	H303	Failure to maintain facility to prevent fire, explosion, and/or release	22 CCR 12 66262.34(d)(2); 40 CFR 1 262.34(d)(4), 265.31
	H306	Failure to have all required emergency equipment	22 CCR 12 66262.34(d)(2); 40 CFR 1 262.34(d)(4), 265.32
	H305	Failure to maintain all required emergency equipment	22 CCR 12 66262.34(d)(2); 40 CFR 1 262.34(d)(4), 265.33
	H308	Failure to maintain adequate aisle space	22 CCR 12 66262.34(d)(2); 40 CFR 1 262.34(d)(4), 265.35
	H798	Failure to complete Uniform Hazardous Waste Manifest exception report when required	HSC 6.5 25123.3(h); 22 CCR 12 66262.42 (a),(c),(d)

Large Quantity Generator - Violations

V	VIOL #	Summary	Code
	H245	Failure to conduct annual employee training and maintain documentation until facility closure	22 CCR 12 66262.34(a)(4); 22 CCR 15 66265.16
	H237	Failure to prepare and implement a contingency plan	22 CCR 12 66262.34(a)(4); 22 CCR 15 66265.51
	H240	Failure to include all required information in the contingency plan	22 CCR 12 66262.34(a)(4); 22 CCR 15 66265.52

Large Quantity Generator - Violations (continued)

V	VIOL #	Summary	Code
	H238	Failure to maintain a copy of the contingency plan on site and/or submit a copy to all responding agencies	22 CCR 12, 66262.34(a)(4); 22 CCR 15 66265.53
	H258	Failure to dispose of hazardous waste within 90 days of accumulation start	HSC 6.5 25123.3(b)(1), 25201; 22 CCR 12 66262.34(a)
	H268	Failure to accumulate hazardous waste in containers that are in good condition	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.171
	H270	Failure to store hazardous waste in containers made of or lined with a material compatible with the hazardous waste to be stored	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.172
	H272	Failure to keep hazardous waste tank/container closed	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.173
	H274	Failure to conduct weekly hazardous waste storage area inspections	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.174
	H289	Failure to conduct daily inspections of hazardous waste tank systems	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.195(a), 66265.195(c)
	H309	Failure to maintain adequate aisle space	22 CCR 12 66262.34(a)(4); 22 CCR 15 66265.35
	H275	Failure to locate reactive and ignitable waste at least 15 meters (50 feet) from the facility's property line	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.176
	H279	Failure to separate incompatible waste during storage	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.17(b), 66265.177
	H304	Failure to maintain facility to prevent fire, explosion, and/or release	22 CCR 12 66262.34(a)(4); 22 CCR 15 66265.31
	H291	Failure to meet secondary containment requirements for hazardous waste tank systems or components	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.193
	H294	Failure to immediately remove from service a tank system which is unfit for use and/or comply with applicable requirements	22 CCR 15 66265.196
	H292	Failure to meet tank system closure requirements	22 CCR 15 66265.111, 66265.114, 66265.197
	H286	Failure to obtain and/or maintain a new hazardous waste tank assessment by a professional engineer	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.192(a)
	H800	Failure to complete an assessment or reassessment of a hazardous waste tank as required	22 CCR 15 66265.192(h)
	H312	Failure to conduct hazardous waste tank system cathodic protection system inspections as required	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.195(b), 66265.195(c)
	H815	Failure to comply with air emmisions requirements for hazardous waste in containers	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.178
	H816	Failure to comply with air emmisions requirements for hazardous waste in tanks	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.202
	H307	Failure to have all required emergency equipment	22 CCR 12 66262.34(a)(4); 22 CCR 15 66265.32
	H301	Failure to inspect and/or maintain all safety/emergency equipment as required	22 CCR 12 66262.34(a)(4); 22 CCR 15 66265.33
	H244	Failure to complete Uniform Hazardous Waste Manifest exception report when required	22 CCR 12 66262.42(a),(b),(d)
	H799	Failure to complete certification of waste minimization on all manifests	22 CCR 12 66262.27(a)
	H257	Failure to adequately complete, and maintain for review, all requirements of the source reduction evaluation review and plan (SB-14)	HSC 6.5 25244.19, 25244.21; 22 CCR 31 67100.5
	H254	Failure to properly prepare a source reduction evaluation review and plan every four years	HSC 6.5 25244.19; 22 CCR 31 67100.7, 67100.8
	H255	Failure to prepare a summary progress report and submitted it to DTSC every four years	22 CCR 31 67100.9

Universal Waste Generator - Violations

V	VIOL #	Summary	Code
	H318	Failure to comply with all universal waste training requirements	22 CCR 23 66273.36
	H321	Faillure to meet universal waste labeling requirements	22 CCR 23 66273.34
	H330	Universal waste accumulation exceeded the 1 year limit	22 CCR 23 66273.35
	H329	Failure to disposal of universal waste at an appropriate destination facility	22 CCR 23 66273.31(a)
	H320	Failure to properly prepare and/or retain shipping papers for all universal waste shipped	22 CCR 23 66273.38; 49 CFR 1 172.201(e)
	H325	Failure to handle waste aerosol cans to prevent fire, explosion, and/or release	HSC 6.5 25201.16(e)
	H328	Failure to meet accumulation standards for aerosol cans	HSC 6.5 25201.16(f)
	H326	Failure to properly clean up and/or contain spills of electronic devices, CRTs and/or CRT glass	22 CCR 23 66273.33.5

Waste Lead Acid Battery Generator - Violations

V	VIOL #	Summary	Code
	H290	Failure to meet requirements for handling, storing, and/or transporting lead acid batteries	22 CCR 16 66266.81(a)(1)
	H293	Failure to properly manage, store, and/or label damaged lead acid batteries	22 CCR 16 66266.81(b)
	H250	Failure to maintain documentation for disposal of lead acid batteries for 3 years	22 CCR 16 66266.81(a)(4)(B)
	H261	Failure to meet all requirements when accepting spent lead acid batteries	22 CCR 16 66266.81(a)(3)

SUMMARY OF OBSERVATIONS/VIOLATIONS

☒ **No violations of hazardous waste laws/regulations were discovered. KERN CUPA greatly appreciates your efforts to comply with all the laws and regulations applicable to your facility.**

☐ **Violations were observed/discovered as listed below. All violations must be corrected by implementing the corrective action listed by each violation. If you disagree with any of the violations or corrective actions required, please inform the CUPA in writing.**

ALL VIOLATIONS MUST BE CORRECTED WITHIN 30 DAYS OR AS SPECIFIED. CUPA must be informed in writing with a certification that compliance has been achieved. A false statement that compliance has been achieved is a violation of the law and punishable by a fine of not less than $2,000 or more than $25,000 for each violation. Your facility may be reinspected any time during normal business hours. If a second reinspection becomes necessary due to non compliance, a reinspection charge of $115.00 per hour may be charged to the facility.

You may request a meeting with the Program Manager to discuss the inspection findings and/or the proposed corrective actions. The issuance of this Summary of Violations does not preclude the CUPA from taking administrative, civil, or criminal action.

INSPECTION COMMENTS:

COMMENTS: **Go to http://www.kernpublichealth.com/hazardous-materials for forms and information.**

Inspector: Lana Elfstrom
Inspection Date: 01/17/2019

Signature of Facility Representative:

EMPLOYEE TRAINING PLAN REQUIREMENTS AND TEMPLATE

All facilities are required to create and implement an employee training plan. Below is a template of requirements for the Hazardous Materials Business Plan and Hazardous Waste Generator program elements. This template will help facilities ensure that all requirements for each program are covered and will help draft a site-specific plan for your facility. Training requirements for the Hazardous Materials Business Plan and Hazardous Waste Generator programs can be found in Health and Safety Code Chapter 6.95 Article 1, Chapter 6.5, Title 19 § 2732, and Chapter 22 of California Code of Regulations § 66265.16. This template may be uploaded onto CERS and will satisfy the above mentioned regulations.

1. Programs
   a. Facility maintains hazardous materials at or above the reporting quantities of 55 gallons of a liquid, 500 pounds of a solid, and/or 200 cubic feet of a compressed gas

      [X] YES Complete section 1b

   b. Hazardous Materials Business Plan Requirements (HSC § 25504(c))
      i. Methods of safe handling of hazardous materials

Employees follow Personal Protective Equipment (PPE) requirements listed on all hazardous material Safety Data Sheets (SDS).

      ii. Safety procedures in the event of a release or threatened release of a hazardous material as described in Emergency Action/Contingency Plan

Emergency Response Objectives & Strategies:
1. Ensure the Safety of Citizens & Response Personnel
2. Control the Source of Release
3. Manage Coordinated Response Effort
4. Maximize Protection of Environmentally- Sensitive Areas
5. Contain and Recover Spilled Material
6. Recover and Rehabilitate Injured Wildlife
7. Remove Hazardous Material from Impacted Areas

      iii. Procedures for coordination with local emergency organizations

The Incident Command System (ICS) structure will be used to manage all emergency response organizations during any incident.

iv. Communication and alarm systems

Verbal alarm will be made at site and and emergency page will be sent to all employees cellular devices during emergency.

v. Use of emergency response equipment and supplies employees may use

Hand held fire extinguishers are present throughout each site. Emergency response to include standard PPE and air monitoring equipment

vi. Procedures for using, inspection of, repairing, and/or replacing facility emergency and monitoring equipment

All emergency monitoring equipment is inspected monthly and before each use.

vii. Evacuation/re-entry procedures and assembly point locations

During emergency, employees will muster at front gate at facility and will not re-enter until emergency situation has been resolved and all are accounted for.

c. Facility stores/generates hazardous waste

- [x] YES — Complete section 1d
- [ ] NO — Do not complete section 1d

d. Hazardous Waste Generator Requirements (HSC Chapter 6.5, 22 CCR § 66265.16)

i. Proper packaging and labeling of all waste

All hazardous waste is stored in Main Storage Area or designated Satellite Storage Area. Hazardous waste must be labeled with contents and accumulation date.

ii. On-site management and storage requirements

All hazardous waste is stored in Main Storage Area or designated Satellite Storage Area. Hazardous waste must be labeled with contents and accumulation date. Waste shipments are tracked and accounted for through Corporate Waste Advisor.

iii. Proper use of safety equipment and hazardous waste management supplies

PPE requirements are determined by materials SDS and the Company Safety Manual.

iv. Off-site transportation requirements

All off-site transportation is done by Contractor to an approved waste facility.

v. Interaction with waste haulers and disposal sites including manifesting

Done on an as needed basis. All waste goes to facilities on an approved waste list. All manifests are sent to the Department of Toxic Substances Control (DTSC) and are kept at facility.

vi. Conducting and documentation off periodic inspections

Documentation of inspections are located on the Weekly Hazardous & Universal Waste Inspection Log.

Frequency of inspections: (Defined as every 7 Days)

2. Required Training Topics – By Job Title

While all topics in section 1 must be covered, not every individual must be trained in each topic for respective program(s). Training given to each individual will commensurate with the tasks assigned to that employee.

Example: An employee who physically handles hazardous wastes but does not fill out or manage manifests needs training in handling not manifesting, while the clerical person responsible for the manifests needs training in manifesting but not handling the wastes.

Training on MSDS (Material Safety Data Sheets) including specific hazard(s) of each chemical to which employees may be exposed, including routes of exposure (i.e. inhalation, ingestion, absorption, etc.) is required.

Procedures for specific job titles (optional):

All company employees complete Hazardous Waste Awareness and Hazard Communication training on an annual basis.

3. Personal Responsibilities

   Responsibility for ensuring the training plan is compliant to all requirements and implementation is assigned to: Field Regulatory Specialist

   Special Responsibilities are as follows:

TRAINING TASK	ASSIGNED TO
Hazardous Waste Awareness	Web Based Training (WebCAT)
Hazard Communication	Web Based Training (WebCAT)
First Aid and Automated External	American Red Cross
Defibrillator	

4. Training Frequency

   New employees will successfully complete training within 6 months after date of employment or assignment to a new position at facility. All employees are to receive at least annual training, including refresher courses. In the event of new assignments or changes in operation, training will be provided before the new assignment or change in operation takes place. Employees will not handle hazardous materials and/or hazardous waste without supervision until trained.

   Date of last training: Completed Annually

   Date of next training: Completed Annually

   Additional dates for refresher courses (optional):

COURSE	DATE

5. Training Documentation

   All training must be documented. Training records on current personnel shall be kept until closure of the facility. Training records on former employees shall be kept for at least three years from the date the employee last worked at the facility. Records that document that the requirements, trainings, and job experience have met must be kept and maintained.

Training records are kept: within the internal Web based training program

CALIFORNIA ENVIRONMENTAL REPORTING SYSTEM (CERS)

CONSOLIDATED EMERGENCY RESPONSE / CONTINGENCY PLAN

Prior to completing this Plan, please refer to the INSTRUCTIONS FOR COMPLETING A CONSOLIDATED CONTINGENCY PLAN

FACILITY ID # A1.	CERS ID # A2.	DATE OF PLAN PREPARATION/REVISION (MM/DD/YYYY) A3.
	10230871	01/14/2022

BUSINESS NAME *(Same as Facility Name or DBA - Doing Business As)* A4.
Torrance Valley Pipeline Company LLC

BUSINESS SITE ADDRESS A5.
19662 Highway 33 Rd.

BUSINESS SITE CITY A6.		ZIP CODE A7.
Mckittrick	CA	93251

TYPE OF BUSINESS (e.g., Painting Contractor) A8.	INCIDENTAL OPERATIONS (e.g., Fleet Maintenance) A9.
Pipeline Operator	Pipeline Maintenance

THIS PLAN COVERS CHEMICAL SPILLS, FIRES, AND EARTHQUAKES INVOLVING (Check all that apply): A10.

☒ 1. HAZARDOUS MATERIALS; ☒ 2. HAZARDOUS WASTES

INTERNAL FACILITY EMERGENCY RESPONSE WILL OCCUR BY (Check all that apply): B1.

☒ 1. CALLING PUBLIC EMERGENCY RESPONDERS (e.g., 9-1-1)
☒ 2. CALLING HAZARDOUS WASTE CONTRACTOR
☒ 3. ACTIVATING IN-HOUSE EMERGENCY RESPONSE TEAM

In the event of an emergency involving hazardous materials and/or hazardous waste, all facilities must IMMEDIATELY:

1. Notify facility personnel and evacuate if necessary in accordance with the Emergency Action Plan (Title 8 California Code of Regulations §3220);
2. Notify local emergency responders by calling 9-1-1;
3. Notify the local Unified Program Agency (UPA) at the phone number below; and
4. Notify the State Warning Center at (800) 852-7550.

Facilities that generate, treat, store or dispose of hazardous waste have additional responsibilities to notify and coordinate with other response agencies. Whenever there is an imminent or actual emergency situation such as an explosion, fire, or release, the Emergency Coordinator must follow the appropriate requirements for the category of facility and type of release involved:

1. Title 22 California Code of Regulations §66265.56. Emergency Procedures for generators of 1,000 kilograms or more of hazardous waste in any calendar month.
2. Title 22 California Code of Regulations §66265.196. Response to Leaks or Spills and Disposition of Leaking or Unfit-for-Use Tank Systems.
3. Title 40 Code of Federal Regulations §302.6. Notification requirements for a release of a hazardous substance equal to or greater than the reportable quantity.
4. Title 22 California Code of Regulations §66262.34(d)(2) and Title 40 Code of Federal Regulations §262.34(d)(5)(ii) for generators of less than 1000 kilograms of hazardous waste in any calendar month.

Following notification and before facility operations are resumed in areas of the facility affected by the incident, the Emergency Coordinator shall notify the local UPA and the local fire department's hazardous materials program, if necessary, that the facility is in compliance with requirements to:

1. Provide for proper storage and disposal of recovered waste, contaminated soil or surface water, or any other material that results from an explosion, fire, or release at the facility; and
2. Ensure that no material that is incompatible with the released material is transferred, stored, or disposed of in areas of the facility affected by the incident until cleanup procedures are completed.

EMERGENCY RESPONSE PHONE NUMBERS:		
AMBULANCE, FIRE, POLICE AND CHP		9-1-1
CALIFORNIA STATE WARNING CENTER (CSWC)/CAL OES.		(800) 852-7550

INTERNAL FACILITY EMERGENCY COMMUNICATIONS OR ALARM NOTIFICATION WILL OCCUR BY (Check all that apply): C11.

- ☑ 1. VERBAL WARNINGS;
- ☐ 2. PUBLIC ADDRESS OR INTERCOM SYSTEM;
- ☑ 3. TELEPHONE;
- ☐ 4. PAGERS;
- ☐ 5. ALARM SYSTEM;
- ☐ 6. PORTABLE RADIO

NOTIFICATIONS TO NEIGHBORING FACILITIES THAT MAY BE AFFECTED BY AN OFF-SITE RELEASE WILL OCCUR BY (Check all that apply): C12.

- ☑ 1. VERBAL WARNINGS;
- ☐ 2. PUBLIC ADDRESS OR INTERCOM SYSTEM;
- ☑ 3. TELEPHONE;
- ☐ 4. PAGERS;
- ☐ 5. ALARM SYSTEM;
- ☐ 6. PORTABLE RADIO

EMERGENCY COORDINATOR CONTACT INFORMATION: Scott Hedlund (661) 381-8038 C13.

PRIMARY EMERGENCY COORDINATOR NAME: Anthony Mooney PHONE NO.: (661) 763-7641 PHONE NO.: (661) 345-7643

ALTERNATE EMERGENCY COORDINATOR NAME: Cory Engle PHONE NO.: (805) 503-0787 PHONE NO.: (805) 503-0787

☐ Check if additional Emergency Coordinator contact and address information is available onsite or by calling PHONE NO.:

Note: If more than one alternate emergency coordinator is designated, attach a list in order of responsibility.

D. EMERGENCY CONTAINMENT AND CLEANUP PROCEDURES

Check the applicable boxes to indicate your facility's procedures for containing spills and preventing and mitigating releases, fires and/or explosions.

D1.

- ☑ 1. MONITOR FOR LEAKS, RUPTURES, PRESSURE BUILD-UP, ETC.;
- ☑ 2. PROVIDE STRUCTURAL PHYSICAL BARRIERS (e.g., Portable spill containment walls, built-in berms);
- ☑ 3. PROVIDE ABSORBENT PHYSICAL BARRIERS (e.g., Pads, spill pigs, spill pillows);
- ☑ 4. COVER OR BLOCK FLOOR AND/OR STORM DRAINS;
- ☑ 5. LINED TRENCH DRAINS AND/OR SUMPS;
- ☐ 6. AUTOMATIC FIRE SUPPRESSION SYSTEM;
- ☑ 7. ELIMINATE SOURCES OF IGNITION FOR FLAMMABLE HAZARDS;
- ☑ 8. STOP PROCESSES AND/OR OPERATIONS;
- ☑ 9. AUTOMATIC / ELECTRONIC EQUIPMENT SHUT-OFF SYSTEM;
- ☑ 10. SHUT OFF WATER, GAS, ELECTRICAL UTILITIES;
- ☑ 11. CALL 9-1-1 FOR PUBLIC EMERGENCY RESPONDER ASSISTANCE AND/OR MEDICAL AID;
- ☑ 12. NOTIFY AND EVACUATE PERSONS IN ALL THREATENED AND/OR IMPACTED AREAS;
- ☑ 13. ACCOUNT FOR EVACUATED PERSONS IMMEDIATELY AFTER EVACUATION;
- ☑ 14. PROVIDE PROTECTIVE EQUIPMENT FOR ON-SITE EMERGENCY RESPONSE TEAM;
- ☑ 15. REMOVE CONTAINERS AND/OR ISOLATE AREAS;
- ☑ 16. HIRE LICENSED HAZARDOUS WASTE CONTRACTOR;
- ☑ 17. USE ABSORBENT MATERIAL FOR SPILL CONTAINMENT;
- ☑ 18. VACUUM SUCTION USING APPROPRIATE VACUUM (e.g., Intrinsically safe) FOR SPILL CONTROL AND/OR CLEANUP;
- ☑ 19. DECONTAMINATE PERSONNEL AND EQUIPMENT WITHIN DESIGNATED AREA AND DISPOSE OF WASTEWATER AS HAZARDOUS WASTE;
- ☑ 20. PROVIDE SAFE TEMPORARY STORAGE OF HAZARDOUS WASTE GENERATED DURING EMERGENCY ACTIONS;
- ☐ 21. OTHER (Specify): D2.

E. FACILITY EVACUATION

THE FOLLOWING ALARM SIGNAL(S) WILL BE USED TO BEGIN EVACUATION OF THE FACILITY (Check all that apply): E1.

E2.

- ☐ 1. BELLS;
- ☐ 2. HORNS/SIRENS;
- ☑ 3. VERBAL (i.e., Shouting);
- ☐ 4. OTHER (Specify):

THE FOLLOWING LOCATION(S) WILL BE USED FOR AN EMERGENCY ASSEMBLY AREA(S) (e.g., Parking lot, street corner): E3.

Main entrance gate south of the facility by Highway 166.

Note: The Emergency Coordinator must account for all onsite employees and visitors after evacuation.

EVACUATION ROUTE S AND ALTERNATE EVACUATION ROUTES ARE DESCRIBED AS FOLLOWS: E4.

- ☑ 1. WRITTEN PROCEDURES DESCRIBING ROUTES, EXITS, AND ASSEMBLY AREAS;
- ☑ 2. EVACUATION MAP(S) DEPICTING ROUTES, EXITS, AND ASSEMBLY AREAS;
- ☐ 3. OTHER (Specify): E5.

Note: Evacuation procedures and/or maps should be posted in visible facility locations and must be included in the Contingency Plan.

F. ARRANGEMENTS FOR EMERGENCY SERVICES

ADVANCE ARRANGEMENTS FOR LOCAL EMERGENCY SERVICES (Check one of the following): F1.

- ☐ 1. HAVE BEEN DETERMINED NOT NECESSARY;
- ☑ 2. THE FOLLOWING ARRANGEMENTS HAVE BEEN MADE (Specify): OSRO contracts our in place with Clean Harbors and Patriot Environmental as listed in our Integrated Contingency Plan. F2.

Note: Advance arrangements with local fire and police departments, hospitals, state and local emergency response teams, and/or emergency services contractors should be made for your facility, if necessary. Large Quantity Generators must describe arrangements in the Contingency Plan.

G. EMERGENCY EQUIPMENT

Check the applicable boxes to list emergency response equipment available at the facility, identify the location(s) where the equipment is kept, and indicate the equipment's capability, if applicable.

TYPE	EQUIPMENT AVAILABLE G1.	LOCATION G2.	CAPABILITY G3.
EXAMPLE	☒ *CHEMICAL PROTECTIVE GLOVES*	*SPILL RESPONSE KIT*	*SINGLE USE, OIL RESISTANT ONLY*
Safety and First Aid	1. ▣ CHEMICAL PROTECTIVE SUITS, APRONS, AND/OR VESTS	Located at Continental Station	Single Use
	2. ▣ CHEMICAL PROTECTIVE GLOVES	Located at Continental Station	Single Use
	3. ▣ CHEMICAL PROTECTIVE BOOTS	Located at Continental Station	Single Use
	4. ▣ SAFETY GLASSES, GOGGLES, AND FACE SHIELDS	In all company vehicles	
	5. ▣ HARD HATS	In all company vehicles	
	6. ▣ AIR-PURIFYING RESPIRATORS		Single Use
	7. ☐ SELF-CONTAINED BREATHING APPARATUS (SCBA)		
	8. ▣ FIRST AID KITS	In company vehicles and control room	Single Use, < 25 employees
	9. ☐ PLUMBED EYEWASH FOUNTAIN AND/OR SHOWER		
	10. ▣ PORTABLE EYEWASH KITS AND/OR STATION	Outside control room exit	Single Use
	11. ☐ OTHER		
Fire Fighting	12. ▣ PORTABLE FIRE EXTINGUISHERS	In company vehicles/see facility maps	Single Use, 25 lb extinguisher
	13. ☐ FIXED FIRE SUPPRESSION SYSTEMS AND/ OR SPRINKLERS		
	14. ☐ FIRE ALARM BOXES		
	15. ☐ OTHER		
Spill Control and Clean-Up	16. ▣ ALL-IN-ONE SPILL KIT	At control room spill kit	Single Use, 95 gallon capacity
	17. ▣ ABSORBENT MATERIAL	At control room spill kit	Single Use, 95 gallon capacity
	18. ▣ CONTAINER FOR USED ABSORBENT	At control room spill kit	Single Use, 95 gallon capacity
	19. ☐ BERM AND/OR DIKING EQUIPMENT		
	20. ☐ BROOM		
	21. ■ SHOVEL	At Continental Station	
	22. ■ VACUUM	Patriot/Clean Harbors	130 BBL per truck
	23. ☐ EXHAUST HOOD		
	24. ☐ SUMP AND/OR HOLDING TANK		
	25. ☐ CHEMICAL NEUTRALIZERS		
	26. ☐ GAS CYLINDER LEAK REPAIR KIT		
	27. ▣ SPILL OVERPACK DRUMS		1-95 gallon overpack at each facility
	28. ☐ OTHER		
Communi-cations and Alarm Systems	29. ▣ TELEPHONES (e.g., Cellular)		
	30. ☐ INTERCOM AND/OR PA SYSTEM		
	31. ☐ PORTABLE RADIOS		
	32. ☐ AUTOMATIC ALARM CHEMICAL MONITORING EQUIPMENT		
Other	33. ☐ OTHER		
	34. ☐ OTHER		

H. EARTHQUAKE VULNERABILITY

Identify areas of the facility that are vulnerable to hazardous materials releases due to seismic motion. These areas require immediate isolation and inspection.

VULNERABLE AREAS (Check all that apply): H1.

- ☐ 1. HAZARDOUS MATERIALS AND/OR WASTE STORAGE AREAS
- ☒ 2. PROCESS LINES AND PIPING
- ☐ 3. LABORATORY
- ☐ 4. WASTE TREATMENT AREA

LOCATIONS (e.g., Shop, outdoor shed, lab): H2.

Throughout facility, below and above ground.

Identify mechanical systems vulnerable to releases / spills due to earthquake-related motion. These systems require immediate isolation and inspection.

VULNERABLE SYSTEMS AND/OR EQUIPMENT (Check all that apply): H3.

- ☐ 1. SHELVES, CABINETS AND/OR RACKS
- ☐ 2. TANKS AND SHUT-OFF VALVES
- ☐ 3. PORTABLE GAS CYLINDERS
- ☒ 4. EMERGENCY SHUT-OFF AND/OR UTILITY VALVES
- ☐ 5. SPRINKLER SYSTEMS
- ☐ 6. STATIONARY PRESSURIZED CONTAINERS (e.g., Propane tank)

LOCATIONS: H4.

Facility is equipped with seismic detection equipment which shuts facility down at 6.0 or above earthquake

I. EMPLOYEE TRAINING

Employee training is required for all employees and/or contractors handling hazardous materials and/or hazardous wastes during normal and/or emergency operations. Most facilities will need to submit a separate Training Plan. However, your CUPA may accept this section as the Training Plan for some small facilities.
Employee training plans may include the following content:

- Applicable laws and regulations;
- Emergency response plans and procedures;
- Safety Data Sheets;
- Hazard communication related to health and safety;
- Methods for safe handling of hazardous substances;
- Hazards of materials and processes (e.g., fire, explosion, asphyxiation);
- Hazard mitigation, prevention and abatement procedures;
- Coordination of emergency response actions;
- Notification procedures for local emergency responders, CUPA, Cal OES, and onsite personnel;
- Communication and alarm systems;
- Personal protective equipment;
- Use and maintenance of emergency response equipment and supplies (e.g. Fire extinguishers, respirators, spill control materials);
- Decontamination procedures;
- Evacuation procedures and evacuation staging locations;
- Identification of facility areas, equipment, and systems vulnerable to earthquakes and other natural disasters.
- OTHER (Specify): Training is web based

Check the applicable boxes below to indicate how the employee training program is administered.

☐ 1. FORMAL CLASSROOM ☐ 2. VIDEOS ☐ 3. SAFETY MEETINGS ☐ 4. STUDY GUIDES / MANUALS I1.

☐ 5. OTHER (Specify): _____ I2.

☒ 6. NOT APPLICABLE SINCE FACILITY HAS NO EMPLOYEES

☐ 7. CHECK IF A SEPARATE EMPLOYEE TRAINING PLAN IS USED AND UPLOADED TO CERS AS A PDF DOCUMENT I3.

☐ 8. CHECK IF EMPLOYEE TRAINING IS COVERED BY THE ABOVE REFERENCED CONTENT AND OTHER DOCUMENTS ONSITE I4.

EMPLOYEE TRAINING FREQUENCY AND RECORDKEEPING TRAINING MUST BE:

- Provided initially for new employees as soon as possible following the date of hire. New employees should not work in an unsupervised position that involves hazardous materials handling and/or hazardous waste management without proper training;
- Provided within six months from the date of hire for new employees at a large quantity generator;
- Ongoing and provided at least annually;
- Amended prior to a change in process or work assignment;
- Given upon modification to the Emergency Response/Contingency Plan.

Large Quantity Generator Training: Large quantity generators (1,000 kg or more) must retain written plan and documentation of employee training which includes:

- A written description of the type and amount of both initial and ongoing training that will be given to persons filling each job position having responsibility for hazardous waste management and/or emergency response.
- The name, job title and job description for each position at the facility related to hazardous waste management.
- Current employee training records must be retained until closure of the facility and former employee training records must be retained for at least three years after termination of employment.

Small Quantity Generator Training: Small quantity generators (less than 1,000 kg) must include basic hazardous waste management and emergency response procedures but a written employee training plan and training records are not required. In order to show that the facility has met the small quantity generator employee training requirement, an employee training plan and training records may be made available.

Hazardous Materials Business Plan Training: Businesses must provide initial and annual employee training that includes the content referenced above. The training may be based on the job position and training records must be made available for a period of at least three years.

Facility ID: FA0000222 CERS ID: _____

Consent: By signing this document, you are consenting to an inspection of the above referenced facility by the Kern County Public Health Services Department, Environmental Health Division, Certified Unified Program Agency (CUPA) for the county of Kern. The State of California has authorized the CUPA to conduct business facility inspections for compliance with the programs listed below. These inspections may include the inspection of all business areas on the property, the review and copying of records, the taking of photographs, and the taking of samples to evaluate compliance with CUPA requirements. The following Health and Safety Code (HSC) sections give the CUPA the authority to inspect:

- Hazardous Waste (Health & Safety Code [HSC § 25185, subd. (a)];
- California Accidental Release Prevention (HSC § 25534.5);
- Hazardous Materials Release Response Plans [HSC § 25508, subd. (a)];
- Underground Storage Tanks – (HSC § 25289); and
- Aboveground Storage Tanks – [HSC § 25270.5, subd. (a)].

Inspection Element: BUS PLAN LARGE LOW RISK 1 UNIT		

File/CERS Review Violations

V	Viol #	Summary	Code
	H335	Failure to adequately complete and submit a HMBP into the California Environmental Reporting System (CERS)	HSC 6.95 25505, 25508(a)(1), 25508(d)
	H344	Failure to complete and submit the Business Activities Page and/or Business Owner Operator Identification Page in CERS	HSC 6.95 25508(a)(1); 19 CCR 4 2729.2(a)(1);
	H342	Failure to complete and submit hazardous material inventory information for all reportable hazardous materials on site in CERS	HSC 6.95 25505(a)(1), 25506, 25508(a)(1)
	H341	Failure to annually review and electronically certify that the business plan is complete, accurate, and up-to-date in CERS	HSC 6.95 25508(c), 25508.2
	H346	Failure to complete and submit a site map with all required content in CERS	HSC 6.95 25505(a)(2), 25508(a)(1)
	H347	Failure to submit an adequate emergency response plan and procedures in CERS	HSC 6.95 25505(a)(3), 25508(a)(1)
	H353	Failure to submit an adequate training program in CERS	HSC 6.95 25505(a)(4), 25508(a)(1)
	H340	Failure to notify property owner in writing that a HMBP is required	HSC 6.95 25505.1
	H336	Failure to provide property owner a copy of the HMBP upon request	HSC 6.95 25505.1

Onsite Inspection Violations

V	Viol #	Summary	Code
	H334	Failure to adequately establish and implement a HMBP	HSC 6.95 25507
	H343	Failure to revise HMBP in CERS within 30 days upon a substantial change in the handler's operation	HSC 6.95 25508.1(f)
	H345	Failure to update Facility Information and/or Hazardous Materials Inventory in CERS within 30 days upon a significant change	HSC 6.95 25508.1(a)-(e)
	H348	Failure to provide initial and annual safety training to all employees and/or failure to document and maintain training records for 3 years	HSC 6.95 25505(a)(4)
	H338	Failure to report a release or threatened release of a hazardous material to the CUPA and to California Office of Emergency Services	HSC 6.95 25510(a)

Inspector: WAQAR RUSTAM **Inspection Date:** 02/18/2016

CONDITIONAL EXEMPTIONS FROM REPORTING REQUIREMENTS

Agricultural handlers are conditionally exempt from electronically submitting Emergency Response and Employee Training Plans in CERS if the following requirements are met:

- Owner/Operator annually submits the Facility Information and Hazardous Materials Inventory electronically into CERS
- Each location/building, where hazardous materials (i.e. pesticides, petroleum products, fertilizers, etc.) are stored, is posted with warning signs that meet the following requirements:
  - Shall be conspicuous and visible from any direction of probable approach
  - Shall be of such size that it is readable from 25 feet and shall be labeled as follows:

> DANGER HAZARDOUS MATERIAL STORAGE AREA
> (the hazardous materials stored within shall be noted by category
> [i.e. pesticides, petroleum products, fertilizers, etc.])
> ALL UNAUTHORIZED PERSONS-KEEP OUT - IN AN EMERGENCY, CONTACT:
> (list the name and phone number of an emergency contact person(s))

  - Shall be repeated in an appropriate language other than English when persons who do not understand the English language may enter the posted location/building
- Owner/Operator provides training for all new employees and annual training, including refresher courses, for all employees in safety procedures in the event of a release or threatened release of a hazardous material, including, but not limited to, familiarity with the emergency plans and procedures

Exempt Facility Violations

V	Viol #	Summary	Code
	H760	Failure to submit Emergency Response/Contingency Plan in CERS when not meeting agricultural handler exemption requirements	HSC 6.95 25507.1, 25508(a)(1); 19 CCR 4 2733, 2734
	H758	Failure to submit Employee Training Plan in CERS when not meeting agricultural handler exemption requirements	HSC 6.95 25507.1, 25508(a)(1); 19 CCR 4 2733, 2734
	H759	Failure to establish and submit a HMBP in CERS when not meeting remote unstaffed facility exemption requirements	HSC 6.95 25505, 25506, 25507, 25507.2, 25508(a)(1)

SUMMARY OF OBSERVATIONS/VIOLATIONS

☒ **No violations of hazardous materials business plan laws/regulations were discovered. KERN CUPA greatly appreciates your efforts to comply with all the laws and regulations applicable to your facility.**

☐ **Violations were observed/discovered as listed below. ALL VIOLATIONS MUST BE CORRECTED WITHIN 30 DAYS OR AS SPECIFIED. CUPA must be informed in writing with a certification that compliance has been achieved. A false statement that compliance has been achieved is a violation of the law and punishable by a fine of not less than $2,000 or more than $25,000 for each violation. Your facility may be reinspected any time during normal business hours. If a second reinspection becomes necessary due to non compliance, a reinspection charge of $100.00 per hour may be charged to the facility.**

You may request a meeting with the Program Manager to discuss the inspection findings and/or the proposed corrective actions. The issuance of this Summary of Violations does not preclude the CUPA from taking administrative, civil, or criminal action.

SUMMARY OF OBSERVATIONS/VIOLATIONS

☒ **No violations of hazardous waste laws/regulations were discovered. KERN CUPA greatly appreciates your efforts to comply with all the laws and regulations applicable to your facility.**

☐ **Violations were observed/discovered as listed below. All violations must be corrected by implementing the corrective action listed by each violation. If you disagree with any of the violations or corrective actions required, please inform the CUPA in writing.**

ALL VIOLATIONS MUST BE CORRECTED WITHIN 30 DAYS OR AS SPECIFIED. CUPA must be informed in writing with a certification that compliance has been achieved. A false statement that compliance has been achieved is a violation of the law and punishable by a fine of not less than $2,000 or more than $25,000 for each violation. Your facility may be reinspected any time during normal business hours. If a second reinspection becomes necessary due to non compliance, a reinspection charge of $100.00 per hour may be charged to the facility.

You may request a meeting with the Program Manager to discuss the inspection findings and/or the proposed corrective actions. The issuance of this Summary of Violations does not preclude the CUPA from taking administrative, civil, or criminal action.

Inspector: MARTY A BROWNFIELD **Inspection Date:** 11/13/2020

CONDITIONAL EXEMPTIONS FROM REPORTING REQUIREMENTS

Agricultural handlers are conditionally exempt from electronically submitting Emergency Response and Employee Training Plans in CERS if the following requirements are met:

- Owner/Operator annually submits the Facility Information and Hazardous Materials Inventory electronically into CERS
- Each location/building, where hazardous materials (i.e. pesticides, petroleum products, fertilizers, etc.) are stored, is posted with warning signs that meet the following requirements:
  - Shall be conspicuous and visible from any direction of probable approach
  - Shall be of such size that it is readable from 25 feet and shall be labeled as follows:

DANGER HAZARDOUS MATERIAL STORAGE AREA
(the hazardous materials stored within shall be noted by category
[i.e. pesticides, petroleum products, fertilizers, etc.])
ALL UNAUTHORIZED PERSONS-KEEP OUT - IN AN EMERGENCY, CONTACT:
(list the name and phone number of an emergency contact person(s))

  - Shall be repeated in an appropriate language other than English when persons who do not understand the English language may enter the posted location/building
- Owner/Operator provides training for all new employees and annual training, including refresher courses, for all employees in safety procedures in the event of a release or threatened release of a hazardous material, including, but not limited to, familiarity with the emergency plans and procedures

Exempt Facility Violations

V	Viol #	Summary	Code
	H760	Failure to submit Emergency Response/Contingency Plan in CERS when not meeting agricultural handler exemption requirements	HSC 6.95 25507.1, 25508(a)(1); 19 CCR 4 2733, 2734
	H758	Failure to submit Employee Training Plan in CERS when not meeting agricultural handler exemption requirements	HSC 6.95 25507.1, 25508(a)(1); 19 CCR 4 2733, 2734
	H857	Failure of agricultural handler to post warning signs on buildings where pesticides, petroleum, or fertilizers are stored as required in the exemption.	HSC 6.95 25507.1(a)(2); 19 CCR 4 2670, 2671
	H759	Failure to establish and submit a HMBP in CERS when not meeting remote unstaffed facility exemption requirements	HSC 6.95 25505, 25506, 25507, 25507.2, 25508(a)(1)

SUMMARY OF OBSERVATIONS/VIOLATIONS

☐ **No violations of hazardous materials business plan laws/regulations were discovered. KERN CUPA greatly appreciates your efforts to comply with all the laws and regulations applicable to your facility.**

☒ **Violations were observed/discovered as listed below. ALL VIOLATIONS MUST BE CORRECTED WITHIN 30 DAYS OR AS SPECIFIED. CUPA must be informed in writing with a certification that compliance has been achieved. A false statement that compliance has been achieved is a violation of the law and punishable by a fine of not less than $2,000 or more than $25,000 for each violation. Your facility may be reinspected any time during normal business hours. If a second reinspection becomes necessary due to non compliance, a reinspection charge of $115.00 per hour may be charged to the facility.**

You may request a meeting with the Program Manager to discuss the inspection findings and/or the proposed corrective actions. The issuance of this Summary of Violations does not preclude the CUPA from taking administrative, civil, or criminal action.

VIOLATIONS

Violation Number	Violation Text	Violation Degree	Comply by
H342	**Failure to complete and electronically submit Hazardous Materials Inventory information for all hazardous materials on site at or above reportable quantities. HSC 6.95 25506, 25505(a)(1), 25508(a)(1)**	**CLASS II VIOLATION**	**12/13/2020**

Inspector: **MARTY A BROWNFIELD** **Inspection Date:** **11/13/2020**

Violation Details & Corrective Action Required:

The facility Owner/Operator needs to make the following revisions to the hazardous materials inventory they have submitted in the California Environmental Reporting System (CERS):

1.) The facility is reporting the "Storage Temperature" and "Storage Pressure" wrong.
a.) All non aerosol containers (cans, buckets, drums, etc) should be reported as being stored "AT" ambient temperature and pressure.
b.) All aerosol spray cans should be reported as being stored "AT" ambient temperature and "ABOVE" ambient pressure.

The facility Owner/Operator has been directed twice before to correct these issues, (1) August 2, 2018, (2) June 23, 2020. These corrections should have been made within 30 days of being told to complete them. (See Attached CERS Pages)

Please complete the required submittal No Later Than December 13, 2020. Please email your Inspector, Marty Brownfield - martyb@kerncounty.com when you have completed the required submittal so the violation can be cleared.

H344 **Failure to complete and electronically submit the Business Activities page and/or Business Owner/Operator Identification page. HSC 6.95 25508(a)(1), 19 CCR 4 2652(a)(1)** **CLASS II VIOLATION** **12/13/2020**

Violation Details & Corrective Action Required:

Facility needs to update the following information in the California Environmental Reporting System (CERS) "Business activities Page"
1.) Change physical address to "actual" location. ie: "AERA Energy Belridge property - Hill Road - Contractor Lot XXX" Currently you are using the AERA street address.
2.) Change the answer to the "Do you generate hazardous waste" from no to YES.

Please complete the required submittal No Later Than December 13, 2020. Please email your Inspector, Marty Brownfield - martyb@kerncounty.com when you have completed the required submittal so the violation can be cleared.

H347 **Failure to establish and electronically submit an adequate Emergency Response/Contingency Plan and procedures for use in the event of a release or threatened release of a hazardous material, including, but not limited to, all of the following:**
(A) Immediate notification contacts to the appropriate local emergency response personnel and to the unified program agency.
(B) Procedures for the mitigation of a release or threatened release to minimize any potential harm or damage to persons, property, or the environment.
(C) Evacuation plans and procedures, including immediate notice, for the business site. HSC 6.95 25505(a)(3), 25508(a)(1) **CLASS II VIOLATION** **12/13/2020**

Violation Details & Corrective Action Required:

The facility's contingency plan currently uploaded in CERS does not contain all required information. (Please refer to attached CERS pages)

The facility Owner/Operator is directed to complete and upload the "Template Format" Consolidated Contingency Plan that is available as a download fillable PDF. Please ensure you also include Kern County Environmental Health office number 661-862-8740 and Kern County Environmental Health 24 Hr. Emergency Response and Spill Reporting Number 661-549-9927 in the areas provided on the template.

Please complete the required submittal No Later Than December 13, 2020. Please email your Inspector, Marty Brownfield - martyb@kerncounty.com when you have completed the required submittal so the violation can be cleared.

	H291	Failure to meet secondary containment requirements for hazardous waste tank systems or components	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.193
	H294	Failure to immediately remove from service a tank system which is unfit for use and/or comply with applicable requirements	22 CCR 15 66265.196
	H292	Failure to meet tank system closure requirements	22 CCR 15 66265.111, 66265.114, 66265.197
	H286	Failure to obtain and/or maintain a new hazardous waste tank assessment by a professional engineer	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.192(a)
	H800	Failure to complete an assessment or reassessment of a hazardous waste tank as required	22 CCR 15 66265.192(h)
	H312	Failure to conduct hazardous waste tank system cathodic protection system inspections as required	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.195(b), 66265.195(c)
	H815	Failure to comply with air emmisions requirements for hazardous waste in containers	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.178
	H816	Failure to comply with air emmisions requirements for hazardous waste in tanks	22 CCR 12 66262.34(a)(1); 22 CCR 15 66265.202
	H307	Failure to have all required emergency equipment	22 CCR 12 66262.34(a)(4); 22 CCR 15 66265.32
	H301	Failure to inspect and/or maintain all safety/emergency equipment as required	22 CCR 12 66262.34(a)(4); 22 CCR 15 66265.33
	H244	Failure to complete Uniform Hazardous Waste Manifest exception report when required	22 CCR 12 66262.42(a),(b),(d)
	H799	Failure to complete certification of waste minimization on all manifests	22 CCR 12 66262.27(a)
	H257	Failure to adequately complete, and maintain for review, all requirements of the source reduction evaluation review and plan (SB-14)	HSC 6.5 25244.19, 25244.21; 22 CCR 31 67100.5
	H254	Failure to properly prepare a source reduction evaluation review and plan every four years	HSC 6.5 25244.19; 22 CCR 31 67100.7, 67100.8
	H255	Failure to prepare a summary progress report and submitted it to DTSC every four years	22 CCR 31 67100.9

Universal Waste Generator - Violations

V	VIOL #	Summary	Code
	H318	Failure to comply with all universal waste training requirements	22 CCR 23 66273.36
	H321	Faillure to meet universal waste labeling requirements	22 CCR 23 66273.34
	H330	Universal waste accumulation exceeded the 1 year limit	22 CCR 23 66273.35
	H329	Failure to disposal of universal waste at an appropriate destination facility	22 CCR 23 66273.31(a)
	H320	Failure to properly prepare and/or retain shipping papers for all universal waste shipped	22 CCR 23 66273.38; 49 CFR 1 172.201(e)
	H325	Failure to handle waste aerosol cans to prevent fire, explosion, and/or release	HSC 6.5 25201.16(e)
	H328	Failure to meet accumulation standards for aerosol cans	HSC 6.5 25201.16(f)
	H326	Failure to properly clean up and/or contain spills of electronic devices, CRTs and/or CRT glass	22 CCR 23 66273.33.5

Waste Lead Acid Battery Generator - Violations

V	VIOL #	Summary	Code
	H290	Failure to meet requirements for handling, storing, and/or transporting lead acid batteries	22 CCR 16 66266.81(a)(1)
	H293	Failure to properly manage, store, and/or label damaged lead acid batteries	22 CCR 16 66266.81(b)
	H250	Failure to maintain documentation for disposal of lead acid batteries for 3 years	22 CCR 16 66266.81(a)(4)(B)
	H261	Failure to meet all requirements when accepting spent lead acid batteries	22 CCR 16 66266.81(a)(3)

SUMMARY OF OBSERVATIONS/VIOLATIONS

☐ **No violations of hazardous waste laws/regulations were discovered. KERN CUPA greatly appreciates your efforts to comply with all the laws and regulations applicable to your facility.**

☒ **Violations were observed/discovered as listed below. All violations must be corrected by implementing the corrective action listed by each violation. If you disagree with any of the violations or corrective actions required, please inform the CUPA in writing.**

ALL VIOLATIONS MUST BE CORRECTED WITHIN 30 DAYS OR AS SPECIFIED. CUPA must be informed in writing with a certification that compliance has been achieved. A false statement that compliance has been achieved is a violation of the law and punishable by a fine of not less than $2,000 or more than $25,000 for each violation. Your facility may be reinspected any time during normal business hours. If a second reinspection becomes necessary due to non compliance, a reinspection charge of $115.00 per hour may be charged to the facility.

You may request a meeting with the Program Manager to discuss the inspection findings and/or the proposed corrective actions. The issuance of this Summary of Violations does not preclude the CUPA from taking administrative, civil, or criminal action.

VIOLATIONS

Violation Number	Violation Text	Violation Degree	Comply by
H236	**Failure to obtain an Identification Number prior to treating, storing, disposing of, transporting or offering for transportation any hazardous waste. 22 CCR 12 66262.12**	**CLASS II VIOLATION**	**12/13/2020**

Violation Details & Corrective Action Required:

The facility is a generator of hazardous wastes (paints, coatings & paint related wastes). Facility has an agreement with AERA Energy to take their waste generated on AERA property to AERA's waste consolidation area for disposal.

The facility's "Temporary" EPA ID Number has been inactive since September 24, 2018. Facility Owner/Operator is directed to obtain a Permanent EPA Hazardous Waste Generator Identification Number from the California Department of Toxic Substances Control.

Please complete the required application to DTSC and submit proff of compliance No Later Than December 13, 2020. Please email your Inspector, Marty Brownfield - martyb@kerncounty.com when you have completed the required submittal so the violation can be cleared.

INSPECTION COMMENTS:

COMMENTS: **Go to http://www.kernpublichealth.com/hazardous-materials for forms and information.**

Inspector: MARTY A BROWNFIELD
Inspection Date: 11/13/2020

Signature of Facility Representative:

Certification: I certify under penalty of perjury that this facility has complied with the corrective actions listed on this inspection form.

Hazardous Materials

Does your facility have on site (for any purpose) at any one time, hazardous materials at or above 55 gallons for liquids, 500 pounds for solids, or 200 cubic feet for compressed gases (include liquids in ASTs and USTs); or is regulated under more restrictive inventory local reporting requirements (shown below if present); or the applicable Federal threshold quantity for an extremely hazardous substance specified in 40 CFR Part 355, Appendix A or B; or handle radiological materials in quantities for which an emergency plan is required pursuant to 10 CFR Parts 30, 40 or 70?	**Yes**

Underground Storage Tank(s) (UST)

Does your facility own or operate underground storage tanks?	**No**

Hazardous Waste

Is your facility a Hazardous Waste Generator?	**Yes**
Does your facility treat hazardous waste on-site?	**No**
Is your facility's treatment subject to financial assurance requirements (for Permit by Rule and Conditional Authorization)?	**No**
Does your facility consolidate hazardous waste generated at a remote site?	**No**
Does your facility need to report the closure/removal of a tank that was classified as hazardous waste and cleaned on-site?	**No**
Does your facility generate in any single calendar month 1,000 kilograms (kg) (2,200 pounds) or more of federal RCRA hazardous waste, or generate in any single calendar month greater than 1 kg (2.2 pounds) of RCRA acute hazardous waste; or generate more than 100 kg (220 pounds) of spill cleanup materials contaminated with RCRA acute hazardous waste.	**No**
Is your facility a Household Hazardous Waste (HHW) Collection site?	**No**

Excluded and/or Exempted Materials

Does your facility recycle more than 100 kg/month of excluded or exempted recyclable materials (per HSC 25143.2)?	**No**
Does your facility own or operate ASTs above these thresholds? Store greater than 1,320 gallons of petroleum products (new or used) in aboveground tanks or containers.	**No**
Does your facility have Regulated Substances stored onsite in quantities greater than the threshold quantities established by the California Accidental Release prevention Program (CalARP)?	**No**

Additional Information

No additional comments provided.

CONSOLIDATED EMERGENCY RESPONSE / CONTINGENCY PLAN

Prior to completing this Plan, please refer to the INSTRUCTIONS FOR COMPLETING A CONSOLIDATED CONTINGENCY PLAN

FACILITY ID #	CERS ID #	DATE OF PLAN PREPARATION/REVISION (MM/DD/YYYY)
FA 0 0 0 0 4 8 5 6 7 (A1.)	10767367 (A2.)	12/03/2020 (A3.)

BUSINESS NAME *(Same as Facility Name or DBA - Doing Business As)* (A4.)
Advanced Industrial Services, Inc.

BUSINESS SITE ADDRESS (A5.)
20322 7th Standard Road Lot 102 Hill Road

BUSINESS SITE CITY (A6.)		ZIP CODE (A7.)
Lost Hills	CA	93251

TYPE OF BUSINESS (e.g., Painting Contractor) (A8.)	INCIDENTAL OPERATIONS (e.g., Fleet Maintenance) (A9.)
Industrial Painting Contractor	Equipment Storage Facility

THIS PLAN COVERS CHEMICAL SPILLS, FIRES, AND EARTHQUAKES INVOLVING (Check all that apply): (A10.)

☒ 1. HAZARDOUS MATERIALS; ☒ 2. HAZARDOUS WASTES

INTERNAL FACILITY EMERGENCY RESPONSE WILL OCCUR BY (Check all that apply): (B1.)

☒ 1. CALLING PUBLIC EMERGENCY RESPONDERS (e.g., 9-1-1)
☒ 2. CALLING HAZARDOUS WASTE CONTRACTOR
☐ 3. ACTIVATING IN-HOUSE EMERGENCY RESPONSE TEAM

In the event of an emergency involving hazardous materials and/or hazardous waste, all facilities must IMMEDIATELY:
1. Notify facility personnel and evacuate if necessary in accordance with the Emergency Action Plan (Title 8 California Code of Regulations §3220);
2. Notify local emergency responders by calling 9-1-1;
3. Notify the local Unified Program Agency (UPA) at the phone number below; and
4. Notify the State Warning Center at (800) 852-7550.

Facilities that generate, treat, store or dispose of hazardous waste have additional responsibilities to notify and coordinate with other response agencies. Whenever there is an imminent or actual emergency situation such as an explosion, fire, or release, the Emergency Coordinator must follow the appropriate requirements for the category of facility and type of release involved:
1. Title 22 California Code of Regulations §66265.56. Emergency Procedures for generators of 1,000 kilograms or more of hazardous waste in any calendar month.
2. Title 22 California Code of Regulations §66265.196. Response to Leaks or Spills and Disposition of Leaking or Unfit-for-Use Tank Systems.
3. Title 40 Code of Federal Regulations §302.6. Notification requirements for a release of a hazardous substance equal to or greater than the reportable quantity.
4. Title 22 California Code of Regulations §66262.34(d)(2) and Title 40 Code of Federal Regulations §262.34(d)(5)(ii) for generators of less than 1000 kilograms of hazardous waste in any calendar month.

Following notification and before facility operations are resumed in areas of the facility affected by the incident, the Emergency Coordinator shall notify the local UPA and the local fire department's hazardous materials program, if necessary, that the facility is in compliance with requirements to:
1. Provide for proper storage and disposal of recovered waste, contaminated soil or surface water, or any other material that results from an explosion, fire, or release at the facility; and
2. Ensure that no material that is incompatible with the released material is transferred, stored, or disposed of in areas of the facility affected by the incident until cleanup procedures are completed.

EMERGENCY RESPONSE PHONE NUMBERS:

	OTHER (Specify): (C7.)	(C8.)
	OTHER (Specify): (C9.)	(C10.)

INTERNAL FACILITY EMERGENCY COMMUNICATIONS OR ALARM NOTIFICATION WILL OCCUR BY (Check all that apply): C11.

- [x] 1. VERBAL WARNINGS;
- [ ] 2. PUBLIC ADDRESS OR INTERCOM SYSTEM;
- [x] 3. TELEPHONE;
- [ ] 4. PAGERS;
- [ ] 5. ALARM SYSTEM;
- [ ] 6. PORTABLE RADIO

NOTIFICATIONS TO NEIGHBORING FACILITIES THAT MAY BE AFFECTED BY AN OFF-SITE RELEASE WILL OCCUR BY (Check all that apply): C12.

- [x] 1. VERBAL WARNINGS;
- [ ] 2. PUBLIC ADDRESS OR INTERCOM SYSTEM;
- [x] 3. TELEPHONE;
- [ ] 4. PAGERS;
- [ ] 5. ALARM SYSTEM;
- [ ] 6. PORTABLE RADIO

EMERGENCY COORDINATOR CONTACT INFORMATION: Ty Johnston C13.

PRIMARY EMERGENCY COORDINATOR NAME: Ty Johnston PHONE NO.: (562) 243-4787 PHONE NO.:

ALTERNATE EMERGENCY COORDINATOR NAME: Jaime Cuevas PHONE NO.: (562) 824-6172 PHONE NO.:

- [ ] Check if additional Emergency Coordinator contact and address information is available onsite or by calling PHONE NO.: -

Note: If more than one alternate emergency coordinator is designated, attach a list in order of responsibility.

D. EMERGENCY CONTAINMENT AND CLEANUP PROCEDURES

Check the applicable boxes to indicate your facility's procedures for containing spills and preventing and mitigating releases, fires and/or explosions.

D1.

- [x] 1. MONITOR FOR LEAKS, RUPTURES, PRESSURE BUILD-UP, ETC.;
- [ ] 2. PROVIDE STRUCTURAL PHYSICAL BARRIERS (e.g., Portable spill containment walls, built-in berms);
- [x] 3. PROVIDE ABSORBENT PHYSICAL BARRIERS (e.g., Pads, spill pigs, spill pillows);
- [ ] 4. COVER OR BLOCK FLOOR AND/OR STORM DRAINS;
- [ ] 5. LINED TRENCH DRAINS AND/OR SUMPS;
- [ ] 6. AUTOMATIC FIRE SUPPRESSION SYSTEM;
- [ ] 7. ELIMINATE SOURCES OF IGNITION FOR FLAMMABLE HAZARDS;
- [x] 8. STOP PROCESSES AND/OR OPERATIONS;
- [ ] 9. AUTOMATIC / ELECTRONIC EQUIPMENT SHUT-OFF SYSTEM;
- [ ] 10. SHUT OFF WATER, GAS, ELECTRICAL UTILITIES;
- [x] 11. CALL 9-1-1 FOR PUBLIC EMERGENCY RESPONDER ASSISTANCE AND/OR MEDICAL AID;
- [x] 12. NOTIFY AND EVACUATE PERSONS IN ALL THREATENED AND/OR IMPACTED AREAS;
- [x] 13. ACCOUNT FOR EVACUATED PERSONS IMMEDIATELY AFTER EVACUATION;
- [ ] 14. PROVIDE PROTECTIVE EQUIPMENT FOR ON-SITE EMERGENCY RESPONSE TEAM;
- [ ] 15. REMOVE CONTAINERS AND/OR ISOLATE AREAS;
- [x] 16. HIRE LICENSED HAZARDOUS WASTE CONTRACTOR;
- [x] 17. USE ABSORBENT MATERIAL FOR SPILL CONTAINMENT;
- [ ] 18. VACUUM SUCTION USING APPROPRIATE VACUUM (e.g., Intrinsically safe) FOR SPILL CONTROL AND/OR CLEANUP;
- [ ] 19. DECONTAMINATE PERSONNEL AND EQUIPMENT WITHIN DESIGNATED AREA AND DISPOSE OF WASTEWATER AS HAZARDOUS WASTE;
- [ ] 20. PROVIDE SAFE TEMPORARY STORAGE OF HAZARDOUS WASTE GENERATED DURING EMERGENCY ACTIONS;
- [ ] 21. OTHER (Specify):

D2.

E. FACILITY EVACUATION

THE FOLLOWING ALARM SIGNAL(S) WILL BE USED TO BEGIN EVACUATION OF THE FACILITY (Check all that apply): E1.

E2.

- [ ] 1. BELLS;
- [ ] 2. HORNS/SIRENS;
- [x] 3. VERBAL (i.e., Shouting);
- [x] 4. OTHER (Specify): Portable Air Horn

THE FOLLOWING LOCATION(S) WILL BE USED FOR AN EMERGENCY ASSEMBLY AREA(S) (e.g., Parking lot, street corner): E3.

Outside the gate on the south side

Note: The Emergency Coordinator must account for all onsite employees and visitors after evacuation.

EVACUATION ROUTE S AND ALTERNATE EVACUATION ROUTES ARE DESCRIBED AS FOLLOWS: E4.

- [ ] 1. WRITTEN PROCEDURES DESCRIBING ROUTES, EXITS, AND ASSEMBLY AREAS;
- [ ] 2. EVACUATION MAP(S) DEPICTING ROUTES, EXITS, AND ASSEMBLY AREAS;
- [x] 3. OTHER (Specify): Exiting any of the two main gate located on the south of the facility

E5.

Note: Evacuation procedures and/or maps should be posted in visible facility locations and must be included in the Contingency Plan.

F. ARRANGEMENTS FOR EMERGENCY SERVICES

ADVANCE ARRANGEMENTS FOR LOCAL EMERGENCY SERVICES (Check one of the following): F1.

- [ ] 1. HAVE BEEN DETERMINED NOT NECESSARY;
- [ ] 2. THE FOLLOWING ARRANGEMENTS HAVE BEEN MADE (Specify):

F2.

Note: Advance arrangements with local fire and police departments, hospitals, state and local emergency response teams, and/or emergency services contractors should be made for your facility, if necessary. Large Quantity Generators must describe arrangements in the Contingency Plan.

G. EMERGENCY EQUIPMENT

Check the applicable boxes to list emergency response equipment available at the facility, identify the location(s) where the equipment is kept, and indicate the equipment's capability, if applicable.

TYPE	EQUIPMENT AVAILABLE G1.	LOCATION G2.	CAPABILITY G3.
EXAMPLE	☒ *CHEMICAL PROTECTIVE GLOVES*	*SPILL RESPONSE KIT*	*SINGLE USE, OIL RESISTANT ONLY*
Safety and First Aid	1. ☐ CHEMICAL PROTECTIVE SUITS, APRONS, AND/OR VESTS		
	2. ☒ CHEMICAL PROTECTIVE GLOVES	Inside equipment storage container	single use nitryl gloves
	3. ☐ CHEMICAL PROTECTIVE BOOTS		
	4. ☒ SAFETY GLASSES, GOGGLES, AND FACE SHIELDS	Inside equipment storage container	ANZI approved
	5. ☒ HARD HATS	Inside equipment storage container	ANZI approved
	6. ☒ AIR-PURIFYING RESPIRATORS	Inside equipment storage container	ANZI approved
	7. ☐ SELF-CONTAINED BREATHING APPARATUS (SCBA)		
	8. ☒ FIRST AID KITS	Inside equipment storage container	OSHA first aid kit requirements
	9. ☐ PLUMBED EYEWASH FOUNTAIN AND/OR SHOWER		
	10. ☒ PORTABLE EYEWASH KITS AND/OR STATION	Inside Office	OSHA requirements
	11. ☐ OTHER		
Fire Fighting	12. ☒ PORTABLE FIRE EXTINGUISHERS	See annotated site map for locations	10 lbs, 20 lbs, Class ABC
	13. ☐ FIXED FIRE SUPPRESSION SYSTEMS AND/ OR SPRINKLERS		
	14. ☐ FIRE ALARM BOXES		
	15. ☐ OTHER		
Spill Control and Clean-Up	16. ☐ ALL-IN-ONE SPILL KIT		
	17. ☒ ABSORBENT MATERIAL	Inside material storage container	Pads
	18. ☐ CONTAINER FOR USED ABSORBENT		
	19. ☐ BERM AND/OR DIKING EQUIPMENT		
	20. ■ BROOM	Next to storage container	Push brooms
	21. ■ SHOVEL	Next to storage container	Square shovels
	22. ☐ VACUUM		
	23. ☐ EXHAUST HOOD		
	24. ☐ SUMP AND/OR HOLDING TANK		
	25. ☐ CHEMICAL NEUTRALIZERS		
	26. ☐ GAS CYLINDER LEAK REPAIR KIT		
	27. ☐ SPILL OVERPACK DRUMS		
	28. ☐ OTHER		
Communi-cations and Alarm Systems	29. ☒ TELEPHONES (e.g., Cellular)	Cell phone or office phone	
	30. ☐ INTERCOM AND/OR PA SYSTEM		
	31. ☐ PORTABLE RADIOS		
	32. ☐ AUTOMATIC ALARM CHEMICAL MONITORING EQUIPMENT		
Other	33. ☐ OTHER		
	34. ☐ OTHER		

H. EARTHQUAKE VULNERABILITY

Identify areas of the facility that are vulnerable to hazardous materials releases due to seismic motion. These areas require immediate isolation and inspection.

VULNERABLE AREAS (Check all that apply): H1.

- [x] 1. HAZARDOUS MATERIALS AND/OR WASTE STORAGE AREAS
- [ ] 2. PROCESS LINES AND PIPING
- [ ] 3. LABORATORY
- [ ] 4. WASTE TREATMENT AREA

LOCATIONS (e.g., Shop, outdoor shed, lab): H2.

In the center of the facility in the open area and inside material storage containers.

Identify mechanical systems vulnerable to releases / spills due to earthquake-related motion. These systems require immediate isolation and inspection.

VULNERABLE SYSTEMS AND/OR EQUIPMENT (Check all that apply): H3.

- [x] 1. SHELVES, CABINETS AND/OR RACKS
- [ ] 2. TANKS AND SHUT-OFF VALVES
- [ ] 3. PORTABLE GAS CYLINDERS
- [ ] 4. EMERGENCY SHUT-OFF AND/OR UTILITY VALVES
- [ ] 5. SPRINKLER SYSTEMS
- [ ] 6. STATIONARY PRESSURIZED CONTAINERS (e.g., Propane tank)

LOCATIONS: H4.

Inside materials storage containers

I. EMPLOYEE TRAINING

Employee training is required for all employees and/or contractors handling hazardous materials and/or hazardous wastes during normal and/or emergency operations. Most facilities will need to submit a separate Training Plan. However, your CUPA may accept this section as the Training Plan for some small facilities.
Employee training plans may include the following content:

- Applicable laws and regulations;
- Emergency response plans and procedures;
- Safety Data Sheets;
- Hazard communication related to health and safety;
- Methods for safe handling of hazardous substances;
- Hazards of materials and processes (e.g., fire, explosion, asphyxiation);
- Hazard mitigation, prevention and abatement procedures;
- Coordination of emergency response actions;
- Notification procedures for local emergency responders, CUPA, Cal OES, and onsite personnel;
- Communication and alarm systems;
- Personal protective equipment;
- Use and maintenance of emergency response equipment and supplies (e.g. Fire extinguishers, respirators, spill control materials);
- Decontamination procedures;
- Evacuation procedures and evacuation staging locations;
- Identification of facility areas, equipment, and systems vulnerable to earthquakes and other natural disasters.
- OTHER (Specify):

Check the applicable boxes below to indicate how the employee training program is administered.

- [x] 1. FORMAL CLASSROOM
- [x] 2. VIDEOS
- [x] 3. SAFETY MEETINGS
- [ ] 4. STUDY GUIDES / MANUALS — I1.
- [ ] 5. OTHER (Specify): _____ I2.
- [ ] 6. NOT APPLICABLE SINCE FACILITY HAS NO EMPLOYEES
- [x] 7. CHECK IF A SEPARATE EMPLOYEE TRAINING PLAN IS USED AND UPLOADED TO CERS AS A PDF DOCUMENT I3.
- [ ] 8. CHECK IF EMPLOYEE TRAINING IS COVERED BY THE ABOVE REFERENCED CONTENT AND OTHER DOCUMENTS ONSITE I4.

EMPLOYEE TRAINING FREQUENCY AND RECORDKEEPING TRAINING MUST BE:

- Provided initially for new employees as soon as possible following the date of hire. New employees should not work in an unsupervised position that involves hazardous materials handling and/or hazardous waste management without proper training;
- Provided within six months from the date of hire for new employees at a large quantity generator;
- Ongoing and provided at least annually;
- Amended prior to a change in process or work assignment;
- Given upon modification to the Emergency Response/Contingency Plan.

Large Quantity Generator Training: Large quantity generators (1,000 kg or more) must retain written plan and documentation of employee training which includes:

- A written description of the type and amount of both initial and ongoing training that will be given to persons filling each job position having responsibility for hazardous waste management and/or emergency response.
- The name, job title and job description for each position at the facility related to hazardous waste management.
- Current employee training records must be retained until closure of the facility and former employee training records must be retained for at least three years after termination of employment.

Small Quantity Generator Training: Small quantity generators (less than 1,000 kg) must include basic hazardous waste management and emergency response procedures but a written employee training plan and training records are not required. In order to show that the facility has met the small quantity generator employee training requirement, an employee training plan and training records may be made available.

Hazardous Materials Business Plan Training: Businesses must provide initial and annual employee training that includes the content referenced above. The training may be based on the job position and training records must be made available for a period of at least three years.

Hazard Communication Program and Training

The purpose of this program is to inform interested persons, including employees, that Advanced Industrial Services, In., is complying with the OSHA Hazard Communication Standard, Title 29 Code of Federal Regulations 1910.1200, by compiling a hazardous chemicals list, using safety data sheets (SDSs), ensuring that containers are labeled or provided other forms of warning, and training our employees.

This program applies to all work operations in our company where employees may be exposed to hazardous chemicals under normal working conditions or during an emergency situation. Under this program, our employees will be informed of the contents of the Hazard Communication Standard, the hazards of chemicals with which they work, safe handling procedures, and measures to take to protect themselves from these chemicals, among other training elements.

Eduardo Ortega/Safety Manager who is the Hazard Communication Program Coordinator, has overall responsibility for the program, including to review and update the program, as necessary. Copies of this written program may be obtained from Eduardo Ortega/Safety Manager who keeps the program located in at the Paramount office. Moreover, all employees, or their designated representatives, may obtain further information about this written program, the Hazard Communication Standard, applicable SDSs, and our chemical list from Eduardo Ortega/Safety Manager.

Finally, if after reading this program, you find that improvements can be made, please contact Eduardo Ortega/Safety Manager. We encourage all suggestions because we are committed to the success of our written Hazard Communication Program. We strive for clear understanding, safe behavior, and involvement in the program from every level of the company.

List of Hazardous Chemicals

Our “chemical inventory” is a list of product identifiers of hazardous chemicals known to be present at our workplace. Anyone who comes in contact with the hazardous chemicals on the list needs to know what those chemicals are and how to protect themselves. That is why it is so important that hazardous chemicals are identified, whether they are found in a container or generated in work operations (for example, welding fumes, dusts and exhaust fumes). The hazardous chemicals on the chemical inventory can cover a variety of physical forms including liquids, solids, gases, vapors, fumes, and mists. Sometimes hazardous chemicals can be identified using purchase orders. Identification of other chemicals may require an actual survey of the workplace.

The chemical inventory is attached to this written Hazard Communication Program. However, the Program Coordinator also keeps a copy of the chemical inventory list located 20322 7th Standard Road, Contractors Row Lot 102, Lost Hills , CA 93251 where it is accessible during work hours. The chemical inventory serves as a list of every hazardous chemical for which an SDS must be maintained.

Safety Data Sheets (SDSs)

SDSs are basically fact sheets for chemicals that pose a physical or health hazard in the workplace. These sheets provide our employees with specific information on the chemicals in their work areas.

Ty Johnston/Supervisor is responsible for obtaining and maintaining the SDSs at our workplace and will contact the chemical manufacturer or vendor if additional research is necessary. All new procurements for the company must be cleared by Ty Johnston/Supervisor.

SDSs are kept readily accessible to all employees during each work shift at the following location(s): Belridge AERA yard office building. Employees may obtain the SDSs sheets during any time of the day during working hours.

Labels and Other Forms of Warning

In most cases, hazardous chemical containers at the workplace must be clearly labeled, tagged, or marked in accordance with the Hazard Communication Standard, either with:

The product identifier, signal word, hazard statement(s), pictogram(s), and precautionary statement(s); or

The product identifier and words, pictures, symbols, or combination thereof, which provide at least “general” information regarding the hazards of the chemicals, and which, in conjunction with the other information immediately available to employees under the Hazard Communication Program, will provide employees with the “specific” information regarding the physical and health hazards of the hazardous chemical.

While not required for in-house labeling, the name and address of the manufacturer, importer, or other responsible party may also be found on the label, tag, or marking. Hazards not otherwise classified do not have to be addressed on a container.

Because the product identifier is found on the label, the SDS, and our chemical inventory, the product identifier links these three sources of information, permitting cross-referencing. The product identifer used by the supplier may be a common or trade name, a chemical name, or a number. Employees should be aware that label information can be verified by referring to the corresponding SDS.

Jaime Cuevas/Shop Foreman is responsible for ensuring that all hazardous chemicals in containers at the workplace have proper labels or other forms of warning that are legible, in English (although other languages may also be included), and displayed clearly on the container or readily available in the work area throughout each work shift, as required. This person will update labels, as necessary. Jaime Cuevas/Shop Foreman also ensures that newly purchased chemicals are checked for labels when containers are received.

Jaime Cuevas/Shop Foreman is responsible for ensuring the proper labeling, tagging, or marking of any shipped containers leaving the workplace. These labels, tags, or marks must provide not only the product identifier, signal word, hazard statement(s), pictogram(s), and precautionary statement(s) but also the name, address, and telephone number of the chemical manufacturer, importer, or other responsible party.

A poster is displayed to inform employees about the Hazard Communication Standard. It is located at the Belridge AERA yard inside the storage container.

If employees transfer chemicals from a labeled container to a portable, secondary container that is intended only for their IMMEDIATE use, no labels, tags, or markings are required on the portable container. Otherwise portable containers must be labeled, tagged, or marked in accordance with our in-house labeling system for workplace containers.

Finally, the following procedures are used to review and update label information when necessary, to ensure that labels that fall off or become unreadable are immediately replaced: by notifying the manufacturer and replacing with the proper label.

Training

Everyone who works with or is potentially "exposed" to hazardous chemicals on the job will receive initial training on the Hazard Communication Standard and the safe use of those hazardous chemicals before starting work. "Exposure" means that "an employee is subjected in the course of employment to a chemical that is a physical or health hazard, and includes potential (e.g., accidental or possible) exposure." Whenever a new chemical hazard is introduced or an old hazard changes, additional training is provided. All training is conducted by Eduardo Ortega/Safety Manager.

Effective information and training is a critical part of the Hazard Communication Program. We train our employees to read and understand the information on labels and SDSs, determine how the information can be obtained and used in their own work areas, and understand the risks of exposure to the chemicals in their work areas, as well as ways to protect themselves. Our goal is to ensure employees know that they are exposed to hazardous chemicals, have the skills to read and use labels and SDSs, and understand how to appropriately follow the protective measures we have established. We urge our employees to ask Eduardo Ortega/Safety Manager questions for greater comprehension.

As part of the assessment of the training program, Eduardo Ortega/Safety Manager asks for input from employees regarding the training they have received and their suggestions for improving it. In this way, we hope to reduce any incidence of chemical-related illness or injury.

Training Content

Any employee who will be handling hazardous chemicals must be trained prior to working with the chemical. Training is conducted yearly. A schedule of training can be obtained by contacting Eduardo Ortega/Safety Manager. Employees are trained by hazard categories (i.e., flammability, carcinogenicity, etc.). The format of the training program consists of Power Point presentations, Handouts, Video and Quiz.

The training program emphasizes these elements:

- Summary of the Hazard Communication Standard.
- What hazardous chemicals are present in operations in employee work areas.
- Chemical and physical properties of hazardous chemicals (e.g., flash point, reactivity, etc.) and how to detect the presence or release of these chemicals (including chemicals in unlabeled pipes).
- Physical hazards of chemicals (e.g., potential for fire, explosion, etc.)
- Health hazards, including signs and symptoms of overexposure, associated with exposure to chemicals and any medical condition known to be aggravated by exposure to them.
- Any simple asphyxiation, combustible dust, and pyrophoric hazards, as well as hazards not otherwise classified, of chemicals in work areas.
- Any steps the company has taken to reduce or prevent exposure to hazardous chemicals, such as engineering controls.
- Procedures to protect against hazards and exposure (e.g., work practices or methods to assure proper use and handling of chemicals and any required personal protective equipment and its proper use and maintenance).
- Procedures for reporting and responding to chemical emergencies.
- How to read and use both the workplace labeling system and labels received on shipped containers.
- The order of information found on SDSs and how to read the information and what it means.
- How to access SDSs and the written Hazard Communication Program, including the chemical inventory.

The procedure to train new employees at the time of their initial assignment is on date of hired they must watch the HazCom *What You Need to Know* video and pass a written quiz by 80% or better. If the employee does not pass the quiz, he must watch the video again and retake the quiz until he gets a passing grade.

Training logs are signed by employees upon completion of their training and are kept by Eduardo Ortega/Safety Manager.

Hazards of Non-routine Tasks

Periodically, employees are required to perform non-routine tasks that involve hazardous chemicals. When employees will be required to perform hazardous non-routine tasks, such as confined space that have the potential to expose employees to hazardous chemicals, we inform them of these hazards by: communication and training in confined space by a competent person.

Hazards of Unlabeled Pipes

Work activities are sometimes performed by employees in areas where hazardous chemicals are transferred through unlabeled pipes. We inform employees of the hazards of chemicals contained in unlabeled pipes in their work areas by: providing training in recognizing potential hazards, pre-job walks and job hazard analysis before work can be performed near pipes.

Multi-Employer Site

When contractors or any other employers' workers will be working at this workplace, the Hazard Communication Program Coordinator, Eduardo Ortega/Safety Manager, will:

- Provide the other employer(s) as follows with SDSs for any of our hazardous chemicals to which their employees may be exposed: by submitting all SDSs to the other employer(s) safety personnel and inform them in writing.
- Relay to other employer(s) all necessary in-house labeling system and precautionary information for normal operations and foreseeable emergencies: by communication and verifying training of all employees.

Moreover, it is the responsibility of Eduardo Ortega/Safety Manager to obtain from each contractor or other employer the appropriate hazard information on chemicals they bring onsite, including SDSs, the labeling system used, and the precautionary measures to be taken in working with or near these chemicals.

Additional Information

As stated earlier, all employees, or their designated representatives, may obtain further information on this written program, the Hazard Communication Standard, applicable SDSs, and the chemical inventory from Eduardo Ortega/Safety Manager.

Hazardous Materials

Does your facility have on site (for any purpose) at any one time, hazardous materials at or above 55 gallons for liquids, 500 pounds for solids, or 200 cubic feet for compressed gases (include liquids in ASTs and USTs); or is regulated under more restrictive inventory local reporting requirements (shown below if present); or the applicable Federal threshold quantity for an extremely hazardous substance specified in 40 CFR Part 355, Appendix A or B; or handle radiological materials in quantities for which an emergency plan is required pursuant to 10 CFR Parts 30, 40 or 70?	**Yes**

Underground Storage Tank(s) (UST)

Does your facility own or operate underground storage tanks?	**No**

Hazardous Waste

Is your facility a Hazardous Waste Generator?	**No**
Does your facility treat hazardous waste on-site?	**No**
Is your facility's treatment subject to financial assurance requirements (for Permit by Rule and Conditional Authorization)?	**No**
Does your facility consolidate hazardous waste generated at a remote site?	**No**
Does your facility need to report the closure/removal of a tank that was classified as hazardous waste and cleaned on-site?	**No**
Does your facility generate in any single calendar month 1,000 kilograms (kg) (2,200 pounds) or more of federal RCRA hazardous waste, or generate in any single calendar month greater than 1 kg (2.2 pounds) of RCRA acute hazardous waste; or generate more than 100 kg (220 pounds) of spill cleanup materials contaminated with RCRA acute hazardous waste.	**No**
Is your facility a Household Hazardous Waste (HHW) Collection site?	**No**

Excluded and/or Exempted Materials

Does your facility recycle more than 100 kg/month of excluded or exempted recyclable materials (per HSC 25143.2)?	**No**
Does your facility own or operate ASTs above these thresholds? Store greater than 1,320 gallons of petroleum products (new or used) in aboveground tanks or containers.	**No**
Does your facility have Regulated Substances stored onsite in quantities greater than the threshold quantities established by the California Accidental Release prevention Program (CalARP)?	**No**

Additional Information

No additional comments provided.

THIS PLAN COVERS CHEMICAL SPILLS, FIRES, AND EARTHQUAKES INVOLVING (Check all that apply): A10.

☒ 1. HAZARDOUS MATERIALS; ☒ 2. HAZARDOUS WASTES

B. INTERNAL RESPONSE

INTERNAL FACILITY EMERGENCY RESPONSE WILL OCCUR BY (Check all that apply): B1.

☒ 1. CALLING PUBLIC EMERGENCY RESPONDERS (e.g., 9-1-1)
☒ 2. CALLING HAZARDOUS WASTE CONTRACTOR
☒ 3. ACTIVATING IN-HOUSE EMERGENCY RESPONSE TEAM

C. EMERGENCY COMMUNICATIONS, PHONE NUMBERS AND NOTIFICATIONS

In the event of an emergency involving hazardous materials and/or hazardous waste, all facilities must IMMEDIATELY:
1. Notify facility personnel and evacuate if necessary in accordance with the Emergency Action Plan (Title 8 California Code of Regulations §3220);
2. Notify local emergency responders by calling 9-1-1;
3. Notify the local Unified Program Agency (UPA) at the phone number below; and
4. Notify the State Warning Center at (800) 852-7550.

Facilities that generate, treat, store or dispose of hazardous waste have additional responsibilities to notify and coordinate with other response agencies. Whenever there is an imminent or actual emergency situation such as an explosion, fire, or release, the Emergency Coordinator must follow the appropriate requirements for the category of facility and type of release involved:
1. Title 22 California Code of Regulations §66265.56. Emergency Procedures for generators of 1,000 kilograms or more of hazardous waste in any calendar month.
2. Title 22 California Code of Regulations §66265.196. Response to Leaks or Spills and Disposition of Leaking or Unfit-for-Use Tank Systems.
3. Title 40 Code of Federal Regulations §302.6. Notification requirements for a release of a hazardous substance equal to or greater than the reportable quantity.
4. Title 22 California Code of Regulations §66262.34(d)(2) and Title 40 Code of Federal Regulations §262.34(d)(5)(ii) for generators of less than 1000 kilograms of hazardous waste in any calendar month.

Following notification and before facility operations are resumed in areas of the facility affected by the incident, the Emergency Coordinator shall notify the local UPA and the local fire department's hazardous materials program, if necessary, that the facility is in compliance with requirements to:
1. Provide for proper storage and disposal of recovered waste, contaminated soil or surface water, or any other material that results from an explosion, fire, or release at the facility; and
2. Ensure that no material that is incompatible with the released material is transferred, stored, or disposed of in areas of the facility affected by the incident until cleanup procedures are completed.

Note: If more than one alternate emergency coordinator is designated, attach a list in order of responsibility.

D. EMERGENCY CONTAINMENT AND CLEANUP PROCEDURES

Check the applicable boxes to indicate your facility's procedures for containing spills and preventing and mitigating releases, fires and/or explosions.

D1.

- [x] 1. MONITOR FOR LEAKS, RUPTURES, PRESSURE BUILD-UP, ETC.;
- [ ] 2. PROVIDE STRUCTURAL PHYSICAL BARRIERS (e.g., Portable spill containment walls, built-in berms);
- [x] 3. PROVIDE ABSORBENT PHYSICAL BARRIERS (e.g., Pads, spill pigs, spill pillows);
- [x] 4. COVER OR BLOCK FLOOR AND/OR STORM DRAINS;
- [x] 5. LINED TRENCH DRAINS AND/OR SUMPS;
- [ ] 6. AUTOMATIC FIRE SUPPRESSION SYSTEM;
- [x] 7. ELIMINATE SOURCES OF IGNITION FOR FLAMMABLE HAZARDS;
- [x] 8. STOP PROCESSES AND/OR OPERATIONS;
- [x] 9. AUTOMATIC / ELECTRONIC EQUIPMENT SHUT-OFF SYSTEM;
- [x] 10. SHUT OFF WATER, GAS, ELECTRICAL UTILITIES;
- [x] 11. CALL 9-1-1 FOR PUBLIC EMERGENCY RESPONDER ASSISTANCE AND/OR MEDICAL AID;
- [x] 12. NOTIFY AND EVACUATE PERSONS IN ALL THREATENED AND/OR IMPACTED AREAS;
- [x] 13. ACCOUNT FOR EVACUATED PERSONS IMMEDIATELY AFTER EVACUATION;
- [x] 14. PROVIDE PROTECTIVE EQUIPMENT FOR ON-SITE EMERGENCY RESPONSE TEAM;
- [x] 15. REMOVE CONTAINERS AND/OR ISOLATE AREAS;
- [x] 16. HIRE LICENSED HAZARDOUS WASTE CONTRACTOR;
- [x] 17. USE ABSORBENT MATERIAL FOR SPILL CONTAINMENT;
- [x] 18. VACUUM SUCTION USING APPROPRIATE VACUUM (e.g., Intrinsically safe) FOR SPILL CONTROL AND/OR CLEANUP;
- [x] 19. DECONTAMINATE PERSONNEL AND EQUIPMENT WITHIN DESIGNATED AREA AND DISPOSE OF WASTEWATER AS HAZARDOUS WASTE;
- [x] 20. PROVIDE SAFE TEMPORARY STORAGE OF HAZARDOUS WASTE GENERATED DURING EMERGENCY ACTIONS;
- [ ] 21. OTHER (Specify): D2.

E. FACILITY EVACUATION

THE FOLLOWING ALARM SIGNAL(S) WILL BE USED TO BEGIN EVACUATION OF THE FACILITY (Check all that apply): E1.

E2.

- [ ] 1. BELLS;
- [ ] 2. HORNS/SIRENS;
- [x] 3. VERBAL (i.e., Shouting);
- [ ] 4. OTHER (Specify):

THE FOLLOWING LOCATION(S) WILL BE USED FOR AN EMERGENCY ASSEMBLY AREA(S) (e.g., Parking lot, street corner): E3.

Main entrance gate south of the facility by Highway 166.

Note: The Emergency Coordinator must account for all onsite employees and visitors after evacuation.

EVACUATION ROUTE S AND ALTERNATE EVACUATION ROUTES ARE DESCRIBED AS FOLLOWS: E4.

- [x] 1. WRITTEN PROCEDURES DESCRIBING ROUTES, EXITS, AND ASSEMBLY AREAS;
- [x] 2. EVACUATION MAP(S) DEPICTING ROUTES, EXITS, AND ASSEMBLY AREAS;
- [ ] 3. OTHER (Specify): E5.

Note: Evacuation procedures and/or maps should be posted in visible facility locations and must be included in the Contingency Plan.

F. ARRANGEMENTS FOR EMERGENCY SERVICES

ADVANCE ARRANGEMENTS FOR LOCAL EMERGENCY SERVICES (Check one of the following): F1.

- [ ] 1. HAVE BEEN DETERMINED NOT NECESSARY;
- [x] 2. THE FOLLOWING ARRANGEMENTS HAVE BEEN MADE (Specify): OSRO contracts our in place with Clean Harbors and Patriot Environmental as listed in our Integrated Contingency Plan. F2.

Note: Advance arrangements with local fire and police departments, hospitals, state and local emergency response teams, and/or emergency services contractors should be made for your facility, if necessary. Large Quantity Generators must describe arrangements in the Contingency Plan.

G. EMERGENCY EQUIPMENT

Check the applicable boxes to list emergency response equipment available at the facility, identify the location(s) where the equipment is kept, and indicate the equipment's capability, if applicable.

TYPE	EQUIPMENT AVAILABLE G1.	LOCATION G2.	CAPABILITY G3.
EXAMPLE	☒ *CHEMICAL PROTECTIVE GLOVES*	*SPILL RESPONSE KIT*	*SINGLE USE, OIL RESISTANT ONLY*
Safety and First Aid	1. ☒ CHEMICAL PROTECTIVE SUITS, APRONS, AND/OR VESTS	Located at Continental Station	Single Use
	2. ☒ CHEMICAL PROTECTIVE GLOVES	Located at Continental Station	Single Use
	3. ☒ CHEMICAL PROTECTIVE BOOTS	Located at Continental Station	Single Use
	4. ☒ SAFETY GLASSES, GOGGLES, AND FACE SHIELDS	In all company vehicles	
	5. ☒ HARD HATS	In all company vehicles	
	6. ☒ AIR-PURIFYING RESPIRATORS		Single Use
	7. ☐ SELF-CONTAINED BREATHING APPARATUS (SCBA)		
	8. ☒ FIRST AID KITS	In company vehicles and control room	Single Use, < 25 employees
	9. ☐ PLUMBED EYEWASH FOUNTAIN AND/OR SHOWER		
	10. ☒ PORTABLE EYEWASH KITS AND/OR STATION	Outside control room exit	Single Use
	11. ☐ OTHER		
Fire Fighting	12. ☒ PORTABLE FIRE EXTINGUISHERS	In company vehicles/see facility maps	Single Use, 25 lb extinguisher
	13. ☐ FIXED FIRE SUPPRESSION SYSTEMS AND/ OR SPRINKLERS		
	14. ☐ FIRE ALARM BOXES		
	15. ☐ OTHER		
Spill Control and Clean-Up	16. ☒ ALL-IN-ONE SPILL KIT	At control room spill kit	Single Use, 95 gallon capacity
	17. ☒ ABSORBENT MATERIAL	At control room spill kit	Single Use, 95 gallon capacity
	18. ☒ CONTAINER FOR USED ABSORBENT	At control room spill kit	
	19. ☐ BERM AND/OR DIKING EQUIPMENT		
	20. ☐ BROOM		
	21. ☒ SHOVEL	At Continental Station	
	22. ☒ VACUUM	Patriot/Clean Harbors	130 BBL per truck
	23. ☐ EXHAUST HOOD		
	24. ☐ SUMP AND/OR HOLDING TANK		
	25. ☐ CHEMICAL NEUTRALIZERS		
	26. ☐ GAS CYLINDER LEAK REPAIR KIT		
	27. ☒ SPILL OVERPACK DRUMS		1-95 gallon overpack at each facility
	28. ☐ OTHER		
Communi-cations and Alarm Systems	29. ☒ TELEPHONES (e.g., Cellular)		
	30. ☐ INTERCOM AND/OR PA SYSTEM		
	31. ☐ PORTABLE RADIOS		
	32. ☐ AUTOMATIC ALARM CHEMICAL MONITORING EQUIPMENT		
Other	33. ☐ OTHER		
	34. ☐ OTHER		

H. EARTHQUAKE VULNERABILITY

Identify areas of the facility that are vulnerable to hazardous materials releases due to seismic motion. These areas require immediate isolation and inspection.

VULNERABLE AREAS (Check all that apply): H1.

- ☐ 1. HAZARDOUS MATERIALS AND/OR WASTE STORAGE AREAS
- ☒ 2. PROCESS LINES AND PIPING
- ☐ 3. LABORATORY
- ☐ 4. WASTE TREATMENT AREA

LOCATIONS (e.g., Shop, outdoor shed, lab): H2.

Throughout facility, below and above ground.

Identify mechanical systems vulnerable to releases / spills due to earthquake-related motion. These systems require immediate isolation and inspection.

VULNERABLE SYSTEMS AND/OR EQUIPMENT (Check all that apply): H3.

- ☐ 1. SHELVES, CABINETS AND/OR RACKS
- ☐ 2. TANKS AND SHUT-OFF VALVES
- ☐ 3. PORTABLE GAS CYLINDERS
- ☒ 4. EMERGENCY SHUT-OFF AND/OR UTILITY VALVES
- ☐ 5. SPRINKLER SYSTEMS
- ☐ 6. STATIONARY PRESSURIZED CONTAINERS (e.g., Propane tank)

LOCATIONS: H4.

Facility is equipped with seismic detection equipment which shuts facility down at 6.0 or above earthquake

I. EMPLOYEE TRAINING

Employee training is required for all employees and/or contractors handling hazardous materials and/or hazardous wastes during normal and/or emergency operations. Most facilities will need to submit a separate Training Plan. However, your CUPA may accept this section as the Training Plan for some small facilities.
Employee training plans may include the following content:

- Applicable laws and regulations;
- Emergency response plans and procedures;
- Safety Data Sheets;
- Hazard communication related to health and safety;
- Methods for safe handling of hazardous substances;
- Hazards of materials and processes (e.g., fire, explosion, asphyxiation);
- Hazard mitigation, prevention and abatement procedures;
- Coordination of emergency response actions;
- Notification procedures for local emergency responders, CUPA, Cal OES, and onsite personnel;
- Communication and alarm systems;
- Personal protective equipment;
- Use and maintenance of emergency response equipment and supplies (e.g. Fire extinguishers, respirators, spill control materials);
- Decontamination procedures;
- Evacuation procedures and evacuation staging locations;
- Identification of facility areas, equipment, and systems vulnerable to earthquakes and other natural disasters.
- OTHER (Specify): Training is web based

Check the applicable boxes below to indicate how the employee training program is administered.

☐ 1. FORMAL CLASSROOM ☐ 2. VIDEOS ☐ 3. SAFETY MEETINGS ☐ 4. STUDY GUIDES / MANUALS I1.

☒ 5. OTHER (Specify): I2.

☒ 6. NOT APPLICABLE SINCE FACILITY HAS NO EMPLOYEES

☐ 7. CHECK IF A SEPARATE EMPLOYEE TRAINING PLAN IS USED AND UPLOADED TO CERS AS A PDF DOCUMENT I3.

☐ 8. CHECK IF EMPLOYEE TRAINING IS COVERED BY THE ABOVE REFERENCED CONTENT AND OTHER DOCUMENTS ONSITE I4.

EMPLOYEE TRAINING FREQUENCY AND RECORDKEEPING TRAINING MUST BE:

- Provided initially for new employees as soon as possible following the date of hire. New employees should not work in an unsupervised position that involves hazardous materials handling and/or hazardous waste management without proper training;
- Provided within six months from the date of hire for new employees at a large quantity generator;
- Ongoing and provided at least annually;
- Amended prior to a change in process or work assignment;
- Given upon modification to the Emergency Response/Contingency Plan.

Large Quantity Generator Training: Large quantity generators (1,000 kg or more) must retain written plan and documentation of employee training which includes:

- A written description of the type and amount of both initial and ongoing training that will be given to persons filling each job position having responsibility for hazardous waste management and/or emergency response.
- The name, job title and job description for each position at the facility related to hazardous waste management.
- Current employee training records must be retained until closure of the facility and former employee training records must be retained for at least three years after termination of employment.

Small Quantity Generator Training: Small quantity generators (less than 1,000 kg) must include basic hazardous waste management and emergency response procedures but a written employee training plan and training records are not required. In order to show that the facility has met the small quantity generator employee training requirement, an employee training plan and training records may be made available.

Hazardous Materials Business Plan Training: Businesses must provide initial and annual employee training that includes the content referenced above. The training may be based on the job position and training records must be made available for a period of at least three years.

J. LIST OF ATTACHMENTS

Check one of the following: J1.

☒ 1. NO ATTACHMENTS ARE REQUIRED; or

☐ 2. THE FOLLOWING DOCUMENTS ARE ATTACHED: J2.

EMPLOYEE TRAINING PLAN REQUIREMENTS AND TEMPLATE

All facilities are required to create and implement an employee training plan. Below is a template of requirements for the Hazardous Materials Business Plan and Hazardous Waste Generator program elements. This template will help facilities ensure that all requirements for each program are covered and will help draft a site-specific plan for your facility. Training requirements for the Hazardous Materials Business Plan and Hazardous Waste Generator programs can be found in Health and Safety Code Chapter 6.95 Article 1, Chapter 6.5, Title 19 § 2732, and Chapter 22 of California Code of Regulations § 66265.16. This template may be uploaded onto CERS and will satisfy the above mentioned regulations.

1. Programs
   a. Facility maintains hazardous materials at or above the reporting quantities of 55 gallons of a liquid, 500 pounds of a solid, and/or 200 cubic feet of a compressed gas

      ☑ YES Complete section 1b

   b. Hazardous Materials Business Plan Requirements (HSC § 25504(c))
      i. Methods of safe handling of hazardous materials

a. Follow all established procedures and perform job duties as trained
b. Be cautious and pay close attention to what you are doing
c. Always use required PPE
d. Make sure all containers are properly labeled and appropriate for material
e. Read SDSs (SDS Online system)
f. Use materials solely for intended purpose
g. Store materials properly
h. Understand emergency procedures

      ii. Safety procedures in the event of a release or threatened release of a hazardous material as described in Emergency Action/Contingency Plan

a. Follow Universal Spill Response Procedures (USRP)
b. Identify potential hazards and determine whether a release has occurred.
c. Activate local emergency systems and take appropriate immediate actions based on level of training and the ability to act safely.
d. Make required notifications and request assistance as needed.
e. Assist responding agencies by providing access to the facility and information about the facility.

      iii. Procedures for coordination with local emergency organizations

a. The Environmental Project Manager will work with the field technicians to determine if the release is subject to California or Federal spill reporting requirements.
b. The Environmental Project Manager will contact the appropriate regulatory agencies and initiate reporting as necessary.
c. Call HazMat One for emergency chemical spill/release services. HazMat One is required by contract to have qualified spill response personnel on-site within 2 hours of being notified of a spill.

iv. Communication and alarm systems

a. An alarm system would notify any maintenance personnel of a potential hazard. Those alarms will vary from High/Low Fuel level, interstitial alarming, and low voltage/high heat readings on batteries.
b. Personnel will use cell phones for contacting appropriate emergency services immediately.
c. Designated personnel (Environmental Project Manager and emergency contacts) will be contacted immediately as a representative is on call 24-7.
d. In the event of a spill or incident, appropriate agencies will be contacted for cleanup and notification.

v. Use of emergency response equipment and supplies employees may use

Facility emergency equipment includes the following:
-Portable fire extinguishers maintained in accordance with NFPA 10
-Portable first aid kits
-Smoke and Heat detection alarms (fire alarms)
-Spill control equipment including pads, absorbent material, shovels, and brooms
- Personal Protective Equipment including gloves, goggles, and face shields
Employees may place absorbent materials in such a manner as to prevent a spill from flowing into a sensitive area. Control and clean-up of spills shall not be performed by staff if the scope of the incident is beyond their capability.

vi. Procedures for using, inspection of, repairing, and/or replacing facility emergency and monitoring equipment

a. All facilities are inspected based on a Preventative Maintenance (PM) schedule not to exceed 90 days.
b. Inspections involve all critical infrastructure at the site, including tanks, generators, batteries, and cooling/heating sytems.
c. Monitoring equipment is regularly checked to ensure it is available and maintained according to manufacturer's specifications.

vii. Evacuation/re-entry procedures and assembly point locations

a. Most site locations are unmanned, and if manned only during regular work hours.
b. If an emergency should occur when employees/visitors are present, proceed to the nearest exit and assemble at a safe distance away from the facility.
c. All emergency exit routes are clearly marked allowing personnel an easy exit in the event of an emergency.
d. If the site is manned, the senior employee on-site is responsible to account for the whereabouts of personnel.

c. Facility stores/generates hazardous waste

- [ ] YES — Complete section 1d
- [x] NO — Do not complete section 1d

d. Hazardous Waste Generator Requirements (HSC Chapter 6.5, 22 CCR § 66265.16)

i. Proper packaging and labeling of all waste

ii. On-site management and storage requirements

iii. Proper use of safety equipment and hazardous waste management supplies

iv. Off-site transportation requirements

v. Interaction with waste haulers and disposal sites including manifesting

vi. Conducting and documentation off periodic inspections

Frequency of inspections: _____

2. Required Training Topics – By Job Title

While all topics in section 1 must be covered, not every individual must be trained in each topic for respective program(s). Training given to each individual will commensurate with the tasks assigned to that employee.

Example: An employee who physically handles hazardous wastes but does not fill out or manage manifests needs training in handling not manifesting, while the clerical person responsible for the manifests needs training in manifesting but not handling the wastes.

Training on SDSs (Safety Data Sheets) including specific hazard(s) of each chemical to which employees may be exposed, including routes of exposure (i.e. inhalation, ingestion, absorption, etc.) is required.

Procedures for specific job titles (optional):

Personnel are required to perform awareness training on a yearly basis, educating employees on hazardous materials. Initial and annual training is	
provided through pre-configured online training environment audio and video presentations. For SPCC sites, there is also an online training for	
SPCC Plans which is required initially and then on a minimum 3 year cycle. In general, the overall training includes:	
a. SDSs	b. SPCC plans
c. HAZMAT business plan materials	d. Emergency Evacuation
e. Safe handling procedures for hazardous materials	f. Procedures for coordination with emergency response agencies
g. Proper use of safety equipment	h. Universal spill response procedures
i. Notification to Environmental Project Managers	

3. Personal Responsibilities

   Responsibility for ensuring the training plan is compliant to all requirements and implementation is assigned to: Environmental Project Manager, Facility Coordinator, Field Managers

   Special Responsibilities are as follows:

TRAINING TASK	ASSIGNED TO

4. Training Frequency

   New employees will successfully complete training within 6 months after date of employment or assignment to a new position at facility. All employees are to receive at least annual training, including refresher courses. In the event of new assignments or changes in operation, training will be provided before the new assignment or change in operation takes place. Employees will not handle hazardous materials and/or hazardous waste without supervision until trained.

   Date of last training: _____

   Date of next training: _____

   Additional dates for refresher courses (optional):

COURSE	DATE

5. Training Documentation

   All training must be documented. Training records on current personnel shall be kept until closure of the facility. Training records on former employees shall be kept for at least three years from the date the employee last worked at the facility. Records that document that the requirements, trainings, and job experience have met must be kept and maintained.

Career Compass Web site, Environmental PM and Field Managers have access.

Training records are kept: _____

Submittal was ***Accepted***; Processed on 8/24/2022 by *FUNK, LAUREL D* for Kern County Environmental Health Services Department

Hazardous Materials

Does your facility have on site (for any purpose) at any one time, hazardous materials at or above 55 gallons for liquids, 500 pounds for solids, or 200 cubic feet for compressed gases (include liquids in ASTs and USTs); or is regulated under more restrictive inventory local reporting requirements (shown below if present); or the applicable Federal threshold quantity for an extremely hazardous substance specified in 40 CFR Part 355, Appendix A or B; or handle radiological materials in quantities for which an emergency plan is required pursuant to 10 CFR Parts 30, 40 or 70?	**Yes**

Underground Storage Tank(s) (UST)

Does your facility own or operate underground storage tanks?	**No**

Hazardous Waste

Is your facility a Hazardous Waste Generator?	**Yes**
Does your facility treat hazardous waste on-site?	**No**
Is your facility's treatment subject to financial assurance requirements (for Permit by Rule and Conditional Authorization)?	**No**
Does your facility consolidate hazardous waste generated at a remote site?	**No**
Does your facility need to report the closure/removal of a tank that was classified as hazardous waste and cleaned on-site?	**No**
Does your facility generate in any single calendar month 1,000 kilograms (kg) (2,200 pounds) or more of federal RCRA hazardous waste, or generate in any single calendar month greater than 1 kg (2.2 pounds) of RCRA acute hazardous waste; or generate more than 100 kg (220 pounds) of spill cleanup materials contaminated with RCRA acute hazardous waste.	**No**
Is your facility a Household Hazardous Waste (HHW) Collection site?	**No**

Excluded and/or Exempted Materials

Does your facility recycle more than 100 kg/month of excluded or exempted recyclable materials (per HSC 25143.2)?	**No**
Does your facility own or operate ASTs above these thresholds? Store greater than 1,320 gallons of petroleum products (new or used) in aboveground tanks or containers.	**Yes**
Does your facility have Regulated Substances stored onsite in quantities greater than the threshold quantities established by the California Accidental Release prevention Program (CalARP)?	**No**

Additional Information

No additional comments provided.

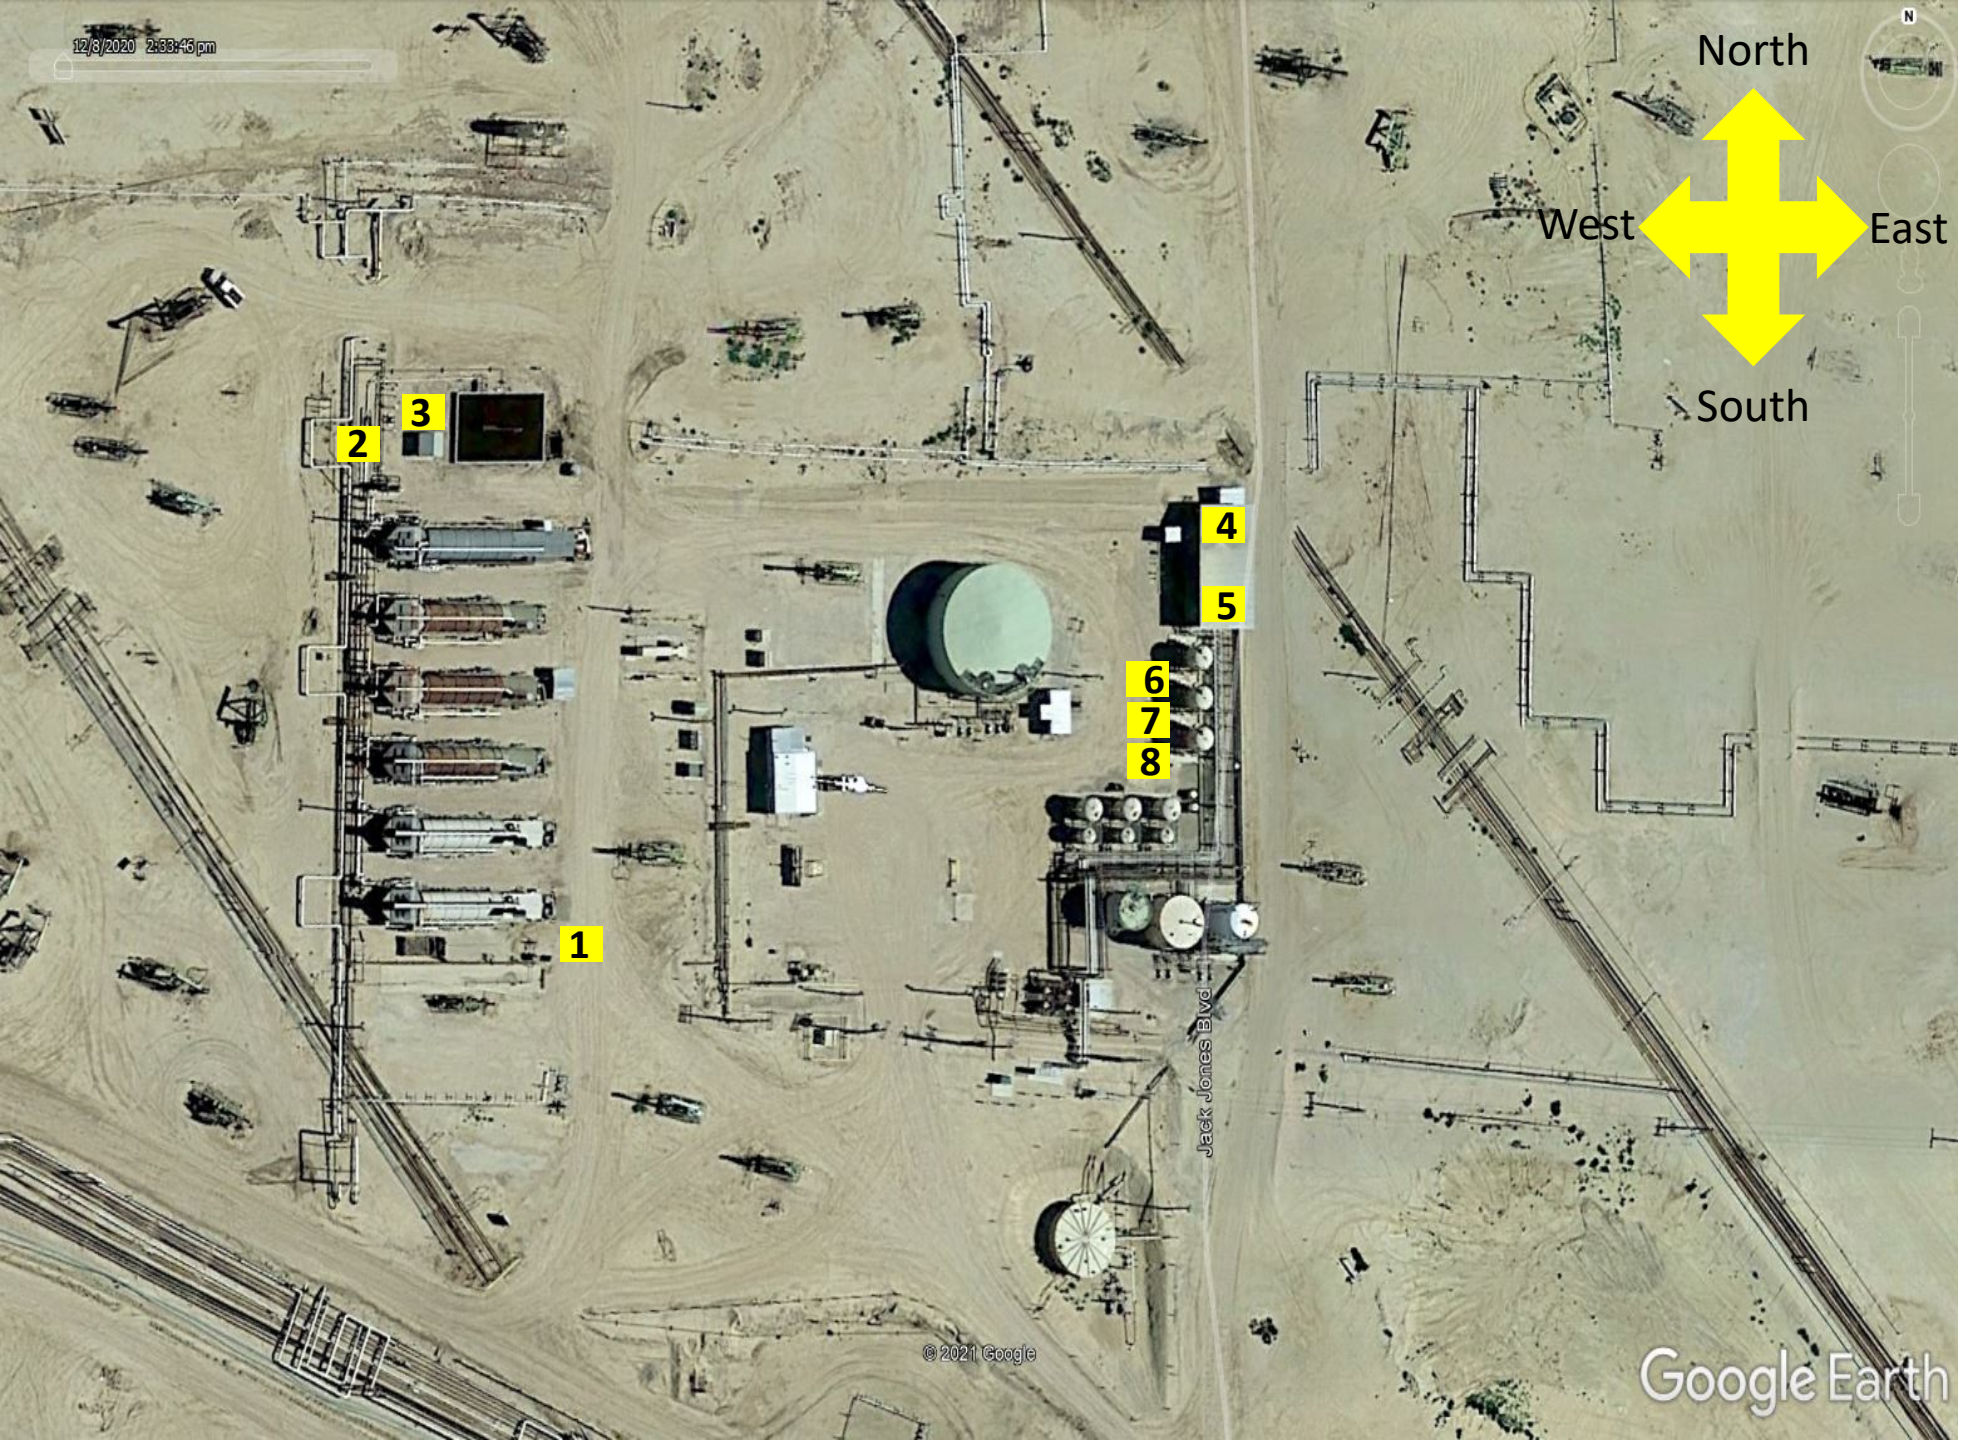
Light Oil Facility Chemicals:

1. Wash Tank-Oil/Water-Tank 101
2. Wash Tank-Oil/Water-Tank 102
3. Crude Oil-Tank 103
4. Crude Oil-Tank 104
5. PFR3573 50% Citric Acid
6. PAO103-Paraffin Dispersant
7. OSW3019-Oxygen Scavenger
8. SCW4003-Forsa Scale Inhibitor
9. CRW6225-Corrosion Inhibitor
10. CRW9070-Corrosion Inhibitor
11. Skim Oil-Tank 106
12. Finrock Rock Drill 100-Lube Oil

Wells with chemical:

1. Well 70-CRW6255 Corrosion Inhibitor
2. Well 673C-FORSA SCW4002 Scale Inhibitor
3. Well743D-CROPCI4U Corrosion Inhibitor

Warehouse Chemicals:



1. Azolla ZS100-Hydraulic Oil
2. Finaroc 100-Rock Drill Oil
3. Carter EP320 Industrial EP Gear Oil
4. Shell S2 M68 Industrial Hydraulic Fluid

Heavy Oil Facility

Chemicals:

1. RBO6671-Water Clarifier
2. FLW163-Flotation Aid
3. DMO7045-Demulisfier
4. DMO8298X-Demulisifer
5. PAO3857D-Paraffin Dispersant
6. CRW6225-Corrosion Inhibitor
7. PFR83-Xylene
8. Tretolite DMO8298X-Demulisifer
9. Forsa PAO3857D-Paraffin Dispersant
10. Crude Oil-Tank 205
11. Crude Oil-Tank 206
12. Crude Oil (Skim)-Tank 202
13. Finrock 100-Rock Drill Oil

Tulare Water Plant Chemicals:

1. Carter EP320-
   Industrial EP Gear Oil
2. Helium Calibration Gas
3. Solvent-SOL142HT
4. Hydrochloric Acid 24.8%
5. Sodium Hydroxide (Na(OH))
   Caustic Soda
6. SRW156-Scale Inhibitor
7. PAO103-Paraffin Dispersant
8. WAW3003-Wetting Agent

Oil Stock Tank

CALIFORNIA ENVIRONMENTAL REPORTING SYSTEM (CERS)

CONSOLIDATED EMERGENCY RESPONSE / CONTINGENCY PLAN

Prior to completing this Plan, please refer to the INSTRUCTIONS FOR COMPLETING A CONSOLIDATED CONTINGENCY PLAN

A. FACILITY IDENTIFICATION AND OPERATIONS OVERVIEW

FACILITY ID # — — 1.

CERS ID A1.: 10231549

DATE OF PLAN PREPARATION/REVISION A2.: 2/7/2022

BUSINESS NAME *(Same as Facility Name or DBA - Doing Business As)* 3.: Berry Corporation-Hill Property

BUSINESS SITE ADDRESS 103.: 18271 Hwy 33

BUSINESS SITE CITY 104.: McKittrick | CA | ZIP CODE 105.: 93251

TYPE OF BUSINESS (e.g., Painting Contractor) A3.: Oil & Gas Exploitation and Production

INCIDENTAL OPERATIONS (e.g., Fleet Maintenance) A4.:

THIS PLAN COVERS CHEMICAL SPILLS, FIRES, AND EARTHQUAKES INVOLVING: (Check all that apply) A5.

☒ 1. HAZARDOUS MATERIALS; ☐ 2. HAZARDOUS WASTES

B. INTERNAL RESPONSE

INTERNAL FACILITY EMERGENCY RESPONSE WILL OCCUR VIA: (Check all that apply) B1.

☒ 1. CALLING PUBLIC EMERGENCY RESPONDERS (i.e., 9-1-1)
☒ 2. CALLING HAZARDOUS WASTE CONTRACTOR
☒ 3. ACTIVATING IN-HOUSE EMERGENCY RESPONSE TEAM

C. EMERGENCY COMMUNICATIONS, PHONE NUMBERS AND NOTIFICATIONS

Whenever there is an imminent or actual emergency situation such as an explosion, fire, or release, the Emergency Coordinator (or his/her designee when the Emergency Coordinator is on call) shall:

1. Activate internal facility alarms or communications systems, where applicable, to notify all facility personnel.
2. Notify appropriate local authorities (i.e., call 9-1-1).
3. Notify the California Emergency Management Agency at (800) 852-7550.

Before facility operations are resumed in areas of the facility affected by the incident, the emergency coordinator shall notify the California Department of Toxic Substances Control (DTSC), the local Unified Program Agency (UPA), and the local fire department's hazardous materials program that the facility is in compliance with requirements to:

1. Provide for proper storage and disposal of recovered waste, contaminated soil or surface water, or any other material that results from an explosion, fire, or release at the facility; and
2. Ensure that no material that is incompatible with the released material is transferred, stored, or disposed of in areas of the facility affected by the incident until cleanup procedures are completed.

INTERNAL FACILITY EMERGENCY COMMUNICATIONS OR ALARM NOTIFICATION WILL OCCUR VIA: (Check all that apply) C1.

☒ 1. VERBAL WARNINGS; ☐ 2. PUBLIC ADDRESS OR INTERCOM SYSTEM; ☒ 3. TELEPHONE;
☐ 4. PAGERS; ☒ 5. ALARM SYSTEM; ☒ 6. PORTABLE RADIO

NOTIFICATIONS TO NEIGHBORING FACILITIES THAT MAY BE AFFECTED BY AN OFF-SITE RELEASE WILL OCCUR BY: (Check all that apply) C2.

☒ 1. VERBAL WARNINGS; ☐ 2. PUBLIC ADDRESS OR INTERCOM SYSTEM; ☒ 3. TELEPHONE;
☐ 4. PAGERS; ☒ 5. ALARM SYSTEM; ☐ 6. PORTABLE RADIO

EMERGENCY RESPONSE PHONE NUMBERS:

AMBULANCE, FIRE, POLICE AND CHP	9-1-1
CALIFORNIA EMERGENCY MANAGEMENT AGENCY (CAL/EMA)	(800) 852-7550
NATIONAL RESPONSE CENTER (NRC)	(800) 424-8802
POISON CONTROL CENTER	(800) 222-1222
LOCAL UNIFIED PROGRAM AGENCY (UPA/CUPA) Kern County Environmental Health	(661) 862-8740 C3.
OTHER (Specify): CUPA- (661)549-9885 or C4.	(661) 549-9927 C5.
NEAREST MEDICAL FACILITY / HOSPITAL NAME: Mercy Southwest Hospital C6.	(661) 663-6000 C7.

AGENCY NOTIFICATION PHONE NUMBERS:

CALIFORNIA DEPT. OF TOXIC SUBSTANCES CONTROL (DTSC)	(916) 255-3545
REGIONAL WATER QUALITY CONTROL BOARD	(559) 445-5116 C8.
U.S. ENVIRONMENTAL PROTECTION AGENCY (US EPA)	(800) 300-2193
CALIFORNIA DEPT OF FISH AND GAME (DFG)	(916) 358-2900
U.S. COAST GUARD	(202) 267-2180
CAL/OSHA	(916) 263-2800
STATE FIRE MARSHAL	(916) 445-8200
OTHER (Specify): CALGEM C9.	(661) 322-4031 C10.
OTHER (Specify): C11.	C12.

D. EMERGENCY CONTAINMENT AND CLEANUP PROCEDURES

SPILL PREVENTION, CONTAINMENT, AND CLEANUP PROCEDURES: (Check all boxes that apply to indicate your procedures for containing spills, releases, fires or explosions; and. preventing and mitigating associated harm to persons, property, and the environment.)

D1.

- [x] 1. MONITOR FOR LEAKS, RUPTURES, PRESSURE BUILD-UP, ETC.;
- [ ] 2. PROVIDE STRUCTURAL PHYSICAL BARRIERS (e.g., Portable spill containment walls);
- [ ] 3. PROVIDE ABSORBENT PHYSICAL BARRIERS (e.g., Pads, pigs, pillows);
- [ ] 4. COVER OR BLOCK FLOOR AND/ OR STORM DRAINS;
- [x] 5. BUILT-IN BERM IN WORK / STORAGE AREA;
- [ ] 6. AUTOMATIC FIRE SUPPRESSION SYSTEM;
- [ ] 7. ELIMINATE SOURCES OF IGNITION FOR FLAMMABLE HAZARDS (e.g. Flammable liquids, Propane);
- [x] 8. STOP PROCESSES AND/OR OPERATIONS;
- [x] 9. AUTOMATIC / ELECTRONIC EQUIPMENT SHUT-OFF SYSTEM;
- [x] 10. SHUT-OFF WATER, GAS, ELECTRICAL UTILITIES AS APPROPRIATE;
- [x] 11. CALL 9-1-1 FOR PUBLIC EMERGENCY RESPONDER ASSISTANCE / MEDICAL AID;
- [x] 12. NOTIFY AND EVACUATE PERSONS IN ALL THREATENED AREAS;
- [x] 13. ACCOUNT FOR EVACUATED PERSONS IMMEDIATELY AFTER EVACUATION CALL;
- [x] 14. PROVIDE PROTECTIVE EQUIPMENT FOR ON-SITE RESPONSE TEAM;
- [x] 15. REMOVE OR ISOLATE CONTAINERS / AREA AS APPROPRIATE;
- [x] 16. HIRE LICENSED HAZARDOUS WASTE CONTRACTOR;
- [x] 17. USE ABSORBENT MATERIAL FOR SPILLS WITH SUBSEQUENT PROPER LABELING, STORAGE, AND HAZARDOUS WASTE DISPOSAL AS APPROPRIATE;
- [ ] 18. SUCTION USING SHOP VACUUM WITH SUBSEQUENT PROPER LABELING, STORAGE, AND HAZARDOUS WASTE DISPOSAL AS APPROPRIATE;
- [ ] 19. WASH / DECONTAMINATE EQUIPMENT W/ CONTAINMENT and DISPOSAL OF EFFLUENT / RINSATE AS HAZARDOUS WASTE;
- [x] 20. PROVIDE SAFE TEMPORARY STORAGE OF EMERGENCY-GENERATED WASTES;
- [ ] 21. OTHER (Specify):

D2.

E. FACILITY EVACUATION

THE FOLLOWING ALARM SIGNAL(S) WILL BE USED TO BEGIN EVACUATION OF THE FACILITY (CHECK ALL THAT APPLY): E1.

- [ ] 1. BELLS;
- [x] 2. HORNS/SIRENS;
- [x] 3. VERBAL (I.E., SHOUTING);
- [x] 4. OTHER (Specify): Cell phones, radios

E2.

THE FOLLOWING LOCATION(S) IS/ARE EVACUEE EMERGENCY ASSEMBLY AREA(S) (i.e., Front parking lot, specific street corner, etc.) E3.

1/2 mile East on contractors road off of HWY33. 35°29'3", 119°44'42"

Note: The Emergency Coordinator must account for all on site employees and/or site visitors after evacuation.

- [x] EVACUATION ROUTE MAP(S) POSTED AS REQUIRED E4.

Note: The map(s) must show primary and alternate evacuation routes, emergency exits, and primary and alternate staging areas, and must be prominently posted throughout the facility in locations where it will be visible to employees and visitors.

F. ARRANGEMENTS FOR EMERGENCY SERVICES

Explanation of Requirement: Advance arrangements with local fire and police departments, hospitals, and/or emergency services contractors should be made as appropriate for your facility. You may determine that such arrangements are not necessary.

ADVANCE ARRANGEMENTS FOR LOCAL EMERGENCY SERVICES (Check one of the following) F1.

- [ ] 1. HAVE BEEN DETERMINED NOT NECESSARY; *or*
- [x] 2. THE FOLLOWING ARRANGEMENTS HAVE BEEN MADE (Specify):

F2.

The following contractor resources are approved vendors for Berry Corporation that could be called when necessary:
> Initial Response - Truitt Oilfield Maintenance, Steve Upton, 661-399-5021
> Initial Response - Accelerated Environmental, Bill Cox, 661-337-0562
> Clean Up & Waste Handling - Patriot Environmental, Dave Larson 661-477-4250

G. EMERGENCY EQUIPMENT

Check all boxes that apply to list emergency response equipment available at the facility and identify the location(s) where the equipment is kept and the equipment's capability, if applicable. [e.g., ☒CHEMICAL PROTECTIVE GLOVES | Spill response kit | One time use, Oil & solvent resistant only.]

TYPE	EQUIPMENT AVAILABLE G1.	LOCATION	CAPABILITY *(If applicable)*
Safety and First Aid	1. ☐ CHEMICAL PROTECTIVE SUITS, APRONS, OR VESTS	G2.	G3.
	2. ☒ CHEMICAL PROTECTIVE GLOVES	G4. Carried by operators	G5. Rubber gloves
	3. ☐ CHEMICAL PROTECTIVE BOOTS	G6.	G7.
	4. ☒ SAFETY GLASSES / GOGGLES / SHIELDS	G8. Carried by operators	G9.
	5. ☒ HARD HATS	G10. Carried by operators	G11.
	6. ☐ CARTRIDGE RESPIRATORS	G12.	G13.
	7. ☐ SELF-CONTAINED BREATHING APPARATUS (SCBA)	G14.	G15.
	8. ☒ FIRST AID KITS / STATIONS	G16. Company Vehicles, field office	G17.
	9. ☐ PLUMBED EYEWASH FOUNTAIN / SHOWER	G18.	G19.
	10. ☒ PORTABLE EYEWASH KITS	G20. Company vehicles	G21. Eye Wash Bottle
	11. ☐ OTHER	G22.	G23.
	12. ☐ OTHER	G24.	G25.
Fire Fighting	13. ☒ PORTABLE FIRE EXTINGUISHERS	G26. Various locations throughout facility, company vehicles	G27.
	14. ☐ FIXED FIRE SYSTEMS / SPRINKLERS / FIRE HOSES	G28.	G29.
	15. ☐ FIRE ALARM BOXES OR STATIONS	G30.	G31.
	16. ☐ OTHER	G32.	G33.
Spill Control and Clean-Up	17. ☐ ALL-IN-ONE SPILL KIT	G34.	G35.
	18. ☐ ABSORBENT MATERIAL	G36.	G37.
	19. ☐ CONTAINER FOR USED ABSORBENT	G38.	G39.
	20. ☒ BERMING / DIKING EQUIPMENT	G40. Tanks, vessels, etc.	G41. AB1960, SPCC
	21. ☒ BROOM	G42. Available at facility	G43.
	22. ☒ SHOVEL	G44. Available at facility	G45.
	23. ☐ SHOP VAC	G46.	G47.
	24. ☐ EXHAUST HOOD	G48.	G49.
	25. ☒ EMERGENCY SUMP / HOLDING TANK	G50. Emergency overflow pits	G51.
	26. ☐ CHEMICAL NEUTRALIZERS	G52.	G53.
	27. ☐ GAS CYLINDER LEAK REPAIR KIT	G54.	G55.
	28. ☐ SPILL OVERPACK DRUMS	G56.	G57.
	29. ☐ OTHER	G58.	G59.
Communi-cations and Alarm Systems	30. ☒ TELEPHONES (Includes cellular)	G60. Carried by Company personnel	G61.
	31. ☐ INTERCOM / PA SYSTEM	G62.	G63.
	32. ☒ PORTABLE RADIOS	G64.	G65.
	33. ☒ AUTOMATIC ALARM CHEMICAL MONITORING EQUIPMENT	G66. Gas Plant, HOF, and Steam Generator site	G67.
Other	34. ☐ OTHER	G68.	G69.
	35. ☐ OTHER	G70.	G71.

H. EARTHQUAKE VULNERABILITY

Identify areas of the facility that are vulnerable to hazardous materials releases / spills due to earthquake-related motion. These areas require immediate isolation and inspection.

VULNERABLE AREAS: (Check all that apply)	H1.	LOCATIONS (e.g., shop, outdoor shed, forensic lab)	
☒ 1. HAZARDOUS MATERIALS / WASTE STORAGE AREA		Chemical containers located throughout facility (see site maps)	H2.
☒ 2. PROCESS LINES / PIPING		Located throughout facility	H3.
☐ 3. LABORATORY			H4.
☐ 4. WASTE TREATMENT AREA			H5.

Identify mechanical systems vulnerable to releases / spills due to earthquake-related motion. These systems require immediate isolation and inspection.

VULNERABLE SYSTEMS: (Check all that apply)	H6.	LOCATIONS	
☐ 1. SHELVES, CABINETS AND RACKS			H7.
☒ 2. TANKS (EMERGENCY SHUTOFF)		Various locations in field	H8.
☒ 3. PORTABLE GAS CYLINDERS			H9.
☒ 4. EMERGENCY SHUTOFF AND/OR UTILITY VALVES			H10.
☐ 5. SPRINKLER SYSTEMS			H11.
☒ 6. STATIONARY PRESSURIZED CONTAINERS (e.g., Propane dispensing tank)			H12.

I. EMPLOYEE TRAINING

Explanation of Requirement: Employee training is required for all employees handling hazardous materials and hazardous wastes in day-to-day or clean-up operations including volunteers and/or contractors. Training must be:

- Provided within 6 months for new hires;
- Amended as necessary prior to change in process or work assignment;
- Given upon modification to the Emergency Response / Contingency Plan, and updated/refreshed annually for all employees.

Required content includes all of the following:

- Material Safety Data Sheets;
- Hazard communication related to health and safety;
- Methods for safe handling of hazardous substances;
- Fire hazards of materials / processes;
- Conditions likely to worsen emergencies;
- Coordination of emergency response;
- Notification procedures;
- Applicable laws and regulations;
- Communication and alarm systems;
- Personal protective equipment;
- Use of emergency response equipment (e.g. Fire extinguishers, respirators, etc.);
- Decontamination procedures;
- Evacuation procedures;
- Control and containment procedures;
- UST monitoring system equipment and procedures (if applicable).

INDICATE HOW EMPLOYEE TRAINING PROGRAM IS ADMINISTERED (Check all that apply) I1.

☒ 1. FORMAL CLASSROOM; ☒ 2. VIDEOS; ☒ 3. SAFETY / TAILGATE MEETINGS;

☒ 4. STUDY GUIDES / MANUALS (Specify): Field Operating Guidelines, Emergency Response Manual/Annual HAZWOPER I2.

☒ 5. OTHER (Specify): Computer-based training I3.

☐ 6. NOT APPLICABLE BECAUSE FACILITY HAS NO EMPLOYEES

Large Quantity Generator (LQG) Training Records: Large quantity hazardous waste generators (i.e., who generate more than 270 gallons/1,000 kilograms of hazardous waste per month) must retain written documentation of employee hazardous waste management training sessions which includes:

- A written outline/agenda of the type and amount of both introductory and continuing training that will be given to persons filling each job position having responsibility for the management of hazardous waste (e.g., labeling, manifesting, compliance with accumulation time limits, etc.).
- The name, job title, and date of training for each hazardous waste management training session given to an employee filling such a job position; and
- A written job description for each of the above job positions that describes job duties and the skills, education, or other qualifications required of personnel assigned to the position.
- Current employee training records must be retained until closure of the facility.
- Former employee training records must be retained at least three years after termination of employment.

J. LIST OF ATTACHMENTS

(Check one of the following) J1.

☐ 1. NO ATTACHMENTS ARE REQUIRED; *or*

☐ 2. THE FOLLOWING DOCUMENTS ARE ATTACHED: J2.

K. SIGNATURE / CERTIFICATION

Certification: Based on my inquiry of those individuals responsible for obtaining the information, I certify under penalty of law that I have personally examined and am familiar with the information submitted and believe the information is true, accurate, and complete, and that a copy is available on site.

Hazardous Materials

Does your facility have on site (for any purpose) at any one time, hazardous materials at or above 55 gallons for liquids, 500 pounds for solids, or 200 cubic feet for compressed gases (include liquids in ASTs and USTs); or is regulated under more restrictive inventory local reporting requirements (shown below if present); or the applicable Federal threshold quantity for an extremely hazardous substance specified in 40 CFR Part 355, Appendix A or B; or handle radiological materials in quantities for which an emergency plan is required pursuant to 10 CFR Parts 30, 40 or 70?	**Yes**

Underground Storage Tank(s) (UST)

Does your facility own or operate underground storage tanks?	**No**

Hazardous Waste

Is your facility a Hazardous Waste Generator?	**No**
Does your facility treat hazardous waste on-site?	**No**
Is your facility's treatment subject to financial assurance requirements (for Permit by Rule and Conditional Authorization)?	**No**
Does your facility consolidate hazardous waste generated at a remote site?	**No**
Does your facility need to report the closure/removal of a tank that was classified as hazardous waste and cleaned on-site?	**No**
Does your facility generate in any single calendar month 1,000 kilograms (kg) (2,200 pounds) or more of federal RCRA hazardous waste, or generate in any single calendar month greater than 1 kg (2.2 pounds) of RCRA acute hazardous waste; or generate more than 100 kg (220 pounds) of spill cleanup materials contaminated with RCRA acute hazardous waste.	**No**
Is your facility a Household Hazardous Waste (HHW) Collection site?	**No**

Excluded and/or Exempted Materials

Does your facility recycle more than 100 kg/month of excluded or exempted recyclable materials (per HSC 25143.2)?	**No**
Does your facility own or operate ASTs above these thresholds? Store greater than 1,320 gallons of petroleum products (new or used) in aboveground tanks or containers.	**No**
Does your facility have Regulated Substances stored onsite in quantities greater than the threshold quantities established by the California Accidental Release prevention Program (CalARP)?	**No**

Additional Information

No additional comments provided.

CALIFORNIA ENVIRONMENTAL REPORTING SYSTEM (CERS)

CONSOLIDATED EMERGENCY RESPONSE / CONTINGENCY PLAN

Prior to completing this Plan, please refer to the INSTRUCTIONS FOR COMPLETING A CONSOLIDATED CONTINGENCY PLAN

A. FACILITY IDENTIFICATION AND OPERATIONS OVERVIEW

FACILITY ID # 0 0 0 3 0 7 7 — 1.

CERS ID A1. 10234243

DATE OF PLAN PREPARATION/REVISION A2. 2/21/2022

BUSINESS NAME *(Same as Facility Name or DBA - Doing Business As)* 3.
Plains Pipeline LP- Belridge

BUSINESS SITE ADDRESS 103.
18667 Waterflood Road

BUSINESS SITE CITY 104. McKittrick

CA

ZIP CODE 105. 93251

TYPE OF BUSINESS (e.g., Painting Contractor) A3.
Pipeline- Crude Oil

INCIDENTAL OPERATIONS (e.g., Fleet Maintenance) A4.
Pumping/Storage

THIS PLAN COVERS CHEMICAL SPILLS, FIRES, AND EARTHQUAKES INVOLVING: (Check all that apply) A5.

☒ 1. HAZARDOUS MATERIALS; ☐ 2. HAZARDOUS WASTES

B. INTERNAL RESPONSE

INTERNAL FACILITY EMERGENCY RESPONSE WILL OCCUR VIA: (Check all that apply) B1.

☒ 1. CALLING PUBLIC EMERGENCY RESPONDERS (i.e., 9-1-1)
☒ 2. CALLING HAZARDOUS WASTE CONTRACTOR
☒ 3. ACTIVATING IN-HOUSE EMERGENCY RESPONSE TEAM

C. EMERGENCY COMMUNICATIONS, PHONE NUMBERS AND NOTIFICATIONS

Whenever there is an imminent or actual emergency situation such as an explosion, fire, or release, the Emergency Coordinator (or his/her designee when the Emergency Coordinator is on call) shall:

1. Activate internal facility alarms or communications systems, where applicable, to notify all facility personnel.
2. Notify appropriate local authorities (i.e., call 9-1-1).
3. Notify the California Emergency Management Agency at (800) 852-7550.

Before facility operations are resumed in areas of the facility affected by the incident, the emergency coordinator shall notify the California Department of Toxic Substances Control (DTSC), the local Unified Program Agency (UPA), and the local fire department's hazardous materials program that the facility is in compliance with requirements to:

1. Provide for proper storage and disposal of recovered waste, contaminated soil or surface water, or any other material that results from an explosion, fire, or release at the facility; and
2. Ensure that no material that is incompatible with the released material is transferred, stored, or disposed of in areas of the facility affected by the incident until cleanup procedures are completed.

INTERNAL FACILITY EMERGENCY COMMUNICATIONS OR ALARM NOTIFICATION WILL OCCUR VIA: (Check all that apply) C1.

☒ 1. VERBAL WARNINGS; ☐ 2. PUBLIC ADDRESS OR INTERCOM SYSTEM; ☒ 3. TELEPHONE;
☐ 4. PAGERS; ☐ 5. ALARM SYSTEM; ☐ 6. PORTABLE RADIO

NOTIFICATIONS TO NEIGHBORING FACILITIES THAT MAY BE AFFECTED BY AN OFF-SITE RELEASE WILL OCCUR BY: (Check all that apply) C2.

☒ 1. VERBAL WARNINGS; ☐ 2. PUBLIC ADDRESS OR INTERCOM SYSTEM; ☒ 3. TELEPHONE;
☐ 4. PAGERS; ☐ 5. ALARM SYSTEM; ☐ 6. PORTABLE RADIO

EMERGENCY RESPONSE PHONE NUMBERS:

AMBULANCE, FIRE, POLICE AND CHP	9-1-1
CALIFORNIA EMERGENCY MANAGEMENT AGENCY (CAL/EMA)	(800) 852-7550
NATIONAL RESPONSE CENTER (NRC)	(800) 424-8802
POISON CONTROL CENTER	(800) 222-1222

D. EMERGENCY CONTAINMENT AND CLEANUP PROCEDURES

SPILL PREVENTION, CONTAINMENT, AND CLEANUP PROCEDURES: (Check all boxes that apply to indicate your procedures for containing spills, releases, fires or explosions; and. preventing and mitigating associated harm to persons, property, and the environment.)

D1.

- [x] 1. MONITOR FOR LEAKS, RUPTURES, PRESSURE BUILD-UP, ETC.;
- [x] 2. PROVIDE STRUCTURAL PHYSICAL BARRIERS (e.g., Portable spill containment walls);
- [x] 3. PROVIDE ABSORBENT PHYSICAL BARRIERS (e.g., Pads, pigs, pillows);
- [x] 4. COVER OR BLOCK FLOOR AND/ OR STORM DRAINS;
- [x] 5. BUILT-IN BERM IN WORK / STORAGE AREA;
- [ ] 6. AUTOMATIC FIRE SUPPRESSION SYSTEM;
- [x] 7. ELIMINATE SOURCES OF IGNITION FOR FLAMMABLE HAZARDS (e.g. Flammable liquids, Propane);
- [x] 8. STOP PROCESSES AND/OR OPERATIONS;
- [x] 9. AUTOMATIC / ELECTRONIC EQUIPMENT SHUT-OFF SYSTEM;
- [x] 10. SHUT-OFF WATER, GAS, ELECTRICAL UTILITIES AS APPROPRIATE;
- [x] 11. CALL 9-1-1 FOR PUBLIC EMERGENCY RESPONDER ASSISTANCE / MEDICAL AID;
- [x] 12. NOTIFY AND EVACUATE PERSONS IN ALL THREATENED AREAS;
- [x] 13. ACCOUNT FOR EVACUATED PERSONS IMMEDIATELY AFTER EVACUATION CALL;
- [x] 14. PROVIDE PROTECTIVE EQUIPMENT FOR ON-SITE RESPONSE TEAM;
- [x] 15. REMOVE OR ISOLATE CONTAINERS / AREA AS APPROPRIATE;
- [x] 16. HIRE LICENSED HAZARDOUS WASTE CONTRACTOR;
- [x] 17. USE ABSORBENT MATERIAL FOR SPILLS WITH SUBSEQUENT PROPER LABELING, STORAGE, AND HAZARDOUS WASTE DISPOSAL AS APPROPRIATE;
- [x] 18. SUCTION USING SHOP VACUUM WITH SUBSEQUENT PROPER LABELING, STORAGE, AND HAZARDOUS WASTE DISPOSAL AS APPROPRIATE;
- [x] 19. WASH / DECONTAMINATE EQUIPMENT W/ CONTAINMENT and DISPOSAL OF EFFLUENT / RINSATE AS HAZARDOUS WASTE;
- [x] 20. PROVIDE SAFE TEMPORARY STORAGE OF EMERGENCY-GENERATED WASTES;
- [ ] 21. OTHER (Specify):

D2.

E. FACILITY EVACUATION

THE FOLLOWING ALARM SIGNAL(S) WILL BE USED TO BEGIN EVACUATION OF THE FACILITY (CHECK ALL THAT APPLY): E1.

- [ ] 1. BELLS;
- [ ] 2. HORNS/SIRENS;
- [x] 3. VERBAL (I.E., SHOUTING);
- [ ] 4. OTHER (Specify):

E2.

THE FOLLOWING LOCATION(S) IS/ARE EVACUEE EMERGENCY ASSEMBLY AREA(S) (i.e., Front parking lot, specific street corner, etc.) E3.

Facility entrance/open space east of facility

Note: The Emergency Coordinator must account for all on site employees and/or site visitors after evacuation.

- [x] EVACUATION ROUTE MAP(S) POSTED AS REQUIRED

E4.

Note: The map(s) must show primary and alternate evacuation routes, emergency exits, and primary and alternate staging areas, and must be prominently posted throughout the facility in locations where it will be visible to employees and visitors.

F. ARRANGEMENTS FOR EMERGENCY SERVICES

Explanation of Requirement: Advance arrangements with local fire and police departments, hospitals, and/or emergency services contractors should be made as appropriate for your facility. You may determine that such arrangements are not necessary.

ADVANCE ARRANGEMENTS FOR LOCAL EMERGENCY SERVICES (Check one of the following) F1.

- [x] 1. HAVE BEEN DETERMINED NOT NECESSARY; *or*
- [ ] 2. THE FOLLOWING ARRANGEMENTS HAVE BEEN MADE (Specify):

F2.

G. EMERGENCY EQUIPMENT

Check all boxes that apply to list emergency response equipment available at the facility and identify the location(s) where the equipment is kept and the equipment's capability, if applicable. [e.g., ☒ CHEMICAL PROTECTIVE GLOVES | Spill response kit | One time use, Oil & solvent resistant only.]

TYPE	EQUIPMENT AVAILABLE G1.	LOCATION	CAPABILITY *(If applicable)*
Safety and First Aid	1. ☐ CHEMICAL PROTECTIVE SUITS, APRONS, OR VESTS	G2.	G3.
	2. ☒ CHEMICAL PROTECTIVE GLOVES	G4. Personal	G5.
	3. ☒ CHEMICAL PROTECTIVE BOOTS	G6. Personal	G7.
	4. ☒ SAFETY GLASSES / GOGGLES / SHIELDS	G8. Personal	G9.
	5. ☒ HARD HATS	G10. Personal	G11.
	6. ☒ CARTRIDGE RESPIRATORS	G12. Personal	G13.
	7. ☐ SELF-CONTAINED BREATHING APPARATUS (SCBA)	G14.	G15.
	8. ☒ FIRST AID KITS / STATIONS	G16. Office	G17.
	9. ☐ PLUMBED EYEWASH FOUNTAIN / SHOWER	G18.	G19.
	10. ☐ PORTABLE EYEWASH KITS	G20.	G21.
	11. ☐ OTHER	G22.	G23.
	12. ☐ OTHER	G24.	G25.
Fire Fighting	13. ☒ PORTABLE FIRE EXTINGUISHERS	G26. Facility, Lab and Personal	G27.
	14. ☐ FIXED FIRE SYSTEMS / SPRINKLERS / FIRE HOSES	G28.	G29.
	15. ☐ FIRE ALARM BOXES OR STATIONS	G30.	G31.
	16. ☐ OTHER	G32.	G33.
Spill Control and Clean-Up	17. ☒ ALL-IN-ONE SPILL KIT	G34. Personal	G35.
	18. ☒ ABSORBENT MATERIAL	G36. Personal	G37.
	19. ☐ CONTAINER FOR USED ABSORBENT	G38.	G39.
	20. ☒ BERMING / DIKING EQUIPMENT	G40. Around all tanks	G41.
	21. ☒ BROOM	G42. Personal; located in office	G43.
	22. ☒ SHOVEL	G44. Personal; located in office	G45.
	23. ☐ SHOP VAC	G46.	G47.
	24. ☐ EXHAUST HOOD	G48.	G49.
	25. ☐ EMERGENCY SUMP / HOLDING TANK	G50.	G51.
	26. ☐ CHEMICAL NEUTRALIZERS	G52.	G53.
	27. ☐ GAS CYLINDER LEAK REPAIR KIT	G54.	G55.
	28. ☐ SPILL OVERPACK DRUMS	G56.	G57.
	29. ☐ OTHER	G58.	G59.
Communi-cations and Alarm Systems	30. ☒ TELEPHONES (Includes cellular)	G60. Personal/Lab	G61.
	31. ☐ INTERCOM / PA SYSTEM	G62.	G63.
	32. ☐ PORTABLE RADIOS	G64.	G65.
	33. ☐ AUTOMATIC ALARM CHEMICAL MONITORING EQUIPMENT	G66.	G67.
Other	34. ☐ OTHER	G68.	G69.
	35. ☐ OTHER	G70.	G71.

H. EARTHQUAKE VULNERABILITY

Identify areas of the facility that are vulnerable to hazardous materials releases / spills due to earthquake-related motion. These areas require immediate isolation and inspection.

VULNERABLE AREAS: (Check all that apply)	H1.	LOCATIONS (e.g., shop, outdoor shed, forensic lab)	
☐ 1. HAZARDOUS MATERIALS / WASTE STORAGE AREA			H2.
☒ 2. PROCESS LINES / PIPING		Tank area and east of tanks.	H3.
☐ 3. LABORATORY			H4.
☐ 4. WASTE TREATMENT AREA			H5.

Identify mechanical systems vulnerable to releases / spills due to earthquake-related motion. These systems require immediate isolation and inspection.

VULNERABLE SYSTEMS: (Check all that apply)	H6.	LOCATIONS	
☐ 1. SHELVES, CABINETS AND RACKS			H7.
☒ 2. TANKS (EMERGENCY SHUTOFF)		Tank Area	H8.
☐ 3. PORTABLE GAS CYLINDERS			H9.
☒ 4. EMERGENCY SHUTOFF AND/OR UTILITY VALVES		Tank Area	H10.
☐ 5. SPRINKLER SYSTEMS			H11.
☐ 6. STATIONARY PRESSURIZED CONTAINERS (e.g., Propane dispensing tank)			H12.

I. EMPLOYEE TRAINING

Explanation of Requirement: Employee training is required for all employees handling hazardous materials and hazardous wastes in day-to-day or clean-up operations including volunteers and/or contractors. Training must be:

- Provided within 6 months for new hires;
- Amended as necessary prior to change in process or work assignment;
- Given upon modification to the Emergency Response / Contingency Plan, and updated/refreshed annually for all employees.

Required content includes all of the following:

- Material Safety Data Sheets;
- Hazard communication related to health and safety;
- Methods for safe handling of hazardous substances;
- Fire hazards of materials / processes;
- Conditions likely to worsen emergencies;
- Coordination of emergency response;
- Notification procedures;
- Applicable laws and regulations;
- Communication and alarm systems;
- Personal protective equipment;
- Use of emergency response equipment (e.g. Fire extinguishers, respirators, etc.);
- Decontamination procedures;
- Evacuation procedures;
- Control and containment procedures;
- UST monitoring system equipment and procedures (if applicable).

INDICATE HOW EMPLOYEE TRAINING PROGRAM IS ADMINISTERED (Check all that apply) I1.

☒ 1. FORMAL CLASSROOM; ☒ 2. VIDEOS; ☒ 3. SAFETY / TAILGATE MEETINGS;

☒ 4. STUDY GUIDES / MANUALS (Specify): Operations & Maintenance Manual; Emergency Response Plan; Safety Manual I2.

☐ 5. OTHER (Specify): _____ I3.

☐ 6. NOT APPLICABLE BECAUSE FACILITY HAS NO EMPLOYEES

Large Quantity Generator (LQG) Training Records: Large quantity hazardous waste generators (i.e., who generate more than 270 gallons/1,000 kilograms of hazardous waste per month) must retain written documentation of employee hazardous waste management training sessions which includes:

- A written outline/agenda of the type and amount of both introductory and continuing training that will be given to persons filling each job position having responsibility for the management of hazardous waste (e.g., labeling, manifesting, compliance with accumulation time limits, etc.).
- The name, job title, and date of training for each hazardous waste management training session given to an employee filling such a job position; and
- A written job description for each of the above job positions that describes job duties and the skills, education, or other qualifications required of personnel assigned to the position.
- Current employee training records must be retained until closure of the facility.
- Former employee training records must be retained at least three years after termination of employment.

J. LIST OF ATTACHMENTS

(Check one of the following) J1.

☒ 1. NO ATTACHMENTS ARE REQUIRED; *or*

☐ 2. THE FOLLOWING DOCUMENTS ARE ATTACHED: J2.

K. SIGNATURE / CERTIFICATION

Certification: Based on my inquiry of those individuals responsible for obtaining the information, I certify under penalty of law that I have personally examined and am familiar with the information submitted and believe the information is true, accurate, and complete, and that a copy is available on site.

APPENDIX G
INTERVIEW FORMS

ASTM 1527-13 or 1527-21 Phase I ESA
USER QUESTIONAIRE

Subject Property Address/Location: North and South Belridge Oil Fields, Centered on 35.501525°, -119.751895° (World Geodetic System of 1984 [WGS 84]).

Type of Property: Developed Oil and Gas Field

Type of Transaction (property acquisition, refinance, lease, etc.): N/A

Why is a Phase I ESA required: The Phase I ESA is prepared in support of a Carbon Capture and Storage Project

Identification of all reliant parties: _____

The User must provide the following information (if available) to the *environmental professional*. Failure to provide this information could result in a determination that *"all appropriate inquiry"* is not complete.

1) Environmental liens that are filed or recorded against the Subject Property (40 C.F.R. § 312.25).
Did a search of land title records (or judicial records where appropriate) identify any environmental liens filed or recorded against the Subject Property under federal, tribal, state, or local law?

A search of land title records did not identify any environmental liens filed or recorded against the property under federal, tribal, state, or local law.

2) Activity and use limitations that are in place on the Subject Property or that have been filed or recorded against the Subject Property. Did a search of land title records (or judicial records where appropriate, see Note 1 above) identify any AULs, such as engineering controls, land use restrictions or institutional controls that are in place at the Subject Property and/or have been filed or recorded against the Subject Property under federal, tribal, state or local law?

A search of land title records did not identify any Activity and Use Limitations (AULs) that have been filed/recorded against the Property or that are in place on the Property, under federal, tribal, state or local law.

3) Specialized knowledge or experience of the person seeking to qualify for the LLP (40 C.F.R. § 312.28).
Do you have any specialized knowledge or experience related to the Subject Property or nearby properties? For example, are you involved in the same line of business as the current or former occupants of the Subject Property or an adjoining property so that you would have specialized knowledge of the chemicals and processes used by this type of business?

No.

4) Relationship of the purchase price to the fair market value of the Subject Property if it were not contaminated (40 C.F.R. § 312.29). Does the purchase price being paid for this Subject Property reasonably reflect the fair market value of the property? If you conclude that there is a difference, have you considered whether the lower purchase price is because contamination is known or believed to be present at the Subject Property?

N/A.

5) Commonly known or reasonably ascertainable information about the Subject Property (40 C.F.R. § 312.30).
Are you aware of commonly known or reasonably ascertainable information about the Subject Property that would help the environmental professional to identify conditions indicative of releases or threatened releases? For example,

- Do you know the past uses of the Subject Property?

  This has been an active oilfield for over 100 years.

- Do you know of specific chemicals that are present or once were present at the Subject Property?

  We do have knowledge of the specific chemicals that have been and are currently present at the subject property. Mostly associated with extraction of Oil and Gas

- Do you know of spills or other chemical releases that have taken place at the Subject Property?

  All spill information is available at CalOES website.

- Do you know of any environmental cleanups that have taken place at the Subject Property?

  If any cleanups have taken place, they will be linked to the associated OES report.

6) The degree of obviousness of the presence or likely presence of contamination at the Subject Property, and the ability to detect the contamination by appropriate investigation (40 C.F.R. § 312.31).
Based on your knowledge and experience related to the Subject Property, are there any obvious indicators that point to the presence or likely presence of releases at the Subject Property?

We are not aware of any areas that have not already been identified by the Phase I ESA report.

EXECUTIVE SUMMARY

Aera Energy LLC (Aera) is proposing to develop a Carbon Capture and Sequestration (CCS) Project at their Belridge facility in western Kern County, California. The CarbonFrontier CCS Project will capture carbon dioxide (CO_2) from existing sources in the South Belridge oil field and transport the CO_2 by pipeline to the North Belridge oil field for geologic sequestration.

A Quantitative Risk Assessment (QRA) has been conducted to assess the potential for acute hazards to the public and the environment associated with the above ground Project facilities. The following activities have been assessed:

- CO_2 capture and compression from existing produced gas streams and flue gas emissions from existing stationary sources.
- Transport of dense phase CO_2 through an in-field pipeline to the North Belridge oil field for sequestration. The main pipeline will be approximately 10-miles in length, with branches to the injection wells.
- Injection of dense phase CO_2 into a depleted oil reservoir at over 8,000 feet deep for permanent geologic sequestration, utilizing 9 injection wells.
- Delivery of hazardous materials.

Loss of containment events from these activities may result in acute public or environmental hazards. A release of CO_2 from underground geologic storage may occur due to migration to the surface via an abandoned well, fault or fracture. The potential for migration to the surface has also been assessed in this analysis, although this will generally result in a slow dissipated release and is unlikely to be acutely hazardous. Extensive monitoring of the injection wells, dedicated monitoring wells, air, soil and vegetation sampling is proposed to identify any potential failures.

Potential hazardous material impacts to the public have been quantified. For any given release, the number of people potentially exposed will depend on the size of the release, time of day, weather conditions, and the likelihood that the public are in the area. The risks have been calculated by estimating the likelihood and consequences of potential release scenarios. Total risks to the public have been summated to calculate the likelihood of exposure to a level of concern.

The overall hazards to the public from all proposed operations have been calculated for potential exposure to toxic levels of concern, potential injury and potential for serious harm or fatality as follows:

Release Source	Population Groups Exposed	Level of Concern	Potential for Significant Injury	Potential for Serious Harm or Fatality
		Likelihood	Likelihood	Likelihood
Produced Gas Transfer - Pipeline Rupture	Vehicles on Hwy-33	1 in 56,000 years	-	-
Carbon Capture and Compression	None	-	-	-
CO_2 Pipeline Transfer – Pipeline Rupture	Vehicles on Hwy-33 Agricultural workers Solar panel workers Berry and Team oil field workers	1 in 2,900 years	1 in 27,000 years	1 in 300,000 years
CO_2 Injection Wells	Team Operating oil field workers	1 in 69 million years	-	-
Leakage of CO_2 from Sequestration Reservoir	None	-	-	-
Amine Truck Transportation	50-mile road traffic from Bakersfield	1 in 92,000 years	-	-
Sulfuric Acid Truck Transportation	50-mile road traffic from Bakersfield	1 in 59,000 years	1 in 250,000 years	1 in 4.6 million years
Total Risk of Public Exposure		**1 in 2,700 years**	**1 in 24,000 years**	**1 in 190,000 years**

The primary source of risk is the CO_2 transfer pipeline from South Belridge carbon capture facilities to North Belridge geologic sequestration. This contributes to 88% of the aggregate risk of exposure to a level of concern for all public populations in the vicinity.

The combined likelihood of public exposure to a concentration that may cause public concern is 1 in 2,700 years.

Potential risks to the public have also been calculated in terms of individual risk and the risk to society as a whole. The levels of risk have been compared to international criteria for tolerability of hazardous material risks from industrial activities. Risks to the public associated with the CarbonFrontier project are within all established criteria.

1. INTRODUCTION

1.1 Background

Aera Energy LLC (Aera) is proposing to develop a Carbon Capture and Sequestration (CCS) Project (Project) at their Belridge facility in western Kern County, California. The CarbonFrontier CCS Project will capture carbon dioxide (CO_2) from existing sources in the South Belridge oil field and transport the CO_2 by pipeline to the North Belridge oil field for geologic sequestration. The Project is located within Aera's oil field boundary.

The Project is subject to operating permits and environmental review, which includes, but is not limited to, the submittal of applications to Kern County Planning and Natural Resources Department and the US Environmental Protection Agency (EPA). These applications require the assessment of risks associated with the Project, including potentially adverse impacts on the environment, health, and safety.

Aera has requested that Dixon Risk Consulting (DRC) conduct a Quantitative Risk Assessment (QRA) to assess the potential for acute hazards to the public and the environment associated with the proposed Project. The QRA will address the likelihood of release and potential impacts associated with safety and environment, in order to assess the risk acceptability.

1.2 Scope of Work

This QRA assesses the acutely hazardous material risks to the public and environment associated with a potential loss of containment event for the proposed CarbonFrontier CCS Project. Carbon dioxide is the primary hazardous material of concern. CO_2 is a naturally occurring atmospheric gas, normally present in air at about 400 parts per million (ppm). In order to sequester CO_2 and store permanently underground in a depleted oil reservoir, CO_2 must be concentrated, treated, compressed, transported and injected deep underground. CO_2 will be compressed into a high-pressure dense phase fluid that exhibits properties between that of a liquid and a gas. On release, multiple phase changes occur causing rapid cooling of the gas and possible solid dry ice formation. The cold heavier than air gas may cause hazards to personnel or the environment as it spreads and dissipates.

This QRA is primarily concerned with acute hazards to the public on neighboring agricultural facilities, travelling on major roads, and neighboring non-Aera oil production workers. An acute risk is an immediate hazard resulting from a short-term event, such as an exposure to a toxic substance. Potential release events may occur due to equipment or operational failures that do not include planned releases such as blowdown events for maintenance.

The following activities have been assessed:

- CO_2 capture and compression from existing Tulare and Diatomite reservoir produced gas streams (Pre-Combustion), at a future site near Gas Plant 32.

- Pipeline transfer of Tulare produced gas from South of Seventh Standard Road to the gas treatment facility at Sulferox Plant 32 (SOX 32), then to the CO_2 Pre-Combustion capture facility.
- CO_2 capture and compression from flue gas emissions from existing stationary sources (Post-Combustion) within the South Belridge oil field. The capture sources are currently proposed to be at the Co-Generation Facility (Cogen) 32 and Steam Generator sites 2868 and 2972.
- Transport of the dense phase CO_2 through pipelines to the North Belridge oil field for injection into dedicated injection wells. The main pipeline will be approximately 10-miles in length, with branches to the injection wells.
- Injection of dense phase CO_2 into Underground Injection Control (UIC) EPA Class VI geologic sequestration wells.
- Bulk delivery of amine solvent and storage.
- Bulk delivery of sulfuric acid and storage.

Loss of containment events from these activities may result in acute public or environmental hazards. A release of CO_2 from underground geologic storage may occur due to migration to the surface via an abandoned well, fault or fracture. The potential for migration to the surface has also been assessed in this analysis, although this will generally result in a slow dissipated release and is unlikely to be acutely hazardous. Extensive monitoring of the injection wells, dedicated monitoring wells, air, soil and vegetation sampling is proposed to identify any potential failures.

Potential hazards to the public associated with acute exposure to hazardous materials have been assessed by calculating both the risk to individuals, and the risk to society as a whole. The risks have been determined by combining the potential severity and likelihood for three selected levels of concern. The levels range from minor injury, to potential fatality.

This QRA has been developed from information provided by Aera for the preliminary design as of October 2022. It has been assumed that the proposed carbon capture facilities are operating at full capacity of 2 million metric tons (MM mt) of CO_2 per year for approximately 20 years.

This scope of work is limited to the CarbonFrontier CCS facilities in the operational phase of the Project. The QRA does not include risks associated with construction or post injection phases of the project. Potential risks to Aera and Aera contract personnel have also not been included in this analysis.

Personnel and environmental hazards associated with long-term fugitive emissions have not been addressed in this analysis. Occupational accidents and other external events are also excluded.

1.3 Quantitative Risk Assessment Methodology

Quantitative Risk Assessment is an established methodology to quantify the risk of potential events, by estimating the likelihood and consequence of these events. Failures can include catastrophic rupture events which may result in a rapid release lasting minutes, or longer duration leak event lasting an hour or more. The dispersion of a hazardous release in the air was estimated through modeling, as described below in Section 5.

The risk to public personnel and the environment has been assessed using the following steps:

- Identify potential release scenarios.
- Assess the causes and frequency of historical incidents.
- Quantify the likelihood of these scenarios using published failure rate data.
- Determine the consequences and potential impact to public personnel and the environment.
- Combine the likelihood and consequences to calculate the risk to individuals and society.
- Assess the significance of the risk of injury, fatality or environmental harm against published risk tolerability criteria.

QRA provides an estimate of the risks, which tends to err on the side of conservatism. The approach was to make reasonable assumptions on the hazards, likelihood of failure and potential impacts of a release. In the process of QRA, numerous assumptions must be made, based on best available information. Where appropriate, sources of these assumptions, estimates and reasoning have been described.

2. PROJECT DESCRIPTION

2.1 Carbon Sequestration Project Overview

The proposed CarbonFrontier CCS Project will capture CO_2 in the South Belridge oil field from existing sources within the oil production operation. Captured CO_2 will be compressed, dehydrated, pumped then transported by an in-field pipeline to the sequestration site in North Belridge. The compressed CO_2 will be injected into a depleted oil reservoir at over 8,000 feet deep for permanent geologic sequestration. Locations of the proposed Project facilities are shown in Figure 2.1, and a preliminary block flow diagram in Figure 2.2.

It is anticipated that the proposed Project will sequester roughly 2 million metric tons (MM mt) of CO_2 per year beginning in 2027, for a period of approximately 20 years.

The South Belridge and North Belridge oil fields are contiguous, and cover an area approximately 13 miles long and three miles wide. Aera is the primary operator within both oil fields.

2.1.1 Source Streams

It is proposed to capture CO_2 from two types of existing sources; from produced natural gas pre-combustion, and from flue gas emissions post-combustion.

Pre-Combustion

This involves separation of CO_2 from existing produced natural gas streams, prior to combustion for steam generation. This source will extract approximately 0.2 MM mt per year of CO_2.

The Belridge Field has two natural gas streams associated with oil production which are proposed for CO_2 capture:

- Diatomite produced gas is associated with the production of light oil from the Diatomite formation. The gas has an average CO_2 content of approximately 36%. The gas is gathered at area compressor stations and routed by pipeline to Section 32, where it is treated to remove hydrogen sulfide (H_2S) in SOX 32.
- Tulare produced gas is associated with the production of heavy oil from the Tulare Sands. The CO_2 content is approximately 75%, and the H_2S content approximately 3,000 ppm. The gas is currently gathered, treated via sulferox to remove H_2S, and co-fired in steam generators for disposal. It is proposed to transfer the Tulare gas to Section 32 for treatment at Sulferox Plant 32. Tulare gas will be combined with the Diatomite gas gathered south of Seventh Standard Road (SOSS), compressed at the Del Sur compressor station, and transferred via pipeline to SOX 32. The pipeline is assumed to be an existing 16-inch diameter line, currently used for Diatomite gas, which is primarily located aboveground. Alternatively, a new 12 to 16-inch diameter pipeline will constructed primarily aboveground for transfer to the SOX 3-2 facility. Pipeline conditions are shown below, and the combined flow composition shown in Table 2.1.

Del Sur Produced Gas Transfer Line	Line Conditions		Line Length	
	Pressure	Temp	ft	miles
16-inch line from Del Sur Compressor Station to SOX 32	170 psig	100°F	18,800	3.6

psig = pounds per square inch gauge

Post-Combustion

CO_2 will be extracted from flue gas emissions at three existing stationary sources:

- The Co-Generation facility next to Gas Plant 32,
- Steam generator site 2868, and;
- Steam generator site 2972.

The generator sites each have ten 85 million British thermal unit (MMBtu) steam generators. These three sources will capture up to approximately 1.4 MM mt per year of CO_2

2.1.2 Carbon Capture Facilities

CO_2 capture and compression equipment will be constructed adjacent to four existing facilities within the developed South Belridge oil field.

It has been assumed that the carbon capture facilities will use solvent based amine absorption technology. This is established technology widely used in industry to remove CO_2 and H_2S from oil production natural gas, and refinery gas and liquid streams. The most commonly used amines are the alkanolamines; monoethanolamine (MEA), diethanolamine (DEA), and methyl diethanolamine (MDEA). Proprietary solvents have been developed with improved performance over traditional MEA, which may offer reduced regeneration energy, better performance for flue gas streams, and reduced solvent loss. The final choice of chemical for amine absorption has not been determined, although the general principles are the same for all absorption processes available.

The proposed design for the CO_2 capture facilities comprises a pre-scrubber, a CO_2 absorber column, a CO_2 stripper column, and associated pumps and heat exchangers. Process conditions and sizes of the vessels have been estimated to conduct the hazard analysis.

An example of an amine absorption carbon capture process flow diagram is shown in Figure 2.3. The gas stream for CO_2 capture enters the CO_2 absorber at the bottom of the column at about 100°F and 110 psig. Lean amine solution at about 30% MEA is pumped into the top of the tower. CO_2 is absorbed in the solvent, and the remaining gases leave from the top of the tower. The CO_2 rich solvent passes out of the bottom of the tower and then is transferred via a buffer vessel and heat exchanger to the amine regenerator tower. A reboiler at the bottom of the regenerator tower heats the solvent to reverse the absorption reaction. CO_2 is stripped from the solvent at about 225°F and 10 psig. The hot lean solvent is recycled back through heat exchangers and a cooler before being pumped back to the CO_2 absorber. The captured CO_2 stream passes to the compression and dehydration section.

2.1.3 CO_2 Compression and Dehydration

The captured CO_2 will be compressed and water removed. At the three post-combustion capture facilities, residual oxygen may also need to be removed.

It has been assumed that the initial compression stages use a centrifugal compressor, and free water is separated out through a series of compression and cooling stages. CO_2 will then be processed through a triethylene glycol (TEG) dehydration unit to reduce the water content to less than 258 ppm concentration. At the three post-combustion capture facilities, residual oxygen will be removed using an oxygen scavenger to less than 50 ppm concentration. The dried dense phase CO_2 will pass through a buffer drum, and then pumped to the CO_2 transfer pipeline at about 1,700 psig and 100°F.

At the North Belridge sequestration field, the CO_2 pressure may be increased as the reservoir pressure increases. A booster pump may be installed at Compressor Station 49 (CS 49) to increase the injection pressure.

2.1.4 CO_2 Pipeline Transport

The CO_2 transfer pipeline from the South Belridge capture facilities to North Belridge sequestration field will run primarily above ground across developed sections, utilizing existing infield pipeline routes. The main pipeline is assumed to be 12-inches in diameter, 10-miles in length, and operate at a pressure of 1,700 psig and temperature of 100°F. Distribution pipelines from CS 49 are assumed to be 12-inches, and lateral lines to the individual injection wells are assumed to be 6-inches in diameter. Lengths have been estimated as follows:

CO_2 Transfer Line	Line Conditions		Line Length	
	Pressure	Temp	ft	miles
4 x 8-inch lines from Pre-C and Post-C to transfer pipeline	1,700 psig	100°F	3,150	0.6
12-inch CO_2 transfer line to CS 49	1,700 psig	100°F	53,400	10.1
12-inch CO_2 distribution lines from CS 49 to sequestration field	1,700 psig	100°F	12,200	2.3
9 x 6-inch CO_2 lateral lines sequestration injection wells	1,700 psig	100°F	6,900	1.3
Total Length			**76,000**	**14.4**

The pipeline is assumed to be high strength carbon steel, designed to ANSI 1500 Class. A Supervisory Control and Data Acquisition (SCADA) pipeline monitoring system will be used for leak detection. The SCADA system shuts down the pipeline if conditions are detected outside pre-set pressure and flow conditions, and alarms will sound alerting to exceedance conditions.

Where the pipeline crosses a road, the pipeline will be within a secondary pipeline, protected from contact with soil. There are approximately 32 pipeline road crossings for a total length of about 800 ft.

As the reservoir pressure increases, it may be necessary to add a booster pump prior to injection, which would be located at CS 49, as shown on Figure 2.6.

2.1.5 CO_2 Sequestration

The proposed sequestration injection will be into the 64 Zone sandstones of the Lower Temblor Formation. These sands have produced oil and gas for almost 100 years and have a large, depleted storage capacity, numerous thick confining layers, high porosity and permeability. It is proposed to cease oil and gas production in the 64 Zone, and utilize the depleted reservoir for dedicated CO_2 sequestration. There are numerous wellbores available to repurpose for CO_2 injection. To repurpose the well, an entirely new CO_2 compatible casing string would be cemented to the surface within an existing wellbore. Wells not selected for injection or monitoring would be abandoned.

It is currently proposed to drill 4 new injection wells, and repurpose 5 existing wells, for a total of 9 injection wells. An additional 4 wells will be repurposed for monitoring. Up to four additional monitoring wells may also be constructed, either as repurposed oil wells and/or new wells, pending further evaluation.

Injection and monitoring wells will be equipped with downhole devices and equipment to evaluate external mechanical integrity of the wells and monitor growth of the CO_2 plume as it dissipates within the sequestration layer. Monitoring equipment will include pressure and temperature gauges and may also include acoustic sensors.

Four existing wells are proposed to monitor the CO_2 injection operations and ensure that the CO_2 injection remains within the 64 Zone reservoir. Monitoring wells neither produce nor inject fluids. Monitoring wells would be used to monitor temperature, pressure, fluid levels, acoustic signals, and for the collection of fluid and gas samples.

As part of the proposed Project, all wells that penetrate the confining zone into the proposed sequestration layer or deeper have been identified. The maximum extent of the plume, or pressure front, which may be created by the injected CO_2 as it dissipates within the sequestration layer has been defined by model simulations using Aera geological data sets and seismic surveys. The below ground area within which the plume may influence is called the Aera of Review (AoR). Within the AoR a total of 111 wells have been identified. Of these wells, 41 are operational, and 70 have been previously abandoned. The legacy abandoned wells have been assessed to verify all wells in the AoR are properly abandoned and ensure the integrity of abandoned wells for CO_2 sequestration. Up to 40 wells have been identified as requiring corrective action, and approximately 40 operational wells that are not to be reused for the proposed Project will be abandoned and plugged.

The EPA regulates the underground injection of fluids through the UIC Program, to ensure the safety of underground sources of drinking water. The EPA established a separate class of wells, UIC Class VI, for dedicated CO_2 geologic sequestration. The EPA tailored Class VI program rules to address the permanent storage of CO_2 and ensure that wells are appropriately sited, constructed, tested, monitored, funded, and closed once injection activities are completed.

The proposed CO_2 injection wells would be regulated by EPA's UIC Class VI well regulations (40 CFR 1467 et seq.).

2.1.6 Amine Solvent Truck Deliveries and Storage

Amine for pre and post combustion are likely to use different solvents, requiring four separate unloading and storage facilities, two near Gas Plant 32, and one at each steam generator sites 2868 and 2972.

It is proposed to import concentrated amine using bulk chemical cargo tanks of up to 6,000 gallons (143 barrels). The concentrated solvent will be stored in 21,000 gallon (500 barrel) tanks. In addition there will be 4 holding tanks of 168,000 gallons (4,000 barrel), one for each capture facility, to contain the working inventory of diluted solvent. After the capture facilities are in operation, it is assumed there will be 21 deliveries of 3,000 gallons per facility per year.

2.1.7 Sulfuric Acid Truck Deliveries and Storage

Sulfuric acid is proposed to be used for water treatment at each of the four carbon capture facilities. Sulfuric acid at 96% concentration will be imported using bulk chemical cargo tanks. It has been estimated there will be up to 6 deliveries of 3,000 gallons per facility per year. The sulfuric acid will be stored in one 8,400 gallon (200 barrel) tank at each facility, which may be constructed of either carbon steel or high-density polyethylene (HDPE).

2.2 Project Vicinity

The South Belridge and North Belridge oil fields are located within the Central Valley portion of Kern County. The two oil fields are contiguous and located approximately seven miles southwest of the community of Lost Hills and west of State Highway 33. Together, these cover an area of approximately 13 miles long and three miles wide.

The proposed CO_2 capture facilities are located within the developed portion of the South Belridge oil field. The CO_2 transfer pipeline to North Belridge will run primarily above ground across developed sections of the field, primarily within existing infield pipeline routes. The proposed CO_2 sequestration field is located in the North Belridge oil field, which is predominately developed with oil and gas production infrastructure. None of the proposed Project facilities are within areas designated as prime farmland or farmland of statewide importance.

Land adjacent to the Project sites is utilized for oil and gas exploration and production, grazing, agriculture and a solar field associated with agricultural development. Aera is the primary oil production operator within both oil fields, with two sections partially operated by third parties.

2.3 Populations

Personnel in the vicinity of a hazardous release could potentially be exposed to harmful concentrations of materials. Public populations include workers in non-Aera operated oil production areas, workers at the solar farm to the west of Highway 33, occupants of vehicles on Highway 33, agricultural workers within the orchards to the east of Highway 33, and a small housing tract on Lost Hills Road, north of Lerdo Hwy. For any given release, the number of

personnel potentially exposed will depend on the size of the release, time of day, weather conditions, and the likelihood that personnel are in the area.

Residential and Sensitive Receptors

A small housing tract of about 30 properties is located on Lost Hills Road, north of Lerdo Hwy, approximately three miles east of the Project site. The closest residential areas and sensitive receptors are located approximately six miles northeast of the Project site, within the community of Lost Hills. This includes the Lost Hills Elementary School and A.M. Thomas Middle School.

Non-Aera Operated Oil Production

There are 2 areas within the Belridge oil production field operated by other production companies; Berry Petroleum Operating LLC in South Belridge Section 19, and Team Operating LLC in North Belridge Section 36, as shown on Figure 2.1. These operators are considered public personnel. The number of non-Aera employees has been estimated based on the density of operating wells in each area. Where there is a high density of wells, it is assumed there will be a greater number of personnel in the area. Typical oil production population densities per square mile have been applied as follows:

Oil Production Population Density	Average Personnel per square mile (per acre)	
	Day	Out of Hours
High	80 (0.13)	10 (0.015)
Medium	30 (0.05)	3 (0.005)
Low	3 (0.005)	0.3 (0.0005)
Very Low	0.5 (0.0008)	0.05 (0.00008)

Operator	Production Field Area	Population Density
Berry Petroleum	South Belridge Section 19, north 50% of section	Medium
Berry Petroleum	South Belridge Section 19, southwest 25% of section	Low
Team Operating	North Belridge Section 36, southwest 30% of section	Medium / Low

For the calculation of potential hazardous material exposures, it has been assumed that oil field workers and contractors are not equally distributed within the oil production areas. The following daytime personnel distribution has been applied:

2 workers in close proximity 50% of the time
4 workers in close proximity 50% of the time

Solar Panel Field

Within Section 7 of South Belridge, there is an area of solar panels owned by Wonderful Nut Farms, which covers about 35 acres. Workers visiting this area are considered public personnel. It has been estimated that an average of two workers will be in the area for 20% of the time during the day.

Highway 33 Population

Highway 33 runs to the east of the Belridge oil field, parallel to the proposed pipeline route, as shown in Figure 2.1. The road is used for vehicles travelling north and south, to or from Highway 46, and for access to the Belridge oil field and agricultural areas.

Annual average daily traffic (AADT) is the primary measure used to evaluate traffic volumes for regional highways. Average daily traffic is measured by the California Department of Transportation (CalTrans) on a sampling basis. CalTrans traffic data was obtained for the years 2016 through 2020[42], and then used to calculate an average hourly volume of traffic on the Highway 33 segment parallel to the Project pipeline as follows:

Average number of vehicles =	8520 per day
Average number of day vehicles =	639 per hour
Average number of night vehicles =	71 per hour
Average vehicle speed =	50 mph

The probability that a vehicle will be within any 100 feet section of the highway has been calculated as:

Day time probability of a vehicle =	0.24 per 100 feet
Night time probability of a vehicle =	0.03 per 100 feet

According to the US Department of Transportation (DOT) Bureau of Transportation Statistics[49], the average vehicle occupancy for all roads and all purpose of travel is 1.6. For work travel only, the average vehicle occupancy is about 1.2. It has been assumed that there is an average of 1.4 personnel in each vehicle due to the high number of work vehicles on Highway 33.

Agricultural Populations

The vicinity surrounding the North and South Belridge oil fields is primarily utilized for agriculture, or is undeveloped land. The closest active orchards are to the east of Highway 33 with agricultural workers a minimum of about 2,000 feet from the proposed CO_2 pipeline route.

The density of agricultural workers has been estimated from county records of the crops grown and typical daytime worker densities for these crops:

Citrus orchards =	25 workers per square mile all year
Pistachio / Almond orchards =	25 workers per square mile, 25% of the year
Pistachio / Almond orchards =	2 workers per square mile, 75% of the year

2.4 Environmental Receptors

Land next to CCS Project sites and along the pipeline route is dominated by intensive oil and gas extraction infrastructure, including; wells, well pads, pipelines and access roads. There are also areas of barren land, annual grassland and low growing dessert scrub.

Wildlife

Habitat in the Project vicinity is generally disturbed by oil and gas exploration and production. Surrounding properties include areas used for agriculture, grazing, and undeveloped private

land. Wildlife that could be impacted by a potentially hazardous release include; insects, reptiles, and small mammals such as rodents, squirrels and foxes.

Surface Aquatic Resources

Stantec Consulting Services Inc. (Stantec) conducted a delineation of aquatic resources for the CarbonFrontier CCS Project[41]. The survey area consisted of the proposed CCS Project facilities, including approximately 13-miles of CO_2 transfer and distribution pipeline routes, and a 500-feet buffer around these facilities. No perennial surface water resources were identified in the survey area. Two seasonal drainage creeks were identified that run from west to east of the pipeline route. To the south of the capture facilities, the Chico Martinez Creek runs from west to east, with no connectivity to navigable water. The ephemeral Chico Martinez Creek is dry most of the year, though it can overflow the creek banks after a heavy rainfall.

No surface aquatic resources were identified that may be at risk due to a potentially hazardous release.

Subsurface Water Resources

A subsurface release of CO_2 may have the potential to impact underground water resources. A search has been conducted for the Project to identify potential water resources.

No water supply wells were identified within the AoR. Two potential underground sources of drinking water (USDWs) were identified, with most of the area either dry or the water contains solid concentrations exceeding acceptable USDW limits. The lowermost potential USDW, is separated from the proposed injection zone by more than 7,000 feet of strata, including many confining zones. Therefore, the injection of CO_2 associated with the development of the proposed storage complex is not expected to impact the groundwater quality of potential USDWs.

2.5 Topography

The land surrounding the proposed capture sites and along the pipeline route is relatively flat. The land slopes gradually from the northwest sequestration field at about 680 feet above sea level, to the southeast portion of the Project area at Steam Generator site 2868 at about 580 feet. For most of the area surrounding Project facilities and the pipeline route, there is a gentle gradient of about 1 percent sloping from west to east.

There is one section of the CO_2 pipeline route that crosses a highly disturbed production area to the north-east of Section 32 facilities, in Section 33 and Section 28. Here there are areas where the gradient is up to 6 percent, and the variable contours may create channels where dispersion of a dense low lying gas may be suppressed.

2.6 Weather Data

The Project vicinity is semi-arid, with an average annual rainfall of 5 to 6 inches. The summers are hot and dry, and the winters cool and damp with frequent ground fog. During calm atmospheric conditions, a thick ground fog may settle along the length of the Central Valley during the late fall and winter. A temperature inversion traps a layer of cool moist air near the surface causing the fog.

Weather conditions at the time of an accidental release will affect the speed of atmospheric dispersion, and the direction in which a hazardous cloud may drift. When wind speeds are low and the atmosphere stable, dispersion is reduced and can lead to increased localized exposure.

Weather data was obtained from the Missouri Triangle weather station #99006 for the years 2004 to 2008. The station is located immediately to the east of the Project area on Highway 33. The data was processed to assign weather stability categories for the various wind directions, wind speeds, solar radiation and time of day. The wind directions and speeds have been plotted as a wind rose as shown in Figure 2.7.

The predominant wind direction is from the west and southwest, which occurs about 47% of the time. Calm conditions, with drifting wind direction and less than 0.5 m/s wind speed occurs about 3% of the time. An additional 6% of the time, the wind speed is approximately 0.5 m/s, which may also be categorized as calm conditions and provides very little wind dispersion. Calm wind conditions occur primarily during the hours of 10 am and 3 pm, when atmospheric turbulence is high. Wind directions are indicated as blowing from, and the percent occurrences summarized as follows:

Wind Direction	Percent Occurrence
N	12
NE	18
E	5
SE	3
S	4
SW	14
W	33
NW	8
Calm	3

Meteorologists have defined six atmospheric stability classes, (A through F), each representing a different degree of turbulence in the atmosphere. During strong to moderate solar radiation, the air is heated near the ground causing it to rise. The atmosphere is considered unstable, and is classified as Pasquill Stability Class A through C, very unstable to slightly unstable. Higher wind speeds and moderate solar radiation are associated with moderate turbulence, classified as Pasquill Stability D. When solar radiation is weak or absent at night there is less turbulence, which is classified as slightly stable Pasquill Stability Class E, or stable Pasquill Stability Class F.

Weather measurements from the Missouri Triangle station were processed to categorize the data into the six atmospheric stability classes. Two meteorological conditions have been selected to represent worst-case and more typical conditions. A worst-case of “F” stability and 1.5 meters per second (m/s) wind speed represents low wind speed during the night when

hazardous vapors may accumulate. A more typical case of “D” stability and 4 meters per second wind speed, represents average weather conditions during the day and part of the night hours. These weather conditions have been applied to conduct atmospheric dispersion modeling of accidental releases as follows:

Day / Night	Stability Class	Wind Speed	Occurrence
Day	D	4 m/s (9 mph)	50 %
Night	F	1.5 m/s (3.5 mph)	34 %
Night	D	4 m/s (9 mph)	16 %

3. HAZARD IDENTIFICATION

A release of hazardous materials associated with the proposed CarbonFrontier CCS Project may result in acute short term exposure to the public. These may be due to a release of CO_2, natural gas, amine or sulfuric acid, and the impact will depend on the size, duration, material condition, and if personnel are in the vicinity at the time of release.

A review of previous incidents has been conducted to identify and quantify the likely hazards. The carbon sequestration industry is relatively new, and there is consequently limited historical information. Analogous industries were assessed to develop potential release scenarios and likelihoods of failure. A search was also made of CO_2 hazards associated with releases in other industries and from naturally occurring sources.

The hazards associated with each operational activity within the proposed CCS Project have been assessed from a review of incidents, these include;

- CO_2 capture and compression.
- Transport of the dense phase CO_2 through pipelines to the North Belridge oil field.
- Injection of dense phase CO_2 for geologic sequestration.
- Migration of CO_2 from geologic storage to the surface.

The preliminary design of the aboveground facilities for capture, compression, transport and injection of CO_2 at the sequestration site has been used to determine where releases could occur. A list of potential release scenarios has been developed in the following section, and the likelihoods of these releases quantified in Section 4.

3.1 Carbon Dioxide Sequestration Industry

Geological formations are currently being considered for numerous underground CO_2 sequestration projects for permanent storage into depleted oil and gas reservoirs and deep saline reservoirs. CO_2 in a supercritical state would be injected into a porous rock formation below ground. The process also requires that the geological formation has an overlying impermeable caprock, such as shale, so that injected CO_2 remains trapped underground. Depleted oil and gas reservoirs are proven geological formations that have trapped oil and gas below ground for millions of years, making these suitable to sequester CO_2.

These technologies have been demonstrated at multiple US and international sites. Worldwide, according to the Global CCS Institute[23], in 2022 there were 30 commercial facilities capturing CO_2, 13 of which are in the United States. These include facilities for both sequestration and enhanced oil recovery (EOR). In addition, there are approximately 34 pilot or demonstration-scale carbon capture facilities.

The transfer of CO_2 to sequestration sites will primarily be via dense phase CO_2 pipelines. The US has the most mileage of CO_2 transmission pipelines in the world, consisting of approximately 5,300 miles of pipelines. The majority of these pipelines supply dense phase CO_2 to the oil and

gas production industry for injection into reservoirs for EOR. Most of this CO_2 comes from high pressure high purity natural underground source domes. CO_2-EOR has been utilized in the US for several decades, primarily in western Texas and southeastern New Mexico. This provides some historical experience of dense phase CO_2 pipeline systems, and injection of CO_2 into depleted oil and gas reservoirs.

CO_2 injection for EOR was first implemented in 1972 in Scurry County, Texas, and was then used successfully throughout the Permian Basin in west Texas. There are nearly 13,000 CO_2-EOR injection wells in the US[1], and Meyer's report to the American Petroleum Institute (API) in 2007[34], provides valuable information and experience in the design and operation of CO_2 injection wells.

The EPA regulates the injection of fluids associated with oil and natural gas production via the UIC Class II program. This includes injection of CO_2 for EOR. The EPA established a separate class of wells, UIC Class VI, in December 2010, for projects where the purpose is dedicated geologic storage. To date, EPA has permitted two Class VI CO_2 injection wells, both at the Archer Daniels Midland (ADM) facility in Decatur, Illinois, and as of January 2023, have 33 injection well applications pending. North Dakota and Wyoming have been delegated primary enforcement authority to administer Class VI applications. To date, North Dakota has permitted two projects; the Red Trail Energy CCS project, and Minnkota's Project Tundra. Additional well permit applications are pending.

In the US, there are currently two facilities injecting the CO_2 solely for geologic sequestration. The first was the ADM facility in Illinois where CO_2 captured from ethanol production is injected into a saline reservoir. A total of more than 4 MM mt of CO_2 has been injected at the site. The second facility is the Red Trail Energy CCS project at its ethanol facility near Richardton, North Dakota. This facility started CCS operations in June 2022.

Since the reforms of Section 45Q carbon tax credit in 2018 and 2022, a total of 84 carbon capture projects have been announced in the US[23]. The tax credit incentivizes carbon capture and sequestration or utilization.

3.2 Analogous Fluid Injection Industries

There has been limited experience world-wide with large-scale CO_2 capture, transfer and sequestration. Analogous industries have therefore been assessed to develop potential release scenarios and likelihoods of failure. Underground natural gas storage, the use of CO_2 for EOR, steam injection for EOR, and acid gas injection into depleted wells for disposal provide some history of fluid injection into oil and gas reservoirs.

3.2.1 Underground Natural Gas Storage

Underground natural gas storage (UNGS) facilities have operated successfully in North America and Europe since the 1970s and provide historical experience relevant to CCS. These facilities are used to store large quantities of gas during off-peak months for withdrawal during peak usage months, balancing seasonal demand. The majority of gas storage projects utilize depleted oil and gas reservoirs, with some projects in saline formations and salt caverns.

Experience with natural gas storage in depleted oil and gas reservoirs is analogous to the proposed underground storage for CO_2.

The successful operation of UNGS projects has been the selection of a suitable reservoir; rock permeability, impermeability of the caprock, geological structure to maintain gas within the designated area and rock characteristics. The injection wells must be properly designed, installed, monitored and maintained, and abandoned wells in and near the project must be located and plugged. UNGS has been safe and effective, though where failures have occurred, it has been due to poor site selection, inadequate injection well monitoring and maintenance, leaking faults, or a failure of abandoned wells. Successful UNGS projects, and potential causes of failure, provide relevant experience to ensure CCS projects are designed for safe operation.

The recent failure of an injection and withdrawal well at Aliso Canyon, California, in 2015, initiated changes in regulatory requirements for UNGS injection and withdrawal wells. This incident is described below in Section 3.3. The Aliso Canyon well was operated with injection and withdrawal through both the well tubing and casing, creating a single point of failure for gas to escape the well bore. This configuration had been used in UNGS projects but is non-standard in the oil and gas industry. Injection wells for CO_2 storage are required to have separation between the inner injection tubing and the outer casing annulus, which provides a secondary barrier and ability to monitor for potential failures. California Division of Geologic Energy Management (CalGEM) revised the UNGS UIC regulations to require operators ensure that a single point of failure does not pose an immediate threat of loss of fluids. The revised regulations also require enhanced mechanical testing programs to identify well leaks or the potential for a leak to occur before it happens. Requirements for the design, operation and monitoring of CO_2 storage injection wells exceed those of the revised CalGEM UNGS UIC regulations. The potential for failure of CO_2 storage injection wells is therefore likely to be significantly lower than the historical performance of UNGS wells.

3.2.2 Carbon Dioxide Enhanced Oil Recovery

CO_2 has been used for EOR since 1972, primarily in western Texas and southeastern New Mexico. When an oil reservoir pressure is depleted through production, CO_2 flooding can be used in reservoirs deeper than 2,000 feet. The injected CO_2 dissolves in the oil and reduces the viscosity. Normally the CO_2 injection is alternated with water injection, where the water drives the oil towards the production zone. There are nearly 13,000 CO_2-EOR injection wells in the US, which provides valuable experience as an analogue for injection of CO_2 into depleted oil and gas reservoirs.

3.2.3 Thermally Enhanced Oil Recovery

Thermally enhanced oil recovery involves the injection of steam into the oil reservoir. By heating the oil with steam, the viscosity is reduced and permeability increased, allowing the oil to more readily flow into the production wells. This method of EOR has been used commercially since the 1960's.

The two primary methods are either cyclic steam injection or continuous injection via dedicated steam injectors. Both methods are utilized for oil reservoirs which are relatively shallow and contain viscous crude oils. Thermal EOR is widely used in the San Joaquin Valley California.

3.3 Carbon Dioxide and Analogous Industry Release Incidents

A review of incidents has been conducted to identify likely hazards associated with the proposed CarbonFrontier CCS Project. There have been a number of industrial and natural releases of CO_2 where injuries and fatalities due to CO_2 inhalation have occurred. Below are details of some CO_2 incidents that illustrate the characteristics of CO_2 releases, and potential impacts on human health and safety, and the environment.

Significant incidents associated with underground natural gas storage, and steam injection into oil and gas production wells for EOR have also been identified. These involve different hazardous materials, though both use similar technology for injection into oil and gas reservoirs.

2/22/2020 Satartia, Mississippi – 24-inch Pipeline Rupture

In 2007, a 31-mile CO_2 pipeline was built to connect the Tinsley oil field near Satartia in Mississippi, to a naturally occurring CO_2 gas supply under Jackson, Mississippi for EOR. In 2020, heavy rains caused a landslide which ruptured the 24-inch pipeline in a guillotine failure. The failure was detected by the SCADA system and quickly shutdown. The liquid CO_2 vaporized on release, creating a large dense cloud. Due to local topography, the plume migrated down the hill and valley towards the village of Satartia, approximately one mile from the pipeline. The plume travelled about twice the distance plume modeling had predicted.

A total of 200 residents were evacuated and 45 residents taken to the hospital, though none required inpatient hospitalization as a result of the release.

11/21/2018 CO_2 Unloading Incident

A CO_2 truck driver died when he failed to disconnect the unloading hose before driving away. The truck contents of about 2.5 mt (5,500 lb) refrigerated CO_2 were released in 15 minutes.

10/23/2015 Aliso Canyon, California, Natural Gas Storage Injection Well Failure

The Aliso Canyon facility in Los Angeles County is one of the largest underground natural gas storage facilities in the United States. Natural gas is stored in a depleted oil and gas sandstone formation at approximately 8,500 feet below ground, with gas being injected and withdrawn through 115 operational wells at the time of the incident. In 2015, there was a well failure, and gas was detected to be leaking from the ground on the hillsides below the wellhead. This incident resulted in a sustained and uncontrolled natural gas leak of approximately 100 thousand tons of methane. Over 5,000 families had to be evacuated, and the well took three and a half months to control.

The well was operated by injection and withdrawal through both the tubing and casing. A single point failure of the well casing allowed gas to escape the well and travel through the rock formation to the surface. The configuration in which both tubing and casing are used for injection and production is non-standard in the oil and gas industry, outside of the underground natural gas storage industry. Typically, oil and gas and production wells only produce fluid through the tubing, and maintain isolation between the tubing and casing. UIC injection wells also operate in a similar configuration, where the casing serves as a secondary barrier to monitor for failures.

6/13/2013 Louisiana, Abandoned Well Underground CO_2 Blowout

In 2013, an underground CO_2 blowout occurred at the CO_2-EOR Delhi field in Louisiana, when two or more plugged and abandoned wells failed underground. Methane, carbon dioxide, oil, water, brine and sands migrated to the surface in a sparsely populated, marshy area. The release lasted for more than six weeks and contaminated the air with CO_2 and methane.

8/9/2011 Mississippi, Abandoned Well CO_2 Blowout

In 2011, an improperly plugged and abandoned well failed at the CO_2-EOR Tinsley Field, Mississippi. There were incomplete records of abandoned wells at the site. A 2,000-feet deep well failed when the reservoir pressure increased on injection of CO_2. The blowout took 37 days to bring under control, sickened one worker, and suffocated deer and other animals[(2)].

6/21/2011 Midway-Sunset, Kern County, Steam Injection for EOR Incident

Steam injection into oil and gas reservoirs for EOR has been used in California for approximately 60 years. There have been a number of recently reported incidents where steam or well fluids have broken through natural geologic barriers and come to the surface.

In June 2011, an oil industry employee died in the Midway-Sunset oil field when the ground beneath him gave way and he fell into a pool of heated well fluid. The surface expression was believed to be due to nearby cyclic steam injection operations and the failure of an old abandoned well. The abandoned well pipe was reported to have been sheared as a result of ground movement. Revised CalGEM UIC regulations were implemented in April 2019[(7)] to prevent a recurrence of this incident.

2008 Mönchengladbach, Germany Incident

During an accident in Mönchengladbach, Germany, in August 2008, over 100 residents suffered from respiratory problems due to a CO_2 release, of which 19 were hospitalized. The incident involved the release of about 15 mt (90 barrels) of fire suppression CO_2 inside a factory, which leaked out of the building. At the time there was no wind, so the dense CO_2 cloud drifted down hill to the lowest lying region where there was a village about 1,500 feet away. The incident illustrated the hazards of CO_2 accumulation in calm or very low wind conditions, and flow of a dense cloud into lower lying areas.

2004 to 2011 In Salah CCS Project, Algeria

The In Salah CCS demonstration project in Algeria was the first commercial onshore facility to inject CO_2 into a depleted gas reservoir for permanent geological storage. Injection of CO_2 starting in 2004, into a 6,200 feet deep sandstone formation. During the project, 3.8 MM mt of CO_2 were injected. Extensive monitoring was conducted, including seismic analysis, sampling using gas tracers, downhole logging, surface gas monitoring and satellite data to monitor surface elevation changes. Monitoring results identified that CO_2 was potentially injected at a rate that caused well pressure to exceed the fracture pressure. Injection was suspended in 2011 after seven years of operations. To date, no leakage has been detected, though satellite monitoring detected deformation of land surfaces, and seismic monitoring indicated possible fracturing.

9/19/2002 CO_2 Storage Tank Explosion

A worker from Reliant Processing in Muleshoe, Texas, was killed when a CO_2 storage tank he was insulating exploded. The explosion was related to a build-up of excessive pressure and brittle fracture of two tanks due to extremely low temperatures. The US Occupational Safety

and Health Administration (OSHA) investigated this incident, and reported that the tanks were originally designed for liquefied petroleum gas (LPG) and not suitable for minimum CO_2 temperatures.

A similar incident occurred in Worms, Germany, in 1988. A catastrophic pressure failure occurred of a 30 mt capacity CO_2 storage tank due to the vessel relief valve icing up. Five weeks prior to the incident, the vessel had also been exposed to an extremely low temperature. The force of the explosion propelled the vessel nearly 1,000 feet, and resulted in 3 fatalities and 8 injuries.

2000 US EPA Fire Suppression System CO_2 Incident Assessment

Carbon dioxide has been used for many years in the special hazard fire protection industry worldwide. However, large quantities are needed to suppress a fire. The minimum CO_2 fire suppressant concentration is 34 percent, which is higher than the lethal concentration. In 2000, the EPA conducted an extensive research project to assess information on deaths, injuries and the risks associated with the use of carbon dioxide as a fire suppressant[50]. From 1975 to 1999, a total of 51 CO_2 incidents were identified that reported a total of 72 deaths and 145 injuries resulting from the discharge of CO_2 from fire extinguishing systems. The main cause was found to be accidental discharge during maintenance or testing. Since the report was published, additional fatal incidents have occurred. The incident in 2008 at Mönchengladbach, Germany, described above was another example of an accidental fire suppressant release.

1986 Lake Nyos, Cameroon

This is the most commonly cited incident involving CO_2 casualties. Lake Nyos is a volcanic lake which is naturally saturated with CO_2 leaking from the magma chamber below. In August 1986, an estimated 1.6 MM mt of CO_2 was suddenly released when the lake waters overturned. Over 1,700 people and 3,500 livestock were killed and thousands more were injured as the cloud travelled along the valley for more than 9 miles.

A similar incident occurred in 1984 at Lake Monoun when water overturned in the volcanic lake. The released CO_2 moved out of the crater and hung in a depression along a nearby river, where 37 people were asphyxiated.

The Lake Nyos incident illustrates the dangers of a large CO_2 release. However, the quantities of CO_2 released at Lake Nyos were several orders of magnitude larger than proposed for the CarbonFrontier CCS Project. The pipeline inventory is less than 1,000 mt, and each carbon capture facility contains a CO_2 inventory of less than 50 mt.

3/17/1982 Sheep Mountain, Loss of CO_2 Production Well Control

In March 1982, a blowout occurred in the Sheep Mountain, Colorado, during the drilling of a CO_2 production well into a natural reservoir at depths of 3,300 to 6,000 ft (1,000 to 1,800 m). The CO_2 release rate was estimated to be about 200 MM scf/day (120 kg/s). The high release rate made this a difficult well to kill, although industry now has a better understanding of managing the control of CO_2 wells[33].

1930's Crystal Geyser, Abandoned Well

Crystal Geyser in Utah is the largest cold geyser in the world. The geyser was unintentionally created in the 1930's after a prospective oil well was drilled about 2,600 ft (800 m) deep into a

fault zone above a natural CO_2 reservoir. Shortly after drilling, the well was abandoned and not properly capped, allowing CO_2 to be released through the well.

Crystal Geyser eruptions last from 7 to 98 minutes with a release rate between 330 and 790 lb/min (2.5 and 6 kg/s). Downwind CO_2 concentrations have been measured during eruptions, averaging about 4,000 ppm (0.4 %) at 160 feet, and 800 ppm at 330 feet[24]. This analysis suggests that even large and rapidly escaping CO_2 from the geyser results in concentrations that are below human health and safety concerns.

3.4 Hazardous Material Incident Databases

A hazardous material incident that meets an agency threshold must be reported by the owner or operator to regulatory authorities. Some authorities make incident reports available, which provides a basis for predicting what can go wrong, what the hazards may be, and how often these incidents occur.

US Department of Transportation (DOT)

Hazardous material transport between two facilities is regulated by the US DOT. This includes all modes of transport, (including; pipeline, railcar, and road) and in each phase of transport, (loading, unloading, and in transit). Significant incidents are required to be reported to the DOT, and records are maintained by Pipeline and Hazardous Materials Safety Administration (PHMSA) of the DOT. The reporting criteria vary depending on the chemical and mode of transport. These incident reports are recorded in the Hazardous Materials Incident Reporting System (HMIRS) database. The database is a useful source of information on hazardous material releases during transportation and casualties resulting from exposure to the hazardous material.

A reportable incident associated with a release from a hazardous liquid or carbon dioxide pipeline system is defined as an event that results in one or more of the following consequences:

- A death, or personal injury necessitating hospitalization, or;
- Explosion or fire, or;
- A release of 5 gallons or more of hazardous liquid or carbon dioxide, or;
- Estimated property damage, cost of clean-up and recovery, and value of lost product exceeding $50,000.

DOT natural gas pipeline reporting requirements are similar, except that the release reporting quantity is defined as; an unintentional estimated gas loss of 3 million cubic feet (MMCF) or more.

Non-pipeline DOT hazardous material transportation reporting requirements include:

- A death, or personal injury necessitating hospitalization, or;
- An unintentional release of a hazardous material, or;

- Public evacuation is required, or;
- A major transportation artery or facility is closed, or;
- A hazardous material cargo tank of 1,000 gallons or greater suffers structural damage.

Operation of CO_2 pipelines in the US are regulated under federal operations guidelines. However, in-field lines are generally exempt from federal pipeline regulations (49 CFR 195.1(b)(8)), and incidents associated with these lines are not included in the DOT PHMSA database.

National Response Center (NRC)

If there is an accidental release of a hazardous substance from a fixed facility or transportation system that meets the reporting threshold, the owner or operator is required to immediately notify the National Response Center (NRC). The NRC is a part of the federally established National Response System and staffed 24 hours a day by the US Coast Guard. The amount of chemical released before emergency notification depends on the particular chemical. For DEA and H_2S, the reportable quantity (RQ) is 100 pounds, whereas there is no RQ for CO_2, MEA or MDEA. For sulfuric acid, the emergency release RQ is 1,000 pounds (65 gallons). However, all releases of any quantity must be reported if there is a threat to human health, an offsite environmental impact, a threat to navigable waters including surface water and drainages, public evacuation, or closure of a transportation artery.

The NRC maintains a database with call logs on each incident. The call logs provide an initial incident description and information on casualties. Significant fixed facility incidents are reportable if the release is above the chemical RQ, or if there is offsite environmental impact. However, smaller releases at fixed facilities less than the RQ are typically not reportable. Most amine solvent and sulfuric acid releases at fixed facilities are less than the RQ, and are therefore not included in the call logs of the NRC.

The reporting thresholds for DOT regulated transportation incidents are lower than NRC thresholds, and therefore have primarily been used to assess the hazard potential for transportation incidents.

California Occupational Safety and Health Administration (Cal-OSHA)

All releases that result in reportable injuries or a discharge to the environment must also be reported to Cal-OSHA. Federal OSHA makes available report summaries on fatality and catastrophic incidents that OSHA investigates. This provides information on potentially significant hazards to personnel and the public associated with the proposed Project. Incidents reviewed involved the release of CO_2 within all industries, storage of amine solvents and sulfuric acid, amine gas treating, and hazardous material transportation.

3.4.1 Carbon Capture and Compression Incident Data

A search has been conducted of reported NRC and OSHA significant incidents to identify potentially hazardous releases of CO_2 and ethanol amines from fixed facilities. These reports were searched covering a 20-year period, 2002 to 2021, to identify potential hazards associated with amine carbon capture facilities and CO_2 compression.

A total of 37 NRC reported incidents were identified, associated with CO_2 fixed facility incidents, one of which was also investigated by OSHA. Releases were reported to dissipate quickly to below hazardous concentrations within process facilities, without causing a threat to the environment or personnel. Excluded from the incident list were over 200 incidents of process vapor combustion releases of CO_2 at a flare or elevated venting due to equipment startup or shutdown. Other excluded incidents were associated with releases from fire extinguishing systems, CO_2 cylinders, dry ice and accumulation of fumes in enclosed areas. Personnel casualties were reported in three food industry incidents due an accumulation of CO_2 within an enclosed, or partially enclosed area.

A search of ethanol amine fixed facility incidents identified a total of 172 relevant NRC reports, and no OSHA significant incident investigations for MEA, DEA or MDEA. 75% of these incidents were at gas treating processes for the removal of H_2S or CO_2, and there were no reports of significant casualties. Approximately 70% of the reports were associated with DEA even though MEA is more commonly used for gas treating. This is likely due to DEA having an RQ of 100 lb, whereas there is no RQ for MEA. This makes DEA releases more likely to be reportable than MEA releases.

A list of the fixed facility incidents for CO_2 and ethanol amines is shown in Table 3.1. The facilities include oil and gas production facilities, gas processing, chemical and industrial gas manufacturers, food industry and warehouse facilities.

3.4.2 CO_2 Pipeline Transportation Incident Data

Incidents meeting the reporting threshold for DOT regulated pipeline systems are reported to the PHMSA of the DOT. The PHMSA database has been searched for incidents involving pipeline transportation of dense phase CO_2 during the 20-year period, 2002 to 2021. A total of 100 records were identified, 25 associated with line pipe, and an additional 75 associated with auxiliary equipment such as valves, meter stations, and pressure relief. The releases were categorized by the size of release and mode of failure, in order to assess the likelihood of release.

Releases have been categorized by following sizes:

- Pinhole: Failure size smaller or equal to the area of a 0.5-inch diameter hole.
- Crack / Hole: Effective diameter of the failure greater than 0.5-inches and less than the pipeline diameter.
- Rupture: Effective failure size the diameter of the pipeline or greater.

To ensure consistency within the PHMSA database and for comparison with other data sources, releases reported to the PHMSA were re-categorized based on the size of the leak or hole as defined above. For example, some records indicated rupture events which were clearly not full bore ruptures from the reported hole dimensions and release quantities. Some PHMSA release cause categories were changed in 2010, so adjustments were made for consistency.

The total length of CO_2 pipelines in operation for each year from 2002 to 2021 has been summed from annual DOT reports submitted by pipeline operators. US operating experience

over the 20 years totals 91,000 mile-years. The likelihood of failure has been calculated by release size per 1,000 mile-years of pipeline operation as follows:

Pipe Release Size	US DOT CO_2 Pipeline Data for Years 2002 to 2021			
	Number of Pipe Release	%	Average Release Size (bbl)	Failure Rate per 1,000 mile-years
Pinhole	15	60	17	0.164
Crack / Hole	9	36	105	0.098
Rupture	1	4	9,532	0.011
Total	**25**			**0.273**

The number of incidents and pipeline operating miles is limited, and therefore the failure rates have a high degree of uncertainty. For example, an incident in 2018 involved the failure of a girth weld. The pipeline was out of service due to maintenance activities and being refilled at the time of failure. If operational, this would likely have resulted in a total rupture of the pipeline, doubling the calculated rupture failure rate above.

Dense phase CO_2 transmission pipelines typically operate at pressures between 1,200 and 2,200 psig, with an average maximum allowable operating pressure (MAOP) of about 2,000 psig. The CO_2 pipeline diameters range from 4 inch to 30 inch, with an average of 17 inches. The average pipeline age is currently 27 years.

Releases associated with pipeline auxiliary equipment have been categorized by the type and size of leak as follows:

Auxiliary Equipment Releases	US DOT CO_2 Pipeline System Data for Years 2002 to 2021		
	Number of Release	%	Average Release Size (bbl)
Auxiliary Equipment on Mainline Pipeline, in Right-Of-Way			
Mainline Valve /Flange Leaks	10	13	55
Mainline Relief Valve Failure / Leak	4	5	1,347
Mainline Connection Failure	4	5	2,450
Mainline Auxiliary Valve Frozen	1	1	41,177
Pump / Meter Station Equipment			
Valve / Flange / Weld Leaks	28	37	9
Connection Failure	3	4	8
Pig Launcher / Receiver Leak	7	9	63
Relief Valve Failure / Leak	18	24	261
Total	**75**		

Releases associated with auxiliary equipment were typically small flange or valve leaks. Medium sized releases occurred due to the failure of relief valves or connection failures. Approximately 75% of these occurred on operator-controlled sites.

The causes of pipeline and auxiliary equipment releases have been categorized as shown in Table 3.2. The predominant causes of failure associated with line pipe are external corrosion (40%) and material failure (48%). The predominant causes of failure associated with auxiliary equipment are gasket and seal leaks, malfunction of control or relief valves, and construction failure.

Over the last 20 years, there have been 2 major CO_2 pipeline releases in the US:

- *2/22/2020 Satartia, Mississippi* - Guillotine failure of 24-inch CO_2 transmission pipeline due to ground movement after heavy rains. This incident is described in Section 3.2.
- *10/7/2020 Yazoo County, Mississippi* – A large release to atmosphere occurred due to a blowdown valve freezing open. Work was being conducted to reconnect the pipeline that had ruptured near Satartia in February 2020. An 8-inch valve froze in the open position due to internal dry-ice formation as CO_2 flashed across the valve. A total of approximately 40,000 barrels (5,200 mt) of CO_2 were released over about 24 hours until the pipeline segment pressure had reduced enough to allow the valve to thaw and be closed. A large CO_2 cloud formed, and the nearby highway closed. Air monitoring was conducted in the surrounding area, and personnel kept at a safe distance.

DOT pipeline incident reports describe releases of CO_2 to have been identified by either flow monitoring equipment, or a visible cloud. Large pipeline failures were identified by SCADA monitoring systems, which initiated shutdown and isolation of mainline valves. A SCADA system will not be able to detect small leaks, but due to the very low temperature on release, these are likely to be detected by the public or employees. Small above ground releases have been identified as a result of ice forming on equipment, or the sound of vapor release due to the high pressure drop, or a low laying vapor cloud formed by moisture condensing. Below ground leaks have been reported as a result of vapors seen at ground level, or ice forming on the ground above a leak. One report described the ground heaving above a CO_2 pipeline due to a 4-foot ball of dry ice below the surface.

No significant injuries or fatalities have occurred due to CO_2 pipeline incidents. The Satartia pipeline rupture in February 2020 resulted in a total of 200 residents being evacuated and 45 residents taken to the hospital. No residents were admitted due to hazardous material exposure.

3.4.3 CO_2 Injection Well Incident Data

There is insufficient operating experience with EPA UIC Class VI injection wells to predict the likelihood of failure from historical events, and to date, no well blowouts have been reported at dedicated storage sites. However, CO_2 has been injected into active oil and gas production formations for EOR since 1972. A search of incident data has been conducted to identify significant releases that have occurred, and assess potential consequences associated with the failure of CO_2 injection wells.

Loss of well control events are not normally reported to the NRC or Federal agencies, unless there is an off-site impact. A search of Texas well reports identified four blowouts associated

with CO_2-EOR wells over a 10-year period, 2012 to 2021. These were due to wellhead equipment failure, three of which were during well workovers.

Releases may also occur due to a well bore leak and migration to the surface, either through the overlaying formation, or via a poorly abandoned well. These incidents result in a slower release which would be detected by monitoring and unlikely to cause an acute health hazard.

Incidents associated with CO_2-EOR and analogous UNGS facilities reported in the media include:

- 6/2/2016 – Cordona Lake, Texas. A faulty wellhead failed, releasing CO_2 about 20-feet into the air. H_2S, CO_2 and hydrocarbon monitoring was conducted, and no hazardous concentrations were detected.
- 12/7/2015 – Gaines, Texas. A CO_2-EOR injection well head failure occurred during well maintenance. The failure caused a blowout and 25 local homes had to be evacuated for nearly a week. There were no reports of injuries. Most concerns were associated with exposure to H_2S, which was present in the CO_2.
- 10/23/2015 – Aliso Canyon UNGS, California. Well casing failure allowed gas to escape the well and travel through the rock formation to the surface. Over 5,000 families had to be evacuated, and the well took three and a half months to control.
- 1/17/2001 – Yaggy UNGS Facility, Kansas. Natural gas was injected for storage into salt caverns at a depth of 600 to 900 feet. An injection / production well casing failed, leaking gas into the rock formation. The gas migrated approximately nine miles underground, and then traveled to the surface through several abandoned brine wellbores. The released gas caused two gas explosions in Hutchinson, Kansas, destroyed buildings and killed two persons in a mobile home park.

From historical records, there is clearly a potential hazard associated with injection well failure. Reports of CO_2 blowouts via the well bore indicate that these incidents may be a concern for acute risks in the local vicinity, although releases have mainly dissipated quickly. Well bore leaks may also occur, and migrate through the rock formation to the surface. Well casing leaks are likely to migrate slowly to the surface without causing acute health hazards, although these may cause serious hazards if migration to the surface is via an idle or improperly abandoned well. An analysis of CO_2-EOR and analogous injection well failure rates is discussed in Section 4.3.

3.4.4 Leakage of CO_2 From Geologic Storage to the Surface

A search of NRC data identified three well incidents associated with CO_2-EOR releases over the 20-year period 2002 to 2021. These incidents were caused in 2018 by CO_2 migration below ground being released to the surface via three improperly plugged and abandoned wells.

Incidents associated with fluid migration from underground storage reported in the media include:

- 8/9/2011 –Tinsley Production Field, Mississippi. A CO_2 blowout occurred at a CO_2-EOR operation via an inadequately abandoned well that took 37 days to control, sickened one worker, and killed deer, birds, fish and other animals.
- 2004 to 2005 – Salt Creek, Wyoming, CO_2-EOR Project. CO_2 was detected seeping to the surface via well bores of poor integrity. There was rapid dispersion of CO_2 at the surface, and well remediation work was performed to eliminate the seeps.
- 1953 – Herscher-Gainsville UNGS Facility, Illinois. Natural gas was injected for storage into a depleted oil reservoir, at a depth of about 1,500 feet. Several months after start of operation, gas started to migrate through the caprock. Leaks were controlled by reducing the injection pressure and pressurizing the formation above the reservoir with water.

The CarbonFrontier CCS reservoir has been carefully selected to ensure permanent storage of CO_2. This reservoir trapped oil and natural gas over geologic timescales and provides compelling empirical evidence of a robust geologic trap. Potential causes of fluid migration out of the reservoir have been identified from a review of incidents at analogous fluid storage facilities. Mitigation and monitoring measures have been proposed to minimize the risks of potential failure modes.

Wells that penetrate the confining zone into the proposed sequestration layer include injection wells, monitoring wells, and abandoned wells. Failure of well integrity creates the highest risk for leakage of fluids to the surface.

Potential failure modes for fluid leakage to the surface include:

- Leaks via well penetrations through the caprock
- Failure of containment due to faults or fractures in the caprock
- Failure of the caprock due to over-pressurization
- Induced fracturing and fault activation due to locally exceeded reservoir pressures
- Seismic activity

A release from the sequestration reservoir will most likely be a slow dissipation to the surface. Seepage of CO_2 is not uncommon in regions influenced by volcanism, and the concentrations measured indicate that it is highly unlikely that a slow leak from a CO_2 storage reservoir will pose a hazard to personnel or the environment.

3.4.5 Amine Unloading and Storage Incident Data

It is proposed to import concentrated amine using bulk chemical cargo tanks and unload into storage tanks. Hazardous materials transport of corrosive materials is regulated by the DOT, and significant incidents reported to the PHMSA of the DOT. Incidents may also be reported to the NRC if there is a threat to human health or the environment. DOT and NRC data were searched over a 20-year period, 2002 to 2021, to identify potential hazards associated with ethanol amine transport and unloading.

A total of 74 release incidents were identified, as summarized in Table 3.3. In transit releases were due to truck collision or equipment failure. Unloading incidents were due to; hose or hose

connection failure, other equipment failure, or operating error. Only 2 injury incidents were reported, both occurred during unloading due to equipment or hose failure.

3.4.6 Sulfuric Acid Unloading and Storage Incident Data

It is proposed to import sulfuric acid using bulk chemical cargo tanks and unload into storage tanks. Hazardous materials transport is regulated by the DOT, and significant incidents reported to the PHMSA of the DOT. Incidents may also be reported to the NRC if there is a threat to human health or the environment. DOT and NRC data were searched covering a 20-year period, 2002 to 2021, to identify potential hazards associated with bulk road transportation and unloading of concentrated sulfuric acid.

A total of 687 relevant release incidents were identified, about 34 per year, as summarized in Table 3.4. Sulfuric acid is widely used across a range of industries, and the higher number of incidents relative to amine solvent transportation is due to the higher number of shipments. Incidents were categorized to determine the mode of failure, size of release, and potential for casualties. Nearly 70% of the release incidents were associated with unloading. A total of 10 incidents were due to unloading sulfuric acid into a tank containing an incompatible chemical, or an incompatible chemical being unloaded into a sulfuric acid storage tank.

3.5 Hazardous Material Casualties

A number of natural and industrial releases of CO_2 have resulted in injuries or fatalities due to CO_2 inhalation. Examples of some major CO_2 release incidents were presented in Section 3.2 to illustrate the potential hazards of CO_2, which were mainly due to large CO_2 releases or where there was restricted dispersion due to confinement. Industrial incidents associated with CO_2 and amine exposure have been identified in Section 3.3 for incidents reported to the DOT, NRC, and State agencies for well regulation and oversight. Due to the limited data available, it is not possible to project the likelihood of casualties from previous incidents. However, these incidents provide a basis to predict the hazards of release.

Carbon Capture and Compression

Carbon capture will involve the use of amine absorption technology. Personnel hazards may occur due to a release of amine or concentrated CO_2 within the process area, where there may be partial confinement from equipment. Amine absorption is widely used in industry to remove CO_2 and H_2S from oil production and refining streams. A total of 172 amine facility incidents were identified over 20 years, with no serious injuries or fatalities reported, as listed in Table 3.1.

A total of 37 incidents were identified to be associated with fixed facilities with CO_2 process streams and compressed CO_2. There was 1 fatality and 2 injury incidents, all associated with releases into confined areas. No casualties were reported associated with amine treating facilities or CO_2 compression.

CO_2 Pipeline Transportation

PHMSA records of 25 CO_2 pipeline releases and 75 auxiliary equipment releases over 20 years, 2002 to 2021, show no fatalities or hospitalized injuries. However, one 24-inch pipeline rupture event in Satartia, Mississippi in 2002 resulted in 45 residents seeking medical attention.

Another incident required the evacuation of surrounding residents. There is clearly the potential for a large CO_2 release to be hazardous a significant distance from the release location.

CO_2 Injection Well Failure

CO_2 injection for EOR has been in operation in the US since the 1970's. There have been no fatality or serious injury incidents reported from approximately 13,000 injection wells in the US. Well control incidents are reported to state agencies, and 2 events were identified that required evacuation of nearby residents over a 20-year period. One of these evacuations was required due to the hazard of H_2S in the naturally occurring CO_2 used for EOR.

CO_2 Leakage from Geologic Storage to the Surface

A release of CO_2 may occur due to underground migration to the surface. These incidents have resulted in a slow dissipated release, and are unlikely to be acutely hazardous except if undetected vapors accumulate in low lying areas.

No incidents of fluid leakage from storage have been identified that have resulted in public casualties due to CO_2 exposure. Sudden large releases from volcanic sources have resulted in significant loss of life due to CO_2 exposure, although these are not comparable in scale to the slow seepage that is possible from CO_2 sequestration.

Amine Unloading and Storage

A total of 44 bulk transportation incidents and 30 bulk storage incidents were identified to be associated with ethanol amines, as listed in Table 3.3. These have resulted in 2 unloading injury incidents, both due to liquid spray on connection failure. On-site personnel are in close proximity to corrosive fluids and possible spray releases during unloading, and will wear personal protective equipment. Public personnel are highly unlikely to be in close proximity to amine unloading and storage facilities.

Sulfuric Acid Unloading and Storage

A total of 687 bulk road transportation and unloading incidents were identified to be associated with concentrated sulfuric acid, as listed in Table 3.4. There were two employee fatality incidents due to major releases; one occurred due to a truck rollover and cargo release, and the other due to an unloading hose connection failure. Approximately 75% of the sulfuric acid injury incidents were associated with on-site personnel exposure during unloading. Aera personnel and contractors will wear personal protective equipment to minimize the risk of potential exposure during unloading. Public personnel are highly unlikely to be in close proximity to sulfuric acid unloading and storage facilities.

During road transit, there have been 13 injury incidents over 20 years. Public personnel or emergency responders were exposed to sulfuric acid releases in 11 of the injury incidents. From data published by the DOT Bureau of Transportation[49], there are an estimated 400,000 sulfuric acid truck deliveries per year. Historically, the likelihood of public exposure to a sulfuric acid release whilst a truck is in transit is very low, approximately 1 in every 700,000 deliveries.

Sulfuric acid is highly reactive, and when mixed with incompatible chemicals in error can result in the release of toxic gas and heat. There have been a total of 10 incidents associated with sulfuric acid when a bulk cargo has unloaded into the wrong storage tank containing an incompatible chemical. One major incident resulted in a toxic gas cloud impacting the

neighboring community, although this was the result of unloading sulfuric acid into a tank containing sodium hypochlorite (bleach), which would not be stored in bulk at the proposed CarbonFrontier facilities.

3.6 Potential Hazardous Release Scenarios

Historical incidents of CO_2 releases and incidents from similar industries, were used to develop potential release scenarios for each CCS operation, as listed in Table 3.4. Estimates have been developed for the likelihood of release, as discussed in Section 4. Hazards associated with these release scenarios are then discussed in Section 5.6.

Table 3.1 NRC Reported CO_2 and Ethanol Amine Fixed Facility Incidents 2002-2021

Facility Type	NRC Reported Releases (2002 to 2021)		
	Number of Releases	Exposure Incidents	
		Fatality	Injury
Fixed Facility CO_2 Releases			
- Oil and Gas Production	5	-	-
- Oil and Gas Processing / Amine Treating	9	-	-
- Chemical / Industrial Gas / Fertilizer	11	-	-
- Food Industry / Warehouse	12	1	2

Table 3.5 Summary of Potential Release Scenarios

Release Source	Scenarios
1. CO_2 Source Stream Pipeline Failure from Del Sur - Medium sized pipeline leak - 16-inch pipeline guillotine failure	Failure of 16-inch above ground pipeline transferring combined Tulare and Diatomite gas flow from Del Sur Compressor Station to SOX 32. Potential CO_2 and H_2S exposure.
2. Carbon Capture and Compression - Vessel or connecting line 2-inch failure - Vessel or connecting line failure - CO_2 compressor 10% pipe diameter failure - CO_2 compressor catastrophic failure - CO_2 buffer vessel failure	Large or medium sized release of amine solution. Potential hazard in close proximity. Large of medium low pressure CO_2 release upstream of compression at 20 psig. Large of medium CO_2 release of gaseous CO_2 within compression and treating section at 500 psig. Large or medium sized release of liquefied CO_2 at 1,300 psig.
3. CO_2 Transfer Line to Sequestration Field - 12-inch pipeline, 2-inch hole release - 12-inch pipeline guillotine rupture - CO_2 booster pump 1-inch hole release - CO_2 booster pump rupture - 12-inch distribution line, 2-inch hole release - 12-inch distribution line, guillotine rupture - 6-inch distribution line, 1-inch hole release - 6-inch distribution line, guillotine rupture	12-inch CO_2 transfer line failure at 1,700 psig and 100^{o}F. Above ground lines. Horizontal high momentum, or impinged low momentum release.
4. CO_2 Sequestration Well Injection - Well head equipment release, 1-inch hole - Loss of well control, 2-inch hole equivalent - Loss of well control, full bore vertical flow - Well casing failure and migration of CO_2 to the surface	Horizontal momentum jet release or impinged low momentum. Worst-case horizontal impinged low momentum release. Vertical full bore release at high flow rate, rapid reduction in flowrate as 4-inch well tubing depressurizes.
5. Leakage of CO_2 From Sequestration Reservoir - Leaks via well penetrations - Faults and fractures - Caprock failure due to over-pressurization - Induced faults or fractures - Seismic activity	Migration of CO_2 from geologic storage to the surface. Slow dissipated release.
6. Amine Unloading and Storage - Bulk truck delivery - Unloading hose or connection failure	Truck leak during transit. Unloading hose leak or failure. 0.5-inch connection failure. Potential hazard in close proximity.
7. Sulfuric Acid Unloading and Storage - Bulk truck delivery - Unloading hose or connection failure - Mix of incompatible chemicals in error	Truck leak during transit. Unloading hose leak or failure. 0.5-inch connection failure. Potential hazard in close proximity. Toxic gas and/or corrosive spray release on mix of incompatible chemicals.

4. RELEASE FREQUENCY ASSESSMENT

The likelihood that a hazardous release will occur, and the potential size of the release, has been estimated using published generic failure rate data. The data has been generated from incident records gathered over a variety of installations and therefore represents an industry average.

The failure rate of a piece of equipment is influenced by a large number of factors, including: design specification, manufacture, application, operating conditions and maintenance. The same piece of equipment may be used in a wide variety of operating conditions and environments, and some attempts have been made to allow for these factors. Published data has been selected for carbon dioxide separation, compression, pipeline transmission, well injection, truck unloading and high-pressure storage. Generic failure rate data have been modified for the CarbonFrontier CCS Project proposed by Aera, based on the proposed design described in Section 2, and historical incident data described in Section 3.

4.1 Process Equipment Failure Rate Data

It is proposed to operate four carbon capture facilities adjacent to existing facilities within the developed South Belridge oil field. The proposed design for the CO_2 capture and compression facilities comprises a pre-scrubber, a CO_2 absorber column, a CO_2 stripper column, and associated pumps and heat exchangers, and a compression and dehydration unit. An example carbon capture process flow diagram is shown in Figure 2.3. It has been assumed that MEA absorption technology will be used. Although the absorption chemicals selected in the final design may be different, the basic hazards and process design are likely to be similar.

Amines used for CO_2 absorption and capture are corrosive, which has been reported as an issue in facilities using MEA. Advanced proprietary amine solvents are likely to be selected for post-combustion absorption, which are reported be less corrosive than MEA. The vapor pressure of proprietary solvents may also be significantly lower, reducing solvent carryover in the overhead absorber gas stream.

Releases for process equipment have been characterized by three different hole sizes:

- Small one-half-inch (5 to 12 mm) diameter
- Medium one inch to two-inch (12 to 50 mm) diameter
- Large over two-inches or rupture (50 mm) diameter

Small leaks are representative of flange leaks, instrument tapping failures and leaks due to corrosion/erosion. These are unlikely to cause a significant hazard for CO_2 or amine releases, and have not been included in the risk analysis. Medium leaks are representative of small connection or line failures, and larger corrosion leaks. Large releases are representative of all large failures, including vessel failure, process line failure, mechanical damage and maloperation.

A summary of generic failure rates selected from literature are shown in Table 4.1 and described below.

4.1.1 Process Vessel Failure Rates

Historical failure rates for process pressure vessels are reported in several data sources, including Center for Chemical Process Safety of the American Institute of Chemical Engineers (CCPS)[10], Smith and Warwick[39], and Lees[31]. CCPS quote an average failure rate for "significant" failures as 1 every 10,000 years (1×10^{-4} per year). This has been taken as the frequency of a 1-inch vessel or connecting pipe failure for smaller vessels, and 2-inch hole for large vessels. From data reported by Smith and Warwick, Lees, and the UK Health and Safety Executive (UKHSE)[46], a large release or rupture occurs at about 1×10^{-5} per year. This has been distributed as 50% instantaneous rupture and 50% large failure resulting in the release of vessel contents over 10 minutes.

The sudden catastrophic rupture of a vessel containing dense phase CO_2 may cause a Boiling Liquid Expanding Vapor Explosion (BLEVE) and flying debris. This is described below in Sections 4.4 and 4.5. To date, there have been three reported CO_2 storage tank BLEVEs due to accidental over-pressurization[16], and one CO_2 cargo truck BLEVE have resulted in casualties. Process vessels are less likely to fail suddenly due to over-pressurization. It has been estimated that 10% of process vessel ruptures will result in a BLEVE.

4.1.2 Process Piping Failure Rates

A study performed by the US Atomic Energy Authority[47] (WASH-1400) has the largest population of piping failure rate data. These represent base failure rates for process piping in an environment where there is minimal vibration, corrosion and erosion. For piping where there is likelihood of corrosion, erosion, vibration or cyclic stresses, a correction factor of 3 to 10 is recommended. The failure rates reported in WASH-1400 with a correction factor applied are comparable with other data sources reviewed, including TNO[12] and UKHSE. The following failure rates have been selected assuming adequate corrosion control:

Full rupture of process piping 6 to 12-inches	$= 6 \times 10^{-8}$ per ft-year
Full rupture of process piping > 12 to 20-inches	$= 2 \times 10^{-8}$ per ft-year
Full rupture of process piping > 20-inches	$= 1 \times 10^{-8}$ per ft-year
1-inch hole in process piping 6 to 12-inches	$= 2 \times 10^{-7}$ per ft-year
2-inch hole in process piping > 12-inches	$= 1 \times 10^{-7}$ per ft-year

4.1.3 Pump Failure Rates

Most pump leaks are due to seal or gland failures. Larger releases are reported by the TNO and UKHSE to occur about 1 every 2,000 years (5×10^{-4} per year), with an effective diameter of 10% of the connecting piping. Lees[31] and TNO report that catastrophic failures occur about 1 every 10,000 years (1×10^{-4} per year). These may be caused by fracture, breakage or collapse of the pump that would typically result in larger releases.

4.1.4 Compressor Failure Rates

Failure rates for compressors have been developed from leak rates and leak size distributions published by the E&P Forum[19] and Lees[31]. Reciprocating compressors are reported to have

failure about 1 every 25 years. Most releases from compressors are small, with approximately 1 percent being large, and 6 percent being medium releases.

4.2 Pipeline Failure Rates

Pipeline failure rates have been calculated from US DOT PHMSA incident data, and compared to data published in Europe. The release sizes and causes of release have been assessed to select appropriate failure rates for CO_2 and produced gas transfer lines proposed for Aera's CarbonFrontier CCS Project.

4.2.1 Pipeline Incident Data

Pipeline failure rates have been calculated for CO_2 pipelines using 20 years of US DOT reported incident data, as discussed in Section 3.3.2. To date, there is limited operating experience with CO_2 pipelines, and therefore predicted failure rates for CO_2 pipelines may not be reliable. There is also insufficient CO_2 pipeline data for analysis on the influence of pipeline diameter and release cause to predict failure rates for the design of the Project pipelines.

It is likely that CO_2 pipelines will experience similar failure rates to natural gas transmission pipelines. These products are both transferred by high pressure pipelines with similar designs and causes of failure as discussed below in Section 4.2.4.

Natural gas transmission pipeline incidents have been reported in the US and Europe for many years, and represent an excellent source of information on pipeline failure rates within a large network of pipelines. Pipeline failure rates have been calculated for both US DOT PHMSA data[49], and for the European Gas Pipeline Incident Group (EGIG) data[17] for the most recent 20 years of data. These are compared below to the failure rate calculated for US DOT CO_2 pipelines:

Source	Failure rate per 1,000 mile-years	Reporting Criteria	Average Diameter (in)
US DOT - PHMSA[49] CO_2 Transmission 2002-2021	0.27	> 5 gallons or > $50,000	17
US DOT - PHMSA[49] Gas Transmission 2002-2021	0.15	> 3 MMSCF > $50,000	19
EGIG[17] Gas Transmission 2000-2019	0.24	All leaks	20

Each of the sources provides data on reportable incidents, which are different for each data source. The PHMSA data includes incidents that meet the DOT reporting thresholds, which are 5 gallons for a CO_2 release and 3 million standard cubic feet (MMSCF) for natural gas. The European reporting threshold for gas transmission pipelines is lower than US DOT reporting threshold, which may result in the higher apparent incident rate for European pipelines, due to the inclusion of smaller leaks in the data.

4.2.2 Distribution of Release Sizes

US DOT and European EGIG gas transmission line data have been analyzed to calculate the failure rate by release size as follows:

Release Size	US DOT Data for Years 2002 to 2021 [49]		
	Number of Pipe Releases	%	Failure Rate per 1,000 mile-years
Pinhole /Crack (<1/2-inch)	271	30%	0.046
Hole	321	36%	0.054
Rupture (=>pipe diameter)	304	34%	0.052
Total	**896**		**0.152**

Release Size	EGIG Data 2000 to 2019 [17]		
	Number of Pipe Releases	%	Failure Rate per 1,000 mile-years
Pinhole /Crack (<1/2-inch)	244	63%	0.149
Hole	94	24%	0.057
Rupture (=>pipe diameter)	50	13%	0.031
Total	**388**		**0.237**

The exclusion of smaller releases in the US DOT data results in an unrealistic release size distribution. The size distribution has been therefore been adjusted using the European EGIG data which includes all release sizes.

4.2.3 Pipeline Diameter and Wall Thickness

The US DOT collects data on pipeline infrastructure from operator annual reports[35]. This includes information on the total length, diameter, installation date, and commodities transported. This data has been used to calculate pipeline failure rates by mile and diameter of pipe.

Pipeline failure rates are reported to be dependent on the diameter of the line. This has been largely attributed in literature to the increase in pipe wall thickness with larger diameter lines, the ability of a pipeline to withstand external impact with increasing wall thickness, and the time interval where corrosion may be detected and addressed before causing a failure. US DOT pipeline rupture failure rates have been calculated for natural gas transmission data by pipeline diameter, as shown in Table 4.2. However, as only releases above the reporting threshold are included in the US DOT data, a correction factor has been applied based on an analysis of the European EGIG data as follows:

Pipeline Diameter	Diameter Factor
=< 4 inches	3.8
> 4 to 8 inches	2.6
> 8 to 12 inches	1.4
> 12 inches	1

The threat of failure related to pipeline diameter and wall thickness for natural gas and CO_2 pipelines is likely to be similar. The average MAOP of CO_2 pipelines has been calculated as approximately 2,000 psig, whereas the average MAOP of natural gas pipelines is approximately 770 psig. The increase in wall thickness and higher grade of steel for CO_2 pipelines compared to natural gas pipelines will likely result in a lower CO_2 pipeline failure rate for a similar diameter pipeline.

4.2.4 Cause of Release

Historically, natural gas and hazardous material liquid pipeline failures are caused by third-party interference, corrosion, construction or material defects (e.g. welds), ground movement or operator errors. US DOT natural gas pipeline ruptures have been categorized by cause of failure and pipeline diameter as shown in Table 4.2. The cause distributions are summarized as follows:

Corrosion	27%
Natural Force Damage	10%
External Impact	31%
Material Failure	27%
Equipment / Operations	2%
Other	3%

Internal Corrosion - Most CO_2 pipelines in the US transport naturally occurring CO_2 sources to oil production areas for EOR. There is little experience of CO_2 pipelines with impurities such as SO_x, NO_x, N_2, O_2, and CO due to combustion, although low concentrations are unlikely to significantly increase the internal corrosion rate with reliable monitoring. Reported experience to date with CO_2 pipelines indicates that the internal corrosion rate is comparable with natural gas pipelines, provided no free water is present. Moisture content of CO_2 entering the pipeline will need to be monitored.

External Corrosion – This has been a major cause of failure for below ground transmission pipelines. External corrosion is less likely for the CCS Project pipelines which are proposed to be predominantly above ground, on raised pipe supports to minimize external corrosion. An external corrosion modification factor of about 0.2 has been suggested in literature for above ground pipelines[(15)].

Natural Force Damage - Natural force damage includes events such as earth movement due to landslide, subsidence, seismic activity, flooding and erosion. The proposed Aera CCS pipelines are to be located across primarily gently sloping terrain, and above ground where there is less force on the pipeline if movement occurs. The probability of failure due to earth movement is likely to be significantly lower than average. An external impact modification factor of about 0.2 has been suggested for above ground pipelines.

External Impact - External impact is primarily due to damage caused by excavation impact on below ground pipelines. The proposed Aera CO_2 pipeline will be above ground and on Aera property where there is greater control over activities. The likelihood of external interference is therefore significantly lower, although there is still the possibility of vehicle impact.

Material Failure / Equipment / Operations - Maintaining dense phase CO_2 within design specifications will be more challenging than with natural gas. There may be additional stresses on the pipeline due to rapid changes in temperature due to a leak, equipment failure or operational error. There is the possibility of brittle failure due to rapid cooling, and ice formation during depressurization. Seals and valves will also need to be specifically selected for CO_2 service. This may increase the likelihood of failure due to equipment and operations.

Overall, the failure rate for an above ground CO_2 pipeline on non-public property is likely to be lower than an equivalent sized below ground gas transmission line. However, due to the uncertainty in potential material failures, equipment and operations, and limited historical data for CO_2 pipelines, it has been conservatively assumed that failure rates for the Project CO_2 pipelines are equivalent to natural gas pipelines. Modification factors have been applied for the above ground produced gas transfer line from Del Sur Compressor Station to SOX 32 for the likely reduction in external corrosion and reduction in the potential for external impact.

4.2.5 CO_2 and Gas Transfer Line Failure Rates

Published data for US DOT natural gas transmission failures have been adjusted to take account of the likely under reporting due to the reporting criteria and adjusted for pipe diameter. The following failure rates have been selected for the proposed above ground CO_2 transfer lines and produced gas transfer line from Del Sur Compressor Station to SOX 32.

Line Diameter	Line Content	Failure Rate (per mile-yr)	
		Medium Hole (2-inch)	Large / Rupture
> 4 to 8 inches	Dense phase CO_2	2.0×10^{-4}	1.1×10^{-4}
> 8 to 12 inches	Dense phase CO_2	1.6×10^{-4}	8.8×10^{-5}
> 12 to 20 inches	Dense phase CO_2	1.3×10^{-4}	7.3×10^{-5}
> 12 to 20 inches	Del Sur Production Gas Transfer	7.8×10^{-5}	4.4×10^{-5}

The overall pipeline release frequencies are shown in Table 4.3.

4.3 Injection Well Failure Rates

A well blowout may occur due to the loss of pressure control causing fluid to migrate up and out of a well. These may be caused by mechanical failure, flawed or damaged equipment, operational error or unpredictable circumstances such as well-head impact. Most well control problems are either quickly controlled by safety equipment, or result in a minor release and are not included in the category of “blowout” in published incident data.

There are few dedicated CO_2 storage injection wells to date, with limited operating experience. Industrial operations such as CO_2-EOR production, natural gas storage, and acid gas injection for permanent geological storage will have differences to dedicated CO_2 storage, but they provide analogues for the likelihood and severity of blowouts that could occur.

Failure rates associated with CO_2 injection wells may also have similarities with production wells. There is more historical experience with oil and gas production wells to allow calculation of failures rates during various well phases, and these have been compared to failure rates reported for other analogous injection wells.

Underground Natural Gas Storage

The storage of natural gas in geological formations has been used in North America and Europe since the 1970's. Depleted oil and gas reservoirs are utilized for 83.5% of this storage, natural aquifers for 12.6% and the remainder in salt caverns and converted coal mines.

The International Energy Agency (IEA) sponsored a study of the natural gas storage industry as an analogue for CO_2 storage in 2006[27]. The gas storage industry experience was assessed for applicability to CO_2 sequestration, and historical failure modes and frequencies were developed. The IEA provided the following estimated well failure rates for world-wide and European data:

Natural gas injection well	2.0×10^{-5} per well-year (world-wide incidents)
Natural gas injection well	5.1×10^{-5} per well-year (European incidents)

The European failure rate calculated was more than twice the likelihood of the world-wide data. This was due to the inclusion of smaller incidents in the European data compared to the world-wide data, which included mainly larger events captured from media reports that resulted in casualties, property damage, site evacuation or uncontrolled leak. Smaller events, such as leaks caused by casing failure that could be easily remedied, were not included in the world-wide incident rates.

The failure modes described for the world-wide significant incident data were as follows:

Well casing failure with gas migration to surface	44% (7 events)
Well control failure with release via well bore	25% (4 events)
Caprock failure or improperly selected reservoir	25% (4 events)
Release via improperly abandoned wells	6% (1 event)

Three of the caprock failure events listed above occurred at saline aquifer storage sites. These were shallower storage facilities without multiple confining layers, and without the proven ability to contain fluids for millions of years such as in depleted oil and gas reservoirs. The fourth event occurred in a relatively shallow depleted gas reservoir due to over-pressurization. None of these events are likely to be relevant for projecting the long-term storage ability of the CarbonFrontier project.

Natural gas storage in geological formations is likely to have greater similarities with CO_2 storage in depleted oil and gas reservoirs than storage in underground caverns. Releases from caverns were reported in 38% of the world-wide incidents, although these are used in only 4% of underground gas storage. The exclusion of cavern events reduces the reported world-wide failure rates by 35%. The failure rate for significant releases is then estimated as:

Natural gas injection well	1.3×10^{-5} per well-year

CO_2-EOR Operations

CO_2 has been injected into active oil and gas production formations for EOR since 1972. Loss of well control events are reported to state agencies, but many states have limited historical records. The Texas Railroad Commission (RRC) maintains the most comprehensive well control records, although incidents are not identified by the type of well, and details are limited for older records.

A study on well blowout rates was conducted by Porse et al in 2014[36] for 3 Texas districts over a 14 year period from 1998 to 2011. This study included the 2 districts where 99% of Texas CO_2-EOR wells are located. A total of 84 well blowouts were identified in these 2 districts, only 1 of which was a CO_2 injection well. The failure rates for production and injection wells were calculated as follows:

Oil well servicing and production	3.0×10^{-5} per production well-year
CO_2 injection well	1.1×10^{-5} per injection well-year

An analysis has been conducted for this QRA using Texas RRC records for the 10 year period, 2012 to 2021. A search was conducted for well control events within the same 2 districts as the Porse study. A total of 61 blowouts were identified, which were then cross checked against well information to identify the type of well. Four of the blowouts were associated with CO_2 injection wells, 2 of which occurred during well workovers. It has been reported in a survey by ARI in 2019[1] that Texas has 6,840 active CO_2-EOR wells, which provides the following injection wells failure rate:

CO_2 injection well	5.8×10^{-5} per injection well-year

Combining the results of both studies results for the 24-year period, an overall CO_2-EOR injection well blowout rate has been calculated as 3.1×10^{-5} per injection well-year.

California Thermally Enhanced Oil Recovery

A study was conducted by Jordon[28] on the frequency and consequences of loss of well control events in California Oil and Gas District 4, from 1991 to 2005. District 4 is located in the southern San Joaquin basin, which includes Kern County. The purpose of the analysis was to assess the risk of well failure associated with steam injection. In District 4, 59% of oil production is via thermally enhanced recovery. Thermal enhancement involves the injection of large quantities of steam into the formation, which has some similarities with CO_2 injection.

Well blowout data was obtained from California Division of Oil, Gas and Geothermal Resources, (DOGGR, now called CalGEM) and newspaper archives. A total of 102 individual blowouts were identified and the following failure rates calculated:

Drilling and completion	4.0×10^{-4} per well in thermally enhanced field
Steam flood injection well	1.4×10^{-4} per injection well-year
Steam flood production well	4.3×10^{-5} per well-year
Thermal well servicing	3.5×10^{-5} per well servicing
Thermal well P&A	1.0×10^{-5} per well (estimated)

Steam blowouts from injection wells migrated out of the well casing to the surface in 70% of incidents, and were released through the well bore in 30% of incidents. There was only one underground blowout identified during the study that occurred via an older abandoned well, despite over 100 years of oil production in the district. Since the study was conducted, a second underground blowout incident occurred at the Midway-Sunset oil field in 2011. An oil industry employee died when the ground beneath him gave way due to the release of reservoir fluids from a nearby steam injection operation. An abandoned well pipe was reported to have been sheared as a result of ground movement, creating a pathway for reservoir fluids to the surface.

The blowout rate was reported to decline significantly during the study period, most likely as a result of increasing experience, improved technology, and/or changes in safety culture.

Offshore Oil and Gas Production

Data on well blowouts is readily available for offshore incidents in the Gulf of Mexico and the North Sea. The US Bureau of Ocean Energy Management (BOEM), and the Norwegian Foundation for Scientific and Industrial Research (SINTEF) publish data on offshore incidents in the Gulf of Mexico, and internationally. This provides a comprehensive database for oil production wells, although the failure rates associated with drilling and completion in a depleted reservoir for CO_2 sequestration are likely to be significantly lower.

Offshore oil well failure rates reported by BOEM and SINTEF were compiled by Bercha under contract to the BOEM as follows[3]:

Drilling and completion	7.1×10^{-4} per well
Well Servicing	3.1×10^{-4} per well servicing
Production	1.1×10^{-4} per well-year

California Oil and Gas Production

Failure rates for oil and gas wells in California have been analyzed from a report on the History of Oil and Gas Well Blowouts in California, 1950 to 1990, published by the California Division of Oil, Gas and Geothermal Resources, 1993[5]. The data is based on a smaller population of wells than the offshore BOEM and SINTEF data, and the incident reporting for earlier years may not be as complete. The following failure rates have been calculated from this data for well servicing and production operations:

Well Servicing and Production	3.1×10^{-4} per well-year

The failure rates reported for California onshore production facilities are consistent with those published for offshore wells. The oil and gas production data includes incidents that occurred before improved well monitoring technology, equipment, and changes in safety culture were implemented. This has been reported to significantly reduce the incidents of well control failure.

Selected Well Failure Rates

Well failure rates for natural gas storage, CO_2-EOR, steam flood operations in Kern County, offshore and onshore oil production are all relatively similar. The reported blowout rates for

Kern County steam injection wells were higher than other sources, possibly due to operation at shallower depths.

The proposed CarbonFrontier CCS Project will utilize an 8,000 deep sandstone formation, which is at low pressure due to depletion from oil and gas production. The risks of an oil and gas blowout associated with well drilling and completion of injection wells is therefore very low. Only failure rates for well servicing and production have been considered in the risk calculations.

The failure rate for an injection well blowout has been selected as 5×10^{-5} per injection well-year, based on injection wells for natural gas storage in geological formations, and CO_2-EOR injection wells in Texas. Many wells control failures reported were not full well bore releases. It has been estimated that well head releases the equivalent to a 2-inch hole occur in 75% of the well control failure events, and full casing flow in 25% of events.

The overall failure rates for loss of well control have been selected as:

Operational Phase	Release Size	Failure Rate (per well-year)
Injection Well Blowout	Full casing diameter flow	1.3×10^{-5}
Injection Well Blowout	2-inch diameter release	3.8×10^{-5}
Wellhead Release	1-inch diameter release	2×10^{-4}
Monitoring Well Blowout	Full casing diameter flow	2.5×10^{-6}
Monitoring Well Blowout	1-inch diameter release	2.3×10^{-5}
Abandoned Well Release	Migration to surface	5.0×10^{-8}

The overall well release frequencies are shown in Table 4.4.

Blowout rates in oil and gas activities are reported by Jordan et al[28] have declined significantly in recent years due to improved technology, increased experience and changes in safety practices. These improvements are likely to be seen in the reliability of CO_2 injection wells.

4.4 Amine Transportation and Storage Failure Rate Data

It is proposed to import concentrated amine using bulk chemical cargo tanks of approximately 6,000 gallons (143 barrels). The concentrated solvent will be stored in 21,000 gallon (500 barrel) tanks. In addition there will be 4 holding tanks of 168,000 gallons (4,000 barrels), one for each capture facility, to contain the working inventory of diluted solvent. After the capture facilities are in operation, it is assumed there will be 21 deliveries of 3,000 gallons per facility per year, with the truck driving 50 miles from the Bakersfield area.

An assessment has been made of hazardous material incidents involving bulk ethanol amine truck transportation, unloading and storage. The likelihood of a hazardous release, and the potential size of the release, has been estimated using published generic failure rate data. The

data has been generated from incident records gathered over a variety of installations and therefore represents an industry average which is not specific to corrosion materials.

Truck Transportation

A chemical release and potential hazard may occur due to truck vehicle collision, roll-over that causes a tank release, or equipment failure on the vehicle.

Truck accident rates are reported in published data as vehicle miles traveled and are typically quoted per million vehicle miles traveled (MVMT). National vehicle and truck accident rates are published annually by the Federal Motor Carrier Safety Administration (FMCSA)[21]. For the year 2020, the average truck accident rate was 1.37 per MVMT. It was reported in a 2001 FMCSA study[20], that hazardous material cargo vehicles had an accident rate about 30% lower than average trucks. The release probability for tank trucks, given an accident, is reported by Harwood[25] to be between 5% and 9%. A release probability of 9% has been selected, which gives an estimate of a truck collision release as 0.09 per MVMT.

Additional incidents occur due to non-collision events, such as; truck non-collision rollover, equipment failures, and operating error. Equipment failures are typically smaller release events. From an assessment of in-transit truck incidents discussed in Section 3.3, these causes resulted in about 65% of releases, to give an overall release estimate of 0.26 per MVMT.

From an assessment of the transportation release sizes reported in the DOT PHMSA database, approximately 90% of the releases were categorized as small, which is less than 5 percent of the cargo.

Truck Unloading

A potential hazard may occur due to an unloading error, hose failure, or failure of connecting equipment. Failure rates have been selected from those reported by the UKHSE[46] for an average hazardous material facility. These were developed from work at chlorine facilities, which are likely applicable to safety precautions for amine unloading.

The following failure rates have been selected for the unloading hose and connections:

Failure equivalent to hose diameter = 4×10^{-6} per operation
Failure equivalent to 0.5-inch diameter = 4×10^{-5} per operation

An assessment has been conducted of unloading incidents reported to the DOT and NRC over a 20-year period, and the results shown in Table 3.3. Incidents not related to hose failures were reported to be due to a component failures and operating error, such as failure to open or close a valve. These releases were typically smaller than those associated with unloading hose failures. An estimate has been made of truck component and operating failure rates as follows:

Release equivalent to 1-inch diameter = 1×10^{-5} per operation

Amine Storage

A storage tank failure may be due to overfill, failure of a pipe connection, or failure of the tank shell. CCPS[10] and Federal Emergency Management Agency (FEMA)[22] quote an average failure rate for “significant” storage tank failures as 1 every 10,000 years per tank. It has been assumed these are equivalent to a medium sized 2-inch failure. The catastrophic failure rate for chemical storage tanks with double walls is reported by FEMA to occur 1 every million years. It

has been assumed that connection failures and holes occur at the same rate as single walled storage tanks.

The likelihood of a tank overfill is dependent on the type of instrumentation provided for level control and the frequency of filling. Failure rates are reported by Lees[31] to be in the order of 1 in 100 to 10,000 years per tank or less. For tanks equipped with high level alarms and independent high-high levels alarms with automatic shutdowns, the likelihood of overfill is reported to be approximately 1 in 10,000 years per tank. It has been estimated that the overfill rate for amine storage tanks will be approximately 1 in 10,000 years per tank, (1×10^{-4} per tank-year) based on 21 deliveries of amine per capture facility per year and typical hazardous material unloading facilities.

The following failure rates have been selected for amine storage tanks:

Storage tank rupture	$= 1 \times 10^{-6}$ per tank
Medium hole / connection 2-inch diam	$= 1 \times 10^{-4}$ per tank
Tank overfill	$= 1 \times 10^{-4}$ per tank

The summary of the overall amine unloading and storage release frequencies are shown in Table 4.5.

4.5 Sulfuric Acid Transportation and Storage Failure Rate Data

It is proposed to import sulfuric acid at 96% concentration using bulk chemical cargo tanks of approximately 3,000 gallons (71 barrels). The sulfuric acid will be stored in one 8,400 gallon (200 barrel) tank at each carbon capture facility. It has been estimated there will be up to 6 deliveries of 3,000 gallons per facility per year, with the truck driving 50 miles from the Bakersfield area.

An assessment has been made of hazardous material incidents involving bulk sulfuric acid truck transportation, unloading and storage. The likelihood of a hazardous release, and the potential size of the release, has been estimated using published generic failure rate data, and historical incident data.

Truck Transportation

A chemical release and potential hazard may occur due to truck vehicle collision, roll-over that causes a tank release, or equipment failure on the vehicle.

Hazardous material truck accident rates are described above for amine transportation as 0.09 collision releases per MVMT. Non-collision release events were the cause of about 75% of the reported releases, to give an overall release estimate of 0.36 per MVMT. More sulfuric acid releases were reported per MVMT than amine due to the greater hazards associated with concentrated sulfuric acid. The release sizes were estimated to be small 90% of the time.

Truck Unloading

A potential hazard may occur due to an unloading error, hose failure, or failure of connecting equipment. Failure rates have been selected from those reported by the UKHSE[46] for an average hazardous material facility, as described above for amine transportation.

The following failure rates have been selected for equipment failures and operating errors:

Failure equivalent to hose diameter	= 4 x 10^{-6} per operation
Failure equivalent to 0.5-inch diameter	= 4 x 10^{-5} per operation
Release equivalent to 1-inch diameter	= 1 x 10^{-5} per operation

Sulfuric Acid Storage

Failure rates for storage tanks, connection failure and tank overfill were developed based on data from CCPS[10], (FEMA)[22], and Lees[31]. These are described above in Section 4.4 for amine storage, and are applicable to sulfuric acid storage.

Storage tank rupture	= 1 x 10^{-6} per tank
Medium hole / connection 2-inch diam	= 1 x 10^{-4} per tank
Tank overfill	= 1 x 10^{-4} per tank

Unloading into Incompatible Chemical Tank

The accidental mixing of many acids and bases or other incompatible chemicals during unloading operations can lead to potentially dangerous reactions, release of heat, and the generation of toxic gas.

An estimate has been made of the number of sulfuric acid truck deliveries per year in the US from the DOT Commodity Flow Survey[49], as 400,000 per year. For the 20-year period of data searched, there have been 10 reported incidents of a bulk sulfuric acid truck being unloaded into a tank containing an incompatible chemical, or an incompatible chemical being unloaded into a sulfuric acid tank. These events resulted in seven injury incidents. This equates to approximately one incompatible chemical incident every million deliveries. Additional less hazardous unloading incidents may have also occurred that were not reportable to the DOT or NRC. A facility incident is reportable if the event results in injuries, or results in the release of a reportable quantity of hazardous material, or there is an off-site impact.

4.6 Earthquake Failure Rates

The Project site is located in California's seismically active San Joaquin Valley region where there are a number of active faults with the potential to produce strong ground motion. Strong ground shaking due to an earthquake may cause damage to line connections or vessels resulting in a release.

The hazards associated with an earthquake are due to ground shaking, ground liquefaction and seismic induced settling. Reports of earthquake damage indicate that differences in the ground types can result in large differences in the damage done. Lees[31] reports, "Bedrock is generally regarded as a sound foundation and alluvium less satisfactory. Alluvium tends to absorb the effects of small earthquakes but to amplify those of larger ones, giving rise to the effect of soil amplification." The Belridge facility is located on alluvium that may have an increased risk of liquefaction and settlement, increasing the potential for process equipment damage.

The likelihood of ground shaking is reported as hazard areas by the US Geological Survey (USGS)[53]. These hazards are expressed in terms of the probability of exceeding a calculated strength. For example, the Project area shows a 2% probability of exceedance of peak ground

accelerations (PGA) of 0.49 g in 50 years, which equates to an annual probability of 1 in 2,500 (4×10^{-4} /year) of the earthquake strength being exceeded each year. The likelihood of peak ground acceleration at the Project site is calculated as:

Probability of Exceedance	Frequency	PGA (g)
10% in 50 years	2×10^{-3} /year (1 in 500 years)	0.26 g
2% in 50 years	4×10^{-4} /year (1 in 2,500 years)	0.49 g

Where: PGA = Peak Ground Acceleration
g = acceleration due to gravity

An earthquake which produces a PGA of 0.6g or greater is estimated to occur at a frequency of less than 1 in 100,000 years (1×10^{-5} /year).

Large earthquakes have the potential to cause damage to below ground lines and storage tanks. Above ground lines and process equipment are designed with some flexibility and are less vulnerable to failure in an earthquake. The CCS Project pipelines are primarily located above ground, with only road crossings passing underground. A review was conducted of reported earthquake damage to process facilities in close proximity to earthquakes to estimate the likelihood of damage.

Kern County Earthquake, 1952 - This earthquake occurred on the White Wolf Fault, twenty-three miles south of Bakersfield, near an oil producing area. Facilities in the area were designed for earthquakes, and generally vessels were well anchored and above ground pipework provided with flexibility. This minimized the reported process damage. However, many storage tanks were damaged, underground linework failed, and two butane storage spheres collapsed due to the failure of supporting columns.

Hyogo-ken Nanbu (Kobe), Japan, 1995 - Two refineries were located about 20 miles from the epicenter of this earthquake. Ground acceleration at these facilities was estimated to be about 0.25g, and no major process damage was reported. Damage occurred to storage tanks and piping joints at a nearby terminal as a result of ground liquefaction.

Kocaeli, Turkey, 1999 - Tupras Refinery was located about 6 miles from the earthquake epicenter. The refinery suffered severe shaking, with a peak ground acceleration estimated at 0.32g. Facilities were built to US earthquake codes, and generally performed well in the earthquake. The refinery was built on solid ground, and did not suffer from serious liquefaction, except at in area on reclaimed land. The earthquake caused significant damage to the tank farm. The spherical pressurized LPG tanks showed no visible damage, and there was no reported damage to process vessels or pipe joints. At a nearby liquefied gas plant, concrete tank supports failed on 2 out of 3 pressurized tanks, although the vessels did not fail.

A report published by the California State Fire Marshal in 1993[8] examined the history of underground hazardous liquid pipeline failures due to earthquake damage, and provides a prediction of the number of incidents as:

0.2 to 0.3g PGA	0.0039 incidents per mile of pipe	3.9×10^{-3} /mile
0.3 to 0.65g PGA	0.035 incidents per mile of pipe	3.5×10^{-2} /mile

The CarbonFrontier CCS Project pipelines and processing equipment will be designed to seismic safety standards which allow some flexibility and movement, although a large earthquake still has the potential to exceed design limits. Above ground pipelines and linework will have a lower likelihood of failure in an earthquake as the lines are not constrained by soil and are designed with some flexibility.

The incident rates for above ground lines have been estimated to be an order of magnitude lower than below ground lines, as follows:

Release Size	**Above Ground Line Failure rate**
Medium	9.8×10^{-7} /mile-year
Large / Rupture	4.2×10^{-7} /mile-year

The risk of an earthquake causing a hazardous release has been included in the overall likelihood of release. An earthquake could result in the failure of the processing equipment, CO_2 pipeline, CO_2 injection equipment or storage tank. These have been added to the generic failure rates summarized in Tables 4.1 and 4.3 for the calculation of release frequencies.

Table 4.1 Predicted Release Frequencies for Carbon Capture and Compression

Equipment	Release Size	Failure Rate	Counts	Release Frequency (per year)
Process Pressure Vessel – feed gas	Large / Rupture	1×10^{-5} per vessel-yr	1 vessel	1×10^{-5}
	2-inch hole	1×10^{-4} per vessel-yr		1×10^{-4}
Pressure Vessel – amine and CO_2	Large / Rupture	1×10^{-5} per vessel-yr	3 vessels	3×10^{-5}
	2-inch hole	1×10^{-4} per vessel-yr		3×10^{-4}
Linework >20-inch feed gas	Large / Rupture	1×10^{-8} per ft-year	300 ft	3×10^{-6}
	2-inch hole	1×10^{-7} per ft-year		3×10^{-5}
Linework 12-inch amine flow	Large / Rupture	6×10^{-8} per ft-year	300 ft	1.8×10^{-5}
	1-inch hole	2×10^{-7} per ft-year		6×10^{-5}
Pumps - amine	Large / Rupture	1×10^{-4} per pump-yr	4 pumps	4×10^{-4}
	1-inch hole	5×10^{-4} per pump-yr		2×10^{-3}
Compressor	Large	4×10^{-4} per compressor-yr	4 compressors	1.6×10^{-3}
	1-inch hole	2.5×10^{-3} per compressor-yr	4 compressors	1×10^{-2}
Pressure Vessels - Compressor and TEG Dehy	Large / Rupture	1×10^{-5} per vessel-yr	7 vessels	7×10^{-5}
	1-inch hole	1×10^{-4} per vessel-yr		7×10^{-4}
Linework 12-inch CO_2 flow	Large / Rupture	6×10^{-8} per ft-year	400 ft	2.4×10^{-5}
	1-inch hole	2×10^{-7} per ft-year		8×10^{-5}
Buffer Drum – dense phase CO_2	Rupture / Instantaneous	1×10^{-6} per vessel-yr	1 vessel	1×10^{-6}
	Large / Rupture	9×10^{-6} per vessel-yr		9×10^{-6}
	1-inch hole	1×10^{-4} per vessel-yr		1×10^{-4}
Pump – dense phase CO_2	Large / Rupture	1×10^{-4} per pump-yr	1 pump	1×10^{-4}
	1-inch hole	5×10^{-4} per pump-yr		5×10^{-4}

Release frequencies shown above are per Carbon Capture facility, assuming the same hazards for all 4 facilities.

Pre-Combustion facility will be located adjacent to Gas Plant 32. It is likely the design will be different from the other 3 capture facilities. Due to uncertainty in the final designs, the same estimated equipment sizes and release frequencies have been assumed for all 4 capture facilities.

Table 4.2 US DOT Natural Gas Transmission Pipeline Ruptures by Cause of Release, Years 2002-2021

Cause	Pipeline Diameter (inches)						Total
	d=<4	4<d =<8	8<d =<12	12<d =<20	20<d =<28	d>28

US DOT pipeline data for years 2002 to 2021
Average pipeline diameter for US DOT natural gas transmission pipelines = 19-inches

Table 4.3 Predicted Release Frequencies for Pipeline Transfer

Equipment	Release Size	Failure Rate (per mile-yr)	Counts	Release Frequency (per year)
CO_2 12-inch transfer pipeline Section 32 to Compressor Station 49	Large / Rupture	8.8×10^{-5}	10.7 miles	9.4×10^{-4}
	Medium Hole 2-inch diam	1.6×10^{-4}	10.7 miles	1.7×10^{-3}
CO_2 12-inch distribution lines from CS 49 to sequestration field	Large / Rupture	8.8×10^{-5}	2.3 miles	2.0×10^{-4}
	Medium Hole 2-inch diam	1.6×10^{-4}	2.3 miles	3.7×10^{-4}
CO_2 9 x 6-inch lateral lines to sequestration injection wells	Large / Rupture	1.1×10^{-4}	1.3 miles	1.4×10^{-4}
	Medium Hole 2-inch diam	2.0×10^{-4}	1.3 miles	2.6×10^{-4}
Produced Gas 16-inch Transfer Pipeline Del Sur to SOX 32	Large / Rupture	4.4×10^{-5}	3.6 miles	1.6×10^{-4}
	Medium Hole 2-inch diam	7.8×10^{-5}	3.6 miles	2.8×10^{-4}

Table 4.4 Predicted Release Frequencies for CO_2 Injection Wells

Operational Phase	Failure Rate (per well-year)	Count	Release Frequency	
Injection Well Blowout Full casing diameter flow	1.3×10^{-5}	9 injection wells	1.1×10^{-4} /yr	1 in 9,000 yrs
Injection Well Blowout 2-inch diameter release	3.8×10^{-5}	9 injection wells	3.4×10^{-4} /yr	1 in 3,000 yrs
Wellhead Release 1-inch diameter release	2×10^{-4}	9 injection wells	1.8×10^{-3} /yr	1 in 560 yrs
Monitoring Well Blowout Full casing diameter flow	2.5×10^{-6}	4 monitoring wells	1.0×10^{-5} /yr	1 in 100,000 yrs
Monitoring Well Blowout 1-inch diameter release	2.3×10^{-5}	4 monitoring wells	9.0×10^{-5} /yr	1 in 11,000 yrs
Abandoned Well Release	5.0×10^{-8}	102 wells	5.1×10^{-6} /yr	1 in 200,000 yrs
Total Well Failure Rate			2.3×10^{-3} /yr	1 in 440 yrs

Table 4.5 Predicted Release Frequencies for Amine Truck Transportation and Storage

Equipment	Release Size	Failure Rate	Counts	Release Frequency (per year)
Truck Transportation	Large 5,600 gallons	0.1 x 0.26 MVMT	50 miles per visit 21 visits per year 4 facilities	1.1×10^{-4}
	Small 60 gallons	0.9 x 0.26 MVMT	50 miles per visit 21 visits per year 4 facilities	9.8×10^{-4}
Unloading Hose or Connection Failure	Unloading rate 2,000 lb/min for 1 min	4×10^{-6} per operation	84 per year	3.4×10^{-4}
	Small Failure 0.5-inch diam	4×10^{-5} per operation	84 per year	3.4×10^{-3}
Unloading error or equipment failure	Medium hole / connection 1-inch	1×10^{-5} per operation	84 per year	8.4×10^{-4}
Storage Tank	Rupture	1×10^{-6} per tank	8 tanks	8×10^{-6}
	Medium hole / connection 2-inch	1×10^{-4} per tank	8 tanks	8×10^{-4}
	Tank Overfill	1×10^{-4} per tank	8 tanks	8×10^{-4}

MVMT = million vehicle miles traveled

Table 4.6 Predicted Release Frequencies for Sulfuric Acid Truck Transportation and Storage

Equipment	Release Size	Failure Rate	Counts	Release Frequency (per year)
Truck Transportation	Large 3,000 gallons	0.1 x 0.36 MVMT	50 miles per visit 6 visit per year 4 facilities	4.3×10^{-5}
	Small 30 gallons	0.9 x 0.36 MVMT	50 miles per visit 6 visit per year 4 facilities	3.9×10^{-4}
Unloading Hose or Connection Failure	Unloading rate 2,000 lb/min for 1 min	4×10^{-6} per operation	24 per year	9.6×10^{-5}
	Small Failure 0.5-inch diam	4×10^{-5} per operation	24 per year	9.6×10^{-4}
Unloading error or equipment failure	Medium hole / connection 1-inch	1×10^{-5} per operation	24 per year	2.4×10^{-4}
Storage Tank	Rupture	1×10^{-6} per tank	4 tanks	4×10^{-6}
	Medium hole / connection 2-inch	1×10^{-4} per tank	4 tanks	4×10^{-4}
	Tank Overfill	1×10^{-4} per tank	4 tanks	4×10^{-4}
	Unloading into incompatible chemical tank	1×10^{-6} per delivery	24 per year	2.4×10^{-5}

MVMT = million vehicle miles traveled

5. CONSEQUENCES OF RELEASE

An accidental release of a hazardous material due to equipment or operational failure may result in a serious hazard to personnel or the environment. In the following section, the potential hazards associated with an accidental release are assessed. The potential hazard areas for each scenario are estimated using dispersion modelling software. Potential vulnerabilities of the public have been calculated by applying a probability that a person may suffer injury or fatality at a minimum defined concentration. Environmental exposure to carbon dioxide may also cause harm to plant or aquatic life.

5.1 Material Properties

A summary of stream compositions is shown in Table 2.1, and the material properties used to conduct consequence modeling are shown in Table 5.1. The following data has been selected to represent the worst-case hazards for analysis.

5.1.1 Properties of Carbon Dioxide

Carbon dioxide is a naturally occurring atmospheric gas, normally present in air at about 400 parts per million (400 ppm). It is an odorless, colorless gas under normal temperature and pressure. It doesn't burn, is heavier than air, and at high concentrations is both an asphyxiant and intoxicant. CO_2 is not very reactive and is nonflammable. The most common reaction is with water, to form carbonic acid.

Pure CO_2 has a critical temperature of about 88^{o}F (31^{o}C) and a critical pressure of 1070 psia (73 atm). At temperatures and pressures above these values, CO_2 is in a supercritical state as a dense phase "fluid" with properties between that of a liquid and a gas. Physical properties of CO_2 are summarized in Table 5.1, and the phase diagram shown in Figure 5.1.

Heat is released or absorbed in each of the phase changes across the solid-gas, solid-liquid and liquid-gas boundaries. On release, multiple phase changes occur. The expansion to atmospheric pressure causes a rapid cooling of the gas to minus 125^{o}F (-87^{o}C), and the formation of solid CO_2 (dry ice). As the release mixes with air, water vapor in the air condenses to form a visible fog. Dry ice particles within the air-carbon dioxide mixture may also contribute to the visible fog. The plume will remain visible until the diluted cloud has warmed sufficiently to sublime all the solid particles within it, and for the cloud temperature to be above the 100 % humidity level for the air-carbon dioxide mixture.

A large release of CO_2 will form a very cold dense plume which can travel significant distances, depending on wind and terrain. Under calm or low wind speed conditions, the plume will move downhill, settling into low-lying areas. This occurred following the February 2020 pipeline failure, when a large dense CO_2 plume migrated downhill towards the village of Satartia, Mississippi, approximately one mile from the pipeline.

5.1.2 Properties of Amine Solvents

Amine based solvents are widely used for H_2S and CO_2 extraction from gas streams. Solvents for CO_2 extraction from pre and post combustion gas streams have not yet been selected. However, all proposed solvents, including the proprietary solvents being considered, are amine based. Properties of MEA have been selected for analysis, as this is the most widely used amine solvent in the oil and gas industry.

MEA is a colorless oily liquid with a slight ammonia odor, combustible and stable under normal conditions. It is classified as a corrosive by the DOT, which can cause severe skin burns and eye damage on contact. MEA is typically diluted to about 30% with water for gas extraction. Physical properties of MEA are summarized in Table 5.1.

5.1.3 Properties of Sulfuric Acid

Sulfuric acid is an odorless, semi-oily liquid that ranges in appearance from clear to yellow. It has a density and viscosity greater than water which is why it is characterized as an oily solution. Concentrated sulfuric acid solutions have negligible vapor pressure at ambient temperature, and therefore do not form toxic vapor clouds, unless under high temperature or conditions that may create acid mist or spray.

Concentrated sulfuric acid is highly corrosive, and can cause severe chemical burns on contact with skin or eyes. It is a strong oxidizer, with powerful dehydrating properties, removing water from other chemical compounds. The dehydration reaction is highly exothermic (produces heat), and can result in acid spray or corrosive fumes. Sulfuric acid also reacts with numerous metals to produce flammable and potentially explosive hydrogen gas.

Inadvertent mixing of sulfuric acid with hydrochloric acid or sodium hypochlorite (bleach) may produce highly toxic gases. This has been the cause of several public impact events. Sulfuric acid is neutralized by mixing with the alkalis, such as caustic soda (sodium hydroxide), although reaction is exothermic and may cause high temperatures unless mixed under controlled conditions.

The physical properties of 96% sulfuric acid are summarized in Table 5.1.

5.1.4 Properties of Hydrogen Sulfide

Hydrogen sulfide is a flammable, colorless gas which has the smell of rotten eggs. H_2S will be present in the produced natural gas transferred from Del Sur Compressor Station to SOX 32 for treating and subsequent CO_2 capture. The concentration of H_2S is projected to be in the range of 2,500 ppm. The CO_2 concentration in the Del Sur produced gas is projected to be above 65%, making the gas non-flammable and potentially toxic for both H_2S and CO_2 exposure.

5.2 Toxicology of Hazardous Materials

A toxic, flammable or corrosive liquid release has the potential to cause harm to the public. The concentration and duration of exposure will determine the level of harm. Levels of concern have been selected for public exposure based on established emergency planning criteria, as described below.

For public emergency planning and response, Protective Action Criteria (PAC) have been established for numerous chemicals[48], which are published as Acute Emergency Guideline Levels (AEGLs), Emergency Response Planning Guidelines (ERPGs), or Temporary Emergency Exposure Limits (TEELs).

Three PAC concentrations represent the severity of hazardous material exposure, with Level 1 being the least and Level 3 being the most severe. The levels are established to estimate the concentrations of a substance above which it is predicted that the general population, including susceptible individuals, when exposed for more than one hour, could experience the following:

PAC-1 Could experience notable discomfort, irritation, or certain asymptomatic, non-sensory effects. However, these effects are not disabling and are transient and reversible upon cessation of exposure.

PAC-2 Could experience irreversible or other serious, long-lasting, adverse health effects or an impaired ability to escape.

PAC-3 Could experience life-threatening health effects or death.

IDLH Immediately Dangerous to Life or Health. The maximum airborne concentration of a substance to which a healthy worker can be exposed for as long as 30 minutes without impairment or the ability to escape.

Emergency exposure levels have been established for ethanol amines such as MEA, sulfuric acid, and hydrogen sulfide. However, no public emergency planning criteria have been established for CO_2. Levels have been selected as described below, based on the definitions of PAC levels and symptoms of exposure at various concentrations.

5.2.1 Carbon Dioxide Toxicology

Carbon dioxide gas is odorless, colorless, does not burn, is heavier than air, and at high concentrations is both an asphyxiant and intoxicant. High CO_2 concentrations will increase the concentration of CO_2 in the blood, which impacts the respiratory, cardiovascular and central nervous systems. It can also cause asphyxiation due to a decrease in oxygen concentration, although this is reported to be a secondary effect.

Symptoms from acute exposure to CO_2 gas in air are shown in Table 5.2 for various concentrations and duration of exposure. CO_2 gas can cause disorientation, confusion, and unconsciousness, which can be dangerous for persons caught in the plume, especially those who are driving. The effects of sub-lethal CO_2 exposure are rapidly reversible once the affected person or animal is removed from the elevated CO_2 concentrations.

A concentration of 0.5% is used by US agencies to define the CO_2 concentration in the workplace considered safe for a 40-hour week. An exposure of 3% CO_2 represents the onset of symptoms after a short exposure of 15 minutes. An exposure of 4% CO_2 (IDLH concentration) represents the maximum concentration that a healthy worker can be exposed to for as long as 30 minutes, before escape impairing effects may be experienced. The IDLH level is also often considered the minimum level for the onset of serious harm to the public. The minimum CO_2

concentration that may be immediately life threatening has been proposed as 7% by the US EPA[50].

No public emergency planning criteria have been established for CO_2. Public criteria have been selected based on the definitions of PAC levels and the IDLH as described above. A study performed by the US EPA in 2000 on fire suppressant risks[50], proposed a minimum level of 2% (20,000 ppm) CO_2 for public adverse impacts. Concentrations of 1% to 2% CO_2 correlate to the extent of the visible cloud due to condensed water vapor. This is the level that will clearly cause alarm, and within the visible cloud area there may be higher concentrations that may cause distress to vulnerable populations. A minimum level of concern for the public has been selected as 1% CO_2 due to the potential impact on vulnerable populations, uncertainty in dispersion, and the extent of a visible cloud.

The CO_2 concentration that may result in adverse health effects or an impaired ability to escape has been selected as 3%. As described in Table 5.2 Toxicological Effects of CO_2, at 3% concentration, breathing may increase to twice the normal rate, with an increase in blood pressure and pulse rate. This may impair the ability of vulnerable populations to escape.

The following CO_2 concentrations have been selected for public emergency criteria:

PAC-1 = 1% (10,000 ppm)
PAC-2 = 3% (30,000 ppm)
PAC-3 = 4% (40,000 ppm)

5.2.2 Amine Toxicology

Liquid or spray mist may produce tissue damage particularly on membranes of eyes and mouth. Inhalation of the spray mist may produce severe irritation of the respiratory tract, characterized by coughing, choking, or shortness of breath. Liquid contact causes local injury to skin, eyes, mouth and throat. First degree burns occur on short exposure, and secondary burns may occur on longer exposure. Personal protective equipment (PPE) should be worn for safe handling.

Emergency response thresholds for public exposure to MEA have been published by the DOE[48] as:

PAC-1 = 6 ppm
PAC-2 = 170 ppm
PAC-3 = 1,000 ppm

5.2.3 Sulfuric Acid Toxicology

Sulfuric acid injuries may occur due to contact with the skin or eyes. Liquid contact with the skin causes serious burns as the acid reacts with water in the skin. Liquid contact with the eyes may cause irreparable damage and blindness. Inhalation of the spray mist may produce severe irritation of the respiratory tract, characterized by coughing, choking, or shortness of breath. A spray may occur on release which then falls to the ground as the liquid droplets lose momentum. An aerosol of tiny droplets may form if the release is at high pressure.

Emergency response thresholds for public exposure to sulfuric acid have been published by the DOE[48] as PACs. For sulfuric acid, these are the same as the AEGLs, developed by the National Advisory Committee for the Development of Acute Exposure Guideline Levels for Hazardous Substances (NAC/AEGL committee). Exposure limits for aerosols and sprays are typically quoted by liquid weight in the air as milligrams per cubic meter (mg/m^3). The following sulfuric acid concentrations have been selected for public emergency criteria:

PAC-1 = 0.2 mg/m^3
PAC-2 = 8.7 mg/m^3
PAC-3 = 160 mg/m3

5.2.4 Hydrogen Sulfide Toxicity

Hydrogen sulfide is a highly irritant gas that attacks the nervous system and causes respiratory paralysis. At lower concentrations (between 0.2 ppm and 100 ppm by volume) H_2S has the easily recognizable smell of rotten eggs, which alerts people of the need to escape. Above an exposure level of about 30 ppm, eye and throat irritation becomes more severe, and may cause injury to sensitive populations. Above about 100 ppm the sense of smell is inhibited, and at lethal concentrations H_2S cannot be detected by smell. The toxicological effects of H_2S are summarized in Table 5.3.

The levels of public concern for significant injury and potential fatality for exposures of up to an hour are the ERPG levels 2 and 3, developed by the American Industrial Hygiene Association (AIHA). The ERPG-1 level is set as 0.1 ppm, which is the minimum concentration for the detection of odor. The DOE PAC level 1 is 0.5 ppm, which is a level for increasing discomfort, and has been selected for the level of potential public concern.

PAC-1 = 0.5 ppm
ERPG-2 = 30 ppm
ERPG-3 = 100 ppm

5.3 Environmental Toxicity

A release of CO_2 to the atmosphere has the potential to impact flora, fauna and surface waters. It is expected to have a similar impact on mammals as humans, with the effect dependent on the mammal behavior and body size[14] . Habitat in the Project vicinity is generally disturbed by oil and gas exploration and production. Surrounding properties include areas used for agriculture, grazing, and undeveloped private land. There may be insects, reptiles, and small mammals impacted by a potentially hazardous release.

The potential impact of CO_2 on plants and soils may occur due to a change in the soil acidity and root asphyxiation. Lake et al. (2012)[29] conducted an experiment to determine the impact of a pipeline rupture on plants. No significant impacts on plant biochemistry were observed, and plant growth was not affected 3 months later. It was concluded that the effects on plants of a catastrophic CO_2 leak are likely to be small and short term. Over a longer duration CO_2 release, there may be effects on local flora. This has been observed at locations where there are natural CO_2 seeps to the surface in geologically active areas.

A release of CO_2 into the environment could potentially affect surface waters during short-term or long-term releases. CO_2 reacts with water to form carbonic acid which increases the acidity of water. At a concentration of greater than 2% CO_2, the increase in acidity may kill fish in the water, and at 1%, the water may be mildly toxic, Saripalli et al. (2003)[38].

A study has been conducted on surface waters in the vicinity by Stantec (2022)[41]. As described in Section 2.4, no surface aquatic resources were identified that may be at risk due to a potentially hazardous release.

5.4 Selected Levels of Concern and Vulnerability Criteria

Public levels of concern have been selected based on public emergency response criteria. These have been selected as PAC-1 concentration, the minimum level for mild transient effects, PAC-2 concentration, which may result significant injury, and PAC-3 concentration, which is the minimum concentration which may result in serious harm or fatality.

Personnel exposed to a minimum level of concern are not necessarily injured. Personnel may be sheltered within buildings or cars, or be able to find shelter from exposure. This is called the vulnerability, and is the probability that a person exposed within the distance to a level of concern will suffer an injury or fatality.

Toxic exposures are not at the same level within the distance to a level of concern. As you get closer to the source of the release, the toxic concentration increases, until near the source there may be a potentially lethal concentration. Average vulnerabilities have therefore been estimated within the range for levels of concern.

5.4.1 Carbon Dioxide Levels of Concern

The release of dense phase CO_2 will vaporize to form a cold dense cloud which initially spreads in all directions, then downwind as it disperses. Physical barriers such as buildings and vehicles may significantly reduce the risk of exposure and ability of personnel to escape. Public levels of concern have been selected based on public emergency response criteria. These have been selected as PAC-1 concentration, the minimum level for mild transient effects, PAC-2, which may result significant injury, and PAC-3, which may result in serious health concerns.

Severity Level	CO_2 Concentration	Release Duration	Vulnerability In Vehicles or Buildings	Vulnerability Outdoors
Level of Public Concern	PAC-1 1%	Continuous release	0.25	1
Potential for Significant Injury	PAC-2 3%	Continuous release	0.25	1
Potential for Serious Harm or Fatality	PAC-3 4%	Continuous release	0.25	1

These severity levels represent the potential for levels of concern proposed by government agencies. However, a CO_2 concentration of 4% may not be life threatening for the majority of the population. The minimum CO_2 concentration that may be immediately life threatening has been proposed as 7% by the US EPA[50], and a CO_2 concentration of 10% or higher may cause

unconsciousness within a few minutes. The UKHSE[44] and the Dutch RIVM[4] have developed time-concentration equations for predicting the likelihood of fatality, which are consistent with those proposed by the US EPA. These time-concentration predictions give a conservative estimate of 50% fatality at 10% concentration of CO_2 for a 20 minute exposure in the general population. These vulnerabilities have been applied for the comparison of risks to established international criteria, as described in Sections 6 and 7.

5.4.2 Well Release Levels of Concern

A release from a CO_2 injection well will have the same levels of concern for toxic exposure as described above for a CO_2 release for personnel in the vicinity.

A review of reported hazards associated with CO_2-EOR well blowouts did not identify any reports of serious injury or fatality events. Two events were identified that required evacuation of nearby residents over a 20 year period, although one of these was reported to be due to H_2S being present in the naturally occurring CO_2.

5.4.3 Explosion Overpressure Levels of Concern

The catastrophic failure of a CO_2 process vessel may result in a BLEVE and explosion overpressure hazards. Personnel hazards include:

- The rapid transition of dense phase liquid from supercritical to atmospheric pressure can create shock waves that cause damage, fatalities, and injuries.
- The cold liquid released may freeze personnel in the immediate vicinity.
- Vessel fragments may be projected with force.

Most injuries and fatalities which result from an explosion overpressure occur due to falling masonry, equipment or flying glass, not directly from the explosion overpressure. Personnel within buildings are therefore more vulnerable to injury or fatality. Personnel outside can physically withstand much high levels of overpressure, and mainly suffer casualties due to debris. The effects of overpressure on personnel and equipment are summarized in Table 5.3.

The effects of overpressure have used to define the levels of concern for the public as follows:

Severity Level	Overpressure	Vulnerability In Buildings	Vulnerability Outdoors
Level of Public Concern Potential minor injury indoors	0.5 psi	0.5	0.1
Potential for Significant Injury	2 psi	0.5	0.2
Potential for Serious Harm or Fatality	3 psi	1	0.5

5.4.4 Ethanol Amine Levels of Concern

The hazards associated with an ethanol amine release incident will occur in close proximity to the release, due to contact or inhalation of a liquid spray or mist. Ethanol amine release incidents were reviewed from DOT and NRC records over a 20-year period. There were a total of 172 amine facility releases reported and no casualties, as listed in Table 3.1. There were a

total of 22 unloading release incidents, 2 of which resulted in minor injuries to employees, as listed in Table 3.3. No public personnel are anticipated within process or unloading areas.

During truck transit, a vehicle collision or equipment failure may result in an ethanol amine release. Over the 20-year period searched there were a total of 28 bulk truck release incidents, an average of 1.4 per year, with no reported injuries associated with amine exposure. Due to the possibility of public or response personnel being in the immediate vicinity of a release during transit, an estimate has been made of the likelihood of a truck incident and release on the Highway 33, adjacent to the Project area, as shown in Table 4.5. The likelihood of public injury due to a transportation release has been conservatively estimated as 1 in 100, due to very few amine injuries being reported from any release source.

5.4.5 Sulfuric Acid Levels of Concern

The hazards associated with a sulfuric acid release incident will occur in close proximity to the release, due to contact or inhalation of a liquid spray or mist. No public personnel are anticipated within process or unloading areas, and therefore no levels of public concern have been selected.

During truck transit, a vehicle collision or equipment failure may result in a sulfuric acid release. Over the 20-year period searched there were a total of 216 bulk truck release incidents, 13 of which resulted in reported casualties. Public personnel or emergency responders were exposed to sulfuric acid releases in 11 of the injury incidents, as listed in Table 3.4. Concentrated sulfuric acid is highly corrosive, and can cause severe chemical burns on contact with skin or eyes. An estimate has been made of the likelihood of a truck incident and release on the Highway 33, adjacent to the Project area, as shown in Table 4.5. The likelihood of public injury due to a transportation release has been estimated as 1 in 20, based on historical incident reports.

Inadvertent mixing of sulfuric acid with an incompatible chemical may occur due to a truck being unloaded into the wrong storage tank. The mixing of sulfuric acid with hydrochloric acid or sodium hypochlorite (bleach) may produce highly toxic gases. This has been the cause of several public impact events. However, bulk hydrochloric acid is not anticipated to be stored at the carbon capture facilities, and sodium hypochlorite will not be stored in bulk. It is therefore unlikely that a highly toxic gas will be released due to inadvertent mixing that could impact the public off-site. The likelihood of error will also be minimized by equipment design, personnel training, and the implementation of unloading procedures.

5.4.6 Hydrogen Sulfide Levels of Concern

The toxicological effects of hydrogen sulfide exposure are shown in Table 5.4. The severity level is dependent on both the duration and concentration of exposure.

The minimum level of concern for hydrogen sulfide exposure for the public has been selected as 0.5 ppm. This is the level where some mild transient discomfort may be experienced, and potential public alarm. The concentration which may result in significant health concerns is the ERPG-2 level of 30 ppm, and the minimum concentration that may result in serious harm or fatality is the ERPG-3 / IDLH level of 100 ppm.

Severity Level	H_2S Concentration	Vulnerability In Buildings	Vulnerability Outdoors
Level of Public Concern	PAC-1 0.5 ppm	0.25	1
Potential for Significant Injury	ERPG-2 30 ppm	0.25	1
Potential for Serious Harm or Fatality	ERPG-3 100 ppm	0.25	1

5.5 Modeling Hazardous Releases

Potentially hazard release scenarios have been identified as summarized in Table 3.4. The likelihoods of these scenarios have then been estimated based on historical data, generic failure rates, and analogous systems in Section 4. The methodologies for calculating the release rates and hazards of a potential release are described in the following section. Distances to potential casualties have been calculated as described below using published formulas and publicly available dispersion models. The dispersion calculations have been performed to hazardous levels of concern defined in Section 5.4 above. These methodologies are expected to provide conservative results.

5.5.1 Release Rate Calculations

Release rates were calculated using standard engineering equations for liquid and gas releases. It has been assumed that the releases are essentially continuous, and will develop to the maximum hazard condition before the source is isolated. Where the release rate is greater than the flow feeding the line, the flow rate has been assumed to be the maximum release rate.

Liquid Release Rate

Liquid release rates have been calculated using Bernoulli's flow equation, as described in the EPA Risk Management Program (RMP) Guidance for Offsite Consequence Analysis[51]. This assumes the fluid pressure is maintained in the vessel or pipeline, and fluid does not flash to two phase prior to release. A two phase release is initially determined by the sonic liquid outflow. As the liquid decompresses, the release rate decays rapidly.

Gas Release Rate

The equation for estimating the release rate of gas from a hole under choked conditions is described in the EPA RMP Guidance[51].

CO_2 Pipeline Release

When a pipeline ruptures, the dense phase gas will flow out of the pipeline at the speed of sound. The pressure and release rate decays rapidly as the pressure in the pipeline falls. As the pressure reduces, CO_2 remaining in the pipeline will transition from being a supercritical fluid phase, to a two-phase liquid and ultimately to gas phase. The released fluid will initially flash to a vapor-liquid with entrained aerosol, and then to a vapor-solid as the pipeline pressure reduces. Three phases may be present at any one time. Dry ice particles may be entrained in the escaping jet, increasing the density and potential size of the plume. Under some conditions, dry ice may rain-out.

The release rate decay was calculated over time using the Morrow decay model described in the TNO Yellow Book[13]. This model was initially developed for releases of LPG from long pipelines. The model is applicable as long as the pressure at the exit is higher than the triple point pressure (75 psig), when dry ice may form in the pipeline. Since maximum hazard distances are determined during the initial high release rate, solidification of CO_2 inside the pipeline below the triple point will not affect the hazard distance calculations[54].

For a full guillotine pipeline rupture, there will be flow from both ends of the pipeline break, doubling the calculated release rate.

Gas Transfer Pipeline Release

When a gas pipeline ruptures, the pressure and release rate decays rapidly over the first minute. The release rate decay was calculated using the Wilson decay model described in the TNO Yellow Book[13], which predicts the mass flow rate as a function of time.

Process Vessel or Pressurized Storage Tank Failure

For a vessel failure, the entire contents of the vessel and connecting lines are assumed to be released within 1 minute. For a hole sized failure, a continuous steady state release was assumed.

5.5.2 Momentum Dispersion

A high-pressure liquid or gas is released with an initial velocity of several hundreds of meters per second. The direction, amount of mixing with air and distance the jet travels are then mainly determined by the velocity of the jet. As the jet loses momentum by mixing with air or impingement, jet momentum will be low enough for the wind speed to have a significant effect in dispersion. Impingement of a jet may significantly reduce the initial behavior and velocity of the release. For example, a jet release within a carbon capture facility is likely to impact equipment, reducing the momentum of the release.

Dense phase CO_2 dispersion was modeled using the SLAB model. The model was developed by the Lawrence Livermore National Laboratory of the United States to simulate the dispersion of dense gases. The code for SLAB is publicly available from the US EPA website, and simulates denser-than-air gas releases for both horizontal and vertically jets.

5.5.3 Low-Momentum Vapor Dispersion

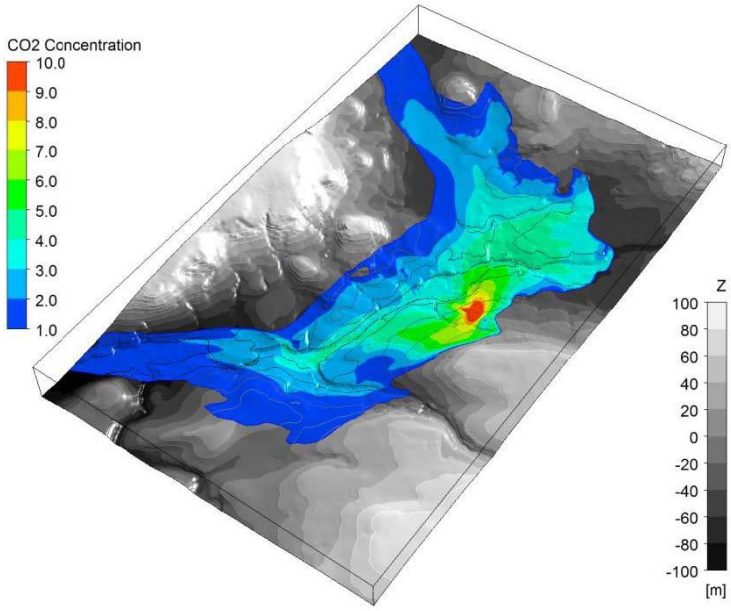
For toxic vapor releases at ground level, the SLAB model was primarily used for calculating heavy gas dispersion. In addition, vapor releases at ground level without significant momentum, the US Environmental Protection Agency and National Oceanic and Atmospheric Administration ALOHA[52] model was run for comparison. This is a publicly available model and is widely used for estimating release distances. Two types of dispersion may be modeled in ALOHA, neutrally buoyant and heavy gas release. A neutrally buoyant plume has approximately the same density as air, and has been used for dispersion of produced gas releases. This model is based on a simple approach described in Turner's Workbook (1974)[43]. The heavy gas model in ALOHA is based on a simplified form of the DEGADIS model developed by Spicer and Havens (1989)[40].

A heavy gas such as CO_2 will travel further along the ground due to gravity slumping. Under these conditions, topographical features can direct the flow of the gas, and gas can accumulate in lower lying areas. A flat-terrain is generally considered the worst-case for hazard distances, although there may be higher concentrations within depressions near to the release source.

Low momentum dispersion models are unable to predict the behavior of dense clouds in very low wind or calm conditions. Models do not accurately predict conditions of "calm" wind less than 1.5 m/s. This is the most hazardous condition for dense gas releases, and the models may therefore under-predict the hazard distances.

5.5.4 Boiling Liquid Expanding Vapor Explosion (BLEVE)

The sudden rupture of a tank or vessel containing dense phase CO_2 may cause a BLEVE. This involves a violent explosion due to the rapid flashing and expansion of vapor, and fragmentation of the vessel. If this occurs, there is the possibility for escalation to nearby equipment due to the explosion overpressure and flying debris.



The calculation of explosion energy has been made using the change in internal energy at the storage conditions, compared to the internal energy of vapor at the triple point. The methodology used is as described in the 2010 book, Guidelines for Vapor Cloud Explosion, Pressure Vessel Burst, BLEVE and flash fire hazards, by CCPS[11].

5.5.5 CO_2 Release and Dispersion Model Verification

The properties and dispersion behavior of a large CO_2 release is complex and not well understood. There are few reports to compare theory to actual incidents. Depressurization of the pipeline on release results in a multiphase release, and determines the speed and release rate decay. Experiments and theoretical calculations have been performed by researchers to improve understanding, but there are many uncertainties associated with the source modeling, and dispersion behavior.

Experiments have been performed to better understand the behavior of a large dense CO_2 cloud. These have demonstrated that dispersion is initially determined by gravity spreading, not by wind speed or direction. The terrain can also have a large effect on the dispersion. Flat terrain is assumed for most dispersion models. A more realistic terrain can be applied with computational fluid dynamic (CFD) codes, though these are complex models. These simulate the impact of typical geographical features on flow dynamics. However, the many assumptions and uncertainties in the models still make it only an approximation.

For the EU CO2PipeHaz project, (2010-2013)[18] CFD dispersion modeling was performed to simulate a pipeline rupture. The results indicate that even with a wind speed of 5 m/s, the presence of the terrain has a large effect on the dispersion of the CO_2 cloud. Rather than being blown downwind, the cloud spread mostly in lateral directions, up and down the simulated valley. The simulated vapor cloud spread is depicted below. This behavior has been reported following the Satartia pipeline rupture in 2019, when the CO_2 cloud travelled down a valley to the village of Satartia 1 mile away.

CO_2 dispersion predictions using a CFD model.

5.6 Calculation of Hazard Distances to Levels of Concern

Hazard distances for the identified release scenarios have been calculated to the vulnerability levels of concern defined in Section 5.4 above. These represent the minimum exposure levels that may result in a public exposure of concern.

The following assumptions were made in calculating the hazard distances:

- Two representative weather conditions have been selected for performing the dispersion calculations under worst-case and typical conditions; Stability Class F with wind speed of 1.5 m/s, and Stability Class D with wind speed of 4 m/s, as described in Section 2.6. Calm conditions of less than 0.5 m/s wind occur approximately 3% of the time, when the hazard distances may be greater.
- Typical industry shutdown systems and safeguards have been assumed in the calculation of release quantity and duration.
- Dense phased CO_2 will flash to a mixture of gas and dry ice particles on release. Solid particles are assumed to be entrained with no rainout, and will sublimate on dilution with air.
- Process releases were modeled assuming typical operating temperatures and pressures.
- A release is assumed to be continuous for the purpose of quantifying the maximum hazard distance, except where instantaneous
- Rural conditions have been applied for atmospheric dispersion of vapor clouds.
- No allowance was made for topography in the dispersion calculations. However, the ground slopes to the SE, and large dense gas releases of CO_2 may tend to drift downhill.

This may increase the risk to offsite populations in the agricultural areas and on the highway.

The direction and momentum of a release may significantly affect the hazard distances. For release scenarios where this would make a significant difference, conservative assumptions were made to calculate the worst-case hazard distance. High-momentum releases will have greater amount of initial air dilution and mixing, whereas low momentum releases will have a higher initial concentration due to less air entrainment. Jet impingement may occur which reduces the release momentum, such as when a release is directed downwards, towards objects, or two ends of a pipeline rupture are directed towards each other. An impinged jet results in a loss of momentum, less initial dilution and greater hazard distances.

Calm weather conditions of less than 0.5 m/s wind occur about 3% of the time. Vapor dispersion models do not adequately predict hazard distances at very low wind speeds, and under these conditions, hazard distances may be greater.

The calculation of hazard distances for each scenario to selected levels of concern for the public are described below, and the results are shown for each scenario in Tables 5.5 to 5.9.

5.6.1 Carbon Capture and Compression Release Hazard Distances

The carbon capture facilities will handle large quantities of feed gas from produced gas and post-combustion flue gas. On release, the feed gas will quickly disperse to below hazardous concentrations. After CO_2 is removed from the feed gas using amine absorption, the CO_2 gas flow is near 100% concentration and potentially more hazardous on release. Gas flows overhead from the CO_2 stripper and through the compression train are modeled as 100% CO_2, at increasing pressure. The stripper pressure will be in the order of about 20 psig with line diameters of about 24-inches. The pressure is increased through 4 stages of compression and dehydration to 1,300 psig with line diameters of about 8-inches. After compression, dense phase liquid CO_2 flows to a buffer drum prior to being pumped to the CO_2 transfer pipeline. The vessel has been assumed to contain 15 minutes of buffer capacity, and on failure could result in the greatest hazard distances.

A major line or vessel failure will result in rapid release of the section contents and automatic shutdown. It has been assumed that the vessel and connecting line contents will be released within 1 minute. A medium sized hole or connection failure has been modeled as a continuous release with a fully developed vapor cloud. Worst-case release scenarios are assumed to occur when the release is impinged and the momentum dissipates quickly.

Hazard distances to CO_2 levels of concern are shown in Table 5.5 for vessel failure scenarios, major line failures, and representative hole releases for a range of pressures in the capture facility.

5.6.2 CO_2 Pipeline Release Hazard Distances

A large hole or line rupture of the CO_2 pipeline will result in the rapid release of the entire pipeline contents. It has been assumed that the loss of pressure will activate the automatic SCADA shutdown system, limiting the release quantity to the pipeline contents. The release

rate will decay rapidly as the contents of the pipeline are released. Within seconds the release rate will have dropped to a fraction of the initial peak value. The maximum cloud size develops in the first few minutes to form a dense cold cloud which initially spreads in all directions.

On release, rapid pipeline depressurization results in multiphase release. Experiments and theoretical calculations indicate that solid CO_2 contents of up to about 36% by mass may occur. On mixing with air, the entrained dry-ice will sublimate reducing the temperature of the cloud.

The maximum discharge rate will occur in the first few seconds of the release, and reduce to about one-tenth the initial flow rate within 5 minutes. The release rate has been averaged over the first 5 minutes, and modeled as an instantaneous release for estimating hazard distances. Approximately 30% of the pipeline contents will be rapidly released in the first 5 minutes, then the release rate will gradually reduce. The initial rapid release may occur from both ends of a guillotine rupture, and the quantity has been doubled to account for this.

The hazards to personnel will be in the immediate vicinity when a failure occurs, and in the path of the dispersing gas cloud. Depending on the weather conditions and wind direction, a large release may impact public populations in areas such as the solar farm and nut farms to the east of Highway 33. Personnel in vehicles may also be impacted if a cloud of sufficient concentration causes vehicle engines to cut out. Oil production workers in non-Aera owned facilities may also be at risk of exposure.

A medium sized failure equivalent to a 1 or 2-inch hole, will be sustained by CO_2 within the pipeline, and is assumed to be a continuous horizontal jet release. The reduction of pipeline pressure may initiate an alarm and shutdown. Aera personnel in close proximity to the pipeline may be exposed to a hazardous CO_2 concentration, although the hazard is unlikely to impact public areas. Greater hazards may occur when there is calm or very low wind conditions, and in areas where the topography may inhibit dispersion of the dense cloud.

Hazard distances to CO_2 levels of concern for pipeline release scenarios are shown in Table 5.6.

5.6.3 Injection Well Release Hazard Distances

Four potential hazard scenarios have been identified:

- Full wellhead failure, resulting in a vertical jet blowout.
- Wellhead failure equivalent in size to a horizontal 2-inch diameter hole.
- Wellhead equipment failure, equivalent to a horizontal 1-inch diameter hole
- Well casing failure and migration to surface.

Hazard distances to CO_2 levels of concern for these scenarios are shown in Table 5.7 and described below.

Full Wellhead Failure with Vertical Jet

A worst-case wellhead failure may result in the release of CO_2 from an open well bore. This has been assumed to be directed vertically. The depth and diameter of the well bore has been used to estimate the initial release volume, and the release rate calculated assuming an open ended decompressing pipeline. The initial release rate has been calculated as an average of 10,000

lb/hr (74 kg/s) during the first minute. The initial flow rate declines quickly as CO_2 is released, and flow from the well is constrained by multiphase flow. Pressure and CO_2 flow from the formation into the well bore may extend the flow duration, and an average flow rate of 4,000 lb/hr (30 kg/s) has been estimated for the first hour.

The release will rapidly expand and cool, resulting in cooling below the freezing point and formation of dry ice. The release will cause a hazard to personnel in the immediate vicinity of the wellhead. The dense vertical jet has been modelled used the SLAB model to estimate downwind CO_2 concentrations. The vertical plume will slump to ground over 100 feet from the wellhead during average wind speeds during the day, with ground level concentrations up to about 3% of CO_2. The maximum hazard occurs in low wind conditions because the carbon dioxide may slump to the ground and accumulated within 50 feet of the wellhead.

2-inch Diameter Horizontal Wellhead Release

A wellhead failure the equivalent size to a 2-inch hole has been selected to represent a large blowout, with a narrow horizontal jet to represent the worst-case threat to personnel in the vicinity. The volume of CO_2 within the wellbore has been used to estimate the potential sustained flow as 1,300 lb/min (10 kg/s).

1-inch Diameter Release from Injection Equipment

A failure of wellhead injection equipment, connection or line, equivalent to a 1-inch hole has been selected to represent a medium sized blowout. A horizontal jet direction represents the worst-case threat to personnel.

Well casing failure and migration to surface

A well bore leak and migration to the surface is likely to be a low velocity diluted release, which may result in an accumulation of CO_2 in the immediate vicinity of the wellhead in calm wind conditions. Underground CO_2 migration from a well bore leak may also find a pathway to the surface via a monitoring or abandoned well bore. This scenario will result in a slow dissipated release and therefore has not been included in the analysis of acute hazards to personnel. However, if undetected, it may cause some local ground level hazards.

5.6.4 Leakage of CO_2 From Sequestration Reservoir

A release of CO_2 may occur due to leakage from the storage reservoir to the surface. This may be caused by leakage via wellbores, fault or fractures, caprock failure, or seismicity.

The rate of wellbore leakage has been simulated by Letellier et al[32]. They concluded that the rate of leakage from a single wellbore with high permeability due to poor quality construction may result in a CO_2 leakage rate of up to 210 lb/min (1.6 kg/s) at the caprock, assuming the plume has reached the wellbore. As the flow progresses through the wellbore, this is likely to be diverted by sinks above the caprock, resulting in a release in the range of 0.1 to 30 lb/min (0.001 to 0.23 kg/s). This release rate is highly unlikely to result in concentrations of concern to the public.

Letellier et al[32] also simulated leakage through a fault and concluded that the median rate for a highly permeable fault is in the range of 13 lb/min (0.1 kg/s). This is in the same order of magnitude as natural volcanic leaks measured in Latera, Italy, which have caused very little impact on the population or ecosystem.

CO_2 leakage from sequestration is likely to result in a slow dissipated release, which is unlikely to be acutely hazardous except if undetected vapors accumulate in low lying areas.

5.6.5 CO_2 BLEVE Hazard Distances

A catastrophic vessel failure may result in the almost instantaneous release of the entire contents. Rupture of a vessel containing pressurized, liquefied CO_2 may be regarded as a BLEVE, causing explosive overpressure with vessel fragments thrown as projectiles. Incidents have occurred due to accidental over-pressurization and / or vessel embrittlement.

Hazard distances for the dispersion of toxic CO_2 concentrations are greater than the localized overpressure hazard, although the overpressure will impact all directions, and personnel within buildings may be more vulnerable than those outside. There is also the possibility of a few large vessel fragments being projected significant distances, but the hazard to nearby populations is primarily due to toxic vapor dispersion.

Explosive release may occur due to the failure of a CO_2 storage tank, CO_2 buffer tank at one of the CO_2 Compression facilities, or a CO_2 cargo truck. The calculated explosion hazard distances to overpressure levels of concern are shown in Table 5.8.

5.6.6 Amine Transportation and Storage Hazards

Potential amine releases have not been modeled to estimate impact areas. The likelihood that an ethanol amine release will occur during transportation has been calculated from generic failure rate data, as described in Section 4.4. The probability that a release will result in injury to public personnel has been estimated as 1 in 100 incidents, based on historical incident reports.

5.6.7 Sulfuric Acid Transportation and Storage Hazards

Potential sulfuric acid releases have not been modeled to estimate impact areas. The likelihood that a sulfuric acid release will occur during transportation has been calculated from generic failure rate data, as described in Section 4.5. The probability that a release will result in injury to public personnel has been estimated as 1 in 20 incidents, based on historical incident reports.

5.6.8 Produced Gas Transfer Pipeline

The produced natural gas transfer line from Del Sur Compressor Station to SOX 32, is projected to contain about 65% CO_2 and 2,500 ppm H_2S. The high concentration of CO_2 makes the gas inflammable, although in the event of a large release, personnel in the vicinity may potentially be exposed to a toxic level of H_2S or CO_2. The 16-inch aboveground line will operate at about 170 psig, and contain a significant inventory of gas.

A potential failure of the produced gas transfer line has been modeled for potential toxic exposure to both H_2S and CO_2. Gas dispersion hazard distances to the levels of concern are shown in Tables 5.5 and 5.9 for a pipeline rupture and 2-inch failure. Hazard distances to levels of concern for H_2S are greater than those of CO_2 except in close proximity to a failure. Produced gas is diluted almost immediately on release to below 700 ppm H_2S, then becomes a more significant hazard than CO_2 when diluted to less than about 100 ppm, the IDLH value. The greater toxic hazard has been selected for calculations of potential impact.

Table 5.2 Toxicological Effects of Carbon Dioxide

CO_2 Concentration in Air	Potential Health Effects 2010 Energy Institute CCS Guidance[16] and USEPA 2000[50]
1 %	Slight increase in breathing rate, possible drowsiness. Possible adverse effects on susceptible groups.
2 %	Breathing rate increases to 50 % above normal level. Prolonged exposure can cause headache, tiredness.
3 %	Breathing increases to twice normal rate and becomes labored. Weak narcotic effect. Impaired hearing, headache, increase in blood pressure and pulse rate.
4 %	IDLH – Maximum concentration from which one could escape without experiencing escape impairing or irreversible health effects within 30 minutes.
4-5 %	Breathing increases to approximately four times normal rate; symptoms of intoxication become evident and slight choking may be felt.
7 %	Minimum concentration that may be immediately life threatening, as proposed by the US EPA[50].
5-10%	Characteristic sharp odor noticeable. Very labored breathing, headache, visual impairment, and ringing in the ears. Judgment may be impaired, followed within minutes by loss of consciousness.
10-15 %	Within a few minutes exposure, dizziness, drowsiness, severe muscle twitching, unconsciousness. Possible fatality.
17-30%	Within one minute, loss of controlled and purposeful activity, unconsciousness, convulsions, coma, death.

IDLH levels are published by the National Institute for Occupational Safety and Health (NIOSH)

Table 5.3 Explosion Overpressure Hazards

Overpressure (psi)	Description of Human Impact	Description of Equipment Impact
0.5	Possible minor injury from broken glass or falling fixtures	Windows may be broken
1	Skin laceration from flying glass and other debris may require medical attention. Creates equivalent wind gust of 40 mph.	Internal damage to buildings. Glass breaks with force
3	May be blown off feet. Possible eardrum rupture. Serious injury inside buildings due to building damage.	Steel frame buildings may be distorted, partial collapse of walls Failure of storage tanks.
6	Eardrum rupture. Injury due to flying debris outdoors, or from being blown off feet Potential fatality within buildings.	Heavy damage to unreinforced buildings. Potential release from small process connections.
10	Threshold for lung hemorrhage. Potential fatality outdoors due to impact. Multiple fatalities within buildings.	Significant process equipment damage causing knock-on releases. Buildings totally destroyed

Table 5.4 Acute Exposure Criteria and Toxicological Effects of Hydrogen Sulfide

H_2S Concentration (ppm)	Potential Effects
0.02 to 0.1	Threshold of smell
0.1 to 30	Increasingly unpleasant rotten eggs odor. Eye and throat irritation.
15	*ACGIH Short-Term Exposure Limit (STEL) for 15 minutes exposure.
30	**ERPG-2 Maximum concentration below which it is believed that nearly all individuals could be exposed for up to one hour without irreversible health effects or impairment of the ability to escape.
100	**ERPG-3 Maximum concentration below which it is believed that nearly all individuals could be exposed for up to one hour without life threatening health effects. ***Immediately Dangerous to Life or Health (IDLH). Maximum concentration from which one could escape without experiencing escape impairing or irreversible health effects.
100 to 300	Loss of sense of smell. Throat and eye irritation within 2 to 15 minutes. Headache, nausea, blurred vision in 30 minutes. Difficulty breathing. Potential loss consciousness after 1 hour.
300 to 700	Difficulty breathing within 1 to 4 minutes. Collapse, unconsciousness within 15 minutes. May be fatal over about 30 minutes exposure.
700 to 1,000	Coughing, collapse and unconsciousness. May be fatal within several minutes.
1,000 to 2,000	Unconsciousness within 2 minutes, respiratory failure and death if not revived promptly.
2,000 +	Unconsciousness almost immediately. Respiratory failure and death within 5 minutes.

* American Conference of Governmental Industrial Hygienists (ACGIH)

** ERPG levels are Emergency Response Planning Guidelines, developed by the American Industrial Hygiene Association (AIHA). These were specifically developed for emergency response planning, and have been adopted by the US Environmental Protection Agency (EPA) to identify levels of concern for hazardous chemicals.

*** IDLH levels are published by the National Institute for Occupational Safety and Health (NIOSH). The IDLH is considered a maximum concentration above which only a highly reliable breathing apparatus is permitted.

Table 5.5 Carbon Capture Facility - CO_2 Dispersion Distances

6. CALCULATION OF RISK

The risks of a hazardous release to the public have been calculated by combining the likelihood of a release, as discussed in Section 4, the hazards of the event, as described in Section 5, and the number of personnel potentially exposed, as described in Sections 2 and 3. Total risks to the public have been summated to calculate the likelihood of exposure to a level of concern. Hazardous release event trees have been used to calculate the likelihood of public harm as described in Section 6.1 below.

The likelihoods of public exposure to harm have then been combined in three different ways; the risk to an individual, to groups of individuals, and to the surrounding public as a whole. However, how do we evaluate whether these risks are low and acceptable? Methodologies have been developed and applied by governments and organizations around the world to evaluate the tolerability of risk. These are described in Sections 6.2 and 6.3 below.

6.1 Hazardous Release Event Trees

A hazardous release may have several different outcomes, and event tree analysis has been used to calculate the likelihood of each potential outcome. The potential for harm will depend on the release location, duration of the release, wind direction and weather conditions at the time of the incident. These have been analyzed by identifying potential release events that may impact the public, calculating the likelihood that a release will cause harm, and summating the likelihoods for each scenario. An example incident event tree for a CO_2 pipeline failure is shown in Figure 6.1.

Pipeline risk has been calculated by dividing the pipeline route into segments with similar public population densities at risk, depending on the wind direction and time of day. The location and number of public populations have been described in Section 2.3. For each event tree outcome, the number of personnel exposed has been calculated using the hazard distances and impact areas to the levels of concern described in Section 5. The likelihood that a hazard will occur, and the population densities within impact areas to CO_2 levels of concern, have been summed for each scenario and pipeline segment to calculate the risk.

Pipeline risk to specific populations, such as workers at the solar farm and the Highway 33 residential property, have been calculated by estimating the length of pipeline from which a release may impact the area or building. The likelihood of wind blowing towards the population, the likelihood of public personnel being present, and the areas where different CO_2 concentrations may occur, have been combined to calculate the risk to each population group.

To avoid double counting casualties within a range of exposure concentrations, the probability of harm for the greater severity level has been subtracted from the lesser severity levels before being summed.

6.2 Methodologies for the Assessment of Risk

There are numerous types of risk in our lives. Risk is the likelihood of experiencing harm, which may be to us, to those around us, to our property, or to our surroundings. QRA has been used in this study to calculate the potential acute hazards to the public due to a hazardous material release and quantify the likelihood of this occurring. Risk is a measure of:

- The *likelihood* of a hazardous material release; and,
- The *consequence*, in terms of public safety, of a hazardous material release.

The likelihood of a hazardous release is derived from historical data on how often accidents and releases occur. The probability that a release will result in public harm is calculated from historical incident reports, calculation of potential worst-case release quantities, modeling of how large an area may be impacted, and how likely public personnel will be in the area of impact.

The risks have been calculated in terms of three potential levels of harm:

- Could experience discomfort or minor injury. The effects are transient and reversible upon cessation of exposure.
- Could experience irreversible or other serious health effects that may require hospitalization.
- Could experience life threatening health effects or fatality.

To assess risks to the public from a proposed hazardous development, various governments and organizations around the world have used the calculation of individual risk and societal risk. Many international corporations have adopted these assessment techniques to evaluate proposed projects, identify causes of risk, select risk mitigation options, and assess the risk tolerability.

Individual and societal risk are calculated and presented in different ways, depending on the type of hazard source and jurisdiction. Risks associated with a fixed facility are often assessed differently to a transportation route, which may impact a large number of individuals along the route. A transportation route may also impact a wide range of route distances, from a short pipeline route of say 1 mile, to a long interstate pipeline of several hundred miles. Risk criteria need to be able to consistently compare different sized projects.

In addition to the calculation of individual and societal risk, a combined total individual risk has also been considered for this project, although there are no established criteria to evaluate if the risks are low or negligible compared to other tolerable risks. The three types of risks are described as follows:

Individual Risk

Individual risk represents the annual risk to a person at a specific location due to potential exposure to hazardous materials. The risk may be presented as plots of equal risk contours from a fixed facility on a map, or as risk transects which represent risk as a function of distance

from a transportation risk source. Different jurisdictions also prescribe slightly different calculation methods, which may include the risk to an individual present at that location 24-hours per day with no protection from buildings, or an occupancy factor which includes the duration individuals are present and either outside or inside a building.

In this study, the individual risk has been calculated by estimating the likely duration that public personnel may be present. The risks of exposure to three levels of concern have been calculated in terms of the likelihood of exposure per year, and the highest individual risks have been identified.

Societal Risk

Societal risk represents the risk to a number of people from the same event. Societal risk is often presented in a graphical way using F-N curves, also called risk profiles. Societal risk F-N curves are shown below to illustrate established risk criteria. F-N curves are plots of cumulative frequency (F) of all events leading to the number (N) or more casualties. The left axis (y-axis) represents frequency (F) or likelihood of an event. For example, 1×10^{-4} per year (1.0E-04 in scientific notation) represents once in 10,000 years of occurring. The bottom axis (x-axis) represents the number of casualties (N) that may occur at the cumulative frequency. A logarithmic plot is normally used because the frequency and number of casualties range over several orders of magnitude.

Combined Individual Risk

The combined individual risk is the likelihood that any public individual may be exposed to a given level of hazardous material harm during one year. All risks associated with the Project are summed, including; the carbon capture facilities, pipeline transportation, and CO_2 injection wells.

6.3 Risk Criteria

The United States federal and California state governments have not adopted individual and societal risk thresholds to define the tolerability of hazardous material risks. This decision is left to local governments and organizations for specific projects. The purpose of establishing tolerability criteria levels is to provide a consistent basis to assess the risks of hazardous materials to the public. Individual and societal risk thresholds adopted by governments and organizations around the world are described below, to provide a basis to compare the risks associated with the CarbonFrontier CCS Project to generally accepted risk criteria.

6.3.1 Development of Risk Criteria

The first comprehensive process industry risk analyses were conducted in the United Kingdom (UK) and the Netherlands in the 1970's and 1980's. From these studies the first risk tolerability criteria were developed. The UK and the Netherlands have led the international effort to develop both individual and societal risk criteria. Other countries, regulatory authorities and companies have based their own use and development of risk criteria on the precedents established in these two countries.

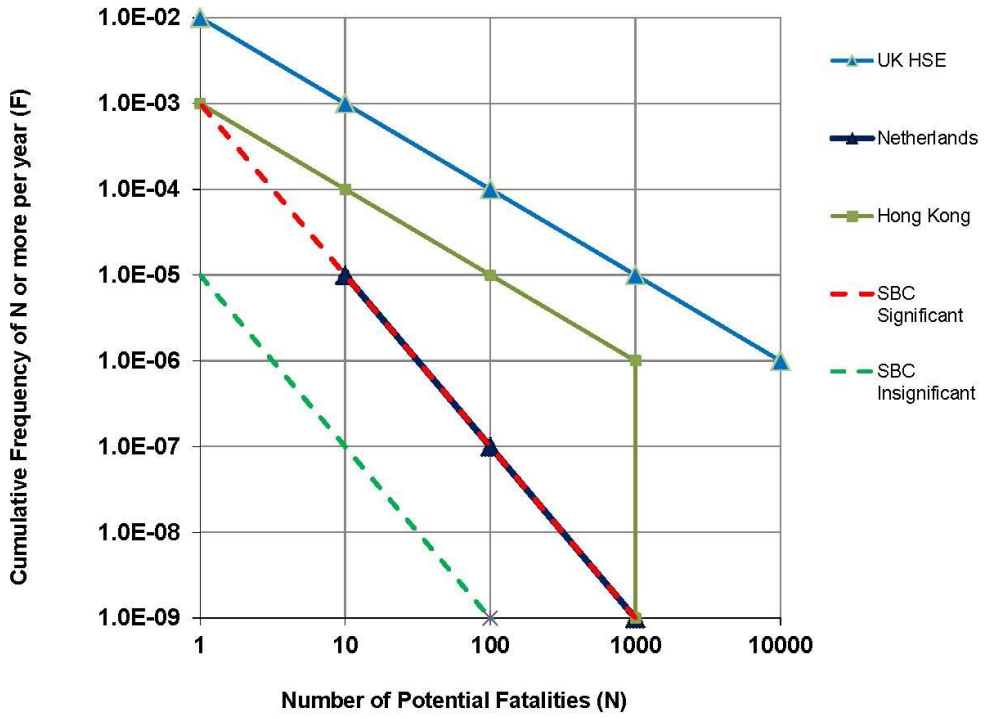
The development of risk criteria is described in the CCPS book, Guidelines for Developing Quantitative Safety Risk Criteria (2009)[9]. This book primarily focuses on the use of individual and societal risk criteria for fixed facilities.

Risk criteria have also been applied to transportation of hazardous materials to assess the tolerability of risk, and to compare the relative risk of transportation modes and routes. The criteria have less consensus internationally than those developed for fixed facilities, and to date, these have mainly been used for pipeline risk assessment, with some limited application for truck transportation routes.

Most risk criteria have been developed as risk of fatality. This is not due to a lack of concern for potential hazards that may cause injury. Data on fatalities are widely recorded and not open to interpretation. In any industrial activity, measures that reduce the risk of fatality will also reduce injuries in proportion. Studies have been performed on the ratios of serious injuries to minor or first aid injury as reported in Lees[31]. The ratios of fatality to serious injury to minor injury are in the order of 1 to 200 to 2,000.

6.3.2 Individual Risk Criteria

Individual risk is typically measured as the likelihood of fatality per year. International criteria have been based on risk levels that are deemed a tolerable increase in the risk of fatality. An increase of one in a million per year has been considered a very small addition to individual risk compared to other accepted risks. The following jurisdictions have established individual risk of fatality criteria for public populations:



Jurisdiction	Broadly Acceptable Public Risk of Fatality per year	
United Kingdom[9]	1×10^{-6} per year	1 in 1,000,000 years
Netherlands[9]	1×10^{-6} per year	1 in 1,000,000 years
Hong Kong[9]	1×10^{-5} per year	1 in 100,000 years
Santa Barbara County, CA[37]	1×10^{-6} per year	1 in 1,000,000 years
California Department of Education[6]	1×10^{-6} per year	1 in 1,000,000 years

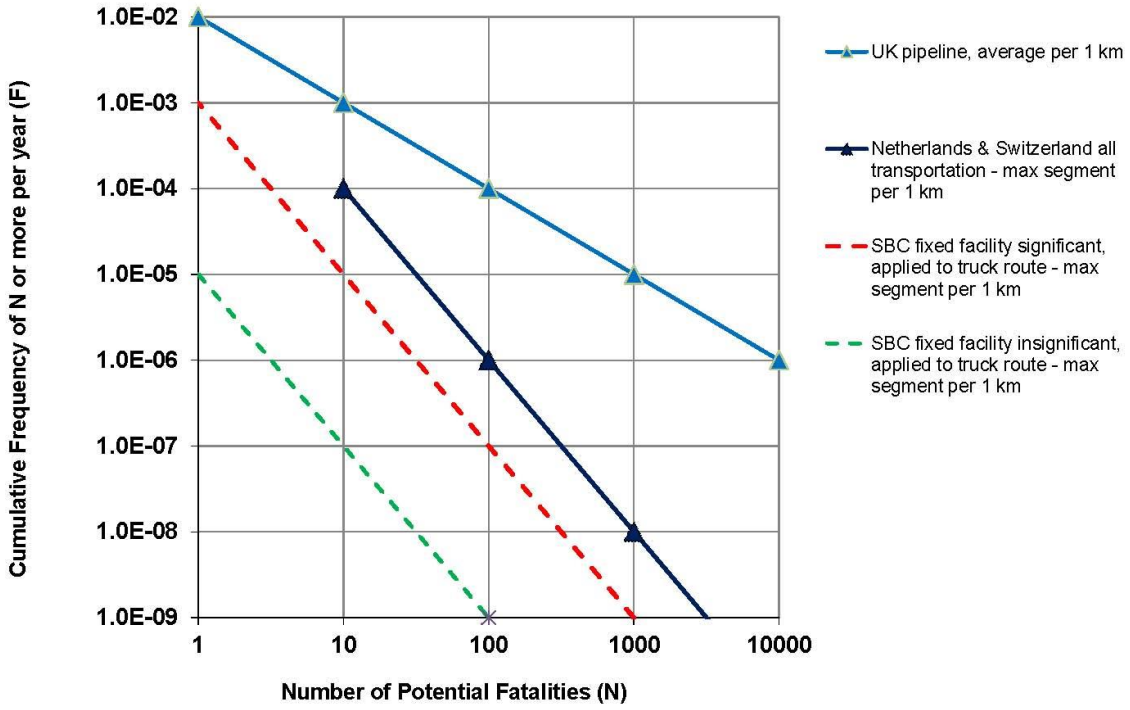
No individual risk criteria have been established for the risk of serious injury (potential hospitalization) or minor injury.

6.3.3 Societal Risk Criteria

Societal risk criteria have less consensus internationally than those developed for individual risk tolerability. The application of criteria also varies widely, making direct comparisons almost meaningless. For example, the UKHSE maximum level of tolerability is used as an initial guide from where reductions in risk must be implemented. However, the Santa Barbara County (SBC) insignificant risk criteria (the dashed green line on the graph below), is effectively used as the maximum societal risk criteria, above which public impacts must be reduced or avoided by implementation of mitigation measures.

A summary of fixed facility societal risk criteria is illustrated as follows:

Transportation societal risk criteria have been applied to assess the tolerability of risk, and to compare the relative risk of transportation modes and routes.



Three approaches have been adopted internationally,

- Summation of risk to a community on the transportation route.
- Average societal risk per unit distance on the transportation route.
- Calculation of the maximum risk per unit distance on the transportation route.

The Netherlands, UK and Swiss authorities have developed societal risk criteria for transportation routes by establishing a route length that is “equivalent” to the public risk of a single major industrial facility. The risk is calculated on a per-unit-length-of-pipeline, road or rail segment basis. The criteria differ in how the risk is calculated and what risk level is “equivalent” to a fixed facility, but use the same principle of establishing a route length for assessing the tolerability of transportation networks of different sizes.

The Netherlands selected transportation criteria on a 1-kilometer (0.62 mile) basis and set the levels as one order of magnitude (10 times) higher than for fixed facilities. This effectively equates the highest 100-meter (328 feet) transportation route risk to a fixed facility risk. The UKHSE has applied the same level of societal risk for a single fixed facility, to the average per 1-kilometer risk of a pipeline affecting a community. This equates an average 1-kilometer pipeline segment to a fixed facility.

A summary of transportation societal risk criteria is illustrated as follows:

Note: 1 km = 1 kilometer

The only societal risk criteria established for risk of injury is the SBC public injury profile. This has been defined for three regions, similarly to the risk of fatality, and is set at two orders of magnitude higher (100 times higher), than the respective fatality profiles. This effectively equates 100 serious injuries to 1 fatality for the risk tolerability ranges. This is consistent with the accident pyramid used in industrial accident prevention theory[31], where 1 fatality may occur for every 200 serious injuries.

Figure 6.1 Example Event Tree – CO_2 Pipeline Segment Failure

CO_2 Pipeline Failure Rate (per mile-yr)	Segment Length (miles)	Day / Night and Weather (Probability)	Wind Direction (Probability)	Potential Impacts (per year)
			½ NW, N, NE, E, ½ SE	Agricultural fields 25 workers per square mile Day Hwy-33 public impact
			0.42	1.3×10^{-5} /yr
		Day D/4		
		0.5	½ SE, S, SW, W, ½ NW	Medium density day oil production field activity 30 workers per square mile
			0.58	1.8×10^{-5} /yr
			½ NW, N, NE, E, ½ SE	Night Hwy-33 public impact
			0.42	4.2×10^{-6} /yr
Large / Guillotine Failure Rate	Segment ID C-6	Night D/4		
8.8×10^{-5} / mile-yr	0.706 miles	0.16	½ SE, S, SW, W, ½ NW	Medium density night oil production field activity 3 workers per square mile
			0.58	5.8×10^{-6} /yr
			½ NW, N, NE, E, ½ SE	Night Hwy-33 public impact
			0.42	8.9×10^{-6} /yr
		Night F/1.5		
		0.34	½ SE, S, SW, W, ½ NW	Medium density night oil production field activity 3 workers per square mile l
			0.58	1.3×10^{-5} /yr

7. RISK RESULTS AND MITIGATION

The risks have been quantified for each process system and for the CarbonFrontier CCS Project as a whole, to rank the various contributors of public risk due to acute hazard exposure. The risks have been calculated by estimating the likelihood and consequence of potential release scenarios.

The selection of release frequencies has been performed using conservative assumptions due to the high degree of uncertainty. There is limited experience in handling dense phase CO_2, so frequencies were developed using best available data from analogous industries. There is also uncertainty in the modeling of hazard distances and concentrations for large CO_2 releases. The calculated risks are therefore likely to be conservative.

7.1 Potential Risks to Public Populations

The following release scenarios may impact public areas at a hazardous material concentration of concern:

Produced Gas Transfer Pipeline

A release from the produced gas transfer pipeline may result in toxic hazards due to both CO_2 and H_2S dispersion. Hazards associated with CO_2 are greater than H_2S in close proximity to the pipeline. As the cloud disperses, concentrations of H_2S are more of a concern, and these have been applied for hazards on Highway 33.

No public areas would be impacted by a worst-case release at a level that could cause significant injury or fatality. A worst-case release may impact the public on Highway 33 and some areas to the east of Highway 33 at an H_2S concentration of 0.5 to 5 ppm. A worst-case event may cause some discomfort due to an unpleasant odor, which will be a brief exposure for personnel driving along the highway.

Carbon Capture and Compression

A large release of CO_2 at a carbon capture and compression facility may impact oil production areas adjacent to the facility. A release of liquefied CO_2 will have the greatest hazard distances of 1,200 feet to a 1% CO_2 concentration under low wind conditions at night. The carbon capture and compression facility at SG 2868 is approximately 1,500 feet from Highway 33, which is the closest capture facility to public populations. No potential public impact associated with carbon capture and compression facilities has been identified.

CO_2 Pipeline Transfer to Sequestration

The proposed CO_2 pipeline route runs parallel to Highway 33, about 2,000 to 3,000 feet distance from the road in the closest areas. In the event of a large release, the cold dense cloud will initially spread laterally, then disperse downwind. With a southwesterly wind (blowing towards the northeast), the cloud may drift over the highway and into agricultural areas to the east of the highway. The concentration at the highway may be in the range of 1% to 2% CO_2, with some areas up to 3% CO_2. The maximum extent of the cloud will reduce within the first 10 minutes as the initial high CO_2 release rate from the pipeline rapidly decays.

Wonderful Nut Farms operate a solar panel area to the west of Highway 33, in close proximity to the proposed pipeline. Public personnel working in the area may be exposed to a concentration of CO_2 greater than 4%, which may result in fatalities. If the wind is directed towards the solar panel area during the day, concentrations may exceed 7% up to 1,200 feet from the release, with a crosswind width of 1,400 feet.

Oil field production workers in areas operated by Berry Petroleum and Team Operating may be exposed to CO_2 in the event of a large pipeline failure. Berry Petroleum, in Section 19 of South Belridge, may be exposed to a level of concern between 1 and 3% CO_2 if a failure occurs in the vicinity and the wind is blowing from the east or north-east. Workers within the Team Operating area in North Belridge may be exposed to a concentration of 1% to 10% CO_2, if a distribution pipeline failure occurs in the vicinity and wind is directed towards the Team Operating area.

CO_2 Sequestration Injection Wells

A major well blowout during calm weather conditions may result in a hazardous CO_2 cloud drifting towards the oil field production area operated by Team Operating. A release at the two closest CO_2 injection wells during adverse weather conditions is highly unlikely to impact neighboring workers, and the risk has been estimated at 1 in 69 million years.

Leakage of CO_2 from Sequestration Reservoir

A leakage of CO_2 from the sequestration reservoir to the surface may occur via a wellbore or through the confining caprock. The leak rate is likely to be low and the release will dissipate quickly. No public personnel will be in the immediate vicinity of the sequestration field.

Amine Truck Transportation

The hazards associated with an ethanol amine release may occur in the immediate vicinity due to contact or inhalation of a liquid spray or mist. During truck transit on the highway, a vehicle collision or equipment failure may result in a release that has the potential to impact public or response personnel with the corrosive liquid. There is no public access to hazardous material unloading and storage areas, and therefore there is no potential for public exposure associated with these operations.

Sulfuric Acid Truck Transportation

The hazards associated with a sulfuric acid release may occur in the immediate vicinity due to contact or inhalation of a liquid spray or mist. Concentrated sulfuric acid is highly corrosive, and can cause severe chemical burns on contact with skin or eyes. During truck transit on the highway, a vehicle collision or equipment failure may result in a release that has the potential to impact public or response personnel. There is no public access to hazardous material unloading and storage areas, and therefore there is no potential for public exposure associated with these operations.

7.2 Aggregate Individual Risk Assessment

The overall hazards to the public from all proposed operations are shown in Table 7.1 for levels of concern, potential injury and potential fatality. These represent the risk of potential exposure, not that harm will occur. For example, the risk of significant injury is the concentration above which the general population, including susceptible individuals, could experience serious health effects or an impaired ability to escape. Most individual will experience breathlessness, with an increase in blood pressure and pulse rate, though without experiencing significant injury that may require hospitalization. The combined individual risks from all identified release sources are summarized as follows:

Release Source	Population Groups Exposed	Level of Concern	Potential for Significant Injury	Potential for Serious Harm or Fatality
		Likelihood	Likelihood	Likelihood
Produced Gas Transfer - Pipeline Rupture	Vehicles on Hwy-33	1 in 56,000 years	-	-
Carbon Capture and Compression	None	-	-	-
CO_2 Pipeline Transfer – Pipeline Rupture	Vehicles on Hwy-33 Agricultural workers Solar panel workers Berry and Team oil field workers	1 in 2,900 years	1 in 27,000 years	1 in 300,000 years
CO_2 Injection Wells	Team Operating oil field workers	1 in 69 million years	-	-
Leakage of CO_2 from Sequestration Reservoir	None	-	-	-
Amine Truck Transportation	50-mile road traffic from Bakersfield	1 in 92,000 years	-	-
Sulfuric Acid Truck Transportation	50-mile road traffic from Bakersfield	1 in 59,000 years	1 in 250,000 years	1 in 4.6 million years
Total Risk of Public Exposure		**1 in 2,700 years**	**1 in 24,000 years**	**1 in 190,000 years**

The primary source of risk is the CO_2 transfer pipeline from South Belridge carbon capture facilities to North Belridge geologic sequestration. This contributes to 88% of the aggregate risk of exposure to a level of concern for all public populations in the vicinity. A major CO_2 pipeline failure is the primary source that may impact public populations to a concentration that may cause significant injury or fatality.

The combined likelihood of public exposure to a concentration that may cause public concern is 1 in 2,700 years.

7.3 Individual Risk Assessment

Individual risk is typically measured as the likelihood of fatality per year. International criteria have been based on risk levels that are deemed a tolerable increase in the risk of fatality, as discussed in Section 6.3 above. An increase of one in a million per year has been considered a very small addition to individual risk compared to other accepted risks. In order to compare the highest individual risks for the current Project against established international risk criteria, the individual risk of fatality has been calculated.

Hazardous material exposures are not at the same level within the distance to a level of concern. As you get closer to the source of the release, the toxic concentration increases, until near the source there may be a potentially lethal concentration. Average vulnerabilities have therefore been estimated within the range for levels of concern.

The level of concern for serious injury or fatality has been selected for CO_2 as 4% concentration. However, a CO_2 concentration of 4% may not be life threatening for the majority of the population. The minimum CO_2 concentration that may be immediately life threatening has been proposed as 7% by the US EPA[(50)]. A vulnerability of 50% has been applied for public exposure to concentrations of CO_2 greater than 4%.

Individual risk of fatality is the measure that is most widely used to evaluate the tolerability of risk. The highest individual risks of fatality have been identified as follows:

Population Group	Individual Risk of Fatality		International Maximum Tolerable Risk
	Frequency	Likelihood	
Workers at the solar panels	3.9×10^{-7} per year	1 in 2,500,000 years	1 in 1,000,000 years
Team Operating oil field workers	5.6×10^{-7} per year	1 in 1,800,000 years	1 in 1,000,000 years

The highest individual risk of fatality is associated with oil field workers at the neighboring Team Operating facility in North Belridge. This risk is less than all internationally established tolerability criteria.

7.4 Societal Risk Assessment

Public societal risks have also been calculated for the highest risk pipeline segment for comparison to established societal criteria that have been deemed a tolerable. Societal risk represents the risk to a number of people from the same event, and is often presented graphically on a logarithmic plot. Societal risks have been calculated for potentially fatal events and serious injury events as described in Section 6.

The highest risks to the public have identified as being due to the potential exposure to CO_2 if a significant pipeline failure was to occur in North Belridge. Team Operating LLC operate a number of wells in North Belridge, which are within about 700 feet at the closest point of the proposed pipeline distribution line.

Societal risks for transportation routes are typically calculated on a route length basis for assessing the tolerability of transportation routes of different sizes and types. Societal risks for the highest risk pipeline segment have been calculated for the proposed Project, and plotted on graphs for comparison to established criteria. These have been calculated for both the risk of potential fatality and the risk of serious injury, as shown in Figures 7.2 and 7.3. The societal risks associated with the proposed CarbonFrontier CCS Project are less than all internationally established tolerability criteria.

7.5 Risk Management and Mitigation

Many risk mitigation measures have been incorporated into the provisional design of the CarbonFrontier CCS Project. The following measures have been applied in the calculation of risks:

General Equipment Design, Control and Monitoring

- The CO_2 pipeline, carbon capture and compression facilities, unloading, storage and injection equipment will be designed according to best industry practices, API RPs and Standards, DOT Part 195 design and construction, and National Association of Corrosion Engineers (NACE) Standards.
- Leak detection and monitoring systems will use electronic SCADA systems for pipeline flow and injection well control.
- Emergency shutdowns to be initiated automatically and manually.
- Monitoring of CO_2 pipeline composition for water content to ensure no free water.
- Appropriate design of blowdown vessels and vents to safely depressurize the CO_2 pipeline in an emergency, or for maintenance.
- Vehicle impact protection along the pipeline and at injection well sites.

Safety Management

CO_2 pipelines in the US are normally under federal operations guidelines (49 CFR 195). Requirements include training, inspections, safety integration, public education, damage prevention programs, communication, facility security and leak detection. It is uncertain if the intra-field pipeline will be regulated under DOT requirements, although the safety management will generally follow DOT guidelines if not specifically under DOT authority.

Aera Energy would operate the field under its well-established and proven management system that incorporates many processes, plans and programs to ensure public and worker health and safety, environmental protection, regulatory compliance, and community involvement. These programs include Spill Prevention, Incident Response, Site Safety, Site Security, Pollution Prevention, Species Protection, Environmental Compliance, Environmental Training, Safety Training, and Community Involvement.

CO_2 Injection Well Design and Maintenance

The technologies and practices associated with geological CO_2 sequestration are all in current commercial operation, and have been so for several decades. These are utilized in CO_2-EOR projects, acid gas disposal injection with CO_2 and underground natural gas storage facilities. Operators have achieved wellbore integrity at levels equivalent to those seen for conventional oil and gas wells.

A summary of CO_2-EOR injection well technology and operating practices was prepared by Meyer for the API[34]. Engineering advances made in the CO_2 injection well design include:

- Corrosion resistant materials such as stainless and alloy steels (316 SS, nickel, Monel, CRA, etc.) for piping and metal component trim,
- Swell resistant elastomer materials such as Buna-N and Nitrile rubbers for downhole packers, and Teflon (PTFE) and Nylon for seals,
- Acid resistant specialty cements and additives, and;
- Automatic control systems to regulate flow and provide real-time monitoring capable of initiating well shutdowns should an unsafe condition be detected.

Periodic Mechanical Integrity Testing (MIT) will be performed on injection wells according to regulations to ensure well integrity. This will include pressure-testing to ensure casing integrity, and testing for potential fluid migration behind the casing, tubing, or packer by use of radioactive, acoustic or thermal detection.

Injection and Reservoir Monitoring

Injection and monitoring wells will be equipped with downhole devices and equipment to evaluate the mechanical integrity of the wells and monitor growth of the CO_2 plume as it dissipates within the sequestration layer. Monitoring equipment will include continuous pressure, temperature and/or distributed acoustic sensors.

Surface Monitoring

Air, soil and vegetation sampling is proposed to identify any potential failures. Surface air monitoring will be conducted using continuous CO_2 monitors at the injection wellheads, and the use of mobile detectors at other infrastructure. Soil gas monitoring will also be conducted at the injection wellheads. Annual vegetation monitoring will be conducted using satellite imagery and field verification.

Emergency Response

An effective emergency response plan will reduce the risk to public and on-site personnel. Specific emergency response procedures will be developed for a CO_2 release, including;

- Emergency response procedures, and training in CO_2 hazards and behavior on release.
- Evacuation plans.
- Shelter in place planning.
- Public communications and emergency hazard warning plan.
- Operations personnel are trained in the Emergency Action Plans (EAPs) and Pre-Incident Planning and Emergency Response Guidelines (PIPERs).
- Annual review of EAPs and PIPERs, and quarterly table top drills.

Figure 7.1 Map of CO_2 Pipeline Rupture – Potential Daytime Hazard Distances

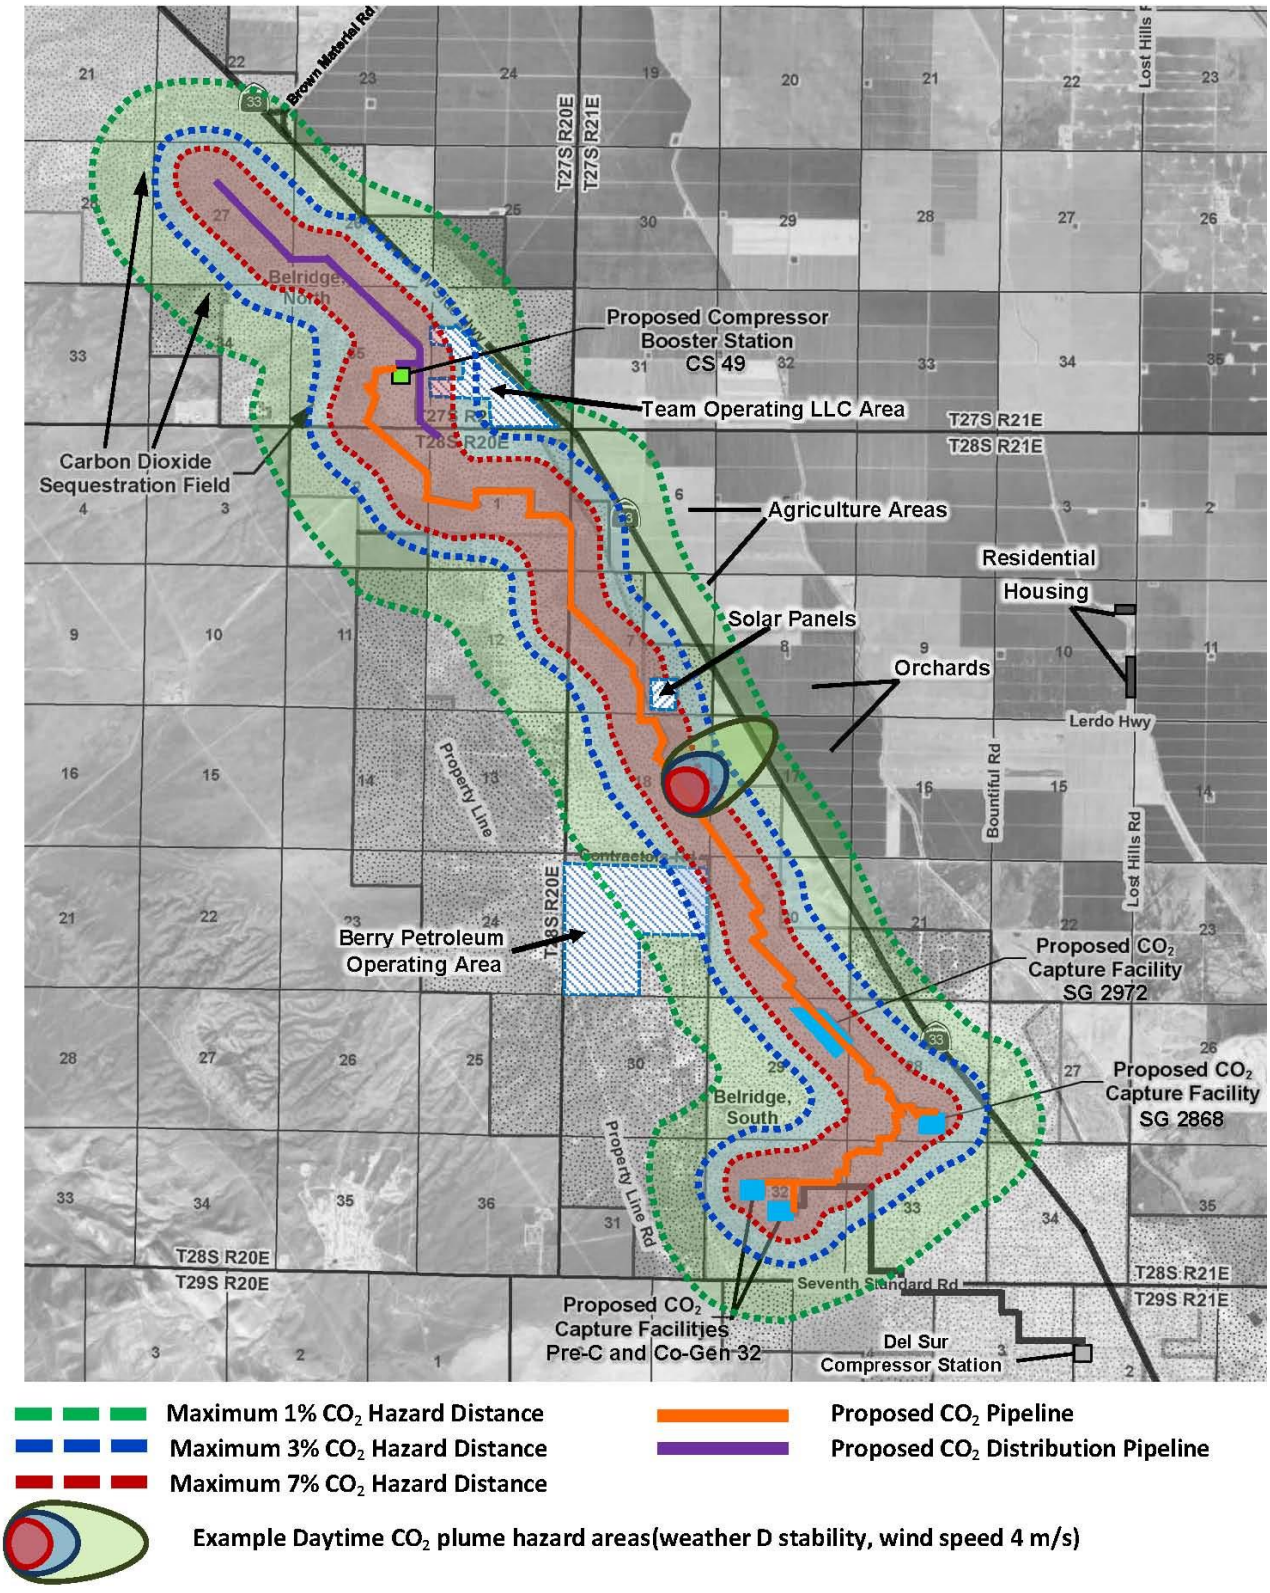


Table 7.1 Summary of Acute Public Exposure Risks by Release Source

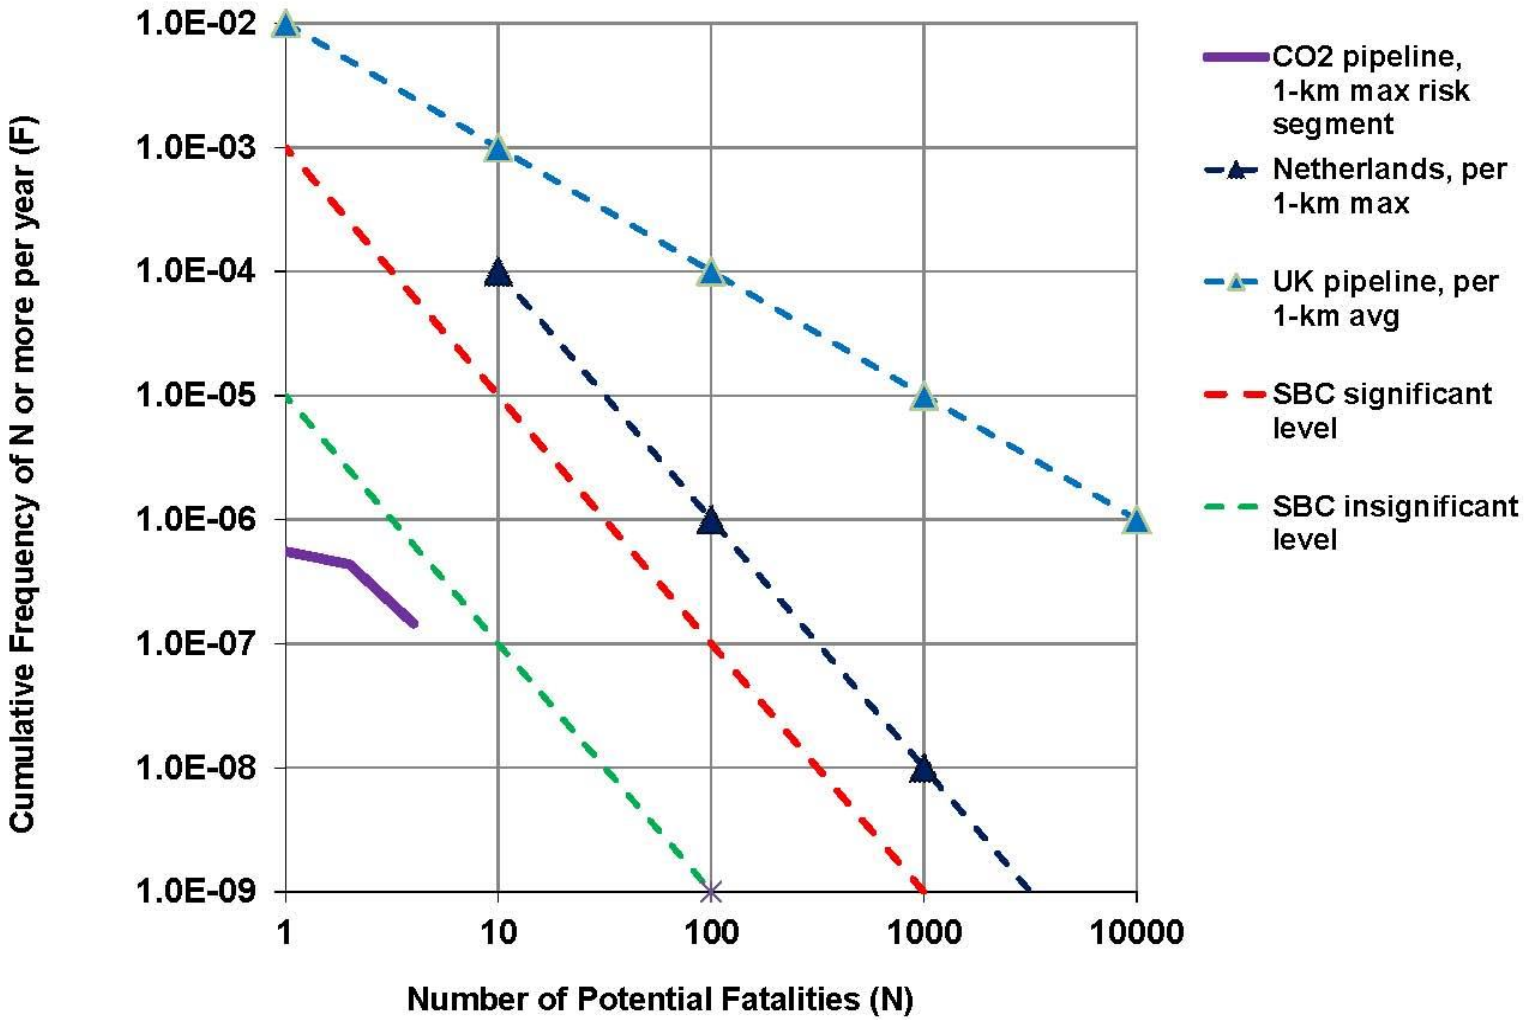
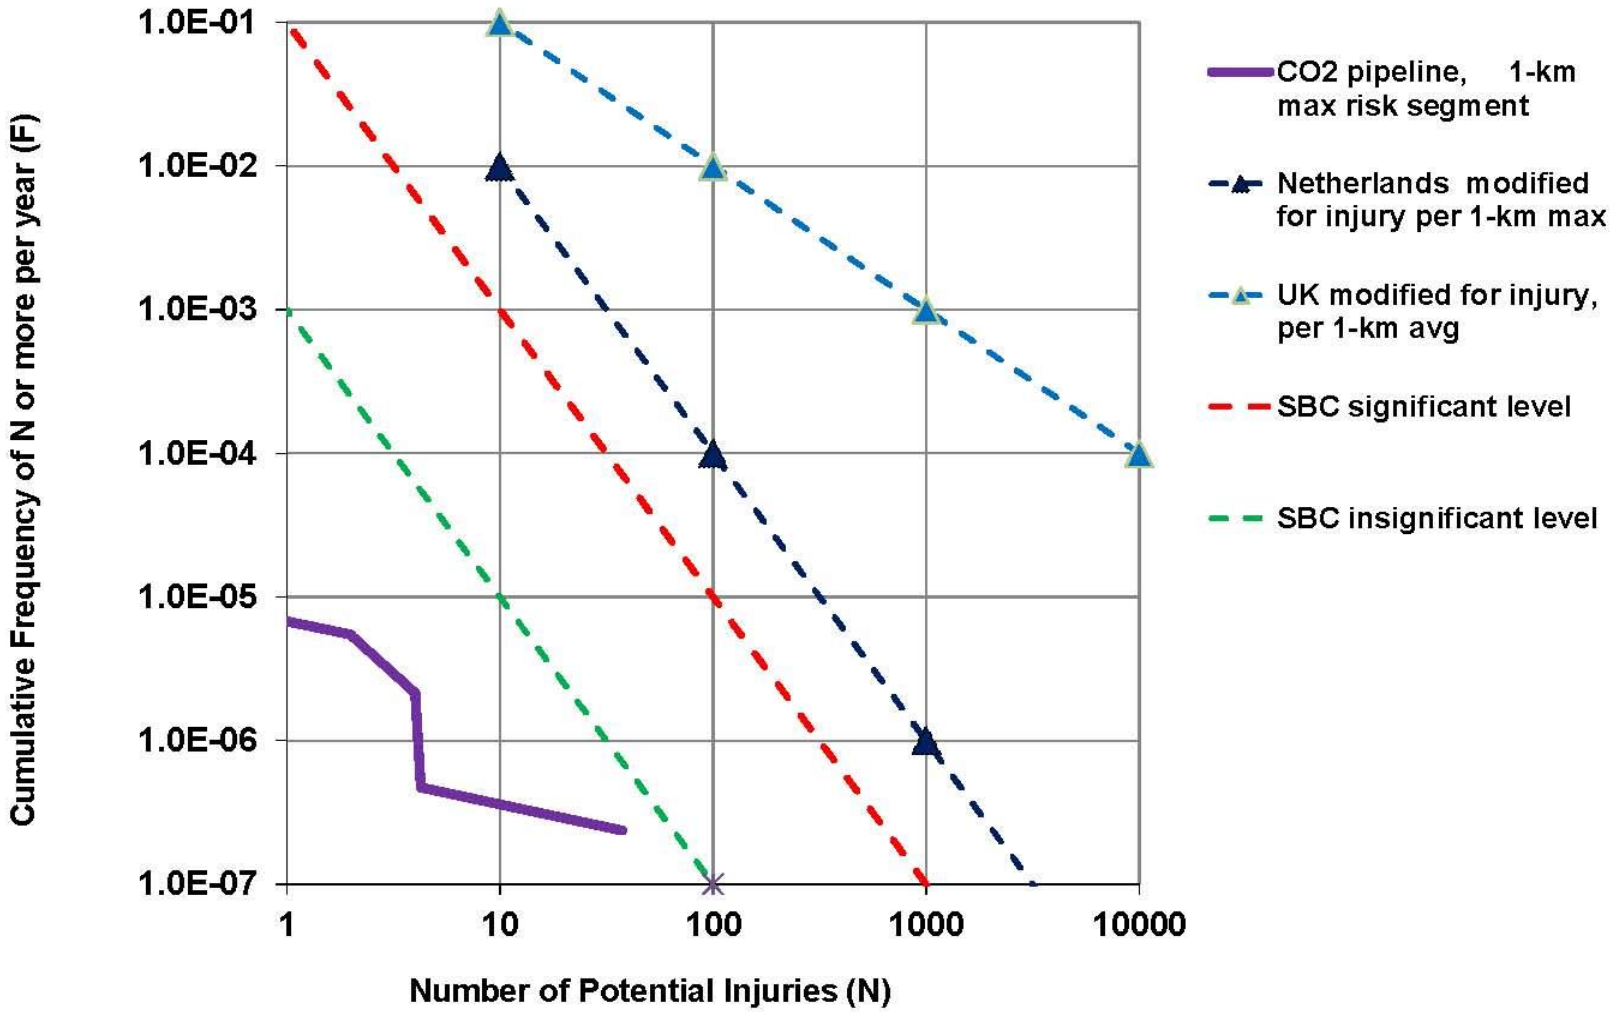


Release Source	Population Group Exposed	Level of Concern**		Potential Injury***		Potential Fatality****		Comments
		Frequency (per year)	Likelihood	Frequency (per year)	Likelihood	Frequency (per year)	Likelihood	
Produced Gas Transfer – 16-in Pipeline from Del Sur Compressor Station to SOX 32								
Pipeline Rupture - H_2S/CO_2 release	Day Hwy-33 traffic	8.9×10^{-6}	1 in 110,000 yrs	None	-	None	-	Exposure duration less than level of concern. Up to 150 persons may experience short H_2S exposure for 7 to 15 seconds at 0.5 to 5 ppm.
Pipeline Rupture - H_2S/CO_2 release	Night Hwy-33 traffic	8.9×10^{-6}	1 in 110,000 yrs	None	-	None	-	Exposure duration less than level of concern. Up to 17 persons, short H_2S exposure of 20 to 40 seconds at 0.5 to 5 ppm.
Carbon Capture and Compression Facilities								
CCS Facilities	None					None	-	
CO_2 Transfer – 12-in Pipeline from Section 32 Capture Facilities to North Belridge Sequestration								
Pipeline Rupture or large release	Day Hwy-33 traffic	5.4×10^{-5}	1 in 19,000 yrs	2.7×10^{-6}	1 in 370,000 yrs	None	-	Exposure duration less than level of concern. Up to 150 persons, may experience short CO_2 exposure for 30 seconds at 1 to 3% CO_2
Pipeline Rupture or large release	Night Hwy-33 traffic	5.4×10^{-5}	1 in 19,000 yrs	2.7×10^{-6}	1 in 370,000 yrs	None	-	Exposure duration less than level of concern. Up to 17 persons, may experience short CO_2 exposure for up to 1 minute at 1 to 3% CO_2
Pipeline Rupture or large release	Agricultural workers	1.1×10^{-4}	1 in 9,100 yrs	None	-	None	-	Likelihood of impacting an agricultural worker to an exposure of CO_2 between 1% and 2%.
Pipeline Rupture or large release	Workers at solar panels	6.6×10^{-6}	1 in 150,000 yrs	2.3×10^{-6}	1 in 430,000 yrs	1.6×10^{-6}	1 in 640,000 yrs	Likelihood of exposing workers at the solar panels to a CO_2 concentration of 1 to 10% that may cause concern, injury or fatality.

Table 7.1 Summary of Acute Public Exposure Risks by Release Source (continued)

Release Source	Population Group Exposed	Level of Concern**		Potential Injury***		Potential Fatality****		Comments
		Frequency (per year)	Likelihood	Frequency (per year)	Likelihood	Frequency (per year)	Likelihood	
CO_2 Transfer – 12-in Pipeline from Section 32 Capture Facilities to North Belridge Sequestration								
Pipeline rupture or medium sized release	Berry Petroleum oil field workers	3.7×10^{-5}	1 in 27,000 yrs	1.2×10^{-5}	1 in 82,000 yrs	None	-	Likelihood of exposing neighboring oil field workers to a CO_2 concentration of 1 to 3% that may cause concern or injury.
Pipeline rupture or medium sized release	Team Operating oil field workers	7.0×10^{-5}	1 in 14,000 yrs	1.7×10^{-5}	1 in 57,000 yrs	3.4×10^{-6}	1 in 300,000 yrs	Likelihood of exposing neighboring oil field workers to a CO_2 concentration of 1 to 10% that may cause concern or injury.
CO_2 Sequestration Injection Wells								
Injection well blowout	Team Operating oil field workers	1.5×10^{-8}	1 in 69 million yrs	None	-	None	-	Likelihood of exposing neighboring oil field workers to a CO_2 concentration of 1 to 2% that may cause concern.
Leakage of CO_2 from Sequestration Reservoir								
Wellbore or caprock leakage	None	None	-	-	-	-	-	No public hazard. Slow dissipated release.
Amine Truck Transportation and Storage								
Amine truck release	50-mile road traffic	1.1×10^{-5}	1 in 92,000 yrs	None	-	None	-	Likelihood of exposing the public or response personnel on the 50-mile highway route from Bakersfield.
Sulfuric Acid Truck Transportation and Storage								
Sulfuric acid truck release	50-mile road traffic	1.7×10^{-5}	1 in 59,000 yrs	4.3×10^{-6}	1 in 250,000 yrs	2.2×10^{-7}	1 in 4.6 million yrs	Likelihood of exposing the public or response personnel on the 50-mile highway route from Bakersfield.
All CarbonFrontier Project Operations								
Total	Aggregate Public Risk	3.8×10^{-4}	1 in 2,700 yrs	4.2×10^{-5}	1 in 24,000 yrs	5.1×10^{-6}	1 in 190,000 yrs	Aggregate likelihoods of exposing the public to a CO_2 concentration that may cause concern, injury or fatality.



** Level of public concern: CO_2 exposure = 1%, H_2S exposure= 0.5 ppm
*** Level of potential injury: CO_2 exposure = 3%, H_2S exposure= 30 ppm
**** Level of potential fatality: CO_2 exposure = 4%, H_2S exposure= 100 ppm

Figure 7.2 Societal Risk of CO_2 Potential Fatality Impacts –Pipeline Highest 1-Kilometer Segment

Note: The highest risk pipeline segment is in North Belridge, where Team Operating LLC operate oil production wells.
Values shown by dashed lines are established societal risk criteria as described in Section 6.
1-km = 1-kilometer (0.62 miles).

Figure 7.3 Societal Risk of CO_2 Potential Serious Injury Impacts –Pipeline Highest 1-Kilometer Segment

Note: The highest risk pipeline segment is in North Belridge, where Team Operating LLC operate oil production wells.
Values shown by dashed lines are established societal risk criteria as described in Section 6.
1-km = 1-kilometer (0.62 miles).

1.0 PROJECT INFORMATION

The proposed Aera CarbonFrontier Project (the "Project") is located within the Central Valley portion of unincorporated western Kern County, California. The Project will capture carbon dioxide in the South Belridge Oil Field and transport the carbon dioxide via pipeline to the North Belridge Oil Field for geologic sequestration. Together, the two Belridge oil fields cover an area that is approximately 13 miles long and three miles wide.

The purpose of this report is to provide a preliminary hydrology study of the proposed improvements. This includes a pre-development versus post-development peak runoff comparison and a scour analysis at major drainageway crossings. Stantec performed a hydrology study for the area of the proposed project features, referred to hereinafter as the "Study Area", and centered 35.501525°, 119.751895° (World Geodetic System of 1984 [WGS 84]). Refer to Figure 1.

1.1 SITE CHARACTERISTICS

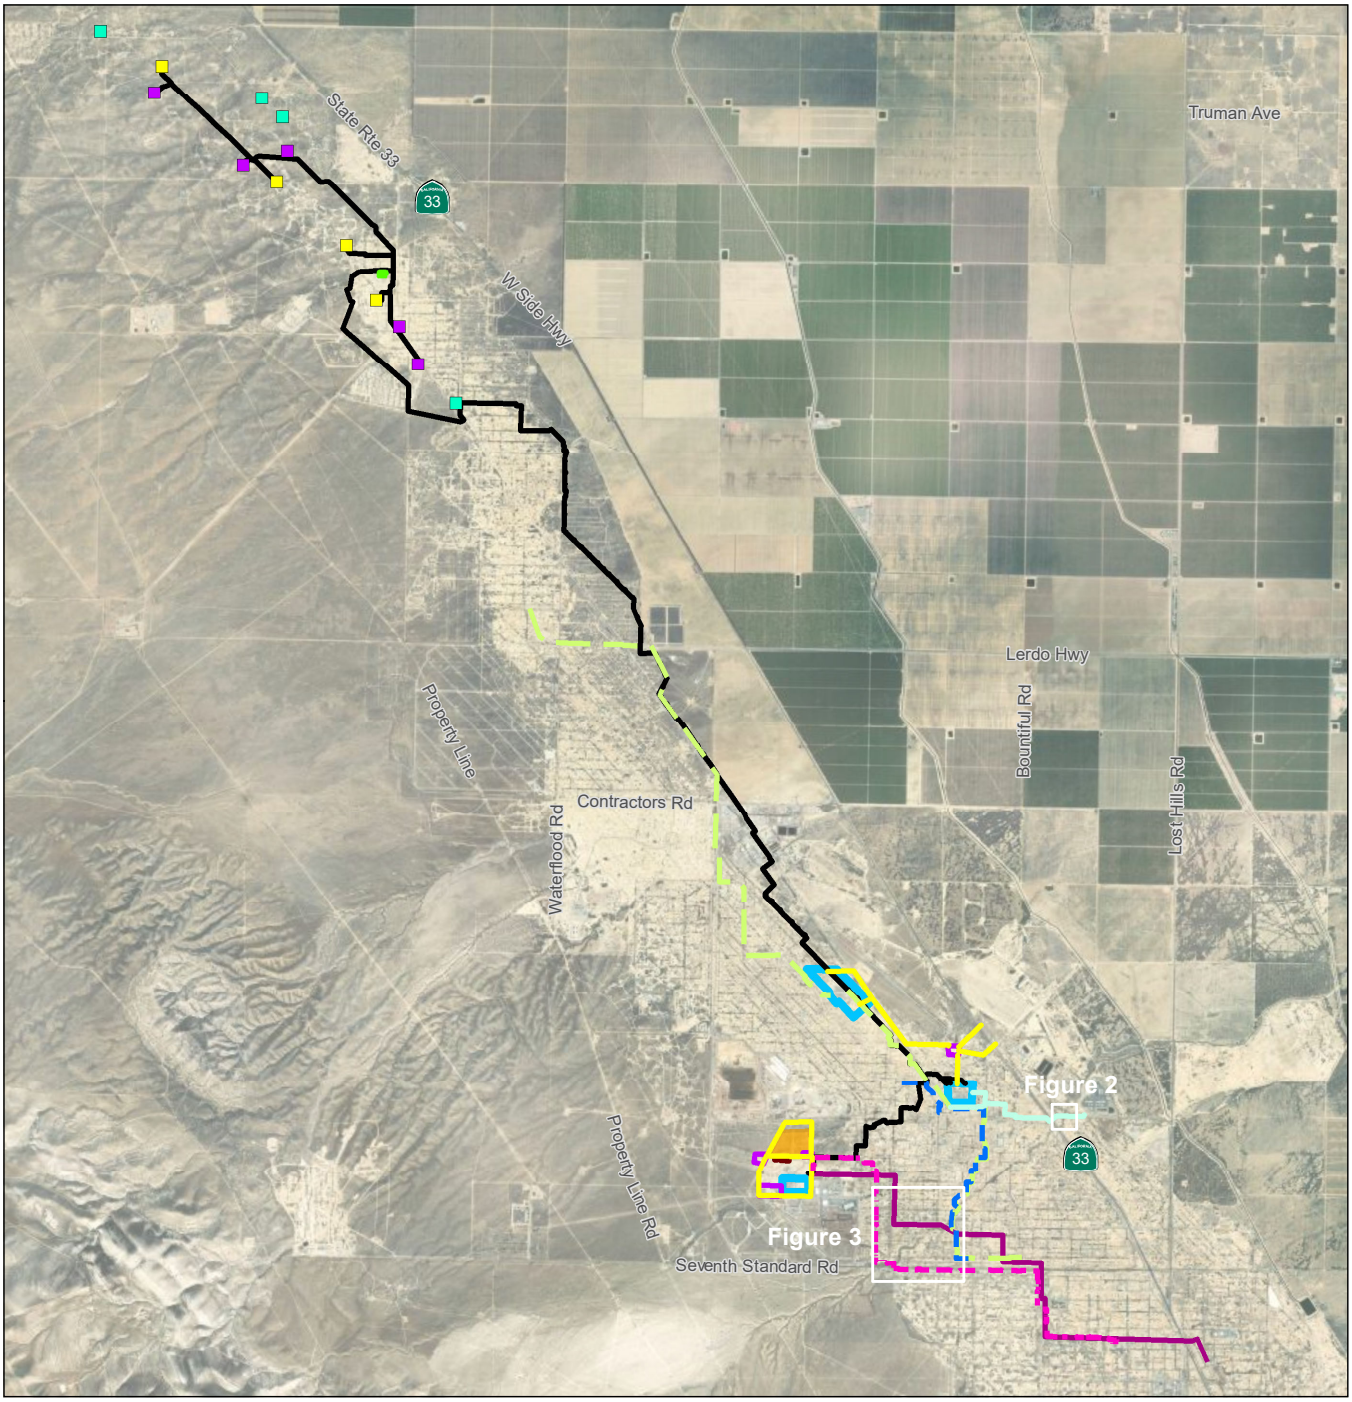
The Hydrologic Soil Group (HSG) was determined using the Natural Resources Conservation Service (NRCS) Web Soil Survey. Due to the extents of the Study Area, the HSG for the subbasins located in close proximity to the Project vary from HSG A to HSG C. The northern half of the Study Area consists primarily of HSG A with pockets of HSG B and HSG C. The southern half of the Study Area consists primarily of HSG A for the subbasins located in the hills west of the Project location and primarily of HSG C for the subbasins located in the valley. The extents of the tributary watersheds can be found in Appendix C.

1.2 PRE-DEVELOPMENT

The site is currently an oil field with a large amount of open space and minimal impervious area. The impervious area consists primarily of roads, parking lots, and buildings. Runoff from the hills to the west of the Study Area drains to the Project Site and ultimately continues east past State Route (SR) 33 (West Side Highway).

The runoff from the hills to the west follows major drainageways down to the valley which then disperses into smaller drainageways before reaching the Project Site or being routed through the Study Area. Chico Martinez Creek is the only major creek that currently still runs across the southern end of the Study Area.

1.3 POST-DEVELOPMENT



1.3.1 Onsite Drainage

The proposed improvements would add a minimal amount of impervious area to the overall Project Site. The increase of impervious area would come from the addition of facilities associated with the transportation and sequestration of carbon dioxide.

There are currently no proposed improvements for the on-site drainage due to the minimal addition of impervious areas.

1.3.2 Offsite Drainage

The addition of the proposed facilities does not appear to have an impact on the drainage of off-site flows, as all new facilities will be located within the existing oil fields.

2.0 HYDROLOGY ANALYSIS

2.1 MODEL SETUP

The hydrology model was set up to only include the watersheds within the Study Area where an increase in impervious area is likely. The watersheds were delineated using United States Geological Survey (USGS) contour topography as more precise contour topography was not available.

Due to the large size of the watersheds within the Study Area, the modeling software GeoHECHMS was used to determine the peak flows. The GeoHECHMS software is a hydrology modeling software developed by CivilGEO that runs on the United States Army Corps of Engineers (USACE) HEC-HMS software. Modeling for this Project used HEC-HMS version 4.5.

The Soil Conservation Service (SCS) Curve Number infiltration (loss) method and the SCS Unit Hydrograph runoff (transform) method were used in GeoHECHMS for determining the stormwater runoff. The Kinematic Wave routing method was used for routing the stormwater.

Additionally, the following parameters were also used for model setup:

- Storm Type: Type I 24-hour
- Storm Duration: 24 hours
- Rainfall Depth (10-year, 24-hour storm):
  1.65 inches
- Rainfall Depth (100-year, 24-hour storm):
  2.99 inches

For this study, peak flow rates were determined for both the 10-year, 24-hour storm and the 100-year, 24-hour storm. Rainfall data was determined using the National Oceanic and Atmospheric Administration (NOAA) Atlas 14.

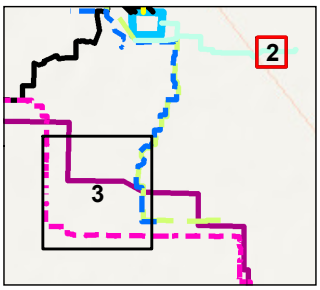
2.2 TIME OF CONCENTRATION

The time of concentration was determined in GeoHECHMS, using the SCS TR-55 method. The time of concentration for each subbasin can be found in the GeoHECHMS report in Appendix C.

3.0 SCOUR ANALYSIS

3.1 Model Setup

The possibility of scour occurring where the proposed pipelines crossed major drainageways was considered. Possible major drainageway crossings in the Study Area were selected using the USGS contour topography as well as aerial imagery of the Project Site. Given this and the peak flows calculated



during the hydrology analysis, it was determined that there are three major drainageway crossings with potential for significant scour located along the Chico Martinez Creek.

The crossing with potential for significant scour includes a proposed water line that will cross over the Chico Martinez Creek just north of Roustabout Rd. as well as two aboveground gas lines, one existing and one proposed, that will cross Chico Martinez Creek north of 7th Standard Road. Figures 2 and 3 show an aerial view of these major crossings.

A scour analysis was performed at these locations using two separate methods: the Blodgett method and the Pemberton and Lara method.

Soil profiles were created using information provided by the NRCS Web Soil Survey. The peak flow calculated for Chico Martinez Creek in the hydrology calculations was then inputted into a GeoHECRAS model to obtain the flow width at this location. GeoHECRAS is a software developed by CivilGEO that runs on the USACE HEC-RAS software. Modeling for this Project used HEC-RAS version 6.1. The soil profiles, peak flows, and flow widths were then used to obtain the scour depth per the general scour methods.

4.0 RESULTS

4.1 PEAK FLOW RUNOFF

Table 1 summarizes the pre-development versus post-development peak runoffs for the 10-year, 24-hour and 100-year, 24- hour storms in cubic feet per second (cfs). The detailed peak flow analysis can be found in Appendix C.

Table 1. Pre and Post Development Peak Runoff Flows

Junction	Pre 10-year Peak Runoff (cfs)	Post 10-year Peak Runoff (cfs)	Pre 100-year Peak Runoff (cfs)	Post 100-year Peak Runoff (cfs)
Junction-01	23.65	23.68	253.84	254.04
Junction-04	7.56	14.58	13.71	26.44
Junction-05	10.23	14.71	19.22	27.28
Junction-06	82.75	82.75	688.43	688.43
Junction-13	65.72	65.72	522.24	522.24

The junctions shown in Table 1 represent the discharge points for the watersheds tributary to the Study Area. Junction-06, specifically, represents the flow for Chico Martinez Creek, which crosses through the Project Site.

Table 1 shows that the proposed improvements within the watersheds for Junction-01, 06, and 13 will have negligible effects on peak flow runoff, due to the negligible amount of new impervious area within these watersheds.

The peak flow runoff for Junction-04 and Junction-05 increase significantly for the post-development conditions. This is because the watersheds tributary to these junctions are relatively small and that it was assumed that these two watersheds would be where most of the new impervious area would be added. Although the final site plans for the new facilities have not been developed at this time, their proposed locations are known. To be conservative with post-development peak flow runoff, it was assumed that the entire boundary of these locations would consist of an impervious surface. This, however, may not be the case once the site plans are developed. If the amount of new impervious area actually created within these watersheds is determined to affect on-site drainage characteristics , , a peak flow management will be used in these locations to help reduce the post-development peak flow runoff.

4.2 SCOUR

4.2.1 Scour Depth

Table 2 below summarizes the scour depths in feet (ft) found using the general scour methods. The table includes scour depth for both the 10-year, 24-hour storm and the 100-year, 24-hour storm. The detailed scour analysis can be found in Appendix D.

Table 2. Scour Depths Using General Scour Methods

Crossing	Storm Event	Blodgett Method Scour Depth (ft)	Pemberton and Lara (Lacey) Scour Depth (ft)	Pemberton and Lara (Blench) Scour Depth (ft)
Water Line	10-Year	11.9	2.1	1.9
Water Line	100-Year	11.9	4.3	3.3
Tulare CVR to Gas Plant 32	10-Year	10.8	1.8	2.9
Tulare CVR to Gas Plant 32	100-Year	10.8	3.7	1.6
Existing Del Sur Gas Line	10-Year	10.8	1.77	0.5
Existing Del Sur Gas Line	100-Year	10.8	3.7	1.6
Existing and Proposed Steam Line	10-Year	10.8	1.77	0.5
Existing and Proposed Steam Line	100-Year	10.8	3.7	1.6

Table 2 shows that the maximum scour depth for all four crossings occurs when the Blodgett general scour method is applied, which is significantly higher than the results obtained using the other methods. The Blodgett method does not consider peak flow or flow width when calculating scour depth. This method only uses the median size of bed material. The soils found in these locations are primarily loam/sandy loam types, which consist of small particles and have a potential for significant scouring.

Additionally, the USGS topography used lacks precision in these relatively flat areas and thus might result in wider flow widths, which in turn results in lower scouring depths when using the Pemberton and Lara methods. Because the Blodgett method only uses median size of bed material, it results in the same scour depth for both the 10-year and 100-year storms.

4.2.2 Chico Martinez Creek

In addition to determining the scour depth potential at the four crossings listed above, the flow width Chico Martinez Creek was determined for the two aboveground gas pipelines. Table 3 summarizes the results of the GeoHECRAS model.

Table 3. Flow Widths For Aboveground Gas Pipeline Crossings

Crossing	Storm Event	Flow Width (ft)
Tulare CVR to GP 32	10-Year	109
Tulare CVR to GP 32	100-Year	265
Existing Del Sur Gas Line	10-Year	181
Existing Del Sur Gas Line	100-Year	264

Table 3 shows the flow widths along Chico Martinez Creek for both the 10-year, 24-hour storm and the 100-year, 24-hour storm. The typical design storm in Kern County, is the 10-year storm. Stantec recommends additional geotechnical study within these areas to develop site-specific recommendations regarding proposed pipe support foundation design and embedment depth for areas within the 100-year storm scour area.

Due to the lack of precision in the topography, the flow widths may be larger than what would be expected to occur for the given storm events. It is recommended that higher precision topography be obtained at these crossing locations to better approximate the recommended setbacks from the creek.

5.0 CONCLUSION

This report has provided a preliminary hydrology study and scour analysis of the proposed Project Site.

The hydrologic analysis has revealed that a negligible amount of impervious area will be added throughout most of the Study Area. However, there are a couple of locations with relatively small watersheds that may require the use of peak flow management structures in order to mitigate the peak flow runoff for post- development conditions. This will depend on the final site plan of the proposed facilities and how much impervious area is added.

The scour analysis results show that the proposed waterline should be placed at a depth of 12 foot at the Chico Martinez Creek crossing. The analysis also shows that pipe supports for the two aboveground pipelines should be embedded 11 feet into the ground at their respective creek crossing. It is recommended that a site-specific geotechnical study be completed to provide pipe support foundation design and embedment information for proposed pipe supports. It is also recommended that the more precise topography be obtained for the crossing locations to better approximate scour and setback distances.

Custom Soil Resource Report for Kern County, California, Northwestern Part

January 12, 2023

Preface

Soil surveys contain information that affects land use planning in survey areas. They highlight soil limitations that affect various land uses and provide information about the properties of the soils in the survey areas. Soil surveys are designed for many different users, including farmers, ranchers, foresters, agronomists, urban planners, community officials, engineers, developers, builders, and home buyers. Also, conservationists, teachers, students, and specialists in recreation, waste disposal, and pollution control can use the surveys to help them understand, protect, or enhance the environment.

Various land use regulations of Federal, State, and local governments may impose special restrictions on land use or land treatment. Soil surveys identify soil properties that are used in making various land use or land treatment decisions. The information is intended to help the land users identify and reduce the effects of soil limitations on various land uses. The landowner or user is responsible for identifying and complying with existing laws and regulations.

Although soil survey information can be used for general farm, local, and wider area planning, onsite investigation is needed to supplement this information in some cases. Examples include soil quality assessments (http://www.nrcs.usda.gov/wps/portal/nrcs/main/soils/health/) and certain conservation and engineering applications. For more detailed information, contact your local USDA Service Center (https://offices.sc.egov.usda.gov/locator/app?agency=nrcs) or your NRCS State Soil Scientist (http://www.nrcs.usda.gov/wps/portal/nrcs/detail/soils/contactus/?cid=nrcs142p2_053951).

Great differences in soil properties can occur within short distances. Some soils are seasonally wet or subject to flooding. Some are too unstable to be used as a foundation for buildings or roads. Clayey or wet soils are poorly suited to use as septic tank absorption fields. A high water table makes a soil poorly suited to basements or underground installations.

The National Cooperative Soil Survey is a joint effort of the United States Department of Agriculture and other Federal agencies, State agencies including the Agricultural Experiment Stations, and local agencies. The Natural Resources Conservation Service (NRCS) has leadership for the Federal part of the National Cooperative Soil Survey.

Information about soils is updated periodically. Updated information is available through the NRCS Web Soil Survey, the site for official soil survey information.

The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, age, disability, and where applicable, sex, marital status, familial status, parental status, religion, sexual orientation, genetic information, political beliefs, reprisal, or because all or a part of an individual's income is derived from any public assistance program. (Not all prohibited bases apply to all programs.) Persons with disabilities who require

alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at (202) 720-2600 (voice and TDD). To file a complaint of discrimination, write to USDA, Director, Office of Civil Rights, 1400 Independence Avenue, S.W., Washington, D.C. 20250-9410 or call (800) 795-3272 (voice) or (202) 720-6382 (TDD). USDA is an equal opportunity provider and employer.

How Soil Surveys Are Made

Soil surveys are made to provide information about the soils and miscellaneous areas in a specific area. They include a description of the soils and miscellaneous areas and their location on the landscape and tables that show soil properties and limitations affecting various uses. Soil scientists observed the steepness, length, and shape of the slopes; the general pattern of drainage; the kinds of crops and native plants; and the kinds of bedrock. They observed and described many soil profiles. A soil profile is the sequence of natural layers, or horizons, in a soil. The profile extends from the surface down into the unconsolidated material in which the soil formed or from the surface down to bedrock. The unconsolidated material is devoid of roots and other living organisms and has not been changed by other biological activity.

Currently, soils are mapped according to the boundaries of major land resource areas (MLRAs). MLRAs are geographically associated land resource units that share common characteristics related to physiography, geology, climate, water resources, soils, biological resources, and land uses (USDA, 2006). Soil survey areas typically consist of parts of one or more MLRA.

The soils and miscellaneous areas in a survey area occur in an orderly pattern that is related to the geology, landforms, relief, climate, and natural vegetation of the area. Each kind of soil and miscellaneous area is associated with a particular kind of landform or with a segment of the landform. By observing the soils and miscellaneous areas in the survey area and relating their position to specific segments of the landform, a soil scientist develops a concept, or model, of how they were formed. Thus, during mapping, this model enables the soil scientist to predict with a considerable degree of accuracy the kind of soil or miscellaneous area at a specific location on the landscape.

Commonly, individual soils on the landscape merge into one another as their characteristics gradually change. To construct an accurate soil map, however, soil scientists must determine the boundaries between the soils. They can observe only a limited number of soil profiles. Nevertheless, these observations, supplemented by an understanding of the soil-vegetation-landscape relationship, are sufficient to verify predictions of the kinds of soil in an area and to determine the boundaries.

Soil scientists recorded the characteristics of the soil profiles that they studied. They noted soil color, texture, size and shape of soil aggregates, kind and amount of rock fragments, distribution of plant roots, reaction, and other features that enable them to identify soils. After describing the soils in the survey area and determining their properties, the soil scientists assigned the soils to taxonomic classes (units). Taxonomic classes are concepts. Each taxonomic class has a set of soil characteristics with precisely defined limits. The classes are used as a basis for comparison to classify soils systematically. Soil taxonomy, the system of taxonomic classification used in the United States, is based mainly on the kind and character of soil properties and the arrangement of horizons within the profile. After the soil

scientists classified and named the soils in the survey area, they compared the individual soils with similar soils in the same taxonomic class in other areas so that they could confirm data and assemble additional data based on experience and research.

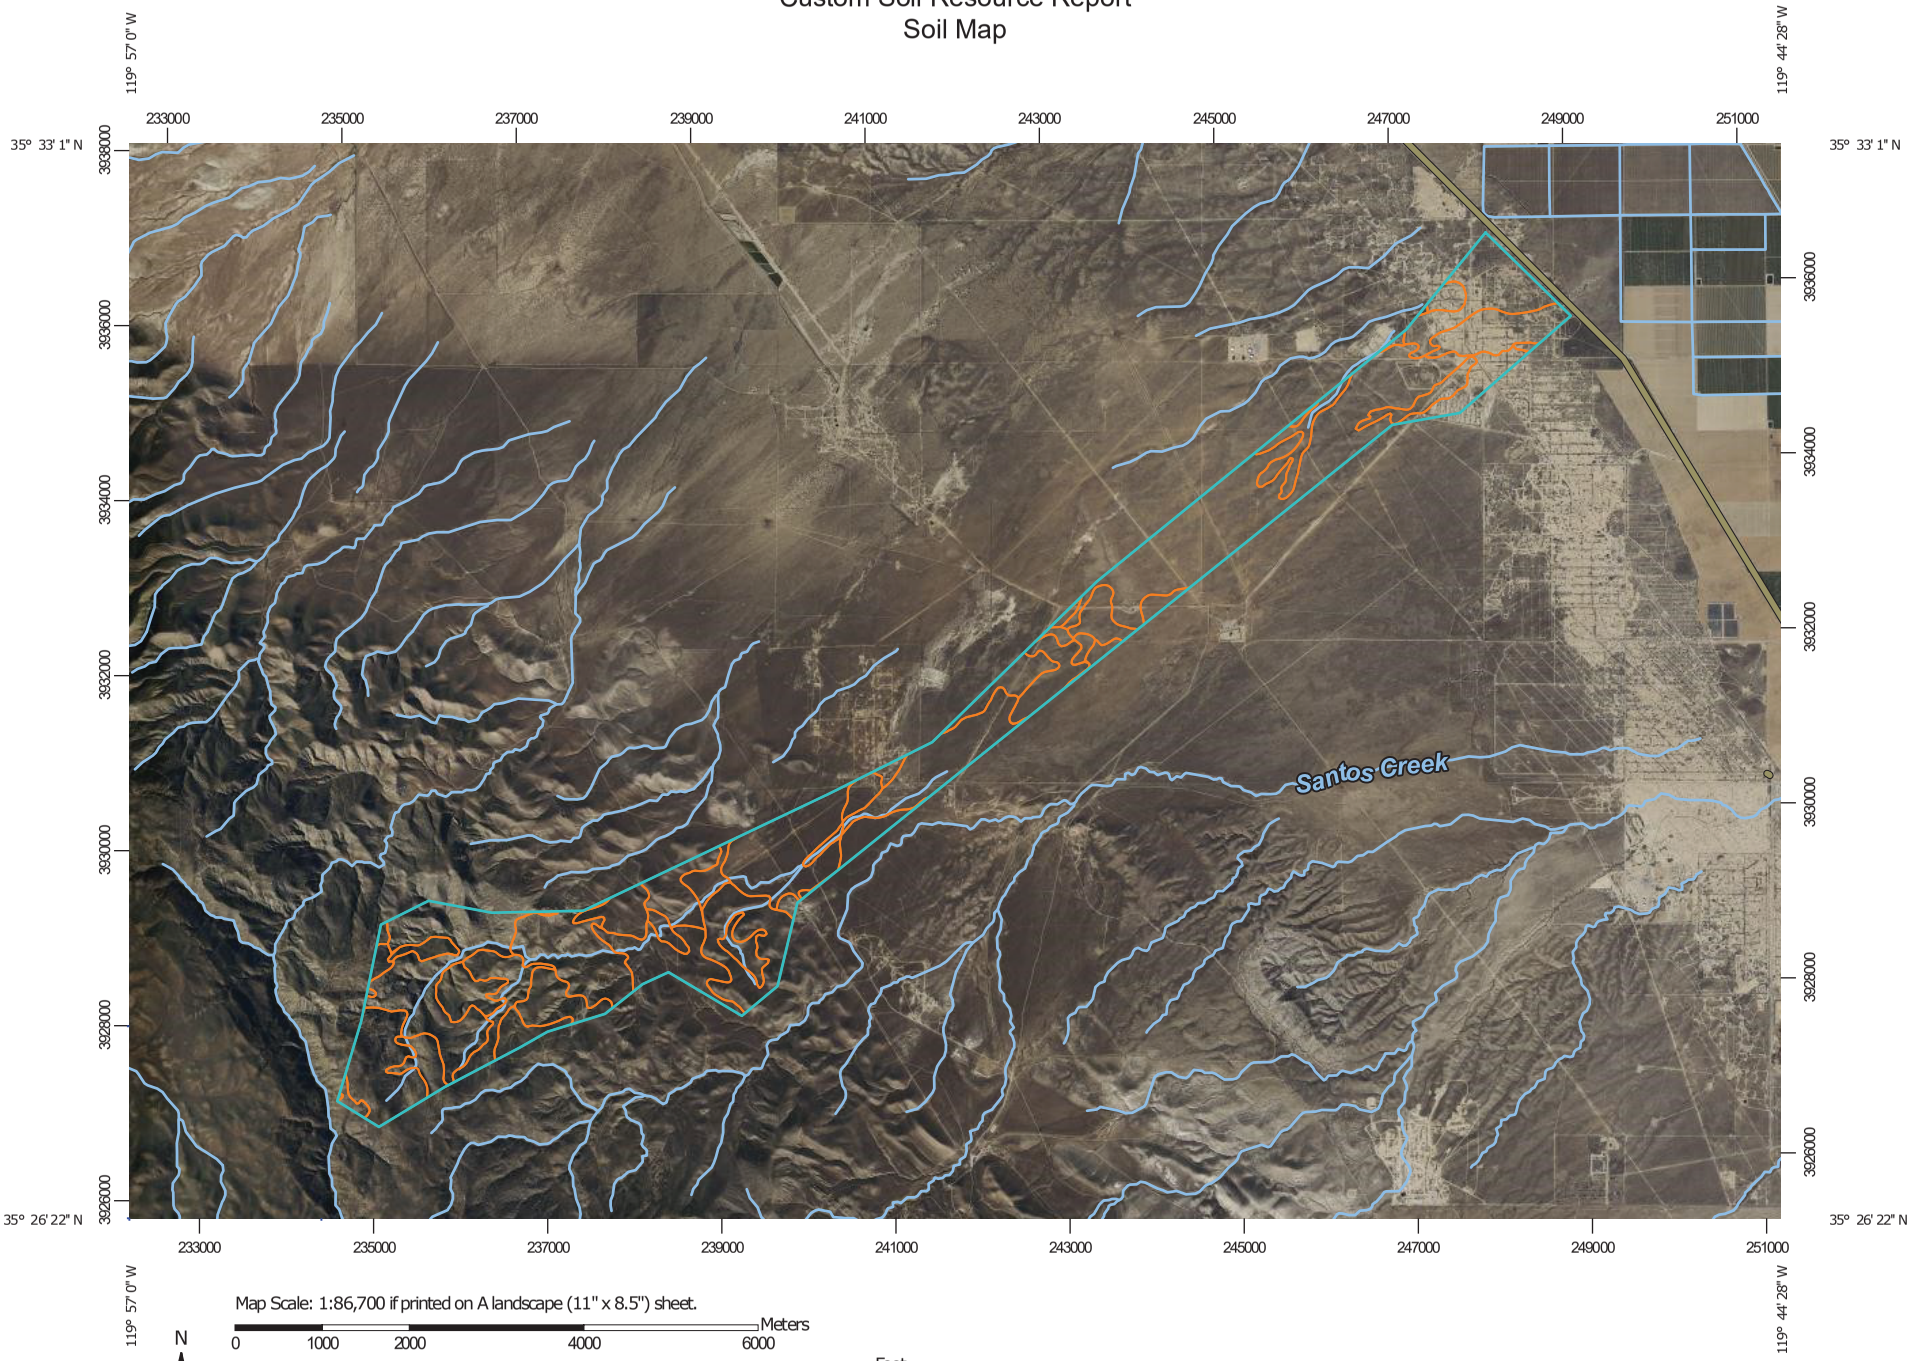
The objective of soil mapping is not to delineate pure map unit components; the objective is to separate the landscape into landforms or landform segments that have similar use and management requirements. Each map unit is defined by a unique combination of soil components and/or miscellaneous areas in predictable proportions. Some components may be highly contrasting to the other components of the map unit. The presence of minor components in a map unit in no way diminishes the usefulness or accuracy of the data. The delineation of such landforms and landform segments on the map provides sufficient information for the development of resource plans. If intensive use of small areas is planned, onsite investigation is needed to define and locate the soils and miscellaneous areas.

Soil scientists make many field observations in the process of producing a soil map. The frequency of observation is dependent upon several factors, including scale of mapping, intensity of mapping, design of map units, complexity of the landscape, and experience of the soil scientist. Observations are made to test and refine the soil-landscape model and predictions and to verify the classification of the soils at specific locations. Once the soil-landscape model is refined, a significantly smaller number of measurements of individual soil properties are made and recorded. These measurements may include field measurements, such as those for color, depth to bedrock, and texture, and laboratory measurements, such as those for content of sand, silt, clay, salt, and other components. Properties of each soil typically vary from one point to another across the landscape.

Observations for map unit components are aggregated to develop ranges of characteristics for the components. The aggregated values are presented. Direct measurements do not exist for every property presented for every map unit component. Values for some properties are estimated from combinations of other properties.

While a soil survey is in progress, samples of some of the soils in the area generally are collected for laboratory analyses and for engineering tests. Soil scientists interpret the data from these analyses and tests as well as the field-observed characteristics and the soil properties to determine the expected behavior of the soils under different uses. Interpretations for all of the soils are field tested through observation of the soils in different uses and under different levels of management. Some interpretations are modified to fit local conditions, and some new interpretations are developed to meet local needs. Data are assembled from other sources, such as research information, production records, and field experience of specialists. For example, data on crop yields under defined levels of management are assembled from farm records and from field or plot experiments on the same kinds of soil.

Predictions about soil behavior are based not only on soil properties but also on such variables as climate and biological activity. Soil conditions are predictable over long periods of time, but they are not predictable from year to year. For example, soil scientists can predict with a fairly high degree of accuracy that a given soil will have a high water table within certain depths in most years, but they cannot predict that a high water table will always be at a specific level in the soil on a specific date.



After soil scientists located and identified the significant natural bodies of soil in the survey area, they drew the boundaries of these bodies on aerial photographs and

identified each as a specific map unit. Aerial photographs show trees, buildings, fields, roads, and rivers, all of which help in locating boundaries accurately.

Soil Map

The soil map section includes the soil map for the defined area of interest, a list of soil map units on the map and extent of each map unit, and cartographic symbols displayed on the map. Also presented are various metadata about data used to produce the map, and a description of each soil map unit.

MAP INFORMATION

The soil surveys that comprise your AOI were mapped at 1:24,000.

Please rely on the bar scale on each map sheet for map measurements.

Source of Map: Natural Resources Conservation Service
Web Soil Survey URL:
Coordinate System: Web Mercator (EPSG:3857)

Maps from the Web Soil Survey are based on the Web Mercator projection, which preserves direction and shape but distorts distance and area. A projection that preserves area, such as the Albers equal-area conic projection, should be used if more accurate calculations of distance or area are required.

This product is generated from the USDA-NRCS certified data as of the version date(s) listed below.

Soil Survey Area: Kern County, California, Northwestern Part
Survey Area Data: Version 15, Sep 1, 2022

Soil map units are labeled (as space allows) for map scales 1:50,000 or larger.

Date(s) aerial images were photographed: Mar 12, 2022—Mar 22, 2022

The orthophoto or other base map on which the soil lines were compiled and digitized probably differs from the background imagery displayed on these maps. As a result, some minor shifting of map unit boundaries may be evident.

Map Unit Legend

Map Unit Symbol	Map Unit Name	Acres in AOI	Percent of AOI
102	Aido clay 30 to 50 percent slopes	363.5	8.7%

Map Unit Descriptions

The map units delineated on the detailed soil maps in a soil survey represent the soils or miscellaneous areas in the survey area. The map unit descriptions, along with the maps, can be used to determine the composition and properties of a unit.

A map unit delineation on a soil map represents an area dominated by one or more major kinds of soil or miscellaneous areas. A map unit is identified and named according to the taxonomic classification of the dominant soils. Within a taxonomic class there are precisely defined limits for the properties of the soils. On the landscape, however, the soils are natural phenomena, and they have the characteristic variability of all natural phenomena. Thus, the range of some observed properties may extend beyond the limits defined for a taxonomic class. Areas of soils of a single taxonomic class rarely, if ever, can be mapped without including areas of other taxonomic classes. Consequently, every map unit is made up of the soils or miscellaneous areas for which it is named and some minor components that belong to taxonomic classes other than those of the major soils.

Most minor soils have properties similar to those of the dominant soil or soils in the map unit, and thus they do not affect use and management. These are called noncontrasting, or similar, components. They may or may not be mentioned in a particular map unit description. Other minor components, however, have properties and behavioral characteristics divergent enough to affect use or to require different management. These are called contrasting, or dissimilar, components. They generally are in small areas and could not be mapped separately because of the scale used. Some small areas of strongly contrasting soils or miscellaneous areas are identified by a special symbol on the maps. If included in the database for a given area, the contrasting minor components are identified in the map unit descriptions along with some characteristics of each. A few areas of minor components may not have been observed, and consequently they are not mentioned in the descriptions, especially where the pattern was so complex that it was impractical to make enough observations to identify all the soils and miscellaneous areas on the landscape.

The presence of minor components in a map unit in no way diminishes the usefulness or accuracy of the data. The objective of mapping is not to delineate pure taxonomic classes but rather to separate the landscape into landforms or landform segments that have similar use and management requirements. The delineation of such segments on the map provides sufficient information for the development of resource plans. If intensive use of small areas is planned, however, onsite investigation is needed to define and locate the soils and miscellaneous areas.

An identifying symbol precedes the map unit name in the map unit descriptions. Each description includes general facts about the unit and gives important soil properties and qualities.

Soils that have profiles that are almost alike make up a *soil series*. Except for differences in texture of the surface layer, all the soils of a series have major horizons that are similar in composition, thickness, and arrangement.

Soils of one series can differ in texture of the surface layer, slope, stoniness, salinity, degree of erosion, and other characteristics that affect their use. On the basis of such differences, a soil series is divided into *soil phases*. Most of the areas shown on the detailed soil maps are phases of soil series. The name of a soil phase commonly indicates a feature that affects use or management. For example, Alpha silt loam, 0 to 2 percent slopes, is a phase of the Alpha series.

Some map units are made up of two or more major soils or miscellaneous areas. These map units are complexes, associations, or undifferentiated groups.

A *complex* consists of two or more soils or miscellaneous areas in such an intricate pattern or in such small areas that they cannot be shown separately on the maps. The pattern and proportion of the soils or miscellaneous areas are somewhat similar in all areas. Alpha-Beta complex, 0 to 6 percent slopes, is an example.

An *association* is made up of two or more geographically associated soils or miscellaneous areas that are shown as one unit on the maps. Because of present or anticipated uses of the map units in the survey area, it was not considered practical or necessary to map the soils or miscellaneous areas separately. The pattern and relative proportion of the soils or miscellaneous areas are somewhat similar. Alpha-Beta association, 0 to 2 percent slopes, is an example.

An *undifferentiated group* is made up of two or more soils or miscellaneous areas that could be mapped individually but are mapped as one unit because similar interpretations can be made for use and management. The pattern and proportion of the soils or miscellaneous areas in a mapped area are not uniform. An area can be made up of only one of the major soils or miscellaneous areas, or it can be made up of all of them. Alpha and Beta soils, 0 to 2 percent slopes, is an example.

Some surveys include *miscellaneous areas*. Such areas have little or no soil material and support little or no vegetation. Rock outcrop is an example.

Kern County, California, Northwestern Part

102—Aido clay 30 to 50 percent slopes

Map Unit Setting

National map unit symbol: hkgc
Elevation: 1,400 to 3,000 feet
Mean annual precipitation: 9 inches
Mean annual air temperature: 64 degrees F
Frost-free period: 200 to 260 days
Farmland classification: Not prime farmland

Map Unit Composition

Aido and similar soils: 85 percent
Minor components: 15 percent
Estimates are based on observations, descriptions, and transects of the mapunit.

Description of Aido

Setting

Landform: Hills
Landform position (two-dimensional): Backslope
Landform position (three-dimensional): Side slope
Down-slope shape: Convex
Across-slope shape: Convex
Parent material: Residuum weathered from sandstone and shale

Typical profile

A - 0 to 10 inches: clay
C - 10 to 26 inches: clay
Cr - 26 to 60 inches: weathered bedrock

Properties and qualities

Slope: 30 to 50 percent
Depth to restrictive feature: 20 to 40 inches to paralithic bedrock
Drainage class: Well drained
Runoff class: Very high
Capacity of the most limiting layer to transmit water (Ksat): Moderately low to moderately high (0.06 to 0.20 in/hr)
Depth to water table: More than 80 inches
Frequency of flooding: None
Frequency of ponding: None
Calcium carbonate, maximum content: 5 percent
Maximum salinity: Nonsaline to very slightly saline (0.0 to 2.0 mmhos/cm)
Available water supply, 0 to 60 inches: Low (about 3.9 inches)

Interpretive groups

Land capability classification (irrigated): None specified
Land capability classification (nonirrigated): 6e
Hydrologic Soil Group: D
Ecological site: R015XF001CA - Clayey Hills 10-14" P.Z.
Hydric soil rating: No

Minor Components

Hillbrick

Percent of map unit: 5 percent
Landform: Hills
Landform position (two-dimensional): Backslope
Landform position (three-dimensional): Side slope
Down-slope shape: Concave
Across-slope shape: Convex
Hydric soil rating: No

Kilmer

Percent of map unit: 5 percent
Landform: Hills
Landform position (two-dimensional): Backslope
Landform position (three-dimensional): Side slope
Down-slope shape: Concave
Across-slope shape: Convex
Hydric soil rating: No

Rock outcrop

Percent of map unit: 5 percent
Hydric soil rating: No

111—Ayar-Hillbrick-Aido complex, 30 to 50 percent slopes

Map Unit Setting

National map unit symbol: hkgn
Elevation: 200 to 3,500 feet
Mean annual precipitation: 8 to 25 inches
Mean annual air temperature: 59 to 64 degrees F
Frost-free period: 200 to 330 days
Farmland classification: Not prime farmland

Map Unit Composition

Ayar and similar soils: 35 percent
Hillbrick and similar soils: 25 percent
Aido and similar soils: 20 percent
Minor components: 20 percent
Estimates are based on observations, descriptions, and transects of the mapunit.

Description of Ayar

Setting

Landform: Mountains, hills
Landform position (two-dimensional): Backslope
Landform position (three-dimensional): Mountainflank, side slope
Down-slope shape: Concave
Across-slope shape: Convex
Parent material: Residuum weathered from sandstone and shale

Typical profile

A - 0 to 11 inches: silty clay
C - 11 to 44 inches: clay
R - 44 to 54 inches: bedrock

Properties and qualities

Slope: 30 to 50 percent
Depth to restrictive feature: 40 to 60 inches to lithic bedrock
Drainage class: Well drained
Runoff class: Very high
Capacity of the most limiting layer to transmit water (Ksat): Moderately low to moderately high (0.06 to 0.20 in/hr)
Depth to water table: More than 80 inches
Frequency of flooding: None
Frequency of ponding: None
Calcium carbonate, maximum content: 15 percent
Maximum salinity: Nonsaline to very slightly saline (0.0 to 2.0 mmhos/cm)
Available water supply, 0 to 60 inches: Moderate (about 7.1 inches)

Interpretive groups

Land capability classification (irrigated): None specified
Land capability classification (nonirrigated): 6e
Hydrologic Soil Group: C
Ecological site: R015XF001CA - Clayey Hills 10-14" P.Z.
Hydric soil rating: No

Description of Hillbrick

Setting

Landform: Hills
Landform position (two-dimensional): Backslope
Landform position (three-dimensional): Side slope
Down-slope shape: Concave
Across-slope shape: Convex
Parent material: Residuum weathered from sandstone and shale

Typical profile

A - 0 to 15 inches: sandy loam
R - 15 to 25 inches: unweathered bedrock

Properties and qualities

Slope: 30 to 50 percent
Depth to restrictive feature: 10 to 20 inches to lithic bedrock
Drainage class: Well drained
Runoff class: Medium
Capacity of the most limiting layer to transmit water (Ksat): Moderately high to high (0.20 to 1.98 in/hr)
Depth to water table: More than 80 inches
Frequency of flooding: None
Frequency of ponding: None
Calcium carbonate, maximum content: 5 percent
Maximum salinity: Nonsaline to very slightly saline (0.0 to 2.0 mmhos/cm)
Available water supply, 0 to 60 inches: Very low (about 1.5 inches)

Interpretive groups

Land capability classification (irrigated): None specified
Land capability classification (nonirrigated): 6e

Hydrologic Soil Group: D
Ecological site: R015XF034CA - Limy Upland (shallow) 9-12" P.Z.
Hydric soil rating: No

115—Bitterwater sandy loam, 9 to 15 percent slopes

Map Unit Setting

National map unit symbol: hkgs
Elevation: 600 to 2,500 feet
Mean annual precipitation: 5 to 8 inches
Mean annual air temperature: 63 to 66 degrees F
Frost-free period: 250 to 275 days
Farmland classification: Not prime farmland

Map Unit Composition

Bitterwater and similar soils: 80 percent
Minor components: 20 percent
Estimates are based on observations, descriptions, and transects of the mapunit.

Description of Bitterwater

Setting

Landform: Hillslopes
Landform position (two-dimensional): Backslope
Landform position (three-dimensional): Side slope
Down-slope shape: Concave
Across-slope shape: Convex
Parent material: Residuum weathered from sandstone and/or shale

Typical profile

A - 0 to 23 inches: sandy loam
C - 23 to 60 inches: sandy loam
Cr - 60 to 70 inches: weathered bedrock

Properties and qualities

Slope: 9 to 15 percent
Depth to restrictive feature: 40 to 60 inches to paralithic bedrock
Drainage class: Well drained
Runoff class: Low
Capacity of the most limiting layer to transmit water (Ksat): High (1.98 to 5.95 in/hr)
Depth to water table: More than 80 inches
Frequency of flooding: None
Frequency of ponding: None
Calcium carbonate, maximum content: 10 percent
Maximum salinity: Nonsaline to very slightly saline (0.0 to 2.0 mmhos/cm)
Available water supply, 0 to 60 inches: Moderate (about 6.6 inches)

Interpretive groups

Land capability classification (irrigated): None specified
Land capability classification (nonirrigated): 7e
Hydrologic Soil Group: A
Ecological site: R015XG008CA - Loamy 5-8" P.Z.
Hydric soil rating: No

Minor Components

Kettleman

Percent of map unit: 7 percent
Landform: Hills
Landform position (two-dimensional): Backslope
Landform position (three-dimensional): Side slope
Down-slope shape: Concave
Across-slope shape: Convex
Hydric soil rating: No

Bitterwater, gravelly sandy loam

Percent of map unit: 7 percent
Landform: Hillslopes
Landform position (two-dimensional): Backslope
Landform position (three-dimensional): Side slope
Down-slope shape: Concave
Across-slope shape: Convex
Hydric soil rating: No

Unnamed, shallower bedrock

Percent of map unit: 3 percent
Landform: Hillslopes
Landform position (two-dimensional): Backslope
Landform position (three-dimensional): Side slope
Down-slope shape: Concave
Across-slope shape: Convex
Hydric soil rating: No

Unnamed, soils with subsoil

Percent of map unit: 3 percent
Landform: Hillslopes
Landform position (two-dimensional): Backslope
Landform position (three-dimensional): Side slope
Down-slope shape: Concave
Across-slope shape: Convex
Hydric soil rating: No

117—Bitterwater gravelly sandy loam, 15 to 50 percent slope s

Map Unit Setting

National map unit symbol: hkgv
Elevation: 600 to 2,000 feet

Mean annual precipitation: 5 to 8 inches
Mean annual air temperature: 63 to 66 degrees F
Frost-free period: 250 to 275 days
Farmland classification: Not prime farmland

Map Unit Composition

Bitterwater and similar soils: 85 percent
Minor components: 15 percent
Estimates are based on observations, descriptions, and transects of the mapunit.

Description of Bitterwater

Setting

Landform: Hillslopes
Landform position (two-dimensional): Backslope
Landform position (three-dimensional): Side slope
Down-slope shape: Concave
Across-slope shape: Convex
Parent material: Residuum weathered from sandstone and/or shale

Typical profile

A - 0 to 23 inches: sandy loam
C - 23 to 60 inches: sandy loam
Cr - 60 to 70 inches: weathered bedrock

Properties and qualities

Slope: 15 to 50 percent
Depth to restrictive feature: 40 to 60 inches to paralithic bedrock
Drainage class: Well drained
Runoff class: Medium
Capacity of the most limiting layer to transmit water (Ksat): High (1.98 to 5.95 in/hr)
Depth to water table: More than 80 inches
Frequency of flooding: None
Frequency of ponding: None
Calcium carbonate, maximum content: 10 percent
Maximum salinity: Nonsaline to very slightly saline (0.0 to 2.0 mmhos/cm)
Available water supply, 0 to 60 inches: Moderate (about 6.6 inches)

Interpretive groups

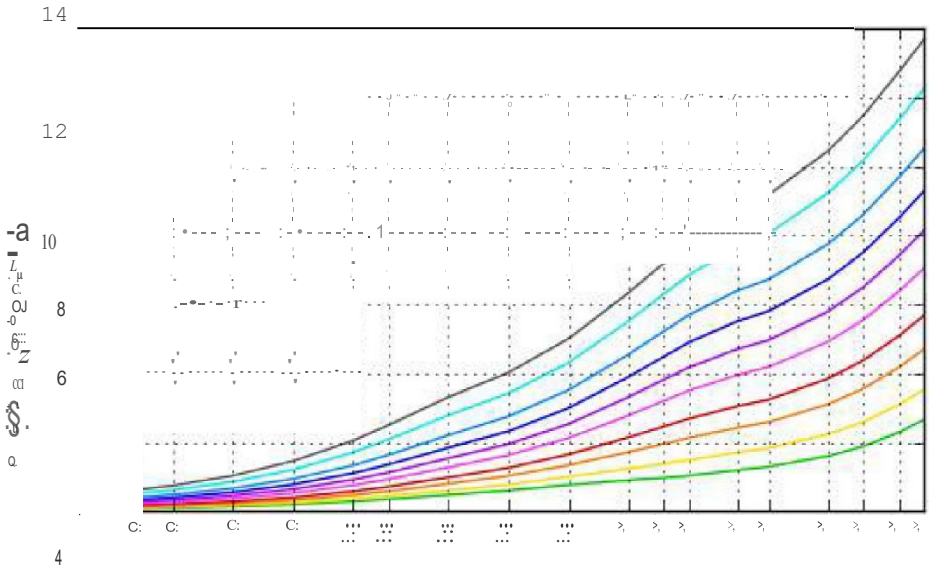
Precipitation frequency (PF) estimates in this table are based on frequency analysis of partial duration series (PDS).



Numbers in parenthesis are PF estimates at lower and upper bounds of the 90% confidence interval. The probability that precipitation frequency estimates (for a given duration and average recurrence interval) will be greater than the upper bound (or less than the lower bound) is 5%. Estimates at upper bounds are not checked against probable maximum precipitation (PMP) estimates and may be higher than currently valid PMP values.

Please refer to NOAA Atlas 14 document for more information.

Project Description

The project is located at **Unnamed Road, McKittrick, CA 93251.** The site is 22,967.685 acres in size.

Purpose

The purpose of this hydrology study is to determine the peak runoff rates for pre-development and post-development conditions.

Methodology Used

The HEC-HMS version 4.5 computer software was used in this hydrology study. The **SCS Curve Number**

infiltration (loss) method and **SCS Unit Hydrograph** runoff (transform) method was used for determining the stormwater runoff**.** The **Kinematic Wave** routing method was used for routing the stormwater**.**

The following scenarios were analyzed in this hydrology study:

Existing Conditions 100yr

This scenario contains:

- 25 delineated subbasin areas and corresponding lag time flow paths.
- 25 routing reaches.
- 18 connecting junctions.

Existing Conditions 10yr

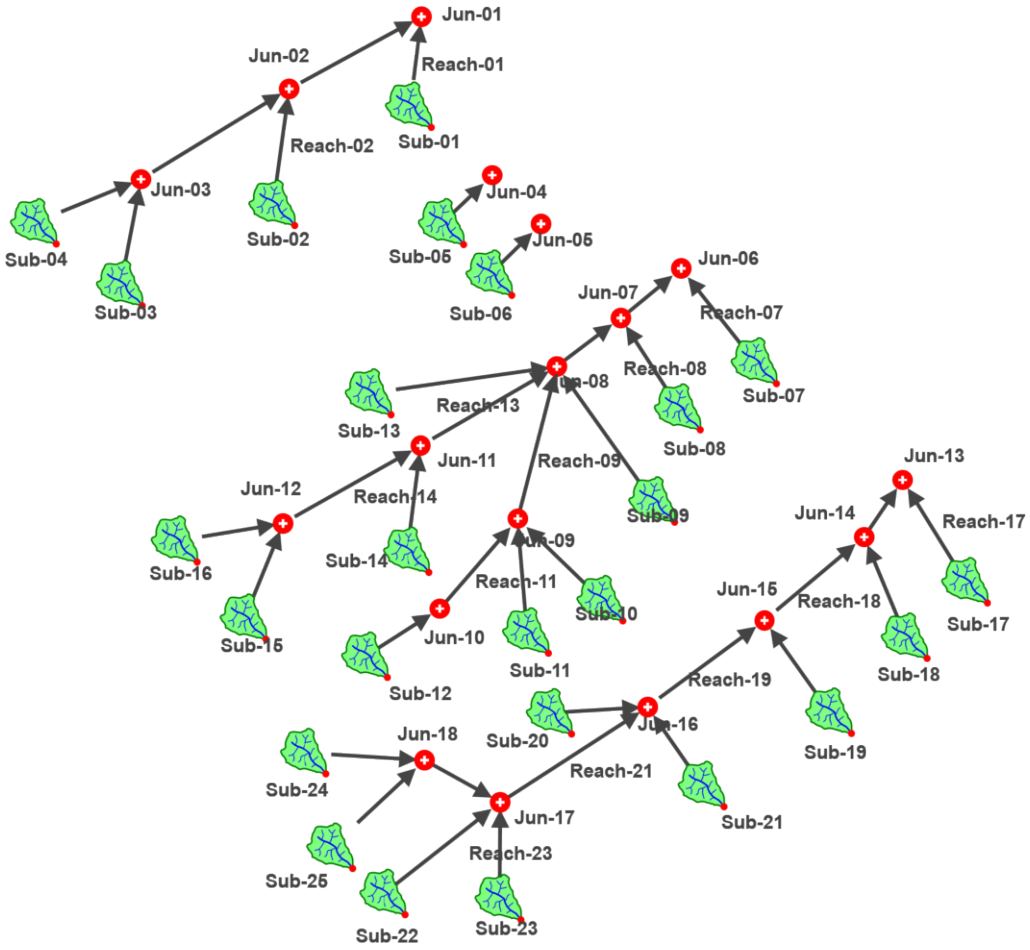
This scenario contains:

- 25 delineated subbasin areas and corresponding lag time flow paths.
- 25 routing reaches.
- 18 connecting junctions.

Proposed Development 100yr

This scenario contains:

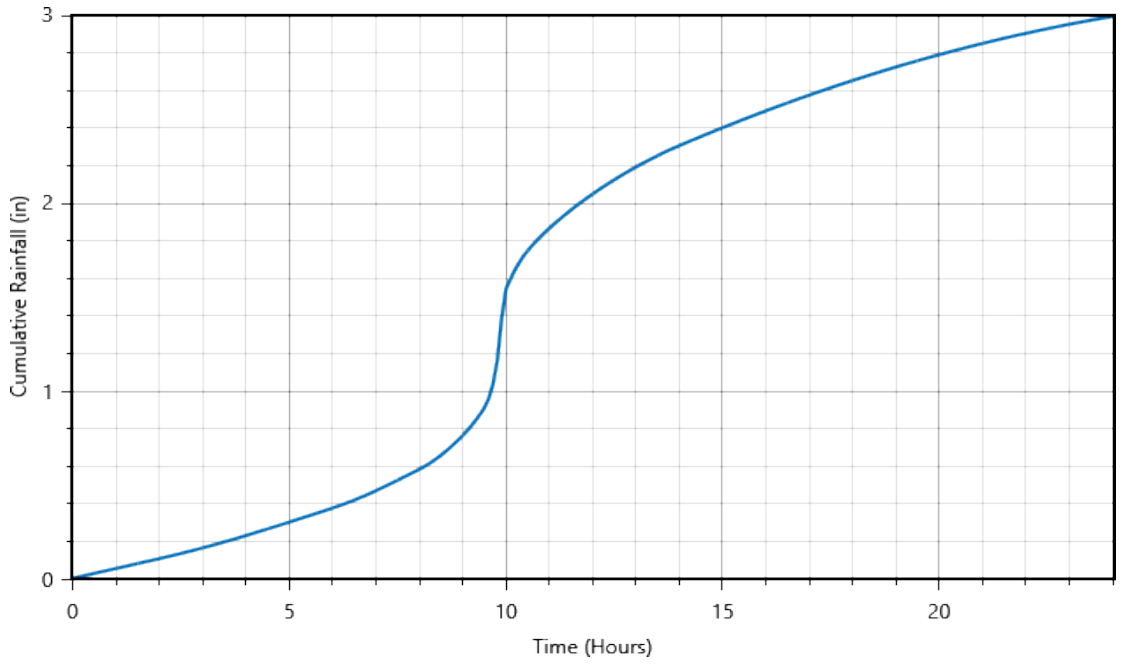
- 25 delineated subbasin areas and corresponding lag time flow paths.
- 25 routing reaches.
- 18 connecting junctions.



Proposed Development 10 yr

This scenario contains:

- 25 delineated subbasin areas and corresponding lag time flow paths.
- 25 routing reaches.
- 18 connecting junctions.



Existing Conditions 100yr

Watershed Routing Diagram

Design Storm

Precipitation type: SCS Storm
SCS storm distribution: Type I
Rainfall depth: 2.99 in

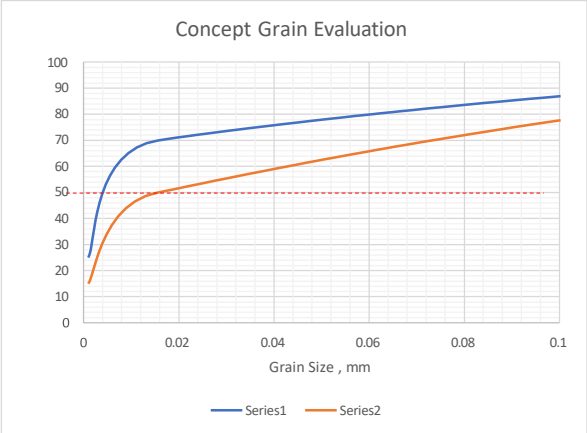
Appendix D Scour Calculations

Potential Produced Water Line

Location: Chico Martinez Creek north of Roustabout Rd County



Sediment Evaluation

Typical Soil Profile in Area of Crossing

Soil Series: Panoche
Decription: Panoche loam

			Percent			
Profile	**Depth, in**	**Description**	**Gravel**	**Sand**	**Silt**	**Clay**
Ap	0 to 7	loam	0	23-52	28-50	7-27
Bw	7 to 24	loam	0	23-52	28-50	7-27
Bk	24 to 60	loam	0	23-52	28-50	7-27

General Scour

Method 1 Per Blodgett (1986)

Figure TS14B–1 Scour observations from typical reaches of alluvial rivers

z_t (mean) = $KD_{50}^{-0.1}$

K^t=	1.42	
D_{50} =	0.004	mm
z_t (mean) =	2.47	ft

z_t (max) = $KD_{50}^{-0.11}$

K =	6.5	
D_{50} =	0.004	mm
z_t (max) =	11.93	ft

Method 2 per Pemberton and Lara (1984)

$z_t = KQ_d^a W_f^b D^c$

Where:

z_t =	maximum sour depth at the cross section, ft	
K =	Coefficient (table TS14B-8)	0.195
Q_d =	design discharge, cfs	688.43
W_f =	flow width at design discharge, ft	110
D_{50} =	median size of bed material, mm	0.004
a, b, c =	exponents (table TS14B-8)	0.3333333 (a), 0 (b), -0.16667 (c) Lacey

Table TS14B–8 Constants for Lacey and Blench relations, U.S. units (D_{50} in mm)

Condition	Lacey				Blench			
	K	a	b	c	K	a	b	c
Straight reach	0.097	1/3	0	–1/6	0.530	2/3	–2/3	–0.1092
Moderate bend	0.195	1/3	0	–1/6	0.530	2/3	–2/3	–0.1092
Severe bend	0.292	1/3	0	–1/6	0.530	2/3	–2/3	–0.1092
Right angle bend	0.389	1/3	0	–1/6	1.105	2/3	–2/3	–0.1092
Vertical rock wall	0.487	1/3	0	–1/6				

Lacey

zt = 4.32 ft

Blench

K =	Coefficient (table TS14B-8)	
Q_d =	design discharge, cfs	
W_f =	flow width at design discharge, ft	
D_{50} =	median size of bed material, mm	
a, b, c =	exponents (table TS14B-8)	

z_t = 3.29 ft

Executive Summary

Stantec Consulting Services Inc. (Stantec) completed a Water Supply Assessment (WSA) report on behalf of Aera Energy LLC (Aera) for the construction and operation of the Aera CarbonFrontier Project (Project). This WSA was conducted in conformance with the requirements of the California Water Code (Water Code), as amended in 2002 by the passage of Senate Bill (SB) 610, except as may have been modified by the scope of work and terms and conditions requested by Aera.

The Project would consist of 49 parcels, totaling approximately 13,243 gross acres of privately owned land parcels predominately developed with oil and gas production and accessory facilities and infrastructure within the South Belridge Oil Field and North Belridge Oil Field in unincorporated Kern County, California. The proposed carbon dioxide (CO_2) sequestration field would be located in the North Belridge Oil Field and would occupy approximately 2,636 acres of land (lateral extent of CO_2 plume).

The Project is located in the San Joaquin Valley portion of western Kern County about seven miles southwest of the community of Lost Hills and about 40 miles west-northwest of Bakersfield. The Project would be bordered on the east by State Route (SR) 33 and on the west, south and north by oil field land parcels and grazing land. The CO_2 generated by the Project would be injected into a designated underground sequestration zone, known as the 64 Zone at depths of approximately 8,500 feet below ground surface.

Aera is seeking approval of a land use application package to the Kern County Planning and Natural Resources Department (Kern County) for a Zone Classification Change and Conditional Use Permit (CUP), and any other required approvals, if any, for the construction and operation of a CCS Project. The Applicant proposes to construct, own, and operate the Project and would also obtain Underground Injection Control (UIC) Class VI injection well permits from the U.S. Environmental Protection Agency (EPA). Stantec analyzed water supplies available to serve the Project, including the water demand anticipated during construction and through operation of the Project facilities.

According to the requirements of Water Code Section 10910(c)(3) the WSA shall include a discussion of, “whether the public water system’s total projected water supplies available will meet the projected water demand associated with proposed Project, in addition to the public water system’s existing and planned future uses.” In summary:

- The Project will be under environmental review pursuant to the requirements of California Environmental Quality Act (CEQA); therefore, the information contained in this assessment will be used to support the analysis contained in the CEQA document.
- The Project meets the definition of a “Project” under Water Code Section 10912(a).
- The Project is located in portions of multiple sections in Townships 27, 28 and 29 South and Ranges 20 and 21 East, Mount Diablo Base and Meridian.

- Portions of the Project are located within the service area of the Belridge Water Storage District (BWSD) which relies on imported State Water Project (SWP) surface water supplies from the California Aqueduct purchased through Kern County Water Agency (KCWA), a State Water Contractor, to meet the water supply needs of its Water Users (BWSD, 2020). BWSD predominantly delivers SWP water to Water Users for agricultural purposes but also provides a small amount of water for industrial use in oil recovery operations at the North Belridge Oil Field and South Belridge Oil Field (Aquilogic, 2022). Buena Vista Water Storage District (BVWSD) relies on Kern River water and to a much lesser extent on purchased SWP water from KCWA. Like BWSD, BVWSD delivers most of their surface water supplies for agricultural use. BWSD has a Table A entitlement of 121,508 acre-feet per year (afy) of SWP water; however, annual allocations and deliveries vary significantly from year to year based on water supply conditions in the State, SWP water conveyance facilities maintenance and Endangered Species Act requirements, the latter as described in *Biological Assessment on the Long-Term Operations, Criteria and Plan for the Central Valley Project and State Water Project* (U.S. Bureau of Reclamation, 2008) and taking into account subsequent Biological Opinions with Reasonable and Prudent Alternative actions prepared by the U.S. Fish and Wildlife Service (USFWS) (USFWS, 2008) and the National Marine Fisheries Service (NMFS, 2009, 2019). BVWSD has a Kern River entitlement of 156,000 afy which varies from year to year based on hydrologic conditions in the Kern River watershed. BVWSD also has a Table A entitlement of 21,300 afy and Article 21 entitlement of 3,750 afy of SWP water which varies due to the same conditions affecting BWSD's SWP entitlement. Domestic water demands will be served by Aera's two groundwater wells

- The Project estimates a water demand of approximately 400 acre-feet (af) over an approximate 3-year construction period and an average of up to approximately 1,223 afy (26,000 barrels per day) for the commercial operation.

- Proposed construction water demands for the Project are anticipated to be purchased from existing BWSD SWP entitlements and other existing long-term water contracts with individuals and delivered to the Project Area via BWSD's 415 North Canal and/or 500 Canal and existing pipeline. Aera also has approximately 7,000AF of surplus SWP and Kern River water banked in various groundwater banking projects through the BWSD that may be accessed at any time, subject to the groundwater bank's pumping capacity. Water demands for commercial operation will be provided by treated produced water from Aera.

- Proposed domestic water demands for commercial operation of the Project are estimated to be 21.72 afy and will be provided by two existing Aera-owned groundwater wells located in the BVWSD.

  Groundwater production from these two wells is 707.48 afy and historical demand over the past five years was 685.93 afy. Total projected water demand is estimated to be 690.50 afy which includes the Project's estimated domestic water demand.

- Groundwater pumped from Aera's two groundwater wells would be provided to meet Project domestic water demands. The groundwater pumped would be extracted from the Kern County Subbasin (Subbasin, Department of Water Resources [DWR] Bulletin 118 Subbasin No. 5-

022.14; DWR, 2021) in the San Joaquin Valley Groundwater Basin. The Subbasin occupies the western part of Kern County in the San Joaquin Valley.

- The Subbasin has been designated as a critically overdrafted high-priority basin by the Department of Water Resources (DWR) (https://gis.water.ca.gov/app/bp-dashboard/final/# accessed January 8, 2022). Five Groundwater Sustainability Plans (GSPs) representing 11 Groundwater Sustainability Agencies (GSAs) were submitted to DWR as required under the Sustainable Groundwater Management Act (SGMA). The five GSPs were prepared by a combined 11 GSAs and including 16 member agencies in the Kern Groundwater Authority (KGA) GSP to sustainably manage the Subbasin under the SGMA. The Project Area is located within the Westside District Water Authority (WDWA) plan area of the KGA GSP (Aquilogic, 2022; GEI, 2022a). A GSP chapter was prepared for the WDWA by Aquilogic (2022), a member agency of the KGA. The WDWA includes the BWSD, Berenda Mesa Water District (BMWD) and Lost Hills Water District (LHWD) in northwestern Kern County.

- Aera's groundwater wells are located in the BVGSA, which is a member agency of the KGA. A GSP chapter was prepared for the BVGSA (GEI, 2022b) and incorporated in the KGA "Umbrella" GSP (GEI, 2022a). The BVGSA corresponds to the BVWSD service area and includes a subset of the BVWSD called the Buttonwillow Management Area (BMA). The BMA occupies 91% percent of the BVWSD service area while the Maples Management Area is non-contiguous and is included in the Kern River GSA GSP (GEI, 2022b). Because the BMA portion of the BVWSD and BVGSA contains Aera's groundwater wells this WSA addresses water supply conditions in the BMA portion of the BVGSA.

- According to the WDWA GSP chapter (Aquilogic, 2022), groundwater production in the WDWA plan area for Water Year (WY)1995 to WY2014 (historical condition) is estimated to be 3,000 afy. Groundwater production in 2020 in the WDWA is reported to be 10,276 af based on the 2020 Agricultural Management Plans (AWMPs) for BWSD, BMWD and LHWD (BWSD, 2021; BMWD, 2021; LHWD, 2021).

- According to the BVGSA GSP chapter (GEI, 2022b), groundwater production in the BVGSA plan area for WY1993 to WY2015 (historical condition) is estimated to be 62,742 afy. Groundwater production in 2020 is not available. BVWSD (personal communication, June 30, 2023) estimated the 2040 water demand to be 140,000 af.

- BVWSD is entitled to 156,000 afy of surface water from the Kern River; however, during the period 2006 to 2015 Kern River deliveries via the East Side Canal averaged 40,887 afy. BVWSD is also contracted with the Kern County Water Agency to receive 21,300 afy of Table A SWP water and 3,750 afy of Article 21 SWP water. During the period 2006 through 2015, BVWSD received an average of 53,099 afy of SWP water via the California Aqueduct (GEI, 2022b). Average surface water deliveries from 2006 to 2015 averaged 93,986 afy. Estimated 2020, 2030 and 2070 surface water deliveries to the BVWSD are 164,192 af, 161,306 af and 160,864 af, respectively (GEI, 2022b). The estimated cumulative and annual decline in groundwater in storage in the BVGSA between WY1993 and WY2015 is 275,480 af and 11,977 afy, respectively

(GEI, 2022b). The estimated annual change in ground in storage between WY1995 and WY2014 using the C2VSimFG-Kern groundwater model is -17,362 afy (Todd, 2019).

- According to the BVGSA GSP (GEI, 2022b), under the 2070 climate change factor, BVGSA has estimated a reduced Kern River entitlement of 147,000 af in 2040, a reduced SWP Table A entitlement of 9,642 afy and a slightly increased Article 21 SWP entitlement of 3,900 afy in 2040.
- According to the KGA GSP (GEI, 2022a), groundwater production in the Subbasin for WY1995-WY2014 (historical condition) is estimated to be 1,590,373 af based on a groundwater model simulation using CV2SimFG-Kern (Todd, 2020) in GEI (2022a).
- Projected groundwater production in the WDWA plan area and the Subbasin is projected to increase to 25,400 (Aquilogic, 2022) and 1,648,770 afy (Todd, 2020) in GEI (2022a), respectively, from WY2021 to WY2040, the latter, based on the CV2SimFG-Kern 2070 climate change conditions and implementation of projects and management actions scenario.
- Estimations of the total storage capacity of the Subbasin were reported in DWR (2006) based on data in 2002 to be 40,000,000 af (KCWA, 2002). The dewatered storage at this time was also reported to be 10,000,000 af (KCWA, 2002). The estimated amount of groundwater in storage from WY1995 to WY2014 in the WDWA is reported to be 42,400,000 af (Aquilogic, 2022). However, this latter estimate appears to more closely coincide with the estimated storage capacity of the Subbasin, not the WDWA, as noted above (DWR, 2006; KCWA, 2002).
- Change in groundwater in storage in the Subbasin between WY1995-WY2014 is estimated to have declined by 5,542,280 af based on an annual decline of 277,114 afy (Todd, 2020) in GEI (2022a).
- Change in groundwater in storage in the Subbasin between WY1995-WY2021 is estimated to yield a decline of 1,812,211 af (Todd, 2020) in GEI (2022a) based on an annual decline of 69,700 afy (Todd, 2020) in GEI (2022).
- The projected average and cumulative change in groundwater in storage in the Subbasin from WY2021 to WY2040 is a decline of about 224,286 afy and 4,485,720 af, respectively (Todd, 2020) in GEI (2022a), based on the CV2SimFG-Kern groundwater model simulated 2070 climate change conditions and implementation of projects and management actions scenario.
- The projected annual average decline in the amount of groundwater in storage in the WDWA plan area from WY2021 to WY2040 taking into account 2070 climate change conditions and implementation of projects and management actions is estimated to be 46,000 afy (Todd, 2020) in (GEI, 2022) and revised to approximately 22,000 afy by Aquilogic (2022) based on assumed modeling discrepancies related to the amount of groundwater production using the CV2SimFG-Kern groundwater model simulation.
- The estimated groundwater recharge in the Subbasin and WDWA plan area in WY1995-WY2014 is 1,400,362 afy (Todd, 2020) in GEI (2022) and 92,341 afy (Aquilogic, 2022), respectively, based on CV2SimFG-Kern groundwater modeling simulations (Todd, 2020) in GEI (2022).

- The estimated WY1995-WY2014 sustainable yield in the Subbasin and the WDWA plan area is 1,313,260 afy (Todd, 2020) in GEI (2022) and 34,079 afy (Aquilogic, 2022), respectively.

1.0 INTRODUCTION

Stantec Consulting Services Inc. (Stantec) conducted a water supply assessment on behalf of Aera Energy LLC (Aera) for the Aera CarbonFrontier Project (Project) located in an unincorporated area of Kern County, California. This water supply assessment was conducted in support of the proposed construction and operation of a carbon capture and sequestration (CCS) facility.

1.1 PROJECT DESCRIPTION

Aera has submitted an application to the Kern County Planning and Natural Resources Department to request approval of a Zone Change and Conditional Use Permit (CUP) for the construction and operation of the proposed Project in the South and North Belridge oil fields.

The proposed Project would capture carbon dioxide (CO_2) from existing produced-gas streams (pre-combustion) and emissions from existing stationary sources (post-combustion) and transport the CO_2 through a pipeline to the North Belridge Oil Field for injection via nine dedicated Underground Injection Control (UIC) Class VI injection wells. It is anticipated that the proposed Project would sequester approximately 30 million metric tons of CO_2 throughout its estimated 20-year lifetime[1].

The Project site is primarily contained within the South and North Belridge oil fields, in the Central Valley portion of western Kern County. The South Belridge and North Belridge oil fields are contiguous and cover an area of approximately 13 miles long and three miles wide. The proposed CO_2 capture facilities are located within the developed portion of the South Belridge Oil Field and include the separation, dehydration, compression, and cooling of CO_2 from both pre-combustion (Pre-C) and produced gas streams from post-combustion (Post-C) flue gas. The proposed CO_2 sequestration field is located within the North Belridge Oil Field, which is predominately developed with oil and gas production.

Gas produced from the Tulare and Diatomite formations via existing oil wells within South and North Belridge would be mixed and conditioned using existing and modified process equipment. Mixing of the Diatomite and Tulare gas streams would start at the Del Sur Field Compressors. Using the existing (modified) compressors, the mixed stream would be transported, via an existing 16” Del Sur gas pipeline to a pre-combustion CO_2 capture facility to be located near Gas Plant 32. The carbon capture facility will include three steel towers of varying height (not exceeding 120 feet), and between 2 to 12 feet in diameter. The gas stream would first be treated to remove sulfur through an existing sulferox (SOX) plant. The de-sulfurized stream would then be cooled to reduce water content and condense heavy hydrocarbons. The CO_2 would be removed from the non-hydrocarbon gas stream using a physical solvent or a traditional amine absorption process. The resulting CO_2 product stream would be cooled, compressed, and piped to the sequestration site.

[1] Note, the operational life of the proposed Project will be controlled by the sequestration reservoir’s storage capacity (currently undergoing review) and volume of CO_2 captured per year which will fluctuate.

In each of the three post-combustion CO_2 capture facilities within Co-generation Plant 32 (at Gas Plant 32) and Steam Generator Stations (SGS) 2862 and 2972, the flue gas would be cooled, then passed through an absorber column where an absorbent will chemically react with and bind about 90% of the CO_2. The remaining flue gas (primarily oxygen, nitrogen, and the remaining uncaptured CO_2), would be vented to atmosphere. The rich absorbent carrying CO_2 is piped to the regenerator column, where through the application of heat, the CO_2 would be released and captured in relatively pure concentration. The CO_2 would be compressed, dehydrated, stripped of oxygen, and piped to the sequestration site. Oil and gas production activities within the underground formation where CO_2 would be stored, known as the 64 zone, would cease as a result of the implementation of the proposed Project.

A new approximately 10-mile, 6- to 12-inch pipeline would be constructed to deliver CO_2 from the capture facilities to the proposed injection wells. The pipeline would be primarily installed aboveground, except where the pipeline would cross main access roads (below ground) within the oil field properties. Distribution piping, each approximately 4- to 8-inches in size, would extend from the main pipeline to the proposed injection wells. The distribution pipelines would also be primarily aboveground on pipe supports, except where the pipelines cross main access roads (below ground) within the oil field.

The proposed Project includes re-purposing five existing oil wells and drilling four new wells for CO_2 injection. Additionally, four existing wells would be converted to monitoring wells to monitor the CO_2 plume. Up to four additional monitoring wells may also be constructed, either as re-purposed oil wells and/or new wells. The proposed Project would also require plugging and abandonment of up to 40 existing oil wells within the North Belridge Oil Field in accordance with state and federal requirements to prevent leakage of CO_2 from the sequestration zone. Additionally, up to 40 wells previously abandoned within the North Belridge Oil Field would be re-abandoned to meet current state and federal plugging requirements. Finally, 13 wells that are adjacent to SGS 2868 and SGS 2972 will need to be abandoned prior to construction of the CO_2 capture facilities at these two locations.

1.1.1 Project Area Information

The Project is comprised of 49 assessor's parcels (Project Area) totaling approximately 13,243 gross acres (Table 1). The permanent disturbance acreage associated with development of the CCS project and associated infrastructure would be less than the gross acreage of the Project Area. The proposed carbon dioxide (CO2) capture facilities are located within the developed portion of the South Belridge Oil Field. The proposed Project Area (including CO2 capture facilities, pipelines, sequestration field, and supporting facilities) is made up of privately owned parcels totaling approximately 13,243 acres of land, predominately developed with oil and gas production and accessory facilities and infrastructure.

1.1.2 Location

The Project Area is located within the Central Valley portion of western Kern County. The South Belridge and North Belridge oil fields are contiguous and located approximately seven miles southwest of the community of Lost Hills and west of SR 33 (Figure 1). Together, the two Belridge oil fields cover an area of approximately thirteen miles long and 3 miles wide.

1.2 DESCRIPTION OF PROPOSED PROJECT

Aera proposes to construct and operate a CCS project, with the CO_2 capture facilities located within the South Belridge Oil Field and transport the CO_2 by pipeline to the North Belridge Oil Field for permanent sequestration via CO_2 injection wells into a designated underground sequestration zone, known as the 64 zone, at depths of approximately 8,500 feet below ground surface. Presented below is a brief discussion of each of the Project components.

New processing facilities and field systems will be constructed. Processing facilities will include: 1) carbon capture facilities constructed adjacent to existing oil field equipment within the South Belridge Oil Field, 2) pipelines to transport the CO_2 stream to the North Belridge Oil Field, 3) dedicated injection wells within the North Belridge Oil Field to inject CO_2 into the dedicated CO_2 sequestration zone. Existing oil wells that penetrate the dedicated CO_2 sequestration zone will be permanently plugged and abandoned (including the removal of surface wellheads) in accordance with applicable laws and regulations.

Field systems will include: 1) additional pipelines to convey produced gas, steam within South Belridge Oil Field, 2) water treatment facilities, and 3) electrical power distribution and supervisory control and data acquisition networks. Project infrastructure will also include on-site road maintenance. Monitoring systems will be constructed, including re-purposing of existing wells, to monitor the CO_2 injection operations in accordance with state and federal requirements. All employee facilities needed to manage the Project will be provided by the existing Aera Belridge facilities.

After the useful life of the Project, the Project infrastructure would be disassembled, and the Project Area would be restored to its pre-development condition.

1.2.1 CO_2 Capture Facilities

Proposed CO_2 capture facilities include the separation, dehydration, compression, and cooling of CO_2 from both pre-combustion (Pre-C) produced gas stream and from post-combustion (Post-C) flue gas. A general discussion of each facility is presented below.

Pre-Combustion Components

Del Sur to GP 32 Line. Gas produced from the Tulare Formation via existing oil wells within the South Belridge Oil Field is transported, via an existing 16-inch diameter 3.3-mile long Wet Gas High Pressure Del Sur pipeline to the Del Sur compressor station and on to GP 32. The Tulare Associated gas stream would need to go through the Del Sur Compressor Station to increase pressure before being transported to GP 32, which would require a short “jumper” line to be constructed. The new jumper line would be approximately 200 feet long.

Tulare Casing Vapor Recover (CVR) to GP 32 Pipeline. Alternatively, gas produced from existing wells in the Tulare Formation will be transported by installing a new 12- to 16-inch 3.5-mile-long pipeline extending from the SOX 2-3 facility east of SR 33 to the existing SOX 3-2 facility, terminating at the GP32 location. The proposed pipeline will be installed primarily aboveground on pipe supports. The pipeline would cross State Route 33 and Seventh Standard Road using horizontal boring techniques.

Section 32 Gas Treating Complex. Prior to CO2 removal, the Tulare gas stream will first be treated to remove sulfur through one of two alternative methods: 1) treatment at the existing SOX Plants 3-2 and 2-3 or 2) the gas will be treated at the existing SOX Plant within the Section 32 Gas Treating Complex. CO_2 will be removed from the combined produced gas stream (Tulare and Diatomite production) using a physical solvent and traditional amine absorption process. Aera has not selected a specific amine solution vendor at this time.

Post-Combustion Capture Facilities

Post-C facilities will be constructed at three existing facilities within the South Belridge Oil Field: Section 32 Cogeneration Facility, Steam Generator Setting 2868, and Steam Generator Setting 2972. Flue gas from each post combustion source will be ducted to its own CO_2 capture facility. CO_2 will be captured using a combination of cooling and amine absorption. The concentrated CO_2 would then be compressed, dehydrated, and stripped of oxygen.

1.2.2 CO_2 Pipelines

Main Pipeline. A new approximately 10-mile, 6- to 12-inch pipeline will be constructed to deliver CO_2 from the capture facilities to the proposed injection wells. The pipeline will be primarily installed aboveground on pipe supports, except where the pipeline will cross main access roads within the oil field properties.

Booster Pump Station. A new booster pump station will be constructed adjacent to the existing Compressor Station 49. The booster pump station would include electric-driven pumps to increase flow rates between the CO_2 capture facilities and the injection wells. Alternatively, booster pumps may be installed within each capture facility.

Distribution Pipelines. Distribution piping, each approximately 4- to 8-inches in size, will extend from the main pipeline to the proposed injection wells. The distribution pipelines will be primarily aboveground on pipe supports, except where the pipelines cross main access roads within the oil field. The pipelines will be installed below ground at the main access road crossings.

1.2.3 Wells

The proposed Project includes re-purposing five existing oil wells and four new wells for use for CO_2 injection activities. Well locations have been carefully selected to minimize disturbance by reusing existing well pads, where feasible, and to allow for the permanent CO_2 sequestration within the dedicated zone. Well pads have been designed to minimize the amount of surface disturbance while meeting the technical constraints of drilling and operating the wells. Additionally, four existing wells will be converted to observation wells to monitor the CO_2 plume. Up to four additional monitoring wells may also be constructed, either as repurposed oil wells and/or new wells.

As part of the proposed Project, up to 40 existing oil wells would be plugged and abandoned within the North Belridge Oil Field in accordance with state and federal requirements to prevent leakage of CO_2 from the sequestration zone. Up to 40 additional wells, previously abandoned within the North Belridge Oil Field, would be re-abandoned to ensure

CO2 will be permanently sequestered. Lastly, 13 existing wells that are adjacent to SGS 2862 and SGS 2972 will need to be plugged and abandoned prior to construction of the CO_2 capture facilities at these two locations.

1.2.4 Support Infrastructure

Water Systems

The proposed Project will require, on average, approximately 1,223 afy (26,000 barrels or 1.09 million gallons per day) of water for use in the CO_2 capture facilities. The proposed Project would primarily use produced water from the Belridge Oil Field. Additional water treatment facilities will be installed at each CO_2 capture facility to treat produced water. Water pipelines would be constructed primarily aboveground to supply water to each of the CO_2 capture facilities.

Steam Lines

One of the project objectives is to reduce the carbon intensity of Aera Energy's produced oil and gas. Approximately nine miles of new 6- to 14-inch diameter steam pipelines would be installed to distribute steam from the SGS 2972 and SGS 2868 sites to areas of the field where steam would otherwise be generated without CO_2 capture. These new steam lines would allow Aera Energy to prioritize generating and supplying steam from the SGS 2972 and SGS 2868 sites with CO_2 capture. An approximately three-mile steam pipeline, constructed primarily aboveground on pipe supports, would extend from SGS 2972 to near Seventh Standard Road, along with an approximately 1.5-mile parallel pipeline from SGS 2868 to near Seventh Standard Road. Also, an approximately four-mile pipeline would extend from SGS 2972 northward to Section 12. Two shorter sections of steam piping would also be installed in other areas of the South Belridge field.

Electrical System Upgrades

Electrical system upgrades will be required to supply electricity to the new facilities. This includes approximately 5,700-feet of 115 kiloVolt (kV) overhead transmission lines from the existing electrical supply grid to two new electrical substations located adjacent to each of the CO_2 capture facilities. Additionally, approximately 13,000 feet of new 12 kV overhead distribution powerlines would extend from the proposed electrical substations to each CO_2 capture facility.

Access Roads

No new roads are proposed as part of the Project. Existing lease roads would be utilized whenever feasible to access the proposed Project areas. Aera Energy will maintain and repair existing roads within the North Belridge Oil Field to provide safe and efficient access to the injection wells and pipelines.

1.2.5 Water Usage

Commercial water demand for the Project CO_2 capture facilities is expected to be on average 1,223 afy (26,000 barrels per day). Water demands for the CO_2 capture facilities will be supplied by treated produced water from the Belridge Oil Field, and SWP water will only be used if sufficient water is

allocated under Aera Energy's water rights. Groundwater would be minimally used as potable water to control rooms, fire/emergency supply as needed, facility housekeeping, and chemical dilution. Water usage during construction, primarily for dust-suppression purposes, is not expected to exceed 400 af. Fresh water demands for the Project are anticipated to be purchased from existing BWSD SWP entitlements and other existing long-term water contracts with individuals and delivered to the Project Area via BWSD's 415 North Canal and/or 500 Canal and existing pipeline. Aera also has approximately 7,000AF of surplus SWP water stored in various groundwater banking projects through the BWSD that may be accessed at any time, subject to the groundwater banking project's pumping capacity. Domestic water demands estimated at 21.72 afy, will be supplied by Aera's two existing groundwater wells in the BVWSD.

1.2.6 Water Storage Tanks

Existing water storage tanks would be utilized for the proposed Project.

1.3 ANNUAL SEQUESTRATION

It is anticipated that the proposed Project would capture and sequester up to 1.6 million metric tonnes of CO_2 per year beginning in 2027 and will contribute to California's goal of carbon net-neutrality by 2045 (Governor's Executive Order B-55-18) by reducing industrial CO_2 emissions.

1.4 CONSTRUCTION ACTIVITIES

The construction period for the Project, from site preparation through construction, testing, and commercial operation, could commence as early as Q1 2025 and would extend for approximately 2.5 years.

Construction of the facility would include the following activities:

- Site preparation;
- Well construction;
- Well abandonments;
- Grading and earthwork;
- Concrete foundations;
- Facility construction;
- Pipeline construction;
- Electrical/instrumentation work;
- Utility connections; and
- Road maintenance.

Construction traffic and operations-related tanker traffic would likely use SR 33 to access the site via Seventh Standard Road. Construction traffic would access the site from SR 33 at existing facility entrances, and Seventh Standard Road. It is estimated that up to 300 workers per day (during peak construction periods) would be required during the construction of the Project.

Construction is expected to primarily occur between 6:00 AM and 5:00 PM, Monday through Friday. Additional hours may be necessary to make up schedule deficiencies or to complete critical construction activities. Some activities may continue 24 hours per day, seven days per week. Well drilling activities will occur 24-hours per day for a period of approximately two weeks per well.

Materials and supplies would be delivered to the Project Area by truck. Truck deliveries would normally occur during daylight hours; however, there may be offloading and/or transporting to the Project Area on weekends and during evening hours.

Earth-moving activities are expected to be limited to the construction of the access roads, well pad preparation, facility pad preparation, and substations. Final grading may include revegetation with low-lying grass or applying earth-binding materials to disturbed areas.

1.5 WORK FORCE

Once the Project is constructed, maintenance would generally be limited to the following:

1. Monitoring CO_2 injection activities;
2. Injection well work-overs;
3. Providing site security; and
4. Facility maintenance.

It is expected that the project would require an operational staff of up to ten full-time employees. The proposed Project would utilize maintenance staff that are currently employees within the South Belridge Oil Field.

The facility would operate seven days a week, 24 hours a day. Maintenance activities may occur seven days a week, 24 hours a day to ensure continuous operations.

1.6 PROJECT FEATURES AND BEST MANAGEMENT PRACTICES

The following sections describe standard Project features and best management practices that would be applied during construction and long-term operation of the Project to maintain safety and minimize or avoid environmental impact.

1.6.1 Waste and Hazardous Materials Management

The Project would have minimal levels of materials onsite that have been defined as hazardous under 40 Code of Federal Regulations, Part 261. The following materials are expected to be used during the construction, operation, and long-term maintenance of the Project:

- Insulating oil for electrical equipment;
- Lubricating oil for maintenance vehicles;
- Various solvents and detergents for equipment cleaning; and
- Gasoline/Diesel for maintenance vehicles.

Hazardous materials and wastes would be managed, used, handled, stored, and transported in accordance with applicable local and state regulations. All hazardous wastes would be maintained at quantities below the threshold requiring a Hazardous Material Management Program: one 55-gallon drum. Though not expected, should any on-site storage of hazardous materials exceed one 55-gallon drum, a Hazardous Material Management Plan would be prepared and implemented.

1.6.2 Spill Prevention and Containment

Hazardous materials would be stored on-site and provided with secondary containment. Spill prevention and containment for construction and operation of the Project would adhere to the EPA's guidance on Spill Prevention Control and Countermeasures Plan and hazardous materials business plan requirements.

1.6.3 Wastewater/Septic System

Existing available domestic water and septic systems are available at existing buildings. Domestic water for the two new control rooms will be supplied by Aera's two existing groundwater production wells located in the Buena Vista Water Storage District (BVWSD). New septic systems or holding tanks will be installed at the new control rooms.

1.6.4 Inert Solids

Inert solid wastes resulting from construction activities may include recyclable items such as paper, cardboard, solid concrete and block, metals, wire, glass, type 1-4 plastics, drywall, wood, lubricating oils and food wastes. Non-recyclable items include insulation, other plastics, vinyl flooring and base, carpeting, paint containers, packing materials, and other construction wastes. A construction waste management plan would be prepared for review by Kern County. Consistent with local regulations and the California Green Building Code, the plan would provide for diversion of a minimum of 50 percent of construction waste from landfill.

Chemical storage tanks (if any) would be designed and installed to meet applicable local and state regulations. Any wastes classified as hazardous, such as solvents, degreasing agents, concrete curing compounds, paints, adhesives, chemicals, or chemical containers, would be stored in an approved storage facility/shed/structure and disposed of as required by local and state regulations. Material quantities of hazardous wastes are not expected.

1.6.5 Health and Safety

Safety precautions and emergency systems would be implemented as part of the design and construction of the Project to ensure safe and reliable operation. Administrative controls would include classroom and hands-on training in O&M procedures, general safety items, and a planned maintenance program. These would work with the system design and monitoring features to enhance safety and reliability.

The Project would have an emergency response plan (ERP). The ERP would address potential emergencies including chemical releases, fires, and injuries. All employees would be provided with communication devices, cell phones, or radios to provide aid in the event of an emergency.

1.7 CLIMATE

The southern San Joaquin Valley region has a semi-arid climate that is characterized by hot, dry summers and cool dry winters. Most of the annual precipitation occurs during the period from November through April. The average minimum and maximum annual temperatures are 49.4 and 77.5 degrees Fahrenheit (°F), respectively, although it is not unusual for the maximum daily temperature to exceed 100 °F in summer (Table 2).

Table 2: Average Monthly Precipitation, Evapotranspiration and Temperature

Month	Average Monthly Precipitation (inches)	Average Monthly Evapotranspiration (inches)	Average Minimum and Maximum Monthly Temperature (°F)	
January	0.94	1.49	36.8	58.5
February	0.73	2.40	40.0	64.7
March	0.71	4.15	43.6	69.9
April	0.70	5.62	47.1	75.5
May	0.24	7.49	52.9	83.6
June	0.03	8.22	59.1	91.7
July	0.07	8.40	63.7	97.4
August	0.01	7.59	62.4	96.4
September	0.09	5.77	58.6	91.1
October	0.18	3.90	50.2	80.0
November	1.09	2.10	41.3	67.4
December	2.15	1.07	37.1	54.2
Annual	6.93	58.20	49.4	77.5

Notes:

°F = degrees Fahrenheit

Source: California Irrigation Management Information System (CIMIS) data for Station 146, Belridge; Calendar Year 1999 – 2022.

California has experienced three declared droughts in the last three decades. In 1976, the state received an average of only 7.4 inches of rain. Until recently, the drought of 1987–1992 was considered the most severe drought in California's history. However, the severity of that drought period has been eclipsed by the historic drought experienced from 2011–2016 and the most recent drought that occurred between 2020 and 2022. Conversely, these drought periods are often offset by periods of intense rainfall that can lead to flooding (e.g., WY2022-2023). This extreme climatic variability is common throughout California.

2.0 WATER SUPPLY PLANNING UNDER SENATE BILL 610

Senate Bill (SB) 610 was passed into law on January 1, 2002. This legislation identified the need to incorporate water supply and demand analysis at the earliest possible stage in the planning process. SB 610 amended portions of the Water Code, including Section 10631, which contains the Urban Water Management Planning Act, as well as adding Sections 10910, 10911, 10912, 10913, and 10915, which describe the required elements of a WSA.

A WSA is designed to build on the information that is typically contained in an Urban Water Management Plan (UWMP). The amendments to Water Code Section 10631 were designed to make WSAs and UWMPs consistent. A key difference between WSAs and UWMPs is that UWMPs are required to be revised every five years, in years ending with either zero or five, while WSAs are required as part of the environmental review process for each individually qualifying Project. Not all providers who prepare a WSA are required to prepare an UWMP.

A companion bill (SB 221) was also passed at the same time as SB 610. This law requires that approval by a city or county of certain residential subdivisions, as defined by California Government Code Section 66473.7(a)(1), must include an affirmative written verification of sufficient water supply. SB 221 is designed as a fail-safe mechanism to ensure that collaboration on identifying water supplies to serve a new large subdivision occurs early in the planning process. This verification must also include documentation of historical water deliveries for the previous 20 years, as well as a description of foreseeable impacts on the availability of water resources in the region of the proposed subdivision.

2.1 WATER SUPPLY ASSESSMENT

The WSA process involves answering the following questions:

- Is the Project subject to CEQA?
- Is it a Project under SB 610?
- Is there a public water system?
- Is there current UWMP that accounts for the Project demand?
- Is groundwater a component of the supplies for the Project?
- Are there sufficient supplies available to serve the Project over the next 20 years?

2.1.1 Is the Project Subject to CEQA?

The first step in the WSA process is determining whether the Project is subject to CEQA. SB 610 amended Public Resources Code Section 21151.9 to read, “Whenever a city or county determines that a Project, as defined in Section 10912 of the Water Code, is subject to this division [i.e., CEQA], it shall comply with part 2.10 (commencing with Section 10910) of Division 6 of the Water Code.”

Conclusion: *The proposed Project will undergo environmental review pursuant to the requirements of CEQA; therefore, the information contained in this assessment would be used to support the analysis contained in the CEQA document.*

2.1.2 Is It a Project Under Senate Bill 610?

The second step in the SB 610 process is to determine if a Project meets the definition of a "Project" under Water Code Section 10912 (a). Under this section, a "Project" is defined as meeting any of the following criteria:

- A proposed residential development of more than 500 dwelling units;
- A proposed shopping center or business establishment employing more than 1,000 persons or having more than 500,000 square feet of floor space;
- A commercial building employing more than 1,000 persons or having more than 250,000 square feet of floor space;
- A hotel or motel with more than 500 rooms; and
- A proposed industrial, manufacturing, or processing plant, or industrial park, planned to house more than 1,000 persons, occupying more than 40 acres of land, or having more than 650,000 square feet of floor area.

The proposed Project would occupy approximately 13,242 acres of land and therefore is considered a Project under Section 19012(a) of the Water Code.

Conclusion: *The proposed Belridge CCS Project meets the definition of a "Project" under Water Code Section 10912(a).*

2.1.3 Is There a Public Water System?

The third step in the WSA process is determining if there is a "public water system" to serve the Project. Section 10912 (c) of the Water Code states, "[A] public water system means a system for the provision of piped water to the public for human consumption that has 3,000 or more service connections."

Conclusion: *Aera's two existing groundwater wells in the BVWSD will provide domestic water supplies to the Project. The Aera wells represent a small non-transient non-community public water system in the Project vicinity serving domestic water supplies to an estimated population of 1,500 through 17 commercial and industrial service connections (https://sdwis.waterboards.ca.gov/PDWW/JSP/WaterSystemDetail.jsp?tinwsys_is_number=1356&tinwsys_st_code=CA&wsnumber=CA1500495). The Aera wells deliver treated domestic water from two active groundwater production wells, Wells 9 and 10. The production capacity of the two wells is 707.48 afy. Historical water demand in the water system over the past five years was 685.93 afy. Projected water demand is estimated to be 690.50 afy which includes the Project domestic water demand.*

2.1.4 Is There a Current UWMP That Accounts for the Project Demand?

Step four in the WSA process involves determining if there is a current UWMP that considers the projected water demand for the Project. The Water Code requires that all public water systems providing water for municipal purposes to more than 3,000 customers, or supplying more than 3,000 afy, must prepare an UWMP, and this plan must be updated at least every 5 years on or before December 31, in the years ending in five and zero. Water Code Section 10910 (c) (2) states, "If the projected water demand associated with the proposed Project was accounted for in the most recently adopted urban water management plan, the public water system may incorporate the requested information from the UWMP in preparing the elements of the assessment required to comply with subdivisions (d), (e), (f), and (g) [i.e., the WSA]."

Conclusion: *Aera's two groundwater wells are located in the BVWSD service area; however, owing to its small number of service connections, 17, and 707.48 afy production capacity from the water system's two wells, it does not meet the minimum requirements for the preparation of an UWMP.*

The BWSD prepared a 2020 AWMP (BWSD, 2021) pursuant to Water Code Section 10826 and Executive Order B-29-15. BWSD currently has a SWP Table A Entitlement of 121,508 af which is allocated as follows (BWSD, 2021):

- *Agricultural Entitlement = 111,157 af*
- *Industrial Entitlement = 5,578 af*
- *Operational Water Losses = 4,773 af*

SWP and supplemental water deliveries by the BWSD between WY1986 and WY2015 based on CV2SimFG-Kern simulations ranged from 79,387 af in 1998 to 143,146 af in 1997 (Todd, 2020) in GEI (2022). Between 2016 and 2020, SWP and supplemental water deliveries by BWSD for agricultural irrigation ranged between 82,958 and 89,333 af and averaged 86,150 af (BWSD, 2021). Over the same time period, SWP and supplemental water deliveries by BWSD for industrial use at the South Belridge Oil Field and North Belridge Oil Field ranged from 587 to 1,077 af and averaged 885 af (BWSD, 2021). BWSD allows its supply contractors the option to pay to temporarily store the surplus water in the Berenda Mesa and/or Pioneer groundwater banking projects that are operated by the Kern County Water Agency (KCWA) (BWSD, 2021). As of 2020, BWSD had stored approximately 85,000 af in these banking projects (BWSD, 2021).

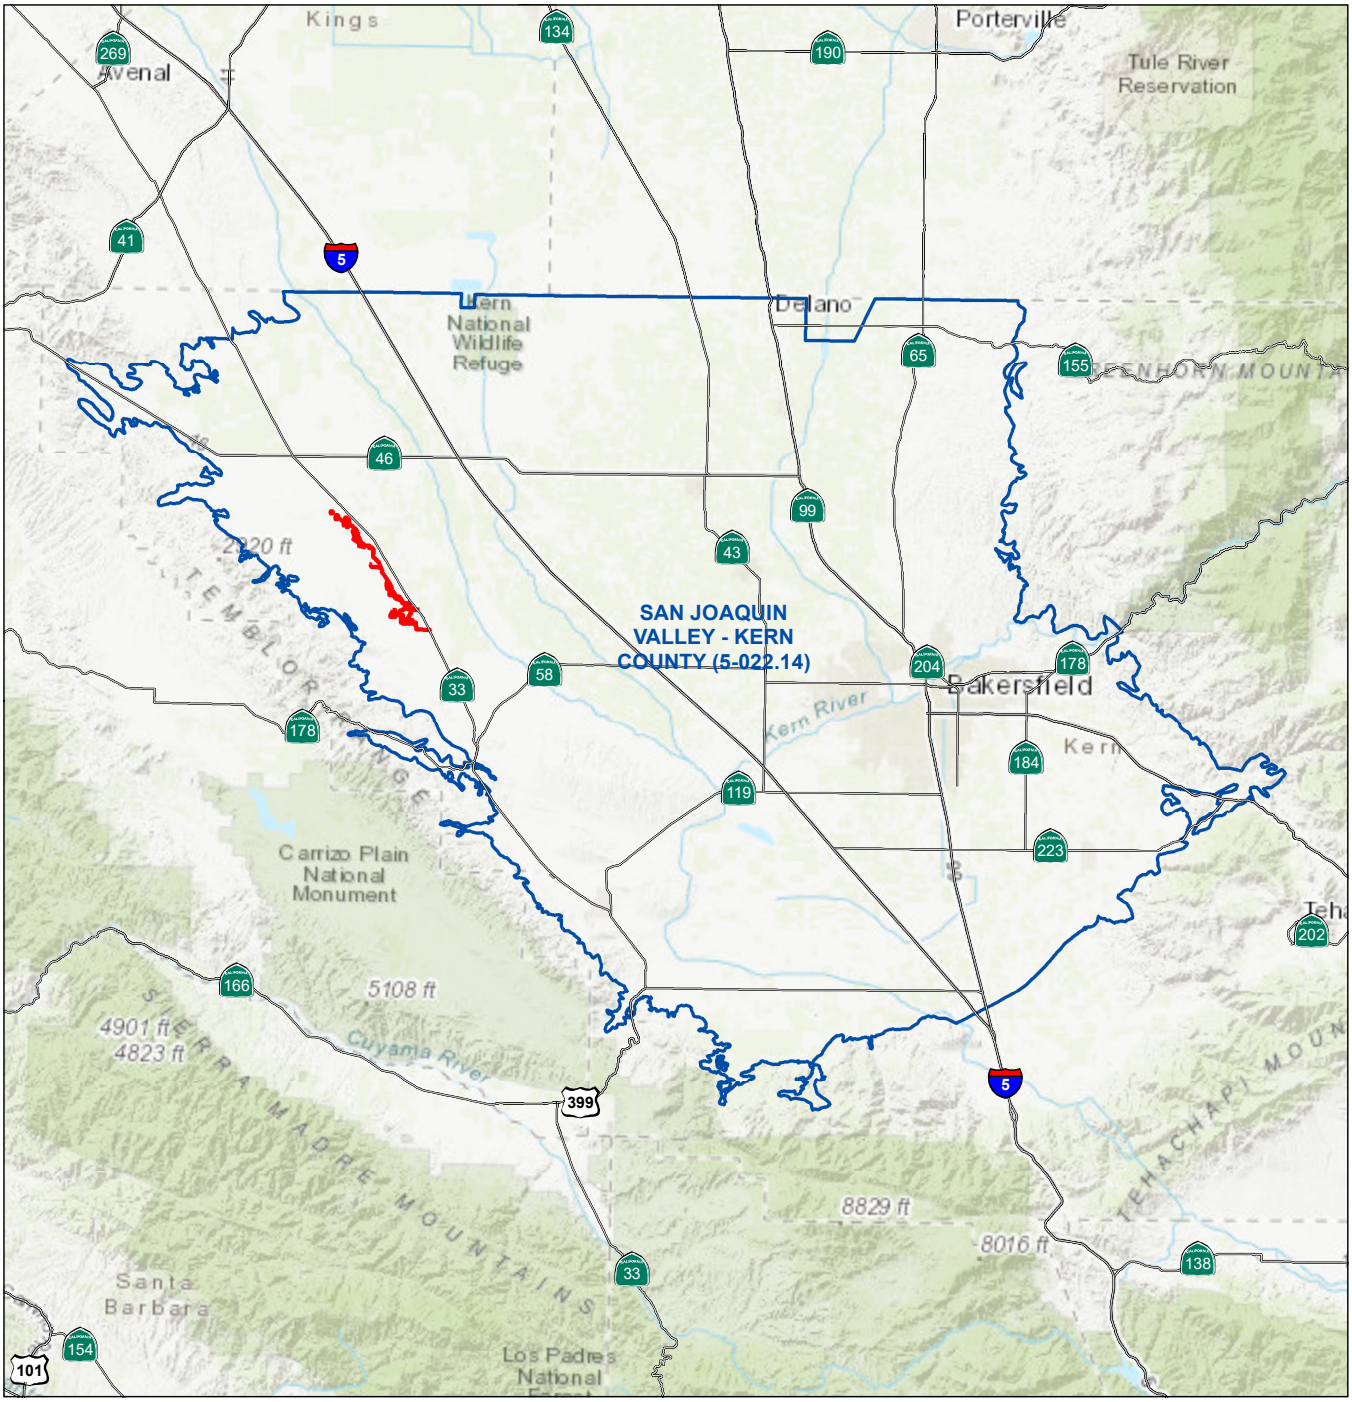
Regulatory restrictions or limitations in SWP Table A Entitlements that impact the amount of SWP water deliveries to BWSD include Endangered Species Act and Sacramento-San Joaquin Delta Biological Opinions by the U.S. Fish and Wildlife Service and National Marine Fisheries Service and water quality limitations promulgated by the State Water Resource Control Board. SWP water delivery restrictions also occur by the DWR for facility maintenance (BWSD, 2021). Climactic conditions such as dry years and extending to multi-year droughts limit the amount of SWP available for delivery.

2.1.5 Is Groundwater a Component of the Supplies of the Project?

This section addresses the requirements of the Water Code Section 110910 (f), paragraphs 1 through 5, which apply if groundwater is a water source for a proposed Project. Pursuant to Water Code Section 10910 (f), the groundwater analysis presented in this analysis focuses on the Kern County Subbasin (Subbasin) of the San Joaquin Valley Groundwater Basin (Figure 2).

Groundwater from Aera's water system will be used to provide domestic water supplies to the Project. The estimated annual commercial domestic water demand for the Project is 21.72 af which will be pumped from Aera's two production wells located in the Subbasin. According to DWR (2006), the Subbasin is located in the southernmost portion of the San Joaquin Valley Groundwater Basin within the southern portion of the Great Valley Geomorphic Province of California (California Geological Survey, 2002). The Great Valley is approximately 400 miles long and up to 70 miles wide in the central portion of the state. The northern third of the Great Valley is occupied by the Sacramento Valley. The southern two-thirds of the Great Valley is occupied by the San Joaquin Valley and is more than 250 miles long and between 20 and 55 miles wide (Burow, et al., 2004). The Great Valley is a northwest trending structural asymmetric trough with the axis located along the western portion of the valley. The San Joaquin Valley is filled with up to 6 miles (32,000 feet) of Jurassic to Holocene marine and continental (i.e., nonmarine) sedimentary deposits (Page, 1986). The San Joaquin Valley extends from the Sacramento-San Joaquin Delta/Stockton Arch on the north to the San Emigdio and Tehachapi Mountains on the south. It is bound on the east by the Sierra Nevada Mountains and on the west by the Coast Ranges, locally named the Temblor Range. Major streams in the San Joaquin Valley drain the western flank of the Sierra Nevada Mountains and include from south to north, the Kern River, Kings River, San Joaquin River and its major tributaries: Fresno, Chowchilla, Merced, Tuolumne, Stanislaus, Calaveras, Mokelumne and Cosumnes Rivers. The San Joaquin River discharges northward into the Sacramento-San Joaquin Delta. The Kern and Kings Rivers discharge internally onto the valley floor.

The Subbasin is bounded on the west by the Temblor Range, on the north by the Kings and Tulare County lines, on the east by the Sierra Nevada Mountains and on the south and southeast by the San Emigdio and Tehachapi mountains, respectively.



Average annual rainfall in the Subbasin averages about 7 inches. Surface water in the Subbasin drains westward from the Sierra Nevada Mountains, eastward from the Temblor Range, and northward from the Tehachapi and San Emigdio mountains. All watersheds that drain the bordering highlands discharge onto the valley floor. Major watersheds in the Subbasin that drain the Sierra Nevada Mountains include from north to south Poso Creek and the Kern River. Major watersheds that drain the Tehachapi Mountains include Caliente Creek and Tejon Creek. Major watersheds that drain the San Emigdio Mountains include from east to west Pleito Creek, San Emigdio Creek and Santiago Creek. There are numerous small watersheds, but no major watersheds in the Subbasin that drain the Temblor Range. Other than the Kern River, most Subbasin streams are ephemeral except during above normal and wet water years (GEI, 2022).

Flow in the Kern River is regulated by Isabella Lake Dam located about 40 miles northeast of Bakersfield to mitigate flooding and store water for agricultural, municipal and industrial uses. Lake Isabella provides

recreational opportunities. Portions of the discharges from the dam provide hydroelectric power. Once on the valley floor, streamflow in the Kern River is largely diverted for the above-mentioned uses while the residual streamflow percolates into the riverbed.

Construction water demand for the Project of approximately 400 af (Aera, 2022a) would be met by surface water deliveries from BWSD from the California Aqueduct. Commercial water demands averaging up to 1,223 afy will be supplied by produced water from the Belridge Oil Field, and SWP water will only be used if sufficient water is allocated under Aera Energy's water rights. BWSD imported water supplies would be delivered to the Project via the Industrial System that is owned and operated by the industrial Water Users including the Applicant and other South Belridge Oil Field and North Belridge Oil Field operators. The Industrial System consists of a pumping plant at BWSD Turnout No. 5 (Bel 5) on the California Aqueduct, and associated pipeline that conveys untreated SWP and supplemental water to the Industrial Zone (i.e., oil fields) (BWSD, 2021). Aera also has approximately 7,000AF of surplus SWP and Kern River water stored in various groundwater banking projects through the BWSD that may be accessed at any time, subject to the groundwater banking project's pumping capacity. As noted above, domestic water demands estimated at 21.72 afy will be provided by two existing groundwater production wells that comprise Aera'swater system.

Conclusion: *Groundwater from two existing groundwater production wells that comprise Aera's water system will be used to provide domestic water supplies to the Project.*

Groundwater Basin Description

The DWR has divided the State into ten hydrologic regions which have been further divided into groundwater basins and subbasins. The Subbasin is located within the San Joaquin Valley Groundwater Basin in the Tulare Lake Hydrologic Region. The Subbasin is underlain by Tertiary and Quaternary-aged unconsolidated non-marine/continental deposits and older Tertiary marine deposits. These deposits thicken toward the axis of the San Joaquin Valley, which in the Subbasin, extends northward beneath and along the western portion of the valley floor and forms an asymmetric trough (Bartow, 1991). Surficial alluvial deposits are generally coarser grained emanating from crystalline rock source areas such as those that comprise the Sierra Nevada, Tehachapi and San Emigdio mountains, but are finer grained near the Temblor Range which is underlain by sedimentary rocks. The alluvial deposits become finer grained with distance from their respective source areas culminating in a series of playa lakes including Kern Lake and Buena Vista Lake. These lakes were formed at the terminus of the Kern River prior to agricultural development in the mid-1800s and the establishment of riparian water rights of the Kern River beginning in the late-1800s which diverted upstream river flows.

Principal freshwater groundwater bearing units in the Subbasin include the following (GEI, 2022a):

- Younger alluvium and flood plain deposits (shallow unconfined aquifer);
- Older Alluvium (unconfined aquifer);
- Tulare Formation (semiconfined/confined aquifer); and
- Kern River Formation (unconfined/semiconfined).

Other locally important groundwater bearing units include the Santa Margarita Sandstone and Olcese Sand in the eastern and northeastern portions of the Subbasin (GEI, 2022a).

The Plio-Pleistocene non-marine Tulare Formation occurs in the central and western portions of the Subbasin and attains a maximum thickness of 2,200 feet (GEI, 2022a). The formation is separated into an upper and lower portion by a confining clay layer called the Corcoran Clay (Croft, 1972) or modified E-clay (Page, 1986). The upper aquifer is unconfined to semiconfined. The lower aquifer is confined. The Corcoran Clay extends from the western to the central portion of the Subbasin. The thickness of the Corcoran Clay ranges between 20 and 100 feet but is typically 10 to 30 feet thick (GEI, 2022).

The Mio-Pliocene to early Pleistocene Kern River Formation occurs along the eastern to central portion of the Subbasin and was derived from erosion of the Sierra Nevada Mountains (GEI, 2022a). The Kern River Formation attains a maximum thickness of 2,600 feet (Bartow and Pittman, 1983). The aquifer is largely unconfined although thin aquitards in the central portion of the Subbasin locally creates semiconfined conditions.

Older alluvial deposits of Pleistocene-age overlie the Tulare and Kern River formations and attain a maximum thickness of 250 feet. These deposits are often indistinguishable from the underlying Tulare and Kern River formations (DWR, 2006). The aquifer is unconfined. The Holocene-age younger alluvium and floodplain deposits are up to 150-feet thick and varies on lithology across the Subbasin. They are

generally coarser grained near the Subbasin boundaries and become finer grained toward the basin bottom where they underlie Kern and Buena Vista Lake beds (GEI, 2022a).

In the Project Area, the Tulare Formation is overlain by the Corcoran Clay Equivalent over most of the South Belridge Oil Field and in the southeastern portion of the North Belridge Oil Field (Gillespie et al, 2019; Aera, 2017). Alluvium overlies the Tulare formation in the South Belridge Oil Field but has been largely removed by erosion in the North Belridge Oil Field exposing the Tulare Formation (Dibblee, 2006a, 2006b). The Tulare Formation is partially saturated beneath the Project Area and is a source of produced water where wells extract oil from this formation. The alluvium in the eastern portion of the SBOF contains perched groundwater in up to two thin aquifers (Aera, 2022b), however, it is not utilized for water supply. Groundwater flow in the alluvium and Tulare formation is to the east and northeast (Aera, 2019). Most of the Project Area is within a California Geologic Energy Management Division-designated Tulare Aquifer Exemption Area (USEPA, 2020).

Groundwater production in the Subbasin for WY1995-WY2014 (current condition) is estimated to be 1,590,373 afy based on the CV2SimFG-Kern groundwater model simulation (Todd, 2020) in GEI (2022). Groundwater production in the WDWA during the same period is estimated to be 3,000 afy (Aquilogic, 2022) and 10,276 in 2020 based on the 2020 AWMPs for BWSD, BMWD and the LHWD (BWSD, 2021; BMWD, 2021; LHWD, 2021). Pumped groundwater is used for blending with SWP water due to the natural poor quality of groundwater for most beneficial uses (Aquilogic, 2022), and the reduced reliability of SWP water supplies (BWSD, 2021; BMWD, 2021; LHWD, 2021). Projected groundwater production in the WDWA and the Subbasin is projected to increase to 25,400 (Aquilogic, 2022) and 1,648,770 afy (Todd, 2020) in GEI (2022a), respectively, from WY2021 to WY2040, the latter, based on the CV2SimFG-Kern 2070 climate change and implementation of projects and management actions scenario. Groundwater production in the BVGSA plan area for WY1993 to WY2015 is estimated to be 62,742 afy (GEI, 2022b).

Estimations of the total storage capacity of the Subbasin were reported in DWR (2006) based on data in 2002 to be 40,000,000 af (KCWA, 2002). The dewatered storage at this time was also reported to be 10,000,000 (KCWA, 2002). The estimated amount of groundwater in storage from WY1995 to WY2014 in the WDWA is 42,400,000 af (Aquilogic, 2022). However, this latter estimate appears to more closely coincide with the estimated storage capacity of the Subbasin, not the WDWA, as noted above (DWR, 2006; KCWA, 2002).

Change in groundwater in storage in the Subbasin between WY1995 and 2014 is estimated to have declined by 5,542,280 af based on an annual decline of 277,114 afy (GEI, 2022a; Todd, 2020). Change in groundwater in storage in the Subbasin between WY1995-2021 is estimated to yield a decline of 1,812,211 af based on an annual decline of 69,700 afy (Todd, 2020) in GEI (2022a). The projected average and cumulative change in groundwater in storage in the Subbasin from WY2021 to WY2040 is a decline of about 224,286 afy and 4,485,720 af, respectively (Todd, 2020) in GEI (2022a), using the CV2SimFG-Kern groundwater model under the 2070 climate change and implementation of projects and management actions scenario. The estimated change in groundwater in storage in the WDWA is estimated to be 46,000 afy using the CV2SimFG-Kern groundwater model simulation and about 22,000 afy by Aquilogic (2022), based on assumed modeling discrepancies related to the amount of groundwater production using the CV2SimFG-Kern groundwater model simulation. The estimated cumulative and annual decline in

groundwater in storage in the BVGSA between WY1993 and WY2015 is 275,480 af and 11,977 afy, respectively (GEI, 2022b). The estimated annual change in groundwater in storage between WY1995 and WY2014 using the C2VSimFG-Kern groundwater model is -17,362 afy (Todd, 2019)

Groundwater recharge in the Subbasin and the WDWA between WY1995 and WY2014 is estimated to be 1,400,362 afy (Todd, 2020) in GEI (2022a) and 92,341 afy based on groundwater model simulation using CV2SimFG-Kern (Aquilogic, 2022). The estimated WY1995-WY2014 sustainable yield in the Subbasin and the WDWA plan area is 1,313,260 afy based on groundwater recharge and outflow (Todd, 2020) in GEI (2022a) and 34,079 afy (Aquilogic, 2022), respectively.

Groundwater quality within the Subbasin is generally good for most beneficial uses and is supplemented with imported SWP, Central Valley Project water and Kern River diversions. However, in the WDWA, groundwater quality is characterized by mostly elevated Total Dissolved Solids (TDS), sulfate and chloride concentrations occurring above California Secondary Drinking Water Maximum Contaminant Levels (SMCLs) of 500 milligrams per liter (mg/l), 250 mg/l and 250 mg/l, respectively (Aquilogic, 2022). Moreover, the TDS concentrations throughout the WDWA often exceed 1,000 mg/l and are considered brackish or saline at higher concentrations. In addition, arsenic occurs locally in groundwater at concentrations exceeding the California Primary Drinking Water MCLs of 10 micrograms per liter (ug/l, Aquilogic, 2022). Although Boron does not have a California or Federal drinking water MCL, California does have a Notification Level of 1,000 ug/l and an agricultural goal of 700 ug/l. Boron concentrations in groundwater in the WDWA largely exceed both the Notification Level and the agricultural goal. Owing to the elevated TDS, chloride, sulfate and boron concentrations groundwater use in the WDWA is primarily used for blending with SWP water for agricultural irrigation (Aquilogic, 2022; BWSD, 2021; BMWD; LHWD, 2021).

Groundwater quality in the BVGSA is variable with TDS concentrations in the northern portion of the plan area greater than 1,500 mg/l and less than 1,000 mg/l in the southern portion of the plan area (GEI, 2022b). Nitrate (as N) concentrations are generally less than 10 mg/l except in the northernmost portion of the plan area where it exceeds 20 mg/l (GEI, 2022b). Arsenic concentrations locally exceed the Primary Drinking Water MCL of 10 ug/l throughout the plan area (GEI, 2022b).

BVWSD is entitled to 156,000 afy of surface water from the Kern River; however, during the period 2006 to 2015 Kern River deliveries via the East Side Canal averaged 40,887 afy. BVWSD is also contracted with the KCWA to receive 21,300 afy of Table A SWP water and 3,750 afy of Article 21 SWP water. During the period 2006 through 2015, BVWSD received an average of 53,099 afy of SWP water via the California Aqueduct (GEI, 2022b). Average surface water deliveries from 2006 to 2015 averaged 93,986 afy. Estimated 2020 and 2040 surface water deliveries to the BVWSD are not individually provided in the BVGSA GSP chapter (GEI, 2022b) or the KGA “Umbrella” GSP (GEI, 2022a). According to the BVGSA GSP (GEI, 2022b), under the 2070 climate change factor, BVGSA has estimated a reduced Kern River entitlement of 147,000 af in 2040, a reduced SWP Table A entitlement of 9,642 afy and a slightly increased Article 21 SWP entitlement of 3,900 afy in 2040.

Groundwater Management

In November 2009, the Governor signed into law SBx7-6, which established the California Statewide Groundwater Elevation Monitoring (CASGEM) Program. Groundwater level data entered into DWR's online CASGEM reporting system by monitoring entities beginning in January 2012 were used to establish groundwater basin prioritization as part of the enactment of the SGMA of 2014. Enactment of the SGMA amended Water Code Section 10720 *et al*. in an effort to provide a statewide system for the sustainable management of groundwater. For medium- and high-priority groundwater basins, SGMA requires the designation of a GSA. GSAs have broad groundwater management powers. For example, GSAs may require groundwater well registration, measurement of groundwater extractions, and filing of annual extractions reports.

The SGMA authorizes GSAs to regulate groundwater extractions by imposing well spacing requirements, limiting extractions, and establishing extraction allocations. The legislation does not apply to adjudicated groundwater basins that are managed by the courts or to basins deemed by DWR to be low priority. The SGMA requires GSAs to adopt GSPs for medium- and high-priority basins. These plans must set the groundwater basin on a course toward sustainable management to eliminate adverse groundwater conditions specified as undesirable results. The law allows a local agency that has, "water supply, water management, or land use responsibilities within a groundwater basin, to elect to be a GSA." The Subbasin has been designated by DWR as a critically overdrafted high-priority basin by the DWR (https://gis.water.ca.gov/app/bp-dashboard/final/# accessed January 8, 2022).

Five GSPs representing 11 GSAs were submitted to DWR as required under the SGMA. The five GSPs were prepared by a combined 11 GSAs and included 16 member agencies in the Kern Groundwater Authority (KGA) GSP to sustainably manage the Subbasin under the SGMA. The Project Area is located within the WDWA plan area of the KGA GSP (Aquilogic, 2022; GEI, 2022). A GSP chapter was prepared for the WDWA by Aquilogic (2022), a member agency of the KGA. The WWDA includes the BWSD, BMWD and LHWD in northwestern Kern County (GEI, 2022, Aquilogic, 2022). Aera's water system is located in the BVWSD which coincides with the BMA in BVGSA. A GSP chapter was prepared for the BVGSA by GEI (2022b), also a member agency of the KGA.

Note: *A combined 11 GSAs were formed in the Subbasin and five GSPs were submitted to DWR. Groundwater management in the Project Area is governed by the KGA GSA.*

Governance and Local Control

The SGMA requires that all high- and medium-priority groundwater basins must establish governance under one or more GSAs by June 30, 2017. GSAs for high- and medium-priority basins must adopt their GSP by January 31, 2022. GSAs for critically overdrafted high-priority basins must adopt their GSP by January 31, 2020. Low-priority basins are not required to prepare a GSP.

The Subbasin is designated under CASGEM as a "critically overdrafted high-priority" groundwater basin. Five GSPs representing 11 GSAs submitted their GSPs to DWR in January 2020. Based on DWR comments to the GSPs, revised GSPs were submitted by the GSAs to DWR in July 2022 (GEI, 2022). On March 2, 2023, DWR deemed the revised KGA GSP (GEI, 2022a) as "inadequate" and jurisdiction of the

GSP was transferred to the State Water Resources Control Board to assist the GSAs in the correction of previously identified deficiencies and possible placement in probationary status.

Conclusion: *The Subbasin has been designated as a critically overdrafted high-priority basin. Five GSPs representing 11 GSAs were submitted to DWR in January 2020. Based on DWR comments to the GSPs, revised GSPs were submitted to DWR in July 2022. On March 2, 2023, DWR deemed the revised KGA GSP (GEI, 2022a) as "inadequate" and jurisdiction of the GSP was transferred to the State Water Resources Control Board to assist the GSAs in the correction of previously identified deficiencies and possible placement in probationary status.*

Groundwater Sustainability Plans

GSPs must include minimum thresholds and measurable objectives to achieve the goal of groundwater basin sustainability within 20 years of GSP implementation. The SGMA defines GSPs that achieve sustainable groundwater management by ensuring that the applicable basin is operated within the sustainable yield. Sustainable yield is defined as the maximum quantity of water that can be withdrawn over a period of years without causing an undesirable result. An undesirable result means one or more of the following effects caused by groundwater conditions occurring throughout the basin:

- Chronic lowering of groundwater levels;
- Significant and unreasonable reduction of groundwater storage;
- Significant and unreasonable seawater intrusion;
- Significant and unreasonably degraded water quality;
- Significant and unreasonable land subsidence that substantially interferes with surface land uses; and/or
- Depletions of interconnected surface water that have significant and unreasonable adverse impacts on beneficial uses of the surface water.

The GSP must include monitoring and management for the basin over a 50-year planning horizon, and plans must articulate measurable objectives to be achieved every 5 years. The DWR will review the plans and will have the power to request changes to a submitted plan. The plan must establish measurable objectives, as well as incremental milestones every 5 years in order to achieve the sustainability goals identified in the plan within 20 years.

As noted above, five GSPs representing 11 GSAs submitted their GSPs to DWR in January 2020. Based on DWR comments to the GSPs, revised GSPs were submitted by the GSAs to DWR in July 2022 (GEI, 2022a). The revised GSPs addressed the six GSP undesirable results and developed a strategy for monitoring five of the six undesirable results. Seawater intrusion was dismissed owing to the considerable distance inland the Subbasin is from a saline water body (e.g., San Francisco Bay and Pacific Ocean). On March 2, 2023, DWR deemed the revised KGA GSP (GEI, 2022a) as "inadequate" and jurisdiction of the GSP was transferred to the State Water Resources Control Board to assist the GSAs in the correction of previously identified deficiencies and possible placement in probationary status.

Conclusion: *The Subbasin has been designated as a critically overdrafted high-priority basin. Five GSPs representing 11 GSAs were submitted to DWR in January 2020. Based on DWR comments to the GSPs,*

revised GSPs were submitted to DWR in July 2022. The GSPs addressed five of the six undesirable results except seawater intrusion, the latter of which is not applicable due to the considerable distance the Subbasin is located from a saline water body. On March 2, 2023, DWR deemed the revised KGA GSP (GEI, 2022a) as "inadequate" and jurisdiction of the GSP was transferred to the State Water Resources Control Board to assist the GSAs in the correction of previously identified deficiencies and possible placement in probationary status.

2.1.6 Are There Sufficient Supplies to Serve the Project Over the Next Twenty Years?

The next step in the WSA process is to prepare the actual assessment of the available water supplies, including the availability of these supplies in all water-year conditions over a 20-year planning horizon and an assessment of how these supplies relate to Project-specific and cumulative demands over that same 20-year period. To be consistent, the analysis horizon of this WSA extends to 2040. Water Code Section 10910 (c)(4) states, "If the city or county is required to comply with this part pursuant to subdivision (b), the water assessment for the Project shall include a discussion with regard to whether the total projected water supplies, determined to be available by the city or county for the Project during normal, single dry, and multiple dry water years during a 20-year projection, will meet the projected water demand associated with the proposed Project, in addition to existing and planned future uses including agricultural and manufacturing uses." Tables 2 and 3 provide future water supply availability for the Project in the Subbasin. The estimates presented in Tables 2 and 3 are based on the Water Year (WY) which is the period October 1 through September 30 of the following year. For WY2020, the period of record is October 1, 2019 through September 30, 2020. The water supply and demand data for WY2020 were taken from *Kern County Subbasin Groundwater Sustainability Plans Second Annual Report Water Year 2020* (Todd, 2021). The water supply and demand data for WY2040 were taken from Attachment H (Todd, 2020) in GEI (2022) and is based on CV2SimFG-Kern groundwater model simulations assuming 2070 climate change conditions and implementation of projects and management actions.

The estimated water demand in the Subbasin in WY2020 is estimated to be 3,075,992 af (Todd, 2021). The projected WY2040 water demand is unknown due to lack of this data in Todd (2020) in GEI (2022a). Current and projected groundwater production in the Subbasin is estimated to be 1,835,054 af in WY2020 (Todd, 2021) and 1,793,459 af in WY2040 (Todd, 2020) in GEI (2022a). Current surface water supplies including imported SWP and CVP water, local streamflow and recycled/reused water is estimated to be 1,405,576 af in WY2020 (Todd, 2021); however, projected WY2040 surface water supplies are unknown due to lack of this data in Todd (2020) in GEI (2022a).

Calendar year 2020 (2020) surface water deliveries in the WDWA plan area, including imported SWP and other surface water and groundwater banking recovery and carryover water, is reported to be 275,522 af based on the 2020 AWMPs for BWSD (BWSD, 2021), BMWD (BMWD, 2021) and LHWD (LHWD, 2021). Projected (calendar year 2040) surface water supplies in the WDWA plan area are estimated to be 266,290 af based on implementation of WDWA plan area-specific projects and management actions (Aquilogic, 2022). 2020 groundwater production in the WDWA plan area of 10,276 af is based on the 2020 AWMPs for BWSD (BWSD, 2021), BMWD (BMWD, 2021) and LHWD (LHWD, 2021). Projected 2040 groundwater production is estimated to be 25,400 af based on implementation of WDWA plan area-

specific projects and management actions number 3c: pumping and reuse of 20,000 afy of brackish groundwater underflow (Aquilogic, 2022). Tables 3 and 4 show future (WY2040) water supply availability in the Subbasin and WDWA Plan Area, respectively.

BVWSD is entitled to 156,000 afy of surface water from the Kern River; however, during the period 2006 to 2015 Kern River deliveries via the East Side Canal averaged 40,887 afy. BVWSD is also contracted with the KCWA to receive 21,300 afy of Table A SWP water and 3,750 afy of Article 21 SWP water. During the period 2006 through 2015, BVWSD received an average of 53,099 afy of SWP water via the California Aqueduct (GEI, 2022b). Average surface water deliveries from 2006 to 2015 averaged 93,986 afy. Estimated 2020, 2030 and 2070 surface water deliveries to the BVWSD are 164,192 af, 161,306 af and 160,864 af, respectively (GEI, 2022b).

Table 3: Future (WY2040) Water Supply Availability in the Subbasin

Current Source	Current Water Year	Single Dry Water Year	Multiple Dry Water Years		
			Year 1	Year 2	Year 3
Groundwater (Subbasin)	1,835,054	1,835,054	1,835,054	1,835,054	1,835,054
Imported Surface Water (SWP and CVP), Local Streamflow, Recycled/Reused Water	1,405,576	1,405,576	1,405,576	1,405,576	1,405,576
Total Supply	3,240,630	3,240,630	3,240,630	3,240,630	3,240,630

Table 4: Future (2040) Water Supply Availability in the WDWA(a) and BVGSA Plan Areas

Current Source (b)	Current (2020) Water Supply (c)	Single Dry Year (d)	Multiple Dry Years (c)		
			Year 1	Year 2	Year 3
Groundwater (WDWA)	10,276	25,400	25,400	25,400	25,400
Groundwater (BVWSD)	62,742	62,742	62,742	62,742	62,742
Imported Surface Water (SWP), Groundwater Banking Recovery Water, and Carryover Water (WDWA)	275,522	266,290	266,290	266,290	266,290
Imported Surface Water (SWP), Kern River Water, and Groundwater Banking Recovery Water (BVGSA)	160,864	160,864	160,864	160,864	160,864
Total Supply	509,404	515,738	515,296	515,296	515,296

Notes:
(a) An estimate of available water supplies in 2040 in the BVGSA is unavailable due to lack of sufficient data in the BVGSA GSP chapter (GEI, 2022b) and KGA Umbrella GSP (GEI, 2022a).
(b) af = acre-feet
(c) WDWA current year (2020) groundwater production and imported surface water deliveries, including groundwater banking recovery and carryover water are based on the 2020 AWMPs for BWSD (BWSD, 2021), BMWD (BMWD, 2021) and LHWD (LHWD, 2021). BVGSA groundwater production estimated based on average annual production over the period WY1993 to WY2015 and estimated 2020 surface water deliveries (GEI, 2022b).

(d) Single and Multiple dry year projections are based on implementation of WDWA plan area-specific projects and management actions number 3c: pumping and reuse of 20,000 afy of brackish groundwater underflow and estimated surface water deliveries (Aquilogic, 2022). Single and multiple dry year projections for surface water deliveries to BVWSD are based on 2070 climate change factors (GEI, 2022b).

Aera's water system currently delivers treated domestic water from two active groundwater production wells, Wells 9 and 10, to industrial and commercial customers. The production capacity of the two wells is 707.48 afy. Historical water demand in the water system over the past five years was 685.93 afy. Projected water demand is estimated to be 690.50 afy which includes the Project domestic water demand. Table 5 presents future (2040) water supply in Aera's water system.

Table 5: Future (2040) Water Supply Availability in Aera's Water System

Current Source	Current (2020) Water Supply	Single Dry Year	Multiple Dry Years		
			Year 1	Year 2	Year 3
Groundwater	685.93	690.50	690.50	690.50	690.50
Total Supply	**685.93**	**690.50**	**690.50**	**690.50**	**690.50**

Notes:
All units in acre-feet

Conclusion: *Groundwater production in the Subbasin and WDWA plan area in WY2020 is estimated to be 1,835,054 af (Todd, 2020) in GEI (2022a). Groundwater production in the WDWA and BVGSA plan areas in 2020 is estimated to be 73,011 af (BWSD, 2021; BMWD, 2021; LHWD, 2021; GEI, 2022b). In 2040, projected groundwater production in the WDWA and BVGSA plan areas is estimated to be 88,142 af (Aquilogic, 2022; GEI, 2022b), which takes into account climate change factors and implementation of projects and management actions number 3 in the WDWA plan area. Surface water deliveries, streamflow diversions and water transfers and exchanges to the Subbasin in WY2020 are estimated to be 1,405,576 af (Todd, 2020) in GEI (2022a). Surface water deliveries in the WDWA plan area in 2020, including SWP and other surface water, and groundwater banking recovery and carryover water are estimated to be 275,522 af based on the AWMPs for BWSD (BWSD, 2021), BMWD (BMWD, 2021) and LHWD (LHWD, 2021). Surface water deliveries in the BVGSA plan area in WY2020 are estimated to be160,864 afy based on 2070 climate change factors (GEI, 2022b). Projected 2040 surface water deliveries in the WDWA plan area re estimated to be 266,290 af (Aquilogic, 2022), which takes into account climate change and implementation of projects and management actions. An estimation of available water supplies in 2040 in the BVGSA is unavailable due to lack of sufficient data in the BVGSA GSP chapter (GEI, 2022b) and KGA Umbrella GSP (GEI, 2022a). Estimated groundwater production in Aera's water system in 2020 is 685.93 af and is projected to increase to 690.50 afy through 2040 once commercial operation of the project commences.*

Project Water Demands

The Project estimates a construction water demand of 400 af over a 2.5-year period which is anticipated to be purchased from existing BWSD SWP entitlements and other existing long-term water contracts with individuals. An annual industrial demand of 1,223 af would be met by treated produced water from the Belridge Oil Field. Aera also has approximately 7,000AF of surplus SWP water stored in various groundwater banking projects through the BWSD that may be accessed at any time, subject to the groundwater banking project's pumping capacity. Domestic water demands estimated at 21.72 afy, will be supplied by Aera's water system, which consists of two production wells. This water demand represents a

de minimis use. It is anticipated that the annual demand will remain constant over the 20-year projection as shown in Table 6.

Table 6: Anticipated Future (2040) Project Water Demand

Land Use Category	Total Acres	Average Water Demand (afy/acre)	Estimated Total Water Demand (afy)
Unincorporated Kern County	13,243	0.092	1,223
TOTAL	13,243	0.092	1,223

Note:
afy = acre-feet per year

Comparison of Available Water Supplies Versus Demand

Section 10910 (c)(3) of the Water Code states, “The water supply assessment for the Project shall include a discussion with regard to whether the public water system’s total projected water supplies available for normal, dry, and multiple dry water years during a 20-year projection will meet the projected water demand associated with the proposed Project, in addition to the public water system’s existing and planned future uses, including agricultural and manufacturing uses.”

As described in *Belridge Water Storage District 2020 Agricultural Management Plan*, (BWSD, 2021), the BWSD has a Table A entitlement of SWP water of 121,508 afy of which 111,157 and 5,578 afy, respectively, are under contract for agricultural and industrial use. The balance, 4,773 afy, is held by BWSD for operational losses. The BWSD has also banked 85,000 af in the Pioneer and Berenda Mesa groundwater banks operated by KCWA. In 2020, surface water deliveries, including imported SWP and other surface water and groundwater banking recovery and carryover water, was reported to be 99,104 af (BWSD, 2021). In 2020, groundwater production in the BWSD was reported to be 1,187 af (BWSD, 2021). BVWSD has a Kern River entitlement of 156,000 afy and a SWP Table A entitlement of 21,300 afy almost all for agricultural use. Although BVWSD has historically stored surplus Kern River and SWP water in various local groundwater banks, the quantity of banked surface water supplies as of 2020 is not available in the BVGSA GSP (GEI, 2022b) or the KGS Umbrella GSP (GEI, 2022a).

In 2020, surface water deliveries, including imported SWP and other surface water and groundwater banking recovery and carryover water totaling 275,522 af was delivered to agricultural and industrial water users in the WDWA (BWSD, 2021; BMWD, 2021; LHWD, 2021). In 2020, groundwater production in the WDWA was 10,276 af (BWSD, 2021; BMWD, 2021; LHWD, 2021). According to the individual 2020 AWMPs for BWSD, BMWD and LHWD, the groundwater was pumped for blending with imported SWP and other surface water supplies due to poor groundwater quality and reduced reliability of SWP water supplies.

In 2020, agricultural and industrial water demands in the BWSD and WDWA plan area were reported to be 128,708 af (BWSD, 2021) and 331,000 af, (BWSD, 2021; BMWD, 2021; LHWD, 2021), respectively.

Tables 7 and 8 present future water supply versus Project water demand in WY2040 based on Attachment H (Todd, 2020) in *Kern Groundwater Authority Groundwater Sustainability Plan* (GEI, 2022a). The projected water budgets presented in GEI (2022a) extend from 2021 to 2070 and take into account

climate change factors and implementation of projects and management actions to sustainably manage groundwater supplies in the Subbasin. It should be noted that the Subbasin GSP water budgets do not quantify water supplies or demands at build-out for any municipality or unincorporated population center in the Subbasin. There are no municipalities in the WDWA and BVGSA plan areas; however, the unincorporated town of Lost Hills is located in the WDWA and the unincorporated town of Buttonwillow is located in the BVGSA. Nevertheless, as shown in Tables 6 and 7 there is ample supply of water available to the Project within the WDWA plan area to meet Project water demands.

Table 7: Future (WY2040) Water Supply Versus Project Water Demand at Build-Out in the Subbasin (a)

Current Source	Current Water Year	Single Dry Water Year	Multiple Dry Water Years		
			Year 1	Year 2	Year 3
Groundwater (Subbasin)	1,835,054	1,835,054	1,835,054	1,835,054	1,835,054
Imported Surface Water (SWP and CVP), Local Streamflow, Recycled/Reused Water	1,405,576	1,405,576	1,405,576	1,405,576	1,405,576
Total Project Demand	1,245	1,245	1,245	1,245	1,245
Total Supply	3,239,385	3,239,385	3,239,385	3,239,385	3,239,385

Note:

(a) All units in acre-feet

(b) Total Project demand is the sum of the estimated quantity of industrial water and domestic water.

Table 8: Future (2040) Water Supply Versus Project Demand at Build-Out in Aera's Water System

Current Source	Future (2040) Water Supply	Single Dry Year	Multiple Dry Years		
			Year 1	Year 2	Year 3
Groundwater	707.48	707.48	707.48	707.48	707.48
Total Project Demand*	21.72	21.72	21.72	21.72	21.72
Estimated Surplus/Shortfall	685.76	685.76	685.76	685.76	685.76

Notes:
All units in afy
Estimates from Aera
* Assumes only the commercial operation domestic water demand portion of the Project that may be supplied by Aera's water system

Conclusion: *The estimated annual demand for the Project is not a de minimis use compared to existing available water supplies in the Subbasin. However, commercial Project water demand is estimated to average up to 1,223 afy and will be produced water from Aera's Belridge Oil Field. Aera also has approximately 7,000AF of surplus surface water stored in various groundwater banking projects through the BWSD that may be accessed at any time, subject to the groundwater bank's pumping capacity.*

Domestic water demands for commercial operation of the Project are estimated to be 21.72 afy and will be provided by Aera's water system. As a result, there are adequate water supplies available in the WDWA and BVGSA plan areas to serve the proposed Project under all water year conditions.

2.1.7 Conclusions

According to the requirements of Water Code Section 10910(c)(3), the water supply assessment shall include a discussion of, "whether the public water system's total projected water supplies available will meet the projected water demand associated with proposed Project, in addition to the public water system's existing and planned future uses."

The following is a summary of the water supply assessment for this Project:

- The Project will be under environmental review pursuant to the requirements of CEQA; therefore, the information contained in this assessment will be used to support the analysis contained in the CEQA document.
- The Project meets the definition of a "Project" under Water Code Section 10912(a).
- The Project is located in the unincorporated portion of Kern County. Construction water demand, estimated to be 400 af over a 2.5-year period, will be served by BWSD and other existing long-term water contracts with individuals. Commercial water demand is estimated to average up to 1,223 afy and will be produced water from Aera. Aera also has approximately 7,000AF of surplus surface water stored in various groundwater banking projects through the BWSD that may be accessed at any time, subject to the groundwater bank's pumping capacity. Domestic water demands for commercial operation of the Project are estimated to be 21.72 afy and will be provided by Aera's water system.
- The construction water demand has not been accounted for in the *BWSD 2020 Agricultural Water Management Plan (BWSD, 2021),* however, 2020 industrial water use in the BWSD was 689 af, and 5,578 afy is budgeted annually by BWSD for industrial water use.
- Groundwater production capacity from Aera'swater system is 707.48 afy and historical demand over the past five years was 685.93 afy. Projected water system water demand is estimated to be 690.50 afy which includes the Project's domestic water demand. Aera'swater system wells are located within the BVWSD and BVGSA in the Subbasin. According to the BVGSA GSP chapter (GEI, 2022b), groundwater production in the BVGSA plan area for WY1993 to WY2015 (historical condition) is estimated to be 62,742 afy. Groundwater production in 2020 is not available. BVWSD (personal communication, June 30, 2023) estimated the 2040 water demand to be 140,000 af.
- BVWSD is entitled to 156,000 afy of surface water from the Kern River; however, during the period 2006 to 2015 Kern River deliveries via the East Side Canal averaged 40,887 afy. BVWSD is also contracted with the Kern County Water Agency to receive 21,300 afy of Table A State Water Project (SWP) water and 3,750 afy of Article 21 SWP water. During the period 2006 through 2015, BVWSD received an average of 53,099 afy of SWP water via the California

Aqueduct (GEI, 2022b). Average surface water deliveries from 2006 to 2015 averaged 93,986 afy. Estimated 2020 and 2040 surface water deliveries to the BVWSD are not individually provided in the BVGSA GSP chapter (GEI, 2022b) or the KGA "Umbrella" GSP (GEI, 2022a). The WSA addresses only the BMA portion of the BVGSA which occupies 91% percent of the BVWSD service area.

- The estimated cumulative and annual decline in groundwater in storage in the BVGSA between WY1993 and WY2015 is 275,480 af and 11,977 afy, respectively (GEI, 2022b). The estimated annual change in ground in storage between WY1995 and WY2014 using the C2VSimFG-Kern groundwater model is -17,362 afy (Todd, 2019).

- The Subbasin has been designated as a critically overdrafted high-priority basin by the DWR and is managed by 11 GSAs that submitted five original and revised GSPs to DWR in January 2020 and July 2022, respectively.

- According to Kern Groundwater Authority Groundwater Sustainability Plan (GEI, 2022a), groundwater production in the Subbasin in WY2020 is estimated to be 1,835,054 af and projected to be 1,648,770 af from WY2021 to WY2040 based on the CV2SimFG-Kern groundwater model simulations assuming 2070 climate change conditions and implementation of projects and management actions.

- According to DWR (2006), groundwater storage capacity in the Subbasin was estimated to be 40,000,000 af in 2002 (KCWA, 2002). The dewatered storage at this time was also reported to be 10,000,000 (KCWA, 2002).

- According to *Kern Groundwater Authority Groundwater Sustainability Plan* (GEI, 2022a), the cumulative change in the amount of groundwater in storage in the Subbasin between 1995 and 2021 is estimated to have declined by 1,812,211 af for an average decline of 69,700 afy.

- The projected cumulative and annual average decline in the amount of groundwater in storage in the Subbasin from WY2021 to WY2040 taking into account 2070 climate change conditions and implementation of projects and management actions is estimated to be 4,485,720 af and 224,286 afy, respectively (Todd, 2020) in (GEI, 2022a).

- The projected annual average decline in the amount of groundwater in storage in the WDWA plan area WY2021 to WY2040 taking into account 2070 climate change conditions and implementation of projects and management actions is estimated to be 46,000 afy (Todd, 2020) in (GEI, 2022a) and revised to approximately 22,000 afy by Aquilogic (2022) based on assumed modeling discrepancies related to the amount of groundwater production using the CV2SimFG-Kern groundwater model simulation.

- The estimated groundwater recharge in the Subbasin and WDWA plan area in WY1995-WY2014 is 1,400,362 afy (Todd, 2020) in (GEI, 2022a) and 92,341 afy (Aquilogic, 2022), respectively, based on CV2SimFG-Kern groundwater modeling simulations (Todd, 2020) in (GEI, 2022).

- The estimated WY1995-WY2014 sustainable yield in the Subbasin and the WDWA plan area is 1,313,260 afy (Todd, 2020) in (GEI, 2022a) and 34,079 afy (Aquilogic, 2022), respectively.

Although there is a historical and projected decline in groundwater in storage in the Subbasin and the WDWA and BVGSA plan areas, there is sufficient imported surface water available from BWSD and Aera's banked water to meet the construction water demands of the Project. In addition, commercial water demands will be met by produced water from Aera and domestic water demands will be served by Aera's water system. As a result, there is sufficient produced water and domestic water supplies available to meet the commercial water demands of the Project.

Based on the results of this assessment, sufficient water supply is available to serve the Project as proposed, and no further analysis should be required.

The conclusions in the Report titled *Aera Energy Carbon Frontier Project Traffic Impact Study* are Stantec's professional opinion, as of the time of the Report, and concerning the scope described in the Report. The opinions in the document are based on conditions and information existing at the time the scope of work was conducted and do not take into account any subsequent changes. The Report relates solely to the specific project for which Stantec was retained and the stated purpose for which the Report was prepared. The Report is not to be used or relied on for any variation or extension of the project, or for any other project or purpose, and any unauthorized use or reliance is at the recipient's own risk.

Stantec has assumed all information received from Aera Energy LLC (the "Client") and third parties in the preparation of the Report to be correct. While Stantec has exercised a customary level of judgment or due diligence in the use of such information, Stantec assumes no responsibility for the consequences of any error or omission contained therein.

This Report is intended solely for use by the Client in accordance with Stantec's contract with the Client. While the Report may be provided by the Client to applicable authorities having jurisdiction and to other third parties in connection with the project, Stantec disclaims any legal duty based upon warranty, reliance or any other theory to any third party, and will not be liable to such third party for any damages or losses of any kind that may result.

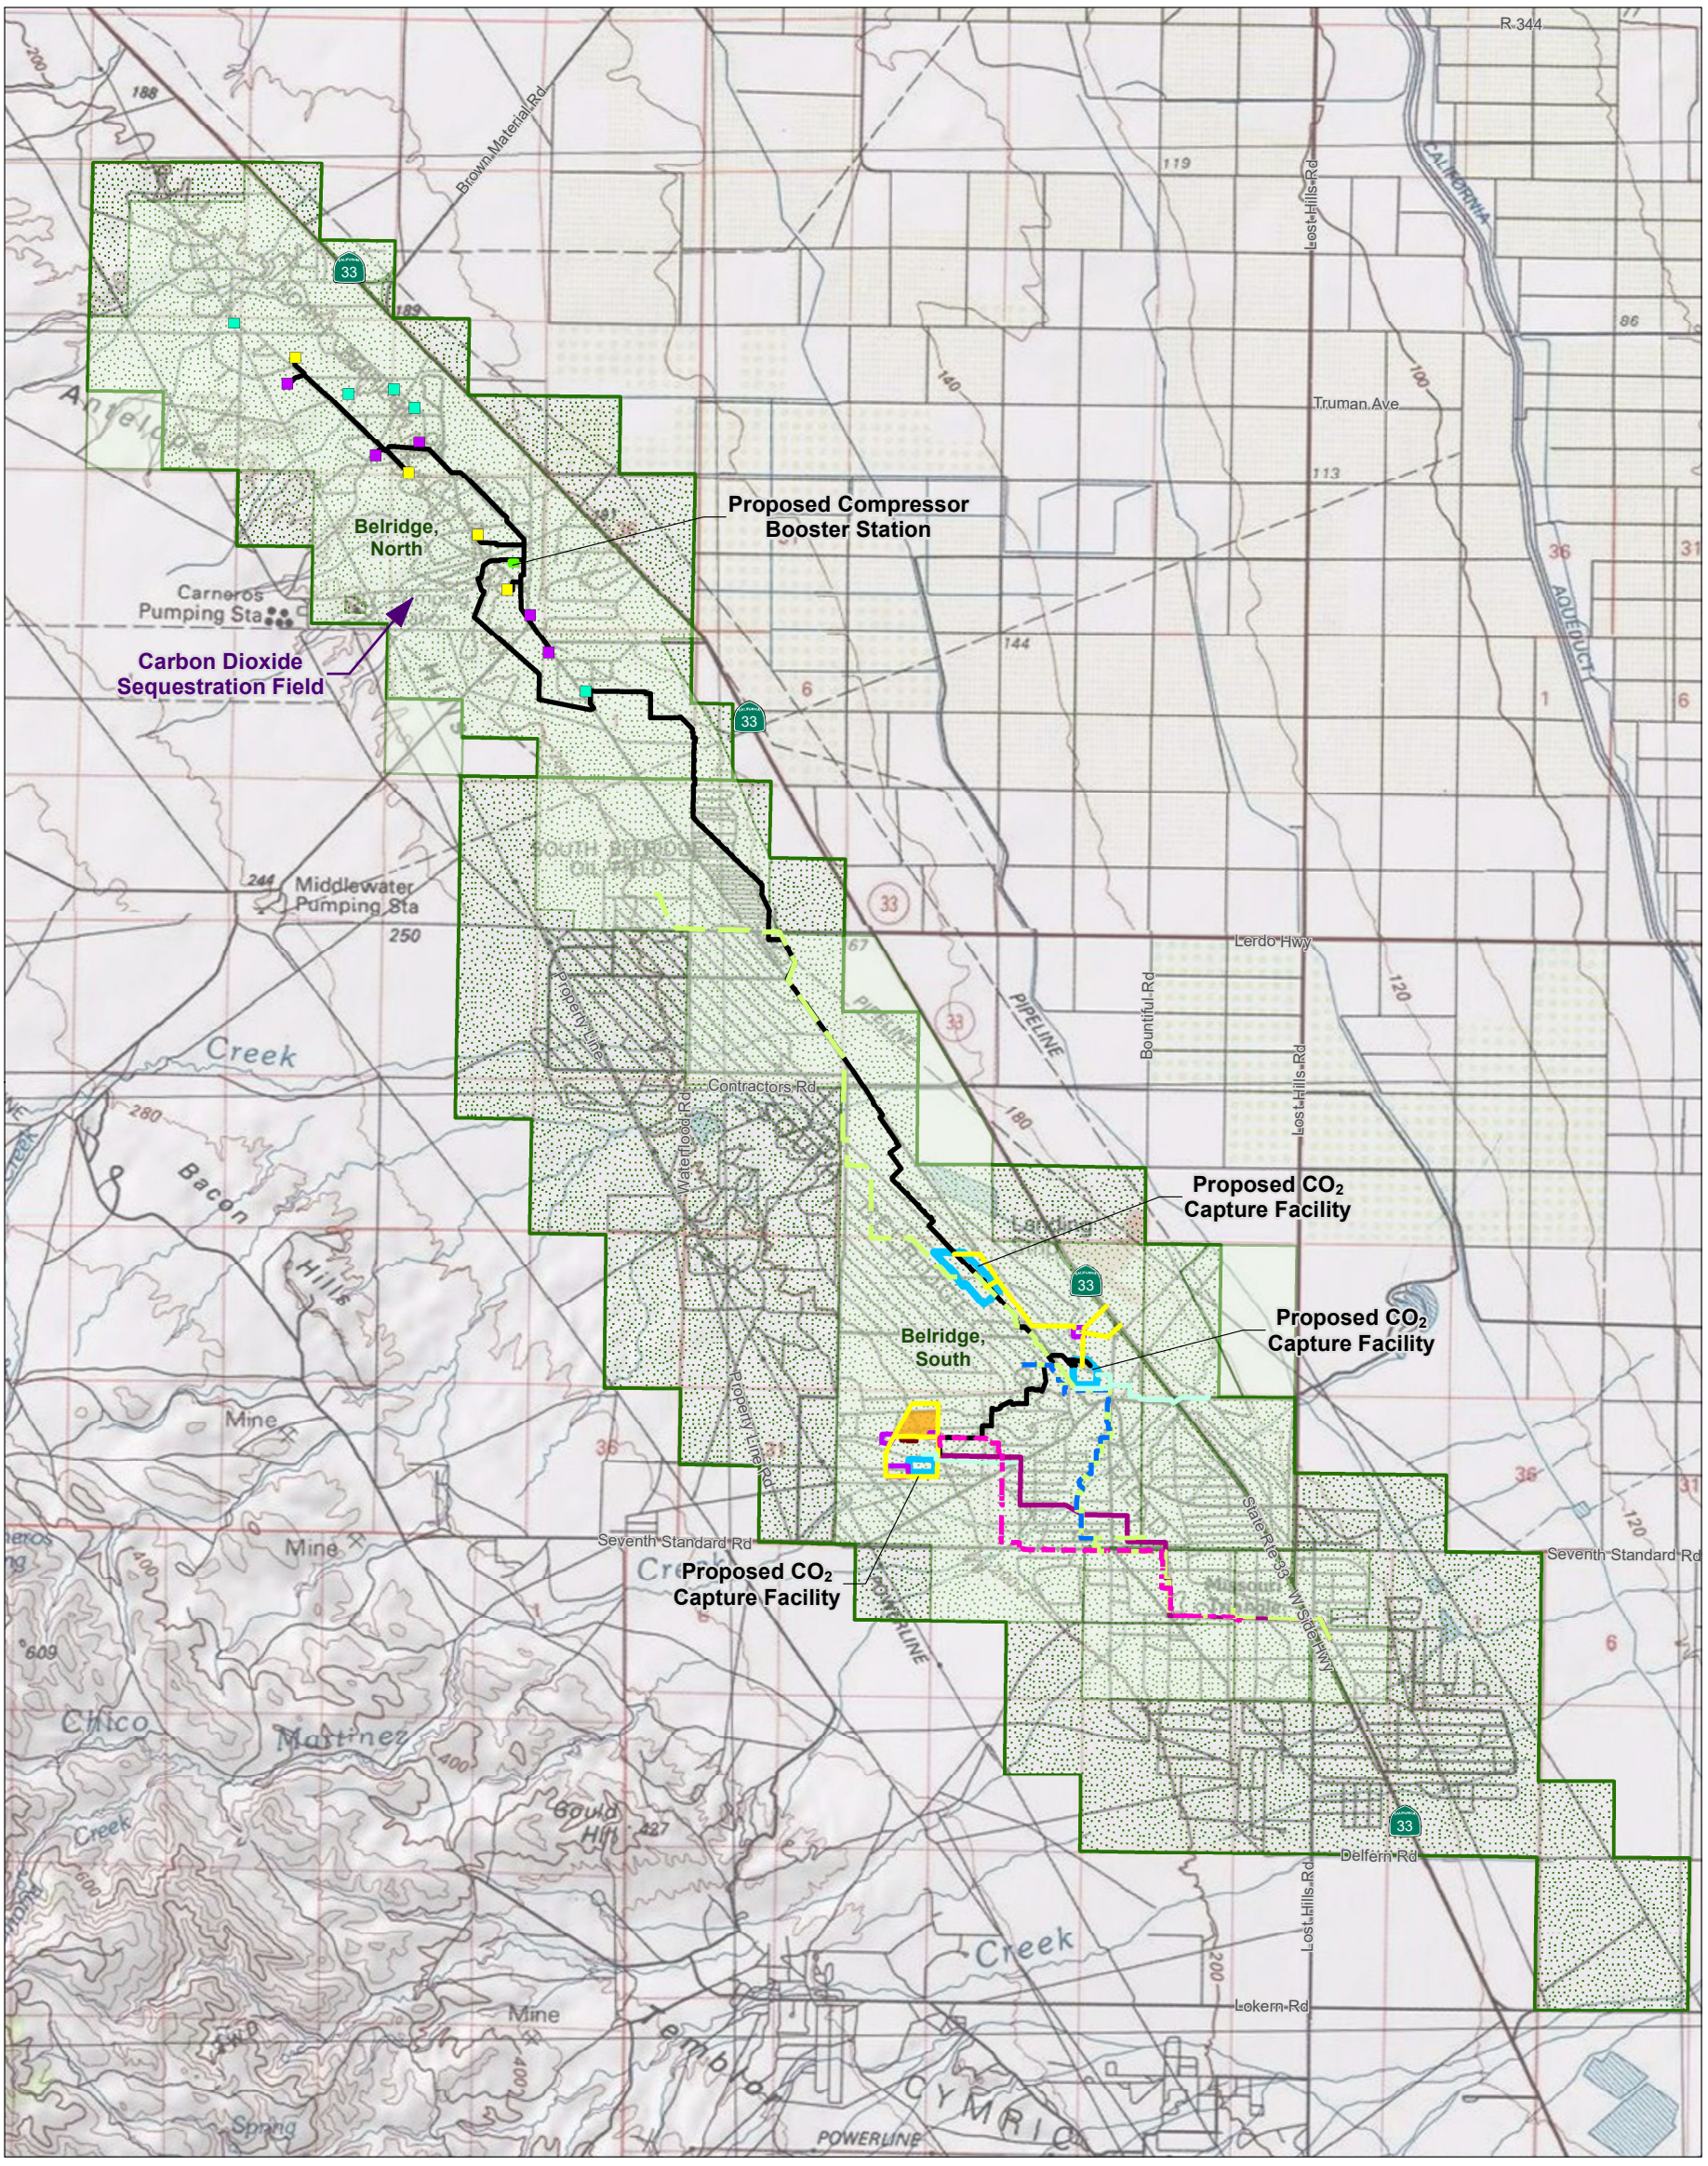
1 Introduction

Stantec Consulting Services Inc. (Stantec) has performed a traffic impact study for the construction and operation of the proposed Aera Energy Carbon Frontier carbon capture and sequestration (CCS) project (Project), located within the South and North Belridge oil fields in western Kern County, California. See Figure 1 for Project Location Map showing the Project location. Aera Energy LLC (Aera Energy) is seeking approval of a conditional use permit for the Project from Kern County Planning and Natural Resources Department (County). The purpose of this analysis is to determine the amount of traffic generated by the Project during construction and operation and to identify the effect of the Project on the roadway circulation system.



1.1 Proposed Project

The Project site is located within the Central Valley portion of western Kern County. The Project would capture CO_2 from existing produced gas streams (pre-combustion) and emissions from existing stationary sources (post-combustion) within the South Belridge Oil Field and transport the CO_2 through a pipeline to the North Belridge Oil Field for injection at dedicated Underground Injection Control (UIC) Class VI injection wells. The proposed underground CO_2 sequestration field, approximately 2,632 acres in size would be located within the North Belridge Oil Field. Oil and gas production activities within the North Belridge 64 zone would cease as a result of the implementation of the proposed Project.

The South Belridge and North Belridge oil fields are contiguous and located approximately seven miles southwest of the community of Lost Hills and west of State Route (SR) 33. Together, the two Belridge oil fields cover an area of approximately 13 miles long and three miles wide. The main entrance to the South Belridge Oil Field where the carbon dioxide (CO_2) capture facilities would be constructed, would be accessible by Main Camp Road, either from private Oasis Road off Seventh Standard Road or directly from Seventh Standard Road, west of SR 33.

The Project injection and monitoring wells, processing facilities, pipelines, and transportation infrastructure would be built out over a 3-year period, anticipated to start in 2025. The Project is expected to operate for up to 20 years until it is deemed uneconomic or undesirable to continue operation.

Based on the data provided by Aera Energy, the number of workers would vary throughout the course of any given year depending upon the construction activities underway. However, during peak construction periods, the estimated number of workers on-site at one time would be approximately 300 workers. After Project buildout, the Project would require an operational staff up to 10 employees on-site.

Stantec has not verified the accuracy and/or completeness of this information and shall not be responsible for any errors or omissions which may be incorporated herein as a result. Stantec assumes no responsibility for data supplied in electronic format, and the recipient accepts full responsibility for verifying the accuracy and completeness of the data.

2 Existing Conditions

2.1 Existing Roadway System

State Route 33 (SR 33) is a two-lane undivided highway, located approximately three miles east of the site, that provide regional access to the Project site. It runs north-south in the vicinity of the Project. Seventh Standard Road, Oasis Drive, and Main Camp Road are local roadways that provide access to the Project area. Access to the CO_2 facilities would be via Main Camp Road, either from the private Oasis Road off Seventh Standard Road or directly from Seventh Standard Road, west of SR 33.

2.2 Existing Traffic Data

This section summarizes existing traffic volumes on roadways that could be affected by the Project. Traffic count data was obtained from the California Department of Transportation (Caltrans) Traffic Census Program for 2021, which is the most recent available year. Table 1 summarizes the annual average daily traffic (AADT), which is the total volume of vehicle traffic for the year divided by 365 days, at three study locations along SR 33 in the vicinity of the Project.

Table 1. Annual Average Daily Traffic Volumes on Potentially Affected Roadway Segments

Roadway Segment	Average Annual Daily Traffic
1. SR 33 south of Junction Route 46	1,950
2. SR 33 south of Lost Hills Road (County Road P213)	1,900
3. SR 33 north of Lokern Road (County Road P208)	1,900

Source of AADT: 2021 Traffic Volumes, Caltrans Traffic Census Program (Caltrans, 2021).
Key: SR = State Route

3 Level of Service Methodology

Level of service (LOS) is a qualitative index of the performance of an element of a transportation system. The LOS for traffic is designated from A through F, with LOS A indicating free-flowing conditions and LOS F indicating severe traffic congestion and delays. The Highway Capacity Manual Sixth Edition (HCM 6), a standard reference published by the Transportation Research Board, contains specific criteria and methods for assessing LOS. LOS characteristics for roadway segments are presented in Table 2.

Table 2. Roadway Level of Service Descriptions

Level of Service	Traffic Flow Description
A	Minimal or no vehicle delay
B	Slight delay to vehicles
C	Moderate vehicle delays, traffic flow remains stable
D	More extensive delays at intersections
E	Long queues create lengthy delays
F	Severe delays and congestion

3.1 Significance Criteria

Kern County historically used a threshold of LOS D for the minimum acceptable operation of its transportation facilities. Facilities under the jurisdiction of Caltrans include freeway segments, ramps, ramp terminals, and arterials. Although Caltrans generally does not designate a LOS standard, for the purpose of this analysis, a Project would be considered to have undesirable effect on traffic and transportation if it would cause the operation of a transportation facility to worsen from LOS D or better.

Table 3 provides typical LOS and AADT volume thresholds for uninterrupted flow rural highways. As shown, a two-lane undivided highway such as SR 33 can typically carry up to 14,000 AADT for conditions of LOS D or better.

Table 3. Roadway Level of Service for Uninterrupted Flow Highways

Lanes	Median	A	B	C	D	E	F
2	Undivided	-	$\leq$ 4,600	8,200	14,000	28,500	> 28,500

3.2 Literature Review

3.2.1 KERN COUNTY GENERAL PLAN

The Kern County General Plan is the foundation and central feature of the local planning process. It is prepared, adopted, and maintained by the County to govern the physical development of all land area under its jurisdiction.

The Circulation Element of the Kern County General Plan consists of the general location and extent of existing and proposed major thoroughfares, transportation routes, terminal, and other local public utilities and facilities that are all corelated with the land use element of the general plan. The purpose of the circulation element is to set up local Goals and guiding Policies about building transportation improvements. Following is a list of the Plan's seven unique Goals:

- *To make certain that transportation facilities needed to support development are available. To ensure that these facilities occur in a timely manner so as to avoid traffic degradation.*
- *Kern County intends to provide plans for circulation infrastructure in support of the Land Use, Open Space and Conservation Element.*
- *To plan for transportation modes available to all segments of the population, including people with restricted mobility.*
- *Kern County will plan for a reduction of environmental effects without accepting a lower quality of life in the process.*
- *Maintain a minimum LOS D for all roads throughout the County unless the roads are part of an adopted Community Plan or Specific Plan which utilizes Smart Growth policies that encourage efficient multi-modal movements.*
- *Coordinate with the California Department of Transportation (Caltrans) regarding various transportation developments within the County.*
- *Kern County through its representatives on the Kern COG Board of Directors shall coordinate with Kern County cities and Caltrans to develop more effective transportation planning and congestion management programs.*

3.3 Existing Traffic Operations

Existing traffic conditions for the study roadway segments were evaluated based on the LOS and AADT thresholds for uninterrupted flow rural highways, shown in Table 3. The roadway capacities for the target LOS D for the county rural roadway segment were compared to the observed traffic volumes noted above in Table 1.

Table 4 shows the maximum daily traffic volumes that would allow the highway segments to maintain an acceptable LOS D, the existing AADT, and LOS. As shown, all the two-lane rural highway segments currently operate at an acceptable LOS ≤B.

Table 4. Existing Level of Service of Study Segments

Roadway Segment	Facility Type	Allowable Daily Service Volume (LOS D)	Average Annual Daily Traffic	LOS
1. SR 33 south of Junction Route 46	Two-lane Rural Highway	14,000	1,950	≤B
2. SR 33 south of Lost Hills Road (County Road P213)	Two-lane Rural Highway	14,000	1,900	≤B
3. SR 33 north of Lokern Road (County Road P208)	Two-lane Rural Highway	14,000	1,900	≤B

4 Project Trip Generation

4.1 Construction Trip Generation

Trip generation is defined as the number of vehicle trips produced by a particular type of land use or project. A trip is defined as vehicle movement in one direction. The total number of trips generated by a particular land use type or project includes both inbound and outbound trips.

During construction, truck trips would be routed on SR 33. Based on the information provided by Aera Energy, construction traffic would access the Project site from Main Camp Road, either from the private Oasis Road off Seventh Standard Road or directly from Seventh Standard Road, west of SR 33.

The proposed CO_2 sequestration field is contained within approximately 2,636 acres of land within the North Belridge Oil Field. Construction of the Project is expected to initiate in Q1 of 2025 and would take approximately 3 years to complete that includes the following tasks:

- Mobilization
- Demolition
- Well abandonments
- Surface Facility Construction
- Pipeline Construction
- Well Drilling/Well Conversion
- Facility Construction
- Pipeline Construction

The analysis of construction trip generation is based on the average daily volume of construction traffic. For the purposes of this analysis, the Project construction trip generation estimates are calculated based on the trips generated by heavy duty trucks (that include construction material delivery and dump trucks, water delivery trucks, etc.,) and the trips generated by the construction workers. Based on the annualized summary of anticipated equipment peak estimates during construction provided by Aera Energy, approximately 272 construction equipment vehicles are expected to travel to the site during the three-year construction period. Construction equipment vehicles would generate a total of 1,088 ADT (2 trips for inbound & outbound of construction equipment delivery to the site and 2 trips for inbound and outbound of construction equipment removal from the site) spread out over the three years of construction. Depending on the construction activities underway, the construction equipment requirements would vary throughout the course of any given year and across the life of the Project. Based on the information provided by Aera Energy, there would be approximately 720 working days (approximately 20 working days per month X 36 months of construction) over the life of the Project. The Project would generate an average of 1.5

construction equipment trips per day if the 1,088 ADT is spread out equally over 720 working days. However, for the purpose of this analysis and assuming that there would be ten times the average 1.5 trips per day during peak construction activity, the Project would generate 15 construction vehicles trips per day.

During construction, the number of workers on the site would vary daily. However, at the peak of construction, the number of workers on site would be 300 workers according to Aera Energy. Due to the rural nature of the Project, local labor would be used to the maximum extent practical. Workers would commute to and from the Project site daily from the nearby population centers. Workers employed in the rural areas of the County typically use strategies to reduce their reliance on single occupancy vehicles to reduce their commute costs, such as vanpools and carpools. Taking these factors into account, an assumption that 50 percent of the construction workers would carpool, there would be 300 trips (150 trips inbound during the AM peak hour and 150 trips outbound during the PM peak hour).

The construction trip generation for the Project is shown in Table 5. As shown, the Project is expected to generate a total volume of approximately 315 ADT, which includes 15 construction vehicle trips and 300 construction worker trips.

Table 5. Trip Generation During Peak Construction

Site	Construction Worker Trips	Construction Vehicle Trips	Total Trips
Aera Energy CCS	300	15	315

4.2 Operations Trip Generation

Based on information provided by Aera Energy, once constructed, the operational aspects of the Project would require a total of up to 10 employees. Assuming 10 employees per day, there would be approximately 25 trips per day based on an average trip rate of 2.5 trips per employee[1], which is generally considered not perceptible and would have no negative or undesirable effects to the surrounding roadway network.

4.3 Project Construction Trip Distribution

The geographic distribution of the Project-generated trips was determined based on the Project site location in relation to the surrounding uses while taking into account proposed driveway location, existing flow patterns and engineering judgement. A conservative scenario for each roadway segment is evaluated by assuming 100% of the Project construction trips assigned to each roadway segment

[1] The average trip rate of 2.5 trips per employee assumes that employee work during the day shift is two trips (one trip in and one trip out). In addition, some employees may travel an extra trip in between (e.g., lunch, errand), and there may be occasional deliveries to the site. Therefore, an average of 2.5 trips per employee is assumed.

individually as a worst-case scenario, i.e., 100% of the Project trips could travel on SR 33 either north or south of Seventh Standard Road.

4.4 Existing Plus Project Construction Conditions

This section describes the potential effects of the Project on traffic and transportation during construction. Project-generated construction traffic was added to existing conditions to represent "existing plus Project construction conditions." Similar to the analysis of the existing traffic conditions, the existing plus Project construction conditions for the roadway segments were evaluated based on the LOS and AADT thresholds for uninterrupted flow rural highways, shown in Table 3. The roadway capacities for the target LOS D were compared to the existing plus Project construction conditions traffic volumes.

As shown in Table 6, all the roadway segments continue to operate at LOS ≤B, even with the addition of construction traffic and are below the target threshold of LOS D.

Table 6. Existing Plus Project Construction Conditions Level of Service of Study Segments

Roadway Segment	Facility Type	Allowable Daily Service Volume (LOS D)	Project Trips	Average Annual Daily Traffic	LOS
1. SR 33 south of Junction Route 46	Two-lane Rural Highway	14,000	315	2,265	≤B
2. SR 33 south of Lost Hills Road (County Road P213)	Two-lane Rural Highway	14,000	315	2,215	≤B
3. SR 33 north of Lokern Road (County Road P208)	Two-lane Rural Highway	14,000	315	2,215	≤B

5 Vehicle Miles Traveled Analysis

The following analysis evaluates Project-related vehicle miles traveled (VMT) and complies with the updated California Environmental Quality Act (CEQA) guidelines that incorporate the requirements of Senate Bill (SB) 743. SB 743 requires the Governor's Office of Planning and Research (OPR) to establish recommendations for identifying and mitigating transportation impacts under CEQA (OPR, 2018). Generally, SB 743 moves away from using delay-based LOS as the metric for identifying Project impacts and uses VMT instead. The final OPR Technical Advisory, released in December 2018, provides guidance on evaluating transportation impacts and VMT and is the guidance on which this analysis is based.

Prior to undertaking a detailed VMT analysis, the OPR Technical Advisory recommends that lead agencies conduct a screening process "to quickly identify when a project should be expected to cause a less-than-significant impact without conducting a detailed study." The OPR Technical Advisory suggests that lead agencies may screen out VMT impacts using project size criteria, maps of low VMT areas,

transit availability, and provision of affordable housing. For this Project, the screening criteria related to project size is applicable in regard to the amount of traffic that is generated.

The OPR Technical Advisory recommends that absent substantial evidence indicating that a project would generate a potentially significant level of VMT or inconsistency with a sustainable communities strategy (SCS) or general plan, projects that generate or attract fewer than 110 trips per day may generally be assumed to cause a less-than-significant transportation impact.

The Project is consistent with the County's General Plan and SCS because the proposed Project would not change the current or planned County roadway system. As discussed in Section 4.2, a conservative estimate of the Project's daily operational trip generation is approximately 25 trips per day based on an average trip rate of 2.5 trips per employee. Therefore, the Project would generate substantially fewer than the 110 trips per day threshold and would result in a less-than-significant transportation impact.

Construction-related VMT is addressed in the context of air quality and greenhouse gas as part of a separate study. Construction VMT is temporary and is not applicable to the transportation thresholds of significance recommended in the OPR Technical Advisory, which are based on a measurement of the operational average VMT per capita.

6 Cumulative Conditions

Cumulative conditions have been considered, as construction of other developments in the vicinity during the same construction timeframe as the Project could have a temporary negative cumulative impact on traffic conditions. Current environmental documents listed on the Kern County website were reviewed to ascertain whether they would be constructed in a similar timeframe and would affect the same roadways as the Project. See Appendix A for the list of cumulative projects in Kern County found on the Kern County Planning website (Kern County, 2023). The list shows that most of the projects are solar farm projects. The traffic from these related projects would have a nominal effect on traffic volumes on the surrounding roadway network due to the remote location of the related project sites as well as due to the fact that the construction trips are short-term and temporary. On this basis, there will be no additional traffic impacts under cumulative conditions.

7 Conclusion

Under existing traffic conditions, all roadway study segments currently operate at LOS ≤B, which meets the target threshold of LOS D. As described in the Project description, construction equipment and vehicles would access the Project site from Main Camp Road, either from private Oasis Road off Seventh Standard Road or directly from Seventh Standard Road, west of SR 33. During the peak construction, the number of trips generated by the construction workers would be 300 trips per day. Construction vehicles would generate a total of 15 ADT. The overall daily trip generation during peak construction is estimated to be 315 ADT.

During construction, with the addition of construction traffic on the study area roadway segments, the ADT for each affected roadway would be below LOS D thresholds, which indicates that there would be no negative or undesirable effects on the roadway segments. Therefore, construction of the Project is not expected to cause any negative effects to the surrounding transportation network.

After construction, the Project would have up to 10 full-time employees that would generate up to approximately 25 trips per day, which is not perceptible and, therefore, would be considered to have no negative effect to the surrounding roadway network.

The Project is consistent with the County's General Plan and SCS and generates substantially fewer daily operational trips than the 110 trips per day threshold of significance for VMT impact. Therefore, based on the OPR recommended screening criteria, the Project would have a less-than-significant transportation impact.

VMT associated with construction of the Project is addressed in the context of air quality and greenhouse gas as part of a separate study. Construction VMT is temporary and is not applicable to the transportation impact thresholds of significance.

RE: AB 52 Tribal Consultation – Applications for Zone Classification Changes and Conditional Use Permits to allow Carbon dioxide (CO_2) capture and sequestration (CCS) on approximately 13,229-acres within the North and South Belridge Oilfields in the San Joaquin Valley of unincorporated Kern County (PP23402).

Dear Mrs. Mauck,

The Kern County Planning and Natural Resources Department is in receipt of a request to process applications for a proposed CCS field on approximately 13,229 acres located in Sections 20, 21, 22, 26, 27, 28, 34, 35, 36 of Township 27 South Range 20 East; Section 1, 2, and 12 of Township 28 South Range 20 East; Section 6, 7, 17, 18, 20, 27, 28, 29, 32, 33, and 34 of Township 28 South Range 21 East; and Section 2, 3, and 4 of Township 29 South Range 21 East. The proposed project, CarbonFrontier by Aera Energy, LLC. would include the installation of up to nine (9) EPA Class VI injection wells, the conversion of four (4) existing wells to CO_2 monitoring wells, amine-based capture equipment at existing facilities within the oilfields, approximately 10 miles of pipeline, and internal access roads. The proposed project would allow for the capture and sequestration of up to 42.6 million metric tons (MM Mt) of CO_2 within a geographically confined underground mineral formation for storage of CO_2 in perpetuity and would contribute to California's goal for carbon neutrality by 2045 (Executive Order B-55-18) by reducing industrial CO_2 emissions.

In compliance with California Assembly Bill No. 52 (AB-52), this Department is requesting your review and comments on the potential impacts on cultural places associated with your tribe by this proposal. Your participation is important at this early stage of processing to ensure that cultural places important to your tribe are identified, and the potential impacts associated with implementation of the project are mitigated.

If you have not responded by **May 15, 2023**, this Department will assume your tribe has declined consultation as per Public Resources Code (PRC) 21080.3.1. Please contact me at (661) 862-5015 or by email at AlvidrezK@kerncounty.com if you have any questions, comments, or request for consultation regarding this proposal.

Sincerely,

Keith Alvidrez

Coachella, CA 92236

RE: AB 52 Tribal Consultation – Applications for Zone Classification Changes and Conditional Use Permits to allow Carbon dioxide (CO_2) capture and sequestration (CCS) on approximately 13,229-acres within the North and South Belridge Oilfields in the San Joaquin Valley of unincorporated Kern County (PP23402).

Dear Mr. Madrigal,

The Kern County Planning and Natural Resources Department is in receipt of a request to process applications for a proposed CCS field on approximately 13,229 acres located in Sections 20, 21, 22, 26, 27, 28, 34, 35, 36 of Township 27 South Range 20 East; Section 1, 2, and 12 of Township 28 South Range 20 East; Section 6, 7, 17, 18, 20, 27, 28, 29, 32, 33, and 34 of Township 28 South Range 21 East; and Section 2, 3, and 4 of Township 29 South Range 21 East. The proposed project, CarbonFrontier by Aera Energy, LLC. would include the installation of up to nine (9) EPA Class VI injection wells, the conversion of four (4) existing wells to CO_2 monitoring wells, amine-based capture equipment at existing facilities within the oilfields, approximately 10 miles of pipeline, and internal access roads. The proposed project would allow for the capture and sequestration of up to 42.6 million metric tons (MM Mt) of CO_2 within a geographically confined underground mineral formation for storage of CO_2 in perpetuity and would contribute to California's goal for carbon neutrality by 2045 (Executive Order B-55-18) by reducing industrial CO_2 emissions.

In compliance with California Assembly Bill No. 52 (AB-52), this Department is requesting your review and comments on the potential impacts on cultural places associated with your tribe by this proposal. Your participation is important at this early stage of processing to ensure that cultural places important to your tribe are identified, and the potential impacts associated with implementation of the project are mitigated.

If you have not responded by **May 15, 2023**, this Department will assume your tribe has declined consultation as per Public Resources Code (PRC) 21080.3.1. Please contact me at (661) 862-5015 or by email at AlvidrezK@kerncounty.com if you have any questions, comments, or request for consultation regarding this proposal.

Sincerely,

Keith Alvidrez

Dear Keith,

Thank you for contacting the Yuhaaviatam of San Manuel Nation (formerly known as the San Manuel Band of Mission Indians) regarding the above-referenced project. YSMN appreciates the opportunity to review the project documentation, which was received by the Cultural Resources Management Department on April 18th 2023. The proposed project is located outside of Serrano ancestral territory and, as such, YSMN will not be requesting to receive consulting party status with the lead agency or to participate in the scoping, development, or review of documents created pursuant to legal and regulatory mandates.

Kind regards,
Ryan Nordness
Cultural Resource Analyst

1.0 EXECUTIVE SUMMARY

This Energy Utilization Study is intended to support the preparation of the Draft Environmental Impact Report (DEIR) for the CarbonFrontier Project (Project). This technical analysis has been prepared to evaluate the Project's energy use during construction and operation.

1.1 PROJECT UNDERSTANDING

Aera Energy LLC (Aera Energy) has proposed a carbon capture and sequestration Project which would capture carbon dioxide (CO_2) from existing produced gas streams (pre-combustion [Pre-C]) and emissions from existing stationary sources (post-combustion [Post-C]) within the South Belridge Oil Field and transport the CO_2 through a pipeline to the North Belridge Oil Field for injection at dedicated Underground Injection Control (UIC) Class VI injection wells. The proposed underground CO_2 sequestration field would be located within the North Belridge Oil Field. Oil and gas production activities within the North Belridge 64 zone would cease as a result of the Project. It is anticipated that the Project would have a maximum forecasted capacity to sequester up to 1.6 million metric tons of CO_2 per year beginning in 2027 and contribute to California's goal of carbon net-neutrality by 2045 (Governor's Executive Order B-55-18) by reducing industrial CO_2 emissions.

1.2 SUMMARY OF ANALYSIS

This section provides a summary of each impact statement and the conclusion of the analysis.

Impact ENG-1: The Project would not result in potentially significant environmental impact due to wasteful, inefficient, or unnecessary consumption of energy resources. **Less Than Significant Impact.**

Impact ENG-2: The Project would not conflict with or obstruct a state or local plan for renewable energy or energy efficiency. **Less Than Significant Impact.**

2.0 INTRODUCTION

2.1 PURPOSE OF ANALYSIS

The purpose of this Energy Utilization Study is to determine the potential energy use, primarily in the form of petroleum fuel, associated with construction and operation of the Project. This evaluation is consistent with the air quality and greenhouse gas (GHG) emissions modelling prepared for the Project by Trinity Consultants (Trinity, 2023).

2.2 PROJECT DESCRIPTION

The Project would include the construction and operation of a carbon capture and sequestration system, with the CO_2 capture facilities located within the South Belridge Oil Field. The CO_2 would be transported by pipeline to the North Belridge Oil Field for permanent sequestration via CO_2 injection wells into a designated underground sequestration zone, known as the 64 Zone, at depths of approximately 8,000 feet below ground surface.

New processing facilities and field systems would be constructed. Processing facilities would include: 1) carbon capture facilities constructed adjacent to existing oil field equipment within the South Belridge Oil Field, 2) pipelines to transport the CO_2 stream to the North Belridge Oil Field, and 3) dedicated injection wells within North Belridge to inject CO_2 into the dedicated CO_2 sequestration zone. Existing oil wells that penetrate the dedicated CO_2 sequestration zone would be permanently plugged and abandoned (including the removal of surface wellheads) in accordance with applicable laws and regulations or repurposed for injection or monitoring activities.

Field systems would include additional pipelines to convey produced gas, water, and steam within South Belridge, as well as electrical power distribution and supervisory control and data acquisition networks and control rooms. Monitoring systems would be constructed, including re-purposing of existing wells, to monitor the CO_2 injection operations in accordance with state and federal requirements.

Electrical system upgrades would be required to supply electricity to the new facilities. This includes approximately 5,700 feet (1.1 mile) of 115 kilovolt (kV) overhead transmission lines from the existing electrical supply grid to two new electrical substations located near the CO_2 capture facilities. Additionally, approximately 13,000 feet of new 12 kV overhead distribution power lines would extend from the proposed electrical substations to each CO_2 capture facility.

Project construction would occur over an approximately 3-year time period starting in 2025. The Project is anticipated to operate for a period of up to 20 years. Following the completion of CO_2 injection operations, decommissioning would occur, which would involve a period of post-injection monitoring, plugging of injection wells, and post-closure site care.

2.2.1 Project Location and Surrounding Land Uses

The Project site is located within the Central Valley portion of western Kern County. The South Belridge and North Belridge oil fields are contiguous and located approximately six miles southwest of the community of Lost Hills and west of State Route (SR) 33. Together, the two Belridge oil fields cover an area of approximately 13 miles long and three miles wide. The proposed CO_2 capture facilities would be located within the developed portion of the South Belridge Oil Field. The proposed CO_2 sequestration field, which is located approximately 10 miles to the northwest in the North Belridge Oil Field, is made up of privately owned parcels totaling approximately 2,636 acres of land, predominately developed with oil and gas production and accessory facilities and infrastructure. Existing land use in the vicinity of the Project site generally includes oil and gas exploration and production, grazing, and agricultural lands.

3.0 ENERGY BACKGROUND

3.1 ENVIRONMENTAL SETTING

Pacific Gas and Electric (PG&E) provides natural gas and electric service to approximately 16 million people throughout a 70,000-square-mile service area in northern and central California, including Kern County (PG&E 2023). In February 2018, PG&E announced that it had reached California's 2020 renewable energy goal three years ahead of schedule (PGE 2018). In 2021, approximately 48 percent of PG&E's electricity came from renewable resources including solar, wind, geothermal, biomass and small hydroelectric sources. Additionally, approximately 91 percent of PG&E's total electric power mix is from GHG-free sources, which includes nuclear and large hydroelectric sources of energy (CEC 2023).

The California Energy Commission (CEC) tracks electricity and natural gas consumption across the state for residential and non-residential sources. In 2021, Kern County used a total of 15,009 GWh of electricity and 1,866 millions of therms of natural gas. Approximately 82 percent of the electricity usage and 95 percent of the natural gas use in the County came from non-residential sources (CEC 2016a, CEC 2016b).

The South Belridge Oil Field is powered by the Co-Generation (Cogen) Plant 32, which was constructed from 1985 to 1986. Cogen 32 is composed of three turbine-driven generator sets, each able to make 20 megawatts (MW) of power. The Cogen 32's output is backed up with a connection to PG&E in the event that any or all of the three Cogen 32 turbines are down for maintenance or temporary outage. The Project would pull available power from Cogen 32 within its existing capacity, and any additional electrical load would be provided by PG&E.

3.2 REGULATORY SETTING

The following includes the key federal, state, and local regulations related to energy resources that are applicable to the Project.

3.2.1 Federal

Federal Energy Regulatory Commission

The Federal Energy Regulatory Commission is an independent agency that regulates the interstate transmission of electricity, natural gas, and oil. The Federal Energy Regulatory Commission also reviews proposals to build liquefied natural gas terminals and interstate natural gas pipelines as well as licensing hydropower projects. Licensing of hydroelectric facilities under the authority of the Federal Energy Regulatory Commission includes input from state and federal energy and power generation, environmental protection, fish and wildlife, and water quality agencies.

National Energy Conservation Policy Act

The National Energy Conservation Policy Act (42 U.S. Code [USC] §8201 et seq.) serves as the underlying authority for federal energy management goals and requirements and is the foundation of most federal energy requirements. The National Energy Conservation Policy Act also established fuel economy standards for on-road motor vehicles in the United States. The National Highway Traffic Safety Administration (NHTSA) is responsible for establishing additional vehicle standards and for revising existing standards. NHTSA and the U.S. Environmental Protection Agency (USEPA) are taking coordinated steps to enable the production of clean energy vehicles with improved fuel efficiency. NHTSA sets the Corporate Average Fuel Economy (CAFE) levels, which are rapidly increasing over the next several years to improve energy security and reduce fuel consumption. In March 2022, the NHTSA finalized CAFE standards for model years 2024 to 2026. The standards require an industry-wide fleet average of approximately 49 miles per gallon for passenger cars and light trucks by model year 2026. The NHTSA projects that the foregoing standards will avoid the consumption of approximately 234 billion gallons of gasoline between model years 2030 to 2050 (NHTSA 2022).

Energy Independence and Security Act of 2007

The Energy Independence and Security Act (EISA) aimed to increase U.S. energy security, increased CAFE standards for motor vehicles, and included provisions related to energy efficiency, such as renewable fuel standards (RFS), appliance and lighting efficiency standards; and building energy efficiency standards. The EISA required increasing levels of renewable fuels to replace petroleum. The USEPA is responsible for developing and implementing regulations to ensure transportation fuel sold into the U.S. contains a minimum volume of renewable fuel.

The RFS programs regulations were developed in collaboration with refiners, renewable fuel products, and other stakeholders and were created under the Energy Policy Act of 2005. The RFS program established the first renewable fuel volume mandate in the U.S. As required under the EISA, the original RFS program required 7.5 billion gallons of renewable fuel to be blended into gasoline by 2012. The RFS program was expanded in several ways that laid the foundation for achieving significant reductions of GHG emissions through the use of renewable fuels, for reducing imported petroleum, and for encouraging the development and expansion of the nation's renewable fuels sector. The updated program is referred to as RFS2, and includes the following:

- EISA expanded the RFS program to include diesel, in addition to gasoline;
- EISA increased the volume of renewable fuel required to be blended into transportation fuel from 9 billion gallons in 2008 to 36 billion gallons by 2022;
- EISA established new categories of renewable fuel and set separate volume requirements for each one; and
- EISA required by the USEPA to apply lifecycle GHG performance threshold standards to ensure that each category of renewable fuel emits fewer GHGs than the petroleum fuel it replaces.

Additional provisions of the EISA address energy savings in government and public institutions, promoting research for alternate energy, additional research in carbon capture, international energy programs, and the creation of "green jobs."

Federal Vehicle Standards

The Energy Policy and Conservation Act of 1975 (EPCA) mandated that the NHTSA establish and implement a regulatory program for motor vehicle fuel economy, known as the CAFE program, to reduce national energy consumption. As codified in Chapter 329 of Title 49 of the USC, as amended by the EISA, EPCA sets forth specific requirements concerning the establishment of average fuel economy standards for passenger cars and light trucks. The EISA, discussed above, amended the EPCA CAFE program requirements by providing the Department of Transportation additional rulemaking authority and responsibilities.

Consistent with its statutory authority in rulemaking to establish CAFE standards for model year 2017 and beyond, NHTSA developed two phases of standards. The first phase included final standards for model years 2017–2021. The second phase, covering model years 2022–2025, included standards that were not final, due to the statutory requirement that NHTSA set average fuel economy standards not more than five model years at a time. Rather, NHTSA wrote that those standards were augural, meaning that they represented its best estimate, based on the information available at that time, of what levels of stringency might be maximum feasible in those model years. In 2012, the agencies jointly adopted more stringent Phase 2 standards for light duty cars and trucks, which would cover model years 2017 through 2025. In August of 2016, the agencies adopted more stringent Phase 2 standards for medium- and heavy-duty vehicles, which would cover model years 2018 through 2027 for certain trailers and model years 2021 through 2027 for semi-trucks, large pickup trucks, vans, and all types and sizes of buses and work trucks.

On March 31, 2020, NHTSA and the USEPA released a new rule, the final Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule, setting CAFE and carbon dioxide emissions standards for model years 2021 through 2026 passenger cars and light trucks. The rule rolls back the 2012 standards for model years 2021 through 2026 for passenger cars and light trucks, which had required an average fleetwide fuel economy equivalent of 54.5 miles per gallon in model year 2025 with a 5 percent annual increase to an average fuel economy of about 40 miles per gallon in model year 2025 with annual increases of 1.5 percent starting in 2021. As a part of issuing the new SAFE rule, NHTSA issued a Final Environmental Impact Statement which found that the relaxed standards would result in increased petroleum consumption which in turn would result in increases to GHG and criteria pollutant emissions known to contribute to adverse health impacts (NHTSA 2020). The estimated increases from the roll back of the 2012 standards are expected to result in more than a billion metric tons additional climate pollution through 2040 as determined by calculating the difference from the reduction of 2 billion metric tons the 2012 rule was expected to accomplish compared to the standards of the 2020 rule (NHTSA 2020). On January 20, 2021, an Executive Order was issued on Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis, which includes review of the Part One Rule by April 2021 and review of the Part Two Rule by July 2021. In response to the Part One Rule, in December 2021, the Department of Transportation withdrew its portions of the SAFE rule. As a result, states are now allowed to issue their own GHG emissions standards and zero-emissions vehicle mandates. In addition, the Part Two Rule was adopted to revise the existing national GHG emission standards for passenger cars and light trucks through model year 2026. These standards are the strongest vehicle emissions standards

ever established for the light-duty vehicle sector and will result in avoiding more than three billion tons of GHG emissions through 2050.

Inflation Reduction Act of 2022

The Inflation Reduction Act (IRA) of 2022 is considered the most ambitious climate law in U.S. history, and is intended to reduce GHG emissions, help build a clean economy, reduce energy costs for Americans, and advance environmental justice. With funding from the IRA, the USEPA has launched a network of clean energy financing and provided grant funding for climate pollution reduction programs (USEPA 2023). The IRA increases the 45Q tax credit to $85 per ton for geologic sequestration of CO_2 from industrial sources.

3.2.2 State

California Public Utilities Commission

The California Public Utilities Commission (CPUC) is a state agency created by a constitutional amendment to regulate privately-owned utilities providing telecommunications, electric, natural gas, water, railroad, rail transit, and passenger transportation services and in-state moving companies. The CPUC is responsible for ensuring that California utility customers have safe, reliable utility services at reasonable rates, while protecting utility customers from fraud. The CPUC regulates the planning and approval for the physical construction of electric generation, transmission, or distribution facilities, and local distribution pipelines of natural gas.

California Energy Code

Compliance with the California Energy Code (CCR Title 24, Part 6, California's Energy Efficiency Standards) and Title 20, Public Utilities and Energy, standards must occur for all new buildings constructed in California. These efficiency standards apply to new construction of both residential and nonresidential (i.e., maintenance buildings and pump station buildings associated with the Program) buildings, and they regulate energy consumed for heating, cooling, ventilation, water heating, and lighting. The building efficiency standards are enforced through the local building permit processes, and local government agencies may adopt and enforce energy standards for new buildings provided that these standards meet or exceed those provided in the Title 24 guidelines.

Warren-Alquist Energy Resources Conservation and Development Act

Initially passed in 1974 and amended since, the Warren-Alquist Energy Resources Conservation and Development Act (Warren-Alquist Act) created the CEC, California's primary energy and planning agency. The seven responsibilities of the CEC are forecasting future energy needs, promoting energy efficiency and conservation through setting standards, supporting energy-related research, developing renewable energy resources, advancing alternative and renewable transportation fuels and technologies, certifying thermal power plants 50 MW or larger, and planning for and directing state response to energy emergencies. The CEC regulates energy resources by encouraging and coordinating research into energy supply and demand problems to reduce the rate of growth of energy consumption. Additionally,

the Warren-Alquist Act acknowledges the need for renewable energy resources and encourages the CEC to explore renewable energy options that would be in line with environmental and public safety goals (Public Resources Code (PRC) Section 25000 et seq.)

California Integrated Energy Policy

Senate Bill (SB) 1389 requires the CEC to "conduct assessments and forecasts of all aspects of energy industry supply, production, transportation, delivery and distribution, demand, and prices. The Energy Commission shall use these assessments and forecasts to develop energy policies that conserve resources, protect the environment, ensure energy reliability, enhance the state's economy, and protect public health and safety." (PRC Section 25301(a)). The CEC adopts an Integrated Energy Policy Report every two years and an update every other year. The most recent version is the 2022 Integrated Energy Policy Report Update (CEC 2022).

California Renewables Portfolio Standard

California's Renewables Portfolio Standard (RPS) was initially established in 2002 by SB 1078, with the initial requirement that 20 percent of electricity retail sales be served by renewable resources by 2017. The program was accelerated in 2006 under SB 107, which required that the 20 percent mandate be met by 2010. In April 2011, SB 2 was signed into law, requiring electricity retailers in the state to procure 33 percent of their energy sources from renewable energy sources by the end of 2020 (CPUC 2021). In addition, SB 350, passed in 2015, directs California utilities to further increase the amount of renewable energy delivered to customers to 50 percent by 2030.

CPUC implements and administers RPS compliance rules for California's retail sellers of electricity, which include large and small investor-owned utilities, publicly owned utilities, electric service providers, and community choice aggregators. The CEC is responsible for the certification of electrical generation facilities as eligible renewable energy resources and adopting regulations for the enforcement of RPS procurement requirements of public owned utilities.

Low Carbon Fuel Standard

In 2007, Executive Order S-01-07 established the Low Carbon Fuel Standard (LCFS) and directed the Secretary for Environmental Protection to coordinate the actions of the CEC, the California Air Resources Board (CARB), the University of California, and other agencies to develop and propose protocols for measuring the "life-cycle carbon intensity" of transportation fuels. CARB adopted the LCFS on April 23, 2009.

The LCFS was subject to legal challenge in 2011. Ultimately, CARB was required to bring a new LCFS regulation for consideration in February 2015. The proposed LCFS regulation was required to contain revisions to the 2010 LCFS and new provisions designed to foster investments in the production of the low-carbon fuels, offer additional flexibility to regulated parties, update critical technical information, simplify and streamline program operations, and enhance enforcement. The regulation was last amended in 2018. The 2018 amendments strengthen the carbon intensive fuel reduction targets beyond 2020 to support the climate goals established in SB 32. Other major changes to the 2018 amendments include

expanding the fuel types and eligible activities to participate in the LCFS (CARB 2018a). One of the specific regulations added in 2018 is the Carbon Capture and Sequestration Protocol under the Low Carbon Fuel Standard (CARB 2018b). The Carbon Capture and Sequestration Protocol establishes methodology for quantifying geological CO_2 sequestration, and permanence requirements related to site characteristics, plume extent evaluation, testing and monitoring, well operation, post-injection site care, and more.

2022 Scoping Plan for Achieving Carbon Neutrality

The 2022 Scoping Plan for Achieving Carbon Neutrality (2022 Scoping Plan) was approved by the CARB in December 2022 and assesses progress toward achieving the state's GHG reduction goals and establishes a path to achieve carbon neutrality no later than 2045. The 2022 Scoping Plan focuses on outcomes needed to achieve carbon neutrality by assessing paths for advancing transportation technology, clean energy deployment, maintenance and preservation of natural and working lands, and others, and is designed to meet the State's long-term climate objectives. Specifically, the 2022 Scoping Plan identifies carbon negative technologies, including nature-based and mechanical carbon sequestration projects, as an essential component in achieving state-wide carbon neutrality (CARB 2022).

3.2.3 Local

Kern County General Plan

The Kern County General Plan, initially adopted in 2004, includes an Energy Element.[1] The following goals and policies from the Energy Element of the Kern County General Plan are applicable to the Project (Kern County 2009):

- **Section 5.2 – Importance of Energy to Kern County**
    - **Policy 1.** Kern County should assert and promote its role as the State's leading energy County.
    - **Policy 4.** The County should actively seek State and federal energy grants and projects to assist in energy planning and development.
    - **Policy 5.** The County shall work with other agencies to define regulatory responsibility concerning energy-related issues, and shall seek to eliminate, insofar as possible, duplicative regulations.
    - **Policy 6.** The County should encourage discussion and mutual cooperation of various energy industries within the County to establish mutual understanding of common needs and issues.

[1] It is noted that Kern County is currently undergoing an update to the General Plan. However, the General Plan Update has not yet been finalized or adopted by the County Board of Supervisors.

  - **Policy 7.** The processing of all discretionary energy project proposals shall comply with California Environmental Quality Act (CEQA) Guidelines directing that the environmental effects of a project must be taken into account as part of project consideration.
  - **Policy 8.** The County should work closely with local, State, and federal agencies to assure that energy projects (both discretionary and ministerial) avoid or minimize direct impacts to fish, wildlife, and botanical resources, wherever practical.
  - **Policy 9.** The County should develop and implement measures which result in long-term compensation for wildlife habitat, which is unavoidably damaged by energy exploration and development activities.

- **Section 5.3.2 – Kern County's Economic Dependence on the Oil Marketplace**
  - **Policy 3.** The County shall encourage the conversion of existing petroleum-related facilities to other productive uses when they are no longer needed or productive.
  - **Policy 4.** The County should encourage the development of renewable energy industries to diversify the energy economy in Kern County.
- **Section 5.4.1 – Cogeneration**
  - **Policy 1.** The County shall allow the continued development of cogeneration facilities in primary oil resource areas and industrial areas.

4.0 MODELING INPUTS AND PARAMETERS

The following discussion explains the methodology and modeling parameters that will be used to estimate the energy demand associated with construction and operations of the Project.

4.1 ENERGY CALCULATION METHODOLOGY

Project energy demand during construction and operations was determined based on Project-specific information and using vehicle and equipment emission factors from the CARB's EMFAC2021 (v1.0.2) and EMFAC OFFROAD2021 (v1.0.4). The energy calculations are included as Appendix A.

The Project's energy consumption and demand were evaluated in comparison to the California Environmental Quality Act (CEQA) thresholds of significance to determine whether the Project would result in a significant impact related to energy.

4.1.1 Construction Assumptions

Construction Schedule

Project construction would require various tasks including facility pad grading, well drilling, pipeline construction, and others. Table 1 shows the anticipated construction components and timing per component.

Table 1: Project Construction Components

Project Component	Construction Days per Component
Facilities Pad Grading	80
Repurposed Injection Well Site Preparation	20
Repurposed Injection Well Drilling	100
Repurposed Monitoring Well Site Preparation	26
Repurposed Monitoring Well Drilling[1]	80
New Well Site Preparation	40
New Well Drilling[1]	60
CO_2 Capture Facilities (4 facilities)	522 days per facility
Compressor Station Construction	80
CO_2 Main Pipeline	390
Distribution Pipelines	260
Electrical Transmission Line	60
Intra-Field Electrical Distribution	60

Project Component	Construction Days per Component
Onsite Electrical Substations	130
Water Pipelines	87
Natural Gas Pipelines	120
Steam Pipeline	88
Demolition	40
On-Site Roads	15-20 Per Well

Notes:
1. The Well Hookup phase timing and equipment is included within the "Well Drilling" phases.

Construction of the components would overlap, and several components would begin construction at the same time. Construction of most components is anticipated to begin in 2025, except construction of the Intra-Field Electrical Distribution system would begin in 2026. The most time-consuming component, construction of the CO_2 Capture Facilities, is expected to finish in 2028.

For this analysis, all construction activity was assumed to occur in the year 2025, except Intra-Field Electrical Distribution, which was assumed to occur in 2026. The construction schedule utilized in the analysis represents a "worst-case" analysis scenario because fuel efficiency for construction equipment increases as the analysis year increases, due to improvements in technology and more stringent regulatory requirements. Therefore, the construction energy demand would be less if the construction schedule is adjusted to occur in later years.

Off-Road Equipment

The off-road equipment fleet and associated horsepower per piece of equipment for each Project component was provided by Aera Energy. The load factor for each piece of equipment was derived from Table G-12 of the California Emissions Estimator Model (CalEEMod) User Guide Appendix G. Consistent with the air quality and GHG emissions modeling, each piece of equipment was assumed to be in use for 8 hours per day, with the exception of drill rigs, which were assumed to operate for 24 hours per day. Off-road equipment energy demand was estimated based on the equipment usage (horsepower-hours) and fuel efficiency (gallons/horsepower-hour), as provided by the EMFAC OFFROAD2021 database. The comprehensive list of off-road equipment is available in Appendix A.

On-Road Vehicle Trips

Table 2 provides a summary of the construction-related vehicle trips.

Table 2: Construction Vehicle Trips

Project Component	Worker Trips per Day	Vendor Trips per Day	Heavy-Duty Truck Trips per Day
Facilities Pad Grading	30	9	0
Repurposed Injection Well Site Preparation	28	9	0

Project Component	Worker Trips per Day	Vendor Trips per Day	Heavy-Duty Truck Trips per Day
Repurposed Injection Well Drilling	34	10	0
Repurposed Monitoring Well Site Preparation	28	9	0
Repurposed Monitoring Well Drilling[1]	34	10	0
New Well Site Preparation	28	9	0
New Well Drilling[1]	34	10	0
CO_2 Capture Facilities	192	56	0
Compressor Station Construction	56	22	0
CO_2 Main Pipeline	58	20	2
Distribution Pipelines	46	17	2
Electrical Transmission Line	24	12	1
Intra-Field Electrical Distribution	24	12	1
Onsite Electrical Substations	36	10	0
Water Pipelines	40	16	2
Natural Gas Pipelines	40	16	2
Steam Pipeline	40	16	2
Demolition	24	8	0
On-Site Roads	16	5	0

Notes:
1. The Well Hookup phase timing and equipment is included within the “Well Drilling” phases.

The number of daily worker trips were based on Aera Energy’s estimate of the average number of daily workers required for each Project component, and assuming two one-way trips per worker per day. Consistent with the air quality and GHG emissions modeling, the worker trip length was estimated at 45 miles per one-way trip. The fleet mix for worker trips was composed of a mixture of passenger cars, light-duty trucks, and medium-duty vehicles.

The number of daily vendor trips were estimated as 0.4 vendor trips per construction worker, in addition to the on-road vehicles that were included in Aera Energy’s provided construction equipment list (i.e., flatbed trucks, mechanic trucks, SUVs, etc.). Consistent with the air quality and GHG emissions modeling, the vendor trip length was estimated at 45 miles per one-way trip. The fleet mix for vendor trips was composed of a mixture of light heavy-duty trucks, medium heavy-duty trucks, and heavy heavy-duty trucks.

The number of heavy-duty truck trips were based on information provided by Aera Energy. The trip length was assumed to be 45 miles, and the fleet mix was composed entirely of heavy-duty trucks.

4.1.2 Operational Assumptions

Operational energy use refers to the energy demand that would occur during operation of the Project. The sources are summarized below.

Motor Vehicles

During the years of peak Project operation, the Project is anticipated to generate approximately 12 average vehicle trips per day. Two of the daily trips would be bulk material and waste deliveries, and 10 would be employee vehicle trips. Consistent with the air quality and GHG emissions modeling, the trip lengths were assumed to be 45 miles per one-way trip. The fleet mix for employees was determined based on Kern County data from EMFAC2021, and the delivery trip fleet mix was assumed to be light-heavy to heavy-heavy duty trucks. Vehicle fuel efficiency was provided by the EMFAC OFFROAD2021 database for an assumed operational year of 2027. Although Project construction would be entirely completed in 2028, operations at the finished facilities may begin in 2027.

Processing Equipment

Most on-site equipment would be powered by electricity, with the exception of those presented in Table 3. Each steam generator would consume between 65 and 90 MMBtu/hr and was assumed to operate 24 hours per day and 365 days per year. The Project may alternatively use existing steam generation from Cogen 32, SGS 2868, or SGS 2972, as capacity is available.

Table 3: Operational Natural Gas-Powered Equipment

Process	Facility	Equipment	Annual Natural Gas Demand (MMBtu)
Pre-C	GP 32	Utility Steam Generator 1	569,400
		Utility Steam Generator 2	569,400
	Cogen 32	Utility Steam Generator 1	648,240
		Utility Steam Generator 2	648,240
		Utility Steam Generator 3	648,240
Post-C	SGS 2868	Utility Steam Generator 1	709,560
		Utility Steam Generator 2	709,560
		Utility Steam Generator 3	709,560
	SGS 2972	Utility Steam Generator 1	788,400
		Utility Steam Generator 2	788,400
		Utility Steam Generator 3	788,400
Natural Gas Compression	Del Sur Compressors	S-1548-433	15,941
		S-1548-434	15,941
		S-1548-435	15,941

5.0 ENERGY ANALYSIS

This section discusses potential energy impacts associated with the Project and provides mitigation measures where necessary.

5.1 CEQA GUIDELINES

The CEQA Guidelines define a significant effect on the environment as "a substantial, or potentially substantial, adverse change in the environment." To determine if a project would have a significant impact on energy the following must be evaluated.

Would the project:

a) Result in potentially significant environmental impact due to wasteful, inefficient, or unnecessary consumption of energy resources, during project construction or operation?

b) Conflict with or obstruct a state or local plan for renewable energy or energy efficiency?

5.2 ENERGY IMPACT ANALYSIS

Impact ENG-1	**Result in potentially significant environmental impact due to wasteful, inefficient, or unnecessary consumption of energy resources, during project construction or operation?**

Impact Analysis

The energy requirements for the Project were determined using the construction and operational estimates generated from the calculation worksheets for energy consumption (Appendix A). This impact addresses the energy consumption from both construction and operations, discussed separately below.

Construction Energy Demand

During construction of the Project, energy resources would be consumed in the form of diesel and gasoline fuel from the use of off-road equipment (i.e., tractors, excavators, cranes) and on-road vehicles (i.e., construction employee commutes, vendor, haul trucks).

Temporary electricity may be required to provide as-necessary lighting and electric equipment; such electricity demand would be met by portable generator sets and, possibly, local distribution. Fuel demand associated with portable generators is incorporated in the off-road equipment estimate provided below. The amount of electricity used during construction would be minimal. Natural gas is not anticipated to be required during construction of the Project.

Off-Road Equipment

Construction activities associated with the Project were estimated to consume 1,240,200 gallons of diesel fuel from the use of off-road equipment. For comparison, in 2021, approximately 3.7 billion gallons of diesel fuel was consumed within California (USEIA 2023). Thus, the diesel fuel required to power the off-road equipment during construction of the Project would represent approximately 0.03 percent of the state's annual diesel demand.

On-Road Vehicles

On-road vehicles for construction workers, vendors, and haulers would require fuel for travel to and from the site during construction. Table 4 provides an estimate of the total on-road vehicle fuel usage during construction.

Table 4: Construction On-Road Vehicle Fuel Consumption

Project Component	Average Fuel Economy (miles/gallon)	Total VMT	Total Fuel Consumption (gallons)
Worker Trips	26.33	21,202,380	805,193
Vendor Trips	7.72	6,407,316	829,718
Haul Trips	6.20	85,050	13,725
Total Construction On-Road Trips		**27,675,666**	**1,647,483**

Notes:
Calculations use unrounded numbers; totals may not appear to sum exactly due to rounding.
VMT = vehicle miles traveled
Source: Appendix A.

As shown above, construction of the Project was estimated to consume 1,647,483 gallons of a combination of gasoline and diesel fuel from on-road vehicles. For comparison, in 2021, approximately 10.2 billion gallons of gasoline for motor vehicles was consumed within California (USEIA 2023). Thus, the fuel required to power the on-road motor vehicles during construction of the Project would represent approximately 0.02 percent of the state's annual gasoline demand.

Conclusion

Overall, construction activities associated with the proposed Project would result in the consumption of petroleum-based fuels. However, there are no unusual Project characteristics that would necessitate the use of construction equipment or vehicles that would be less energy efficient than at comparable construction sites in other parts of the state. Therefore, it is expected that construction fuel consumption associated with the proposed Project would not be any more inefficient, wasteful, or unnecessary than at other construction sites in the region.

Operational Energy Demand

During operations of the Project, energy would be required to fuel the vehicles travelling to and from the site and to power the proposed equipment, pumps, and facility processes.

Transportation Energy Demand

Table 5 provides an estimate of the annual fuel consumed by vehicles traveling to and from the Project site. As shown in the table, annual vehicular fuel consumption is estimated to be 9,479 gallons of a combination of gasoline and diesel fuel.

Table 5: Operational Vehicle Fuel Consumption

Trip Type	Vehicle Type	Percent of Vehicle Trips	Annual VMT	Average Fuel Economy (miles/gallon)	Total Annual Fuel Consumption (gallons)
Employee Trips	Passenger Cars (LDA)	38.53	45,075	31.44	1,434
	Light Trucks and Medium Duty Vehicles (LDT1, LDT2, MDV)	40.69	47,602	23.77	2,003
	Light-Heavy to Heavy-Heavy Diesel Trucks (LHD1, LHD2, MHDT, HHDT)	20.17	23,596	7.83	3,013
	Motorcycles (MCY)	0.32	371	41.98	9
	Other (OBUS, UBUS, SBUS, MH)	0.30	356	7.02	51
	Employee Trip Subtotal	--	*117,000*	--	*6,509*
Delivery Trips	Light-Heavy to Heavy-Heavy Diesel Trucks (LHD1, LHD2, MHDT, HHDT)	--	23,400	7.83	2,988
Total		**--**		**--**	9,479

Notes:
Calculations use unrounded numbers; totals may not appear to sum exactly due to rounding.
VMT = vehicle miles traveled
"Other" consists of buses and motor homes.
Source: Appendix A.

As noted previously, in 2021, California consumed approximately 10.2 billion gallons of gasoline (USEIA 2023). The Project's anticipated consumption of 9,479 gallons of fuel per year represents approximately 0.00009 percent of the state's annual demand for gasoline. Further, over the lifetime of the Project, the fuel efficiency of the vehicles being used by the employees and delivery vehicles is expected to increase. As such, the amount of petroleum consumed as a result of vehicular trips to and from the Project site during operation would decrease over time.

Processing Equipment Energy Demand

Most on-site equipment (i.e., pumps, maintenance, monitoring, communications, etc.) would be powered by electricity from the on-site co-generation facility and supplemented by PG&E, as needed. The expected maximum electric load of the Project is approximately 49 MW. As noted previously, Kern County consumed a total of 15,009 GWh of electricity in 2021 (1.71 GW, or 1,710 MW). The Project's electricity demand would constitute approximately 2.87 percent of the County's annual electricity demand.

The Pre-C process would share the new substation and electrical distribution system that was included for Cogen 32. Post-C facilities would be constructed at the following three existing facilities: Cogen 32, Steam Generator Setting (SGS) 2868, and SGS 2972. The Pre-C facility would have two natural gas-powered steam generators. Each Post-C facility would have three natural gas-powered steam generators, with carbon capture from those steam generators. The Project may alternatively use existing steam generation from Cogen 32, SGS 2868, or SGS 2972, as capacity is available. The total annual natural gas usage was estimated to be 76.3 million therms. Compared to the County's annual usage from 2021 (1,866 million therms), the Project's natural gas use would represent approximately 4.1 percent of the County's natural gas demand.

Although the Project would result in increased demand for energy resources, the energy would be consumed efficiently and would be typical of industrial carbon capture projects. In addition, carbon capture and sequestration projects, such as the proposed Project, are essential to achieve the state's climate goals (CARB 2022); as a result, any energy consumed by the Project is not considered to be wasteful or unnecessary.

Conclusion

Based on the analysis above, the Project would consume energy resources during construction and operations. However, the energy consumption associated with the proposed Project would not be inefficient, wasteful, or unnecessary, and a less-than-significant impact would occur.

Impact ENG-2 Conflict with or obstruct a state or local plan for renewable energy or energy efficiency?

Impact Analysis

The following discussion evaluates Project consistency with applicable plans for renewable energy or energy efficiency during construction and operations.

Construction

During construction, off-road equipment and on-road vehicles would comply with all applicable federal and state requirements. For example, all off-road equipment would be subject to the most recent In-Use Off-Road Diesel-Fueled Fleets Regulations adopted by the CARB, which establish engine efficiency requirements, among other requirements (CARB 2023). Off-road engines are categorized per engine tier,

with Tier 0 being the least efficient and Tier 4 Final being the cleanest and most efficient. Compliance with the In-Use Off-Road Diesel-Fueled Fleets Regulations would ensure that the Project construction fleet would consist of energy-efficient engines. With respect to the on-road vehicle fleet operations, the USEPA and NHTSA have adopted Federal Vehicle Standards with which the Project would comply. The on-road construction fleet would incorporate these standards as they purchase newer model trucks and turn over their fleet. As such, these regulations would have an overall beneficial effect on reducing nationwide fuel consumption over time as older trucks are replaced. Moreover, heavy-duty trucks would be required to comply with CARB's 5-minute idling limits which would reduce fuel consumption. Although the foregoing regulations were primarily designed to reduce air quality emissions, they would also result in an increase in energy efficiency during construction.

Operation

California adopted the RPS in order to increase the amount of renewable energy supplied by utilities within the state. As noted previously, the Project would use electricity from PG&E during operations. PG&E will continue to be subject to state RPS requirements, and the Project would not preclude achievement of the RPS goals. In addition, any new structures developed as part of the Project would comply with federal, state, and local regulations aimed at reducing energy consumption, including the Building Energy Efficiency Standards (California Code of Regulations Title 24, Part 6) the CALGreen Code (California Code of Regulations Title 24, Part 11). Moreover, the Project directly supports the goals laid out in CARB's 2022 Scoping Plan, including the measures related to carbon capture and sequestration. Finally, the Project would be subject to the CARB's Carbon Capture and Sequestration Protocol under the LCFS (CARB 2018b). The LCFS requirements are designed to decrease the carbon intensity of fuels and increase the range of renewable alternatives; therefore, the Project's compliance with the CARB's Carbon Capture and Sequestration Protocol would indirectly support the state plan for renewable energy.

Conclusion

The Project would not conflict with or obstruct a state or local plan for renewable energy or energy efficiency; therefore, the impact would be less than significant.

Total Project Construction VMT (miles)

27,675,666

Total Project Fuel Consumption (gallons)

1,647,483 0.016151795

Source: EMFAC2021 (v1.0.2) Emissions Inventory
Region Type: County
Region: Kern
Calendar Year: 2025
Season: Annual
Vehicle Classification: EMFAC2007 Categories
Units: miles/day for CVMT and EVMT, trips/day for Trips, kWh/day for Energy Consumption, tons/day for Emissions, 1000 gallons/day for Fuel Consumption

VMT = Vehicle Miles Traveled
FE = Fuel Economy

rs. Available: https://ww3.arb.ca.gov/msei/ordiesel/ordas_ef_fcf_2017_v7.xlsx. Accessed: March 2021.

Model Output: OFFROAD2021 (v1.0.4) Emissions Inventory
Region Type: County
Region: Kern
Calendar Year: 2025
Scenario: All Adopted Rules - Exhaust
Vehicle Classification: OFFROAD2021 Equipment Types
Units: tons/day for Emissions, gallons/year for Fuel, hours/year for Activity, Horsepower-hours/y

K.2 Carbon Management Business Park 2023 Report

This page intentionally left blank.

[illegible]

An exploration of carbon management and clean energy industries, and their potential benefits and impacts if developed within a Carbon Management Business Park sited in Kern County.

Technical Report | June 2023

PREPARED BY *BLUE* ***ENGINE***
FOR THE Kern County Planning and Natural Resources Department

ENVISIONING A CARBON MANAGEMENT BUSINESS PARK

This technical report supplements the informational website

cmbp.kernplanning.com

Technical report and website prepared for the
Kern County Planning and Natural Resources Department

by Blue Engine
and with Technical Assistance from the
U.S. Department of Energy Communities-Local Energy Action Program (C-LEAP)

JUNE 2023

Preface

What is a carbon management business park?

Carbon management industries are those that capture carbon dioxide (CO_2) for the purpose of removing it from the atmosphere or preventing its release to the atmosphere. The capture of CO_2 can be either the primary purpose of the industry – where a facility is built exclusively to capture gaseous CO_2 from the atmosphere, or a secondary goal – where CO_2 that is a byproduct of a primary industry process is captured. The Kern County Planning and Natural Resources Department has envisioned a conceptual Carbon Management Business Park, which could be developed as a large industrial park where one or several carbon management industries are located, with the aim of capturing CO_2 at the scale of millions of tons per year. Clean energy industries that support carbon management could be co-located within the park.

About Kern County Planning and Natural Resources Department

The Planning and Natural Resources Department (the Department) provides consolidated land use planning and community development programs for Kern County's residents, landowners and businesses. The Department's mission is to balance the county's economic vitality and resource conservation with the diverse needs of Kern County at large by preparing and implementing programs that are aligned with the county's General Plan. In 2021, with approval from the Kern County Board of Supervisors, the Planning and Natural Resource Department applied for the U.S. Department of Energy's (U.S. DOE) Communities Local Energy Action Plan (C-LEAP) Pilot Initiative. The Department's aim was

to secure expert technical assistance in order to better understand the nascent carbon management sector – what industries are involved, how they work, what they look like, and the potential benefits and impacts those industries could have if developed at a large scale in Kern County. The proposal was successful, and in 2022 Kern County became one of the 24 communities nationwide to be awarded a C-LEAP grant.

About the U.S. DOE Communities-Local Energy Action Program

C-LEAP is a pilot program developed by the U.S. Department of Energy (U.S. DOE) that is designed to facilitate community-driven clean energy transitions by providing supportive services valued at up to $16 million USD. The program partners specifically with communities that are experiencing either direct environmental justice impacts, or direct economic impacts from a shift away from historical reliance on fossil fuels. Kern County faces both of these challenges. C-LEAP recipients are awarded up to 18 months of high-quality technical assistance from a network of national experts in order to help build community clean-energy related economic development action plans.

About Blue Engine

Blue Engine provides advisory services to local governments, communities, and companies or other organizations seeking to develop decarbonization strategies, with particular focus on identifying opportunities and mitigating impacts of the ongoing energy transformation. The team at Blue Engine works closely with its sister company, Climate Now, a multimedia educational resource that produces accessible, expert-driven content – including a weekly podcast, videos, and events across the United States – about how and why the climate is changing, the clean energy technologies available to address and mitigate climate change, and the role of policies, markets, and stakeholder communities in driving the transition to a net-zero emissions global economy. The combined capabilities of Climate Now and Blue Engine allow the team to manage projects that are highly interdisciplinary in nature, and to act as a communication bridge between project experts and stakeholder communities.

About this report

Kern County Planning and Natural Resources Department, in partnership with an executive committee of community leaders who represent the diverse stakeholders of Kern County, was awarded the C-LEAP grant to perform a pre-feasibility analysis for a conceptual carbon management industrial park that could serve as a Clean Energy and Carbon Management Hub for all of California. The envisioned park would comprise 30 million square feet of development on 4,000 acres, and could be supported by over 30,000 acres of solar power. The goal of the pre-feasibility analysis was to understand how much carbon could be

captured in such a facility, what kinds of industries would locate there, and how such a park might impact the surrounding community and environment of Kern County. This report, in conjunction with the website cmbp.kernplanning.com, addresses each of those questions. The website serves as an executive summary of this report, which is meant to provide a comprehensive review of the state of the art of carbon management technologies, and of the clean energy technologies most likely to support them in an industrial park situated in Kern County.

Disclaimer

This document was prepared by Blue Engine for the Kern County Planning and Natural Resources Department, and with support from the U.S. DOE Technical Assistance Team and other academic and industry experts. The purpose of the report is not to endorse or advise a specific strategy of development of a carbon management business park, but to provide a sufficient summary of publicly available information on these industries to allow area property owners, private investors, and the broader community to make their own well-informed strategic development plans. Any content or opinions expressed herein do not reflect the views of the U.S. Department of Energy or members of the U.S. DOE Technical Assistance Team, nor any of the other subject matter and industry experts who so generously contributed their time and knowledge.

Additionally, the research summarized within this report includes results that are experimental in nature, and neither Blue Engine, the Kern County Planning and Natural Resources Department, or any employees of either entity make any warranty, express or implied, or assumes any legal liability or responsibility for the accuracy, completeness, or usefulness of any information herein. 1. Introduction

It is not an overstatement to say that Kern County is integral to feeding and fueling the state of California, and by extension, the United States. Since the discovery of oil in the Kern River Field in 1899, Kern County has led California in oil and gas production.[1] Currently, it produces about 70% of the state's oil,[2] and is host to four of the top seven producing oil fields in the nation.[3] As the southernmost county of California's Central Valley, which produces a quarter of the nation's food,[4] Kern also leads California in the agricultural sector, producing over $8 billion USD in goods from livestock and crops annually.[5]

These industries are important not only for what they export to the rest of the state and the nation, but for what they provide to the residents of Kern County. Nearly 1 in 5 county jobs are directly tied to the agriculture sector.[6] Oil and gas also provides about 2% of jobs in the region,[7] but more significantly, the sector is an important source of county tax revenue. The top ten property tax payers of Kern County are associated with either the extractive or energy sectors,[8] and in total, the oil and gas industry accounts for about a quarter of the county's annual tax revenue.[9] However, as policies are implemented to address climate

change, regional water supplies and global energy use patterns are evolving. As a result, the agriculture and oil and gas sectors of Kern County are also anticipating an evolution.

Decades of drought in the southwestern United States have led to increasing dependence on groundwater resources for irrigation of agricultural lands, resulting in over-depletion of subsurface aquifers and subsidence of the land in the Central Valley. It is anticipated that by 2040, average annual water supplies in the San Joaquin Valley (the southern portion of the Central Valley, where Kern is located) may need to decline by as much as 20%, as climate change drives increasing aridity and as policies such as the Sustainable Groundwater Management Act mandate reduced consumption of water from aquifers.[10] The Public Policy Institute of California estimates that as much as 900,000 acres of farmland could be fallowed in the San Joaquin Valley in the next two decades. Landowners will need viable economic alternatives for creating revenue from their lands, and communities will need new industries that can provide alternative jobs and tax revenue.

The oil and gas industry is also experiencing a shift, as solar and wind become increasingly competitive energy markets,[11] and as focus grows among global, national and regional institutions to reduce the emission of greenhouse gases like carbon dioxide (CO_2). But the oil and gas industry, and in particular, the oil and gas industry *in Kern County*, is uniquely equipped to take the lead in a new market that has incredible growth potential: carbon dioxide removal.

The National Academy of Sciences, Engineering and Medicine estimates that by mid-century it will be necessary to remove 10 billion metric tons of CO_2 from the atmosphere every year to prevent global average temperatures from rising above 2°C.[12] Carbon dioxide removal can be accomplished in a variety of ways – such as through significant re-forestation efforts, through changing agricultural practices to enhance the drawdown and storage of CO_2 in soils, or through restoring wetlands and mangroves along coastal habitats, to name a few.[13] Among the most effective methods of CO_2 removal however, is carbon capture and sequestration (CCS), or the process of trapping CO_2 from the atmosphere and from point sources of CO_2 emissions (like chimney stacks of large industrial facilities) and then pumping the CO_2 deep underground, into geologic layers in the subsurface that trap and hold the CO_2, much like it trapped and held the fossil fuels from which that CO_2 was derived. This technique is effective for two reasons: first, it is much easier to account for how much CO_2 is captured and sequestered via CCS than to estimate CO_2 drawdown from nature-based solutions like reforestation or soil re-generation, because gas pressures and flow rates of the CO_2 being pumped underground can be measured. Second, CO_2 that is pumped into well-characterized geologic layers of

[10] Escriva-Bou, *et al.* (2023) The future of agriculture in the San Joaquin Valley. [6]
[11] Lazard (2021) Levelized cost of energy. [8]
[12] National Academies of Sciences, Engineering, and Medicine (2019) Negative Emissions Technologies and Reliable Sequestration: A Research Agenda. p. 9. [9]
[13] Climate Now (2021) Carbon Dioxide Removal (CDR). [3]

the subsurface is effectively trapped there indefinitely – it will be hundreds or thousands of years, at least, before that CO_2 returns to the atmosphere.[14]

CCS is a nascent industry – less than 100 million metric tons of CO_2 is injected in the subsurface globally, and almost all of that injection is for the purpose of enhanced oil recovery (in which injected CO_2 pressurizes oil-filled cracks and pore spaces, helping push oil out of the ground) rather than permanent underground storage.[15] But new federal and state policies are incentivizing growth in CCS for the purpose of permanent CO_2 storage in the United States, and Kern County is extremely well positioned to benefit from those incentives. The geologic layers beneath Kern County that have allowed it to be such a prolific producer of oil and gas are the same kinds of layers that are perfectly suited for CO_2 storage. In fact, sediments underlying California's Central Valley have been identified as having among the highest CO_2 storage capacity in the nation, with storage potential of billions of tons of CO_2.[16] Additionally, companies and employees within the oil and gas industry who have been established in Kern County for decades have the requisite knowledge to safely and effectively drill injection wells, transport CO_2 from sources of capture to injection sites, and sequester CO_2 underground. Kern County is home to more than 7,000 direct employees of the oil and gas sector,[17] who already have the skillsets needed for carbon capture and storage. As of this report's publication, three companies in Kern County have begun the permitting process through the U.S. Environmental Protection Agency to develop the types of wells needed (called EPA Class VI wells) for CO_2 injection and permanent geologic storage.[18] For those wells to be cost effective, there will need to be a significant source of CO_2 – on the scale of millions of metric tons annually – available for injection. Where all that CO_2 could come from has yet to be determined, but one possibility is a dedicated carbon management park, which would locate existing and new industries that capture or produce CO_2 in close proximity to the injection sites.

1.1 What is a carbon management park?

In Spring 2022, Kern County was among the inaugural group of recipients for the Communities LEAP (Local Energy Action Program, or C-LEAP) technical assistance grant from the U.S. Department of Energy.[19] The Kern County Planning and Natural Resources Department's goal in obtaining this C-LEAP grant was to answer a question: could repurposing challenged agricultural lands with the development of one or several large-scale industrial parks designed for the express purpose of capturing CO_2 be an economically viable source of new jobs and revenue to Kern County over the coming

[14] Climate Now (2021) Carbon Dioxide Removal: Carbon Capture and Storage, Part II. [5]
[15] Climate Now (2021) Carbon Dioxide Removal: Carbon Capture and Storage, Part I. [4]
[16] Teletzke, G. (2018) Evaluation of Practicable Subsurface CO2 Storage. [13]
[17] U.S. Department of the Interior (no date) Natural Resources Revenue Data: Kern County. [10]
[18] EPA (last updated May 19, 2023) Class VI wells permitted by EPA. [16]
[19] U.S. Department of Energy (no date) Communities LEAP Pilot. [15]

decades? If so, what types of industries would be best suited for such a park, and what considerations should be taken in whether, where and how much to develop?

With technical assistance from the C-LEAP program, these questions are addressed through a Carbon Management Business Park pre-feasibility analysis, presented in the form of an interactive website hosted by the Kern County Planning and Natural Resources Department, and accompanied by this report. The analysis is designed to clarify the costs and benefits of a variety of emerging carbon management and clean energy industries, and based on these costs and benefits, to provide the necessary information for local residents and decision-makers to determine which carbon management technologies might be best suited for the region.

As principal investigator for the C-LEAP award, the Kern County Planning and Natural Resources Department developed a hypothetical framework for the carbon management park, envisioning a 30 million square foot park on 4,000 acres, with another 30,000 acres dedicated to solar power, that would be sited far from urban areas, in fallowed farmlands that are no longer viable for agriculture. The park would be closely situated to areas where EPA Class VI well permits for deep CO_2 storage are already being processed,[20] allowing regional infrastructure to work together. A variety of carbon management and clean energy technologies could be co-located within the park, and proximity to rail and interstate highways would provide connections with nearby transportation hubs like Los Angeles and Stockton that would expand the potential feedstock supply chains for the industrial park and potential end users for clean energy production.

Blue Engine Strategies was contracted by the Kern County Planning and Natural Resources Department to complete the pre-feasibility analysis, by gathering and synthesizing information about a suite of industries that could potentially be co-located on such a park. Each industry type was examined through a set of 4 lenses: technological, societal, environmental and economic. Information was collected through the following methods:

- Continuous research support and technical assistance from a team of experts from the U.S. Department of Energy through the C-LEAP Program
- Interviews with research experts at universities and national research laboratories, and with industry representatives
- Consultation with an Executive Committee of regional leaders, organized by the Planning and Natural Resources Department
- Independent scholarship of the latest published research, policies and regional data relevant to these technologies

This report provides a detailed summary of the pre-feasibility analysis. In addition, Blue Engine constructed a website, cmbp.kernplanning.com, that serves as an Executive Summary for this report. The website provides an interactive site map that can help users envision what such a park might look like, and explores a variety of the technologies that

[20] EPA (last updated May 19, 2023) Class VI wells permitted by EPA. [16]

could feasibly be incorporated into a carbon management and clean energy business park. The website provides an overview of how each technology investigated in this report works, how it might benefit from co-location with other technologies in a shared industrial space, and what impacts and benefits such a technology would have on the regional community and environment.

Please note, the purpose of this analysis is not to endorse any carbon management technology or specific business park configuration for development in Kern County. The purpose of the website and report is to provide a useful synthesis of relevant information about carbon management and clean energy to stakeholders, developers and planners in the Kern County community, to ensure that they have a holistic understanding of these novel industries. With such a resource, private investors and local stakeholders will be better equipped to plan how the region's energy economy should grow in a well-informed and transparent manner.

Any development of a carbon management business park in Kern County would be facilitated by private investors. Those investors would be required to submit a proposal to the Kern Planning and Natural Resources Department that would include a specified location and a Specific Plan designating the industries and land uses to be built. An Environmental Impact Report (EIR) would be required and the EIR and Specific Plan would go through a full public process.

1.2 How to read this report

This report is laid out in ten sections subsequent to this introduction. The first section (Section 2) provides a summary of the federal and state policy landscape that is relevant to all the carbon management industries examined here, and is intended as a general resource that is referred to in subsequent sections. Sections 3 through 5 examine industries whose primary or secondary purpose is to capture CO_2 for permanent underground storage, and Sections 6 through 10 examine industries that could support carbon management industries (e.g. energy storage or water treatment), could benefit from co-location with carbon management industries (e.g. hydrogen via electrolysis), and/or are tangential to carbon management industries (e.g. CO_2 transport and CO_2 utilization). The use of CO_2 for enhanced oil recovery is not examined in this report. Finally, Section 11 provides a brief examination of how carbon management industries might take advantage of partnerships with (and be a benefit for) the dominant regional industry of agriculture.

This report represents a synthesis of information derived from academic literature, publicly available data and subject matter and industry expertise. For each factor of analysis, the aim is to provide as quantitative an assessment of the state of the industry as possible. Where specific estimates of a variable were available (such as land use, energy or water use requirements) a specific value or range of values is given, with the range encompassing all published estimates that could be verified as reasonable based on corroborating reports or expert discussions. Because carbon management industries are novel and in a phase of

rapid growth and innovation, it is expected that all systems will become more efficient, smaller and less expensive in the coming decades than the technologies described here.

All costs listed in this report are given in U.S. dollars, and are reported as the dollar value used in the source material, unless explicitly noted otherwise in the text. That is, except for references in which cost estimates were older than 10 years or reported in a non-U.S. currency (noted in text), the dollar amount reported is the same as that reported in the referenced material and is not adjusted for inflation since the year of reference publication. This approach was taken for three reasons: (1) To maximize transparency with regards to how all calculations in this report were made and from where all information was obtained, and thus we avoided inflation corrections to reduce the possibility of confusion or miscalculation; (2) Most cost estimates are derived from references published within the last 5 years, which means inflation would increase the cost estimates by less than 20%.[21] Nearly all technologies examined in this report have cost uncertainties much greater than 20%, and we report the full range of cost estimates aggregated from multiple sources; (3) Given the rapidity with which carbon management industries are growing, cost reductions that have likely occurred in the last 1-5 years from "learning by doing" may partially or completely offset the cost increases resulting from inflation.

A detailed techno-economic analysis of potential fiscal and economic benefits of the carbon management industry to Kern County was completed in parallel to the construction of this report by the Natelson Dale Group, Inc., and is appended at the end of the report.

2. Policy Brief

International pressure to address climate change is spurring significant public and private interest in the development of carbon management technologies, and a variety national and state policies that enhance the benefits of deploying these technologies are making them particularly viable for development in Kern County. However, the building and operating of these technologies still must adhere to environmental, land use, and other existing policies if deployed.

In this report section, we endeavor to outline the topline general policy items that would impact carbon management implementation within Kern County. Thus, this section does not adhere to the lenses of analysis used throughout the rest of this report—this is intended as an informational addendum to the report at large.

- The first section explores the international case for limiting greenhouse gas concentrations in the atmosphere, as well as the natural and technological pathways available to remove carbon dioxide (CO_2) from the atmosphere.
- The second section outlines the United States' federal climate goals and California's state climate goals.
- The third section outlines the permitting and environmental requirements that projects looking to site in Kern County would need to adhere to in designing and constructing a carbon management facility, like the hypothetical carbon management business park.
- The fourth and final section outlines the subsidies and incentives available for implementing carbon management practices and related monetary benefits for emissions reduction.

2.1 International goals and the case for CCS

According to the IPCC, limiting global warming to 1.5°C is imperative to preserving the well-being of people and natural ecosystems.[1] It is considered a crucial target by the international community because climatic and environmental changes past that point become more drastic and unpredictable.[2] For example, limiting warming to 1.5°C is expected to lead to declines in coral reefs of 70-90% globally; however, warming of 2°C would lead to a near-total loss of coral reefs.[3]

Based upon the potential future pathways seen in Figure 2.1, meeting the future on the best possible terms relies upon not only rapidly lowering global emissions, but also removing more CO_2 from the atmosphere that we generate. The gray band at the bottom of the illustration demonstrates scenarios of net CO_2 removal. There are both natural and technological pathways to remove CO_2 from the atmosphere.

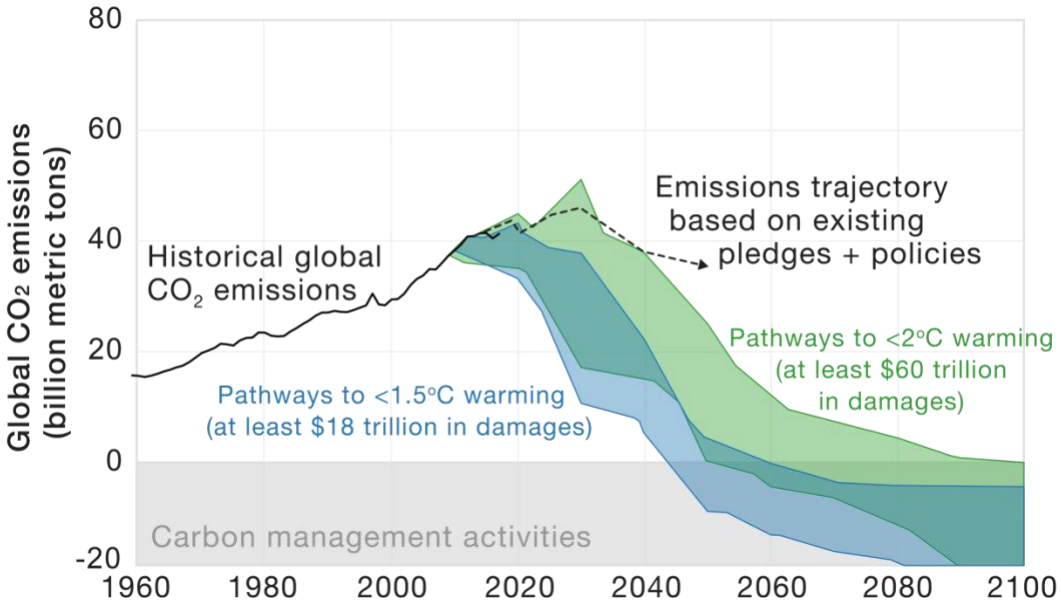

Figure 2.1. Illustration of CO_2 emissions pathways that could be employed to ensure global average temperatures remain below 2°C (green shaded region) or 1.5°C (blue shaded region). As temperatures rise, the cost of mitigating damages from extreme weather events like heat waves, floods and droughts will rise at a disproportionately higher rate.[4] Each region represents an aggregate of multiple modeled pathways that could maintain the desired temperature limits. Nearly all pathways require global CO_2 emissions to become net-negative by mid- or end-century, which will require the employment of carbon management activities to remove CO_2 from the atmosphere.[5] Adapted from Wikimedia commons: Mitigation Pathways.

[5] Rogelj, *et al.* (2018) Scenarios limiting global mean temperature increase below 1.5°C. [41]

Natural processes, such as plant growth in forests and wetlands or ocean acidification, serve to sequester atmospheric carbon, but can also have undesirable effects once they pass natural thresholds.[6] For example, ocean acidification impacts the biodiversity of the ocean as it makes it difficult for coral and oysters to form their robust shells.[7] Plant-based solutions—like afforestation and wetland restoration—are promising because they are not only beneficial for sequestering CO_2, but also serve to support climate resilience and ecosystem health in the region.[8] However, these natural solutions – even when environmentally beneficial – can be problematic from a carbon management perspective, because it is difficult to assess how much CO_2 is being removed from the atmosphere from such interventions, and how long it will remain trapped in these organic reservoirs.[9]

Technological processes can also assist in removing CO_2 from the atmosphere and are generally termed carbon capture and storage (CCS). Many of the technological options available for capture—including DAC, BiCRS/BECCS, and point-source capture (with steel as an example industry)—are explored within this report at large, in Sections 3, 4, and 5, respectively. The primary value of these technologies is that they can prevent CO_2 from entering the atmosphere or remove it directly from the air.[10] Furthermore, if scaled adequately, these systems have the potential to remove CO_2 at much faster rates than natural processes.[11] They also can remove CO_2 with a smaller land footprint than natural solutions like reforestation, though the costs are generally higher per ton of CO_2 removed for technological solutions.[12] Given the time-sensitive nature of climate change, technological processes may be necessary to slow the rise in atmospheric CO_2 before we reach critical tipping points.[13] Achieving a global warming of under 2°C likely requires the use of carbon removal technologies *in addition to* substantial reductions in standard greenhouse gas emissions.[14]

2.2 Federal and state climate goals

The U.S. federal government has set ambitious targets for climate action in the coming decades. By 2030, the goal is to reduce greenhouse gas emissions to 50% of 2005 levels—by 2050, the target is to reach net-zero emissions.[15]

[15] The White House (no date) National Climate Task Force. [47]

In recent years, federal action on climate change has been supported by the Bipartisan Infrastructure Law (BIL) and the Inflation Reduction Act (IRA).[16] The BIL package awarded funding for over 20,000 projects and supports efforts to modernize the electric grid, expand rail and other public transportation, as well as maintaining other key infrastructure like roads, bridges, and water treatment facilities.[17] The IRA tackles climate more directly, with consumer rebates to install energy efficient appliances, tax credits for solar or electric vehicle purchases, and measures to directly reduce pollution and implement community-scale clean energy solutions.[18] A full exploration of the IRA's climate-related provisions is included in the Subsidies & Incentives section below.

As a state, California has set goals that are more ambitious than federal goals. By 2045, California is aiming to be carbon neutral.[19] This includes a goal to reduce natural gas consumption by 94% and greenhouse gas emissions by 85%.[20] These goals also rely upon ramping up carbon capture and sequestration efforts within California. In the most recent scoping plan announced by the California Air Resources Board (CARB), California targets to remove "20 million metric tons CO_2 equivalent ($MMTCO_2e$) by 2030 and 100 $MMTCO_2e$ by 2045" from the atmosphere to meet its climate targets.[21] This is aligned with the findings of other recent California-specific reports on reaching carbon neutrality, like Lawrence Livermore National Laboratory's Getting to Neutral.

2.3 Permits

2.3.1 Local land use

- Applicable for facilities with CO_2 capture, transport, or storage that takes physical place within, or in certain parts, of city or county boundaries.
- Agency level: local government
- Turnaround timeline: more than 18 months

The authorization of land use encompasses the physical footprint of the facility, from the types of activities allowed in certain areas, to the detailed aspects of facilities such as building height, traffic, noise, and other environmental impacts. Any planned CCS facilities must follow the city or county's zoning and land-use ordinance.

Carbon management projects on sites previously developed for similar purposes (like establishing a BiCRS facility by retrofitting a retired bioenergy plant, see Section 4) might

[21] Office of Governor Newsom (November 16, 2022) California Releases World's First Plan. [36]

face fewer hurdles, since some uses might have been allowed already for existing facilities—however, this is not always the case. For instance, the installation of tall columns for carbon capture solvent or a gas flare may face minimal review when placed at an existing refinery that would have been permitted for much taller distillation columns, but could face higher scrutiny at a former power plant site, where they might exceed specified height limits for the site.

Transportation via pipeline will likely face a high level of scrutiny and review, regardless of the existing right-of-ways (ROW) in place. One way to reach compliance is to seek amendment of a county's zoning map to allow uses or activities commonly related to carbon capture and storage.[22] Such a measure would likely only be appropriate if it is in the county's long-term interests and economic plan, as opposed to authorizing a single project.

2.3.2 CO_2 Pipelines — Easements and ROWs

- Applicable for CO_2 transport.
- More than one agency could be involved and projects would generally involve private parties (including the pipeline owner and landowners)
- Timeline: more than 18 months

Permitting pipelines is often difficult and time consuming because most pipelines are sited across land held by a variety of owners. Thus, it is more attractive to route pipelines in such a way that it crosses large land holdings in the hands of fewer owners. Surface ownership of a pipeline might cross private, local government, state, federal, and tribal, as well as existing third-party easements. Under an easement—a legal agreement conferring to the pipeline owner the right to site, construct and operate the pipeline on a landowner's property—the holder is granted the right to travel over another's property.[23]

Areas with existing pipelines run may offer potentially easier pathways to siting. Depending on the contract language, opportunities for new development may already exist under existing easements or ROW agreements. The success of this strategy hinges on how the existing easements are written and if they provide for addition of a new pipeline or for repurposing or modification of an existing one.

Regulation of any CO_2 pipelines constructed would fall under the purview of the Pipeline and Hazardous Materials Safety Administration (PHMSA) at the federal level[24] and the Office of the State Fire Marshal (OSFM) at the state level.[25] A full exploration of the permitting and regulatory requirements for CO_2 pipelines can be found in Section 9.

2.3.3 Title V Air Permit

- Applicable for facilities with CO_2 capture, especially those that emit pollutants into the air
- Agency level: local air district, and potentially U.S. EPA
- Timeline: approximately 1 year

In California, air districts are the local regulators that implement federal Clean Air Act requirements, as well as other state-level regulations regarding emissions, for pollution sources within the region.[26] Any CCS project would likely have to engage these local air districts to receive air permits. Eastern Kern Air Pollution District (EKACPD) is the local regulator for eastern Kern County, while western Kern County falls under the authority of the San Joaquin Valley Air Pollution Control District (SJVAPCD).[27]

To gain a Title V operating permit, an institution or person that is constructing, altering, replacing, or operating any source that emits, may emit, or may reduce emissions must obtain preconstruction permit authorization before commencing construction as well as a permit to operate from their local air district.[28] For projects built on Indian and tribal lands within the borders of the United States, the U.S. EPA is required to issue operating permits instead.[29] Exemptions are limited to very low-emitting, minor equipment, such as engines on compressors or emergency generators, but full requirements for non-major sources are laid out in Code 40 of Federal Regulations.[30] It's particularly applicable to carbon management industries that operate in the CO_2 capture stage, because these types of facilities may emit other air pollutants in addition to the CO_2 that they are capturing, such as NO_x or particulate emissions, and fugitive emissions from some kinds of amine-based CO_2 scrubbers could produce volatile organic compound (VOC) emissions.

California, as a state, is required to develop state implementation plans (SIPs) to achieve National Ambient Air Quality Standards (NAAQS), for six criteria pollutants: ground-level ozone, particulates, carbon monoxide, lead, sulfur dioxide and nitrogen dioxide.[31, 32] Whether or not a state has achieved NAAQS attainment goals in a given pollution type determines the type of permit process that a new facility must pursue.

- Attainment areas: Prevention of Significant Deterioration (PSD) permits are required for new major sources or for making a major modification.[33]

[32] EPA (January 20, 2023) Basic Information about Air Quality SIPs. [17]
[33] EPA (January 24, 2023) Prevention of Significant Deterioration Basic Information. [20]

- Non-attainment areas: Non-Attainment New Source Review (NNSR) permits are required for new major sources or for major sources making substantial modifications.[34]

The required mitigation action is stricter in non-attainment areas and requires achieving the Lowest Achievable Emissions Rate (LAER), as well as the use of offsets to the extent allowed or available.[35] Offsets are specific to each pollutant category, but specialized cases outlined by the EPA allow offsets from alternate sources at a 2-to-1 ratio.[36] In attainment areas, the corresponding requirement is Best Available Control Technology (BACT) for any "major new or modified sources."[37]

Table 2.1. Air quality attainment data for Kern County

Pollutant	EKAPCD[a]		SJVAPCD[b]	
	Federal	**State**	**Federal**	**State**
Ozone (1 hour)	Attainment	Nonattainment	Attainment	Severe Nonattainment
Ozone (8 hour)	Severe Nonattainment	Nonattainment	Extreme Nonattainment	Nonattainment
PM10	Attainment	Nonattainment	Attainment	Nonattainment
PM2.5	Attainment	Unclassified	Nonattainment	Nonattainment
Carbon Monoxide	Attainment	Unclassified	Attainment	Attainment
Nitrogen Dioxide	Unclassified	Attainment	Attainment	Attainment
Sulfur Dioxide	Unclassified	Attainment	Attainment	Attainment
Lead Particulates	Attainment	Attainment	Unclassified	Attainment

a. Eastern Kern Air Pollution Control District
b. San Joaquin Valley Air Pollution Control District

The California Ambient Air Quality Standards (CAAQS) are typically stricter than NAAQS requirements, but NAAQS attainment takes precedence "due to federal penalties for failure to meet federal attainment deadlines."[38, 39] Both NAAQS and CAAQS use 'attainment' or 'unclassified' and 'non-attainment' designations—an attainment or unclassified designation means an area meets or exceeds the standard for that compound, whereas

[38] CARB (no date) Ambient Air Quality Standards. [6]
[39] CARB (no date) California Ambient Air Quality Standards. [7]

non-attainment is used for areas that fail to meet the standard.[40] Table 2.1 summarizes Kern County's current status for major pollutants.

In addition to PSD and NNSR permitting, installation of carbon management facilities and associated equipment will likely trigger additional Clean Air Act Title V permitting under the local air district. The Title requires major sources of air pollutants and certain other sources to obtain an operating permit, operate in compliance with it, and certify compliance at least annually.[41]

2.3.4 California Environmental Quality Act (CEQA) Guidelines

In California, CEQA requires a project to identify significant environmental impacts of their activities, and to avoid or mitigate those impacts.[42] A project that may cause direct physical changes to the environment or an anticipated indirect change must comply with CEQA.[43] Most proposals for physical development need to comply with CEQA, but other projects which do not immediately result in physical development (like adopting a general or community plan) need to comply as well.[44]

For every project, an initial review of potential environmental effects must be conducted.[45] Depending on the initial review of the potential impacts of a project, CEQA may require the project to conduct a full environmental impact report (EIR).[46] If there are feasible alternative options or mitigation strategies available for the project to notably reduce its environmental impact, then a project cannot be approved as originally submitted.[47]

CEQA requires that an initial review determine the significance of a project's expected greenhouse gas emissions.[48] Under CEQA's definitions, greenhouse gasses "includes but is not limited to: carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons and sulfur hexafluoride."[49]

Regulated air pollutants under CEQA include nitrogen oxides (NO_x) and volatile organic compounds (VOCs), ozone-depleting substances (CFC and HCFC), particulate matter, carbon monoxide (CO), sulfur dioxide (SO_2) and lead. CEQA also evaluates greenhouse gas (GHG) emissions,[50] in which project-specific GHG emissions must be analyzed for their

ability to contribute globally to climate change,[51] unless the project is exempted from CEQA.

2.4 Subsidies & Incentives

2.4.1 California Low Carbon Fuel Standard (LCFS)

California's LCFS is a market-based policy, first adopted in 2009 and implemented in 2011, that aims to diversify California's energy mix by setting annual carbon intensity (CI) benchmarks and encouraging the adoption of low-CI fuels under the oversight of the California Air Resources Board (CARB).[52] In 2018, the LCFS was extended by CARB from 2020 to 2030, with a goal of reaching a 20% CI reduction target from 2010 levels by 2030.[53]

The system operates based on CI life cycle assessments conducted by CARB, which "examines the GHG emissions associated with the production, transportation, and use of a given fuel" along with notable indirect impacts, and then gives the fuel in question a CI score.[54] CARB's model does not rely just on carbon dioxide emissions, but also emissions of methane, nitrous oxide, and other greenhouse gases.[55] After each fuel is scored based on its lifetime emissions, it is compared to a CI benchmark set by CARB that declines each year.[56] Fuels with CI scores lower than the benchmark will generate LCFS credits that year, whilst fuels that exceed the CI benchmark generate deficits.[57]

In short, the system grades fuels based on their relationship with the annual target—fuels that have a CI lower than the target will produce LCFS credits, while fuels that have a CI higher than the target have a deficit that must be fulfilled to meet the standard.[58] This deficit can be remedied by either generating LCFS credits directly or purchasing LCFS credits from another supplier in order to meet the annual target.[59] LCFS applies only for fuels used for transportation, including gasoline, diesel, and their alternatives.[60]

Under the LCFS, all "petroleum importers, refiners, and wholesalers" selling fuels in the California market are regarded as Regulated Parties (RPs).[61] Providers of clean, alternative fuels that already meet the relevant 2030 carbon intensity benchmark are exempt from the

LCFS, but may opt-in to the program as RPs to receive credits for the fuels they sell in California.[62] The LCFS system hinges on the LCFS Reporting Tool (LRT), which serves as a central database where RPs must record the transaction-level information anytime that "transportation fuels are imported, refined, or sold in California."[63] (The LRT may also be referred to as the LRT-CBTS, or the LCFS Reporting Tool and Credit Bank & Transfer System.)[64] The LRT serves to track all transactions, and also serves to sum the credits and deficits for a given RP to track their compliance status in relation to the annual CI target.[65] If credits are used in an annual compliance report to offset deficits for an RP, those credits are retired; otherwise, LCFS credits generated or acquired by an RP do not sunset or decline in value over time.[66] Owners of credits can only sell or trade credits to other RPs in the system currently at a deficit, and parties that are not recognized as RPs are forbidden from holding any LCFS credits.[67]

In addition to credit generating fuels, the LCFS has provisions to generate credits through approved non-fuel activities that can help reduce transportation emissions at large.[68] This includes what CARB refers to as project-based crediting and capacity-based crediting under LCFS.[69] Project-based credit opportunities can include using renewable hydrogen at a facility generating transportation fuels, developing a direct air capture (DAC) facility to capture historic transportation emissions, and investments that reduce an existing transportation fuel facility's emissions, like using renewable energy or adopting carbon capture and storage (CCS).[70] Capacity-based credits are attainable by RPs that own hydrogen fueling equipment or zero-emission vehicle infrastructure.[71]

Starting in 2019, the LCFS began allowing the use of CCS technologies to "reduce emissions associated with the production of transport fuels" in California to generate LCFS credits—this included DAC projects.[72] To qualify, projects must meet CCS Protocol requirements, which encompass a variety of carbon management projects, as long as they lead to storage of captured CO_2 in depleted oil and gas reservoirs or saline formations onshore *or* are used for enhanced oil recovery (EOR) in oil and gas reservoirs.[73] Table 2.2 shows different types of CCS projects that can qualify to generate credits under the LCFS.

Table 2.2. Qualifications for CCS projects to meet LCFS standards.[74]

	Direct Air Capture Projects	CCS at Oil & Gas Production Facilities	CCS at Refineries Projects	All other CCS Projects (e.g. CCS with Ethanol)
Location of CCS project	Anywhere in the world	Anywhere, provided they sell the transportation fuel in California	Anywhere, provided they sell the transportation fuel in California	Anywhere, provided they sell the transportation fuel in California
Storage site	Onshore saline or depleted oil and gas reservoirs, or oil and gas reservoirs used for CO_2-EOR			
Credit method	Project-based	Project-based, under the Innovative Crude Provision	Project-based, under the Refinery Investment Credit Program	Project-based or fuel pathway
Earliest date which existing projects eligible	Any	2010	2016	Any
Requirements	Project must meet requirements specified in CCS Protocol			
Additional restrictions	None	Must achieve minimum CI or emission reduction	None	None

DAC facilities located anywhere in the world can generate LCFS credits by choosing to opt in to the LCFS program.[75] DAC projects are an exception to the general requirements of LCFS credits, as they are "not required to sell any transportation fuel into the California market to generate credits."[76] Even so, the rules around DAC project eligibility are tightly defined. If CO_2 captured by a DAC facility was used to create a synthetic fuel for sale in California, it wouldn't qualify for project-based crediting and would instead need to seek a separate fuel pathway in order to generate LCFS credits.[77]

California's LCFS credits can also be stacked with federal 45Q tax credits (Section 2.4.3).[78] There are no restrictions on obtaining both incentives as long as the responsible party adheres to the rules and regulations of both systems.

2.4.2 Inflation Reduction Act (IRA)

The Inflation Reduction Act (IRA) was signed into law on August 16, 2022 and encompasses a wide range of new policy directives spanning healthcare, tax compliance, and energy and

environment issues (Figure 2.2).[79] Here, only the energy and environment directives are explored; other policy items included in the IRA are outside of the scope of this report.

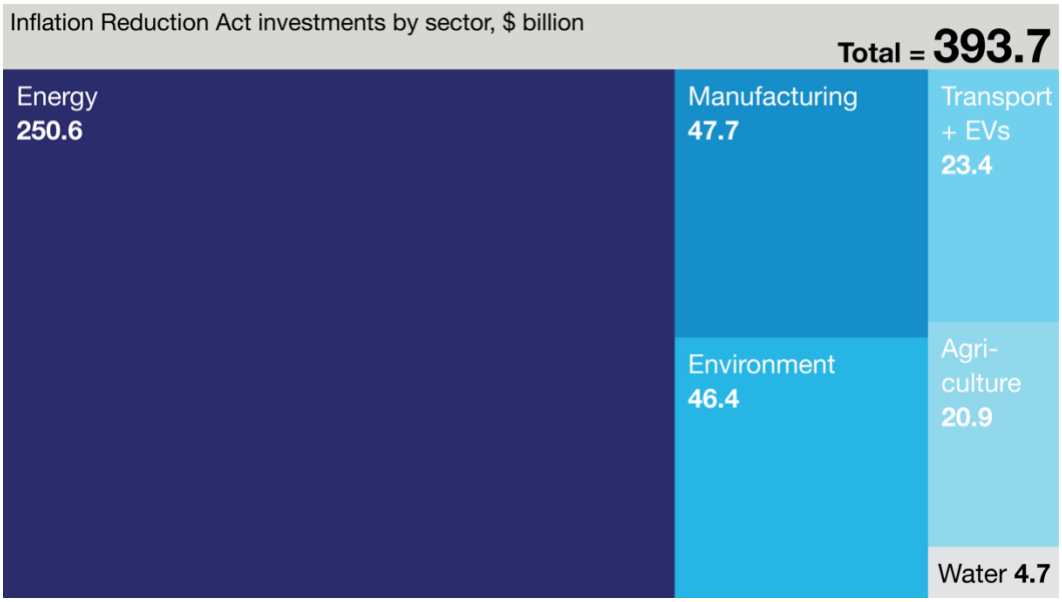

Figure 2.2. Scaled graphic indicating the amount of investment by sector, in billion USD, allocated under the Inflation Reduction Act.[80]

The diversity of climate investments in the IRA, as seen below, is extensive. Funding will be disbursed through grants, loan guarantees, and tax incentives, with tax incentives being the largest share of available funding under the IRA.[81] This includes tax credits for individuals associated with purchasing heat pumps and electric vehicles (new or used), as well as credits for businesses or utilities that are generating zero-carbon electricity, nuclear power, sustainable aviation fuels, or qualifying clean hydrogen.[82] It is worth noting that the time horizons and credit amounts differ based on sector.

The IRA also incorporates provisions aimed to bolster domestic production of goods. Facilities must "meet prevailing wage and apprenticeship requirements" to attain full eligibility under the IRA's tax credit system.[83] These requirements also impose specific requirements, as applicable, to specific initiatives. For example, attaining the full consumer EV tax credit is dependent on a sliding scale of how many of the materials in the battery

were recycled within North America or extracted in countries with whom the U.S. maintains free-trade agreements.[84]

Other provisions in the IRA are designed to aid in transitioning workers from fossil fuels to other energy industries. The IRA includes incentives for companies looking to develop solar or wind farms to locate in regions where coal facilities have recently discontinued operations.[85] It also includes some tailored worker benefits, like the development of a permanent federal trust aimed at supporting coal miners living with black lung disease.[86] Another angle of its transition-oriented policies is its expansion of support for hydrogen-based fuels and CCS, explored in the sections below.[87]

2.4.3 45Q Federal Tax Credits

The 45Q tax credit was introduced in 2008 as an incentive to develop carbon capture, use, and sequestration projects within the United States.[88] Over time, the credit's value has increased—as of the end of 2022, due to the Inflation Reduction Act (IRA), these credits were valued at \$85/ton CO_2 permanently stored and \$60/ton CO_2 used for enhanced oil recovery (EOR).[89] The values are higher for carbon captured via direct air capture (DAC) processes, where the values rise to \$180/ton CO_2 permanently stored and \$130/ton CO, for use in EOR.[90]

Changes in the IRA also extended the eligibility window for new projects to qualify.[91] Now, projects must begin construction by January 2033 in order to qualify for 45Q credits.[92] It also imposes updated minimums on the amount of CO_2 a facility must capture annually to qualify for credits: "18,750 tonnes per year for power plants (provided at least 75% of the CO2 is captured), 12,000 tonnes per year for other facilities, and 1,000 tonnes per year for DAC facilities."[93]

2.4.3 45V Federal Tax Credits

The hydrogen fuel benefits are dispensed through the new tax incentive 45V, in which producers of hydrogen with 'near-zero emissions' can earn \$3 per kilogram of hydrogen produced with no cap on the number of kilograms the producer can receive the incentive

for.[94] The exact structure of these benefits, however, will depend on rules that are still being written by the Treasury Department; until they have developed a clear definition for 'near-zero emissions,' it is difficult to guess what standards a producer would need to meet to be eligible for the $3/kilogram incentive.[95]

2.5 Additional California-Specific Policies

In California, there are some specific policies that will impact the avenues of carbon management activity that can be pursued, which are external to the permitting requirements outlined above, nor do they constitute as incentives, at least at this moment.

First, a recent package of climate bills that was signed last fall by Governor Gavin Newsom included multiple state bills relevant to carbon management efforts. SB 1314 effectively bans the utilization of any captured CO_2 to be used for enhanced oil recovery (EOR) in the state.[96] As a result, carbon management entities will need to identify other avenues of utilization or storage for their captured CO_2. SB 905 requires that the California Air Resources Board (CARB) establishes a "Carbon Capture, Removal, Utilization, and Storage Program."[97] Under SB 905, CARB must also set up a unified permit for California-based carbon capture, utilization and storage (CCUS) projects, establish a centralized database for California-based carbon management projects, and implement financial responsibility regulations for CO_2 storage operators to retain responsibility for a minimum of 100 years following their most recent CO_2 injection at a well site.[98]

Other statewide policies are likely to have indirect effects on carbon management efforts. California's Sustainable Groundwater Management Act (SGMA) from 2014 requires that state groundwater supplies be brought back into long-term balance by 2040,[99] which may limit the availability of freshwater supplies to Kern County and neighboring areas, depending on the region's hydrology over the coming decades. SGMA requires the development of local groundwater sustainability agencies (GSAs), formed as partnerships between city and/or county governments, irrigation districts, water districts, or other local bodies.[100] Each GSA submits plans to the state to meet SGMA's objectives, with a focus on implementing responsible groundwater management for their region.[101] The California Department of Water Resources (DWR) oversees implementation, giving routine assessments and providing technical assistance, and the State Water Resources Control

Board is entrusted with intervening in a basin's management if its sustainability plans fail.[102] With regulations like SGMA in place to protect local water supplies, water-intensive industries—like liquid direct air capture (L-DAC) or hydrogen production via electrolysis—may find it more difficult to locate in water-stressed regions. Issues relating to available freshwater supplies in Kern County are explored more in Section 8.1.4.

CARBON MANAGEMENT TECHNOLOGIES

3. Direct Air Capture

TECHNOLOGY AT A GLANCE

- Industry is in early commercial stages: Globally, a cumulative ~10,000 metric tons CO_2 are captured each year by other projects[1]
- Current cost per metric ton CO_2 captured: $94-877 USD/ton CO_2
- Projected cost per metric ton CO_2 captured at scale: $60-200 USD/ton CO_2
- 200-240 acres of land use required per million metric tons CO_2 captured
- Key advantages of this technology in Kern County: minimal feedstock requirements or waste; solid-direct air capture (S-DAC) has the potential to capture water as well as CO_2
- Key concerns for this technology in Kern County: noise and vibration levels with large-scale projects, high energy demands, poor clarity on job creation potential

3.1 Technology Summary

Direct Air Capture (DAC) is a technology that captures carbon dioxide (CO_2) directly from the atmosphere, usually through a mechanical system, although some passive capture techniques are also being developed. In a mechanical system, fans or wind are used to drive ambient air through a contactor unit, where the air passes across a chemical sorbent

[1] Values in this section are summarized from the suite of references cited herein, and are explained in further detail in each subsequent section.

that selectively reacts with and traps CO_2, allowing the other components of the air to pass through and exit the system. Currently, the most developed adsorbent materials are in liquid or solid forms.[2]

3.1.1 Description: How it Works

DAC can be thought of as an engineered equivalent to photosynthesizing plants, except that DAC captures CO_2 from the atmosphere at a faster rate and with a much smaller land footprint than biomass. Furthermore, DAC delivers CO_2 in a pure, compressed form. Captured atmospheric CO_2 can be permanently and safely stored in geologic reservoirs to deliver negative emissions, or be used to produce low carbon intensity products, such as synthetic fuels that work in existing vehicles and infrastructure.[3]

Current DAC technologies are primarily distinguished by using one of two types of sorbent: liquid solvents (L-DAC) and solid sorbents (S-DAC). In both techniques, DAC pulls air from the atmosphere and passes it over the sorbent material. The sorbent material captures the carbon dioxide, and the rest of the air passes through and exits the DAC unit. L-DAC typically uses hydroxide solutions (a liquid solvent) as the bonding sorbent, whereas S-DAC relies on a CO_2 "filter" or dry amine-based chemical sorbents.[4] In both cases, the CO_2 from the air is chemically bound into a new compound, and then is subsequently broken down to release 1) a high-purity stream of CO_2 for storage, and 2) the original sorbent components for reuse. Figures 3.1 and 3.2 illustrate the multi-stage process of DAC's operational system, distinguished by the solid sorbent (S-DAC) and liquid solvent (L-DAC) technologies, respectively.

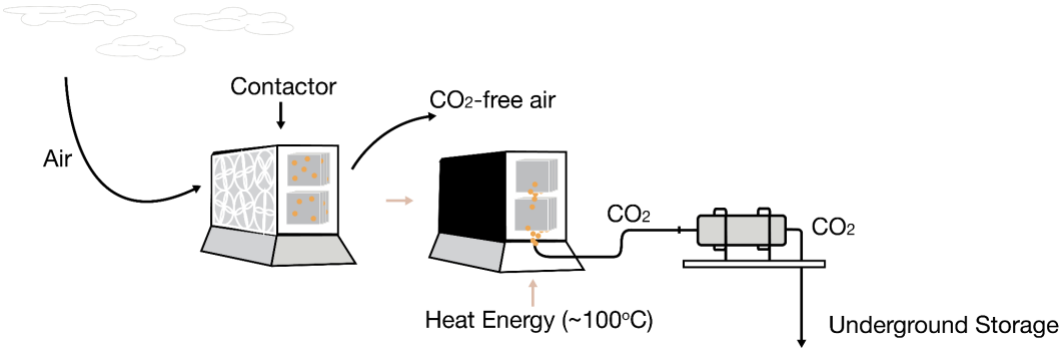

Figure 3.1. Schematic of S-DAC operation.[5] Step 1: ambient air enters the air contactor unit and CO_2 is absorbed onto a solid sorbent. Step 2: Heat exposure (± vacuum pressure) releases CO_2 from sorbent material and a concentrated stream of CO_2 is produced. Step 3: Sorbent is cooled, thereby reactivating it for reuse in the air contactor.

[2] IEA (2022) DAC Report. [40]

[4] IEA (2020) CCUS in Clean Energy Transitions. p. 82. [41]

[5] Larsen *et al.* (2020) Capturing New Business. [44]

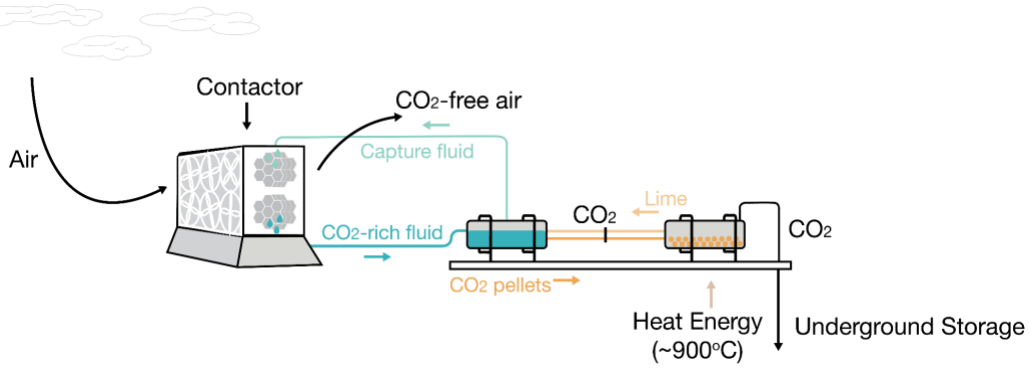

Figure 3.2. Schematic of L-DAC operation.[6] Step 1: ambient air enters the contactor and CO_2 reacts with capture fluid to produce carbonate. Step 2: Carbonate reacts with hydroxide to form small pellets. Step 3: Pellets are heated to produce lime and a concentrated stream of CO_2. Step 4: Lime from the calciner reactivates capture solution for reuse in contactor.

Both technologies require electricity and heat to operate; the electricity drives the fans and controls inlet systems, while the heat releases the trapped CO_2. However, S-DAC requires only temperatures of only ~100°C to break the chemical bonds linking the CO_2 to the sorbent material, whereas L-DAC requires temperatures around 900°C.[7,8] Such temperatures are difficult to reach using renewable energy sources like wind or solar. If natural gas is used to attain the necessary heat, the associated CO_2 released from the use of L-DAC technology would need to be recaptured and stored to avoid counteracting the benefit of DAC.[9]

3.1.2 State of Development

DAC is a relatively new industry that is still in the early stages of development.[10,11] As of the drafting of this report, large-scale commercial deployment of DAC does not exist, but several companies have developed pilot projects with limited commercialization that are capturing CO_2 on the scale of thousands of metric tons per year.[12] Some, but not all, of these pilot projects include geologic sequestration or utilization of the captured CO_2.[13] Because DAC technology is still in its infancy, there are few straightforward assessments of how the technology and business model of DAC will adapt to industrial scaling, although there is reason to expect that economies of scale and technological innovation will have

positive effects.[14] The earliest breakthrough paper describing a working direct air capture system was written by Geoffrey Holmes and David Keith of Carbon Engineering in 2012, specifically discussing an L-DAC system.[15] The following year, the first pilot-scale deployment of DAC was launched by the Swiss company, Climeworks, which utilizes S-DAC technology.[16] With only about a decade since its early breakthroughs, DAC technology still needs research, innovation, and further technological breakthroughs to reach its maturity at scale.

As of April 2022, there are 18 DAC plants currently operating worldwide, capturing approximately 0.01 Mt CO_2/year.[17] Companies leading the industry with the most developed DAC technology are Climeworks, Carbon Engineering and Global Thermostat. These companies are primarily focused on developing megaton facilities: plants that will operate at the scale of capturing millions of metric tons of CO_2 annually (Mt CO_2/year), and have progressed the furthest towards opening commercial, large scale DAC plants.[18,19]

Two commercial plants, developed by Climeworks, are currently operating in Switzerland and selling CO_2 to greenhouses and beverage companies for carbonation.[20] The latest plant to come online from Climeworks is Orca, launched in 2021 and capturing 4,000 metric tons of CO_2 per year for storage in basalt formations in Iceland.[21] The Orca pilot plant is also a test facility for CO_2 mineralization, in which CO_2 is sequestered in porous basalt where it can react with host minerals and form the carbonate solid $CaCO_3$, precluding any risk of leakage.[22] In North America, both Carbon Engineering and Global Thermostat have been operating a number of pilot plants, with Carbon Engineering, in collaboration with Occidental (Oxy), currently designing what would be the world's first megaton DAC facility, called 1pointfive, in the Permian Basin region of west Texas anticipated to be operational in 2024.[23, 24]

3.1.2.1 Operational projects - examples

Orca Facility, Climeworks, Iceland

Launched in September of 2021, the Orca plant (Figure 3.3a) is currently the largest DAC plant in the world.[25] Located in Hellisheidi, Iceland, the plant has a carbon removal capacity of 4,000 metric tons per year.[26] The plant was developed as a collaboration between Climeworks (using their S-DAC technology) and Carbfix, an industry-research consortium that is piloting the development of underground storage of CO_2 through mineralization.[27] The facility consists of eight collector containers, with an annual CO_2 capture capacity of 500 metric tons each.[28] The containers are arranged around a central process hall that accommodate electrical and processing equipment, allowing the company to operate and control the facility remotely.[29] The DAC plant is strategically located in proximity with the Hellisheidi Geothermal Power Plant, which supplies the heat and electricity required to run the direct air capture process at low cost.[30] The Orca footprint is 8,600 square feet, equivalent to the square footage of approximately four urban houses.[31] This translates to a per ton CO_2 land use requirement of 2.15 square feet per ton of CO_2 captured.

[32] Climeworks (2021) Orca. [23]
[33] Climeworks (June 28, 2022) Climeworks takes another major step. [22]

The capital and operational costs of the Orca plant are covered in part by the sale of carbon credits in the voluntary carbon offset marketplace, where private buyers can purchase the capture and storage of CO_2 on a per-metric ton basis to offset their own emissions.[34] The Orca plant sells the most expensive carbon offset credits in the world, costing as much as €1,000 per metric ton of CO_2 removed.[35] Climeworks' clientele for carbon offset credits includes Microsoft, Swiss Re, Shopify and Audi.[36] Jan Wurzbacher, co-chief of Climeworks, said commercial demand had been so high that the plant was nearly sold out of credits for its entire 12-year lifespan, prompting the accelerated development of their next plan: the Mammoth DAC facility (Figure 3.3b).[37] Mammoth uses the same technological design as Orca, will also be sited in Hellisheidi, Iceland, and will also sequester the CO_2 via mineralization in Iceland's basalt-rock subsurface, but will have a nominal CO_2 capture capacity of 36,000 tons per year. The plant is expected to be operational in 2024.[38]

DAC 1 Facility, Carbon Engineering, US

DAC 1 is a megaton DAC plant in development in west Texas by the companies 1pointfive and Carbon Engineering. Operation is expected to begin in 2024.[39] The plant will use Carbon Engineering's liquid solvent system (L-DAC), which uses a potassium hydroxide (KOH) solution as the sorbing fluid that binds the CO_2.[40] The facility will be assembled as "a scalable setup" consisting of modular contactors (Figure 3.4a, from Carbon Engineering's pilot facility in British Columbia) that will require a land size of 0.2 km^2, not including energy land use, to reach its 1 $MtCO_2$/yr capture target.[41] High-temperature release and separation of the CO_2 and regeneration of the liquid solvent will be performed using natural gas as the thermal energy source.[42] Because this facility will be sited in the Permian Basin region, which has ideal subsurface reservoirs for geological sequestration, transport of the separated CO_2 to a permanent storage site will be minimal.[43] The initial phase of DAC 1 is focused on a first capture train with a planned capture capacity of 0.5 $MtCO_2$/year; the total capacity of the project will subsequently increase to 1 $MtCO_2$/year.[44,45]

1pointfive and Carbon Engineering have raised money to cover the capital costs of this project from corporate sponsors, including a multi-million dollar direct investment from United Airlines, and hope to further offset costs by making the most of existing policy incentives, including the federal 45Q tax credit and California's Low Carbon Fuel Standard (LCFS) program.[46] More information about these policies and the incentives they provide for DAC can be found in Section 3.4 of this report.

3.1.2.2. Technological innovations on the horizon

In terms of future development, technological designs that emphasize modular and relatively simple DAC approaches are generally favored because they allow for simplified mass production and can be scaled up easily for deployment.[49] Achieving economies of scale by producing large volumes of standard parts may also accelerate DAC's deployment and shorten technology learning curves, which will help to reduce costs. Additional technological trends that are being explored by many DAC startup companies include passive air contact and use of natural sorbents. Some notable start-ups in the DAC space that are indicative of these trends are Carbon Capture Inc, Sustaera, Mission Zero, and Noya. These companies are primarily in the design and development stage of their pilot projects.

Two startup companies are worth particular note for the innovative alternatives they are developing to traditional liquid-solvent or solid-sorbent based DAC systems, which may be

[49] Shayegh, Bosetti, Massimo (2021) Future Prospects of DAC Technologies. p. 3. [64]

critical for reducing the operational costs of DAC, and helping bring it to market more quickly.

Heirloom

Heirloom is a startup in the early phase of development. It has yet to deploy its first facility (slated for 2023), but is notable because it is attracting some of the largest investments in new carbon removal technologies from venture investment leaders like Microsoft co-founder Bill Gates's Breakthrough Energy Ventures, and because it has the lowest estimated cost of any direct air capture technology.[50,51] Heirloom had developed an approach that optimizes passive carbon capture absorption using one of the most abundant natural resources on the surface of the earth: limestone. Limestone is composed of calcium carbonate, and is the primary feedstock for cement production.[52] To produce cement, limestone is heated in the presence of water at high temperatures (~900°C) to form lime and a pure stream of CO_2, exactly the same process of solvent regeneration in L-DAC systems.[53,54] The lime is then hydrated to form calcium hydroxide or slaked lime—the slaked lime, when exposed to air, will naturally react with CO_2 to re-form calcium carbonate.[55] Heirloom's technological innovation is to optimize natural carbonation of the lime during passive exposure to air, eliminating the need for fans or high-cost solvents.[56] The primary (and extremely inexpensive) feedstock of limestone, once converted to lime, can be re-used multiple times in a process of calcification (CO_2 absorption) and lime regeneration (CO_2 release).[57] Given the nascent stage of this company's development, specific information regarding the technical and operational requirements of such a process are not yet available, but with the exception of the high-cost solvent chemicals and water requirements for L-DAC, are likely to be similar.

Verdox

Another company in the early stages of development, called Verdox, is exploring a different alternative approach to liquid-solvent or solid-sorbent based DAC (L-DAC and S-DAC). Their Electro-swing Adsorption (ESA) technology is composed of a large, specialized battery that absorbs carbon dioxide from the air, or other gas stream, as it passes over charged electrodes.[58] When the electrodes are discharged, they release the concentrated carbon dioxide gas.[59] The technology works by alternating between charging and

discharging, thus relying on only electricity to run—the process has no heat or water needs.[60] ESA is able to capture carbon dioxide from any concentration, down to roughly 400 parts per million currently found in the atmosphere.[61] The technology is attractive for its high efficiency of raw materials and energy relative to more established direct air capture methods, using about 1GJ/tCO_2, or about 10-20% of the energy requirements for L-DAC and S-DAC (see Section 3.1.3.2).[62,63] Verdox is still in the testing phase of technology development, having been awarded a Department of Energy Advanced Research Projects-Energy (ARPA-E) research grant in 2020.[64] Anticipated capital and operational costs of a pilot-scale project, once deployed, are projected to be ~ $50-100 per metric ton of CO_2 captured.[65]

3.1.3 Operational Needs

This section provides a synopsis of the land use, energy, feedstock, waste disposal and other operational needs of the representative technologies for this industry, aggregated from literature review and interviews with industry experts. Because L-DAC and S-DAC are the most advanced direct air capture technologies, these are the only two DAC approaches considered here and in subsequent sections. Alternative DAC technologies, such as passive air capture or ESA, may be appropriate candidates for a research and development incubator facility.

3.1.3.1 Land use requirements

One of the key benefits of DAC as a carbon management technology is that it can be sited in any location that is economical, because unlike point-source carbon capture technologies, which require concentrated CO_2 streams (such as those emitted from CO_2-emitting industries like steel or concrete manufacturing, see Section 5 of this report) the source of CO_2 - ambient air - is accessible anywhere. Thus, a DAC plant could be co-located next to a plant which requires CO_2 as a feedstock or on top of a geological storage site to minimize costs and secondary emissions associated with transporting the CO_2 via truck, rail or pipeline.[66] DAC can also be co-located with other types of CO_2 capture facilities.[67]

A second benefit of DAC is that the direct land footprint of DAC is smaller than that of alternative carbon-removal processes. Land requirements for DAC are controlled by 1) the

size of the contactor and 2) the spacing requirements of multiple contactors and contactor configuration.[68] Contactors are generally designed to be modular: easily transportable and stackable (e.g. Figures 3.3 and 3.5). Contactors from Carbon Engineering, a commercial L-DAC company, are about 23 ft long by 16 ft tall and 16 ft wide.[69] Climeworks, a commercial company with the largest existing capture capacity for S-DAC systems, has contactors the size of a standard shipping container, or about 40 ft long by 8 ft wide by 8.5 ft high.[70] Units cannot be too geographically concentrated within a site, as some units would be taking in air that has already been depleted in CO_2 by nearby contactor units.[71] Although the actual footprint required for the contactors is small, there would need to be ample space between sets of contactors to build an effective facility.

Figure 3.5 is a schematic representation of the physical footprint of a 1 $MTCO_2$/year DAC facility. The size, height and orientation of the contactor arrays is based off the original design of solvent-based L-DAC by the company Carbon Engineering, with the cross-sectional inlet of the contactor oriented normal to the land surface.[72] More recent designs from this company have a configuration in which fans are parallel to the land surface (Figure 3.4). The height of the pictured tower, with four vertically stacked units, is approximately 65 feet (20 meters) and over 650 feet long, and could capture 50,000-100,000 metric tons of CO_2 annually.[73] To capture 1 $MtCO_2$/year, process engineer and DAC expert Howard Herzog estimates that you would need 25-30 of Carbon Engineering's contactor rows in a facility, and they would have to be spread far enough apart to ensure that the exhaust of one row of units does not interfere with the inlet of another row.[74] Given that no DAC facilities exist at a scale above *thousands* of metric tons of annual CO_2 capture, no field tests exist to determine the optimal spacing between contactor rows. In a schematic representation of a 1 $MtCO_2$/yr facility developed by the American Physical Society, contactor rows were spaced 250 m (820 ft) apart, to ensure that CO_2-depleted air exiting one contactor would be replenished before reaching the next.[75] Using the APS's spacing estimate, the land footprint of Carbon Engineering's original design for a 1 $MtCO_2$ capture facility (25-30 contactor rows) would be about 300-360 acres, or 1.2-1.5 km^2. If we created the same framework for an S-DAC system modeled after Climeworks' Orca facility in Iceland, also creating 40-unit long rows, one contactor row would be able to capture ~40,000 metric tons of CO_2 annually.[76] Scaling accordingly, the footprint of a 1 $MtCO_2$/yr facility would be 190-230 acres, or 0.8-0.95 km^2, assuming the same 66-80% efficiency that

[76] The Orca facility in Iceland contains 4 units of 2 stacked contactors, each ~40 ft long on the air inlet side, and ~ 8 ft deep. The facility captures approximately 4,000 metric tons of CO_2 annually.

Dr. Herzog estimated for L-DAC systems.[77] These numbers are comparable to published estimates of L-DAC and S-DAC land use requirements, which range from 0.2-7 km^2 and 0.2-2 km^2, respectively (Table 3.1).[78,79,80,81] Further complicating land use estimates, DAC systems can make use of vertical space by stacking DAC contactors much higher than 2-4 units, and thus allowing for a far smaller footprint required for megaton-scale facilities.[82]

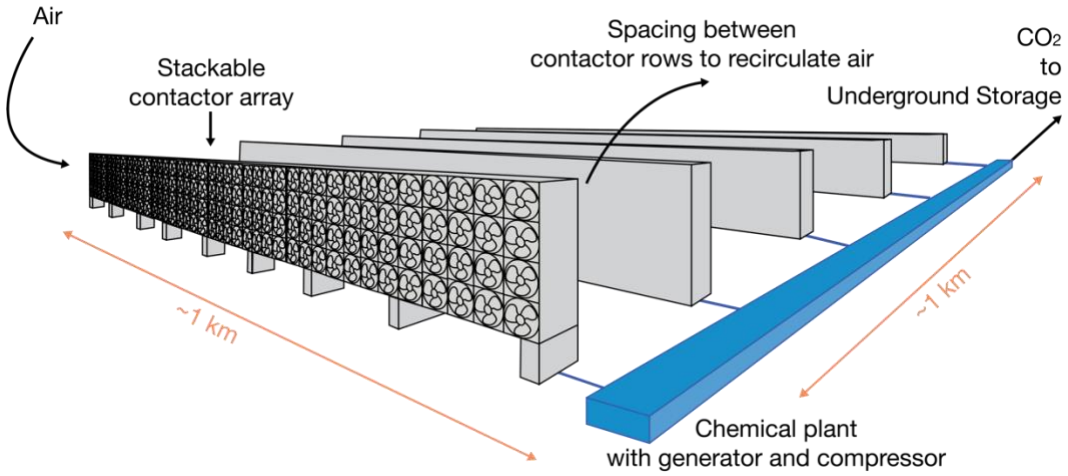

Figure 3.5. A conceptual drawing of a 1MtCO_2 DAC system, consisting of 10 m (33 ft) tall and 1 km (0.6 mile) long contactor structures and a facility for sorbent regeneration and CO_2 gas compression. Adapted from the American Physical Society[83] and Heidel et al. (2011).[84]

Indirect land use, resulting from the energy source needed to provide heat and electricity to a DAC facility, is generally much more significant than direct land use itself, but is dependent on the type of DAC sorbent (L-DAC or S-DAC) and the type of energy source in question.[85] For an L-DAC plant capturing one million tons of CO_2 annually powered entirely by solar PV, around 34 km^2 of land would be needed, whereas natural gas only requires 0.4 km^2.[86] However, L-DAC systems require heating temperatures of ~900°C (Table 3.1), and as of the publication of this report, there is not an at-market tool for converting solar or wind energy into process heat at those temperatures.[87] Thus, published land use estimates for

energy demand as a function of energy source for L-DAC have generally assumed that heat energy is derived from natural gas or geothermal sources, but that alternative renewable energy sources like wind and solar could provide the power needed for electricity.[88] In contrast, S-DAC requires maximum sorbent regeneration temperatures of only ~80-100°C (Table 3.1), and thus both heat and electrical energy can be supplied by existing at-market wind or solar energy technologies. For a 1 million metric ton S-DAC plant, energy sourced from natural gas would require a 0.26km^2 footprint, whereas solar requirements would be about 21km^2 (Table 3.1).[89]

Additional siting and footprint considerations

In addition to general land use considerations, attention needs to be paid to regional climate, dominant local airflows, and other meteorological conditions in the area, to identify preferred DAC technologies, optimal siting, and operational needs.[90] Humidity and average ambient temperatures are particularly important, because they can have large impacts on the capture productivity, energy efficiency, and water demands of DAC systems.

A recent study of S-DAC processes identified optimal capture productivity at low ambient temperatures, and much lower energy efficiency and capture productivity at higher ambient temperatures (Figure 3.6).[91] This is because solid sorbent materials not only absorb CO_2, but also water vapor from the air.[92] Although researchers agree that meteorological conditions will impact a DAC facility's effectiveness, findings are mixed as to these impacts. When looking specifically at Climeworks's S-DAC process, more water absorption from the atmosphere was found to reduce the sorbent's capacity for CO_2 sorption.[93] In overarching studies of amine-based solid sorbents for DAC, higher humidity was found to increase the sorbent's CO_2 capture capacity but increase the energy use of the chemical process, while higher temperatures led to both higher energy demand and lower productivity—and these effects interact with one another.[94] As seen in Figure 3.6, at ambient temperatures above ~20°C (68°F), increases in relative humidity also begins to negatively impact capture productivity and energy efficiency.[95] In water scarce regions, however, sorption of both water and CO_2 may be considered a technological benefit, as captured water could be put to new use. Similarly, the company Carbon Engineering, which employs L-DAC systems, is avoiding places with colder climates to avoid unwanted viscosity of the liquid solvent, while at the same time avoiding dry and hot places to

minimize evaporation of the liquid solvent, which leads to constant water loss and an increased possibility of leaking some of the captured CO_2.[96]

Table 3.1. Comparison of S-DAC and L-DAC key features.[a]

	S-DAC	L-DAC
CO_2 separation	Solid adsorbent	Liquid solvent
Specific energy consumption (GJ/tCO_2)	3.4-5.9	5.3-12.4
Share as heat consumption (%)	75-80%	80-100%
Share as electricity consumption (%)	20-25%	0-20%
Regeneration temperature	80-120°C	Around 900°C
Regeneration pressure	Vacuum	Ambient
Capture capacity	Modular (e.g. 50 tCO_2/yr per unit)	Large-scale (e.g. 0.5 to 1 $MtCO_2$/yr)
Net water requirement (tH_2O/tCO_2)	-2 to none	0-50
Life cycle emissions ($tCO_{2\text{-emitted}}/tCO_{2\text{-captured}}$)	0.03-0.91	0.1-0.4
Levelized cost of capture (USD/tCO_2)	Up to $540	Up to $340
Main advantages	• Possible net water production • Less capital-intensive • Modular • Operation can rely on low-carbon energy only • Novel and therefore more likely to see cost reduction	• Less energy-intensive • Large-scale capture • Operation relies on commercial solvents • Technology adapted from existing commercial units
Main trade-offs	• More energy-intensive • Manual maintenance required for adsorbent replacement	• More capital-intensive • Relies on natural gas combustion for solvent regeneration (with potential for full electrification in the future)
Land requirements	**S-DAC**	**L-DAC**
DAC footprint ($km^2/MtCO_2$)	0.2-2 (Median = 1.0)	0.2-7 (Median – 0.8)
Natural gas energy source ($km^2/MtCO_2$)	0.26	0.43
Solar energy source ($km^2/MtCO_2$) (with NG as a heat source – L-DAC only)	2	36 (5 + 0.37)
Wind energy source ($km^2/MtCO_2$) (with NG as a heat source – L-DAC only)	217	364 (51 + 0.37)

[96] Herzog (2021) DAC: A Process Engineer's View. 28:06-29:59. [35]

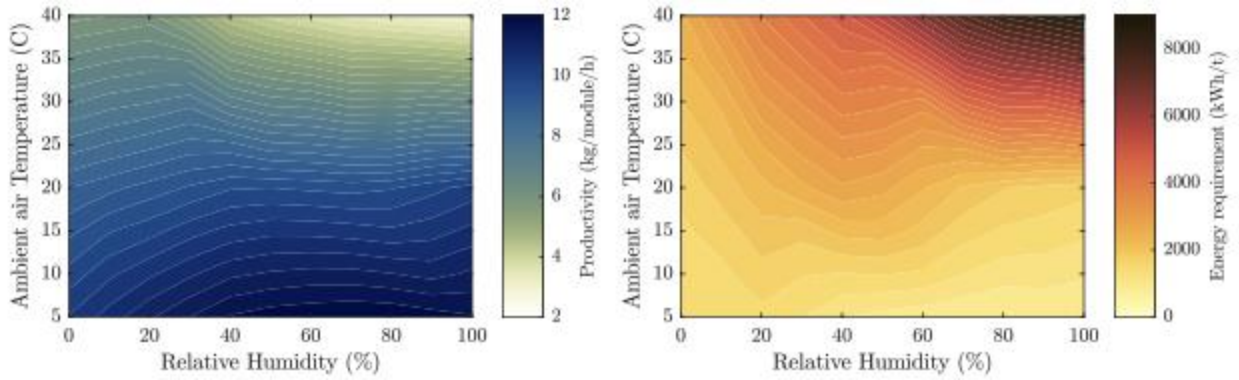

Figure 3.6. Productivity and specific energy requirements for S-DAC as a function of ambient temperature and humidity. Reproduced with permission from Wiegner et al. (2022)[97].

Land use estimates also have to anticipate less than 100% operational efficiency. H. Herzog estimated 66-80% of total DAC capacity would be operational at any given time, and a life-cycle assessment of Climeworks technologies estimated a carbon capture efficiency of 85-93%.[98,99] L-DAC contactors can "theoretically operate continuously at steady state without interruption" though they require regular maintenance.[100] However, S-DAC must operate using a batch operation which requires having multiple units in parallel.[101] At any one time, some contactor units will be in operation capturing CO_2, while the remaining contactor units are in their regeneration state, releasing CO_2 from the filters.[102]

3.1.3.2 Energy requirements

The energy requirement as well as per-ton cost of any carbon-dioxide removal technology is heavily influenced by the concentration of CO_2 in the main feedstock of the plant. For DAC, that feedstock is ambient air, which has CO_2 concentrations of a little over 400 parts per million, a small fraction of industrial-scale flue gas, which can be 5 to >90% CO_2.[103,104] The extremely dilute stream makes it difficult and energy-intensive to separate CO_2 from air relative to more established industrial point source carbon scrubbers.[105,106]

[106] IEA (2020) CCUS in Clean Energy Transitions. p. 82. [41]

The amount of energy needed for DAC also depends on the technology. For L-DAC, the most energy-intensive component of the capture process is the thermal regeneration step (Figure 3.2), in which the carbonate pellets holding the sorbed atmospheric CO_2 are combusted to release a stream of high-purity CO_2 and regenerate the lime solvent additive (CaO).[107] This process requires heating to temperatures up to 900°C.[108,109] In comparison, the regeneration step for S-DAC sorbent only requires a temperature of 80–120°C.[110,111] The result is that, while both technologies require about 80% of their energy for heating and 20% for electricity, estimates of the total energy need for L-DAC ranges from 5.3-10.7 gigajoules per ton of CO_2 captured (GJ/tCO_2), whereas S-DAC requires about 3.4 to 5.8 GJ/tCO_2 (Table 3.1), or 1.5-3.0 and 0.9-1.6 MWh/tCO_2, respectively.[112,113] In existing pilot facilities, energy sources include geothermal (the Orca facility in Iceland), waste heat (Climeworks' first pilot plant in Hinwil, Switzerland) or natural gas with carbon capture (Carbon Engineering).[114,115] Using solar power to supply both heat and electricity energy is a feasible option for S-DAC, given the lower required heat generation temperatures, but to deliver heat up to 900°C for L-DAC technologies, is not feasible unless paired with a high-temperature industrial battery solution (see Section 7 on energy storage industries).[116] Estimates of the scale of solar installation required to supply 100% of the heat and electrical energy needs of a $1MtCO_2/yr$ DAC facility (assuming industrial battery use as needed) are provided in Table 3.2. Installed capacity for the solar fields were calculated following the equation:

MWh (energy supplied) = MW (installed capacity of facility) x (8760 hours in a year) x Capacity factor (E3.1)

where the capacity factor for solar panels in Kern County is 32.8%.[117,118] Solar acreage is calculated on the basis of ~7 acres per MW installed solar capacity.[119,120] With these values,

a megaton L-DAC facility would require on average 830 MW installed solar capacity (range = 508-1034 MW), or a ~5800 acre solar field. S-DAC would require an average of 420 MW installed solar capacity (range = 329-561 MW), or ~2900 acres of solar panels.

3.1.3.3 Other operational needs

Waste disposal requirements

Because the only feedstock for DAC systems is air, and the only output is CO_2, there are no significant waste streams from DAC plants.[121] Minor anticipated sources of waste are replacement of parts, and of the solid or liquid sorbent materials once their regenerative capacity has declined. It is not clear how many iterations of regeneration are possible before sorbents will need replacement, but may be on the scale of many dozens of capture cycles.[122] L-DAC sorbents are primarily composed of strong bases such as NaOH or KOH.[123,124] As standard industrial salts, these compounds have well established regulation and disposal procedures.[125,126] Sorbent materials currently being tested for S-DAC technologies include metal–organic frameworks (MOFs), zeolites, activated carbon, silica materials, carbon nanotubes, porous organic polymers, and carbon molecular sieves.[127] These are solid, non-reactive and non-hazardous materials that are common in many chemical laboratories, and do not pose a hazardous waste risk.

Warehousing requirements

Warehousing could be minimal for DAC, as there's no feedstock related to the capture other than ambient air, which does not require storage.

Transportation & pipeline requirements

Transportation and pipeline needs for a site should be minimal—adsorbents or solvents may need to be moved in and out of the plant at regular intervals to ensure the contactors remain in working order, a process that would likely rely on trucks for transport. The most likely pipeline needs for any site would be a pipeline to move the CO_2 to storage or, for L-DAC, pipelines to bring in natural gas, hydrogen, or other materials to support its high thermal energy needs. Please refer to Section 9 of the full report for more information on transportation requirements for more information about pipelines and other transportation options for safely moving CO_2 offsite for geologic storage.

3.2 Societal Impacts

3.2.1 Job creation potential

3.2.1.1 Number and types of jobs

The largest existing DAC project is 0.0004% the size of a megaton (million ton) capture facility, meaning that estimates of the job creation potential of this industry is highly speculative and must be based on growth trajectories of similar industries. The United Kingdom, which aims to capture 20-30 $MtCO_2$/yr by 2030, is anticipating 50,000 carbon capture-related jobs, translating to ~2,000 jobs per million tons of CO_2 sequestered.[129] The Rhodium Group estimated that construction, engineering and equipment manufacturing sectors combined could see at least 3,000 new jobs for every one million ton DAC plant, though the bulk of these jobs are in the initial plant investment period.[130] The breakdown of those jobs are as follows:

- >1500 jobs created from the equipment manufacturing process
- 657 jobs created from the engineering and design phase
- 721 jobs created from the construction phase
- 278 jobs created from operation and maintenance activities

[128] Data from: Baker *et al.* (2020) Getting to Neutral, p. 78, National Academies of Sciences, Engineering, and Medicine (2019) Negative Emissions Technologies and Reliable Sequestration: A Research Agenda, p. 222, and this study.
[129] United Kingdom Department for International Trade (2022) CCUS Investor Roadmap. p. 4. [71]
[130] Larsen *et al.* (2020) Capturing New Jobs. p. 15. [45]

- Additional job creation in supporting industries like the energy production sector.[131]

While it is not entirely clear how these estimates would scale, it is likely that some would grow more linearly than others. For example, operation and maintenance might not have significantly higher job creation potential at a 2 megaton DAC plant than a 1 megaton facility, but construction, manufacturing and supporting industries would.[132]

For the DAC 1 facility led by 1pointfive and Carbon Engineering, planned to capture 1 megaton per year, the reported permanent job estimate is about 75, with ~1,000 on-site construction jobs.[133] CarbonCapture Inc.'s Project Bison, a DAC hub planned for Wyoming with a goal of creating a 5 megaton DAC facility by 2030, is estimating the plant will support "more than 200 permanent jobs" in the state.[134] When compared to the Rhodium Group figure for a 1 megaton facility, these real facility estimates appear to reflect how permanent job potential is unlikely to scale proportionally for larger DAC facilities.

It is also critical to note that the job opportunities in several categories of the Rhodium Group estimate are not guaranteed to directly benefit local communities where a DAC facility is sited. This is particularly true for equipment manufacturing, engineering, and design. If a facility scale is large enough, it could provide an economic incentive to co-locate equipment manufacturing in the region.[135] However, it is recommended that concrete actions are taken to prepare both the industry and potential local workers for these new jobs to be sited in the region. One such action is to develop legally binding mechanisms ensuring that communities have the opportunity to benefit from available jobs and negotiate for other types of benefits beyond jobs. These agreements could take the form of a Community Benefit Agreement, a negotiated legal agreement between community groups and project developers that guarantees community benefits in exchange for a community's agreement to accept the project, or a Project Labor Agreement, an agreement between contractors and unions laying out the terms for a project. Project Labor Agreements can include Community Workforce Agreements, which require that the contractor hire a negotiated percentage of local, low-income or other marginalized workers, or that they collaborate with local organizations to provide job training programs and provide job quality specifications.[136]

3.2.2.2 Training pipelines

Direct jobs that would be based onsite—such as construction, operation and maintenance, and electricity generation and distribution—require skill sets that are transferable from

[136] Lebling *et al.* (2022) Building DAC. [47]

other projects and industries, like fossil fuel and energy sectors.[137,138] As mentioned above, facility developers can work with local organizations and institutions to provide relevant training to take on these roles. This collaboration with local organizations to provide job training can be seen in Project Bison, where developers are already working with local community colleges in Wyoming to set up training programs for new positions at DAC facilities.[139]

3.2.2 Quality of Life

3.2.2.1 Location

The lack of dangerous feedstocks, waste streams or pollutants associated with DAC results in little to no health or environmental risk from the operation of DAC towards the local community. Key considerations that remain are:

1. Energy use: due to the enormous use of energy required to run DAC facilities, developers need to ensure that energy required for DAC doesn't compete with other existing uses, such as domestic and local industry.
2. Noise: a single DAC contactor unit operates much like a large fan or HVAC system, and thus is comparably loud.[140] One large HVAC air conditioner emits 50-70 decibels of sound, about the same as other home appliances (refrigerator, dishwasher, vacuum). This sound dissipates relatively quickly; 50 feet away from a unit the noise level would be about halved, to 25-45 decibels (comparable sounds are whispering, rustling leaves).[141] However, further research is warranted to assess how sound levels increase as multiple contactor units are combined.
3. Vibration: there is no clear data or discussion on the vibrational impact of DAC, but a megaton facility would have tens of thousands of contactors with rotating fan blades, it is a consideration. Several solutions exist to reduce the impacts of industrial vibration, including hardware, pads and mats designed to absorb vibration.[142]
4. Aesthetics: because DAC systems are modular, there is room for preference in whether towers are built very tall, to reduce the overall ground footprint, or kept low to minimize visual impact.

[142] Sorbothane Inc. (no date) Vibration Isolation in Industrial and Manufacturing Equipment. [66]

5. Commuting considerations: new roads and increased commuting for employees could increase traffic, and thus road noise and pollution for nearby residents.[143]

3.2.2.2 Multi-use potential

DAC contactors must be spaced far enough apart to prevent the CO_2-free exhaust from one contactor becoming the intake air for the next contactor.[144] The optimal configuration to prevent this is still in the design phase, and likely specific to the conditions of the facility site.[145] As a result, it is possible that there will be large swaths of available space between contactor rows that could have alternative uses, such as the siting of other facilities, part of the solar energy supply for the DAC units, or livestock grazing (depending on disruptiveness of noise and vibration of the contactor units).[146] Additionally, DAC can be placed on top of, or adjacent to other industrial facilities, as shown by Climeworks' DAC-1 plant, which is built on the roof of a municipal waste incinerator.[147]

3.3 Environmental Impacts

3.3.1 Water requirements

3.3.1.1 Minimum volume requirements

Water requirements for DAC are highly dependent on the chosen technology. While L-DAC requires significant amounts of water to dilute the hydroxide solution, some S-DAC technologies produce water as a byproduct of CO_2 absorption.[148, 149]

For L-DAC to capture one ton of CO_2, various sources estimate as little as 1 to more than 20 tons of water is needed to dilute the hydroxide solution that binds CO_2.[150,151,152] Water is not actually a feedstock in the L-DAC process, but is a component in the circulating solvent solution. Although that solution can be repeatedly regenerated, water must be regularly added to compensate for evaporation loss and, to a lesser degree, drift loss that occurs

[152] An et al. (2022) Impact of L-DAC. p. 7. [4]

during the sorbent-air contacting process.[153] The intensity of evaporation, and thus the H_2O needed for CO_2 captured, depends on the molarity of the hydroxide solvent and the relative humidity of ambient air. More concentrated solutions of hydroxide result in less water loss, as does higher ambient humidity.[154] For example, experiments conducted at relative humidity levels above 65%, for solutions with a concentration of 7.2 M NaOH or 2 M KOH effectively mitigated evaporative water loss.[155,156] In contrast, experiments conducted at ambient temperatures over 30°C and at relative humidity levels below 20%, water loss was higher than 20 metric tons of H_2O per ton CO_2 (Figure 3.7).[157]

In the case of S-DAC, water is used, but is contained and continuously recycled within closed-loop systems.[158] Under specific operating conditions, S-DAC can also *produce* fresh water as a byproduct of the CO_2 capture. Climeworks' solid sorbent system is an example, yielding approximately 0.8-2 metric tons of water per metric ton of CO_2 captured.[159] Other S-DAC technologies, like the process used by Global Thermostat, use steam condensation for sorbent regeneration.[160] These S-DAC systems are more water intensive, requiring up to 1.6 tons of water per metric ton of CO_2 captured.[161]

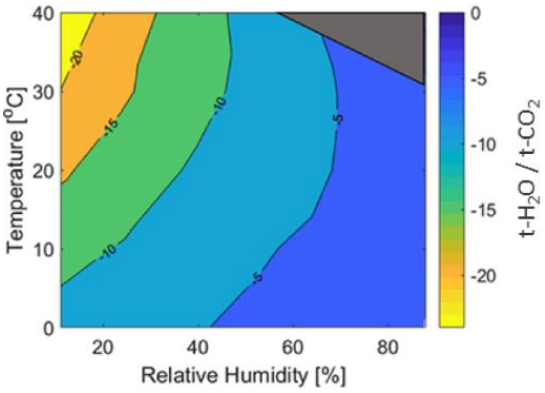

Figure 3.7. Net water consumption per metric ton of CO_2 capture using L-DAC technology, as a function of climate conditions. Reproduced with permission from An et al. (2022).[162] Kern County humidity and temperature highs in the summer and humidity and temperature lows in the winter winter are about 27% and 97°F (36°C), and 57% and 38°F (3°C), respectively,[163] meaning water consumption in Kern County would likely range from ~4-20 tons of water used per ton CO_2 captured.

3.3.2 Other potential impacts

DAC facilities are expected to produce zero or-near zero emissions onsite that could be hazardous to the environment or human health.[164] Hazardous waste is not a significant concern for DAC facilities, as reviewed in Section 3.1.3.2. Wastewater is also not generated in significant amounts in DAC processes, as the only water used is contained within close-loop systems. Solid waste buildup can occur in the CO_2 recovery equipment, as happens in traditional monoethanolamine (MEA) scrubbers that are used for point source carbon capture.[165] Similar environmental regulation and disposal guidelines would need to be followed. Chemicals used in sorbent plants would degrade over time as heat is applied to release captured CO_2, but those degradation products (e.g., ammonia) are expected to be contained within the DAC plant and not released into the environment, and have established regulation and disposal protocols (Section 3.1.3.2).[166]

3.4 Economic Impacts

3.4.1 Business Model

There are two primary revenue streams possible for a DAC development: private carbon credits or benefits from federal and state incentives.

Selling carbon credits to the voluntary carbon offset market

DAC developers can either seek private companies to invest in their carbon removal project, allow carbon credits to be purchased to offset their CO_2 emissions, or both. Companies such as Stripe, Shopify, and SwissRe have purchased carbon credits from DAC facilities to offset their CO_2 emissions.[167] Other companies are helping develop capture projects. United Airlines is investing in DAC directly via funding on the 1pointfive and Carbon Engineering project, in line with its commitment to become carbon neutral by 2050.[168] And Microsoft is both purchasing DAC removal carbon credits from Climeworks and, through its Climate Innovation Fund, is investing in the Climeworks Orca facility in Iceland.[169]

[167] Clancy (April 13, 2022) Stripe, Shopify, Alphabet, Meta and McKinsey will spend almost $1 billion on carbon removal. [17]

[168] Rucinski (December 10, 2020) United Airlines invests in a carbon-capture project. [63]

[169] Climeworks (July 13, 2022) Climeworks becomes first supplier of long-term, technology-based carbon removal. [19]

Utilizing federal and state incentives

A DAC plant that sequesters captured CO_2 into saline or other geologic formations is also eligible to take advantage of the 45Q tax credit, which, since the adoption of the U.S. Inflation Reduction Act, provides $180 per ton of CO_2 sequestered via DAC.[170] Moreover, DAC companies are eligible for the California Low Carbon Fuel Standard (LCFS) credit, which credits technologies that reduce transportation-derived greenhouse gas emissions.[171] DAC is eligible under the program because it removes CO_2 produced by gas-powered cars and trucks.[172] LCFS credits vary in price based on supply and demand within the credit marketplace, but from January 2018 to December 2022 ranged from $62 to $217 per metric ton CO_2.[173] 45Q and LCFS credits can be "stacked" (i.e. both credits given for one metric ton of carbon removed), such that, given historical LCFS prices, incentive revenue can be expected to be in the range of ~$242-$397 per metric ton CO_2.[174] Incentive credits cannot, however, be used in tandem with the voluntary carbon offset marketplace (for a summary of relevant policy and regulations pertaining to all carbon management industries, refer to Section 2 of this report).

3.4.2 Business Costs

Estimates of the current cost of carbon capture for DAC systems are highly variable, ranging in the published literature of the last decade from less than $100 per metric ton CO_2 captured to more than $1,000 per metric ton.[175] There are two reasons for the high variability. First, given the newness of the technology, all existing facilities are still in the testing or pilot scale. That means there are no large-scale facilities to directly assess cost, and ongoing research is continuously identifying lower-cost sorbent materials and optimal operating conditions.[176] Second, there are a large number of variables required for any techno-economic assessment of a new industry, and the assumptions used to determine each variable are different across different publications. In general, costs are assessed and reported through a 'Lifetime Cost Assessment' (LCA) model, or the summative cost per metric ton CO_2 of the capital costs (the prices of the equipment that make up the DAC facility), operational costs (including maintenance and labor), and energy costs (heat + electricity), normalized over the lifetime of the plant.[177,178] In some cases, costs related to

[178] Carbonplan (no date) DAC cost calculator. [14]

the transport and permanent storage of captured CO_2 are also included (these are not accounted for here, but can be explored further in Section 9). Typically, the most significant drivers of cost uncertainty are the sorbent used and the source and cost of electricity.[179]

A summary of recent published estimates for DAC costs are presented in Tables 3.3 and 3.4, and a breakdown of how capital, operational and energy costs are estimated is detailed in the following sections. Current levelized costs for net CO_2 removed for the solid sorbent–based approach (S-DAC) range from \$89 to \$600/tCO_2, with the greatest variable being the type of adsorbent and energy source.[180] The cost range for the solvent-based approach (L-DAC) is \$156 to \$506/tCO_2, with the strongest control on price being the source of thermal energy.[181] Experts predict that these costs could fall significantly within the next decade, to ~\$100-200/tCO_2, and potentially as low as \$60/tCO_2 by 2040 or 2050, with the assumption that the technology will continue to grow and there will be cost reductions due to economies of scale (see Table 3.5, 'Future costs').[182,183]

3.4.2.1 Cost to build (upfront costs)

Capital cost consists mostly of the construction expenses needed to establish the facility from scratch, including the procuring equipment and construction materials and the cost of labor. For S-DAC systems, the equipment components that comprise capital expenditures (CapEx) are the adsorbent material (>90% of total capital costs), and the blower, vacuum pump, condenser and contactor.[184] Adsorbent materials range enormously in cost and efficacy, drive the greatest uncertainty in cost for S-DAC systems, and have the greatest potential to drop in cost due to further innovation.[185] L-DAC facilities are more capital-intensive, with necessary equipment including the contactor array (~30% of CapEx), the slacker, causticizer and clarificator (how the liquid solvent is produced and regenerated, ~20% of CapEx), the oxy-fired calciner (how the CO_2 is released and the lime regenerated, ~40% of CapEx) and the air separation unit and condenser (provides oxygen to the calciner, ~10% of CapEx).[186,187]

[187] Ozkan *et al.* (2022) Current DAC Status. p. 10. [59]

For an average L-DAC system with a capacity of 1 million metric tons per year CO_2 removal, estimated upfront capital costs range from $675 million to $1.255 billion, if the building of clean energy infrastructure is not included (Table 4). Existing pilot L-DAC facilities are run with natural gas, which releases CO_2 that must also be captured. A 2019 study from the National Academy of Sciences, Engineering and Medicine (NASEM) included a techno-economic analysis of co-locating a PV solar + battery system that supplied electricity directly to a putative million ton L-DAC facility and to an electrolyzer, which produces green hydrogen (H_2) via electrolysis (see Section 6) that can be combusted to drive the calciner operation. The added capital expense of these components leads to a net cost to build of $1,921-3,045 million for a 1 million metric ton CO_2 capture facility.[188]

An average S-DAC system with a 1 million metric ton CO_2 capture capacity is estimated to cost $630-1,700 million to build (Table 3.3).[189] This does not include the cost of building any energy-supplying infrastructure.

Annualizing the total capital costs to a per ton CO_2 cost allows us to better assess total costs of varying carbon management industries by making it possible to calculate the collective cost of capital, operations and energy. Annualizing costs requires assumptions about the lifetime of the plant (typically estimated to be in operation for 20-30 years), and the weighted average cost of capital (WACC), or discount rate, which are used in combination to determine the capital recovery factor (also called the fixed charge rate or annuity factor) - an assessment of the combined cost of equity and debt over the lifetime of the facility.

The capital recovery factor (crf) is determined based on the following equation, where N = the facility lifetime in years: [190,191]

$$crf = (WACC \cdot (1+WACC)^N)/((1+WACC)^N - 1). \quad \text{(E3.2)}$$

Levelized capital costs, in turn can then be calculated as:

$$CapEx (\$/ton\ CO_2) = (Cost\ to\ Build\ Facility/Capture\ Capacity\ of\ Facility) \cdot crf \quad \text{(E3.3)}$$

In Tables 3.3-3.5, capital recovery factors range from 7.5-12.5%. This leads to a levelized CapEx rate (or annualized rate) of $76-205 per ton CO_2 for S-DAC, and $52-365 per ton CO_2 for L-DAC.

			$231	**MEAN Levelized Cost**

a. Energy costs are highly variable due to market fluctuations. The values here reflect energy cost estimates from the sited references at time of publication.
b. Some publications report only levelized cost analysis, without distinguishing capital and operational costs.
c. LCA is higher than CapEx+OpEx+Energy because it incorporates the cost factor resulting from emitting CO_2 from the natural gas energy source (i.e. every ton CO_2 captured by the process is partially offset by CO_2 emitted, and thus the *net* cost per ton CO_2 removed is greater).
d. Reported operating cost of Carbon Engineering pilot facility in Canada.
e. Costs originally reported in Euros. Converted to USD using the 2019 average exchange rate.[194]

[193] Keith *et al.* (2018) A process for capturing CO_2 from the atmosphere. p. 1581. [42]
[194] IRS (no date) Yearly average currency exchange rates. [38]

Table 3.5. Anticipated change in cost of DAC[a] per metric ton CO_2 captured.

Anticipated Future LCA Cost ($/ton CO_2)		
2035	$100-200	Ozkan et al. (2022) Current DAC Status
2050	$60	Ozkan et al. (2022) Current DAC Status
2050	$60-80[b]	Ozkan et al. (2022) Current DAC Status

a. Includes both S-DAC and L-DAC.
b. Costs originally reported in Euros. Converted to USD using the 2019 average exchange rate.[195]

3.4.2.2 Operational costs

Operational costs involve the maintenance and labor for the various equipment pieces and the facility. NASEM (2019) provided a detailed breakdown of operational components for L-DAC facilities and Baker et al. (2020) does the same for S-DAC. Both are summarized in Table 3.6.

Table 3.6. Operational expenses for a 1 million ton CO_2 capture DAC facility.

L-DAC - from NASEM (2019)[196]		
Maintenance	$18-33 million/yr[a]	Estimated as ~3% of total capital requirement
Labor	$6-10 million/yr	Estimated as 30% of maintenance cost
Makeup and waste removal	$5-7 million/yr	Includes replacement of hydroxide solution (≥$500/ton KOH), lime (≥$250/t $Ca(OH)_2$), water (≥$0.30/t H_2O), waste disposal (≥$260/t)
Energy Supply	See Section 2.4.2.3	
S-DAC - Baker et al. (2020) Getting to Neutral.[197]		
Maintenance	~$22 million/yr	~10-17% of total capital requirement (from Baker et al., Fig. 41)
Labor	~$7 million/yr	~30% of maintenance cost (from Baker et al., Fig. 41)
Energy Supply	See Section 2.4.2.3	

a. For a megaton facility, this is equivalent to $18-33/t$CO_2$, and so forth for each cost estimate.

3.4.2.3 Energy costs

A critical variable, and perhaps the most poorly constrained for DAC, is the cost of energy. This is because there is uncertainty about the amount of energy necessary (1.5-3.0 MWh/tCO_2 and 0.9-1.6 MWh/tCO_2, for L-DAC and S-DAC, respectively, as shown in Table 1),

[195] IRS (no date) Yearly average currency exchange rates. [38]
[196] National Academies of Sciences, Engineering, and Medicine (2019) Negative Emissions Technologies and Reliable Sequestration: A Research Agenda. p. 207. [55]
[197] Baker *et al.* (2020) Getting to Neutral. p. 86. [6]

how that energy could be sourced (published estimates consider a coal, natural gas, natural gas with CCS, solar, wind, nuclear, geothermal, waste heat or a combination of these), and then, for each of these, their local costs, given regional variability with capacity factor (particularly for solar and wind), and resource accessibility.

Existing pilot DAC facilities use natural gas (Carbon Engineering, L-DAC), geothermal heat (Climeworks Orca Facility, S-DAC) or waste heat (Climeworks pilot facility, S-DAC) as their energy source. With natural gas, or any fossil fuel, either the CO_2 emissions resulting from energy generation must be also captured - adding to the cost of the energy source, or the *net* CO_2 capture capacity of the facility decreases.[198] This is modeled by use of a cost factor, whereby:

$$\text{Cost factor} = 1/1\text{-}x \quad \text{(E3.4)}$$

And x is the amount of CO_2 emitted by the facility per ton of CO_2 captured. If x is near or greater than 1, and thus the cost factor approaches infinity, the facility can be considered uneconomical. If coal is the fuel source, the *net* capture capacity of a million ton facility drops to 0-0.11 million tons CO_2 per year ($MtCO_2$/yr), making it effectively useless. A natural gas facility has a net capacity of 0.11-0.42 $MtCO_2$/yr, and natural gas with CCS (as done by Carbon Engineering) has a net capacity of 0.49-0.99 $MtCO_2$/yr.[199] All non-fossil fuel sourced energy supplies (geothermal, waste heat, nuclear, green hydrogen, wind, solar) have a cost factor that approaches 1, and a net capacity that approaches its intended capacity.

To summarize the range of possibilities, Table 3.7 lists all energy sources considered in the references cited within Tables 3.3 and 3.4, and/or considered in this analysis. Note that for operations that use fossil fuels without carbon capture as their energy source, net capture capacity will be less than intended capacity.

Table 3.7. Energy expenses for a 1 million ton CO_2 capture DAC facility.

L-DAC						
Energy Type		**Energy Need (MWh/tCO_2)**		**Levelized Energy Cost ($/MWh)[a,b]**		**Total Energy Cost ($/$tCO_2$)**
Thermal	**Electric**	**Thermal**	**Electric**	**Thermal**	**Electric**	
Natural gas (NG)		2.1-3.0	0.2-0.5	$19-74		$45-257
NG + CCS (oxy-combustion)		2.1-3.0	0.2-0.5	$50		$117-174
NG+CCS (oxy-comb.)	Solar PV + battery (elec.)	2.1-3.0	0.2-0.5	$50	$28-37 + $15	$151-231
Green H_2	Solar PV + battery (elec.)	2.1-3.0	0.2-0.5	$48-108	$28-37 + $15	$109-350

Energy costs are subject to significant market fluctuations. 4. This study (Section 4)
b. Energy costs are subject to significant market fluctuations.

3.4.3 Regional benefits

3.4.3.1 Land availability and renewable energy potential

While the DAC technology itself represents one of the most efficient carbon management techniques available in terms of CO_2-capture potential per acre, the enormous energy requirements of the technology will require a significant land footprint if energy is supplied entirely by renewable energy. Thus DAC facilities aiming to run entirely on fossil-free sources would benefit from locations with optimal solar potential and an abundance of available land (please see Section 3.1.1.2 for detailed analysis).

3.4.3.2 Proximity to optimal underground CO2 storage

For any carbon management technology, levelized cost per ton of CO_2 captured increases significantly as a function of distance from an underground storage site.[203] Being located in

[201] Bertrand *et al.* (2019) Regional waste heat valorisation. p. 454-468. [7]
[202] Lazard (October 2021) Lazard's levelized cost of energy analysis. [46]
[203] [illegible]

close proximity with established Class VI EPA wells should reduce operational costs, decrease planning, permitting and construction time for extensive pipeline infrastructure, and increase the business viability of a DAC plant.

3.4.3.3 Co-location advantages

L-DAC requires water and a high-temperature heat source to operate. As such, it would benefit from co-location with energy storage companies designed to provide industrial heat from clean energy—for example, green or blue hydrogen (Section 6) or heat batteries (Section 7), and potentially, water generating industries, such as S-DAC (Section 3.3.1) or some forms of BiCRS technologies (Section 4).

4. Biomass CO_2 Removal and Storage

TECHNOLOGY AT A GLANCE:

- 2.5 million metric tons CO_2 captured annually by other projects, globally[1]
- Estimated cost per metric ton CO_2 captured: $30-400 USD/ton CO_2
- Projected cost per metric ton CO_2 captured at scale: $61-288 USD/ton CO_2
- ~180-400 acres of land use required per million metric tons of CO_2 captured
- Key advantages of this technology in Kern County: around 470,000 tons of agricultural waste produced annually in Kern Co., close proximity to consumers of low-carbon fuels (including synthetic fuels and green hydrogen) due to California's Low Carbon Fuel Standard (LCFS).
- Key concerns for this technology in Kern County: Differences in potential air impacts from gasification/pyrolysis and combustion of biomass. Changes in biomass waste availability in the future due to climate change. Variable water requirements.

4.1 Technology Summary

Biomass Carbon Removal and Storage (BiCRS) encompasses a range of technologies that convert biomass into smaller molecular components, allowing CO_2 to be separated and sequestered, either through underground storage or in long-lived applications.[2] BiCRS is a

[1] Values in this section are summarized from the suite of references cited herein and are explained in further detail in each subsequent section.
[2] NETL (no date) Carbon Dioxide Removal Program. [64]

relatively new category of carbon management technologies,[3] and is an umbrella term for any technology making use of biomass for the purposes of carbon capture, including Bioenergy with Carbon Capture and Storage (BECCS), one of the longest-established carbon management industries.[4] BECCS is a distinct subcategory of BiCRS because it has a markedly different end goal, despite using the same technological processes. While the rest of BiCRS technologies prioritize CO_2 removal and storage as the primary technological aim, the focus of BECCS is fuel and energy production from biomass, and carbon capture and storage (CCS) represents an optional industrial component that neutralizes the carbon emissions of the primary commodity of power generation.

4.1.1 Description

BiCRS takes advantage of a natural mechanism of carbon dioxide removal: the storage of CO_2 in vegetation via photosynthesis. Rather than allowing stored CO_2 to return to the atmosphere as occurs when plants, trees and other organic matter die and decompose, these resources can be collected and chemically modified to produce clean CO_2 for underground storage ± biofuels. Biomass can be sourced from agricultural, forest, industrial or municipal waste, or from dedicated crops, forestry, or cultivated algae.[5] Generally, waste biomass is the preferred source of BiCRS feedstock because there are fewer competing uses (as in forestry and agriculture), and it typically costs less than biomass sources that require dedicated cultivation (like agriculture or algae).

There are a variety of processes used to convert biomass into CO_2 + other (potentially useful) organic compounds, which are generally divided into categories: biochemical and thermochemical conversion.[6] Biochemical conversion involves using living microorganisms — typically yeast or bacteria — to convert biomass into biofuels, and the most commonly used and simplest biomass-to-energy process in the U.S. is biochemical conversion of corn to ethanol via fermentation.[7] In fermentation, biomass feedstock is pretreated with an acid or base solution to break down biomass cell material into simple sugars.[8] Yeast or bacteria is added to drive fermentation reactions that produce ethanol + CO_2 + residue materials (including water, solvents and residual solids), which are then separated from each other for various uses or sequestration.[9]

A simplified version of the biomass conversion reaction: [10]

$$C_6H_{12}O_6 \text{ (glucose)} \rightarrow 2C_2H_5OH \text{ (ethanol)} + 2CO_2 \text{ (carbon dioxide)} \quad \text{(R4.1)}$$

Other biomass conversion processes add to or amend this process in order to utilize more complex plant structures, like agricultural residues (e.g. straw, corn stover, nut shells, fruit pits) or other lignocellulosic raw materials (e.g. wood chips, waste from forest management).[11] In low temperature deconstruction (also a form of biochemical conversion), enzymes or chemicals are used to break down the more starchy or woody materials into simple sugars in a process called hydrolysis (Figure 4.1).[12] High-temperature deconstruction comprises all *thermochemical* forms of biomass conversion, with the three primary methods being pyrolysis, gasification and hydrothermal liquefaction. Each of these methods use extreme heat and pressure to break down the biomass feedstocks into a suite of solid, liquid and gaseous components.

During pyrolysis, biomass is rapidly heated in an oxygen-free environment to temperatures of 500-700°C to produce gasses and a solid residue (biochar).[13] The biochar is removed, and the gasses are cooled, causing some of the vapor to condense into a liquid "bio-crude" oil. The remaining gas, called syngas (a combination of CO_2, CO, H_2, and light hydrocarbons) can be further distilled to separate the CO_2 from the combustible gasses, which can be used to provide heat for the reaction.[14]

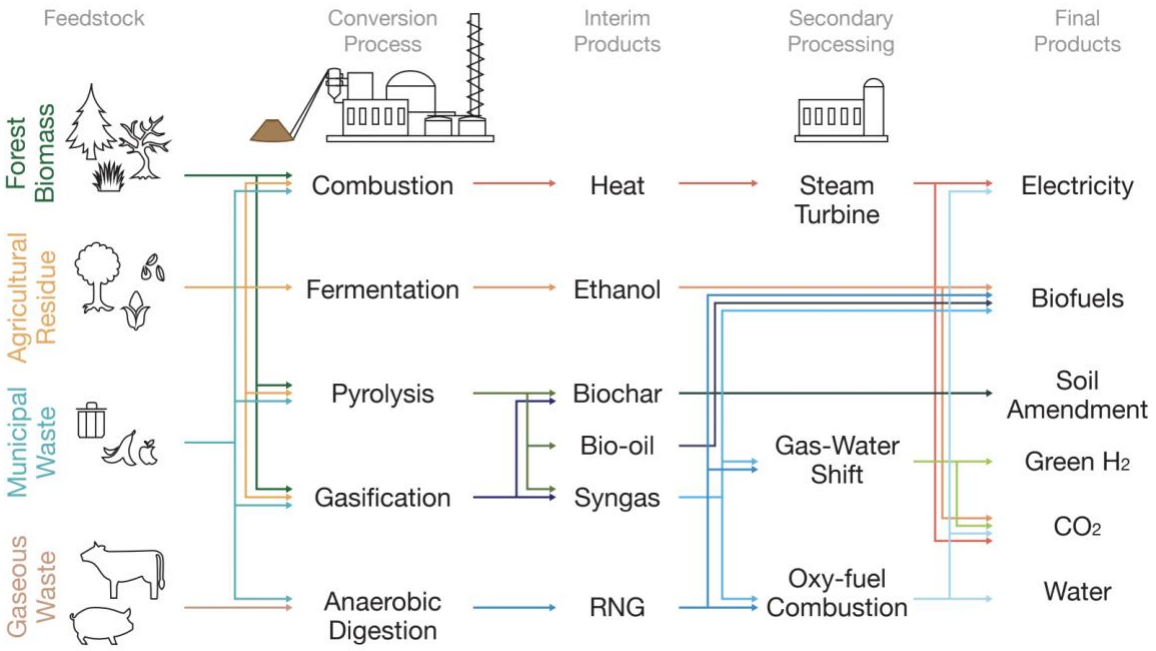

Figure 4.1. Summary of the potential feedstocks, processes, and products of biomass conversion. Adapted from Sandalow *et al.* (2021).[15]

[14] ARS (no date) What is pyrolysis? [2]
[15] Sandalow *et al.* (2021) BiCRS Roadmap. p. 28. [80]

Gasification occurs under even higher temperature conditions, above 700°C, and in the presence of some oxygen, but the reaction is controlled so that – like pyrolysis – combustion does not take place.[16] Instead, the biomass is converted into CO, H_2 and CO_2.[17] In a second step called a water-gas shift reaction, the carbon monoxide is reacted with water to form more hydrogen gas and carbon dioxide: $CO + H_2O \rightarrow CO_2 + H_2$.[18] The H_2 gas can then be sold as hydrogen fuel, known as green hydrogen.

Hydrothermal liquefaction is the preferred process when using wet feedstocks like algae[19] or municipal solid waste.[20] Thermal conversion takes place under moderate temperatures (200-300°C) and elevated pressures to form liquid bio-crude oil and biochar.

Finally, biomass can be directly combusted to create steam or heat to be used as a direct source of energy. These types of bioenergy power plants can be fitted with post-combustion carbon capture technology that scrubs CO_2 from gaseous byproducts to form a bioenergy with carbon capture and storage (BECCS) power station.[21] CO_2 capture rates can be as high as 90%[22] and it can be retrofitted onto existing power stations.

Post-capture combustion works similarly to point-source capture. An advantage of the technology is that it could easily be retrofitted to existing power plants[23] and is now considered ready for massive-scale deployment.[24] Amine absorption technology is the most common carbon dioxide binding chemical to be used in CCS, but other chemicals such as hot potassium carbonate (HPC) could be viable as well.[25]

Other capture technologies, such as oxy-fuel or pre-combustion technologies, are either relatively untested or inefficient.[26] Oxy-fuel combustion, as the name implies relies on combustion (rather than pyrolysis or gasification) in the presence of a pure or mostly-oxygen gas stream, rather than standard air.[27] The process relies on three primary components: an air separation unit to generate oxygen stream, an oxy-combustion boiler for the combustion itself, and then filtering the flue gas to remove pollutants and compress CO_2 for storage or use.[28] Compared to traditional combustion, oxy-fuel systems produce

about one-fourth the volume of flue gas emissions, making it easier to capture pollutants (including SO_x, NO_x, particulates, and mercury) from the gas, which is primarily composed of CO_2.[29] Furthermore, oxy-fuel pollution can reduce the amount of pollutants formed, such as NO_x.[30] This makes it far easier to purify and capture the CO_2 emissions to abate them.[31] However, challenges—high capital costs, energy usage, and difficulty with oxygen separation—have made it difficult for oxy-fuel combustion systems to be cost-competitive.[32]

4.1.2 State of Development

The key technological elements in BiCRS processes (biomass drying and pelletizing, gasification, anaerobic digestion, biomass boilers, CO_2 capture and separation, geologic storage and monitoring) are mature and commercially available at scale today in various industries, but have been combined for the explicit purpose of biomass carbon removal and storage in only a few instances.[33] 16 facilities are in operation at commercial-scale, though few are exercising their maximum capacity to store the carbon they are extracting from biomass.[34] However, several commercial-scale operations that emphasize carbon management are in the planning, development or pilot phase.[35,36]

4.1.2.1 Commercial Scale Examples

Illinois Basin Decatur Project, Decatur, Illinois

This five-year pilot project is a collaboration of the Illinois State Geological Society (ISGS), the Archer Daniels Midland Company (ADM), Schlumberger Carbon Services, and other subcontractors.[37] CO_2 is sourced as a byproduct of ADM's corn ethanol facility.[38] The pilot plant successfully injected approximately 1 million metric tons of CO_2 derived from biofuel production into a saline reservoir from November 2011 to November 2014. The success of this pilot led to a second commercial scale project, called IL-CCS project, which began operation in 2016.[39]

The IL-CCS project never met its stated aims of annually injecting one million tons of the carbon dioxide byproduct of the ethanol production process, to a depth of more than 7,000

feet in the Mt. Simon Sandstone saline aquifer of the Illinois basin.[40] According to the EPA, the plant's annual sequestered CO_2 emissions as of 2021 are less than 500 thousand tons,[41] which is significantly less than what was projected.[42] ADM receives tax credits of $20 per ton of carbon sequestered, and as of 2020, has received $281 million in total federal funding for both the Decatur and IL-CCS projects.[43,44]

Drax Power Stations, North Yorkshire, UK

The Drax Power Station is a biomass-to-power plant working to transition into a bioenergy + carbon capture and storage (BECCS) facility as part of the Zero Carbon Humber industrial cluster in northern England.[45] The project is supported by the UK Government, with the stated goal of being the first net zero carbon industrial cluster in the nation, with Drax aiming to be carbon-negative by 2030.[46]

Drax converted four out of six existing 645 MW coal power units to generate over 2.5 GW of electricity from biomass combustion.[47] They are in the process of piloting carbon capture and storage technologies to pair with the biomass facility, but cannot fully deploy CCS until transportation and storage infrastructure has been established and there is a policy framework or carbon marketplace in place that allows revenue generation for companies that produce negative emissions.[48] Drax uses wood pellets as the main feedstock of their power plant, primarily sourced from their factories in North America,[49] and estimates they will eventually be able to capture up to 8 million metric tons of carbon dioxide each year, starting with a first BECCS unit operational by 2027.[50]

Kore Infrastructure, Los Angeles, California

Kore Infrastructure has designed a proprietary pyrolyzer unit that can be added to existing installations.[51] Kore's process is a slow pyrolysis process operating at temperatures above 1000°F without oxygen, creating a biogas and carbon-rich biochar as products.[52] Most of the energy requirements are met using the biogas generated by the pyrolysis process, and

the overall reaction generates more energy output than it consumes.[53] Once created, the generated biogas can be upgraded into renewable natural gas (RNG) or hydrogen.[54] Their business model is designed to meet multiple needs, either by setting up their system—along with biomass procurement and operation and maintenance assistance—for another company's onsite location, or by offering waste or energy services, by serving as waste disposal or as a source of natural gas, hydrogen, biogas, or biochar.[55] Currently, their largest operating facility is located in Los Angeles and serves SoCalGas, processing 24 tons of feedstock daily.[56] The SoCalGas facility opened in August 2021.[57]

Their process is rated at technology readiness level 7,[58] meaning it had a successful operating pilot at commercial-scale.[59] Given the approval of strict air quality districts in California and their eligibility for LCFS credits for biogas, RNG, or hydrogen gas,[60] it can be reasonably expected that Kore expects their operations to be scalable in the California market.

4.1.2.2 Development Phase Examples

Clean Energy Systems, multiple sites in California

Rather than building facilities from scratch, Clean Energy Systems (hereafter CES) has been purchasing old biomass power plants throughout California and retrofitting them to bring them back online as BiCRS facilities.[61] Within Kern County, CES has been running a biomass plant at Kimberlina as a 'proof of concept' facility,[62] a 40-acre site for R&D, sub-commercial, and commercial activities and currently the world's largest oxy-fuel combustion plant.[63] Their largest project currently in permitting is the Mendota BiCRS Project.[64] At Mendota, CES plans to set up a 20-year commercial facility that will convert biomass into carbon-negative grid electricity using oxy-fuel combustion.[65]

CES's oxy-fuel combustion system works by burning fuels (including, but not limited to, natural gas, gas generated on-site, synfuel, and landfill or bio-digester gas) alongside

oxygen gas and water "at near-stoichiometric conditions."[66*] Crucially, the water in question can be recycled or even untreated water without inhibiting the oxy-fuel combustion reaction.[67] The primary products of the reaction are CO_2 and steam, with CES reporting carbon capture rates of 100% for the produced CO_2.[68] However, how CES plans to store or use their captured CO_2 seems unclear. The EPA reports their Class VI well application was withdrawn,[69] and their website's suggestion of using captured CO_2 for enhanced oil recovery (EOR)[70] would violate language in California's SB 1314.[71]

Mote, Los Angeles, California

Mote, a Culver City-based cleantech startup, is planning to build a $100 million biomass to hydrogen energy plant with carbon sequestration on 5 acres of unincorporated land in Kern County, pending securing financing, government approval and permits.[72] The plant will extract carbon dioxide and hydrogen via gasification from wood waste from farms, forestry, and other resources.[73] The hydrogen gas will be sold to hydrogen fuel station operators, and the CO_2 will be sequestered into deep underground saline aquifers or retired oil wells.[74] Mote's first facility expects to produce approximately 60,000 kg of carbon-negative hydrogen (green hydrogen) per day, which translates to 450,000 tons of CO_2 captured per year from biomass and available for permanent sequestration.[75]

Mote's business model will provide cost-competitive green hydrogen and carbon removal credits to the wide economy and take advantage of rebates from the federal tax credit for CCS projects (45Q) as well as California's Low Carbon Fuel Standard (LCFS).[76] In May 2022, Mote announced that they had secured commitments for over 450 thousand tons of feedstock for their production.[77] Working with Fluor, an industry leading engineering, procurement and construction (EPC) firm, to execute the Front-End Loading 2 (FEL-2), Mote plans to begin construction in 2023 and be fully operational by 2025.[78]

InterEarth, Australia

InterEarth is in the pilot phase of its operations, investigating the efficacy of shallow biomass burial. Their current model involves heavily trimming local trees, digging six-meter deep pits into salty groundwater, burying the tree matter and monitoring equipment, and refilling the pit to test if the salty water will successfully prevent the organic materials from releasing their stored carbon dioxide.[79*] Tests of the efficacy of their model are still ongoing, but they estimate that – if successful – the technology could be used to bury as much as 1 billion metric tons of carbon (nearly 4 billion metric tons of CO_2) annually, at a cost of less than $50 USD per ton.[80] At least 4-5 more years of monitoring the pilot projects are necessary to establish the efficacy of the technique. For reference, globally, about 140 billion tons of biomass waste is produced each year.[81]

Charm Industrial, San Francisco, California

Charm Industrial is a new start-up utilizing a two-part pyrolysis processing model, which should reduce the physical footprint required for a facility.[82] In general, pyrolysis generates biochar (or charcoal), bio-oil, and hydrogen gas, but the proportions of the products are dependent on the speed and heat of the pyrolysis process.[83] For their feedstock, Charm has

[79] Rathi (March 15, 2022) Carbon Pickling. [77]

* The 'salty groundwater' in question here is not naturally formed saline aquifers, which would be found much deeper than 6 meters below ground, but salty groundwater formed after farming practices in the region disturbed the groundwater table and accelerated the accumulation of salt. See Rathi (March 15, 2022) Carbon Pickling [77] for more information.

[83] Bolan *et al.* (2022) Applications of Biochar. p. 151. [9]

been utilizing agricultural wastes from central California.[84] Charm has experimented with yielding a variety of pyrolysis products in their efforts to sequester carbon dioxide—originally they looked at maximizing biochar yield, then pivoted to hydrogen production, and currently have found success in focusing on bio-oil.[85] Bio-oil is viscous and prone to solidifying, making it a weak fuel source but a promising candidate for carbon sequestration, as its tendency to solidify makes carbon dioxide leaks highly unlikely.[86] Furthermore, working with bio-oil has cost advantages over other forms of sequestration; bio-oil "would be cheaper to inject than CO2 gas captured from the air or from a power plant, since CO2 has to be compressed into a form that can be pumped underground."[87] However, financing larger projects using Charm's bio-oil process will likely rely on changes within the federal and state policy landscape. Bio-oil sequestration is currently not eligible for the federal 45Q tax credit program or recognized by California's Low Carbon Fuel Standard (LCFS), though Charm is pushing for policy changes to recognize the potential of bio-oil.[88] Charm is optimistic about scaling up their operations in the near future and Kern County could be a favorable location, as Charm indicates they are looking for new sites to operate with minimal transportation needs and available agricultural waste for feedstocks.[89]

4.1.2.3 Planning Phase Examples

San Joaquin Renewables Project, McFarland, California

The San Joaquin Renewables (hereafter SJR) project is a planned venture of Frontline Bioenergy, an Iowa-based company currently operating a commercial-scale gasification plant in Montana and a demonstration pyrolysis plant in Iowa.[90] According to SJR, the project will operate as a renewable natural gas (RNG) facility and could be considered either a BiCRS or BECCS project—they are aiming to maximize their potential bioenergy output from agricultural waste via gasification, but will also be sequestering carbon dioxide on-site "deep underground in an EPA class VI sequestration well."[91] The SJR project is in permitting with the City of McFarland, California and has secured up to $165 million in funding for development and construction from Cresta Fund Management and Silverpeak Energy Partners.[92] SJR is also seeking permitting to site their class VI well for carbon

sequestration within the City of McFarland; their permit application is still undergoing review by the EPA.[93]

SGH2 Energy, Lancaster, California

SGH2 Energy is a producer of green hydrogen using a patented "plasma-enhanced thermal catalytic conversion process" of gasification which operates at temperatures of 3500°-4000°C and produces a clean stream of hydrogen and carbon dioxide with reportedly "no toxins or pollution."[94] A plan for permanent CO_2 storage has not yet been specified by the company. According to SGH2's technical overview, "Lawrence Berkeley National Lab has found that for every ton of hydrogen produced, our process displaces 23 to 31 tons of carbon dioxide. That's 13 to 19 tons more carbon dioxide avoided than other fossil-free hydrogen production processes, which rely on electrolysis from renewable energy."[95] Their process has yet to be tested at commercial scale. Costs per kilogram of hydrogen produced by this process are competitive relative to the existing hydrogen market, as they estimate a cost of $2-3/kg hydrogen for their process compared to a $10-13/kg hydrogen range for electrolysis-based blue hydrogen production.[96] SGH2 Energy is planning to build a facility in Lancaster, California, just south of Kern County's boundary with LA County. The Lancaster plant would generate 3.8 million kg of green hydrogen utilizing 42,000 tons of recyclable waste annually supplied by the City of Lancaster, saving the city an estimated $50 to $75 per ton of waste annually due to avoided landfill space and processing costs.[97] The City of Lancaster is required to sort and supply a feedstock of recyclables for use by SGH2 Energy, and in exchange, will receive co-ownership of the facility.[98] The Lancaster facility is designed for a 5-acre industrial lot scheduled to open in the first quarter of 2023, and is estimated to support the creation of 35 full-time positions once operational.[99]

4.1.3 Operational Needs

4.1.3.1 Land use requirements

A BiCRS facility designed for commercial scale will likely have a large physical footprint, as the volumes of biomass to be sorted and converted will be extensive and need appropriate space to be stored and treated.[100] The overall land footprint for BECCS is estimated at between 1,000 and 17,000 km^2 per million tons of CO_2 removed, depending on location and the source for the biomass (e.g. forest and agricultural residues, and purpose-grown

energy crops).[101] Since we are focusing on scenarios where facilities could rely on existing waste biomass—rather than growing dedicated crops—we have chosen to emphasize the likely footprint of the facility itself where pyrolysis, gasification, or other biomass conversion would take place.

Based on scaling existing facility size estimates and interviews with industry representatives, the estimated physical footprint for a BiCRS facility capturing 1 million metric tons of CO_2 annually is 180 to 400 acres. The unscaled estimates, with their years indicated and estimated capture capacity represented by circle size, are illustrated in Figure 4.3. These estimated acreages do not account for land used to grow biomass for processing (as ideally, biomass will be sourced as waste from existing local agriculture and forestry partners) or external energy use needs, which will vary by plant design and efficiency.

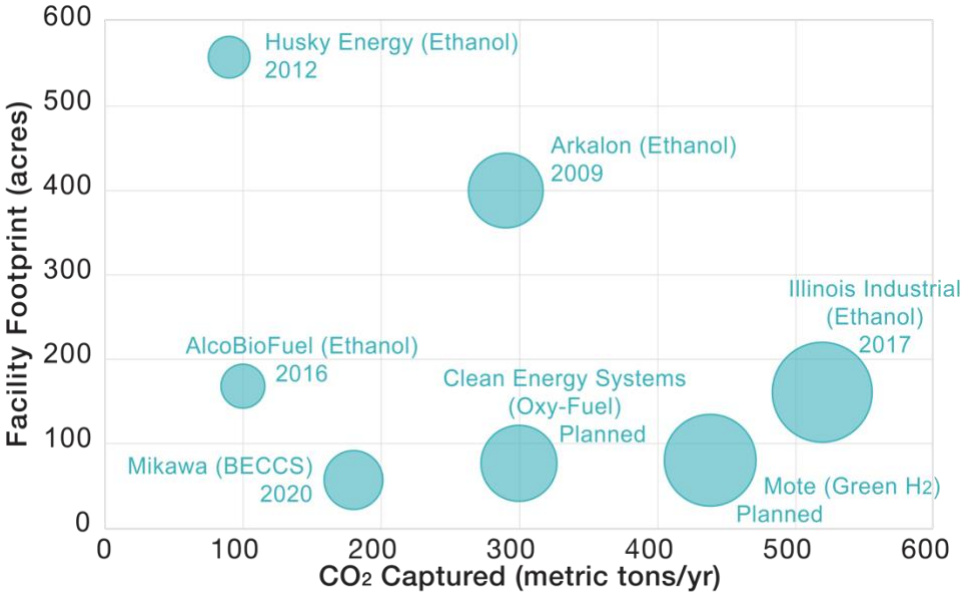

Figure 4.3. Land use requirements of existing and planned BiCRS/BECCS facilities as a function of their CO_2 capture potential. Footprint sizes were either reported directly from operator data or were measured digitally using publicly available satellite imagery.

The plant itself will typically involve a small handful of buildings (3-5) with a conveyor belt to bring in biomass from outdoors, as well as piles of biomass for processing and (depending on the facility) evaporation ponds for wastewater.[102] The tallest installation at a facility would be a gas flare, with an estimated height of 100 feet.[103] Typically, most of the acreage for a plant is dedicated to biomass storage and electricity generation.[104]

4.1.3.2 Energy requirements

The energy requirements of a BiCRS facility are opaque. Based upon the variety of conversion methods available and the lack of commercial-scale facilities operating with the goal of sequestration, rather than bioenergy, there is a wide error range for any estimates about energy usage. As such, it is best to evaluate projects billed as BECCS projects on their energy requirements, as there is a greater availability of information to analyze.

As bioenergy facilities, BECCS facilities will have an energy-positive process—meaning they produce more energy output than they consume to process the biomass via pyrolysis or gasification. This energy output can be producing electricity for the grid or generating synthetic fuels for consumers. For every metric ton of CO_2 captured at a BECCS facility, the estimated energy output is 0.83 MWh.[105] This is simply a representative example for a woody biomass-based facility but other estimates may differ substantially, as many bioenergy projects only report their energy output, not the total energy generated or the amount used to sustain their pyrolysis or gasification reactions, and the energy content of the biomass material may differ.

Due to the high temperatures needed for pyrolysis or gasification, facilities require an energy source for heat. For BiCRS/BECCS, this energy is typically supplied by the biomass itself, which contains energy, or by the fuels (syngas, hydrogen, or other products) that are produced on-site as products by breaking down biomass. Depending on the model, some pyrolyzers need external fuel to start the process,[106] which can be supplied from renewable sources like green hydrogen, renewable natural gas (RNG), or biodiesel.

For BECCS, energy requirements will also depend greatly on the plant's thermal efficiency.* Capturing carbon dioxide from the flue gas, which is commonly the source of carbon dioxide in post-combustion technology, of an energy conversion plant requires energy input.[107] As a result, the net energy efficiency of the plant is lowered. However, larger BECCS power stations are expected to have higher thermal efficiencies at 30% - 36%.[108] Higher thermal efficiency means the plant requires less energy to run the system, and subsequently lowering the cost of capital and operating expenses. Although current operational BECCS plants have yet to reach the million metric tons of CO_2 capture range, recent BECCS development shows that larger plant sizes are feasible.[109] For instance, Drax

---

[105] NREL (2022) Examining Supply-Side Options to Achieve 100% Clean Electricity by 2035. p. 13. [66] In this report, the finding is reported as net negative emissions of 1.2 metric tons of CO_2 per MWh—converting to be in terms of per metric ton of CO_2 gives the 0.83 MWh figure reported above.

[106] Industry representative, personal communication, September 21, 2022.

* Thermal efficiency is a performance measure of a device that uses thermal energy, which measures the ratio of the heat that becomes useful work.

[109] IEA (2020) CCUS in Clean Energy Transitions. [49]

Power Station has a capacity from biomass of 2,595 MW[110] and, as of 2018, operates with a thermal efficiency of 38% or more.[111] They estimate that the installation of CCS equipment in their power plant will decrease their thermal efficiency to 37%, so the change in efficiency due to the addition of carbon capture will be relatively small.[112]

4.1.3.3 Other operational requirements

Waste disposal requirements

The reaction products for biomass conversion and their disposal requirements will differ depending on the conversion process used by a given company. Reaction products outside of the main three—solid biochar, liquid bio-oil, and hydrogen gas—typically fall into the following categories.

Unless operating at extremely high temperatures, biomass processing generates ash and fine particulates, which can be accumulated and sold as a fertilizer product.[113] Water is often used in these processes for cooling or scrubbing, generating varied qualities of wastewater—some processes generate water clean enough for direct reuse in agricultural irrigation, whilst others hold wastewater and sludge in on-site evaporation ponds until it can be sent for proper treatment.[114, 115] Although some reaction products can be reused in other applications, non-hazardous industrial wastes will have to be landfilled. Items in this category include spent catalyst and any solid waste generated from spent material, like dolomite, silicates, or heavier ash.[116]

Of the standard three products generated via biomass pyrolysis, biochar is typically the least sought-after product, as bio-oil and hydrogen gas can both be upgraded into usable fuels. This means the solid biochar, or charcoal, generated by a pyrolysis-based biomass plant needs a designated end-of-life trajectory. Fortunately, biochar is both safe and more useful than most industrial waste products, and thus is less likely to be landfilled or otherwise discarded. A range of academic literature on biochar has identified uses including carbon storage, as a soil amendment, as a soil conditioner for contaminant immobilization, or as a catalyst for various uses.[117,118] Resale of biochar for agricultural uses is the most common existing use, as it can be added in livestock feed, used as a treatment for increased soil fertility, or mixed in with compost or other organic materials to prevent

[118] Lee, Kim, Kwon (2017) Biochar as a Catalyst. p. 70. [58]

nutrient leaching.[119] Biochar can also be used to remediate sites contaminated by oil and gas or mining operations, as its high porosity makes it a promising material to sequester chemicals from heavy metals to volatile organic carbons (VOCs).[120] There have also been studies conducted regarding the viability of using biochar as a cover for landfill waste disposal.[121]

Warehousing requirements

Warehousing for a BiCRS operation will likely need to be extensive, as any commercial-scale facility would likely be dealing with thousands of tons of biomass daily for processing.[122] The source and quality of the feedstocks—for example, if it's delivered already dehydrated or in its raw form—will likely dictate the amount of space needed for biomass storage. There will also need to be ample space for storing byproducts like biochar before their sale or disposal. In interviews with experts,[123] facility size was estimated to require approximately 80 acres of land to accommodate the storage of feedstocks, on-site electricity generation, and evaporation pools for wastewater, as well as necessary buildings for processing. Gas-fired facilities would be 3 stories tall and processing is estimated to require 3 of these buildings, though figures on estimated square footage are unavailable. Other facilities have had much smaller warehousing requirements—SGH2 Energy's entire Lancaster hydrogen plant fits on a 5 acre industrial lot because their feedstocks are regularly replenished under their agreement with the city, reducing the need to store large amounts of feedstock on-site.[124] Based upon this wide range of warehousing needs and total acreage presented by biomass firms, this requirement is likely flexible depending on contract terms and the feedstocks being processed.

Transportation requirements

In capturing carbon dioxide from biomass for sequestration, the most preferred facility sites are either co-located with a viable biomass source to eliminate transporting biomass, or located on-site with a sequestration well, to avoid needing to transport carbon dioxide for storage.[125] Transporting biomass often requires some pre-processing and is conducted using trains or trucks. When possible, rail is preferable to trucking, as it has lower costs—especially over longer distances—and lower externalities, according to the Government Accountability Office (GAO).[126] Rail can require upfront investments to build new tracks,

[125] Stolaroff *et al.* (2021) Transport for Carbon Removal Projects. p. 3. [86]
[126] Stolaroff *et al.* (2021) Transport for Carbon Removal Projects. p. 3. [86]

depending on the region's existing infrastructure, so trucks are typically used for shorter distances.

Byproducts of BiCRS processes, from hydrocarbon fuels and grid electricity to biochar, would require transportation offsite to be used by customers. These transportation considerations should be taken seriously, as without proper planning, the carbon efficiencies of BiCRS could be lost in trying to sustain a market for related goods reliant on increased carbon emissions for transport.

Infrastructure & Pipeline requirements

Initial deployment of BiCRS should consider the availability of surrounding existing infrastructure to minimize the costs and complexities of long-distance transport of either carbon dioxide, biomass feedstock, and biofuel distributions.

Given that Kern County has appropriate geology for long-term carbon sequestration underground, any BiCRS facility should try to locate as close to an injection site as possible, limiting the need for extensive pipework to handle the supercritical carbon dioxide fluid. However, the pipeline requirements for carbon dioxide are not specialized—their requirements are well-understood due to decades of prior manufacturing and use in the U.S. For more details on carbon dioxide transport, particularly pipeline transport, please refer to Section 9 of this report.

Other requirements

Sequestering carbon underground requires clearing a number of legal and permitting hurdles. Although Kern County and other parts of California's Central Valley are seen as prime real estate for carbon sequestration from a geological perspective, it may be more complex to get all of the legal and regulatory matters aligned and have local landowners on board.[127]

Another hurdle comes into play when using hydrogen as fuel: "There is very little refueling infrastructure and even fewer fuel cell-powered heavy duty vehicles" already in existence.[128] Ensuring biomass-to-hydrogen production timelines match up with the development and scale of hydrogen-fueled technology will be critical to the success of a green hydrogen project. For further exploration of biomass-based green hydrogen considerations, please see Section 6 of this report.

4.1.4 Carbon Capture Potential

The carbon capture potential of BiCRS and BECCS is highly promising, though restricted regionally based on resource use constraints. On average, "biomass is roughly half carbon by weight," so if processed efficiently the carbon removed from biomass is substantial.[129]

---

[127] Baker *et al.* (2020) Getting to Neutral. p. 7. [8]

[128] Hanley (May 22, 2020) Lancaster, California Will Be Home To World's Largest Renewable Hydrogen Plant. [44]

[129] Sandalow *et al.* (2021) BiCRS Roadmap. p. 7. [80]

However, biomass can also be utilized for other applications in agriculture and construction that also repurposes or stores its carbon content—often the local context will determine if the financial cost and carbon benefits balance out in favor of a BiCRS or BECCS facility, or repurposing products for other uses.

Based upon the best estimates in the literature, experts posit that "roughly 2.5 to 5.0 $GtCO_2$/year could be removed from the atmosphere and stored by 2050 using biomass produced with minimal environmental impact."[130] Here, 'minimal environmental impact' means without repurposing other productive landscapes, like agricultural lands or forests, to grow biomass dedicated crops or using other carbon-rich materials like forests for biomass feedstocks.

Furthermore, biomass that decays anaerobically in other settings, like landfills, produces methane in addition to carbon dioxide, thus contributing multiple greenhouse gas emissions into the atmosphere.[131] Thus for biomass-rich materials that are routinely landfilled, such as household organic wastes, the carbon removal potential could be even greater than expected as it would prevent the production of multiple forms of carbon-based pollutants.

However, quantifying the overall impacts of a BiCRS or BECCS facility will depend on the full life-cycle analysis (LCA) of a specific project. In a full LCA, it would be possible to identify how much carbon the plant material holds and the amount that could be captured in a given gasification or pyrolysis process, but also the carbon intensity of other steps, like transporting biomass, processing and/or dehydrating biomass, or sending finished products aside from CO_2 to market. Existing LCAs conducted for different BECCS models have indicated that net emissions can differ considerably depending upon the feedstock, conversion method, and carbon capture method used by a given facility.[132]

4.2 Societal Impacts

4.2.1 Job creation potential

4.2.1.1 Number and types of jobs

Because BiCRS facilities at commercial scale are quite rare, the most relevant data to approximate job creation is to examine commercial-scale BECCS operations using likely BiCRS feedstocks available in Kern County, namely agricultural waste and municipal organic waste.

[130] Sandalow *et al.* (2021) BiCRS Roadmap. p. vi. [80]

[131] LMOP (April 21, 2023) Basic Information About Landfill Gas. [56]

[132] Almena *et al.* (2022) Carbon dioxide removal potential from decentralised bioenergy. p. 9-11. [5]

Fulcrum Bioenergy's first commercial plant in Reno, NV, capable of processing 175,000 tons of landfill waste annually, supports over 100 permanent jobs.[133] Looking at estimates for upcoming projects under Fulcrum's umbrella, there is also a large requirement for construction workers to build these facilities—anywhere from 1,000 to 1,200 jobs created in the construction process, though these positions are not permanent.[134,135] San Joaquin Renewables, who is planning to sequester carbon on-site though at a smaller facility, predicts its operation will sustain 45-50 full-time employees.[136] In industry interviews, some operators estimated smaller staff needs—closer to 25 for a full facility, even for a facility processing up to 219,000 tons of biomass annually.[137] Given this wide range of jobs figures across different biomass facility models, it appears that permanent job creation is not clearly correlated with facility capacity.

The Drax plant in the UK, as it converts from bioenergy to BECCS, is estimated to generate over 4,000 direct jobs annually during the CCS construction phase from 2024 to 2028.[138] Once Drax has been fully converted to BECCS, it is expected to support an estimated operations and maintenance staff of up to 800 employees.[139] After the facility is operational, it could further generate 2,300 indirect and 4,100 induced jobs.[140] Given that Drax claims that full BECCS operations at their facility would result in the removal of about 8 million metric tons of CO_2 per year, which would make it the largest CO_2 capture and storage project globally,[141] it makes sense that these estimates are much higher than those of other BiCRS or BECCS facilities.

It is worth noting that scaled estimates for the million metric tons per year of CO_2 capture range for other facilities generate much smaller estimates, somewhere in the range of 45 to 150 full-time jobs created. Although some estimates range lower or higher, as seen in Table 4.1, the 45 to 150 range seems like the most consistent estimate based on both scaling existing facilities and any literature estimates, with an average of 102 jobs estimated per million metric tons of CO_2 captured annually. It is important to note that biomass facility jobs are not expected to necessarily scale linearly with plant size (in terms of CO_2 capture potential), as can be seen in the range of permanent jobs associated with already-existing facilities. Furthermore, the possibilities of increased automation and remote monitoring means that steps should be taken in the planning and permitting process to ensure jobs for any new carbon management facility benefits local communities.

4.2.2.2 Training pipelines

In conversations with industry experts, we found that oftentimes, facilities like to recruit locally where possible, though local hiring can be dependent on the specific skills needed. Some facilities that specialize in retrofitting old power plants or other infrastructure into BiCRS or BECCS facilities have found that since existing employees already know the plant well, they can be easily kept on and retrained as necessary, keeping all workforce demands local.[142]

For the Drax plant, there are concerns regarding the challenges in labor and skills supply due to the lack of specialist skill in key manufacturing sectors as required by the plant.[143] This will need to be addressed with a combination of a direct apprenticeship scheme, early investment in the next generation of workers, and endorsement of vocational work at a local school.[144]

[144] Vivid Economics (2020) Delivering Jobs at Drax. p. 29-30. [92]

4.2.2 Quality of Life

4.2.2.1 Location

At existing biomass-based plants, noise is a common concern for area residents. For example, a safety valve at the Drax Power Station, when opened, generates a sound so loud that residents 2.5 miles from the station reported that they were awoken by the noise.[145] It is anticipated that mitigation is possible with sound-dampening design within buildings.[146] Siting away from residential areas and incorporating sound dampening materials in construction would likely mitigate noise at nearby communities.

Given that burning is the traditional disposal method for agricultural and forestry wastes, moving to process agricultural waste at a BiCRS or BECCS facility could lead to lower emissions; potentially up to 95-99% lower than they would be if the biomass was burned instead.[147] Biomass-based facilities which produce emissions or pollutant discharge will need to adhere to a federal Title V operating permit. For Kern County, developers would need to obtain permit authorization to construct and operate before commencing construction, and a permit to operate from Eastern Kern Air Pollution Control District (EKAPCD) or San Joaquin Valley Air Pollution Control District (SJVAPCD).[148]

4.2.2.2 Multi-use potential

There is multi-use potential for BECCS and BiCRS facilities, although examples are limited. Feedstock generation from nearby agricultural waste can be considered a multi-use byproduct of the primary agriculture industry. For the facilities themselves, noise pollution generated by biomass processing would need to be addressed, but co-locating community facilities with processing plants is possible. A waste-to-energy plant located in central Copenhagen, Denmark – called Amager Bakke – was designed to be a public recreational facility as well as a power plant.[149] The building, which converts municipal waste to electricity, is topped with a hiking trail and artificial ski slope. While Amager Bakke does not capture CO_2, it sets a precedent for the possibility of innovative proposals that could integrate other businesses or community facilities with BiCRS/BECCS facilities.

4.3 Environmental Impacts

4.3.1 Water requirements

4.3.1.1 Minimum volume requirements

Water requirements vary depending on the conversion process used to process the biomass intake, but is low under every well-understood conversion pathway. The largest lifetime intake of water in the BiCRS life-cycle is that required for actually growing the biomass in question. As long as dedicated feedstock crops are not being grown to sustain the facility (i.e. the biomass in question is agricultural or forestry waste), it is likely the water would have been used anyway. In fact, biomass is frequently 'de-watered' before conversion, aside from supercritical water extraction,[150] so it's actually likely that facilities will be generating some volume of wastewater in the process.

However, in case there needs to be a dedicated feedstock crop to feed the facility, sustainable agriculture practices which reduce water consumption could reduce the additional water withdrawal.[151] However, a study shows a potential tradeoff between land use pressure and water consumption. For instance, to reduce land use one might choose to grow crops with higher yields which require higher water volume. If we include the water consumption to grow the feedstock, the total amount of water to deliver 12 Gt carbon dioxide per year through BECCS would account for 3% of the total amount of water currently used by human activities.[152]

Information about San Joaquin Renewable's current process appears to corroborate these assumptions. Their method requires some water vapor to gasify biomass, but also produces "irrigation-quality water" as a product of its conversion process, resulting in a net gain in water.[153] A diagram illustrating their model is included below in Figure 4.4.[154] With that said, these are assumptions—the water demands of any project may differ based upon their conversion method, kinetics, biomass source, or other factors.

4.3.1.2 Minimum quality requirements

As discussed above, water is not a necessary component to most BiCRS conversion processes, with some BiCRS processes even generating a net gain of water in the process. However, water availability issues in future projections are still poorly understood.[155]

4.3.2 Air quality

Data availability for distinctions between biomass pyrolysis, gasification, and combustion with respect to emission impacts is limited, largely because most studies restrict themselves to a single type of biomass feedstock or single type of biomass conversion process, if not both. For this reason, we have chosen to highlight findings from coal, which is fossilized organic material from wetlands[157] and has clearly understood data due to decades of use with all three technologies. Although the comparison is imperfect, it provides useful insight into the differences between conversion types. The primary benefit of pyrolysis and gasification, from an emissions perspective, is the high temperatures and pressures of the biomass conversion generate a syngas stream of emissions that makes it simpler to separate out criteria air pollutants (including NO_x and SO_x) as well as trace contaminants including mercury, cadmium, arsenic, and selenium.[158]

4.3.3 Other potential impacts

Some types of biomass production damage ecosystems, hurt local farmers, or increase emissions.[159] The American ethanol industry has been a notable offender, as its push to grow biofuel crops has contributed to deforestation with little to no clear carbon reduction benefits.[160]

Any biomass plant will have to consider the land use impact associated with feedstock production. If there are no land use changes because biomass would be sourced from

[160] Sandalow *et al.* (2021) BiCRS Roadmap. p. 12. [80]

waste and residues from existing land uses, the impact will be little to zero.[161] If biomass feedstock needs are to come from dedicated agriculture soil, 380 to 700 Million hectares of land area is needed to deliver the global BiCRS sequestration potential of 12 GT per year carbon dioxide.[162] Change in local land cover, or extensive withdrawal of water from irrigation sources, will impact the climate in regions as far as a few hundred kilometers downwind.[163]

Land use change would also potentially cause indirect impacts, such as initiating new competition with other land uses, such as food-production, wood production, or residential land, which could lead to changes in the market for related commodity supplies and prices.[164] Given the abundance of potential biomass waste feedstocks in California in the form of agriculture waste, forest residues and municipal waste,[165] a significant volume of BiCRS facilities could be operational without the need to cultivate bioenergy crops – and their downstream effects – in the region.

4.4 Economic Impacts

4.4.1 Business Model

Whether a project defines itself as BiCRS or BECCS, the business model generally depends on the ability to outweigh fixed costs (i.e. levelized capital costs, labor expenses, taxes) and flexible costs (i.e. costs of energy use, biomass, transport) with income (i.e. selling products and/or carbon credits).

BiCRS and BECCS technologies have a number of revenue streams, depending on the outputs they prioritize in the gasification or pyrolysis process. All of these processes will generate CO_2 for permanent sequestration, and thus will be eligible for the 45Q federal tax credit.[166] As of 2022, the 45Q tax credit totaled $85/ton CO_2 for every ton permanently stored and $60/ton CO_2 for every ton used in enhanced oil recovery (EOR).[167] Due to California's SB 1314, captured CO_2 effectively cannot be used for EOR within the state.[168] Most biomass projects will also generate bioenergy products, which can be sold as electricity or fuel; BECCS processes will aim to maximize the potential bioenergy output. For gasification, the

hydrogen gas created can be sold as a product—this economic opportunity is explored more in Section 6.4 of this report, which addresses the business of hydrogen production.

At the start of 2022, there were 16 operational facilities classified as BECCS facilities,[169] though some items on this list—like Charm Industrial—would likely be better described as BiCRS. An estimated 50 additional facilities are currently under development.[170] As for expanding the amount of BiCRS/BECCS facilities in the future, reduced costs in various technological pathways will help reduce the economic barriers, but the primary hurdle to scaling is anticipated to be generating new institutional arrangements and stakeholder consensus.[171] In short, most of the expected barriers are political and institutional in nature, rather than economic or technical.[172]

Most companies currently working on biomass facilities are working with large upfront capital investors and planning to fund their sequestration through a mixture of tax credits, selling carbon offsets, and/or selling byproducts (syngas, biochar, etc). Biomass conversion technologies can produce products aside from CO_2, including biochar and biofuels. As mentioned above, biochar can be used for a variety of agricultural and industrial applications. In recent years, biochar has sold for amounts ranging from $9 to $42 per cubic foot of biochar, with variations depending on the type, texture, quality, and sale venue.[173] Biofuels can vary considerably depending on the process in question: ethanol from fermentation,[174] hydrogen from gasification or fast pyrolysis,[175] or synthetic fuels generated by upgrading bio-oil.[176] For RNG and hydrogen fuel, the sale comes with additional benefits, as these fuels can often qualify for other state and federal subsidies.[177,178] More details about these economic incentives established via policy for various lower-carbon fuels can be found in Section 2, and specific information for hydrogen incentives can be found in Section 6.

The other avenue of revenue is the carbon credit market, of which there are both governmental and private options available. For the government carbon market, there are benefits at the federal and state level, with the 45Q tax credit and depending on the products and their intended market, can also be eligible for California's LCFS credits. For BiCRS or BECCS projects that generate alternative fuels for sale in California—including renewable natural gas, hydrogen, or electricity[179]—should be eligible for Low Carbon Fuel

Standard (LCFS) credits, though uses like electricity would need to demonstrate their contribution to lowering state transportation carbon intensity.[180] LCFS credits between 2018 and 2022 varied between $62 and $218 per ton of CO_2 reduced.[181] The most recent price updates can be found on the California Air Resources Board LCFS credit dashboard, which posts LCFS price averages from the preceding week every Tuesday.

In speaking with industry experts, some BiCRS facilities have been selling their energy as electricity to the grid currently, but are planning to convert to more lucrative alternative energy sources, like selling hydrogen to consumers, once there is a sustained market and distribution network nearby.[182] This reflects the adaptivity of biomass-based energy facilities—depending on the current energy market, the biomass content can be converted into different materials to meet local needs.

4.4.2 Business Costs

Combining the estimated capital and operational costs—capital costs, feedstock costs, fixed and variable operating costs—of BiCRS/BECCS, outlined below, results in an estimated cost per ton CO_2 of $61-288, which aligns well with industry estimates of $88-288.[183]

4.4.2.1 Cost to build (upfront costs)

The estimated capital costs for constructing a BiCRS/BECCS facility capable of capturing 1 million metric tons of CO_2 annually ranges from $350 million to $1.2 billion, based on scaled estimates. This range has been corroborated by industry representatives. If a BiCRS/BECCS facility ran for 30 years, the average capital cost per metric ton of CO_2 would fall between $30-189. Given that estimates in the academic literature for BECCS typically range from $30 to $400 per metric ton of CO_2,[184] the scaled estimates calculated in this study appear quite reasonable.

Costs can also vary depending on the inputs a facility requires, and between BiCRS and BECCS processes, the largest differences typically originate from energy needs. Biomass pyrolysis or gasification will generate thermal heat, and many facilities can be largely or fully energy self-sufficient by utilizing this heat to meet the plant's energy needs. For BECCS facilities, the process is optimized to maximize the bioenergy output—whether it be heat, electricity, or fuel—leaving excess energy available to sell. However, this often requires upfront investment to reuse process heat or build off-grid renewables of heat-to-electricity equipment to support any on-site electricity needs.

[184] Fuss *et al*. (2018) Negative emissions. p. 12. [39]

4.4.2.2 Operational costs

Operational costs on-site will involve maintenance and repairs, staff, monitoring, and any taxes. In terms of fueling their conversion processes, facilities will also need access to biomass feedstocks, which vary in terms of seasonal availability and cost. Not only do these materials need to be purchased (or obtained through another standing arrangement) and then chipped and dried, they also must be transported to the facility via train or truck.[185] Feedstock costs are often the largest estimated category in assessing a facility's operational costs. However, costs can vary widely—items like municipal solid waste (MSW) or some agricultural residues, like pistachio shells or almond hulls, are already collected and processed, making them easy to purchase at relatively low additional cost.[186] Other materials that require collection directly from the field, or processing steps like chipping or drying for forestry waste, can increase the cost of biomass feedstocks.[187] In general, placing facilities within close proximity of CO_2 storage sites and large quantities of biomass to use results in lower overall costs per ton CO_2 by reducing the transportation burden at both ends.[188]

Within the operational costs, there are fixed and variable expenses at play. Fixed operating costs—such as routine maintenance and labor costs—are typically estimated at 2-7% of the capital costs;[189] breaking down the estimated capital costs per ton CO_2 gives an estimated range from $1-13 per ton of CO_2 in fixed operating costs. Variable operational costs—such as unplanned maintenance, waste disposal, or non-biomass feedstocks—range from $10-27 per ton CO_2.[190] As mentioned above, biomass feedstock costs are typically the largest cost category, and can vary considerably depending on the type of biomass and the distance it needs to be moved. Based on the estimates available, a good range is approximately $20-60 per ton CO_2.[191,192] Combining these estimates, you would get a range of operating costs per ton CO_2 of $31-100.

4.4.3 Regional benefits

Businesses looking to start commercial-scale BECCS and BiCRS operations are drawn to southern California locations, including operations eyeing Kern County specifically. Due to the region's promising geography for underground carbon sequestration and relative abundance of agricultural waste feedstocks, there are clear assets to siting a BiCRS or BECCS facility in Kern County. These benefits would also extend beyond the county: in a

study of CO_2 removal options for California at-large, experts found that "NNBFs [net-negative biofuels], and specifically biomass gasification to hydrogen, had the largest potential and among the lowest cost of carbon removal options for California."[193]

4.4.3.1 Proximate feedstocks

Feedstocks for biomass carbon capture are abundantly available in Kern County, and the available feedstocks are highly preferred from a climate perspective. Both the area's high concentration of agricultural waste and steady supply of municipal organic waste could be used to fuel a BiCRS facility in the region. Within California, there is an estimated 55 million tons (Mt) of biomass available annually for energy applications, not including energy crops.[194] Within Kern County, the 2019 County Crop Report determined that 237,000 tons of almond hulls and shells and 236,000 tons of biomass were produced from the local agriculture industry.[195] The collective ~470,000 tons of biomass would be enough to support a ~620,000 ton CO_2 capture BiCRS facility—see Section 11 for more details about these calculations in relation to local agricultural waste.

4.4.3.2 Proximate consumers

Depending on the process used to extract carbon from oven-dried biomass, a byproduct of BiCRS facilities using slow pyrolysis processing is biochar—a material which can be applied to crop fields to improve soil fertility.[196] Given agriculture's large footprint in the area, this could produce a symbiotic relationship, with farms supplying agricultural waste feedstock and consuming the carbon-rich biochar produced by a local BiCRS facility.

There may also be proximate consumers for other biofuel or carbon offsets given the relative closeness of both Los Angeles and the Bay Area. Regional leaders in the digital technology space, such as Stripe in San Francisco, have been key investors in start-ups working towards carbon removal strategies.[197]

4.4.3.3 Co-location advantages

The primary co-location advantage for biomass processing facilities is the ability to share infrastructure for common needs—CO_2 transport for sequestration or use, onsite water supplies, and the potential of using electricity from a shared solar array or other off-grid power source with other companies. Co-locating reduces the costs, and therefore risks, of each player within the carbon management park.

5. CO_2-emitting Industries

TECHNOLOGY AT A GLANCE:

- Point source carbon capture is a technique applied to industrial and energy facilities that emit large concentrations of CO_2. The technology is commercially available and used in over 30 energy plants and manufacturing facilities worldwide, but its cost (and thus level of deployment) varies as a function of facility type.[1]
- Of the many industries that could use point source carbon capture, the steel industry was the most practical to investigate for purposes of location in Kern county.
- Carbon capture in the steel industry is in an early commercial stage: globally, there is 1 steel mill operating with carbon capture.
- Several techniques for producing low carbon steel are in the pilot or demonstration phase, and are explored briefly here, although they would not involve capture and storage of CO_2, and thus would not qualify as a carbon management technology.
- Current cost per metric ton CO_2 captured from steel: \$68-114 USD/ton CO_2.
- Projected cost per metric ton CO_2 captured at scale: \$40-90 USD/ton CO_2.
- Key advantages of this technology in Kern County: steel mills can provide hundreds of high paying jobs, many of which do not require post-secondary education.
- Key concerns for this technology in Kern County: steel mills do produce emissions, wastewater and solid byproducts that will have to be mitigated to meet regional environmental and safety standards.

[1] Values in this section are summarized from the suite of references cited herein, and are explained in further detail in each subsequent section.

5.1 Technology Summary

5.1.1 Description: How it Works

5.1.1.1 Point Source Carbon Capture

Many industries and energy facilities produce CO_2 as a byproduct of their processing activities, collectively accounting for about half of global greenhouse gas emissions.[2,3] However, most of these industries and facilities can employ a technology called *point source carbon capture*, which scrubs CO_2 from significant points of exhaust before they are released to the atmosphere. In contrast to Direct Air Capture (DAC, Section 3) and Biomass with Carbon Removal and Storage (BiCRS, Section 4), which are designed to remove human-derived CO_2 emissions from the ambient air, point source capture prevents the release of CO_2 before it is emitted. Point source carbon capture is at an advanced state of technological development, and many techniques are commercially available today that can be used to trap CO_2 from the exhaust of coal and natural gas power plants and boilers, or in the industries of natural gas processing, petrochemical development, fertilizer development, iron and steel manufacture, cement production and paper mills.[4] Despite this, only about 230 million metric tons of CO_2 are captured annually,[5] less than 1% of the 28 billion metric tons of CO_2 emitted from these sectors globally each year.[6]

Of those facilities that do employ carbon capture, most in operation today use a solvent-based approach, illustrated in Figure 5.1.[7] Rather than directly emitting CO_2-bearing flue gas through exhaust chimneys of a plant or facility, the flue gas is diverted to a separate *absorption tower*, where it is mixed with a liquid solvent. The solvent has either chemical properties that cause the CO_2 to readily dissolve into the fluid (for example having a mildly basic pH),[8] or a component of the solvent physically attracts the CO_2, such that it is drawn out of the flue gas and sorbs onto the surface of the molecular component in the capture fluid.[9] The flue gas is returned to the chimney and released; the CO_2-rich capture fluid is transferred to a stripping tower (or capture tower), where the CO_2 is separated from the solvent. In chemical solvents, this is accomplished by increasing the temperature (making

[9] [illegible]. [5]

the CO_2 exolve as a gas). In physical solvents, pressure is decreased such that CO_2 is more stable as a gas than bound to the surface of the in-solvent physical adsorbents.[10]

A less common capture technique makes use of membranes (mostly used for natural gas processing). Membranes are permeable physical barriers that allow gasses to pass through at variable rates, effectively separating some gas molecules from others.[11] Like physical solvents, membranes are used in processes that have high concentrations of CO_2 in the flue gas stream, whereas chemical solvents are more efficient when CO_2 makes up less than 15% of the flue gas.[12]

The cost (and thus feasibility) of point source carbon capture is directly proportional to the concentration (or partial pressure) of CO_2 in the exhaust stream, and is therefore industry specific.[13] Carbon capture technology for gas streams with CO_2 concentrations higher than 25% have been used in industrial applications since the 1940s[14], and technologies currently exist that can capture CO_2 from gas streams with concentrations as low as hundreds of parts per million (as in the atmosphere). But to date, CO_2 point source capture has not been implemented on a large scale due to lack of financial or regulatory incentives.[15]

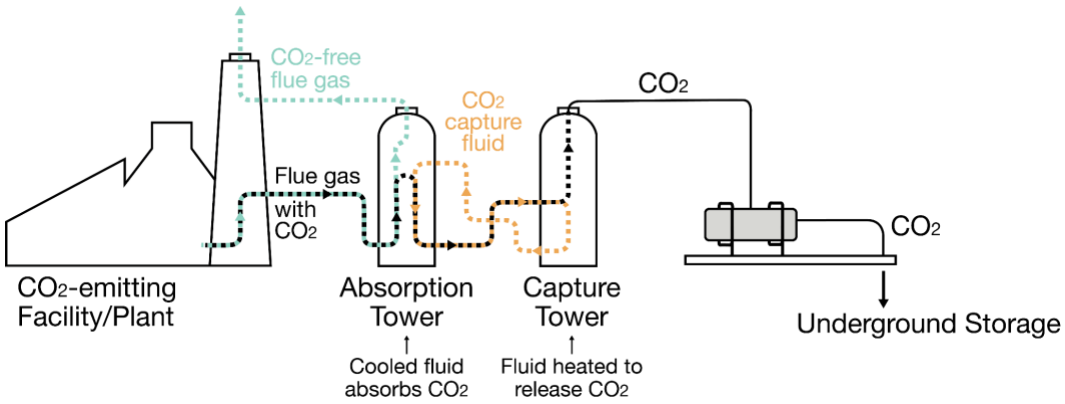

Figure 5.1. Generalized schematic of point source carbon capture. Adapted from Kearns et al. (2021).[16]

Industries for which point source capture is applicable for the purpose of carbon capture are summarized in Table 5.1. For the purposes of this analysis, our mandate was to explore industries for which there are existing or planned facilities in Kern County, and that might reasonably be included in a carbon management business park. According to the EPA

Facility Level Information on GreenHouse gases Tool (FLIGHT), Kern County has 44 facilities that reported significant CO_2 emissions in 2021,[17] and are divided into the following sectors:

- 15 Power plants
- 20 Petroleum and natural gas systems or refineries
- 4 Agriculture and/or food processing facilities
- 2 Waste facilities (Bakersfield and Clean Harbors landfills)
- 2 Cement facilities
- 1 Mine (Borax - boron mine and refinery)

Agricultural facilities and landfills - while sources of emissions - are not viable candidates for point source capture because greenhouse gas emissions are diffuse, rather than concentrated from a single or few point(s) of exhaust (although waste could be diverted from landfills to a BiCRS facility, see Section 4). The cement and borax facilities are site dependent, meaning that although point source carbon capture could be a viable carbon management option in these industries, facilities are located adjacent to the mine or quarry from which raw material is extracted, and thus are not likely candidates for development in a dedicated carbon management park. Finally, because the business park under consideration would utilize renewable energy sources and is intended to be complementary rather than additive to the existing oil and gas sectors of Kern County, we have excluded investigation of power plants, natural gas processing, and petroleum refineries from this analysis. For additional information on the potential of point source capture for these CO_2-emitting industries, the interested reader is referred to two recent reports from the International Energy Agency on carbon capture utilization and storage (CCUS) in clean energy transitions[18] and the role of CCUS in low-carbon power systems.[19]

Another CO_2-emitting industry is not yet operating in Kern County but may be in the future. The San Diego-based Pacific Steel Group announced in April 2022 that it plans to build a state-of-the-art steel plant in southeast Kern County, with construction beginning in 2025.[20] As of the publication of this report, Pacific Steel Group's proposal is under planning and permitting review by the county.

Steel mills are technologically diverse. Depending on the type of steel production employed, they can produce as much as 2.4 tons of CO_2 for every ton of steel produced (Table 5.2), or – with the most advanced technologies – no CO_2.[21] Here, we examine the

g. These industries can are examples of BiCRS/BECCS, and are discussed further in Section 4.

5.1.1.2 Steel Production and Carbon Emissions

There are a variety of production routes for steel, which vary as a function of the iron source material being used. Source materials include iron ore, the raw material mined from geologic deposits, direct reduced iron (DRI), which is formed by reducing iron ore in the presence of natural gas or a coal derivative, and recycled scrap steel. Integrated steel plants

can produce steel from any of these sources, typically using a *blast furnace* (BF) to convert iron ore to reduced iron, and using a *basic oxygen furnace* (BOF) to convert the reduced iron, DRI and/or scrap steel to new steel products.[26]

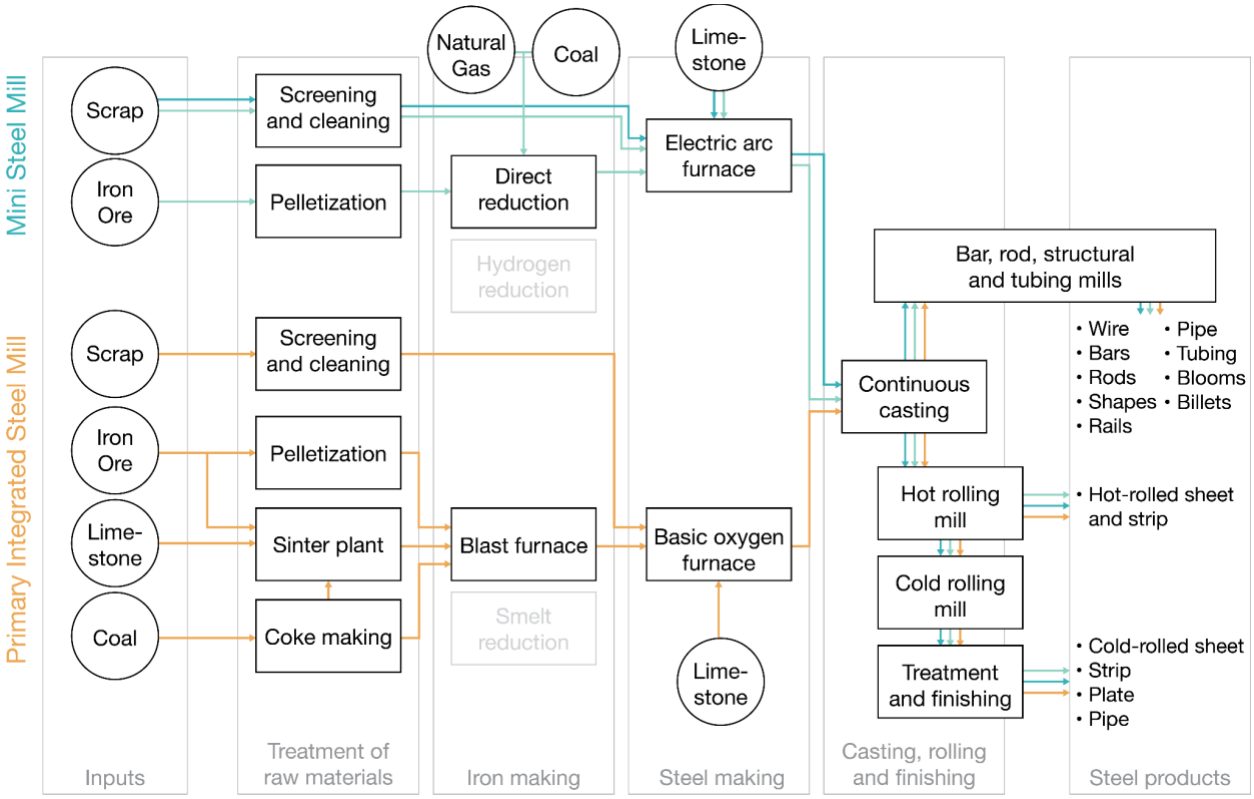

Figure 5.2. Process pathways for the two main methods of iron and steel production, blast furnace + basic oxygen furnace (BF-BOF, typical in integrated steel mills) and the electric arc furnace (typical in mini mills that use scrap ± direct reduced iron (DRI) as an iron source. Adapted from de Beer et al. (2003).[27]

These types of steel facilities currently account for over 70% of global steel production,[28] but since the 1960's[29] a new type of mill, called mini mills, are becoming increasingly common and are now the predominant mill type in the United States.[30] Mini mills (and even more recently, micro mills)[31] use a technology called *electric arc furnaces* to re-melt, refine and alloy scrap steel, or less commonly, DRI. Because they do not require the raw materials (iron sinter and/or pellets and coke) or extremely high heat needed to reduce iron ore in a

blast furnace, these smaller mills are able to produce steel at cost-competitive rates with the significantly larger integrated steel mills. Their growth potential is simply limited by the availability of scrap steel or DRI.[32]

[32] de Beer *et al.* (2003) Emissions from iron and steel production. [24]

[33] Our World in Data (no date) Carbon dioxide emissions factor. [63]

The intensity of CO_2 emissions produced during the steelmaking process is dependent on the steelmaking route used, and thus integrated steel mills, mini mills, and scrap-specific mini mills have very different emissions profiles.[34] To break down the sources of CO_2 emissions associated with each type of steelmaking process, and its potential for capture or mitigation, in the following sections we examine each step of steelmaking systematically. A flow chart outlining each step in steel making, and how those steps vary by process, is provided in Figure 5.2, and a summary of the sources and volume of greenhouse gas emissions from each step is provided in Table 5.2.

Treatment of raw materials

To make new steel, raw iron ore (the oxidized iron material mined from geologic formations) must be reduced to metallic iron,[35] which must then be treated by the addition or removal of carbon and other trace metals to achieve an alloy with the desired properties (i.e. strength, hardness, ductility, or weldability).[36] Luckily, once made, steel is an excellent candidate for recycling. Scrap steel, which is the steel discarded as waste either during manufacture or from products at the end of their useful life, can be repeatedly turned back into new steel, while retaining its original properties.[37]

Every steel manufacturer uses some amount of scrap to produce new steel.[38] In dedicated scrap mini mills, scrap represents 100% of the raw material for steel production. In regions where scrap is scarce, mini mills will supplement scrap with metallic iron converted from ore via the direct reduction (direct reduced iron, or DRI) method.[39] In integrated steel mills, scrap is most commonly combined with pig iron, the material made from iron ore using a blast furnace (Figure 5.3).[40]

[40] IIMA (no date) About Metallics. [43]

The preparation of scrap material for recycling into new steel products is relatively minimal - it involves collection, cleaning, and sorting.[41,42] However, creation of metallic iron (either DRI or pig iron) requires the conversion of iron ore into a form that can be fed into the smelter or furnace. Two conversion processes are used: pelletization (for DRI and pig iron) and sinter plants (for pig iron only).[43] Pelletization occurs in a pellet plant, which can be cited at the ore mine or steel mill, and involves first crushing and grinding iron ore, and then forming 'green balls' of material by aggregating the iron grounds with crushed limestone, clays, and water. The balls are hardened for transport and loading through an *induration process*; they are dried, fired in a kiln at temperatures up to 1350°C, and cooled.[44] Sinter plants prepare iron ore by combusting it at ~1300-1480°C with limestone and coke breeze (used as the fuel) to produce a carbon-rich, porous clinker.[45] Formation of raw iron (pig iron or DRI) is often measured in 'tons of hot metal.'[46] For each ton of hot metal, about 1.5-1.7 tons of pellets or sinter is required.[47,48]

In integrated mills, coke is another raw material that needs to be treated in preparation for iron making. Coking is the process of converting metallurgical coal to the porous, carbon-rich material 'coke.' Metallurgical coal is heated to temperatures up to 1125°C, melting and releasing any volatiles, and then re-solidifying as coke.[49] About 0.3-0.5 tons of metallurgical coal are used for each ton of hot metal produced.[50]

Pelletization, sintering and coking all emit CO_2 - about 0.02-0.05, 0.3-0.4, and 0.03-0.10 tons CO_2 per ton hot metal, respectively.[51,52] The combined impact of these emissions on the carbon intensity of final steel products derived from a given steel production pathway is detailed in Table 5.2.

Iron making

In integrated steel making, iron pellets, sinter, and coke are combined in a *blast furnace* (Figure 5.4) to form hot iron metal, or in its cooled form, pig iron. Coke is used as a fuel - combusting to help the furnace reach the melting temperatures of iron (as much as 2000°C[53]), as a reductant - accepting oxygen from the iron oxides in the ore material to

produce metallic iron and CO_2, and as a charger - increasing the carbon content of the iron, which is critical for processing to steel in the *basic oxygen furnace*.[54] Within the steel making process, blast furnaces represent the largest source of CO_2 emissions, about 70% of emissions in an integrated plant.[55] For each ton of steel produced,[56] about 1.3-1.4 tons of CO_2 are released.[57]

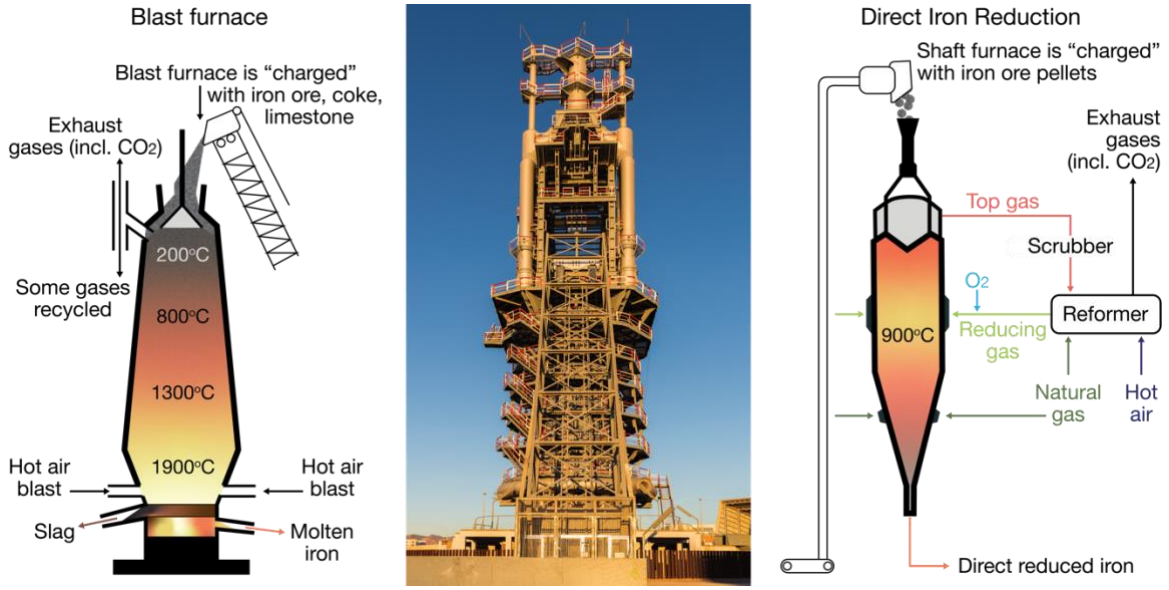

Figure 5.4. a. Schematic of iron production via blast furnace. b. Blast furnace, Port of Sagunto, Spain. Image credit: Wikimedia Commons, Diego Delso, CC BY-SA 4.0. c. Schematic of direct reduced iron production (modeled after the Midrex process, one of several flow processes for DRI). Adapted from International Iron Metallics Association. DRI facilities are of a similar scale to blast furnaces – the shaft furnace is a multi-story scaffolded building, with an attached conveying system for the iron ore pellet charge.

Direct reduced iron is an alternative to pig iron that can be used in *electric arc furnaces*. It has a significant advantage over the blast furnace in terms of emissions because it does not require coke as a fuel or additive. Rather, a natural gas- or coal-derived reducer, called syngas ($CO + H_2$), is used to remove oxygen from the pelletized iron ore. This process takes place in solid state; the ore never actually melts. Thus, required temperatures for the process are much lower, reaching only 900-1000°C. Because iron is not melted, impurities present in the ore are retained in the DRI product. This can mean additional additives will

[55] Fan, Friedmann (2021) Low-carbon production of iron and steel. p. 831. [30]

[56] Some references report emissions in tons of hot metal (what emerges from the iron making process), whereas other references report emissions as a function of tons of steel. de Beer *et al.* (2003) Emissions from iron and steel production (p. 26) reports that hot metal comprises 65-90% of steel output, the balance being from scrap. To maintain continuity, we assume that 0.9 tons of hot metal are used to produce 1 ton of steel, with scrap steel comprising the remaining steel input.

[57] Fan, Friedmann (2021) Low-carbon production of iron and steel. p. 833. [30]

be needed in the steel-making step to extract unwanted impurities or to add under-represented elements, like carbon, that control desired steel properties.[58,59] The combustion of coal or natural gas to produce DRI emits between 0.5 and 1.0 tons of CO_2 per ton steel (Table 5.2).[60]

Two other processes are worth noting briefly here: smelt reduction and hydrogen steel production. Smelt reduction is an alternative mechanism for producing pig iron that employs direct reduction of iron ore fines (omitting the pelletization or sintering step) in the presence of coal.[61] The technology is mature, but has seen very little penetration in the global iron production market, likely because it is more expensive than conventional blast furnace-basic oxygen furnace (BF-BOF) production, but more carbon intensive than scrap-EAF or DRI-EAF processes.[62]

Hydrogen-blended, or hydrogen fueled steel production are clean-energy alternatives to existing steel production, that are still in the early development or demonstration stages of technological readiness. These technologies would adapt existing BF, DRI, and smelting reduction reactors to operate with H_2 as part or all of the reducing agent and fuel source for the ironmaking step of steel production, resulting in reduced or eliminated process emissions of CO_2.[63]

Steel making

Once crude iron has been produced, it is introduced into a furnace to further refine to steel. The purpose of this step is to remove any undesired impurities from the source iron, and to adjust the concentration of carbon and other desirable elements that imbue steel with specific properties optimized for its final intended use.[64] Basic oxygen furnaces (BOFs) are traditionally used in integrated mills, with iron sourced primarily from blast furnaces, with scrap and occasionally DRI to supplement.[65] The furnace is a large and pear-shaped reactor, where pure oxygen is blown into the vessel to react with the liquid iron metal. Carbon, and other impurities, are oxidized by the iron and separated, creating CO_2 gas and a metal-oxide-rich slag.[66] The molten and purified steel are separated and transported to a finishing facility for casting and rolling (Figure 5.2). BOFs are enormous, housed in buildings that can be as much as 80 meters (~260 feet) high. This is to accommodate the gravity feed equipment, oxygen lance and off-gas cooling systems.[67]

In mini steel mills (and some integrated mills), the electric arc furnace (EAF) is used in the steel making step. This process involves using a high-current electric arc to melt steel scrap (± DRI), which is chemically adjusted by varying the melting temperature and "charging" with DRI, pig iron and limestone (for slag formation). Because EAF is less oxidizing than BOF, steels made by this process typically have higher carbon contents than BOF steel, and CO_2 emissions from the EAF are lower - about 0.4 to 0.12 tons of CO_2 is released per ton of steel processed in an EAF, compared to 0.14 to 0.21 tons of CO_2 per ton steel in BOF processes (Table 5.2). An EAF furnace is much smaller than a BOF, with a shell diameter ranging from ~6-9 meters (20-30 feet), and able to process 100-300 tons of steel melt at a time.[68]

Casting, rolling and finishing

Most steel facilities use continuous casting (rather than ingot casting) to cool and prepare steel for shaping into a range of final products.[69] In this process, liquid steel is continuously fed into short, vertical water-cooled copper molds. The outer most shell of the steel 'strand' is solidified, allowing them to be rolled out of the copper molds, as the inside continues to cool and solidify. Once solidified, the steel is cut into billets, blooms or slabs (distinguished by size), which are then shaped into finished products.[70] Such shaping takes place through rolling and finishing operations - hot rolling (done immediately after the slabs have been cast) and cold rolling (done once the slabs are cooler than their recrystallization

[68] Britannica.com (no date) Primary Steelmaking. [7]

[70] de Beer *et al*. (2003) Emissions from iron and steel production. p. 31. [24]

temperature) are used to reduce slab thickness and ensure thickness uniformity,[71] and further cutting to the preferred shape and size of the final steel product. An analysis performed for the Steel Manufacturers Association[72] estimated that high-temperature heat emissions related to this portion of the steel making process was between 0.07 and 0.22 tons CO_2 per ton steel (Table 5.2), with lower values being associated with younger, more efficient facilities.

5.1.1.3 Carbon Capture in the Steel Industry

Pilot studies and research on the application of carbon capture as a decarbonization solution in the steel industry has been most closely applied to integrated mills, where blast furnaces produce ~80% of the mill's emissions (Table 5.2).[73] Retrofitted carbon capture devices on the blast furnace could capture as much as 65% of CO_2 emissions, and an additional ~10-20% could be conserved by adding oxygen and combusting the exhaust stream (composed of CO + CO_2) to provide heat energy to the furnace or other plant facilities.[74,75] It is possible to apply commercially available carbon capture devices to other components of the integrated mill system (coke production, sinter production and the BOF), but as these produce a smaller fraction of total emissions, capturing CO_2 from these sources is likely not cost-effective for a globally-traded industry that must operate on tight profit margins.[76] For example, when blast furnace gas is combusted in the presence of air, the concentration of CO_2 in the exhaust is about 27 vol%. In contrast, the composition of off-gas from a basic oxygen furnace includes only about 16 vol% CO_2.[77] Thus, the basic oxygen furnace produces less CO_2 to capture, and does so at a higher price per ton CO_2 captured.

DRI can also be designed or retrofitted with carbon capture, with the possibility of capturing as much as 80% of CO_2 emissions, although the lower concentrations of carbon in the flue gas make this process more challenging and expensive than carbon capture for BF-BOF.[78] The only commercially operating steel mill with carbon capture in the world - in Abu Dhabi, U.A.E. - captures carbon from the DRI process (see Section 5.1.2.2). An alternative decarbonization approach for DRI is using green hydrogen (produced via electrolysis or gasification of biomass, see Sections 6 and 4, respectively) as a carbon-free replacement fuel, but adapting the EAF technology for this fuel is far from technologically ready, and could be prohibitively expensive until the cost of producing green hydrogen decreases.[79,80]

[80] [illegible]

EAF, like the blast furnace, emits an exhaust stream of CO + CO_2, which could be captured or re-used for its waste heat. However, even less CO_2 is emitted per ton of steel in this process than the BOF or raw material treatments (Table 5.2), making it unlikely that capture would ever be cost effective. In fact, for most EAFs, the emissions produced by creating the grid-sourced electricity needed to operate the facility are more than double the direct emissions from the furnace,[81] and thus supplying an EAF mini mill with off-grid, carbon-free electricity would be the most efficient decarbonization approach for these kinds of facilities. While such a facility would produce low-carbon steel, it would not be considered a carbon management industry, as no appreciable carbon capture could take place.

Some researchers have proposed powering the EAF with natural gas via oxy-fuel combustion, rather than grid or renewable-sourced electricity.[82] Oxy-fuel combustion combusts natural gas (or biomass-derived syngas, or renewable natural gas) in the presence of a pure oxygen stream, creating outputs of a pure stream of CO_2, water and electricity (see Section 4).[83] Thus, a mill could produce low-carbon steel and CO_2 for capture. If a scrap mini mill were powered entirely by natural gas with oxy-fuel combustion, approximately 0.06-0.25 (~0.15 on average) tons of CO_2 would be produced per ton of steel produced. Using oxy-fuel combustion from natural gas to power a DRI-EAF mini mill would produce about 0.65-1.08 tons of CO_2 per ton of steel, and for a BF-BOF mill it would produce about 0.89-1.38 tons of CO_2 per ton of steel (Table 5.2).[84]

5.1.2 State of Development

The technological readiness of carbon capture in the steel industry is a two-part problem: first, what is the state of development of point source carbon capture technology? Second, to what extent is such technology (or other decarbonization technologies) ready to be implemented within the steel sector? Here, we will give a brief summary of the state of development of point source carbon capture, with a focus on the most developed approach: chemical solvents. Then we will highlight global examples of decarbonization efforts in the steel industry, with a focus on carbon capture and green hydrogen substitution.

5.1.2.1 Point Source Carbon Capture

Chemical and physical solvents have been in commercial use for decades, and technological development in this space has been focused on reducing the costs of such solvents so that they can be used in industries that produce more diffuse gas streams, or where profit margins are tight.[85] Examples of cost-saving innovations include creation of water-lean solvents, which require a much lower energy input to regenerate the solvent (release the CO_2), simply because less water needs to be boiled. Ion Clean Energy is a

[85] Kearns *et al*. (2021) CCS readiness and costs. p. 12. [45]

commercial company that produces water-lean liquid solvent capture plants, and more recently, Pacific Northwest National Lab developed a technique that uses an oil-based instead of water based solvent, reducing water requirements by as much as 97%.[86,87] Another next-generation solvent technology comes from the company Saipem. They have identified a biologically-derived enzyme that speeds a naturally slow carbonate salt solvent. The increased capture efficiency allows more CO_2 to be captured with a smaller stripper (and thus smaller footprint and lower capital costs), and the carbonate salt technology has the added benefits of being able to regenerate with hot water, rather than steam (so waste heat can be used as an energy source), and producing no hazardous waste byproducts.[88,89]

Another company, Carbon Clean, is also driving cost savings by modularizing and reducing the physical footprint of their carbon capture technology. Their carbon capture system is the size of a shipping container, and can capture up to 35,000 metric tons of CO_2 annually. That is about one tenth the size of conventional carbon capture facilities.[90] Carbon Clean is developing a variety of projects in California, and globally. It is working with Cemex in Victorville, CA to capture carbon at a cement plant,[91] and with Chevron to create a pilot facility in Kern County that would capture CO_2 from a gas turbine at the Kern River Eastridge cogeneration plant.[92,93] They have also launched a demonstration facility in India, capturing 5 metric tons of CO_2 per day from the blast furnace of Tata Steel's Jamshedpur plant.[94]

5.1.2.2 Example Projects in the Steel Industry

In the steel industry, scrap-based mini mills powered by carbon-free energy are the optimal solution for decarbonizing the sector. However, although ~85% of steel waste is recycled as scrap, it is not enough to meet the global demand for steel.[95] In terms of carbon capture as a decarbonization solution for ore-sourced steel making, DRI is the most technologically advanced. Carbon capture applied to smelt reduction or blast furnace process gas is still in the development to demonstration stages.[96] Replacing hydrocarbons (coke, coal and natural gas) with hydrogen as the reduction agent and/or fuel, is also still in development stages.[97] Below is a sample of key leaders in each of these innovations.

Al Reyadah CCUS Project, Abu Dhabi, U.A. Emirates

The first (and as of this report's publication, only) fully commercial carbon capture and storage facility for the iron and steel industry is at a DRI plant in Abu Dhabi, where an existing facility was retrofitted with traditional liquid solvent capture technology (using monoethanolamine, or MEA, which is the industry leading solvent). The project was launched in 2016, and captures 800,000 metric tons of CO_2 annually, for enhanced oil recovery use (EOR) in nearby onshore oil fields. $15 billion US of seed funding was supplied from the government of Abu Dhabi to launch the project.[98]

CO2 Ultimate Reduction in the Steelmaking Process (COURSE50), Japan

Since 2008, a consortium of Japan's steel manufacturers has been working on experimental technologies to reduce emissions in BF-BOF steel plants through hydrogen reduction of iron in the blast furnace and capture of blast furnace off-gas. The project was commissioned and financed by the New Energy and Industrial Technology Development Organization.[99] So far, the project has been able to reduce blast furnace emissions by ~10% through supplementing coke with hydrogen. Continuing work focuses on development of novel chemical absorbents and physical adsorption technologies for BF carbon capture.[100]

STEPWISE Project, Luleå, Sweden

Funded through the European Union's Horizon 2020 Low Carbon Energy programme, the STEPWISE Project aims to create a demonstration scale facility of sorption-enhanced water-gas shift (SEWGS) carbon capture for blast furnace gas. The pilot plant is a retrofit of the SSAB steel plant in Luleå, Sweden, and is able to capture 14 metric tons of CO_2 per day. The aim of the technology is to improve the efficiency of conversion of CO in the blast furnace off-gas to CO_2, which is currently a highly energy-intensive process. Such improvement has the potential to reduce BF emissions by 85%, reduce the energy requirement of capture by 60%, and the cost by 25%. While the pilot plant is operational, the extent to which these goals are achieved is still being investigated.[101,102]

HYBRIT Project, Luleå, Sweden

Launched by three private companies in 2016 (SSAB, LKAB and Vattenfall), the HYBRIT initiative aims to develop a completely fossil-free value chain for steel production, using fossil-free pelletization, electricity and hydrogen. A pilot facility for producing fossil-free sponge iron (the output of DRI) was commissioned in 2020, and a pilot facility for hydrogen storage in a rock cavern facility launched in September 2022.[103] In August 2021, SSAB

produced the world's first fossil-free steel using HYBRIT technology at its pilot facility - in which DRI is produced with 100% hydrogen as the fuel and reducing agent.[104]

Boston Metal, United States

Boston Metal, a steel startup company in the United States, is developing an alternative technique for direct reduction of iron that uses *electricity* as the reducing agent, rather than hydrocarbons or hydrogen. Called Molten Oxide Electrolysis (MOE), the technology works by heating iron in a cell to 1600°C, in the presence of an electrolyte solution (i.e. water containing dissolved salts). The iron ore becomes molten, and an inert anode placed in the electrolyte solution is electrified, driving an electrical current through the molten iron that splits the bonds between iron and oxygen in the ore:

$$Fe_2O_3 + e^- \rightarrow Fe + O_2 \qquad (R5.1)$$

The process is anticipated to be cost competitive with traditional BF-BOF steel production, but is still being validated in the industrial environment. Demonstration facilities are planned for 2024, with the aim of commercial operation by 2026.[105]

Rocky Mountain Steel, Colorado

Rocky Mountain Steel, based in Pueblo, Colorado was the first integrated steel mill built in the U.S. west of the Mississippi River, having been in operation since 1882.[106] Today, it no longer operates as an integrated mill, but rather a scrap steel mill - recycling scrap into rails for train tracks, pipes and re-bar.[107] In 2022, the company broke ground on developing the first steel mill to run almost entirely on solar power. Construction of the solar project that will power the mill is ongoing at the time of writing this report, but will use 750,000 solar panels, located on ~1,800 acres, to provide more than 90% of the mill's power needs.[108]

Mojave Micro Mill, Kern County, California

In May 2022, the Pacific Steel Group announced plans to develop a state-of-the-art 'green steel' micro mill in the Mojave Desert of Kern County. The mill would be a 100% scrap-EAF mill, modeled after a similar mill that is in development in Mesa, Arizona, that has an expected opening date in 2023. The Mojave facility would be powered at least partially by local renewable energy (solar), and would produce up to 380,000 tons of steel annually.[109] It would use MIDA-Micromill technology from the company Danieli, which also produced the Mesa, Arizona facility, and a similar plant in Durant, Oklahoma.[110] In terms of development status for the Mojave Micro Mill, the Pacific Steel Group has submitted a

development proposal for the project, and the project is currently undergoing the public environmental review process pursuant to the California Environmental Quality Act.[111]

5.1.3 Operational needs

This section provides a synopsis of the land use, energy, feedstock, waste disposal and other operational needs of the representative technologies for the steel industry that employs carbon management and/or clean energy technologies. Information was aggregated from literature review and interviews with industry experts.

Integrated steel mills that employ primarily BF-BOF steel making technology are quite distinct from mini mills in terms of their footprints, operational needs, and steel output. An integrated steel mill typically produces 3 million tons or more of steel annually, whereas mini mill production capacity is about 1 million tons per year.[112] Micro mills (and even nano mills), like the Mojave Micro Mill that is currently in development (see Section 5.1.2.2), produce even less - on the order of 200,000-500,000 tons of steel per year.[113] Additionally, integrated mills are dependent on primary ores (iron ore and metallurgical coal for coke), and so have traditionally been located close to these natural resources and/or along major waterways where transport of raw materials is possible.[114] Although located close to major rail and road transportation routes, Kern County is distantly located from any significant iron or coal natural resources, and is unlikely to be suitable for a large-scale integrated steel mill. Thus, for the purposes of this study, we will focus on the requirements and impacts of mini- and micro mills that use scrap as a primary feedstock, with DRI as a potential supplementary feedstock, if future regional demand outpaces the availability of scrap metal.

Considering that this industry is being evaluated in the context of its role as a carbon management industry, it is also worth noting the needs and impacts that such a facility will have in terms of its CO_2 output as well as its steel output. To this end, we considered three mini mill scenarios in the impact analyses that comprise the remainder of this report section. The scenarios are based on the direct and indirect (energy-sourced) CO_2 emissions profiles described in Table 5.2, and are as follows:

1. A scrap-based mini mill powered by solar energy, in which **0 tons of CO_2 can be captured per ton steel produced** (direct emissions are not easily captured, and the solar energy source is emission-free).
2. A scrap based mini mill that utilizes oxy-fuel combustion of natural gas, producing an average of **~0.15 tons CO_2 that can be captured per ton of steel** (full range is 0.06-0.25 tons CO_2 per ton steel).

[113] Millennium Steel (May 25, 2017) Mini mills, micro mills, nano mills. [58]

[114] Anderton (August 6, 2015) Micro steel mills are competitive. [3]

3. A mini mill that utilizes DRI with point source capture for 100% of its iron source and oxyfuel combustion of natural gas as its energy source. Point source capture can capture up to 80% of DRI emissions,[115] or ~0.42-0.84 tons CO_2 per ton steel produced. Combined with the CO_2 produced from oxy-fuel combustion (0.65-1.08 tons CO_2 per ton steel), this method would produce, on average, **~1.3 tons CO_2 per ton steel produced** (full range is 1.07-1.50 tons CO_2 per ton steel).

A steel mill that utilized DRI and oxy-fuel combustion (the most emissions-intensive scenario) would need to produce about 770,000 tons of steel annually to emit 1 million tons of CO_2. The same size facility utilizing only scrap and solar energy, or scrap and oxy-fuel combustion, would emit 0 tons CO_2 and ~115,000 tons CO_2, respectively. For the purposes of understanding the impacts of a steel facility in Kern County, data from existing steel mills and published estimates are normalized both to a 1 million ton (Mton) steel production capacity (for consideration of impact per ton steel), and to a 770,000 ton (770 kton) steel production capacity (for consideration of impact per million tons CO_2, noting that such a value is a *maximum* CO_2 output estimate).

5.1.3.1 Land use requirement

There are myriad existing examples of mini steel mills that can be utilized to approximate the land use requirements for this industry. As of 2022, 71% of the domestic U.S. steel supply was produced in 101 mini mills across the country.[116] Table 5.3 provides a representative sampling of U.S. mini and micro mills, denoting their production capacity (in annual steel output) and land footprint. The footprint to steel output ratio for these facilities is diverse, suggesting flexibility in land use needs, depending on the cost and availability of land. The facilities investigated have annual steel outputs ranging from 350,000 tons to 1.2 million tons. For comparative purposes, the land use to output ratio was normalized, producing a range of 140 to 1,071 acres used per million tons (Mton) of steel production, with an average footprint of 663 acres/Mtons. Similarly, to a 770,000 ton steel mill, which could produce *up to* 1 million tons of CO_2 (see Section 5.1.3), would use 129 to 825 acres per million tons of CO_2 produced, with an average footprint of 510 acres per 770kton steel mill.

a. These six mills will be used for comparative purposes throughout the multi-lens analysis of the steel industry. For this, and all future references to these sites, references are detailed in Table 5.7.

5.1.3.2 Energy Requirements

As detailed in Table 5.2, the primary energy needs for a scrap-based steel mill come from the electric arc furnace (EAF), which requires about 1.3-3.3 GJ (=0.4-0.9 MWh) of energy per ton of steel produced.[117,118] Casting, rolling and finishing the hot steel that is made in the EAF into usable products requires another ~0.02-2.2 GJ (0.01-0.6 MWh)/ton steel.[119] If DRI is made on site from pelletized iron ore feedstock, it would contribute an additional 10.9-16.1 GJ (3.0-4.5 MWh) of energy needs,[120] increasing the facility's energy requirements by an order of magnitude.[121] It is important to note that DRI requires temperatures of 900-1000°C to reduce the iron ore in the presence of a reduction agent like natural gas, syngas or hydrogen. Such high temperatures cannot be directly supplied by solar-derived electricity without also utilizing a heat battery (see our section on energy storage). Capturing carbon from DRI requires additional energy input: point source capture using advanced chemical solvent technologies demands about 2.5-3 GJ (0.7-0.8 MWh) of energy per ton of CO_2 captured, which translates to an additional energy demand of about 1.1-1.3 GJ (0.3-0.35 MWh) per ton steel produced via DRI-EAF.[122] Finally, Pelletization requires about 1.9 GJ (0.5 MWh) of energy per ton of steel, and while this step can be done at the

steel mill site, it is more commonly done at the mine where iron is sourced,[123,124] so is not included in the energy analysis here.

Estimates of the scale of solar installation required to supply 100% of the heat and electrical energy needs of a steel mill are calculated following the equation: [125]

MWh (energy supplied) = MW (installed capacity of facility) x (8760 hours in a year) x Capacity factor (E5.1)

where the capacity factor for solar panels in Kern County is 32.8%.[126] Solar acreage is calculated on the basis of ~7 acres per MW installed solar capacity.[127,128] With these values, a 770,000 ton steel mini mill utilizing only scrap and solar energy would need about 690-2,900 acres of solar fields to supply the electricity demand. A 770,000 ton DRI mini mill using solar energy and only capturing CO_2 from process emissions of iron reduction would need 6,400-11,255 acres of solar fields (with heat battery storage) to operate. However, in this scenario, only 320,000 tons of CO_2 could be captured annually. A mini mill using oxy-fuel combustion with carbon capture as the sole power supply would require no solar input.

In addition to solar energy, two other potential power supplies for mini mills are explored here: oxy-fuel combustion of natural gas (or alternatives like syngas or renewable natural gas) with carbon capture, and combustion of hydrogen gas.

Oxy-fuel Combustion

Oxy-fuel combustion is a process in which hydrocarbon-based fuels are combusted in a specialized chamber in the presence of a pure stream of oxygen (± an inert carrying agent, like purified CO_2). Normally, we combust fuels in the presence of air, which produces a series of partial reactions that convert the hydrocarbons to CO_2, CO, and a variety of unreacted residues that can be grouped as "volatile organic compounds" or VOCs. These products instantly mix with the surrounding air to produce a dilute stream of CO_2, making it difficult – and expensive – to separate the CO_2. In oxy-fuel combustion, the only inputs in the reaction are hydrocarbons and oxygen, and the reaction can be controlled so that the only products are H_2O (water) and CO_2. Because the reaction is taking place in a vacuum, rather than in the presence of air, the CO_2 product does not become diluted, and thus can easily (and cheaply) be separated for storage. Oxy-fuel combustion technology is generally at the large prototype or pre-demonstration stage of development.[129]

Two examples of companies developing oxy-fuel combustion technologies are Clean Energy Systems and NET Power. Clean Energy Systems designs oxy-fuel turbines (the

[129] I□□ □□□□

reaction chambers for oxy-fuel combustion) using technology adapted from rocket engine design, to optimize the combustion reaction.[130] They have a pilot facility in Kern County and are in the process of converting several biomass power plants into Biomass Carbon Removal and Storage (BiCRS) facilities in California (see Section 4.1.2.4). NET Power has developed a form of oxy-fuel combustion called the Allam-Fetvedt power cycle, which uses the pure CO_2 produced from the combustion process as a streaming agent that carries heat energy and new pure CO_2 and H_2O streams, optimizing the efficiency of the process.[131,132]

Hydrogen Fuel

Green hydrogen, or hydrogen that is derived from non-CO_2 emitting processes, like electrolysis (see Section 6) or biomass gasification with carbon capture (see Section 4), has enormous potential in helping to decarbonize iron and steel production, because it can work both as a fuel source, powering high-temperature operation of the DRI and EAF, and as an iron reducing agent, further reducing the necessity of coke or natural gas in the iron-refining process.[133] One company, SSAB in Sweden, has successfully fossil-free steel, using green hydrogen in the production process. Their work is currently at the demonstration stage (see Section 5.1.2.2). If hydrogen is used to power steel production and act as a reducing agent, the steel made will be carbon emissions free (a clean technology), but would not be a source of CO_2 for carbon capture.

5.1.3.2 Other Operational Requirements

Waste disposal requirements

Steel production from EAFs produce a variety of byproducts, including metal dusts, slag, wastewater, and gaseous emissions,[134] each of which needs to be handled appropriately on- or offsite, following state and federal regulations. Slag is relatively inert, and can be repurposed in other industrial applications, like construction.[135] Dust creation is a bigger issue, as on average, EAFs produce about 10 kilograms of dust per metric ton of steel, which can have a variety of heavy metals in it: zinc, lead, cadmium, chromium, and nickel. However, there are a variety of available mitigation measures that can minimize the hazard of dust creation, including: locating operational facilities inside enclosed buildings, selecting a feed quality (steel scrap or iron pellets) that have low concentrations of impurities or heavy metals, use fabric filters and other dry dust collection methods[136].

[135] World Bank Group (1998) Mini Steel Mills. p. 342. [89]

[136] World Bank Group (1998) Mini Steel Mills. p. 342. [89]

In terms of wastewater, mini mills can produce up to 80 cubic meters (~21,000 gallons) of wastewater per metric ton of steel produced.[137] Like the dust, wastewater can have high concentrations of metals, totaling up to 3,000 milligrams per liter of water. That is about equivalent to 0.3% of the water being dissolved or suspended solids. These solids can be removed from settling, creating sludges that then need to be properly disposed of following environmental and safety guidelines. With proper treatment, the wastewater can be recycled to minimize the water demands of steel production.[138] Additionally, many of the metals that are concentrated in steel mill wastewater are of interest in development of clean energy technologies. Recovering critical metals from fluids, like waste waters of mining and industrial processes, is beginning to be explored,[139] and could warrant further investigation, both in its potential for an alternative revenue stream, and as a solution for waste mitigation.

The variety of methods described here (and for gas emissions, in Section 5.4.2) to manage and minimize waste from steel mills is not meant to be comprehensive, but is intended to illustrate that solutions already exist to address secondary products of steel production. Like any industrial facility hosted within a carbon management park, environmental and safety impacts of a steel mill would be assessed through a public process, and if approved, all facilities would be reviewed and mitigated in accordance with the California Environmental Quality Act (CEQA).

Warehousing requirements

Warehousing is a necessity at steel mills, both to hold a reserve of iron feedstock (whether steel scrap or iron pellets), and steel product. Although no explicit information could be found on storage requirements for feedstock or product, aerial and satellite imagery of existing steel mills suggests that whether storage is in enclosed warehouses or open air depends on regional preferences and regulation.

Transportation and pipeline requirements

Steel scrap and/or iron pellets will need to be delivered to a mini mill facility, and products will likely be sold nationally or internationally. Therefore, access to rail and shipping lanes are high priorities for steel industries. The availability of rail in Kern County, and its proximity to ports along the West Coast both make it an attractive site for steel production.

5.2 Societal Impacts

5.2.1 Job creation potential

5.2.1.1 Number and types of jobs

On average, it takes 1.5 man-hours to produce a ton of steel, with some mini mills able to produce a ton of steel with only 0.5 man-hours, due to increased efficiency and automation.[140] Given this range, a 770,000 ton steel mill could produce about 200-600 full-time equivalent jobs. This approximated range is consistent with job creation estimates reported from recently built U.S. micro mills, which, scaled to 770,000 ton steel production capacity, would produce on average ~400 permanent jobs. Details of these job estimates are given in Table 5.4.

Of the example steel mills examined in Table 5.4, two provide estimates of job growth in relation to facility construction. The 600,000 ton High Bar LLC steel mill in Arkansas, and the 430 thousand ton Nucor Steel mill being developed in North Carolina report generating 600 and 500 construction jobs, respectively. Scaled to a 770,000 ton facility, a steel mill could provide up to 900 short term jobs in construction. Additionally, such a facility would produce thousands of indirect jobs to support facility needs, such as solar and battery installation jobs.

According to a 2022 Congressional Research report,[141] the average annual wage of steel workers in 2020 was $88,325 USD, higher than both the national average in manufacturing ($73,397 USD), and the median national household income across all sectors ($71,186 USD)[142] for that year. Steel product manufacturing (casting, rolling, and finishing steel into final products) accounted for about 40% of the job market in 2020, and had an average annual wage of $68,585 USD.[143] Reported annual salary for the example steel micro mill manufacturing jobs support this average, with salaries ranging from $60,000-$140,000 plus benefits, with higher salaries associated with technical positions (see Appendix D for complete reference list).

5.2.2.2 Training pipelines

Most jobs in the iron and steel industry require a high school diploma or equivalent and may involve an apprenticeship training program. A significant amount of training is done on-the-job.[144] This is likely particularly true for steel product manufacturing. However, with sector wide goals of decarbonization and digital transformation, the steel industry is

increasingly looking for more trained or specialized workers.[145] The World Steel Association has a published fact sheet emphasizing the need for skilled workers in metallurgy, materials science, physics, chemistry, engineering, environment, mathematics, information technology and computer science, languages, business, and accountancy.[146]

5.2.2 Quality of Life

5.2.2.1 Location

Steel mills do emit fine materials and gasses that can have harmful health effects, like particulate matter, lead, nitrous oxides (NO_x), and sulfur oxides (SO_x), although there are techniques mills can use to trap matter and minimize emissions[147] (see Section 5.3.2). Any mill developed within the carbon management park would be required to submit an environmental impact report and undergo pre-development review and operational monitoring to ensure emissions impacts remain within federal and state determined safety standards.

[145] Maldonado-Mariscal *et al.* (2023) Skills intelligence in the steel sector. [56]
[146] World Steel Association (2021) Working in the steel industry. [94]
[147] World Bank Group (1998) Mini Steel Mills. [89]

Steel mill operations are also loud[148,149] – with most operational equipment emitting noise at levels that require hearing protection for workers.[150] It is possible to design steel mills in ways that diffuse noise levels to minimize noise pollution in the vicinity. One steel mill in New Zealand integrated several noise-minimizing solutions into their facility, and measured noise levels about 0.75 miles from the facility of ~45 decibels, a typical sound level for an urban neighborhood.[151]

5.2.2.2 Multi-use potential

Steel mills are among the most land intensive of the carbon management industries investigated in this report (Appendix D, Figure D.1), and as that land use involves warehousing of large volumes of feedstocks, enclosed buildings housing large manufacturing equipment, and warehousing (and treatment) of products and byproducts, it is unlikely that the land allocated to a steel mill would be well suited for multi-use potential. That being said, there is a plethora of opportunity in co-locating such an industry with other carbon management and clean energy technologies, explored in detail in Section 5.4.3.3.

5.3 Environmental Impacts

5.3.1 Water requirements

5.3.1.1 Minimum volume requirements

Steel mills require water to operate, primarily for cooling, but secondarily for equipment descaling, dust scrubbing and other processes. On average, steel mills that use electric arc furnaces require a water intake of 7,400 gallons of water per metric ton of steel produced, but discharge 7,000 gallons of water (about 94% of intake water), for a net water requirement of 400 gallons per metric ton of steel.[152] It is also notable that the range in water use from plant to plant varies widely, suggesting that there are a variety of process configurations that can minimize water use and water waste. The most comprehensive publicly available assessment of water use in the steel industry was a report published by the World Steel Association (WSA) in 2011.[153] They examined water usage in 8 EAF steel plants (and 17 integrated plants, not discussed here), whose water intake ranged from 290 gallons of water per metric ton of steel produced, to over 18,000 gallons of water per metric

[152] World Steel Association (2020) Water management in the steel industry - Fact Sheet. [93]
[153] World Steel Association (2011) Water management in the steel industry - Full Report. [92]

ton of steel.[154] The strongest control on water use intensity was whether water used for cooling was circulated or merely used one time ("once-through cooling"). In regions where water resources are abundant, once-through cooling can have minimal environmental impact, while also being cost effective, but given that only 25% of EAF plants examined by the WSA report used once-through cooling, water-circulation cooling appears to be a well-established technique in the industry.[155]

Discharged water from steel mills can be treated and reused, or returned to the source.[156] The extent of treatment required will depend on the original water composition and its use in the steelmaking process. Water that is used for cooling never actually comes into contact with material or equipment, so does not require the same level of treatment as that used for descaling and dust scrubbing. Water used for these latter purposes could have a significant amount of dissolved solids, including metals and oil and gas residues,[157] that would need to be treated before water could be reused (see Section 8 for a summary of water treatment techniques and applications). If water is recirculated within the steel mill to minimize waste, it needs to be cooled and desalinated between uses. This could be energy and time intensive, but in the context of a carbon management business park, it is also a synergistic opportunity. If a thermal network were integrated into a carbon management park, waste heat in the form of hot process water from the steel mill could potentially supply heat energy to other co-located industries, and the cooled water could be circulated back to the steel mill for reuse.

5.3.1.2 Minimum quality requirements

Water for steel manufacturing can come from a variety of sources, with EAF mills examined by the World Steel Association using freshwater (potable water), groundwater, brackish water, seawater, and other non-potable water as sources.[158] Gray (reclaimed) water, of which there is an abundance in California (see Section 8), could be used similarly, minimizing the impact on local fresh water sources. Depending on the water source used, and its role in the steel making process, a variety of pre-treatment processes may be necessary, all of which are well established techniques. These include biological control or disinfection for reclaimed water, demineralization, desalination, distillation, filtration, reverse osmosis, and softening.[159] For further information, interested readers should refer to Section 8 of this report, as well as the WSA report on water use in the steel industry.

5.3.2 Other potential impacts

5.3.2.1 Criteria pollutants from operation

Two sources of atmospheric pollutants should be considered in the context of steel as a carbon management industry. First, there is the production of steel itself, and then there are emissions related to power generation for steel production, which - if it is in the form of oxy-fuel combustion with carbon capture, can have associated non-CO_2 emissions.

In the electric arc furnace (the steel making phase of production), scrap metal is "charged", or combined with DRI, pig iron (from integrated mills) and/or limestone, to add or remove impurities in the steel that control its properties (like strength and ductility). Elements that are separated out of the steel form a metal-oxide rich slag and small amounts of CO2 (not enough to be economically captured) and other gas or fine particulate emissions.[160] The slag is a waste byproduct that can typically be used in other industrial processes (see Section 5.1.3.2), and therefore poses little environmental risk.

Particulate emissions emitted from the EAF (and to a lesser degree from other steps in the steel making process) include particulate matter composed of iron and iron oxides, and depending on the composition of the source iron could also include heavy metals such as zinc, chromium, nickel, lead, and cadmium. Gaseous pollutants such as NO_x, CO, SO_2, and volatile organic compounds (VOCs) can also be emitted.[161,162] These emissions can be captured and scrubbed from facility exhaust streams, to keep facility emissions under regulated limits. Techniques for trapping emissions include locating the EAF in an enclosed building, using hoods to evacuate dust into dust arrestment equipment, using scrubbers to attract gasses, and using equipment like cyclones, baghouses, and electrostatic precipitators to further attract and trap dust. However, regular maintenance and monitoring of facilities is critical to prevent fugitive emissions.[163]

If natural gas (or synthetic natural gas or RNG) is used with oxy-fuel combustion and carbon capture and storage to power some or all of the steel-making processes, emissions associated with such combustion must also be considered. Thus far, this is difficult. There are few detailed studies of the emissions resulting from oxy-fuel combustion, and those emissions seem to be dependent on the fuel used (coal vs. natural gas vs. biomass), the oxygen/fuel ratio, and the combustion technique.[164] However, it appears that overall, gaseous emissions and particulate matter emissions from oxyfuel combustion are

[160] World Bank Group (1998) Mini Steel Mills. p. 342. [89]

[161] Environmental Protection Agency (EPA) (2009) Emission factor documentation. p. 5. [26]

[163] World Bank Group (1998) Mini Steel Mills. p. 342. [89]

[164] Senior *et al.* (2013) Emissions from oxyfuel combustion. [71]

considerably lower than emissions related to traditional air-fired combustion.[165,166] Integrating flue gas filtering processes into the oxy-fuel combustion process can also eliminate pollutants from any flue gas stream, as the Allam-Fedtvedt power cycle does for NO_x and SO_x.[167]

Ultimately, any project sited in Kern County, California, including those developed in a carbon management park like that examined here, would be considered through a public process, where the environmental impacts specific to the technologies and fuels being used in any given facility will be reviewed and mitigated in accordance with the California Environmental Quality Act (CEQA).

5.4 Economic Impacts

5.4.1 Business Model

Unlike other carbon management industries investigated in this report (DAC and BiCRS, in Sections 3 and 4, respectively), the capture and sequestration of CO_2 is not a primary objective or product of CO_2-emitting industries. Thus, the only motivations that a CO_2-emitting industry will have to capture and store carbon are financial (if the CO_2 can be sold as a product or for a financial credit), or through pressure, whether regulatory or from consumers. A 2021 feasibility analysis by the Global CCS Institute examined the factors common to commercially operating point source capture facilities, that made them economically viable.[168] At the time, there were 28 operational facilities in the world (as of the writing of this report there are 35, according to the GCCSI facilities database, see Appendix A). Every single one of those operations had at least one of the following characteristics, and all but 1 had at least two:

1. They were capturing CO_2 from the lowest-cost point sources: natural gas processing, fertilizer production, bioethanol production, chemical manufacturing (23 facilities)
2. They sold their CO_2 to enhanced oil recovery (EOR) operations to offset costs (23 facilities).
3. Their country of operation provided grant support, tax credits, or had a government provision for carbon capture (17 facilities.)
4. Their country of operation was Norway, the only nation that implements a carbon tax (2 facilities).

[168] Rassool *et al.* (2021) CCS in the circular carbon economy. p. 7. [67]

Since the publication of GCCSI's report, the outlook for point source carbon capture has become more promising. Recent innovations in "water-lean" capture amine technology is helping the cost of capture decrease, even for industries with more dilute exhaust emissions.[169,170] Additionally, the 2022 Inflation Reduction Act raised the amount of the 45Q tax benefit for CO_2 capture and storage processes other than direct air capture (DAC) to $85 per ton stored,[171] meaning that even at the current state of technological development, every CO_2-emitting industry has the potential to entirely offset the cost of capture carbon with a tax credit (Table 5.1). This is particularly important for industries that are traded on international markets, like steel, in which the need to remain cost competitive allows for very low profit margins and little flexibility for added cost.[172] Additional policies that could further encourage the adoption of carbon capture in the steel industry, specifically, include those that encourage the purchase of low-carbon or clean energy products (e.g. Buy Clean incentives), thereby increasing their market demand, or those that would create a regulatory framework for allowable carbon-intensity of domestically manufactured or purchased products.[173]

5.4.2 Business Costs

For point source carbon capture facilities, capture equipment is most commonly retrofitted onto existing infrastructure, adding to the baseline cost of producing the primary industry output. As mentioned in Section 5.1, the concentration of CO_2 within the gas stream emitted from an industrial facility is proportionally related to the cost of capture. This is illustrated in occurs for two reasons:

1. More dilute streams require larger process equipment. This is because lower concentrations of CO_2 mean a higher total gas volume processed per ton of CO_2. Thus, the total size of equipment also needs to be larger to process the greater volume of gas. Additionally, higher CO_2 concentrations are more reactive - the CO_2 will transfer more rapidly from the source gas to the solvent than at low CO_2 partial pressures - thus speeding the time of the reaction. Faster reactions mean less necessary contact time between source gas and solvent, and thus smaller capture equipment, reducing capital costs.[174]
2. More energy is required to capture more dilute CO_2. At high partial pressures, CO_2 can be captured using "physical" solvents - those in which the CO2 is bound to the surface of the a substance via electro-magnetic attraction, forming a weak bond (called van der Waals bonds) that is easily broken by modestly decreasing the

[170] Clifford (January 24, 2023) New technique from U.S. national lab promises to strip carbon dioxide. [18]

[171] Carbon Capture Coalition (2022) IRA. p. 2. [10]

[172] I□□ □□□□

pressure or increasing the temperature of the system. In contrast, low-concentration CO_2 generally requires selective "chemical" solvents to be use - those which trap CO_2 by forming stronger chemical bonds, that can only be broken by increasing temperatures significantly. The higher temperatures needed for solvent regeneration directly translate to higher energy needs, and therefore higher cost.[175]

An additional relevant factor to the cost of carbon capture is the scale of deployment. An impact analysis by the Global Carbon Capture and Storage Institute determined that economies of scale could drive cost decreases considerably when moving from pilot scale (thousands of metric tons of capture annually) to commercial scale (hundreds of thousands of metric tons of capture annually), with costs reaching a minimum at capture rates above ~400 thousand metric tons of CO_2 capture per year.[176] In their analysis, economies of scale reduced carbon capture costs for natural gas and coal power generation by about 40% and 20%, respectively. Figure 5.6, adapted from the GCCSI report, illustrates both controls on the cost of point source carbon capture: the x-axis showing how increasing concentrations (partial pressures) of CO_2 in industry flue gas decreases the levelized cost of carbon capture, and the error bars reflecting the range in cost of capture at any given CO_2 concentration due to the scale of capture at any given facility.

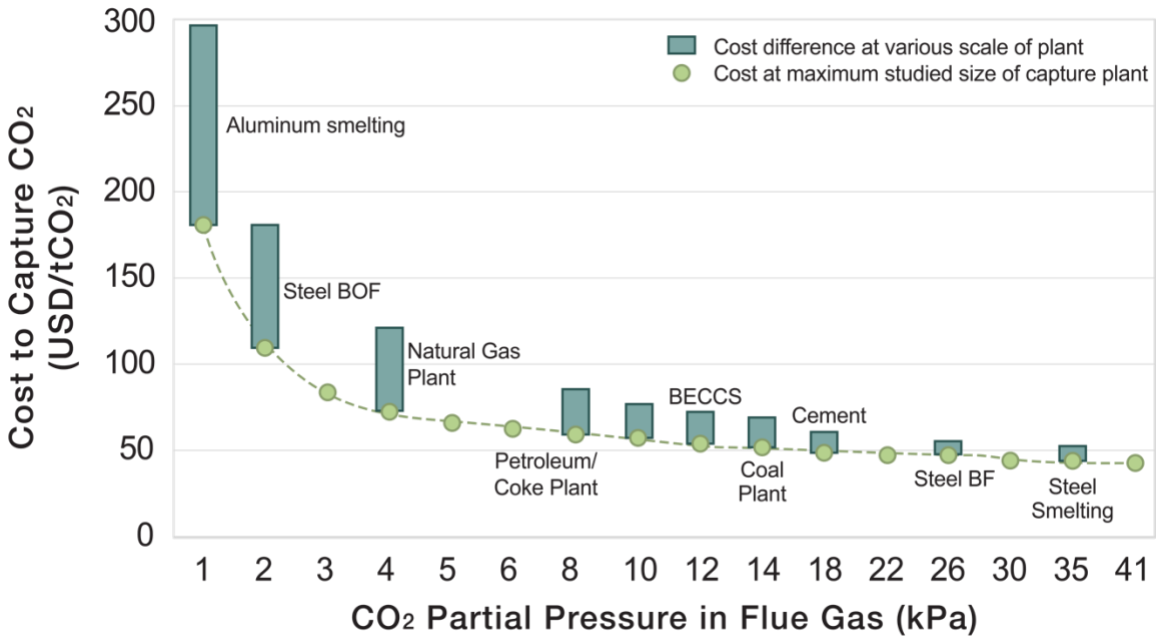

FIGURE 5.6. Levelized cost of carbon capture per metric ton CO_2 as a function of CO_2 partial pressure and operational scale, with the largest capacity capture facilities demonstrating the lowest cost at any given partial pressure. Adapted from Kearns et al. (2021) CCS readiness and costs.

[175] Kearns *et al.* (2021) CCS readiness and costs. p. 26-27. [45]

[176] Kearns *et al.* (2021) CCS readiness and costs. p. 31. [45]

To compare the relative costs of different carbon management industries (DAC, BiCRS, or point source capture), a 'Lifetime Cost Assessment' (LCA) model is used. The LCA is the total cost per metric ton CO_2 resulting from the cost of building the facility (capital costs), the cost of maintenance and labor (operational costs), and the cost of energy (heat + electricity), over the lifetime of the plant. However, for a micro steel mill, the cost of carbon capture is a comparatively small addition to the cost of building the mill. For simplicity, we assess the costs of creating the mill, and of capturing carbon from the mill separately. A micro steel mill that uses scrap and clean energy (0 tons CO_2 emissions per ton steel) would cost about $398-848 per ton steel produced. A scrap mill that used oxy-fuel combustion for energy would cost ~$407-903 per ton steel produced, with the added cost of CO_2 capture being ~$68-112 per ton CO_2. A mill that used direct reduced iron (DRI) with point source carbon capture and oxy-fuel combustion would cost ~$586-975 per ton steel produced, and the average cost of CO_2 capture would be $75-114 per ton CO_2. These estimated ranges are broken down in Table 5.5 and explained in detail below.

Table 5.5. Levelized cost per ton steel produced, by steel mill configuration.

Cost (USD per ton steel)[a]	Scrap-EAF + solar	Scrap-EAF + oxyfuel	DRI-EAF w. CCUS + oxyfuel	DRI-EAF + hydrogen
Cost to build steel mill (CapEx)	$88-125	$88-125	$88-125	$114-194
Feedstock (scrap steel or iron pellet)	$192-557	$192-557	$81-154	$157-267
Fixed operation & maintenance (OpEx)	$77-116	$77-116	$77-116	$90-153
Energy (solar, natural gas or green H_2)	$41-50	$40-88	$243-433	$226-508
Total Levelized Cost	**$398-848**	**$397-886**	**$489-828**	**$587-1,122**
Oxy-fuel combustion (Cap+OpEx)	--	$10-17	$59-97	--
DRI point source capture (Cap+OpEx)	--	--	$38-50	--
Total Levelized Cost Including Capture	**$398-848**	**$407-903**	**$586-975**	**$587-1,122**

a. See text for references for each estimated cost.

5.4.2.1 Cost to Build (upfront costs)

We can get a rough estimate of the capital expenditures, or cost to build a steel mini mill based on the six example mills listed in Table 5.5, which have been recently built, or are currently in development (detailed references for each of these sites is provided in Table 5.7). These mills, which produce between 350 and 1,200 thousand tons of steel annually, would cost $250 million to $1.7 billion dollars to construct. Normalizing those capital costs to the size of a steel mill that could capture up to 1 million tons of CO_2 annually (while producing ~770 thousand tons of steel), gives a range in capital costs between ~$460 million and $1.9 billion (average value is $680 million USD). If we annualized these costs, assuming a facility lifetime of 30 years and a capital recovery factor of 12.5% (see Section

3.4.2.1 for a detailed explanation of this calculation), the levelized capital cost of these normalized facilities ranges from ~$73-172 USD per ton steel produced. Such values closely approximate the estimated capital costs of DRI-EAF steel mills reported in the International Energy Agency (IEA)'s 2020 report on iron and steel technology.[177] They report a minimum CapEx for DRI-EAF of $88 USD per ton steel produced, but include an ~40% uncertainty to account for cost variability across regions, resulting in a CapEx range of $88-125. For the sake of consistency with the published literature, this is the CapEx range we employ in our levelized cost analysis (table 5.5). It is important to note that we approximate the same CapEx value for the scrap-EAF and DRI-EAF mills, and the added capital costs of CO_2 stemming from point source capture equipment (in the DRF-EAF with CCUS + oxy-fuel scenario) is accounted for separately.

Table 5.6. Reported capital expenditures for new or developing EAF mills.

Facility Name[a]	Year Operational	Annual Steel Output	Capital Costs (CapEx)	Normalized CapEx (per 770k tons steel)
		(kton steel)	million USD	million USD
Mojave Micro Mill, CA (proposed)	2025+	380	$350	$709
CMC Mesa Plant (II), AZ	2023	500	$300	$462
HighBar LLC, Osceola, AK	2024	600	$500	$642
Nucor Steel, Brandenburg, KY	2022	1,200	$1,700	$1,091
CMC Durant Plant, OK	2017	350	$250	$550
Nucor Steel, Davidson Co, NC	2024	430	$350	$627
MEAN		**577**		**$680**

a. These six mills are used for comparative purposes throughout the multi-lens analysis of the steel industry. For this, and all other references to these sites, references are detailed in Table 5.7.

5.4.2.2 Operational Costs

Operational costs fall into two categories: fixed costs (labor and maintenance) and variable costs (price of feedstocks). For scrap mills, the feedstock is steel scrap, which due to supply chain disruptions and the COVID-19 coronavirus, fluctuated significantly in recent years. Between January 2020 and March 2023, steel scrap ranged from $192-557 USD per ton.[178] Iron ore, the raw material feedstock for DRI-EAF, has also fluctuated, ranging from $81-154 USD in 2022 and 2023.[179] Reported fixed operational costs range from $77-116 USD.[180,181]

[177] [illegible]

[179] Trading Economics (no date) Iron Ore. [82]

[180] [illegible]

[181] M'barek *et al.* (2022) Global steel production costs. [54]

5.4.2.3 Energy Costs

Scrap-EAF mills require ~0.95MWh of energy production per ton steel (see Table 5.2), and DRI-EAF mills with point source capture require about 5 MWh per ton steel (see Section 5.1.3.2). If powered by solar with industrial scale battery storage, energy costs are estimated to be $43-52 USD/MWh ($28-37/MWh for solar energy + $15/MWh for battery storage).[182] Natural gas prices, based on a three year average, range from $43-92/MWh.[183] Combining these rates, we obtain an estimated cost of energy of $41-50 USD per ton steel for a scrap-EAF mill powered by solar, $40-88 USD per ton for a scrap-EAF mill powered by natural gas, and $211-461 USD per ton for a DRI-EAF mill with point source capture powered by natural gas. A steel mill powered by hydrogen would produce would not require the infrastructure or additional energy demand needed for point source capture. Thus, a DRI-EAF mill would require only about 4.7 MWh per ton steel produced. Costs for fossil-free green hydrogen range from ~$1.60-3.60 USD per kg (Section 6), or about $48-108 per MWh. Thus, green hydrogen energy costs for a scrap-EAF mill would be about $46-103 USD per ton steel, and for a DRI-EAF mill would be about $226-508.

5.4.2.4 Carbon Capture Costs

Finally, for mini-mills that are emitting appreciable CO_2, the capital and operational costs of capture via oxy-fuel combustion and point-source capture from DRI are additive to the costs of simply operating the mill. If these costs can remain under the $85 USD federal tax credit 45Q,[184] then carbon capture can be cost-effective, or even serve as an additional form of revenue. In the IEA's 2020 economic analysis of steel production, they estimated the combined capital and operational costs of post-combustion point source carbon capture, when applied to a DRI-EAF mill, to range from $38 to 50 USD per ton of steel. Given that about 0.42 tons of CO_2 can be captured via DRI point source capture per ton of steel made, the capture cost per ton CO_2 is $90-119 USD, within the cost range reported by the GCCSI (Figure 5.6).[185] Separately, a 2017 European techno-economic study of oxy-fuel combustion provided an estimated cost range of €71-116 EUR per ton CO_2 captured in 2014 currency. Converting those values to 2023 USD,[186,187] equates to an oxy-fuel combustion cost per ton of CO_2 captured of $68-112 USD.

A scrap-EAF mill that uses oxy-fuel combustion with capture produces, on average, 0.15 tons of CO_2 per ton steel (Table 5.2). At a cost of $68-112 USD per ton of CO_2, there would be an added net levelized cost to steel production of $10-17 USD per ton of steel (Table 5.5). A DRI-EAF mill, which is much more energy-intensive, would produce, on average, 0.87 tons of CO_2 via oxyfuel combustion, resulting in an added levelized cost to steel

[182] Lazard (October 2021) Levelized cost of energy analysis. [52]

[186] Macrotrends (no date) Euro Dollar Exchange Rate. [55]

[187] Bureau of Labor Statistics (no date) CPI Inflation Calculator. [8]

production of $59-97 USD per ton steel. The additional 0.42 tons of CO_2 captured via point source capture in a DRI-EAF mill add $38-50 USD per ton steel.[188] The total cost of carbon capture for a DRI-EAF mill with oxy-fuel combustion is $97-147 USD per ton of steel produced, and an average cost of CO_2 capture of $75-114 USD per ton CO_2.

5.4.3 Regional benefits

5.4.3.1 Proximate feedstocks

The primary feedstocks for mini mills are scrap steel or pelletized iron ore. Kern County, while not rich in geologic iron resources, has an advantage in its location along major rail and interstate routes, and adjacent to the Pacific Coast and associated shipping lanes. Abundant domestic and international steel scrap could be readily available for processing in this region. Pelletized iron could be similarly shipped along such routes. Additionally, because steel-making is such an energy-intensive, close proximity to abundant clean energy, whether in the form of solar energy, green hydrogen, or oxy-fuel combustion of RNG or biomass-derived syngas, Kern County (and a potential carbon management park) offer significant opportunities for accessible clean energy.

5.4.3.2 Proximate consumers

The same proximity to highly populated areas, as well as rail, interstate and shipping routes are also advantageous for the sale of steel, a product that is traded on an international marketplace.

5.4.3.3 Co-location advantages

Steel produces a relatively smaller amount of CO_2 emissions than BiCRS/DAC - and thus development of dedicated CCUS compression, transport and storage infrastructure may not be economically viable for a stand-alone facility.[189] Co-location and sharing infrastructure with other industries that produce larger amounts of CO_2 could allow for cost-effective capture of CO_2 from steelmaking, even in smaller plants that produce significantly less than 1 million tons of CO_2 annually.

Clean Energy Technologies

6. Hydrogen Production

TECHNOLOGY AT A GLANCE

- There are many ways to produce hydrogen, which are at different degrees of technical readiness. Here we examine blue hydrogen (commercially operational), green hydrogen via electrolysis (commercial demonstration phase), and green hydrogen via biomass (pilot and early demonstration phase).[1]
- Current costs per kilogram H_2 produced: $1.30-10.60 USD/kg H_2
- Current cost of CO_2 capture: $125-257 USD/ton CO_2 (green hydrogen from biomass), ~$82 USD/ton CO_2 (blue hydrogen from steam methane reforming+carbon capture and storage [SMR+CCS])
- Projected costs reductions per kilogram H_2 produced at scale: 20-50%
- Key advantages of this technology in Kern County: close proximity to feedstocks for some production methods (agricultural waste for green hydrogen from biomass, natural gas for blue hydrogen from SMR+CCS), located within the largest hydrogen market in the U.S., abundant renewable energy can make green hydrogen via electrolysis cost-competitive with other techniques
- Key concerns for this technology in Kern County: high energy and water demands for green hydrogen via electrolysis, potential for air pollutants - particularly from blue hydrogen via SMR+CCS - warrants further investigation, the hydrogen market is still quite nascent and will require large infrastructure investments before it can scale significantly

[1] Values in this section are summarized from the suite of references cited herein, and are explained in further detail in each subsequent section.

6.1 Technology Summary

In looking for alternative fuels to traditional hydrocarbons (including gasoline and diesel), both scientific experts and policymakers have turned to hydrogen as a potential fuel of the future, as it does not generate carbon emissions when burned.[2] Hydrogen is highly abundant, but most commonly is chemically bound in the compounds of other familiar substances, like water (H_2O) or methane (CH_4, which is natural gas). To use hydrogen as a fuel, it must be isolated from those compounds.[3] In this section, we present a brief overview of the variety of processes available to generate hydrogen gas (H_2), with a focus on two forms of hydrogen that are considered to produce little or no CO_2 emissions in their production: green and blue hydrogen.

6.1.1 Methods of Hydrogen Production

Hydrogen can be produced via several different methods, which for short-hand discussions have been categorized into a color key system, with each color indicating the production technique. Understanding this system is useful for research and discussions about the hydrogen industry and when thinking about the viability and trade-offs of given production methods. (Note, hydrogen itself is a colorless gas; the color system is simply a convenient notation device, but describes only the difference in hydrogen generation technique. There is no difference in the visual, physical, or chemical properties of hydrogen gas derived from these different production methods).[4]

While most applications of this color key system use commonly agreed upon definitions for each color, there is not a regulatory or industry standard, so some sources may have differences in what processes they include under each color. In this section, we provide a brief overview of the hydrogen labeling system, giving the commonly agreed upon definitions of each color. Then, we will examine the three forms of hydrogen production that would be most relevant for consideration in a carbon management and clean energy industrial park: green hydrogen via electrolysis, green hydrogen via biomass, and blue hydrogen.

6.1.1.1 The Hydrogen Color System

Unless otherwise noted, all definitions of the hydrogen color key system are derived from National Grid, an electricity distribution company operating in the United States and United Kingdom.[5]

Green hydrogen production refers to production techniques that generate no greenhouse gas byproducts. Most commonly, this is achieved via a process known as electrolysis,

[2] FuelCellWorks (November 28, 2022) 'Gold Hydrogen' Is an Untapped Resource. [31]
[3] EPA (September 13, 2022) Green Vehicle Guide: Hydrogen Fuel Cell Vehicles. [28]
[4] National Grid (no date) Hydrogen Colour Spectrum. [50]
[5] National Grid (no date) Hydrogen Colour Spectrum. [50]

wherein clean energy (like solar or wind) is used in an electrochemical reaction to split water molecules into hydrogen and oxygen. However, other non-carbon emitting techniques, such as gasification of biomass to form pure streams of H_2 and CO_2 gasses, combined with carbon capture, also qualify as green hydrogen.[6]

Blue hydrogen production refers to the conversion of methane (natural gas) to hydrogen via a process called steam reforming, which – like gasification from biomass – generates both hydrogen and carbon dioxide. In blue hydrogen generation, generated CO_2 is captured via point source capture technologies (see Section 5) reducing the carbon-intensity of hydrogen generation.

Gray hydrogen production also refers to steam reforming methane (natural gas), but does not incorporate the carbon capture processes necessary to reduce emissions. Currently, gray hydrogen is the most commonly used production process to generate hydrogen.

Black and brown hydrogen production relies on using pure coal or lignite (brown coal) to generate hydrogen, by gasification of the coal resulting in hydrogen as a byproduct. This is understood to be one of the most environmentally harmful ways to produce hydrogen.

Pink hydrogen production refers to the process of electrolysis, where water is split into hydrogen and oxygen, akin to green hydrogen. Unlike green hydrogen, though, it relies on nuclear power to sustain the electrochemical reaction. Some sources refer to this with other similar colors, like purple or red.[7]

Turquoise hydrogen production involves a process called methane pyrolysis, which converts methane to hydrogen and solid carbon, called "carbon black."[8] Carbon black has many industrial uses, but this method of hydrogen production has yet to operate at a commercial scale.

Yellow hydrogen production is a less commonly used and newer term, referring specifically to hydrogen production via electrolysis fueled by solar power. As such, yellow hydrogen is a subcategory of green hydrogen.

White hydrogen refers to hydrogen that does not need to be produced, but that is naturally occurring in geologic formations and could be accessed via fracking. At present, there are no plans or strategies to mine hydrogen, and opinions are mixed as to whether naturally-occurring hydrogen gas even exists. The National Renewable Energy Laboratory (NREL) states that hydrogen gas is not naturally-occurring, but there is growing optimism from other scientists that naturally-occurring hydrogen may be abundant beneath the Earth's surface.[9]

6.1.1.2 Envisioning hydrogen production in Kern County

Given the current economy, climate, and resources of Kern County, and the developmental objectives of a carbon management and clean energy industrial park, only some hydrogen production approaches were identified as warranting exploration in this study. The following production methods were ruled out:

- Black/brown and pink hydrogen production make little sense to explore at this juncture, given Kern County's current and anticipated energy mix.
- White hydrogen production is still within very early stages of technological development and will require significant further research before it is ready for commercial demonstration.
- Turquoise hydrogen is still within very early stages of development. Although it is not examined extensively here, production is very similar to other forms of biomass gasification and pyrolysis, which are described in detail in Section 4.
- Yellow hydrogen is a type of green hydrogen, and thus will be examined briefly in the discussion of hydrogen via electrolysis.
- Gray hydrogen production, given its large, unmitigated greenhouse gas emissions footprint, is incompatible with the park's guiding principle of hosting carbon management and clean energy industries.

Green hydrogen (via electrolysis or biomass gasification) and blue hydrogen production are potential clean energy or carbon management technologies that could feasibly be adopted in a Kern County carbon management park, and we explore each of these in this report. Given that more than one production method can be classified as 'green hydrogen,' the nomenclature used in this report will always specify both the color key and the process of production, to avoid ambiguity: hydrogen via electrolysis (green), hydrogen via biomass gasification (green), and hydrogen via steam methane reforming (SMR) + CCS (blue). Finally, because hydrogen production via biomass gasification with carbon capture is a form of Biomass with Carbon Dioxide Removal and Storage (BiCRS), most of the information on this method of hydrogen production is also contained in the BiCRS/BECCS section of this report (Section 4) and is cross-referenced accordingly.

6.1.2 Green and Blue Hydrogen Description: How it Works

6.1.2.1 Green hydrogen via Electrolysis

Hydrogen production via electrolysis involves using an electric current to drive an electrochemical reaction in which water is split into its constituent elements, hydrogen and oxygen:[10]

$$H_2O \rightarrow H_2 + \tfrac{1}{2}O_2 \qquad \text{(R6.1)}$$

[10] AFDC (no date) Hydrogen Production and Distribution. [6]

There are a variety of machines, called electrolyzers, that can sustain this electrochemical reaction to produce hydrogen, using varying techniques, which are reviewed here.

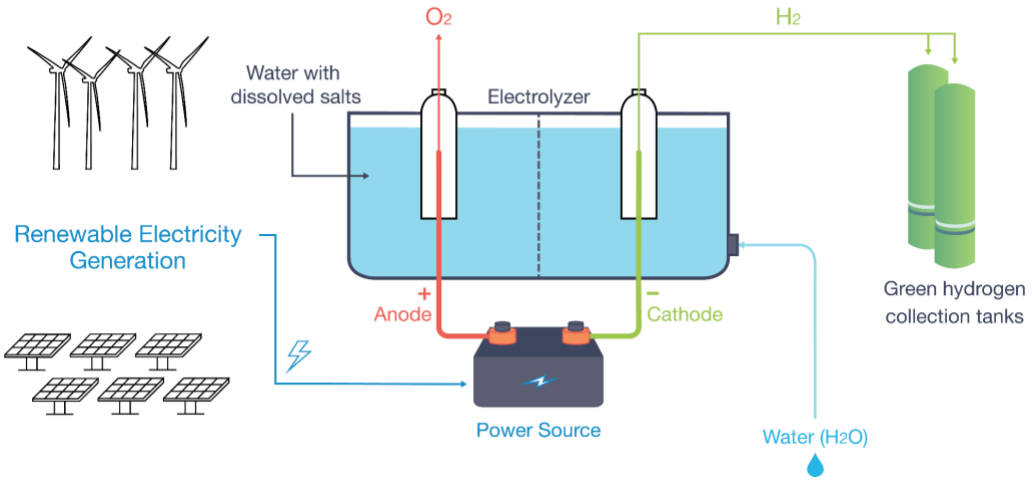

Figure 6.1. Schematic of the process of producing hydrogen via electrolysis: renewable energy provides electricity to power a cathode and anode placed in a water + dissolved salt solution. The electric current created breaks water (H_2O) molecules into hydrogen and oxygen.

The most well-established method, alkaline electrolysis, has existed for more than two centuries. Alkaline electrolysis uses an electrochemical cell, where a cathode and anode are placed in an electrolyte solution, which is a water-based solution with salts (Figure 6.1).[11] When voltage is applied to the cell, water molecules are reduced by electrons at the cathode to produce hydrogen gas and negatively charged hydroxide (OH^-). The hydroxide ions will be electrically attracted to the anode, and by placing a membrane between the anode and cathode, the hydrogen gas molecules can be separated from the negatively charged hydroxide ions. At the anode, the hydroxide ions are oxidized, producing oxygen gas, and releasing water molecules and electrons back to the electrolyte solution (see reactions R6.2 + R6.3):[12]

Cathode reaction: $2H_2O + 2e^- \rightarrow H_2 + 2OH^-$ (R6.2)

Anode reaction: $2OH^- \rightarrow \frac{1}{2}O_2 + H_2O + 2e^-$ (R6.3)

Hydrogen gas is separated from the electrolyte solution to be dried (removing any H_2O vapor), cleaned (involving the removal of oxygen impurities),[13] and depending on the end use, compressed.[14] The reactions in the electrolyte solution (R6.2 + R6.3) generate heat; if this heat is harnessed during the process, it can help improve the cell's overall energy

efficiency.[15] Alkaline electrolysis represents a *type* of electrochemical cell, which is often used as a kind of battery. For a general explanation of electrochemical cells and reduction-oxidation reactions, please see Section 7.1.1 of this report.

Most new hydrogen via electrolysis projects today use a different process that relies on a proton exchange membrane (PEM).[16] Here, instead of a liquid electrolyte solution, water is pressed through a stack of two electrodes with a polymer membrane in between (Figure 6.2). At the anode, the water reacts to form oxygen, hydrogen ions (H^+), and electrons; the hydrogen ions can then move selectively across the membrane, a specialty solid plastic material,[17] towards the cathode.[18] The electrons are moved to the cathode side as well through an external circuit, as they cannot pass through the membrane.[19] On the cathode side, the hydrogen ions and electrons combine, forming hydrogen gas.[20]

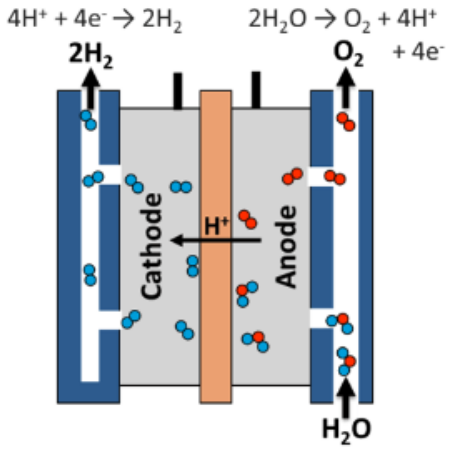

Figure 6.2. Schematic of a proton exchange membrane. Image credit: U.S. Department of Energy.[21]

There is a third electrolysis technology—solid oxide electrolysis (SOE)—that is rising in prominence, but alkaline and PEM systems are far more common for commercial applications. It is explored briefly here for comprehensiveness, but future sections on hydrogen via electrolysis primarily focus on alkaline and PEM systems. The electrolyte in these systems is a solid ceramic that selectively allows negatively charged ions to pass through at high temperatures—in this case, the negative ion is oxygen (O^{2-}).[22] Water enters at the cathode as steam, where it combines with negative ions brought in via the external

circuit to form hydrogen gas and O^{2-}.[23] Once formed, the oxygen ions pass through the solid ceramic membrane to the anion, where the oxygen ions react to form oxygen gas and electrons that will supply the external circuit.[24]

Many projects currently emphasize "power-to-hydrogen" or "power-to-gas" initiatives, where excess renewable energy—when it is available from the grid—is channeled to electrolyzers to create hydrogen.[25, 26]

6.1.2.2 Green Hydrogen via Biomass Gasification

There are a variety of ways to treat biomass in order to produce an energy-rich product and CO_2 byproduct that can be captured for permanent storage, which are detailed in Section 4 of this report. The most relevant in the context of hydrogen is a process called gasification, a two-step process in which first, biomass is reacted with steam and oxygen at high temperatures (>700°C) and pressure, converting it into gaseous components – primarily CO, CO_2, and H_2.[27] In the second step, called a water-gas shift reaction, the carbon monoxide (CO) is reacted with water to produce more CO_2 and H_2, along with a small amount of heat.[28] The resulting products are two streams of high-purity gasses: CO_2 for permanent storage, and H_2 for fuel use. Pyrolysis, the high-pressure and high-temperature process used to create turquoise hydrogen from methane, is a technique that can also be applied to biomass to produce CO_2 and a variety of hydrocarbon byproducts, and is also detailed further in Section 4.

6.1.2.3 Blue Hydrogen via Steam Methane Reforming (SMR) + CCS

Hydrogen via steam methane reforming (SMR) + CCS relies on an interconnected series of processes to transform methane (CH_4) and water (H_2O) into hydrogen (H_2) and CO_2. In the initial SMR reaction, steam reacts with methane in a high-pressure container with a catalyst to produce syngas, a mixture of hydrogen, carbon monoxide, and carbon dioxide.[29] As an endothermic reaction, SMR requires heat for the reaction to proceed—requiring about 206 kJ of heat energy per mol of methane.[30,31] (Steam reforming can be used to generate hydrogen from other hydrocarbon fuels, like propane or gasoline, but SMR is the most

common choice for hydrogen production, as it is the cheapest and most efficient.[32,33]) Like gasification, the next step is typically a water-gas shift reaction, where the carbon monoxide generated in SMR is reacted with more steam in the presence of a catalyst to form more hydrogen, carbon dioxide, and a small amount of heat.[34] The final step, pressure-swing adsorption, removes the carbon dioxide and other gasses from the final products, leaving a pure stream of hydrogen gas.[35]

Once separated from the hydrogen gas stream, the carbon dioxide generated in the SMR and water-gas shift steps can be purified, compressed, and transported for permanent underground storage, preventing it from entering the atmosphere and contributing to climate change. In gray hydrogen production (from SMR without CCS), for every kilogram of hydrogen produced, approximately 9 kilograms of CO_2 is generated.[36] With carbon capture and storage attached, the estimated emissions of SMR hydrogen production drops to 1-5 kilograms of CO_2 generated per kilogram of hydrogen.[37] Although this reduces the impacts of SMR, it does not make the process carbon-neutral—blue hydrogen still releases CO_2 into the atmosphere. This is explored in further detail in Section 6.3 on the environmental impacts of hydrogen production.

6.1.3 State of Development

Blue hydrogen via SMR + CCS, green hydrogen via electrolysis and green hydrogen from biomass are all commercially operational processes that are ready to be scaled up, but hydrogen production from electrolysis and biomass gasification in particular are currently deemed too costly to be competitive with less environmentally-friendly hydrogen production methods.

In addition to the hydrogen production methods detailed here, and in the color classification summary (Section 6.1.1.1), there are several emerging hydrogen production techniques that are still in the early research and development stage. It is beyond the scope of this study to detail each of these emerging technologies, but a list of their names is provided for the interested reader who would like to explore further. Hydrogen production techniques still in the experimental phase include processes like photo-electrochemical solar water splitting, solar high-temperature thermochemical cycles, high-temperature electrolysis, photo-biological conversion, bio-derived conversion, microbial conversion and generating hydrogen from aluminum scrap.[38]

Below, we provide brief summaries of extant companies or projects that are representative of the three hydrogen production techniques explored here.

6.1.3.1 Example projects

Electrolysis: Air Liquide, Bécancour, Québec

Air Liquide's facility in Bécancour is discussed at length in Section 6.1.4, as a case study for operational needs of electrolysis. This facility has the largest operating electrolyzer of its kind in the world—a 20 MW PEM electrolyzer developed with Cummins technology.[39] This 20 MW capacity was obtained by a four-module configuration of HyLYZER 1000-30 units, which are 5 MW each.[40] The facility is run using grid hydropower resources from Hydro-Québec, an almost-all renewable source of energy.[41]

Figure 6.3. Digital rendering of the planned alkaline electrolysis facility in Lancaster, California, under construction by Element Resources. Image credit: Element Resources.

Electrolysis: Element Resources, Lancaster, California

At the planned Lancaster Energy Center, Element Resources intends to set up an electrolysis site on 1,165 acres with an electrical capacity of 135 MW using alkaline electrolysis.[42] The primary reason for the large land footprint is the electricity demand, which will be met using solar photovoltaic (PV) panels installed on-site. Their estimated hydrogen output per year, once fully operational, is 18,750 metric tons per year.[43]

Biomass Gasification: Mote, Los Angeles, California

Mote, a Culver City-based cleantech startup, is planning to build a $100 million biomass to hydrogen energy plant with carbon sequestration on 5 acres of unincorporated land in Kern County, pending securing financing, government approval and permits.[44] The plant will extract carbon dioxide and hydrogen via gasification from wood waste from farms, forestry, and other resources.[45] The hydrogen gas will be sold to hydrogen fuel station operators, and the CO_2 will be sequestered into deep underground saline aquifers or retired oil wells. Mote expects to produce approximately 7,000 metric tons of carbon-negative hydrogen (green hydrogen) annually, which translates to ~150,000 metric tons of CO_2 captured from biomass and available for permanent sequestration.[46]

Mote's business model will provide cost-competitive green hydrogen by partly offsetting their costs with income from the storage of CO_2. They will either take advantage of carbon removal credits in the voluntary carbon credit market, or of rebates from the federal tax credit for CCS projects (45Q) as well as California's Low Carbon Fuel Standard (LCFS).[47] In May 2022, Mote announced that they had secured commitments for over 450 thousand tons of feedstock for their production.[48] Working with Fluor, an industry leading engineering, procurement and construction (EPC) firm, to execute the Front-End Loading 2 (FEL-2), Mote plans to begin construction in 2023 and be fully operational by 2025.[49] A digital rendering of their planned facility is shown in Figure 6.4.

Steam Methane Reforming: Air Products, Texas & Louisiana

Air Products has deployed retrofitted carbon capture to two existing hydrogen via SMR facilities in Texas, and is now planning a more ambitious project: building the world's largest SMR + CCS facility in Louisiana, planned to go online in 2026.[50] The Louisiana Clean Energy Complex webpage states they expect to capture over 5 million tons of CO_2 annually from SMR + CCS hydrogen production, expecting that they'll capture 95% of the CO_2 generated during the process.[51] According to Air Products, this would position them to be the largest CCS plant in the world. If they can attain this 95% capture rate in practice, it would be a higher capture rate than any reported estimates for SMR with CCS found in the literature during the preparation of this report. Total planned investment for the project amounts to $4.5 billion, and the project would create an estimated 170 permanent jobs and another 2,000 positions during the construction phase.[52]

6.1.4 Operational Needs

6.1.4.1 Land use requirement

The scale of a commercial hydrogen facility is generally described in terms of how much energy it is able to produce annually (its MW capacity), rather than the physical footprint that it would occupy, meaning published descriptions of land use needs from operators are rare. Furthermore, given the rapid rate of technological innovation and plans to scale up production in this sector, most existing facilities are significantly smaller than planned future facilities. As such, experts have largely been approximating facility footprints based "on engineering estimates, rather than plot optimization based on real experience."[53]

For hydrogen via electrolysis, the largest currently active site in the world is Air Liquide's site in Bécancour, Quebec, which began production in January 2021.[54] It has a capacity of 20 MW and can generate over 8.2 metric tons per day of hydrogen; their plant relies on hydropower from Hydro-Québec for its nearly-all renewable energy source.[55] The Bécancour facility relies on four proton exchange membrane (PEM) electrolyzers to generate its hydrogen, which are approximately the size and shape of very round water towers.[56]

Estimates aggregated by the International Renewable Energy Agency (IRENA) can help refine size estimates for future hydrogen facilities that would be larger than Bécancour, as

[53] IRENA (2020) Green Hydrogen Cost Reduction. p. 41. [38]
[54] Air Liquide (February 8, 2021) World's Largest PEM Electrolyzer. [2]
[55] Air Liquide (February 8, 2021) World's Largest PEM Electrolyzer. [2]
[56] Air Liquide (February 8, 2021) World's Largest PEM Electrolyzer. [2]

is expected to become common if hydrogen is to be a widely-used fuel in the future. In a 2014 study, IRENA estimated that a 100 MW capacity electrolyzer would require ~6,300 m^2 (1.55 acres) of land.[57] For reference, a 100 MW electrolyzer would produce about 50,000 kilograms of H_2 per day[58] (that is the equivalent to about 50,000 gallons of gasoline production per day[59]).

Later studies of 100 MW capacity facility designs generated smaller estimates than this initial figure, with a 2017 study estimating a footprint of 3,500 m^2 (0.86 acres) and a 2018 study estimating a footprint of 4,500 m^2 (1.11 acres).[60] In regards to even larger facilities, a 2017 study by Siemens predicted a 300 MW capacity electrolyzer facility would need 15,000 m^2 (3.71 acres).[61] Relative to other industrial energy facilities that produce electricity or fuel, these are relatively modest land use requirements.[62,63]

The accuracy of these estimates will be easier to determine moving forward, as companies have begun planning and constructing facilities in the hundreds of MW capacity range. A 100 MW hydrogen via electrolysis facility run by RWE Generation is planned for Lingen, Germany as part of the world's first publicly-accessible hydrogen network.[64]

6.1.4.2 Energy requirements

Hydrogen production is an extremely energy intensive process, particularly for electrolysis, because of the strength of the chemical bonds that need to be broken between the hydrogen and oxygen ions within a water molecule. For hydrogen production via electrolysis, the efficiency of the reaction generally ranges between 60-81%, depending on the technology used.[65] This means that for every 100 MW of electricity used to drive an electrolysis reaction, about 60-81 MW of energy value is produced in the form of hydrogen fuel. That is equal to a production rate of about 43,600-58,900 kg of H_2 produced each day,[66] with one kg of H_2 having about the same energy content as one gallon of gasoline. If all of the hydrogen currently produced in the world (about 69 million metric tons annually) was

*1kg of hydrogen has an energy value ("lower heating value") of about 33.3 kWh, and 60-81MW of energy value translates to 525,600-700,800 MWh of energy production in a year.

generated using electrolysis, it would require 3,600 terawatt hours (TWh) of electricity, more than the total annual electrical output of the European Union—a staggering energy demand.[67] To put that energy demand in a domestic perspective, if hydrogen were to replace US gasoline consumption (requiring about 135 million tons of hydrogen annually[68]), producing that hydrogen via electrolysis would use nearly twice the amount of electricity that currently powers the entire United States.[69,70,71]

A biomass gasification facility producing 1 million tons of CO_2 for capture can produce about 70,000 tons of hydrogen if it is powered entirely through an external source of energy.[72] For a facility to be self-sufficient (effectively needing no external energy input), about 30% of the syngas produced in the gasification step of hydrogen production is needed.[73] In this case, for every million tons of CO_2 produced, only about 50,000 tons of hydrogen is produced.[74] Whether and to what degree produced syngas or external energy sources are used depends on the relative cost of available energy sources, and the marketplace value of green hydrogen. If green hydrogen is far more valuable than other energy sources, facilities may use electricity or other fuels to produce the hydrogen, so they can sell as much of what they generate as possible. If prices are relatively equivalent, or green hydrogen prices decline to be cheaper than other fuels, facilities will likely opt to use some of the generated hydrogen to power the facility.

Most of the energy needs for biomass hydrogen production are used to attain the necessary heat and pressure to gasify the organic feedstock. The exact amount of required heat energy is difficult to ascertain, as the process is still relatively new, and most technical information regarding any individual gasification technique is proprietary. The fact that most facilities meet this energy need with their own supply of syngas, also leads to its often being unreported. Regardless of the scale of heat energy requirements, if solar-sourced energy were used, it would need to be paired with heat batteries, which likely would make it uneconomical compared to utilizing a portion of the syngas. As for the electricity demands, most facilities either pursue a grid connection as back-up or set up their own solar panels to meet any electrical demand. For a facility capturing 1 million metric tons of CO_2, the estimated solar capacity would be 135 MW, occupying ~945 acres, just to meet the electricity needs.[75]

[75] Industry representative, personal communication, September 8, 2022.

For SMR + CCS, there is no expected electricity demand, as the SMR process can be driven using internally generated waste heat, but there is a requirement of 3.4 kilograms of natural gas (methane) input per kilogram of hydrogen generated.[76] If waste heat is not employed to support the heat necessary for the SMR and water-gas shift reactions, then additional natural gas (methane) may be needed to meet the heat energy requirements.

6.1.4.3 Other operational requirements

Waste disposal requirements

During electrolysis, two gaseous products are created: hydrogen gas (H_2) and oxygen gas (O_2). Most electrolyzer plants choose to release their oxygen gas directly into the atmosphere,[77] but the oxygen could hypothetically be packaged and sold for use in metal processing, stone and glass production, chemical manufacturing, or for medical uses.[78] If these uses were pursued, the oxygen would likely need to be compressed and given warehouse space before it could be shipped to end users.

If the water source for electrolysis is not delivered at the necessary purity to go straight into an electrolyzer, then it may require additional on-site filtration, which produces minerals (mostly salt) that will need to be disposed of.[79] For a plant generating 45 metric tons of hydrogen gas daily using water directly from municipal supplies, the estimated weekly mineral production was about one dumpster worth of material for disposal.[80,81] A 100 MW hydrogen electrolysis facility, which produces slightly more H_2 (about 50 metric tons daily),[82] would need just over one dumpster per week. In the long term, another category of expected waste will be the electrolyzer stacks themselves, which typically require replacement on a 7 to 11 year timescale depending on the electrolyzer type.[83]

For hydrogen production via biomass gasification, all of the reaction products—hydrogen, CO_2, biochar—can be sold for use or permanently sequestered. It is only equipment that should require a waste disposal strategy at end-of-life, which will be component specific, depending on whether it can be recycled or needs to be landfilled. Further information about gasification products and disposal can be found in Section 4.1.4.2 of this report.

For hydrogen production via SMR + CCS, the picture is similar to biomass gasification—once all of the steps have been completed, the only process outputs should be hydrogen,

[83] UK Department of Business, Energy & Industrial Strategy (2021) Hydrogen Production Costs. p. 19. [77]

CO_2, and a small amount of heat.[84] None of these products require waste disposal, unless there are any impurities in the methane gas stream that would result in small amounts of gaseous waste.[85] The hydrogen and CO_2 can be packaged for sale or sequestration, and the heat would ideally be cycled back into the process or directed towards a co-located industry for use. Again, only equipment that requires replacement should need separate waste disposal practices.

Warehousing requirements

For all methods of hydrogen production, the most likely warehousing requirement will be a site to compress and store the hydrogen for transport once formed. Both hydrogen production via biomass gasification and via SMR + CCS will also create CO_2 that must be compressed and transported off-site, ideally to geologic storage, to minimize environmental impacts.

Hydrogen production via electrolysis may require similar infrastructure to store oxygen if they plan to sell it instead of releasing it.

For hydrogen production via biomass gasification, a facility will need biomass on hand to gasify (i.e. Figure 6.3), and these facilities often have drying warehouses on-site to prepare the biomass for processing.[86] Since these facilities will generate other byproducts, like biochar, that can be sold, it is likely that they will need other buildings to process and store these products for shipment.

Transportation requirements

Over short distances, hydrogen can be transported via pipeline, truck, or rail.[87] With that said, pure hydrogen gas is extremely hard to transport. It can be compressed, liquefied, or converted temporarily into a metal hydride (fuel cell) in order to be transported.[88] Given that hydrogen is the lightest and smallest element in the universe, hydrogen gas is the lowest density gas. Hydrogen gas is also extremely flammable when mixed with even small amounts of air, so leaks or other malfunctions in transport could be extremely hazardous.[89] As such, it would be an extensive challenge to retrofit existing transport methods for safe use with hydrogen. Rather, new, dedicated infrastructure (pipelines, hydrogen compression or conversion technologies, and appropriately designed tanker and shipping vessels) will need to be developed. Technologies to scale up the cooling and compressing of hydrogen for commercial-scale transport are still in the research and development phase.[90] Based on the current state of the industry, consensus is that mass transport of

hydrogen by sea will not be commercially viable until the mid-2030s,[91] limiting viable hydrogen markets over the next decade to those accessible by onland routes.

Currently, long-distance transport of hydrogen is conducted by converting hydrogen into chemical intermediates and then moving the intermediates to a final destination, where it can then be converted back into hydrogen gas for use. The intermediates used as energy carriers will likely be compounds like methylcyclohexane (organic hydride).[92] Methylcyclohexane can be imported and exported globally and is less dangerous to transport than pure hydrogen, as it remains a liquid at standard temperature and pressure and is chemically stable.[93, 94] The Chiyoda Corporation has already successfully demonstrated this process, using a mixture of toluene and hydrogen to generate methylcyclohexane in Brunei, transporting the methylcyclohexane over sea using a chemical tanker to Japan, and then using a dehydrogenation process on Japanese shores to supply the hydrogen for industrial facilities.[95]

In short, because of its molecular structure, hydrogen gas will require development of entirely new transportation networks and usage infrastructure than that used in our existing natural gas economy.[96] This new infrastructure will need to develop at a significant pace in order to ensure the economic viability of any large-scale hydrogen production facility.

Pipeline requirements

In the United States, there are approximately 1,600 miles of hydrogen pipelines[97] under the regulation of the federal Pipeline & Hazardous Materials Safety Administration (PHMSA).[98] Regulating hydrogen pipelines in the United States has been under the purview of the U.S. Department of Transportation (DOT), PHMSA's parent agency, since 1970 due to 49 CFR Part 192.[99]

Although hydrogen can be moved alongside natural gas at concentrations up to 15% hydrogen with only minor modifications required in a natural gas pipeline, moving hydrogen at higher concentrations of purity will require more substantial modifications or new pipeline infrastructure.[100]

6.1.5 Carbon Capture Potential

The carbon capture potential associated with hydrogen production differs depending on the process under consideration.

To generate hydrogen via electrolysis, no CO_2 should be produced unless the energy to sustain the reaction is sourced from a non-renewable resource. As we are only considering electrolysis conducted with renewable resources—like wind or solar—in this analysis, this production process should not be generating carbon for capture. It would exist as a clean energy industry, rather than a carbon management industry.

To generate hydrogen via biomass gasification, CO_2 will be created as a byproduct of hydrogen production. However, recovery rates of these carbon emissions are quite high (over 90%),[101] allowing nearly all the CO_2 produced onsite to be compressed and transported for permanent underground storage. Between 50,000 to 70,000 tons of hydrogen can be generated via biomass gasification per every 1 million tons of CO_2 produced, depending on how the facility's energy needs are met.[102]

To generate hydrogen via SMR + CCS, CO_2 will be created through multiple stages of production in both the initial SMR reaction and the subsequent water-gas shift reaction.[103] Given that gray hydrogen production (SMR without CCS) produces about 9 kilograms of CO_2 per kilogram hydrogen, while the estimate for blue hydrogen production (SMR + CCS) is 1-5 kilograms of CO_2 per kilogram hydrogen, the carbon capture and storage potential of SMR + CCS should range from 4-8 kilograms CO_2 per kilogram hydrogen produced.[104] This would correspond to a capture rate of 44-88% of the CO_2 emissions generated by hydrogen production via SMR. Some recent models have stated that carbon capture from SMR has a maximum removal capacity of 90%.[105]

6.2 Societal Impacts

6.2.1 Job creation potential

6.2.1.1 Number and types of jobs

There are no average industry estimates across types of hydrogen production methods, and no public methodology for arriving at these estimates. Some studies have projected that nationwide, hydrogen-related jobs in the United States could number almost one million by 2030, but these jobs are expected to disproportionately benefit highly-skilled and

[101] Patrizio *et al.* (2021) CO_2 mitigation or removal. p. 1-2. [62]

[105] Katebah *et al.* (2022) Analysis of production costs in Steam-Methane Reforming. p. 9. [41]

well-paid technical and professional workers.[106] Thus training workers to take on these new positions in the workforce will be essential to keeping jobs within local communities.

There are a few specific case studies we can use to approximate job creation potential in hydrogen production. Air Products, for their planned SMR + CCS facility in Louisiana designed to capture over 5 million tons of CO_2 annually, has projected the creation of 170 permanent jobs with an average salary of $93,000.[107] For hydrogen production via biomass gasification, this study assumes that the number and type of jobs will not vary significantly from other biomass gasification facilities covered in Section 4 of this report—for specifics on those job figures, please see Section 4.2.1.1. A similar case study reporting jobs for a large scale electrolysis facility has not been found.

6.2.2.2 Training pipelines

A U.S. Department of Energy (DOE) study on the implementation of a hydrogen economy between 2020 and 2050 found that many American workers would need new skills for the hydrogen economy, and that training and retraining programs would need to be established to fill this gap.[108] Unfortunately, the DOE's reporting does not provide depth on what training would be necessary or the likely occupations (and anticipated earnings) associated with the growth of hydrogen production.[109]

A wide range of skill levels are expected to engage with the hydrogen economy at-large (including hydrogen production, transport, and use), with experts anticipating that the hydrogen economy will include experts with graduate education, but also "include jobs that require associate's degrees, long-term on-the-job training, or trade certifications – and lead to jobs that pay higher than US average wages."[110] Furthermore, Plug Power, a company currently constructing electrolyzer facilities in the United States, has specifically referenced that a skilled workforce in the region was desirable for planning where to locate electrolyzer plants.[111] Setting up programs at local community colleges and universities to provide specialized training to take on roles in hydrogen production is a crucial way to support these nascent industries and ensure new, high-paying jobs in the region benefit local community members. By establishing local programs to train workers in these skills, it could attract hydrogen investment opportunities to the overall region; existing regional benefits for Kern County specifically are explored in Section 6.4.3.

6.2.2 Quality of Life

6.2.2.1 Location

Hydrogen production via electrolysis is generally a quiet process—a facility in western New York describes the actual electrolyzer as "silent."[112] The loudest equipment on site are the compressors, used to cool hydrogen post-production to prepare for transport. The impact of the compressor noise can be mitigated by placement inside a building far from the site boundary, allowing the sound to disperse over distance.[113]

Hydrogen generated via biomass gasification will have more components that can generate noise, as well as some outdoor equipment (ex. conveyor belts to transport biomass) that would be hard to dampen except with distance from population centers. The loudest components of the operation—such as the engine and compressor—should be housed in insulated materials to dampen the machinery noise.[114] Other equipment like blowers and coolers inside the plant can also contribute noise, as well as any noise from equipment to transport biomass to the site and transport co-products off-site for distribution.[115] For a facility capturing 1 million tons of CO_2 annually, about 1,800 tons of feedstock (~90 tractor-trailer truckloads) need to be delivered each day,[116] which could contribute to noise and traffic in nearby communities. As a result, anticipated overall site noise can be a determining factor in siting a new biomass gasification facility.[117]

SMR processes can be quite loud, with on-site noise near the reformer loud enough to cause ear damage and fatigue to personnel.[118] Ensuring there is adequate hearing protection available for workers, as well as that noise level surveys for the site and surrounding area do not exceed local regulations, is essential for any proposed SMR + CCS site.[119]

The full life-cycle of hydrogen production, transport, and use can generate a range of pollutants, which may have health impacts for nearby populations – the full spectrum of these emissions is explored in Section 6.3.2.

[119] EIGA (no date) Combustion Safety for Steam Reformer Operation. p. 13. [29]

6.2.2.2 Multi-use potential

Currently, most hydrogen is produced on the same site where it is used, making hydrogen a key co-location opportunity for heavy, heat-reliant industries and transportation hubs like train depots, airports, and shipping ports.

The multi-use potential of hydrogen production sites for community spaces is more narrow—with both biomass gasification and SMR + CCS being relatively hot and requiring stringently-controlled conditions to maximize efficiency, opportunities for community use on-site are unlikely. Hydrogen production via electrolysis may offer multi-use potential, as the production process is relatively quiet, making it potentially an attractive prospect for school field trips for scientific demonstration.

However, the risks of hydrogen could make such facilities intrinsically a poor candidate for multi-use opportunities. If handled improperly, hydrogen can cause fires or explosions, and since hydrogen gas is very light and odorless, leaks can be exceedingly difficult to detect before hydrogen concentrations exceed its lower flammability limit in air.[120] This risk can be reduced by designing hydrogen facilities with key features (like sloped and vented roofs) that leave hydrogen space to escape, so it is not trapped to mix with air in a sealed space.[121] Overall, since hydrogen gas will need to be handled carefully on-site to protect workers, permitting other uses or untrained people to the site could be logistically difficult.

6.3 Environmental Impacts

The environmental impacts of hydrogen production are significant, particularly given that most hydrogen production taking place today is derived from natural gas and coal (gray, black and brown hydrogen). Annual global CO_2 emissions from hydrogen are equivalent to the combined annual CO_2 emissions of the United Kingdom and Indonesia, or approximately 830 million metric tons of CO_2 a year.[122] For reference, in 2021, the United States emitted approximately 5 billion metric tons of CO_2,[123] so current hydrogen production would be equal to about 16.6% of annual CO_2 emissions in the United States. Implementing less carbon-intensive methods of hydrogen production is important for reducing emissions and air pollution, regardless of the potential uptake of hydrogen as a fuel. Building a sustainable future relies upon diversifying the energy sources used to generate hydrogen and utilizing less carbon-intensive production practices than the industry currently uses.[124]

6.3.1 Water requirements

6.3.1.1 Minimum volume requirements

For hydrogen production via electrolysis, the volume requirements of water are proportional to the output of hydrogen generated in the facility. As such, large hydrogen electrolyzers correspond to large water requirements by volume. For every two molecules of water put in an electrolyzer, two molecules of hydrogen (H_2) are created, assuming 100% efficiency.[125] However, real-world electrolyzers will suffer inefficiencies that means this 1:1 ratio will not hold in reality, and given the vast difference in molecular weight and size of a water molecule and a hydrogen gas molecule, put in terms of mass, water to hydrogen ratios are significantly higher than 1:1. Published estimates of the theoretical minimum water demand for electrolysis are as low as 9.1 liters (or 2.4 gallons) of water per kilogram of hydrogen.[126] In practice, electrolyzer operators have found that it takes approximately 12 liters (or 3 gallons) of water to produce every kilogram of hydrogen created via electrolysis.[127]

Although experts are working to reduce the water requirements needed for hydrogen production via biomass gasification, currently, water is used to perform the water-gas shift reaction to generate hydrogen and purify the gaseous products. Some forms of gasification rely on steam or supercritical water, which can increase the overall water demand. The most conservative facilities use about equal quantities of biomass and water in their process.[128] There is some potential for water reuse; water is used to purify gas, allowing contaminants like SO_x or NO_x to dissolve into aqueous species. Once H_2 and CO_2 streams have been purified, the water is separated from them, carrying contaminants with them as dissolved components that can settle out. That water is typically stored in evaporation ponds on site, and could be treated for reuse with appropriate equipment.[129] Currently, the estimated water use for a biomass hydrogen facility capturing a million metric tons of CO_2 per year ranges between 266 and 1840 acre-feet of water each year.[130] That equates to about 15.0-103.6 liters (or about 3.9-27.4 gallons) of water needed to produce one kilogram of hydrogen via biomass gasification.*

A full life-cycle analysis for hydrogen production via SMR + CCS found that per kilogram of hydrogen generated, the process consumed 6 to 13 liters (or 1.6-3.4 gallons) of water.[131]

[131] Valdez (August 11, 2022) Electrolyzers and Water. [79]

This is corroborated by other studies, which placed the water demand for SMR and the subsequent water-gas shift reaction combined at 9.7 liters (or 2.6 gallons) of water per kilogram of hydrogen produced.[132]

Given these relatively high water use figures across production methods, hydrogen production may be a poor fit for water-stressed regions like Kern County, as freshwater is already overallocated.[133] The strain on local water resources could be reduced if highly purified, reclaimed or recycled water could help meet this need, a subject that is explored in Section 8 of this report on water treatment.

6.3.1.2 Minimum quality requirements

For electrolysis, the water quality threshold is extremely high—the water used in electrolyzers "needs to be as pure as possible."[134] The water used in an electrolyzer should be distilled and/or deionized, to preserve the efficiency and lifetime of the equipment.[135] Membrane-based electrolyzers require water to be of type II purity, though operate better with water of type I purity, which is even more filtered.[136]

6.3.2 Air quality

An electrolyzer itself does not produce gaseous emissions other than H_2 and O_2. Any emissions associated with electrolysis will therefore come from its power supply. A full life-cycle analysis study of electrolyzer options fueled by different energy sources in Colombia found that wind-powered electrolysis was the most air quality-friendly option when looking at methane (CH_4), CO_2, NO_x, SO_x, and particulate matter emissions.[137] Any fossil-free, renewable energy supply will minimize emissions for electrolysis, with remaining life cycle emissions profiles reflecting third-order, upstream (manufacturing and construction) and downstream (end-of-life) related emissions.

In contrast, generating hydrogen via biomass gasification can create direct air pollutants, including carbon monoxide (CO), NO_x, methane (CH_4), and a small amount of soot (particulate matter[138]),[139] although if the feedstock source for gasification is agricultural waste, forest waste or municipal waste that would otherwise have degraded through crop burning, wildfire or landfill decomposition, the net effect of using gasification on air quality

[139] Ahmed *et al.* (2019) Emissions factors. p. 221. [1]

is likely to be an improvement. There are few published studies comparing emissions from biomass gasification to combustion (what happens in bioenergy generation plants) or open burning, but what information is available suggests a significant reduction in criteria pollutants with gasification. Examples include a comparative study of coal gasification versus traditional coal-fired powerplants by the National Energy Technology Laboratory.[140] Their study showed a significant decrease in SO_x, NO_x, particulate matter and CO_2 emissions in gasification relative to traditional combustion. While the feedstock is different, the organic matter in coal and the organic matter in biomass can be expected to respond similarly to thermochemical processing. Another study found that less NO_x, CO, CH_4, CO_2 and soot was emitted from small scale biomass gasification plants, when compared to open burning.[141] And finally, the planned San Joaquin Renewables facility (described in Section 4.1.2.7) anticipates the emissions impact of their gasification facility will be far more favorable than open pile burning (commonly employed in the San Joaquin Valley today) —with a minimum of a 95% reduction in VOCs, 96% reduction in NO_x, 99% reduction in CO, and 99% reduction in particulate matter released relative to biomass burning.[142]

Blue hydrogen from SMR with CCS also produces both criteria air pollutants and greenhouse gasses aside from CO_2.[143] These emissions included VOCs, NO_x, CO, SO_2 and both large (PM_{10}) and small ($PM_{2.5}$) particulate matter* in the criteria air pollutants, and CH_4 and nitrous oxide (N_2O) as additional greenhouse gasses.[144] Researchers found that VOC, NO_x, and CO emissions per kilogram of hydrogen produced decreased as facility size increased, with an anticipated cause that larger facilities (in terms of expected hydrogen output) may have emissions control technologies that capture different pollutants.[145] Other emissions, though, showed little correlation with the facility size by anticipated hydrogen output, making it difficult to gauge how much other emissions categories can be effectively minimized.[146]

Finally, recent has identified some risk of using hydrogen as a fossil-alternative fuel, due to hydrogen's ability to act as an indirect greenhouse gas, warming the atmosphere on short-term (years to decadal) timescales.[147] When combusted, hydrogen reacts with oxygen to form water vapor, which in the stratosphere, can trap heat. Hydrogen that leaks from operations or is offgassed can also drive production of other greenhouse gasses, including

[140] NETL (no date) Emissions advantages of gasification. [49]

* Particulate matter emissions are often reported in terms of the size of the particles—PM_{10} refers to particles smaller than 10 micrometers (μm), and $PM_{2.5}$ to particles smaller than 2.5 μm.

[144] Sun *et al.* (2019) Criteria Air Pollutants and Greenhouse Gas Emissions. p. 4. [75]

[145] Sun *et al.* (2019) Criteria Air Pollutants and Greenhouse Gas Emissions. p. 16. [75]

[146] Sun *et al.* (2019) Criteria Air Pollutants and Greenhouse Gas Emissions. p. 16. [75]

[147] Ocko, Hamburg (2022) Climate consequences of hydrogen emissions. p. 9349. [54]

methane, ozone, and water vapor in the atmosphere, mostly through indirect pathways.[148] Although both hydrogen via electrolysis and hydrogen via SMR + CCS will have significant climate benefits compared to fossil fuel systems on 100-year timescales by reducing the amount of CO_2 released to the atmosphere, some studies suggest that in the short term (first 20 years after adoption), green hydrogen via electrolysis may only halve the impact of emissions from fossil-fuel use and blue hydrogen via SMR + CCS could potentially worsen immediate climate impacts by increasing emissions of methane and hydrogen in the short term.[149]

When used as a fuel, hydrogen can also generate NO_x in the atmosphere. During hydrogen combustion, enough heat is present to cause atmospheric nitrogen and oxygen to form NO_x in an endothermic reaction.[150] Atmospheric NO_x can have detrimental effects for humans, including respiratory symptoms like the development of asthma, as well as environmental harms, including acid rain and nutrient pollution in waterways and coastal areas.[151] NO_x emissions from hydrogen boilers or engines can be minimized by controlling combustion conditions or by scrubbing NO_x from post-combustion flue gasses.[152]

Ultimately, any project sited in Kern County, California, including those developed in a carbon management park like that examined here, would be considered through a public process, where the environmental impacts specific to the technologies and fuels being used in any given facility will be reviewed and mitigated in accordance with the California Environmental Quality Act (CEQA).

6.3.3 Other potential impacts

In many cases, hydrogen fuel is not the most effective solution for reducing greenhouse gas emissions—if a technology can run directly on clean energy or renewable electricity, that is typically a much more efficient power source.[153] However, for industries and processes that are difficult to electrify, hydrogen could be an excellent alternative to fossil fuels. Hydrogen has been explored as a fuel for heavy-duty transport (planes, freight rail, or trucking) or to produce the heat necessary to create products like ceramics, steel, and concrete.[154,155,156] In the context of a carbon management business park, where several industries could be co-located, on-site production of hydrogen may provide a valuable industrial heat energy source. However, a detailed techno-economic and environmental

[156] Roberts (January 31, 2023) This climate problem is bigger than cars and much harder to solve. [68]

impact analysis will be crucial when considering whether hydrogen is the most cost-effective and environmentally-efficient fuel option for such industries.

6.4 Economic Impacts

6.4.1 Business Model

Hydrogen is the primary product of electrolysis, biomass gasification and SMR with CCS, and in the future will most likely be sold primarily as a fuel product for transportation and industrial uses. Today, the infrastructure required for such end-use applications is not yet well established. Thus, most hydrogen currently produced goes to other purposes, such as in oil refining, to remove sulfur from natural gas distribution streams or in the production of synthetic fertilizers.[157, 158] Global demand for hydrogen has been steadily rising since 1975, both for direct applications (in oil refining and ammonia production) and indirect applications (methanol, synthetic fuels, and direct reduced iron steel production).[159]

Currently, the costs of hydrogen production are cheapest for more environmentally destructive processes like gray hydrogen, with blue and green forms of hydrogen being the most expensive. In 2020, the cost to generate a kilogram of hydrogen was $0.70 for SMR with no CCS (gray hydrogen), $1.30 for SMR with CCS (blue hydrogen), and $3 for solar-powered electrolysis (green/yellow hydrogen).[160] The cost differential is primarily due to the significantly higher energy demand (and thus energy cost) of electrolysis relative to steam methane reforming.[161] Any opportunities to lower the energy costs of electrolysis can therefore help this technique become cost competitive with gray hydrogen production. For example, when created using excess renewables from the grid, the production cost goes down to about $1.60 per kilogram (in 2020 dollars).[162] Depending on the availability of excess renewable resources in coming years, green hydrogen could become cost competitive with blue hydrogen within the next decade.[163] If a carbon tax were to be imposed, nationally or internationally, on CO_2 emitting power generation processes, like gray hydrogen, that could also equalize the cost differential between production methods, by penalizing the more environmentally destructive gray hydrogen production.[164]

Currently, the high cost of green hydrogen is considered to be the "brick wall" for global hydrogen production—it does not make sense to scale up production or end-use infrastructure until there are efficient and cheap ways to generate hydrogen that also do

[164] Climate Now (October 18, 2021) Pricing carbon around the globe. 01:21. [17]

not contribute to greenhouse gas emissions, and solutions to the barriers to reaching commercial scale and competitive market costs in this space have yet to be realized.[165] In the United States, a tax incentive designated in the Inflation Reduction Act (IRA) of 2022 could change this picture by making environmentally-friendly hydrogen production methods more economically favorable. Under the new tax incentive, producers of hydrogen with 'near-zero emissions' can earn $3 per kilogram of hydrogen produced with no cap on the number of kilograms the producer can receive the incentive for.[166] This is exceptionally good news for hydrogen generated via electrolysis with renewable energy, as $3/kilogram is about the average cost of production, so any sales of their hydrogen would be profit. The exact structure of these benefits, however, will depend on rules that are still being written by the Treasury Department; until they have developed a clear definition for 'near-zero emissions,' it is difficult to guess what standards a producer would need to meet to be eligible for the $3/kilogram incentive.[167] In a worst-case scenario, the benefits could flow to companies that are still releasing large amounts of greenhouse gas emissions in the hydrogen production process, either via using methane as a feedstock or relying on grid electricity generated by fossil fuels to meet the high energy demands of electrolysis or gasification.[168]

Two other potential revenue streams are worth noting. First, in California, Low Carbon Fuel Standard credits (LCFS, see Section 2) are designed to promote switching from fossil fuels to low-carbon fuels in the transportation sector, and could provide an additional revenue stream for green hydrogen projects (from electrolysis or biomass). However, any hydrogen produced from fossil fuels—including blue hydrogen formed from SMR + CCS—would be ineligible for LCFS credits.[169] From 2018-2022, the LCFS credit has ranged from $62-218.[170] Second, federal incentive 45Q provides a tax benefit for CO_2 capture and storage processes other than direct air capture (DAC) of $85 per ton stored, for which green hydrogen via biomass gasification and SMR + CCS could be eligible. Hydrogen producers would need to choose between the 45Q and 45V federal tax credits; they cannot receive both.[171]

6.4.2 Business Costs

6.4.2.1 Cost to build (upfront costs)

The cost and efficacy of electrolyzers is projected to become more favorable in the near-term future, given that this field has seen greater investments in research and development

and economies of scale.[172] There are a wide range of levelized cost estimates available, but costs for large electrolysis facilities are poorly established. Additionally, these cost estimates vary widely based on capacity and the type of electrolyzer in question. A small PEM electrolyzer generating one cubic meter of hydrogen (≈11.126 kg H_2) per hour would likely be less than $8,000, but a commercial-scale facility would require a much larger capacity, either by running a lot of small units or building specialized large electrolyzers.[173] A compilation from the International Council on Clean Transportation (ICCT) of levelized capital cost estimates for different types of electrolyzers as a function of their price per kW and price per kg H_2 is presented in Table 6.1.[174] In general, alkaline electrolyzers are the cheapest to purchase upfront, primarily because they do not require any precious metals to operate.[175,176] Alkaline electrolyzers have a longer expected lifetime than PEM electrolyzers as well.[177]

Another study, which focused only on PEM electrolyzers, is consistent with the ICCT's meta-analysis. They provide an estimated total levelized cost of production that incorporates capital and energy costs. Depending on whether grid energy, solar, or wind is used, production costs of electrolysis facilities with existing technology varied between $4.22 and $6.27 per kilogram of hydrogen produced.[178]

For AE electrolyzers, the largest share of the capital cost is devoted to the electrolyzer stack, accounting for 50% of the estimated capital costs.[179] Although large alkaline electrolyzers have been built before in North America, Africa, Asia, and Europe, most large facilities were decommissioned in the late 20th century, so there are large uncertainties in projecting current costs for a new alkaline electrolyzer facility based on the costs of existing stock.[180] For PEM electrolyzers, about 60% of the capital cost is associated with the electrolyzer stack.[181]

Costs for electrolyzers are expected to decline sharply with advances in the electrode and membrane materials and improvements in manufacturing.[182,183] Additional, economies of scale resulting from significant increases in production capacity are expected to further

c. For IEA (2019), cost estimates described as 'long term.'

For biomass gasification that generates hydrogen and CO_2, the capital cost of a facility that could capture 1 million tons of CO_2 would be ~$278 million to $328 million.[189] If the facility operated for 30 years, the capital costs over the lifetime of the facility would be ~$24-52 per

[188] Christensen (2020) Costs from Electrolysis. p. 18. [16]

[189] Wu *et al.* (2023) Carbon capture in hydrogen production by biomass gasification. p. 6. [85] Note: In figures in Wu, Lan, and Yao (2023), these estimates appear lower (approximately $241 to $285 million) as they correspond to a facility capturing 868,000 metric tons of CO_2 per year (see the supplementary material, Table S4 for CO_2 capture rates by scenario). In this report, all Wu, Lan, and Yao (2023) estimates are presented in-text as scaled figures for a million ton facility, to ensure consistency between carbon management industries when possible.

ton of CO_2 (assuming a capital recovery factor of 7.5-12.5%; see Section 3.4.3.1 for details).[190] Both capital and operating costs for biomass-based hydrogen production vary depending on the energy source, which varies across plant designs. In general, self-sustaining plants—which can meet their own energy needs—are the most expensive to build, but have the lowest operational costs.[191] Plants that receive some or all of their energy from external sources are typically cheaper to construct, but more expensive to operate and maintain.[192] It is worth noting that the cost range for most biomass plants, as outlined in Section 4.4, exceeds the range presented here. As the cost estimates here are derived from a single study, and it is likely that hydrogen production via biomass gasification will closely resemble other biomass-based plants, considering the larger variability in capital costs of biomass-conversion facilities in general may be worthwhile.

For SMR facilities in general (gray and blue hydrogen), there are a large number of constituent parts required to contain the entire reaction sequence and limit the escape of pollutants like particulate matter and NO_x.[193] Adding CCS equipment to the SMR process (blue hydrogen) generally results in an estimated capital cost increase of 50%.[194] When also accounting for the operation and maintenance of a facility over its lifetime, however, the distributed cost addition of carbon capture to SMR is anticipated to result in a ~13% increase in total levelized production cost.[195] A recent techno-economic study of hydrogen production for SMR + CCS estimated a levelized capital cost of $0.28/kg hydrogen.[196] This model assumes that SMR without CCS emits 8.5 kilograms CO_2 per kilogram hydrogen but SMS with CCS emits only 1.2 kilograms of CO_2. Thus, we can estimate that for every kilogram of hydrogen produced via SMR + CCS, 7.3 kilograms of CO_2 will be captured.[197] If we assume a facility capturing 1 million metric tons of CO_2 per year, it will generate about 137,000 tons (or 137 million kg) of hydrogen per year. For a capital recovery factor (crf) between 7.5 and 12.5% (see Section 3.4.2.1),[198] the cost to build such a facility would be about $300-510 million USD.

This estimate is relatively well-aligned with planned investment in the Air Products facility currently being constructed in Louisiana. Air Products states that it will cost about $4.5 billion to build, own, and operate their facility with a capture capacity of over 5 million tons of CO_2 annually.[199] Scaling capital expenditures of $300-510 million USD/ton CO_2 to a 5

million ton facility, suggests that capital costs will represent one third to over half of the total investment costs, the remainder presumably coming from operation, maintenance and the cost of the feedstock methane.

6.4.2.2 Operational costs

For an electrolyzer, the stacked membranes inside the machine must be replaced about every 7 to 10 years.[200] The British government estimates the replacement period for electrolyzer membrane stacks varies with the technology type, with alkaline stacks requiring replacement every 9 years, PEM stacks requiring replacement every 11 years, and SOE stacks requiring replacement every 7 years, assuming a 30-year facility lifetime.[201] Fixed operational costs will also include labor, administrative costs, maintenance, insurance, and taxes.[202] Alkaline electrolysis systems also have relatively high maintenance costs throughout their lifetimes due to the variety of equipment needed to pump, clean, and store the electrolyte solution and to filter out and clean the hydrogen.[203] The ICCT economic analysis of electrolysis states that most techno-economic models estimate fixed operational costs (labor and maintenance) as 1-3% of capital expenditures. Based on the range of capital costs summarized in Table 6.1, fixed operation costs of modern electrolyzers are about \$4-84 USD/kW (or \$0.02-\$0.32 USD/kg H_2), with their preferred operating cost estimate of \$40-50 USD/kW (\$0.15-0.19 USD/kg H_2).[204] Variable costs will largely be electricity costs, which can vary considerably over time (and even be zero, if a facility is using excess energy from renewables or the grid). The ICCT model estimates variable operating costs of \$0.08 USD/kg H_2.[205]

For a biomass gasification plant, operational costs are expected to range from approximately \$60 million to \$101 million for a facility capable of capturing a million metric tons of CO_2 annually.[206] The feedstock costs—amounting to approximately \$44 million annually—are the largest share of the operating costs.[207] If these costs were reduced, it would lower the annual operating expenses notably. The next big cost categories come

[206] Wu *et al*. (2023) Carbon capture in hydrogen production by biomass gasification. p. 6. [85] Note: In figures in Wu, Lan, and Yao (2023), these estimates appear lower (approximately \$52 to \$88 million) as they correspond to a facility capturing 868,000 metric tons of CO_2 per year (see the supplementary material, Table S4 for CO_2 capture rates by scenario). In this report, all Wu, Lan, and Yao (2023) estimates are presented in-text as scaled figures for a 1 million ton facility, to ensure consistency between carbon management industries when possible.

[207] Wu *et al*. (2023) Carbon capture in hydrogen production by biomass gasification. p. 6. [85]

from chemical, material, and utility costs, while labor, maintenance, and waste treatment make up a relatively small amount of the operating expenses.[208] These operational costs, combined with capital costs, result in a total levelized cost of about $2.50-$3.60 per kilogram of hydrogen produced, which translates to an estimated range of $125-257 per metric ton of CO_2 captured.

Finally, for any SMR plant, the majority of operational costs are variable; they depend on the cost of methane (natural gas) in the market at a given time, and can account for 45-75% of overall production costs (including capital costs).[209] However, the addition of a carbon capture component also adds additional operating costs and maintenance responsibilities for an operator.[210] In modeling SMR + CCS with a 90% carbon capture rate, the estimated variable operating cost (the energy costs for running the facility) amounted to $0.88 per kilogram of hydrogen,[211] and the additional costs for carbon capture, including separation, purification, compression, pipeline transport, and injection add up to about $0.60/kg hydrogen,[212] or $82 USD/ton CO_2.[213] Translated to total annual operating costs for a facility capturing one million metric tons of CO_2 each year, these amounts should come out to approximately $120 million USD and $82 million USD, respectively, and combined with the estimated capital expenditures, the total levelized production cost of SMR + CCS is ~$1.76 USD/kg H_2.

6.4.3 Regional benefits

California is already among the top three hydrogen-producing states in the U.S.[214] Additionally, the hydrogen market is strong in California—the state is home to 71% of all fuel cell EVs in the county and maintains the largest number of hydrogen fueling stations by far.[215] California also hosts a wide variety of industries that would be hard to fully electrify (such as cement and concrete manufacturing), thus making them prime candidates to transition to alternative fuels like hydrogen.[216] A large amount of credit for the growth of the hydrogen market in California is due to the state's carbon cap-and-trade program, which incentivizing the growth of hydrogen through a carbon credit marketplace.[217] With

existing demand already in the region and sector-wide growth anticipated, Kern County is a promising locale for companies looking to develop hydrogen fuels.

6.4.3.1 Proximate feedstocks

For hydrogen produced via biomass gasification, Kern County's agricultural waste could become a supply of feedstock to generate hydrogen and capture CO_2. This theme is touched upon at greater length in Section 11.2.1 on the potential relationship between local agriculture and biomass-based carbon management facilities. For SMR+CCS, Kern County is home to the state's largest oil and gas fields and produces 78% of the state's total natural gas production.[218]

6.4.3.2 Proximate consumers

As mentioned above, one of the strengths of locating in the region would be a proximate consumer base. All of the approximately 15,000 consumer cars in the U.S. that are fuel cell EVs are located in California, which is the only state with a network of retail hydrogen fueling stations to make them usable.[219] Kern County's proximity to the port of Los Angeles, the busiest shipping port in North America,[220] also holds promise for the hydrogen industry - both as an access point for international trade, and because hydrogen holds potential as a fossil-free fuel source for the shipping industry.[221]

6.4.3.3 Co-location advantages

Locating alongside carbon management industries could have benefits for a hydrogen production facility. If generating hydrogen via electrolysis, an electrolyzer could utilize water generated as a byproduct of some carbon management industries, such as S-DAC (Section 3), depending on the water quality.

If generating hydrogen via steam reforming and CCS, co-location could have multiple benefits. Steam reforming and the water-gas shift reaction could similarly use water generated from other industries in their production process, and the transport and sequestration needed for permanent underground storage of CO_2 could be shared infrastructure with other carbon management industries in the park.

6.4.3.4 Other

For hydrogen production via electrolysis, which relies on renewable energy to avoid carbon emissions, California and the American Southwest is a highly promising region to bring down production costs, given the extremely high solar and wind energy potential in the region (Figure 6.5). Given the significant impact that electricity costs have on the market

[218] KEDF (2021) The economic contribution of the oil and gas industry in Kern County. p. 1. [42]

competitiveness of green hydrogen from electrolysis, the renewable energy potential of Kern County and the surrounding region is a remarkable asset for this industry.

7. Battery and Energy Storage Solutions

TECHNOLOGY AT A GLANCE

- Energy storage solutions come in a wide variety of form, many of which are fully commercial, and others of which are still in early research and development stages.[1]
- Lithium-ion batteries are currently the most widely used technology for utility-scale energy storage.
- Installation of large energy storage facilities is unlikely to create many jobs, but can produce a variety of societal benefits, like eliminating the need of fossil-based peaker power plants, and providing increased grid reliability.
- Adding energy storage to solar or wind power supplies increases the cost by ~$5-39, but the cost of batteries has decreased 97% in the last 3 decades, and is projected to continue becoming less expensive.
- Key advantages of this technology to Kern County: it ensures a continuous clean energy supply to any industries sited in a carbon management park, and potentially to the local grid, and can provide a fossil-free source of industrial heat to industries that require it.
- Key concerns for this technology in Kern County: environmental and safety risks vary by battery type, and further assessment to identify the optimal storage approach for the region and needs of the carbon management park will be necessary.

[1] Values in this section are summarized from the suite of references cited herein, and are explained in further detail in each subsequent section.

7.1 Technology Summary

Since 2020, wind and solar energy have become the cheapest form of electricity generation in most parts of the world, and their costs have continued to decrease year over year.[2,3] The sunny and arid climate of Kern County is particularly well suited for these renewable energy sources, and as such is host to the largest commercial solar project and among the largest commercial wind energy projects in the United States.[4] Such abundant, fossil-free energy is particularly attractive to carbon management industries for two reasons. First, many carbon management industries are energy intensive, with energy costs representing their largest operational expense. Thus, minimizing the price per kWh of electricity used is critical to ensuring facilities are economically viable. Second, most carbon management industry's business model depends on the *net* amount of CO_2 removed or prevented from entering the atmosphere, which means that if such industries are powered by carbon-emitting fuels, their carbon capture efficiency (and thus potential for revenue) is reduced.[5]

Wind and solar are examples of variable renewable electricity (VRE) – they only generate electricity when the sun is shining or the wind is blowing, and the intensity of the electricity the generate depends on weather conditions.[6] Battery storage solutions are a way to smooth fluctuations in energy supply, by storing excess energy generated by renewables during highly productive periods and then releasing that energy to meet electricity or heat demands during periods of lower productivity.[7] For solar energy, for example, this could mean storing excess energy during the day and releasing it at night, when the sun is not out to generate additional power.

To support renewables and decarbonization objectives, the International Energy Agency (IEA) predicts that globally, energy storage will need to scale up to 266 GW of storage capacity by 2030—in 2017, global energy storage capacity was 176.5 GW—to keep climate change under 2°C of warming.[8] To support the development of a clean energy and carbon management industrial park in Kern County, it is worth assessing the degree to which energy storage solutions would need to be integrated with local renewable energy generation in order to provide sufficient, continuous power that meets the needs of any industries locating within the park.

7.1.1 Description: How it works

In this report, we define energy storage technologies as devices that take in any form of renewable energy, store that energy in various forms, and then release energy as electricity

[2] Masterson (July 5, 2021) Renewables were the world's cheapest source of energy in 2020. [33]
[3] Lazard (2021) Levelized cost of energy. [28]
[4] CSUB (no date) Energy in Kern County. [5]

[8] EESI (February 22, 2019) Fact Sheet | Energy Storage. [20]

or heat to be used on demand. A summary of the more widely used energy storage technologies are listed in Table 7.1, along with the characteristics of each storage type that typically define its most suitable applications.

As the aim here is to understand storage solutions that could support a carbon management park in Kern County, we will focus on off-grid technologies with rechargeable, industrial-scale potential that can provide intermediate to longer-duration storage, and will produce energy in the form of electricity or in the form of heat. Some energy storage solutions are eliminated based on Kern's geography and resources. For example, pumped-storage hydropower (PSH) systems have been used in the United States for a century, and currently constitute 95% of energy storage facilities nationally, but are a poor fit for Kern given its largely arid climate.[9] This section will also cover hydrogen-based batteries, with the assumption that the hydrogen utilized for this energy storage is produced through low-carbon processes—for more on hydrogen production, please refer to Section 6 of this report.

Table 7.1. Characteristics of selected energy storage types.[10]

	Max Power Rating (MW)	Discharge Time	Max Cycles or Lifetime	Energy Density (Wh/l)	Round-Trip Efficiency
Pumped hydro	3,000	4h - 16h	30-60 years	0.2-2	70-85%
Compressed air	1,000	2h - 30h	20-40 years	2-6	40-70%
Molten salt (thermal)	150	hours	30 years	70-210	80-90%
Li-ion battery	100	1min - 8h	1,000-10,000 cycles	200-400	85-90%
Lead-acid battery	100	1min - 8h	6-40 years	50-80	80-90%
Flow battery	100	hours	12,000-14,000 cycles	20-70	60-85%
Hydrogen	100	mins - week	5-30 years	600 (at 200bar)	25-45%
Flywheel	20	secs - mins	20,000-100,000 cycles	20-80	70-95%

7.1.1.1 Electricity storage

Most of the batteries discussed in this report rely on the same basic electrochemical process: reduction-oxidation (redox) reactions. In redox reactions, electrons move between one molecule and another molecule; the substance losing electrons is oxidized and the substance gaining electrons is reduced.[11] It may sound counterintuitive that the substance

[9] EESI (February 22, 2019) Fact Sheet | Energy Storage. [20]
[10] EESI (February 22, 2019) Fact Sheet | Energy Storage. [20]
[11] Chemistry LibreTexts (July 1, 2019) Batteries. [9]

gaining electrons should be 'reduced', but reduction is referring to the overall charge of a particle, not how many electrons it has. Because electrons are negative, the overall charge of the substance gaining electrons will be a less positive number; it will be reduced.[12]

In a battery system, the site where oxidation (electron loss) occurs is called the anode, and the site where reduction (electron gain) occurs is called the cathode.[13] These processes occur simultaneously in a redox reaction, and the electrons lost in one part of a battery system will be the same as the electrons gained in another part of the system. When these redox processes occur with a wire to capture the electric charge, it constitutes an electrochemical (or Galvanic) cell—the basic principle of most electric batteries.[14] Here, we explore three types of electrochemical batteries: lithium-ion, flow, and molten salt. While the constituent parts of each of these electric batteries can look quite different, they all share the components shown in Figure 7.1: in addition to the cathode and anode, there is an electrolyte, separator, and two current collectors.[15] The role of each of these components when a battery charges or discharges can be described in the context of each of the four battery types that are detailed below.

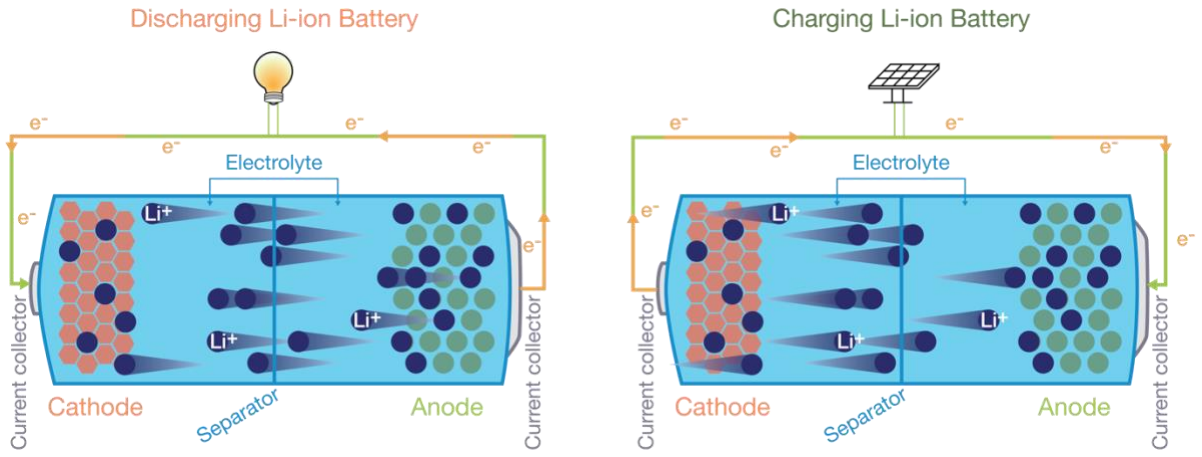

Figure 7.1. Schematic of lithium-ion electric battery storage.[16]

Lithium-ion batteries

Lithium-ion (Li-ion) batteries are what are typically used for mobile energy storage applications, such as in consumer electronics like cell phones, and in electric vehicles.[17]

[12] Chemistry LibreTexts (July 1, 2019) Batteries. [9]
[13] Chemistry LibreTexts (July 1, 2019) Batteries. [9]
[14] Chemistry LibreTexts (July 1, 2019) Batteries. [9]
[15] Minos (February 28, 2023) How lithium-ion batteries work. [35]
[16] Minos (February 28, 2023) How lithium-ion batteries work. [35]
[17] EESI (February 22, 2019) Fact Sheet | Energy Storage. [20]

During a discharge cycle (when energy is being released from the battery), lithium that is stored in the anode gets ionized, meaning it converts to a lithium ion (Li^+) and an electron.

$$Li^o \rightarrow Li^+ + e^- \quad \text{(R7.1)}$$

The lithium ion is carried through the battery via the electrolyte, a liquid solution containing dissolved salts, to the cathode. A porous separator allows the lithium ions to pass through the electrolyte solution towards the cathode, but prevents the passage of electrons within the battery structure. Thus, the cathode becomes concentrated with positively charged lithium ions, and the electrons collect near the negative current collector. The charge differential drives the electrons to travel along the external electrical circuit, creating an electric current that can provide electricity to an external device. Electrons are collected at the positive current collector, and recombined with the lithium ions, to form elemental lithium that is stored in the cathode. When all the lithium has migrated from the anode to the cathode, the battery is "empty" and needs to be recharged. Charging the battery works in the reverse direction of discharging: lithium ions are released by the cathode and received by the anode.[18,19]

$$Li^+ + e^- \rightarrow Li^o \quad \text{(R7.2)}$$

Advantages of the Li-ion battery is that it is highly efficient and energy dense (Table 7.1), being able to discharge as much as 90% of the energy used to charge, and able to provide a large amount of power from a relatively small battery, which is why these are particularly advantageous for mobile applications like phones, laptops and cars. Typically, these types of can supply a charge for a few hours, and they can go through the discharge/recharge cycle about 1,000-10,000 times,[20] meaning they usually need to be replaced within ~10 years.[21]

Flow batteries

Flow batteries can exist in a variety of forms and designs, but are primarily distinguished from standard rechargeable batteries (like Li-ion batteries) because the electroactive materials in a flow battery are dissolved within electrolyte solutions, rather than stored within one or the other electrode as they are in conventional rechargeable batteries (Figure 7.2).[22]

In a flow battery, the electrolyte solution is stored in two separate tanks, with an anolyte tank replacing the anode and a catholyte tank replacing the cathode in a standard electrochemical cell.[23] These tanks are separate from regenerative cell stacks (or the reaction unit), wherein electrolytes are pumped in from the tanks to charge and discharge

[18] Minos (February 28, 2023) How lithium-ion batteries work. [35]

[23] IRENA (2017) Electricity Storage and Renewables. p. 86. [26]

the system using reversible chemical reactions.[24] The separate tanks can remain charged for long periods without experiencing degradative effects, making them an appealing solution for long-term energy storage.[25]

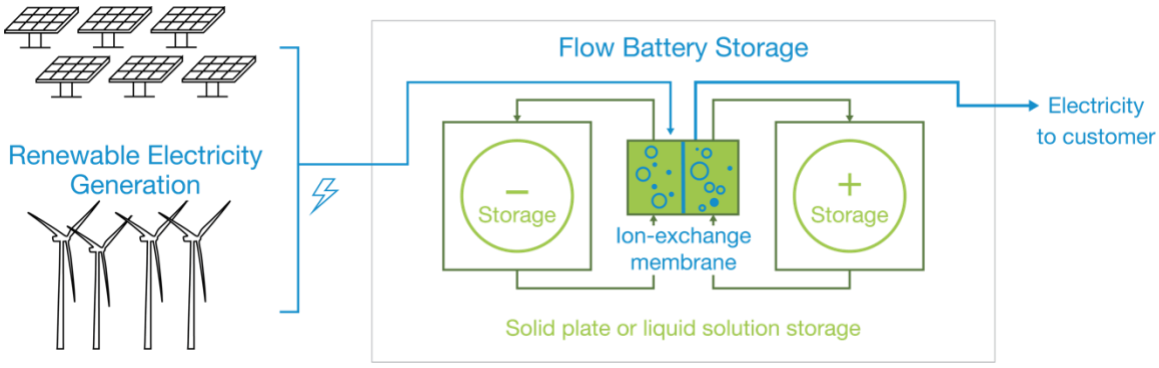

Figure 7.2. Schematic of flow battery electricity storage.

A flow battery is considered 'pure flow' if both the anolyte and catholyte are stored outside the cell stacks and only flow in during operation; if one or more of the electrolyte materials are stored within the cell stacks, then the flow battery is considered to be a 'hybrid' flow battery.[26] Within this overarching split between pure and hybrid flow, there are other subcategories defined by the materials used or the physical state of the active materials, as seen in the IRENA categorization below (Figure 7.3).[27]

Flow batteries are attractive for stationary applications as they are 100% recyclable, nonflammable, easily rechargeable, and approach the same high efficiency of Li-ion batteries, but with much longer lifetimes.[28] Many battery storage providers are looking to scale up their flow battery capacities, particularly flow batteries that rely on vanadium,[29] a material that is abundant and does not degrade through charge/recharge cycles.[30] Canadian company CellCube has deployed vanadium flow batteries in Australia, Vietnam, and South Africa, and British company Invinity is working with the Energy Superhub Oxford to create the UK's largest flow battery system.[31]

Molten salt batteries

As the name implies, molten salt batteries use a salt, in a liquid, molten state to act as the electrolyte in an electrochemical battery. These systems are often called high-temperature batteries, as high temperatures are necessary to keep the active materials in a liquid state.[33] When the temperature is lowered, the molten salt "freezes," or solidifies, allowing them to store their charge in an inactive state for up to months at a time.[34] Molten salt technologies are the most common kind of "thermal electricity storage", currently accounting for about 75% of global thermal storage capacity.[35] (Although these batteries operate at high temperatures, they deliver energy as electricity rather than heat, hence their categorization as electricity storage rather than as heat storage.)

In one example of the molten salt battery – the sodium beta battery – the anode is molten sodium while the cathode (and membrane) is constructed of beta-aluminum (β''-Al_2O_3).[36] The system works by using sodium ion transport across the membrane to store or release energy from the battery.[37]

A similar iteration of the high-temperature battery replaces the beta-aluminum with molten sulfur as the cathode and is known as the sodium sulfur (NaS) battery.[38*] The anode and cathode are separated by a solid ceramic of sodium alumina, which only allows positively-

* Element S can be spelled as sulfur (American English) or sulphur (British English). In this report, all references have been standardized to American spelling, but the original source uses British spelling. Both spellings refer to the same element.

charged sodium ions to pass through its surface.[39] Operation relies on the system maintaining temperatures of 300-350°C to keep the active materials liquid, which can make it difficult for these batteries to operate intermittently.[40] However, these systems are highly efficient, with an average efficiency of 89%.[41] Sodium sulfur batteries are already installed at dozens of sites in Japan and Abu Dhabi, assisting with voltage control and power reliability.[42]

Currently, molten salt tanks (while molten) lose about 1% of their stored heat per day—after two weeks, their capacity has gone down to about 85%.[43] Research conducted at Pacific Northwest National Laboratory (PNNL) demonstrated that freezing and thawing molten salt creates a rechargeable battery that stores energy more effectively and inexpensively for weeks or months on end.[44] If scaled up, these research findings could help make the most of the high efficiency of these batteries by extending the timespan they can effectively store energy for future use.

7.1.1.2 Compressed Air Energy Storage (CAES)

Compressed air energy storage (CAES) systems do not rely on a chemical process, but rather in storing energy through pressurized air that can then be deployed as necessary. It does this by compressing ambient air (or another gas) and storing it at high pressure underground—when additional electricity generation is required, the compressed air is heated and expanded in a turbine connected to a generator, producing power.[45]

Utility-scale CAES was first deployed in the 1970s, at capacities of around 290 MW, so the technology is well-established and understood even for large-scale storage needs.[46] CAES systems now encounter high costs associated with storing compressed air and relatively low capacities for these systems, with research and development efforts for this technology focused on addressing these obstacles.[47] Estimated efficiencies for CAES range from 40-70%.[48]

7.1.1.3 Thermal/heat storage

Energy does not always need to be stored, or delivered, in the form of electricity. For some industrial and commercial facilities, storing heat energy is more important for sustaining

their operations. This includes steel, iron, cement, and chemical manufacturing, which all require high heat to fuel their primary processes.[49] Globally, about half of the world's energy consumption is in the form of heat energy.[50]

Most thermal energy storage systems rely on heating a medium—like water, salt, or rocks—and then placing this material in an insulated environment so it retains heat.[51] The type of medium used to store energy determines the system's classification: sensible (water and rock), latent (water, ice, or salt hydrates), and thermochemical reactions (i.e. chemical reactions and sorption processes).[52] In sensible storage, when heat is needed, cold water is pumped onto the heated material to generate steam (Figure 7.4).[53,54] Depending on the needed energy use, the steam can be used directly to heat a facility, or indirectly to turn turbines and generate electricity.[55] If the heat is converted back into electricity for use, the system averages only 47% round-trip efficiency (i.e. only 47% of the power put into the system as electricity will come back out as electricity).[56] In contrast, delivering stored energy in the form of heat can have a round-trip efficiency as high as 90%.[57] Thus, using the heat directly is ideal where possible, but relies on the industrial heat needs of co-located processes.

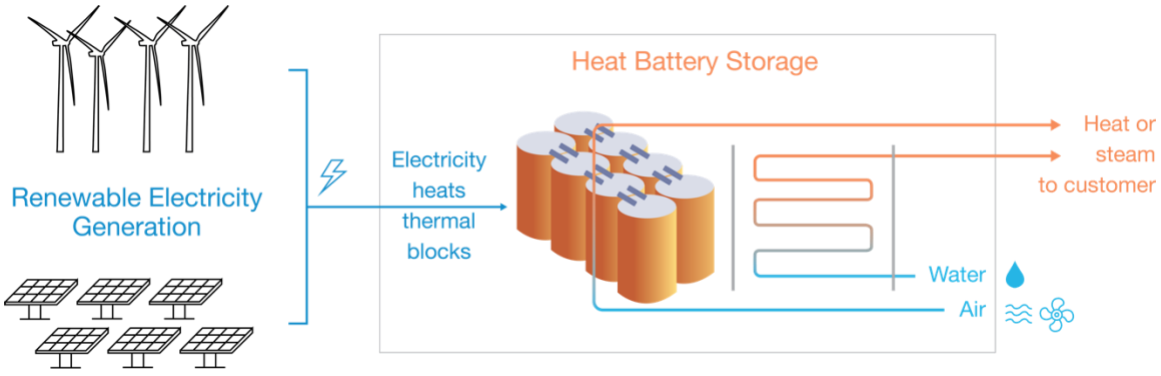

Figure 7.4. An example of sensible thermal storage, modeled after the operational design of Rondo Energy (see Section 7.1.2.1).

Whereas sensible storage relies on changing the temperature of the storage medium to release or absorb heat as needed, latent systems change the phase of the material without

changing the temperature to release energy—both a phase change and temperature change can occur in the same material concurrently, though.[58] The last system type, thermochemical, relies on chemical reactions taking place on the surface of a material to release or absorb heat. These systems can adapt renewable energy into heat to be stored and released, or capture waste heat for use in other processes.[59]

Utility-scale heat storage systems can balance energy supply and demand across timescales from daily to seasonally,[60] making them a versatile solution for both short- and long-term needs. Since most of the processes addressed in this report require heat rather than cooling, we emphasize the capacity of this technology to store heat energy, but the process can work conversely, to provide residential or industrial cooling.[61]

7.1.1.4 Hydrogen Fuel Cells

Fuel cells are another energy storage solution that can be deployed to support energy needs in a range of sectors, including transportation, commercial and residential buildings, and for industrial-scale energy storage.[62] Fuel cells operate similarly to batteries, but rather than cycling back and forth between discharging and recharging the energy stored, fuel cells thermochemically transform fuel to produce electricity and heat. Therefore, fuel cells – much like a gasoline-powered car – can only produce energy for as long as fuel is being supplied. Although fuel cells can use a wide range of fuels to operate, most focus has been directed towards the potential of using hydrogen in fuel cells, given that their only byproducts are electricity, heat, and water.[63]

Like a standard chemical battery, fuel cells have an anode and a cathode placed on either side of an electrolyte.[64] Fuel is introduced at the anode and air is introduced at the cathode. The fuel molecules are separated to create positively charged ions (protons in the case of hydrogen) and electrons; the positively charged ions migrate across the electrolyte to the cathode, while the electrons move towards the cathode via an external circuit, creating an electric current. At the cathode, the positive ions and electrons reunite and react with oxygen from the air stream to form a new molecule in an exothermic (heat-generating) reaction.[65] For the case of hydrogen fuel, the reaction progresses as follows:

$$\tfrac{1}{2}O_2 + 2e^- + 2H^+ \rightarrow O^{2-} + 2H^+ \rightarrow H_2O + \textit{heat} \qquad \text{(R7.3)}$$

[63] EERE (no date) Fuel Cells. [41]
[64] EERE (no date) Fuel Cells. [41]
[65] EERE (no date) Fuel Cells. [41]

Over traditional combustion engines, fuel cells have many advantages—they operate at higher efficiencies, have fewer (sometimes zero) emissions, are quiet to operate, and do not form air pollutants on-site that harm human health.[66]

Currently, fuel cells are rarely used for utility-scale energy storage applications, although research and development programs, both publicly and privately supported, aim to increase the longevity and reliability of fuel cell systems, so that they can become a technologically and economically viable option.[67,68] The primary area of interest for utility-scale storage with renewable energy sources is *reversible* hydrogen fuel cells. Just like other hydrogen fuel cells, they generate electricity and heat using air and hydrogen fuel.[69] However, the systems can also function in reverse—when there's excess renewable energy available, these cells can store that energy in the form of hydrogen by using the excess renewable energy to break apart water into hydrogen and oxygen, a process known as electrolysis.[70] Then, this hydrogen can be used to fuel the cell when the intermittent renewable energy source declines,[71] helping to balance out energy production and energy use schedules. (A full exploration of hydrogen production via electrolysis is available in Section 6.1.1.2 of this report.)

Technological progress still needs to be made before reversible hydrogen fuel cells are commercially ready. One issue is that commercial-scale fuel cells and electrolyzers currently deploy different catalysts to support the electrolysis/combustion reactions. For one piece of equipment to do both jobs, a new device would need to be developed to get around these catalytic differences.[72] One has been developed, called a proton conducting fuel cell (PCFC), but the device cannot yet maintain the power output needed for most practical applications.[73]

7.1.2 State of Development

The state of development for these technologies is mixed, with some utility-scale batteries already having been commercially available for decades while others are still in the research and development space. Pumped hydropower storage and compressed air energy storage (CAES) are two examples of energy storage solutions that have existed for many decades.[74] The majority of newly-deployed utility-scale projects are focused on lithium-ion

batteries.[75] For those technologies that are still in development, the U.S. Department of Energy (DOE) is working to accelerate innovation, so that they can quickly reach commercial scale operations and contribute to national and international goals of rapidly decarbonizing the economy.[76] A summary compiled by the Massachusetts Institute of Technology (MIT) of development statuses for a variety of energy storage technologies, as well as the ancillary industries that support them (mining and processing of critical minerals, battery recycling or up-cycling, and development of infrastructure to support the production and distribution of hydrogen for fuel cells) is given in Table 7.2. Most technologies fall in a range of developmental stages because of ongoing innovations aimed at optimizing and scaling energy storage.

a. Shaded region(s) denote one or more technology types in the relevant stage of readiness. Because there are several battery types in each technology category, more than one current innovation status may exist.

One energy storage technology that we have not explored extensively in this report due to its still being in very early stages of development are metal-air batteries, in which electricity is released through the spontaneous oxidation of a common metal (i.e. zinc, iron,

[75] IEA (September 2022) Grid-Scale Storage. [25]
[76] Blaustein (May 6, 2022) Rechargeable Molten Salt Battery. [2]
[77] MIT (2022) The Future of Energy Storage. p. xiv. [32]

aluminum) by air.[78] A spontaneous reaction is one that is thermodynamically favorable - it will progress naturally without external forcing (like the addition of heat or pressure). As a corollary to other electro-chemical redox batteries, here the metal is the anode material during discharge and the cathode is a porous material that allows the air to pass through and react with the electrolyte to form hydroxyl ions. The hydroxyl ions react with the metal, producing oxidized metal and free electrons. For example:

$$FeO_{metal} + OH^- \rightarrow FeO(OH)_{goethite} + e^- \quad \text{(R7.4)}$$

Although a zinc-based metal-air battery was first proposed in 1878, they are most commonly used today in small, often disposable, consumer electronics, and their deployment for utility-scale storage has yet to be proven.[79] If metal-air batteries can be scaled, they would have key advantages over other battery types: their theoretical specific energies exceed standard lithium-ion batteries by magnitudes of 5 to 50, depending on the type of metal used, and do not have the same overheating risks as lithium-ion battery cells (see Section 7.2.2).[80] While, attaining these high specific energies has not yet been achieved in practice, and currently, these systems are not cost-competitive with most other types of electrochemical battery storage,[81] this example of the potential for innovation and development is worth keeping in mind. With the speed at which new technologies are evolving in the battery space, the utility-scale battery storage options that seem most practical now may look very different even in a few years.

7.1.2.1 Example projects

Electrical Storage: Fluence, headquarters in Arlington, Virginia

Fluence is an energy storage technology and service provider that is run by Siemens and AES. The company was launched in 2018.[82] Fluence provides grid-scale and industrial-strength energy storage solutions, with scalable energy capability ranging from 2 MW to >500 MW and discharge duration of 6+ hours. Their advanced lithium ion sealed cells come in modular packaging, pre-installed with the necessary battery racks and modules, heating and cooling system, power supply, controllers, and safety components.[83] Fluence offers both short- and long-duration units ("cubes") that can be configured and combined on a site; a short-duration cube is approximately 2.5 x 2.5 x 2.2 m, while a long-duration cube is 2.5 m x 2.5 m x 2.1 m.[84]

Heat Storage: Rondo Energy, Alameda, California

Rondo Energy converts wind and solar energy—either directly from the source or indirectly through the grid—into heat energy that can be stored and deployed as needed (see Figure 7.4).[85] This is an example of a sensible thermal energy system. When wind or solar energy is available, either through the grid or in an off-grid system, Rondo's process uses electric heating elements (called Joule heaters) to turn that electrical energy into high-temperature heat energy. The heating elements are placed near bricks, warming them to temperatures up to 1500°C (~2730°F). These bricks can store heat very effectively for long periods, with thermal losses of less than 1% per day. To release the heat for use, air is directed through the heated bricks, where it rises to temperatures over 1000°C (~1830°F)—the release of heat into the system can be easily adjusted by controlling the air flow out of the brick stack. This heat can then be delivered to a facility as superheated air or superheated steam, with temperatures, pressures, and heat medium (air or water) optimized to meet a facility's specific needs.[86]

7.1.3 Operational Needs

7.1.3.1 Physical footprint

Most energy storage sites report their size in terms of megawatt (MW) capacity, rather than a physical footprint. A good rule of thumb in the field is that per megawatt hour (MWh), the estimated land use for battery storage is 1,000 square feet.[87] The size will scale accordingly. Most energy storage applications require less than 10 acres of total land use.[88]

A battery storage facility called Saticoy, opened by Averon Asset Management in Ventura County in 2021, represents what a typical battery storage site in southern California would look like (Figure 7.5). It houses a 100 MW (or 400 MWh) energy storage system, enough to power the entirety of Ventura County for half an hour or the city of Oxnard for four hours.[89] The system is made up of 142 Megapacks, Tesla's utility-scale battery units, with performance management software from Power Factors.[90]

Another facility, Crimson Storage, is located on 2,000 acres of Bureau of Land Management (BLM) land in Riverside County, California (Figure 7.6).[91] As of the writing of this report, it

[92] Lewis (October 19, 2022) The world's largest single-phase battery. [30]

[93] Wagman (June 29, 2021) Averon opens 100 MW/400 MWh battery energy storage facility in California. [60]

The world's largest energy storage facility is Vistra Energy's Moss Landing Energy Storage Facility, with a capacity of 400 MW or 1600 MWh, also located in California (Monterey County).[94] In this project, battery units were stacked into a retrofitted turbine building in an old power plant that is approximately three football fields long.[95] Moss Landing is an interesting example of reusing existing energy infrastructure to meet new needs and the ability to stack battery units to reduce the land footprint of these facilities, both features that could inform the development of new energy storage projects.

7.1.3.2 Energy requirements

When assessing energy requirements for energy storage, the necessary metric to consider is round-trip efficiency. Not all of the energy that is stored in a battery can be used later—some amount of the energy is lost in the process. Depending on type of battery storage, the round-trip efficiency varies between 40-90% (Table 7.1), meaning that somewhere between 40% and 90% of the energy put into the battery can be withdrawn later for use.[96] Efficiencies can also alter over time for the same system. Aging systems generally have lower efficiencies due to degradation of the battery itself.[97] Systems can also decline in efficiency depending on the length of time that energy is stored in a particular medium before it is discharged; for example, molten salt batteries lose an estimated 1% of their stored energy every day.[98] For relatively short-term storage needs, molten salt could be incredibly efficient, but meeting longer-term needs could require other battery types or trying novel ideas, like freezing the entire molten salt system to hold the energy.[99] Thus, intended usage needs to be a determining factor for the type of storage chosen—large-scale battery storage systems are designed differently to meet short-term needs as opposed to long-term ones.

The storage duration – or how long an energy storage solution can supply energy to the user – depends upon the system's rated power capacity and the energy capacity. Most sites describe themselves in terms of rated power capacity, or the maximum rate of power discharge that a battery system can attain from a full charge expressed in kilowatts (kW) or megawatts (MW).[100] However, the total amount of power that can be stored by a battery system is the energy capacity, which is expressed in kilowatt-hours (kWh) or megawatt-hours (MWh). For a system rated 1 MW of power capacity storing 4 MWh of usable energy capacity (i.e. holding 4 MWh that can be released from the system with its efficiency), the

[100] Greening the Grid (September 2019] Grid-Scale Battery Storage. p. 2. [24]

storage duration of the system would be 4 hours.[101,102] Determining the correct battery storage system for different applications will rely on matching up typical energy usage with battery characteristics in terms of the rated power capacity and the energy capacity.

7.1.3.2 Other operational requirements

Waste disposal requirements

Day-to-day, waste disposal requirements are generally not needed for energy storage systems. Most systems can run and rerun using the same materials thousands or tens of thousands of times (Table 7.1). The end-of-life disposal for these systems is often opaque, though. For example, utility-scale use of lithium-ion batteries has been growing rapidly, but there are no standardized disposal guidelines for these batteries, which only have a 15-20 year lifetime.[103] These batteries also cannot be disposed of in traditional landfills; not only would it be wasteful of expensive and finite materials, but elements within the battery like cobalt, manganese, and nickel can harm soil and groundwater.[104] Battery recycling is not as advanced as battery production, but it is quickly growing into a large scale industry of itself, as demand for the critical materials that compose batteries increases. For example, in 2023, the U.S. Department of Energy granted Redwood Materials, a lithium-ion battery recycling company based in Carson City, Nevada, a conditional $2 billion USD loan to build out its battery recycling campus. The expansion is expected to 1,600 full-time employees and support the production of more than 1 million electric vehicles per year.[105]

Warehousing requirements

Energy storage technologies are essentially warehouses for electricity and/or heat. Some forms of energy storage may benefit from (or require) housing within a building, but as the only feedstock and product is energy, the need for ancillary on-site warehousing is highly unlikely.

Transportation requirements

Transportation requirements for battery energy storage systems should involve the transfer of electricity from a power source (e.g. wind or solar), and when needed, to an electricity or heat user. Electricity will be transported in the form of power lines. Heat can be transported as steam or hot air. The length of these transport lines is minimized the closer energy source, storage system, and end user are sited together, which is one of the key benefits of Kern County for carbon management industry development. High efficiency renewable energy and storage systems could be sited adjacent to a large-scale business park, reducing technical hurdles and costs of energy transfer.

[105] LPO (February 9, 2023) LPO offers conditional commitment to Redwood Materials. [31]

7.1.3 Carbon Capture Potential

Energy storage systems do not capture or sequester carbon dioxide emissions. However, these technologies are expected to play a key role in transitioning from carbon-intensive energy sources—like coal, oil, and natural gas—to lower-carbon renewables like wind and solar. This is because traditional fossil fuel energy infrastructure can operate continuously and consistently, but renewable sources like wind and solar can be more intermittent in their supplies. To ensure reliable operation of any technology requiring heat or electricity, battery storage is required alongside renewables to sustain continuous or on-demand operations.

It is worth noting that battery storage is not inherently carbon-neutral, and over its life-cycle (manufacture to end-of-life) can emit CO_2 and other greenhouse gasses. How much it emits depends on the *indirect* emissions that occur during production of the energy that it stores (batteries can store energy indiscriminately of the source). If it's cheapest to store and then deploy energy that originates from a fossil fuel facility, then batteries will actually enable a very carbon-intensive energy mix. Currently, most incentives for battery storage expansion do not require the energy to be sourced from renewable resources, meaning that battery storage deployment has actually *increased* carbon emissions relative to a national grid with no storage.[106]

This is relevant to a carbon management industry that uses CO_2 credits (either from public incentives like the federal 45Q tax credit, or from the private carbon credit market) for revenue, because they can only receive income for the *net* CO_2 that they remove from the atmosphere (or prevent from being emitted). If their energy source is carbon-emissions-intensive, that will reduce the viability of their business model. Thus, battery storage needs to be coupled with low-carbon energy sources—sources that are much less carbon-intensive than existing energy sources—to produce maximum revenue potential as well as maximum climate benefits.[107]

7.2 Societal Impacts

7.2.1 Job creation potential

7.2.1.1 Number and types of jobs

By 2050, it is estimated that between research and development, manufacturing, installation, and operation and maintenance, the energy storage industry is expected to create 370,000-450,000 jobs in North America, or nearly 2,000 jobs for every GW of storage capacity installed.[108] Of these roles, only installation and maintenance jobs will be

[106] Roberts (July 21, 2018) Batteries have a dirty secret. [49]
[107] Roberts (July 21, 2018) Batteries have a dirty secret. [49]
[108] ACPA (2021) Clean Energy Labor Supply. p. 18. [1]

necessarily sited at energy storage facilities, and only maintenance jobs will be permanent, long-term, on-site roles. Given that a primary design goal for energy storage is high durability, and low maintenance, there would likely be very few permanent maintenance jobs created.

In terms of installation jobs, the Crimson Energy Storage Project - a 350MW battery storage facility in Riverside County (Figure 7.6) created 140 jobs during peak construction.[109] A 45MW energy storage facility planned in Massac County, Texas, anticipates the creation of 100 short-term jobs during construction.[110]

Sectors of the energy storage industry that have the largest growth potential are manufacturing (38% of all industry job growth) and project development (25%), which includes services like consulting, finance, research, legal support, architecture, engineering, and other specialized design services.[111] Battery recycling is also likely to experience significant growth (see Section 7.1.3.2). While project development jobs could locate onsite, local policies that incentivize or mandate energy storage companies to hire local workers to fill as many roles as possible is a strong driver for expanding the community benefits of these kinds of projects.[112] Manufacturing and recycling do not need to be co-located with installation sites, but given their job growth potential, an assessment of the benefits and risks of encouraging these types of facilities to locate in the region warrants further investigation.

7.2.2.2 Training pipelines

A training needs assessment for energy workforce development conducted by the New York State Energy Research and Development Authority (NYSERDA), identified a suite of thirteen technical, business, manufacturing, and general training needs to create a strong workforce in the energy storage sector.[113] Most of these needs, such as fundamental knowledge of energy storage technology, technical skills training for installation and maintenance, electrician training, regulatory and permitting processes, advanced manufacturing skills, interconnection processes, and safety training, can be learned through on-the-job training, apprenticeships, professional association training programs, or trade schools. Some skills such as engineering, system design expertise, and business and finance modeling, will require advanced post-secondary degrees.

An assessment of job growth potential across the entire clean energy sector (wind, solar and storage) by the American Clean Power Association reported average wages for clean energy occupations to range from $33,710-$158,100 (in 2020 USD), with higher paying

[113] NYSERDA (2021) Energy Storage Workforce Development. [39]

positions requiring advanced degrees.[114] They projected that 65% of job-years created across these occupations would have an annual average wage higher than the national average of $56,310 (in 2020 USD).[115]

7.2.2 Quality of Life

7.2.2.1 Location

Battery storage facilities can be beneficial to communities, especially ones that are heavily reliant on variable energy sources, prone to extreme weather conditions, and/or suffer from transmission issues or grid unreliability. Battery storage facilities can replace "peaker plants"—typically fossil fuel-reliant power plants that run intermittently to meet peak demand on the grid.[116] Peaker plants are frequently located in disadvantaged communities, where they release greenhouse gasses and other emissions, some of which harm human health. Energy storage facilities can also replace aging facilities on the grid in need of decommissioning (such as the Moss Landing Energy Storage Facility, Section 7.1.3.1), which reduces the burden for ratepayers on paying for necessary infrastructure updates.[117] Because battery storage solutions can meet multiple needs, be deployed at a variety of scales, and utilize different storage technologies, there is a good deal of flexibility in ensuring the benefits of storage are realized by local communities.

Battery storage facilities do not locally emit any pollutants that cause harm to human health.[118] This is part of why battery storage solutions generally make a favorable replacement to traditional peaker plants—they can help meet periods of high energy demand without emitting harmful pollutants into local communities.

In general, battery storage systems are described as being "no louder than the average residential home air conditioning system."[119] The noise is derived from inverters, transformers, and fans needed to keep the equipment running,[120] though the exact equipment parts and their noise levels will differ between types of battery storage systems. With a planned 56 inverters, 56 transformers, and 40 HVAC units, the total noise level at a 1,000-foot distance from a 125MW facility operating at maximum sound level was 59.2 dB,[121] about as loud as normal conversational voices when people are standing about 3 feet apart.[122]

[121] Burns & McDonnell (2019) Battery Energy Storage System Sound Study. p. 23. [3]
[122] OSHA (no date) Occupational Noise Exposure. [40]

Light pollution is uncommon for battery storage sites, but is something that would need to be evaluated based on the site-specific needs and the facility type.

Battery storage does come with some risks that will impact both on-site workers and, to a lesser extent, quality of life for nearby residents. Utility-scale battery storage sites can be a fire and explosion risk.[123] For example, with lithium-ion batteries, there is the risk of *thermal runaway*, wherein one battery pack overheats, leading to a domino effect causing other units to overheat, which can create a fire or explosion within or across battery packs. If the battery packs catch fire, toxic gasses including carbon monoxide, hydrogen fluoride, and hydrogen chlorine can be released. If batteries are damaged during disposal, they can have similar hazards. With diligent on-site management and strong federal and state regulation, these hazards can be minimized to protect workers and nearby communities.[124]

7.2.2.2 Multi-use potential

Most battery storage systems can be easily co-located with other facilities, as exemplified by the diversity of sites upon which they already exist in urban, residential and remote environments, including private homes. One multi-use example comes from Duke Energy, which is planning to build a solar microgrid and battery storage facility next to Johns Hopkins Middle School in Pinellas County, Florida.[125] The 2.5 MW battery is designed to store energy from the solar microgrid to be deployed to support the school, which also acts as a hurricane shelter, or to the local power grid.

7.3 Environmental Impacts

7.3.1 Water requirements

7.3.1.1 Minimum volume requirements

Water intake amounts vary across battery types, and the relationship between water use (by volume) and capacity to store and release energy is not well reported, to the best of our knowledge, for any industry other than pumped hydropower storage facilities that rely on water from a nearby river being moved into a reservoir with a power station and then released back into the river (in this case, the net water use is very small).[126]

Many energy storage systems require water as a solution medium—redox flow batteries rely on aqueous (water-based) solutions to store the salts needed to generate electricity,[127] but the extent to which that water needs to be replenished (and thus the water demand of

[123] Garcia (October 6, 2021) FAQ: Community-Level and Large-Scale Battery Energy Storage. [23]

[126] Casey (November 30, 2022) Underground Water Battery. [6]
[127] MIT (2022) The Future of Energy Storage. p. 29. [32]

such batteries over time) is not well reported. CAES facilities often need water to be pumped underground to dissolve the salts in underground storage caverns, which become a reservoir to store the compressed air for the system.[128] This generates brackish water that needs to be removed from the ground and treated before reuse (see Section 8 on water treatment techniques).[129]

Current lithium-ion batteries do not require water—in fact, most perform better in very dry conditions—but some teams are working on new lithium-ion batteries that can absorb water or use liquid materials instead of being a 'dry-cell' battery.[130]

7.3.2 Other potential impacts

For an industry as diverse as this, it is not possible to clearly outline all potential environmental impacts (positive or negative) in a region that develops utility scale storage. Even within the same category, different battery types do not carry same risks or potential environmental impacts.

Ultimately, any project sited in Kern County, California, including those developed in a carbon management park like that examined here, would be considered through a public process, where the environmental impacts specific to the technologies and fuels being used will be reviewed and mitigated in accordance with the California Environmental Quality Act (CEQA).

Two general points, however, can be made. First, battery and other energy storage systems do not generate criteria air pollutants.[131] In fact, because battery storage facilities often replace emergency generators or traditional power plants that run on fossil fuels, battery storage can serve to improve local air quality by replacing energy facilities that do emit pollutants.[132] Second, on a more global scale, battery production does have environmental impacts resulting from the extraction of critical materials (like lithium and cobalt) used to manufacture batteries, and from their disposal. As energy storage technologies scale up, a significant focus of research and development is on optimizing battery longevity and efficiency, and on improving mining practices and identifying raw materials that can replace critical minerals whose sourcing is often unsustainable and/or ethically fraught.[133]

7.4 Economic Impacts

7.4.1 Business Model

The global energy storage market size is currently valued at $59 billion, and is anticipated to grow by at least 900% by 2035.[134] This is due primarily to the dramatic increase expected in our reliance on variable renewable energy (VRE) sources like wind and solar. In 2020, VREs provided 9% of global energy supplies. It is projected to rise to almost 70% of global energy supplies by 2050,[135] due both to commitments by nations and municipalities to reduce their carbon emissions, and to the fact that since 2020, onshore wind and solar power have been the least expensive forms of energy generation to build.[136]

Business models for utility-scale battery storage typically relies on the mismatch between energy supply and demand. With variable renewable electricity (VRE) sources like wind and solar, energy production highs and lows are based on the weather. Battery facilities buy electricity during periods of high VRE availability, when electricity is the cheapest, and then sell and distribute the electricity when VRE availability is low for a higher price.[137] This system enables battery facilities to generate consistent profits, while also providing a few co-benefits. First, implementing battery storage reduces demand for peaker plants, which are typically sustained using fossil fuels, to meet peak periods of electricity demand, thereby reducing CO_2 and other types of emissions. Second, it levels out energy costs for ratepayers from industrial to household scale. In California, as more battery facilities have come online, the variability between minimum and maximum energy prices has decreased, introducing greater consistency to energy pricing (Figure 7.7).[138]

The build-out of energy storage systems is not always driven by pure economics—rebates and other government incentives can drive additional uptake by making the economics more favorable, and mandates can ensure broad uptake, even when the economics are unfavorable. For example, in 2018, the Federal Energy Regulatory Commission (FERC) mandated that regional transmission organizations (RTOs) begin to adopt energy storage practices and that energy storage facilities are classed as "generation facilities."[139] In December 2020, the U.S. Congress passed the Better Energy Storage Technology Act, authorizing over USD 1 billion over five years to support the research and commercialisation of a range of storage technologies, with a focus on multi-hour distribution (balancing daily variation in VRE availability, and long-duration storage, that addresses seasonal VRE variability.[140] Although more regulatory changes will be necessary

to keep pace with expected changes in the energy grid, these policies offer a promising groundwork to remove unnecessary regulatory barriers and encourage greater participation of energy storage in the national electricity market.[141]

7.4.2 Business Costs

7.4.2.1 Cost of energy: Installed cost of storage

When considering the cost of energy storage, there are a few key takeaways:

1. Storage cost is dependent on the storage technology and energy capacity.
2. The price of energy has dropped significantly in the last few decades, and is expected to continue dropping.
3. The capital and operational costs associated with storage development do not translate to a levelized cost of energy in the same way that other energy commodities do, because energy storage is not a stand alone energy provider - it only operates in conjunction with an energy source.

We will unpack these takeaways in this, and the following section.

[141] Shim (November 13, 2018) Enthusiasm for Energy Storage. [54]
[142] CEC (November 2021) Buy Low, Sell High. [4]

Determinants of installed cost of storage

A 2022 study undertaken by the Pacific Northwest National Laboratory (PNNL)[143] examined commercially available energy storage technologies, with the aim of assessing how their costs varied as a function of power capacity (the amount of energy they can provide at a given time, in MW or kW) and energy capacity (the total amount of energy they can store on a single charge, in MWh or kWh), and how these costs are likely to evolve by 2030. Their comparison was across two variables: installed cost and levelized cost of storage (LCOS). Installed cost is addressed here, and LCOS is discussed in Section 7.4.2.2.

Table 7.3. Installed cost of energy storage in 2021.[144]

Battery Type[a]	Power Capacity Range (MW)	Installed Cost ($/kWh)	Installed Cost ($/kW)	Operating Costs ($/kW-yr)	Decommis-sioning Costs ($/kWh)
Lithium-Ion (LFP)[b]	1-10	$360-519	$922-9,128	$2.79-23.30	$2.65
Lithium-ion (NMC)[c]	1-10	$410-576	$1,031-10,405	$6.18-29.59	--
Lead Acid	1-10	$412-607	$1,090-10,457	$4.05-31.46	$16.89-33.28
Vanadium Redox Flow	1-10	$356-836	$1,522-$9,054	$4.85-26.48	$22.95-59.27
Zinc	1-10	$440-631	$1,172-10,798	$10.56-27.65	--
CAES	100-1,000	$16-295	$1,087-1,784	$9.82-18.56	--
Pumped storage hydropower	100-1,000	$221-511	$1,716-2,625	$15.58-28.19	--
Gravitational	100-1,000	$190-731	$1,706-7,600	$14.28-34.37	--
Thermal	100-1,000	$130-595	$1,568-3,944	$6.95-42.77	--
Hydrogen	100-1,000	$126-295	$2,949-3,033	$16.89-23.90	--

a. The most commonly utilized battery types are described in this report. For details on all battery types, see Viswanathan et al. (2022) PNNL energy storage cost assessment.
b. Lithium-ferrophosphate
c. Nickel-manganese-cobalt

Installed costs comprise the net of capital expenses (raw materials, project development, engineering, procurement, construction and grid integration). These costs are detailed in Table 7.3, along with operating costs (fixed operations and maintenance, losses associated with round-trip efficiency (RTE),[145] and in some cases a warranty) and decommissioning costs (disconnection, removal, site remediation and recycling/disposal), and are given as

[143] Viswanathan *et al.* (2022) PNNL energy storage cost assessment. [59]

[144] Viswanathan *et al.* (2022) PNNL energy storage cost assessment. [59]

[145] Note: round-trip efficiency (RTE) is the percentage of the energy used to charge a storage system that is released during discharge. See Table 7.1 for typical RTEs by battery type.

ranges that reflect cost variation as function of power capacity (specified by storage type) and storage duration, in hours.

For any of these technologies, installation costs in terms of energy capacity ($/kWh) decrease with increasing storage duration (see Figure 7.8), but in terms of power capacity ($/kW) and operating costs, they increase with storage duration.[146] Installation costs also decrease with increasing power capacity, due to economies of scale.[147]

Projected decreases in battery costs

The outlook for rapidly decreasing costs for energy storage is quite promising, on the basis of historical trends. Since 1991, the price of lithium-ion batteries has decreased 97%.[148] Like other technological innovations (such as solar and wind power), economies of scale and learning by doing have driven significant, systematic decreases in the cost of production with every doubling of installed capacity. For lithium-ion batteries, this 'learning rate' has been a price decline of about 18.9% for every cumulative capacity doubling.[149] Using this learning rate, as well as anticipated growth in energy storage installation capacity, it is possible to make projected estimates of what costs will be in the future. A cost analysis from MIT estimated that by 2050, lithium ion batteries may have decreased an additional 37-74% in price, while less developed technologies could see even greater cost decreases (up to 91% for flow batteries and up to 97% for metal-air batteries).[150]

7.4.2.2 Cost of energy storage: Levelized cost of storage

The cost of energy is often assessed as a levelized cost, that is incorporating capital, operational, labor and feedstock costs, what is the total cost of producing energy ($/kWh or $/MWh) for a given facility, over the lifetime of that facility?[151] Assessing the levelized cost of storage is slightly more complicated, as it requires not only consideration of the above factors, but also how much the storage system would be used annually (annual hours discharged), the cost of energy needed to charge the energy storage system and the round-trip efficiency (RTE). These variables are combined to calculate the levelized cost of storage (LCOS) as follows:

$$LCOS = [(fcr \times CapEx) + O\&M_{fixed})/AH + ECC, \quad \text{(E7.1)}$$

where fcr = the fixed charge rate (%), CapEx is the present value of capital expenditures, $O\&M_{fixed}$ are fixed operating and maintenance costs, AH is the annual hours discharged, and ECC is the electricity charging cost (purchased energy [$/kWh] divided by RTE [%]).[152]

[151] Lazard (2021) Levelized cost of energy. [28]

[152] Viswanathan *et al.* (2022) PNNL energy storage cost assessment. p. 120-121. [59]

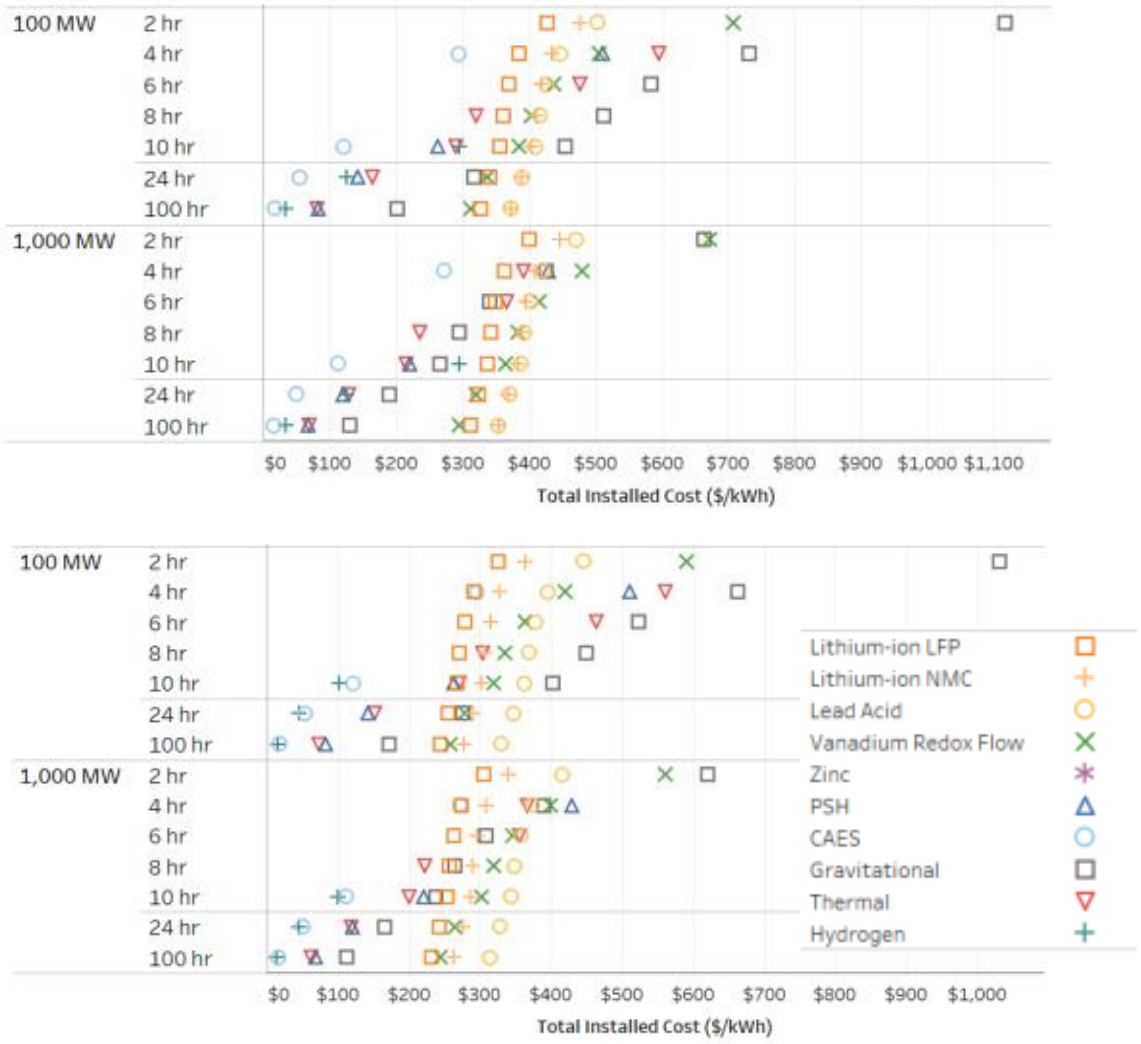

Figure 7.8. Total installed cost of energy solutions, as a function of storage duration and power capacity, showing estimated 2021 values (a) and projected 2030 values (b). Values are shown for power capacities of 100 and 1,000 MW. Data and image credit: Pacific Northwest National Laboratory.[153]

The energy system cost assessment from PNNL (2022) included an LCOS analysis of all studied energy storage systems, and found that levelized costs ranged from about $0.10-1.30 USD/kWh for large (100-1,000 MW) storage systems, with most costs falling between $0.10 and $0.40 (the higher costs were associated with systems that had 100 hr storage duration).[154] For comparison, grid electricity in California is about $0.12-0.65 USD/kWh.[155] It is also important to note that battery storage does not work alone - it operates in tandem with an energy source, like wind or solar - with the direct energy source supplying power sometimes (to the grid and the storage system) and the energy storage system supplying

[153] Viswanathan *et al.* (2022) PNNL energy storage cost assessment. p. ix-x. [59]

[155] EIA (February 2023) Average price of electricity. [16]

power other times. Therefore it is most useful to think of how energy storage adds to the levelized cost of energy production from wind or solar, which is about $0.03-0.05 USD/kWh.[156]

The National Renewable Energy Laboratory reports added costs per MWh (= 1,000 x kWh) of $5-39 for energy storage (from their own models and the published literature), with much of the range reflecting the inclusion or omission of tax credits. In a practical example, during a 2018 bidding war for new energy capacity for electricity provider Xcel Energy in Colorado, the median price for energy storage and wind was $21/MWh, and it was $36/MWh for solar and storage. This compares to $18/MWh and $29.50/MWh, respectively, for wind and solar solutions without storage.[157]

7.4.3 Regional benefits

California leads the nation in energy storage, with 215 operational projects providing ~4,200 MW of energy,[158] and plans to grow. Among utility-scale facilities, about 75% of planned development between 2022 and 2025 is concentrated in California and Texas.[159] As such, there are already companies active in the energy storage space with a sizable presence in the California market.

Local laws and regulations in California also make it an attractive location for utility-scale energy storage projects. The California Energy Commission (CEC) predicts that to meet the requirement of Senate Bill 100 for a carbon-free electricity system by 2045, 49,000 MW of battery storage capacity will need to be integrated into the electricity grid.[160] To reach these goals, new state legislation has removed some of the subdivision and zoning requirements that extended project timelines, making it more straightforward to develop a battery energy storage facility in California.[161]

7.4.3.1 Proximate feedstocks

Battery storage systems have minimal feedstocks in the traditional sense. These systems need inputs and catalysts to fuel the redox reactions that support most electrical storage, but these materials can often be reused for many charge/discharge cycles. Thus, having local supplies of materials to meet this need is not a major concern—depending on the battery type, replacement of component chemicals may not be necessary for a decade or longer.

Depending on the system type, water intake will be the most important feedstock consideration. For aqueous systems like redox flow batteries, water is necessary for

[160] CEC (November 2021) Buy Low, Sell High. [4]
[161] Colthorpe (August 31, 2022) California zoning exemption granted. [10]

sustained operation. However, some forms of redox flow batteries have optimized reuse of the liquid electrolyte solutions, with vanadium redox flow batteries having a liquid electrolyte with near-100% recyclability.[162] As a result, this water requirement can vary greatly, even within the same family of batteries, due to the material differences between electrolyte solutions, catalysts, and other components.

Other battery types—like standard dry-cell lithium-ion batteries—are corroded by water,[163] so locating them in arid regions, a common feature in Kern County, could be a great locational fit based on the region's climate and the battery's optimal operating conditions.

7.4.3.2 Proximate consumers

Battery storage has multiple benefits for carbon management and clean energy industries. Many of these processes require energy input to capture carbon or generate other products, but given the goals of the carbon management park, would need to find ways to meet this energy demand while minimizing their operational carbon output. Battery storage can serve to smooth out energy supply availability by storing solar energy during peak production periods and releasing it while the solar supply is negligible (i.e. at night), so facilities can maintain continuous operation. Thermal batteries can also convert renewable energy solar and wind energy into high temperature heat, which is needed in some carbon management industries, particularly L-DAC (Section 3) and steel (Section 5).

7.4.3.3 Co-location advantages

There will already be a large amount of renewable energy resources around to support the carbon management and clean energy industries on-site; batteries bridge the gap between supply and need imbalances.

If the system is entirely off-grid, a battery storage provider could secure procurement agreements directly with park facilities. If the system has a grid connection, the battery storage provider could also secure procurement agreements with local utility companies.

8. Water Treatment

TECHNOLOGY AT A GLANCE

- Industry has wide-scale public implementation: globally, 48% of wastewater is treated, with 11% destined for reuse.[1] In the U.S., an estimated 91.1% of wastewater is safely treated.[2]
- Water treatment is energy-intensive[3] and varies in size and complexity based on the amount and quality of water received and the necessary quality for use after treatment.[4]
- Key advantages of this technology in Kern County: regional water supply is already overallocated[5] and subject to frequent drought conditions.[6] Water reclamation and reuse could support new industries while minimizing impacts on existing agricultural and residential water use.
- Key concerns of this technology in Kern County: Water treatment is well-understood and highly regulated for safety. Facilities should be sited where odors, light, and noise pollution will not bother communities and implemented in the context of a sustainable regional water use plan.

8.1 Technology Summary

Water use is a critical consideration in the design of any new industrial center, especially in California, which is in the midst of a multi-decadal megadrought.[7] State policies require restoration of the groundwater aquifers[8] that have been traditionally relied upon to compensate for shortages in surface water resources, further exacerbating the need for water conservation.[9] In Kern County, industries requiring abundant fresh water would directly compete with regional agriculture, municipalities and existing industries. However, the state of California produces more than 3.4 million acre-feet of wastewater annually[10] (see below for definitions) that has the potential to be remediated and repurposed for industrial use. The viability of such an option is dependent upon interest, cost, and needs of the envisioned park, which will vary depending upon the types of industries that choose to locate on-site. In this section, we provide a general overview of water treatment facilities, and how they differ as a function of the purity needs of treated water. For readers unfamiliar with industrial scale water treatment and use, relevant key terms and policies are outlined here.

Acre-foot is a standard measurement for large volumes, representing the amount of water needed to cover one acre of land with one foot of water. One acre-foot is equivalent to 326,000 gallons of water.[11] For reference, it would take the average household in California between six months and two years to use this volume of water.[12]

Alternative water is a catch-all term for water sources that are not surface or standard groundwater collection. According to the U.S. Department of Energy (DOE), this includes "Harvested rainwater, stormwater, sump-pump (foundation) water; Graywater [also spelled greywater or grey water]; Air-cooling condensate; Rejected water from water purification systems; Reclaimed wastewater; [and] Water derived from other water reuse strategies."[13] Graywater and reclaimed wastewater are of particular interest here. **Graywater** constitutes water lightly used for domestic or industrial use aside from toilets, and typically requires less processing than wastewater.[14] **Wastewater** is a broader category, including sewage, water used in heavier industrial processes, and stormwater as

well as graywater; it can contain a wider range of pollutants and thus requires more processing, depending on the quality necessary for reuse.[15]

Influent refers to the water entering a treatment plant, and **effluent** refers to the same water after it has undergone treatment and is leaving a treatment plant.[16] The quality and volume of influent and effluent will vary across facilities.

8.1.1 Description: How it Works

Wastewater processing works utilizing a well-established model, though the steps may differ based on the quality of the influent, amount of water processed, and age of the facility. There are a few consistent steps across models, however, with one exception that distinguishes the two primary types of plants: conventional treatment, in which a sedimentation tank is part of the treatment process, or direct filtration, which does not use a sedimentation step.[17] The list below describes **primary treatment**, typical for all wastewater treatment plants. Depending on the quality of the influent water and the necessary quality of effluent flow, secondary or tertiary systems can be implemented to further clean the supply.

- **Preliminary treatment**: influent water passes through coarse screening and grit removal processes to remove large materials, like manmade objects, rocks, or gravel.[18]
- **Coagulation**: chemicals are added to the water to "stick" small particulates together.[19]
- **Flocculation**: as particulates begin to clump together, water is added to large tanks with slowly-mixing paddles, which bring particles together to form floc.[20]
- **Sedimentation**: the water slowly passes through a sedimentation tank, where the floc settles at the bottom of the tank to be pumped out while the water moves out of the tank.[21,22] Direct filtration systems skip this step.[23]
- **Filtration**: the water enters a filter, typically a concrete box with sand and gravel supported on an underdrain structure, which removes remaining suspended particles.[24]

[23] College of the Canyons (November 22, 2020) Water Treatment Facilities. [22]
[24] College of the Canyons (November 22, 2020) Water Treatment Facilities. [22]

- **Disinfection**: prior to discharge, water is often treated with chlorine gas or a mix of chlorine and ammonia in a process called chloramination to kill microorganisms.[25] The maximum residual disinfectant level (MRDL) for effluent water leaving the plant is 4.0mg/L, and most effluent averages free and total chlorine concentrations "between 2.5 and 3.5 mg/L" when leaving a treatment facility.[26]

While these steps are common to nearly all water treatment facilities, some can be removed or other steps can be introduced, depending on the water quality and planned destination for effluent flow. The flowchart in Figure 8.1 provides an example, demonstrating the water treatment process used at the Granollers Wastewater Treatment Plant, built in Spain in 1992.[27] This system includes far more intermediary steps to clean its water before discharge. The figure also details the steps necessary to process sludge (raw primary biosolids), a byproduct of water treatment.[28]

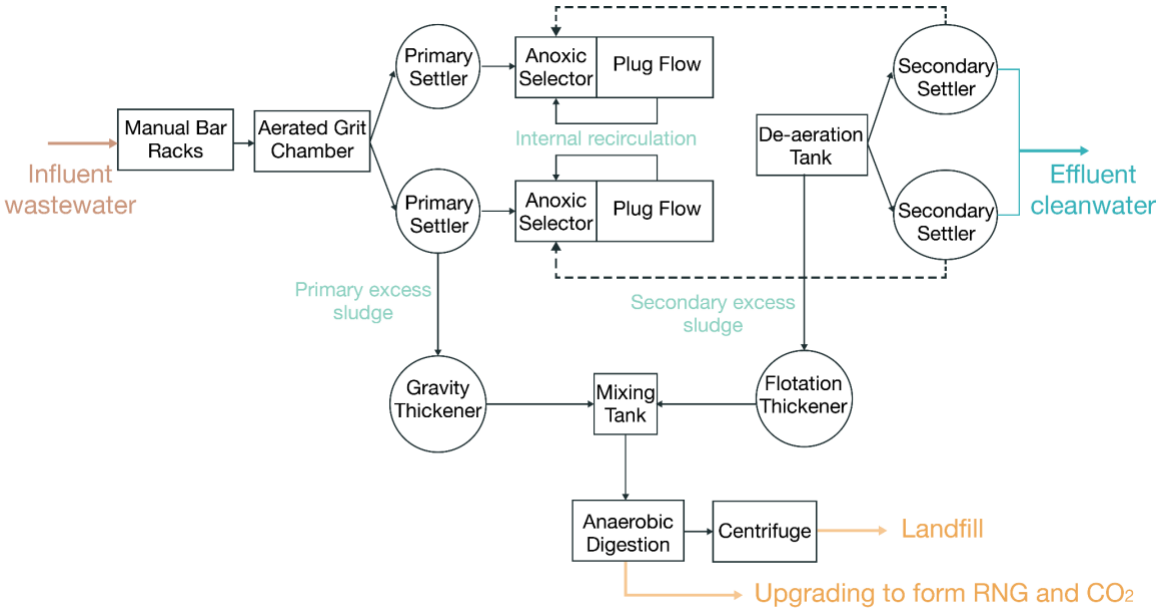

Figure 8.1. Flow chart demonstrating some typical steps of a wastewater treatment process; adapted from Vidal et al. (2002) and other sources.[29]

Cleaning water for industrial use may be less intensive than is required for a wastewater treatment plant producing drinking water quality effluent. The European Union's guidelines for water reuse, which draws on existing best practice, outlines that "industrial water reuse

is highly determined by the exact quality needs of the individual industrial process and/or product as well as the costs of producing water of the required quality compared to other suitable sources."[30] Thus, there are few 'industry standards' that can be used to define the necessary processes (and costs) of industrial water reuse—it will depend on the types of industries that could be located within the park and the water volume and quality necessary to operate a given facility.

Another freshwater alternative for industrial water (or drinking or irrigation water) is desalination, which is the process of stripping dissolved salts from seawater or other brines. As Kern County is within 100 miles of the Pacific Ocean, desalination of seawater would provide an effectively limitless volume of water for industrial development, albeit at a high price. Desalination is up to four or five times the cost per gallon for treatment, when compared to graywater or wastewater treatment plants.[31] It is considered in this study for the purpose of comparison with treatment of graywater or wastewater, and as a point of consideration for future development in the region, given that freshwater resources are anticipated to become ever more scarce with climate change.[32]

There are two main techniques for desalination, each reviewed briefly here. In reverse osmosis (RO), influent is passed through a series of semi-permeable membranes in order to remove the salts and other impurities found in seawater, as shown schematically in Figure 8.2.[33,34]

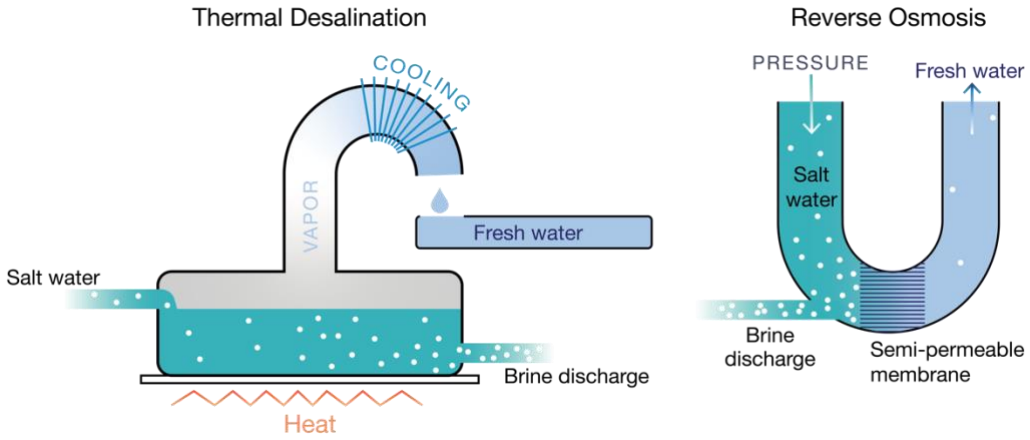

Figure 8.2. Thermal desalination and reverse osmosis are two techniques for producing fresh water from saline waters like seawater or brines. Adapted from the Texas Comptroller of Public Accounts.[35]

[30] EU Water Directors (no date) Common Implementation Strategy. p. 24. [35]

[34] Ang *et al.* (2015) Integrated/Hybrid Membrane Processes. [3]
[35] Texas Comptroller of Public Accounts (no date) Texas Water Tour: Desalination. [73]

In thermal desalination, heat is used to evaporate seawater, creating pure water vapor and a briny residue. The vapor is subsequently condensed into fresh liquid water. Waste heat from power plants or refineries is often used to supply the heat source.[36] Thermal desalination can be accomplished through vapor compression (VC), in which heat derived from mechanically compressed vapor is used to drive evaporation of the seawater influent. Alternatively, multi-stage flash distillation (MSF) and multi-effect distillation (MED) employ multi-step evaporation/condensation processes, taking advantage of how the boiling point of water varies as a function of salinity to optimize energy efficiency. Steam or the seawater influent itself is used as the carrying agent for the heat, which boils seawater in a series of vessels (or "effects"), producing vapor and a more salty brine. The brine is moved to the next vessel, which induces boiling at a higher temperature, producing more vapor and a saltier brine, that is transferred to the next vessel, and so forth, iterating as many times as is desired.[37,38]

8.1.2 State of Development

Water treatment and transport has been employed for centuries,[39] and are a common feature of public drinking water systems throughout the United States[40] (and the world). But new technologies that are particularly important in water-scarce regions like Kern County, such as desalination of seawater or wastewater treatment that provides water effluent that is clean enough for irrigation or drinking purposes, are not yet widely used on a commercial scale in the United States. Only about 1% of water is recycled in the U.S.,[41,42] and less than 3 gallons of every 1 million gallons of water used each day in the U.S. comes from desalination.[43]

For the purposes of this investigation, we have examined two water treatment facilities that are typical for water reuse in irrigation or landscaping, and a small set of facilities across the nation that fall within the 1% of plants that are designed to generate usable water to directly meet local needs and increase water circularity. Water treatment facilities specifically designed to meet the needs of an industrial park are not well-covered in the literature, given the vast diversity of requirements that might entail. However, lessons gleaned from existing facilities can provide a general sense of the parameters, needs, impacts and benefits of a water treatment or desalination facility to nearby industries or communities.

8.1.2.1 Example projects

Bee Ridge Water Reclamation Facility, Sarasota County, Florida[44]

This facility in Sarasota County has a capacity of 12 million gallons per day (GPD), making it the largest of the county's water treatment plants. Wastewater is moved to the site through a series of underground pumps and lifting stations. Once at the site, the influent water goes through four major cleaning steps: screening for inorganic materials, biological processing, filtration, and disinfection. Biosolids removed during the treatment process are separated out and composted.

Effluent water that leaves the Bee Ridge facility after processing is reclaimed water that is suitable to meet commercial and residential needs for landscaping and irrigation. This reduces the demand to use potable water—which could be used in homes for cooking and cleaning—for outdoor use.

Lancaster Water Reclamation Plant, Lancaster, California[45]

This facility in Lancaster, just south of Kern County, has a capacity of 18 million GPD. It employs primary, secondary, and tertiary processing, so the facility can generate reclaimed water suitable for agricultural, municipal, industrial, and parkland uses, including maintenance of water levels in regional parks and migratory bird ponds. An estimated 12.6 million gallons per day of reclaimed water is used from the Lancaster facility every day.

The Lancaster facility also saves its byproducts; biosolids are dried and can be used for compost or soil additives. The methane (biogas) generated on-site from processing wastewater is used to meet the heat requirements of the anaerobic digesters.

Direct potable reuse (DPR) water treatment demonstration facilities, United States

Although it is possible to generate reused water at the quality necessary for safe drinking water, few states allow treated wastewater to be pumped directly into homes—currently, only Texas and (on a case-by-case basis) Arizona allow direct distribution of treated water as potable tap water (direct potable reuse, or DPR).[46] Both Big Spring and Wichita Falls, in Texas, have used DPR to support local water supplies, with Wichita Falls relying on the practice to generate 5 million gallons of treated water per day to support the city during the end of a 5-year drought.[47]

In California, cities like San Diego and Los Angeles have begun to consider the implementation of DPR to diversify their own water supplies.[48] The State Water Control Resources Board is expected to release updated regulations this year that would allow DPR

[48] Constantino (August 19, 2022) What's in your drinking water? [23]

in the state.[49] To prove the viability and safety of DPR to the public, San Diego ran a demonstration advanced purification facility from 2009 to 2013 allowing the public to tour the plant and try the water, but avoided any legal trouble by not sending any of the DPR water to taps.[50] Los Angeles plans to undertake a similar demonstration facility in 2024 to act as "proof of concept" for city residents about the safety of DPR.[51] Experts estimate that California has the potential to triple its current water reuse rate to 2.8 million acre-feet annually.[52]

8.1.3 Operational Needs

8.1.3.1 Land use requirements

Water treatment plants can have large land use requirements. The physical footprint of a facility can comprise a series of open ponds and/or buildings, depending on facility scale and local regulations.[53] Quality of the influent and effluent can also shape facility size—more intensive treatment can introduce additional filtration steps requiring extra equipment or ponds—and facilities often locate, when possible, on larger sites than needed to both leave room for future expansion and avoid bothering nearby communities with any noise, light, or odor pollution from the treatment plant.[54]

It is important to note that facility acreage and facility capacity (the amount of water a treatment plant can process) are not strongly correlated. In the United States, the largest treatment plants by capacity have maximum physical footprints of about one square kilometer (~247 acres), with an average size of around 0.6 square kilometers (~148 acres).[55] For a regionally representative example, the Bakersfield Wastewater Treatment Plant No. 2, processing 13.7 million gallons per day or about 15,345 acre-feet of water per year,[56] occupies ~645 acres of land.[57]

Design plans also differ considerably, depending on how much of the processing equipment is visible from the outside of the facility. An advantage of water treatment facilities relative to other industries included in this report, is the wide potential for alternative uses, including natural or open spaces, or public use spaces (see Section 8.2.2). An image demonstrating the potential appeal in the landscape and for nearby residents is shown in Figure 8.3.

8.1.3.2 Energy requirements

Water treatment is an extremely energy-intensive process, using approximately 650 MWh per acre-foot of treated water.[60] Electricity costs alone can account for 25% to 40% of a water treatment facility's annual operating budget,[61] and within most municipal areas, wastewater treatment facilities are the largest single electricity consumer.[62] Energy requirements for water treatment depend on the quality of influent water being processed, considering both the type of contaminants involved, and their concentration in the influent. These factors determine the technologies and methods used to treat the water and are thus highly correlated with energy consumption.[63] The most energy intensive practices are generally also the most expensive, with seawater desalination requiring more electricity than cleaning wastewater or graywater.[64]

Aside from treatment facilities themselves, transporting water before or after treatment also requires a great deal of energy, simply because water is heavy to move. For reference, one acre-foot of water weighs 1,360 U.S. tons (~1,233 metric tons).[65] In California, the State Water Project – a suite of canals, pipelines, reservoirs, and hydroelectric power facilities that serve as a freshwater delivery system across the state[66] – is "the state's single largest user of electricity" as the infrastructure needed to support pumping water between regions is highly energy intensive.[67]

Innovative state and federal programs are helping facilities to reduce their energy consumption through improvements in energy recovery, benchmarking usage, and efficiency upgrades to onsite equipment.[68] Scientists and engineers are even optimistic that ambitious wastewater treatment plants could become net energy creators, rather than users, in the future.[69] This is primarily due to their ability to use the biogas and thermal heat produced on-site more efficiently with measures like co-digestion and fuel cell systems.[70] However, given the present average energy requirements of water treatment facilities (650 MWh/acre-foot), approximately 1.6 acres of solar energy would be required to treat an acre-foot of water.* Water needs from the various carbon management systems explored in this report range from less than 0 acre-feet per million metric tons of CO_2 captured (S-DAC and some forms of BiCRS), to as much as ~16,000 acre-feet of water needed per million tons CO_2 (L-DAC, see Figure 8.4). The high-end estimate translates to about 25,312 acres of solar panels needed to support sufficient water treatment.

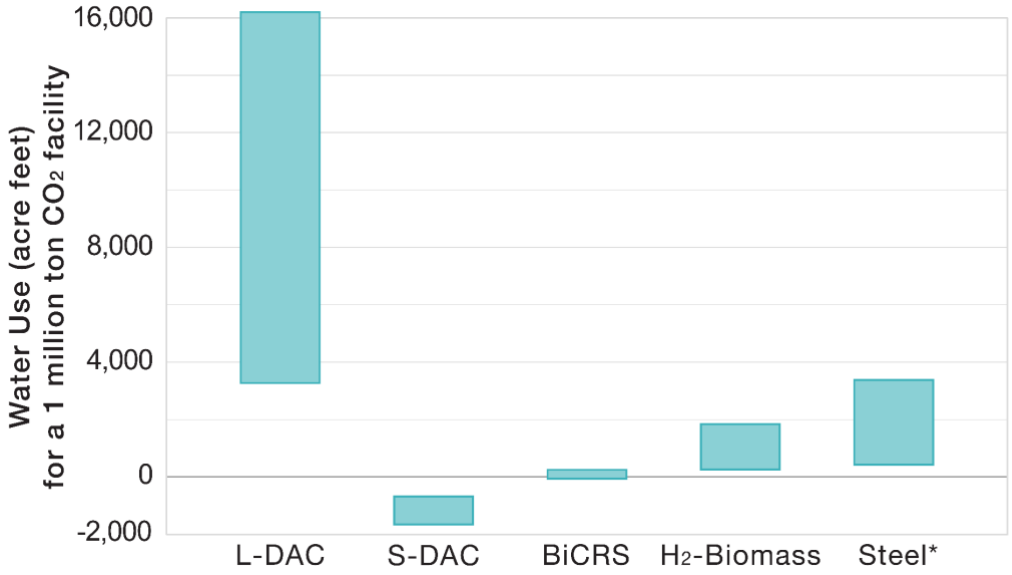

Figure 8.4. Water use across carbon management industries, based on this study (see Sections 3, 4 and 5). Hydrogen production via biomass, steel and particularly L-DAC technologies are water-intensive practices, using as much as 16,200 acre-feet of water annually, that could be sourced from treated graywater or (less economically) desalinated seawater.

8.1.3.3 Other operational needs

Waste disposal requirements

Wastewater treatment plants generate bio-solids and methane gas as byproducts of the water purification process.[71] According to the EPA, the methane produced on-site is frequently used by water treatment plants as fuel, rather than being disposed of or sold.[72] However, the methane produced can be sold as renewable natural gas (RNG) to other firms as long as its production and storage meets necessary federal and state standards.[73] This could encourage circularity within a water treatment plant or within a carbon management industrial park at large, particularly given the potential for generating electricity plus CO_2, or hydrogen fuel plus CO_2, through oxy-fuel combustion or methane steam reforming, respectively (see Sections 4 and 6).

Biosolids are another byproduct that are produced by physically and chemically treating the solids separated out during the water purification process to generate a nutrient-rich, semisolid product.[74] These solids can be used productively on agricultural and mining sites to improve soil structure, add nutrients, and improve water reuse, with secondary benefits including reduced landfilling and reduced use of synthetic fertilizers.[75] If not reused, biosolids must be disposed of by surface disposal methods, such as landfilling or incineration.[76]

Warehousing requirements

To store influent prior to treatment and effluent before it is sent to customers, water treatment facilities typically require a large amount of onsite storage. Water awaiting treatment is often held in ground lakes or pools.[77]

Because treated water is also often stored onsite until it can be transported to a customer, facilities can require millions of gallons worth of space to store cleaned water.[78] Onsite storage helps to regulate water supply to align with demand, both of which can vary seasonally.[79] Furthermore, onsite storage serves to further reduce the amount of nitrogen, microorganisms, and suspended solids present in treated water, so water leaving storage can also be cleaner than when it first leaves the treatment plant.[80] Depending on the

[80] Pescod (1992) Wastewater treatment. [60]

location and quality, effluent can be directly discharged into 'receiving waters' such as nearby rivers or streams, removing the need to store effluent flow for distribution.[81]

Transportation requirements

The influent and effluent from any water treatment plant would need to move between potential sources – agricultural fields, commercial or industrial facilities, or the ocean – to the plant, and then into the carbon management park. Depending on the yield of the plant and the park's water usage, additional infrastructure may be necessary to transport water to alternate consumers or to nearby aquifers in need of replenishment.

In California, water is typically transported using open canals, aqueducts, or pipelines.[82] The size of this equipment, as well as its operating needs and costs, will depend on the anticipated load.[83] Moving water can be energy-intensive over any topographical features, as pumps will be necessary to accommodate any increases in altitude along the route; as a result, the most efficient pipelines would move water near flat or declining geography to benefit from gravity.[84] A good example of this type of infrastructure operating without energy-intensive pumps is the nearby Los Angeles aqueduct, which runs through the eastern portion of Kern County.[85, 86]

Pipeline requirements

Pipeline requirements would depend upon a facility's size and anticipated influent and effluent flows. A low intensity project may only require polyvinyl chloride (PVC) pipes, while larger projects would require steel pipes.[87] Investing in durable and easily-repairable equipment is generally the most cost-effective option in the long run by minimizing future repair and maintenance costs.[88]

8.1.4 Local Context - Current Water Use

Given the overall focus of this report on the potential development of a carbon management industrial park, an entire segment on water use—including the viability of on-site water treatment options—may appear to be out of scope. However, water is often critical to ensuring sustained and successful facility operations, thus the local context of water availability in Kern County is worth examining.

[88] Frankel (November 10, 2021) Wastewater Treatment System Cost? [37]

California is in a state of drought, having experienced a series of such dry years since at least 2000, that the few wet years in between have not been enough to replenish groundwater or support plant regeneration.[89] Currently, over 80% of Kern County is experiencing 'exceptional drought' conditions.[90]

In Kern County, precipitation is low due to the arid climate—the county seat of Bakersfield receives an average of 6.49 inches of rain per year.[91] Yet the area uses water to support a diverse range of communities, industries, and farms; in an average year, agriculture receives 2,294,000 acre-feet of water and municipalities and industry receive 166,000 acre-feet of water across Kern County.[92] Only about one-quarter of the water used originates from local surface sources, like the Kern River or smaller streams.[93] Most of the region's water is derived from underground reservoirs or is brought in from the State Water Project (via the California Aqueduct) or the federal Central Valley Project (via the Friant-Kern Canal).[94]

Water is overallocated across California when compared to supply, with a 2014 study from University of California researchers finding that "[in] the state's major river basins, water rights account for up to 1000% of natural surface water supplies."[95] For the Kern River, this figure stood at 631%.[96] Additionally, overpumping of underground aquifers as an alternative water source has led to land subsidence, with approximately half the land in the San Joaquin Valley experiencing significant land subsidence (over one foot in surface ground level change) by 1970.[97] In this context, land subsidence occurs when water is removed from under the ground and the land at the surface drops down as a result.[98] These environmental changes have caused significant concern, and the state has sought to resolve these impacts of reduced aquifer replenishment and land subsidence with laws like the Sustainable Groundwater Management Act (SGMA) of 2014.[99]

Given this regional context, any ways in which newly developing industries in Kern County can make use of non-freshwater sources, like treated graywater or desalinated seawater, or in which industries that produce water as a byproduct of carbon management (S-DAC and some forms of BiCRS) could co-locate with more water intensive industries, warrant examination.

8.2 Societal Impacts

8.2.1 Job creation potential

8.2.1.1 Number and types of jobs

Water management will likely generate relatively few jobs past any necessary construction phases; however, the initial construction of any treatment facilities or canals would be labor-intensive endeavors.[100]

California's water supply is heavily monitored and managed by existing staff attempting to balance demands from industry, agriculture, and power generators, in addition to communities and natural habitats.[101] Any additional permanent jobs created in this sector will likely be skilled jobs to remotely manage flows, supplies, and make executive decisions during periods of drought.[102]

There could be some full-time, on-site jobs generated by a water treatment facility. The majority of these would likely require vocational training, but would not require extensive secondary education, as 85% of national water-related occupations are filled by workers

[100] Kane, Tomer (2018) Renewing the water workforce. p. 17. [50]
[101] Escriva-Bou, A. *et al.* (2019) Dams in California. p. 1. [34]
[102] California Department of Water Resources (no date) Careers. [13]

who have less than a bachelors degree.[103,104] Furthermore, water infrastructure jobs are generally good jobs, with an average wage that exceeds the national average and equates to a livable wage in most of the country.[105]

For a large water treatment facility, staffing needs would likely be around a few dozen employees. For reference, Bakersfield's Wastewater Treatment Plants 2 and 3, processing 13.7 and 17.3 million gallons per day of influent water (or approximately 15,346 and 19,378 acre-feet per year), support 11 and 19 jobs, respectively.[106]

8.2.2.2 Training pipelines

Anyone with a high school diploma or GED with appropriate experience can become certified to fill most water treatment roles.[107] All states set their own guidelines for certification for water operators.[108]

Most training for working with water infrastructure relies on developing skills and knowledge through applied learning, rather than emphasizing traditional postsecondary education.[109] Some specialized jobs within the water workforce—including architects, environmental engineers, and computer systems managers—typically require a postsecondary degree and earn higher pay.[110]

8.2.2 Quality of Life

8.2.2.1 Location

Light pollution is a frequent complaint regarding water treatment sites close to communities.[111] Since the facilities process water continuously, the site must be well-lit at all hours of the day for the safety of its employees, who are walking around and operating large equipment. Newly-designed plants have taken on a variety of innovative features to try and address light pollution concerns. The Newtown Creek plant (seen in Figure 8.3) has used a mixture of blue and white lighting to provide both an artistic and safe amount of light without disturbing residents.[112] A LEED-certified wastewater treatment plant located in Dryden, Ontario optimized their design to use the lowest possible light levels whilst still

[111] ACE (2005) Washington Aqueduct: Environmental Impact Statement. p. 5-13. [4]
[112] L'Observatoire International (no date) Newtown Creek. [53]

meeting security requirements.[113] Another facility in Adelaide, Australia is using infrared lighting to monitor all the external features and security gates of their water plant, so only the inside of buildings require visible lighting for operation.[114] Although light pollution is a serious concern, there are innovative options available to protect worker safety and reduce light pollution for any nearby residents.

Noise complaints are another frequent issue with locating water treatment plants close to residential areas.[115] Given the fans, motors, pumps, and compressors needed to run the plant, noise can build up.[116] The most common problem is not just an increase in ambient noise, but different parts of equipment that produce unique but similar tones, creating a 'pulsating' effect for human ears that can be perceived as doubling the sound coming from the plant.[117] Designing the plant to accommodate for noise can resolve most of these problems. Construction plans should locate large equipment away from residential areas, minimize the potential openings in the building for sound to escape, and include necessary sound-dampening materials like acoustical louvers and HVAC duct silencers.[118] Recent software developments, namely variable frequency drives (VFD), can adjust the speed of rotation for devices based upon the required load, which can dramatically lower the sound pressure generated.[119]

If the water being processed involves any raw sewage, as is true of most wastewater plants, odor becomes another concern for the plant. Depending on the chemicals and processes used to cope with biological waste, the resulting biosolids may also release a noticeable smell, typically due to "ammonia, amines, and reduced sulfur-containing compounds" present in the biosolids.[120] Odors can be mitigated with intentional design. At the Dryden plant (Figure 8.4), a fan is placed over the influent flow entrance to draw off air into a set of biofilters and charcoal, leaving most of the facility odor-free to house offices and other space for workers.[121]

8.2.2.2 Multi-use potential

Multi-use projects with water treatment plants are rare, likely due to their size and high potential for noise pollution. Although plants like the Newtown Creek treatment facility have been designed with unique tanks, lighting, and glass walkways to draw visual interest

[121] Lund (September 2017) Plant Earns LEED Recognition. [55]

from passersby, akin to an art exhibit, these designs are uncommon and do not involve any nontraditional users on the actual site.

There are some unique water treatment facilities that have evolved for multi-use purposes. The R.C. Harris Water Treatment Plant in Toronto, Ontario processes about 30% of the city's drinking water, but also is a notable Art Deco building with public access to the grounds and has served as a frequent filming location for TV and movies.[122] The plant used to be fully open for public access until security concerns arose in the early 2000s, but still allows some public access for special events.[123] Similarly, water treatment plants in China and the United States have managed to incorporate both indoor and outdoor botanical gardens for public enjoyment.[124,125]

8.3 Environmental Impacts

8.3.1 Water requirements

8.3.1.1 Minimum volume requirements

For graywater and wastewater treatment plants, the volume of influent and effluent hardly differs. By weight, wastewater is 99.9% water, with only the remaining 0.1% of organic and inorganic compounds, as well as microorganisms, being removed by the filtration process.[126] Thus the yield of water that will be released as effluent is quite high. There is no minimum volume requirement to operate a water treatment plant, though efficiency varies—both in terms of maximizing water reuse and equipment lifetime—if the plant is processing much more or much less water than it was designed to handle.[127]

For desalination specifically, the technology used to remove salts from seawater will determine the minimum volume requirements necessary. Using reverse osmosis (RO), approximately half of the initial volume of water run through the process can be desalinated—the remainder is returned to the water source.[128] This is considered a relatively good yield for desalination processes.

The salient question for volume requirements—what will the average daily water needs of the carbon management park look like—is also the most difficult to answer, as different technologies exhibit a vast range of water consumption patterns. For biomass-based

[128] Beswick *et al.* (2021) Does the Green Hydrogen Economy Have a Water Problem? p. 3168. [8]

processes (BiCRS and BECCS), facilities can typically run close to neutral on water use. Some processes are even net-positive on water and can generate water as a reaction byproduct at a quality suitable for agricultural use.[129] Other technologies, like hydrogen production via electrolysis, require water to generate any output. 9 kg of water must be used to generate a single kg of hydrogen fuel (Section 6), with some companies reporting that in the field, the best estimate is 12 kg per kg of hydrogen produced due to water vapor loss.[130, 131]

8.3.1.2 Minimum quality requirements

Water quality needs are dependent on the intended use of the treated water. For agricultural uses or industrial cooling needs, water can typically be less filtered than would be necessary for drinking water. To use water in chemical processes like electrolysis, the water must meet high standards of purity (i.e. be distilled and/or deionized) to preserve the efficiency and lifetime of the equipment.[132] Membrane-based electrolyzers require water to be of type II purity, though operate better with water of type I purity, which is even more filtered.[133]

8.3.3 Other potential impacts

Redirecting water use in any way may impact existing usage covenants, or harm the well-being of local communities, farms, or wildlife. Given the exceptional drought conditions in Kern County discussed in Section 8.1.4, directing already-purified water for industrial use from existing sources that are already stretched for existing and new housing would be difficult.

In terms of environmental impact, generating more usable water for the park from otherwise undesirable sources, including graywater, stormwater, seawater, or wastewater, can be construed as a net positive. If a water treatment facility can purify otherwise unusable water to be clean enough for industrial, agricultural, or residential uses, and in excess of the quantities needed by members of the carbon management park, this water can help alleviate shortages in the county's current supplies. Excess purified water could be traded through California's water markets to help keep agricultural producers in business during dry years. It could even be stored in the area's underground aquifers to replenish the over-drained supply and prevent continued land subsidence in the southern San Joaquin Valley. Further, excess energy generation from other industries (such as electricity from oxyfuel combustion of biomass, or waste heat from BiCRS or steel

industries) could be used as a cost-effective and carbon-free energy source for treating alternative waters for regional use.

8.4 Economic Impacts

8.4.1 Business Model

The profitability of water is a complex question due to the array of existing regulations and allocations involved and the unusually low price of water.[134] Low tariffs on water use are intended to protect economically vulnerable residential consumers, but also effectively undercharge all users—including those in industry and agriculture—for their current water use.[135] This system means that despite scarcity, water is generally undervalued, and thus rarely conserved or reused.[136] At the macro scale, investing in large facilities for generating more clean water from less pure sources is seen as an expensive and unnecessary investment when water access is currently cheap in monetary terms. However, as scarcity increases, there is a "huge opportunity" to adopt reuse and recycling practices for industrial water that will mitigate risks associated with climate change as the American West becomes more arid.[137]

Because of the high costs associated with these projects, the federal government offers a range of funds, loan guarantees, and grant programs that can provide funding for projects aiming to increase water reuse, reclamation, and efficiency.[138] Most programs emphasize community or local government leadership, and may be ineffective options for an industrial park—more research would be needed to determine the viability of pursuing federal water reuse funding for a specific project. Likely, policy intervention or necessity due to scarcity will be the levers that encourage more widespread adoption of water conservation, reuse, and desalination within California.[139]

Finally, under California law, water is a public resource, although its use can be subject to private rights.[140] Presumably, the revenue potential of a water treatment facility within a carbon management industrial park would depend on how projects were permitted and funded. If the County itself owned a water treatment plant, it could presumably sell the water (within the park or outside of it) or store it in aquifers. It is less clear whether there is a profitable model for a privately owned and operated water treatment plant. California does operate a water market where a purifier could recuperate costs by selling water,

[139] James (August 11, 2022) California expected to lose 10% of its water within 20 years. [48]
[140] Green (no date) A Primer on California's Water Issues. [42]

though most of the water traded in California originates from surface sources.[141] 46% of all water traded in California is done between buyers and sellers in the same county.[142] In the last decade, farmers in the San Joaquin Valley and cities have been the largest buyers in the water trading market, so it is likely that there would be substantial interest in Kern County around purchasing any water generated from industrial park activity or from treatment of alternative waters, not to mention the potential of selling to industrial players within the park to support their operations.[143]

8.4.2 Business Costs

Capital and operational costs for water treatment can be difficult to ascertain. First, there is currently no federal or non-federal standard for what factors should be included or excluded when reporting estimated capital or operating expenses.[144] Furthermore, both the capital and operational costs are dependent upon changeable factors; for example, for capital costs, this includes the volume and quality of the influent water and for operating costs, this includes the costs of labor and electricity.

8.4.2.1 Cost to build (upfront costs)

Costs to build a facility depend upon its capacity (usually measured in gallons per day, hereafter GPD) and purity of the influent. Wastewater treatment centers capable of processing 150,000 GPD for industrial use typically cost $500,000 to $1.5 million upfront.[145] For reference, 150,000 GPD is equivalent to 168 acre-feet of water treated per year, and water-intensive carbon management facilities investigated in this report could require up to 16,200 acre-feet per million tons of CO_2 captured (Figure 8.4).

Depending on the other technologies needed to filter and process the water and the level of purity required for the effluent, costs can grow significantly—up to many millions in additional upfront costs. Reverse osmosis (RO), a desalination process, and ion exchange (IX), which can remove minerals and ions to generate deionized water for chemical processes like electrolysis,[146] both would add an estimated capital cost of under $5 million for smaller GPD systems.[147] Complete distillation and purification via zero liquid discharge (ZLD)—essentially, a water treatment plant that does not release water with any solid or liquid contaminants into the natural environment, like streams or groundwater, instead

[147] SAMCO (October 12, 2017) Industrial Water Treatment System Cost? [66]

recycling the water routinely on-site[148]—would be considerably more expensive, running up to $10 million for systems capable of handling GPD in the thousands.[149]

8.4.2.2 Operational costs

Operational costs for water treatment vary considerably based upon influent quality,[150] and are dependent upon material costs, electricity costs, labor costs, and costs from third-party services.[151]

Treating graywater and other wastewater is less cost-intensive than treating seawater or other brackish water via desalination. To generate the same quantity of usable water, the costs of operation for desalination are typically two to four times higher than for wastewater treatment.[152] In a study of treatments to recycle irrigation water for greenhouses, researchers found that the costs ranged from $0.07 to $1.00 to treat 1,000 gallons of water, depending on the treatment method,[153] equating to between $38,325 and $547,500 per year for a 150,000 GPD facility. That's over a tenfold increase between the lowest and highest cost treatment option, and irrigation water generally has less impurities requiring treatment compared to wastewater or seawater, suggesting operational costs would be higher for a wastewater treatment facility or desalination plant.

8.4.3 Regional benefits

With population increases and a decades-long cycle of droughts afflicting the American West, innovative projects to generate more usable water should be drawn to locations like Kern County, with its abundance of open land to locate a facility and steady mix of agricultural, industrial, and residential water consumers.

8.4.3.1 Proximate feedstocks

Within Kern County, the largest water users are in the agricultural sector.[154] Agriculture produces substantial runoff of graywater, as up to half of the water used in crop irrigation evaporates or becomes runoff.[155] If captured and reused, this graywater would constitute an existing and accessible source of water for the carbon management park.

The western edge of Kern County is located less than 100 miles from the Pacific coastline, making it a potential site for desalination projects. A desalination facility could also be

[155] Balsom (September 28, 2020) Water Usage In The Agricultural Industry. [7]

located on the coast and utilize pipelines or canals to transport water into Kern County for industrial or agricultural uses.

8.4.3.2 Proximate consumers

In addition to potential users within a carbon management industrial park, treated water could be utilized by residents as drinking water or for agricultural use, depending on the quality of water available and the amount produced in excess of the carbon management park's needs. For water that is not purified to drinking water standards, underground storage to replenish regional aquifers would be an option. As groundwater, the water would be purified further within the aquifers, making it usable to consumers above the surface in the future.[156]

8.4.3.3 Co-location advantages

Kern's existing supply of clean energy from wind and solar—amounting to over half of California's total renewable energy supply—may be appealing for water treatment plants, which are energy-intensive operations.[157] Similarly, depending on the energy and heating needs of a facility, locating on-site in the carbon management park may be a good way to reuse heat or energy that would otherwise be lost from other processes, like converting biomass or steel production.

9. Carbon Dioxide Transport

TECHNOLOGY AT A GLANCE

- Industry is well established: CO_2 pipelines have been in operation in the U.S. for more than 50 years.[1]
- Pipelines are typically the most cost-effective option for overland transport of CO_2. Average levelized cost for pipeline transport is $10-20 per metric ton CO_2, but values can be higher or lower depending on length of pipeline, pipeline capacity, and siting logistics (terrain, securing rights-of-way, urbanization, etc.).
- CO_2 pipelines are typically constructed ~3 feet below the surface, so they do not create a visual or sound impact at the surface, and can co-locate with other land uses.
- Key advantages of this technology in Kern County: Would provide a cost-effective solution for transporting CO_2 between producer(s) in the region and sites that are permitted for injecting CO_2 underground for the purpose of permanent geologic storage.
- Key concerns for this technology in Kern County: Safety hazards related to leaks or ruptures of pipelines are exceedingly rare, but if a large rupture occurs, CO_2 can pose a health risk in the immediate vicinity. Siting pipelines in remote areas and following all federal and state regulations regarding monitoring and emergency response protocols in event of a leak are critical. Additionally, regulatory

[1] Values and information in this section are summarized from the suite of references cited herein, and are explained in further detail in each subsequent section.

frameworks for construction of CO_2 pipelines in California are not yet well-established.

9.1 Technology Summary

Between any potential carbon dioxide source or production and sequestration, safe transport is required. Pipelines, rail cars, trucks, and ships are all available forms of transport for carbon dioxide. In most cases, pipelines are the most cost-efficient choice,[2] especially for moving long or routine distances over land. These pipelines compress the carbon dioxide into a single phase (it can be gaseous, liquid, dense-phase or supercritical, depending on pipeline specifications) and then maintain controlled temperature and pressure conditions to safely deliver the carbon dioxide to its end use.[3] For the carbon management industrial park being examined here, that end use would be permanent geologic storage, taking place deep underground in nearby sequestration sites that have been appropriately permitted for such use, with the possible exception of some CO_2 utilized by other co-located industries (see Section 10).

9.1.1 Description: How It Works

Pipelines are the standard transportation choice for moving large volumes of carbon dioxide for extended distances (on the order of hundreds to thousands of miles) along overland routes,[4] especially when the sources and sinks are located at fixed points, as they are intended to be for proposed projects in Kern County. CO_2 pipelines are made from externally coated steel line pipe[5] and operate at high pressures to transport carbon dioxide between sources and sequestration sites.[6] There is also an external cathodic protection applied to prevent corrosion on the outside of the pipe.[7]

Because impure CO_2 streams (containing traces of NO_x, SO_x, O_2 or H_2O) can have corrosive effects on alloys and polymers,[8] non-steel or composite metal pipelines are not permissible to transport carbon dioxide under California law without an exemption approved by the federal Pipeline and Hazardous Materials Safety Administration (PHMSA).[9] Pipelines are more complex than a single steel tube, though. They have a range of parts, including "valves, compressors, booster pumps, pig launchers and receivers, batching stations and instrumentation, metering stations, and Supervisory Control and Data Acquisition (SCADA)

systems."[10] The number and complexity of these constituent parts is dependent on the pipeline's length, topography of the pipeline route, the need to adjust for pressure along-route pressure variability, and safety monitoring requirements.

Before pipeline transport, carbon dioxide must be dehydrated and not surpass certain oxygen or hydrogen sulfide (H_2S) concentrations to avoid internal corrosion of the pipeline or constituent parts, or cause stress cracking in the steel.[11] When necessary, there are coatings designed for the inside of pipelines in addition to the standard external coating.[12] Theoretically, corrosion-resistant pipeline could be designed that allowed for the transportation of carbon dioxide with higher concentrations of water or H_2S present.[13] However, given the high risks of H_2S to human health if a pipeline were to rupture or leak, purifying the carbon dioxide prior to transport is likely to remain a necessity.[14]

Figure 9.1. Installation of the Cortez Pipeline, a 30" diameter carbon dioxide pipeline located in New Mexico, during a maintenance upgrade conducted and documented by STATS Group. Image credit: STATS Group.

Finally, carbon dioxide needs to be condensed prior to transport, which requires specialized compressors.[15] Although similar compressors have been utilized in the natural gas industry, the unique properties of carbon dioxide require some design, material and sizing modifications.[16] Once compressed, carbon dioxide can be transported as a gas, liquid,

solid, dense phase substance, or supercritical fluid (Figure 9.2), depending on the pipeline length, requirements, and location.[17] The most common pipelines constructed in the United States are intended for liquid or dense phase carbon dioxide transport, with liquid being more common near population centers and dense phase more common in sparsely populated regions.[18] Although it can be transported in a variety of physical states, for a given pipeline, operators need to keep the carbon dioxide in the same state for all steps of transportation, as two-phase flows can interfere with compressors or other key equipment, increasing the odds of pipeline failure.[19] Optimizing CO_2 pipeline transport relies upon reducing impurities and controlling temperature and pressure to avoid unexpected pressure drops.[20] Since carbon dioxide exhibits nonlinear patterns of compressibility and density, pipeline operators typically develop point-by-point estimations of fluid properties along the pipeline's length using computational modeling.[21]

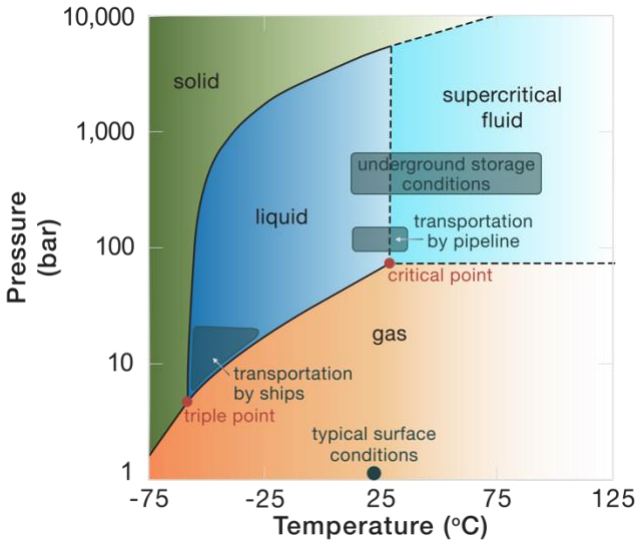

Figure 9.2. CO_2 is a gas at standard surface temperatures and pressures. When transported for permanent underground storage via pipeline, pipeline pressure and temperature is controlled to keep CO_2 in a denser phase. Dense phase liquids and supercritical fluids demonstrate properties of both a fluid and a gas - they can flow easily like a gas, but their high density allows for high flow capacity. Adapted from Paul et al. (2012).[22]

Commercial carbon dioxide pipelines, in which CO_2 is in a dense liquid phase or supercritical fluid phase for the entire journey, typically operate at pressures between 1,200 pounds per square inch gauge (psig) and 2,200 psig (83-152 bar), though some pipelines have higher maximum pressures in the 2,500 to 2,800 psig (172-193 bar) range.[23] These higher pressures allow the operator to minimize costs by increasing flow capacity for the

[23] EEIA (no date) Key Excerpts on CO2 Transport. p. 3. [7]

pipeline.[24] To ensure that the CO_2 remains in a dense phase state along the entire pipeline length, pumps are used to recover any pressure losses that can occur due to friction of elevation changes.[25] The allowable temperature range for the pipeline will differ between projects, with the minimum set based upon the winter ground temperature and the maximum set by the compressor-station output temperature and any temperature limits imposed by the pipeline coating composition.[26] A standard temperature range for carbon dioxide pipeline operation falls between 55 and 110°F.[27]

Pressure and temperature are not the only factors which impact carbon dioxide behavior. For example, the fluid flow rate responds to changes in pipeline diameter—for larger pipeline diameters, the fluid flow rate decreases, which should result in fewer pressure drops within the pipeline.[28] Extensive modeling is required to determine the most efficient and cost-effective balance of pipeline size, number of compressors, and route design.[29]

In general, CO_2 pipelines will need to be purpose-built to handle carbon dioxide, especially when intended for transporting large quantities of carbon dioxide or covering long distances. Pipelines designed to transport natural gas, for example, are in a different class according to the American National Standards Institute (ANSI)—they are not built to the same maximum pressure rating necessary for transporting carbon dioxide.[30] Some pipelines built for other energy purposes have been retooled to transport carbon dioxide at lower flow rates and/or for distances shorter than 100 miles.[31] Federal requirements for pipeline construction are set by PHMSA and are covered at greater length in Section 9.1.4.

9.1.2 State of Development

Carbon dioxide pipelines already constitute a small but growing industry. The United States is a global leader in the area, having established some of the first carbon pipelines in the 1970s.[32] As of 2015, the U.S. had over 4,400 miles of active carbon dioxide pipelines, with that figure growing every year.[33]

The vast majority of carbon dioxide pipeline projects support enhanced oil recovery (EOR) in Texas and the American West; the number currently deployed for sequestration is

smaller.[34] However, because the technical and regulatory requirements for safely and efficiently moving carbon dioxide are the same regardless of end use, pipelines developed for EOR can be used as a case study for new pipeline systems being constructed for permanent CO_2 sequestration.

9.1.2.1 Example projects

Pipeline companies: Kinder Morgan, Houston, TX and Trimeric, Buda, TX

Installation of pipelines are typically performed by third parties, rather than carbon management companies, sequestration companies, or even pipeline operators.[35] Kinder Morgan is the largest transporter of carbon dioxide in North America, although they also operate many of their pipeline systems. They have capacity to transport as much as 1.5 billion cubic feet (>77,000 metric tons) of CO_2 daily.[36] Although their operations are mostly sourcing CO_2 from natural source fields and delivering it to oil and gas operations for the purpose of enhanced oil recovery, the logistics of pipeline transport are the same for CO_2 sourced from capture industries and transported for the purpose of injection and permanent storage. Kinder Morgan's largest pipeline is 500 miles long and spans from Colorado to Texas.

Trimeric is another example of a third party company that could support pipeline development. They design CO_2 purification and compression facilities, and their company has served as technical experts and design engineers on a wide range of research programs supported by the U.S. Department of Energy, and for carbon dioxide pipeline projects in the United States.[37] Their process engineers have worked on all stages of the CO_2 transportation and storage process, including dehydration, cooling, pumping, liquefaction, compression, purification, and sequestration pumping.[38]

South West Hub Project, Western Australia

The South West Hub project, which broke ground in 2012, is designed to connect point source carbon emissions in industrial centers south of Perth to sequestration sites underneath the Lesueur sandstone formation in saline aquifers.[39] Publicly available video and conference papers largely emphasize the research conducted on validating Lesueur's feasibility as a sequestration site—the pipeline infrastructure needed for the project is less emphasized.[40] However, its overall model matches well with Kern's potential projects, where a number of known carbon producing or capturing sites within a carbon

[40] Sharma, Van Gent (2018) The Australian South West Hub Project. p. 12-14. [32]

management park will be directly connected with a sequestration site using the same pipeline infrastructure.

The South West Hub also presents an interesting form of management, as the project originated as a collaboration between the Western Australia Department of Mines, Industry Regulation and Safety, acting as the project lead, and industrial producers in the energy and chemicals space.[41] This project may be valuable as a type example for private-public partnership in carbon management projects.

9.1.3 Operational Needs

9.1.3.1 Land use requirement

Most carbon dioxide pipelines are relatively small, ranging from 12-28 inches in diameter,[42] and operate similarly to pipelines used for decades in the oil and natural gas industries, though they often operate at higher pressures.[43] On land, pipelines are typically buried 3 to 4 feet beneath ground level—thus at surface level, the physical footprint of the pipeline is invisible, except at metering or pumping stations.[44]

The siting of a pipeline is determined by state authorities; federal authorities are only implicated if a project crosses federal lands, uses federal funding, or if a project sought federal intervention to grant eminent domain.[45] Pipeline operators who operate as public utilities or common carriers may have greater flexibility over their siting options, as state and federal authorities can grant the powers of eminent domain to these projects to acquire land,[46] and because of existing rights-of-way utilities possess for other pipeline systems, like natural gas.[47] In lengthy pipeline projects, it is near impossible to site a project without exercising eminent domain.[48]

9.1.3.2 Energy requirements

Condensing the carbon dioxide gas into a dense state for transport requires a large energy input to reach appropriate pressurization, ranging from 90-120 kWh per metric ton of CO_2,[49] about the same amount of energy needed to power a home for 3-4 days.[50] CO_2 compressors can be fueled by "electricity, natural gas or diesel engines, steam, or a combination of

these,"[51] and could be the responsibility of either the pipeline operator or the capturing industry. For industries like DAC and steel, compression represents between 25% and <1% of the energy needs for CO_2 capture.[52]

Maintaining constant pressure and flow specifications along the length of the pipeline also requires energy input (using compression or pumps), although it is a small fraction of the energy needed for compression, and can be minimized through intentional route designs that take advantage of gravity to maintain flow through the pipeline.[53,54] Choosing between compressors or pumps to maintain constant pressure conditions within the pipeline depends on the intended physical state for transport—compressors are needed for gas, whereas pumps can be used for liquid or dense phase carbon dioxide.[55,56] Given the park's goal of carbon management, using low-carbon energy sources to power initial CO_2 compression and any additional pumps or compressors along the length of the pipeline should be a priority.

9.1.3.3 Other operational needs

Waste disposal requirements

There should be no waste disposal requirements for regular operation and maintenance of CO_2 pipelines, unless the pipeline or monitoring equipment requires replacement. Then, the old equipment would need to be disposed of or recycled accordingly.

The carbon dioxide itself often needs to be dehydrated and treated to reach a certain purity percentage (generally 95%) for efficient and safe transport, so preparing CO_2 for transport will likely produce some byproducts to dispose or reuse, like water and hydrogen sulfide (H_2S).[57] It is important to remove water from CO_2 streams because it can react with carbon dioxide to form carbonic acid (H_2CO_3) in the pipeline, which can cause corrosion. Similarly, hydrogen sulfide can interact with any remaining water to form sulfuric acid, another corrosive compound. Additionally, because H_2S is toxic to humans at any concentration exceeding 200 parts per million (ppm), for the safety of any communities located near a CO_2 pipeline, both water and H_2S should be restricted to reduce the likelihood and resulting risk of a pipeline rupture.[58] Water could be filtered and reused onsite in the industrial park (see Section 8). The most common disposal method for hydrogen sulfide is injection into deep geologic storage, as surface storage of sulfur generally constitutes a liability for the

[58] Forbes *et al.* (2008) CCS Guidelines. p. 43. [12]

producer.[59] However, this purification process would likely be the responsibility of a different party—i.e. the company capturing or generating carbon dioxide within the carbon management park—rather than the pipeline operator, and for many types of CO_2 capture explored in this report (BiCRS, DAC, oxy-fuel combustion), H_2S is not known to be a significant contaminant.

Warehousing requirements

There are no inherent warehousing requirements for transporting carbon dioxide, but the value of housing some carbon outside of the pipeline to maintain a constant supply, and therefore pressure, is likely advantageous.

9.2 Societal Impacts

9.2.1 Job creation potential

9.2.1.1 Number and types of jobs

Monitoring and upkeep of a local pipeline network will likely create between 8-20 high-wage permanent jobs.[60] CCS initiatives are also projected to generate indirect employment, as new pipeline manufacturing projects and administrative staff will be necessary in addition to jobs created on-site.[61] These indirect jobs may not be locally concentrated, however.

9.2.1.2 Training pipelines

Jobs in CO_2 transport require a mix of skill levels but overlap considerably with skills in other pipeline management or engineering jobs (like those in the oil and gas industry) and other heavy industries.[62]

9.2.2 Quality of Life

9.2.2.1 Location

Unlike transport via rail, truck, or ship, there is no noise or light pollution from a pipeline that would disturb nearby communities. Additionally, because CO_2 pipelines are buried, they produce no significant visual disturbances to the landscape. The primary issue relevant to locational justice is both the real and perceived risks of a pipeline leak or rupture.

---

[59] Forbes *et al*. (2008) CCS Guidelines. p. 43. [12]

[60] Carbon Capture Coalition (no date) Jobs and Project Development Status. p. 4. [3]

[61] Townsend *et al*. (2020) Thought Leadership. p. 15. [37]

[62] Carbon Capture Coalition (no date) Jobs and Project Development Status. p. 4. [3]

We explore this issue here, first in the context of general public's attitudes towards pipeline safety, and then with a focus on the actual risks associated with transporting CO_2.

Pipelines related to the energy sector have a long history of generating locational justice concerns, primarily for the environmental, health and safety hazards that they can bring. Some key examples from the oil and gas sector where locational justice has become a widespread public concern because of risk to local ecosystems, water resources and safety include the Dakota Access Pipeline,[63] Enbridge's Line 3,[64] and the Coastal GasLink project in Canada.[65] Given the historically large public debates around these major pipeline projects, the idea of placing any new pipelines in or near a community could drive resistance among local residents and environmental groups, even though piping carbon dioxide has a different purpose, and carries different risks (and safety mitigation measures) than piping oil or natural gas. For example, regional chapters of environmental organizations are already organizing against the construction of new carbon dioxide pipelines in other parts of the country. The Iowa chapter of the Sierra Club has been resisting three proposed pipelines primarily because the carbon transported has an unclear end-of-life—there has been varied messaging about whether it will be sequestered or used for EOR.[66]

Addressing the general public's hesitancy or resistance to development of pipeline networks requires open communication and education about the real hazards associated with CO_2 pipelines, how they differ from other types of pipelines, what mitigation strategies ensure low safety risks associated with these kinds of pipeline, and the current and developing regulatory frameworks that are designed to assess and monitor pipeline safety standards.

Safety risks associated with CO_2 pipelines

Unlike natural gas and other fossil fuels, carbon dioxide is not flammable or explosive, and if leaked in small quantities, will dissipate into the air without creating a hazardous situation.[67] But, in large quantities (over 40,000 ppm, or comprising more than 4% of inhaled air) it acts as an asphyxiant,[68] and if released quickly from the pressurized conditions of a dense phase or supercritical phase pipeline, can cause flash freezing - producing temperatures immediately around a pipeline rupture that are well below freezing, which can cause brittle failure of the remaining pipeline and exacerbate further

[68] FSIS (2020) Carbon dioxide health hazard information sheet. [13]

rupturing.[69] This means that small leaks present little health or safety risk,[70] and in fact, over the 50 years that CO_2 pipelines have operated in the U.S. there has been only one reported injury and no deaths related to pipeline operation.[71,72] A significant pipeline rupture, however, could pose a safety hazard. If a breach were to occur, carbon dioxide could be released into the atmosphere in high concentrations; because CO_2 is more dense than ambient air, rather than dissipating as it is released, it can concentrate in low-lying areas, risking the health of any residents in the area.[73]

Although leaks are uncommon, a significant event did occur near a population center in 2020. That year, a carbon dioxide pipeline ruptured near Satartia, Mississippi, sending 49 residents to the hospital. Residents reported seeing an eerie green cloud that left them "nauseated and dazed."[74] Carbon dioxide itself is odorless and colorless—the green shade of the gas reported in Satartia is thought to be due to high amounts of hydrogen sulfide in the supply, which likely worsened the health impacts on residents.[75] The Satartia rupture is thought to be the first outdoor CO_2 mass exposure event resulting from a pipeline failure globally.[76] However, as pipeline mileage increases in the future, potential for these types of accidents could grow. The federal Pipeline and Hazardous Materials Safety Administration, or PHMSA (responsible for pipeline safety and monitoring), has responded to the Satartia leak by promising additional regulations for CO_2 pipeline safety, with a focus on emergency preparedness.[77]

Mitigation options for CO_2 pipelines

To reduce public concerns about pipelines in general, other hazardous materials transported via pipeline – like natural gas – are typically odorized, so residents can identify a gas leak and evacuate. In theory, the same practice is possible for carbon dioxide moved through pipelines, although there are currently no requirements in place to odorize carbon dioxide prior to transport for the purpose of public safety.[78] There are some promising contenders for odorants, like disulfides or thioethers, although they increase pipeline operation costs and dilute the purity of the carbon dioxide stream.[79]

Compared to other types of pipelines, carbon dioxide pipelines are more susceptible to longitudinal running fractures, which can be a brittle or ductile weakness in the pipeline,

causing it to "unzip" several hundred meters.[80] To mitigate the severity of a potential rupture, propagation of these kinds of fractures can be inhibited with the placement of fracture arrestors along the pipeline. The arrestors are typically placed every 500 meters (545 yards) along the length of the pipeline, minimizing the distance a fracture can spread.[81,82]

Additionally, a variety of monitoring fixtures, both internal and external, can be used to ensure the pipeline is secure, or provide warning for emergency response if a rupture occurs. Meters can be placed along the pipeline to conduct computational pipeline monitoring (CPM) leak-detection, though this is not yet a regulatory requirement as it can be technically difficult to implement.[83] Other types of monitoring—including pressure point analysis or aerial and visual surveys—can also be used to identify potential leaks.[84]

Finally, the most effective safety measure for CO_2 pipelines is siting them far from urban or residential areas. Because CO_2 settles rather than dissipates, any impact from a pipeline leak will occur in the vicinity of the pipeline, although determination of safe distances from pipelines that experience an accidental rupture remains ongoing.[85]

Regulatory authority and monitoring

The Occupational Health and Safety Administration (OSHA) imposes safety regulations that impact carbon dioxide pipeline operators, including workplace safety laws that ban carbon dioxide exposure exceeding 5,000 ppm.[86] Requirements for pipeline construction and management have also been standardized by PHMSA within the U.S. Department of Transportation,[87] and operators that fail to meet standards of environmental safety can be issued with notices and fined.[88]

In response to the Satartia pipeline rupture, PHMSA initiated new rulemaking processes to strengthen regulations on carbon dioxide pipeline safety, including updating standards on emergency preparations and response, that may impose new requirements for the safe construction, maintenance, and operation of future pipelines.[89] As of the writing of this report, PHMSA has not released any new regulations determined from this rulemaking process. Currently, PHMSA regulations only apply to pipelines transporting supercritical carbon dioxide at a minimum of 90% purity. Projects where the carbon dioxide is in a liquid

or gas state, as well as lower-purity pipelines, remain less regulated.[90] Furthermore, PHMSA's current guidelines do not regulate maximum concentrations of water or hydrogen sulfide contaminants in CO_2,[91] despite their presence making pipelines more susceptible to corrosion and failure, and the added health risk of H_2S if a leak occurs.

In the state of California, the Pipeline Safety Division (PSD) of the Office of State Fire Marshal regulates supercritical and hazardous liquid pipelines (including CO_2 pipelines) following the 49 Code of Federal Regulation (CFR), Part 195 and the Elder California Pipeline Safety of 1981.[92] However, in 2022, the California state legislature passed law SB-905, stating that no new CO_2 pipelines can be built until the federal government updates its CO_2 pipeline policies with stronger safety regulations, or until state lawmakers can develop their own pipeline standards, based on recommendations from the California Natural Resources Agency (CNRA).[93] To this end, CNRA submitted a proposal to the California legislature in March 2023 for establishing a state framework and standards for intrastate CO_2 pipelines, which is now being considered.[94] Such a framework is critical not only for ensuring the safe handling and transportation of CO_2 for permanent sequestration, but also for ensuring public acceptance of nascent carbon management industries.

9.2.2.2 Multi-use potential

Since onshore pipelines are typically beneath the surface once installed, the land surface above a pipeline can still be used for a variety of purposes. Some forms of agriculture that require ample underground space for plant roots may be inappropriate, but myriad other applications should be sustainable on overlapping land, while keeping in mind the advantage of siting CO_2 far from human activity for safety reasons.

9.3 Environmental Impacts

9.3.1 Water requirements

No references were found identifying any water requirements for the operation of CO_2 pipelines. Given the technology, it is unlikely that water is necessary for operation beyond that generally required for construction.

9.3.2 Other potential impacts

California's Central Valley is naturally susceptible to seismic activity, and small earthquakes in the region are common and larger-scale seismic events are possible. This environmental stressor will exacerbate external pressure on any pipelines constructed and will need to be accounted for in construction and operational monitoring plans, as is done for all pipeline systems in the region.

9.4 Economic Impacts

9.4.1 Business Model

Business models for the operation of carbon dioxide pipelines can be flexible from project to project, based upon the operator's structure. For example, the owner or operator of the transport infrastructure could charge either CO_2 suppliers or CO_2 purchasers a tariff for using the pipeline network.[95] Given the proposed setup of a carbon management park as a putative CO_2 source and a sequestration well operator as a CO_2 "purchaser," both avenues of tariffs seem possible—either charging a tariff to members of the park to sequester their carbon dioxide off-site, or a transport tariff being covered as part of a carbon offset payment or other arrangement where an external company would act as a carbon purchaser.

Under either scheme, the pipeline operator can choose between different tariff calculation models. The two most common options are charging based upon the distance moved, by summing the specific costs per segment of pipeline traveled, or determining a system average cost to charge all users of the network (i.e. a flat rate per ton CO_2).[96] Based upon the current end-to-end structure of the pipeline that would be built for this project (modeled as a single business park producing CO_2 and supplying it to a single site for sequestration), a system average cost and total distance traveled would likely come out to near-identical tariffs. However, if the carbon management park model proves successful, there could be multiple parks in different locations, sharing a single pipeline system, in which case a preferred tariff model would have to be determined across parties.

The time horizon for profitability of a CO_2 pipeline network will depend upon the tariff rate and the total capital cost—without external incentives, it would likely take a few years before tariffs offset the millions spent on permitting, construction, and monitoring.

[96] Abramson *et al.* (2020) Transport Infrastructure for CCS. p. 31. [1]

9.4.2 Business Costs

9.4.2.1 Cost to build (upfront costs)

Upfront costs are a substantial hurdle to constructing CO_2 pipelines. In general, costs depend on the terrain, environment, and existing regulations around right-of-way.[97] Shorter pipelines requiring few bends and avoiding existing features in the built environment constitute the cheapest conditions for pipeline construction,[98] as does avoiding heavily built areas like cities and suburbs. The Greencore Pipeline in Montana, which spans private ranches as well as state and federal public lands was built for $68,635 per diameter inch mile; meanwhile, the Webster Pipeline built in the industrial and suburban districts south of Houston, Texas cost $199,176 per diameter inch mile to construct.[99] According to a 2018 IPCC report, population density and terrain are the largest determinants of cost: "Onshore pipeline costs may increase by 50 to 100% or more when the pipeline route is congested and heavily populated. Costs also increase in mountains, in nature reserve areas, in areas with obstacles such as rivers and freeways, and in heavily urbanized areas because of accessibility to construction and additional required safety measures."[100] Pipeline right-of-ways can amount to 4%-25% of the overall pipeline construction costs, with estimates at the lower end of this range in rural areas and higher end of this range in suburban or urban areas.[101]

In 2020, the Great Plains Institute developed a techno-economic analysis of building national CO_2 transport infrastructure to support near- and medium-term carbon capture and storage capacity at a national scale. They modeled how much of a variety of pipelines (distinguished by diameter, and therefore CO_2 flow rate capacity) would be necessary to capture CO_2 from the most economically feasible point sources of carbon dioxide existing today, and determined capital, labor and operation and maintenance costs of pipeline infrastructure as a function of pipe diameter and length. A summary of their analysis is detailed in Table 9.1, for the purpose of illustrating a few key points.

First, reducing the pipeline's length by siting the carbon source (like a carbon management park) and sequestration well projects close together, drastically lowers all costs (capital, labor and maintenance) for the pipeline operator.[102] Second, while smaller pipe diameters do result in lower costs per mile, due to lower material costs, large diameter pipelines are ultimately more cost efficient, as long as they are operating at capacity. The more CO_2 that is transported through the pipeline systems, the lower the effective cost per ton of CO_2.[103] The calculated costs of CO_2 transport per ton-mile (how much it costs to move one ton of

[103] Abramson *et al*. (2020) Transport Infrastructure for CCS. p. 29. [1]

CO_2 one mile) is lower than most summative estimates of the levelized cost of CO_2 transport (usually ~ $10-20 per ton of CO_2 from source to sink, see below), because most point sources of carbon would be unable to provide enough CO_2 for the pipeline to operate at capacity. For example, the calculations in Table 9.1 indicate that a 100 mile, 24" pipeline operating at full capacity would cost $1 per ton of CO_2 transported. However, that requires that the pipeline is transporting 25 million tons of CO_2 annually. The largest facility capturing CO_2 for the purpose of sequestration (not EOR) in the US today is the Illinois Industrial ethanol plant (operated by Archer Daniels Midland Co.),[104] which is capturing CO_2 at a rate of about 500,000 tons annually.[105] At that rate, it would cost over $50 per ton of CO_2 to pipe it for 100 miles in a 24" pipeline, and $15 per ton of CO_2 in an 8" pipeline. Such sensitivity to CO_2 capacity demonstrates the value of developing concentrated sources for large amounts of CO_2, such as could be achieved by co-locating CO_2-emitting industries and/or carbon removal industries like DAC or BiCRS/BECCS in a single business park.

Table 9.1. Capital and operating costs of CO_2 pipelines as a function of pipe diameter and segment length[106]

Pipe diameter	Segment capacity	Segment length	Capital costs	Labor costs	Annual O&M costs	Cost per Mile[a]	Cost per tCO_2-mile[b]
(inches)	($MtCO_2$/yr)	(miles)	(million USD)			(million USD)	(US cents)
8"	<5	8,560	$3,436	$3,672	$72.6	$1.1	1.8 ¢
12"	3-7	5,834	$4,195	$2.928	$49.5	$1.5	1.6 ¢
16"	6-11	2,675	$2,888	$1,777	$22.7	$2.0	1.5 ¢
20"	10-16	1,790	$2,704	$1,498	$15.2	$2.6	1.4 ¢
24"	15-25	59	$99	$63	$0.5	$3.0	1.0 ¢
30"	24-33	16	$34	$23	$0.1	$3.8	0.97 ¢

a. The sum of capital, labor and annual O&M costs (assuming a 30 year lifespan), divided by segment length.
b. The sum of labor and annual O&M costs normalized to maximum segment capacity and pipeline lifespan with the levelized capital cost, divided by the segment length. (Modeled for a 30 year lifespan and capital recovery factor of 12.5%.)

Another report which performed cost-benefit analyses of nation-wide decarbonization plans - Princeton's Net-Zero America report - calculated regionally specific building costs for CO_2 pipeline networks. To build a main CO_2 pipeline fully across the region of southern California, the report estimates a cost of $1.2 billion for 239 miles[107] of a 36" diameter

[104] Rassool *et al.* (2021) CCS in the circular carbon economy. [30]

[106] Data from Abramson et al. (2020) Transport Infrastructure for CCS. p. 23, 29. [1]
[107] Email correspondence with Chris Greig and Andrew Pascale, January 24-25, 2023.

pipeline, or $139,470 per diameter inch mile.[108,109] The cost per user (whether CO_2 supplier or buyer) for this pipeline could be reduced by incorporating other carbon dioxide pipelines into this system, creating a regional network in southern California to connect carbon producers or capture sites to sequestration sites in Kern County. The best layout for a hypothetical hub system to connect multiple sources with a single sink—whether it be "tree with branches" or "hub and spoke" (Figure 9.3)—would depend upon angles the pipelines from the sources are placed at relative to each other.[110]

Innovative financing could also reduce the overall capital needed to sustain regional scale pipeline networks. Financing options, including private activity bonds (PAB) or master limited partnerships (MLP), should be explored by any potential operator to reduce the direct capital required to start up operations.[111]

In addition to construction costs, it is also critical to consider the time needed for an onshore pipeline to go from development to deployment – estimated at four to six years.[112] Opening of a pipeline this decade, for instance, would require setting an ambitious project timeline now to be able to clear all the regulatory requirements needed, complete construction, and pass safety and environmental quality checks prior to deployment.

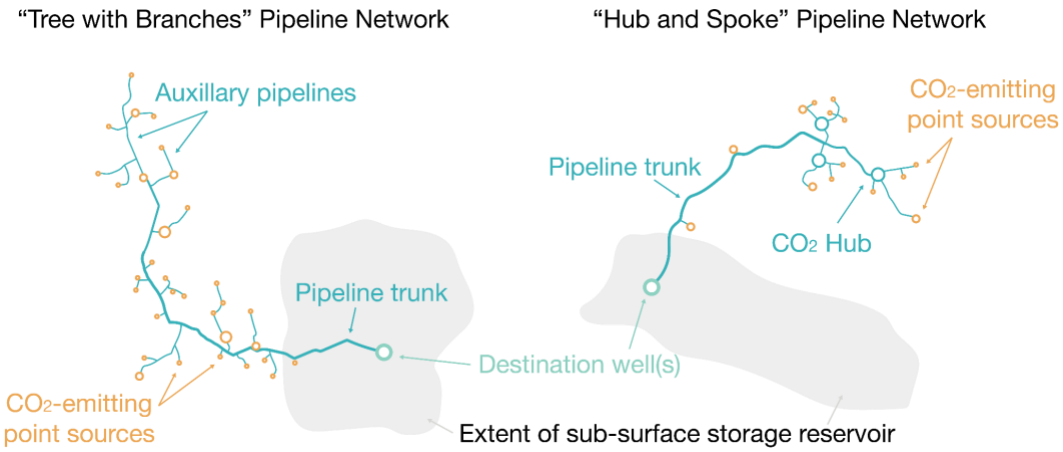

Figure 9.3. CO_2 transport pipelines are most cost-effective when built as a network, connecting multiple CO_2 sources to an underground storage site. The two most common pipeline network designs are a 'tree with branches' model, which has a single main line with many small, single-input offshoots, and a 'hub and spoke' model, where CO_2 sourced from several small facilities ('spokes') are combined in a 'hub' before being joined to a main pipeline.

[112] ZEP (no date) The Costs of CO2 Transport. [41]

Finally, it is worth noting that the expense of building and maintaining a CO_2 pipeline is not typically a significant portion of the cost of carbon capture and storage projects. Up to 90% of carbon management project costs come from the capture process itself, and the energy needed for CO_2 compression.[113] Transport is a relatively small portion of the overall cost of capturing CO_2 for the purpose of permanent underground storage.

9.4.2.2 Operational costs

Operation and management (O&M) costs of a pipeline vary by industry, as they are dependent on the required maintenance and monitoring technology. One estimate of O&M and labor costs – from the Great Plains Institute[114] – is given in Table 9.1. Such costs are often estimated to be between 4 and 7% of the original capital cost.[115] In scenarios explored by Princeton's Net-Zero America study, which looked at potential paths to get to net-zero nationwide by 2050, the estimated average cost to move a ton of CO_2 – considering capital as well as O&M costs – would range between $10-20, depending on the location.[116] For long distances or CO_2 derived from low-capacity sources (see Section 9.4.2.1), the cost would increase, but approximately 90% of carbon dioxide moved throughout this hypothetical national network could be moved for under $20/ton CO_2.[117]

As discussed above, there are additional safety considerations for an operator with locating pipelines near population centers, thus siting pipelines too close to communities can result in both higher upfront and heavier monitoring costs for operators.

9.4.3 Regional benefits

Any carbon management business park of the form considered in this study would likely find pipelines to be the most cost-effective form of CO_2 transport to locations suited for permanent underground storage. Additionally, regions like Kern County, where there is suitable geology and growing industry interest in developing CO_2 sequestration sites (as of the writing of this report, three companies have applied for permits from the EPA to construct Class VI wells for the purpose of CO_2 sequestration), development of a pipeline network is crucial. If a large carbon management park was developed within Kern County to act as the primary CO_2 source, pipeline distances could be exceptionally short by industry terms, requiring tens to a few hundred miles of pipeline, rather than hundreds to thousands (the county is 180 miles across at its widest point). Not only would short distances reduce the costs of construction and maintenance, but all of construction, monitoring, and taxation would fall under the same set of state and county regulations for the entire length of the pipeline, reducing regulatory or bureaucratic hurdles.

[117] Greig, Pascale, Wagner (2021) Net-Zero America Annex I. p. 33-34. [14]

9.4.3.1 Proximate consumers

As Kern County is already pursuing permits for a sequestration site and investigating the feasibility of a carbon management park, transport of carbon dioxide will be necessary to link these two distinct projects to fulfill their potential.

When applying for LCFS (Low Carbon Fuel Standard) or CARB (California Air Resources Board offset) credits, there will need to be a new legal arrangement drawn up between the supplier, the sequesterer, and the transporter about who will claim the credits and how they will be divided amongst parties within this relationship.[118]

9.4.3.2 Co-location advantages

The primary advantage of a carbon management park that can act as a 'hub' is particularly evident when dealing with transport. Pipelines are time-consuming to design and permit, expensive to safely build and monitor, and require meeting a range of regulations and environmental quality checks. Any company developing a pipeline project would want to ensure that there would be steady interest in carbon dioxide transport; the occupants of a carbon management park, who are either generating or capturing carbon dioxide, would be of substantial appeal because they would constitute a reliable source of carbon to transport. As for members of the industrial park, having another player provide the pipeline infrastructure can reduce overall costs and risks of their operation, as they can focus on the carbon capture and purification, but leave the transportation and sequestration portion to other companies. Thus co-locating has the appeal of distributing risk across a set of players.

9.4.3.3 Other

Although technically tricky to accomplish due to the differences between the material and safety requirements of oil pipelines versus carbon dioxide pipelines, there are operational projects that have retrofitted existing oil pipelines to transport carbon dioxide. In the Netherlands, the OCAP pipeline has been transporting carbon dioxide since 2004 using a retrofitted oil pipeline that had been out of commission for 25 years.[119] The right pipeline operator may be able to reuse existing oil and natural gas pipelines[120] in Kern County by upgrading them to the necessary specifications to safely move carbon dioxide, which could be less costly than constructing a new pipeline and reduce the burdens of permitting and obtaining right-of-ways. If such re-purposing is deemed unsafe for CO_2 transport be the ongoing assessment of state safety regulations,[121] it is worth investigating whether existing right-of-ways for these pipeline systems could be used for CO_2 transport as well, minimizing the time and expense of identifying and purchasing rights to new right-of-ways.

10. Carbon Dioxide Utilizing Industries

TECHNOLOGY AT A GLANCE

- There are a diverse suite of industries that can incorporate CO_2 into their production process or their final products. Most industries are in pilot or early demonstration phases of CO_2 integration. The exception is the food and beverage industry, which uses about 15 million tons of CO_2 annually.[1]
- The most promising industries for scaling up CO_2 utilization to the million-ton scale are in cement and concrete manufacturing, building materials manufacturing, synthetic carbon fuels, and plastics, polymers and other chemical manufacturing.
- Significant investment in research and development (± policy incentives) will be needed to bring costs down relative to competing, non-CO_2 utilizing products.
- Key advantages of these technologies to Kern County: co-location within a carbon management industrial park and near abundant clean solar and wind power will reduce operational costs and make CO_2-utilizing products more economically viable.
- Key concerns for this technology in Kern County: each CO_2-utilizing industry has its own suite of impacts and benefits, which warrant further investigation. Additionally, most CO_2-utilizing industries do not permanently store CO_2; it is (re)-released to the atmosphere on the order of months to years. Case by case life cycle analyses of the carbon removal benefit of a CO_2-utilizing practice will be necessary to understand whether it provides any climate benefit, and whether it is eligible for state or federal carbon removal incentives.

[1] Values and information in this section are summarized from the suite of references cited herein, and are explained in further detail in each subsequent section.

10.1 Technology Summary

Interest from governments,[2] companies[3] and scientists[4] around the growth of the carbon management industry is primarily for the purpose of carbon dioxide removal: pulling CO_2 from the atmosphere (through processes like DAC or BiCRS) or preventing CO_2 emissions from point sources (like steel mills), and storing that CO_2 permanently and safely underground to reduce the impacts and mitigate the costs of climate change. However, until the U.S. Inflation Reduction Act that passed in 2022 increased financial incentives for carbon sequestration, carbon capture for the purpose of permanent storage was, for the most part, not financially feasible.[5] As an alternative, several researchers and companies have explored options for using CO_2 in products, in ways that would either remove it from the atmosphere on timescales of decades to centuries, or replace products or feedstocks that would otherwise produce more greenhouse gas emissions.[6]

Even with the increased cost effectiveness of carbon management for the purpose of removal and storage, the research and innovations of recent decades in CO_2 utilization has seeded or expanded potential commercial markets for CO_2 that could complement sequestration programs, and those markets could grow in scale to using as much as tens of millions of tons of CO_2 annually by mid-century.[7]

The primary industries expected to use CO_2 are food & beverages, concrete & other building materials, fuels, and chemical manufacturing opportunities, and in this section, we provide a review of each of these sectors and how CO_2-utilization can be integrated into their products or supply chains. Because this section is an examination of several different nascent industries, and detailed evaluation of each is beyond the scope of this report, rather than presenting CO_2-utilizing industries in the format common to other industries examined here (through technological, societal, environmental and economic lenses), we will provide brief descriptions of each category of CO_2-utilizing industries, examining their state of development and describing example projects (Section 10.1), and then will consider the potential of these industries from a business model standpoint (Sections 10.2 and 10.3).

Note that the industries described in this section are not necessarily exhaustive examples of uses for CO_2. For example, it can be used to increase agricultural productivity or in cleaning or medical processes – but these uses are either addressed in other sections of the larger report or are negligible in the context of how much CO_2 they would utilize. As such, these uses are not explored in this section. Finally, one application of CO_2-utilization

is not addressed in this section at all: Enhanced Oil Recovery, or EOR. While globally, EOR is by far the largest market for CO_2, it is not a relevant market to consider for the purpose of a carbon management business park in Kern County, given that state law SB-905 prohibits operators from injecting CO_2 produced in a carbon management project into the subsurface for the purpose of enhanced oil recovery.[8]

10.1.1 Types of Industries

CO_2 can be used in its pure state for several purposes – an example many are familiar with is beverage carbonation. Currently, most commercial processes that rely on CO_2 use it directly.[9] However, if the goal of CO_2 utilization is to create a measurable impact in the reduction of atmospheric greenhouse gases, it will have to be adopted by industries that would use tens or hundreds of millions of tons of CO_2 annually. These types of industries – concrete, fuels, plastics and polymers, and other chemicals – require chemical or biological conversion of the CO_2 into usable products, which can be technologically complex and energy intensive. A summary of the wide range of industrial applications for CO_2 is shown in Figure 10.1, adapted from a comprehensive report on CO_2 utilization from the International Energy Agency (IEA),[10] to which the reader is referred for further information on the topic.

The CO_2 utilization market is relatively small (currently, about 25-35 million tons of CO_2 are used in non-EOR industries),[11,12] and likely to remain so in the short term, as carbon management companies that could cost-effectively source CO_2 are still in nascent stages of development, and the markets most likely to be large consumers of CO_2 (building materials and fuels) will require years of testing to ensure they meet regulatory and safety standards.[13] Additionally, adoption of CO_2 utilization practices will require either 1) a clear economic benefit compared to current techniques for an industrial activity or product development, or 2) a clear and measurable climate benefit to the utilization of CO_2 that adds enough value to its use that additional costs can be offset. For most CO_2-utilizing industries, neither of these goals has been clearly achieved yet – more expansive and improved methods to analyze the life-cycle emissions of CO_2-utilizing products will be necessary to inform the best policy and investment decisions for the future.[14] In the following sections, we provide a brief summary of the state of the art for CO_2 utilization in the food and beverage, concrete, building material, fuel, plastic & polymer, and chemical industries.

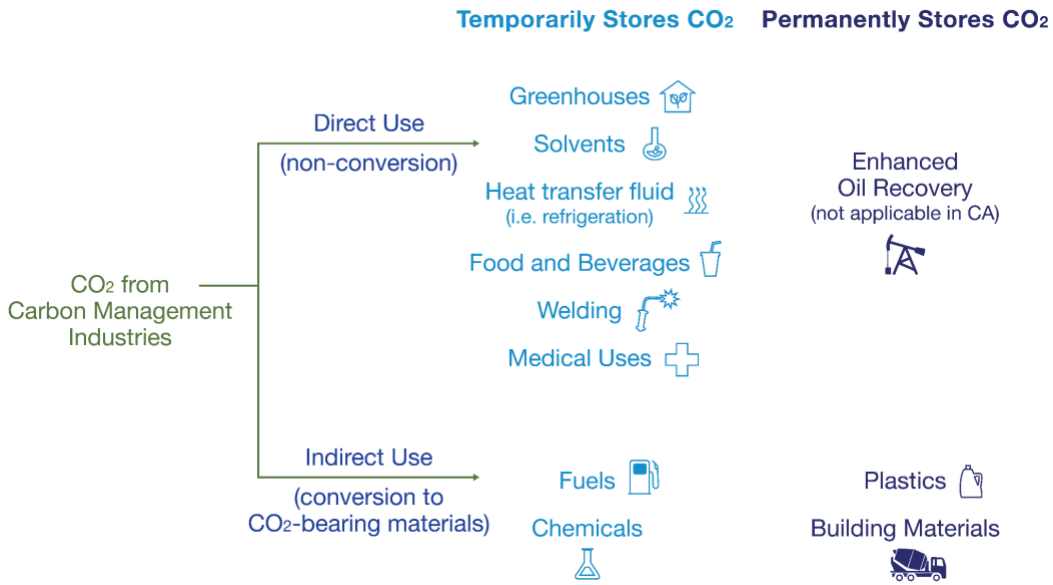

Figure 1. A summary of direct uses of CO_2 (including in greenhouses, in food and beverages and solvents) and indirect uses of CO_2 (including fuels, plastics, and building materials). Adapted from IEA (2019).[15]

10.1.1.1 Food & Beverages

Currently, the largest industry for CO_2 utilization (excluding EOR and fertilizers, see notes above) is the food and beverage industry, which purchases about half of the CO_2 on the market – approximately 15 million tons in 2015.[16,17] Carbonated beverages comprise about half of the use in the food and beverage industry,[18] but CO_2 is also used as a produce preservative, a freezing agent for meat, or to keep food items cold in transport as dry ice.[19] Food and beverage opportunities for CO_2 utilization are among the least useful in terms of atmospheric carbon dioxide removal; the CO_2 that is utilized will only be stored temporarily in the product before returning to the atmosphere.[20] However, it is one of the more well-established CO_2-utilization industries, with captured CO_2 already used on a commercial scale.

Another promising avenue of food and beverage applications is associated with chemical manufacturing opportunities. For example, sodium bicarbonate, or baking soda, can be formed through the chemical conversion of CO_2 (its chemical formula is Na_2CO_3). Baking soda is both widely used in commercial baked goods and sold directly to consumers.[21]

Chemical compounds formed by converting CO_2 are explored at large in Section 10.1.1.6 on chemical manufacturing.

Example Project: Coca-Cola HBC Switzerland, Switzerland

A Coca-Cola franchised bottler in Switzerland purchased captured CO_2 from the first commercially operating DAC facility in the world for use in beverage carbonation for its Valser sparkling water.[22] Climeworks' first generation Hinwil DAC facility supplied CO_2 to the bottling company from 2017 until the retirement of the facility in January 2023.[23] Presently, Coca-Cola is considering ways to expand its use of captured CO_2 across its products and Climeworks is looking to expand their CO_2 utilization offerings beyond Switzerland as their operations grow.[24, 25]

Example Project: Air Company, New York, New York

Air Company is a carbon utilization company that uses CO_2 conversion technology to produce carbon negative alcohol products, such as vodka, as well as personal care products including perfume and hand sanitizer.[26] Air Company's technology obtains CO_2 from point-source capture sources, then combines that CO_2 with green hydrogen (hydrogen via electrolysis) to create an alcohol mixture that is distilled and forms the basis for their product offerings.[27] They also rely wholly on clean energy (wind and solar) to support their processes.[28]

Air Company is planning to add fuel products to their commercial-scale offerings, namely sustainable aviation fuels, ethanol, and methanol (see Section 10.1.1.4).[29] Their aviation fuels have been successfully used by the U.S. Air Force in pilot-scale tests, and the company is currently in the process of scaling their operation to a commercial demonstration phase.[30] If expanded to all potential areas of business that Air Company has scoped (food, personal care and fuels), they anticipate their technology "could avoid 10.8% of global CO_2 emissions, the equivalent of more than 4.6 billion tons of CO_2 annually."[31]

10.1.1.2 Concrete

Concrete production is very carbon-intensive, accounting for at least 8% of global CO2 emissions.[32] Moreover, concrete demand is quickly accelerating—we use three times more concrete than we did 40 years ago, and as more nations industrialize, demand growth is expected to continue.[33] Thus decarbonizing concrete production has a clear positive impact on reducing global greenhouse gas emissions. There are already small-scale manufacturing facilities developing lower-carbon concrete, but it will require immense scaling and regulatory reforms before these products can replace traditional concrete.[34]

In general, CO_2 utilization in concrete production falls into two categories: 1) replacing water for curing, or 2) as a raw material within the concrete mixture. Both uses represent examples of CO_2 utilization that provide sequestration on the order of decades, so could benefit from carbon offset marketplaces or regulatory incentives for CO_2 storage.[35] CO_2 curing is both a mature and particularly promising avenue for CO_2 use, as it provides the co-benefits of decreasing water use, decreasing the production time for curing, and producing a higher-strength concrete. Additionally, the amount of CO_2 necessary for concrete curing is relatively minimal, so does not add significant manufacturing costs to cement production, even with the still relatively high costs of capture CO_2. Meanwhile, using CO_2 directly in the production process is a developing area of technology. Injecting CO_2 directly into concrete changes its material composition and could affect its properties—at this early stage of development, it is not yet clear to what degree. CO_2-rich concrete could have material properties that are essentially the same – or better – than conventional concrete.[36]

In terms of market readiness, barriers for CO_2-rich concrete are cost- and policy-related. One way to keep costs low while the industry (and availability of CO_2) evolves, is by injecting CO_2 into precast concrete materials, like concrete bricks, at a central facility rather than incorporating captured CO_2 into onsite concrete mixing or curing of concrete at building sites (see example projects below).[37]

In terms of policy barriers, all types of concrete are highly regulated for safety reasons. As such, extensive testing and regulatory reforms are necessary before any CO_2-utilizing concrete could be used for high-stability purposes. Thus, early market opportunities will likely rely on less-intensive concrete uses, like paving roads or poured concrete floors.[38]

[33] *Nature* (September 28, 2021) Concrete's colossal carbon footprint. [43]

[34] IEA (2019) Putting CO_2 to Use. p. 12. [34]

[35] The federal tax credits 45Q provides a reduced tax-credit for industrial uses of CO_2 (compared to permanent storage) as long as emissions reductions can be clearly demonstrated. From: IEA (November 4, 2022) Section 45Q credit for carbon oxide sequestration. [35]

[36] IEA (2019) Putting CO_2 to Use. p. 12, 54-55. [34]

[37] IEA (2019) Putting CO_2 to Use. p. 55-56. [34]

[38] IEA (2019) Putting CO_2 to Use. p. 12. [34]

Although developers are working on promising new industrial processes in this field, experts anticipate that the hurdles in scaling and deploying CO_2-utilizing concrete will be regulatory, rather than technical, in nature.[39]

Example Project: Carbicrete, Montreal, Quebec

Canadian company Carbicrete has developed a new process to reduce their carbon emissions that both changes the constituent parts of the concrete to be less carbon intensive and relies on CO_2 to cure its final concrete product.[40] Rather than mixing cement with aggregates and water to generate their concrete, they replace the cement with steel slag, which is incorporated into the mixture on industry standard equipment—removing the requirement for cement altogether.[41] Then, they mold precast concrete blocks that are cured with CO_2 in a specialized chamber, taking 24 hours to reach their full strength.[42] In testing, they have found their concrete has up to 30% higher compressive strength, improved freezing and thawing resistance, and the same water absorption properties of traditional concrete.[43]

Across Carbicrete's production process, more CO_2 is absorbed in the concrete than is emitted in manufacturing, making their concrete production carbon negative.[44] Currently, Carbicrete relies on captured industrial point-source emissions for its CO_2, but it is hoping to move to using CO_2 from Direct Air Capture (DAC) facilities in the future so they are actively removing existing CO_2 from the atmosphere.[45]

Example Project: CarbonCure, Halifax, Nova Scotia

CarbonCure's process relies on incorporating CO_2 directly into the concrete mix, where the CO_2 reacts with calcium ions within the cement (composed primarily of lime, or CaO and $Ca(OH)_2$) in order to form calcium carbonate ($CaCO_3$).[46] They market a range of products from their technology, including ready concrete mix, concrete bricks, precast concrete, and reclaimed water.[47] Their technology decreases both the water and carbon intensity of their concrete in comparison to traditional concrete.[48]

It's expected that over the next 30 years, about half of the emissions from new construction will come from embodied carbon, which is the carbon emitted during the manufacture of

[48] CarbonCure (no date) Innovative CO_2 Technologies. [14]

building materials.[49] CarbonCure's goal is that with their associated products, they could remove 500 million metric tons of embodied CO_2 from the environment by 2030, equivalent to taking 100 million cars off the road.[50]

Example Project: Solidia Technologies, San Antonio, Texas

Solidia Technologies is developing two processes for reducing CO_2 emissions associated with concrete production: one is to adjust the chemistry of the cement mix and the other - like other companies - is to use a CO_2 curing process.[51] Their cement formula is more silica-rich and less lime-rich than the most common cement recipe, Portland cement. Because lime production (converting limestone rock ($CaCO_3$) to lime (CaO and $Ca(OH)_2$) is an energy intensive process that releases CO_2 in the atmosphere, a cement chemistry with less lime has the effect of lowering the CO_2 emissions, energy requirements, and raw materials intensity of the cement and subsequent concrete products.[52]

The lime-poor cement is combined with sand granules to generate their concrete, which undergoes CO_2 curing. In the CO_2 curing process, the CO_2 reacts with the cement in the concrete to form calcium carbonate ($CaCO_3$), strengthening the material and chemically trapping the CO_2.[53] This process makes the concrete higher performing, reduces production costs, and drastically reduces the curing time to less than 24 hours, compared to a full 4 weeks for traditional concrete.[54]

If implemented globally, Solidia anticipates that their technologies could reduce carbon emissions from concrete production by up to 70%.[55]

10.1.1.3 Building Materials

CO_2 can be utilized for building materials other than concrete as well, with most applications involving the remediation of metal waste materials into carbonates that can be used as aggregates in construction.[56] Fly ash and steel slag are two examples of alkaline wastes - materials that have high concentrations of reactive metals like calcium and magnesium. These kinds of metals chemically bond with CO_2 to form solid carbonate materials ($CaCO_3$ and $MgCO_3$) that permanently bind the carbon. Carbonation of 1 ton of fly ash can sequester about 0.07-0.25 tons CO_2, and carbonation of 1 ton of blast furnace slag from steel operations requires about 0.26-0.38 tons CO_2. Not all of the CO_2 used is bound up in the product, but the cost of CO_2 input encourages recycling the CO_2 such that the majority of the CO_2 input will be sequestered. Producing carbonates from metal waste is a

[55] Solidia Technologies (no date) Impact. [51]
[56] IEA (2019) Putting CO_2 to Use. p. 59. [34]

relatively new industry, and life-cycle assessments of the CO_2-reduction potential of carbonated waste products are limited and often not transparent – substantial analytical work is still needed to establish the climate benefits possible from these processes.[57]

However, a co-benefit of metal-waste carbonation is that it binds harmful metals that could leach into the environment and cause harm, and it helps eliminate the costs of tailings or hazardous waste disposal in mining and industrial applications.[58] Thus, these practices have the potential to reduce the environmental impact of existing industrial sites requiring remediation and protect industrial communities from future environmental harm.

Carbonation of metallic wastes for construction aggregates does face economic hurdles before significant scaling can take place. Since building materials are readily and cheaply available, it is difficult for materials generated from waste to be economically competitive in the marketplace.[59] As a result, early markets are likely to appear only where there are large amounts of waste to process and tightening regulations incentivize safe remediation of that waste. Examples include regions around the world that are increasing regulations around disposing bauxite residue (informally called "red mud") from aluminum production,[60] and regions where industrial waste disposal is expensive, like the European Union (EU).[61] Regulations can also present hurdles, however; for example, EU law currently prohibits the integration of waste into commercial products, which could present challenges for bringing a carbonated aggregate generated from waste into the European market.[62]

Example Project: Carbon8, United Kingdom

In the UK, Carbon8 works to capture CO_2 from industrial sources and then, at the same site, react that CO_2 with residues and byproducts that would otherwise be destined for landfilling.[63] Once formed, these carbonated materials can be used for "a variety of applications including in cement blocks, road filler and green roofing substrate."[64] Carbon8's technology is notable because it can sequester CO_2 for long periods and has a relatively short production time, with an estimated time for its carbon capture and storage process of 20 minutes.[65]

10.1.1.4 Synthetic Carbon Fuels

Another budding industrial opportunity for CO_2 use is to incorporate captured CO_2 into new carbon fuels. These fuels could replace conventional fuels in use today, including gasoline, aviation fuels, methane, and methanol.[66] This prospect has clear potential: by volume, synthetic carbon fuels rank as the biggest use potential for CO_2, with the ability to provide a lower-carbon fuel option for industries with few non-carbon fuel alternatives, like the aviation industry, or by replacing fossil fuels with an option that is simpler to use and store than pure hydrogen fuels. However, synthetic carbon fuels come with challenges as well: generating fuels from CO_2 is very energy-intensive, and existing fuel standards may be difficult to meet with synthetic CO_2-derived fuels. Additionally, upon combustion of these fuels, CO_2 will be re-released into the atmosphere, and so these products are not pathways for permanent CO_2 removal and storage, and thus not eligible for carbon credits, or policies that incentivize carbon removal.[67]

Production of synthetic carbon fuels can be carried out through one of two pathways, either direct or indirect.[68] Both pathways involve combining CO_2 and H_2 for chemical conversion, summarized by this simplified reaction:

$$CO_2 + H_2 \text{ (or } H_2O) + \text{energy} \rightarrow \text{Hydrocarbon fuel} + O_2 \qquad \text{(R10.1)}$$

The direct pathway relies on hydrogenation, and the indirect pathway on a reverse gas-water shift process followed either by a Fischer-Tropsch (FT) or methanol synthesis process. Not all of these processes are equally ready for commercial deployment. Hydrogenation, FT, and methanol synthesis are all mature processes, but the reverse water-gas shift is still at the demonstration scale.[69] Other processes that develop CO_2-derived fuels via chemical or biological pathways are still in the research and development phase.[70]

Regardless of production pathway, producing synthetic carbon fuels is an energy intensive process, which significantly contributes to their high cost relative to fossil fuels. For example, in creating CO_2-derived methane and methanol, electricity accounts for 40-70% of production costs and is the primary reason that production costs exceed traditional methane and methanol by 2 to 7 times.[71] With improvement, CO_2-derived methanol may become price-competitive in the marketplace, but other fuels produced from CO_2 – methane, diesel, gasoline, and aviation fuel – are expected to require policy interventions

[66] IEA (2019) Putting CO_2 to Use. p. 9. [34]
[67] IEA (2019) Putting CO_2 to Use. p. 7-10. [34]
[68] IEA (2019) Putting CO_2 to Use. p. 10. [34]
[69] IEA (2019) Putting CO_2 to Use. p. 18. [34]
[70] IEA (2019) Putting CO_2 to Use. p. 9. [34]
[71] IEA (2019) Putting CO_2 to Use. p. 10. [34]

to compete with traditional fuels.[72] Some of the policy avenues that could precipitate this change in demand are explored in Section 10.3.2.

The energy demand of synthetic carbon fuels is intuitive - production of these fuels is essentially a reversal of the combustion reaction we use to obtain energy:

$$\text{Hydrocarbon fuel} + O_2 \rightarrow CO_2 + H_2O \text{ (or } H_2\text{)} + \text{energy} \quad \text{(R10.2)}$$

Thus, synthetic carbon fuels will only have value if the energy used to create them produces less CO_2 than would come from simply combusting fossil fuels. For example, using electricity generated from a coal-fired power plant to create synthetic carbon fuel could emit more CO_2 than it avoids. Thus, for any production facility, a full life-cycle analysis would be necessary to examine how beneficial these CO_2-derived fuels are when compared to traditional fuels.

Example Project: Carbon Engineering - Air to Fuels, British Columbia, Canada

Carbon Engineering is one of two leading companies in the development of Direct Air Capture (the other being ClimeWorks, see Section 3), having operated a pilot Liquid Direct Air Capture (L-DAC) facility in Sqamish, British Columbia since 2015.[73] In addition to their work in capturing CO_2 for the purposes of underground sequestration, the company's Air to Fuels program develops synthetic fuels that are drop-in compatible with existing infrastructure and engines. Their process involves reacting CO_2 captured from the air with green hydrogen derived from electrolysis (see Section 6) to create hydrocarbons that can be converted into synthetic gasoline, diesel or jet fuel.[74] In 2019, the reported cost to produce these fuels was ~ $4 USD per gallon.[75]

Example Project: George Olah Renewable Methanol, Svartsengi, Iceland

The George Olah Renewable Methanol facility, located in Svartsengi, Iceland, is the first industrial scale operation converting captured CO_2 to methanol fuel.[76] The facility was commissioned in 2011 and reuses 5,500 metric tons of CO_2 annually. It relies on captured CO_2 from a nearby geothermal power plant (point-source capture) to synthesize methanol via a catalytic reaction with H_2.[77]

Example Project: Air Company, New York, New York

Air Company is developing a variety of products utilizing CO_2, including alternative fuels, and is described in detail in Section 10.1.1.1.

10.1.1.5 Plastics & Polymers

Today, fossil fuels are not only used for energy production, but are a primary feedstock in the production of a variety of plastics, polymers and their derivatives: materials that are collectively described as the *petrochemical* industry. In the long term, decarbonization efforts would ideally reduce fossil fuel use in petrochemicals in addition to the energy sector, and to this end, plastics and polymer production is an industry with a strong potential for reusing captured CO_2 to create new products.[78]

A clear benefit to incorporating CO_2 into plastics and polymers is that it requires relatively low energy input, making it cost-competitive with many traditional manufacturing practices, and it reduces the raw materials necessary from fossil fuels.[79] However, this is not a fix-all solution—at least currently, CO_2 can only replace part of the raw material from fossil fuels necessary to form plastics or polymers, up to approximately 50% of the final products' mass.[80] Full life-cycle analyses would be necessary to quantify the degree to which CO_2-utilization reduces the emissions associated with polymer production. Additionally, while the longevity of CO_2-derived plastics and polymers could provide an environmental benefit in the form of long-term storage sites for CO_2, the accumulation of non-degradable plastic waste creates a different environmental hazard that needs to be considered.[81]

Example Project: Econic, United Kingdom

UK manufacturer Econic is using CO_2 to produce polyurethane, which is used in foam, coatings, sealants, elastomers and other products.[82] Their process relies on replacing a percentage of the material's polyols—cross-linking agents—with carbon dioxide, which serves not only to bind the CO_2 but also replaces a highly expensive standard polyol material, propylene oxide.[83] As a result, Econic estimates that their process will not only lower carbon emissions, but also save money for manufacturers.[84] Econic products are in development - with full scale production of their polyol technology planned to begin in 2024.[85]

10.1.1.6 Chemical Development

Most of the products discussed in the previous sections involved some form of chemical conversion of CO_2 into a new product. However, there are other ways to chemically convert CO_2 that does not fit clearly into these large, existing industrial sectors, like fuels, building

[85] Econic (January 12, 2023) Econic Technologies Named on the 2023 Global Cleantech 100. [23]

materials or plastics. This section encompasses products of CO_2-conversion that are outside of the previously described sectors, as well as some processes of chemical conversion that are in early stages of laboratory testing, but could have promising future applications.

Through processes described as biological conversion, CO_2 can be converted into fatty acids, amino acids, and proteins.[86] Synthetic amino acids and proteins can be used in animal feed or, in the future, to generate meat alternative products.[87]

Electrochemical conversion of CO_2 could produce a wide variety of products, including carbon monoxide and carbon nanomaterials.[88] Some products, like methanol and formic acid, can be generated through thermochemical or electrochemical conversion of CO_2.[89] These products are exceedingly versatile and useful. Carbon monoxide is used in the formation of an array of other chemical materials, including long-chain hydrocarbons for fuel and methanol. Carbon nanomaterials, depending on their specific shape and characteristics, can be used in fuel cells, batteries, automotives, and water treatment.

Methanol can be formed with CO_2, CO, and H_2 molecules, and serves as a reactant for forming other chemical compounds, including acetic acid, formaldehyde, and long-chain hydrocarbons. It can also be used as a fuel (see Example Project: George Olah Renewable Methanol in Section 10.1.1.4) – although less energy-dense than gasoline, methanol can be used in some gas-powered engines with minor modifications.[90] Lastly, formic acid can be formed through a multi-step process, but has thus far been rarely commercialized as it relies on an expensive catalyst and can be difficult to separate out at the product end.[91] Formic acid (or CH_2O_2) can be used as a food additive, pesticide (depending on local regulations), in cleaning products, in dyeing or treating fabric and paper products, and as an organic reagent for chemists.[92]

10.2 Growth in CO_2-Utilizing Industries: Obstacles and Opportunities

The International Energy Agency (IEA) has identified four primary factors that will determine the market viability of a CO_2-utilizing technology: scalability, competitiveness, climate benefits, and the policy & regulatory framework in place.[93] The IEA's analysis of

[86] ten Have (December 20, 2022) Don't bury money. [55]

[92] PubChem (no date) Formic Acid (Compound). [50]
[93] IEA (2019) Putting CO_2 to Use. p. 28. [34]

each of these factors are summarized briefly here, with additional focus given to national and state policies and funding opportunities that could impact growth of CO_2-utilizing industries in California.

10.2.1 Scalability

For new technologies, supply chains and infrastructure to produce new products take time to develop. In terms of CO_2-utilizing industries, key supply inputs are CO_2 and clean energy (and in some cases, hydrogen). For projects to grow from R&D testing scale to commercial production, large supplies of these inputs will be necessary, which requires either siting such industries close to input sources, or developing significant infrastructure (100% utility-scale energy and a large CO_2 (± H_2) pipeline networks). While these supply frameworks are in development, it will likely be several decades before such inputs are widely available.[94] Co-locating CO_2-utilizing industries in regions close to points of CO_2 capture, green hydrogen production, and abundant potential for clean, renewable energy, as would be the case in a carbon management business park in Kern County, would be highly advantageous, particularly before the infrastructure to support national supply chains is available.

Another critical determinant to scalability is marketplace demand, which varies widely across the products examined here. For example, demand for some of the sophisticated chemicals made with CO_2 will likely be constrained to chemical engineering firms, specialized labs, and other chemical industries. Meanwhile, demand for a product like concrete has grown exponentially over the last century,[95] and with applications across a wide variety of sectors that grow in tandem with population growth and social-economic development (residential, industrial, municipal, and commercial), is likely to continue such growth. Demand is also not fixed – new technologies may shift what materials are most in demand in ways that have not been considered here – but the ability to project future demand and revenue potential will certainly shape the types of initiatives that are pursued and funded within this early, exploratory phase. The IEA estimates that the five largest potential CO_2-utilization markets (fuels, chemicals, building materials from waste, building materials from minerals – essentially, concrete and cement, and CO_2 to boost plant yields – discussed in Section 11) each have the potential to scale up to tens of millions of tons of CO_2 use annually, on a global scale.[96]

10.2.2 Competitiveness

CO_2-utilizing products that will see success at a commercial scale are those whose use or CO_2-based production pathway can be easily implemented and have the lowest production costs, especially when ranked against alternatives. This will depend on the costs of the technology itself, the market price, and the cost of inputs—material, energy, labor. For

[94] Larson *et al.* Net-Zero America: Final Report Summary. [40]

[95] Andrew (2018) Global CO2 emissions from cement production. [4]

[96] IEA (2019) Putting CO_2 to Use. p. 1. [34]

example, plastics and polymers made with CO_2 reuse are expected to be quite competitive, as there's little additional equipment needed for production, the process can actually save money in material cost for manufacturers, and these products could be sold near the existing average market price for these plastic and polymer products.

In contrast, carbon-based synthetic fuels will need to compete against fossil fuels that have been historically abundant and heavily subsidized.[97] Building materials, like concrete, will need to compete on a global market where profit margins are low, so additional production costs are difficult to absorb without some kind of policy incentives.[98] Both of these types of CO_2-utilizing industries will likely need some kind of policy intervention to support their adoption during early stages of development (see Section 10.2.4).

10.2.3 Climate benefits

Life cycle emissions and other environmental benefits associated with products that utilize captured CO_2 is often difficult to characterize, but will be essential for quantifying the impact and cost-benefit of adopting products that utilize CO_2, as is determining the life cycle emissions of the products they displace. For example, for building aggregates that are developed from combining industrial waste (slag and tailings) with CO_2, there are clear benefits—not only does the construction industry have new aggregates to work with, the technology reduces wastes that could leach harmful metals into the environment. However, for an item like plastics or polymers, addition of CO_2 into the production process does not displace the need for raw materials from fossil fuels to create these products—the impacts are limited as current technologies do not fully displace the reliance on fossil fuels.

Benefits are also enhanced when the necessary energy to complete these processes is reduced through in the CO_2-utilization process compared to traditional methods, and/or if it supplied through clean sources near the production site. Depending on the region, this could include solar, wind, hydropower, geothermal, and/or nuclear energy sources.

Finally, the benefits of CO_2 reuse will be driven by the amount of time that the CO_2 is stored within the product. For building materials and concrete, this is on the order of years or decades; for beverages and fuels, this could be only a few weeks or months. Longer storage of the CO_2 within the product enhances the climate benefits by acting more as a CO_2 removal solution, whereas products with short storage spans only serve to recycle existing atmospheric CO_2, avoiding further CO_2 additions from fossil sources.

10.2.4 Funding Opportunities & Policy Support

To date, most of the investment in CO_2-utilization technologies has come from the private sector. Between 2008 and 2018, private investment in the form of venture capital and

[97] IEA (February 2023) Fossil Fuels Consumption Subsidies 2022. [32]

[98] Khung, Crete (2022) Life cycle assessment (LCA) and cost-benefit analysis for low carbon concrete. [38]

growth equity for start-ups in the CO_2-use space reached nearly $1 billion USD, globally.[99] It is worth noting that level of investment pales in comparison to other clean energy sectors. Global investment in electrified transport topped $139 billion dollars USD in 2020 alone, and $304 billion dollars USD were invested in renewable energy in the same year.[100] However, public funding and policy support is beginning to gain momentum within state and federal governments. The simplest and most direct policy support for CO_2-utilization is the development of incentives, guidelines or policies for using low-carbon products, or requiring products to stay below a maximum carbon-intensity (i.e. limit of how much CO_2 per unit product was emitted).[101] While politically less popular, another effective policy strategy is placing a price on carbon (a carbon tax), that reflects the cost of – and provides revenue for – mitigating climate change, while also encouraging the use of carbon-negative materials over carbon-intensive materials.[102]

As a climate leader within the nation, California has some statewide policies already informing practices in some CO_2 utilization areas. Federally, the United States supported research and development of CO_2 use through a variety of grant programs, and is beginning to develop additional policy incentives.

10.2.4.1 Relevant California State Policies

With a state-wide commitment to be carbon-neutral by 2045,[103] laws are being developed to directly address CO_2-emitting industries, many of which are industries that can use CO_2 (concrete and cement, fuels, plastics and chemicals). For example, California's SB 596, passed in 2021, requires the cement industry to reach net-zero carbon emissions by 2045, are changing the landscape by making climate improvements a necessity.[104,105] However, the high costs of decarbonizing some processes—like creating cement and concrete—have led operators to seek ways to work with the government to lower emissions.[106] California's Air Resources Board (CARB) is scheduled to release a comprehensive strategy to guide the state's cement industry to meet this goal by July 1, 2023, including defining metrics for greenhouse gas intensity, coordinating strategy with other state agencies, and incorporating ways to leverage state and federal incentives and market demand to promote low-carbon cement.[107]

[107] CARB (2022) SCOPING PLAN FOR ACHIEVING CARBON NEUTRALITY. p. 48. [8]

California's climate policies have also prevented the use of CO_2 for certain uses. SB 905 (2022) bans the use of captured CO_2 for enhanced oil recovery (EOR),[108] a process where CO_2 is injected into existing oil fields to extract hard-to-reach deposits, thereby extending the lifetime of oil fields.[109] SB 1314 (2022) effectively bans the use of CO_2 injection for EOR, explicitly citing that the state's support of CCUS technologies is driven by a desire to advance towards a carbon-neutral society rather than extending the lifetime of fossil fuel production facilities.[110]

10.2.4.2 Relevant United States Federal Funding Programs and Policies

At the federal level, funding in CO_2 utilization has primarily been in the form of grants for early-phase research and development (R&D). The 2009 American Reinvestment and Recovery Act (ARRA) invested $100 million USD in R&D projects focused on innovative CO_2 conversion projects,[111] notably in the building materials and chemical production industries.[112] From 2012-2017, a portion of the U.S. Department of Energy (DOE)'s Carbon Storage Program (between ~$1 and 10 million USD annually) funded an R&D portfolio of projects specifically in the space of carbon use and reuse.[113] A similar program (the Climate Innovation Research Opportunity investment program) launched in 2021, providing another $100 million USD grant program for low-carbon energy technologies, including those in the field of carbon capture and utilization.[114] The 2020 Energy Act authorized the Department of Energy to allocate nearly $7 billion USD in funds for various carbon management and removal programs, including carbon utilization.[115] Additional funding is planned from the 2021 Infrastructure Investment and Jobs Act, with $12 billion USD earmarked for investments in carbon capture, utilization and storage technology.[116]

Section 45Q in the tax code provides a credit for qualified uses of CO_2, most commonly used for EOR in the oil and gas sector, but other uses can qualify if they fall into certain categories. The language of Section 45Q(f)(5)(A) permits 45Q credits for processes that fix CO_2 via photosynthesis or chemosynthesis or chemical conversion that securely stores carbon, but other uses could become eligible if a commercial market exists and the use of qualified CO_2 is determined to be eligible for 45Q by the Secretary of Energy.[117]

In general, experts agree that governments need to develop more incentive structures to encourage CO_2 utilization, as well as more robust policies in place to quantify reduced or

avoided emissions resulting from CO_2-utilizing products or production pathways. Underpinning any policies or incentives with transparent measurement, reporting, and verification standards will be crucial to ensuring that development of CO_2 utilization programs results in meaningful emissions reductions or carbon removal.[118] Although this sounds straightforward, developing these standards is difficult due to the range of products that can be developed utilizing CO_2, and the need to assess the life cycle impacts of CO_2-utilizing products as compared traditional manufacturing methods for those same kinds of products.[119]

Finally, adaptations in existing legislation and regulations will also be required for the widespread adoption of CO_2-utilizing materials, especially in long-lived products like concrete and building materials that, for public health and safety reasons, are highly regulated. Without a clear regulatory pathway to the adoption of CO_2-utilizing materials as replacements for the carbon-intensive products used today, continued development and commercial scaling of these technologies will not be possible.

11. Connections with Regional Agriculture

OPPORTUNITIES AT A GLANCE

- Kern County's agricultural sector emits over 2 million tons of CO_2 annually, 65% of which comes from the degradation of agricultural waste, including livestock waste.[1]
- 482,000 tons of agricultural waste and 625,000 tons of livestock manure are produced in Kern County annually, and could be converted into renewable fuels, pure streams of CO_2, and/or a source of water.
- Conversion of 100% of Kern County's biomass waste could produce over 900 thousand metric tons of CO_2 annually.
- Biochar is a byproduct of BiCRS + BECCS processes, which could serve as a nutrient-adding alternative to fertilizer for regional croplands.
- Additional products of carbon management industries that could be useful to regional agriculture are water (depending on carbon management technology) and CO_2, which can be used to enhance greenhouse production.

[1] Values and information in this section are summarized from the suite of references cited herein, and are explained in further detail in each subsequent section.

11.1 Kern County's Agricultural Sector

Agriculture is a major industry throughout California's Central Valley, a region that produces about a quarter of the nation's food.[2] In Kern County alone, agricultural output is valued at over $8 billion annually,[3] making it the highest producing agricultural county in California by value in 2021.[4] The agriculture sector also leads the county in land use,[5] water use,[6] and employment,[7] providing nearly 1 in 5 county jobs directly, and supporting a variety of indirect jobs (i.e. sales of equipment, fertilizers, feed, and other supplies, or supplying food an beverage processing facilities). As such, understanding the ways in which carbon management and clean energy technologies can enhance, benefit from, or compete with this sector are worth considering.

A full examination of agriculture and its projected development in Kern County is beyond the scope of this report. Rather, in this section we will provide a brief overview of the current state of the industry, highlighting strengths, challenges and potential synergistic pathways between agriculture and the development of one or more carbon management business parks in the region.

11.1.1 The Current Agriculture Industry

Kern County's farmland is expansive, covering 2,295,497 acres of land according to the USDA's 2017 Census of Agriculture.[8] That means that farmland accounts for 44% of Kern county's land area of 5,206,176 acres.[9] Although over 80% of the county's sales are in crops, land use is more evenly distributed between livestock and crops, with 53% of farmland designated as pastureland and 42% of farmland designated as cropland.[10]

Agriculture requires more than land to flourish, though, and the water needed to irrigate Kern County's croplands is in jeopardy. In Kern County today, 2,294,000 million acre-feet of water is devoted to the agriculture industry.[11] That represents 93% of total municipal,

[11] WAKC (no date) Water in Kern County. [47]

industrial and agricultural water use in the county. More than 70% of that water is sourced from reservoirs to the north of the county, or from groundwater in subsurface aquifers.[12] With more frequent droughts impacting the region and the implementation of laws like the 2014 Sustainable Groundwater Management Act (SGMA), which requires local water users to achieve sustainable groundwater use by 2040,[13] less water will be available for irrigation from rain and snowfall, and significantly less water will be available from underground aquifers.[14,15] The Public Policy Institute of California estimates the combined impact of climate change and the SGMA could result in as much as 900,000 acres of fallowed farmland in the San Joaquin Valley by 2040. The number can be lessened (but not eliminated) with improved water trading rules, infrastructure investments, and improved agricultural productivity.[16]

Development of carbon management business parks like that considered here, provide a potential revenue-generating alternative to agriculture in fallowed croplands, while carbon management itself directly combats the primary driver of climate change-induced droughts. Below, we explore how principles of carbon management – both in collaboration with some of the carbon management industries described in this report and applied directly to agricultural practices – could help farms transition under these new circumstances.

Table 11.1. Agriculture-related emissions in Kern County and California[a]

Emissions Source	Kern 2005[b]	CA 2005[c]	CA 2020[c]	% Change[d]
Livestock enteric fermentation	633,214	10.5 million	11.0 million	+5%
Livestock manure management	741,173	10.4 million	11.6 million	+12%
Crop growing & harvesting	575,572	8.2 million	6.8 million	-17%
Fuel combustion	74,511	4.6 million	2.3 million	-50%

11.1.2 Carbon Capture Potential

In 2012, the Kern County Department of Planning and Community Development created an inventory of community-wide greenhouse gas emissions, estimating the county's sector by sector emissions impact in 2005, in units of metric tons CO_2-equivalent (CO_{2e}). The agriculture sector sequestered ~400,000 metric tons of CO_{2e}, annually, through the process of photosynthesis and plant growth, but released over 2 million tons of CO_{2e} through enteric fermentation (digestive gasses of livestock), manure management, crop growing and harvesting, and fuel combustion (Table 11.1).[17] The report forecasted an ~30% increase in emissions by 2020, but no subsequent studies have been undertaken at the county level. At the state level, livestock related emissions have increased 5-12%, crop-related emissions have decreased 17%, and fuel combustion-related emissions have decreased 50%, with the net effect being very little change in agriculture sector emissions since 2020.[18] Of these emissions, some can be reduced through partnerships with biomass with carbon dioxide removal (BiCRS) technologies, detailed in Section 11.2, while others can be reduced through low carbon farming techniques, which are introduced briefly here. With sustainable practices and low-carbon techniques, farms can reduce their overall impacts on the environment. From low-till farms and crop cover to technical systems equipped to monitor water and nutrient levels, there are a variety of potential avenues to reduce the carbon intensity of farming.

About 28% of Kern County's agricultural emissions come from crop growing and harvesting, which includes fertilizer use, soil preparation and disturbance, and crop residue burning.[19] Many of these emissions can be reduced through the practice of *carbon farming*, a set of farming tactics that sequester carbon or reduce the GHG emissions of agriculture by focusing on the importance of CO_2 drawdown via photosynthesis as a carbon removal strategy.[20] An example is no-till farming practices, in which the topsoil is left undisturbed, preventing it from releasing its stored carbon into the atmosphere.[21] Other practices, like cover cropping, also serve to sequester carbon in soils and keep the ground nutrient-rich for other crops. With cover crops, new roots help feed the soil's ecosystem of fungi, bacteria, and other organisms over time, gradually increasing the soil's carbon levels.[22]

Currently, these practices are not standard for agricultural land in the region—the USDA found that in Kern County, less than 10% of farms are no-till or reduced-till and that only 2% of farms have cover crops.[23] However, interest has been rising in these practices nationally, and many feel there could be economic benefits as well as climate benefits

[23] NASS (no date) Agriculture Census: Kern County. [32]

associated with their adoption. Reporting from the USDA indicates that shifting from conventional to continuous no-till farming uses a third of the amount of diesel for farm equipment per acre, saves time in field maintenance, and can save money in future years as the more nutrient-dense soil requires less water and fertilizer to thrive.[24] Agricultural planners in Minnesota have reported that the net profit from farms earning $5.25 per acre with conventional farming can increase up to $112 per acre with a combination of no-till and cover cropping practices.[25]

More technologically driven carbon farming techniques include implementation of advanced monitoring equipment and automated systems, which can also help reduce water and fertilizer usage on agricultural lands. A variety of sensors are available to monitor farmland conditions: temperature sensors, electrochemical sensors for nutrient levels and pH, mechanical sensors to monitor soil compression or displacement, airflow sensors to test soil air penetration, and dielectric sensors for calculating soil moisture levels.[26] These systems can also be equipped to identify environmental threats like drought stress early, giving farmers more time to plan and mitigate such risks to their livelihood. [27]

11.2 Potential Relationships with a Carbon Management Business Park: Feedstocks and Products

11.2.1 Agricultural Waste as Carbon Management Feedstocks

Industries under the carbon management umbrella, though they all aim to sequester carbon, utilize different feedstocks and produce varied byproducts of capture. For biomass with carbon dioxide removal or biomass-to-energy with carbon capture and storage processes (collectively referred to as BiCRS, see Section 4), the feedstock is biomass. From an environmental perspective, the biomass source is ideally waste from existing agriculture or forest management practices. Examples specific to agriculture include plant residues (stalks, pits, shells) from harvest seasons, tree trimmings, or other discarded organic material. Obtaining BiCRS feedstocks from such sources solve two problems: they reduce the potential land and water use impacts of BiCRS that would result from producing dedicated feedstock crops, and they prevent the release of CO_2 that has already been trapped in that biomass material back to the atmosphere. Often, agricultural residues are left to decompose on the cropland,[28] releasing their carbon content as either methane (CH_4)

[28] Lal (2005) World crop residues production and implications of its use as a biofuel. [26]

or CO_2 into the atmosphere, or are they burned.[29] The latter technique, common in orchards and vineyards, also releases air pollutants like SO_2, nitrous oxides, and particulate matter,[30] and are a particular health hazard to the regional community.[31]

In Kern County in 2021, 482,000 tons of almond hulls, almond shells and crop biomass were produced.[32] From 2000-2020, between 200,000 and 1,200,000 tons of agricultural waste were burned in the San Joaquin Valley each year.[33] The variation is due to increasing burn prohibitions from 2003-2011, which were relaxed over the following decade in response to drought-related fallowing of croplands. In 2021, the California Air Resources Board (CARB) renewed their plan to phase out agricultural burning entirely by 2024,[34] meaning disposal alternatives will be required for the region's agricultural waste. Currently, CARB is offering a grant program that incentivizes 'whole orchard recycling' as an alternative to burning.[35,36] Whole orchard recycling involves the chipping and grinding of waste material, which is then re-incorporated into the soil. It has the advantage of restoring soil nutrients, but may still release greenhouse gasses to the atmosphere as it decomposes into the soil. Another disadvantage is that it is a tax-funded program that may not run indefinitely. A more ideal solution to agricultural waste removal is identifying a buyer, for which BiCRS industries would be strong candidates.

Based on the average amount of carbon in organic feedstocks (~49% by mass of the dry tonnage),[37] the agriculture waste in Kern County alone could produce as much as 860,000 metric tons of CO_2 for geologic storage, depending on the BiCRS technique applied. If all of the San Joaquin Valley's agricultural waste were used for carbon management (approximating from the maximum rate of annual burning), as much as 2 million metric tons of CO_2 could be produced for geologic storage.

11.2.2 Renewable Natural Gas (RNG)

Another industry that relies heavily on biomass inputs is the renewable natural gas (RNG) industry. RNG relies on capturing the biomethane released from decomposing biomass, which can then be captured and compressed for use as natural gas.[38] A wide variety of

[37] Baker *et al.* (2020) Getting to Neutral. p. 31. [4]

[38] Murillo (August 8, 2022) A RNG Facility Will Be Opening Soon in Lost Hills. [31]

biomass can be used for RNG—agriculture waste and dairy manure are the most relevant for this section, but waste from food, wastewater, and landfills can also be used for RNG.[39]

Over the last decade, RNG has already been making inroads within Kern County. The CalBioGas cluster in Kern County is a joint venture wherein local dairy farmers use onsite dairy digesters to capture methane (CH_4), which is then shipped to a central upgrading facility run by California BioEnergy and Chevron that converts the methane into RNG.[40] A company described in detail in the BiCRS section of this report (Section 4), San Joaquin Renewables, is planning to site its first waste biomass-to-RNG facility in McFarland and will be producing RNG alongside its plans to capture and sequester CO_2.[41] Once active, their RNG will be transported using pipelines from regional energy provider SoCalGas.[42] SoCalGas has been actively embracing RNG as an energy alternative, with nine RNG projects currently connected to their system.[43] By 2030, SoCalGas is aiming to have 20% RNG in the natural gas supply that it sends to core customers.[44] Given these recent and upcoming projects, it appears that there is substantial interest in future RNG expansion in Kern County.

A significant contribution to the enthusiasm for RNG comes from economic incentives – under California's Low Carbon Fuel Standard (LCFS) program, in effect until at least 2030, RNG can qualify for LCFS credits in any situation where RNG is replacing "conventional transportation fuel in California,"[45] significantly subsidizing the cost of production (see Section 4). But there are carbon management incentives worth considering as well.

Anaerobic digestors, which are a typical first step in the conversion of biomass waste (particularly livestock manure) to RNG, produce *biogas*, which is a mixture of methane, CO_2 and other trace gasses.[46] About 18-27% of livestock manure solids (dry weight) will be converted to biogas.[47] Biogas is then *upgraded* to produce RNG (Figure 11.1),[48] by stripping the CO_2 and other gasses, leaving pure biologically-derived methane that can serve as a drop-in replacement anywhere methane is used. The ratio of CO_2 to CH_4 in the biogas is about 30-40 mol% CO_2 and 60-70 mol% CH_4.[49] That means that for the 625,000 tons of

[49] Yentekakis, Goula (2017) Biogas management. p. 3. [48]

livestock manure produced by Kern County in 2021,[50] about 150,000 tons of biogas can be produced, which can be separated into about 4 million cubic feet of RNG as well as 85,000 tons of CO_2 for geologic storage.[51]

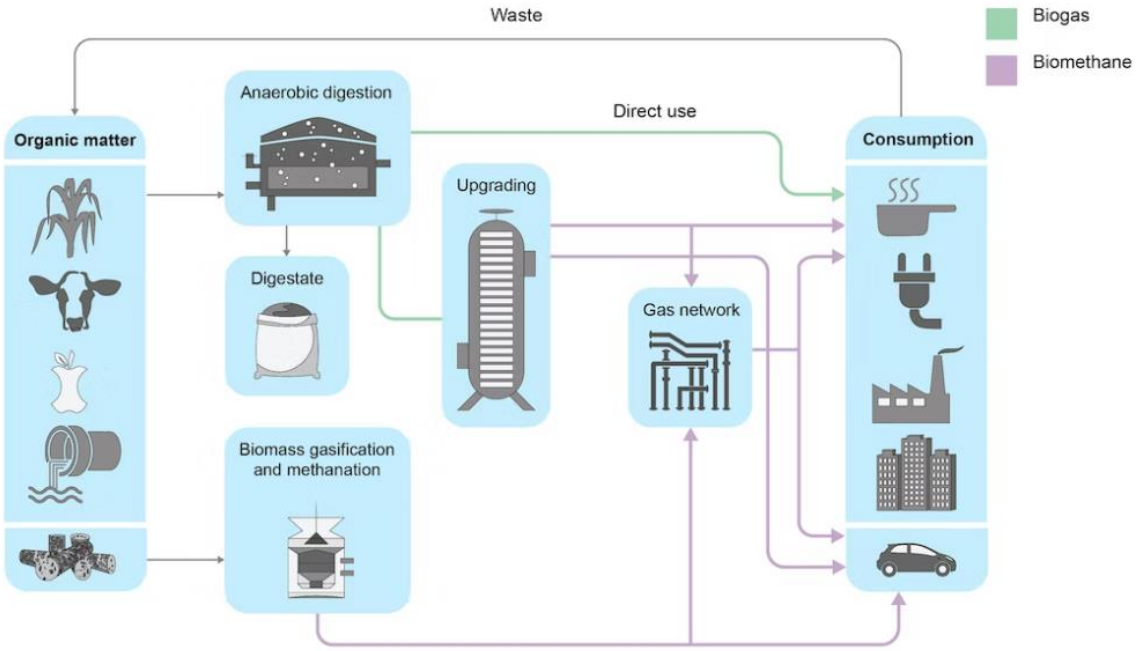

Figure 11.1. Schematic of RNG production. Image credit: International Energy Agency (IEA).[52]

11.2.2 Carbon Management Byproducts as Agricultural Supplements

Some BiCRS process used to convert biomass also generate useful byproducts for agriculture. For example, biomass processed via pyrolysis and gasification produces biochar, a soil additive that can support soil microorganisms, mitigate heavy metal toxicity, and raise soil pH.[53,54] Biochar can often be applied in place of traditional fertilizers, which has downstream benefits for the environment, as it prevents nitrogen runoff into

[50] Kern County Department of Agriculture and Measurement Standards (2022) 2021 Kern Agricultural Crop Report. [23] (Note: we are assuming dry tons. This is not explicitly stated in the report, but is consistent with the fraction of California's livestock farms located in Kern County and the state-wide dairy manure biomass estimate in Baker *et al.* (2020) Getting to Neutral. p. 32., which is listed in bone-dry tons.)

[51] Assumptions made in this calculation: Livestock manure was reported as dry tons, conversion factor to biogas is 25%, molar ratio of CO_2 to CH_4 is 30%:70%, 1 metric ton of methane at atmospheric pressure is 57,800 cubic feet.

[52] IEA (no date) Introduction to biogas and methane. [21]

[53] ARS (no date) What is Pyrolysis? [2]

[54] ARS (no date) Exploring the Benefits of Biochar. [1]

waterways and the release of excess nitrous oxide (N_2O) into the atmosphere—a greenhouse gas that warms the planet 300 times as much as CO_2.[55]

Additionally, some biomass gasification processes and S-DAC facilities generate water as a byproduct. The biomass gasification for San Joaquin Renewables uses local wood waste and nut shells to generate water along with biochar, renewable natural gas (RNG), and CO_2 for sequestration.[56] Clean Energy Systems, which has an existing test facility at Kimberlina in Kern County,[57] and purchased the idle Delano biomass facility, also in Kern, with plans to develop it into a BiCRS facility (still in the pre-permitting and assessment phase),[58] also produces water as a byproduct of their oxy-fuel combustion system (Section 4). Though utilizing an entirely different process, Climeworks' solid direct air capture (S-DAC) system also generates water alongside CO_2, generating 0.8-2 tons of water per ton of CO_2 captured.[59]

11.3 Other Collaborative Opportunities

11.3.1 Multi-Use Potential

Another potential opportunity for symbiosis between regional agriculture and carbon management industries is to share resources—primarily land, but potentially water as well—with local agriculture.

If water resources become increasingly scarce and farmers are being required by new groundwater policies to make decisions to permanently fallow unproductive land, then land could be rented or sold to carbon management companies, who may have large land use requirements to operate facilities (especially if they rely on solar power). In this arrangement, the land would continue to be profitable through the rents paid. Additional funding could be raised if farmers sold water to carbon management industries to operate. Some companies in the green energy and carbon management space are explicitly looking for landowners to partner with to deploy their processes, including NovoHydrogen, a company planning to develop local hydrogen fuels without degrading the land,[60] and InterEarth, looking for sites appropriate for their direct biomass burial method.[61]

Some technologies hold the promise of being able to operate with high mobility or to be decentralized, with nodal facilities spread out over large areas. In terms of high mobility, one example is Charm Industrial—their biomass pyrolyzer equipment can fit in the back of

[61] InterEarth (no date) For Farmers. [20]

a semi-trailer and can be driven directly to a site, so biomass doesn't have to be transported to a central processing facility.[62] Charm also pays farmers to be able to collect their biomass, and their unit can be temporarily stationed on the edge of a field during harvest season, when there is an abundance of waste biomass, and then offsite the rest of the year.[63] In terms of diffuse land use, direct air capture (DAC) is a prime example of technology that works well spread out across the land. Although DAC contactors can be placed anywhere (see Section 3), there is likely a minimum spacing of several hundred yards between contactors, to ensure the CO_2-free exhaust of one contactor fan does not directly feed into the next.[64] The space between contactors could be used for other land-intensive purposes, like farming or solar panels. However, there are uncertainties about how well crops would handle growing in between units that absorb CO_2 from the atmosphere, as plants also need to absorb CO_2 from the atmosphere to grow successfully.[65] This issue warrants further investigation.

11.3.2 Greenhouses

Greenhouses are experiencing a period of growth in California, driven primarily by drought conditions and an increasing consumer demand for organic and locally-grown produce.[66] This is because greenhouses promote higher productivity, even in less optimal environments: farming can take place on a smaller land footprint with lower water usage while still obtaining high crop yields.[67] Innovations like UC Santa Cruz's solar greenhouse, which uses transparent solar panels to filter light and help offset operational costs, are working towards the development of greenhouses that could be used "in most of California" rather than just along the coast.[68] Although these developments are still in pre-commercial stages, it presents another opportunity for the long-term future of agriculture in Kern County and California at large.

If greenhouses were implemented in Kern County, some of the CO_2 captured by carbon management industries could be supplied to the greenhouses to encourage plant growth. CO_2 must be very pure to not damage the plants,[69] but increasing the CO_2 concentration of the ambient air inside greenhouses can increase yields of some crops by up to 25-30% with CO_2 application.[70] Typically, greenhouses obtain CO_2 from combustion of natural gas, which also serves as a heat source for the facility. A retrofitted oil pipeline in the

Netherlands spanning over 180 miles demonstrates a viable alternative: the pipeline supplies 500,000 metric tons of CO_2 annually (captured from hydrogen production) to over 600 greenhouses in the region, and without the need of producing CO_2 from natural gas combustion, the greenhouses are able to switch to more sustainable heat sources.[71]

11.3.3 Other Potential Opportunities

This report is not comprehensive. There are other opportunities in the agribusiness space that may work symbiotically with carbon management technologies but were not identified to be good fits for Kern County at this time, and thus were not explored further here, although some examples are discussed in greater detail in other sections of the report. These include developing dedicated biomass crops to sustain BiCRS operations (also addressed in Section 3) or using CO_2 to promote algae growth to generate petroleum substitutes[72] (also addressed in Section 10).

A proposed component of the Carbon Management Business Park is a dedicated Research and Development Incubator, which would be an ideal setting for the exploration of new ways that local agriculture and carbon management industries could serve one another.

Appendices

Appendix A. Existing commercial and industrial power facilities with CCS

Appendix B. Commercial and industrial power facilities with CCS in advanced development

Appendix C. Commercial and industrial power facilities with CCS in early development

Appendices A-C are summarized from the Global CCS Institute (GCCSI) CO_2RE Facilities Database, a list of all historical, active, and developing carbon-capture related projects worldwide. The database is maintained, and updated regularly to reflect status updates and new projects. The lists represented by Appendices A-C represent the status of the global carbon management industry as of the publication of this report. The database was sampled for this report on March 18, 2023.[1]

Appendix D. Comparative analysis of carbon management industries

A primary objective of this report is to provide an accessible resource for cost-benefit analysis of a variety of carbon management technologies that could hypothetically be developed in Kern County. We developed quantitative estimates of 6 key metrics across all 5 carbon management technologies examined in detail (L-DAC, S-DAC, BiCRS, green hydrogen from biomass, and steel with point source carbon capture):

- Land use
- Energy use
- Water use
- Job growth potential
- Cost to build (a proxy for potential county tax revenue)

[1] Global CCS Institute (GCCSI). CO_2RE Facilities Database. Published (no date). Accessed March 18, 2023 from https://co2re.co/FacilityData.

- Cost per ton CO_2 (a reflection of the competitiveness of the industry in the emerging carbon market)

Details of how each estimate was determined is given in the relevant section of the report, but how each industry compares with each other across these six metrics is shown visually in Appendix D across a suite of Figures D.1- D.6. The same figures are provided in the Comparative Analysis section of the companion website, at cmbp.kernplanning.com.

Appendix D.
Comparative analysis of carbon management industries

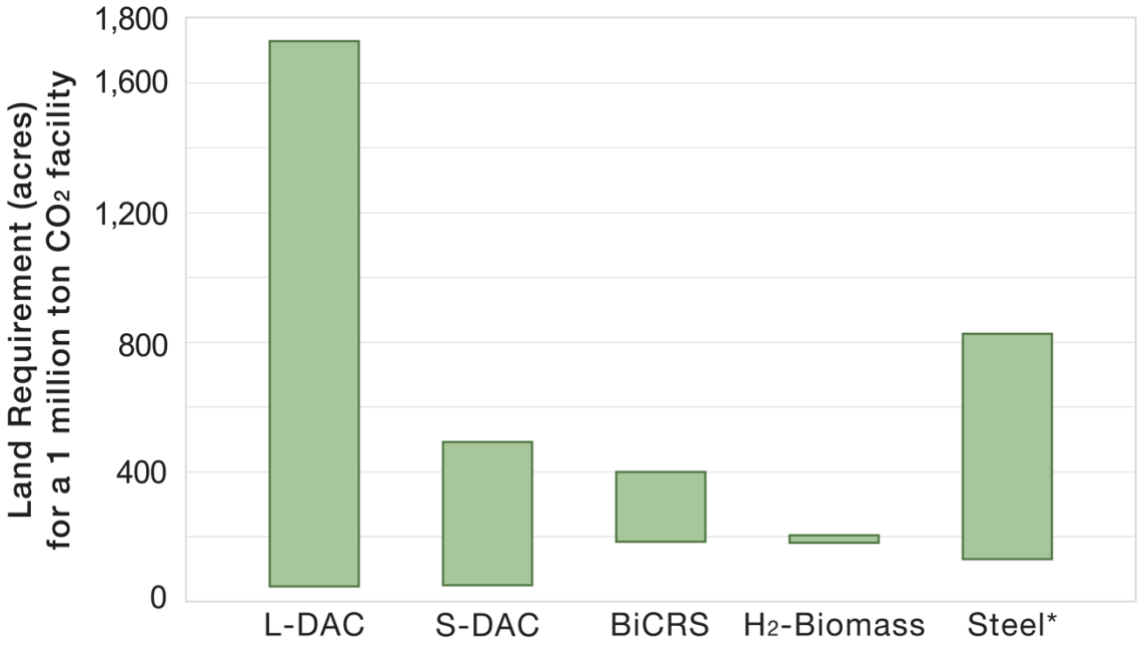

Figure D.1. Land Use. To capture 1 million metric tons of CO_2, the land use requirements of facilities vary considerably. Across the examined industries, estimated footprints range from 0.08 to 2.73 square miles (49-1730 acres). In cases where there is not an operational facility with the capacity to capture carbon at the million ton scale (L-DAC, S-DAC and green hydrogen from biomass) these footprints are industry-provided estimates of needed space. For established industries (steel and BiCRS), the range of values reflects the variability of existing facility footprints, most of which are not actively capturing CO_2. The range in land use is mostly due to availability and affordability of land, and the retrofitting of these types of facilities with carbon capture equipment would likely not result in a significant change in areal footprint. *A steel facility of the size modeled here could produce up to 1 million tons of CO_2, but it depends on the source of iron and type of energy used.

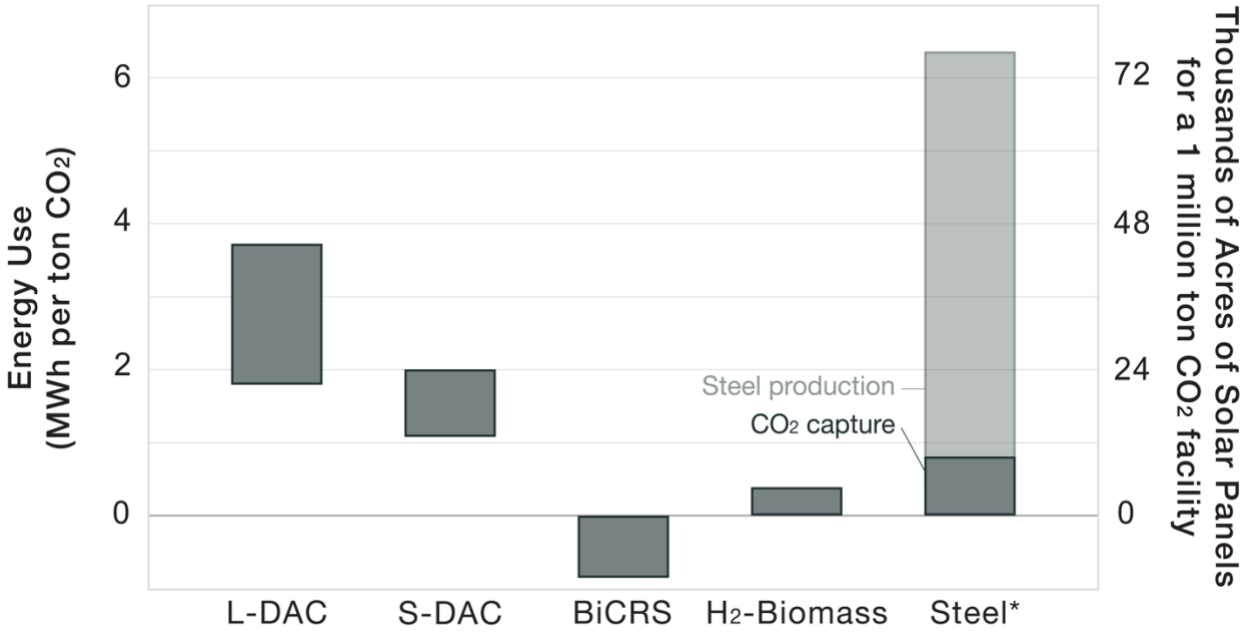

Figure D.2. Energy Use. Most carbon management industries (L-DAC, S-DAC, green hydrogen from biomass, and steel) are energy intensive, requiring both electricity and heat energy. DAC technologies require the largest amounts of energy per ton of CO_2 captured, whereas most of the energy demand for steel goes into steel production (the light shaded region) rather than CO_2 capture (the dark shaded region). Green hydrogen from biomass is less energy-intensive, and like steel, the energy needs also generate a different primary output: production of H_2 gas. Other forms of BiCRS (including BECCS) generate more energy than they consume, and are thus able to power their own production, with some facilities also selling energy to the grid. As a result, BiCRS facilities do not require an external energy supply unless it is more profitable to sell their output (i.e. biofuel, syngas) than to use it to operate the facility. An additional critical factor to note is that any facility using solar PV for their energy needs will also require electricity and heat storage (batteries) to ensure uninterrupted supply of electricity and that heat is provided at the required temperatures (100-1000°C, depending on industry). *A steel facility of the size modeled here could produce up to 1 million tons of CO_2, but it depends on the source of iron and type of energy used. The more power supplied by solar energy, the less CO_2 the steel mill would produce.

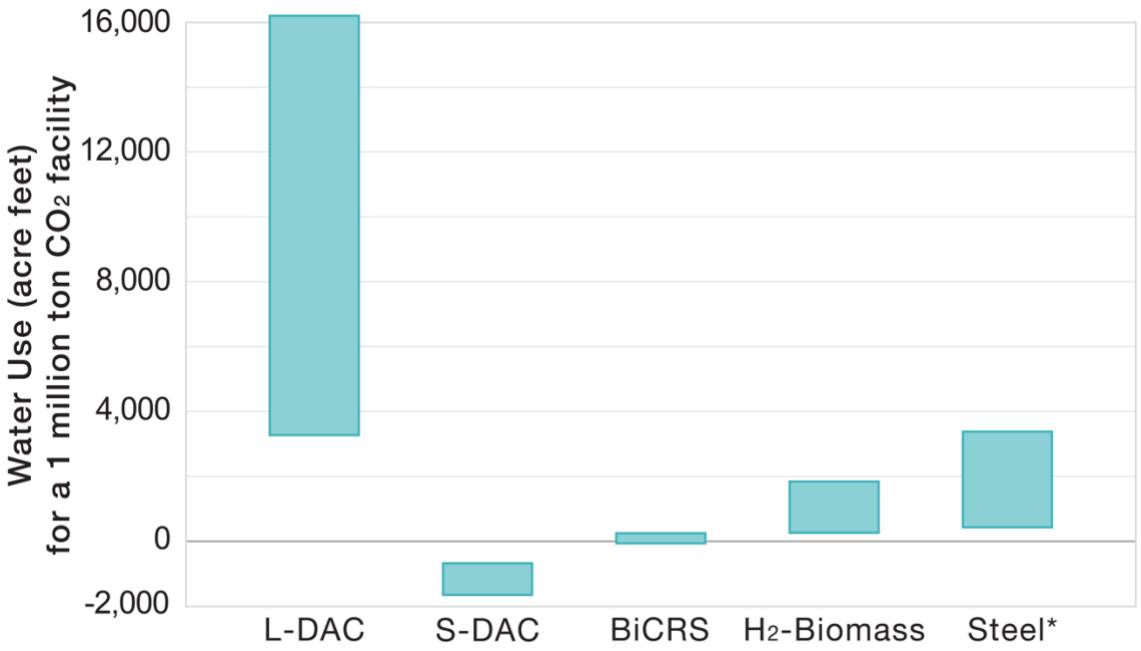

Figure D.3. Water Use. Water use is one of the most variable categories across carbon management industries. Hydrogen production via biomass, steel and particularly L-DAC technologies are water-intensive practices, using as much as 16,200 acre feet of water annually. Meanwhile, BiCRS and S-DAC technologies can actually generate excess water by capturing it from biomass feedstocks or the atmosphere. This water yield depends on the specific process a facility uses, but could be as much as 1,650 acre feet annually. Due to the arid environment in large parts of Kern County, mindfulness about the water intensity of these industries is crucial to ensure supplies can continue to meet a mixture of residential, agricultural, and industrial demands for decades to come. *A steel facility of the size modeled here could produce up to 1 million tons of CO_2, but it depends on the source of iron and type of energy used.

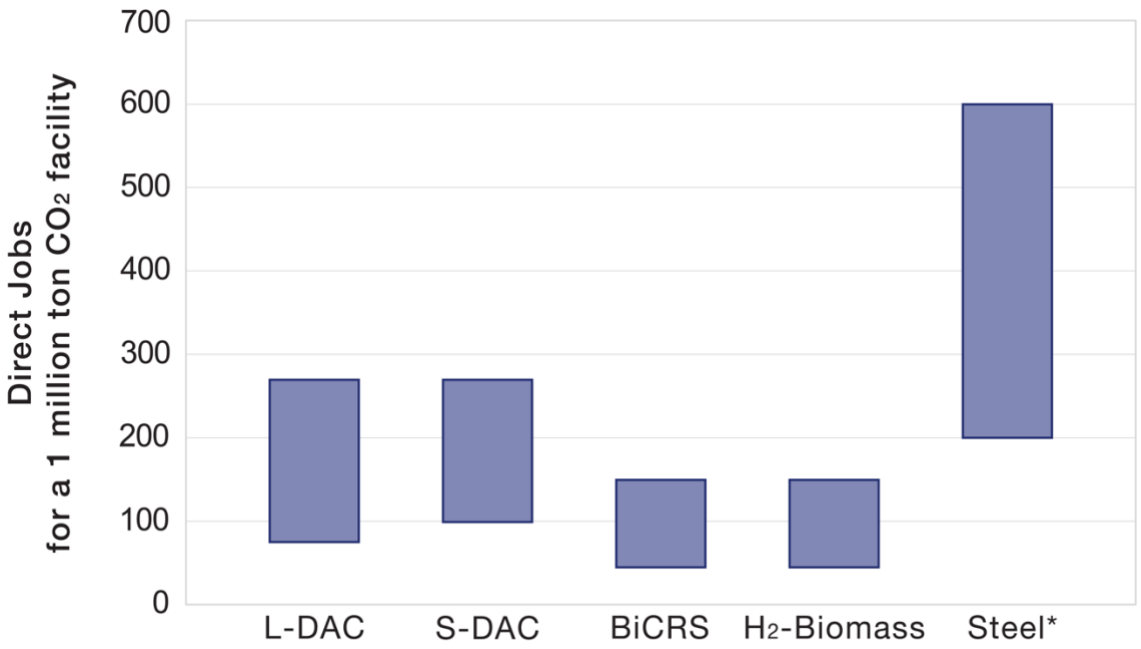

Figure D.4. Job Development Potential. The job growth potential of carbon management facilities can be difficult to quantify, as different companies rely on different processes—even within the same industry—that shapes their labor demands. Industries like BiCRS and hydrogen production via biomass expect to have lower labor demands, similar to that required to operate bioenergy power plants that do not utilize carbon capture. L-DAC and S-DAC have larger expected labor demands, mainly to monitor and maintain contactor units, although it is possible that some of these jobs could be performed remotely, and would not necessarily benefit the host community. Steel is likely to provide the most jobs. It is important to note that job growth potential for many of these industries was determined from the number of jobs at smaller facilities, and because the need for workers does not scale linearly with facility size, these are rough estimates. Furthermore, the possibilities of increased automation and remote monitoring means that steps should be taken in the planning and permitting process to ensure jobs for any new carbon management facility benefits local communities. *A steel facility of the size modeled here could produce up to 1 million tons of CO_2, but it depends on the source of iron and type of energy used.

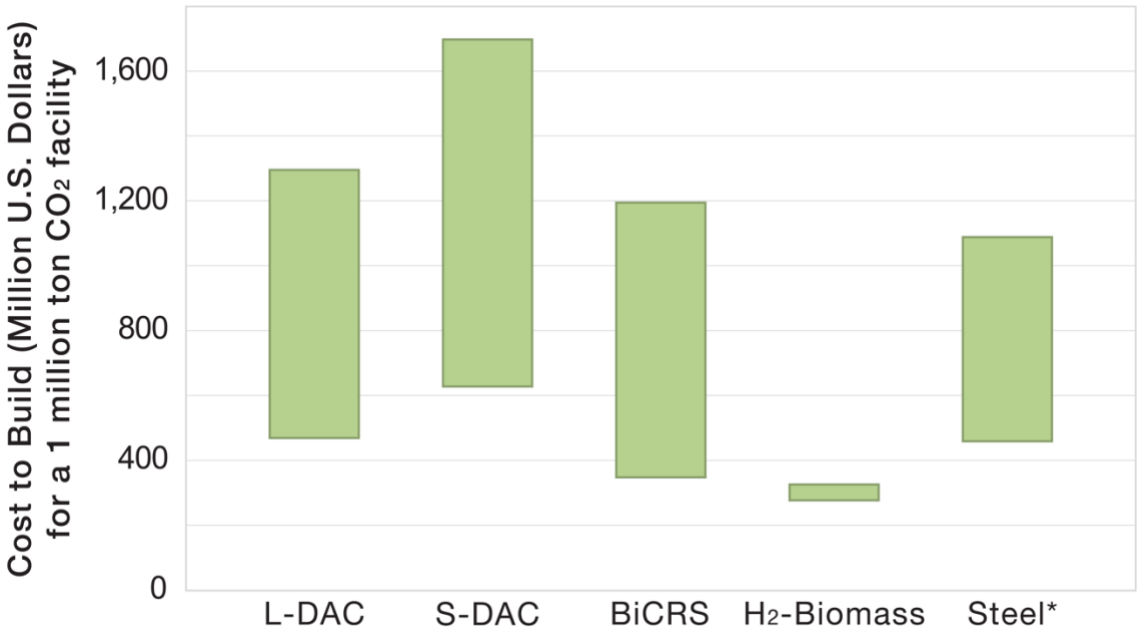

Figure D.5. Cost to Build. Building a new carbon management site comes with considerable expense—securing land, planning, engineering, permitting and zoning, environmental assessments, and other details will need to be handled before construction even begins. Across all of these carbon management industries, upfront costs range from $278 million to 1.7 billion. Costs are generally expected to be higher for the direct air capture industries (L-DAC and S-DAC) than for the biomass-based hydrogen production, BiCRS and steel facilities. However, many of these industries have never been built at a scale that could capture 1 million metric tons of CO_2 per year, which accounts for the large ranges of uncertainty in their upfront costs. *A steel facility of the size modeled here could produce up to 1 million tons of CO_2, but it depends on the source of iron and type of energy used.

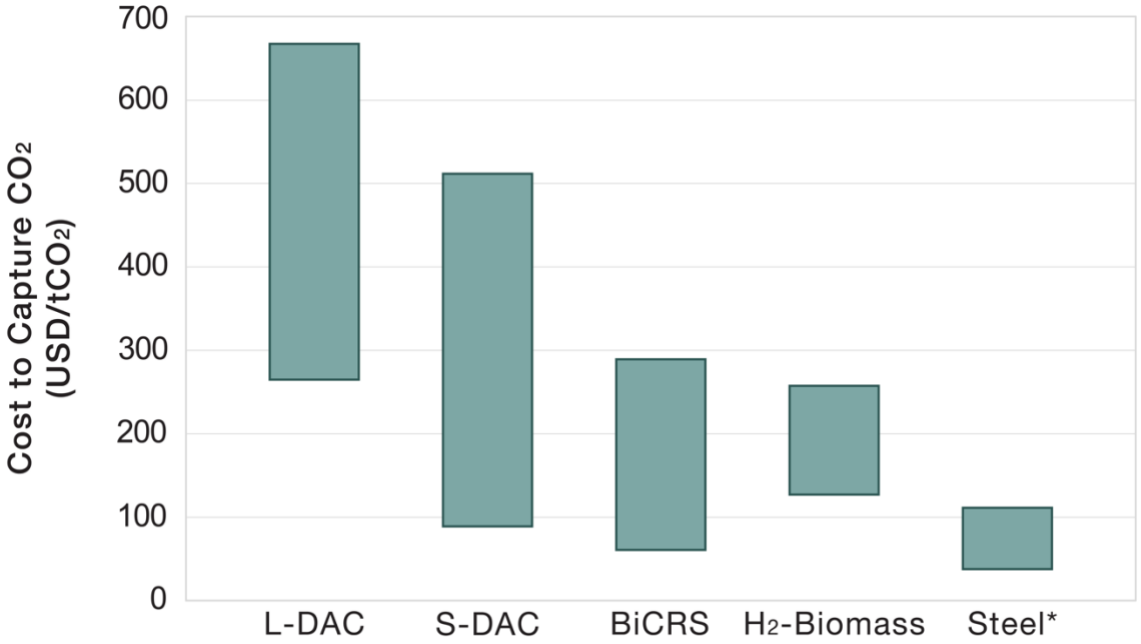

Figure D.6. Cost to Capture. The levelized cost per metric ton of CO_2 is a good way to consider overall costs—it accounts for the cost of building the facility (capital costs), the cost of maintenance and labor (operational costs), and the cost of energy (heat + electricity) over the lifetime of the plant. In these estimates, the plant lifetime has been fixed at 30 years to standardize estimates, though some of these facilities may have longer or shorter lifetimes. The cost of carbon capture is lowest for steel emissions, given the relatively high concentration of CO_2 in exhaust gases from this kind of facility, as well as the maturity of the technology. Biomass-based carbon capture (BiCRS or biomass hydrogen production) also generally have lower levelized cost estimate ranges than direct air capture (L-DAC and S-DAC). However, it is worth noting that 1) all of these costs are likely to decrease as carbon capture technologies mature, and 2) which of these industries is economically viable depends both on the levelized cost and on the potential sources of revenue to recoup that cost, which varies across industries. *The cost to capture CO_2 for the steel facility only considers the cost of building and operating the capture equipment. It does not incorporate the capital and operational costs of the steel mill itself.

1.0 INTRODUCTION

This report evaluates the potential fiscal and economic benefits that would be created by the development of a carbon management industry in Kern County. Specifically, the report quantifies the direct fiscal and economic impacts of the proposed Carbon Management Business Park (CMBP), and the indirect impacts that would be generated by related firms that the CMBP would support elsewhere in Kern County.

1.1. Categories of Benefits Evaluated

The study considers the following categories of fiscal and economic benefits:

Fiscal Benefits

- Property tax revenue accruing to the County of Kern General Fund and Fire Fund
- Sales tax revenue accruing to the County of Kern General Fund
- Property tax revenue accruing to city General Funds
- Sales tax revenue accruing to city General Funds

Broader Economic Benefits

- Jobs created
- Payroll created
- Total business activity (the dollar volume of "output") supported

Given the undefined nature of the indirect (offsite) benefits of the CMBP, the study does not attempt to quantify potential benefits to individual/specific cities (since the specific locations of supported businesses are unknown). Instead, potential city-level benefits are shown as aggregate numbers (i.e., for all cities combined).

1.2. Profile of Business Types in CMBP

As conceived by the Kern County Planning and Natural Resources Department, the proposed CMBP would encompass 4,200 acres in unincorporated Kern County. Although a specific site has not been identified yet, it is anticipated that the park would be developed on agricultural land that would be rezoned for industrial uses and the location would generally be west of Interstate 5.

The assumed mix of carbon management and related activities within the CMBP is as follows:

Business Type (Carbon Capture Technology)	Area
Liquid Direct Air Capture (L-DAC)	400 acres
Solid Direct Air Capture (S-DAC)	500 acres
Biomass Carbon Removal and Storage (BiCRS)	600 acres
Green Hydrogen (H2)	600 acres
Steel Micro Mill	600 acres
Research & Development Incubator Site	500 acres
Administrative Offices + Ancillary Clean Energy Industries	1,000 acres
Total (with 31 million square feet of industrial building space)	4,200 acres

1.3. Overview of Study Scope and Methodology

In completing this study, The Natelson Dale Group, Inc. (TNDG) has relied on industry profiles (for each of the above business types) prepared by Blue Engine for the CMBP project. In particular, the Blue Engine team has quantified the following economic variables for each CMBP component:

- Permanent (operational) jobs
- Operations and maintenance costs
- Capital costs

Blue Engine has also provided general descriptions of the types of carbon capture businesses that might be the "tenants" within each component of the park. From these descriptions, TNDG has selected specific industries (i.e., NAICS codes) representative of these business types for purposes of evaluating the projects fiscal and economic impacts.

The direct property tax impacts of the CMBP have been estimated by TNDG based on projected land re-assessment (from converting the underlying land from agricultural and industrial uses) plus anticipated improvement costs (based on the Blue Engine data). Indirect property taxes (i.e., from offsite businesses that would be developed as part of a countywide carbon management industry anchored by the CMBP) have been estimated using the IMPLAN model[1].

The IMPAN model has also been used to estimate direct and indirect sales tax revenue, as well as broader economic impacts such as job creation, payroll, and supported countywide business activity.

Due to the somewhat speculative nature of the CMBP (composed of industries that in many cases are still in early stages of development globally), the Blue Engine research is understood to provide general/

[1] This model was developed by researchers at the University of Minnesota and is widely used in economic impact analysis throughout the Country. This software is classified as an "Input-Output" (IO) model that computes all of the economic impacts of industries in a user-defined region (in this case, Kern County), including the estimated local expenditures of employees of both project-direct and supplier firms. The current version of the IMPLAN model divides the economy into 546 sectors that correspond to 4-digit and 5-digit NAICS codes.

approximate estimates of costs and employment. As such, the Blue Engine numbers are often expressed in broad ranges (e.g., the Liquid Direct Air Capture operation would support 75 to 270 permanent jobs per 1 million in CO2 captured annually). Since TNDG's analysis stems from the Blue Engine estimates, TNDG's numbers are expressed in terms of a "Low Scenario" and a "High Scenario" corresponding the Blue Engine's ranges.

2.0 EXECUTIVE SUMMARY

2.1. Fiscal Benefits of Carbon Management Industry

Table II-1, on the following page, summarizes the potential fiscal benefits of the proposed CMBP and the related countywide carbon management industry. All dollar amounts are expressed in 2023 dollars.

Fiscal Benefits to County of Kern. At full buildout, the CMBP and related offsite industries would generate total property tax income (General Fund plus Fire Fund) of $24.2 million (Low Scenario) to $56.2 million (High Scenario) per year.[2]

Total sales tax income to the County's General Fund is projected to range between $4.2 million and $7.9 million per year.[3]

Fiscal Benefits to Incorporated Cities. Whereas the direct impacts of the CMBP would occur in unincorporated Kern County (where the park would be located), the indirect impacts associated with the overall carbon management industry would potentially be spread throughout the county. Given the undefined nature of these indirect benefits, the study does not quantify potential benefits to individual/ specific cities (since the specific locations of supported businesses are unknown). Instead, potential city-level benefits are shown as aggregate numbers (i.e., for all cities combined).

The CMBP and related offsite industries would generate total property tax income to city General Funds of $4.5 million (Low Scenario) to $8.4 million (High Scenario) per year.

Total sales tax income (to city General Funds) is projected to range between $8.4 million and $15.6 million per year.[4]

[2] The projections of property tax generation are largely driven by the very substantial capital facility investments associated with carbon management projects. For purposes of this study, assessed valuation has been estimated based on total capital investments at the time facilities are completed and put into operation. To the extent these capital facility values are depreciated without offsetting capital reinvestments, property tax revenues from these facilities could decline over time.

[3] The sales tax projections are derived from the IMPLAN model; the IMPLAN estimates for Kern County have been adjusted by TNDG to reflect the recent passage of Measure K, which effectively doubles the County's local sales tax rate.

[4] A significant portion of the sales tax revenue projected in this analysis would be derived from indirect impacts (i.e., CMBP businesses making purchases at other Kern County firms) and induced impacts (i.e., CMBP employees spending their payroll incomes at local businesses). Since many of these indirect/induced expenditures would occur in incorporated cities, the CMBP would create larger sales tax impacts to city General Funds than to the County's General Fund.

Note: County Property Tax includes General Fund and County Fire Fund.

2.2. Broader Economic Benefits

Table II-2, on the following page, summarizes the broader economic benefits of the proposed CMBP and the related countywide carbon management industry. All dollar amounts are expressed in 2023 dollars.

Total business activity supported. The potential volume ("output") associated with the CMBP and related offsite activities is projected to range from $4.5 billion (Low Scenario) to $6.9 billion (High Scenario) per year.

Total jobs supported. At full buildout, the CMBP and related offsite activities would directly and indirectly support 13,500 to 22,000 permanent jobs.

Total payroll generated. The total direct and indirect payroll associated with these jobs is projected to range from $1.1 billion to $1.8 billion per year, representing an average annual wage of approximately $80,000.

Note: CMBP = Carbon Management Business Park

3.0 DETAILED SUMMARY OF FISCAL AND ECONOMIC IMPACTS

This section provides a detailed summary of the ongoing fiscal and economic impacts associated with the CMBP. For fiscal impacts, the analysis shows the ongoing property tax and sales tax revenues that would be generated for the County and incorporated cities in the County. For economic impacts, the analysis shows annually-recurring impacts related to employment, employee compensation, value added, and output (i.e., total dollar volume of business activity).

3.1. CMBP Sales Tax and Property Tax Impacts

Tables III-1 and III-2 (pages 9 and 10) show the direct and indirect sales tax and property tax impacts associated with each proposed CMBP component, along with the total for the entire proposed CMBP. Table III-1 shows the "low" scenario (reflecting more conservative direct employment and operating cost estimates), while Table III-2 shows the "high" scenario (reflecting higher direct employment and operating cost estimates).

3.2. CMBP Economic Impacts

Tables III-3 and III-4 (pages 11 and 12) show the direct and indirect/induced economic impacts associated with each proposed CMBP component, along with the total for the entire proposed CMBP. Table III-1 shows the "low" scenario (reflecting more conservative direct employment and operating cost estimates), while Table III-2 shows the "high" scenario (reflecting higher direct employment and operating cost estimates).

United States Environmental Protection Agency

How EPA's UIC Class VI Regulations Work to Ensure the Protection of Groundwater Resources

What is geologic sequestration?

Geologic sequestration (GS) of carbon dioxide (CO_2) is the injection of CO_2 deep underground to prevent it from entering the atmosphere, thereby helping to mitigate climate change. The CO_2 is injected through specially constructed wells that extend into deep rock formations. These formations have been tested and selected based on geologic characteristics indicating that they can safely contain the CO_2 for long-term storage.

How does the UIC program protect drinking water near geologic sequestration sites?

Under the Safe Drinking Water Act, EPA is tasked with protecting public health by regulating and overseeing the nation's public drinking water supplies. The EPA's Underground Injection Control (UIC) program regulates six classes of wells for the injection of fluids such as water, wastewater, brines, and CO_2 into the subsurface. *UIC regulations are designed to protect underground sources of drinking water (USDWs) by preventing the movement of contaminants out of injection formations and into USDWs. (The diagram on the second side of this pamphlet shows USDWs as the uppermost geologic formations in the figure.) Wells injecting CO_2 for GS are classified as UIC Class VI wells.*

The UIC program regulates all aspects of the injection wells of a GS project including project siting, well construction, injection operations, testing and monitoring, emergency response, financial responsibility, and eventual plugging and closure of the wells and injection sites. The UIC program implements the regulations through permitting, site inspections, required reporting, and compliance reviews to ensure that well owners/operators comply with the regulations. Regulations for Class VI wells are the most rigorous of the UIC program. **The sections below describe how UIC regulations for GS projects protect our underground drinking water resources, with additional details shown in numbered items on the diagram on the second page of this pamphlet.**

How can the public participate?

Public participation and transparency are important components of the UIC regulatory framework. Draft injection well permits for GS projects are published for public review. The public may comment on the draft permits, request and attend public hearings, and in some cases file appeals with the Environmental Appeals Board. Transparency is promoted through communications with communities and providing information from project start through closure.

What are key steps for planning GS projects, and how do they protect USDWs?

The Class VI regulations provide multiple safeguards to protect USDWs, beginning at the initial permitting stage. The owner/operator submitting a permit application for a Class VI well must:

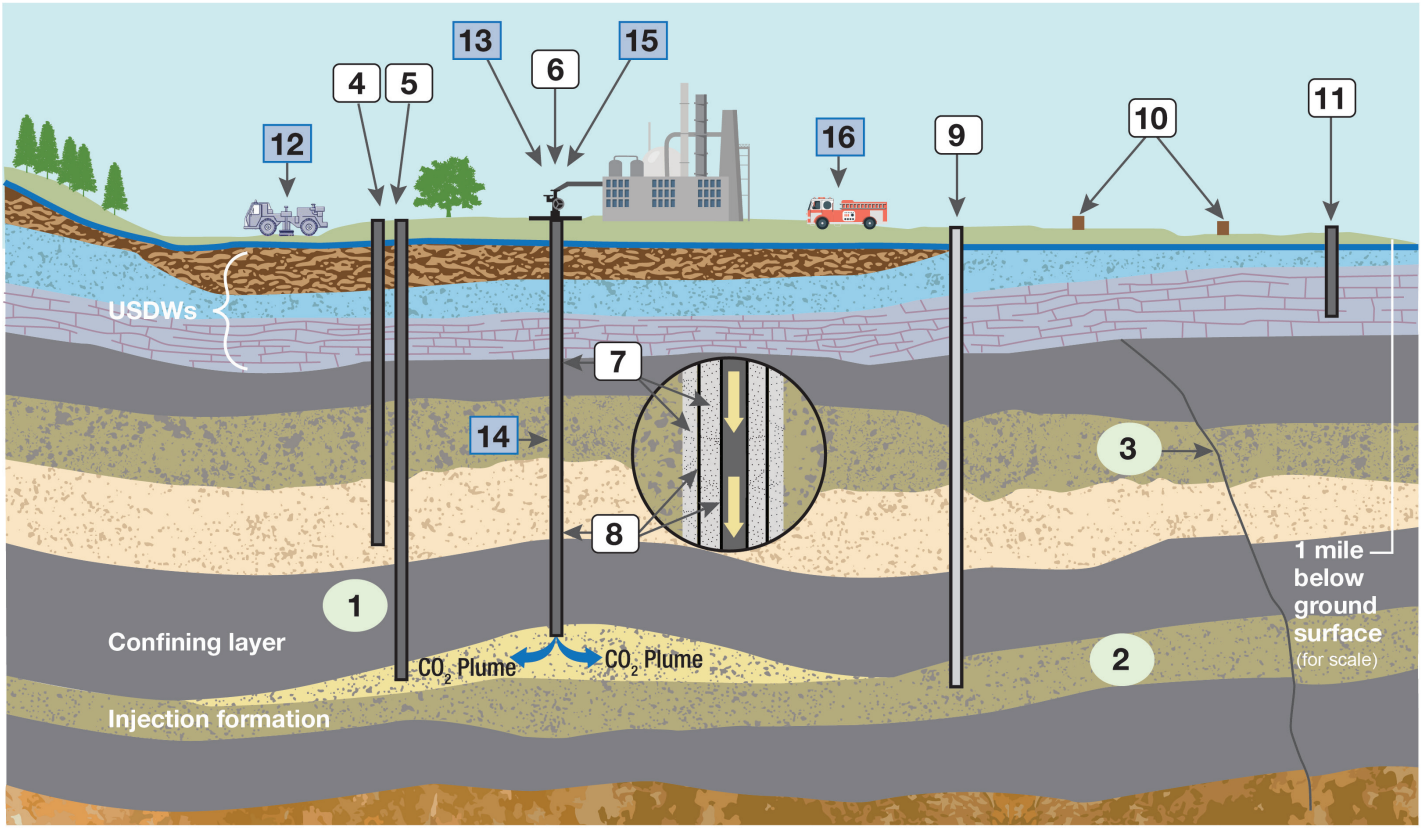
- ***Evaluate the project site*** to document that the geology is suitable for GS and that CO_2 will not leak and migrate to USDWs. This includes identifying both a geologic confining layer to prevent the CO_2 from leaking upward (#1 in diagram on page 2) and an injection formation that can dependably hold and provide long-term storage of the injected CO_2 (see #2). Other geologic features (such as faults) are evaluated to confirm that they will not compromise storage and containment and affect USDWs (#3).
- ***Determine the Area of Review (AoR)***, which is the footprint on the land surface above the subsurface area that could be influenced by CO_2 injection. This is the area where owners/operators will take measures to protect USDWs by identifying other wells, and possibly remediating old or abandoned wells (#9) to ensure that CO_2 does not leak through them.
- ***Meet financial responsibility requirements*** that ensure that the private costs associated with a Class VI well are not passed along to the public and that funding is available to address any problems that could affect USDWs.

How is an injection well constructed and operated to be protective of USDWs?

- ***Construction requirements*** include multiple protective layers of corrosion resistant steel casing and cement (#7 and #8). These requirements help to ensure that CO_2 does not leak out of the well or out of the injection formation along the well itself and migrate to a USDW. The wells are tested for leaks and to confirm proper construction before injection begins. Wells are tested routinely during operations (#14),
- ***Operational requirements***, including safe injection pressure and rate (#6, #13), are established by testing prior to starting injection. Maintaining safe injection pressure and rate avoids fracturing the injection formation. This helps ensure that the injected CO_2 remains where intended and does not migrate to other formations, including those containing USDWs. Safe pressures and rates are set in permit conditions and are continuously monitored at the wellhead during operations (#15).

United States Environmental Protection Agency

What other activities are required for Class VI well operations that help protect USDWs?



- ***Testing and monitoring*** will provide early warning or evidence in the event of well leaks, unexpected pressure changes, or movement of CO_2 out of the injection formation that could impact USDWs. The injection well is periodically tested for physical integrity and corrosion (#14). The owner/operator uses deep monitoring wells to measure the subsurface pressure and CO_2 in the injection formation (#5). Other monitoring wells are used to monitor groundwater quality above the confining layer (#4). Surface-based seismic surveys (#12) also help track the CO_2 plume.

- ***Emergency response*** requirements require that owners/operators report any evidence of potential dangers to USDWs within 24 hours, including evidence of CO_2 leakage, noncompliance with permit conditions, or malfunction of the injection system (#16).

What activities are required after injection is complete?

- ***Post-injection site care*** begins with well plugging according to an approved well plugging plan. This ensures that CO_2 will not migrate up through the injection well. Testing and monitoring continue according to an approved post-injection site care (PISC) plan. The default period of post-injection site care is 50 years, but the UIC Director can approve a shorter time if the owner/operator demonstrates no danger to USDWs.

- ***Site closure*** can take place when monitoring indicates that the plume and formation pressure are stable and there will be no danger to USDWs. Closure includes removal of surface equipment and site restoration (with grading, planting of vegetation) to conditions approved by the UIC Director. The UIC Director will not authorize the site to be permanently closed until data demonstrate no danger to USDWs.

Through the Underground Injection Control (UIC) program, EPA protects underground sources of drinking water (USDWs) by regulating the construction, operation, permitting, and closure of injection wells that are used for the underground storage or disposal of fluids. Class VI wells are specifically used to inject carbon dioxide (CO_2) into deep rock formations. The UIC permitting authority reviews Class VI permit applications to ensure that injected CO_2 will remain within deep, isolated formations, protecting human health and the environment.

KEY

Site geology
Injection, monitoring, and other wells
Drinking water resource protection practices
Water table

1 Thick, impermeable confining layer prevents CO_2 from leaking upward
2 Permeable injection formation will hold injected CO_2
3 Testing shows that the fault is inactive and sealed against movement of CO_2
4 Water quality is tracked in the permeable formation above the confining layer using a monitoring well
5 Pressure and CO_2 in the injection formation are tracked using a monitoring well
6 CO_2 injection well is permitted for safe operation with many safeguards
7 Cementing prevents CO_2 from moving outside of the well
8 Well materials are corrosion-resistant
9 Properly plugged and abandoned well prevents CO_2 movement between formations
10 Seismic activity is monitored using surface equipment as needed
11 Shallow groundwater well is isolated from the injection formation by multiple impermeable layers
12 Seismic surveys are used to study the geology and track the location of CO_2 through images of the subsurface
13 Safe CO_2 injection pressure avoids damaging the injection formation
14 Regular testing confirms the physical integrity of the well
15 Injection pressure and flow are continually monitored
16 Emergency response plan is in place and ready to be implemented

K.4 Source Identification Memo

This page intentionally left blank.

Source Identification Technical Memorandum

1. Overview

This memorandum describes additional carbon dioxide (CO_2) sources for the Carbon TerraVault I Project (CTV I) beyond the initial source identified in the Draft Environmental Impact Report (EIR) and Recirculated Draft EIR for CTV I (State Clearinghouse 2022030180). Through the addition of the CO_2 sources described herein, CTV I would serve as a "carbon hub," defined as the process of capturing and storing CO_2 in a defined geographic location, whereby more than one capture method or source is applied for maximized carbon capture and storage (CCS).

Source Limitations

CCS is a process that captures, compresses, transports, and stores large amounts of CO_2. This process is often paired with large greenhouse gas (GHG) emitting facilities and/or with facilities that directly capture CO_2 from the atmosphere. Any additional CO_2-emitting facilities added to the CTV I carbon hub would be limited to sources that are capable of mitigating criteria pollutants from the CO_2 capture and transportation process with no net increase for existing operations.

The project sources are limited in this analysis to the following areas:

- Location only within Kern County
- Blue hydrogen production
- Green hydrogen production
- Biomass carbon removal and storage (BiCRS)
- Cement production
- Green steel production (electric arc)
- Oilfield field gas streams
- Power plants
- Direct air capture
- Alternative fuel production

The listed allowable sources and the potential CCS strategies for CTV I are further discussed in Section 3, *Allowed Additional Carbon Sources,* below.

2. Specific Additional Carbon Sources

In the Recirculated Draft EIR for CTV I, Chapter 3, *Project Description*, Section 3.4.1, *CO_2 Capture Sites,* subsection *Future Sources – Identification*, details specific companies that have formally announced they have contracts or discussion with the applicant, California Resources Corporation (CRC), to send CO_2 to CTV I. All projects in unincorporated Kern County will require approval of the base industry in an appropriately zoned parcel with CO_2 capture and transport requiring an additional Conditional Use Permit (CUP) and EIR for compliance with the California Environmental Quality Act (CEQA). All CO_2 pipelines also require a CUP and EIR for compliance with CEQA. All CO_2 sources in any incorporated city

in Kern County must show compliance with the preparation of an environmental document, with Kern County as a Responsible Agency, and not an exemption from such review.

3. Allowed Additional Carbon Sources

This section identifies other CO_2 sources allowed by Kern County for storage in CTV I. All allowable CO_2 sources must be geographically located within Kern County. The section also discusses the various CCS strategies and associated industries that are allowable for future incorporation into CTV I. This discussion is predominantly guided by the commenters on the CTV I Draft EIR, the California Air Resources Board (CARB) 2022 Scoping Plan, and the technical document prepared for Kern County titled *Envisioning a Carbon Management Business Park* (BE 2023), provided as Appendix K-2 to the Draft EIR.

Oil and Gas Operations

While oil extraction in California has declined since 1986 from 402 million barrels per year to 6 million barrels per year in 2020, there is still demand for finished fossil fuels (gasoline diesel, and jet fuel), primarily for transportation (CARB 2022). The CARB 2022 Scoping Plan recognizes that California is a net exporter of finished fossil fuels and further provides that a phasedown of fossil fuel extraction should be managed with consideration of exports. If in-state extraction were to be phased out fully, the future petroleum demand by in-state refineries would be met through increased crude imports. This could lead to "leakage," as defined by Assembly Bill 32 (AB 32): "a reduction in emissions in GHGs within the state that is offset by an increase in emissions of GHGs outside the state."

Kern County produces approximately 70 percent of the state's oil (BE 2023). The geologic layers in Kern County meet the requirements for CO_2 storage and, therefore, position the County with a favorable opportunity for CO_2 capture at oil and gas refineries. Oil and gas operations, as noted by commenters on the Draft EIR for CTV I, would be an allowed source of CO_2 storage in CTV I, as these sources are within the County. Proposed oil and gas sources include the CRC Oil and Gas CUP Buena Vista, the CRC Oil and Gas CUP Elk Hills, and the Carbon Terra Vault Clean Energy Park.

Alternative Fuels

The Low Carbon Fuel Standard (LCFS) has successfully spurred demand for alternative fuels, such as renewable diesel, sustainable aviation fuel, biomethane, and electricity, as all have gained significant market share (CARB 2022). Currently, electricity and hydrogen are the primary fuels used for zero-emissions vehicles. Alternative fuel refineries can be repurposed from existing refineries and retrofitted to include various available CCS technologies. These sources would be eligible for LCFS credits.

Hydrogen Production

Hydrogen production is gaining traction as a clean energy fuel alternative because of its ability to power fuel cells in zero-emission vehicles (OEERE 2024). The demand for hydrogen is increasing due to other potential sector transitions as well, including industrial uses, transportation, power generation, energy storage, and grid balancing (DOE 2020). Today, hydrogen is mainly used for feedstock in ammonia, food, drug production, petrochemical, and refinery processing.

The types of hydrogen production being considered for the CTV I carbon hub involve the "splitting off" of hydrogen from carbon, which can be done using several different processes, as described below:

- **Thermochemical processes**: use energy in various resources such as gas, coal, or biomass to release hydrogen from their molecular structure. The resulting heat, in combination with closed-chemical cycles, produces hydrogen from feedstocks such as water.
- **Electrolytic processes**: use electricity to split water into hydrogen and oxygen molecules.
- **Direct solar water splitting processes**: use light energy to split water into hydrogen and oxygen molecules.
- **Biological processes**: use bacteria and microalgae to produce hydrogen through biological reactions using sunlight or organic matter. These methods are currently in the research and development phase, with some pilot demonstrations underway.

These methods have been further categorized into a color key system for productive research and discussions about the hydrogen industry and the various types of hydrogen production. It is important to note that hydrogen is a colorless gas and that the color system is simply a convenient notation device. No differences in visual, physical, or chemical properties are weighted when reviewing these different production methods. Green hydrogen and blue hydrogen are further discussed in this memo, as potential future sources would fall into these categories as acceptable carbon capture and removal industry practices for storage within CTV I.

Green Hydrogen

Green hydrogen production refers to production techniques that generate no GHG byproducts, mostly achieved by electrolysis from renewable resources. Renewable energy generation sources such as solar power and wind are dynamic and sometimes produce excess energy in times of low demand, and vice versa. Green hydrogen production has the potential to offer flexibility to shift production to match resource availability. This technology is well developed and available commercially.

Blue Hydrogen

Blue hydrogen refers to the production method of thermochemical process and electrolysis, whereby the conversion of methane (natural gas) to hydrogen relies on a process called steam reforming, which generates both hydrogen and CO_2. The CO_2 generated is captured via point source carbon technologies to be stored underground in perpetuity, reducing carbon emissions. The U.S. Department of Energy estimates that 99% of hydrogen production is sourced from fossil fuels, with 95 percent from natural gas reforming by steam-methane reforming (SMR) (DOE 2020). Natural gas reforming is the process of building upon existing natural gas pipeline delivery infrastructure for hydrogen production. This reform includes using existing natural gas facilities and the available methane from natural gas for hydrogen production. In the SMR process, the natural gas is heated with steam to generate hydrogen, with CO_2 byproducts that can be further captured for storage, collectively known as “blue hydrogen.”

How Blue Hydrogen Works

Blue hydrogen relies on the thermochemical processes method for splitting methane and water into hydrogen and oxygen. Sources used for this process are finite and include either methane or coal, plus water as a feedstock. This process is known as natural gas reforming, or SMR, discussed in further detail below. Unlike grey hydrogen (which uses the SMR process but does not include CCS to reduce emissions), blue hydrogen emits less carbon into the atmosphere, as it involves the deployment of a CCS system, storing the carbon in perpetuity below adequate geological layers. Because the production of

blue hydrogen is dependent on finite resources, including methane and coal, there is potential for retrofitting existing assets and pipelines while achieving lower carbon emissions.

Steam-Methane Reforming (SMR) + Carbon Capture and Sequestration (CCS)

SMR involves transforming methane (CH_4) and water into hydrogen and CO_2. In the first reaction, steam reacts with methane in a high-pressure container, which requires both a catalyst and heat (endothermic) in order to produce "syngas," a mixture of hydrogen, carbon monoxide, and CO_2. Large amounts of heat from this initial reaction (206 kilojoules of heat energy per mol of methane) are required for the reaction to proceed, which is a "water-gas shift reaction" wherein carbon monoxide generated reacts with more steam and a catalyst to form more hydrogen, CO_2, and small amounts of heat (OEERE, 2023). Finally, the last step is a "pressure-swing adsorption," which removes the CO_2 and other gases from the final products, leaving a pure stream of hydrogen gas.

1. Steam-methane reforming reaction

$CH_4 + H_2O$ (+ heat) → $CO + 3H_2$

2. Water-gas shift reaction

$CO + H_2O \rightarrow CO_2 + H_2$ (+ small amount of heat)

Once the CO_2 is separated from the gas stream, it can then be transported for permanent underground storage. The hydrogen can be packaged for sale, and the heat would ideally be cycled back into the process or redirected to a facility for further use. The transportation of CO_2 to the storage reservoir typically requires miles of pipeline for delivery. The storage of CO_2 underground is what differentiates blue hydrogen from grey hydrogen production, and it is estimated that at best, CCS capture efficiencies are expected to reach 85 to 95 percent, leaving 5 to 15 percent of the CO_2 to be emitted (IRENA 2020).

Summary of Blue Hydrogen

Blue hydrogen production has the potential to supply the demand in hydrogen by use of retrofitting existing natural gas pipelines. It is estimated that nationally, 95 percent of hydrogen production is derived from natural gas reforming, or SMR. However, blue hydrogen production has limitations in that it is dependent on fossil fuels and associated carbon emissions with point sources. Other criteria air pollutants may be released; however, researchers found that the amounts of volatile organic compounds, nitric oxide, and CO_2 decreased as the facility size increased, suggesting that larger facilities may have emissions control technologies that capture different pollutants (BE 2020).

While technological refinements and improvements are underway, significant water requirements needed to perform the water-gas shift reaction persist. Studies show that per kilogram of hydrogen generated, the SMR and water-gas shift reaction require 2.6 gallons of water per kilogram of hydrogen produced (BE 2023). As California grapples with record-year droughts, wastewater may be treated and repurposed for industrial use, but the viability of such an option is dependent on local interest, cost, and needs (BE 2023).

Carbon Dioxide Removal

Based on evidence cited in the CARB 2022 Scoping Plan, CO_2 removal will be necessary to achieve net negative emissions. Carbon removal can be nature-based or mechanical. Nature-based solutions involve enhancing natural and working lands for biological processes in vegetative material to remove and store

carbon from the ambient air. Another form of CO_2 removal is mechanical, which involves direct air capture (DAC).

Direct Air Capture

DAC technology typically involves a system wherein ambient air is pulled through a unit with a sorbent that first binds $C0_2$ to a compound, and later uses heat to break that bond for $C0_2$ separation. There are two types of DAC technologies—solid (S-DAC) and liquid (L-DAC)—distinguished by the type of sorbent material they use. Both involve passing air pulled from the atmosphere over the sorbent. In both techniques, the $C0_2$ derived from the air is chemically and temporarily bound into a new compound, only to be broken down into a pure stream of $C0_2$ for storage and the remaining original sorbent for reuse (BE 2023). Both technologies require electricity and heat for final outcomes.

Solid Direct Air Capture

S-DAC relies on a filtering process using dry amine-based chemical sorbents. This process happens through an adsorption/desorption process, whereby adsorption takes places at ambient temperature and pressure, and desorption occurs through a temperature vacuum swing process. Breaking the bonds of $C0_2$ and the sorbent requires temperatures of around 215 degrees Fahrenheit (^oF). This technique has the potential to capture several tens of tonnes of CO_2 per year. S-DAC plants are designed to be modular and can include as many units as needed.

Liquid Direct Air Capture

L-DAC typically uses hydroxide solutions (a liquid solvent) and is based on two chemical loops. The first loop takes place in what is called a contactor and brings atmospheric air into contact with an aqueous basic solution (such as potassium hydroxide) that captures the CO_2. Then, the second loop releases the CO_2 from the solution in a series of units operating at temperatures of 572 to 1,652 ^oF (IEA 2022). This temperature is difficult to reach using renewable sources, and if natural gas is used, CO_2 would need to be recaptured to offset further CO_2 emissions.

Direct Air Capture Technologies

DAC technologies are still emerging, and significant research and development efforts support the advancement of such technologies. A single unit for S-DAC technology has the ability to capture several tens of tonnes of CO_2 per year, and an S-DAC plant can be designed to include and operate as many units as feasible. These quantities are expected to increase as technologies emerge and costs are reduced.

Water needs for DAC technology vary depending on the technology used, ambient temperature, and humidity. L-DAC requires water for operations (50 tonnes of water per tonne of $C0_2$), while S-DAC can extract water from the air, alongside CO_2 (0.8 to 2 tonnes of water per tonne of CO_2 captured from the atmosphere). In dry climates S-DAC could provide water (for its own use or, for instance, to feed a water electrolyser to produce hydrogen and subsequently synthetic fuels together with the captured CO_2), whereas in humid climates, S-DAC may struggle to keep up with the amount of water to be removed from the atmosphere. Compared to other carbon removal methods, DAC requires a smaller land footprint (IEA 2022). Adequate geological layers for storing carbon are necessary for perpetual carbon sequestration.

Biomass Carbon Removal and Storage

BiCRS is an umbrella term for various technologies that utilize biomass, such as agricultural byproducts, for CCS. BiCRS includes a range of technologies that utilize the collection of naturally stored CO_2 in

biomass for breakdown. Biomass can be sourced from material that naturally stores and contains CO_2, including agricultural and forest byproducts, or industrial or municipal waste. This conversion of biomass can be divided into two categories: biochemical and thermochemical conversion.

Biochemical conversion involves using living microorganisms to convert biomass into biofuels, with the most common method being the biochemical conversion of corn to ethanol through fermentation. Other biomass sources require a modification to natural fermentation in order to break down more complex plant structures. This includes high-temperature deconstruction, wherein extreme heat and pressure are needed to break down biomass feedstocks.

Thermochemical conversion refers to the breakdown of biomass to be directly combusted to create steam or heat to be used as a direct source of energy. These types of bioenergy plants can be fitted with post-combustion carbon capture technology that scrubs CO_2 from gaseous byproducts to form a bioenergy with carbon capture storage (BECCS). BECCS is a distinct form of BiCRS, and primarily focuses on fuel and energy production from biomass, whereas CO_2 CCS neutralizes carbon emissions for the power generation industry.

Technological methods in BiCRS and the capture of CO_2 include retrofitting biomass power plants that convert biomass into carbon-negative electricity grid by using oxy-fuel combustion. The footprint necessary for these sources is considerable. According to *Envisioning a Carbon Management Business Park*, the estimated physical footprint for a facility capturing 1 million metric tons of CO_2 annually is 180 to 400 acres (BE 2023) (Appendix K-2). In addition, for BiCRS/BECCS, high temperatures are needed for the conversion, and energy requirements will depend on the plant's thermal efficiency.

Point Source Carbon Capture

Many of California's industries produce CO_2 as a byproduct of their processing activities—specifically, the combustion of fossil gas necessary for three broad industry needs: electricity, steam, and process heat. The industrial sector contributes significantly to the state's economy and includes a diverse range of facilities such as cement plants, refineries, glass manufacturers, oil and gas producers, paper manufacturers, mining operations, metal processors, and food processors (CARB 2022). While these industries collectively account for about half of global GHG emissions, many facilities can employ a technology known as "point source carbon capture," which scrubs CO_2 from points of exhaust prior to being released into the atmosphere. Unlike DAC and BiCRS, which remove CO_2 from the ambient air, point source capture *prevents* the release of CO_2 into the atmosphere.

Technologies for point source capture are available for cement plants, iron and steel manufacture, natural gas power plants and boilers, fertilizer development, and paper mills. According to *Envisioning a Carbon Management Business Park*, Kern County has 44 facilities that reported significant CO_2 emissions in 2021 (BE 2023) (Appendix K-2). The following point source facilities are divided into the following industries:

- 20 petroleum and natural gas systems or refineries
- 15 power plants
- Two waste facilities
- Two cement facilities
- One mine (boron mine and refinery)

Cement Plants

Cement plants are a significant source of CO_2 emissions as they require the combustion of fossil gas and processing, wherein combustion accounts for 40 percent of emissions. Due to the high heat required, cement plants are one of a few industries that are hard to decarbonize. Even if the sector were to operate using only zero-carbon fuels, process emissions are significant; thus, carbon capture is necessary to fully decarbonize manufacturing. Senate Bill 596 requires the CARB to develop a strategy for the state's cement sector to achieve net-zero emissions. In response, CARB aims for CCS on 40 percent of stone, clay, glass, and cement plants by 2035 and on all facilities by 2045 to minimize leakage and address emissions (CARB 2022).

With CCS at cement plants, full electrification using alternative fuels such as hydrogen could bolster hydrogen demand. With the state's carbon cap-and-trade program, the growth of hydrogen through a carbon credit marketplace is incentivizing.

Steel Plants – Electric Arc Furnaces

Steel forging requires high heat and onsite combustion, with few electrification options to replace fossil gas for high heat requirements, and as such is among the industries hard to decarbonize. Steel mills are technologically diverse and, depending on the type of production, they can produce as much as 2.4 tonnes of CO_2 for every ton of steel produced. A common, and now predominant, mill type is the mini mill, or micro mill, which uses a technology called "electric arc furnaces" (EAF) to re-melt andrefine alloy scrap steel, commonly direct reduced iron. These mills do not require raw materials and require less high heat to reduce iron ore. However, their growth potential is limited by the availability of scrap steel.

The EAF process involves using a high-current electric arc to melt steel scrap, which ultimately emits less CO_2 than steel making with basic oxygen furnaces. The steel scrap can be retrofitted with carbon capture to capture as much as 80 percent of CO_2 emissions. Some researchers propose powering EAF with natural gas via oxy-fuel combustion rather than grid or renewable sourced electricity. This would result in a mill that could produce low-carbon steel and CO_2 for capture.

Natural Gas Power Plants

Many techniques for carbon capture at point source are available today to capture CO_2 from the exhaust of coal and natural gas power plants. Most use a solvent-based approach, rather than directly emitting CO_2-bearing flue gas through exhaust chimneys of a plant or facility. This process utilizes an absorption tower, where it is mixed with a liquid solvent that physically attracts the CO_2, then drawn out of the flue gas and captured.
