necessary, which results in reduction of the toxicity of the waste~~. (RTC, 9/29/11)

~~*7.3.3.5 Short-Term Effectiveness*~~

~~The cap construction would provide immediate short-term effectiveness since worker risk is low and impacts on environment are minor (grading operations). Liquid infiltration, gas migration, and physical contact would be controlled upon cap placement. Because the disturbance to the sludge would be limited, hazardous gas generation would be minimal.~~ (RTC, 9/29/11)

~~*7.3.3.6 Implementability*~~

~~Technical implementation of Alternative 2 is relatively easy. The alternative uses conventional construction technologies~~. (RTC, 9/29/11)

~~*7.3.3.7 Cost*~~

~~The estimated capital cost of Alternative 2 is $5,206,314. The estimated net present value of operating and maintenance costs is $1,563,800. Therefore, the total present value cost of Alternative 2 is $6,770,114. Table 7-1 presents a cost breakdown of Alternative 2.~~ (RTC, 9/29/11)

~~*7.3.3.8 State Acceptance*~~

~~State acceptance of Alternative 2 will be assessed during the public comment period.~~ (RTC, 9/29/11)

~~*7.3.3.9 Community Acceptance*~~

~~Community acceptance of Alternative 2 will be assessed during the public comment period~~. (RTC, 9/29/11)

7.3.3 Alternative 2A – Capping with Selective Excavation

7.3.3.1 Overall Protection of Human Health and the Environment

Overall protection of human health and the environment is moderate to high with this remedial alternative. The exposure routes for receptors as identified in the HHRA are dermal contact with sludge, ingestion of sludge, and inhalation of soil gas. Selective excavation would remove the Haack Rework area sludge material that is associated with potential gas risks. The sludge in the three sumps would be capped, reducing the risk associated with dermal contact and ingestion. Additionally, a gas control and monitoring system would be installed beneath the cap to control gas which may be generated by the sludge. High overall protection is not achieved with this method due to the source remaining onsite. (RTC, 9/29/11)

7.3.3.2 Compliance with ARARs

Compliance with ARARS is ~~high~~ moderate (RTC, 1/9/13) with this remedial alternative. ARARs potentially applicable to Site remedial actions are provided in Table 4-2. Precautions would be required to ensure that short-term community and worker exposures to dust, noise, truck traffic, and VOC emissions are limited to acceptable levels during soil excavation and handling, per AQMD standards.(RTC, 9/29/11) This remedial alternative is compliant with the Groundwater ARARs by implementing institutional controls limiting onsite extraction of groundwater. Groundwater data has indicated that the sumps are not contributing to offsite impacts; therefore, institutional controls limiting onsite extraction are sufficient for groundwater ARAR compliance. (RTC, 11/6/12)

At some locations of the Site groundwater in the A-zone may encounter the waste material where excavations are the deepest. Waste impacted groundwater has been documented at Well MW-5A which is located immediately down gradient of the Haack Sump. Where these impacts occur the groundwater is characterized by a lower pH, occurrence of gasoline range hydrocarbons, the occurrence of some volatile organic compounds in the low ppb range, elevated concentrations of some metals and modifications to its inorganic groundwater chemistry. However these impacts are attenuated over a short lateral distance down-gradient of the waste as documented in wells MW-3A and MW-4A which are located within or downgradient of the Site's sumps. Impacts to deeper water bearing zones have not been confirmed as the groundwater impacts observed in Well MW-5A are not observed in the B-zone monitoring wells at the Site and the geochemistry of the two water bearing zones are noticeably different suggesting limited hydraulic communication. (RTC, 1/9/13)

The Bellflower Aquiclude groundwater in the vicinity of the Site is naturally degrade as evidence by the Total Dissolved Solids (TDS) concentrations in the A-zone and the TDS and chloride concentrations in the B-zone which exceed the recommended secondary MCL values as documented in the up-gradient, background wells (wells MW-1A and MW-1B). During development of the Site's existing monitoring wells prior to reinstituting the groundwater monitoring program in 2006, some wells were pumped dry and development operations were halted to allow for recharge. This observation suggests that the two hydraulic zones immediately beneath the Site have limited yield that cannot be sustained over time. The naturally degraded groundwater quality and limited yield of the Bellflower Aquiclude at the Site indicates that human use of the groundwater beneath the Site is not likely. (RTC, 1/9/13)

The California Regional Boards are required to assure that the beneficial uses of municipal and domestic supply are designated for protection wherever those uses are presently being attained. This ARAR requirement may not be applicable to the Site because the groundwater upgradient of the Site is naturally degraded and the beneficial uses requirement is not presently being attained . Institutional controls preventing onsite extraction or use of groundwater should be sufficient for groundwater ARAR compliance. (RTC, 1/9/13)

7.3.3.3 Long-Term Effectiveness and Permanence

Long-term effectiveness and permanence is moderate to high for this remedial alternative. The permanent cap with the below-cap and perimeter passive gas control system provides long-term effectiveness. To maintain the long-term integrity of the cap and related remedial measure components, maintenance and monitoring would be provided. If the Site is developed, the parking lot surface above the cap should be maintained by the future property owner(s) to prevent cracking and/or ponding of surface water. If gas monitoring indicates concentrations in excess of acceptable values, the below-cap and perimeter vertical gas migration control wells can be made active, which adds to long-term effectiveness in controlling the migration of gas to the environment. (RTC, 9/29/11)

Based on its location, the Site is potentially at risk for high ground shaking and liquefaction during an earthquake. High ground shaking would minimally affect this alternative because its planned future use is a parking lot. Liquefaction may result in differential settlement of the cap; however, the differential settlement can be corrected with maintenance of the cap. High ground shaking would minimally affect this alternative because its planned future use is a parking lot; however, veneer stability may be compromised. Damage due to a loss of veneer stability may be repaired with maintenance. (RTC, 11/6/12)

High long-term effectiveness and permanence is not achieved with this method due to maintenance requirements. (RTC, 9/29/11)

7.3.3.4 Reduction of Toxicity, Mobility, or Volume through Treatment

Reduction in toxicity, mobility, or volume through treatment is moderate ~~to high~~ (RTC 1/9/13) with this remedial alternative. The cap design would include a gas collection system that can be connected to a treatment system during start-up and continued use, if necessary, based upon start-up monitoring results. If the gases are treated, some reduction in toxicity would be realized. The cap and site drainage improvements would provide a reduction in mobility of the waste as infiltration of water would be mitigated. (RTC, 9/29/11) ~~No reduction in waste volume would be realized with this remedial measure~~. Waste volume would be reduced with the removal of the Haack Rework material; however, the sludge contained in the Cooper and Haack sumps would not be reduced. (RTC, 1/9/13)

Mobility of the sludge would be reduced with this Alternative. On the Haack Sump, there is evidence of sludge movement from beneath the cap at the edges of the concrete and asphalt cover. The installation of low-hydraulic conductivity layer, associated anchor trench, along with existing soil containment, will minimize the lateral migration of sludge. (RTC, 9/29/11)

Gas transport at the Site occurs as a result of diffusion; therefore, the rate of lateral migration of gas constituents is very low. If necessary, the perimeter vertical gas migration control wells can be activated to collect potentially migrating gases and/or remove in-place gases from subsurface soils. The collected gas can be treated if necessary, which results in reduction of the toxicity of the waste. (RTC, 9/29/11)

7.3.3.5 Short-Term Effectiveness

The short-term effectiveness of Alternative 2A is moderate to high. Cap construction would be performed above the existing surfaces on the Cooper and Haack sumps reducing gas generation, gas migration, and dermal contact risks from the exposed sludge. The Cooper sumps currently have an exposed geomembrane covering the sludge which minimizes dermal contact and gas migration. The high-strength geotextile will be installed above the existing geomembrane in a manner that minimizes damage to the existing liner surface (e.g., hand placement). Prior to the installation of the high-strength geotextile, only limited foot traffic will be permitted above the sumps. (RTC, 9/29/11)

The existing concrete and asphalt surfaces will be maintained above the Haack Sump. The geosynthetic cap components (geostrips, gas extraction geocomposite, GCL, HDPE geomembrane, and drainage geocomposite) will be installed directly above the foundation soil overlying the concrete and asphalt surfaces and anchored outside of the

perimeter of the sumps as identified in the RI, between the Cooper North and Haack Sumps (RTC, 1/9/2013), or to the sheetpile along Artesia Boulevard. The sludge between the Cooper North and Haack Sumps is discontinuous and degraded, and occurs deeper than the proposed anchor trench depth of 3 ft bgs, as identified in the RI. Therefore gas generation due to the construction of the anchor trench between the Cooper North and Haack Sumps is anticipated to be minimal to non-existent. (RTC, 1/9/2013) By maintaining the current concrete and asphalt surfaces, the dermal contact and gas migration risks are minimized during construction. (RTC, 9/29/11)

The short-term effectiveness of Alternative 2A is not high due to the excavation and offsite transport of the Haack Rework material. If the Haack Rework soil material were used as fill beneath the cap, a reduced construction time is achievable as less imported material would be needed. Additionally, there would be a reduced risk of exposure to the public during transport to the final disposal facility. (RTC, 9/29/11)

The cap construction would provide immediate short-term effectiveness since worker risk is low and impacts on environment are minor (grading operations). Liquid infiltration, gas migration, and physical contact would remain controlled due to limited disturbance of the existing surfaces. Because the disturbance to the sludge would be limited, hazardous gas generation would be minimal. (RTC, 9/29/11)

The duration of Alternative 2A, not including preliminary startup of the gas control system, is estimated at approximately 129 calendar days. The estimated construction breakdown schedule is provided in Appendix A. (RTC, 9/29/11)

7.3.3.6 Implementability

Technical implementation of Alternative 2A is relatively easy; however, construction implementation due to the urban setting of the Site, as well as Site size constraints and property owner agreements, create implementation challenges as discussed below. (RTC, 9/29/11)

Urban Setting

Due to the urban setting of the Site, traffic and close proximity to sensitive receptors affect the implementability of Alternative 2A. Traffic will increase the length of time to haul impacted material to an offsite disposal facility and the time to import material such as fill for the foundation layer. Alternative work hours may be proposed to reduce the effects of traffic on construction activities. Close proximity to sensitive receptors concerns are mitigated by leaving the existing surfaces on the sumps in place and by providing continuous monitoring during excavation of the Haack Rework area. The technologies for continuous monitoring are readily available and can easily be deployed at the Site during construction. (RTC, 9/29/11)

Site Size

The majority of the Cooper property contains sludge within the North and South sumps, while approximately one quarter of the Haack property contains the Haack Sump. Of the Haack property not containing the sump, approximately half is sloped and elevated leaving the one quarter available for construction staging and storage. As a result, easements and/or leases may be necessary on the southern Los Angeles Department of Public Works (LADPW) property to provide additional space and additional site ingress/egress. Furthermore, due to the eastern sludge boundary corresponding to the Cooper property boundary, the eastern drainage channel and anchor trench will be located within the LADPW property and will require fill to be placed to maintain and control drainage of that parcel. Additional agreements with the LADPW will be required in order to construct the cap. (RTC, 9/29/11)

By leaving the existing surfaces in place, material may be staged above the Haack Sump while construction is occurring on the Cooper Sumps. Additionally, the reduced fill needed for Alternative 2A requires less imported material and material stockpiling. The lower ground pressure equipment which will be used to place the fill above the high strength geotextile is generally smaller than traditional equipment, thereby requiring less storage space than larger, heavier equipment. As a result, while Alternative 2A has implementation challenges due to the Site size and location, the design of the Alternative 2A cap reduces the effect of the challenges. (RTC, 9/29/11)

7.3.3.7 Cost

The estimated capital cost of Alternative 2A is ~~$4,544,913 $5,774,550,.(RTC, 11/6/12)~~ $5,844,150. (RTC, 1/9/13) However, a cost savings of approximately $314,500 may be achieved by using the Haack Rework soil-sludge material onsite as foundation soil. (RTC, 11/6/12) The estimated net present value of operation and maintenance costs is ~~$1,563,800~~ ~~$2,822,100. (RTC, 11/6/12)~~ $4,882,500 (RTC, 1/9/2013). Therefore, the total present value cost of Alternative 2A is ~~$6,108,713 $8,596,650. (RTC, 11/6/12)~~ $10,726,650. (RTC, 1/9/13) Table 7-1 presents a cost breakdown of Alternative 2A. (RTC, 9/29/11)

7.3.3.8 State Acceptance

State acceptance of Alternative 2A will be assessed during the public comment period. (RTC, 9/29/11)

7.3.3.9 Community Acceptance

During the May 10, 2011 meeting between the DTSC and City of Gardena (City), the City expressed concerns regarding the appearance of Alternative 2 (since removed

[RTC, 9/29/11]) being similar to a "landfill," and the height of the cap being too high. The City expressed the desire that the final remedial alternative be consistent with the vision and goal of future development for the Site. (RTC, 9/29/11)

Alternative 2A is a lower cap option for the Site. The maximum height of the cap is approximately 25.5 ft amsl near the center of the Site. This elevation is approximately 5.5 ft higher than Artesia Boulevard north of the Haack Property. Immediately adjacent to Artesia Boulevard, the maximum height of the cap and associated retaining wall is 23 ft amsl, or 3 ft higher than Artesia Boulevard. The elevation of the cap on the Cooper Property is similar to the elevation of the railroad grade immediately east of the Cooper Property. The final cap surface will consist of Class II aggregate base to support construction of a parking lot consistent with the future commercial development of the Site. Additionally, the cap structure has been designed to support loading associated with traffic and parking. Lower areas of the cap such as drainage channels may be filled to provide a more level surface on which to construct a future parking lot, provided the functionality of the cap is not compromised. (RTC, 9/29/11)

7.3.4 Alternative 3 – Capping with Neutralization/Stabilization and Selective Excavation

7.3.4.1 Overall Protection of Human Health and the Environment

Capping of the partially stabilized/neutralized sludge, combined with selective excavation, would provide moderate ~~to high~~ (RTC 1/9/13) overall protection of human health and the environment. The exposure routes for receptors as identified in the HHRA are dermal contact with sludge, ingestion of sludge, and inhalation of soil gas. Neutralization/stabilization of the sludge would further improve the pH, neutralize acid gases, fixate lead, and provide long-term strength (Stantec, 2008). This Alternative is not ranked higher because (RTC, 1/9/13) the neutralization/stabilization process would require substantial mixing of the sludges, releasing hazardous gases and odors, thereby requiring a tent and gas treatment system to control gas emissions during construction. Selective excavation and consolidation within the sumps would remove the eastern overflow and Haack Rework area with the associated gas risks. Further, this Alternative does not address localized groundwater impacts at the Site (RTC, 1/9/13). The sumps would be capped, reducing the risk associated with dermal contact and ingestion. Additionally, a gas control and monitoring system would be installed beneath the cap to control gas which may be generated by the sludge.

7.3.4.2 Compliance With ARARs

ARARs potentially applicable to Site remedial actions are shown in Table 4-2. Alternative 3 would provide moderate compliance with ARARs. (RTC, 1/9/2013).

Precautions would be required to ensure that short-term community and worker exposures to dust, noise, truck traffic, and VOC emissions are limited to acceptable levels during soil mixing and handling, per ambient air quality health standards.

This remedial alternative is compliant with the Groundwater ARARs by implementing institutional controls limiting onsite extraction of groundwater. Groundwater data has indicated that the sumps are not contributing to offsite impacts; therefore, institutional controls limiting onsite extraction are sufficient for groundwater ARAR compliance. (RTC, 11/6/12) This Alternative does not remediate the groundwater; therefore, this Alternative is not given a "high" ARAR compliance rating. (RTC, 1/9/13)

7.3.4.3 Long-Term Effectiveness and Permanence

The permanent cap with stabilization/neutralization and the below-cap and perimeter passive gas control system provide moderate to high (RTC, 11/6/12) long-term effectiveness. Routine maintenance and monitoring would be provided and would positively contribute to the long-term effectiveness of the remedial measure. If gas monitoring indicates impacts in excess of acceptable values, the below-cap and perimeter vertical gas migration control wells can be made active, which adds to long-term effectiveness in controlling the migration of gas to the environment.

Based on its location, the Site is potentially at risk for high ground shaking and liquefaction during an earthquake. High ground shaking would minimally affect this alternative because its planned future use is open space; however, veneer stability may be compromised. Damage due to a loss of veneer stability may be repaired with maintenance. Liquefaction may result in differential settlement of the cap; however, the differential settlement can be corrected with maintenance of the cap. (RTC, 11/6/12)

7.3.4.4 Reduction of Toxicity, Mobility, and Volume Through Treatment

The toxicity of the sludge would be reduced through stabilization/neutralization by improving the pH, neutralizing acid gases, fixating lead, and providing long-term strength (Stantec, 2008). The cap design would include a gas collection system that can be connected to a treatment system during start-up and continued use, if necessary, based upon start-up monitoring results. If the gases are treated, some reduction in toxicity would be realized. The cap and Site drainage improvements would provide a reduction in mobility of the waste as infiltration of water would be mitigated; hence, migration of liquids from waste would be reduced. An increase in waste volume through bulking would be realized with the remedial measure.

Gas transport at the Site occurs as a result of diffusion; therefore, the rate of lateral migration of gas constituents is very low. If necessary, the perimeter vertical gas migration control wells can be activated to collect potentially migrating gases and/or

remove in-place gases from subsurface soils. The collected gas can be treated if necessary, which results in reduction of the toxicity of the waste.

7.3.4.5 Short-Term Effectiveness

Stabilization/neutralization would require the mixing of the top 3 feet of sludge with $Ca(OH)_2/CaCO_3$. In order to mix the top 3 feet of sludge, the existing cover on the Cooper Sumps would require removal, temporarily increasing the risks associated with the sumps and decreasing the effectiveness of this Alternative. During the exposed period, stormwater could come into contact with the sludge, increasing the volume of materials requiring treatment. While fencing around the Site would be continuously maintained to prevent trespasser entry, animals, such as birds, may enter the Site and either become entrapped in the sludge or potential spread sludge to off-site areas. Additionally, during sludge mixing, ~~As a result,~~ (RTC, 11/6/12)significant quantities of acid gases would be released. Therefore, there may be an increased, short-term risk during mixing activities which would require mitigation through treatment of the acidic gases. The cap construction would provide short-term effectiveness as liquid infiltration, gas migration, and physical contact would be controlled upon cap placement.

7.3.4.6 Implementability

Alternative 3 may be difficult to implement due to the mixing of $Ca(OH)_2/CaCO_3$ compounded with the urban setting of the Site and the Site size. (RTC, 11/6/12) During mixing operations, significant quantities of acid gases would be released which would require treatment. Uncontrolled reactions have been known to occur when neutralizing acid sludges which require constant supervision to prevent the uncontrolled release of hydrogen sulfide gas. (RTC, 11/6/12) A tent would be necessary to contain the gases for treatment prior to discharge to the atmosphere. Due to the size of the sumps, a tent large enough to span the sumps to locations where stable foundations can be achieved may be difficult or impossible to engineer or construct. Similarly to Alternative 2A, the urban setting of the Site increases the impacts the construction would have on area traffic and the proximity to sensitive receptors. Business operations near the Site operate 24-hours a day meaning limiting mixing activities to night-time work only would still affect the public. Significant quantities of neutralizing material as well as soil would need to be imported and stored at the Site; the importing of material could significantly impact traffic as large trucks are forced to enter the Site off Artesia Blvd. Storage at the Site is limited due to the sumps and topography with staging, office, and storage areas limited to the eastern portion of the Haack Property. Stormwater controls or treatment systems, such as retention basins, would be limited by the amount of space at the site. (RTC, 11/6/12)

7.3.4.7 Cost

The estimated capital cost of Alternative 3 ~~is~~ ranges between ~~$11,144,880~~ $11,219,880(1/9/13) and ~~$35,402,274~~ ~~$12,566,880~~ $12,646,280 (1/9/13). This range is due to the variable cost of neutralization admixture, $CaCO_3$ and $CaOH_2$. The costs are highly variable based where the material is sourced from, shipping costs, and construction activities. The high cost variability adds to the low cost rating of this Alternative due to the uncertainty of prices during construction. (RTC, 11/6/12) The estimated net present value of operating and maintenance costs assuming quarterly groundwater and soil vapor probe monitoring for 30 years (RTC, 1/9/2013) is ~~$1,563,800~~ ~~$2,822,100. (RTC, 11/6/12)~~ $4,882,500 (RTC, 1/9/2013). Therefore, the total present value cost of Alternative 3 ~~is $36,966,074~~ ranges from ~~$13,996,980 to $15,388,980. (RTC, 11/6/12)~~ $16,102,380 to $17,528,780 (RTC, 1/9/13). Table 7-2 presents a cost breakdown of Alternative 3.

7.3.4.8 State Acceptance

State acceptance of Alternative 3 will be assessed during the public comment period.

7.3.4.9 Community Acceptance

As discussed in Section 7.3.3.9, the City of Gardena expressed concerns regarding the appearance of Alternative 3 and the desire for a final remedial alternative to be consistent with future development plans. As a result, Alternative 3 has low community acceptance. ~~Community acceptance of Alternative 3 will be assessed during the public comment period.~~ (RTC, 11/6/12)

7.3.5 Alternative 4 – Excavation with Offsite Disposal

7.3.5.1 Overall Protection of Human Health and the Environment

Alternative 4 would provide moderate to high (RTC, 1/9/2013) protection of human and health and the environment by removing the sludge and rework material from the Site. The risk to human health through dermal contact, inhalation, or ingestion would be eliminated because the sludge and rework material would be removed and disposed of offsite. During construction activities and transport of the material, risk to human health and the environment would be increased as significant quantities of acid gases would be released when the sludge is disturbed. Furthermore, there is an increased risk to human health during transport of the material as it would require hauling to a facility where transport would potentially expose many more individuals to the sludge than if it were to remain onsite.

7.3.5.2 Compliance With ARARs

ARARs potentially applicable to Site remedial actions are shown in Table 4-2. Alternative 4 would provide high compliance with ARARs. (RTC, 1/9/2013) ~~Excavation and offsite disposal of sludge can be difficult or impossible to perform in compliance with applicable emissions, disposal, and transportation regulations.~~ (RTC, 1/9/2013) Precautions would be required to ensure that short-term community and worker exposures to dust, noise, truck traffic, and VOC emissions are limited to acceptable levels during soil excavation and handling, per ambient air quality health standards. Poor groundwater quality (as documented in MW-05A immediately adjacent) may be improved as the suspected sludge source is removed. (RTC, 11/6/12)

7.3.5.3 Long-Term Effectiveness and Permanence

Alternative 4 would provide high long-term effectiveness and permanence ~~is effective and permanent~~ (RTC, 1/9/2013) since the impacted material would be removed from the Site.

7.3.5.4 Reduction of Toxicity, Mobility, and Volume Through Treatment

Alternative 4 would provide low to moderate reduction of toxicity, mobility, and volume of the sludge or rework material through treatment. This alternative creates a large amount of waste compared to the other alternatives presented and discussed. This waste should be taken into consideration for evaluating these criteria. (RTC, 1/9/2013) Alternative 4 will ~~not~~ (RTC, 1/9/2013) reduce the toxicity ~~or volume~~ (RTC, 1/9/2013) of the sludge or rework material. The mobility of the sludge would be temporarily increased due to transportation of the sludge, then (RTC, 1/9/2013) reduced since it would be disposed of in an appropriate facility with a bottom liner system. The migration of sludge constituents is further reduced by the admixture prior to transport which was shown to reduce leaching and gas generation during the Treatability Study (Appendix A, Stantec, 2008). The volume of the sludge would ~~double~~ increase approximately 20 to 40 percent (RTC, 11/12/13) following admixture. Other wastes that would be produced during treatment include impacted groundwater, vapor treatment associated liquid and solid wastes, and decontamination wastes. Taking these wastes into consideration, Alternative 4 would provide low to moderate reduction of toxicity, mobility, and volume of sludge and associated wastes through treatment. (RTC, 1/9/2013)

7.3.5.5 Short-Term Effectiveness

Alternative 4 would provide moderate short-term effectiveness ~~is effective in the short term~~ (RTC, 1/9/2013) by removing the sludge and rework material from the Site; however, in order to neutralize the sludge for off-site disposal, risks associated with the

sludge are temporarily increased. Neutralization of the sludge requires deep mixing of the sludge with $Ca(OH)_2/CaCO_3$. In order to mix the sludge, the existing sump covers would require removal, temporarily increasing the risks associated with the sumps and decreasing the effectiveness of this Alternative. During the exposed period, stormwater could come into contact with the sludge, increasing the volume of materials requiring treatment. While fencing around the Site would be continuously maintained to prevent trespasser entry, animals, such as birds, may enter the Site and either become entrapped in the sludge or potentially spread sludge to off-site areas. Additionally, during sludge mixing, ~~significant~~ large quantities of acid gases, when compared to the other alternatives presented and discussed, (RTC, 1/9/2013) would be released. Therefore, there may be an increased, short-term risk during mixing activities which would require mitigation through treatment of the acidic gases. ~~The cap construction would provide short-term effectiveness as liquid infiltration, gas migration, and physical contact would be controlled upon cap placement. (RTC, 11/6/12~~) (RTC, 1/9/2013)

7.3.5.6 Implementability

Implementability ~~Implementation~~ of Alternative 4 would be low~~challenged~~ (RTC, 1/9/2013) due to the sludge depth, site proximity to sensitive receptors, site size, (RTC, 11/6/12) and site access issues. The majority of the sludge to be excavated is previously undisturbed sludge, which has a less viscous consistency than the degraded soil-sludge material that is proposed to be removed in Alternative 2A and Alternative 3. (RTC, 1/9/2013) As an area is excavated, sludge would flow to the newly excavated portion of the sump. The depth of the excavation would be between 0.5 and ~~23.5~~ 17.5 (RTC, 11/6/12) ~~feet~~ ft bgs (RTC, 1/9/13), depending on the sump, and due to the size of the Site there would not be enough room to slope the sides of the excavation. Therefore, shoring would be required, which would limit the ability to "chase" impacted materials laterally during excavation and obtain side wall conformance samples. Shoring may be used, but due to the discontinuity of sludge material, during mixing of the reagent and sludge, acid gas containment and treatment would be necessary. A tent would be necessary to contain the gases for treatment prior to discharge to the atmosphere. Due to the size of the sumps, a tent large enough to span the sumps to locations where stable foundations may be achieved would be difficult to implement. An equipment hood may provide the necessary containment; however, the working area is limited by the size of the hood.

Similarly to Alternatives 2A and 3, the urban setting of the Site increases the impacts the construction would have on area traffic and the proximity to sensitive receptors. Business operations near the Site operate 24-hours a day meaning limiting mixing activities to night-time work only would still affect the public. Significant quantities of neutralizing material as well as soil would need to be imported and stored at the Site; the importing of material could significantly impact traffic as large trucks are forced to

enter the Site off Artesia Blvd. Storage at the Site is limited due to the sumps and topography with staging, office, and storage areas limited to the eastern portion of the Haack Property. Stormwater controls or treatment systems, such as retention basins, would be limited by the amount of space at the site. (RTC, 11/6/12)

7.3.5.7 Cost

The estimated capital cost of Alternative 4 is high compared to the alternatives presented and discussed, and (RTC, 1/9/2013) ~~is $54,067,350~~ ranges between $26,217,950 and $28,991,650. The costs are highly variable based where the admixture material is sourced from, shipping costs, and construction activities. The high cost variability adds to the low cost rating of this Alternative due to the uncertainty of prices during construction. (RTC, 11/6/12) The estimated net present value of groundwater monitoring costs is ~~$620,500~~ $113,200. (RTC, 11/6/12) Therefore, the total present value cost of Alternative 4 is ~~$54,687,850~~ between $26,331,150 and $29,104850. (RTC, 11/6/12) Table 7-3 presents a cost breakdown of Alternative 4.

7.3.5.8 State Acceptance

State acceptance of Alternative 4 will be assessed during the public comment period.

7.3.5.9 Community Acceptance

~~Community acceptance of Alternative 4 will be assessed during the public comment period.~~ (RTC 9/29/11) During the 10 May 2011 meeting with the DTSC and City of Gardena, the City felt Alternative 4 best achieved their future development goals (RTC, 11/6/12); therefore, this Alternative receives a moderate to high ranking for community acceptance (1/9/2013).

8. COMPARATIVE ANALYSIS OF ALTERNATIVES

8.1 General

In this section, the final remedial alternatives are compared by using the detailed analysis criteria. The purpose of this comparative analysis is to identify the relative advantages and disadvantages of each final remedial alternative and to provide a basis for identifying the preferred remedial alternative.

8.2 Final Remedial Alternatives

8.2.1 General

In Table 8-1, each final remedial alternative is assigned a ranking for each detailed analysis criterion. These rankings range from "low" to "high" and are accompanied by a numeric ranking from 1 to 5 (Note 3, below). At the conclusion of the comparative analysis, the preferred remedial alternative is identified.

8.2.2 Overall Protection of Human Health and the Environment

~~Alternative 1, No Action, does not provide adequate protection of human health and the environment. No further assessment or comparison with this alternative is provided. Alternative 2 would perform better than Alternative 3. While Alternative 3 stabilizes/neutralizes a portion of the sludge, the mixing of the reagent releases hazardous amounts of hydrogen sulfide and sulfuric acid gas. Alternative 4 would provide very good protection of human health and the environment with the removal of the impacted materials; however, because of the risks associated with hazardous gas generation during excavation and transportation of the material, the overall protection is deemed moderate~~. (RTC, 9/29/11)

Alternative 1, No Action, does not provide adequate protection of human health and the environment. No further assessment or comparison with this alternative is provided. Alternative 2A performs better than Alternatives 3 and 4 due to disturbance of only the degraded Haack Rework sludge material. As demonstrated in the Treatability Study and Surface Flux Testing (RTC, 1/9/13) (Stantec, 2007), disturbing the non-degraded sludge results in the generation of significant quantities of hydrogen sulfide and sulfur dioxide. Significant mechanical disturbance of the non-degraded sludge occurs in Alternatives 3 and 4. Both Alternatives 2A and 3 would leave the majority of the sludge onsite, which reduces their overall protection of human health and the environment; however,

---

(3) A numeric ranking of "1" is lowest, or worst; "5" is highest, or best. With respect to cost, "1" is most expensive; "5" is least expensive.

Alternative 4 excavates the sludge from the Site and transports the sludge along public streets and highways en route to final disposal at the Buttonwillow Facility. During transport, the public may become potentially exposed to the sludge due to traffic accidents resulting in a sludge release or gas release from the truck. The same transport risks are not anticipated with transport of the Haack Rework soil-sludge material as proposed in Alternative 2A due to the degraded nature of this sludge and the significantly reduced volume of sludge to be transported. (RTC, 9/29/11)

8.2.3 Compliance With ARARs

~~Alternative 2 would perform better with respect to ARARs due to the reduction of gas emissions when compared to Alternatives 3 and 4.~~ (RTC, 9/29/11)

~~Alternative 2A would perform with respect to ARARs due to the minimal gas emissions, reduced truck traffic, and lack of sludge exposed to air and possible stormwater when compared to Alternatives 3 and 4. (RTC, 9/29/11)~~ (RTC, 1/9/13)

Alternative 4 would perform the best with respect to ARARs due to the removal of the sludge and source for potential onsite groundwater impacts. All Alternatives perform well with respect to ARAR compliance; however, Alternatives 2A and 3 are ranked lower because a potential source for onsite groundwater impacts remains in place. (RTC, 1/9/13)

8.2.4 Long-Term Effectiveness and Permanence

~~Alternative 3 is ranked higher than Alternative 2 with respect to long-term effectiveness and permanence. Both alternatives would be effective and permanent over the long-term with maintenance; however, because Alternative 3 neutralizes the sludge, the treatment is likely more permanent. Alternative 4 provides the greatest long-term effectiveness and permanence since the sludge is removed from the site and disposed of offsite.~~ (RTC, 9/29/11)

Alternative 4 is ranked the highest for long-term effectiveness and permanence because the sludge is removed from the site and disposed of offsite. (RTC, 1/9/13) Alternative 3 is ranked higher than Alternative 2A with respect to long-term effectiveness and permanence. Both alternatives would be effective and permanent over the long term with maintenance; however, because Alternative 3 neutralizes some of (RTC, 11/6/12) the sludge, the treatment is likely more permanent. (RTC, 9/29/11)

Based on its location, the Site is at risk for high ground shaking and liquefaction during an earthquake regardless of the remedial alternative. High ground shaking would minimally affect Alternatives 2A and 3 because of their planned future use as a parking lot or open space, respectively. High ground shaking on Alternatives 2A and 3 slopes

may result in veneer failure and liquefaction may result in differential settlement of the cap. Both the veneer failure and differential settlement can be corrected with maintenance of the cap. (RTC, 11/6/12) Alternative 4 provides the greatest long-term effectiveness and permanence since the sludge is removed from the site and disposed of offsite. (RTC, 9/29/11)

8.2.5 Reduction of Toxicity, Mobility, and Volume through Treatment

~~Alternative 3 would slightly reduce toxicity and mobility through partial in-situ treatment of the source zone; however, toxicity would increase as acid gases are released during mixing of the sludge for treatment. Alternatives 2 and 3 would reduce mobility of the sludge by limiting infiltration and wind erosion. Alternative 4 would reduce the mobility of the sludge after offsite disposal since the disposal landfill would be equipped with a liner system to collect leachate; however, transport of the material would temporarily increase the potential mobility.~~ (RTC, 9/29/11)

Alternatives 2A and 3 would reduce mobility of the sludge by limiting infiltration and wind erosion. Alternative 3 would slightly reduce toxicity and mobility through partial in-situ treatment of the source zone; however, toxicity would increase as gases are released during mixing of the sludge for treatment. The volume of material within the sumps would increase due to bulking during neutralization and increase the cap height by a minimum of 3 ft. In Alternative 3, the net toxic material (non-stabilized sludge) would be reduced. The volume of sludge material in the sumps would remain the same with Alternative 2A. Treatment of sludge with Alternative 4 would ~~double the volume of waste material to be disposed~~ increase the volume of waste material to be disposed of by 20 to 40 percent due to neutralization (RTC, 11/12/13) as well as generate more waste from decontamination water, spent vapor treatment carbon, and ponded dust and emissions control liquid. (RTC, 1/9/13) Alternative 4 would reduce the mobility of the sludge after offsite disposal since the disposal landfill would be equipped with a liner system to collect leachate; however, transport of the material would temporarily increase the potential mobility. (RTC, 9/29/11)

8.2.6 Short-Term Effectiveness

~~Alternative 2 would perform the best with respect to short-term effectiveness. Unlike Alternatives 3 and 4, Alternative 2 does not significantly disturb the sludge thereby minimizing the release of acid gas. Both Alternatives 2 and 3 incorporate a cap into the final design which would provide an immediate reduction in risk due to inhalation, dermal exposure, and ingestion. Alternative 4 would provide a reduction in risk after the sludge was transported offsite; however, risk is temporarily increased in the short-term during sludge disturbance and transport.~~ (RTC, 9/29/11)

Alternative 2A would perform the best with respect to short-term effectiveness. Unlike Alternatives 3 and 4, Alternative 2A does not significantly disturb the sludge, thereby minimizing the release of gas. The existing surfaces, which have been shown to reduce the migration of gas, will remain in place during construction resulting in limited sludge disturbance and therefore, gas generation. Alternatives 2A and 3 incorporate a cap into the final design which would provide a reduction in risk due to inhalation, dermal exposure, and ingestion. (RTC, 9/29/11)

Alternatives 3 and 4 significantly disturb the sludge, which has been demonstrated to generate significant quantities of hydrogen sulfide and sulfur dioxide gas requiring tenting and gas control systems during mixing and excavation operations. The gas control system, incorporating a tent, blower, and treatment system, would significantly increase the amount of time to remediate the Site due to the limited operating space within the enclosed facility. Additionally, waste materials from the treatment system components, such as a scrubber, could generate additional waste, which could increase the total volume of hazardous materials at the Site. (RTC, 11/6/12) The length of time would be increased due to the use of smaller equipment as well as down time during treatment system maintenance. (RTC, 9/29/11)

Alternative 4 would provide a reduction in risk after the sludge was transported offsite; however, risk is temporarily increased in the short-term during sludge disturbance and transport. Given that the weight of material estimated for offsite disposal is approximately ~~49,900 tons and a typical end dump truck capacity is 14 tons, approximately 3,565 truck loads are anticipated for Alternative 4~~ 45,900 CY and a typical end dump truck capacity is 16 CY(RTC, 11/6/12, approximately ~~3,565~~ 2,870 (RTC, 11/6/12 truck loads are anticipated for Alternative 4. Smaller, 16 CY trucks are proposed for Site work due to the limited space available onsite for staging and operating larger trucks (RTC, 11/6/12) Additionally, using the estimated 20 trucks per day discussed in Section ~~3.3.3~~ 6.1.2.2, trucks (RTC, 11/6/12) transport of the sludge would require a minimum of ~~179~~ 160 (RTC, 11/6/12) days for transport, which does not include additional delays due to limitations from tenting and gas control during excavation. (RTC, 9/29/11)

Due to the nature of the sludge disposal within the sumps, Alternative 4 would require the excavated sumps to be exposed for periods of time during confirmation sampling. Temporary backfill of sludge in the interim would generate the potential for non-impacted material to become impacted through contact, thereby increasing the amount of material excavated and the time to remediate. (RTC, 9/29/11)

The durations of the Alternatives are estimated at 129, 235, and 301 calendar days for Alternatives 2A, 3, and 4, respectively. The construction duration of Alternative 2A is approximately half of Alternative 3 and 4 times less than Alternative 4, meaning the

potential exposure time of sludge hazards to workers is significantly reduced. Additionally, the construction impacts on the community including truck traffic and visual distractions are significantly reduced with Alternative 2A. The estimated construction schedules are provided in Appendix ~~A~~ (RTC, 9/29/11) E.(RTC, 11/6/12)

8.2.7 Implementability

~~Alternatives 3 and 4 pose significant implementation issues due to the gas generation during mixing and excavation of the sludge. Gas control and treatment would be necessary during mixing and excavation of the sludge. Construction of a tent to contain the gases would be difficult to perform due to low bearing capacity of the sludge and the area the tent would need to span (minimum of the Cooper North sump). Gases captured by the tent would need treatment prior to discharge. (RTC, 9/29/11)~~

~~Alternative 2 is relatively easy to implement. A stabilization layer on the Cooper sumps would be placed first to provide a surface in which to install the foundation and gas collection, barrier, and cover layers. Disturbance of the sludge would be limited to the eastern overflow and Haack Rework, which are significantly degraded and would release significantly less acid gas than the sludge in the Haack and Cooper Sumps (Appendix A, Stantec, 2008). The materials necessary for construction are available and do not require admixtures or special equipment.~~ (RTC, 9/29/11)

All Alternatives are difficult to implement due to the site location and size; however, the design of Alternative 2A limits the effects of these challenges on construction. These challenges are discussed in further detail below: (RTC, 9/29/11)

Urban Setting

Due to the urban setting of the Site, traffic and close-proximity to sensitive receptors affect the implementability of all Alternatives. Traffic will increase the length of time to haul impacted material to an offsite disposal facility and the time to import construction materials such as fill. (RTC, 9/29/11)

Alterative 2A requires the least amount of imported and exported material, thus reducing overall truck traffic on Artesia Boulevard. Both Alternatives 3 and 4 require significant truck traffic to import stabilization material as well as, in the case of Alternative 4, export sludge offsite. As discussed previously in Section 6.1.4.2, 3,565 truck loads are estimated for transport of excavated sludge to an offsite facility, which could negatively affect the traffic flows in the vicinity of the Site. (RTC, 9/29/11)

Site Size

The majority of the Cooper property contains sludge in the North and South sumps, while approximately one quarter of the Haack property contains the Haack Sump. The

portion of the Haack property not containing the sump is split into a sloped and elevated portion and a flatter portion that could be available for construction staging and material storage. Furthermore, easements and/or leases may be necessary on the Los Angeles Department of Public Works (LADPW) property for grading and fill placement to provide for surface water flow and collection, as well as providing additional space and additional site ingress/egress. (RTC, 9/29/11)

Alternatives 3 and 4 require stockpiling of stabilization material; therefore, the time for stabilization is directly proportional to how much material is available onsite to mix. If only limited quantities of material are available onsite due to storage area constraints, the length of time to implement Alternatives 3 and 4 will increase. (RTC, 9/29/11)

Site Proximity to Sensitive Receptors

Alternatives 3 and 4 pose significant implementation issues due to the gas generation during mixing and excavation of the sludge and the potential impacts to neighboring sensitive receptors. Gas control and treatment would be necessary during mixing and excavation of the sludge. Construction of a tent to contain the gases would be difficult to perform due to low bearing capacity of the sludge and the area the tent would need to span (minimum of the Cooper North sump). Gases captured by the tent would need treatment prior to discharge. In addition, the size of the tent and treatment system would further reduce the space available on the Site to stage construction including equipment storage, stockpiling of fill material, and construction facilities. (RTC, 9/29/11)

Implementation of Alternative 2A has fewer engineering and health and safety complications. By maintaining the existing surfaces, gas generation from the sumps would be minimized and continuous monitoring with readily available vapor suppression equipment will provide a means to minimize potential effects of gas generation during excavation in the Haack Rework area. In addition, Alternative 2A requires less imported material and material stockpiling, thus reducing the effects of traffic and the reduced Site size on construction. As a result, while Alternative 2A has implementation challenges due to the Site size and location, the design of the Alternative 2A cap reduces the effect of the challenges. (RTC, 9/29/11)

8.2.8 Cost

~~Alternative 2 has the lowest capital of approximately $5,206,314 and O&M cost, with Alternatives 3 and 4 having comparable capital costs of $35,402,274 and $54,067,350, respectively. Alternatives 2 and 3 have identical net present value O&M costs of approximately $1,563,800. Alternative 4 has the lowest net present value O&M cost of approximately $620,500. Alternative 2 has the lowest combined remedial cost.~~ (RTC, 9/29/11)

Alternative 2A has the lowest capital cost of approximately ~~$4.5~~ $5.8 million, with Alternatives 3 and 4 having ~~having comparable~~ low-range capital costs of approximately ~~$35.4~~ $11.1 million and ~~$54.1~~ $26.2 million, respectively and high-range costs of approximately $12.6 and $29.1 million. (RTC, 11/6/12) Alternatives 2A and 3 have identical net present value O&M costs of approximately ~~$1.6~~ ~~$2.8~~ (RTC, 11/6/12) $4.9 (RTC, 11/12/13) million. (RTC, 11/6/12) Alternative 4 has the lowest net present value O&M cost of approximately ~~$0.6 million~~ $113,200. Alternative 2A has the lowest combined remedial cost and is not dependent on the highly variable neutralization admixture cost which may vary from as low as $300/ton to as high as $750/ton or more. (RTC, 11/6/12)

8.2.9 State Acceptance

In accordance with USEPA guidance, this criterion will be addressed when DTSC is making its final remedial decision and the ROD is being prepared.

8.2.10 Community Acceptance

~~In accordance with USEPA guidance, this criterion will be addressed when DTSC is making its final remedial decision and the ROD is being prepared.~~ (RTC, 9/29/11)

During the May 10, 2011 meeting between the DTSC and the City, the City expressed concerns regarding the appearance of the former (RTC, 11/6/12) Alternative 2 being similar to a "landfill," and the height of the cap being too high. The City expressed the desire that the final remedial Alternative be consistent with the vision and goal of future development for the Site. (RTC, 9/29/11)

Alternative 2A provides a reduced cap thickness, and accounts for future use as a parking lot subgrade consistent with the City's vision for commercial development. Alternative 3 proposes a cap sloping upward to a maximum elevation of 35 ft amsl, which makes parking lot construction more difficult above the high grades and slopes of the Site. Alternative 4 proposes the Site is excavated and filled. Alternative 4 best incorporates the City's vision for commercial development; however, given the potential health risks associated with implementation, short-term effectiveness, and cost challenges, Alternative 2A provides the best compromise to meet the City's development vision. (RTC, 9/29/11)

8.3 Preferred Remedial Alternative

~~Based on the comparative analysis of the remedial alternatives, the alternative that meets the RAOs and ranks the highest is Alternative 2, capping with selective excavation. The elements of Alternative 2 are~~: (RTC, 9/29/11)

- Prepare a construction Health and Safety Plan and Construction Quality Assurance Plan; (RTC, 9/29/11)
- Place a 3.5-foot stabilization layer across the Cooper North and South sumps consisting of gravel, sand, and geocell; (RTC, 9/29/11)
- Excavate the Haack Rework area, segregating the overburden soil from the sludge/soil mixture; (RTC, 9/29/11)
- Install retaining wall (sheet pile) along northern perimeter (Artesia Blvd); (RTC, 9/29/11)
- Place the Haack Rework material and other site soils as the foundation layer above the stabilization layer with horizontal gas collection pipes embedded. The foundation layer would increase in thickness and would be graded such that the final surface would drain at 3 percent to the cap perimeters; (RTC, 9/29/11)
- Install vertical gas migration control wells; (RTC, 9/29/11)
- Install geosynthetic layers consisting of, from bottom to top, a gas collection geocomposite, GCL, 60-mil HDPE geomembrane, and drainage geocomposite; (RTC, 9/29/11)
- Place 2 feet of cover soil above the geosynthetics; (RTC, 9/29/11)
- Install groundwater monitoring wells; (RTC, 9/29/11)
- Operate the below-cap gas collection system and the perimeter vertical gas migration control well system as active systems for a period of at least 2 weeks. Following the start-up period, operate the below-cap gas collection system and vertical gas migration control well system passively. During passive operation, monitor the performance of the proposed alternative remedial measure with a system of perimeter gas migration sentry wells outside the limit of the perimeter vertical gas migration control wells. If the monitoring data indicate significant gas migration from the waste, convert the system to active gas control and, if required, include gas treatment; (RTC, 9/29/11)
- Prepare a Risk Management Plan; (RTC, 9/29/11)
- Perform semi-annual groundwater monitoring; and (RTC, 9/29/11)
- Complete a formal review of remediation effectiveness after five years. (RTC, 9/29/11)

This remedial alternative effectively mitigates the risk from ingestion, inhalation, and dermal contact with onsite soils for both future non-residential and residential occupants of buildings on site, and future landscapers and utility workers. This alternative also

~~effectively mitigates the risk from dermal contact with site groundwater through the cap and institutional controls including the Health and Safety Plan and Risk Management Plan.~~ (RTC, 9/29/11)

~~Alternative 2 readily meets the criteria of overall protection of human health and the environment and satisfies ARARs. When evaluated against the balancing criteria, Alternative 2 provides short-term effectiveness as well as long-term effectiveness and permanence. It is readily implementable and presents an effective balance of cost against the other criteria. Alternative 2 also would accommodate future potential redevelopment of the Site~~. (RTC, 9/29/11)

~~Figures 6-2 through 6-7 demonstrate the conceptual design of Alternative 2 and are for the purposes of evaluating costs in this Feasibility Study. The overall height of the cap may be reduced by alternatives such as flatter final cap slopes and a narrower stabilization layer which will be evaluated and presented in the Remedial Action Plan (RAP). The final design for Alternative 2 will be presented in the RAP~~. (RTC, 9/29/11)

Based on the comparative analysis of the remedial alternatives, the alternative that meets the RAOs and ranks the highest is Alternative 2A, capping with selective excavation. The elements of Alternative 2A are (RTC, 9/29/11):

- Prepare a construction HASP and CQA Plan;
- Prepare a Risk Management Plan;
- High-strength geotextile installation;
- Select excavation of impacted material;
- Containment of sludge along Artesia Boulevard;
- Capping of sludge;
- Installation of gas control and monitoring system;
- Institutional controls;
- Perform semi-annual groundwater monitoring; and
- Complete a formal review of cap effectiveness after five years. (RTC, 9/29/11)

This remedial alternative effectively mitigates the risk from ingestion, inhalation, and dermal contact with onsite soils for future non-residential occupants of buildings onsite, and future landscapers and utility workers. This alternative also effectively mitigates the risk from dermal contact with Site groundwater through the cap and institutional controls including the Health and Safety Plan and Risk Management Plan. (RTC, 9/29/11)

Alternative 2A readily meets the criteria of overall protection of human health and the environment and satisfies ARARs. When evaluated against the balancing criteria, Alternative 2A provides short-term effectiveness as well as long-term effectiveness and permanence. It is implementable and presents an effective balance of cost against the other criteria. Alternative 2A also would accommodate future potential redevelopment of the Site. (RTC, 9/29/11)

Figures ~~3-1~~ 6-1 through ~~3-10~~ 6-8, 6-13, and 6-15 (RTC, 11/6/12) demonstrate the conceptual design of Alternative 2A and were prepared for the purposes of evaluating costs in this Addendum. The design for Alternative 2A will be presented in the Remedial Action Plan. (RTC, 9/29/11)

EVALUATION OF BEARING CAPACITY WITH RESPECT TO VEHICLE LOADING

PURPOSE

The purpose of this calculation package is to evaluate the bearing capacity of soft, low permeability sludge when heavy vehicular loading is applied to the overlying soil cap. The intent of the calculation is to demonstrate adequate margin of bearing capacity when the cap system is subject to temporary H 20 loading.

From top to bottom, the cap overlying the sludge consists of the following:

- 3-inch thick asphalt paving (assumed minimum thickness);
- 12-inches Class 2 aggregate base;
- Drainage geocomposite;
- 60-mil High Density Polyethylene (HDPE) geomembrane;
- Gas collection geocomposite;
- 12-inches (minimum) of foundation soil;
- High-strength woven geotextile; and
- Existing hypalon geomembrane.

The cap is proposed to serve as a parking lot for future site development.

PROCEDURE

The bearing capacity of the sludge was determined using the method outlined in the Naval Facilities Engineering Command Engineering Design Manual (NAVFAC, 1986) for shallow footings with concentric loads. The loading imposed on the sludge from an H 20 vehicle on the cap surface was estimated using Bousinnesq stress distribution as presented by NAVFAC (1986). Stabilization/reinforcement provided by the high strength geotextile and the asphalt surfacing was neglected in this calculation.

Vehicle Loading Estimation

The assumed loading on the cap is modeled as an H 20-44 truck as defined in the 2004 California Department of Transportation (Caltrans) Bridge Design Specifications (Attachment A). Caltrans H 20-44 loading specifies a rear axle load of 32,000 pounds

(lbs). Assuming that the rear axle is equipped with dual 315/80R22.5 tires with a maximum dual tire load of 8,270 lbs (Attachment B), the load from each tire on the rear axle is determined:

$$Load\ per\ Tire = \frac{32{,}000 lbs}{4} = 8{,}000 \text{lbs}$$

Michelin (2013) provides a loaded tire width of 12.5 inches for a 315/80R22.5 tire and a recommended maximum inflation pressure of 130 pounds per square inch (psi) (Attachment B). The estimated loaded area is calculated to be:

$$Area\ per\ Tire = \frac{8{,}000\ lb}{130\ psi} = 61.5\ \text{in}^2$$

The estimated loaded length is calculated to be:

$$Length\ of\ 1\ Tire = \frac{61.5 in^2}{12.5 in} = 4.9\ \text{in}$$

Since the dual tires are close together, the total contact area for the set of dual tires can be estimated as twice the contact area of one tire (123 in^2).

The loading at the top of the sludge was estimated using Boussinesq vertical stress distribution through the minimum 2.25 foot thick cap. A surface load of 16,000 lbs (2 tires) was distributed below a surface contact area with a width of 25 inches (2 tires * 12.5 inches per tire) and a length of 4.9 inches (Attachment B). As presented in Attachment C, at a depth of 2.25 feet, the vertical stress imposed below the center of the vehicular loading area is estimated to be approximately 1,350 pounds per square foot (psf).

Bearing Capacity Analysis

The ultimate bearing capacity (q_{ult}) was determined based on the following equation presented in NAVFAC (1986) for cohesive materials with surface loading (depth, D = 0 feet):

$$q_{ult} = cN_c$$

where:

q_{ult}= Foundation ultimate bearing capacity (psf)

c = cohesion of the foundation (sludge) (psf) = 300 psf*

N_c = Bearing capacity coefficient (psf) = 5.53

* The sludge material is estimated from Cone Penetration Test (CPT) soundings performed at the site to have undrained shear strength between approximately 300 psf and 1,600 psf.

An expression for N_c as a function of the angle of internal friction of the sludge (N_c = 5.53 for ϕ = 0) and was determined based on NAVFAC (1986) (Attachment D). The lower bound ultimate bearing capacity was determined by:

$$q_u = (300\,psf)(5.53) = 1{,}659\,psf$$

The lower bound factor of safety (FS) against bearing capacity failure of the sludge is estimated by:

$$FS = \frac{q_u}{qe} = \frac{(1{,}659\,psf)}{(1{,}350\,psf)} = 1.2$$

The table below summarizes the calculated factors of safety for the estimated range of sludge strength.

Sludge Strength (psf)	Calculated q_{ult} (psf)	Calculated FS
300	1,659	1.2
600	3,318	2.5
900	4,977	3.7
1,200	6,636	4.9
1,600	8,848	6.6

DISCUSSION

A design applications guide (Synthetic Industries, 1998) for a similar application of a lagoon cover presents a discussion of factor of safety criteria for bearing capacity evaluation (Attachment E). For temporary loading conditions, such as vehicular loading, the referenced publication states that a factor of safety of 1.5 is appropriate, with a factor of safety as low as 1.2 that could be used if the foundation strength is

either well known or conservatively estimated. For this evaluation, the selected 300 psf strength of the sludge is considered the lower bound (conservatively estimated) and results in a factor of safety of 1.2, neglecting contribution from the geotextile. With an estimated strength of 600 psf, which is a relatively conservative strength from the estimated strength range, the calculated FS is equal to 2.5, which is in the rage of FS considered appropriate for (permanent) foundation design, commonly using FS between 2.5 and 3.0.

The geotextile above the sludge would provide separation and stabilization for the cap. As the soil is loaded from the surface, the surrounding soil is held in place, preventing a local punching (shear) failure; this change in the soil failure mode from local shear to general shear allows about 80% additional loading before the soil strength is exceeded (Propex, 2011 – Attachment F).

The reinforcement action (strength) of the geotextile would be generated by the application of vertical stresses causing vertical and lateral deformations of the cap materials and the geotextile. In paved applications such as this project, the allowable deformation to reduce significant pavement cracking is relatively low, and the reinforcement action would not be as applicable.

Additionally, the asphalt pavement would provide some lateral distribution/reduction of the applied vehicle load at the top of the sludge, which has been neglected in this calculation.

RESULTS

Because the factors of safety determined with respect to bearing capacity of the sludge and the H 20-44 loading at the cap surface, sludge bearing capacity failure is not anticipated.

Long Haul

XDN®2 GRIP

The all-weather, directional, premium drive tire optimized for exceptional traction with no compromise on tread wear.

- Michelin's Matrix™ siping technology helps provide exceptional traction on dry and slippery surfaces. Over 1,300 biting edges combine to help provide excellent levels of traction while the 3 dimensional Matrix™ sipes lock together for the stability norma
- Extra-wide tread (nearly 1" wider than Michelin XDN tire) helps provide stability while helping to improve handling and mileage.
- Full 28/32 tread depth helps provide long original tread life.
- Wide, open shoulder grooves help deliver additional traction balanced with tread life.

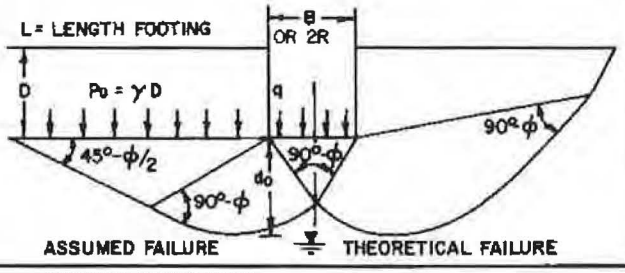
CIRCULAR FOOTING:

$q_{ult} = \gamma D N_q + 0.6 \gamma R N_\gamma$

FOR COHESIVE FOUNDATION SOILS (ϕ = 0)

CONTINUOUS FOOTING:



$q_{ult} = cN_c + \gamma D$

SQUARE OR RECTANGULAR FOOTING:

$q_{ult} = cN_c \left(1 + .3\frac{B}{L}\right) + \gamma D$

CIRCULAR FOOTING:

$q_{ult} = 1.3 cN_c + \gamma D$

ASSUMED CONDITIONS:

1. $D \leq B$
2. SOIL IS UNIFORM TO DEPTH $d_o > B$.
3. WATER LEVEL LOWER THAN d_o BELOW BASE OF FOOTING.
4. VERTICAL LOAD CONCENTRIC.
5. FRACTION AND ADHESION ON VERTICAL SIDES OF FOOTING ARE NEGLECTED.
6. FOUNDATION SOIL WITH PROPERTIES c, ϕ, γ

FIGURE 1
Ultimate Bearing Capacity of Shallow Footings With Concentric Loads

DESIGN GUIDELINES (cont'd)

Step 4. Calculate the Bearing Capacity Safety Factor

Check to ensure that the fill soil/geotextile system has sufficient bearing capacity to support the construction equipment loading during placement of initial lift of soil. Use a classical net bearing capacity approach [12], modified for squeezing if the soft soil is relatively thin [13], where only additional (i.e. equipment) loadings, are considered.

Calculate the net bearing capacity of the foundation soil, q_{net} :

$$q_{net} = c_{us} N_c$$

where:

c_{us} = Average Undrained Soil / Sludge shear strength, psf
Note: if varies, average through depth = 1.5 (W+2T) , ft.

N_c = 5.14, when $(W+2T) < 2 D_s$
otherwise, $N_c = 4.14 + 0.5 [(W+2T) / D_s]$

Calculate the Bearing Capacity safety factor for the foundation soil, FS_{bc} :

$$FS_{bc} = q_{net} / q_{ac}$$

The minimum bearing capacity safety factor acceptable for design is a critical engineering parameter that is selected based upon engineering judgement. The bearing capacity calculated is for the extreme equipment loading scenario present for only a short period of time. Therefore, safety factors greater than 1.5 are considered acceptable. However, the designer may recognize that because the consequences of failure are small (pulling the dozer out of sludge) that lower safety factors may be an acceptable risk, since the equipment can move in response to unsatisfactory behavior, i.e. failure won't be catastrophic. In these scenarios, when the undrained shear strength is well known or conservatively estimated safety factors as low as 1.2 can be acceptable.

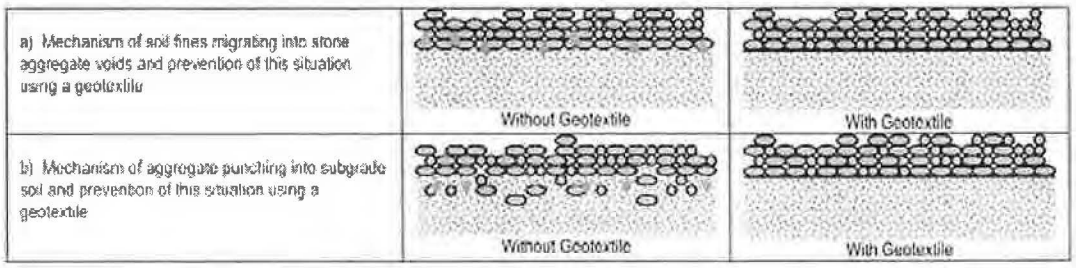
GEOTEXTILE FUNCTIONS IN PAVED AND UNPAVED ROADS

FORWARD

The most common use of geotextiles is beneath paved and unpaved roadways, and this is referred to as the separation/stabilization application. Geotextiles used in paved and unpaved roadways actually provide several benefits through primarily four geotextile functions: Separation, Stabilization, Reinforcement, and Filtration.

The benefits derived from these four geotextile functions are most significant when subgrade soils are weak, i.e., CBR < 3. These benefits are well documented in the literature. However, long-term benefits (improved pavement performance over time) from separation in applications where the subgrade is competent, (i.e., CBR >3), are just now beginning to surface, as roads 30 years old have been exhumed and have maintained their full structural section since they were built over a geotextile.

This Engineering Bulletin describes the functions of a geotextile beneath roadways. For design assistance using geotextiles beneath either paved or unpaved roads, the use of our free Roadways And Civil Engineering (R.A.C.E.) software is recommended.



SEPARATION

Geotextile separation is defined as the introduction of a flexible, porous textile placed between dissimilar materials so that the integrity and functioning of both materials can remain intact or be improved (Koerner, 1994).

In paved and unpaved roadways where granular aggregate is placed on fine-grained sols, two detrimental mechanisms occur over time without the use of a geotextile separator:

1. First, the fine-grained soils enter into the voids of the granular aggregate, preventing it from draining properly and the aggregate loses the required rock-to-rock contact, greatly diminishing the strength of the aggregate support layer and accelerating road failure (Figure 1).
2. Second, the granular aggregate punches into the fine-grained soil, thereby decreasing the effective thickness of the aggregate layer (Figure 1).

FIGURE 1.
From: FHWA Designing with Geosynthetics, Robert M. Koerner, 1994.

Properly selected woven and nonwoven geotextiles prevent these failure mechanisms from occurring, thereby greatly improving the performance of a road. For these reasons, separation is considered to be a very important geotextile function and is the key to the longevity of the road. Also, over the years, road builders have felt obligated to use a tight, well graded aggregate to help minimize subgrade soil migration upward. This proved to be only partially effective and, to the detriment of the road, these tight aggregates were weaker because they would not drain. The use of a separation geotextile allows the use of stronger, more free-draining aggregates with stronger AASHTO drainage coefficients. If a geogrid is used, there is no effective separation and a less cost effective tight aggregate must be used. The tight, well-graded aggregate recommended for use with geogrids, actually negates the structural benefit of using the geogrid.

STABILIZATION

Paved and unpaved roadway applications are long-term stabilized in two ways when a geotextile is placed at the subgrade/aggregate interface. First, when the aggregate is compacted over the top of a geotextile, the individual stones are "seated" making impressions in the geotextile and the subgrade. This interaction locks the bottom of the aggregate into a fixed position, thus stabilizing the aggregate layer indefinitely. An expensive geogrid is not needed to effect this interaction stabilization. Also, the subgrade soil is stabilized beneath the geotextile. This is because as the soil is loaded, from the top, the surrounding soil is held down in place, preventing a local punching, or shear failure. This change in the soil failure mode from local shear to general shear allows about 80% additional loading before the soils strength is exceeded. This mechanism allows for a reduced structural section over a subgrade stabilized with a geotextile. The use of less base aggregate and/or pavement section thickness over a geotextile saves the owner up front and, the permanent preservation of the entire structural section saves the owner down the road with additional years of maintenance-free service.

These first two functions, Separation and Stabilization, act together as the key reasons roads over geotextiles cost less and last longer. It is for this reason that the two terms are often used together to describe this application...a separation/stabilization geotextile.

REINFORCEMENT

Geotextile reinforcement is defined as the synergistic improvement of a total system's strength created by the introduction of a geotextile (good in tension) into a soil (good in compression but poor in tension) or other disjointed and separated material (Koerner, 1994).

In paved and unpaved roadway applications, geotextiles provide tensile reinforcement through frictional interaction with base course materials, thereby reducing applied stresses on the subgrade and preventing rutting caused by subgrade overstress.

Properly selected woven and nonwoven geotextiles provide reinforcement in roadways. However, woven geotextiles typically have a higher tensile modulus than a comparable nonwoven. By providing high tensile strength at low strains (i.e., high modulus) woven geotextiles generally are considered better reinforcement materials than nonwoven geotextiles which typically provide high strength at high elongations (low modulus). Therefore, benefits derived from the reinforcement function are dependent on the amount of system deformation allowed. In unpaved roads, a large amount of deformation is sometimes allowed and the reinforcement function of a geotextile can provide significant benefits. In paved roads, allowable system deformation is usually very low and, as a result, reinforcement is generally not considered to be applicable in most paved roadways but separation and stabilization are still key functions. Likewise, geogrids are rarely strained enough to provide a reinforcement function in roads. There is a misconception that geogrids are stronger than woven geotextiles. Much less expensive woven reinforcement geotextiles are available with much higher strengths and moduli than available geogrids.

FILTRATION

Geotextile filtration is defined as the equilibrium geotextile-to-soil system that allows for adequate liquid flow with limited soil loss across the plane of the geotextile over a service lifetime compatible with the application under consideration (Koerner, 1994).

In paved and unpaved roadway applications, geotextiles provide filtration through their defined openings that retain soil particles but allow the flow of water. This results in a free-draining pavement system. In paved and unpaved roadways, filtration is similar to separation. However a geotextile that is a good separator (a barrier) will not always be able to provide adequate filtration (retain particles and allow water flow). Properly selected, woven and nonwoven geotextiles can provide filtration in paved and unpaved roadway applications, thereby improving pavement performance. Depending on site conditions (e.g. if the subgrade is extremely wet) the filtration function may be as important as the other functions. This is because if water is trapped in the subgrade when a load is applied, pore pressures immediately build up and weaken the soil, even to the point of creating an unstable, "waterbed" effect, if severe. Propex supplies both woven and nonwoven geotextiles with greater ability to pass water than will ever be required beneath a road.

SUMMARY

All four of these geotextile functions are in effect to varying degrees when a geotextile is used in the separation/stabilization application beneath paved and unpaved roads. The life of a geotextile in this application is considered indefinite since the most harsh treatment the geotextile receives is during the actual construction, not in the long term use. Durability testing has shown that polypropylene geotextiles can last over 200 years in the ground.

For information on how to design both paved and unpaved roads, with and without the benefit of a separation/stabilization geotextile, please request a copy of our free design software, Roadways And Civil Engineering (R.A.C.E.). The software also helps you select the proper geotextile and allows you to quantify the significant cost savings associated with the use of a geotextile beneath your roads.

Wasser Polyflex 204

Product Description

Polyflex 204 is a high performance membrane of Polyurea. It provides excellent insulation and is resistant to a variety of chemical products. It can be used in a wide range of climatic conditions while continuing to offer excellent durability. Applications are done primarily by brush and roller. Due to its aliphatic nature the product is suitable in exterior applications. It has high solid content and remains flexible. While it can be used as a repair kit, it can also be used as a complete water proofing membrane

Area of Use

Substrates

Over properly prepared:

- Ferrous Metal
- Aluminum/Non-Ferrous Metal
- Galvanized Metal
- Concrete
- Concrete Block
- Geotextile

Possible Uses

- Steel or Concrete Tanks
- Refineries
- Food Processing Facilities
- Water and Wastewater Treatment Facilities
- Chemical Processing Facilities
- Pulp and Paper Mills
- Concrete Structures
- Dry Holds/Wet Holds
- Pipes
- Containment and Secondary Containment
- Floors
- Material Handling Equipment
- Port and Pier Facilities

Ready Reference Information

Color: Various colors

Type of cure: 2 components
Binder: Aliphatic

***Solids by volume:** 91%*
***Solids by weight:** 90%*
*combine with the catalyst

V.O.C.: 96 g/l

Flash Point: 102° F
Recommended dry film thickness/coat: 40 mils
1000 microns

Theoretical Coverage:
At 1 mil: 1461 ft^2/gal
At 25 microns: 135 m^2/3.78 liter

Ratio: 1:1

Pot Life: 20 minutes max
Shelf Life: 1 year

Drying Times and Temperatures*

Gel Time: 45 minutes
Tack free: 4 hours
To recoat: 2 hours minimum; 24 hours maximum
Hard dry: 24 hours
*(may vary with climatic conditions)

Product Features

- Superior anti-corrosive protection for steel and concrete in cold service climates.
- Protective membrane on metal, masonry, silos, all kinds of pipes and stone slabs.
- Application on geotextile to form ponds, to retain overflow, prevent effluent leakage, water and petroleum product leakage.
- Provides an excellent waterproof protection on rigid urethane insulation.
- Garage and parking decks.
- Can be used to repair or replace an existing membrane.
- Excellent abrasion resistance.

Surface Preparation

See Wasser's Polyurea Application Guide.

Application Information

For Polyurea and/or polyurethane membranes:*
Roughen the surface of Polyflex with a 40 grit (or less) abrasive, remove dust with a dust rag or vacuum. Make sure the surface is clean, dry and dust free before the application. Clean the surface with acetone, let the acetone evaporate and apply the repair kit.

For concrete: Make sure the concrete surface is dry and clean. The grout and loose particles on concrete surface need to be cleaned before the application. If a hardener was used in the concrete, it must be roughened with a Blastrac machine or equal impact tools. Direct or primed applications can be done.(Blastrac is a registered trademark of the Wheelabrator Corporation.)*

For steel: First remove all grease, oil, salt contaminants and dirt in accordance with SSPC SP-1 solvent cleaning procedure. High pressure water wash using salt solubilizing agents can be used to remove the remaining salt. SSPC SP6 or SSPC SP10 may be used depending on the application.*

** Consult your Wasser representative for specific and detailed applications as well as choosing the appropriate primer.*

Performance Testing Data

Resistance to tearing:
(ASTM D-624-C) Tear strength = 21.6 N/mm(123.1 PLI)

Wasser Corporation 4118 B Place NW Suite B Auburn, WA 98001

Mr. Kyle Christie
Remediation Manager
Atlantic Richfield Company
6 Centerpointe Drive
La Palma, California 92048

Subject: **Addendum to the Revised Final Draft Feasibility Study for the Gardena Sumps Site:**
Optional Alternative 2A Cover
Gardena Sumps Site
Gardena, California

Dear Mr. Christie,

Geosyntec Consultants, Inc. (Geosyntec) has prepared this Addendum to the Revised Final Draft Feasibility Study (Revised Final Draft FS) in response to comments received from Department of Toxic Substances Control (DTSC) and the City of Gardena (City). The DTSC and City comments on the Revised Final Draft FS were presented in meetings held 11 July, 30 August, and 5 September 2013. The Addendum presents and discusses the changes to Alternative 2A resulting from the comments as well as future Site development concerns. A detailed analysis and ranking of the Optional Alternative 2A Cover will not be performed as the changes associated with the Optional Alternative 2A Cover do not affect the analyses of Alternative 2A presented in the Revised Final Draft FS (Geosyntec, 2013).

OPTIONAL ALTERNATIVE 2A COVER

Introduction

During the meeting on 11 July 2013, the DTSC expressed the City's concerns with the height and appearance of the proposed retaining wall along the northern edge of the Haack Sump and a portion of the Cooper North Sump. In response to this concern, the DTSC request Atlantic Richfield Company (ARC) to evaluate an alternative design that would eliminate the proposed retaining wall. Geosyntec has conceptually redesigned Alternative 2A in this Area. The retaining wall was eliminated and grading in the area affected by the elimination of the retaining wall (the "Optional Alternative 2A Cover") was revised to accommodate a minimum 5 percent (%) slope

draining to the north and terminating at a 6 to 9 inch (in.) concrete curb immediately adjacent to the Artesia Boulevard (Blvd.) sidewalk. The curb will deter unintended light traffic across the slope, act as a water-stop for drainage from the slope, and accommodate the slight variations in the existing Haack Sump concrete slab surface elevation. The modifications necessary to eliminate the retaining wall and allow for the Optional Alternative 2A Cover will require waivers of some requirements in California Code of Regulations, Title 22 (22 CCR). The elements of Optional Alternative 2A Cover are discussed in more detail in the following Sections.

Cap Modifications

The Optional Alternative 2A Cover will be comprised of the same foundation and gas collection layers, and low-hydraulic conductivity layer as described in the Revised Final Draft FS for Alternative 2A. The Optional Alternative 2A Cover foundation layer will have no minimum thickness to accommodate the northern border slope and requires a 30-foot set-back southward from the Artesia Boulevard sidewalk before the cover system has sufficient strength to allow for vehicle traffic. To allow vehicle traffic over the cover to the south, the foundation layer will thicken from north to south at an approximate minimum slope of 2.5 percent until a minimum foundation layer thickness of 0.5 foot (ft) and 1 ft on the Haack and Cooper Sumps, respectively, is achieved. In addition, the erosion protection layer will have no minimum requirement and will thicken southward with an approximate minimum slope of 5 percent until 1 foot of Class II aggregate base is present over the drainage geocomposite. As a result, a 30 ft wide landscaped strip will border the northern Gardena Sumps site where no vehicle traffic will be permitted. The revised grading and cross sections are shown on Figures 1 through 4.

There are no proposed changes to the gas collection layer, high-strength geotextile, or low-hydraulic conductivity layer resulting from this cap modification. Drainage above the low-hydraulic conductivity layer and below the erosion protection layer will be accommodated with the geocomposite drainage layer as described in the Revised Final Draft FS (Geosyntec, 2013).

Drainage

A 6 to 9 in. concrete curb is proposed between the border of the Haack and Cooper North sumps and the Artesia Blvd. sidewalk where drainage would otherwise run off the Site. The curb will minimize the amount of run off flowing from the Site onto the Artesia Blvd. sidewalk as well as support a trench drain or shallow water conveyance feature at the toe of the slope. The variation in height of the curb is proposed due the variable height of the existing Haack Sump concrete slab relative to the sidewalk. The variable height will also support drainage to the east and west. The curb will further prevent inadvertent light traffic, such as foot traffic, bicycles, and/or

wheelchairs, from entering the sloped portion of the cover. The cover slope and concrete curb are shown in Detail 2 on Figure 7.

Monitoring and Control Systems

The Optional Alternative 2A Cover does not affect the gas monitoring and control system or the groundwater monitoring program. The sheet pile cut-off wall is still proposed along the northern edge of the Haack Sump and a portion of the Cooper Sump; however, the wall will not extend above the existing ground surface. As a result, no additional gas extraction wells are proposed in this area. The locations of the gas control system components are shown on Figures 5 and 6 with the Revised Alternative 2A Cover grading.

Land Use Covenants

Institutional controls were discussed in the Revised Final Draft FS; however, the specific land use covenants (LUCs) are described herein. The term "land use covenants" includes written instruments and agreements restricting land uses, easements, servitudes, and land use restrictions. The LUCs entered into or required by DTSC will "run with the land," i.e., are binding on current and subsequent property owners, and remain in effect until they are formally removed or modified (DTSC, 2003). The list of LUCs presented is not all-encompassing; other necessary LUCs may be identified in the future.

LUCs identified for the Site include maintenance requirements, zoning restrictions, limited development above the cover, and limited excavation in and around the cover. Specific LUCs for the property owner(s) and responsible parties (RPs) are listed below:

- The property owner(s) will be responsible for maintenance of a parking lot or other non-structural surface above the Alternative 2A engineered cap such as asphalt paving, concrete, or vegetation;
- The property owner(s) will be responsible for maintaining vegetation and ensuring minimal root depth of vegetation;
- The property owner(s) will be responsible for maintenance of necessary fencing, gates, and walls around the Site;
- The property owner(s) will be responsible for posting and maintaining notification signs within onsite buildings, the RPs will be responsible for posting and maintaining signs within open spaces;

- The property owner(s) will notify the DTSC and RPs of activities within limits of cover such as trenching or filling and not proceed with activities without a written approval of activities;
- The Cooper and Haack properties will be restricted to open space, commercial use, or industrial use;
- Pumping and removal of shallow groundwater beneath the Site will be restricted except for sampling and monitoring purposes;
- Use of the Cooper and Haack properties will be limited to those which will not disturb the integrity of the cap or monitoring systems;
- The property owner(s) will notify the DTSC and RPs of any disturbance of the soil, such as excavation, grading, removal, trenching, mining, or drilling of gas, oil, or water wells on the Properties. Excavation, grading, removal, trenching, mining, and/or drilling will be limited and only as approved by the DTSC and RPs on the capped portions of the Cooper and Haack properties;
- Easements will be granted to the DTSC and RPs for inspection, surveillance, monitoring, maintenance, or other purposes necessary to protect public health or safety;
- Subdivision of the Cooper or Haack Properties will be prohibited;
- Notifications will be required for those purchasing, leasing, subleasing, and/or renting the property stating that residual contamination exists. Notifications will be provided by the RPs or owner, as appropriate;
- Notification to the DTSC of any sale, lease, or other conveyance of the properties by the owner or RPs, as appropriate; and
- Requirement for a deed notice notifying potential purchasers that the properties have been used to manage hazardous waste and that use of the properties is restricted.

The LUCs will be recorded at the county recorder's office so they will be found during a title record search of the property deed.

REGULATORY WAIVERS

A waiver would be necessary from the requirements in 22 CCR in order to remove the minimum foundation and erosion protection material thicknesses presented for the Optional Alternative 2A Cover. The specific requirements that would need to be waived are provided below:

- Foundation Layer

  - Requirement: “A foundation layer shall be provided for the compacted barrier layer of the final cover… …The layer shall be compacted at a moisture content sufficient to achieve the density required to provide adequate support for the nonearthen membrane…” (22 CCR Section 66264.228(e)(4))
  - Discussion: The foundation layer would be reduced to zero at the northern Haack and portion of the Cooper North Sumps property line. The existing concrete slab in the Haack Property and in-place soil in the Cooper North Property will provide support for the gas collection geocomposite and overlying low-hydraulic conductivity layer.
- Cover Soil
  - Requirement: “The owner or operator shall provide a layer of top soil of thickness sufficient to support vegetation for erosion controlled deep enough to prevent root penetration into the filter layer. The top soil shall have characteristics to protect the compacted layer against drying that would lead to cracking, to resist erosion and to support vegetation growth…” (22 CCR Section 66264.228(e)(12))
  - Discussion: The 1-ft. thick cover soil at Site will primarily be Class II Aggregate Base in accordance with the proposed parking lot end use. In the sloped areas, the cover soil will be a vegetative cover soil with a thickness that may be reduced to zero.

Other waivers of requirements in 22 CCR may be required once the final design of Optional Alternative 2A is completed.

The gas collection system and geomembrane will be supported by either the existing concrete slab on the Haack Property or existing in-place soil on the Cooper Property. The geomembrane will be protected by the overlying geocomposite with vegetative cover soil, Class II Aggregate Base, artificial turf, or concrete or other durable materials.

SPECIFIC PLAN COMPLIANCE

The City developed the Artesia Corridor Specific Plan (Specific Plan) which establishes the development vision for the properties on the south side of Artesia Boulevard between Western and Normandie Avenues (TPC, 2006). The Specific Plan designates the vast majority of the Gardena Sumps site for commercial use.

Site Layout

The Alternative 2A conceptual design complies with the City's Specific Plan. Commercial/retail structures up to 80,000 sf in size may be accommodated outside of the Alternative 2A engineered cap portion. Space may be allocated above the capped portions of the property for parking.

Utilities and Lighting

Utilities for the building may be accommodated by trenching outside of the capped portions of the Gardena Sumps site, primarily parallel to the Haack and Cooper boundaries on the west and south. Some electrical conduit may be installed within or above the aggregate base layer of the cover in accordance with the Risk Management Plan discussed in the Revised Final Draft FS (Geosyntec, 2013). Parking lot lighting may be accommodated by installing light poles around the perimeter of the parking lot and/or within the parking lot outside of the cover. Within the capped portion of the Gardena Sumps site, lighting structures with minimal foundations depths would be suitable.

Long Term Monitoring

Long term monitoring at the Gardena Sumps site will include settlement, groundwater, and soil gas monitoring. If development occurs shortly after the remedy is implemented, monitoring locations can be incorporated into the development features such as walkways, vegetative strips, etc. to limit disruption to the commercial activities during monitoring events. If development occurs after monitoring locations have been installed, monitoring locations could be moved to accommodate the development.

Zoning

The Strategic Plan has identified the Gardena Sumps site for commercial development. The Site-Specific Action Levels (SSALs) identified in the Revised Final Draft FS were a derivation of risk-based concentrations for the Gardena Sumps site's constituents of concern (COCs). These SSALs were used to identify areas of the Gardena Sumps site which would require action based on cancer and non-cancer risks for residential receptors, the most conservative receptor. The areas of the Gardena Sumps site in excess of the residential SSALs were addressed in Alternative 2A through capping or select excavation. As a result, the Gardena Sumps site can accommodate the less conservative, commercial receptor development.

CONCLUSIONS

The Optional Alternative 2A Cover does not impact the evaluation and comparison of Alternative 2A to the nine evaluation criteria (USEPA, 1988). Alternative 2A readily meets the criteria of overall protection of human health and the environment and satisfies Applicable or Relevant and Appropriate Requirements (ARARs). When evaluated against the balancing criteria, Alternative 2A provides short-term effectiveness as well as long-term effectiveness and permanence. It is implementable and presents an effective balance of cost against the evaluation criteria. Alternative 2A also would accommodate future potential redevelopment of the Site (Geosyntec, 2013). As a result, Alternative 2A, as revised by this Addendum, is the preferred remedy for the Site.

If you have any questions, please contact Mrs. Rebecca Oliver at (858) 716-2926.

Sincerely,

Rebecca F. Oliver, P.E.

Transmittal: **Response to Comments on the Revised Final Draft Feasibility Study Report**
Gardena Sumps Site
Southwest Corner of Artesia Boulevard and Normandie Avenue
Gardena, California
DTSC Site No. 400067

Dear Mr. Cully:

Geosyntec Consultants (Geosyntec), on behalf of the Atlantic Richfield Company (ARC), is pleased to provide this response to Department of Toxic Substances Control's (DTSC) comments on the Updated Revised Final Draft Feasibility Study Report (Updated Revised Final Draft FS). These responses were prepared to address the DTSC comments dated 13 December 2013 and 6 January 2014. The DTSC comments are provided below in *italics* with ARC's response following.

COMMENTS

1. No further comment.

2. No further comment.

3. No further comment.

4. The Material in the Haack Rework area is distinctly different than the material in the sumps, composed of soil-sludge material and soil overburden according to the feasibility study (FS), so excavation of this area would not provide the same information as the pilot study previously discussed in comments from DTSC. ESPO stands by its opinion regarding the value of a pilot study but notes that at this point the decision on whether or not to require a pilot study is a management decision. In the absence of a pilot study the contingency plan included in section

6.1.2.2 will need to account for any uncertainty regarding gas generation potential and should be reviewed and approved by DTSC before construction is allowed to commence.

ARC agrees that the Contingency Plan will provide provisions for gas-generation uncertainty and will be reviewed and approved by DTSC.

5. No further comment.

6. The September 2012 ESPO comment requested the basis of the assumption that sludge material beneath Artesia Boulevard and the adjacent sidewalk be clarified. This comment was in part related to ESPO's understanding that sludge material has daylighted through cracks/seams in this area in the past. The basis of the assumption was not adequately clarified in the April Response to Comments but the requirement for "low permeability asphaltic concrete" was added, apparently in an effort to address DTSC's concerns. The FS should provide adequate justification for considering the sludge material to be already capped that specifically addresses the daylighting of sludge material through seams and cracks in the current surface. The need for low permeability asphaltic concrete should be evaluated and only be required if it is determined necessary to prevent unacceptable exposures.

Sludge has not been observed to daylight through cracks or seams in the sidewalk or Artesia Boulevard pavement. Sludge has been observed to daylight at the northeast corner of the Haack property where sludge material has seeped out from beneath the existing Haack concrete pad onto the ground surface adjacent to the fence separating the Haack property and the grass strip immediately south of the Artesia Boulevard sidewalk. Additionally, sludge material has been observed to daylight along cracks and seams in the Haack parking lot. With the proposed Alternative 2A remedy, these seep areas would be capped with the engineered final cover system and laterally constrained at the property boundary with the proposed sheet pile wall.

Beneath Artesia Blvd, sludge was identified in boring AB-101 at a depth of approximately 5.5 feet bgs. As documented in the boring log, the sludge material is overlain by approximately 2.7 feet of silt with reworked brick and sludge fragments, approximately 2.0 feet of roadway base, and 0.8 feet of asphalt (Stantec, 2010). These layers effectively act as a barrier providing protection from unacceptable exposure by minimizing dermal, ingestion, and inhalation risk. As a result, the low permeable asphalt concrete would only add minimal enhancement of the existing exposure protection. The requirement has been removed from the Updated Revised Final Draft FS (Attachment 1).

7. No further comment.

8. ESPO: No further comment.

HERO: HERO recommends that the RAP provide a more detailed description of the proposed monitoring, action levels, and descriptions of the actions to be taken to prevent on and off-Site exposures. A discussion and recommendations on action levels and monitoring are provided here.

PELs are not appropriate standards for protection of the general public. In addition the point of compliance for PELs is the work area while the point of compliance for protecting the public is the fence-line. Alternate action levels and sampling locations will be required to protect the nearby businesses and residents. These action limits and monitoring are discussed below. Monitoring plans and actions to be taken if the levels are exceeded will depend on multiple factors including the proposed remedy chosen, monitoring frequency and locations and the technical feasibility of measuring low levels of the chemicals of concern.

A) The main potential source of risks are the high levels of sulfur dioxide (SO2) generated when the sludge material is disturbed. Concurrent with remedial work continuous fence-line monitoring will be required (upwind and downwind) to evaluate whether the emissions of sulfur dioxide are exceeding short term action limits for protecting the general public. Appropriate action levels are the California ambient air quality standards. The California 1-hour time weighted average action levels for sulfur dioxide (SO2) dioxide is 655 ug/m3 (0.25 ppm). In addition, for a 24-hour period (time weighted average), the SO2 levels should not exceed 105 ug/m3 (0.04 ppm). These action levels are health based levels to protect people with asthma who are at risk from low levels of SO2.

B) Hydrogen sulfide (H2S) will also require monitoring due to the potentially very low levels which may impact the neighboring businesses and residents. For hydrogen sulfide (H2S) the California ambient air quality criteria 1-hour time weighted average limit is 42 ug/m3 (0.03 ppm). There is no 24-hour standard. This standard is based upon odor however it must be noted that the odor detection threshold for is even lower (11 ug/m3) . It is also worthwhile to note that the Project should also comply with SCAQMD rule 402 which deals with nuisances including odors. Since the remedial actions proposed will take on the order of ½ to 1-year it is also important to consider chronic health effects from hydrogen sulfide. The OEHHA chronic reference exposure level is 10 ug/m3. Therefore to be protective of risks from chronic exposures

as well as to prevent odor nuisances HERO recommends an action level of 10 ug/m3. HERO notes that the analytical methods for hydrogen sulfide measurements may not permit real time/high frequency monitoring at these detection limits. If that is the case it may also be appropriate to include periodic monitoring for H2S using laboratory based methods, especially at times of work activity where sulfide gases are more likely to be generated.

C) AQMD rule 403 In addition to vapors and gases, there will be other routine monitoring which will be required to comply with AQMD rule 403 for the generation of dust including PM 2.5 (50 ug/m3 downwind versus upwind).

D) Sampling locations: Due to the presence of potentially impacted neighbors in multiple directions, there will need to be multiple monitoring points.

E) Worker Protection: HERO also notes that based upon the description above and the extent of what is defined as "the work area" it may be that the location of the proposed monitoring will not be appropriate for monitoring workers exposure since "the perimeter of the work zone" may be expected to have lower concentrations than the breathing zone of the workers. An industrial hygienist should oversee the health and safety plan including the monitoring of air to protect workers.

The RAP will provide a more detailed description of the proposed monitoring, action levels, and descriptions of the actions to be taken to minimize on and off-Site exposures associated with soil gas.

23. No further comment.

24. No further comment.

25. ESPO's original comment was: "Section 7.3.3.5 Short-Term Effectiveness. The text states cap construction would be performed above the existing surfaces, reducing gas generation. ESPO notes the anchor trench for the high strength geotextile runs, in part, between the Cooper North and Haack Sumps, creating the potential for disturbing sludge that was shown to generate gases in the Treatability Study. This section should discuss the potential for excavating gas generating sludge material, the required actions to prevent unacceptable exposures, and how this may affect the short term effectiveness and implementability of Alternative 2A. Geosyntec's April 12 response was: "Gas generation is not anticipated during the construction of the anchor trench. The depth of the anchor trenches (3 feet) is anticipated to be above the sludge reported in the area. Additionally, the sludge which runs between the Cooper North and Haack sumps is similar to the Haack rework material in that it is discontinuous and degraded and therefore gas generated from the disturbance of this sludge is anticipated to be minimal." To which ESPO replied in the May 23 memo: "ESPO could not find a figure that provides the location of the high-strength geotextile anchor trench. Please provide a figure (similar to 6-2) that depicts the high-strength geotextile anchor trench location in detail sufficient to allow us to evaluate its elevation above the sludge on Section A of Figure 6-3, or inform us which existing figure contains this information, so we may complete our review. Also, the response states an anchor trench depth of three feet while section 6.1.2.3 states this anchor trench will be two-foot by two-foot. Please clarify and revise the response or report as necessary." Geosyntec's follow-up

response of November 12th referred ESPO to Detail 7 on Figure 6-13. Detail 7 on Figure 6-13 does not provide the information request. The location of the high-strength geotextile anchor trench between the Cooper North and Haack sumps should be shown on Figure 6-2, or similar, and indicated on Section A of Figure 6-3 so we can evaluate its elevation above the sludge and the potential for construction activities to disturb gas generating sludge material. If a concrete anchor system will be employed in this area to avoid the need for an anchor trench, please provide a detail for its construction.

The approximate location of the high-strength geotextile is shown on the revised Figures 6-2 and 6-3 (Attachment 2). The location was selected to be outside of the existing geomembrane cap while allowing enough room for the proposed 2 foot by 2 foot high strength geotextile anchor trench and the proposed 2 foot by 2 foot high density polyethylene (HDPE) geomembrane anchor trench. Based on borings CPB28, CPB29, and CPB30 performed during the Remedial Investigation (RI) between the Haack and Cooper North sumps, degraded soil-sludge was encountered intermittently between the ground surface and 7 to 8 feet below the ground surface (ft bgs). As a result, degraded soil-sludge may be encountered during both anchor trench excavations in this area. Degraded soil-sludge will be removed as necessary during anchor trench construction and anchor trenches will be backfilled with non-impacted soil. Degraded soil-sludge handling and potential gas generation will be managed in accordance with the Contingency Plan.

26. No further comment.

27. No further comment.

28. The current RTC indicates that an average shear wave velocity of 520 meters per second was used for the upper 30 meters of soil based on a review of subsurface explorations presented in the 2008 Revised Draft Remedial Investigation by Stantec. This shear wave velocity corresponds to Site Class C, very dense soil or soft rock. However, our review of subsurface information in the referenced report as well as previous boring logs indicates that the subsurface conditions do not justify use of Site Class C (Site Class D appears more appropriate). Please indicate the basis for using Site Class C, or revise the report to use Site Class D, and evaluate the effects of the increase predicted peak ground acceleration.

The calculated average shear wave velocity within top 30 m, or 100 ft, of the profile, or V_{s30}, of 520 m/s falls within Site Class C category of the California Building Code (CBC, see Table 1613.5.2 of CBC for reference). In accordance with CBC, Site Class D should be used "*when the*

soil properties are not known in sufficient detail to determine the site class." Based on the review of the CPT logs and soil data, it was determined that the soil properties are known in sufficient detail and, therefore, Site Class C was selected for the site.

29. No further comment.

30. No further comment.

31. No further comment.

32. No further comment.

33. No further comment.

34. No further comment.

35. No further comment.

36. No further comment.

37. No further comment.

38. ESPO believes the estimate of 40 feet for the zone of influence is optimistic but has no further comments regarding this issue for the feasibility study.

Acknowledged.

39. No further comment.

40. The response has adequately addressed the previous comment. However, we note that if the optional Alternative 2A presented with the RTC is selected, the majority [sic] *the sloping section of the cap likely will not be adequate for supporting the indicated traffic loads.*

Noted. ARC agrees that sloped areas will not be adequate for supporting indicated traffic loads. The sloped portions of the cap will be protected from traffic loads by curbs to prevent inadvertent access to those areas.

41. No further comment.

42. No further comment.

43. No further comment.

44. No further comment. However, ESPO notes detailed cost estimates were not provided and the updated costs to no appear to include financial assurance.

Cost tables were not included as only the report text needed to be updated for the new operations and maintenance costs; the cost tables already included the revised costs.

New Comments on Optional Alternative 2A as proposed in the November 12 RTC

45. It is not clear if the proposed Optional Alternative 2A is a revision to Alternative 2A or if both the original Alternative 2A and the Optional Alternative 2A will be included in the revised FS. The text in the response to comments section of the November 12, 2013 correspondence from Geosyntec indicates Alternative 2A has been revised to eliminate the portion of the sheet pile wall extending above the ground surface along Artesia Boulevard and renamed Optional Alternative 2A. The body of the FS indicates the new proposal is an option whose details are included in the appendices. If the proposal to eliminate the retaining wall is an option to Alternative 2A then the manner in which it has been included in the FS is acceptable. If the proposal to eliminate the retaining wall is a revision then the FS should be revised as necessary (text, tables, figures, etc.) to incorporate the changes into [sic] *body of the document to avoid confusion.*

The Optional Alternative 2A presented in Attachment 4 is not intended to replace Alternative 2A. It is an optional substitute for Alternative 2A.

46. Attachment 4 Optional Alternative 2A Cover, Cap Modifications. The proposed modification will result in a significant strip of the high-strength geotextile and geomembrane with minimal to no cover, rendering them vulnerable to degradation from the elements and incidental damage from activities on the cover. How will degradation of these membranes or damage from activities such as landscaping maintenance be prevented?

The high-strength geotextile will be protected by the overlying geocomposite and geomembrane. Landscaping in the form of decorative rock, artificial turf, or planter box-type vegetation structures will limit maintenance and potential impacts to the geomembrane. If necessary,

cushion geotextiles may be used above the geomembrane where geocomposite is not present to prevent damage from installed landscaping.

47. Attachment 4 Optional Alternative Cover, Drainage. A trench drain likely will not be feasible adjacent to the sheet pile wall. The base layer in this area of the site is either a concrete slab or the high-strength geotextile and the thickness of the foundation layer above the concrete/geotextile is described as zero inches, leaving no space for a trench. A surface water conveyance could work if the impermeable membrane layer extends under the conveyance and wraps up the curb to prevent intrusion of surface water where the membrane meets the curb/sheet pile. ESPO notes this configuration will likely be difficult to construct and the proposed design does not allow many options for field modifications should difficulties arise. While these details would normally be covered in a review of the design document, this issue has the potential to render the proposed modification to Alternative 2A infeasible. Please include details on how surface water intrusion will be prevented at the impermeable membrane and sheet pile wall/curb interface.

High strength geotextile is not present above the Haack Sump or adjacent to the sheet pile wall. The geomembrane will run below the drainage channels where drainage channels are present over sludge and will wrap up the curb. A concrete-lined swale may be utilized for stormwater management control as shown in Detail 4 on Figure 7 (Attachment 3). The distance between the property line and concrete cap above the Haack Sump varies, as does the height of the concrete cap above the existing ground surface. As a result, a small portion of the existing concrete cap may need to be removed or modified to incorporate the swale. Minimal runoff is anticipated along the curb as cap runoff from the 2 percent slopes (parking lot area) will be redirected with curbs and/or surface drainage features prior to descending the 5 percent slopes.

48. Attachment 4 Optional Alternative 2A Cover, Regulatory Waivers. The decision to grant the required waivers is a management decision but ESPO notes a reduction in the thickness of the foundation layer and cover soil has implications for the longevity and performance of this remedy. See comments 46 and 47.

Noted.

If you have questions or require additional information about the enclosed report, please contact Mr. Kyle Christie with ARC at 714-670-5303.

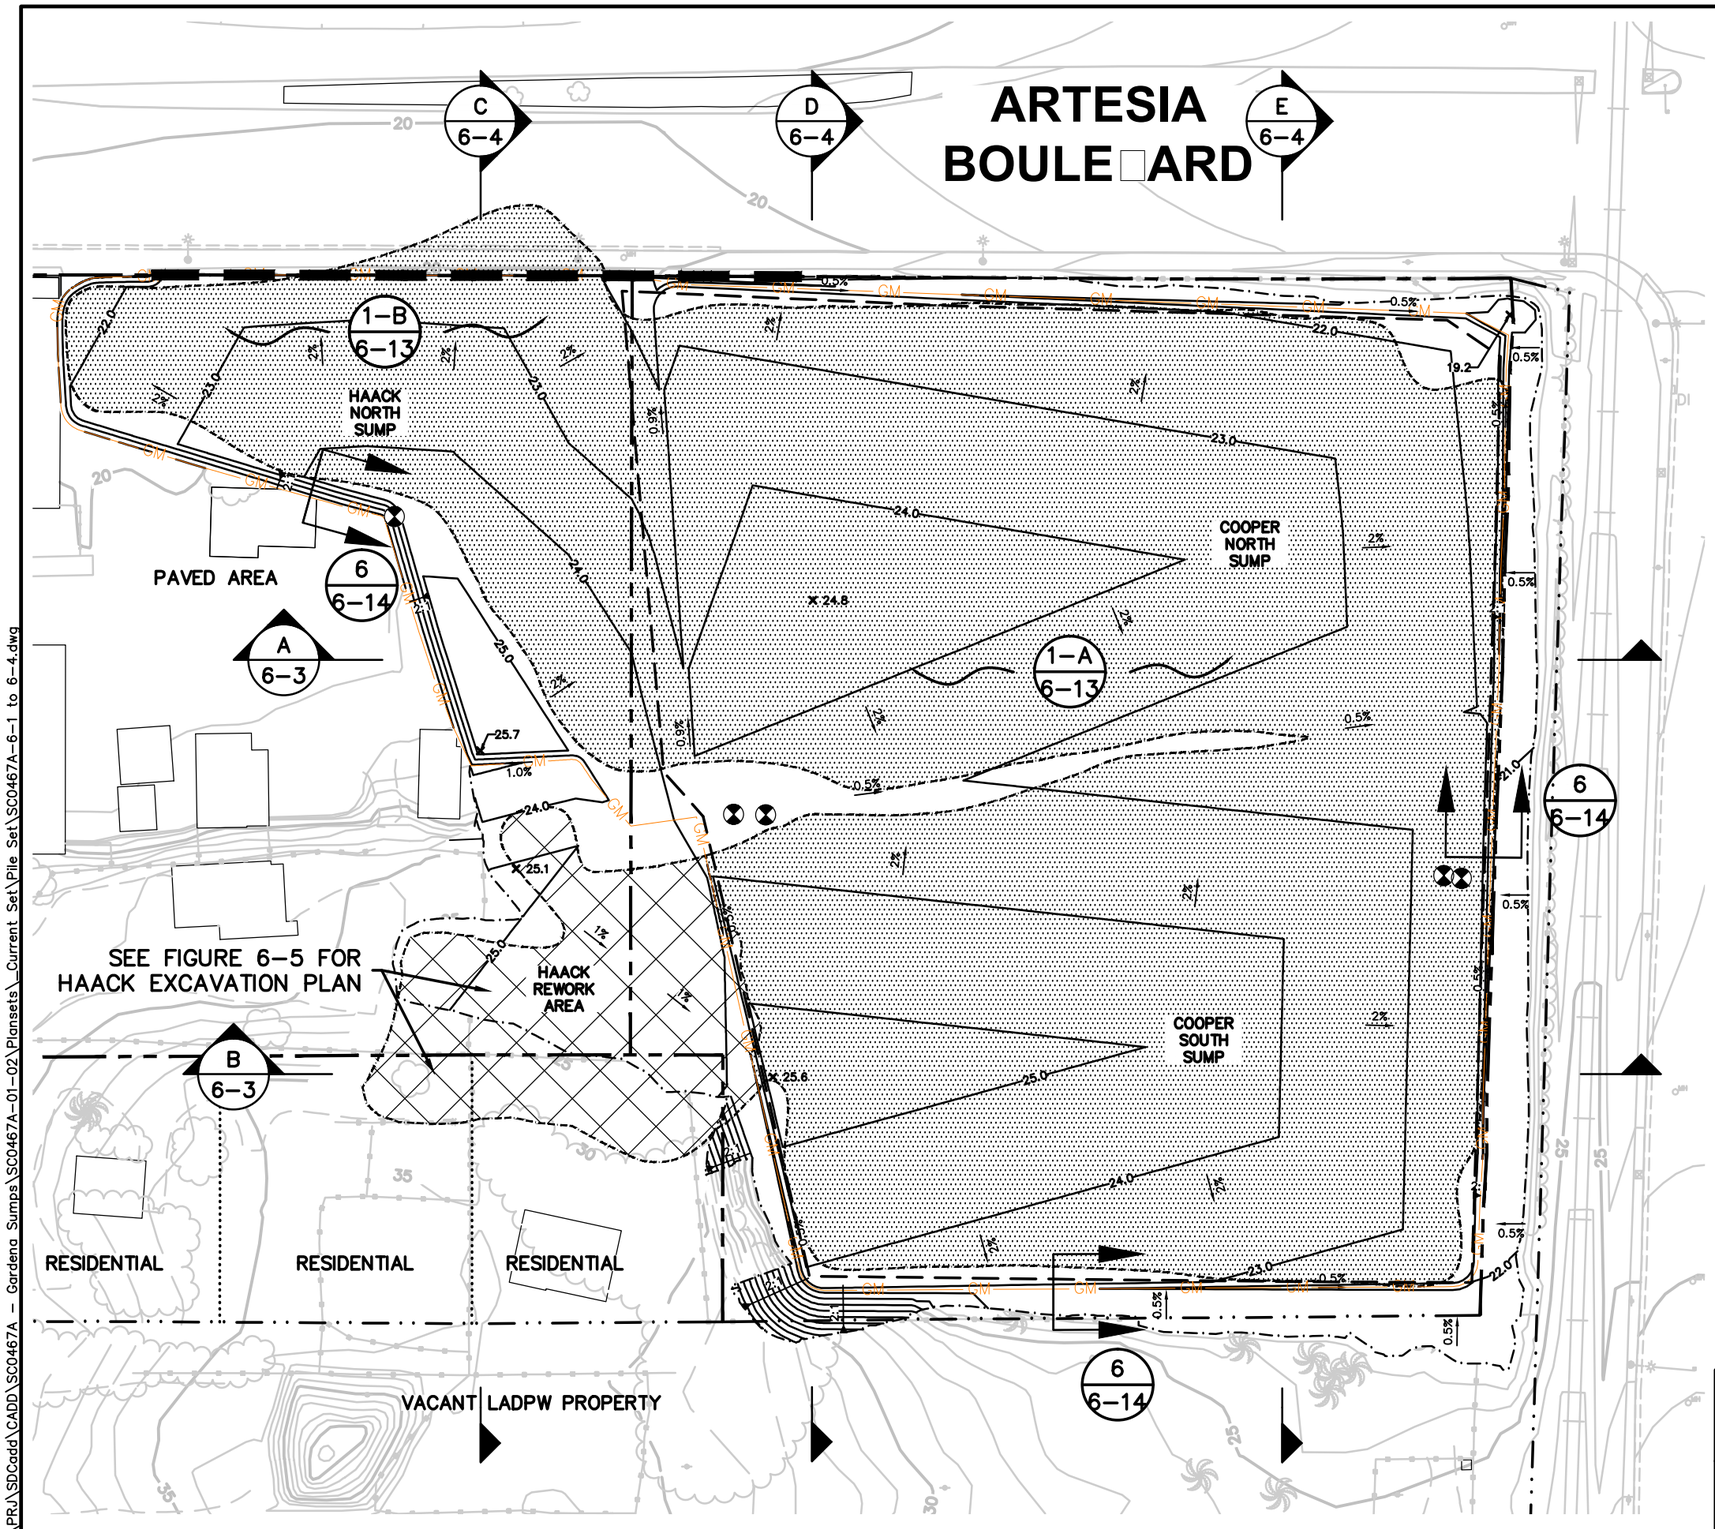
6.1.2.1 General Overview

The Site is generally divided into three areas: the Cooper North and South Sumps on the Cooper Property, the Haack Sump and the Haack Rework Area located primarily within the Haack property, four residential properties, land owned by Los Angeles County and a small area of land beneath the Artesia Boulevard right-of-way. Because these areas of the Site are divided among different property owners, the properties may not all be available for remedial construction at one time. The following sections describe, in general, the proposed Alternative 2A approach for each area. Section ~~3.3~~ 6.1.2.2 (RTC, 11/6/12) describes the remedial implementation approach for the entire Site in greater detail. (RTC, 9/29/11)



As described ~~in the Draft FS (Geosyntec, 2011),~~ previously (RTC, 11/6/12), the sludge material beneath the Artesia Boulevard South sidewalk and Artesia Boulevard are below road base material and asphalt or sidewalk concrete. The concrete and asphalt surface prevent ingestion and direct contact with the sludge as well as reduce its mobility by containing the sludge. (RTC, 11/6/12) This sludge material is considered to be already capped~~; however, institutional controls will include a requirement for repaving the area with "low-permeability asphaltic concrete" and increased maintenance of the asphalt surface in this area.~~(RTC, 1/16/14) ~~and therefore was not addressed in the Draft FS and will not addressed in Alternative 2A.~~ (RTC, 11/6/12)

Future access from current and/or future utility and/or construction workers will be addressed in the Risk Management Plan (RMP). The RMP will describe contaminants remaining onsite, known locations of impacts, contact information, and minimum, recommended personal protective equipment for current and future utility and/or construction workers. Institutional controls will include requirements (RTC, 11/6/12) that the City of Gardena and/or Caltrans provide notice of potential subsurface hazardous materials in the area of Artesia Boulevard where sludge is potentially located, prior to (RTC, 11/6/12) issuing work permits. (RTC, 2/10/12) Institutional controls will also include requirements related to Site development and cap loading restrictions. (RTC, 11/6/12)

Cooper North and South Sumps

The existing geomembrane will remain in place with the cap installed above. The geomembrane will provide a construction surface and preliminary support during installation of the overlying materials. Furthermore, the existing surfaces minimize the dermal contact and gas inhalation exposure risks to the construction workers during installation of the cap. (RTC, 11/6/12)

Subject: Response to Comments dated 19 February 2014
Gardena Sumps, Gardena, California

Dear Mr. Guerbaz,

Geosyntec Consultants (Geosyntec), on behalf of the Atlantic Richfield Company (ARC), is pleased to provide this response to Department of Toxic Substances Control's (DTSC) comments on the Updated Revised Final Draft Feasibility Study Report (Updated Revised Final Draft FS). These responses were prepared to address the DTSC comments dated 19 February 2014. The DTSC comments are provided below in italics with ARC's response following. For ease of review, the "No Further Comment" responses are not repeated herein.

COMMENTS

28. The RTC states that Site Class C was selected based on CPT logs and soil data, and that a shear wave velocity of 520 m/s was calculated for the upper 100 feet of the soil profile. Our previous comment was based on a review of blow count data and CPT tip resistance equivalent blow counts which appear to indicate Site Class D. Please provide the shear wave calculations, or shear wave field measurements for our review.

Geosyntec used information from CPT sounding logs CPB09-GW, CPB25-GW, CPB26-GW, CPB27-GW, and HPB-10 (Attachment 1) and the Mayne and Rix [1995] and Mayne [2007] correlations to evaluate representative shear wave velocity (Vs) at the site. The calculations were performed assuming that groundwater level is 20 feet (ft) below the existing ground surface the average calculated Vs was 505 meters per second (m/s). Sites with Vs ranging of 505 m/s classify as the IBC Site Class C (370 m/sec < Vs < 760 m/sec).

40. We note that additional protection may be needed near the curb/sheet pile where the geocomposite appears to be exposed to the environment (as shown in attachment 3, Figure 7, Detail 4).

Agreed, if the Optional Alternative 2A approach is selected, protection of the geocomposite will be incorporated into the final design.

47. The response states that high-strength geotextile is not adjacent to the sheet pile wall. Section 6.1.2.2 of the revised FS states the high-strength geotextile is to be secured to the sheet pile wall in the north-west corner of the Cooper North Sump. If the high-strength geotextile will be terminated in an anchor trench adjacent to the sheet pile wall in this area instead of being secured to the sheet pile wall, the test in section 6.1.2.2 should be revised. Also, it is ESPO's understanding that any curb along the interface between the 2 percent sloped parking area and 5 percent sloped landscaped area will not be installed as part of the remedy but will be part of the parking lot construction to be complete at a later date by others. As such, calculations of runoff for the design of the northern drainage feature should include appropriate portions of the parking lot/aggregate base surface.

Section 6.1.2.2 states "where available space onsite limits traditional anchor trenches, the high-strength geotextile may be secured with concrete anchors or attached to sheet piles with battens." Anchorage of the high-strength geotextile will be determined during final design when final grading, sheet pile location, and drainage features are finalized. Anchorage will be by one or a combination of the following: anchor trench, concrete anchors, and/or sheet pile batten.

The interim drainage of the site prior to parking lot development will be evaluated during final design. Temporary berms or other diversion structures with down drains may be implemented to minimize runoff from the 2 percent aggregate base surface onto the 5 percent slopes.

Subject: RE: Gardena Sumps Waivers

Hi Mustapha,
ESPO has reviewed the CCR 66264.228 waiver request and light pole foundation calculation package from Geosyntec.

We have the following comments on the waiver request.

1. The waiver discussion for the Foundation Layer states the surface on which the GCL and geomembrane will be installed will be able to support the overlying materials, which satisfies the purpose of the foundation layer if not the technical requirements of CCR 66264.228.
2. The Waiver discussion for the Cover Soil states alternative cover materials will be used to protect the geomembrane, which fulfills the purpose of the cover soil layer.
3. We believe installation of these alternative materials and reduced thickness of the foundation layer will likely increase the potential for damage to the geomembrane during construction/maintenance and may lead to a reduced service life of the cover system. These issues can be managed, but DTSC should monitor them closely and the Operations and Maintenance Plan should include urgent repair/response procedures.

We have the following comments on the Light Pole Calculation Package:

1. The wind load calculations do not consider a light fixture at the top of the pole for the overturning moment. The calculations should be revised to include a light fixture and the report should note that when light poles are installed if the selected light fixture has a larger surface area than that used for the included calculations then new calculations must be performed.
2. The fundamental period equation on page 3 of 8 (T = 0.1N (s)) appears to be in error, since it is based on building structures, but the proposed lighting is a non-building structure. Equation 12.8-7 of ASCE 7-10 appears more appropriate and the report should be revised to use the proper equation.
3. The Site Class E presented on page 3 of 8 of the "Analysis of Light Pole Foundation Design, Gardena Sumps, Gardena, California" appears to be conservative based on site subsurface conditions. The FS had used Site Class C, However, Site Class D appears more appropriate. However, use of the more conservative Site Class E is acceptable.

Let me know if you have any questions or wish to discuss our comments.

Subject: FW: Gardena Sumps Waivers

Good afternoon Perry
Last week I met with Stantec, Geosyntec and ARC from the Gardena Sump site. Geopsyntec discussed the optional alternative 2a instead of the option of the wall opposed by the city. I forwarded to you the e-mail that Geosyntec sent me for approval of the waver of 22CCR requirements. Please review and let me know if this option sounds. Do you want me to send a work request or the e-mail is sufficient?. Thank you for your help Perry

Hi Mustapha,

It was nice meeting you the other day. Per our conversation, please find the regulatory requirements from 22 CCR with a note/discussion regarding the waiver, if necessary. I have also attached the light pole foundation calculation we discussed.

Please let me know if you have any questions or need anything else.

Thanks,
Becky

Cover Component	22 CCR	Waiver/Discussion
Foundation Layer	A foundation layer shall be provided for the compacted barrier layer of the final cover. If needed, the foundation layer shall contain herbicide sufficient to prevent vegetative growth, and shall be free of decomposable organic matter. The layer shall be compacted at a moisture content sufficient to achieve the density required to provide adequate support for the nonearthen membrane. The unit shall be compacted before any portion of the final cover is installed.	A foundation layer may not be p the curb and the cushion layer (concrete or soil). The surface in installed will be able to support minimum 1 foot of foundation a vehicle loading will be restricte
Cushion Layer	If a synthetic membrane is used in the final cover system, the owner or operator shall provide a layer of material above the synthetic membrane of the final cover, and a layer of material below this synthetic membrane, to protect the membrane from damage	No waiver required
Compacted Barrier Layer	A compacted barrier layer of clean earth shall be provided above the foundation layer, and shall be provided around the unit to a depth as low as the level at which the owner or operator has deposited waste, to prevent lateral migration of waste and gas and vapor from the waste. The layer of earth shall be wholly below the average depth of frost penetration, and shall be compacted at a moisture content sufficient to achieve a percent compaction that has been demonstrated, with the specific cover material to be used, to prevent the downward entry of water into the foundation layer for a period of at least 100 years. The earthen material shall contain herbicide sufficient to prevent growth of vegetation. The slope of the final top surface of the compacted barrier layer shall be sloped after allowance for settling and subsidence to prevent the build up of hydraulic head. The owner or operator may use nonearthen materials for the barrier layer provided it is demonstrated to the satisfaction of the Department that a barrier layer of alternative composition will equally impede movement of fluid and be as durable as a compacted earthen barrier. If hazardous waste is underlain by a liner containing a synthetic membrane, then a synthetic membrane shall be provided in the final cover above the compacted barrier layer.	No waiver required

	The membrane shall be made of material chemically resistant to the waste at the facility, whether or not contact between the membrane and the waste is anticipated, and shall have thickness and strength sufficient to withstand the stresses to which it shall be including shear forces, puncture from rocks or penetration from roots.	
Drainage Layer	The owner or operator shall provide a water drainage layer, blanket or channel above the compacted barrier layer of the final cover to provide a path for water to exit rapidly.	No waiver required
Filtration Layer	The owner or operator shall provide a filter layer above the water drainage layer to prevent soils from clogging the drainage layer.	No waiver required
Cover Soil	The owner or operator shall provide a layer of top soil of thickness sufficient to support vegetation for erosion controlled deep enough to prevent root penetration into the filter layer. The top soil shall have characteristics to protect the compacted layer against drying that would lead to cracking, to resist erosion and to support vegetation growth. Unless vegetation on the cover would pose a significant fire hazard unacceptable to the fire prevention authority or would interfere with a planned postclosure use of the site that is acceptable to the Department, the owner or operator shall provide conditions favorable for hearty growth of vegetation that will provide erosion control without forming roots that would penetrate the compacted earth cover, and shall estimate the cost of providing such conditions and vegetation as part of the cost of closure. Vegetation for closed disposal areas shall be selected to require minimum watering and maintenance. Plantings shall not impair the integrity of containment structures or the final cover.	The cover soil layer will be non- and the cover soil depth may no some distance away from the c cushion geosynthetic, and/or co protect the geomembrane.
Final Cover Slopes	Permanent disposal areas shall be graded at closure so that with allowance for settling and subsidence, the slope of the land surface above all portions of the cover, shall be sufficient to prevent ponding of water. Such areas shall be graded to drain precipitation away from the disposal area. Portions of the land surface above the cover unavoidably slopes great enough to invite erosion which cannot be readily controlled by vegetation shall be protected by gunite, riprap or other material sufficient to provide erosion control.	No waiver required
Perimeter Drainage	At and after closure, permanent disposal areas shall have drainage systems capable of transporting water from the water drainage layer away from the closed facility and capable of diverting surface runoff away from or around disposal areas, containment structures, leachate collection systems and monitoring facilities. Drainage systems shall be capable of	No waiver required

	preventing erosion of containment structures. Drainage system components themselves shall be lined or otherwise protected against erosion.

Cc: Gathungu, Peter@DTSC
Subject: RE: Gardena Sumps RTCs Dated 3-24-2014

This is a follow-up to their response, we still need more information. Peter is asking for the actual calculations they performed and the shear wave velocity calculated for each CPT. Their response dated March 24, 2014 did not include this information. Peter did some calculations on his own and the classification is on the bubble, it could be C or D. He would like to see the actual numbers, instead of interpolating plots, before we proceed.

To: Myers, Perry@DTSC
Subject: Gardena Sumps RTCs Dated 3-24-2014

Hi Perry,

The 3-24-2014 RTC to Comment #28 from Geosyntec states that an average shear wave velocity (Vs) of 505 meters per second (m/s)was calculated from five CPTs. My calculations based on the CPT profiles for CPB27-GW, and SPT blow counts for HPB-10 indicate that the soils may fall in Site Class C, or borderline between Site Class C and D. These calculation were based on the CPT profiles based on averaging of the indicated profile. It is not clear what method was used to calculate the shear wave velocity. Inclusion of shear wave velocity calculations as well as the calculated shear wave velocity at each CPT would be helpful for clarity and completeness.

SHEAR WAVE VELOCITY EVAULATION AT GARDENA SUMPS BASED ON CONE PENETRATION TESTING DATA

PURPOSE

The purpose of this calculation package is to document the average shear wave velocity calculations at the Gardena Sumps project site (Site) based on the provided geotechnical investigation data. The calculations documented herein were developed to assist the Department of Toxic Substances Control in providing a site classification at the Site for seismic design.

BACKGROUND

Between 23 January 2006 and 23 February 2006, Gregg Drilling (Gregg) use a 25-ton rig to performed cone penetration tests (CPTs) to depths of up to 100 feet below ground surface (ft bgs) at the Site (Stantec, 2008). According to ASCE 7-10, the site classification to be used in seismic design is based on the average shear wave velocity in the upper 100 feet (ft) of the soil profile. CPTs CPB09, CPB25, CPB26, CPB27, and HPB10 were performed to a depth of 100 ft bgs; therefore, these five CPTs were used to analyze the shear wave velocity at the Site. The CPT results from these locations are included as Attachment 1.

ASSUMPTIONS

Based on the CPT data provided, Geosyntec subdivided the measurements into 10 ft thick layers (layers) and determined the average cone bearing resistance and pore pressure across each layer. The soil behavior type of each layer was determined based on correlations between the corrected cone tip resistance and friction ratio (Robertson, 1990). The layers were classified as either cohesive or noncohesive soil based on the prevalent soil behavior type in each layers.

In determining the total stress and effective stress versus depth at the site, a unit weight of 120 pounds per cubic foot was assumed across the entire depth of the soil profile and the water table was assumed to be at a depth of 20 ft based on data from the boring logs.

CALCULATION METHODS

Two empirical formulas were employed for calculating the average shear wave velocity versus depth at the Site. The Mayne (2007) formula applies to cohesionless-type soil.

$$V_s = 277\ {q_c}^{0.13}\ {\sigma'_{vo}}^{0.27} \qquad \text{(Mayne, 2007)}$$

V_s is the average shear wave velocity in meters per second (m/sec);
q_c is the cone tip resistance in Megapascal (MPa); and
σ'_{vo} is the effective stress: the difference between the total stress, σ, and the pore water pressure, μ, in MPa.

The Mayne and Rix (1995) formula applies to cohesive-type soil.

$$V_s = 1.75\ {q_t}^{0.627} \qquad \text{(Mayne and Rix, 1995)}$$

$$q_t = q_c - u(1 - a_n)$$

V_s is the average shear wave velocity in m/sec;
q_t is the corrected cone tip resistance in Kilopascal (KPa);
u is the pore pressure in KPa; and
a_n is the cone tip end area ratio = 0.85 (dimensionless).

For each of the five CPTs conducted at the Site, the empirical formulas above were used to evaluate the average shear wave velocity at each layer. The average shear wave velocity across the entire depth for each of the five CPTs was calculated using the formula below:

$$V_{savg} = \frac{\sum_{i=1}^{10} 30\ m}{\sum_{i=1}^{10} \frac{d_i}{V_{si}}}$$

V_{savg} is the average shear wave velocity across the entire soil profile depth = 30 meters (m);
d_i is the layer thickness = 3 m; and
V_{si} is the average shear wave velocity across each layer in m/sec.

RESULTS

The average shear wave velocity results for each of the CPTs are summarized in Table 1 below and the calculations are included in Attachment 2.

Table 1. Average Shear Wave Velocity at Gardena Sumps.

CPT Location	Average Shear Wave Velocity (m/sec)
CPB09	615
CPB25	353
CPB26	472
CPB27	453
HPB10	601
Average	**499**

The average shear wave velocity calculated based on the five cone penetration tests that extended to a depth of 100 ft is approximately 500 m/sec for the Site. According to ASCE 7-10, the Site is classified as Site Class C (very dense soil to soft rock) due to the fact that the soil shear wave velocity is in the range between 370 m/sec and 760 m/sec.

ANALYSIS OF LIGHT POLE FOUNDATION DESIGN
GARDENA SUMPS,
GARDENA, CALIFORNIA

PURPOSE

The purpose of this calculation package is to evaluate the feasibility of constructing an above grade foundation to support a light pole over the proposed final cover system for the Gardena Sumps closure project. Details of the final cover system are provided in the Update Revised Final Draft Feasibility Study (Geosyntec 2013).

This calculation is not intended to serve as final design for development of the Gardena Sumps site. The purpose of this calculation is to demonstrate the feasibility of light pole development over the proposed Alternative 2A cover. Design of the future lighting at the Site will be the responsibility of the Site Developer.

LOADING

The loads evaluated for the design of the light pole foundation included bending moments cause by wind loading and seismic loading.

For the purpose of this evaluation, a 20 foot high, 5-inch diameter, 0.188-inch thick wall, round, straight, aluminum light pole manufactured by Hapco (Attachment A) with two, 16" x 21" x 6.75" luminaires manufactured by Sterner attached to the light pole with two, 2" x 4" x 8" arms (Attachment L) are assumed. The unit weight of the aluminum pole is assumed to be 5 pounds per foot (lb/ft) with a luminaire weight of 36 lbs for a total weight (W_{ip}) of 172 lbs. Typical values for the unit weight of Schedule 40 aluminum piping are presented in Attachment B.

Wind Loading

The wind loading on the light pole was calculated in accordance with the 2013 California Building Code (CBC), Section 1609.6.3 (Attachment C):

$$P_{net} = 0.00256V^2 K_z C_{net} K_{zt}$$

where:

P_{net} = Design wind pressure to be used in determination of wind loads on buildings or other structures or their components and cladding (psf)

z = Height above Ground Level = 20 ft

K_z = Velocity Pressure Exposure Coefficient = 0.62 for exposure category B (Attachment D and Attachment E, 1 of 3)

K_{zt} = Topographic Factor = 1.0 assuming no hills or escarpments nearby (Attachment E, 2 of 3)

C_{net} = Net pressure coefficient = 0.97 for a round, non-building structure where the ratio between the height of the structure and the diameter is at least 25 (Attachment F).

V = Basic wind speed = 100 miles per hour (mph) for Risk Category I (Attachment J)

$$P_{net} = 0.00256(100)^2(0.62)(0.97)(1.0)$$

$$P_{net} = 15.4 \text{ psf}$$

In accordance with CBC 2013, Section 1609.6.3 the designed wind force shall not be less than 16 psf. Therefore, for the purpose of this calculation, **P_{net} = 16 psf**

To calculate the resultant force on the light pole imposed by the wind force, the design wind force is multiplied by the projected area of the light pole and luminaire, where the projected area is calculated as follows:

$$P = P_{net}(A_P + A_l)$$

where:

$A_p = d \cdot z$ = Projected area of the light pole.

z = Height of the light pole = 20 ft

d = Pole diameter = 5 in

$$A_p = \frac{5in}{12\ ^{in}/_{ft}}(20ft) = 8.3\ ft^2$$

and:

$A_l = (h \cdot l) + (h_{arm} \cdot l_{arm})$ = Projected area of the luminaire (assume two luminaires on opposite sides of the light pole plus the support arm from the light pole).

h = Height of luminaire= 6.75 in (Attachment L)

l = Length of luminaire = 21 in (Attachment L)

h_{arm} = Height of luminaire arm = 4 in (Attachment L)

l_{arm} = Length of luminaire arm = 8 in (Attachment L)

$$A, = \frac{6.75in \times 21in}{144\,in^2/ft^2}(2) + \frac{(4in \times 8in)}{144\,in^2/ft^2}(2) = 2.4\,ft^2$$

The resultant wind load calculated on the light pole becomes:

$$P = P_p + P_l$$

$$P_p = 16psf \times (8.3\,ft^2) = 132.8lbs$$

$$P_l = 16psf \times (2.4\,ft^2) = 38.4lbs$$

The maximum moment imposed by the wind loading is then calculated as follows:

$$M_{max} = P_p X_p + P_l X_l$$

where:

X_p = The moment arm for the resultant force acting at the center of the light pole since the design wind pressure is assumed to be uniformly distributed = 10 ft

X_l = The moment arm for the luminaire is assumed to be the height of the light pole = 20 ft

$$M_{max} = (132.8lbs)(10ft) + (38.4lbs)(20ft) = 2{,}096lb - ft$$

Seismic Loading

The seismic base shear (V) is calculated from the following equation when the fundamental period, T, is greater than 0.06 seconds (Attachment G, 1 of 7):

$$V = C_s W$$

where:

W = Total seismic weight = 5 lbs/ft x 20 ft + (36 lb x 2) = 172 lbs

C_s = Seismic response coefficient

where the approximate fundamental period is calculated as follows (Attachment G, 5 of 7):

$$T_a = C_t h_n^x \ (s)$$

and,

n = structural height

C_t and x = approximate period parameters from Table 12.8-2 (Attachment G, 6 of 7)

$$T_a = 0.02 * 20ft^{0.75} = 0.189\ s > 0.06\ s$$

The seismic response coefficient is calculated from the following equation (Attachment G, 2 of 6):

$$C_s = 0.044 S_{DS} I_e$$

where:

SDS = Five percent damped design spectral response acceleration for a period of 0.2 seconds. Determined for the site (33.88835°N, 118.30896°W) assuming Site Class E (soft clay soil) using the online United States Geological Survey (USGS) online application (Attachment H) = 0.969g

I = Importance factor based on a Risk Category I = 1.0 (Attachment G, 7 of 7)

The seismic response coefficient is calculated to be:

$$C_s = 0.044 * 0.969 * 1.0 = 0.043$$

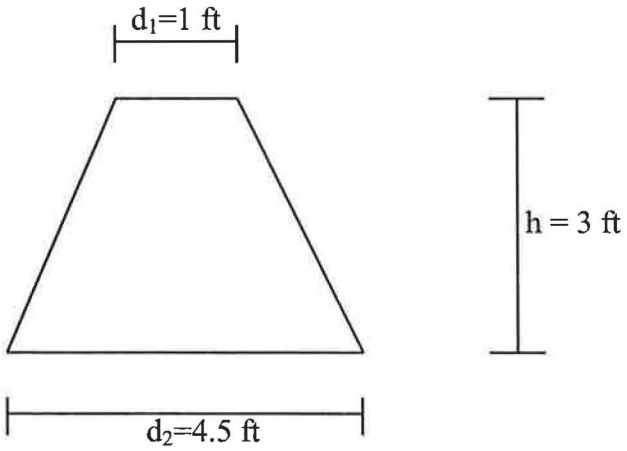
The fundamental period of the structure is greater than 0.06s and therefore the seismic base shear is calculated as follows:

$$V = (0.043)(172lbs) = 7.4\ lbs$$

Since the light pole does not contain any support other than at the base, the base shear is assumed to be applied at the top of the light pole creating a maximum moment of:

$$M_{max} = (7.4lbs)(20ft) = 148\ lb - ft$$

Design Loading



Since the maximum moment imposed by the wind is greater than that imposed by the seismic base shear (2096 lb-ft > 148 lb-ft), the wind loading governs.

FOUNDATION DESIGN

The foundation of the light pole is designed to resist the dead load and overturning moment of the light pole without being embedded into the soil since the cover soil overlying the proposed geosynthetic cover of the impoundment is restricted to a thickness of 1-foot. In addition, the foundation is designed such that the bearing pressure of the foundation does not exceed the bearing capacity of the underlying sludge (conservatively disregarding the cover system soil, rock, and reinforcement elements).

The design of the reinforcement for the footing is not included in this calculation package since the purpose is address the feasibility of the foundation and is not intended for construction.

The footing for the light pole is designed as a reinforced concrete truncated cone with a base diameter of 4.5 feet, a top diameter of 1 foot, and a height of 3 feet.

The volume of footing is calculated as follows:

$$V = \frac{1}{3}\pi h(r_1^2 + r_2^2 + r_1 + r_2)$$

where:

h = the height of the foundation.

r_1 = the radius at the top of the foundation.

r_2 = the radius at the bottom of the foundation.

$$V = \frac{1}{3}\pi \times 3ft((0.5ft)^2 + (2.25ft)^2 + 0.5ft + 2.25ft) = \mathbf{25.3ft^3}$$

The weight of the concrete footing is then calculated as:

$$W_c = V\gamma_c$$

where:

W_c = The weight of the concrete foundation (lbs)

γ_c = The unit weight of concrete = 150 lbs/ft^3

$$W_c = 25.3ft^3 \times 150\,{}^{lb}/_{ft^3} = 3795\ lbs$$

Check the bearing pressure imposed by the concrete footing is less than the bearing capacity of the underlying sludge:

Bearing Capacity Analysis

$$q_u = cN_c \qquad \text{(Attachment K)}$$

where:

q_u= Foundation ultimate bearing capacity (psf)

c = cohesion of the soil foundation (psf) = 300 psf*

N_c = Bearing capacity coefficient (Attachment K) = 5.14

* The sludge material is estimated from CPT soundings performed at the site to have an undrained shear strength of approximately 300 psf (Stantec, 2008).

$$q_u = 300 \times 5.14 = 1542\ psf$$

Utilizing a factor of safety of 3, the bearing capacity of the sludge material becomes approximately **500 psf.**

Bearing Pressure Analysis

$$p_{footing} = \frac{W_c + W_{lp}}{A_f} = \mathbf{250\ psf}$$

where:

W_{lp} = The total weight of the light pole plus luminaire

$W_{lp} = 5\ ^{lb}/_{ft} \times 20lb + (36lb \times 2) = 172lb$

$A_f = \pi r_2^2 = 15.9\ ft^2$

250 psf < 500 psf, therefore the bearing capacity of the sludge can support the concrete footing.

Check Factor of Safety Against Overturning

The overturning moment imposed by the wind loading on the light pole is resisted by the weight of the concrete footing. The concrete footing is a symmetric truncated cone and therefore the resultant of the weight of the footing acts at the center of the footing. The capacity for the footing to resist the overturning moment imposed by the wind load is applied at a distance of 2.25 feet from the center of the footing.

$$FS = \frac{M_n}{M_{max}}$$

where:

FS = The factor of safety against overturning.

M_n = The nominal moment strength of the concrete footing.

M_{max} = The maximum moment imposed at the top of the footing due to the wind load.

$$M_n = (W_c + W_{lp})X$$

where:

X = The moment arm for the resultant force due to the weight of the concrete footing acting at the perimeter of the footing.

$$M_n = (3795bs + 172lbs) \times 2.25ft = 8926\ lb - ft$$

And:

$$FS = \frac{8926lb - ft}{2096lb - ft} = \mathbf{4.3}$$

Check maximum bearing pressure due to eccentric loading

The footing carries moment in addition to a vertical load and therefore an eccentric loading condition is created. The maximum bearing pressure is evaluated assuming the area of the footing is reduced by twice the eccentricity. The maximum pressure exerted by the footing accounting for the eccentric loading is calculated as follows (Attachment I):

$$p_{max} = \left(\frac{W_c + W_{lp}}{A_f}\right)\left(1 + \frac{6\epsilon}{D}\right)$$

where:

D = The diameter of the bottom of the footing = 4.5 ft

ϵ = The eccentricity due to the moment and vertical load

$$\epsilon = \left(\frac{M_{max}}{W_c + W_{lp}}\right) = 0.53$$

and:

$$p_{max} = \left(\frac{3795 + 172}{15.9}\right)\left(1 + \frac{6 \times 0.53}{4.5}\right) = 425.8\ psf$$

425.8 psf is less than the allowable bearing capacity of the sludge (500 psf), therefore the bearing capacity of the sludge can support the concrete footing under eccentric loading conditions.

RESULTS

The results of the analyses presented herein demonstrate that a concrete footing shaped as a truncated cone with a top diameter of 1 ft, bottom diameter of 4.5 ft, and a height of 3 ft can support the dead load and overturning moment of the assumed 20 foot tall aluminum light pole with two, 16" x 21" x 6.75" luminaires (including support arms) on the surface of the proposed cap. In addition, the bearing capacity of the sludge material underlying the proposed cap can support the proposed concrete footing.

Round Straight Aluminum Pole, tenon top, hinged base (73145 Series)

Shaft:
Pole shaft shall be constructed of extruded tube of 6063 aluminum alloy per ASTM B221 and shall be full-length heat treated after welding on the base flange to T-6 temper. Shaft shall be free of longitudinal welds. Pole shaft cap, when required, shall be of cast aluminum of 443 or 356F aluminum alloy and attached utilizing stainless steel hardware.

CATALOG NUMBER SYSTEM
Complete the catalog number with the entry codes below.

WALL THICKNESS:
B = .125" **C** = .156" **D** = .188"

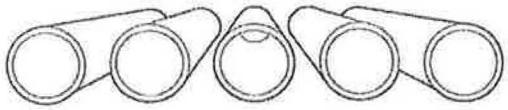
BUTT DIAMETER:
4 = 4" **5** = 5"

TOP DIAMETER:
- = no taper

BASE STYLE:
H = Hinged

FINISH: ** (add as suffix)
BA = Black Powder Paint
BH = White Powder Paint
BM = Bronze Powder Paint
BV = Dark Green Powder Paint
GC = Gray Powder Paint
01 = Satin
- Other finishes available, consult factory

SPECIFY MOUNTING:
Tenon Mount: Specify Tenon diameter (2.375", 2.875", 4.0", etc.) and length (3", 4", etc.)
Side mounting: Specify luminaire type, quantity and orientation. Luminaire drilling must be supplied at time of order.



NOTES:
Effective Projected Area (EPA) in square feet. EPA's calculated using wind velocity (mph) indicated plus 30% gust factor. EPA's are calculated assuming 25 lbs. per square foot of EPA to a maximum of 100 lbs. Maximum EPA is based on the luminaire weight shown. Increased luminaire weight reduces the maximum EPA.

Dimensions are in inches. All weights are approximate.

Attachment B

q_h = Wind velocity pressure, psf (kN/m^2) determined from Section 27.3.2 of ASCE 7.

Concrete and clay roof tiles complying with the following limitations shall be designed to withstand the aerodynamic uplift moment as determined by this section.

1. The roof tiles shall be either loose laid on battens, mechanically fastened, mortar set or adhesive set.
2. The roof tiles shall be installed on solid sheathing which has been designed as components and cladding.
3. An underlayment shall be installed in accordance with Chapter 15.
4. The tile shall be single lapped interlocking with a minimum head lap of not less than 2 inches (51 mm).
5. The length of the tile shall be between 1.0 and 1.75 feet (305 mm and 533 mm).
6. The exposed width of the tile shall be between 0.67 and 1.25 feet (204 mm and 381 mm).
7. The maximum thickness of the tail of the tile shall not exceed 1.3 inches (33 mm).
8. Roof tiles using mortar set or adhesive set systems shall have at least two-thirds of the tile's area free of mortar or adhesive contact.

1609.6 Alternate all-heights method. The alternate wind design provisions in this section are simplifications of the ASCE 7 Directional Procedure.

1609.6.1 Scope. As an alternative to ASCE 7 Chapters 27 and 30, the following provisions are permitted to be used to determine the wind effects on regularly shaped buildings, or other structures that are regularly shaped, which meet all of the following conditions:

1. The building or other structure is less than or equal to 75 feet (22 860 mm) in height with a height-to-least-width ratio of 4 or less, or the building or other structure has a fundamental frequency greater than or equal to 1 hertz.
2. The building or other structure is not sensitive to dynamic effects.
3. The building or other structure is not located on a site for which channeling effects or buffeting in the wake of upwind obstructions warrant special consideration.
4. The building shall meet the requirements of a simple diaphragm building as defined in ASCE 7 Section 26.2, where wind loads are only transmitted to the main windforce-resisting system (MWFRS) at the diaphragms.
5. For open buildings, multispan gable roofs, stepped roofs, sawtooth roofs, domed roofs, roofs with slopes greater than 45 degrees (0.79 rad), solid freestanding walls and solid signs, and rooftop equipment, apply ASCE 7 provisions.

1609.6.1.1 Modifications. The following modifications shall be made to certain subsections in ASCE 7: in Section 1609.6.2, symbols and notations that are specific to this section are used in conjunction with the symbols and notations in ASCE 7 Section 26.3.

1609.6.2 Symbols and notations. Coefficients and variables used in the alternative all-heights method equations are as follows:

C_{net}= Net-pressure coefficient based on K_d [(G) (C_p) - (GC_{pi})], in accordance with Table 1609.6.2.

G = Gust effect factor for rigid structures in accordance with ASCE 7 Section 26.9.1.

K_d = Wind directionality factor in accordance with ASCE 7 Table 26-6.

P_{net}= Design wind pressure to be used in determination of wind loads on buildings or other structures or their components and cladding, in psf (kN/m^2).

1609.6.3 Design equations. When using the alternative all-heights method, the MWFRS, and components and cladding of every structure shall be designed to resist the effects of wind pressures on the building envelope in accordance with Equation 16-35.

$$P_{net} = 0.00256V^2K_zC_{net}K_{zt} \quad \textbf{(Equation 16-35)}$$

Design wind forces for the MWFRS shall not be less than 16 psf (0.77 kN/m^2) multiplied by the area of the structure projected on a plane normal to the assumed wind direction (see ASCE 7 Section 27.4.7 for criteria). Design net wind pressure for components and cladding shall not be less than 16 psf (0.77 kN/m^2) acting in either direction normal to the surface.

1609.6.4 Design procedure. The MWFRS and the components and cladding of every building or other structure shall be designed for the pressures calculated using Equation 16-35.

1609.6.4.1 Main windforce-resisting systems. The MWFRS shall be investigated for the torsional effects identified in ASCE 7 Figure 27.4.6.

1609.6.4.2 Determination of K_z and K_{zt}. Velocity pressure exposure coefficient, K_z, shall be determined in accordance with ASCE 7 Section 27.3.1 and the topographic factor, K_{zt}, shall be determined in accordance with ASCE 7 Section 26.8.

1. For the windward side of a structure, K_{zt} and K_z shall be based on height z.
2. For leeward and sidewalls, and for windward and leeward roofs, K_{zt} and K_z shall be based on mean roof height h.

Attachment C

Main Wind Force Resisting System – Part 1	All Heights
Velocity Pressure Exposure Coefficients, K_h and K_z	
Table 27.3-1	

Height above ground level, z		Exposure		
ft	(m)	B	C	D

25	(7.6)	0.66	0.94	1.12
30	(9.1)	0.70	0.98	1.16
40	(12.2)	0.76	1.04	1.22
50	(15.2)	0.81	1.09	1.27
60	(18)	0.85	1.13	1.31
70	(21.3)	0.89	1.17	1.34
80	(24.4)	0.93	1.21	1.38
90	(27.4)	0.96	1.24	1.40
100	(30.5)	0.99	1.26	1.43
120	(36.6)	1.04	1.31	1.48
140	(42.7)	1.09	1.36	1.52
160	(48.8)	1.13	1.39	1.55
180	(54.9)	1.17	1.43	1.58
200	(61.0)	1.20	1.46	1.61
250	(76.2)	1.28	1.53	1.68
300	(91.4)	1.35	1.59	1.73
350	(106.7)	1.41	1.64	1.78
400	(121.9)	1.47	1.69	1.82
450	(137.2)	1.52	1.73	1.86
500	(152.4)	1.56	1.77	1.89

Notes:

1. The velocity pressure exposure coefficient K_z may be determined from the following formula:

   For $15 \text{ ft.} \le z \le z_g$: $K_z = 2.01\ (z/z_g)^{2/\alpha}$

   For $z < 15$ ft.: $K_z = 2.01\ (15/z_g)^{2/\alpha}$

2. α and z_g are tabulated in Table 26.9.1.
3. Linear interpolation for intermediate values of height z is acceptable.
4. Exposure categories are defined in Section 26.7.

Attachment D

Surface Roughness B: Urban and suburban areas, wooded areas, or other terrain with numerous closely spaced obstructions having the size of single-family dwellings or larger.

Surface Roughness C: Open terrain with scattered obstructions having heights generally less than 30 ft (9.1 m). This category includes flat open country and grasslands.

Surface Roughness D: Flat, unobstructed areas and water surfaces. This category includes smooth mud flats, salt flats, and unbroken ice.

26.7.3 Exposure Categories

Exposure B: For buildings with a mean roof height of less than or equal to 30 ft (9.1 m), Exposure B shall apply where the ground surface roughness, as defined by Surface Roughness B, prevails in the upwind direction for a distance greater than 1,500 ft (457 m). For buildings with a mean roof height greater than 30 ft (9.1 m), Exposure B shall apply where Surface Roughness B prevails in the upwind direction for a distance greater than 2,600 ft (792 m) or 20 times the height of the building, whichever is greater.

Exposure C: Exposure C shall apply for all cases where Exposures B or D do not apply.

Exposure D: Exposure D shall apply where the ground surface roughness, as defined by Surface Roughness D, prevails in the upwind direction for a distance greater than 5,000 ft (1,524 m) or 20 times the building height, whichever is greater. Exposure D shall also apply where the ground surface roughness immediately upwind of the site is B or C, and the site is within a distance of 600 ft (183 m) or 20 times the building height, whichever is greater, from an Exposure D condition as defined in the previous sentence.

For a site located in the transition zone between exposure categories, the category resulting in the largest wind forces shall be used.

EXCEPTION: An intermediate exposure between the preceding categories is permitted in a transition zone provided that it is determined by a rational analysis method defined in the recognized literature.

26.7.4 Exposure Requirements.

26.7.4.1 Directional Procedure (Chapter 27)

For each wind direction considered, wind loads for the design of the MWFRS of enclosed and partially enclosed buildings using the Directional Procedure of Chapter 27 shall be based on the exposures as defined in Section 26.7.3. Wind loads for the design of open buildings with monoslope, pitched, or troughed free roofs shall be based on the exposures, as defined in Section 26.7.3, resulting in the highest wind loads for any wind direction at the site.

26.7.4.2 Envelope Procedure (Chapter 28)

Wind loads for the design of the MWFRS for all low-rise buildings designed using the Envelope Procedure of Chapter 28 shall be based on the exposure category resulting in the highest wind loads for any wind direction at the site.

26.7.4.3 Directional Procedure for Building Appurtenances and Other Structures (Chapter 29)

Wind loads for the design of building appurtenances (such as rooftop structures and equipment) and other structures (such as solid freestanding walls and freestanding signs, chimneys, tanks, open signs, lattice frameworks, and trussed towers) as specified in Chapter 29 shall be based on the appropriate exposure for each wind direction considered.

26.7.4.4 Components and Cladding (Chapter 30)

Design wind pressures for components and cladding shall be based on the exposure category resulting in the highest wind loads for any wind direction at the site.

26.8 TOPOGRAPHIC EFFECTS

26.8.1 Wind Speed-Up over Hills, Ridges, and Escarpments

Wind speed-up effects at isolated hills, ridges, and escarpments constituting abrupt changes in the general topography, located in any exposure category, shall be included in the determination of the wind loads when buildings and other site conditions and locations of structures meet all of the following conditions:

1. The hill, ridge, or escarpment is isolated and unobstructed upwind by other similar topographic features of comparable height for 100 times the height of the topographic feature (100H) or 2 mi (3.22 km), whichever is less. This distance shall be measured horizontally from the point at which the height H of the hill, ridge, or escarpment is determined.
2. The hill, ridge, or escarpment protrudes above the height of upwind terrain features within a 2-mi (3.22-km) radius in any quadrant by a factor of two or more.
3. The structure is located as shown in Fig. 26.8-1 in the upper one-half of a hill or ridge or near the crest of an escarpment.

Attachment E, 1 of 3

4. $H/L_h \geq 0.2$.
5. H is greater than or equal to 15 ft (4.5 m) for Exposure C and D and 60 ft (18 m) for Exposure B.

26.8.2 Topographic Factor

The wind speed-up effect shall be included in the calculation of design wind loads by using the factor K_{zt}:

$$K_{zt} = (1 + K_1K_2K_3)^2 \qquad (26.8\text{-}1)$$

where K_1, K_2, and K_3 are given in Fig. 26.8-1.

If site conditions and locations of buildings and other structures do not meet all the conditions specified in Section 26.8.1 then $K_{zt} = 1.0$.

26.9 GUST-EFFECTS

26.9.1 Gust-Effect Factor: The gust-effect factor for a rigid building or other structure is permitted to be taken as 0.85.

26.9.2 Frequency Determination

To determine whether a building or other structure is rigid or flexible as defined in Section 26.2, the fundamental natural frequency, n_1, shall be established using the structural properties and deformational characteristics of the resisting elements in a properly substantiated analysis. Low-Rise Buildings, as defined in 26.2, are permitted to be considered rigid.

26.9.2.1 Limitations for Approximate Natural Frequency

As an alternative to performing an analysis to determine n_1, the approximate building natural frequency, n_a, shall be permitted to be calculated in accordance with Section 26.9.3 for structural steel, concrete, or masonry buildings meeting the following requirements:

1. The building height is less than or equal to 300 ft (91 m), and
2. The building height is less than 4 times its effective length, L_{eff}.

The effective length, L_{eff}, in the direction under consideration shall be determined from the following equation:

$$L_{eff} = \frac{\sum_{i=1}^{n} h_i L_i}{\sum_{i=1}^{n} h_i} \qquad (26.9\text{-}1)$$

The summations are over the height of the building where

h_i is the height above grade of level i
L_i is the building length at level i parallel to the wind direction

26.9.3 Approximate Natural Frequency

The approximate lower-bound natural frequency (n_a), in Hertz, of concrete or structural steel buildings meeting the conditions of Section 26.9.2.1, is permitted to be determined from one of the following equations:

For structural steel moment-resisting-frame buildings:

$$n_a = 22.2/h^{0.8} \qquad (26.9\text{-}2)$$

For concrete moment-resisting frame buildings:

$$n_a = 43.5/h^{0.9} \qquad (26.9\text{-}3)$$

For structural steel and concrete buildings with other lateral-force-resisting systems:

$$n_a = 75/h \qquad (26.9\text{-}4)$$

For concrete or masonry shear wall buildings, it is also permitted to use

$$n_a = 385(C_w)^{0.5}/h \qquad (26.9\text{-}5)$$

where

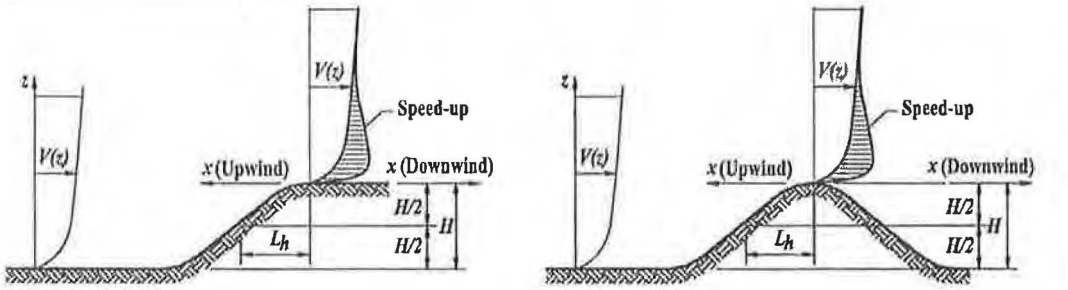
$$C_w = \frac{100}{A_B}\sum_{i=1}^{n}\left(\frac{h}{h_i}\right)^2 \frac{A_i}{\left[1+0.83\left(\frac{h_i}{D_i}\right)^2\right]}$$

where

h = mean roof height (ft)
n = number of shear walls in the building effective in resisting lateral forces in the direction under consideration
A_B = base area of the structure (ft^2)
A_i = horizontal cross-section area of shear wall "i" (ft^2)
D_i = length of shear wall "i" (ft)
h_i = height of shear wall "i" (ft)

26.9.4 Rigid Buildings or Other Structures

For rigid buildings or other structures as defined in Section 26.2, the gust-effect factor shall be taken as 0.85 or calculated by the formula:



$$G = 0.925\left(\frac{1+1.7g_Q I_{\bar{z}} Q}{1+1.7g_v I_{\bar{z}}}\right) \qquad (26.9\text{-}6)$$

$$I_{\bar{z}} = c\left(\frac{33}{\bar{z}}\right)^{1/6} \qquad (26.9\text{-}7)$$

Notes:

1. For values of H/L_h, x/L_h and z/L_h other than those shown, linear interpolation is permitted.
2. For $H/L_h > 0.5$, assume $H/L_h = 0.5$ for evaluating K_1 and substitute $2H$ for L_h for evaluating K_2 and K_3.
3. Multipliers are based on the assumption that wind approaches the hill or escarpment along the direction of maximum slope.
4. Notation:
   - H: Height of hill or escarpment relative to the upwind terrain, in feet (meters).
   - L_h: Distance upwind of crest to where the difference in ground elevation is half the height of hill or escarpment, in feet (meters).
   - K_1: Factor to account for shape of topographic feature and maximum speed-up effect.
   - K_2: Factor to account for reduction in speed-up with distance upwind or downwind of crest.
   - K_3: Factor to account for reduction in speed-up with height above local terrain.
   - x: Distance (upwind or downwind) from the crest to the building site, in feet (meters).
   - z: Height above ground surface at building site, in feet (meters).
   - μ: Horizontal attenuation factor.
   - γ: Height attenuation factor.

Attachment F

EXCEPTIONS:

a. Where the inclusion of storage loads adds no more than 5% to the effective seismic weight at that level, it need not be included in the effective seismic weight.
b. Floor live load in public garages and open parking structures need not be included.

2. Where provision for partitions is required by Section 4.2.2 in the floor load design, the actual partition weight or a minimum weight of 10 psf (0.48 kN/m^2) of floor area, whichever is greater.
3. Total operating weight of permanent equipment.
4. Where the flat roof snow load, P_f, exceeds 30 psf (1.44 kN/m^2), 20 percent of the uniform design snow load, regardless of actual roof slope.
5. Weight of landscaping and other materials at roof gardens and similar areas.

12.7.3 Structural Modeling

A mathematical model of the structure shall be constructed for the purpose of determining member forces and structure displacements resulting from applied loads and any imposed displacements or P-delta effects. The model shall include the stiffness and strength of elements that are significant to the distribution of forces and deformations in the structure and represent the spatial distribution of mass and stiffness throughout the structure.

In addition, the model shall comply with the following:

a. Stiffness properties of concrete and masonry elements shall consider the effects of cracked sections.
b. For steel moment frame systems, the contribution of panel zone deformations to overall story drift shall be included.

Structures that have horizontal structural irregularity Type 1a, 1b, 4, or 5 of Table 12.3-1 shall be analyzed using a 3-D representation. Where a 3-D model is used, a minimum of three dynamic degrees of freedom consisting of translation in two orthogonal plan directions and rotation about the vertical axis shall be included at each level of the structure. Where the diaphragms have not been classified as rigid or flexible in accordance with Section 12.3.1, the model shall include representation of the diaphragm's stiffness characteristics and such additional dynamic degrees of freedom as are required to account for the participation of the diaphragm in the structure's dynamic response.

EXCEPTION: Analysis using a 3-D representation is not required for structures with flexible diaphragms that have Type 4 horizontal structural irregularities.

12.7.4 Interaction Effects

Moment-resisting frames that are enclosed or adjoined by elements that are more rigid and not considered to be part of the seismic force-resisting system shall be designed so that the action or failure of those elements will not impair the vertical load and seismic force-resisting capability of the frame. The design shall provide for the effect of these rigid elements on the structural system at structural deformations corresponding to the design story drift (Δ) as determined in Section 12.8.6. In addition, the effects of these elements shall be considered where determining whether a structure has one or more of the irregularities defined in Section 12.3.2.

12.8 EQUIVALENT LATERAL FORCE PROCEDURE

12.8.1 Seismic Base Shear

The seismic base shear, V, in a given direction shall be determined in accordance with the following equation:

$$V = C_s W \qquad (12.8\text{-}1)$$

where

C_s = the seismic response coefficient determined in accordance with Section 12.8.1.1
W = the effective seismic weight per Section 12.7.2

12.8.1.1 Calculation of Seismic Response Coefficient

The seismic response coefficient, C_s, shall be determined in accordance with Eq. 12.8-2.

$$C_s = \frac{S_{DS}}{\left(\frac{R}{I_e}\right)} \qquad (12.8\text{-}2)$$

where

S_{DS} = the design spectral response acceleration parameter in the short period range as determined from Section 11.4.4 or 11.4.7
R = the response modification factor in Table 12.2-1
I_e = the importance factor determined in accordance with Section 11.5.1

The value of C_s computed in accordance with Eq. 12.8-2 need not exceed the following:

$$C_s = \frac{S_{D1}}{T\left(\frac{R}{I_e}\right)} \quad \text{for} \quad T \le T_L \qquad (12.8\text{-}3)$$

$$C_s = \frac{S_{D1}T_L}{T^2\left(\frac{R}{I_e}\right)} \quad \text{for} \quad T > T_L \qquad (12.8\text{-}4)$$

Attachment G, 1 of 7

15.3.2 Greater Than or Equal to 25 Percent Combined Weight Condition

For the condition where the weight of the nonbuilding structure is equal to or greater than 25 percent of the combined effective seismic weights of the nonbuilding structure and supporting structure, an analysis combining the structural characteristics of both the nonbuilding structure and the supporting structures shall be performed to determine the seismic design forces as follows:

1. Where the fundamental period, T, of the nonbuilding structure is less than 0.06 s, the nonbuilding structure shall be considered a rigid element with appropriate distribution of its effective seismic weight. The supporting structure shall be designed in accordance with the requirements of Chapter 12 or Section 15.5 as appropriate, and the R value of the combined system is permitted to be taken as the R value of the supporting structural system. The nonbuilding structure and attachments shall be designed for the forces using the procedures of Chapter 13 where the value of R_p shall be taken as equal to the R value of the nonbuilding structure as set forth in Table 15.4-2, and a_p shall be taken as 1.0.
2. Where the fundamental period, T, of the nonbuilding structure is 0.06 s or greater, the nonbuilding structure and supporting structure shall be modeled together in a combined model with appropriate stiffness and effective seismic weight distributions. The combined structure shall be designed in accordance with Section 15.5 with the R value of the combined system taken as the lesser R value of the nonbuilding structure or the supporting structure. The nonbuilding structure and attachments shall be designed for the forces determined for the nonbuilding structure in the combined analysis.

15.3.3 Architectural, Mechanical, and Electrical Components

Architectural, mechanical, and electrical components supported by nonbuilding structures shall be designed in accordance with Chapter 13 of this standard.

15.4 STRUCTURAL DESIGN REQUIREMENTS

15.4.1 Design Basis

Nonbuilding structures having specific seismic design criteria established in reference documents shall be designed using the standards as amended herein. Where reference documents are not cited herein, nonbuilding structures shall be designed in compliance with Sections 15.5 and 15.6 to resist minimum seismic lateral forces that are not less than the requirements of Section 12.8 with the following additions and exceptions:

1. The seismic force-resisting system shall be selected as follows:
   a. For nonbuilding structures similar to buildings, a system shall be selected from among the types indicated in Table 12.2-1 or Table 15.4-1 subject to the system limitations and limits on structural height, h_n, based on the seismic design category indicated in the table. The appropriate values of R, Ω_0, and C_d indicated in the selected table shall be used in determining the base shear, element design forces, and design story drift as indicated in this standard. Design and detailing requirements shall comply with the sections referenced in the selected table.
   b. For nonbuilding structures not similar to buildings, a system shall be selected from among the types indicated in Table 15.4-2 subject to the system limitations and limits on structural height, h_n, based on seismic design category indicated in the table. The appropriate values of R, Ω_o, and C_d indicated in Table 15.4-2 shall be used in determining the base shear, element design forces, and design story drift as indicated in this standard. Design and detailing requirements shall comply with the sections referenced in Table 15.4-2.
   c. Where neither Table 15.4-1 nor Table 15.4-2 contains an appropriate entry, applicable strength and other design criteria shall be obtained from a reference document that is applicable to the specific type of nonbuilding structure. Design and detailing requirements shall comply with the reference document.
2. For nonbuilding systems that have an R value provided in Table 15.4-2, the minimum specified value in Eq. 12.8-5 shall be replaced by

$$C_s = 0.044 S_{DS} I_e \qquad (15.4\text{-}1)$$

The value of C_s shall not be taken as less than 0.03.

And for nonbuilding structures located where $S_1 \geq 0.6g$, the minimum specified value in Eq. 12.8-6 shall be replaced by

$$C_s = 0.8 S_1/(R/I_e) \qquad (15.4\text{-}2)$$

EXCEPTION: Tanks and vessels that are designed to AWWA D100, AWWA D103, API

Attachment G, 2 of 7

All other self-supporting structures, tanks, or vessels not covered above or by reference standards that are not similar to buildings		1.25	2	2.5	NL	NL	50	50	50

[a]NL = no limit and NP = not permitted.
[b]See Section 15.7.3a for the application of the overstrength factors, Ω_0, for tanks and vessels.
[c]If a section is not indicated in the Detailing Requirements column, no specific detailing requirements apply.
[d]For the purpose of height limit determination, the height of the structure shall be taken as the height to the top of the structural frame making up the primary seismic force-resisting system.
[e]Sections 15.7.10.5a and 15.7.10.5b shall be applied for any Risk Category.
[f]Detailed with an essentially complete vertical load carrying frame.

Attachment G, 3 of 7

650 Appendix E, and API 620 Appendix L as modified by this standard, and stacks and chimneys that are designed to ACI 307 as modified by this standard, shall be subject to the larger of the minimum base shear value defined by the reference document or the value determined by replacing Eq. 12.8-5 with the following:

$$C_s = 0.044 S_{DS} I_e \qquad (15.4\text{-}3)$$

The value of C_s shall not be taken as less than 0.01.

And for nonbuilding structures located where $S_1 \geq 0.6g$, the minimum specified value in Eq. 12.8-6 shall be replaced by

$$C_s = 0.5 S_1/(R/I_e) \qquad (15.4\text{-}4)$$

Minimum base shear requirements need not apply to the convective (sloshing) component of liquid in tanks.

3. The importance factor, I_e, shall be as set forth in Section 15.4.1.1.
4. The vertical distribution of the lateral seismic forces in nonbuilding structures covered by this section shall be determined:
   a. Using the requirements of Section 12.8.3, or
   b. Using the procedures of Section 12.9, or
   c. In accordance with the reference document applicable to the specific nonbuilding structure.
5. For nonbuilding structural systems containing liquids, gases, and granular solids supported at the base as defined in Section 15.7.1, the minimum seismic design force shall not be less than that required by the reference document for the specific system.
6. Where a reference document provides a basis for the earthquake resistant design of a particular type of nonbuilding structure covered by Chapter 15, such a standard shall not be used unless the following limitations are met:
   a. The seismic ground accelerations, and seismic coefficients, shall be in conformance with the requirements of Section 11.4.
   b. The values for total lateral force and total base overturning moment used in design shall not be less than 80 percent of the base shear value and overturning moment, each adjusted for the effects of soil–structure interaction that is obtained using this standard.
7. The base shear is permitted to be reduced in accordance with Section 19.2.1 to account for the effects of soil–structure interaction. In no case shall the reduced base shear be less than $0.7V$.
8. Unless otherwise noted in Chapter 15, the effects on the nonbuilding structure due to gravity loads and seismic forces shall be combined in accordance with the factored load combinations as presented in Section 2.3.
9. Where specifically required by Chapter 15, the design seismic force on nonbuilding structures shall be as defined in Section 12.4.3.

15.4.1.1 Importance Factor

The importance factor, I_e, and risk category for nonbuilding structures are based on the relative hazard of the contents and the function. The value of I_e shall be the largest value determined by the following:

a. Applicable reference document listed in Chapter 23.
b. The largest value as selected from Table 1.5-2.
c. As specified elsewhere in Chapter 15.

15.4.2 Rigid Nonbuilding Structures

Nonbuilding structures that have a fundamental period, T, less than 0.06 s, including their anchorages, shall be designed for the lateral force obtained from the following:

$$V = 0.30 S_{DS} W I_e \qquad (15.4\text{-}5)$$

where

V = the total design lateral seismic base shear force applied to a nonbuilding structure
S_{DS} = the site design response acceleration as determined from Section 11.4.4
W = nonbuilding structure operating weight
I_e = the importance factor determined in accordance with Section 15.4.1.1

The force shall be distributed with height in accordance with Section 12.8.3.

15.4.3 Loads

The seismic effective weight W for nonbuilding structures shall include the dead load and other loads as defined for structures in Section 12.7.2. For purposes of calculating design seismic forces in nonbuilding structures, W also shall include all normal operating contents for items such as tanks, vessels, bins, hoppers, and the contents of piping. W shall include snow and ice loads where these loads constitute 25 percent or more of W or where required by the authority having jurisdiction based on local environmental characteristics.

15.4.4 Fundamental Period

The fundamental period of the nonbuilding structure shall be determined using the structural

Attachment 6, 4 of 7

C_s shall not be less than

$$C_s = 0.044 S_{DS} I_e \geq 0.01 \qquad (12.8\text{-}5)$$

In addition, for structures located where S_1 is equal to or greater than $0.6g$, C_s shall not be less than

$$C_s = 0.5 S_1 / (R/I_e) \qquad (12.8\text{-}6)$$

where I_e and R are as defined in Section 12.8.1.1 and

S_{D1} = the design spectral response acceleration parameter at a period of 1.0 s, as determined from Section 11.4.4 or 11.4.7

T = the fundamental period of the structure(s) determined in Section 12.8.2

T_L = long-period transition period(s) determined in Section 11.4.5

S_1 = the mapped maximum considered earthquake spectral response acceleration parameter determined in accordance with Section 11.4.1 or 11.4.7

12.8.1.2 Soil Structure Interaction Reduction

A soil structure interaction reduction is permitted where determined using Chapter 19 or other generally accepted procedures approved by the authority having jurisdiction.

12.8.1.3 Maximum S_s *Value in Determination of* C_s

For regular structures five stories or less above the base as defined in Section 11.2 and with a period, T, of 0.5 s or less, C_s is permitted to be calculated using a value of 1.5 for S_S.

12.8.2 Period Determination

The fundamental period of the structure, T, in the direction under consideration shall be established using the structural properties and deformational characteristics of the resisting elements in a properly substantiated analysis. The fundamental period, T, shall not exceed the product of the coefficient for upper limit on calculated period (C_u) from Table 12.8-1 and the approximate fundamental period, T_a, determined in accordance with Section 12.8.2.1. As an alternative to performing an analysis to determine the fundamental period, T, it is permitted to use the approximate building period, T_a, calculated in accordance with Section 12.8.2.1, directly.

12.8.2.1 Approximate Fundamental Period

The approximate fundamental period (T_a), in s, shall be determined from the following equation:

$$T_a = C_t h_n^x \qquad (12.8\text{-}7)$$

where h_n is the structural height as defined in Section 11.2 and the coefficients C_t and x are determined from Table 12.8-2.

Alternatively, it is permitted to determine the approximate fundamental period (T_a), in s, from the following equation for structures not exceeding 12 stories above the base as defined in Section 11.2 where the seismic force-resisting system consists

Table 12.8-1 Coefficient for Upper Limit on Calculated Period

Design Spectral Response Acceleration Parameter at 1 s, S_{D1}	Coefficient C_u
≥ 0.4	1.4
0.3	1.4
0.2	1.5
0.15	1.6
≤ 0.1	1.7

Table 12.8-2 Values of Approximate Period Parameters C_t and x

Structure Type	C_t	x
Moment-resisting frame systems in which the frames resist 100% of the required seismic force and are not enclosed or adjoined by components that are more rigid and will prevent the frames from deflecting where subjected to seismic forces:		
Steel moment-resisting frames	0.028 (0.0724)[a]	0.8
Concrete moment-resisting frames	0.016 (0.0466)[a]	0.9
Steel eccentrically braced frames in accordance with Table 12.2-1 lines B1 or D1	0.03 (0.0731)[a]	0.75
Steel buckling-restrained braced frames	0.03 (0.0731)[a]	0.75
All other structural systems	0.02 (0.0488)[a]	0.75

[a]Metric equivalents are shown in parentheses.

Attachment G, 5 of 7

entirely of concrete or steel moment resisting frames and the average story height is at least 10 ft (3 m):

$$T_a = 0.1N \qquad (12.8\text{-}8)$$

where N = number of stories above the base.

The approximate fundamental period, T_a, in s for masonry or concrete shear wall structures is permitted to be determined from Eq. 12.8-9 as follows:

$$T_a = \frac{0.0019}{\sqrt{C_w}} h_n \qquad (12.8\text{-}9)$$

where C_w is calculated from Eq. 12.8-10 as follows:

$$C_w = \frac{100}{A_B} \sum_{i=1}^{x} \left(\frac{h_n}{h_i} \right)^2 \frac{A_i}{\left[1 + 0.83 \left(\frac{h_i}{D_i} \right)^2 \right]} \qquad (12.8\text{-}10)$$

where

A_B = area of base of structure, ft^2
A_i = web area of shear wall i in ft^2
D_i = length of shear wall i in ft
h_i = height of shear wall i in ft
x = number of shear walls in the building effective in resisting lateral forces in the direction under consideration

12.8.3 Vertical Distribution of Seismic Forces

The lateral seismic force (F_x) (kip or kN) induced at any level shall be determined from the following equations:

$$F_x = C_{vx} V \qquad (12.8\text{-}11)$$

and

$$C_{vx} = \frac{w_x h_x^k}{\sum_{i=1}^{n} w_i h_i^k} \qquad (12.8\text{-}12)$$

where

C_{vx} = vertical distribution factor
V = total design lateral force or shear at the base of the structure (kip or kN)
w_i and w_x = the portion of the total effective seismic weight of the structure (W) located or assigned to Level i or x
h_i and h_x = the height (ft or m) from the base to Level i or x
k = an exponent related to the structure period as follows:
for structures having a period of 0.5 s or less, k = 1
for structures having a period of 2.5 s or more, k = 2
for structures having a period between 0.5 and 2.5 s, k shall be 2 or shall be determined by linear interpolation between 1 and 2

12.8.4 Horizontal Distribution of Forces

The seismic design story shear in any story (V_x) (kip or kN) shall be determined from the following equation:

$$V_x = \sum_{i=x}^{n} F_i \qquad (12.8\text{-}13)$$

where F_i = the portion of the seismic base shear (V) (kip or kN) induced at Level i.

The seismic design story shear (V_x) (kip or kN) shall be distributed to the various vertical elements of the seismic force-resisting system in the story under consideration based on the relative lateral stiffness of the vertical resisting elements and the diaphragm.

12.8.4.1 Inherent Torsion

For diaphragms that are not flexible, the distribution of lateral forces at each level shall consider the effect of the inherent torsional moment, M_t, resulting from eccentricity between the locations of the center of mass and the center of rigidity. For flexible diaphragms, the distribution of forces to the vertical elements shall account for the position and distribution of the masses supported.

12.8.4.2 Accidental Torsion

Where diaphragms are not flexible, the design shall include the inherent torsional moment (M_t) resulting from the location of the structure masses plus the accidental torsional moments (M_{ta}) caused by assumed displacement of the center of mass each way from its actual location by a distance equal to 5 percent of the dimension of the structure perpendicular to the direction of the applied forces.

Where earthquake forces are applied concurrently in two orthogonal directions, the required 5 percent displacement of the center of mass need not be applied in both of the orthogonal directions at the same time, but shall be applied in the direction that produces the greater effect.

12.8.4.3 Amplification of Accidental Torsional Moment

Structures assigned to Seismic Design Category C, D, E, or F, where Type 1a or 1b torsional irregularity exists as defined in Table 12.3-1 shall have the effects accounted for by multiplying M_{ta} at each level by a torsional amplification factor (A_x) as illustrated in

Attachment 6, 6 of 7

for each beam, girder, or truss either directly to its supporting elements or to slabs designed to act as diaphragms. Where the connection is through a diaphragm, the member's supporting element shall also be connected to the diaphragm. The connection shall have the strength to resist a force of 5 percent of the unfactored dead load plus live load reaction imposed by the supported member on the supporting member.

1.4.5 Anchorage of Structural Walls

Walls that provide vertical load bearing or lateral shear resistance for a portion of the structure shall be anchored to the roof and all floors and members that provide lateral support for the wall or that are supported by the wall. The anchorage shall provide a direct connection between the walls and the roof or floor construction. The connections shall be capable of resisting a strength level horizontal force perpendicular to the plane of the wall equal to 0.2 times the weight of the wall tributary to the connection, but not less than 5 psf (0.24 kN/m^2).

1.4.6 Extraordinary Loads and Events

When considered, design for resistance to extraordinary loads and events shall be in accordance with the procedures of Section 2.5.

1.5 CLASSIFICATION OF BUILDINGS AND OTHER STRUCTURES

1.5.1 Risk Categorization

Buildings and other structures shall be classified, based on the risk to human life, health, and welfare associated with their damage or failure by nature of their occupancy or use, according to Table 1.5-1 for the purposes of applying flood, wind, snow, earthquake, and ice provisions. Each building or other structure shall be assigned to the highest applicable risk category or categories. Minimum design loads for structures shall incorporate the applicable importance factors given in Table 1.5-2, as required by other sections of this Standard. Assignment of a building or other structure to multiple risk categories based on the type of load condition being evaluated (e.g., snow or seismic) shall be permitted.

When the building code or other referenced standard specifies an Occupancy Category, the Risk Category shall not be taken as lower than the Occupancy Category specified therein.

1.5.2 Multiple Risk Categories

Where buildings or other structures are divided into portions with independent structural systems, the classification for each portion shall be permitted to be determined independently. Where building systems, such as required egress, HVAC, or electrical power, for a portion with a higher risk category pass through or depend on other portions of the building or other structure having a lower risk category, those portions shall be assigned to the higher risk category.

1.5.3 Toxic, Highly Toxic, and Explosive Substances

Buildings and other structures containing toxic, highly toxic, or explosive substances are permitted to be classified as Risk Category II structures if it can be demonstrated to the satisfaction of the authority having jurisdiction by a hazard assessment as part of an overall risk management plan (RMP) that a release of the toxic, highly toxic, or explosive substances is not sufficient to pose a threat to the public.

To qualify for this reduced classification, the owner or operator of the buildings or other structures

Table 1.5-2 Importance Factors by Risk Category of Buildings and Other Structures for Snow, Ice, and Earthquake Loads[a]

Risk Category from Table 1.5-1	Snow Importance Factor, I_s	Ice Importance Factor—Thickness, I_i	Ice Importance Factor—Wind, I_w	Seismic Importance Factor, I_e
I	0.80	0.80	1.00	1.00
II	1.00	1.00	1.00	1.00
III	1.10	1.25	1.00	1.25
IV	1.20	1.25	1.00	1.50

[a]The component importance factor, I_p, applicable to earthquake loads, is not included in this table because it is dependent on the importance of the individual component rather than that of the building as a whole, or its occupancy. Refer to Section 13.1.3.

S_S =	1.616 g	S_{MS} =	1.454 g	S_{DS} =	0.969 g
S_1 =	0.597 g	S_{M1} =	1.433 g	S_{D1} =	0.956 g

For information on how the SS and S1 values above have been calculated from probabilistic (risk-targeted) and deterministic ground motions in the direction of maximum horizontal response, please return to the application and select the "2009 NEHRP" building code reference document.

For PGA_M, T_L, C_{RS}, and C_{R1} values, please view the detailed report.

Attachment H

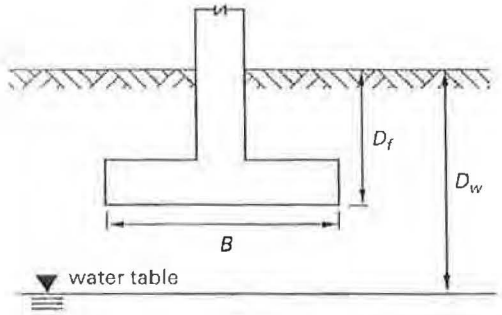
$$q_{ult} = \tfrac{1}{2}\rho_b g B N_\gamma + \rho_b g D_f N_q \quad \text{[SI]} \quad 36.14(a)$$

$$q_{ult} = \tfrac{1}{2}\gamma_b B N_\gamma + \gamma_b D_f N_q \quad \text{[U.S.]} \quad 36.14(b)$$

(c) When the water table is between the base of the footing and the surface, linear interpolation is used between cases (a) and (b). This is equivalent to using the submerged density in the first term as in (a) above, and calculating the third term in Eq. 36.1 as

$$\left(\rho_d g D_w + \left(\rho_d - 1000\ \frac{\text{kg}}{\text{m}^3}\right) g(D_f - D_w)\right) N_q = \left(\rho_d g D_f + \left(1000\ \frac{\text{kg}}{\text{m}^3}\right) g(D_w - D_f)\right) N_q \quad \text{[SI]} \quad 36.15(a)$$

$$\left(\gamma_d D_w + \left(\gamma_d - 62.4\ \frac{\text{lbf}}{\text{ft}^3}\right)(D_f - D_w)\right) N_q = \left(\gamma_d D_f + \left(62.4\ \frac{\text{lbf}}{\text{ft}^3}\right)(D_w - D_f)\right) N_q \quad \text{[U.S.]} \quad 36.15(b)$$



General Principle 3: For sand, if the water table depth, D_w, is greater than $D_f + B$ (i.e., more than a distance B below the base of the footing), the bearing capacity is not affected. Calculate the bearing capacity from Eq. 36.1 as if there was no water table.

$$q_{ult} = \tfrac{1}{2}\rho_d g B N_\gamma + \rho_d g D_f N_q \quad \text{[SI]} \quad 36.16(a)$$

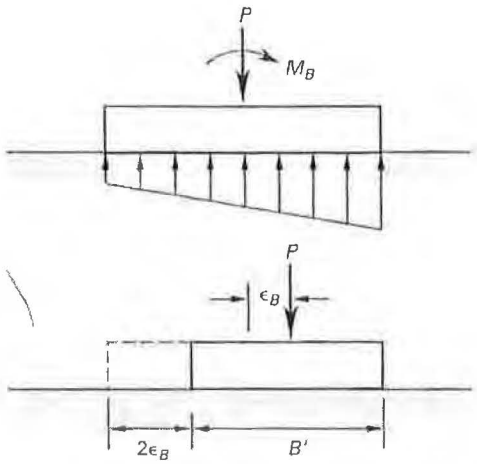
$$q_{ult} = \tfrac{1}{2}\gamma_d B N_\gamma + \gamma_d D_f N_q \quad \text{[U.S.]} \quad 36.16(b)$$

General Principle 4: For sand, if the water table depth, D_w, is between D_f and $D_f + B$, the bearing capacity is calculated using the drained density in the $D_f N_q$ term, and a weighted average of the drained and submerged densities in the BN_γ term.

Figure 36.5 *Water Table Beneath a Footing*

10. ECCENTRIC LOADS ON RECTANGULAR FOOTINGS

If a rectangular footing carries a moment in addition to its vertical load, an eccentric loading situation is created. Under these conditions, the footing bearing capacity should be analyzed assuming an area in which the size is reduced by twice the eccentricity.



$$e_B = \frac{M_B}{P};\ e_L = \frac{M_L}{P} \quad 36.17$$

$$L' = L - 2e_L;\ B' = B - 2e_B \quad 36.18$$

$$A' = L'B' \quad 36.19$$

This area reduction places the equivalent force at the centroid of the reduced area. The equivalent width B' should be used in Eq. 36.1, and both B' and L' should be used in the ratio B'/L' used to determine shape factors. The footing bearing capacity is reduced in two ways. First, a smaller B in Eq. 36.1 results in a smaller q_{ult} and q_a. Second, a smaller q_a results in a smaller allowable load (i.e., $P = q_a B' L'$).

Figure 36.6 *Footing with Overturning Moment*

Although the eccentricity is independent of the footing dimensions, a trial-and-error solution may be necessary when designing footings. Trial and error is not required when analyzing a rectangular footing of known dimensions.

Assuming $M_L = 0$ and $e_B = e$ and disregarding the concrete and overburden weights, the actual soil pressure distribution is given by Eq. 36.20. B' and L' should not be used in Eq. 36.20 because these variables place the load at the centroid of the reduced area, assuming a uniform pressure distribution.

$$p_{max},\ p_{min} = \left(\frac{P}{BL}\right)\left(1 \pm \frac{6e}{B}\right) \quad 36.20$$

If the eccentricity, e, is sufficiently large, a negative soil pressure will result. Since soil cannot carry a tensile stress, such stresses are neglected. This results in a reduced area to carry the load.

If the resultant force is within the middle third of the footing, the contact pressures will be distributed over the entire footing. That is, the maximum eccentricity without incurring a reduction in footing contact area will be $B/6$.

Attachment I

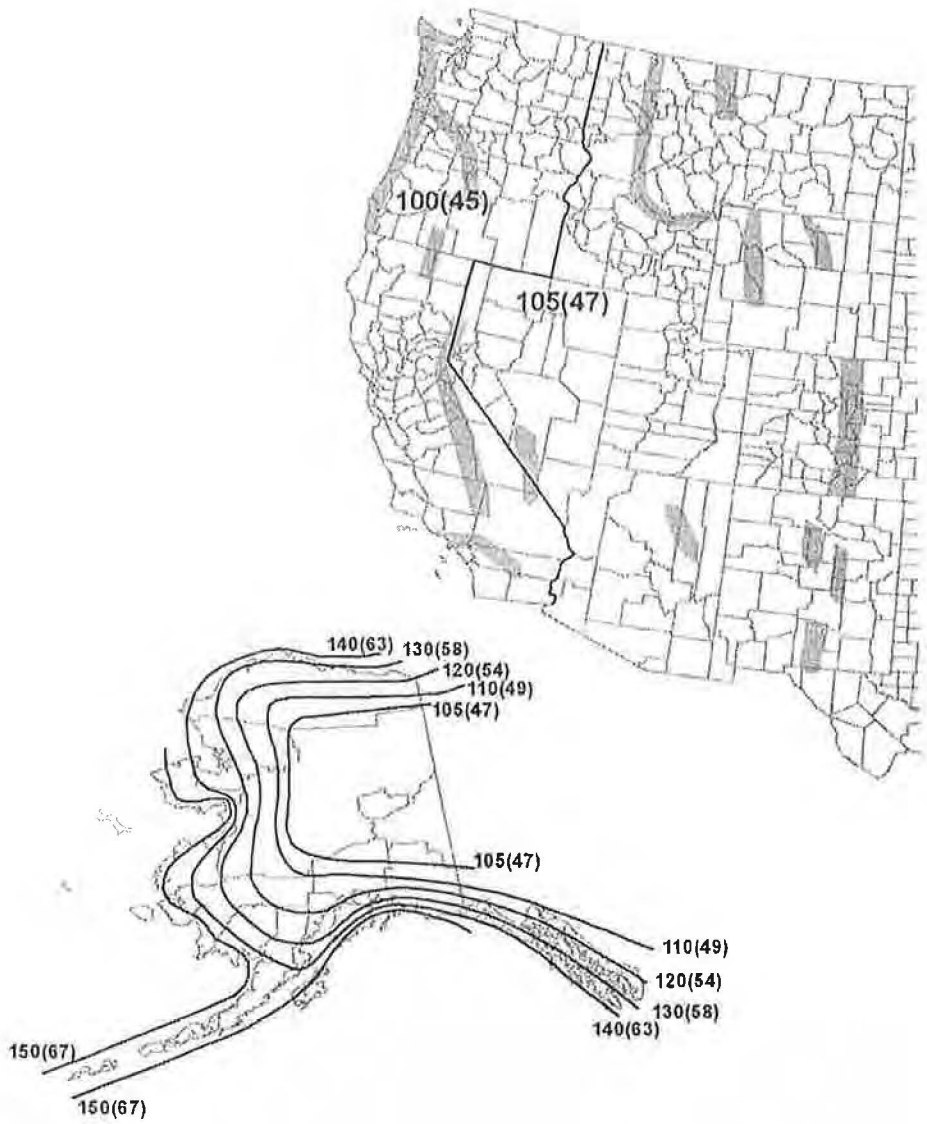


Figure 26.5-1C Basic Wind Speeds for Risk Category I Buildings and Other Structures.

Notes:

1. Values are nominal design 3-second gust wind speeds in miles per hour (m/s) at 33 ft (10m) above ground for Exposure C category.
2. Linear interpolation between contours is permitted.
3. Islands and coastal areas outside the last contour shall use the last wind speed contour of the coastal area.
4. Mountainous terrain, gorges, ocean promontories, and special wind regions shall be examined for unusual wind conditions.
5. Wind speeds correspond to approximately a 15% probability of exceedance in 50 years (Annual Exceedance Probability = 0.00333, MRI = 300 Years).

Attachment J

Figure 36.3 Spread Footing Dimensions

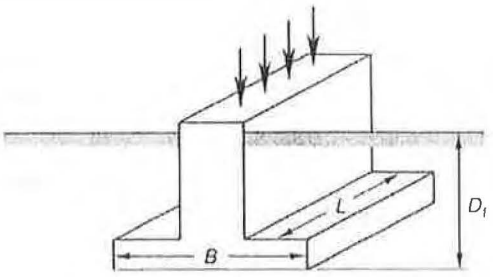

Table 36.4 N_c Bearing Capacity Factor Multipliers for Various Values of B/L

B/L	multiplier
1 (square)	1.25
0.5	1.12
0.2	1.05
0.0	1.00
1 (circular)	1.20

Table 36.5 N_γ Multipliers for Various Values of B/L

B/L	multiplier
1 (square)	0.85
0.5	0.90
0.2	0.95
0.0	1.00
1 (circular)	0.70

Several researchers have recommended corrections to N_c to account for footing depth. (Corrections to N_q for footing depth have also been suggested. No corrections to N_γ for footing depth have been suggested.) There is considerable variation in the method of calculating this correction, if it is used at all. A multiplicative correction factor, d_c, which is used most often, has the form

$$d_c = 1 + \frac{KD_f}{B} \qquad 36.2$$

K is a constant for which values of 0.2 and 0.4 have been proposed. The depth factor correction is applied to N_c along with the shape factor correction in Eq. 36.1.

Once the ultimate bearing capacity is determined, it is corrected by the *overburden*, giving the *net bearing capacity*. This is the net pressure the soil can support beyond the pressure applied by the existing overburden.

$$q_{net} = q_{ult} - \rho g D_f \quad \text{[SI]} \qquad 36.3(a)$$
$$q_{net} = q_{ult} - \gamma D_f \quad \text{[U.S.]} \qquad 36.3(b)$$

The *allowable bearing capacity* is determined by dividing the net capacity by a factor of safety. The safety factor accounts for the uncertainties in evaluating soil properties and anticipated loads, and also on the amount of risk involved in building the structure. A safety factor between 2 and 3 (based on q_{net}) is common for average conditions. Smaller safety factors are sometimes used for transient load conditions such as from wind and seismic forces.

$$q_a = \frac{q_{net}}{F} \qquad 36.4$$

6. BEARING CAPACITY OF CLAY

Clay is often soft and fairly impermeable. When loads are first applied to saturated clay, the pore pressure increases. For a short time, this pore pressure does not dissipate, and the angle of internal friction should be taken as $\phi = 0°$. This is known as the $\phi = 0°$ case or the *undrained case*, which is the critical condition for saturated clays. As discussed in Chap. 35, the undrained shear strength of clays is equal to the cohesion, which is one-half of the unconfined compressive strength.

$$S_u = c = \frac{S_{uc}}{2} \qquad 36.5$$

If $\phi = 0°$, then $N_\gamma = 0$ and $N_q = 1$. If there is no surface surcharge (i.e., $p_q = 0$), the ultimate bearing capacity is given by Eq. 36.6.

$$q_{ult} = cN_c + \rho g D_f \quad \text{[SI]} \qquad 36.6(a)$$
$$q_{ult} = cN_c + \gamma D_f \quad \text{[U.S.]} \qquad 36.6(b)$$
$$q_{net} = q_{ult} - \rho g D_f = cN_c \quad \text{[SI]} \qquad 36.7(a)$$
$$q_{net} = q_{ult} - \gamma D_f = cN_c \quad \text{[U.S.]} \qquad 36.7(b)$$

The allowable clay loading is based on a factor of safety, which is typically taken as 3 for clay.

$$q_a = \frac{q_{net}}{F} \qquad 36.8$$

From Eqs. 36.6 and 36.7, it is evident that the cohesion term dominates the bearing capacity in cohesive soil.

Example 36.1

An individual square column footing carries an 83,800 lbf (370 kN) dead load and a 75,400 lbf (335 kN) live load. The unconfined compressive strength of the supporting clay is 0.84 tons/ft^2 (80 kPa), and its specific weight is $\gamma = 115$ lbf/ft^3 ($\rho = 1840$ kg/m^3). $\phi = 0$. The footing is covered by a 6.0 in (0.15 m) thick basement slab whose upper surface is flush with the original grade. The footing thickness is initially unknown. Neglect depth correction factors. Do not design the structural steel. Specify the footing size and thickness.

Attachment K, 1 of 2

5. GENERAL BEARING CAPACITY EQUATION

With *general shear failures*, the soil resists an increased load until a sudden failure occurs. *Local shear failure* occurs in looser, more compressible soils and at high bearing pressures. The boundaries between these types of behavior are not distinct, and the methods of calculating general shear failure are commonly used for most soil conditions.

The *ultimate* (or *gross*) *bearing capacity* for a shallow wall footing is given by Eq. 36.1, which is known as the *Terzaghi-Meyerhof equation*. The equation is valid for both sandy and clayey soils. p_q is an additional surface surcharge, if any.

$$q_{ult} = \tfrac{1}{2}\rho g B N_\gamma + cN_c + (p_q + \rho g D_f)N_q \quad \text{[SI]} \quad 36.1(a)$$

$$q_{ult} = \tfrac{1}{2}\gamma B N_\gamma + cN_c + (p_q + \gamma D_f)N_q \quad \text{[U.S.]} \quad 36.1(b)$$

Various researchers have made improvements on the theory supporting this equation, leading to somewhat different terms and sophistication in evaluating N_γ, N_c, and N_q. The approaches differ in the assumptions made of the shape of the failure zone beneath the footing. However, the general form of the equation is the same in most cases.

Figure 36.2 and Table 36.2 can be used to evaluate the *capacity factors* N_γ, N_c, and N_q in Eq. 36.1. Alternatively, Table 36.3 can be used. The bearing capacity factors in Table 36.2 are based on Terzaghi's 1943 studies. The values in Table 36.3 are based on Meyerhof's 1955 studies and others, and have been widely used. Other values are also in use.

Figure 36.2 *Terzaghi Bearing Capacity Factors*

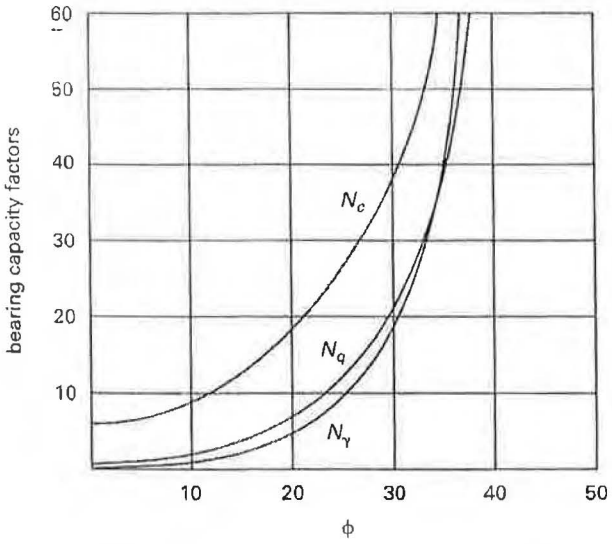

Table 36.2 *Terzaghi Bearing Capacity Factors for General Shear*[a]

38	61.4	48.9	64.1	78.0
40	75.3	64.2	93.7	109.4
42	93.7	85.4	139.3	155.6
44	118.4	115.3	211.4	224.6
46	152.1	158.5	328.7	330.4
48	199.3	222.3	526.5	496.0
50	266.9	319.1	873.9	762.9

[a] Curvilinear interpolation (graphical or methods from Ch. 12) may be used. Do not use linear interpolation.
[b] As predicted by the Vesic equation, $N_\gamma = 2(N_q + 1)\tan\phi$.

Equation 36.1 is appropriate for a foundation in a continuous wall footing. Corrections for various footing geometries, called *shape factors*, are presented in Tables 36.4 and 36.5 using the parameters identified in Fig. 36.3. The bearing capacity factors N_c and N_γ are multiplied by the appropriate shape factors when they are used in Eq. 36.1.

SPECIFICATIONS

Housing

The luminaire housing shall be mitre-formed construction from a single piece of aluminum extrusion, with only a single seam located on the back of the box where the arm detail is located. The sidewall extrusion shall incorporate an integral structural rib for additional strength and support that runs the full perimeter of the housing. The luminaire canopy shall be of aluminum sheet that is crowned and crimped directly into a specially designed upper lip of the sidewall extrusion. This lip shall be lined with an isocryl gasket prior to the crimping process to form a fully sealed canopy without the use of silicone or welds.

Door Frame & Lens Assembly

Door frame shall be mitre-cut construction from a single piece of aluminum extrusion and mechanically fastened with no welds. The entire frame assembly is to always be fully anodized in a natural finish. An extruded silicone gasket shall run the entire perimeter of the frame to form a compression seal directly to the housing when shut to create a fully sealed optical chamber. A thermal and impact resistant tempered clear glass lens is set mechanically into the door frame. The entire perimeter of the glass lens is surrounded by a one-piece E.P.D.M gasket that seals directly to the frame and to the reflector assembly to prevent intrusion by moisture, dust, and other contaminants. Door shall open by a tool-less push button in the front of the housing, and shall hinge on aluminum door pins that slide into the housing sidewall. Door shall be self-retained, and catches with a spring-loaded safety latch to prevent accidental dropping before the door hinges completely open. The entire door frame assembly can then be removed without tools by sliding and lifting the assembly from the center of the housing.

Arm Assembly

Single piece extruded aluminum arm is standard with an optional aluminum decorative insert (color/finish to be specified). The arm is fastened to the pole via (2) non-slip tie-rod channels serving as a compression member with (2) 1/2" zinc-plated steel tie-rods and lock nuts in tension between pole and luminaire.

Optical Systems

Reflectors '2H', '3H', and '5H' are precision hydroformed aluminum, chemically brightened, and are anodized to a semi-specular finish. All wire way or socket entrances are gasketed and sealed with a silicone grommet to form a fully sealed optical chamber when the hydroformed reflector seals directly to the glass lens on the door. Reflector '2S', '3S', '4L', '4W', and '5S' are fabricated segmented systems that are manufactured from highly specular aluminum sheet that has been electrochemically brightened and sealed with a clear coat finish. All segmented reflectors are sealed directly to the glass lens on the door, and the housing itself becomes the fully sealed optical chamber when the door is in the closed position. All reflector systems hinge directly on the door and are latched shut in compression via a tool-less clamping wire-form system. Reflectors can be hinged, removed, or rotated directly on the door without the use of any tools for easy cleaning or re-lamping when required.

Electrical

All electrical components are cULus recognized, factory tested, and mounted to an extruded aluminum ballast tray that sits directly on the door assembly. The extruded aluminum ballast tray is finned for heat dissipation and is fastened to the door via a single thumbscrew and slide-catch for tool-less removal. Each high power factor ballast is capable of starting temperatures down to -20° F (-28.90° C). The 600-volt insulated wiring shall be installed between socket and ballast components via electrical quick disconnects. A Sterner designed Primary Electrical Disconnect system (male/female plug system) is mounted to the ballast tray and housing respectively. The primary electrical circuit shall be disconnected as soon as the door drops in the open position, thus eliminating any exposed live electrical connections and possible shock hazard during service. The entire fixture is cULus listed for wet location use.

Finish

Finished parts shall be washed in a multi-stage phosphate processing system and then finished with a standard polyester urethane powder coat paint. The door frame assembly shall always be anodized in a natural finish with the ballast tray being e-coated in black. Optional anodized finishes are available and shall use an electrolytic process to oxidize and colorize the aluminum for a finish that is extremely resistant to flaking, fading, and corrosive environments. Standard powder colors are dark bronze, black, white, and natural aluminum. Standard anodized colors are bronze (light, medium, dark), black, and natural aluminum. Custom powder, anodized, and wet finishes are available (contact factory for availability).

Subject: Response to Comments dated 19 June 2014
Gardena Sumps, Gardena, California

Dear Mr. Guerbaz,

Geosyntec Consultants (Geosyntec), on behalf of the Atlantic Richfield Company (ARC), is pleased to provide this response to Department of Toxic Substances Control's (DTSC) comments on the Final Feasibility Study Report (Final FS). These responses were prepared to address the DTSC comments dated 19 June 2014. The DTSC comments are provided below in italics with ARC's response following. For ease of review, the "No Further Comment" responses are not repeated herein.

COMMENTS

1. Previous comment number 8. The text in section 6.1.2.2, Vapor Control During Construction, was not changed to include protection of off-site receptors as was stated in the RTC.

Noted. The section has been revised as follows: "Additionally, fixed monitoring will be performed around the perimeter of the Site to alert workers when the PEL is detected so work activities can pause and/or be altered to ~~prevent additional releases~~ **minimize impacts to off-site receptors.**"

2. Previous Comment number 25. The text from the RTC dated 27 January 2014 regarding the potential to encounter degraded soil-sludge during construction of the anchor trench for the high-strength geotextile, and therefore generate gas, was no included in Section 7.3.3.5. The following text from that RTC should be included in Section 7.3.3.5. "Based on borings CPB28, CPB29, and CPB30 performed during the Remedial Investigation (RI) between the Haack and Cooper North sumps, degraded soil-sludge was encountered intermittently between the ground

surface and 7 to 8 feet below the ground surface (ft bgs). As a result, degraded soil-sludge may be encountered during both anchor trench excavations in this area. Degraded soil-sludge will be removed as necessary during anchor trench construction and anchor trenches will be backfilled with non-impacted soil. Degraded soil-sludge handling and potential gas generation will be managed in accordance with the Contingency Plan."

Noted. This language has been added to Section 7.3.3.5.

3. Previous comment number 46. The 27 January 2014 RTC states "The high-strength geotextile will be protected by the overlying geocomposite and geomembrane. Landscaping in the form of decorative rock, artificial turf, or planter box-type vegetation structures will limit maintenance and potential impacts to the geomembrane. If necessary, cushion geotextiles may be used above the geomembrane where geocomposite is not present to prevent damage from installed landscaping." This text should be included in Section 6.1.2.3 Optional final Cover Configurations (No Retaining Wall).

Noted. This language has been added to Section 6.1.2.3.

The updated Final FS will be provided under a separate cover. If you have questions or require additional information, please contact Mr. Kyle Christie with ARC at 714-670-5303.

Sincerely,

Rebecca Oliver, P.E.

EXECUTIVE SUMMARY

The Gardena Sumps Site contains sumps that were formerly used for disposal of sludge from Southern California petroleum operations. Treatability testing was performed on sludge collected from three locations on the Site to determine the physical and chemical properties of the sludge and to evaluate potential methods for treatment. The testing showed that the acidity of the sludge ranged from 6.1 to 20.8 percent by weight. The Cooper South Sump had the highest acidity with an average value of 19 percent. The soils below the Cooper North and Cooper South Sumps had a neutral to slightly basic pH, but soil samples collected from the Haack property at 10 feet below grade had a low pH of approximately 3.0. Petroleum sludge with this characteristic is often referred to acid sludge.

The Site sludge is highly viscous, ranging from 1.7×10^6 to 2.5×10^6 centipoises (cP) at a reference temperature of 140 ^{o} F. The sludge softening point ranges from 158 ^{o} F to greater than 210 ^{o} F. The high viscosity and softening point cause the sludge to exhibit solid-like properties. However, it is still subject to gradual deformation and viscoelastic flow when placed under stress, but these properties can be eliminated by solidification treatment. Solidification may be achieved by soil amendment using bituminous stabilization where the sludge serves as a bitumen for cementation of soil particles.

Testing showed that the sludge can be neutralized by treatment using 25 percent treatment reagent addition by weight where the treatment reagent is comprised of 50 percent hydrated lime and 50 percent calcium carbonate fines. Approximately 10 percent water addition was also required to help activate the lime and carbonate reactions. The addition of 50 percent soil by weight during this mixing will also effectively solidify the waste so it is no longer susceptible to viscoelastic deformation. This treatment also fixates metals, such as lead and neutralizes acid gases such as hydrogen sulfide and sulfur dioxide.

Although the treatability testing showed the sludge can be neutralized, it was also determined that: the sludge will release entrained sulfur dioxide (SO_2) and hydrogen sulfide (H_2S) gases when disturbed for solidification treatment. Also, in its current state, the sludge is highly impermeable and solidification treatment will increase its permeability. The cost for treatment is prohibitive due to the need to mitigate vapor emissions of sulfur dioxide and hydrogen sulfide. Similar treatment was evaluated at the McColl Superfund site in Fullerton California and Thomas Ranch Site in Corona California, with similar wastes, and found unsafe and uneconomical because of the extraordinary engineering controls required.

Although treatability testing shows that the sludge can be treated, important considerations must be evaluated before making a decision to treat. The Site sludge has a high potential to release H_2S and SO_2 when disturbed. The release of H_2S and SO_2 as a result of the sludge disturbance presents an unacceptable barrier to treatment, whereas, these gases are stable in the undisturbed sludge. Therefore, the exposure risks associated with treating the sludge exceeds the risk of leaving the sludge in place.

1.0 INTRODUCTION

On behalf of Atlantic Richfield Company (Atlantic Richfield), SECOR International Inc. (SECOR) has prepared this Acid Sludge Characterization and Treatability Study Report to assist in determining the most appropriate remedy for handling and remediation of sludge at the Gardena Sumps Site (the Site) in Gardena, California. The testing was performed to determine the physical and chemical characteristics of sludge and to provide information on the feasibility of stabilization and neutralization of the sludge. The Acid Sludge Characterization and Treatability Study Report describes testing performed as part of the Remedial Investigation/Feasibility Study (RI/FS) response action specified in Section VII-C of the Consent Decree (CD) between Atlantic Richfield and the California Department of Toxic Substances Control (DTSC) signed on June 16, 2004 by Atlantic Richfield. The CD has been entered into the court records of the United States District Court for the Central District of California on November 4, 2004.

The treatability study was performed in accordance with guidelines form "Guide to Conducting Treatability Studies under CERCLA'" (USEPA 1992a). An additional guidance document, "Guidance for Data Quality Assessment" (USEPA 1998) was used for planning data validation as part of the post-Data Quality Objective process outlined in USEPA (1993).

1.1 Site Description

1.1.1 Site Name and Location

The Site is located at the southwest corner of the intersection of Artesia Boulevard and Normandie Avenue, in the City of Gardena, Los Angeles County, California (Figure 1). The Site occupies approximately 5.6 acres and is subdivided into two parcels of approximately 3.0 acres (Cooper Property) and 2.6 acres (Haack Property). The Site (Figure 2) is bordered to the south by a Los Angeles County Department of Public Works (LACDPW) property and the concrete-lined Dominguez Flood Channel, and the west by commercial and residential buildings. Properties surrounding the Cooper Property and Haack Property consist of mixed residential, commercial, and light industrial development areas. Two large sumps containing wastes comprised primarily of a petroleum waste known as "acid sludge" cover approximately 80 percent of the Cooper Property (referred to as the "Cooper North" and "Cooper South" sumps). One covered sludge sump exists on the Haack Property (referred to as the "Haack Sump"). A smaller area, referred to as the Haack Rework Area, is located south of the Haack Sump. These sumps and the Haack Rework Area are the areas of concern (AOC) that are the subject of the RI/FS, and the sludge within the sumps and rework area is the focus of this treatability study. The individual sump locations are shown in Figure 2.

1.1.2 History of Operations

California DTSC files and title records contain information indicating the Site was originally owned by A.H. and Florence Vaughan in the early 1920s and was used for the grazing of cattle. Mr. and Mrs. Vaughan, while retaining ownership, leased to Mr. George McGhee, who in turn lease for stock and royalties the rights to mine clay on the Site to the Moneta Brick Company (a.k.a. Moneta Brickyard or Higgins Brickyard), a local brick manufacturing company during the late 1920s and early 1930s. Moneta excavated clay from three to four pits on the Site. The original total depths of the pits were never documented and were unknown prior to the RI. However, recent remedial investigations by SECOR indicate that the depth of sludge in the

Cooper North and Cooper South Sumps generally extends no deeper than 7 feet below ground surface (BGS) on the Cooper Property.

Between the 1940s and the 1960s, ownership of the property was transferred through a number of parties. By January 1948, S&L Manufacturing Company owned the property. During the late 1950s the Aircraft Magnesium Corporation (currently out-of-business) leased and operated a metal casting facility on the Haack Property. On January 26, 1959, Mr. William Ward acquired the eastern property. In May 1960, Clarence and Genevieve Haack acquired the western 2.6-acre property from the then bankrupt S&L Manufacturing. By November 1962 the parking lot on the Haack property had been substantially enlarged, and additional structures had been constructed by 1965. The Clarence Haack Living Trust currently owns that parcel. In September 1977, Mr. Thomas Cooper acquired from Mr. William Ward the eastern property, which he still owns.

A more detailed explanation of the Site's history can be found in §2.1 of the RI.

1.1.3 Prior Removal and Remediation Activities

The Cooper North and Cooper South Sumps located on the Cooper Property were capped with a geosynthetic liner installed by the OHM Corporation in July 1993 as a part of the DTSC's environmental program at the site.

1.2 Waste Stream Description

1.2.1 Waste Matrix

The primary waste matrix of concern in the sumps is a sludge known as "acid sludge", but for purposes of this report it will be referred to as "sludge". All refineries used sulfuric acid for treatment and purification of petroleum products in the early 1900s. The acid treatment process was largely phased out during the 1940s and was replaced by more efficient processes and solvent extraction techniques. Acid treatment removed impurities from petroleum products such as asphaltines and nitrogen and sulfur-containing compounds. The sludge produced from this process is a heavy asphaltic pitch-like material with acidic properties. The acidity is typically difficult to remove from the pitch-like material as most of the acidity is entrained within the material or is chemically affixed as sulfonated functional groups. Sulfur dioxide (SO_2) gas can become entrained within the sludge from oxidation reactions between residual sulfuric acid and hydrocarbon. When the sludge is disturbed, the SO_2 gas can be released into the air. This is more likely to occur in sludge that has a residual acidity of 10 percent or greater. Entrained hydrogen sulfide (H_2S) gas may also be released from sludge when it is disturbed. This acidic sludge is generally characterized as a tar-like to pitch-like material that exhibits solid-like properties at ambient conditions but that is subject to viscoelastic creeping flow when exposed to elevated temperatures or direct sunlight.

1.2.2 Contaminants of Concern

Previous testing of the sludge indicates that it contains elevated concentrations of semi-volatile organic compounds (SVOCs) and polynuclear aromatic hydrocarbons (PAHs). The sludge has a low pH value ranging from 1.3 to 3.7 standard units. Elevated concentrations of metals were found in some areas of the sludge. Volatile organic compounds (VOCs) were present in low amounts in some sludge samples. The sludge also contained sulfides, residual sulfuric acid, and entrained SO_2 gas. Several compounds or elements were detected in the sludge or surrounding soil included: anthracene, benzene, chromium, copper, H_2S, lead, methyl

anthracene isomers, methyl ethyl benzene, methyl fluorine, nickel, phenanthrene, pyrene, SO_2, toluene, trimethylbenzene, and trimethylnaphthalene isomers.

The principal contaminants associated with potential future risk from exposure to soil and sludge that were identified in the 1995 Baseline Human health Risk Assessment (BHHRA)(Tetra Tech, 1995) were: chrysene, benzo(b)fluoranthene, and benzo(a)pyrene. The potential future risk was based on a scenario where the cap/cover and fencing at the Cooper Property and the concrete/soil cover at the Haack Property are not maintained or are removed.

1.3 Treatment Technology Description

1.3.1 Treatment Process and Scale

This treatability study was performed with the objectives of characterizing the physical and chemical properties of sludge at the Site as well as for evaluation of potential stabilization and neutralization methods for the sludge. Stabilization and neutralization are physical/chemical treatments that are performed for purposes of building strength in the sludge while immobilizing specific contaminants. Stabilization for sludge does not involve pozzolanic treatment (silicate-based fixation), but instead stability of the waste is achieved by bituminous stabilization. Bituminous stabilization refers to the fixation of solids by the addition of a bituminous material. In the case of sludge stabilization, the sludge serves as the bitumen while other additives (usually soil) serve as the solids. Neutralizing reagents such as calcium oxide (CaO), calcium hydroxide [$Ca(OH)_2$], calcium carbonate ($CaCO_3$), or other alkaline reagents are added to neutralize the residual acidity in the sludge while providing chemical fixation for metals. This treatability study was simulated at a bench-scale level to determine an appropriate mix recipe for stabilization and neutralization.

1.3.2 Operating Features

This treatability study did not explore mixing methods and technologies used for combining reagents with the sludge. Since the sludge is pitch-like in consistency at this Site, a blending head chould be attached to an excavator in an attempt to improve the break-down of the sludge during mixing and blending.

Issues of off-gas are a major concern during full-scale treatment of the sludge. In particular, there is a strong potential to release SO_2 and H_2S gases as the sludge is broken apart. This bench-scale treatability study evaluated the potential of the sludge to release SO_2 and H_2S gases.

2.0 TREATABILITY STUDY APPROACH

2.1 Test Objectives and Rationale

The objectives of the treatability testing for the Gardena Sumps site were to define and evaluate the following:

- Physical and chemical characteristics of the sludge;
- Types of chemical reagents and quantity of reagents required to neutralize the sludge;
- How the addition of a stabilizing agent to the sludge affects its properties;
- Potential exposure risks to sulfurous gases by disturbing or heating the sludge;
- Mobility of contaminants from both treated and untreated sludge;
- Long-term effectiveness of treatment with respect to contaminant immobility; and
- Costs associated with treatment.

2.2 Treatability Study Sampling

SECOR collected samples from seven boring locations at the Site during January and February of 2006 for purposes of treatability testing. Three of the sample borings were located within the Cooper North Sump, three were located within the Cooper South Sump, and one boring was located within the Haack Rework Area. The samples were collected using a tracked, lightweight, hydraulic direct-push Rhino™ unit and were shipped inside 1.5-inch diameter acetate liners with each liner having a length of approximately 1.5-feet. The sample locations of the borings are shown in Figure 3. Copies of the Chain of Custody Records are attached in Appendix A.

The acetate liners were sealed at each end, placed inside large zip-lock packaging, and shipped inside coolers to SECOR's Treatability Testing Laboratory in Sylvania, Ohio. The arrival dates for the samples and number of samples received from each boring are summarized below.

- Ten (10) core samples of sludge labeled "CPB15-TS-2" arrived at the treatability testing laboratory on January 26, 2006 from boring CPB15 located in the Cooper South Sump;

- Fourteen (14) core samples of sludge labeled "CPB07-TS-2" arrived at the treatability testing laboratory on February 2, 2006 from boring CPB07 located in the Cooper North Sump;

- Twenty (20) core samples of sludge labeled "CPB02-TS-2" arrived at the treatability testing laboratory on February 23, 2006 from boring CPB02 located in the Cooper North Sump;

- Four (4) samples of soil labeled "CPB02-TS-7" arrived at the treatability testing laboratory on February 23, 2006 from boring CPB02 located in the Cooper North Sump;

- Sixteen (16) core samples of sludge labeled "CPB14-TS-2" arrived at the treatability testing laboratory on February 23, 2006 from boring CPB14 located in the Cooper South Sump;

- Two (2) core samples of soil labeled “CPB14-TS-5” arrived at the treatability testing laboratory on February 23, 2006 from boring CPB14 located in the Cooper South Sump;

- Two (2) core samples of soil labeled “CPB14-TS-7” arrived at the treatability testing laboratory on February 23, 2006 from boring CPB14 located in the Cooper South Sump;

- Twenty-two (22) core samples of sludge labeled “CPB06-TS-2” arrived at the treatability testing laboratory on February 23, 2006 from boring CPB06 located in the Cooper North Sump;

- Four (4) core samples of soil labeled “CPB06-TS-8” arrived at the treatability testing laboratory on February 23, 2006 from boring CPB06 located in the Cooper North Sump;

- Fifteen (15) core samples of sludge labeled “CPB18-TS-2” arrived at the treatability testing laboratory on February 23, 2006 from boring CPB18 located in the Cooper South Sump;

- Four (4) core samples of soil labeled “CPB18-TS-8” arrived at the treatability testing laboratory on February 23, 2006 from boring CPB18 located in the Cooper South Sump;

- Twenty-one (21) core samples of sludge labeld “HPB05-TS-5” arrived at the treatability testing laboratory on March 17, 2006 from boring HPB05 located in the Haack Rework Area; and

- Four (4) core samples of soil labeled “HPB05-TS-10” arrived at the treatability testing laboratory on March 17, 2006 from boring HPB05 located in the Haack Rework Area.

A total number of 138 samples were received from the Site (118 sludge samples and 20 soil samples).

2.3 Experimental Design and Procedures

The procedures used for testing the sludge and soil samples collected from the Site are summarized in the sections below.

2.3.1 Acidity

Sludge and soil samples were collected from the seven different borings for acidity testing using the following procedure:

- A ten gram sample of sludge or soil was placed into a 250-milliliter glass sample jar;
- Ten milliliters of acetone were added to the sample jar if the sample was sludge (acetone was not used for acidity testing of soil samples) and the sample was swirled until the sludge dissolved;

- After dissolving the sample in acetone, any remaining solids were broken apart with a stainless-steel spatula so that no solid piece was larger than 1/8th inch in size;
- 90 milliliters of deionized water were added to the sample jar;
- The sample jar was covered with a Teflon-lined lid and placed in a tumbler for mixing at a tumbling speed of 18 rotations per minute (rpm) for a period of 24 hours to allow for the extraction of the acid;
- After 24 hours of tumbling, the pH was tested and the sample was titrated to a pH of 8.3 using a 0.5 M solution of sodium hydroxide while mixing the sample with a magnetic stir bar;
- The volume of sodium hydroxide used to raise the pH to 8.3 was recorded;
- The sample was mixed for an additional 30 minutes with additional sodium hydroxide added if needed until each sample maintained a pH greater then 8.3 after 30 minutes of mixing; and
- The acidity of each sample was calculated by dividing the mass of the sodium hydroxide added to the sample by the total weight of the sample, using molar mass ratios to convert the alkaline demand into standard terms of acidity in reference to $CaCO_3$.

2.3.2 Wet Density

Wet densities of the sludge samples were determined from each of the seven Site boring locations using a Fann Model 140 mud balance. This instrument is a self-contained measuring device used to determine the density of a material in the range of 52.5 to 180 pounds per cubic foot. The procedure for measuring density of the sludge with the balance is summarized below.

- The balance cup was cleaned with acetone and dried before each test;
- The base of the balance was placed onto a level surface to perform the testing;
- The balance cup was filled with sludge to a mark 1.4 millimeters below the top of the balance cup;
- The lid of the cup was placed onto the cup and pushed into place;
- If the lid did not fit firmly onto the cup, small amounts of sludge were removed until the lid could be pushed onto the cup to create a flat sludge surface in contact with the lid;
- The knife edge of the balance arm was placed onto the fulcrum and the rider was moved along the balance arm until the assembly was balanced on the fulcrum;
- A reading was taken from the side of the rider closest to the balance cup; and
- The sample cup was emptied and cleaned for the next sample analysis.

2.3.3 Moisture

The moisture content of the sludge samples was determined using a modified American Standard Testing Method (ASTM) D 2216 procedure. A summary for this procedure is described below.

- The tare weights of 70-millimeter aluminum weigh boats were recorded;
- Samples of sludge were placed into the aluminum weight boats and the combined weight was recorded;
- The samples were heated in a convection oven at 200 ^{o}F for 24 hours;
- After 24 hours, the samples were removed and allowed to cool;
- The cooled samples were weighed and the final weights were recorded;
- The wet and dry weights of the samples were calculated by subtracting the tare weight of the 70-millimeter aluminum weigh boat from both the initial and final sample weights; and
- The percent moisture (wet basis) was calculated by subtracting the final weight from the initial weight, dividing that value by the initial weight, and multiplying the result by 100.

2.3.4 Viscosity

The resistance that a material exhibits to flow (the ratio of shearing stress to rate of shear) is called viscosity. Materials with a low viscosity require very little shear stress to induce flow, while materials with high viscosity require a great deal of shear stress. Viscosity is typically reported in terms of centipoises (cP). One cP is equivalent to one kg/cm-sec. To put viscosity into perspective, the viscosities of several types of materials are shown below at a reference temperature of 68 ^{o}F.

Water = 1 cP
Kerosene ~ 200 cP
Lubrication oil ~ 1,000 cP
Asphalt ~ 100,000 cP

Materials with a viscosity less than 20,000 cP are generally considered liquids. Materials with viscosities greater than 20,000 cP are often referred to as gels. If a gel has solid-like characteristics but can still be molded, then the material is typically referred to as a viscoelastic fluid. Materials that exhibit no flowable or moldable properties are considered a solid.

Viscosity testing was performed on sludge samples from each Site boring location to better classify the materials with respect to solid-like characteristics, resistance to flow and deformation. Testing was performed on the sludge samples at various temperatures to obtain viscosity data as a function of temperature. Any material that did not deform enough for viscosity testing at a temperature of 200 ^{o}F was classified as a solid. The samples were tested using the following procedure:

- A Model 345060, Extech Instruments Digital Viscotester equipped with a R2 high-viscosity rotor was used to obtain viscosity readings in the range of 10,000 to 400,000 cP;

- The Digital Viscotester was zeroed with the R2 rotor affixed to the instrument;
- One hundred grams of sample were placed into a 250-milliliter beaker and heated in a convection oven to three different temperatures;
- The sample was removed from the oven and immediately mixed with a stainless steel spatula to assure uniformity;
- The R2 rotor from the Viscotester was immersed into the sample to the test line;
- Viscosity readings were recorded for the material at each different temperature, with the sample being mixed with the spatula prior to testing to assure a uniform temperature profile in the sludge;
- Readings were converted from the instrument reporting values of deciPascal-seconds to conventional values of cP by multiplying the readout number by a conversion factor of 100;
- When the sample cooled to 100 ^{o} F, or produced a viscosity over 400,000 cP, the rotor to the Viscotester was removed from the sample; and
- The data was tabulated and plotted onto semi-log graphs to show the viscosity of each sludge sample as a function of temperature.

2.3.5 Softening Point

The softening point of a tarry or bituminous substance is defined as the temperature at which the material takes on flowable properties. Samples of sludge from each of the seven Site boring locations were tested for softening point. The softening point test was performed using ASTM Method D36. This procedure involves shaping the sludge into two horizontal disks for testing. The sludge is heated to 200 ^{o} F and poured into two shouldered brass rings to form the disks, each having a diameter of 20 millimeters and a thickness of 6.4 millimeters. A steel load ball having a mass of 3.5 grams is placed onto each disk, and the disks are then heated inside a bath of distilled water. The softening point is reported as the mean temperature at which the two disks soften enough to allow the ball to penetrate through the disk. The procedure for determining the softening point of the sludge samples is summarized below:

- Two shouldered brass rings were packed with warmed samples of sludge;
- A 800-milliliter Pyrex beaker was filled with 500-milliliters of refrigerated distilled water;
- A brass ring holder and assembly were placed into the beaker and the shouldered brass rings were placed onto the ring holder;
- A glass thermometer was placed into the center of the beaker, supported by the brass ring holder and assembly;
- A 3.5-gram steel load ball was placed onto the center of the sludge sample in each shouldered brass ring using the load ball centering device to center the load;
- The beaker and the immersed brass ring holder assembly were placed on a hot plate and slowly heated at a controlled rate;
- When the sludge softened to the point where the weight of the steel load ball could penetrate the sludge, the temperature of the water bath was recorded; and

- A temperature reading was obtained for both sludge disks and the mean value was recorded as the sample softening point.

2.3.6 Neutralization and Stabilization Testing

After initial waste characterization testing determined the range of acidity in the samples, testing was performed to determine potential mix recipes for neutralization of the sludge. The chemical reagents evaluated for neutralization and stabilization were portland cement, CaO, $Ca(OH)_2$ and $CaCO_3$.

The addition rate of the chemical and the particle size play an important role in the reaction kinetics and final consistency of the neutralized material. The reagent samples used during testing activities were within the particle size range of 5 to 20 mesh to provide a high surface area for reaction with minimal dust problems.

Evaluation of neutralizing agents was conducted as follows:

- 1,500 grams of sludge was crushed and mixed to create a uniform mixture of sludge for testing;
- The sample was divided into 15 zip-lock bags each containing 100 grams of sludge;
- Pre-calculated masses of Portland cement, CaO, $Ca(OH)_2$, and mixtures of $CaCO_3$ with CaO and $Ca(OH)_2$ were added to the zip-lock bags for neutralizing/stabilizing testing based on dosage estimates obtained from the acidity testing;
- The materials were mixed inside each zip-lock bag for no more than 30 seconds to minimize the loss of heat and moisture from reaction;
- The mixtures were each placed into 250-milliliter insulated containers and sealed with insulated lids;
- A digital thermometer was pushed through an opening in the top of the lid so the sensing portion of the thermometer rested firmly in the treated sludge;
- The temperature of the treated sludge was recorded as a function of time to monitor reaction kinetics and heat generation;
- Measurements were recorded at a minimum of one reading per minute; and
- Recording of temperature data was discontinued once the temperature of the material began to decrease inside the insulated container.

After the reaction time data were collected, the samples were allowed to cure inside the insulated container for 24-hours before testing the samples for unconfined compressive strength by penetrometer. The density and volume expansion of the samples were recorded, and the pH of each sample was also tested by EPA Method 9045.

2.3.7 Vapor Evolution

Sulfurous gases can be released from tiny gas pockets within acidic sludge when the sludge is broken apart or when the viscosity of the sludge is substantially reduced through heating. Gases are also released if the sludge is heated above the boiling point of water due to steam stripping of gases from the sludge. In addition, VOCs may be released from the sludge as it is heated during the neutralization reaction. The potential release of sulfurous gases and VOCs as a function of sample temperature was determined as part of this treatability testing.

The vapor evolution testing was conducted using the procedures summarized below:

- 100-gram samples of sludge were placed loosely into 250-milliliter sample jars equipped with Teflon-lined septa caps and 5-gram samples of sludge were placed into 40-ml vials;
- The samples were heated in a water bath to bring the samples to specified temperatures in the range of 60 ^{o}F to 212 ^{o}F;
- After one hour of equilibration, a syringe was used to remove a vapor sample from the septa cap of the vials for analysis of benzene, toluene, ethylbenzene, xylene (BTEX) and total volatile hydrocarbons;
- The headspace in the 250-milliliter sample jars were measured for H_2S and SO_2 using a VRAE Model PGM-7800 multi gas monitor;
- Each sludge was tested at 60^{o}F, 100 ^{o}F, 140 ^{o}F, 180 ^{o}F and 212 ^{o}F; and
- Vapor concentrations for each sludge sample were recorded as a function of sample temperature.

2.3.8 Metal and Organic Mobilization

Metals in sludge can generally be stabilized if the pH of the sludge is adjusted into the pH range of 8 to 11. The optimal pH for treatment is often dependant upon many chemical constituents in the sludge and how they interact with the treatment reagent. To evaluate the optimal treatment pH range, testing was performed by preparing treated sludge samples having pH values within the range of 8 to 11. The testing was performed using the following procedures:

- Four 500-gram samples of sludge were crushed inside one-gallon zip-lock bags;
- The samples were dosed with 24, 25, 26 and 27 percent of the 50/50 weight/weight (w/w) reagent mixture of $Ca(OH)_2/CaCO_3$ and labeled as *Treated Sludge-1, Treated Sludge-2, Treated Sludge-3* and *Treated Sludge-4*, respectively;
- A 10-gram sample of treated sludge was removed from each treated sample for testing by simulated Synthetic Precipitation Leachate Procedure (SPLP) by adding 200 milliliters of SPLP Extraction Fluid #1 to the sample inside a 250-milliliter sample jar and tumbling the sample for 20 hours at 18 rpm;
- The samples were removed from the tumbler and tested for pH to determine if the samples were adequately dosed to provide an SPLP extract pH within the optimal range

of 8 to 11, and samples falling outside this range were slightly adjusted with additional CaO for correction if necessary; and

- The four samples were sent to Merit Laboratories, Inc. for analyses of heavy metals, PAHs, and VOCs by SPLP extract.

In addition to this testing, samples of treated and untreated sludge were analyzed by the Toxic Characteristic Leaching Procedure (TCLP) for Resource Conservation and Recovery Act (RCRA) metals and VOCs.

2.3.9 Long-Term Leaching Analysis

Testing was conducted using a representative composite sludge sample prepared by combining equal amounts of material from the Cooper North and Cooper South Sumps. The treated composite sample was subjected to a long term leaching test to evaluate the long-term stability of the treated sludge with respect to contaminant mobility. The leaching test involved a dynamic extraction test using the following procedure:

- 40 grams of sludge treated with 5 grams of $Ca(OH)_2$ and 5 grams of $CaCO_3$ was placed into a one-liter glass sample jar with Teflon-lined lid with 950 milliliters of SPLP solution;

- The sample jars were tumbled for 24 hours at a rotational speed of 18 rpm at a temperature of approximately 70 degrees F;

- After the samples tumbled for 24-hours**,** they were removed from the tumbler and allowed an additional two hours of contact time and solids settling;

- The water portion of the sample was removed and filtered for analyses and a new 950-gram aliquot of SPLP extract solution was added to the sample;

- For every second extraction, the extract water was sent to Merit Laboratories, Inc. for analyses of heavy metals, PAH's, and VOCs;

- Samples of each second extract were tested for alkalinity by sulfuric acid titration to a pH value of 4.5, and

- The extraction procedure was repeated for ten extraction cycles.

2.3.10 Permeability

Permeability testing was performed using modified ASTM D5084, Method C using a representative composite sample of sludge prepared by combining equal amounts of material from the Cooper North and Cooper South Sumps. This procedure is especially designed for determining the permeability of a disturbed or remolded material. The testing was performed on two composite sludge samples, one treated and one untreated. The procedures for performing sludge permeability are summarized below.

- A sample of untreated sludge was heated to a temperature of approximately 200 ^{o}F in a microwave to quickly soften the sludge sample without dehydrating it so it could be compacted within a permeability cell for testing;

- Two one-inch diameter polyvinyl chloride (PVC) cylinders were filled with treated and untreated sludge to create sludge columns 12 inches in depth, using a ½-inch diameter tamper rod to remove air pockets from the sludge during filling of the cylinders;

- The bottom of the cylinders were covered with a screen mesh and capped with a bushing equipped with a breathable burette to collect infiltration water;

- A five-foot column of water was placed over the intervals of treated and untreated sludge;

- Removable caps with a 1/8-inch drilled breathing hole were placed at the top of the columns to allow the head of water to be maintained at a constant elevation and pressure over time;

- The columns were monitored daily for need of water addition and the burettes were monitored and recorded daily for water accumulation; and

- The permeability of treated and untreated sludge samples were calculated using Darcy's law as shown below.

$$Q = kA(\Delta h/L)$$

Where:

Q = Flow of liquid (cm^3/sec)
k = Hydraulic conductivity (cm/sec)
Δh = Gradient (cm) = 5 ft or 152.4 cm
L = Length of column (cm) = 1 ft or 30.5 cm
A = Cross-sectional area of flow (cm^2) = 5.57 cm^2

2.3.11 Evaluation of a Soil Additive

As part of the bituminous stabilization process, soil can be added to sludge to create a mixture of bitumen and solid that has strength properties. The addition of soil to the neutralized material can make the material more cohesive and manageable with greater strength characteristics and improved density. Testing was conducted to determine whether the addition of native soil to the treatment mixture would improve the quality of the final mix, and to evaluate the volume expansion associated with the soil addition. The testing was performed using the following protocol:

- Three zip-lock bags containing 50, 75, and 100 grams of soil were each filled with 100 grams of sludge;

- A pre-calculated mass of required neutralizing agent (12.5 grams of $Ca(OH)_2$ and 12.5 grams of $CaCO_3$) were added to the samples;

- The samples were mixed for 30 seconds inside the zip-lock bags to minimize heat and moisture loss;

- The materials from each bag were placed into 250-milliliter insulated containers with an insulated lid;
- A digital thermometer was the placed through an opening in the lids of each insulated container so that the measuring point rested firmly inside the treated sludge;
- The temperatures were recorded as a function of time with measurements taken once every minute until a temperature rise was no longer observed in the sample for a period of five minutes;
- The samples were allowed to cure in the closed containers for a period of 24-hours;
- The samples were tested for unconfined compressive strength by penetrometer;
- The pH of each sample was tested using USEPA Method 9045; and
- The samples were placed into an oven to evaluate viscoelastic flow properties as a function of soil addition at a temperature of 220 ^{o} F.

2.3.12 Evaluation for Thermal Treatment

Testing was performed on a representative composite sample of sludge from the Cooper North and Cooper South Sumps to provide data necessary for assessing thermal treatment. Given the high sulfur content of the sludge, thermal treatment could potentially result in high emissions of SO_2 gas. Although initial indicators suggest that thermal treatment will have both high risk and high cost, a sample of the sludge was analyzed for the following parameters:

- Heating Value in BTUs/Pound by calorimeter (ASTM-D240);
- Sulfur Content by ASTM Method D129;
- Diesel Range Organic Compounds (DRO) and Gasoline Range Organic Compounds (GRO) by EPA Method 8015;
- VOCs by EPA Method 8260; and
- SVOCs and Polynuclear Aromatic Hydrocarbons (PAH) by EPA Method 8270.

2.3.13 Evaluation of Moisture/Density Relationship for Treated Sludge

Testing was performed to determine the optimal combination of moisture content and dry density for the stabilized/neutralized sludge. The testing was performed using a representative composite sample of sludge prepared by combining equal amounts of material from the Cooper North and Cooper South Sumps. The testing involved the following procedures:

- Four samples of treated sludge were prepared, each consisting of 1,000 grams of sludge treated with 25 percent of the 50/50 (w/w) $Ca(OH)_2/CaCO_3$ reagent mix and 50 milliliters of water to facilitate the reaction;
- Soil was added to three of the treated sludge samples at ratios of 25%, 50% and 75% of the initial mass of untreated sludge;
- Each sample was compacted inside a standard mold by the drop of a standard weight at different moisture contents;

- After compaction, the samples were weighed and the moisture was determined by oven drying;
- Moisture-density relationships were determined in accordance with ASTM D 698;
- Data from testing were plotted to generate optimal moisture content plots for each sample; and
- The amount of water addition required during treatment was calculated based on the average optimal moisture content of the three samples.

2.3.14 Testing for Asphaltic Qualities

The property that contains the Cooper North and Cooper South Sumps was purchased in 1977 by Mr. Thomas Cooper as a speculative purchase due to the high volume of tar-like sludge located on the Site. Mr. Cooper contracted with a laboratory to perform preliminary testing to determine if the sludge would have acceptable asphaltic cement qualities if it were neutralized with sodium hydroxide. Per the information provided by Mr. Cooper, the results of the testing showed that the material had a flash point greater than 400 ^{o}F, an American Petroleum Institute (API) gravity of approximately 10, and a pour point greater than 150 ^{o}F. Based on these data, Mr. Cooper believes that the material may have commercial value for recycling. Due to the heavy nature of the sludge, its potential uses are likely limited to use as an asphaltic cement or asphaltic roofing material. Therefore, preliminary testing was performed on samples of sludge to determine if the material may have suitable qualities for recycling as asphaltic cement or roofing asphalt. As part of this preliminary evaluation, the sludge was evaluated against the following modified ASTM procedures:

• ASTM D 2493	Standard Viscosity-Temperature Chart for Asphalts
• ASTM D 946	Standard Specification for Penetration-Graded Asphalt Cement for Use in Pavement Construction
• ASTM D 6154	Standard Specification for Chemically Modified Asphalt Cement for Use in Pavement Construction
• ASTM D 2170	Standard Test Method for Kinematic Viscosity of Asphalts (Bitumens)
• ASTM D 3381	Standard Specification for Viscosity-Graded Asphalt Cement for Use in Pavement Construction
• ASTM D 113	Standard Test Method for Ductility of Bituminous Materials
• ASTM D 36	Standard Test for Softening Point of Bitumen
• ASTM D 5	Test Method for Penetration of Bituminous Materials
• ASTM D 92	Test Method for Flash and Fire Points by Cleveland Open Cup
• ASTM D 2042	Test Method for Solubility of Asphaltic Materials
• ASTM D 312	Standard Specification for Asphalt Used in Roofing

2.4 Equipment and Materials

The following lists are a summary of the equipment, materials and reagents used to conduct the characterization testing:

<u>Equipment and Materials</u>
Laboratory Balance
Laboratory fume hood

70-mm aluminum weigh boats
Stainless-steel spatula
Convection oven
Laboratory tumbler
Harvard compaction unit
Microwave
Magnetic stirrer
Magnetic stir bars
Hot Plate
Refrigerator
VRAE PGM-7800 multi gas monitor
Fann Model 140 mud balance
Whatman No. 2 filter paper
Extech Model 345060 digital Viscotester
ASTM D36 ring and ball Apparatus
800-ml Pyrex beaker
Digital thermometers
Oakton pH meter
Oakton ORP meter
Oakton InfraPro 1 Model 35629-00 infrared thermometer
One-liter glass jars
1-inch diameter PVC permeability cells
Shimadzu Model 9A GC with FID
Water bath
Burettes
Graduated cylinders
40-milliliter unpreserved vials with Teflon-lined septum
Gas-Tight vapor syringes
Two-ounce and four-ounce jars with Teflon-lined lids

Reagents
Distilled water
Acetone
Sodium hydroxide
Phenolphthalein
CaO fines
$Ca(OH)_2$
$CaCO_3$ fines
Portland cement

2.5 Data Management

Data collected during the treatability testing were stored in electronic spreadsheets that were updated throughout the study. The data was backed up daily to avoid loss of data during the study. These data were used at the completion of the study to generate graphs and table for reporting purposes. Data from off-site laboratories were received as electronic files and are included in Appendix B of this report.

2.6 Deviations from the Work Plan

The original work plan did not include testing for asphaltic properties of the sludge. This extra testing was added to evaluate the potential for recycling the sludge as asphalt to provide information to better evaluate the recycling option as part of the feasibility study.

3.0 RESULTS AND DISCUSSION

3.1 Data Analysis and Interpretation

The results of the laboratory testing for characterization and stabilization testing are summarized in the sections below.

3.1.1 Acidity

The results of acidity testing for the 118 sludge and 20 soil samples collected from the Gardena site are provided in Tables 1 through 7. The testing showed that the sludge was very acidic with acidity values ranging from 6.1 to 20.8 percent by weight reported in terms of $CaCO_3$ acidity per EPA Method 305.2. The sludge varied in composition and acid content as a function of sump location, thus indicating that the sludge may have been placed into the sumps at different time frames and that it possibly originated from different sources. The borings from the Cooper South Sump had the highest acidity with values ranging from 18.0 to 20.8 percent expressed in reference to $CaCO_3$ with an average acidity of 19.0 percent. The Cooper North Sump was less acidic, but it still had average boring acidity values ranging from 12.2 to 13.4 percent expressed in reference to $CaCO_3$. Sludge samples collected in the Haack Rework Area had a wide range of acidity values which is likely a result of this area being previously disturbed during development. The average acidity value for the sludge collected from the Haack property was 10.4 percent.

Samples of the soil underlying the sludge were collected at borings CPB02, CPB06, CPB14, CPB18, and HPB05 for acidity and pH testing. The results of the testing are summarized in Tables 1, 2, 4, 6 and 7, respectively. The testing showed that the soil beneath the sludge in the Cooper North and Cooper South Sumps had near neutral to slightly basic pH conditions, thus indicating that the acidity in the sludge in these areas is strongly bound within the sludge by chemically and physically means which makes it largely immobile. The soils on the Haack property, however, were acidic with pH values in the range of 2.94 to 3.35. The average acidity of the soil was 0.4 mg/kg $CaCO_3$.

3.1.2 Wet Density

Samples of sludge from each of the seven borings were tested for density using a Fann mud balance. The results of the testing are summarized in Tables 1 through 7. The densities for the samples ranged from 1.01 g/cc (63 lb/ft^3) to 1.27 g/cc (79 lb/ft^3). The average density of the sludge collected from the Cooper North Sump was 1.05 g/cc (65.7 lb/ft^3) and the average density of the sludge from the Cooper South Sump was more dense at 1.17 g/cc (72.8 lb/ft^3). The sludge collected in the Haack Rework Area had an average density of 1.20 g/cc (74.9 lb/ft^3).

3.1.3 Moisture

The results of moisture testing for the 118 sludge samples and 20 soil samples collected from the Gardena site are attached in Tables 1 through 7. The average moisture of the sludge at the seven boring locations ranged from 9.8 to 22.3 percent on a wet basis. The moisture of the soil below the sludge ranged from 12.1 to 25.6 percent on a wet basis. The soil below the Cooper North Sump was noted to have higher moisture contents (24.2 percent) when compared to the soil below the Haack Rework Area which averaged 14 and 16.9 percent moisture, respectively.

3.1.4 Viscosity

Substances with viscosities greater than 20,000 cP are generally classified as gels because the material is too viscous to pump and transport in typical piping systems. When a deformable material approaches a viscosity of 500,000 cP, it begins to take on solid-like properties. However, if a solid-like material lacks crystal structure, it can still deform under load. Solid-like materials with deformable properties are called viscoelastic materials. The sludge from the Cooper North and Cooper South Sumps is classified as a viscoelastic material. It is a brittle solid when sampled that easily breaks apart into small pieces. However, the pieces generally exhibit viscoelastic flow over time which causes the pieces to slowly gel together to form back into a monolithic solid-like structure.

The viscosities of the sludge samples collected from borings CPB02, CPB06, CPB07, CPB14, CPB15, and CPB18 were tested at different temperatures to determine material viscosity as a function of temperature. The viscosity data were plotted as semi-log graphs to generate trend lines for modeling the viscosity of the sludge as a function of temperature in accordance with ASTM Method D 2493. Using the trend line data, the viscosity of each sludge sample was determined at reference temperatures of 60 ^{o} C and 135 ^{o} C in terms of poise for ease of comparison to typical asphalt standards. The graphs and calculated viscosity values are summarized in Tables 1 through 6.

The results of the testing show that the sludge in the Cooper North Sump had a slightly lower viscosity than the sludge in the Cooper South Sump. The sludge in the Cooper North Sump had an average viscosity of 1,700,000 cP (17,000 poise) at 60 ^{o} C while the viscosity of sludge in the Cooper South Sump averaged 2,500,000 cP (25,000 poise) at 60 ^{o} C. Sludge collected from the Haack property in the Haack Rework Area was heated to 220 ^{o} F but it was still too viscous to test for viscosity, thus indicating the sludge may contain other solids from disruption during development activities in that area.

3.1.5 Softening Point

The softening point test defined in ASTM Method D36 was developed for bitumens and viscoelastic materials that do not have a crystal structure or well-defined melting point. Instead of melting, these materials will slowly soften with temperature. ASTM Method D36 defines the softening point temperature of a material as the point where the substance converts from a solid-like material to a material with some flowable properties. The softening point of sludge samples from borings CPB02, CPB06, CPB07, CPB14, CPB15, CPB18 and HPB05 were tested in accordance with ASTM Method D36. The results of the testing are summarized in Tables 1 through 7.

The results of the testing show that the softening point of the sludge samples from the Cooper property ranged from 158 ^{o} F to 185 ^{o} F. The sludge in the Cooper North Sump had a slightly lower softening point than the sludge in the Cooper South Sump. The sludge in the Cooper North Sump had an average softening point of 159 ^{o} F while the average softening point for the sludge in the Cooper South Sump was 180 ^{o} F. The softening point of the sludge collected in the Haack Rework Area was greater than 210 ^{o} F.

3.1.6 Neutralization and Stabilization Testing

Neutralization and stabilization testing was performing on a composite sample of sludge collected from the Cooper North and Cooper South Sumps using five different reagent mixes. The reagents tested included:

- CaO;
- a 50/50 (w/w) mix of CaO and $CaCO_3$;
- calcium hydroxide [$Ca(OH)_2$];
- a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$; and
- portland cement.

The testing with these reagents evaluated reaction temperatures as a function of time at three different dosages for the composite sludge sample. Ten milliliters of distilled water were added to each test to serve as a wetting solution to stimulate the reaction. The testing was performed inside insulated and sealed reaction containers so the reaction temperature could be monitored with time. Temperature data from the testing are shown in Tables 8 through 12 as a function of time for each reagent mixtures. After the materials had cured for 24 hours, the unconfined compressive strength, density, volume expansion, and pH of the samples were tested. These values are shown in Table 13.

The test results showed that the use of CaO for neutralization created too much heat due to the amounts of reagent needed for neutralization and the associated exothermic release of energy from the reaction of CaO with the acid and moisture in the sludge. The high temperatures caused the sludge to become sticky and it increased the odor and emissions from the sludge during treatment.

Portland cement performed poorly as a treatment reagent with respect to neutralization and stabilization when compared to other reagents. The addition of 40 percent portland cement to the sludge was not enough to neutralize the acidity of the sludge. The portland cement also resulted in a material having less compressive strength than the sludge treated with CaO or $Ca(OH)_2$.

The $Ca(OH)_2$ neutralized the sludge without the production of excessive heat while also producing good strength in the treated material. However, it offered little buffering as a stand-alone reagent so it was difficult to neutralize the sludge without over-dosing or under-dosing with respect to pH. When the $Ca(OH)_2$ was dosed with an equivalent amount of $CaCO_3$, it improved the buffering of the treated material and prevented it from becoming too acidic or too basic as shown in Table 13. Based on these results, the best-suited treatment reagent for the sludge was determined to be a 50/50 (w/w) mixture of $Ca(OH)_2$ and $CaCO_3$. The appropriate amount of this reagent required for treatment of the Cooper North Sump was approximately 21 percent reagent by weight and the appropriate amount of reagent required for treatment of the Cooper South Sump was approximately 29 percent reagent by weight.

3.1.7 Vapor Evolution Testing

The next phase of testing involved the determination of potential rates of off-gas evolution during full-scale mixing operations as a function of temperature. Testing was performed on sludge samples obtained from the Cooper North Sump, the Cooper South Sump and the Haack Rework Area. Headspace analyses were performed on the sludge samples at temperatures of 60 ^{o}F, 100 ^{o}F, 140 ^{o}F, 180 ^{o}F and 212 ^{o}F. A VRAE Model PGM-7800 multi gas monitor was used to monitor H_2S and SO_2 in the samples. The concentration of volatile BTEX and TPH (a combination of GRO and DRO in the headspace) was monitored by GC. The vapor testing results are summarized in Tables 14, 15 and 16. The VOCs detected in the vapor headspace as a function of temperature are shown in Figures 4, 5 and 6 for the Cooper North, Cooper

South and the Haack Rework Area, respectively. A discussion of the VOC results and sulfurous gas emissions (H_2S and SO_2) are summarized below.

3.1.7.1 VOC and TPH Headspace Results

The GC analyses showed that no benzene was emitted from the sludge samples at temperatures ranging from 60 to 212 ^{o} F. Toluene was below the detection limits of 0.5 ppm_v at 60 ^{o} F in the vapor headspace for sludge samples from the Cooper North and Cooper South Sumps. However, as the sludge was heated, toluene was detected in the vapor headspace. The highest concentration observed in the vapor headspace was 21.4 ppm_v in the Cooper South Sump sludge sample at 212 ^{o} F. Ethylbenzene and xylenes were at or near detection limits in the vapor headspace of Cooper North and Cooper South Sump sludge samples at 60 ^{o} F. However, when the sludge was heated to 212 ^{o} F, the concentration of ethylbenzene increased to a high of 5.1 ppm_v and the concentration of xylenes increased to a high of 23.5 ppm_v. These data indicate that BTEX will not present a health and safety issue with respect to construction work since the concentrations are less the Occupational Safety and Health Administration (OSHA) permissible exposure limits (PELs). The OSHA PELs for toluene, ethylbenzene and xylenes are 200 ppm_v, 100 ppm_v and 100 ppm_v, respectively.

Total petroleum hydrocarbons (TPH) was monitored in the vapor headspace as a function of temperature, where TPH represents the total concentration of VOCs detected for gasoline range organics (GRO) and diesel range organics (DRO). Initial concentrations of TPH in the vapor headspace were below 12.5 ppm_v in the Cooper North and Sooper South Sump samples at 60 ^{o} F. However, TPH concentrations increased exponentially with increasing temperature. At 212 ^{o} F, the concentrations of TPH in the vapor headspace of samples from the Cooper North and Sooper South Sump were 259 ppm_v and 223 ppm_v, respectively. These data indicate that TPH (as petroleum distillates) will not present a health and safety issue with respect to construction work since the concentrations are less the OSHA PEL of 500 ppm_v for petroleum distillates.

The sludge samples collected from the Haack Rework Area had substantially lower concentrations of BTEX and TPH in the vapor headspace of the samples. Benzene and ethylbenzene were below detection limits of 0.5 ppm_v at all temperature ranges. The concentration of toluene in the vapor headspace of sludge was also below detection limits except at 212 ^{o} F where 0.8 ppm_v was detected in the vapor headspace. Xylenes were also below detection limits except at 212 ^{o} F where 2.5 ppm_v toluene was detected in the vapor headspace. TPH in the headspace was below detection limits at 60 ^{o} F, and increased to a maximum value of 26.6 ppm_v at 212 ^{o} F. These data indicate that the sludge samples collected from the Haack Rework Area on the Haack property are highly weathered. These sludge samples will also likely not present a threat to construction workers since the vapor concentrations of BTEX and TPH are well below the OSHA PELs.

3.1.7.2 H_2S and SO_2 Headspace Results

H_2S and SO_2 were monitored in the headspace of sludge samples at various temperatures. The results showed that these sulfurous gases were readily emitted from disturbed and heated sludge samples in the Cooper North and Cooper South Sumps. The vapor concentrations of SO_2 in equilibrium with sludge samples from both sumps exceeded 150 ppm_v at 60 ^{o} F. The vapor concentration of H_2S was 408 ppm_v for the Cooper North Sump and 471 ppm_v for the Cooper South Sump at 60 ^{o} F, but at higher temperatures it exceeded 500 ppm_v for both sumps. These data show that H_2S and SO_2 will both present an exposure risk to workers and the community if the sludge is disturbed for neutralization and stabilization treatment. The OSHA PELs for H_2S and SO_2 are 10 ppm_v and 2 ppm_v, respectively.

The sludge samples collected from the Haack Rework Area had substantially lower concentrations of H_2S and SO_2 in the vapor headspace. The vapor concentrations of SO_2 in equilibrium with sludge samples ranged from 8 to 71 ppm_v. The vapor concentration of H_2S ranged from 2 to 50 ppm_v. These data show that H_2S and SO_2 emissions from sludge on the Haack property could present an exposure risk to workers and the community if the sludge is disturbed for neutralization and stabilization. However, the sludge appears to be more highly weathered so emissions of H_2S and SO_2 will be much lower than the H_2S and SO_2 emissions that are likely to result from disturbing the sludge on the Cooper property.

3.1.8 Metal and Organic Mobilization

Treated and untreated composite samples of sludge from the Cooper North and Cooper South Sumps were sent to Merit Laboratories, Inc. for analyses of total RCRA metals, VOCs, SVOCs and PAHs and for analyses of leachable RCRA metals and organics by both the TCLP and SPLP. The relevant test results for the untreated sludge sample and treated sludge sample are attached in Table 17 and copies of laboratory analytical data are attached in Appendix B. The significance of the test results are discussed in the sections below.

3.1.8.1 Untreated Sludge Leachate

Analyses showed that the composite sludge sample contained 22.4 mg/kg lead and 1.2 mg/kg barium. The TCLP extract contained 0.24 mg/l lead and 0.06 mg/l barium, thus indicating that the sludge would not be characterized as a hazardous waste under the definitions and exclusions given in 40 CFR Part 21 for lead or barium, even in a final TCLP extract of pH 3.97. The SPLP extract contained 0.31 mg/l lead and less than 0.01 mg/l barium at a final SPLP extract pH of 2.15. Note that the SPLP extract had a lower pH than the TCLP, likely a result of acetate buffering in the TCLP extract. This indicates that the SPLP will be more likely to produce leaching effects in laboratory analyses than the TCLP.

The analyses for total SVOCs, PAHs and VOCs identified the following constituents in the sludge:

- Benzo(a)anthracene 70,000 ug/kg
- Chrysene 160,000 ug/kg
- 2-Methylnaphthalene 30,000 ug/kg
- Phenanthrene 200,000 ug/kg
- Pyrene 60,000 ug/kg
- Ethylbenzene 200 ug/kg
- Toluene 400 ug/kg
- Xylenes 1,000 ug/kg
- 2-methylnapthalene 1,900 ug/kg
- 1,2,4-trimethylbenezene 700 ug/kg
- 1,3,5-trimethylbenzene 500 ug/kg
- 1,2,3-trimethylbenzene 1,100 ug/kg

Despite the presence of these compounds within the sludge itself, no PAHs or SVOCs were identified in the SPLP extract for the untreated sludge above the detection limit of 5 ug/l. This indicates that the SVOCs and PAHs within the sludge are largely immobile. Toluene was detected in the SPLP extract of the untreated sludge at 7 ug/l and 1,2,3-trimethylbenzere was detected in the SPLP extract at 1 ug/l.

Analysis of the sludge for TPH as GRO and DRO showed that the sludge contained 70 mg/kg GRO and 39,000 DRO. This shows that only 3.9 percent of the sludge is comprised of organics in the C_6 to C_{28} hydrocarbon range, thus showing that the majority of organics in the sludge have a very high molecular weight in excess of 400.

3.1.8.2 Treated Sludge Leachate

Samples of composite sludge treated with a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$ at dosage rates of 22, 24, 26 and 28 percent reagent by weight with respect to the original mass of untreated sludge were subjected to SPLP testing. The results showed that the treatment produced non-detectable concentrations of RCRA metals and SVOCs in each of the SPLP extracts, with the exception of barium which was detected at 0.01 mg/l. This shows that the treatment reduced the concentration of leachable lead by the SPLP to less than 0.03 mg/l.

3.1.9 Long-term Leaching

A long-term leaching test was performed on a composite sludge sample from the Cooper North and Cooper South Sumps that was treated at dosage of 25 percent of the 50/50 (w/w) $Ca(OH)_2$ and $CaCO_3$ reagent mix. The sample was subjected to the SPLP extraction procedure daily, with new extract water being added to the sample after each SPLP extraction to evaluate the long-term leaching effects after multiple extractions. The leachate from every other extraction was filtered and sent to Merit Laboratories, Inc. for analyses of PNAs, RCRA metals and VOCs. The extracts were also tested in the laboratory for pH and alkalinity. The results of the analyses are shown in Table 18.

The long-term leach tests produced similar results to the standard SPLP. Barium was detected at 0.01 to 0.02 mg/l in the first six sequential SPLP extracts, but was below detection limits in the eighth and tenth extractions. Ethylbenzene was detected at 0.001 mg/l in all of the sequential SPLP extractions except the tenth extraction which was below detection limits. An initial toluene concentration of 0.007 mg/l was detected in the second and fourth sequential extraction, but concentrations slowly decreased to 0.003 mg/l by the eighth and tenth extraction. The concentrations of 1,2,4-trimethylbenzene and 1,2,3-trimethylbenzene were each in the range of 0.002 to 0.003 mg/l throughout the sequential extraction process. Acetone was detected in most of the extracts at a concentrations ranging from 0.05 to 0.09 mg/l, and 2-methylnaphthalene was detected only in the fourth sequential extraction at a concentration of 0.005 mg/l.

There are three significant observations from the long-term leaching test. First, lead did not leach from the sludge even after ten sequential SPLP extractions, thus indicating that treatment of the sludge with CaO and $CaCO_3$ provides long-term stability for lead. Second, trace concentrations of barium, ethylbenzene, toluene and xylenes leached from the treated sludge, but the concentrations were well below the primary drinking water standards. Finally, trace concentrations of trimethylbenzene isomers, 2-methylnapthalene and acetone leached from the treated sludge, but there are no primary or secondary drinking water standards for these compounds.

Alkalinity analyzes showed that the average alkalinity of the SPLP leachates was 20 mg/l. Therefore, an estimated 0.2 grams of $CaCO_3$ was removed from the treated sludge during the ten sequential extractions compared to the 5 grams of $CaCO_3$ originally added to the sludge. This shows that only 4 percent of the alkalinity was removed from the sludge during the ten

sequential extractions, thus indicating that the many more extractions could have been performed while still maintaining alkaline stability in the treated material.

3.1.10 Permeability

Composite samples of untreated and treated sludge from the Cooper North and Sooper South Sumps were tested for permeability. The treated sample consisted of a composite sludge sample treated with 15 percent calcium hydroxide and 15 percent $CaCO_3$ fines by weight. The testing was performed using disposable permeability to avoid hydrocarbon and acid fouling of the acrylic cylinders and o-rings in a standard permeability cells. The permeability cells contained a remolded sludge cylinder that was 1.048 inches in diameter and one foot in length. A five-foot column of water was placed over the sludge. After the cells were constructed, they were placed into operation and inspected regularly to assure that the head of water on the columns was maintained at five feet. The volume of water collected from the burettes at the bottom of the columns was monitored over time to quantify the flow of water through the column as a function of time. These data were used to calculate the hydraulic conductivity of the sludge using Darcy's Law:

In the cell containing untreated sludge, no water permeated through the cell during four weeks of testing, thus indicating that the permeability is less than 1×10^{-8} cm/sec. For the treated sample of sludge, the material was saturated with water inside the cell prior to testing because the permeability was anticipated to be much higher. When testing was initiated after allowing for 24 hours of equilibrium, testing showed that water flowed through the compacted material at a high flowrate averaging 15 ml/min or 0.25 cm^3/sec. Using Darcy's Law, the hydraulic conductivity of the treated sample was calculated to be 9×10^{-3} cm/sec which is characteristic of silty sand.

3.1.11 Evaluation of a Soil Additive

Four composite samples of sludge were treated with 25 percent reagent comprised of a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$. Prior to adding the reagent, the samples were amended with 0, 25, 50 and 75 percent soil by weight using a composite Site soil sample prepared from borings CPB-2, CPB-6, CPB-14 and CPB-18. The soil was added to determine if it could improve the physical properties of the treated sludge during bituminous stabilization. The reagent was quickly mixed into the samples which were then immediately placed into insulated containers to measure reaction kinetics. After 24 hours of cure time, the samples were tested for compressive strength, density, volume expansion and pH. The results of the tests are summarized in Tables 19 and 20.

The testing showed that the addition of soil to the neutralized sludge improved the density of the treated material and maintained high strength. Because the sludge at the Site is so viscous, it was difficult to assess how the soil additive worked as a stabilization material for bituminous stabilization at ambient temperatures. Therefore, samples of neutralized sludge treated with 0, 25, 50 and 75 percent soil were compacted into cores using a Harvard compaction apparatus and the cores were placed into a convection oven at $220\ ^0$ F to test the stability of the sludge. A photograph of the cores after 24 hours of heating is shown in Figure 7. The testing showed that the neutralized samples containing no soil exhibited viscoelastic flow at $220\ ^o$ F. The samples containing 25 percent soil exhibited minor viscoelastic properties, and the samples containing 50 and 75 percent soil by weight exhibited no viscoelastic properties. These test results show that the addition of 50 percent soil to neutralized sludge by weight converts the sludge into a stable solid material, even at elevated temperatures that exceed the softening point of the sludge.

3.1.12 Evaluation for Thermal Treatment

Sample analysis using EPA Method 8270 detected five SVOCs and/or PAHs in the sludge as summarized in Section 3.1.8.1. The analytical data are summarized in Table 21 and are included in Appendix B. Although the sludge was found to contain approximately 4 percent diesel-range organics, the majority of hydrocarbon in the sludge was comprised of very large-chain hydrocarbons having a molecular weight greater than 400. When the sludge was tested for BTU value, it was found to have a very high heating value of 13,000 BTUs per pound. This confirms that the sludge is comprised primarily of organics. However, the sludge also had an elevated sulfur content of approximately 7 percent. This high sulfur content suggests that incineration or fuel combustion of the sludge is not a viable treatment alternative due to the large amount of SO_2 gas that would be emitted during combustion. Over 1,800 cubic feet (280 pounds) of SO_2 gas could be emitted for each ton of sludge incinerated or combusted. Site-wide, the total mass of SO_2 generated by thermal treatment of the sludge would exceed 2,600 tons. Due to health and safety considerations and the high cost of vapor treatment, incineration is not recommended for the sludge.

3.1.13 Evaluation of Moisture/Density Relationship

Four samples of sludge treated with 25 percent of a 50/50 (w/w) mix of $Ca(OH)_2$ and $CaCO_3$ were tested for moisture/density relationship to determine optimal dry density and moisture content for compaction after treatment. Testing was performed on a sample without soil amendment and on three samples amended with 25, 50 and 75 percent soil by weight with respect to the initial weight of untreated sludge. Samples were amended with differing amounts of water and compacted with the Harvard compaction apparatus to develop a moisture/density relationship for each sample. The results of the analyses are attached in Appendix C.

The test results showed that the neutralized sludge without soil amendment had a very low maximum dry density of 52.3 lb/ft^3 and high optimum moisture content of 46.7 percent. When the neutralized sludge was amended with 25 percent soil, the maximum dry density increased to 64.1 lb/ft^3 and the optimum moisture content decreased to a more reasonable value of 29.5 percent. The neutralized sludge sample amended with 50 percent soil had a maximum dry density of 68.8 lb/ft^3 and an optimum moisture content of 25.7 percent, and the sample amended with 75 percent soil had a maximum dry density of 71.6 lb/ft^3 and an optimum moisture content of 24.4 percent. The Harvard compaction data are summarized in Figure 8. A review of the graph shows the maximum dry density becomes asymptotic near 70 lb/ft^3 and optimum moisture contents approach 25 percent in this range. These values can therefore be used as target values for treatment with soil amendment because they correspond to optimum density and moisture values at soil amendment ratios that also demonstrated stability under thermal stress as described in Section 3.1.11.

3.1.14 Testing for Asphaltic Qualities

In a January 15, 2003 letter to DTSC, Mr. Cooper outlined a remedial alternative for clean-up of the Gardena Sumps. Mr. Cooper stated that sludge in the Cooper North and Cooper South Sumps yielded properties for petroleum characteristics including an API gravity of about ten, a flash point greater than 400 ^{o}F, and a pour point exceeding 150 ^{o}F. In addition, Mr. Cooper noted that the pH around 2.0 was due to a two-phase mixture of oil and water. Mr. Cooper acknowledged slightly elevated levels of certain metals in the sludge, but attributed the presence of lead in the sludge to automobile exhaust emissions (with lead as a component) due to the close proximity of the sumps to the highway. Mr. Cooper estimated the volume of sludge in the Cooper North and Cooper South Sumps to be approximately 15,000 cubic yards (~15,000 tons) based upon a sump depth of four to six feet BGS. Mr. Cooper considered two remedial

option alternatives: (1) recycling by on-site excavation and on-site treatment by heating and mixing with caustic solution to raise pH, followed by off-Site transport; and (2) on-site excavation and off-site transport to a facility for processing to make the material commercially acceptable. To evaluate the potential for the two recycling options, samples of the sludge were tested for comparison purposes to ASTM asphalt standards.

Due to the heavy nature of the sludge, the end use for sludge neutralized with sodium hydroxide would be limited to either (1) asphalt cement for use in pavement construction or (2) roofing asphalt. Both types of asphalt have different grade classifications based largely on viscous properties. Asphalt cement can be classified either by viscosity (AC-2.5, AC-5, AC-10, AC-20, AC-30 or AC-40) with the AC-2.5 being the least viscous (~250 poise) and the AC-40 being the most viscous (~4,000 poise), or it can be classified by penetration (40-50, 60-70, 85-100, 120-150 or 200-300) where the 40-50 asphalt is least penetrable (4 to 5 mm by ASTM D5) and the 200-300 asphalt is most penetrable (20 to 30 mm by ASTM D5). Roofing asphalts are classified as Type I, Type II, Type III or Type IV with the Type I being the least viscous and the Type IV being the most pitch-like. All of these asphalts must meet specific qualifications for marketability. A summary of some of these specifications are shown in Tables 22 to 24.

Historic attempts to recycle this type of material for use in asphalt have failed because the material is generally "inferior in quality."[1] However, testing was performed on the sludge as part of this treatability study to determine if the sludge had suitable characteristics to meet the specifications for any of the asphalt categories described above. The results of the testing are summarized in the sections below.

3.1.14.1 Viscosity Specifications for Asphalt

The resistance that a material exhibits to flow (the ratio of shearing stress to rate of shear) is called viscosity. Materials with a low viscosity require very little shear stress to induce flow, while materials with high viscosity require a great deal of shear stress. Viscosity is typically reported in terms of cP which is equivalent to one kg/cm-sec.

Asphalt cements are named after their viscosity grade. The main asphalt cement grades are AC-2.5, AC-5, AC-10, AC-20, AC-30, AC-40. The viscosity tests are typically performed by measuring the time it takes for a fixed volume of the liquid to flow through a calibrated glass capillary viscometer beneath an accurately reproducible head and at a controlled temperature. However, testing laboratories have determined that sludge is too viscous to be measured by capillary viscometers. Therefore, viscosity testing was performed on samples of sludge from each boring using a viscometer designed for testing of asphalts with high viscosities.

The results of the testing showed that the viscosity of the sludge at 140 ^{0} F ranged from 19,000 to 26,000 poise. Viscosity-graded asphalt specifications fall into the range of 200 to 4,800 poise. Based on these analyses, the sludge appears to be too viscous and pitch-like to meet the specifications for viscosity-graded asphalt cement used in pavement construction. Penetration-graded asphalt cement and roofing asphalt do not have a viscosity specification.

3.1.14.2 Penetration Specifications for Asphalt

Penetration testing is a specification that pertains to asphalt cements in pavement construction and roofing asphalts. This test is performed according to ASTM standards at a temperature of 77 ºF (25 º C). The conventional test involves placing a needle onto the asphalt with a 100-

[1] W.A. Gruse and D.R. Stevens, The Chemical Technology of Petroleum, McGraw-Hill Book Company, 1942, pg 642.

gram weight affixed to the needle. The weighted needle is allowed to penetrate the asphalt for period of five seconds, and the depth of the penetration is then measured in tenths of a millimeter. The asphalt is then graded based on the depth of penetration, with the penetration value corresponding directly to the depth in tenths of a millimeter that the needle punctured the asphalt over the five second time interval.

Penetration testing was performed on samples of sludge using modified ASTM D 5. The testing showed that the sludge had a penetration value of approximately 10 to 15. This value is too low to meet the requirements for asphalt cement used in pavement construction.

The penetration specifications for roofing asphalt are as follows:

- Type I 18 to 60
- Type II 18 to 40
- Type III 15 to 35
- Type IV 12 to 15

The penetration value of the sludge does fall with the penetration value range of the most viscous roofing asphalt (Type IV).

3.1.14.3 Solubility in Specifications for Asphalt

The ASTM testing method D 2042 is a testing method to determine the solubility level of an asphalt specimen with little or no mineral matter. All roofing asphalts and asphalt cements require a solvent solubility of at least 99 percent. The purpose for this test is to determine the active organic cementing constituents (i.e. bitumen) in the asphalt specimen.

This test was modified for use with the sludge using acetone as the solvent. Weighted samples of sludge were dissolved in acetone and were then filtered using Whatman No. 2 filter paper to determine the amount of solids in the sludge. The filter paper was then further flushed with three successive rinses of 50 ml of acetone. The testing showed that the solubility of sludge in solvent was approximately 93 percent with the remaining percentage of non-soluble constituents appearing to be coke fines. These values indicate that the asphalt contains too many coke fines to meet the specifications for asphalt cement or roofing tar.

3.1.14.4 Ductility Specifications for Asphalt

The ductility of a bituminous material is measured by elongating a specimen of the material at a specified temperature and speed, and determining how far it will stretch before it breaks into two separate pieces. This test is generally run at a temperature of 25 ± 0.5 ºC, and at a speed of 5 cm/min ± 5.0%. The ASTM D 113 procedure requires that the sample be heated to a temperature so it is fluid enough to pour into a mold on a brass plate coated with glycerin or some substance to prevent the sample from sticking. The mold holding the sample is then cooled to room temperature for a period of 30 to 40 minutes and placed in a water bath. The sample is completely submerged and maintained at the specified temperature for 30 minutes. The sample is then removed and immediately tested. The distance that the sample stretches in centimeters before the specimen ruptured is its ductility.

Samples of sludge were heated at temperatures in accordance with the thin-film oven test and poured into a clay mold to simulate the dimensions shown in the ASTM D 133 test for ductility. However, when any amount of stress was placed on the specimens, the samples immediately broke apart due to the brittle, pitch-like characteristics of the sludge. Ductility specifications for

asphalt cement are in the range of 10 to 100 cm, and ductility specifications for roofing asphalt are in the range of 1.5 to 10 cm. The Site sludge will not meet these specifications due to its brittle, pitch-like nature.

3.1.14.5 Softening Point Specifications for Asphalt

The softening point of the sludge samples from the Site ranged from 158 to 185 ^{o}F. Asphalt cement used for construction of pavement generally does not have a softening point specification. However, asphalt used for roofing has the following specifications:

- Type I 135 to 151 ^{o}F
- Type II 158 to 176 ^{o}F
- Type III 185 to 205 ^{o}F
- Type IV 210 to 225 ^{o}F

Therefore, the softening point analyses indicate that the sludge would fall into acceptable softening point ranges for a Type II roofing asphalt.

3.1.14.6 API Gravity

The petroleum industry often classifies petroleum products in terms of an API scale rather than in terms of density. The API scale was developed based on the fact that most petroleum hydrocarbon substances have a specific gravity falling into the range of 0.768 to 0.996 grams per cubic centimeter (g/cc). The calculation for API gravity is as follows:

$$\text{API Gravity} = (141.5/\rho) - 131.5$$

The term ρ is the specific gravity of the material at 60 ^{o}F in units of g/cc. Testing showed that the specific gravity of all of the sludge samples exceeded 1.0. Based on these values, the sludge would produce a negative API gravity value. This indicates that the API gravity of the sludge is generally lower than 10 as was reported by previous testing.

3.1.14.7 Summary of Asphalt Testing

Testing of the sludge indicates that it will have low marketability as recycled asphalt, even when neutralized, for the following reasons:

- The sludge is a brittle, glass-like material with little to no ductility;
- The viscosity of the sludge is too high for use as asphalt cement in road construction;
- The sludge contains a high concentration of impurities and suspended solids which causes it to fail to meet the test for asphalt solubility for both asphalt cement and roofing asphalt;
- The sludge has a negative API gravity;
- The softening point falls into acceptable ranges for a Type II roofing asphalt, but the sludge fails to meet most of the remaining specifications for Type II roofing asphalt; and
- Penetration values for the sludge were too low for use as asphalt cement but meet the specifications for Type IV roofing asphalt.

Although the sludge shares the softening point specifications for Type II roofing asphalt and the penetration specifications for Type IV roofing asphalt, it fails to meet the ductility requirements for either of these asphalt grades. The brittle nature of the material gives it undesirable

properties because the material is easily cracked and sheared, thus making it unsuitable for roofing or pavement construction applications.

3.2 Comparison to Test Objectives

The following objectives for the treatability study were achieved:

- The physical characteristics (strength, viscosity, softening point, density, moisture, permeability, ductility and penetration value) and chemical characteristics (acidity, pH, hydrocarbon composition, heating value and solvent solubility) were determined for sludge samples collected from the Site;

- The most suitable chemical reagent mixture for treatment of sludge was determined to be a 50/50 (w/w) mix of $Ca(OH)_2/CaCO_3$ with dosages in the range of 20 to 30 percent reagent to sludge by weight providing effective neutralization of the sludge;

- The stabilization/neutralization testing demonstrated that neutralization of the sludge with the 50/50 (w/w) mix of $Ca(OH)_2/CaCO_3$ and 50 percent soil amendment improved the strength properties of the sludge by eliminating its viscoelastic flow properties and providing for a compacted compressive strength that exceeded 50 pounds per square inch (psi);

- The vapor evolution testing showed that there was a high potential to release sulfurous gases (H_2S and SO_2) by disturbing or heating the sludge;

- SPLP testing showed that lead was partially soluble (0.04 mg/l) in untreated sludge (although largely immobile due to low permeability), and that lead in the treated sludge was immobile due to low solubility (<0.005 mg/l), while all other constituents in the sludge were largely immobile;

- Long-term leaching tests on the treated sludge showed that after multiple extractions, lead was effectively immobilized, PAHs remained immobile, and select VOCs leached from the sludge, but at concentrations below drinking water standards; and

4.0 CONCLUSIONS AND RECOMMENDATIONS

The following conclusions and recommendations can be drawn from the results of the treatability testing:

4.1 Conclusions

- The acidity of the sludge ranges from 6.1 to 20.8 percent acidity in reference to $CaCO_3$ acidity per EPA Method 305.2;

- Sludge in the Cooper South Sump has the highest average acidity (19 percent as $CaCO_3$) while the sludge in the Cooper North Sump and Haack Rework Area averaged 12.9 and 10.4 percent, respectively;

- Soil samples collected from below the Cooper North and Cooper South Sumps had a neutral to slightly basic pH, but soil samples collected from 10 feet below grade at the location of the Haack Rework Area had a low pH value around 3.0;

- Density testing showed that the sludge density ranged from 63 to 79 lb/ft^3,

- The moisture in the sludge ranges from 9.8 to 25.6 percent on a wet basis;

- The viscosity of the sludge at 140 ^{o} F ranged from 1,700,000 to 2,500,000 cP, thus showing that the sludge has solid-like properties, but also that the sludge is subject to slow viscoelastic deformation and flow;

- The softening point of the sludge ranged from 158 ^{o} F to greater than 210 ^{o} F;

- The most suitable chemical reagent mixture for treatment of sludge was determined to be a 50/50 (w/w) mix of $Ca(OH)_2/CaCO_3$ with dosages in the range of 20 to 30 percent reagent to sludge by weight providing effective neutralization of the sludge with the addition of 10 percent water to drive the necessary neutralization reactions;

- Disrupting or heating the sludge will result in the release of H_2S and SO_2 gases, but the release of VOCs from the sludge should be *deminimus* unless the sludge is heated;

- SPLP testing produced lower leachate pH values when compared to TCLP extractions;

- The SPLP extracts for untreated sludge contained 0.31 mg/l lead, but lead was below the detection limits of 0.03 mg/l in SPLP extracts for treated sludge;

- Long-term leaching tests showed that the treated sludge maintained sufficient alkalinity over multiple extractions to provide for continued stabilization of lead;

- The permeability of the untreated sludge was less than $1x10^{-8}$ cm/sec due to the monolithic, asphaltic, properties of the untreated sludge, but the permeability of the material increased to $9x10^{-3}$ cm/sec after treatment;

- The addition of 50 percent soil to the sludge during treatment provided bituminous stabilization of the sludge that eliminated the viscoelastic flow properties of the sludge when heated to temperatures as high as 220 ^{o} F;

- The sludge has a high BTU value of 13,000 BTUs/lb, but the high sulfur content of the sludge (7 percent sulfur) would make incineration or use of the sludge as a fuel prohibitively expensive due to sulfur-removal and vapor treatment requirements;

- The target moisture content and dry density for treated sludge are 25 percent moisture content on a dry basis (33 percent wet basis) and 70 lb/ft^3 which can be achieved by the addition of 50 percent soil to the neutralized sludge;

- Testing for asphaltic qualities of the sludge indicates that it will be unsuitable for use as recycled asphalt for road construction or roofing since it has no ductility, high viscosity, and high solids content; and

4.2 Recommendations

The treatability testing shows that sludge at the Site can be treated in a manner that neutralizes acidity, neutralizes acid gases (H_2S and SO_2), fixates lead, and provides long-term strength properties by eliminating viscoelastic deformation. These properties can be accomplished by treating the sludge with a 50/50 (w/w) mix of $Ca(OH)_2/CaCO_3$ at an average dosage of 25 percent reagent to sludge by weight. The addition of water is required (approximately 10 percent by weight) to drive the necessary neutralization reactions, and the addition of 50 percent soil by weight is required for effective solidification.

Although the methodology described above can be used to treat the sludge, disruption of the sludge releases H_2S and SO_2 gas. These gases are stable and safely encapsulated when the sludge is undisturbed. Similar sludge projects like the McColl Superfund Site in Fullerton, California, Thomas Ranch in Corora, California, and the Whitehouse Waste Oil Pits in Whitehouse, Florida are examples of sites that were originally slated for excavation and/or treatment. However, the selected remedies were later changed to capping due to concerns about worker safety, vapor emissions, odors, and/or the effectiveness of treatment versus capping. These factors should be strongly considered for this Site as well since the sludge has a high potential to release H_2S and SO_2 gas. Furthermore, although treatment can provide fixation of contaminants and eliminate viscoelastic deformation, the final treated material will still contain high concentrations of calcium sulfate after treatment. Calcium sulfate is highly hydrophilic which can increase the swelling potential of soils as a function of moisture. This might have implications on future development if the treated material were left in place.

Report Summary

Lab Sample ID(s): S25980.01-S25980.06
Project: 37BP.XB006.05
Submitted Date/Time: 02/28/2006 09:45
Sampled by: Daniel Oberle
P.O. #: 37BP.XB006.0

Report Notes

Results relate only to items tested as received by the laboratory.
Methods may be modified for improved performance.
Results reported on a dry weight basis where applicable.
"Not detected" indicates that parameter was not found at a level equal to or greater than the RDL.
Report shall not be reproduced except in full, without the written approval of Merit Laboratories.

Report Summary

Lab Sample ID(s): S26158.01-S26158.05
Project: 37BP.XB006.06
Submitted Date/Time: 03/10/2006 10:30
Sampled by: Dan Oberle
P.O. #: 37BP.XB006.0

Report Notes

Results relate only to items tested as received by the laboratory.
Methods may be modified for improved performance.
Results reported on a dry weight basis where applicable.
"Not detected" indicates that parameter was not found at a level equal to or greater than the RDL.
Report shall not be reproduced except in full, without the written approval of Merit Laboratories.

Analytical Laboratory Report

Lab Sample ID: S26158.04
Sample Tag: LTL-8
Collected Date/Time: 03/09/2006
Matrix: Water
COC Reference: 029271

Sample Containers

#	Type	Preservative(s)	Refrigerated?	Arrival Temp. (C)	Thermometer #
1	1 L Amber	None	Yes	3.5	IR
1	125ml Plastic	HNO3	Yes	3.5	IR
2	40 ml Glass	HCL	Yes	3.5	IR

Analysis	Results	Units	RDL	Method	Run Date/Time	Analyst	CAS #	Flags

Acrylonitrile	Not detected	ug/L	2	8260B	03/17/06 16:44	JGH	107-13-1	
Bromobenzene	Not detected	ug/L	1	8260B	03/17/06 16:44	JGH	108-86-1	
Bromochloromethane	Not detected	ug/L	1	8260B	03/17/06 16:44	JGH	74-97-5	
Dibromomethane	Not detected	ug/L	5	8260B	03/17/06 16:44	JGH	74-95-3	
Dichlorodifluoromethane	Not detected	ug/L	5	8260B	03/17/06 16:44	JGH	75-71-8	
Diethyl ether	Not detected	ug/L	10	8260B	03/17/06 16:44	JGH	60-29-7	
Hexachloroethane	Not detected	ug/L	5	8260B	03/17/06 16:44	JGH	67-72-1	
Methyl iodide	Not detected	ug/L	1	8260B	03/17/06 16:44	JGH	74-88-4	
Tetrahydrofuran	Not detected	ug/L	90	8260B	03/17/06 16:44	JGH	109-99-9	
Trichlorofluoromethane	Not detected	ug/L	1	8260B	03/17/06 16:44	JGH	75-69-4	
1,2,3-Trimethylbenzene	3	ug/L	1	8260B	03/17/06 16:44	JGH	526-73-8	
trans-1,4-Dichloro-2-butene	Not detected	ug/L	1	8260B	03/17/06 16:44	JGH	110-57-6	

Analytical Laboratory Report

Merit Laboratories, Inc.

Lab Sample ID: S26158.05
Sample Tag: LTL-10
Collected Date/Time: 03/09/2006
Matrix: Water
COC Reference: 029271

Sample Containers

#	Type	Preservative(s)	Refrigerated?	Arrival Temp. (C)	Thermometer #
1	1 L Amber	None	Yes	3.5	IR
1	125ml Plastic	HNO3	Yes	3.5	IR
2	40 ml Glass	HCL	Yes	3.5	IR

Analysis	Results	Units	RDL	Method	Run Date/Time	Analyst	CAS #	Flags
Extraction / Prep.								
Mercury Digestion	Completed			7470A	03/10/06 10:30	JRT		
Metal Digestion	Completed			3015A	03/14/06 12:00	SLS		
PNA Extraction	Completed			3510C	03/13/06 13:46	EMR

Sylvania, OH 43560

Project:	Gardena Sumps
Job No.:	37BP.XB006.06
Task:	3236.0
Sample ID:	Neutralized Sludge #1
Tested By:	DWO
Date:	3/19/2006

MOISTURE/DENSITY RELATIONS FOR FINE-GRAINED SOILS (ASTM D 698)

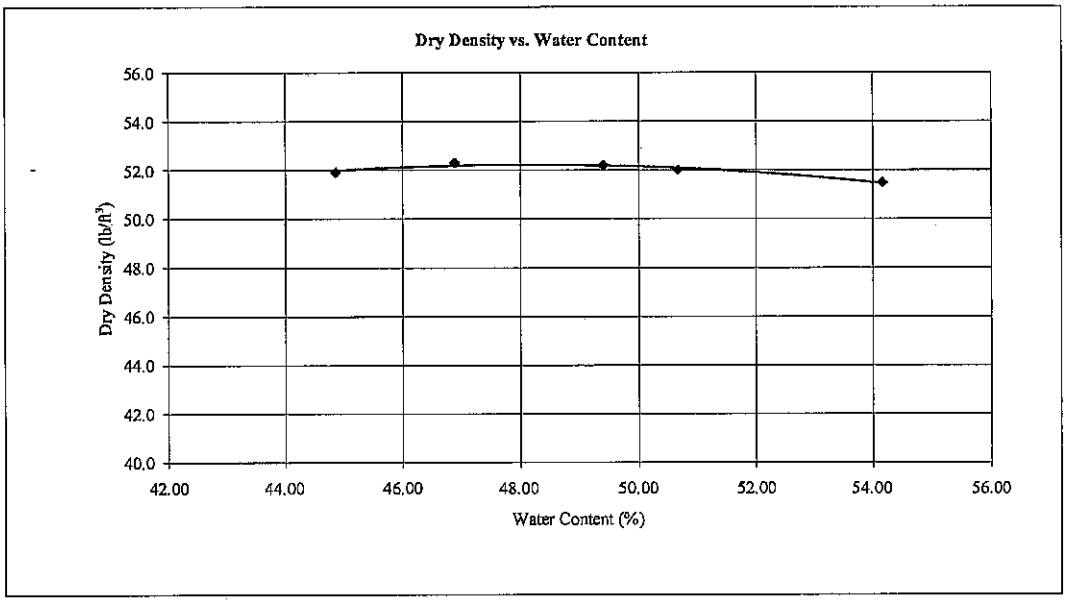
Standard Compactive Effort Using the Harvard Miniature Compaction Apparatus

Soil Description:

Neutralized Acid Sludge - No Soil Addition

Harvard Miniature Compaction Test

Initial Soil Data



Mass of Tare =	2.03	grams
Mass of $Soil_{Moist}$ =	78.3	grams
Mass of $Soil_{Dry}$ =	54.3	grams
Mass of Water =	24	grams
Initial Water Content =	44.20	%

Compaction Mold Data

Mass of Mold =	185.00	grams
Volume of Mold =	6.24E-05	m^3

Compaction Data

Target ω (%)	Water Added (grams)	Tare Mass (grams)	Tare + $Soil_{wet}$ (grams)	Tare + $Soil_{dry}$ (grams)	Wet Material (grams)	Dry Material (grams)	Actual ω (%)	Wet Density (Mg/m^3)	Dry Density (Mg/m^3)	Dry Density (lb/ft^3)
44	0.0	2.03	77.26	53.96	75.23	51.93	44.87	1.21	0.83	51.9
46	2.0	2.04	78.88	54.35	76.84	52.31	46.89	1.23	0.84	52.3
48	3.0	2.04	80.02	54.23	77.98	52.19	49.42	1.25	0.84	52.2
50	4.0	2.04	80.39	54.04	78.35	52.00	50.67	1.26	0.83	52.0
52	5.0	2.05	81.40	53.52	79.35	51.47	54.17	1.27	0.82	51.5

Maximum Dry Density	
(Mg/m^3)	(lb/ft^3)
0.84	52.3

Optimum Water Content (%)
46.7

Comments:

Analysis was conducted using standard 20 lb. spring with 25 tamps per lift.

APPENDIX C

Risk-Based Concentration Derivation

DERIVATION OF RBCS

The results of the Human Health Risk Assessment (HHRA) indicated that areas of the Site may potentially exceed target risk goals (e.g., greater than 1×10^{-4} to 1×10^{-6}) under current and potential future uses. To assist in the Feasibility Study (FS), Site-specific risk-based concentrations (RBC) for the chemicals of concern (COCs) have been derived. The RBCs represent the concentrations of chemicals in the relevant environmental media (e.g., soil, soil gas, and groundwater) that would be considered safe for current and future land uses under conservative (i.e., protective) exposure conditions. RBCs can be used to identify individual sample locations where chemical concentrations exceed the RBC and if any additional actions (e.g., investigation, remediation, engineering controls, or institutional controls) are warranted.

RBCs were developed for each chemical identified as a COC or "risk driver" in the risk characterization of the HHRA (Geosyntec, 2010) based on each receptor group and assuming site-specific soil characteristics. For worker exposures (commercial/industrial and construction worker), chemicals that contributed to a risk greater than 1×10^{-5} were included, for residential and trespasser scenarios a 1×10^{-6} risk threshold was used. RBCs were derived for arsenic, benzo(a)pyrene equivalent (BaP-eq), hexavalent chromium, benzene, and naphthalene in soil; benzene in soil gas; and dibenz(a,h)anthracene in groundwater.

RBCs were derived for commercial/industrial, construction, residential, and trespasser scenarios using the Conceptual Site Model (CSM), exposure algorithms, exposure assumptions and toxicity criteria employed in the quantitative HHRA (Geosyntec, 2010). The RBCs are considered in the selection of Site-specific Action Levels (SSALs) for use in the Feasibility Study. Site-specific action levels are applied to the COCs within each environmental media and can be based on risk assessment (RBCs) or background concentrations. Background concentrations, as discussed in Section 2.2 of the HHRA (Geosyntec, 2010), are selected as the SSAL for chemicals in which RBCs are below background. This is the case for arsenic and BaP-eq for the residential scenario.

The following section presents the methodology used to derive soil, soil gas, and groundwater RBCs for the COCs identified in the HHRA.

1. Methodology

Deriving RBCs for COCs in soil, soil gas, and groundwater requires information regarding the level of human intake of the chemical (exposure assessment), the relationship between intake of the chemical and its toxicity (toxicity assessment), and the acceptable target risk. The sections below present the equations used in the development

of RBCs for soil, soil gas, and groundwater, which is consistent with agency guidance used in the HHRA. The methodology used to derive the RBCs for the selected COCs is based principally on guidance provided by the USEPA (1989; 1991) and the Cal-EPA (1999).

Various demarcations of acceptable risk have been established by regulatory agencies. The USEPA has established acceptable levels of risk at Superfund sites. The National Oil and Hazardous Substances Pollution Contingency Plan (NCP; 40 CFR 300) indicates that lifetime incremental cancer risks posed by a site should not exceed a range of one in one million (1×10^{-6}) to one hundred in one million (1×10^{-4}) and noncarcinogenic chemicals should not be present at levels expected to cause adverse health effects (i.e., a Hazard Index [HI] greater than 1). Additional risk management considerations such as technical feasibility, economic, social, political, and legal factors may be part of the final risk management decision. The DTSC considers the 1×10^{-6} risk level as the generally accepted point of departure for unrestricted land use. A target risk level of 1×10^{-5} is frequently used for construction and commercial/industrial exposure scenarios.

A target risk level of 1×10^{-5} and a noncancer hazard index of 1 were used to derive commercial/industrial and construction worker RBCs. The target risk of 1×10^{-5} is the midpoint of the cancer risk range considerable acceptable to USEPA (USEPA, 1991) and the target risk commonly used at commercial/industrial sites under DTSC oversight. For residential and trespasser receptor groups, a risk level of 1×10^{-6} and a noncancer hazard index of 1 were used.

1.1 RBCs for Soil, Soil Gas, and Groundwater: Cancer Health Effects

The equations below describe the relationship between estimated intake, toxicity, and potential risk for cancer health effects (USEPA, 1989).

For COCs in Soil:

$$RBC_S_C = \frac{TR}{(CSF_{oral})\times(IF_{oral} + IF_{dermal}) + (URF)\times(IF_{inh,s})}$$

For COCs in Soil Gas:

$$RBC_SG_C = \frac{TR}{(URF)\times(IF_{inh,v})}$$

For COCs in Groundwater:

$$RBC_GW_C = \frac{TR}{\left(CSF_{oral} \times IF_{dermal,GW}\right)}$$

Where:

RBC_S_C	=	risk-based concentration for soil based on cancer effects (mg/kg);
TR	=	target cancer risk level (unitless);
CSF_{oral}	=	cancer slope factor for oral (ingestion and dermal contact) exposures $(mg/kg \cdot d)^{-1}$;
IF_{oral}	=	intake factor for ingestion (kg soil per kg body weight per day);
IF_{dermal}	=	intake factor for dermal contact (kg soil per kg body weight per day);
URF	=	inhalation unit risk factor $(\mu g/m^3)^{-1}$;
$IF_{inh,s}$	=	intake factor for inhalation of COCs from soil (mg/m^3 per mg/kg);
RBC_SG_C	=	risk-based concentration for soil gas to indoor air based on cancer effects (mg/m^3);
$IF_{inh,v}$	=	intake factor for indoor inhalation of COCs (mg/m^3 per mg/m^3);
RBC_GW_C	=	risk-based concentration for dermal contact with groundwater based on cancer effects (µg/L); and
$IF_{dermal,GW}$	=	intake factor for dermal contact with COCs in groundwater (mg per event per kg body weight per day).

The formulas for developing the soil, soil gas, and groundwater intake factors, the exposure parameters that were used to estimate the intake factors, as well as the oral CSFs and inhalation URFs for COCs were presented in the HHRA. The exposure parameters, emission factors and toxicity factors are reproduced in this document and are presented in **Tables 1, 2** and **3**, respectively. Derivation of the RBCs for carcinogens is presented in **Attachment A**. The vapor intrusion model spreadsheets are presented in **Attachment B**.

1.2 RBCs for Soil, Soil Gas, and Groundwater: Noncancer Health Effects

The equations below describe the relationship between estimated intake, toxicity, and risk for noncancer health effects (USEPA, 1989).

For COCs in Soil:

$$RBC_S_{NC} = \frac{THI}{\left(\frac{IF_{oral}}{RfD_{oral}}\right) + \left(\frac{IF_{dermal}}{RfD_{oral}}\right) + \left(\frac{IF_{inh,s}}{RfC}\right)}$$

For COCs in Soil Gas:

$$RBC_SG_{NC} = \frac{THI}{\left(\frac{IF_{inh,v}}{RfC}\right)}$$

For COCs in Groundwater:

$$RBC_GW_{NC} = \frac{THI}{\left(\frac{IF_{dermal,GW}}{RfD_{oral}}\right)}$$

Where:

RBC_S_{NC}	=	risk-based concentration for soil based on noncancer effects (mg/kg);
THI	=	target noncancer hazard index (unitless);
IF_{oral}	=	intake factor for ingestion (kg soil per kg body weight per day);
RfD_{oral}	=	noncancer reference dose for oral (ingestion and direct-contact) exposures (mg/kg·d);
IF_{dermal}	=	intake factor for dermal contact (kg soil per kg body weight per day);
$IF_{inh,s}$	=	intake factor for inhalation of COCs from soil (mg/m^3 per mg/kg from soil);
RfC	=	noncancer reference concentration for inhalation exposure (mg/m^3);
RBC_SG_{NC}	=	risk-based concentration for soil gas to indoor air based on noncancer effects (mg/m^3);
$IF_{inh,v}$	=	intake factor for indoor inhalation of COCs (mg/m^3 per mg/m^3);
RBC_GW_{NC}	=	risk-based concentration for dermal contact with groundwater based on noncancer effects (µg/L); and
$IF_{dermal,GW}$	=	intake factor for dermal contact with COCs in groundwater (mg per event per kg body weight per day).

The formulas for developing the soil, soil gas, and groundwater intake factors, the exposure parameters that were used to estimate the intake factors, as well as the noncancer oral RfDs and inhalation RfCs for COCs were presented in the HHRA. The exposure parameters, emission factors and toxicity factors are reproduced in this document and are presented in **Tables 1, 2** and **3**, respectively. Derivation of the RBCs for noncarcinogens is presented in **Attachment A**. The vapor intrusion model spreadsheets are presented in **Attachment B**.

2. RBC and SSAL Results

The RBCs for soil are presented in **Table 4**, for soil gas in **Table 5**, and for groundwater in **Table 6**. RBCs are presented for both cancer and noncancer effects; cancer effects generally produce lower RBCs. The selected SSALs, considering background concentrations, are presented in the last column for each receptor group.

For arsenic in soil, the DTSC screening level of 12 mg/kg considered background for southern California sites (Cal-EPA DTSC, 2007) was used as the SSAL for residential receptors because this value is greater than its residential RBC (0.39 mg/kg).

For benzo(a)pyrene equivalents in soil, a concentration of 0.9 mg/kg considered representative of background PAH concentrations in southern California soils was used as the SSAL for residential receptors because this value is greater than the residential RBC for benzo(a)pyrene (0.037 mg/kg).

3. Summary

The soil, soil gas, and groundwater SSALs will be used for comparison to Site COC data to evaluate if they are below their respective SSALs and hence, to assess potential health risks associated with detected compounds at the Site. The results of the comparison will be used to determine if further action may be warranted as a part of the FS process.

Notes:

SSAL: site-specific action level

RBCnc: risk-based concentration based on noncancer effects

RBCc: risk-based concentration based on cancer effects

Selected SSALs are the lowest between RBCc and RBCnc, or the background concentration for chemicals in which the RBCs were below background (e.g., arsenic and BaP-eq for the residential scenario).

[1] For arsenic, the DTSC screening level of 12 mg/kg (Cal-EPA DTSC, 2007), considered representative of background in southern California soils, was selected as the SSAL.

[2] For benzo(a)pyrene, a concentration of 0.9 mg/kg, considered representative of background PAH concentrations in southern California soils, was selected as the SSAL.

Notes:

Soil gas to indoor air pathway

SSAL: site-specific action level

RBCnc: risk-based concentration based on noncancer effects

RBCc: risk-based concentration based on cancer effects

Selected SSALs are the lowest between RBCc and RBCnc

Soil gas RBCs were derived using default soil properties for soil type loam in the model

Table 6
Summary of Groundwater SSALs
Gardena Sumps Site

Chemical of Concern	Site-Specific Action Levels for Groundwater (µg/L)		
	Construction		
	Site-Specific RBCnc	Site-Specific RBCc	Selected SSAL
PAHs			
Dibenz[a,h]anthracene	--	2.0E+00	2.0E+00

Notes:

" -- " not applicable

SSAL: site-specific action level

RBCnc: risk-based concentration based on noncancer effects

RBCc: risk-based concentration based on cancer effects

Selected SSAL is the lowest between RBCc and RBCnc

DETERMINATION OF HIGH STRENGTH GEOTEXTILE REINFORCEMENT

PURPOSE

The purpose of this calculation package is to present the design procedure for selecting the reinforcement tensile strength and strain required for the construction of cover soils over soft, low-permeability sludge using a high-strength geotextile.

PROCEDURE

The method for selecting the high strength geotextile is adopted from the procedure presented by R.D. Espinoza and P.J. Sabatini (Espinoza and Sabatini, 2008). The procedure utilizes the "finger fill soil placement technique" which consists of placing high-strength reinforcement over soft, low permeability sludge and building parallel narrow berms over the reinforcement. This procedure considers the proposed construction sequence, takes advantage of the ability of the high-strength reinforcement to withstand tensile stresses, and considers large vertical displacement due to the applied load. The analysis procedure is presented in Attachment A.

Bearing Capacity Analysis

The bearing failure in the sludge takes place if the average applied pressure (p_{ap}) exerted by the berm and construction equipment is greater than the foundation ultimate bearing capacity (q_u).

$$q_u = cN_c$$

where:

q_u= Foundation ultimate bearing capacity (psf)

c = cohesion of the soil foundation (psf) = 150 psf*

N_c = Bearing capacity coefficient (psf)

* The sludge material is estimated from CPT soundings performed at the site to have an undrained shear strength of approximately 300 psf (Stantec, 2008). A factor of safety of 2 has been applied to the cohesion value of the sludge material for the purposes of this calculation.

An expression for N_c as a function of the ratio between the berm average width, B, and the thickness of the foundation soil layer, D, is given by (Bonaparte et al. 1987).

N_c = 5.14 for B/D < 2

4.41+0.5(B/D) for B/D ≥ 2 (Attachment A, 2 of 8)

The berm width is determined by considering the equivalent length and width of the construction equipment assumed for placement and the lateral spreading angle of the loading through the foundation soil. For the purpose of this calculation, a D6R-LGP dozer was assumed for berm placement. The following properties for the equipment are used for this calculation (Attachment B).

b = Equipment width (blade width) = 13.1 ft

L = Equipment length = 10.7 ft

W = Equipment weight = 45,200 lb

A = Ground contact area = 9,254 in^2

P_{eq} = Equipment pressure = W/A = 4.9 psi or 706 psf

The width of the berm is taken at the bottom of the berm determined by the load distribution through the berm soil.

$$L_b = b + 2h\tan(\alpha)$$

$$L_b = 13.1\,ft + 2 \times 1\,ft \times \tan(26.6) = \mathbf{14.1\,ft}$$

where:

h = Berm thickness (ft) = 1 ft

α = The lateral load spreading angle through the berm (deg) = 26.6 deg.

For a berm width of 14.1 feet and a foundation soil layer thickness (sludge thickness) of 17.5 ft, B/D is less than 2 and a value of 5.14 for N_c is used.

$$q_u = 150\,psf \times 5.14 = \mathbf{771\,psf}$$

Next the average applied pressure created by the berm and construction equipment can be estimated as:

$$P_{ap} = \gamma h + P_{eq}\left[\frac{bL}{(b + 2h\tan\alpha)(L + 2h\tan\alpha)}\right] - \left[\frac{C_r h_c(b + L + 4h\,tan\alpha)}{(b + 2h\tan\alpha))(L + 2h\tan\alpha)}\right]$$

(Attachment A, 3 of 8)

where:

γ = Unit weight of berm soil (pcf) = 120 pcf

h_c = Crust thickness (ft) = 0 ft

C_r = Crust cohesion (psf) = 0 psf

For the purpose of this calculation the sludge is not assumed to have a crust at the surface. Therefore, the average applied pressure becomes:

$$P_{ap} = \gamma h + P_{eq}\left[\frac{bL}{(b + 2h\tan\alpha)(L + 2h\tan\alpha)}\right]$$

$$P_{ap} = (120\ pcf)(1\ ft) + 706\ psf\left[\frac{(13.1\ ft)(10.7\ ft)}{(13.1\ ft + 2(1\ ft)\ (\tan 26.6))(10.7\ ft + 2(1\ ft)(\tan 26.6))}\right]$$

$$\boldsymbol{P_{ap} = 720\ psf}$$

It is recommended that reinforcement be required if the factor of safety between the average applied pressure, Pap, exerted by the berm construction equipment and the ultimate bearing capacity, q_u is less than 1.25 (Attachment A, 6 of 8). The factor of safety becomes:

$$FS = \frac{q_u}{P_{ap}} = \frac{771\ psf}{720\ psf} = \mathbf{1.07}$$

A high-strength geotextile will be required to provide the additional bearing capacity required to construct the foundation layer for the cover system.

Required Reinforcement

The additional bearing capacity required is provided by the high-strength geotextile under the berm and heave areas. The applied load, i.e. weight of the berm and construction equipment, is supported by the combination of the bearing capacity of the sludge and the high strength geotextile under the berm, q_{gb}. As the sludge is displaced

laterally and "mud waves" are created, the reinforcement outside the loaded area exerts a downward vertical pressure, q_{gh}, on the sludge outside the loaded area. This effect provides additional stabilizing pressure against bearing capacity instability. The ultimate bearing capacity, q_{ur}, of the soil with the high-strength geotextile becomes:

$$q_{ur} = cN_c + q_{gb} + q_{gh}$$ (Attachment A, 4 of 8)

$$q_{gb} = \left(\frac{2J}{L_b}\right) \varepsilon_{gb} \ln\left(\tan \beta_b + \sqrt{1 + tan^2 \beta_b}\right)$$

$$q_{gh} = \left(\frac{2J}{L_b}\right) \varepsilon_{gh} \ln\left(\tan \beta_h + \sqrt{1 + tan^2 \beta_h}\right)$$

where:

J = The reinforcement elastic modulus (lb/ft)

β_b = The reinforcement angle of deflection at the berm boundary (deg)

ε_{gb} = The constant strain of the reinforcement under the berm (%)

β_h = The reinforcement angle of deflection at the heaved area edges (deg)

ε_{gh} = The constant strain of the reinforcement outside the berm (%)

To determine the required tensile strength and strain of the geotextile the deflection under the applied load and the deflection ratio must be estimated as follows:

$$r_b = \left(\frac{P_{ap}}{E_u}\right) (H_s)$$ (Attachment 8)

$$= \left(\frac{720\ psf}{15{,}000\ psf}\right) \times 17.5\ ft = \mathbf{0.84\ ft}$$

$$E_u = (100) c_{u=}$$

$$= 100 \times 150\ psf = \mathbf{15{,}000\ psf}$$

where:

r_b = Maximum reinforcement vertical displacement (ft)

H_s = Sludge thickness (ft), maximum is 17.5 ft

E_u = Average modulus of deformation for low permeability sludge (psf)

The deflection ratio is then equal to the estimated vertical displacement divided by the width of the berm.

$$\frac{r_b}{l_b} = \frac{0.84\ ft}{14.1 ft} = \mathbf{0.060}$$ (Attachment A)

Next the ratio between the berm width and the spacing between the berms is selected. For the purpose of this calculation the distance between the berms is assumed to be equal to two times the berm width.

$$\rho = \frac{L_h}{L_b} = 2,$$

In order to estimate the additional bearing capacity due to the membrane effect, an assumption of the deformed shape of the reinforcement is made and expressions for the constant reinforcement strains both under the berm and in the heaved areas can be written as follows:

$$\varepsilon_{gb} = \frac{1}{2}\left[\sec\beta_b + \frac{\ln(\tan\beta_b + \sec\beta_b)}{\tan\beta_b}\right] - 1$$ (Attachment A, 5 of 8)

$$\varepsilon_{gh} = \frac{1}{2}\left[\sec\beta_h + \frac{\ln(\tan\beta_h + \sec\beta_h)}{\tan\beta_h}\right] - 1$$

$$\varepsilon_{avg} = \frac{\varepsilon_{gb} + \rho\varepsilon_{gh}}{1+\rho}$$

Where the reinforcement angle of deflection at the berm boundary is determined using the following expression:

$$tan\beta_b = 4\frac{r_b}{l_b}$$

$$tan\beta_b = 4 \times \frac{0.84\ ft}{14.1\ ft} = \mathbf{0.24}$$

$$\boldsymbol{\beta_b = 13.50}$$

And the reinforcement angle of deflection of the heaved area is determined using the following expression:

$$\tan\beta_h = \frac{\tan\beta_b}{\rho^2}$$

$$tan\beta_h = \frac{0.240}{4} = \mathbf{0.06}$$

$$\boldsymbol{\beta_h = 3.43}$$

Therefore;

$$\varepsilon_{gb} = \frac{1}{2}\left[\sec 13.5 + \frac{\ln(\tan 13.5 + \sec 13.5)}{\tan 13.5}\right] - 1 = \mathbf{0.0095 \text{ or } 0.95\%}$$

$$\varepsilon_{gh} = \frac{1}{2}\left[\sec 3.43 + \frac{\ln(\tan 3.43 + \sec 3.43)}{\tan 3.43}\right] - 1 = \mathbf{0.00060 \text{ or } 0.060\%}$$

$$\varepsilon_{avg} = \frac{0.0095 + 2*0.00060}{1+2} = 0.00357 \textbf{ or } \mathbf{0.357\%}$$

Using the average reinforcement strain, the normalized additional bearing capacity pressure can be determined using the following expression:

$$\lambda_q = \frac{q_{avg}}{2J/L_b} = \varepsilon_{avg}\left[\ln(\tan\beta_b + \sec\beta_b) + \frac{1}{\rho}\ln(\tan\beta_h + \sec\beta_h)\right]$$

(Attachment A, 4 of 8)

$$\lambda_q = 0.00357\left[\ln(\tan 13.5 + \sec 13.5) + \frac{1}{2}\ln(\tan 3.43 + \sec 3.43)\right] = \mathbf{0.00096}$$

The average reinforcement strain can then be used to determine the reinforcement elastic modulus necessary. (Since the factor of safety is greater than 1 but less than 1.25, the reinforcement elastic modulus is calculated assuming $P_{ap} - cNc = 1$):

$$J = \left(p_{ap} - cN_c\right)\frac{L_b}{2\lambda_q}$$

$$J = (1)\frac{14.1 \text{ ft}}{2\times 0.00096} = 7{,}344 \text{ lb/ft}$$

The reinforcement average stress is then calculated using the average reinforcement strain and the elastic modulus. A factor of safety is applied to the required strength.

$$T_r = F_s J \varepsilon_{avg}$$

$$T_r = 6.6 \times 7{,}344 \times 0.00357 = \mathbf{173.0\ lb/ft}$$

where:

T_r = The tensile strength required for the high strength geotextile

F_s = Factor of Safety

The factor of safety is determined from the following individual reduction factors for bearing capacity (Koerner 1999, Attachment C):

RF_{ID} = Reduction factor for installation damage = 1.1

RF_{CR} = Reduction factor for creep = 4.0

RF_{CD} = Reduction factor for chemical degradation = 1.5

RF_{BD} = Reduction factor for biological degradation = 1.0

$F_s = 1.1 * 4.0 * 1.5 * 1.0 = 6.6$

Finally, the allowable strain of the high-strength geotextile is limited to five percent. Since the calculated required reinforcement strain is less than 5%, the calculated tensile strength is increased in order to establish the required strength at the low strains.

$$T_{(5\%)} = T_r \frac{0.05}{\varepsilon_r}$$

$$T_{(5\%)} = 173.0 \frac{0.05}{0.00357} = \mathbf{2{,}423\ lb/ft}$$

RESULTS

The required tensile strength for the high-strength geotextile using the method described in this calculation package is equal to 2,423 lb/ft. Geosyntec recommends the use of a Propex Geotex 4 x 4 woven, polypropylene, high-strength geotextile with a wide width

tensile strength of 2,604 lb/ft in the cross-machine direction at a strain of 5%, or equivalent, to support the construction of the soil cover system of the sludge ponds.

Received 14 September 2006, revised 24 October 2007, accepted 27 February 2008

ABSTRACT: This paper presents a design procedure for selecting the reinforcement tensile strength and strain that are required for the construction of cover soils over soft low-permeability sludge using the 'finger fill soil placement technique', which consists in placing a high-strength reinforcement over the soft, low-permeability sludge and building parallel narrow berms over the reinforcement. The design procedure described in this paper: (1) considers the proposed construction sequence; (2) takes advantage of the ability of the high-strength reinforcement to withstand tensile stresses; and (3) considers the large vertical displacement due to the applied load. The proposed design procedure allows the design engineer to select the reinforcement characteristics as well as the initial berm thickness and spacing.

1. INTRODUCTION

Residual materials of many manufacturing processes (e.g. paper mill, coal tars) comprise high-moisture, low-permeability, fined-grained sludge by-products that are usually contained in lined lagoons. The undrained shear strength of these materials can be as low as 0.48 to 2.4 kN/m^2, except for the top 0.30 to 0.60 m, which is usually stronger because of desiccation. Because of the low-permeability characteristics of this type of sludge, relatively inexpensive dewatering techniques cannot be used to reduce the sludge moisture content as a means to increase the sludge shear strength. The present methodology is applicable to soft, low-permeability sludge material.

Closure of these lagoons may be accomplished by constructing a soil cover over the sludge surface. Typically this soil cover will include a minimum thickness of 0.46 m of compacted soil and a 0.15 m thickness of vegetative support soil over a 1 mm thick, high-density polyethylene (HDPE) synthetic cover. Depending upon the size of the lagoon, additional fill material under the HDPE synthetic cover, which is several meters thick at its highest point, may be required to provide an adequate slope to allow for surface water drainage.

Because of the soft and weak nature of the sludge foundation materials, unless there is a thick and hard crust, even low ground pressure construction equipment having imposed ground stresses as low as 21 to 35 kPa will cause a bearing capacity failure of the sludge foundation, resulting in excessive vertical displacements and a resulting inability to construct the soil cover system safely. For this reason, special construction techniques must be used during the installation of the soil cover system to avoid (1) sinking of the construction equipment into the sludge and/or (2) using excessive amounts of fill owing to mixing of the fill with the underlying sludge.

A construction technique, sometimes referred to as the 'finger fill soil placement technique', which has been successfully used to build over soft soils, is discussed by Broms (1987) and Andrews and Richardson (1999). This technique consists in placing a high-strength geosynthetic reinforcement (typically woven geotextile) over the lagoon to be covered, and anchoring the reinforcement at the edge of the lagoon. Intermediate parallel narrow berms are then constructed over the reinforcement: these berms are then gradually extended across the lagoon. The intermediate parallel berms may need to be constructed concurrently to provide sufficient lateral support to the adjacent berms. Finally, the berms are widened to cover the entire lagoon. Placement of the geosynthetic reinforcement over the lagoon and construction of the parallel berms may be

1072-6349 © 2008 *Thomas Telford Ltd*

Attachment A 1 of 8

facilitated by the presence of a dry crust at the surface, as it may allow low-pressure equipment and/or workers over the lagoon well before the contribution of the reinforcement is realized. The construction technique is illustrated in Figure 1.

The portion of the applied load (i.e. the weight of the berm and construction equipment) that exceeds the foundation soil bearing capacity is supported via a membrane effect exerted by the high-strength geotextile under the loaded area. In addition, as the soil under the load is displaced laterally and 'mud waves' are created, the reinforcement outside the loaded area is stretched and additional bearing capacity is mobilized. In effect, the high-strength geotextile outside the loaded area induces a vertical force in much the same way as a surcharge pressure outside the loaded area provides additional bearing capacity. The membrane effect is a particular application of plane stress theory to structural elements that cannot withstand bending moments. The stresses that are applied perpendicular to the reinforcement are equilibrated by forces that are tangent to the reinforcement.

Although bearing capacity failure of the soft soil takes place during construction, with the associated large vertical displacements, typical design procedures are based on limit equilibrium theory and assume that the main failure mechanism is slope stability failure or bearing capacity due to the weight of the construction equipment and the berm. Consequently, the observed vertical displacements are neglected in the analysis, and limit equilibrium theory is commonly used to evaluate the high-strength geotextile contribution to the stability of the berm and the construction equipment (Andrews and Richardson 1999). In this paper, the large vertical displacement that is commonly observed during construction over soft soils is considered in the analysis to calculate the reinforcement contribution to stability. A summary of the main assumptions in the analyses presented in this paper and a discussion of their limitations are presented below.

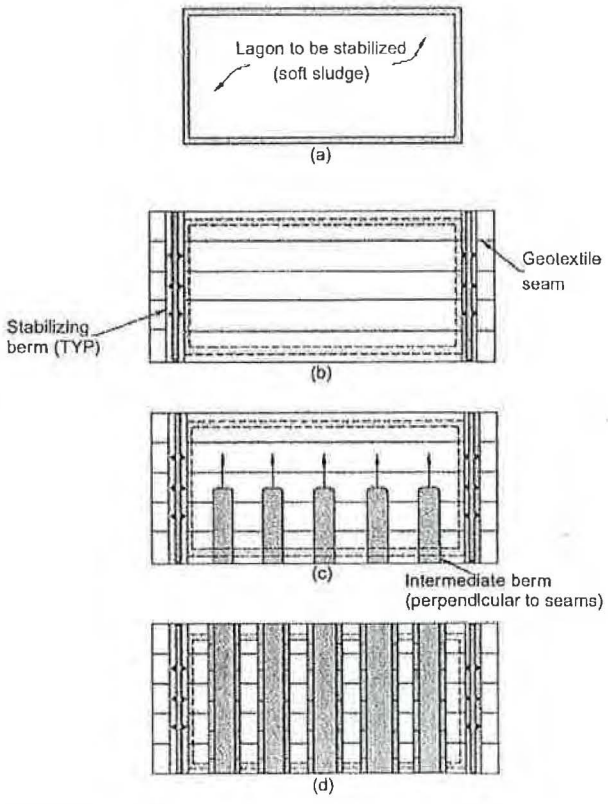

Figure 1. Construction sequencing—soft soil sludge stabilization using high-strength reinforcement geotextiles: (A) lagoon filled with soft sludge; (b) install geotextile over lagoon and place stabilizing berms; (c) construct intermediate berms; (d) widen intermediate berms

- The model is based on two-dimensional plane-strain conditions. Hence the main mode of failure is bearing capacity in the direction perpendicular to the alignment of the berm. This assumption is consistent with the construction technique described above (i.e. symmetrical loading of the soft sludge as the intermediate parallel berms are constructed simultaneously), and with the fact that the equipment is not close to the front edge of the berm.
- The sludge has a relatively low permeability. Hence the analysis considers short-term loading conditions in which lifts of fill are placed on top of the high-strength geotextile over a relatively short period of time (i.e. undrained loading). Thus displacement of sludge by the construction equipment takes place under constant volume.
- Because the undrained shear strength of the soil is relatively low, the analysis considers bearing capacity failure of the sludge due to the loads imposed by the construction equipment together with the lift of soil being placed.
- The edges of the high-strength geotextiles are appropriately anchored to withstand the imposed loads, and fully develop the membrane effect. This contribution is based upon the estimated vertical displacement due to the imposed vertical loads: the weaker the sludge, the higher the membrane contribution.

2. ANALYSIS

In this case, bearing capacity failure takes place if the average applied pressure (p_{ap}) exerted by the berm and construction equipment is greater than the foundation ultimate bearing capacity (q_u). Classical methods can be used to estimate the ultimate bearing capacity of shallow foundations on cohesive soils subject to undrained loading conditions. Thus

$$q_u = cN_c \tag{1}$$

where c is the cohesion of the soil foundation, and N_c is a dimensionless bearing capacity coefficient. An expression for N_c as a function of the ratio between the berm average width, B, and the thickness of the foundation soil layer, D, is given by (Bonaparte *et al.* 1987)

$$N_c = \begin{cases} 5.14 & \text{for } B/D < 2 \\ 4.14 + 0.5(B/D) & \text{for } B/D \geq 2 \end{cases} \tag{2}$$

Attachment A 2 of 8

The average applied pressure (p_{ap}) created by the berm and construction equipment can be estimated as

$$p_{ap} = \gamma h + p_{eq}\left[\frac{bL}{(b+2h\tan\alpha)(L+2h\tan\alpha)}\right] - \left[\frac{c_r h_c(b+L+4h\tan\alpha)2}{(b+2h\tan\alpha)(L+2h\tan\alpha)}\right] \quad (3)$$

where γ is the unit weight of the berm soil; h and h_c are the berm soil and crust thickness, respectively; p_{eq} is the ground pressure applied by the construction equipment; α is the lateral load spreading angle through the berm; c_r is the crust cohesion; and b and L are the shoe width and length of the construction equipment, respectively. The lateral spreading angle (α) reflects how the load is distributed through the fill,and typically varies from 26.6° (1H:2V) to 45° (1H:1V) (Sellmeijer *et al.* 1982).

As described above, the sludge material being capped may form a crust at its surface as the sludge loses moisture. The presence of a crust without cracks further reduces the load applied to the soft sludge. As the pressure of the construction equipment tries to punch through the crust, shear stresses are developed across the crust thickness. The third term in Equation 3 takes this effect into account.

Bearing capacity failure of relatively soft cohesive materials results in relatively large ground surface settlements of the loaded area. This failure mechanism (i.e. large displacements) can be used advantageously during construction by placing a high-strength reinforcement over the soft soils with a relatively flat surface. As a result of these settlements, the reinforcement is stretched (Figure 2) and hence is subjected to tension. These tensile forces increase as the settlement increases.

The evaluation of the reinforcement contribution to support the applied load is based on the observation that large settlements usually occur during bearing capacity failure on soft soil (Giroud and Noirey 1981; Broms 1987). For the case where a reinforcement is placed over the soft sludge and fill is placed in the form of narrow berms (Figure 1), as the soft sludge is laterally displaced by the intermediate berms sinking into the sludge, the reinforcement under and outside the intermediate berms is gradually stretched and, at the same time, the tension in the reinforcement is gradually increased. The reinforcement stretching results in stabilizing stresses (i.e. membrane effect) that can be viewed as an additional bearing capacity. This additional bearing capacity provided by the reinforcement depends on the depth of penetration of the berm into the sludge, and on the height, width, and spacing of the berms.

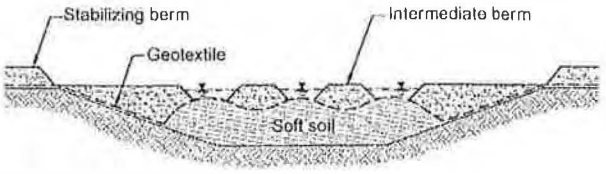

Figure 2. Soft soil stabilization with high-strength geotextiles

The additional bearing capacity results from the high-strength geotextile under the berm and heave areas (Figure 3). The applied load (i.e. the weight of the berm and construction equipment) is partially supported by the bearing capacity of the sludge and the high-strength geotextile under the berm (q_{gb}). As the sludge is displaced laterally and 'mud waves' are created, the reinforcement outside the loaded area is stretched by the mud waves. As a result, the reinforcement exerts a downward vertical pressure (q_{gh}) on the sludge outside the loaded area (Figure 3), reducing its heave potential. This effect provides an additional stabilizing pressure against bearing capacity instability. Thus the ultimate reinforced bearing

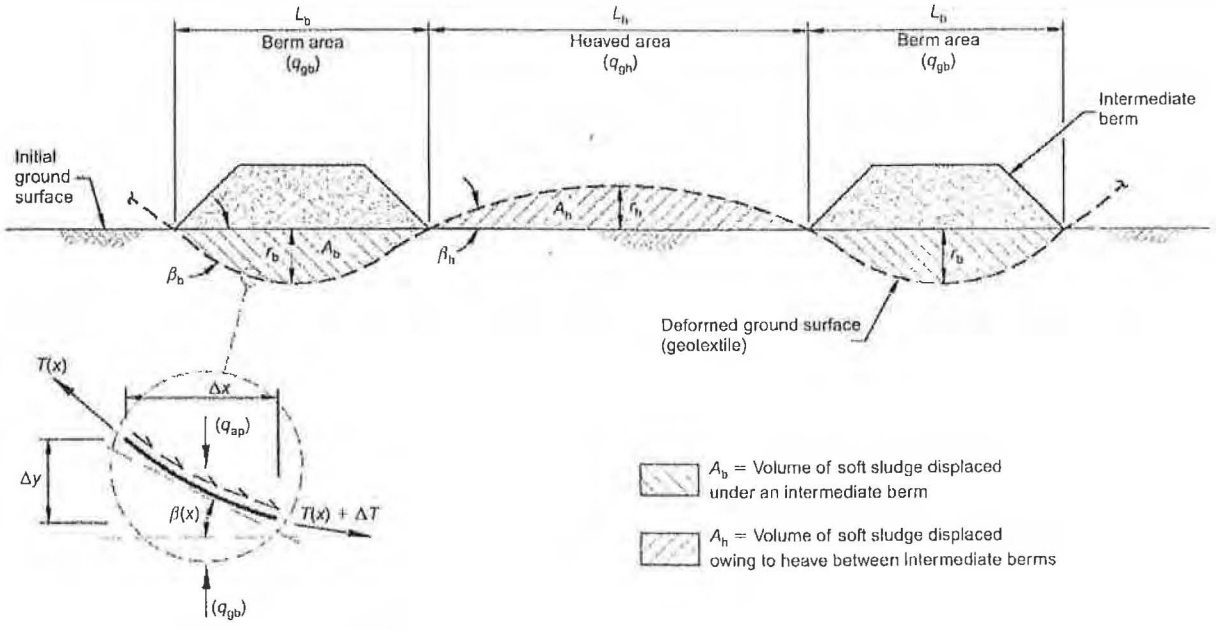

Figure 3. Membrane effect model

Attachment A 3 of 8

capacity (q_{ur}) of the soil with a high-strength reinforcement that includes the high-strength geotextile of the reinforcement under the berm (q_{gb}), and in the heaved areas (q_{gh}), can be written as (Espinoza and Bray 1995)

$$q_{ur} = cN_c + q_{gb} + q_{gh} \tag{4}$$

where

$$q_{gb} = \frac{1}{L_b}\int_{-L_b/2}^{L_b/2} q_g(x)\mathrm{d}x \tag{5a}$$

$$q_{gh} = \frac{2}{L_h}\int_{L_b/2}^{(L_h/2)+(L_b/2)} q_g(x)\mathrm{d}x \tag{5b}$$

$$q_g(x) = T_h(x)\frac{\mathrm{d}^2 y(x)}{\mathrm{d}x^2} \tag{5c}$$

L_b is the width of the berm; L_h is the separation distance between berms; $q_g(x)$ is a pressure distribution function that describes the contribution to bearing capacity along the length of the high-strength reinforcement due to membrane effect (Espinoza 1994). As depicted in Figure 3, $T_h(x)$ is the horizontal component of the variation of the tensile forces in the reinforcement and $y(x)$ is a function that describes the distribution of vertical displacement along the reinforcement. The limits of the integral in Equation 5b represent the contribution of half the heaved area on one side of the berm. A factor of 2 is used in the numerator of Equation 5b to indicate that the sludge material is displaced from underneath the loaded area to both sides of the berm. Equations 5a, 5b and 5c assume that the high-strength geotextile has been placed taut, and that no slippage has occurred between the high-strength geotextile and the surrounding soil (i.e. the high-strength geotextile elongates as the subgrade deforms). In reality, the contribution of the high-strength geotextile is somewhat reduced by the amount of slack that typically results after installation. This effect can be considered in the design by subtracting the expected slack from the calculated geotextile elongation.

The horizontal component of the tensile forces in the reinforcement can be expressed as

$$T_h(x) = T(x)\cos\beta \tag{6}$$

where $T(x)$ is the tensile forces in the reinforcement and β (which is also a function of x) is the angle that the deformed reinforcement makes with the horizontal line. Figure 3 shows the angles that the deformed high-strength geotextile makes with the horizontal line at the boundaries of the berm and heaved areas, denoted β_b and β_h, respectively. The tensile forces and the angle of the deformed reinforcement can be written as

$$T(x) = J\varepsilon(x) \tag{7a}$$

$$\cos\beta = \frac{1}{\sqrt{1+(\mathrm{d}y/\mathrm{d}x)^2}} \tag{7b}$$

where ε and J are the reinforcement tensile strain and the elastic modulus, respectively. Replacing Equation 6 into Equation 5c, and the resulting expression into Equations 5a and 5b, yields

$$q_{gb} = \frac{1}{L_b}\int_{-L_b/2}^{L_b/2} J\varepsilon(x)\left[1+\left(\frac{\mathrm{d}y}{\mathrm{d}x}\right)^2\right]^{-\frac{1}{2}}\left(\frac{\mathrm{d}^2 y}{\mathrm{d}x^2}\right)\mathrm{d}x \tag{8a}$$

$$q_{gh} = \frac{2}{L_h}\int_{L_b/2}^{(L_b/2)+(L_h/2)} J\varepsilon(x)\left[1+\left(\frac{\mathrm{d}y}{\mathrm{d}x}\right)^2\right]^{-\frac{1}{2}}\left(\frac{\mathrm{d}^2 y}{\mathrm{d}x^2}\right)\mathrm{d}x \tag{8b}$$

An expression for the high-strength geotextile contribution under the soil berm (q_{gb}) and in the heaved areas (q_{gh}) can be obtained by assuming that the strain along the reinforcement is constant and integrating Equation 8a (Espinoza 1994), to give

$$q_{gb} = \left(\frac{2J}{L_b}\right)\varepsilon_{gb}\,ln(tan\beta_b + \sqrt{1+\tan^2\beta_b}) \tag{9}$$

where β_b is the reinforcement angle of deflection at the berm boundary (Figure 3), and ε_{gb} is the assumed constant strain of the reinforcement under the berm. A similar expression can be obtained for the contributions of the reinforcement in the heaved area (q_{gh}) by integrating Equation 8b, assuming that the strain along the reinforcement in the heaved area is constant, to give

$$q_{gh} = \left(\frac{2J}{L_h}\right)\varepsilon_{gh}\,ln(tan\beta_h + \sqrt{1+\tan^2\beta_h}) \tag{10}$$

where β_h is the reinforcement angle of deflection at the heave area edges (Figure 3), and ε_{gh} is the constant strain of the reinforcement outside the berm. Equations 9 and 10 can be used to calculate the additional bearing capacity (q_{avg}) due to membrane effect of the high-strength geotextile reinforcement under the berm and the heaved areas. Hence the additional bearing capacity can be written as the sum of q_{gb} (Equation 9) and q_{gh} (Equation 10):

$$\frac{q_{avg}}{2J/L_b} = \varepsilon_{gb}\ln(\tan\beta_b + \sec\beta_b) + \frac{1}{\rho}\varepsilon_{gh}\ln(\tan\beta_h + \sec\beta_h) \tag{11}$$

where ρ is the berm spacing ratio, given by

$$\rho = \frac{L_h}{L_b} \tag{12}$$

Assuming further that the reinforcement between the berms is pulled towards the berm as it sinks into the sludge, it is reasonable to assume that the elongation along the entire reinforcement is uniform (Giroud and Noirey 1981). Hence the additional average bearing capacity (q_{avg}) due to the contribution of the reinforcement can be written as

$$\frac{q_{avg}}{2J/L_b} = \varepsilon_{avg}\left[\ln(tan\beta_b + \sec\beta_b) + \frac{1}{\rho}\ln(\tan\beta_h + \sec\beta_h)\right] \tag{13}$$

where

Attachment A 4 of 8

$$\varepsilon_{avg} = \frac{\varepsilon_{gb} + \rho\varepsilon_{gh}}{1+\rho} \tag{14}$$

In order to estimate the additional bearing capacity due to membrane effect using Equation 13, an assumption of the deformed shape of the reinforcement will need to be made. Typically, deformation of reinforcement over soft soils is approximated by parabolas (e.g. Giroud and Noirey 1981; Raumann 1982). With this assumption, expressions for the constant reinforcement strains both under the berm (ε_{gh}) and in the heaved area (ε_{gh}), as a function of the maximum reinforcement vertical displacement (r_b and r_h, respectively) and reinforcement length (L_b and L_h, respectively) are given by (Espinoza 1994)

$$\varepsilon_{gb} = \frac{1}{2}\left[\sec\beta_b + \frac{\ln(\tan\beta_b + \sec\beta_b)}{\tan\beta_b}\right] - 1 \tag{15a}$$

$$\varepsilon_{gh} = \frac{1}{2}\left[\sec\beta_h + \frac{\ln(\tan\beta_h + \sec\beta_h)}{\tan\beta_h}\right] - 1 \tag{15b}$$

where

$$\tan\beta_b = \frac{4\,r_b}{L_b} \tag{16a}$$

$$\tan\beta_h = \frac{4\,r_h}{L_h} \tag{16b}$$

Equations 16a and 16b for $\tan\beta_b$ and $\tan\beta_h$ correspond to the slopes of the deformed shape of the reinforcement (i.e. a parabola) at the edge of the berm (Figure 3).

As construction of the soil cover over the sludge will result in an essentially undrained response, the low-permeability sludge can be assumed to be incompressible during loading. Thus no volume change occurs in the short term, and the volume of subgrade displaced downwards by settlement must be equal to the volume displaced upwards by heave. For plane-strain conditions this corresponds to the area under the berm being equal to the area in the heaved area. Hence a relation between the maximum vertical reinforcement displacement under the berm (r_b) and the reinforcement heave (r_h) is obtained by equating the areas under the parabolas (Figure 3) to give

$$\frac{4}{3}r_b L_b = \frac{4}{3}r_h L_h \tag{17}$$

Using Equations 16a, 16b, and 17, an expression for the angle of deflection of the heaved area (β_h) can be derived as

$$\tan\beta_h = \frac{4r_b}{\rho^2 L_b} = \frac{\tan\beta_b}{\rho^2} \tag{18}$$

Using the equations derived above, the additional average bearing capacity (q_{avg}) due to the contribution of the reinforcement can be obtained. Figure 4 shows the variation of the normalized additional bearing capacity pressure (λ_q) as a function of r_b/L_b and ρ, where λ_q is defined as

$$\lambda_q = \frac{q_{avg}}{2J/L_b} \tag{19}$$

As expected, Figure 4 indicates that for wider berm spacing (i.e. higher values of L_h/L_b) there is less contribution of the reinforcement to the additional bearing capa-

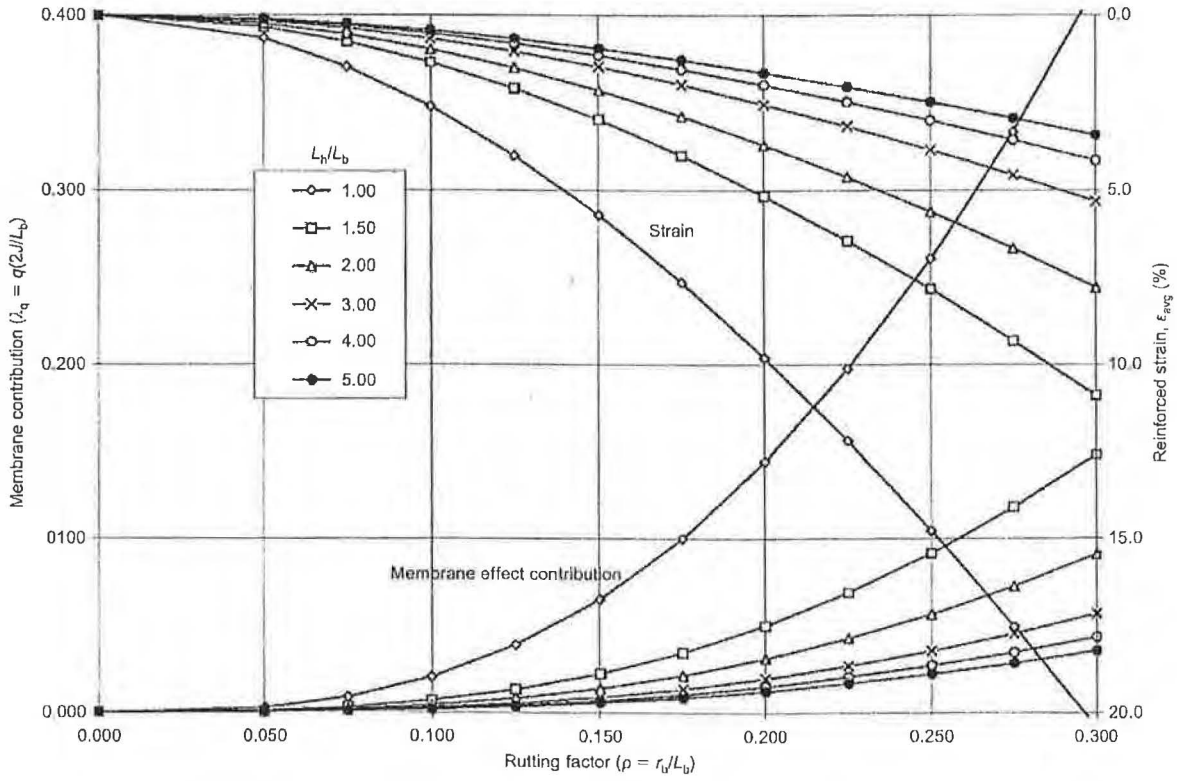

Figure 4. Additional bearing capacity provided by reinforcement

Attachment A 5 of 8

city pressure and a correspondingly lower value of strain in the high-strength geotextile. Also, Figure 4 shows that the reinforcement contribution decreases significantly when the berm spacing ratio ρ is greater than 1.

The maximum vertical displacement of the berm (r_b) during loading can be initially estimated by relating the applied load, Equation 3, to the average sludge modulus of deformation (E_u) and the minimum of the sludge thickness (H_s) or twice the applied load width using the expression

$$r_b = \left(\frac{p_{ap}}{E_u}\right)\min(H_s, 2b) \tag{20}$$

The average sludge modulus of deformation can be obtained from the empirical correlations for soft clays given by (CGS 1978)

$$E_u = (100 - 500)c_u \tag{21}$$

Equation 21 applies to soft sensitive soils. As noted in Equation 20, to limit the estimated maximum vertical displacement in thick deposits of sludge, the sludge thickness that has an influence in the calculation of vertical displacements is limited to twice the width of the applied load.

3. PROPOSED DESIGN PROCEDURE

The following steps are proposed to apply this procedure for the design of a soil cover over soft low-permeability sludge.

1. Select the berm geometry (thickness and width). A layer 0.30 to 0.6 m thick is recommended. The width shall be at least the width of the equipment to be used.
2. Calculate the average applied pressure (p_{ap}) caused by the berm and construction equipment (Equation 3).
3. Evaluate N_c and calculate the foundation bearing capacity (unreinforced).
4. If the factor of safety against bearing capacity is less than 1.25, calculate the additional capacity to be provided by the reinforcement (i.e. $p_{ap} - cN_c$).
5. Estimate the deflection under the weight of the equipment and lift of soil (r_b) and the deflection ratio (i.e. r_b/L_b).
6. Select the allowable strain to be developed in the reinforcement (ε_a). For high-strength (woven) geotextiles, the ultimate tensile strain varies between 10% and 30%. It is recommended to limit the allowable strain to one-half of the ultimate tensile strain of the reinforcement (i.e. factor of safety against rupture equal to 2).
7. Select the berm spacing ratio $\rho = L_h/L_b$. Start with a spacing ratio of 1.
8. Estimate the expected vertical displacement under the berm using Equation 20, or by other means.
9. Using Figure 4 or Equation 13, estimate the load factor ratio $\lambda_q = q_{avg}L_b/2J$.
10. Calculate the reinforcement modulus (J) required to provide the necessary support as $J = (p_{ap} - cN_c)L_b/2\lambda_q$. If an unreasonably high modulus J is calculated, reduce the spacing between adjacent berms. Also, the berm thickness may be increased to increase the berm vertical displacement, and hence the membrane contribution.
11. Calculate the berm separation using Equation 12.
12. Calculate the reinforcement average strain using Equation 14 and the corresponding average tensile stress (i.e. $J\varepsilon_{avg}$).
13. Calculate the required reinforcement strain ($F_s\varepsilon_{avg}$) and the corresponding required tensile stress (i.e. $F_sJ\varepsilon_{avg}$), where F_s is the factor of safety against rupture.

4. APPLICATION EXAMPLE

Assuming that the sludge thickness is 6.0 m with an undrained shear strength of 0.5 kPa, the bearing capacity analysis and the required reinforcement to allow construction of the final cover system are calculated using the equations derived in this paper for two dozer types (D3C-LGP-5(II) and D4H-LGP(II)), berm vertical displacement, berm widths, sludge shear strength, and berm spacing (Tables 1 and 2). As shown in the tables (first row), applying a 0.30 m lift with a D3C-LGP-5(II) dozer results in a factor of safety against bearing capacity significantly less than 1.0 (i.e. 0.13): hence reinforcement is required.

For the sludge characteristics, a factor of 500 in Equation 21 was considered appropriate to estimate the vertical displacement. The estimated deflection due to pressure applied by the berm and light equipment is 0.5 m, and the corresponding deflection ratio is 0.14. For a berm spacing ratio of 2 (i.e. approximately twice the width of the berm), the required tensile strength with a factor of safety against rupture is 91 kN/m at a 3.8% strain (J = 2373 kN/m). If heavier equipment (i.e. D4H-LGP(II)) is used (see the second row of Tables 1 and 2), larger deflection under the berm (i.e. 0.70 m) would be obtained, and the required tensile strength with a factor of safety against rupture would be 88 kN/m at a 9.7% strain (J = 908 kN/m).

All the parameters for the next two examples (third and fourth rows) are equivalent to the examples described above except for the sludge strength, which is twice as high (i.e. c_u = 1 kPa). As shown in the last column, by doubling the shear strength of the sludge an approximately fourfold reduction of the required reinforcement strength is obtained.

5. SUMMARY AND CONCLUSIONS

A simple methodology for selecting the appropriate reinforcement requirements for construction of a soil cover over a soft sludge using the finger fill soil placement technique has been developed. Unlike limit equilibrium methods, the proposed methodology takes into consideration the expected large settlement due to the weight of the construction equipment and berm. Consequently, the proposed methodology considers not only the tensile strength of the reinforcement but also its stiffness. As shown in the

Attachment A 6 of 8

Table 1. Evaluation of required tensile strength and strain: equipment and berm characteristics

Equipment	Equipment characteristics								
	Lift thickness (m)	Shoe width (m)	Equipment pressure, p_{eq}		L (m)	b (m)	L_{eq} (m)	b_{eq} (m)	p'_{eq} (kPa)
			(lbf/in^2)	(kPa)					
D3C-LGP-5 (II)	0.30	1.0	2.5	17.4	2.5	3.0	2.8	3.3	14.0

analysis, and in the design charts developed, the reinforcement stiffness (i.e. modulus) has a significant influence on the reinforcement contribution.

As expected, a larger reinforcement modulus results in a larger reinforcement contribution for the same amount of vertical displacement. Consequently, to optimize the contribution of the reinforcement, both maximum tensile strength and strain (or the modulus) must be specified.

NOTATIONS

Basic SI units are shown in parentheses.

B berm average width (m)
b shoe width of construction equipment (m)
c cohesion of soil foundation (Pa)
c_r crust cohesion (Pa)
c_u undrained soil shear strength (Pa)
D thickness of foundation soil layer (m)
E_u average modulus of deformation of low-permeability sludge (Pa)
F_s factor of safety against rupture (dimensionless)
$F_sJ\varepsilon_{avg}$ required tensile stress (Pa)
$F_s\varepsilon_{avg}$ required reinforcement strain (dimensionless)
H_s sludge thickness (m)
h berm soil thickness (m)
h_c berm crust thickness (m)
J elastic modulus times material thickness [$J = (p_{ap} - cN_c)L_b/2l_q$] (N/m)
$J\varepsilon_{avg}$ average tensile stress (N/m)
L_b width of berm (m)
L_h separation distance between berms (m)
l shoe length of construction equipment (m)
N_c bearing capacity coefficient (dimensionless)
p_{ap} average applied pressure (Pa)
p_{eq} ground pressure applied by construction equipment (Pa)
q_{avg} additional bearing capacity (Pa)
$q_g(x)$ pressure distribution function (Pa)
q_{gb} membrane effect under berm (Pa)
q_{gh} membrane effect in heaved areas (Pa)
q_u ultimate bearing capacity (Pa)
q_{ur} ultimate reinforced bearing capacity (Pa)
r berm spacing ratio ($r = L_h/L_b$) (dimensionless)
r_b maximum reinforcement vertical displacement under berm (m)
r_h maximum reinforcement vertical displacement in heaved area (m)
$T(x)$ tensile force in reinforcement per linear meter (N/m)
$T_h(x)$ horizontal component of variation of tensile forces per linear meter in reinforcement (N/m)
$y(x)$ distribution of vertical displacement along reinforcement (m)
α lateral load spreading angle (degrees)
β angle of geomembrane deformation (degrees)
β_b reinforcement angle of deflection at berm boundary (degrees)
β_h reinforcement angle of deflection at heave area edges (degrees)
γ unit weight of berm soil (N/m^3)

Attachment A 7 of 8

ε reinforcement tensile strain (dimensionless)
ε_a strain developed in reinforcement (dimensionless)
ε_{gb} constant strain of reinforcement under berm (dimensionless)
ε_{gh} constant strain of reinforcement outside berm (dimensionless)
λ_q load factor ratio ($\lambda_q = q_{avg}\ L_b/2J$) (dimensionless)

TABLE 2.11 RECOMMENDED REDUCTION FACTOR VALUES FOR USE IN EQ. (2.24a)

Application Area	Range of Reduction Factors			
	Installation Damage	Creep*	Chemical Degradation	Biological Degradation
Separation	1.1 to 2.5	1.5 to 2.5	1.0 to 1.5	1.0 to 1.2
Cushioning	1.1 to 2.0	1.2 to 1.5	1.0 to 2.0	1.0 to 1.2
Unpaved roads	1.1 to 2.0	1.5 to 2.5	1.0 to 1.5	1.0 to 1.2
Walls	1.1 to 2.0	2.0 to 4.0	1.0 to 1.5	1.0 to 1.3
Embankments	1.1 to 2.0	2.0 to 3.5	1.0 to 1.5	1.0 to 1.3
Bearing capacity	1.1 to 2.0	2.0 to 4.0	1.0 to 1.5	1.0 to 1.3
Slope stabilization	1.1 to 1.5	2.0 to 3.0	1.0 to 1.5	1.0 to 1.3
Pavement overlays	1.1 to 1.5	1.0 to 2.0	1.0 to 1.5	1.0 to 1.1
Railroads (filter/sep.)	1.5 to 3.0	1.0 to 1.5	1.5 to 2.0	1.0 to 1.2
Flexible forms	1.1 to 1.5	1.5 to 3.0	1.0 to 1.5	1.0 to 1.1
Silt fences	1.1 to 1.5	1.5 to 2.5	1.0 to 1.5	1.0 to 1.1

*The low end of the range refers to applications which have relatively short service lifetimes and/or situations where creep deformations are not critical to the overall system performance.

where

T_{allow} = allowable tensile strength,
T_{ult} = ultimate tensile strength,
RF_{ID} = reduction factor for installation damage,
RF_{CR} = reduction factor for creep,
RF_{CD} = reduction factor for chemical degradation,
RF_{BD} = reduction factor for biological degradation, and
ΠRF = value of cumulative reduction factors.

Note that Eq. (2.24a) could have included additional site-specific terms, such as reduction factors for seams and intentionally made holes. It also could have been formulated with fractional multipliers (values ≤ 1.0) placed in the numerator of the equation or on the opposite side of the equation, as with the *load-factor design method*. It has been put in this form following other studies (e.g., Voskamp and Risseeuw [63]). While the equation indicates tensile strength, it can be applied to burst strength, tear strength, puncture strength, impact strength, and so on.

2.4.2 Flow-Related Problems

For problems dealing with flow through or within a geotextile, such as filtration and drainage applications, the formulation of the allowable values takes the following form. Typical values for reduction factors are given in Table 2.12. Note that these values must be tempered by the site-specific conditions, as in Section 2.4.1. If the laboratory test includes the mechanism listed, it appears in the equation as a value of 1.0.

$$q_{allow} = q_{ult}\left(\frac{1}{RF_{SCB} \times RF_{CR} \times RF_{IN} \times RF_{CC} \times RF_{BC}}\right) \tag{2.25a}$$

EVALUATION OF REINFORCEMENT LAYER ANCHOR TRENCH CAPACITY
GARDENA SUMPS
GARDENA, CALIFORNIA

OBJECTIVE

The project includes the installation of a high-strength geotextile to support the construction of a cover system over soft sludge material at the Gardena Sumps project located in Gardena, California. The objective of this calculation package is to evaluate the tensile strength capacity at the termination of the reinforcement layer anchor system. The anchorage strength is compared to the high strength geotextile tensile strength to evaluate the reinforcement layer pull-out potential. The high-strength geotextile strength calculation is presented in a separate calculation package.

METHOD OF ANALYSIS

Anchor trench capacity is evaluated using methods and equations presented by Koerner et al (2002) and are included as Attachment A.

Koerner et al (2002) presents design equations developed from static equilibrium to evaluate the allowable geosynthetic tension from an anchor trench (see Attachment A). The equation considers frictional resistance due to (i) overburden pressures, (ii) anchor trench side slopes, and (iii) base of the anchor trench. The proposed design equation for determination of the allowable geomembrane tension from an anchor trench is:

$$T = \frac{q_b \times L_{RO} \times \tan\delta + 2\left[K_o \times (\sigma_v)_{avg} \times d_{AT} + \sigma_{vB} \times L_{AT}\right] \tan\delta}{\cos\beta - \sin\beta \tan\delta} \qquad (1)$$

where:

T = Tensile force in the geotextile (lb/ft);

q_b = Surcharge pressure due to cover soil over the geotextile (psf);

$= \gamma_s \times d_{cs}$;

γ_s = Unit weight of cover and backfill soil (pcf);

d_{cs} = Depth of cover soil (ft);

L_{RO} = Runout length subjected to overburden;

δ = minimum friction angle between geotextile and the soil;

K_o = coefficient of earth pressure at rest = 1-sinϕ;

$(\sigma_v)_{ave}$ = average vertical stress in anchor trench;

σ_{vB} = total vertical stress at the bottom of the anchor trench;

ϕ = friction angle of backfill soil in anchor trench;

d_{AT} = depth of the anchor trench;

L_{AT} = width of the anchor trench; and

β =sideslope angle, measured from horizontal.

ANALYSIS

Evaluating Variables

Since tension will develop in the geotextile (see the calculation package "Determination of High Strength Geotextile Reinforcement") due to the construction of the soil cover over the soft sludge material, frictional forces will be mobilized along the geosynthetic and soil interfaces on the side and base of the anchor trench. The maximum anticipated load due to soil cover construction is approximately 2,423 lb/ft (Geosyntec, 2012).

- A friction angle of 30 degrees will be used to represent the interface friction value between the anchor trench backfill and the woven geotextile (GSI, 2007, Attachment B).

- For determination of the surcharge due to soil overburden, q, and the vertical and horizontal overburden stresses, σ_h and σ_v, a unit weight of overburden soil of 120 pounds per cubic foot (pcf) was used based on typical values for the shallow onsite soils. For evaluation of the effective horizontal overburden stress based on the coefficient of earth pressure at rest, a friction angle of 30 degrees was selected based on typical values for the shallow onsite soils.

The following properties for the anchor trench were assumed:

- The depth of cover soil is equal to 1 ft over the run-out length of the geotextiles;
- The run-out length of the geotextile is equal to 15 feet, which is based on the approximate width of the first "finger berm" (see the calculation package "Determination of High Strength Geotextile Reinforcement");
- The width of the anchor trench is 2 ft;
- The depth of the anchor trench is 3 ft; and
- The slope of the reinforcement layer is approximately flat, i.e. $\beta = 0$

Analysis

From Equation (1):

$$T = \frac{q_b \times L_{RO} \times \tan\delta + 2\left[K_o \times (\sigma_v)_{avg} \times d_{AT} + \sigma_{vB} \times L_{AT}\right] \tan\delta}{\cos\beta - \sin\beta \tan\delta}$$

$$q_b = \gamma_s \times d_{cs}$$

$$q_b = 120\ pcf \times 1\ ft = \mathbf{120\ psf}$$

$$K_o = (1 - \sin\emptyset)$$

$$K_o = (1 - \sin 30) = \mathbf{0.5}$$

$$(\sigma_v)_{avg} = \gamma_s(d_{cs} + 0.5 d_{AT})$$

$$(\sigma_v)_{avg} = 120\ pcf(1\ ft + 0.5 \times 3ft) = \mathbf{300\ psf}$$

$$\sigma_{vB} = \gamma_s(d_{cs} + d_{AT})$$

$$(\sigma_v)_{avg} = 120\ pcf(1\ ft + 3ft) = \mathbf{480\ psf}$$

Therefore,

$$T = \frac{120\ psf \times 15\ ft \times \tan 30 + 2[0.5 \times 300\ psf \times 3\ ft + 480\ psf \times 2\ ft] \tan 30}{\cos 0 - \sin 0 \tan 30} = \mathbf{2,667\ lb/ft}$$

T = 2,667 lb/ft > 2,423 lb/ft OK

CONCLUSIONS

The tensile capacity of the anchorage system as calculated herein exceeds the expected tensile loads (from the calculation package entitled "Determination of High Strength Geotextile Reinforcement"). The expected tensile load due to the soil cover construction over soft soils at the site was evaluated to be 2,423 lb/ft (Geosyntec, 2012). The capacity of the proposed anchor trenches is 2,667 lb/ft. Therefore, the anchorage design for the geomembrane is adequate.

and

$$\sigma_{allow}\cdot t\cdot(\cos\beta - \sin\beta\cdot\tan\delta_C) = \gamma_s\cdot d_{CS}\cdot L_{RO}\cdot\tan\delta_C + (1-\sin\phi)\cdot\gamma_s\cdot(d_{CS}+0.5\cdot d_{AT})\cdot d_{AT}\cdot(\tan\delta_C+\tan\delta_F)$$

so that

$$\sigma_{allow}\cdot t = (840)(144)(0.060)/12 = 605 \text{ lb/ft } (8.83 \text{ kN/m}) \text{ and } (605)[(\cos 18.4°) - (\sin 18.4°)(\tan 18°)] = (110)(1)(\tan 18°)(L_{RO}) + (0.5)(110)(2)(2)(\tan 18° + \tan 22°$$

or

$$(605)(0.846) = (35.74)\cdot L_{RO} + (220)(0.729) \text{ which yields } 512.83 = (35.74)\cdot L_{RO} + 160.38 \text{ or } L_{RO} = 9.86 \text{ ft } (2.96 \text{ m}$$

Thus, use the runout length $L_{RO} = 10$ ft (3 m).

The geomembrane can also be extended along the trench bottom to increase resistance force, which is called an L-shaped rectangular anchor trench. A typical lay out in an L-shaped rectangular anchor trench, which is widely used in landfill projects is shown in Figure 4.10. In order to establish the static equilibrium equation, two imaginary and frictionless pulleys are assumed at the top edge and the bottom corner of the anchor trench, as shown in Figure 4.10 (Qian, 1995). This assumption again allows the geomembrane to be considered as a continuous member.

The friction force above a runout geomembrane is always neglected in the anchor trench design, since the cover soil probably moves together with the geomembrane as it deforms.

From $\Sigma F_H = 0$

$$T\cdot(\cos\beta) = (F_{RO})_B + (F_{AT})_L + (F_{AT})_R + (F_{AB})_B + (F_{AB})_U \quad (4.23)$$

The friction force between the geomembrane and the underlying soil at the bottom of the anchor trench is

$$(F_{AB})_B = \sigma_{vB}\cdot L_{AT}\cdot\tan\delta_C \quad (4.24)$$

The friction force between the geomembrane and the overlying soil at the bottom of the anchor trench is

$$(F_{AB})_U = \sigma_{vB}\cdot L_{AT}\cdot\tan\delta_F \quad (4.25)$$

Because $\sigma_{vB} = \gamma_s\cdot(d_{CS}+d_{AT})$,

$$(F_{AB})_B = \gamma_s\cdot(d_{CS}+d_{AT})\cdot L_{AT}\cdot\tan\delta_C \quad (4.26)$$

and

$$(F_{AB})_U = \gamma_s\cdot(d_{CS}+d_{AT})\cdot L_{AT}\cdot\tan\delta_F \quad (4.27)$$

Substituting Equations 4.15, 4.17, 4.18, 4.26, and 4.27 into Equation 4.23 gives

$$T\cdot(\cos\beta - \sin\beta\cdot\tan\delta_L) = \gamma_s\cdot d_{CS}\cdot L_{RO}\cdot\tan\delta_C + \gamma_s\cdot(\tan\delta_C+\tan\delta_F)[(1-\sin\phi)\cdot\gamma_s\cdot(d_{CS}+0.5\cdot d_{AT})\cdot d_{AT} + (d_{CS}+d_{AT})\cdot L_{AT}]$$

Attachment A, 1 of 3

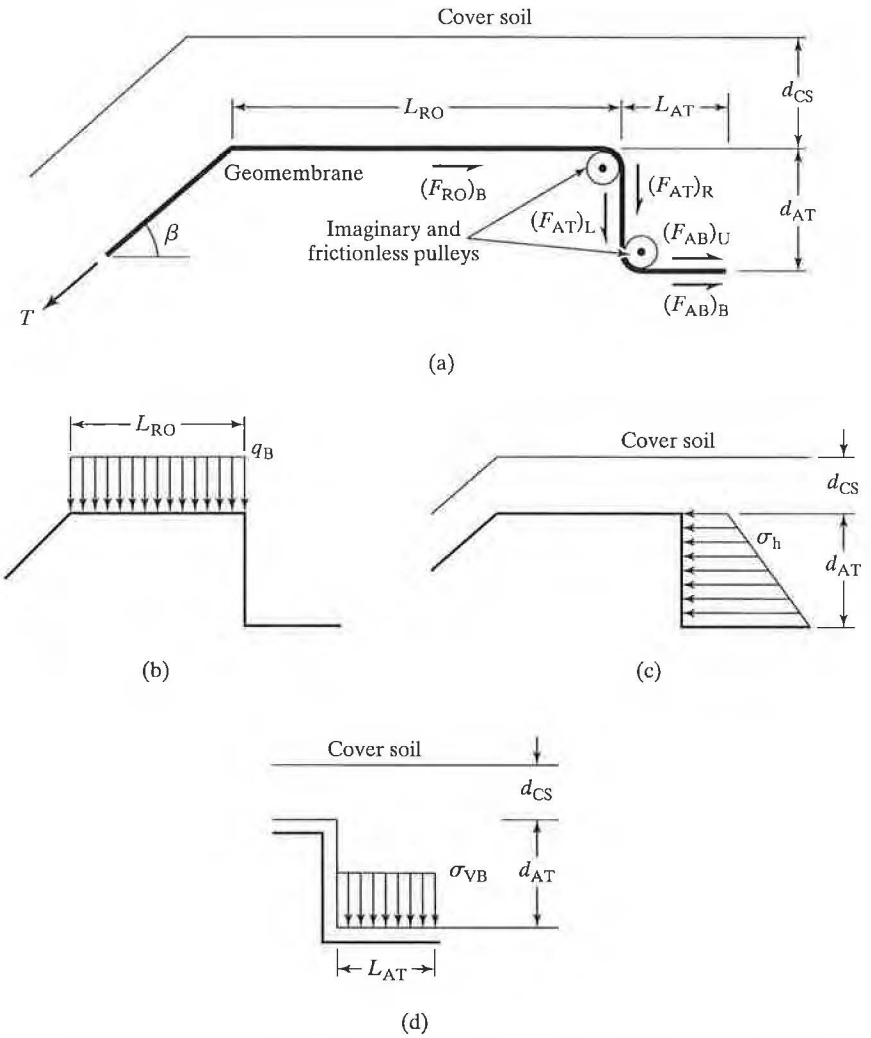

FIGURE 4.10 Cross Section of Geomembrane Runout Section with an L-Shaped Rectangular Anchor Trench and Related Stresses and Forces Involved

which leads to

$$T = \frac{\gamma_s \cdot d_{CS} \cdot L_{RO} \cdot \tan\delta_C + \gamma_s \cdot [(1 - \sin\phi) \cdot \gamma_s \cdot (d_{CS} + 0.5 \cdot d_{AT}) \cdot d_{AT} + (d_{CS} + d_{AT}) \cdot L_{AT}](\tan\delta_C + \tan\delta_F)}{\cos\beta + \sin\beta \cdot \tan\delta_C} \tag{4.28}$$

or

$$T = \frac{q_B \cdot L_{RO} \cdot \tan\delta_C + [K_o \cdot (\sigma_v)_{ave} \cdot d_{AT} + \sigma_{vB} \cdot L_{AT}](\tan\delta_C + \tan\delta_F)}{\cos\beta - \sin\beta \cdot \tan\delta_C} \tag{4.29}$$

Attachment A, 2 OF 3

When $\delta_C = \delta_F = \delta$, Equation 4.28 becomes

$$T = \frac{\gamma_s \cdot d_{CS} \cdot L_{RO} \cdot \tan\delta + 2 \cdot \gamma_s \cdot [(1 - \sin\phi) \cdot \gamma_s \cdot (d_{CS} + 0.5 \cdot d_{AT}) \cdot d_{AT} + (d_{CS} + d_{AT}) \cdot L_{AT}] \cdot \tan\delta}{\cos\beta - \sin\beta \cdot \tan\delta} \quad (4$$

and Equation 4.29 becomes

$$T = \frac{q_B \cdot L_{RO} \cdot \tan\delta + 2 \cdot [K_o \cdot (\sigma_v)_{ave} \cdot d_{AT} + \sigma_{vB} \cdot L_{AT}] \cdot \tan\delta}{\cos\beta - \sin\beta \cdot \tan\delta} \quad (4$$

where T = geomembrane tensile force (i.e., anchor trench resistance force) unit width;
$(F_{RO})_B$ = friction force beneath runout geomembrane;
$(F_{AT})_L$ = friction force between the left side of the geomembrane and the side wall of the anchor trench;
$(F_{AT})_R$ = friction force between the right side of the geomembrane and the side wall of the anchor trench;
$(F_{AB})_B$ = friction force between the geomembrane and the underlying soil the bottom of the anchor trench;
$(F_{AB})_U$ = friction force between the geomembrane and the overlying soil a the bottom of the anchor trench;
$(\sigma_v)_{ave}$ = average vertical stress in anchor trench;
K_o = coefficient of at-rest earth pressure;
L_{RO} = runout length;
d_{CS} = depth of cover soil;
d_{AT} = anchor trench depth;
γ_s = unit weight of cover and backfill soil;
ϕ = friction angle of backfill soil in anchor trench;
δ_C = friction angle between the geomembrane and the underlying soil
δ_F = friction angle between the geomembrane and the backfill soil;
δ = friction angle between the geomembrane and the soil; and
β = sideslope angle, measured from horizontal.

The design of an anchor trench is considered to be adequate if mobilized st lies between the yield stress and allowable stress of the geosynthetic component should be mentioned that many manufacturers specify 1.5-feet- (0.45-m)-deep anc trenches and a 3.0-feet- (0.90-m)-long runout section.

EXAMPLE 4.5

Calculate the resistant capacity of a given geomembrane in a L-shaped rectangular anc trench of known dimensions. The geomembrane is 60-mil (1.5-mm) HDPE with an ultin strength (at yield) 2,100 lb/in^2 (14,500 kN/m^2) and an allowable strength 840 lb/in^2(5,800 kN/

4.6 Geotextiles against Soils

Appendix Figures 8a and 8b present NW-NP geotextiles against granular soils. Peak and residual shear strengths are both 33° and both adhesions are zero. This indicates that the shear plane is being forced into the soil as anticipated with the open structure of NW-NP geotextiles. There are many points in the data set, and the R^2-values are high. For NW-HB geotextiles as seen in Appendix Figures 8c and 8d the response is quite different. Peak and residual friction angles 28° and 16°, respectively, and adhesions are zero. Note that there are very few points in the data set, however the R^2-values are very high. Appendix Figures 8e and 8f give woven slit film geotextile against granular soils. The peak and residual friction angles are a surprisingly high 32° and 29°, respectively, with zero adhesion. The collected data of different geotextiles to granular soils is given in Table 9.

Table 9. Different geotextiles against granular soils.

Geotextile Type	Peak Friction (deg)	Residual Friction (deg)	Peak Adhesion (kPa)	Residual Adhesion (kPa)
Nonwoven, Needle Punched	33	33	0	0
Nonwoven, Heat Bonded	28	16	0	0
Woven, Slit Film	32	29	0	0

The data for these same geotextile types against cohesive soils is now presented. Appendix Figures 9a and 9b show a NW-NP geotextile against cohesive soil with peak and

Attachment B 1 of 2

residual friction angles of 30° and 21°, respectively. The peak has an adhesion of 5 kPa while the residual is zero. There is a reasonable number of data points and reasonable R^2-values in the peak strength response, but the data is not as well behaved in the residual strength responses. For a NW-HB geotextile against cohesive soil the data appears in Appendix Figures 9c and 9d. Peak and residual friction angles are 29° and 10° (somewhat less than with the NW-NP geotextile), with a slight adhesion accompanying the peak response. The data points are sparse. Finally, the woven slit film against cohesive soil is given in Appendix Figures 9e and 9f. Peak and residual friction angles are 29° and 19°, with zero adhesion in both cases. To compare and contrast the different geotextiles against cohesive soils see Table 10.

Table 10. Different geotextile against cohesive soils.

Geotextile Type	Peak Friction (deg)	Residual Friction (deg)	Peak Adhesion (kPa)	Residual Adhesion (kPa)
Nonwoven, Needle Punched	30	21	5.0	0
Nonwoven, Heat Bonded	29	10	0.9	0
Woven, Slit Film	29	19	0	0

4.7 Internal Shear Strength of GCLs

All of the data in this report has been performed according to ASTM D5321; recall Section 3.5 in this regard. In 1998, ASTM released a specific test method for GCLs. It is ASTM D6243, "Standard Test Method for Determination of Internal and Interface Shearing Resistance of a Geosynthetic Clay Liner by the Direct Shear Method". Unfortunately, the status for repeatability, reproducibility and uncertainty are unavailable for this more recent test method. That said, it is assumed that the majority of the GCL tests were performed by suitable modification of ASTM D5321.

Appendix Figures 10a and 10b present peak and residual internal shear strengths of reinforced GCLs. By far, the majority of the data is for needle punched GCLs (rather than the

Subject: **Addendum to the Revised Final Draft Feasibility Study for the Gardena Sumps Site:**
Optional Alternative 2A Cover
Gardena Sumps Site
Gardena, California

Dear Mr. Christie,

Geosyntec Consultants, Inc. (Geosyntec) has prepared this Addendum to the Revised Final Draft Feasibility Study (Revised Final Draft FS) in response to comments received from Department of Toxic Substances Control (DTSC) and the City of Gardena (City). The DTSC and City comments on the Revised Final Draft FS were presented in meetings held 11 July, 30 August, and 5 September 2013. The Addendum presents and discusses the changes to Alternative 2A resulting from the comments as well as future Site development concerns. A detailed analysis and ranking of the Optional Alternative 2A Cover will not be performed as the changes associated with the Optional Alternative 2A Cover do not affect the analyses of Alternative 2A presented in the Revised Final Draft FS (Geosyntec, 2013).

OPTIONAL ALTERNATIVE 2A COVER

Introduction

During the meeting on 11 July 2013, the DTSC expressed the City's concerns with the height and appearance of the proposed retaining wall along the northern edge of the Haack Sump and a portion of the Cooper North Sump. In response to this concern, the DTSC request Atlantic Richfield Company (ARC) to evaluate an alternative design that would eliminate the proposed retaining wall. Geosyntec has conceptually redesigned Alternative 2A in this Area. The retaining wall was eliminated and grading in the area affected by the elimination of the retaining wall (the "Optional Alternative 2A Cover") was revised to accommodate a minimum 5 percent (%) slope

draining to the north and terminating at a 6 to 9 inch (in.) concrete curb immediately adjacent to the Artesia Boulevard (Blvd.) sidewalk. The curb will deter unintended light traffic across the slope, act as a water-stop for drainage from the slope, and accommodate the slight variations in the existing Haack Sump concrete slab surface elevation. The modifications necessary to eliminate the retaining wall and allow for the Optional Alternative 2A Cover will require waivers of some requirements in California Code of Regulations, Title 22 (22 CCR). The elements of Optional Alternative 2A Cover are discussed in more detail in the following Sections.

Cap Modifications

The Optional Alternative 2A Cover will be comprised of the same foundation and gas collection layers, and low-hydraulic conductivity layer as described in the Revised Final Draft FS for Alternative 2A. The Optional Alternative 2A Cover foundation layer will have no minimum thickness to accommodate the northern border slope and requires a 30-foot set-back southward from the Artesia Boulevard sidewalk before the cover system has sufficient strength to allow for vehicle traffic. To allow vehicle traffic over the cover to the south, the foundation layer will thicken from north to south at an approximate minimum slope of 2.5 percent until a minimum foundation layer thickness of 0.5 foot (ft) and 1 ft on the Haack and Cooper Sumps, respectively, is achieved. In addition, the erosion protection layer will have no minimum requirement and will thicken southward with an approximate minimum slope of 5 percent until 1 foot of Class II aggregate base is present over the drainage geocomposite. As a result, a 30 ft wide landscaped strip will border the northern Gardena Sumps site where no vehicle traffic will be permitted. The revised grading and cross sections are shown on Figures 1 through 4.

There are no proposed changes to the gas collection layer, high-strength geotextile, or low-hydraulic conductivity layer resulting from this cap modification. Drainage above the low-hydraulic conductivity layer and below the erosion protection layer will be accommodated with the geocomposite drainage layer as described in the Revised Final Draft FS (Geosyntec, 2013).

Drainage

A 6 to 9 in. concrete curb is proposed between the border of the Haack and Cooper North sumps and the Artesia Blvd. sidewalk where drainage would otherwise run off the Site. The curb will minimize the amount of run off flowing from the Site onto the Artesia Blvd. sidewalk as well as support a trench drain or shallow water conveyance feature at the toe of the slope. The variation in height of the curb is proposed due the variable height of the existing Haack Sump concrete slab relative to the sidewalk. The variable height will also support drainage to the east and west. The curb will further prevent inadvertent light traffic, such as foot traffic, bicycles, and/or

wheelchairs, from entering the sloped portion of the cover. The cover slope and concrete curb are shown in Detail 2 on Figure 7.

Monitoring and Control Systems

The Optional Alternative 2A Cover does not affect the gas monitoring and control system or the groundwater monitoring program. The sheet pile cut-off wall is still proposed along the northern edge of the Haack Sump and a portion of the Cooper Sump; however, the wall will not extend above the existing ground surface. As a result, no additional gas extraction wells are proposed in this area. The locations of the gas control system components are shown on Figures 5 and 6 with the Revised Alternative 2A Cover grading.

Land Use Covenants

Institutional controls were discussed in the Revised Final Draft FS; however, the specific land use covenants (LUCs) are described herein. The term "land use covenants" includes written instruments and agreements restricting land uses, easements, servitudes, and land use restrictions. The LUCs entered into or required by DTSC will "run with the land," i.e., are binding on current and subsequent property owners, and remain in effect until they are formally removed or modified (DTSC, 2003). The list of LUCs presented is not all-encompassing; other necessary LUCs may be identified in the future.

LUCs identified for the Site include maintenance requirements, zoning restrictions, limited development above the cover, and limited excavation in and around the cover. Specific LUCs for the property owner(s) and responsible parties (RPs) are listed below:

- The property owner(s) will be responsible for maintenance of a parking lot or other non-structural surface above the Alternative 2A engineered cap such as asphalt paving, concrete, or vegetation;
- The property owner(s) will be responsible for maintaining vegetation and ensuring minimal root depth of vegetation;
- The property owner(s) will be responsible for maintenance of necessary fencing, gates, and walls around the Site;
- The property owner(s) will be responsible for posting and maintaining notification signs within onsite buildings, the RPs will be responsible for posting and maintaining signs within open spaces;

- The property owner(s) will notify the DTSC and RPs of activities within limits of cover such as trenching or filling and not proceed with activities without a written approval of activities;
- The Cooper and Haack properties will be restricted to open space, commercial use, or industrial use;
- Pumping and removal of shallow groundwater beneath the Site will be restricted except for sampling and monitoring purposes;
- Use of the Cooper and Haack properties will be limited to those which will not disturb the integrity of the cap or monitoring systems;
- The property owner(s) will notify the DTSC and RPs of any disturbance of the soil, such as excavation, grading, removal, trenching, mining, or drilling of gas, oil, or water wells on the Properties. Excavation, grading, removal, trenching, mining, and/or drilling will be limited and only as approved by the DTSC and RPs on the capped portions of the Cooper and Haack properties;
- Easements will be granted to the DTSC and RPs for inspection, surveillance, monitoring, maintenance, or other purposes necessary to protect public health or safety;
- Subdivision of the Cooper or Haack Properties will be prohibited;
- Notifications will be required for those purchasing, leasing, subleasing, and/or renting the property stating that residual contamination exists. Notifications will be provided by the RPs or owner, as appropriate;
- Notification to the DTSC of any sale, lease, or other conveyance of the properties by the owner or RPs, as appropriate; and
- Requirement for a deed notice notifying potential purchasers that the properties have been used to manage hazardous waste and that use of the properties is restricted.

The LUCs will be recorded at the county recorder's office so they will be found during a title record search of the property deed.

REGULATORY WAIVERS

A waiver would be necessary from the requirements in 22 CCR in order to remove the minimum foundation and erosion protection material thicknesses presented for the Optional Alternative 2A Cover. The specific requirements that would need to be waived are provided below:

- Foundation Layer

  - Requirement: “A foundation layer shall be provided for the compacted barrier layer of the final cover… …The layer shall be compacted at a moisture content sufficient to achieve the density required to provide adequate support for the nonearthen membrane…” (22 CCR Section 66264.228(e)(4))
  - Discussion: The foundation layer would be reduced to zero at the northern Haack and portion of the Cooper North Sumps property line. The existing concrete slab in the Haack Property and in-place soil in the Cooper North Property will provide support for the gas collection geocomposite and overlying low-hydraulic conductivity layer.
- Cover Soil
  - Requirement: “The owner or operator shall provide a layer of top soil of thickness sufficient to support vegetation for erosion controlled deep enough to prevent root penetration into the filter layer. The top soil shall have characteristics to protect the compacted layer against drying that would lead to cracking, to resist erosion and to support vegetation growth…” (22 CCR Section 66264.228(e)(12))
  - Discussion: The 1-ft. thick cover soil at Site will primarily be Class II Aggregate Base in accordance with the proposed parking lot end use. In the sloped areas, the cover soil will be a vegetative cover soil with a thickness that may be reduced to zero.

Other waivers of requirements in 22 CCR may be required once the final design of Optional Alternative 2A is completed.

The gas collection system and geomembrane will be supported by either the existing concrete slab on the Haack Property or existing in-place soil on the Cooper Property. The geomembrane will be protected by the overlying geocomposite with vegetative cover soil, Class II Aggregate Base, artificial turf, or concrete or other durable materials.

SPECIFIC PLAN COMPLIANCE

The City developed the Artesia Corridor Specific Plan (Specific Plan) which establishes the development vision for the properties on the south side of Artesia Boulevard between Western and Normandie Avenues (TPC, 2006). The Specific Plan designates the vast majority of the Gardena Sumps site for commercial use.

Site Layout

The Alternative 2A conceptual design complies with the City's Specific Plan. Commercial/retail structures up to 80,000 sf in size may be accommodated outside of the Alternative 2A engineered cap portion. Space may be allocated above the capped portions of the property for parking.

Utilities and Lighting

Utilities for the building may be accommodated by trenching outside of the capped portions of the Gardena Sumps site, primarily parallel to the Haack and Cooper boundaries on the west and south. Some electrical conduit may be installed within or above the aggregate base layer of the cover in accordance with the Risk Management Plan discussed in the Revised Final Draft FS (Geosyntec, 2013). Parking lot lighting may be accommodated by installing light poles around the perimeter of the parking lot and/or within the parking lot outside of the cover. Within the capped portion of the Gardena Sumps site, lighting structures with minimal foundations depths would be suitable.

Long Term Monitoring

Long term monitoring at the Gardena Sumps site will include settlement, groundwater, and soil gas monitoring. If development occurs shortly after the remedy is implemented, monitoring locations can be incorporated into the development features such as walkways, vegetative strips, etc. to limit disruption to the commercial activities during monitoring events. If development occurs after monitoring locations have been installed, monitoring locations could be moved to accommodate the development.

Zoning

The Strategic Plan has identified the Gardena Sumps site for commercial development. The Site-Specific Action Levels (SSALs) identified in the Revised Final Draft FS were a derivation of risk-based concentrations for the Gardena Sumps site's constituents of concern (COCs). These SSALs were used to identify areas of the Gardena Sumps site which would require action based on cancer and non-cancer risks for residential receptors, the most conservative receptor. The areas of the Gardena Sumps site in excess of the residential SSALs were addressed in Alternative 2A through capping or select excavation. As a result, the Gardena Sumps site can accommodate the less conservative, commercial receptor development.

CONCLUSIONS

The Optional Alternative 2A Cover does not impact the evaluation and comparison of Alternative 2A to the nine evaluation criteria (USEPA, 1988). Alternative 2A readily meets the criteria of overall protection of human health and the environment and satisfies Applicable or Relevant and Appropriate Requirements (ARARs). When evaluated against the balancing criteria, Alternative 2A provides short-term effectiveness as well as long-term effectiveness and permanence. It is implementable and presents an effective balance of cost against the evaluation criteria. Alternative 2A also would accommodate future potential redevelopment of the Site (Geosyntec, 2013). As a result, Alternative 2A, as revised by this Addendum, is the preferred remedy for the Site.

If you have any questions, please contact Mrs. Rebecca Oliver at (858) 716-2926.

Sincerely,

Rebecca F. Oliver, P.E.

Stantec Consulting Services Inc.
3777 Worsham Avenue, Suite 200, Long Beach CA 90808-1774

February 24, 2015
File: 185850299.500

Attention: Mr. Mustapha Guerbaz
Remedial Project Manager
Brownsfield and Environmental Restoration Program
Department of Toxic Substances Control
5796 Corporate Avenue
Cypress CA 90630

Dear Mr. Guerbaz,

Reference: Temporary Cover Installation at the Haack Rework Area
Gardena Sumps Site, DTSC Project No. 401218
Southwest Corner of West Artesia Boulevard and Normandie Avenue
Gardena, California 90247

Stantec Consulting Services Inc. (Stantec), on behalf of Atlantic Richfield Company (ARC), has prepared this report on the installation of the temporary cover over the existing geomembrane covering the Haack Rework area. This work was outlined in the *Work Plan for Temporary Cover Installation at the Haack Rework Area* presented to the Department of Toxic Substances Control (DTSC) on October 21, 2014. The Work Plan was approved by the DTSC on November 12, 2014. This temporary cover will prevent rainwater infiltration and/or accidental dermal exposure until the final remedy is implemented as proposed in Geosyntec Consultant's July 1, 2014 *Revised Final Feasibility Study Report (FS Report)*.

All remedy alternatives evaluated in the *FS Report* would remove the temporary cover, geomembrane, and waste material from the Haack Rework Area. For this reason ARC requested this temporary cover to be placed over the existing geomembrane in the Haack Rework Area.

Site Description

The Site is located on the southwest corner of Artesia Boulevard and Normandie Avenue, in the City of Gardena, Los Angeles County, California (Figure 1). The Site occupies approximately 5.6 acres and is subdivided into two parcels of approximately 3.0 acres (Cooper Property) and 2.6 acres (Haack Property). The Site (Figure 2) is bordered to the south by a Los Angeles County Department of Public Works (LACDPW) property and the concrete-lined Dominguez Flood Channel and to the west by commercial and residential buildings.

The area where the temporary cover is to be placed is in the central eastern portion of the Haack Property (Figure 3) that is currently covered with 45 mil geomembrane material. The geomembrane was installed by the DTSC in 1994, and had become degraded over the years with a number of rips and tears.

Reference: **Temporary Cover Installation at the Haack Rework Area**
Gardena Sumps Site, DTSC Project No. 401218
Southwest Corner of West Artesia Boulevard and Normandie Avenue
Gardena, California 90247

Health & Safety

Prior to start of field activities, Stantec updated the site-specific health and safety plan (HASP) in compliance with 29 CFR 19.10.120(e). All personnel working on the site were required to review the HASP prior to beginning work and signed an agreement that they will adhere to the conditions in the HASP. Additionally, all site field personnel and subcontractors were ARC Control of Work (CoW) trained.

The following health and safety protocol were followed while on site:

1. Site workers conducted a daily tailgate meeting and review the Site Specific Health and Safety Plan;

2. An ARC Hazard Identification Task Risk Assessment (HITRA) were completed and reviewed by Stantec personnel and subcontractors prior to implementation of work;

3. The following Personal Protective Equipment (PPE) were worn:

    a. Hard hat
    b. Steel toe boots
    c. Safety glasses
    d. Long sleeve shirts and pants
    e. Safety vest
    f. Latex, Kevlar, and/or leather gloves as appropriate
    g. Particulate dust masks as needed

4. All equipment operators were certified to operate the specific piece of equipment they were using such as skip loaders and/or Bobcat type of equipment.

Scope of Work

The following scope of work was followed to install the temporary cover over the original geomembrane cover at the Haack Rework Area:

1) Cleaned off debris and soil from adjacent slope with flat shovels and brooms;

2) Patched existing rips and tears using surplus polypropylene ethylene copolymer (PEC) geomembrane material in general accordance with Stantec's June 25, 2013 *Interim Cover Maintenance Plan*. No testing of repairs were performed as this is a temporary repair;

Reference: **Temporary Cover Installation at the Haack Rework Area**
Gardena Sumps Site, DTSC Project No. 401218
Southwest Corner of West Artesia Boulevard and Normandie Avenue
Gardena, California 90247

3) Installed Americover® 20 mil Reinforced Heavy Duty White sheeting (Americover®) over the original PEC cover. The Americover sheeting is constructed of reinforced polyethylene film on two sides that encapsulate a grid pattern of polyester yarn, and a hot sheet of polyethylene, to form a very strong three layer product (Attachment A). The Americover® sheeting was in approximate 20 x 50 foot sections and were connected using double-side tape with a 3 inch overlap. The overlap was sealed using 4 inch wide, heavy-duty tape that has weather resistant polyethylene backing with a rubber adhesive provided by Americover;

4) The Americover® sheeting extended beneath the existing Cooper Sumps perimeter fence to a length that covered the western edge of the new Cooper Sumps liner, and beneath the Best Management Practice (BMPs) devices currently placed around the perimeter;

5) Placed a minimum of two layers of sand bags (BMPs) around the perimeter of the covered area above the Americover® sheeting that is between the Haack Rework Area and Cooper Sumps; and

6) Placed 3-4 inches of clean Class II Base Rock, not compacted, above the Americover® sheeting to prevent sunlight degradation.

Figure 3 shows the location of the temporary cover installation. Figure 4 shows the cover placement for the Haack Rework Area temporary cover. Attachment B has photographs of the old geomembrane, the covering of Americover®, and the final soil covering.

The Haack Rework Area will be inspected during the quarterly groundwater monitoring events in general compliance with Stantec's June 25, 2013 *Interim Cover Maintenance Plan.* The results of these inspections will be documented in the *Annual Cover Inspection and Maintenance Report*, submitted to the DTSC annually.

- Railroad Car Covers
- Temporary Walls
- Asbestos, Lead, or Mold Abatement Applications
- Building Enclosures
- Scaffold Wrapping
- Remediation Covers
- Underslab Vapor Retarders
- Crawlspace

Product Description

Americover's PSR offers several advantages in different applications. With its 1000 denier polyester string the Americover's PSR series offers excellent tear strength at the string and the open areas between the strings provide outstanding elongation properties. These physical characteristics make our PSR the appropriate material for a wide variety of applications.

Americover's PSR Films are manufactured using a blend of the best virgin polyethylene resins formed into two skins. These skins act as the "bread" to the reinforced "sandwich" encapsulating a grid pattern of polyester string and a hot sheet of polyethylene to form a three layer product suitable for multiple applications.

Product Use

PSR 20WW is significantly stronger and more tear resistant than standard 20 mil poly films. The extrusion lamination process and high strength reinforcement scrim make these films exceptionally strong.

Size & Packaging

Standard rolls are 6.75' x 100', 13.34' x 100' and 20' x 100'. Custom sizes available to meet your specifications.

Environmental Oversight Agreement
for the City of Gardena, Gardena Sumps Site

Docket No. HSA-FY 17/18-092

1. INTRODUCTION

This Environmental Oversight Agreement ("Oversight Agreement") is made between the City of Gardena ("City" or "Local Agency") and the California Environmental Protection Agency, Department of Toxic Substances Control ("DTSC") in connection with a "blighted property" as that term is defined in Health and Safety Code Section 25403(b).

1.1. Purpose of Agreement. The purpose of this Oversight Agreement is to facilitate the City's investigation of the Gardena Sumps property, located within the City's and DTSC's jurisdiction; to provide for reimbursement of DTSC's oversight costs; and to assist the City in meeting the requirements to complete the investigation plan. Under this Oversight Agreement, the City may request (and pay for) oversight without any commitment to move forward with a project and may request early consultation with DTSC, where desirable.

1.2. Parties. DTSC and the City are each a "Party" to, and collectively are the "Parties" to, this Oversight Agreement.

1.3. Jurisdiction.

1.3.1. City's Jurisdiction. The City is authorized by Section 25403 to take certain actions in response to blighted properties within its corporate boundaries. Section 25403.1, subdivision (a)(1)(A) authorizes the Local Agency to take any action that the Local Agency determines is necessary and that is consistent with other state and federal laws to investigate or clean up a release of hazardous material (as that term is defined in Health and Safety Code section 25403(i)), on, under, or from a blighted property located within the Local Agency, whether the Local Agency owns the property or not, if the applicable provisions in Health and Safety Code section 25403.1, subdivisions (a) and (b) are satisfied. In addition, Health and Safety Code sections 25403.1(a)(2)(B) and 25403.4 recognizes the need for the Local Agency to pay the DTSC's costs pursuant to an agreement. This Oversight Agreement includes payment of the DTSC's costs to review and approve the investigation plan and conduct certain oversight of completion of that plan.

1.3.2. DTSC Jurisdiction. Health and Safety Code section 25403 et seq. authorizes DTSC to enter an Oversight Agreement with a Local Agency with respect to a blighted property and calls for cost reimbursement agreements between DTSC and local agencies.

1.4 Property. The Parties intend for this Oversight Agreement to be utilized in connection with the Cooper portion of the Gardena Sumps property (Gardena Sumps), which is located on the southwest corner of Artesia Boulevard and Normandie Avenue,

and is identified by Los Angeles County Parcel Numbers 6106-036-034 and 6106-036-035.

2. AGREEMENT

THE PARTIES HEREBY AGREE AS FOLLOWS:

2.0. Activities to be Conducted. DTSC and the City will undertake activities as specified in this Oversight Agreement and as more specifically detailed in Exhibits A, B, and C. The Parties acknowledge and agree that all work performed pursuant to this Oversight Agreement is intended to be consistent with applicable laws and regulations, including, but not limited to, Health and Safety Code sections 25403-25403.8.

2.1. Intentionally Omitted.

2.2. Amendment of Exhibits. Upon approval in writing by the Oversight Agreement Manager for DTSC and by the City, any one or more of the Exhibits may be amended and the Exhibits, as amended, will be incorporated into this Oversight Agreement.

2.3 Additional Activities. Activities in addition to those specified in an agreed upon Scope of Work may be conducted, and DTSC oversight provided, pursuant to amendment(s) to an Exhibit in accordance with Sections 2.2 and 2.8. If DTSC expects additional oversight costs to be incurred related to these additional activities, DTSC will provide an estimate of the additional oversight cost to the City as an amendment to Exhibit B as provided in section 2.8.

2.4 Oversight Agreement Managers and Project Managers. Patrick Hsieh is designated by DTSC as its Project Manager for this Oversight Agreement. Mitchell G. Lansdell is designated by the City as its Manager for this Oversight Agreement. Each Party to this Oversight Agreement will provide at least ten (10) days advance written notice to the other of any change in its designated Oversight Agreement Manager. DTSC and the City may designate a Project Manager for the property incorporated into this Oversight Agreement. Both DTSC and the City reserve the right to appoint different Project Managers, pursuant to this Oversight Agreement, for different projects that may be ongoing at the same time.

2.5 Notices and Submittals.

2.5.1 All notices, documents and communications that are to be given under this Oversight Agreement, unless otherwise specified, will be sent to the respective Parties at the following addresses

To DTSC:

Patrick Hsieh
Brownfields & Environmental Restoration Program
Department of Toxic Substances Control
5796 Corporate Avenue
Cypress, California 90630

To the City:

Mitchell G. Lansdell, City Manager (retired)
City of Gardena
1700 W. 162nd Street, Room 112
Gardena, 90247-3778

2.5.2 The Parties will give such notices to known property owners and other parties as required by applicable law.

2.6 DTSC Document Review and Approval. If DTSC determines that any report, plan, schedule or other document submitted for approval pursuant to this Oversight Agreement does not meet the conditions in this Oversight Agreement or fails to protect public health or safety or the environment, DTSC will consult with the City and return comments to the City with recommended changes.

2.7 Extension Requests. If the City is unable to perform any activity or submit any document within the time required under this Oversight Agreement, the City may, prior to expiration of the time, request an extension of the time in writing. The extension request shall include a justification for the delay. All such requests shall be in advance of the date on which the activity or document is due.

2.8 Payment. A current estimate of DTSC's oversight costs with respect to the Scope of Work described in Exhibit A is contained in Exhibit B. The Parties understand that the estimate set forth in Exhibit B cannot be relied upon as the final cost figure. The City agrees to pay (1) all costs incurred by DTSC in association with preparation of this Oversight Agreement; (2) for review of documents submitted by the City subsequent to the effective date of this Agreement; and (3) all costs incurred by DTSC in implementing, providing oversight, or conducting other activities pursuant to this Oversight Agreement. Costs incurred include interest on unpaid amounts that are billed and outstanding more than 60 days from the date of DTSC's quarterly invoice. DTSC will notify the City when its charges approach sixty-five percent (65%) of the total Cost Estimate prepared for the property. The Parties agree to evaluate the budget to determine if either a revised estimate or scope of work is needed at the time of the written notice or whether the City wishes to terminate as provided in Section 24 of the Standard Provisions (Exhibit D). If DTSC or the City anticipates a change in the Scope of Work or the need for revision of the Cost Estimate, DTSC will provide a revised estimate in advance of exceeding the total cost estimate.

2.8.1 In anticipation of the activities to be completed under this Oversight Agreement, the City will make an advance payment of $33,305 to DTSC no later than thirty (30) days after the effective date of this Oversight Agreement. If the City's advance payment does not cover all costs payable to DTSC under this subsection, DTSC will invoice the City quarterly. The City agrees to pay the additional costs within sixty (60) days of receipt of DTSC's quarterly invoice.

2.8.2 All payments made by the City for activities performed pursuant to this Oversight Agreement will be by check made payable to the "Department of Toxic Substances Control," and bearing on its face the project code for the property (DTSC Site Code 301801) and the Contract Number of this Oversight Agreement. Payments should be made to:

Department of Toxic Substances Control
Accounting/Cashier
1001 I Street, 21st Floor
P.O. Box 806
Sacramento, California 95812-0806

2.9 Exhibits. Standard provisions of this Oversight Agreement are contained in Exhibit D (Oversight Agreement Standard Provisions), attached to this Oversight Agreement. All exhibits attached to this Oversight Agreement, including Exhibit D, are incorporated into this Oversight Agreement by reference.

2.10. Effective Date. The effective date of this Oversight Agreement is the date when this Oversight Agreement is fully executed.

2.11. Representative Authority. Each undersigned representative of the Parties to this Oversight Agreement certifies that she or he is fully authorized to enter into the terms and conditions of this Oversight Agreement and to execute and legally bind the Party to this Oversight Agreement.

2.12. Counterparts. This Oversight Agreement may be executed and delivered in any number of counterparts, each of which when executed and delivered shall be deemed to be an original, but such counterparts shall together constitute one and the same document.

C EXCAVATION PILOT TEST AND FEASIBILITY ANALYSIS WORK PLAN (to be attached once reviewed and approved)

D OVERSIGHT AGREEMENT STANDARD PROVISIONS

EXHIBIT A

INITIAL SCOPE OF WORK: GARDENA SUMPS EXCAVATION PILOT TEST AND FEASIBILITY ANALYSIS WORK PLAN

The following tasks may be completed as part of this Oversight Agreement:

TASK 1. Technical Consultation and Assistance With Work Plan for Pilot Test.

DTSC will provide technical consultation and assistance to the City in connection with developing an Excavation Pilot Test and Feasibility Analysis Work Plan (Work Plan) to implement a pilot test designed to evaluate various issues (including but not limited to those specified on Exhibit A-1) that may arise in connection with an excavation-oriented remedy at the Gardena Sumps site. Technical consultation may include, but is not limited to, participating in meetings and/or conference calls; researching responses to City's questions; reviewing and approving technical reports; conducting site visits; and performing other related activities requested by the City. DTSC's technical consultation shall not include actual physical cleanup of the Gardena Sumps site.

TASK 2. The final Work Plan, when approved by DTSC, shall be included as Exhibit C to the Oversight Agreement .

TASK 3. The parties agree to meet and confer regarding public participation efforts they may undertake including, but not limited to, the issuance of a Fact Sheet related to the Work Plan activities.

TASK 4. The City will comply with California Environmental Quality Act (CEQA) as applicable for all activities conducted under the Oversight Agreement.

TASK 5. The City and its contractor will submit to DTSC the draft Work Plan within 45 days of the effective date of this Agreement.

TASK 6. The City will work with its contractor, under DTSC field oversight, to implement the Work Plan within sixty (60) days of DTSC approval of the Work Plan. The City may request an extension of up to sixty (60) days, if needed, to obtain City Council approval of the full funding to implement the Work Plan.

TASK 7. The City and its contractor will submit to DTSC a Work Plan Report describing the collected data and recommendations in connection with the evaluation of the excavation-oriented remedy alternative within 45 days of completing field activities.

EXHIBIT A-1

DTSC'S GOALS FOR SLUDGE PILOT STUDY GARDENA SUMPS SITE
AS PROVIDED TO GARDENA

GAS GENERATION

- Quantify generation of hydrogen sulfide and sulfur dioxide gases to determine potential threat to workers and public
- Evaluate containment measures such as
    - Tent
    - Hood over auger
    - Spray-on products (Hydroseal, Odex)
    - Gas treatment methods

SOLIDIFICATION/NUETRALIZATION OF SLUDGE

- Evaluate methods of mixing sludge and amendments to facilitate excavation and off-haul
    - Bucket mixing
    - Auger
    - Pug mill
- Evaluate different amendment mixtures using the results of the previous bench-scale testing, or perform new testing

TRANSPORTATION

- Determine effective methods of or need for odor control
- Is direct loading necessary/feasible
- Evaluate haul truck accessibility
- Can amended or un-amended sludge be stockpiled and under what conditions

DISPOSAL

- Identify receiving facilities and their requirements
- Identify any treatment necessary to meet disposal facility requirements
- Feasibility of Clean Harbors Buttonwillow performing amendment/neutralization, excavation and disposal

EXHIBIT D

OVERSIGHT AGREEMENT STANDARD PROVISIONS

1. The Standard Provisions in this Exhibit D are incorporated by reference into and are a part of the Oversight Agreement. The Standard Provisions have been placed in this Exhibit D for reasons of administrative efficiency. As used herein Local Agency has the meaning provided in Health and Safety Code section 25403.

2. Payment Provisions. Subject to Section 2.8 of the Oversight Agreement, if any bill is not paid by the Local Agency within sixty (60) days after it is sent by DTSC, the Local Agency may be deemed to be in material default of this Oversight Agreement.

If an advance payment is called for under Section 2.8 of this Oversight Agreement, and if such advance payment exceeds DTSC's actual costs for Oversight Agreement preparation, consultation, review, approval, oversight and other activities conducted under this Oversight Agreement, DTSC will provide an accounting for expenses and refund the difference within one hundred-twenty (120) days after termination of this Oversight Agreement in accordance with Section 24 of this Exhibit. In no other case will the Local Agency be entitled to a refund from DTSC or to assert a claim against DTSC for any amount paid or expended under this Oversight Agreement.

3. Billing Dispute Resolution. If the Local Agency disputes a DTSC billing, or any part of a DTSC billing, the Local Agency will notify DTSC's designated Oversight Agreement Manager and attempt to resolve the dispute informally. If the Local Agency desires a formal dispute resolution process with regard to the billing, the Local Agency will file a request for dispute resolution in writing within 45 days of the date of receiving the bill in dispute, or by such later deadline as the Parties may agree to in writing. The written request will describe all issues in dispute and will set forth the reasons for the dispute, both factual and legal. The Local Agency will send the written request to:

Special Assistant for Cost Recovery and Reimbursement Policy
Department of Toxic Substances Control
P.O. Box 806
Sacramento, CA 95812-0806

The Local Agency will also send a copy of the written request for dispute resolution to the person designated in subsection 2.5.1 of this Oversight Agreement to receive submittals. A decision on the billing dispute will be rendered by the person designated above or other DTSC designee. The existence of a dispute shall not excuse, stay or suspend any other compliance obligation or deadline required pursuant to this Oversight Agreement.

4. Communications. All DTSC approvals and decisions made regarding submittals and notifications will be communicated to the Local Agency in writing by DTSC's Oversight Agreement Manager or his/her designee. No informal advice, guidance, or suggestions or comments by DTSC regarding reports, plans, specifications, schedules or any other writings by the Local Agency shall be construed to relieve the Local Agency

of the obligation to obtain such written approvals.

5. Endangerment During Implementation. In the event DTSC determines that any activity or operations caused by or on behalf of the Local Agency or its agents (whether or not pursued in compliance with this Oversight Agreement) may pose an imminent or substantial endangerment to the health and safety of people on any property or in the surrounding area or to the environment: i) the Local Agency will take the necessary actions as directed by DTSC to abate the endangerment it created for such period of time as may be needed to abate the endangerment; or ii) if DTSC determines that conditions require DTSC to exercise its authority to abate the endangerment, the Local Agency may stop further implementation of this Oversight Agreement. However, if the Local Agency stops implementation, the Local Agency must meet the conditions under Section 12 of this Exhibit (Notification of Environmental Condition) and, if necessary, must revise the applicable Scope of Work and meet the stop-work conditions as provided in Section 23 of this Exhibit (Amendments). If DTSC determines that an endangerment is the result of Local Agency actions that have caused a release of hazardous materials or substantially worsened the endangerment, the Local Agency will take those reasonable steps DTSC determines are necessary to mitigate the condition that the Local Agency caused or substantially worsened and to secure the property in order to avoid endangerment to the community. These steps may include installing a protective cover, constructing fencing and signage or other appropriate means to protect public health and the environment. The Local Agency will not be compelled to fully assess or mitigate a release of hazardous materials if DTSC determines that the Local Agency did not cause or substantially worsen the release.

6. Condition Precedent. It is expressly understood and agreed that DTSC's receipt of the advance payment, if any, described in subsection 2.8.1 of this Oversight Agreement is a condition precedent to any obligation of DTSC to provide consultation, oversight, review and/or comment on documents or to provide any work or perform any activity pursuant to this Oversight Agreement.

7. Record Retention. DTSC will retain all cost records associated with the work performed under this Oversight Agreement for such time periods as may be required by applicable state law. The Local Agency may request to inspect all documents that support DTSC's cost determination in accordance with the Public Records Act, Government Code section 6250 *et seq.*

8. Project Coordinator. The work performed pursuant to this Oversight Agreement will be under the direction and supervision of a qualified Project Coordinator, with expertise in the cleanup of sites impacted by hazardous materials. The Local Agency will submit: a) the name and address of the Project Coordinator; and b) in order to demonstrate expertise in the cleanup of sites impacted by hazardous materials, the resume of the Project Coordinator. The Local Agency will promptly notify DTSC of any change in the identity of the Project Coordinator. All engineering and geological work shall be conducted in conformance with applicable state law, including but not limited to, Business and Professions Code sections 6735 and 7835.

9. Access. If DTSC determines access is necessary in order to perform any of the tasks contained in Exhibit A (Scope of Work), the Local Agency will exercise its best efforts to provide access for its contractors and representatives, DTSC and its representatives, and any other governmental entity with jurisdiction over any aspect of this project, to the property subject to this Oversight Agreement for which access is needed. In the event that such access is not provided, it is understood that the implementation of tasks identified in this Agreement for the property for which access cannot be obtained may not proceed. The Local Agency will also exercise its best efforts to provide access for DTSC and its representatives access and/or obtain access to any area beyond the boundaries of the Property subject to this Oversight Agreement to which access is necessary to implement this Oversight Agreement. To the extent such access is obtained by the Local Agency, such access will be provided to DTSC's employees, contractors, and consultants at all reasonable times. Nothing in this section is intended or shall be construed to limit in any way the right of entry or inspection that DTSC or any other agency may otherwise have by operation of any law. To the extent such access can be legally obtained by DTSC or the Local Agency, DTSC and its authorized representatives shall have the authority to enter and move freely about all of the property at the property at all reasonable times for purposes including, but not limited to: inspecting records and operating logs, sampling activities, administering any other aspects of this Oversight Agreement relating to the property, reviewing the progress of the Local Agency in carrying out the terms of this Oversight Agreement, conducting such tests as DTSC may determine are necessary, and verifying the data submitted to DTSC by the Local Agency.

10. Sampling, Data and Document Availability. The Local Agency will submit to DTSC a listing of all known reports in its possession, including sample analysis results, environmental assessment reports, and any other information in its possession pertinent to the hazardous materials management and/or release, characterization and cleanup of the property. The Local Agency will provide copies of any non-privileged reports or information requested by DTSC and will identify privileged or other confidential documents that the Local Agency is not providing. The Local Agency will also inform DTSC of any other known reports and documents, not in its possession, pertinent to the hazardous materials release, characterization and cleanup of a property, including the name of the document (if known) and the identity and address of the person/entity with possession of the document (if known).

11. Notification of Field Activities. The Local Agency will inform DTSC at least seven (7) days in advance of all field activities which the Local Agency undertakes, including activities the Local Agency directs a third party to undertake, pursuant to this Oversight Agreement at the property and will allow DTSC and its authorized representatives to take duplicates of any samples collected by the Local Agency pursuant to this Oversight Agreement.

12. Notification of Environmental Condition. The Local Agency shall notify DTSC's Agreement Manager immediately upon learning of any condition posing an immediate threat to public health or safety or the environment. Within seven (7) days of the Local Agency's discovery of such a condition, the Local Agency shall submit a brief report to

DTSC, setting forth the events that occurred and the measures taken, if any, in response to those events.

13. Preservation of Documentation. The Local Agency will maintain a central repository of the data, reports, other documents that it prepares pursuant to this Oversight Agreement and other documents relevant to the activities conducted under this Oversight Agreement. All such data, reports and other documents regarding the property will be preserved by the Local Agency for a minimum of six (6) years after the conclusion of all activities carried out under this Oversight Agreement with respect to the property. If DTSC requests that some or all of these documents be preserved for a longer period of time, the Local Agency will either: (i) comply with that request, (ii) deliver the documents to DTSC, or (iii) permit DTSC to copy the documents prior to destruction. Following the expiration of the six-year minimum retention period for documents regarding the property, the Local Agency will notify DTSC in writing at least ninety (90) days before destroying any documents prepared pursuant to this Oversight Agreement with respect to the property. If any litigation, claim, negotiation, audit or other action involving the records has been started before the expiration of the six-year period with respect to the property, the related records will be retained until the completion and resolution of all issues arising from that action or until the end of the six-year period, whichever is later.

14. Time Periods. Unless otherwise specified, time periods begin from the date this Oversight Agreement is fully executed, and "days" means calendar days. "Business days" means all calendar days that are not weekends or official State holidays.

15. Local Agency Liabilities. This Oversight Agreement shall not be construed in any manner as an admission by the Local Agency of any fact or liability of any kind, nor shall this Oversight Agreement be considered or interpreted as an admission or an assumption by the Local Agency of any liability or acknowledgment of liability or responsibility for the investigation or assessment of, response or remediation to any environmental condition on the property or the costs of such activities, for which the Local Agency is not otherwise liable or responsible. Nothing in this Oversight Agreement shall constitute or be considered a satisfaction or release from liability for any condition or claim arising as a result of Local Agency's past, current, or future operations. Nothing in this Oversight Agreement is intended or shall be construed to limit the rights of any of the Parties with respect to claims arising out of or relating to the release, discharge, deposit or disposal of hazardous materials at the property or at any other location, if such hazardous materials are removed from the property.

16. State Government Liabilities. The State of California (State) shall not be liable for any injuries or damages to persons or property resulting from acts or omissions by the Local Agency or its directors, officers, employees, agents, representatives, successors, assigns, contractors or consultants in carrying out any action or activity pursuant to this Oversight Agreement. Neither DTSC nor the State may be deemed to be a party to any contract entered into by the Local Agency or its directors, officers, employees, agents, successors, assigns, contractors or consultants in carrying out any action or activity pursuant to this Oversight Agreement.

17. Third Party Actions. In the event that the Local Agency is a party to any suit or claim for damages or contribution to which DTSC is not a party, relating to the property subject to this Agreement, the Local Agency will notify DTSC in writing within ten (10) days after service of the complaint in the third-party action. However, failure to give such notice within 10 days will not be a material breach of this agreement, and this requirement confers no rights on any third parties not party to this Agreement.

18. Reservation of Rights. DTSC and the Local Agency each reserve the following rights.

a. DTSC reserves its right to pursue cost recovery under the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA), as amended, California Health and Safety Code sections 25201.9, 25343, 25360, 33459.3, subdivision (m) and any other law. The Local Agency reserves its rights to pursue cost recovery under the California Health and Safety Code section 25403.3 and any other applicable section of the law.

b. Nothing in this Oversight Agreement is intended or shall be construed to limit, preclude or affect the authority of DTSC to pursue any legal, equitable or administrative remedies pursuant to state or federal law or to take any action authorized by law or equity to protect public health and safety or the environment and recovering the costs thereof, including DTSC's authority to take action, or require other persons to take action, under chapter 6.5 or chapter 6.8 of division 20 of the Health and Safety Code or under the Polanco Act and to recover DTSC's costs for those actions.

c. Nothing in this Oversight Agreement shall constitute or be construed as a waiver, defense to, or limitation on of the Local Agency's rights (including any covenant not to sue or release), with respect to any claim, cause of action, or demand in law or equity that the Local Agency may have against any person, as defined in section 101(21) of CERCLA, or Health and Safety Code section 25319, who is not a signatory to this Oversight Agreement.

19. Compliance with Applicable Laws. Nothing in this Oversight Agreement relieves the Local Agency from complying with all applicable laws and regulations, and the Local Agency will conform to all actions required by this Oversight Agreement to all applicable federal, state and local laws and regulations.

20. California Law. This Oversight Agreement shall be governed, performed and interpreted under the laws of the State of California.

21. Parties Bound. This Oversight Agreement applies to and is binding, jointly and severally, upon each signatory and upon any successor agency of either the Local Agency or the State of California that may have responsibility for and jurisdiction over the subject matter of this Oversight Agreement. No change in the ownership or corporate or business status of the Property or any owner of the Property shall alter any signatory's responsibilities under this Oversight Agreement.

22. Severability. If any portion of this Oversight Agreement is ultimately determined

not to be enforceable, that portion will be severed from the Oversight Agreement and the severability shall not affect the enforceability of the remaining terms of the Oversight Agreement.

23. Amendments. Except as otherwise specified in this section and in section 2.2 of this Oversight Agreement, this Oversight Agreement may be amended as specified in this section to withdraw the property from this Oversight Agreement. The Local Agency may withdraw the property from this Oversight Agreement by giving written notice to DTSC that the Local Agency will stop work on that property within the next thirty (30) days. DTSC may withdraw the property by giving written notice to the Local Agency that DTSC will stop work on the Property within the next thirty (30) days. The effective date of withdrawal is the end of the 30 day notice period. Prior to stopping work on the property, the Local Agency must ensure that the property will pose no greater public health or environmental risk than it posed prior to the Local Agency's activities on the property. In the event that the Local Agency withdraws the property from this Oversight Agreement, the Local Agency will be responsible for DTSC's costs through the effective date of withdrawal. The Scope of Work may be amended by mutual written agreement of the parties. Such amendments or modifications are effective on the third business day following the day the last Party signing the amendment or modification sends its notification of signing to the other Party. The Parties may agree to a different effective date.

24. Termination for Convenience. Except as otherwise provided in this Section, each Party to this Oversight Agreement reserves the right to unilaterally terminate this Oversight Agreement for any reason, or for no reason. Termination requires that either Party give a thirty (30) day advance written notice of the election to terminate this Oversight Agreement to the other Party. Prior to termination the Local Agency must ensure that the property will pose no greater public health or environmental risk as a result of the Local Agency activities than it posed prior to the Local Agency's activities at the property. In the event that this Oversight Agreement is terminated under this section and subject to Section 2.8 of the Oversight Agreement, the Local Agency will be responsible for DTSC's costs through the effective date of termination.

April 22, 2019
REF: 19-094

Nick Ta, Project Manager
Department of Toxic Substances Control
5796 Corporate Avenue
Cypress, CA 90630

Subject: GARDENA SUMPS, 301801 (sm)

Dear Mr. Ta:

In light of the ongoing, DTSC-sanctioned excavation of "Pit F" at the Ascon Landfill in Huntington Beach, the City of Gardena has determined to discontinue preparation of a work plan for a pilot study to assess the same remedy at the Gardena Sumps site. Accordingly, this letter will serve as an Official 30-Day Notice of Termination of the Oversight Agreement, dated February 20, 2018, entered into by Gardena and DTSC.

The City of Gardena would ask that DTSC move forward with approval of the feasibility study for the Sumps once the analysis in that document is updated to reflect (1) the results of the Pit F excavation, (2) the conclusions in DTSC's 2015 EIR for the Ascon landfill site (i.e., that highly odorous wastes of the types found at both Ascon Pit F and Gardena Sumps can be safely excavated and sent for off-site disposal), and (3) the other pertinent documents associated with the Pit F excavation (e.g., DTSC's May 2017 approval of the final Remedial Design Report for Ascon Landfill). The analysis and conclusions in the draft feasibility study provided most recently to Gardena (July 2014) obviously do not reflect the extensive record supporting DTSC's 2015-2019 decision-making for Pit F. That record calls into question much of the analysis presented in the July 2014 draft feasibility study, hence the need for an updated version.

The City would also ask that following approval of an updated feasibility study, DTSC promptly move forward with development of a Remedial Action Plan ("RAP") for the Sumps, and then with the applicable public review and comment processes under Chapter 6.8 of the Health and Safety Code and CEQA. The RAP should evaluate Arco's preferred capping remedy (Alternative 2a) and the excavation remedy (Alternative 4) in a fashion that, among other things:

- is consistent with and acknowledges the experience gained via the Pit F remediation process;
- is free from the persistent pro-capping/anti-excavation bias noted by DTSC's "ESPO" staff (discussed on page 2 of Mr. Lansdell's March 21, 2017, letter to Deputy Director Nazemi);
- addresses the failure to comply with ARARs noted by EPA's reviewer (also addressed in Mr. Lansdell's letter to Deputy Director Nazemi);

TASHA CERDA, Mayor / ART KASKANIAN, Mayor Pro Tem
MARK E. HENDERSON, Councilmember / DAN MEDINA, Councilmember / RODNEY G. TANAKA, Councilmember
MINA SEMENZA, City Clerk / J. INGRID TSUKIYAMA, City Treasurer / EDWARD MEDRANO, City Manager / PETER L. WALLIN, City Attorney

- fairly and honestly evaluates, as part of the cost criterion evaluation and consistent with DTSC Management Memo EO-02-002-MM, the differential impacts on land values as between Alternatives 2a and 4;

- documents what progress Arco has made toward securing the so-called institutional control agreements on which its "implementability" analysis has long relied in order to leave unremediated hazardous wastes in public rights of ways and on property neither owned nor controlled by Arco; and

- allows for implementation of Alternative 4 if the Pit F remediation is successful and Alternative 4 otherwise performs satisfactorily according to the remedy selection criteria set forth in the National Contingency Plan and Section 25356.1(d) of the Health and Safety Code.

A RAP that addresses these points head on and honestly will have greater credibility with the public and will be more likely to survive a CEQA challenge. A RAP that fails to address these points could leave the Department with another Exide-like environmental justice black eye, and perhaps liability for fees incurred by a CEQA petitioner. Other than Arco, no one benefits from that scenario.

The City appreciates your assistance and looks forward to moving the project forward.

Respectfully,

EDWARD MEDRANO
City Manager

Subject: GARDENA SUMPS, 301801 (sm)

Dear Mr. Ta:

On April 22, 2019 the City Manager of Gardena sent a letter to DTSC indicating that the City was not supportive of Alternative 2A. This letter is to inform you that the City is no longer holding to that position and is now supportive of the 2A alternative in order to facilitate the development project which is being proposed by InSite, a specialized builder of self-storage and industrial developments.

InSite made a presentation at the Gardena City Council meeting on May 26, 2020 of the proposed project at the Gardena Sump site. While the City Council could not approve a project at this time, they did indicate their support and encouraged InSite to file its development applications.

Please feel free to contact me if you have any questions regarding this matter.

Respectfully,

Clint Osorio

APPROVAL OF FINAL FEASIBILITY STUDY FOR THE GARDENA SUMPS, 1450 W. ARTESIA BLVD., GARDENA, CA 90447 (DTSC SITE CODE. 401218)

Dear Mr. Carmel:

The California Department of Toxic Substances Control (DTSC) has reviewed the final Feasibility Study Report (FS), dated July 1, 2014. The Report was submitted by Geosyntec Consultants on behalf of Atlantic Richfield Company (ARC) for the Gardena Sumps Site (Site) as a requirement of Consent Decree CV04-7882-AHM (JTLx). The FS includes a summary of the remedial investigation, remedial action objectives, and a comparative analysis of the identified applicable remedial technologies and alternatives based on the National Contingency Plan's nine criteria.

The Site is approximately 5.6 acres, consisting of 2 parcels currently owned by the Haack family and the Cooper family trust. The Site was developed as a clay mine during the 1920s by the Moneta Brick Company. Clay mining resulted in excavations that were reportedly used for refinery sludge disposal beginning in approximately 1940. By September 1946, the Haack, Cooper South and Cooper North Sumps had been filled with sludge. By December 1951, the western portion of the Haack Sump had been covered by asphalt and a concrete slab, and was converted into a parking lot. On October 1, 1952, the northern-most strip of the Site property was sold to the State of California for a highway easement (now Artesia Blvd).

Currently, the two Cooper sumps are capped by a geosynthetic liner that was installed by OHM Corporation (OHM) in July 1993 under DTSC oversight. An additional geosynthetic liner was placed over the 1993 liner in August 2013. Currently, the Haack property is leased to various tenants who operate small businesses, including a U-Haul rental agency, a metal fabricating, blasting and painting company, and an auto body repair shop.

Remedial investigations at the Site identified the sludge volumes in the sumps to be 6,700 cubic yards (cy), 7,000 cy, and 2,250 cy in the Cooper South, Cooper North, and Haack Sumps, respectively. Constituents identified in the sludge included volatile fuel hydrocarbons (VFHs), total extractable hydrocarbons (TEHs), volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), polynuclear aromatic hydrocarbons (PAHs), Title 22 metals, mercury, and hexavalent chromium. The Feasibility Study evaluated four remedial alternatives, including: no action, capping with selective excavation, capping with selective excavation and stabilization/neutralization, and excavation with offsite disposal.

DTSC staff has reviewed the FS and hereby approves the FS. Please submit the Final Feasibility Report with the stamp and signature of a registered California professional engineer or registered California professional geologist. DTSC requests that a Remedial Action Plan be submitted to proceed with the remedial action for the sludge waste at the Site. As part of DTSC's public participation process, a community survey will need to be initiated to ascertain community interest in the Site. DTSC requests ARC coordinate the initiation of the community survey with the DTSC project manager.

If you have any questions regarding the project, please contact Nick Ta, the project manager at (714) 484-5381 or by email at: nicholas.ta@dtsc.ca.gov, or the Unit Supervisor, Patrick Hsieh at (714) 484- 5442 or by email at: patrick.hsieh@dtsc.ca.gov.

Sincerely,

A. Edward Morelan

Subject: Final Feasibility Report Certification
Gardena Sump
Gardena, California

Dear Mr. Ta,

Geosyntec Consultants, Inc. (Geosyntec) has prepared this certification for the Final Feasibility Study Report (FS) dated 1 July 2014 on behalf of Atlantic Richfield Company (ARC) for the Gardena Sumps Site (Site) as a requirement of Consent Decree CV04-7882-AHM (JTLx). Geosyntec understands that the Department of Toxic Substances Control (DTSC) approved the FS on 14 July 2020 and is requesting California Professional Engineer certification.

The FS was prepared by or under the direct oversight of Ms. Rebecca Oliver, a Professional Civil Engineer in the State of California. Ms. Oliver's certifying stamp and signature has been provided with this letter to be included with the FS.

Please contact Ms. Oliver if you have any questions or need any additional information at (619) 810-4032.

Sincerely,

Madeline Downing
Senior Staff Engineer

Rebecca Oliver, P.E.

Executive Summary

Station No.: Gardena Sumps Site
Address: 1440 West Artesia Blvd., Gardena CA (SW Corner of Artesia Blvd & Normandie Avenue)
Reporting Period: July - September 2020 (Third Quarter) Semi-Annual
Atlantic Richfield Company Environmental Engineer/Phone No.: Mr. Charles Carmel / (562) 512-1020
Consulting Co./Contact Person/Phone No.: Stantec / Kelly C. Brown, PG / (562) 354-2638
Stantec Project No.: 185850766.300
Primary Agency/Regulatory ID No.: CA DTSC / Mr. Nick Ta, Supervisor
Other Agencies to Receive Copies: None

WORK PERFORMED THIS PERIOD [July through September 2020]:

1. Issued notifications to DTSC and stakeholders regarding Third Quarter 2020 Semi-Annual groundwater sampling event.
2. Completed quarterly groundwater gauging and sampling at on-site groundwater monitoring wells on August 18 and 19, 2020.
3. Conducted monthly perimeter fence, gates, and signs inspections.
4. Performed quarterly cover inspection for the Cooper and Haack Rework Properties during the Semi-Annual groundwater sampling event.
5. Prepared and submitted the Second Quarter 2020 Status Reports.
6. Prepare the *Third Quarter 2020 Semi-Annual Groundwater Monitoring Report*.

WORK PROPOSED FOR NEXT PERIOD [October 2020 through March 2021]:

1. Prepare and submit the Third and Fourth Quarter 2020 Reports.
2. Submit the Third Quarter *2020 Semi-Annual Groundwater Monitoring Report*.
3. Issue notifications to DTSC and stakeholders regarding the First Quarter 2021 Semi-Annual groundwater sampling event.
4. Perform the First Quarter 2021 Semi-Annual groundwater sampling event in February 2021.
5. Conduct monthly perimeter fence, gates, and signs inspections.
6. Perform quarterly site cover inspection and site repair activities (as necessary).
7. Perform weed abatement (as necessary).
8. Submit Remedial Action Plan.

Current Quarter's Groundwater Results Summary / Remarks		
Agency Directive Requirement	Perform Semi-Annual Groundwater Monitoring	
Compliance Goal	N/A – Monitoring performed under a consent decree	
Frequency/Date(s) of Monitoring and Sampling	Semi-Annual – Third Quarter 2020 / August 18 and 19, 2020	
Liquid-Phase Hydrocarbon Present	No	
Water Wells (within 4,000-ft) and Their Respective Directions	T3S/R14W-S25P4 S.B.B.M. ≈1,200 ft / WNW (Dalton #1)	
Closest Surface Water	Dominguez Channel ≈ 100-200 ft / South	
Current GW Remediation Techniques	Not Applicable	
Permits for Discharge	Not Applicable	
Monitoring Well Summary	4 zone A monitoring wells on-site, 1 intermediate zone monitoring well on-site, 3 zone B wells on-site. 8 of the 10 monitoring wells were gauged and sampled this quarter. Wells MW-01A and MW-01B have been removed from the sampling plan after approval from the DTSC on October 30, 2014 and are now only inspected for integrity annually during the first quarter event. Wells MW-01A and MW-01B were mistakenly also gauged and inspected this quarter but are not used in reported data.	
Quantity of Purge Water Generated	Approximately 25 gallons	
Monitored Zones	A (upper hydraulic zone)	B (lower hydraulic zone)
Depths to Groundwater	12.51 to 19.70 ft. BTOC	15.41 to 21.61 ft. BTOC
Range in Groundwater Elevation	5.75 to 7.25 ft. MSL	3.95 to 4.48 ft. MSL
Groundwater Flow Direction	South-southeast (A180)	East-southeast (A108)
Horizontal Groundwater Gradient (ft./ft.)	0.0040	0.0019
Vertical Groundwater Gradient (ft./ft.)	0.030 to 0.045 (downward)	
Approximate Horizontal Groundwater Velocity Beneath the Site	0.034 ft./day	0.071 ft./day
Analytical Findings	The Third Quarter 2020 Semi-Annual sampling event results are generally consistent with the analytical data from the previous sampling events (since May of 1994).	
Problems Encountered this Quarter	Well MW-01A&B were also inspected and gauged this quarter, but not used in data calculations.	
Key Findings This Quarter	Water levels are relatively stable in both the upper hydraulic zone and in the lower hydraulic zone, with only minor increases and decreases in both.

1.0 INTRODUCTION

The Gardena Sumps Site (the Site) is located at the southwest corner of Artesia Boulevard and Normandie Avenue in the City of Gardena, Los Angeles County, California (Figure 1). The Site occupies approximately 5.6 acres and is subdivided into two parcels of approximately 3.0 acres (Cooper Property) and 2.6 acres (Haack Property). For this report, the adjacent Los Angeles Department of Public Works (LADPW) land immediately south of the Cooper Property is also considered a portion of the Site. Properties surrounding the Cooper and Haack Properties are used for residential, commercial, and light industrial purposes. Approximately 80 percent of the surface area of the Cooper Property consists of two large sumps that are covered with geo-synthetic material. These sumps contain apparent refinery wastes (subsequently referred to as "sludge"). A smaller sludge sump also underlies the northeastern portion of the Haack Property (Figure 2).

Quarterly monitoring and sampling were agreed to as part of the Consent Decree (US District Court, Central District of California, 2004), entered into between California Department of Toxic Substances Control (DTSC) and Atlantic Richfield Company (ARC), which became effective November 4, 2004 (§VIIC, paragraph 2, lines 2-3). SECOR International Incorporated (SECOR), now known as Stantec Consulting Services Inc. (Stantec), working on behalf of ARC, started quarterly monitoring activities in January 2006. At present, eight wells are included in the monitoring program (MW-02A/B, MW-03A/B, MW-04A/B, MW-05A and G-4). Wells MW-01A and MW-01B were approved for removal from the regular sampling program in a letter from the DTSC dated October 30, 2014 and will no longer be sampled. The DTSC granted ARC's request to terminate sampling of these two wells with the stipulation that they would be monitored annually during the Second Quarter groundwater monitoring event and kept in good condition so that they might be utilized in the future should the need arise. Wellhead integrity monitoring and maintenance of these two wells has previously been reported in the Second Quarter Groundwater Monitoring Report of each year. On September 8, 2017, ARC requested a reduction in sampling from quarterly to semi-annually and this request was granted by the DTSC in a letter dated October 12, 2017. Sampling at the site now occurs only during the first and third quarters each year. Wellhead integrity monitoring, maintenance and reporting will occur during the first quarter semi-annual event each year. To date, groundwater monitoring, sampling, and analytical activities through the third calendar quarter of 2020 have been completed. This report presents the findings of the Third Quarter 2020 Semi-Annual groundwater sampling event.

2.0 SITE BACKGROUND

The Site was used for grazing livestock until the late 1920's when the Moneta Brick Company (a.k.a. Higgins Brickyard) started excavating clay for commercial use. They continued mining clay from the Site through the early 1930's. In the early 1940's the clay pits, created by the mining operations, were used to dispose of refinery sludge allegedly from petroleum refining situated in Southern California. During the late 1950's and early 1960's waste material from a metal casting facility located on the Haack property may also have impacted the properties. The Aircraft Magnesium Corporation, which operated this facility at that time, is no longer in business.

In early 1981, the California Department of Health Services (DHS) and the U.S. Environmental Protection Agency (USEPA) became the first regulatory agencies to address the environmental issues at the Site. In 1982, four off-site groundwater monitoring wells (G-1 through G-4) were constructed by the USEPA beyond the perimeter of the Site (Figure 2). The wells were installed in saturated portions of the Bellflower Aquiclude. Well G-4, the only DHS/USEPA well that still exists, is not screened in either the upper hydraulic Zone A or lower hydraulic Zone B that have until recently been monitored by four well clusters (MW-01A/01B, MW-02A/02B, MW-03A/03B, and MW-04A/04B) and well MW-05A. Wells MW-01A/01B were approved for removal from the regular sampling plan in a letter dated October 30, 2014 and are no longer being sampled.

Historical analytical results for organic compounds in groundwater from these four "G" series wells yielded results that were below the method detection limit (MDL) for the compounds examined. Continued groundwater monitoring of these wells by regulatory agencies yielded similar results. Three of these wells (G-1, G-2, and G-3) have subsequently been destroyed during development of properties surrounding the Site.

In 1993/1994, three well clusters (MW-01A/B, MW-02A/B, and MW-03A/B) were installed to monitor two hydraulic zones within the Bellflower Aquiclude beneath the Site. The depths to the two hydraulic zones, designated Zone A (upper) and Zone B (lower), are approximately 15 to 25 and 75 to 80 feet below ground surface (bgs), respectively. Well construction details for these six wells, and four previously installed USEPA wells are summarized in Table 1. Complete details can be found in Appendix D of the RI/FS Workplan dated November 11, 2005 (SECOR, 2005).

In February 2007, an additional well cluster (MW-04A/B) was installed on Site near the western boundary of the Cooper Property. This fourth well cluster is used to monitor saturated zones A and B. Well construction data for these two wells are summarized in Table 1. More detail is included in Appendix A of the 2007 First Quarter Groundwater Monitoring Report, dated April 18, 2007 (SECOR, 2007a).

During the Third Quarter 2009, MW-05A was installed in the U-Haul parking lot of the Haack Property. This well is used to monitor the upper hydraulic zone (zone A) immediately downgradient of a portion of the Haack sump. Well construction data for this well is summarized in Table 1.

Wells MW-01A/01B were approved for removal from the regular sampling program in a letter dated October 30, 2014 and are no longer being sampled. The DTSC granted the ARC request to terminate sampling of these two wells with the stipulation that they should be inspected each year during the second quarter groundwater monitoring event and kept in good condition so that they might be utilized at some time in the future should the need arise. Condition inspection and maintenance of these two wells is to be reported in the Second Quarter Groundwater Monitoring Report. However, in October 2017, the DTSC approved semi-annual sampling of site wells. Inspection of these two wells now occurs during the First Quarter Semi-Annual sampling event of each year.

3.0 SAMPLING PROCEDURES

Groundwater Gauging. On August 18, 2020, ten groundwater monitoring wells (MW-01A/1B, MW-02A/B, MW-03A/B, MW-04A/B, MW-05A, and G-4) were gauged for depth to groundwater. Wells MW-01A and MW-01B are inspected during the first quarter of each year, however they were inspected and gauged during this event. After the purging and sampling of each well, the wells are normally gauged for total depth from designated measuring points at the top of the PVC well casings (Table 2). Well G-4 is not normally gauged for total depth due to the presence of a dedicated pump blocking the passage of the depth sounder. During this and the previous two field events the well MW-02A may have been incorrectly gauged for total depth (deeper than possible). The discrepancy is being investigated.

Groundwater Purging. On August 18 and 19, 2020, groundwater purging was performed. Due to past vandalism, well MW-04B is currently purged with a decontaminated rental pump and dedicated Teflon® tubing. The remaining groundwater monitoring wells are equipped with dedicated QED Well Wizard™, low-flow gas actuated submersible bladder pumps. The Well Wizard™, submersible bladder pumps are constructed with a stainless-steel outer sleeve and a Teflon® lined internal bladder. Each Well Wizard™ pump is 3.5-feet long with an outside diameter of 1.5-inches. The inlet portal is located at the base of the pump. The pumps are positioned with the base inlet situated in the center of the well screen interval. Teflon® tubing is installed to convey purge and sample water from the pump outlet to the surface and as a gas-actuation line to operate the pump bladder.

Purging and sampling was accomplished in accordance with American Society for Testing and Materials (ASTM) Method D6771 using low-flow techniques. A typical purge rate of approximately 0.10 to 0.30 gallons per minute is used for each well. Following ASTM Method D6771, the minimum volume of groundwater purged prior to sampling was equal to at least three times the volume of water within the discharge tubing and bladder of the dedicated pump.

During purging, water quality parameters for both upper (A) and lower (B) hydraulic zone wells were monitored with Horiba U-52 Water Quality Multi-Parameter meters, and Solinst Depth to Water Meters. Due to improved accuracy and reliability of the newer Horiba U-52 meters with respect to turbidity measurements, separate turbidity meters are no longer being used. Parameters monitored included electrical conductivity (EC), pH, temperature, dissolved oxygen (DO), oxidation-reduction potential (ORP), and turbidity (NTU's). The rental vendor calibration forms are provided in Appendix A. Purging continued until at least three tubing/bladder volumes of water were removed, and water quality parameter measurements had stabilized. Copies of the field data sheets containing the gauging, well purging and sampling data are also provided in Appendix A.

Groundwater Sampling. On August 18 and 19, 2020, groundwater sampling was performed immediately following purging of each well. Groundwater sampling procedures followed the protocol outlined in the Quality Assurance Project Plan (QAPP) and the Field Sampling Plan (FSP),

of the RI/FS Workplan (SECOR, 2005). Groundwater samples were collected using dedicated (except where noted), gas-actuated, submersible bladder pumps. Samples were discharged directly into containers provided by the laboratory that were appropriate for the analysis to be performed. Samples collected for dissolved metals analyses were filtered in the field using in-line 0.45-micron filter cartridges. The sample containers were secured with caps, labeled, and placed on ice for transport to Test America Analytical Testing Corporation of Irvine, California (Test America), a State certified laboratory, for analysis. Strict chain-of-custody procedures were followed during sample handling. Chain-of-custody records were maintained for all samples collected. In addition to the samples obtained from the monitoring wells, field blanks prepared in the field, and laboratory-prepared trip blanks were analyzed. One blind duplicate sample is collected from well MW-02A each quarter (labeled this quarter as RS-SUMP-20200819), was included with the samples to verify the integrity of the field and laboratory procedures. All samples were submitted to Test America and tested for the typical full suite of analytes.

Waste Disposition. During the Third Quarter 2020 Semi-Annual sampling event approximately 25 gallons of purge water were generated and were temporarily stored on Site in a 55-gallon D.O.T. approved container. Upon completion of the sampling event, the purge water drum was removed and shipped to an approved recycling facility. A copy of the shipping documentation is contained in Appendix A.

Groundwater Analytical Methods. Per the RI/FS Work plan all groundwater samples (except as described above) were analyzed for the following analytes, employing the USEPA methods indicated.

Analytes	USEPA Method	Notes
Gasoline range organics (GRO; hydrocarbon range C4 through C12, inclusive)	8015B	This analysis has been identified in historic reports for the Site as Total Petroleum Hydrocarbons modified for gasoline (TPHg) (by GC/MS (CA LUFT) EPA Method 8015 modified for gasoline (8015 M).
Volatile organic compounds (VOC's)	8260B	Selected analytical results are listed in Summary Tables. Acetone was not analyzed. RL were limits lowered to match CA state MCL's in June, 2009. Complete analytical results are given in an appendix to this report.
Semi-Volatiles (SVOC's)	8270C	Only Bis (2-ethylhexyl) Phthalate is listed in Summary Tables. RL were limits lowered to match CA state MCL's in June, 2009. Complete analytical results are given in Appendix-C of this report.
Polynuclear Aromatic Hydrocarbons (PAH's)	8270C	During the First Quarter 2006, only on-site wells were analyzed for PAH's. During subsequent quarters, all wells have been analyzed for PAH's. Currently done by EPA Method 8270C. Due to CA state MCL's Benzo(a)Pyrene is tested by method 8270-C SIM.
Chromium VI	7199	Changed from 7196A, May 2009 at DTSC request.
Mercury (Hg)	7470A and 7470A-Dissolved	Samples were analyzed for both suspended and dissolved Mercury.

Analytes	USEPA Method	Notes
Other Metals	6020 and 6020-Dissolved	Samples were analyzed for both suspended and dissolved Metals.
pH	9040B	pH is also measured in the field with a Horiba U-52
Total sulfide	SM 4500-SD	Earlier reports show this by method 376.2
General Minerals & Inorganics	Numerous methods	General Minerals testing was discontinued in the third quarter of 2012.

4.0 GROUNDWATER MONITORING AND SAMPLING RESULTS

Groundwater Gradient. The observed groundwater gradient, flow direction and velocity for the current quarter 2020 sampling event are generally consistent with historical observations. Figure 3 depicts the elevation of groundwater observed during the current sampling event in monitoring wells completed in the Upper Hydraulic Zone A. Figure 4 presents data for Lower Hydraulic Zone B during the current sampling event. After calculating the groundwater elevations of the wells and plotting them on a scaled map, the horizontal groundwater gradient in Hydraulic Zone A was estimated at 0.0041, directed towards the South with an azimuth of 180 degrees for the current 2020 event (Figure 3, Table 2). The horizontal groundwater gradient in the Hydraulic Zone B was estimated at a gradient of 0.0019, directed to the East-southeast, with an azimuth of 108 degrees for the current 2020 event (Figure 4, Table 2). The vertical hydraulic gradient between the upper and lower hydraulic zones varies from 0.030 at MW-03 to 0.045 at MW-02 and is directed downwards (Table 2). Monitoring wells MW-01A and MW-01B which have been removed from the sampling plan and are generally only gauged and inspected in the first quarter sampling event were also inspected and gauged this quarter, however they were not used in data calculations (Table 2, Figures 3 and 4).

During the current Third Quarter of 2020, the Hydraulic Zones A and B both showed very little water level change compared to the previous sampling event during the First Quarter 2020. Minor fluctuations in the upper hydraulic Zone-A ranged from a 0.12 foot increase at well MW-02A to a decrease of 0.13 feet at MW-05A. The lower hydraulic Zone-B also showed minor fluctuations with an increase of 0.07 feet at well MW-03B and a decrease of 0.12 feet at MW-04B for the current Third Quarter 2020 event.

The top of the screened interval for well MW-02A has been several feet below the groundwater surface elevations each quarter since it was constructed and is currently approximately 4.76 feet below the groundwater surface. Groundwater elevations at well MW-03A have historically been and are currently within the screened interval. The groundwater surface elevations for well MW-04A has also been variably above or within the screened interval since installation and is currently 0.68 feet below the top of the screen, within the screened interval. The current groundwater elevation at MW-05A places it 0.25 feet below the top of the screen, within the screened interval.

Figure 5a illustrates the stratigraphic soil types and well completion schedule for each groundwater monitoring well. Figure 5b shows a hydrograph and a pH record of each well covering the period when groundwater monitoring has been performed at the Site (early 1994 to the present). Figure 5c illustrates the velocity and direction of the groundwater utilizing rose diagrams that cover the period from 1994 to the present. The two rose diagrams depict the horizontal groundwater flow velocity, the flow direction, and the frequency the flow occurred at a given velocity in a given direction. These diagrams display data for both the upper hydraulic Zone A and for the lower hydraulic Zone B beneath the Site. The groundwater flow velocities and calculations are summarized in Table 2.

Groundwater Analytical Results. Complete analytical reports from Eurofins Calscience Irvine and chain-of-custody documentation are provided in Appendix C. Selected results are compiled in Tables 3 through 8; presented on Figures 3 and 4; and are summarized below. Concentrations qualified by a "J flag" are estimated values detected at a level below the quantifiable method RL and above the MDL. Concentrations which are greater than the established MCL's are identified in a gray highlighted analyte result box in the tables.

All eight groundwater monitoring wells sampled showed no detectable concentrations of GRO at or above the RL (Table 3) during the current Third Quarter 2020 Semi-Annual sampling event. The sample from MW-05A had a J-flag detection of GRO with an estimated concentration of 40 J µg/L.

VOC's above the RL were not detected in any of the eight wells sampled during the current quarter's sampling event.

There were also no VOC's reported between the MDL and RL (J-flag detection) this sampling event.

Methylene Chloride (also known as dichloromethane) was not detected in any of the eight wells sampled during the current sampling event.

Only one SVOC was found to exceed the RL during the current sampling event. The SVOC 2,6-dinitrotoluene was detected above the RL in well MW-03B (23 µg/L). This is an anomalous detection of an analyte not normally found on site. This well will be watched for further anomalies.

Another SVOC, sometimes detected is Bis(2-ethylhexyl) phthalate (DEHP), however it was not detected above the RL this during this sampling event (Table 4). DEHP is used as a plasticizer in the manufacturing of PVC. DEHP was detected at a J-flag concentration in one of the eight wells this event. It was detected in MW-02B (4.3 J µg/L).

There were five SVOC's detected between the RL and MDL during this event. Benzoic acid was detected in seven of the eight wells ranging from 0.99 J µg/L in MW-04B to 2.2 J µg/L in well G-4. Di-n-octyl phthalate was detected in well MW-02B (3.6 J µg/L). Acenaphthene (0.064 J µg/L) and benzyl alcohol (0.057 J µg/L) were detected in well MW-03B. Also found was 2,4-dimethylphenol (0.093 J µg/L) in well MW-05A (Table 4).

One of two Polynuclear Aromatic Hydrocarbons (PAH's) being tested for, Chrysene and Pyrene, was detected above the RL in one of the eight wells sampled during the current quarter's sampling event. Pyrene was detected in well MW-05A with a concentration of 0.20 µg/L (Table 4).

Chloroform was not reported from any of the samples collected during the current event. In the past, chloroform has been detected at very low reportable concentrations in the field blanks, and rarely chloromethane.

The pH levels reported since 1994 to present are provided in Table 4 and illustrated in Figure 5b. When field and laboratory pH measurements are available, then both measurements are reported in Table 4. The pH levels have remained relatively constant for all monitoring wells since Stantec (previously SECOR) began sampling in the First Quarter of 2006. During each sampling event the pH reading for well MW-05A is typically lower than all the other wells. The current pH field reading of 6.27 (Table-4 and Figure 5B).

Total Sulfides were not reported in concentrations above the RL in any of the eight wells sampled during the current sampling event (Appendix C). Reactive Sulfides are no longer measured due to changes in the USEPA protocol (Table 4).

For each reporting period since the year 2000, and again during the current sampling event, both dissolved (starting 2006) and non-dissolved-phase barium have been detected above the RL in all wells (Tables 5 and 6). Barium has often been detected at the up-gradient and off-Site wells MW-01A and MW-01B which are no longer being sampled. The highest concentration of barium detected this sampling event was in well MW-03-A, [Total Metals (110 µg/L) and Dissolved Metals (110 µg/L)].

Reportable trace concentrations of arsenic were detected during the current quarter's sampling event in both dissolved and non-dissolved phases. Arsenic above the RL was reported in samples from four of the eight wells sampled for Total Metals and from four of the eight for Dissolved Metals. Total Metals Arsenic was detected above the RL in MW-03B, MW-04B, MW-05A, and G-4. Dissolved Metals Arsenic above the RL was found in the same wells (Tables 5 and 6). MW-05A showed the highest concentrations of Arsenic for the Total Metals (8.2 µg/L) and for Dissolved Metals (7.1 µg/L) phases.

Arsenic was also detected in J-flag concentrations for Total Metals and for Dissolved Metals, respectively, in MW-02A (0.55 J and 0.51 J µg/L), MW-02B (0.95 J and 0.95 J µg/L), MW-03A (0.65 J and 0.60 J µg/L) and well MW-04A (0.79 J and 0.80 J µg/L) (Tables 5 and 6).

No wells showed elevated concentrations of metals during the current sampling event (above the California DPH MCL's.

Mercury was not detected above the RL or in J-flag concentrations during the current sampling event (Tables 5 and 6). It was reported in J-flag concentration in well MW-04A (0.14 J µg/L).

Hexavalent Chromium (Chrome VI) was not reported above the RL during the current sampling event (Table 4 and Appendix C). It was reported in J-flag concentrations in wells MW-03A (0.50 J µg/L) and MW-04A (0.27 J µg/L).

Three wells showed zinc concentrations above the RL during this sampling event. MW-02B showed 26 J µg/L, G-4 showed 21 J µg/L, and MW-05A had a detection of 120 µg/L for total metals and 89 µg/L for dissolved metals (Table 6).

Quality Control / Quality Assurance: Upon receipt of the analytical data from Eurofins Calscience, Stantec reviewed the data from groundwater samples, and field quality control samples including a duplicate sample, field blanks, and trip blanks. A quality assurance/quality control (QA/QC) sample, identified as RS-SUMP-20200819 was collected on August 19th during the Third Quarter 2020 sampling event. Sample RS-SUMP-20200819 was a blind duplicate sample collected from down-gradient well MW-02A. The duplicate sample during this event showed identical results to the MW-02A sample for GRO and all VOC analytes tested. Trip and field blank results for all VOCs analyzed were non-detect during the Third Quarter 2020 sampling event. These quality control samples are taken to confirm the integrity of the field sampling and sample handling processes for this sampling event. The laboratory also employs its own QA/QC procedures. Those results are shown in their laboratory reports (Appendix A). All laboratory QA/QC results are within acceptable limits, except where otherwise noted.

5.0 CONCLUSIONS

The following conclusions are drawn from the quarterly groundwater monitoring and sampling data:

- The Third Quarter 2020 Semi-Annual sampling event results are generally consistent with the analytical data from past sampling events (since February 2006).
- Groundwater levels have relatively stable across both hydraulic zones, showing little change, with maximum variances showing a drop of 0.013 feet in MW-05A to an increase or rise in groundwater elevation of 0.12 feet in MW-02A.

6.0 PROPOSED MONITORING ACTIVITIES

Stantec anticipates performing quarterly cover inspection and maintenance (as necessary) and semi-annual groundwater monitoring activities at the Site during the First Quarter of 2021. These activities include, but are not limited to the following items:

- Perform semi-annual groundwater gauging and sampling at groundwater monitoring wells MW-02A/2B, MW-03A/3B, MW-04A/4B, MW-05A, and G-4 in February 2021;
- Perform quarterly site cover inspection, maintenance, and repair (as necessary);
- Perform weed abatement as necessary; and
- Perform monthly monitoring of site fence, gates, and signs integrity.

7.0 STANDARD LIMITATIONS

This report was prepared in accordance with the scope of work outlined in Stantec's contract and with generally accepted professional engineering and environmental consulting practices existing at the time this report was prepared and applicable to the location of the site. It was prepared for the exclusive use of Atlantic Richfield Company for the express purpose stated above. Any re-use of this report for a different purpose or by others not identified above shall be at the user's sole risk without liability to Stantec. To the extent that this report is based on information provided to Stantec by third parties, Stantec may have made efforts to verify this third-party information, but Stantec cannot guarantee the completeness or accuracy of this information. The opinions expressed and data collected are based on the conditions of the site existing at the time of the field investigation. No other warranties, expressed or implied, are made by Stantec.

GRAPH NOTES:

1. ALL pH MEASUREMENTS TAKEN JUNE 15, 2000 WERE OBTAINED USING pH PAPER INSTEAD OF A pH METER. THUS, DATA RESOLUTION WAS LIMITED TO WHOLE pH UNITS.
2. DURING THE SECOND QUARTER 2007 THE INSTRUMENT USED TO MEASURE pH IN WELLS COMPLETED IN THE UPPER SATURATED ZONE HAD CALIBRATION ISSUES THAT RESULTED IN SLIGHTLY LOWER pH VALUES. DURING THE THIRD QUARTER 2007 A CALIBRATION ISSUE DEVELOPED IN THE INSTRUMENT USED TO MEASURE pH VALUES IN WELLS WITHIN THE LOWER SATURATED ZONE RESULTING IN SLIGHTLY ELEVATED pH VALUES.
3. WELL G-4 CASING WAS DAMAGED IN EARLY 2017. IT WAS REPAIRED IN 2018 AND RE-SURVEYED FOR ELEVATION BY STANTEC SURVEYORS ON MAY 5, 2018.

Notes
ft bgs = Feet below ground surface
ft MSL = Feet Mean Sea Level
-- = Not applicable / Not analylized
* = Assumed from data for G-4
Total depth of well and screen intervals determined from downhole camera inspection conducted on December, 15, 2005
** = Well G-4 casing was damaged in early 2017. It was repaired in 2018 and resurveyed on May 5, 2018. Former elevation was 27.12' AMSL.

Notes:
GRO = Gasolone Range Organics by modified EPA Method 8015B
* = Analyte was quantitated below the established linear calibration range. Amount reported is an estimate.
ND = Not Detected. This data was obtained from a summary table of a report not prepared by SECOR/Stantec.
<# = Analyte was not detected above the Reporting Limit (#)
µg/L = micrograms per liter
na = Not applicable
-- = Not applicable / Not analyzed
J = Analyte was detected between the MDL and the RL
MB or B = Analyte detected in the method blank
LH,AY = Due to sample matrix effects, the surrogate recovery was outside of acceptance limits.
PV = Hydrocarbon result partly due to individual peak(s) in quantity range.
Results highlighted with **Bold** font indicate results > RL
(1) - National Primary Drinking Water Regulations - EPA Region 9
(2) - California Department of Public Health
MCLs = Maximum Contaminant Levels
bold # Results highlighted with a gray box indicate results > MCL
During Q2, 2017 GW event, due to vandalism (hinges on well lid cut off and pump stolen), MW-04B and G-4 were sampled using a bailer and analyzed only for GRO and VOC's.
During Q3, 2017 GW event, due to vandalism (monument was found damaged), a no-purge sample was collected from G-4. A trip blank was not collected on 8/17/17 due to VOA breakage.

Notes:
& 09-29-10 = wells were re-sampled on 9/29/2010 for SVOC analytes.
* = Analyte was quantitated below the established linear calibration range. Amount reported is an estimate.
** = pH was measured in the field using a Horriba U-22XB water quality meter
J = Analyte was detected between the MDL and the RL
LN,AY = The MS &/or the MSD were below acceptance limits due to sample matrix interference.
ND = Not Detected. This data was obtained from a summary table of a report not prepared by SECOR.The actual laboratory reports are not available, thus MDL's can not be determined for this
ND* = no MDL for reactive sulfide identified by the laboratory
<# = Analyte was not detected above the Reporting Limit (#)
NS = Not sampled
D = detected below quantitation limit
MB or B = Analyte present in Method Blank
µg/L = micrograms per liter
-- = Not applicable / Not analyzed
pH measurements on June 15, 2000 were obtained using pH paper
pH measurements reported prior to 2006 were obtained from a summary table of a report not prepared by SECOR. The pH measurements are presumed to have been obtained in the field.
Results highlighted with **Bold** font indicate results > RL
(1) - National Primary Drinking Water Regulations - EPA Region 9
(2) - California Department of Public Health
(3) - Identified as Benzo(a)pyrene for MCL
(4) - Identified as Total Chromium for MCL
MCLs = Maximum Contaminant Levels
bold # Results highlighted with a gray box indicate results > MCL
1 - MCL for PAHs undifferentiated based on Benzo(a)pyrene.
2 - Secondary MCL (SMCL)
na = Not applicable
During Q2, 2017 GW event, due to vandalism (hinges on well lid cut off and pump stolen), MW-04B and G-4 were sampled using a bailer and analyzed only for GRO and VOC's.
During Q3, 2017 GW event, due to vandalism (monument was found damaged), a no-purge sample was collected from G-4.

Notes:
* = Analyte was quantitated below the established linear calibration range. Amount reported is an estimate.
** = Method in water by manual cold vapor
CQ = Analyte concentration greater than 10 times the blank concentration
J = Analyte was detected between the MDL and the RL
LN,AY = The MS &/or the MSD were below acceptance limits due to sample matrix interference.
ND = Not Detected.
MB or B = Analyte present in Method Blank
B-1 = Analyte present in Method Blank, Analyte concentration in sample is greater than 10x the concentration found in the method blank
<# = Analyte was not detected above the Reporting Limit (#)
ug/L = micrograms per liter
na = Not applicable
-- = Not applicable / Not analyzed
Results highlighted with **Bold** font indicate results > RL
(1) - National Primary Drinking Water Regulations - EPA Region 9
(2) - California Department of Public Health
(3) - Secondary MCL per CCR Title 22, Div. 4, Chapter 15, Article 16
MCLs = Maximum Contaminant Levels
bold # Results highlighted with a gray box indicate results > MCL
During Q2, 2017 GW event, due to vandalism (hinges on well lid cut off and pump stolen), MW-04B and G-4 were sampled using a bailer and analyzed only for GRO and VOC's.
During Q3, 2017 GW event, due to vandalism (monument was found damaged), a no-purge sample was collected from G-4.

Notes:
<# = Analyte was not detected above the Reporting Limit (#)
ND = Not Detected.
-- = Not applicable / Not analyzed
na = Not applicable
CQ = analyte concentration greater than 10 times the blank concentration
J = Analyte was detected between the MDL and the RL
MB or B = Analyte present in Method Blank
ug/L = micrograms per liter
Results highlighted with **Bold** font indicate results > RL
(1) - National Primary Drinking Water Regulations - EPA Region 9
(2) - California Department of Public Health
(3) - Secondary MCL per CCR Title 22, Div. 4, Chapter 15, Article 16
MCLs = Maximum Contaminant Levels
bold # Results highlighted with a gray box indicate results > MCL
-- = Not applicable / Not analyzed
During Q2, 2017 GW event, due to vandalism (hinges on well lid cut off and pump stolen), MW-04B and G-4 were sampled using a bailer and analyzed only for GRO and VOC's.
During Q3, 2017 GW event, due to vandalism (monument was found damaged), a no-purge sample was collected from G-4.

Notes:

Use G = good, F = fair, and P = poor for well/seal conditions

All wells are custom fitted with QED flush mounted well caps

KECK Water Level meters used for Shallow wells: GEOTECH

KECK Water Level meters used for Deep wells: GEOTECH

YSI used for deep wells: HORIBA U52

YSI used for shallow wells: HORIBA U52

Turbidity measurements are recorded with a LaMotte turbidity meter.

Number of drums on site:	on arrival	on leaving	(approximate volume-gallons)
soil	0	0	
trash/ppe	0	0	
water	0	1	
empty	1		

Comments: Horiba multi-parameter units are now pre-calibrated in the rental office prior to use in the field, turbidity measurements are through the Horiba units

SEE CALIBRATION CERTIFICATE.

This report has been electronically signed and authorized by the signatory. Electronic signature is intended to be the legally binding equivalent of a traditionally handwritten signature.

Results relate only to the items tested and the sample(s) as received by the laboratory.

The results listed within this Laboratory Report pertain only to the samples tested in the laboratory. The analyses contained in this report were performed in accordance with the BPLAMP Technical Specifications, applicable federal, state, local regulations and certification requirements as well as the methodologies as described in laboratory SOPs reviewed by the BPLAMP. This Laboratory Report is confidential and is intended for the sole use of Eurofins TestAmerica and its client. This report shall not be reproduced, except in full, without written permission from TestAmerica. The signature on the cover page extends to the case narrative and all the data and forms in the package. The Chain of Custody is included and is an integral part of this report.

Qualifiers

GC/MS Semi VOA

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

GC VOA

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

HPLC/IC

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Metals

Qualifier	Qualifier Description
^	ICV,CCV,ICB,CCB, ISA, ISB, CRI, CRA, DLCK or MRL standard: Instrument related QC is outside acceptance limits.
B	Compound was found in the blank and sample.
F1	MS and/or MSD recovery exceeds control limits.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

General Chemistry

Qualifier	Qualifier Description
F1	MS and/or MSD recovery exceeds control limits.
HF	Field parameter with a holding time of 15 minutes. Test performed by laboratory at client's request.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)

Glossary (Continued)

Abbreviation	These commonly used abbreviations may or may not be present in this report.
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job ID: 440-270516-1

Laboratory: Eurofins Calscience Irvine

Narrative

Job Narrative
440-270516-1

Comments
This report was revised to correct sample IDs for samples TB-SUMP and FB-SUMP to add sampling dates to the names 20200818

Receipt
The samples were received on 8/18/2020 6:00 PM; the samples arrived in good condition, and where required, properly preserved and on ice. The temperatures of the 2 coolers at receipt time were 4.2º C and 4.3º C.

GC/MS VOA
Method 8260B: The continuing calibration verification (CCV) associated with batch 440-621204 recovered above the upper control limit for n-Butylbenzene and Ethylbenzene. The samples associated with this CCV were non-detects for the affected analytes; therefore, the data have been reported. The associated samples are impacted: MW-05A (440-270516-1), G-4 (440-270516-2), MW-03B (440-270516-3), MW-03A (440-270516-4), TB-SUMP-20200818 (440-270516-5), FB-SUMP-20200818 (440-270516-6) and (CCVIS 440-621204/2).

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

GC/MS Semi VOA
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

HPLC/IC
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

GC VOA
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Metals
Method 7470A: The matrix spike / matrix spike duplicate (MS/MSD) recoveries for Mercurypreparation batch 440-621288 and 440-621291 and analytical batch 440-621418 were outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample (LCS) recovery was within acceptance limits.

Method 6020: The matrix spike / matrix spike duplicate (MS/MSD) recoveries for preparation batch 440-622041 and 440-622042 and analytical batch 440-622194 were outside control limits for Zinc. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample (LCS) recovery was within acceptance limits.

Method 6020: The method blank for preparation batch 440-622041 and analytical batch 440-622194 contained Zinc above the method detection limit. This target analyte concentration was less than half the reporting limit (RL); therefore, re-extraction and/or re-analysis of samples was not performed.

Method 6020: The initial calibration verification (ICV) result for batch 440-622171 was above the upper control limit for Silver. Sample results were non-detects, and have been reported as qualified data.

Method 6020: The continuing calibration verification (CCV) associated with batch 440-622171 recovered above the upper control limit for Beryllium. The samples associated with this CCV were non-detects for the affected analytes; therefore, the data have been reported. The associated samples are impacted: G-4 (440-270516-2), MW-03B (440-270516-3) and MW-03A (440-270516-4).

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

General Chemistry
Method SM 4500 S2 D: The matrix spike / matrix spike duplicate (MS/MSD) recoveries for analytical batch 440-621667 were outside control limits. Sample matrix interference is suspected because the associated laboratory control sample (LCS) recovery was within acceptance limits.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Job ID: 440-270516-1 (Continued)

Laboratory: Eurofins Calscience Irvine (Continued)

Organic Prep
Method 3510C: Insufficient sample volume was available to perform a matrix spike/matrix spike duplicate (MS/MSD) associated with preparation batch 570-89056. LCS/LCSD was performed to meet QC requirements.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

VOA Prep
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Note: Since laboratory accreditations are subject to change, Eurofins Calscience places the ownership of method, analyte & accreditation compliance upon out subcontract laboratories. This sample shipment is forwarded under chain-of-custody. If the laboratory does not currently maintain accreditation in the State of Origin listed above for analysis/tests/matrix being analyzed, the samples must be shipped back to the Eurofins Calscience laboratory or other instructions will be provided. Any changes to accreditation status should be brought to Eurofins Calscience attention immediately. If all requested accreditations are current to date, return the signed Chain of Custody attesting to said compliance to Eurofins Calscience.

Possible Hazard Identification	Sample Disposal (A fee may be assessed if samples are retained longer than 1 month)
Unconfirmed	☐ Return To Client ☐ Disposal By Lab ☐ Archive For _____ Months

Question	Answer	Comment
Radioactivity wasn't checked or is </= background as measured by a survey meter.	True	
The cooler's custody seal, if present, is intact.	N/A	Not present
Sample custody seals, if present, are intact.	N/A	Not Present
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	True	
Cooler Temperature is acceptable.	True	
Cooler Temperature is recorded.	True	
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	True	
There are no discrepancies between the containers received and the COC.	True	
Samples are received within Holding Time (excluding tests with immediate HTs)	True	
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	True	
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	True	
Sample Preservation Verified.	True	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
Containers requiring zero headspace have no headspace or bubble is <6mm (1/4").	True	
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True	
Residual Chlorine Checked.	N/A

This report has been electronically signed and authorized by the signatory. Electronic signature is intended to be the legally binding equivalent of a traditionally handwritten signature.

Results relate only to the items tested and the sample(s) as received by the laboratory.

The results listed within this Laboratory Report pertain only to the samples tested in the laboratory. The analyses contained in this report were performed in accordance with the BPLAMP Technical Specifications, applicable federal, state, local regulations and certification requirements as well as the methodologies as described in laboratory SOPs reviewed by the BPLAMP. This Laboratory Report is confidential and is intended for the sole use of Eurofins TestAmerica and its client. This report shall not be reproduced, except in full, without written permission from TestAmerica. The signature on the cover page extends to the case narrative and all the data and forms in the package. The Chain of Custody is included and is an integral part of this report.

Qualifiers

GC/MS Semi VOA

Qualifier	Qualifier Description
*	LCS or LCSD is outside acceptance limits.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

HPLC/IC

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Metals

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

General Chemistry

Qualifier	Qualifier Description
F1	MS and/or MSD recovery exceeds control limits.
HF	Field parameter with a holding time of 15 minutes. Test performed by laboratory at client's request.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job ID: 440-270581-1

Laboratory: Eurofins Calscience Irvine

Narrative

Job Narrative
440-270581-1

Comments
No additional comments.

Receipt
The samples were received on 8/19/2020 5:00 PM; the samples arrived in good condition, and where required, properly preserved and on ice. The temperatures of the 2 coolers at receipt time were 1.5º C and 4.2º C.

GC/MS VOA
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

GC/MS Semi VOA
Method 8270C SIM: The laboratory control sample (LCS) and / or laboratory control sample duplicate (LCSD) for preparation batch 570-89524 and analytical batch 570-89863 recovered outside control limits for the following analytes: 4-Chloroaniline, Aniline, and N-Nitrosodimethylamine. These analytes were biased high in the LCS and were not detected in the associated samples; therefore, the data have been reported.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

HPLC/IC
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

GC VOA
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Metals
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

General Chemistry
Method SM 4500 S2 D: The matrix spike / matrix spike duplicate (MS/MSD) recoveries for analytical batch 440-622049 were outside control limits. Sample matrix interference is suspected because the associated laboratory control sample (LCS) recovery was within acceptance limits.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Organic Prep
Method 3510C: Insufficient sample volume was available to perform a matrix spike/matrix spike duplicate (MS/MSD) associated with preparation batch 570-89524. LCS/LCSD was performed to meet QC requirements.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

VOA Prep
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

This Detection Summary does not include radiochemical test results.

Detection Summary

Client: Stantec Consulting Corp.
Project/Site: BP Gardena Sumps

Job ID: 440-270581-1

Client Sample ID: RS-SUMP-2020819 — Lab Sample ID: 440-270581-5

No Detections.

Client Sample ID: TB-SUMP-2020819 — Lab Sample ID: 440-270581-6

No Detections.

Client Sample ID: FB-SUMP-2020819 — Lab Sample ID: 440-270581-7

No Detections.

This Detection Summary does not include radiochemical test results.

Client: Stantec Consulting Corp.

Note: Since laboratory accreditations are subject to change, Eurofins Calscience places the ownership of method, analyte & accreditation compliance upon out subcontract laboratories. This sample shipment is forwarded under chain-of-custody. If the laboratory does not currently maintain accreditation in the State of Origin listed above for analysis/tests/matrix being analyzed, the samples must be shipped back to the Eurofins Calscience laboratory or other instructions will be provided. Any changes to accreditation status should be brought to Eurofins Calscience attention immediately. If all requested accreditations are current to date, return the signed Chain of Custody attesting to said complicance to Eurofins Calscience.

Possible Hazard Identification	Sample Disposal (A fee may be assessed if samples are retained longer than 1 month)

Question	Answer	Comment
Radioactivity wasn't checked or is </= background as measured by a survey meter.	True	
The cooler's custody seal, if present, is intact.	N/A	Not present
Sample custody seals, if present, are intact.	N/A	Not Present
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	True	
Cooler Temperature is acceptable.	True	
Cooler Temperature is recorded.	True	
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	True	
There are no discrepancies between the containers received and the COC.	True	
Samples are received within Holding Time (excluding tests with immediate HTs)	True	
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	True	
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	True	
Sample Preservation Verified.	True	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
Containers requiring zero headspace have no headspace or bubble is <6mm (1/4").	False	Headspace larger than 1/4".
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True	
Residual Chlorine Checked.	N/A

GARDENA SUMPS
Southwest Corner of Artesia Boulevard and Normandie Avenue
Gardena, California

WELL ID	Date Installed	Date Abandoned	Well Diameter (inches)	Well Material	Top of Casing Elevation (ft MSL)	Surface Elevation (ft MSL)	Total Depth of Boring (ft bgs)	Total Depth of Well (ft bgs)	Screen Interval (ft bgs)	Screen Interval (ft MSL)
MW-01A	02/16/94	--	4"	sch. 40 PVC	23.55	23.55	40	40	27-37	-2.95 to -12.95
MW-01B	02/14/94	--	4"	sch. 40 PVC	23.69	23.69	92	86	80-85	-55.73 to -60.73
MW-02A	01/26/94	--	4"	sch. 40 PVC	19.15	17.38	31.5	31.5	15.5-25.5	1.88 to -8.12
MW-02B	01/23/94	--	4"	sch. 40 PVC	19.36	17.08	90	83	75.5-80.5	-58.42 to -63.42
MW-03A	01/21/94	--	4"	sch. 40 PVC	25.45	23.46	31.5	27	15.5-25.5	7.96 to -2.04
MW-03B	01/18/94	--	4"	sch. 40 PVC	25.51	23.54	90	83.5	76.5-81.5	-52.96 to -57.96
MW-04A	02/15/07	--	4"	sch. 40 PVC	24.02	21.16	30	28	18-28	6.02 to -3.98
MW-04B	02/16/07	--	4"	sch. 40 PVC	23.99	21.19	88	85	75-80	-51.01 to 56.01
MW-05A	07/20/09	--	4"	sch. 40 PVC	20.21	20.50	30.5	28	13-23	7.5 to -2.5
G-1	12/1/1982*	1987 or 1988	4"	PVC*	--	--	70	62	50-55	-25.92 to -30.92
G-2	12/1/1982*	1987 or 1988	4"	PVC*	--	--	70	65	40-50	-14.91 to -24.91
G-3	12/1/1982*	1987 or 1988	4"	PVC*	--	--	65	65	50-60	-24.94 to -34.94
G-4	12/01/82	--	2"	PVC	26.79**	25.14	65	65	45-55	-19.86 to -29.86

Notes
ft bgs = Feet below ground surface
ft MSL = Feet Mean Sea Level
-- = Not applicable / Not analylized
* = Assumed from data for G-4
Total depth of well and screen intervals determined from downhole camera inspection conducted on December, 15, 2005
** = Well G-4 casing was damaged in early 2017. It was repaired in 2018 and resurveyed on May 5, 2018. Former elevation was 27.12' AMSL.

Top of well casing and surface elevation surveyed by WM Holdings, Incorporated on September 7, 2005 and March 1, 2007.
During the first quarter 2010 the screened interval for MW-05A was edited to show the correct MSL interval.
3-5-2018 elevation survey by Stantec PLS survey

Notes:
During 3Q-2010 wells were re-sampled 09-29-10 for SVOC's
ft MSL = Feet Mean Sea Level
ft btoc = Feet below top of casing
NM = Not Measured
NC = Horizontal Groundwater Gradient & Velocity Not calculated off of Cooper Sump Site
-- = Not applicable / Not analyzed
Groundwater Monitoring Well Elevations, Surveyed by M.W. Holdings Inc., September 9, 2005 and March 1, 2007.
New Groundwater Monitoring Well (MW-05A) Elevation, Surveyed by M.W. Holdings Inc., August 10, 2009
Groundwater velocity calculations based on an assumed average porosity (n) and hydraulic conductivity (K) of the upper and lower monitored zones of 0.34 and 2.8 f/d, and 0.458 and 17 f/d respectively.
On October 30, 2014, DTSC approved the removal of MW-01A and MW-01B from the groundwater sampling plan.
** = Casing height changed by damage prior to the 8/16/17 sampling event. Groundwater elevation not calculated.
*** = repaired casing height, casing resurveyed on 3-5-2018 by Stantec PLS Survey
On October 12, 2017, the DTSC approved sampling reduction to Semi-Annually, 1st and 3rd quarters only

Notes:
GRO = Gasolone Range Organics by modified EPA Method 8015B
* = Analyte was quantitated below the established linear calibration range. Amount reported is an estimate.
ND = Not Detected. This data was obtained from a summary table of a report not prepared by SECOR/Stantec.
<# = Analyte was not detected above the Reporting Limit (#)
µg/L = micrograms per liter
na = Not applicable
-- = Not applicable / Not analyzed
J = Analyte was detected between the MDL and the RL
MB or B = Analyte detected in the method blank
LH,AY = Due to sample matrix effects, the surrogate recovery was outside of acceptance limits.
PV = Hydrocarbon result partly due to individual peak(s) in quantity range.
Results highlighted with **Bold** font indicate results > RL
(1) - National Primary Drinking Water Regulations - EPA Region 9
(2) - California Department of Public Health

Table 3
Summary of Volatile Organic Compounds Measured in Groundwater and Surfacewater
GARDENA SUMPS
Southwest Corner of Artesia Boulevard and Normandie Avenue
Gardena, California

EPA Method:			8015B	8260 B										
			GRO	Volatile Organic Compounds										
Sample ID	Date Sampled	Notes	C4 - C12 (ug/L)	Acetone (ug/L)	Benzene (ug/L)	Bromodi-chloro-methane (ug/L)	Chloroform (ug/L)	Dibromo-chloro-methane (ug/L)	Naphthalene (ug/L)	PCE (ug/L)	Toluene (ug/L)	m,p-Xylenes (ug/L)	o-Xylene (ug/L)	1,2,4-Tri-methyl-benzene (ug/L)	1,3,5- Tri-methyl-benzene (ug/L)

California DPH MCLs (2)			na	na	1	na	na	na	na	5	150	1,750		na	na

MCLs = Maximum Contaminant Levels

bold # Results highlighted with a gray box indicate results > MCL

RL Change = in 2nd Qtr 2009 the RL's and MDL's were lowered to more closely match the CA State limits on those analytes.

On October 30, 2014, DTSC approved the removal of MW-01A and MW-01B from the groundwater sampling plan.

For safety and security reasons, the surface water sampling locations in the Dominguez Flood Control Channel (DFCC) have been re-located.

During Q2, 2017 GW event, due to vandalism (hinges on well lid cut off and pump stolen), MW-04B and G-4 were sampled using a bailer and analyzed only for GRO and VOC's.

During Q3, 2017 GW event, due to vandalism (monument was found damaged), a no-purge sample was collected from G-4. A trip blank was not collected on 8/17/17 due to VOA breakage.

California DPH MCLs (2)			6	na	0.2 (3)	na	na	10	na	na

Notes:
& 09-29-10 = wells were re-sampled on 9/29/2010 for SVOC analytes.
* = Analyte was quantitated below the established linear calibration range. Amount reported is an estimate.
** = pH was measured in the field using a Horriba U-22XB water quality meter
J = Analyte was detected between the MDL and the RL
LN,AY = The MS &/or the MSD were below acceptance limits due to sample matrix interference.
ND = Not Detected. This data was obtained from a summary table of a report not prepared by SECOR.The actual laboratory reports are
ND* = no MDL for reactive sulfide identified by the laboratory
<# = Analyte was not detected above the Reporting Limit (#)
NS = Not sampled
D = detected below quantitation limit
MB or B = Analyte present in Method Blank
µg/L = micrograms per liter
-- = Not applicable / Not analyzed
Add.Data = additional data located (Sep 2006) and included in this table, reference DTSC, 2000 and 2001 report.
pH measurements on June 15, 2000 were obtained using pH paper
pH measurements reported prior to 2006 were obtained from a summary table of a report not prepared by SECOR. The pH measurements are presumed to have been obtained in the field.
Results highlighted with **Bold** font indicate results > RL
(1) - National Primary Drinking Water Regulations - EPA Region 9
(2) - California Department of Public Health
(3) - Identified as Benzo(a)pyrene for MCL
(4) - Identified as Total Chromium for MCL
MCLs = Maximum Contaminant Levels
bold # Results highlighted with a gray box indicate results > MCL
Prior to 2006, some table data was incorrectly represented in mg/L and has been updated to correctly reflect µg/L.
For safety and security reasons, the surface water sampling locations in the Dominguez Flood Control Channel (DFCC) have been re-located.
During the second quarter 2007 the instrument used to measure pH in wells completed in the upper saturated zone had calibration issues that resulted in slightly lower pH values.
During the third quarter 2007 a calibration issue developed in the instrument used to measure pH values in wells within the lower saturated zone resulting in slightly elevated pH values.
RL Change = in 2nd Qtr 2009 the RL's and MDL's were lowered to more closely match the CA State limits on those analytes.
Total Sulfides test method changed to SM 4500-SD in 5-2009
pH test method changed to SM 4500-H,B in 2010
1 - MCL for PAHs undifferentiated based on Benzo(a)pyrene.
2 - Secondary MCL (SMCL)
na = Not applicable
California Maximum Contaminant Level (MCL) for hexavalent chromium which was changed to 10 micrograms per liter (ug/L) and became effective on July 1, 2014. Updated MCL on table to reflect new MCL limits on 3Q2014.
On October 30, 2014, DTSC approved the removal of MW-01A and MW-01B from the groundwater sampling plan.
During Q2, 2017 GW event, due to vandalism (hinges on well lid cut off and pump stolen), MW-04B and G-4 were sampled using a bailer and analyzed only for GRO and VOC's.
During Q3, 2017 GW event, due to vandalism (monument was found damaged), a no-purge sample was collected from G-4.

Notes:
* = Analyte was quantitated below the established linear calibration range. Amount reported is an estimate.
** = Method in water by manual cold vapor
+ = Sampling occurred between August 10 and 17, 1987
CQ = Analyte concentration greater than 10 times the blank concentration
J = Analyte was detected between the MDL and the RL
LN,AY = The MS &/or the MSD were below acceptance limits due to sample matrix interference.
ND = Not Detected. This data was obtained from a summary table of a report not prepared by SECOR. The actual laboratory reports are not available, thus MDL's can not be determined for this data.
MB or B = Analyte present in Method Blank
B-1 = Analyte present in Method Blank, Analyte concentration in sample is greater than 10x the concentration found in the method blank
<# = Analyte was not detected above the Reporting Limit (#)
ug/L = micrograms per liter
na = Not applicable
-- = Not applicable / Not analyzed
Results highlighted with **Bold** font indicate results > RL
(1) - National Primary Drinking Water Regulations - EPA Region 9
(2) - California Department of Public Health
(3) - Secondary MCL per CCR Title 22, Div. 4, Chapter 15, Article 16
MCLs = Maximum Contaminant Levels
bold # Results highlighted with a gray box indicate results > MCL
Prior to 2006, some table data was incorrectly represented in mg/L and has been updated to correctly reflect µg/L.
On October 30, 2014, DTSC approved the removal of MW-01A and MW-01B from the groundwater sampling plan.
For safety and security reasons, the surface water sampling locations in the Dominguez Flood Control Channel (DFCC) have been re-located.
During Q2, 2017 GW event, due to vandalism (hinges on well lid cut off and pump stolen), MW-04B and G-4 were sampled using a bailer and analyzed only for GRO and VOC's.
During Q3, 2017 GW event, due to vandalism (monument was found damaged), a no-purge sample was collected from G-4.

Notes:
<# = Analyte was not detected above the Reporting Limit (#)
ND = Not Detected. This data was obtained from a summary table of a report not prepared by SECOR.
The actual laboratory reports are not available, thus MDL's can not be determined for this data.
-- = Not applicable / Not analyzed
na = Not applicable
CQ = analyte concentration greater than 10 times the blank concentration
J = Analyte was detected between the MDL and the RL
MB or B = Analyte present in Method Blank
ug/L = micrograms per liter
Results highlighted with **Bold** font indicate results > RL
(1) - National Primary Drinking Water Regulations - EPA Region 9
(2) - California Department of Public Health
(3) - Secondary MCL per CCR Title 22, Div. 4, Chapter 15, Article 16
MCLs = Maximum Contaminant Levels
bold # Results highlighted with a gray box indicate results > MCL
Prior to the 2008 sampling event, dissolved metals was not tested for in surface water samples.
-- = Not applicable / Not analyzed
On October 30, 2014, DTSC approved the removal of MW-01A and MW-01B from the groundwater sampling plan.
For safety and security reasons, the surface water sampling locations in the Dominguez Flood Control Channel (DFCC) have been re-located.
During Q2, 2017 GW event, due to vandalism (hinges on well lid cut off and pump stolen), MW-04B and G-4 were sampled using a bailer and analyzed only for GRO and VOC's.
During Q3, 2017 GW event, due to vandalism (monument was found damaged), a no-purge sample was collected from G-4.

EXECUTIVE SUMMARY

Pursuant to California Health and Safety Code Section 25356.1, this document presents the Remedial Action Plan (RAP) for the Gardena Sumps Site (Site) located at the southwest corner of Artesia Boulevard and Normandie Avenue in Gardena, California. The RAP was prepared by Geosyntec Consultants, Inc. (Geosyntec) on behalf of Atlantic Richfield Company (ARC) for submittal to the California Environmental Protection Agency (CalEPA), Department of Toxic Substances Control (DTSC). The Administrative Record for this Site is included in Appendix A of this RAP.

This RAP addresses the Cooper North sump, Cooper South sump, Haack sump, and Haack Rework Area on the Site. The three sumps and the Haack Rework Area are referred to as the areas of concern (AOCs) in this RAP.

The Cooper sumps currently are capped by a geosynthetic material that was installed by OHM Corporation (OHM) in July 1993 as part of the DTSC's environmental program at the Site. An additional geosynthetic liner was placed over the 1993 liner in August 2013. The Haack Sump has been covered by asphalt and a concrete slab. Currently the Haack property is leased to various tenants who operate small businesses, including a U-Haul rental agency, a metal fabricating, sand blasting and painting company, and an auto body repair shop. Three buildings and numerous small trailer-type storage structures are present on the Haack property.

Based on the Draft Human Health Risk Assessment (HHRA) (Geosyntec, 2010), primary risk driving chemicals were identified as constituents of concern (COCs) from the list of constituents of potential concern (COPC). The primary COCs identified in the Cooper and Haack Sumps as well as in the Haack Rework Area are: (i) Soil: arsenic, hexavalent chromium, naphthalene, and the benzo(a)pyrene toxicity equivalent (BaP-eq); (ii) Air: benzene, hydrogen sulfide; and (iii) Groundwater: dibenz(a,h)anthracene.

The most suitable remedial alternative for the AOCs at the Site was evaluated based on the selection criteria described in the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) guidance document (United States Environmental Protection Agency [USEPA], 1988). In a letter dated 14 July 2020, DTSC approved ARC's Feasibility Study (FS) (Geosyntec, 2014). Based on the comparative analysis of the remedial alternatives, Alternative 2A - Capping with selective excavation was identified as the alternative that meets the Remedial Action Objectives (RAOs) and ranks the highest. This alternative consists of excavating the Haack Rework area and a portion of sludge overflow along the eastern limits of the Cooper Sumps and consolidating the materials above the Cooper North and South Sumps. A cap consisting

of a stabilization layer, foundation layer, low-hydraulic conductivity layer, and erosion resistance layer would be constructed above the sumps. A vapor control and monitoring system would be installed beneath the cap and around the sumps, and groundwater monitoring would continue.

This remedial alternative effectively mitigates the risk from ingestion, inhalation, and dermal contact with soils from the AOCs for both future non-residential and residential occupants of buildings on Site, and future landscape and utility workers. This alternative also effectively mitigates the risk from dermal contact with Site groundwater through construction of the cap and institutional controls.

Alternative 2A readily meets the criteria of overall protection of human health and the environment and satisfies Applicable or Relevant and Appropriate Requirements (ARARs). When evaluated against the balancing criteria, Alternative 2A provides short-term effectiveness as well as long-term effectiveness and permanence. It is readily implementable and presents an effective balance of cost against the other criteria. Alternative 2A also would best accommodate future potential redevelopment of the Site.

Additional remedial alternatives considered included:

1. Alternative 1 – No action.
2. Alternative 3 – Capping with selective excavation and stabilization/neutralization, which included mixing the top 3 feet (ft) of sludge in the Cooper North and South Sumps with reagent to stabilize/neutralize the sludge. The Haack Rework area and a portion of sludge overflow along the eastern Cooper Sumps would be mixed with the stabilized/neutralized material. A cap consisting of a foundation layer, low-hydraulic conductivity layer, and erosion resistance layer would be constructed above the Cooper North and South and Haack Sumps. A vapor control and monitoring system would be installed beneath the cap and around the sumps, groundwater monitoring would continue, and institutional controls would be implemented.
3. Alternative 4 – Excavation of sludge with off-Site disposal. The sludge would be mixed with the neutralizing agent and loaded into trucks for disposal off-Site. Major components of this alternative include concrete and asphalt removal, odor and air emissions control, excavation and mixing of sludge, transportation to the disposal facility, confirmation sampling, sump backfill, and ongoing groundwater monitoring.

Redevelopment plans for the Site have been proposed by a developer but have not yet been approved nor has the developer purchased the property at this point. ARC has provided a copy of the RAP to the developer and has engaged them in conversation regarding the nature of their development and how it would fit with the selected remedy. The redevelopment plans are generally consistent with the remedy presented in this RAP. To the extent that the redevelopment plans are approved in such a manner so as to be consistent with the remedy, ARC will coordinate with the developer, as necessary, to carry out redevelopment at the Site to the extent practical and appropriate.

Consistent with the Public Participation requirements for the RAP process, the public participation process will include:

- Development of a mailing list, including at a minimum, all commercial, industrial, and residential occupants within at least a ¼-mile radius;
- Fact sheet preparation and mailing;
- Public notice and public hearing;
- 45-day comment period; and
- A response to comments document sent to all individuals who submitted formal public comments.

Public access for review of the project documents, including previously distributed documents, is available at the following locations:

1. INTRODUCTION

Pursuant to California Health and Safety Code Section 25356.1, this document presents the Remedial Action Plan (RAP) for the Gardena Sumps Site (Site) located at the southwest corner of Artesia Boulevard and Normandie Avenue in Gardena, California. The RAP was prepared by Geosyntec Consultants, Inc. (Geosyntec) on behalf of Atlantic Richfield Company (ARC) for submittal to the California Environmental Protection Agency (CalEPA), Department of Toxic Substances Control (DTSC).

1.1 Purpose

This RAP summarizes the Remedial Investigation (RI) performed by Stantec and documented in the Revised Draft 2006 Remedial Investigation Report (Revised Draft RIR) (Stantec, 2008) and the Addendum to the 22 August 2008 Revised Draft 2006 Remedial Investigation Report (Addendum to the Revised Draft RIR) (Stantec, 2010b), which was approved by the Department of Substances Control (DTSC) in a letter dated 8 March 2011 (DTSC, 2011). This RAP also summarizes the evaluation and selection of the preferred remedial alternative, outlines the design objectives and criteria, and summarizes the design components, implementation plan, monitoring, schedule, and other regulatory requirements for the remedy approved in the Feasibility Study (FS) for the Cooper North sump, Cooper South sump, Haack sump, and the Haack Rework Area, constituting the areas of concern (AOCs).

1.2 Public Participation

Consistent with the Public Participation requirements for the RAP process, the public participation process will include:

- Development of a mailing list, including at a minimum, all commercial, industrial, and residential occupants within at least a ¼-mile radius;
- Fact sheet preparation and mailing;
- Public notice and public hearing;
- 45-day comment period; and
- A response to comments document sent to all individuals who submitted formal public comments.

Public access for review of the project documents, including previously distributed documents, is available at the following locations:

Other information on the Site may be accessed at:

DTSC EnviroStor Website:
http://www.envirostor.dtsc.ca.gov/public/

1.3 Terms of Reference

On 2 November 2004, the United States (US) District Court for the Central District of California entered a Consent Decree in the case of California Dept. of Toxic Substances Control, et al. v. Atlantic Richfield Company (Consent Decree) (DTSC, 2004). The Consent Decree dictates the remedial responsibilities assumed by ARC and governs the preparation of a RAP. The Consent Decree requires the final draft RAP to be consistent with the National Contingency Plan (NCP) and Health and Safety Code (H&SC) Section 25356.1, et seq.

1.4 RAP Organization

The remainder of the RAP is organized as follows:

- Section 2, Site Background, presents physical characteristics of the Site, owner/operator information, permits, regulatory status, and facility history.
- Section 3, Summary of Remedial Investigations, summarizes the RI activities, results of testing, and provides the conceptual site model (CSM) abstracted from the Revised Draft Remedial Investigation (Stantec, 2008).
- Section 4, Summary of Removal Actions, summarizes removal actions completed at the Site.
- Section 5, Summary of Risk Assessment, Remedial Action Objectives and Site Cleanup Levels, presents the constituents of concern (COCs) and Site risks

abstracted from the Draft Human Health Risk Assessment (HHRA) (Geosyntec, 2010). The remedial action objectives (RAOs) and applicable or relevant and appropriate requirements (ARARs) are also discussed in this section.

- Section 6, Summary and Evaluation of Alternatives, describes the screening of potential remedial action technologies against evaluation criteria and presents a comparative analysis of the alternatives.
- Section 7, Remediation in Areas of Concern, summarizes the design components, implementation plan, monitoring, schedule, and other regulatory requirements for the remedy proposed in Section 6.
- Section 8, References, presents the references used in the preparation of this report.

2. SITE BACKGROUND

2.1 General

This section includes information on Site location and description, Site history, geology, and hydrogeology. The information presented in this section generally has been excerpted from the Revised Draft RIR (Stantec, 2008).

2.2 Site Location and Description

The Site is located at 1440 West Artesia Boulevard, in the southwest corner of the Artesia Boulevard and Normandie Avenue intersection, in the City of Gardena, Los Angeles County, California (Figure 1-1). Generally, the area surrounding the Site is bordered to the south by the Los Angeles County Department of Public Works (LACDPW) Dominguez Flood Channel, to the east by the Southern Pacific Railroad right-of-way and Normandie Avenue, to the west by commercial properties, and to the north by Artesia Boulevard, although a small portion of Artesia Boulevard is included within the Site.

The Site, shown on Figure 1-2, is approximately 6.48 acres of mixed-use development (i.e., residential and commercial) and primarily consists of two properties, the Cooper property and the Haack property. The Cooper property is comprised of two large sumps (referred to as the "Cooper North" and "Cooper South" sumps). The Haack property contains one modified sump (referred to as the "Haack sump") and the "Haack Rework Area," which is a reworked and mixed sludge-soil area south of the Haack sump. The Haack Rework Area encroaches onto the extreme northern portions of the two easternmost residential lots. Commercial property is located west of the Haack sump, and four residential properties are located south of the commercial property and the Haack sump.

This RAP addresses the three sumps and the Haack Rework Area, which are referred to in this RAP as the AOCs.

2.3 Site History, Operation, and Ownership

The Revised Draft RIR documents the Site history and presents historic aerial photographs. Please refer to the Revised Draft RIR (Stantec, 2008) for details.

2.4 Agency Involvement

DTSC oversight began in 1988 when it determined that the presence of hazardous substances in the soil at the Site posed an imminent and substantial endangerment to

public health and the environment. In 1992, the DTSC issued an Imminent and Substantial Endangerment Order and Remedial Action Order requiring respondents to undertake certain cleanup measures at the Site. OHM Corporation installed a geosynthetic cap over the sumps in 1993 as part of the DTSC's environmental program at the Site. On 2 November 2004, the DTSC entered into a Consent Decree with ARC which directed ARC to:

- Complete removal actions;
- Prepare a Public Participation Plan (PPP);
- Perform and prepare an RI;
- Perform interim screening and evaluation of remedial technologies;
- Perform Treatability Studies;
- Prepare a Baseline Risk Assessment;
- Prepare an FS;
- Evaluate the California Environmental Quality Act (CEQA); and
- Prepare a RAP.

2.5 Climatology

The climate in Gardena is controlled by the strength and position of a semi-permanent high-pressure cell over the eastern Pacific Ocean. The high-pressure cell generally creates a pattern of early morning cloudiness, afternoon sunshine, and minor temperature fluctuations throughout the year.

Complete-year historic climate data is available for 30 years between 1961 and 1990 for the nearby Torrance Municipal Airport, located approximately 5 miles southwest of the Site at approximately 33.80 degrees north (°N) and 118.33 degrees west (°W) and 108 feet (ft) above mean sea level (amsl) (WorldClimate.com, 2013). According to the data, the annual average temperature for the area is 62.8 degrees Fahrenheit (°F) with an average monthly high temperature of 79.9°F occurring in August, and an average monthly low temperature of 45.1°F occurring in January. Rainfall occurs mostly from November through April as generally mid-latitude storms move through the area. An average of approximately 13.6 inches of rain falls each year. Summers are often dry, with the exception of occasional rainfall from thundershowers of tropical origin. The average wind is from the west at a speed of 7.8 miles per hour (mph).

2.6 Topography

The Site is located in a generally low-lying coastal plain that is relatively flat. Artesia Boulevard to the north ranges in elevation from approximately 20 ft amsl to 22 ft amsl in the vicinity of the Site and slopes slightly to the west. Normandie Avenue to the east ranges in elevation from approximately 24 ft amsl to 22 ft amsl and slopes slightly to the north. The top of the slopes of concrete-lined Dominguez Channel to the south of the Site are at an approximate elevation of 25 ft amsl and the channel flows to the west. The residential properties to the south of the Site generally range from 25 ft amsl to 35 ft amsl and slope to the west. The commercial property to the west slopes to the northeast with a maximum elevation of approximately 29 ft msl in the southwest corner to a minimum elevation of approximately 21 ft msl in the northeast corner adjacent to Artesia Boulevard.

The surface elevation of the Cooper North, Cooper South, and Haack Sumps is approximately 20 ft amsl. The Haack Rework Area ranges in elevation from approximately 20 ft amsl to 35 ft amsl.

2.7 Geology

The following discussion is based on California Department of Water Resources (CalDWR) Bulletin No. 104, Planned Utilization of the Ground Water Basins of the Coastal Plain of Los Angeles County, Appendix A — Ground Water Geology, dated June 1961, reprinted April 1988 (CalDWR, 1961) and discussions contained in reports from previous investigations (CalEPA, 1994; URS, 1994; and Stantec, 2008).

The Site is located in the Los Angeles Coastal Plain and is underlain by a thick sequence of marine and continental sediments that were deposited in a broad synclinal depression. This depression is generally referred to as the Los Angeles Basin. The Los Angeles Basin is bisected by the northwest trending Newport-Inglewood uplift, which divides the Coastal Plain into two smaller synclinal troughs. The Site is located in the West Coast Basin, which constitutes the southwest portion of the Los Angeles Basin.

The Site is located near the junction of the Torrance Plain and the Dominguez Erosion Gap. The Torrance Plain runs west of and parallel to the hills of the Newport-Inglewood uplift from the Ballona Gap southeast to the Dominguez Gap. The Plain is a broad featureless area only slightly dissected locally by the Dominguez Creek (Dominguez Channel).

According to boring logs in the Ecology and Environmental, Inc. (EEI) (1986), Metcalf and Eddy (1992), CalEPA (1994) and URS (1994) reports, sediments underlying the Site,

to the maximum explored depth of 92 ft below ground surface (bgs), consist primarily of a mixture of clays and silts with interbeds of sand. Copies of the available boring logs from these previous studies are provided in Appendix F and summarized in Table 13 of the Revised Draft RIR (Stantec, 2008). This stratigraphy correlates in general with the observed conditions in borings completed in conjunction with the Revised Draft RIR (Stantec, 2008) and the Addendum to the Revised Draft RIR (Stantec, 2010b), which reached a maximum depth of 100 ft bgs.

2.8 Hydrogeology

The following discussion is based on CalDWR Bulletin No. 104, Planned Utilization of the Ground Water Basins of the Coastal Plain of Los Angeles County, Appendix A - Ground Water Geology, dated June 1961, reprinted April 1988 (CalDWR, 1961) and discussions contained in reports from previous investigations (CalEPA, 1994; URS, 1994; Stantec, 2008).

The Site is located in what is known as the West Coast Groundwater Basin. The West Coast Groundwater Basin has existing beneficial uses for municipal and domestic supply wells, agricultural supply, industrial process supply, industrial service supply, and aquaculture (Los Angeles Regional Water Quality Control Board [LARWQCB], 1994). This basin is hydraulically isolated from other, larger groundwater basins in the Coastal Plain by the regional Newport-Inglewood Fault. The Site is underlain by Holocene and late-Pleistocene Age alluvial and marine deposits, which include the Bellflower Aquiclude at the ground surface, and the Gardena and/or Gage Aquifers of the Lakewood Formation beneath the aquiclude. Major underlying aquifers (beneath the Lakewood Formation) are the Lynwood and the Silverado Aquifers of the San Pedro Formation.

The uppermost defined unit within the basin, and the unit the Site is located within, is the Bellflower Aquiclude. Regionally, the Bellflower Aquiclude contains interfingered zones of permeable and less permeable sediments. The zones with modest to relatively high hydraulic conductivity consist of fine to coarse sand with gravel and silty sand. These coarser grained sediments vary in thickness from 10 to 60 ft and are not laterally continuous. However, in some areas, these permeable zones can contain significant amounts of water. Little beneficial use is made of water in these shallow, discontinuous hydraulic zones because well yields tend to be low and water quality generally poor (CalDWR, 1961).

The Gardena/Gage, Silverado, and Lynwood Aquifers are all capable of storing or conveying groundwater in significant quantities and constitute major sources of groundwater in the West Coast Groundwater Basin. The Lynwood and Silverado

Aquifers are primary sources for domestic water supply, while the Gardena and Gage Aquifers are a secondary domestic water supply source. Neither the Gardena nor Gage Aquifers are currently pumped for domestic use. The intervening finer-grained aquitards have not been named. These aquitards, including those that separate the Gardena and Gage Aquifers from the Lynwood Aquifer and the Lynwood Aquifer from the Silverado Aquifer, are discontinuous in nature and absent in some areas.

Immediately beneath the Site, there are two hydraulic groundwater zones within the Bellflower Aquiclude: Zone A (upper) and Zone B (lower), which are approximately 15 to 25 and 75 to 80 ft bgs, respectively. Site groundwater monitor wells are screened within these two zones. General groundwater chemistry analyses were performed at the Site to evaluate if a hydraulic interconnection exists between Zone A and Zone B due to the existence of a downward vertical gradient between the two zones. The groundwater chemistry analysis indicated the two zones are characterized by different groundwater geochemistry. The concrete lined Dominguez Channel influences the flow direction of the shallow Zone A groundwater southward while the deeper Zone B groundwater has a flow direction to the east – southeast. Groundwater monitoring at the Site over the past seven years indicates that COCs are not migrating vertically or laterally over any significant distance from the locations of the waste material.

2.9 Surface Water

The area surrounding the Site is urbanized, with surface waters that drain via storm drains into the Dominguez Channel. The Dominguez Channel is a concrete-lined flood-control structure immediately south of the Site. The upstream portion of the modern-day Dominguez Channel originates several miles west-northwest of the Site, and it drains surface water to the southeast where it discharges to the Cerritos Channel of the Los Angeles Harbor. Surface water at the Site generally drains towards the north and east following site topography, and is intercepted by a flood control storm drain located at the northeast corner of the Site adjacent to the intersection of Artesia Boulevard and Normandie Avenue.

Historically, the Dominguez Channel flowed along a natural channel bed located approximately several hundred feet west and north of the Site where it flowed eastward into Laguna Dominguez. Presently the shallow groundwater beneath the Site is influenced by the concrete lined Dominguez Channel and flows southward.

3. SUMMARY OF REMEDIAL INVESTIGATIONS

3.1 General

The nature and extent of hydrocarbon and metal impacts at and surrounding the Site have been evaluated through several investigation programs conducted since 1982. Sludge, soil, surface water, groundwater, and soil vapor have been investigated. The following sections provide a summary of findings for each of these media. Figures 3-1 through 3-3 depict the locations of soil matrix, soil vapor, and groundwater samples, respectively, collected during the RI. Details of the investigations and findings can be found in the Revised Draft RIR (Stantec, 2008) and the Addendum to the Revised Draft RIR (Stantec, 2010b).

3.2 Sludge and Soil

As a part of the RI, Stantec investigated the Cooper South Sump, the Cooper North Sump, The Haack Sump, the Haack Rework Area, as well as other on-Site and off-Site areas to delineate the vertical and horizontal extents of continuous (nonreworked) sludge and sludge-induced impacts to soil. The investigation included over 300 subsurface soil and sludge samples analyzed for the following organic and inorganic constituents:

- Volatile fuel hydrocarbons (VFHs);
- Total extractable hydrocarbons (TEHs);
- Volatile organic compounds (VOCs);
- Semi-volatile organic compounds (SVOCs);
- Polynuclear aromatic hydrocarbons (PAHs);
- Title 22 metals;
- Mercury; and
- Hexavalent chromium.

Detected constituents in soil and sludge samples analyzed as part of the RI investigation are provided in the Revised Draft RIR (Stantec, 2008) and updated in the Addendum to the Revised Draft RIR (Stantec, 2010b). The delineation of sludge is shown on Figure 1-2 and described in the sections below. The thickness of sludge in the sumps and the Haack Rework Area, as identified in the Stantec 2008 and Stantec 2010 reports, is variable due to uneven basal surfaces and interlayered reworked sand deposits.

3.2.1 Cooper South Sump

Typical average total thickness of sludge in the Cooper South Sump is approximately 4 to 5 ft with a maximum thickness of 11.5 ft. Lateral impacts of sludge in soil are negligible. Approximately 6,700 cubic yards (CY) of sludge was calculated by Stantec to be in the Cooper South Sump (Stantec, 2010b).

3.2.2 Cooper North Sump

Typical average total thickness of sludge in the Cooper North Sump is approximately 6 ft with a maximum thickness of 15.5 ft. Chrysene was detected in one boring up to 11 ft beneath the sludge. Some TEH and PAH constituents were detected approximately 6 ft laterally from this sump in depths up to 15 ft bgs, indicating some lateral migration in soil to the north; however, other borings indicated lateral impacts of sludge in soil in other directions is negligible. Approximately 7,000 CY of sludge was calculated by Stantec to be in the Cooper North Sump (Stantec, 2010b).

3.2.3 Haack Sump

Typical total thickness of sludge in the Haack Sump is approximately 4 to 5 ft with a maximum thickness of 12 ft. Boring logs indicated the western and central areas of the sump had been reworked, possibly during Site development in the late 1940s. Approximately 2,250 CY of sludge was calculated by Stantec to be in the Haack Sump (Stantec, 2010b).

3.2.4 Haack Rework Area

The Haack Rework Area consists of deposited sludge, soil, and debris in discontinuous and mixed layers of varying thickness beneath a soil cover. Sludge deposits in the Haack Rework Area slope and thicken to the northeast, to a maximum thickness of 6 ft. Approximately 670 CY of sludge material was calculated by Stantec to be in the Haack Rework Area (Stantec, 2010b).

3.3 Surface Water

Surface water samples were collected upstream and downstream of the Site from the Dominguez Channel in 2006 and 2008. Analytical data from these samples indicated elevated concentrations of gasoline range organics (GRO) and VOC analytes in contrast to the non-detections for those analytes in groundwater monitored at the Site. Based on the organic chemical parameters, the Site is not impacting surface water quality in the channel. Overall, the observed concentrations of metals in surface water adjacent to the

Site support the same conclusion that the Site groundwater conditions are not impacting surface water quality (Stantec, 2008).

3.4 Soil Vapor

The soil vapor investigation activities evaluated the subsurface concentrations of VOCs, hydrogen sulfide, and methane at various locations across the Site for use in the baseline HHRA. Constituent concentrations reported above the detection limit for targeted VOCs included benzene, toluene, ethylbenzene, m-,p-,o-xylenes, 1,3,5-trimethylbenzene, and Freon 113.

During the 2009 RI activities, additional samples were collected from 22 semi-permanent direct-push soil vapor probes. Samples collected near the Haack administrative building showed no VOCs greater than California Human Health Screening Levels (CHHSLs). On the residential properties, benzene from the sample collected from the former corral (SV-135) was the only constituent reported higher than the specific constituent CHHSL value. The results elsewhere at the Site during the 2009 RI activities generally confirmed the results of the 2006 RI (Stantec, 2010a).

An Air Pathway Analysis (APA) was performed during the 2006 investigation to evaluate the exposure pathway of outdoor inhalation of vapors. The APA showed disturbed sludge can be generally characterized as having moderate to high area source emissions as compared to the low to moderate source emissions for undisturbed sludge. Odor analyses confirmed the potential for sulfur compounds from disturbed sludge to create nuisance odors to people in the area or downwind of the disturbed sludge. The APA also showed individual compound emissions are greatly affected by the existing surface coverings and concrete slab (Stantec, 2008).

3.5 Groundwater

Groundwater is currently monitored from wells G-4 and MW-05A, screened in the upper (Zone A) hydrogeologic unit, and from four additional wells screened in both the Zone A and lower (Zone B) hydrogeologic zones (MW-02A/B, MW-03A/B, and MW-04A/B). Data collected during first quarter 2019 indicated groundwater elevations ranging from 6.17 to 7.82 ft amsl in Zone A and from 3.11 to 4.35 ft amsl in Zone B. Groundwater in Zone A generally flows to the south from Artesia Boulevard to the Dominguez Channel while groundwater in Zone B generally flows to the east.

Results of the first quarter 2019 semi-annual groundwater monitoring event are generally consistent with the analytical results from past sampling events since February 2006.

MW-05A continues to indicate the presence of GRO above the reporting limit; however, there is no Maximum Contaminant Level (MCL) for GRO. Although Bis(2-ethylhexyl)Phthalate has been detected above the MCL in wells MW-02B, MW-03B, MW-04A, and G-4 in the past, only well MW-03B had a detection above the MCL during the first quarter 2019. While concentrations of metals continue to be detected in all monitor wells, only MW-05A has had exceedances of beryllium, cadmium, and nickel above MCLs (Stantec, 2019).

3.6 Fate and Transport

Based on the results from previous investigations and the extensive field work performed as part of the Revised Draft RIR (Stantec, 2008) and the Addendum to the Revised Draft RIR (Stantec, 2010b), the current CSM suggests:

- The undisturbed sludge at the Site does not pose a threat to surface water and does not pose a threat to shallow (Zone A) or deeper (Zone B) groundwater quality throughout much of the Site. Shallow groundwater is impacted (lower pH, total & dissolved metals) south of the Haack sump; however, these impacts are not detected in samples collected downgradient of the sumps;
- The undisturbed sludge at the Site does not pose a substantive threat to the air quality in the immediate vicinity of the Site. Isolation of the sludge from temperature fluctuations above approximately 100 °F would further minimize this potential impact.
- The undisturbed sludge does not pose a threat to further contamination of soil surrounding the sludge by leaching of constituents of potential concern (COPCs) from the sludge; and
- The transport mechanisms identified during the HHRA are wind, erosion and dust; volatilization to indoor and ambient air; and leaching to groundwater (Geosyntec, 2010).

3.7 Treatability Studies Conducted

As part of the RI, a treatability study was conducted by Stantec to define and evaluate the physical and chemical characteristics of the sludge and evaluate neutralization/stabilization options. Characteristics of the sludge evaluated included acidity, wet density, moisture, viscosity, and softening point. Components of the neutralization/stabilization evaluation included:

- Potential of off-vapor evolution during full-scale mixing operations;

- Analysis of mobilization of organics and metals in treated and untreated sludges including long-term leaching analysis;
- Permeability testing;
- Analysis of soil additives;
- Testing for the potential for thermal treatment;
- Evaluation of moisture/density relationships for sludge and sludge/soil mixtures; and
- Analysis of asphaltic quality.

Testing indicated the sludge can be neutralized by using 25 percent treatment reagent addition by weight where the treatment reagent is comprised of 50 percent hydrated lime (calcium hydroxide, Ca(OH)2) and 50 percent calcium carbonate (CaCO3) fines. Approximately 10 percent water addition was also required to help activate the lime and carbonate reactions. The addition of 50 percent soil by weight during this mixing will also effectively solidify the waste so it is no longer susceptible to viscoelastic deformation. This treatment also effectively fixates lead, as demonstrated through long-term leaching tests, and neutralizes acid gases such as hydrogen sulfide and sulfur dioxide (Stantec, 2008).

4. SUMMARY OF REMOVAL ACTIONS

Since the Site was identified by the DTSC in 1981, three removal actions have been performed. The following section summarizes the removal actions completed at the Site.

4.1 1993 – Interim Cover Construction

In 1993, the DTSC prepared an Engineering Evaluation/Cost Analysis Report (EECAR) for the Site with the objective of preventing human dermal contact with the sludge. The EECAR identified three alternatives to achieve the stated objective: Haul and Dump (Alternative 1), Recycling (Alternative 2), and Construction of Cover (Alternative 3). The EECAR identified Alternative 3 as the proposed removal action (DTSC, 1993a).

Between 14 June and 6 August 1993, the removal action was implemented. The interim cover was constructed to prevent dermal contact with the sludge over an area of approximately 114,000 square feet (sf). Further investigation of the Site was identified as additional work to be completed (DTSC, 1993b).

4.2 1994 – Sludge Seepage Removal

Between 10 January and 24 January 1994, a layer of clean fill dirt was placed above exposed areas of sludge on the Southern Pacific Railroad right-of-way to the east. Additionally, a fence was installed around an approximately 12,000 sf portion of the Southern Pacific Railroad right-of-way bordering the Site (DTSC, 1994).

4.3 1998 – Haack Property Cover Construction

As part of the legal settlement between the DTSC and Mr. Clarence Haack (Haack property owner), DTSC Docket #91/92-012, Mr. Haack was responsible for abating the risk to human health from the sludge on his property. The Removal Action Workplan (RAW) identified three alternative treatment options: haul and dump (Alternative 1), Recycling (Alternative 2), and Construction of Cover (Alternative 3).

Alternative 3 was found to be the best option for the Haack Property. The cover reportedly consists of a 6-mil thick visqueen vapor barrier, with 2 inches of sand above and below to provide protection, and a concrete cap. The concrete cap included steel reinforcement within a minimum 6-inch thick slab.

4.4 2013 – Interim Cover Replacement

An additional geosynthetic liner was placed over the 1993 liner in August 2013. The new 45-mil reinforced polypropylene (RPP) geomembrane material was hot air welded along internal seams and seam taped and hot air welded to the underlying original geomembrane along the perimeter of the existing cover by Barber-Webb Co., Inc (BW). At the conclusion of cover repair, twenty-five pound sand bags constructed out of geomembrane material were placed on top of the cover at 25-ft intervals. Additional details of the new liner construction are provided in the Annual Cover Inspection and Maintenance Report prepared by Stantec dated 31 January 2014 (Stantec, 2014).

5. SUMMARY OF RISK ASSESSMENT, REMEDIAL ACTION OBJECTIVES AND SITE CLEANUP LEVELS

This section describes the development of RAOs and target cleanup levels for the Site. The process of developing the RAOs depends upon the assessment of risk to identified receptors at the Site and in the Site vicinity. A discussion of the HHRA at the Site follows.

5.1 Constituents of Potential Concern

The COPCs for the Site were developed and discussed in the hazard identification section of the HHRA (Geosyntec, 2010). United States Environmental Protection Agency (USEPA) guidance states the list of chemicals should include all chemicals that were:

- Positively detected in at least one sample;
- Detected above levels of the same chemicals found in associated blank samples;
- Tentatively identified, but may be associated with the Site based on historical information;
- Transformation products of detected chemicals; and
- Detected above naturally occurring levels (background).

During the HHRA, those contaminants posing a potential risk to receptors at the Site were identified as COPCs and can be found in Table 5-1 for soil, soil vapor, and groundwater.

5.2 Human Health Risk Assessment

5.2.1 Approach

The draft HHRA included an evaluation of health risks to potentially exposed receptor populations consisting of commercial/industrial workers, construction workers, hypothetical future residents, and trespassers. Potential exposures were evaluated for these populations assuming existing physical Site conditions (without the existence of the protective caps on the Cooper and Haack properties and prior to any future remediation efforts at the Site). In addition, a current residential scenario was included for the immediate adjacent off-Site residential area (Geosyntec, 2010).

Future development of the Site and the immediate adjacent off-Site residential area would be zoned for commercial as designated in the City of Gardena's report titled Artesia Corridor Specific Plan (The Planning Center [TPC], 2006). A more conservative hypothetical future residential scenario was included in the HHRA to evaluate potential

risks under an unrestricted land use scenario. For the construction worker scenario, shallow groundwater was also evaluated assuming that outdoor vapor inhalation and dermal contact could potentially occur when groundwater is exposed in an open excavation (Geosyntec, 2010).

To evaluate the spatial distribution of risk driving chemicals, two types of comparison criteria were developed for each chemical identified in the risk characterization: (1) those based on background; and (2) risk-based concentrations (RBCs) or target risk concentrations which are based on each receptor group and assuming Site-specific soil characteristics and a target risk goal. For worker exposures (commercial/industrial and construction worker) a target risk goal of 1 in 100,000 (1×10-5) was used. For residential and trespasser scenarios a 1 in 1,000,000 (1×10-6) target risk goal was used. For those chemicals in which the RBCs are below background, the background concentration is used as the comparison criteria. This is the case for arsenic for residential and commercial/industrial worker scenarios, and benzo(a)pyrene toxicity equivalent (BaP-eq) for the residential scenarios (Geosyntec, 2010).

5.2.2 Results

The results of the HHRA indicate exposures to on-Site soils may potentially exceed target risk goals for all potential receptor scenarios evaluated: commercial/industrial worker, construction worker, hypothetical future on-Site/current off-Site resident, and trespasser. The primary contributors to the risk estimates were arsenic, hexavalent chromium, naphthalene, and predominantly the carcinogenic PAHs as represented by the BaP-eq concentration. The majority of locations where concentrations of these chemicals were elevated occurred within areas of known sludge material which are currently covered by the existing geomembrane cap, soil, concrete, and/or asphalt (Geosyntec, 2010).

5.3 Constituents of Concern

Following completion of the HHRA, primary risk driving chemicals were identified as COCs from the list of COPCs (see Section 5.1). These chemicals were identified as primary risk drivers because they are the most ubiquitous chemicals throughout the Site and because they are co-located with a majority of the COPCs (i.e., the risk associated with the COCs would encompass the COPCs). Based on the HHRA, the primary COCs at the Site are:

- Soil: arsenic, hexavalent chromium, naphthalene, and the BaP-eq.
- Air: benzene, hydrogen sulfide.

- Groundwater: dibenz(a,h)anthracene.

These COCs are present in the Cooper and Haack Sumps as well as in the Haack Rework Area. Methane has been detected at low concentrations around the Site but was not identified as a COC based on the HHRA. Due to the potential explosive risk associated with methane, it has been included as an RAO.

5.4 Remedial Action Objectives

RAOs are goals specific to various media and apply to those media that have been identified as posing an unacceptable risk based on the HHRA work performed for the Site. The RAOs for on-Site soils, soil vapor, and groundwater are:

- Prevent ingestion/direct contact with sludge and/or soil having 10-5 to 10-6 excess cancer risk from carcinogenic constituents as represented by arsenic, hexavalent chromium, naphthalene, and the BaP-eq concentration;
- Prevent dermal contact with shallow groundwater having 10-5 excess cancer risk from carcinogenic PAHs as represented by dibenz(a,h)anthracene;
- Prevent dermal contact with low pH, PAH containing sludge;
- Prevent inhalation of VOCs, as represented by benzene, posing excess cancer risk levels of 10-5 to 10-6; and
- Prevent explosive risks associated with methane.

5.5 Future Site Use

The Site is currently used for residential and commercial/industrial applications. The DTSC has requested the following three future land use scenarios be evaluated for the Site:

- Current land use will continue; residential properties would remain, and Cooper and Haack areas would remain commercial/industrial;
- Use the Site for residential only; and
- Use the Site for commercial/industrial only.

Although not planned to accommodate residential redevelopment, as a conservative approach to meet the DTSC request, the residential cleanup goals will be used, which are the most stringent.

The City of Gardena has developed the City of Gardena Master Plan (TPC, 2006) which indicates the Site would be developed in the future as commercial property with a mix of commercial buildings and parking. To accommodate this development plan and constraints of the Site, The City of Gardena requested the remedial design be compatible with a parking lot or open space end use incorporating curbs, gutters, light poles, and utilities.

5.6 Target Cleanup Levels

The target cleanup levels for the Site were developed with consideration given to the following factors:

- Hypothetical future use scenario;
- RAOs; and
- Potential Site health risk.

The Site-Specific Action Levels (SSALs) shown in Tables 5-2, 5-3, and 5-4 were developed for each of the COCs identified in Section 5.3. Cleanup criteria either are numeric goals to be achieved through remediation or are non-numeric, performance-based criteria. The cleanup levels shown in Tables 5-2, 5-3, and 5-4 were used to guide the selection and screening of remedial technologies and the development and detailed analysis of remedial alternatives. A discussion of the development of cleanup criteria follows.

5.6.1 Site-Specific Action Levels

Soil cleanup criteria are based on the derivation of RBCs for Site COCs. RBCs were developed for each chemical identified as a COC or "risk driver" in the risk characterization of the HHRA (Geosyntec, 2010) based on each receptor group and assuming Site-specific soil characteristics. RBCs were derived for arsenic, BaP-eq, hexavalent chromium, benzene, and naphthalene in soil (Table 5-2); benzene in soil vapor (Table 5-3); and dibenz(a,h)anthracene in groundwater (Table 5-4). The derivation of these concentrations is provided in Appendix B of the HHRA (Geosyntec, 2010). RBCs are presented for both cancer and noncancer effects; cancer effects generally produce lower RBCs. The selected SSALs, considering background concentrations, are presented in Tables 5-2 through 5-4 for each receptor group.

For arsenic in soil, the DTSC screening level of 12 milligrams per kilogram (mg/kg), which is considered background for southern California sites (Cal-EPA DTSC, 2007), was used as the SSAL for residential receptors.

For BaP-eq in soil, a concentration of 0.9 mg/kg, considered representative of background PAH concentrations in southern California soils, was used as the SSAL for residential receptors (CalEPA DTSC, 2009).

6. SUMMARY AND EVALUATION OF ALTERNATIVES

The FS, approved by DTSC on 14 July 2020, screened alternatives for remediation of the AOCs at the Site. The objectives of the FS were to identify remedial technologies available to address COCs at the AOCs, to assemble remedial alternatives, to evaluate the remedial alternatives against the nine criteria outlined in the CERCLA guidance document, and to recommend a preferred alternative.

The approach used in the FS first defined RAOs and ARARs for the AOCs at the Site, then evaluated remedial technologies for addressing the RAOs and ARARs. The remedial technologies judged inapplicable or ineffective were eliminated from further evaluation. Retained process options underwent screening to assess effectiveness, implementability, and cost. The selected methods were then assembled into four potential remedial alternatives. A detailed evaluation of these alternatives was performed using the nine criteria required by the CERCLA guidance document (USEPA, 1988). Finally, based on a comparative analysis of the remedial alternatives, the FS recommended a preferred alternative for the AOCs. The DTSC approved the FS in a letter dated 14 July 2020.

6.1 Screening of Remedial Technologies

Potentially applicable technologies for soil remediation were screened based on effectiveness, implementability, and cost. The remedial alternatives determined to be most applicable to the AOCs, including a no action alternative, are defined below.

- Alternative 1 – No action.
- Alternative 2A – Capping with selective excavation.
- Alternative 3 – Capping with selective excavation and stabilization/neutralization.
- Alternative 4 – Excavation with off-Site disposal.

6.2 Evaluation Criteria

The CERCLA guidance document explains the nine criteria are used to evaluate each remedial alternative (USEPA, 1988). The first two criteria relate directly to findings that must be made in the Record of Decision (ROD) for the Site. These are categorized as threshold criteria that a selected remedy must meet.

1. Overall Protection of Human Health and the Environment – This criterion requires evaluation of how the alternative achieves and maintains protection of human health and the environment. The overall assessment of protectiveness draws on

the assessments conducted under other evaluation criteria, especially long-term effectiveness and permanence, short-term effectiveness, and compliance with ARARs. Evaluation of the overall protectiveness of an alternative focuses on whether an alternative achieves adequate protection and describes how risks posed through each pathway are eliminated, reduced, or controlled through treatment, engineered controls or institutional controls. This evaluation also considers whether an alternative poses any unacceptable short-term or cross-media impacts.

2. Compliance with ARARs – This criterion requires an evaluation of how the alternative complies with identified ARARs and applicable advisories or guidance that are "to be considered." ARARs are generally categorized as action-specific, location-specific, or chemical-specific Federal or state-promulgated requirements. A list of potential Federal and state action-specific, location-specific, and chemical-specific ARARs have been identified for the AOCs at the Site and are included in Table 6-1.
3. Long-Term Effectiveness and Permanence – This criterion requires evaluation of the long-term effectiveness of the remedial alternative in maintaining protection of human health and the environment following implementation of the alternative.
4. Reduction of Toxicity, Mobility, and Volume Through Treatment – This criterion evaluates the anticipated performance of the treatment technologies the alternative comprises, and assesses their ability to reduce the toxicity, mobility and volume of contaminated materials through the use of treatment.
5. Short-Term Effectiveness – This criterion requires an assessment of the protection of human health and the environment during construction and implementation of the remedial alternative until RAOs are met. The following factors are addressed as appropriate for each alternative: protection of the community during remedial actions, protection of workers during remedial actions, environmental impacts, and time until remedial response objectives are achieved.
6. Implementability – This criterion requires an assessment of the technical and administrative feasibility of an alternative, including the availability of required services and materials to execute the alternative. How each alternative is impacted by the property ownership (i.e., one, large, single property or seven individual properties) will also be discussed.
7. Cost – This criterion requires evaluation of the anticipated capital costs and operation and maintenance (O&M) costs of an alternative.

8. State Acceptance – This criterion allows for consideration of preferences or apparent concerns by the DTSC.
9. Community Acceptance – This criterion allows for consideration of the community's preferences or concerns regarding remedial alternatives. DTSC formally considers the community's preferences or concerns after the FS Report and RAP are prepared.

6.3 Remedial Alternatives Considered

The four remedial alternatives developed from the retained remedial technologies are described below.

6.3.1 Alternative 1 – No Action

Alternative 1 consists of no remedial actions or institutional controls to address soils above target cleanup levels.

6.3.2 Alternative 2A – Capping with Selective Excavation

Alternative 2A consists of excavating the Haack Rework Area and a portion of sludge overflow along the eastern perimeter of the Cooper Sumps and consolidating the materials above the Cooper North and South Sumps. A cap consisting of a stabilization layer, foundation layer, low-hydraulic conductivity layer, and erosion resistance layer would be constructed above the sumps. A vapor control and monitoring system would be installed beneath the cap and around the sumps, and groundwater monitoring would continue. The northern edge of the Haack Sump cap would slope to terminate at an elevated curb adjacent to the sidewalk along Artesia Boulevard. Institutional controls consisting of a Health and Safety Plan (HASP), Construction Quality Assurance (CQA) Plan, and Risk Management Plan (RMP) would be implemented. Alternative 2A replaced Alternative 2 in the Draft FS dated February 2011. Alternative 2A is consistent with the former Alternative 2 in that capping and selective excavation of the sludge in the Haack Rework Area are evaluated. However, the cap proposed in Alternative 2A is significantly lower in overall height than the cap of former Alternative 2.

6.3.3 Alternative 3 – Capping with Selective Excavation and Stabilization/Neutralization

This alternative includes mixing the top 3 ft of sludge in the Cooper North and South Sumps with reagent to stabilize/neutralize the sludge. The Haack Rework Area and a portion of sludge overflow along the eastern Cooper Sumps would also be mixed with

the stabilized/neutralized material. A cap consisting of a foundation layer, low-hydraulic conductivity layer, and erosion resistance layer would be constructed above the Cooper North and South and Haack Sumps. A vapor control and monitoring system would be installed beneath the cap and around the sumps, and groundwater monitoring would continue. Institutional controls consisting of a HASP, CQA Plan, and RMP would be implemented.

6.3.4 Alternative 4 – Excavation with Off-Site Disposal

This alternative includes excavation of sludge with disposal off-Site. The sludge would be mixed with neutralizing agent and loaded into trucks for disposal off-Site. Major components of this alternative include concrete and asphalt removal, excavation and mixing of sludge, transportation to the disposal facility, confirmation sampling, sump backfill, and groundwater monitoring.

6.4 Alternatives Analysis and Recommended Alternative

The purpose of the evaluation of relative performance of the alternatives is to select a preferred remedial alternative that will be most suitable for the AOCs at the Site, based on the CERCLA guidance document (USEPA, 1988). In the comparative analysis and evaluation, the remedial alternatives are weighed against each of the nine criteria in the CERCLA guidance document, and comparisons between alternatives are made to assist in screening out inferior alternatives and selecting a preferred alternative. The preferred alternative becomes the alternative that meets the threshold criteria (Section 6.2, criteria 1 and 2), and best achieves a balance between the balance criteria (Section 6.2, criteria 3 through 7). The modifying criteria (Section 6.2, number 8 and 9) are used to guide DTSC to project modifications, if needed. Below is a summary of the evaluation.

6.4.1 Comparative Evaluation of the Alternatives

1. Overall Protection of Human Health and the Environment – Alternative 1, No Action, does not provide adequate protection of human health and the environment. No further assessment or comparison with this alternative is provided. Alternative 2A would perform better than Alternative 3. While Alternative 3 stabilizes/neutralizes a portion of the sludge, the mixing of the reagent releases potentially hazardous amounts of hydrogen sulfide and sulfur dioxide gas. Alternative 4 would provide very good protection of human health and the environment with the removal of the impacted materials; however, because of the risks associated with hazardous vapor generation during excavation and transportation of the material, the overall protection is deemed moderate.

2. Compliance with ARARs – Alternative 2A would perform better with respect to ARARs due to the reduction of vapor emissions when compared to Alternatives 3 and 4.

3. Long-Term Effectiveness and Permanence – Alternative 3 is ranked higher than Alternative 2A with respect to long-term effectiveness and permanence. Both alternatives would be effective and permanent over the long-term with maintenance; however, because Alternative 3 neutralizes the sludge, the treatment is likely more permanent. Alternative 4 provides the greatest long-term effectiveness and permanence since the sludge would be removed from the AOCs at the Site and disposed off-Site.

4. Reduction of Toxicity, Mobility, and Volume Through Treatment – Alternative 3 would slightly reduce toxicity and mobility through partial in-situ treatment of the source zone; however, toxicity would increase as sulfur dioxide gases are released during mixing of the sludge for treatment. Alternatives 2A and 3 would reduce mobility of the sludge by limiting infiltration and wind erosion. Alternative 4 would reduce the mobility of the sludge after off-Site disposal since the disposal landfill would be equipped with a liner system to collect leachate; however, transport of the material would temporarily increase the potential mobility.

5. Short-Term Effectiveness – Alternative 2A would perform the best with respect to short-term effectiveness. Unlike Alternatives 3 and 4, Alternative 2A does not significantly disturb the sludge, thereby minimizing the release of sulfur dioxide gas. Both Alternatives 2A and 3 incorporate a cap into the final design which would provide an immediate reduction in risk due to inhalation, dermal exposure, and ingestion. Alternative 4 would provide a reduction in risk after the sludge was transported off-Site; however, risk is temporarily increased in the short-term during sludge disturbance and transport.

6. Implementability – Alternatives 3 and 4 pose significant implementation issues due to the vapor generation during mixing and excavation of the sludge. Vapor control and treatment would be necessary during mixing and excavation of the sludge. Construction of an enclosure to contain the vapors would be difficult to perform due to low bearing capacity of the sludge to support the enclosure structure and the area the enclosure would need to span (enclosure structural support would need to be founded on native soils outside the limits of each sump, creating a need for the enclosure to span the entire width of each sump). Vapors captured by the enclosure would need treatment prior to discharge.

   Alternative 2A is relatively easy to implement. A stabilization layer on the Cooper sumps would be placed first to provide a surface on which to install the foundation

and vapor collection, barrier, and cover layers. Disturbance of the sludge would be limited to the eastern overflow and Haack Rework Area, which are significantly degraded and would release significantly less sulfur dioxide gas than the sludge in the Haack and Cooper Sumps (Appendix A, Stantec, 2008). The materials necessary for construction of Alternative 2A are available and do not require admixtures or special equipment.

7. Cost[1] – Alternative 2A has the lowest capital cost of approximately $6MM (not including Alternative 1). Alternative 3 has capital costs ranging from approximately $11MM to $13MM while Alternative 4 capital costs range from approximately $28MM to $29MM. Alternatives 2A and 3 have identical net present value O&M costs of approximately $5MM. Alternative 4 has the lowest net present value O&M cost of approximately $120K. Alternative 2A has the lowest combined remedial cost.
8. State Acceptance – In accordance with USEPA guidance, this criterion will be addressed when DTSC is making its final remedial decision and the RAP approval letter is being prepared.
9. Community Acceptance – In accordance with USEPA guidance, this criterion will be addressed when DTSC is making its final remedial decision and the RAP approval letter is being prepared.

6.4.2 FS-Recommended Alternative

Based on the comparative analysis of the remedial alternatives, the alternative that meets the RAOs and ranks the highest is Alternative 2A, capping with selective excavation with an optional cover that will eliminate the need for a retaining wall adjacent to Artesia Boulevard to accommodate the City of Gardena's request for future potential redevelopment of the AOCs at the Site as a parking lot to support future commercial operations adjacent to the remedy. This remedial alternative effectively mitigates the risk from ingestion, inhalation, and dermal contact with on-Site soils for both future non-residential and residential occupants of buildings on Site, and future landscapers and utility workers. This alternative also effectively mitigates the risk from dermal contact with Site groundwater through the cap and institutional controls including the HASP and RMP.

Alternative 2A readily meets the criteria of overall protection of human health and the environment and satisfies ARARs. When evaluated against the balancing criteria,

[1] All costs are in 2014 values consistent with the approved FS (Geosyntec, 2014).

Alternative 2A provides short-term effectiveness as well as long-term effectiveness and permanence. It is readily implementable and presents an effective balance of cost against the other criteria. Alternative 2A also would best accommodate future potential redevelopment of the Site.

In addition to the cap elements discussed in the following sections, Alternative 2A includes institutional controls. The controls include restrictions on land use as a residence, day care center for children, long-term care hospital, or a traditional public or private school for persons less than 21 years of age, without DTSC consent.

7. REMEDIATION IN THE AREAS OF CONCERN

7.1 Introduction

As presented in Section 6.4, Alternative 2A was selected in the FS as the most suitable remedial alternative for the AOCs at the Site because it meets the primary objective of protecting public health and the environment and minimizes negative impacts to the extent reasonably practical. The DTSC approved the FS in a letter dated 14 July 2020. The following sections summarize the remedy components, sequence of work activities, safety, traffic, community relations procedures, and schedule for the FS-approved remedy.

7.2 Components of the FS-Approved Remedy

The components of Alternative 2A (FS-Approved Remedy), include:

1. Degraded and soil-sludge mixture (Haack Rework Area) excavation;
2. Consolidation of excavated degraded and soil-sludge mixture materials in the AOCs;
3. Site grading for excavated areas;
4. Grading and installation of a cap (cap) over the Cooper North and Cooper South sumps, including the following layers:
    a. Stabilization layer
    b. Foundation layer
    c. Low hydraulic conductivity layer
    d. Erosion resistance layer
5. Installation of a retaining wall system along the north side of the Haack sump;
6. Installation of a vapor control and monitoring system;
7. Groundwater monitoring system; and
8. Vegetation and Site Restoration.

The Alternative 2A cap overview, including layout and feature locations relative to the AOC and Site boundaries and surrounding features is depicted on Figure 7-1. Alternative 2A cap design detail and cross section profile references are shown on Figure 7-2. East-west and north-south cross-sections of the Alternative 2A cap are shown on Figures 7-3

and 7-4, respectively. Figures 7-9 and 7-10 show the soil vapor control system and monitor probes, respectively.

7.3 Sequence of Work

The general sequence for implementing the FS-approved remedy is summarized below. A more detailed sequence of activities and design requirements will be provided during the remedial design process. Descriptions of design configurations and work sequences below are subject to change based on the remedial design process.

1. Mobilization and Setup: Mobilize equipment (excavators, loaders, trucks, water tanks, foam applicators, etc.), materials, and construction personnel. Set up office trailers, staging areas, temporary utilities, and access roads. An initial topographic survey will be performed at the AOCs prior to the start of work.
2. Vapor Monitoring and Control: Air monitoring will be conducted during excavation activities for health and safety as well as for nuisance odors. Workers will be provided personal health and safety monitoring devices such as hydrogen sulfide and sulfur dioxide indicator badges. The devices alert workers when the permissible exposure limit (PEL, 10 parts per million [ppm] and 2 ppm for hydrogen sulfide and sulfur dioxide, respectively) is nearing so workers can exit the work area or change practices. Additionally, fixed monitoring will be performed around the perimeter of the Site to minimize impacts to off-Site receptors. Odor control measures, such as foam suppressants and/or misting sprayers, will be available at the Site should it be necessary to mitigate odors. Additional details are provided in Section 7.4 below.
3. AOC Clearing and Demolition: Demolish and remove structures, pavement, vegetation, and debris remaining within the remedy construction area on the Haack and Cooper properties and demolish relevant residential structures that conflict with remedy implementation. Prior to demolition, buildings will be evaluated for the presence of lead-based paint, asbestos, and/or polychlorinated biphenyls (PCBs). Materials from clearing and demolition will be characterized and disposed of based on characterization sampling results at inert waste landfills, non-hazardous, and/or hazardous disposal facilities. Monitor wells that are not compatible with the remedial design will be abandoned according to applicable regulations.
4. Anchor Trench Excavation and Cap Stabilization Layer: Install a high-strength geotextile above the existing Cooper Sump geomembrane and anchor the perimeter of the geotextile in an anchor trench.

5. Sheet Pile Wall Installation: Sheet piles will be installed to a maximum depth corresponding to the bottom depth of the identified sludge in the Cooper North and Haack Sumps. Sheet piles will be terminated above ground surface so that sheet pile stickup can be integrated into the retaining wall required along the north edge of the Haack sump to facilitate cap construction. The sheet piles will be coated to minimize corrosion of the steel due to the low pH and high hydrogen sulfide environment. The sheet pile cut-off wall will provide a physical barrier between the sludge remaining in the Haack and Cooper North Sumps and Artesia Boulevard and adjacent sidewalk. The sheet pile wall will aid in the mitigation of lateral migration of soil vapor.

6. Installation of Vapor Collection and Control System: The Vapor Collection and Control system will be comprised of below-cap horizontal vapor collection geostrips (Item 8b), perimeter vertical vapor migration control wells, vapor treatment system, soil vapor monitor probes, and groundwater monitor wells.

    a. Vertical Vapor Migration Control Wells: A series of alternating air inlet and vapor extraction wells will be placed no more than every 80 ft along the perimeter of the cap, except where sheet piles are installed as shown on Figure 7-9. The wells would be installed to approximately 2 ft above the groundwater "A" horizon. The air inlet and vapor extracting wells act to create a "curtain" of air surrounding the sumps, minimizing the horizontal migration of vapor without extracting vapor from the sludge.

        The system of vapor migration control wells will be designed to be a passive system that, as a contingency, can be converted readily to an active system. The system will operate actively for a startup period following completion of the remedial action construction at the AOCs. Based on the concentrations of constituents detected during the startup period, the system will remain active or switch to passive operation with the option for active control in the future. The system may be converted to passive operation with written prior approval from the DTSC. The decision to make the system active again would be based upon future gas monitoring at the AOCs.

        During active vapor extraction, a vacuum will be applied to the vapor extraction wells, thus extracting vapors from these wells, which will be conveyed to a treatment system for treatment prior to discharge to the atmosphere. The location of the system is shown on Figures 7-6 and 7-9. The vacuum pressure in the vapor extraction wells imparts a vacuum on the soils surrounding each vapor extraction well. With the air inlet wells

equally spaced between the vapor extraction wells, the air inlet forces a "short-circuiting" of the flow into the vapor extraction wells. The "short circuiting" effect creates a preferential flow path between the air inlet and vapor extraction wells, thereby allowing the system to "sweep" or "flush" vapors migrating from the sludge material laterally without extracting vapors from within the sludge (Figure 7-10).

b. Vapor Treatment System: The vapor treatment system will include conveyance piping from the extraction wells, treatment pad, and treatment system. Conveyance piping will be installed in the approximate locations shown on Figures 7-6 and 7-9. The treatment system will be installed on a temporary skid and include granular activated carbon (GAC) vessels specifically formulated for treatment of hydrogen sulfide and sulfur dioxide. The temporary skid will be installed in the location shown on Figures 7-6 and 7-9.

   The vapor treatment system will be operated actively for a time period, which will be defined in a future Operation, Maintenance, and Monitoring (OMM) Plan. During initial operation, soil vapor data, including constituents extracted and their concentrations, will be collected. The need for active vapor collection will be based on the extracted soil vapor COC concentrations and associated, calculated health risk goals. If start-up data indicates COC concentrations are below risk-based trigger concentrations, and therefore, active vapor collection is not needed, the system may be converted to a passive system which vents to the atmosphere or is turned off with no venting.

   Soil vapor samples will be collected from the treatment system on a regular basis to evaluate the operation of the system and/or migration of soil vapor and to comply with South Coast Air Quality Management District (SCAQMD) permit requirements. Sample results will be compared to risk-based trigger concentrations developed with the OMM Plan for each COC.

c. Soil Vapor Monitor Probes: Multi-level soil vapor monitor probes will be placed outside of the perimeter of the cap. The monitor probes will be installed in accordance with Detail 5 on Figure 7-7 and spaced, on average, 300 ft apart to detect potential subsurface vapor migration, if any.

d. Groundwater Monitor Wells: The existing groundwater monitor well network, or some subset of the network, will be monitored at an appropriate frequency. Groundwater monitor wells may be used to

monitor for soil vapor. Details of the typical groundwater monitor well is shown as Detail 3 on Figure 7-7.

7. Sludge Excavation and Consolidation:

    a. Sludge and soil materials will be excavated from the Haack Rework Area, portions of the high strength woven geotextile anchor trench, and certain areas outside the limits of the cap as shown on Figure 7-2. The Haack Rework Area will be excavated to an elevation of approximately 20 ft amsl, as shown on Figure 7-5. Anchor trench materials and sludge located along the north east perimeter of the Cooper North Sump will be excavated to the extent sludge is found outside the limits of the anchor trench. Excavated materials will be utilized as a portion of the cap system stabilization layer and/or foundation layer.

    b. Confirmation Sampling: Post-excavation confirmation samples will be obtained from the sloped portions (side walls or slopes of excavation not covered by cap) of the Haack Rework Area once target excavation elevations have been achieved. Confirmation sampling will be performed at a frequency of one sample per 50 lineal feet of side wall or slope, with samples collected from the lower two-thirds of the side wall or slope. Confirmation sample results will be compared to risk-based cleanup goals described in Section 5.6. For locations where test results indicate concentrations in excess of cleanup goals, additional material will be excavated from side walls or slopes, 25 ft on either side of the confirmation sample exceeding cleanup goals, then either hauled and disposed of off-Site or used as cap stabilization and/or foundation material. Additional confirmation test will be performed in area of exceedance once additional materials are removed and the original sample number will be appended with an alpha code designation (e.g., sample 4 will be retested and labeled as 4A, 4B, etc., until confirmation results indicate values less than cleanup goals).

    c. Vapor suppression foams, soil, plastic sheeting, and/or spray applied cover materials will be used as necessary during the excavation and construction work to mitigate fugitive vapors and excessive odors. The use of vapor controls will be based on personnel and perimeter air monitoring devices. At the completion of excavation activities each day, a vapor suppressing foam, soil, plastic sheeting, and/or spray applied cover will be used to cover the exposed surface of the excavation and stockpiles of impacted materials from the excavation to minimize release of vapors overnight.

8. Cap System Construction:

    a. Foundation Soil: The foundation soil will be placed above the high-strength geotextile (Cooper Sumps) or asphalt/concrete surface (Haack Sump). The foundation soil will consist of excavated material from the Haack Rework Area and the anchor trench excavations. The foundation soil layer minimum thickness will be 0.5 ft (Haack Sump) and 1 ft (Cooper Sumps). Where necessary around the cap system perimeter, the foundation layer will be graded (thinned) to blend with the existing ground surface. The foundation soil will be placed in lifts until foundation grades are met (i.e., 1 ft below the cap grades shown on Figures 7-1 and 7-2). The slopes will be a minimum of 2 percent (%) to reduce impacts on drainage due to settlement of the foundation material and/or sludge.

    b. Vapor Collection Layer: Rows of vapor collection geostrips will be placed at the surface of the finished foundation layer. The geostrips will generally be 6 to 12 inches wide and up to 1 inch thick, and consist of a geosynthetic filter fabric surrounding a molded polyethylene core (US Fabrics, 2011). The molded polyethylene core provides a pathway for the vapor to travel, while the filter fabric prevents soil intrusion into the core. A polyethylene core and polypropylene geotextile, which are more resistant to acidic environments, will be required in the technical specifications. The vapor collection geocomposite will be placed above the geostrip rows and the foundation layer (Figure 7-6).

    c. Low Hydraulic Conductivity Layer: The low hydraulic conductivity layer will be placed above the foundation soil and vapor collection geostrips and geocomposite and will consist of a geosynthetic clay liner (GCL) overlain by a 60 mil high-density polyethylene (HDPE) geomembrane (Details 1-A and 1-B, Figure 7-7).

    d. Anchor Trenches: The GCL and HDPE geomembrane will be secured by an anchor trench around the perimeter of the cap. The anchor trench will vary in configuration depending on the termination condition. Along the cap perimeter, the anchor trench will consist of a v-shaped trench filled with soil and concrete to form a surface water drainage ditch (Detail 6, Figure 7-8). Along portions of the northern and western perimeter, the GCL and HDPE will be anchored with a rectangular anchor trench (Detail 7, Figure 7-8). Along the northern edge of the Haack sump, where sheet piles are located, the geosynthetic materials will be secured to the sheet piles using battens.

e. Drainage Layer: The drainage layer will overlie the low hydraulic conductivity layer and provide a means to drain surface water that percolates through the erosion resistance layer to minimize head build up on the low hydraulic conductivity layer. The drainage layer will consist of a geocomposite (geonet core bounded by nonwoven geotextile) that will daylight along the perimeter of the cap to promote drainage towards the perimeter of the cap and into surface water management features (concrete ditches).

f. Erosion Resistance Layer: The erosion resistance layer will overlie the drainage geocomposite and will consists of 1 ft of an aggregate base material (Details 1-A and 1-B, Figure 7-7). The aggregate base material will be resistant to foreseeable erosion effects caused by wind-scour, raindrop impact, and runoff prior to Site development.

g. Haack Protection Layer: At the northern-most portion of the Haack Sump, along the retaining wall and sheet pile wall alignment adjacent to Artesia Boulevard, the geosynthetics and sheet pile wall will be protected by landscaping in the form of decorative rock, artificial turf, and/or planter box-type vegetation structures. These features will also limit maintenance. If necessary, cushion geotextiles may be used above the geomembrane where geocomposite is not present to prevent damage from installed landscaping.

h. Curb Installation: Immediately adjacent to the Artesia Boulevard sidewalk, the Haack Sump and a portion of the Cooper North Sump caps will terminate at a concrete curb. The curb will deter unintended light traffic across the slope, act as a water-stop for drainage from the slope and accommodate slight variations in the existing Haack Sump concrete slab surface elevation.

9. Final Administrative Work: Establish final AOC conditions, implement monitoring and maintenance requirements: soil vapor and groundwater monitoring, and operate the vapor collection system. Implement administrative controls/restrictive covenants.

10. Groundwater Monitoring: Groundwater and soil vapor monitoring will be established and documented in the OMM Plan. The vapor mitigation system will be operated actively for a period of time defined in a future OMM Plan. During initial operation, soil vapor data, including constituents extracted and their concentrations, will be collected. The need for active vapor collection will be based on the extracted soil vapor COC concentrations and associated, calculated

health risk goals. If start-up data indicates that COC concentrations are below risk-based trigger concentrations, and therefore, active vapor collection is not needed, the system may be converted to a passive system which vents to the atmosphere.

7.4 Site Safety Procedures

7.4.1 Air Monitoring

7.4.1.1 Air Monitoring During Implementation

An Air Monitoring Plan (AMP) will be prepared prior to implementation of the remedial action. The AMP will be approved by DTSC and will include, at a minimum, the following monitoring and control measures described in the following sections.

7.4.1.2 Air Monitoring Objectives:

- Monitor COPC changes in ambient air resulting from excavation and grading of impacted Site materials.
- Identify if mitigation measures are necessary to meet SCAQMD permit conditions during excavation and grading activities.
- Monitor ambient air at Site perimeter to prevent off-Site migration during excavation and grading and provide additional control measures, as needed.

The AMP will supplement the HASP and will consider data collected during the RI. It is anticipated that potential air emissions from the Haack Rework Area excavation and grading will be low due to the significantly degraded sludge within the rework material.

Air monitoring will be performed at the working areas and up- and down-wind areas near the Site perimeter as discussed in Section 7.3 above. Wind direction and velocity will be documented during field activities with an on-Site weather station. Dust will be monitored with particulate monitors while VOCs will be monitored with photoionization detectors (PIDs). Odors, such as those indicating hydrogen sulfide or sulfur dioxide, will be monitored with personal indicator badges. Nuisance odors will be evaluated by an on-Site, trained individual. Mitigation measures, such as the use of vapor suppression foams, soil, plastic sheeting, and/or spray-applied covers, will be used as necessary.

7.4.1.3 Work Area Monitoring

Workers will wear hydrogen sulfide and sulfur dioxide indicator badges which alert workers when the PEL (10 ppm and 2 ppm for hydrogen sulfide and sulfur dioxide,

respectively) is nearing. This allows the worker to exit the work area or change practices before the PEL is reached. In addition, air monitoring will be conducted at excavation equipment and up- and down-wind of the work area using a PID to monitor for VOCs in accordance with the SCQAMD Rule 1150/1166/1466 permit. Dust monitoring will be performed downwind.

7.4.1.4 Perimeter Monitoring

Perimeter monitoring will be performed for VOCs, dust, and odors resulting from hydrogen sulfide and sulfur dioxide. If action levels are exceeded at the perimeter, response actions will be undertaken such as stopping or changing work activities, applying water for dust suppression and applying foam suppressants and/or using misting sprayers for odor suppression.

7.4.2 Mitigation of Odor

Hydrogen sulfide and sulfur dioxide are known to be emitted from the sludge when it is disturbed. Odor control measures, such as foam suppressants and/or misting sprayers, will be available at the Site should it be necessary to mitigate odors. If sludge material is staged on-Site prior to off-Site disposal, stockpiles and/or roll-off bins will be covered to minimize odor. In addition, at the completion of excavation activities each day, a vapor suppressing foam, soil, plastic sheeting, and/or spray-applied cover will be used to cover the exposed excavation and stockpiles to minimize release of vapors.

7.5 Traffic Control

Truck traffic is anticipated to be greatest during mobilization/demobilization and off-Site transportation and disposal of any Haack Rework Area sludge. A City-approved traffic plan will be developed to establish the trucking route, operating times, maximum number of trucks per day, and other requirements to reduce adverse impacts to the City of Gardena.

7.6 Worker Protection

A Project HASP will be developed which outlines the actions to protect workers during remedy implementation. The HASP will include, but not be limited to, the following:

- Health and safety-related roles and responsibilities of key personnel: Project Manager and Project Safety Officer;

- A stop-work authority requirement for all work locations and workers. The stop-work authority grants any worker the ability to stop work if an unsafe condition is identified that could cause substantial harm or imminent danger to health and safety of workers, the public, or the environment.
- Air monitoring procedures in work areas for VOCs, hydrogen sulfide, sulfur dioxide, and dust.
- Safety Data Sheets (SDSs) for chemicals that could be found in sludge and/or brought to the Site by workers.
- Identification of Site-specific safety hazards including: chemical exposure; heavy equipment; and fire, temperature, acoustic, biological, dust, and physical hazards. The process to identify and mitigate these hazards will be included.
- Safety measures when performing tasks such as excavation, backfill, sheet pile installation, and liner deployment.
- Hazard communication procedures.
- Training requirements for workers.
- Work zone designations and access control.
- Personal protective equipment (PPE) requirements for work tasks and within specific work zones.
- Medical surveillance requirements for workers.
- Decontamination procedures for workers and equipment.
- Contingency plans for spills, fires, or other emergencies.

The HASP will be reviewed and approved by the DTSC prior to implementing the remedy.

7.7 Community Relations

Residents and commercial business owners in the surrounding community will be kept informed of activities through community outreach. Community relation activities may include issuance of fact sheets and/or public meetings, if needed. Community members may ask questions and obtain information via a telephone number established for the project. The DTSC will update the DTSC EnviroStor website with project documents as they become approved.

7.8 Permit Requirements and Implementation

Several permits will be required to implement the Site remedy. Anticipated permits include:

- Grading permit,
- SCAQMD Rule 1150/1166/1466/403 permits,
- Encroachment permits,
- Traffic permit,
- State Water Resources Control Board (SWRCB) Construction General Permit (CGP), and
- SCAQMD permit to operate vapor treatment system.

7.9 Implementation Schedule

The duration for implementation of the remedy is estimated to be approximately six months. This time frame does not include the final remedial design or contracting and permitting. The remedial design, contracting, and permitting are anticipated to be completed approximately one year after approval of the CEQA findings and all documentation related to implementation of this RAP.

7.10 Reporting

During implementation of the remedy, DTSC will be kept appraised of progress with routine progress reports. The frequency of these reports will be determined during the design phase.

Upon completion of the remedy, a report will be prepared documenting the remedial activities. The report will include, at a minimum, a description of the work conducted, as-built drawings of the cap and vapor collection and control system, any analytical data collected during implementation, copies of all permits obtained for implementation of the remedy, waste manifests for any material disposed of off-Site, and certification by a licensed professional that the cap was installed in accordance with all applicable regulations.

7.11 Site Redevelopment

Redevelopment plans for the Site have been proposed by a developer but have not yet been approved nor has the developer purchased the property at this point. ARC has provided a copy of the RAP to the developer and has engaged them in conversation regarding the nature of their development and how it would fit with the selected remedy. The redevelopment plans are generally consistent with the remedy presented in this RAP. To the extent that the redevelopment plans are approved in such a manner so as to be consistent with the remedy, ARC will coordinate with the developer, as necessary, to carry out redevelopment at the Site to the extent practical and appropriate.

TABLE 5-1
CONSTITUENTS OF POTENTIAL CONCERN
Gardena Sumps, Gardena, California

Geosyntec consultants

Soil		
1,1,1,2-Tetrachloroethane	Chlorobenzene	Methylene chloride
1,2,3-Trichlorobenzene	Chloroethane	Molybdenum
1,2,4-Trimethylbenzene	Chromium	Naphthalene
1,3,5-Trimethylbenzene	Chromium VI	n-Butylbenzene
1,3-Dichlorobenzene	Chrysene	Nickel
Acenaphthene	Cobalt	n-Propylbenzene
Acenaphthylene	Copper	Oil range organics (C29-C40)
Aluminum	Dibenz(a,h)anthracene	o-Xylene
Anthracene	Dibromochloromethane	Phenanthrene
Antimony	Diethyl phthalate	p-Isopropyltoluene
Arsenic	Diesel range organics (C13 - C28)	Pyrene
Barium	Extractable fuel hydrocarbons (C10 - C40)	sec-Butylbenzene
Benzene	Extractable fuel hydrocarbons (C13 - C40)	sec-Butylbenzene
Benzo(a)anthracene	Extractable fuel hydrocarbons (C8 - C40)	Selenium
Benzo(a)pyrene	Ethylbenzene	Silver
Benzo(b)fluoranthene	Fluoranthene	Styrene
Benzo(g,h,i)perylene	Fluorene	tert-Butylbenzene
Benzo(k)fluoranthene	Gasoline range organics (C4 - C12)	Thallium
Benzoic acid	Indeno(1,2,3-cd)pyrene	Toluene
Beryllium	Iron	trans-1,3-Dichloropropene
Bis(2-ethylhexyl)phthalate	Isopropylbenzene	Vanadium
Bromobenzene	Lead	Volatile fuel hydrocarbons (C4-C12)
Butyl benzyl phthalate	m,p-Xylenes	Zinc
Cadmium	Mercury	
Soil Gas		
1,1-Difluoroethane (LCC)	Chloroethane	
1,2,4-Trimethylbenzene	Chloroform	
1,2-Dichloro-1,1,2,2-tetrafluoroethane	Chloromethane	
1,2-Dichloroethane	Cyclohexane	
1,3,5-Trimethylbenzene	Dichlorodifluoromethane	
1,3-Butadiene	Ethylbenzene	
1,4-Dioxane	Freon 113	
2,2,4-Trimethylpentane (Isoctane)	Heptane	
2-Butanone	Hexane	
4-Ethyltoluene	m,p-Xylene	
4-Methyl-2-pentanone	Methylene chloride	
Acetone	Naphthalene	
Benzene	o-Xylene	
Bromodichloromethane	Propylene	
Bromoform	Styrene	
Carbon disulfide	Tetrachloroethene	
Carbon tetrachloride	Toluene	
Chlorobenzene	Trichloroethene	
Chloroethane	Trichlorofluoromethane

1,2,4-Trimethylbenzene	Chloride	Mercury
1,2-Dichlorobenzene	Chloroethane	Methylene chloride
1,2-Diphenylhydrazine/Azobenzene	Chloromethane	Molybdenum
1,3,5-Trimethylbenzene	Chromium	Naphthalene
1,4-Dichlorobenzene	Chromium VI	Nickel
2,4-Dimethylphenol	Chrysene	Nitrate-N
2-Methylnaphthalene	Cobalt	Oil range organics (C29-C40)
2-Methylphenol	Copper	o-Xylene
Acenaphthylene	Dibenz(a,h)anthracene	Phenanthrene
Antimony	Diethyl phthalate	Phenol
Arsenic	Di-n-butyl phthalate	Potassium
Barium	Di-n-octyl phthalate	Pyrene
Benzene	Diesel range organics (C13 - C28)	Selenium
Benzo(a)anthracene	Extractable fuel hydrocarbons (C13 - C40)	Silver
Benzo(b)fluoranthene	Ethylbenzene	Sodium
Benzo(g,h,i)perylene	Fluorene	Sulfate
Benzo(k)fluoranthene	Gasoline range organics (C4 - C12)	Sulfide
Benzoic acid	Indeno(1,2,3-cd)pyrene	Thallium
Benzyl alcohol	Iron	Toluene
Beryllium	Isophorone	Vanadium
Bis(2-ethylhexyl)phthalate	Lead	Xylenes, total
Butyl benzyl phthalate	m,p-Xylenes	Zinc
Cadmium	Magnesium	
Calcium	Manganese	

TABLE 5-2
SUMMARY OF SITE-SPECIFIC ACTION LEVELS FOR SOIL
Gardena Sumps, Gardena, California

Geosyntec consultants

Chemicals of Concern	Site-Specific Action Levels for Soil (mg/kg)											
	Commercial/Industrial			Construction			Residential			Trespasser		
	Site-Specific RBCnc	Site-Specific RBCc	Selected SSAL	Site-Specific RBCnc	Site-Specific RBCc	Selected SSAL	Site-Specific RBCnc	Site-Specific RBCc	Selected SSAL	Site-Specific RBCnc	Site-Specific RBCc	Selected SSAL
Inorganics												
Arsenic	2.7E+02	1.7E+01	1.7E+01	6.2E+01	1.2E+02	6.2E+01	2.2E+01	3.9E-01	1.2E+01[(1)]	3.8E+03	8.5E+01	8.5E+01
Chromium VI	3.0E+03	5.4E+01	5.4E+01	6.1E+02	7.3E+01	7.3E+01	2.3E+02	1.2E+00	1.2E+00	4.9E+04	3.2E+02	3.2E+02
Polyaromatic Hydrocarbons												
Benzo(a)pyrene	2.0E+04	1.6E+00	1.6E+00	5.5E+03	1.1E+01	1.1E+01	1.7E+03	3.7E-02	9.0E-01[(2)]	2.2E+05	6.2E+00	6.2E+00
Volatile Organic Compounds												
Benzene	6.7E+02	2.4E+01	2.4E+01	1.6E+02	1.4E+02	1.4E+02	1.2E+02	4.8E-01	4.8E-01	1.4E+04	1.8E+02	1.8E+02
Naphthalene	8.5E+02	2.5E+02	2.5E+02	1.9E+02	1.4E+03	1.9E+02	1.8E+02	4.9E+00	4.9E+00	1.8E+04	1.9E+03	1.9E+03

Notes:

BaP-eq: benzo(a)pyrene toxicity equivalent

mg/kg: milligram per kilogram

RBCc: risk-based concentration based on cancer effects

RBCnc: risk-based concentration based on noncancer effects

SSAL: site-specific action level

Selected SSALs are the lowest between RBCc and RBCnc, or the background concentration for chemicals in which the RBCs were below background (e.g., arsenic and BaP-eq for the residential scenario).

(1) For arsenic, the DTSC screening level of 12 mg/kg (Cal-EPA DTSC, 2007), considered representative of background in southern California soils, was selected as the SSAL.

(2) For benzo(a)pyrene, a concentration of 0.9 mg/kg, considered representative of background PAH concentrations in southern California soils, was selected as the SSAL.

TABLE 5-3

SUMMARY OF SITE-SPECIFIC ACTION LEVELS FOR SOIL VAPOR

Gardena Sumps, Gardena, California

Geosyntec consultants

Chemical of Concern	Site-Specific Action Levels for Soil Gas (µg/L)					
	Commercial/Industrial			Residential		
	Site-Specific RBCnc	Site-Specific RBCc	Selected SSAL	Site-Specific RBCnc	Site-Specific RBCc	Selected SSAL
Benzene						
5 ft bgs	3.2E+02	1.0E+01	1.0E+01	3.8E+01	1.0E-01	1.0E-01
10 ft bgs	5.5E+02	1.8E+01	1.8E+01	6.5E+01	1.8E-01	1.8E-01
12 ft bgs	6.4E+02	2.1E+01	2.1E+01	7.6E+01	2.1E-01	2.1E-01
15 ft bgs	7.8E+02	2.5E+01	2.5E+01	9.3E+01	2.5E-01	2.5E-01

Notes:

Soil gas to indoor air pathway

ft bgs: feet below ground surface

RBCc: risk-based concentration based on cancer effects

RBCnc: risk-based concentration based on noncancer effects

SSAL: site-specific action level

µg/L: micrograms per liter

Selected RBCs are the lowest between RBCc and RBCnc

Soil gas RBCs were derived using default soil properties for soil type loam in the model

Values revised per response to comments package dated 4/4/12

TABLE 5-4

SUMMARY OF SITE-SPECIFIC ACTION LEVELS FOR GROUNDWATER

Gardena Sumps, Gardena, California

Geosyntec consultants

Chemical of Concern	Site-Specific Action Levels for Groundwater (µg/L)		
	Construction		
	Site-Specific RBCnc	Site-Specific RBCc	Selected SSAL
Polyaromatic Hydrocarbons			
Dibenz[a,h]anthracene	--	2.0E+00	2.0E+00

Notes:

" -- " not applicable

RBCc: risk-based concentration based on cancer effects

RBCnc: risk-based concentration based on noncancer effects

SSAL: site-specific action level

µg/L: micrograms per liter

Selected SSAL is the lowest between RBCc and RBCnc

TABLE 6-1
APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS
Gardena Sumps, Gardena, California

Geosyntec consultants

Requirement	Prerequisites	Citation	ARAR Determination (A, RA, or TBC)	Comments
CHEMICAL-SPECIFIC APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS				
Clean Air Act (42 USC 7401-7671) Regulated by the SCAQMD				
Primary and secondary national standards for ambient air quality to protect public health and welfare (including standards for particulate matter and lead)	Air contamination affecting public health and welfare	40 CFR 50.4-50.12	A	SCQAMD standards from State Implementation Plan and California Air Resources Board are more restrictive
Resources Conservation and Recovery Act (42 USC 6901-6991[i]) Regulated by the CalEPA, DTSC				
Defines RCRA hazardous waste; a solid waste is toxic, based on the TCLP, if the waste exceeds the TCLP maximum concentrations	Waste	22 CCR 66261.21-66261.24, 66261.100	A	Applicable for material disposed of off-Site
Definition of "non-RCRA hazardous waste"	Waste	22 CCR 66261.22, 66261.24, 66261.101, 66261.3	A	Applicable for determining whether a waste is non-RCRA hazardous waste
Safe Drinking Water Act (42 USC 300(f-j) - 26) Regulated by the SWRCB				
MCLs for organic and inorganic chemicals of concern in drinking water.	Public water system	40 CFR 141.61 (a,b), 141.62(b), & 141.11	RA	Leachate from the sumps may impact groundwater that has a designated beneficial use as municipal water. The Lynwood, Silverado, Gardena, and Gage aquifers have designated domestic water supply use.
Non-zero MCLGs for organic and inorganic chemicals of concern in drinking water	Public water system	40 CFR 141.50 & 141.51	RA	Leachate from the sumps may impact groundwater that has a designated beneficial use as municipal water. The Lynwood, Silverado, Gardena, and Gage aquifers have designated domestic water supply use.
California Safe Drinking Water and Toxic Enforcement Act (California Health and Safety Code 25249.5 - 25249.13) Regulated by the SWRCB				
Primary MCLs for inorganic chemicals of concern in drinking water	Drinking water source	22 CCR 64431 and 64449	RA	Leachate from the sumps may impact groundwater that has a designated beneficial use as municipal water. The Lynwood, Silverado, Gardena, and Gage aquifers have designated domestic water supply use.
Public health goals for inorganic chemicals in drinking water	Drinking water source	Health and Safety Code 116365	TBC	Guidelines established by the Office of Environmental Health Hazard assessment based on health considerations; HHRA was performed with Site-specific conditions and acceptable risk was identified
LOCATION-SPECIFIC APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS				
No location-specific ARARs were identified for the Gardena Sumps Site; the Site is not located in a sensitive or protected area	----	----	----	----
ACTION-SPECIFIC APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS				
Porter-Cologne Water Quality Control Act (California Water Code, Division 7) Regulated by the SWRCB				
Any activity that could affect water quality must not result in water quality parameters exceeding appropriate beneficial use water quality objectives	Contaminants affecting waters of the state	Los Angeles Basin Water Quality Control Plan	A	Groundwater protection standards are set at levels consistent with identified beneficial use for the area
State antidegradation policy applicable to both surface and groundwater requiring that discharges to waters of the state be regulated to achieve the "highest water quality consistent with maximum benefit to the people of the State"	Contaminants affecting waters of the state	Los Angeles Basin Water Quality Control Plan	A	Groundwater protection standards are set at levels consistent with identified beneficial use for the area
Requires that quality of the waters of the state that is better than needed to protect all beneficial uses be maintained unless certain findings are made. Discharges to high-quality waters must be treated using best practicable treatment or control necessary to prevent pollution or nuisance and to maintain the highest quality water. Requires cleanup to background water quality or to lowest concentrations technically and economically feasible to achieve. Beneficial uses must, at least, be protected.	Contaminants affecting waters of the state	SWRCB Res. 68-16	A	Groundwater protection standards are set at levels consistent with identified beneficial use for the area

TABLE 6-1
APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS
Gardena Sumps, Gardena, California

Geosyntec consultants

Requirement	Prerequisites	Citation	ARAR Determination (A, RA, or TBC)	Comments
California Hazardous Waste Control Laws Regulated by the Cal EPA, DTSC				
Person who generates waste shall determine if that waste is hazardous waste	Waste	22 CCR 66262.10 & 66262.11	A	Materials in sumps are hazardous in certain areas; hydrogen sulfide emissions in excess of 500 ppm_v are also hazardous
Owners and operators of a RCRA surface impoundment, waste pile, land treatment unit, or landfill shall conduct a monitoring and response program for each regulated unit	Unit which has waste which may pose a threat to human health or the environment	22 CCR 66264.91	A	A monitoring and response program will be prepared as part of the final remedial design
Requirements for monitoring groundwater, surface water, and the vadose zone	Hazardous waste unit	22 CCR 66264.97	A	Requirements will be determined as part of the final remedial design
Design and construction requirements for the foundation, earth-barrier, and vegetation-support layers of the final cover	Discharge of hazardous waste to land after 7/18/97 for treatment, storage, or disposal	22 CCR 66264.228	A	General design elements included in this RAP; final design and construction requirements will be determined as part of the final remedial design
Requires that hazardous wastes be covered by a low-permeability cover of specific properties. The cover will prevent the downward entry of water to the closed unit for at least 100 years. Provides for post-closure care and maintenance of the cover and related components. Toxic or flammable gas or vapor must be controlled for as long as it is emitted from the Site.	Discharge of hazardous waste to land after 7/18/97 for treatment, storage, or disposal	22 CCR 66264.310	A	General design elements included in this RAP; final design and construction requirements will be determined as part of the final remedial design
Solid Waste Disposal Regulatory Reform Act Regulated by the SWRCB and CalRecycle				
Waste dischargers are responsible for accurate characterization of waste; defines designated nonhazardous solid waste and inert waste	Discharge of nonhazardous waste to land after 7/18/97 for treatment, storage, or disposal	27 CCR 20220 (b,c,d) and 20230 (b)	A	----
Requires detection monitoring; once a significant release has occurred, evaluation or corrective action monitoring is required	Discharge of water to land after 7.18.1997	27 CCR 20385 (a) (1) and (2)	A	Water quality monitoring required for closed units, unless they are clean-closed
Defines water quality protection standards that apply during closure and post-closure maintenance periods	Discharge of water to land after 7.18.1997	27 CCR 20390, 20395, and 20400	A	Water quality protection standards in WDRs must be met as demonstrated in detection monitoring program
Establishes requirements for gas monitoring and controls as related to closure and post-closure of units	Discharge of water to land after 7.18.1997	27 CCR 20921 to 20937	A	Gas monitoring required for closed units
Defines point of compliance as hydraulically downgradient from the unit and requires soil, surface water, and groundwater monitoring with RAOs for 3 years after cleanup	Discharge of water to land after 7.18.1997	27 CCR 20405, 20410, and 20415	A	WDRs will specify monitoring locations
Closure and postclosure maintenance submittal requirement showing that the unit will meet performance standards and will comply with waste containment and precipitation and drainage control	Discharge of water to land after 7.18.1997	27 CCR 20950	A	Relevant to Site closure
Requirements for final cover slopes, foundation layer, low-hydraulic conductivity layer, and erosion-resistance layer and mandates cover maintenance plan and annual cost estimates	Discharge of water to land after 7.18.1997	27 CCR 21090	A	Relevant to Site closure
Requires access control, site protection, and signage during closure and postclosure	Discharge of water to land after 7.18.1997	27 CCR 21135	A	Relevant to Site closure
Sets design criteria for final covers of units	Discharge of water to land after 7.18.1997	27 CCR 21140	A	Relevant to Site closure
Requires monitoring and analysis of differential settlement during the postclosure period	Discharge of water to land after 7.18.1997	27 CCR 21142	A	Relevant to Site closure
Requires minimum of 1.5 factor of safety for static and seismic stability of final unit face	Discharge of water to land after 7.18.1997	27 CCR 21145 and 21750	A	Relevant to Site closure
Requires postclosure maintenance of final cover and control systems for no less than 30 years	Discharge of water to land after 7.18.1997	26 CCR 21180	A	Relevant to Site closure
Requires that postclosure land uses shall protect public health and safety, prevent damage to the unit, and prevent public contact with waste	Discharge of water to land after 7.18.1997	26 CCR 221190 (a)	A	Relevant to Site closure

TABLE 6-1
APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS
Gardena Sumps, Gardena, California

Geosyntec consultants

Requirement	Prerequisites	Citation	ARAR Determination (A, RA, or TBC)	Comments
Clean Air Act (42 USC 7401-7671) Regulated by the SCAQMD				
Limits visible emissions from a single source	Air emissions	SCAQMD Rule 401	A	Applicable for construction activities
Prohibits discharge of materials that cause injury, detriment, nuisance, or annoyance to the public; endanger the comfort, repose, health, or safety of the public; or cause or have tendency to cause injury or damage to business or property	Air emissions	SCAQMD Rule 402	A	Applicable for construction activities
Shall not cause or allow emissions of fugitive dust such that the presence of dust remains visible in the atmosphere beyond the property line of the emission source and shall not allow PM10 levels to exceed 50 mg/m^3	Generation of fugitive dust	SCAQMD Rule 403	A	Applicable for construction activities
Prohibits discharge into the atmosphere of particulate matter in excess of specified	Generation of particulates	SCAQMD Rule 404	A	Applicable for construction activities
Limits equipment from discharging particulate emissions in excess of 0.99 to 30 lbs/hr, based on a given process weight	Generation of particulates	SCAQMD Rule 405	A	Applicable for construction activities
Limits carbon monoxide and sulfur dioxide from any equipment other than that used for mobile equipment propulsion or stationary equipment engines	Air contaminant sources except mobile equipment or stationary engines	SCAQMD Rule 407	A	Applicable for construction activities
Prohibits building or using equipment which reduces or conceals an emission otherwise constituting a violation	Air emissions	SCAQMD Rule 408	A	Applicable for construction activities
Limits particulate emissions from the exhaust of a combustion source (other than an internal combustion engine) to 0.23 g/m^3 at 12% carbon dioxide averaged over 15 minutes	Combustion sources except internal combustion engines	SCAQMD Rule 409	A	Applicable for construction activities
Limits emissions of sulfur compounds from gaseous fuels to no more than 40 ppm, 0.05 percent by weight (liquid fuels), and 0.56 pounds of sulfur per million BTUs (solid fossil fuels)	Combustion sources using liquid or solid fossil fuels	SCAQMD Rules 431.1, 431.2, 431.3	A	Applicable for construction activities
Limits concentrations of oxides of nitrogen from any non-mobile sources fuel-burning equipment, averaged over 15-minutes, to a range of 125 to 300 ppm (gaseous fuels) and 225 to 400 ppm depending on equipment size	Non-mobile equipment using gaseous, liquid, or solid fuels	SCAQMD Rule 474	A	Applicable for construction activities
Specifies emissions testing, monitoring procedures, or handling or hazardous pollutants such as beryllium, benzene, mercury, vinyl chloride, and asbestos	Hazardous air pollution	SCAQMD Reg. X NESHAPS	A	Applicable for construction activities
Sets emissions standards for nitrous oxides, volatile organic compounds, and carbon monoxide from gaseous and liquid fuels portable engines	Portable engines used on construction site	SCAQMD Rule 1110-2	A	Applicable for construction activities
Requires person excavating a landfill to identify mitigation measures to ensure that a public nuisance does not occur	Excavation of inactive landfill	SCAQMD Rule 1150	A	Applicable for construction activities
Limits volatile organic compound emissions from contaminated soil to less than 50 ppm; for higher emissions an approved mitigation plan, describing removal methods and mitigations measures must be obtained	Volatile organic compounds in soil being excavated	SCAQMD Rule 1166	A	Applicable for construction activities
All new sources of air pollution that may result in a net emission increase of any non-attainment air contaminant or any halogenated hydrocarbon are to employ Best Available Control Technology; limits emissions of non-methane organic compounds to less than 1 lb/day	Non-attainment contaminant or halogenated hydrocarbon	SCAQMD Rule 1303	A	Applicable for construction activities
Requires equipment to be constructed with Best Available Control Technology; non-attainment emission increases must be offset and substantiated with modeling that the equipment will not significantly increase concentrations of nonattainment emissions.	New/modified equipment which may cause issuance of a non-attainment contaminant	SCAQMD Reg XII New Source Review	A	Applicable for construction activities
Defines health risk assessment methodology; exempts nonmethane organic compounds from controls if the health risk is less than 1 in 1 million	nonmethane organic compounds	SCAQMD Rule 1401	A	----

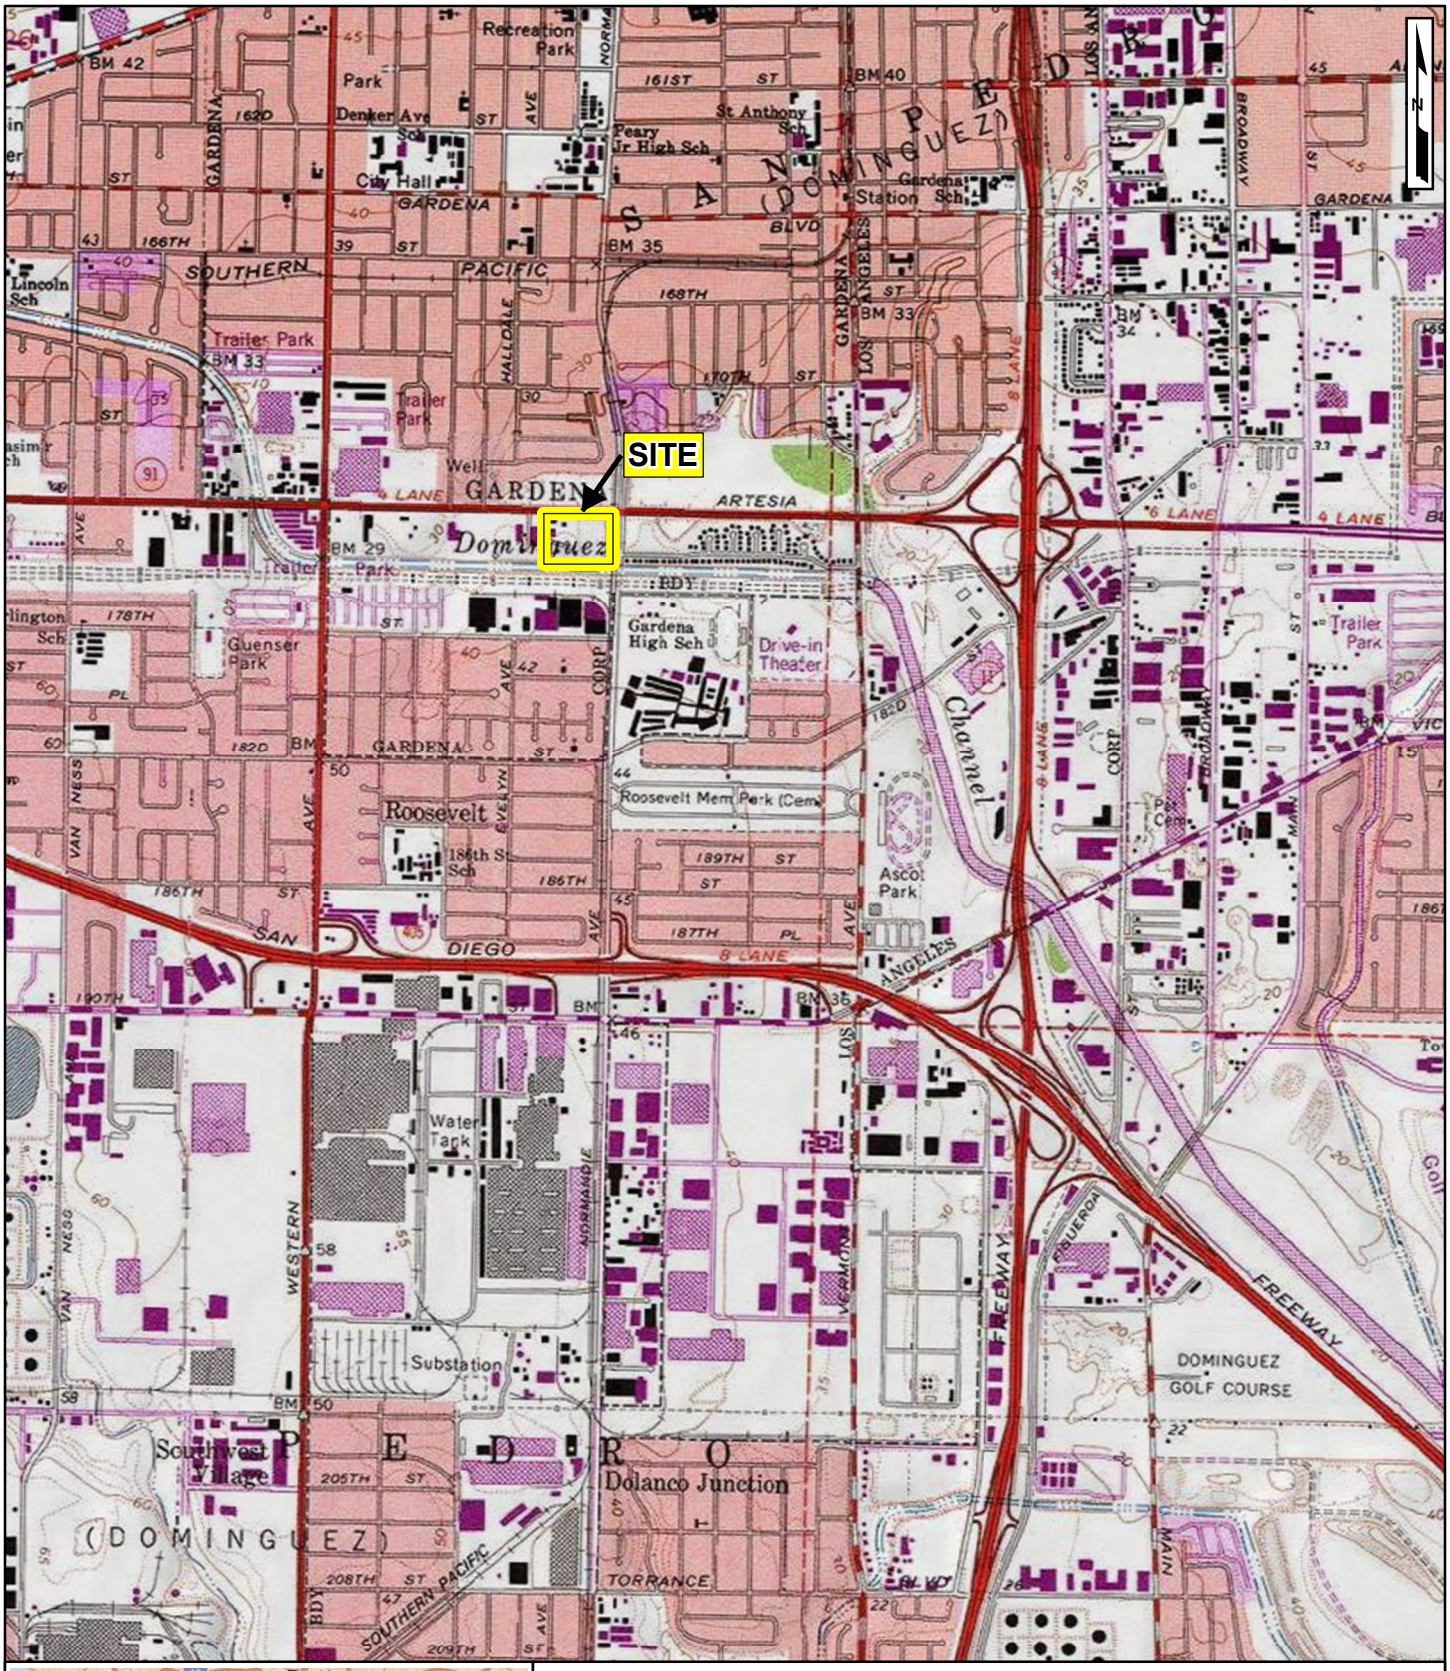
TABLE 6-1
APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS
Gardena Sumps, Gardena, California

Geosyntec consultants

Requirement	Prerequisites	Citation	ARAR Determination (A, RA, or TBC)	Comments
Clean Water Act (33 USC 1251-1387) and Porter-Cologne Water Quality Control Act (California Water Code, Division 7) Regulated by the SWCRB and Los Angeles RWQCB				
Waste Management Units undergoing final closure, with 1 acre of disturbance or more, must comply with substantive requirements for eliminating most non-stormwater discharges, developing and implementing a stormwater pollution prevention plan, and monitoring stormwater discharges	Construction activity on site larger than 1 acre	SWRCB Order 99-08-DWQ; SWRCB Res. 2001-046	A	Site exceeds 1 acre
Requires incorporation of permanent Best Management Practices to control stormwater runoff pollution after completion of the project; requires monitoring, sampling, and analysis of stormwater discharges under specified circumstances	Long-term operation and maintenance of site	SWRCB Order R8-2002-0012	A	Stormwater pollution controls required for long-term maintenance
Miscellaneous State Provisions for Institutional Controls				
Provides conditions under which land-use restrictions apply to successive owners of land	Transfer site to new owner	Ca. Civil Code 1471	A	Institutional controls apply to future Site use
Prohibits certain uses of land containing hazardous waste without a specific variance	Hazardous waste property	California Health and Safety Code 25232 (b)(1)(A-E)	A	Institutional controls that will contain appropriate restrictive covenants to be finalized during the final remedial design
OSWER Directive – Air Stripper Control Guidance (9355.8-28)				
Guidance regarding the use of emission controls at CERCLA sites; will be used to develop air emissions controls if necessary	----	----	----	----
Air Toxic "Hot Spot" Act (California Health and Safety Code § 44300 et seq.) as implemented by the SCAQMD and overseen by the Air Resources Board under CCR, Title 17, Section 93300 et seq.				
This statute and its regulations require operators of regulated facilities to prepare and submit inventory emission plans and reports and, in some cases, the preparation of health risk assessments. Only applicable if facility uses or releases a "listed" substance and releases more than 25 tons/year of total organic gases, particulate matter, nitrogen oxides or sulfur oxides.	----	----	TBC	The risk assessment required under the "Hot Spot" Act is more stringent than that performed under the FS because the FS risk assessment calculated risks due to exposure to soil and groundwater at the Site, not risks attributable to treatment processes from the remedial alternatives.

NOTES:

A - Applicable requirement (cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under Federal or State environmental or facility citing laws that specifically address a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance found at a CERCLA site)



RA - Relevant and appropriate requirement (cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under Federal environmental or State environmental or facility siting laws that, while not applicable to a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance at a CERCLA site, address problems or situations sufficiently similar to those encountered at the CERCLA site that their use is well suited to the particular site)

TBC - To be considered (Federal and State nonpromulgated standards, policies, or guidance documents and local requirements)

NA - Not applicable

ARAR - Applicable or Relevant and Appropriate Requirement
BTU - British Thermal Unit
CalEPA - California Environmental Protection Agency
CCR - California Code of Regulations
CERCLA - Comprehensive Environmental Response, Compensation, and Liability Act
CFR - Code of Federal Regulations
DTSC - California Department of Toxic Substances Control
DWQ - Division of Water Quality
EPA - Environmental Protection Agency
FS - Feasibility Study
g/m^3 - grams per cubic meter
HHRA - Human Health Risk Assessment
lb/day - pound per day
lbs/hr - pounds per hour
mg/m^3 - milligrams per cubic meter
MCL - Maximum contaminant level
MCLG - Maximum contaminant level goal
OSWER - Office of Solid Waste and Emergency Response
PM10 - Particulate Matter with diameters generally 10 micrometers and smaller
ppm - parts per million
ppm_v - parts per million by volume
RAO - Remedial Action Objective
RAP - Remedial Action Plan
RCRA - Resources Conservation and Recovery Act
RWQCB - Regional Water Quality Control Board
SCAQMD - South Coast Air Quality Management District
SWRCB - California State Water Resources Control Board
TCLP - Toxic characteristic leaching procedure
USC - United States Code
WDR - Waste Discharge Requirement

APPENDIX A

Administrative Record (Reserved for Final Remedial Action Plan)

APPENDIX B

Statement of Reasons (Reserved for Final Remedial Action Plan)

STATEMENT OF REASONS

FOR [SITE NAME]

REMEDIAL ACTION PLAN

Pursuant to California Health and Safety Code (HSC), section 25356.1(d), the California Environmental Protection Agency (Cal/EPA), Department of Toxic Substances Control (DTSC) has prepared this Statement of Reasons as part of the attached Remedial Action Plan (RAP) for the [site name] at [site address: street, city, county and State].

The RAP presents a summary of the Remedial Investigation (RI) to address [list types of chemicals contaminants, compounds found] that have been detected in [list media, e.g. soil, groundwater, surface water] at and near the [site name]. The RAP summarizes the results of a Baseline Risk Assessment performed to determine the potential risks to public health and the environment associated with the [list types of chemical contaminants, compounds found]. The RAP also provides a discussion of the feasible remedial alternatives that were evaluated in the Feasibility Study (FS). The RAP recommends a remedial alternative that will meet the objectives of protecting public health and the environment. The RAP proposes remediation of [list media to be cleaned up] by [describe proposed remedial measures].

The DTSC believes that the attached RAP complies with the law as specified in California Health and Safety Code, section 25356.1. Section 25356.1(e) requires that RAPs "shall include a statement of reasons setting forth the basis for the removal and remedial actions selected." The statement of reasons "shall also include an evaluation of the consistency of the removal and remedial actions proposed by the plan with the federal regulations and factors specified in subdivision (d)..." Subdivision (d) specifies six factors against which the remedial alternatives in the RAP must be evaluated. The proposed remedial action is consistent with the National Oil and Hazardous Substances Pollution Contingency Plan (the National Contingency Plan, "NCP"), the federal Superfund regulations. The attached RAP has addressed all these factors in detail. A brief summary of each factor follows. The statement of reasons also includes the preliminary Nonbinding Allocation of Responsibility (NBAR) as required by HSC section 25356.1(e).

1. Health and Safety Risks - Section 25356.1(d)(1)

   The chemicals of concern identified for this site are [list chemicals of concern by media].

The risk assessment evaluated potential exposures for [list scenarios considered, e.g., residential, worker, etc.]. [Discuss those pathways which represent a possible health risk].

2. Beneficial Uses of the Site Resources - Section 25356.1(d)(2)

   [Discuss beneficial uses of surface water, groundwater, land].

3. Effect of the Remedial Actions on Groundwater Resources

   Available technologies were evaluated to meet remedial action objectives for soil and groundwater. A variety of scientific engineering approaches and technologies were considered. [For sites with soil and groundwater problems, it may be appropriate to say: "The primary remedial action objectives are to reduce chemical concentrations in groundwater, limit the migration of chemicals from the soil into groundwater, and restrict further downgradient movement of contaminated groundwater."] [Describe beneficial uses of groundwater]. The proposed remedial alternative will result in [describe impact on groundwater].

4. Site-Specific Characteristics - Section 25356.1(d)(4)

   Chemicals in soil and groundwater beneath the site have been extensively characterized. [Describe the following: 1) Potential for offsite migration; 2) Commingling, if present, with other contamination; and 3) Site-specific soil/hydrogeological conditions which may affect contaminant movement].

5. Cost-Effectiveness of Alternative Remedial Action Measures - Section 25356.1(d)(5)

   The proposed remedial action alternative [describe alternative] was the most cost-effective alternative to meet the cleanup objectives.

6. Potential Environmental Impacts of Remedial Actions – Section 25356.1(d)(6)

   All potential impacts will be mitigated under the proposed remedial alternative. The proposed remedial alternative will not create any significant environmental impacts. Because of this, a Negative Declaration was proposed pursuant to the California Environmental Quality Act (CEQA) for the recommended remedial alternative. An Environmental Study Checklist was completed for the [site name] which discussed potential environmental impacts of the recommended remedial alternative, as well as actions that will be taken to reduce or eliminate these potential environmental impacts during implementation. The CEQA Environmental Study Checklist and proposed Negative Declaration are being distributed (under separate cover) for a 30-day public comment period. [For the

Final RAP, revise the last sentence to indicate that CEQA documents were distributed]

7. Preliminary Nonbinding Allocation of Financial Responsibility - Section 25356.1(e)

   The RAP must include a "nonbinding preliminary allocation of responsibility (NBAR) among all identifiable potentially responsible parties at a particular site, including those parties which may have been released, or may otherwise be immune, from liability..." (HSC section 25356.1(e)). The current NBAR for the [site name], as issued by the DTSC, is presented on the next page. [The NBAR should be printed on DTSC letterhead]

Re: Response to DTSC's Review Comments to Draft Remedial Action Work Plan for the Gardena Sumps, 1450 W. Artesia Blvd., Gardena, California 90248 (Site Code: 19490135)

Dear Mr. Ta,

On behalf of Atlantic Richfield Company (ARC), Geosyntec Consultants, Inc. (Geosyntec) has prepared these responses to the Department of Toxic Substances Control (DTSC) comments dated 31 March 2021 on the draft Remedial Action Plan (draft RAP) dated 18 January 2021. DTSC's comments on the draft RAP include comments from DTSC's Engineering and Special Projects Office (ESPO). A teleconference call to discuss the comments was held between ARC, DTSC, and Geosyntec representatives on 20 April 2021.

Responses are provided for each DTSC comment and DTSC comments are numbered and provided in italics. A revised RAP will be submitted to DTSC upon receipt of DTSC concurrence with the responses.

We appreciate the opportunity to work with you and the DTSC on this matter and we look forward to your response. If you have any questions, please do not hesitate to contact Lisa Hall at (909) 259-9130 or lhall@geosyntec.com.

Sincerely,

Jonathan H. Gillen

DTSC REVIEW COMMENTS – DRAFT REMEDIAL ACTION PLAN FOR THE GARDENA SUMPS SITE

DTSC Comment (italics):

1. *The following background is composed of adapted excerpts from the Executive Summary and Introduction of the Draft RAP.*

   "Gardena Sumps Site (Site) is located at the southwest corner of Artesia Boulevard and Normandie Avenue in Gardena, California. This RAP addresses the Cooper North sump, Cooper South sump, Haack sump, and Haack Rework Area on the Site. The Cooper sumps currently are capped by a geosynthetic material that was installed in July 1993. An additional geosynthetic liner was placed over the 1993 liner in August 2013. The Haack Sump has been covered by asphalt and a concrete slab."

   A description of the surface of the Haack Rework Area was not readily apparent in the Draft RAP to the ESPO reviewer.

Response:

The Executive Summary will be updated to include the following description of the Haack Rework Area:

> "The Haack property contains the Haack sump and the Haack Rework Area. The Haack Rework Area is a reworked and mixed sludge-soil area south of the Haack sump. Most of the Haack Rework Area currently is vegetated with various trees, shrubs and grass. The eastern portion of the Haack Rework Area is incorporated under the existing Cooper South sump geosynthetics cap. The southern portion of the Haack Rework Area extends onto the extreme northern portions of the two easternmost residential lots."

Section 2 of the RAP will be updated to be consistent with the Executive Summary and include the following statement:

> "Most of the Haack Rework Area currently is vegetated with various trees, shrubs, and grass. The eastern portion of the Haack Rework Area is incorporated under the existing Cooper South sump geosynthetics cap."

DTSC Comment (*italics*):

2. *Section 3 presents a "Summary of Remedial Investigations", and Section 3.3, "Surface Water", describes that the observed GRO presence in samples of surface water from the adjacent Dominguez Channel cannot be due to the Gardena Sumps Site because GROs are not detected in groundwater at the Gardena Sumps Site.*

   These statements are following in Section 3.5 by statements describing the presence of GRO's in the groundwater at the Gardena Sumps Site.

Thus, the conclusion in Section 3.3 is not well supported. ESPO recommends the noted conclusion in the Draft RAP be revised or the supporting evidence be more clearly expressed.

Response:

Section 3.3 will be updated to provide further clarification regarding surface water. The text will be modified to state the following (underlined text constitutes new, updated text):

"Surface water samples were collected upstream and downstream of the Site from the Dominguez Channel in 2006 and 2008. Analytical data from these samples indicated ~~elevated~~ concentrations of gasoline range organics (GRO) to be an estimated concentration of 58 J µg/L, which is just above the reporting limit of 50 µg/L, in both upgradient and downgradient 2006 samples. Samples collected in 2008 were below the reporting limit in both upgradient and downgradient samples. Although GROs have been detected in the past in one monitor well, MW-05A, located on the north portion of the Haack Property and adjacent to the Haack Sump area, GRO concentrations have been trending downward since 2018, with the last three sampling events below the reporting limit. GRO concentration data, obtained in 2009 and collected from groundwater hydropunch locations GWP100 and GWP101 between MW-05A and the Dominguez Channel, indicate that GROs do not impact the water quality of the Dominguez Channel south of the Site (Stantec, 2010). ~~and VOC analytes in contrast to the non-detections for those analytes in groundwater monitored at the Site.~~ VOCs, including PCE and TCE, have been measured in surface water within the Dominguez Channel both upgradient and downgradient of the Site. These VOCs are not present in groundwater beneath the Site.

Based on the organic chemical parameters, the Site is not impacting surface water quality in the channel. Overall, the observed concentrations of metals in surface water adjacent to the Site support the same conclusion that the Site groundwater conditions are not impacting surface water quality (Stantec, 2008)."

Section 3.5 will be updated to reflect recent groundwater monitoring data and to clarify and agree with the footnote in Section 3.3. The text will be modified to state the following (underlined text constitutes new, updated text):

"Results of the third quarter 2020 semi-annual groundwater monitoring event are generally consistent with the analytical results from past sampling events since February 2006. GRO concentrations in MW-05A, located on the north portion of the Haack Property and adjacent to the Haack Sump area, have generally continued to decrease since 2018 with the last three sampling events below the reporting limit. Groundwater and surface water data obtained between MW-05A and the Dominguez Channel (i.e., groundwater hydropunch investigation locations, and existing monitor

wells) indicate that GROs are not observed in groundwater adjacent to or near the portion of the Dominguez Channel that is adjacent to the Site. The groundwater quality data indicates that GROs observed in MW-05A are not migrating to the Dominguez Channel. Throughout 2019 and 2020, neither SVOCs nor metals have been detected above their respective MCLs. ~~Although Bis(2-ethylhexyl) Phthalate has been detected above the MCL in wells MW-02B, MW-03B, MW-04A, and G-4 in the past, only well MW-03B had a detection above the MCL during the first quarter 2019. While concentrations of metals continue to be detected in all monitor wells, only MW-05A has had exceedances of beryllium, cadmium, and nickel above MCLs (Stantec, 2019).~~"

DTSC Comment (italics):

3. *Section 6.4.2, "FS – Recommended Alternative", describes the protective nature of the selected alternative in the following excerpt:*

"Based on the comparative analysis of the remedial alternatives, the alternative that … ranks the highest is Alternative 2A, capping with selective excavation … This remedial alternative effectively mitigates the risk from ingestion, inhalation, and dermal contact with on-Site soils for both future … occupants … and future landscapers and utility workers."

However, ESPO was unable to find the specified separation between the hazardous waste and future users of the property, i.e. the thickness of the cover. Continuing the concern about separation in the paragraph above, ESPO provides the excerpt below from Page 32 of Section 7.3, "Sequence of Work":

"7. Sludge Excavation and Consolidation:

a. Sludge and soil materials will be excavated from the Haack Rework Area … Excavated materials will be utilized as a portion of the cap system…"

ESPO recommends the Draft RAP be revised to specify the separation between hazardous waste and future potential users that will be maintained in the future design.

Response:

Figure 7-7, Detail 1-A and Detail 1-B (pg. 77 of the draft RAP PDF) show the cover (i.e., cap) systems. These details include the proposed cap components and minimum foundation soil thicknesses. The details include the minimum specified thicknesses for soil components. The minimum cap thickness will be 2 feet in the Cooper Sumps, and 1.5 feet (not including the existing surfacing materials) in the Haack Sump Area.

Section 7.3, item number 8.a of the RAP describes the foundation soil material and geometry. The text will be updated with the following to indicate that (i) the foundation layer thickness may vary across the site; and (ii) details for cap system components are shown on Figure 7-7 (underlined text constitutes new, updated text):

"a. Foundation Soil: The foundation soil will be placed above the high-strength geotextile (Cooper Sumps), relocated sludge materials (used as stabilization layer material and/or foundation layer material as appropriate), or asphalt/concrete surface (Haack Sump). The foundation soil will consist of excavated material from the Haack Rework Area and the anchor trench excavations. The foundation soil layer minimum thickness will be 0.5 ft (Haack Sump) and 1 ft (Cooper Sumps). The foundation layer soil thickness may increase above the minimum thickness as necessary to achieve the design goals for grading, waste separation, and surface water conveyance. Where necessary around the cap system perimeter, the foundation layer will be graded (thinned) to blend with the existing ground surface. The foundation soil will be placed in lifts until foundation grades are met (i.e., 1 ft below the cap grades shown on Figures 7-1 and 7-2). The slopes will be a minimum of 2 percent (%) to reduce impacts on drainage due to settlement of the foundation material and/or sludge. The foundation layer and other cap components are shown on Figure 7-7, Details 1-A and 1-B."

DTSC Comment (italics):

4. *ESPO notes the passage describing the proposed sheet piling on Page 32 of Section 7.3, "Sequence of Work", which is excerpted below:*

"5. Sheet Pile Wall Installation: Sheet piles will be installed to … the bottom depth of the identified sludge in the … Sumps. … The sheet piles will be coated to minimize corrosion of the steel due to the low pH and high hydrogen sulfide environment. The sheet pile cut-off wall will provide a physical barrier between the sludge remaining in the … Sumps and … adjacent sidewalk. The sheet pile wall will aid in the mitigation of lateral migration of soil vapor."

The above excerpt makes clear the significant long term role of the sheet piling component of Alternative 2A in protecting public health. ESPO highlights Arco's understanding that the proposed sheet piling requires maintenance in the following excerpt from Section 6.4.1 of the Draft RAP:

"3. Long-Term Effectiveness and Permanence – Alternative 3 is ranked higher than Alternative 2A with respect to long-term effectiveness and permanence. Both alternatives would be effective and permanent over the long-term with maintenance"

To obtain the required long term effectiveness ESPO recommends the proposed coated sheet piling include a cathodic protection scheme, with maintenance prescribed in the anticipated documents, land use covenant or other (Item 9 on Page 34).

Response:

Section 7.3, item number 5 of the RAP will be updated with the following text:

"a. Sheet Pile Wall Maintenance: Sheet piles will be designed and installed with appropriate corrosion mitigation measures. Details of corrosion mitigation measures will be presented in the design. Additional maintenance of the exposed portion of the sheet pile wall after construction may be required due to vandalism, accidents, or other damage. Maintenance requirements will be included as part of a monitoring and maintenance plan or as part of a land use covenant."

DTSC Comment (*italics*):

5. *ESPO notes contradictory Site end use descriptions in the following passages from Section 5.5, "Future Site Use":*

"The … City of Gardena Master Plan … indicates the Site would be developed in the future as commercial property with a mix of commercial buildings and parking.

"DTSC has requested the following three future land use scenarios be evaluated for the Site: … Cooper and Haack areas would remain commercial/industrial"

"The City of Gardena requested the remedial design be compatible with a parking lot or open space end use"

The above contradictory passages indicate that the loadings that the underlying soils would need to support is not established. ESPO finds no discussion of estimated long term stiffness of the proposed soil cover and the underlying existing Cooper and Haack soils and other materials.

ESPO does find the following soil cover construction detail on Page 33 and Sheet 7-7 of the Draft RAP:

8. Cap System Construction:

a. Foundation Soil: The foundation soil will be placed above the high-strength geotextile (Cooper Sumps) or asphalt/concrete surface (Haack Sump). The foundation soil layer minimum thickness will be 0.5 ft (Haack Sump) and 1 ft (Cooper Sumps).

ESPO recognizes that future ownership and development plans are not finalized (Section 7.11). However, ESPO submits the caution that if Arco constructs a soil cover only capable of supporting a parking lot, then the future owners would face a significant challenge modifying the soil cover to support commercial buildings.

Given Arco's stated intention to support future development on the Site, as evidenced by the following passage from Page xi describing the soil cover alternative, Alt. 2A:

"Alternative 2A also would best accommodate future potential redevelopment of the Site."

ESPO recommends that Arco propose a remedial design to accommodate the highest structural loading consistent with, "future potential redevelopment of the Site". Such a design would provide long term protection for construction workers and neighbors, as sought in the FS.

Response:

Section 5.5 of the RAP will be reworded to state the following:

> "Future Site use considerations have been identified by DTSC, the City of Gardena, and the Site owner. Specific future Site uses, as described in this document will be accommodated in the design phase of the work. The basis of design and specific design parameters will be considered during the design phase of work. As discussed with DTSC, the basis of design and design parameters cannot incorporate or consider all potential future uses or redevelopment scenarios; therefore, any additional redevelopment work, beyond the current specific and intended uses, should be considered in future permitting processes at the time of the future redevelopment."

As discussed with DTSC in our 20 April 2021 teleconference call, the current basis of design cannot consider or incorporate all potential future uses; therefore, future redevelopment of the site will be restricted by a land use covenant and will be subject to the permitting processes applicable at the time of future redevelopment, including DTSC review of proposed development that differs from final remedy design.

DTSC Comment (*italics*):

6. *Related to the prior ESPO Comment, ESPO recommends that the Draft RAP be revised to provide an evaluation of the long term effectiveness of the soil vapor collection system. In particular, such soil vapor collection systems typically include an estimation of future settlement and provisions to mitigate potential local "dips" in the vertical alignment which collect liquids and occlude the gas flow. ESPO requests the revised Draft RAP provide such a discussion.*

Response:

Section 6.3.2 of the RAP will be updated to include the following statements (underlined text constitutes new, updated text):

"A vapor control and monitoring system would be designed and installed beneath the cap and around the sumps, and groundwater monitoring would continue. The vapor control system would include a flexible gas collection system designed to accommodate the long-term operation of the system."

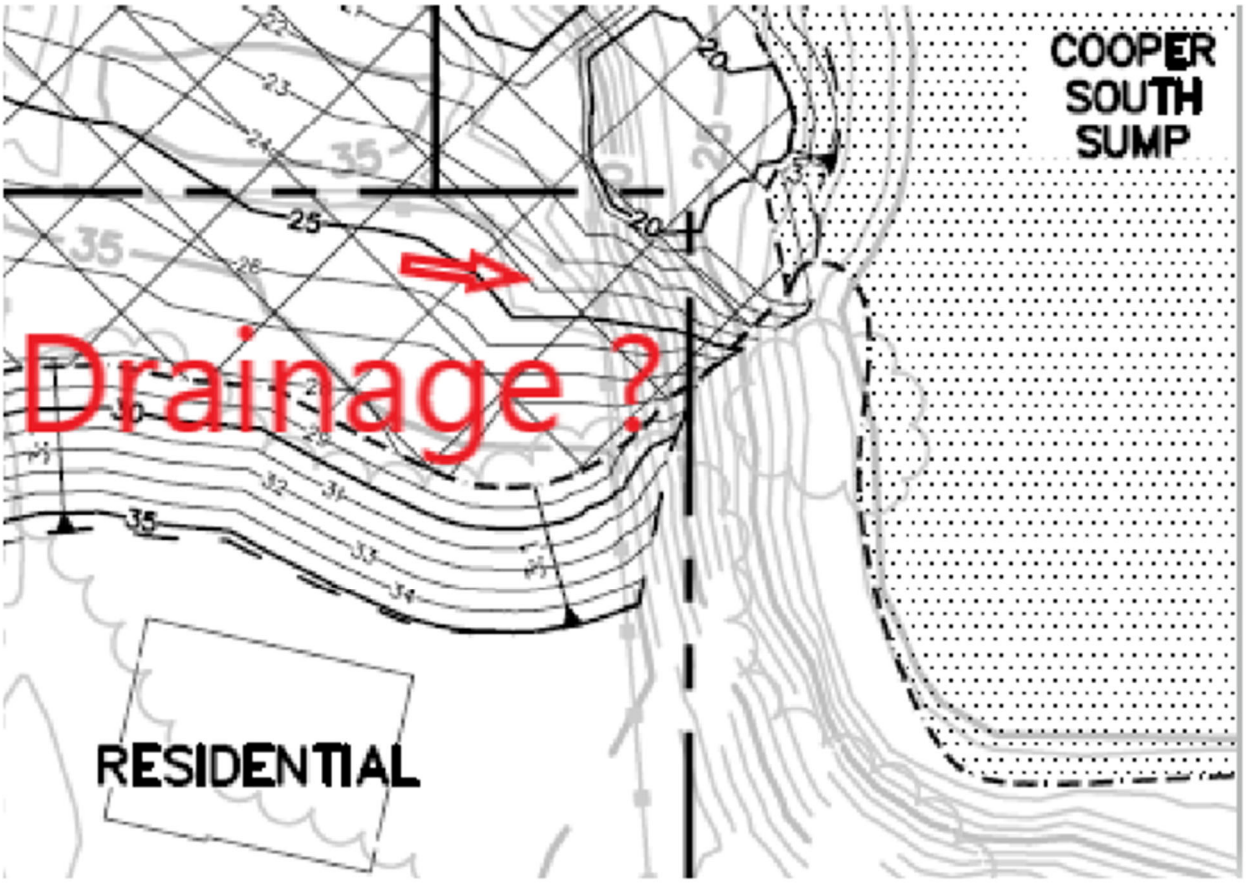
Section 7.3, item number 6 of the RAP will be updated to include the following statement:

"The system will be designed to accommodate differential settlement, maintain gas flow, and mitigate condensate buildup."

DTSC Comment (*italics*):

7. *ESPO expects rainfall will quickly cause rills and progressive erosion on the proposed 2:1 side slope of aggregate base specified on Detail 6 of Sheet 7-8. The function of the cover would be compromised.*

   ESPO recommends the slope be revised to 3:1.

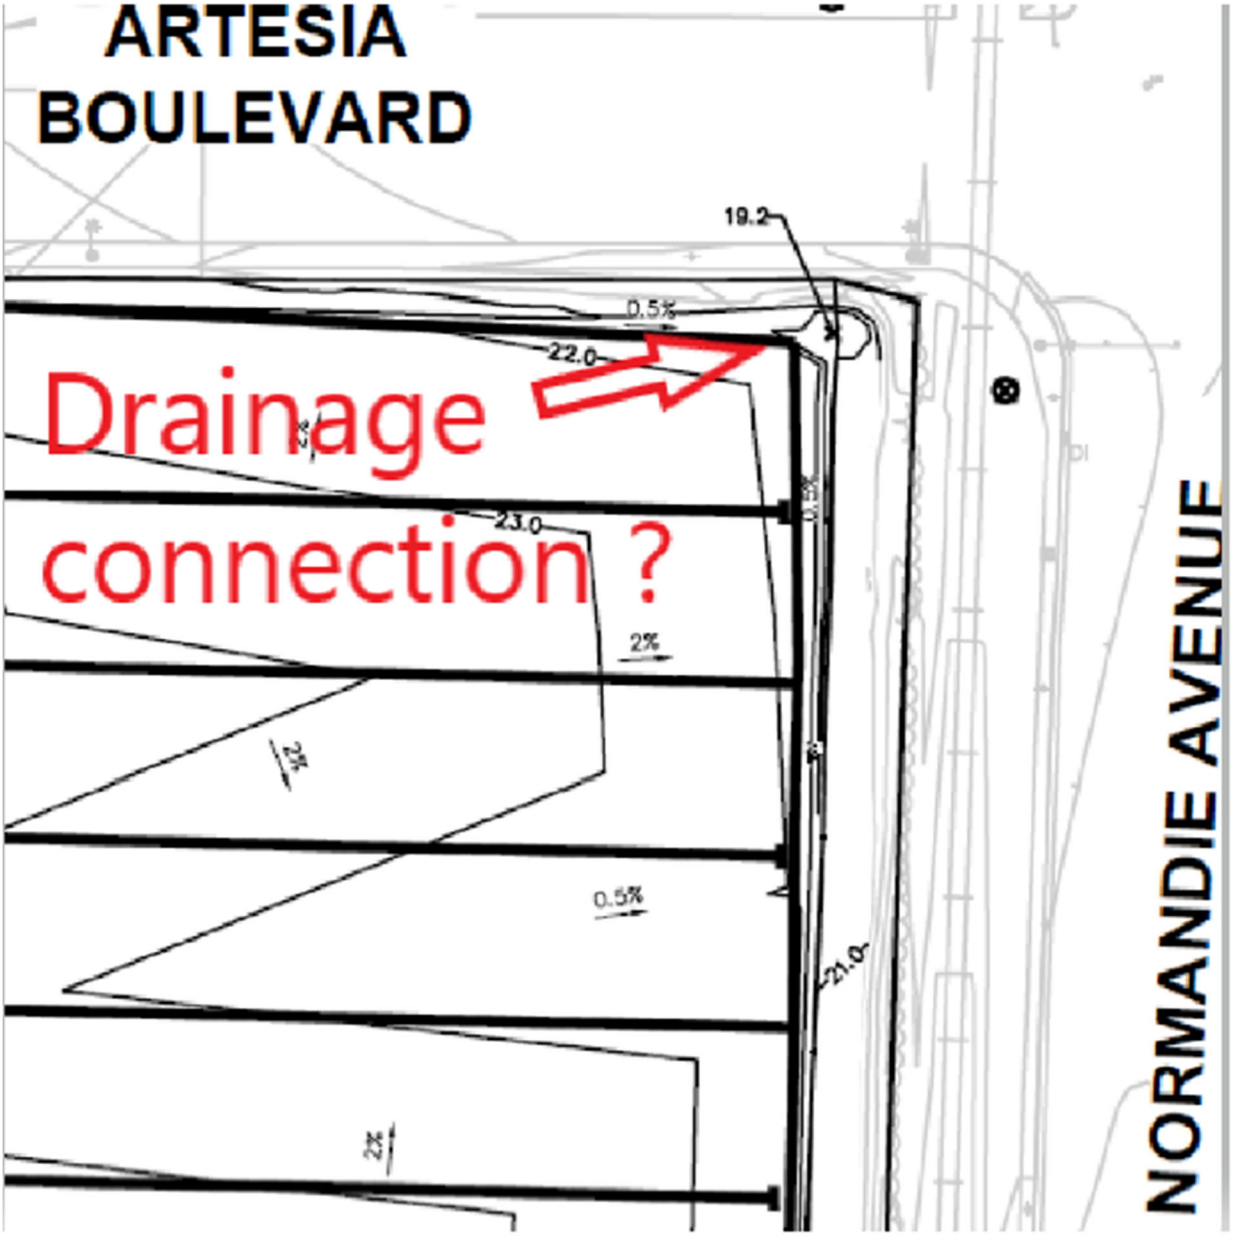


Response:

ESPO's comment is acknowledged. Erosion control and surface water drainage will be included as part of the basis of design for the final design grades. Appropriate erosion control measures will be included in the remedy design to mitigate erosion potential. Slopes will be evaluated for stability as part of the remedy design. Detail 6 on Sheet 7-8 will be revised to state that the slope will be "2:1 (maximum)" indicating no slopes will be steeper than 2:1.

DTSC Comment (*italics*):

8. *The location of Section B on Sheet 7.3 is not shown on the plan view of Sheet 7-5, hence it is difficult to understand the resulting surface and drainage outfall, as shown with red highlight in the two excerpted figures below:*



POST EXCAVATION
BACKFILL GRADE
APPROXIMATE LOCATION OF
HIGH STRENGTH GEOTEXTILE
HAACK REWORK AREA
EL.= 25.56 FT
LODS
COOPER SOUTH
1+00
2+00
3+00
DISTANCE (FEET)
SECTION B

ESPO notes that ponded water, if that is the result of the proposed grades, would undermine the intended containment of the remedial design.

ESPO notes an additional drainage concern on the excerpt from Sheet 7-6 shown below where the tie-in to downstream storm water improvements is not shown.

ESPO recommends the drainage details be clearly shown on the plans. ESPO also recommends the LODS (Limit of Disposed Sludge) be displayed on Sheet 7.5.

Response:

The images included by ESPO in the comments represent interim (e.g., temporary construction) conditions for the areas shown. Section 7.3, item number 7 will be updated to include the following detail regarding contact water management during sludge excavation and consolidation:

> " b. Contact water, including stormwater run-on, stormwater run-off, antecedent rainfall, and groundwater which comes into contact with the sludges or materials containing potential COCs, will be managed during construction through

> interim contact water management controls. These may include pumps, erosion and sediment controls, diversion berms, etc. Water within work areas will be managed to prevent ponding and to remove excess water prior to construction of remedy features. Details regarding requirements for contact water management will be included in the remedy design documents (e.g., specifications)."

The Limit of Disturbed Sludge (LODS) referenced by the ESPO represents the pre-remedy condition. ESPO recommends displaying the LODS on Sheet 7.5, which represents post-remedy construction conditions; therefore, the LODS shown on Sheet 7.5 would not be an accurate depiction. The LODS will be included on design drawings and figures showing pre-remedy construction conditions (i.e., existing conditions drawing). Because the LODS will be modified during construction, the LODS will not be included on drawings or figures that represent interim or post-construction conditions.

Stantec Consulting Services Inc.
3777 Worsham Avenue Suite 200, Long Beach CA 90808-1774

January 15, 2021
File: 185850766.400

Attention: Mr. Nicholas Ta
California Department of Toxic Substances Control
Southern California Cleanup Operations Branch – Cypress Office
5796 Corporate Avenue
Cypress, California 90630-4732

Dear Mr. Ta,

Reference: Annual Cover Inspection and Maintenance Report
January to December 2020
Gardena Sumps Site, DTSC Project No. 400067
1440 West Artesia Boulevard, Gardena CA, 90247
Southwest Corner of West Artesia Boulevard and Normandie Avenue

On behalf of Atlantic Richfield Company (ARC), Stantec Consulting Services Inc. (Stantec) has prepared this summary report addressing the geomembrane cover inspections and maintenance activities performed at the Gardena Sumps Site (the Site) in 2020. The Site is located at the southwest corner of the intersection of Artesia Boulevard and Normandie Avenue in the City of Gardena, Los Angeles County, California (Figures 1 and 2). The cover inspection and maintenance activities were conducted pursuant to §VII-A2 of the Consent Decree for US District Court Case Number CV04-7882–AHM (JTLx). ARC signed this Consent Decree on June 16, 2004 with the California Department of Toxic Substances Control (DTSC). The consent decree was entered into the court records of the United States District Court for the Central District of California on November 4, 2004. A detailed Interim Cover Maintenance Plan (ICMP) was submitted to the DTSC on December 16, 2004 by SECOR International Incorporated (SECOR, now Stantec) to provide a framework for ensuring cover integrity until final remediation could be achieved. On June 25, 2012, the ICMP was updated and included a new format for the cover repairs log and Site inspection report. The June 25, 2012 updated ICMP addresses the requirements for periodic inspections, documentation, maintenance, repairs, and reporting.

The purpose of this document is to present the results of cover inspection and maintenance activities performed by Stantec during the 2020 calendar year. A comprehensive cover inspection and maintenance report covering the period from December 2004 through April 2007 was submitted to DTSC on April 18, 2007. A second report covering the partial year of April 19 through December 31, 2007 was submitted on January 4, 2008. Since that time, Stantec has submitted a yearly cover inspection and maintenance summary report to the DTSC for activities conducted during the calendar year, from January through December, in January of the following year. Per the June 25, 2012 updated ICMP, long-term quarterly monitoring of cover integrity will continue and be documented during 2021. This report addresses cover inspection and maintenance activities that occurred from January through December 2020.

Southwest Corner of West Artesia Boulevard and Normandie Avenue

SITE GROUNDWATER SAMPLING, INSPECTIONS, AND MAINTENANCE VISITS

As requested by the DTSC, Stantec conducts monthly inspections of the perimeter fence and gates, and signage. During the reporting period, there have been a total of twenty-two site visits. Site visits were for the purpose of conducting monthly perimeter fence, gate, and sign inspections; semi-annual groundwater monitoring and sampling, quarterly cover inspections; and for general site maintenance. The dates and purposes of Site Visits during 2020 are summarized below.

1.	1/27/2020	Monthly Site Visit. Graffiti observed on 5 of 8 Proposition 65 signs installed along perimeter fence.
2.	2/18/2020	First Quarter 2020 Semi-Annual groundwater sampling event, First Quarter 2020 Cover Inspection and Monthly Site Visit. Well MW-05A vault gasket was noted as worn and needing repair. No damage to cover was noted. A tree was identified as having fallen onto and causing damage to the chain-link perimeter fence in the southwest portion of the Site. A breach was identified and temporarily fixed in perimeter fence along Normandie Avenue near Gate 2. Approximately 10-foot-long section of privacy windscreen had been cut out and removed along Artesia Boulevard. Weed growth is present.
3.	2/26/2020	Site Maintenance. Replaced vault gasket at well MW-05A. Conducted general cleanup along perimeter fence. Installed new warning signs and replaced missing privacy windscreen on perimeter fence along Artesia Boulevard.
4.	3/3/2020	Monthly Site Visit. Weeds are present. Graffiti observed on 6 of 8 Proposition 65 signs installed along perimeter fence. Waste drums were removed from Site during the site visit.
5.	4/3/2020	Monthly Site Visit. Weeds are present. Graffiti present on Proposition 65 signs.
6.	5/1/2020	Monthly Site Visit and Second Quarter 2020 Cover Inspection. No damage to cover noted. Weed growth present. Breaches identified along the Los Angeles Department of Public Works (LADPW) perimeter fence on Normandie Avenue. Replaced graffiti covered Proposition 65 signs on perimeter fence along Artesia Boulevard and Normandie Avenue.
7.	5/26/2020	Site Maintenance. Assessed perimeter fence and windscreen for proper repairs.
8.	6/10/2020	Site Maintenance. Repaired breaches along perimeter fence along Normandie Avenue. Covered graffiti identified on perimeter fence windscreen facing Artesia Boulevard.
9.	6/11/2020	Monthly Site Visit. Weeds present on LADPW property. Breaches identified on LADPW property in perimeter fence along Normandie Avenue.
10.	7/7/2020	Monthly Site Visit. Breach identified in the perimeter fence on Artesia Boulevard. The windscreen and chain-link fence were cut where the breach was identified.

Reference: **Annual Cover Inspection and Maintenance Report**
January to December 2020Gardena Sumps Site, DTSC Project No. 400067
1440 West Artesia Boulevard, Gardena CA, 90247
Southwest Corner of West Artesia Boulevard and Normandie Avenue

		Gate panel located in the southeast portion of the LADPW perimeter fence was noted as unsecured.
11.	7/8/2020	Site Maintenance. Fence breach along Artesia Boulevard and windscreen was repaired.
12	7/28/2020	Site Maintenance. Repaired breaches in LADPW property a second time in perimeter fence along Normandie Avenue. Reset gate panel on new hinges attached to the perimeter fence. Covered graffiti identified on windscreen facing Artesia Boulevard.
13.	8/18/2020	Third Quarter 2020 Semi-Annual groundwater sampling event and Monthly Site Visit. Weed growth observed next to wells MW-03A/3B and well G-4 on LADPW property.
14.	8/19/2020	Third Quarter 2020 Cover Inspection. No damage to cover was noted. Weed growth present.
15.	8/25/2020	Site Maintenance. Repaired chain-link fence and removed tree stump and fallen tree branches located in the southwest portion of Site.
16.	9/10/2020	Monthly Site Visit. Breaches identified on LADPW Property in perimeter fence along southern boundary of Site.
17.	9/15/2020	Site Maintenance. Repaired fence breaches in LADPW property along the southern portion of perimeter fence.
18.	10/8/2020	Monthly Site Visit. No issues identified.
19.	10/28/2020	Fourth Quarter 2020 Cover Inspection. Damage to southeast portion of the LADPW perimeter fence was noted. Warning signs were observed to be missing at entry gate in the southern portion of perimeter fence. Weed growth present in interior Site perimeter and in areas on the LADPW property around wells MW-3A/B and G-4. Sandbags on top of the western portion of cover were noted to have deteriorated. A 12-inch cut was observed in the cover in the southeast portion of the Site.
20.	11/4/2020	Site Maintenance. Installed new warning signs on south entry gate of Site. Repaired the 12-inch cut identified in the cover. Repaired breaches identified in the southern portion of the perimeter fence.
21.	11/9/2020	Monthly Site Visit. Weeds are present on the LADPW property.
22.	12/9/2020	Monthly Site Visit. Burnt vegetation and soil was observed near the southeast corner of the cover due to fire. Graffiti was identified on a Caution sign attached to the southeast gate to the Site. One lock was noted as missing from the southeast gate. A chain and lock used to secure a fence panel (attached to the southeast

January to December 2020Gardena Sumps Site, DTSC Project No. 400067
1440 West Artesia Boulevard, Gardena CA, 90247
Southwest Corner of West Artesia Boulevard and Normandie Avenue

corner of the perimeter fence) were removed and left on the ground apparently by fire department personnel.

Inspection of the cover is performed during the semi-annual groundwater sampling events in the First and Third Quarters of each year and during the Second and Fourth quarters of each year as separate site visits. On October 12, 2018, Stantec received a letter from the DTSC approving semi-annual events. Starting in the beginning of 2018 the groundwater sampling events were scheduled to occur in the first and third quarters each year. Cover inspection and cover maintenance events conducted during 2020 were performed in general accordance with Stantec's June 25, 2012 updated ICMP. During the regular Quarterly site visits, punctures, rips and/or tears, degradation of previous repairs/patches or traffic related wear in the cover, if present, are identified and an assessment is made to determine the need for repair

COVER INSPECTION AND MAINTENANCE

The geomembrane cover in the entire eastern portion (Cooper Property) of the Site was re-covered in the fall of 2013. A small patch of approximately 1 square foot was installed in December 2020. The perimeter of the Site is inspected for fence, sign and gate damage or vandalism monthly. The entire Site is regularly inspected quarterly, sometimes coinciding with the quarterly groundwater monitoring event, for any signs of damage, failed seams, or tar seeps. Quarterly Cover Inspection Reports for 2020 are provided in Attachments A through D. Geomembrane photograph repair logs for repairs conducted by Stantec during the year (when repairs have been performed) are provided as Attachment E.

The following summarizes observations, findings and activities conducted during each quarter of this reporting year.

First Quarter 2020:

On February 18, 2020, the First 2020 Semi-Annual groundwater sampling event and First Quarter Cover Inspection was conducted. No damage to the cover was observed.

Second Quarter 2020:

On May 1, 2020, the Second Quarter 2020 Cover Inspection was conducted. No damage to the cover was observed.

Third Quarter 2020:

On August 19, 2020, the Second 2020 Semi-Annual groundwater sampling event and Third Quarter Cover Inspection was conducted. No damage to the cover was observed.

Fourth Quarter 2020:

On October 28, 2020, the Fourth Quarter 2020 Cover Inspection was conducted. Sandbags on top of the western portion of cover were noted to have some deterioration; they will continue to be monitored for further deterioration. A 12-inch cut was also observed in the cover located in the southeast portion of the Site. On November 4, 2020, Stantec repaired the 12-inch cut in the cover.

Cover inspection reports for the First Quarter through Fourth Quarter 2020 are provided in Attachments A through D, and photographs of cover repairs are provided in Attachment E.

STANDARD LIMITATIONS

This report was prepared in accordance with the scope of work outlined in Stantec's contract and with generally accepted professional engineering and environmental consulting practices existing at the time this report was prepared and applicable to the location of the Site. It was prepared for the exclusive use of ARC and local regulatory agencies, for the express purpose stated above. Any re-use of this report for a different purpose or by others not identified above shall be at the user's sole risk without liability to Stantec. To the extent that this report is based on information provided to Stantec by third parties, Stantec may have made efforts to verify this third-party information, but Stantec cannot guarantee the completeness or accuracy of this information. The opinions expressed, and data collected are based on the conditions of the Site existing at the time of the field investigation. No other warranties expressed or implied are made by Stantec.

If you have any questions or comments regarding the contents of this letter, please call either Mr. Kelly C. Brown with Stantec at 562-354-2638 or Mr. Wade Melton with ARC at 360-594-7978.

Cypress, CA 90630-4732

Dear Mr. Ta,

Reference: QUARTERLY PROGRESS REPORT – SECOND QUARTER 2021
GARDENA SUMPS SITE, DTSC Project No. 401218
Southwest Corner of West Artesia Boulevard and Normandie Avenue
Gardena, California 90247

On behalf of Atlantic Richfield Company (ARC), Stantec Consulting Services Inc. (Stantec) is submitting this Progress Report for the Second Quarter 2021 to the California Department of Toxic Substances Control (DTSC) per Section VI.D of the *Gardena Sumps/ARC Consent Decree*, CV04-7882-AHM(JTLx) (the Decree), effective November 4, 2004. The Gardena Sumps Site (the Site) is located at the southwest corner of West Artesia Boulevard and Normandie Avenue in the City of Gardena, California.

The progress updates included in this report describe: (1) specific actions taken by or on behalf of ARC during the previous reporting period; (2) actions expected to be undertaken during the current reporting period; (3) all planned activities for the next reporting period; (4) any requirements under the Decree that were not completed; (5) any problems or anticipated problems in complying with the Decree; and (6) results of sample analyses, tests, and other data generated under the Decree during the previous reporting period, and any significant findings from these data. Status of the primary action items are summarized here:

Primary Actions / Requirements	**Status**
• Notification of Project Coordinator and Project Team	(Completed – November 2004)
• Interim Cover Maintenance Plan	(Completed – December 2004)
• Communication and Coordination Plan (CCP)	(Completed – December 2004)
• Site and Adjacent Property Access	(Completed – December 2005)
• Site Maintenance & Removal Actions Workplan	(Completed – February 2005)
• Initial Site Maintenance, Fence, and Cover Repair	(Completed – September 2005)
• RI/FS Workplan, Final	(Completed – November 2005)
• Public Participation Plan (PPP), Final	(Completed – November 2005)
• RI/FS Field Investigation	(Completed – February 2007)
• Draft RI Report, submitted for DTSC review	(Completed – August 2007)
• Respond to DTSC comments on Draft RI Report	(Completed – August 20, 2008)
• Revised Draft RI Report, submitted to DTSC	(Completed – August 22, 2008)
• Quarterly Groundwater Monitoring & Sampling	(Ongoing from First Quarter 2006)

GARDENA SUMPS SITE, DTSC Project No. 401218
Southwest Corner of West Artesia Boulevard and Normandie Avenue
Gardena, California 90247

- ARC, Stantec and Geosyntec prepared responses to DTSC comments within their November 21, 2008 letter. (Issued - February 12 and 26, 2009)
- RI Workplan Addendum submitted to DTSC (Completed - June 15, 2009)
- RI Field Investigation (Completed - October 2009)
- Draft Memorandum – Data Gap Analysis submitted to DTSC (Completed – February 2, 2010)
- Draft Human Health Risk Assessment, submitted to DTSC (Completed - May 25, 2010)
- Addendum to the August 22, 2008 Revised Draft 2006 Remedial Investigation Report, submitted to DTSC (Completed - December 14, 2010)
- Draft Feasibility Study Report submitted to DTSC (Issued - February 11, 2011)
- Revised Human Health Risk Assessment Report to DTSC (Issued - June 1, 2011)
- Addendum to Draft Feasibility Study Report to DTSC (Issued - September 30, 2011)
- Revised Draft Feasibility Study Report to DTSC (Issued April 4, 2012)
- Revised 2011 Annual Cover Repair and Maintenance Report and a Revised Interim Cover Maintenance Plan (ICMP) (Issued - June 27, 2012)
- Revised Final Draft Feasibility Study Report (includes responses to DTSC August 15, 2012 Remedy Review memorandum and September 5, 2012 Remedy Review letter) (Issued – November 5, 2012)
- Response to Comments on Revised Final Draft Feasibility Study Report (Issued – April 12, 2013)
- Placement of new liner material over existing liner on Cooper Property (Performed August / September 2013)
- Response to Comments on Revised Final Draft Feasibility Study Report (Issued – November 12, 2013)
- Final Feasibility Study Report to DTSC (Issued – May 21, 2014)
- Response to DTSC Comment Memorandums on Cover Inspection Report (Issued – June 23, 2014)
- Revised Final Feasibility Study Report to DTSC (Issued – July 1, 2014)
- Request to Remove Monitoring Wells MW-01A and MW01B from Groundwater Sampling Program
  - (Issued - October 16, 2014)
- Work Plan for Temporary Cover at the Haack Rework Area (Issued – October 21, 2014)
- Temporary Cover Installation at the Haack Rework Area Report (Issued – February 24, 2015)
- Request for Groundwater Monitoring and Sampling Reduction for the Gardena Sumps Site (Issued – March 9, 2017)
- Monitoring Well Sampling Reduction Request (Issued – September 8, 2017)
- Semi-Annual Groundwater Sampling Schedule (Issued – October 26, 2017)

- Comments on Gardena's Sludge Excavation Pilot Test Work Plan submitted (Issued – August 13, 2018)
- Final Feasibility Study Certification Letter (Issued – August 3, 2020)
- Draft Remedial Action Plan (RAP) (Issued - January 18, 2021)

SUMMARY OF ACTIONS TAKEN DURING THE QUARTER (April - June, 2021)

Following is a summary of significant actions completed during the reporting period:

- Submitted the First Quarter 2021 Semi-Annual Groundwater Monitoring Report (April 7, 2021).
- Performed the Second Quarter 2021 site geomembrane cover inspection and maintenance activities.
- Conducted monthly inspection of site perimeter fence, gates, and locks, and signs for security breaches, maintenance, and/or graffiti removal.
- Draft RAP under review by DTSC.
- DTSC public participate and notification in progress.

SUMMARY OF ACTIONS TO BE TAKEN IN THE NEXT QUARTER (July - September, 2021)

The following actions are expected to be undertaken within the current quarter:

- Submit the Second Quarter 2021 Progress Report.
- Perform the Third Quarter 2021 Semi-Annual Groundwater Monitoring event.
- Perform the Third Quarter 2021 site geomembrane cover inspection and maintenance activities.
- Perform monthly perimeter fence, gate, and sign inspections for security breaches, maintenance, and/or graffiti removal.
- Perform weed abatement activities (as necessary).
- Prepare the Third Quarter 2021 Progress Report.
- Finalize RAP.

SECURITY MEASURES

The following actions were performed during the quarter to insure adequate security at the site:

- April 12, 2021: Stantec inspected the site perimeter fence and gates for integrity. No breaches were identified and the gate locks were present and locked. The hazardous waste signs were present. A portion of the wind screen along Artesia Boulevard was missing.

- May 14, 2021: Stantec inspected the site perimeter fence and gates for integrity. No breaches were identified, the gate locks were present and locked, and the hazardous waste signs were present. Minor

GARDENA SUMPS SITE, DTSC Project No. 401218
Southwest Corner of West Artesia Boulevard and Normandie Avenue
Gardena, California 90247

repair to the wind screen along Artesia Boulevard was conducted as was weed abatement along outer perimeter fence.

- June 18, 2021: Stantec inspected the site perimeter fence and gates for integrity. No breaches were identified to the Gardena Sumps site, the gate locks were present and locked, and the hazardous waste signs were present. Stantec replaced 150 feet of windscreen along the Artesia Boulevard perimeter fence.

REQUIREMENTS NOT COMPLETED PER THE DECREE

To date all requirements have been initiated or completed per the Decree and DTSC-approved extensions. In letter dated October 30, 2014, the DTSC approved the removal of wells MW-01A and MW-01B from the sampling program. These wells will continue to be inspected for integrity annually during the First Quarter sampling events. On October 12, 2107, DTSC approved ARC's request dated September 8, 2017 to reduce quarterly groundwater sampling to semi-annual. Groundwater sampling is performed in the first and third quarters of each year.

POTENTIAL PROBLEMS IN COMPLYING WITH THE DECREE

DTSC has approved the Final Feasibility Study in letter dated July 14, 2020. On January 18, 2021, ARC submitted the draft RAP to DTSC for review.

RESULTS OF SAMPLE ANALYSES AND TESTS FROM FIRST QUARTER SEMI-ANNUAL 2021 FIELD ACTIVITIES

The results of groundwater monitoring from the First Quarter 2021 Semi-Annual event, including sample analysis, were submitted to the DTSC on April 7, 2021.

CLOSING

The next Progress Status Report will be submitted to the DTSC by October 6, 2021.

Should you have questions or need additional information regarding the current project status, please contact Mr. Wade Melton with the Atlantic Richfield Company at (360) 594-7978.
