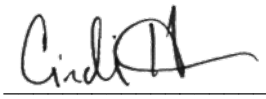
SUBJECT: NOTICE OF PREPARATION (NOP) OF A DRAFT ENVIRONMENTAL IMPACT REPORT (EIR) FOR THE CARBONFRONTIER CARBON CAPTURE SEQUESTRATION (CCS) PROJECT BY AERA ENERGY, LLC.

The Kern County Planning and Natural Resources Department as Lead Agency (per CEQA Guidelines Section 15062) has determined that preparation of an Environmental Impact Report (per CEQA Guidelines 15161) is necessary for the proposed project identified below. The Planning and Natural Resources Department solicits the views of your agency as to the scope and content of the environmental information which is germane to your agency's statutory responsibilities in connection with the proposed project. Your agency may need to use the EIR prepared by our agency when considering your permit or other approval of the project.

You are invited to view the NOP and submit written comments regarding the scope and content of the environmental information in connection with the proposed project should you wish to do so. Due to the limits mandated by State law, your response must be received by **July 10, 2023 at 5:00 p.m**. Comments can be submitted to the Kern County Planning and Natural Resources Department at the address shown above or to HooverC@kerncounty.com. A Scoping Meeting will be held on **Friday, June 23, 2023 at 1:30 p.m.** at the address listed above.

PROJECT TITLE: CarbonFrontier CCS Project by Aera Energy, LLC (PP23402); PLN22-00137: ZCC No. 4, Map No. 51; ZCC No. 3, Map No. 74; ZCC No. 4, Map No. 75; CUP No. 9, Map No. 51; CUP No. 7, Map No. 74; CUP No. 7, Map No. 75; CUP No. 9, Map No. 96.

PROJECT LOCATION: The proposed project site is located within the Central Valley portion of unincorporated Kern County and is comprised of forty-seven (47) privately owned parcels and two (2) provisional parcels, within the administrative boundaries of the North and South Belridge oilfields. The North and South Belridge oilfields are contiguous and located west of Highway 33, approximately seven miles southwest of the community of Lost Hills (population 2,370) . Additionally, the proposed project is located within Sections 20, 21, 22, 26, 27, 28, 34, 35, and 36 of Township 27 South, Range 20 East; Sections 1, 2, and 12 of Township 28 South, Range 20 East; Sections 6, 7, 17, 18, 20, 27, 28, 29, 32, 33, and 34 of Township 28 South Range 21 East; and Sections 2, 3, and 4 of Township 29 South, Range 21 East of the Mount Diablo Base and Meridian (MDBM).



PROJECT DESCRIPTION: The project proponent is proposing to construct and operate a CCS project within the North and South Belridge oilfields. Implementation of the proposed project includes the following requests:

- Zone Classification Change (ZCC) from A-1 (limited Agriculture) to A (Exclusive Agriculture) on approximately 1,737 acres and from NR (Natural Resources – 20 acre minimum) to A (Exclusive Agriculture) on approximately 47 acres.
- Conditional Use Permit (CUP) to allow a CCS facility, associated Class VI geologic sequestration injection wells, and related improvements for storage of CO_2 on approximately 13,229 acres. CCS has been determined to be a storage operation under the Kern County Zoning Ordinance, Section 19.08.085 and Section 19.06.020. Therefore, CCS in either existing formation or tanks is an allowed use with a CUP in the following districts:
    - A District (Exclusive Agriculture)
    - M-2 District (Medium Industrial)
    - M-3 District (Heavy Industrial)

The proposed project would capture CO_2 from existing sources within the South Belridge oil field and transport it by pipeline to dedicated Class VI injection wells within the North Belridge oil field to be injected into identified geologically confined reservoirs for storage. The underground CCS formation is a depleted oil and gas reservoir with saline formation water. The CO_2 distribution pipelines, and associated infrastructure would be new construction. Implementation of the project would also require permits from the Federal Environmental Protection Agency (EPA) for up to nine (9) Class VI injection wells in compliance with the UIC Program for Class VI injection wells (40 CFR 146.81 et seq.).

The proposed project area has been identified as a location suitable for such storage and a potential to contribute to California's goals for carbon neutrality by 2045 by reducing industrial uses to no net contribution and potentially supporting direct removal of CO2 from the air. California executive order B-55-18 mandates that the state achieve carbon neutrality by 2045 and maintain net negative emissions thereafter. (https://livermorelabfoundation.org/2019/12/19/getting-to-neutral/).

DATE: June 9, 2023

TO: Surrounding Property Owners within 1,000 Feet of Project Boundary; and Interested Parties

FROM: Kern County Planning and Natural Resources Department
2700 "M" Street, Suite 100
Bakersfield, CA 93311

SUBJECT: Notice of Preparation of an Environmental Impact Report – CarbonFrontier Carbon Capture Sequestration (CCS) Project by Aera Energy, LLC (PP23402).

Dear Sir or Madam:

The Kern County Planning and Natural Resources Department has determined that preparation of an Environmental Impact Report (EIR) is necessary for the proposed project identified below. The purpose of this letter is to notify interested parties and surrounding property owners within 1,000 feet of the project boundaries of this determination. A copy of the Initial Study/Notice of Preparation (IS/NOP) prepared for this proposed project is available for viewing at the following Kern County website:

https.//kernplanning.com/planning/notices-of-preparation/

The purpose of the IS/NOP is to describe the proposed project, specify the project location, and to identify the potential environmental impacts of the project so that Responsible Agencies and interested persons can provide a meaningful response related to potential environmental concerns that should be analyzed in the Environmental Impact Report.

You are invited to view the NOP and submit written comments regarding the scope and content of the environmental information in connection with the proposed project should you wish to do so. Due to the limits mandated by State law, your response must be received by **July 10, 2023 at 5:00 p.m.** Comments can be submitted to the Kern County Planning and Natural Resources Department at the address shown above or to HooverC@kerncounty.com. A Scoping meeting will be held on **Friday, June 23, 2023 at 1:30 p.m.** at the address listed above.

Please be advised that any comments received after the dates listed above will still be included in the public record for this project and made available to decision makers when this project is scheduled for consideration at a public hearing. Please also be advised that you will receive an additional notice in the mail once a public hearing date is scheduled for this project. You will also be provided additional opportunities to submit comments at that time.

PROJECT TITLE: CarbonFrontier CCS Project by Aera Energy, LLC (PP23402); PLN22-00137: ZCC No. 4, Map No. 51; ZCC No. 3, Map No. 74; ZCC No. 4, Map No. 75; CUP No. 9, Map No. 51; CUP No. 7, Map No. 74; CUP No. 7, Map No. 75; CUP No. 9, Map No. 96.

PROJECT LOCATION: The proposed project site is located within the Central Valley portion of unincorporated Kern County and is comprised of forty-seven (47) privately owned parcels and two (2) provisional parcels, within the administrative boundaries of the North and South Belridge oilfields. The North and South Belridge oilfields are contiguous and located west of Highway 33, approximately seven (7) miles southwest of the community of Lost Hills (population 2,370). Additionally, the proposed project is located within Sections 20, 21, 22, 26, 27, 28, 34, 35, and 36 of Township 27 South, Range 20 East; Sections 1, 2, and 12 of

Township 28 South, Range 20 East; Sections 6, 7, 17, 18, 20, 27, 28, 29, 32, 33, and 34 of Township 28 South Range 21 East; and Sections 2, 3, and 4 of Township 29 South, Range 21 East of the Mount Diablo Base and Meridian (MDBM).

PROJECT DESCRIPTION: The project proponent is proposing to construct and operate a CCS project within the North and South Belridge oilfields. Implementation of the proposed project includes the following requests:

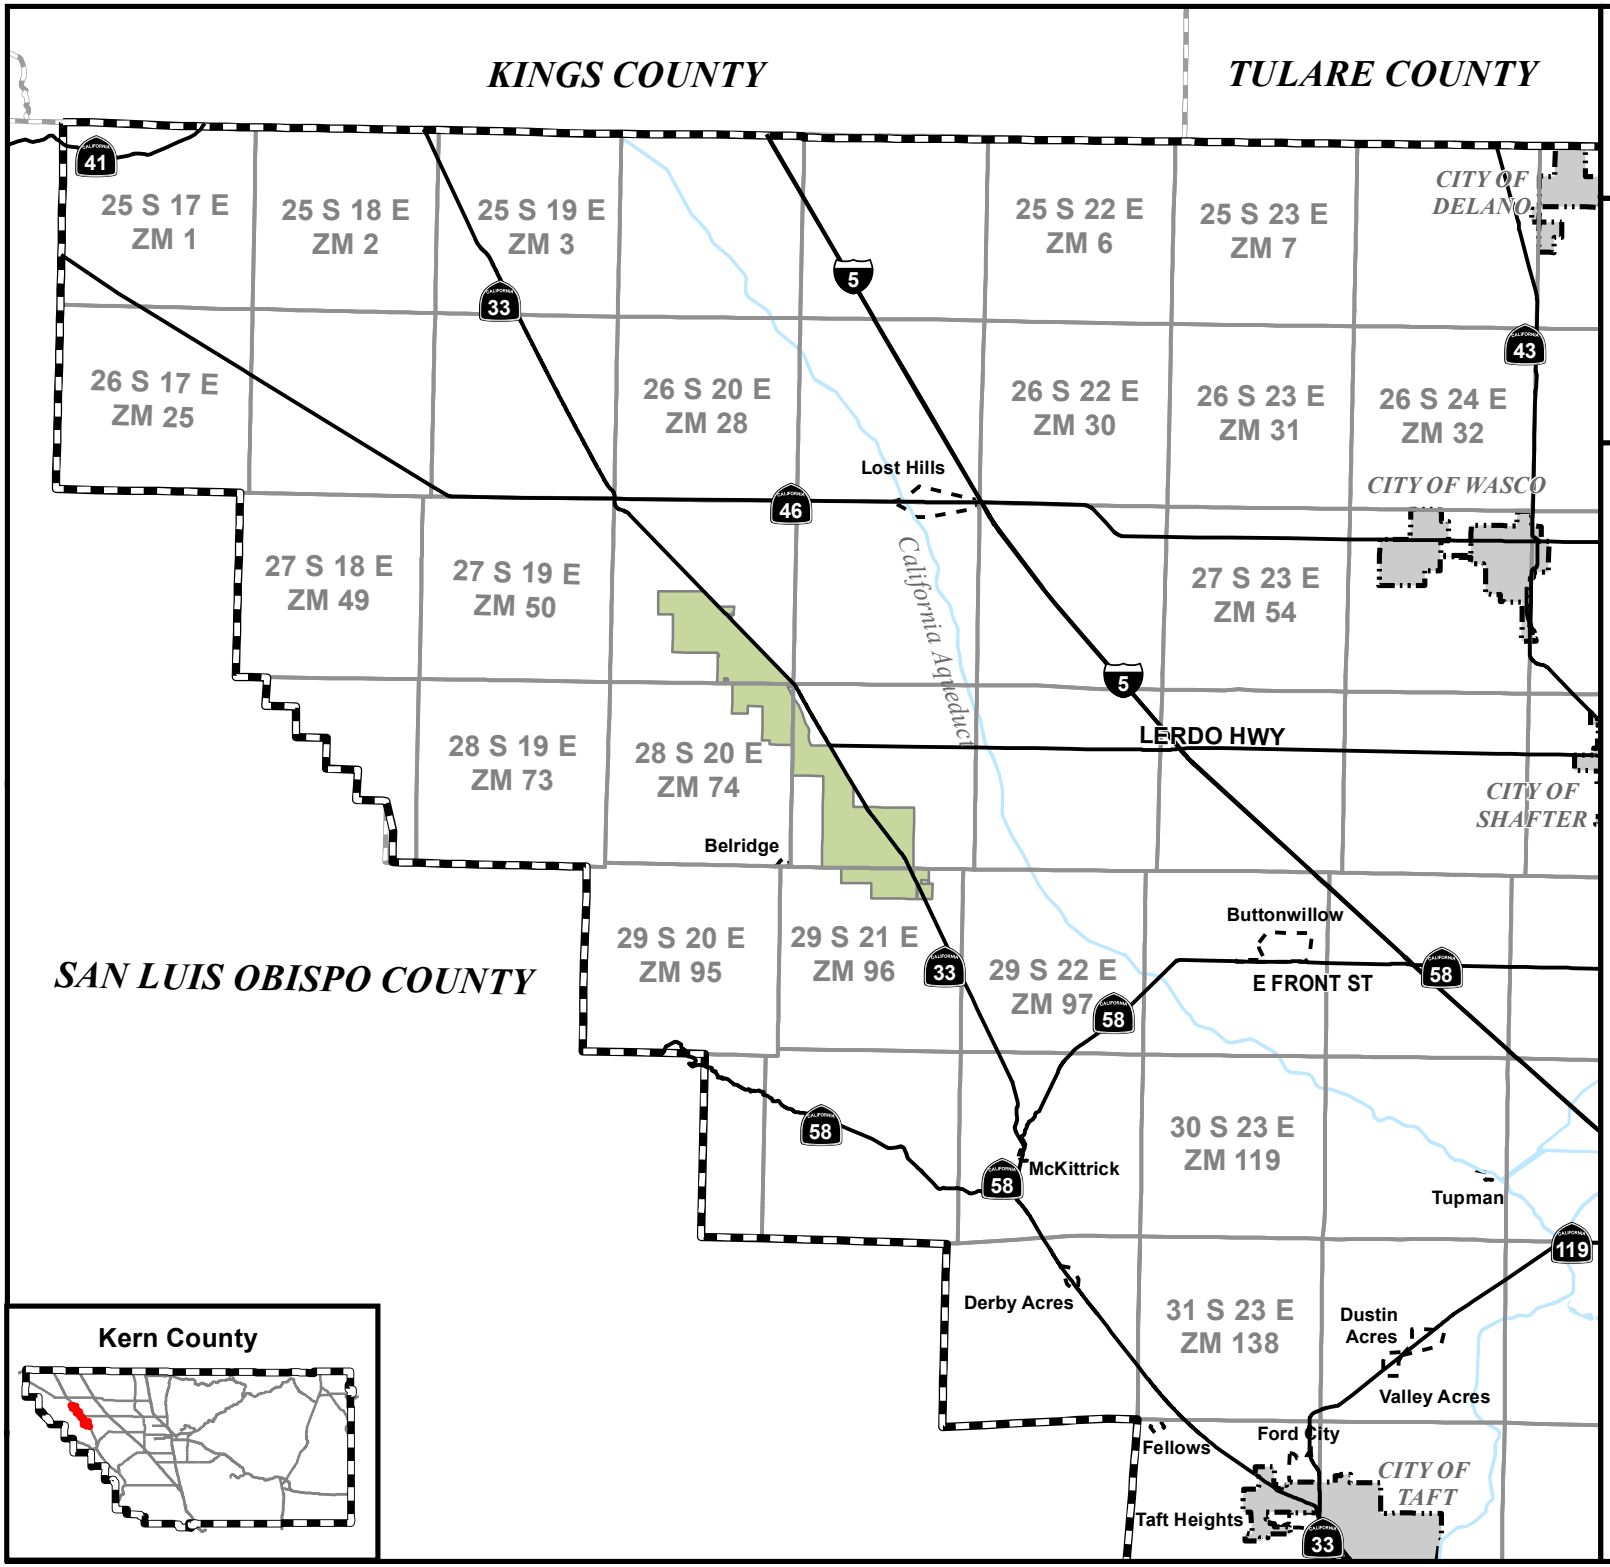
- Zone Classification Change (ZCC) from A-1 (limited Agriculture) to A (Exclusive Agriculture) on approximately 1,737 acres and from NR (Natural Resources – 20 acre minimum) to A (Exclusive Agriculture) on approximately 47 acres.

- Conditional Use Permit (CUP) to allow a CCS facility, associated Class VI geologic sequestration injection wells, and related improvements for storage of CO_2 on approximately 13,229 acres. CCS has been determined to be a storage operation under the Kern County Zoning Ordinance, Section 19.08.085 and Section 19.06.020. Therefore, CCS in either existing formation or tanks is an allowed use with a CUP in the following districts:

    - A District (Exclusive Agriculture)
    - M-2 District (Medium Industrial)
    - M-3 District (Heavy Industrial)

The proposed project would capture CO_2 from existing sources within the South Belridge oil field and transport it by pipeline to dedicated Class VI injection wells within the North Belridge oil field to be injected into identified geologically confined reservoirs for storage. The underground CCS formation is a depleted oil and gas reservoir with saline formation water. The CO_2 distribution pipelines, and associated infrastructure would be new construction. Implementation of the project would also require permits from the Federal Environmental Protection Agency (EPA) for up to nine (9) Class VI injection wells in compliance with the UIC Program for Class VI injection wells (40 CFR 146.81 et seq.).

The proposed project area has been identified as a location suitable for such storage and a potential to contribute to California's goals of for carbon neutrality by 2045 by reducing industrial uses to no net contribution and potentially supporting direct removal of CO2 from the air. California executive order B-55-18 mandates that the state achieve carbon neutrality by 2045 and maintain net negative emissions thereafter. (https://livermorelabfoundation.org/2019/12/19/getting-to-neutral/).



Should you have any questions regarding this project, or the Initial Study/Notice of Preparation, please feel free to contact me by phone at (661) 862-8629 or email HooverC@kerncounty.com.

Sincerely,

Cindi Hoover

Present Land Use/Zoning/General Plan Designation: Oil and Gas Exploration and Production / A (Exclusive Agriculture), A-1 (Limited Agriculture, NR (20) (Natural Resources – 20 acre min) / 8.1 (Intensive Agriculture), 8.3 (Extensive Agriculture), 8.4 (Mineral and Petroleum), 8.1/2.5 (Intensive Agriculture – Flood Hazard Overlay), 8.3/2.5 (Extensive Agriculture – Flood Hazard Overlay), 8.4/2.5 (Mineral and Petroleum – Flood Hazard Overlay).

Project Description: The CarbonFrontier CCS Project, as proposed by AERA Energy, LLC would develop an approximate 13,229 acre carbon capture and sequestration field, associated Class VI geologic sequestration injection wells, and related improvements for storage of Carbon Dioxide (CO_2). The proposed project would capture CO_2 from existing sources within the South Belridge oil field and transport it by pipeline to dedicated Class VI injection wells within the North Belridge oil field to be injected into identified geologically confined reservoirs for storage. The underground CCS formation is a depleted oil and gas reservoir with saline formation water. The CO_2 distribution pipelines, and associated infrastructure would be new construction.

Implementation of the proposed project includes the following requests:

- Zone Classification Change (ZCC) from A-1 (limited Agriculture) to A (Exclusive Agriculture) on approximately 1,737 acres and from NR (Natural Resources – 20 acre minimum) to A (Exclusive Agriculture) on approximately 47 acres.

- Conditional Use Permit (CUP) to allow a CCS facility, associated Class VI geologic sequestration injection wells, and related improvements for storage of CO_2 on approximately 13,229 acres. CCS has been determined to be a storage operation under the Kern County Zoning Ordinance, Section 19.08.085 and Section 19.06.020. Therefore, CCS in either existing formation or tanks is an allowed use with a CUP in the following districts:

    - A District (Exclusive Agriculture)
    - M-2 District (Medium Industrial)
    - M-3 District (Heavy Industrial)

Implementation of the proposed project would also require permits from the Federal Environmental Protection Agency (EPA) for up to nine (9) Class VI injection wells in compliance with the UIC Program for Class VI injection wells (40 CFR 146.81 et seq.).

The proposed project area has been identified as a location suitable for such storage and a potential to contribute to California's goals for carbon neutrality by 2045 by reducing industrial uses to no net contribution and potentially supporting direct removal of CO2 from the air. California executive order B-55-18 mandates that the state achieve carbon neutrality by 2045 and maintain net negative emissions thereafter. (https://livermorelabfoundation.org/2019/12/19/getting-to-neutral/).

INTRODUCTION

Pursuant to the California Environmental Quality Act (CEQA), the Kern County Planning and Natural Resources Department (County) will initiate the preparation of an Environmental Impact Report (EIR) for the CarbonFrontier Project in the unincorporated area of western Kern County, California.

1. Project Description

1.1. Project Location

The CarbonFrontier Project (proposed project) is a proposal by Aera Energy, LLC (project proponent) to construct and operate a carbon capture and sequestration (CCS) field on approximately 13,229 acres of privately owned land. CCS facilities would be composed of four (4) carbon dioxide (CO_2) capture facilities, up to nine (9) injection wells, up to eight (8) monitoring wells, CO_2 pipelines, and the surface projection of the CO_2 sequestration field capable of storing up to 43 Million Metric Tons (MM Mt) of CO_2.

The proposed project site is located within the Central Valley portion of unincorporated Kern County and is comprised of forty-seven (47) privately owned parcels and two (2) provisional parcels, within the administrative boundaries of the North and South Belridge oilfields. The North and South Belridge oilfields are contiguous and located west of Highway 33, approximately seven miles southwest of the community of Lost Hills (population 2,370).

The proposed project is located within Sections 20, 21, 22, 26, 27, 28, 34, 35, and 36 of Township 27 South, Range 20 East; Sections 1, 2, and 12 of Township 28 South, Range 20 East; Sections 6, 7, 17, 18, 20, 27, 28, 29, 32, 33, and 34 of Township 28 South Range 21 East; and Sections 2, 3, and 4 of Township 29 South, Range 21 East of the Mount Diablo Base and Meridian (MDBM). The proposed project area can be seen in Figure 1 – Regional Vicinity.

Primary access to the project site would be from Oasis Road, a private road, accessed from Seventh Standard Road, west of Highway 33, which can be seen in Figure 2 – Local Vicinity. The access road connects to a network of existing dirt roads within the field; depending on the final locations of the injection wells and accessory facilities and infrastructure, new internal access roads may be constructed. These new roads would most likely be compacted dirt roads as well.

1.2. Environmental Setting

The proposed project site is situated in the western extent of the valley region in unincorporated Kern County. The County's geography includes, among other features, mountainous area, agricultural lands, and deserts. Kern County is California's third largest County in land area and encompasses approximately 8,200 square miles with the current estimated population being 914,193 residents.

As previously discussed, the project site is located within the administrative boundary of the South and North Belridge oilfields. Combined, the two oilfields cover an area approximately thirteen (13) miles long and three (3) miles wide. The oil fields are predominantly developed with oil and gas production and accessory facilities and infrastructure. The primary operator within both oilfields is Aera Energy, LLC. The proposed CO_2 capture facilities would be located within the developed portion of the South Belridge oilfield. The proposed injection wells, monitoring wells and CO_2 sequestration field would be located in the North Belridge oilfield. Pipelines would transect both fields. The infield pipelines would primarily be

installed above ground, except where the pipelines would cross main access roads (below ground) within the oil field properties. The CO_2 sequestration field would be comprised of 2,636 acres of land in which CO_2 would be injected and stored underground in a depleted oil and gas reservoir.

The proposed project parcels are not designated by the California Department of Conservation (DOC) as Prime Farmland, Farmland of Statewide Importance, or Unique Farmland. However, the proposed project site has two (2) parcels (APN: 068-220-26 and 085-210-42) subject to Farmland Security Zone (FSZ) contracts and three (3) parcels subject to Williamson Act Land Use Contracts; one (1) parcel (APN: 068-210-13) designated as non-prime; one (1) parcel (APN: 068-200-33) designated as mixed; and one (1) parcel (APN: 085-220-37) designated as prime, as shown in *Figure 3 – Active Land Use Contract*. Furthermore, twenty-four (24) parcels are included within the boundaries of Agriculture Preserve numbers 5 and 2, as shown in Figure 4 – Agricultural Preserve.

The proposed project site is within the San Joaquin Valley Air Basin, under the regulatory authority of the San Joaquin Valley Air Pollution Control District. The Federal Emergency Management Agency (FEMA) delineates flood hazard areas on its Flood Insurance Rate Maps (FIRMs). A majority of the proposed project site is designated as Zone "X" on the FIRMs, which indicates the site is not in an area of flood hazard, as shown in Figure 5 – Flood Hazard. However, portions of the proposed pipeline routes are located within the FIRMs and are designated as Zone "A" flood hazard area, which indicates the site has a 1% chance of flooding. There are no State-designated Alquist-Priolo Earthquake Fault Zones within the proposed project site. No portion of the project site is identified as a wetland area on the National Wetlands Inventory.

Additionally, the proposed project site is not located within a Kern County-designated mineral recovery zone, however, the majority of the North and South Belridge oilfields are designated by the Kern County General Plan for Mineral and Petroleum exploration and extraction. Please see *Figure 6 – Existing General Plan Designations.* Most parcels within the proposed project boundary have a zone classification of A (Exclusive Agriculture), with the exception of five parcels which have a zone classification of A-1 (Limited Agriculture) and a portion of one (1) parcel which currently has a zone classification of NR (20) (Natural Resources – 20 acre minimum) as shown in *Figure 7 – Existing Zoning Classifications.* The project proponent has requested a zone classification change to A (Exclusive Agriculture) on parcels with a current zone classification of A-1 (Limited Agriculture) or NR (20) (Natural Resources – 20 acre minimum) *Figure 8 – Proposed Zoning Classifications.*

Table 1: Project Assessor Parcel Numbers, Existing Map Code Designation, Existing and Proposed Zoning, & Acreages, below identifies the individual parcels, their respective assessor parcel numbers (APN), acreages, and existing general plan and zoning designations.

Table 1: Project Assessor Parcel Numbers, Existing Map Code Designation, Existing and Proposed Zoning, & Acreages

APN	Existing Map Code Designations	Existing Zoning	Proposed Zoning	Section Township Range	Acres	Land Use Contract/ Designation	Agriculture Preserve

Surrounding Land Uses

Table 2, Existing Project Site and Surrounding Properties, Existing Land Use, General Plan Map Code Designations, and Zoning, identifies the existing land use, the existing general plan land use designation,

and the existing zone classification within the proposed project site. Additionally, such conditions are described for adjacent lands to the north, east, south, and west of the proposed project site.

Table 2: Existing Project Sites and Surrounding Properties, Existing Land Use, General Plan Map Code Designations, and Zoning

Location	Existing Land Use	Existing General Plan Map Code Designations	Existing Zoning
Project Site	Oil and Gas Exploration and Production	8.1 (Intensive Agriculture) 8.3 (Extensive Agriculture) 8.4 (Mineral and Petroleum) 8.1/2.5 (Intensive Agriculture / Flood Hazard Overlay) 8.3/2.5 (Extensive Agriculture / Flood Hazard Overlay) 8.4/2.5 (Mineral and Petroleum / Flood Hazard Overlay)	A (Exclusive Agriculture) A-1 (Limited Agriculture) NR (20) (Natural Resources – 20 acre min)
North	Oil and Gas Exploration and Production, Undeveloped Land, Agriculture	8.3 (Extensive Agriculture)	A (Exclusive Agriculture)
East	Agriculture	8.1/2.5 (Intensive Agriculture / Flood Hazard Overlay) 8.1 (Intensive Agriculture) 8.3 (Extensive Agriculture)	A (Exclusive Agriculture)
South	Oil and Gas Exploration and Production	8.4 (Mineral and Petroleum) 8.4/2.5 (Mineral and Petroleum / Flood Hazard Overlay)	A (Exclusive Agriculture)
West	Oil and Gas Exploration and Production, Undeveloped Land	8.3 (Extensive Agriculture) 8.3/2.5 (Extensive Agriculture / Flood Hazard Overlay) 8.4 (Mineral and Petroleum) 8.4/2.5 (Mineral and Petroleum / Flood Hazard Overlay)	A (Exclusive Agriculture) A-1 (Limited Agriculture)

The surrounding land uses of the proposed project site include oil and gas exploration and production, grazing, and agricultural lands. The closest sensitive receptor to the proposed project site includes one residence approximately 400 feet from the project boundary, and approximately 3,970 feet from the nearest proposed injection well, located east of State Route 33 and adjacent to the North Belridge oilfield. The

nearest schools are Lost Hills Elementary School and A.M. Thomas Middle School located at 20979 Lobos Court approximately six (6) miles northeast of the proposed project site. Additionally, the nearest recreational facility is the Lost Hills Wonderful Park located approximately seven (7) miles northeast of the proposed project site.

The proposed project would be served by the Kern County Sheriff's Office (KCSO) for law enforcement and public safety, Kern County Fire Department (KCFD) for fire protection, and Kern County Medical Emergency Service for emergency medical and rescue services. The nearest KCSO substation that would serve the project is located in the City of Taft at 315 N. Lincoln Street. Additionally, fire protection and emergency medical service would be provided by the KCFD fire station (Station No. 26) located at 14670 Lost Hills Road in the community of Lost Hills.

The proposed project is not located within an Airport Sphere of Influence (SOI), per the Kern County Airport Land Use Compatibility Plan (ALUCP). The nearest airport is the Buttonwillow Airport approximately 14 miles southeast of the proposed project site.

1.3. Project Description

Aera Energy, LLC is proposing to construct and operate a CCS project within the North and South Belridge oilfields. The proposed project requires a Zone Classification Change (ZCC) from A-1 (limited Agriculture) to A (Exclusive Agriculture) on approximately 1,737 acres, from NR (Natural Resources – 20 acre minimum) to A (Exclusive Agriculture) on approximately 47 acres and a Conditional Use Permit (CUP) to allow a CCS capture facility, associated Class VI geologic sequestration injection wells, and related improvements for storage of CO_2 on approximately 13,229 acres. The proposed project CUP boundary is shown in Figure 9 – Proposed Project CUP Boundary.

The project would capture CO_2 from existing sources within the South Belridge oil field and transport it by pipeline to dedicated Class VI injection wells within the North Belridge oil field to be injected into identified geologically confined reservoirs for storage. The underground CCS formation is a depleted oil and gas reservoir with saline formation water, situated at a depth of approximately 8,500', more than a mile below potential underground sources of drinking water. Prior to project commencement, oil and gas production activities would cease within the underground CCS formation where CO_2 would be stored. The CO_2 distribution pipelines, and associated infrastructure would be new construction and sized to accept CO_2 from existing sources within the South Belridge oil field. This area has been identified as a location suitable for such storage and the potential to contribute to California's goals for carbon neutrality by 2045 by reducing industrial uses to no net contribution and potentially supporting direct removal of CO_2 from the air. California executive order B-55-18 mandates that the state achieve carbon neutrality by 2045 and maintain net negative emissions thereafter.(https://livermorelabfoundation.org/2019/12/19/getting-to-neutral/).

Implementation of the project would require permits from the Federal Environmental Protection Agency (EPA) for up to nine (9) Class VI injection wells in compliance with the Underground Injection Control (UIC) Program for Class VI injection wells (40 CFR 146.81 et seq.). Area of Review (AOR) modeling has been performed to define the anticipated limits of the CCS field. The Area of Review is the region surrounding the geologic sequestration project where Underground Sources of Drinking Water (USDWs) may be endangered by the injection activity. The area of review is delineated using computational modeling that accounts for the physical and chemical properties of all phases of the injected carbon dioxide stream and displaced fluids, and is based on available site characterization, monitoring, and operational data as set

forth in 40 CFR 146.84 (Underground Injection Control (UIC) Program Class VI Implementation Manual for UIC Program Directors, EPA 816-R-18-001, January 2018).

All employee facilities needed for the proposed project would be provided by the existing Aera Belridge facilities. Over the life of the proposed project, the CO_2 capture facilities would require on average approximately 918 acre feet per year (AFY). This preliminary estimate is based on seasonal high temperatures and the average daily water use is expected to be less than 26,000 barrels per day.

The proposed project would primarily use produced water from the Belridge oilfield. Fresh water would be minimally used for utility purposes including, but not limited to fire protection, lavatories, showers, equipment cleaning, dust control, grading, compaction, and only used in the process if sufficient water is available under existing water rights. Fresh water would be sourced from existing State Water Project entitlements with the Belridge Water Storage District and from existing Aera-owned groundwater wells located in the Buena Vista Water Storage District. Water treatment facilities would be installed at the CO_2 capture facilities to treat produced water. Pipelines for water would be constructed and installed primarily aboveground connecting the new water treatment facilities to existing water distribution pipelines and water injection wells.

Electrical demand for the proposed project is estimated to be up to 49 megawatts (MW), which will be provided by the existing Section 32 Cogeneration facility and existing utility electrical service connections. If project energy demands are forecasted to exceed existing self-generation and electrical service capacity, a supplemental load request would be pursued with the utility provider and may warrant upgrades to power distribution infrastructure.

The proposed project would capture CO_2 from existing Tulare and Diatomite reservoir produced gas streams (Pre-Combustion) and emissions from flue gas emissions from existing stationary sources (Post-Combustion) within the South Belridge oilfield, described in more detail below, and transport the CO_2 through pipelines to the North Belridge oilfield for injection at dedicated UIC Class VI injections wells.

Pre-Combustion

Produced natural gas from existing operations will be directed to a dedicated CO_2 capture facility to be located near Gas Plant 32 (GP 32) in Section 32, Township 28 South, Range 21 East of the Mount Diablo Base and Meridian. The CO_2 capture facility would include three steel towers up to 120 feet in height and between 2 to 12 feet in diameter. Other equipment within the facility will include heat exchangers, transfer pumps, compressors, and a storage area for process chemicals.

A physical solvent or a traditional amine absorption process would be used to remove the CO_2 from the produced gas stream. In the CO_2 capture facility, the produced gas stream would be passed through an absorber column where the absorbent would chemically react with and bind over 90 percent of the incoming CO_2. The rich absorbent carrying the CO_2 would be piped to a regenerator column and through the combination of reduced pressure and applied heat the CO_2 would be released from the absorbent and captured in nearly pure concentration. Following the CO_2 release, the reconstituted absorbent would be recycled back to the absorber column. The captured CO_2 would then be cooled, compressed, and pumped by pipeline to the permitted Class VI injection wells to be stored in the underground CCS sequestration field located within the North Belridge oilfield.

Post-Combustion

Three post-combustion CO_2 capture facilities would be constructed to remove CO_2 from the exhaust streams at three existing facilities. The post-combustion CO_2 capture facilities would be located at the Section 32 Cogeneration facility, Steam Generation Site 2868, and Steam Generation Site 2972 within the South Belridge oil field. The CO_2 capture and processing facilities would include the separation, dehydration, compression, and cooling of CO_2 from flue gas emissions at the existing stationary sources. The post-combustion CO_2 capture facilities would use a similar chemical process as described above for the pre-combustion facility. The remaining flue gas would continue to be vented to the atmosphere as allowed under the facilities current permits issued by the San Joaquin Valley Air Pollution Control District.

Proposal

Implementation of the proposed project includes the following requests:

(a) Zone Classification Changes (ZCC), as follows:

- A-1 (Limited Agriculture) to A (Exclusive Agriculture) on approximately 1,737.38 acres comprised of five (5) parcels;
- NR (20) (Natural Resources – 20 gross acres) to A (Exclusive Agriculture) on approximately 47 acres comprised of a portion of one (1) parcel.

(b) Conditional Use Permit (CUP) to allow for the construction and operation of a Carbon capture and sequestration field, within the A (Exclusive Agriculture) Zone District. Carbon Capture and Sequestration (CCS) has been determined to be a storage operation under the Kern County Zoning Ordinance, Section 19.08.085 and Section 19.06.020. Therefore, CCS in either existing formations or tanks is an allowed use with a Conditional Use Permit (CUP) in the following districts:

- A District (Exclusive Agriculture)
- M-2 District (Medium Industrial)
- M-3 (Heavy Industrial)

1.4. Project Objectives

The project proponent has defined the following objectives for the proposed project:

- Construct and operate facilities and infrastructure to capture, transport, inject, and permanently sequester up to 43 MM Mt of CO_2 in a safe, secure, and economically feasible manner for storage, not enhanced recovery;
- Minimize new disturbance by siting and designing project facilities and infrastructure within the existing developed oil field footprint;
- Reduce the carbon intensity of Aera's produced oil and gas by capturing CO_2 from produced gas and stationary sources;
- Generate environmental, social, and economic benefits for Kern County and the State of California by implementing low carbon technologies, developing CCS infrastructure, and providing living-wage jobs in the region; and

- Contribute to California's goal to achieve carbon neutrality by 2045 (Executive Order B-55-18) by integrating carbon capture in existing operations as well as ending oil and gas production from select reservoirs and repurposing them for the permanent storage of CO_2.

1.5. Proposed Discretionary Actions/Required Approvals

The Kern County Planning and Natural Resources Department as the CEQA Lead Agency (per CEQA Guidelines Section 15052) has discretionary responsibility for the CarbonFrontier Project owned by AERA ENERGY, LLC. To implement this project, the project proponent may need to obtain discretionary and ministerial permits/approvals including, but not limited to, the following:

- Federal
    - Environmental Protection Agency Underground Injection Control – Class VI Permit
    - U.S. Fish and Wildlife Service (USFWS) Section 10 Incidental Take Permit and Habitat Conservation Plan (if required).
    - United States Army Corps of Engineers Section 404 Permit (if required)
    - Pipeline Approval – U.S. Department of Transportation – Pipeline and Hazardous Materials Safety Administration (if required)
- State
    - California Department of Fish and Wildlife (CDFW)
        - Section 2081 Incidental Take Permit (State-listed endangered species) (if required)
        - Section 1602 Lake or Streambed Alteration Agreement (if required)
    - Central Valley Water Quality Control Board (RWQCB)
        - Waste Discharge Requirements
        - Regional Water Quality Certification (401 Permit) (if required)
        - National Pollution Discharge Elimination System (NPDES) Construction General Permit
        - General Construction Stormwater Permit (Preparation of a SWPPP) (if required)
    - California Department of Transportation (Caltrans)
        - Right-of-Way Encroachment Permit (if required)
        - Permit for Transport of Oversized Loads (if required)
    - California Department of Conservation - Geological Energy Management Division (CalGEM)
        - Well Abandonment Permit (if required)

- Local
    - Kern County
        - Certification of Final Environmental Impact Report
        - Adoption of Mitigation Monitoring and Reporting Program
        - Adoption of 15091 Findings of Fact and 15093 Statement of Overriding Considerations
        - Approval of Zone Classification Change
        - Approval of Conditional Use Permits
        - Approval of Kern County Grading (if required)
        - Approval of Kern County Building Permits
        - Approval of Fire Safety Plan
    - San Joaquin Valley Air Pollution Control District
        - Approval of Fugitive Dust Control Plan
        - Authority to Construct (ATC)
        - Permit to Operate (PTO)

The preceding discretionary actions/approvals are potentially required and do not necessarily represent a comprehensive list of all possible discretionary permits/approvals required. Other additional permits or approvals from responsible agencies may be required for the proposed project.

In addition, although not required to implement the proposed project, the project proponent may seek a determination from the California Air Resources Board for Permanence Certification under the Low Carbon Fuel Standard's CCS Protocol.

2. Kern County Environmental Checklist Form

2.1. Environmental Factors Potentially Affected

In accordance with CEQA Guidelines, the County intends to prepare an Environmental Impact Report (EIR) to evaluate potential environmental effects of the project and to propose mitigation measures to reduce any significant effects identified.

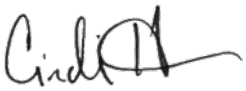
The environmental factors checked below would be potentially affected by this project, involving at least one impact that is a "potentially significant impact" as indicated by the Kern County Environmental Checklist. As such, the analysis contained within the EIR will focus on these issue areas.

☒ Aesthetics	☒ Agricultural and Forestry Resources	☒ Air Quality
☒ Biological Resources	☒ Cultural Resources	☒ Energy
☒ Geology and Soils	☒ Greenhouse Gas Emissions	☒ Hazards and Hazardous Materials
☒ Hydrology and Water Quality	☒ Land Use and Planning	☒ Mineral Resources
☒ Noise	☒ Population and Housing	☒ Public Services
☒ Recreation	☒ Transportation and Traffic	☒ Tribal Cultural Resources
☒ Utilities/Service Systems	☒ Wildfire	☒ Mandatory Findings of Significance

2.2. Determination

(To be completed by the Lead Agency)

Based on this initial evaluation:



☐ I find that the proposed project COULD NOT have a significant effect on the environment, and a NEGATIVE DECLARATION will be prepared.

☐ I find that although the proposed project could have a significant effect on the environment, there will not be a significant effect in this case because revisions in the project have been made by or agreed to by the project proponent. A MITIGATED NEGATIVE DECLARATION will be prepared.

☒ I find that the proposed project MAY have a significant effect on the environment, and an ENVIRONMENTAL IMPACT REPORT is required.

☐ I find that the proposed project MAY have a "potentially significant impact" or "potentially significant unless mitigated" impact on the environment, but at least one effect (a) has been adequately analyzed in an earlier document pursuant to applicable legal standards, and (b) has been addressed by mitigation measures based on the earlier analysis as described on attached sheets. An ENVIRONMENT IMPACT REPORT is required, but it must analyze only the effects that remain to be addressed.

☐ I find that although the proposed project could have a significant effect on the environment, because all potentially significant effects (a) have been analyzed adequately in an earlier EIR or NEGATIVE DECLARATION pursuant to applicable standards, and (b) have been avoided or mitigated pursuant to that earlier EIR or NEGATIVE DECLARATION, including revisions or mitigation measures that are imposed upon the proposed project, nothing further is required.

Re: Notice of Preparation of a Draft Environmental Impact Report: – CarbonFrontier Carbon Capture Sequestration (CCS) Project by Aera Energy, LLC (PP23402)

Dear Kern County Planning and Natural Resources Department:

The Center for Biological Diversity and the Central California Environmental Justice Network (CCEJN) submit these comments on the Notice of Preparation (NOP) of an Environmental Impact Report (EIR) for the CarbonFrontier Carbon Capture Sequestration Project by Aera Energy, LLC (PP23402) (hereinafter, the project, or the Aera CCS project). The proposed project involves capturing carbon dioxide (CO_2) from sources in the South Belridge oil field and transporting it in as-yet undisclosed number of pipelines to up to nine injection wells in the North Belridge oilfield with the capacity to store 43 million metric tons (MM Mt).

As a threshold matter, our organizations disagree with the premise that carbon capture and sequestration (CCS) should play a role in achieving our state's goal of reaching near-zero emissions by midcentury in order to limit global warming to 1.5°C. CCS regularly over-promises and under-delivers on its carbon capture benefits all while keeping dirty industries like fossil fuels alive, making it a false solution that diverts attention and resources from transitioning to clean, renewable energy. Instead of approving carbon storage, the County should phase out fossil fuel development to prevent catastrophic climate change and environmental injustice.

If the County continues to consider the project, as explained in detail below, it must first commit to providing the public with at least 90 days to review and comment on the draft EIR (DEIR), hearings, and translations of relevant project materials.

Specific to the DEIR, the County must adequately analyze and mitigate the project's full array of potential impacts to the environment. Transporting compressed CO_2 is extremely risky to people and the environment, as any leak can lead to serious injury or death to those even miles away. The State has not yet clarified regulatory authority over carbon pipelines, nor has it written regulations addressing carbon pipeline safety standards. In addition, storing carbon underground can contaminate drinking water and trigger earthquakes. Even if the applicant has modeled the injected carbon's area of review (AoR), this could change based on the application process for wells with EPA. The County must wait until EPA's review of the Class VI permits is complete and the permits are issued so that the full array of project activities are known and can be

assessed. Finally, because the project will prolong use of fossil fuels and unacceptably endanger and impact the environment, the County should deny the requested conditional use permit.

I. The Kern County Planning Department Should Provide the Public with At Least 90 Days for Comment and at Least Two Hearings on the Draft EIR.

While we recognize that the present comment period is on the NOP for the EIR, for the reasons described below, we urge the County to offer at least 90 days for public comment once the draft EIR is released.[1] The County should also hold at least two public hearings once the draft EIR is available.[2] We also request that the County translate the EIR and other key documents—including press releases, summaries, and presentations—into Spanish, Punjabi and any other language translation requested by county residents. In light of the significant Spanish- and Punjabi- speaking populations throughout Kern County, the County should also provide Spanish, Punjabi, or other language interpretation requested at any public meetings.

There are several reasons why more time to comment public hearings is necessary. First, it is likely that the Aera CCS EIR will be only the first or second CEQA review of a CCS project in state history, and the public must have ample time to review, consider, and comment on such an activity of statewide significance.

Second, CCS projects produce an array significant public safety and environmental impacts and risks, such as groundwater contamination, dangerous releases of compressed CO_2, earthquakes, and air pollution.[3] The public needs more than 30 days to review an EIR discussing such a wide array of significant impacts that could result from deployment of technology that is new to the state.

Third, the proposed project location is near highly-impacted, vulnerable, and overburdened residents of the San Joaquin Valley. The input, questions, and perspectives of those who will be most affected by the proposed projects must be heard, and allowing only 30 days for review and comment on the EIR—or requiring residents to seek a comment extension and wait for an answer—does not serve this purpose.

It is therefore imperative that the County provide at least 90 days for public comment throughout the CEQA process, hold at least two hearings on the draft EIR, and translate all materials and hearings.

II. The EIR Should Consider Other Alternatives that Would Advance the State's Carbon Neutrality Goals While Protecting Communities and the Environment.

Art. 40 (2018), https://www.frontiersin.org/articles/10.3389/fenrg.2018.00040/full; Zoback, Mark D. et al., Earthquake triggering and large-scale geologic storage of carbon dioxide, 109 PNAS 10164 (2012), https://www.pnas.org/content/109/26/10164.

The EIR must identify and consider alternatives to the project that would avoid impacts to environmental justice communities near the project and protect the air, water, and species of Kern County. One of the primary purposes of the project appears to be "contribution to the goals of California for carbon neutrality by 2045." A much better way to achieve these goals, however, is to phase out oil and gas extraction at the Belridge oil fields. The County should analyze this as a project alternative.

Phasing out oil production in the Belridge oil fields would be especially impactful because South Belridge is one of the top five highest carbon-intensity oil fields in California, contributing 12% of the estimated upstream emissions from California-sourced oils.[4] North Belridge ranks as number 22 for statewide GHG emissions from oil fields.[5]

Phasing out operations in the oil fields, replacing oil production with renewable energy, and developing a just transition program for oil workers has significant potential to advance GHG reduction goals while creating jobs that are better shielded from the market contractions of a fading industry.[6]

III. More Information is Required to Properly Describe the Project and Analyze its Impacts Under CEQA.

The NOP does not adequately describe the project, including its associated network of pipelines. The EIR must include a much more detailed description to enable decision-making that considers environmental consequences and environmental characteristics.[7] Under CEQA, a project description must represent the "whole of an action" to be undertaken by the lead agency; "an accurate project description is necessary for an intelligent evaluation of the potential environmental effects of a proposed activity."[8] Moreover, the project description and analysis must include "future action" that is "a reasonably foreseeable consequence of the initial project" and would "be significant in that it will likely change the scope or nature of the initial project or its environmental effects."[9]

For example, the NOP only provides that the project would "capture CO_2 from existing sources within the South Belridge oil field and transport it by pipeline to dedicated Class VI injection wells within the North Belridge oil field to be injected into identified geologically confined reservoirs for storage," and that "infield pipelines would primarily be installed above ground, except where the pipelines would cross main access roads (below ground)" (emphasis added). This is insufficient. Courts have routinely held that EIRs must include information about

the associated transportation method and its impacts.[10] The location of project components will dictate environmental impacts and their significance. The DEIR must disclose exactly how many miles of pipeline will be constructed, where the pipelines will be located, what the pipelines will be made of (since CO_2 pipelines are extremely dangerous and prone to corrosion), the distance of pipelines to sensitive receptors, and any emergency preparedness measures.[11] The DEIR must then analyze the potential impacts of these pipelines, including the impact of potential leaks, as well as how certain weather events that are happening with increasing frequency—such as extreme temperature fluctuations and flooding—could heighten the risk of leaks..

In addition to information about the project's pipelines, other aspects of the project that must be better defined and analyzed in the EIR include:

1. The number and location of injection wells (which is particularly important for identifying potentially-impacted species and historic sites);
2. The carbon injection rate (the NOP lists only the amount of carbon injection over the life of the project, but not the injection rate, yearly estimates, or expected life of the project);
3. The sources of carbon;
4. The properties of the carbon to be injected (particularly since the carbon will come from different sources);
5. The type of chemicals that will be used, as well as where and how they will be stored; and
6. The quantity, location, and impact of the construction of "new internal access roads."

And while the County has indicated that "[t]ransport of CO2 by pipeline is covered by Kern County Oil and Gas Ordinance and related [Supplemental Recirculated Environmental Impact Report ("SREIR")] (2020/2021) and requires an Oil and Gas Conformity Review permit for construction and operation,"[12] the County will not be able to rely on the SREIR for an analysis of the pipeline's impacts. If upheld, the SREIR "addresses County jurisdictional activities that occur as ancillary activities *in support of oil and gas production* in these areas, including, for example, electric transmission lines, pipelines, and access roads."[13] There is no evidence that a CO_2 pipeline transporting carbon to be stored long term in the oil field would support oil and gas *production*, meaning the SREIR is inapplicable.

Further, the County must consider and reconcile its project description with the information Aera is providing EPA for the project's Class VI permits. For example, according to

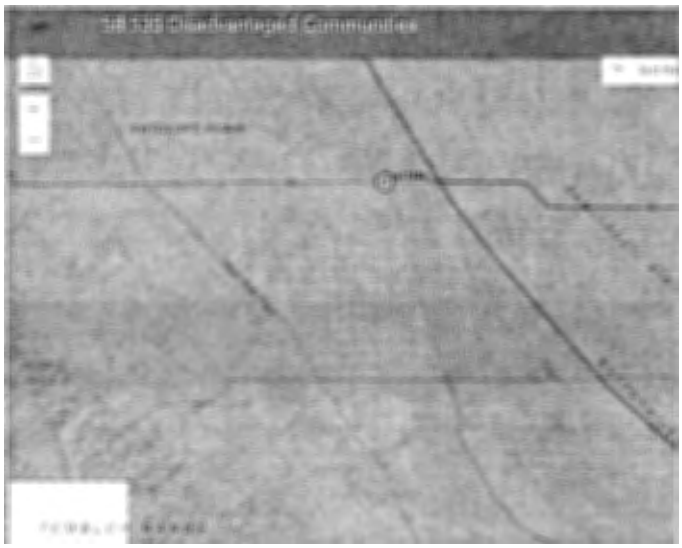
EPA the project will capture 3.6 million metric tons of CO_2/year for seven years, meaning the project will inject roughly 27 MM Mt total of captured CO_2.[14] In contrast, the NOP says the project will inject and sequester 43 MM Mt of CO_2. There must be some explanation and accounting for these vastly different numbers.

IV. The County Must Take a Hard Look at the Environmental Impacts of the Whole Project.

The NOP rightly finds that the project has the potential to contribute to significant impacts. A thorough assessment of the project's water quality, habitat and wildlife, environmental justice and public health, seismicity, climate change, and other impacts is necessary to inform the County's decision-making process and afford the fullest protection of communities and the environment.

The DEIR must analyze the whole of the project, including injection and pipeline activities. Even though the Aera CCS Project will require injection permits from EPA, the up to nine injection wells are a critical part of the project's impacts, and must be analyzed together (along with the pipeline) in the DEIR. This likely means that the DEIR cannot be complete until the EPA Class VI permits are issued.



A. Environmental Justice and Sensitive Receptors

Kern County must consider how the environmental and public health burdens of the project might disproportionately impact certain vulnerable and historically-harmed populations.[15] The White House Environmental Justice Advisory Council has called CCS projects a "type[] of project that will *not* benefit a community," noting that "it would be unreasonable to have any climate investment working against historically harmed communities."[16] Simply because a project is touted as a climate solution does not mean the County can assume it will benefit nearby disadvantaged communities.

The proposed project location is described as the North and South Belridge oil fields, approximately seven miles southwest from the community of Lost Hills (population 2,370)." The community of Buttonwillow (pop. 1,443) is approximately 14 miles southeast of the project site. These communities are designated as "disadvantaged" by the California EPA because they fall within the top 25% scoring areas from CalEnviroScreen—the higher the score, the higher the

level of pollution burden relative to other California census tracts.[17] Lost Hills is currently in the 86th percentile for pollution burden;[18] Buttonwillow is in the 96th percentile.[19]

Above: SB 535 Disadvantaged Communities in the Vicinity of the Project Area

More broadly, Kern County and communities near the project area have a high percentage of residents of color, that are linguistically isolated, and/or that have less than a high school education. In Lost Hills, over 60% of residents did not complete high school, and 90% of adults' primary language is Spanish.[20] The poverty level in Lost Hills is more than 1.5 times the rate of poverty in the rest of California.[21] In Buttonwillow, nearly 40% of residents were born in Latin America, and 35% of residents live below the poverty line.[22] It is critical that the EIR address the environmental justice impacts of the project and incorporate mitigation measures to address the high levels of pollution and emissions at sensitive receptors surrounding the project.

Further, the DEIR must fully consider how dangerous CO_2 leaks can be. The NOP notes that the nearest sensitive receptor to the proposed project site is a residence only 400 feet from the project boundary, and approximately 3,970 feet from the nearest proposed injection well. The nearest schools are Lost Hills Elementary School and A.M. Thomas Middle School, approximately six miles northeast of the proposed project site. The residence and schools are at risk of serious harm if there is a leak of compressed CO_2, which is an asphyxiant that is heavier than atmospheric air, meaning it does not disperse easily and can travel and harm people even

miles away.[23] This was the case in 2020 with Satartia, Mississippi when a CO2 pipeline ruptured and caused dozens to be hospitalized and hundreds evacuated.[24] Because compressed CO2 prevents combustion vehicle engines from working, residents had a difficult time escaping in their cars, and emergency vehicles had a difficult time accessing those who were "near death and foaming at the mouth" from carbon dioxide exposure.[25] These are serious risks Kern County must take seriously and analyze in the DEIR, for both nearby receptors as well as on-site workers.

B. Seismicity and Carbon Leakage

California is one of the most seismically active states in the U.S. and earthquakes pose a risk in the project area. Studies link CO_2 injection to earthquakes.[26] For example, a 2012 study concluded that large-scale geologic storage of CO_2 carries has a "high probability" of triggering earthquakes, finding that "[b]ecause even small- to moderate-sized earthquakes threaten the seal integrity of CO_2 repositories, in this context, large-scale CCS is a risky, and likely unsuccessful, strategy for significantly reducing greenhouse gas emissions."[27] A 2013 study found a strong correlation between earthquakes and CO_2 injection for enhanced oil recovery.[28] The full range of foreseeable seismic impacts should therefore be evaluated in the DEIR, particularly given the evidence that injection activities have been linked to earthquakes.

Relatedly, Aera proposes to inject the captured carbon into a "depleted oil and gas reservoir with saline formation water." The DEIR must analyze the potential for leaks due to abandoned oil and gas wells throughout the oil field, which could cause (on their own, or in combination with seismic events) CO_2 to leak up through the surface and both undermine climate goals and create public safety harms.

C. Climate Change & Air Pollution

CEQA requires that EIRs consider a project's reasonably foreseeable indirect impacts on the environment,[29] which includes indirect greenhouse gas (GHG) emission impacts. An

[29] Cal. Code Regs., tit. 14, § 15064(d).

environmental review must evaluate these impacts to the extent doing so is feasible and the effects are not speculative.[30] CEQA Guidelines Appendix G requires lead agencies to evaluate whether "the project [would] generate greenhouse gas emissions, either directly or indirectly, that may have a significant impact on the environment."[31]

In the DEIR, Kern County must not only analyze GHG emissions from the construction, operation, and maintenance of the injection wells, it also must analyze and mitigate emissions associated with transporting the carbon, and with any production of carbon and associated air emissions (along with any non-captured fuel that is generated and later combusted) that would not have otherwise occur in the absence of the project providing an incentive and location for sequestration—these emissions are reasonably foreseeable and significant consequences of the project.

Kern County must also disclose and analyze the amount (or percentage) of carbon the Aera CCS Project claims it will capture. The NOP says that the project's amine absorption processes will "react with and bind over 90 percent of the incoming CO_2." The DEIR must account for the CO_2 that is not captured in the amine processes. In addition, CCS projects historically have over-promised and under-delivered on their carbon capture promises.[32] For example, Chevron's natural gas-and-CCS project promised 80% capture, but after five years, achieved less than half of that.[33] A Stanford study found that the energy penalty of CCS can be up to 25% (meaning, whatever the capture promise is must be reduced by the energy penalty to calculate the true capture benefit) and concluded that CCS can increase air pollution and is not efficient at reducing carbon in the atmosphere.[34]

On the air pollution issue, the Jacobson study concluded that even if a project could achieve 100 percent capture from the capture equipment, "it is still worse, from a social cost perspective, than replacing a coal or gas plant with a wind farm because carbon capture never reduces air pollution and always has a capture equipment cost."[35] The DEIR must therefore consider what equipment is being used to capture carbon and address air pollution, and not assume that just because the project proposes to capture emissions that this will eliminate air pollution.

Finally, the project NOP says that "flue gas would continue to be vented to the atmosphere as allowed under the facilities current permits." The DEIR must disclose the pollutants contained in this flue gas and the amounts likely to occur.

D. Water Quality

Kern County currently faces severe water pollution,[36] and the project threatens to make the problem worse if injected carbon migrates from the injection sites. The County must obtain the information from EPA concerning the nine Class VI injection wells (permitted under the federal Safe Drinking Water Act) in order to fully disclose and analyze the project's impacts to water quality.

Further, the NOP estimates that the project will use "less than 26,000 barrels per day" of water, which is estimated to mostly derive from Belridge oilfield produced water. The DEIR must disclose and analyze what exactly it means to use produced water in CCS operations, and what the risks are of spills, leaks, and contamination from these practices.

E. Chemicals

The NOP says the project will involve a "storage area for process chemicals" because "a physical solvent or a traditional amine absorption process would be used to remove the CO2 from the produced gas stream." The DEIR must disclose and analyze the volume of chemicals that will be stored onsite, how those chemicals will get to the project location, plans for disposal, and impacts from possible leaks and spills on the environment and worker safety.

F. Species and Habitat

The project's construction and operation of the injection wells and other project components, including transportation and carbon capture, are likely to adversely impact biological resources in the Belridge/Lost Hills area.

Under the California Endangered Species Act, all state agencies "shall seek to conserve endangered species and threatened species."[37] And, "state agencies should not approve projects as proposed which would jeopardize the continued existence of any endangered species or threatened species . . . if there are reasonable and prudent alternatives available."[38] The federal Endangered Species Act[39] also affords protections to imperiled species in the Belridge area. The area of the project overlaps with the habitats of numerous federally managed species and habitats.

The list below includes the species that, according the U.S. Fish and Wildlife Service, could be affected by activities in the project location.[40] Of course, the EIR also must consider impacts to species that will be impacted by ancillary transportation and construction activities that extend beyond the oilfield boundaries.

- San Joaquin Wooly-threads / Endangered

In addition to the federally listed species named above, the County must consult with the California Department of Fish and Wildlife (CDFW) on state listed species. According to 2022 documents on the North and South Belridge oil fields from CDFW, the oil fields contain potentially suitable habitat within the well pad footprints and/or adjacent to the wells that can serve as refugia, denning, breeding, foraging, and dispersal habitat for the following species: the blunt-nosed leopard lizard (*Gambelia sila*), the giant kangaroo rat (*Dipodomys ingens*), the San Joaquin kit fox (*Vulpes macrotis mutica*), the Swainson's hawk (*Buteo swainsoni*), the San Joaquin antelope squirrel (*Ammospermophilus nelsoni*), the State Candidate for Listing Temblor legless lizard (*Anniella alexanderae*) and Crotch bumble bee (*Bombus crotchi*), the California jewelflower (*Caulanthus californicus*), and the State species of special concern short-nosed kangaroo rat (*Dipodomys nitratoides brevinasus*), burrowing owl (*Athene cunicularia*), American badger (*Taxidea taxus*), western spadefoot (*Spea hammondi*), LeConte's thrasher (*Toxostoma lecontei*), loggerhead shrike (*Lanius ludovicianus*), San Joaquin coachwhip (*Masticophis flagellum ruddocki*), California glossy snake (*Arizona elegans occidentalis*), legless lizard (*Anniella spp.*), and coast horned lizard (*Phrynosoma blainvilli*) as well as State Watch List species prairie falcon (*Falco mexicanus*) and California horned lark (*Eremophila alpestris actia*), other nesting birds, and potential impacts to streams.[41] This list should not been taken as exhaustive or a replacement for consultation with relevant agencies.

V. The Planning Department Must Analyze the Potential Cumulative Impacts, Including from Other CCS Projects Proposed for the Area.

CEQA requires that EIRs analyze cumulative impacts, including impacts created or compounded as a result of the combination of the project evaluated in the EIR together with other closely related past, present, and reasonably foreseeable projects.[42] A project has "cumulatively considerable" impacts when its effects are "considerable when viewed in connection with the effects of" related projects.[43]

There are several closely related, foreseeable CCS projects proposed for Kern County and the surrounding areas. The Planning Department must take these projects (listed below, though this list should not be viewed as authoritative, as more projects may exist) and any other related and foreseeable projects into account when evaluating the cumulative impacts of the Aera

[41] CDFW, Special Status Species Information for the North and South Belridge Oil Fields (Nov 1, 2022), on file.
[42] Cal. Code Regs., tit. 14, § 15355.
[43] Cal. Pub. Res. Code § 21083(b); *see also* Cal. Code Regs § 15355(b)(2).

CCS proposal. This evaluation must include considering the impacts to public safety from the dangers of compressed carbon pipelines, injection, and storage (including leaks).

Proposed CCS projects in the project area include:

1. Elk Hills Carbon TerraVault 1 – a project (under CEQA review by Kern County) to take local industrial sources of CO_2 by a combination of truck, pipeline and/or rail to the dedicated Class VI injection wells in the Elk Hills oil field;[44]
2. Delano bioenergy with carbon capture and sequestration – a project to convert woody biomass into electricity or transportation fuel in Delano, CA (Kern County);[45]
3. Mendota bioenergy with carbon capture and sequestration — a project to convert biomass into transportation fuel and sequester the carbon in Class VI storage wells near Mendota, CA (Fresno County);[46]
4. San Joaquin Renewables – a project to convert orchard biomass into natural gas for transportation fuel and sequester the carbon in Class VI storage wells near McFarland, CA (Kern County);[47] and
5. Elk Hills Carbon TerraVault 26R – a project to capture CO2 from oil field operations, direct air capture, and a newly constructed hydrogen facility for injection into the Elk Hills oil field.[48]
6. Direct Air Capture hub in Kern County – a project to capture CO_2 from the atmosphere and sequester it for storage in Kern County.[49]

Consideration of each CCS project in isolation is not permissible under CEQA. The Planning Department must also consider the CCS project in light of Kern County's oil and gas ordinance, which, if upheld in court, would accelerate oil and gas development over the next two decades, allowing up to 43,000 new wells. CO_2 injection activities will add to the air quality, water quality, and public health risks from drilling and injecting for traditional production in communities that are already overburdened.

VI. Instead of Creating Carbon Storage, the County Must End Fossil Fuel Development to Prevent Catastrophic Climate Change and Halt Further Environmental Injustices.

From the outset, we reject the premise that CCS is a necessary—or even appropriate—approach to addressing the climate crisis and pollution burdens borne by frontline communities. Further, the proposed project *itself* will emit GHGs, even if it purports to capture and store other sources' climate-harming emissions. As such, the proposed project is inconsistent with California's goals to reduce emissions and protect vulnerable residents.

CCS is a false climate solution championed by polluting industries—such as the biomass and fossil fuel industries—to enable business-as-usual operations, all while diverting resources from the needed transition to clean, cheaper renewable energy. In fact, CCS is *not* required under Intergovernmental Panel on Climate Change pathways to limit temperature rise to 1.5°C and avert climate catastrophe.[50] At the state level, CCS is also not necessary for California to achieve its climate goals, and deploying CCS would be inconsistent with state orders directing that policies and programs undertaken to achieve carbon neutrality must "improve air quality and support the health and economic resiliency of . . . particularly low-income and disadvantaged communities."[51]

After billions of dollars of investment and decades of development, CCS projects around the world have consistently failed to meet their GHG emission reduction promises. In July 2021, Chevron, operator of Australia's only commercial-scale CCS project, admitted that its self-described "world's biggest CCS project" failed to meet its five-year target of sequestering 80% CO_2,[52] instead only sequestering 30%.[53] In the U.S., CCS equipment on the Petra Nova coal-

[52] Mazengarb, Michael, *Chevron admits failure of $3 billion CCS facility in Western Australia*, Inst. For Energy Econ. & Fin. Analysis (July 19, 2021), https://ieefa.org/chevron-admits-failure-of-3-billion-ccs-facility-in-western-australia/.

[53] Milne, Peter, *Chevron's five years of Gorgon carbon storage failure could cost $230 million,* Sydney Morning Herald, Nov. 11, 2021, https://www.smh.com.au/environment/climate-change/chevron-s-five-years-of-gorgon-carbon-storage-failure-could-cost-230-million-20211110-p597uf.html; Morton, Adam, *'A shocking failure': Chevron criticized for missing carbon capture target at WA gas project,* Guardian, July 18, 2021, https://www.theguardian.com/environment/2021/jul/20/a-shocking-failure-chevron-criticised-for-missing-carbon-capture-target-at-wa-gas-project.

fired powerplant in Texas achieved only a 50% CO_2 capture rate,[54] before being shut down indefinitely for being uneconomic. And these real-world failures of CCS projects do not even take into account the *lifecycle* emissions of CCS projects. One Stanford study of the lifecycle emissions associated with Petra Nova CCS project found that "the [CCS] equipment captured the equivalent of only 10-11% of the emissions they produced, averaged over 20 years."[55]

When the lifecycle GHG impacts of carbon capture and storage are taken into account, any purported climate benefits evaporate. For one, carbon capture is incredibly energy intensive, reducing the net GHG benefits.[56] Second, there is always a risk that CO_2 transported via pipeline, rail, or truck, and then stored underground, could leak back to the atmosphere.[57] Researchers estimate that a minor leakage of stored CO_2 could reduce the benefit of CCS by up to 35%.[58] Third, lifecycle studies of CCS projects show that CCS "reduces only a small fraction of carbon emissions, and it usually increases air pollution."[59] A Stanford study recommended replacing fossil fuels with renewables such as wind or solar, rather than encouraging and investing in CCS.[60]

CONCLUSION

In conclusion, the Aera CCS DEIR must take a hard look at the potential environmental impacts associated with the whole of the project, and Kern County should ultimately deny Aera's application for a conditional use permit. The project is dangerous and subverts California's progress toward a carbon free future. At the very least, the County must delay preparation of a

Carbon Capture and Storage Is About Reputation, Not Economics

Supermajors Saving Face More Than Reducing Emissions

Executive Summary

The Australian Government proposes to broaden the scope of its Climate Solutions Fund[1] to include the ability to invest in carbon capture, use and storage (CCS or CCUS) projects.

This expansion of scope is essential if CCS projects are to be undertaken as CCS projects:

- are prohibitively expensive compared to other greenhouse gas emissions mitigation options, such as renewable energy and energy storage technologies;
- offer no financial return for investors; and
- have a dubious track-record. Even the Global CCS Institute - a booster organisation for CCS - acknowledges in its 2019 *Global Status of CCS* report that CCS is at best a minor contributor to decarbonisation, addressing up to 9% of greenhouse gas (GHG) emissions by 2050.[2]

There isn't one example of a CCS project anywhere in the world that offers a financial justification for investing in CCS.

In the absence of a carbon price, CCS will never provide a return on investment.

European oil companies—in particular, Equinor, Shell and Total—are investing in CCS, notwithstanding the lack of return, because it is an important part of their decarbonisation narrative and supports their aims to be seen as "responsible" energy companies.

There isn't one example of a CCS project anywhere in the world that offers a financial justification for investing in CCS.

The Australian Labor Party's recent statement that it remains "open to CCS" but insists that CCS must *not* be funded by the Clean Energy Finance Corporation (CEFC) nor the Australian Renewable Energy Agency (ARENA), makes sense. These bodies

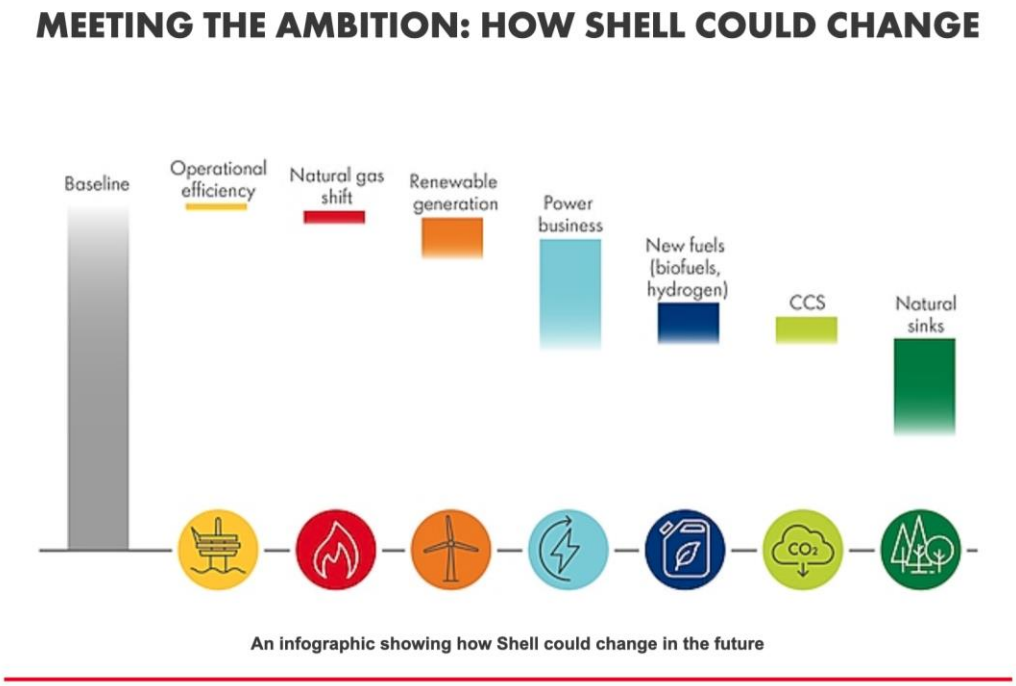
[2] Global CCS Institute. Global Status of CCS 2019.

are intended to facilitate the increased flow of finance into the commercialisation and deployment of Australian based renewable energy, energy efficiency and low carbon technologies."[3] With CCS, there is no flow of finance into the CCS sector because there is no business case. With a carbon price, this might change: the market could then decide how much to invest in CCS projects.

Despite the Minerals Council of Australia's recent hollow statement about the Paris Agreement in its "Climate Action Plan"[4], decarbonisation of electricity, electrification of mining, and the use of green hydrogen in minerals processing will be the contributions its' members make to combating increasing emissions, rather than the limited benefits afforded by CCS.

There is no flow of finance into the CCS sector because there is no business case.

CCS, Carbon Sinks and a Carbon Price



Oil majors Total and Shell have both emphasised the role that CCS, carbon sinks and a carbon price play in their ability to meet their long-term net-zero objectives.

Figure 1 shows directionally how Shell could meet its goal. Although this is not intended to be a precise chart, it is noteworthy the proportion of the reduction attributed to "natural sinks" (i.e., planting trees) and CCS.

Patrick Pouyanné, Chairman and CEO of Total, has stated, "We have the technology to capture and reinject carbon. The real question is how to do it in a way that is economically sustainable. That brings us back to the issue of carbon pricing."[5] In relation to CCS for coal-fired power generation, Pouyanné has said, "… I know that people advocate… for clean coal, but frankly, clean coal means a lot of CCS, and I would like to see where the CCS technologies are."[6]

IEEFA supports the idea that a carbon price is essential to achievement of large-scale carbon emission reductions. However, the fact that both companies' CEOs refer to this almost as a precondition to their climate goals invites scepticism about their commitment to unilateral action on CCS. Each company currently spends an immaterial percentage of annual capital expenditure on CCS[7], so it is arguable that CCS is little more than a helpful marketing message to support their boarder decarbonisation ambitions.

It is arguable that CCS is little more than a helpful marketing message.

What is Carbon, Capture and Storage?

Carbon capture, use and storage (CCS or CCUS) encompasses an integrated suite of technologies that can prevent large quantities of carbon dioxide (CO_2) from being released into the atmosphere as a consequence of using fossil fuels.

This technology has been applied in a wide range of industries since 1972 when several natural-gas processing plants in the Val Verde area of Texas began

[7] None of their investments are quantified in annual reports.

employing carbon capture to supply CO_2 for enhanced oil recovery (EOR) operations. Since then, more than 200 million tonnes of CO_2 have been captured and injected deep underground.

The net emissions impact of CCS must include emissions from the energy used in the process (up to 20% more than an operation without CCS) and the emissions from any oil extracted using EOR.

CCS Involves Three Major Steps:

1. **Capture**: The separation of CO_2 from other gases produced at large industrial process facilities such as coal and natural-gas-fired power plants, steel mills, cement plants and refineries.

2. **Transport**: Once separated, the CO_2 is compressed and transported via pipelines, trucks, ships or other methods to a suitable site for geological storage.

3. **Storage**: CO_2 is injected into deep underground rock formations, usually at depths of one kilometre or more, depleted oil or gas fields, deep saline aquifer formations or other forms of underground caverns, though it could apply to any form of storage.

The 'usage' component includes applications of the carbon in industrial processes such as the manufacture of synthetic diesel, biofuels, solvents and polymers.

A Good Idea but…

CCS is an excellent idea: if greenhouse gasses can be prevented from entering the atmosphere, we can continue traditional fossil fuel activities without worrying about the devastating effects of the changing climate.

The Global CCS Institute report quotes Lord Nicholas Stern, Bill Gates and other experts in the fields of climate, engineering and finance all emphasising the crucial role CCS has to play in addressing rising emissions.

There Are Some Key Problems However:

- Storage solutions can and do leak methane;

- The energy cost involved in the process materially reduces its net benefit; and,

- It doesn't make any economic sense, absent a whole-of-economy price on carbon emissions, supported by carbon border taxes (as proposed by the European Union).

What Can Go Wrong… and Does

Transportation and storage are two key areas of concern.

'Captured' carbon must be separated, transformed and, in most cases, transported to the sequestration site. The energy used in this process and the leakages that can occur during transportation and handling can materially reduce the net impact of the CCS process.[8]

Further, the underground storage into which the carbon is injected is not always secure. Wells have weaknesses and gaps. Fracking causes long-term subterranean instability, and seismic activity could dislodge even the most carefully stored carbon. Leaks in the Aliso Canyon natural gas storage facility in 2015 "released 97,100 metric tons of methane to the atmosphere,"[9] doubling the methane emission rate of the entire Los Angeles basin.

The underground storage into which carbon is injected is not always secure.

According to geologists, leaks should not be a practical concern for carbon dioxide (CO_2) storage if the CCS process is carefully implemented. However, further research concludes that the consequences of a minor leakage could reduce the benefit of CCS by up to 35%.[10]

The fossil gas industry has failed to systematically cap, sterilise and monitor abandoned gas wells over the last few decades, so methane leakage is massively underreported and largely ignored (thanks to regulatory capture and constant defunding of EPA departments). Further, the industry resists accepting liability for leakages.

The Economics of CCS Are Wrong

Whilst the technical issues of CCS can probably be addressed with engineering solutions over time, the more significant problem is a financial one.

CCS is an expensive process that generates very little revenue. Aside from limited pricing signals from emissions trading systems, there is no financial reason to invest in CCS. Consequently, there are no commercially viable examples of CCS anywhere in the world.

---

[9] Science. Methane emissions from the 2015 Aliso Canyon blowout in Los Angeles, CA. 18 March 2016.
[10] Frontiers in Energy Research. Bearing the Cost of Stored Carbon Leakage. 15 May 2018.

The traditional financial justification for doing CCS is for enhanced oil recovery (EOR). With oil prices currently well below breakeven for oils sands extraction, this does not begin to cover the costs of CCS.

With costs in the order of US$4,200 per kilowatt[11] for a power plant equipped with CCS, even if it works, CCS is a poor investment, multiples of the cost of new renewable energy even when the addition cost of firming is included.

There are no commercially viable examples of CCS anywhere in the world.

It is no surprise that the few operating CCS plants globally are government subsidised.

Playing With Someone Else's Money

Shell

Royal Dutch Shell promotes CCS as a key factor in its new, bold emission reductions strategy: to bring down its net carbon footprint of products by 50% by 2050. As a then new CEO in 2014, Ben van Beurden told the audience in a keynote speech at Columbia University that CCS could remove up to 90% of emissions from power generation. In 2015, Shell promised investment in CCS, coinciding with the opening of the Quest CCS facility in Canada. At every AGM since, van Beurden has returned to CCS as a key part of the solution.

To date, Shell has two CCS projects: Quest in Alberta, Canada, funded by the Albertan and Canadian governments and operated by Shell; and Gorgon in Western Australia, a project in which the project principals (Shell and Chevron) are financially motivated *not* to operate the CCS plant. The Gorgon plant has failed to meet its targets every year, notwithstanding a $60 million subsidy from the Western Australian government.

Shell's actual outlay in CCS over the years remains to be seen. Its overall investment in renewables is well behind its stated targets.[12] Any progress Shell demonstrates in removing carbon from the atmosphere using CCS (1m tonnes per annum at Quest and up to 4m tonnes at Gorgon) should be seen in light of Shell's total emissions of 656 million tonnes per annum (80Mt scope 1 and 2; 576Mt scope 3).[13]

Total SA

Total SA has also promised massive investment in CCS to remove up to 5 million tonnes of CO_2 per annum (8% of Total's scope 1 and 2 GHG emissions and 1% of

[11] EIA. PetroNova is one of two carbon capture and sequestration power plants in the world. 31 October 2017.
[12] NS Energy. "Royal Dutch Shell could be set to miss out on its green energy targets". 3 January 2020.
[13] Shell. Shell Sustainability Report 2019.

scope 1/2/3 emissions).[14]

Total SA is an investor in Equinor's Sleipner CO_2 storage as well as, with Shell and Equinor, the larger Nordic project under development, Northern Lights.[15]

Equinor

Equinor, the Norwegian state oil and gas producer, has been investing in CCS since 1996, mainly because Norway has had a carbon price since 1991. Its Sleipner CO2 storage and Snøhvit CO2 storage facilities have cumulatively captured and stored around 22 million tonnes of CO2. Compared to the rest of the fossil fuel industry, this is considerable achievement but this pales into insignificance when one considers that Equinor is responsible for over 330m tonnes of CO2-e emissions every year (scope 1, 2 and 3). With the carbon price, there is a modest economic return on its CCS operations but the impact on emissions is immaterial in the scheme of Equinor's contribution to global warming. By way of comparison, Equinor's scope 3 emissions increased by 26 million tonnes per annum from 2014 to 2018.[16]

Capturing Carbon at Power Stations Proves Fraught

CCS is more problematic in relation to power stations.

Boundary Dam in Saskatchewan, Canada and Petro Nova in Texas are the only power stations to implement a CCS retrofit that were completed in North America this past decade.

Boundary Dam, owned by the Saskatchewan utility, SaskPower, cost C$1.3bn to the retrofit, was years behind schedule, and operated at less than 50% capacity when it finally commenced.[17] Only one power unit has been retrofitted and SaskPower made a decision not to apply the technology to the other units.

Kemper was to be the shining example of 'clean' coal. The cost blew out to US$7.5bn, and the project was abandoned.

Petro Nova cost US$1bn, at approximately $4,200/KW, and captures 33% of emissions from one unit (654MW).[18] The carbon was intended to be supplied for enhanced oil recovery (EOR) but the price has fallen dramatically since the initial modelling was done and the project is a financial failure. It receives a $50/t subsidy

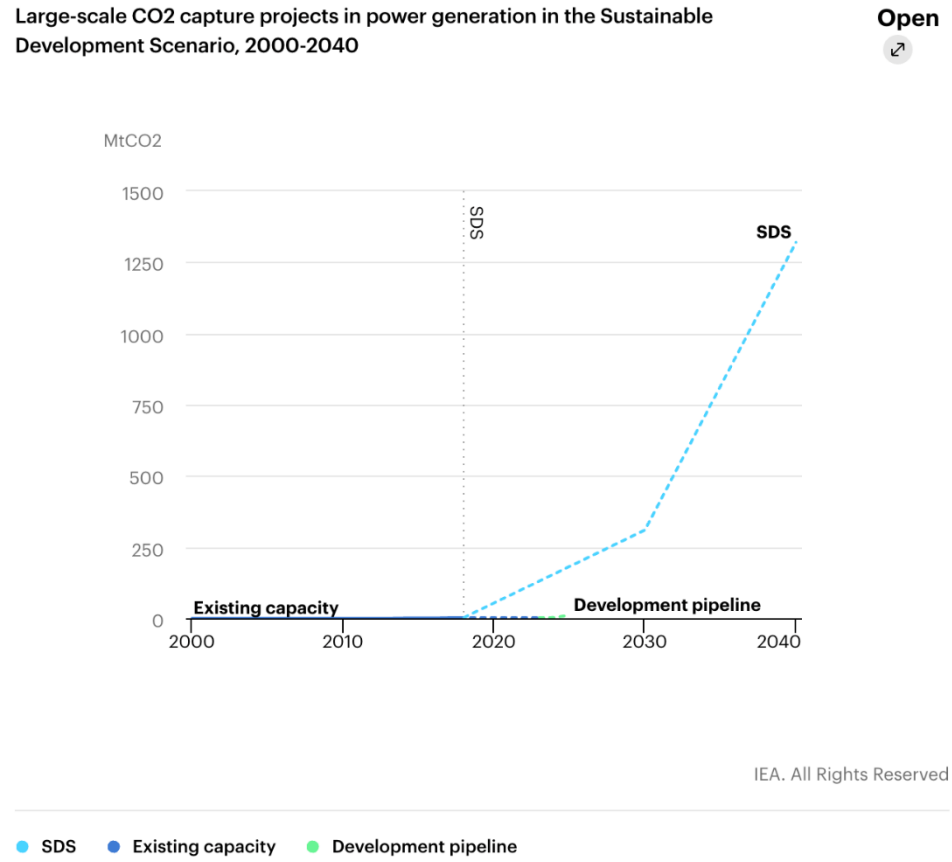
from the U.S. Government—effectively a carbon price—to keep it running at this minimal level.

Kemper was to be the shining example of 'clean' coal. A massive new coal-fired power station in Mississippi—possibly the largest project ever in the state—promised jobs and cheap, clean electricity. The $2.4bn estimated cost ($4,100/KW) blew out to US$7.5bn and the project was abandoned.[19]

There is no business case for gas CCS other than as a corporate social responsibility initiative, and there is no business case for coal CCS at all.

Conclusion



The IEA identifies CCS as mitigating up to 9% of GHG emissions by 2050 but notes:

> *"With only two large-scale CCUS power projects in operation at the end of 2018 and a combined capture capacity of 2.4 million tonnes of CO2 (MtCO2) per year, CCUS in power remains well off track to reach the 2030 Sustainable Development Scenario (SDS) level of 350 MtCO2 per year.*
>
> *As CCUS applied to power is at an early stage of commercialisation, securing investments will require complementary and targeted policy measures such as tax credits or grant funding. Support for innovation needs to target cost reductions and broaden the portfolio of CCUS technologies."*[20]

Figure 2 highlights the IEA's assessment of the huge gap between aspiration and reality in relation to power CCS.

[19] EIA. Petron ova is one of two carbon capture and sequestration power plants in the world. 31 October 2017.
[20] IEA. Tracking Power 2019.

Figure 2: IEA Highlights the Gap Between CCS Ambition and Reality

Source: IEA.

If the Australian Government wishes to encourage the development of CCS in Australia, in both gas and power, a carbon price would be a much better policy than the subsidisation of uneconomic CCS project proposals.

Confronting the Myth of Carbon-Free Fossil Fuels

Why Carbon Capture Is Not a Climate Solution

The world is confronting a climate emergency. Avoiding climate catastrophe requires immediate and dramatic reductions in greenhouse gas (GHG) emissions that are possible only with a significant investment of public resources in proven mitigation measures, beginning with eliminating fossil fuel use and halting deforestation. Carbon capture and storage (CCS) and carbon capture, utilization, and storage (CCUS) will not address these core drivers of the climate crisis or meaningfully reduce GHG emissions, and should not distract from real climate solutions.

CCS and CCUS technologies are not only *unnecessary* for the rapid transformation required to keep warming under 1.5°C, they *delay* that transformation, providing the fossil fuel industry with a license to continue polluting. This brief argues that carbon capture technologies:

- Do not remove carbon from the atmosphere, and in fact worsen the climate crisis when used to boost oil production.
- Have not been proven feasible or economic at scale and can only contain a fraction of source emissions.
- Prolong dependence on fossil fuels and delay their replacement with renewable alternatives.
- Create environmental, health, and safety risks for communities saddled with CCS infrastructure, such as pipelines and underground storage.

CCS Isn't Carbon Negative, or Even Carbon Neutral

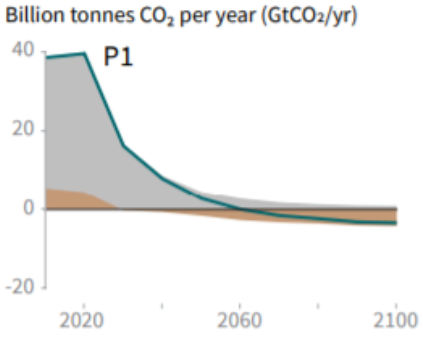
CCS and CCUS refer to processes that collect or "capture" carbon dioxide generated by high-emitting activities — such as coal- and gas-fired power production or plastics manufacturing — and then transport those captured emissions to sites where they are either used for industrial processes or stored underground.[1]

CCS does not *remove* carbon from the atmosphere, although it is often erroneously conflated with "CO_2 removal" or "negative emission" technology. At best, CCS prevents some emissions caused by the combustion of carbon-based fuels from reaching the atmosphere — provided that the captured gases are not later released.

In practice, however, CCS masks the harmful carbon emissions from the underlying source, enabling that source to continue operating rather than being replaced altogether, while creating additional risks, impacts, and costs associated with the CCS infrastructure itself. Moreover, the injection of captured carbon into oil wells to enhance oil recovery — the most pervasive use of CCS today — exacerbates global warming by boosting oil production and prolonging the fossil fuel era.[2]

Large-Scale CCS is Neither Viable Nor Necessary

The unproven scalability of CCS technologies and their prohibitive costs mean they cannot play any significant role in the rapid reduction of global emissions necessary to limit warming to 1.5°C. Despite the existence of the technology for decades and billions of dollars in government subsidies to date, deployment of CCS at scale still faces insurmountable challenges of feasibility, effectiveness, and expense.



Existing CCS facilities capture less than 1 percent of global carbon emissions. The 28 CCS facilities currently operating globally have a capacity to capture only 0.1 percent of fossil fuel emissions, or 37 megatons of CO_2 annually. Of that capacity, just 19 percent, or 7 megatons, is being captured for actual geological sequestration.[3] The vast majority, as discussed ahead, is being used to produce more oil.

CCS pilot projects have repeatedly overpromised and underdelivered. The Petra Nova carbon capture facility installed at a coal-fired power station near Houston, Texas, in 2017 illustrates the failure of CCS to deliver meaningful emissions reductions and the folly of deploying CCS in service of fossil fuel extraction and use.

During its operation, the CCS system only captured 7 percent of the power plant's total CO_2 emissions, well below the company's promises to reduce CO_2 emissions by 90 percent.[4] The captured carbon from Petra Nova had been used for enhanced oil recovery, but the 2020 collapse in oil price and demand rendered this uneconomic. The CCS operation and the gas plant used to power it have been shut down indefinitely, leaving the coal-fired plant as emissions-intensive as ever.[5]

The surest approach to avoiding climate catastrophe does not involve CCS. According to the Intergovernmental Panel on Climate Change (IPCC), the emissions reduction pathway with the best chance of keeping warming at or below 1.5°C makes *limited to no* use of engineered carbon capture technologies. This pathway involves a rapid phaseout of fossil fuels along with limited carbon removal by *natural sources* such as reforestation

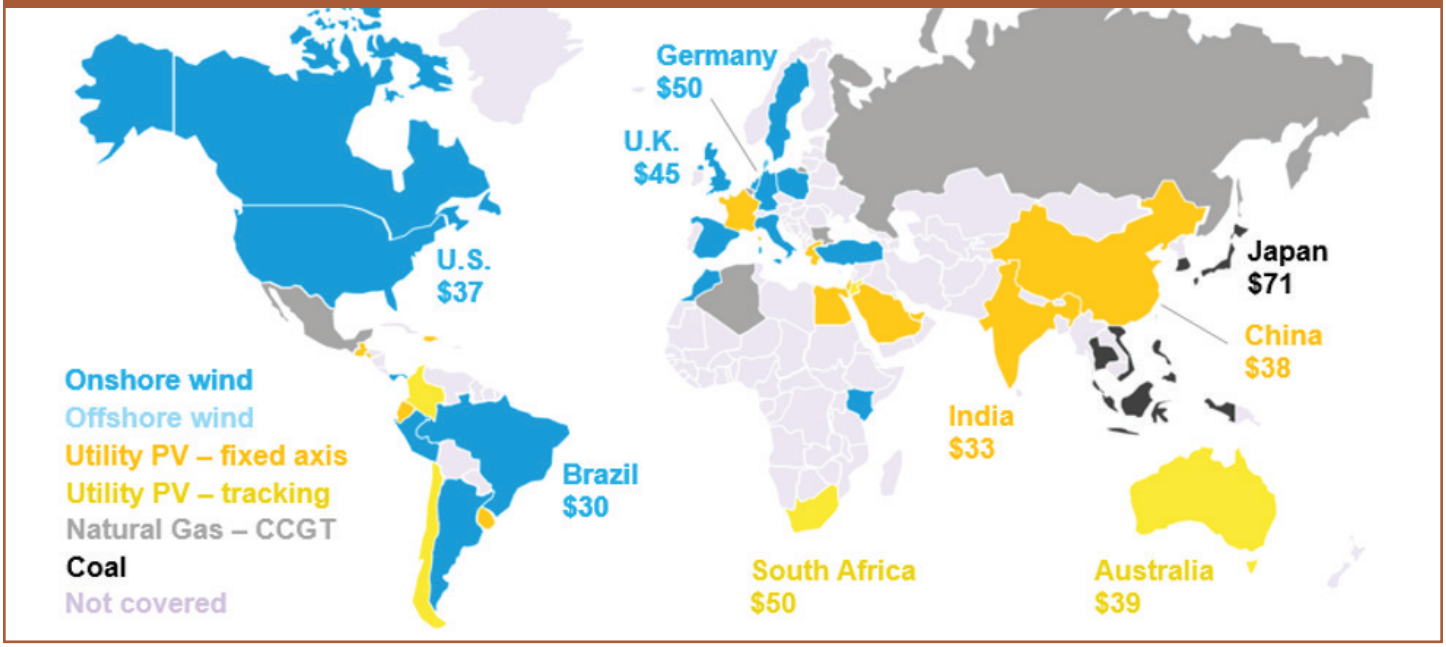
FIGURE 1
IPCC 1.5°C Pathway 1

P1: A scenario in which social, business, and technological innovations result in lower energy demand up to 2050 while living standards rise, especially in the global South. A down-sized energy system enables rapid decarbonisation of energy supply. Afforestation is the only CDR option considered; neither fossil fuels with CCS nor BECCS are used.

Graphic Source: IPCC

and enhanced soil carbon uptake.[6] The IPCC points to "uncertainty in the future deployment of CCS,"[7] and cautions against reliance on the technology, given "concerns about storage safety and cost"[8] and the "non-negligible risk of carbon dioxide leakage from geological storage and the carbon dioxide transport infrastructure."[9]

In January 2021, the 1,500 member-organizations of Climate Action Network (CAN) International adopted a shared position statement that the largest network of climate organizations worldwide "does not consider currently envisioned CCS applications as proven sustainable climate solutions." The organizations warned that CCS "risks distracting from the need to take concerted action across multiple sectors in the near-term to dramatically reduce emissions." Accordingly, CAN urged that "[a]ll government subsidies, loans, grants, tax credit, incentives, and financial support for fossil fuels and technologies that use or otherwise support the continued use of fossil fuels, including CCS, should be phased out as soon as possible."[10]



A 1.5°C pathway is possible without CCS. By transitioning the transportation, industry, and building sectors to 100 percent clean, renewable energy through rapid electrification and phase out of fossil fuels, and enhancing natural carbon sequestration through improved land management and restoration, it is possible to keep warming at or below 1.5° C *without* CCS.[11]

Clean energy is also cheaper energy. Plummeting renewable energy costs are rapidly making electrification with clean sources like solar and wind less expensive than producing power with fossil fuels.[12] A 2020 analysis by Bloomberg New Energy Finance found that solar and wind are already the cheapest energy sources for two-thirds of the world's population. Rapidly declining costs make renewable energy cheaper than continuing to operate existing coal and gas facilities in many places.[13]

Similarly, plummeting costs are quickly making battery storage a cheaper option for ensuring grid reliability than new gas peaker plants.[14] The US Energy Information Administration (EIA) projects that renewables will account for 71 percent of new US electricity generating capacity in 2021.[15]

The failure to account for the energy transition's market and technological disruptions to coal- and gas-fired power plants means not only that they are outcompeted

by alternatives and systematically overvalued,[16] but also that "the overwhelming majority of these conventional facilities will become financially unviable and their assets stranded over the next decade or so."[17] Tacking CCS onto these soon-to-be stranded power plants is as economically ill-founded as it is environmentally unsound.

From a purely economic perspective, CCS does not make sense. Economists and energy analysts note that CCS projects are "prohibitively expensive compared to other GHG emissions mitigation options, such as renewable energy and energy storage technologies."[18] Adding CCS onto a fossil-fueled power plant inevitably makes operating the underlying source more expensive. As the authors of the energy transition study summarized above observed, "Coal and gas power plants with integrated carbon capture and storage (CCS) are doubly mispriced (overvalued)."[19] With coal- and gas-fired power stations already becoming more costly than renewable alternatives, adding CCS simply makes them even less economic and even less necessary.

A recent assessment of the economic viability of using CCS with gas-fired power plants demonstrates this reality, noting that mature carbon capture technologies are poorly suited to gas and pose an even larger energy penalty for fossil gas than for coal.[20] For a new-build gas-fired plant, CCS could more than double the construction costs and increase the cost of energy produced (known as levelized cost of energy) by up to 61 percent.[21]

As a result, CCS is not economic for gas-fired power plants even when it takes full advantage of existing federal subsidies, as discussed below, and when the captured carbon is used to produce more oil.[22] The authors of the study proposed a solution of injecting even more federal funding into CCS.

The simpler, surer, and cheaper solution is to end this and similar subsidies for the fossil fuel economy and invest the savings in accelerating the transition to clean energy.

Even for the Hard-to-Decarbonize Industrial Sector, CCS Is Not the Answer

The industrial sector accounted for 27 percent of US GHG emissions in 2019.[23] As the rationale for wide CCS deployment in the energy sector rapidly fades, CCS proponents are increasingly arguing that CCS will be needed to reduce emissions in heavy-emitting industries like steel, cement, petrochemicals, and aluminum. While the challenges to decarbonizing these industries are real, the potential for CCS to contribute to major emission reductions is routinely and often dramatically overstated. All too frequently, the advocacy for industrial CCS overlooks or downplays considerations like cost, alternatives to fossil fuel inputs, and the risks posed by transporting and storing captured carbon underground.

Applying CCS to high-emitting industrial activities, like petrochemical, steel, or cement manufacturing, is not economical. GHG emissions from these industries come from a diverse array of sources, including electricity consumption, on-site fossil fuel combustion, and process emissions, which make installing and operating CCS even more complex and generally more costly than it is in the power sector.

A recent analysis co-authored by a Chevron researcher highlights how these costs and complexities weaken the case for significant CCS deployment in the industrial sector. Beginning with a candidate pool of more than 1,500 US industrial facilities identified by the Environmental Protection Agency, the researchers immediately eliminated nearly 700 facilities, accounting for roughly half of all US industrial emissions, because the industries involved — including oil, gas, and coal production — "are not suitable for carbon capture retrofit."[24] By contrast, a transition away from fossil fuels would dramatically curtail such emissions.

From the remaining 656 facilities, the researchers identified only 123 facilities, less than 10 percent of the 1,500 facilities in the initial pool, that could capture carbon economically, even with full use of available federal subsidies and enhanced oil recovery.[25] And among that handful of facilities, many major sources of GHG emissions could not be captured.

For example, the petroleum refining industry is the largest source of industrial emissions other than fossil fuel production itself, yet less than 19 percent of refinery emissions were amenable to carbon capture. For metals processing, including steel, only a quarter of process emissions were amenable to CCS.[26] In total, the researchers identified only 68.5 metric tons of CO_2 per year from industrial process emissions that could be economically captured,[27] representing just 8 percent of all industrial emissions in the US.

Even this figure significantly overstates the potential of CCS in the industrial sector because the analysis excluded the indirect energy inputs that account for the largest single component of industrial sector emissions.[28] The authors did so on the grounds that the energy provided comes from the electrical grid, meaning associated emissions can be reduced more directly through other means, such as renewable energy.

Renewable sources for electricity and heat can dramatically reduce industrial emissions. Most industrial sector emissions are created by burning fossil fuels to produce the electricity and heat that power

FIGURE 3
Breakdown of the Number of Facilities and Their Emissions by Industrial Sector, Type of Emissions, and CO_2 Capture Potential

	refining[a]	chemicals	bioethanol	metals	minerals	pulp & paper	total
All Facilities in the Continuous U.S. Non-Suppliers of CO_2							
number of facilities	123	360	174	289	369	214	**1529**
total emissions [$MtCO_2$-eq/yr]	163	138	60	93	114	38	**606**

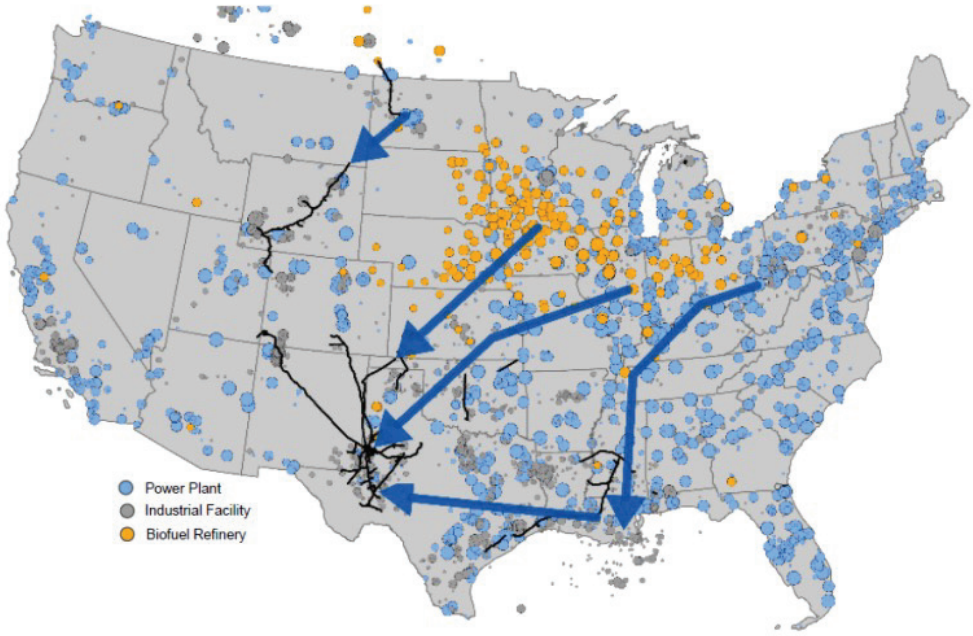
manufacturing processes. Thus, decarbonizing the electricity grid by shifting to renewable sources provides the most direct route to slashing emissions in these industries. For example, the World Economic Forum estimates that 60 percent of carbon emissions from electricity-intensive aluminum production could be eliminated simply by producing that electricity from renewable sources.[29] In March 2021, a report by the International Aluminum Institute agreed that decarbonizing electricity grids provides the surest, most direct, and likely most cost-effective pathway to significant emission reductions in this energy-intensive industry.[30]

As currently equipped, the industrial sector uses fossil fuels not only for electricity, but for the heat that fuels industrial processes. Fossil fuel combustion for that heat accounts for about 58 percent of US industrial emissions and about 10 percent of overall global GHG emissions.[31] Electricity from clean power sources like solar and wind has the potential to provide low-carbon heat to many industrial systems.[32]

Concentrated solar thermal systems, for example, use solar energy for generating heat. One company has demonstrated this system works for reaching temperatures of more than 1,000°C.[33] From the heat used in kilns during the process of making cement,[34] to the high energy demand from electricity that goes into producing aluminum,[35] clean sources of electricity could displace fossil fuels consumed in a growing array of industrial processes, dramatically curtailing the largest single source of industrial GHG emissions and, with it, the purported benefits of CCS deployment in those industries.



CCS obscures the role of reduction, reuse, and recycling in lowering industrial emissions. Proponents of industrial CCS routinely ignore that one of the most effective ways to reduce industrial emissions from high-emitting sectors like steel, aluminum, and plastics is to reuse existing materials, increase recycling rates, and produce less of the virgin material that is the major driver of emissions. This contrast is particularly notable in the case of plastics and petrochemicals, where the fracking boom of the last decade has driven a massive buildout of new plastics infrastructure even as communities around the world recognize that we need to reduce, not increase, our production and use of disposable plastics.

Even for aluminum, which is already heavily recycled, increasing the recycling of scrap metal could avoid 200 million tons of GHG emissions per year.[36] Replacing virgin steel with increased use of scrap metal or direct reduced iron also has high potential to reduce emissions from steel production — potential that should be tapped, given that CCS technology for steel remains immature and economically unproven, according to industry analysis.[37]

Applying CCS to industrial sources requires massive infrastructure buildout. Even assuming carbon can be captured effectively and economically from an industrial process, that does not assure it can be safely sequestered. The geographic distribution of CO_2 storage sites is a limiting factor for CCS deployment in industry.[38] The overwhelming majority of industrial facilities including those in high-emitting industries like cement, steel, and aluminum, were sited to ensure access to critical

FIGURE 4

Map of CO_2-Emitting Facilities Compared to Viable Geological Storage Sites

Elizabeth Abramson, Regional Carbon Capture and Transport Opportunities for Storage in Louisiana. Presentation to "Developing CCUS Projects in Louisiana and the Gulf Coast" (USDOE/USEA/GCCSI) November 17, 2020. *https://www.globalccsinstitute.com/wp-content/uploads/2020/11/PPT-LA_Day-1-and-Day-2.pdf* at slide 42.

resources like steam, electricity, water, and end markets, not carbon storage.

Accordingly, only a small fraction of existing or proposed facilities in these sectors are located in areas suitable for CO_2 storage. Storing carbon captured from such facilities would demand a vast network of new pipelines, some running hundreds of miles, and carrying hazardous CO_2 through populated areas.

Transporting carbon to storage sites and injecting it underground involves further risks and costs. As discussed more fully below, this reality means that the growing risks of carbon capture will be borne disproportionately by the few communities already living near concentrations of both heavy industry and potential storage or injection sites.

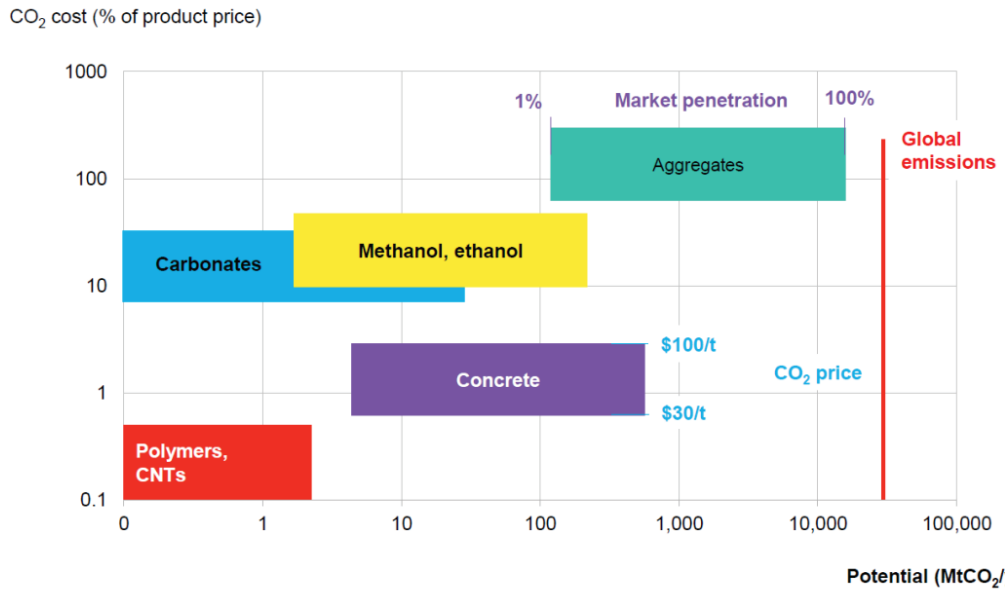
CCS Perpetuates Fossil Fuel Systems and Impacts

By design, CCS enables an underlying emissions-generating activity to continue — by capturing some of the CO_2 it would otherwise emit. The promise of CCS is being used to rationalize — and subsidize — continued investment in fossil fuel infrastructure that would lock in emissions of CO_2 and other pollutants for decades to come.

Even in its idealized form, CCS only prevents a fraction of emissions from the underlying source. At every stage of their lifecycle, including extraction, refining, transport, use, and disposal, fossil fuels release a wide array of pollutants, many of which pose known or suspected hazards to humans and the environment. For example, a study released in February 2021 by Harvard University and University College London researchers found that fine particulate matter (PM2.5) from burning fossil fuels is responsible for millions of deaths worldwide. In 2018, approximately one in five deaths overall, or 8.7 million premature deaths, were linked to PM2.5 pollution from fossil fuels.[39]

CCS does nothing to address these hazards.[40] Indeed, by requiring greater use of fossil fuels to power the CCS process itself, CCS may actually exacerbate them. In the energy sector, there is compelling evidence that the negative climate, environmental, and health impacts of adding carbon capture to fossil fuels are substantially

greater than simply replacing fossil fuels altogether with clean alternatives.[41] As discussed more fully above, the deployment of industrial CCS raises similar concerns.



Using captured carbon to produce still more fossil fuels accelerates the climate crisis. At present, carbon capture is not economically viable without enhanced oil recovery or the production of combustible fuels, making the technology inseparable from the fossil economy. Enhanced oil recovery (EOR) is a technique through which CO_2 — either from natural sources or captured carbon — is injected into underground oil reservoirs to boost oil and gas production from old wells. In essence, CO_2 waste products from a fossil fuel-burning activity are used to generate more fossil fuels, propping up the unsustainable fossil fuel energy system.

More than 80 percent of all CCS capacity deployed to date has been used for EOR.[42] And the majority of CCS projects in active development also incorporate EOR. The US Department of Energy estimates this could result in up to 48 billion additional barrels of oil used in the US alone by 2030.[43] This is disastrous from a climate mitigation perspective, since it will result in more oil extracted and more carbon emissions from the oil burned. The emissions impact from burning oil produced with CO_2 + EOR is currently excluded from lifecycle analyses touting the technology.[44] While the resulting CO_2 emissions may be invisible to carbon accountants, their presence in the atmosphere and their impact on the climate remains real and significant.

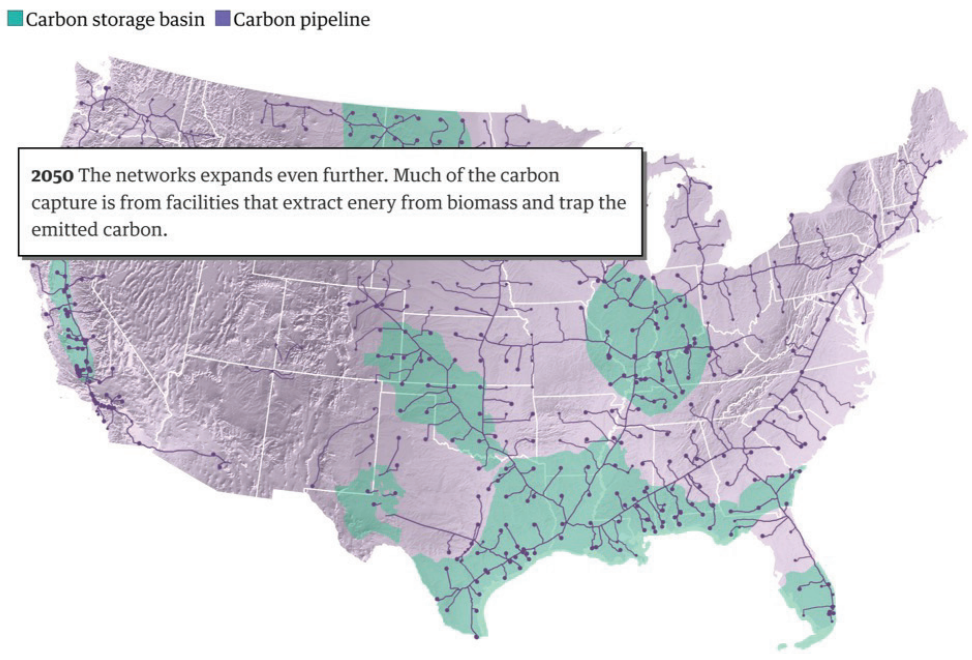
Proponents of CCUS argue that "[t]he most efficient strategy to reduce the concentration of CO_2 in the atmosphere is to convert it to useful chemicals and fuels."[45] But such proposals confront a fundamental challenge: global emissions of CO_2 are orders of magnitude greater than global demand for CO_2 in products. In 2018, the world emitted more than 37 billion tons of CO_2 and other GHGs from fossil fuel combustion for energy and industry.[46] By contrast, it used just 230 million tons of CO_2 for commercial purposes — equal to just 0.5 percent of total annual emissions. Two uses alone — EOR and fertilizer production — account for more than 85 percent of all CO_2 consumed globally.[47] All other commercial and industrial uses combined account for just 20 million tons of CO_2 each year, a mere drop in the bucket.

The touted uses of CO_2 are also unviable. Using captured carbon to produce combustible fuels, including via EOR, defeats any climate mitigation purpose, as the fuels release the carbon back into the atmosphere. Transforming CO_2 into chemicals requires massive

FIGURE 5
CO_2 Utilization Markets and Sensitivity to CO_2 Prices

BNEF Executive Factbook 2021 at 56: https://assets.bbhub.io/professional/sites/24/BNEF-2021-Executive-Factbook.pdf

amounts of energy, which is why only a handful of commercialized chemicals use CO_2 in significant quantities.[48] Technologies for embedding captured carbon in plastics, for example, are currently confined to laboratory environments, and neither technologically nor economically proven at scale.[49] Just as importantly, using captured carbon to increase production of plastics — which are themselves made from fossil fuels — would compound the plastics crisis while doing little to address the climate crisis.[50] Proposals to store captured carbon in concrete are no more promising. Storing 1 pound of CO_2 requires 100 times its weight in concrete when embedded in cement mix and over 1,000 times its weight when embedded in standard concrete blocks.[51] Embedding coal combustion wastes or industrial slag in concrete does not eliminate smokestack emissions and increases risks of toxic leaching from the treated materials.[52] Just as using captured carbon to produce more oil increases emissions, embedding industrial wastes into new products does nothing to curb emissions from the activity that generated the waste.



CCS subsidies end up in oil industry pockets. The tax credit for CCS projects (under Section 45Q of the US Internal Revenue Code, which Congress extended in December 2020) is the main federal policy support for CCS. Its biggest beneficiaries are oil companies that claim the credit for injecting carbon into underground oil deposits to produce more oil, through EOR.[53] The tax credit thus functions as a fossil fuel subsidy.[54]

Moreover, the lack of adequate monitoring of CCS activities means claimed credits may be based on little more than hot air, not on stored carbon.[55] For example, an investigation by the US Treasury's Inspector General for Tax Administration found that fossil fuel companies improperly claimed nearly $900 million in tax credits under Section 45Q.[56]

The push for carbon capture and storage primarily benefits the fossil fuel industry. The most vocal and active proponents of CCS are oil and gas, petrochemical, and utility companies. They tout the necessity and promise of carbon capture to protect a business model that is contributing to climate catastrophe.[57]

In addition to investing directly in carbon capture ventures, companies in the fossil fuel industry promote

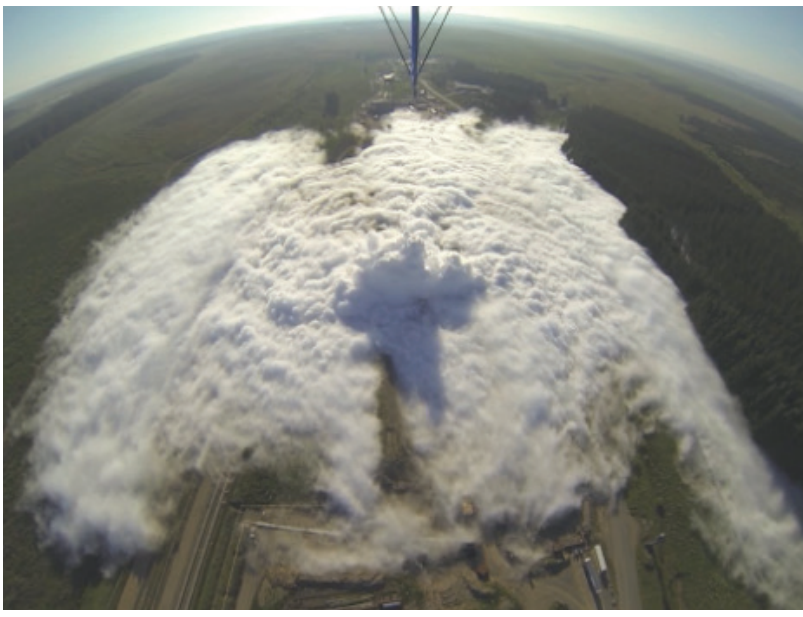
Oliver Milman, Alvin Chang & Rashida Kamal, The race to Zero: can America reach net-zero emissions by 2050. The Guardian (March 15, 2021). https://www.theguardian.com/us-news/2021/mar/15/race-to-zero-america-emissions-climate-crisis

CCS advocacy, research, and policy through an array of corporate consortia, industry-government working groups, and funding partnerships with universities. For example, the Global CCS Institute, an international think tank dedicated to accelerating CCS deployment, includes various coal, oil and gas, and energy and utility companies as members, and a handful of national and sub-national governments.[58] Corporate polluters benefit from promoting CCS, while the environmental and community impacts of scaling up the CCS industry are too often ignored.

CCS Poses a Growing and Poorly Understood Threat to Communities & the Environment

Scaling up the technology and infrastructure required to capture, compress, transport, and store CO_2 entails significant risks.[59] Whether paired with fossil fuel power plants or industrial manufacturing, CCS technology demands massive infrastructure buildout. In terms of scale, it is estimated the CCS industry and associated infrastructure would need to be two to four times larger by 2050 than the current global oil industry.[60] As the IPCC has noted, extensive deployment of CCS "will require a large network of pipelines."[61] To date, the heavy environmental footprint and safety and health hazards[62] associated with CCS infrastructure have been largely overlooked.[63]

The transportation of compressed CO_2 raises a host of health and safety concerns. Especially when moved over long distances and/or through heavily populated areas, piping CO_2 poses risks similar to those associated with fossil fuel pipelines, from land disturbance and water contamination to the danger of explosions and other accidents. These risks are rarely disclosed or discussed in public discussion of CCS.



Effective transport through pipelines requires that CO_2 be shipped at very high pressure and extremely low temperatures, demanding pipelines capable of withstanding those conditions. The presence of moisture or contaminants can make this condensed CO_2 corrosive to the steel in those pipelines, increasing the risk of leaks, ruptures, and potentially catastrophic running fractures.

Because of the intense pressures involved, explosive decompression of a CO_2 pipeline releases more gas, more quickly, than an equivalent explosion in a gas pipeline.[64] Video recordings of pipeline failure tests under controlled conditions demonstrate that even a modest rupture can spread freezing CO_2 over a wide area within seconds.[65] The emergence of a running pipeline rupture could extend impacts the entire length of a pipeline segment.[66]

As a paper published by the Institution of Chemical Engineers Symposium cautions: "The combination of the massive amount of CO_2 released in a relatively short period of time, the resulting dense cloud followed by solid discharge and its slow sublimation will pose a major challenge to safety practitioners when dealing with the hazards associated with the failure of pressurized CO_2 pipelines."[67]

The IPCC recognizes that "carbon dioxide leaking from a pipeline forms a potential physiological hazard for humans and animals."[68] These risks take several forms.

The explosive rupture of a pipeline and its associated shockwave pose immediate physical risks to nearby people and property. In areas closest to the pipeline, a release of CO_2 can quickly drop temperatures to minus 60°C, coating the surrounding area with super-cold dry ice.[69] At high concentrations, CO_2 is a toxic gas and an

CO_2 cloud from a rupture test performed at DNV GL Spadeadam, Photo: DNV GL

Photo Credit: Mississippi Emergency Management Agency

asphyxiant capable of causing "rapid 'circulatory insufficiency', coma and death."[70] And potential contaminants in CO_2 streams, such as hydrogen sulfide (H_2S) can dramatically compound these risks.[71]

Accidents are inevitable as CO_2 pipelines are increasingly built in populated areas. In February 2020, a 24-inch high-pressure pipeline containing carbon dioxide and sulfur dioxide ruptured in Yazoo County, Mississippi. According to the Mississippi Emergency Management Agency, more than 300 residents were evacuated and[46] dozens were hospitalized.[72] The pipeline owner, Denbury Enterprises, operates hundreds of miles of CO_2 pipelines in the Gulf Coast and Rocky Mountain regions. At least two Denbury pipelines run through the heavily polluted petrochemical corridor known as Cancer Alley,[73] predominately populated by communities of color.

These safety hazards and environmental risks fall disproportionately on marginalized communities. Fossil fuel and petrochemical infrastructure, and the threats to health and public safety that infrastructure creates, already overburden Black, Brown, and Indigenous communities. The deployment of CCS threatens to significantly increase these risks, particularly in the regions being most heavily targeted for new CCS buildouts.

Both the Gulf Coast of Texas and Cancer Alley in southern Louisiana have been widely touted as potential epicenters for industrial CCS development due to existing concentrations of oil, gas, and petrochemical infrastructure, along with oil fields and salt domes that are the most viable injection and storage sites.[74] CCS proposals in other regions also focus on areas where energy and industrial infrastructure are concentrated, which are typically in or adjacent to poor neighborhoods and communities of color. The expansion of CCS would add a significant new source of pollution and safety risks in Black, Brown, and Indigenous communities already suffering the disproportionate and deadly impacts of environmental racism.

Conclusion

CCS and CCUS are not only unnecessary, ineffective, uneconomic, and unsafe; the technologies are also exceptionally risky, prop up the fossil fuel industry and carbon-intensive industrial activities, and distract from the urgent task of transitioning away from fossil fuels at a time when the US and the world must dramatically accelerate that transition. These technologies, and the dangerous myth they perpetuate of climate-safe fossil fuels, have no place in US climate policies and financing. Such policies should focus instead on phasing out fossil fuels and implementing proven climate mitigation strategies on an urgent, comprehensive basis, reflecting their fundamental importance for this and all future generations.

In conclusion, pure H^- conduction was realized in the $La_{2-x-y}Sr_{x+y}LiH_{1-x+y}O_{3-y}$ system. The present success in the construction of an all-solid-state electrochemical cell exhibiting H^- diffusion confirms not only the capability of the oxyhydride to act as an H^- solid electrolyte but also the possibility of developing electrochemical solid devices based on H^- conduction.

GAS INFRASTRUCTURE

Methane emissions from the 2015 Aliso Canyon blowout in Los Angeles, CA

S. Conley,[1,2]*† G. Franco,[3] I. Faloona,[2] D. R. Blake,[4] J. Peischl,[5,6] T. B. Ryerson[6]†

Single-point failures of natural gas infrastructure can hamper methane emission control strategies designed to mitigate climate change. The 23 October 2015 blowout of a well connected to the Aliso Canyon underground storage facility in California resulted in a massive release of natural gas. Analysis of methane and ethane data from dozens of plume transects, collected during 13 research-aircraft flights between 7 November 2015 and 13 February 2016, shows atmospheric leak rates of up to 60 metric tons of methane and 4.5 metric tons of ethane per hour. At its peak, this blowout effectively doubled the methane emission rate of the entire Los Angeles basin and, in total, released 97,100 metric tons of methane to the atmosphere.

Large volumes of processed natural gas are stored underground to accommodate variability in energy demand on diurnal to seasonal time scales. Underground storage facilities constitute strategic gas reserves in many countries worldwide, with a volume equal to 10% of global annual consumption (*1*). Roughly 86% of stockpiled natural gas in the United States is stored at high pressure in depleted subsurface oil reservoirs (*2*). The Aliso Canyon storage facility, a depleted subsurface oil reservoir in the San Fernando Valley 40 km northwest of Los Angeles, CA, has a total capacity of 168 billion standard cubic feet (SCF) (4.79×10^9 m^3) at standard temperature and pressure, of which only 86 billion SCF (2.5×10^9 m^3; the "working capacity") is routinely accessed for commercial use (*2*). It is the fourth largest facility of its kind in the United States, accounting for 2.1% of the total U.S. natural gas storage in 2014 (*2*). Processed natural gas is composed primarily of methane (CH_4), a powerful greenhouse gas, and ethane (C_2H_6), both of which can lead to background tropospheric ozone production; at sufficiently high concentrations, natural gas leaks pose an explosion hazard and, if inhaled, can induce nausea, headaches, and impaired coordination. Exposure to odorants that are added to natural gas, which are typically sulfur-containing compounds such as tetrahydrothiophene [$(CH_2)_4S$] and 2-methylpropane-2-thiol [*t*-butyl mercaptan; $(CH_3)_3CSH$] can cause short-term loss of the sense of smell, headaches, and respiratory tract irritation. Major natural gas leaks therefore can have adverse impacts on climate, air quality, and human health.

On 23 October 2015, a major natural gas leak of indeterminate size was reported in the Aliso Canyon area and was later identified as originating from SS-25, one of 115 wells connected to the subsurface storage reservoir. The SS-25 well began oil production in 1954 and was converted to a gas storage well in 1973 (*3*). Seven unsuccessful attempts to close the leak have been reported. A relief well intercepted the leaking pipe at a depth of ~2600 m, below the subsurface breach; heavy fluid injection (a "bottom kill") temporarily halted the leak on 11 February 2016, and cement injection sealed the well on 18 February 2016 (*4*).

We deployed a chemically instrumented Mooney aircraft in 13 flights from 7 November 2015 to 13 February 2016. We measured CH_4 and C_2H_6 to quantify the atmospheric leak rate and to assess air quality downwind of the leaking well (*5*). Ground-based whole-air sampling (WAS) with stainless steel canisters on 23 December 2015, followed by laboratory analysis, provided information on the chemical speciation of the leaking hydrocarbon mixture. We used the continuous airborne data and the ground-based WAS canister

data to fingerprint the plume's chemical composition, quantify the atmospheric leak rate, and document trends in the leak rate over time.

The airborne chemical data showed the continuing transport on northerly winds of exceptionally high concentrations of CH_4 and C_2H_6 into the densely populated San Fernando Valley, a few kilometers south of the leaking well (Fig. 1). The plume C_2H_6-to-CH_4 enhancement ratio (ER) derived from linear least-squares regression fits to the 23 December 2015 continuous airborne data is identical, within total uncertainties propagated by quadrature addition of errors (*6*), to the plume ER derived from WAS canister data taken at the surface on the same day (Fig. 2A).

The hydrocarbon composition of WAS canister samples taken at surface locations in the San Fernando Valley (Fig. 1) on 23 December 2015 (*5*) is consistent with a leak of pipeline-quality processed natural gas with a hydrocarbon composition of ~95% CH_4, ~4% C_2H_6, and ~0.3% propane (C_3H_8) (table S1). Plume enhancements of natural gas liquids (ethane, propane, and butanes) and condensates (pentanes and longer-chain hydrocarbons that are liquid at ambient temperature and pressure) were detected (table S1) and were probably responsible for reports of oily deposits on surfaces in downwind residential areas. Trace enhancements of benzene, toluene, ethylbenzene, and xylene isomers (the so-called BTEX compounds) were also detected at ratios of 0.001% or lower relative to CH_4 (table S1).

Benzene is a known human carcinogen (*7*); thus, population exposure to benzene from the Aliso Canyon leak has received particular attention. Composition data from the WAS canisters indicate a benzene-to-CH_4 enhancement ratio of $(5.2 \pm 0.1) \times 10^{-6}$ (uncertainties throughout are ±1 SEM), which is broadly consistent with an ER of ~7×10^{-6} found in highly concentrated samples that were collected ~3 m downwind of the SS-25 well site (*8*). Together, these samples suggest minimal variation over time in the benzene composition of the leaking gas. Publicly available benzene data, reported in near-daily 12-hour air samples (*9*), were often below the detection limit of 1 nmol/mol [or 1 part per billion (ppb)] of the contract laboratories used for the analyses, but these data also show a relatively constant ER over time. Plume benzene enhancements can be estimated from the abundant CH_4 data by multiplying plume CH_4 enhancements by the benzene-to-CH_4 ER determined using the research-grade WAS canister samples. Sulfur-containing odorants were not measured, but concentrations above the odor threshold can be estimated similarly (Fig. 1) from observed CH_4 enhancements by assuming an industry-standard value of ~5 parts per million (ppm) of total odorant in processed natural gas (*10*).

Continuous airborne CH_4 and C_2H_6 data were taken on each flight between 11 AM and 3:30 PM (local time) with a resolution of 30 m along-track during repeated crosswind transects at multiple altitudes from 60 to 1400 m above ground. These data define the horizontal and vertical extent of the leaking natural gas plume on each flight (Fig. 1 and fig. S1). The flights provided highly spatially resolved data from which an atmospheric mass flux can be accurately calculated (*11*) within well-defined uncertainties (*12*). Plumes from nearby landfills have low concentrations of CH_4, are easily identified by their lack of co-emitted C_2H_6, and were eliminated from further analysis. Background levels of CH_4 and C_2H_6 were measured during aircraft transects on multiple flights immediately upwind, confirming the SS-25 well as the dominant source of enhanced natural gas to the region. Operational restrictions on aircraft flight patterns were imposed by the elevated terrain at the leak site, the highly controlled airspace of the San Fernando Valley, and the proximity to approach corridors of the nearby Van Nuys Airport (Fig. 1). These restrictions were overcome by performing crosswind transects at multiple altitudes immediately downwind of the leak site,

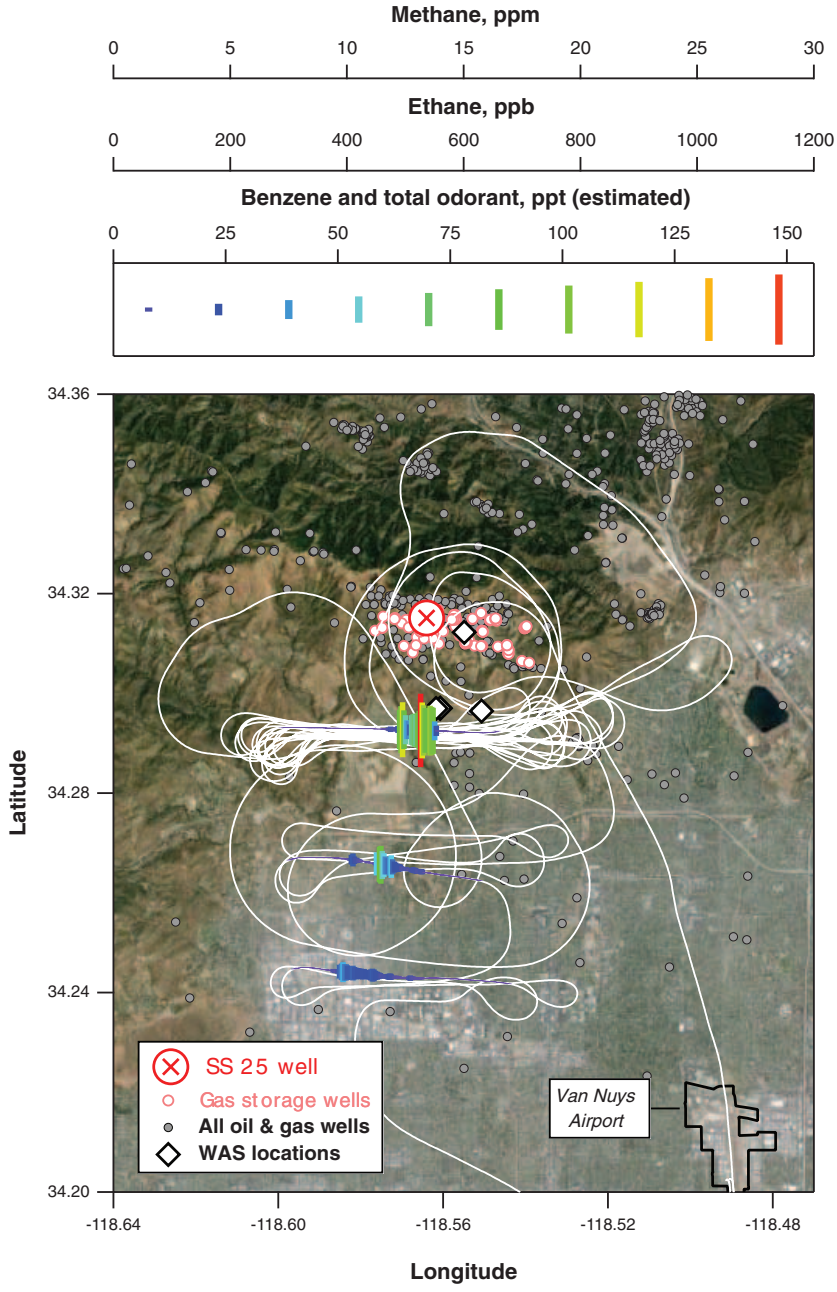

Fig. 1. Aliso Canyon gas plume transport into populated areas. Airborne chemical data illustrate plume transport into the San Fernando Valley; data from 10 November 2015 are shown. Plume enhancements above the local background (colored markers) from example transects are plotted along the flight track (white line) and can be scaled using the legends at top to yield measured CH_4, measured C_2H_6, estimated benzene based on the WAS benzene-to-CH_4 ER, and estimated total odorant (assuming 5 ppm in the leaking gas). Benzene and total odorant are in parts per trillion by volume (ppt).

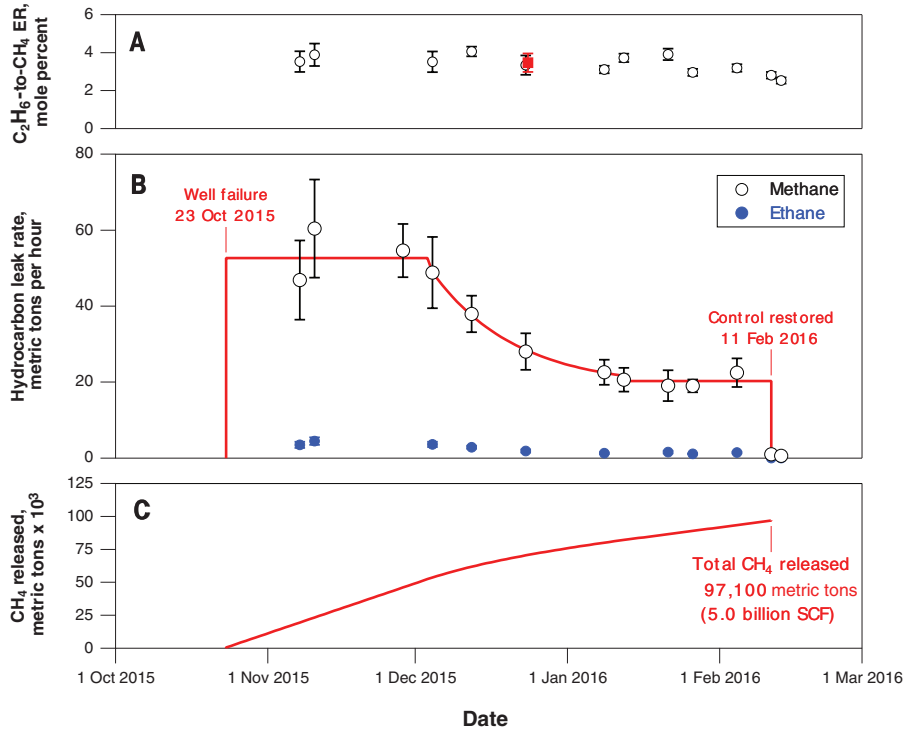

Fig. 2. Time series of the Aliso Canyon natural gas leak. (**A**) Plume C_2H_6-to-CH_4 ERs from airborne measurements (open circles) and ground-based WAS measurements (red square). (**B**) Leak rates (in metric tons per hour) of CH_4 (open circles) and C_2H_6 (blue circles), determined from airborne measurements. The red line is a fit to the airborne CH_4 data, assuming an average leak rate from the blowout (day 0) to day 43, an exponential decrease between days 43 and 80, and an average leak rate thereafter to day 112, when control was restored. (**C**) The total amount of CH_4 released (in metric tons), calculated from the fit in (B). Error bars indicate ±1 SEM.

which enabled accurate reconstruction of a vertical concentration profile, even before the plume had completely mixed throughout the full vertical extent of the atmospheric boundary layer (*5*).

The chemical data show that the airborne sampling captured the full vertical extent of the lofted plumes on each flight day (fig. S1). Atmospheric mass fluxes calculated from the chemical data from each transect collected downwind (*5*) suggest an average leak rate of 53 ± 3 metric tons of CH_4 and 3.9 ± 0.3 metric tons of C_2H_6 per hour for the first six weeks of the leak, decreasing thereafter (Fig. 2B and table S2). The decreasing trend, which began around the first week of December 2015 (Fig. 2B and table S2), is consistent with decreasing reservoir pressure in response to the withdrawal of gas through other storage wells connected to the subsurface reservoir, which was done in a deliberate effort to slow the leak (*13*). The lack of a decrease in the leak rate after the first week of January 2016 is consistent with the cessation of withdrawals to maintain a minimum working pressure in the reservoir, which supplied natural gas to customers in the greater Los Angeles basin throughout the leak duration.

These data demonstrate that the blowout of a single well in Aliso Canyon temporarily created the largest known anthropogenic point source of CH_4 in the United States (*14*), effectively doubling the leak rate of all other sources in the Los Angeles basin combined (*15, 16*). Further, at its peak, this leak rate exceeded that of the next largest point source in the United States—an underground coal mine in Alabama—by over a factor of 2 (*14*) and was a factor of 10 larger than the CH_4 leak rate reported from the Total *Elgin* rig blowout in the North Sea in 2012 (*17*). The Aliso Canyon CH_4 leak rates were comparable to the total CH_4 emission rates of entire oil and gas production regions in the United States [e.g., the Barnett shale, 76 metric tons per hour (*18*); the Haynesville shale, 80 metric tons per hour (*19*); the Fayetteville shale, 39 metric tons per hour (*19*); and the northeastern Marcellus shale, 15 metric tons per hour (*19*)].

Our aircraft flights after the "bottom kill" confirmed the cessation of flow from the SS-25 well on 11 February 2016 and revealed a residual leak rate of <1 metric ton of CH_4 per hour (Fig. 2B and table S2), consistent with nonzero leak rates observed at other natural gas, oil, and petrochemical facilities nationwide (*16*, *18*–*24*). These data show that over its 112-day duration, the Aliso Canyon natural gas leak released a total of 97,100 metric tons (5.0 billion SCF) of CH_4 (Fig. 2C) and 7300 metric tons (0.2 billion SCF) of C_2H_6 to the atmosphere, which is equal to 24% of the CH_4 and 56% of the C_2H_6 emitted each year from all other sources in the Los Angeles basin combined (*16*).

This CH_4 release is the second largest of its kind recorded in the United States, exceeded only by the 6 billion SCF (115,000 metric tons) of natural gas released in the 2004 collapse of an underground storage facility in Moss Bluff, TX, and greatly surpassing the 0.1 billion SCF (1900 metric tons) of natural gas leaked from an underground storage facility near Hutchinson, KS, in 2001 (*25*). Aliso Canyon will have the largest climate impact by far, however, given that an explosion and subsequent fire during the Moss Bluff release combusted most of the leaked CH_4, immediately forming CO_2. The total release from Aliso Canyon will substantially affect the State of California greenhouse gas (GHG) emission targets for the year (*26*) and is equivalent to the annual energy sector CH_4 emissions from medium-sized European Union nations (*27*). The radiative forcing from this amount of CH_4, integrated over the next 100 years, is equal to that from the annual GHG emissions of 572,000 passenger cars in the United States (*28*). The volume of CH_4 released represents only 3% of the total capacity of the Aliso Canyon storage facility, raising the possibility of substantial additional emissions if the leaking SS-25 well had not been sealed, or if the remaining natural gas had not been withdrawn through other wells, before the reservoir was completely exhausted to the atmosphere.

The agreement reached at the 21st Conference of the Parties (COP21) to the UN Framework Convention on Climate Change (*29*) includes specific requirements for the Parties to account for anthropogenic GHG emissions with accuracy and completeness. In the post-COP21 world, rapid evaluation of episodic GHG release events, such as the Aliso Canyon blowout, will be an essential contribution to meeting these requirements.

Our analysis quantifies a massive CH_4 release using a rapid, direct, and repeatable method with known accuracy. As such, results from this method serve as reference values for less direct and timely estimates that use retrievals of surface (*30, 31*), airborne (*32*), and/or satellite remote sensing observations (*33*). For example, our airborne method offers a priori estimates of the Aliso Canyon leak rates that can be used for inverse modeling analysis of continuous in situ CH_4 monitoring data from fixed ground sites (*15, 34*). This incident highlights the utility of rapid-response airborne chemical sampling in providing an independent, time-critical, accurate, and spatially and temporally resolved leak rate, as well as in ascertaining the source location and plume chemical composition. Such information can help to document human exposure, formulate optimal well-control intervention strategies, quantify the efficacy of deliberate control measures, and assess the climate and air quality impacts of major unanticipated chemical releases to the atmosphere (*35, 36*).

BIOCHEMISTRY

Fine-tuning of a radical-based reaction by radical *S*-adenosyl-L-methionine tryptophan lyase

Giuseppe Sicoli,[1,2] Jean-Marie Mouesca,[1,2] Laura Zeppieri,[3] Patricia Amara,[3] Lydie Martin,[3] Anne–Laure Barra,[4] Juan C. Fontecilla-Camps,[3] Serge Gambarelli,[1,2]* Yvain Nicolet[3]*

The radical *S*-adenosyl-L-methionine tryptophan lyase NosL converts L-tryptophan into 3-methylindolic acid, which is a precursor in the synthesis of the thiopeptide antibiotic nosiheptide. Using electron paramagnetic resonance spectroscopy and multiple L-tryptophan isotopologues, we trapped and characterized radical intermediates that indicate a carboxyl fragment migration mechanism for NosL. This is in contrast to a proposed fragmentation-recombination mechanism that implied Cα–Cβ bond cleavage of L-tryptophan. Although NosL resembles related tyrosine lyases, subtle substrate motions in its active site are responsible for a fine-tuned radical chemistry, which selects the Cα–C bond for disruption. This mechanism highlights evolutionary adaptation to structural constraints in proteins as a route to alternative enzyme function.

Nosiheptide, produced by *Streptomyces actuosus*, is a highly modified, sulfur-rich, polythiazolyl macrocyclic peptide antibiotic (*1*). This compound exhibits highly potent activity against multidrug-resistant strains of several gram-positive pathogens (*2*–*5*). Originating from a 13-residue-long, ribosomally synthesized peptide, nosiheptide contains a central tetra-substituted pyridine ring, five thiazole rings, and an unusual indolic acid (*6*, *7*). The latter is produced by the tryptophan lyase (NosL) enzyme, which converts L-tryptophan to the methylindolic acid (MIA) precursor that is subsequently inserted into the thiopeptide (*8*, *9*). NosL belongs to the radical *S*-adenosyl-L-methionine (SAM) protein superfamily, which uses a reduced $[Fe_4S_4]^+$ cluster and SAM to initiate a 5′-deoxyadenosyl radical (5′-dA•)–based reaction (*10*). Homologous tyrosine lyases (CofH, ThiH, and HydG) cleave the Cα–Cβ bond of tyrosine, producing a *p*-cresyl radical and dehydroglycine (DHG) (*11*–*15*).

Because of the prevalence of tyrosyl and tryptophanyl radicals in proteins, it was initially proposed that the H-atom abstraction from L-tyrosine and L-tryptophan by the highly reactive 5′-dA• should take place at the L-tyrosine phenol group and at the L-tryptophan indole nitrogen, respectively (*9*, *12*, *14*). However, a recent NosL structure in complex with L-tryptophan (*16*) indicates that the H-atom abstraction takes place at the amino nitrogen atom (Fig. 1A). Biochemical studies confirmed that this abstraction in NosL is the first step in the conversion of L-tryptophan into MIA. NosL can perform β-scissions from the amino-centered radical intermediate at either Cα–Cβ or Cα–C when using L-tryptophan analogs (*17*, *18*). These observations suggest a relative propensity of NosL for substrate promiscuity that, combined with slight differences in

Methane emissions from the 2015 Aliso Canyon blowout in Los Angeles, CA

S. Conley, G. Franco, I. Faloona, D. R. Blake, J. Peischl and T. B. Ryerson (February 25, 2016)

Science **351** (6279), 1317-1320. [doi: 10.1126/science.aaf2348] originally published online February 25, 2016

Editor's Summary

The magnitude of a major methane leak

The Aliso Canyon underground gas storage facility outside Los Angeles, CA, houses enormous natural gas reserves. One well at the site experienced a blowout in late October 2015 and began leaking gas until it was sealed in February 2016. Over the course of 13 flights in the region, Conley *et al.* sampled the air column and determined daily release rates of methane (a powerful greenhouse gas) and ethane throughout the leak. The methane release rates were nearly double that of the entire Los Angeles region combined. Thus, single vulnerabilities can have major implications for state and federal climate policy.

Appendix 19

California-sourced oil is the primary contributor to the average carbon intensity of all oil refined in California. 19

There is strong overlap between California fields employing enhanced oil recovery techniques and those with the most upstream emissions 20

There is significant overlap in California between fracking permits, enhanced oil recovery and the most carbon-intensive oil extraction. 21

Executive Summary

Despite California's reputation as a global climate leader, California-sourced oils are now among the most climate-damaging in the world and are rapidly becoming even more so. This report analyzes the state's oil production and refining to show the dramatic increase in California oil's carbon intensity over roughly the past decade. It finds that California-sourced oils have gone from bad to worse and are now dirtier than oils refined here from other states and global regions including the Middle East, South America, Africa, Canada and Mexico.

California has a huge impact as the nation's seventh-largest producer of crude oil and the third-largest oil refiner. In 2020 California oil companies produced more than 144 million barrels of crude oil, and state regulators issued more than 1,900 permits for new oil wells. This takes our state in the wrong direction at a critical juncture, as the scientific consensus tells us that we must phase out fossil fuel extraction to keep global heating below 1.5 degrees Celsius and prevent climate catastrophe.

Our findings on the worsening carbon intensity of California oil give state leaders an even greater opportunity — and responsibility — to confront ongoing health harms, climate damage and environmental racism by ending new oil and gas approvals and immediately banning fracking in the state. In April 2021 Gov. Gavin Newsom ordered state regulators to ban fracking by 2024 and study the phaseout of California oil production by 2045, but the climate and health crises demand action now, not decades in the future.

We studied upstream carbon intensity values (from exploration to refinery gate) provided by the California Air Resources Board for all oils refined in California. We found that the average carbon intensity of all oil refined in California is increasing, but the average carbon intensity of just the oil produced in California is increasing far faster. The carbon intensity of California-sourced oil is growing at twice the rate of all oils refined in California, and nearly three times the rate of oils produced outside of California (Figure E1). By 2019 the average carbon intensity of California-sourced crudes was more than one-and-a-half times greater than that of crudes produced outside of California.

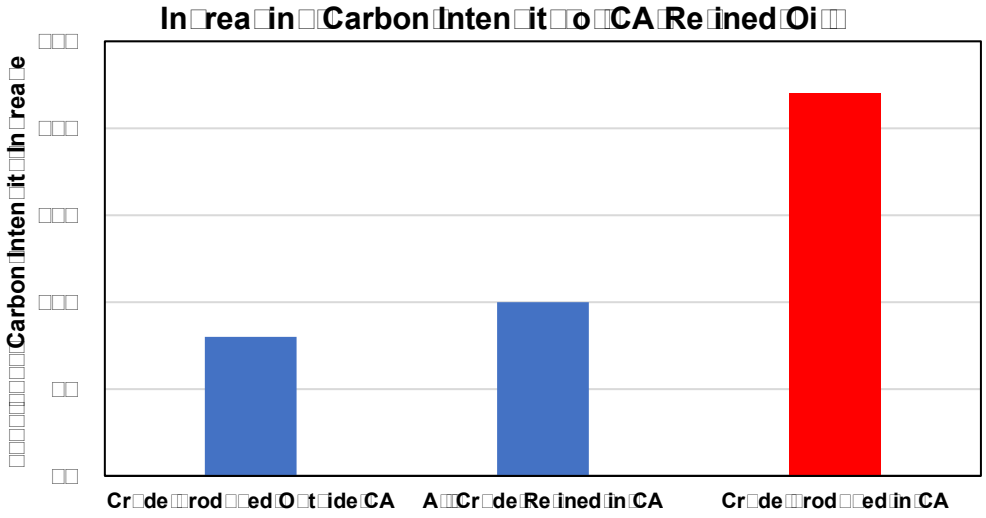

Figure E1: Increase in average carbon intensity between 2012 and 2019 for: (1) crude produced outside CA; (2) all crude refined in CA; (3) crude produced in CA.

Further evidence of California-sourced oil's outsized carbon footprint can be found in its contribution to the average carbon intensity of California-refined oil. California oil was 31% of all oil refined in California between 2012 and 2019 but was responsible for 39% of upstream carbon emissions.

Thus, on average, California oil emits more carbon dioxide per barrel than the rest of the global supply refined in California. So, although California oil production is declining, the increase in carbon intensity is helping to cancel out the climate benefits of declining production.

We also found that oil produced and refined in California is more climate-damaging than the notoriously dirty Canadian tar sands crude refined here. In 2019 the average upstream carbon intensity of California-sourced oil exceeded that of Canadian tar sands crude refined in California, with 98 kg CO_2eq/barrel for California oil and 90 kg CO_2eq/barrel for Canadian tar sands crude.

To avoid the worst dangers of climate change, the world must transition away from fossil fuels. No jurisdiction is better suited than California to lead the way in phasing out dirty oil and gas production. For California this means an end to approvals for new oil and gas wells and an immediate ban on fracking and related extreme techniques that only amplify the damage from extraction.

While a full phaseout of in-state production will take some time, it needs to be much faster than Gov. Newsom's 2045 target. A health-and-safety buffer should also be implemented immediately to prevent oil and gas drilling in communities and to protect public health and safety from air pollution and other harms of oil and gas extraction. Without taking these steps, California cannot protect the climate or the state's most vulnerable communities.

San Ardo Oil Field by Loco Steve/Flickr

Introduction: California's Oil Production Undermines Its Climate, Environmental Justice and Public Health Goals

Despite California's image as a leader on climate and the environment, the state's oil industry contributes heavily to dangerous climate-heating pollution. California is the nation's seventh-largest producer of crude oil and the third-largest oil refiner.[1] In 2020, California oil companies produced more than 144 million barrels of crude oil, while Gov. Newsom's state regulators issued more than 1,900 permits for new oil wells.[2] The flood of permits for new oil wells runs directly counter to the imperative to phase out fossil fuel extraction to prevent the worst climate damages. It also perpetuates the environmental justice and health crises caused by oil and gas extraction in California.

Overwhelming scientific consensus has shown that without deep and rapid emissions reductions, global warming will exceed 1.5 degrees Celsius compared to preindustrial levels, resulting in catastrophic damage around the world.[3] Every fraction of additional warming above 1.5 degrees will worsen these harms, threatening lives, livelihoods, the environment and global security for this and future generations. Because 75% of global greenhouse gas emissions and 85% of U.S. emissions come from fossil fuels,[4] phasing out fossil fuel extraction and combustion is of urgent necessity to avert climate catastrophe.

Unfortunately, today the world faces a fossil fuel "production gap" of tremendous proportions: Producers currently plan to extract far more fossil fuels than a livable planet will allow.[5] There is enough oil, gas and coal in already developed fields and mines globally — that is, places where the infrastructure is built and the capital is sunk — to far exceed the carbon budget for 1.5 degrees C if these reserves were all produced and burned.[6] This means that meeting global climate goals

requires an immediate halt to the approval of new fossil fuel projects and a phaseout of existing oil, gas and coal extraction *before* the reserves in existing fields and mines are fully depleted.[7]

Nowhere in the world is better suited than California, with its wealthy, diverse economy and vibrant clean energy sector, to lead the way in a rapid phaseout of oil and gas extraction. To date, however, progress has been slow and insufficient. Gov. Newsom's order for regulators to study how to phase out oil extraction by 2045 could allow another two and a half decades of toxic inaction.

To make matters worse, much of the remaining oil in California's largest oilfields is heavy and carbon intensive.[8] The "heaviness" of an oil is defined by its API gravity, which is a measure of the oil's density. A crude oil is "light" if it has an API gravity of more than 31.1 degrees, "medium" if it has an API gravity from 22.3 to 31.1 degrees, "heavy" if it has an API gravity from 10 to 22.3 degrees and "extra heavy" if under 10 degrees. In 2018, 68% of California's crude oil production was heavy.[9] Heavy oils are especially climate-damaging because they often require energy-intensive techniques such as hydraulic fracturing, waterflood, steamflood and cyclic steam to extract. This greater energy demand results in greater greenhouse gas emissions as well as greater health and safety risks.

The heaviness of oil contributes to its carbon intensity, with heavier oils tending to be more carbon intensive. Carbon intensity is a value that estimates the emissions from the production, processing and transport of crude oil. Our study of carbon intensity values for oil refined in California, provided by the California Air Resources Board, shows that California-sourced oils are especially dirty in a global context and that their carbon intensity is rapidly increasing.

Oil and gas production in California has also caused an environmental justice and public health crisis in California. Eighteen percent of the state's population lives within a mile of at least one oil or gas well.[10] The highest-density oil and gas extraction areas are predominantly located near low-income communities and communities of color.[11] These communities are disproportionately exposed to the health harms associated with oil and gas extraction such as cancer,[12] respiratory illnesses[13] and pregnancy complications. Two recent studies focused on California specifically found associations between proximity to oil and gas production and preterm birth and low birth weight.[14] A recent Harvard study found that an estimated 34,000 Californians died prematurely in one year because of fossil fuel pollution.[15]

California's failure to rein in the dirty oil extraction within its own borders, using increasingly energy-intensive and dangerous techniques, completely undermines its climate, health and justice goals.

Study Description

California refines crude oil from countries around the world, including (as of 2019) Angola, Argentina, Brazil, Canada, Colombia, Ecuador, Equatorial Guinea, Ghana, Iraq, Kuwait, Mexico, Nigeria, Oman, Peru, Russia, Saudi Arabia, Trinidad and United Arab Emirates. California also refines oil from other U.S. states including Alaska, New Mexico, North Dakota, Texas and Utah, along with oil from federal offshore sources. The remaining oil refined in California comes primarily from its own 158 major oilfields.

California's 2019 oil production was only 27% of the total 600 million barrels refined in California.[16] In 2019, 13% of the oil refined in California was from other U.S. states, predominantly Alaska, New Mexico, North Dakota, Utah and Wyoming. Notably, the oils refined from these states were all light based on API gravity.[17] Similarly, oil refined in California from the Middle East (mainly Saudi Arabia, Iraq and Kuwait), constituting 26% of oil refined in California in 2019 and the dominant foreign source, was light.[18]

The only significant foreign source of heavy oil refined in California is South America (mainly Ecuador, Colombia and Brazil), constituting 22% of oil refined in 2019.[19] Oils from Canada and Mexico, including the infamous Canadian tar sands oils, are comparable in heaviness to California oils, but as less than 5% of the total oil refined in California in 2019, they are a relatively small source.[20]

For oil refined in California, the Oil Production Greenhouse gas Emissions Estimator (OPGEE) is the model used to estimate the emissions from oil from different sources, or the carbon intensity, extending from initial oil exploration to the arrival of the oil at the refinery gate.[21]

Since 2012 the California Air Resources Board (CARB) has provided carbon intensity estimates for all oils refined in California, measured in grams CO_2 per megajoule (g/MJ — grams of CO_2 eq produced per MJ of energy derived from oil).[22] The carbon intensity values are attributed to the production and transport of the crude oil supplied as petroleum feedstock to California refineries, so emissions that occur during the refining process or thereafter are not considered. Carbon intensity (CI), as a measure of greenhouse gas emissions derived from a given crude, is one way to quantify the relative harms of different crudes to the climate.

Using the carbon intensity values of the various refined oils, CARB calculates an average carbon intensity for a given year by doing a weighted average based on the volume of oil from a given source:

$$Average\ carbon\ intensity = \frac{(Crude\ Vol.\#1 * CI\ \#1) + (Crude\ Vol.\#2 * CI\ \#2) + (Crude\ Vol.\#3 * CI\ \#3) + \cdots}{Total\ Volume\ of\ Oil\ Refined\ in\ CA}$$

where "crude vol." is the amount of oil from a given source and "CI" is the corresponding carbon intensity of that oil.

For our study, we used the same method and CARB's own average carbon intensity values of individual crudes to determine the average carbon intensity of different subsets of oil refined in California, including the average carbon intensity of only oils produced in California and only oils produced outside of California. The following is an example calculation of the average carbon intensity of oil from California oilfields:

$$Average\ carbon\ intensity\ of\ CA\ oil = \frac{(Crude\ Vol.\ CA\ \#1 * CI\ CA\ \#1) + (Crude\ Vol.CA\ \#2 * CI\ CA\ \#2) + (Crude\ Vol.CA\ \#3 * CI\ CA\ \#3) + \cdots}{Total\ Volume\ of\ Oil\ Produced\ and\ Refined\ in\ CA}$$

where "crude vol. CA" is the amount of oil from a given California oilfield and "CI CA" is the corresponding carbon intensity of that oil.

Using a conversion factor of 5,813.4 MJ per barrel as an approximation,[23] all carbon intensity values in the following analysis were converted from grams CO_2 per megajoule to kilograms CO_2eq per barrel (kg CO_2eq/bbl). With carbon intensity in terms of barrels and using values for barrels of oil production, upstream emissions from oil refined in California between 2012 and 2019 were also estimated.

Oil field in Bakersfield by Babette Plana/Flickr

San Ardo Oil Field by Drew Bird Photography

Results

The carbon intensity of oil produced in California has increased 22% since 2012, increasing the overall carbon intensity of all crude refined in the state.

The average carbon intensity of all crudes refined in California has gone up 10% between 2012 and 2019, increasing from an average of 66 kg CO_2eq/barrel in 2012 to 73 kg CO_2eq/barrel in 2019. This is an increase of about 1.5% per year. Meanwhile, for just the crudes extracted from California oilfields, the average carbon intensity has gone up 22% between 2012 and 2019, increasing from 81 kg CO_2eq/barrel in 2012 to 98 kg CO_2eq/barrel in 2019. This is an increase of about 3.1% per year or double the rate of increase for the carbon intensity of all oils refined in California. For all crudes not produced in California, the average carbon intensity has gone up 8% between 2012 and 2019, increasing from 59 kg CO_2eq/barrel in 2012 to 64 kg CO_2eq/barrel in 2019. This is an increase of about 1.2% per year, or about half the increase observed for crudes produced in California (Table 1, Figure 1).

So, although the average carbon intensity of all oil refined in California is increasing, the average carbon intensity of California-produced oil is increasing far faster: twice the rate of all oils refined in California, and nearly three times the rate of oils originating outside of California. This complements an earlier estimate that the carbon intensity of California crudes on a per barrel basis increased by 39% between 2000 and 2017.[24]

Year	All Crude Refined in CA	CA-Produced Crude	Crude Produced Outside CA
2012	66.04	80.57	58.89
2013	66.10	80.63	58.72
2014	65.05	82.26	56.45
2015	70.11	86.97	61.80
2016	70.57	87.55	62.67
2017	69.35	87.72	62.32
2018	71.80	97.20	62.96
2019	72.78	98.07	63.66

Table 1: Average carbon intensity (CI) of oil refined in California between 2012 and 2019 in units of kg CO_2eq/barrel: (1) all crude refined in CA; (2) CA-produced crude; (3) crude produced outside CA.

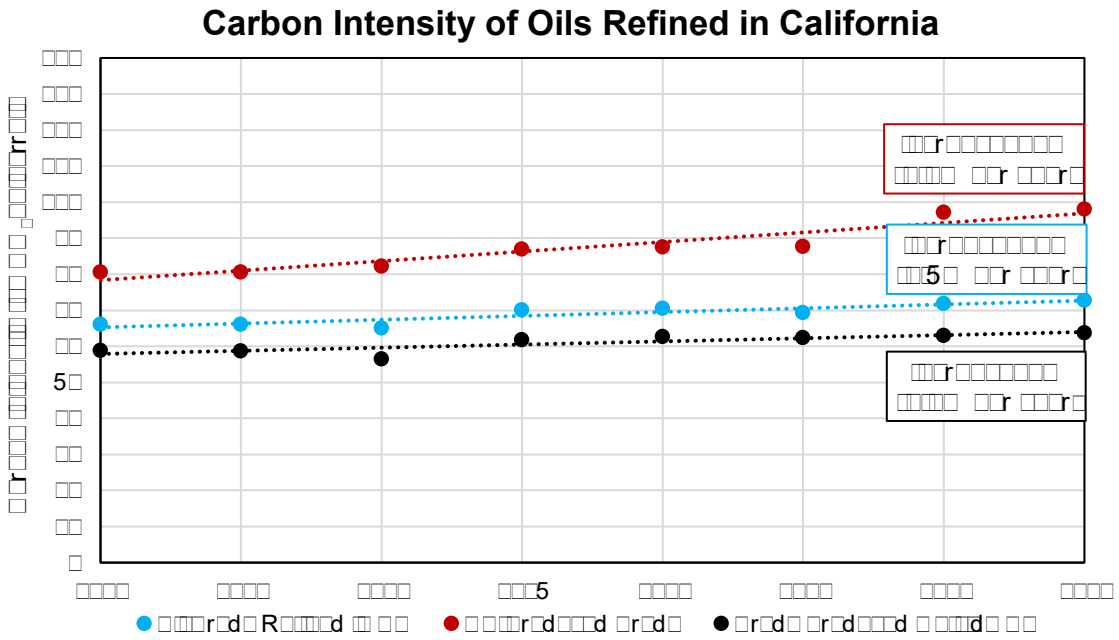

Figure 1: Increase in average carbon intensity over time for: (1) all crude refined in CA; (2) CA-produced crude; (3) crude produced outside CA.

<u>The high carbon intensity of California-sourced oils can be traced to just a few key California oilfields.</u>

As of 2019, California had 158 major oilfields, but five oilfields contributed more to California's average carbon intensity and upstream emissions than all others combined. These five fields in order of decreasing contribution are Midway-Sunset, South Belridge, Cymric, Kern River and San Ardo. Between 2012 and 2019, Midway-Sunset contributed 22% of the estimated upstream emissions from California-sourced oils; South Belridge contributed 12%; Cymric contributed 10%; Kern River contributed 9% and San Ardo contributed 8%. The remaining 39% was contributed by the other 153 major California oilfields (Figure 2):

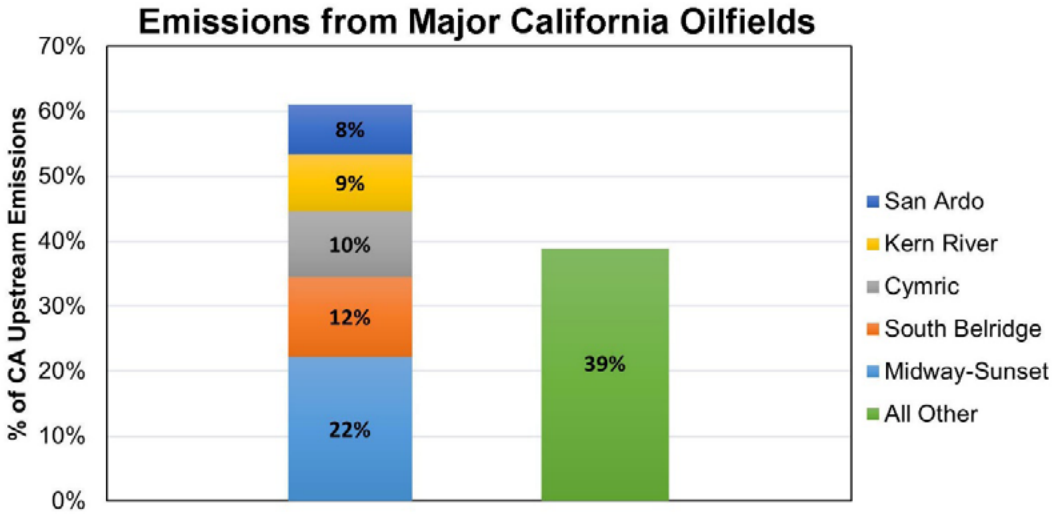

Figure 2: The top 5 California fields in terms of their contributions to the average carbon intensity and upstream emissions of California-sourced oils between 2012 and 2019. "All other" refers to all California oilfields outside of the top 5.

The contribution of specific oilfields to the average carbon intensity of California-sourced oils is strongly linked to total oil production (Figure 3), with Midway-Sunset, Kern River, South Belridge and Cymric being in the top five for contributing to California-sourced oils' average carbon intensity and the top five for California oil production. San Ardo, though in the top five for its contribution to California carbon intensity, ranks eighth in terms of oil production. The discrepancy is due to the relatively high carbon intensity of San Ardo oil.

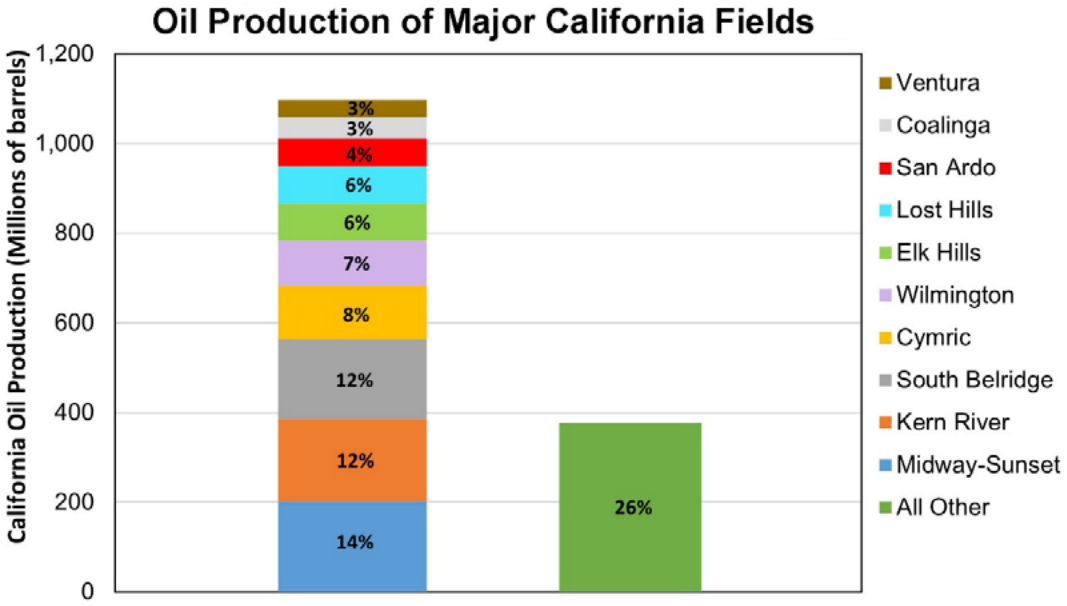

Figure 3: California's top 10 oilfields in terms of cumulative oil production between 2012 and 2019. Percent values displayed represent the percent of total California oil production. "All other" refers to all California oilfields outside of the top 10.

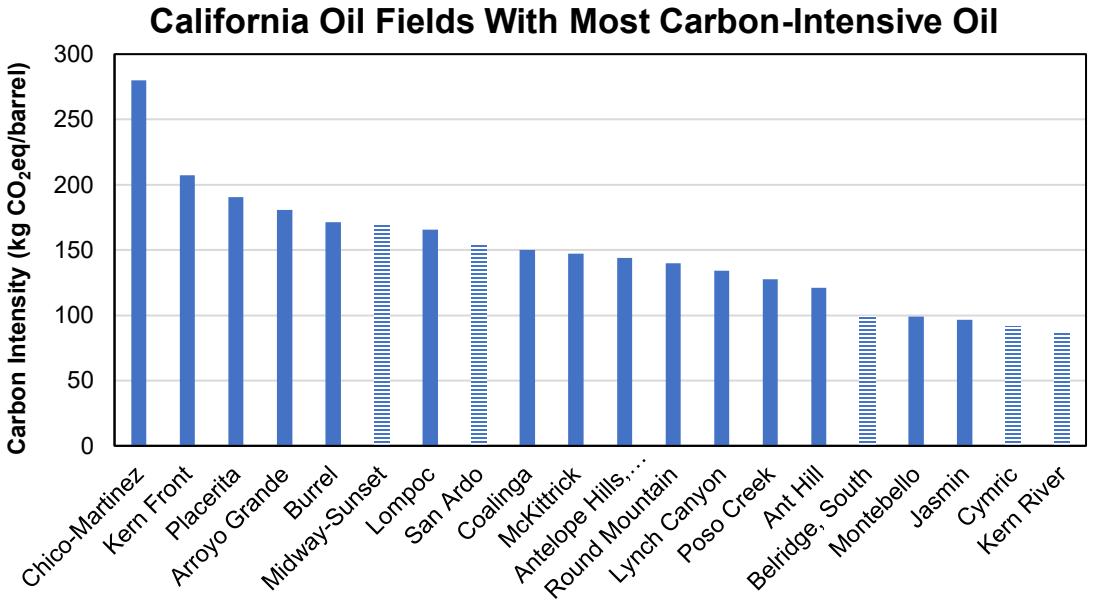
In terms of their contribution to the average carbon intensity of California-sourced oils, none of the top five California oilfields are in the top five for individual carbon intensity, although all are in the top 20 (Figure 4). This highlights the importance of both carbon intensity and production volume in determining the contribution of any given oilfield to the average carbon intensity and upstream emissions.



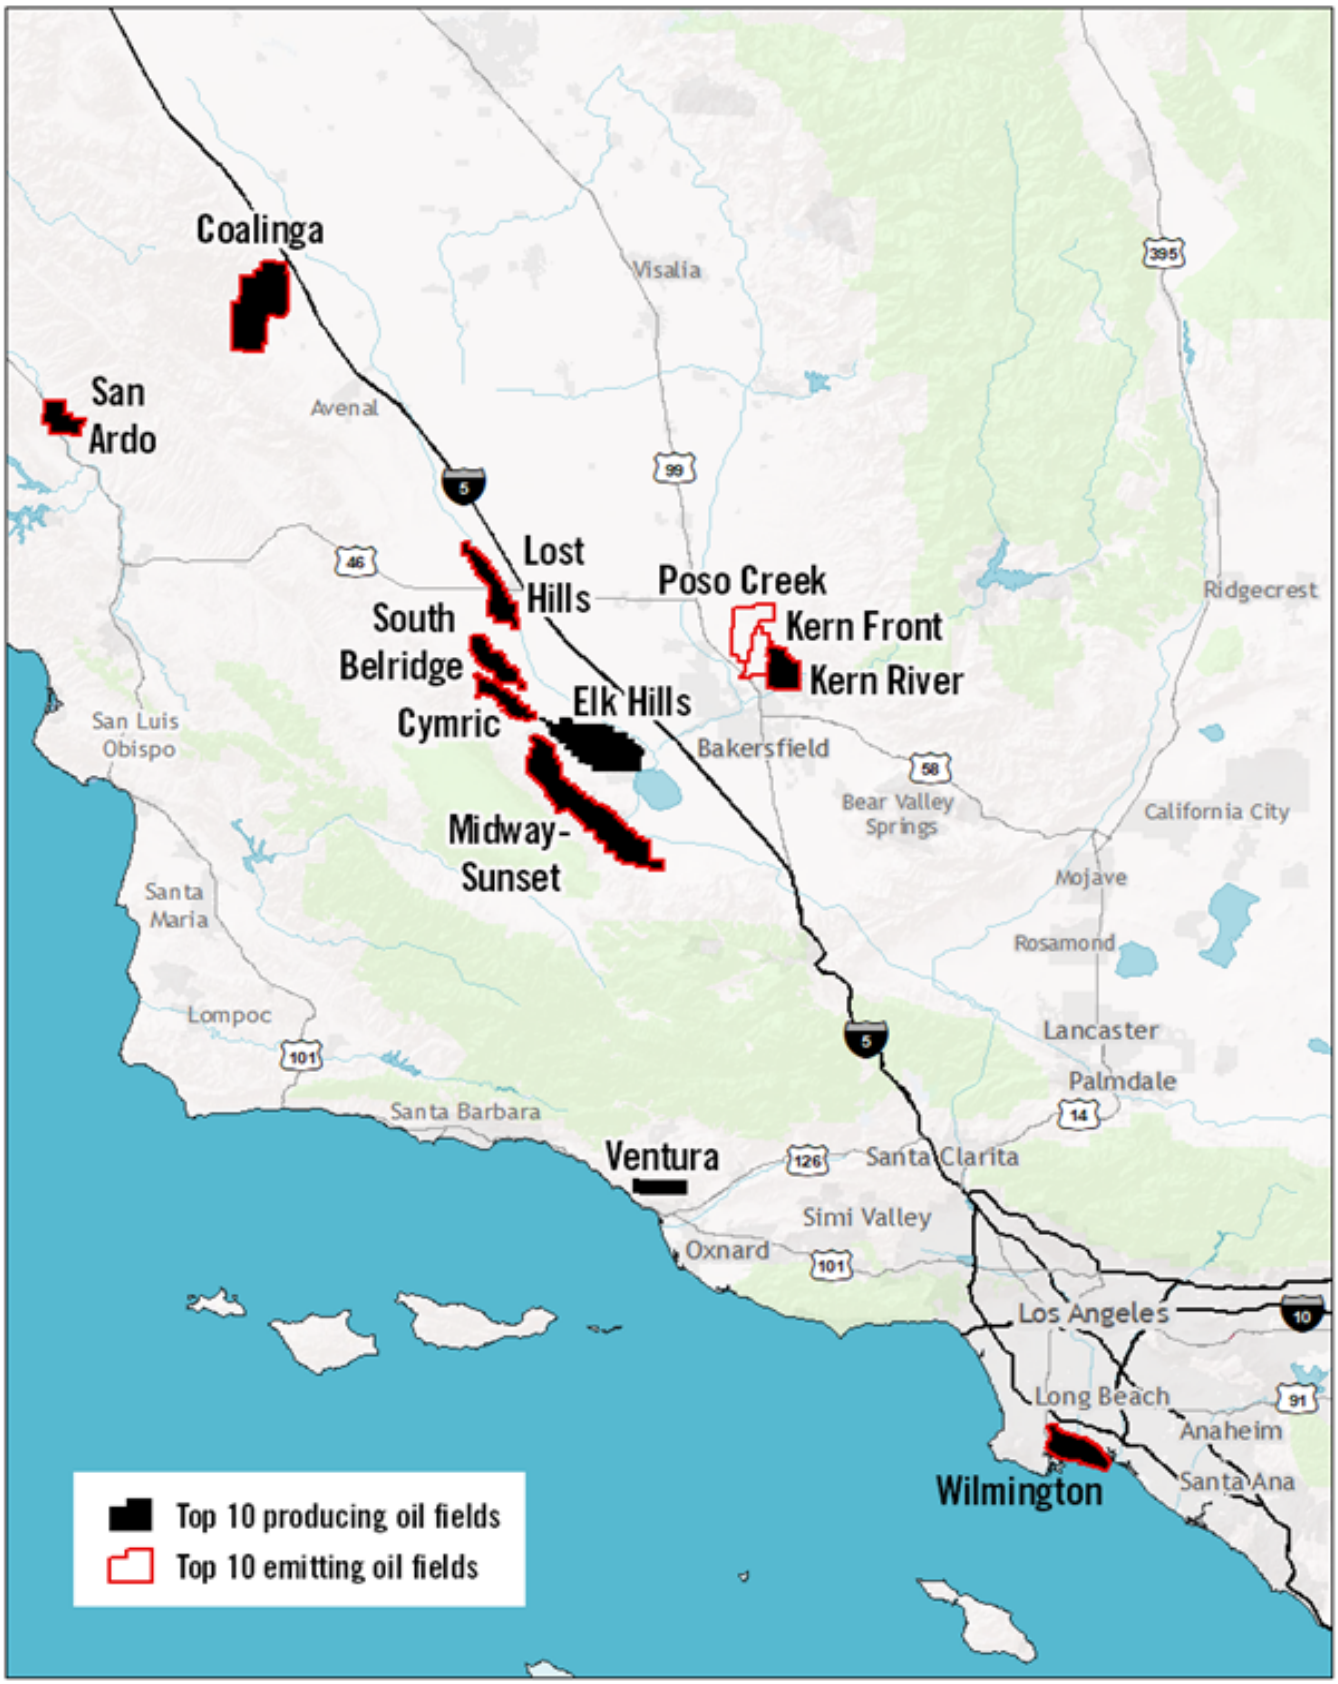


Figure 4: California's top 20 oilfields based on carbon intensity in 2019. The top 5 based on their contribution to the total upstream emissions of California-sourced oils are distinguished with horizontal stripes.

Top 10 Most Productive California Oilfields vs. Top 10 Carbon Dioxide Emitters

It's no surprise that California's top oil-producing fields also tend to contribute the most to California oil's upstream carbon dioxide emissions. Eight of the top 10 emitters are also in the top 10 for oil production. That means the fields producing the most oil also produce some of the dirtiest and most damaging crude, worsening California's overall contribution to dangerous global heating.

California oil is now more carbon intensive than notoriously dirty Canadian tar sands crude.

Our 2017 study found that three quarters of oil produced in California was as climate-damaging as Canadian tar sands crude, which is infamous for being exceptionally dirty.[25] This report shows that California oil has become more carbon intensive since that time.

In 2019 the average upstream carbon intensity of California oil exceeded that of Canadian tar sands crude with about 98 kg CO_2eq/barrel for California oil and about 90 kg CO_2eq/barrel for Canadian tar sands crude refined in California. Moreover, between 2012 and 2019, the average carbon intensity of Canadian tar sands crude refined in California declined, while the average carbon intensity of California-sourced oil increased (Figure 5). This may be due to California refineries refining proportionally less of the dirtiest Canadian oils over time.

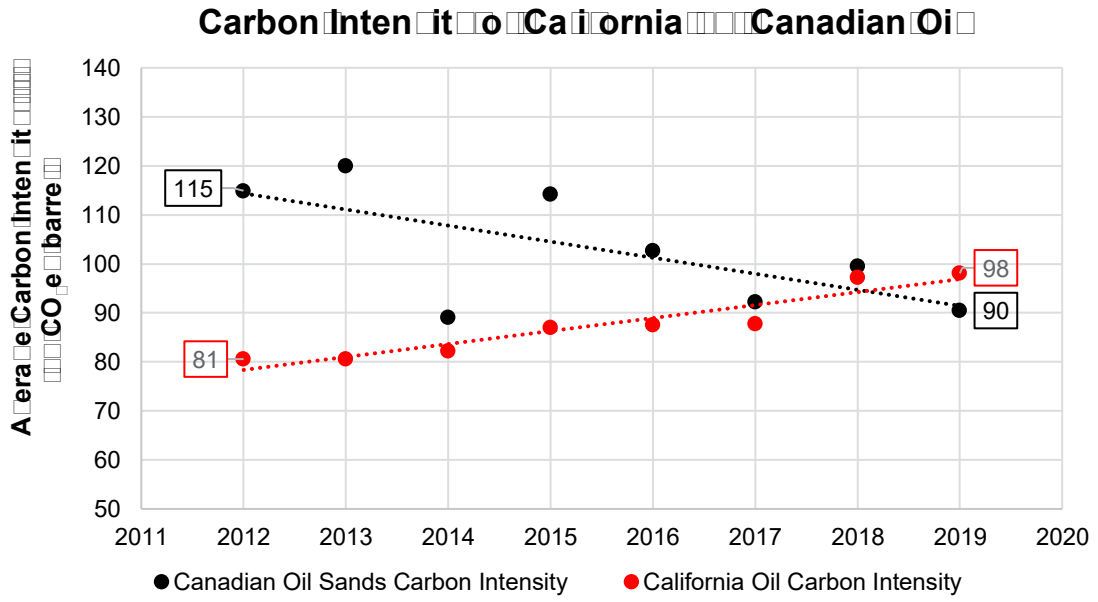

Figure 5: Change in average carbon intensity over time of Canadian oil sands crude vs. California-sourced oil. Here, average carbon intensity and average upstream emissions are interchangeable.

The last point is evidenced by the difference in the range of carbon intensities of Canadian crudes between 2012 and 2019. In 2012, the range was 44 to 142 kg CO_2eq/barrel, whereas in 2019 it was 47 to 171 kg CO_2eq/barrel. Even though the range shifted up in 2019, indicating dirtier oil streams being refined from Canada, the overall average carbon intensity was less in 2019 than in 2012, meaning a smaller proportion of these dirtier oils were refined.

Tar sands in Alberta
by Dru Oja Jay, Dominion

The increase in carbon intensity of California-sourced oils is partially canceling out the benefits of the decline in California oil production.

California's oil production has been in long-term decline since 1985 (Figure 6):

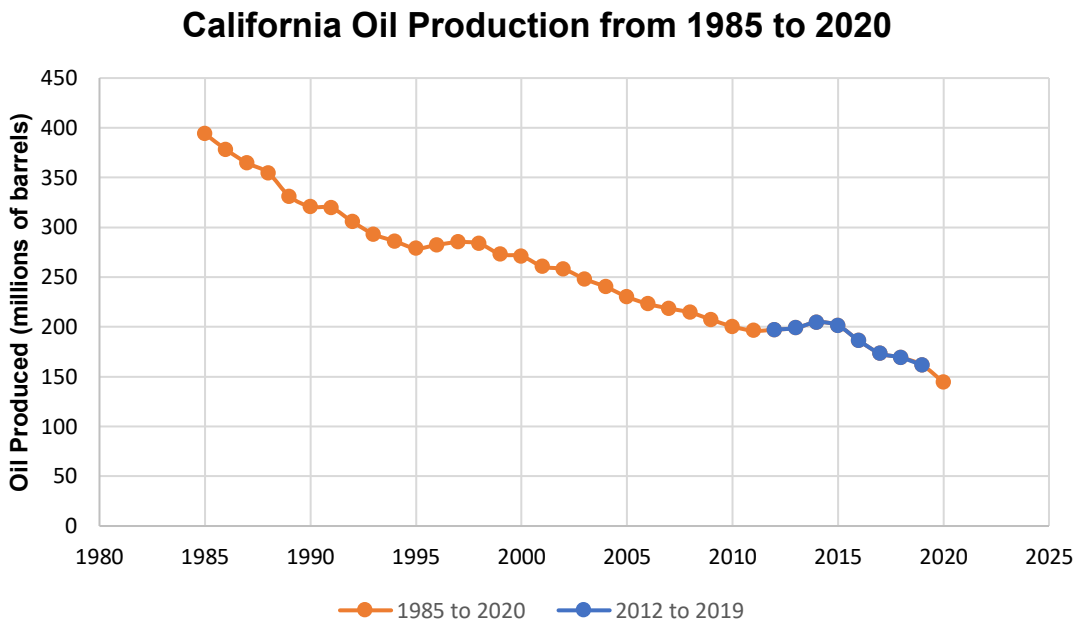

Figure 6: California oil production from 1985 to 2020.[26]

This trend holds in the 2012 to 2019 timeframe of our analysis, with the first three years holding a relatively steady annual amount of oil production, and 2015 to 2019 seeing declines in both oil production and upstream emissions from California-sourced oils (Figure 7).

However, the rate of decline in oil production from 2015 to 2019 exceeded the rate of decline in upstream emissions. While oil production declined by 22% between 2015 and 2019, upstream emissions only declined by 13%. If we compare 2012 and 2019, oil production was 20% less in 2019 than in 2012, whereas upstream emissions were only 3% less. Both cases make clear that the increase in carbon intensity of California-sourced oils is partially canceling out the climate benefits of California's oil-production decline.

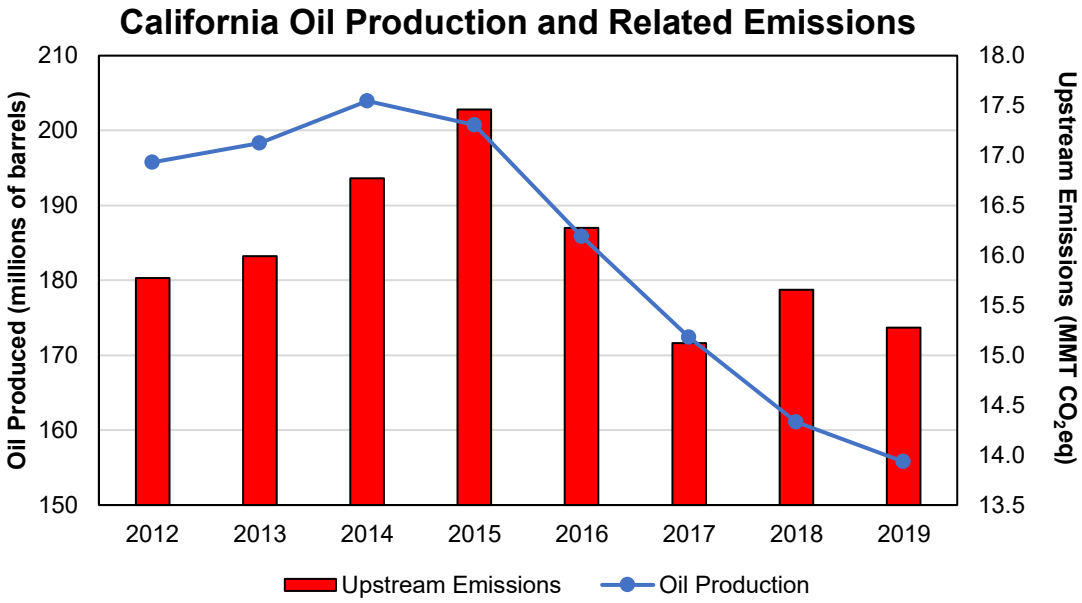

Figure 7: Upstream emissions from California-sourced oils vs. California oil production between 2012 and 2019.

For example, upstream emissions in 2015 were about 18.1 MMT CO_2eq. So if upstream emissions declined by 22% between 2015 and 2019, as oil production did, then emissions in 2019 would be about 14.1 MMT CO_2eq. Instead upstream emissions in 2019 were 15.8 MMT CO_2eq, or about 1.7 MMT CO_2eq more. Assuming this value is 20% of lifecycle emissions (upstream emissions + midstream refining emissions + downstream end use emissions; assumption addressed in more detail in the Discussion), then the lifecycle emissions would be about 8.5 MMT CO_2eq more, or an additional 2% of California's total emissions (based on a 2018 estimate of California total emissions).

Thus, increasing carbon intensity is reducing California's potential progress on reducing greenhouse gas emissions. To maximize emissions reductions, policymakers should both reduce oil production and eliminate enhanced oil-recovery techniques that increase the carbon intensity of California oils.

San Ardo Oil Field by Drew Bird Photography

Discussion

A phaseout of California oil production does not require an increase in imports.

Proponents of business-as-usual oil extraction in California often say that limiting oil production in California will require an increase in imports from parts of the world where oil is produced with fewer environmental safeguards. This is simply incorrect.

A 2018 study found that the decline in production that would result if California stopped approving new oil wells would be approximately equal to the decline in oil consumption forecast by the California Air Resources Board's (CARB's) "Scoping Plan" to reduce greenhouse gas emissions (Figure 8).[27] Ending the approval of new oil wells and accelerating the ongoing decline in the state's oil production would, therefore, not require an increase in imports.

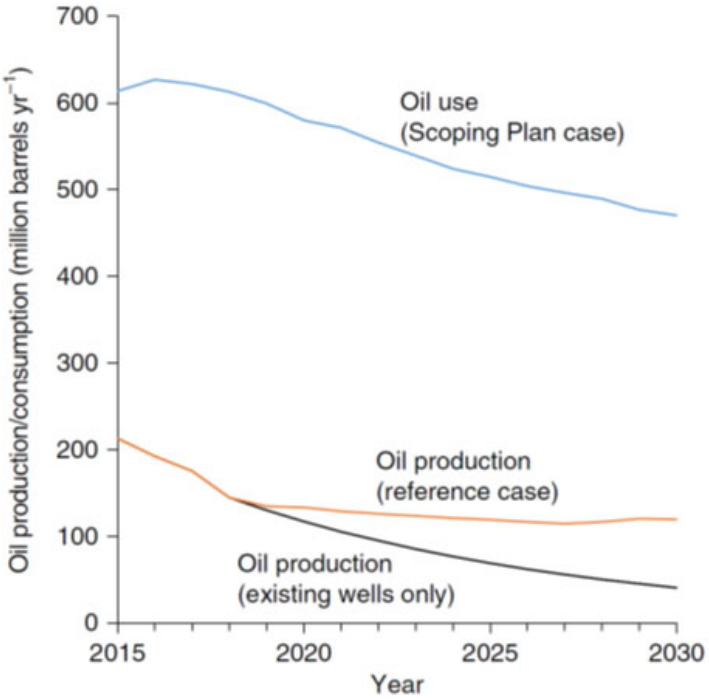

Figure 8: California's projected decline in oil production and consumption. (1) Reference scenario (orange line): developed by the U.S. Energy Information Administration, the state's annual oil production decline trajectory if it continues issuing new drilling permits; (2) No new wells (black line): production drawdown if California stopped issuing drilling permits; (3) Scoping Plan scenario (blue line): estimate of future oil use based on California's Scoping Plan (for gasoline, diesel and liquefied petroleum gas), the federal government (for residual and other oil), and the federal government and the California Energy Commission (for jet fuel). Figure and data from Erickson, P. et al. (2018).[28]

An update to the findings of the 2018 study using data from a 2020 CARB-commissioned study that charted three pathways for California carbon neutrality by 2045 strengthens this conclusion. Under CARB's "Balanced" and "Zero Carbon Energy" scenarios, the decline in California oil demand between 2020 and 2030 would exceed the decline in oil production if the state stopped issuing permits for new oil wells.[29] Thus, under California's current climate policies, California can and should simultaneously reduce in-state oil production and oil imports.

In 2020 oil production in California dropped to 144 million barrels, or by 10.6% compared to 2019.[30] According to state regulators, only 138 new wells were drilled, despite the issuance of permits for nearly 2,000 new wells.[31] Meanwhile, imports dropped by 27% from 433 million barrels to 316 million barrels.[32]

These declines are largely because of less oil consumption during the COVID-19 pandemic, but this further emphasizes the point that as California oil demand decreases, declines in production from halting new oil well permits would not need to be compensated for with increases in imports. With decreasing demand, in a no-new-permits scenario, both production and imports would decline, leading to a global decline in fossil fuel reliance.

However, research by Communities for a Better Environment reveals a troubling trend: In recent years California refineries have increased their production of gasoline for *export* to Pacific Rim countries, maintaining demand for imports despite falling oil use within the state.[33] If California allows this trend to continue, then it will continue to prop up imports. This emphasizes the need for the state to pursue a just transition that winds down all phases of the fossil fuel lifecycle, including refining.

A phaseout of oil extraction in California would not only get rid of an exceptionally dirty source of crude, but it would also lead to an overall global reduction in oil production and decrease in global carbon emissions. This is because every barrel of California oil left in the ground will reduce overall oil supply, resulting in a net decrease of about half a barrel of oil consumption globally.[34] Thus, actions taken in California to curb oil production will have global ramifications.

California's oil and gas regulatory failures have worsened the state's public health and environmental justice crises.

The oil industry's argument that production limits here will cause more production in places with weaker environmental safeguards is not only wrong, but also morally reprehensible because it minimizes California's regulatory failures and the public health and environmental justice crises caused by in-state oil production.

California's long-term regulatory failures are shocking and include the following:

- California is virtually the only major oil-producing state with no minimum setback distance between wells and homes, schools or other sensitive receptors, despite the grave health harms from oil and gas pollution.
- An EPA audit in 2011 found widespread failures in enforcing state regulations pertaining to the safety of oil and gas-related underground injection projects.[35]
- The California Geologic Energy Management Division (CalGEM) admitted in 2015 that thousands of oil and gas wells were improperly injecting wastewater into California's protected underground sources of drinking water, leading to the widespread contamination of the state's water supplies.[36] Half a decade later, the state has reneged on multiple commitments to remedy the situation and our water supplies are still being sacrificed to the oil industry.[37]
- California's lax waste-disposal laws allow oil industry wastewater to be dumped into unlined pits, which has led to multiple additional instances of groundwater contamination.[38]
- Loosening regulations on steam injection pressure led to multiple large-scale spills in Central California in 2019. CalGEM has yet to collect any fines for a 1.3-million-gallon spill in the Cymric oilfield,[39] and a separate spill of over 4 million gallons is still ongoing.[40] These spills contaminate the environment and threaten wildlife.
- Reports uncovered that multiple regulators had financial interests in oil companies,[41] and numerous top agency officials have gone on to work for the industry.
- Dozens of injection projects were approved under "dummy" files that had no underlying review for the project.[42]
- CalGEM has brought virtually no enforcement actions in response to illegal pollution.[43]
- CalGEM also has failed to comply with the environmental review and public participation requirements of the California Environmental Quality Act, despite acknowledging the environmental harms of extraction.[44]

California's regulatory record on oil and gas does not justify claims that it has the toughest environmental regulations in the world. On the contrary, it highlights the urgent need to phase out dangerous and dirty fossil fuel production in the state.

Lifecycle emissions make California oils' climate harms even more pronounced.

The carbon intensity values provided by the Air Resources Board only consider upstream emissions from oil, or the emissions from extracting and transporting oil up to the refinery gate. However, every step of the fossil fuel life cycle produces greenhouse gas pollution, including midstream refining and downstream combustion.

While we take comparisons of the upstream data from CARB as representative of the relative "dirtiness" of different oils refined in California, the overall climate impact of oils refined in California depends on the total lifecycle emissions. The emissions from midstream and downstream processes typically exceed upstream emissions. This is apparent when considering previously reported lifecycle emissions of California's top five oils in terms of upstream emissions — Midway-Sunset, South Belridge, Cymric, Kern River and San Ardo (Table 2):[45]

Field	2017 Upstream Emissions ($kg CO_2eq/bbl$)	2017 Lifecycle Emissions ($kg CO_2eq/bbl$)	% Upstream Emissions
Midway-Sunset	146	725	20%
South Belridge	86	690	12%
Cymric	112	600	19%
Kern River	56	650	9%
San Ardo	159	760	21%

Table 2: For California's top oilfields in terms of upstream emissions, listed are the upstream emissions estimates from 2017, most recent lifecycle emissions estimates from 2017, and upstream emissions per barrel as a percentage of lifecycle emissions per barrel.

Comparing the 2017 (the year with the most recent lifecycle emissions data) upstream and lifecycle emissions of the top five fields, we find that midstream and downstream processes constitute a greater proportion of emissions than upstream processes. Taking the above five fields as an example, upstream emissions are most often around 20% of the total lifecycle emissions. This agrees with an estimate by the Stockholm Environmental Institute in which factoring in upstream emissions increases the total emissions per barrel of oil by at least 25%,[46] which would likewise make upstream emissions about 20% of the total.

Putting this into perspective, California's total CO_2eq emissions across all sectors in 2018 was 425 MMT CO_2eq. In just 2018, upstream emissions from California-sourced oil were about 16 MMT CO_2eq. Assuming upstream emissions are about 20% of total lifecycle emissions, lifecycle emissions from California-sourced oil in 2018 would be about 80 MMT CO_2eq, which would make them almost 20% of California's total emissions in 2018 (Table 3).

Year	Oil Production (bbl)	Upstream Emissions (MMT CO_2eq)	Lifecycle Emissions (MMT CO_2eq)	Total CA Emissions (MMT CO_2eq)	% Upstream Emissions	% Lifecycle Emissions
2012	196	15.8	78.9	451.6	3.5%	17%
2013	198	16.0	80.0	447.6	3.6%	18%
2014	204	16.8	83.9	443.4	3.8%	19%
2015	201	17.5	87.3	440.8	4.0%	20%
2016	186	16.3	81.4	429.2	3.8%	18%
2017	172	15.1	75.6	424.5	3.6%	18%
2018	161	15.7	78.3	425.3	3.7%	18%
2019	156	15.3	76.4	--	--	--

Table 3: For the years 2012 to 2019, listed are barrels of California oil production, estimated California upstream emissions, estimated lifecycle emissions assuming upstream emissions are 20% of lifecycle emissions, and total California emissions across sectors. Using those values, upstream and lifecycle emissions as a percentage of total California emissions were calculated and listed.

The importance of considering lifecycle emissions is even more apparent when looking at the carbon intensity of California's refining itself. As follows from California both producing and accepting some of the dirtiest oil for refining, California's refining processes are exceptionally dirty.

Because California refines the heaviest crude on average, California refineries emit more CO_2eq per barrel of crude refined than those in any other major U.S. refining region. For 2013 to 2017, the average carbon intensity of California refining was 59.3 kg CO_2eq/barrel, whereas the U.S. average over the same time was 49.3 kg CO_2eq/barrel. Some individual refineries in California have refining carbon intensities as high as 79 kg CO_2eq/barrel.[47]

California-sourced oil's excessive upstream emissions burden not only California's population but the entire planet with some of the world's dirtiest refining.

California's Gas Production is More Climate-Damaging Than Coal And Threatens Public Health and Safety.

While California is the seventh-largest oil producer and third-largest oil refiner, it ranks 14th in U.S. fossil gas production, with nearly 200 billion cubic feet produced in 2019. California's gas production, however, is also exceptionally dirty, dangerous and carbon intensive.

A recent report from the California Energy Commission assumes fossil gas as part of California's energy mix well into the future, treating it as a bridge fuel. However, methane — a superpollutant 87 times more powerful than CO2 at warming the climate over a 20-year period — leaks during all phases of oil and gas production.

If the methane leakage rate is greater than 2.4% of the gas produced, then the climate damage from the methane leakage cancels out any climate benefit that gas achieves over coal at the smokestack over a 20-year period.

Therefore, depending on the overall leakage rate, fossil gas provides little or no climate benefit over coal: In fact, fossil gas may even be worse.

A recent analysis found that the methane leakage rate in the San Joaquin Valley is 4.8%, making gas sourced from this region not only worse than coal on a 20-year timescale, but also the worst in the continental United States.

In addition to its role as a major climate pollutant, gas production also threatens public health and safety. The 2015 gas leak disaster at the Aliso Canyon gas storage facility near Los Angeles resulted in 109,000 metric tons of methane entering our atmosphere—the largest-known methane release in U.S. history.

The Aliso Canyon disaster boosted statewide greenhouse gas emissions, set back emissions-reduction goals and sickened nearby residents with symptoms including dizziness, headaches, nausea, eye, nose and throat irritation, nose bleeds and likely long-term effects yet to be identified. Clearly the risks of keeping gas infrastructure in place far exceed any benefits.

Though California's dirty oil is the focus of the present study, it must be considered in the context of California's overarching dirty fossil fuel industry. The continued extraction of both exceptionally dirty oil and gas only makes a stronger case for the rapid phaseout of fossil fuels to mitigate substantial climate and public health harms.

Conclusion

Because climate change is driven primarily by fossil fuel production and combustion, most of the world's fossil fuels must stay in the ground to avoid the worst dangers of climate change. Worldwide, there are more than enough fossil fuels in already developed production fields to far exceed targets to limit warming to 1.5 degrees C or even 2 degrees C.[48] New fossil fuel development and infrastructure is thus unsafe and unjustified, and fossil fuel production must be phased out globally within the next several decades. With one of the world's wealthiest economies and some of the world's dirtiest oil, California needs to lead the way in ending fossil fuel production.

To address the climate damage, health harms and environmental injustice caused by its increasingly dirty oil production, Gov. Newsom should direct his regulators to end approvals for new oil and gas wells and other fossil fuel projects and commit to a plan to phase out existing extraction far faster than 2045. Newsom should also act now, not in 2024, to ban fracking and related extreme techniques that amplify the damage from extraction. Newsom should immediately implement a health-and-safety buffer to prevent oil and gas drilling in communities and protect public health and safety from the air pollution and other harms of oil and gas extraction. Without taking these crucial steps, California cannot protect the climate or the state's most vulnerable communities.

Appendix

California-sourced oil is the primary contributor to the average carbon intensity of all oil refined in California.

Although California oil was about 31% of all oil refined in California between 2012 and 2019, it was responsible for about 39% of the carbon intensity, or about 39% of the emissions leading up to the refinery gate (upstream emissions).

Calculated using the carbon intensity values provided by CARB, it is estimated that upstream emissions of oils refined in California between 2012 and 2019 were about 343 million metric tons CO_2eq (MMT CO_2eq). It follows that oil not produced in California constituted about 69% of all oil refined in California but was responsible for only 61% of the emissions leading up to the refinery gate.

As a reference, if all oils refined in California had the same carbon intensity, then their contribution to the total emissions leading up to the refinery gate would be the same as their contribution to the total volume of oil refined in California. So, a contribution to the carbon intensity that is more than the contribution to total oil refined indicates a carbon intensity above the overall average. In turn, a contribution to the carbon intensity that is less than the contribution to the total volume of oil refined indicates a carbon intensity below the overall average. This further indicates that, on average, California oil is more polluting per barrel than the rest of the global supply refined in California.

This fact holds when considering just the oil produced in the U.S. that is refined in California. Oil produced in the U.S., including oil produced in California, constitutes 46% of the oil refined in California, but 54% of the upstream emissions. However, if broken down further, oil produced in the U.S. *excluding* oil produced in California constitutes 15% of the oil refined in California but 16% of the upstream emissions.

In other words, the contribution of U.S. oil, including California, to upstream emissions is 1.2 times its contribution to the total production. The contribution of U.S. oil, excluding California, to upstream emissions is 1.05 times. And the contribution of California oil to the total upstream emissions is 1.3 times its contribution to the total production. So, normalized to production, oil produced in California contributes more to the upstream emissions for California-refined oils than other U.S. oils (Figure 9).

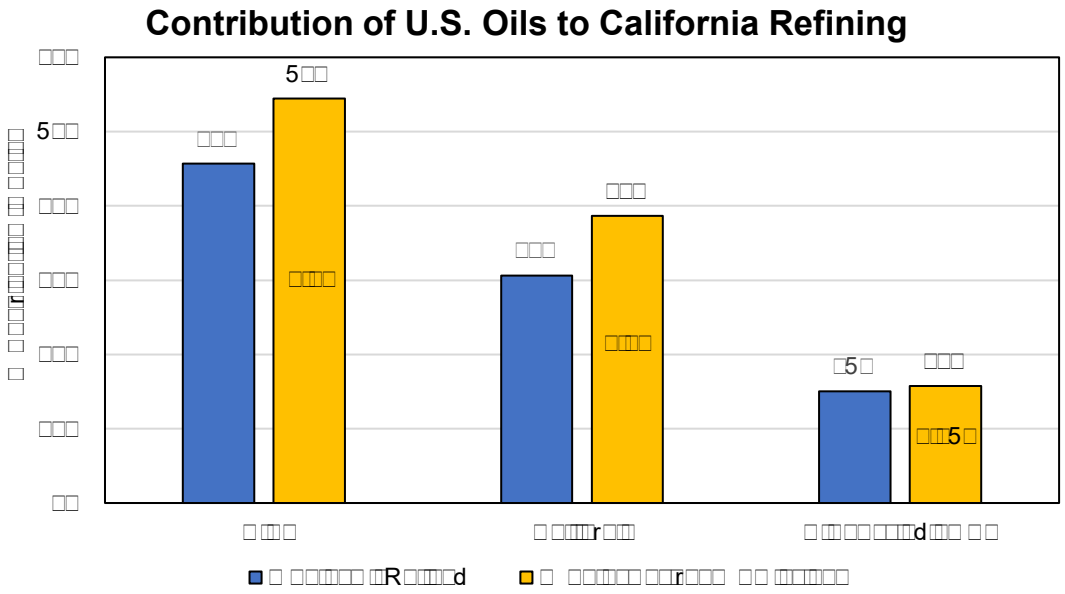

Figure 9: For U.S.-sourced oil including California, California-sourced oil, and U.S.-sourced oil excluding California, the volume of oil as a percentage of all oil refined in CA (% Total Oil Refined) vs. oil as its percent contribution to the total upstream emissions of all oil refined in CA (% Total Upstream Emissions). Also labeled on the orange bars is the multiple by which a given region's contribution to the total upstream emissions compares to its contribution to the total oil refined. Here, the contribution to average carbon intensity and the contribution to upstream emissions are interchangeable.

There is strong overlap between California fields employing enhanced oil recovery techniques and those with the most upstream emissions.

Enhanced oil recovery techniques such as cyclic steam and steamflooding are known to be energy-intensive compared to conventional oil extraction with the result being greater associated greenhouse gas emissions. In California, 19 fields have cyclic steam wells (Figure 10) while 18 fields have steamflood wells (Figure 11), with significant overlap of the two groups.

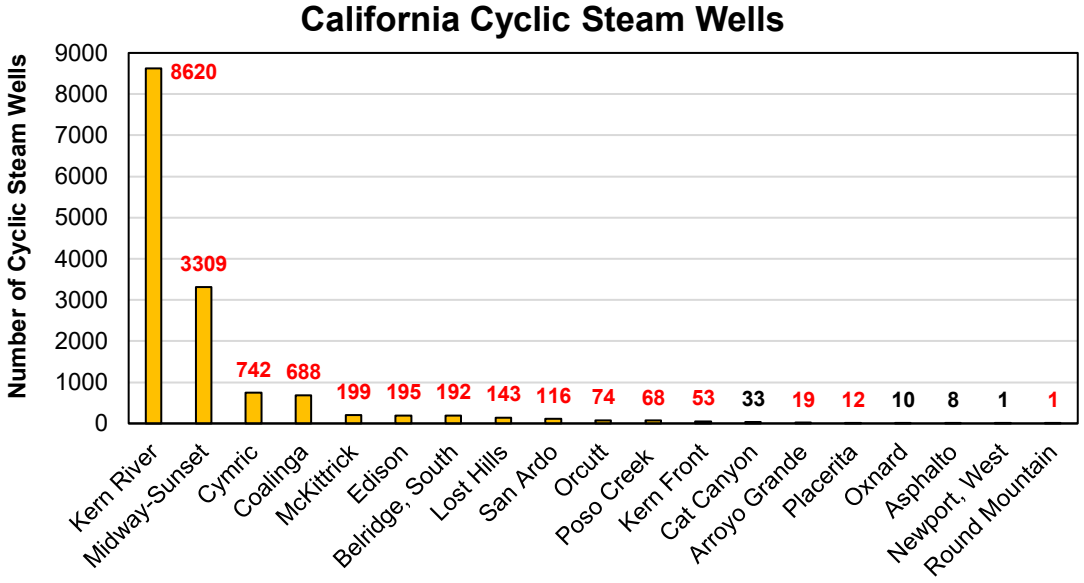

Figure 10: Cyclic steam wells in California based on 2020 data. The number of cyclic steam wells in each oilfield is labeled. The oilfields that are also in the top 20 for upstream emissions have red labels.

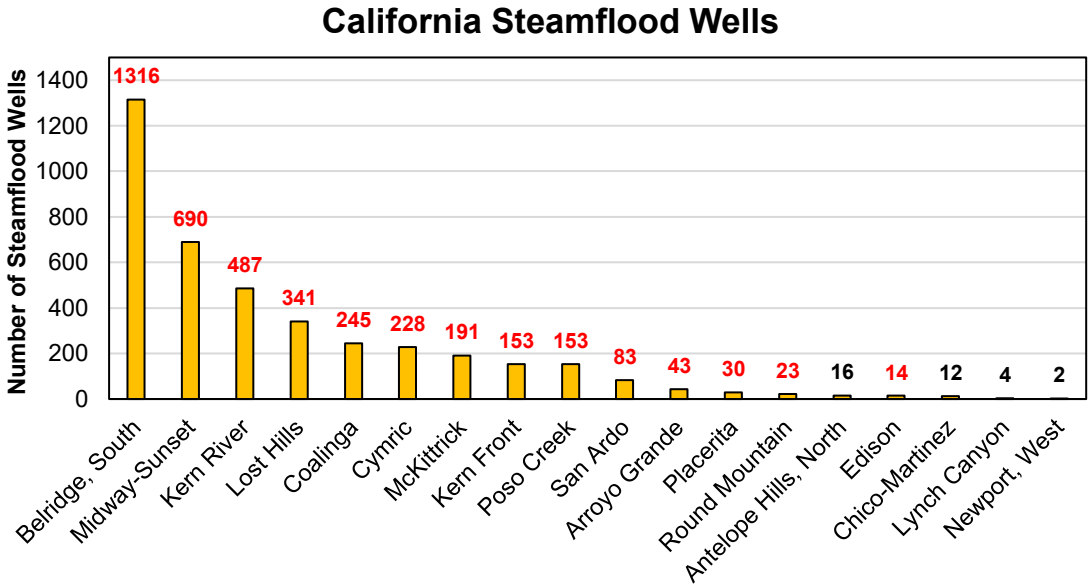

Figure 11: Steamflood wells in California based on 2020 data. The number of steamflood wells in each oilfield is labeled. The oilfields that are also in the top 20 for upstream emissions have red labels.

Notably, of the 19 oilfields with cyclic steam wells, 15 rank in the top 20 for their contribution to upstream emissions from California-sourced oils. Of the 18 oilfields with steamflood wells, 14 rank in the top 20 for their contribution to upstream emissions. Also, four of the top five oilfields in terms of upstream emissions rank highly in terms of numbers of steam wells: Kern River, Midway-Sunset, and Cymric are 1, 2, and 3, respectively, for number of cyclic steam wells while South Belridge, Midway-Sunset, and Kern River are 1, 2, and 3, respectively, for number of steamflood wells. The top five oilfields for upstream emissions (the four mentioned, plus San Ardo) together have 70% of California's steamflood wells and 90% of California's cyclic steam wells, or 85% of California's total steam wells (cyclic steam + steamflood).

There is significant overlap in California between fracking permits, enhanced oil recovery and the most carbon-intensive oil extraction.

In 2020, 1,929 oil and gas drilling permits were issued in California with 1,052 of them, or 55%, going to the top five fields contributing the most to greenhouse gas emissions. Of the top five fields, South Belridge received the most with 351, then Midway-Sunset with 346, Cymric with 221, Kern River with 111 and San Ardo with 23.

Of the total permits, 1,359 were for oilfields in the top 20 for carbon intensity (Figure 6).

Finally, of the total permits, 65 were for cyclic steam wells and 64 were for steamflood wells. Out of the 129 total cyclic steam and steamflood well permits, 78 permits, or 60%, were for fields in the top five for greenhouse gas emissions.

In 2020, 84 permits for fracking were issued with 24, or 29%, for South Belridge. Another 36, or 43%, were issued for Lost Hills Oil Field. Lost Hills has not been previously mentioned, but it is noteworthy as number seven in terms of oilfield greenhouse gas emissions. The remaining permits were granted to North Belridge which is number 22 in terms of oilfield greenhouse gas emissions.

As is the case with existing enhanced oil recovery wells, the oilfields being granted oil and gas drilling and fracking permits are those that already contribute the most to California oil's greenhouse gas emissions, hence maintaining a vicious cycle.

ABSTRACT

The Human-induced Earthquake Database, *HiQuake*, is a comprehensive record of earthquake sequences postulated to be induced by anthropogenic activity. It contains over 700 cases spanning the period 1868–2016. Activities that have been proposed to induce earthquakes include the impoundment of water reservoirs, erecting tall buildings, coastal engineering, quarrying, extraction of groundwater, coal, minerals, gas, oil and geothermal fluids, excavation of tunnels, and adding material to the subsurface by allowing abandoned mines to flood and injecting fluid for waste disposal, enhanced oil recovery, hydrofracturing, gas storage and carbon sequestration. Nuclear explosions induce earthquakes but evidence for chemical explosions doing so is weak. Because it is currently impossible to determine with 100% certainty which earthquakes are induced and which not, *HiQuake* includes all earthquake sequences proposed on scientific grounds to have been human-induced regardless of credibility. Challenges to constructing *HiQuake* include under-reporting which is ~30% of M ~4 events, ~60% of M ~3 events and ~90% of M ~2 events. The amount of stress released in an induced earthquake is not necessarily the same as the anthropogenic stress added because pre-existing tectonic stress may also be released. Thus earthquakes disproportionately large compared with the associated industrial activity may be induced. Knowledge of the magnitude of the largest earthquake that might be induced by a project, M_{MAX}, is important for hazard reduction. Observed M_{MAX} correlates positively with the scale of associated industrial projects, fluid injection pressure and rate, and the yield of nuclear devices. It correlates negatively with calculated inducing stress change, likely because the latter correlates inversely with project scale. The largest earthquake reported to date to be induced by fluid injection is the 2016 M 5.8 Pawnee, Oklahoma earthquake, by water-reservoir impoundment the 2008 M ~8 Wenchuan, People's Republic of China, earthquake, and by mass removal the 1976 M 7.3 Gazli, Uzbekistan earthquake. The minimum amount of anthropogenic stress needed to induce an earthquake is an unsound concept since earthquakes occur in the absence of industrial activity. The minimum amount of stress *observed* to modulate earthquake activity is a few hundredths of a megapascal and possibly as little as a few thousandths, equivalent to a few tens of centimeters of water-table depth. Faults near to failure are pervasive in the continental crust and induced earthquakes may thus occur essentially anywhere. In intraplate regions neither infrastructure nor populations may be prepared for earthquakes. Human-induced earthquakes that cause nuisance are rare, but in some cases may be a significant problem, e.g., in the hydrocarbon-producing areas of Oklahoma, USA. As the size of projects and density of populations increase, the potential nuisance of induced earthquakes is also increasing and effective management strategies are needed.

1. Introduction

Natural processes that modulate the spatial and temporal occurrence of earthquakes include tectonic stress changes, migration of fluids in the crust, Earth tides, surface ice and snow loading, heavy precipitation, atmospheric pressure changes, sediment unloading and groundwater loss (e.g., Kundu et al., 2015). Such processes perturb stress on faults by only small amounts but, since rock failure in earthquakes is a critical process, nucleation of each event is ultimately brought about by a final, incremental change in stress. It is thus unsurprising that anthropogenic activity that perturbs stress in the crust, even slightly, can modulate seismicity. In most cases such effects probably go unnoticed (Section 7.1) but as industrial projects proliferate and grow in scale the number of cases where a link is obvious is increasing.

Mining- and dam-induced earthquakes have been recognized for several decades. Now concern is growing about earthquakes induced by hydraulic fracturing for shale-gas extraction and waste-water disposal

by injection into boreholes. Seismicity may also increase in hydrocarbon reservoirs as they enter their late phases of production. The full extent of human activities that may induce earthquakes is, however, wider than generally appreciated. We conducted an extensive search to build as complete a catalog as possible of cases of induced seismicity reported to date. Our work expands previous reviews that include a general overview by McGarr et al. (2002), lists by Nicol et al. (2011) and Suckale (2009), and a review of 198 M ≥ 1 events by Davies et al. (2013). Our new database of human-induced earthquakes, *HiQuake*, contains over 700 cases of anthropogenic projects postulated to induce earthquake activity. It is publically available at www.inducedearthquakes.org (Wilson et al., 2017).

We constructed *HiQuake* by searching for case histories in published papers, conference abstracts, books, reports and the world-wide web, and through personal communications. The credibility of individual cases varies from extremely low to overwhelming, with most cases in between. There is no rigorous way of quantifying the likelihood that a particular claim for human induction is correct, and many arguments for anthropogenesis are presented as tentative by authors and challenged by other researchers, e.g., the 1983 M_W 6.2 Coalinga, California, event (Section 3.3.2). There is thus no rigorous way of defining a "credibility cut-off" below which a case history should be excluded from the database. For this reason we adopted the only reliable policy which was to include all cases without regard to plausibility. *HiQuake* thus lists all projects proposed on scientific grounds (not religious or moral) to have induced earthquakes and judgment regarding the credibility of any individual case is the responsibility of the user. *HiQuake* therefore comes with a caveat emptor. It is up to the database user to judge the strength of arguments for anthropogenic induction of any particular case included. For convenience, details of our information sources are included in the database.

In this paper we present the basics of relevant, fundamental, but sometimes-misunderstood background issues. Following this we give examples of seismicity postulated to be related to:

a) Surface operations,
b) Extraction of mass from the subsurface,
c) Introduction of mass into the subsurface, and
d) Explosions.

We sub-divide each category. In some cases, categorization is tentative because more than one anthropogenic process preceded or was ongoing at the time of the earthquakes, e.g., fluid extraction and injection are often conducted simultaneously in hydrocarbon reservoirs. Finally, we summarize features of the database and comment on related issues with which scientists are currently grappling.

1.1. Intraplate earthquakes

Plate tectonic theory in its simplest form considers plates to be rigid and expects most large earthquakes to occur in plate boundary zones. The fact that intraplate earthquakes occur, and may be large, is prima facie evidence that the plates are not rigid but also deform in their interiors. Intraplate stress changes cyclically as stress diffuses through them following the great[1] earthquakes and volcanic events that sum to bring about what geologists model as smooth plate movements (Foulger et al., 1992; Heki et al., 1993). The configuration of plate boundaries is geometrically unstable and evolving. For example, in Europe the formation of extensional features such as the Rhine Graben (Germany) is likely a consequence of southerly migration of the collision zone between Africa and Europe ("slab roll-back"). Intraplate European seismicity is probably related to the same process (Fig. 1) (Nielsen et al., 2007).

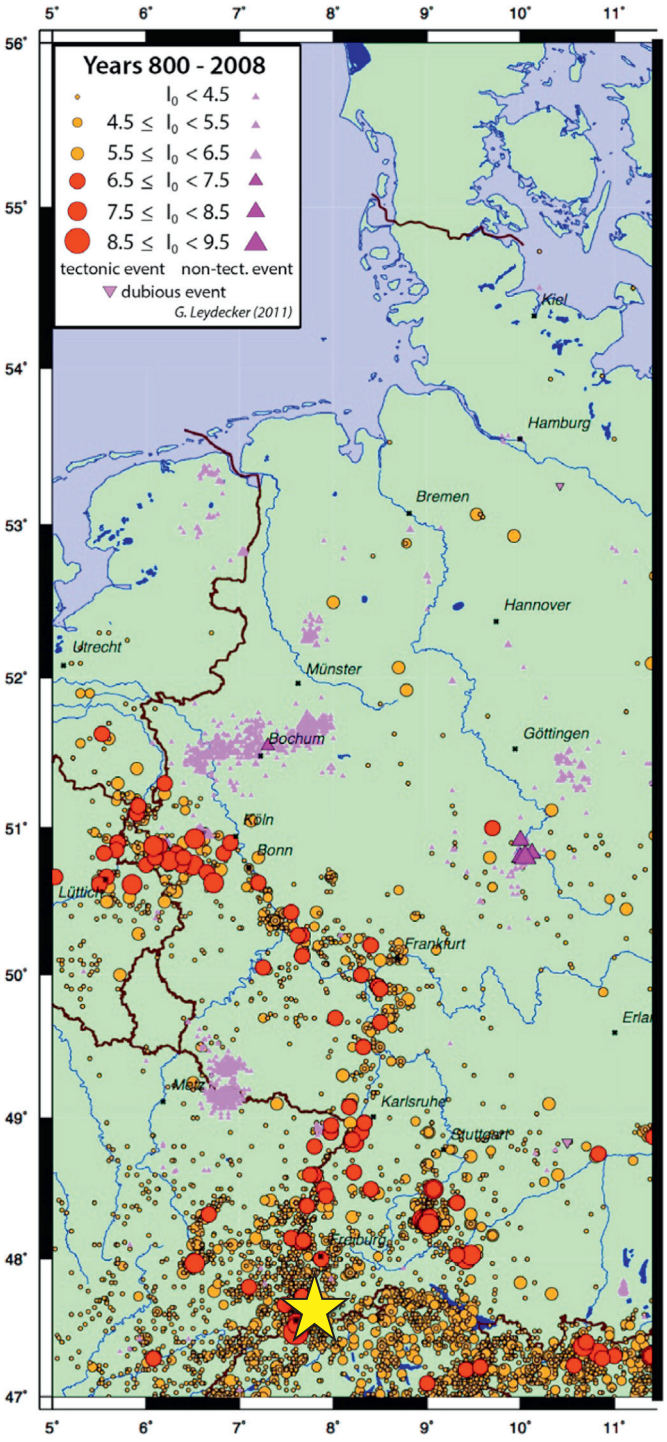

Fig. 1. Map of central Europe showing historical earthquakes with different epicentral intensities from 800 CE (from Stein et al., 2015). Yellow star: city of Basel, Switzerland.

Intraplate seismicity is commonly assumed to be spatially stable so future earthquakes occur where events have occurred in the past. This assumption has recently been re-visited as a result of geodetic work done in the New Madrid Seismic Zone, USA (e.g., Newman et al., 1999; Stein et al., 2009). There, it is generally expected that future large earthquakes will follow the damaging 1811–1812 sequence of four M ≥ 7 earthquakes (e.g., Johnston and Schweig, 1996). As a result, significant resources have been invested in earthquake hazard mitigation. Recent GPS surveying has, however, failed to detect any ongoing

[1] Earthquakes are classified as Great (8 or more), Major (7–7.9), Strong (6–6.9), Moderate (5–5.9), Light (4–4.9) and Minor (3–3.9).

strain build-up (Stein et al., 2009). This led to the proposal that the spatial distribution of intraplate earthquakes in general is not stationary and that the locations of past large earthquakes are not a good predictors of future earthquakes (Liu and Stein, 2016). Wrong forecasts of the location of future large earthquakes may lead to inefficient deployment of hazard-reduction resources and thus have significant implications for public safety.

A non-stationary spatial pattern of seismicity accords with evidence that the crust is critically stressed in most intraplate regions. Stress measurements made in boreholes commonly show that stress is close to the depth-dependent strength of the crust as estimated by laboratory experiments (e.g., Brudy et al., 1997; Zoback and Healy, 1984). The ambient pore pressure is generally close to hydrostatic, the crust is pervasively faulted, and faults that are well oriented for slip in the ambient stress field are commonly close to failure. This is consistent with observations that human-induced seismicity may occur, and even be large, in regions that have been historically aseismic.

1.2. Induced, triggered, stimulated, and nuisance earthquakes

Many if not all earthquakes induced by human activity release more stress than artificially added to the crust. McGarr et al. (2002) suggested the terms "induced" for earthquakes where the stress change caused by human activity is comparable to the shear stress causing a fault to slip, "triggered" where the anthropogenic stress change is much smaller, and "stimulated" where there are insufficient data to make the distinction.

It is beyond dispute that in many cases seismic strain energy released in earthquakes is many orders of magnitude larger than that introduced into the crust by the industrial activity. In this paper, however, we use the term "induced" for all earthquakes related to human activity because:

a) All earthquakes probably release some pre-existing strain energy and are thus likely to be "triggered". Only where rock is entirely unstressed initially could this not be so and that is not possible in a heterogeneous, gravitating half-space. Even nuclear tests, which are purely explosive sources, trigger the release of some regional tectonic stress as shown by shear components in their focal mechanisms (e.g., Toksöz and Kehrer, 1972).
b) The amount of tectonic strain energy loaded into the crust that is relieved seismically, on what time-scale, and the amount released aseismically are poorly understood. In rapidly deforming regions aseismic deformation can be measured geodetically (e.g., Heki et al., 1997) and surface subsidence is commonly observed above producing reservoirs (e.g., the Wilmington Oilfield, California; Kovach, 1974; Nagel, 2001). Only a fraction of the total strain energy is relieved seismically but it is difficult to determine what this fraction is. Surface geodetic data have low sensitivity to fault motion at depth. Estimates of the percentage of strain energy dissipated aseismically vary from ~20% to 1000% of that released seismically (Villegas-Lanza et al., 2016). The recent under-prediction of the magnitude of the 2011 M_W 9 Tohoku-oki, Japan, earthquake which killed >18,000 people and did incalculable economic damage, showed that our assumptions regarding the length of the "seismic cycle" may be incorrect. Even large earthquakes may not relieve all the stress on a fault so our ability to estimate long-term stress buildup in the crust is limited. The same considerations hold true for industrial projects. If the timescale of energy release is underestimated, and with it the size of the largest expected earthquake (which dominates the energy budget because of the fractal nature of earthquake magnitudes), the maximum expected earthquake magnitude (M_{MAX}) may be underestimated.
c) It is at best impractical and at worst fundamentally impossible to determine how much of the strain energy released in a seismic event pre-existed. Even in cases where the energy released is comparable to that industrially added (e.g., McGarr, 1991), much of the latter may have been relieved by aseismic deformation such as ground subsidence or inflow of water at depth. These processes may themselves trigger earthquakes or load adjacent regions to seismic failure (e.g., Guglielmi et al., 2015).

We use the term "induced" neutrally, and without implications for the origin of the total seismic stress change, in accord with the usage of the Committee on Induced Seismicity Potential (Hitzman, 2013). That committee uses the term "induced" to mean "earthquakes related to human activities".[2]

We use the term "nuisance" earthquakes for those that cause societal inconvenience. This inconvenience may be physical or psychological. It includes objectionable damage to infrastructure or the environment, public concern, annoyance or distress about ground shaking, noise or environmental effects such as hydrological changes. Clearly no seismological parameter, e.g., magnitude or intensity of ground shaking, can quantify nuisance because it is dependent on the culture of those affected. Nuisance earthquakes are those that need health-and-safety management. That requires an evidence base to which it is hoped the present review will contribute.

1.3. Factors involved in the nucleation of earthquakes

Shear slip on fault planes, with or without crack-opening or closing components, is the most common earthquake source process. Factors involved in nucleation, i.e. the onset of motion, include:

- the coefficient of friction on the fault plane;
- compressive normal stress on the fault plane;
- pore pressure in the fault zone; and
- shear stress on the fault.

According to the widely used Coulomb Theory, the shear stress required for failure τ is

$$\tau = \tau_0 + \mu(\sigma_n - p) \quad (1)$$

where τ_0 is the cohesion, μ is the coefficient of friction, σ_n is the normal stress across the fault, and p is the pore pressure in the fault zone (e.g., McGarr et al., 2002). The onset of an earthquake may thus result from reduction of the cohesion or normal stress on the fault plane or increase in the shear stress or pore pressure.

The loss or gain of overlying mass, introduction of fluid into a fault zone, or the imposition of vertical and/or horizontal stress by other means, e.g., stress transfer from nearby earthquakes, can bring a fault closer to failure. Where there are rapid temperature changes, e.g., where cold water is injected into geothermal areas, thermal effects may also be a significant.

Both the addition and removal of material industrially is associated with earthquakes. Removal of water from aquifers (Section 3.1) and rock from mines (Section 3.2) may reduce the confining stress on fault planes. Introduction of water via reservoir impoundment (Section 2.1.1) or injection (Section 4.1) may alter the fluid pressure in fault zones. Cessation of groundwater pumping, e.g., out of mines, may result in influx of groundwater and increase in pore pressure (Section 4.1.7). Addition of solid mass at the surface may also alter hydrological

[2] *"Some researchers (e.g., McGarr et al., 2002) draw a distinction between "induced" seismicity and "triggered" seismicity. Under this distinction, induced seismicity results from human-caused stress changes in the Earth's crust that are on the same order as the ambient stress on a fault that causes slip. Triggered seismicity results from stress changes that are a small fraction of the ambient stress on a fault that causes slip. Anthropogenic processes cannot "induce" large and potentially damaging earthquakes, but anthropogenic processes could potentially "trigger" such events. In this report we do not distinguish between the two and use the term "induced seismicity" to cover both categories."* Quoted from Hitzman, M. W. (Ed.) (2013), Induced Seismicity Potential in Energy Technologies x + 248 pp., National Academies Press, Washington, D.C.

conditions (Section 2.1.2).

Theories for the mechanism of induced earthquakes include the asperity model of Pennington et al. (1986) which suggests that fluid extraction results in differential compaction or aseismic fault motion, increasing stress on locked faults. This stress is eventually relieved when asperities break. The poroelastic model of Segall (1985, 1992) suggests that declining pore pressures resulting from fluid extraction cause contraction of the reservoir rocks and stress build-up. *Ad hoc* theories for individual earthquakes may provide candidate explanations *a posteriori*. However, developing a method that can reliably predict *a priori* which industrial projects will induce earthquakes and which not remains a work in progress.

1.4. Earthquake locations

Earthquakes in the *HiQuake* database span the period 1868 to 2017. Seismological technology has improved vastly during this period, but even today the standard of monitoring is non-uniform. Many projects may not be monitored at all until nuisance seismicity begins. In contrast, others may be monitored by dense seismic networks installed well in advance to obtain a pre-operational baseline (e.g., Cladouhos et al., 2013). As a result, data in *HiQuake* such as locations, magnitudes and focal mechanisms are non-uniform in quality.

Inaccurate hypocentral locations hamper efforts to associate earthquakes with operations, especially if the errors are larger than the separation between boreholes or producing horizons. An example is the case of the Crooked Lake, Alberta, earthquake sequences, thought to have been induced by shale-gas hydrofracturing (Section 4.1.6) (Schultz et al., 2015). A pre-operational seismic baseline was not available for medium-magnitude earthquakes, there was little information on local crustal structure, and most of the seismic data were from stations > 100 km away. As a result, it is unclear whether the lack of spatial correlation of some events with operations is real or a consequence of inaccurate locations.

The largest source of hypocentral uncertainty is imperfect knowledge of crustal structure. This factor is not included in the error estimates computed by many commonly used hypocenter-location programs which typically base uncertainty estimates on root-mean-square arrival-time residuals, assuming no errors in the crustal model used. Such residuals may be unrealistically small for systematically mislocated hypocenters. Advanced earthquake location methods using relative locating ("double-differencing"; Waldhauser and Ellsworth, 2000) or waveform cross-correlation (Got et al., 1994) can improve the accuracy of locations *relative to one another* but do not reduce systematic errors in the absolute locations. Accurate depths may be out of reach if geometrically strong data are unavailable. Errors in hypocentral depth are typically 2–3 times the error in horizontal (epicentral) location. Insufficient stations and sparse networks are also hindrances (Section 4.2.1).

Obtaining accurate local crustal velocity models in the neighborhood of small-scale industrial projects may be challenging. Information may be limited to well-logs, global or national crustal models, or models from analogous geological areas (e.g., Schultz et al., 2015). Such models are not adequate for reducing location uncertainties to sub-hectometer (100 m) levels. Ideally, high-quality crustal models based on active-source seismic surveying and/or one- and three-dimensional inversions of local earthquake data will be available. Projects will be monitored by dense networks of seismic stations with stations every 1–2 km^2. Experimental designs of this kind can return locations accurate to about a hectometer. Reducing errors still further requires calibration shots (Foulger and Julian, 2014).

In order to inform discussions regarding whether earthquakes are induced or natural, a pre-operation baseline is required. For this purpose, seismic networks must be deployed prior to commencement of operations. An effort to establish such a baseline for the entire UK prior to possible expansion of shale-gas hydrofracturing was recently made by Wilson et al. (2015).

1.5. Earthquake magnitudes

Magnitudes given for earthquakes often differ by up to a whole magnitude unit because:

- Traditional scales such as local magnitude (M_L) use measurements of the amplitudes of certain seismic phases recorded on seismic stations. Amplitudes are a poor measure of the size of an earthquake because they are influenced by factors such as the orientation of the fault that slipped and source-to-station crustal structure. Because of these and other factors, measurements at different stations may yield different magnitudes for the same earthquake.
- Different magnitude scales such as M_L and surface-wave magnitude (M_s) use different types of seismic waves, resulting in both systematic and random differences in the magnitudes calculated. For example, shallow earthquakes excite stronger surface waves than deep earthquakes, so M_S underestimates the sizes of deeper earthquakes compared with M_L.
- Seismological practice is notoriously non-standard in respect of magnitudes, and local magnitude scales and practices often depart considerably from those originally defined. Many local seismic stations and networks use their own customized magnitude scales, often constructed by calibrating them using a few earthquakes measured in common with the nearest permanent or calibrated station. That station may in turn have been calibrated in the same way. M_L technically refers to recordings made on Wood-Anderson seismographs, but such instruments are now rare. As a result, magnitudes reported from one seismic network may not be comparable to those reported from another, even if the same magnitude scale has, in theory, been used.

It is beyond the scope of this paper to render all magnitudes to a single scale and in this paper we therefore do not discriminate between magnitude types reported. We record the information currently available in the *HiQuake* database, e.g., M_L (local magnitude), m_b (body-wave magnitude), M_S (surface-wave magnitude), M_d (duration magnitude) and M_W (moment magnitude). Where magnitude type is not specified we use the notation M. Where several different estimates are published, we preferentially cite M_W. If M_W is not available, and more than one other magnitude has been published, we cite the largest. Rendering all the magnitudes to M_W is a task for future work.

1.6. Earthquake counts

The total number of earthquakes detected for a sequence depends on the density of seismic monitoring. This may change with time, e.g., if additional seismic stations are installed after nuisance seismicity has begun. Earthquakes are a fractal phenomenon, and their numbers increase by about an order of magnitude for each reduction in magnitude unit. If earthquake counts are to be meaningfully compared, they must thus be related to a common low-magnitude cut-off threshold.

The numbers of earthquakes induced may be of interest where monitoring networks are stable since this parameter may serve as a sensitive strainmeter. As a result, earthquake counts have been particularly useful for monitoring active volcanoes. The availability of many earthquakes is an advantage for purposes such as tracking injected fluids. From the point of view of potential damage the earthquakes of most relevance are the relatively few large-magnitude events and possibly only the largest (M_{MAX}).

1.7. The database

The approach we used to construct the database is described in detail by Wilson et al. (2017). Challenges intrinsic to the task included:

Table 1
Data recorded in the database.

Column contents
Country
Project name
Project type (subclass)
Longitude
Latitude
Project end date
Project start date
End date of seismicity or monitoring
Start date of seismicity or monitoring
Magnitude type
Delay time
Date of largest earthquake
Depth of largest earthquake
Distance of largest earthquake from induction activity
Year of largest earthquake
Lithology/resource
Distance of furthest earthquake from induction activity
Depth of induction activity
Typical depth of earthquakes
Previous seismicity
Tectonic setting
Injection/extraction rate
Dam height
Total volume or mass injected/extracted
Units of injection/extraction rate
Maximum wellhead pressure during injection
Units of total volume or mass injected/extracted
Stress change postulated to have induced earthquake
Change in reservoir pressure
Bottom-hole temperature
Area of project

Project type

- Incomplete reporting (Section 7.1);
- Ambiguous reporting, e.g., “Seismicity is not reported”;
- Lack of reported data, e.g., operational parameters not given;
- Uncertainty regarding whether or not the earthquakes were induced, e.g., some postulated associations are based simply on short-term temporal correlations or weak spatial correlations unsupported statistically and possibly coincidences. We dealt with this by including all cases (Section 1);
- Multiple possible induction processes ongoing simultaneously, e.g., hydrocarbon extraction and wastewater injection;
- Non-uniformity of magnitude reporting (Section 1.5). We report M_W if available, and if not the largest other magnitude;
- Lack of suitable networks to detect earthquakes. For some studies, instruments were installed only after the onset of seismicity (Section 1.4);
- Poor location accuracies (Section 1.4).

A list of database column headings is given in Table 1. The full *HiQuake* database is available as an Excel spreadsheet and references as an EndNote library at http://www.inducedearthquakes.org.

1.8. Earthquakes and belief systems

Public attitudes to induced earthquakes may have major implications for industrial projects, but human reactions to earthquakes may not be based on science. Because of their apparently chaotic and spontaneous nature, and lack of obvious direct causes, earthquakes have for millennia been explained in terms of folklore, religion, and other belief systems (e.g., Harris, 2012). This includes Chinese, Russian and Japanese folklore and the religions of the ancient Greeks and Polynesians. All three mainstream Abrahamic religions–Christianity, Islam and Judaism–are based on ancient texts that attribute earthquakes to shortfalls in human moral behavior.

Recent cases where belief-system-based explanations for earthquakes have had significant societal impacts include:

- In 2015, the Malaysian government attributed a M_W 6.0 earthquake that killed 18 people to tourists posing nude on Mt. Kinabalu, one of the country's sacred mountains.
- In 2014 local people in the Altai Mountains, Siberia, attributed earthquakes to the removal of the mummified remains of a 5th-century BC noblewoman for archaeological research.
- In 2010, the American evangelist Pat Robertson attributed the devastating M_W 7.0 Haiti earthquake to an alleged “pact to the Devil” made by escaped slaves to ensure success of the successful 1791–1804 anti-slavery insurrection on the island.

These examples illustrate the importance of public information and outreach when planning industrial projects that might induce earthquakes.

2. Surface operations

2.1. Adding mass

Earthquakes have been postulated to have been induced by three kinds of surface-mass addition. These are water impoundment behind dams (168 cases), erecting heavy buildings (1 case), and engineering coastal sediments (1 case).

The earliest report of earthquakes induced by water reservoir impoundment is from Reservoir Mead, Nevada and Arizona, USA (Carder, 1945). Several probable water-reservoir-induced earthquakes have resulted in fatalities and extensive property damage. The largest earthquake claimed to have been induced in this way is the 2008 M ~8 Wenchuan, China, earthquake, which has been associated with impoundment of the reservoir behind the Zipingpu dam. Reports of earthquakes induced by erecting heavy buildings and engineering coastal sediments are, in comparison, rare.

2.1.1. Water impoundment behind dams

A well-studied example is that of the Koyna Dam, India (Fig. 2). A detailed overview of this case, along with a review of reservoir-induced earthquakes, is given by Gupta (2002). The 103-m-high Koyna Dam was raised in 1962 and contains a reservoir up to 75 m deep and 52 km long. Five years after it was completed, a sequence of earthquakes with magnitudes up to M_S 6.3 occurred causing ~200 deaths and slightly damaging the dam. The largest earthquake nucleated at shallow depth, probably < 5 km, and its epicenter was ~10 km downstream from the dam. Earthquake activity has continued subsequently, correlating to some extent with water level in the reservoir (Fig. 3) (Talwani, 1995). A M > 5 event occurs there about every four years.

A second notable example is the Nurek dam, Tadjikistan (Keith et al., 1982; Leith et al., 1981; Simpson and Soboleva, 1977; Simpson and Negmatullaev, 1981). Building of this dam began in 1961 and, at 317 m, it is currently the highest in the world. It contains a reservoir ~10 km^3 in volume (Fig. 4). The largest earthquake to have occurred there to date is the 1972 M_S 4.6 event (Simpson and Negmatullaev, 1981). Seismicity is ongoing and there is evidence for correlation with periods of increase in water depth (Fig. 5).

The largest-volume reservoir in the world is 1.64×10^{11} m^3 and is contained by the 111-m-high Aswan dam, Egypt. Earthquakes induced there are thought to occur in two depth intervals i.e. ~0–10 km and ~15–25 km (Figs. 6 and 7). This vertical separation is postulated to indicate two different processes/environments of induction (Awad and Mizoue, 1995). The largest earthquake observed there to date is the 1981 M 5.7 earthquake, thought to have nucleated in the deeper zone.

A rare case where induced seismicity damaged the dam itself is that

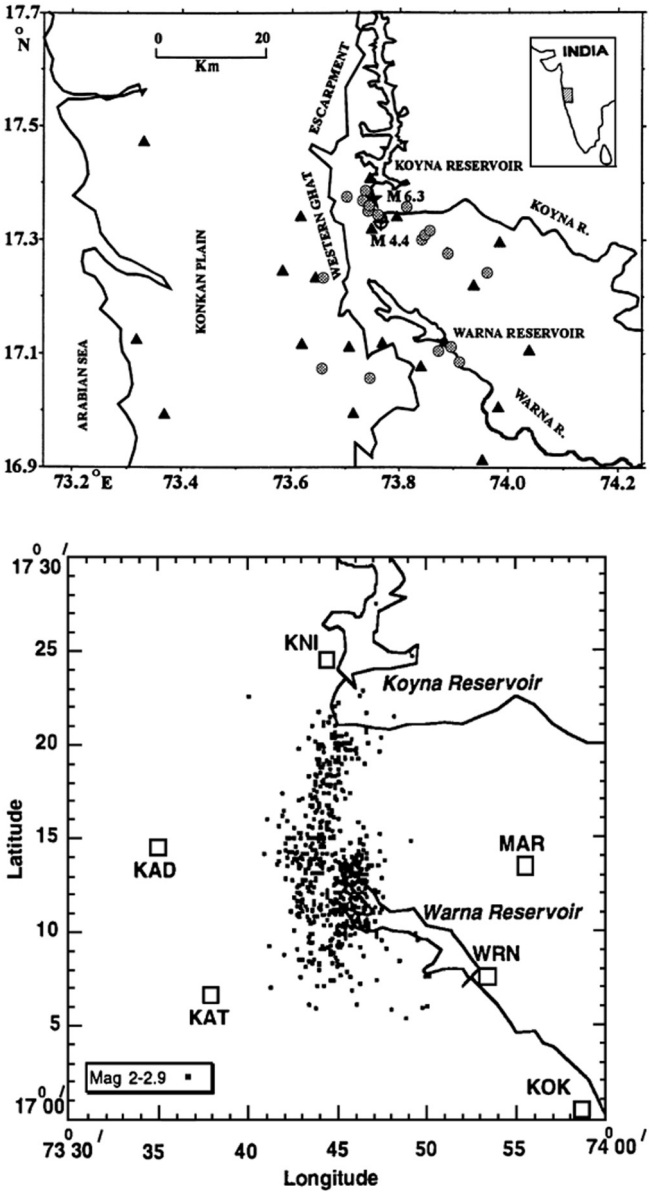

Fig. 2. Top: Map of Koyna area, India, showing the dam, reservoir, seismic stations (triangles) and boreholes (dots). Bottom: Same area showing earthquakes with M 2–2.9 for the period October 1993 to December 1994.
(From Gupta (2002).)

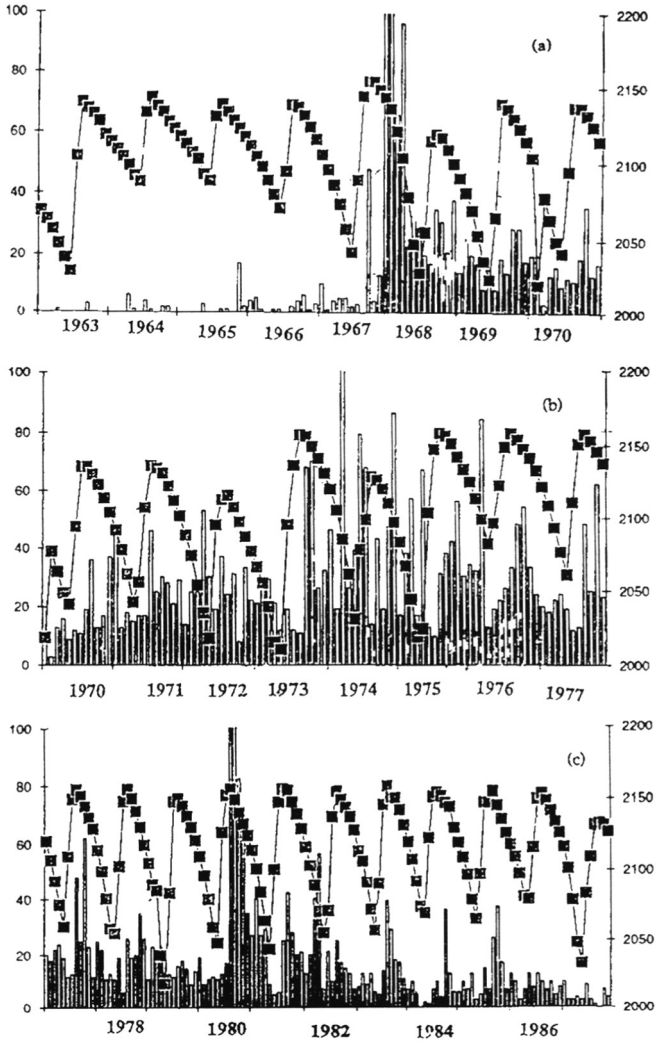

Fig. 3. Number of earthquakes in the region of the Koyna dam, India, for the period 1963–1986 (left axes), along with reservoir water level (right axes, in m).
(From Talwani (1995).)

of the 105-m-high Xinfengjian Reservoir, China. Impoundment of the 1.39×10^{10} m^3 volume reservoir began in 1959 and seismic activity started a month later. A M_S 6.1 earthquake occurred in 1962 which caused minor cracking of the dam.

A case of particular interest is that of the May 2008 M_W ~8 Wenchuan, China, earthquake (Fig. 8). This earthquake was so large relative to the height of the nearby Zipingpu dam (156 m) and the volume of the reservoir (~10^9 m^3) that it is controversial whether it was induced or not. It occurred ~20 km from the dam within months of full reservoir impoundment. The earthquake caused ~90,000 deaths, collapsed roads and bridges, and serious damaged >100 towns.

The activated zone lies at the transition between the low-strain-rate (<10^{-10}/year), stable Sichuan Basin and the tectonically active Tibet plateau where strain rates are >10^{-8}/year. The transition is marked by the multi-stranded Longmenshan fault zone which accommodates thrust and strike-slip motion. Paleoseismic work suggests an earthquake recurrence time of ~7000 years for M 7–8 earthquakes (Klose, 2012).

Prior to impoundment of the reservoir there had been ~40 recorded earthquakes per month in the vicinity of the dam. In October 2005, seismicity increased as impoundment started and the water level rose rapidly by ~80 m. The water level peaked in October 2006 at ~120 m above pre-impoundment levels. Earthquake activity surged to ~90 events per month but reduced thereafter (Fig. 9).

The 2008 M_W ~8 mainshock nucleated at ~16 km depth and thrust motion propagated up toward the surface beneath the reservoir. Rupture transitioned to strike-slip motion and propagated laterally along the fault in both directions, rupturing >300 km of the Longmenshan thrust belt with an average slip of 2.4 m, peaking at 7.3 m. The source time function, which lasted 90 s, indicated that failure occurred in five sub-events that sequentially released 9%, 60%, 8%, 17% and 6% of the total moment (Fig. 9) (Zhang et al., 2008, Yong Zhang, personal communication). The average stress drop during the earthquake was 18 MPa, peaking at 53 MPa. Like other great earthquakes, this event owed its large size to progressive activation of adjacent fault segments in a chain of sub-events.

The increase in shear and normal stresses, caused by the reservoir, that were orientated to encourage slip on the fault were no more than a few kPa (Klose, 2012). This is small, even compared with the stress changes associated with Earth tides (Section 7.3). Klose (2012) suggests that the additional stress modulated the timescale on which the earthquake occurred, advancing it in time by ~60 years. It has been much disputed whether such a small stress perturbation was sufficient

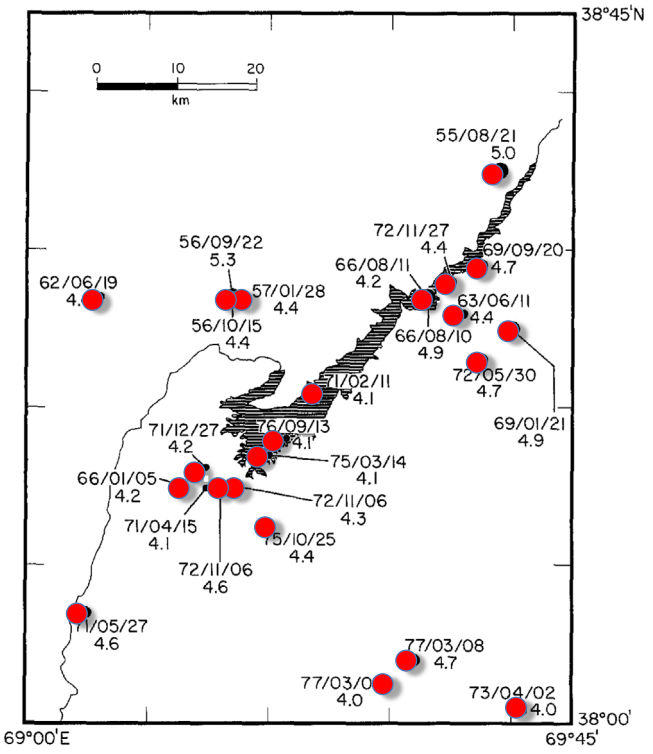

Fig. 4. Map of Nurek dam and reservoir, Tadjikistan, showing earthquakes with M ≥ 4.0 for 1955–1979.
(From Simpson and Negmatullaev (1981).)

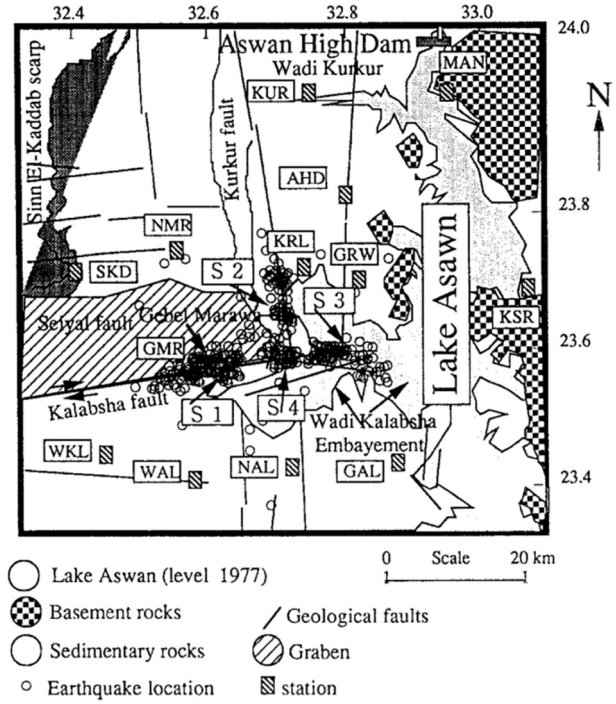

Fig. 6. Map showing Lake Aswan, Egypt, and epicenters of induced earthquakes. (From Awad and Mizoue (1995).)

to trigger such a large earthquake. A more relevant question is whether the reservoir could have induced the initial M_W ~7.5 sub-event, since it is that sub-event which started the cascade of segment failures that grew the earthquake to M_W ~8.

An unusual dam-related seismic sequence occurred in association with the Beni Haroun hydraulic complex in the Mila region, 30 km west of the city of Constantine, Algeria (Semmane et al., 2012). This complex comprises a main dam 120 m high and a reservoir with a capacity of ~10^9 m^3. It is connected by pipelines to the secondary Oued Athmania reservoir, ~15 km south of the main dam (Fig. 10). A 6-km section of pipeline passes through a mountain as a lined tunnel 1.4–3.6 m in diameter. To reach this part of the pipeline water is pumped up ~600 m higher than the Beni Haroun reservoir. The pipeline has a capacity of 600,000 m^3/day.

In 2007, a sequence of earthquakes up to M_d 3.9 occurred. It is thought to have been induced by leakage into the ground of ~400,000 m^3 of water as it was being pumped between the reservoirs. More than 7200 earthquakes were recorded over a ~2-month period. The water leaked from the tunnel via defective joints and penetrated deep into the ground via fractures, faults and karst cavities. Earthquakes started within days of the leakage (Fig. 10). The area had no prior record of such swarm activity and installation of the complex

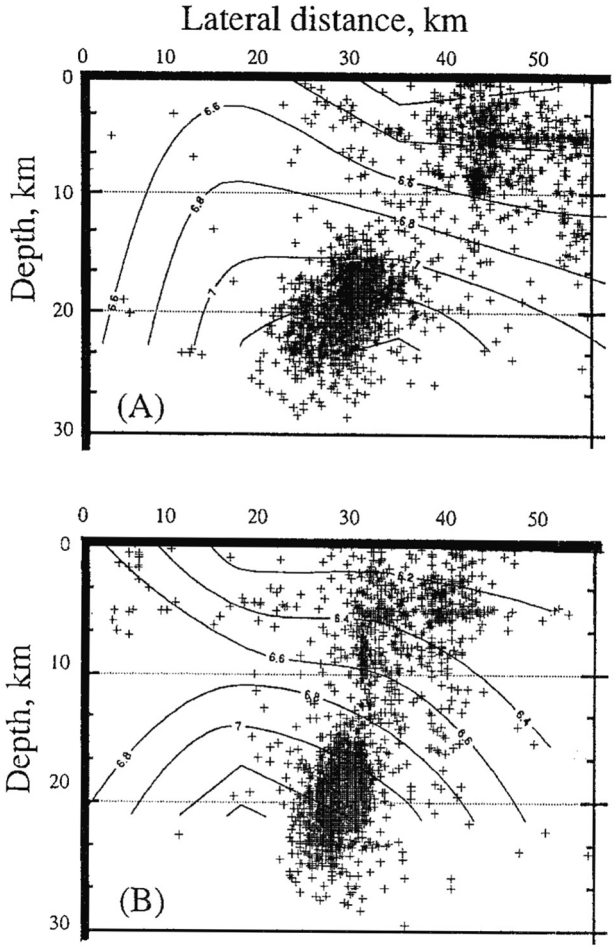

Fig. 7. Cross sections showing hypocentral distribution of earthquakes postulated to have been induced by impoundment of Lake Aswan.
(From Awad and Mizoue (1995).)

in 2000 had not been associated with an increase in seismicity. The events did no damage but were heard loudly and alarmed local people unaccustomed to earthquakes (Semmane et al., 2012).

The Colorado River, USA, contains numerous dams. The two largest are the 220-m-high Glen Canyon dam, a concrete arch that impounds Reservoir Powell, Arizona, and the Hoover dam, ~600 km further downstream, that impounds Reservoir Mead, mostly in Nevada. Glen Canyon dam is built in Mesozoic sedimentary rocks whereas the Hoover dam is built in Tertiary volcanics, part of the tectonically active basin-range province. In keeping with expectations, the latter is seismogenic but the former is not (Fig. 11).

Currently, attention is focused on the 181-m-high Three Gorges dam, China. Its 4×10^{10} m^3 water reservoir was fully impounded in 2010 and power generated came online in 2012. Total generation capacity is 22,500 MW. The area lies in a seismogenic region that includes two major fault lines. The reservoir is not the largest in the world, but earthquakes are already being reported with a M_L 4.6 event occurring in 2014.[3]

2.1.2. Erecting tall buildings

Lin (2005) suggested that erection of the ~500-m high Taipei 101 building, Taiwan, influenced the pattern of seismicity in the immediate neighborhood of the building. This 7×10^8 kg building increased stress on the ground at its base by ~0.47 MPa. In the eight-year period prior to building, nine earthquakes with $M_L \leq 2.0$ occurred whereas during the eight-year period that spanned construction and followed it, 20 earthquakes up to M 3.8 occurred. Earthquakes were unusually frequent during the construction period (Fig. 12).

This is the only published case to date proposing earthquakes were induced by erecting a heavy building. Taiwan lies in a convergent plate boundary zone where the Philippine Sea plate subducts beneath the Eurasian plate at the Manila trench. As a consequence it is seismically active.

This case raises the question of whether other such examples exist, e.g., in Japan. The building that is currently the tallest in the world, the 825-m-high Burj Khalifa, Dubai, weighs less than the Taipei 101 building, at only 4.5×10^8 kg. There are no known reports of changes in earthquake activity from the New York or Tokyo regions where large buildings are common, though to our knowledge the issue has not been studied in detail.

2.1.3. Coastal land gain

Klose (2007b) suggested that the 2007 M_L 4.2 Folkestone, Kent, UK, earthquake was triggered by geo-engineering of shingle accumulation in the harbor since 1806. There is substantial coastal land loss as a result of erosion to the southwest and northeast of Folkestone, but land gain by artificial shingle accumulation in Folkestone harbor has been ongoing for ~200 years. An estimated total of $\sim 2.8 \times 10^9$ kg had accumulated by 2007, four times the mass of the Taipei 101 building. This altered the stress by an estimated 0.001–0.03 MPa at 2 km depth. The earthquake epicenter lay ~1 km (epicentral error ~ 5 km) from the shingle, and nucleated at shallow depth.

2.2. Surface operations: removing mass

Operations that remove mass from the surface and are reported to induce earthquakes are limited to quarrying. *HiQuake* contains 16 such cases. The largest earthquake that has been associated with quarrying is the 2013 M 6.1 Kuzbass, Siberia, event (Emanov et al., 2014; Yakovlev et al., 2013). It occurred in the Bachatsky open-cast coal mine which is 10 km long, 2.2 km wide, excavated up to 320 m deep, and produces $> 9 \times 10^6$ t of coal per year. The earthquake collapsed buildings in local communities and was felt in neighboring provinces.

Moderate earthquake activity had been detected in the mine in early 2012 when a M_L 4.3 event and associated aftershocks occurred. A dense local seismic network was installed, and recorded a low level of small earthquakes with magnitudes up to ~M_L 2. Event magnitudes increased with time, and 15 months later a M_L 3.9 event occurred followed a month later by the M 6.1 mainshock.

2.3. Surface operations: summary

The impoundment of water in reservoirs behind dams induces earthquakes in abundance and accounts for 168 (24%) of all cases in *HiQuake*. Ignoring natural lakes where dams have made minor changes to the water level, reservoirs are up to 8502 km^2 in area (Lake Volta, behind the Akosombo Dam, Ghana). Earthquakes may thus be induced throughout relatively large regions.

Eight cases of induced earthquakes with M > 6 have been proposed, associated with the dams at Zipingpu (China), Lake Hebgen (USA) (Klose, 2013), Polyphyto (Greece), Koyna (India), Kariba (Zambia/Zimbabwe), Kremasta (Greece), Hsingfengkiang (China) and Killari (India). In China there are 348 reservoirs with volumes exceeding 0.1 km^3. Of these, 22 (6.3%) are reported to be seismogenic.

Gupta (2002) reviews theories for the mechanism of triggering. Stresses induced by reservoirs at the depths where earthquakes occur are small, perhaps of the order of 0.1 MPa. This is much smaller than the 1–10 MPa stress drops that are typical in earthquakes. They are, nevertheless, larger than seismogenic Earth tidal stresses (Section 7.3). The mechanism of induction may be that the surface load alters

(From Zhang et al. (2008).)

hydraulic conditions at depth, causing fluid to migrate into fault zones and increase pore pressure. This may also explain the seismicity postulated to have been induced by the Taipei 101 building, Taiwan (Section 2.1.2) and shingle accumulation at Folkstone, UK (Section 2.1.3).

3. Extraction from the subsurface

3.1. Groundwater extraction

Five cases of earthquakes associated with artificial lowering of the water table have been postulated. The 2011 M_W 5.1 Lorca, Spain, event, suggested to have been induced by groundwater extraction (Fig. 13) (González et al., 2012), caused extensive damage to the town of Lorca, seriously damaging both modern and historic buildings, killing nine people and injuring several hundred (Fig. 14).

The region lies in a transpressive shear zone containing thrust- and strike-slip faults, in the Nubia-Eurasia plate boundary. The M_W 5.1 mainshock nucleated on the Alhama de Murcia fault at unusually shallow depth (~3 km). This fault has generated several large earthquakes over the past few centuries. Geodetic data from radar interferometry and GPS surveying constrained co-seismic deformation that

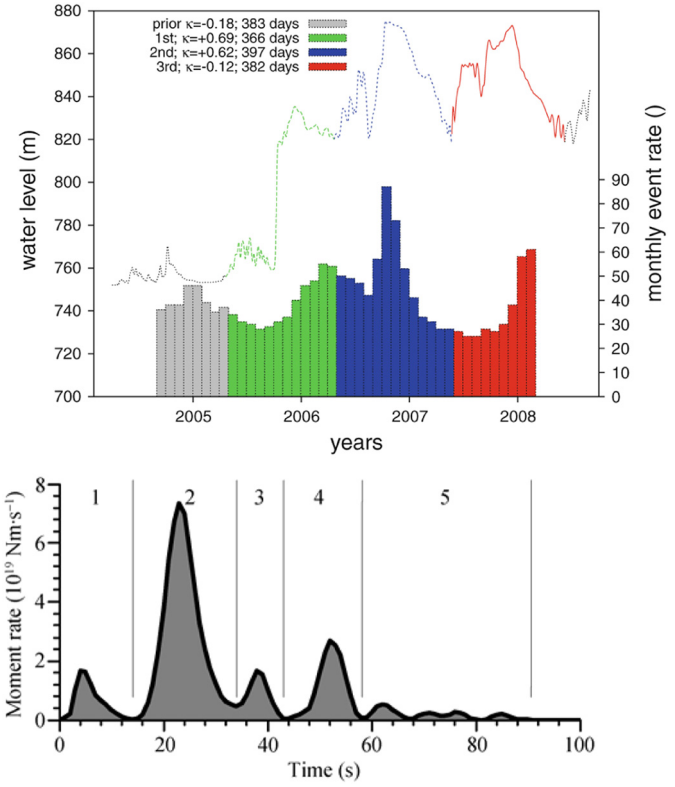

Fig. 9. Top: Water level change in the Zipingpu, China, water reservoir and earthquake event rate in the vicinity prior to the May 2008 M_W ~8 Wenchuan earthquake (from Klose, 2012). Bottom: Source time function of the 2008 great Wenchuan, China earthquake (from Zhang et al., 2008).

was consistent with slip of up to ~15 cm on a ~10 × 10 km section of the fault in the depth interval ~ 1–4 km (Fig. 15).

To the southeast, groundwater pumping 1960–2010 had lowered the water table by > 250 m. The surface had concurrently subsided by > 10 cm/year, totaling > 2 m. Significant environmental effects had occurred as a result (Fig. 16).

A slip deficit of up to ~12 cm had probably accumulated in the Alhama de Murcia fault since the previous large earthquake on the fault segment ~200 years earlier. Calculated Coulomb stress changes induced by water removal were consistent with a crustal unloading process that enabled tectonically accumulated stress to be released in the 2011 event. González et al. (2012) concluded that cumulative long-term hydraulic unloading, coupled with the location and type of the fault with respect to the depleting aquifer, contributed to the stress conditions that precipitated the earthquake.

Other cases of induced seismicity of this kind include the 2015 M_W 7.8 Gorkha, Nepal, earthquake which has been linked to groundwater depletion beneath the Indo-Gangetic Plain to the south (Kundu et al., 2015). This thrust earthquake caused ~8000 deaths and ~$10 billion of economic loss, ~50% of the Gross Domestic Product of Nepal.

The Indo-Gangetic Plain is the most intensely irrigated region in southeast Asia and has the highest population density. It covers ~2.5×10^6 km^2 and is home to ~0.5 billion people. Groundwater is extracted at a rate of ~23×10^{12} m^3/year, the largest rate of groundwater loss on Earth (Fig. 17). This load is being removed from the footwall of the Main Himalayan Thrust and encourages slip in the fault zone in a similar way to the Lorca case (Fig. 18) (Kundu et al., 2012).

The Coulomb failure stress change has been ~0.003–0.008 MPa since 1960 (Kundu et al., 2012). This is at the lower limit of that induced by Earth tides (Section 7.3) but is comparable to the natural rate of stress accumulation on the Main Himalayan Thrust of ~0.001–0.002 MPa/year. Dewatering of the Indo-Gangetic Plain is thus accelerating stress accumulation on the Main Himalayan Thrust by 4.5–20%.

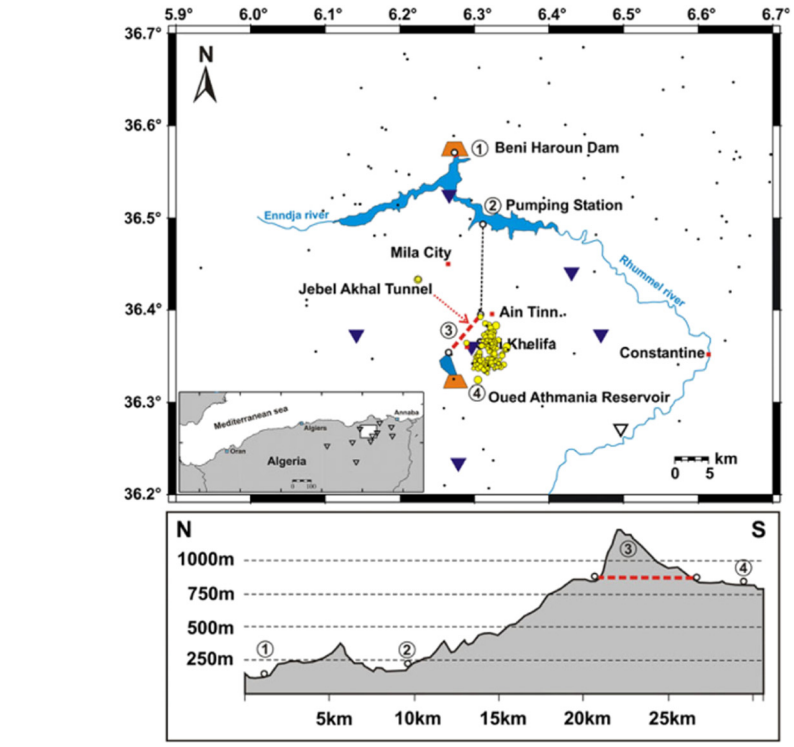
Groundwater beneath the San Joaquin Valley, California, has been depleted by ~1.6×10^{11} m^3 over the past ~150 years (Amos et al., 2014; McGarr, 1991). The most rapid depletion occurs during the summer agricultural growing months and the most rapid natural recharge during the winter and spring. Annual fault-normal seasonal stress variations on the San Andreas fault zone from this source are ~0.001 MPa, encouraging earthquakes in summer and autumn. The stress rate is similar to that calculated for the Main Himalayan Thrust from dewatering the Indo-Gangetic Plain and the predicted seasonality in seismicity is seen in earthquakes with M > 1.25.

A similar process was suggested to modulate seismicity in the Gran Sasso chain in the central Apennines, Italy (Bella et al., 1998). There, tunneling for construction of a highway 1970–1986 significantly changed the hydrology of natural springs. Changes in the spatial pattern of local seismicity, an increase in seismic rate, and the occurrence of three M > 3 events were postulated to be linked to the hydraulic changes. Klose (2007a) attributes the 1989 M_L 5.6 Newcastle, New South Wales, Australia, event to the dewatering of deep coal mines.

3.2. Mining

Mine excavations perturb stresses in surrounding rocks and may reduce some components from values initially of the order of 100 MPa to atmospheric (0.1 MPa). The resulting stress differences can exceed the strength of competent rocks and cause earthquakes. These are traditionally known as “rock bursts” or “coal bumps”.

Lately, excellent seismic data have been recorded on dense, multi-component arrays installed for hazard mitigation purposes. Propagation paths are often short, pass through homogeneous rock, and data are free from the effects of the weathered surface layer that degrade surface observations. Significant advances in understanding the source physics of earthquakes have been achieved using these data. It has been shown that many mining-induced earthquakes have net implosive source mechanisms, consistent with partial closure of the artificial voids created by the removal of mass (e.g., Feignier and Young, 1992; Kusznir et al., 1982; Rudajev and Sileny, 1985; Wong and McGarr, 1990; Wong et al., 1989). Miller et al. (1998a, Section 3.4) give a detailed review of this.



3.2.1. Traditional mining

Mining seismicity may be disproportionately serious because of the large loss of life and resources caused. This includes environmental damage such as surface subsidence which may render buildings beyond repair. Mitigating mining-induced seismicity is a major technical challenge, and might become a limiting factor to the industry (e.g., Tang et al., 2010).

During the ~50-year period 1949–1997, over 2000 coal bursts occurred in 33 mines in China, killing several hundred people and costing > 1300 days in lost production (Tang et al., 2010). In 2007 some 102 coal mines and 20 other mines reported seismicity (Fig. 19). Seven of these were associated with events of M > 4.0 and 27 with events of M ≥ 3.0 (Li et al., 2007). Earthquakes are shallow, occurring at 0–7 km depth. The largest coal mining event that has occurred in China is the 1977 M_L 4.3 event at Taiji mine, Beipiao, Liaoning (Li et al., 2007).

Coal mining in China is increasing in depth of extraction and volume removed, and the problem of mining-induced seismicity is increasing also (Figs. 20 and 21). The demand for coal and other minerals requires, in the absence of other solutions, that this trend continues. The problem of mining-induced earthquakes may thus grow unless management solutions are found.

Perhaps the most spectacular case of mining-induced seismicity occurred in 1989 in the Volkershausen Ernst Thaelmann/Merkers potash mine, Germany. An event with M_L 5.6 (Bennett et al., 1994; Knoll,

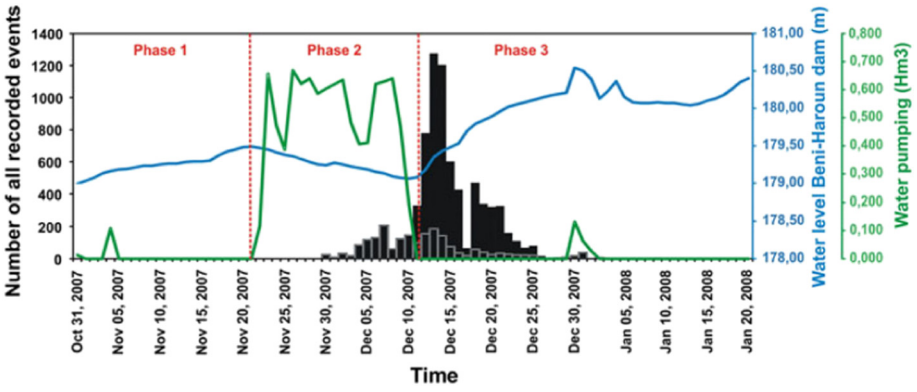


Fig. 10. Map of hydraulic system in Mila region, Algeria. Top: Water transport system (dashed lines) from Beni Haroun dam to Oued Athmania reservoir. Red dashed line: tunnel through Mt. Jebel Akhal; black dots: seismicity for 2006–2007; triangles: seismic stations; yellow dots: epicenters of earthquakes postulated to have been induced. This exemplifies the effect of varying the number of seismic stations. (From Semmane et al. (2012).)

1990) was associated with the collapse of ~3200 pillars throughout an area of ~6 km^2 in the depth range 850–900 m. A large part of the local town of Düren was devastated, damaging several hundred buildings and totally destroying 19. Three people were killed and several injured. The event was probably multiple, with three main sub-events of M_L 4.4, 5.1 and 5.5. The M_L 5.5 sub-event was attributed partly to fluid waste injection which increased pore pressure by ~0.3–1.1 MPa, and this may have initiated an earthquake which led to collapse of the pillars (Knoll, 1990).

A case that involved litigation over the cause of a fatal mine-related earthquake is the 2007 M_W 4.1 Crandall Coal Mine, Utah, event. Nine miners and rescuers were killed by a gallery collapse. The cause of the collapse was variously attributed to triggering by a natural earthquake or unsafe back-stripping mining practices. The seismic moment tensor of the event was not consistent with shear slip on a fault, as expected for a natural earthquake, but with a rapidly closing crack, as expected for a gallery collapse (Fig. 22) (Dreger et al., 2008). The following year, the US Mine Safety and Health Administration levied fines totaling $1.85

million for unsafe mining practices at Crandall Coal Mine.

The UK has a long history of mining dating from the Neolithic period that includes flint, lead, copper, coal, tin and gold (Fig. 23). During the 19th and 20th centuries coal mining reached its peak and in 1913, ~ 3 x 10^8 t were extracted from 3024 mines. Some of these were excavated to depths of ~1200 m and extended several kilometers offshore beneath the North Sea.[4,5] *HiQuake* includes the largest earthquake recorded in each major UK coalfield.

Wilson et al. (2015) reviewed UK earthquakes to determine a national baseline for seismicity in advance of possible future shale-gas hydrofracturing. They used the earthquake database of the British Geological Survey. Of the ~8000 onshore British earthquakes in that catalog for 1970–2012 they estimated ~21% to have been anthropogenic, the majority caused by coal mining (Fig. 24). Coal production and earthquakes correlate (Fig. 25) (Wilson et al., 2015). A large reduction in seismicity accompanied a fall in production during the 1984–85 miners' strike. The economic cost of that strike is estimated to have been several billion pounds, from which it can be calculated that mitigation of each earthquake with $M_L \geq 1.5$ cost ~£10 million. The earthquake rate recovered in line with coal production when the strike ended in 1985.

The region most renowned for large mining-induced earthquakes is South Africa. There, two of the world's richest ore bodies are mined–the gold-bearing conglomerates of the Witwatersrand Basin and the platinum-bearing pyroxenites of the Bushveld Complex. Both bodies extend to depths of several kilometers, and mining depths exceed 3.5 km (Durrheim, 2010). The current regional stress field is extensional but tectonically inactive. Mining-induced earthquakes are accompanied by collapses of up to ~1 m in the vertical that contract galleries in the form of horizontal tabular voids for up to several kilometers of their lengths. Earthquakes up to m_b 5.6 have occurred (President Brand mine, Welkom, in 1994).

The problem of induced seismicity in South Africa became apparent early in the 20th century when mining penetrated to several hundred meters depth. It is now a major issue and great efforts are made to mitigate the risk. These include development of the safest possible mining techniques, optimal design of equipment, and seismological monitoring. Fatality rates have been reduced but still number several tens of deaths per year (e.g., Amidzic et al., 1999; Boettcher et al., 2015; deBruyn and Bell, 1997; Durrheim, 2010; Durrheim et al., 2013; Durrheim et al., 2006; Heesakkers et al., 2005; Jaku et al., 2001; Julià et al., 2009; Kozlowska et al., 2015; Lippmann-Pipke et al., 2011; Milev and Spottiswoode, 2002; Richardson and Jordan, 2002; Wright et al., 2003; Yabe et al., 2015; Ziegler et al., 2015).

An example is a M_L 4.0 event that occurred in Western Deep Levels East gold mine in 1996. It nucleated in complex geology ahead of

mining and extensively damaged the area. Work had involved removing a large pillar left by earlier, smaller-scale mining. This damaging earthquake had a significant impact and resulted in improved seismicity management strategies (Amidzic et al., 1999).

An even larger event, with M_L 5.3, occurred in the Klerksdorp district, South Africa, in 2005. It seriously damaged the nearby town of Stilfontein, injuring 58 people. Two mineworkers in a nearby gold mine were killed and thousands of others were evacuated. This earthquake was attributed to stress loading by past mining (Durrheim et al., 2006). It highlighted the problem of poor documentation of historic mining activities, a difficulty faced by all nations with long traditions of mining. It also showed that earthquakes induced by one industrial project can endanger others nearby. Its delayed occurrence illustrates that seismic hazard may remain a problem after mine closure.

McGarr (1992a) used the exceptionally high-quality data collected on the state-of-the-art monitoring networks installed in deep South African gold mines to derive full moment tensors for 10 Witwatersrand mining-induced earthquakes with M 1.9–3.3. The earthquakes were of two types. Seven involved substantial coseismic volumetric reduction combined with normal faulting and three had no significant volumetric component. Those with volumetric components probably involved interaction between a mine stope and a shear fault (McGarr, 1992a).

These conclusions were confirmed by later workers. Julià et al. (2009) obtained focal mechanisms for 76 mine tremors with M 0.5–2.6 at the deep AngloGold Ashanti Savuka gold mine. These events were recorded on 20 high-frequency geophones in the mine. The largest

principal stress was vertical and was relieved by a combination of volumetric closure and normal faulting, consistent with the vertical closure of galleries. Richardson and Jordan (2002) studied seismicity associated with five deep mines in the Far West Rand district using data recorded 1994–2000 on in-mine arrays. Seismic rates exceeded 1000 events/day. Some earthquakes occurred within 100 m of active mining faces. Those events were attributed to blasting, stress perturbations from the excavation, and closure of stopes. Other events were distributed throughout the mining region, had M > 3, and were similar to regional tectonic earthquakes.

3.2.2. Solution mining

Solution mining recovers minerals via boreholes drilled into the deposit. A lixiviant–a liquid used to dissolve the target mineral–is pumped into the resource via an injection borehole, circulates through the rock dissolving the mineral, and is extracted via a production well. The lixiviant may be water (e.g., to extract salt), or acid or sodium bicarbonate to extract metals (e.g., uranium, copper, gold or lithium).

(From Kundu et al. (2015)).

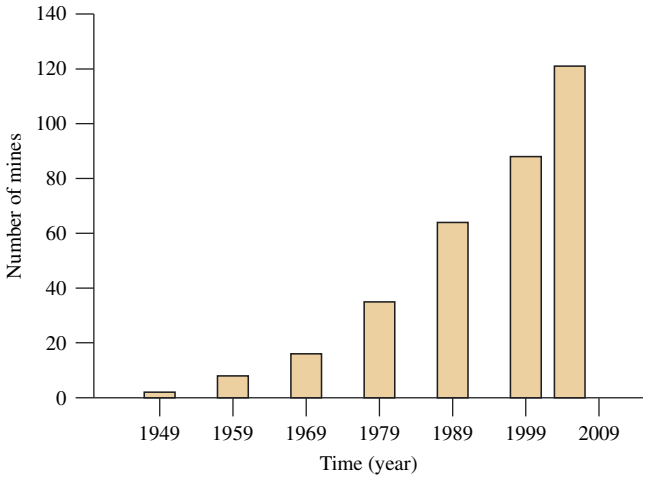

Fig. 20. Number of mines in China with rockburst hazard vs. time.
(From Li et al. (2007)).

Roughly half the world's uranium is produced by solution mining.

HiQuake contains eight cases of seismicity postulated to be associated with solution mining. At the Vauvert Field, France, brine is produced from a layer at 1900–3000 m depth comprising ~50% salt. Water is circulated through fractured zones via a well doublet. Some cavities created dissipate by salt creep but earthquakes occur where this process cannot keep up with mass removal. Seismicity also results from hydraulic fracturing used to create porosity. Over 125,000 earthquakes with M −3 to −0.5 occurred 1992–2007 have been located (Godano et al., 2010).

In the USA three cases are documented, from Attica and Dale (New York) and Cleveland (Ohio). Of three M_L ~5 events that occurred near Attica, in 1929, 1966 and 1967, two had hypocentral depths as shallow as 2–3 km (Herrmann, 1978). They are postulated to have been induced by salt solution mining (Nicholson and Wesson, 1992).

In China, a M_L 4.6 earthquake occurred in 1985 in association with solution mining of salt from depths of 800–1800 m at the Zigong salt mine, Sichuan Province (Li et al., 2007). This earthquake induced the highest intensity of ground shaking measured for any mining-induced earthquake in China. It is the largest mining-related event of any kind known from China.

At Mishraq, Iraq, earthquakes occurred in association with mining of sulfur by injecting hot (~150 °C) water at pressures of 0.6–0.8 MPa into layers up to 190 m deep (Terashima, 1981). Surface subsidence of up to several mm/day resulted in surface cracking. Felt earthquakes occurred 1973–1975 and were most numerous at times of high injection rate.

3.2.3. *Tunnel excavation*

Earthquakes accompanying excavation of tunnels and cavities have been reported in 20 cases. These include excavations for power-station housing (e.g., the underground powerhouse of the Pubugou, China hydroelectric station), water transport at hydro-electric and nuclear power stations (e.g., the Yuzixi hydro-electric station, China, and the Forsmark nuclear plant, Sweden), and road and railway transport (e.g., the Ritsem tunnel, Sweden, and the Qinling railway tunnel, China) (Tang et al., 2010).

The 57-km-long Gotthard Base Tunnel, Switzerland, part of the New Alpine Traverse through the Swiss Alps (Husen et al., 2012), was excavated for freight and passenger rail transport 2002–2006 using drilling and blasting. Three “Multi-Function Stations” (MFSs) divide the tunnel into five sections.

A series of 112 earthquakes with M_L −1.0 to 2.4 occurred

Right: 369 events postulated to be induced by coal mining. These correlate spatially with major coalfields (dark gray).
(From Wilson et al. (2015).)

2005–2007 in association with excavation of the southernmost station, MFS Faido. The largest event was just 0.5–1.0 km deep and felt strongly at the surface. The station cavity was damaged including flaking of the reinforced walls and upwarping of the floor by ~0.5 m. The seismicity correlated spatially and temporally with excavation of the station (Figs. 26 and 27). Accurate locations obtained using a dense, temporary seismic network showed that the earthquakes occurred at a similar depth to the tunnel. Some correlated with rockbursts in the tunnel shortly after blasting.

The focal mechanism of the largest earthquake indicated normal faulting on a steep plane 50–170 m long belonging to the local fault system. The tunnel traverses igneous and metamorphic rocks and a complex of structures with different rheological properties, including faulted and heavily fractured sections. Modeling suggested the earthquakes resulted from an unfavorable juxtaposition of rocks with different rheologies in a fault zone. The horizontal stresses added by the excavations were relieved by shrinking of the tunnel which reactivated the fault zone.

3.3. Hydrocarbons

Suckale (2009, 2010) reviewed seismicity induced by hydrocarbon production. There are ~67,000 hydrocarbon fields worldwide (Li, 2011) including ~1500 giant and major fields, and ~1,000,000 producing oil and gas wells. Seismic response to production varies and no seismicity is reported for most fields. Reporting is, however, incomplete, and many fields are not instrumented (Section 7.1). Earthquakes account for only a small percentage of the deformation associated with reservoir compaction with the majority being taken up by ground subsidence or counteracted by fluid recharge from the sides.

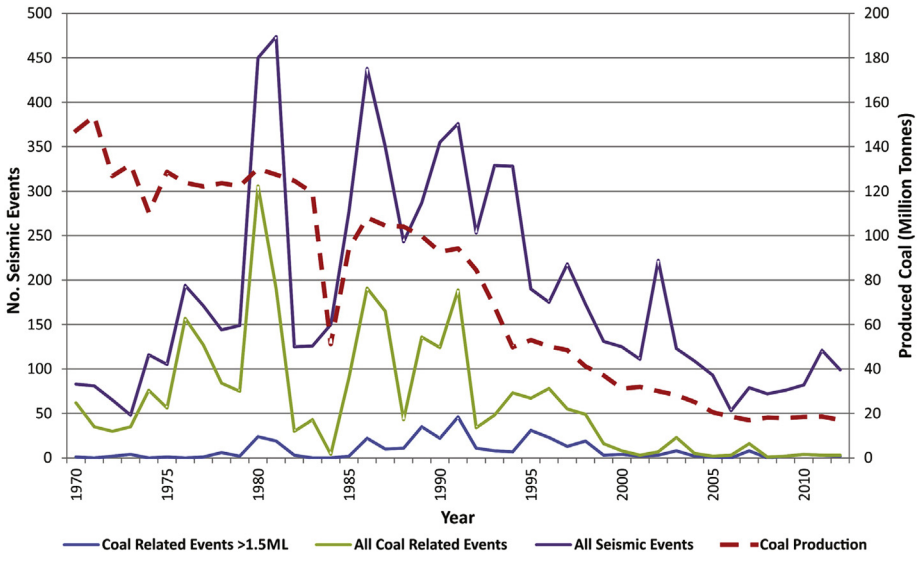

Fig. 25. UK coal production (dotted red line) vs. numbers of earthquakes postulated to be induced (blue line: $M_L \geq 1.5$, green line: all postulated coal-related events, purple line: all located earthquakes in the British Geological Survey database) for the period 1970–2012. The effect of the miners' strike of 1984 can be seen clearly in the drop in production and seismicity.
(From Wilson et al. (2015).)

Bottom: local magnitudes. Open circles: earthquakes for which magnitude could only be computed using data from one station. Gray band marks the end of the excavation work.
(From Husen et al. (2012).)

The earthquakes reported often occur on faults that were either previously unknown or considered to be inactive.

3.3.1. Gas

There are 36 cases of seismicity postulated to have been induced by extraction of natural gas. These are from Canada (1 case), China (1 case), France (2 cases), Germany (7 cases), Italy (1 case), the Netherlands (18 cases), Oman (1 case), the USA (4 cases) and Uzbekistan (1 case).

The most extreme case is that of the Gazli reservoir, Uzbekistan. In 1976 and 1984, three M_S ~7 earthquakes occurred, seriously damaging the local town of Gazli and causing one death and ~100 injuries (Simpson and Leith, 1985). An additional M_S 5.7 event occurred in 1978. Events occurred as follows:

1956 the Gazli field was discovered;
1963 pipelines to the Urals industrial region were completed;
1966 production of ~20 × 10^9 m^3/year of gas began. Reservoir pressure was ~7 MPa;
1968–71 production peaked;
1976 pressure had declined to 3–3.5 MPa; two M_S ~7 earthquakes occurred;
1978 a M_S 5.7 earthquake occurred;
1984 a M_S ~7 earthquake occurred;
1985 pressure had declined to 1.5 MPa.

Gas was produced from a reservoir at ~2 km depth, hosted in an open anticline of tight Paleogene sandstones. This structure is cut by several blind faults and the M_S ~7 earthquakes are thought to have occurred on one of these (Fig. 28). Fault-plane solutions suggest that they occurred on a north-dipping, easterly striking thrust fault, consistent with regional tectonics. Extrapolation of this fault to shallow depth suggests that it intersects with the gas reservoir. In addition to this geometric correspondence, Simpson and Leith (1985) cite as additional evidence that these events were induced:

- previous seismic quiescence;
- an anomalous magnitude distribution which involved three M_S ~7 events rather than a mainshock-aftershock sequence;
- the large decrease in pressure in the reservoir; and
- unusual downwards rupture propagation.

That these earthquakes were induced has been challenged, e.g., by Bossu et al. (1996), on the grounds that the stress perturbation on the fault was too small to have triggered such large earthquakes. Possible analyses of this case are limited because data on operations are sparse. However, the Gazli case is important because of its implications for the maximum possible magnitude of earthquakes that could be induced by gas extraction.

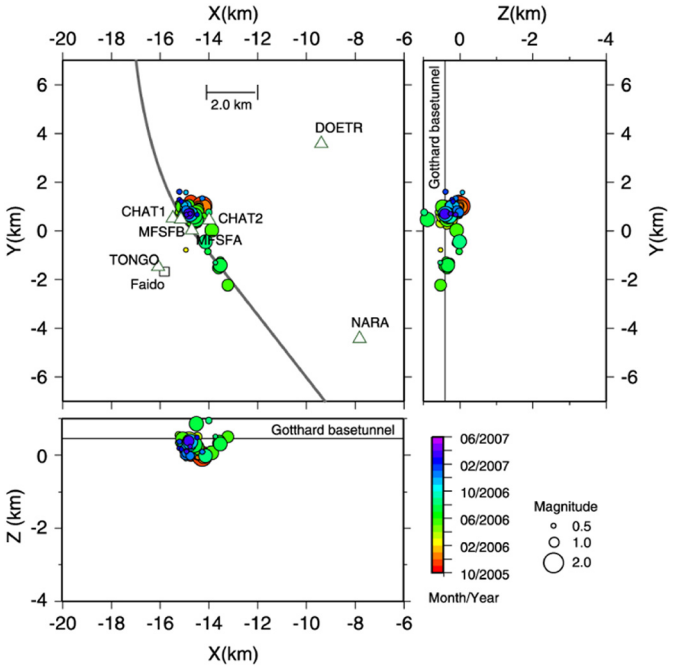

Fig. 27. Hypocenter locations of earthquakes in the vicinity of the multi-function station Faido, Switzerland, October 2005–June 2007.
(From Husen et al. (2012).)

The largest such postulated earthquake in Europe is the 1951 M 5.5 event that occurred in the previously aseismic Caviaga Gasfield, Po Valley, Italy (Caloi et al., 1956). There, large-scale extraction of methane at pressures > 10 MPa had been underway. The earthquake cannot be well studied because limited instrumentation was in place at the time. Simple analysis of paper recordings suggested that the largest, M_L 5.5 event, nucleated at ~5 km depth and had a thrust mechanism.

The case of Caviaga is the only M ≥ 5 gas-extraction-induced earthquake reported for Europe. Several other European gas-extraction projects are associated with M ≥ 4 seismicity. The Lacq Gasfield, France, has generated earthquakes up to M_L 4.2 and > 2000 were located there from 1974 to 1997 (Bardainne et al., 2008).

Production at Lacq started in 1957 with extraction of gas from a depth of 3.2–5 km, beneath a 600-m-deep oilfield. The reservoir occupies a 20-km-long fractured anticline in Mesozoic limestones sealed by Cretaceous marl. Reservoir pressure decreased from 66 MPa to 2.3 MPa 1957–2008 and the surface subsided ~6 cm.

The first earthquake noticed, the 1969 M 3–4 event, occurred after the gas pressure had declined to 36 MPa. This, and the subsequent seismicity, are unlikely to have been natural because of their location in the gas field and because Lacq is 30 km north of the nearest seismically active structure, the Pyrenean Frontal Thrust. About 70% of the earthquakes located above the gas reservoir, many on faults optimally-oriented with respect to the stress perturbation caused by gas removal. Poorly oriented faults tended to be aseismic. There is poor correlation between the surface subsidence and the seismicity. Seismicity migrated from the center to the periphery of the reservoir (Fig. 29). Comparison of the distribution of hypocenters with deformation models favored the model of Odonne et al. (1999) rather than that of Segall (1989) (Fig. 30).

In The Netherlands, ~300 gas fields are produced. Of these, just a few percent are seismically active but globally this is a high rate of reported seismogenesis. The induction mechanism is thought to be differential compaction (Gee et al., 2016).

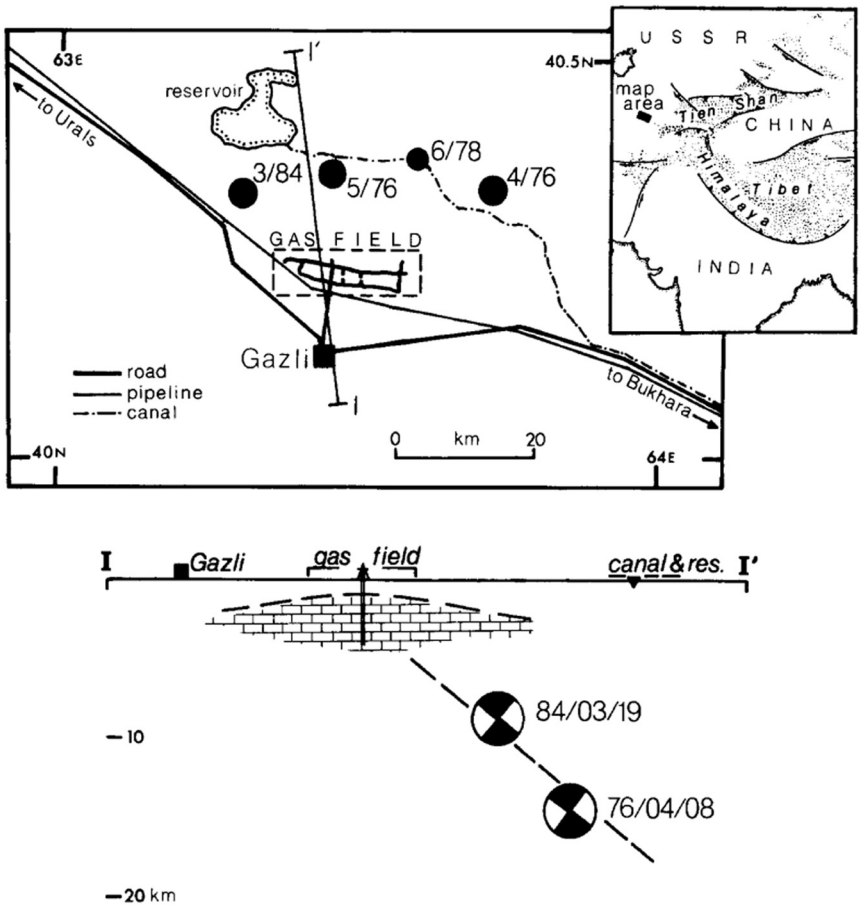

Fig. 28. Top: Map of the Gazli, Uzbekistan, area showing epicenters of the three M ~7 earthquakes in 1976 and 1984, and the M 5.7 earthquake in 1978. Bottom: Cross-section with hypocenters projected at their distance from the town of Gazli, with focal mechanisms of the M_S 7.0 events of 8 April 1976 and 19 March 1984. The fault plane (dashed line) is deduced from geodetic data. (From Simpson and Leith (1985).)

Colors: different earthquake clusters; dashed and solid gray lines: isobaths of the gas field; black lines: faults; crosses: location uncertainties for three swarms. (From Bardainne et al. (2008).)

One of the largest earthquakes attributed to induction in The Netherlands is the 2012 Groningen M_L 3.6 event. In addition to this a further 8 events with M > 3.0 have occurred in that field (Fig. 31). Seismicity was first recorded in December 1991 when the reservoir reached ~28% depletion, some 28 years after the start of gas extraction in 1962 (Fig. 32).

The Netherlands has a low rate of historic seismicity compared with neighboring countries where much higher rates are associated with the Upper Rhine Graben (Figs. 33 and 34) (van Eck et al., 2006). Currently, the majority of earthquakes in the northern Netherlands is associated with gas extraction. Several hundred have been recorded in the Groningen Field. This reservoir, the largest natural gas field in Europe and the tenth-largest in the world, originally contained ~3×10^9 m^3 of gas in a porous sandstone formation up to 300 m thick and 45 × 25 km in area. Both the seismic rate and the magnitudes of the largest

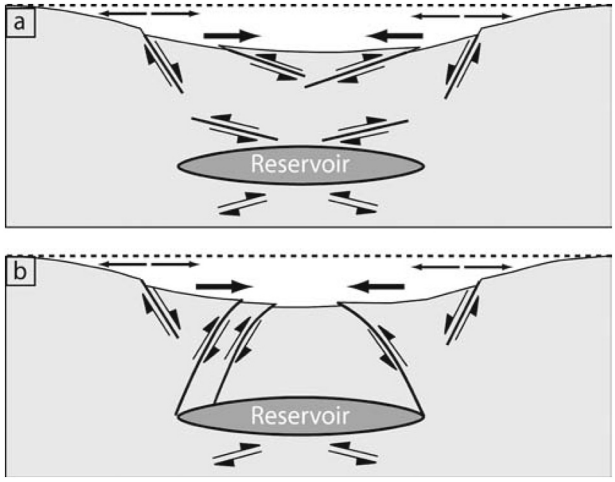

Fig. 30. Deformation models of (a) Segall (1989), and (b) Odonne et al. (1999) for a depleting subsurface reservoir. Both models predict extensional deformation on the flanks and compressional deformation centrally in the field. (From Bardainne et al. (2008).)

earthquakes have increased with time (Fig. 32). An apparent increase in the slope of the Gutenberg-Richter distribution (the "*b*-value") with time is consistent, however, with a progressive reduction in the proportion of large to small earthquakes (van Eck et al., 2006; Van Wees et al., 2014). Reservoir compaction is greatest in two northwesterly trending zones of the reservoir and the earthquakes correlate with the southernmost of these (Fig. 35).

A renowned case in the USA is the Fashing Gasfield, Texas (Fig. 36) (Pennington et al., 1986). Production there started in 1958 from 3.2 km depth. By 1983 the pressure had decreased by ~7 MPa and a M 3.4 earthquake occurred (Fig. 37). The depleting reservoir was replenished by reinjecting produced water. In 1992 a M 4.3 earthquake occurred and in 2011 a M_W 4.8 event. This case is usually considered jointly with the nearby Imogene Oilfield (Section 3.3.2).

3.3.2. Oil

In many oilfields multiple processes are underway simultaneously including oil and gas extraction, waste-water disposal, water injection to aid oil recovery and hydrofracturing or thermal fracturing. It may thus be difficult to attribute unambiguously any seismicity to oil extraction alone (Section 1.7). Nevertheless, we have identified eight cases where earthquakes have been postulated to be associated with oil extraction. These are from the USA, Iran, Russia and Norway. This is very few compared with the ~1,000,000 producing oilfields worldwide (Section 3.3).

One of the earliest reports of earthquakes accompanying oil production is from Goose Creek, Texas, where small earthquakes occurred in the 1920s (Fig. 38). Following the extraction of several million barrels of oil an area ~10 km^2 in size subsided by up to 1 m over an ~8-year period (Nicholson and Wesson, 1992; Pratt and Johnson, 1926). Goose Creek is a coastal region and a substantial area sank below sea level requiring industrial infrastructure to be adapted to the flooded conditions.

The largest earthquake attributed to oil extraction in *HiQuake* is the M_W 6.2 1983 Coalinga, California, event. This event, along with the 1985 M_W 6.1 Kettleman North Dome earthquake and the 1987 M_L 5.9 Montebello Fields (Whittier Narrows) earthquake, both in California, were attributed to the removal of oil from fields in uplifting anticlines (McGarr, 1991). The Coalinga and Whittier Narrows events were widely felt and caused multiple deaths and injuries (Fig. 39).

All three events nucleated at ~10 km depth. McGarr (1991) suggested that net extraction of oil and water reduced the average density of the upper crust, and that the seismic deformation approximately

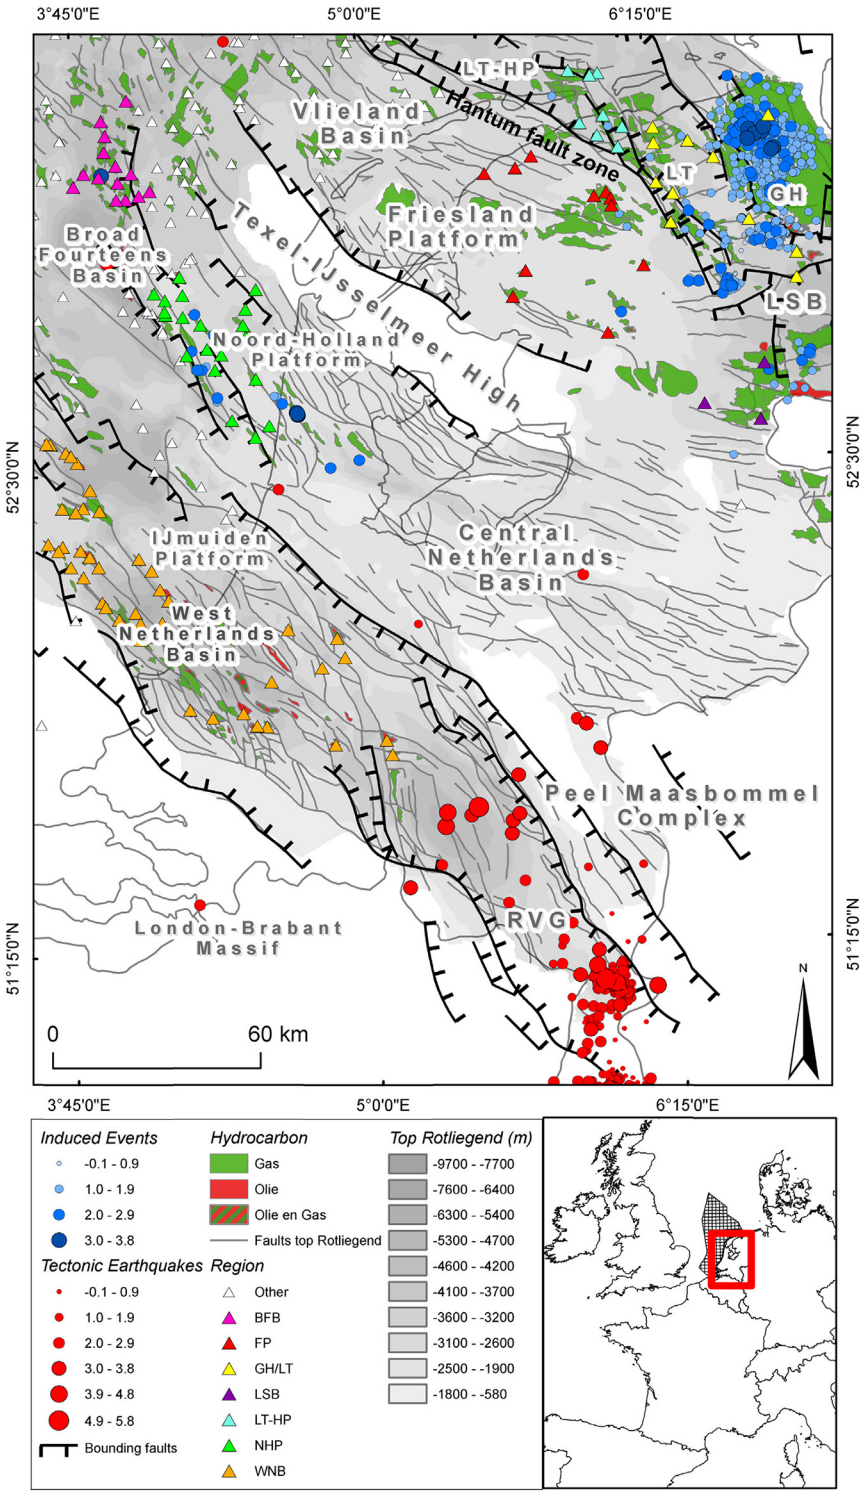

Fig. 31. Tectonic map, seismicity, and hydrocarbon reservoirs in the Netherlands. Regional location of the main map is shown in the lower right panel. Red circles: natural seismicity; blue circles: induced seismicity; green: gas reservoirs; red: oil reservoirs; solid lines: major fault zones; triangles: where leak-off tests have been performed. BFB = Broad Fourteen Basin, FP = Friesland Platform, GH/LT = Groningen High/Lauwerszee Trough, LSB = Lower Saxony Basin, LT-HP = Lauwerszee trough-Hantum Platform, NHP = Noord Holland Platform, WNB = West Netherlands Basin, RVG = Roer Valley Graben, PB = Peelrand Block, EL = Ems Low. (From Van Wees et al. (2014).)

restored isostatic equilibrium (Fig. 40). This was challenged by Segall (1989) who concluded that depletion of the reservoir would have only loaded the nucleation region by ~0.01–0.03 MPa. Nicholson and Wesson (1992) suggested that the earthquake might have occurred in response to larger stresses imposed by fluids migrating into the mid-to-lower crust. They suggested changes in pressure resulting from withdrawal of oil induced fluid migration and brought the fault closer to failure. The Coalinga earthquake has also been attributed to extraction of groundwater for irrigation from the nearby San Joaquin valley (Section 3.1) (Amos et al., 2014). The Coalinga earthquake contributed to stress released six years later in the 1989 M_W 6.9 Loma Prieta earthquake. This event ruptured a section of the San Andreas fault system 96 km south of San Francisco causing 63 deaths, 3757 injuries and $5.6–6 billion of damage (Reasenberg and Simpson, 1992). The 1933 M_L 6.3 Long Beach, California, earthquake which killed > 100 people and did $40 million of damage may have resulted from oil production in the nearby Wilmington and Huntington Beach Oilfields (Section 4.1.3) (Nicholson and Wesson, 1992).

There is little dispute that earthquakes were induced primarily by oil extraction from the Imogene Oilfield, Texas (Pennington et al.,

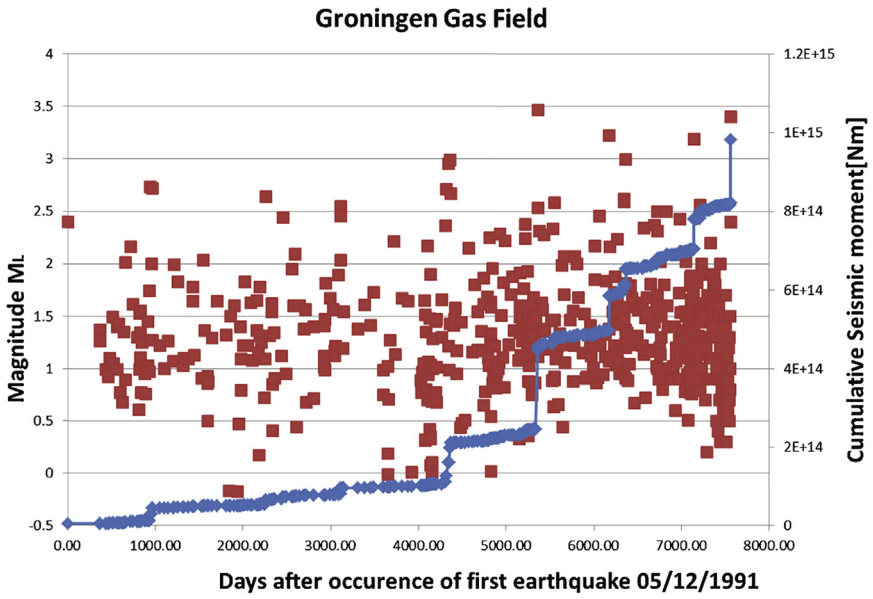

Fig. 32. Magnitude of induced events in the Groningen Gasfield, Netherlands, 5 December 1991–16 August 2012, and cumulative seismic moment in N m.
(From Van Wees et al. (2014).)

1986). This field lies ~25 km from the seismogenic Fashing Gasfield (Section 3.3.1; Fig. 36). In 1984 a M_L 3.9 earthquake occurred in the Imogene Oilfield, followed by aftershocks 2–3 km deep near the reservoir bounding fault.

The Imogene Oilfield occupies Cretaceous limestone bounded by high-angle faults that splay at shallow depth. Production began in 1944 from a 33-m-thick horizon at 2.4 km depth. By 1973 reservoir pressure had dropped from 25 MPa to ~10 MPa. It was flooded 1972–1978 with 55,000 m^3 of water via injection wells to mitigate this pressure reduction. This is, however, much less than the ~1 million m^3 of oil and gas produced, and flooding ceased several years before the 1984 earthquake. As a consequence, the seismicity has been attributed to depressurization of the field as a result of oil depletion.

The most spectacular example of subsidence and induced earthquakes associated with a producing oilfield is that of the Wilmington Field, California (Figs. 41 and 38). Oil production began in 1936 and over the following 30 years up to 9 m of subsidence and 3.6 m of horizontal contraction occurred. Strain rates were >1000 times greater than along locked sections of the San Andreas fault (Kovach, 1974; Segall, 1989).

Earthquakes began to occur above and below the reservoir when reduction in pressure reached ~10 MPa. Eight earthquakes with M_L 2.4–5.1 occurred on shallow, low-angle bedding planes. The largest, which occurred in 1949, sheared off hundreds of production wells causing >$9 million of damage. An area of ~5.7 km^2 was affected and up to 20 cm of ground deformation occurred (Nicholson and Wesson, 1992; Segall, 1989). Seven of the earthquakes occurred during the oil production period and one after significant water flooding began in 1958 to mitigate the subsidence. No further earthquakes occurred after 1961 and subsidence had been arrested by 1966. In this case seismicity may have been stopped, rather than induced, by the introduction of fluids.

Despite large quantities of oil being produced in the Middle East there are only two accounts of earthquakes postulated to have been induced by extraction there. One reports hundreds of earthquakes up to M_L 4.24 in the Uthmaniyah-Hawaiyah and Haradh divisions of the Ghawar oil/gas field, Saudi Arabia. These earthquakes occurred underneath producing horizons and are attributed to fluid extraction. Focal mechanisms suggest the active elements are crust-penetrative basement faults (Mogren and Mukhopadhyay, 2013).

The other example is from Kuwait, where 465 M 0.3–4.3 earthquakes occurred 1997–2007. A large percentage occurred in the oilfields, including the Sabiriyah, Raudhatain, Bahra, Minagish, Umm Gudair, Wafra, Abduliyah and Dharif Fields (Fig. 42). Some of this activity is likely associated with oil extraction (Al-Enezi et al., 2008). The largest proposed induced event related to Middle Eastern oilfields is the 1993 M 4.7 event in Kuwait. It may have been induced by the 1990 gushing and burning of oil wells by Iraqi armed forces leading to rapid pore pressure reduction and changes in subsurface stress (Bou-Rabee and Nur, 2002).

3.4. Geothermal production (heat/fluids)

Small, natural earthquakes are common in wet, high-temperature geothermal areas, and were known in Iceland as “hverakippur” (trans: “hot-spring bump”) before they were studied scientifically. They are likely caused by a combination of active tectonics in plate-boundary zones and volcanoes, and natural geothermal heat loss. The latter causes cooling and contraction of the geothermal heat source and stress is relieved by rock fracturing with a component of tensile failure. Both the opening and closing of voids have been identified seismically (Foulger, 1988a, 1988b; Foulger and Long, 1984; Foulger et al., 1989; Miller et al., 1998a; Miller et al., 1998b; Ross et al., 1999). Production from geothermal fields by extraction of hot fluids will enhance natural fluid- and heat-loss and may increase seismic rates.

As for hydrocarbon reservoirs, it may be difficult to attribute confidently earthquakes in exploited geothermal areas where multiple processes are underway. They may also be induced by natural recharge, either shallow, cold groundwater or deep hot water. *HiQuake* contains only six cases where earthquakes are postulated to have been induced by geothermal production. These cases are the Cerro Prieto Field, Mexico (Glowacka and Nava, 1996), the Reykjanes and Svartsengi Fields, Iceland (Keiding et al., 2010), Larderello, Italy (Batini et al., 1985), The Geysers, USA (Eberhart-Phillips and Oppenheimer, 1984) and Olkaria, Kenya (Simiyu and Keller, 2000).

The largest were strike-slip events in the Imperial Valley (1979, M_L 6.6), Victoria (~30 km southeast of the Cerro Prieto field; 1980, M 6.1), and at Cerro Prieto (1987, M 5.4) (Fig. 43). Glowacka and Nava (1996) base this proposal on qualitative correlations between increased fluid extraction and seismic moment release, with delays of ~1 year (Fig. 44).

Electrical power production at Cerro Prieto began in 1973. Steam and water at 250–350 °C is produced from 1500 to 3000 m depth. Over 1 km^3 of fluid was extracted 1973–1996. The region is part of the plate

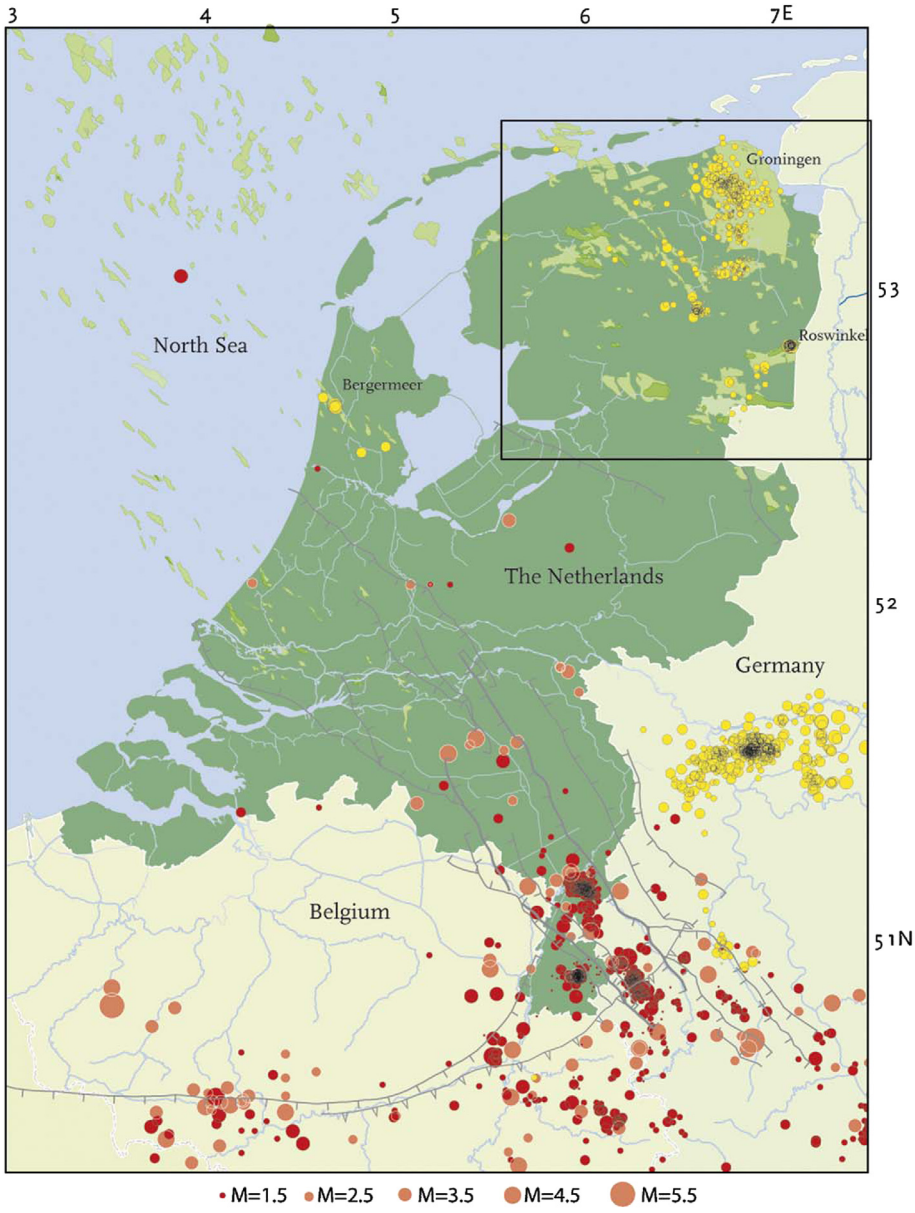

Fig. 33. Seismicity in the Netherlands and surrounding region since 1900. Red circles: natural tectonic earthquakes; yellow circles: suspected induced earthquakes (usually mining or gas exploitation); gray solid lines: mapped faults in the upper-North-Sea formation; light green: gas fields. Detail of boxed region shown in Fig. 34. (From van Eck et al. (2006).)

boundary between the Pacific and North America and tectonics are dominated by the strike-slip Imperial fault which has a history of M > 6 earthquakes. Glowacka and Nava (1996) found the numerical data insufficient to support statistically a correlation between production and large earthquakes but argue that pore pressure decreases of a few MPa in the geothermal field were sufficient to have triggered them. Majer and McEvilly (1981, 1982) suggested, on the basis of data from local, temporary seismic networks, that earlier increases in production correlated with increases in small earthquakes.

Correlation between geothermal production and earthquakes has been proposed at the Reykjanes and Svartsengi geothermal areas, Iceland (Keiding et al., 2010). In some areas, deformation associated with extension along the plate boundary and ~5 cm/a of subsidence resulting from geothermal fluid extraction were detected 1992–2009 using Interferometric Synthetic Aperture Radar (InSAR) and GPS data. Swarms of earthquakes up to M_L 4.1 occurred on the flanks of the rifts containing the geothermal areas. The events were postulated to have been induced by stress changes from geothermal fluid extraction (Fig. 45) but it is not possible to rule out a tectonic origin.

The Geysers geothermal field, California, is a vapor-dominated field that has been exploited for over 150 years, lately generating electricity. It is intensely seismically active (Fig. 46) and earthquakes occurred even before large-scale fluid injections began (Fig. 47). The pre-injection seismicity, and some current seismicity, is likely production-related (Eberhart-Phillips and Oppenheimer, 1984). It is difficult to distinguish production- from injection-related seismicity because both processes are underway simultaneously. Over the last 50 years or so, the seismic rate has, however, correlated grossly with injection (Section 4.1.5).

3.5. *Extraction from the subsurface: summary*

Mining is the commonest cause of extraction-related earthquakes and contributes 267 cases to *HiQuake*. Five cases relate to groundwater and six to geothermal resources. The largest earthquakes postulated to be induced by subsurface extraction are the M_W 7.8 Gorkha, Nepal, earthquake, the M_L 6.1 Bachatsky, Russia, earthquake, the M_S 7.3 Gazli, Uzbekistan earthquake and the M_L 6.6 Cerro Prieto, Imperial Valley, Mexico, earthquake.

In the case of groundwater-withdrawal cases, stress changes as small as 0.001 MPa have been postulated to induce events (e.g., for the 2015

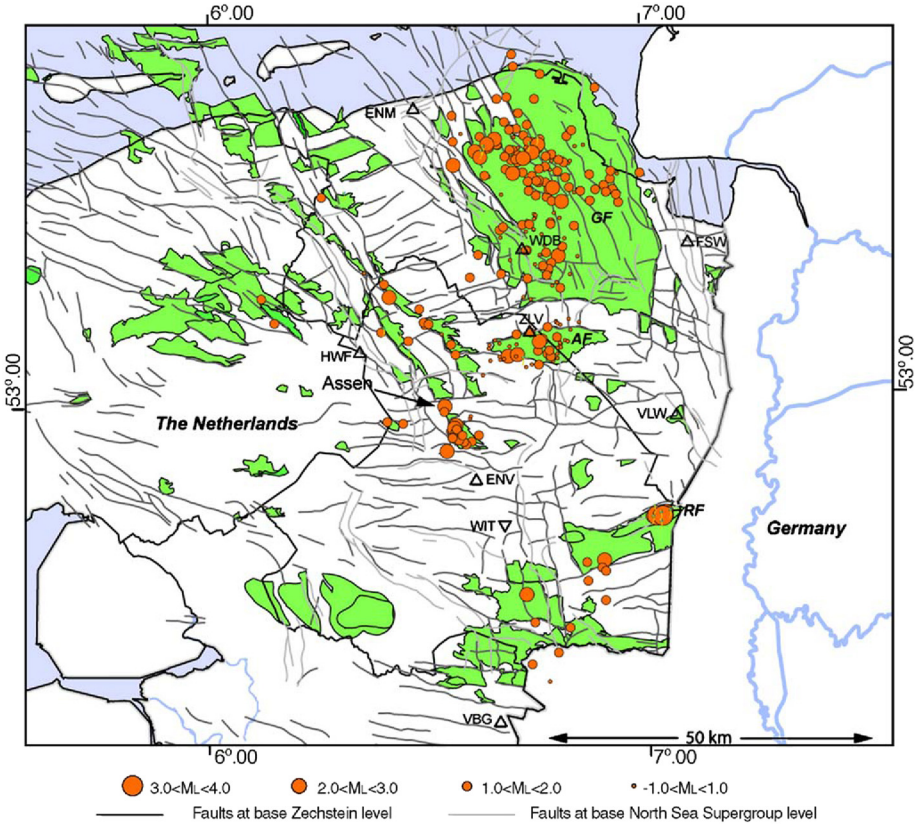

Fig. 34. Map showing produced gas fields (green), major fault structures and seismicity (orange dots) in the northeast Netherlands (boxed region of Fig. 33). RF: Roswinkel Field; GF: Groningen Field; EF: Eleveld Field; AF: Annerveen Field.
(From van Eck et al. (2006).)

M_W 7.8 Gorkha, Nepal, earthquake; Kundu et al., 2015). This is small even compared with Earth tides (Section 7.3). The ability of such small stresses to induce earthquakes is theoretically in keeping with the self-similar, critical earthquake nucleation process. However, such small effects may be comparable to many other natural and anthropogenic processes such as weather and the expansion of cities.

The sizes of postulated gas-extraction induced earthquakes are shown in Fig. 48 for the 35 cases where this parameter is reported. There is a continuous spectrum of sizes with the exception of the M_S 7.3 Gazli, Uzbekistan, event, which is 1.8 magnitude units larger than the second largest.

Although oil extraction removes large masses from the crust, few earthquakes have been attributed to this process. Possible reasons are:

- the process is only weakly seismogenic, perhaps because natural aquifer influx (peripheral or bottom water) partially replaces mass extracted;
- under-reporting; and
- ambiguity of induction process, since fluid injection often accompanies production.

4. Injection into the subsurface

The burgeoning issue of injection-related earthquakes was highlighted by Ellsworth (2013) who pointed out the recent dramatic increase in earthquake rate for M ≥ 3 events in the central and eastern USA. More than 100 such earthquakes occurred annually, on average, 2010–2012 compared with just 21 events/year on average 1967–2000. Despite incomplete reporting, *HiQuake* shows that increasing incidence of injection-related earthquakes is not confined to the USA.

Fluids are injected into the ground for diverse reasons including (Table 2):

- solution mining (Section 3.2.2);
- disposal of by-products;
- enhancing oil recovery;
- fracturing rock (i.e. the very process that causes earthquakes);
- research into the earthquake nucleation process;
- disposing of hot waste water;
- underground storage of natural gas, hydrogen and compressed air; and
- CO_2 geostorage to reduce emissions.

In addition, passive groundwater inflow may occur when reservoirs are produced, or pumping to suppress groundwater levels is terminated in abandoned mines.

HiQuake contains 180 cases where injections have been postulated to induce seismicity. Whereas in general, the removal of mass from the crust is expected to reduce the normal stress that prevents slip on faults, the introduction of fluids into faulted rock is expected to increase the pore pressure that encourages failure. Both these changes thus, capriciously, are expected to induce earthquakes. In the case of injections, in addition to the direct hazard from earthquakes, there is the added risk that if the target formation or its caprock are ruptured the injected fluid might escape. This could add to hazard, e.g., where the injectate is polluted water, natural gas or CO_2.

4.1. Liquid

4.1.1. Military waste

HiQuake contains only one case where seismicity was, to a high degree of confidence, induced by the injection of military waste. This is the legendary case of the so-called Denver earthquakes. It raised widespread awareness among seismologists and the general public that human activity can induce earthquakes.

The incident began in 1961 when the Army Corps of Engineers drilled a 3.7-km deep well into highly fractured crystalline Precambrian basement at the Rocky Mountain Arsenal, northeast of Denver,

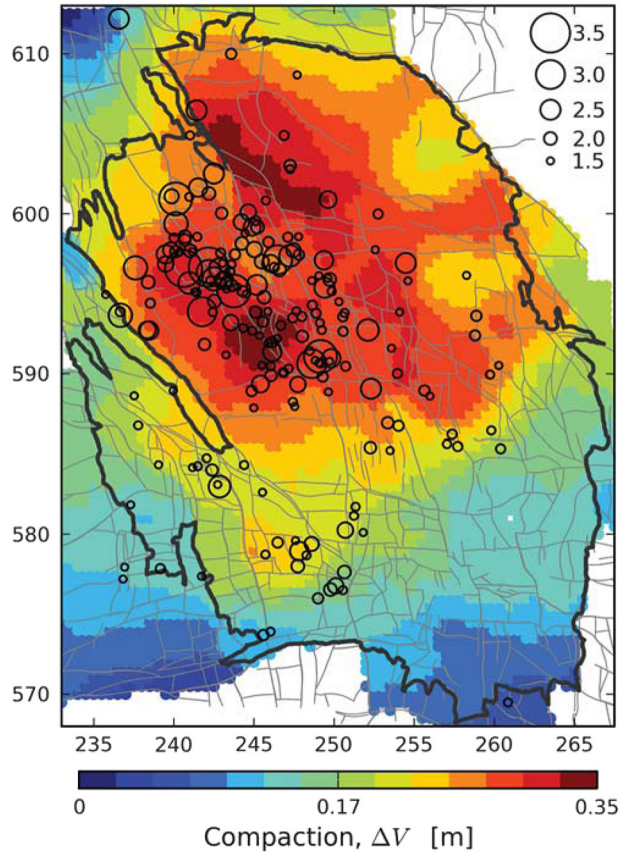

Fig. 35. The Groningen Gasfield. Earthquake epicenters for events with M ≥ 1.5 for the period 1995–2012, superimposed on a model of reservoir compaction for 1960–2012. Black line: perimeter of the Groningen Gasfield; thin gray lines: faults close to the reservoir level. Map coordinates are kilometers in the Dutch national triangulation coordinate system (Rijksdriehoek).
(From Bourne et al. (2015).)

(From Pennington et al. (1986).)

Colorado (Evans, 1966; Hsieh and Bredehoeft, 1981). The purpose of the well has been reported to have been disposal of contaminated wastewater which was done by injection into the bottom, unlined,

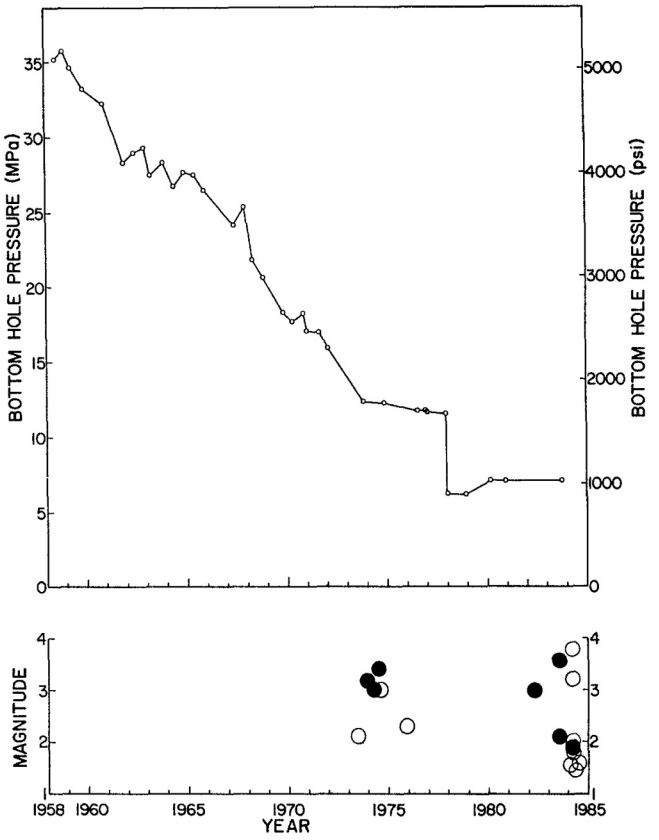

Fig. 37. Pressure history of a well near the fault in the Fashing Gasfield along with known earthquakes in the Fashing-Pleasanton area. Black dots: earthquakes from the Fashing area; open circles: earthquakes from the Pleasanton (Imogene) area.
(From Pennington et al. (1986).)

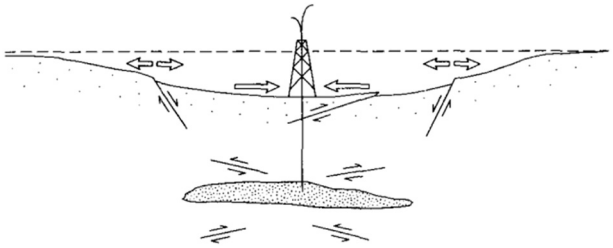

Fig. 38. Schematic cross section summarizing surface deformation and faulting associated with fluid withdrawal. Normal faults develop on the flanks of the field, as observed at the Goose Creek, Texas, Oilfield. Reverse faults develop above reservoirs as observed at Wilmington, Buena Vista Hills, the Pau Basin and beneath the Strachan Field.
(From Segall (1989).)

21 m. Disposal began in March 1962 at pressures ranging from atmospheric to ~7.2 MPa above formation pressure. In the four-year period up to 1966 625,000 m^3 of fluid were injected.

Minor earthquakes started to occur in the Denver area shortly after injection began and by 1967 over 1500 earthquakes, some of which were M 3–4, had been recorded (Fig. 49). The correlation between volume injected and frequency of earthquakes, along with epicenters located < 8 km from the well, led Evans (1966) to suggest they had been induced.

Although waste disposal ceased in 1966, earthquake activity continued and in 1967 three earthquakes with $M_L > 5$ occurred, damaging infrastructure in Denver. Seismicity then declined and by the early 1980s had essentially ceased. Ironically, the large earthquakes that occurred after the end of injection weakened the temporal correlation between earthquakes and injection and thus the case argued for

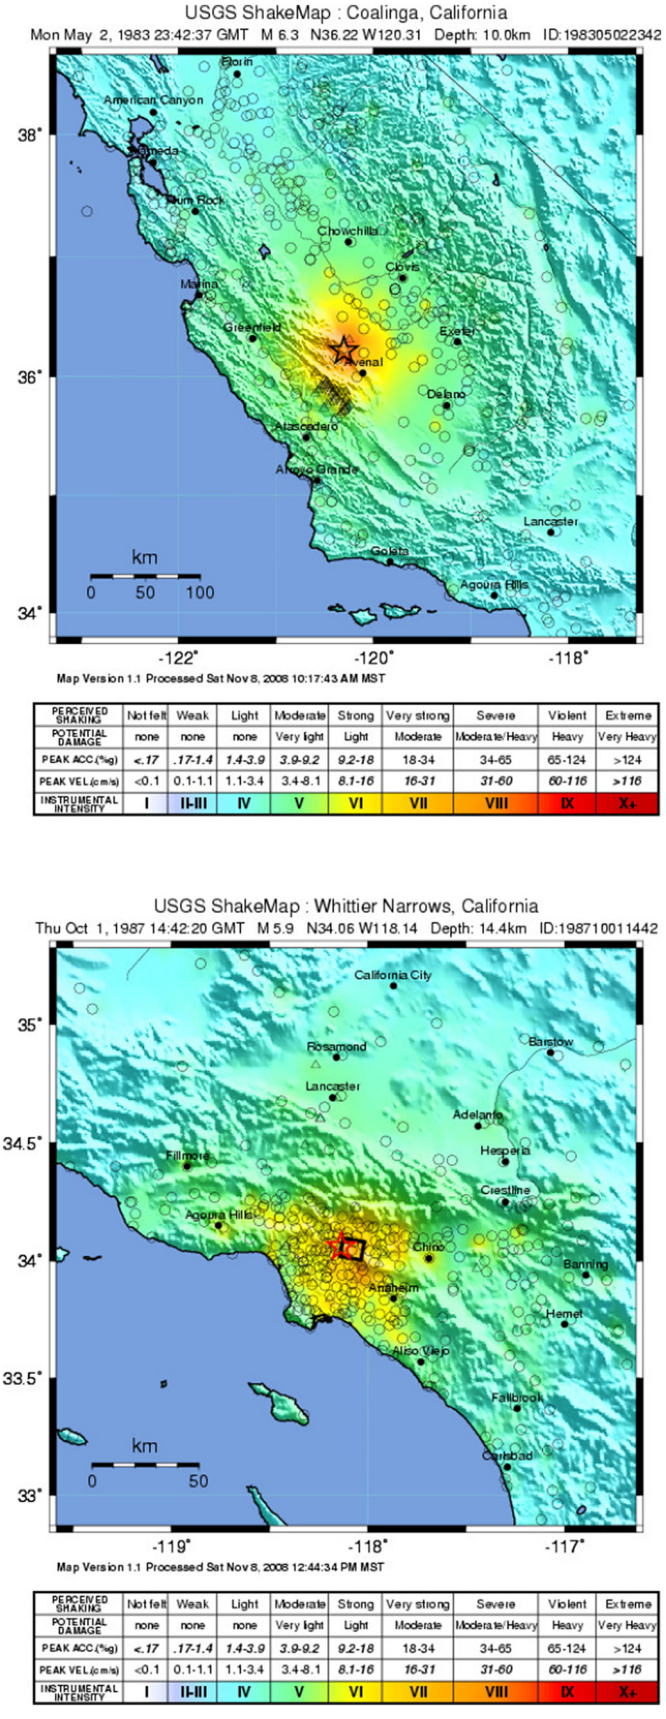

Fig. 39. U.S. Geological Survey shake maps (http://earthquake.usgs.gov/earthquakes/shakemap/). Top: 1983 M_W 6.2 Coalinga, California earthquake, which injured 94 people and was felt throughout half the state. Bottom: 1987 M_L 5.9 Whittier Narrows, California earthquake, which killed six people. Ground shaking was felt throughout the regions shown in the maps and ranged from Light (cool colours) to Severe (warm colours). See the U.S. Geological Survey webpage for more details.

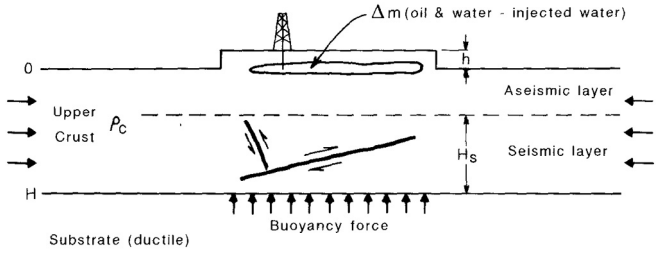

Fig. 40. Schematic cross section showing proposed crustal response mechanism to oil production. Mass removal results in a vertical force imbalance causing seismic deformation in the seismogenic layer. This deformation, together with aseismic deformation in the shallow crust, restores isostatic balance.
(From McGarr (1991).)

induction. Diffusion of the fluid would have continued after injection stopped, however, and could account for the ongoing seismicity (Healy et al., 1968).

4.1.2. Wastewater disposal

Large quantities of connate brine, sometimes mixed with water, are typically co-produced with oil, especially as fields age. Water-to-oil ratios may exceed 20 (Gluyas and Peters, 2010). It is commonly re-injected into depleted oilfields for disposal, to maintain reservoir pressure, and to promote sweep thus aiding oil recovery. Injected cold water commonly leads to thermal fracturing, especially in low-permeability reservoirs. Thermal fracturing is a desirable outcome as it facilitates lower injection pressures (and thus lower pump power requirements and costs) to be used. In California alone there are currently ~2300 wastewater injection wells.

HiQuake contains 33 cases of induced seismicity attributed to waste fluid injection. Of these, three are in Canada, two in China, one in Italy and 27 in the USA. An interesting case is that of Paradox Valley, Colorado, so-named because the Dolores River runs transversely across the valley. This case is noteworthy because of the apparently large distances from the injecting well of some of the postulated induced earthquakes (Ake et al., 2005; Block et al., 2015; King et al., 2014; Yeck et al., 2015).

At Paradox Valley, brine is injected into a sub-horizontal layer of Mississippian-age limestone at the bottom of a 4800-m-deep well. The objective is to reduce the salinity of Dolores River water and, as a consequence, the Colorado River into which it flows. Salt enters the Dolores River by inflow of groundwater ~8 times more saline than sea water. To manage this, shallow brine is extracted from the ground from nine production wells and re-injected at greater depth via a single disposal well at surface pressures up to 35 MPa (Yeck et al., 2015). Continuous injection has been underway since 1996. In the following two decades > 5700 earthquakes surmised to have been induced were located, including a M 4.3 event in 2000 (Fig. 50). Some epicenters lie > 10 km from the disposal well and a few are up to ~25 km distant.

The 1986 M_W 4.9 Painesville, Ohio, earthquake was possibly induced and occurred close to critical infrastructure (Ahmad and Smith, 1988; McGarr, 2014; Nicholson et al., 1988). This event, which was felt in 11 states and parts of Canada, occurred in Precambrian basement. It was within 17 km of the Perry Nuclear Power Plant on the edge of Lake Erie, and ground acceleration reached 0.23 g. The injection of 1.2×10^6 m^3 of liquid agricultural waste into three wells ~12 km away was implicated. These injections began in 1976. The mainshock and associated M < 2.5 aftershocks thus occurred a decade after injections began by which time pressure had increased by 11.8 MPa at the injection location.

Whether this earthquake sequence was induced is controversial. Prior to instrumentation, similar earthquakes occurred in 1906, 1928, 1943 and 1958 (i.e. about every ~20 years) in the area. The 1986 earthquakes thus may have been natural. The long delay of seismicity after the start of injection also erodes confidence that the two processes

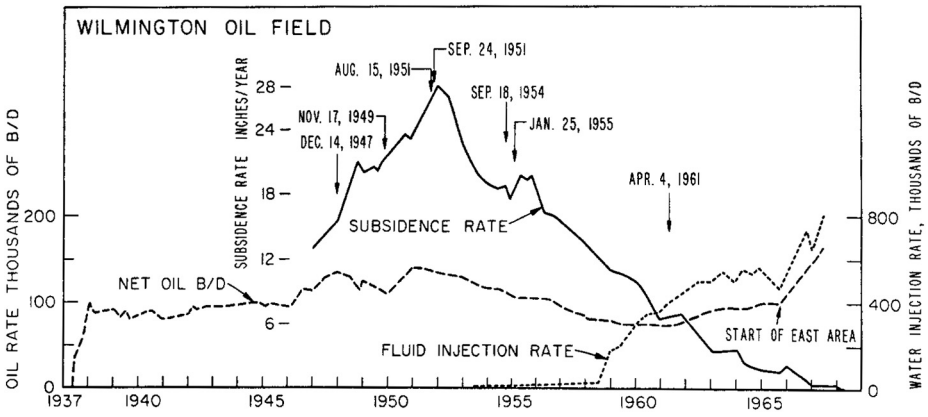

Fig. 41. For the Wilmington Oilfield, California, subsidence rate in the center of the field, oil production and water injection rates. Arrows show dates of major damaging earthquakes.
(From Kovach (1974).)

were linked (Hitzman, 2013). However, the many cases of postulated delayed earthquake induction that have occurred subsequently render it more plausible that the 1986 Painesville earthquakes were induced.

A European case is that of the 2012 M_L 5.9 Emilia-Romagna, Italy, earthquake sequence which resulted in 27 fatalities (Cartlidge, 2014). It was postulated that hydrocarbon exploitation at the Mirandola Field and geothermal exploitation at Casaglia contributed to stress changes that induced this sequence.

Because of serious impact to people and infrastructure a commission was established to investigate whether it was induced (Styles et al., 2014). The commission found statistical correlations with production parameters in the weeks before the earthquakes but concluded stress changes resulting from reservoir depletion had not contributed. It concluded that, while an anthropogenic effect could not be ruled out, it was "highly unlikely" that the sequence had been induced.

A link between injection pressure and induced earthquakes is reported for the Huangjiachang Gasfield, Sichuan Basin, China (Lei et al., 2013). Few earthquakes occurred there until injection wellhead pressure exceeded 2 MPa. After that, > 5000 M > 1.0 earthquakes occurred close to reservoir depth, the largest with M_L 4.4.

The Sichuan Basin is relatively tectonically stable with sparse historic seismicity. Gas occupies shallow, high-porosity Paleozoic and Mesozoic limestone/dolomite anticlines. Faults cross both reservoirs and basement. The Huangjiachang Gasfield is small and hosted in fractured, jointed, karstified Permian limestone at 2500 m depth. Wastewater injection began there in 2007. For the first two years, water was introduced under atmospheric pressure and seismic rates were low. In 2009 injection pressures were increased, ultimately reaching

(From Glowacka and Nava (1996).)

2.1–2.9 MPa, and earthquakes began to occur.

Particularly vigorous seismicity was reportedly induced by wastewater disposal in the Rongchang Field, also in the Sichuan Basin (Lei et al., 2008). Starting in 1989, two months after water injection began > 32,000 earthquakes up to M_L 5.2 were recorded. The largest event reactivated a thrust fault in the basement and earthquake locations suggested that failure occurred in both reservoir and basement.

An unprecedented surge in seismic rate occurred in Oklahoma in 2009 (Fig. 51) (Ellsworth, 2013). During 2008–2013 Oklahoma was the most seismically active state in the USA for M > 3 earthquakes, exceeding even California, which hosts the San Andreas fault zone, and the New Madrid Seismic Zone, formerly considered to be the most hazardous intraplate seismic zone in the USA. The largest event since 1950 in the New Madrid Seismic Zone has been M 4.9. In Oklahoma the M_W 5.8 Pawnee earthquake occurred in 2016.

Faults in Oklahoma are widespread but only one is known to have been active historically. This is the Meers fault, which is thought to have generated M 6.5–7 earthquakes over the last 3500 years (McNamara et al., 2015). The injection of water for enhanced oil recovery has been practiced in Oklahoma since the 1930s and the 1952 M ~5.6 event (the El Reno earthquake) may have been related to oil and gas extraction (Nicholson and Wesson, 1992). Hough and Page (2015) investigated whether the population of Oklahoma has been sufficiently stable historically for comparable earthquake activity to have been noted. The population has been large and well-distributed since the early 20th century, suggesting that that knowledge of M ≥ 4 earthquakes is nearly complete (Fig. 52). The occurrence of industrially induced earthquakes in Oklahoma currently are essentially beyond doubt.

As elsewhere, multiple industrial processes are underway simultaneously in the hydrocarbon fields of Oklahoma so it is difficult to be certain which induced any particular earthquake. In addition to production there are ~7000 injection wells that are used for:

- disposal of produced brine (the dominant use);
- enhanced oil recovery;
- hydrofracturing to increase permeability in shale; and
- disposal of hydrofracture fluid.

Most of the fluid is injected into the Arbuckle Group, a sequence of carbonates and sandstones overlying Precambrian crystalline basement (Fig. 53).

The largest and most damaging earthquake to have occurred in Oklahoma is the 2016 M_W 5.8 Pawnee earthquake. This exceeded the well-studied 2011 M_W 5.7 Prague earthquake which is confidently associated with wastewater disposal into a depleted oilfield (e.g., Keranen et al., 2013). The Prague earthquake was felt in 17 states and in Chicago, 1000 km away. It caused considerable damage, destroying 14 houses and injuring two people. This and the Pawnee earthquake are the largest in the world associated with waste-water disposal and have led to re-assessment of the potential size of injection-induced earthquakes and the delay time following the onset of operations.

Earthquake activity in the Prague area began in February 2010 with a M_W 4.1 earthquake in the Wilzetta Oilfield. This lies within the ~200-km-long Pennsylvanian Wilzetta fault zone (Fig. 54). In 2011 the activity culminated in the Prague sequence that included three earthquakes with M_W 5.0, 5.7, and 5.0 in November, and prolific aftershocks. Hypocentral locations and focal mechanisms from 1183 aftershocks clarified the geometry of the hypocentral zone (Fig. 55) (Keranen et al., 2013). Strike-slip motion occurred on steeply dipping planes that intersect sedimentary layers and basement. The tip of the initial rupture plane lay within ~200 m of active injection wells at ~1 km depth.

In the Wilzetta zone, oil is contained in fault-bounded structural traps that are barriers to fluid migration through the porous limestone host formation. Where the Prague sequence occurred, production has been ongoing since the 1950s but has now declined. Three waste-disposal injection wells which came online in 1993 are nearby (Fig. 55). They inject water into sealed rock compartments at ~1.3–2.1 km depth.

Over the 17-year period 1993–2011 injection pressure increased from atmospheric, reaching 3.6 MPa by 2006. Seismicity may have started when the injected volume exceeded that extracted from the fault-bounded compartment. Once the compartment had been refilled ongoing injection may have reduced confining stress on the reservoir-

Table 2
Classification categories of underground injection wells in The Code of Federal Regulations of the USA (40 CFR 144.6-Classification of wells).[a]

Class of well	Purpose
Class I	Industrial and municipal waste disposal wells
Class II	Oil and gas related injection wells
Class III	Injection wells for solution mining
Class IV	Shallow hazardous and radioactive injection wells
Class V	Wells for injection of non-hazardous fluids into or above underground sources of drinking water
Class VI	Wells used for geologic sequestration of CO_2

[a] https://www.epa.gov/uic/general-information-about-injection-wells#regulates.

bounding faults which failed as a consequence. More stress was released than corresponds to the total volume injected, so tectonic stress was probably also released. Both injection and M > 3 earthquakes continue in the Wilzetta Field.

Fig. 56 shows seismicity and oil production in Oklahoma over the last century. Between 2009 and 2014, 26 M ≥ 4 events occurred in the state with over 100 M ≥ 3.5 events in 2014 alone. Monthly statewide wastewater injectate volume has doubled since 1997 (Walsh and Zoback, 2015). Correlations between earthquakes and injection or production are rare, and Fig. 57 shows earthquakes and fluid injections for the entire state and for individual study areas. Earthquakes do not correlate with faults and most earthquakes occur in the least faulted part of Oklahoma.

Faults that fail in Oklahoma are probably those favorably oriented relative to the regional stress direction. Most events occur at 5–6 km depth in the basement on faults kilometers or tens of kilometers in length. Such faults can maximally sustain M 5–6 earthquakes. Some earthquakes occur on well-known faults that have larger seismic potentials. The length of segments activated can be determined from aftershock distributions.

Oklahoma earthquake activity exhibits both similarities and differences to other induced seismicity. No short-term monthly correlation with injection is apparent and seismicity surged long after the start of injections, 17 years in the case of the Prague sequence. In this it resembles the Wilmington Oilfield, California, where induced seismicity began years after water injection started for enhanced oil recovery (Section 4.1.3). However, it is unlike the "Denver earthquakes" sequence (Section 4.1.1) where seismicity began almost immediately after injections. Induced earthquake sequences do not necessarily start with the largest event, and stress from earlier events may trigger larger ones.

In addition to induction by hydrocarbon-related operations, earthquakes in Oklahoma are also triggered by distant large earthquakes ("remote triggering"). Van der Elst et al. (2013) noted that a M_W 4.1 event near Prague occurred following the 27 February 2010 M_W 8.8 Maule, Chile, earthquake (Fig. 58). Stress changes resulting from distant earthquakes can be calculated and can reveal the failure susceptibilities of faults.

4.1.3. Water injected for enhanced oil recovery

Oil recovery is enhanced by injecting low-salinity water, water-alternating-gas and water viscosifiers, and by thermal and chemical methods to modify either the viscosity of the fluids or the surface properties of the host reservoir. Distinguishing earthquakes induced by these processes from events induced by oil extraction is not straightforward if both are underway simultaneously. Temporal associations are persuasive, e.g., if seismicity surges shortly after water injection commences in producing oilfields that were previously aseismic.

HiQuake contains 38 cases of seismicity proposed to have been induced by enhanced oil recovery. Of these, 24 are from the USA and the rest from Canada, China, Denmark, France, Kuwait, Norway, Romania, Russia and Turkmenistan.

The classic example is that of the Rangely Oilfield, Colorado, where induced earthquakes could be controlled (Section 4.1.8) (Raleigh et al., 1976). Water was injected in wells up to 2 km deep where formation pressure was ~17 MPa. The seismic rate could be increased or decreased by varying the pore pressure around 26 MPa. This case raised hopes that earthquakes might be controlled, including damaging events on the San Andreas fault system. However, it was quickly realized that the fractal nature of earthquakes is such that the stress released by a few moderate earthquakes cannot substitute for a single large earthquake. Thus, hopes that damaging earthquakes might be averted by using engineering means were not realized.

The largest earthquakes postulated to have been induced by enhanced oil recovery are the M 6.2 1983 Coalinga event, the 1985 M_W 6.1 Kettleman North Dome event, and the 1987 M_L 5.9 Montebello Fields (Whittier Narrows) event, all in California. The primary cause for these earthquakes was, however, most likely oil extraction (Section 3.3.2) (McGarr, 1991).

More clear-cut examples come from the Newport-Inglewood fault zone, Los Angeles Basin, California. Of the 3 billion barrels (~ 490,000,000 m^3) of original reserves in the giant Wilmington Oilfield, 2.7 billion (~440,000,000 m^3) have been removed. Early production may have contributed to the damaging 1933 M_L 6.3 Long Beach, California, earthquake, and the events of 1947, 1949, 1951, 1954, 1955 and 1961 (Section 3.3.2) (Kovach, 1974).

Water flooding for enhanced oil recovery and to counteract massive subsidence started in the Wilmington Oilfield in 1954. Earthquakes up

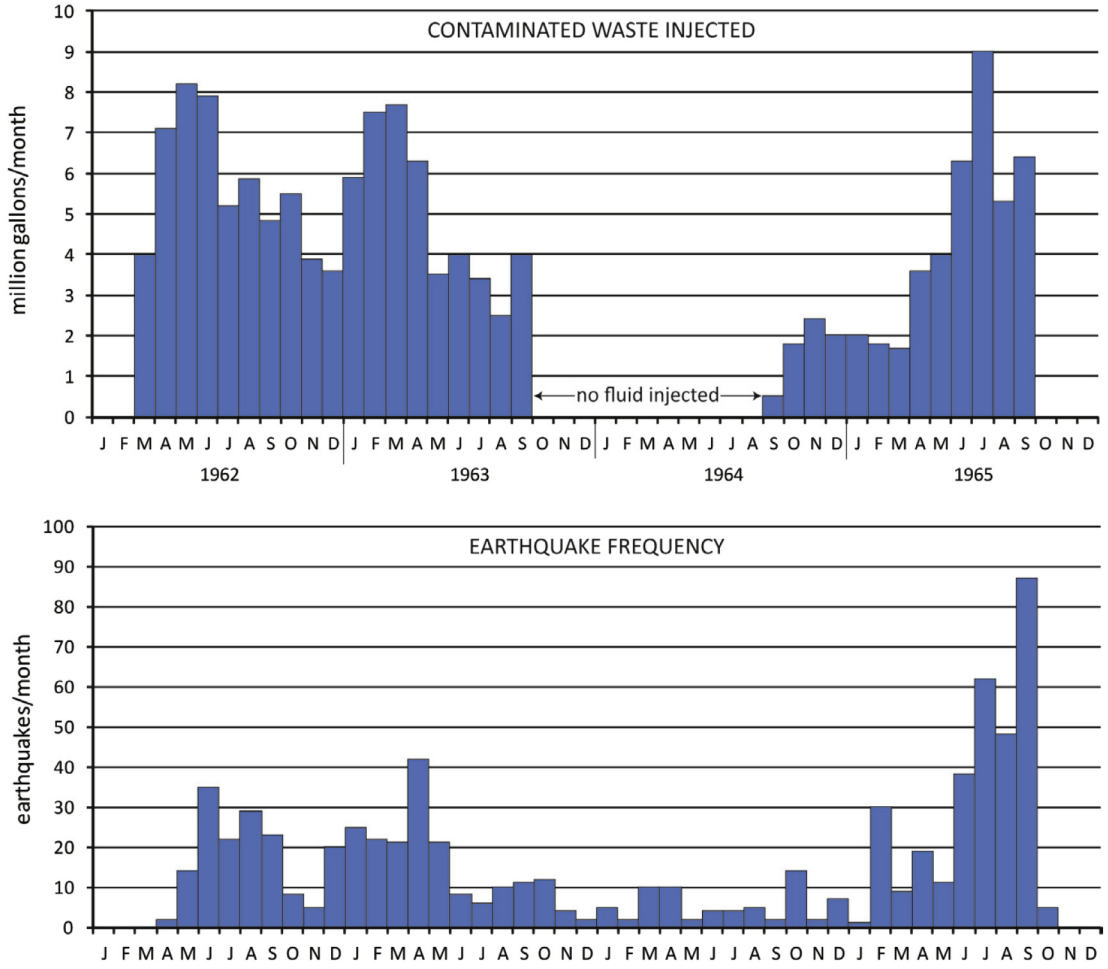

Fig. 49. Volume of waste injected into the Rocky Mountain Arsenal borehole and earthquake frequency. (Redrawn by Hitzman (2013) from Healy et al., 1968).

to M 3.0 that are thought to have correlated with injection volumes occurred in 1971. Injection was continued at approximately the same volumetric rate as production and seismicity did not continue (Nicholson and Wesson, 1992).

A more persuasive case of water-flooding-induced seismicity which caused significant damage and loss of life is that of the Inglewood Field, ~20 km further north along the Newport-Inglewood fault zone. In 1963 an earth dam containing the nearby Baldwin Hills Reservoir failed,

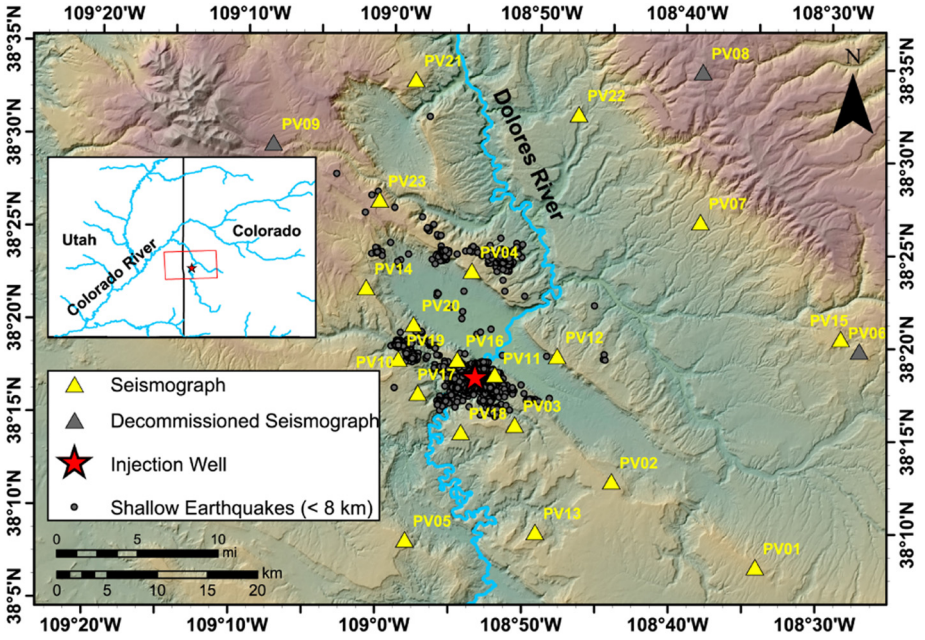

Fig. 50. The region around Paradox Valley, Colorado (the northwest-oriented depression). Yellow triangles: seismic stations; gray circles: earthquakes thought to be induced by brine injections.
(From Yeck et al. (2015).)

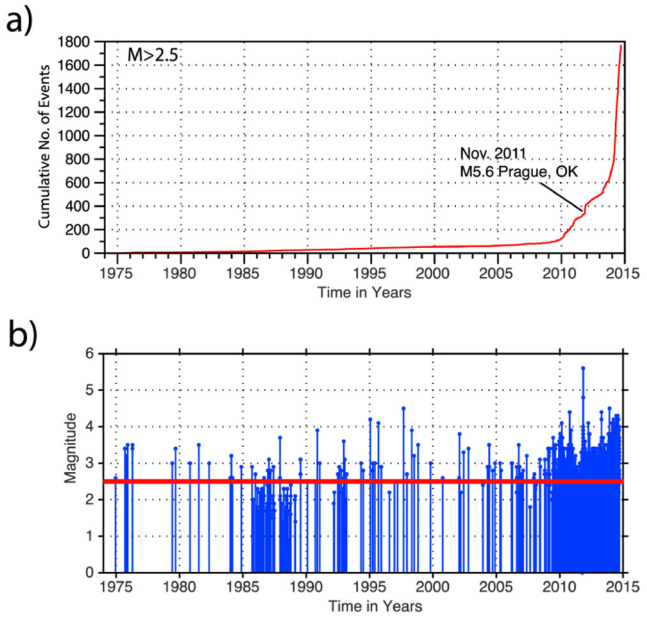

Fig. 51. Earthquakes recorded on the National Earthquake Information Center (NEIC) (http://earthquake.usgs.gov/contactus/golden/neic.php) system for the period 1975 through 2014. a) Cumulative seismicity in Oklahoma with M > 2.5. b) Earthquake magnitudes.
(From McNamara et al. (2015).)

releasing 11 × 10^6 m^3 of water into a residential area. This flood damaged over 1000 homes, killed five people and caused $12 million of damage. Failure of the dam was attributed to cumulative fault displacements that resulted from water flooding of the Inglewood Oilfield for enhanced oil recovery (Castle and Yerkes, 1976; Hamilton and Meehan, 1971).

Discovered in 1924, the Inglewood Oilfield occupies an anticline within a zone of faults and folds. Reserves were initially 430 million barrels but the field is now ~93% depleted. For the first three decades production occurred under only exsolution-gas- (pressure depletion) and peripheral-water drive. Some 83 × 10^6 m^3 of oil, water and sand were extracted. Pressures declined from 3.9 to 0.34 MPa by the 1950s. A well-defined subsidence bowl centered on the oilfield developed. Subsidence was up to 1.75 m during 1911–1963. Horizontal displacements were up to 0.68 m 1934–1961 with radially oriented extension. The Baldwin Hills reservoir lay on the edge of this subsidence bowl.

In 1954 a water-flood program for enhanced oil recovery began. Deformation accelerated immediately. A sharp reduction in subsidence occurred in the eastern part of the field. Horizontal displacements and strain were consistent with the operations and a tectonic origin for the deformation could be rejected to a high degree of certainty.

Shallow seismicity increased in 1962 and the following year the Baldwin Hills dam ruptured. It was deduced that movement on one of the faults allowed water to flow into the soil under the dam, resulting in failure. This case, and that of the Wilmington Oilfield, highlights the risk of major hydrocarbon operations near to dense populations, particularly where prior tectonic activity is known.

4.1.4. Enhanced Geothermal Systems (EGS)

Extraction of geothermal heat from rock with insufficient natural water was pioneered in the 1970s by the "hot dry rock" projects of Fenton Hill, New Mexico, and Cornwall, UK. These did not lead to economic development and were abandoned. The technology was resurrected early in the 21st century as "Enhanced Geothermal Systems" (EGS). An important milestone in this was the report "*The Future of Geothermal Energy*", prepared by the Massachusetts Institute of Technology for the U.S. Department of Energy (Tester et al., 2006).[6]

The fundamental concept of EGS is to pump high-pressure fluid into a well to hydrofracture and thermofracture hot rock, enhancing permeability and creating an underground heat exchanger. Later, cold water is pumped down an injection well, it circulates through the hot rock, and hot water and steam are extracted via production wells drilled into the fractured rock.

The objective of injection is to produce a network of fractures in the otherwise low-permeability target formation. As for shale-gas hydrofracturing, earthquakes are an inevitable consequence of a successful EGS project. Dense seismometer networks are installed prior to hydrofracturing to enable the best possible earthquake locations, magnitudes and source mechanisms. Such state-of-the-art projects are advancing basic seismology.

Notable EGS projects have been conducted at:

- Fenton Hill, New Mexico (e.g., Ferrazzini et al., 1990);
- Cornwall, UK (e.g., Turbitt et al., 1984);
- Soultz-sous-Forêts, France (e.g., Baisch et al., 2010; Calo et al., 2014);
- Basel, Switzerland (e.g., Zang et al., 2014a);
- Newberry volcano, Oregon (Cladouhos et al., 2013);
- the Coso geothermal area, California (Section 4.1.5) (Julian et al., 2010);
- Desert Peak, Nevada (Chabora et al., 2012); and
- Cooper Basin, Australia (e.g., Asanuma et al., 2005).

The Fenton Hill, New Mexico, hot dry rock project was the first of its kind. It was completed in 1977 in rock at ~2.6 km depth 185 °C. Work continued into the 1990s, achieving production of ~10 MW thermal, but was terminated because of lack of funding.

An early modern EGS project commenced at Soultz-sous-Forêts, in the central Upper Rhine Graben, France in 1987 (Fig. 59) (Baisch et al., 2010; Calo et al., 2014). The site lies in highly fractured granite overlain by ~1400 m of sediments. It contains three ~5000 m deep injection wells and several shallower wells. Massive hydraulic stimulations were performed at depths > 4000 m. In 2000, well GPK2 was stimulated with ~23,000 m^3 of water at flow rates of 30–50 l/s and overpressures of up to 13 MPa. Well GPK3 was stimulated in 2003 with ~37,000 m^3 of water at similar flow rates and overpressures. Well GPK4 was stimulated twice with a total of ~22,000 m^3 of fluid. In 2010 the project began to deliver 1.5 MW to the grid.

The injections were monitored using a sparse seismic network of multi-component, down-hole sensors at 1500–3500 m depths. More than 114,000 earthquakes were detected at rates of up to 8000 events/day (Fig. 60). Activity migrated away from the injection wells with time and the largest events occurred after injection stopped. Such behavior causes problems for "traffic light" systems for adjusting injection strategies to avoid large earthquakes on the basis of ongoing seismicity. Earthquake magnitudes eventually reached M_L 2.9 and caused public concern. After the largest event in 2003 the flow rates and injected volumes were reduced. The project demonstrated that better understanding of induced seismicity is needed if it is not to jeopardize commercial implementation of EGS technology.

The most infamous example of nuisance seismicity induced by EGS operations is from Basel, Switzerland. The city of Basel lies where the Upper Rhine Graben intersects the Jura Mountains fold/thrust belt (Fig. 1). Basel has a history of large earthquakes, including the largest historical event in NW Europe, the M ~6.5 earthquake of 1356 which destroyed the city. There may have been additional M ~7 events post-Pleistocene.

A summary of this project is provided by Häring et al. (2008) and a 2014 Special Issue of Geothermics (Zang et al., 2014a). The project was

[6] http://geothermal.inel.gov and http://www1.eere.energy.gov/geothermal/egs_technology.html.

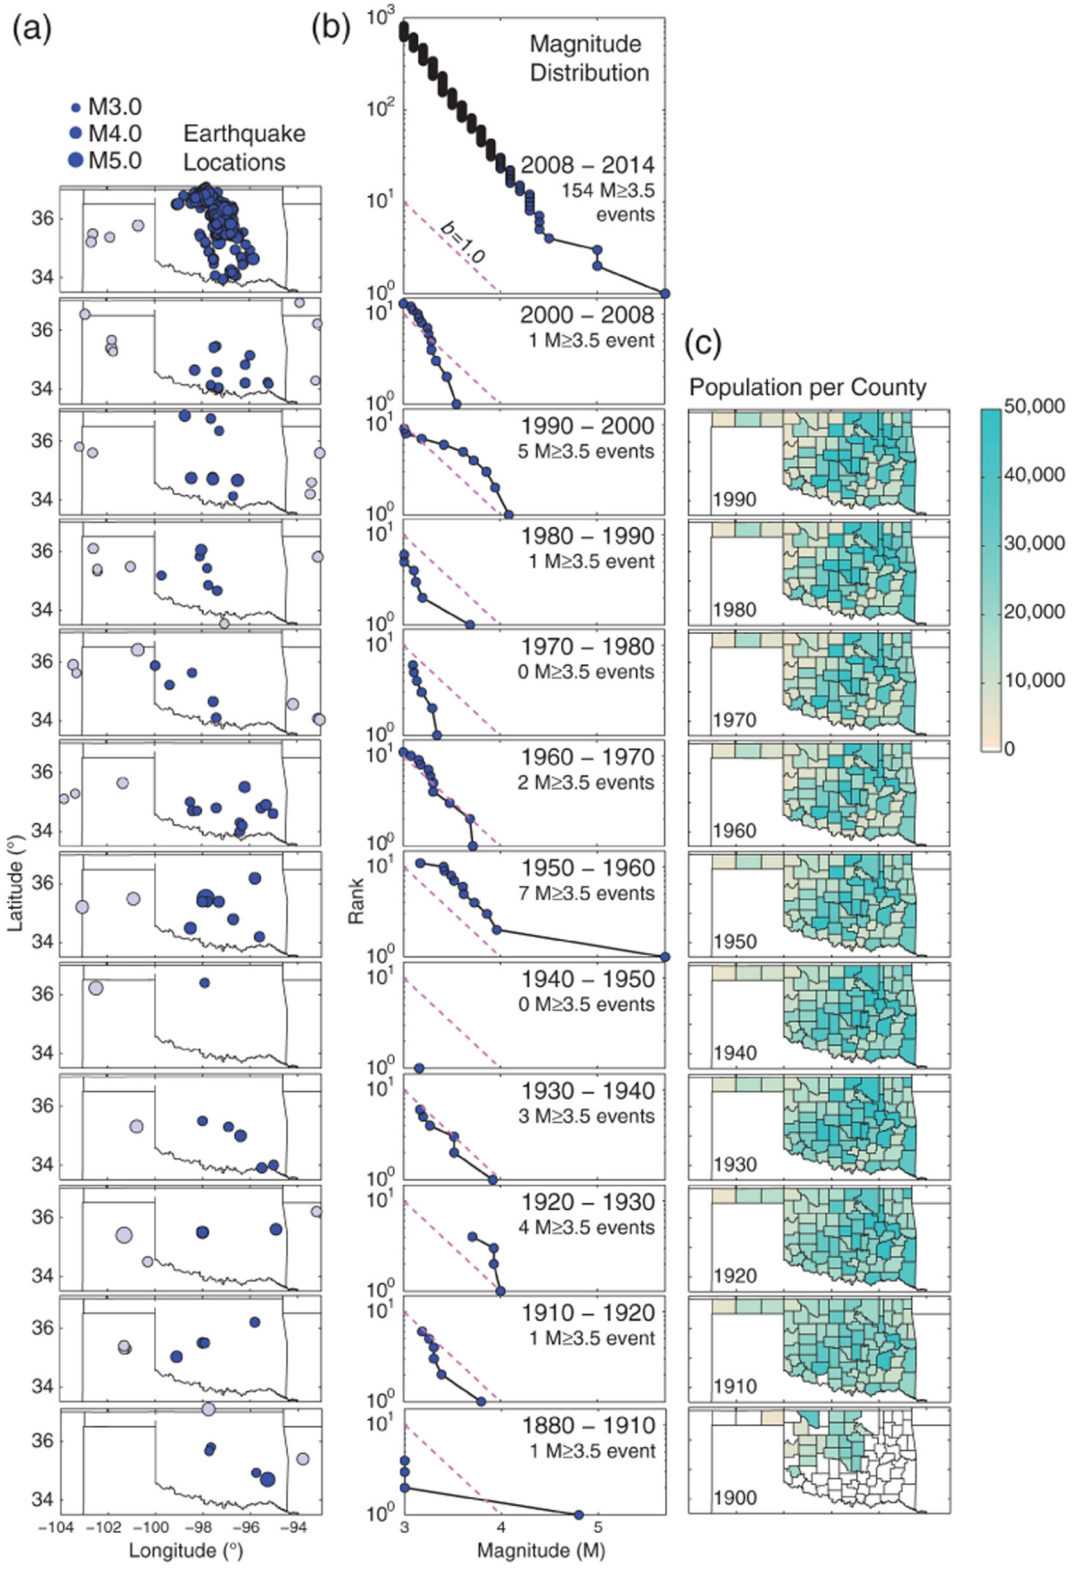

Fig. 52. Oklahoma seismicity. Left panels: Earthquake locations: blue–Oklahoma, gray–neighboring states. Center panels: magnitudes plotted cumulatively 1880–2014. Right panels: human population by county.
(From Hough and Page (2015).)

designed to provide power to Basel. A seismic network was installed in 2006 and the Basel-1 well drilled to 5 km depth. The wellbore intersects 2.4 km of sedimentary rocks and 2.6 km of granitic basement.

The granite in the open hole below 4629 m was hydraulically stimulated by injecting 11,570 m^3 of fluid. It was planned to inject for 21 days. However, seismicity became intense during the first 6 days, with events up to M_L 2.6 occurring at ~4.6–5.0 km depth. These events precipitated cessation of injection in response to a pre-approved procedure. Five hours later an earthquake with M_L 3.4 occurred and a further three M > 3 events followed over the next 56 days (Fig. 61).

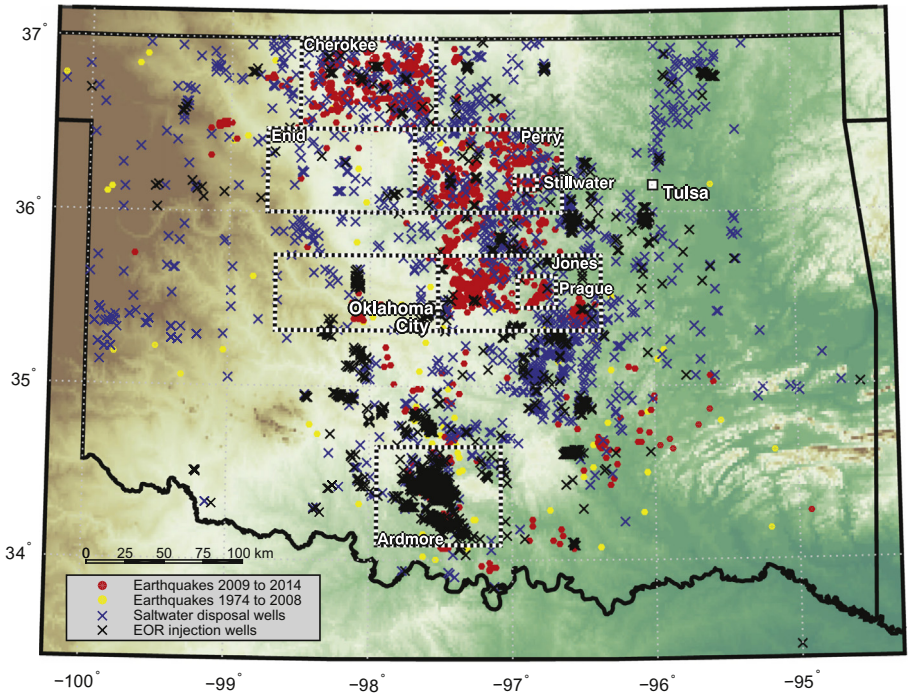

Fig. 53. Earthquakes and injection wells in Oklahoma. (From Walsh and Zoback (2015).)

There was considerable citizen anxiety and the project is now abandoned.

EGS has been extensively conducted in Cooper Basin, Australia, where the largest earthquake induced to date was M_W 3.7. Cooper Basin is ideal for EGS. It lies in the interior of Australia, remote from population centers. Significant oil and gas resources were explored and exploited since the 1960s and industrial infrastructure was left in place that was used from 2002 when geothermal exploration started. The target heat source is granitic rocks with temperatures up to 240 °C at 3.5 km depth. These are the hottest known granitic rocks in the world at economic drilling depths that are not near active volcanoes.

Six wells were drilled into the granite to 3629–4852 m depths. Four are in the Habanero Field and the other two are 9 and 18 km away in the Jolokia and Savina Fields. EGS fluid injections were conducted 2003–2012 (e.g., Asanuma et al., 2005; Baisch et al., 2009; Baisch et al., 2006; Baisch et al., 2015; Kaieda et al., 2010). These induced up to 20,000 earthquakes well-recorded by dense, modern seismic networks.

Although all the stimulations were conducted in the same granite formation, they induced variable seismic responses (Fig. 62). These are exemplified by two carried out in 2010 and 2012 (Baisch et al., 2015). The 2010 stimulation injected fluid into the Jolokia well at > 4000 m depth. It induced only minor seismic activity, even at extremely high fluid pressures (~120 MPa), and the injection rate achieved was only ~1.0 l/s, one to two orders of magnitude less than typical. Only 73 earthquakes with M_L −1.4 to 1.0 were recorded over an eight-day stimulation period and an additional 139 over the next six months. The largest was M 1.6 which occurred 127 days after injection ceased–another case where the largest event occurred after injection finished. Hypocenters clustered around the injection well a few tens or hundreds of meters away, suggesting that they occurred on fractures poorly oriented for slip in the regional stress field.

The 2012 stimulation in well Habanero 4 injected 34,000 m^3 of water at 4100–4400 m depths with flow rates > 60 l/s, and wellhead pressures of ~50 MPa. This induced > 29,000 earthquakes with M_L

−1.6 to 3.0 recorded on a local 24-station network. From these data, 21,720 locations and 525 focal mechanisms were derived. This may be the most prolific EGS-induced earthquake dataset ever collected. In contrast to the well-hugging, sub-vertical fracture activated by stimulation of well Jolokia 1, the Habanero 4 stimulation activated a single, sub-horizontal fault zone only a few meters thick, extending > 1.5 km from the well. Failure was consistent with the regional stress field.

These remarkably different seismic responses characterized injections in different wells penetrating the same granite formation. This exemplifies the challenge of predicting the behavior of formations under stimulation, even when excellent geological knowledge is available. Despite the major technological advances achieved in the Cooper Basin project, due to low oil prices and changing government priorities, the project was decommissioned in 2016.

Despite the challenges that currently face development of EGS, much has been learned recently that will underpin the future of the industry. Because it is known beforehand that projects induce seismicity, exemplary seismic monitoring and public outreach practices have been developed. These include installing custom-designed networks of three-component borehole instruments well in advance of operations to obtain a pre-operational baseline for seismic activity. Data are streamed to public websites and outreach includes town-hall meetings, seismometers in public buildings in nearby communities, distributing information to the public by talks, printed materials and the internet, and involving local communities in the commercial activity.

4.1.5. Geothermal reinjection

Water is re-injected into exploited geothermal fields to maintain pressure. Although classified technically as renewable resources geothermal fields are, in reality, not so. If large quantities of hot fluid are removed at high rates for many years, exceeding natural recharge, the resource becomes depleted and progressive reduction in reservoir pressure leads to reduced production. To maintain pressure water is re-injected while avoiding cooling production wells.

The most remarkable case of seismicity attributed to geothermal reinjection is The Geysers field, California (Fig. 46). The Geysers is a rare vapor-dominated reservoir that lies in the strike-slip regime of the San Andreas fault system, California. Exploitation began in the 1860s. Steam was first used to generate electricity in 1922 when 1 kW was produced. Production peaked in 1987 at about 3.5×10^3 kg s^{-1} of steam from which 1800 MW of electricity was generated (Fig. 47).

Power production decreased thereafter because the modest amount of reinjection done could not maintain declining steam pressure. Condensate was the main re-injectate and less was available than the amount of water produced. Reservoir pressure is sub-hydrostatic and thus the water could be reintroduced at atmospheric pressure, i.e. it was poured into boreholes and drained back into the reservoir under gravity.

The US Geological Survey routinely locates > 10,000 earthquakes/year at The Geysers. The annual seismic rate is currently 200–300 M 2 earthquakes and 1–2 M 4 earthquakes. The Geysers earthquake dataset is without doubt the richest set of induced earthquake data available in the world with > 250,000 located events in the catalog of the Northern California Earthquake Data Center.[7]

For many years it was not acknowledged that the industrial activity induced the earthquakes. However, as data accumulated the link could not be denied. It was initially assumed that the earthquakes resulted from the contracting reservoir collapsing in on itself. Surface subsidence rates are up to 5 cm/year (Lofgren, 1978; Mossop and Segall, 1999; Vasco et al., 2013).

It is now clear that seismicity correlates better with reinjection than

production (e.g., Majer and Peterson, 2007; Stark, 1990). It has been possible to make this link since 1998 when the first of two major water-acquisition and reinjection projects began. The South East Geysers Effluent Project (SEGEP) began to re-inject water via a 46-km-long pipeline from Lake County that delivers up to 22 × 10^6 l/day of gray water. In 2003 the second project came online, the Santa Rosa Geysers Recharge Project (SGRP), which delivers up to 41 × 10^6 l/day via a 64-km-long pipeline from Santa Rosa (Fig. 47) (Majer and Peterson, 2007). Surges in earthquake rate correlate with the increases in water injection with those projects. Surges of earthquakes also correlate with individual

injections and injection wells (Majer and Peterson, 2007; Stark, 1990), e.g., in the high-temperature northwest Geysers in 2004 (Fig. 63).

Ground shaking from earthquakes with Modified Mercalli intensities of II–VI are felt daily in settlements near The Geysers. The largest earthquake that has occurred is the 2014 M_W 4.5 event. On the basis of historical seismicity, the absence of long faults in the reservoir, and the lack of epicentral alignments, Majer et al. (2007) estimated that the largest earthquake that could occur was M ~5.0. An extensive review of The Geysers seismicity is provided by Majer and Peterson (2007). They conclude that the seismicity results from a diverse set of processes that may work independently or together and either enhance or possibly reduce seismicity. To the processes listed in Section 1.3, thermal contraction from cooling the rock matrix can be added.

A second example of particularly rich geothermal-induced seismicity is from the Coso geothermal field. This field lies in the southwestern corner of the Basin and Range province in eastern California, at a right releasing step-over in the southern Owens Valley fault zone (Monastero et al., 2005). It lies on a US Navy weapons test site, and is thus uninhabited and not generally accessible to the public. Electricity has been generated since the 1980s, producing about 250 MW. Because there is a shortage of local water, only about half the volume produced is replaced by reinjection and the local water table has lowered greatly.

Tectonic seismicity is intense in the region, but even in this context the geothermal field is anomalously seismogenic. Several thousand locatable earthquakes per year occur within the ~5 × 5 km production field, the majority of which must be induced. These earthquakes have

(2015).)

been used for detailed research (e.g., Julian et al., 2004; Julian et al., 2007; Kaven et al., 2014; Monastero et al., 2005). Most production and reinjection data are proprietary, so published correlations between operations and seismicity are rare.

One of these rare cases is described by Julian et al. (2007). In 2005 an existing well was used for an EGS experiment. Fluid was injected at rates of up to 20 l/s into well 34-9RD2 in order to increase permeability and enhance production in nearby producing wells. 34-9RD2 was reworked prior to the injection to deepen it and replace the existing slotted liner with an un-slotted one.

Major unexpected circulation-loss zones were encountered resulting in a total loss of up to 20 l/s of drilling mud at 2672 m depth. The planned EGS project thus instantly metamorphosed into an unplanned reinjection operation. A vigorous earthquake swarm began immediately. High-resolution locations, relative locations, and full moment tensors were determined using an exceptionally high-quality dataset acquired on 36 digital, three-component seismic stations of the permanent network operated by the Geothermal Program Office of the US Navy augmented by temporary stations.

The swarm opened, in tensile mode, several hundred meters of a preexisting fault immediately adjacent to the well. The existence of this structure, deduced from the seismic evidence, was confirmed by surface geological mapping and a borehole televiewer log. This was an early demonstration of the potential of earthquake techniques to study the detailed subsurface fracture network in a geothermal reservoir.

In Europe, three geothermal projects have been associated with M > 3 induced earthquakes, all in Italy:

- the Larderello-Travale area (M_{MAX} 3.2);
- the Monte Amiata geothermal field (M_{MAX} 3.5); and
- the Torre Alfina Field (M_{MAX} 3.0).

Of these, the most notable case is Larderello-Travale, Tuscany, which, like The Geysers, is a rare vapor-dominated system. Tuscany is tectonically active with transcurrent-transtensional-strike-slip deformation, high thermal gradients and temperatures up to 400 °C. There are several geothermal fields of economic interest. The shallower Larderello-Travale reservoirs occupy Triassic carbonate and evaporite rocks and the deeper ones fractured metamorphic basement.

Larderello-Travale has generated electricity almost continuously since 1904, and is thought to have a long history of seismicity. In the early 1970s, injection of cold condensate from the power plants started to recharge the upper reservoir and a seismic network was installed (Batini et al., 1985; Batini et al., 1980).

Seismicity is variable in rate and *b*-values. The events are mostly < 8 km deep, with 75% 3.0–5.5 km deep. The largest event reported

Fig. 64. States of the USA where shale-gas hydrofracturing is currently ongoing.

was M 3.2 and occurred in 1977. Events have significant non-shear focal mechanism components, indicating tensile failure (Kravania et al., 2000). Because of the long history of seismic activity it has been suggested that many events are natural. However, there is a clear correlation between injected volume and seismic rate (Batini et al., 1985; Evans et al., 2012).

4.1.6. Shale-gas hydrofracturing

Gas-bearing shale formations are hydrofractured ("fracked") to increase permeability and release the contained gas. It is typically done by drilling shallow horizontal wells into the target formation. Fluids are injected containing chemicals and solids designed to propagate fractures and prop them open. It is extensively applied in the USA where it has brought about a major reduction in the cost of natural gas (Fig. 64). As a result of this success there is widespread interest in the technology in other countries. However, in regions where population density is high there may be public concern about potential environmental effects, including ground-water pollution, industrialization and induced earthquakes.

Although over 2.5 million shale-gas hydrofracturing jobs have been completed worldwide, maximum earthquake magnitudes for only 21 cases have been reported. Of these cases, eight are from the USA, 12 from Canada, and one from the UK (Baisch and Vörös, 2011; de Pater and Baisch, 2011). This is only 0.001% of all shale-gas hydrofracturing jobs (Section 7.1). Of those cases, moderately large earthquakes are reported from British Columbia (M 4.4, 4.4 and 3.8 events) and Alberta (M_L 4.4), both in Canada (Kao et al., 2015; Schultz et al., 2015). In the USA the largest shale-gas hydrofracturing-related earthquakes reported have been four M > 3 events in Oklahoma and Ohio (Darold et al., 2014; Skoumal et al., 2015).

These statistics are misleading because the fundamental purpose of hydrofracturing in gas-bearing shale is to crack the rock. Thus, all successful hydrofracturing jobs induce earthquakes but an aim is that they do not cause nuisance. Meeting this objective is helped in the USA and Canada by operating in regions of low population density. Seismic monitoring is often done because the earthquake locations indicate the location and volume of the fracture network created. However, if nuisance seismicity is not induced there is little reason to report it publically. Seismic analyses focus on investigating the spatial distribution and mode of fracturing, the results are not of public interest, and they are likely to remain proprietary.

A remarkable case was associated with injection operations in 2013 near Crooked Lake, Alberta. There, the largest shale-gas hydrofracturing-related earthquakes on record were induced. The target formation was Devonian Duvemay organic-rich shale. Operations involved multi-stage, high-pressure injections of proppant with weight-in-well ~60 MPa and volumes of a few thousand cubic meters. Of ~3000 hydrofracturing operations in Alberta in 2013, only three (0.1%) are reported to have been accompanied by noteworthy seismicity, with 160 events up to M_L 4.4 being observed over a ~2-year period (Schultz et al., 2015).

The quality of information about the sequences is limited because there were no local seismic stations. Data from distant stations were subject to sophisticated processing and suggested close spatial and temporal correlation with the shale-gas hydrofracturing (Fig. 65). Correlation also occurred between injection stages, a "screen-out" (i.e. interruption in slurry flow causing shutdown of injection) and seismicity. Associations between screen-outs and seismicity are reported from elsewhere (Clarke et al., 2014; Skoumal et al., 2015). The seismicity may have hampered operations at Crooked Lake.

The Horn River Basin, British Columbia, is a major shale gas production area. Hydrofracturing commenced in 2006 and gas production peaked in 2010 and 2011 (Farahbod et al., 2015). Prior to the hydrofracturing, seismic rates were low. Only 24 earthquakes with M 1.8–2.9 were located locally in a ~2-year period. When hydrofracturing started the seismic rate increased to > 100 earthquakes/year and correlated with hydrofracturing (Fig. 66). A logarithmic correlation between seismic moment, maximum magnitude and volume injected was observed (Fig. 67).

For the entire Horn River Basin, injected volume was more closely related to seismicity than injection pressure. Increases in volume increased earthquake frequency but not magnitude. Large earthquakes ($> 10^{14}$ N m, i.e., $M_W \sim 3.5$) occurred only when ~150,000 m^3 of fluid were injected per month. Time lags between injections and seismicity ranged from days to months.

The embryonic UK shale-gas industry began with the unfortunate case of the 2011 Preese Hall, Lancashire, earthquake sequence. There, the first UK dedicated multi-stage shale-gas hydrofracturing operation was conducted in a 1000-m section of the Carboniferous gas-bearing Bowland Shale. Following the injection of 2245 m^3 of fluid and 117 t of proppant, a nearby M_L 2.3 earthquake was reported by the British Geological Survey. The earthquake was felt, and was unusual in that location. The nearest monitoring station was 80 km away. Additional

seismic stations were deployed rapidly but no aftershocks recorded. UK shale-gas hydrofracturing thus started with a rare phenomenon–the suspected induction of a nuisance earthquake.

Operations continued, but about six weeks later a second felt event of M_L 1.5 occurred ~1.0 km from the well. Citizen disquiet followed and operations were suspended. A total of 52 earthquakes in the magnitude range M_L −2.0 to 2.3 were detected with similar waveforms to the two largest events. A government enquiry and 18-month suspension of operations ensued while the problem was investigated. The close relationship between hydrofracturing and seismicity left little doubt that the earthquakes had been induced (Fig. 68).

The UK Department of Energy and Climate Change (DECC) commissioned a review and recommendations for mitigation of seismic risk associated with future shale-gas hydrofracturing operations in the UK. Recommendations included monitoring test injections prior to the main injections, monitoring fracture growth during injections, near-real-time seismic monitoring, and halting or changing injection strategy at the occurrence of seismicity with a threshold magnitude of M_L 0.5 (Green et al., 2012).

Detailed studies of the locations and fault mechanisms of the poorly recorded seismicity, combined with seismic reflection data, showed that the earthquakes probably occurred a few hundred meters below the well perforations on a fault that was not previously known (Clarke et al., 2014; Green et al., 2012). The fault does not intersect the borehole but was close enough that hydrofracture fluid may have leaked into it. The structure is an ancient transpressional fault that formed at the end of a Carboniferous basin inversion which had been inactive for 260 Ma. This case illustrates that even long-inactive faults, which are common in most continental crust, are close to failure and may be induced to slip by nearby injections.

4.1.7. Allowing mines to flood

Removal of rock from mines lowers confining stress on nearby faults and brings them closer to failure. The simultaneous pumping out of water during mining lowers pore pressure, increasing the strength of faults and counteracting the effect of rock removal. These processes roughly balance until a mine is abandoned and pumping stopped. After this, natural groundwater recharge may encourage seismicity.

A classic case is that of the 1994 Cacoosing Valley, Pennsylvania, earthquake sequence (Fig. 69) (Seeber et al., 1998). Groundwater recharge is implicated in a M_L 4.4 earthquake that occurred beneath an 800-m-wide carbonate quarry from which ~4×10^6 m^3 had been removed. The earthquake caused ~$2 million of damage to nearby homes. The quarry had been excavated to an average depth of 50 m over the 58-year time period 1934–1992. Groundwater pumping done during the mining period stopped after mining ceased and the water table rose by ~10 m in a few months. The rock is permeable karstic carbonate and depletion of groundwater, along with subsequent recharge, likely extended over a wider area than the footprint of the quarry.

Earthquake activity commenced approximately five months after

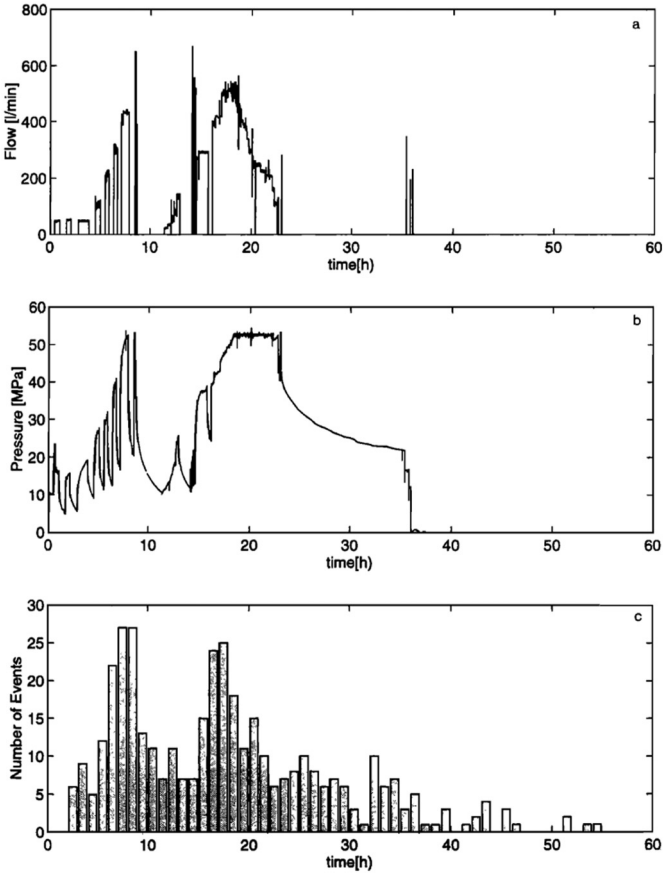

Fig. 71. Flow rates, pressure and number of earthquakes induced by brine injection into the Kontinentales Tiefbohrprogramm der Bundesrepublik Deutschland (KTB–the German Continental Deep Drilling Program) borehole during a 60-hour period. (From Zoback and Harjes (1997).)

pumping ceased. A rapidly deployed temporary seismometer recorded 67 aftershocks. They occurred in the upper 2.5 km in a planar pattern interpreted as the fault plane that slipped. Focal mechanisms suggested the mainshock had a thrust mechanism. The earthquakes occurred in the hanging-wall block such that unloading by rock removal would have encouraged slip. Surprisingly, the seismicity did not activate any of the plentiful, known, large-displacement faults in the region. Instead, stress was released on a set of small, unmapped faults which probably had a more suitable orientation. The mining had reduced confining stress by ~0.13 MPa, while the M_L 4.4 mainshock had a stress drop of 1–4 MPa.

The Cacoosing Valley event may have been similar to one that occurred two decades earlier beneath a large quarry at Wappingers Falls, New York (Pomeroy et al., 1976). A m_b 3.3 earthquake occurred there in 1974. Again, the mainshock and aftershocks nucleated at exceptionally shallow depth with some as shallow as 0.5 km. Slip occurred on a reverse fault immediately below the quarry and had a source mechanism consistent with the regional stress field. Over the preceding ~75 years ~30×10^6 m^3 of rock had been removed by open-casting down to a depth of ~50 m. This changed the stress by ~1.5 MPa at the surface and reduced the normal stress on faults below.

4.1.8. Research projects

In the wake of the Denver, Colorado earthquakes (Section 4.1.1) there was speculation that earthquakes might be controllable. Partly as a result, a series of earthquake-induction experiments have been conducted for research purposes. These have investigated the physical properties of natural fault zones and the processes that accompany earthquake occurrence. *HiQuake* contains 13 cases of earthquakes induced by research projects.

The first such project was conducted in 1969 at the Rangely Oilfield, Colorado (Raleigh et al., 1976). This oilfield occupies Mesozoic and Paleozoic sedimentary rocks at ~1700 m depth and is underlain by crystalline basement at ~3000 m. There is little local faulting, but earthquake activity had occurred with water flooding for enhanced recovery (Section 4.1.3). A seismograph array and prior earthquake record were therefore available. Fluid pressure in wells near the

(From Gaite et al. (2016).)

earthquakes was experimentally cycled to investigate the effect on the seismicity. There was close correlation between seismicity and high pore pressure and events up to M_L 3.1 were induced (Fig. 70).

In 1970 another experiment was conducted at Matsushiro, Japan. A volume of 2883 m^3 of water at wellhead pressures of 1.4–5.0 MPa was pumped into an 1800-m-deep well to test whether earthquakes were induced by increasing pore pressure in a fault zone. After several days of injection earthquake activity started within a few kilometers of the well (Ohtake, 1974).

After a hiatus in experimenting of 16 years, in 1990, perhaps the best known research experiment to study fluid-induced seismicity was begun–the Kontinentales Tiefbohrprogramm der Bundesrepublik Deutschland (KTB)–the German Continental Deep Drilling Program. Extensive literature documents this project including a 1997 special section of Journal of Geophysical Research (No. 102) (e.g., Baisch and Harjes, 2003; Baisch et al., 2002; Bohnhoff et al., 2004; Erzinger and Stober, 2005; Fielitz and Wegler, 2015; Grasle et al., 2006; Jahr et al., 2005; Jahr et al., 2007; Jahr et al., 2008; Jost et al., 1998; Shapiro et al., 2006; Zoback and Harjes, 1997).

The main borehole was drilled 1990–1994 to a depth of 9.1 km. The first hydraulic stimulation was conducted in 1994 at depths and pressures close to the brittle-ductile transition. About 400 earthquakes up to M_L 1.2 were induced at about 8.8 km depth (Fig. 71). Focal mechanisms were consistent with stress measured in the borehole. Seismicity began within a few hours of pumping and a few tens of meters from the borehole. Modeling suggested that the earthquakes occurred in response to pressure perturbations of < 1 MPa, i.e. $< 1\%$ of the ambient, hydrostatic pore pressure at the nucleation depth.

An important conclusion of this experiment was that differential stress in the crust is limited by the frictional strength of well-oriented, pre-existing faults ("Byerlee's Law") and the crust is in brittle failure equilibrium even at great depth in stable intraplate areas. Hydraulic experiments at the site have continued up to recent years (e.g., Jahr et al., 2008).

A 1997 project in the Philippines injected 36,000 m^3 of water into a well intersecting a creeping portion of the Philippine Fault at the Tongonan geothermal field. The water entered the formation at 1308–2177 m below the surface (Prioul et al., 2000). Several hundred earthquakes occurred but all were away from the fault in the geothermal reservoir. Prioul et al. (2000) concluded that tectonic stress on the fault is relieved aseismically and as a consequence there was no differential shear stress to be released by the water injection.

In the same year, a water-injection experiment was conducted in the Nojima fault zone, Japan, shortly after it ruptured in the 1995 M 6.9 Kobe earthquake (Tadokoro et al., 2000). This experiment gathered information on the physical properties of a fault plane in the immediate post-rupture period. Over periods of a few days, 258 m^3 of water were injected into an 1800-m-deep borehole at a pressure of ~ 4 MPa at the surface, entering the fault zone at 1480–1670 m depth. An increase in M -2 to 1 seismicity occurred a few days after each injection. It was concluded that the fault zone was highly permeable and could slip with pore-fluid pressure increases of $< 10\%$.

Two additional experiments have been conducted in recent years, the first in 2013 as part of the Wenchuan Earthquake Fault Science Drilling (WFSD) project (Ma et al., 2015). This project studied the fault healing process. Over a four-month period 47,520 m^3 of water at 10–15 MPa was injected at rates of up to 1.7 l/s into a 552-m-deep well that intersected a fault zone at 430 m depth. The fault was activated and over 20,000 earthquakes up to M ~ 1 were detected by downhole observations. The hypocentral zone suggested failure in the same sense as the regional stress.

A similar phenomenon was reported by Guglielmi et al. (2015) in an experiment that stimulated an inactive fault in a carbonate formation. The experiment injected 0.95 m^3 of water into a 518-m-deep

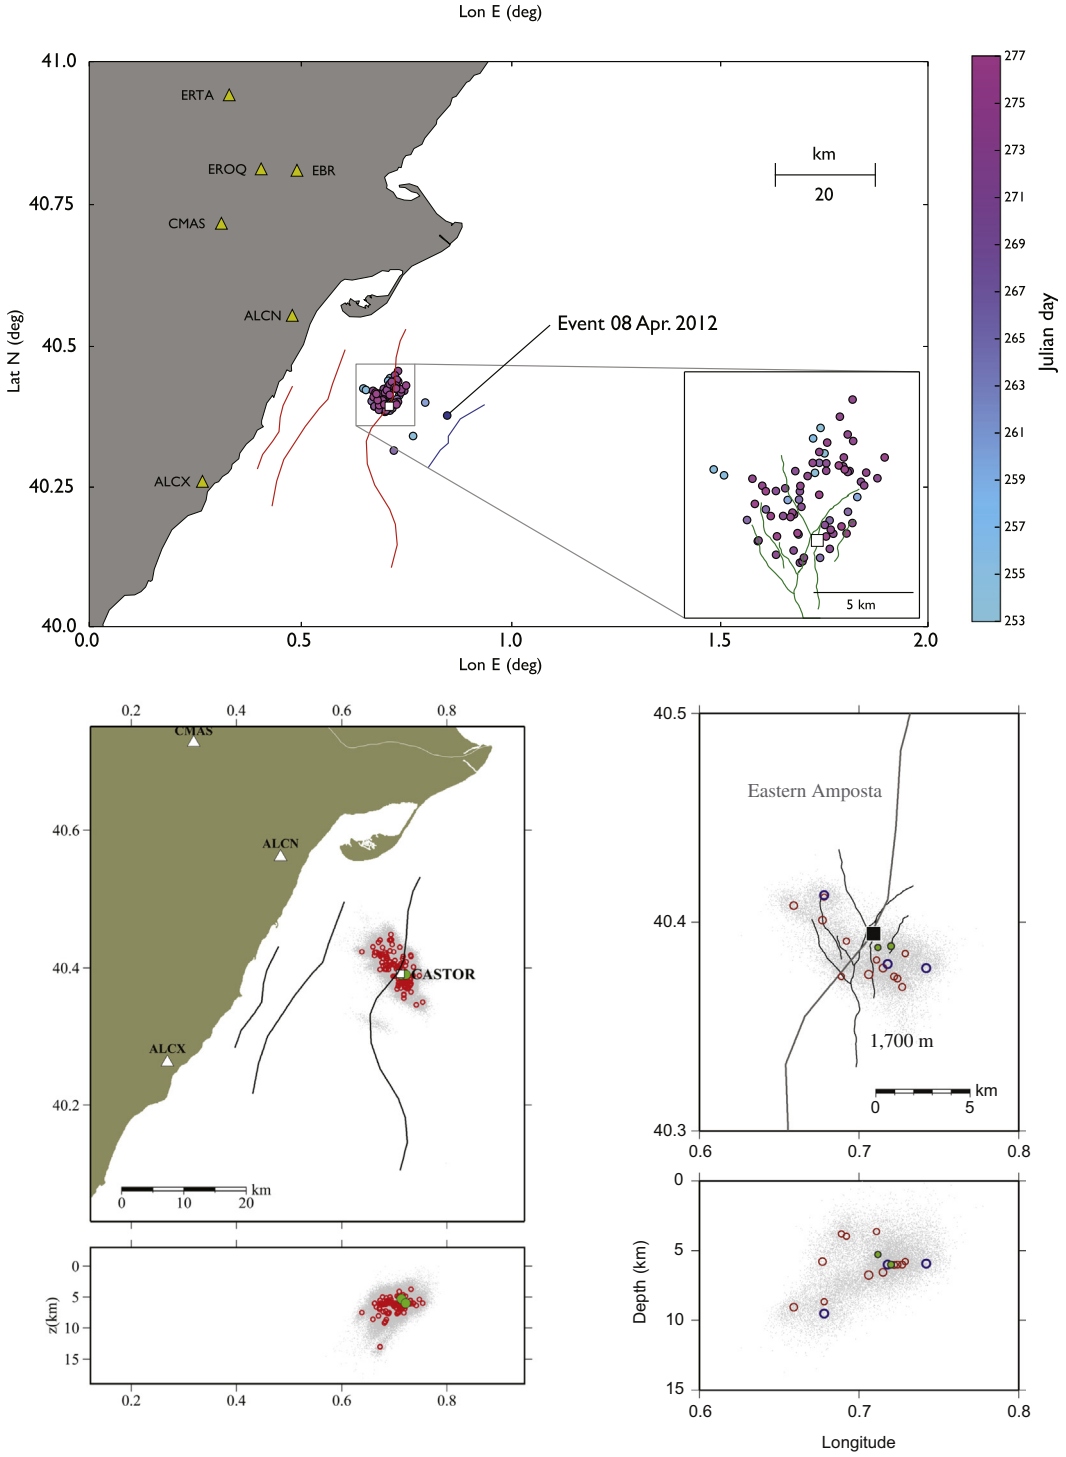

Fig. 75. Top: Faults and epicenters for the largest events in the 2013 earthquake sequence in the old Amposta Field. underground experimental facility in southeastern France where a vertical well intersected a fault at 282 m depth. Aseismic shear slip started at a pressure of ~1.5 MPa, and ~80 earthquakes occurred a few meters from the injection point. These accounted for only a small fraction of the slip on the fault, however. The accumulated moment at the end of the experiment was $M_o = 65 \times 10^9$ N m (equivalent to an earthquake with M_W 1.17). This was far larger than the moment released by the seismicity, which totaled $M_o < 2$ N m. Aseismic slip dominated deformation in the fault zone and the earthquakes occurred in rock mass outside the pressurized zone. Other experiments have been performed in a salt solution mine at Cerville-Buissoncourt in Lorraine, France (Kinscher et al., 2015; Mercerat et al., 2010) and the Wairakei geothermal field, New Zealand (Allis et al., 1985; Davis and Frohlich, 1993).

This multi-decade, multi-national research endeavor has answered some critical questions, not always those originally posed and not

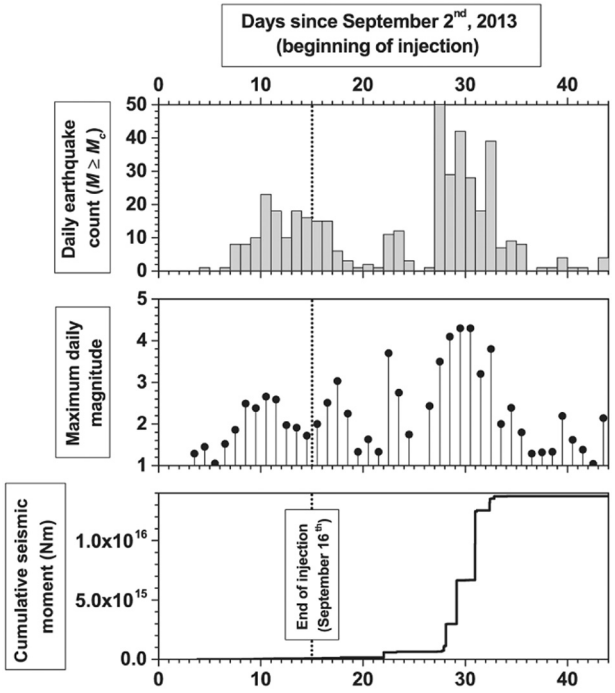

Fig. 76. Temporal evolution of seismicity with M > 2 associated with the Castor project, Spain, for 44 days from the beginning of gas injection, 2 September 2013. Top: daily number of events. Center: maximum daily magnitude. Bottom: cumulative seismic moment.
(From Cesca et al. (2014).)

always with the preferred answer. Relieving in a controlled way the stress naturally released in large earthquakes is scientifically challenging. The continental crust is near to failure, even to great depths and where large faults are not known. Earthquakes can be induced by relatively small stress perturbations, but in some cases stress on a targeted fault is relieved aseismically. In these cases, motion on that fault may induce secondary earthquakes in the surrounding rock mass. Fluid injection may thus induce primarily aseismic slip, and seismicity may be a secondary effect, with imperfect spatial correlation with the injection activities. In many cases of induced seismicity more stress is released than is loaded on faults artificially, since pre-existing tectonic stress is also released. However, the southeastern France experiment illustrates that the reverse sometimes occurs–some of the anthropogenically loaded stress may be released aseismically.

4.2. Gas

4.2.1. Natural gas storage

To stabilize supply and increase energy security nations store natural gas reserves, often underground. In May 2015, 268 underground gas storage facilities existed or were planned in Europe (Fig. 72) and over 400 in the USA.

Depleted hydrocarbon reservoirs, aquifers, and salt cavern formations are obvious repositories because they are usually well understood geologically and engineering infrastructure including wells and pipelines may already be in place. They may also be conveniently close to consumption centers.

HiQuake contains seven cases of induced seismicity reported to have been associated with underground gas storage:

- Gazli, Uzbekistan (Simpson and Leith, 1985);
- the Castor project (in the old Amposta Field), Spain (Cesca et al., 2014; Gaite et al., 2016);
- Bergermeer, Norg and Grijpskerk, Netherlands (Anonymous, 2014);
- Háje, Czech Republic (Benetatos et al., 2013; Zedník et al., 2001);

and

- Hutubi, China (Tang et al., 2015).

At the Bergermeer Gasfield, a few earthquakes up to M 0.7 occurred in 2013 in association with the injection of cushion gas. Up to 15 earthquakes per month up to M 1.5, several of which were felt, were reported for the Háje storage facility. Larger earthquakes occurred in association with gas storage at Hutubi, with over 700 earthquakes up to M 3.6 in the period 2009–2015.

The Gazli Gasfield, Uzbekistan, is primarily renowned for the three damaging M_S ~7 earthquakes that caused death and destruction in the local town of Gazli in 1976 and 1984 (Section 3.3.1). When this field had been largely depleted, it was used for storage. Gas was cycled in and out as required. Plotnikova et al. (1996) report seismicity up to M 5 induced by this process that correlates with the amount of gas stored.

The best-documented case history is that of the 2013 Castor project, Spain. This project aimed to use a depleted oilfield in the Gulf of Valencia, the old Amposta Field, ~20 km from the coast of north-eastern Spain (Fig. 73). It was planned to store 1.3×10^9 m^3 of natural gas there, sufficient to meet 25% of Spain's storage requirements. Earthquakes began shortly after the commencement of gas injection, however, the largest of which was M_W 4.3. Public reaction to the earthquakes was negative, not least because the population was sensitized after the 2011 M_W 5.1 Lorca earthquake only two years before, 250 km to the south along the coast (Section 3.1). We understand that as a result of the earthquakes the project has been discontinued.

The old Amposta oil reservoir occupies fractured and brecciated Lower Cretaceous dolomitic limestone and is one of several in the region (Fig. 74). It produced 56 million barrels (~9×10^6 m^3) of an estimated total in-place volume of 140 million barrels of oil (22×10^6 m^3) 1973–1989. Secondary injection for enhanced recovery was not needed because of strong natural water drive. After 1989 the depleted field lay dormant.

Installation of the necessary infrastructure for conversion of the reservoir into a gas storage facility commenced in 2009 and included a platform and gas pipeline. Injection of an initial ~10^8 m^3 (at 25 °C and 0.1 MPa pressure) of cushion gas (i.e. gas intended as permanent inventory in the reservoir) was conducted in 2013 at 1.75 km below sea level.

Three days after injection began, seismicity with events up to M 2.6 occurred (Figs. 75 and 76). Injection was stopped after 12 days but earthquakes continued to occur. The largest, a M_W 4.3 event, occurred two weeks after injection stopped. In total, over 1000 earthquakes were detected, > 420 with M ≥ 2 (Fig. 76). Seismicity was still ongoing in 2016 (Gaite et al., 2016).

Accurate hypocentral locations were difficult to calculate because the project, being offshore, was monitored by a seismic network with limited coverage. The closest station was 26 km from the Castor platform and, since most of the stations were on land, there was restricted azimuthal coverage (Gaite et al., 2016). As a result, different studies of the hypocentral locations yield different results and even the orientation of the hypocentral distribution as a whole (which might reveal the activated fault structure) and the hypocentral depths (which might show proximity to the injection site) vary significantly between studies. Both NW and NE orientations for the hypocentral zone are reported, along with depths that vary from close to the gas injection depth to several kilometers deeper (Fig. 75) (e.g., Cesca et al., 2014; Gaite et al., 2016).

The epicentral area forms part of the dominantly ENE-WSW Catalan-Valencian normal-faulting extensional region (Perea et al., 2012) and focal mechanism studies of the mainshock show motion compatible with slip in this sense (Cesca et al., 2014). The most significant potentially seismogenic feature near the old Amposta Field is the 51-km-long, NE-SW oriented, Fosa de Amposta fault system (Gaite et al., 2016). If such a major fault zone were to rupture in its entirety a M 5–7 earthquake could occur (Fig. 77). Combined interpretation of the

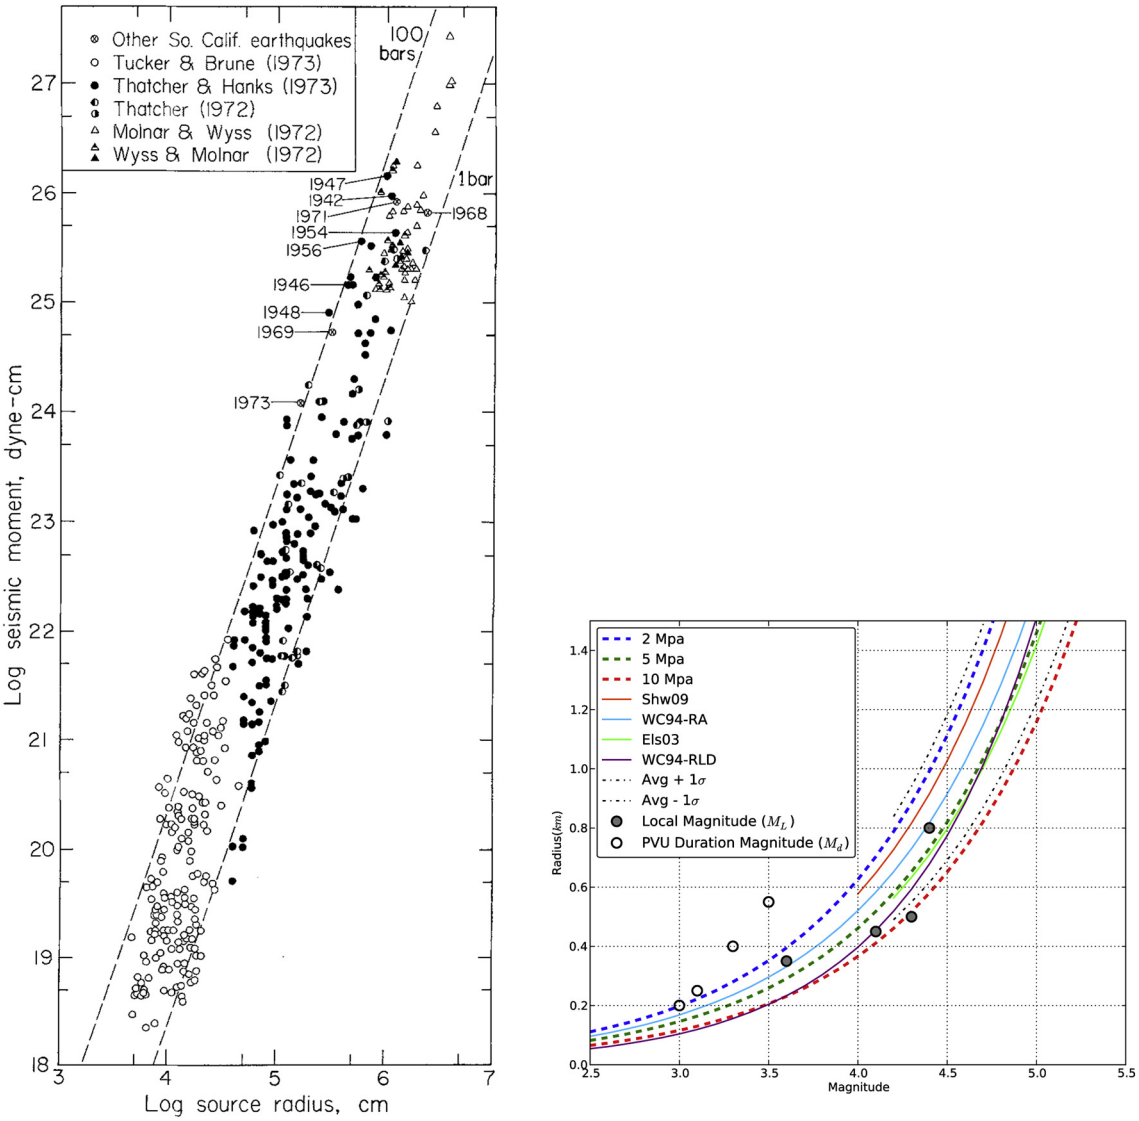

Fig. 77. Left: Set of data for small earthquakes showing the relationship between seismic moment and source radius. Dashed lines are of constant stress drop (Hanks, 1977). Right: Rupture radius vs. duration earthquake magnitude for several models. Black dotted lines: average of these relationships ± 1σ; blue, green and red dashed lines: relationships derived from the moment-magnitude relation of Hanks and Kanamori (1979) for stress drops of 2, 5 and 10 MPa respectively, and estimated fault radius using half the rupture-length-at-depth parameter; gray and white circles: values for individual earthquakes induced at Paradox Valley, Colorado.
(From Yeck et al. (2015).)

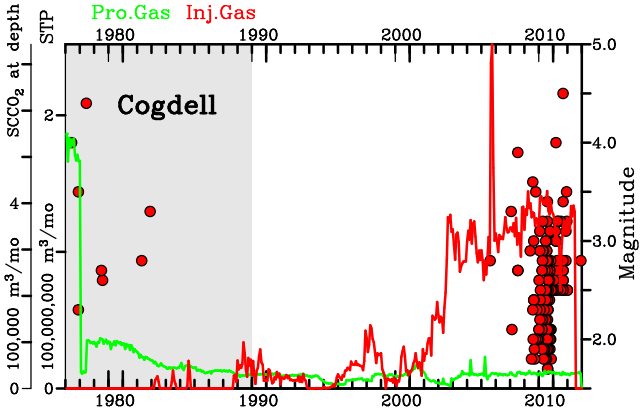

Fig. 78. Operations and seismicity at the Cogdell Oilfield, Texas. Green: monthly volumes of natural gas produced; red: gas injected; red dots: earthquakes detected 1977–2012. There was a clear increase in seismic activity from 2006, five years after the start of CO_2 injection.
(From Gan and Frohlich (2013).)

locations and source mechanisms suggests that this fault was not activated, however.

The seismicity was unusual for the area in both magnitude and seismic rate compared with the preceding two decades (Fig. 73). Although earthquake activity occurs along the coast of Spain to the north and south, the Pyrenees mountain chain in Portugal, and the coast of North Africa, no significant historical seismicity was known on the fault system local to the Castor project prior to the gas injection. For this reason, and because of the close spatial and temporal correlation with gas injection, there is little doubt that the earthquakes were induced.

4.2.2. CO_2 for oil recovery

There are approximately 100 enhanced oil recovery injection sites where CO_2 is used, mostly in Texas. *HiQuake* contains two cases where seismicity is postulated to be induced by this process. These are at the Cogdell Field, Texas (Gan and Frohlich, 2013) and Weyburn Oilfield, Saskatchewan (Maxwell and Fabriol, 2004; Verdon et al., 2013). The latter is a hybrid project and also classified as a Carbon Capture and Storage (CCS) project (Section 4.2.3).

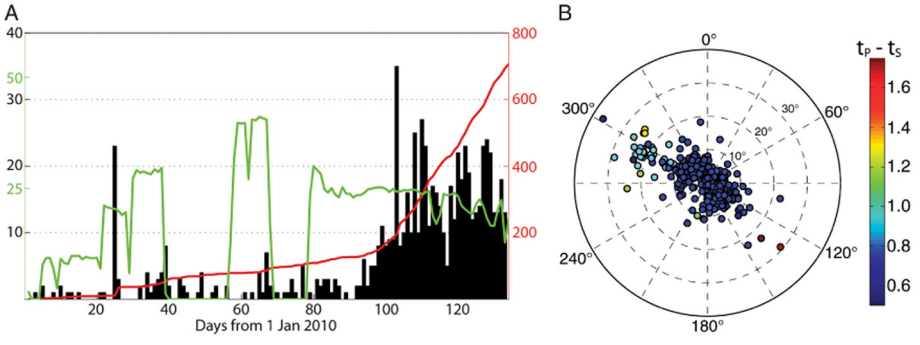

Fig. 81. Microseismicity at In Salah, Algeria. A: Black: daily seismicity rate; red: cumulative number of events January–April 2010; green: CO_2 injection rate in millions of standard cubic feet per day (1 million standard cubic feet of gas per day at 15 °C = 28,250 m^3/day). B. Event arrival angles in polar projection, colored by differential *S*- and *P*-wave arrival times.
(From Verdon et al. (2013).)

Early on in its history, the Cogdell Oilfield generated earthquakes surmised to have been induced by water injection (Gan and Frohlich, 2013). Lately, CO_2 has been injected and is associated with earthquakes up to M_W 4.4 (Fig. 78).

The Cogdell Oilfield is a large subsurface limestone reef mound, not a fault-bounded oil trap, and there are no mapped faults nearby. Production began in 1949 and 1957–1983 oil recovery was enhanced by brine injection. This was associated with earthquakes, including a M_L 5.3 event in 1978. This earthquake was only poorly located as a result of the rudimentary nature of seismic monitoring in Texas at the

Fig. 82. Aerial photograph of the Nevada test site, USA. View of Yucca Flat looking south-southeast. Center of ring road is at 37°N 9.57′, 116°W 4.63′, elevation 4400 m (https://en.wikipedia.org/wiki/Nevada_Test_Site).

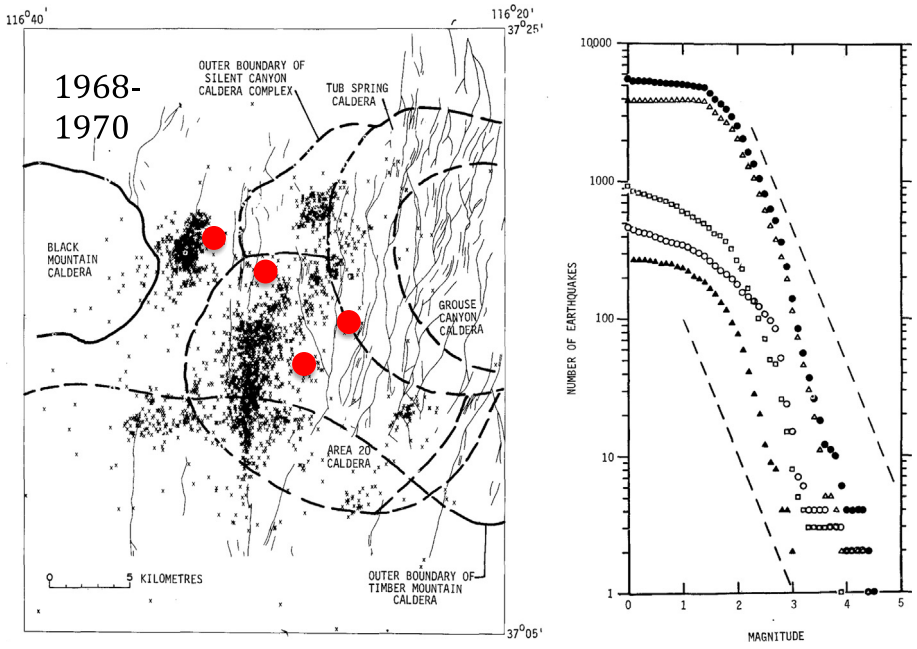

Fig. 83. Left: Epicenters of aftershocks of the Benham (1968), Jorum (1969), Purse (1969), and Handley (1970) nuclear explosions at the Nevada Test Site. Heavy lines: caldera boundaries; light lines: basin-range faults; red dots: locations of nuclear explosions. Dots: entire recording period; open triangles: the period Benham to Purse; solid triangles: Purse to Jorum; circles: Jorum to Handley; squares: Handley to the end. Dashed lines have a slope of −1; the data above M 2 define *b*-values of about −1.4 (from McKeown, 1975).

time. Davis and Pennington (1989) suggested that the earthquakes correlated with injection volume and high reservoir pressure gradients.

Gas injection began in 2001 and grew to a constant, high level of ~40 × 10^6 m^3/month from 2004. It was introduced at ~2.1 km depth, 20 MPa pressure and 75 °C, under which conditions CO_2 is supercritical. In 2006, after 23 years of seismic quiescence and following a significant increase in gas injection rate, earthquakes began again. Over the following five years 18 events with M > 3 occurred and in 2011 one of M_W 4.4.

A 21-month period March 2009–December 2010 could be studied in detail because at this time USArray, a rolling program to cover the entire country with temporary seismic stations,[8] swept across Texas. During this period the network recorded 93 locatable events, many within 2 km of wells actively injecting gas. Locations and focal mechanisms showed that the events occurred on previously unknown faults. Although the neighboring Kelly-Snyder and Salt Creek Fields have similar operational histories, seismicity is not induced in them.

4.2.3. Carbon Capture and Storage (CCS)

In the case of Carbon Capture and Storage (CCS), in addition to causing a nuisance, induced earthquakes could rupture the impermeable containment caprock that contains the CO_2 in the storage reservoir, and release it back into the environment. Carbon geostorage is in its infancy, but 20–30 tests are already underway globally, including eight operational commercial-scale plants.[9] Of these, three are seismogenic. An illustrative range of seismic responses is provided by the Sleipner Field, the Weyburn Field (Saskatchewan, Canada) and In Salah

[8] http://www.usarray.org.

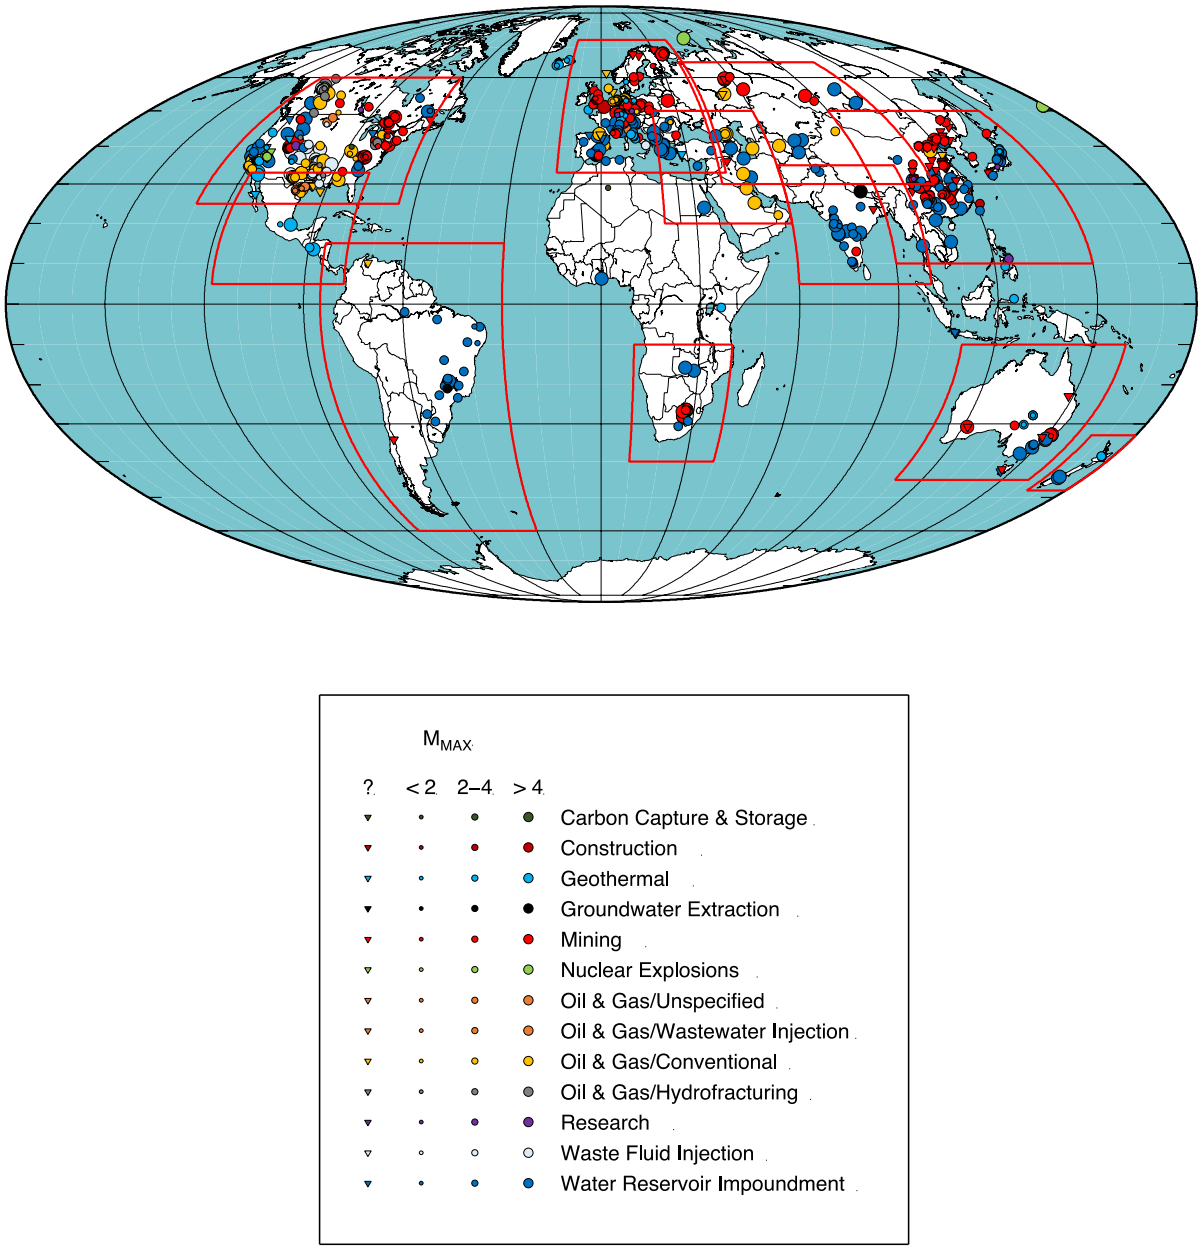

Fig. 84. Cases of human-induced seismicity world-wide, in Mollweide projection, centered on the Greenwich meridian. Colors of symbols indicate different categories of seismogenic activity. Circle sizes indicate the magnitudes of the largest reported induced earthquakes in each category, and inverted triangles indicate cases for which this magnitude was not reported. Red boxes show the locations of the regional maps.

(Algeria) (Verdon et al., 2013).

Since 1996 $\sim 10^6$ t/year of CO_2 has been removed from the natural gas produced from the Sleipner Field (Norwegian North Sea) and re-injected into a shallow saline aquifer (the Utsira Formation). This aquifer is large and comprises well-connected, little-faulted sandstone with high porosity and permeability at ~1 km depth beneath North Sea mean sea level. By 2011 the total volume of CO_2 injected amounted to only ~0.003% of the available pore space. No pore-pressure increase, mechanical deformation or seismicity has been detected for the entire > 20 years of injection. The Sleipner Field is, however, not seismically monitored locally so small earthquakes would go undetected. The nearest earthquakes to the Sleipner Field listed in the British Geological Survey catalog are a M_L 3.5 event at 1 km distance and a M 2.5 earthquake at 6 km distance. The uncertainties in these locations are large.

The Weyburn Oilfield, Saskatchewan, Canada, has been exploited for 45 years and is somewhat seismogenic. CO_2 injections started in 2000 both for enhanced oil production and CO_2 sequestration and now $\sim 3 \times 10^6$ t/year are injected annually. This is accompanied by minor, low-magnitude earthquake activity (Fig. 79). Some earthquakes clustered near injection wells, but no clear temporal correlations are apparent.

In contrast, vigorous earthquake activity accompanied CO_2 sequestration at the producing In Salah Gasfield, Algeria. There, CO_2 was injected into a low-permeability, 13–20% porosity, ~20-m-thick fractured sandstone in a non-producing, water-dominated part of field at 1850–1950 m depth. Hundreds of earthquakes accompanied surface uplift.

CO_2 injection at In Salah 2004–2013 amounted to a total of $\sim 3.85 \times 10^6$ t of CO_2 which was produced from nearby gas wells and

[9] http://www.ccsassociation.org/faqs/ccs-globally/.

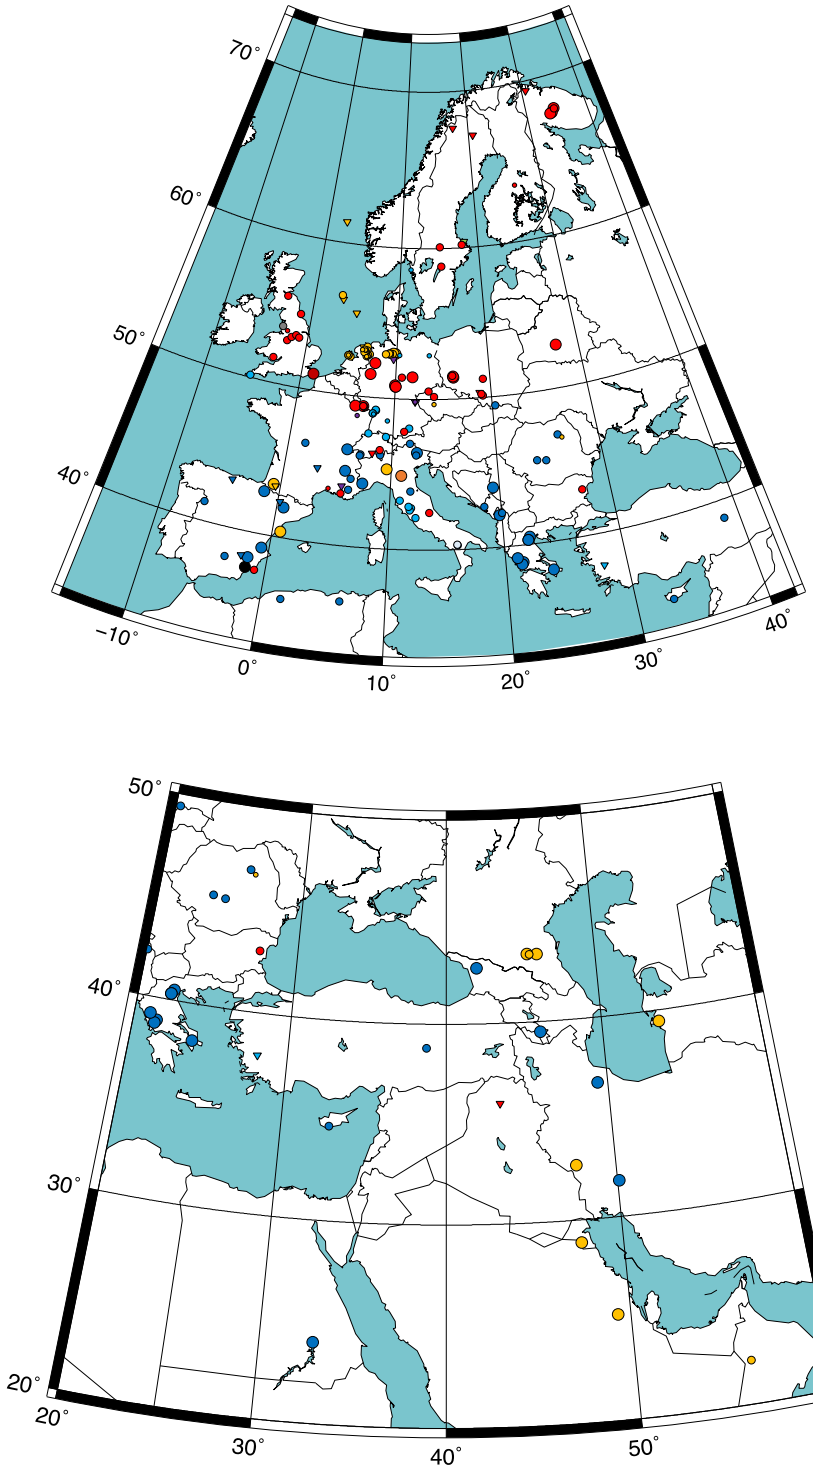

Fig. 85. Same as Fig. 84 except for (top) Europe, and (bottom) Middle East.

re-injected via horizontal boreholes. There was little pressure communication with the producing part of the field. Pore pressures increased from initial conditions of ~18 MPa at the injection points to ~30 MPa while reducing in the production parts of the reservoir (Fig. 80). Deformation monitoring detected surface-blistering type uplift of up to ~1 cm/year locally around the injection wells.

A nearby borehole seismometer detected over 1000 events in 2010. The data were consistent with locations in the receiving formation beneath the injection well though there was no correlation with CO_2 injection (Fig. 81). The project was subsequently terminated because of seal integrity concerns.

Verdon et al. (2013) conclude that at Sleipner, where the target aquifer is large and pressure increases during injection minimal, little deformation, either seismic or aseismic, results. At Weyburn, deformation and seismicity may be partly mitigated by ongoing oil extraction which serves to offset pressure increase resulting from the CO_2 injections. At In Salah, however, the formation into which CO_2 is injected had poor pressure communication with the producing parts of the reservoir and natural gas extraction did not compensate for the injections. Pore pressures increased as a consequence leading to both seismic and aseismic deformation.

Another seismogenic CCS demonstration site is at Decatur, Illinois

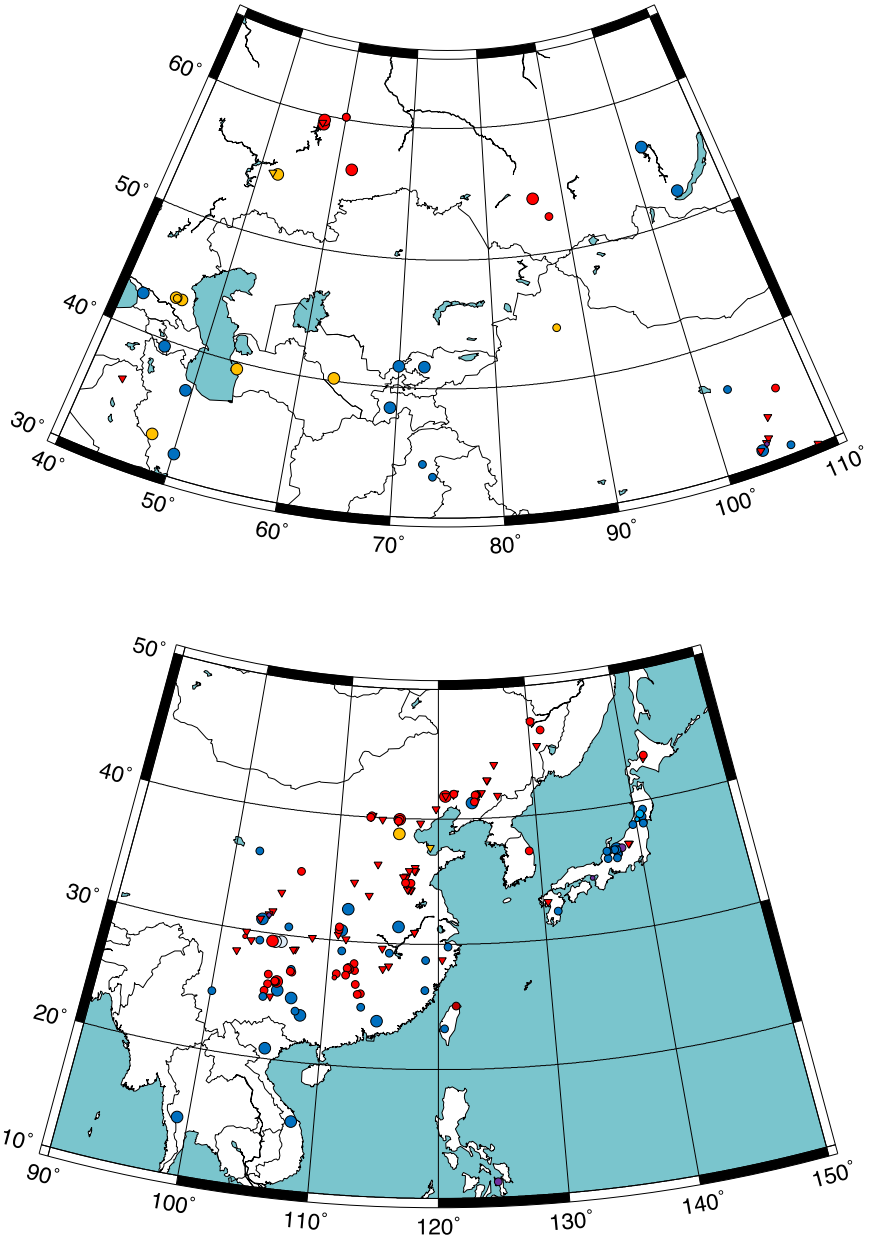

Fig. 86. Same as Fig. 84 except for (top) central Asia, and (bottom) east Asia.

(Kaven et al., 2015). There, ~10^6 t of supercritical CO_2 were injected over a period of three years at a depth of 2.1 km into a regionally extensive, 460-m-thick high porosity/permeability sandstone. The CO_2 used is a by-product of local ethanol production. Approximately 180 earthquakes up to M_W 1.26 occurred over about two years within a few kilometers of the injection well and at the approximate depth of injection. Kaven et al. (2015) concluded that earthquakes nucleated on preexisting faults in the basement well oriented with respect to the regional stress field. Little seismic hazard is posed to the host formation because the earthquakes are remote and small.

All other CCS projects have been shorter in duration and with total volumes no more than 10s or 100s of thousands of tonnes. CCS projects have developed recently in China where eleven projects are reported (Huaman and Jun, 2014). Limited information is available on these projects and none regarding seismicity induced.

4.2.4. Injection into the subsurface: summary

Diverse fluids are injected into the ground for various reasons and related seismogenic behavior is variable. For most projects no earthquakes are reported. For others, small earthquakes occur that are of insufficient general interest to publish details. For a small minority induced seismicity is sufficiently troublesome to hinder operations or result in project abandonment.

Correlations between seismic and operational parameters vary. Earthquakes thought to be induced may be co-located with injections to 10 s or 100 s of meters or they may occur tens of kilometers away. Earthquakes may begin as soon as operations start or be delayed for decades. Small operations may induce large earthquakes and large operations may be aseismic.

Why is Oklahoma highly seismogenic while large-scale injection projects are conducted in many states of the USA without nuisance earthquakes occurring? We are not aware of any current theories as to why this is.

5. Explosions

Since the first test of a nuclear device, the Trinity explosion of July 16, 1945, approximately 2000 such tests have been conducted by eight

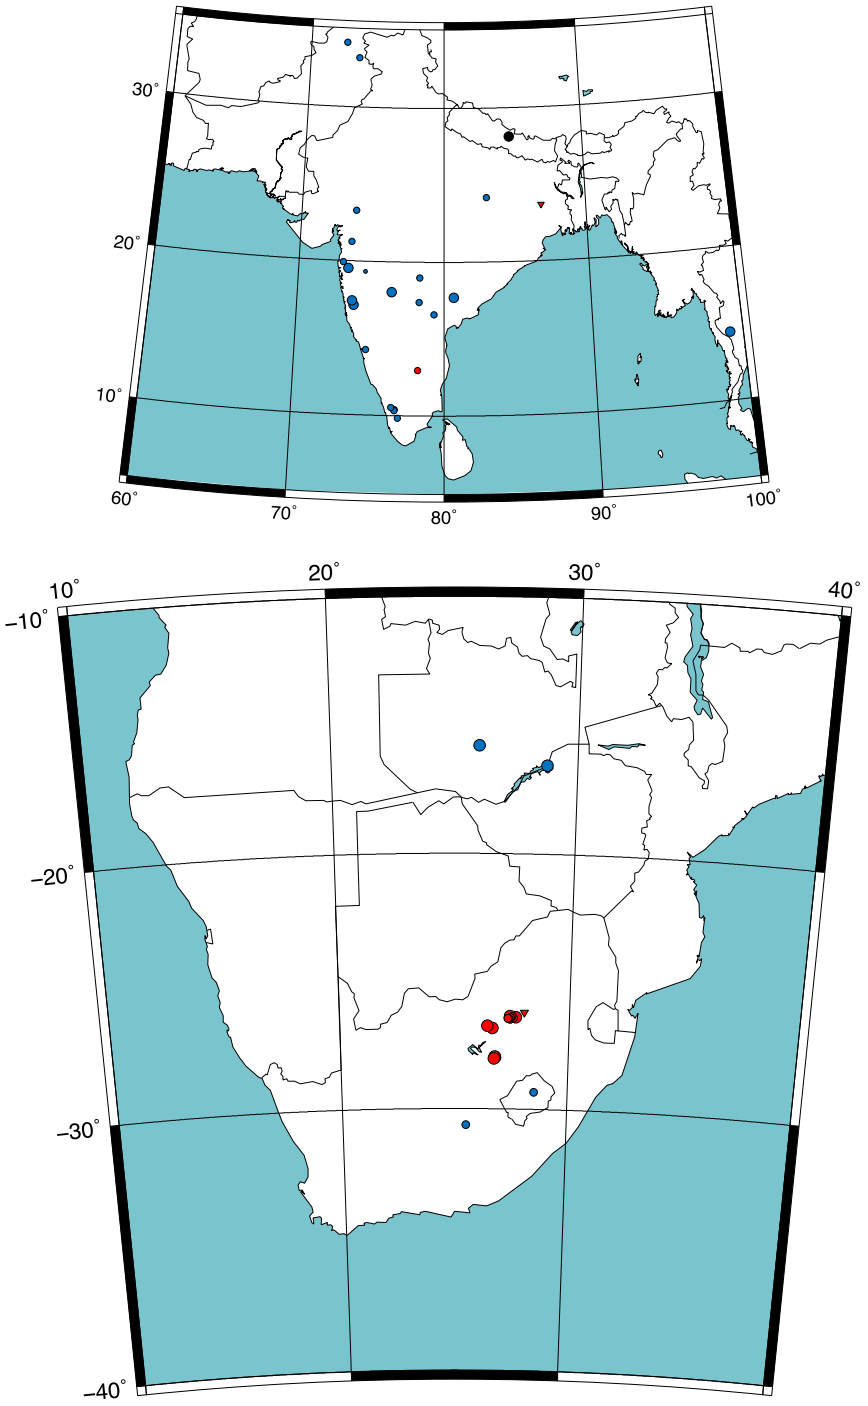

Fig. 87. Same as Fig. 84 except for (top) India and vicinity, and (bottom) southern Africa.

nations, 1352 of them underground. Seismicity was reported to be associated with 22 of these, 21 in the USA and one in Russia (Boucher et al., 1969; Engdahl, 1972; Hamilton et al., 1972; McKeown, 1975; McKeown and Dickey, 1969).

American nuclear tests were conducted at the Nevada Test Site for the 48-year-period 1945–1992 (Fig. 82). Boucher et al. (1969) investigated the possibility of induced seismicity associated with 16 nuclear tests by searching the University of Nevada database of earthquake locations. They reported induced earthquakes after all of the 10 tests where the explosion itself registered $m_b \geq 5.0$. The explosions themselves are not included in the *HiQuake* database. The largest earthquake induced was at least one magnitude unit smaller than the inducting explosion. Earthquakes may have been induced by many, if not all of the tests, but been too small to be clearly recorded.

A test ironically named Faultless (19/1/1968) induced clearly visible surface slip on faults up to 40 km away, even though the test was only one megaton in yield. Ground deformation associated with this, and other nuclear tests, has been captured on film (McKeown and Dickey, 1969).[10]

Detailed studies of the seismicity induced by large nuclear tests were done for the Benham (19/12/1968), Purse (07/05/1969), Jorum (16/09/1969) and Handley (26/03/1970) tests (Fig. 83) (Hamilton et al., 1972; McKeown, 1975). Earthquakes occurred immediately after the tests and clustered on Pahute Mesa where a 4-km-thick sequence of volcanic rocks contains both caldera- and basin-range-type normal

[10] See, for example, https://www.youtube.com/watch?v=6ETHnsKnKiA.

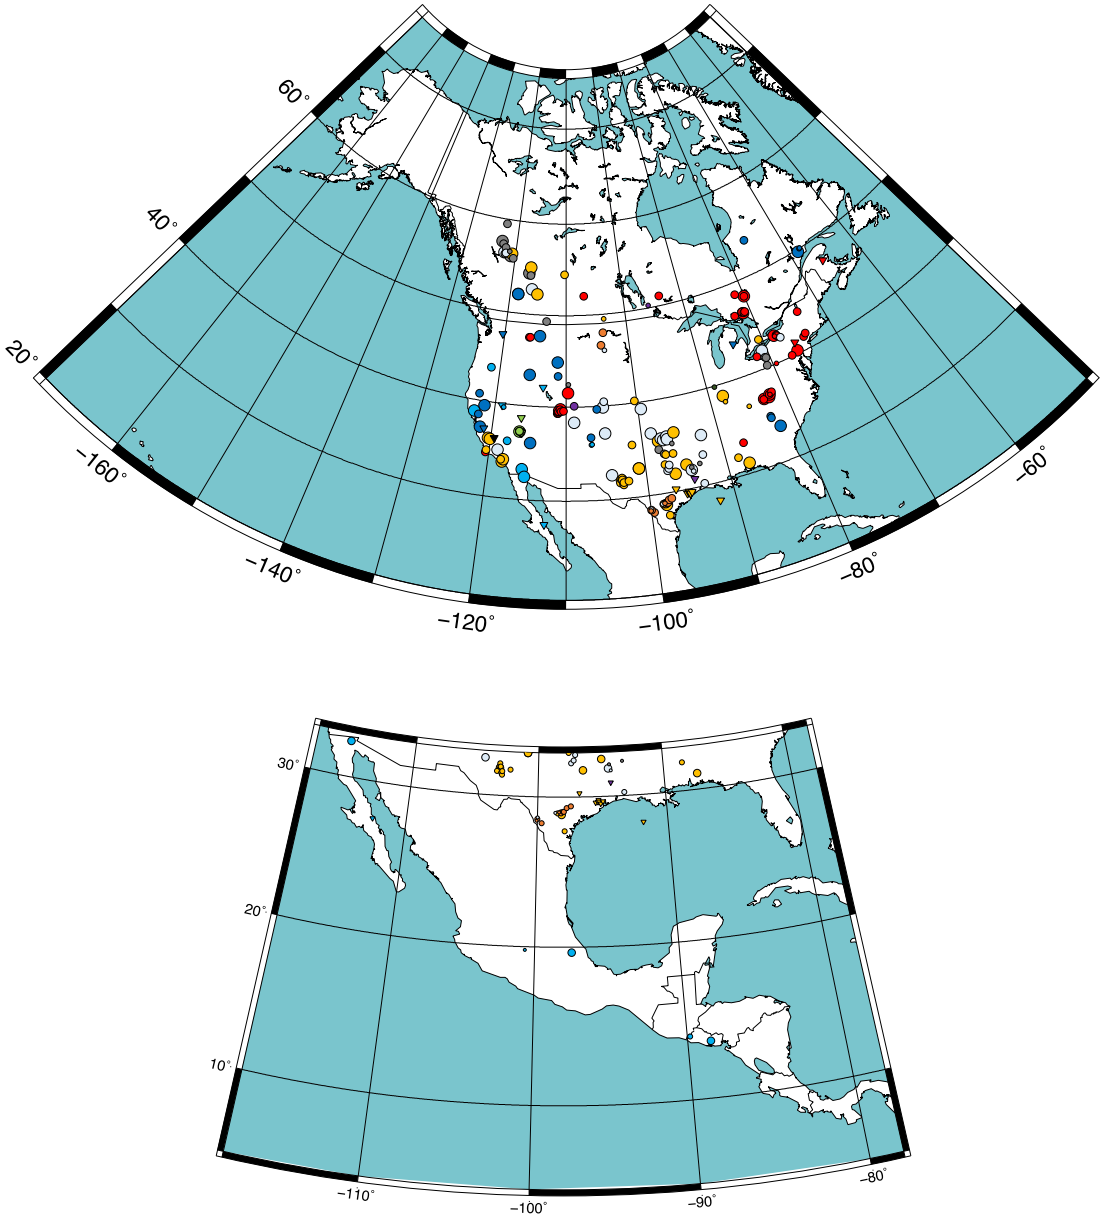

Fig. 88. Same as Fig. 84 except for (top) North America, and (bottom) central America.

faults. Most of the earthquakes induced occurred 10–70 days after the tests, at < 5 km depths and closer than ~15 km to ground zero. The locations of the earthquakes were mostly controlled by local geological structure and lay on faults in the caldera ring-fracture zones (Fig. 83) (McKeown and Dickey, 1969).

Underground nuclear tests in Amchitka, Alaska, resulted in permanent displacement on faults up to 1 m in the vertical and 15 cm in the horizontal for faults up to 8 km long (McKeown and Dickey, 1969). Both the Milrow (1969) and Cannikin (1971) tests generated several hundred small earthquakes with M < 4, thought to be related to deterioration of the explosion cavity. The sequences concluded with large, complex events and simultaneous subsidence of the surface resulting from final collapse of the explosion cavity. In the case of the Cannikin test, small events continued up to 13 km from ground zero for several weeks. The earthquakes are thought to have released ambient tectonic stresses. The more modest post-test seismic response from tests in Amchitka compared with those conducted in Nevada may result from the lower level of tectonic stress (Engdahl, 1972). Tectonic stress is also released simultaneously with the explosions themselves, as shown by blast focal mechanisms involving both shear and explosive components (Fig. 22) (Toksöz and Kehrer, 1972; Wallace et al., 1983). The largest earthquake induced by a nuclear test had a magnitude of m_b 4.9 and was associated with collapse of the cavity of the Cannikin, Amchitka test.

Most large chemical explosions are associated with rocket launching, military research and operations, and accidents in the military, space-program and industrial sectors. Such explosions may be equivalent of several kilotonnes (kt) of TNT. They occur at the surface on land or on ships and are thus poorly coupled to the ground. Tsunamis, but not earthquakes, have been reported in association with some of these.

It has been suggested that deep penetrating bombs may modulate earthquake activity. Balassanian (2005) examined earthquake activity over ~2-year periods spanning bombing incidents at Kosovo, Yugoslavia (1999), Baghdad, Iraq (1991), Tora Bora, Afghanistan (2001) and Kirkuk, Iraq (2003). It was suggested that the incidence of M ≥ 5 earthquakes increased within 1000 km and one year of the bombings at Kosovo and Tora Bora but not after those at Baghdad and Kirkuk.

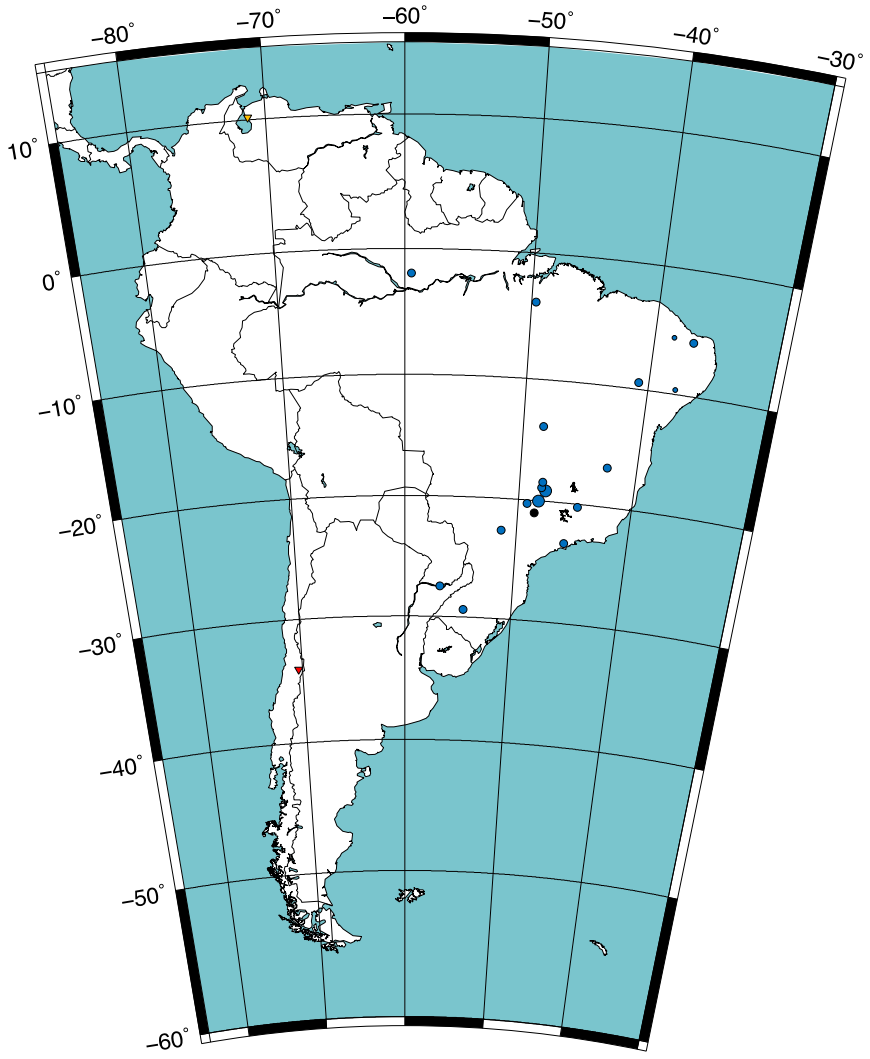

Fig. 89. Same as Fig. 84 except for South America.

Arkhipova et al. (2012) suggested that the 23 October 2011 M 7.8 Van earthquake, eastern Turkey, was encouraged by mass bombing associated with the Libyan conflict, 1300–1500 km away.

Deep penetrating bombs explode at depths of a few meters in the ground, improving the coupling by factors of several tens of percent compared with equivalent surface explosions. Nevertheless, deep penetrating bombs are generally not larger than the equivalent of ~1 kt of TNT, much smaller than the megatonne- or multi-megatonne scale typical of nuclear devices reported to have induced earthquakes. In the case of the nuclear tests, earthquakes have been induced out to a maximum of ~40 km away and activity has decayed away over periods of a few days or weeks (Boucher et al., 1969). Given the relatively small subsurface effects of chemical explosions and the great distances and relatively long time delays of earthquakes postulated to have been induced by them, these suggestions must be considered speculative.

6. Summary

Human-induced earthquakes are reported from every continent except Antarctica (Fig. 84). Figs. 85–90 show regional maps for Europe, the Middle East, central- and east Asia, India and vicinity, southern Africa, North-, central- and South America, Australia and New Zealand. Induced seismicity correlates with industrial activity and not with tectonic plate boundaries.

The magnitudes of the largest earthquakes (M_{MAX}) associated with projects of different types vary widely. The largest have been reported for water reservoirs, conventional oil and gas exploitation, and geothermal operations. Median magnitudes also vary between project types but the most commonly reported are $3 \leq M < 4$ which apply to water reservoirs, construction, conventional oil and gas, hydrofracturing, mining, and research projects. For some types of project the number of cases reported is small. For all project types it is essentially certain that large numbers of smaller induced earthquake sequences have not been reported.

Relationships between seismic and operational parameters have been suggested for a number of projects. For example, seismic moment released and volume injected correlate in shale gas hydrofracturing operations at the Etsho area, Horn River Basin, British Columbia (Fig. 67) (Farahbod et al., 2015). Of interest for future projects is what correlations might exist for all projects of the same kind.

From the point of view of nuisance, the magnitudes of the largest earthquakes induced are the most important. Seismic rate and total number of earthquakes are of secondary importance because the fractal nature of earthquakes means that most are small. Because a large and systematic part of the true dataset is missing (i.e. the unreported cases) correlations with operational parameters cannot convey any information on average M_{MAX}. Of interest is whether *the largest* M_{MAX} for projects of a particular kind correlates with operational parameters.

Fig. 91 shows a plot of M_{MAX} vs. water reservoir volume for 126 cases. The magnitude of *the largest* M_{MAX} (i.e., the apparent M_{MAX} ceiling) increases with reservoir volume. However, there is no correlation between M_{MAX} and reservoir volume for the dataset as a whole. If

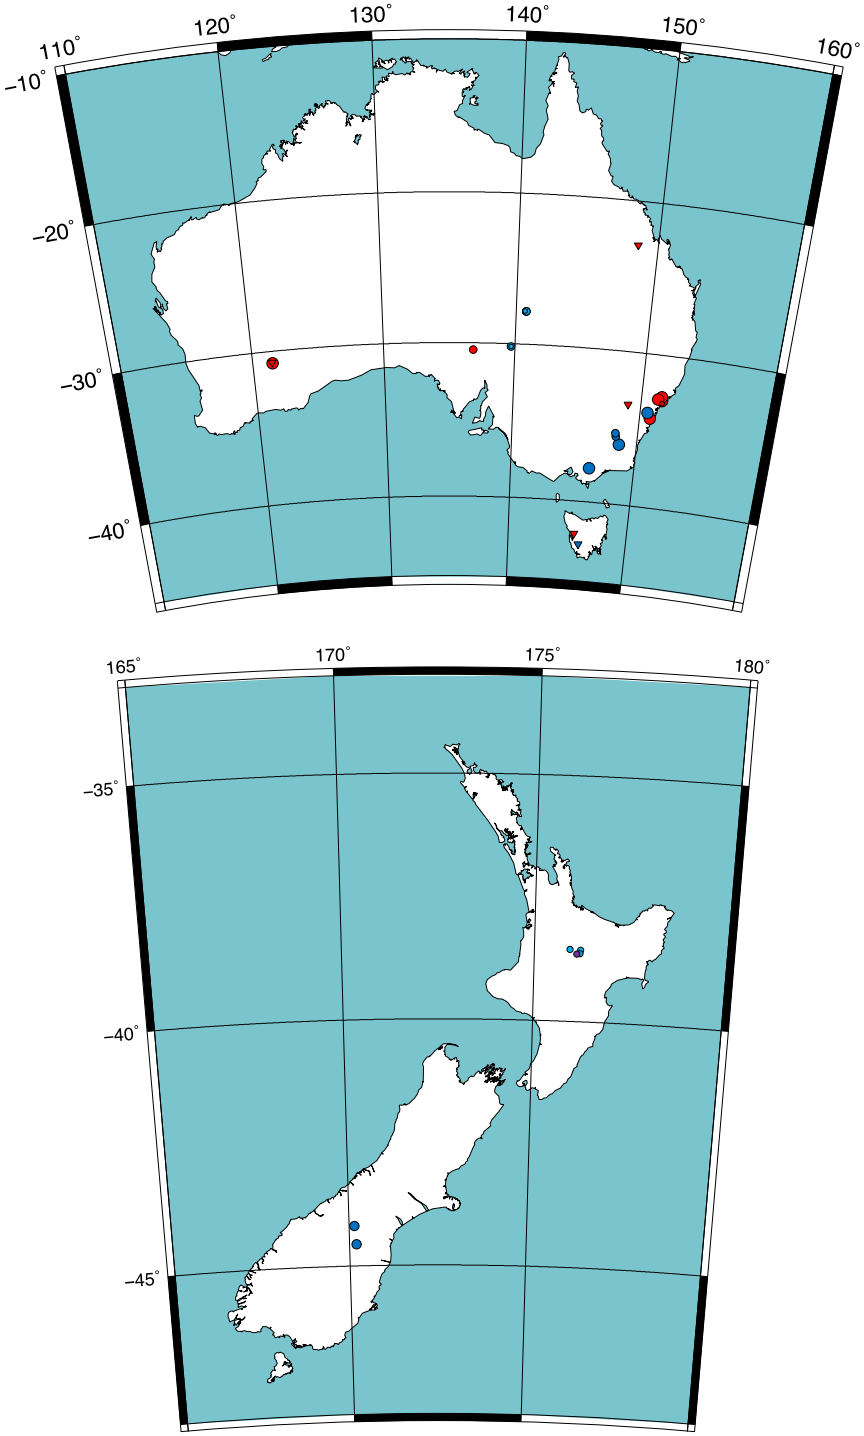

Fig. 90. Same as Fig. 84 except for (top) Australia, and (bottom) New Zealand.

reporting were complete, the region of the plot beneath the observed M_{MAX} upper bound would probably be entirely populated with points. Because the reported data are biased in this way we have not calculated correlation coefficients between all values of M_{MAX} and other parameters.

Relationships observed include:

- *Water reservoir volume* (Fig. 91): Volumes plotted range from 0.004 km^3 to 164 km^3. There is a nearly linear boundary to the upper left of the cloud of points which suggests a relationship between reservoir volume and largest observed M_{MAX}. The 2008 M_W ~8 Wenchuan, China, event, which is disputed because of its seemingly disproportionately large size, also plots on this alignment.
- *Water reservoir mass per unit area* (Fig. 92): The largest M_{MAX} (i.e. the upper bound of M_{MAX}) increases with reservoir water mass per unit area.
- *Volume added or removed in surface operations* (Fig. 93): The largest M_{MAX} increases with this parameter.
- *Volume of material removed from the subsurface* (Fig. 94): We combined conventional oil and gas, geothermal, and mining-produced volumes. The largest reported M_{MAX} increases with volume removed. The relationship for M_{MAX} for injection volumes proposed by McGarr (2014) on the basis of theoretical considerations fits these data well (Fig. 95).

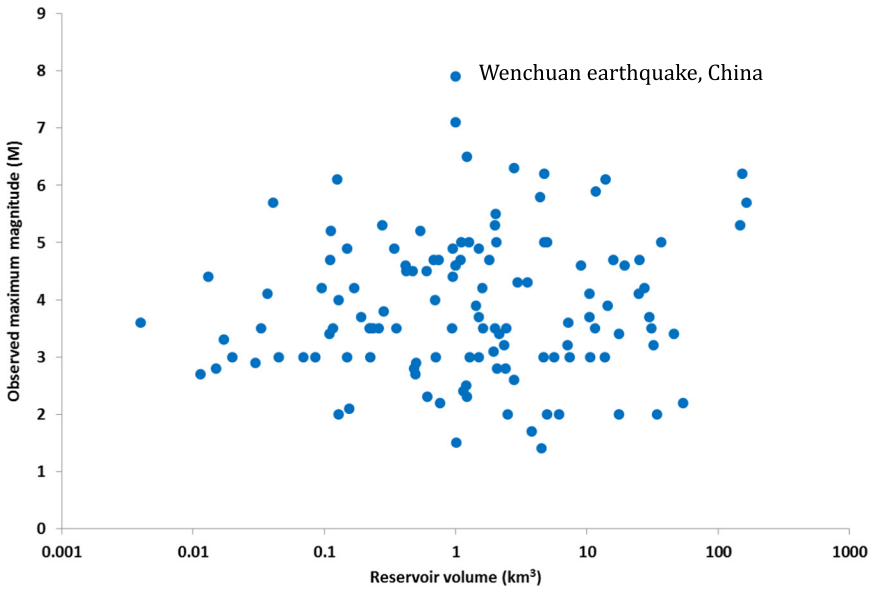

Fig. 91. Plot of M_{MAX} vs. water reservoir volume for the 126 cases for which data are available.

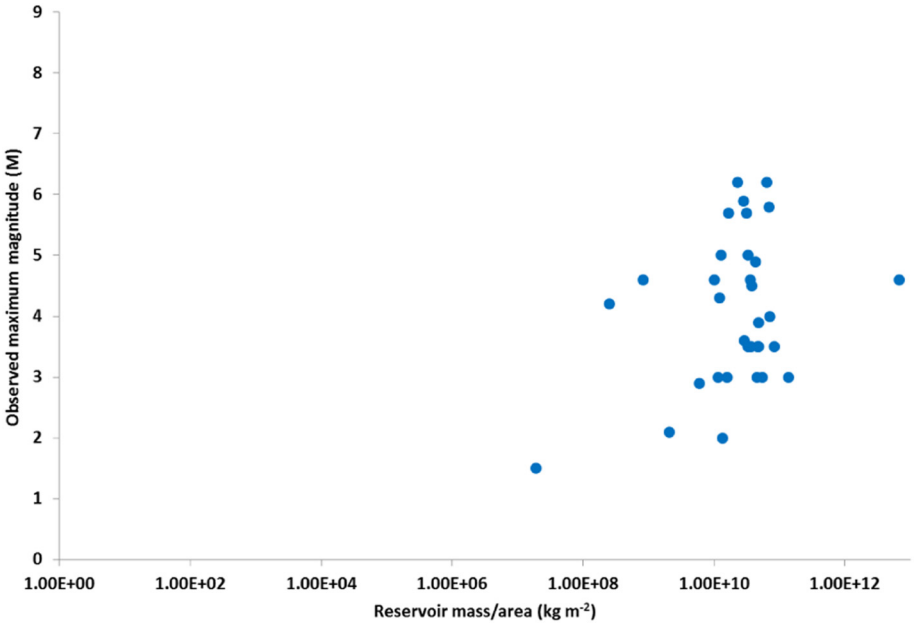

Fig. 92. Plot of M_{MAX} vs. water reservoir mass per unit area for the 33 cases for which data are available.

- *Shale-gas hydrofracturing – injection pressure, rate and volume* (Fig. 96): The largest M_{MAX} increases with all these parameters, in agreement with the relationship proposed by McGarr (2014).
- *Injected volume for all projects* (Fig. 97): Data from 69 cases are available to study this parameter. The largest earthquake plotted is the 2011 M_W 5.7 Prague, Oklahoma, event. This and a small number of additional earthquakes, mostly postulated to be induced by waste fluid injection, slightly exceed the upper-bound magnitude limit proposed by McGarr (2014).
- *Injection pressure* (Fig. 98): Data are available for 79 cases. Pressures range from atmospheric to 89 MPa. There is a tendency for the largest M_{MAX} to reduce with maximum injection pressure.
- *Volume or proxy volume removed from or added to the subsurface* (Fig. 99): We calculated volume or proxy volume (mass converted to volume using an appropriate density) for 218 cases. There is a clear upper bound to M_{MAX}. The relationship proposed by McGarr (2014) for injection volumes fits this wider dataset well with a few exceptions.
- *Mass removed from or added to the subsurface* (Fig. 100): As for volume, there is a clear linear observed upper bound to M_{MAX}.
- *Yield of nuclear devices* (Fig. 101): M_{MAX} for induced earthquakes correlates with explosion size for the seven cases for which data are available. This finding is in agreement with the correlation between the activated-fault length and explosive yield at Pahute Mesa, Nevada Test Site (McKeown and Dickey, 1969).
- *Project scale* (Fig. 102): We updated the plot of McGarr et al. (2002) with 20 additional cases. The data generally confirm the earlier observations. Two cases exceed the empirical upper bound of McGarr et al. (2002)–the 1979 M_L 6.6 Imperial Valley, California, earthquake (linked to the Cerro Prieto geothermal field; Section 3.4) and the 2008 $M_W \sim 8$ Wenchuan, China, earthquake (Section 2.1.1).
- *Project type* (Fig. 103): The largest earthquakes postulated to have been induced, in order of decreasing magnitude, are associated with water reservoirs, groundwater extraction and conventional oil and gas operations. These have all been linked to earthquakes with $M > 7$. Only relatively small earthquakes have been postulated to be associated with CCS, research experiments, construction and hydrofracturing. The number of projects in each category varies.

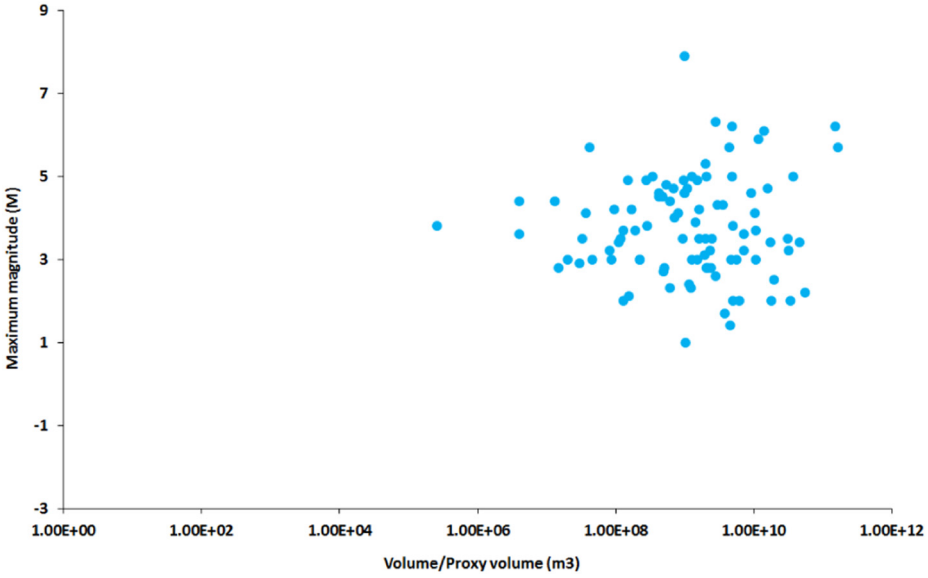

Fig. 93. Plot of M_{MAX} vs. volume added or removed by surface operations.

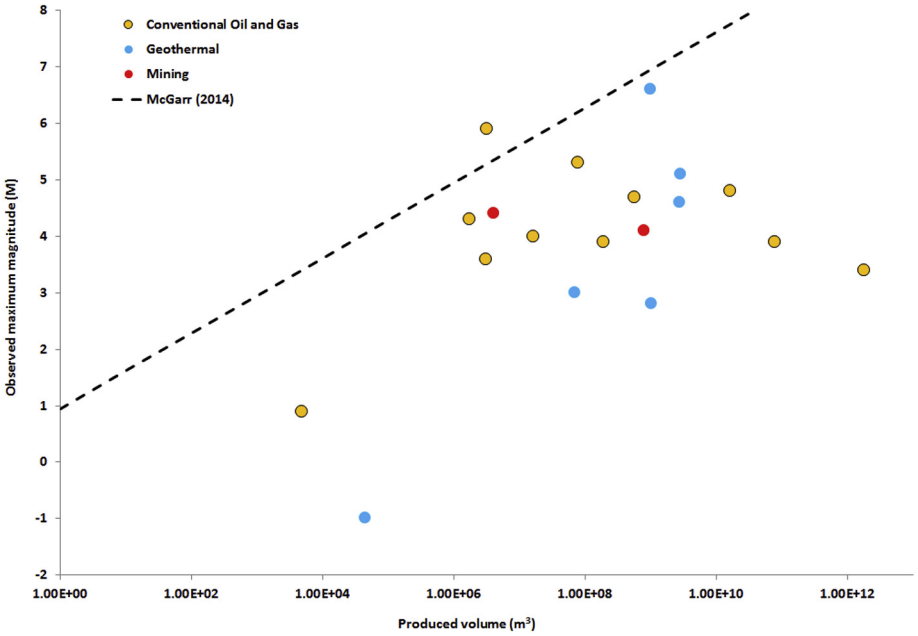

Fig. 94. M_{MAX} vs. produced volume (m^3) for 23 projects that involved extraction of mass from the subsurface. Some of these projects also involved injection, so their association with extraction is not certain. The upper limit to M_{MAX} proposed by McGarr (2014) on the basis of theoretical considerations is also plotted.

- *Distance of epicenter from the inducing project* (Fig. 104): There is a slight tendency for the largest reported M_{MAX} to decrease with distance from the project.

A relationship is not observed for:

- *Dam height* (Fig. 105): Data are available for 159 cases, many from Brazil, China, and the USA.
- *Water reservoir area* (Fig. 106): Areas of seismogenic reservoirs range from 1.6 km^2 to 53,600 km^2. The result that there is no significant tendency for the largest M_{MAX} to increase with reservoir area is perhaps unsurprising because large parts of reservoirs may be shallow.
- *Pressure change in subsurface reservoirs* (Fig. 107): No correlation was found for the 55 cases where data are available.
- *Injection rate for all projects* (Fig. 108): Although some individual projects report correlations there is no clear correlation for projects as a whole.

Fig. 109 shows the distribution of induced earthquakes by tectonic regime. The most numerous cases are from intraplate areas (79% of all cases) with the next largest category (13%) located in convergent plate-boundary zones. Most large industrial projects are conducted on land and most land is in the interior of plates with plate boundaries comprising relatively (though not absolutely) narrow zones. Most spreading plate boundaries are in the oceans and currently beyond reach of industrial development. Because induced earthquakes are mostly in intraplate regions they affect regions not traditionally associated with seismicity nor accustomed to it.

The lack of a relationship between M_{MAX} and operational parameters such as injection rate, coupled with the difficulty of predicting which projects will be seismogenetic and which not, suggests that non-operational parameters are important. The pre-existing stress state is the most obvious such parameter. Several lines of research indicate that most faults in the crust are nearly critically stressed, though they may not be optimally oriented to slip under ambient conditions. The local geology, in particular pre-existing faults and fractures, must be important for understanding the extreme variations in seismogenesis

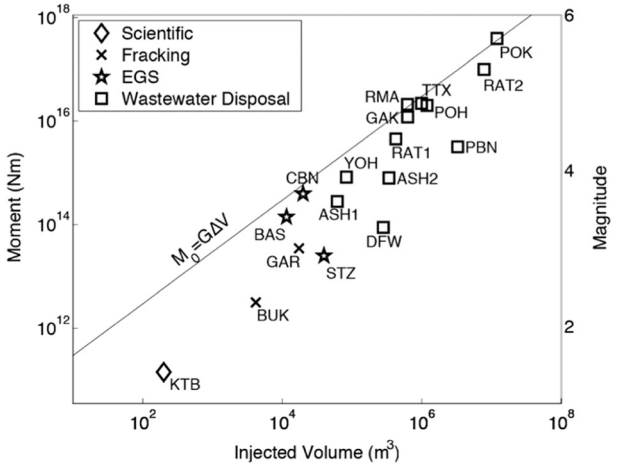

Fig. 95. Maximum seismic moment and magnitude vs. total volume of injected fluid from the start of injection until the time of the largest induced earthquake. The line relates the theoretical upper bound seismic moment to the product of the modulus of rigidity and the total volume of injected fluid, and fits the data well.
(From McGarr (2014).)

between apparently similar projects in different locations. In order for large earthquakes to occur, long faults that are suitably orientated and stressed must pre-exist.

The empirical results of this study have implications for individual projects. For example, at The Geysers geothermal field, California, net production (i.e. total production minus re-injection) since 1960 has been $\sim 1.7 \times 10^9$ m^3. The relationship of McGarr (2014), which links fluid-injection volume to the largest M_{MAX} (Fig. 97) fits well data from all volumetric projects. This relationship predicts that the upper bound to induced earthquakes associated with The Geysers volume change is M 7.0. This geothermal field has a maximum NW-SE long dimension of ~21 km. The largest induced earthquake reported from projects of this scale is ~M 6.6 (Fig. 102). Fig. 110 shows a histogram of numbers of seismogenic geothermal power-producing fields ranked by size (data from Bertani, 2010). The larger the geothermal operation the more likely it is that induced earthquakes are reported.

The largest earthquake that has occurred to date at The Geysers is the 2014 M_W 4.5 event. There is no evidence that a fault long enough to sustain a M 6.6 or 7.0 earthquake exists in the reservoir. However, The Geysers lies between the regional Mercuryville fault to the southwest and the Collayomi fault zone to the northeast, within the active Pacific/North America transform plate boundary zone. There is no evidence that the Mercuryville fault zone is active but the Collayomi fault zone contains at least one active fault (Lofgren, 1981).

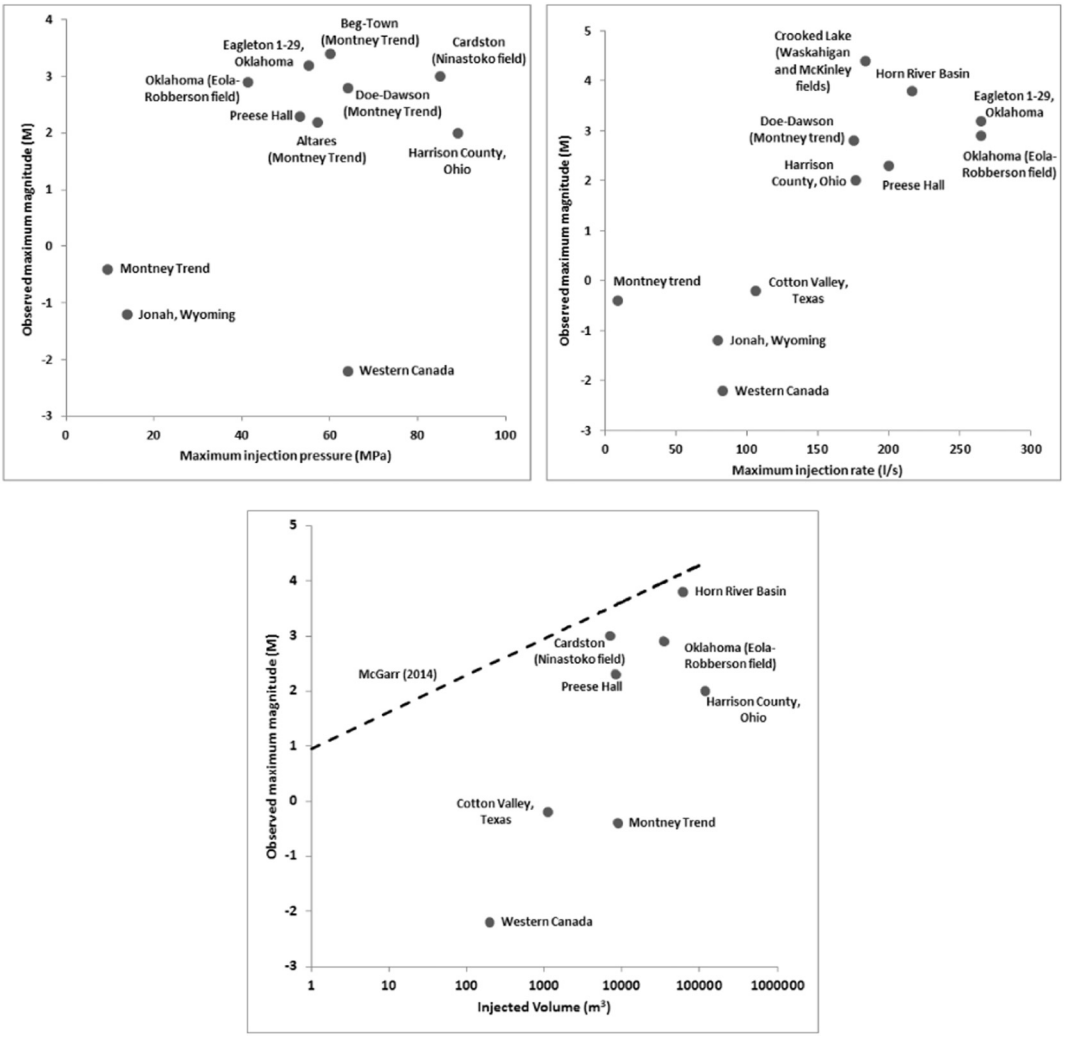

Fig. 96. For all cases of shale-gas hydrofracturing-induced earthquakes in our database where data are available, top left: M_{MAX} vs. maximum injection pressure, top right: M_{MAX} vs. maximum injection rate, and bottom: M_{MAX} vs. injected volume.

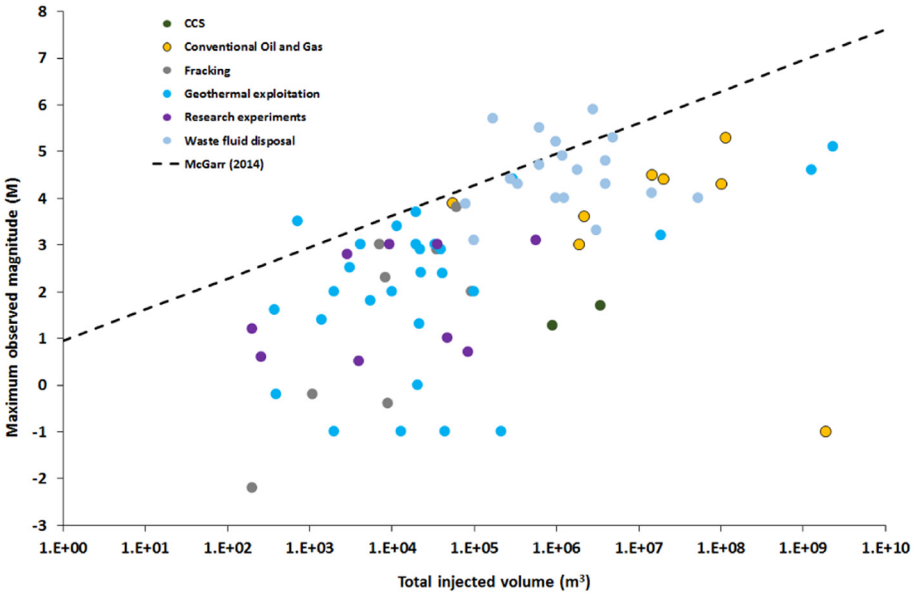

Fig. 97. M_{MAX} vs. total injected volume for the 69 cases of induced seismicity for which data are available. The upper-bound magnitude limit proposed by McGarr (2014) on the basis of theoretical considerations is also plotted.

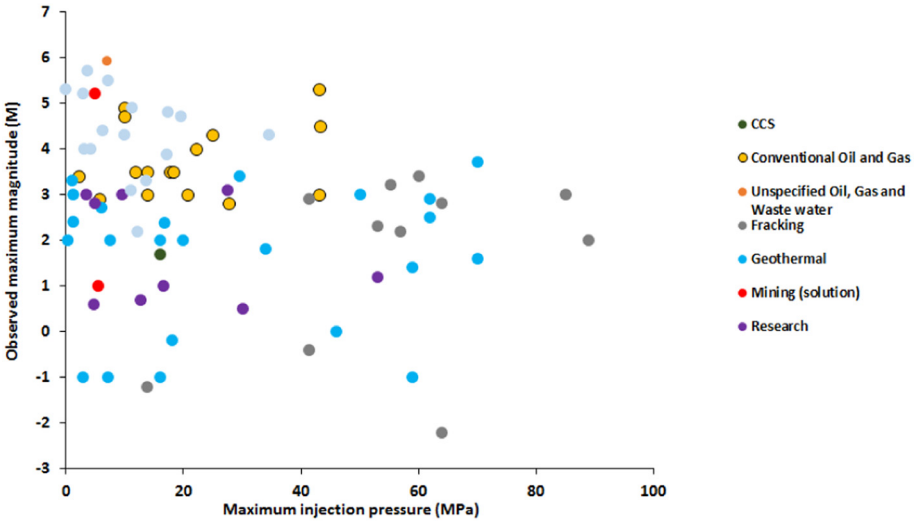

Fig. 98. M_{MAX} vs. maximum wellhead injection pressure for the 79 cases where data are reported.

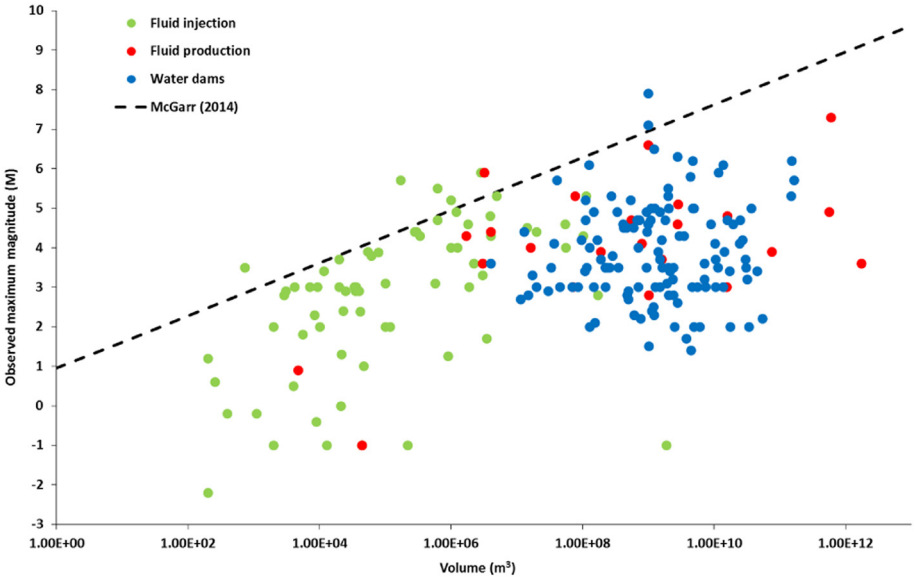

Fig. 99. M_{MAX} vs. volume or proxy volume of material removed or added for the 218 cases for which data are available, along with the relationship proposed by McGarr (2014) on the basis of theoretical considerations. Volumes and proxy volumes were estimated as follows: Water dams–the volume of the impounded reservoir; fluid injection or extraction–fluid volume injected into or extracted from the subsurface; mining–mass of material excavated, converted to volume using an appropriate density; construction–relevant mass converted to volume using an appropriate density for the building materials; CCS–mass of injected CO_2 converted to volume using a density of liquid CO_2 of 1100 kg/m^3.

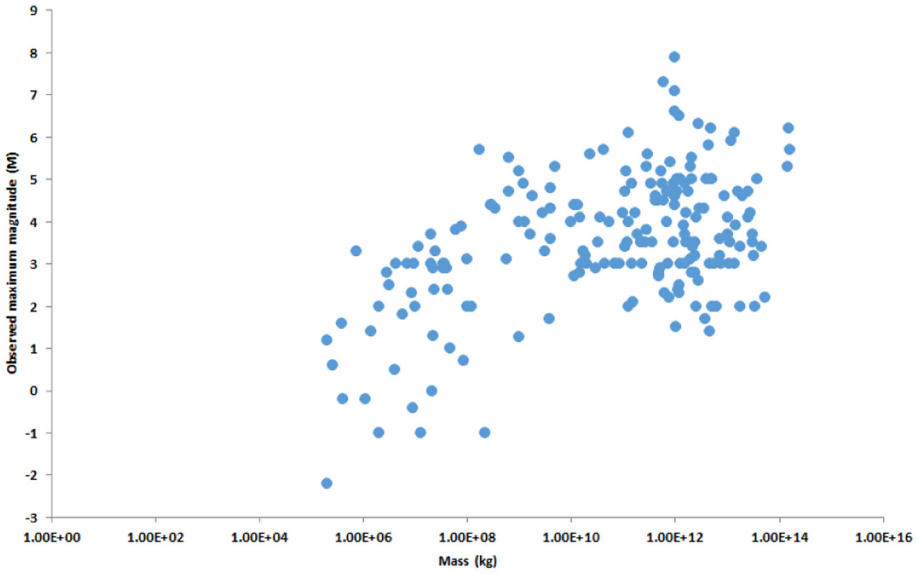

Fig. 100. M_{MAX} vs. mass of material removed or added for the 203 cases where data are available. Water volumes were converted to mass using a density 1000 kg/m^3. Oil and gas are not included in this plot except where quantity was reported in units of mass. Project types plotted include CCS, construction, conventional oil and gas, shale-gas hydrofracturing, geothermal, mining, research experiments, waste fluid injection and water reservoirs.

7. Discussion and conclusions

7.1. How common are induced earthquakes?

The total number of industrial projects in various categories, along with the number reported to be seismogenic are given in Table 3. Without doubt under-reporting is severe. Seismicity at projects remote from settlements is likely to escape notice. Known cases may not be publicized unless they are large and of nuisance or unusual interest. For example, ~2.5 million shale-gas hydrofracture jobs have now been completed world-wide. All successful hydrofracturing projects induce small earthquakes but only 21 cases have been reported (Table 3; Section 4.1.6). The absence of reports of seismicity does not correspond to an absence of seismicity. Statements such as "no seismicity is reported" does not equate to "no induced earthquakes occurred" or "no earthquakes were observed". Some earthquakes may also have been reported by national seismic networks without their induced nature being recognized.

M_{MAX} for the 562 seismogenic projects where this parameter is reported is shown as a plot of cumulative number of cases vs. M_{MAX} in Fig. 111. The linearity of the distribution at the high-magnitude end suggests that reporting is complete for M_{MAX} 5 and above, and that underreporting becomes progressively greater for projects smaller than M_{MAX} 4. Downward extrapolation of the linear, M_{MAX} 5–7 part of the plot suggests that ~30% of M ~4 induced earthquakes have gone unrecognized or unreported, 60% of M ~3 events and ~90% of those with M ~2 (Table 4).

The hydrocarbon fields around Britain provide a regional example of this problem. Comparison of the UK earthquake database of the British Geological Survey with maps of hydrocarbon fields in the North Sea suggests correlations between fields and earthquake locations (Fig. 112). Expanded maps of several fields are shown in Fig. 113. Epicenters cluster near the Beatrice Oilfield (Moray Firth), the Britannia Gasfield, the Southern North Sea Gas Province and the Leman Gasfield.

Most of the recorded earthquakes in the southern North Sea occur in or near fields developed in Permian Rotliegend reservoirs. There, gas is produced using simple pressure depletion from the original hydrostatic pressure. Water is not injected to support production. Many of the poorer-quality wells used to explore and appraise this gas province were prop-fracked to obtain initial gas flow and a few fields (e.g.,

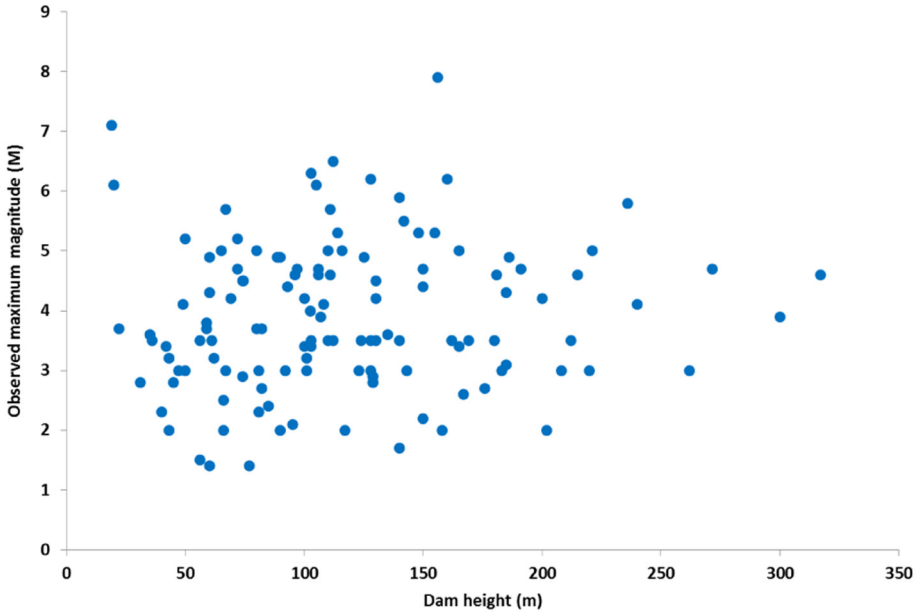

Fig. 105. M_{MAX} vs. dam height for the 159 cases of seismogenic water reservoirs for which data are available.

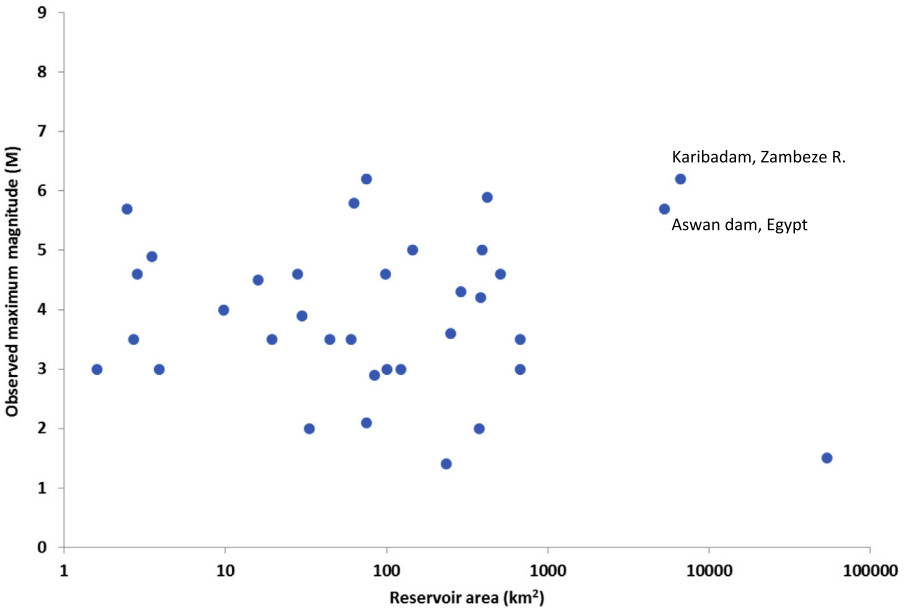

Fig. 106. M_{MAX} vs. water reservoir area for the 35 cases for which data are available.

Clipper South, Gluyas and Swarbrick, in press, 2017; Purvis et al., 2010) used hydrofracturing in development wells. The Viking Graben contains mostly oilfields that were developed by allowing natural pressure decline to deliver the first oil and then injecting water to support continued production. The water used is seawater at typical North Sea temperatures of ~4 °C, while the reservoirs are at 90–140 °C. The central North Sea and Moray Firth contain a heterogeneous mix of oil and gas fields produced by a combination of pressure depletion and water injection. When discovered some fields were naturally at high pressure and close to the fracture gradient.

Many of these activities are potentially seismogenic. Nevertheless, there are no reports of induced seismicity from these fields. Comparison of seismicity with hydrocarbon production information available from DECC for 1975–2008 shows no temporal correlations and, because the North Sea was seismogenic before hydrocarbon production started, it cannot be ruled out that the seismicity is natural. Detailed work on individual events and their possible connection to operations in individual oil and gas fields is required to resolve this ambiguity (Wilson et al., 2015).

7.2. Hydraulics

Groundwater influences earthquake occurrence. Overwhelming, observational data show that pore pressure in fault zones strongly influences seismicity (Section 1.3). The suggestions that large-scale extraction of groundwater influences seismicity imply an unfortunate association between earthquakes and human need to manage water for utilization and flood control.

The five cases we found of earthquakes suggested to be linked to groundwater extraction raise the question of whether other earthquakes that were both shallow and where major water table changes have occurred were induced. An example is the 2011 M 7.1 Christchurch, New Zealand, earthquake (Fig. 114). The city of Christchurch is built on what was once an extensive swamp fed by the rivers Avon and Heathcote and numerous smaller streams. Major engineering works have changed the hydrology there over the last century.

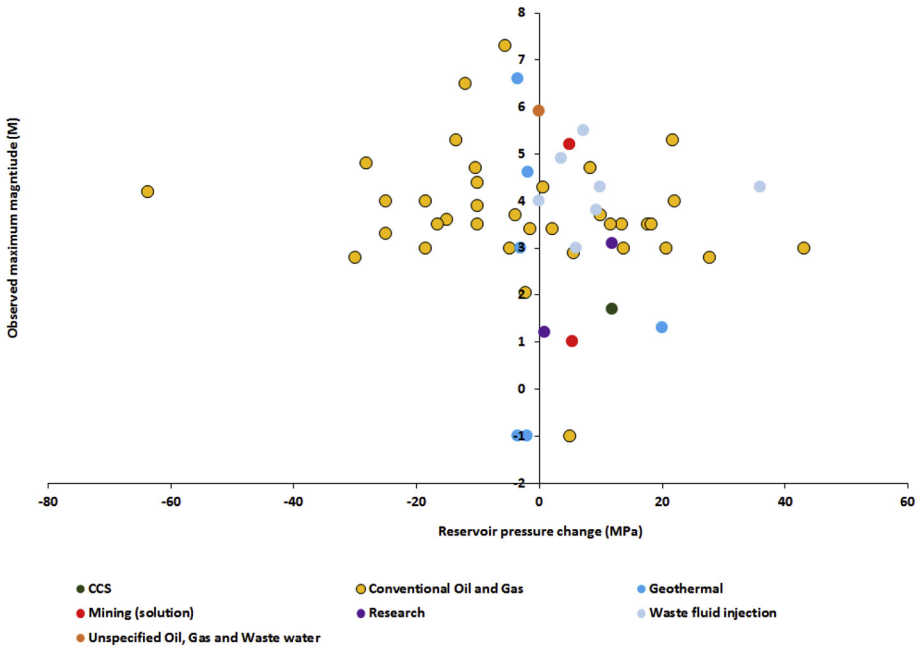

Fig. 107. M_{MAX} vs. change in reservoir fluid pressure resulting from production/injection for the 55 cases where data are available. We include 9 cases of conventional oil and gas where the pressure change results from both injection and production.

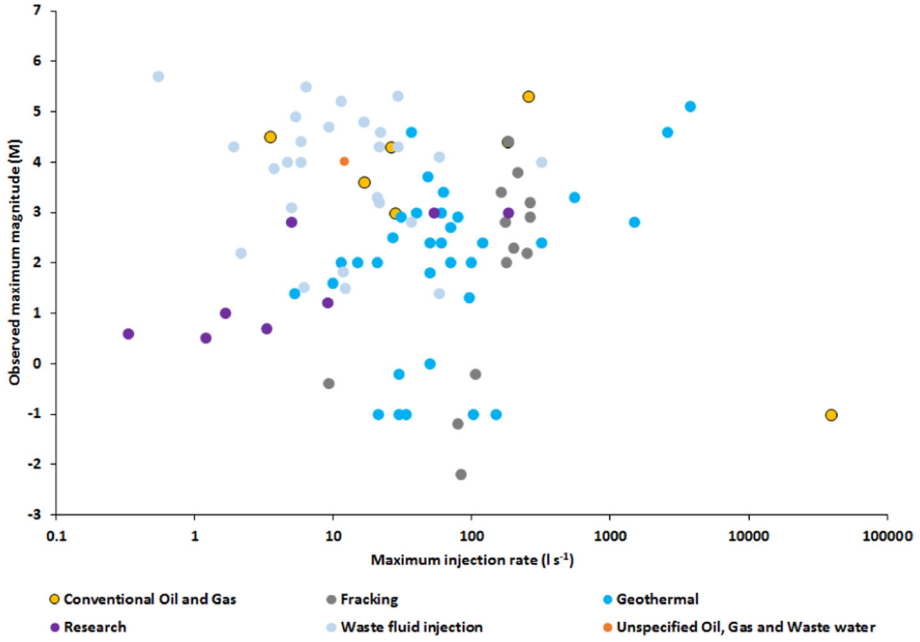

Fig. 108. M_{MAX} vs. maximum injection rate for the 88 cases for which data are reported. Rates of injection varied from 0.33 to ~40,000 l/s. At rates greater than ~1000 l/s, values apply to entire fields rather than individual wells.

The 1811–1812 New Madrid earthquakes occurred in the central Mississippi river valley. This renowned sequence included three M ~7 earthquakes and about seven with M > ~6.5. These earthquakes are remarkable for having been felt at distances of up to 1700 km as a result of efficient transmission of seismic waves through the eastern USA lithosphere. They are also remarkable in occurring in an intraplate area. They are a paradox in any paradigm that expects large earthquakes to occur in plate boundary zones.

The New Madrid earthquakes occurred at and just south of the confluence of the 6000 m^3/s Middle Mississippi and the 8000 m^3/s Ohio rivers which forms the Lower Mississippi River. The possibility that the earthquake activity is linked to local hydraulics has been suggested previously but not seriously entertained. In view of the growing evidence that hydraulic changes can modulate the seismic behavior of faults it may be timely to revisit this possibility with investigation into pre-earthquake hydraulic activity and numerical modeling.

Hydraulic effects may explain why both mass addition and removal can induce earthquakes. This is illustrated by the fact that the commonest earthquake-induction process is mining (i.e. mass removal–38% of cases; Fig. 115) and the second most common is water reservoir impoundment (i.e. mass addition–24%). Hydraulic changes induced by mass redistribution may result in migration of fluid into fault zones, increasing pore pressure. This process may explain the possible induction of earthquakes by erecting the Taipei 101 building (Section 2.1.2). It may also explain earthquake induction by hydrocarbon extraction in the absence of fluid injections, since natural groundwater recharge may occur.

Global earthquake databases show that moderate earthquakes are fairly common near large lakes and reservoirs, e.g., in east Africa, even though induction has not been proposed. Intraplate earthquakes in the UK are not currently understood. At least 21% of UK earthquakes in the

British Geological Survey catalog are thought to be related to mines, but many others are probably natural. The seismic rate in the UK is ~one M_L 3.6 event/year (Wilson et al., 2015). A possible link with hydraulics is under investigation (Graham et al., 2017).

7.3. How much stress loading is required to induce earthquakes?

Earthquakes occur naturally, without any human intervention at all. The minimum amount of added anthropogenic stress needed for an earthquake to start is thus zero.

Many natural processes contribute to stress build-up on faults. These include tectonic deformation, volcanism, natural heat loss, isostatic uplift following deglaciation or oceanic unloading, Earth tides, intraplate deformation resulting from distant plate boundary events, remote large earthquakes, erosion, dissolution, the natural migration of groundwater and weather. To these are added industrial activities. It is an ill-posed question to ask the origin of the final stress increment that "broke the camel's back" and precipitated an earthquake. In the case of large earthquakes this question may be akin to asking whether one particular skier of many was responsible for an avalanche.

Instead of viewing industrial activity as inducing earthquakes, it could instead be viewed as modulating the timescale on which inevitable earthquakes occur. Unfortunately it cannot be known what events would have occurred had the industrial activity not been done because history cannot be re-run with a change of circumstance. Furthermore, had an equivalent earthquake occurred at a different time, it cannot be known if it would have affected people and infrastructure to the same extent. Nevertheless, in the cases of many industrial projects, the association between earthquakes and the project is

Table 3
Induced seismicity statistics for the total numbers of projects of different types, the number that are seismogenic, and related data.

Project type	# projects	# cases in the database	% projects that are seismogenic	Observed maximum magnitude (M_{MAX})	# seismogenic projects reported by Hitzman (2013)	Source for # projects

Table 4
Number of reported M_{MAX} values and number predicted from downward extrapolation of the linear trend of earthquakes with M_{MAX} 5–7 shown in Fig. 111.

M_{MAX}	# reported earthquakes	# predicted earthquakes
7	4	4
6	17	16
5	68	67
4	181	~250
3	371	~1000
2	497	~4000

undeniable. The clear induction of some earthquakes by very small incremental stresses means that objections to induced status on the grounds that the stress perturbation was too small may be weak.

Anthropogenic stress changes proposed to have induced earthquakes range from a fraction of a MPa (e.g., Keranen et al., 2014), the equivalent of about a meter of rock overburden, to several tens of MPa (Table 5) (Fig. 116). For example, both the 2007 M_L 4.2 Folkestone, UK, earthquake and the 2008 $M_W \sim 8$ Wenchuan, China, earthquake have been attributed to anthropogenic stress changes of only a few kPa.

The question "How much stress change is needed to induce earthquakes?" may be unanswerable. However, it may be possible to address the question "What is the smallest stress change observed to induce earthquakes?" This can be attempted using natural stress changes known to correlate with earthquakes, as follows (Table 6).

7.3.1. Earth tides

The spatial non-uniformity of the gravitational fields of the Sun and Moon (and to a much smaller extent, other celestial bodies) produces differential stresses in the solid body of Earth approaching 0.005 MPa. Loading of the solid Earth by ocean tides produces additional stresses that can be about an order of magnitude larger but depend strongly on geographic location. The stress drops of most earthquakes are 1–10 MPa so tides might sometimes have a detectable effect on earthquake occurrence.

Most early studies of earthquakes and tides failed to find any significant correlation. The main cause of this failure was probably oversimplification of the problem. Both stresses and earthquake mechanisms are tensors, but many studies looked, for example, for correlations between seismicity and tidal amplitude ranges, effectively treating both stress and earthquake mechanism as scalars. Another difficulty with such analyses was the difficulty of computing ocean tides from the complicated shapes of ocean basins.

There were, however, two exceptions to this failure. First, deep moonquakes, detected by seismometers placed by Apollo astronauts, correlate strongly with tides (Latham et al., 1973). Second, earthquakes at volcanic and geothermal areas show a tidal effect that is easily detected (e.g., McNutt and Beavan, 1981). Recently, studies that account for earthquake focal mechanisms and compute ocean loading accurately have found that shallow thrust-faulting earthquakes correlate significantly with tidal stresses (Cochran et al., 2004).

7.3.2. Static stress changes resulting from large earthquakes

The 1989 M_W 6.9 Loma Prieta, California, earthquake modulated seismicity from around the epicenter out to distances where the coseismic stress changes were ≥ 0.01 MPa (equivalent to ~0.4 m of overburden) (Reasenberg and Simpson, 1992). The 1992 M_W 7.3 Landers, California, earthquake also modulated nearby seismicity. Aftershocks were abundant up to about two source dimensions from the mainshock (a few tens of km), where the Coulomb stress on optimally orientated faults was increased by > 0.05 MPa. They were sparse where stress was reduced by this amount (Fig. 117). The 1992 M_W 6.5 Big Bear aftershock occurred in a region where stress was increased by 0.3 MPa (King et al., 1994). The effect of static stress changes on neighboring faults has also been expressed in terms of the number of years by which the next large earthquake has been advanced in time (e.g., King et al., 1994; Reasenberg and Simpson, 1992).

7.3.3. Remote triggering

The 1992 M_W 7.3 Landers, California, earthquake is remarkable because it precipitated earthquake activity up to 17 source dimensions distant from the mainshock (1250 km). Most of this activity occurred at volcanic or geothermal areas such as Yellowstone. Static stress changes are vanishingly small at such distances. These remote earthquakes are thought to have been triggered by dynamic stress changes of a few tenths of a MPa in the propagating shear- and surface elastic waves interacting with fluids in hydrothermal and magmatic systems (Hill et al., 1993). This phenomenon of "remote triggering" has subsequently been observed elsewhere. When first unambiguously recognized following the Landers earthquake, it was thought only volcanic and

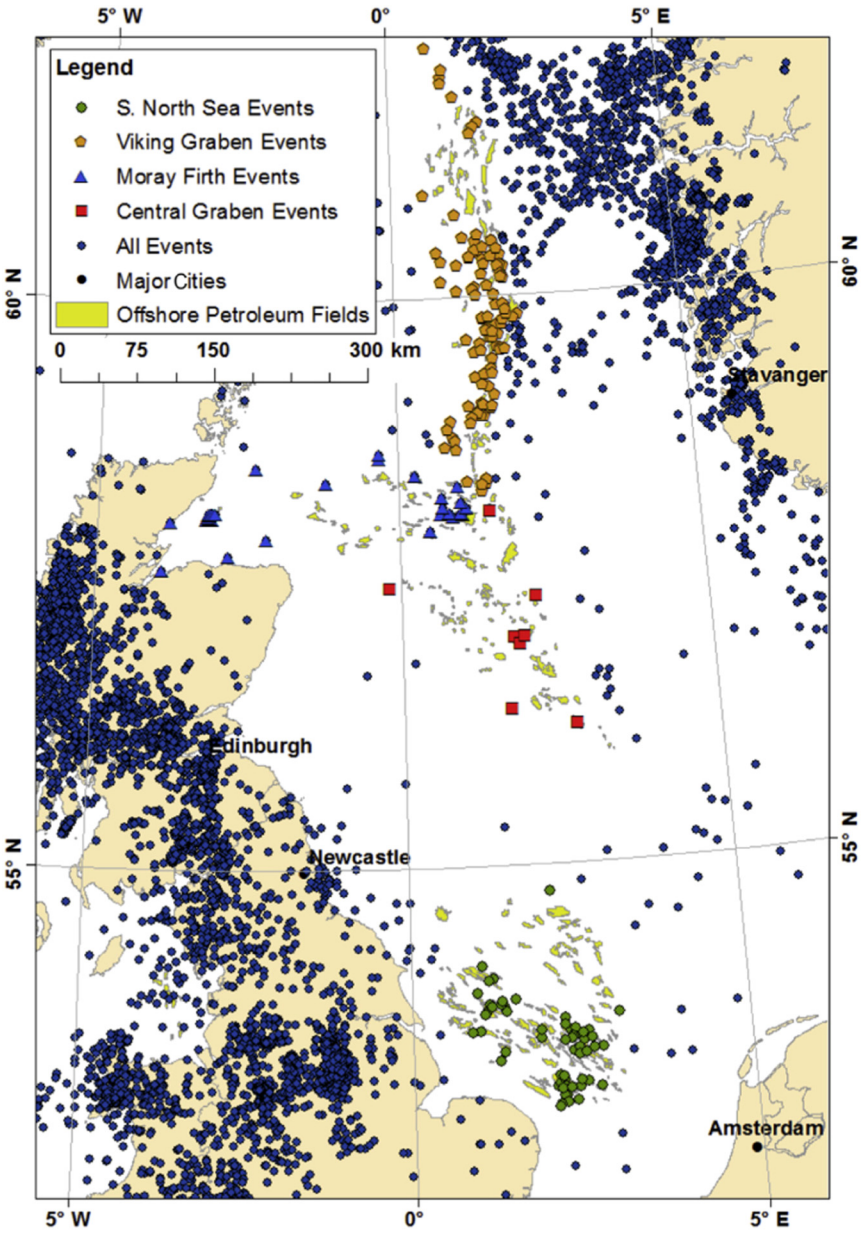

Fig. 112. Epicenters from the UK earthquake catalog of the British Geological Survey. Orange circles: Viking Graben events; blue triangles: Moray Firth events; red squares: Central Graben events; green circles Southern North Sea Gas Province events; yellow shading: offshore hydrocarbon fields.
(From Wilson et al. (2015).)

geothermal areas were affected and the process might reveal the locations of geothermal areas previously unknown. However, remote triggering has now been reported in other environments, e.g., the hydrocarbon region of Oklahoma (Fig. 58) (van der Elst et al., 2013).

7.3.4. Weather

A number of studies have postulated that earthquakes were induced by heavy rainfall (e.g., Husen et al., 2007; Roth et al., 1992). Correlations have also been suggested between "slow earthquakes" (accelerated creep on faults) and atmospheric pressure changes accompanying typhoons in Taiwan (Liu et al., 2009). Such pressure changes alter stress on land areas but not beneath the ocean because seawater flow maintains pressure equilibrium offshore. The effect contributes a stress change of ~0.003 MPa that encourages slip on coast-parallel thrust faults.

7.4. How large are induced earthquakes?

Stress changes postulated induce earthquakes do not correlate with stress drops brought about by the earthquakes or magnitudes. Counter-intuitively, M_{MAX} reported for induced sequences *decreases* with increasing calculated stress perturbation (Fig. 116). The final size of an earthquake is determined by how much of a fault was sufficiently stressed to move once activation began. If slip on a fault reduces to zero before the next event on the same fault starts, a series of discrete events is recognized. If slip does not stop, the event may grow and all the strain release is considered to have occurred in a single event. Great earthquakes that rupture much of the lithosphere typically comprise a cascading chain of M ~7 sub-events, each triggered by the stress changes resulting from the previous ones. Although likely very rare, it cannot be ruled out that industrial activity could contribute to the onset of an initial sub-event. It is also not uncommon for foreshocks to occur immediately preceding the onset of a mainshock several magnitude units higher. An initial M_W 5 earthquake in Oklahoma may have triggered successive earthquakes, including the M_W 5.7 event the following day (Keranen et al., 2013). In the case of the great 2008 M_W ~8 Wenchuan earthquake (Section 2.1.1), once the first sub-event began slip on the fault did not stop until several large fault segments had failed.

This view is consistent with the findings of McGarr (2014). He derived a relationship that related volume injected to the size of injection-

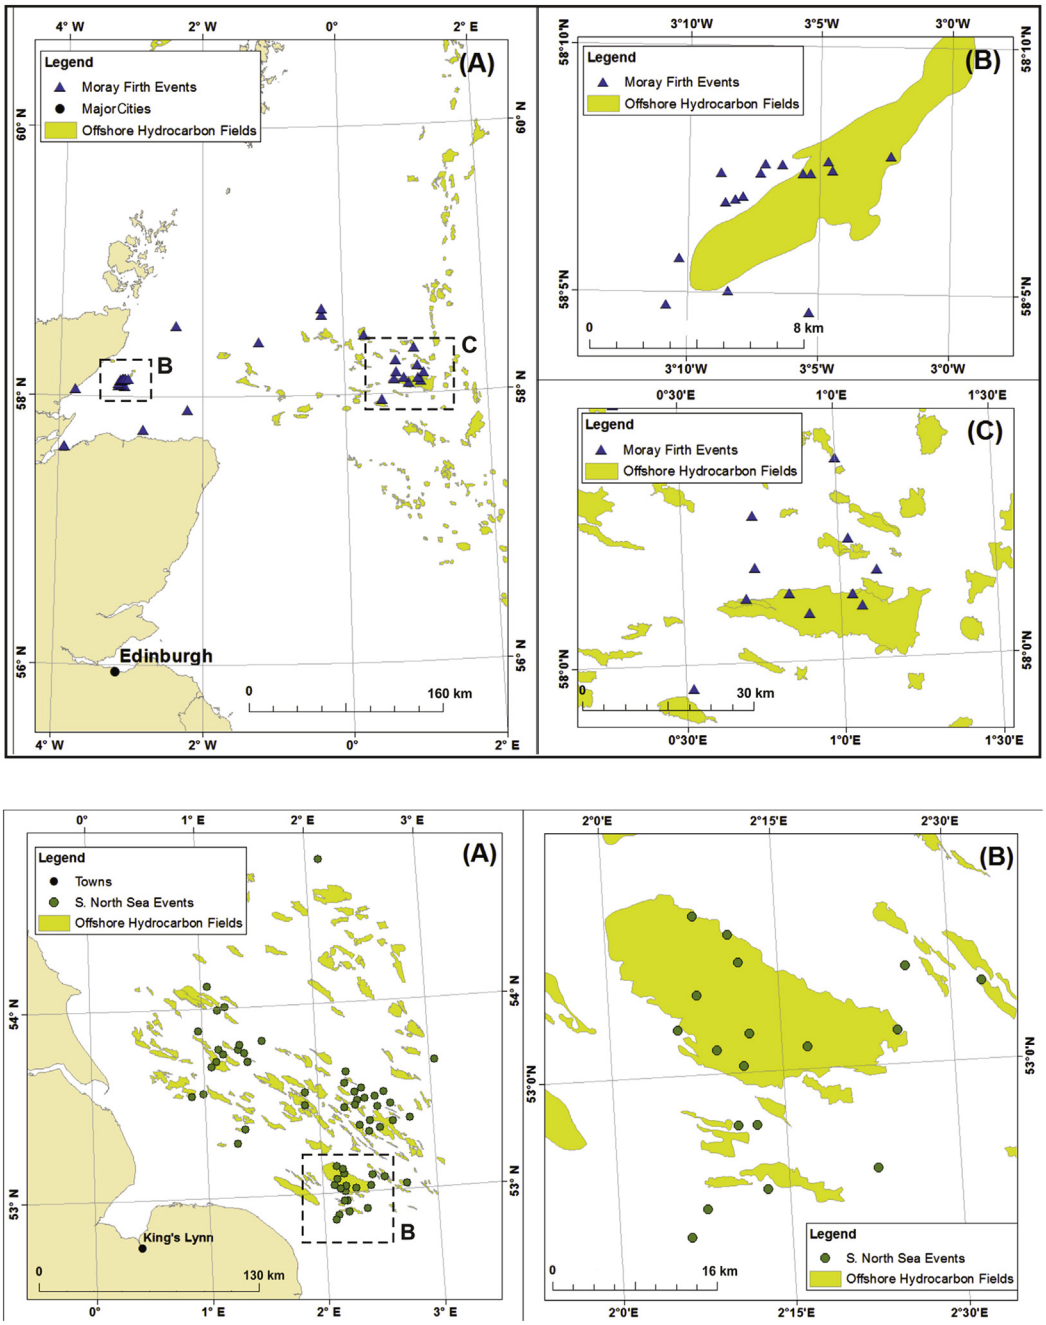

Fig. 113. Expanded view of some parts of Fig. 112. Top row: A–the Moray Firth. Yellow: hydrocarbon fields; blue triangles: earthquakes. B–the Beatrice Oilfield. C–the Britannia Gasfield. Bottom row: A–the Southern North Sea Gas Province. Green dots: earthquakes. Bottom row: B–the Leman Gasfield.
(From Wilson et al. (2015).)

induced earthquakes and showed that it fit well observations of 18 of the largest-magnitude earthquakes (Fig. 95). However, he also pointed out that this upper bound only applies to induced earthquakes whose source regions were confined to the volumes directly affected by the injection, and that if fault slip propagated outside of this volume then larger earthquakes could occur.

7.5. Natural or induced?

The strength of evidence for earthquake induction varies greatly between cases. For some examples the association with an industrial activity is beyond reasonable doubt. For example, over 250,000 earthquakes have been located in a tight cluster in The Geysers geothermal area, California, by the U.S. Geological Survey during the last half century. At the other end of the spectrum, induction has been suggested for cases where only one earthquake occurred and the calculated stress changes were smaller than those induced by Earth tides, e.g., for the 2007 M_L 4.2 Folkestone, UK, earthquake (Klose, 2007b). For those cases, mere coincidence cannot be ruled out (Sections 2.1.3 and 7.3). The suggestion that earthquakes were induced over 1000 km away and over a year later by bombing of cities with non-nuclear weapons is not persuasive strongly supported (Section 5).

The number of postulated induced cases is increasing rapidly and with it the urgency for management strategies. It is desirable, not only to know *a posteriori* whether an earthquake was natural or induced, but also to forecast which projects may be seismogenic in future and how great the hazard is likely to be. In the past, schemes have been proposed to address the question whether earthquakes are natural or induced. For

Conversions for commonly used units of pressure.

1 bar = 0.1 MPa, equivalent to ~4 m of rock overburden
1 atm = 0.1 MPa
1 kg/cm^2 = 0.1 MPa
1 lb/in.^{2} (psi) = 6.9 × 10^{-3} MPa
1 acre-foot of water/football field[a] = 29 × 10^{-6} MPa
Hydrostatic gradient = 10 MPa/km
Lithostatic gradient = ~25 MPa/km

[a] American football, including end zones.

example, Davis and Frohlich (1993) list seven questions to profile a seismic sequence and judge whether it was induced or not (Table 7). In the light of the large number of case histories now available, some of these parameters can be re-examined:

1. *Whether the region had a previous history of seismicity*. Induced earthquakes have now been postulated to occur in both historically seismic and aseismic areas. Evidence from research in boreholes suggests that faults everywhere are close to failure, regardless of the known history of seismicity.
2. *Close temporal association with the induction activity*. Reported delays in the onset of postulated inducted seismicity vary from essentially zero to several decades.
3. *In the case of injection-related earthquakes, proximity of a few kilometers*. Distances of up to 25 km have now been reported (Fig. 104; Section 4.1.2).
4. *Known geological structures that can channel flow*. Many earthquakes postulated to be induced have been attributed to previously unknown faults.
5. *Substantial stress changes*. Stress changes as small as a few kPa have been postulated to induce earthquakes (Section 2.1.3).

Simple criteria for deciding whether an earthquake is induced or not are elusive. There is extreme diversity in the circumstances of cases. Postulated induction activities may take place over time periods from a few minutes to decades. The volumes of material added or removed vary over many orders of magnitude and the maximum magnitude of events postulated to be induced vary from M < 0 to M ~ 8.

Several unusual characteristics are commonly reported for earthquakes suspected of having been induced. These include:

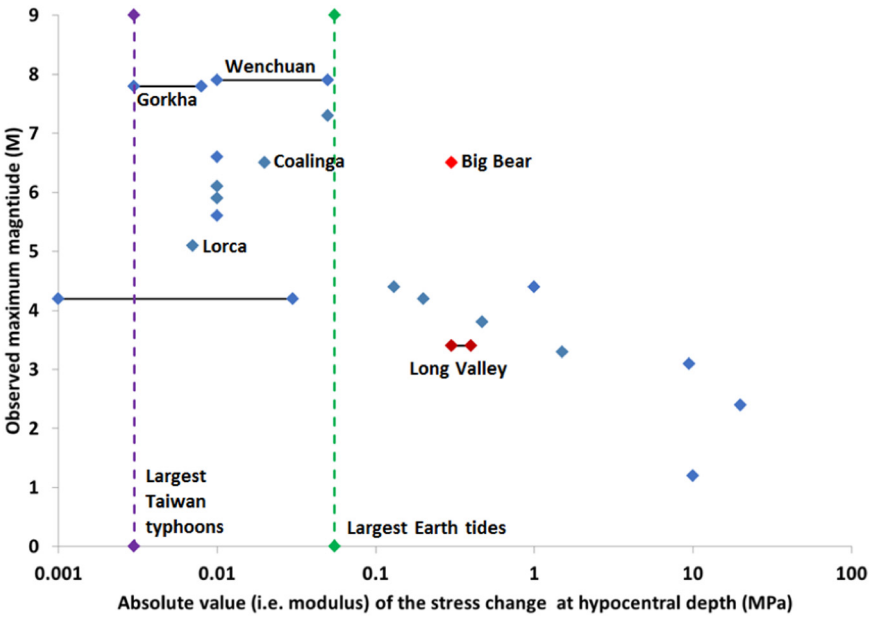

Fig. 116. M_{MAX} vs. absolute value of stress changes calculated by various authors to have occurred at the hypocentral depths of possibly induced earthquakes. Vertical dashed green line: largest Earth tides; vertical dashed purple line: largest Taiwan typhoons. Blue diamonds: earthquakes proposed to have been human-induced, diamonds connected by solid black lines: ranges of stress changes calculated. Some example earthquakes are labeled. Red diamonds: natural earthquakes that followed the 28th June 1992 M_W 7.3 Landers, California, earthquake (data from Hill et al., 1993). The Big Bear earthquake is proposed to have been induced by static stress changes, and the Long Valley earthquakes by the dynamic stresses from the surface waves.

Table 6
Stress changes associated with some natural processes postulated to induce earthquakes.

Effect	Stress change (MPa)
Earth tides	0.05
Seismic static stress changes	0.03
Remote triggering	~0.5
Typhoons	0.003

1. Unusually shallow nucleation depths (e.g., the 2011 M_W 5.1 Lorca, Spain, earthquake, Section 3.1);
2. Occurrence on previously unknown faults ("blind faults"; e.g., in the Cogdell oilfield, Texas, Section 4.2.2);
3. Release of stress in the same sense as the regional on suitably orientated structures (e.g., in Oklahoma, Section 4.1.2);
4. The largest earthquake in a sequence occurring after the induction activity has ceased, suggesting that fluid diffusion is important (e.g., the 1962–1968 Denver earthquakes, Section 4.1.1);
5. Faults in the basement beneath water and hydrocarbon reservoirs being reactivated, sometimes transecting the sedimentary formations above (e.g., the Coalinga, California, earthquake; Section 3.3.2).

These observations raise a number of questions. For example, if induced seismicity commonly occurs on previously unknown faults, could hazard be reduced by extensive subsurface mapping prior to operations? Since the crust is thought to be pervasively faulted and near to failure essentially everywhere, it is not clear this would be the case–perhaps everywhere should be considered potentially seismogenic. Also, if large earthquakes occur after operations have stopped, for how long should seismic hazard mitigation measures be continued after the end of a project?

More reliable, but less universally applicable ways of discriminating include:

1. Simple spatial and temporal associations, e.g., earthquakes beginning to occur as soon as injection starts and close to the injection point;
2. Earthquakes occurring in previously aseismic regions;
3. Visual observation, e.g., gallery collapses in mines or ground rupture when a nuclear test is conducted;
4. Earthquake focal mechanisms, e.g., discriminating between natural, shear-faulting earthquakes and volumetric mining collapses, as was done by McGarr (1992a, 1992b) for well-recorded earthquakes in South African gold mines and Dreger et al. (2008) for a mine collapse in Utah.

Work is currently ongoing to develop additional ways of discriminating induced from natural earthquakes. These include using statistical features of background earthquakes and clustered sub-populations. For example, Zaliapin and Ben-Zion (2016) have suggested several statistical features that may distinguish induced seismicity from natural tectonic activity including a higher rate of background events and more rapid aftershock decay.

7.6. Why are earthquakes induced by some industrial projects and not others?

In addition to needing an explanation for why earthquakes occur at particular projects, any theory for induced earthquakes must also explain why they do not occur at most projects. This endeavor is hampered by under-reporting (Section 7.1; Table 3). A necessary pre-requisite to explaining induced seismicity as a whole or in different categories is to know its true extent.

For industrial activity as a whole, reports of induced earthquakes are extraordinarily rare (Table 3). Induced nuisance earthquakes are even rarer. Only ~2% of mines, water reservoirs, and CCS projects are reported to be seismogenic. All other categories of project for which we found data were < 2% seismogenic.

Individual cases are diverse and site-specific and the lack of similarities is perhaps a stronger feature than common factors. With the exception of large geothermal projects and hydrofracturing (where almost all are probably seismogenic but only 0.001% are reported to be so) it is seemingly unpredictable which projects will report induced earthquakes. Many if not most induced earthquakes, except at hydrofracturing projects, were unexpected. On the other hand, a research experiment that specifically aimed to induce seismicity, by injecting water into an active fault zone, failed to do so (Section 4.1.8) (Prioul et al., 2000).

A majority of induced earthquakes occur in intraplate areas (Fig. 109). This is not surprising in view of the fact that rocks are close to failure everywhere so the potential for inducing earthquakes in intraplate and plate-boundary regions may be similar (Section 1.1). This,

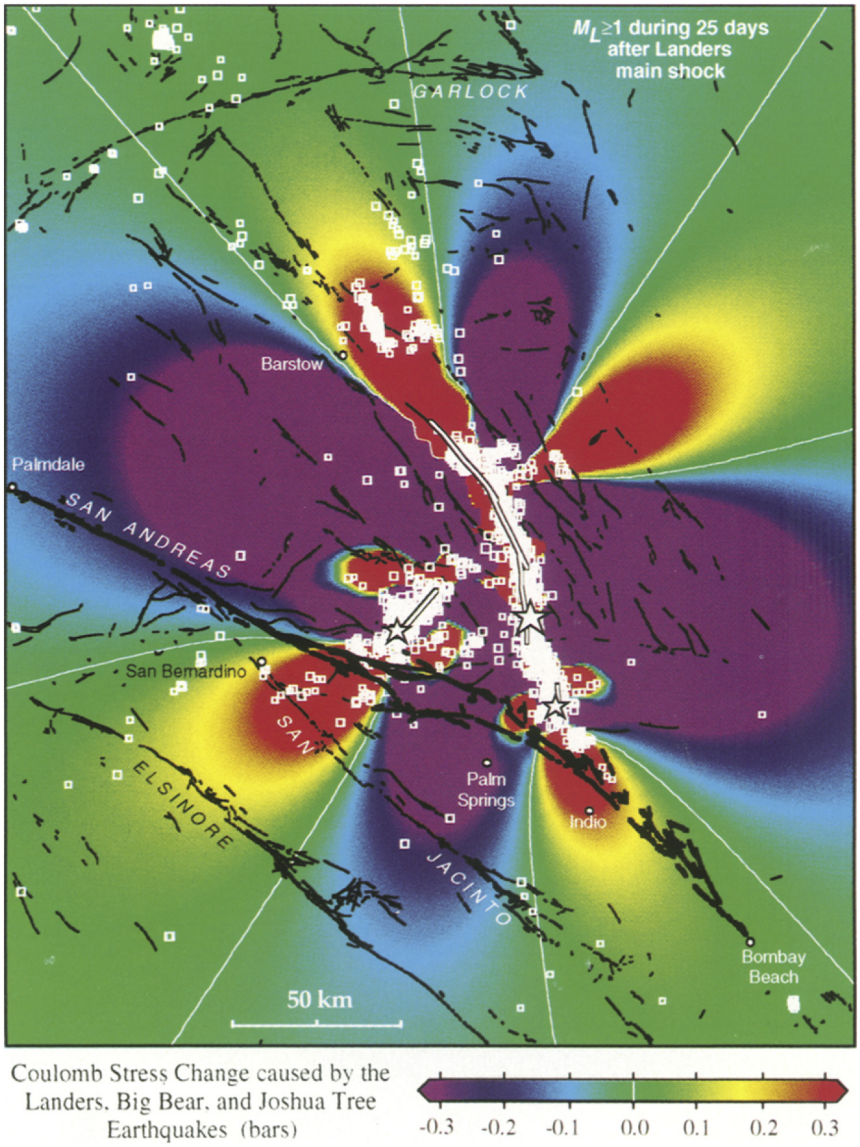

Fig. 117. Coulomb stress changes at a depth of 6.25 km caused by the M_W 7.3 Landers, California, earthquake and large aftershocks. (From King et al. (1994).)

Table 7
Seven questions proposed by Davis and Frohlich (1993) to diagnose earthquakes induced by fluid injection. (From Davis and Frohlich (1993).)

	Question	Earthquakes clearly not induced	Earthquakes clearly induced	I Denver, Colorado	II Painesville, Ohio
	Background seismicity				
1	Are these events the first known earthquakes of this character in the region?	NO	YES	YES	NO
	Temporal correlation				
2	Is there a clear correlation between injection and seismicity	NO	YES	YES	NO
	Spatial correlation				
3a	Are epicenters near wells (within 5 km)?	NO	YES	YES	YES?

4b	Are changes in fluid pressure at hypocentral locations sufficient to encourage seismicity?	NO	YES	YES	NO?
	Total “YES” answers	0	7	6	3

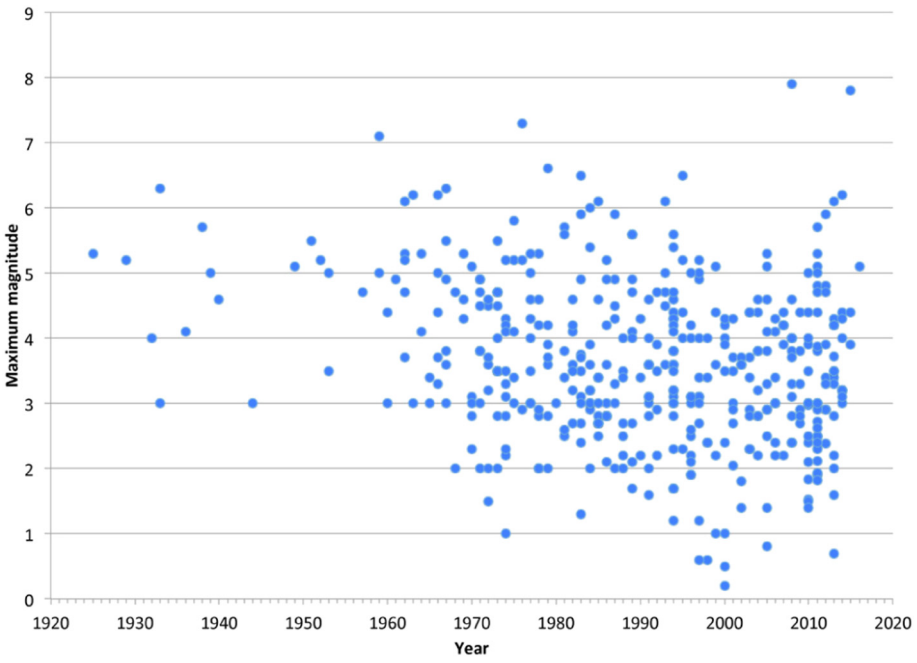

Fig. 118. M_{MAX} vs. year for the 419 cases where data are available.

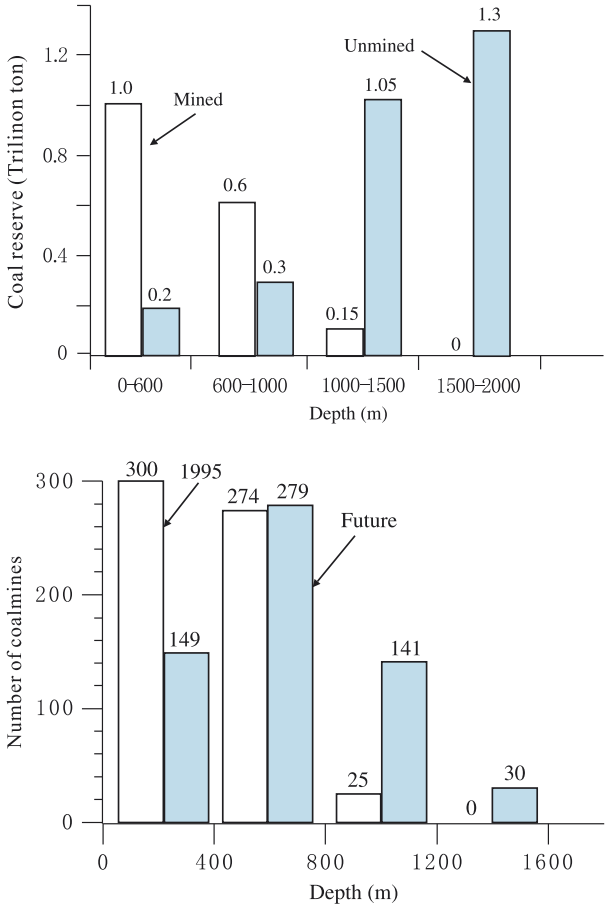

Fig. 119. Top: Depth distribution of Chinese coal reserves (1995 statistics). Bottom: Depth distribution of 599 state-owned Chinese coal mines.
(From Li et al. (2007).)

coupled with many earthquake sequences being unexpected and in areas previously aseismic, means that populations may be unprepared. To add to this, pre-industrial seismic risk assessments may be difficult if there is no history of seismicity or seismic monitoring. Wilson et al. (2015) recently tried to rectify this problem for the UK in advance of possible expansion of the shale-gas industry by estimating a baseline for UK seismicity.

For most non-research purposes the parameter of importance is not whether seismicity is induced but whether nuisance seismicity is induced (Section 1.2). M_{MAX} is thus critical. Section 6 describes an initial examination of *HiQuake* for correlations. The currently observed upper limit to M_{MAX} correlates with water reservoir volume and mass per unit area, volume added or removed at the surface, volume extracted or added to the subsurface, injection pressure (negative correlation), rate and volume, the yield of nuclear tests and scale of project. Most of these are basically measures of project size. Factors such as reservoir pressure change and injection/extraction rate do not correlate with the observed M_{MAX} ceiling.

Suggestions for what operational parameters might be adjusted to mitigate induced seismicity include injecting into formations that are sealed from the basement, and avoiding known faults. There has, however, yet to be a demonstration of an approach that works in general for projects of a particular type. It is also not clear how we would we recognize success since there can be no evidence for the earthquake that did not occur.

7.7. Future trends

7.7.1. Earthquake prediction

There is presently no reliable method to predict earthquakes. Current approaches to reducing hazard comprise long-term forecasting based on the history of past earthquakes including instrumental data, historical information, and paleoseismology using methods such as trenching (e.g., Obermeier, 1996). This approach assumes that patterns of seismicity persist in local areas. It cannot make predictions, even in plate boundary zones (Lindh, 2005), and may work even more poorly in intraplate areas (Section 1.1) (Brooks et al., n.d.; Stein et al., 2015). In regions with little history of seismicity it may not be possible to implement.

Nicol et al. (2011) reviewed this issue from the point of view of CCS. Focus tends to be on reservoir-scale pressure increases and the effect of crustal loading on local faults is not routinely considered. Modeling crustal loading or unloading, along with the likely effects on groundwater, might be fruitful avenues of approach. Another useful approach

could be to study jointly surface deformation and seismicity. The technology to measure surface deformation is well developed. Both satellite and ground-based methods are available but rarely have integrated studies with ground truthing been reported. InSAR and GPS were applied to the depleted Alkmaar Gas Field in the Netherlands (Gee et al., 2016), and Intermittent SBAS satellite data were used to confirm the deformation from earlier GPS work. These results could potentially be integrated with legacy earthquake data.

The two types of data have been jointly interpreted in the case of several projects (e.g., Goertz-Allmann et al., 2014; Keiding et al., 2010). However, systematic relationships have not been explored for induced earthquakes as a whole.

7.7.2. Monitoring recommendations

Good industrial practice first and foremost requires high-quality information. Projects that have the potential to induce earthquakes should be monitored seismically and geodetically. Joint interpretation of these two types of data is more powerful than either in isolation. In addition to the nuisance of seismic deformations (i.e. earthquakes), aseismic deformations can alter the surface and cause nuisance such as infrastructure damage, flooding, and other changes to groundwater circulation.

Geophysical monitoring need not necessarily be elaborate and can be tailored to the circumstances. Unless there is evidence or compelling expectations for earthquakes or surface deformation, minimal instrumentation will suffice. Data should be publically available to all stakeholders.

The current paper contributes a full review of what type of projects have been claimed to induce earthquakes in the past. This is currently the best guide identifying what projects will induce earthquakes in future.

7.7.3. Earthquake management

The largest reported induced earthquake has increased with time from M 6.3 in 1933 to ~M 8 in 2008 (Fig. 118). The number of reported cases has also increased greatly, probably because of the increasing number of large-scale industrial projects. The lower magnitude threshold of reporting is reducing, probably partly because of improved monitoring. These statements, and others made in this paper, should be viewed in the context that they are underpinned by a database of all earthquakes postulated to be induced, with no selection for credibility.

There is a growing need to manage the problem of industrially induced earthquakes and this is well-illustrated by coal mining in China (Section 3.2.1). The expanding Chinese economy is founded on coal as an energy source but at the same time shallow resources are being rapidly depleted (Fig. 119). The future trend is thus to go deeper (Li et al., 2007). In the two decades from 1980 to 2000 the average mining depth increased from 288 m to 500 m. Now, over 75% of the coal has been removed from the top 1000 m and the recent increase in mine seismicity there results largely from increases in mining depth and the size of galleries. Super-deep mines (> 1200 m in depth), such as have induced seismicity in South Africa for decades, are planned in China for the future. Fluid injection for waste disposal, enhanced oil recovery, hydrofracturing and geothermal energy, are also expanding rapidly and have resulted in some of the most significant increases in induced seismicity in recent years (Ellsworth, 2013). Other industries such as building dams and CCS may expand over the coming years.

Management of the problem is moving forward rapidly as additional stakeholders become involved (e.g., Wang et al., 2016). For example, the issue of induced earthquakes is now of concern to the US Army Corps of Engineers because of the threat to critical federal infrastructure, e.g., levees and dams. No societal benefit comes without price–there is no such thing as a free lunch. However, public policy, engineering, preparation, and outreach can enable economically and societally beneficial projects to go ahead under appropriate health-and-safety conditions and in contexts that are understood and acceptable to stakeholders.

Acknowledgments

This work benefitted from discussions with and assistance from Julian Bommer, Kosuke Heki, Tianhui Ma, Steve Spottiswoode, Michelle Grobbelaar, Deborah Weiser, Irene Beardsley and Dan Bloomberg. Ang Li assisted with locating Chinese cases. The authors thank Art McGarr and two anonymous reviewers for helpful reviews, and Giuliano Panza, Editor, for handling the manuscript. The project was funded by the Nederlandse Aardolie Maatschappij BV (NAM), Schepersmaat 2, 9405 TA Assen, The Netherlands. This paper is based on a report submitted to Jan van Elk and Dirk Doornhof (NAM).

Gas injection may have triggered earthquakes in the Cogdell oil field, Texas

Wei Gan[a,b] and Cliff Frohlich[b,1]

[a]School of Earth Sciences and Resources, China University of Geosciences, Beijing 10083, China; and [b]Institute for Geophysics, Jackson School of Geosciences, University of Texas at Austin, Austin, TX 78758-4445

Edited by Donald W. Forsyth, Brown University, Providence, RI, and approved October 4, 2013 (received for review June 13, 2013)

Between 1957 and 1982, water flooding was conducted to improve petroleum production in the Cogdell oil field north of Snyder, TX, and a contemporary analysis concluded this induced earthquakes that occurred between 1975 and 1982. The National Earthquake Information Center detected no further activity between 1983 and 2005, but between 2006 and 2011 reported 18 earthquakes having magnitudes 3 and greater. To investigate these earthquakes, we analyzed data recorded by six temporary seismograph stations deployed by the USArray program, and identified 93 well-recorded earthquakes occurring between March 2009 and December 2010. Relocation with a double-difference method shows that most earthquakes occurred within several northeast–southwest-trending linear clusters, with trends corresponding to nodal planes of regional focal mechanisms, possibly indicating the presence of previously unidentified faults. We have evaluated data concerning injection and extraction of oil, water, and gas in the Cogdell field. Water injection cannot explain the 2006–2011 earthquakes, especially as net volumes (injection minus extraction) are significantly less than in the 1957–1982 period. However, since 2004 significant volumes of gases including supercritical CO_2 have been injected into the Cogdell field. The timing of gas injection suggests it may have contributed to triggering the recent seismic activity. If so, this represents an instance where gas injection has triggered earthquakes having magnitudes 3 and larger. Further modeling studies may help evaluate recent assertions suggesting significant risks accompany large-scale carbon capture and storage as a strategy for managing climate change.

triggered seismicity | fluid injection | carbon sequestration

Induced seismicity related to underground injection of liquids has been widely reported (1–10) but there are very few reports of gas injection triggering earthquakes large enough to be felt or cause damage at the surface. Thus, the injection-induced earthquakes of concern are not the tiny events accompanying hydrofracturing that have magnitudes of 1.5 or smaller; rather, they are the larger-magnitude earthquakes sometimes caused by injection for water flooding, enhanced production, or waste disposal.

For liquid injection, it is plausible that triggered earthquakes occur when fluids reach suitably oriented preexisting faults, reducing the normal stress and hence the friction, and releasing regional tectonic shear stresses. The same mechanism should allow gas injection to trigger earthquakes. Recently Zoback and Gorelick (11) argued that there is a "high probability that earthquakes will be triggered" by the large-scale injection of CO_2 as a strategy to reduce greenhouse gases; however, they offered no examples of CO_2-injection-triggered earthquakes. Also, we are unaware of any reports of gas-injection-triggered earthquakes having magnitudes exceeding 3 (M3).

The present investigation concerns seismic activity and injection in petroleum fields in Scurry and Kent Counties, Texas (Figs. 1 and 2). The northern field straddling the Scurry–Kent county line is the Cogdell field. The larger field in Scurry County west of Snyder is called the Kelly–Snyder field, or sometimes the Scurry Area Canyon Reef Operators Committee unit. These fields produce from the Horseshoe Atoll, which accumulated in the Late Paleozoic and is one of the largest subsurface limestone reef mounds in the world (12, 13).

The Cogdell field underwent water flooding for secondary recovery between 1956 and 1982 and the earliest earthquakes detected there occurred in November 1974; the largest was an M4.6 on June 16, 1978 (14). Davis and Pennington (1) found that Cogdell seismic activity was correlated with the net liquid injection rate, with the first earthquakes occurring almost 20 y after injection commenced (Fig. S1). They modeled fluid pressures in the field and concluded that the earthquakes occurred at the boundaries of relatively low-pressure areas surrounded by higher-pressure regions. Although they suggested the earthquakes occurred on preexisting faults, there are no faults on regional tectonic maps and available locations of aftershocks did not occur along lineations or elongated clusters (Fig. 3).

There is a history of gas injection as well as water injection in the Kelly–Snyder and Cogdell fields. Northern sections of the Kelly–Snyder field have been undergoing CO_2 injection to enhance recovery since 1971 (17). In 2008 some Kelly–Snyder wells were used for a monitoring and modeling case study to learn about carbon capture use and geologic storage applications (18). Finally, in the Cogdell field, injection of CO_2 to enhance recovery began in 2001 and has been ongoing with nearly constant injection volumes since 2004.

For gas injection at wells in the Cogdell and Kelly–Snyder fields, the database available for this study reports monthly gas volumes at surface pressures and temperatures (STP 1 bar and 15 °C), and does not specify whether the gas injected is CO_2 or methane. At the depth of injection in Cogdell (~2.1 km) the pressure and temperature are ~200 bars and ~75 °C; under these conditions CO_2 is a supercritical fluid ($SCCO_2$) with a volume

Significance

Between 2006 and 2011 a series of earthquakes occurred in the Cogdell oil field near Snyder, TX. A previous series of earthquakes occurring 1975–1982 was attributed to the injection of water into wells to enhance oil production. We evaluated injection and extraction of oil, water, and gas in the Cogdell field. Water injection cannot explain the 2006–2011 earthquakes. However, since 2004 significant volumes of gas including CO_2 have been injected into Cogdell wells. If this triggered the 2006–2011 seismicity, this represents an instance where gas injection has triggered earthquakes having magnitudes 3 and larger. Understanding when gas injection triggers earthquakes will help evaluate risks associated with large-scale carbon capture and storage as a strategy for managing climate change.

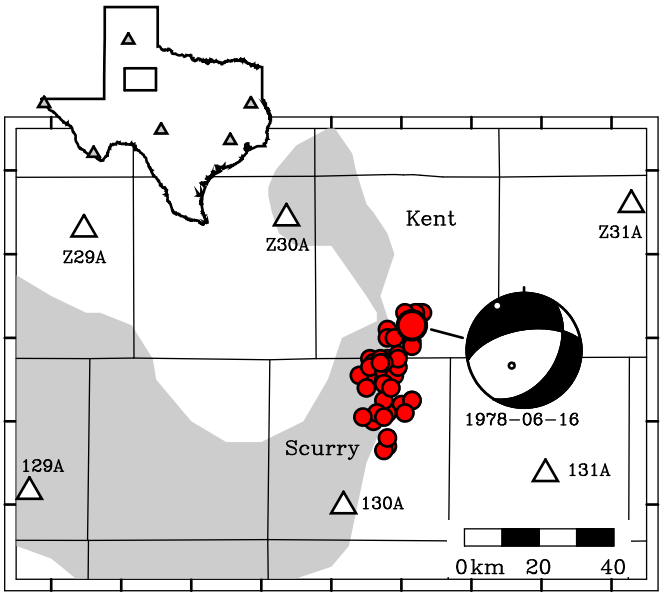

Fig. 1. Map showing location of study area, with earthquakes (red circles) reported by the NEIC 1977–2012, and USArray Transportable Array stations (white triangles) operating March 2009–December 2010 (Table S1). Gray shaded area indicates extent of Horseshoe Atoll. (*Inset*) Rectangle in Texas shows map boundaries; gray triangles in inset are seismograph stations operating in 2005 before passage of USArray. Light lines are county boundaries; labels indicate Scurry and Kent Counties.

~1/339th of that at STP; for methane the volume is ~1/180th of that at STP.

In the Cogdell, since 2004 monthly gas injection volumes have exceeded 85 million m^3/mo at STP (Fig. 4). Thus, at the depth of injection this corresponds to 250,000 m^3/mo for CO_2 and 475,000 m^3/mo for methane. In Cogdell and elsewhere, injected $SCCO_2$ and/or methane are often mixed with water, and the mixtures may undergo phase changes as they move away from the site of injection, so the volumes calculated at depth (e.g., left axis on Fig. 4) are only approximate.

The National Earthquake Information Center (NEIC) reports no Cogdell earthquakes between 1983 and 2005, but since 2006 they list 38 events that appear to be from a different population than earlier seismic activity (Fig. S3). The 2006–2011 epicenters include 18 with magnitudes M3 and greater and one on September 11, 2011, with moment magnitude (M_W) 4.4; if similar events had occurred between 1983 and 2005 most would have been detected and reported by the NEIC (19). Between 2009 and 2011 the EarthScope USArray temporary seismic stations were deployed in Texas; during this period we found 105 epicenters in the Cogdell area in the catalogs from the NEIC, the International Seismological Center (ISC), and the Array Network Facility (ANF), the organization that manages USArray data. Of these, 97 occurred between March 2009 and December 2010 when the six USArray stations surrounding Cogdell were all operational.

The focus of the present investigation is to analyze the characteristics of the recent Cogdell seismicity and to evaluate its relationship with water and gas injection. Although some of the recent earthquakes occurred at distances as great as ~5 km from active injection wells (Fig. 3), induced earthquakes at greater distances have been observed elsewhere (2, 3), especially where injection has been ongoing for many years. The fortuitous presence of the USArray stations between 2009 and 2011 makes it possible to identify much smaller earthquakes and determine their epicenters more accurately than during prior or subsequent times (Fig. 1).

Results

Earthquake Locations and Focal Mechanisms. The relocated epicenters (red circles, Fig. 3) cluster into several discrete groups. Overall they form a much less diffuse pattern than the epicenters reported in the ANF catalog (Fig. S4).

Certain linear features in the groups are approximately consistent with focal mechanism nodal planes. In the north a group of five events (labeled "A" in Fig. 3) forms a lineation trending just north of east, approximately the same as the trend (80° east of north) as the most steeply dipping nodal plane of the June 16, 1978, earthquake (Table S2). About 4 km to the southwest there are two more groups; one with 14 events (group B) forms a tight cluster, whereas the other group of 30 events (group C) lies along a distinct line trending ~45° east of north. Still further south are several more clusters; groups D, E, F, and G all lie along a line trending about 25° east of north. This is nearly identical to the 23° east of north trend of a nodal plane for the August 8, 2010, earthquake which is a member of group F. Finally, two small outlier clusters (H and J) of three and two events, respectively, lie ~2–3 km to the west of the other events.

The linear features in the relocated epicenters, including some approximately coincident with nodal planes, suggest that the seismic activity may occur along preexisting faults. As noted in previous studies (1, 13), the absence of mapped faults is unsurprising considering that the Cogdell and Kelly–Snyder reservoirs are reef buildups rather than fault-bounded traps.

No accurate location is available for the largest historical Cogdell earthquake (June 16, 1978; M4.6) because of near-absence of contemporary nearby regional seismographs. However, the

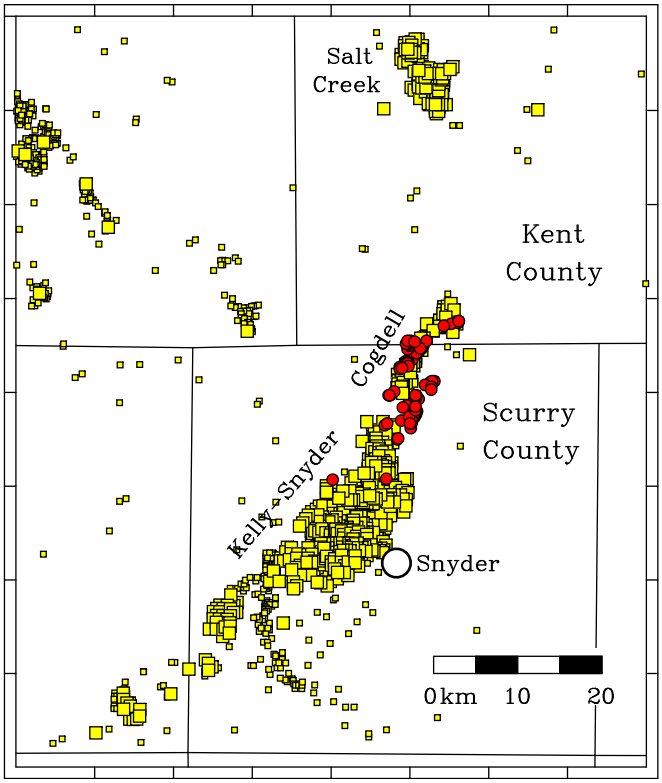

Fig. 2. Map of study area, showing 2009–2011 earthquakes (red circles) located in this study, and wells injecting water (yellow squares). Large squares, wells where monthly injection volumes exceeded 16,000 m^3/mo for one or more months during 2004–2011 period. White circle indicates town of Snyder, TX. Labels "Cogdell," "Kelly–Snyder," and "Salt Creek" are petroleum fields discussed in the text.

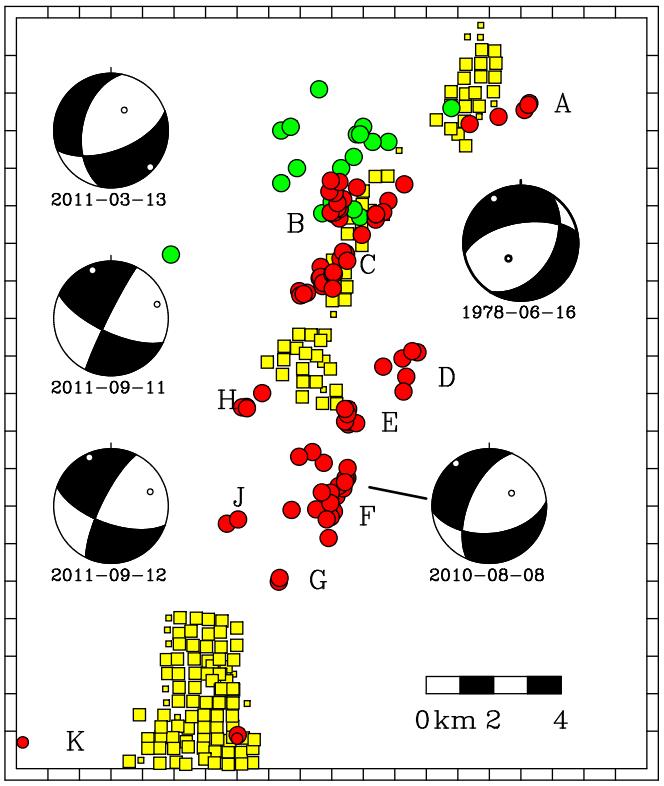

Fig. 3. Map showing 2009–2011 earthquakes relocated in this study (red circles), earthquakes occurring 1979–1980 (green circles) reported by Harding (15), gas injection wells active since 2004 (yellow squares), and focal mechanisms for regional events. Focal mechanisms are from the St. Louis group (16); labels indicate the date of occurrence (Table S2). Only the August 8, 2010, mechanism is for an earthquake relocated in this study. Larger red circles are epicenters occurring between March 2009 and December 2010 relocated using the double-difference method; two smaller red circles at southernmost boundary of plot are single-event locations of outlier events. Labels "A" through "K" indicate clusters discussed in *Results*. The 1979–1980 epicenters were determined from data collected by a temporary local network. For gas injection wells, larger symbols indicate wells where maximum monthly injection rate exceeds 2.8 million m^3/mo at standard conditions (8360 m^3/mo at depth for $SCCO_2$).

epicenters of aftershocks determined by a temporary local network in 1979–80 (green circles in Fig. 3) are mostly within a few kilometers of group B of 2009–2011 epicenters, suggesting that the 1978 epicenter may have been nearby, and that the present seismicity is a renewal of the earlier activity.

Seismicity and Injection/Extraction of Liquids and Gas. For wells in the Cogdell field, the available digital database has continuous monthly reports of oil produced, water extracted, water injected, gas produced, and gas injected extending back to 1990 (Figs. 4 and 5). Before that, and especially before 1982, the data are incomplete; Davis and Pennington (1) retrieved some of this information from records stored on microfiche and reported that the net volume of fluid extracted before 1982 exceeded 300,000,000 m^3 (Fig. S1).

Since 1990, however, volumes of water/oil injection and production have been roughly comparable, generally in the range of 400,000–800,000 m^3/mo (Fig. 5). A brief spike of higher injection volumes did take place in July and August of 2006 and this coincides with the renaissance of earthquake activity (the M2.8 August 8, 2006 event). However, there are no sustained changes in injection or extraction rates occurring before the 2006–2011 seismic activity, and no obvious overall changes in volumes of liquid extraction, injection, or the net during or before the 2006–2011 period when the field again became seismically active.

In contrast, a significant increase in gas injection (Fig. 4) in the Cogdell field took place before the 2006–2011 earthquake activity. $SCCO_2$ injection began in 2001, but rates were negligible until 2002, when sustained injection at rates of ~40 million m^3/mo at standard conditions (125,000 m^3/mo at depth for $SCCO_2$) began in the cluster of wells near label A in Fig. 3. In 2003 sustained injection at rates of ~25–50 million m^3/mo (80,000–160,000 m^3/mo at depth for $SCCO_2$) began in the cluster of wells near H in Fig. 3; the rates in August and September of 2006 were anomalous and exceeded 85 million m^3/mo (250,000 m^3/mo at depth for $SCCO_2$). Also in 2006, injection at rates averaging ~25 million m^3/mo (80,000 m^3/mo at depth for $SCCO_2$) began in the cluster of wells near B and C in Fig. 3. In August–September 2006 this group of wells also experienced a 2-mo spike in injection where rates were 70–82 million m^3/mo (209,000–242,000 m^3/mo at depth for $SCCO_2$). For Cogdell as a whole, the combined effect is that gas injection rates were about 113 million m^3/mo (334,000 m^3/mo at depth for $SCCO_2$) between 2004 and 2012, and there was a temporary increase to more than 225 million m^3/mo (668,000 m^3/mo at depth for $SCCO_2$) in August of 2006, just as the first earthquake in the 2006–2011 sequence was detected.

Gas injection rates also increased for wells in the northern Kelly–Snyder field (wells near K label in Fig. 3), but this occurred somewhat later than in Cogdell. For Kelly–Snyder wells north of the southern boundary of Fig. 3, injected volumes first exceeded 42 million m^3/mo (125,000 m^3/mo at depth for $SCCO_2$) in July 2009, and increased to rates that averaged more than 285 million m^3/mo (840,000 m^3/mo at depth for $SCCO_2$) after July 2010.

Discussion and Summary

Earthquakes Possibly Triggered by Gas Injection. The most significant result of this investigation is that gas injection may have contributed to triggering a sequence of earthquakes occurring since 2006 in and near the Cogdell field in Texas. This sequence followed a 24-y interval when no earthquakes were detected. The post-2006 sequence followed significant increases in gas injection in the Cogdell field (Fig. 4) and many earthquake epicenters were within 2 km of actively injecting wells (groups A–C, E, and

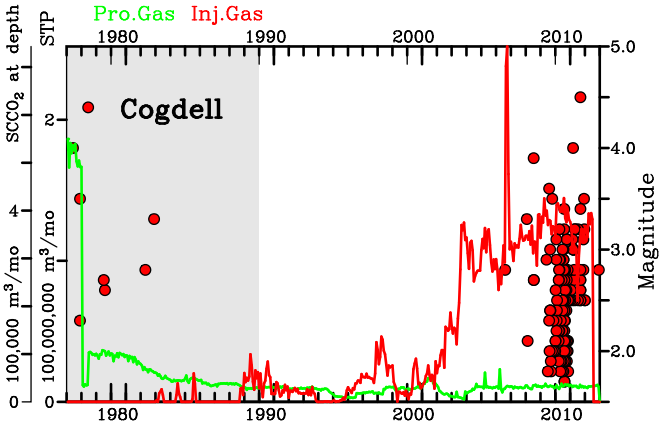

Fig. 4. For the Cogdell field, monthly volumes of natural gas produced (green line), gas injected (red line), and earthquakes detected from 1977 to 2012 (red circles). Volumes on left axes are as reported by RRC for gas at surface at STP, and for CO_2 at 200 bars and 75 °C ($SCCO_2$ at depth). Volumes at depth are highly approximate because the pressure–temperature effect differs for natural gas and CO_2, and because injected gas is often mixed with water and the physical properties of the mixture changes after injection. Gas volume data are from RRC and IHS digital database for the region labeled "Cogdell" in Fig. S2. Gas volume data before 1990 (gray area) are incomplete (see *Materials and Methods*).

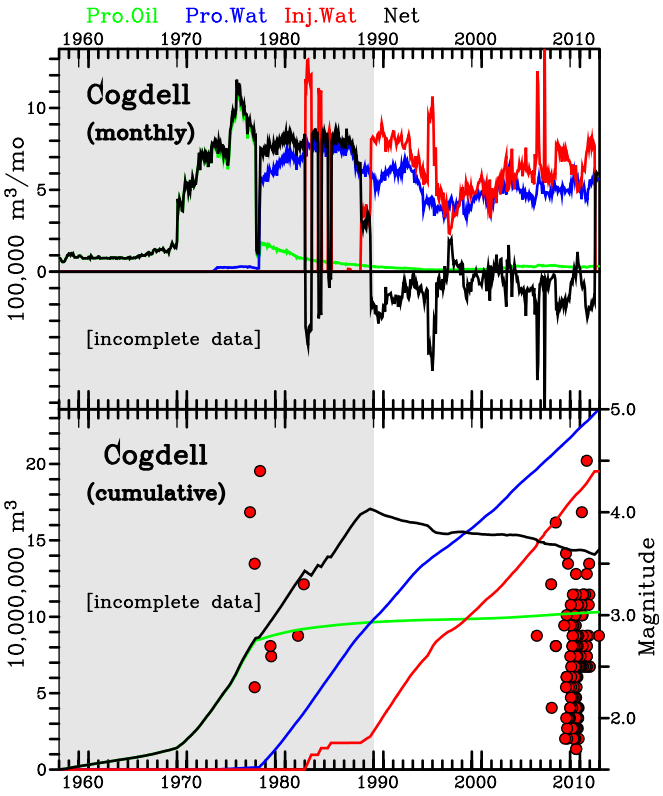

Fig. 5. For the Cogdell field, monthly (*Upper*) and cumulative (*Lower*) volumes of oil produced (green line), water produced (blue line), water injected (red line), and net volume extracted (black line: oil + water produced minus water injected). Red circles and right axis are earthquakes detected from 1977 to 2012. Volume data are from RRC and IHS digital database for the region labeled "Cogdell" in Fig. S2. Data before 1990 (gray area) are incomplete (see *Materials and Methods*).

H in Fig. 3). Between 1990 and 2006 there were no significant changes in rates of injected water except for a 1-y interval beginning in 1995 and 2 mo in 2006 (Fig. 5).

Since 1990 net cumulative volumes (liquid extracted minus injected) have been negative, i.e., the volume of material at depth has increased, and amount to about 20,000,000 m^3 (Figs. 5 and 6). When this volume is adjusted to account for the effect of extracted and injected gas, an additional ~20,000,000 m^3 since 2004 is attributable to injected gas (red line, Fig. 6). Thus, if one attributes the seismicity either to overpressuring reducing friction on faults, or to exceeding the capacity of "effectively sealed compartments," as Keranen et al. (10) recently suggested might contribute to causing a 2011 M5.7 earthquake in Oklahoma, it is plausible that injected gas played a dominant role.

This is an unusual and noteworthy instance where gas injection may have contributed to triggering earthquakes having magnitudes of 3 or larger, as the 2006–2012 sequence included 18 earthquakes with magnitudes exceeding 3, and an M_W4.4 earthquake that occurred September 11, 2011. A recent review of induced seismicity associated with CO_2 storage reported no instances where gas injection triggered seismicity (20). Microseismic monitoring has accompanied $SCCO_2$ injection projects at fields in Australia, Algeria, and Utah (21, 22), but in each case recorded seismic activity had magnitudes of zero or less, even in fields where interferometric synthetic aperture radar measurements showed that surface uplifts of several centimeters accompanied the injection. Two reportedly induced or triggered earthquakes with magnitudes of M7 occurred in 1976 and 1984 in gas fields in Gazli, Soviet Uzbekistan (23); however, these have been associated with massive gas extraction (not injection), and there is controversy about whether they are induced or natural.

Faulting in the Cogdell Region? The recent seismic activity provides strong evidence for the presence of subsurface faults in the Cogdell region. The five currently available focal mechanisms (Fig. 3) include both predominantly normal-faulting and strike slip mechanisms; all five have nearly horizontal tension axes along a north-northwest–south-southeast direction. The observed northeast–southwest-trending linear features in the relocated epicenters, some approximately parallel to the nodal planes, are consistent with the hypothesis that seismicity is releasing tectonic stress along previously existing faults. The observation that some of the 2009–2011 epicenters are near locations reported in 1979–1980 (15) suggests these may be the same faults or part of the same fault system active 1974–1982. Elsewhere in Texas, in Dallas–Fort Worth (8), earthquakes apparently triggered by the injection of water occur along similar northeast–southwest-trending linear features.

Unanswered Questions. If the recent Cogdell earthquakes are triggered, it is still puzzling why there are no earthquakes in similar nearby fields (Fig. 2) such as the Kelly–Snyder field and the Salt Creek field. Like Cogdell, both fields have experienced a combination of years of sustained injection/extraction of water/oil, followed by recent increases in gas injection (Fig. 6 and Figs. S5–S8). Since 1990, when the injection/extraction data are complete, within all three fields liquid injection and extraction rates have been approximately equal, whereas the injection of gas has increased the volume of material at depth (Fig. 6).

This observation, and the fact that no other gas injection sites have reported earthquakes with magnitudes as large as 3, suggests that despite Zoback and Gorelick's (11) concerns, it is possible that in many locations large-volume CO_2 injection may not induce earthquakes. What is different about Cogdell that allows earthquakes

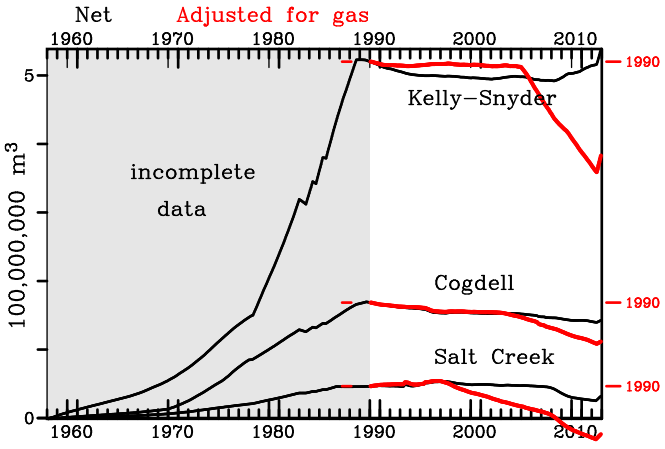

Fig. 6. Comparison of net cumulative volumes extracted for the Cogdell, Salt Creek, and Kelly–Snyder fields. Black line is oil + water produced minus water injected. Red line is volume adjusted for gas produced and injected after 1990 to approximate volume removed at production depth since 1990. Adjusted volumes are determined by assuming gas extracted is methane, and injected gas is CO_2; thus, red line is black line plus (1/180) gas produced minus (1/339) gas injected; at production depths where temperature is ~75 °C and pressure is ~200 bars, volumes of natural gas and CO_2 are ~(1/180) and ~(1/339), respectively, of volumes at surface conditions (see introduction in text). Volume data are from IHS digital database for the three regions (Fig. S2). Data before 1990 (gray area) are incomplete (see *Materials and Methods*). Ticks labeled "1990" on right axis show net volume as of 1990; note that since 1990 effect of gas injection is to decrease cumulative volume extracted, i.e., to increase the volume at depth.

to occur there? Detailed modeling investigations (21, 24) of hydrology and subsurface stress, comparing subsurface conditions in the Cogdell, Kelly–Snyder, and Salt Creek fields, might provide answers to this question. There have been preliminary monitoring and modeling of the consequences of $SCCO_2$ injection in the Kelly–Snyder (SACROC) unit (25, 26). The presence of detectable seismic activity in the Cogdell field and its absence in the apparently similar Kelly–Snyder and Salt Creek fields makes these fields attractive candidates for detailed geomechanical modeling, as has been recently applied to CO_2 injection sites near the coast of Italy (27). It would be informative to apply similar analyses to the Cogdell field, incorporating information about faulting, our reported epicentral locations, and Texas Railroad Commission (RRC) data concerning extraction/injection rates at individual wells.

Utility of USArray Data. As in our previous investigation of triggered seismicity in the Barnett Shale of northeast Texas (9), the present study is an apt example of a positive but unanticipated benefit of the USArray Temporary Array, part of the National Science Foundation-funded EarthScope program. EarthScope was conceived and funded before recent concerns about possible hazards from earthquakes triggered by water injection associated with disposal of hydrofracturing wastes (27) or by $SCCO_2$ injection for carbon sequestration (11, 28, 29). Analysis of USArray data makes it possible to determine accurate epicenters for small events and evaluate their proximity to nearby wells; it is plausible that similar analysis could provide critical information about possibly triggered earthquakes elsewhere.

For studies of this kind, the most serious limitation of USArray data is that it is difficult to assess the focal depths of triggered earthquakes with data collected at 70-km average station spacing. In the present study we arbitrarily fixed the depths at 5 km. To obtain more accurate depths from travel times one needs data from stations situated at intervals of a few kilometers or less. Alternatively, if very accurate information about crustal structure were available, reliable depths might be determined using currently available data by comparing recorded waveforms with synthetics.

Materials and Methods

Information concerning volumes of gas, oil, and water injected and extracted at individual wells is publicly available from the Texas RRC. The RRC regulates activity related to petroleum production and issues permits for drilling wells; by law, petroleum producers must provide the RRC with information concerning well locations, depths, and monthly volumes of injection/extraction of oil, water, and gas. Originally this information was filed as paper records and archived on microfiche. Nowadays most of these data are stored digitally. There has been some effort to convert older data; because this required keypunching there are occasional errors. This study mostly used RRC data as compiled by the company IHS Inc. Generally, before about 1990 the digital information is only partially complete. We wrote computer programs to sum data from individual wells and construct volume/time histories for specific fields and geographic areas. The RRC reports volumes of liquids in units of barrels. Because the volumes of oil and other fluids depend on pressure and on amounts of dissolved gas, subsurface volumes may differ slightly from volumes measured at the surface; however, in this study we use the conversion factor 1 m^3 = 6.29 barrels. The RRC reports volumes of gases in thousands of cubic feet at STP; the conversion factor is 1,000 ft^3 = 35.3 m^3.

This investigation analyzed earthquakes recorded by the six USArray stations surrounding the study area (Fig. 1 and Table S1). These were simultaneously operational from March 2009 to December 2010. During this period, the combined NEIC-ISC-ANF catalogs report 97 earthquakes located in northern Scurry and southern Kent Counties. We downloaded three-component seismograms from the USArray stations for these events from the Incorporated Research Institutions for Seismology Data Management Center.

To obtain more accurate locations for these events, we manually picked primary (P) and secondary (S) phases at all six stations. Then, to ensure we were picking the same feature for each phase and thus improve relative location accuracy, we plotted phases for multiple events together (Fig. S9) and adjusted the time picks. P and S arrival time were thus picked with a precision of 20 ms or better for most phases.

We determined preliminary epicenters for 93 of these events using a standard iterated least-squares program, fixing the focal depths at 5 km because USArray station spacing (~70 km) is too large to allow determining meaningful depths. We then jointly relocated the events to determine station corrections and more accurate trial locations. Finally, we relocated using the double-difference program HYPODD (30), obtaining relative locations for 90 events (Fig. 3 and Table S3). The rms residuals for the resulting locations were all 0.12 s or less, and most were smaller than 0.05 s. For relocations we used the CHELSEA (southwest Oklahoma) crustal model used by the Oklahoma Geological Survey for routine network locations (31).

ACKNOWLEDGMENTS. We thank Sue Hovorka, J. P. Nicot, Tip Meckel, Eric Potter, and one anonymous reviewer for helpful comments that improved this manuscript. We especially thank reviewers Wayne Pennington and Bill Ellsworth, who provided helpful comments on two preliminary versions of this work. We also thank Felix Waldhauser for helping us use his double-difference algorithm to locate earthquakes having fixed focal depths. This research was partially supported by National Natural Science Foundation of China Grant 41174076 and by the US Geological Survey (USGS) Department of the Interior, under USGS Award G13AP00023.

A Review of the Role of Fossil Fuel-Based Carbon Capture and Storage in the Energy System

1. Introduction

Carbon capture and storage (CCS) is a climate change mitigation system with potential applications for decarbonising industrial processes, electricity generation, hydrogen production and providing carbon dioxide removals (CDR[1]). The focus of this report is the role of CCS in the energy sector, particularly in relation to 2030 climate change targets.

While CCS for CDR[2] features in the majority of GHG emissions pathways compatible with the 1.5°C goal of the UN Paris Agreement on Climate Change [1, 2], and it is expected to have a significant role in mitigating emissions from heavy industries, its role in low carbon energy is less clear. Expectations for the role of CCS in electricity generation in international, European and UK energy pathways have decreased – which is likely due to slow deployment of coal and gas CCS, coupled with faster progress in renewables, energy storage and demand-side technologies [4]. Most (81% of global capacity) CCS deployment to date has been for enhanced oil recovery (EOR)[6]. Notionally, its use in EOR should provide expertise and bring down costs as the technology transfers into carbon mitigation, but progress on this has been slow over the past decade [4]. If CCS is to have a meaningful role in mitigation, deployment would need to accelerate markedly. Emphasis on CCS has notably shifted to industrial applications and fossil fuel-based hydrogen production.

Overall, the role fossil fuel-based CCS can and should have in energy system decarbonisation is unclear. Global carbon budgets are increasingly constrained with substantial progress in energy sector decarbonisation required by 2030 [1, 8, 9], while significant levels of CCS are not expected until 2030 at the earliest. It is still unclear what the preferred option for decarbonising heating, long-distance transport (including aviation and shipping) and feedstock hydrogen in industrial processes will be, and CCS related products are still considered as options. However, the extent to which fossil fuel-based CCS can be a part of low carbon energy systems will also depend on the level of residual emissions from hydrogen and electricity production and fuel supply [10, 11] allowable in future carbon budgets. Delays in CCS roll out also

[1] Carbon Dioxide Removal (CDR) approaches are also referred to as greenhouse gas removal (GGR) and as negative emissions technologies (NETs).
[2] For example, through bioenergy CCS (BECCS) and direct air capture (DAC) systems.

mean that developments elsewhere are salient. CCS applications for transport, power and heating services may depend upon how it performs relative to other low carbon generators (renewables and nuclear), demand management and the electrification of transport and heating. Consequently, policy makers would be expected to have low, or zero, fossil fuel CCS energy scenarios for climate change targets to reflect these uncertainties.

This report provides an overview of CCS development to date and its expected role in future decarbonisation, considering the global context but with a focus on the UK. The focus of this report is primarily on the near-term deployment of CCS in energy systems. Section 2 of the report reviews the expectations for CCS in current energy and climate scenarios. In Section 3 the progress to date is assessed, and in Section 4 key issues for future deployment of CCS are considered.

2. The Role of CCS in Scenarios and Policy

CCS features prominently in many energy and climate change scenarios and strategies for meeting climate change mitigation targets. This includes the Intergovernmental Panel on Climate Change (IPPC), European Commission, International Energy Agency (IEA) and the UK Committee on Climate Change (CCC). It is, however, apparent that the current trend of CCS deployment worldwide has yet to reach the pace of development necessary for these scenarios to be realised.

The mitigation potential of CCS for fossil fuel power generation in the energy sector features in many IPCC emissions pathways and future IEA energy scenarios. In the case of the IPCC, there are also 1.5°C pathways with no fossil fuel CCS or BECCS, which rely instead on social, business and technological innovations that lead to lower energy demand (LED - low energy demand scenarios). Under the LED scenarios, afforestation is the only CDR alternative, and nuclear is also considered [13].

For those emissions pathways with high reliance on CCS in the energy sector, however, there is inconsistency between the CCS projects currently in the pipeline and interim and these long-term expectations. Furthermore, existing CCS facilities for fossil fuel power generation are dominated by coal, despite projections for natural gas to replace coal-fired power generation in many archetypal pathways even with CCS. This section reviews the expectations for CCS in key energy and climate change scenarios and strategies. In the next section, this is then contrasted with the current status of CCS development.

IPCC - Special Report on Global Warming of 1.5°C

The ***Intergovernmental Panel on Climate Change*** (IPCC) in its special report on global warming of 1.5°C published in 2018 [14] shows that reliance on CCS to meet climate targets varies depending on the emissions pathways. Three out of four archetypal

model pathways feature fossil fuel CCS. Within the CCS featured pathways there is a range between a limited role scenario (cumulative 348 $GtCO_2$ stored by 2100, of which BECCS is 151 $GtCO_2$) to a more extensive role scenario (cumulative 1,218 $GtCO_2$ stored by 2100, of which BECCS is 1,191 $GtCO_2$). Under these emissions pathways, CCS reduces CO_2 emissions from natural gas-based and, to a lesser extent, from coal-based power generation. The role of CCS combined with bioenergy production (BECCS) plays an even bigger part in most of the 1.5 °C emissions pathways with its potential to remove CO_2 from the atmosphere and thus delivering net negative emissions [1]. There are IPCC 1.5°C pathways (the LED scenarios) that do not include CCS or BECCS at all, which involve radically and immediately reducing energy demand, with CDR achieved through afforestation.

The IPCC illustrative pathways also show that the share of renewables for electricity generation in 2050 increases at different levels (63%-81%) across all the pathways. Inversely, for three out of the four IPCC model scenarios, the shares of coal, oil and gas as primary energy sources are expected to decline by 2050 relative to 2010 for all the model pathways. In relation to this, while the deployment of CCS on natural gas and coal power stations varies widely across IPCC pathways, in most cases the deployment of natural gas CCS is greater than coal CCS.

International Energy Agency Scenarios

The IEA Sustainable Development Scenario (SDS) lays out a major transformation of the global energy system it considers consistent with supporting the achievement of the Sustainable Development Goals (SDGs); affordable and clean energy access (SDG7), climate action (SDG13) and air quality (SDG3). The IEA SDS analysis includes a pathway without any CDR technology (global mean temperature rise below 1.8°C at a 66% probability), and one with CDR (consistent with a global mean temperature rise of 1.5 °C with a 50% chance - requiring around 300 Gt of CDR, which is less than the median level of CDR in the IPCC 1.5 °C scenarios) [15]. The contribution of CCS to energy-related CO_2 emissions reductions in the SDS is 9%, compared to 37% from efficiency improvements and 32% from renewables.

In the *SDS,* the role of CCS in the power sector is more limited compared to previous IEA scenarios (i.e. the *450 Scenario*[3]). The current SDS relies more on renewable energy in the power sector with 8,100 TWh of electricity generation from wind and solar PV compared to 3,900 TWh from nuclear and CCS; in contrast, the former IEA *450 Scenario* projected 3,600 TWh of electricity from wind and solar PV and 7,100 TWh from nuclear and CCUS. This reflects a change in expectations on the deployment of fossil fuel CCS power generation relative to renewables for delivering decarbonisation in IEA analysis.

[3] The 450 Scenario refers to the CO_2 concentration of 450 ppm consistent with a 50% chance of limiting global temperature rise below 2°C

In the IEA SDS, the power sector is expected to reach a decarbonisation rate of 90% by 2050. Under this scenario, CCS (and nuclear energy) supplement the role of renewable energy, increasing the share of low-carbon electricity generation to 84% by 2040. CCS combined with coal and gas power contributes to 5% of the electricity generation mix by 2040 in contrast to a 67% share from renewable sources and 11% from nuclear. In terms of energy generation, 1,909 TWh of electricity are produced from coal- (994 TWh) and natural gas- (915 TWh) based power CCS in contrast to 26,065 TWh of electricity generation from renewables in the latest IEA pathways.

European Commission: The European Green Deal

In response to the European Green Deal and the targets of the Paris Agreement, the European Union has committed to achieving climate-neutrality by 2050 and reducing emissions by 55%[4] from a 1990 baseline by 2030. The proposed transition to climate neutrality includes investments and directives on CCS, smart infrastructure and innovative technology, smart grids, hydrogen networks and energy storage. Regarding CCS, the 2009 EU CCS Directive provides a framework on the geological storage of carbon dioxide regulates mainly the CO_2 storage phase. It also includes some provisions related to the CO_2 capture and transport phases with the intention to facilitate the integration of the CCS supply.

The European Commission [16] has stated a key role of CCS deployment to meet the EU's long-term GHG emissions reduction target by 2050. The Commission expects CCS to become one of the few technology options to cut direct emissions at scale from industrial processes and serve as a low-carbon technology when combined with fossil fuel-based generation to provide flexibility to energy systems, with increasing variable renewable sources [16]. However, it also indicates that the role of CCS has diminished with the faster deployment of renewable energy and other technologies to reduce emissions from industrial processes [16]. Despite this, CCS is still considered necessary to capture and store the CO_2 from carbon-intensive industries; in the transition of fossil fuel-derived hydrogen production and for the deployment of bioenergy with CCS at scale to achieve negative emissions. The European Commission's Hydrogen Strategy as a whole however emphasises electrolysis derived hydrogen (targeting 40 GW of electrolysis capacity by 2030) [17].

The European Union via the EU Innovation Fund (circa 10 billion euros), and using revenues from around 450 allowances of the EU Emissions Trading Scheme, is financing innovation projects including renewable energies, CCS, energy storage and industrial low-carbon processes [18]

UK - Committee on Climate Change

[4] Recently voted on by the European Parliament and may increase to 60% by 2030 against 1990 baseline

The Committee on Climate Change (CCC) has advised the UK Government to reduce GHG emissions reduction to 'net-zero' by 2050 under the UK's obligations to the Paris Agreement. The CCC in their Net Zero report [19] introduced new scenarios to illustrate options on how to reduce emissions from current levels. The CCC indicates that current UK policies are insufficient to meet even the previous 80% of emissions by 2050 target and that efforts in climate policy need to ramp-up [20].

In statements made to date, the CCC considers CCS systems essential to deliver net-zero GHG emissions by contributing to the projected increase supply of low-carbon electricity, hydrogen production, and the requirement of GHG removal through BECCS systems [21]. The CCC has *Core*, *Further Ambition* and *Speculative* scenarios. The Core scenario represents findings on low-cost low-regret options, the *Further Ambition* scenario involves more challenging and costly options than those in the *Core* scenario, and the *Speculative* scenario includes options considered to be at low-level of technology readiness, higher cost and with barriers to public acceptability. The extent to which CCS contributes to the net-zero target, however, varies within the scenarios and involves an aggregate annual capture and storage between 75-175 $MtCO_2$ in 2050 and a major CO_2 transport and storage infrastructure servicing at least five clusters [19].

Under the *Further Ambition* Scenario, CCS has a larger role across industry, greenhouse gas removals (i.e. BECCS), hydrogen production and power generation, with up to 175 $MtCO_2$ captured and stored in 2050. In the power sector, CCS integration with gas-fired or biomass power plants would be required to supply some flexible electricity generation and complement the remaining 5% share needed to fully decarbonize the electricity supply in 2050. Under this scenario, 57 $MtCO_2$ /year and 46 $MtCO_2$/year would respectively be captured and stored from fossil-based electricity generation with CCS and fossil fuel-derived hydrogen production with CCS. This scenario also assumes higher CO_2 capture rates of 95% [19] than the conventional 90% capture rate usually assumed in the literature for power-CCS plants. Technology options and economic challenges of higher CO_2 capture rates are further discussed later in this report.

The CCC also finds that CCS progress has stalled in the UK due to slow movement on UK policy for CCS deployment. Although CCS has recently begun to be discussed as a priority again slow progress leaves the UK with currently no CCS facilities in operation or construction at this time [20]. In these scenarios, a minimum of two CCS clusters are expected to operate by 2030 capturing at least 10 $MtCO_2$ per year. This is on the basis of the government leading infrastructure deployment, with long-term contracts for carbon capture and encouraging investment. These scenarios also include the development of hydrogen, mainly through natural gas reforming, assumed to operate at scale by 2030 in industrial CCS clusters, as well as policy frameworks across energy generation, industry, and greenhouse gas removals. The CCC highlights in particular that the UK should take advantage of the significant potential in regional CCS storage capacity, estimated in 78 Gt and equivalent to over 150 $MtCO_2$ stored per year [19].

In an illustrative generation mix of the power system in 2050, the share of electricity generation through natural gas power stations with CCS could reach up to 23% in the mix, although this could be partially replaced by nuclear power and alternative renewable technologies. The main supply of electricity would derive from variable renewables with a minimum 59% share. Additionally, electricity from BECCS (6%), nuclear (11%) and others sources (i.e. existing bioenergy and hydropower, and hydrogen or ammonia to provide back-up) would complement the generation mix [20].

The UK Government and the Department for Business, Energy & Industrial Strategy (BEIS):

As part of the UK Government, the Department for Business and Industrial Strategy (BEIS) considers that CCS technology has a significant role to play in meeting the net-zero target. CCS is expected to contribute to the decarbonisation of the power and industry sectors, produce fossil-based hydrogen and achieve large-scale commercial greenhouse gas removal [22]. Specifically, in the power sector, CCS is expected to capture and store the 45 $MtCO_2$ emissions per year from existing natural gas CCGT[5] based electricity generation, assuming a 95% CO_2 capture rate. Emissions from these systems are currently equivalent to 12% of UK emissions [22]. In the production of fossil fuel based-hydrogen via natural gas reforming or biomass gasification CCS would capture CO_2 as a by-product.

The UK Government considers CCS infrastructure likely to be delivered for the net-zero target with a substantial CO_2 storage capacity (78 billion tonnes of CO_2) using reservoirs deep underground off the UK coastline [22]. To this end, research investment competitions for greenhouse gas removals and development plans for six industrial CCS have been supported. The Government has also invested over £130 million in R&D and innovation with the aim of reducing CCS costs. They are supporting innovative technologies such as those developed by C-Capture (i.e. pilot testing of non-amine capture technology at Drax power station); Carbon Clean Solutions on novel carbon capture solvent and the Allam cycle technology, used by NET Power, capable of 100% capture rate at costs similar to an unabated CCGT [23].

Since the Clean Growth Strategy [23], the government committed to deploy CCS at scale during the 2030s subject to costs coming down sufficiently and to invest up to £800 million in developing CCS infrastructure to support the decarbonisation of our power and industrial sectors [21].[6] Recently enhanced ambition to begin construction of two CCS hubs in the mid-2020s and a further two created by 2030 has been announced [24]. The role of CCS is, however, considered essential by BEIS to reduce the costs of meeting the 2050 target contributing to lower emissions across industry, power, heating and transport sector [23].

[5] Combined Cycle Gas Turbine
[6] See BEIS (2020) https://www.gov.uk/government/news/beis-in-the-budget

In scenarios with a significant role for CCS, deployment is required through the 2020s, with the delivery of major projects by 2030 at the latest (particularly in UK scenarios). In the case of the IEA projections for the role of CCS in the energy sector have been downgraded. In the UK changing expectations in the role of CCS in energy are manifest in the National Grid Future Energy Scenarios, wherein in 2015 CCS coal and natural gas power generation is significant in scenarios [25] but absent in the 2020 scenarios [26]. The role of CCS in National Grid scenarios 2020 is exclusively in combination with bioenergy and for hydrogen production for heat and transport [26]. This reflects a shift in the expectations for fossil fuel CCS from the power sector to hydrogen and a greater emphasis on CCS for CDR and industry. In the next section, the current status of CCS worldwide is reviewed. The delays in CCS deployment discussed may in part explain this shift. Table 1 provides a review of the role of CCS in key scenarios reviewed.

Table 1:Summary of the role of CCS on energy and climate change scenarios and strategies for the IPCC, IEA and UK Committee on Climate Change

Report	Emissions reduction by 2050	Characteristic of CCS contribution/participation
IPCC 1.5°C Global Warming report	91%-97% CO_2 emissions reduction by 2050 (relative to 2010) across the four illustrative 1.5°C model pathways. 78%-89% reduction in Kyoto GHG emissions by 2050 (relative to 2010) across the four illustrative model pathways	CCS (including BECCS) contribution to CO_2 emissions reduction leads to cumulative CO_2 stored until 2100 spanning (four illustrative model pathways) between: The lowest share**, zero GtCO2 for low-energy demand-LED scenarios** to **348 $GtCO_2$ stored in a sustainability-focused scenario** of which BECCS 151 $GtCO_2$, to **686 GtCO2 stored in a middle-of-the-road scenario** of which BECCS 414 $GtCO_2$, to the highest share **1218 $GtCO_2$** for the **resource and energy-intensive scenario** of which BECCS 1191 $GtCO_2$.
IEA - World Energy Outlook 2019	In the Sustainable Development Scenarios (SDS): The emissions trajectory of SDS decline by 730 Mt on average each year compared with a 400 Mt annual decline in the 450 Scenario.	**2776 Mt of CO_2, from the energy-related GHG emissions, are captured and stored through CCS by 2050.** CCUS contributes 9% of the energy-related CO_2 emissions reductions. Across all sectors, around 0.7 Gt of CO2 emissions are captured each year by 2030; this rises to almost 2.8 Gt in 2050 where CCS is equally split between power and industry. **Under the SDS in the power sector**, CCUS is applied to over 320 GW of coal- and gas-fired power generation capacity by 2040, with 20 GW per year from late 2020's to 2040. **1323 $MtCO_2$ are captured and stored through CCS in the power sector**
CCC – UK Net Zero Report (2019a, 2019b)	In the Further Ambition Scenario (required to get to net-zero GHG emissions): 96% reduction in all GHG emissions by 2050 compared to 1990 levels, remaining in 35 $MtCO_2e$ in 2050 CO_2 emissions slightly below net-zero Remaining emissions from agriculture and aviation.	**In the UK,** CCS captures and stores an aggregated annual 175 MtCO2 in 2050 (from zero $MtCO_2$ in 2017). CCS to integrate with hydrogen, electrification and resource efficiency, the portfolio of options for emissions reduction: **CCS in electricity generation:** 57 Mt CO_2 captured and stored through fossil power generation with CCS. Decarbonised gas via CCS and hydrogen contributes with 5% for full (100%) electricity decarbonisation in 2050 and remaining emissions are of 3 Mt CO_2e **CCS in Hydrogen production:** 46 Mt CO_2 captured and stored through fossil hydrogen production with CCS **CCS in Industry:** 24 Mt CO_2 captured and stored **BECCS:** 44 $MtCO_2$ captured and stored. Bioenergy combined with CCS to produce electricity, biofuels for aviation and in buildings off the gas grid

3. The Current Status of CCS

The CCS concept, for long-term sequestration of CO_2, has been successfully demonstrated on a technical basis since 1996, however, scaling up deployment and applications outside of the chemical sector and oil and gas processing beyond EOR as a business model has been slow. The Global CCS Institute (GCCSI) notes that in 2010 ~10 Mt of CO_2/year CCS capacity was operational, with a further 150 Mt CO_2/year in some form of development, yet by 2020 only 39 Mt CO_2/year was in operation[7], with ~75 Mt CO_2/year capacity in some form of development (see Figure 4 of GCCSI [6]). This represents a decade of very limited progress in terms of CCS project development. Projects in development fell to as low as ~30 Mt CO_2/year in 2017 [27] reflecting various cancellations in early and advanced development projects. The IEA's 2019 scenarios for meeting SDGs considers 840 Mt CO_2/year of CO_2 capture (of which 81 Mt CO_2/year is BECCS and 189 Mt CO_2/year is used rather than stored) overall by 2030 [4], implying deployment averaging 80 Mt CO_2/year capacity per year over the coming decade. This is roughly equivalent to adding 25 projects globally each year with a capacity similar to the proposed Scotland CCS cluster (3-4 Mt CO_2/year) with the additional difficulty of the long deployment timelines for CCS projects. This will require overcoming the financial and risk barriers to the technology observed so far.

Carbon capture technology for use in the energy industry (primarily oil extraction) has been in place since the 1970s, with research into applications for long term sequestration accelerating through the 1980s (e.g. with the start of the MIT Carbon Capture and Sequestration Technologies programme in 1989). The role of CCS expressly for environmental goals was demonstrated in the 1996 Sleipner gas project [28], but clearer expectations around the role of CCS in climate policy became increasingly apparent around 2008. The UK Committee on Climate Change 'Building a Low Carbon Economy' in 2008 recommended CCS as an option for power generation (with coal and gas) and likely essential for some industrial applications [29]. This informed a policy process to develop CCS, firstly for coal power stations, pursuing deployment by the early 2020s [30]. A key international indicator for CCS expectations in this period was the G8 (Group of Eight) commitment to launch 20 large scale CCS projects by 2010 with broad deployment (19 to 43 large projects) of operational CCS by 2020 [31]. The IEA's CCS Roadmap in 2009 set a goal of 100 projects globally capturing 300 Mt CO_2/year by 2020 [4]. Deployment progressed slowly in relation to this, with only five projects developed by 2012. However, by 2014 the first commercial CCS power station at Boundary Dam in Canada was completed. In the UK two R&D competitions to develop demonstration projects in the UK between 2008 and 2015 produced significant research outputs on CCS application but ultimately did not lead to a demonstration project. The failure of the UK competitions

[7] Accounting for mothballed operations at Petra Nova and Lost Cabin facilities in 2020.

was primarily attributed to uncertainty around the economic feasibility of CCS, with a £1 billion state investment into CCS ultimately not materialising at the end of the second competition process [32]. The ownership structure (i.e. responsibility for the 'full chain' of CCS processes) expected of project developers is also considered a factor [33]. Additionally, a key driver of this initial round of investment in UK CCS was to mitigate carbon from coal power generation, which is now no longer a significant part of the UK electricity mix.

To date globally, 28 CCS plants are developed to the operational stage (although 2 are currently suspended), five of them with integrated dedicated geological storage and the remaining 22 using the CO_2 captured for enhanced oil/gas recovery (EOR/EGR) applications [6].

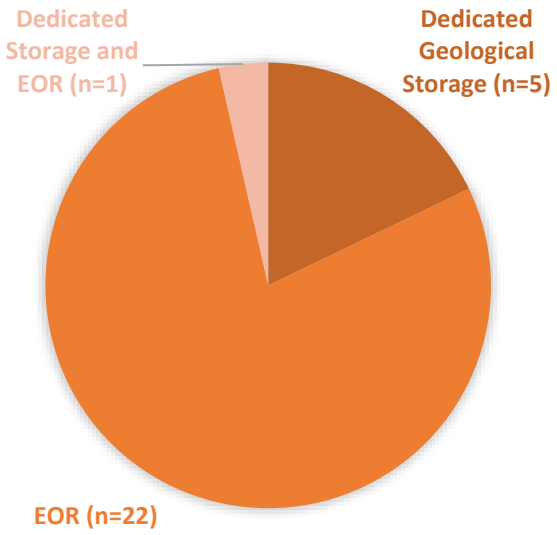

Figure 1: Operational CCS Projects by type of CO_2 storage. Based on the Global CCS Institute. The Global Status of CCS: 2020. (2020)

The CO_2-EOR process entails the injection of CO_2 in an oil reservoir, working as a solvent to swell and mobilise the oil previously trapped in rock's spaces and with the final purpose of increasing oil production in a well. The CO_2 is permanently trapped in the space that originally held the oil [27]. The global capture capacity of the operational CCS plants stands around 37 Mt CO_2/year, where approximately just 19% (~7 Mt CO_2/year) is used for the sole purpose of CO_2 emissions avoidance through dedicated CO_2 storage and the rest applied for EOR processes.

The GCCSI [6] also reports that two large-scale CCS facilities are under construction with an aggregated CO_2 capture capacity between 1.91 Mt CO_2/year and end-use applications in EOR. The expected start date of operation of these projects is in the late2020s. An additional 37 projects are in the pipeline, 13 of which are in advanced

development using a dedicated front end engineering design (FEED)[8] approach and comprising a mix of dedicated storage (seven), EOR (four) and under evaluation (two). From the 21 CCS projects in early development, the majority (16) are planning to have CO_2 dedicated geological storage.

The natural gas processing industry embeds the highest number of CCS plants (11 facilities in operation) using industrial separation to capture the CO_2 and the majority with EOR application eight). These industries can capture the CO_2 at relatively low costs due to its high concentration in the gas streams [27]. Other industry sectors with projects integrating CCS, whether for emissions mitigation or as an inherent stage of the production process, are the power generation sector (one), fertiliser production (four), hydrogen production for oil refining (three), synthetic natural gas production (one), ethanol production (three) and iron and steel production (one)[6]. The emphasis on using EOR applications for existing CCS plants is because the majority of these facilities are located in the US where onshore EOR is a long-established process, with many miles of existing CO_2 pipelines. Furthermore, in the absence of strict regulations and cost on CO_2 emissions, there is little incentive to develop CCS for mitigation. Hence, EOR is so far one of the economically feasible ways to capture and store CO2 while extracting more oil. It is therefore notable that at this stage CCS planned deployment remains dominated by EOR – which has a minor role in expected CCS scenarios by 2030 (see Section 2).

CCS deployment in Europe and the UK

Among the 28 operational large-scale CCS facilities worldwide, two are located in Norway (Sleipner: 1 Mt CO_2/year and Snøhvit: 0.7 Mt CO_2/year) capturing and storing 1.7 Mt CO_2/year of CO_2 from the natural gas processing industry in dedicated storage sites [6][4]. In addition to the two operating CCS projects, the Longship CCS project in Norway is projected to commence operation by 2024 and capture up to 0.8 Mt CO_2/year of CO_2 from the Norcem's cement factory and the Fortum waste-to-energy plant facility [34]. The CO_2 transportation and off-shore storage will be managed by the Northern Lights consortium through an open-access infrastructure using existing oil and gas infrastructure. In addition to the CO_2 captured from the capture plants in Norway, Northern Lights is expected to serve as transportation and storage for other capture sites across Europe [34].

Despite a regulatory framework for CCS being in place through the 2009 CCS Directive, CCS deployment in Europe outside of Norway has not yet materialised. Compared to other regions like North America with 12 CCS large-scale facilities in operation, the integration of CCS to current power and industry sectors in Europe has been much slower.

[8] **Front End Engineering Design** is an approach used to control project expenses and thoroughly plan a project before a fix bid quote is submitted. It is conducted after completion of Conceptual Design or Feasibility Study, and before the Engineering, Procurement and Construction.

Progress on CCS deployment in Europe is however projected to accelerate in the mid and later 2020's with as many as 10 large scale CCS projects (six in the UK, two in the Netherlands, one in Norway and one in 1 Ireland) being proposed. Most of these projects are to function as part of CCS hubs and clusters in industrial installations and using shared infrastructure for the CO_2 transportation and storage network to reduce costs of the CCS supply chain. This, however, represents the current best case, with the UK Government so far only committed to 'at least two' industrial hubs by 2030.

The operation of the planned CCS facilities is expected to capture up to 26.7 Mt CO_2/year; 22.7 Mt are planned for injection in dedicated geological storage sites, with 4Mt captured from Drax (in conjunction with bioenergy) under evaluation [6]. The total CO_2 storage capacity available in Europe is estimated by the GCCSI to be 300 Gt [6].

In relation to funding and policy aspects, 10 billion euros are expected to be available for the Innovation Fund, the largest European fund financing CCS, as part of the portfolio of low-carbon technologies and processes. CCS is also part of the current European Commission strategy to achieve climate neutrality by 2050, with contributions spanning between 52 to 606 $MtCO_{2/}$ year in 2050 across scenarios. It is anticipated to have a more limited capacity in the power sector, instead, its proposed role is more relevant as an industrial decarbonisation alternative and for hydrogen production.

Within the UK, there are five clusters which have received funding to develop cluster plans under the first stage of the Industrial Decarbonisation Challenge Fund; bids to the second stage deployment plans have been submitted and are expected to commence early 2021. The *Net Zero Teesside* project is one of the initial CCS clusters under development estimating to capture up to 6 Mt CO_2/year of CO_2 emissions from a new commercial-scale natural gas power plant, that has completed the Stage 2 Consultation stage of the 'Development Consent Order' process, and also from other existing industrial processes. This cluster is expected to start operation by 2030. Furthermore, the Zero Carbon Humber cluster, also under development, is planned to capture CO_2 up to 10 Mt CO_2/year when fully operational from a BECCS plant (Drax biomass-power station) and from the production of hydrogen to fuel the industry sector. The Acorn Full Scale CCS project plans to function as a major fossil fuel based-hydrogen production pathway with a CCS transport and storage hub located at St Fergus in Scotland. The project was awarded the first carbon dioxide appraisal and storage licence by the Oil and Gas Authority in the UK and has stated it could commence operation in 2025. The Net Zero Teesside and Acorn projects could use the Northern Lights open-access infrastructure as an alternative CO_2 transportation and storage option. The other two clusters receiving funding from the Industrial Decarbonisation Challenge Fund (stage 1) are the HyNet North West industrial cluster for hydrogen production and the South Wales Industrial Cluster.

CCS in the power sector

The abatement of fossil CO_2 emissions through CCS deployment in the power sector remains limited, with currently two large-scale CCS facilities incorporated into coal-fired power plants, both in North America. Together, these facilities have a combined capture capacity of 2.4 Mt CO_2/year and use the CO_2 captured for EOR. This deployment is considered to be significantly off-track to meet climate change targets [4]; compared for example to the target of 310 Mt CO_2/year for power generation alone in 2030 by the IEA's Sustainable Development Scenario [15]. This would require an increase in CCS capacity in the power sector of approximately 129 times the existing capture capacity from the two existing power plants with CCS integration.

The first large-scale CCS facility in the power sector consisted of the integration of a CCS system in the Unit 3 of the *Boundary Dam* coal-fired power plant in Canada. It started operation in 2014 with a capture capacity of 1 Mt CO_2/year, resulting in a cumulative 3.4 Mt CO_2 captured up to July 2020. The capture method is the Shell Cansolv post-combustion CO_2 capture technology with a target capture rate of 90% [35]. The CO_2 is compressed and transported to Weyburn oil field for EOR and a smaller portion is stored in a dedicated saline aquifer (Aquistore project) to monitor and evaluate the safety and permanency of the deep underground CO_2 storage. The capital cost of the plant was reported to be 600 million Canadian dollars (~455 million USD) [36] and a capture cost of USD 100 per tonne CO_2.

Several conditions enabled the deployment of Boundary Dam CCS, including the opportunity to sell the CO_2 captured for EOR; grant supports, subsidy provision by government, and the prospect of low-cost CO_2 transport and storage [27]. The key driver, however, was the environmental regulation introduced by the Canadian government to meet emissions performance standards consistent with natural gas generation, therefore the only options were to retrofit (addition of a CCS unit to an existing power plant instead of adding it to a new plant) with CCS, switch to natural gas or decommission the plant [37].

Petra Nova Carbon Capture is the second commercial coal-fired power plant with CCS integration, located in Texas, USA. It started to operate in 2017 with a capture capacity of 1.4 Mt CO_2/year. It has accumulated 3.4 Mt of CO_2 captured and stored for EOR during the third phase (demonstration and monitoring) of the project between 2017-2019 [27]. The facility is however currently offline due to low oil prices [6, 38]. The capital cost of the project was USD 334 million and the levelised capture cost for this plant reduced to USD 65 per tonne CO_2, compared to Boundary Dam (although modifying existing infrastructure may have contributed to cost savings). The capture method used is an advanced amine-based CO_2 absorption technology (KM-CDR Process) [39].

The rationale behind the deployment of the plant was also different from Boundary Dam, as Petra Nova was constructed as an enhanced oil recovery project and received a significant grant (USD 190 million) from the US Government Clean Coal Power Initiative Program [36]. Furthermore, it has received emissions credits. Operation of CCS at the plant has however been reportedly affected by low oil prices [38].

As such, at this point, CCS deployment in sectors that it is primarily envisaged for (particularly in Europe) – natural gas power CCS, fossil fuel hydrogen production, industrial capture outside of oil and gas sector and carbon dioxide removals – is currently minimal or non-existent. Therefore, while technological aspects for capture technologies, transport and storage have been demonstrated, integrated systems delivering CCS services for key decarbonisation activities remain a future prospect. In the next section, the future potential for fossil fuel CCS in the energy system is reviewed. It suggests a limited role for CCS in energy system decarbonisation over the coming decade (2020-2030), but renewed policy priorities to establish CCS processes by 2030.

4. The Future Potential of CCS

Despite its representation across most model pathways for meeting climate change goals, research evidence collated in Rogelj et al [2] identifies uncertainty around the future deployment of CCS given the slow pace of deployment and lack of incentives, policies and regulation for CCS implementation compared to what is expected to be delivered by CCS infrastructure. Given the prominence of CCS in most mitigation pathways and its current limited improvement, the large-scale deployment of CCS as an option depends on the further development of the technology for permanent CO_2 (as opposed to EOR) in the near term.

This section considers some of the issues CCS faces in meeting the expectations identified in the energy and climate scenarios it features in (Section 2), specifically around emissions, technical attributes, regulation, and cost and complexity.

BOX 1: Technical Attributes of CCS

Among the stages comprising CCS, the CO_2 capture is the most energy-intensive and costly, imposing a considerable energy penalty to the process [3]. Energy penalty is a common metric applied to the power generation sector that compares the performance (efficiency) of a plant with CCS compared to a similar one without it [5]. It can be interpreted as the additional energy input (fuel) required to maintain a power's plant output at the same level, or the loss of power output for a constant energy input [7].

There are various types of CO_2 capture technology, featuring inherent advantages and limitations, and at different stages of development; post-combustion, oxyfuel combustion and pre-combustion.

In the ***post-combustion capture technology***, the CO_2 is separated and captured, from the flue gases (nitrogen, water, CO_2, and other impurities) after the fuel combustion in a power plant or industrial process. The main advantage of this technology is the feasibility for retrofits of existing industrial plants without further large equipment investments and low impact on the process operation [3].

The main energy input is required in the form of low pressure steam for the solvent regeneration process, imposing a significant efficiency penalty. Part of the steam generated to produce electricity in the power plant is diverted for the amine solvent regeneration, thus imposing an energy penalty between 15-28% for pulverised coal power plants and 15-16% for natural gas combined cycle plants with integrated post-combustion capture [5].

In ***oxyfuel combustion capture***, fuel (coal, gas, or biomass) is burned in a mixture of oxygen and recycled CO_2 (to control the temperature inside the boiler) producing a gas mainly formed of CO_2 and water vapour. The CO_2 is separated afterwards by a condensation process [3].

The major advantage of this is simple and low-cost CO_2/H_2O separation. It also has the potential of retrofitting for existing power plants. The energy penalty (around 19%) is imposed by the energy-intensive air separation process [12]. Therefore the development of more efficient air separation systems might also enhance the overall process efficiency [3].

The ***pre-combustion capture technology*** entails a reaction between coal, natural gas or biomass and air, oxygen and/or stem to produce a syngas comprised mainly by CO, H_2, CH_4 and CO_2. The syngas reacts with steam in a water-gas shift reactor to produce CO_2 and more H_2. The CO_2 is later separated using physical or chemical absorption methods, resulting in two separate gas streams: a pure CO_2 gas and hydrogen-rich fuel.

Because pre-combustion capture involves steam reforming or gasification process, this route has limitations on the operating flexibility as gasification is a more complex and novel technology than combustion. The capital costs are higher forcing full load operation to produce syngas. The operating condition of the pre-combustion technology varies to post-combustion because in pre-combustion the syngas is at higher pressures (2-7 MPa) and high CO_2 concentration content, therefore the compression and desorption requirements are not so demanding, resulting in lower efficiency penalties [3]. Energy penalties range between 5-20% for Integrated Gas Combined Cycle (IGCC) power plants combined with pre-combustion capture CCS.

Emissions

Mitigating climate change in line with the goal of staying well below 2°C of warming depends on a timely transition to low carbon energy [40]. In contexts such as the UK, legislative targets require net-zero greenhouse gas emissions by 2050, which for the energy system means almost zero CO_2 emissions [19]. It is not only what is achieved by an endpoint target (such as 2050), but the extent to which cumulative CO_2 emissions – the primary driver of long term climate change [40] – are limited over time that ultimately matters. The emissions associated with a given future technology and its contribution to mitigation at a given time are therefore of particular importance. The remaining global carbon budgets published by the IPCC imply immediate and sustained reductions in emissions, with a reduction in global CO_2 of ~45% against a 2010 baseline required by 2030 for a chance of 1.5°C [14]. The EU is considering a mitigation target of over 55% relative to 1990 by 2030 and the UK recently updated its 2030 target to 68% cut in emissions by 2030 against the 1990 baseline [41], entailing significant additional progress on heating and transport by 2025 [21]. Analysis by Anderson et al suggests that mitigation rates in countries such as the UK should be even greater (~10% per annum, up from recent historical trend of 3% per annum), decarbonising energy systems by 2035 to 2040 [8]. By all measures, significant progress in energy system decarbonisation is required over the coming decade particularly in developed nations such as within Europe.

Within many of the pathways proposed for reaching these targets, CCS has various roles in industrial decarbonisation, power sector decarbonisation and CDR (see Section 2). CCS offers a means of capturing ongoing emissions of CO_2 from existing industrial processes such as iron & steel and cement, providing an option to decarbonise these typically hard to abate emissions. Hydrogen via electrolysis also offers an alternative to CCS based decarbonisation of steel production. The IEA World Energy Outlook 2019 reports that CCS together with energy and material efficiency supports the decarbonisation of heavy industries, such as cement, iron and steel production, and the refining sub-sector of oil and gas extraction [15]. In the IEA SDS, CCS contributes to 21% of savings in energy-related CO_2 emissions in industry [15]. They also note that the current pipeline of projects, however, is far short of what is required under this scenario to abate emissions from key industrial sectors of the economy [15]. Carbon dioxide removal with CCS is central to national net-zero targets in the UK [19]. In the case of energy provision through fossil fuel CCS, however, there are apparent limitations to the role that it may be able to play within highly constrained future carbon budgets.

In the case of natural gas CCS power stations, there are residual emissions that would contribute to direct territorial CO_2 emissions of at least 39 $kgCO_2e/MWh$ (assuming a 90% CO_2 capture rate) [42]. Upstream emissions of greenhouse gases (notably methane) associated with extraction, processing and transport increase with CCS

application due to increased energy use for capture and reduced efficiency meaning life cycle emissions of at least 123 kgCO_2/MWh [10].[9]

Steam methane reforming (SMR) and autothermal reforming (ATR) processes of transforming natural gas feedstock into hydrogen also entail greenhouse gas emissions in production and across the supply chain. The UK CCC estimates emissions savings on a whole life basis of 65% to 85% when switching from natural gas to hydrogen from fossil fuel CCS for home heating [11]. Producing fossil fuel-based hydrogen with CCS is estimated to produce 50 gCO_2/kWh to 188 gCO_2/kWh (process and supply emissions) [11]. Similarly, a report by Navigant reports a range of 51 gCO_2/kWh to 63 gCO_2/kWh for producing CCS derived hydrogen [43]. As such whether fossil fuel-based hydrogen is sufficiently low carbon – from UK Net Zero and relative to global remaining carbon budgets – to have a major role in energy provision is an important consideration.

With these considerations in mind, the IEAGHG note that scenarios for a constrained global carbon budget, especially for 1.5°C and high probability well below 2 °C cumulative budgets, have limited fossil fuel CCS energy production [42]. The UK CCC similarly concludes that hydrogen utilisation should be prioritised for niche functions and where derived from fossil fuel conversion would not have a widespread role in low carbon scenarios [11].

These emissions considerations assume a 90% to 95% CO_2 capture rate, which as discussed below, could in principle be increased (however with increased upstream emissions through increased fuel use). There may also be wider environmental impacts (as is the case with any scale-up of a technology) not captured in a global warming potential (CO_2e) focused assessment. However, the lack of sufficient data on natural gas CCS power station capture rates, CCS hydrogen production operations, or any CCS energy application with >90% capture rate, means that it is prudent to await these results before applying high capture rates to these emissions factors.

Potential higher capture rates (99%)

In power generation plants with CCS, the CO_2 capture rate has been historically fixed at 85% - 90% due to associated captures costs of flue gas streams with low CO_2 concentration (below mol-20%). The two large-scale power plants with CCS retrofit used this capture rate as target (*Boundary Dam* and *Petra Nova*) and IAMs used a 90% capture rate in their assessments, assuming 10% of residual emissions.

Recent studies by the IEAGHG [10] looking at the feasibility of reaching near zero emissions in fossil-CCS concluded that in theory there are no technical barriers to

[9] The data presented in table 9 of IEAGHG (2019) 'Towards zero emissions CCS in power plants using higher capture rates or biomass' provides this breakdown based on the best performing emissions data for natural gas fired turbines.

increasing the capture rate across the three main capture technologies. However, trade-offs should be considered as costs (total plant cost and levelised costs of electricity) are expected to increase, in some cases modestly, depending on the capture technology. Additionally, the plant's performance is expected to decline (i.e. higher energy penalties) and the indirect emissions from fossil fuel use increase. Alternatives to increasing the CO_2 capture rate above 90% and the implications of higher capture rates on costs and plant's performance are presented in more detail below for each of the three main carbon capture technologies. While optimisation for CO_2 capture at a CCS facility presents opportunities to mitigate direct emissions, it also has implications for indirect emissions and validation against actual performance is still required [10].

For ***post-combustion capture***, pathways for reaching higher CO_2 capture rates are through increasing the effectiveness of the CO_2 separation process or co-firing with biomass, which could result in relatively lower costs depending on the biomass type. The increase in costs will also depend on the type of power plant. In ultra-supercritical coal (USC) power-CCS plant with 99.7% CO_2 capture, the levelised cost of electricity (LCOE) can increase by 8% and the CO_2 avoided cost (CAC) by 6%. Further, co-firing with 10% of biomass in the same plant could increase, instead, the LCOE by just 2% and the CAC by 1.4%. In a CCGT-CCS plant, a 99% of CO_2 capture increases the LCOE by 6.6% and CAC by 7.8% [10]. Concerning the net plant efficiency, a 99% capture rate decreases the net plant efficiency by 5% in a USC power plant configuration and by 4.5% in a CCGT plant. The cofiring of biomass (10%) would avoid a further reduction in the plant's efficiency for a USC coal-CCS plant and a neutral CO_2 emission intensity with a 90% capture rate.

Pathways to increase the CO_2 capture rate in ***oxy-combustion capture process*** are achieved via a reduction in the inert gases of the CO_2 stream by using oxygen with higher purity and/or reducing the air leakage to the boiler [10]. CO_2 can also be recovered by passing the vent gases from CO_2 purification to a membrane separation unit [44]. From a performance and costs perspective, increasing the capture rate from 90% to 98% could reduce the plant's net electrical efficiency by -1% and increase the total plant costs (TPC) by 2% and the LCOE by 3%, while reducing the cost of CO_2 avoidance by -4%.

For **pre-combustion capture**, increasing the capture rate to 98.6% in a coal-based Integrated Gasification Combined Cycle power plant leads to a 2% reduction in the plant's electrical efficiency, and higher total plant costs by 4% and LCOE by 4.2%. These figures almost doubled the efficiency penalty and costs increase, compared to oxy-combustion capture, however, the CO_2 avoidance costs also decrease by around 3.6% [44]. Reducing the CO_2-slip emissions in the flue gas could be attained by improving the carbon conversion (water-gas shift reaction conditions) and the CO_2 separation process. As in other processes that increase the gross fuel input into the power plant to account for energy penalties of the capture stage, doing so has

consequences for environmental and human health impacts through the coal supply chain.

Table 2 collates performance data reported by the IEAGHG [10, 44]on the implication of higher CO_2 capture rates and/or biomass cofiring to reach near 100% CO_2 direct emissions reduction in comparison to standard CCS integration with 90% capture rate:

Table 2. Implications of higher CO_2 capture rates on plant net efficiency, LCOE and CAC

Capture technology	Characteristics	Change in plant efficiency	Change in TPC	Change in LCOE	Change in CAC
Post-combustion capture [10]	USC-power plant (99% capture rate)	↓ 5%	↑ 6.6%	↑ 8%	↑ 6%
	10% biomass cofiring (90% capture rate)	0%	↑ 1.9%	↑ 2%	↑ 1.4%
	NGCC power plant (99% capture rate)	↓ 4.5%	↑ 6.5%	↑ 6.6%	↑ 8%
Oxy-combustion capture [44]	SC-power plant (98% capture rate)	↓ 1.1%	↑ 2.2%	↑ 3%	↓ 4%
Pre-combustion capture [44]	Coal-IGCC plant (98.6% capture rate)	↓ 2.4%	↑ 4.1%	↑ 4.2%	↓ 3.6%

Overall, increasing the capture rate in oxy-fuel combustion and pre-combustion CCS would marginally increase costs and reduce the plant's efficiency, also the CO_2 abatement costs could decrease for both capture technologies. More detrimental results are observed for post-combustion capture plants using coal or natural gas and better results for biomass cofiring keeping the same 90% capture rate. Numbers are more favourable for oxy-combustion capture because of a relatively simpler and low-cost CO_2 separation process. IEGHG [10] also highlight that these findings need validation through demonstration in real-life operation across the different CO_2 capture routes and, that indirect emissions from the coal and/or natural gas power–CCS plant supply chains should be minimised in parallel to direct emissions in order to decrease total lifecycle emissions.

Global CO_2 storage capacity

CO_2 storage starts with the injection of the captured CO_2 into deep underground geological reservoirs, such as deep saline formations and depleted oil and gas reservoirs, for permanent storage. The porous rock layer is overlaid by an impermeable layer of rocks that seals the reservoir and prevents the upward migration of CO_2 and escape into the atmosphere.

The estimations of global CO_2 storage capacity vary hugely and have many uncertainties. These estimates indicate that capacity is potentially sufficiently large to meet the global demand for CO_2 storage [4, 5] [45]. Global estimates of storage capacity sit between 8,000 Gt and 55,000 Gt CO_2 [4] whereas 600-2,000 Gt of cumulative CO_2 are expected to be stored by 2100 to keep CO_2 concentrations

between 400-500 ppm [4] for global climate targets. A larger storage potential capacity exists for onshore reservoirs (6,000 Gt to 42,000 Gt) compared to offshore (2,000 Gt to 13,000 Gt) and the regions with largest capacities are in Eurasia, North America and Africa [4]. For context, annual global emissions of CO_2 for energy were at around 35 $GtCO_2$ in 2019 [46].

Emissions pathways consistent with 1.5 °C (with no or limited overshoot) indicate that CCS could produce up to 1,200 $GtCO_2$ for storage. On the other hand, IPCC 2005 estimates a technical potential of at least about 2,000 $GtCO_2$ of storage capacity in geological formations [47]. In general, the storage capacity of all these global estimates is larger than the cumulative CO_2 stored via CCS in 1.5°C pathways over this century.

This storage capacity varies within regions, with USA, China and West Europe accounting for almost half of the global CO_2 storage capacity under 1.5°C and 2°C scenarios. For the top five regions that include USA, China, Western Europe, India and Russia, the storage demand fits within the regional storage capacity except for Russia, where the CO_2 storage required for this region exceeds the estimated capacity for a 2°C scenario with 66% probability [45].

Overall, there is broad agreement on the match, at a global level, between the demand of CO_2 storage and the technical potential capacity of CO_2 storage in geological formations, at least for CO_2 storage operation until the year 2050 (IPCC[14] and GCCSI [6]). Under the IEA Sustainable Development Scenario, the demand of CO_2 storage required (220 Gt CO_2) between 2020-2070 could be met by the lower end of the estimated CO_2 storage capacity (8,000 Gt).

To attain a large annual CO_2 storage rate, the IEAGHG estimates that approximately 30-60 storage sites need to be characterised and deployed annually until 2050, with these numbers expected by the GCCSI to double when including negative emissions storage [27].

For certain regions, such as, in China, Japan and South Korea, the source-sink matching is more uncertain and could be potentially limited, compared to other regions where regional storage supply is more developed, i.e. North America, Europe and Brazil [5]. Furthermore, by 2100, there is more uncertainty on the real CO_2 storage capacity for different regions.

Detailed assessment and careful selection of the storage sites is considered essential to guarantee the safety and permanency of the CO_2 stored and to reduce risks of potential CO_2 leakage to the atmosphere or groundwater [4].

The costs associated with CO_2 storage are lower compared to the capture process, however, is considered an essential factor to CCS deployment in the coming decades [4]. CO_2 storage costs range between negative costs (approximately -30 USD/t CO_2) for EOR applications, to costs ranging between 10 USD/t CO_2 with60% of the onshore storage capacity, to even higher costs for offshore storage, 60% of offshore capacity

is available at costs below 60 USD/t CO_2. The cheapest options among the different reservoirs are the depleted oil and gas sites [4].

The development of CCS industrial clusters that pools the transport and storage demands to share the infrastructure is expected to contribute to reducing transport and storage costs [4].

Risks over CO_2 leakage and long-term geological stability

The leakage of CO_2 refers to the unintended escape of the fluid from the storage site.

One of the barriers identified to large-scale CCS deployment has been the risk associated with the safety of the CCS infrastructure, particularly during CO_2 transportation and storage[5, 48]. For instance, CO_2 leakage and over-pressurisation are common concerns underscored in public acceptance analysis [49].

Practical experience gained through the operation of many industrial-scale CCS projects in the oil and gas industry; in addition to pilot-scale research projects have provided further knowledge on the physical and chemical phenomena affecting the stability of a storage site. Advanced monitoring tools and modelling capability is also available to assess with more precision the behaviour of the CO_2 plume in the storage site [28]. These advances have provided a better understanding and common agreement on the safety of long-term storage and the low probability of CO_2 leakage if the storage sites are characterised, monitored and managed in an adequate manner [48].

On the other hand, the stability of a geological storage site can be managed through its local pressurisation, limiting the CO_2 injection into the well to prevent wellbore fracturing. Additionally, to oversee regional pressurisation of the storage sites, management strategies for pressure and waste brine disposal should be considered [5]. The absence of these strategies to control the reservoir pressurisation imposes limits to the CO_2 storage capacity, as pressures in the reservoirs need to maintained under certain values to avoid induce fractures or reactivate faults in the sealing caprock [5].

With regard to storage integrity, the IPCC SRCCS considered that "for well-selected, designed geological storage sites the vast majority of the injected CO_2 will gradually be immobilised by various trapping mechanisms and in that case be retained for millions of years. Because of the trapping mechanisms identified storage would become more successful over longer time frames" [47]. This body of research concluded that CO_2 storage is by and large a safe operation if storage sites are properly selected, characterised and managed, thus reinforcing the message in the IPCC SRCCS [47, 48].

Regulatory frameworks to monitor and oversee the safety of CCS infrastructure

A robust legal and regulatory framework is important to ensure appropriate site selection and safe operation of geological CO_2 storage sites. This already exists in

many countries, with the UK having launched a licencing process.[10] Project developers and public authorities have to address public concerns through effective stakeholder engagement [4].

To address and minimise the risks associated to CO_2 leakage during long-term storage, as well as the geological stability of the storage site, it is important that liabilities are allocated and managed among the stakeholders of the CCS supply chain.

Risks should be distinguished depending on their potential impacts, whether it is a local environmental and safety issue or a global "climate-related leakage risks [28]. Policymakers and project developers have agreed that practical, well-defined legislation and a strong global regulatory framework are necessary for CCS to reach its potential.

Programmes of Monitoring, Measurement, and Verification (MMV) are considered essential to ensure that CO_2 storage meets operational, regulatory and community expectations, using the experience of the oil, gas, and groundwater industries [5, 27].

Cost and Complexity

The financing of CCS projects has been an ongoing issue causing delays to project development. Most carbon capture projects developed to date have revenue from the utilisation of CO_2 in EOR, particularly in North America. For example, the Petra Nova CCS project's reliance on revenue from EOR is highlighted by its recent mothballing since the fall in oil prices in 2020 [38]. The development of Sleipner CCS projects in 1996 and Boundary Dam to CCS in 2014 can be attributed to tax and regulatory regimes in Norway and Canada [37] respectively that made CCS economically beneficial for the ongoing operation of the facility.

This is in part a reflection of the scale, complexity, and consolidated nature of CCS projects, which face similar challenges to nuclear in terms of deployment. For example, the capture, transport and storage aspects of CCS have been described as quite distinct, but co-reliant businesses which multiply the risks to a potentially unmanageable degree if a single developer responsible for the whole 'chain' is not in place to handle this [33, 50]. This has been an observed problem in the UK where the attribution of long term CO_2 storage liabilities to the private sector and ownership of the full-chain of CCS processes are seen as a barrier to development [33]. Research by Wilson et al [51] suggests that these 'lumpy' characteristics of technologies such as CCS can in part explain why more modular technologies such as solar photovoltaics, wind energy and battery storage have deployed at a faster rate. De-risking CCS sufficiently to facilitate the required capital investment into CCS infrastructure appears to be a core challenge that requires long term state intervention in some form (if EOR is not part of the business model). This seems particularly acute for 'transport and

[10] See https://www.ogauthority.co.uk/licensing-consents/carbon-storage/

storage' (T&S) operators for whom there are high up front capital costs with expected multi-decadal operating lifetimes [50, 52].

In relation to costs, the UK CCC estimated that in 2050 using CCS combined to mid-merit electricity generation would have CO_2 abatement costs ranging between 115-120 £/tCO_2 and generation costs around 108 £/MWh. However, if CCS would have to be part of firm low carbon power in gas-fired power plants abatement, costs would be lower 48 £/tCO_2 and generation costs around 70-80 £/MWh [19]. Although costs are expected to be higher for CCS as a mid-merit generation technology, this is considered to be the preferred alternative so renewables have higher priority over CCS and power-CCS would precede over unabated fossil-based power generation.

Support for new CCS will likely need to subsidise ongoing revenue for CCS enabled products (electricity, hydrogen, or carbon removal) or offer long term avoided costs (e.g. a carbon tax) to make industrial process capture attractive. The current Contracts for Difference (CfD) mechanism (essentially a guaranteed minimum price for electricity sold over a period of time), capacity and/or flexibility payments for electricity grid services (e.g. frequency response, black start, and inertia). CCS power generation in the UK is now not expected until 2030 and the form and scale of public subsidy is not clear. In the meantime, costs associated with technologies such as offshore wind have seen their levels of required support (as viewed through UK CfD payments) fall from over £100/MWh to less than £40/MWh. While capacity factors for offshore wind have improved, they do not provide dispatchable power equivalent to existing power stations. Capacity or other grid service payments may be needed to compete with low marginal costs per unit of electricity from renewables while valuing potential dispatch, inertia, and flexibility benefits of CCS power stations relative to renewables. Here too CCS may face increasing competition from energy storage and demand response offerings over the coming decade. The European Zero Emissions Platform review for the industry identified a likely need for state support for transportation and storage aspects of the CCS industry akin to electricity and water network investments [52]. This is a key issue as new CCS projects in the UK for long term geological storage are unlikely to progress until the policy and investment for T&S are agreed. A delay in agreeing to this will postpone the deployment of CCS further.

5. Summary

Highly constrained global carbon budgets for meeting the goals of the Paris Agreement require significant progress in energy sector decarbonisation by 2030, particularly in developed economies [8]. This is increasingly being reflected in national policies to increase the rate of decarbonisation in relation to 2030 as well as setting longer term targets. While the longer-term application of CCS in industrial processes and for carbon dioxide removal retains a significant role in climate scenarios, this is not necessarily the case for fossil fuel-based CCS in the energy sector (see Section 2). CCS deployment in the energy system for power, heat and transport decarbonisation has to-date been largely non-existent, with significant deployment now not expected

until 2030. As such the role of natural gas- and coal-based CCS for power generation has been downgraded in future energy pathway scenarios. In contexts such as Europe, with supra-national and national targets to cut emissions by over 50% against 1990 levels by 2030 – through which the energy sector would change significantly - CCS deployment is likely now too slow (see Section 3). Focus recently has in part shifted to the role of CCS with fossil fuel-based hydrogen as an alternative vector. There are at present disparities in the extent to which CCS is featured in future hydrogen pathways, relative to electrolysis based hydrogen and electricification alternatives. The European Commission [17] assume limited if any role for CCS in hydrogen provision, while in the UK its application varies across scenarios considerably [19, 26]. This reflects concern about residual emissions from capture and fuel supply stages of the CCS hydrogen life cycle in the context of constrained carbon budgets, and that commercial applications of this technology are still forthcoming (see Section 4). The technical feasibility of higher CO_2 capture rates (>95%) and application of capture throughout the fuel supply chain may address these issues, but until this can be demonstrated and costs are clarified it is prudent to have energy pathways without fossil fuel CCS in policy scenarios for meeting climate change goals.

The Carbon Capture Crux

Lessons Learned

Executive Summary

Carbon capture and storage (CCS) is a 50-year-old technology with variable results in capturing and storing carbon dioxide. Project developers have almost always reused the captured carbon for enhanced oil recovery (EOR), producing oil and gas and more emissions.

Carbon capture's role has been rejigged as a climate solution in recent years with its diverse applications being proposed to decarbonise fossil fuel plants and hard-to-abate sectors.

Some widely cited authorities are fuelling the debate on the role of this technology as a climate solution, including the International Energy Agency in both its Energy Technologies Perspectives[1] report and Net Zero by 2050 report.

This push has given a platform to polarising views on carbon capture utilisation and storage (CCUS) and carbon capture and storage (CCS): is it a greenwash to extend the life of fossil fuel assets[2] or a panacea to avert catastrophic climate change consequences?[3]

Is CCS/CCUS a greenwash to extend the life of fossil fuel assets or a panacea to avert catastrophic climate change consequences?

This report aims to shed light on the different applications and conceptualisations of CCUS/CCS, demystifying the technology's applications, concepts and categorisations. It explains the dichotomy between enhanced oil recovery and carbon capture within dedicated geological structures, and the difference between carbon capture and utilisation (CCU), CCUS and CCS. It uses a four-tiered structure to provide an overview of all carbon capture applications, which includes gas processing, power generation, industry application/production, and carbon dioxide removal technologies (CDR).

Finally, 13 flagship cases (10 in operation, two that have failed and one that has been suspended) comprising about 55% of the total nominal capture capacity

operating worldwide have been reviewed in detail. The projects are flagship in different senses, with each of them having unique aspects of importance.

Our sample is comprehensive, enough to learn lessons about the whole sector. IEEFA estimates that the studied cases have captured more than two-thirds of all anthropogenic carbon dioxide captured in history.

Appendix 1 summarises our case studies.

What We Found

Further extrapolated in our conclusion at the end of this report, we found:

- Failed/underperforming projects considerably outnumbered successful experiences.
- Successful CCUS exceptions mainly existed in the natural gas processing sector serving the fossil fuel industry, leading to further emissions.
- The elephant in the room of the application of CCS/CCUS in the natural gas processing sector: Scope 3 emissions are still not being accounted for.
- Captured carbon has mostly been used for enhanced oil recovery (EOR): enhancing oil production is not a climate solution.
- Using carbon capture as a greenlight to extend the life of fossil fuels power plants is a significant financial and technical risk: history confirms this.
- Some applications of CCS in industries where emissions are hard to abate (such as cement) could be studied as an interim partial solution with careful consideration.

Section 1: Introduction to Carbon Capture and its Applications

Although carbon capture utilisation and storage (CCUS) technologies have been in use for half a century, they have gained more traction in recent years. This is especially true after widely cited energy authorities, such as the International Energy Agency (IEA), pushed them more in their portfolio of climate solutions.

The IEA's Energy Technologies Perspectives (ETP)[4] report, published in 2020, emphasises the role of CCUS and carbon capture and storage (CCS) in the clean energy transition.[5] The IEA's seminal Net Zero 2050 report, published in 2021,[6] had similar messaging. The two reports helped rejuvenate the argument for CCUS/CCS as a climate solution.

The Intergovernmental Panel on Climate Change (IPCC)'s six assessment reports provided a platform for polarising voices on CCUS/CCS, namely whether it is

[4] IEA. Energy Technology Perspectives. September 2020.
[5] IEA. CCUS in Clean Energy Transitions – Part of Energy Technology Perspectives. September 2020.
[6] IEA. Net Zero by 2050. May 2021.

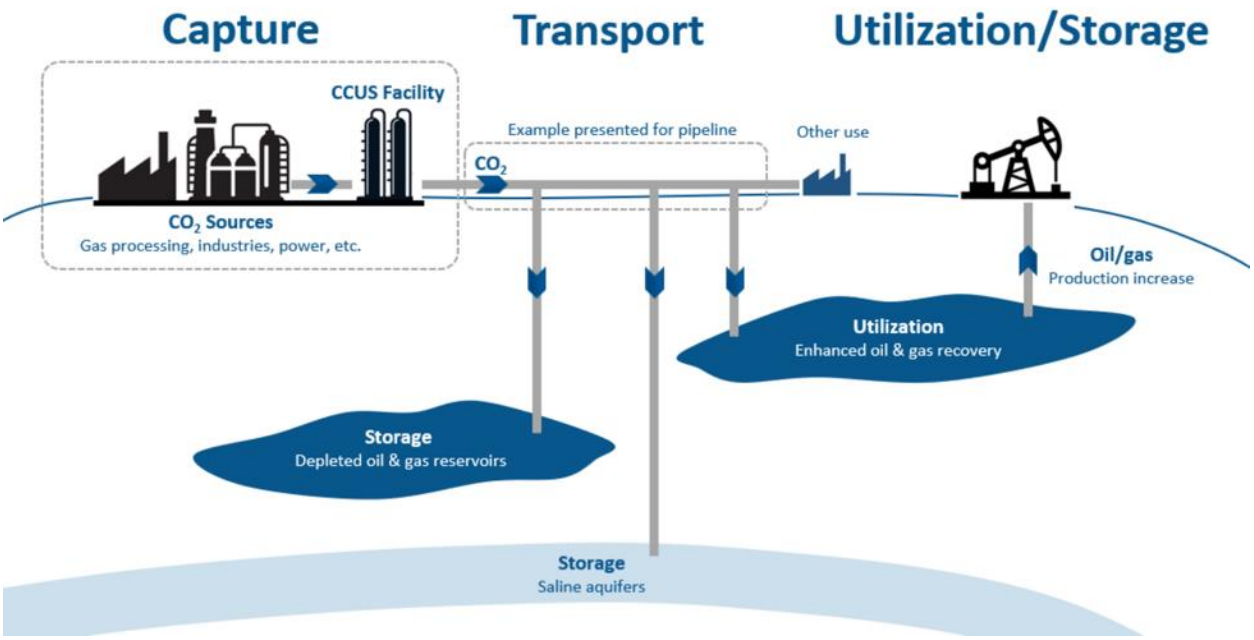
greenwashing to extend the life of fossil fuel assets[7] or a panacea to avert catastrophic climate change consequences.[8] The nuance of the arguments likely depended on where interests lie, and truth on such a divisive topic is, of course, complex.

The vastly diverse application of CCUS/CCS often muddles the understanding of the technologies, particularly for uninitiated stakeholders who may mistakenly think of CCUS/CCS as a single subject.

The vastly diverse application of CCUS/CCS often muddles the understanding of the technologies.

CCUS/CCS is not a monolithic topic. Each CCUS/CCS application is largely running on separate tracks of maturity and cost projection. It covers various technologies and processes, contrasting environmental and social risks and opportunities, and differing mitigation potentials across multiple applications.

This report sheds light on different applications and conceptualisations of CCUS/CCS from a historical perspective and reviews most real-world flagship cases. It provides stakeholders, investors and policymakers with historical lessons from this technology. The report also tries to answer questions on whether CCUS/CCS is a climate solution in different contexts.



That the technology is in its infancy is not a realistic view. The climate change clock is ticking, and time is limited for trial and error. Stakeholders should take the experiences gained through half a century of utilising these technologies seriously in strategising future pathways for overcoming high emissions and climate change.

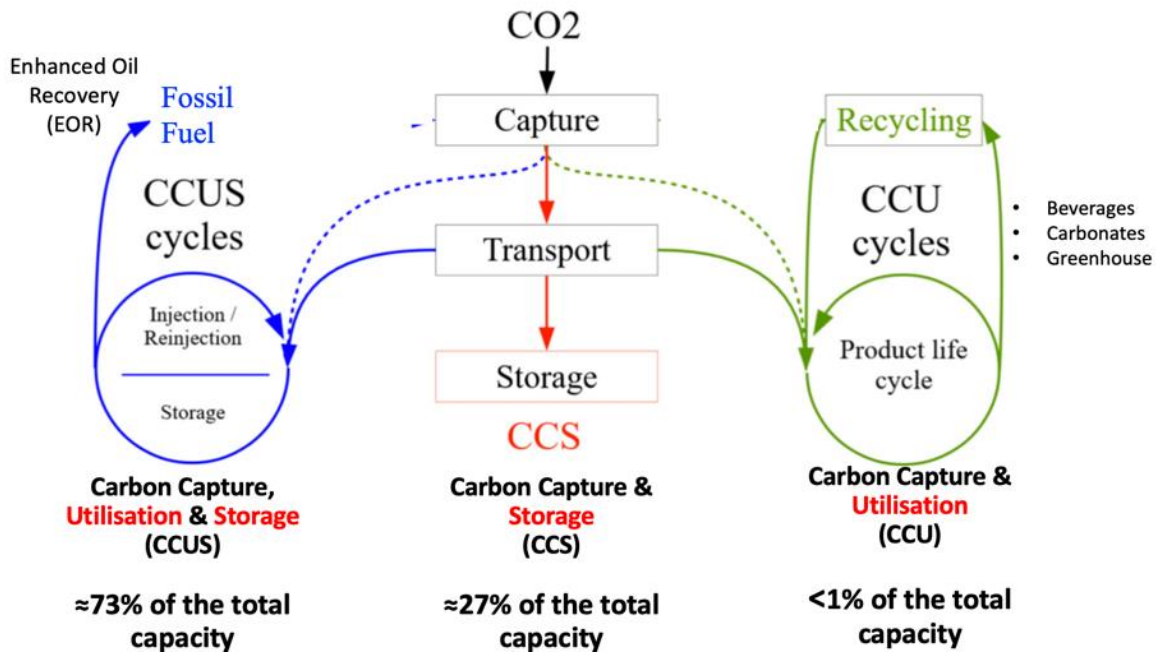
What are CCUS, CCS and CCU?

CCUS encompasses three distinct parts: capture, transport, and storage or utilisation, as depicted in Figure 1. Carbon dioxide (CO_2) captured from various stationary sources, such as chemical processes and power generation plants, is transported to sites and stored or utilised, mainly underground.

[7] Crikey. Vested interests: fossil-fuel fans will use IPCC report to peddle carbon capture scam. 9 August 2021.
[8] Global CCS Institute. IPCC Report Reaffirms Carbon Capture and Storage as a Critical Technology for Mitigating Climate Change. 5 April 2022.

Figure 1: CCUS Schematics

Source: IEEFA, Carbon Capture in the Southeast Asian Market Context. 2022.



Often this CO_2 is sold as a commodity to oil and gas companies who use it to enhance their hydrocarbon production, hence the term enhanced oil recovery (EOR).[9] In this sense, carbon (C) is captured (C) and then utilised (U) by pumping it into the depleted oil and gas fields, pushing more oil and gas out of the wells and then stored (S) underground.

When CO_2 (C) is captured (C) and stored (S) underground in saline aquifers or other underground deposits and is not used for EOR, the process is called CCS.[10]

There is also a niche application of captured carbon (CC) for utilisation (U) and recycling into other valuable products, such as carbonates and beverages, and more recently products such as cement and plasterboard blocks.[11] This application is about capturing carbon and utilising it (CCU). However, compared to CCUS and CCS, the share of CCU is so far negligible (Figure 2).

[9] Global Carbon Capture Storage Institute (GCCSI). Global status of CCS 2021. 2021.
[10] From now on in this report, whenever the project is EOR, the term CCUS is used and if the project is not an EOR project and has a dedicated geological structure to store the carbon, the term CCS is used.

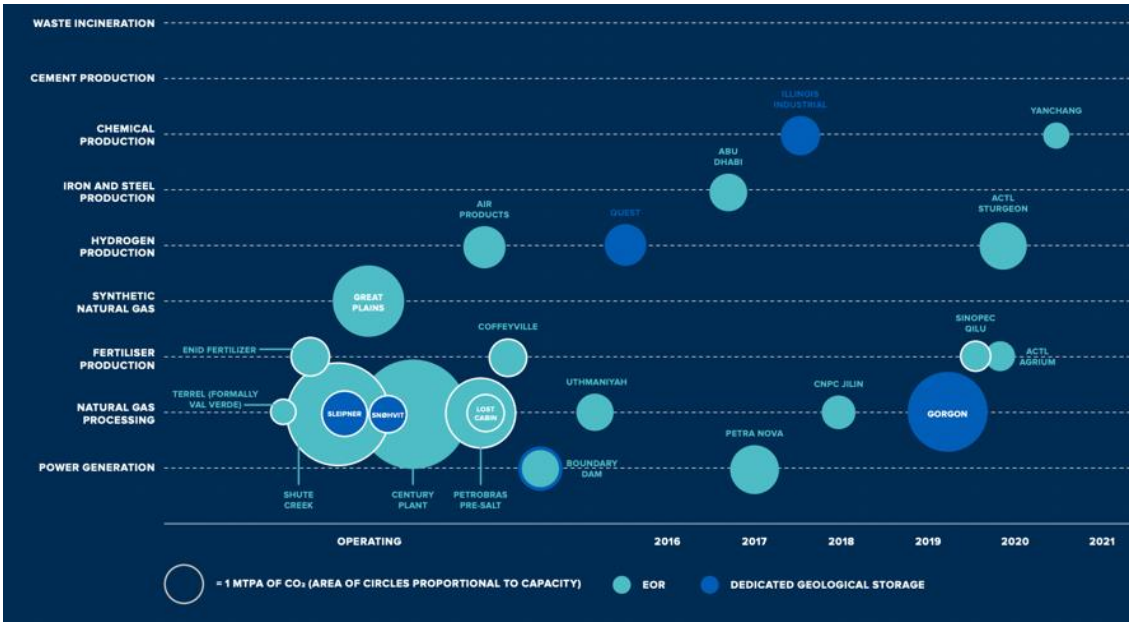
Enhanced Oil Recovery: Injecting CO_2 to Emit CO_2



Historically, carbon capture applications have been dominated by enhanced oil recovery (EOR).

CCUS, or EOR with CO_2 (CO_2-EOR), is the largest industrial use of carbon dioxide. The basic idea is that oil and gas companies inject the pressurised CO_2 into existing oil and gas reservoirs to squeeze out more hydrocarbons.

Today, EOR is the only industrial use of CO_2 to have reached considerable scale—EOR projects use about 73% of the CO_2 captured each year globally in recent years.[12] The figure was higher in previous decades (see Section 2). Figure 3 shows the dominance of EOR in carbon capture project applications.

[12] Global CCS Institute. Global Status of CCS 2021. 2021, p. 63.

Figure 3: Dominance of Enhanced Oil Recovery in Carbon Capture Applications

Source: Global Status of CCS Report, Global CCS Institute, 2018.

EOR enhances the oil production rate from fields that have passed the maximum output rate. Therefore, oil producers can make money by revitalising oil fields with declining production rates.

However, EOR itself leads to CO_2 emissions both directly and indirectly. The direct impact is the emissions from the fuel used to compress and pump CO_2 deep into the ground. The indirect impact is the emissions from burning the hydrocarbons that could not have come out without EOR (so-called 'Scope 3 emissions'). When a car in the street or a jet plane uses EOR-induced oil, it still emits CO_2.

In sum, CO_2-EOR uses carbon dioxide to produce more oil rather than curbing its emissions. The additional oil produced this way either gets burned or used for industrial processes, both resulting in CO_2 emissions. Therefore, any claim that CO_2-EOR systems ultimately reduce CO_2 emissions by their nameplate capacity is an overstatement.[13]

About three-quarters of the CO_2 captured annually by multi-billion-dollar CCUS facilities, roughly 28 million tonnes (MT) out of 39MT total capture capacity, is

[13] Institute for Energy Economics and Financial Analysis (IEEFA). Boundary Dam 3 Coal Plant Achieves Goal of Capturing 4 Million Metric Tons of CO_2 But Reaches the Goal Two Years Late. April 2021.

reinjected and sequestered in oil fields to push more oil out of the ground. This oil then gets refined, burnt and, at least partially, returned to the atmosphere.[14]

According to ExxonMobil, the company has stored 120MT of CO_2, 40% of the total anthropogenic CO_2 that humans have captured.[15] Therefore, the inference is that the total cumulative captured CO_2 figure is 300MT.

Looking at the total anthropogenic carbon that humans have captured during the last 50 years demonstrates that carbon capture technology has been serving the oil industry. IEEFA has estimated that the vast majority of the total 300MT of captured carbon throughout history found its use in EOR (~80–90%), and a small proportion of carbon capture projects (~10–20%) have stored carbon in dedicated geological structures, without using it for EOR.

Table 1: Share of CCUS vs CCS in Capturing Carbon; 50-years Cumulative and 2021[16]

Carbon Capture Type	Accumulated Captured CO_2 (Million Tonnes)	Share of Current 39MTPA Capture Capacity (%)
Enhanced Oil Recovery (EOR) - CCUS	>240 MT (80-90%)	~73%
Dedicated Geological Storage - CCS	<60 MT (10-20%)	~27%
Total	~300	100

Source: ExxonMobil, Global CCS Institute Report 2021, IEEFA, IEEFA Estimates.

[14] Several pieces of research discuss the emissions profile of CO_2-EOR systems through different lifecycle periods and boundaries. Some of them show that the CO_2-EOR could be emission-positive in some long-term situations and some discuss the CO_2-EOR as being carbon negative. Most research papers generally compare the emission profile of two types of oil: the conventionally produced oil and the CO_2-EOR-produced oil and conclude that the CO_2-EOR type produces relatively less emissions compared to the conventional one as CO_2-EOR stores some of the injected CO_2 in the ground. It is a true but misleading comparison. In fact, the emission comparison should be between a CCS plant with a dedicated geological structure to sequester CO_2 and a CO_2-EOR system (a CCS plant which serves the oil recovery where the captured CO_2 is injected into the ground to produce more oil). In this case, the CO_2-EOR system would produce more emissions considering the Scope 3 emissions when the oil is burnt plus the amount of CO_2 that comes out with the oil during the recovery process and potential fugitive emissions along the way of CO_2 transportation.

[15] ExxonMobil. Carbon Capture and Storage.

[16] For some of the projects the data on the capturing performance is not available publicly and their average designed capture capacity based on the Global CCS Institute annual reports have been used as a proxy to estimate the volume of captured carbon. Apart from the normal estimation error, the calculated figures are the best estimates based on the available data.

Demystifying Carbon Capture Applications

As opposed to being a monolithic subject, CCUS is an aggregate of technology applications across varying sectors, each sector largely running in its own development tracks and with its own drivers and maturity level. While similarities in technology may exist among different CCUS applications, they may involve different technicalities and approaches.

The four main domains for categorising carbon capture applications are:

1. Gas processing
2. Power generation
3. Industry application/production
4. Carbon dioxide removal (CDR) technologies

Gas processing has been the main CCS application globally. The extracted raw gas has a CO_2 content that needs removal to produce a marketable gas for distribution through pipelines or liquefied in LNG plants for export. Producing the primary usable product (i.e., natural gas) is not possible without separating CO_2. That is why the sector has used carbon capture technology for decades, not necessarily as a climate-friendly solution. On top of that, selling the captured CO_2,[17] mainly to oil producers for EOR, has enhanced the economic viability of gas development projects.

Power generation is a newer use case of CCS to decarbonise the power sector. It is known as post-combustion carbon capture as it aims to capture the CO_2 after burning the fuel. Pre- and post-combustion capture describes the stage of CO_2 capture, whether before or after burning the fuel. The strategic value lies in the ability to retrofit existing fossil-fuelled power plants with carbon capture facilities. This application has shown that it is not commercially advanced and raises several environmental concerns. As previously reported, CCS for power has also faced technical challenges in meeting performance targets. It is not cost competitive with renewables and storage as a climate change mitigation option for the power sector.[18, 19]

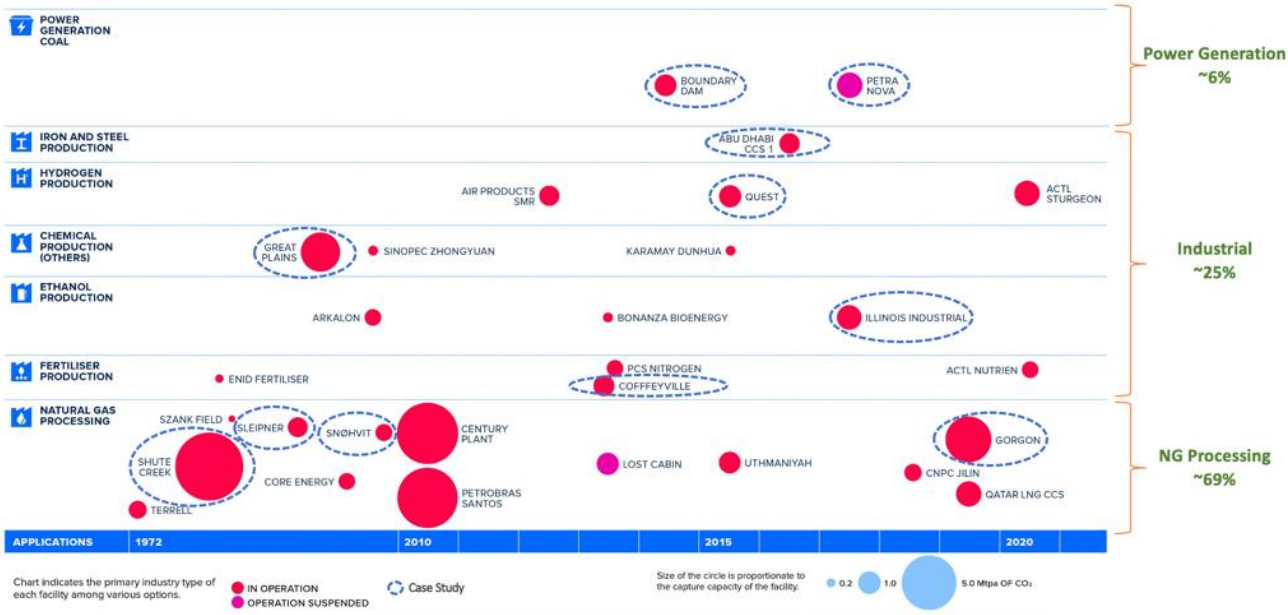
CCS is not cost competitive with renewables and storage as a climate change mitigation option for the power sector.

[17] Geological Storage of Carbon Dioxide (CO_2). 3 – Modelling the injectivity, migration and trapping of CO2 in carbon capture and storage (CCS). 2013.
[18] IEEFA. Where's the Beef? Enchant's San Juan Generating Station CCS Retrofit Remains Behind Schedule, Financially Unviable. May 2021.
[19] Ahmed Abdulla, Ryan Hanna, Kristen R Schell, Oytun Babacan and David G Victor. Explaining successful and failed investments in U.S. carbon capture and storage using empirical and expert assessments. Environmental Research Letters, Volume 16, Number 1. 29 December 2020.

Industrial applications of CCS are very diverse. Companies use it to capture carbon from ethanol, methanol, fertiliser, blue hydrogen and syngas production plants. Also, its application extends to hard-to-abate industries, such as steel and cement production. Carbon capture is an established business in some industrial applications, such as fertilisers and ethanol, while other applications are exploring it for technical and commercial competitiveness at scale.

The conclusion about whether carbon capture technologies could be part of the solution for the decarbonisation of industries is not that straightforward. Using carbon capture technologies needs careful research for each application in different industries and business environments. In some applications, with current high commodity prices, using green hydrogen is starting to look more attractive. It is worth studying carbon capture as an interim solution in a few others.

Carbon dioxide removal (CDR) technologies—bioenergy with carbon capture and storage (BECCS) and direct air carbon capture and storage (DACCS)—are not well advanced technically and commercially. Theoretically, these technologies could offer environmental and social usefulness by capturing carbon from the atmosphere, thus providing the option of negative emissions, should they prove cost-competitive and commercially robust technologies. However, the operating capacity of CDR is virtually zero[20] compared to the 39 million tonnes per annum (Mtpa) CCS industry.



Thirteen Flagship Cases Reviewed

This report reviewed 13 operational large-scale CCS projects—including two flagship projects that failed and one that was mothballed—in terms of their history, economics and performance.[21]

As depicted in Figure 4, we fit sub-sectors identified by the Global CCS Institute into three of the four main categories of carbon capture applications. There is no category for CDR technologies in the figure as CDR is a nascent field and as noted above, the operational capacity of CDR is currently close to zero compared to the other technologies, with just one small project in Iceland.[22]

[20] For example, Orca, a direct air capture facility in Iceland that opened in September 2021, has the capacity to remove about 4000 tonnes of CO_2 a year—equivalent to the annual emissions of around 790 cars. Reuters. World's largest plant capturing carbon from air starts in Iceland. 14 September 2021.
[21] We include in our report two case studies, the Kemper Coal Gasification project and the In Salah CCS project—both of which failed—so they have not been depicted in Figure 4. Also, one of these 11 mentioned cases (Petra Nova) has been mothballed since mid-2020.
[22] Reuters. World's largest plant capturing carbon from air starts in Iceland. 14 September 2021.

Figure 4: Carbon Capture Case Studies

Source: Global CCS Institute 2021, IEEFA.

Natural gas processing dominates carbon capture projects with about 69% of total operational capacity worldwide. It is followed by industrial application, with about 25% of total capacity. Industrial applications with at least one operational CCS project include iron and steel, hydrogen, ethanol, fertiliser, and other chemical production. And a tiny proportion of about 6% is from the power generation sector. Considering the Petra Nova project shut down in 2020, the figure for power generation would be less than 3%.

In this report, we study five flagship projects in the *gas processing sector* to share the lessons from their technical performance and business processes. Four projects are operational, namely **Shute Creek** in the U.S., **Sleipner** and **Snøhvit** in Norway and **Gorgon** in Australia. The Norwegian cases are important as they have been among the few cases that could meet their designed capturing rate, mostly thanks to the unique regulatory/ business environment for Norway's oil and gas companies. Regarding their capture capacity, these four projects account for about half of the active CCS projects in the natural gas processing sector. Despite having some successful projects in this sector, several projects have underperformed their designed capture rate. We look at one such project, **In Salah** in Algeria.

Next we study three projects that have operated in the *power sector*: **Petra Nova** and **Kemper** in the U.S. and **Boundary Dam** in Canada. Petra Nova was mothballed indefinitely in 2020 and the Kemper coal gasification project failed. The report investigates the reasons. Petra Nova and Boundary Dam are the retrofits of two old coal power plants.

Finally, we have chosen five important projects to study for the *industrial applications* of carbon capture. We study these flagship cases in different sub-

sectors of the industry: the **Quest** project in the hydrogen production sub-sector; the **Great Plains CCUS** project in the chemical production sub-sector; the **Illinois Industrial CCS** project in the ethanol production sub-sector; **Coffeyville** in the fertiliser production sub-sector; and **Abu Dhabi CCUS** in hard-to-abate industries worldwide. These five projects account for about 65% of the current capacity of CCS/CCUS projects in industrial applications.

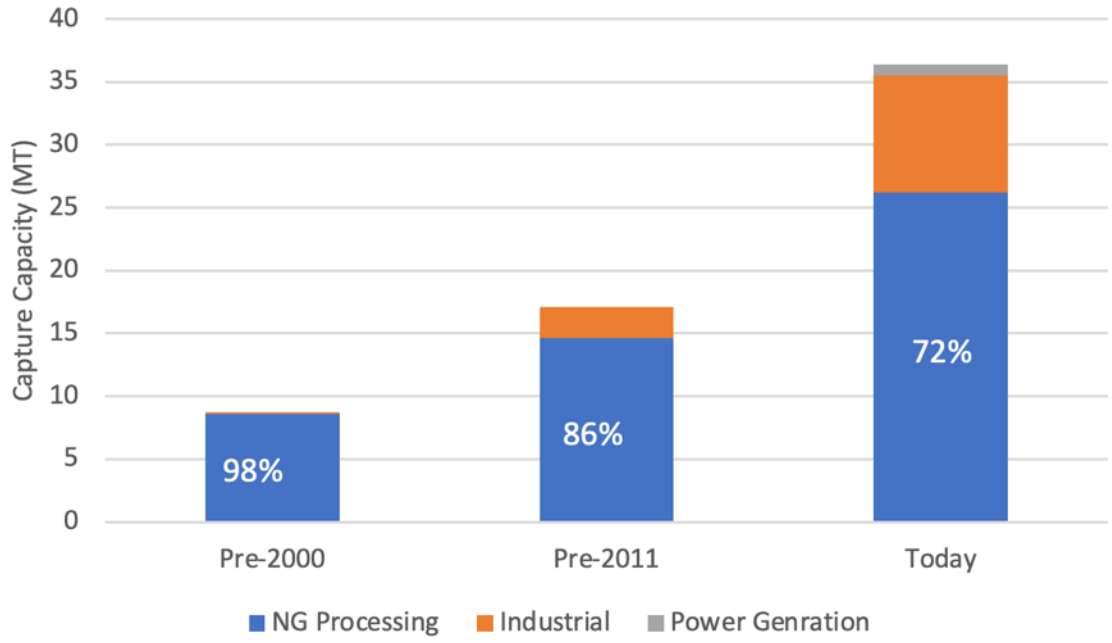
As this report analyses the carbon capture technology through a historical perspective and focuses on existing projects to derive lessons from failures and successes, it does not include any studies of CDR projects.

We cover all 13 flagship projects considering criteria such as their importance, availability of data, age, capacity and performance. Each project has had a unique aspect of importance, cumulatively accounting for around 55% of the total current operational capacity worldwide. Therefore, this sample is comprehensive enough to learn lessons about the whole sector.

IEEFA estimates that the studied cases have captured more than two-thirds of all 300MT of anthropogenic CO_2 in history.

Section 2. Carbon Capture Application in the Natural Gas Processing Sector

Gas processing has been the main CCS/CCUS application globally, with about 70% of current total operational capacity worldwide. Essentially for every 10 CCS/CCUS projects, seven projects are in the natural gas processing sector today.



Looking back a decade, the figure was about 86% before 2011 and more than 98% pre-2000 (Figure 5). These figures demonstrate the historical dominance of natural gas processing as an application of carbon capture technology.

The key point about this application of CCS/CCUS is that producing the primary usable product (i.e., natural gas) is not possible without separating CO_2.

The extracted raw gas from any gas field has CO_2 content ranging from less than 3%[23] to 80%[24] in rare cases. This needs to be removed to produce a marketable gas for distribution through pipelines or liquefied in LNG plants for export. Therefore, capturing carbon was a part of the production process for oil and gas companies, regardless of the ultimate disposal or use of carbon dioxide (i.e., venting or using it for another purpose).

[23] IEEFA. Should Santos' Proposed Barossa Gas 'Backfill' for the Darwin LNG Facility Proceed to Development? March 2021.
[24] Energy Procedia. Worldwide development potential for sour gas. April 2011.

Figure 5: Historical Natural Gas Processing Share in CCS/CCUS Applications

Source: Global CCS Institute 2021,[25] IEEFA.

From a historical perspective, climate concerns did not figure in CCUS/CCS projects commissioned before the mid-1990s. In fact, the narrative around CCUS/CCS projects before the global community started to take climate change risks more seriously (i.e., since the Kyoto protocol of 1997) was more about economics than the environment. The only thing is that since the 1970s, oil and gas companies have decided to derive value from a CO_2 by-product, which used to be vented.

The reason was that in the 1970s and early 1980s, a massive supply shortage in the oil market—due to Iran's revolution and its consequent war with Iraq—pushed oil prices up dramatically. Oil companies, on the other hand, were seeking to increase the dropped production rate from their depleting oil wells in the U.S. Pumping CO_2 into the depleted wells to enhance the oil recovery was a promising solution.

Abundant captured CO_2 from the natural gas processing plants was among the most important driving forces behind developing CO_2-EOR technologies. Shute Creek Treating Facility in the U.S., the largest CCUS/CCS facility (7Mtpa) in the world, belongs to this era.

[25] Excluding suspended Lost cabin and Petra Nova Projects.

The economic narrative of using CO_2 for EOR gradually started to change in the 1990s towards an environmental one that sees carbon capture as a climate solution. The Sleipner project, commissioned in 1996, was the first carbon capture project with a dedicated geological structure (CCS), and the ultimate destination of captured CO_2 was a saline formation. Furthermore, it was the first project capturing CO_2 and not using it for EOR.

Due to the regulatory and business environment in Norway, Sleipner has been among the most successful projects of its kind, followed by another Norwegian project, Snøhvit, commissioned in 2007.

With the changing narrative, some authorities started to regulate oil and gas developments conditional on having a CCS facility to capture and sequester the CO_2 emissions of the field. The failed Gorgon project in Australia is an example.

Case Studies

In this section, we review Shute Creek, Sleipner, Snøhvit, and Gorgon in terms of their performance, history and economics.

Shute Creek

The Largest and the Third Oldest CCUS Project in the World

Shute Creek was commissioned in 1986 by ExxonMobil near the LaBarge field in southwest Wyoming, U.S. Gas from the field comprises just 21% methane (regarded as the marketable gas) and 65% CO_2—as such, it is considered among the highest CO_2 and lowest thermal energy content commercially produced gas in the world.

For Shute Creek's business model to work, considering revenue streams from selling products other than methane was inevitable. There was abundant CO_2 from LaBarge and, at the time of commissioning, nearby fields in Colorado and Wyoming were thirsty for CO_2 for enhanced oil recovery (EOR). Carbon capture was integral to the business model's cash generation.

Oil prices were high when the project was conceived in the early 1980s. After the project was commissioned, the tacit assumptions of long-term high oil prices and of oil producers' ongoing inflated demands for CO_2 for EOR were proved in error with two decades of a bearish oil market with low prices.

Shute Creek became a "Sell or Vent" project.

Shute Creek became a "Sell or Vent" project. It could either sell the CO_2 to third parties or vent the CO_2 when prices were low and EOR was uneconomic. The excess CO_2 that could not be sold for EOR has been vented over the years.

As part of the Shute Creek Treating Facility, the carbon capture plant originally captured about 4.3Mtpa.[26] In 2008, the Oil and Gas Conservation Commission questioned Exxon's effort to market the CO_2 and examined possible changes to the permit to vent. Exxon started an expansion project, completed in 2010, that delivered 50% more capture capacity (6–7Mtpa).[27]

With a nominal capacity of about 7Mtpa, Shute Creek is the world's largest CCS facility.[28]

[26] ZeroCO2.no. Shute Creek.
[27] Massachusetts Institute of Technology. LaBarge Fact Sheet: Carbon Dioxide Capture and Storage Project.
[28] Global CCS Institute. Global Status of CCS 2020. 2020.

The plant has captured more anthropogenic CO_2 than any other carbon capture project in the world[29] but it belongs to an era in which there was little public discussion about climate change and little climate-friendly motivation behind commissioning such projects.

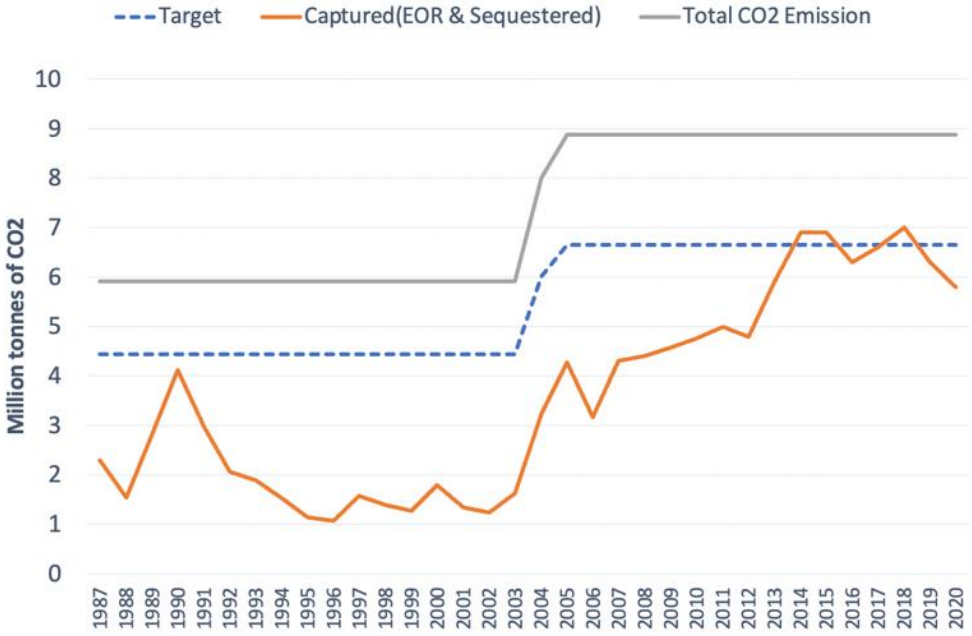
Economics and Performance

The original cost for the whole Shute Creek Treating Facility, including the capturing facility, was US$170 million. In 2010 an extra US$86 million was provided to expand the carbon capture facility from 4.3Mtpa to 7Mtpa.[30]

In February 2022, ExxonMobil made the final investment decision to expand its carbon capture at La Barge by 1.2Mtpa at an estimated cost of $400m. It is expected that the expansion will be operational by 2025.[31]

The gas composition entering Shute Creek is 65% CO_2, 21% methane, 7% nitrogen, 5% hydrogen sulphide (H_2S) and 0.6% helium. The Shute Creek Treating Facility separates CO_2, methane and helium for sale. Concentrated acid gas stream, which includes 40% CO_2, is also injected into a carefully selected section of the same reservoir removing and storing approximately 0.4MT of CO_2 per year that is not sold for EOR.

The facility was not planned to have a dedicated geological structure for CO_2 storage, accounting for its "Sell or Vent" status. Were there a customer to buy the CO_2, it would be captured, compressed and transported. With fewer customers in the time of low oil prices, the excess captured CO_2 would be vented.



In the first 17 years of weak oil prices, from the beginning of the project to 2003, the plant rarely captured and sold more than 2Mtpa. Since then, soaring oil prices enabled Shute Creek to sell more of its CO_2 for EOR, volumes increasing until 2014 in step with historically high oil prices. From 2014 to 2020, despite oil prices starting to fall, ExxonMobil still managed to sell a high volume of CO_2 for EOR.[32]

Figure 6 summarises the performance of the Shute Creek CCUS plant over its 35-year lifetime. Despite its improved performance over recent years, the plant has reached its capturing capacity target (about 75% of total CO_2 emissions) in only a few of those years. At all other times, the plant has fallen short, mostly by a wide margin.

On average, the Shute Creek CCUS facility has fallen short of its capacity by about 36% over its lifetime, translating to approximately 66MT of CO_2 released into the atmosphere. Essentially, just half of CO_2 emissions captured and the other half vented.

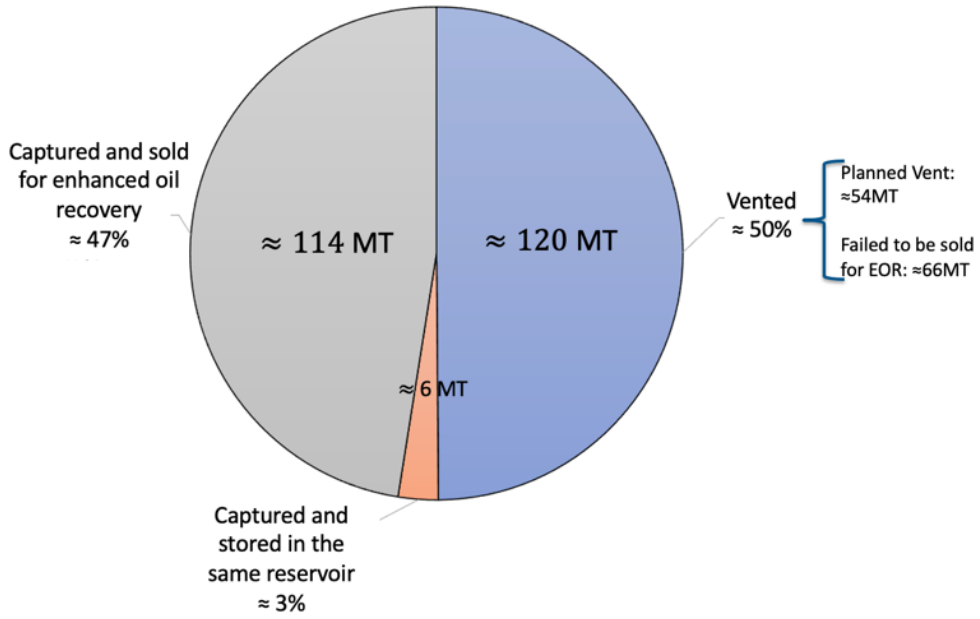
Figure 6: Capturing Performance Trend of the Shute Creek CCUS Plant (1987–2020)

Source: IEEFA Estimates, ExxonMobil Energy and Carbon Summary Reports 2019, 2020, 2021. -- Energy Procedia.

Figure 7 provides a lifetime performance snapshot of the Shute Creek CCUS plant.



To the end of 2020, IEEFA estimates the treating facility on its own directly produced 240MT of CO_2, of which about 47% (114MT) was captured and used to recover oil (EOR).

Over its lifetime, about 3% of total CO_2 emissions has been sequestered in the same geological formation from which the feeding gas is extracted. The remaining 50% of the CO_2 content of the Shute Creek gas, estimated at about 120MT, has been vented. These numbers suggest that the CCUS plant has reduced the gas at the Shute Creek field only from extremely high CO_2 content (65%) to very high (33%).

To put it into perspective, that figure of 120MT is greater than the combined national emissions of Norway, Sweden and Finland in 2018, according to the World Bank.[33]

Sleipner and Snøhvit: Norwegian Successful Experiences

Sleipner

Sleipner CO_2 Storage Project, commissioned in 1996 and located in the Central North Sea between the UK and Norway, was the world's first commercial carbon capture project with a dedicated geological structure for CO_2 sequestration.[34] It was also the world's first demonstration of CCS technology for a deep saline storage reservoir and the first large-scale CCS project to become operational in Europe.[35] To date, it has been among the world's most successful (if not the most successful) carbon capture projects, reaching its target capacity throughout many years of operation with no evidence of leakage or harmful CO_2 movement in the formation.

The natural gas produced from the Sleipner West field contains 4–9% CO_2, so needing to be reduced to less than 2.5% to produce marketable gas. The additional proportion of the CO_2 content of the extracted gas from the field is captured and pumped back to the Utsira geological storage, a 200–250 metres thick massive sandstone formation. The

[34] Massachusetts Institute of Technology. Sleipner Fact Sheet: Carbon Dioxide Capture and Storage Project.
[35] Global CCS Institute. Introduction to Industrial Carbon Capture and Storage. June 2016.

estimated storage capacity is 600 billion tonnes of CO_2. Studies have shown that there is no leakage of the CO_2 from this formation into other horizons.[36]

The main motivation for adding this extra step in the hydrocarbon processing facility there—instead of venting the gas—was the Norwegian CO_2 tax introduced in 1991.

The capturing and injection capacity of the project is between 0.85Mtpa[37] and 1Mtpa[38] as cited by different sources.[39, 40] The project stakeholders are Equinor as the operator (~58.3%), ExxonMobil (~17.2%), LOTOS Exploration and Production Norge (15%) and KUFPEC (~9.4%).[41]

The experience from Sleipner was effective in designing and implementing different regulatory frameworks for carbon storage around the world. For example, it was used as a guide for the EU Directive on geological storage of carbon dioxide (adopted by the European Parliament in 2009). Amendments to the London Protocol and the Convention for the Protection of the Marine Environment of the North-East Atlantic (or OSPAR Convention) to allow for CO_2 storage in offshore geological formations also used the Sleipner project as a benchmark.[42]

Snøhvit

Snøhvit is a liquefied natural gas (LNG) development in the Barents Sea off northern Norway, commissioned in 2007. The extracted gas contains 5–8% CO_2 by volume, which is solidified into dry ice under the pressure and temperature conditions of liquefying natural gas and therefore must be removed before the gas is processed into LNG.

As the Norwegian government mandated CCS as a condition to approve Snøhvit's licence, Equinor, the operator of the project, proceeded on a carbon capture project to avoid venting the separated CO_2 from the field. Instead of venting, after the unprocessed raw natural gas stream is transported 143km to shore into the Hammerfest LNG plant in the far north of the country to be liquefied, the removed CO_2 is pumped back to the Snøhvit field offshore through a separate pipeline, to be injected in the geological reservoir 2600 metres beneath the seabed. The company says "a shale cap which lies above the sandstone will seal the reservoir and ensure that the CO_2 stays underground without leaking to the surface".[43]

The LNG project consists of nine wells, eight for production and one for injecting CO_2. The removal process at the LNG plant is designed to capture 0.7Mtpa of CO_2 at full

capacity. Injection of CO_2 started in April 2008, a year after the gas plant started production.[44] In early 2010, It was announced that it had discovered that there was less storage capacity than expected at the Snøhvit injection site.[45]

A fire in September 2020 at the Hammerfest LNG plant led to it being shut down for more than 18 months.[46] It has resumed operation recently and is preparing to produce LNG again.[47]

Economics and Performance

Stringent emission regulations were the key drivers behind these Norwegian CCS projects.

Carbon Dioxide Tax

The key drivers that enabled these two projects to proceed were the CO_2 tax and climate quota obligation, introduced by the Norwegian government in 1991 and 2005, respectively.

Stringent emission regulations were the key drivers behind these Norwegian CCS projects.

Norway was one of the first countries in the world to impose a CO_2 tax, legislated in the Act on Tax on CO_2 Emissions in Petroleum Activities on the Continental Shelf. This requires companies to pay a CO_2 tax on the combustion of gas, oil, and diesel in petroleum activities in the designated offshore area, as well as on CO_2 or natural gas emissions.[48]

For 2022, the tax rate is NOK 1.65 per standard cubic metre of gas or per litre of oil or condensate. For combustion of natural gas, this is equivalent to NOK 705 per tonne of CO_2. For emissions of natural gas, the tax rate is NOK 1066 per standard cubic metre.[49]

The government in its new climate plan for 2021–2030 has announced that the total CO_2 price of emissions will increase in line with the increase in the tax on non-ETS (Emissions Trading System) emissions subject to an emissions tax, so the total CO_2 price in 2030 will be about NOK 2000/tonne measured in fixed 2020 NOK—almost three times the current price.[50]

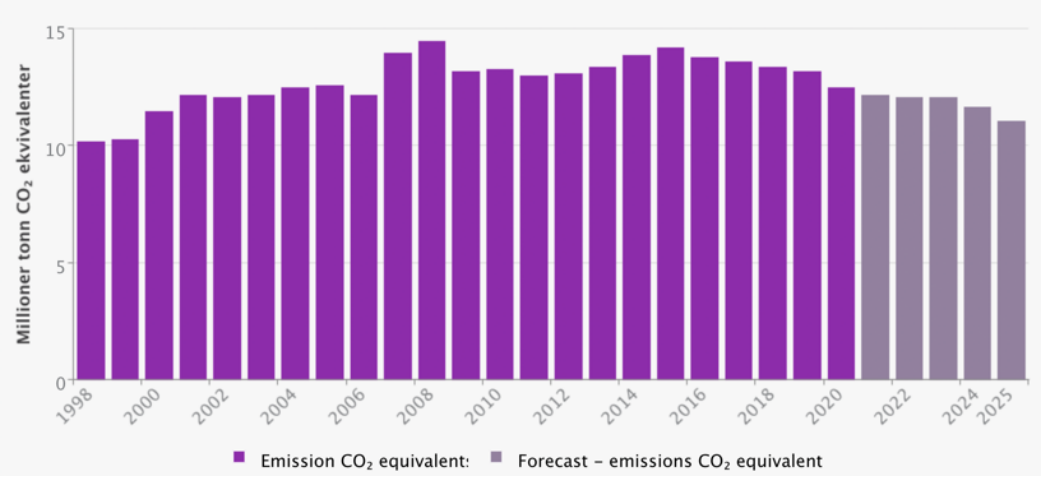
[50] Ministry of Climate and Environment. Norway's comprehensive climate action plan. 1 August 2021.

Quota Obligation



The Climate Quota Act, enacted in 2005, connects Norway to the EU's quota system for greenhouse gas emissions, and the country joined the European Emission Trading System in 2008. Norwegian companies are subject to the same quota obligations as those in the EU. The system is currently in its fourth period, which runs until 2030.[51]

The EU quota system establishes a maximum level of total emissions. This ceiling is reduced on an annual basis to ensure that the system contributes to the system's set emission target when the relevant quota period expires. Quotas are either auctioned or allocated free. In recent years, the CO_2 price in the EU quota system has been increasing, putting a greater burden on polluters.

The combination of the CO_2 tax and quota obligation means that the companies on the continental shelf are facing an extremely high price per tonne for emitting CO_2. The figure is significantly higher than the tax most companies in other sectors must pay in Norway and massively higher than the obligations on similar oil and gas companies in other countries with fossil-based economies.

With these instruments in place, emissions from the Norwegian petroleum sector have been virtually stable during the past decade (Figure 8) with relatively stable oil and gas production (Figure 9). Under the effect of coming, more stringent regulations, emissions are expected to decrease. The Norwegian Ministry of the Environment has described CO_2 taxes as the most important tool for reducing emissions.[52]

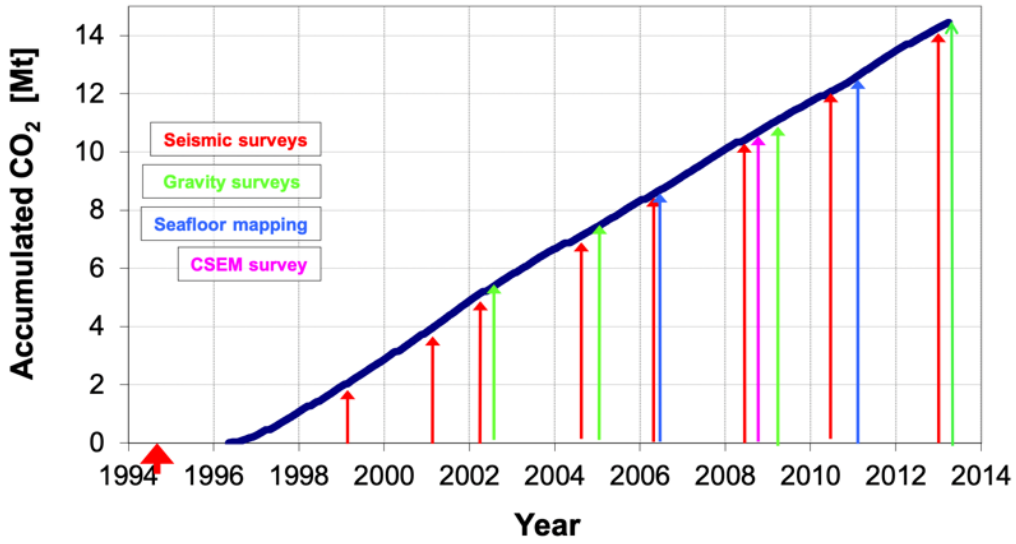
CCS Was Financially Viable for Norwegian Cases

The regulatory framework that was the main motivation for these CCS projects in turn made them economic and pushed the oil and gas industry to adopt CCS in extraction facilities.



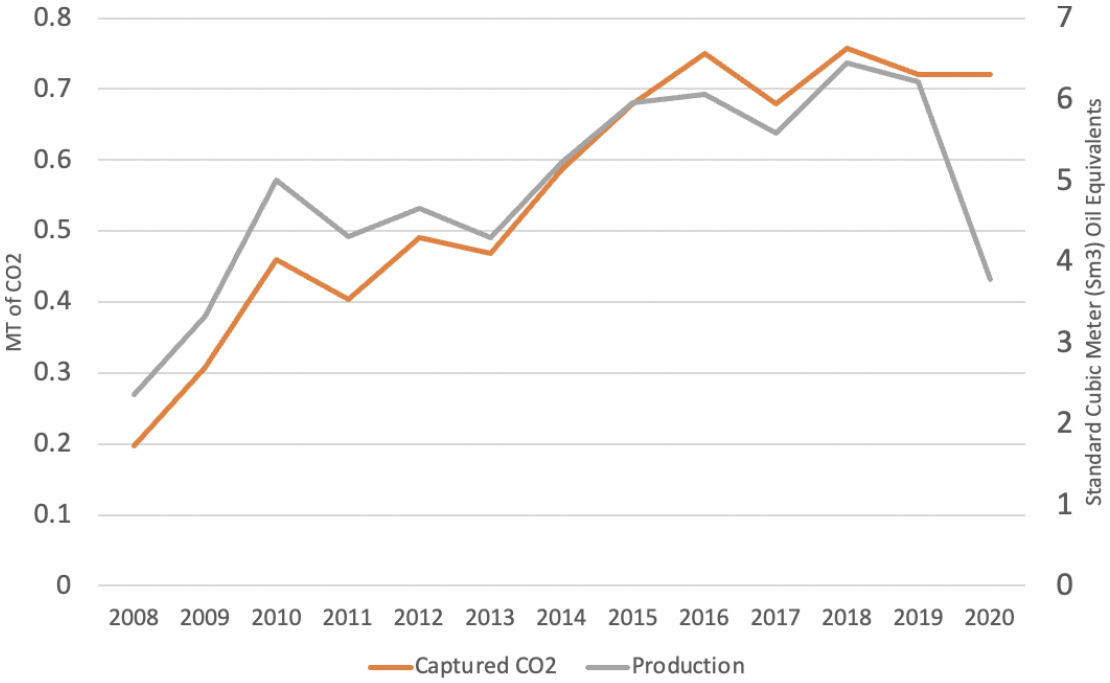
When the Sleipner CCS project was commissioned in 1996, five years after the Norwegian government introduced the carbon tax, the levy on natural gas processing in the North Sea petroleum extraction sector was US$49 per tonne of CO_2.[53] Had the operators vented, for example, 1MTof CO_2 in that first year, the tax bill would have been US$49 million. On the other hand, the additional investments to compress and inject the removed CO_2 amounted to about US$100 million in 1996).[54] Injecting CO_2 was estimated to cost about $17 per tonne.[55] Considering injection averaged about 0.9Mtpa, the partner companies could have recovered the capital cost and operating injection cost of the project in the first few years of the project.

[53] Annegrete Bruvoll og Bodil Merethe Larsen. Greenhouse gas emissions in Norway: Do carbon taxes work? Statistics Norway, Research Department. Discussion Papers No. 337. December 2002.
[54] Olav Skalmeraas. Vice President CCS, Statoil. Sleipner carbon capture and storage project. In ICE Group. 3 February 2017.
[55] Massachusetts Institute of Technology. Sleipner Fact Sheet: Carbon Dioxide Capture and Storage Project.

The same 'carrot and stick' measures applied to the Snøhvit project, with millions of dollars saved in avoiding the carbon tax while complying with stringent emission regulations.

The Sleipner CCS project has operated consistently near its capturing capacity. Figure 10 shows the project's capturing performance up to 2014. It demonstrates the steady performance of the carbon capture facility.

Figure 10: Sleipner CCS Injection and Monitoring History (1994–2014)



Source: Statoil, The Sleipner CCS Experience, 2014.

Snøhvit's capturing rate has been increasing since its commissioning in 2008, surpassing its capture target of 0.7Mtpa in recent years. Figure 11 shows the capture performance of the project. The reason that Snøhvit had been capturing less than its 0.7MT nominal capacity in the early years of the project was not due to its underperformance. This is evident from the gas production level of the project from which Snøhvit CO_2 is sourced (second axis of Figure 11). The correlation between the production and capturing rates confirms the steady performance of the carbon capture facility with its nominal capacity in recent years, where the production of the field stands at its maximum as well (Figure 11).

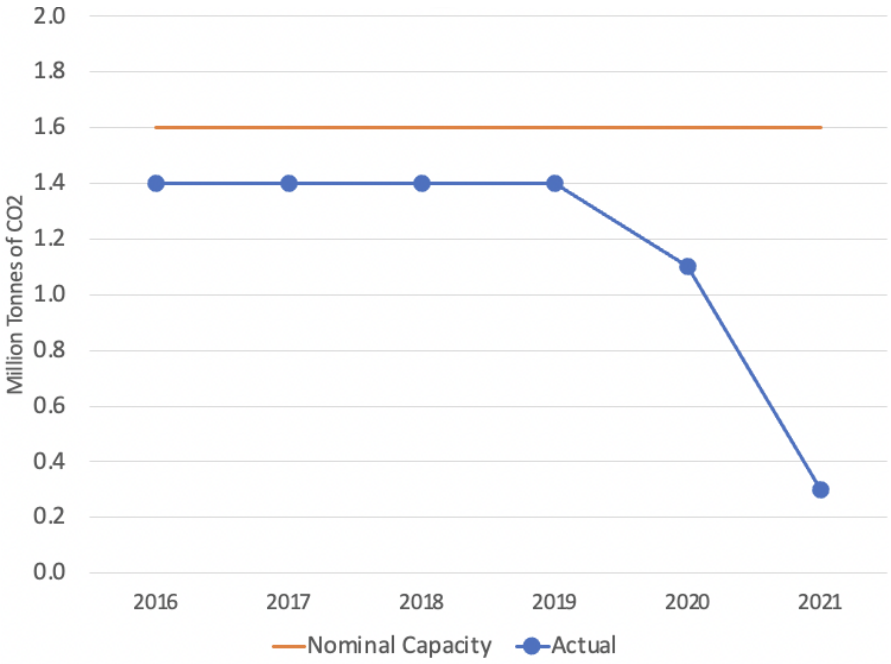
Since commissioning in 2008, Snøhvit has captured more than 7MT of CO_2, averaging 0.55–0.6MT annually.[56]

[56] Olav Skalmeraas. Sleipner carbon capture and storage project. 3 February 2017.

Figure 11: Snøhvit Project: Production vs Captured CO_2

Source: Norwegian Petroleum, Snøhvit. Environmental Science and Technology Letters, 2022.

Figure 12, based on Equinor's 2021 sustainability report, demonstrates the total CO_2 captured and stored per year by the projects it operates. Cumulative capacity of Snøhvit and Sleipner is depicted as the orange line in the graph. Other than in the past two years, there is a consistent trend in capturing carbon.



The drop in capturing rate in 2020 and 2021 was due to the fire in September 2020[57] in the Hammerfest LNG plant, which fed CO_2 back to Snøhvit. The low capture for those years is not related to the CCS plant underperformance.

Moreover, Sleipner field's production has been in its late tail phase[58] throughout the last decade, otherwise the capture figures of the two projects would be at their 1.6MT nominal capacity.

In the past two decades, several research efforts on these two projects have reported no leakage or harmful movement of stored CO_2 in the reservoirs.[59, 60]

Gorgon

World's Largest CCS Project

The Gorgon LNG project on Barrow Island off the Pilbara coast of Western Australia is the world's largest such projects, with export capacity of 15.6MT of LNG and provides the state with up to 300 terajoules (TJ) of domestic gas daily.[61]

The plant was planned to be equipped and simultaneously started with the world's largest carbon capture project with dedicated geological structure in 2016.[62]

It has a nominal maximum capacity of 4Mtpa accounting for 40% of the capacity of all CCS projects with dedicated geological storage operating around the globe.[63] The Gorgon CCS project was initially planned to capture and inject underground more than

[61] WA Department of Mines, Industry Regulation and Safety. Gorgon Carbon Dioxide injection project. Website accessed August 2022.
[62] Massachusetts Institute of Technology. Gorgon Fact Sheet: Carbon Dioxide Capture and Storage Project.
[63] Global CCS Institute. Global Status of CCS 2021. 2020.

100 million tonnes of CO_2 over its life. This was supposed to reduce Gorgon's greenhouse gas emissions by about 40%.[64]

The CCS project was meant to start operations concurrently with the LNG plant in March 2016, though several technical problems meant CCS injection did not start until August 2019. As a result, the facility completely missed its targets for the first three and a half years.

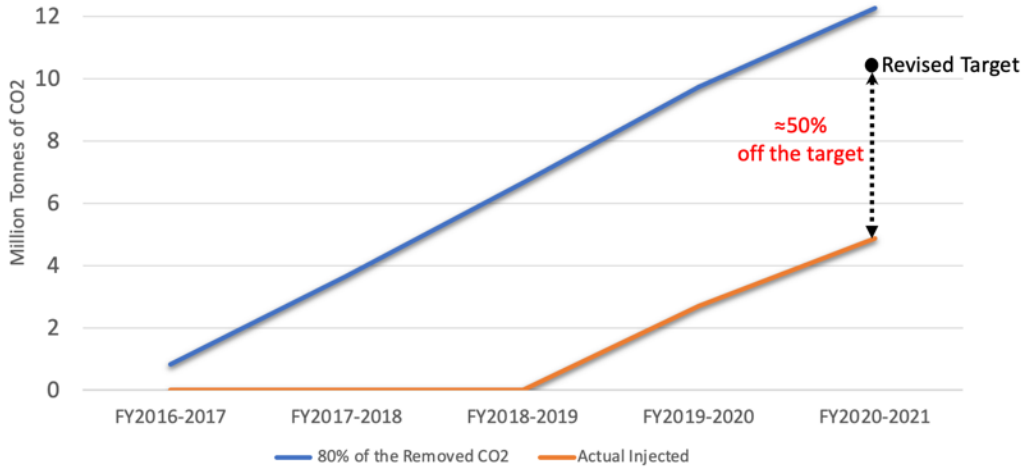
The Gorgon Project is a joint venture between the Australian subsidiaries of Chevron, the operator (47.3%), ExxonMobil (25%), Shell (25%), Osaka Gas (1.25%), Tokyo Gas (1%) and JERA (0.417%).[65]

Economics and Performance

The Gorgon CCS project started with great fanfare, both as Australia's largest project and as the world's largest CCS project with a dedicated geological structure. It received $60 million from the Australian government as part of the Low Emissions Technology Demonstration Fund.[66]

The $3.1 billion Gorgon plant produced its first LNG cargo in March 2016[67] but the first CO_2 injection from its CCS facility[68] did not occur until three and a half years later. Start-up checks in late 2017 found leaking, corroded valves and excess water in the pipeline between the LNG plant and the injection wells, a potential cause of corrosion.[69]

Technical problems did not end there. In January 2021, it was reported[70] that the WA Department of Mines, Industry Regulation and Safety had ordered Gorgon to reduce the volume of carbon captured by the project, due to structural issues. Essentially, sand was blocking the well that reinjects water underground, compromising the crucial pressure management system.



A closer look at Gorgon's CCS target and results demonstrates the project's considerable underperformance in the first five years. Calculated on a five-year rolling average commencing on 18 July 2016, Chevron committed to ensure that at least 80% of reservoir CO_2 removed during processing at the gas treatment plant, that would otherwise be vented to the atmosphere, would be injected underground.[71] On this

[69] The West Australian. Carbon hiccup for Chevron with 5 million-tonne greenhouse gas problem at Gorgon LNG plant. 19 December 2017.
[70] Boiling Cold. Chevron's Gorgon emissions to rise after sand clogs $3.1bn CO_2 injection system. 12 January 2021.
[71] Chevron. Gorgon Gas Development and Janz feed Gas Pipeline Environmental Performance Report 2021. November 2021, p. 45.

basis, the Gorgon CCS plant should have captured at least 12.3MT of the removed CO_2 in its five years of operation.

The environmental performance reports show that the plant had injected only 4.9MT by July 2021. The shortfall from the five-year target is claimed to be 5.23MT CO_2.[72] Putting all this together, it can be inferred that the Gorgon CCS project's revised target for the first five-year period was about 10.1MT and it failed to meet this target by about 50% (Figure 13 shows the cumulative trend of Gorgon's sequestered CO_2 versus the cumulative target trend).[73]

Figure 13: Gorgon CCS Plant's Performance (Cumulative Trend, 2016–2021)

Source: Gorgon Environmental Performance Reports 2015–2020 & 2021

In the Gorgon 2021 environmental performance report, Chevron cited planned and unplanned maintenance among other causes for the underperformance of the plant.[74]

Gorgon's technical troubles and ongoing "unplanned" maintenance after five years illustrate some of the inherent and unique risks of CCS, despite the technology's decades of operation.

Gorgon has recently agreed to acquire and surrender credible greenhouse gas offsets recognised by the West Australian government to offset its target shortfall of 5.23MT of CO_2. Estimates of what this may cost Gorgon vary from US$100 million to US$184 million.

---

[72] Chevron. Gorgon Gas Development and Janz feed Gas Pipeline Environmental Performance Report 2021. November 2021, p. 45.
[73] In its latest environmental performance report published in November 2021, four months after the first five-year period ended, Chevron stated that 5.5MT had been injected in the five years of the project's lifetime.
[74] Chevron. Gorgon Gas Development and Janz feed Gas Pipeline Environmental Performance Report 2021. November 2021, p. 44.

The project is expected to run for 40–45 years, after which there will be a closure period of 15 years. Post-closure, liability will be handed over to the WA government.

The project also has failed to reach its five-year rolling average (ending July 2022) target.[75]

Other Big CCS/CCUS Project Failures in the Natural Gas Processing Sector

Apart from the operating projects, several projects in this sector have failed or been suspended due to technical issues and/or environmental concerns. A case in point is the In Salah project in Algeria.

In Salah

The In Salah project in Algeria was a CCS project with a total cost of US$2.7 billion. Equinor (Previously Statoil) was the operator, and the announced capture capacity was 1–1.2Mtpa.[76]

Injection started in 2004 and was suspended in 2011 due to concerns about the integrity of the seal. Nevertheless, the project successfully stored 3.8MT of CO_2 in the Krechba Formation during its lifetime.[77]

Analysis of the reservoir, seismic and geo-mechanical data from 2010 led to the decision to suspend CO_2 injection in June 2011. Concerns about possible vertical leakage into the caprock led to an intensified R&D program to understand the geo-mechanical response to CO_2 injection at this site.[78]

Lost Cabin is another example of a project in which CO_2 injection was suspended in 2018. It was a CCUS project (CO_2-EOR) with a capacity of 0.9Mtpa started in 2013 in Fremont County, Wyoming, U.S. ConocoPhillips and Denbury were the companies involved in the project.[79]

Just after five years of operation, in 2018, a fire occurred at the Lost Cabin Gas Plant in Wyoming, resulting in the shutdown of the plant's CCUS facility. There was an expectation that operations would restart by the end of 2020 with a lower capture

rate of 0.7Mtpa.[80] But it did not happen, and the latest Global CCS Institute report, published in late 2021, still labels the project as suspended.[81]

Enhanced Oil Recovery Business Dominates Natural Gas Processing Sector

Natural gas processing has been the main CCS/CCUS application historically, with about 70% of current total operational capacity worldwide. The first CCUS project, Terrel, established in 1972, was in the U.S.

Developing such projects was not about environmental or climate concerns in the 1970s. Separating CO_2 from extracted raw gas is essential to producing marketable and flammable natural gas. It was/is a technical must.

Further, during the energy crisis in the 1970s and 1980s, the interest in capturing the separated CO_2 and selling it to oil companies to enhance the rate of their oil production started to increase. It was a win-win deal for both gas producers who could increase their revenue by selling a previously vented CO_2 to oil companies and for the oil companies who could revitalise their ageing depleted oil wells and get more oil out of them to sell in those eras of the bullish oil market. Hence, economics was the second incentive behind developing such projects in that era.

This is evident in the share of carbon capture projects servicing EOR activities (CCUS) compared to the carbon capture projects with dedicated geological storage for sequestering the carbon without using it for EOR(CCS). Nevertheless, more than 73% of operational projects in the natural gas processing sector remain dedicated to EOR projects.

More than 73% of operational projects in the natural gas processing sector remain dedicated to EOR projects.

And as EOR is about producing more oil and gas, encouraging investment in these fossil fuels negates the very initial claimed emission reduction goal for carbon capture technology.

Scope 3 Emissions—the Elephant in the Room

Gas processing CCS/CCUS covers a tiny proportion of the value chain emissions compared to CCS/CCUS in other sectors.

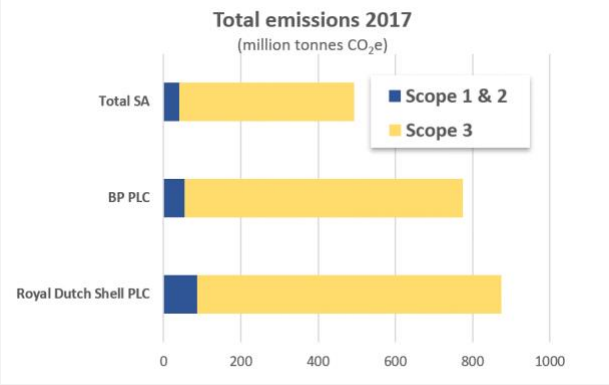
As gas processing CCUS is largely about 'capturing excess CO_2', it is obvious that CCUS in the sector is *not* about reducing Scope 3 emissions from the final

[80] Global CCS Institute. Global Status of CCS 2020.
[81] Global CCS Institute. Global Status of CCS 2021.

combustion/use of gas. Rather it is about minimising production-related Scope 1 emissions from gas with excessive CO_2 content. This is in contrast to most other CCUS applications in the industrial and power sector, which aim to minimise the emissions coming from the end consumption of fossil fuels, whether by combustion or as feedstock materials.[82]

Therefore, giving the green light to new oil and gas projects just because of CCS/CCUS promises attached to those projects is not climate friendly.

Even if the CCS/CCUS facilities work at their capacity (which was not the case historically, barring some exceptions), such projects could only manage a minor proportion of the value chain emissions they themselves produce by adding CCS/CCUS.



The gas burnt at the end of the value chain produces the biggest chunk of emissions, which CCU/CCUS proposals do not address.

Scope 1, 2 and 3 Emissions

Value chain emission of different products is categorized into three different scopes, as outlined by the Green House Gas (GHG) Protocol Corporate Standard.

Scope 1 emissions constitutes emissions from sources owned or controlled by the producer company. Scope 2 represents indirect emissions from purchased energy inputs such as electricity or heat which are not generated directly by the company. Scope 3 represents all other emissions in the value chain, including those located in the upstream (input) and downstream (output) part of the company's process.

Specific for companies involved in energy *extraction*, it is important to note that the end product emissions (Scope 3) constitute a much greater portion of the overall (Up to 90%). Below chart further illustrates the typical emission scopes for oil & gas companies.

Source: Trucost, S&P Global Market Intelligence.

[82] IEEFA. Carbon capture in the Southeast Asian market context: sorting out the myths and realities in cost-sensitive markets. April 2022.

Lessons Learned

In general, due to its association with EOR and historic capture rate issues,[83, 84] carbon capture in the natural gas processing sector has minimal environmental and social credibility as a decarbonisation option.

The most obvious point is that there is no more room for a new EOR project (CCUS) as it contradicts net-zero goals and emission reduction activities. In contrast, EOR has been the central part of the carbon capture application in this sector and others historically.

A new EOR project (CCUS) contradicts net-zero goals and emission reduction activities.

What about capturing and storing carbon without using it for oil production (CCS)?

As clearly stated in the seminal IEA's Net Zero 2050 report,[85] there should be no new oil and gas field developments if the world wants to reach net zero by 2050 and avert the catastrophic consequences of climate change. Therefore, any new oil and gas development should not get a green light, with or without CCS.

Even if a CCS project could capture a majority of the oil and gas facilities' emissions (which most projects show is unlikely), it could only capture 10–15% of the value chain emissions of oil and gas produced by those fleets (i.e., Scope 1 and 2 emissions). Roughly 80–90% of the emissions are Scope 3 emissions,[86] and CCS projects cannot do anything about that.

The niche remainder of existing gas processing units are not 'new' and would be operating through the next one or two decades until renewables, green hydrogen and battery technologies take up the whole energy system. They might provide cases to think about, but there are still risks associated with these.

There is no confidence that the proposed CCS projects could meet their designed capture rates. Except for a few successful cases in a unique regulatory environment, such as Norway, with high carbon taxes and stringent environmental regulations, the history of carbon capture technology is full of failed or underperformed projects. This report has studied some of the biggest ones.

There is also no room to bet billions of dollars on projects that could not meet expectations. Instead, there are proven, cost-effective, and established investment alternatives to battle climate change, such as solar and wind energy.

The other problem with CCS projects is the availability of suitable geological storage locations nearby the projects to make the finance of CCS work.

Monitoring is another challenge—the trapped CO_2 underground needs monitoring for centuries to ensure it does not come back to the atmosphere. Leakages and fugitive emissions in the long term are serious risks. It is impossible to guarantee that the stored CO_2 will stay underground and not leak into the atmosphere. There are several real-world examples of failure in keeping gas underground. The best example is the California Aliso Canyon gas leak in 2015, the worst man-made greenhouse gas disaster in U.S. history when 97,000MT of methane leaked into the atmosphere.[87] The other one is the In Salah project in Algeria, which was a CCS project with a total cost of US$2.7 billion.[88] Injection started in 2004 and was suspended in 2011 due to concerns about the integrity of the seal and suspicious movements of the trapped CO_2 under the ground.

It is impossible to guarantee that the stored CO_2 will stay underground and not leak into the atmosphere.

There will always be a risk of such disasters for any CCS project. The IPCC's Carbon Dioxide Capture and Storage Special Report stated:

> *"CO_2 storage is not necessarily permanent. Physical leakage from storage reservoirs is possible via (1) gradual and long-term release or (2) sudden release of CO_2 caused by disruption of the reservoir."*[89]

The other challenge is liability. The question of who will be responsible for long-term monitoring of the geological structure is crucial. Large oil and gas companies mainly benefiting from the gas developments must be liable for any failure/leakage and monitoring costs of CCS projects, specifically if they get subsidies, grants and tax credits for capturing the carbon.

The most recent example of the liability challenge is the Gorgon CCS project discussed earlier. The expected project life is 40–45 years, after which there will be a closure period of 15 years. Post closure, the Western Australian government,[90] essentially taxpayers, take over the project's liability.

Section 3: Carbon Capture Application in the Power Sector

As one of the highest emitting sectors, the power sector (electricity and heat production) had the largest increase in CO_2 emissions by sector in 2021. This accounted for 46% of the global increase in emissions in 2021. CO_2 emissions from the sector neared 14.6 gigatonnes (GT), their highest ever level.[91]

Power plants inherently emit large volumes of CO_2.

Power plants inherently emit large volumes of CO_2. For example, a 1 gigawatt (GW) coal plant could emit 5–7MT of CO_2 annually.[92]

The most recent proposed application for CCS/CCUS is retrofitting existing, and usually old,

[91] IEA. Global Energy Review: CO_2 Emissions in 2021. March 2022.
[92] Global Energy Monitor. Estimating carbon dioxide emissions from coal plants. Accessed on 3 February 2022.

fossil-based power plants with carbon capture technology to reduce their staggering emissions.

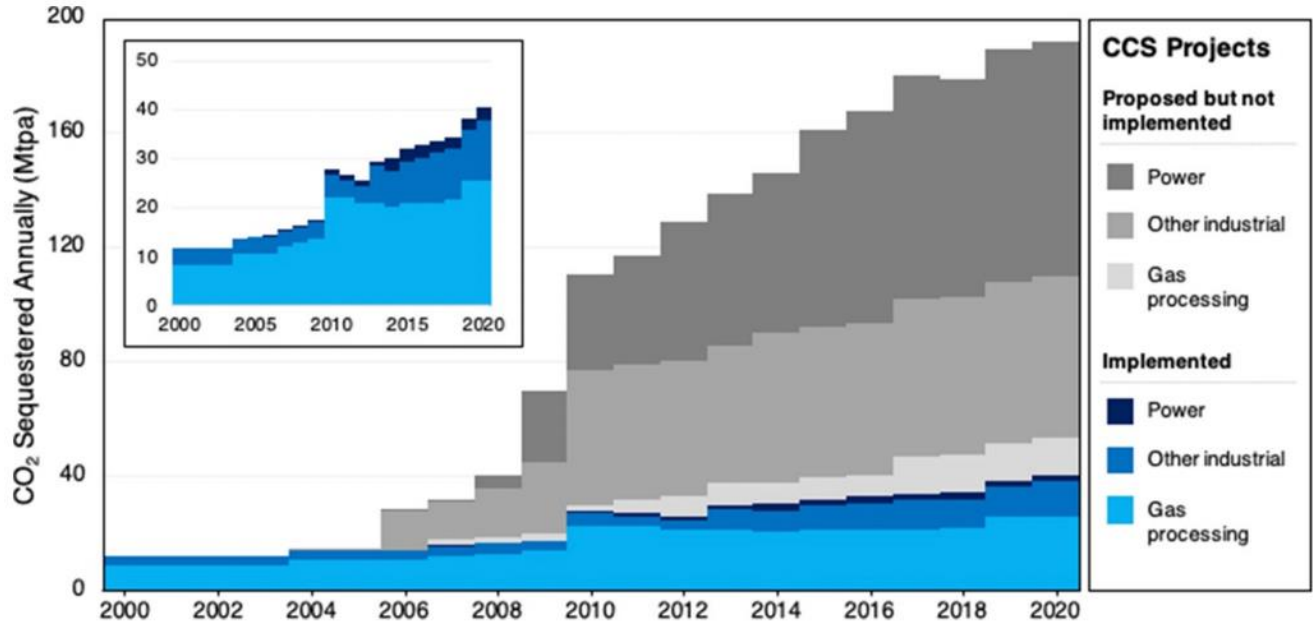
CCUS for the power sector is more costly and complex than other applications due to the diluted CO_2 in the flue gas stream, as evidenced by the string of historical issues in retrofitting CCUS into power plants with several failed projects and cost blowouts. In contrast to gas processing and certain industrial processes that could generate exhaust gas with 40–90% CO_2 composition, coal plants emit gases that typically only contain 10–14% CO_2, while gas power plants generate 4–5% CO_2.[93] Small in concentration but large in terms of absolute volume globally.

Over the years, IEEFA has published a comprehensive body of knowledge in assessing the economics and viability of CCS/CCUS projects,[94] particularly its application in the power sector. Capturing CO_2 consumes a lot of energy, effectively reducing the amount of electricity delivered to consumers.[95] Under normal operation, power plants already consume a portion of the power they generate for self-use. CCS/CCUS impose additional energy penalties into the mix, typically by drawing steam or power to operate the capture process.

This also means that more fossil fuels will need burning to generate the same amount of electricity in a non-CCUS power plant. Decades of technological progress have been devoted to increasing coal power plant efficiency from the sub-38% of subcritical plants to the ~45% of Ultra Super Critical (USC) plants. A loss of 8–12% poses a substantial barrier for many CCS/CCUS applications.[96]

To be able to compete in the electricity market context, the high cost of CCS/CCUS projects will need compensation—by selling the captured CO_2, receiving government incentives, or charging a premium price to consumers. However, these pathways are not guaranteed and also could lead to financial instability for the project or environmental externalities in the case of using CO_2 for EOR.

Selling captured CO_2 for EOR contradicts the very goal of capturing carbon.



Government incentives could flow into fast-growing, efficient, and clean, renewable energy technologies and battery and storage sectors. Selling captured CO_2 for EOR contradicts the very goal of capturing carbon as it leads to producing fossil fuels. Moreover, considering the EOR business as a cash-generating business for power

plant owners is a flawed assumption. EOR activities highly correlate with oil prices, and the demand for CO_2 would be as volatile as oil prices. IEEFA has elaborated on this issue in previous research.[97]

Apart from the financial side, carbon capture has shown a track record of technical failures since 2000. Close to 90% of proposed CCS capacity in the power sector has failed at the implementation stage or was suspended early.[98] Figure 14 reflects the results of recent research by academic institutions and universities in Canada and the U.S. It depicts the failure of carbon capture technology in the power sector.

Figure 14: Global Implemented Annual CCS/CCUS Projects By Sectors

Source: Abdulla et al, 20201, Environmental Research Letters.

Globally, there is only one operating power generation CCUS, which is located at the Boundary Dam plant in Canada. A second CCUS plant, Petra Nova in the U.S., was operational between 2017 and 2020 and later reported to be "shut down indefinitely" after only four years.[99] Both of these plants have been studied in this report, and important lessons were elicited.

It might be the case that there are more proposals for CCUS projects in the power sector, especially as the narrative is becoming attractive in Southeast Asian countries with relatively young fossil power plant fleets. However, the historical lessons clearly suggest that no more greenfield coal or gas powerplants should be

greenlit just because of an embedded CCS facility in its design plans. Also, in the case of CCUS proposals for existing and ageing power plants, to prevent them from getting stranded, investors should know that these projects will likely face financial and technical difficulties that will put them in trouble. The era of fossil-based power plants is over, and renewable technologies plus storage capabilities are the future solutions serving net-zero goals.

Case Studies

In this section, only two carbon capture projects ever operationalised in the power sector have been studied. As the power sector has a track record of failures in utilising carbon capture technologies to curb emissions, the Kemper coal gasification power plant, one of the biggest failures that led to the most expensive power plant ever built, has also been studied.

Petra Nova

The Only Post-combustion Project in the U.S. Was Shut Down After Four Years

There have been only two post-combustion CCS plants commissioned to date. The Petra Nova project was the second and the only one operationalised in the U.S. It was designed to reduce carbon emissions from a power plant southwest of Houston, Texas. Project partners NRG Energy and JX Nippon Oil retrofitted one the boilers at the W. A. Parish Generating Station—with post-combustion carbon capture treatment technology to manage exhaust emissions.

The 45-year-old powerplant has a total capacity of 3.7GW and the CCS was fitted in January 2017 to a boiler in its Unit 8 with 240 megawatts (MW) capacity.[100]

Citing low oil prices during the COVID-19 pandemic, the plant was shut down in May 2020,[101] a common issue with CO_2-EOR projects that are typically very sensitive to oil price volatility.

The amine-based absorption technology, developed by Japanese technology giants Mitsubishi and Kansai Electric Power[102] removes CO_2 from the exhaust gas through a basic absorber-stripper system, then compresses it into liquid. The captured CO_2 was piped 130km away to the sandstone Frio Formation of the West Ranch oil field and after being used to increase the rate of oil recovery, was stored at a depth of about 1500 metres.

As with most CCS projects in North America, generating cash from selling CO_2 for EOR was one of the main incentives for launching this project.

[100] U.S. Department of Energy, Petra Nova – W.A. Parish Project.
[101] NRG. Petra Nova Status Update, August 2020.
[102] Carbon Capture and Sequestration Technologies, Massachusetts Institute of Technology. Petra Nova W.A. Parish Fact Sheet: Carbon Dioxide Capture and Storage Project.

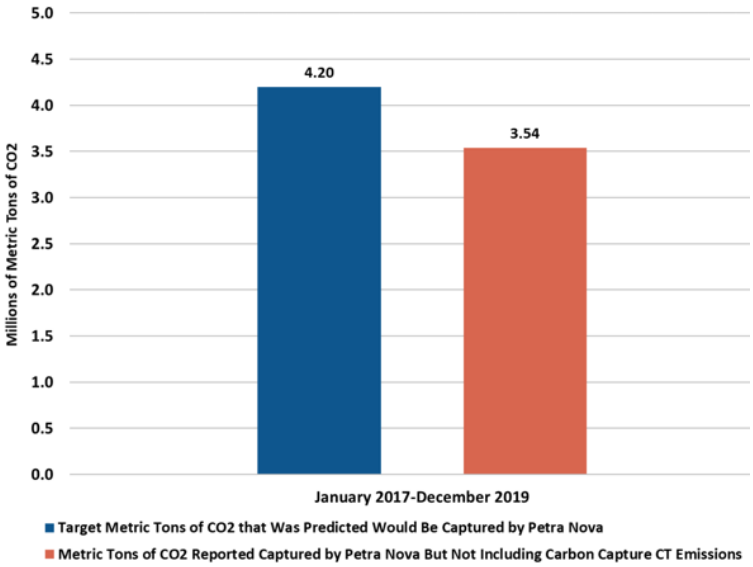
To meet the Clean Coal Power Initiative requirements of the U.S. Department of Energy (DOE), the Texas Bureau of Economic Geology established a scheme for monitoring CO_2 injection and movement beneath the rock structures.

Economics and Performance

Installing the Petra Nova carbon emissions reduction system cost about US$1 billion. Known funding sources were US$190 million provided by the DOE in the form of grants and appropriation, US$250 million by Japanese banks as a loan and US$300 million invested by NRG Energy and JX Nippon Oil.[103]

The main enabler in its business model was the revenue from selling captured CO_2 to the adjacent oil field. This project was expected to run for at least 20 years to enhance the rate of oil production in the West Ranch field from less than 1000 barrels per day to more than 15,000 per day. When the project was first proposed, oil prices were very high (US$100 per barrel) and the very optimistic and unrealistic assumption, given the global transition away from fossil fuels, was that the price would not drop. In 2017, the oil price was about US$50 per barrel and there was a net loss from oil production at the field.[104]

On 1 May 2020, NRG shut down Petra Nova, citing low oil prices during the COVID-19 pandemic.[105, 106] The plant had also reportedly suffered frequent outages and missed its carbon sequestration goal by 17% over its short three years life.



Petra Nova had reportedly suffered frequent outages and missed its carbon sequestration goal by 17%.

The plant was originally expected to capture at least 1.4 million metric tons of CO_2 annually (33% of carbon emission from unit 8 of the powerplant), or a total of 4.2 million metric tons from 2017 to 2019.[107, 108] However, as Figure 15 shows, the project fell well short of that goal during its first three years of operation. IEEFA estimated that the shortfall of 662,000 fewer tonnes in CO_2 captured would have cost investors about US$23 million. It was supposed to recover investment costs via.

[108] U.S. Department of Energy, Office of Scientific and Technical Information (OSTI). W.A. Parish Post-Combustion CO_2 Capture and Sequestration Project, Final Public Design Report. February 2017.

If the 20-year prospective lifetime of the plant is considered,[109] the cost to investors would have been at least US$150 million.[110]

Figure 15: Projected vs Actual Amount of CO_2 Captured by Petra Nova CCS Plant

Source: U.S. Department of Energy, NRG, Inc.

Moreover, the net amount of CO_2 reduction by Petra Nova would be less than the cited 3.54MT as the plant's built-in gas turbine had emitted about 1.1MT of CO_2 by May 2020.

The Petra Nova CCS project met neither the investors' financial expectations nor the specified CO_2 capture, the pre-assumed high-capacity factor of the power plant or the expected EOR rates. Over the past four years, according to company financial reports, NRG recorded three separate impairment charges related to the plant and to Petra Nova Parish Holdings, the subsidiary that operates the facility. The impairments have totalled US$310 million.

Paradoxically, these projects needed the power plant to produce more CO_2 to sell to oil companies and make money. So, they need an unrealistically high capacity factor to run and generate electricity. While research shows the capacity factor for fossil-based power plant is declining around the world.[111]

---

[109] Considering the full 20 years of operation for the plant is not a plausible assumption as it is highly correlated with oil price fluctuations, which practically shut down the plant just after three years. As the future unfolds a business model heavily reliant on a highly volatile oil price would not seem to be prosperous.

[110] Dennis Wamsted, David Schlissel. IEEFA. Petra Nova Mothballing Post-Mortem: Closure of Texas Carbon Capture Plant Is a Warning Sign. August 2020.

[111] Bruce Robertson, Milad Mousavian. IEEFA. Australia's Gas-fired Recovery Under Scrutiny Inaccurate Assumptions Behind Fossil Fuel Power Plants' Capacity Factor Leads to Financial Overvaluations. June 2021.

Based on the IEA Clean Coal centre report on CCS project costs published in 2020, the levelised cost of capturing CO_2 in Petra Nova was about $60–$70 per tonne. The real levelised cost would be much higher, however, as this study assumes an unrealistically high capacity factor of 85% for the plant.[112] Historical operation data shows the capacity factor of the plant to be about 63%.[113] The financial viability of similar projects, when sensitivity of cash flow is added to oil price fluctuations, must be questioned.

The validity of such projects, which use CO_2 to produce yet more fossil fuel, also must be challenged.

Boundary Dam

The Only Post-combustion CCS Plant in the World

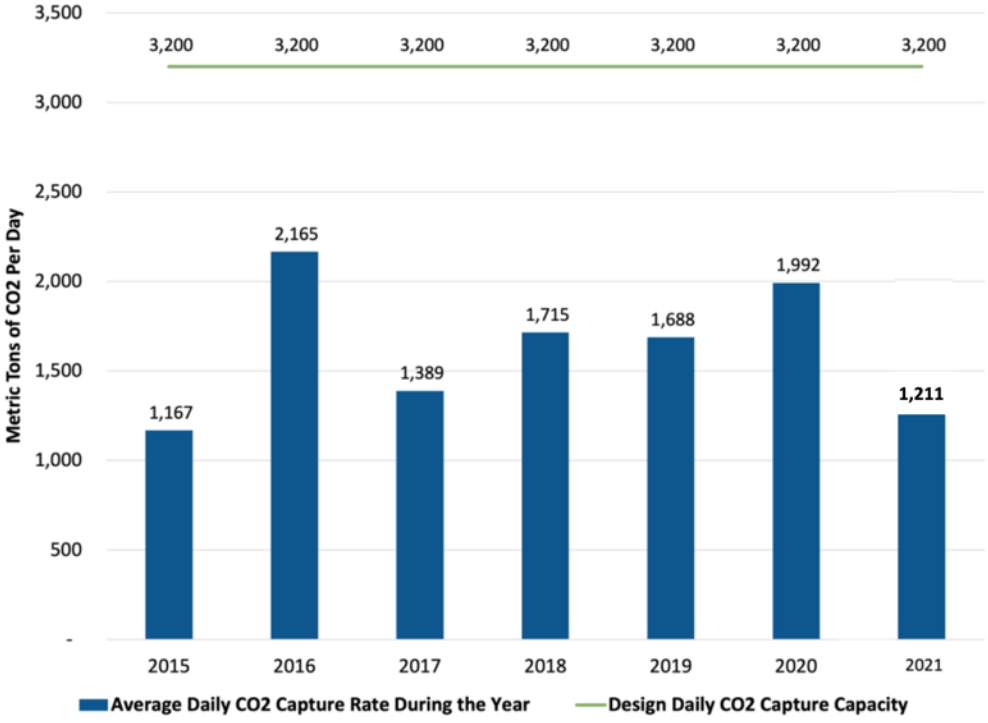
The Boundary Dam Integrated Carbon Capture and Storage project was retrofitted to the lignite-fired Unit 3 of the 50-year-old Boundary Dam power plant in Saskatchewan, Canada. It was recognised as the first coal-fired power plant to use post-consumption CCS technology.[114]

Commissioned in October 2014, it is now the only operating coal-fired power plant in the world that captures CO_2. This project was re-sized from an earlier plan to build a 300MW clean coal facility, shelved by the previous provincial government because of its escalating cost (from US$1.5 billion to US$3.8 billion).

This smaller-scale project was initiated after the Canadian government gave the province C$240 million. It could capture CO_2 using post-consumption amine technology but also was equipped with facilities to capture sulphur dioxide and nitrogen oxides.[115]

Economics and Performance

The original estimated construction cost of the Boundary Dam project was US$1.3 billion but the ultimate figure was US$1.5 billion. Of the original estimate, US$800 million was for the CCS process, with the balance for retrofit costs.



Besides selling electricity, the main revenue stream came from the contract with Cenovus Energy of Calgary, which were supposed to purchase the majority volume of 1Mtpa of captured CO_2 for EOR projects operated by Cenovus near the Weyburn oil field. While a majority of the 1Mtpa of CO_2 captured from Boundary Dam Unit 3 is expected to be sold for EOR operations at the Weyburn oil field, Aquistore provides a

[114] The Globe and Mail, Energy and Resources. SaskPower unveils world's first carbon capture coal plant. October 2014.
[115] IEAGHG. Integrated Carbon Capture and Storage Project at Saskpower's Boundary Dam Power Station. August 2015.

facility for "buffer" storage against EOR sales fluctuations.[116] Cenovus also set up injection wells and built a 60km-plus pipeline connecting the Weyburn EOR project to Boundary Dam.[117]

The initial goal of the project was capturing about 1 million metric tons of CO_2 each year or 3200 tonnes daily. However, the plant has captured an average of slightly more than 615,000 metric tons annually. Data published by SaskPower, the operator of the project, suggests that the Boundary Dam 3's average CO_2 capture rate to date is about 50%, not the targeted 90%.[118] It has barely achieved the latter figure on any single day and has never done so over any extended period.[119] Despite SaskPower's announcement regarding improvements and upgrading facilities during plant outages, as Figure 16 shows, the plant still falls well short of the original daily goal.[120]

Figure 16: Projected vs Actual Boundary Dam CO_2 Daily Capture Rate

Source: SaskPower's Monthly Boundary Dam Status Updates

[116] Global CCS Institute. Aquistore: CO2 Storage at the World's First Integrated CCS Project – Project Summary Report. 2015.
[117] Carbon Capture and Sequestration Technologies, Massachusetts Institute of Technology. Boundary Dam Fact Sheet: Carbon Dioxide Capture and Storage Project.
[118] SaskPower. BD3 Status Update: March 2021.
[119] IEEFA. Boundary Dam 3 Coal Plant Achieves Goal of Capturing 4 Million Metric Tons of CO_2 But Reaches the Goal Two Years Late. April 2021.
[120] SSRN. SaskPower's Boundary Dam Unit 3 Carbon Capture Facility – The Journey to Achieving Reliability. March 2021.

Consequently, it took until March 2021 for Boundary Dam 3 to capture 4 million metric tons of CO_2, a yield that should have been met more than two years earlier, in October 2018.

SaskPower had counted on sales of CO_2 at US$19 (C$25) a tonne for Cenovus Energy's Enhanced Oil Recovery project. Without such sales, SaskPower's income was down. And without the expected CO_2 volume, Cenovus Energy collected US$9 million (C$12 million) in payments under the penalty provisions in its CO_2 supply contract.[121] SaskPower also became embroiled in two separate legal disputes with contractors over payments.[122]

The levelised cost of capturing CO_2 in Boundary Dam 3 has been calculated at about $100–$120 per tonne. As with Petra Nova, the underlying assumption for this calculation is that the plant operates at 85% capacity factor—which does not match SaskPower's monthly operating reports. The $100–$120 figure could be considered as the lowest cost of capturing carbon for the lower bound of Boundary Dam 3's carbon capturing cost.[123]

This project, though still operating, is struggling to meet the pre-specified targets.

Kemper Coal Gasification CCS Plant

A Failure and the Most Expensive Power Plant Ever Built

Gas and electric utility Southern Company's Kemper facility was supposed to be a flagship "clean coal" project. Initially proposed in 2008, the greenfield project near Meridian, Mississippi, U.S., was pegged to cost less than US$3 billion and to be running in 2014. It did not unfold as envisioned. Not only was it delayed for more than three years and cost more than US$7 billion, but the company also cancelled the integrated gasification combined cycle (IGCC) and carbon capture portions of the project.

Kemper was designed as a first-of-a-kind plant with a system that produced gasified coal to be burned in a modified combined cycle gas power plant and a carbon capture system that would pull the CO_2 from the gasified coal pre-combustion.[124]

The gasification process and associated emissions controls were expected to produce marketable quantities of ammonia and sulphuric acid as well as the captured CO_2, which was slated for use in EOR.[125] The main argument in favour of the project was that the CO_2 capture would bring the plant's emissions down to levels comparable with conventional combined-cycle gas-fired generators.

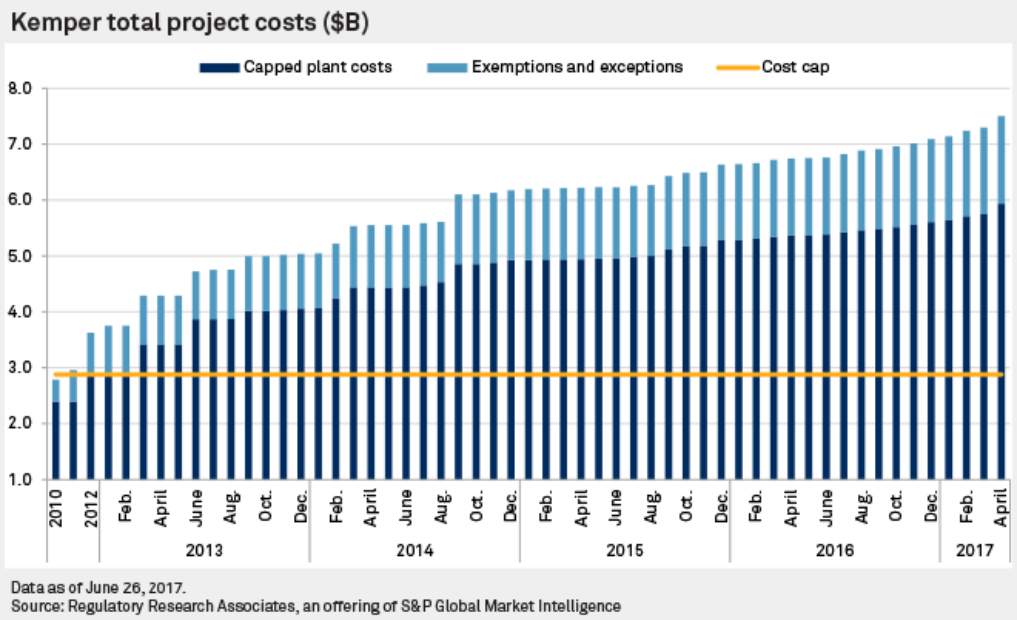
[121] Carbon Capture and Sequestration Technologies, Massachusetts Institute of Technology, Boundary Dam Fact Sheet: Carbon Dioxide Capture and Storage Project.
[122] RenewEconomy. The fallout from SaskPower's Boundary Dam CCS debacle. November 2015.
[123] IEEFA. Where's the Beef? Enchant's San Juan Generating Station CCS Retrofit Remains Behind Schedule, Financially Unviable. May 2021.
[124] IEEFA. Holy Grail of Carbon Capture Continues to Elude Coal Industry. November 2018.
[125] U.S. Department of Energy. Southern Company – Kemper County, Mississippi.

Essentially, the Kemper gasification process turned the relatively straightforward operation of burning coal to boil the water, running the steam turbine and producing electricity into a complicated chemical process that strips gas from coal to be used in a combined cycle gas turbine (CCGT) accompanied by a steam boiler/generator that uses the heat created through the chemical syngas production for electricity production.[126] These complicated steps were essentially added to use the lignite coal extracted from the Mississippi mine, which has 4 billion tonnes of reserves. Lignite or so-called 'brown coal' is considered the most harmful type of coal for human health as its heat value relative to the amount of CO_2 and sulphur it releases is lower than all other grades of coal.[127]

Economics and Performance

Running Kemper's commercial scale on-site equipment, including coal gasification and carbon capture, was expected to consume 30% of the plant's 830MW gross output. A typical natural gas-fired plant consumes just 3–4% of its gross output to run internal equipment. The conventional combined-cycle gas units at Kemper came online in late 2013.[128]



The Kemper project was approved in 2010 by the Mississippi Public Service Commission. Southern Company estimated the US$2.9 billion project would be in operation by the end of 2014. There was no reasonable estimate of either the cost or the commissioning date. Some consultants warned about cost underestimation at the time.[129]

Costs steadily increased as construction proceeded, as shown in Figure 17, and its commercial in-service date was repeatedly delayed. The "cost cap" represents that adopted by the Mississippi Public Service Commission, based on Southern Company's original cost estimate.[130]

Kemper began producing electricity in mid-2014 as a CCGT, burning natural gas, but problems with the operation of its unproven gasification systems—which were to have come online that same year—further added to costs and delays. These led to a 250% increase in the cost of the project, to US$7.5 billion.

Figure 17: Kemper IGCC Project's Increasing Cost (US$)

Source: SNL Financial, a unit of S&P Global Market Intelligence.

These technical and financial failures led to the Mississippi Public Service Commission calling for burning coal to cease and for gas to be used in CCGT. The commission said Kemper's gasification technology would not be used or useful in serving Mississippi customers. It found the technology had not operated reliably and was not likely do so in the near future.[131]

The Kemper "clean coal" journey ended in 2017 with the failed coal gasification idea. Southern Company was left with the then most expensive power plant ever built.[132]

Lessons Learned

Using CCS/CCUS in the power sector is the latest application of the technology, which has been gaining traction recently.

Despite generous funding and numerous incentives to push the technology in this sector (such as the 45Q Tax Credit in the U.S.[133]), it has shown a disappointing track record of failures, with a majority of the proposed CCS/CCUS capacity failing at the implementation stage or getting suspended early. Looking at the historical trajectory, technical issues have been one of the most prominent barriers. A lot of projects failed to operate at their theoretically designed capturing rates. As a result,

[131] Southern Company. Southern Company and Mississippi Power announce suspension of gasification operations at Kemper. June 2017.
[132] Bloomberg. Coal's Best Hope Rising with Costliest U.S. Power Plant. April 2014.
[133] Global CCS Institute. 45Q: The "Most Progressive CCS-Specific Incentive Globally" Is Now Open for Business. 24 March 2021.

the 90% emission reduction target generally claimed by the industry has been unreachable in practice.

There has not been any operational project that could meet its capture target so far. Petra Nova, marketed as a flagship breakthrough in this area, underperformed by 17% in four years of its operation before being mothballed indefinitely in 2020. Boundary Dam 3, the only active carbon capture project in the power sector worldwide, has captured less than its pre-specified target by a wide margin (about 50%).

The 90% emission reduction target generally claimed by the industry has been unreachable in practice.

CCS/CCUS for the power sector is more costly and complex than other applications due to the diluted CO_2 in the flue gas stream, as evidenced in the string of historical issues in retrofitting carbon capture technologies into power plants with several failed projects and cost blowouts.

The financial side of the CCS/CCUS business in the power sector is also problematic. Capturing CO_2 consumes a lot of energy, effectively reducing the amount of electricity that can go to consumers. It imposes additional energy penalties into the mix, typically by drawing steam or power to operate the capture process.

In a competitive electricity market, the high cost of CCS/CCUS will lead to financial instability for the project or environmental externalities in the case of using CO_2 for EOR.

The investment cost for such complex facilities is also staggering. This is evident in the case of the Kemper coal gasification plant that left investors with the most expensive power plant ever built at US$7.5 billion.

All in all, the technology should not be marketed as a quick fix for power sector emissions and make policymakers feel relieved about the world-saving technology just around the corner. It has not worked financially or technically. Instead, we should address the root of the problem, which is fossil-based energy production. Embedding carbon capture technologies in the proposed plan for building power plants and promoting such new fossil-based fleets in emerging economies such as Southeast Asia would have a deteriorating effect on climate in the long term.

Proven, cost-effective and climate-friendly alternatives reduce the dependency on fossil fuels and the risk of ending up with billions of dollars of stranded assets.

Section 4: Carbon Capture Application in Industry

The application of carbon capture in heavy industries and chemical production is diverse and complex.

It is not a monolithic subject: each application has its own specifications and considerations. It covers various technologies and processes, contrasting risks and opportunities, and differing mitigation potentials across multiple applications. Some domains in this sector need greater exploration, such as CCU, which is about utilising and recycling captured carbon into other valuable products such as cement and plasterboard blocks.[134]

In this section, we categorise the industrial application of carbon capture technologies into three categories:

1. Hydrogen production
2. Chemical production
3. Hard-to-abate industries

[134] Australian National University Reporter. Cementing future climate action. 2021.

Hydrogen Production

Hydrogen could play an important role in decarbonising industries, but what colour of hydrogen?

Different colours are used to differentiate hydrogen production methods. Grey hydrogen production utilises natural gas using steam reformation. It is an energy-intensive process that emits a lot of carbon dioxide. Blue hydrogen, often touted as a clean energy alternative, is essentially the same as grey hydrogen. The difference is that carbon dioxide emissions are captured during production using carbon capture technologies. And green hydrogen is made by electrolysing water into hydrogen and oxygen with renewable energy.

Green hydrogen is the real climate-friendly solution.

History shows that capturing more than 90% of emissions from industrial processes is very unlikely. Hence, betting on blue hydrogen is not a promising solution and only keeps the fossil fuel status quo. Instead, green hydrogen, with its rapidly plunging cost, would be the clean alternative in industries that run or plan to run on hydrogen.

Chemical production mainly comprises the production of fertilisers, ethanol, methanol and syngas. We analyse the CCS application in each sub-sector by reviewing a project in each area. Results are mixed, with most projects underperforming by a considerable margin and few others presenting a relatively better performance. As hydrogen has an important role in many processes in different sub-sectors, pro-fossil fuel groups have pushed blue hydrogen. However, wherever hydrogen is applicable technically, green hydrogen would be the solution due to the financial and imminent cost-efficiency.

CCS/CCUS should not be an excuse to greenwash and encourage the establishment of new fossil-based fleets in different industries.

The final area of focus in the industrial application of carbon capture technology is the steel and cement industry, so-called hard-to-abate industries. These two industries constitute 13–14% of the total greenhouse gas emissions worldwide and are critical to decarbonising.[135] The only active CCUS project in this sector is in Abu Dhabi, United Arab Emirates. Although no official data on the performance or finance of the project are available, we reviewed this project based on different accessed sources that were publicly available. The steel sector is in the early years of utilising this technology. Studies could be done on probable projects. However, as the carbon capture technology in different sectors has not reached its target and hopes, investing in such a high-risk, capital-intensive technology in the short time we are left with does not seem to be a sustainable solution.

Instead, alternative methods of steel production, such as scrap steel recycling, emit about 80% less CO_2 per tonne of crude steel than other forms of steel production

[135] Imperial College London. 'Greening' cement and steel: 9 ways these industries can reach net zero. 28 March 2022.

used today. Green hydrogen leading to the production of "green steel"[136] also looks to be a more promising method to follow.

The cement industry is somehow different from all of the other applications of carbon capture technology, as CO_2 is an inevitable by-product of chemical reactions in cement production. Carbon capture technologies seem useful in this industry if they aren't used as an excuse to postpone other methods now under investigation to reinvent the processes and make cement production green.

All in all, compared to the natural gas processing and power sectors, there are few sub-sectors in the industrial application where carbon capture could be considered as an interim option for decarbonisation while the research and development studies being done in parallel reach readiness and maturity levels to be commercialised. Even in these sub-sectors, such as cement, rigorous environmental and technical conditions need to be satisfied.

Blue hydrogen is not "clean" hydrogen.

Hydrogen could play an important role in decarbonising some energy-thirsty industries, whether for sectors that are hard to electrify or to address seasonal energy storages.

Some companies use CCS to promote the expansion of hydrogen made from natural gas. This type of hydrogen is typically labelled blue hydrogen as opposed to green hydrogen, which is produced with renewable energy.

Blue hydrogen is emissions intensive.

Blue hydrogen is an emissions-intensive process, even with CCS. It is also currently uncompetitive with its green cousin as global gas prices soar. Recent research from Cornell and Stanford Universities found that:

> *"Considering both the uncaptured carbon dioxide and the large emissions of unburned, so-called 'fugitive' methane emissions inherent in using natural gas, the carbon footprint to create blue hydrogen is more than 20% greater than burning either natural gas or coal directly for heat, or about 60% greater than using diesel oil for heat."*[137]

Researchers at the Australian National University came to similar conclusions in a recent scientific paper published in January 2022.

> *"We find that emissions from gas or coal-based hydrogen production systems could be substantial even with CCS, and the cost of CCS is higher than often assumed."*[138]

[136] Fuel Cells and Hydrogen Joint Undertaking. Making Steel Green Through Hydrogen.
[137] Cornell Chronicle. Touted as clean, "blue" hydrogen may be worse than gas. August 2021.
[138] Science Direct. Clean Hydrogen? Comparing the emissions and costs of fossil fuel versus renewable electricity based hydrogen. January 2022.

Blue hydrogen is uneconomic in the face of high gas prices.

In addition, blue hydrogen seems to be no longer economic in the near future compared to green hydrogen. The gas market is global and very volatile. Prices can quickly fluctuate due to geopolitical issues, weather disruptions, supply and/or demand variations, etc. Blue hydrogen project economics are tied to this volatility. Expected production costs published only a year ago are significantly higher today, raising questions about continued policy support for the blue hydrogen technology. Unlike gas, renewables can be more regionally or locally located and are free from annual fuel cost dependency.

Green hydrogen projects can capitalise on this advantage and offer an alternative route to hydrogen production that generates near-zero emissions at a cost that could become cheaper than blue hydrogen no later than 2030. Although where possible, direct renewables use should be the alternative instead of producing green hydrogen.

Blue hydrogen's sensitivity to volatility in the gas market is alarming.[139] During 2021–2022, European gas prices have risen fivefold to more than €100/MWh, radically changing the cost dynamics for blue hydrogen. However, even with gas at €80/MWh, asset management company Alliance Bernstein has estimated blue hydrogen exceeds €6/kg.[140]

Blue hydrogen's sensitivity to volatility in the gas market is alarming.

Electrolyser costs are also falling fast. According to BloombergNEF's global head of strategy, Kobad Bhavnagri, green hydrogen's unit costs will be lower than US$2/kg by 2030 worldwide and US$1/kg by 2050.[141] Tenfold reduction in the cost of electrolysers and cheap renewable energy presents a "serious problem" for investments in blue hydrogen and will force gas companies to "think again", according to Bhavnagri.

[139] IEEFA. Russia sanctions and gas price crisis reveal danger of investing in "blue" hydrogen. May 2022.
[140] Reuters. Hydrogens civil war reveals its winner. 31 March 2022.
[141] Recharge News. 'White elephants' | Green hydrogen will be cheaper than blue H2 in all parts of world by 2030, says BNEF. 17 May 2022.

IEEFA has done extensive work on why blue hydrogen is not a climate solution from a technical, financial and environmental perspective.[142, 143, 144, 145, 146]

Case Studies

This section studies the following five important carbon capture projects in industrial applications: the Quest project is the project that has captured CO_2 more than any other CCS/CCUS project in the hydrogen production sub-sector; the Great Plains CCUS project is the largest and the oldest project in the chemical production (others) sub-sector producing Syngas; the Illinois Industrial CCS(IL-CCS), the largest and latest project commissioned in the ethanol production sub-sector; Coffeyville, the largest application of CCUS in the fertiliser production sub-sector; and Abu Dhabi CCUS is the only CCUS project operationalised in hard-to-abate industries worldwide.

These five projects account for about 65% of the current capacity of CCS/CCUS projects in industrial applications. IEEFA estimates that these five projects have captured 70–80% of all CO_2 captured by the industrial application of CCS/CCUS projects worldwide so far.

Quest CCS Project

The Athabasca Oil Sands Project, a joint venture between Shell Canada (60%), Chevron (20%) and Marathon Oil Sands L.P. (20%), proposed the development work in 2011 on a CCS project to help manage CO_2 from the Scotford Upgrader. This facility, near Fort Saskatchewan in Alberta, Canada, upgrades the extracted oil from the oil sands for refineries nearby. Shell started construction in September 2012 after receiving approval from Alberta's Energy Resources Conservation Board. The CCS plant was commissioned in August 2015 and reached commercial operation in Q4 of 2015.[147, 148]

Canadian Natural Resources Limited (CNRL) gained majority ownership of Quest in March 2017 as part of its C$12.7 billion acquisition of Shell's oil sands operations.[149] As of 2020, the Quest project ownership was 70% CNRL, 20% Chevron and 10% Shell.

[149] Financial Post. Shell mulls more carbon capture projects in Alberta as Quest hits 5 million tonne milestone. 10 July 2020.

The Quest project targeted the capture of up to 1.2Mtpa (a proposed 27MT over the project life) of CO_2 from the Scotford Upgrader and aimed to permanently store it deep underground, reducing 35% of the CO_2 of the upgrader.[150, 151] The carbon dioxide is captured from the Scotford steam methane reformer units, which produce hydrogen for upgrading bitumen. The CO_2 is then transported about 65km by underground pipeline to an injection location near the Scotford Upgrader and stored at 2300 metres in a geological formation.[152] The project's engineering, procurement and construction was managed by Fluor Canada.[153]

The project delivered 1Mtpa in the first five years of operation,[154] on the way to an estimated 10.8MT for the first decade of operation. The storage capacity of the field has been reported at 27MT and the project life has been estimated at about 25 years.

Economics and Performance

Construction of the Quest project cost C$790 million and the total capital cost over 2009–2015 was C$1395 million. Of this, more than 40% (C$573 million) was funded by the Canadian and Alberta governments. A double CO_2 credit was also agreed, using a C$30/t[155] price to give the project C$60/t CO_2 reduction credits (and additional government funding of C$26/t). It adds C$1985 million of estimated project receipts from the Alberta and Canada governments until the end of the project's life.

On this basis, the total estimated government subsidies over the project's life is C$2.56 billion or C$95/t.[156]

Source: Shell Canada Energy, 2017 Annual Report

In terms of performance, Quest almost hit its yearly targets. The CCS plant was supposed to capture at least 1Mtpa and up to 1.2Mtpa. Taking the average of 1.1Mtpa as the target capture rate, to the end of 2020 it should have captured 5.5MT of CO_2. Based on the company's disclosures, the actual captured amount was 5.38MT; almost equal.

Figure 18 illustrates yearly amount captured and injected by the plant (orange line) versus the project's target (blue line). As depicted in the graph, the Quest plant largely performed at the targeted level until 2019. In 2020, the 15% drop in the injection rate reflects underperformance during the pandemic. However, the plant almost reached the overall pre-defined target after five years of operation.

Figure 18: Target vs Actual Capture Rate of Quest CCS Plant (2016–2020)

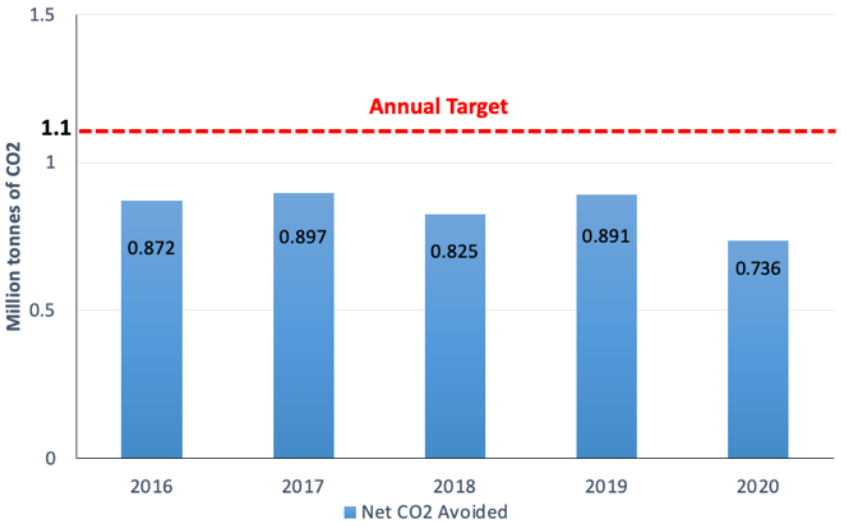
Source: Quest Annual Status Reports, IEEFA Analysis

The Real Amount of CO_2 "Avoided" Is Lower than What Was Just Captured

Limiting analysis to the cumulative amount of CO_2 captured by the plant is an incomplete conclusion about the performance of CCS plants as capturing operations produce additional CO_2 emissions.

The amount of CO_2 captured is not the net amount of CO_2 prevented from being emitted into the atmosphere. Any operation of the plant—such as absorbance, dehydration, compression, transport and injection—needs energy, the source of which is fossil fuel. That fuel and the fossil-based electricity used in each step produce CO_2 emission.

According to the Quest annual data, in the five years depicted in Figure 18 above, 1.16MT of CO_2 were emitted through the whole carbon capture and sequestration process (i.e., capture, transport and storage). So more than 21% of the 5.38MT of captured CO_2 was offset by the emitted CO_2.



On this calculation, the net avoided CO_2 in the project's first five years was 4.22MT not 5.38MT. A similar calculation applies to each CCS plant that sources energy from fossil fuels. The 'net avoided CO_2' criterion reflects the real impact of CCS projects from an emissions reduction perspective.

Figure 19 compares the yearly amount of avoided CO_2 from the Scotford Upgrader with the target amount. For the Quest CCS operation, the net avoided amount did not exceed 0.9MT in any year, or only about 32% of the yearly CO_2 emission of the Upgrader and CCS plant together.

Extrapolating this trend and considering approximately 0.24MT of CO_2 emitted each year in capture, transport and storage indicate the CCS operation on its own would emit 6MT of CO_2 during the project's lifetime.

Accordingly, to the end of the project's life, the total amount of avoided CO_2 would be about 21MT instead of 27MT. Further, the government's subsidy per tonne of avoided CO_2 turns out to be C$120, considerably higher but more realistic than the C$95 figure.

Figure 19: Net CO_2 Avoided vs CO_2 Yearly Capture Target (2016–2020) – Includes Emissions from the CCS Operations

Source: Quest Annual Status Reports, IEEFA Analysis

Chemical Production (Ethanol, Fertiliser, Syngas etc.)

Chemical production could be the most convoluted application area for carbon capture technologies. This is because of the diversity of chemical products produced in this sector and of the technologies can be applied. It includes but is not limited to nitrogen-based fertilisers, such as ammonia and urea ammonium nitrate, ethanol and biofuel products, methanol, and reformed and synthetic gas. For many of the processes, blue hydrogen has been proposed. However, wherever hydrogen is applicable technically, green hydrogen would be the solution, not blue, due to the financial and emission reasons discussed earlier. For example, for nitrogen-based fertilisers, which need hydrogen to produce the final product, any type of coal gasification or petroleum coke gasification to produce hydrogen and then capture the released CO_2 with CCS facilities should not be greenlit. Instead, green hydrogen should be considered a climate-friendly alternative.

If there is no alternative to current processes in each of these applications, then carbon capture could be considered if:

- it does not promote EOR
- it does not extend or is used as an excuse to extend the life of any type of fossil asset
- a safe storage location is identified, and a long-term monitoring plan and compensation mechanism in case of failure are developed
- liability of the projects is not handed over to the taxpayers.

In the following section, three of the biggest CCS/CCUS projects ever built in each sub-sector of chemical production have been reviewed. All of these projects are located in the U.S.: the Great Plains Synfuels Plant producing syngas from lignite coal gasification, which is planned to be redeveloped into a blue hydrogen project; the Illinois Industrial Carbon Capture and Storage, the largest project of its kind tied with biofuel production; and finally, the Coffeyville Gasification Plant, the biggest CCUS project in the fertiliser production sector.

Great Plains Synfuels Plant

The Great Plains Synfuels Plant (GPSP) in Beulah, North Dakota, is a coal gasification plant that has produced synthetic natural gas (SNG) from lignite coal since 1984.

Coal gasification is a highly emitting process and lignite, also known as brown coal, used in this plant is considered the most harmful type of coal for human health due to the large amount of CO2 and sulphur it releases in combustion.[157]

Hence, the motivation behind such a heavily polluting project could be simply the abundance of cheap feedstock in the U.S. The National Energy Technology Laboratory (NETL) of the U.S. Department of Energy (DOE) estimates that about 200 years' worth of consumption remains in the U.S.[158]

Operated by the Dakota Gasification Company's (DGC), the GPSP is the only coal-to-SNG gasification plant in operation in the U.S. Annually, the plant consumes about 6MT of coal to produce 54 billion standard cubic feet of SNG as well as some chemical by-products.[159] The SNG (95% methane) is piped to the Northern Border Pipeline, which transports gas from Canada, Montana, and North Dakota to the Ventura, Iowa area, where it connects with numerous pipelines that supply the eastern U.S.

[157] Heal. Lignite coal – health effects and recommendations from the health sector. December 2018.
[158] National Energy Technology Library, U.S. Department of Energy. Hydrogen & Synthetic Natural Gas from Coal.
[159] National Energy Technology Library, U.S. Department of Energy. Great Plains Synfuels Plant.

After 16 years of operation and venting millions of tonnes of CO2, capturing and selling of CO2 to the nearby oil producers started in October 2000. The CO2 is pumped via an onshore 315km pipeline for EOR in two carbonate fields, the Cenovus Energy-owned Weyburn field (with demand rate of 6500 tonnes per day) and Apache company-owned Midale field (with demand rate of 1200 tonnes per day).[160]

CO_2 Leakage Case

Following claims of leakage from the Weyburn site in January 2011, operator Cenovus and the International Performance Assessment Centre for Geologic Storage of CO_2 (IPAC-CO_2) launched investigations. The "leaking" gas was discovered to be naturally occurring biogenic CO_2, originating from biological processes in the soil, rather than injected CO_2. The 2012 report discovered no potential CO_2 pathways from pipelines or other infrastructure.[161]

Economics and Performance

GPSP was commissioned by American Natural Resources company (ANR). However, as it was not easy to secure financing for such a huge project, ANR formed a partnership with several other natural gas utility companies which became known as the Great Plains Gasification Associates (GPGA). This allowed the U.S. DOE to back funding for the plant.[162]

The plant was built in response to the energy crisis of the 1970s.[163] Total cost for design and construction was roughly U$2 billion of which a $1.5 billion loan was guaranteed by the DOE.[164] Construction began in 1981.[165]

In addition, the CO_2 monitoring and storage project in Weyburn and Midale fields was conducted between 2000 and 2011 (at an estimated cost of U$70 million).[166] And the cost of pipeline was US$100 million.[167]

According to the DOE's NETL, the separated CO_2 was emitted into the atmosphere for the first 16 years of the project's lifetime due to lack of demand. In October 2000, the operator started capturing and selling CO_2 to oil companies for EOR in the nearby fields. The capacity at the beginning of the project was reported to be about 105 million standard cubic feet per day (~2Mtpa) or 60% of total CO_2 produced by the plant.[168] This

[167] School of GeoSciences, University of Edinburg. Great Plains Synfuels Plant: Project Details.
[168] National Energy Technology Library, U.S. Department of Energy. Weyburn Project. n

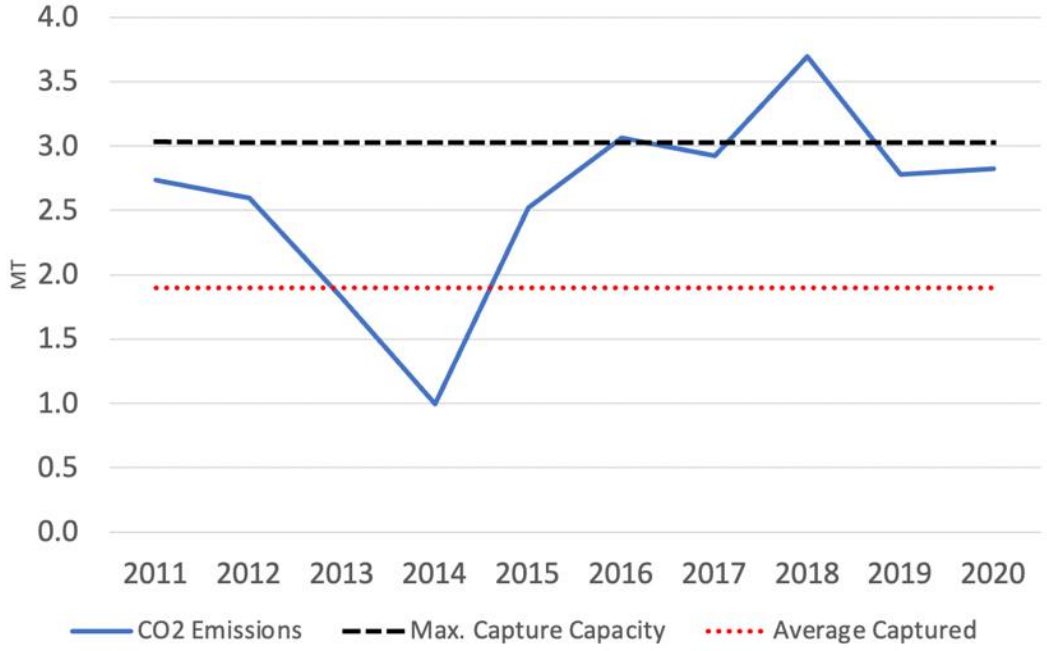
capacity increased to about 3Mtpa in 2006 by installing the third CO_2 compressor to meet the needs of Apache Canada Ltd for EOR. Up to 2007, CO_2 sales exceeded 11MT.[169]

For the first six years of operation the carbon capture facility averaged 1.8–1.9Mtpa, very close to its nominal capture capacity.

No detailed data and information have been found regarding the plant's annual capture performance. Based on cumulative figures from the MIT CCS database[170] and National Petroleum Council report,[171] it had captured and transported nearly 38MT of CO_2 for geological sequestration up to 2020. Factoring in the capacity expansion to 3Mtpa in 2006, the total amount CO_2 captured and sold for EOR until 2020 was 27MT.

The average annual capture rate for the 14 years post-expansion has remained ~1.9 Mtpa, or about 1MT lower than the maximum capture capacity for these years.

The first hypothesis is that this underperformance could be due to lower gas production in the main synthetic gas production plant. Should this be the case, the CCS plant would not be underperforming. On the other hand, the alternative hypothesis is that CCS plant underperformance, technical problems or lack of demand from oil companies would result in the uncaptured CO_2 being vented into the air.



Looking at the U.S. Environmental Protection Agency (EPA) data of the plant's CO_2 emissions for the period 2011–2020 confirms the underperformance hypothesis.

Figure 20 shows the CO_2 emissions from the synthetic gas (syngas) production process (blue line), maximum capture capacity of the plant (black dotted line) and the average yearly captured CO_2 of the plant (red dotted line).

It essentially shows that during this decade the amount of CO_2 produced by the plant was higher than the average 2MT capture rate (2014 excepted). The CCS facility had the capacity to capture all of the CO_2 produced by the syngas process (but for 2018, when CO_2 production exceeded the maximum 3MT capturing capacity).

Figure 20: Great Plains Synfuels Plant CO2 Emissions vs Capture Performance (2011–2020)

Source: National Energy Technology Laboratory (NETL), Department of Energy. U.S. Global CCS Institute. 2021. U.S. Environmental Protection Agency (EPA), Greenhouse Gas Reporting Program (GHGRP). IEEFA

The cumulative tallies for CO_2 captured and produced during 2011–2020 show that the CCS plant underperforms by about 25%. During the decade, it captured about 19MT of CO_2 to be sold for producing more oil and vented another 6–7MT. (Figure 21).

It is important to note that the overall figure for emitted CO_2 should be considerably higher as the above figures exclude the emissions from the CCS facility operations, potential leaks through pipelines and fixtures and the CO_2 emitted in reinjecting at the EOR point.

An Imminent Blue Hydrogen Redevelopment for Plant

In 2021, Bakken Energy and Mitsubishi Power Americas announced plans to purchase GPSP from Dakota Gasification Co., which is financially in trouble. The deal was expected to be finalised by April 2022.[172] It is part of a plan to create a hydrogen hub in Dakota.[173] It has been labelled "clean" hydrogen. However, the hub will focus on the production of blue hydrogen, derived from natural gas with CO_2 emissions captured, and sequestered underground or used for EOR. The hydrogen will come

[172] AP. North Dakota gas plant to be redeveloped for clean energy. 17 August 2021.
[173] AP. Companies aim to build 'clean hydrogen' hub in North Dakota. 3 June 2021.

from natural gas produced in North Dakota's oil fields or from gas from the Dakota Gasification plant, or a mix of both.

The hub is not a green hydrogen project as it is essentially producing gasified hydrogen and capturing its CO_2 by-product. Blue hydrogen is neither a climate-friendly solution or an economically sound choice compared to green hydrogen, as discussed earlier.

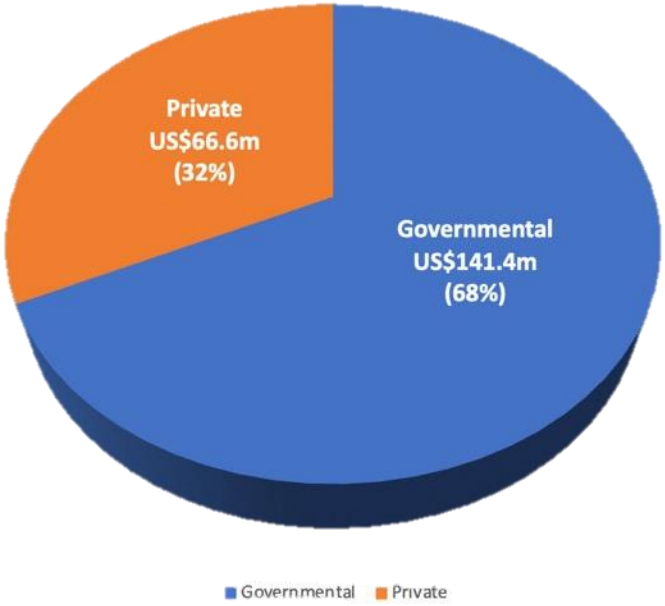
Illinois Industrial Carbon Capture and Storage (IL-CCS)

In 2011, Archer Daniels Midland (ADM), one of the world's largest agribusiness companies, started the Decatur carbon capture project with partners. As part of the U.S. DOE's Regional Carbon Sequestration Partnerships initiative, and with funding from the DOE, it started as a research and development project in industrial CCS, in Illinois.

Having passed pre-specified targets for capturing carbon and showing no CO_2 leakage, the project moved ahead to the design and implementation phases and captured and stored 1MT of CO_2 from 2011 to 2014.[174]

With the successful completion of the Decatur demonstration project, ADM and corporate partner Schlumberger Carbon Services continued on to the larger- scale Illinois Industrial Carbon Capture and Storage (IL-CCS) plant with a 1Mtpa capturing and storing capacity. Started in 2017, as the world's first large-scale CCS project from a biofuel source, it relied on the Mount Simon Sandstone saline formation as its dedicated geological structure to store the captured carbon. The CO_2 not being used for EOR was to be stored more than 2000 metres underground.[175]

The gas from the ADM biofuel plant is a >99% pure CO_2 stream that is a by-product of fuel-grade ethanol production via anaerobic fermentation of corn stover (harvest remnants).[176]



Economics and Performance

Following the success of the Decatur project, backed by about US$106 million in federal funding and US$21 million from the corporate partners, site characterisation and permitting of IL-CCS was finished in 2014 and the project started to capture and inject CO_2 in 2017.

[174] Carbon Capture and Sequestration Technologies, Massachusetts Institute of Technology. Illinois Industrial Carbon Capture and Storage (IL-CCS) Fact Sheet: Carbon Dioxide Capture and Storage Project.
[175] Carbon Capture and Sequestration Technologies, Massachusetts Institute of Technology. Illinois Industrial Carbon Capture and Storage (IL-CCS) Fact Sheet: Carbon Dioxide Capture and Storage Project.
[176] Carbon Capture and Sequestration Technologies, Massachusetts Institute of Technology. Illinois Industrial Carbon Capture and Storage (IL-CCS) Fact Sheet: Carbon Dioxide Capture and Storage Project.

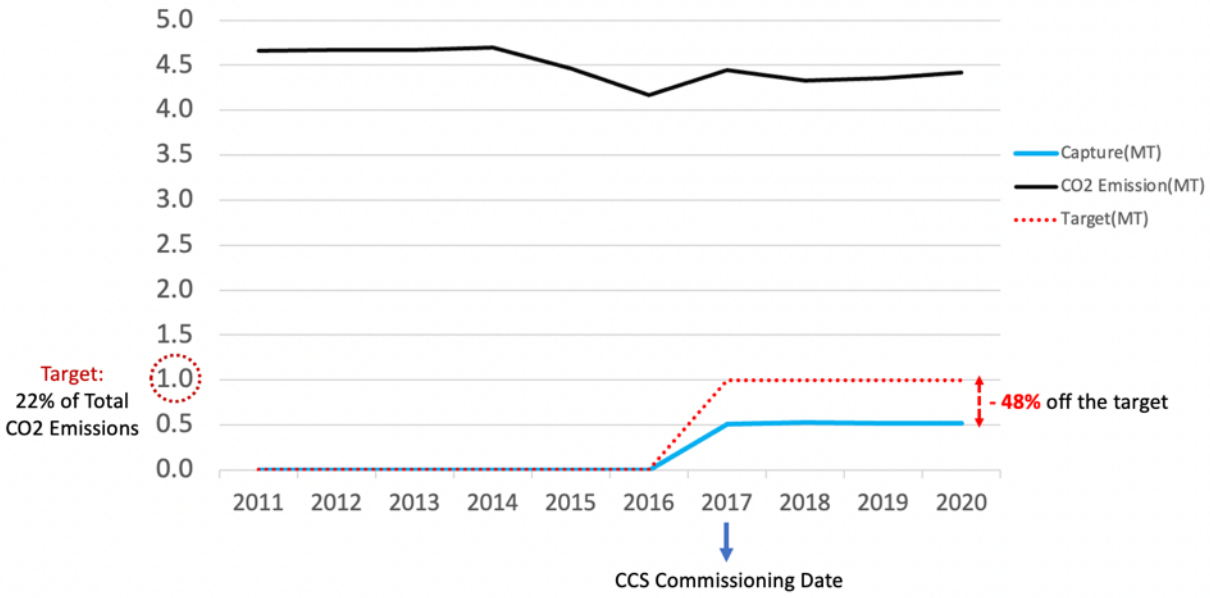
The cost of the project was US$208 million, of which US$141.4 million came via the DOE's CCS grants. Essentially, the project was 68% government funded (Figure 21).[177, 178, 179]

Figure 21: IL-CCS Finance Portfolio

Source: U.S. Spending.gov.

Looking at total CO_2 emissions of the ADM biofuel plant, the figure is four to five times higher than the designed capture target of 1Mtpa. On average, the plant has emitted 4.5MT of CO_2 annually. In the best-case scenario, if the CCS facility could capture at its theoretical capacity, it would contain only 22% of the plant's CO_2 emissions. This illustrates how technically and economically challenging it is to reach capture rates of >80% that are usually claimed for CCS facilities. The technical difficulty is evident in the quote by engineering consultancy WSP, advisor to ADM for a carbon reduction feasibility study in 2020:

> *"The ability to capture stack emissions and sequester them is likely 10 years out, due to the technology and energy needed to separate and process the stack gas sufficiently to inject the CO_2 in the sequestration well."*[180]



Moving from theory to practice, the reality is even starker. EPA data illustrate that the CCS facility has been performing at about half of its designed capacity since the beginning of the project (Figure 22).

The facility is underperforming by 48% to the end of 2020,[181] meaning that it could capture and sequester only up to 12% of the total CO_2 emissions of the ADM biofuel plant. The emission problem is still there and, essentially, the US$200m-plus CCS retrofit could not solve that.

Coffeyville Resources Nitrogen Fertilizers Plant

Coffeyville Resources Nitrogen Fertilizers Plant incorporated in 2003[182] in Kansas, U.S., produces ammonia and urea ammonium nitrate (UAN) fertilisers. It gasifies petroleum coke to produce hydrogen, from which it synthesises ammonia and UAN fertilisers. An oxygen separation plant provides oxygen for the gasifiers, as well as nitrogen needed downstream for reaction with hydrogen to produce ammonia. Syngas is cleaned in a dual-stage acid gas removal process, delivering Hydrogen sulfide (H_2S) and CO_2 in separate streams.

A proportion of the separated CO_2 is used to produce UAN but most of the gas was vented in the first decade of the plant's operation.

[181] The data was accessible through until end of 2020.
[182] Bloomberg. Coffeyville Resources Nitrogen Fertilizers.

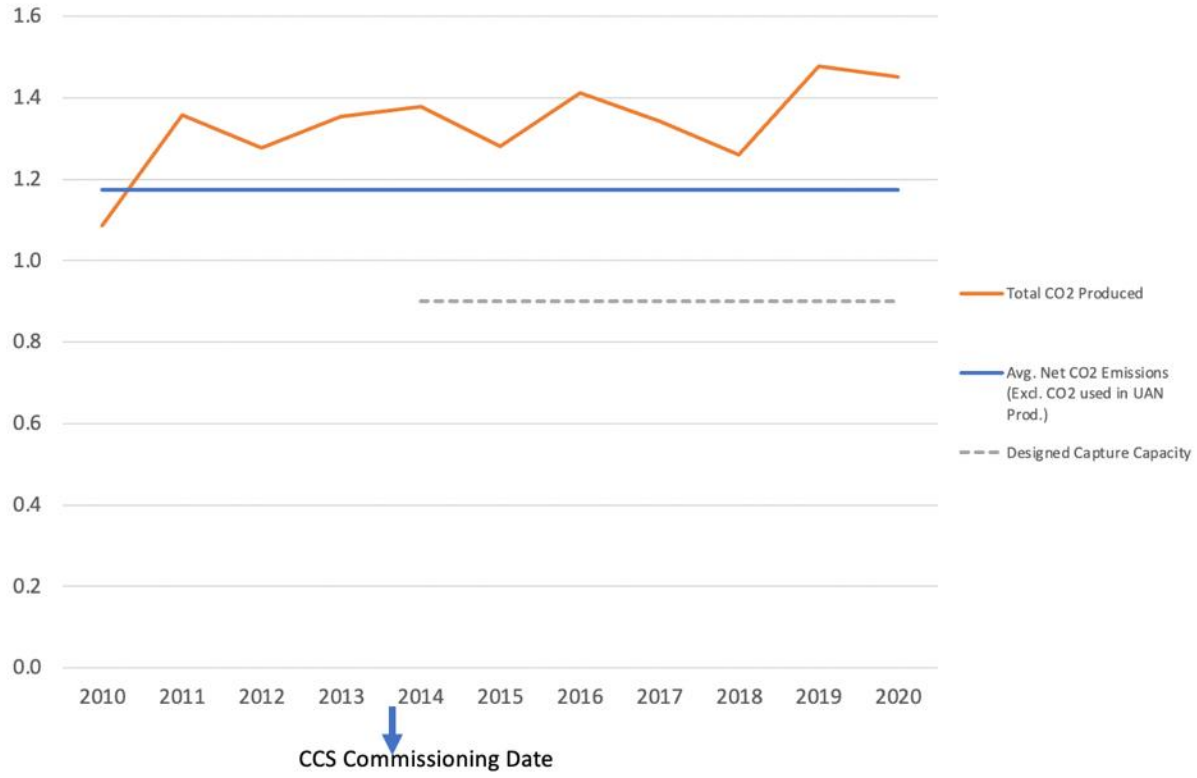
The plant produces about 5% of total UAN demand in the U.S. and is close to extensive fertiliser markets in the Midwest, lowering the distribution costs of its products.

In 2011, subsidiaries of Chaparral Energy and CVR Energy (the owner and operator of the Coffeyville plant) reached a purchase and sale agreement to capture CO_2 from the plant, which Chaparral needed for EOR operations in north-eastern Oklahoma. The plant started to capture CO_2 in June 2013. Under the agreement, the majority of the plant's CO_2 was planned to be captured by Chaparral, which constructed a CO_2 compression facility at the plant site and installed about 110km of pipeline to deliver it to its North Burbank Unit in Osage County in Oklahoma.[183]

Economics and Performance

Blue Source, LLC, a carbon-reduction advisory company, initiated the idea of capturing greenhouse gas from the fertiliser plant and injecting it into ageing petroleum fields to boost oil output. With Chaparral Energy and CVR Energy, it planned and executed the CCS retrofitting and construction of the pipeline. The project was estimated to cost between US$50 million and US$$80 million.[184] The project was finished, and injection started in 2013.[185]

U.S. EPA data for total CO_2 produced by the fertiliser plant is shown in Figure 23 (orange line). However, as a step in the UAN production process, part of the CO_2 produced during the acid gas removal process is then used in production of UAN. Hence, the net emitted CO_2 is lower than the total CO_2 produced. Based on industry averages[186] and scattered data publicly available on the facility's UAN production figures,[187] the average CO_2 produced (excluding the amount used in UAN production) is an estimate (blue line).



No public data has been found on the yearly capture performance of the plant over its whole lifetime. For illustration, the maximum capture capacity of the plant (Figure 23, grey dotted line) accounts for up to 80% of its CO_2 emissions. Some research shows that the plant could have overperformed during 2017–2019 by about 16%, which is an acceptable result.[188] However, the question remains as to whether the plant has achieved maximum capacity each and every year since 2013, given very few CCS/CCUS projects have done so historically. Also, it is notwithstanding that captured CO_2, when used for EOR, at least partly negates the original figure of reduced carbon.

As most of the CO_2 created in these plants assist in the production of hydrogen to be used in fertiliser production, replacing green hydrogen with current processes of producing syngas hydrogen from petroleum coke seems to be more efficient and climate friendly than the technically challenging and extremely expensive carbon

Hard-to-abate Industries (Steel and Cement)

Source of ~14% of Global CO_2 Emissions

Steel and cement are named hard-to-abate industries as it is technically and financially difficult to completely electrify them using renewable energy. Yet, according to Imperial College London, cement and steel production contribute to 6.5% (2.3 billion tonnes) and 7% (2.6 billion tonnes) of global CO_2 emissions, respectively.[189] That is partly owing to the large quantities of use of these materials: concrete is the second-most-consumed product on the planet, after clean water. It is also due to their carbon-intensive manufacturing: the chemical reactions and the burning of fossil fuels to deliver the extreme temperatures required all release CO_2.

[189] Imperial College London. 'Greening' cement and steel: 9 ways these industries can reach net zero. 28 March 2022.

Carbon capture has been discussed recently as one of the solutions contributing to decarbonising these heavy polluting industries.

There is only one operating CCUS plant in the steel sector and no commercialised CCS plant in the cement industry.

There is no public data on the performance and finance of the only operating CCUS project in Abu Dhabi, United Arab Emirates. Hence, there is not much to learn from the history of the application of CCS/CCUS in this industry. However, the technical failures of CCS/CCUS in other sectors are alarming. This is important as the time to reach net zero targets is very limited, and there is little room for trial and error. Nevertheless, there is a lot of research and development going on to decarbonise these two industries with different options[190, 191] and CCS/CCUS has been considered as one of the alternatives.

There is only one operating CCUS plant in the steel sector.

Steel

There are three main steel production processes.

1. The most widespread is the integrated blast furnace and basic oxygen furnace process (BF-BOF), in which iron oxide is reduced to iron inside the blast furnace with coke (derived from coking coal) as a reducing agent. The product of the blast furnace, carbon-rich pig iron, is then processed into steel in a basic oxygen furnace, where oxygen is blown through the molten pig iron to reduce its carbon content. In 2020, global crude steel production totalled 1.88 billion tonnes, and of this, 73% came via the BF-BOF process.[192]

2. A second primary steelmaking pathway is to produce direct-reduced iron (DRI), which is then further processed into steel in an electric arc furnace (EAF). DRI is produced by directly reducing iron ore without melting, usually using a mixture of carbon monoxide and hydrogen derived from natural gas. Although, these can also come from gasified coal. This method provides the final steel product with around 36% less CO_2 emissions.[193]

[190] Imperial College London. 'Greening' cement and steel: 9 ways these industries can reach net zero. 28 March 2022.
[191] IEEFA. Green steelmaking will need technology and mining advances. 1 July 2022.
[192] World Steel Association. World Steel in Figures 2021 now available. 3 June 2021.
[193] IEEFA. Iron Ore Quality a Potential Headwind to Green Steelmaking. 28 June 2022.

DRI does not use coking coal. An increasing number of steel companies are seeking to develop technology that uses 100% hydrogen in the DRI-EAF process—potentially zero-carbon green hydrogen, produced via renewable energy-powered electrolysis.[194] And due to the reasons discussed earlier, green hydrogen is the fuel for heavy industries' future. Any type of coal gasification/methane reformation to produce hydrogen and then capturing its carbon with CCS/CCUS—that is, blue hydrogen—does not seem to be a climate saviour or cost-efficient option.

3. As an alternative to primary steel manufacture, recycling scrap steel is an option with around 80% lower CO_2 emissions.[195] Also called secondary steelmaking, this technology does not require iron ore or coking coal. An electric arc furnace is charged with steel scrap, which is melted to form new steel. Renewable energy can power EAFs, reducing carbon emissions for the scrap EAF process to almost zero. Although there are limitations on the volume of available scrap and some quality issues, even a little increase in this type of production instead of BF-BOF would be a gamechanger.

Although there is a long way to go in the steel sector, green hydrogen seems to be a more promising pathway than CCS. As discussed, it will be a cost-effective option in the next few years.

The steel sector is in the early years of utilising this technology. Studies could be done on probable projects. But, as carbon capture technology in different sectors has not reached its target and hopes, investing in such a high-risk, capital-intensive technology in the short time we are left with does not seem a sustainable solution.

Green hydrogen seems to be a more promising pathway than CCS.

Instead, alternatives such as scrap steel recycling or green hydrogen leading to the production of "green steel"[196] looks a more promising path to follow.

Cement

The cement industry is somehow different from all of the other applications of carbon capture technology, as CO_2 is an inevitable by-product of chemical reactions in cement production. The process is known as calcination when crushed limestone is heated and releases calcium oxide (CaO) and CO_2.[197]

$$CaCO_3 + heat \rightarrow CaO + CO_2$$

[194] IEEFA. Iron Ore Quality a Potential Headwind to Green Steelmaking. 28 June 2022.
[195] IEEFA. The facts about steelmaking: Steelmakers seeking Green Steel. 2022.
[196] Fuel Cells and Hydrogen Joint Undertaking. Making Steel Green Through Hydrogen.
[197] University of Mosul. Calcination of Limestone.

The heat for the process and the chemical reaction itself produce CO_2.

Second only to water, concrete is the most consumed material in the world.[198] Considering these two facts, it is one of the most challenging industries to decarbonise.

Carbon capture technologies seem to be useful in this industry if they are not used as an excuse to postpone other methods now under investigation to reinvent processes and make cement production green.

For example, one of the recent innovations in this sector is using the captured carbon in other industries to produce cement and plasterboard blocks.[199] These processes are worth being funded and studied.

Abu Dhabi CCUS Plant (Al Reyadah)

The First and Only CCUS Plant in the Steel Sector

The Abu Dhabi CCUS plant, commissioned in 2016 in Mussafah, Abu Dhabi, United Arab Emirates, is the only commercial-scale CCUS facility in the world that captures CO_2 from the flue gas of a steel production facility. The final application of the captured CO_2 is EOR in the Abu Dhabi National Oil Company's (ADNOC) nearby oil fields.[200]

The main objectives of the project were reducing the carbon footprint of the United Arab Emirates, implementing EOR in subsurface oil reservoirs, and freeing up natural gas that would have been used for oil field pressure maintenance.[201] From the emissions perspective, such objectives seem incompatible with climate targets, as the CO_2 is used to increase oil production and free up other emission-intensive fossil fuels.

Economics and Performance

The project cost was US$122 million,[202] and it was developed by Abu Dhabi carbon capture company Al Reyadah, a joint venture between ADNOC and clean energy company Masdar,[203] with respective stakes initially of 51% and 49%. ADNOC bought out Masdar's share in January 2018.[204]

[198] Engineering Failure Analysis. Cement and concrete as an engineering material: An historic appraisal and case study analysis. 2014.
[199] Australian National University Reporter. Cementing future climate action. 2021.
[200] The University of Edinburgh. School of Geoscience. Al Reyadah: Project Details.
[201] Carbon Sequestration Leadership Forum. Al Reyadah Carbon Capture, Use, and Storage (CCUS) Project. May 2017.
[202] The National News, Business. Abu Dhabi starts up world's first commercial steel carbon capture project. 5 November 2016.
[203] Power Engineering International. MENA's first CCUS project now operational. 6 January 2017.
[204] The University of Edinburgh. School of Geoscience. Al Reyadah: Project Details. 2022.

The project includes capturing, compressing and dehydrating the CO_2 and then conveying it via a 43km underground pipeline for EOR injection to ADNOC's North East Bab (NEB) (Al Rumaitha) and Bab onshore oilfields.

The project was set to capture and transport 800,000 tonnes per year of CO_2 and, tentatively, was part of an overall master plan to create a CO_2 network and hub for managing future CO_2 supply and injection requirements in the United Arab Emirates.[205]

Technically, the plant is the largest CO_2 project of any type in the Persian Gulf region,[206] the Middle East's first commercial-scale CO_2 capture plant and the project with the world's highest pressure (240 bar) CO_2 transfer pipeline at the time of commissioning. ADNOC has announced plans to expand the capacity of this program by more than 500%, aiming for 5MT of CO_2 annually by 2030.[207]

Phase 2 of the project, set for commissioning in 2025,[208] aims to capture 1.9 to 2.3Mtpa CO_2 from its gas processing plant for EOR in the same reservoir. At the same time, the company plans to increase production to 5 million barrels of oil equivalent (boe) daily in 2030.[209]

The CO_2 to be captured by CCS plant(s) would have a considerable contribution to expanding that production, raising the question yet again: Is using CCS for EOR really reducing emissions?

Lessons Learned

Steel and cement are responsible for 13–14% of total global emissions, and the demand for these two materials is increasing. Therefore, decarbonising these two crucial industries is necessary if the world wants to reach net-zero emissions by 2050. CCUS/CCS has been proposed as one of the pathways for pursuing the decarbonisation of these two industries.

The application of CCUS/CCS in the steel and cement sector is a relatively new area with only one ~6-year-old operating project in Abu Dhabi with no publicly published data on its performance. Essentially, there is not much to learn from the application of CCS/CCUS in these two industries. However, based on limited knowledge of the technology trajectory in other applications with common processes as these industries, as well as other solutions being developed and researched in parallel, future CCS/CCUS application in the steel and cement industry could be projected to some extent.

[209] Drilling Contractor, Increased hydrocarbon production, sustainability programs go hand in hand to create a resilient upstream. 27 April 2021.

Green hydrogen or recycling scrap steel should be prioritised in the steel sector over CCUS/CCS to capture carbon from gasification, reformation, or burning fossil fuels.

In the cement sector, however, as CO_2 is the by-product of the fundamental chemical reaction of producing cement, CCUS/CCS projects could be considered cautiously. Other innovative methods should be pursued to reinvent the whole process toward green and zero-emissions cement.[210] For example, one recent innovation in this sector is using the captured carbon in other industries to produce cement and plasterboard blocks.[211] Cambridge University researchers have proposed zero-emissions cement.[212] Both innovations are worth exploring.

Meanwhile, carbon capture could be used as long as the captured carbon is not used for EOR. CCUS/CCS also should be used only if the technical performance reaches close to nominal capture capacities, in contrast with general trends throughout history. Also, it could be considered an interim option as long as it does not distract financial flows from fundamental and innovative solutions to reinventing the cement production process.

Conclusion

Failed/Underperforming Projects Considerably Outnumbered Successful Experiences

The immediate inference from the projects reviewed is that the number of failures and the underperformance of these projects with carbon capture technology has outnumbered the successful projects considerably. Ten of the 13 flagship projects reviewed, comprising 90% of the total capture capacity in our sample, have failed or are underperforming mostly by large margins.

While a limited sample, predominantly focusing on projects in operation, additional research[213] looking (from a different angle) at the number of failures of all of the proposed/initiated projects since 2000 conveys, in essence, a similar message. Further, recently published research by the Imperial College London[214] on the capture performance of operating projects since 1996 confirms the underperformance of most projects against their designed/claimed capture capacity.

Successful CCUS Exceptions Mainly Existed in the Natural Gas Processing Sector Serving the Fossil Fuel Industry, Leading to Further Emissions

The natural gas processing sector historically dominates the application of carbon capture technology. Extracted raw gas has a carbon dioxide (CO_2) content that needs removal to produce a marketable (methane) gas for distribution through pipelines to customers or liquefied in LNG plants for export.

Producing the primary usable product (i.e., natural (methane) gas) is impossible without separating CO_2. This explains why the sector has been using carbon capture technology for decades, not necessarily as a climate-friendly solution, but as an inevitability to produce the fossil-fuel natural gas. On top of that, selling the captured CO_2 primarily to oil producers for enhanced oil recovery improves the economic viability of gas development projects. Sleipner and Snøhvit have two of the most successful among the few successful projects in the history of carbon capture being used in this sector.

The IEA's Net Zero by 2050 report, one of the seminal energy transition roadmap documents worldwide, has explicitly expressed alarm about the danger of developing any new oil and gas projects globally. It emphasised not developing any new oil and gas projects if the world wants to reach net zero by 2050.

The Elephant in the Room of the Application of CCS/CCUS in the Natural Gas Processing Sector: Scope 3 Emissions Are Still Not Being Accounted for

Gas processing CCS/CCUS covers a tiny proportion of the value chain of emissions compared to CCS/CCUS in other sectors. As gas processing CCUS is largely about 'capturing excess CO_2', it is obvious that CCUS in the sector is not about reducing Scope 3 emissions from the final combustion/use of gas. Rather, it is about minimising production-related Scope 1 emissions from gas with excessive CO_2 content. This is in contrast to most other CCUS applications in the industrial and power sector, which aim to minimise the emissions coming from the end consumption of fossil fuels.

As such, giving the green light to new oil and gas projects just because of CCUS/CCS promises attached to those projects is not climate friendly. Even if the CCS/CCUS facilities work at their capacity (which has not been the case historically, barring some exceptions), such projects could only manage a minor proportion of the value chain emissions of themselves by adding CCS/CCUS.

The gas burnt at the end of the value chain produces the most significant chunk of emissions.

The gas burnt at the end of the value chain produces the most significant chunk of emissions, which CCU/CCUS proposals do not address.

Captured Carbon Has Mostly Been Used for Enhanced Oil Recovery (EOR): Enhancing Oil Production Is Not a Climate Solution

Today, EOR is the only industrial use of CO_2 to have reached a considerable scale. In recent years, EOR projects have used about 73% of the CO_2 captured globally each year. This figure was greater in previous decades.

EOR enhances the oil production rate from fields that have passed the maximum output rate. The basic idea is that oil and gas companies inject the pressurised CO_2 into existing oil and gas reservoirs to squeeze out more hydrocarbons. Oil producers can make money by revitalising oil fields with declining production rates.

EOR itself leads to CO_2 emissions. CO_2-EOR uses carbon dioxide to produce more oil rather than curbing its emissions. The additional oil produced this way either is burned or used for industrial processes, both resulting in CO_2 emissions. Therefore, any claim that CO_2-EOR systems ultimately reduce CO_2 emissions by their nameplate capacity is an overstatement.

About three-quarters of the CO_2 captured annually by multi-billion-dollar CCUS facilities, roughly 28MT out of 39MT total capture capacity, is reinjected and sequestered into oil fields to push more oil out of the ground. This oil then gets refined, burnt and, at least partially, returned to the atmosphere.

IEEFA has estimated that the vast majority of the total captured carbon throughout history found its use in EOR (~80–90%), and a small proportion of carbon capture projects (~10–20%) have stored carbon in dedicated geological structures, without using it for EOR.

Relatively speaking, carbon capture and storage with dedicated geological structures (CCS) is better than CCUS, which is essentially EOR. Any carbon capture project with the final goal of enhancing oil production would not be a climate solution, regardless of whether the carbon capture facility could reach its capture capacity.

Using Carbon Capture as a Greenlight to Extend the Life of Fossil Fuels Power Plants Is a Financial and Technical Risk: History Confirms this

CCS/CCUS for the power sector, one of the most recent proposed applications of carbon capture technology, is more costly and complex than other applications due to the diluted CO_2 in the flue gas stream. This is evident by the string of historical issues in retrofitting CCS/CCUS into power plants with several failed projects and cost blowouts. In contrast to gas processing and certain industrial processes that could generate exhaust gas with 40–90% CO_2 composition, coal plants emit gases that typically only contain 10–14% CO_2, while gas power plants generate 4–5% CO_2. While this may seem small in concentration, it is large in terms of absolute volume globally.

Capturing CO_2 consumes a lot of energy, effectively reducing the amount of electricity delivered to the consumers. This also means that more fossil fuels will need to keep burning to generate the same amount of electricity in a non-CCUS power plant.

Capturing CO_2 consumes a lot of energy.

To compete in a competitive electricity market context, the high cost of CCS/CCUS will need compensation by selling the captured CO_2, receiving government incentives, or charging a premium price to consumers. However, these pathways are not guaranteed and could also lead to financial instability for the project or environmental externalities, especially in the case of using CO_2 for EOR. Government

incentives should instead flow into fast-growing, efficient, and clean renewable energy technologies and the battery and storage sectors.

Further, apart from the financial argument, carbon capture has shown a track record of technical failures since 2000. Close to 90% of proposed CCS capacity in the power sector has failed at the implementation stage or was suspended early.

Some Applications of CCS in Industries Where Emissions Are Hard to Abate (Such as, Cement) Could be Studied as an Interim Partial Solution with Careful Consideration

Industrial applications of CCS are very diverse. Carbon capture is an established business in some industrial applications, such as fertilisers and ethanol, while other applications are exploring it for technical and commercial competitiveness at scale.

The conclusion about whether carbon capture technologies could be part of the solution for the decarbonisation of industries is not that straightforward. Using carbon capture technologies needs careful research for each application in different industries and business environments. In some applications, with the current high commodity prices, using green hydrogen is a better way to go rather than blue hydrogen.

History shows that capturing 90% (or more) of emissions from industrial processes is very unlikely. Hence, betting on blue hydrogen is not a promising solution and only keeps the fossil fuel status quo. Instead, green hydrogen, with its rapidly plunging cost, would be the clean alternative in industries that run or plan to run on hydrogen.

It is, however, worth studying carbon capture as an interim solution in some sectors, such as cement.

This report studies five flagship cases in different sub-sectors that account for about 65% of the total existing industrial carbon capture capacity. Chemical production mainly comprises the production of fertilisers, ethanol, methanol, and syngas. We analyse the CCS application in each sub-sector by reviewing a project in each area. The results are mixed, with most projects underperforming by a considerable margin and few others presenting a relatively better performance. As hydrogen has an important role in many processes in different sub-sectors, pro-fossil fuel groups have pushed for blue hydrogen. However, wherever hydrogen is applicable technically, green hydrogen would be the better solution due to the financial and imminent cost-efficiency.

The final area of focus in the industrial application of carbon capture technology is the steel and cement industry, so-called hard-to-abate industries. Steel and cement are responsible for 13–14% of total global emissions, and the demand for these two materials is increasing. Therefore, decarbonising these two crucial industries is necessary if the world aims to reach net-zero emissions by 2050.

The steel sector is in the early years of utilising carbon capture technology. Studies could be done on probable projects. However, as carbon capture technology in different sectors has *not* reached its target and hopes, investing in such a high-risk, capital-intensive technology in the short time before needing to reach net zero by 2050 does *not* seem to be a sustainable solution. Instead, alternative methods of steel production such as scrap steel recycling emit about 80% less CO_2 per tonne of crude steel than other forms of steel production used today, and green hydrogen leading to the production of "green steel"[215] looks like a more promising method to follow.

The cement industry is somehow different from all of the other applications of carbon capture technology, as CO_2 is an inevitable by-product of chemical reactions in cement production. Carbon capture technologies seem useful in this industry if they aren't used as an excuse to postpone other methods now under investigation to reinvent the processes and make cement production 'green'.

In all of these industrial applications, CCS/CCUS could be studied if:

- it does not promote EOR
- it does not extend or is used as an excuse to extend the life of any type of fossil asset
- a safe storage location is identified, and a long-term monitoring plan and compensation mechanism in case of failure are developed
- the liability of the projects is not handed over to the taxpayers.

Lessons Learned: Insights for the Way Forward

The natural gas processing and power sector, where carbon capture technologies would extend the life of fossil fuel assets (even if its use could overcome historical technical and financial issues), is not in line with net zero goals.

There are a few sub-sectors for industrial application, however, where carbon capture could be considered an interim option for decarbonisation if it doesn't distract the research and development studies being done in parallel to reinvent the production process. Even in such sub-sectors, such as cement, the technical prosperity of the technology is uncertain. Considering the climate clock is ticking, rigorous environmental and technical conditions need to be satisfied if these few applications are to be greenlit.

The application of CCUS/CCS in the steel and cement sector is a relatively new area with only one ~6-year-old operating project in Abu Dhabi with no publicly published data on its performance. Essentially, there is not much to learn from the application of CCS/CCUS in these two industries. However, based on limited knowledge of the technology trajectory in other applications but with common processes as in these industries, as well as other solutions being developed and

[215] Fuel Cells and Hydrogen Joint Undertaking. Making Steel Green Through Hydrogen.

researched in parallel, future CCS/CCUS applications in the steel and cement industry could be projected to some extent.

Green hydrogen or recycling scrap steel should be prioritised in the steel sector over CCUS/CCS to capture carbon from gasification, reformation, or burning fossil fuels.

In the cement sector, as CO_2 is the by-product of the fundamental chemical reaction of producing cement, CCUS/CCS projects could be considered cautiously. Other innovative methods should be pursued to reinvent the whole process toward green cement. Meanwhile, carbon capture could be used as long as the captured carbon is not used for EOR. CCUS/CCS should only be used if the technical performance reaches close to nominal capture capacities, contrasting with general trends of its application throughout history. Also, it could be considered an interim option as long as it does not divert financial flows from fundamental and innovative solutions reinventing the cement production process.

For other industrial applications, wherever hydrogen is applicable technically, green hydrogen seems to be the way to go due to the financial and imminent cost-efficiency.

Appendix 1

Project	Flagship Aspect	Year Capturing Started	Type	Country	Size[216] (Mtpa)	Sector	Performance Against Designed Capture Rate[217]	Comment
Abu Dhabi	The first and only CCS plant in the steel sub-sector	2016	Enhanced oil recovery (CCUS	UAE	0.8	Industrial (hard-to-abate sector)	No data has been published publicly	The project is 100% government owned
Boundary Dam	The only project operating in the power sector worldwide	2014	Mostly enhanced oil recovery (CCUS)	Canada	1	Power sector	Under-performing by about 50%	A 50-year-old coal power plant retrofitted with the carbon capture facility
Coffeyville	The largest project operating in the fertiliser production sub-sector	2013	Enhanced oil recovery (CCUS	U.S.	0.9	Industrial (chemical production)	No public data was found on the lifetime performance. Only some research shows that the plant over-performed during 2017–2019 by about 16%.	The CO_2 was vented until the year 2013, then some agreements with nearby oil companies were finalised to sell the CO_2
Gorgon	Largest and one of the more recent CCS projects in the world	2019	Dedicated geological structure (CCS)	Australia	4	Gas processing sector	Under-performing by about 50%	Started after 3.5 years delay with a track record of technical failures. Compensating under-performance will cost up to US$184 million.
Great Plains	The largest carbon capture project in all sectors other than natural gas processing	2000	Enhanced oil recovery (CCUS)	U.S.	3	Industrial (chemical production)	Lifetime under-performance of 20–30%	The project started capturing CO_2 16 years after the syngas plant was commissioned. In 2022, it has been planned to be redeveloped into a blue hydrogen project.
Illinois Industrial Carbon Capture and Storage (IL-CCS)	The largest and the latest project commissioned in the ethanol production sub-sector	2017	Dedicated geological structure (CCS)	U.S.	1	Industrial (chemical production)	Under-performing by about 45–50%	The project was 68% government funded. It has only captured about 12% of the yearly total CO_2 emissions of the biofuel plant so far
In Salah	One of the largest operating CCS projects of our time	2004	Dedicated geological structure (CCS)	Algeria	1.1	Gas processing sector	Failed after seven years of operation	Started in 2004. Concerns about possible vertical leakage into the caprock led to investigations, and finally, the project was suspended in 2011

[216] There are different sizes for some projects in different sources. In those cases, the average size has been considered.
[217] For some of the projects, scattered data from different sources has been complied to calculate the performance. An estimated interval is provided for the performance.

Kemper	It was planned to be a first-of-a-kind plant, capturing CO_2 from producing gasified coal, and using gas in the modified gas power plant to produce electricity	2014 (without Carbon Capture)	Enhanced oil recovery (CCUS)	U.S.	3	Power sector	Failed to be started	Technical problems led to a 250% increase in the previously estimated cost of the project from U$3b to US$7.5 billion. The carbon capture idea was cancelled in 2017. It was the most expensive power plant ever built.
Petra Nova	The only project in the power sector in the U.S.	2017	Enhanced oil recovery (CCUS)	U.S.	1.4	Power sector	Under-performed by 17% in four years of its operation and then shut down.	It was mothballed indefinitely in 2020 citing low oil prices during the COVID-19 pandemic
Quest	One of the operating projects in the hydrogen production sub-sector operating at its design capacity	2015	Dedicated geological structure (CCS)	Canada	1.1	Industrial (hydrogen production)	Performing close to the capture capacity	The project got off the ground thanks to huge government funding estimated at C$95 per tonne of CO_2 captured until the end of the project's lifetime. It captures 35% of the CO_2 emissions of the oil upgrader.
Shute Creek	Largest and one of the oldest carbon capture projects in the world	1986	Enhanced oil recovery (CCUS)	U.S.	7	Gas processing sector	Lifetime under-performance of 36%	It is estimated that the lifetime under-performance of the project against its capturing capacity is approximately equivalent to the combined emissions from Sweden and Denmark in 2019
Sleipner	First commercial carbon capture project with a dedicated geological structure worldwide	1996	Dedicated geological structure (CCS)	Norway	0.9	Gas processing sector	Performing close to the capture capacity	It is among a few successful cases located in Norway. An exceptionally high carbon tax and stringent regulatory environment linked to the ETS are among the drivers. The gas project is in its tail of production lifetime.
Snøhvit	One of the two successful Norwegian carbon capture projects	2007	Dedicated geological structure (CCS)	Norway	0.7	Gas processing sector	Performing close to the capture capacity	It is one of the successful cases which is located in Norway. An exceptionally high carbon tax and stringent regulatory environment linked to the ETS are among the drivers.

About IEEFA

The Institute for Energy Economics and Financial Analysis (IEEFA) examines issues related to energy markets, trends and policies. The Institute's mission is to accelerate the transition to a diverse, sustainable and profitable energy economy. www.ieefa.org

The health and climate impacts of carbon capture and direct air capture

Mark Z. Jacobson

Data from a coal with carbon capture and use (CCU) plant and a synthetic direct air carbon capture and use (SDACCU) plant are analyzed for the equipment's ability, alone, to reduce CO_2. In both plants, natural gas turbines power the equipment. A net of only 10.8% of the CCU plant's CO_2-equivalent (CO_2e) emissions and 10.5% of the CO_2 removed from the air by the SDACCU plant are captured over 20 years, and only 20–31%, are captured over 100 years. The low net capture rates are due to uncaptured combustion emissions from natural gas used to power the equipment, uncaptured upstream emissions, and, in the case of CCU, uncaptured coal combustion emissions. Moreover, the CCU and SDACCU plants both increase air pollution and total social costs relative to no capture. Using wind to power the equipment reduces CO_2e relative to using natural gas but still allows air pollution emissions to continue and increases the total social cost relative to no carbon capture. Conversely, using wind to displace coal without capturing carbon reduces CO_2e, air pollution, and total social cost substantially. In sum, CCU and SDACCU increase or hold constant air pollution health damage and reduce little carbon before even considering sequestration or use leakages of carbon back to the air. Spending on capture rather than wind replacing either fossil fuels or bioenergy always increases total social cost substantially. No improvement in CCU or SDACCU equipment can change this conclusion while fossil fuel emissions exist, since carbon capture always incurs an equipment cost never incurred by wind, and carbon capture never reduces, instead mostly increases, air pollution and fuel mining, which wind eliminates. Once fossil fuel emissions end, CCU (for industry) and SDACCU social costs need to be evaluated against the social costs of natural reforestation and reducing nonenergy halogen, nitrous oxide, methane, and biomass burning emissions.

Broader context

The Intergovernmental Panel on Climate Change concludes that carbon capture and storage/use (CCS/U) and synthetic direct air carbon capture and storage/use (SDACCS/U) are helpful technologies for avoiding 1.5 °C global warming. However, no study has evaluated their performance or social cost compared with merely replacing fossil with renewable electricity. Here, data from CCU and SDACCU equipment powered by natural gas are evaluated. Only 10.8% of the CCU plant's CO_2-equivalent (CO_2e) emissions and 10.5% of the CO_2 removed from the air by SDACCU are captured over 20 years; only 20–31% are captured over 100 years. Moreover, both plants increase air pollution and social cost *versus* no capture. Powering the equipment with wind instead of gas reduces CO_2e but allows the same pollution as and increases the social cost *versus* no capture. Replacing coal with wind (without capture) reduces CO_2e, pollution, and social cost substantially. In sum, spending on capture rather than wind replacing fossil or bioenergy always increases social cost. No improvement in CCU or SDACCU equipment can change this conclusion while fossil emissions exist. Once fossil emissions end, CCU (for industry) and SDACCU social costs must be evaluated against those of reforestation and reducing nonenergy halogen, nitrous oxide, methane, and biomass burning emissions.

Introduction

Carbon capture and storage (CCS) and use (CCU) involve the installation of equipment in a coal, natural gas, oil, or biomass electric power or heat generating facility to remove carbon dioxide (CO_2) from the exhaust and either sequester it underground or in a material (CCS) or sell it for industrial use (CCU).

Synthetic direct air carbon capture and storage (SDACCS) or use (SDACCU) is the removal of CO_2 from the air by chemical reaction. Upon removal, the CO_2 is either sequestered (SDACCS) or sold (SDACCU). SDACCS differs from natural direct air carbon capture and storage (NDACCS), which is the natural removal of carbon from the air by either planting trees or reducing biomass burning.

Both CCS/U and SDACCS/U have been proposed as technologies to reduce atmospheric CO_2 and global warming. For example, IPCC[1] states that "capture, utilization, and storage" (CCS/U) can help reduce 75–90% of global CO_2 emissions and that it is "technically proven at various scales." They also identify SDACCS as a method to limit warming to 1.5 °C.

Historically, researchers have assumed CCS/U removes 85–90% of CO_2 exhaust with an energy penalty of ~25%.[2–4] An energy penalty is the additional electricity required to run the carbon capture equipment per unit electricity produced by the power plant for normal electricity consumption. However, until recently,[5] no public data from a commercial power plant with CCU were available to test these numbers. Similarly, until recently,[6] no data were available to evaluate an operating SDACCU plant. Models have also not evaluated the social cost of air pollution that CCS/U and SDACCS/U increase due to their energy use. Air pollution already kills 4–9 million people worldwide annually.[7] Evaluating the emissions and social (energy plus health, plus climate) cost of any proposed technology is critical given the enormous cost of eliminating world emissions (~$100 trillion – Table S9 of ref. 8).

Prior studies have also not evaluated the opportunity cost of using renewable electricity to power CCS/U or SDACCS/U equipment instead of using the renewable electricity to displace fossil fuel power plants. Given limited national budgets, the enormous cost of reducing global air pollution and carbon emissions, and limitations in land areas available in each country to install renewables to replace fossil energy, it is essential to compare the air pollution and carbon emissions of using renewables to power carbon capture equipment with, instead, displacing fossil fuel electricity directly with renewables, thus avoiding emissions in the first place.

Coal-CCU plant

This study first quantifies the carbon dioxide equivalent (CO_2e) emissions from a retrofitted pulverized coal boiler connected to a steam turbine at the W. A. Parish coal power plant near Thompsons, Texas. The plant was retrofitted with carbon capture (CC) equipment as part of the Petra Nova project and began using the equipment during January 2017. The CC equipment (240 MW) receives 36.7 percent of the emissions from the 654 MW boiler. The equipment requires about 0.497 kWh of electricity to run per kWh produced by the coal plant (Table 2, footnote g). A natural gas turbine with a heat recovery boiler was installed to provide this electricity. A cooling tower and water treatment facility were also added. The retrofit cost $1 billion ($4200 per kW) beyond the coal plant cost.[9]

CO_2 from the gas turbine is not captured. Natural gas production also has upstream CO_2e emissions, including CH_4 leaks, which are not captured. Upstream CO_2 and CH_4 emissions from the coal plant are also uncaptured. Table 1 shows the January through June CO_2 coal combustion emission data[5] from the plant before (in 2016) and after (in 2017) the addition of the CC equipment. The table also shows the gas combustion emissions from powering the CC equipment. The table then

Table 1 Columns a–d: raw emissions for January through June 2016 and 2017 from the 654 MW (-all-coal) Petra Nova coal-CCU unit.[5] The 2016 data are before carbon capture was added. The 2017 data include combustion CO_2 from the coal plant and, separately, from the natural gas combined cycle turbine installed to run the CC equipment. Columns e–h: emissions (in units of kg-CO_2 per MWh) for the 240 MW (coal-CC) portion of the 654 MW coal unit subject to carbon capture in 2016 and 2017. Column e equals column (a) multiplied by K = 0.4536 kg lb^{-1}. Column f equals $[b - a(1 - F)]K/F$, where b and a are the CO_2 stack emission rates for each month in 2017 (column b) and 2016 (column a), respectively, and F = 0.367 = 240 MW/654 MW is the fraction of the coal unit subject to carbon capture. Column g equals column c multiplied by K/F

translates the emissions from the full 654 MW coal unit to the 240 MW portion of the unit subject to CC. When upstream emissions are excluded, the CC equipment captures an average of only 55.4% (Table 2) of coal combustion CO_2 (rather than 90%) and only 33.9% of coal plus gas combustion CO_2.

Table 2 and Fig. 1 expand results from Table 1 to account for upstream emissions from the mining and processing of coal and natural gas. The CC equipment reduces coal and gas combustion plus upstream CO_2 a net of only 10.8% over 20 years (Fig. 1) and 20% over 100 years. 20 years is a relevant time frame to avoid 1.5° global warming and resulting climate feedbacks.[1]

When wind, instead of gas, is used to power the CC equipment, CO_2e decreases by 37.4% over 20 years and 44.2% over 100 years compared with no CC (Table 2 and Fig. 1). The CO_2e decrease exceeds that in the CCU-gas case because wind powering CC equipment case does not result in any combustion or upstream emissions from wind, as seen in Fig. 1.

However, using the wind electricity that powers the CC equipment instead to replace coal electricity directly at the same plant reduces CO_2e by 49.7% compared with no CC (Table 2 and Fig. 1). It is not 100% because only the wind used to run the capture equipment replaces coal. More wind would be needed to replace the whole coal plant. This third strategy is the best for reducing CO_2e among the three cases. Using solar PV to replace coal directly results in a similar benefit as using wind.

But, CO_2e is only part of the story. Because CCU equipment does not capture health-affecting air pollutants, air pollution emissions continue from coal and rise by about 25% compared with no capture from the use of natural gas to run the Petra Nova equipment (Table 2). Even when wind powers the CC equipment, air pollution from the coal plant continues as before (but not from using the new wind turbine). Only when wind partially replaces the use of coal itself does air pollution decrease by $\sim$50% (Table 2).

The equipment cost of new coal and wind electricity in the U.S. are a mean of \$102 per MWh and \$42.5 per MWh, respectively.[10] The capital cost of CC equipment, \$4200 per kW,[9] is about 74% the capital cost of a new coal plant (\$5700 per kW),[10] suggesting that new coal plus CCU is 1.74 $\times$ \$102 per MWh/\$42.5 per MWh = 4.2 times the equipment cost of new wind. Since CC equipment reduces only 10.8% of coal CO_2e over 20 year and 20% over 100 year, the equipment for coal-CCU powered by natural gas alone costs 39 and 21 times that of wind-replacing coal per mass-CO_2 removed over 20 and 100 years, respectively.

Major additional social costs associated with coal electricity generation are air pollution and climate costs. The health cost of coal emissions in the U.S. is calculated as a mean of \$80 per MWh, which is much lower than the world average (\$169 per MWh, Table 2, footnote m). Since the use of CC equipment requires 50% more electricity than the coal plant produces but the health cost of natural gas emissions are about half those of coal, the use of gas to run the CC equipment increases health costs by $\sim$25% compared with no capture (Table 2, row o). Mean climate costs of U.S. emissions are estimated as \$152 per MWh, close to the world mean of \$160 per MWh (Table 2, footnote m). CC equipment with natural gas is estimated to reduce this cost by only 10.8% and 20% over 20 and 100 years, respectively (Table 2, row n).

In sum, the total social cost (equipment plus health plus climate cost) of coal-CCU powered by natural gas is over twice that of wind replacing coal directly (Table 2 and Fig. 1). Moreover, the social cost of coal with CC powered by natural gas is 24% higher over 20 years and 19% higher over 100 years than coal without CC. Thus, no net social benefit exists of using CC equipment. In other words, from a social cost perspective, using CC equipment powered by natural gas causes more damage than does doing nothing at all.

When wind powers CC equipment, the social costs are still 6% and 2% higher over 20 and 100 years, respectively, than not using CC (Table 2 and Fig. 1). Although wind-powering-CC decreases CO_2e, thus climate cost, compared with coal without CC, wind-CC allows the same air pollution emissions from coal as no CC, and the cost of the wind plus CC equipment outweighs the CO_2e cost reduction (Fig. 1).

Only when wind replaces coal electricity production directly does the total social cost drop 43% compared with no CC (Table 2). This is the best scenario. A similar benefit occurs if wind replaces natural gas and no CC is used.

Some may argue that (a) the six months of data with *versus* without the CC equipment are insufficient for drawing conclusions about this plant and (b) future plants may improve upon the Petra Nova plant. Whereas both points are valid, in order for the social cost of using the CC equipment powered by natural gas to be less than that of doing nothing, the CO_2e reemitted by the Petra Nova plant would need to be 37% or less instead of 89.8% over 20 years. However, this is all but impossible, because 59.2% of the re-emissions is due to upstream coal and gas emissions and natural gas combustion emissions, so little to do with how effective the CC equipment is at capturing carbon. In other words, even if the CC equipment captured 100% of the stack CO_2, which no-one is proposing is feasible, the reemissions would still be 59.2%. This is because controlling 100% of the coal stack emissions can reduce only 40.8% of the total upstream plus stack coal emissions due to the additional upstream and combustion emissions of the gas plant over a 20 year time frame. As such, the data indicate that no technological improvement will result in the social cost of using CC equipment powered by natural gas being less than that of not using the equipment.

When CC is powered by wind, it is theoretically possible, albeit challenging, to reduce the total social cost below that of no CC. However, it is impossible to reduce the total social cost below that of wind replacing coal electricity directly because wind-powering-CC also incurs a CC equipment cost and never reduces air pollution or mining from coal, whereas wind replacing coal incurs no CC equipment cost and eliminates coal air pollution and mining.

SDACCU plant

This section evaluates the efficiency of CO_2 removal from the air by an SDACCU facility,[6] where electricity for the air capture

Published on 21 October 2019. Downloaded by Stanford Libraries on 12/4/2019 4:28:01 PM.

Table 2 Comparison of relative CO_2e emissions, electricity use, and electricity social costs among three scenarios related to the Petra Nova coal-CCU facility, each over a 20 year and 100 year time frame. The first scenario is using natural gas to power the carbon capture (CC) equipment. This is based on data from the Petra Nova facility (Table 1). The second scenario is running the CC equipment with onshore wind instead of natural gas. The third is using the same quantity of wind electricity required to run the CC equipment to instead replace coal electricity from the coal plant. In all cases, the additional energy required to run the CC equipment is equivalent to 49.7% of the energy output of the coal plant (footnote g). The coal plant has a nameplate capacity of 654 MW, but only 240 MW (36.7%) is subject to CC. The numbers in the table are all based on the portion subject to CC. All emission units (including of natural gas emissions) are g-CO_2e per kWh-coal-electricity-generation

[a] Coal upstream emissions are estimated as 27 g-CO_2 per MJ = 97.2 g-CO_2 per kWh.[11] Upstream emissions include emissions from fuel extraction, fuel processing, and fuel transport. Upstream CO_2 emissions (from the portion of the coal plant not replaced) for the wind-replacing some coal cases (last two columns) are the same as in the other cases, but multiplied by 0.503, which equals 1 minus the fraction of coal electricity used to run the carbon capture equipment, which is derived in footnote g. Since the electricity used to run the CC equipment is used to replace coal in this case, upstream coal emissions are reduced accordingly. [b] For coal, the 100 year CO_2e from CH_4 leaks is estimated from (ref. 12, slide 17). The emission factor is derived from that number and the 100 year GWP of CH_4, 34 from ref. 13. The 20 year CO_2e is then derived from the resulting emission factor (4.1 g-CH_4 per kWh) and the 20 year GWP of CH_4, 86. Emissions in the wind cases are reduced as described under footnote a. [c] The average coal stack emission rate for the Petra Nova facility in 2016, prior to the addition of CC equipment, is from Table 1, column e. In the wind-replacing-coal cases (last two columns), the emission rate is reduced as described under footnote a. [d] The coal-stack CO_2 remaining after capture is from Table 1, column f. [e] The natural gas combustion emissions resulting from powering the CC equipment is from Table 1, column g. [f] Natural gas upstream leaks are obtained by dividing the raw emission rate of CO_2 from natural gas for each month January through June 2017 from Table 1 (in kg-CO_2 per MWh-coal-electricity) by the molecular weight of CO_2 (44.0098 g-CO_2 per mol) to give the moles of natural gas burned per MWh-coal-electricity. Multiplying the moles burned per MWh by the fractional number of moles burned that are methane (0.939)[14] and the molecular weight of methane (16.04276 g-CH_4 per mol) gives the mass intensity of methane in the natural gas burned each month (kg-CH_4-burned per MWh-coal-electricity). The upstream leakage rate of methane is then the kg-CH_4-burned per MWh-coal-electricity multiplied by $L/(1-L)$, where $L = 0.023$ is the fraction of all methane produced (from conventional and shale rock sources) that leaks,[15] giving the methane leakage rate in kg-CH_4 per MWh-coal-electricity. This leakage rate is conservative based on a more recent full-lifecycle leakage rate estimate of methane from shale rock alone of $L = 0.035$.[16] Using the latter estimate would result in CCS/U with natural gas re-emitting even more CO_2e than calculated here. Multiplying the kg-CH_4 per MWh-coal-electricity by the 20- and 100 year GWPs of CH_4 (86 and 34, respectively)[13] gives the CO_2e emission rate of methane leaks each month. The monthly values are linearly averaged over January through June 2017. [g] The non-CH_4 upstream CO_2e emissions rate is estimated as 15 g-CO_2 per MJ-gas-electricity = 54 g-CO_2 per kWh-gas-electricity.[11] Multiplying that by 0.497 MWh-electricity from natural gas per MWh-coal-electricity produced gives 26.8 kg-CH_4 per MWh-coal-electricity. 0.497 MWh-electricity from natural gas per MWh-coal-electricity produced, or 49.7%, is calculated by dividing the average gas combustion emission from Petra Nova (200.9 g-CO_2 per kWh-coal from the present table) by the combustion emissions per unit electricity from a combined cycle gas plant (404 g-CO_2 per kWh-natural-gas). [h] The percent CO_2 reemitted for the wind cases (last two columns) equals row k for the wind cases divided by row d for either of the non-wind cases. [i] CO_2e emissions relative to coal with no CC equipment. [j] Air pollution emissions relative to coal with no CC equipment. In the natural gas cases, all air pollution from coal emissions still occurs. Although gas is required to produce 0.497 MWh of electricity for the CC equipment per MWh of coal electricity, gas is assumed to be 50% cleaner than coal, so the overall air pollution in this case increases only 25% relative to the no CC case. In the wind-CC cases, all upstream and combustion emissions from coal still occur. [k] The electricity required (for end-use consumption plus to run the CC equipment) in all CC cases is 49.7% higher than with no CC. In the wind-replacing coal case, no electricity is needed to run the CC equipment, but electricity is still needed for end use. [l] The private energy cost in all CC cases is assumed to be 74% higher than coal with no CC because the CC equipment (including the gas plant) costs $4200 per kW, which represents about 74% of the mean capital cost of a new coal plant ($5700 per kW) from.[10] For simplicity, it was assumed that the cost of a wind turbine running the CC equipment was the same as of a gas turbine running the equipment. In the wind-replacing-coal cases, the cost of coal was assumed to be a mean of c = $102 per MWh and of wind, w = $42.5 per MWh.[10] The final ratio was calculated as $(0.503c + 0.497w)/c$. [m] The social cost before changes is the private energy cost of new coal without CCU [$102 per MWh from ref. 10] plus air pollution mortality, morbidity, and non-health environmental costs of coal power plant emissions in the U.S. plus the global climate costs of U.S. emissions ($152 per MWh).[18] U.S. coal power plant emissions health costs are estimated as $80 per MWh, which is twice the background grid health cost of $40 per MWh.[17] In the worldwide average, from the same source, the health cost of background grid emissions is estimated as $169 per MWh, so use of the U.S. number here is likely to underestimate the health costs of using carbon capture outside the U.S. [n] The social cost after changes is the sum of the private energy cost multiplied by row q, the air pollution health cost multiplied by row o, and the climate cost multiplied by row n.

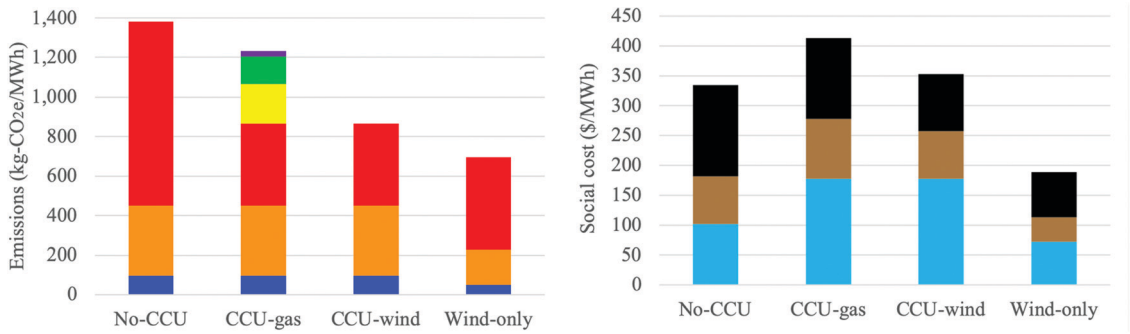

Fig. 1 Left: CO_2e emissions, averaged over 20 years, from the Petra-Nova coal plant before (No-CCU) and after (CCU-gas) the addition of CCU equipment powered by natural gas. Also shown are emissions when the CCU equipment is powered by wind energy (CCU-wind) and when the portion of wind energy used to power the CCU equipment is instead used only to replace a portion of the coal power (thus some power is generated by coal and some by wind). Blue is upstream CO_2e from coal mining and transport aside from CH_4 leaks; orange is upstream CO_2e from coal mining CH_4 leaks; red is coal combustion CO_2; yellow is natural gas combustion CO_2; green is CO_2e from natural gas mining and transport CH_4 leaks; and purple is natural gas mining and transport CO_2e aside from CH_4 leaks. Right: Mean estimate of social costs per unit electricity over 20 years generated by the coal plant (in the first three cases) or the residual coal plant plus replacement wind plant (fourth case) for each of the four cases shown on the left. Light blue is the cost of electricity generation plus CCU equipment; brown is air pollution health cost; and black is 20 year climate cost. All data are from Table 2.

(AC) equipment is provided by a natural gas combined cycle turbine.

Table 3 indicates that, averaged over 20 and 100 years, 89.5% and 69%, respectively, of all CO_2 captured by the AC equipment is returned to the air as CO_2e. The emissions come from mining, transporting, processing, and burning the natural gas used to power the equipment.

In comparison with taking no action, using SDACCU equipment powered by natural gas also increases air pollution due to the combustion and upstream emissions associated with natural gas. With no action, SDACCU further incurs an equipment cost. Thus, although SDACCU powered by natural gas reduces some CO_2e, the equipment cost and air pollution cost far outweigh that decrease, resulting in a near doubling of the total social cost per MWh of electricity use relative to the health and climate cost per MWh of coal power plant emissions (Fig. 2).

Even when zero re-emissions occur, such as when wind powers the SDACCU equipment, the mean social cost of using SDACCU still exceeds that of doing nothing (Fig. 2). On the other hand, using wind to replace coal electricity instead of to run the AC equipment eliminates CO_2e and air pollution emissions and their associated costs from the coal. The resulting social cost is $\sim$15% of that from wind powering SDACCU equipment (Table 3 and Fig. 2). A similar result is found when wind replaces a natural gas plant instead of a coal plant. In fact, there is no case where wind powering an SDACCU plant has a social cost below that of wind replacing any fossil fuel or bioenergy power plant directly. The reasons are that wind-powering-SDACCU always incurs an SDACCU equipment cost that wind alone never incurs and SDACCU always allows air pollution and mining to continue whereas wind always eliminates air pollution and mining.

Discussion

Tables 1–3 suggest virtually no carbon benefit of and greater air pollution damage from CCS/U and SDACCS/U before considering the disposition of the captured CO_2.

Three reasons this result has not been identified previously, aside from the lack of data, are that previous studies and models did not consider upstream fossil emissions, the air pollution social cost resulting from the additional energy needs, or the higher fossil emissions due to using renewable electricity for CC or AC equipment instead of to displace fossil electricity. Air pollutants not captured by CC or AC equipment from fossil or bioenergy plants include CO, NO_x, SO_2, organic gases, mercury, toxins, black and brown carbon, fly ash, and other aerosol components.

Ref. 4 found that even after assuming 90% capture by equipment (and ignoring upstream and combustion emissions to run the capture equipment), renewables return better on investment than CC. The results here suggest that a specific coal-CCU plant reduces only 10.5% and 20% of the plant's overall CO_2e over 20 and 100 years, respectively, while increasing air pollution and land degradation (from additional mining). More than half the re-emissions are due to upstream coal and gas emissions and natural gas combustion emissions to run the CC equipment. In addition, CC always incurs an equipment cost and never reduces air pollution, whereas renewables have no such equipment costs and always reduce air pollution. For all these reasons, renewables replacing fossil fuels or bioenergy are a lower social-cost investment to address climate than even[4] found.

SDACCS/U powered by natural gas similarly increases air pollution by increasing fossil energy consumption and upstream mining. Clean electricity used to run SDACCS/U equipment does not increase air pollution but keeps it the same. However, the social cost of using that clean electricity to replace fossil fuels or bioenergy is always lower than the social cost of using the electricity to run SDACCS/U equipment. The reasons are that SDACCU equipment always incurs a cost that renewables never incur and SDACCU always allows air pollution and fuel mining to continue, whereas renewables eliminate air pollution and fuel mining.

The results here are independent of the fate of the CO_2 after it leaves the CC equipment, thus apply to CC with bioenergy (*e.g.*, BECCS/U) or cement manufacturing. The CC equipment

Table 3 Comparison of relative CO_2e emissions, electricity private costs, and electricity social costs among three scenarios related to the carbon engineering SDACCU plant, each over a 20 year and 100 year time frame. The first scenario is using an on-site natural gas (NG) combined cycle turbine to power the direct air capture (DAC) equipment. The DAC equipment does not capture the gas emissions; if it did, the results would be the same, since if the equipment captured turbine CO_2 emissions, it would not capture the equivalent CO_2 from the air. The third scenario involves using the same wind turbine electricity to instead replace coal power generation without using AC equipment. All emission units (rows a–f, i) are kg-CO_2e per MWh

[a] Ref. 6. Assumes values for DAC with wind electricity are the same as DAC with natural gas electricity. [b] Ref. 19. [c] Same methodology as in Table 2, footnote f, but using the CO_2 combustion emissions from row (b) here. [d] Ref. 11. [e] Assumes wind that would otherwise be used to run the SDACCU equipment instead directly replaces coal electricity, its upstream CO_2 combustion, its upstream CH_4 leaks, and its stack combustion CO_2 emissions. The overall emission rates from coal are obtained from Table 2, row d. [f] Low and high wind electricity costs for wind-replacing coal are from.[10] Others are from the formula provided. [g] The U.S. health cost of $40 per MWh for the background grid per MWh is from ref. 17. [h] The ratio of the health cost in the scenario to that of the background grid is defined as zero for the wind-replacing coal case, since wind produces zero emissions during its operation. In comparison, wind running SDACCU equipment allows those coal emissions, which are about twice background grid emissions per unit energy, to continue, so the factor in that scenario is 2. Natural gas running SDACCU equipment not only allows those coal emissions to continue, but it also produces 50% more emissions, assumed equal to background grid emissions per MWh, so the factor in that scenario is 3. [i] The U.S. climate cost of $152 per MWh for the background grid is from ref. 17 and 18. [j] The ratio of the climate cost of the scenario to that of the background grid is defined as zero for the wind-replacing coal case, since wind produces zero emissions during its operation. For the other cases, it is simply the absolute CO_2e emission reduction in the case minus that in the wind case all divided by that in the wind case, where all values are from row i.

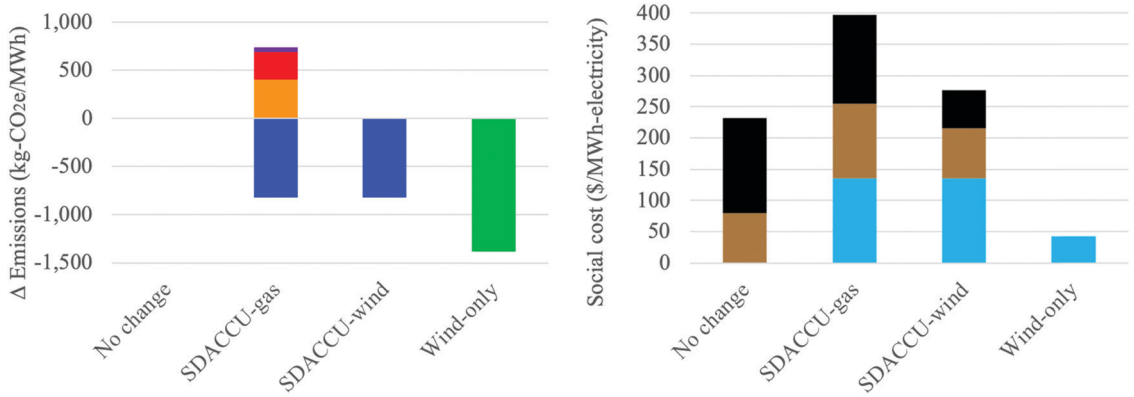

Fig. 2 Left: Change in CO_2e emissions, averaged over 20 years, per unit electricity needed to run SCACCU equipment resulting from either no action (no-change), using an SDACCU plant with equipment powered by natural gas (SDACCU-gas), using an SDACCU plant with equipment powered by wind (SDACCU-wind), and using the same quantity of wind required to run the SDACCU equipment but to replace coal power directly (wind-only). Blue is the removal of CO_2 from the air by the SDACCU equipment; orange is the natural gas turbine emissions; red is the CO_2e from natural gas mining and transport CH_4 leaks; purple is natural gas mining and transport CO_2e aside from CH_4 leaks; and green is the CO_2e emission reduction due to replacing coal power with wind power. Right: Mean estimate of social costs per unit electricity over 20 years for each of the four cases shown on the left. Light blue is the cost of equipment (either air capture equipment plus gas turbine, air capture equipment plus wind turbine, or wind turbine alone); brown is air pollution health cost; and black is 20-year climate cost. All data are from Table 3, except that the costs in the no-change case are the health and climate costs of coal power plant emissions ($80 per MWh health cost and $152 per MWh climate cost – Table 2, footnote m). Such emissions costs are used as the background because the wind-only case removes such emissions.

always requires energy. If the energy comes from a fossil fuel, mining and combustion emissions from the fuel cancel most CO_2 captured. If it comes from a renewable, total social costs are still always greater than using the renewable to replace fossil fuels or bioenergy directly.

When the fate of captured CO_2 is considered, the problem may deepen. If CO_2 is sealed underground without leaks, little added emissions occur. If the captured CO_2 is used to enhance oil recovery, its current major application, more oil is extracted and burned, increasing combustion CO_2, some leaked CO_2, and air pollution. If the captured CO_2 is used to create carbon-based fuel to replace gasoline and diesel, energy is still required to produce the fuel, the fuel is still burned in vehicles (creating pollution), and little CO_2 is captured to produce the fuel with. A third proposal is to use the CO_2 to produce carbonated drinks. However, along with the issues previously listed, most CO_2 in carbonated drinks is released to the air during consumption. In addition, the quantity of CO_2 needed for carbonated drinks is small compared with the CO_2 released by fossil fuels globally.

Another argument for using SDACCS/U is that it will be needed for removing CO_2 from the air once all fossil fuels are replaced with renewables. If renewables are then used to power SDACCS/U they can reduce CO_2 without incurring an air pollution cost. However, the question at that point is whether growing more trees, reducing biomass burning, or reducing halogen, nitrous oxide, and non-energy methane emissions is a more cost-effective method of limiting global warming.

In sum, SDACCS/U and CCS/U are opportunity costs, not close to zero-carbon technologies. For the same energy cost, wind turbines and solar panels reduce much more CO_2 while also reducing fossil air pollution and mining, pipelines, refineries, gas stations, tanker trucks, oil tankers, coal trains, oil spills, oil fires, gas leaks, gas explosions, and international conflicts over energy. CCS/U and SDACCS increase these by increasing energy use and always increase total social costs relative to using renewables to eliminate fossil fuel and bioenergy power generation directly.

This report is developed from information clearly in the public domain. The views expressed in this document represent the opinion of the author.

I. Introduction

Accufacts Inc. ("Accufacts") was asked to review and comment on various aspects related to carbon dioxide transmission pipeline safety and federal pipeline safety regulations within the U.S. In recent years there has been considerable discussion about how to address carbon dioxide emissions and global warming through carbon capture, utilization, and sequestration (aka "CCUS" or "CCS"). CCS efforts are intended to help mitigate climate change by capturing carbon dioxide emissions both before and after they are released to the atmosphere and permanently storing such material deep in underground geological structures.

The federal Pipeline Safety Act ("PSA") directs the U.S. Department of Transportation ("DOT") to issue detailed safety standards with regard to the design, construction, operation, and maintenance of CO_2 pipelines.[1, 2] In turn, the DOT has delegated its authority to the Pipeline and Hazardous Materials Safety Administration ("PHMSA"). The PSA's broad mandate is supplemented by detailed federal regulations.[3] The PSA expressly prohibits state and local regulation that interferes with or supplements federal safety standards for interstate pipelines.[4] States meeting certain conditions may supplement federal pipeline safety regulation on their intrastate pipelines as long as such state regulations are not in conflict with federal pipeline safety regulations.

The U.S. has the most mileage of CO_2 transmission pipelines in the world, consisting of approximately 5,150 miles, out of a total 229,287 miles of hazardous liquid transmission pipelines within the U.S.[5] The vast majority, if not all, of these CO_2 existing pipelines are driven by enhanced oil recovery ("EOR") efforts that increase oil production utilizing CO_2 in a supercritical state. Most of this supercritical state CO_2 comes from high pressure higher purity natural underground source domes. It is an excellent solvent for EOR efforts, but the CO_2 must be injected into oil fields as a supercritical fluid.

CCS efforts are driven by an entirely different purpose such that CO_2 used for CCS could be shipped as a gas or a non-supercritical liquid. However, current federal safety regulations regulate only pipelines that transport supercritical CO_2 containing over 90% carbon dioxide molecules, and not pipelines that ship CO_2 in these other lower concentrations or forms, leaving a large regulatory gap. Moreover, even the regulations for supercritical CO_2 pipelines are incomplete or inadequate and place the public at

great risk, especially from the tens of thousands of miles of CO_2 pipelines that may be driven by CCS efforts.[6]

A flurry of multibillion dollar CO_2 pipeline proposals have recently been announced, likely driven by enhanced tax credit incentives provided by Internal Revenue Code § 45Q.[7, 8, 9] Congress provided these enhancements in the Bipartisan Budget Act of 2018, and expanded by the Infrastructure Investment and Jobs Act of 2021 ("Acts of 2018 and 2021").[10] As intended, these laws accelerated CCS and CO_2 pipeline development efforts, because they make such credits more available and valuable to certain generators of CO_2 emissions and require projects to start construction by January 1, 2026.[11] Since most carbon dioxide emitters are likely considerable distances from suitable deep, permanent underground storage sites, it is understandable that CO_2 transmission pipelines may be needed between emitters and these storage sites. If CO_2 pipeline mileage increases as projected, the CO_2 pipeline network could soon rival the existing oil and natural gas pipeline networks in size and complexity. PHMSA would be faced with the greatest and fastest pipeline expansion in the history of the U.S. pipeline industry, and many of these pipelines could threaten the safety of countless individuals and communities.

This report is intended to increase regulator and public awareness of the regulatory challenges posed by this proposed massive expansion in CO_2 pipeline mileage and the unique safety risks of transporting CO_2, especially in its supercritical state. It focuses on a higher-level review of the more technical pipeline safety matters, based on decades of pipeline safety experience including pipeline failure investigations, process engineering and process safety management practice, as well as years of experience in processing and handling many tons of liquid CO_2. This report also makes specific recommendations for improvements in federal pipeline safety regulations needed to fill regulatory gaps and ensure public safety. The proposed CO_2 pipeline boom presents

PHMSA with an unprecedented challenge; hopefully, this report will help PHMSA rise to this challenge.

II. A brief history of U.S. federal CO_2 pipeline safety regulation

PHMSA and its predecessor agencies, such as the Office of Pipeline Safety, have historically relied on more prescriptive minimum safety approaches. In the past several decades federal minimum pipeline safety regulations have, by the industry's lobbying, shifted to more "performance-based" approaches that rely heavily on certain industry standards or recommended practices, some of which are incorporated by reference into federal pipeline safety regulation.[12] This industry driven shift can result in changes in pipeline safety regulations without proper public input. A prime example may be in the development of CO_2 transmission pipeline safety regulations that historically have been a very small percentage of overall transmission pipeline mileage in the U.S. This country may be facing a significant increase in CO_2 transmission pipeline mileage without appropriate pipeline safety regulatory development or enactment, leaving the country and the public ill prepared for a tsunami of CO_2 pipeline construction.

Congress, in Section 211 of the Pipeline Safety Reauthorization Act of 1988, required that the DOT regulate carbon dioxide transported by pipeline facilities. Part of this concern was driven by a 1986 natural carbon dioxide release event in Lake Nyos, Cameroon spanning many miles with over 1,700 fatalities, underscoring the dangers and possible consequences of CO_2 releases.[13] On July 12, 1991, federal regulators issued a minimalist final rule that mainly added the words "and carbon dioxide" to existing federal minimum pipeline safety regulations developed for hazardous liquid petroleum pipelines (49CFR§195). It opted to not issue standards specifically applicable to supercritical CO_2 pipelines due to the small number of already existing and anticipated CO_2 pipelines. Even though the situation is about to change dramatically, PHMSA has not proposed to review and overhaul its CO_2 pipeline standards, such that these limited regulations are still in effect today.[14] As a result, many of PHMSA's regulations no longer are adequate to protect public safety.

For example, under federal regulations "carbon dioxide" is defined as follows:

> "Carbon Dioxide means a fluid consisting of more than 90 percent carbon dioxide molecules compressed to a supercritical state."[15]

---

[12] 49CFR§195.3 What documents are incorporated by reference partly or wholly in this part?

[13] Federal Register / Vol. 56, No. 113 / Wednesday, June 12, 1991/Rules and Regulations, Research and Special Programs Administration (RSPA), DOT, Docket No. PS-112, Amendment 195-45, RIN 2137-AB72, 49CFR Part 195, "Transportation of Carbon Dioxide by Pipeline," final rule.

[14] *Ibid*, p. 26924.

[15] 49CFR§195.2 Definitions.

The above definition is clearly not appropriate to deal with CCS CO_2 pipelines, nor is that its intent as demonstrated further in this report.

Existing U.S. CO_2 transmission pipelines are primarily located in sparsely developed or more rural locations and, as mentioned previously, involve approximately 5,150 miles moving CO_2 mostly from natural underground sources/domes to EOR projects. The current definition of "carbon dioxide" does not include pipelines that transport supercritical carbon dioxide streams in which CO_2 makes up less than 90 percent of the stream. It also excludes pipelines that transport CO_2 as a non-supercritical liquid or gas. In 1991, there were only a very limited number of pipelines transporting CO_2 in these other forms that apparently didn't justify the need for federal regulation, which is not the case now.

In 2011, Congress, in the Pipeline Safety, Regulatory Certainty, and Job Creation Act of 2011, Section 15, mandated that the Secretary of Transportation "prescribe minimum safety standards for the transportation of carbon dioxide by pipeline in a gaseous state." As a result, PHMSA issued a report in early 2015 entitled "Background for Regulating the Transportation of Carbon Dioxide in a Gaseous State."[16] Unfortunately, PHMSA never issued new regulations for transportation of CO_2 as a gas.

Thus, PHMSA currently has no regulations applicable to pipelines transporting CO_2 as a gas, liquid, or in a supercritical state at concentrations of CO_2 less than 90 percent. This regulatory gap means that current federal pipeline safety regulations are clearly inadequate because CO_2 pipeline companies could develop CO_2 gas and liquid pipelines that fall outside of this narrow federal rule. The definition of "carbon dioxide" should be modified so that all CO_2 transmission pipelines are regulated by federal law and held to appropriate minimum safety standards. Otherwise, CO_2 pipelines could be designed, constructed, operated, and maintained with no federal or state oversight.

III. CO_2 transmission pipelines can take on three basic forms

CO_2 transmission pipelines can be designed to transport carbon dioxide either as a supercritical state fluid, a liquid (aka in a subcritical or chilled state), or as a gas. Within the industry the term "dense phase" is often used to label CO_2 pipelines operating in either a supercritical state fluid or in a liquid phase as explained below. It is odd that the proposed new CO_2 transmission pipeline applications recently reviewed have not clearly stated in what phase they are designed to operate, their temperature ranges, nor their quality requirements.[17] The key characteristics of supercritical, liquid, and gaseous CO_2 transmission pipelines are summarized below.

---

[16] PHMSA report dated February 2015, posted to the 2016 docket under PHMSA-2016-0049-001 at www.regulations.gov.

[17] For example, see Summit Carbon Solutions, "Application to the South Dakota Public Utilities Commission for a Permit for the SCS Carbon Transport LLC (SCS) Pipeline Under the Energy Conversion and Transmission Facility Act – Document Number: SCS-0700-ENV-05-PE-009-A," dated February 7, 2022.

i. Supercritical state CO_2 transmission pipelines

Pure CO_2 has a critical temperature of about 88 ºF (33 ºC) and a critical pressure of approximately 1070 psia, or pounds force per square inch absolute (73 atm). At temperatures and pressures above these critical values, CO_2 is not technically a liquid and instead is in a supercritical state as a dense phase "fluid" or vapor with properties between that of a liquid and a gas. This supercritical fluid will not condense to liquid within the pipeline, as long as the temperature remains above the critical temperature, no matter how high the pressure is increased above the critical pressure. If the temperature along a supercritical state pipeline drops below the critical temperature, part of the fluid will condense to liquid with a higher density than the fluid. If the pressure along a supercritical state pipeline drops below 1070 psia, part of the CO_2 will convert to a gas/liquid mixture depending on the temperature.

The primary reason that the existing 5,000 or so miles of CO_2 pipelines transport CO_2 in a supercritical state is because CO_2 in this state is an excellent solvent having no liquid surface tension. It readily dissolves oil trapped in porous rock. In contrast, CO_2 destined for sequestration could be transported as a gas or liquid, because sequestration does not, as a practical matter, need the CO_2 to be in a supercritical state, and federal law does not require transportation in a supercritical state. In fact, a clever pipeline operator could employ loopholes to avoid federal pipeline safety oversight by PHMSA. Clearly the sources and needs of CO_2 for EOR are not the same as those for the CCS objective, which is to remove CO_2 from the atmosphere.

CO_2 supercritical fluid transmission pipeline operating pressures usually range from 1,200 to 2,200 pounds force per square inch gauge, or psig. The higher pressure is set based on the maximum operating pressure ("MOP") usually related to a pipe specification limit.[18] There are a minor number of CO_2 supercritical state pipelines that have been designed to operate at much higher MOPs (*e.g.*, 3200 psig). Moving CO_2 as a dense phase supercritical state fluid permits the use of pumps along a pipeline instead of compressors that would be needed to move the material if it were a gas. For pipelines, the use of pumps to move higher density fluids requires smaller, less complex, equipment that is more efficient in moving mass along a pipeline than compressors (*i.e.*, pumps are cheaper to build, install, maintain, and operate than compressors). In addition, the higher MOPs of supercritical state CO_2 pipelines permit them to utilize smaller diameter pipe, albeit much stronger pipe, to move the same tonnage of CO_2 as compared to shipment as a gas. In contrast, gas pipelines require larger diameter pipe to move the same tonnage, because they must usually operate at pressures lower than the supercritical pressure (1070 psig), otherwise some of the CO_2 could convert to a liquid

[18] MOP stands for maximum operating pressure for liquid pipelines and is defined in federal minimum pipeline safety regulations that provide conditions for "normal" operation of pipelines. Pipelines are permitted to exceed MOP within certain limits, under certain situations.

(depending on the temperature along the pipeline) and such liquid slugs would severely damage/destroy the compressors used in gas pipelines.

While there are many cost/efficiency advantages to moving CO_2 in a supercritical state, there is one well known threat associated with supercritical state operation. A CO_2 pipeline operating in a supercritical state can be more prone to pipe running ductile fractures than hazardous liquids or natural gas pipelines. Running ductile fractures are unusual and particularly dangerous fractures that can "unzip" a CO_2 transmission pipeline for extended distances exposing great lengths of the buried pipeline. These extreme rupture forces throw tons of pipe, pipe shrapnel, and ground covering, generating large craters along the failed pipeline. It is well known that CO_2 pipelines operating in dense phase, either supercritical or as a liquid, are particularly susceptible to such running ductile fractures. Although current federal regulations recognize this risk, they do not contain any detailed requirements that specifically identify how to address fracture propagation threats. Though there are various approaches well known in the industry (*i.e.*, pipe steel fracture toughness parameters, usually for new pipe, and/or mechanical arrestors such as valves, thicker/tougher pipe transitions) such approaches should be specifically mentioned in safety regulation.[19] To address this risk, PHMSA should revise federal regulations, especially for supercritical CO_2 pipelines, to specifically mitigate the effects of these fracture propagation forces. The current regulations do not adequately address these CO_2 fracture risks.

ii. Liquid CO_2 transmission pipelines

Subcooled or subcritical state means to transport CO_2 as a liquid that usually requires chilling and/or cooling of the stream slightly below ambient temperatures to assure the pipeline is operated in one phase, that of a liquid. For new pipelines this also may require the use of pipeline insulation, though not always, to reduce temperature increase of the CO_2 along the pipeline, assuring it stays as a liquid. It is important that cooling stay well above the pipe carbon steel brittle transition temperature of approximately - 20 ºF to avoid the threat of catastrophic pipeline rupture. Despite these obstacles, transporting CO_2 as a liquid, basically at its highest density, which is typically about double the density of CO_2 fluid in its supercritical state, allows the pipeline transportation of more tonnage of carbon dioxide with even smaller diameter pipe than a supercritical state operation, as well as lower MOPs. Because the liquid phase operation also has a lower viscosity, a liquid CO_2 pipeline system for a given length can utilize a fewer number of pump stations that can have major advantages over supercritical state or gas pipeline approaches needed to move similar tonnage of CO_2. For CCS objectives, liquid phase CO_2 transmission pipelines additional efficiency over their supercritical state or gas counterparts may justify the additional cooling infrastructure along such

[19] 49 CFR§195.111 Fracture propagation. The regulation states in full: "A carbon dioxide pipeline system must be designed to mitigate the effects of fracture propagation." Thus, pipeline safety law contains no detailed standards to prevent running ductile fractures leaving much room for misinterpretation.

pipelines. It is worth emphasizing that PHMSA chose to not issue regulations for CO_2 pipelines designed to operate as a liquid, so such pipelines are currently unregulated.

iii. CO_2 gas transmission pipelines

New pipelines designed to move CO_2 as a gas in a transmission pipeline is not likely, given that the system must be operated at lower pressures. For a CO_2 gas pipeline, the MAOP must not exceed approximately 1,000 psig at normal operating temperatures, so that the CO_2 is maintained as a gas and does not convert to a liquid as this could be disastrous for the pipeline's compressors.[20] For an equivalent daily CO_2 tonnage pipeline capacity, the requirement to keep design pressure lower drives such new gas pipeline approaches to much higher pipe diameters than their liquid or supercritical state pipeline alternatives. However, specific situations may exist where existing liquid or larger diameter natural gas pipelines could be "repurposed" into primarily CO_2 gas service.[21] Such change in service, will most likely be highly limited in its pipeline mileage and, in my opinion, should exceed the requirements identified in ADB-2014-04, addressing repurposing of natural gas pipelines or liquid pipelines. For example, an Advisory Bulletin, or ADB, does not carry the force of promulgated pipeline safety regulation but is issued to more quickly alert pipeline operators of PHMSA concerns on certain issues. ADB-2014-04 does not address, nor was it intended to address, the specific additional challenges associated with unique fracture propagation risks associated with CO_2 transmission pipelines as previous discussed. While there are unique situations where nonoperating or underutilized pipelines exist, there are several factors that can make repurposing of such pipelines to CO_2 gas service economically attractive, given the billions of dollars in tax credit incentives associated with CCS under the Acts of 2018 and 2021, and the associated start construction deadline. The critical deadlines to meet tax credit triggers could make timing of such conversions more favorable than routing and construction of new CO_2 pipelines for CCS. Such pipeline conversions would be at much greater risk of failure from CO_2 service than conventional hydrocarbon or new construction CO_2 pipelines, given the unique and increased potential for CO_2 pipeline ruptures from various risks associated with CO_2 operation. Only time will tell, given the economic temptations and timing thresholds, whether such repurposing of an existing transmission pipeline to CO_2 service will prove practical for CCS utilization.

[20] MAOP stands for maximum allowable operating pressure, which is the standard for gas pipelines and is defined in federal minimum pipeline safety regulations that provide conditions for "normal" operation of pipelines. Pipelines are permitted to exceed MAOP within certain limits, under certain situations.

[21] See DOT PHMSA, Advisory Bulletin, ADB-2014—04, "Pipeline Safety: Guidance for Pipeline Flow Reversals, Product Changes and Conversion to Service," Docket No. PHMSA–2014–0040, Sept 12, 2014.

IV. CO_2 transmission pipelines pose different risks than traditional hydrocarbon transmission pipelines

Carbon dioxide gas is odorless, colorless, doesn't burn, is heavier than air, and is an asphyxiant and intoxicant, making CO_2 pipeline releases harder to observe and avoid especially as a released plume spreads and migrates well off the pipeline right-of-way. CO_2 properties differ from those for materials moved in hazardous hydrocarbon liquid or natural gas transmission pipelines. CO_2 pipeline releases significantly increase the possible "affected" or "potential impact" area identified in federal regulations addressing hydrocarbon transmission pipelines upon pipeline rupture release, and CO_2 pipeline ruptures have a greater potential to endanger the public. Current federal pipeline safety regulations do not incorporate these important CO_2 differences to assure safety to the public. Federal pipeline safety regulatory changes are warranted if CO_2 pipeline mileage is to be increased dramatically in the U.S., especially under CCS. CO_2 transmission pipelines have many unique failure dynamics such that a rupture may impact significantly greater geographic areas than hydrocarbon pipelines. In particular, a combination of CO_2 phase/temperature changes may result in explosive pipe release forces as the CO_2 converts to gas. Moreover, CO_2's lack of odor and invisibility means that it may not be possible for citizens and first responders to determine if they are in a hazard area before they are harmed, unless they have access to a CO_2 detection meter. It is important that anyone using such CO_2 detection meters assure that such equipment has been properly calibrated/maintained and users properly trained in their use and limitations. Once a CO_2 pipeline release has been warmed by the surrounding environment, it travels unseen influenced by gravity, terrain, and the wind, preferentially settling in low spots, displacing air and providing no warning to persons and animals caught in the invisible release plume. Hydrocarbon pipeline releases that haven't ignited, can usually be detected by unusual smell or sight, which makes CO_2 pipeline releases different and harder to detect by emergency responders or the public.

During a CO_2 pipeline rupture release, multiple phase changes can result not only in the significant lowering of temperature near the pipe failure site, but also the likelihood of solid CO_2 formation (i.e., dry ice). Dry ice particles within the fluid can contribute to fogging in the air and ground around the pipeline release, as well as the formation of dry ice within the pipeline upstream/downstream of the pipe failure site that can impact the rate of release out of a pipe failure. Such dry ice blockage can result in temporary restriction/blockage within the pipe, affecting release rate, especially for smaller diameter transmission pipelines experiencing rupture fracture.

In CO_2 pipelines experiencing smaller, slower rate releases, often called leaks, such as through minor holes or cracks, the resulting lower rate CO_2 rich clouds may disperse/dissipate after a short time. In much larger rate releases, such as pipeline rupture fractures caused from various anomalies or pipeline threats, the resulting release of cold gas and dry ice solid mixtures can be quite dangerous (see video of

DNV rupture failure test of an CO_2 8-inch diameter pipeline).[22] The CO_2 released from a pipeline will be heavier than air, and the high-rate release from a pipe rupture will form cold dense gas fog clouds comprised of dry ice particles and visible water vapor as the humidity in the air condenses from the extreme cooling. Such high-rate releases can produce areas of low visibility from "fog," both from dry ice particles and water condensation. The CO_2 pipeline rupture fog becomes transparent when eventually warmed by the surrounding environment. Upon warming, the CO_2 plume can flow considerable distances from the pipeline unobserved, traveling over terrain, displacing oxygen while settling or filling in low spots. Oxygen displacement can starve gasoline or diesel powered equipment, such as first responder and private vehicles, causing such equipment to malfunction or even shut off, and cause pilot lights on furnaces, stoves, and natural gas fireplaces to go out. Oxygen displacement by CO_2 gas can cause asphyxiation of humans and animals, that can lead to death. Further, CO_2 gas can cause disorientation, confusion, and unconsciousness, which can be dangerous for persons caught in the plume, especially those who are driving, using power equipment, or exposed to cold weather. Cooling of a CO_2 release can also impact the rate of release and exacerbate pipe fracture propagation during rupture. Clearly, dispersion modeling for analyzing potential impact areas for CO_2 pipeline failures and their related released gas plumes, must consider the propensity of heavier than air CO_2 gas to displace oxygen and to follow the terrain as terrain factors can play a critical role in evaluating a potential area and receptors that could be affected by a CO_2 pipeline release. It is vitally important to not underestimate the potential distance that a CO_2 pipeline rupture plume can reach and affect, especially in nonlevel terrain. Additional safety margins should be employed in populated areas when using dispersion modeling results for CO_2 pipeline releases.

Before the U.S. is blanketed with a major increase in CO_2 transmission pipeline mileage driven by CCS efforts, substantial changes need to be implemented in federal pipeline safety regulations specifically addressing the unique dangers of CO_2 in transmission pipelines in any phase. CO_2 is not flammable. It doesn't burn or explode/detonate from ignition, so heat radiation is not an issue of concern as in conventional hydrocarbon pipelines. CO_2 can, however, generate similar overpressure "blast" forces upon pipeline rupture (from the high-rate releases associated with pipeline fracture failure, see previous referenced 8-inch CO_2 pipeline rupture test). CO_2 pipeline rupture and resulting rapid "blast like" expansion forces dissipate quickly with distance from the pipeline but can easily extend well beyond the pipeline right of way. The areas potentially impacted by ruptures of oil and gas transmission pipelines are well defined in current federal regulations, which estimate how far liquid hydrocarbon will spread and the blast or burn radius resulting from a natural gas pipeline rupture. The danger zone for human life for hazardous hydrocarbon liquid and natural gas pipeline releases is generally measured in feet, albeit many thousands of feet for larger diameter higher pressure pipelines.

[22] Video of 2013 DNV Spadeadam Research and Testing test experiment of dense phase CO_2 8-inch buried pipeline rupture, https://www.dnv.com/oilgas/laboratories-test-sites/dense-phase-spadeadam-video.html.

In contrast, a CO_2 pipeline's impact area may be measured in miles, not feet. This is likely because:

- CO_2 pipeline ruptures can release many tons of CO_2,
- the compressed CO_2 will expand into gas phase upon pipeline rupture and fill a much larger volume that it did inside the pipe, and
- the CO_2 may not disperse quickly because it is heavier than air, meaning that it will tend to flow toward and settle in low lying areas including ravines, valleys, and basements.

Current federal pipeline safety regulations do not provide any methodology for assessing the hazard zone for CO_2 pipelines or require that pipeline operators adequately address this risk.

V. Impact of impurities on CO_2 pipelines

The amounts and types of impurities in a CO_2 stream can have an impact on pipeline design and approaches. Current CO_2 pipeline regulations, which only address CO_2 pipelines greater than 90% CO_2 concentration compressed to a supercritical state, make no mention as to the level of non-CO_2 impurities such as H_2S, which can be lethal even in very low parts per million concentrations. Also, impurities can affect the range of safe operating pressures. Most of the natural sources of CO_2 for existing pipelines contain CO_2 well above 90%, but this may not be the case for all CO_2 streams captured from industrial facilities. Federal regulation should be modified to adequately regulate CO_2 pipelines used for CCS, and subsequent transportation by transmission pipeline, especially because CCS pipelines may operate differently from those used for EOR. Such federal regulatory improvements should focus on public safety for all forms/phases of CO_2 transmission pipelines. There are some very pure sources of CO_2 emitters, such as ethanol plants and some hydrogen reformers, that emit very high concentrations of CO_2 to the atmosphere that require very little, if any, impurity treatment to prepare for pipeline transportation for CCS.[23] Unlike most of the currently existing CO_2 pipelines whose sources are underground natural gas domes or reservoirs, CSS pipelines may be supplied from various sources where the concentration of CO_2 is quite low and needing concentration, processing, and treatment for contaminant removal before it may be safely transported by pipeline.

There appears to be no transmission pipeline in the U.S. that transports pure CO_2, although there are pipelines that move very high concentrations of CO_2, well above 90%, containing only small levels, of impurities, especially those from natural sources of CO_2. Such CO_2 rich sources can still contain impurities, such as hydrogen sulfide, methane, carbon monoxide, oxygen, nitrogen oxide, sulphur oxide, hydrogen, or

[23] My experience is that purity from such CO_2 specialized emitters can exceed 99.9 % with trace impurities.

water.[24] The types and amounts of impurities in a CO_2 rich pipeline is largely driven by the source of CO_2, and proper operation of associated upstream treatment equipment to assure the material meets pipeline quality specifications, which is not always assured. At relatively low levels of impurities, such as at trace or levels in the lower parts per million, the specific effects of the impurities on the overall stream critical thermodynamic properties (such as enthalpy, entropy, density, and viscosity), are not significantly impacted. However, higher impurity concentrations, such as impurities measured in percentage concentrations should not be ignored as they can impact the critical pressure, but more importantly the critical temperature, such that even a percent or two change in impurity levels can result in unexpected phase change from dense phase fluid to other phases. Such phase changes may impact the system hydraulics, and to some extent the rupture release dynamics should the pipeline fail.

Two impurities that might be possible in CO_2 pipelines merit mention given their unique dangers to pipelines and the public: water and H_2S. CO_2 pipelines are usually made from carbon steel and require special maximum water quality specifications typically measured in the part per million, or its equivalent, that prevents the possibility of free water forming anywhere in the pipeline system. The presence of free water in a CO_2 stream permits the formation of carbonic acid in the pipeline, an acid that has a ferocious appetite for carbon steel. Given the rapidity and unpredictability at which carbonic acid can attack pipelines, prudent CO_2 pipeline operators have voluntarily established maximum water quality limitations for their input streams. Given the risks associated with carbonic acid attack, PHMSA should not leave this critical factor to company discretion, but instead should adopt federal regulations that specify a maximum water quality limitation for CO_2 pipelines.

Hydrogen sulfide, or H_2S, is mentioned here because of a curious item identified in an article related to a supercritical state CO_2 pipeline rupture failure in Mississippi in early 2020.[25] The observations noted in the article by responders of a "green cloud" from the pipeline release, is a possible indication of high levels of H_2S. Further investigation indicates that the source of the CO_2 (Jackson Dome) has levels of H_2S at 5 percent, or 50,000 ppm. In contrast, the Centers for Disease Control and Prevention states that a level of 300 parts per million is "immediately dangerous to life or health."[26] While the H_2S level that transitions into "sour" gas is not defined in federal

[24] For example, see Suoton P. Peletire, Nejat Rahmanian, Iqbal M. Mujtaba, "Effects of Impurities on CO_2 Pipeline Performance, Chemical Engineering Transactions," Vol. 57, 2017.

[25] Dan Zegart Huffpost article, "The Gassing of Satartia," August 26, 2021 at https://www.huffpost.com/entry/gassing-satartia-mississippi-co2-pipeline_n_60ddea9fe4b0ddef8b0ddc8f,

[26] https://www.cdc.gov/niosh/idlh/7783064.html. It is my understanding that while a few states have attempted to impose H_2S limits on intrastate pipelines, there is no such federal pipeline safety regulation limiting H_2S on transmission pipelines, even though there are OSHA H_2S limits on workplace workers, much lower than 300 ppm.

pipeline safety regulations, serious questions need to be raised about this specific CO_2 pipeline operation.

For CCS generated CO_2, from fuel combustion emission, an expected source for CCS, H_2S is not a likely contaminant of the stream with trace levels of H_2S in the less than 1 ppm to be expected. Treatment for the removal of water and water quality enforcement control limitations, however, are critical for CCS pipelines transporting CO_2 from combustion sources. Yet, current federal pipeline safety regulations also do not require that this risk be addressed.

VI. Areas needing additional federal pipeline safety focus for CO_2 pipelines

Based on my experiences, the following are my preliminary observations on specific areas where CO_2 pipeline safety regulation improvement efforts should focus.

1. **PHMSA should update the definition of carbon dioxide in current regulation.**
   The current "carbon dioxide" definition incorporated into pipeline safety regulation is driven by EOR and does not or may not apply to all CO_2 pipelines that may be developed for CCS projects. Federal regulations need to be modified to assure that federal standards apply to all CO_2 transmission pipelines that transport CO_2 for CCS projects, including all supercritical, gas, and liquid CO_2 transmission pipelines.

2. **PHMSA needs to identify in regulation the potential impact areas for CO_2 pipeline ruptures.**
   The unique, and potentially very large impact areas for CO_2 pipeline ruptures need to be developed, defined, and promulgated into pipeline regulations. As mentioned previously, these areas are most likely to be measured in miles, not feet.

3. **Specific CO_2 pipeline federal regulations should not be based solely on industry Recommended Practices.**
   Changes in the CO_2 pipeline safety regulation are needed and should be prescribed to avoid misinterpretation or misuse. Recent efforts by many in the industry to rely on more performance-based standards, even those incorporated by reference, have proven ineffective and disastrous. Such industry efforts also remove an important party to pipeline safety regulatory development, the public. Ironically, it is the public that has the most to lose from inadequate pipeline safety regulation if such referenced citations are not clear, relevant, effective, and cannot be enforced in assuring pipeline safety.

4. **PHMSA should specifically identify how to incorporate fracture propagation protection on CO_2 transmission pipelines.**
   Given the differential propensity for CO_2 pipelines to propagate fractures along the pipeline upon rupture, regulations should specifically list pipeline design methods to arrest CO_2 fracture propagation.

5. **PHMSA should mandate the use of odorant injection into CO_2 transmission pipelines.**
   Given the inability to detect or observe a CO_2 pipeline release, it is time to require the use of odorant injection in such pipelines, especially those pipelines that are not in unpopulated areas, to assist the public in identifying dangerous releases.

6. **PHMSA should require CO_2 pipeline operators to update their required procedural manuals related to coordination with local emergency response agencies for CO_2 pipeline ruptures.**
   The major differences and uniqueness of CO_2 pipeline releases compared to hydrocarbon pipelines require that pipeline operators improve the sections of their federally mandated operation, maintenance, and emergencies procedural manuals for emergency response to CO_2 pipeline ruptures.[27] In particular, operators must be required to periodically and fully inform, train, and equip key local officials and emergency responders with regard to special response actions unique to CO_2 pipeline releases. Moreover, upon a rupture, pipeline operators must inform state and local emergency personnel so that they can quickly and adequately protect impacted citizens and themselves.

7. **PHMSA should establish regulations setting specific maximum contaminant impurities for CO_2 pipelines.**
   Given the various sources and the unique risk associated with the introduction of water into a CO_2 pipeline, PHMSA should prescribe the maximum concentration of water allowed in them. This requirement goes well beyond a quality specification given the ability of water to rapidly cause CO_2 pipeline failures in unpredictable ways. Given the wide range of impurity sources for CO_2 streams for CCS, PHMSA should review a full range of limits for all common impurities and consider establishing maximum levels for all impurities that pose a safety risk in federal pipeline safety regulations.

8. **PHMSA should strengthen federal regulations for conversion of existing pipelines to CO_2 pipeline service.**
   It is not clear whether the public interest is best served by CO_2 shipment in existing transmission pipelines converted to CO_2 service. Further, the general conditions of PHMSA's advisory bulletin are not adequate for conversion to CO_2 pipelines. PHMSA should fully investigate the risks of such conversions and issue regulations appropriate to the serious risks that could result from repurposing a pipeline for CO_2 service.

VII. Conclusions

Current federal minimum pipeline safety regulations focus on higher concentration CO_2 pipelines transporting CO_2 in a supercritical state for use in oil production. Such

[27] 49CFR§195.402 and 49CFR§192.605 Procedural manual for operations, maintenance, and emergencies.

regulations are incomplete or in conflict with the intent of CCS, to reduce CO_2 content in the atmosphere to address global warming. Federal pipeline safety regulation concerning CO_2 pipelines need specific changes to address the likely expansion of CO_2 transmission pipeline mileage expected by CCS efforts enhanced by the Acts of 2018 and 2021.

Certain manufacturing processes, such as ethanol and some hydrogen reforming refinery units, produce CO_2 emission that are very pure CO_2, with only trace amounts of contaminants, that are higher priority choices for CCS and associated pipelines, most likely new liquid transmission pipelines, especially under the immense tax credits associated with the Acts of 2018 and 2021. Current federal pipeline safety regulations, however, are not adequate to deal with the additional pipeline risks associated with the expected significant increase in associated CO_2 transmission pipelines under CCS.

The country is ill prepared for the increase of CO_2 pipeline mileage being driven by federal CCS policy. Federal pipeline safety regulations need to be quickly changed to rise to this new challenge, and to assure that the public has confidence in the federal pipeline safety regulations.[28]

Carbon capture and storage (CCS) is considered a key technology for reducing CO_2 emissions into the atmosphere. Nonetheless, there are concerns that if injected CO_2 migrates in the crust, it may trigger slip of pre-existing faults. In order to test if this is the case, covariations of carbon, hydrogen, and oxygen isotopes of groundwater measured from Uenae well, southern Hokkaido, Japan are reported. This well is located 13 km away from the injection point of the Tomakomai CCS project and 21 km from the epicenter of September 6th, 2018 Hokkaido Eastern Iburi earthquake (M 6.7). Carbon isotope composition was constant from June 2015 to February 2018, and decreased significantly from April 2018 to November 2019, while total dissolved inorganic carbon (TDIC) content showed a corresponding increase. A decrease in radiocarbon and $\delta^{13}C$ values suggests aquifer contamination by anthropogenic carbon, which could possibly be attributable to CCS-injected CO_2. If such is the case, the CO_2 enriched fluid may have initially migrated through permeable channels, blocking the fluid flow from the source region, increasing pore pressure in the focal region and triggering the natural earthquake where the brittle crust is already critically stressed.

Keywords: Hokkaido earthquake, carbon capture and storage-CO_2 injection, groundwater, carbon isotopes, radiocarbon

INTRODUCTION

There is a global consensus that some form of carbon capture and storage (CCS) technology is necessary to reduce CO_2 emission associated with fossil fuel combustion into the atmosphere (IPCC Special Report, 2005). The majority of research into this technology has focused on securely isolating CO_2 from the Earth's surface and storing it in a reservoir which is sealed by an impermeable cap rock (Johnson et al., 2005; Michael et al., 2011). This strategy should prevent CO_2 from leaking into the closest areas around the injection well but it may promote horizontal flow of CO_2-rich fluids through available permeable horizons. Interactions between injected fluids and high angle faults may result in

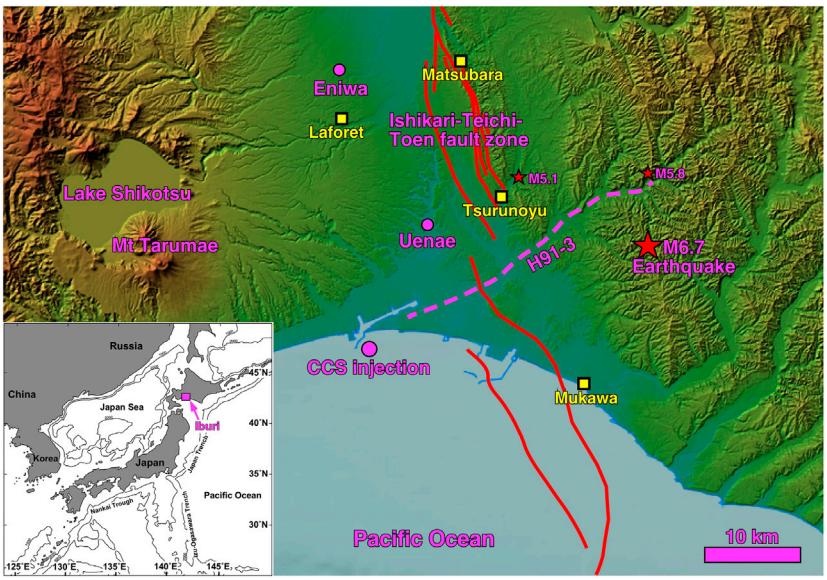

FIGURE 1 | Location of Uenae and Eniwa sampling wells in the Hokkaido Iburi region; the CCS-CO_2 injection point (purple dots); and main shock epicenter (M6.7) of the 2018 Hokkaido Eastern Iburi earthquake (red star). Two additional red stars denote the epicenters of the M5.1 earthquake on July 1st, 2017 and of the largest (M5.8) aftershock on February 21st, 2019. The red lines represent active faults in the Ishikari-Teichi-Toen fault zone (ITTFZ). The purple dashed line denotes the seismic reflection transect H91-3. Yellow squares show hot springs sampled for helium isotopes. The inset map shows the location of the Iburi region in Hokkaido, Japan.

fluid accumulation and increases in pore pressure in the region around the area. This increase in pressure may propagate to much deeper regions where the brittle crust is already critically stressed and perhaps trigger slippage of pre-existing faults (Zoback and Gorelick, 2012). This mechanism is similar to the triggering of anthropogenic seismicity during high-pressure hydraulic injection experiments (Grigoli et al., 2018). However, to date, there are no case studies reported on the possible environmental consequences of CCS-CO_2 injection.

The 2018 Hokkaido Eastern Iburi earthquake (M6.7) occurred on September 6th, 2018 in Northern Japan, close to the major active Ishikari-Teichi-Toen Fault Zone (ITTFZ), with a focal depth of 37 km (Asano and Iwata, 2019). The earthquake triggered large landslides and caused severe damage to the surrounding area with 36 casualties. Uniform strain accumulation was observed in this area from data collected by a global navigation satellite system in very recent years (Ohzono et al., 2019). The large-scale Tomakomai CCS demonstration project, built in the same region, was initially suspected to have indirectly caused the earthquake (KIKO network, 2019). The Japan CCS Co. Ltd.—the company that developed the project - reported that the CO_2 injection point was too far from the epicenter to produce any appreciable amount of strain change or to induce an earthquake (Japan CCS, 2019). However, many concerns still exist regarding the potential relationship between large-scale CO_2 injection and local earthquakes, and given that there is little consensus as to the potential consequences, further study is needed. Deep wells close to the CCS site may provide direct evidence of the CO_2 leakage that can potentially trigger natural earthquakes.

GROUNDWATER SAMPLES

We collected groundwater samples from wells used for producing commercial bottled mineral water at Uenae and Eniwa sites, located 13 and 29 km from the CCS Tomakomai site, respectively (**Figure 1**). Commercial water has a precise production date and both the chemical compositions and stable isotopic composition are well preserved (Tsunogai and Wakita, 1995; Onda et al., 2018), with the exception of helium because of the high permeability of this gas through PET bottles. We purchased as many bottles as possible covering a period of three years before and a year and half after the M6.7 earthquake. Both wells are 90–100 m deep and tap a volcanic-sedimentary aquifer belonging to the Shiatsu pyroclastic flow, which erupted in the Late Pleistocene (Nakagawa et al., 2018). High-quality drinking

mineral water is available from altered ignimbrite units. Chemical compositions of representative samples from Uenae and Eniwa sites are listed in **Table 1** together with temperature and pH. Twenty-one untreated bottled water samples were analyzed for carbon, hydrogen and oxygen isotopes. The samples cover the period from June 2015 to February 2020, and include the critical period between April 2016 and December 2019, when a total of 300 kilotons of CO_2 were injected, as well as the timing of the M6.7 Hokkaido earthquake event in September 2018.

Carbon, Hydrogen, Oxygen, and Helium Isotopes, and ^{14}C Activity Measurements

We have carefully selected unopened mineral water bottles to avoid contamination by air CO_2, which has a different isotopic composition than dissolved carbonates. Carbon isotopes were measured at the Atmosphere and Ocean Research Institute, University of Tokyo, Japan with a conventional continuous flow mass spectrometer (Delta V plus, Thermo Fisher) after standard decarbonation with phosphoric acid. Experimental details followed the methodology provided in Zhao et al. (2019). The $^{13}C/^{12}C$ ratios were calibrated against our in-house standard, converted to conventional V-PDB units, and expressed as δ values in per mil (‰). Total Dissolved Inorganic Carbon (TDIC) concentrations were estimated by a peak height method with standard samples of known amounts of TDIC. Experimental errors on carbon isotopes and TDIC concentrations were calculated by repeated measurements of standard samples. Hydrogen ($^2H/^1H$) and oxygen ($^{18}O/^{16}O$) isotopes of water were measured with a cavity ring-down spectrometer without any preprocessing at Geotop, Université du Québec à Montréal, Canada, using a Los Gatos LGR-T-LWIA-45-EP, and then verified at the Atmosphere and Ocean Research Institute, University of Tokyo, Japan (Onda et al., 2018) using a L2120-I Analyzer (PICARRO Co. Ltd.). They were calibrated against in-house standards, converted to the conventional V-SMOW units, and expressed as δ values in per mil (‰). Experimental errors on hydrogen and oxygen isotopes were calculated by repeated measurements of standard samples. TDIC was precipitated and purified. It was then reduced into pure amorphous carbon and the $^{14}C/^{12}C$ ratios were measured with a compact AMS system at the Institute of Surface-Earth System Science, Tianjin University, China (Dong et al., 2019). Extracted helium and neon from spring water samples were purified with hot Ti getters and charcoal traps held in liquid nitrogen. The $^4He/^{20}Ne$ ratios were measured by online QMS, and helium was separated from neon by a cryogenic charcoal trap. The $^3He/^4He$ ratios were measured with a noble gas mass spectrometer (Helix SFT, Thermo Fisher). Experimental details are provided in Sano et al. (2008).

Tomakomai Carbon Capture and Storage Demonstration Project

A large-scale CCS demonstration project was undertaken by the Japanese government in the Tomakomai site in Hokkaido, Japan (**Figure 1**). Intensive stakeholder engagement was implemented by the Japan CCS company because the operation was taking place in the port area close to a highly populated city. The CO_2 source was offgas derived from a hydrogen production unit of an oil refinery located in the region. A high purity CO_2 (>99%) was recovered from the offgas by an amine scrubbing process and the gaseous CO_2 was compressed and then injected into two different offshore geological reservoirs (Yamanouchi et al., 2011; Sawada et al., 2018). The host reservoirs are the shallow Moebetsu Formation located at a depth of approximately 1000 m below the seabed and the deep Takinoue Formation with the depth of 2400 m. The former is a Lower Quaternary saline aquifer composed of 200 m thick sandstone, while the latter is a Miocene saline aquifer which consists of volcanic and volcaniclastic rocks with a thickness of 600 m. A schematic diagram of geological section is referred from Tanaka et al. (2017) and reproduced in **Supplementary Figure S1**. The CO_2 injection of the shallow reservoir started in April 2016 and continued until November 2019. A total of 300 kilotons of gaseous CO_2 was injected gradually (**Supplementary Figure S2**). A smaller amount of CO_2, approximately 100 tons, was injected into the deeper reservoir.

DISCUSSION

Temporal Variations of Stable and Radioactive Isotopes in Groundwater

The $\delta^{13}C$ values and the TDIC contents, δ^2H and $\delta^{18}O$ values, and ^{14}C activity were measured in commercially-bottled groundwater as stated above, and are listed in **Table 2**. The $\delta^{13}C$ value of the TDIC in Uenae well groundwater was constant at −17.8 ± 0.2‰ from June 2015 through February 2018, and then decreased to −18.8 ± 0.2‰ with some fluctuation (**Figure 2A**). The TDIC concentration at Uenae was also constant from June 2015 to February 2018, and increased significantly in December 2018, which is the inverse of the observed trend for $\delta^{13}C$ (**Figure 2B**). On the other hand, the $\delta^{13}C$ of TDIC in groundwater from the Eniwa well decreased over time, from −18.5‰ to −20.9‰, except for October 2017, while TDIC concentration remained constant at 0.68 ± 0.03 mmol/L, except for the most recent sample. Injected CO_2 was the by-product of a hydrogen production unit of an oil refinery (Sawada et al., 2018). Its $\delta^{13}C$ value should therefore have been lighter than −25‰ (Hoefs, 2018) and its ^{14}C activity close to zero, because fossil fuels are too old to contain any anthropogenic ^{14}C. Injection began in April 2016 and reached 100 kilotons of CO_2 in November 2017 (**Supplementary Figure S2**), which is approximately one third of the total injected amount (Tanaka et al., 2014; Japan CCS, 2020). There was no heavy rain or flooding in the region during this period. Additionally, there is no large bridge or dam construction close to the observation wells that could have altered the groundwater system and triggered the earthquake (Gupta and Iyer, 1984). The Uenae site is located in non-volcanic frontal arc region, even though it is close to the volcanic front. There is no known cause, and no physical or chemical processes, capable of changing geochemical parameters such as carbon isotopes of groundwater except for oxidation of organic matter.

**Experimental errors of each values are as follows: δ^2H (0.6‰), $\delta^{18}O$ (0.2‰), $\delta^{13}C$ (0.2‰), TDIC (0.2 mmol/L).*

There may be a deep magmatic carbon component in the region close to Uenae (Marumo et al., 1995; Nitta and Inoue, 2011). The $\delta^{13}C$ values of approximately −4‰ in magmatic CO_2 is much heavier than that of present groundwater TDIC. Addition of a magmatic component should increase $\delta^{13}C$ values of our samples. However this is not the case. The observed increase in TDIC contents at Uenae may be attributable to the CO_2 injected at the Tomakomai site, because of the concomitant decrease in $\delta^{13}C$ (**Figure 2A**), which is also observed in the ^{14}C activity of the total carbonate (**Supplementary Figure S3**). It is possible to calculate $\delta^{13}C$ values of CO_2 in the samples under the chemical and isotopic equilibrium of groundwater (Barbieri et al., 2020). When we take into account the mass balance equation of TDIC, Mg^{2+}, Ca^{2+}, SO_4^{2-} using data set of **Table 1** and assuming the $\delta^{13}C$ value of −7‰ in local carbonate rock (Nitta and Inoue, 2011), $\delta^{13}C$ values of hypothetical CO_2 gas in the Uenae sample would become approximately −50‰, much lighter than those of present groundwater TDIC. This may be attributable to the discrepancy between the referred local carbonate and the true $\delta^{13}C$ value of calcite in aquifer system.

At the Uenae site, both δ^2H and $\delta^{18}O$ groundwater values were constant at −60.1 ± 0.5‰ and −8.52 ± 0.15‰, respectively, from June 2015 to February 2018 (**Figures 2C,D**). These values then fluctuated and decreased significantly down to −62.2‰ and −9.3‰, respectively, from April 2018 to December 2018. These variations are similar to those of the carbon isotopes, and may be attributable to groundwater mixing with light δ^2H and $\delta^{18}O$ of summer precipitation in the region (Kawaraya et al., 2016; **Supplementary Figure S4**). At Eniwa, δ^2H values decreased slightly from −62.8‰ to −64.3‰ and consistently from June 2016 to February 2020, while $\delta^{18}O$ values remained constant with the value of −9.43‰ except for the most recent sample of −9.98‰. These oxygen isotope values may be explained by the mixing of local surface meteric water and a deep high temperature water (Nitta and Inoue, 2011).

Potential Triggering Mechanism of the Hokkaido Earthquake

Previous studies have indicated a high probability that earthquakes are triggered by the injection of large volumes of CO_2 into the brittle crust (Zoback and Gorelick, 2012; Nicol et al., 2011). In this case study, the possible link between groundwater geochemical anomalies, the Hokkaido earthquake, and the CCS-CO_2 injection was examined. **Figure 3** shows a schematic vertical cross-section of the studied region before the CCS CO_2 injection of April 2016 (Stage 1), including two features: **Figure 3A** (top) is P-wave velocity (Vp) structure of the crust and uppermost mantle in the region (Kobayashi et al., 2019). A part of this figure (red square) is enlarged in **Figure 3B**, which shows geological structure of the seismic section along H91-3 in **Figure 1** (Yokokura et al., 2014). The CO_2 injected in the Moebetsu and Takinoue Formations are shown by broken curves. ITTFZ and Uenae indicate the major active fault system and the monitoring well, respectively. There may be upward natural fluid flows by buoyancy through a fault system as well as permeable aquifer (black arrows in **Figures 3A,B**) where a deeper flow (**Figure 3A**) was suggested by a seismological study (Hua et al., 2019). The upper boundary of Takinoue Formation is consistent with the active fault in the left side of diagram, but it is discrepant in the right. The branch position is approximately 1 km left side beneath the Uenae site.

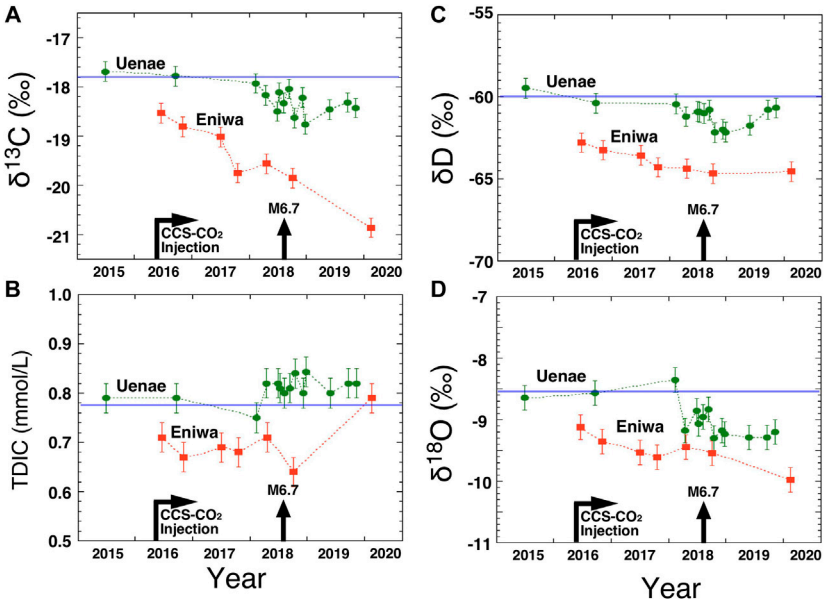

FIGURE 2 | Temporal variations of **(A)** $\delta^{13}C$ values of total carbonate in mineral water **(B)** total dissolved inorganic carbon (TDIC) concentration (mmol/L), **(C)** $\delta^{2}H$, and **(D)** $\delta^{18}O$ values of mineral water. Error bars show 2σ values. Blue lines represent averages of three samples (2015, 2016, and april 2018) from the Uenae well. Start dates of CCS-CO_2 injection and origin time of M6.7 earthquakes (M6.7 in **Figure 1**) are indicated by arrows in **(A)** and **(D)**.

Figure 4 shows the cross-section of two years after the injection of CO_2 (Stage 2), which is also immediately before the M6.7 earthquake. This indicates a geochemical model explaining the possible role of CO_2 in triggering the M6.7 earthquake, together with the distribution of earthquake occurred in the region and the hypothetical CO_2 accumulation zone. A large amount of CO_2, up to the 100 kilotons injected by the Tomakomai CCS project at the time, may have accumulated below the cap rock. Regional CO_2 monitoring indicates no apparent CO_2 leakage immediately above or in the vicinity of the cap rock (Sawada et al., 2018; Japan CCS, 2019). Long before the M6.7 earthquake, a seismic reflection survey was conducted along transect H91-3 by the National Institute of Advanced Industrial Science and Technology, AIST (Yokokura et al., 2014), as illustrated in **Figure 1**. The seismic survey revealed a low-angle fault, starting from the CCS-CO_2 injection area and dipping eastward (orange dotted line in **Figures 3A**,**4A**,**5A**). Generally speaking, a fault plane is a mechanically weak and possibly a more permeable surface than the surrounding region. There was upward natural fluid flow though the low-angle fault and Takinoue Formation (black arrows in **Figure 3B**). Injected CO_2 of Takinoue layer could be dissolved in local saline groundwater and make a high-pressure gas-water mixture, which can not go downward but may have temporally interrupted the fluid flow and the internal pressure could be buildup in the region. The increased pressure may propagate into deeper part, that is reverse direction of natural fluid flow, subject to the trajectory of pink dotted arrows in **Figures 4A,B**. Then dilatation may occur in the fault system (Arrows in circles in **Figure 4B**). The presence of this increase of pore pressure is suggested by the increase of natural earthquakes that took place along the fault in 2017 and 2018, when compared to those in 2016 (see **Supplementary Figure S5**).

The major part of the CO_2 injected in the Moebetsu Formation may be mixed with saline water which subsequently moved along the permeable layer towards the east as indicated by green arrow in **Figures 4A,B**. Most of the CO_2-fluid (gas-water mixture) may arrive at the area beneath the Uenae site, where there is no permeable connection between the Moebetsu Formation and shallow volcanic-sedimentary aquifer. Our sampling well taps the latter aquifer. Some part of CO_2-fluid may travel further eastward and will arrive at the region beneath the ITTFZ. When the high-pressure fluid encountered another high angle fault, which is possibly part of the ITTFZ, the CO_2-fluid may have accumulated in the region (**Figures 4A,B**), building up the pore pressure. There may be a pre-existing fault closer to the seismogenic fault of the M6.7 earthquake, at the western edge of the low-Vp zone (**Figure 4A**). In addition, low Vp/Vs was identified east of the slip area, suggesting the presence of water or fluid (Kobayashi et al., 2019). Before the M6.7 earthquake, there may have been natural upward fluid flow in the region parallel to the seismogenic fault (Hua et al., 2019). When the anthropogenic CO_2-fluid accumulated above this area, natural fracture flow may have been blocked, increasing pore pressure in the region. This increase as well as hydrological perturbations in the Takinoue Formation may have propagated to a much deeper region, and high pressure finally arrived at the focal zone of the M6.7 earthquake, again this is the reverse direction of natural fluid flow (dotted line in **Figure 3A**). It may have induced dilation of fault system and then have triggered the natural slip of pre-existing faults in a region where the brittle crust was already critically stressed.

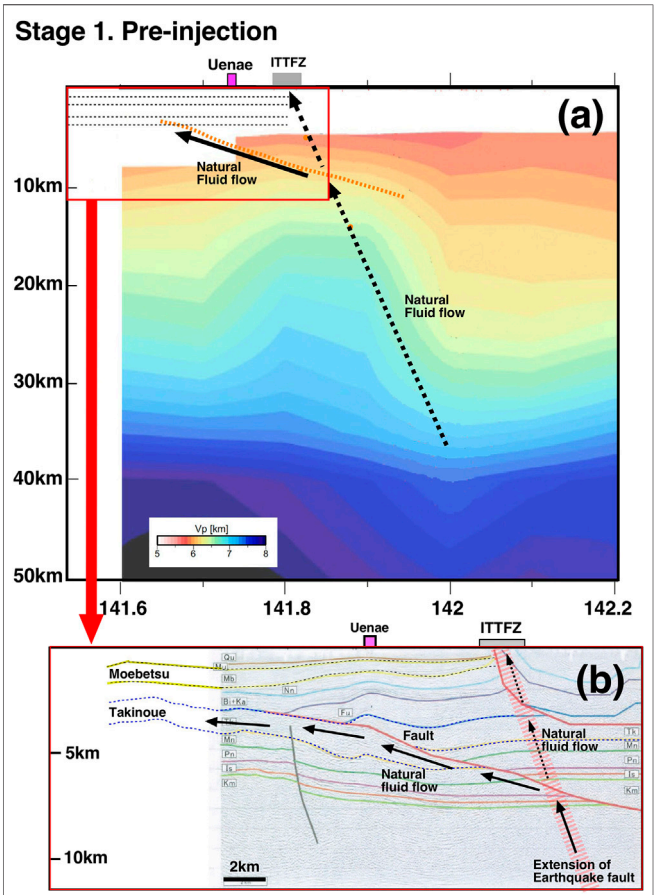

FIGURE 3 | Schematic vertical cross-section of the Hokkaido Iburi region along the H91-3 seismic profile of **Figure 1**, and its extension southwest and northeast before CCS-CO_2 injection **(A)** P-wave velocity (Vp) structure of the crust and uppermantle in the region. The orange dotted curve shows a fault determined by seismic reflection survey, which corresponds to the red solid line in bottom figure. The black solid and dotted arrows show possible natural fluid flows in the region supported by a seismological study. **(B)** Modified subsurface structure of the seismic section along H91-3 in **Figure 1** reported by Yokokura et al. (2014). Red square of top figure is enlarged here. The red solid line is the active fault. Uenae and ITTFZ denote the position of Uenae site and ITTFZ.

Part of CO_2-fluid may have ascended through the ITTFZ fault zone by buoyancy and introduced into the Shiatsu aquifer at a 90–100 m depth, where the Uenae monitoring well draws groundwater (green arrows in **Figures 4A,B**). The increase in TDIC concentration and the concomitant decrease in $\delta^{13}C$ values and ^{14}C activity in the Uenae mineral water would be caused by the injected low-$\delta^{13}C$ and ^{14}C-free CO_2. Concordant with the TDIC concentration and carbon isotopic variation, both $\delta^{2}H$ and $\delta^{18}O$ values also decrease over time (**Figure 2**). Their relationship has a slope of 2.2 in the $\delta^{18}O$-$\delta^{2}H$ diagram (**Supplementary Figure S4**), departing from the Global Meteoritic Water Line, which has a slope of 8. This suggests that the water carrying the injected CO_2 may have a low $\delta^{18}O$ value, and is then mixed with Uenae groundwater, which recharges possibly in the region (**Supplementary Figure S4**).

Figure 5 shows the cross-section after the M6.7 earthquake. The aftershock distribution of the M6.7 event coincides closely with the seismogenic fault. It is worth noting that the extension of the seismogenic fault estimated from the source fault model (Asano and Iwata, 2019) of the M6.7 earthquake (solid red line in **Figure 5A**) connects the epicenter with the ITTFZ at the surface (wide dotted red line; **Figure 5B**). Aftershocks of the M6.7 event terminated at a depth of ~10 km, where the pore pressure was high and the region may be ductile due to the interruption of natural fluid flow by CO_2 injection. After the earthquake, new fluid flow may occur beneath the ITTFZ (**Figures 5A,B**), which will be discussed in the latter section.

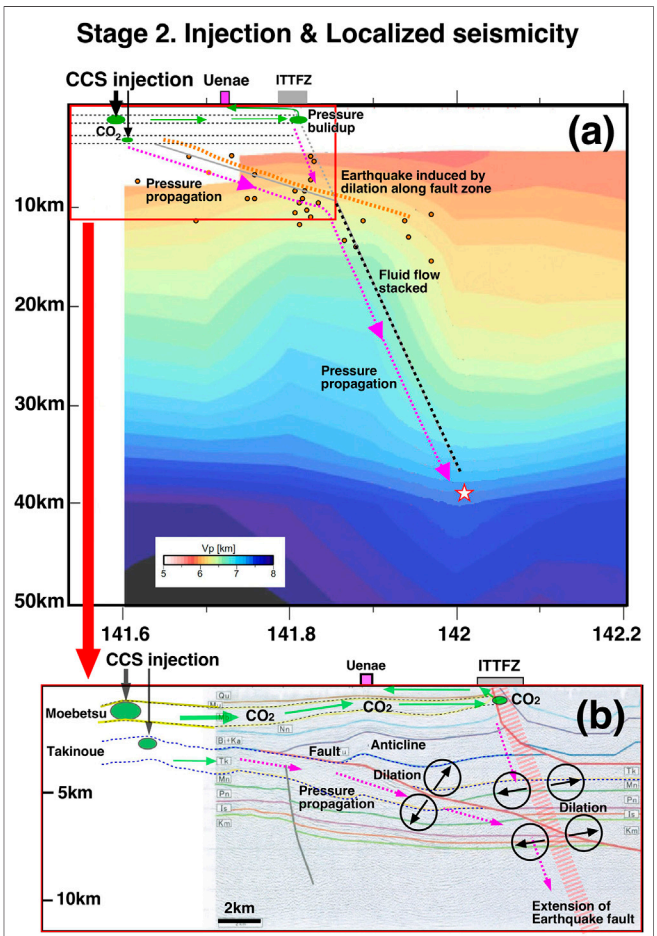

FIGURE 4 | Schematic vertical cross-section of the Hokkaido Iburi region along the H91-3 seismic profile of **Figure 1**, and its extension southwest and northeast in two years after CCS-CO_2 injection and immediately before the M6.7 earthquake **(A)** P-wave velocity (Vp) structure of the crust and upper mantle in the region. The red dotted arrows and gray thin line show possible pressure propagation and a pre-existing fault in the region, respectively. The orange dotted curve denotes a fault found by seismic reflection survey. Orange dots are possibly induced earthquakes by dilation along fault zone. **(B)** Modified subsurface structure of the seismic section along H91-3 in **Figure 1** reported by Yokokura et al. (2014). Red square of top figure is enlarged here. The green solid arrows and red dotted arrows show movement of CO_2 fluid and direction of pressure propagation, respectively. Arrows in circles indicate the dilation due to pore pressure.

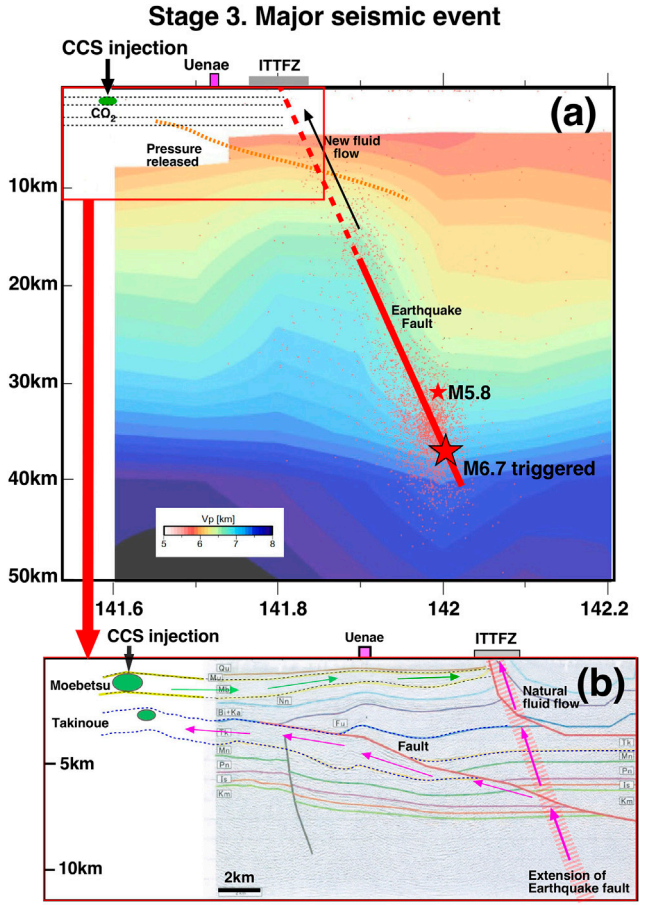

FIGURE 5 | Schematic vertical cross-section of the Hokkaido Iburi region along the H91-3 seismic profile of **Figure 1**, and its extension southwest and northeast soon after the M6.7 earthquake **(A)** P-wave velocity (Vp) structure of the crust and uppermantle in the region. The red solid line and dotted line show earthquake fault and hypothetical new fluid flow, respectively. The orange dotted curve denotes a fault found by seismic reflection survey. Distributions of small red dots are aftershocks. A large red star indicates the position of main shock (M6.7). **(B)** Modified subsurface structure of the seismic section along H91-3 in **Figure 1** reported by Yokokura et al. (2014). Red square of top figure is enlarged here. The red solid arrows and green arrows are direction of CO_2 fluid movement and possible pressure propagation.

Velocity of Anthropogenic Fluid Flow

In the proposed geochemical model, the velocity of the CO_2-fluid flow should correspond with the sequence of events (i.e., the injection of CO_2, the groundwater anomaly, and the M6.7 earthquake) for it to be considered realistic (**Figures 3–5**). In the case of the Uenae well, the carbon anomaly began in April 2018, while CO_2-injection began in April 2016. The total distance from the CCS injection point to Uenae is estimated to be ca. 30 km along the trajectory of movement simulated in the model (green arrows in **Figure 4A**). The average fluid velocity is then calculated to be approximately 40 m/day. This value is higher than the typical confined groundwater velocity of 1 m/day (Shibasaki, 1981), but is consistent with the maximum velocity calculated for Japanese sedimentary basins of 40 m/day (Shibasaki, 1981) and the value > 50 m/day of volcanic CO_2-fluid flow observed at the 1986 eruption of Izu-Oshima volcano in Japan (Sano et al., 1988; Sano et al., 1995). If we assume a velocity of 40 m/day, the first phase of injected CO_2 may have arrived at the build up and accumulation zone (**Figure 4A**) in September 2017, which is one year before the M6.7 earthquake. This may have been a sufficient amount of time for pore pressure to build up in the deep focal region. Considering a high-pressure injected CO_2 and enhanced permeability along the fault plane, one may assume a faster velocity than 40 m/day, similar to the case of above Izu-Oshima volcano. During the great 2011 Tohoku-Oki earthquake (Mw 9.0), a velocity of 4 km/day was estimated for the upward migration of mantle fluids along the fault plane at the subducting plate interface (Sano et al., 2014). This value is two orders of magnitude greater than 40 m/day. If this higher fluid flow rate is applied to our model, the injected CO_2-fluid phase could have reached the accumulation point within 5 days of injection. On the other hand, a groundwater flow rate from ITTFZ to the Uenae well may be slower than 40 m/day. Therefore, either groundwater anomalies might have not yet have appeared in the more distant Eniwa well after the M6.7 earthquake, because the distance between the two wells is ca. 20 km (**Figure 1**), or significant increase of total carbonate in February 2020 (**Figure 2B**) may be due to the CCS-CO_2 injection.

**ASW correction is following Sano and Fischer (2013).*

Natural Fluid Flow Paralleling the Seismogenic Fault

For the model to be valid, it must be assumed a fluid flow through a pre-existing fault plane (**Figures 3A,B**), before the M6.7 Eastern Iburi earthquake. The fluid in the source zone may have originated from the dehydration of the subducting Pacific slab beneath southern Hokkaido, a phenomenon clearly identified by low-seismic velocity anomalies, high attenuation, and high Poisson's ratio (Hua et al., 2019). Tomography suggests that the fluid from the slab dehydration ascended through the forearc mantle wedge and then entered the seismogenic fault in the crust, triggering the 2018 Eastern Iburi earthquake. The same mechanism also caused the 1995 M7.2 Kobe earthquake (Zhao et al., 1996), as well as the

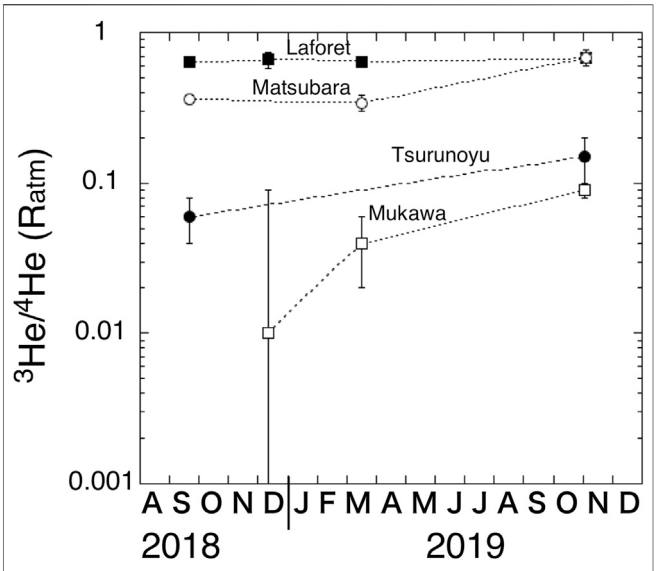

FIGURE 6 | Temporal variations of air-corrected ^{3}He/^{4}He ratios and normalized to the air ratio (Ratm = 1.382 × 10^{-6}), measured in natural springs after the M6.7 earthquake at Mukawa, Tsurunoyu, Matsubara, and Laforet in Hokkaido, Japan. Error bars are 2σ.

2000 M7.3 western Tottori earthquake and the 2016 M6.6 central Tottori earthquake in southwestern Japan, where the Philippine Sea plate is subducting (Zhao et al., 2018). If this is the case, the deep fluid would have a mantle helium signature with a high ^{3}He/^{4}He ratio (Sano and Fischer, 2013). We collected hot and mineral spring water samples from four sites around the ITTFZ after the M6.7 Eastern Iburi earthquake (**Figure 1**) and measured the ^{3}He/^{4}He and ^{4}He/^{20}Ne ratios at different sampling times (**Table 3**; **Figure 6**). At three sites close to the ITTFZ (Matsubara, Tsurunoyu, and Mukawa), the air-corrected ^{3}He/^{4}He ratios increased significantly after the M6.7 earthquake. In September 2018, the ^{3}He/^{4}He ratio is 0.36 ± 0.03 Ra at Matsubara and 0.06 ± 0.02 Ra at Tsurunoyu. Immediately after the M6.7 earthquake, in November 2019, the ratio increased to 0.68 ± 0.08 Ra at Matsubara and 0.15 ± 0.05 Ra at Tsurunoyu; it was 0.01 ± 0.08 Ra at Mukawa in December 2018, but increased to 0.09 ± 0.01 Ra in November 2019. In contrast, the ratio is almost constant, at 0.66 ± 0.04 Ra, at the Laforet site located far from the ITTFZ (**Figure 1**). These results suggest that a mantle helium component was slightly enriched in the ITTFZ subsurface region fluids after the M6.7 earthquake. Before CCS-CO_2 injection, there may have been steady state fluid flow including a small mantle helium component (**Figures 3A,B**). Immediately before and during the M6.7 event, the natural fluid flow may have been interrupted by high pore pressure caused by CO_2 accumulation (**Figures 4A,B**). Consequently, the surface manifestation of mantle helium may have ceased or have been weakened. After the M6.7 earthquake, new channels may have been created from the deep crust to the ITTFZ subsurface region. The ^{3}He/^{4}He ratios of natural springs then increased significantly because of the connection to the mantle source (**Figure 6**). Therefore, the overall variation of the measured helium isotopes in groundwater supports the proposed geochemical model of the M6.7 Eastern Iburi earthquake triggering.

Relationship Between δ^{13}C and ^{14}C Activity of Groundwater Carbonate

There is a simple correlation between observed δ^{13}C values and ^{14}C activity of total carbonate in groundwater samples from the Uenae well (**Supplementary Figure S6**) with a correlation coefficient, r^2 = 0.85. There may be three independent carbon components in subduction-type region (Sano and Marty, 1995): 1) surface carbon (a mixture of organic and marine carbonate carbon) with intermediate δ^{13}C (−10‰ in surface meteoric water by Nitta and Inoue, 2011) and high ^{14}C; 2) anthropogenic (CCS injection) carbon with low δ^{13}C (−25‰) and low ^{14}C; and 3) deep-seated carbon (possibly derived from the mantle) with high δ^{13}C (−6‰) and low ^{14}C. The correlation between δ^{13}C and ^{14}C may be explained by the binary mixing of the surface and anthropogenic CCS carbon from September 2016 to May 2019. Even though there is an increase of mantle helium component in hot and mineral springs close to the ITTFZ region (**Figure 6**), a substantial amount of deep-seated carbon was not introduced into the Uenae aquifer after the M6.7 earthquake, which should have made the δ^{13}C value higher. This mechanism should be studied more precisely in future work.

CONCLUSION

In conclusion, secular variations of carbonate contents, carbon isotopes (δ^{13}C), and ^{14}C activity in groundwater at the Uenae well, southern Hokkaido, Japan may have some relation to the CO_2 injection from the Tomakomai CCS demonstration project in the area. Considering the position of the pre-existing fault, the natural earthquakes that occurred between 2016 and 2017, and the crustal structure of the region, the injected CO_2 fluid may have interrupted a natural fluid flow in the deep Takinoue Formation and may have increased pore pressure in the area. The injected CO_2 fluid in the shallow Moebetsu Formation, may have flowed into the region just beneath ITTFZ region. The accumulation of CO_2-fluid could have potentially interrupted the natural upward fluid flow, thereby increasing the pore pressure in the focal area, and possibly triggering the 2018 Hokkaido Eastern Iburi earthquake. A part of CO_2-fluid may be incorporated in the aquifer of the Uenae site and may have induced chemical and isotopic variations of the groundwater. Future projects should consider regional sampling of noble gas and stable isotopes to confirm the potential influence of carbon sequestration on seismicity.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/**Supplementary Material**, further inquiries can be directed to the corresponding author.

AUTHOR CONTRIBUTIONS

YS designed the study. YS, TK, TS, and A-TC conducted field trips and sample collection. KS measured carbon isotopes and carbonate

contents in groundwater. NT analyzed groundwater oxygen and hydrogen isotopes. NT, TK, and A-TC measured helium isotopes and helium/neon ratios of hot spring samples. SX analyzed C-14 of carbonate in groundwater. JY and YN provided geological interpretations of the area. J-OP and DZ provided the seismological model and implication. YS, GS and DP wrote the manuscript. All authors contributed to the final manuscript preparation.

FUNDING

This work was partly supported by a research grant from the Japan Society for the Promotion of Science (17H00777).

ACKNOWLEDGMENTS

We gratefully acknowledge the regional mineral water companies for groundwater sampling. We thank KT for reviewing the paper and TM for help with analyzing hydrogen and oxygen isotopes of water samples. J-FH is thanked for hydrogen and oxygen isotopic analyses at Geotop in Montreal, Canada. We thank reviewers for constructive comments.

IEEFA op-ed: Reality of carbon capture not even close to proponents' wishful thinking

Guest editorial in the Denver Post by IEEFA's director of resource planning analysis, David Schlissel

August 4, 2019 (Denver Post) — Jon Caldara's op-ed on **Xcel's Colorado Energy Plan** attacks the utility company and the broader environmental community, saying that the latter is motivated primarily by feelings of virtue rather than cold hard facts. Guess what? The facts are not in Caldara's favor.

The only evidence Caldara presents for his opposition to the planned closure of two of the Comanche coal-fired plants is a study done for the U.S. Department of Energy by a former DOE employee.

Worse, a detailed review of the study shows that it is fatally flawed, based on overly optimistic and unsupported assumptions about the construction costs of carbon capture equipment as well as the effectiveness of such technology.

Further, the DOE-commissioned study completely ignores the fact that the financial viability of the entire project depends on being able to sell the captured carbon dioxide (CO_2) for use in enhanced oil recovery activities. When the additional oil produced through this oil recovery is burned or used as a chemical feedstock, it, in turn, would emit substantial amounts of CO_2, thereby offsetting reductions in emissions at the plant.

On the cost question, the DOE-commissioned report rests on the assumption that the carbon capture equipment could be built for 45 percent less than the only comparable unit currently operational in the U.S., a much smaller facility in Texas called Petra Nova that was launched late in 2016. The Petra Nova facility cost $1 billion (or roughly $4,400 per installed kilowatt). The DOE study asserts that the Comanche project could be built for just $2,450 per kw — but offers no evidence to support such a drastic reduction in cost.

The study also asserts that, on average, the Comanche plant would operate with a 75 percent capacity factor (that is, it would produce 75 percent of the electricity it is theoretically capable of producing during a given year) after the carbon capture retrofits are completed. A check of actual plant operating data conducted by the Institute for Energy Economics and Financial Analysis shows that since 2010 it has only achieved a 75% capacity factor in a single year — to assume that Comanche would perform this well on a consistent basis after all the new CO_2 capture equipment is installed is highly unrealistic.

Similarly, officials from the DOE have reported that the average cost of capturing CO_2 at Petra Nova is about $60 per ton. However, again with no actual experience on which to base its analysis, the study assumes that the cost of capturing CO_2 at Comanche can be cut to between $36.42 and $39.70 per metric ton — a reduction of about 40% made, not by hands-on experience but by computer keystrokes.

Some of this assumed cost reduction can be traced to the study's projection that the new Comanche CO_2 capture equipment will operate at 90% effectiveness. When NRG built the Petra Nova plant it made similar projections.

However, results from the first two years of full operation show that the Texas facility captured between 65% and 70% of the CO_2 at the plant, and that does not take into account the emissions from the natural gas turbine used to run the carbon capture equipment. Factoring those emissions into the equation lowers the effective capture rate to about 50%.

Performance at another plant, this one in Saskatchewan, Canada, has been similar. That plant, Boundary Dam Unit 3, was also built with the promise that it would capture 90% of the unit's annual emissions, but overall, the plant has a capture rate of about 51%.

Here again, reality trumps Caldara's wishful thinking. If Caldara is truly interested in cold hard facts, he would be better off doing a little more research.

*This article appeared in the Denver Post on August 4, 2019 under the headline: **Reality of carbon capture not even close to proponents' wishful thinking**. David Schlissel was invited to submit a response to an editorial by Jon Caldera that argued against the closure of two coal-fired power plants and in favor of funding carbon capture storage to make the plants more economically viable. The original article was entitled: **Xcel Energy should consider carbon capture to save the planet and our pocketbooks**

Stanford study casts doubt on carbon capture

Current approaches to carbon capture can increase air pollution and are not efficient at reducing carbon in the atmosphere, according to research from Mark Z. Jacobson.

BY TAYLOR KUBOTA

One proposed method for reducing carbon dioxide (CO_2) levels in the atmosphere – and reducing the risk of climate change – is to capture carbon from the air or prevent it from getting there in the first place. However, research from **Mark Z. Jacobson (https://profiles.stanford.edu/mark-jacobson)** at Stanford University, **published (https://pubs.rsc.org/en/content/articlelanding/2019/ee/c9ee02709b/unauth#!divAbstract)** in *Energy and Environmental Science*, suggests that carbon capture technologies can cause more harm than good.

"All sorts of scenarios have been developed under the assumption that carbon capture actually reduces substantial amounts of carbon. However, this research finds that it reduces only a small fraction of carbon emissions, and it usually increases air pollution," said Jacobson, who is a professor of civil and environmental engineering. "Even if you have 100 percent capture from the capture equipment, it is still worse, from a social cost perspective, than replacing a coal or gas plant with a wind farm because carbon capture never reduces air pollution and always has a capture equipment cost. Wind replacing fossil fuels always reduces air pollution and never has a capture equipment cost."

(https://news.stanford.edu/wp-content/uploads/2020/10/Roadmap-featured.jpg)

Research by Mark Z. Jacobson, professor of civil and environmental engineering, suggests that carbon capture technologies are inefficient and increase air pollution. Given this analysis, he argues that the best solution is to instead focus on renewable options, such as wind or solar, replacing fossil fuels. *(Image credit: Getty Images)*

Jacobson, who is also a senior fellow at the **Stanford Woods Institute for the Environment (http://woods.stanford.edu/cgi-bin/index.php)**, examined public data from a coal with carbon capture electric power plant and a plant that removes carbon from the air directly. In both cases, electricity to run the carbon capture came from natural gas. He calculated the net CO_2 reduction and total cost of the carbon capture process in each case, accounting for the electricity needed to run the carbon capture equipment, the combustion and upstream emissions resulting from that electricity, and, in the case of the coal plant, its upstream emissions. (Upstream emissions are emissions, including from leaks and combustion, from mining and transporting a fuel such as coal or natural gas.)

Common estimates of carbon capture technologies – which only look at the carbon captured from energy production at a fossil fuel plant itself and not upstream emissions – say carbon capture can remediate 85-90 percent of carbon emissions. Once Jacobson calculated all the emissions associated with these plants that could contribute to global warming, he converted them to the equivalent amount of carbon dioxide in order to compare his data with the standard estimate. He found that in both cases the equipment captured the equivalent of only 10-11 percent of the emissions they produced, averaged over 20 years.

This research also looked at the social cost of carbon capture – including air pollution, potential health problems, economic costs and overall contributions to climate change – and concluded that those are always similar to or higher than operating a fossil fuel plant without carbon capture and higher than not capturing carbon from the air at all. Even when the capture equipment is powered by renewable electricity, Jacobson concluded that it is always better to use the renewable electricity instead to replace coal or natural gas electricity or to do nothing, from a social cost perspective.

Given this analysis, Jacobson argued that the best solution is to instead focus on renewable options, such as wind or solar, replacing fossil fuels.

Efficiency and upstream emissions

This research is based on data from two real carbon capture plants, which both run on natural gas. The first is a coal plant with carbon capture equipment. The second plant is not attached to any energy-producing counterpart. Instead, it pulls existing carbon dioxide from the air using a chemical process.

Jacobson examined several scenarios to determine the actual and possible efficiencies of these two kinds of plants, including what would happen if the carbon capture technologies were run with renewable electricity rather than natural gas, and if the same amount of renewable electricity required to run the equipment were instead used to replace coal plant electricity.

While the standard estimate for the efficiency of carbon capture technologies is 85-90 percent, neither of these plants met that expectation. Even without accounting for upstream emissions, the equipment associated with the coal plant was only 55.4 percent efficient over 6 months, on average. With the upstream emissions included, Jacobson found that, on average over 20 years, the equipment captured only 10-11 percent of the total carbon dioxide equivalent emissions that it and the coal plant contributed. The air capture plant was also only 10-11 percent efficient, on average over 20 years, once Jacobson took into consideration its upstream emissions and the uncaptured and upstream emissions that came from operating the plant on natural gas.

Due to the high energy needs of carbon capture equipment, Jacobson concluded that the social cost of coal with carbon capture powered by natural gas was about 24 percent higher, over 20 years, than the coal without carbon capture. If the natural gas at that same plant were replaced with wind power, the social cost would still exceed that of doing nothing. Only when wind replaced coal itself did social costs decrease.

For both types of plants this suggests that, even if carbon capture equipment is able to capture 100 percent of the carbon it is designed to offset, the cost of manufacturing and running the equipment plus the cost of the air pollution it continues to allow or increases makes it less efficient than using those same resources to create renewable energy plants replacing coal or gas directly.

"Not only does carbon capture hardly work at existing plants, but there's no way it can actually improve to be better than replacing coal or gas with wind or solar directly," said Jacobson. "The latter will always be better, no matter what, in terms of the social cost. You can't just ignore health costs or climate costs."

This study did not consider what happens to carbon dioxide after it is captured but Jacobson suggests that most applications today, which are for industrial use, result in additional leakage of carbon dioxide back into the air.

Focusing on renewables

People propose that carbon capture could be useful in the future, even after we have stopped burning fossil fuels, to lower atmospheric carbon levels. Even assuming these technologies run on renewables, Jacobson maintains that the smarter investment is in options that are currently disconnected from the fossil fuel industry, such as reforestation – a natural version of air capture – and other forms of climate change solutions focused on eliminating other sources of emissions and pollution. These include reducing biomass burning, and reducing halogen, nitrous oxide and methane emissions.

"There is a lot of reliance on carbon capture in theoretical modeling, and by focusing on that as even a possibility, that diverts resources away from real solutions," said Jacobson. "It gives people hope that you can keep fossil fuel power plants alive. It delays action. In fact, carbon capture and direct air capture are always opportunity costs."

Bearing the Cost of Stored Carbon Leakage

Adriano Vinca[1,2]*, *Johannes Emmerling*[1,3] *and Massimo Tavoni*[1,3,4]

Carbon capture and sequestration (CCS) is considered a key technology for stabilizing climate change. However, leakage of CO_2 from stored carbon can potentially undermine the value of carbon storage as a mitigation option. Thus, monitoring and verifiability of CO_2 storage should be encouraged through policy provisions such as accounting and pricing of leaked emissions. Here we assess different institutional and economic mechanisms for accounting for carbon leakage. Using an integrated assessment model we quantify the impacts on the climate, the economy and the mitigation strategies. Results show that carbon leakage can reduce the share of fossil based CCS by up to 35%, if it is controlled and correctly priced. Biomass based CCS is less affected. Accounting for leakage leads to an increase of climate policy costs of up to 0.4 percentage points due to increased emissions.

HIGHLIGHTS

- Carbon leakage from CCS can lead to up to 25 $GtCO_2$ of additional emissions throughout the twenty-first century for a leakage rate of 0.1% per year.
- CCS deployment is lowered, by as much as 30% (Fossil) and 10% (BECCS), when leakage is taken into account.
- Carbon prices increase by around 5 per cent. Overall policy costs increase by about 0.2–0.4 percentage points.
- If not taken into consideration nor priced, leakage contributes to an additional 0.01–0.02 degrees of temperature increase.
- China, Latin America, the U.S., and Canada have the highest expected leakage.

1. INTRODUCTION

The increasing awareness of possibly irreversible damages of global warming has pushed both public opinion and governments toward the support of increasingly stringent climate mitigation measures. However, the path toward climate change policies is correlated to both technological and economic challenges (IPCC, 2014). Among typical mitigation strategies, Carbon Capture and Storage (CCS) and Carbon Dioxide Removal (CDR) represent valuable alternatives to renewable energy sources. According to existing studies IPCC (2014), the CCS potential will have an important role in reducing the carbon intensity of electricity. CCS might thus represent a considerable share

of emission reduction in the energy sector (Metz et al., 2005; Finkenrath, 2011; NAS, 2015; GCCSI, 2016).

CCS and CDR can also help reduce the costs of mitigation. Nonetheless, their development has not been as fast as expected in the last decades (Davidson et al., 2017). This low deployment can be associated with the absence of adequate incentives, lack of public acceptance, and to technological uncertainties associated with CCS (IEA, 2016; Lipponen et al., 2017). Among these barriers, carbon leakage from stored CO_2 could counteract the usefulness of carbon sequestration to help limiting global temperature increase (van der Zwaan and Smekens, 2009). In this paper, we analyze the impact of CO_2 leakage on the propsects of CCS in the power sector and the economic costs of mitigation[1].

We evaluate different policy provisions to help take leakage into account. Several problems can arise with leakage. Estimating its size is difficult and costly, since monitoring techniques have focused on small scale case studies so far (Romanak et al., 2012; Dethlefsen et al., 2013). A second source of uncertainty is related to the economic liability of leaked emissions (Wilson et al., 2003; Imbus et al., 2013). Finally, leakage might depend on the stringency of the climate policy. To address these questions, we use an integrated assessment model to examine three main dimensions: climate targets, leakage rates and policy provisions to counteract it. We consider the 2 and 1.5°C temperature increase targets by 2100, a range of possible leakage rates consistent with the literature, and different cases of pricing and liability of carbon leakage in the atmosphere. On this last point, we analyze whether leaked CO_2 is (a) not monitored nor taken into account in the carbon budget, (b) taken into account for the chosen carbon budget, but not priced at the carbon price, e.g., due to institutional or technological constraints, or (c) taken into account in the carbon budget and priced at the carbon price. These three cases allow us to disentangle the importance of monitoring and pricing leaked emissions.

2. BACKGROUND INFORMATION

2.1. CO_2 Transportation and Storage

Carbon dioxide, once removed from the exhaust gases of a power plant, can be re-used for industry purposes or stored (GCCSI, 2011). Capture, transportation, and storage or use each require the construction and maintenance of additional infrastructure, along with associated costs (Metz et al., 2005; GCCSI, 2011; Benson et al., 2012). After storage, transporting CO_2 to storage or use sites is the next important cost component. Although transportation through pipelines of dense supercritical CO_2 appears to be the most convenient technology for inland transport, other options, including shipping, are conceivable for particular cases (e.g., remote offshore distances) (Cole et al., 2011; ZEP, 2011). The costs for pipeline transportation comprise both capital costs (e.g., pipeline construction, pipe coating, protection systems) and operations costs (e.g., surveillance, maintenance, expert supervision) (McCoy and Rubin, 2008).

When it comes to the options for carbon storage, here we focus on geological storage, which comprises several different storage options under ground. Among the different storage options, only a few are considered reliable for large scale injections: underground saline aquifers, depleted or expiring oil and gas fields, and coal beds. Deep saline aquifers are geological formations of porous rocks, permeable and saturated with water, that allow the withdrawal of non-potable water (IEAGHG, 2008). Also oil and gas fields where extraction is declining are interesting options for CO_2 storage. Enhanced oil recovery (EOR) consist of injecting CO_2 in declining oil fields to boost oil extraction due to fluid pressure. Being an economically convenient technique, it has already been used in the U.S. for many decades. However, traditional EOR was not intended to maximize carbon storage, and the amount of CO_2 trapped has always been relatively low (Godec et al., 2011; IEA, 2015). Depleted oil or gas fields can be reliable storage sites, as they have naturally stored natural gas for thousands of years and have been geologically fully characterized. Coal seams that are uneconomic to mine may still contain methane trapped in coal pores, which may be released via Enhanced Coal Bed Methane (ECBM) recovery (IEA-ETSAP, 2010). Similar to EOR, ECBM consists of injecting CO_2 into the the coal bed, some of which displaces the CH_4 and remains sequestered in its place. Other potential CO_2 storage options, such as CO_2 mineralization or deep ocean storage, although considered important potential future storage options by some sources (Sanna et al., 2014; Romanov et al., 2015), are excluded from the current study due to their high current and uncertain future costs, public acceptance issues, and uncertain impacts on ecosystems (IEA, 2008).

Since estimating global or regional available storage capacity requires extensive investigation of vast geological areas and the use of advanced measurement processes, the uncertainty on available capacity is still high. Dooley (2013) considers a theoretical global capacity of 35,300 $GtCO_2$, which is reduced to an effective and then practical potential of 13,500 and 3,900 $GtCO_2$, respectively. In the IEAGHG (2011, 2016) reports, an average global availability of 11,152 $GtCO_2$ is estimated, which is an order of magnitude that is accepted also by other authors (Hendriks et al., 2004; Koelbl et al., 2014).

With regard to the geological storage costs, the variability in the literature is even higher, since many studies describe specific sites, which can have different properties one from another, such as the storage type, regional geology, and pre-built infrastructure. For example, Rubin et al. (2015) estimates a cost range of between 1 and 18 $\$/tCO_2$. Similar values are reported in IEAGHG (2011) and ZEP (2011)[2]. Concerning ECBM and EOR storage options, the estimated costs range from negative to high positive values, depending on whether the process is used to boost gas or oil extraction, or to optimize CO_2 storage (Gale, 2004; Koelbl et al., 2013, 2014).

2.2. Carbon Leakage

With the term leakage, or seepage, we refer to undesired CO_2 losses to the atmosphere due to infrastructure or

[1]Note that we therefore do not consider direct air capture (DAC) or other CDR options, which face additional technical and other uncertainties.

[2]Every cost in this study is expressed in 2005 US Dollars.

storage malfunctions. Leakage could occur during CO_2 transportation, underground injection, or after storage. Leakage from transportation is due to pipeline losses, but can be considered unlikely due to pipeline monitoring systems that measure pressure losses (GCCSI, 2014). The injection process can also lead to unwanted CO_2 leakage: injection requires a wellbore, a conduit where upward flows are possible. Finally, undesired loss of CO_2 from storage sites can occur due to imperfect storage sealing. Pipeline and injection losses are referred to as instantaneous leakage, as they take place at the same time period of capture and before the CO_2 is stored. On the contrary, seepage from storage sites is delayed in time, meaning that CO_2 can also leak from under ground several years after being captured. In this case, leakage is related to the cumulative quantity of CO_2 that has been stored in the past. This aspect is critical as one of the main issues related to CCS deployment is the long term suitability of storage options (Metz et al., 2005; van der Zwaan and Gerlagh, 2009b). Moreover, there is still high uncertainty about the true reliability of storage sites. As the long term response of storage sites could hinder CCS effectiveness as a mitigation option, we focus our attention on storage leakage.

The damages that leakage might cause can be distinguished between local and global (Wilson et al., 2003). From the local point of view, meaning a few kilometers around the storage site, concentrated CO_2 leakage could be harmful for people and livestock. Another problem caused by CO_2 losses is ground water contamination. Seepage could reach groundwater aquifers, rather than reaching directly the atmosphere surface (Bielicki et al., 2015; Deng et al., 2017). This would lower the aquifer water pH and could lead to the release of harmful metals, an effect known as acidification (Little and Jackson, 2010). Alternatively, acidification might also occur during the injection in saline aquifers, degrading the well cements (Celia et al., 2015). These local issues might raise discussions on storage management and public acceptance, however they have less consequences at a global level. By contrary, this article focuses on CO_2 leakage into the atmosphere as a global issue that contributes to global warming. In particular, the prospect of leakage could hinder the mitigation potential of fossil fuel CCS, hampering its future deployment. Consequently, it would lead to an increase in climate policy costs (van der Zwaan and Smekens, 2009). For this reason it is important to understand the magnitude of leakage, which is captured typically through the leakage rate, that is, the rate at which CO_2 leakage occurs at a specific storage site per year in terms of the stored carbon.

Bielicki et al. (2015) summarizes results on percentage of stored emissions from the storage sites, with different levels of permeability and compares the results with the U.S. Department of Energy aim of not more than 1% leaked CO_2 in total (Bielicki et al., 2016). Assuming a pessimistic estimate of rock permeability equal to $10^{-10}m^2$, 10% of stored volumes are expected to leak within 30 years, with permeability of $10^{-12}m^2$, the leaked emissions decrease to about 0.1% during the same period. However, an evaluation of leaked quantities over larger time horizons like 100 or 1,000 years, which are the time frames usually considered by institutions like the DOE or IPCC, is still missing. According to Bielicki et al. (2015) only the case with $10^{-12}m^2$ permeability would conform to the storage permanence goal of 1% leakage. These permeability assumptions have been tested in the GCAM model by Deng et al. (2017), obtaining leakage over the twenty-first century of between ~0.003 and ~0.2%[3]. Another finding is that with a low injection rate, leakages are higher at the beginning, while in the long term this might change. The behavior of leakage rates could therefore depend also on time: in particular, the percentage of CO_2 lost with respect to the total stored amount could exponentially decay or show an S-shaped behavior. These complex paths try to replicate some important geological and fluid-dynamic aspects of CO_2 leakage. For example, the exponentially decaying curve stands for a storage site where CO_2 leaks at first easily, then increasingly more scarcely due to the fact that only the best trapped CO_2 remains in the storage site. An S-shaped curve would represent the CO_2 leaking through multiple layers of media (van der Zwaan and Gerlagh, 2009a,b). However, as in van der Zwaan and Smekens (2009), leakage rate could be also reasonably well approximated as a constant percentage of the cumulative stored quantity within each storage site. Summing up, according to the IPCC (Metz et al., 2005), storage sites are probably reliable and safe, meaning they release very low or practically zero leakages. van der Zwaan and Smekens (2009) suggest a maximum acceptable value for the leakage rate below 0.5% per year, while for Bielicki et al. (2015) lower leakage rates are conceivable. In this study we therefore consider the maximum leakage rate of 0.1% per year, which implies leakage of 9.5% over a century, while a more reasonable leakage rate that we test is 0.01%/*year*, which leads to a theoretical leakage of 1% of injected CO_2 over 100 years[4].

As leakage remains uncertain, it is of vital importance to ensure effective and reliable monitoring systems that consistently measure CO_2 flows. In recent years, several studies have addressed the issue of monitoring leakage flows to the atmosphere or affecting underground aquifers (Benson and Hepple, 2005; Dethlefsen et al., 2013). Monitoring seepage implies scanning a large area of land in proximity of storage sites, and there is not a consolidated or standardized approach yet, rather a number of research and demonstration projects (Jones et al., 2009; Etheridge et al., 2011; Romanak et al., 2012). Moreover, to guarantee an effective control on storage sites, the responsibilities and consequences of seepage must be clearly outlined, covered through appropriate regulation and, if applicable, covered under carbon pricing schemes (Imbus et al., 2013). Problems can arise when private companies or public institutions responsible for the injected CO_2 do not monitor adequately, leading to undetected leakage. Considering the long term outlook, some regulations envisage a transition in responsibilities from private operators to governments after a certain number of years (e.g., 50 years) or in case of company closures. Furthermore, assuming leakage occurs and is correctly detected and measured, someone has to pay for local damages

[3]Note that these values are modeled leakage rates over the century and thus depend on the timing and deployment of CCS and carbon storage.

[4]These values per century are theoretical, meaning the amount of gas that would leak if it was all stored on the first year. The real leakage per century will depend on the intertemporal storage profile of the model, see **Figure 2**.

and for the cost of global externality it is generating. In the case of a carbon pricing scheme, the latter cost is set by the carbon price. Also in this case, dodging responsibility by private or public authority would inhibit the economic benefits of CCS or CDR.

Not all countries have appropriate or specific regulation to address the safety and liability issue. Liu et al. (2016) provides a review of existing regulations in some developed countries and compares them with general Chinese environmental regulation. As an example, EU regulation establishes the payment for emissions credits in the Emissions Trading System (ETS) system for the storage operator (EU, 2009). Other useful measures are insulation of the perforation of the well, re-injection in more safe sites and insurance plans, also for companies that go bankrupt (Lackner and Brennan, 2009; Imbus et al., 2013). In conclusion, we have seen how important it is to assign responsibilities for monitoring and compensate leakage damages. Therefore, we included these aspects in this exercise, developing some scenarios that mimic successful or failed monitoring, pricing, and management of stored emissions.

3. METHODOLOGY

We use an integrated assessment model (IAM) to simulate the impact of leakage on the set of mitigation strategies. IAMs are tools which are routinely used to evaluate global climate policies. Currently, many integrated assessment models use aggregated storage cost and availability curves, notably the ones from Hendriks et al. (2004). For this exercise, we disaggregated the storage according to different types of storage including their respective potential and costs. Moreover, transportation costs also vary according to the storage site considered. Finally, we added leakage from the different storage sites and assessed a set of scenarios capturing different climate policies, leakage rates, and options to consider leaked carbon emissions. We use the WITCH (World Induced Technical Change Hybrid) integrated assessment model in this study.

WITCH is a global integrated assessment model with two main distinguishing features: a regional game-theoretic setup, and an endogenous treatment of technological innovation for energy conservation and decarbonization (Emmerling et al., 2016). A top-down inter-temporal Ramsey-type optimal growth model is hard linked with a representation of the energy sector described in a bottom-up fashion, hence the hybrid denomination. The regional and intertemporal dimensions of the model make it possible to differentiate and assess the optimal response to several climate and energy policies across regions and over time. The non-cooperative nature of international relationships is explicitly accounted for via an iterative algorithm which yields the open-loop Nash equilibrium between the simultaneous activity of a set of representative regions. Regional strategic actions interrelate through greenhouse gas (GHG) emissions, dependence on exhaustible natural resources, trade of fossil fuels and carbon permits, and technological research and development (R&D) spillovers. R&D investments are directed toward either energy efficiency improvements or development of carbon-free breakthrough technologies. Such innovation accumulates over time and spills across countries in the form of knowledge stocks and flows. R&D investments, along with investments in energy technologies and the final goods sector, are endogenously determined in the intertemporal optimization. Within the energy sector, for new renewable energy sources (wind and solar), battery development, and advanced biofuels, learning is also taken into account through one or two factor learning curves, which determine future capital costs. The competition for land use between agriculture, forestry, and bioenergy, which are the main land-based production sectors, is described through a soft link with a land use and forestry model (GLOBIOM, Global Biosphere Management Model). A climate model (MAGICC) is used to compute climate variables from GHG emission levels, and an air pollution model (FASST) is linked to compute air pollutant concentrations.

Concerning CCS in the model, we consider four coal technology options (including the possibility of retrofitting existing plants), one gas and one biomass technology with carbon capture. The model includes seven types of storage (saline aquifers, EOR sites, depleted oil and gas fields, all either onshore or offshore, and onshore ECBM sites), each characterized by a maximum available capacity, a storage cost and an average distance from power plants. Apart from storage costs for the different types, all values are regionally differentiated. Finally, we account for an average specific transport cost dependent on the distance calibrated as $c'_{tr} = 0.006667\$/tCO_2\ km$ (Rubin et al., 2015). The total cost of captured CO_2 transport and storage $C_{t\&s}[\$/year]$ is therefore evaluated according to the following equation, where the dimensions are time (t), regions (n), and type of storage (k_{st}):

$$C_{t\&s}(t,n) = \sum_{k_{st}} Q_{st}(k_{st},n,t) \cdot \left(c'_{tr} \cdot l_{tr}(n,k_{st}) + c_{st}(k_{st}) \right) \quad (1)$$

Here, Q_{st} $[GtCO_2/year]$ represents the yearly quantity of CO_2 captured by CCS plants, l_{tr} [km] represents the average distance, and c_{st} $[\$/tCO_2]$ the storage cost. We consider an annual leakage rate λ_{lk} of between $0.0\%/year$ and up to $0.1\%/year$ and include leaked emissions in the model. The cumulative amount of CO_2 stored CUM_{st} $[GtCO_2]$ is therefore calculated based on annual stored values, considering that the model is run at a time step of 5 years, and including possible leakage every time period:

$$\begin{aligned} CUM_{st}(k_{st},n,t+1) \;=\; & CUM_{st}(k_{st},n,t) \cdot (1-\lambda_{lk}(k_{st},n,t))^5 \\ & + 5 \cdot Q_{st}(k_{st},n,t) \end{aligned} \quad (2)$$

Here, λ_{lk} stands for the leakage rate, or the percentage of CO_2 stored in the previous year that is lost due to leakage and emitted in the atmosphere. This set of equations allow us to represent the transport and storage chain as a single cost function, differentiated across regions. The cost function for each storage type follows a step increase in function of the cumulative stored quantity, where each step means a switch from a cheap but

replete storage type to the immediate next, more expensive site. Finally, annual leaked emissions Q_{leak} are computed as follows:

$$Q_{leak}(n,t) = \sum_{k_{st}} \lambda_{lk}(k_{st},n,t) \cdot CUM_{st}(k_{st},n,t) \quad (3)$$

It should be noted that Q_{leak} in period t is accounted for based on CUM_{st} in t, which is not including the emission captured in the same period, but only until $t-1$. This is to represent delay in leakage.

4. SCENARIO DESIGN

Based on this model implementation of storage, transportation, and leakage of CO_2, we explore a set of 31 scenarios to capture the following dimensions: leakage rates, climate targets, and policy provisions. We implement different leakage rates (LR) starting from zero leakage, 0.01%, 0.05%, and up to 0.1% per year.

Secondly, we consider different stringency of climate policies, represented by carbon budgets covering total CO_2 emissions from fossil fuels and industrial processes from 2010 to 2100. In addition to the business as usual (BAU) case without a future climate policy, we consider cases of 550, 1,000, and 1,600 $GtCO_2$ corresponding to roughly 1.5, 2.0, and 2.5°C of global warming in 2100, according to the definition in the IPCC AR5 report (Edenhofer et al., 2014; Vuuren et al., 2017)[5]. When running these scenarios, the model sets a constraint on emitted CO_2 equal to the budget and solves finding the cost optimal solution for attaining the target.

Finally, we differentiate the economic and policy treatment of carbon leakage emissions. In particular, we consider whether or not (a) leaked emissions are priced (through a carbon tax or the price of emission permits) or not, and (b) the leaked emissions are included in the carbon budget of the policy maker. Four cases are possible based on these distinctions: In the first case (NN), leakage is not taken into account in the policy target nor priced, e.g., due to technical, institutional, or political barriers. This case allows us to assess the climatic impact of leakage if it is not taken into account for climate targets, nor in emission pricing schemes. The other limiting case, where pricing and monitoring are effective (YY), constitutes the first best case where the actual climate target is attained, and leakage is treated the same way as other carbon emissions and priced at the marginal cost of abatement. The two remaining cases represent different institutional, economic, and technological situations: In the YN case, leakage is anticipated for the climate policy goal, while due to monitoring or institutional constraints, the source cannot be taxed or held accountable. Hence, in this case, other mitigation options are required to counteract leakage emissions. Hypothetically, in the fourth situation (NY), on the other hand, pricing leakage emissions is possible and implemented, but the climate policy does not take leakage into account a situation which is not realistic and hence we do not consider it here.

[5]The IPCC AR5 Scenarios Database documents the long-term scenarios as reviewed in the Fifth Assessment Report (AR5) of Working Group III of the Intergovernmental Panel on Climate Change (IPCC) (Edenhofer et al., 2014).

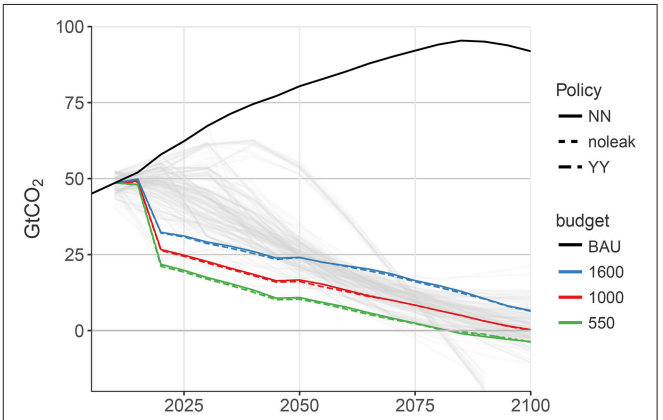

FIGURE 1 | Global greenhouse gas emissions ($GtCO_{2eq}$) across scenarios. For target different from BAU, leakage is set to 0 or 0.1%/*year*. In gray are plotted the scenarios form the AR5 Scenario Database in line with the 2°C.

As summarized in **Table 1**, we consider three different policy prescriptions (NN, YN, YY) for three different carbon budgets (1600, 1000, 550 $GtCO_2$) and three leakage rates (0.01, 0.05, 0.1 %/*year*, total: 27 scenarios), in addition to the four scenarios without leakage (BAU, 1,600, 1,000, 550).

5. RESULTS

The different sets of scenarios show different patterns in terms of emissions, CCS deployment, and economic costs. Firstly, looking at overall greenhouse gas emissions, **Figure 1** shows the no leakage and high leakage scenarios and compares them to the scenarios of the AR5 database that are consistent with the two degree target (Edenhofer et al., 2014). Overall, emissions

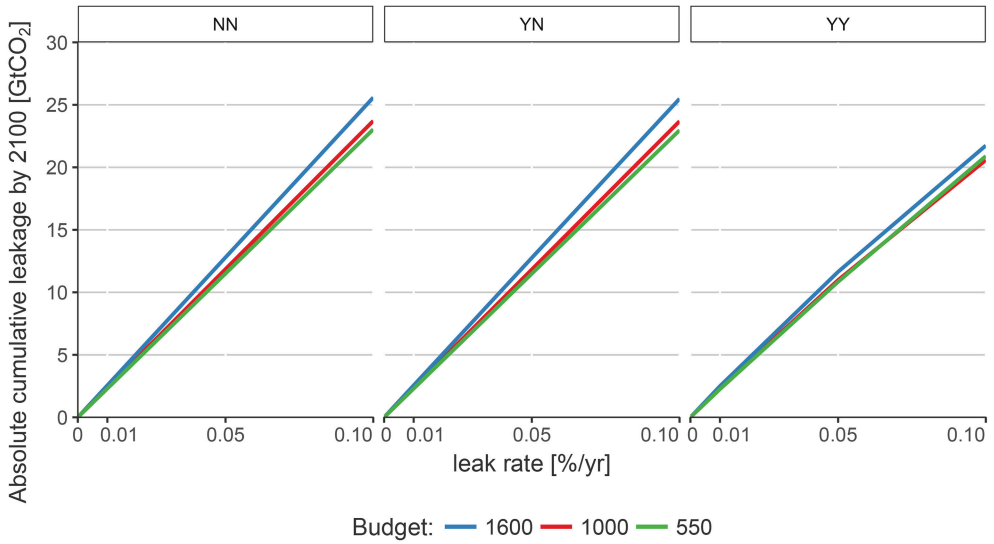

FIGURE 2 | Cumulative leaked emissions in the different scenarios [$GtCO_2$]. Captured emissions are around 700–750 $GtCO_2$ for NN and YN scenarios and 650–700 $GtCO_2$ for the YY scenario.

are only mildly affected by carbon leakage at the global scale, and the mitigation pathways are dominated by the stringency of the carbon budgets. In particular in the 550 scenarios, total emissions become negative toward the end of the century. The difference between cases where leakage (set as 0.1%/*year* of stored CO_2) is well accounted for (YY) and when it is not (NN) is small compared to total emissions, though still visible.

Looking closer at the leaked emissions, one can see that leakage can contribute to emissions as shown in **Figure 2**. The amount of leakage over this century in the NN and YN scenarios ranges from 2.5 $GtCO_2$ (for a leakage rate of 0.01%/*year*) to around 25 $GtCO_2$ for a leakage rate of 0.1%/*year*. Moreover, while it is quite similar for the different climate targets, it shows the highest values always for the 1,600 $GtCO_2$ scenario, where fossil-based CCS is widely deployed. Comparing the leakage to the amount of captured emissions for the NN and YN scenarios (around 700–750 $GtCO_2$), we get around 0.5% of leakage until 2100 for the low leakage rate, and 3% for the high leakage rate cases. These values are virtually unchanged in the YN and NN scenarios, where leakage is not priced and hence does not affect CCS deployment. However, in the YY scenario, when the effect and cost of leakage are fully accounted for, the model responds with a reduction in leakage, linked to a reduction in CCS technology adoption and captured emissions. For the highest leakage rate of 0.1%, captured emissions are lowered by about 5–10 $GtCO_2$ across the different climate targets. The percentage of leaked emission on the total captured between 2015 and 2100 is however similar to the previous scenarios. If compared to Deng et al. (2017), our results show higher percentage of emission leaking over the century given similar leakage rates. This is due to their assumption that most of leaked emissions do not reach the surface, but are priced and thus have a negative impact on CCS deployment.

Leaked emissions have an impact on the climate, in terms of CO_2 concentrations and global temperature increase, shown in **Figure 3**. In absolute terms, variations in global mean temperature increase in 2100 are relatively small, of the order of magnitude of 0.01°C when leaked emissions are not monitored. For the YN and YY scenarios where leakage is accounted in the carbon budget target, the results show a small temperature decrease with increasing leakage rate. This can be explained due to different timing of emissions, notably due to the early shift to zero carbon technologies replacing CCS. While overall the temperature effect is relatively small, it still implies further exacerbation of global warming when leakage is not accounted in the budget, which might be relevant for the most stringent scenarios.

Figure 4 shows that the reduction in CCS (in terms of capacity reduction by 2100) is linked to the leakage rate, and to whether it is priced and accounted for in the carbon budget: only in the case where the costs of leaked emissions are accounted for in the economy through carbon pricing (YY) is CCS substantially reduced. Therefore, in the scenarios where countries do not pay for their leaked emission, CCS is not affected, both in the case where seepage is considered in the carbon budget or not (YN and NN scenarios). This result can be explaind since leakage can not be directly linked to the storage owners and the capturing power plant. The CCS reduction is particularly high for fossil fuel based CCS where the reduction reaches between 10 and up to 35 per cent of the capacity without leakage. Bio-energy with carbon capture and storage (BECCS), on the other hand, shows reductions lower than 10%. That is, for biomass CCS, leakage seems to provide a less important barrier, even with a leakage

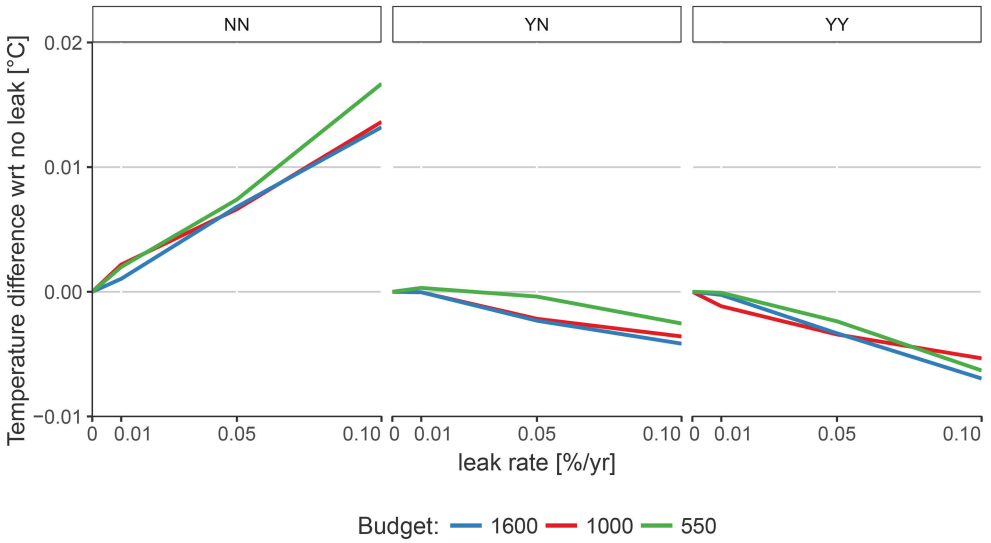

FIGURE 3 | Global mean temperature increase compared to no leakage case [°C].

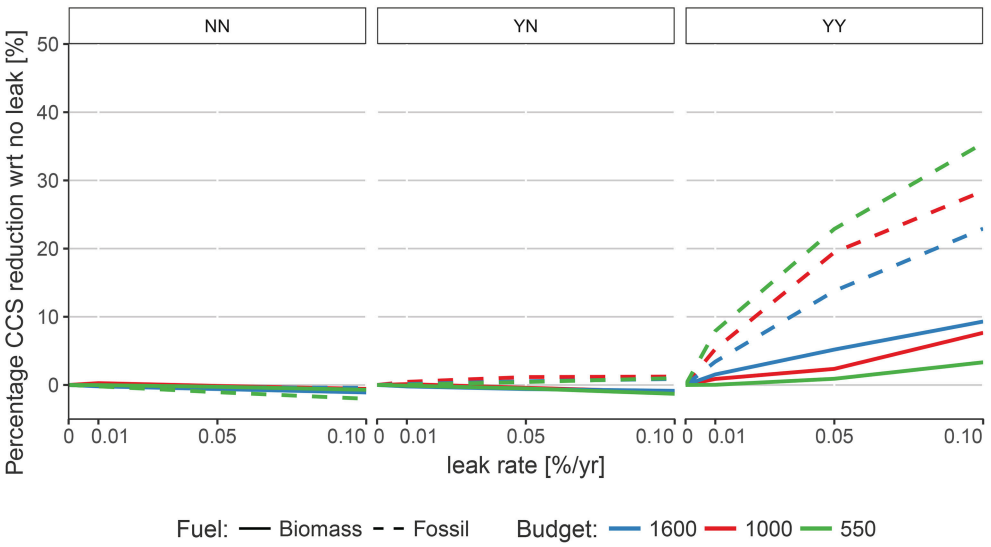

FIGURE 4 | Capacity reduction in CCS compared to no leakage case [%]. The reference values of total installed capacity by 2100 in case of zero leakage are: 61 *TW* (biomass) and 52 *TW* (fossil) for the 1,600 scenario, 63 *TW* (bio) and 37 *TW* (fossil) for 1,000 $GtCO_2$ and 75 *TW* (bio) and 25 *TW* (fossil) in the 550 $GtCO_2$ case.

rate of 0.1% per year, especially in the most stringent 1.5°C scenario. Moreover, it is interesting to note that the ordering across stringency of the climate targets is reversed for fossil fuel and biomass based CCS: The more stringent the scenario considered, the lower the impact on BECCS and the higher the reduction of fossil based CCS. This result is in line with the intermediary role of fossil fuel based CCS found e.g., in Rogelj et al. (2015), van der Zwaan and Smekens (2009) and Deng et al. (2017), even if these two latter studies did not consider stringent scenario such as the 1.5°C (550 $GtCO_2$).

In terms of economic costs of carbon leakage, we first look at the implied carbon price required to meet the different climate targets. **Figure 5** shows the increase in carbon price with respect to the no leakage cases, noticeable for scenarios where leakage is included in the carbon budget. The standard carbon prices in the three scenarios in the year 2020 to implement the carbon budgets of 1,600, 1,000, and 550 $GtCO_2$ are 79, 164, and 318 $\$/tCO_{2eq}$ respectively, and grow at a rate of 5% per year[6]. Comparing to these default scenarios the leakage cases, first note that the NN scenario does not show any change in the carbon price as leakage increases, since it is not considered for the policy

[6]Note that therefore the relative difference in carbon prices shown in **Figure 5** are constant over time and across regions.

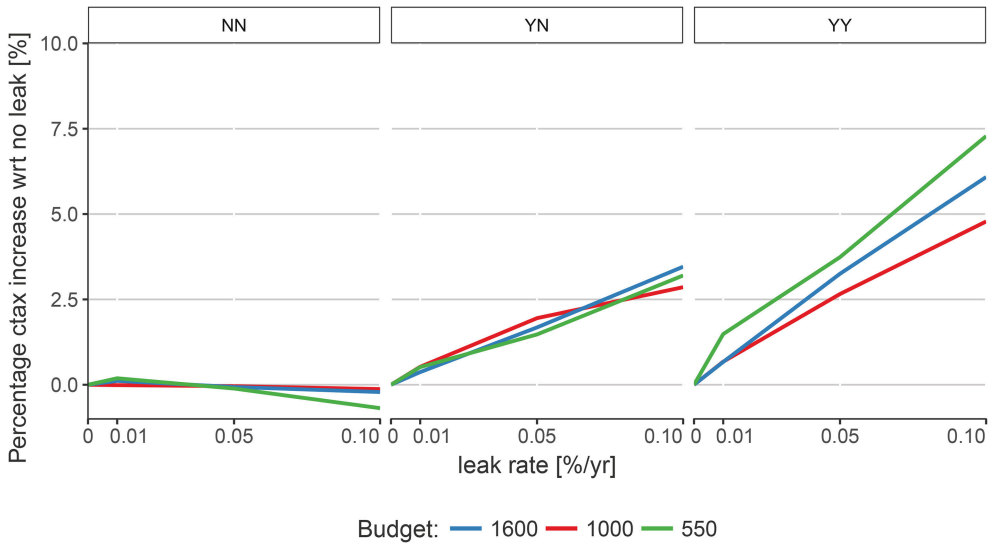

FIGURE 5 | Relative increase of the carbon price compared to no leakage case [%]. The carbon prices in 2,020 for 1,600, 1,000, and 550 $GtCO_2$ (no leakage case) are 79, 164, and 318 $\$/tCO_{2eq}$ respectively.

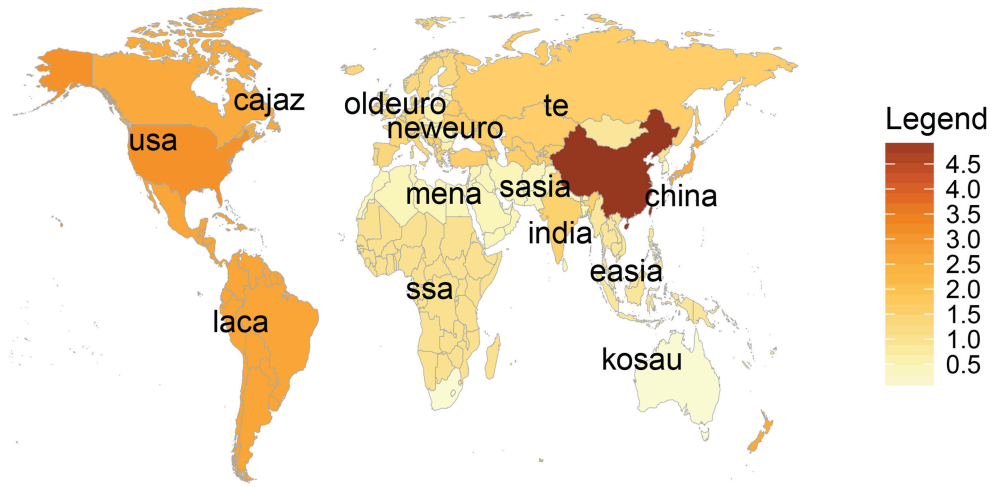

FIGURE 6 | Cumulative leaked emissions by 2100 in the scenario 550, NN and leakage rate of 0.1 $\%/year$ [$GtCO_2$].

design. When seepage affects the carbon budget available for each climate policy, it becomes necessary to mitigate this effect using other technological strategies more expensive than CCS. This results in an increase of carbon price in the YN and YY scenarios, which ranges from 2.5 to 7.5%. When leakage is not priced (YN), it still leads to a higher carbon price due to the reduced global carbon budget, albeit to a lesser extent, resulting from higher mitigation effort based on the most cost-effective mitigation options available. When it is also priced, the cost-effective potential of CCS is significantly reduced, resulting in higher use of more expensive mitigation options such as energy efficiency improvements or renewable energy sources. Across carbon budgets, it should be noted that, although the relative variation in the carbon tax is similar, in absolute value it differs significantly.

The previous results showed how uncontrolled seepage would affect global climate and how, even well monitored leakage might be binding for CCS development and would lead, globally, to a more expensive energy system. Now we focus on the regionally differentiated modeling results, focusing here on the most stringent scenario (550) and using the 0.1% leakage rate, while for smaller rates the results scale down almost linearly as shown before.

As shown in **Figure 6**, the cumulative leaked emissions are not evenly distributed across regions: China, the United States, Canada/Japan (cajaz), and Latin America (laca) countries are

expected to extensively use CCS power plants, and therefore are projected to leak more than 2 $GtCO_2$, with China reaching 5 $GtCO_2$ by 2100 (see **Table 2** for the description of the regions).

Given the relatively high carbon price required to achieve the stringent climate policy targets, leakage can imply substantial additional costs of emissions, according to the carbon price in place. In the aforementioned regions with high projected leakage potential, this amounts to values between 75 and 200 billion USD over the century, with exception of 550 billion for China, see the left panel in **Figure 7** (all values reported there refer to NPV cumulative values from 2015 to 2100, discounted at a 5% discount rate). In the scenario 550, NN with high leakage, the (discounted) yearly value of leaked emissions in 2100 reaches up to 12 billion USD in China and about 7 billion USD in Latin America. Globally, the yearly leakage in 2100 of 0.78 $GtCO_2$ amounts to a discounted value of 54 billion USD. Given the relatively small carbon budget consistent with the 1.5 degree scenario, the additional 25 $GtCO_2$ of leaked carbon emissions associated with the high leakage rate (0.1%/*year*) scenario represent a significant cost, with particular economic implications for some regions. Moreover, we can compare which regions have to bear the additional costs if, while initially not being priced, now leaked emissions are accordingly priced and the climate target is the same, i.e., moving from scenario YN to YY. The right part of **Figure 7** shows the additional cost of leakage emissions when they are priced at the global carbon price (YY) compared to the case where they are not (YN): almost all regions show a negative difference, meaning that they reduce expenses when leakage is well regulated. In Canada/Japan (cajaz), including the leakage costs in the economy does not lead to a large CCS reduction. Therefore, the higher carbon price in the YY scenario results in higher costs for the country. This occurs mainly because the use of BECCS late in the century seems essential for these countries. In countries where CCS is only marginally profitable, its optimal deployment is reduced facing leakage, and hence the required carbon price is slightly higher, while leakage is significantly reduced. Since the latter effect dominates, those countries gain in terms of the value of carbon.

These are the value of losses that would not be payed by companies or countries in absence of regulation. But they can also be seen as a waste of money for a country which is investing in climate mitigation policies, and the cost of re-abating leaked emission. Moreover, other costs, like local or climate change damages are not accounted in this estimation, therefore the real economic loss might be even higher. Note that in both cases the carbon price increases with leakage rate, as more expensive low carbon technologies are installed to compensate seepage. However the YY scenario represents a perfect regulation system where CCS owners pay for the leaked emissions, so that use of CCS is reduced and the carbon price increases further. This behavior is considered more convenient than continuing using CCS and paying for leakage. The difference in total leakage costs can be considered as the regional gain or loss if leakage is well regulated or not. Moreover, we also compare the GDP of all scenarios to

TABLE 2 | Regions of the WITCH model.

WITCH region	Description
usa	United States of America
oldeuro	Western Europe (EU15+EFTA)
neweuro	Eastern Europe (EU12+European EITs excluding FSU countries)
kosau	South Korea, South Africa, Australia
cajaz	Canada, Japan, New Zealand
te	Non-EU Eastern European countries, including Russia
mena	Middle East and North Africa
ssa	Sub Saharan Africa
sasia	South Asia (except India)
china	China, including Taiwan
easia	South East Asia, including Indonesia
laca	Latin America, Mexico and Caribbean
india	India

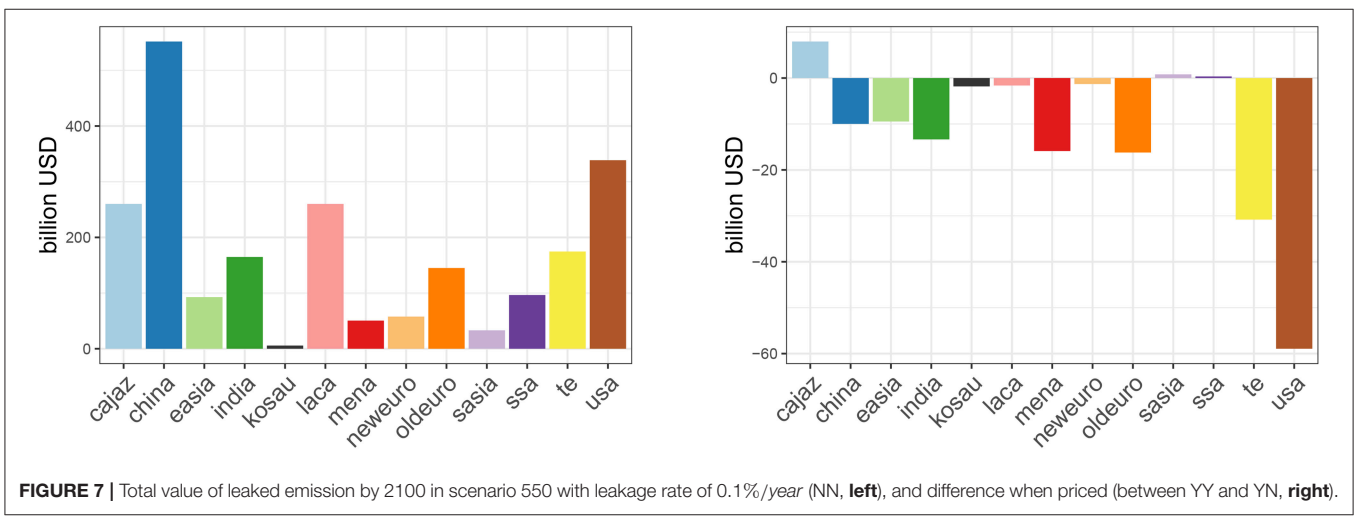

FIGURE 7 | Total value of leaked emission by 2100 in scenario 550 with leakage rate of 0.1%/*year* (NN, **left**), and difference when priced (between YY and YN, **right**).

TABLE 3 | Policy Cost with respect to BAU for different leakage rates and pricing policies [% of GDP].

Leakage rate	0	0.01%/year		0.05%/year		0.1%/year	
CB\policy		YN	YY	YN	YY	YN	YY
1,600	3.38	3.39	3.40	3.42	3.47	3.46	3.54
1,000	5.64	5.66	5.68	5.72	5.75	5.77	5.86
550	8.52	8.53	8.55	8.56	8.68	8.64	8.86

analyze the changes in policy costs with respect to the BAU scenario. **Table 3** reports the policy cost for the aforementioned scenarios. We confirm the above mentioned trend of policy cost[7] increasing with leakage rate and from zero leakage case to YY setting. Overall, policy costs increase in the range of 0.1–0.2% in the YN case due to the higher mitigation effort needed. If moreover leakage is priced, they increase by a further 0.1-0.2 percentage points. For instance, in the stringent 550, YY scenario and for a leakage rate of 0.1%, the costs of staying below 1.5° increase from 8.5% to almost 8.9% due to leakage.

6. CONCLUSION

The purpose of this work is to expand the assessment of leakage impact on CCS deployment and climate policies. We consider different institutional and economic settings reproducing issues in monitoring and paying for possible leakage. Furthermore, we perform analysis over leakage rates, and over three different climate scenarios, including the 1.5 and 2°C temperature increase target by 2100, particularly relevant after the Paris agreement in 2015. The results show that carbon leakage can lead to up to 25 $GtCO_2$ of additional emissions throughout the twenty-first century for a leakage rate of 0.1% per year, which represents about 3% of total captured emissions. Considering a more optimistic leakage rate (0.01%), only 0.5% of injected emissions would leak by 2100. If accounted for in the carbon budget and priced, CCS deployment is expected to be lowered by up to 35% (fossil) and 10% (BECCS) for high leakage rates. This means that CCS remains an important technology for mitigation in the power sector, notably coal and gas based in less stringent scenarios, and biomass fueled for the 1.5°C scenario. Due to more early-on abatement, considering leakage leads to slightly lower global warming in the long run. If not taken into consideration nor priced, on the other hand, it leads to an around 0.01–0.02 degrees higher global mean temperature. Overall, policy costs increase by about 0.2–0.4 percentage points (of GDP loss) due to considered leakage. In terms of regional distribution, China, Latin America, the U.S., and Canada have the highest leakage amount to be expected by 2100. The associated economic value of this quantity ranges across regions from 70 to more than 200 billion USD. Finally, we demonstrated how appropriate monitoring and accounting of leakage imply a reduction in use of CCS and also economic saving for most countries.

[7] measured as NPV of GDP differences in global GDP discounted at a 5% rate.

The Gassing Of Satartia

A CO2 pipeline in Mississippi ruptured last year, sickening dozens of people. What does it forecast for the massive proposed buildout of pipelines across the U.S.?

By Dan Zegart
August 26, 2021

It was just after 7 p.m. when residents of Satartia, Mississippi, started smelling rotten eggs. Then a greenish cloud rolled across Route 433 and settled into the valley surrounding the little town. Within minutes, people were inside the cloud, gasping for air, nauseated and dazed.

Some two dozen individuals were overcome within a few minutes, collapsing in their homes; at a fishing camp on the nearby Yazoo River; in their vehicles. Cars just shut off, since they need oxygen to burn fuel. Drivers scrambled out of their paralyzed vehicles, but were so disoriented that they just wandered around in the dark.

The first call to Yazoo County Emergency Management Agency came at 7:13 p.m. on February 22, 2020.

“CALLER ADVISED A FOUL SMELL AND GREEN FOG ACROSS THE HIGHWAY,” read the message that dispatchers sent to cell phones and radios of all county emergency personnel two minutes later.

First responders mobilized almost immediately, even though they still weren't sure exactly what the emergency was. Maybe it was a leak from one of several nearby natural gas pipelines, or chlorine from the water tank.

through the hills above town, less than half a mile away. Denbury Inc, then known as Denbury Resources, operates a network of CO2 pipelines in the Gulf Coast area that inject the gas into oil fields to force out more petroleum. While ambient CO2 is odorless, colorless and heavier than air, the industrial CO2 in Denbury's pipeline has been compressed into a liquid, which is pumped through pipelines under high pressure. A rupture in this kind of pipeline sends CO2 gushing out in a dense, powdery white cloud that sinks to the ground and is cold enough to make steel so brittle it can be smashed with a sledgehammer.

Even Durward Pettis, a contract welder for Denbury and chief of the local Tri-Community Volunteer Fire Department, didn't figure out that the mystery fog was CO2 for a full 15 minutes. He'd directed first responders to set up three roadblocks to prevent traffic from entering the area. But it wasn't until 7:30 p.m. that word went out that they'd need self-contained breathing apparatus, or SCBA, to enter Satartia and evacuate the town's 42 residents, many of them elderly, and about 250 others who lived just outside town. By then, rescuers and residents were already in motion, fleeing the gas or evacuating others.

Even once Pettis figured it out, none of the sheriffs' deputies and volunteer firefighters had any emergency training in CO2 leaks. Neither did staff at two area hospitals, which had detrimental consequences for gas victims, according to interviews with many of the 49 who were hospitalized.

"It was bad enough that I thought my mama wouldn't make it, and she still has trouble breathing," said Army veteran Hugh Martin, who fled Satartia in a pickup truck with his 78-year-old mother as he struggled to remain conscious. "She never had asthma or COPD, now she's on inhalers full time."

Even months later, the town's residents reported mental fogginess, lung dysfunction, chronic fatigue and stomach disorders. They said they have trouble sleeping, afraid it could happen again.

investigation into the Satartia pipeline rupture, and the safety of CO2 pipelines. It is based on interviews with more than 60 witnesses, victims, first responders, lawyers, medical and toxicological experts, pipeline and petroleum experts, and public health officials; and a review of medical records, police and fire reports, 911 recordings, emergency dispatch logs, internal documents from the Mississippi Emergency Management Agency and the state Department of Environmental Quality, as well as federal pipeline incident reports.

Meanwhile, the federal government is taking the first steps to vastly increase the size of the nation's carbon dioxide pipeline network as a way of fighting climate change. Our investigation reveals that such pipelines pose threats that few are aware of and even fewer know how to handle.

"We got lucky," said Yazoo County Emergency Management Agency director Jack Willingham, who oversaw the rescue effort. "If the wind blew the other way, if it'd been later when people were sleeping, we would have had deaths."

A Deadly Gas

Carbon dioxide has long been used to euthanize laboratory rodents and other small animals, a practice animal welfare organizations now consider inhumane due to the suffering the gas inflicts on the animals. Each year, CO2 accidents kill about 100 workers worldwide — often in basements of restaurants that use CO2-charged systems for their bar mixers — or in industrial accidents.

Carbon dioxide is an asphyxiant that displaces ambient oxygen, making it more difficult to breathe. Smaller exposures cause coughing, dizziness and a panicky feeling called "air hunger." As CO2 concentrations get higher and exposure times longer, the gas causes a range of effects from unconsciousness to coma to

performance and inducing a confused, drunken-like state.

Denbury's entire business is built around piping carbon dioxide to oilfields and a few industrial users in two operational centers in the Gulf Coast and the Rockies. It owns or has an interest in 14 oil fields in Mississippi, Texas and Louisiana, which are connected by five CO2 pipelines spanning 925 miles. Among its properties is Tinsley Field, adjacent to Satartia, which became Mississippi's first commercially successful oil field in 1939.

Left: The Tinsley oil field in Tinsley, Mississippi, on July 23, 2021. Right: A CO2 gas pipeline remains active in Satartia, Mississippi, that same day.
Rory Doyle for HuffPost

In 2007, Denbury built its 31-mile Delta pipeline to connect Tinsley to the Jackson Dome, an extinct volcano under Jackson, Mississippi, whose 4.6 trillion cubic feet of naturally occurring CO2 gas supplies all of the company's fields. Denbury extended the Delta line 77 miles to Louisiana's Delhi field in 2009.

Denbury uses the CO2 for enhanced oil recovery, or EOR, which uses the gas to flush more oil out of wells. About 20% to 40% of the oil in a field can be recovered through conventional drilling and injecting water into the reservoir. Injecting CO2 after that can increase the yield up to 60%.

Tinsley itself suffered a sizeable CO2 "blowout" — where injected CO2 explodes out of the ground along with water, mud and drilling fluids — in 2011 that took 37 days to bring under control, sickened one worker, and killed deer, birds, fish and other animals.

Denbury had already had two other blowouts in Mississippi, one requiring the evacuation of local homes in Amite County in 2007. Another underground CO2 blowout at Delhi field in 2013 lasted for more than six weeks and contaminated the air with unsafe levels of both CO2 and methane.

Denbury and other companies that do EOR are well versed in the dangers of CO2. At Denbury's Heidelberg Field in eastern Mississippi, signs warn of a CO2 hazard and say SCBA must be worn, and there are muster stations where workers gather if there is a release. The company also has safety pamphlets on its website — one for the public called "Pipeline Safety Is Everybody's Responsibility" and another for first responders titled, "AWARE: Tactics for Responding to a CO2 Pipeline Leak." None of the emergency workers interviewed for this story had seen either.

While the risks of CO2 exposure were well established, the Satartia gassing was the first known instance of an outdoor mass exposure to piped CO2 gas anywhere in the world, according to Marcelo Korc, chief of the World Health Organization's Climate Change and Environmental Determinants of Health Unit, whose staff researched injuries from CO2 pipeline leaks in response to an inquiry from HuffPost.

The sun sets on the village of Satartia alongside the Yazoo River in July.
Rory Doyle for HuffPost

Korc's staff also found that CO2 from the Jackson Dome is contaminated with hydrogen sulfide, a deadly gas that likely worsened residents' symptoms and also accounts for the gas cloud's odor and greenish color, since pure CO2 is odorless and colorless.

Denbury declined to answer specific questions for this story, sending only a statement:

> *On February 22, 2020, at approximately 7:00 p.m., Denbury Enterprises' Delta pipeline experienced a sudden rupture and release of CO2 gas near Satartia, Mississippi. Before, during, and after the event, Denbury's main*

release and the surrounding environment. Denbury and its personnel were quickly in the community, working directly with nearby leadership and any individual residents affected by the event to ensure that any needs arising from the event were met. We have continued to work closely with the community and have made significant contributions to local emergency response organizations to support the important role they play in keeping the community safe. Denbury has cooperated fully with all federal, state, and local agencies who responded to the incident. The federal agency charged with regulating the pipeline continues its review and investigation of the incident, and Denbury continues to cooperate fully with their efforts.

Beyond the suffering of those who lived through it, the fact that the Biden administration is poised to commit unprecedented billions to carbon capture and sequestration (CCS) technology — putting CCS at the center of the country's strategy for reducing greenhouse gas emissions — further magnifies the importance of Satartia's CO2 accident.

The historic hike in federal support for CCS infrastructure includes taking the first steps toward the construction of a continent-spanning network of pipelines in order to move America's many millions of tons of CO2 to storage areas where, theoretically, the gas can be injected deep underground and sequestered indefinitely.

Some experts estimate this network will need to be as large as or even larger than the 2.6 million miles of existing petroleum pipelines. Meanwhile, there are only 5,000 miles of existing CO2 lines, meaning there is little experience with a wide range of operational — and safety — issues likely to arise from such a massive new system.

Nevertheless, Biden's climate team; his Department of Energy and three of its former secretaries; most utilities; the coal industry and the governments of several coal states; ExxonMobil, the rest of Big Oil and other major industrial corporations; several climate NGOs; the AFL-CIO; and a bipartisan group that

some form.

“We want to build more pipes,” DOE Secretary Jennifer Granholm told a reporter in June. “There’s a lot of jobs that are associated with decarbonizing … and I think pipes are one of those opportunities.”

But the rush to build and operate an integrated CCS and pipeline system has so far taken place with little examination of the safety issue, as the people of Satartia learned.

Korc of the WHO worried that the basic science done long ago on many toxic chemicals, including petroleum products, has never been done for CO2.

“The exposure studies simply don’t exist,” he said.

Satartia was, in effect, an unwitting case study for a monumental project.

Gas victim DeEmmeris Burns in July 2021, near the site where he was rescued in Satartia.
Rory Doyle for HuffPost

“They Can’t Come Evacuate Y’all”

DeEmmeris Burns was returning to his mother’s house in Satartia from a fishing trip with his brother Andrew Burns and cousin Victor Lewis when they heard an explosion and then a deafening roar, like a jet engine. The stench of rotten eggs filled the car.

DeEmmeris Burns immediately thought: pipeline explosion. He knew there was one nearby, but other than its approximate location, knew nothing else about it.

They were driving on Perry Creek Road, a gravel and dirt country lane that hugs its namesake waterway and passes close to but below the location of the pipe rupture. They were almost at his mother’s house.

explosion.

“You got to get out. We’re close, we’re coming to get you,” Burns shouted over the roar of escaping gas.

On the other end of the call, 65-year-old Thelma Brown was trying to figure out why her son sounded so strange. He was hollering, breathing heavily, not making sense. She knew the pipeline he was talking about; it runs about half a mile from her house. But she hadn’t smelled anything. She heard her son frantically repeating, “Cut the air! Cut everything off! Cut the air!” And then, silence.

She tried calling him back. No answer. She rang the other two men’s cell phones, but got nothing.

Inside the car, the three men rolled up the windows to keep out whatever it was they were driving through. Then the engine died.

“Hunh,” Burns said. “Car shut off.”

Minutes later, Thelma’s sister, Linda Garrett, who lived just down the road, smelled the gas and called too. Thelma repeated what her sons had told her before their call dropped.

Garrett hung up with Thelma and called 911, but the dispatcher didn’t seem to know about a gas leak.

“Do I need to be getting out of here?” Garrett asked. The 911 operator said she’d call her back and let her know.

“She can’t breathe. She’s on the floor right now”

0:00 / 3:43

Garrett noticed her own breathing was becoming labored. Then her daughter Lynett Garrett and 14-year-old granddaughter, Makaylan Burns, who had been out picking up a pizza for dinner, staggered in the door.

Makaylan seemed to be in full-blown respiratory distress, and Lynett was unable to talk. She pounded on the dining room table and panted.

“What is it? What’s wrong? What is it?” Garrett shouted.

Makaylan dropped to the floor, unconscious.

Garrett tried 911 again. This time the operator acknowledged that there was a gas leak.

“They have shut the highway down because of it. They’re not letting anyone in, they can’t come evacuate y’all,” she said.

Garrett was afraid if they left the house, all three of them would pass out. She insisted on an ambulance. The dispatcher said one would meet them outside of town.

Gas victims Linda Garrett (right) and her granddaughter, Makaylan Burns, in Garrett's kitchen in Satartia in July.
Rory Doyle for HuffPost

Garrett and Lynett carried Makaylan out to the car. Garrett had a bad back and both adults were having trouble breathing, but they managed to get the teenager into the back seat, still unconscious.

Lynett drove and Garrett stayed on the phone with 911 as the operator told them the best route out of town. But after a few minutes, Garrett's breath "just cut out." "We ain't going to make it," she said, before she blacked out. Lynett drove to where they were supposed to meet the ambulance, but it didn't show up, and she had to drive to the hospital.

Back at her house, Thelma Brown ran outside to round up her 8- and 3-year-old grandchildren. She brought them into her bedroom, along with her 2-month-old grandson. The oldest, who has asthma but hadn't suffered an attack for some

gave some to the 3-year-old too, since she had been outside. Brown closed the windows and blocked air from coming in under the door with a wet towel.

Other relatives called, urging her to get out. But her pickup had a flat, and she was alone with three children. Her daughter was supposed to come get the kids after work, but called and told Brown that all the roads into the area were blocked off. Garrett told Brown what 911 had told her: that emergency workers were not coming into town to evacuate victims.

“I talked to the Lord. I said, ‘Lord, me and these kids going to bed,’” recalled Brown. “And I said, ‘We’re going to stay here until somebody comes and gets us out of here.’”

She waited for her son and the others to show up. She fell asleep.

Rory Doyle for HuffPost

At the same time, a group of friends were cooking crayfish and sipping beer at a fishing camp along the Yazoo River. It was getting dark when Hugh Martin noticed the rotten egg smell. Soon they were all wheezing and breathing hard. Martin's friend, Casey Sanders, collapsed onto the ground, then quickly came to.

Coughing and choking, everyone somehow made it to their vehicles. Martin jumped into his white pickup truck and drove up onto the levee that separates the town from the river. The glare of his headlights illuminated a green, misty fog. The suffocating feeling was nearly intolerable. "Only thing I been through worse than this was the gas chamber when I was in the Army training for Desert Storm," he said. "And that was CS gas." CS gas is a type of tear gas.

He called his elderly mother, Marguerite Vinson, who told him she was feeling dizzy.

"Got your shoes on, mama?" he asked, trying to keep the anxiety out of his voice. He told her to meet him in the carport of their home, not far from the fishing camp. After stopping once to throw up out of the truck window, he made it home.

"I saw mama standing there, holding her phone, and she was weak at the knees. And I just grabbed her and throwed her in the truck," said Martin. "Then I just took off and headed for the highway."

At the stop sign at Route 3 was a checkpoint, but he blew by it, heading north to the hospital in Yazoo City. His mother lay motionless on the passenger's seat: Her eyes were open, but she stared blankly ahead when he spoke to her.

At the hospital, he found others from the crayfish cook, including Casey Sanders, and learned that her teenage son, Nathan Weston Sanders, and his girlfriend were missing, after leaving the fishing camp minutes before the explosion.

Sanders had collapsed. She couldn't revive him and didn't know where they were. Now, Sanders' father and another man from the crayfish gathering were driving back into the fog to look for them.

An Improvised Response

Sheriff's Officer Terry Gann was at a grocery store, taking a break from a long day working a double homicide when he received an EMS alert about a motorist who had a seizure due to a "green fog" crossing Route 433 east of the town.

"My friend, she's laying on the ground, she's shaking, she's drooling out of the mouth"

0:00 / 2:51

Yazoo is Mississippi's biggest county at 923 square miles, but it's an economically disadvantaged one, with just 11 sheriff's officers who get called in for everything from tornadoes and floods to industrial accidents. Even though he is the county's only criminal investigator, Gann works the disasters too. At 7:32 p.m., he headed toward Satartia in his truck.

EMS advised responders that self-contained breathing apparatus was required to enter the "hot zone" inside the roadblocks, where the gas had settled. Gann didn't have SCBA with him, but he went in anyway.

had gone missing in the gas plume, not far from the ruptured pipe. The cloud was moving slowly northwest, so first Gann took the road over the levee to enter the village from the south to evacuate any remaining residents.

Terry Gann, chief investigator for the Yazoo County Sheriff's Department, with the truck he used to rescue gas victims in Satartia.
Rory Doyle for HuffPost

He did a round of checks on houses, banging on doors and peering through windows, but found no one. Around him he saw — and felt — the cloud. “It’s like I just ran a mile as fast as I could. My ears were popping. My face was burning like a sunburn.”

River, out of the cloud, to catch his breath and get the vehicle running, then returned to check more houses. Just outside of town, he found a young man and woman pacing the middle of an intersection.

“It was almost like something you’d see in a zombie movie. They were just walking in circles,” he said. “I kept telling ’em, ‘Y’all get in the truck.’ And they would just look at me with this blank look on their face. And the girl was holding a phone up to her head but she wasn’t saying nothing. … Finally I just yelled at ’em, I said, ‘Get in the truck or you’re gonna die!’”

Gann shoved the dazed teenagers into the back seat, not knowing it was Nathan Weston Sanders and his girlfriend.

After picking up a woman he found unresponsive in a stalled car, his engine began sputtering again, so he returned to the command post to meet the ambulance. By the time they got there, Gann himself could barely breathe and had to be given oxygen.

He did one last search of Satartia, then messaged dispatch, “Everyone evacuated” at 9 p.m. He radioed that he was heading for Perry Creek Road, which hadn’t yet been searched.

That worried Jack Willingham, director of Yazoo County Emergency Management Agency, since Gann had been breathing high levels of CO2 for nearly two hours and was panting audibly over the radio. His speech was often slurred and when it wasn’t, it didn’t always make sense. Willingham ordered Gann to leave the “hot zone” immediately and get medical attention.

But Gann, disoriented by the lack of oxygen, got lost and never made it to Perry Creek. With radio guidance, he met an ambulance that took him to a hospital in Yazoo City. After two hours of oxygen treatments, he went home, utterly spent.

'em, I said, 'Get in the truck or you're gonna die!'

By then, however, a three-man team of Vicksburg firefighters was on its way to Perry Creek Road.

They were driving a UTV, or utility task vehicle, a small ATV-like two-seater with an open cargo bed in back that held spare air bottles and tools. Jerry Briggs, fire coordinator for Warren County, squatted in the cargo area with Warren County 911 director Shane Garrard, while Lamar Frederick, a Vicksburg fire chief, drove. Each wore 60 pounds of fire protective clothing and gear, including SCBA.

After making their own fruitless search of the village, they decided that rather than return empty handed, they would enter the blast area via Perry Creek Road. The roar of the ruptured pipeline was deafening as they approached.

A half mile up Perry Creek Road, they saw a car with its lights on and windows up just as the UTV began stalling.

"We got victims," Frederick yelled above the roar.

Inside the small red Cadillac sedan were three men: DeEmmeris and Andrew Burns, and Victor Lewis. DeEmmeris Burns lay across the backseat in the fetal position. The other two were slumped against the windows, white foam coming out of their noses and mouths, their clothes stained with urine and excrement. The firemen thought they were too late.

The doors were stuck, so Briggs smashed the right rear window. The three were still breathing, though just barely. The rescuers shook them and tried sternum rubs, but got no reaction.

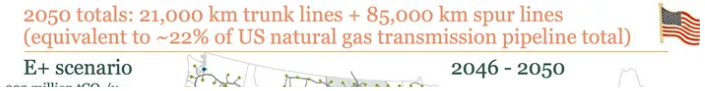
Warren County firefighter Jerry Briggs in July with the utility task vehicle he used during the February 2020 gas leak in Satartia.
Rory Doyle for HuffPost

Panting in exhaustion and sweating under all their gear, they managed to get all three out and cram them into the UTV.

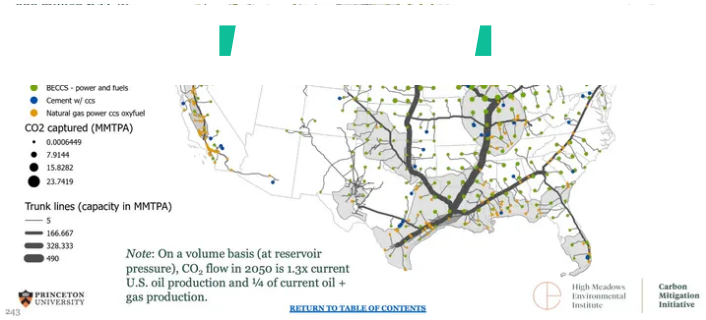
They headed toward the south command post. After a few minutes of fresh air, the victims began to stir. Then they tried to stand up. They seemed about to fall off when a truck full of county deputies met up with the UTV, and one of the deputies bear-hugged the men into place until they met the ambulance.

The firemen had just a few minutes to breath fresh air and chug water before Willingham sent them to evacuate a group of mostly elderly residents just across the river. Willingham and the National Weather Service office in Jackson were tracking the plume as it headed northwest, and Willingham was determined to get ahead of it.

monitoring contractor, the Center for Toxicology and Environmental Health; the environmental remediation firm E3; an investigator for the federal Pipeline Hazardous Materials Safety Administration (PHMSA); and officials from the Mississippi's Emergency Management Agency and Department of Environmental Quality.



At 11:06 p.m., the Denbury team "observed no product coming from the failure location," according Denbury's report to PHMSA. The leak was officially declared over.



A Massive Buildout

Once the province of a few policy wonks and coal companies, shipping carbon dioxide and storing it underground has gotten much more mainstream attention in recent years amid a tsunami of conferences, draft legislation and interest groups.

The fossil fuel industry has gotten behind CCS as a technology that, it hopes, would allow continued production so long as the emissions are buried underground. But the immense network of pipelines needed to transport carbon dioxide to locations where it would be stored deep below ground weren't discussed publicly until recently, nor was how such a rapid, unprecedented pipeline buildout could be done.

A much-touted December 2020 Princeton University study — funded in part by the oil industry — calls for a 65,000-mile system by 2050, which means adding 60,000 miles to the current 5,000 miles of CO2 pipeline. The new system would be organized into a spider web of continent-spanning trunk lines as large as 4′ in diameter — twice the size of the Satartia pipeline — fed by a system of smaller spur lines.

Princeton Net-Zero America Report

But even 65,000 miles of pipeline could only move 15% of current U.S. greenhouse gas emissions. To have any effect on climate change "would entail CO2 pipeline capacity larger than the existing petroleum pipeline system," which totals 2.6 million miles, according to a 2020 study in Biophysical Economics and Sustainability.

Beginning with the Bush administration, the U.S. government has spent over $8 billion to promote carbon capture and storage (CCS). But almost all of the CO2 in current pipelines is used for enhanced oil recovery rather than being injected deep into the earth for secure geologic storage, and enhanced oil recovery produces more emissions than it sequesters. Almost none of today's CO2 is manmade, but comes from natural sources like the Jackson Dome.

Proposals like Princeton's would likely require extending CO2 pipelines into heavily populated areas, across mountains and other natural barriers. The cost of such an enormous system is driving some to suggest simply repurposing existing natural gas pipelines to move CO2.

But because CO2 is corrosive and will eat through the carbon steel used in petroleum pipelines if contaminated with even small amounts of water, CO2 pipelines have to be manufactured to a higher standard and the purity of the gas carefully monitored. And research shows that CO2 from a commonly used carbon capture technique is particularly likely to have water in it. CO2 pipelines also run at significantly higher pressures than natural gas pipelines, which in turn requires more energy-gobbling compressor stations along the line to keep the CO2 in a liquid state.

existing natural gas pipelines to move CO2. The American Petroleum Institute has also highlighted the risks.

Yet an influential white paper produced jointly by the Energy Futures Initiative, headed by former U.S. Energy Secretary Ernest Moniz, and the AFL-CIO proposes doing just that. “Repurposing the expansive U.S. network of existing oil and gas pipelines presents a ripe opportunity to lower costs for CO2 transport,” said the report.

Moniz was Biden’s energy adviser in his 2020 presidential campaign, and oversaw billions in spending on CCS in his time at the Department of Energy. He and his team are considered leading experts on both natural gas and carbon dioxide infrastructure. Yet the petroleum industry’s own longstanding warnings about mixing gas technology with carbon dioxide are nowhere to be found in a 79-page report or its 299 footnotes.

“So much of it is about cost cutting, finding ways to do things cheaper and where can you make compromises,” said Carroll Muffett, president of the Center for International Environmental Law and co-author of a highly critical report on CCS and pipelines.

Muffett noted that CO2 behaves differently from natural gas inside a pipeline — in ways that make a CO2 rupture uniquely dangerous.

“Because of the intense pressures involved, explosive decompression of a CO2 pipeline releases more gas, more quickly, than an equivalent explosion in a gas pipeline,” noted a report by CIEL and the Environmental Working Group, and “even a modest rupture can spread freezing CO2 over a wide area within seconds.”

A complicating factor in the Satartia accident was the presence of hydrogen sulfide. A Mississippi Emergency Management Agency email from the night of the accident said the leak contained an “unknown amount of pressurized CO2 with H2S.” CO2 is often contaminated with hydrogen sulfide, and Muffett points

health effects that can include damage to the nervous system, lungs, liver and heart.

Even CO2 by itself, however, can be quite lethal. On a summer day in 1986, a thick plume of CO2 from a volcanic lake in Cameroon killed 1,746 people. Birds dropped out of the sky and whole families died together in minutes.

Short of death, however, there is a wide range of CO2 inhalation effects, which include dizziness, headache, nausea, shortness of breath, increased heart rate, memory disturbances, lack of concentration, disorientation, convulsions, and unconsciousness — symptoms that closely track those of Satartia's gassing victims.

Unfortunately, few emergency rooms are familiar with the range of its effects.

A Scramble At The Hospital

When DeEmmeris Burns woke up, he was sitting in a chair near a nurse's station. He had no idea how he got to the hospital.

An IV was running down his arm, and his brother and cousin were in adjoining chairs. His lungs burned and his head ached. He was still in his soiled clothes.

"They didn't put us in rooms. I mean, it was just all bad," he remembered. "The nurses weren't prepared for this."

The hospitals told HuffPost that they responded appropriately under standard protocols for a mass toxic incident, but would not comment on specific cases.

At around 12:30 a.m., Sarah Belk, who had grown up with the Burns brothers, found the three sitting in chairs, wrapped in a single blanket. Belk had brought her own mother and daughter to the ER after they escaped from Sataria.

> ***realizing the extent of what was going on with these people," she said.***
>
> *Sarah Belk*

Andrew Burns asked where they were, and she told them they were at the hospital in Vicksburg, that their car stalled in the cloud of gas, and they'd been found unconscious. They were shivering "like they were in shock," Belk said.

She saw their stained clothes and the dried foam on their faces. All three were thirsty. No one was attending to them, and the nurses seemed dismissive and rude, Belk said.

"I felt that they were not realizing the extent of what was going on with these people," she said.

Belk's 16-year-old daughter, Ellie, had thrown up, and was still red-faced from the lack of air during her escape from Satartia. Belk's 57-year-old mother, who has COPD, was also struggling to breathe, and after more than an hour of gas exposure, her complexion "was gray." But Belk said she still struggled to get them oxygen or basic attention. The hospital seemed overwhelmed.

Belk let the three men borrow her phone to call their families.

"I'm like, 'What's going on?'" Berneva Lewis, Victor Lewis' mother, remembered. "'We're at the hospital.' That's all they could tell me on the phone. I'm like, 'What happened?' They're like, 'They said we were in gas.'"

Given how disoriented they were, Lewis was startled to get a call at 2 a.m. saying the men were being released. "It was ridiculous. They were out before I could even get to the hospital," she said.

father's home in Vicksburg. They were still in the same clothes they'd worn upon arrival.

Of some 49 gassing victims who went to the hospital, almost all were treated at Merit Health River Region in Vicksburg or Baptist Memorial Hospital in Yazoo City. But the victims say neither facility seemed prepared for how to deal with this kind of disaster. In response to questions from HuffPost, both hospitals acknowledged they based treatment on standard toxic event protocols, which included setting up unheated outdoor decontamination tents to undress and wash victims — despite temperatures in the low 40s that day.

Neither hospital said they'd received any special training in handling a CO2 pipeline incident. Medical records for four gassing victims treated at Baptist Memorial — and for six of those from Merit River Region, including the Burns brothers and Lewis — seem to reflect confusion about what they were exposed to.

"Asphyxiation by environmental toxic gas, accidental or unintentional initial encounter. CO2, H2S, chlorine gas exposure from ruptured gas line," reads the report for all four of the Baptist patients. Later the records cite "natural gas exposure."

"They [were] nowhere near ready for something like that to happen," Hugh Martin said. "They were understaffed, but they also didn't know what the hell they were dealing with."

For Denbury, An "Incident" Without Consequences

Denbury knew about the accident before anyone. At 7:07 p.m., a low pressure alarm at its Texas headquarters alerted the company that the pipeline was leaking, and the company closed the main operating valves for the Satartia section of the line at 7:15 p.m., according to Denbury's incident report to the federal Pipeline and Hazardous Materials Safety Administration (PHMSA).

responders, but both Fire Chief Durward Pettis and county Emergency Management Director Jack Willingham said nobody called them.

Denbury had no contact with them until Pettis called the company at about 7:45 p.m., according to the Yazoo County emergency dispatch log, and even then provided no guidance on the response or how to treat CO2 inhalation victims.

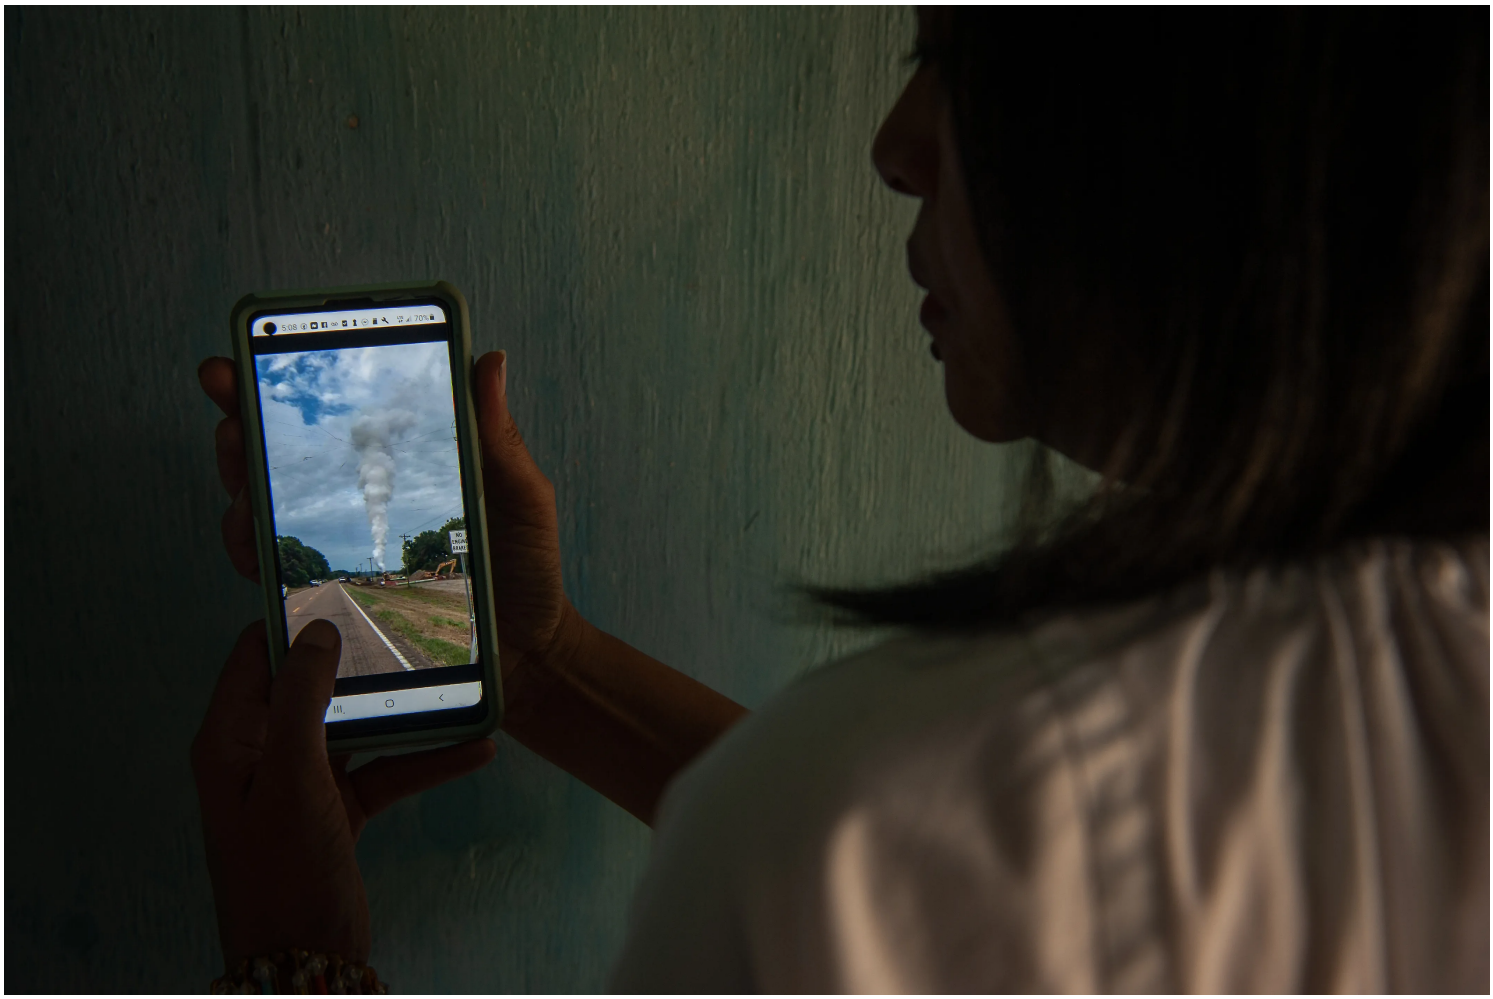
Without that guidance, 911 operators told callers there had been a natural gas pipeline rupture. But natural gas and CO2 are quite different. Natural gas is lighter than air, travels straight up, and is highly flammable. Exposure to CO2 mixed with hydrogen sulfide, on the other hand, can cause death from asphyxiation as well as lung damage. Residents of Sartaria were given no information about how to respond to such a mixture.

In the weeks that followed, Denbury also appears not to have disclosed the extent of the pipeline breach to investors.

“The affected pipeline segment was [isolated] within minutes of detection,” Denbury’s Senior Vice President of Operations David Sheppard said during a Feb. 25 quarterly earnings call. “And as a precaution, the area surrounding the leak site was evacuated, including residents of the small nearby town of Satartia. No injuries to local residents, our employees, our contractors were reported in association with the leak.”

LEFT: The CO2 pipeline rupture. RIGHT: Vehicles pass over the pipeline explosion site in Satartia in July.
Yazoo County Emergency Management Agency/Rory Doyle for HuffPost

To date, that is Denbury's most detailed public statement on the CO2 pipeline leak. Its filings with the Securities and Exchange Commission make no mention of a pipeline accident or leak, the evacuation, the injuries to residents, or any other details. Its 2021 annual report made two oblique references to the explosion, noting an oil production decline in 2020 at its Delhi, Louisiana, oil field "due to the lack of CO2 purchases between late-February and late-October 2020 as a result of the Delta-Tinsley CO2 pipeline being down for repair during that period" and "$4.3 million of costs associated with the Delta-Tinsley CO2 pipeline repair."



Denbury did disclose a total of 46 hospitalizations and 200 evacuees — the latter a little lower than the number reported by other sources — in its incident report to PHMSA.

Denbury also did not disclose that on Oct. 7, 2020, there was another accident while reconnecting the damaged pipeline section. While workers did a "controlled blow-down" to remove any remaining CO2 from the section, a valve "froze in the open position due to internal ice formation" and gas poured out, according to Denbury's report to the state Department of Environmental Quality. Multiple attempts to close it failed, and some residents had to be evacuated that night on short notice. But the second incident lasted longer — almost an entire

22 incident lasted four hours and released 31,407 barrels.

Why the pipeline initially ruptured also has yet to be determined. A PHMSA spokesman declined to comment on when its official report on the incident might be released.

Meanwhile, Denbury sent a section of the pipeline to a metallurgical lab for testing. Based on those findings and its contention that the pipeline was “code compliant,” it theorized in its report to PHMSA that soil movement caused by persistent heavy rains “induced axial stresses” that caused a rupture.

Berneva Lewis plays a video of an October 2020 gas leak in Satartia.
Rory Doyle for HuffPost.

evacuations along the Yazoo and Mississippi rivers. But Chad Jones, a plaintiff's lawyer representing gassing victims who is also a geologist, said flooding is common in the Delta, and should have been anticipated when the pipeline was built in 2007. Jones noted several other factors that should have been taken into account during construction as well: the soil in the area, called loess, is unstable and prone to shifting and mudslides, and building a pipeline through such soil requires special techniques because any rupture in that area would send the gas downhill into Satartia.

"They might claim an act of God," said Jones, "but I mean, we can prove that it wasn't."

Denbury Resources filed for bankruptcy five months after the incident, citing the pandemic crash in oil prices. It emerged from Chapter 11 in September 2020 after shedding $2.1 billion in debt and its old name. In March 2021, the newly restructured Denbury Inc. gave a presentation at the 26th Annual Credit Suisse Energy Summit recounting highlights of 2020, including "record levels of safety performance for the fourth consecutive year."

Among the new capital investments for 2021 that Denbury CEO Chris Kendall and other officials unveiled was a $7 million plan boosting CO2-based drilling operations in the Tinsley field — using the same pipeline that ruptured in 2020.

The Next Day

Officer Terry Gann got three hours of sleep before heading back to Satartia.

Abandoned vehicles were everywhere — doors ajar, many with their windows smashed from the rescue efforts. Gann had the keys to several, and rescuers set up a kind of lost and found on the side of the road.

Gann helped Denbury personnel, including technicians with gas measuring equipment, escort villagers back to their homes. The rotten egg odor was still heavy in the air.

technician's gas meter hit the red zone, and they had to leave until levels went down.

That evening, Satartia Mayor Kathy Nesbit, Pettis and several Denbury representatives presided over a standing-room-only meeting at First Baptist Church. Bruce Augustine, Denbury's operations manager, told the crowd that the company was "very happy that the air monitoring we've done shows that everyone can now return to their homes."

Denbury officials said they would be stationed at the town hall to deal with any problems or complaints, and that residents would be promptly reimbursed for medical bills. While there was some discussion of safety measures to prevent a repeat disaster, nothing definite was promised.

Nesbit, an intensive care nurse who had been working at River Region hospital the night before, tried to dispel fears of long-term health effects. "It is a natural chemical in our bodies," she said. "So it's not a poison that's going to infiltrate you and eventually kill you."

That was cold comfort to many survivors, some of whom noted pointedly that Nesbit hadn't been in town that night and didn't experience being inside the plume.

When it was over, Thelma Brown and Berneva Lewis thanked Vicksburg firefighters Jerry Briggs and Shane Garrard for saving their sons. "That was when they actually told us about the condition that the guys were in and how they were very near death and foaming at the mouth," Brown said.

Warren County firefighters Shane Garrard (left) and Lamar Frederick in Vicksburg, Mississippi, in July. They're next to the utility task vehicle they used during the February 2020 gas leak in Satartia.
Rory Doyle for HuffPost.

DeEmmeris and Andrew Burns and Victor Lewis were still in no shape to go to any meetings. After a sleepless night, more vomiting and severe headaches, they spent early Sunday on oxygen, being monitored and having bloodwork done at the University of Mississippi Medical Center in Jackson, the state's flagship teaching hospital. Even after that, Lewis told his mother, who is a nurse, that he still felt terrible.

She took all three to another doctor the next day, and tests revealed that their blood CO2 levels were still alarmingly high. The doctor said they would need to remain on oxygen until the numbers came down, and sent them to a pulmonologist.

medical bills quickly. Residents were asked to drop by Town Hall to discuss compensation for other losses, like pain and suffering. Those who accepted were paid on the spot, but waived their right to sue or discuss the settlement.

But many victims, some of whom say they are still sick, anxious and unable to fully return to their previous lives, weren't interested in a deal and decided to sue. The Burns brothers and Lewis hired Robert Gibbs, a well known lawyer from Jackson. Their suit will claim Denbury failed to properly maintain the pipeline or take necessary safety precautions to prevent exposure to hazardous gas, Gibbs said.

Another who decided to sue was Martin, whose occasional breathing difficulties from mild COPD have required much more frequent use of his inhaler since the February 2020 incident.

Medical records also show that months after the incident, his 78-year-old mother, who had no previous history of breathing difficulties, was using albuterol constantly, getting oxygen treatments, and had to be hospitalized for a week in March 2020 after he found her lying unresponsive in bed and having trouble breathing.

Marguerite Vinson was frustrated that not only was she not recovering, she seemed to be getting sicker.

"I can't think half-right! And I just wear out. Anything I try to do, it's hard to do if it requires exertion," she said.

Linda Garrett said Denbury asked to meet with her three weeks after the incident and offered her a package deal — $5,000 each for her, her daughter and granddaughter, which she refused. She said she heard one neighbor, who is white, had been offered $10,000, and that another white neighbor had been given $18,000 compensation for cows that miscarried after the incident.

"They value a cow more than they do a human," Garrett said.

Not long after the gassing, DeEmmeris Burns' phone rang. According to Burns, the voice on the other end identified himself as Denbury CEO Chris Kendall.

"He asked me 'How's everything going?'" said Burns. "I just told him I've got someone talking for me now."

"You Should've Told Us."

Over a year and a half after the gassing incident, the Burns brothers and Lewis still have not returned to work. They were under a doctor's care until February 2021, when they were taken off oxygen, said Gibbs. DeEmmeris Burns moved out of his mother's house because, he said, it's too painful for him to drive up Perry Creek Road.

Gibbs said his and some nine other law firms representing the Satartia CO2 plaintiffs have joined forces as the Denbury Litigation Group. While Gibbs represents only the three Perry Creek Road victims, some lawyers have as many as 60 or 70 clients. None has yet filed suit, awaiting the long-delayed Pipeline and Hazardous Materials Safety Administration report on the reasons for the accident.

Martin said he hopes a lawsuit will pry out all the facts about what happened that night and why.

"If there's this many malfunctions in that one section of pipeline, somebody was at fault, or they were passing inspections they shouldn't have passed," said Martin. "That's what we need to find out."

Nevertheless, opinions differ as to how or even whether Denbury should be held accountable. One reason may be an inherent reluctance to criticize the oil and gas industry, a source of scarce well-paid jobs as well as a statewide political power. Some are willing to consider the pipeline rupture "an act of God," though

of the disaster.

The sun sets on the village of Satartia alongside the Yazoo River in July.
Rory Doyle for HuffPost

Interestingly, only a few of the residents interviewed for this article had heard of carbon capture and sequestration — and none knew about plans for a greatly expanded CO2 pipeline network.

“That doesn’t make any sense,” said Martin. “Not when they can’t control what they’ve already got. I think there’s real basic questions that need to be answered

Linda Garrett said she still struggles with back pain from carrying Makaylan to the car that day. Makaylan's asthma, which had been in remission, is worse than ever, and both her daughter and granddaughter remain traumatized. She wants the company punished.

Denbury, she said, should have warned the town before there was an emergency.

"If you cared about us, you and the pipeline, you should have let us know," Garrett said. "But you didn't let us know nothing. You just telling us now. That doesn't seem right to me. Sometimes we have to be held accountable for the things that happen."

CORRECTIONS: *An earlier version of this article misidentified a person affected as Lynett Burns. The woman's name is Lynett Garrett. An earlier version of this article also misquoted Hugh Martin as saying his Army training for Desert Storm included "cyanide gas," rather than "CS gas."*

Earthquake triggering and large-scale geologic storage of carbon dioxide

Mark D. Zoback[a,1] and Steven M. Gorelick[b]

Departments of [a]Geophysics and [b]Environmental Earth System Science, Stanford University, Stanford, CA 94305

Edited by Pamela A. Matson, Stanford University, Stanford, CA, and approved May 4, 2012 (received for review March 27, 2012)

Despite its enormous cost, large-scale carbon capture and storage (CCS) is considered a viable strategy for significantly reducing CO_2 emissions associated with coal-based electrical power generation and other industrial sources of CO_2 [Intergovernmental Panel on Climate Change (2005) IPCC Special Report on Carbon Dioxide Capture and Storage. Prepared by Working Group III of the Intergovernmental Panel on Climate Change, eds Metz B, et al. (Cambridge Univ Press, Cambridge, UK); Szulczewski ML, et al. (2012) *Proc Natl Acad Sci USA* 109:5185–5189]. We argue here that there is a high probability that earthquakes will be triggered by injection of large volumes of CO_2 into the brittle rocks commonly found in continental interiors. Because even small- to moderate-sized earthquakes threaten the seal integrity of CO_2 repositories, in this context, large-scale CCS is a risky, and likely unsuccessful, strategy for significantly reducing greenhouse gas emissions.

carbon sequestration | climate change | triggered earthquakes

The combustion of coal for electrical power generation in the United States generates approximately 2.1 billion metric tons of CO_2 per year, ~36% of all US emissions. In 2011, China generated more than three times that much CO_2 by burning coal for electricity, which accounted for ~80% of its total emissions. (According to the Energy Information Agency of the US Department of Energy, total CO_2 emissions in China were 8.38 billion metric tonnes in 2011, with 6.95 billion tons from coal burning, nearly all of which is used electrical power generation.) From a global perspective, if large-scale carbon capture and storage (CCS) is to significantly contribute to reducing the accumulation of greenhouse gases, it must operate at a massive scale, on the order of 3.5 billion tons (1) of CO_2 per year, a volume roughly equivalent (2) to the ~27 billion barrels of oil currently produced annually around the world. (Under reservoir conditions, one billion tons of CO_2 occupies a volume of ~1.3 billion cubic meters, equivalent to 8.18 billion barrels. Thus, 3.5 billion tons of carbon dioxide would correspond to a volume of approximately 28.6 billion barrels. There are currently ~850,000 wells producing oil around the world.) Moreover, a leak rate from underground CO_2 storage reservoirs of less than 1% per thousand years is required for CCS to achieve the same climate benefits as renewable energy sources (3).

Before embarking on projects to inject enormous volumes of CO_2 at numerous sites around the world, it is important to note that over time periods of just a few decades, modern seismic networks have shown that earthquakes occur nearly everywhere in continental interiors. Fig. 1, *Upper* shows instrumentally recorded earthquakes in the central and eastern United States and southeastern Canada. Fig. 1, *Lower* shows instrumentally recorded intraplate earthquakes in south and east Asia (4). The seismicity catalogs are complete to magnitude (M) 3. The occurrence of these earthquakes means that nearly everywhere in continental interiors a subset of the preexisting faults in the crust is potentially active in the current stress field (5, 6). This is sometimes referred to as the *critically stressed* nature of the brittle crust (7). It should also be noted that despite the overall low rate of earthquake occurrence in continental interiors, some of the most devastating earthquakes in history occurred in these regions. In eastern China, the M 7.8, 1976 Tangshan earthquake, approximately 200 km east of Beijing, killed several hundred thousand people. In the central United States, three M 7+ earthquakes in 1811 and 1812 occurred in the New Madrid seismic zone in southeast Missouri.

Because of the critically stressed nature of the crust, fluid injection in deep wells can trigger earthquakes when the injection increases pore pressure in the vicinity of preexisting potentially active faults. The increased pore pressure reduces the frictional resistance to fault slip, allowing elastic energy already stored in the surrounding rocks to be released in earthquakes that would occur someday as the result of natural geologic processes (8). This effect was first documented in the 1960s in Denver, Colorado when injection into a 3-km-deep well at the nearby Rocky Mountain Arsenal triggered earthquakes (9). Soon thereafter it was shown experimentally (10) at the Rangely oil field in western Colorado that earthquakes could be turned on and off by varying the rate at which water was injected and thus modulating reservoir pressure. In 2011 alone, a number of small to moderate earthquakes in the United States seem to have been triggered by injection of wastewater (11). These include earthquakes near Guy, Arkansas that occurred in February and March, where the largest earthquake was M 4.7. In the Trinidad/Raton area near the border of Colorado and New Mexico, injection of produced water associated with coalbed methane production seems to have triggered a number of earthquakes, the largest being a M 5.3 event that occurred in August. Earthquakes seem to have been triggered by wastewater injection near Youngstown, Ohio on Christmas Eve and New Year's Eve, the largest of which was M 4.0. Although the risks associated with wastewater injection are minimal and can be reduced even further with proper planning (11), the situation would be far more problematic if similar-sized earthquakes were triggered in formations intended to sequester CO_2 for hundreds to thousands of years.

Deep borehole stress measurements confirm the critically stressed nature of the crust in continental interiors (12), in some cases at sites directly relevant to the feasibility of large-scale CCS. For example, deep borehole stress measurements at the Mountaineer coal-burning power plant on the Ohio River in West Virginia indicate a severe limitation on the rate at which CO_2 could be injected without the resulting pressure build-up initiating slip on preexisting faults (13). Because of the low permeability of the formations at depth, pore pressure increases would be expected to trigger slip on preexisting faults if CO_2 injection rates exceed approximately 1% of the 7 million tons of CO_2 emitted by the Mountaineer plant each year. Similarly, stress measurements at Teapot Dome, Wyoming, the US government-owned oil field where pilot CO_2

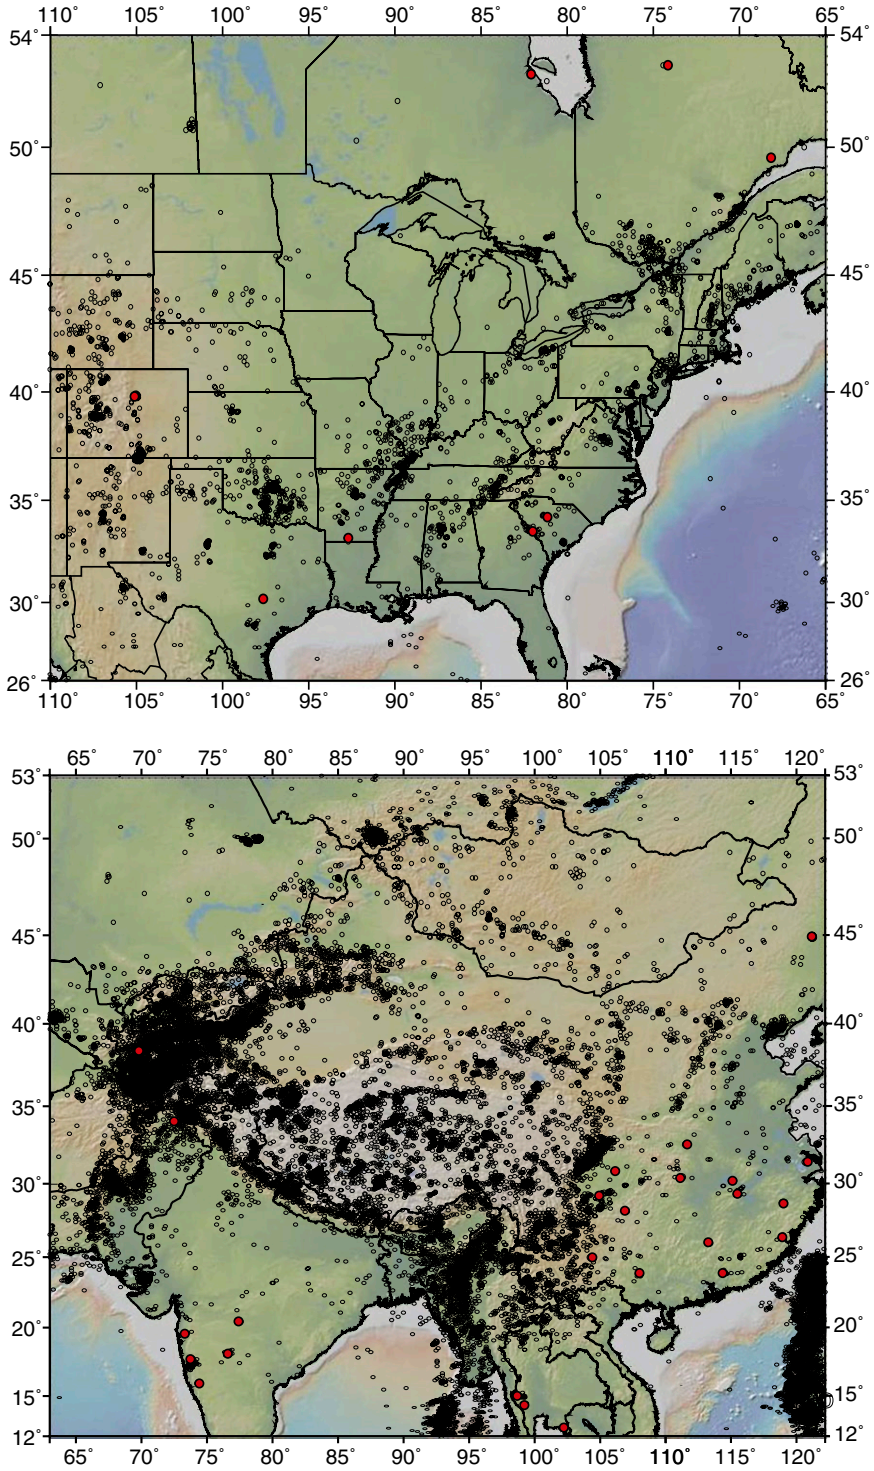

Fig. 1. *Upper*: Instrumentally recorded seismicity and damaging historical earthquakes in the central and eastern United States and southeastern Canada. Red dots indicate sites of reservoir-induced seismicity. *Lower*: Seismicity of south and east Asia and sites of reservoir-induced seismicity. Both data sets are available from the US Geological Survey (4).

injection projects have been considered, show that very small pressure buildups are capable of triggering slip on some preexisting faults (14).

Dam construction and water reservoir impoundment produce much smaller pore pressure changes at depth than are likely to occur with CO_2 sequestration, but many have triggered earthquakes at various sites around the world (15) (red dots in Fig. 1). Except for the much smaller pore pressure increases at depth, reservoir-triggered earthquakes are a good analog for the potential for seismicity to be triggered by CO_2 injection. Both activities cause pore pressure increases that act over large areas and are persistent for long periods. Three reservoir impoundments in eastern Canada (located in the ancient, stable core of the North American continent) triggered earthquakes as large as M 4.1 and M 5 at the two sites (Fig. 1), despite the fact that the pore pressure increases at depth were extremely small.

Triggered Earthquakes and Seal Integrity

Our principal concern is not that injection associated with CCS projects is likely to trigger large earthquakes; the problem is that even small to moderate earthquakes threaten the seal integrity of a CO_2 repository. In parts of the world with good construction practices, it is unusual for earthquakes smaller than approximately M 6 to cause significant human harm or property damage. Fig. 2 uses well-established seismological relationships to show how the magnitude of an earthquake is related to the size of the fault that slipped and the amount of fault slip that occurred (16). As shown, faults capable of producing M ~6 earthquakes are at least tens of kilometers in extent. (The fault size indicated along the abscissa is a lower bound of fault size as it refers to the size of the fault segment that slips in a given earthquake. The fault on which an earthquake occurs is larger than the part of the fault that slips in an individual event.) In most cases, such faults should be easily identified during geophysical site characterization studies and thus should be avoided at any site chosen for a CO_2 repository. (Faults in crystalline basement rocks might be difficult to recognize in geophysical data. We assume, however, that any site chosen as a potential CO_2 repository would be carefully selected, avoiding the possibility of pressure changes in the CO_2 repository from affecting faults in crystalline basement.) The problem is that site characterization studies can easily miss the much smaller faults associated with small to moderate earthquakes.

Although the ground shaking from small- to moderate-sized earthquakes is inconsequential, their impact on a CO_2 repository would not be. Most of the geologic formations to be used for long-term storage of CO_2 are likely to be at depths of approximately 2 km—deep enough for there to be adequate sealing formations to isolate the CO_2 from the biosphere but not so deep as to encounter formations with very low permeability. Given large volumes of CO_2 injected into selected formations for many decades, if a small to moderate earth-

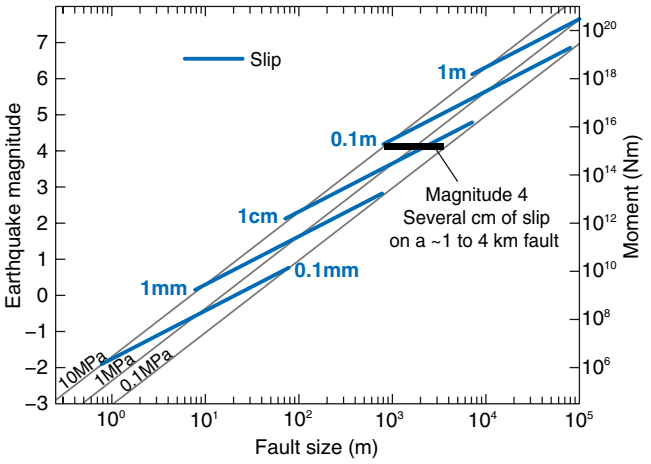

Fig. 2. Relationships among various scaling parameters for earthquakes. The larger the earthquake, the larger the fault and amount of slip, depending on the stress drop in a particular earthquake. Observational data indicate that earthquake stress drops range between 0.1 and 10 MPa.

quake were to be triggered in a geologic formation at approximately 2 km depth, it could jeopardize the seal integrity of the storage formation. For example, if a M ~4 earthquake were to be triggered by CO_2 sequestration (17)—an event that would be widely felt in a populated area but for which shaking would be unlikely to cause harm or damage—it would be associated with several centimeters of slip on a fault several kilometers in size. Because laboratory studies show that just a few millimeters of shear displacement are capable of enhancing fracture and joint permeability (18), several centimeters of slip would be capable of creating a permeable hydraulic pathway that could compromise the seal integrity of the CO_2 reservoir and potentially reach the near surface.

Safe Sequestration

It is important to emphasize that CCS can be valuable and useful for reducing greenhouse gas emissions in specific situations. A good example is the injection of CO_2 into the Utsira formation (19) at the Sleipner gas field in the North Sea, where a significant amount of CO_2 is coproduced with natural gas. After separating the CO_2 from the produced gas, approximately 1 million tons of CO_2 per year has been injected over the past 15 y without triggering seismicity. Assuming isolation from the near surface, injection into highly porous and permeable reservoirs that are laterally extensive would produce small increases in pressure in response to CO_2 injection. Moreover, weak, poorly cemented sandstones are expected to deform slowly in response to applied geologic forces. In such reservoirs, the stresses *relax* over time, and such formations are not prone to faulting (20). In this regard, the Utsira formation is ideal for CO_2 sequestration. It is isolated from vertical migration by impermeable shale formations, and it is highly porous, permeable, laterally extensive, and weakly cemented.

To contribute significantly to greenhouse gas emission reductions (2), roughly 3,500 sites similar to the Utsira formation would have to be found at convenient locations around the world, assuming comparable injection rates of approximately 1 million tons of CO_2 per year. In fact, it would take approximately 85 such sites coming on line each year to reach a goal of storing approximately 1 billion tons of CO_2 by midcentury. Clearly this is an extraordinarily difficult, if not impossible, task if only highly porous and permeable and weakly cemented formations are to be used.

Of course, rather than using potentially problematic geologic formations close to coal-burning power plants for sequestration (as illustrated by the Mountaineer case study cited above), relatively ideal formations for CO_2 storage could be sought on a regional basis to accommodate emissions from a number of plants. One example of this is the potential use of the Mt. Simon sandstone in the Illinois basin. The Mt. Simon is porous, permeable, and regionally extensive. However, models of injection of 100 million tons of CO_2 per year for 40 y predicts (21) increases in pore pressure of several megapascals over a region of ~40,000 km^2. The approximate area of significantly increased pore pressure resulting from injection is shown as the blue-shaded area in Fig. 3, essentially adjacent to the Wabash fault zone, where a series of moderate natural earthquakes occurred in the spring of 2008, the largest being M 5.2. Paleoseismic data indicate the occurrence of much larger nearby earthquakes (some greater than M ~7) in the recent geologic past (22). Importantly, the 100 million ton annual CO_2 injection rate used in the

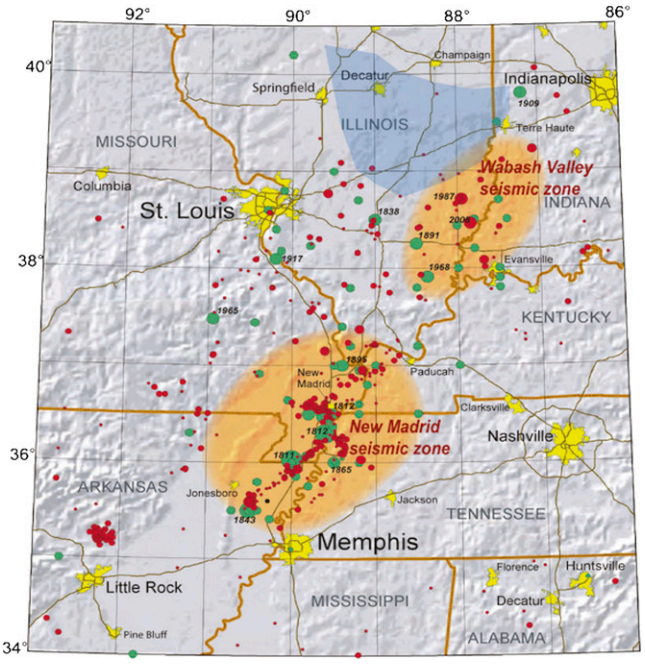

Fig. 3. Instrumentally recorded seismicity in the New Madrid and Wabash Valley seismic zones (modified from ref. 23). Red circles indicate earthquakes that occurred from 1974 to 2002 with magnitudes larger than 2.5 located using modern instruments. Green circles denote earthquakes that occurred before 1974. Larger earthquakes are represented by larger circles. The area shown in blue corresponds to the area where a pressure increase of several megapascals would result from injecting 100 million tons per year of CO_2 into the Mt. Simon sandstone in the Illinois Basin for 40 y (19).

Downloaded from https://www.pnas.org by 66.27.191.3 on March 24, 2022 from IP address 66.27.191.3.

modeling only represents approximately one seventh of the CO_2 generated by the coal-burning power plants in the Ohio River Valley alone.

Because of the need to carefully monitor CO_2 repositories with observation wells, geophysical and geochemical monitoring systems, etc., it is likely that most sites will have to be located on land or very near shore. Otherwise, highly porous reservoirs located offshore, like those adjacent to salt domes along the US Gulf Coast, would be relatively ideal sites because salt formations are known to be excellent seals for hydrocarbons.

Depleted oil and gas reservoirs are potentially suitable for CO_2 storage for a variety of reasons—an infrastructure of wells and pipelines exist, and there is a great deal of geologic and subsurface property data available to characterize the subsurface from decades of study. In addition, from an earthquake-triggering perspective, depleted reservoirs are attractive because at the time injection of CO_2 might start, the pore pressure would be below the value that existed before petroleum production. Thus, there could be significant injection of CO_2 before pressures increase to preproduction values, thereby reducing the potential for triggering earthquakes.

There are a number of potential issues to consider before using depleted oil and gas reservoirs for CO_2 storage, the most important of which are capacity and geographic distribution. The reasons that there is such interest in using saline aquifers for CO_2 storage is that they are potentially well distributed with respect to likely sources of CO_2, and they could presumably accommodate the enormous volumes of CO_2 that need to be stored. If one were only to consider the United States, storing the 2.1 billion tons of CO_2 currently generated annually by coal-burning power plants in depleted oil and gas reservoirs would require injection of CO_2 at a rate of approximately 17 billion barrels per year; a rate equivalent to eight times current US annual oil production and more than four times US peak annual oil production that occurred in the early 1970s. In addition, it is important to make sure that production-related activities, such as water flooding during secondary recovery, did not compromise the seal capacity of the reservoirs. There also needs to be careful study of the wells in the depleted oil or gas field to make sure that poorly cemented well casings, especially in older wells, will not be pathways for release of stored CO_2 (23). Finally, there are likely to be complicated legal questions concerning ownership and liability that will need to be worked out on a case-by-case basis.

Although enhanced oil recovery (EOR) using CO_2 (in which CO_2 is injected to dissolve in oil and reduce its viscosity) would be a beneficial use of CO_2, it is important not to confuse this with CCS. In CCS the goal is to inject large quantities of CO_2 into available pore space and store it there for hundreds to thousands of years. When CO_2 is used for EOR, the CO_2 dissolved in the oil is separated and captured from produced oil and then reinjected. Thus, smaller volumes of CO_2 are used, and the long-term storage capacity of the reservoir is not an issue.

Many CCS research projects are currently underway around the world. Much of this work involves characterization and testing of potential storage formations and includes a number of small-scale pilot injection projects. Because the storage capacity/pressure build-up issue is critical to assess the potential for triggered seismicity, small-scale pilot injection projects do not reflect how pressures are likely to change (increase) once full-scale injection is implemented. Moreover, even though limitations on pressure build-up are among the many factors that are evaluated when potential formations are considered as sequestration sites, this is usually done in the context of not allowing pressures to exceed the pressure at which hydraulic fractures would be initiated in the storage formation or caprock. In the context of a critically stressed crust, slip on preexisting, unidentified faults could trigger small- to moderate-sized earthquakes at pressures far below that at which hydraulic fractures would form.

As mentioned above, sequences of small to moderate earthquakes were apparently induced by injection of waste water near Guy, Arkansas, Trinidad, Colorado, and Youngstown, Ohio in 2011 and on the Dallas-Ft. Worth airport, Texas. Although these earthquakes were widely felt, they caused no injury, and only the Trinidad earthquake resulted in any significant damage. However, had similar earthquakes been triggered at sites where CO_2 was being injected, the impacts would have raised pressing and important questions: Had the seal been breached? Was it still safe to leave previously injected CO_2 in place?

In summary, multiple lines of evidence indicate that preexisting faults found in brittle rocks almost everywhere in the earth's crust are subject to failure, often in response to very small increases in pore pressure. In light of the risk posed to a CO_2 repository by even small- to moderate-sized earthquakes, formations suitable for large-scale injection of CO_2 must be carefully chosen. In addition to being well sealed by impermeable overlaying strata, they should also be weakly cemented (so as not to fail through brittle faulting) and porous, permeable, and laterally extensive to accommodate large volumes of CO_2 with minimal pressure increases. Thus, the issue is not whether CO_2 can be safely stored at a given site; the issue is whether the capacity exists for sufficient volumes of CO_2 to be stored geologically for it to have the desired beneficial effect on climate change. In this context, it must be recognized that large-scale CCS will be an extremely expensive and risky strategy for achieving significant reductions in greenhouse gas emissions.

Re: 2023060293, CarbonFrontier CCS Project by Aera Energy, LLC, Kern County

Dear Ms. Hoover:

The Native American Heritage Commission (NAHC) has received the Notice of Preparation (NOP), Draft Environmental Impact Report (DEIR) or Early Consultation for the project referenced above. The California Environmental Quality Act (CEQA) (Pub. Resources Code §21000 et seq.), specifically Public Resources Code §21084.1, states that a project that may cause a substantial adverse change in the significance of a historical resource, is a project that may have a significant effect on the environment. (Pub. Resources Code § 21084.1; Cal. Code Regs., tit.14, §15064.5 (b) (CEQA Guidelines §15064.5 (b)). If there is substantial evidence, in light of the whole record before a lead agency, that a project may have a significant effect on the environment, an Environmental Impact Report (EIR) shall be prepared. (Pub. Resources Code §21080 (d); Cal. Code Regs., tit. 14, § 5064 subd.(a)(1) (CEQA Guidelines §15064 (a)(1)). In order to determine whether a project will cause a substantial adverse change in the significance of a historical resource, a lead agency will need to determine whether there are historical resources within the area of potential effect (APE).

CEQA was amended significantly in 2014. Assembly Bill 52 (Gatto, Chapter 532, Statutes of 2014) (AB 52) amended CEQA to create a separate category of cultural resources, "tribal cultural resources" (Pub. Resources Code §21074) and provides that a project with an effect that may cause a substantial adverse change in the significance of a tribal cultural resource is a project that may have a significant effect on the environment. (Pub. Resources Code §21084.2). Public agencies shall, when feasible, avoid damaging effects to any tribal cultural resource. (Pub. Resources Code §21084.3 (a)). **AB 52 applies to any project for which a notice of preparation, a notice of negative declaration, or a mitigated negative declaration is filed on or after July 1, 2015.** If your project involves the adoption of or amendment to a general plan or a specific plan, or the designation or proposed designation of open space, on or after March 1, 2005, it may also be subject to Senate Bill 18 (Burton, Chapter 905, Statutes of 2004) (SB 18). **Both SB 18 and AB 52 have tribal consultation requirements**. If your project is also subject to the federal National Environmental Policy Act (42 U.S.C. § 4321 et seq.) (NEPA), the tribal consultation requirements of Section 106 of the National Historic Preservation Act of 1966 (154 U.S.C. 300101, 36 C.F.R. §800 et seq.) may also apply.

The NAHC recommends consultation with California Native American tribes that are traditionally and culturally affiliated with the geographic area of your proposed project as early as possible in order to avoid inadvertent discoveries of Native American human remains and best protect tribal cultural resources. Below is a brief summary of portions of AB 52 and SB 18 as well as the NAHC's recommendations for conducting cultural resources assessments.

Consult your legal counsel about compliance with AB 52 and SB 18 as well as compliance with any other applicable laws.

AB 52

AB 52 has added to CEQA the additional requirements listed below, along with many other requirements:

1. Fourteen Day Period to Provide Notice of Completion of an Application/Decision to Undertake a Project: Within fourteen (14) days of determining that an application for a project is complete or of a decision by a public agency to undertake a project, a lead agency shall provide formal notification to a designated contact of, or tribal representative of, traditionally and culturally affiliated California Native American tribes that have requested notice, to be accomplished by at least one written notice that includes:

- **a.** A brief description of the project.
- **b.** The lead agency contact information.
- **c.** Notification that the California Native American tribe has 30 days to request consultation. (Pub. Resources Code §21080.3.1 (d)).
- **d.** A "California Native American tribe" is defined as a Native American tribe located in California that is on the contact list maintained by the NAHC for the purposes of Chapter 905 of Statutes of 2004 (SB 18). (Pub. Resources Code §21073).

2. Begin Consultation Within 30 Days of Receiving a Tribe's Request for Consultation and Before Releasing a Negative Declaration, Mitigated Negative Declaration, or Environmental Impact Report: A lead agency shall begin the consultation process within 30 days of receiving a request for consultation from a California Native American tribe that is traditionally and culturally affiliated with the geographic area of the proposed project. (Pub. Resources Code §21080.3.1, subds. (d) and (e)) and prior to the release of a negative declaration, mitigated negative declaration or Environmental Impact Report. (Pub. Resources Code §21080.3.1(b)).

- **a.** For purposes of AB 52, "consultation shall have the same meaning as provided in Gov. Code §65352.4 (SB 18). (Pub. Resources Code §21080.3.1 (b)).

3. Mandatory Topics of Consultation If Requested by a Tribe: The following topics of consultation, if a tribe requests to discuss them, are mandatory topics of consultation:

- **a.** Alternatives to the project.
- **b.** Recommended mitigation measures.
- **c.** Significant effects. (Pub. Resources Code §21080.3.2 (a)).

4. Discretionary Topics of Consultation: The following topics are discretionary topics of consultation:

- **a.** Type of environmental review necessary.
- **b.** Significance of the tribal cultural resources.
- **c.** Significance of the project's impacts on tribal cultural resources.
- **d.** If necessary, project alternatives or appropriate measures for preservation or mitigation that the tribe may recommend to the lead agency. (Pub. Resources Code §21080.3.2 (a)).

5. Confidentiality of Information Submitted by a Tribe During the Environmental Review Process: With some exceptions, any information, including but not limited to, the location, description, and use of tribal cultural resources submitted by a California Native American tribe during the environmental review process shall not be included in the environmental document or otherwise disclosed by the lead agency or any other public agency to the public, consistent with Government Code §6254 (r) and §6254.10. Any information submitted by a California Native American tribe during the consultation or environmental review process shall be published in a confidential appendix to the environmental document unless the tribe that provided the information consents, in writing, to the disclosure of some or all of the information to the public. (Pub. Resources Code §21082.3 (c)(1)).

6. Discussion of Impacts to Tribal Cultural Resources in the Environmental Document: If a project may have a significant impact on a tribal cultural resource, the lead agency's environmental document shall discuss both of the following:

- **a.** Whether the proposed project has a significant impact on an identified tribal cultural resource.
- **b.** Whether feasible alternatives or mitigation measures, including those measures that may be agreed to pursuant to Public Resources Code §21082.3, subdivision (a), avoid or substantially lessen the impact on the identified tribal cultural resource. (Pub. Resources Code §21082.3 (b)).

7. Conclusion of Consultation: Consultation with a tribe shall be considered concluded when either of the following occurs:

a. The parties agree to measures to mitigate or avoid a significant effect, if a significant effect exists, on a tribal cultural resource; or

b. A party, acting in good faith and after reasonable effort, concludes that mutual agreement cannot be reached. (Pub. Resources Code §21080.3.2 (b)).

8. Recommending Mitigation Measures Agreed Upon in Consultation in the Environmental Document: Any mitigation measures agreed upon in the consultation conducted pursuant to Public Resources Code §21080.3.2 shall be recommended for inclusion in the environmental document and in an adopted mitigation monitoring and reporting program, if determined to avoid or lessen the impact pursuant to Public Resources Code §21082.3, subdivision (b), paragraph 2, and shall be fully enforceable. (Pub. Resources Code §21082.3 (a)).

9. Required Consideration of Feasible Mitigation: If mitigation measures recommended by the staff of the lead agency as a result of the consultation process are not included in the environmental document or if there are no agreed upon mitigation measures at the conclusion of consultation, or if consultation does not occur, and if substantial evidence demonstrates that a project will cause a significant effect to a tribal cultural resource, the lead agency shall consider feasible mitigation pursuant to Public Resources Code §21084.3 (b). (Pub. Resources Code §21082.3 (e)).

10. Examples of Mitigation Measures That, If Feasible, May Be Considered to Avoid or Minimize Significant Adverse Impacts to Tribal Cultural Resources:

a. Avoidance and preservation of the resources in place, including, but not limited to:

i. Planning and construction to avoid the resources and protect the cultural and natural context.

ii. Planning greenspace, parks, or other open space, to incorporate the resources with culturally appropriate protection and management criteria.

b. Treating the resource with culturally appropriate dignity, taking into account the tribal cultural values and meaning of the resource, including, but not limited to, the following:

i. Protecting the cultural character and integrity of the resource.

ii. Protecting the traditional use of the resource.

iii. Protecting the confidentiality of the resource.

c. Permanent conservation easements or other interests in real property, with culturally appropriate management criteria for the purposes of preserving or utilizing the resources or places.

d. Protecting the resource. (Pub. Resource Code §21084.3 (b)).

e. Please note that a federally recognized California Native American tribe or a non-federally recognized California Native American tribe that is on the contact list maintained by the NAHC to protect a California prehistoric, archaeological, cultural, spiritual, or ceremonial place may acquire and hold conservation easements if the conservation easement is voluntarily conveyed. (Civ. Code §815.3 (c)).

f. Please note that it is the policy of the state that Native American remains and associated grave artifacts shall be repatriated. (Pub. Resources Code §5097.991).

11. Prerequisites for Certifying an Environmental Impact Report or Adopting a Mitigated Negative Declaration or Negative Declaration with a Significant Impact on an Identified Tribal Cultural Resource: An Environmental Impact Report may not be certified, nor may a mitigated negative declaration or a negative declaration be adopted unless one of the following occurs:

a. The consultation process between the tribes and the lead agency has occurred as provided in Public Resources Code §21080.3.1 and §21080.3.2 and concluded pursuant to Public Resources Code §21080.3.2.

b. The tribe that requested consultation failed to provide comments to the lead agency or otherwise failed to engage in the consultation process.

c. The lead agency provided notice of the project to the tribe in compliance with Public Resources Code §21080.3.1 (d) and the tribe failed to request consultation within 30 days. (Pub. Resources Code §21082.3 (d)).

The NAHC's PowerPoint presentation titled, "Tribal Consultation Under AB 52: Requirements and Best Practices" may be found online at: http://nahc.ca.gov/wp-content/uploads/2015/10/AB52TribalConsultation_CalEPAPDF.pdf

SB 18

SB 18 applies to local governments and requires local governments to contact, provide notice to, refer plans to, and consult with tribes prior to the adoption or amendment of a general plan or a specific plan, or the designation of open space. (Gov. Code §65352.3). Local governments should consult the Governor's Office of Planning and Research's "Tribal Consultation Guidelines," which can be found online at: https://www.opr.ca.gov/docs/09_14_05_Updated_Guidelines_922.pdf.

Some of SB 18's provisions include:

1. Tribal Consultation: If a local government considers a proposal to adopt or amend a general plan or a specific plan, or to designate open space it is required to contact the appropriate tribes identified by the NAHC by requesting a "Tribal Consultation List." If a tribe, once contacted, requests consultation the local government must consult with the tribe on the plan proposal. **A tribe has 90 days from the date of receipt of notification to request consultation unless a shorter timeframe has been agreed to by the tribe.** (Gov. Code §65352.3 (a)(2)).

2. No Statutory Time Limit on SB 18 Tribal Consultation. There is no statutory time limit on SB 18 tribal consultation.

3. Confidentiality: Consistent with the guidelines developed and adopted by the Office of Planning and Research pursuant to Gov. Code §65040.2, the city or county shall protect the confidentiality of the information concerning the specific identity, location, character, and use of places, features and objects described in Public Resources Code §5097.9 and §5097.993 that are within the city's or county's jurisdiction. (Gov. Code §65352.3 (b)).

4. Conclusion of SB 18 Tribal Consultation: Consultation should be concluded at the point in which:

- **a.** The parties to the consultation come to a mutual agreement concerning the appropriate measures for preservation or mitigation; or
- **b.** Either the local government or the tribe, acting in good faith and after reasonable effort, concludes that mutual agreement cannot be reached concerning the appropriate measures of preservation or mitigation. (Tribal Consultation Guidelines, Governor's Office of Planning and Research (2005) at p. 18).

Agencies should be aware that neither AB 52 nor SB 18 precludes agencies from initiating tribal consultation with tribes that are traditionally and culturally affiliated with their jurisdictions before the timeframes provided in AB 52 and SB 18. For that reason, we urge you to continue to request Native American Tribal Contact Lists and "Sacred Lands File" searches from the NAHC. The request forms can be found online at: http://nahc.ca.gov/resources/forms/.

NAHC Recommendations for Cultural Resources Assessments

To adequately assess the existence and significance of tribal cultural resources and plan for avoidance, preservation in place, or barring both, mitigation of project-related impacts to tribal cultural resources, the NAHC recommends the following actions:

1. Contact the appropriate regional California Historical Research Information System (CHRIS) Center (https://ohp.parks.ca.gov/?page_id=30331) for an archaeological records search. The records search will determine:

- **a.** If part or all of the APE has been previously surveyed for cultural resources.
- **b.** If any known cultural resources have already been recorded on or adjacent to the APE.
- **c.** If the probability is low, moderate, or high that cultural resources are located in the APE.
- **d.** If a survey is required to determine whether previously unrecorded cultural resources are present.

2. If an archaeological inventory survey is required, the final stage is the preparation of a professional report detailing the findings and recommendations of the records search and field survey.

- **a.** The final report containing site forms, site significance, and mitigation measures should be submitted immediately to the planning department. All information regarding site locations, Native American human remains, and associated funerary objects should be in a separate confidential addendum and not be made available for public disclosure.
- **b.** The final written report should be submitted within 3 months after work has been completed to the appropriate regional CHRIS center.

3. Contact the NAHC for:

a. A Sacred Lands File search. Remember that tribes do not always record their sacred sites in the Sacred Lands File, nor are they required to do so. A Sacred Lands File search is not a substitute for consultation with tribes that are traditionally and culturally affiliated with the geographic area of the project's APE.

b. A Native American Tribal Consultation List of appropriate tribes for consultation concerning the project site and to assist in planning for avoidance, preservation in place, or, failing both, mitigation measures.

4. Remember that the lack of surface evidence of archaeological resources (including tribal cultural resources) does not preclude their subsurface existence.

a. Lead agencies should include in their mitigation and monitoring reporting program plan provisions for the identification and evaluation of inadvertently discovered archaeological resources per Cal. Code Regs., tit. 14, §15064.5(f) (CEQA Guidelines §15064.5(f)). In areas of identified archaeological sensitivity, a certified archaeologist and a culturally affiliated Native American with knowledge of cultural resources should monitor all ground-disturbing activities.

b. Lead agencies should include in their mitigation and monitoring reporting program plans provisions for the disposition of recovered cultural items that are not burial associated in consultation with culturally affiliated Native Americans.

c. Lead agencies should include in their mitigation and monitoring reporting program plans provisions for the treatment and disposition of inadvertently discovered Native American human remains. Health and Safety Code §7050.5, Public Resources Code §5097.98, and Cal. Code Regs., tit. 14, §15064.5, subdivisions (d) and (e) (CEQA Guidelines §15064.5, subds. (d) and (e)) address the processes to be followed in the event of an inadvertent discovery of any Native American human remains and associated grave goods in a location other than a dedicated cemetery.

If you have any questions or need additional information, please contact me at my email address: Cameron.Vela@nahc.ca.gov

Sincerely,

Cameron Vela

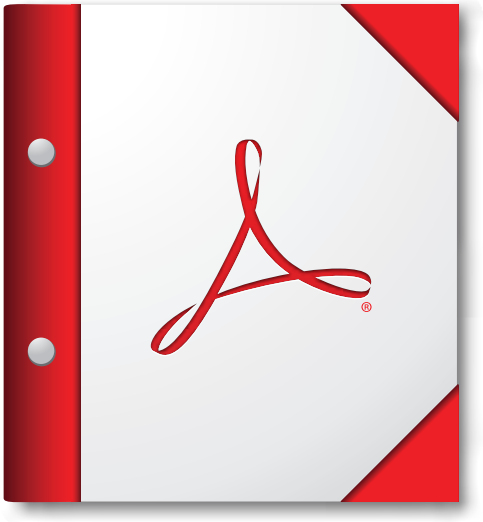
KERN COUNTY

To: Planning and Natural Resources Department
Cindi Hoover

Date: June 14, 2023

From: Public Works Department
Floodplain Management Section
Kevin Hamilton, by Brian Blase

Phone: (661) 862-5098
Email: BlaseB@kerncounty.com



Subject: Preparation of an Environmental Impact Report
CarbonFrontier Carbon Capture Sequestration Project

Our section has reviewed the attached subject documents and has the following comments:

The subject property is subject to flooding.

Therefore, this section recommends the following be included as Conditions of Approval for this project:

Associated flood hazard requirements will need to be incorporated into the design of this project per the Kern County Floodplain Management Ordinance.

For the best experience, open this PDF portfolio in Acrobat X or Adobe Reader X, or later.

Subject: Carbon Frontier Carbon Capture and Sequestration Project (Project)
Notice of Preparation (NOP)
State Clearinghouse No. 2023060293

Dear Cindi Hoover:

The California Department of Fish and Wildlife (CDFW) received a NOP from the Kern County Planning and Natural Resources Department for the above-referenced Project pursuant to the California Environmental Quality Act (CEQA) and CEQA Guidelines.[1]

Thank you for the opportunity to provide comments and recommendations regarding those activities involved in the Project that may affect California fish and wildlife. Likewise, CDFW appreciates the opportunity to provide comments regarding those aspects of the Project that CDFW, by law, may be required to carry out or approve through the exercise of its own regulatory authority under Fish and Game Code.

CDFW ROLE

CDFW is California's **Trustee Agency** for fish and wildlife resources and holds those resources in trust by statute for all the people of the State (Fish & G. Code, §§ 711.7, subd. (a) & 1802; Pub. Resources Code, § 21070; CEQA Guidelines § 15386, subd. (a)). CDFW, in its trustee capacity, has jurisdiction over the conservation, protection, and management of fish, wildlife, native plants, and habitat necessary for biologically sustainable populations of those species (*Id*., § 1802). Similarly, for purposes of CEQA, CDFW is charged by law to provide, as available, biological expertise during public agency environmental review efforts, focusing specifically on

[1] CEQA is codified in the California Public Resources Code in section 21000 et seq. The "CEQA Guidelines" are found in Title 14 of the California Code of Regulations, commencing with section 15000.

DocuSign Envelope ID: B66CA338-5670-4253-A936-6B363E05ED41

projects and related activities that have the potential to adversely affect fish and wildlife resources.

CDFW is also submitting comments as a **Responsible Agency** under CEQA (Pub. Resources Code, § 21069; CEQA Guidelines, § 15381). CDFW expects that it may need to exercise regulatory authority as provided by the Fish and Game Code. As proposed, for example, the Project may be subject to CDFW's lake and streambed alteration regulatory authority (Fish & G. Code, § 1600 et seq.). Likewise, to the extent implementation of the Project as proposed may result in "take" as defined by State law of any species protected under the California Endangered Species Act (CESA) (Fish & G. Code, § 2050 et seq.), related authorization as provided by the Fish and Game Code will be required.

Fully Protected Species: CDFW has jurisdiction over species of birds, mammals, amphibians, reptiles, and fish designated by statute as "fully protected" pursuant to Fish and Game Code sections 3511, 4700, 5050, and 5515. Take of any fully protected species is prohibited and CDFW cannot authorize their incidental take except as specifically provided for in Fish and Game Code; none of those specific exceptions are applicable to this project.

Nesting Birds: CDFW has jurisdiction over actions with potential to result in the disturbance or destruction of active nest sites or the unauthorized take of birds. Fish and Game Code sections that protect birds, their eggs and nests include sections 3503 (regarding unlawful take, possession or needless destruction of the nest or eggs of any bird), 3503.5 (regarding the take, possession or destruction of any birds-of-prey or their nests or eggs), and 3513 (regarding unlawful take of any migratory nongame bird).

Unlisted Species: Species of plants and animals need not be officially listed as Endangered, Rare, or Threatened (E, R, or T) on any State or federal list to be considered E, R, or T under CEQA. If a species can be shown to meet the criteria for E, R, or T, as specified in the CEQA Guidelines section 15380, CDFW recommends it be fully considered in the environmental analysis for the Project.

PROJECT DESCRIPTION SUMMARY

Proponent: Aera Energy, LLC

Objective: Aera Energy, LLC proposes the construction and operation of a carbon capture and storage (CSS) facility over portions of the existing and contiguous South Belridge and North Belridge oil fields near the community of Lost Hills in western Kern County. In the NOP, Kern County Planning and Natural Resources Department indicates that the CCS facility would involve the construction of appurtenant structures

DocuSign Envelope ID: B66CA338-5670-4253-A936-6B363E05ED41

for the capture, transport, and subsurface injection (geologic sequestration) of carbon dioxide (CO_2). Once the Project is implemented, CO_2 would be captured at newly constructed facilities within the South Belridge oil field and transported in newly constructed pipelines to existing abandoned oil wells in the North Belridge oil field. These wells will be retrofitted to function as injection wells and used to inject the captured CO_2 into the depleted underground oil- and gas-bearing geologic formation where it will be permanently sequestered.

The Kern County Planning and Natural Resources Department will prepare an Environmental Impact Report (EIR) for the Project. The NOP lacks detailed information with regard to the actual footprint of the Project (Project Site) within the oil fields, and does not address ground disturbance, staging, laydown, or other specific Project-related activities which could threaten biological resources and result in significant environmental impacts within the Project Site. CDFW expects these details will be provided in the EIR. CDFW also expects additional detail will be provided in the EIR addressing:

- the need for nightwork during construction or operations/maintenance of the facilities;
- construction of the pipeline (aboveground vs underground, support of aboveground sections);
- the phase of the CO_2 transported through the pipeline (gaseous or liquid); and
- potential catastrophic events (and emergency responses to those events) which could occur along the pipeline, at the capture facilities, and at the injection facilities over the life of the Project.

Location: The Project Site exists within the administrative boundaries of the existing South Belridge and North Belridge oil fields, which adjoin each other (one immediately north of the other) and are generally west of State Route 33 and north and south of Lerdo Highway. The oil fields containing the Project Site are approximately seven miles southwest of the community of Lost Hills and approximately 30 miles northwest of the city of Bakersfield in Kern County, California.

Timeframe: n/a

COMMENTS AND RECOMMENDATIONS

Special-Status Species: Special-status species are known to exist in the vicinity of the Project Site, there is the potential for the Project to impact State and federally listed species. Records from the California Natural Diversity Database (CNDDB) show that the following special-status species, including State and federally listed species (CDFW 2023) could be impacted: the State threatened and federally endangered San Joaquin kit fox (*Vulpes macrotis mutica*); the State and federally endangered and State fully

DocuSign Envelope ID: B66CA338-5670-4253-A936-6B363E05ED41

protected blunt-nosed leopard lizard (*Gamelia sila*); the State and federally endangered and California Rare Plant Ranked (CRPR) 1B.1 California jewelflower (*Caulanthus californicus*); the State and federally endangered giant kangaroo rat (*Dipodomys ingens*), Tipton kangaroo rat (*Dipodomys nitratoides nitratoides*); the State threatened San Joaquin antelope squirrel (*Ammospermophilus nelsoni*), tricolored blackbird (*Agelaius tricolor*), and Swainson's hawk (*Buteo swainsoni*); the federally endangered and State species of special concern Buena Vista Lake ornate shrew (*Sorex ornatus relictus*); the federally endangered and CRPR 1B.2 San Joaquin woollythreads (*Monolopia congdonii*) and Kern mallow (*Eremalche parrye ssp. kernensis*); the candidates for State listing Temblor legless lizard (*Anniella alexanderae*) and Crotch bumble bee (*Bombus crotchii*); the State species of special concern burrowing owl (*Athene cunicularia*), short-nosed kangaroo rat (*Dipodomys nitratoides brevinasus*), Tulare grasshopper mouse (*Onychomys torridus tularensis*), western spadefoot (*Spea hammondii*), American badger (*Taxidea taxus*), San Joaquin coachwhip (*Masticophis flagellum ruddocki*), and Le Conte's thrasher (*Toxostoma lecontei*); and the CRPR 1B.1, 1B.2 and 4.2 California alkali grass (*Puccinellia simplex*), Coulter's goldfields (*Lasthenia glabrata ssp. coulteri*), heartscale (*Atriplex cordulata var. cordulata*), Lost Hills crownscale (*Atriplex coronata var. vallicola*), recurved larkspur (*Delphinium recurvatum*), showy golden madia (*Madia radiata*), and Hoover's eriastrum (*Eriastrum hooveri*).

CDFW recommends that a habitat assessment be conducted at and in the vicinity of the Project Site for the aforementioned plant and animal species. The assessment should be conducted by a qualified biologist knowledgeable with the species and any potentially suitable habitat identified should be surveyed by a qualified biologist for the potential presence of these species as part of the biological technical studies conducted in support of the EIR. If the surveys reveal the aforementioned listed and candidate species occur at and/or near the Project Site, the EIR should include either measures to avoid take of those species, or the Project proponent's commitment to obtaining incidental take authorization under Section 2081 of Fish and Game Code, as appropriate, if avoidance will be unfeasible. Similarly, if the surveys reveal the aforementioned unlisted species, the EIR should include a commitment by the Project proponent to consult with CDFW, prior to commencing the Project, to identify and implement appropriate measures to avoid or minimize impacts to those species. It should be noted that blunt-nosed leopard lizard is State fully protected, therefore, no "take", incidental or otherwise, can be authorized by CDFW; complete avoidance of this species is required to comply with State law.

CDFW recommends that the surveys for blunt-nosed leopard lizard, San Joaquin kit fox, tricolored blackbird, Swainson's hawk, and burrowing owl be conducted in accordance with the species-specific protocols which can be found here:

DocuSign Envelope ID: B66CA338-5670-4253-A936-6B363E05ED41

https://wildlife.ca.gov/Conservation/Survey-Protocols. CDFW recommends that the surveys for the aforementioned special status and CRPR plants be surveyed for by a qualified botanist following the "Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Sensitive Natural Communities" which can also be found at: https://wildlife.ca.gov/Conservation/Survey-Protocols.This protocol, which is intended to maximize detectability, includes identification of reference populations to facilitate the likelihood of field investigations occurring during the appropriate floristic period. In the absence of protocol-level surveys being performed, additional surveys may be necessary. If take could occur as a result of Project-related activities, consultation with CDFW may be warranted.

Nesting birds: CDFW recommends that Project ground-disturbing activities occur during the bird non-nesting season; however, if ground-disturbing or vegetation-disturbing activities must occur during the nesting season (February 1st through September 15th), the Project applicant is responsible for ensuring that implementation of the Project does not result in violation of the Migratory Bird Treaty Act or relevant Fish and Game Codes as referenced above.

To evaluate Project-related impacts on nesting birds, CDFW recommends that a general habitat assessment for nesting birds be conducted as part of the biological technical studies conducted in support of the EIR. Depending on the results of that assessment, CDFW further recommends that the EIR for this Project include that a qualified biologist conduct a pre-construction survey for active nests no more than 10 days prior to the start of ground- or vegetation-disturbance to maximize the probability that nests that could potentially be impacted are detected. CDFW also recommends that surveys cover a sufficient area around the Project Site to identify nests and determine their status. A sufficient area means any area potentially affected, either directly or indirectly, by the Project. In addition to direct impacts (i.e. nest destruction), noise, vibration, and movement of workers or equipment could also affect nests. CDFW recommends that a qualified biologist establish a behavioral baseline of all identified nests. Once Project activities begin, CDFW recommends having a qualified biologist continuously monitor nests to detect behavioral changes resulting from the Project. If behavioral changes occur, CDFW recommends halting the work causing that change and consulting with CDFW for additional avoidance and minimization measures.

If continuous monitoring of identified nests by a qualified biologist is not feasible, CDFW recommends the EIR include a minimum no-disturbance buffer of 250 feet around active nests of non-listed bird species and a 500-foot no-disturbance buffer around active nests of non-listed raptors. These buffers are advised to remain in place until the breeding season has ended or until a qualified biologist has determined that the birds have fledged and are no longer reliant upon the nest or on-site parental care for survival. Variance from these no-disturbance buffers is possible when there is a

DocuSign Envelope ID: B66CA338-5670-4253-A936-6B363E05ED41

compelling biological or ecological reason to do so, such as when the Project Site would be concealed from a nest site by topography. CDFW recommends that a qualified biologist advise and support any variance from these buffers and notify CDFW in advance of implementing a variance.

CNDDB: Please note that the CNDDB is populated by and records voluntary submissions of species detections. As a result, species may be present in locations not depicted in the CNDDB but where there is suitable habitat and features capable of supporting species. A lack of an occurrence record in the CNDDB does not mean a species is not present. In order to adequately assess any potential Project-related impacts to biological resources, surveys conducted by a qualified biologist during the appropriate survey period(s) and using the appropriate protocol survey methodology are warranted in order to determine whether or not any special status species are present at or near the Project Site.

Project Alternatives Analysis: CDFW recommends that the information and results obtained from the biological technical surveys, studies, and analysis conducted in support of the project's CEQA document be used to develop and modify the Project's alternatives to avoid and minimize impacts to biological resources to the maximum extent possible. When efforts to avoid and minimize have been exhausted, remaining impacts to sensitive biological resources may need to be mitigated to reduce impacts to a less than significant level, if feasible.

Cumulative Impacts: CDFW recommends that a cumulative impact analysis be conducted for all biological resources that will either be significantly or potentially significantly impacted by implementation of the Project, including those whose impacts are determined to be less than significant with mitigation incorporated or for those resources that are rare or in poor or declining health and will be impacted by the project, even if those impacts are relatively small (i.e. less than significant). CDFW recommends cumulative impacts be analyzed using an acceptable methodology to evaluate the impacts of past, present, and reasonably foreseeable future projects on resources and be focused specifically on the resource, not the Project. An appropriate resource study area identified and utilized for this analysis is advised. CDFW staff is available for consultation in support of cumulative impacts analyses as a trustee and responsible agency under CEQA.

Lake and Stream Alteration: The Project may be subject to CDFW's regulatory authority pursuant to Fish and Game Code section 1600 et seq. Fish and Game Code section 1602 requires the Project proponent notify CDFW prior to commencing any activity that may (a) substantially divert or obstruct the natural flow of any river, stream, or lake; (b) substantially change or use any material from the bed, bank, or channel of any river, stream, or lake; or (c) deposit debris, waste or other materials that could pass

DocuSign Envelope ID: B66CA338-5670-4253-A936-6B363E05ED41

into any river, stream, or lake. “Any river, stream, or lake” includes those that are ephemeral or intermittent as well as those that are perennial in nature. The EIR should address the potential Project-related impacts to all streams at and near the Project Site. For additional information on notification requirements, please contact our staff in the LSA Program at (559) 243-4593, or R4LSA@wildlife.ca.gov.

Federally Listed Species: CDFW recommends consulting with the USFWS on potential impacts to federally listed species including, but not limited to the aforementioned San Joaquin kit fox, blunt-nosed leopard lizard, California jewelflower, giant kangaroo rat, Tipton kangaroo rat, Buena Vista Lake ornate shrew, San Joaquin woollythreads, and Kern mallow. Take under the Federal Endangered Species Act (FESA) is more broadly defined than CESA; take under FESA also includes significant habitat modification or degradation that could result in death or injury to a listed species by interfering with essential behavioral patterns such as breeding, foraging, or nesting. Consultation with the USFWS in order to comply with FESA is advised well in advance of any ground disturbing activities.

CDFW is available to meet with you ahead of draft EIR preparation to discuss potential impacts and possible mitigation measures for some or all of the resources that may be analyzed in the EIR. If you have any questions, please contact Steven Hulbert, Senior Environmental Scientist Specialist, at the address provided on this letterhead, by telephone at (559) 575-6415, or by electronic mail at Steven.Hulbert@wildlife.ca.gov.

Sincerely,

DocuSigned by:

Subject: Carbon Frontier Carbon Capture and Sequestration Project (Project)
Notice of Preparation (NOP)
State Clearinghouse No. 2023060293

Dear Cindi Hoover:

The California Department of Fish and Wildlife (CDFW) received a NOP from the Kern County Planning and Natural Resources Department for the above-referenced Project pursuant to the California Environmental Quality Act (CEQA) and CEQA Guidelines.[1]

Thank you for the opportunity to provide comments and recommendations regarding those activities involved in the Project that may affect California fish and wildlife. Likewise, CDFW appreciates the opportunity to provide comments regarding those aspects of the Project that CDFW, by law, may be required to carry out or approve through the exercise of its own regulatory authority under Fish and Game Code.

CDFW ROLE

CDFW is California's **Trustee Agency** for fish and wildlife resources and holds those resources in trust by statute for all the people of the State (Fish & G. Code, §§ 711.7, subd. (a) & 1802; Pub. Resources Code, § 21070; CEQA Guidelines § 15386, subd. (a)). CDFW, in its trustee capacity, has jurisdiction over the conservation, protection, and management of fish, wildlife, native plants, and habitat necessary for biologically sustainable populations of those species (*Id*., § 1802). Similarly, for purposes of CEQA, CDFW is charged by law to provide, as available, biological expertise during public agency environmental review efforts, focusing specifically on

[1] CEQA is codified in the California Public Resources Code in section 21000 et seq. The "CEQA Guidelines" are found in Title 14 of the California Code of Regulations, commencing with section 15000.

DocuSign Envelope ID: B66CA338-5670-4253-A936-6B363E05ED41

projects and related activities that have the potential to adversely affect fish and wildlife resources.

CDFW is also submitting comments as a **Responsible Agency** under CEQA (Pub. Resources Code, § 21069; CEQA Guidelines, § 15381). CDFW expects that it may need to exercise regulatory authority as provided by the Fish and Game Code. As proposed, for example, the Project may be subject to CDFW's lake and streambed alteration regulatory authority (Fish & G. Code, § 1600 et seq.). Likewise, to the extent implementation of the Project as proposed may result in "take" as defined by State law of any species protected under the California Endangered Species Act (CESA) (Fish & G. Code, § 2050 et seq.), related authorization as provided by the Fish and Game Code will be required.

Fully Protected Species: CDFW has jurisdiction over species of birds, mammals, amphibians, reptiles, and fish designated by statute as "fully protected" pursuant to Fish and Game Code sections 3511, 4700, 5050, and 5515. Take of any fully protected species is prohibited and CDFW cannot authorize their incidental take except as specifically provided for in Fish and Game Code; none of those specific exceptions are applicable to this project.

Nesting Birds: CDFW has jurisdiction over actions with potential to result in the disturbance or destruction of active nest sites or the unauthorized take of birds. Fish and Game Code sections that protect birds, their eggs and nests include sections 3503 (regarding unlawful take, possession or needless destruction of the nest or eggs of any bird), 3503.5 (regarding the take, possession or destruction of any birds-of-prey or their nests or eggs), and 3513 (regarding unlawful take of any migratory nongame bird).

Unlisted Species: Species of plants and animals need not be officially listed as Endangered, Rare, or Threatened (E, R, or T) on any State or federal list to be considered E, R, or T under CEQA. If a species can be shown to meet the criteria for E, R, or T, as specified in the CEQA Guidelines section 15380, CDFW recommends it be fully considered in the environmental analysis for the Project.

PROJECT DESCRIPTION SUMMARY

Proponent: Aera Energy, LLC

Objective: Aera Energy, LLC proposes the construction and operation of a carbon capture and storage (CSS) facility over portions of the existing and contiguous South Belridge and North Belridge oil fields near the community of Lost Hills in western Kern County. In the NOP, Kern County Planning and Natural Resources Department indicates that the CCS facility would involve the construction of appurtenant structures

DocuSign Envelope ID: B66CA338-5670-4253-A936-6B363E05ED41

for the capture, transport, and subsurface injection (geologic sequestration) of carbon dioxide (CO_2). Once the Project is implemented, CO_2 would be captured at newly constructed facilities within the South Belridge oil field and transported in newly constructed pipelines to existing abandoned oil wells in the North Belridge oil field. These wells will be retrofitted to function as injection wells and used to inject the captured CO_2 into the depleted underground oil- and gas-bearing geologic formation where it will be permanently sequestered.

The Kern County Planning and Natural Resources Department will prepare an Environmental Impact Report (EIR) for the Project. The NOP lacks detailed information with regard to the actual footprint of the Project (Project Site) within the oil fields, and does not address ground disturbance, staging, laydown, or other specific Project-related activities which could threaten biological resources and result in significant environmental impacts within the Project Site. CDFW expects these details will be provided in the EIR. CDFW also expects additional detail will be provided in the EIR addressing:

- the need for nightwork during construction or operations/maintenance of the facilities;
- construction of the pipeline (aboveground vs underground, support of aboveground sections);
- the phase of the CO_2 transported through the pipeline (gaseous or liquid); and
- potential catastrophic events (and emergency responses to those events) which could occur along the pipeline, at the capture facilities, and at the injection facilities over the life of the Project.

Location: The Project Site exists within the administrative boundaries of the existing South Belridge and North Belridge oil fields, which adjoin each other (one immediately north of the other) and are generally west of State Route 33 and north and south of Lerdo Highway. The oil fields containing the Project Site are approximately seven miles southwest of the community of Lost Hills and approximately 30 miles northwest of the city of Bakersfield in Kern County, California.

Timeframe: n/a

COMMENTS AND RECOMMENDATIONS

Special-Status Species: Special-status species are known to exist in the vicinity of the Project Site, there is the potential for the Project to impact State and federally listed species. Records from the California Natural Diversity Database (CNDDB) show that the following special-status species, including State and federally listed species (CDFW 2023) could be impacted: the State threatened and federally endangered San Joaquin kit fox (*Vulpes macrotis mutica*); the State and federally endangered and State fully

DocuSign Envelope ID: B66CA338-5670-4253-A936-6B363E05ED41

protected blunt-nosed leopard lizard (*Gamelia sila*); the State and federally endangered and California Rare Plant Ranked (CRPR) 1B.1 California jewelflower (*Caulanthus californicus*); the State and federally endangered giant kangaroo rat (*Dipodomys ingens*), Tipton kangaroo rat (*Dipodomys nitratoides nitratoides*); the State threatened San Joaquin antelope squirrel (*Ammospermophilus nelsoni*), tricolored blackbird (*Agelaius tricolor*), and Swainson's hawk (*Buteo swainsoni*); the federally endangered and State species of special concern Buena Vista Lake ornate shrew (*Sorex ornatus relictus*); the federally endangered and CRPR 1B.2 San Joaquin woollythreads (*Monolopia congdonii*) and Kern mallow (*Eremalche parrye ssp. kernensis*); the candidates for State listing Temblor legless lizard (*Anniella alexanderae*) and Crotch bumble bee (*Bombus crotchii*); the State species of special concern burrowing owl (*Athene cunicularia*), short-nosed kangaroo rat (*Dipodomys nitratoides brevinasus*), Tulare grasshopper mouse (*Onychomys torridus tularensis*), western spadefoot (*Spea hammondii*), American badger (*Taxidea taxus*), San Joaquin coachwhip (*Masticophis flagellum ruddocki*), and Le Conte's thrasher (*Toxostoma lecontei*); and the CRPR 1B.1, 1B.2 and 4.2 California alkali grass (*Puccinellia simplex*), Coulter's goldfields (*Lasthenia glabrata ssp. coulteri*), heartscale (*Atriplex cordulata var. cordulata*), Lost Hills crownscale (*Atriplex coronata var. vallicola*), recurved larkspur (*Delphinium recurvatum*), showy golden madia (*Madia radiata*), and Hoover's eriastrum (*Eriastrum hooveri*).

CDFW recommends that a habitat assessment be conducted at and in the vicinity of the Project Site for the aforementioned plant and animal species. The assessment should be conducted by a qualified biologist knowledgeable with the species and any potentially suitable habitat identified should be surveyed by a qualified biologist for the potential presence of these species as part of the biological technical studies conducted in support of the EIR. If the surveys reveal the aforementioned listed and candidate species occur at and/or near the Project Site, the EIR should include either measures to avoid take of those species, or the Project proponent's commitment to obtaining incidental take authorization under Section 2081 of Fish and Game Code, as appropriate, if avoidance will be unfeasible. Similarly, if the surveys reveal the aforementioned unlisted species, the EIR should include a commitment by the Project proponent to consult with CDFW, prior to commencing the Project, to identify and implement appropriate measures to avoid or minimize impacts to those species. It should be noted that blunt-nosed leopard lizard is State fully protected, therefore, no "take", incidental or otherwise, can be authorized by CDFW; complete avoidance of this species is required to comply with State law.

CDFW recommends that the surveys for blunt-nosed leopard lizard, San Joaquin kit fox, tricolored blackbird, Swainson's hawk, and burrowing owl be conducted in accordance with the species-specific protocols which can be found here:

DocuSign Envelope ID: B66CA338-5670-4253-A936-6B363E05ED41

https://wildlife.ca.gov/Conservation/Survey-Protocols. CDFW recommends that the surveys for the aforementioned special status and CRPR plants be surveyed for by a qualified botanist following the "Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Sensitive Natural Communities" which can also be found at: https://wildlife.ca.gov/Conservation/Survey-Protocols.This protocol, which is intended to maximize detectability, includes identification of reference populations to facilitate the likelihood of field investigations occurring during the appropriate floristic period. In the absence of protocol-level surveys being performed, additional surveys may be necessary. If take could occur as a result of Project-related activities, consultation with CDFW may be warranted.

Nesting birds: CDFW recommends that Project ground-disturbing activities occur during the bird non-nesting season; however, if ground-disturbing or vegetation-disturbing activities must occur during the nesting season (February 1st through September 15th), the Project applicant is responsible for ensuring that implementation of the Project does not result in violation of the Migratory Bird Treaty Act or relevant Fish and Game Codes as referenced above.

To evaluate Project-related impacts on nesting birds, CDFW recommends that a general habitat assessment for nesting birds be conducted as part of the biological technical studies conducted in support of the EIR. Depending on the results of that assessment, CDFW further recommends that the EIR for this Project include that a qualified biologist conduct a pre-construction survey for active nests no more than 10 days prior to the start of ground- or vegetation-disturbance to maximize the probability that nests that could potentially be impacted are detected. CDFW also recommends that surveys cover a sufficient area around the Project Site to identify nests and determine their status. A sufficient area means any area potentially affected, either directly or indirectly, by the Project. In addition to direct impacts (i.e. nest destruction), noise, vibration, and movement of workers or equipment could also affect nests. CDFW recommends that a qualified biologist establish a behavioral baseline of all identified nests. Once Project activities begin, CDFW recommends having a qualified biologist continuously monitor nests to detect behavioral changes resulting from the Project. If behavioral changes occur, CDFW recommends halting the work causing that change and consulting with CDFW for additional avoidance and minimization measures.

If continuous monitoring of identified nests by a qualified biologist is not feasible, CDFW recommends the EIR include a minimum no-disturbance buffer of 250 feet around active nests of non-listed bird species and a 500-foot no-disturbance buffer around active nests of non-listed raptors. These buffers are advised to remain in place until the breeding season has ended or until a qualified biologist has determined that the birds have fledged and are no longer reliant upon the nest or on-site parental care for survival. Variance from these no-disturbance buffers is possible when there is a

DocuSign Envelope ID: B66CA338-5670-4253-A936-6B363E05ED41

compelling biological or ecological reason to do so, such as when the Project Site would be concealed from a nest site by topography. CDFW recommends that a qualified biologist advise and support any variance from these buffers and notify CDFW in advance of implementing a variance.

CNDDB: Please note that the CNDDB is populated by and records voluntary submissions of species detections. As a result, species may be present in locations not depicted in the CNDDB but where there is suitable habitat and features capable of supporting species. A lack of an occurrence record in the CNDDB does not mean a species is not present. In order to adequately assess any potential Project-related impacts to biological resources, surveys conducted by a qualified biologist during the appropriate survey period(s) and using the appropriate protocol survey methodology are warranted in order to determine whether or not any special status species are present at or near the Project Site.

Project Alternatives Analysis: CDFW recommends that the information and results obtained from the biological technical surveys, studies, and analysis conducted in support of the project's CEQA document be used to develop and modify the Project's alternatives to avoid and minimize impacts to biological resources to the maximum extent possible. When efforts to avoid and minimize have been exhausted, remaining impacts to sensitive biological resources may need to be mitigated to reduce impacts to a less than significant level, if feasible.

Cumulative Impacts: CDFW recommends that a cumulative impact analysis be conducted for all biological resources that will either be significantly or potentially significantly impacted by implementation of the Project, including those whose impacts are determined to be less than significant with mitigation incorporated or for those resources that are rare or in poor or declining health and will be impacted by the project, even if those impacts are relatively small (i.e. less than significant). CDFW recommends cumulative impacts be analyzed using an acceptable methodology to evaluate the impacts of past, present, and reasonably foreseeable future projects on resources and be focused specifically on the resource, not the Project. An appropriate resource study area identified and utilized for this analysis is advised. CDFW staff is available for consultation in support of cumulative impacts analyses as a trustee and responsible agency under CEQA.

Lake and Stream Alteration: The Project may be subject to CDFW's regulatory authority pursuant to Fish and Game Code section 1600 et seq. Fish and Game Code section 1602 requires the Project proponent notify CDFW prior to commencing any activity that may (a) substantially divert or obstruct the natural flow of any river, stream, or lake; (b) substantially change or use any material from the bed, bank, or channel of any river, stream, or lake; or (c) deposit debris, waste or other materials that could pass

DocuSign Envelope ID: B66CA338-5670-4253-A936-6B363E05ED41

into any river, stream, or lake. “Any river, stream, or lake” includes those that are ephemeral or intermittent as well as those that are perennial in nature. The EIR should address the potential Project-related impacts to all streams at and near the Project Site. For additional information on notification requirements, please contact our staff in the LSA Program at (559) 243-4593, or R4LSA@wildlife.ca.gov.

Federally Listed Species: CDFW recommends consulting with the USFWS on potential impacts to federally listed species including, but not limited to the aforementioned San Joaquin kit fox, blunt-nosed leopard lizard, California jewelflower, giant kangaroo rat, Tipton kangaroo rat, Buena Vista Lake ornate shrew, San Joaquin woollythreads, and Kern mallow. Take under the Federal Endangered Species Act (FESA) is more broadly defined than CESA; take under FESA also includes significant habitat modification or degradation that could result in death or injury to a listed species by interfering with essential behavioral patterns such as breeding, foraging, or nesting. Consultation with the USFWS in order to comply with FESA is advised well in advance of any ground disturbing activities.

CDFW is available to meet with you ahead of draft EIR preparation to discuss potential impacts and possible mitigation measures for some or all of the resources that may be analyzed in the EIR. If you have any questions, please contact Steven Hulbert, Senior Environmental Scientist Specialist, at the address provided on this letterhead, by telephone at (559) 575-6415, or by electronic mail at Steven.Hulbert@wildlife.ca.gov.

Sincerely,

STATE CLEARINGHOUSE

Good morning Ms. Oviatt,

Please see below comments from the California Geologic Energy Management Division (CalGEM) regarding the **CarbonFrontier Carbon Capture and Sequestration by Aera Energy, LLC; SCH # 2023060293** project.

PROJECT DESCRIPTION:
The project proponent is proposing to construct and operate a CCS project within the North and South Belridge oilfields.

COMMENTS:
The parcels are located within the North and South Belridge administrative boundaries, and it is an active oil and gas field. As listed in section 1.5 "Proposed Discretionary Actions/Required Approvals" of the Notice of Preparation Draft Environmental Impact Report (EIR), the applicant shall obtain permits/approvals from the respective agencies as required.

The applicant shall file proper permitting with CalGEM for any required oil and gas operations.

Sincerely,

Victor D. Medrano
Associate Oil and Gas Engineer | Central District

Subject: Notice of Preparation of an Environmental Impact Report – CarbonFrontier Carbon Capture Sequestration Project by Aera Energy, LLC. (PP23402).

I have reviewed the above noted project Notice of Preparation of EIR and recommend the following conditions be placed on the Conditional Use Permits:

1. Prior to issuance of a building or grading permit: All survey monuments shall be tied out by a Licensed Land Surveyor. A corner record for each monument or record of survey shall be submitted to the County Surveyor for review and processing, per Section 8771 of the Professional Land Surveyor's (PLS) Act.

2. Prior to Final Inspection: All survey monuments that were destroyed during construction shall be re-set or have a suitable witness corner set. A post construction corner record for each monument re-set or a record of survey shall be submitted to the County Surveyor for processing, per Section 8771 of the Professional Land Surveyor's Act.

3. Upon completion of project: All survey monuments shall be accessible by a Licensed Land Surveyor or their representatives, with prior notice, per Section 8774 of the PLS Act and Civil Code 846.5 (a).

Thank you for the opportunity to review and comment on this project. Should you have any questions please contact me.

2) Health Risk Screening Assessment

[illegible] a health risk screening assessment is required for an application if the District concludes that the emissions unit [illegible] a risk management review pursuant to District Rule 2520, Federally Mandated Operating Permits, Section 6.3.2. The District's risk management policy for permitting new and modified sources [illegible] specifies that permitting actions for units exempted from BACT requirements due to low emissions [illegible] a health risk screening assessment to demonstrate that the unit's impact is less than the District's risk management policy thresholds.

[illegible] determine if the proposed emissions increase from this project will require a health risk assessment, the applicant submitted a health risk screening assessment [illegible] the District's Risk Management Policy for Permitting New and Modified Sources. The District reviewed the assessment and performed its own risk screening analysis using the District's HRSA Tool, which is based on the California Air Pollution Control Officers Association (CAPCOA) Hot Spots Analysis and Reporting Program (HARP) risk assessment guidance. The District's analysis is based on the annual emissions and the stack parameters listed in the application. The analysis was performed to determine the incremental cancer risk, chronic hazard index, and acute hazard index associated with the proposed project. The District's analysis determined that the cancer risk is less than one in one million (1.0), the chronic hazard index is less than 1.0, and the acute hazard index is less than 1.0. Therefore, the project is not required to perform a more refined health risk assessment.

[illegible] Prioritization and Risk Management Policy Analysis
A "Prioritization" is the recommended method for a conservative screening [illegible] determine risks associated with [illegible] [illegible] prioritization is based on the California Air Pollution Control Officers Association's (CAPCOA) methodology.

[illegible] District's analysis is based on [illegible] emissions and [illegible] parameters listed in the application. The analysis was performed to determine the [illegible] cancer risk, chronic hazard index, and acute hazard index associated with the proposed project. The District's analysis determined that the cancer risk is less than one in one million (1.0), the chronic hazard index is less than 1.0, and the acute hazard index is less than 1.0. Therefore, the project is not required to perform a more refined health risk assessment.

4) Voluntary Emission Reduction Agreement

Criteria pollutant emissions may result in emissions exceeding the District's significance thresholds. Therefore, unless the Project Specific Determination demonstrates that the Project's emissions are less than the District's significance thresholds, the Lead Agency should require the applicant to enter into a VERA with the District. In this VERA, the project proponent agrees to mitigate project emissions by providing funds for the District's incentives programs. The funds are used to reduce emissions by the amount specified in the project's Specific Determination. The project proponent should provide a copy of the executed VERA to the Lead Agency and the District prior to issuance of the first discretionary approval. Upon payment of the VERA fee, the project proponent will not be responsible for implementing the emission reduction measures. The District will use the fee to implement emission reduction projects within two years of receiving the payment. In the event the District is unable to secure sufficient emission reductions, the project proponent may be required to implement on-site measures or pay an in-lieu fee.

The VERA is a mitigation measure by which a project proponent provides pre-project funding to the District that results in the reduction of emissions sufficient to offset the project's emissions. The project proponent should not commence construction activities until the VERA has been executed and the first discretionary approval has been issued. Information about how to enter into a VERA with the District may be obtained by contacting the District's Fresno office. The VERA must be executed before the project can be relied upon to mitigate air quality impacts.

5) Applicability and Timing of Voluntary Emission Reduction Agreements

The Lead Agency should contact the District to determine if a VERA is appropriate for a project. If a project proponent and the Lead Agency choose to enter into a VERA, the project proponent should submit an application to the District's Fresno office. The District will then prepare the VERA and forward it to the project proponent. The project proponent should execute the VERA and return it to the District. The District will then execute the VERA and return a fully executed copy to the project proponent and the Lead Agency.

6) District Rule and Regulation

The District's rules and regulations may require a project to implement measures to reduce emissions. Prior to the issuance of a project's first discretionary approval, the District will review the project to determine which District rules and regulations may apply to the project. The District's

r[illegible] [illegible] District's r[illegible] [illegible] [illegible] [

6c) Other District Rule and Regulation

Prior to operation, the project may be subject to the following District Rules: Regulation II (Permit Requirements), Rule 2201 (New and Modified Stationary Source Review Rule), Rule 4002 (National Emission Standards for Hazardous Air Pollutants), Rule 4101 (Visible Emissions), Rule 4102 (Nuisance), Rule 4601 (Architectural Coatings), Rule 4641 (Cutback, Slow Cure, and Emulsified Asphalt, Paving and Maintenance Operations), Rule 4702 (Internal Combustion Engines), Rule 4901 (Wood Burning Fireplaces and Wood Burning Heaters), Rule 4905 (Natural Gas-Fired, Fan-Type Central Furnaces), Rule 5550 (Indirect Source Review), Rule 5530 (Fugitive PM10 Prohibitions), and Rule 9510 (Indirect Source Review Fee).

7) District Comment Letter

The District recommends that a copy of the District's comments be provided to the project proponent.

If you have questions or require further information, please contact Mr. Mark Montelongo by e-mail at mark.montelongo@valleyair.org or by phone at (559) 230-5860.

Sincerely,

Brian Clements

SENT VIA EMAIL

Ms. Cindi Hoover – Division Chief
Kern County Planning and Natural Resources Department
2700 M Street
Bakersfield, CA 93301

Dear Ms. Hoover:

Thank you for the opportunity to review the Notice of Preparation for the Draft Environmental Impact Report proposing to build a Carbon Capture Sequestration Facility (Project). The Project site is comprised of 47 privately owned parcels and 2 provisional parcels located west of State Route (SR) 33, approximately 7 miles southwest of the Community of Lost Hills, in the County of Kern.

Per the site plan, the primary access to the Project site would be from Oasis Road (a private road), accessed from 7th Standard Road, west of SR 33. Oasis Road is connected to a network of existing dirt roads inside a field. New internal access roads may be constructed, but these roads will likely be compacted dirt roads.

Caltrans provides the following comments consistent with the State's smart mobility goals that support a vibrant economy and sustainable communities:

- A transportation impact study scoping meeting with Caltrans District 6 staff to discuss the most appropriate methodology for this analysis is recommended. Prior to the scoping meeting, a detailed operational statement should be submitted for review. This should include the nature of operations, hours of operation, number of expected AM and PM peak hour vehicle trips, and truck percentage. Please also provide information about future expansion phases of the project, if any, as this will allow for a more accurate assessment of the trips generated by the development. Once this information is provided, we will be able to complete our review and determine if a Traffic Impact Study (TIS) or other mitigation is required.

- Vicinity maps, regional location maps, and a site plan clearly showing project access in relation to nearby roadways and key destinations, ingress, and egress for all project components should be clearly identified. Please identify the State right-of-way (ROW). Project driveways, the State Highway System, local roads, intersections, interchanges, pedestrian and bicycle routes, car/bike parking, transit routes, and facilities should be mapped.

- Evidence indicates the project has the potential to impact additional environmental resources along SR 33. Caltrans analysis is an attempt to help the lead agency avoid any potential delays to the Project' encroachment permit process. The EIR should identify, evaluate, and propose mitigation for potential impacts to the SHS, including the entire width of the State right-of-way. To avoid delays to the encroachment permit process, a thorough environmental analysis will be required for the proposed mitigation of impacts to the SHS and should be included in the environmental document.

- As a point of information, any work completed in the State's right-of-way will require a Caltrans encroachment permit. An encroachment permit must be obtained for all proposed activities for placement of encroachments within, under, or over the State highway rights-of-way. Activity and work planned in the State right-of-way shall be performed to State standards and specifications, at no cost to the State. Engineering plans, calculations, specifications, and reports (documents) shall be stamped and signed by a licensed Engineer or Architect. Engineering documents for encroachment permit activity and work in the State right-of-way may be submitted using English Units. The Permit Department and the Environmental Planning Branch will review and approve the activity and work in the State right-of-way before an encroachment permit is issued. The Streets and Highways Code Section 670 provides Caltrans discretionary approval authority for projects that encroach on the State Highway System. Encroachment permits will be issued in accordance with Streets and Highway Codes, Section 671.5, "Time Limitations." Encroachment permits do not run with the land. A change of ownership requires a new permit application. Only the legal property owner or his/her authorized agent can pursue obtaining an encroachment permit.

- Prior to an encroachment permit application submittal, the project proponent is required to schedule a "Pre-Submittal" meeting with District 6 Encroachment Permit Office. To schedule this meeting, please call the Caltrans Encroachment Permit Office - District 6: 1352 W. Olive, Fresno, CA 93778, at (559) 383-5047 or (559) 383-5235.

- Please review the permit application - required document checklist at: https://forms.dot.ca.gov/v2Forms/servlet/FormRenderer?frmid=TR0402&distpath=MAOTO&brapath=PERM.

- Please also review the permit application - processing checklist at: https://dot.ca.gov/programs/traffic-operations/ep, and at, https://dot.ca.gov/-/media/dot-media/programs/traffic-operations/documents/encroachment-permits/tr-0416-a11y.pdf.

If you have any other questions, please contact Scott Lau at (559) 981-7341 or scott.lau@dot.ca.gov.

Sincerely,

AGENDA

KERN COUNTY PLANNING & NATURAL RESOURCES DEPARTMENT

Scoping Meeting

Kern County Public Services Building
2700 "M" Street, Public Meeting Room 1-A
Bakersfield, California 93301

June 23, 2023 – 1:30 p.m.

Pursuant to revised Section 21083.9 of the Public Resources Code, California Environmental Quality Act, effective January 1, 2002, this scoping meeting is being held to receive agency comments on the preparation of the Environmental Impact Reports (EIR) on certain projects. The process of determining the scope, focus, and content of the EIR is known as "scoping." Scoping helps to identify the range of actions, alternatives, environmental effects, methods of assessment, and mitigation measures to be analyzed in depth, and eliminate issues from the detailed study that are not important to the decision at hand. This is not a public hearing; however, the public may be present and offer comments. If you attend as a member of the public to address an item on the agenda, please let the chairperson know when discussion begins on that item. Each project will be presented by staff followed by an opportunity for comments for the record.

C. ADJOURNMENT:

AMERICANS WITH DISABILITIES ACT
(Government Code Section 54953.2)

Disabled individuals who need special assistance to attend or participate in the scoping meeting may request assistance at the Kern County Planning Department or by calling Alyssa Torres at (661) 862-8615. Every effort will be made to reasonably accommodate individuals with disabilities by making meeting materials available in alternative formats. Requests for assistance should be made five (5) working days in advance whenever possible.

SUMMARY OF PROCEEDINGS

KERN COUNTY AGENCY SCOPING MEETING

Kern County Planning and Natural Resources Department
2700 M Street, Suite 100
Bakersfield, California

Conference Room 1A

Date June 23, 2022

STAFF ATTENDANCE:
Cindi Hoover, Division Chief
Keith Alvidrez, Planner I

The meeting convened at 1:30 p.m. with introductions from Staff that were in attendance and outlining the purpose of the scoping meeting. Items were then discussed in order as identified on the agenda.

NOTICE OF PREPARATION PROJECT:

Environmental Impact Report – Notice of Preparation:
Belridge Carbon Capture Sequestration Project by Aera Energy, LLC (PP23402)

Twelve (12) members of the public were present. No public comments were presented.

Public testimony closed at approximately 1:41 p.m.

1. EXECUTIVE SUMMARY

Trinity Consultants has completed an Air Quality Impact Analysis (AQIA) for the proposed CarbonFrontier Project (Project) by Aera Energy LLC. (Aera Energy). The Project would be located within the Central Valley portion of western Kern County. The South Belridge and North Belridge oil fields are contiguous and located approximately six miles southwest of the community of Lost Hills and west of State Route (SR) 33. Together, the two Belridge oil fields cover an area of approximately 13 miles long and three miles wide. Aera Energy is the primary operator within both oil fields. The main entrance to the South Belridge Oil Field is located at the private Oasis Road along Seventh Standard Road west of SR 33.

The Project site is comprised of forty-six (46) privately owned parcels, within the administrative boundaries of the North and South Belridge oil fields. The North and South Belridge oil fields are contiguous and located west of Highway 33, approximately seven miles southwest of the community of Lost Hills.

The proposed carbon capture and sequestration (CCS) Project would capture carbon dioxide (CO_2) from existing produced gas streams (pre-combustion) and emissions from existing stationary sources (post-combustion) within the South Belridge Oil Field and transport the CO_2 through a pipeline to the North Belridge Oil Field for injection at dedicated Underground Injection Control (UIC) Class VI injection wells. The proposed underground CO_2 sequestration field, approximately 2,636 acres in size (maximum modeled CO_2 plume area), would be located within the North Belridge Oil Field with surface and mineral rights held by Aera Energy and other private owners. Oil and gas production activities would cease within the underground geologic formation where CO_2 would be stored, prior to commencement of the Project.

It is anticipated that the proposed Project would capture and sequester up to 1.6 million metric tons of CO_2 per year beginning in 2027 and contribute to California's goal of carbon net-neutrality by 2045 (Governor's Executive Order B-55-18) by reducing industrial CO_2 emissions.

The proposed Project's construction would include the following criteria pollutant emissions: reactive organic gases (ROG), carbon monoxide (CO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), and suspended particulate matter (PM_{10} and $PM_{2.5}$). Project operations would generate air pollutant emissions from mobile sources, energy sources, and area sources. Project construction and operational activities would also generate greenhouse gas (GHG) emissions. Criteria and GHG emissions were estimated using the California Emissions Estimator Model (CalEEMod) Version 2022.1.1.13 (California Air Pollution Control Officers Association (CAPCOA) 2022), which is the most current version of the model approved for use by the San Joaquin Valley Air Pollution Control District (SJVAPCD), AP-42 emission factors, manufacture emission guarantees, and Tanks ESP.

Table 4-3 **through 4-8** present the Project's construction emissions, baseline operational mobile source emissions, operational mobile source emissions increase, baseline operational stationary source emissions, operational stationary source emission increase and total emissions from oil and gas operations from wells on a per well basis. As discussed in Section 4.11, the Project will reduce the overall GHG emissions impact to air quality. SJVAPCD uses a single threshold for determination of significance for both project specific and cumulative impacts. Section 5.0 discusses both a qualitative and quantitative evaluation of the cumulative impacts that the Project's contribution would pose.

2. INTRODUCTION

2.1 Purpose

This AQIA was prepared pursuant to the SJVAPCD Guidance for Assessing and Mitigating Air Quality Impacts (GAMAQI) (SJVAPCD 2015), the Kern County Planning and Community Development Department's (KCPD) Air Quality Preparation Guidelines (KCPD 2006), and the California Environmental Quality Act (CEQA) Statute and Guidelines (CEQA 2023).

2.2 General Project Description

Aera Energy is proposing the CarbonFrontier Project to capture CO_2 from existing produced gas streams (pre-combustion) and emissions from existing stationary sources (post-combustion) within the South Belridge Oil Field and transport the CO_2 through pipelines to the North Belridge Oil Field for injection at dedicated Class VI injection wells. The proposed Project includes a request to the Kern County Planning and Natural Resources Department for approval of a Zoning Change and CUP and any other required approvals, if any, for the construction and operation of the proposed Project, as follows:

Aera Energy proposes to capture and sequester approximately 1.6 million metric tons per year within the 64 Zone reservoir of the North Belridge Oil Field over a period of approximately 20 years[1]. The project would be sized to accept CO_2 from additional sources, totaling 3.3 million metric tons per year. The proposed CO_2 related facilities, pipelines, Class VI injection wells and associated CO_2 monitoring wells would be located within the CUP boundary.

The proposed Project includes the following components:

- **CO_2 Capture Facilities.** One pre-combustion capture facility and three post-combustion capture facilities.
- **Pipelines.** An approximately 10-mile main CO_2 pipeline, CO_2 distribution lines to each injection well, and produced gas, water, and steam pipelines.
- **Wells.** Development/Conversion and operation of up to nine CO_2 injection wells, and up to eight monitoring wells. Up to 55 existing oil wells would be plugged and abandoned within the North Belridge Oil Field, and up to 40 additional wells, previously abandoned within the North Belridge Oil Field, would be re-abandoned to meet current state and federal plugging requirements. Further, 21 production wells would be plugged and abandoned within the proposed capture facility areas in South Belridge,
- **Access Roads.** Maintenance, repair, and improvement of existing field access roads.
- **Water Systems.** Construction of water treatment facilities at each of the CO_2 capture facilities.
- **Electrical Transmission.** Construction of approximately 6,840 feet of 115 kV overhead transmission lines from the existing Aera Energy-owned electrical supply grid to two new electrical

[1] Note, the operational life of the proposed Project will be controlled by the sequestration reservoir's storage capacity (currently undergoing review) and volume of CO_2 captured per year which will fluctuate.

substations located adjacent to the CO_2 capture facilities. Also, two existing PG&E electrical substations may require upgrades at full Project build-out.

- **Networks.** Electrical power distribution, and supervisory control and data acquisition (SCADA) networks.

The surrounding area, as shown in **Figure 2-1**, is comprised of oil and gas exploration and production, grazing, and agricultural lands. The Project site is located within the Central Valley portion of western Kern County. The South Belridge and North Belridge oil fields are contiguous and located approximately six miles southwest of the community of Lost Hills and west of State Route (SR) 33. Together, the two Belridge oil fields cover an area of approximately 13 miles long and three miles wide. Aera Energy is the primary operator within both oil fields. The main entrance to the South Belridge Oil Field is located at the private Oasis Road along Seventh Standard Road west of SR 33.

The Project is proposed to be implemented in phases to maximize efficiency and help moderate construction activity levels. Most of the processing facility construction would occur over a three-year time period, expected to start in 2025 after the applicable permits are issued.

CO_2 capture facility and infrastructure construction would occur for approximately three years, starting with the Pre-C facility construction at the Gas Plant in section 32 (GP 32). Sequential construction would occur for construction of the Post-C facilities located at the section 32 cogeneration facility (COGEN 32) and the two Steam Generation Stations (SGSs). Injection well pad construction, drilling and plugging and abandonment activities, and pipeline construction activities would begin concurrently with the start of facility construction. Installation of CO_2 distribution pipelines, installation of intra-field electrical distribution, and well hookups would occur throughout the three-year period.

Figure 2-2 depicts the Project site's topography based on Kern County's Interactive County Map (Kern 2023). The Project site's elevation varies from 460 to 760 feet above mean sea level.

Figure 2-2. Project Site Topography

3. SETTING

Protection of the public health is maintained through the attainment and maintenance of ambient air quality standards for various atmospheric compounds and the enforcement of emissions limits for individual stationary sources. The Federal Clean Air Act requires that the U.S. Environmental Protection Agency (EPA) establish National Ambient Air Quality Standards (NAAQS) to protect the health, safety, and welfare of the public. NAAQS have been established for ozone (O_3), CO, NO_2, SO_2, PM_{10} and $PM_{2.5}$, and lead (Pb). California has also adopted ambient air quality standards (CAAQS) for these "criteria" air pollutants. CAAQS are more stringent than the corresponding NAAQS and include standards for hydrogen sulfide (H_2S), vinyl chloride (chloroethene), and visibility reducing particles. The U.S. Clean Air Act Amendments of 1977 required each state to identify areas that were in non-attainment of the NAAQS and to develop State Implementation Plans (SIP's) containing strategies to bring these non-attainment areas into compliance. NAAQS and CAAQS designation/classification for Kern County are presented in **Section 3.1** below.

Responsibility for regulation of air quality in California lies with the California Air Resources Board (CARB) and the 35 local air districts with oversight responsibility held by the EPA. CARB is responsible for regulating mobile source emissions, establishing CAAQS, conducting research, managing regulation development, and providing oversight and coordination of the activities of the 35 air districts. The air districts are primarily responsible for regulating stationary source emissions and monitoring ambient pollutant concentrations. CARB also determines whether air basins, or portions thereof, are “unclassified,” in “attainment” or in “non-attainment” for the NAAQS and CAAQS relying on statewide air quality monitoring data.

3.1 Air Quality Standards

The Project area is located within Kern County’s portion of the San Joaquin Valley Air Basin (SJVAB or Basin). Kern County is included among the eight counties that comprise the SJVAPCD. The SJVAPCD acts as the regulatory agency for air pollution control in the Basin and is the local agency empowered to regulate air pollutant emissions for the Project area. **Table 3-1** provides the NAAQS and CAAQS.

Table 3-1. Federal & California Air Quality Standards

Pollutant	Averaging Time	NAAQS	CAAQS
		Concentration	
O_3	8-hour	0.070 ppm (137 µg/m^3)[a]	0.070 ppm (137 µg/m^3)
	1-hour		0.09 ppm (180 µg/m^3)
CO	8-hour	9 ppm (10 µg/m^3)	9 ppm (10 µg/m^3)
	1-hour	35 ppm (40 µg/m^3)	20 ppm (23 µg/m^3)
NO_2	Annual Average	53 ppb (100 µg/m^3)	0.030 ppm (57 µg/m^3)
	1-Hour	100 ppb (188.68 µg/m^3)	0.18 ppm (339 µg/m^3)
SO_2	3-Hour	0.5 ppm (1,300 µg/m^3)	
	24 Hour	0.14 ppm (365 µg/m^3)	0.04 ppm (105 µg/m^3)
	1-Hour	75 ppb (196 µg/m^3)	0.25 ppm (655 µg/m^3)
Particulate Matter (PM_{10})	Annual Arithmetic Mean		20 µg/m^3
	24-Hour	150 µg/m^3	50 µg/m^3
Fine Particulate Matter ($PM_{2.5}$)	Annual Arithmetic Mean	12 µg/m^3	12 µg/m^3
	24-Hour	35 µg/m^3	
Sulfates	24-Hour		25 µg/m^3
Pb[d]	Rolling Three-Month Average	0.15 µg/m^3	
	30 Day Average		1.5 µg/m^3
H_2S	1-Hour		0.03 ppm (42 µg/m^3)
Vinyl Chloride (chloroethene)	24-Hour		0.010 ppm (26 µg/m^3)
Visibility Reducing particles	8 Hour (1000 to 1800 PST)		[b]

ppm = parts per million
ppb = parts per billion
mg/m^3 = milligrams per cubic meter
µg/m^3 = micrograms per cubic meter

Source: CARB 2016

a. On October 1, 2015, the national 8-hour ozone primary and secondary standards were lowered from 0.075 to 0.070 ppm

b. In 1989, CARB converted both the general statewide 10-mile visibility standards and the Lake Tahoe 30-mile visibility standard to instrumental equivalents, which are “extinction of 0.23 per kilometer” and “extinction of 0.07 per kilometer” for the statewide and Lake Tahoe Air Basin standards, respectively.

Under the provisions of the U.S. Clean Air Act, the Kern County portion of the SJVAB has been classified as nonattainment/extreme, nonattainment/severe, nonattainment, attainment/unclassified, attainment, or unclassified under the established NAAQS and CAAQS for various criteria pollutants. **Table 3-2** provides the SJVAB's designation and classification based on the various criteria pollutants under both NAAQS and CAAQS.

Table 3-2. SJVAB Attainment Status

Pollutant	NAAQS[a]	CAAQS[b]
O_3, 1-hour	No Federal Standard[f]	Nonattainment/Severe
O_3, 8-hour	Nonattainment/Extreme[e]	Nonattainment
PM_{10}	Attainment[c]	Nonattainment
$PM_{2.5}$	Nonattainment[d]	Nonattainment
CO	Attainment/Unclassified	Attainment/Unclassified
NO_2	Attainment/Unclassified	Attainment
SO_2	Attainment/Unclassified	Attainment
Pb (Particulate)	No Designation/Classification	Attainment
H_2S	No Federal Standard	Unclassified
Sulfates	No Federal Standard	Attainment
Visibility Reducing Particulates	No Federal Standard	Unclassified
Vinyl Chloride	No Federal Standard	Attainment

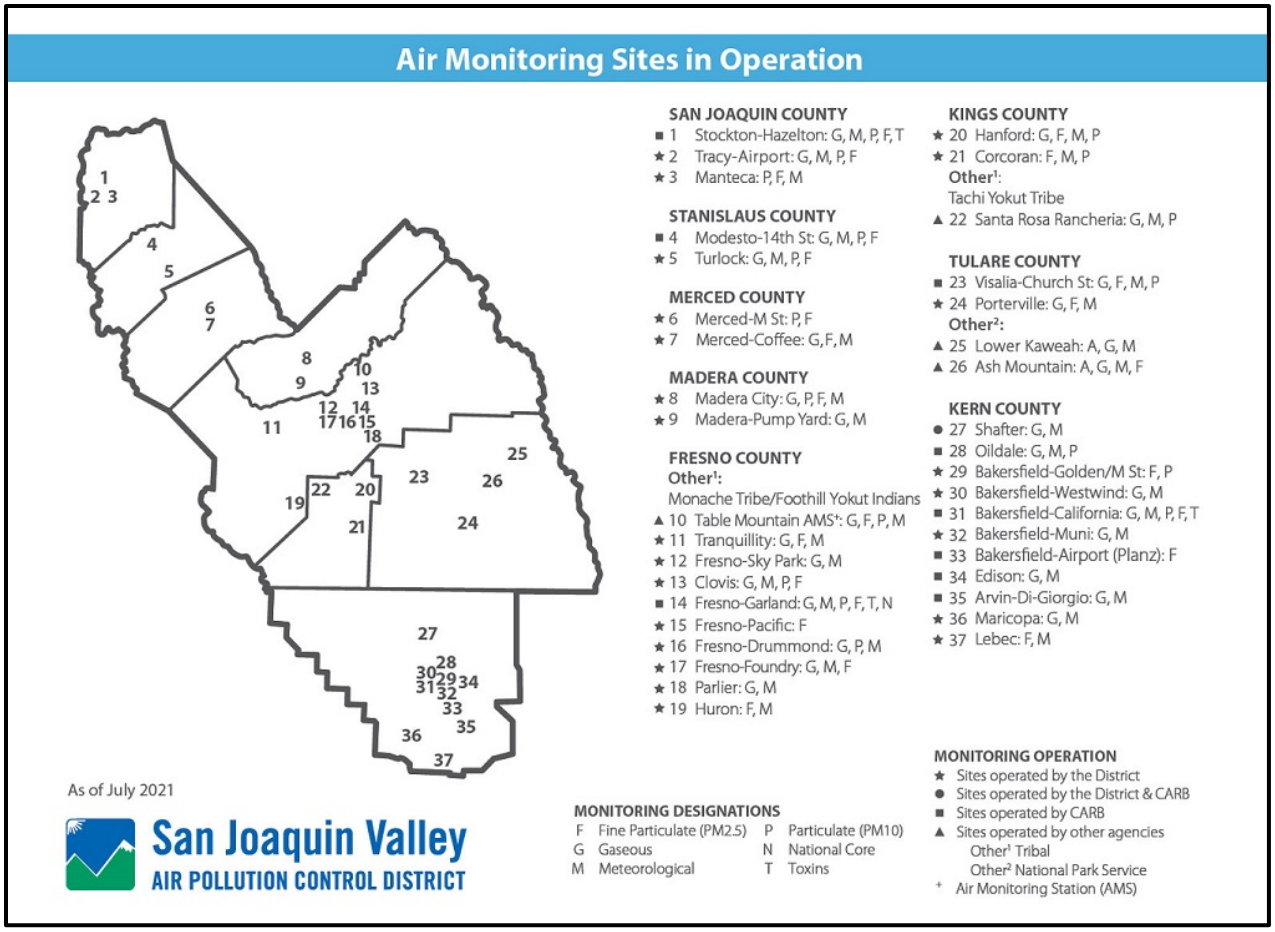
Source: SJVAPCD 2022a

Note:

a. See 40 CFR Part 81

b. See CCR Title 17 Sections 60200-60210

c. On September 25, 2008, EPA redesignated the San Joaquin Valley to attainment for the PM_{10} National Ambient Air Quality Standard (NAAQS) and approved the PM_{10} Maintenance Plan.



d. The Valley is designated nonattainment for the 1997 $PM_{2.5}$ NAAQS. EPA designated the Valley as nonattainment for the 2006 $PM_{2.5}$ NAAQS on November 13, 2009 (effective December 14, 2009).

e. Though the Valley was initially classified as serious nonattainment for the 1997 8-hour O_3 standard, EPA approved Valley reclassification to extreme nonattainment in the Federal Register on May 5, 2010 (effective June 4, 2010).

f. Effective June 15, 2005, the EPA revoked the federal 1-hour O_3 standard, including associated designations and classifications. EPA had previously classified the SJVAB as extreme nonattainment for this standard. EPA approved the 2004 Extreme Ozone Attainment Demonstration Plan on March 8, 2010 (effective April 7, 2010). Many applicable requirements for extreme 1-hour O3 nonattainment areas continue to apply to the SJVAB.

The SJVAPCD, along with CARB, operates an air quality monitoring network that provides information on average concentrations of those pollutants for which Federal or State agencies have established NAAQS and CAAQS, respectively. The monitoring stations in the San Joaquin Valley are depicted in **Figure 3-1**.

Figure 3-1. SJVAPCD Monitoring Network

Source: SJVAPCD 2022b

3.2 Existing Air Quality

For the purposes of background data and this air quality analysis, this analysis relied on data collected in the last three years for the CARB monitoring stations that are located in the closest proximity to the project site. **Table 3-3** provides the background concentrations for O_3, particulate matter of 10 microns (PM_{10}), particulate matter of less than 2.5 microns ($PM_{2.5}$), CO, NO_2, SO_2, and Pb. Information is provided for the Bakersfield – 5558 California Avenue, Bakersfield – 410 E. Planz Road, Bakersfield – Golden State Highway Oildale – 3311 Manor Street, Maricopa – Stanislaus Street, and Shafter – Walker Street monitoring stations for 2019 through 2021. No data is available for H_2S, Vinyl Chloride or other toxic air contaminants in Kern County.

Table 3-3. Existing Air Quality Monitoring Data in Project Area

Pollutant and Monitoring Station Location	Maximum Concentration			Days Exceeding Standard		
	2019	2020	2021	2019	2020	2021
O_3 – 1-hour CAAQS (0.09 ppm)						
Bakersfield - 5558 California Ave	0.097	0.110	0.090	2	3	0
Oildale - 3311 Manor Street	0.099	0.109	0.107	1	3	6

The following is a description of criteria air pollutants, typical sources and health effects and the recently documented pollutant levels in the project vicinity.

3.2.1 Ozone (O_3)

The most severe air quality problem in the San Joaquin Valley is high concentrations of O_3. High levels of O_3 cause eye irritation and can impair respiratory functions. High levels of O_3 can also affect plants and materials. Grapes, lettuce, spinach and many types of garden flowers and shrubs are particularly vulnerable to O_3 damage. O_3 is not emitted directly into the atmosphere but is a secondary pollutant produced through photochemical reactions involving hydrocarbons and nitrogen oxides (NOx). Significant O_3 generation requires about one to three hours in a stable atmosphere with strong sunlight. For this reason, the months of April through October comprise the "ozone season." O_3 is a regional pollutant because O_3 precursors are transported and diffused by wind concurrently with the reaction process. The data contained in **Table 3-3** shows that the Bakersfield, Oildale and Maricopa areas exceeded the 1-hour average ambient O_3 CAAQS and the 8-hour average ambient O_3 NAAQS and CAAQS during the 2019 through 2021 period.

3.2.2 Suspended Particulate Matter (PM_{10} and $PM_{2.5}$)

Both State and Federal particulate standards now apply to particulates under 10 microns (PM_{10}) rather than to total suspended particulate (TSP), which includes particulates up to 30 microns in diameter. Continuing studies have shown that the smaller-diameter fraction of TSP represents the greatest health hazard posed by the pollutant; therefore, EPA has recently established NAAQS for $PM_{2.5}$. The project area is classified as attainment for PM_{10} and non-attainment for particulates under 2.5 microns ($PM_{2.5}$) for NAAQS.

Particulate matter consists of particles in the atmosphere resulting from many kinds of dust and fume-producing industrial and agricultural operations, from combustion, and from atmospheric photochemical reactions. Natural activities also increase the level of particulates in the atmosphere; wind-raised dust and ocean spray are two sources of naturally occurring particulates. The largest sources of PM_{10} and $PM_{2.5}$ in Kern County are vehicle movement over paved and unpaved roads, demolition and construction activities, farming operations, and unplanned fires. PM_{10} and $PM_{2.5}$ are considered regional pollutants with elevated levels typically occurring over a wide geographic area. Concentrations tend to be highest in the winter, during periods of high atmospheric stability and low wind speed. In the respiratory tract, very small particles of certain substances may produce injury by themselves or may contain absorbed gases that are injurious. Particulates of aerosol size suspended in the air can both scatter and absorb sunlight, producing haze and reducing visibility. They can also cause a wide range of damage to materials.

Table 3-3 shows that PM_{10} levels regularly exceeded the CAAQS but not the NAAQS at two monitoring stations over the three-year period of 2019 through 2021. **Table 3-3** shows that $PM_{2.5}$ NAAQS were exceeded from 2019 through 2021. Similar levels can be expected to occur in the vicinity of the Project site.

3.2.3 Carbon Monoxide (CO)

Ambient CO concentrations normally correspond closely to the spatial and temporal distributions of vehicular traffic. Relatively high concentrations of CO would be expected along heavily traveled roads and near busy intersections. Wind speed and atmospheric mixing also influence CO concentrations; however, under inversion conditions prevalent in the San Joaquin Valley, CO concentrations may be more uniformly distributed over a broad area.

Internal combustion engines, principally in vehicles, produce CO due to incomplete fuel combustion. Various industrial processes also produce CO emissions through incomplete combustion. Gasoline-powered motor vehicles are typically the major source of this contaminant. CO does not irritate the respiratory tract but passes

through the lungs directly into the blood stream, and by interfering with the transfer of fresh oxygen to the blood, deprives sensitive tissues of oxygen, thereby aggravating cardiovascular disease, causing fatigue, headaches, and dizziness. CO is not known to have adverse effects on vegetation, visibility, or materials.

Table 3-3 reports no CO data is available for the three-year period from 2019 through 2021; historically Bakersfield area data for CO has been below the CAAQS and NAAQS.

3.2.4 Nitrogen Dioxide (NO_2) and Hydrocarbons

Kern County has been designated as an attainment area for the NAAQS for NO_2. NO_2 is the "whiskey brown" colored gas readily visible during periods of heavy air pollution. Mobile sources and oil and gas production account for nearly all of the County's NOx emissions, most of which is emitted as NO_2. Combustion in motor vehicle engines, power plants, refineries and other industrial operations are the primary sources in the region. Railroads and aircraft are other potentially significant sources of combustion air contaminants. Oxides of nitrogen are direct participants in photochemical smog reactions. The emitted compound, nitric oxide, combines with oxygen in the atmosphere in the presence of hydrocarbons and sunlight to form NO_2 and O_3. NO_2, the most significant of these pollutants, can color the atmosphere at concentrations as low as 0.5 ppm on days of 10-mile visibility. NOx is an important air pollutant in the region because it is a primary receptor of ultraviolet light, which initiates the reactions producing photochemical smog. It also reacts in the air to form nitrate particulates.

Motor vehicles are the major source of reactive hydrocarbons in the basin. Other sources include evaporation of organic solvents and petroleum production and refining operations. Certain hydrocarbons can damage plants by inhibiting growth and by causing flowers and leaves to fall. Levels of hydrocarbons currently measured in urban areas are not known to cause adverse effects in humans. However, certain members of this contaminant group are important components in the reactions, which produce photochemical oxidants.

Table 3-3 shows that the Shafter area exceeded the 1-hour average ambient NO_2 NAAQS and CAAQS for the 2019 through 2021 period. Hydrocarbons are not currently monitored.

3.2.5 Sulfur Dioxide (SO_2)

Kern County has been designated as an attainment area for the NAAQS for SO_2. SO_2 is the primary combustion product of sulfur, or sulfur containing fuels. Fuel combustion is the major source of this pollutant, while chemical plants, sulfur recovery plants, and metal processing facilities are minor contributors. Gaseous fuels (natural gas, propane, etc.) typically have lower percentages of sulfur containing compounds than liquid fuels such as diesel or crude oil. SO_2 levels are generally higher in the winter months. Decreasing levels of SO_2 in the atmosphere reflect the use of natural gas in power plants and boilers.

At high concentrations, SO_2 irritates the upper respiratory tract. At lower concentrations, when respirated in combination with particulates, SO_2 can result in greater harm by injuring lung tissues. Sulfur oxides (SOx), in combination with moisture and oxygen, results in the formation of sulfuric acid, which can yellow the leaves of plants, dissolve marble, and oxidize iron and steel. SOx can also react to produce sulfates that reduce visibility and sunlight.

Table 3-3 shows no data has been reported over the three-year period in Kern County.

3.2.6 Lead (Pb) and Suspended Sulfate

Ambient Pb levels have dropped dramatically due to the increase in the percentage of motor vehicles that run exclusively on unleaded fuel. Ambient Pb levels in Elk Hills are well below the ambient standard and are

expected to continue to decline; the data reported in **Table 3-3** only shows the highest concentration as the number of days exceeding standards are not reported. Suspended sulfate levels have stabilized to the point where no excesses of the State standard are expected in any given year.

3.3 Climate

The most significant single control on the weather pattern of the San Joaquin Valley is the semi-permanent subtropical high-pressure cell, referred to as the "Pacific High." During the summer, the Pacific High is positioned off the coast of northern California, diverting ocean-derived storms to the north. Hence, the summer months are virtually rainless. During the winter, the Pacific High moves southward allowing storms to pass through the San Joaquin Valley. Almost all of the precipitation expected during a given year occurs from December through April. During the summer, the predominant surface winds are out of the northwest. Air enters the Valley through the Carquinez strait and flows toward the Tehachapi Mountains. This up-valley (northwesterly) wind flow is interrupted in early fall by the emergence of nocturnal, down-valley (southeasterly) winds which become progressively more predominant as winter approaches. Wind speeds are generally highest during the spring and lightest in fall and winter. The relatively cool air flowing through the Carquinez strait is warmed on its journey south through the Valley. On reaching the southern end of the Valley, the average high temperature during the summer is nearly 100 degrees Fahrenheit (°F). Relative humidity during the summer is quite low, causing large diurnal temperature variations. Temperatures during the summer often drop into the upper 60s. In winter, the average high temperatures reach the mid-50s and the average low drops to the mid-30s. In addition, another high-pressure cell, known as the "Great Basin High," develops east of the Sierra Nevada Mountain Range during winter. When this cell is weak, a layer of cool, damp air becomes trapped in the basin and extensive fog results. During inversions, vertical dispersion is restricted, and pollutant emissions are trapped beneath the inversion and pushed against the mountains, adversely affecting regional air quality. Surface-based inversions, while shallow and typically short-lived, are present most mornings. Elevated inversions, while less frequent than ground-based inversions, are typically longer lasting and create more severe air stagnation problems. The winter season characteristically has the poorest conditions for vertical mixing of the entire year.

Meteorological data for various monitoring stations is maintained by the Western Regional Climate Center. Meteorological data for the Project site is expected to be similar to the data recorded at the Buttonwillow monitoring station. This data is provided in **Table 3-4**, which contains average precipitation data recorded at the Buttonwillow monitoring station. Over the 115-year period from January of 1901 through June of 2016 (the most recent data available), the average annual precipitation was 5.64 inches.

Table 3-4. Buttonwillow Weather Data

3.4 Climate Change and Greenhouse Gases

3.4.1 Global Climate Change

"Global climate change" refers to change in average meteorological conditions on the earth with respect to temperature, precipitation, and storms, lasting for decades or longer. The term "global climate change" is often used interchangeably with the term "global warming," but "global climate change" is preferred by some scientists and policy makers to "global warming" because it helps convey the notion that in addition to rising temperatures, other changes in global climate may occur. Climate change may result from the following influences:

- Natural factors, such as changes in the sun's intensity or slow changes in the Earth's orbit around the sun;
- Natural processes within the climate system (e.g., changes in ocean circulation); and/or
- Human activities that change the atmosphere's composition (e.g., through burning fossil fuels) and the land surface (e.g., deforestation, reforestation, urbanization, and desertification).

As determined from worldwide meteorological measurements between 1990 and 2005, the primary observed effect of global climate change has been a rise in the average global tropospheric temperature of 0.36 degree Fahrenheit (°F) per decade. Climate change modeling shows that further warming could occur, which could induce additional changes in the global climate system during the current century. Changes to the global climate system, ecosystems, and the environment of California could include higher sea levels, drier or wetter weather, changes in ocean salinity, changes in wind patterns or more energetic aspects of extreme weather (e.g., droughts, heavy precipitation, heat waves, extreme cold, and increased intensity of tropical cyclones). Specific effects from climate change in California may include a decline in the Sierra Nevada snowpack, erosion of California's coastline, and seawater intrusion in the Sacramento-San Joaquin River Delta.

Human activities, including fossil fuel combustion and land use changes, release carbon dioxide (CO_2) and other compounds cumulatively termed greenhouse gases (GHGs). GHGs are effective at trapping radiation that would otherwise escape the atmosphere. This trapped radiation warms the atmosphere, the oceans, and the earth's surface (USGCRP, 2014). Many scientists believe "most of the warming observed over the last 50 years is attributable to human activities" (IPCC, 2017). The increased amount of CO_2 and other GHGs in the atmosphere is the alleged primary result of human-induced warming.

GHGs are present in the atmosphere naturally, released by natural sources, or formed from secondary reactions taking place in the atmosphere. They include CO_2, methane (CH_4), nitrous oxide (N_2O), and O_3. In the last 200 years, substantial quantities of GHGs have been released into the atmosphere, primarily from fossil fuel combustion. These human-induced emissions are increasing GHG concentrations in the atmosphere, therefore enhancing the natural greenhouse effect. The GHGs resulting from human activity are believed to be causing global climate change. While human-made GHGs include CO_2, CH_4, and N_2O, some (like chlorofluorocarbons [CFCs]) are completely new to the atmosphere. GHGs vary considerably in terms of Global Warming Potential (GWP), the comparative ability of each GHG to trap heat in the atmosphere. The GWP is based on several factors, including the relative effectiveness of a gas to absorb infrared radiation and the length of time that the gas remains in the atmosphere ("atmospheric lifetime"). The GWP of each gas is measured relative to CO_2, the most abundant GHG. The definition of GWP for a particular GHG is the ratio of heat trapped by one unit mass of the GHG to the ratio of heat trapped by one unit mass of CO_2 over a specified time period. GHG emissions are typically measured in terms of pounds or tons of "CO_2 equivalents" (CO_2e).

Methane is produced when organic matter decomposes in environments lacking sufficient oxygen. Natural sources of CH_4 production include wetlands, termites, and oceans. Human activity accounts for the majority of the approximately 500 million metric tons of CH_4 emitted annually. These anthropogenic sources include the mining and burning of fossil fuels; digestive processes in ruminant livestock such as cattle; rice cultivation; and the decomposition of waste in landfills. The major removal process for atmospheric CH_4, the chemical breakdown in the atmosphere, cannot keep pace with source emissions; therefore, CH_4 concentrations in the atmosphere are rising.

Worldwide emissions of GHGs in 2008 were 30.1 billion metric tons of CO_2e and have increased considerably since that time (United Nations, 2011). It is important to note that the global emissions inventory data are not all from the same year and may vary depending on the source of the data (U.S. EPA, 2019). Emissions from the top five emitting countries and the European Union accounted for approximately 70% of total global GHG emissions in 2014. The United States was the number two producer of GHG emissions behind China. The primary GHG emitted by human activities was CO_2, representing approximately 76% of total global GHG emissions (U.S. EPA, 2019).

In 2017, the United States emitted approximately 6.5 million metric tons of CO_2e. Of the six major sectors nationwide (electric power industry, transportation, industry, agriculture, commercial, and residential), the electric power industry and transportation sectors combined account for approximately 57% of the GHG emissions; the majority of the electrical power industry and all of the transportation emissions are generated from direct fossil fuel combustion. Between 1990 and 2017, total United States GHG emissions rose approximately 1.3% (U.S. EPA, 2019).

Worldwide, energy-related CO_2 emissions are expected to increase at an average rate of 0.6% annually between 2018 and 2050, compared with the average growth rate of 1.8% per year from 1990 to 2018. Much of the increase in these emissions is expected to occur in the developing world where emerging economies, such as China and India, fuel economic development with fossil fuel energy. Developing countries' emissions are expected to grow above the world average at a rate of approximately 1% annually between 2018 and 2050 and surpass emissions of industrialized countries by 2025 (U.S. EIA, 2019).

CARB is responsible for developing and maintaining the California GHG emissions inventory. This inventory estimates the amount of GHGs emitted into and removed from the atmosphere by human activities within the state of California and supports the Assembly Bill (AB) 32 Climate Change Program. CARB's current GHG emission inventory covers the years 2000 through 2017 and is based on fuel use, equipment activity, industrial processes, and other relevant data (e.g., housing, landfill activity, and agricultural lands).

In 2017, emissions from statewide emitting activities were 424 million metric tons of CO_2 equivalent (MMT CO_2e), which is 5 MMT CO_2e lower than 2016 levels. 2017 emissions have decreased by 14% since peak levels in 2004 and are 7 MMT CO_2e below the 1990 emissions level and the State's 2020 GHG limit. Per capita GHG emissions in California have dropped from a 2001 peak of 14.1 tonnes per person to 10.7 tonnes per person in 2017, a 24% decrease (CARB 2019).

CARB estimates that transportation was the source of approximately 40% of California's GHG emissions in 2017, followed by electricity generation at 15%. Other sources of GHG emissions were industrial sources at 21%, residential plus commercial activities at 10%, and agriculture at 8% (CARB 2019).

CARB has projected the estimated statewide GHG emissions for the year 2020, which represent the emissions that would be expected to occur with reductions anticipated from Pavley I and the Renewables Electricity Standard (30 MMT CO_2e total), will be 509 MMT of CO_2e (CARB, 2014). GHG emissions from the transportation and electricity sectors as a whole are expected to increase at approximately 36% and 20% of total CO_2e emissions, respectively, as compared to 2009. The industrial sector consists of large stationary sources of GHG emissions and the percentage of the total 2020 emissions is projected to be 18% of total CO_2e emissions. The remaining sources of GHG emissions in 2020 are high global warming potential gases at 6%, residential and commercial activities at 10%, agriculture at 7%, and recycling and waste at 2%.

3.4.2 Effects of Global Climate Change

Changes in the global climate are assessed using historical records of temperature changes that have occurred in the past. Climate change scientists use this temperature data to extrapolate a level of statistical significance specifically focusing on temperature records from the last 150 years (the Industrial Age) that differ from past climate changes in rate and magnitude.

The Intergovernmental Panel on Climate Change (IPCC) constructed several emission trajectories of GHGs needed to stabilize global temperatures and climate change impacts. In its Fifth Assessment Report, the IPCC predicted that the global mean temperature change from 1990 to 2100 could range from 1.1 degree Celsius (°C) to 6.4 °C (8 to 10.4 °Fahrenheit) (IPCC, 2013). Global average temperatures and sea levels are expected to rise under all scenarios (IPCC, 2014). The IPCC concluded that global climate change was largely the result of human activity, mainly the burning of fossil fuels. However, scientific literature is not consistent regarding many of the aspects of climate change, the actual temperature changes during the 20th century, and contributions from human versus non-human activities.

Effects from global climate change may arise from temperature increases, climate sensitive diseases, extreme weather events, and degradation of air quality. There may be direct temperature effects through increases in average temperature leading to more extreme heat waves and less extreme cold spells. Those living in warmer climates are likely to experience more stress and heat-related problems. Heat-related problems include heat rash and heat stroke, drought, etc. In addition, climate-sensitive diseases may increase, such as those spread by mosquitoes and other disease-carrying insects. Such diseases include malaria, dengue fever, yellow fever, and encephalitis. Extreme events such as flooding and hurricanes can displace people and agriculture. Global warming may also contribute to air quality problems from increased frequency of smog and particulate air pollution.

According to the 2006 California Climate Action Team (CAT) Report, several climate change effects can be expected in California over the course of the next century (CalEPA, 2006). These are based on trends established by the IPCC and are summarized below.

- A diminishing Sierra snowpack declining by 70% to 90%, threatening the state's water supply.

- A rise in sea levels, resulting in the displacement of coastal businesses and residences. During the past century, sea levels along California's coast have risen about seven inches. If emissions continue unabated and temperatures rise into the higher anticipated warming range, sea level is expected to rise an additional 22 to 35 inches by the end of the century. Sea level rises of this magnitude would inundate coastal areas with salt water, accelerate coastal erosion, threaten vital levees and inland water systems, and disrupt wetlands and natural habitats. (Note: This condition would not affect the proposed Project area, as it is a significant distance away from coastal areas.)
- An increase in temperature and extreme weather events. Climate change is expected to lead to increases in the frequency, intensity, and duration of extreme heat events and heat waves in California. More heat waves can exacerbate chronic disease or heat-related illness.
- Increased risk of large wildfires if rain increases as temperatures rise. Wildfires in the grasslands and chaparral ecosystems of southern California are estimated to increase by approximately 30% toward the end of the 21st century because more winter rain will stimulate the growth of more plant fuel available to burn in the fall. In contrast, a hotter, drier climate could promote up to 90% more northern California fires by the end of the century by drying out and increasing the flammability of forest vegetation.
- Increasing temperatures from 8 to 10.4 °F under the higher emission scenarios, leading to a 25% to 35% increase in the number of days that ozone pollution levels are exceeded in most urban areas (see below).
- Increased vulnerability of forests due to forest fires, pest infestation, and increased temperatures.
- Reductions in the quality and quantity of certain agricultural products. The crops and products likely to be adversely affected include wine grapes, fruit, nuts, and milk.
- Exacerbation of air quality problems. If temperatures rise to the medium warming range, there could be 75 to 85% more days with weather conducive to ozone formation in Los Angeles and the San Joaquin Valley, relative to today's conditions. This is more than twice the increase expected if rising temperatures remain in the lower warming range. This increase in air quality problems could result in an increase in asthma and other health-related problems.
- A decrease in the health and productivity of California's forests. Climate change can cause an increase in wildfires, an enhanced insect population, and establishment of non-native species.
- Increased electricity demand, particularly in the hot summer months.
- Increased ground-level ozone formation due to higher reaction rates of ozone precursors.

3.4.3 Global Climate Change Regulatory Issues

In 1988, the United Nations established the Intergovernmental Panel on Climate Change to evaluate the impacts of global warming and to develop strategies that nations could implement to curtail global climate change. In 1992, the United Nations Framework Convention on Climate Change established an agreement with the goal of controlling GHG emissions, including methane. As a result, the Climate Change Action Plan was developed to address the reduction of GHGs in the United States. The plan consists of more than 50 voluntary programs. Additionally, the Montreal Protocol was originally signed in 1987 and substantially amended in 1990 and 1992. The Montreal Protocol stipulates that the production and consumption of compounds that deplete O_3 in the stratosphere (chlorofluorocarbons [CFCs], halons, carbon tetrachloride, and methyl chloroform) were phased out by 2000 (methyl chloroform was phased out by 2005).

On September 27, 2006, Assembly Bill 32 (AB32), the California Global Warming Solutions Act of 2006 (the Act) was enacted by the State of California. The legislature stated, "Global warming poses a serious threat to the economic well-being, public health, natural resources, and the environment of California." The Act caps California's GHG emissions at 1990 levels by 2020. The Act defines GHG emissions as all of the following gases: carbon dioxide (CO_2), methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride. This agreement represents the first enforceable statewide program in the U.S. to cap all GHG emissions from major industries that includes penalties for non-compliance. While acknowledging that national

and international actions will be necessary to fully address the issue of global warming, AB32 lays out a program to inventory and reduce GHG emissions in California and from power generation facilities located outside the state that serve California residents and businesses.

AB32 charges CARB with responsibility to monitor and regulate sources of GHG emissions in order to reduce those emissions. CARB has adopted a list of discrete early action measures that can be implemented to reduce GHG emissions. CARB has defined the 1990 baseline emissions for California and has adopted that baseline as the 2020 statewide emissions cap. CARB is conducting rulemaking for reducing GHG emissions to achieve the emissions cap by 2020. In designing emission reduction measures, CARB must aim to minimize costs, maximize benefits, improve, and modernize California's energy infrastructure, maintain electric system reliability, maximize additional environmental and economic co-benefits for California, and complement the state's efforts to improve air quality.

Subsequent legislation by the California legislature has included Senate Bill (SB) 32, which expanded upon AB32 to reduce GHG emissions to 40% below the 1990 levels by 2030; AB197 which increased the legislative oversight of the CARB by adding two legislatively appointed non-voting members to the CARB Board and provided additional protection to disadvantaged communities; SB350, which increased California's renewable energy electricity procurement goal and SB100, which established a landmark policy requiring renewable energy and zero-carbon resources to supply 100 percent of electrical retail sales to end use customers and 100 percent of electricity procured to serve state agencies by 2045.

Global warming and climate change have received substantial public attention for more than 20 years. For example, the United States Global Change Research Program was established by the Global Change Research Act of 1990 to enhance the understanding of natural and human-induced changes in the Earth's global environmental system, to monitor, understand, and predict global change, and to provide a sound scientific basis for national and international decision-making. Even so, the analytical tools have not been developed to determine the effect on worldwide global warming from a particular increase in GHG emissions, or the resulting effects on climate change in a particular locale. The scientific tools needed to evaluate the impacts that a specific project may have on the environment are even farther in the future.

The California Supreme Court's CEQA decision on the Newhall Ranch development case, Center for Biological v. California Department of Fish and Wildlife (November 30, 2015, Case No. 217763), determined that the project's Environmental Impact Report (EIR) did not substantiate the conclusion that the GHG cumulative impacts would be less than significant. The EIR determined that the Newhall Ranch development project would reduce GHG emissions by 31 percent from business as usual (BAU). This reduction was compared to California's target of reducing GHG emissions statewide by 29 percent from business as usual. The Court determined that "the EIR's deficiency stems from taking a quantitative comparison method developed by the Scoping Plan as a measure of the greenhouse gas reduction effort required by the state as a whole, and attempting to use that method, without adjustments, for a purpose very different from its original design." In the Court's final ruling it offered suggestions that were deemed appropriate use of the BAU methodology:

1. Lead agencies can use the comparison to BAU methodology if they determine what reduction a particular project must achieve in order to comply with statewide goals,
2. Project design features that comply with regulations to reduce emissions may demonstrate that those components of emissions are less than significant, and
3. Lead agencies could also demonstrate compliance with locally adopted climate plans or could apply specific numerical thresholds developed by some local agencies.

Kern County, the Lead CEQA agency for this Project, has not developed specific thresholds for GHGs. As discussed in **Section 4.1**, the SJVAPCD, a CEQA Trustee Agency for this Project, has developed thresholds

to determine significance of a proposed project – either implement Best Performance Standards or achieve a 29% reduction from BAU (a specific numerical threshold). However, the SJVAPCD has established their BAU and baseline emissions based on the years 2002-2004 and 2020, respectively. The 2020 projected baseline has passed, and at this time, no new guidance has been approved for determining BAU and projected baseline for the next target year. Therefore, the 29% reduction from BAU cannot be applied to the subject Project in order to determine significance. Additionally, a Best Performance Standards threshold has not been established. For this Project, however, there will be a net benefit for GHG emissions. Therefore, the GHG analysis for this Project follows the suggestions from the Court's ruling on the Newhall Ranch development project in order to determine significance using the Project's design features.

4. IMPACT ASSESSMENT

4.1 Significance Criteria

To determine whether a proposed Project could create a potential CEQA impact, local, State, and Federal agencies have developed various means by which a project's impacts may be measured and evaluated. Such means can generally be categorized as follows:

- Thresholds of significance adopted by air quality agencies to guide lead agencies in their evaluation of air quality impacts under the CEQA.
- Regulations established by air districts, CARB and EPA for the evaluation of stationary sources when applying for Authorities to Construct, Permits to Operate and other permit program requirements (e.g., New Source Review).
- Thresholds utilized to determine if a project would cause or contribute significantly to violations of the ambient air quality standards or other concentration-based limits.
- Regulations applied in areas where severe air quality problems exist.

Summary tables of these emission-based and concentration-based thresholds of significance for each pollutant are provided below along with a discussion of their applicability.

4.1.1 Thresholds Adopted for the Evaluation of Air Quality Impacts under CEQA

In order to maintain consistency with CEQA, the SJVAPCD (2015) adopted guidelines to assist applicants in complying with the various requirements. According to the SJVAPCD's GAMAQI, a project would have potentially significant air quality impacts when the project:

- Creates a conflict with or obstructs implementation of the applicable air quality plan;
- Causes a violation of any air quality standard or generates substantial contribution towards exceeding an existing or projected air quality standard;
- Results in a cumulatively considerable net increase of any criteria pollutant for which the project region is designated non-attainment under a NAAQS and CAAQS (including emissions which exceed quantitative thresholds for O_3 precursors);
- Exposes sensitive receptors to substantial pollutant concentrations; or
- Creates objectionable odors that affect a substantial number of people.

The SJVAPCD GAMAQI thresholds are designed to implement the general criteria for air quality emissions as required in the CEQA Guidelines, Appendix G, Paragraph III (Title 14 of the California Code of Regulations §15064.7) and CEQA (California Public Resources Code Sections 21000 et. al). SJVAPCD's specific CEQA air quality thresholds are presented in **Table 4-1**.

Table 4-1. SJVAPCD CEQA Thresholds of Significance

Criteria Pollutant	Significance Level	
	Construction	Operational
CO	100 tons/yr	100 tons/yr
NOx	10 tons/yr	10 tons/yr
ROG	10 tons/yr	10 tons/yr
SOx	27 tons/yr	27 tons/yr
PM_{10}	15 tons/yr	15 tons/yr
$PM_{2.5}$	15 tons/yr	15 tons/yr
Source: SJVAPCD 2015		

4.1.2 Thresholds for Ambient Air Quality Impacts

CEQA Guidelines – Appendix G (Environmental Checklist) states that a project that would "violate any air quality standard or contribute substantially to an existing or projected air quality violation" would be considered to create significant impacts on air quality. Therefore, an AQIA should determine whether the emissions from a project would cause or contribute significantly to violations of the NAAQS or CAAQS (presented above in **Table 3-1**) when added to existing ambient concentrations.

The EPA has established the Federal Prevention of Significant Deterioration (PSD) program to determine what comprises "significant impact levels" (SIL) to NAAQS attainment areas. A project's impacts are considered less than significant if emissions are below PSD SIL for a particular pollutant. When a SIL is exceeded, an additional "increment analysis" is required. As the Project would include modification to a stationary source under new source review (NSR), it would be subject to either PSD or NSR review. The PSD SIL thresholds are used with ambient air quality modeling for a CEQA project to address whether the Project would "violate any air quality standard or contribute substantially to an existing or projected air quality violation." Ambient air quality emissions estimates below the PSD SIL thresholds would result in less than significant ambient air quality impacts for both a project and cumulative CEQA impact analysis. The SJVAB is classified as non-attainment for the O_3 NAAQS and, as such, is subject to "non-attainment new source review". PSD SILs and increments are more stringent than the CAAQS or NAAQS and represent the most stringent thresholds of significance.

4.1.3 Thresholds for Hazardous Air Pollutants

The SJVAPCD's GAMAQI states, "From a health risk perspective there are basically two types of land use projects that have the potential to cause long-term public health risk impacts:

- Type A Projects: Land use projects that will place new toxic sources in the vicinity of existing receptors, and
- Type B Projects: Land use projects that will place new receptors in the vicinity of existing toxics sources" (SJVAPCD 2015).

Since, the Project is a Type A project a health risk analysis will be required. **Table 4-2**Table 4-2 presents the thresholds of significance used with toxic air contaminants when evaluating hazardous air pollutants (HAPs).

Table 4-2. Measures of Significance - Toxic Air Contaminants

Agency	Level	Description
Significance Thresholds Adopted for the Evaluation of Impacts Under CEQA		
SJVAPCD	Carcinogens	Maximally Exposed Individual risk **equals or exceeds** 20 in one million.
	Non-Carcinogens	**Acute**: Hazard Index **equals or exceeds** 1 for the Maximally Exposed Individual.
		Chronic: Hazard Index **equals or exceeds** 1 for the Maximally Exposed Individual.
Source: SJVAPCD 2015		

4.1.4 Cumulative Impacts Threshold of Significance

Attachment A of Kern County's Guidelines for Preparing an Air Quality Assessment for Use in Environmental Impact Reports states "the following threshold are defined for purposes of determining cumulative effects as the baseline for "considerable". "Projects in the San Joaquin Valley Air Pollution Control District...will be subject to the following significance thresholds". The thresholds outlined in the guidelines mirror the individual project

significance thresholds of 15 tons per year for PM_{10} and 10 tons per year for NO_X and ROG. Therefore, owing to the inherently cumulative nature of air quality impacts, the threshold for whether a project would make a cumulatively considerable contribution to a significant cumulative impact is simply whether the project would exceed project-level thresholds.

4.1.5 Global Climate Change Thresholds of Significance

On December 17, 2009, SJVAPCD adopted Guidance for Valley Land-use Agencies in Addressing GHG Emission Impacts for New Projects under CEQA (SJVAPCD 2009); which outlined the SJVAPCD's methodology for assessing a project's significance for GHGs under CEQA. The following criteria was outlined in the document to determine whether a project could have a significant impact:

- Projects determined to be exempt from the requirements of CEQA would be determined to have a less than significant individual and cumulative impact for GHG emissions and would not require further environmental review, including analysis of project specific GHG emissions. Projects exempt under CEQA would be evaluated consistent with established rules and regulations governing project approval and would not be required to implement Best Performance Standards (BPS).
- Projects complying with an approved GHG emission reduction plan or GHG mitigation program which avoids or substantially reduces GHG emissions within the geographic area in which the project is located would be determined to have a less than significant individual and cumulative impact for GHG emissions. Such plans or programs must be specified in law or approved by the lead agency with jurisdiction over the affected resource and supported by a CEQA compliant environmental review document adopted by the lead agency. Projects complying with an approved GHG emission reduction plan or GHG mitigation program would not be required to implement BPS.
- Projects implementing Best Performance Standards would not require quantification of project specific GHG emissions. Consistent with CEQA Guidelines, such projects would be determined to have a less than significant individual and cumulative impact for GHG emissions.
- Projects not implementing Best Performance Standards would require quantification of project specific GHG emissions and demonstration that project specific GHG emissions would be reduced or mitigated by at least 29%, compared to Business-as-Usual (BAU), including GHG emission reductions achieved since the 2002-2004 baseline period. Projects achieving at least a 29% GHG emission reduction compared to BAU would be determined to have a less than significant individual and cumulative impact for GHG.
- Notwithstanding any of the above provisions, projects requiring preparation of an Environmental Impact Report for any other reason would require quantification of project specific GHG emissions. Projects implementing BPS or achieving at least a 29% GHG emission reduction compared to BAU would be determined to have a less than significant individual and cumulative impact for GHG.

4.2 Project Related Emissions

This document was prepared pursuant to the SJVAPCD's GAMAQI. The GAMAQI identifies separate thresholds for a project's short-term (construction) and long-term (operational) emissions.

Project emissions were estimated for the following project development stages:

- Short-term (Construction and Demolition) – Construction emissions of the proposed Project were estimated in CalEEMod based on estimated construction schedule, equipment and manpower provided by Aera Energy.
- Long-term (Operations) – Long term emissions were also estimated in CalEEMod, EMFAC2021, TanksESP, AP-42 Emission Factors, manufacturer guaranteed emission factors, and San Joaquin Valley Air Pollution Control District Permit to Operate Emission Factors.

4.2.1 Short-Term Emissions

The CalEEMod equipment list was updated to reflect the list of proposed construction equipment that was provided by Aera Energy. Applying model defaults as well as a conservative analysis approach, construction emissions were estimated according to the supplied construction schedule starting in 2025. Anticipated construction equipment and schedules can be found in **Appendix B**. The dates entered into the CalEEMod program may not represent the actual dates the equipment will operate; however, the total construction time is accurate, and therefore, all estimated emission totals are conservative and reflect a reasonable and legally sufficient estimate of potential impacts. All construction equipment activity assumption levels were based on the specified CalEEMod default values for equipment horsepower, load factors and hours per day.

CO_2 capture facility and infrastructure construction would occur over a period of approximately three years, starting with the Pre-C facility construction at GP 32. Sequential construction would occur for construction of the Post-C facilities located at COGEN 32 and the two SGSs. Injection well pad construction, drilling and plugging and abandonment activities, and pipeline construction activities would begin concurrently with the start of facility construction. Installation of CO_2 distribution pipelines, intra-field electrical distribution, and well hookups would occur throughout the three-year period.

Demolition

The proposed CO_2 capture facility areas currently contain piping and other idle equipment that would be removed, and wells that would be permanently abandoned, prior to construction of the proposed facilities. There is some debris from former operations, such as broken concrete, in scattered locations throughout the Project site. Debris would be reused or recycled to the extent feasible. Five shipping pumps, two water tanks, two electrical transformers, a water heater, an electrical panel, and one moisture separator would be removed or demolished on the land north of GP 32; all equipment is out of service. Demolition of various oil production facilities (old pipelines) and equipment (a production header) would occur on approximately nine acres of land around SGS 2868. Miscellaneous rubble piles would also be cleared. Demolition of various oil production facilities (including old foundations and pipelines) and equipment would occur on approximately 16 acres of land in areas around SGS 2972.

The proposed CO_2 capture facility areas also contain abandoned structures that would be demolished prior to construction of the proposed facilities. Demolition of a sulfur treatment facility, maintenance shed, old equipment yard, and a building would occur on approximately 1.5 acres of land at GP 32. The to-be-demolished building holds a former Control Room, Lab, Conference Room, and associated offices. The old equipment yard currently stores three gas compressors and five cylindrical gas tanks, which would be relocated prior to demolition. One storage building would be demolished on the land northeast of GP 32.

Grading

The Project would require minor grading of the proposed CO_2 capture facility sites, totaling approximately 40 acres, most of which is previously disturbed area. The Project would maximize the use of existing roads, well pads, and cleared areas wherever possible. Proposed cut and fill volumes are approximately 203,000, cubic yards total. Well pads would be approximately 145 feet by 280 feet in area. Each well pad would be cleared of vegetation and leveled to prepare it for well drilling. Excess soils would be transported to a designated fill location within the Project site for re-use as fill material or moved off-site to an appropriate soils disposal or reuse facility.

Additional ground disturbance would occur for construction of the utilities component of the Project, as a result for the water pipelines and overhead power lines. The estimated disturbance from the Project pipelines

would be minimized as most would be located aboveground, placed on existing and new pipe supports and along existing pipeline corridors. The estimated ground disturbance for the 115 kV and 12 kV power lines would be approximately 2.1 acres.

Well Pads and Roadways

Well locations have been carefully selected to minimize disturbance by reusing existing well pads, where feasible, and to allow for the permanent CO_2 sequestration within the dedicated zone. Well pads have been designed to minimize the amount of surface disturbance while meeting the technical constraints of drilling and operating the wells. Areas within the designated well pad area would be cleared of all vegetation and other deleterious material utilizing heavy equipment. The proposed wells would be constructed on existing well pads; however, these pads may need to be cleared of encroaching vegetation or enlarged to meet Project requirements. Earthwork would be completed utilizing conventional equipment (e.g., dozers, loaders, scrapers, motor graders, excavators, sheep's foot compactors, smooth drum rollers, water trucks. etc.). Well pad prep emissions are captured under the total emissions of all oil and gas activities on a per well basis calculated in Section 4.2.3 below and therefore not calculated in this section.

Drilling

Drilling rigs would operate 24 hours per day while drilling, and depending on the type of well, would operate consecutively for up to 14 days at each location. The specific rig has not been determined at this time, but the rig will be the equivalent to Kenai #18.

Kenai #18 is 279 feet long and 145 feet wide with a footprint of approximately 33,500 square feet. The rig has a 121-foot-tall mast which sits on the drill rig floor. However, Kenai #18 has a 750,000-pound static hook load capacity, which exceeds Aera Energy's standard currently used for drilling in the San Joaquin Valley.

Since a larger rig footprint may be required as the Project develops, Aera Energy is planning to utilize the larger rig (Kenai #18 or equivalent). Additional drilling equipment for either rig would include the following: fluid handling equipment, waste storage containers, four generators, mud handling system, blow out prevention equipment, spill prevention equipment, hydrogen sulfide detection equipment, three mud pumps, cuttings bin, catwalk, trailer (also referred to as "doghouse") and others. Note, the equipment listed is for a typical drilling operation, the exact equipment list and layout may vary depending on the specific well to be drilled. Well drilling emissions are captured under the total emissions of all oil and gas activities on a per well basis calculated in Section 4.2.3 below and therefore not calculated in this section.

Facilities Construction

The following outlines construction procedures associated with grading and installation of the processing facilities in consecutive order:

- *Staging*. Material and equipment would be gathered on-site;
- *Inspection*. Material and equipment would be inspected for quality assurance. Construction equipment would be verified to meet applicable environmental regulations. Equipment operators and field workers would be verified to possess the proper qualifications;
- *Civil*. Soil would be graded and excavated. Concrete equipment foundations, pipe supports, pads and containment would be poured;

- *Equipment*. Major vessels and equipment would be set on foundations;
- *Supports*. Pipe supports would be installed;
- *Plant Piping*. Piping, valves, and instrumentation would be installed between equipment and vessels. Welds would be radiographed and connections strength tested;
- *Electrical.* Electrical panels, conduit, and power wiring would be installed;
- *Instrumentation*. Instrumentation signal wiring and tubing would be installed. Terminations would be made at the instrumentation and connections would be tested;
- *Corrosion Control*. Piping and non-galvanized structural steel would either be insulated or primed and painted. Buried steel piping would be coated or wrapped with protective coatings. Cathodic protection may be used in certain areas to protect buried steel piping from external corrosion. Insulating kits would be used to protect buried steel piping from external corrosion. Insulating kits would be used to isolate above-ground from buried piping;
- *Start-Up Preparation*. All valves and instrumentation would be put in normal operating positions/modes for start-up. All safety devices would be checked for proper operation;
- *Personnel Training*. Operators, mechanics, and instrument mechanics would be trained to operate and maintain the facilities;
- *Start-Up*. Plant would be started and tested for proper operation. Any problems or issues would be resolved; and
- *Operation.* Normal operation would commence.

Main Pipeline Construction

Construction and installation of the CO_2 pipeline would be primarily aboveground, resting either on existing pipe supports or new supports. At designated internal road crossings, the pipeline would be installed by conventional trenching.

The sequence of construction activities for the CO_2 pipeline component of the Project is summarized below. Construction of the CO_2 pipeline is scheduled to take approximately six months.

- *Mobilization and Staging.* Prior to construction, the contractor would mobilize the site and establish staging areas for materials and equipment storage. Construction equipment would be staged along the route and would progress with the pipe installation.
- *Surveying, Staking and Flagging.* The centerline would be marked at line-of-sight intervals, at points of intersection (including offset stakes marking the edges of the right-of-way, and at all known underground facilities. In addition, any environmentally sensitive areas (i.e., biological, cultural, and/or hydrological resources) would be clearly marked.
- *Clearing and Grading.* The majority of the temporary construction easement occurs along the previously disturbed pipeline corridors. Where necessary, existing vegetation would be cleared and

the ground within the construction right-of-way would be graded and smooth to provide safe and efficient operation of construction equipment.

- *Hauling and Stringing.* The pipe would be hauled by truck to one of the staging areas where it would be offloaded by cranes and loaded onto stringing trucks to be delivered to the construction right-of-way.

- *Pipe Supports.* Pipe supports would be constructed at approximately 20-foot to 30-foot intervals along the pipeline, as needed. A truck-mounted drill would be used to auger a 24-inch to 36-inch diameter hole approximately six to eight feet deep. The pre-fabricated steel, or alternate, pipe support would be set into the hole and the hole would then be filled with concrete.

- *Trenching.* The typical trench would be approximately five feet deep and between two and five feet wide. Excavated soils may be preserved and used as backfill materials at the site of origin. Spoil piles would be placed along the trench in areas where a temporary construction easement is available. Materials deemed unsuitable for backfill would be disposed of off-site and/or transported to Aera Energy's Belridge road-mix facility for re-use in accordance with all applicable regulations.

- *Jack-and-Bore.* Jack-and-bore tunneling would be utilized at road crossings, where required. This methodology is used for horizontal pipeline construction and entails the excavation of pits on either side of the crossing and use of a boring machine with a cutting 'head', auger, and casing. The auger and casing are pushed behind the 'head' as it cuts through the ground. The auger carries the debris back to the pit as the head cuts. Jack-and-bore horizontal tunneling is anticipated to take approximately 10 days to complete at each location. Additional locations may be added based on circumstances that are unknown at this time, such as utility conflicts or requirements imposed by the County or Caltrans. Typical horizontal bores are 10 feet deep and require entry pits of approximately 15 feet by 40 feet and receiving pits of approximately 10 feet by 15 feet. In any location where Jack and Bore is used, there is only one entry pit and one exit pit.

- *Pipe Placement, Welding and Coating.* New pipeline segments would be inspected to locate and repair any faults or voids in the pipeline coating prior to being lowered into the trench. In areas where the pipe is joined within the ditch, "bell holes" would be dug at each pipe joint to facilitate access for welding and joint coating application. These welds would typically be made in the ditch, with the pipe at its final elevation and alignment. Welding and Coating would apply to all areas throughout the Project.

- *Weld Inspection.* All welds would be inspected in accordance with state and federal welding requirements. When inspected radiographically, all radiographs would be recorded and interpreted for acceptability in accordance with American Petroleum Institute 1104. All rejected welds would be repaired or replaced as necessary and re-radiographed. The inspection reports would be kept for the life of the pipeline.

- *Line Lowering, Backfill and Compaction.* For conventional open trench segments, the welded pipe segments or individual pipe lengths would be lifted and lowered into the trench by side boom tractors. The native material excavated from the pipeline trench would either be reused as backfill, transported to Aera Energy's Belridge road-mix facility, or would be hauled and disposed off-site to at an approved landfill facility. Required backfill material would be compacted with compaction rollers and/or hydraulic tampers and undergo compaction testing to ensure that all trench locations

are compacted in accordance with standard engineering practices and permit requirements. All trenches would either be fenced, backfilled, or covered with steel plates at the end of each workday.

- *Aboveground Equipment Installation.* The majority of aboveground equipment would be pre-fabricated at a staging area and then transported to the respective locations for final assembly and tie-in to the pipeline facilities. Valve and meter set assembly locations would be either paved or graveled.

- *Hydrostatic Testing.* In accordance with the applicable codes and regulations, the pipeline would undergo hydrostatic testing prior to operation by pumping water into the test sections, pressurized to design-test pressure, and maintained that pressure for a minimum amount of time to identify defects in construction. Water to be used for hydrotest will be from local water systems. Discharged water will be stored into temporary tanks and held for testing. After results of the samples are analyzed, the water may be used for dust control at the project site or used for additional testing on other pipeline segments. The Storm Water Protection and Prevention Plan prepared by Aera Energy would also include Best Management Practices in case the hydrotest is not successful initially.

- *Pigging.* Pipeline pigs are devices that are inserted into and travel throughout the length of a pipeline driven by a product flow to perform functions, such as cleaning or dewatering and provide information on the condition of the line, as well as the extent and location of any problems. After the pipeline has been hydrostatically tested and dewatered, the contractor would run several utility pigs of various types to remove as much water as possible and any remaining small debris from within the pipeline.

- *Cleanup and Restoration.* All construction material and debris would be removed and disposed of at appropriate landfills or recycled. Clean up and restoration would be ongoing throughout the project and when an active site is completed, the area shall be restored to surface grade. In upland areas, the right-of-way would be regraded to its approximate pre-construction contour and stabilized or restored to pre-construction conditions, in compliance with all relevant permits. All staging areas and temporary extra workspaces would be recontoured to pre-construction conditions and would be stabilized or restored in accordance with all relevant permits. All asphalt repairs would be made in accordance with the current County requirements. As a final step, the route within unpaved portions of the roadway shoulder or private right-of-way would be marked with approximately five-foot-high pipeline markers placed in accordance with PHMSA standards.

- *Operations and Maintenance.* Maintenance of pipeline and auxiliary facilities would continue to be performed as required by state and federal requirements.

Intra-Field Pipelines

The field gathering and distribution system would be designed to locate pipeline corridors primarily along existing pipeline corridors on raised pipe supports to minimize external corrosion. The sequence of general construction procedures associated with the installation of intra-field pipelines would be similar to the CO_2 pipeline construction described above and would follow the process listed below:

- Mobilization and Staging;

- Surveying, Staking and Flagging;

- Clearing and Grading;
- Hauling and Stringing;
- Pipe Placement, Welding, Inspection, and Coating; and
- Pipeline Installation and Testing.

Intra-Field Electrical Distribution

The intra-field electrical distribution system would be constructed concurrently with injection well drilling, re-purposing, and CO_2 capture facility construction. Once poles are erected, the conductor would be strung from conductor pull and tension sites at the end of the power line interconnection alignment moving from one pole to the next. Each conductor would be pulled into place at a pre-calculated sag and then tension-clamped to the end of each insulator. The sheaves and vibration dampers and accessories would be removed once installation is complete.

Transmission Power Line Construction

Aera Energy would construct, operate, and maintain approximately 1.26-miles of new 115-kV transmission lines to the Aera Energy-owned substations located at the Project site. The estimated permanent disturbance of the 115 kV electrical interconnection would be two acres with four acres of temporary disturbance. To support the major construction efforts, electrical connections are anticipated to be in place prior to significant field activities. Additional improvements to off-site PG&E substations may also be necessary; however, those potential improvements have not been specified at this time.

Primary access to the power line interconnection sites would be using existing access roads. Construction of the power line interconnection would be completed by the designated contractor. The new wood poles would require approximately six to eight feet of embedment. Construction would involve temporary ground disturbance around each new power pole location (approximately a 50-foot radius) as well as temporary ground disturbance associated with access to each pole location (approximately a 15-foot-wide access route). All new poles and access thereto would be located within existing oil field production areas or along a dirt road. Pole work areas would likely be located approximately every 400 feet for 115kV lines, and 200 feet for 12kV lines. Where final design allows, power pole work areas would overlap. Final design would determine final power pole locations. Temporary staging and lay down areas may also be needed for the construction of the interconnection facilities but would primarily use existing disturbed/developed areas.

Substations. Two new substations will be constructed near the proposed CO_2 capture facilities. Each substation would require approximately 1 acre.

Power Line Removal/Construction. The 6,840 feet of new 115 kV power lines would be supported by up to approximately 17 wooden poles. The approximately 13,000 feet of new 12kV overhead distribution power lines would be supported by 65 wooden poles. The wooden poles would be embedded approximately six feet deep.

Pole installation would consist of the following basic steps:

- Deliver new pole at pole site;
- Auger new hole using line truck attachment or hand dig if the line truck cannot access the site;

- Backfill around the pole;
- Install bottom section by line truck, crane;
- Install top section by line truck, crane; and
- Install switches where necessary. There may be several SCADA-operable or other switches at the point of interconnection and elsewhere.

Once poles are erected, conductor would be strung from conductor pull and tension sites at the end of the power line interconnection alignment. The average distance is 4,000 feet between pull and tension sites. Each conductor would be pulled into place at a pre-calculated sag and then tension-clamped to the end of each insulator. The sheaves and vibration dampers and accessories would be removed once installation is complete.

Transmission Power Line construction and substation improvements are anticipated to take approximately six months.

SJVAPCD's required construction site measures for all projects were also applied:

- Water exposed areas 3 times per day; and
- Reduce vehicle speed to less than 15 miles per hour.

Table 4-3 presents the Project's short-term emissions based on the anticipated construction period.

Table 4-3. Short-Term Project Emissions

4.2.2 Long-Term Operations Emissions

Long-term emissions are caused by operational mobile, area, and energy sources. Long-term emissions would consist of the following components:

4.2.2.1 Fugitive Dust Emissions

Operation of the Project site at full build-out is not expected to present a substantial source of fugitive dust (PM_{10}) emissions. The main source of PM_{10} emissions would be from vehicular traffic associated with the Project site.

PM_{10}, on its own as well as in combination with other pollutants, creates a health hazard. The SJVAPCD's Regulation VIII establishes required controls to reduce and minimizing fugitive dust emissions. The following SJVAPCD Rules and Regulations apply to the proposed Project (and all projects):

- Rule 4102 - Nuisance
- Regulation VIII – Fugitive PM10 Prohibitions
  - Rule 8011 - General Requirements
  - Rule 8021 - Construction, Demolition, Excavation, Extraction, and Other Earthmoving Activities
  - Rule 8041 - Carryout and Trackout
  - Rule 8051 - Open Areas

The Project would comply with applicable SJVAPCD Rules and Regulations, the local zoning codes, and additional emissions reduction measures recommended later in this analysis, in Section 7, Mitigation and Other Recommended Measures.

4.2.2.2 Mobile Source Exhaust Emissions

Project-related transportation activities from employees and various other oil and gas operations would generate mobile source ROG, NOx, SOx, CO, PM_{10}, and $PM_{2.5}$ exhaust emissions. Exhaust emissions would vary substantially from day to day but would average out over the course of an operational year. The Traffic Impact Study (Stantec 2023) analyzed the potential for operational vehicular traffic from the operations and maintenance of the compression and pumping facility. The traffic study estimated 25 average daily trips (ADT) from worker vehicles.

Operational Mobile Source Assumptions:

- Baseline has 25 dedicated workers making 50 ADTs per day.
- Project includes an additional 10 workers making 25 ADTs (per traffic study).
- 50-mile trip distance.
- EMFAC2021 v1.0.2 was used to estimate mobile source emission.
  - County: Kern
  - Calendar Year: Baseline 2022, Post-Project 2026
  - Season: Annual
  - Vehicle Category: EMFAC202x (LDA, LDT1 and LDT2)
  - Model Year: Aggregate
  - Speed: Aggregate
  - Fuel: Gasoline

4.2.2.3 Stationary Source Emissions

Proposed CO_2 capture facilities include the separation, dehydration, compression, and cooling of CO_2 from both pre-combustion (Pre-C) produced gas stream and from post-combustion (Post-C) flue gas. A general discussion of each facility is presented below.

Pre-Combustion

The Pre-C carbon capture facility would treat produced gas from the Diatomite and Tulare formations. Gas produced from the Tulare Formation is not currently processed at Gas Plant 32. To capture CO_2 from this gas stream, a combination of new and existing pipelines will be used to deliver the Tulare gas stream to the Pre-C capture facility located at GP 32. Two transport route alternatives are described below.

Del Sur to GP 32 Line. Gas produced from the Tulare Formation via existing oil wells within South Belridge would be transported, via an existing 16-inch diameter 3.3-mile long pipeline operating at approximately 150 pounds per square inch gauge. It is known as the Wet Gas Del Sur pipeline to GP 32. The Tulare gas stream would need to go through the Del Sur Compressor Station to increase pressure before being transported to GP 32, which would require a "jumper" pipeline to be constructed. The new jumper pipeline would be approximately 200 feet long. One existing idle compressor at the Del Sur Compressor Station would be put back in service to accommodate the Tulare gas. The Del Sur compressors would also be upgraded with new materials/trim for corrosion resistance.

Tulare CVR to GP 32 Pipeline. Alternatively, gas produced from the Tulare Formation via existing oil wells within South Belridge will be transported via a new 12- to 16-inch diameter 3.5-mile pipeline constructed primarily aboveground from the SOX 2-3 facility east of SR 33 to the SOX 3-2 facility, then to GP 32. The proposed pipeline will be constructed aboveground on pipe supports over most of its length. The pipeline will cross SR 33 and Seventh Standard Road using horizontal boring techniques. Alternatively, the produced gas may be commingled in existing gas pipelines along the pipeline route.

GP 32. The Tulare gas stream would first be treated to remove sulfur through one of two alternative methods: 1) treatment at the existing SOX Plants 3-2 and 2-3 or 2) the gas would be treated at the existing SOX Plant within the GP 32. CO_2 would be removed from the combined produced gas stream (Tulare and Diatomite production) using a physical solvent or traditional amine absorption process or equivalent. Aera Energy has not yet selected a specific amine solution vendor. The facility will include three steel towers of varying height, but none taller than 120-feet in height and between 2 to 12 feet in diameter. Supporting this facility will be several heat exchangers, transfer pumps, compressors, and storage area for make-up chemicals. Additionally, a 1.45 mile aboveground gas pipeline between GP 32 and SGS 2868 has been included in the project to consolidate produced gas use at the SGS 2972 and SGS 2868 capture facilities.

Post-Combustion

Post-C facilities would be constructed at three existing facilities within the South Belridge Oil Field: COGEN 32, SGS 2868, and SGS 2972. Flue gas from each Post-C source would be ducted to dedicated CO_2 capture

facilities. CO_2 would be captured using an amine absorption process or equivalent process. The concentrated CO_2 would then be compressed, dehydrated, and stripped of oxygen.

Similar to Pre-C facility, each Post-C facility will include three main towers of varying height, but none taller than 140-feet in height and between 16 to 37 feet in diameter. The towers may be split into parallel trains of smaller diameter. Supporting this facility will be several heat exchangers, transfer pumps, compressors, and storage area for make-up chemicals.

The Project will have stationary source emissions from dilute amine storage tanks, fresh amine storage tanks, sulfuric acid tanks, cooling towers, steam generators, and fugitive emissions from components. The permitted fugitive emissions are from valves, threads, flanges, and other components associated with the Project and has been estimated using the California Implementation Guidelines for Estimating Mass Emissions of Fugitive Hydrocarbon Leaks at Petroleum Facilities. Tanks will have trace amounts of volatile organic compound (VOC) and will not be included in the criteria pollutant emissions summary below but will be included in the health risk assessment. Stationary source emission calculations can be found in **Appendix B**. **Table 4-6** summarizes the baseline emissions from existing facilities where the new carbon capture facilities will be located. **Table 4-7** summarizes the post-project permitted source emission increases from the existing facilities and the new carbon capture facilities.

Stationary Source Emissions Assumptions:

- Baseline Emissions used 2022 Annual Emissions Inventory for COGEN32, SGS 2868 and SGS 2972.
- Baseline Emissions used average emissions 2009-2016 Annual Emissions Inventory for GP32 in order to portray a fair representation of the baseline emissions of what the GP32 was operating at prior to being idled and what the facility will be operating at prior to the start of the current Project.
- The Del Sur Compressors will increase fuel usage by 100% with the implementation of the Project.
- A cooling tower will be added at each facility.
- Three utility steam generators will be added at each post-combustion facilities and two utility steam generators at the pre-combustion facility.
- The new carbon capture facilities with amine units will have additional fugitive emissions and were calculated using the California Implementation Guidelines for Estimating Mass Emissions of Fugitive Hydrocarbon Leaks at Petroleum Facilities based on the component counts of all valves, pump seals, others, connectors, and flanges associated with these facilities.
- Existing natural gas turbines at COGEN32 will have increased fuel usage as a result of this Project (Fuel increases can be found in **Appendix B**).
- Existing steam generators at SGS 2868 and SGS 2972 will have increased fuel usage as a result of this Project, however, these increases will be offset by decreases at other existing steam generators at Belridge. (Fuel increases can be found in **Appendix B**) Additionally, these increases will continue to be less than the current permitted levels requiring no changes to the existing permits to operate. Therefore, increased emissions for these existing steam generators were not included for permitted emissions increases; however, these emissions will be included in the health risk assessment since the location of these emissions have changed.

Table 4-6. Baseline Project (Operational) Emissions

4.2.3 Total Emissions of All Oil and Gas Activities on a Per Well Basis

A suggested mitigation of the Project is to enter into a Voluntary Emission Reduction Agreement (VERA) to reduce the Project's impacts from NO_X, ROG, and PM_{10} net incremental emissions that are not addressed as conditions of SJVAPCD permitting to a no net increase over criteria pollutants that would otherwise exist without development of the Project. The Oil and Gas Emission Reduction Agreement (OG-ERA) is a required mitigation for new well permits under the Oil and Gas Conformity Review and Minor Activities Permit. One of the menu options to achieve the mandated emission reductions is to pay a calculated mitigation fee. The Kern County Planning Department has calculated total emissions of all oil and gas activities on a per well basis and is segmented into 1000 foot well depth increments. The VERA fee would be calculated based on the calculated emission tonnage for the total wells of the Project. **Table 4-12** list the Project's wells, well depths and associated total emissions (NO_X, ROG, and PM_{10}).

Table 4-8. Total Emissions on a Per Well Basis

Description	Depth (ft)	Emissions (Tons)
Injector	8,000-9,000	6.17
Injector	8,000-9,000	6.17

4.3 Potential Impact on Sensitive Receptors

Sensitive receptors are defined as locations where young children, chronically ill individuals, the elderly or people who are more sensitive than the general population reside, such as schools, hospitals, nursing homes, and daycare centers. There are no known sensitive receptors within 2 miles of the Project site.

4.4 Potential Impacts to Visibility to Nearby Areas

Visibility impact analyses are intended for stationary sources of emissions which are subject to the Prevention of Significant Deterioration (PSD) requirements in 40 CFR Part 60; they are not usually conducted for area sources. Because the Project's PM_{10} emissions increase is predicted to be less than the PSD threshold levels, an impact at any Class 1 area or military/airspace operation within 100 kilometers of the Project (including San Rafael Wilderness, Domeland Wilderness, Edwards Air Force Base, China Lake Naval Weapons Station, and the entire R-2508 Airspace Complex) is extremely unlikely. Therefore, based on the Project's predicted less-than significant PM_{10} emissions after mitigation, the Project would be expected to have a less than significant impact to visibility at any Class 1 area or military/airspace operation.

4.5 Potential Impacts from Carbon Monoxide

Ambient CO concentrations normally correspond closely to the spatial and temporal distributions of vehicular traffic. Relatively high concentrations of CO would be expected along heavily traveled roads and near busy intersections. CO concentrations are also influenced by wind speed and atmospheric mixing. CO concentrations may be more uniformly distributed when inversion conditions are prevalent in the valley. Under certain meteorological conditions, CO concentrations along a congested roadway or intersection may reach unhealthful levels for sensitive receptors, e.g. children, the elderly, hospital patients, etc. This localized impact can result in elevated levels of CO, or "hotspots" even though concentrations at the closest air quality monitoring station may be below NAAQS and CAAQS.

The localized Project impacts depend on whether ambient CO levels in the Project vicinity would be above or below NAAQS. If ambient levels are below the standards, a project is considered to have significant impacts if a project's emissions exceed one or more of these standards. If ambient levels already exceed a state standard, a project's emissions are considered significant if they would increase one-hour CO concentrations by 10 ppm or more or eight-hour CO concentrations by 0.45 ppm or more. There are two criteria established by the SJVAPCD's GAMAQI by which CO "Hot Spot" modeling is required:

1. A traffic study for the project indicates that the Level of Service (LOS) on one or more streets or at one or more intersections in the project vicinity would be reduced to LOS E or F; or
2. A traffic study indicates that the project would substantially worsen an already existing LOS F on one or more streets or at one or more intersections in the project vicinity.

According to the traffic study (Stantec 2023) prepared for this Project existing Project roadway segments currently operate at an LOS B or better and would reach no worse than an LOS D during construction of the Project. Therefore, CO "Hotspot" Modeling was not required or conducted for this Project and no concentrated excessive CO emissions are expected to be caused once the proposed Project is completed.

4.6 Predicted Health Risk Impacts

GAMAQI recommends that Lead Agencies consider situations wherein a new or modified source of Hazardous Air Pollutants (HAPs) is proposed for a location near an existing residential area or other sensitive receptor when evaluating potential impacts related to Hazardous Air Pollutants (HAPs).

The proposed Project would result in emissions of HAPs of diesel particulate matter (DPM) from construction equipment exhaust and operational emissions from combustion emissions from steam generators, tanks emissions and particulate emissions from the cooling towers and would be located near existing residents and workers; therefore, an assessment of the potential risk to the population attributable to emissions of hazardous air pollutants from the proposed Project is required.

To predict the potential health risk to the population attributable to emissions of HAPs from the proposed Project, ambient air concentrations were predicted with dispersion modeling to arrive at a conservative estimate of increased individual carcinogenic risk that might occur as a result of continuous exposure over a 3-year construction timeline for the facilities and a 67-year lifetime for operational exposure. Similarly, predicted concentrations were used to calculate non-cancer chronic and acute hazard indices (HIs), which are the ratio of expected exposure to acceptable exposure. The basis for evaluating potential health risk is the identification of sources with increased HAPs.

Health risk is determined using the Hotspots Analysis and Reporting Program (HARP2) software distributed by the CARB; HARP2 requires peak 1-hour emission rates and annual-averaged emission rates for all pollutants for each modeling source (CARB 2015). Assumptions used to calculate the emission rates for the proposed Project are outlined below.

The most recent version of EPA's AMS/EPA Regulatory Model - AERMOD was used to predict the dispersion of emissions from the proposed Project. The analysis employed all of the regulatory default AERMOD model keyword parameters, including elevated terrain options.

For construction health impacts, diesel particulate matter emissions from diesel on-site construction equipment and HHD trucks from hauling and vendor trips were modeled as area sources for on-site construction activity on the property. Diesel particulate matter was calculated using CalEEMod for on-site

construction equipment. A unit emission rate of 1 grams/second (g/sec) was input to AERMOD for the area source.

For operational health impacts, combustion emissions from steam generators, tanks emissions and particulate emissions from the cooling towers were modeled as point sources. Cooling tower HAP emissions were calculated using AP-42 emission factors. Steam generator combustion HAP emissions were calculated using the SJVAPCD's Toxic Profile #237. Tank emissions were calculated using AP-42 and the Tanks ESP Program. Fugitive leaks were modeled as an area source and calculated using site specific gas composition and emission factors from CAPCOA. A unit emission rate of 1 grams/second (g/sec) was input to AERMOD for the volume sources.

Discrete receptors were placed on houses within close proximity of the Project site. Additionally, a tier of discrete receptors was placed 110 meters from the project boundary to represent all workers in every direction of the project site. This will generate a worst-case scenario for the off-site oil-field and ag workers located within a close proximity to the Project. A total of 598 discrete off-site receptors were analyzed. Elevated terrain options were employed for the Project area.

SJVAPCD-provided, AERMET UStar processed meteorological datasets for the Missouri Triangle monitoring station, calendar years 2004 through 2018 was input to AERMOD (SJVAPCD 2018). This was the most recent available dataset available at the time the modeling was conducted. Rural dispersion parameters were used because the operation and the majority of the land surrounding the facility is considered "rural" under the Auer land use classification method (Auer 1978).

Plot files generated by AERMOD were uploaded to the Air Dispersion Modeling and Risk Assessment Tool (ADMRT) program in the Hotspots Analysis and Reporting Program Version 2 (HARP 2) (CARB 2015). ADMRT post-processing was used to assess the potential for excess cancer risk and chronic and acute non-cancer effects using the most recent health effects data from the California EPA Office of Environmental Health Hazard Assessment (OEHHA). HARP2 site parameters were set for the mandatory minimum pathways of inhalation, soil ingestion, dermal, and mother's milk. In addition to the aforementioned pathways, the home-grown garden pathway was included as well. Risk reports were generated using the derived OEHHA analysis method for carcinogenic risk and non-carcinogenic chronic and acute risk. Site parameters are included in the HARP2 output files. Total cancer risk was predicted for each receptor. A hazard index was computed for chronic non-cancer health effects for each applicable endpoint and each receptor. A hazard index for acute non-cancer health effects was computed for each applicable endpoint and each receptor.

SJVAPCD has set the level of significance for carcinogenic risk at twenty in one million, which is understood as the possibility of causing twenty additional cancer cases in a population of one million people. The level of significance for chronic and acute non-cancer risk is a hazard index of 1.0. All receptors were modeled as residential receptors with a 70-year exposure. This is conservative since all on-site receptors, worker receptors and business receptors would be exposed less than 70 years.

The carcinogenic risk and the health hazard index (HI) for chronic non-cancer risk at the point of maximum impact (PMI) do not exceed the significance levels of twenty in one million (20×10^{-6}) and 1.0, respectively for the proposed Project. The PMIs are identified by receptor location and risk and are provided in **Table 4-9**. The electronic AERMOD and HARP2 output files are provided in **Attachment E**.

Table 4-9. Potential Maximum Impacts Predicted by HARP

	Value	UTM East	UTM North
Excess Cancer Risk	6.65E-06	251003.06	3926087.12
Chronic Hazard Index	1.55E-02	251950.08	3925329.29
Acute Hazard Index	4.74E-02	251003.06	3926087.12

As shown above in **Table 4-9**, the maximum predicted cancer risk for the proposed Project is 6.65E-06. The maximum chronic non-cancer hazard index for the proposed Project is 1.55E-02. The maximum acute non-cancer hazard index for the proposed Project is 4.74E-02. Since the PMI remained below the significance threshold for cancer, chronic, and acute risk, this Project would not have an adverse effect to any of the surrounding communities.

The potential health risk attributable to the proposed Project is determined to be *less than significant* based on the following conclusions:

1. Potential carcinogenic risk from the proposed Project is below the significance level of twenty in a million at each of the modeled receptors; and
2. The hazard index for the potential chronic non-cancer risk from the proposed Project is below the significance level of 1.0 at each of the modeled receptors.
3. The hazard index for the potential acute non-cancer risk from the proposed Project is below the significance level of 1.0 at each of the modeled receptors.

Therefore, the potential risk to the population attributable to emissions of HAPs from the proposed Project would be less than significant.

4.7 Potential Impacts from Valley Fever

The proposed Project has the potential to generate fugitive dust and suspend Valley Fever spores with the dust that could then reach nearby sensitive receptors. It is possible that onsite workers could be exposed to Valley Fever spores as fugitive dust is generated during construction. In order to mitigate potential risk, the proposed Project would provide training and personal protective respiratory equipment to construction workers and provide information to all construction personnel and visitors about Valley Fever. Therefore, the exposure to Valley Fever would be minimized. With the implementation of the mitigation measures, dust from the construction of the proposed project would not add significantly to the existing exposure level of people to this fungus, including construction workers, and impacts would be reduced to less-than-significant levels.

4.8 Potential Impacts from Asbestos

Naturally occurring asbestos can be released from serpentinite and ultramafic rocks when the rock is broken or crushed. At the point of release, the asbestos fibers may become airborne, causing air quality and human health hazards. These rocks have been commonly used for unpaved gravel roads, landscaping, fill projects, and other improvement projects in some localities. Asbestos may be released to the atmosphere due to vehicular traffic on unpaved roads, during grading of development projects, and at mining operations.

Serpentinite and/or ultramafic rock are known to be present in 44 of California's 58 counties. These rocks are particularly abundant in the counties associated with the Sierra Nevada foothills, the Klamath Mountains, and Coast Ranges. However, according to information provided by the Department of Conservation Division of Mines and Geology, the project site is not located in an area where naturally occurring asbestos is likely to be present (CDCDMG, 2000). Therefore, impacts associated with exposure of construction workers and nearby sensitive receptors to asbestos would be less than significant.

4.9 Odor Impacts and Mitigation

The SJVAPCD's GAMAQI states "An analysis of potential odor impacts should be conducted for both of the following two situations:

1. Generators – projects that would potentially generate odorous emissions proposed to locate near existing sensitive receptors or other land uses where people may congregate, and
2. Receivers – residential or other sensitive receptor projects or other projects built for the intent of attracting people locating near existing odor sources." (SJVAPCD 2015).

The GAMAQI also states, "The District has identified some common types of facilities that have been known to produce odors in the San Joaquin Valley Air Basin. These are presented in Table 6 (Screening Levels for Potential Odor Sources), along with a reasonable distance from the source within which, the degree of odors could possibly be significant. [Table 6] can be used as a screening tool to qualitatively assess a project's potential to adversely affect area receptors." (SJVAPCD, 2015). Because the Project is an existing oil and gas operation and there are no receptors located within a 1-mile radius of the Project, the Project is not expected to be a new source of objectionable odors.

Based on the provisions of the SJVAPCD's GAMAQI, the proposed Project would not exceed any screening trigger levels to be considered a source of objectionable odors or odorous compounds (SJVAPCD, 2015). Furthermore, the Project site is a permitted stationary source which is required to abide by the nuisance rules and regulations of the SJVAPCD. Additionally, the Project emissions estimates indicate that it would not be expected to adversely impact surrounding receptors. As such, the proposed Project would not be a source of any odorous compounds nor would it likely be impacted by any odorous source.

4.10 Impacts to Ambient Air Quality

As stated in the GAMAQI (2015, p 96-97), SJVAPCD has developed screening levels for requiring an Ambient Air Quality Analysis (AAQA). The SJVAPCD recommends that an AAQA be performed for all criteria pollutants when emissions of any criteria pollutant resulting from project construction or operational activities exceed the 100 pounds per day screening level, after compliance with Rule 9510 requirements and implementation of all enforceable mitigation measures.

The Project will be entering into a VERA which will reduce average daily emissions for construction and operational activities associated with this Project to a no net increase level. Therefore, an AAQA is not required for this Project.

4.11 Impacts to Greenhouse Gases and Climate Change

The proposed Project will have GHG emissions from construction and operation. These GHG emissions include emissions from area, energy, mobile, water, and waste sources. New regulations and new technologies in the future, and phase out of old equipment over time, will lead to a reduction of GHG emissions, but the reduction is not currently quantifiable. Additionally, the Project, as proposed, has the capacity to capture and sequester up to roughly 1.6 million metric tons of CO_2 per year, with a total sequestration capacity up to 40 million metric tons of CO_2. The installed capture facilities will have a capture efficiency of 95% at the pre-combustion facility and 90% at the post-combustion facilities. The Project will achieve net negative GHG emissions impact.

Table 4-10. Estimated GHG Emissions for First Source – Belridge Facilities (MT/Year)

Year	Pre-Combustion Emissions (De Sur and GP32)	Post-Combustion Emissions (COGEN32, SGS2972 & SGS2868)	Total Plants Emissions	Capture Facilities Mobile & Indirect Electricity Emissions	Captured and Injected Emissions
Baseline	249,050	870,126	1,119,176	-	-
Capture Year 1 (2027)	276,945	1,128,497	1,405,442	17,609	700,000
Capture Years 2-19 (2028-2045) per year	312,749	1,460,688	1,773,437	40,249	1,600,000
Total Years 1-19 (2027-2045)	**5,906,418**	**27,420,889**	**33,327,307**	**742,091**	**29,500,000**

In addition to Aera Energy-sourced CO2, the Project will have the capacity to import CO_2 from outside sources. With the addition of imported CO_2, Aera Energy may sequester up to 3.3 million metric tons per year. Although no outside sources of CO_2 have been identified at this time, it is reasonable to assume that Aera Energy would begin importing CO_2 in year 5 of project operation.

The Project will not result in emissions of hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), sulfur hexafluoride (SF_6), or the other gases identified as GHG in AB32. The proposed Project may be subject to future regulations developed by CARB to address GHG emissions.

4.11.1 Feasible and Reasonable Mitigation Relative to Global Warming

CEQA requires that all feasible and reasonable mitigation be applied to the project to reduce the impacts from construction and operations on air quality. The SJVAPCD's "Non-Residential On-Site Mitigation Checklist" was utilized in preparing the mitigation measures and evaluating the project's features. These measures include using controls that limit the exhaust from construction equipment and using alternatives to diesel when possible. Additional reductions would be achieved through the regulatory process of the air district and CARB as required changes to diesel engines are implemented which would affect the product delivery trucks and limits on idling.

Since the Project reduces GHG emissions it is possible to determine whether the Project individually would have a significant impact on global warming or climate change, the Project would contribute to reductions in cumulative GHG emissions in California as well as related health effects. Therefore, it is possible to assess, with certainty, whether the Project's contribution would be cumulatively considerable, within the meaning of CEQA Guidelines Sections 15065(a)(3) and 15130.

The strategies currently being implemented by CARB may help in reducing the Project's GHG emissions and are summarized in the table below.

Table 4-11. Select CARB GHG Emission Reduction Strategies

Strategy	Description of Strategy
Vehicle Climate Change Standards	AB 1493 (Pavley) required the state to develop and adopt regulations that achieve the maximum feasible and cost-effective reduction of climate change emissions emitted by passenger vehicles and light duty trucks. Regulations were adopted by CARB in Sept. 2004.
Diesel Anti-Idling	In July 2004, CARB adopted a measure to limit diesel-fueled retail motor vehicle idling.
Other Light-Duty Vehicle Technology	New standards would be adopted to phase in beginning in the 2017 model year.
Alternative Fuels: Biodiesel Blends	CARB would develop regulations to require the use of 1% to 4% Biodiesel displacement of California diesel fuel.
Alternative Fuels: Ethanol	Increased use of ethanol fuel.
Heavy-Duty Vehicle Emission Reduction Measures	Increased efficiency in the design of heavy-duty vehicles and an educational program for the heavy-duty vehicle sector.

Not all of these measures are currently appropriate or applicable to the proposed Project. While future legislation could further reduce the Project's GHG footprint, the analysis of this is speculative and in accordance with CEQA Guidelines Section 15145, will not be further evaluated in this AQIA.

CEQA Guidelines Section 15130 notes that sometimes the only feasible mitigation for cumulative impacts may involve the adoption of ordinances or regulations rather than the imposition of conditions on a project-by-project basis. Global climate change is this type of issue. The causes and effects may not be just regional or statewide, they may also be worldwide. Given the uncertainties in identifying, let alone quantifying the impact of any single project on global warming and climate change, and the efforts made to reduce emissions of GHGs from the Project through design, in accordance with CEQA Section 15130, any further feasible emissions reductions would be accomplished through CARB regulations adopted pursuant to AB32. Given that the Project has a net negative impact on GHG emissions it can be assumed the Project will comply with any local and statewide air quality and climate plans.

5. CUMULATIVE IMPACTS

By its very nature, air pollution has a cumulative impact. The District's nonattainment status is a result of past and present development within the SJVAB. Furthermore, attainment of ambient air quality standards can be jeopardized by increasing emissions-generating activities in the region. No single project would be sufficient in size, by itself, to result in nonattainment of the regional air quality standards. Instead, a project's emissions may be individually limited, but cumulatively considerable when taken in combination with past, present, and future development within the San Joaquin Valley Air Basin. When assessing whether there is a new significant cumulative effect, the Lead Agency shall consider whether the incremental effects of the project are cumulatively considerable. "Cumulatively considerable" means that the incremental effects of an individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects [CCR §15064(h)(1)]. Per CEQA Guidelines §15064(h)(3) a Lead Agency may determine that a project's incremental contribution to a cumulative effect is not cumulatively considerable if the project will comply with the requirements in a previously approved plan or mitigation program, including, but not limited to an air quality attainment or maintenance plan that provides specific requirements that will avoid or substantially lessen the cumulative problem within the geographic area in which the project is located. (SJVAPCD 2015)

Attachment A of Kern County's *Guidelines for Preparing an Air Quality Assessment for Use in Environmental Impact Reports* states "The following threshold[s] are defined for purposes of determining cumulative effects as the baseline for "considerable". Projects in the San Joaquin Valley Air Pollution Control District…will be subject to the following significance thresholds". The thresholds outlined in the guidelines mirror the individual project significance thresholds of 15 tons per year for PM_{10} and 10 tons per year for NO_X and ROG. Therefore, owing to the inherently cumulative nature of air quality impacts, the threshold for whether a project would make a cumulatively considerable contribution to a significant cumulative impact is simply whether the project would exceed project-level thresholds. This AQIA, however, also considered the impacts of the proposed Project in conjunction with the impacts of other projects previously proposed in the area. The following cumulative impacts were considered:

- Cumulative O_3 Impacts (ROG and NOx) from numerous sources within the region including transport from outside the region. O_3 is formed through chemical reactions of ROG and NOx in the presence of sunlight.
- Cumulative CO Impacts produced primarily by vehicular emissions.
- Cumulative PM_{10} Impacts from within the region and locally from the various projects. Such projects may cumulatively produce a significant amount of PM10 if several projects conduct grading or earthmoving activities at the same time; and
- Hazardous Air Pollutant (HAP) Impacts on sensitive receptors.

5.1 Cumulative Regional Air Quality Impacts

The most recent, certified SJVAB Emission Inventory data available from the SJVAPCD is based on data gathered for the 2020 annual inventory[2]. This data will be used to assist the SJVAPCD in demonstrating attainment of Federal 1-hour O_3 Standards (SJVAPCD 2007). **Table 5-1** provides a comparative look at the impacts proposed by the proposed Project to the SJVAB Emissions Inventory.

[2] SJVAPCD Emissions for Aggregated Stationary, Area-Wide, Mobile, and Natural Sources

Table 5-1. Comparative Analysis Based on SJV Air Basin 2020 Inventory - Tons per Year

	ROG	NOx	CO	SOx	PM_{10}	$PM_{2.5}$
Kern County - 2020	21,535	15,878	27,339	511	13,651	3,723

Proposed Project's % of SJVAB	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

Note: This is the latest inventory available as of May 2023
*Does not include permitted emissions that will be offset during permitting process or well emissions that will be mitigated through a VERA.
Source: CARB 2022b

As shown in **Table 5-1** the proposed Project does not pose a substantial increase to basin emissions, as such basin emissions would be essentially the same if the Project is approved.

Table 5-1, **5-2**, and **5-3** provide CARB Emissions Inventory projections for the year 2025 for both the SJVAB and the Kern County portion of the air basin. Looking at the SJVAB Emissions predicted by the CARB year 2025 emissions inventory, the Kern County portion of the air basin is a moderate source of the emissions. The proposed Project produces a small portion of the total emissions in both Kern County and the entire SJVAB.

Table 5-2. Emission Inventory SJVAB 2025 Projection - Tons per Year

Kern County Percent of SJVAB	23.19%	41.27%	20.47%
Source: CARB 2022b			

As shown above, the proposed Project would pose an inconsequential impact on regional O_3 and PM_{10} formation. The regional contribution to these cumulative impacts would be negligible and additionally, the Project would not exceed cumulatively considerable thresholds since the Project would be less than thresholds outlined in Kern County's *Guidelines for Preparing an Air Quality Assessment for Use in Environmental Impact Reports*. Therefore, this Project would not be considered cumulatively considerable in its contribution to regional O_3 and PM_{10} impacts.

5.2 Cumulative Local Air Quality Impacts

No tentative development projects within a one-mile radius of the proposed Project area were identified. The cumulative projects are typically listed only as geographical reference to demonstrate the construction activity within a one-mile radius of the proposed Project. The number and sizes of these projects are of no particular significance since the cumulative considerable thresholds established by Kern County are based on Project specific thresholds which are inherently cumulative in nature.

As no cumulative projects were identified within a one-mile radius, emissions estimates were not calculated. Additionally, any projects either currently under construction or, at a minimum, approved by the planning department for consistency with applicable regulation, for the purposes of this analysis, it is assumed that they are in conformance with the regional AQAP.

5.3 Cumulative Hazardous Air Pollutants

The GAMAQI also states that when evaluating potential impacts related to HAPs, "*impacts of local pollutants (CO, HAPs) are cumulatively significant when modeling shows that the combined emissions from the project and other existing and planned projects will exceed air quality standards*." Because the Project would not be a significant source of HAPs, the proposed Project would also *not be expected to pose a significant cumulative CO or HAPs impact*.

5.4 Cumulative Carbon Monoxide (CO) – Mobile Sources

The SJVAPCD's GAMAQI has identified CO impacts from impacted traffic intersections and roadway segments as being potentially cumulatively considerable. Traffic increases and added congestion caused by a project can combine to cause a violation of the SJVAPCD's CO standard also known as a "Hotspot". There are two criteria established by the GAMAQI by which CO "Hot Spot" modeling is required:

- A traffic study for the project indicates that the Level of Service (LOS) on one or more streets or at one or more intersections in the project vicinity will be reduced to LOS E or F; or
- A traffic study indicates that the project will substantially worsen an already existing LOS F on one or more streets or at one or more intersections in the project vicinity.

According to the traffic study (Stantec 2023) that was prepared for this Project, all roadway segments continue to operate at LOS less than or equal to B. Therefore, due to the location and traffic increase anticipated from this Project, impacted intersections and roadway segments are anticipated to operate at a LOS of C or better. Therefore, CO "Hotspot" Modeling was not conducted for this Project and no concentrated excessive CO emissions are expected to be caused once the proposed Project is completed.

6. CONSISTENCY WITH THE AIR QUALITY ATTAINMENT PLAN

Air quality impacts from proposed projects within Kern County are controlled through policies and provisions of the SJVAPCD and the Kern County General Plan (KCPD 2009). In order to demonstrate that a proposed project would not cause further air quality degradation in either the SJVAPCD's plan to improve air quality within the air basin or the federal requirements to meet certain air quality compliance goals, each project should also demonstrate consistency with the SJVAPCD's adopted Air Quality Attainment Plans (AQAP) for O_3 and PM_{10}. The SJVAPCD is required to submit a "Rate of Progress" document to CARB that demonstrates past and planned progress toward reaching attainment for all criteria pollutants. The California Clean Air Act (CCAA) requires air pollution control districts with severe or extreme air quality problems to provide for a 5% reduction in non-attainment emissions per year. The AQAP prepared for the San Joaquin Valley by the SJVAPCD complies with this requirement. CARB reviews, approves or amends the document and forwards the plan to the EPA for final review and approval within the SIP.

Air pollution sources associated with stationary sources are regulated through the permitting authority of the SJVAPCD under the New and Modified Stationary Source Review Rule (SJVAPCD Rule 2201). Owners of any new or modified equipment that emits, reduces or controls air contaminants, except those specifically exempted by the SJVAPCD, are required to apply for an Authority to Construct and Permit to Operate (SJVAPCD Rule 2010). Additionally, best available control technology (BACT) is required on specific types of stationary equipment and are required to offset both stationary source emission increases along with increases in cargo carrier emissions if the specified threshold levels are exceeded (SJVAPCD Rule 2201, 4.7.1). Through this mechanism, the SJVAPCD would ensure that all stationary sources within the project area would be subject to the standards of the SJVAPCD to ensure that new developments do not result in net increases in stationary sources of criteria air pollutants.

6.1 Required Evaluation Guidelines

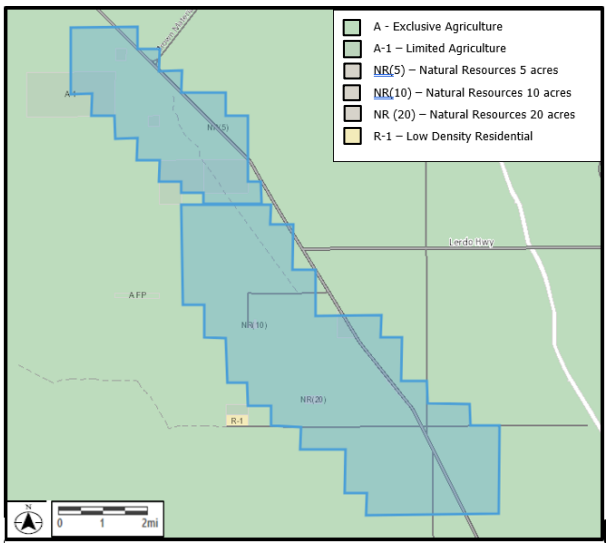
State CEQA Guidelines and the Federal Clean Air Act (Sections 176 and 316) contain specific references on the need to evaluate consistencies between the proposed project and the applicable AQAP for the project site. To accomplish this, CARB has developed a three-step approach to determine project conformity with the applicable AQAP:

1. *Determination that an AQAP is being implemented in the area where the project is being proposed*. The SJVAPCD has implemented the current, modified AQAP as approved by CARB.
2. *The proposed project must be consistent with the growth assumptions of the applicable AQAP*. The proposed Project land use type was not anticipated in the current growth assumptions. Therefore, growth assumptions in the Kern County General Plans will be modified with the approval of the proposed Project.
3. *The project must contain in its design all reasonably available and feasible air quality control measures*. The proposed Project incorporates various policy and rule-required implementation measures that will reduce related emissions.

The CCAA and AQAP identify transportation control measures as methods to further reduce emissions from mobile sources. Strategies identified to reduce vehicular emissions such as reductions in vehicle trips, vehicle use, vehicle miles traveled, vehicle idling, and traffic congestion, in order to reduce vehicular emissions, can be implemented as control measures under the CCAA as well. Additional measures may also be implemented through the building process such as providing electrical outlets on exterior walls of structures to encourage use of electrical landscape maintenance equipment or measures such as electrical outlets for electrical systems on diesel trucks to reduce or eliminate idling time.

As the growth represented by the proposed Project will be updated in the Kern County General Plan and incorporated into the AQAP, conclusions may be drawn from the following criteria:

1. That, by definition, the proposed emissions from the Project are below the SJVAPCD's established emissions impact thresholds;
2. That the primary source of emissions from the Project will be motor vehicles that are licensed through the State of California and whose emissions are already incorporated into CARB's San Joaquin Valley Emissions Inventory.



Based on these factors, the Project appears to be *consistent with the AQAP*.

6.2 Consistency with the Kern County Council of Government's Regional Conformity Analysis

The Kern Council of Governments (Kern COG) Regional Conformity Analysis (Kern COG 2018) Determination demonstrates that the regional transportation expenditure plans (Destination 2042 Regional Transportation Plan and Federal Transportation Improvement Program) in the Kern County portion of the San Joaquin Valley air quality attainment areas would not hinder the efforts set out in CARB's SIP for each area's non-attainment pollutants (CO, O_3, and PM_{10}). The analysis uses an adopted regional growth forecast, governed by both the adopted Kern COG Policy and Procedure Manual and a Memorandum of Understanding between the County of Kern and Kern COG (representing itself and outlying municipal member agencies).

The Kern COG Regional Conformity Analysis considers General Plan Amendments (GPA) and zone changes that were enacted at the time of the analysis as projected growth within the area based on land use designations incorporated within the Kern County General Plan. Land use designations that are altered based on subsequent GPAs that were not included in the Regional Conformity Analysis were not incorporated into the Kern COG analysis. Consequently, if a proposed project is not included in the regional growth forecast using the latest planning assumptions, it may not be said to conform to the regional growth forecast. Under the current Kern County Zoning, the Project site is designated as "A: Exclusive Agriculture, A-1: Limited Agriculture and NR(20): Natural Resources (20 acres)" (see **Figure 6-1**).

Figure 6-1. Kern County Zoning

Item 2 under Section 3 – Model Maintenance Procedure, of the Kern COG Regional Transportation Modeling Policy and Procedure Manual states "*Land Use Data – General Plan land capacity data or "Build -out capacity" is used to distribute the forecasted County totals, and may be updated as new information becomes available, and is revised in regular consultation with local planning departments.*"

Under current policies, only after a General Plan Amendment (GPA) is approved, can housing and employment assumptions be updated to reflect the capacity changes. Since the proposed development does not require a GPA but does require a zone change, the existing growth forecast could be modified to reflect these changes. In order to determine whether the forecasted growth for the Project area is sufficient to account for the projected increases in employment, an analysis based on Kern COG regional forecast was conducted.

The adopted growth forecast for the project site is distributed to Traffic Analysis Zones (TAZ). In order to evaluate the impacts to the proposed Project area, a one-mile radius analysis was conducted that included TAZ 2066, 2069, and 2070. In order to be considered "consistent" and, therefore, in conformance with the AQAP, population, housing and employment increases would need to occur over the same time as the adopted growth forecast. As the proposed Project is occurring at an existing oil and gas operation and add only a small amount of additional operational workers; it is assumed that the employment increase associated with the proposed Project is within the adopted growth forecast.

7. MITIGATION AND OTHER RECOMMENDED MEASURES

To ensure that Project is in compliance with all applicable SJVAPCD rules and regulations and emissions are further reduced, the applicant should implement and comply with a number of measures that are either recommended as a "good operating practice" for environmental stewardship or they are required by regulation. Some of the listed measures are regulatory requirements or construction requirements that would result in further emission reductions through their inclusion in Project construction and long-term design. The following measures either have been applied to the Project through the CalEEMod model and would be incorporated into the Project by design or would be implemented in conjunction with SJVAPCD rules as conditions of approval.

7.1 SJVAPCD Required PM_{10} Reduction Measures

As the Project would be completed in compliance with SJVAPCD Regulation VIII, dust control measures would be taken to ensure compliance specifically during grading and construction phases. The required Regulation VIII measures are as follows:

- Water previously exposed surfaces (soil) whenever visible dust is capable of drifting from the site or approaches 20% opacity.
- Water all unpaved haul roads a minimum of three-times/day or whenever visible dust from such roads is capable of drifting from the site or approaches 20% opacity.
- Reduce speed on unpaved roads to less than 15 miles per hour.
- Install and maintain a track out control device that meets the specifications of SJVAPCD Rule 8041 if the site exceeds 150 vehicle trips per day or more than 20 vehicle trips per day by vehicles with three or more axles.
- Stabilize all disturbed areas, including storage piles, which are not being actively utilized for production purposes using water, chemical stabilizers or by covering with a tarp or other suitable cover.
- Control fugitive dust emissions during land clearing, grubbing, scraping, excavation, leveling, grading, or cut and fill operations with application of water or by presoaking.
- When transporting materials offsite, maintain a freeboard limit of at least 6 inches and cover or effectively wet to limit visible dust emissions.
- Limit and remove the accumulation of mud and/or dirt from adjacent public roadways at the end of each workday. (Use of dry rotary brushes is prohibited except when preceded or accompanied by sufficient wetting to limit visible dust emissions and use of blowers is expressly forbidden).
- Stabilize the surface of storage piles following the addition or removal of materials using water or chemical stabilizer/suppressants.
- Remove visible track-out from the site at the end of each workday.
- Cease grading or other activities that cause excessive (greater than 20% opacity) dust formation during periods of high winds (greater than 20 mph over a one-hour period).

7.2 Recommended Measures to Reduce Equipment Exhaust

In addition, the GAMAQI guidance document lists the following measures as approved and recommended for construction activities. These measures are recommended:

- Maintain all construction equipment as recommended by manufacturer manuals.
- Shut down equipment when not in use for extended periods.
- Use electric equipment for construction whenever possible in lieu of diesel or gasoline powered equipment.

- Curtail use of high-emitting construction equipment during periods of high or excessive ambient pollutant concentrations.
- All construction vehicles shall be equipped with proper emissions control equipment and kept in good and proper running order to substantially reduce NOx emissions.
- On-Road and Off-Road diesel equipment shall use diesel particulate filters if permitted under manufacturer's guidelines.
- On-Road and Off-Road diesel equipment shall use cooled exhaust gas recirculation (EGR) if permitted under manufacturer's guidelines.
- All construction workers shall be encouraged to shuttle (car-pool) to retail establishments or to remain on-site during lunch breaks.
- All construction activities within the project area shall be discontinued during the first stage smog alerts.
- Construction and grading activities shall not be allowed during first stage O_3 alerts. First stage O_3 alerts are declared when the O_3 level exceeds 0.20 ppm (1-hour average).

7.3 Other Measures to Reduce Project Impacts

The following measures are recommended to further reduce the potential for long-term emissions from the Project. These measures are required as a matter of regulatory compliance:

- The Project design shall comply with applicable standards set forth in Title 24 of the Uniform Building Code to minimize total consumption of energy.
- Applicants shall be required to comply with applicable mitigation measures in the AQAP, SJVAPCD Rules, Traffic Control Measures, Regulation VIII and Indirect Source Rules for the SJVAPCD.
- The developer shall comply with the provisions of SJVAPCD Rule 4601 - Architectural Coatings, during the construction of all buildings and facilities. Application of architectural coatings shall be completed in a manner that poses the least emissions impacts whenever such application is deemed proficient.
- The applicant shall comply with the provisions of SJVAPCD Rule 4641 during the construction and pavement of all roads and parking areas within the project area. Specifically, the applicant shall not allow the use of:
  - Rapid cure cutback asphalt;
  - Medium cure cutback asphalt;
  - Slow cure cutback asphalt (as specified in SJVAPCD Rule 4641, Section 5.1.3); or Emulsified asphalt (as specified in SJVAPCD Rule 4641, Section 5.1.4).
  - The developer shall comply with applicable provisions of SJVAPCD Rule 9510 (Indirect Source Review).

Fourth High:	Jun 18	0.082	Sep 5	0.083	Jun 18	0.077
National 2015 Std (0.070 ppm):						
# Days Above the Standard:		24		25		11
Nat'l Standard Design Value:		0.087		0.085		0.080
National Year Coverage:		99		99		100
California Std (0.070 ppm):						
# Days Above the Standard:		28		25		11
California Designation Value:		0.096		0.094		0.088
Expected Peak Day Concentration:		0.096		0.095		0.090
California Year Coverage:		97		97		99

Notes:

Eight-hour ozone averages and related statistics are available at Bakersfield-5558 California Avenue between 1994 and 2021. Some years in this range may not be represented.

All averages expressed in parts per million.

An exceedance of a standard is not necessarily related to a violation of the standard.

State and national statistics may differ for the following reasons:

National 8-hour averages are truncated to three decimal places; State 8-hour averages are rounded to three decimal places.

State criteria for ensuring that data are sufficiently complete for calculating 8-hour averages are more stringent than the national criteria.

Daily maximum 8-hour averages associated with the National 0.070 ppm standard exclude those 8-hour averages that have first hours between midnight and 6:00 am, Pacific Standard Time.

Daily maximum 8-hour averages associated with the National 0.070 ppm standard include only those 8-hour averages from days that have sufficient data for the day to be considered valid.

Year Coverage indicates the extent to which available monitoring data represent the time of the year when concentrations are expected to be highest. 0 means that data represent none of the high period; 100 means that data represent the entire high period. A high Year Coverage does not mean that there was sufficient data for annual statistics to be considered valid.

* means there was insufficient data available to determine the value.

Annual Average:		39.0		*		*
3-Year Maximum Annual Average:		43		39		*
Year Coverage:		94		89		0

Notes:

Daily PM10 averages and related statistics are available at Bakersfield-5558 California Avenue between 1994 and 2021. Some years in this range may not be represented.

All averages expressed in micrograms per cubic meter.

The national annual average PM10 standard was revoked in December 2006 and is no longer in effect. Statistics related to the revoked standard are shown in *italics* or *italics* .

An exceedance of a standard is not necessarily related to a violation of the standard.

All values listed above represent midnight-to-midnight 24-hour averages and may be related to an exceptional event.

State and national statistics may differ for the following reasons:

- State statistics are based on California approved samplers, whereas national statistics are based on samplers using federal reference or equivalent methods. State and national statistics may therefore be based on different samplers.
- State statistics for 1998 and later are based on local conditions (except for sites in the South Coast Air Basin, where State statistics for 2002 and later are based on local conditions). National statistics are based on standard conditions.
- State criteria for ensuring that data are sufficiently complete for calculating valid annual averages are more stringent than the national criteria.

Measurements are usually collected every six days. Measured days counts the days that a measurement was greater than the level of the standard; Estimated days mathematically estimates how many days concentrations would have been greater than the level of the standard had each day been monitored.

3-Year statistics represent the listed year and the 2 years before the listed year.

Year Coverage indicates the extent to which available monitoring data represent the time of the year when concentrations are expected to be highest. 0 means that data represent none of the high period; 100 means that data represent the entire high period. A high Year Coverage does not mean that there was sufficient data for annual statistics to be considered valid.

* means there was insufficient data available to determine the value.

Notes:

Daily PM2.5 averages and related statistics are available at Bakersfield-Golden State Highway between 1999 and 2021. Some years in this range may not be represented.

All averages expressed in micrograms per cubic meter.

An exceedance of a standard is not necessarily related to a violation of the standard.

State statistics are based on California approved samplers, whereas national statistics are based on samplers using federal reference or equivalent methods. State and national statistics may therefore be based on different samplers.

Year Coverage indicates the extent to which available monitoring data represent the time of the year when concentrations are expected to be highest. 0 means that data represent none of the high period; 100 means that data represent the entire high period. A high Year Coverage does not mean that there was sufficient data for annual statistics to be considered valid.

* means there was insufficient data available to determine the value.

Aera Energy
Bakersfield, CA

Assumptions

- SDS provides little information about the cycloamine's so they are approximated using the following assumptions:
  - Molecular weight is directly proportional to relative vapor density
  - Vapor pressure of pure water is 0.2 psi. The dilute amine solution has a lower vapor pressure than water. Hence the cycloamine is less volatile than water and the concentrated amine solution is conservatively assumed to have the same vapor pressure as the dilute solution.
  - Chemical data from SDS provided by Anthony Gurrola on 4/24/23
- Raw water and cooling water meet the definition of clean produced water, so no emissions are calculated from those tanks
- Pressure vessels do not breath and hence the only emissions from those systems are fugitive and accounted for in fugitive sections

Chemical Information

Chemical Name	Molecular Weight[1]	Liquid Density[2] (lb/gal)	Vapor Pressure (psi)	Percent Composition by Weight	
Dow Monoethanolamine	61.08	8.51	0.00725189	99.8% Monoethanolamine, 0.2% Diethanolamine	-4.926493154
Piperazine	86	8.65	0.06767871	69% Piperazine, 33% Water, 0.3% Ethylenediamine	-2.692983624

[1]Molecular weight of amine compounds is calculated using relative vapour density data. $MW_{compound}$ = Relative Density * MW_{air} = 4.5 * 9

[2]Liquid Density = Specific $Gravity_{compound}$ * $Density_{water}$

Tank Specifications

Tank Name	Annual Throughput[3] (gal/yr)	Max Hourly Throughput (gal/hr)	Diameter (ft)	Height (ft)	Construction Material	Nominal Operating Pressure (psig)	Min Vent Relieving Pressure (psig)	Max Vent Relieving Pressure (psig)	Max Liquid Level (ft)	Min Liquid Level	Roof Slope[4] (in/ft)	Max. [3]Annual Throughput calculated as follows:

- Dilute Amine Throughput = Max Hourly Throughput * 8760 hours
- Fresh Amine & Piperazine = Yearly Chemical Usage (tpy) * 2000 (lbs/ton) / density (lbs/gal)
- Yearly chemical usage from "Post-C Chemicals.xlsx" provided by Aera Energy

[4]Tank roof slope is unkown at this time so, per AP-42, Section 7.1, a conservative value of 0.0625 ft/ft or 0.75 in/ft is used.

Assumptions

- SDS provides little information about the cycloamine's so they are approximated using the following assumptions:
  - Molecular weight is directly proportional to relative vapor density
  - Vapor pressure of pure water is 0.2 psi. The dilute cylic amine solution has a lower vapor pressure than water. Hence the cycloamine is less volatile than water and the concentrated amine solution is conservatively assumed to have the same vapor pressure as the dilute solution.
  - Chemical data from SDS provided by Anthony Gurrola on 4/24/23
- Raw water and cooling water meet the definition of clean produced water, so no emissions are calculated from those tanks
- Pressure vessels do not breath and hence the only emissions from those systems are fugitive and accounted for in fugitive sections

Chemical Information

Chemical Name	Molecular Weight[1]	Liquid Density[2] (lb/gal)	Vapor Pressure[3] (psi)	Percent Composition by Weight
Dilute Cyclic Amine	130.5	8.91	1.89E-03	52% Cycloamine, 41.5% Water, 0.5% Ethylene Glycol
Concentrated Cyclic Amine	130.5	8.89	1.89E-03	99.5% Cycloamine, 0.5% Ethylene Glycol
Sulfuric Acid	98.08	15.36	1.93E-02	96% Sulfuric Acid, 4% Water

[1]Molecular weight of amine compounds is calculated using relative vapour density data. $MW_{compound}$ = Relative Density * MW_{air} = 4.5 * 9

[2]Liquid Density = Specific $Gravity_{compound}$ * $Density_{water}$

Table of Contents

1. Basic Project Information

1.1. Basic Project Information

1.2. Land Use Types

1.3. User-Selected Emission Reduction Measures by Emissions Sector

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

2.2. Construction Emissions by Year, Unmitigated

2.3. Construction Emissions by Year, Mitigated

3. Construction Emissions Details

3.1. Paving (2025) - Unmitigated

3.2. Paving (2025) - Mitigated

5. Activity Data

5.1. Construction Schedule

5.2. Off-Road Equipment

5.2.1. Unmitigated

5.2.2. Mitigated

5.3. Construction Vehicles

5.3.1. Unmitigated

5.3.2. Mitigated

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

5.5. Architectural Coatings

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

5.6.2. Construction Earthmoving Control Strategies

5.7. Construction Paving

5.8. Construction Electricity Consumption and Emissions Factors

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

5.18.1.2. Mitigated

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

5.18.1.2. Mitigated

5.18.2. Sequestration

5.18.2.1. Unmitigated

5.18.2.2. Mitigated

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - On-Site Roads
Construction Start Date	1/30/2025
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
Other Asphalt Surfaces	40.0	Acre	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

Criteria Pollutants (lb/day for daily, ton/yr for annual) and GHGs (lb/day for daily, MT/yr for annual)

5. Activity Data

5.1. Construction Schedule

Phase Name	Phase Type	Start Date	End Date	Days Per Week	Work Days per Phase	Phase Description
Paving	Paving	1/30/2025	2/26/2025	5.00	20.0	—

5.2. Off-Road Equipment

5.2.1. Unmitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Paving	Graders	Diesel	Average	1.00	8.00	259	0.41
Paving	Off-Highway Trucks	Diesel	Average	1.00	8.00	408	0.38
Paving	Rubber Tired Loaders	Diesel	Average	1.00	8.00	232	0.36
Paving	Crawler Tractors	Diesel	Average	1.00	8.00	585	0.43
Paving	Rubber Tired Dozers	Diesel	Average	2.00	8.00	207	0.40

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor

Paving	Graders	Diesel	Average	1.00	8.00	259	0.41
Paving	Off-Highway Trucks	Diesel	Average	1.00	8.00	408	0.38
Paving	Rubber Tired Loaders	Diesel	Average	1.00	8.00	232	0.36
Paving	Crawler Tractors	Diesel	Average	1.00	8.00	585	0.43
Paving	Rubber Tired Dozers	Diesel	Average	2.00	8.00	207	0.40

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Paving	—	—	—	—
Paving	Worker	8.00	45.0	LDA,LDT1,LDT2
Paving	Vendor	—	10.6	HHDT,MHDT
Paving	Hauling	0.00	20.0	HHDT
Paving	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Paving	—	—	—	—
Paving	Worker	8.00	45.0	LDA,LDT1,LDT2
Paving	Vendor	—	10.6	HHDT,MHDT
Paving	Hauling	0.00	20.0	HHDT
Paving	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)
Paving	0.00	0.00	0.00	0.00	40.0

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
Other Asphalt Surfaces	40.0	100%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Construction: Construction Phases	Work days per phase provided by Applicant.

Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Trips and VMT	Estimated trip length.

5. Activity Data

5.1. Construction Schedule

Phase Name	Phase Type	Start Date	End Date	Days Per Week	Work Days per Phase	Phase Description

Grading	Grading	6/2/2025	6/27/2025	5.00	20.0	—

5.2. Off-Road Equipment

5.2.1. Unmitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Grading	Graders	Diesel	Average	2.00	8.00	259	0.41
Grading	Rubber Tired Dozers	Diesel	Average	2.00	8.00	207	0.40
Grading	Off-Highway Trucks	Diesel	Average	2.00	8.00	407	0.38
Grading	Rubber Tired Loaders	Diesel	Average	2.00	8.00	232	0.36
Grading	Crawler Tractors	Diesel	Average	2.00	8.00	585	0.43
Grading	Generator Sets	Diesel	Average	2.00	8.00	18.0	0.74
Grading	Other Construction Equipment	Diesel	Average	3.00	8.00	130	0.42

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Grading	Graders	Diesel	Average	2.00	8.00	259	0.41
Grading	Rubber Tired Dozers	Diesel	Average	2.00	8.00	207	0.40
Grading	Off-Highway Trucks	Diesel	Average	2.00	8.00	407	0.38
Grading	Rubber Tired Loaders	Diesel	Average	2.00	8.00	232	0.36
Grading	Crawler Tractors	Diesel	Average	2.00	8.00	585	0.43
Grading	Generator Sets	Diesel	Average	2.00	8.00	18.0	0.74
Grading	Other Construction Equipment	Diesel	Average	3.00	8.00	130	0.42

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Grading	—	—	—	—
Grading	Worker	15.0	45.0	LDA,LDT1,LDT2
Grading	Vendor	—	10.6	HHDT,MHDT
Grading	Hauling	0.00	20.0	HHDT
Grading	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Grading	—	—	—	—
Grading	Worker	15.0	45.0	LDA,LDT1,LDT2
Grading	Vendor	—	10.6	HHDT,MHDT
Grading	Hauling	0.00	20.0	HHDT
Grading	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)
Grading	—	—	40.0	0.00	—

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Dust From Material Movement	40 acres of disturbed land.
Construction: Trips and VMT	Estimated trip length.

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - Facilities Pad Grading 32 Cogen v2
Construction Start Date	1/30/2025
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
User Defined Industrial	1.00	User Defined Unit	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

Criteria Pollutants (lb/day for daily, ton/yr for annual) and GHGs (lb/day for daily, MT/yr for annual)

Grading	Off-Highway Trucks	Diesel	Average	2.00	8.00	407	0.38
Grading	Rubber Tired Loaders	Diesel	Average	2.00	8.00	232	0.36
Grading	Crawler Tractors	Diesel	Average	2.00	8.00	585	0.43
Grading	Generator Sets	Diesel	Average	2.00	8.00	18.0	0.74
Grading	Other Construction Equipment	Diesel	Average	3.00	8.00	130	0.42

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Grading	Graders	Diesel	Average	2.00	8.00	259	0.41
Grading	Rubber Tired Dozers	Diesel	Average	2.00	8.00	207	0.40
Grading	Off-Highway Trucks	Diesel	Average	2.00	8.00	407	0.38
Grading	Rubber Tired Loaders	Diesel	Average	2.00	8.00	232	0.36
Grading	Crawler Tractors	Diesel	Average	2.00	8.00	585	0.43
Grading	Generator Sets	Diesel	Average	2.00	8.00	18.0	0.74
Grading	Other Construction Equipment	Diesel	Average	3.00	8.00	130	0.42

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Grading	—	—	—	—
Grading	Worker	15.0	45.0	LDA,LDT1,LDT2
Grading	Vendor	—	10.6	HHDT,MHDT
Grading	Hauling	0.00	20.0	HHDT
Grading	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Grading	—	—	—	—
Grading	Worker	15.0	45.0	LDA,LDT1,LDT2
Grading	Vendor	—	10.6	HHDT,MHDT
Grading	Hauling	0.00	20.0	HHDT
Grading	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)
Grading	—	—	40.0	0.00	—

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Dust From Material Movement	40 acres of disturbed land.
Construction: Trips and VMT	Estimated trip length.

CCS - Facilities Pad Grading SP286B Custom Report

Table of Contents

1. Basic Project Information

1.1. Basic Project Information

1.2. Land Use Types

1.3. User-Selected Emission Reduction Measures by Emissions Sector

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

2.2. Construction Emissions by Year, Unmitigated

2.3. Construction Emissions by Year, Mitigated

3. Construction Emissions Details

3.1. Grading (2025) - Unmitigated

3.2. Grading (2025) - Mitigated

5. Activity Data

5.1. Construction Schedule

5.2. Off-Road Equipment

5.2.1. Unmitigated

5.2.2. Mitigated

5.3. Construction Vehicles

5.3.1. Unmitigated

5.3.2. Mitigated

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

5.5. Architectural Coatings

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

5.6.2. Construction Earthmoving Control Strategies

5.7. Construction Paving

5.8. Construction Electricity Consumption and Emissions Factors

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

5.18.1.2. Mitigated

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

5.18.1.2. Mitigated

5.18.2. Sequestration

5.18.2.1. Unmitigated

5.18.2.2. Mitigated

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - Facilities Pad Grading SP286B
Construction Start Date	8/21/2025
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
User Defined Industrial	1.00	User Defined Unit	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

Criteria Pollutants (lb/day for daily, ton/yr for annual) and GHGs (lb/day for daily, MT/yr for annual)

5. Activity Data

5.1. Construction Schedule

Phase Name	Phase Type	Start Date	End Date	Days Per Week	Work Days per Phase	Phase Description

Grading	Grading	8/21/2025	9/17/2025	5.00	20.0	—

5.2. Off-Road Equipment

5.2.1. Unmitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Grading	Graders	Diesel	Average	2.00	8.00	259	0.41
Grading	Rubber Tired Dozers	Diesel	Average	2.00	8.00	207	0.40
Grading	Off-Highway Trucks	Diesel	Average	2.00	8.00	407	0.38
Grading	Rubber Tired Loaders	Diesel	Average	2.00	8.00	232	0.36
Grading	Crawler Tractors	Diesel	Average	2.00	8.00	585	0.43
Grading	Generator Sets	Diesel	Average	2.00	8.00	18.0	0.74
Grading	Other Construction Equipment	Diesel	Average	3.00	8.00	130	0.42

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Grading	Graders	Diesel	Average	2.00	8.00	259	0.41
Grading	Rubber Tired Dozers	Diesel	Average	2.00	8.00	207	0.40
Grading	Off-Highway Trucks	Diesel	Average	2.00	8.00	407	0.38
Grading	Rubber Tired Loaders	Diesel	Average	2.00	8.00	232	0.36
Grading	Crawler Tractors	Diesel	Average	2.00	8.00	585	0.43
Grading	Generator Sets	Diesel	Average	2.00	8.00	18.0	0.74
Grading	Other Construction Equipment	Diesel	Average	3.00	8.00	130	0.42

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Grading	—	—	—	—
Grading	Worker	15.0	45.0	LDA,LDT1,LDT2
Grading	Vendor	—	10.6	HHDT,MHDT
Grading	Hauling	0.00	20.0	HHDT
Grading	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Grading	—	—	—	—
Grading	Worker	15.0	45.0	LDA,LDT1,LDT2
Grading	Vendor	—	10.6	HHDT,MHDT
Grading	Hauling	0.00	20.0	HHDT
Grading	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)
Grading	—	—	40.0	0.00	—

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Dust From Material Movement	40 acres of disturbed land.
Construction: Trips and VMT	Estimated trip length.

CCS - Facilities Pad Grading SP2972 Custom Report

Table of Contents

1. Basic Project Information

1.1. Basic Project Information

1.2. Land Use Types

1.3. User-Selected Emission Reduction Measures by Emissions Sector

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

2.2. Construction Emissions by Year, Unmitigated

2.3. Construction Emissions by Year, Mitigated

3. Construction Emissions Details

3.1. Grading (2025) - Unmitigated

3.2. Grading (2025) - Mitigated

5. Activity Data

5.18.2.1. Unmitigated

5.18.2.2. Mitigated

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - Facilities Pad Grading SP2972
Construction Start Date	2/12/2026
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
User Defined Industrial	1.00	User Defined Unit	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Grading	—	—	—	—
Grading	Worker	15.0	45.0	LDA,LDT1,LDT2
Grading	Vendor	—	10.6	HHDT,MHDT
Grading	Hauling	0.00	20.0	HHDT
Grading	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Grading	—	—	—	—
Grading	Worker	15.0	45.0	LDA,LDT1,LDT2
Grading	Vendor	—	10.6	HHDT,MHDT
Grading	Hauling	0.00	20.0	HHDT
Grading	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)
Grading	—	—	40.0	0.00	—

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Dust From Material Movement	40 acres of disturbed land.
Construction: Trips and VMT	Estimated trip length.

CCS - CO2 Capture Facility - GP32 Custom Report

Table of Contents

1. Basic Project Information

1.1. Basic Project Information

1.2. Land Use Types

1.3. User-Selected Emission Reduction Measures by Emissions Sector

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

2.2. Construction Emissions by Year, Unmitigated

2.3. Construction Emissions by Year, Mitigated

3. Construction Emissions Details

3.1. Building Construction (2025) - Unmitigated

3.2. Building Construction (2025) - Mitigated

3.3. Building Construction (2026) - Unmitigated

3.4. Building Construction (2026) - Mitigated

3.5. Building Construction (2027) - Unmitigated

3.6. Building Construction (2027) - Mitigated

5. Activity Data

5.1. Construction Schedule

5.2. Off-Road Equipment

5.2.1. Unmitigated

5.2.2. Mitigated

5.3. Construction Vehicles

5.3.1. Unmitigated

5.3.2. Mitigated

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

5.5. Architectural Coatings

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

5.6.2. Construction Earthmoving Control Strategies

5.7. Construction Paving

5.8. Construction Electricity Consumption and Emissions Factors

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

5.18.1.2. Mitigated

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

5.18.1.2. Mitigated

5.18.2. Sequestration

5.18.2.1. Unmitigated

5.18.2.2. Mitigated

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - CO2 Capture Facility - GP32
Construction Start Date	6/30/2025
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
User Defined Industrial	1.00	User Defined Unit	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

5. Activity Data

5.1. Construction Schedule

Phase Name	Phase Type	Start Date	End Date	Days Per Week	Work Days per Phase	Phase Description
Building Construction	Building Construction	6/30/2025	6/1/2027	5.00	502	—

5.2. Off-Road Equipment

5.2.1. Unmitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Building Construction	Tractors/Loaders/Backhoes	Diesel	Average	6.00	8.00	67.0	0.37
Building Construction	Rollers	Diesel	Average	3.00	8.00	8.00	0.38
Building Construction	Air Compressors	Diesel	Average	6.00	8.00	50.0	0.48
Building Construction	Cranes	Diesel	Average	3.00	8.00	6.00	0.29
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	42.0	0.42
Building Construction	Rough Terrain Forklifts	Diesel	Average	3.00	8.00	300	0.40
Building Construction	Rough Terrain Forklifts	Diesel	Average	6.00	8.00	73.0	0.40
Building Construction	Other Construction Equipment	Diesel	Average	1.00	8.00	73.0	0.42
Building Construction	Generator Sets	Diesel	Average	6.00	8.00	18.0	0.74
Building Construction	Skid Steer Loaders	Diesel	Average	1.00	8.00	45.0	0.37
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	130	0.42

Building Construction	Aerial Lifts	Diesel	Average	6.00	8.00	475	0.31
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	45.0	0.42
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	8.00	0.42
Building Construction	Welders	Diesel	Average	9.00	8.00	18.0	0.45
Building Construction	Rubber Tired Loaders	Diesel	Average	3.00	8.00	42.0	0.36

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Building Construction	Tractors/Loaders/Backhoes	Diesel	Average	6.00	8.00	67.0	0.37
Building Construction	Rollers	Diesel	Average	3.00	8.00	8.00	0.38
Building Construction	Air Compressors	Diesel	Average	6.00	8.00	50.0	0.48
Building Construction	Cranes	Diesel	Average	3.00	8.00	6.00	0.29
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	42.0	0.42
Building Construction	Rough Terrain Forklifts	Diesel	Average	3.00	8.00	300	0.40
Building Construction	Rough Terrain Forklifts	Diesel	Average	6.00	8.00	73.0	0.40
Building Construction	Other Construction Equipment	Diesel	Average	1.00	8.00	73.0	0.42
Building Construction	Generator Sets	Diesel	Average	6.00	8.00	18.0	0.74
Building Construction	Skid Steer Loaders	Diesel	Average	1.00	8.00	45.0	0.37
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	130	0.42
Building Construction	Aerial Lifts	Diesel	Average	6.00	8.00	475	0.31
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	45.0	0.42
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	8.00	0.42

Building Construction	Welders	Diesel	Average	9.00	8.00	18.0	0.45
Building Construction	Rubber Tired Loaders	Diesel	Average	3.00	8.00	42.0	0.36

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Building Construction	—	—	—	—
Building Construction	Worker	96.0	45.0	LDA,LDT1,LDT2
Building Construction	Vendor	0.00	10.6	HHDT,MHDT
Building Construction	Hauling	0.00	20.0	HHDT
Building Construction	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Building Construction	—	—	—	—
Building Construction	Worker	96.0	45.0	LDA,LDT1,LDT2
Building Construction	Vendor	0.00	10.6	HHDT,MHDT
Building Construction	Hauling	0.00	20.0	HHDT
Building Construction	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005
2026	0.00	204	0.03	< 0.005
2027	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Off-Road Equipment EF	CalEEMod Appendix D: Default Data Tables - Table 3.4 OFFROAD Equipment Emission Factors (g/bhp-hr)

Construction: Trips and VMT	Estimated trip length.

5.18.2.1. Unmitigated

5.18.2.2. Mitigated

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - CO2 Capture Facility - 32 Cogen
Construction Start Date	2/27/2025
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
User Defined Industrial	1.00	User Defined Unit	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

Criteria Pollutants (lb/day for daily, ton/yr for annual) and GHGs (lb/day for daily, MT/yr for annual)

5. Activity Data

5.1. Construction Schedule

Phase Name	Phase Type	Start Date	End Date	Days Per Week	Work Days per Phase	Phase Description
Building Construction	Building Construction	2/27/2025	1/29/2027	5.00	502	—

5.2. Off-Road Equipment

5.2.1. Unmitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor

Building Construction	Tractors/Loaders/Backh	Diesel	Average	6.00	8.00	67.0	0.37
Building Construction	Rollers	Diesel	Average	3.00	8.00	8.00	0.38
Building Construction	Air Compressors	Diesel	Average	6.00	8.00	50.0	0.48
Building Construction	Cranes	Diesel	Average	3.00	8.00	6.00	0.29
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	42.0	0.42
Building Construction	Rough Terrain Forklifts	Diesel	Average	3.00	8.00	300	0.40
Building Construction	Rough Terrain Forklifts	Diesel	Average	6.00	8.00	73.0	0.40
Building Construction	Other Construction Equipment	Diesel	Average	1.00	8.00	73.0	0.42
Building Construction	Generator Sets	Diesel	Average	6.00	8.00	18.0	0.74
Building Construction	Skid Steer Loaders	Diesel	Average	1.00	8.00	45.0	0.37
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	130	0.42
Building Construction	Aerial Lifts	Diesel	Average	6.00	8.00	475	0.31
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	45.0	0.42
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	8.00	0.42
Building Construction	Welders	Diesel	Average	9.00	8.00	18.0	0.45
Building Construction	Rubber Tired Loaders	Diesel	Average	3.00	8.00	42.0	0.36

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Building Construction	Tractors/Loaders/Backhoes	Diesel	Average	6.00	8.00	67.0	0.37
Building Construction	Rollers	Diesel	Average	3.00	8.00	8.00	0.38
Building Construction	Air Compressors	Diesel	Average	6.00	8.00	50.0	0.48
Building Construction	Cranes	Diesel	Average	3.00	8.00	6.00	0.29

Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	42.0	0.42
Building Construction	Rough Terrain Forklifts	Diesel	Average	3.00	8.00	300	0.40
Building Construction	Rough Terrain Forklifts	Diesel	Average	6.00	8.00	73.0	0.40
Building Construction	Other Construction Equipment	Diesel	Average	1.00	8.00	73.0	0.42
Building Construction	Generator Sets	Diesel	Average	6.00	8.00	18.0	0.74
Building Construction	Skid Steer Loaders	Diesel	Average	1.00	8.00	45.0	0.37
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	130	0.42
Building Construction	Aerial Lifts	Diesel	Average	6.00	8.00	475	0.31
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	45.0	0.42
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	8.00	0.42
Building Construction	Welders	Diesel	Average	9.00	8.00	18.0	0.45
Building Construction	Rubber Tired Loaders	Diesel	Average	3.00	8.00	42.0	0.36

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Building Construction	—	—	—	—
Building Construction	Worker	96.0	45.0	LDA,LDT1,LDT2
Building Construction	Vendor	0.00	10.6	HHDT,MHDT
Building Construction	Hauling	0.00	20.0	HHDT
Building Construction	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Building Construction	—	—	—	—
Building Construction	Worker	96.0	45.0	LDA,LDT1,LDT2
Building Construction	Vendor	0.00	10.6	HHDT,MHDT
Building Construction	Hauling	0.00	20.0	HHDT
Building Construction	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005
2026	0.00	204	0.03	< 0.005
2027	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

CCS - CO2 Capture Facility - SP286B Custom Report

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - CO2 Capture Facility - SP286B
Construction Start Date	9/18/2025
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
User Defined Industrial	1.00	User Defined Unit	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

Criteria Pollutants (lb/day for daily, ton/yr for annual) and GHGs (lb/day for daily, MT/yr for annual)

5. Activity Data

5.1. Construction Schedule

Phase Name	Phase Type	Start Date	End Date	Days Per Week	Work Days per Phase	Phase Description
Building Construction	Building Construction	9/18/2025	8/20/2027	5.00	502	—

5.2. Off-Road Equipment

5.2.1. Unmitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Building Construction	Tractors/Loaders/Backhoes	Diesel	Average	6.00	8.00	67.0	0.37
Building Construction	Rollers	Diesel	Average	3.00	8.00	8.00	0.38
Building Construction	Air Compressors	Diesel	Average	6.00	8.00	50.0	0.48
Building Construction	Cranes	Diesel	Average	3.00	8.00	6.00	0.29
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	42.0	0.42
Building Construction	Rough Terrain Forklifts	Diesel	Average	3.00	8.00	300	0.40
Building Construction	Rough Terrain Forklifts	Diesel	Average	6.00	8.00	73.0	0.40
Building Construction	Other Construction Equipment	Diesel	Average	1.00	8.00	73.0	0.42
Building Construction	Generator Sets	Diesel	Average	6.00	8.00	18.0	0.74
Building Construction	Skid Steer Loaders	Diesel	Average	1.00	8.00	45.0	0.37
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	130	0.42

Building Construction	Aerial Lifts	Diesel	Average	6.00	8.00	475	0.31
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	45.0	0.42
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	8.00	0.42
Building Construction	Welders	Diesel	Average	9.00	8.00	18.0	0.45
Building Construction	Rubber Tired Loaders	Diesel	Average	3.00	8.00	42.0	0.36

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Building Construction	Tractors/Loaders/Backhoes	Diesel	Average	6.00	8.00	67.0	0.37
Building Construction	Rollers	Diesel	Average	3.00	8.00	8.00	0.38
Building Construction	Air Compressors	Diesel	Average	6.00	8.00	50.0	0.48
Building Construction	Cranes	Diesel	Average	3.00	8.00	6.00	0.29
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	42.0	0.42
Building Construction	Rough Terrain Forklifts	Diesel	Average	3.00	8.00	300	0.40
Building Construction	Rough Terrain Forklifts	Diesel	Average	6.00	8.00	73.0	0.40
Building Construction	Other Construction Equipment	Diesel	Average	1.00	8.00	73.0	0.42
Building Construction	Generator Sets	Diesel	Average	6.00	8.00	18.0	0.74
Building Construction	Skid Steer Loaders	Diesel	Average	1.00	8.00	45.0	0.37
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	130	0.42
Building Construction	Aerial Lifts	Diesel	Average	6.00	8.00	475	0.31
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	45.0	0.42
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	8.00	0.42

Building Construction	Welders	Diesel	Average	9.00	8.00	18.0	0.45
Building Construction	Rubber Tired Loaders	Diesel	Average	3.00	8.00	42.0	0.36

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Building Construction	—	—	—	—
Building Construction	Worker	96.0	45.0	LDA,LDT1,LDT2
Building Construction	Vendor	0.00	10.6	HHDT,MHDT
Building Construction	Hauling	0.00	20.0	HHDT
Building Construction	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Building Construction	—	—	—	—
Building Construction	Worker	96.0	45.0	LDA,LDT1,LDT2
Building Construction	Vendor	0.00	10.6	HHDT,MHDT
Building Construction	Hauling	0.00	20.0	HHDT
Building Construction	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005
2026	0.00	204	0.03	< 0.005
2027	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Off-Road Equipment EF	CalEEMod Appendix D: Default Data Tables - Table 3.4 OFFROAD Equipment Emission Factors (g/bhp-hr)

Construction: Trips and VMT	Estimated trip length.

CCS - CO2 Capture Facility - SP2972 Custom Report

Table of Contents

1. Basic Project Information

1.1. Basic Project Information

1.2. Land Use Types

1.3. User-Selected Emission Reduction Measures by Emissions Sector

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

2.2. Construction Emissions by Year, Unmitigated

2.3. Construction Emissions by Year, Mitigated

3. Construction Emissions Details

3.1. Building Construction (2026) - Unmitigated

3.2. Building Construction (2026) - Mitigated

3.3. Building Construction (2027) - Unmitigated

3.4. Building Construction (2027) - Mitigated

3.5. Building Construction (2028) - Unmitigated

3.6. Building Construction (2028) - Mitigated

5. Activity Data

5.1. Construction Schedule

5.2. Off-Road Equipment

5.2.1. Unmitigated

5.2.2. Mitigated

5.3. Construction Vehicles

5.3.1. Unmitigated

5.3.2. Mitigated

5.4. Vehicles

5.18.2. Sequestration

5.18.2.1. Unmitigated

5.18.2.2. Mitigated

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - CO2 Capture Facility - SP2972
Construction Start Date	3/12/2026
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
User Defined Industrial	1.00	User Defined Unit	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

Criteria Pollutants (lb/day for daily, ton/yr for annual) and GHGs (lb/day for daily, MT/yr for annual)

5. Activity Data

5.1. Construction Schedule

Phase Name	Phase Type	Start Date	End Date	Days Per Week	Work Days per Phase	Phase Description
Building Construction	Building Construction	3/12/2026	2/11/2028	5.00	502	—

5.2. Off-Road Equipment

5.2.1. Unmitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor

Building Construction	Tractors/Loaders/Backh	Diesel	Average	6.00	8.00	67.0	0.37
Building Construction	Rollers	Diesel	Average	3.00	8.00	8.00	0.38
Building Construction	Air Compressors	Diesel	Average	6.00	8.00	50.0	0.48
Building Construction	Cranes	Diesel	Average	3.00	8.00	6.00	0.29
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	42.0	0.42
Building Construction	Rough Terrain Forklifts	Diesel	Average	3.00	8.00	300	0.40
Building Construction	Rough Terrain Forklifts	Diesel	Average	6.00	8.00	73.0	0.40
Building Construction	Other Construction Equipment	Diesel	Average	1.00	8.00	73.0	0.42
Building Construction	Generator Sets	Diesel	Average	6.00	8.00	18.0	0.74
Building Construction	Skid Steer Loaders	Diesel	Average	1.00	8.00	45.0	0.37
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	130	0.42
Building Construction	Aerial Lifts	Diesel	Average	6.00	8.00	475	0.31
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	45.0	0.42
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	8.00	0.42
Building Construction	Welders	Diesel	Average	9.00	8.00	18.0	0.45
Building Construction	Rubber Tired Loaders	Diesel	Average	3.00	8.00	42.0	0.36

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Building Construction	Tractors/Loaders/Backhoes	Diesel	Average	6.00	8.00	67.0	0.37
Building Construction	Rollers	Diesel	Average	3.00	8.00	8.00	0.38
Building Construction	Air Compressors	Diesel	Average	6.00	8.00	50.0	0.48
Building Construction	Cranes	Diesel	Average	3.00	8.00	6.00	0.29

Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	42.0	0.42
Building Construction	Rough Terrain Forklifts	Diesel	Average	3.00	8.00	300	0.40
Building Construction	Rough Terrain Forklifts	Diesel	Average	6.00	8.00	73.0	0.40
Building Construction	Other Construction Equipment	Diesel	Average	1.00	8.00	73.0	0.42
Building Construction	Generator Sets	Diesel	Average	6.00	8.00	18.0	0.74
Building Construction	Skid Steer Loaders	Diesel	Average	1.00	8.00	45.0	0.37
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	130	0.42
Building Construction	Aerial Lifts	Diesel	Average	6.00	8.00	475	0.31
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	45.0	0.42
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	8.00	0.42
Building Construction	Welders	Diesel	Average	9.00	8.00	18.0	0.45
Building Construction	Rubber Tired Loaders	Diesel	Average	3.00	8.00	42.0	0.36

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Building Construction	—	—	—	—
Building Construction	Worker	96.0	45.0	LDA,LDT1,LDT2
Building Construction	Vendor	0.00	10.6	HHDT,MHDT
Building Construction	Hauling	0.00	20.0	HHDT
Building Construction	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Building Construction	—	—	—	—
Building Construction	Worker	96.0	45.0	LDA,LDT1,LDT2
Building Construction	Vendor	0.00	10.6	HHDT,MHDT
Building Construction	Hauling	0.00	20.0	HHDT
Building Construction	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2026	0.00	204	0.03	< 0.005
2027	0.00	204	0.03	< 0.005
2028	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Off-Road Equipment EF	CalEEMod Appendix D: Default Data Tables - Table 3.4 OFFROAD Equipment Emission Factors (g/bhp-hr)
Construction: Trips and VMT	Estimated trip length.

CCS - Compressor Station Custom Report

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - Compressor Station
Construction Start Date	1/1/2025
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
User Defined Industrial	1.00	User Defined Unit	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

Building Construction	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Trips and VMT	Estimated trip length.
Construction: Off-Road Equipment EF	CalEEMod Appendix D: Default Data Tables - Table 3.4 OFFROAD Equipment Emission Factors (g/bhp-hr)

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - CO2 Main Pipeline
Construction Start Date	1/1/2025
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
User Defined Industrial	1.00	User Defined Unit	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

5. Activity Data

5.1. Construction Schedule

Phase Name	Phase Type	Start Date	End Date	Days Per Week	Work Days per Phase	Phase Description
Pipeline	Building Construction	1/1/2025	6/30/2026	5.00	390	—

5.2. Off-Road Equipment

5.2.1. Unmitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Pipeline	Welders	Diesel	Average	4.00	8.00	48.0	0.45

Pipeline	Tractors/Loaders/Backhoes	Diesel	Average	3.00	8.00	67.0	0.37
Pipeline	Excavators	Diesel	Average	3.00	8.00	172	0.38
Pipeline	Cranes	Diesel	Average	4.00	8.00	300	0.29
Pipeline	Cranes	Diesel	Average	1.00	8.00	62.0	0.29
Pipeline	Other Construction Equipment	Diesel	Average	2.00	8.00	226	0.42
Pipeline	Other Construction Equipment	Diesel	Average	1.00	8.00	425	0.42
Pipeline	Rollers	Diesel	Average	1.00	8.00	33.0	0.38
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	232	0.36
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	125	0.36

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Pipeline	Welders	Diesel	Average	4.00	8.00	48.0	0.45
Pipeline	Tractors/Loaders/Backhoes	Diesel	Average	3.00	8.00	67.0	0.37
Pipeline	Excavators	Diesel	Average	3.00	8.00	172	0.38
Pipeline	Cranes	Diesel	Average	4.00	8.00	300	0.29
Pipeline	Cranes	Diesel	Average	1.00	8.00	62.0	0.29
Pipeline	Other Construction Equipment	Diesel	Average	2.00	8.00	226	0.42
Pipeline	Other Construction Equipment	Diesel	Average	1.00	8.00	425	0.42
Pipeline	Rollers	Diesel	Average	1.00	8.00	33.0	0.38
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	232	0.36
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	125	0.36

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Pipeline	—	—	—	—
Pipeline	Worker	29.0	45.0	LDA,LDT1,LDT2
Pipeline	Vendor	0.00	10.6	HHDT,MHDT
Pipeline	Hauling	0.00	20.0	HHDT
Pipeline	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Pipeline	—	—	—	—
Pipeline	Worker	29.0	45.0	LDA,LDT1,LDT2
Pipeline	Vendor	0.00	10.6	HHDT,MHDT
Pipeline	Hauling	0.00	20.0	HHDT
Pipeline	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005
2026	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Trips and VMT	Construction equipment provided by Applicant.

CCS - Distribution Pipeline Custom Report

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - Distribution Pipeline
Construction Start Date	1/1/2025
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
User Defined Industrial	1.00	User Defined Unit	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

Pipeline	Rollers	Diesel	Average	1.00	8.00	33.0	0.38
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	125	0.36
Pipeline	Other Construction Equipment	Diesel	Average	1.00	8.00	425	0.42

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Pipeline	—	—	—	—
Pipeline	Worker	23.0	45.0	LDA,LDT1,LDT2
Pipeline	Vendor	0.00	10.6	HHDT,MHDT
Pipeline	Hauling	0.00	20.0	HHDT
Pipeline	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Pipeline	—	—	—	—
Pipeline	Worker	23.0	45.0	LDA,LDT1,LDT2
Pipeline	Vendor	0.00	10.6	HHDT,MHDT
Pipeline	Hauling	0.00	20.0	HHDT
Pipeline	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.

Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Trips and VMT	Estimated Trip Length.

5. Activity Data

5.1. Construction Schedule

Phase Name	Phase Type	Start Date	End Date	Days Per Week	Work Days per Phase	Phase Description
Building Construction	Building Construction	4/24/2025	7/16/2025	5.00	60.0	—

5.2. Off-Road Equipment

5.2.1. Unmitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Building Construction	Rubber Tired Dozers	Diesel	Average	1.00	8.00	207	0.40
Building Construction	Off-Highway Trucks	Diesel	Average	1.00	8.00	407	0.38
Building Construction	Other Construction Equipment	Diesel	Average	1.00	8.00	226	0.42
Building Construction	Other Construction Equipment	Diesel	Average	4.00	8.00	180	0.42
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	210	0.42

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Building Construction	Rubber Tired Dozers	Diesel	Average	1.00	8.00	207	0.40
Building Construction	Off-Highway Trucks	Diesel	Average	1.00	8.00	407	0.38

Building Construction	Other Construction Equipment	Diesel	Average	1.00	8.00	226	0.42
Building Construction	Other Construction Equipment	Diesel	Average	4.00	8.00	180	0.42
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	210	0.42

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Building Construction	—	—	—	—
Building Construction	Worker	12.0	45.0	LDA,LDT1,LDT2
Building Construction	Vendor	0.00	10.6	HHDT,MHDT
Building Construction	Hauling	0.00	20.0	HHDT
Building Construction	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Building Construction	—	—	—	—
Building Construction	Worker	12.0	45.0	LDA,LDT1,LDT2
Building Construction	Vendor	0.00	10.6	HHDT,MHDT
Building Construction	Hauling	0.00	20.0	HHDT
Building Construction	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.

Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Trips and VMT	Estimated trip length.

5. Activity Data

5.1. Construction Schedule

Phase Name	Phase Type	Start Date	End Date	Days Per Week	Work Days per Phase	Phase Description

Building Construction	Building Construction	2/12/2026	5/6/2026	5.00	60.0	—

5.2. Off-Road Equipment

5.2.1. Unmitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Building Construction	Rubber Tired Dozers	Diesel	Average	1.00	8.00	207	0.40
Building Construction	Off-Highway Trucks	Diesel	Average	1.00	8.00	407	0.38
Building Construction	Other Construction Equipment	Diesel	Average	1.00	8.00	226	0.42
Building Construction	Other Construction Equipment	Diesel	Average	4.00	8.00	180	0.42
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	210	0.42

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Building Construction	Rubber Tired Dozers	Diesel	Average	1.00	8.00	207	0.40
Building Construction	Off-Highway Trucks	Diesel	Average	1.00	8.00	407	0.38
Building Construction	Other Construction Equipment	Diesel	Average	1.00	8.00	226	0.42
Building Construction	Other Construction Equipment	Diesel	Average	4.00	8.00	180	0.42
Building Construction	Other Construction Equipment	Diesel	Average	3.00	8.00	210	0.42

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Building Construction	—	—	—	—
Building Construction	Worker	12.0	45.0	LDA,LDT1,LDT2
Building Construction	Vendor	0.00	10.6	HHDT,MHDT
Building Construction	Hauling	0.00	20.0	HHDT
Building Construction	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Building Construction	—	—	—	—
Building Construction	Worker	12.0	45.0	LDA,LDT1,LDT2
Building Construction	Vendor	0.00	10.6	HHDT,MHDT
Building Construction	Hauling	0.00	20.0	HHDT
Building Construction	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2026	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Trips and VMT	Estimated trip length.

CCS - Onsite Electrical Substation Custom Report

Table of Contents

1. Basic Project Information

1.1. Basic Project Information

1.2. Land Use Types

1.3. User-Selected Emission Reduction Measures by Emissions Sector

2. Emissions Summary

5.18.2.1. Unmitigated

5.18.2.2. Mitigated

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - Onsite Electrical Substation
Construction Start Date	1/30/2025
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
User Defined Industrial	1.00	User Defined Unit	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

Criteria Pollutants (lb/day for daily, ton/yr for annual) and GHGs (lb/day for daily, MT/yr for annual)

5. Activity Data

5.1. Construction Schedule

Phase Name	Phase Type	Start Date	End Date	Days Per Week	Work Days per Phase	Phase Description

Building Construction	Building Construction	1/30/2025	7/30/2025	5.00	130	—

5.2. Off-Road Equipment

5.2.1. Unmitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Building Construction	Tractors/Loaders/Backhoes	Diesel	Average	3.00	8.00	92.0	0.37
Building Construction	Bore/Drill Rigs	Diesel	Average	1.00	8.00	68.0	0.50
Building Construction	Rollers	Diesel	Average	1.00	8.00	8.00	0.38
Building Construction	Air Compressors	Diesel	Average	1.00	8.00	50.0	0.48
Building Construction	Other Construction Equipment	Diesel	Average	1.00	8.00	6.00	0.42
Building Construction	Cranes	Diesel	Average	1.00	8.00	250	0.29
Building Construction	Rough Terrain Forklifts	Diesel	Average	1.00	8.00	73.0	0.40
Building Construction	Skid Steer Loaders	Diesel	Average	1.00	8.00	45.0	0.37
Building Construction	Aerial Lifts	Diesel	Average	2.00	8.00	60.0	0.31
Building Construction	Cement and Mortar Mixers	Diesel	Average	1.00	8.00	7.00	0.56
Building Construction	Trenchers	Diesel	Average	1.00	8.00	80.0	0.50

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Building Construction	Tractors/Loaders/Backhoes	Diesel	Average	3.00	8.00	92.0	0.37
Building Construction	Bore/Drill Rigs	Diesel	Average	1.00	8.00	68.0	0.50
Building Construction	Rollers	Diesel	Average	1.00	8.00	8.00	0.38
Building Construction	Air Compressors	Diesel	Average	1.00	8.00	50.0	0.48

Building Construction	Other Construction Equipment	Diesel	Average	1.00	8.00	6.00	0.42
Building Construction	Cranes	Diesel	Average	1.00	8.00	250	0.29
Building Construction	Rough Terrain Forklifts	Diesel	Average	1.00	8.00	73.0	0.40
Building Construction	Skid Steer Loaders	Diesel	Average	1.00	8.00	45.0	0.37
Building Construction	Aerial Lifts	Diesel	Average	2.00	8.00	60.0	0.31
Building Construction	Cement and Mortar Mixers	Diesel	Average	1.00	8.00	7.00	0.56
Building Construction	Trenchers	Diesel	Average	1.00	8.00	80.0	0.50

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Building Construction	—	—	—	—
Building Construction	Worker	18.0	45.0	LDA,LDT1,LDT2
Building Construction	Vendor	0.00	10.6	HHDT,MHDT
Building Construction	Hauling	0.00	20.0	HHDT
Building Construction	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Building Construction	—	—	—	—
Building Construction	Worker	18.0	45.0	LDA,LDT1,LDT2
Building Construction	Vendor	0.00	10.6	HHDT,MHDT
Building Construction	Hauling	0.00	20.0	HHDT
Building Construction	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Off-Road Equipment EF	CalEEMod Appendix D: Default Data Tables - Table 3.4 OFFROAD Equipment Emission Factors (g/bhp-hr)
Construction: Trips and VMT	Estimated trip length.

CCS - Water Pipeline Custom Report

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - Water Pipeline
Construction Start Date	1/30/2025
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
User Defined Industrial	1.00	User Defined Unit	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

5. Activity Data

5.1. Construction Schedule

Phase Name	Phase Type	Start Date	End Date	Days Per Week	Work Days per Phase	Phase Description

Pipeline	Building Construction	1/30/2025	5/30/2025	5.00	87.0	—

5.2. Off-Road Equipment

5.2.1. Unmitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Pipeline	Welders	Diesel	Average	3.00	8.00	48.0	0.45
Pipeline	Tractors/Loaders/Backhoes	Diesel	Average	2.00	8.00	67.0	0.37
Pipeline	Excavators	Diesel	Average	2.00	8.00	172	0.38
Pipeline	Other Construction Equipment	Diesel	Average	2.00	8.00	226	0.42
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	232	0.36
Pipeline	Rollers	Diesel	Average	1.00	8.00	33.0	0.38
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	125	0.36

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Pipeline	Welders	Diesel	Average	3.00	8.00	48.0	0.45
Pipeline	Tractors/Loaders/Backhoes	Diesel	Average	2.00	8.00	67.0	0.37
Pipeline	Excavators	Diesel	Average	2.00	8.00	172	0.38
Pipeline	Other Construction Equipment	Diesel	Average	2.00	8.00	226	0.42
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	232	0.36
Pipeline	Rollers	Diesel	Average	1.00	8.00	33.0	0.38
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	125	0.36

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Pipeline	—	—	—	—
Pipeline	Worker	20.0	45.0	LDA,LDT1,LDT2
Pipeline	Vendor	0.00	10.6	HHDT,MHDT
Pipeline	Hauling	0.00	20.0	HHDT
Pipeline	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Pipeline	—	—	—	—
Pipeline	Worker	20.0	45.0	LDA,LDT1,LDT2
Pipeline	Vendor	0.00	10.6	HHDT,MHDT
Pipeline	Hauling	0.00	20.0	HHDT
Pipeline	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Trips and VMT	Construction equipment provided by Applicant.

CCS - CVR Gas Pipeline Custom Report

Table of Contents

1. Basic Project Information

5.18.2.1. Unmitigated

5.18.2.2. Mitigated

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - CVR Gas Pipeline
Construction Start Date	1/1/2025
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
User Defined Industrial	1.00	User Defined Unit	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

Criteria Pollutants (lb/day for daily, ton/yr for annual) and GHGs (lb/day for daily, MT/yr for annual)

5. Activity Data

5.1. Construction Schedule

Phase Name	Phase Type	Start Date	End Date	Days Per Week	Work Days per Phase	Phase Description
Pipeline	Building Construction	1/1/2025	3/25/2025	5.00	60.0	—

5.2. Off-Road Equipment

5.2.1. Unmitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Pipeline	Welders	Diesel	Average	3.00	8.00	48.0	0.45
Pipeline	Tractors/Loaders/Backhoes	Diesel	Average	2.00	8.00	67.0	0.37
Pipeline	Excavators	Diesel	Average	2.00	8.00	172	0.38
Pipeline	Other Construction Equipment	Diesel	Average	2.00	8.00	226	0.42
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	232	0.36
Pipeline	Rollers	Diesel	Average	1.00	8.00	33.0	0.38
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	125	0.36

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Pipeline	Welders	Diesel	Average	3.00	8.00	48.0	0.45

Pipeline	Tractors/Loaders/Backhoes	Diesel	Average	2.00	8.00	67.0	0.37
Pipeline	Excavators	Diesel	Average	2.00	8.00	172	0.38
Pipeline	Other Construction Equipment	Diesel	Average	2.00	8.00	226	0.42
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	232	0.36
Pipeline	Rollers	Diesel	Average	1.00	8.00	33.0	0.38
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	125	0.36

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Pipeline	—	—	—	—
Pipeline	Worker	20.0	45.0	LDA,LDT1,LDT2
Pipeline	Vendor	0.00	10.6	HHDT,MHDT
Pipeline	Hauling	0.00	20.0	HHDT
Pipeline	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Pipeline	—	—	—	—
Pipeline	Worker	20.0	45.0	LDA,LDT1,LDT2
Pipeline	Vendor	0.00	10.6	HHDT,MHDT
Pipeline	Hauling	0.00	20.0	HHDT
Pipeline	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Trips and VMT	Construction equipment provided by Applicant.

CCS - Steam Pipeline Custom Report

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - Steam Pipeline
Construction Start Date	7/17/2025
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
User Defined Industrial	1.00	User Defined Unit	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

5. Activity Data

5.1. Construction Schedule

Phase Name	Phase Type	Start Date	End Date	Days Per Week	Work Days per Phase	Phase Description

Pipeline	Building Construction	7/17/2025	11/17/2025	5.00	88.0	—

5.2. Off-Road Equipment

5.2.1. Unmitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Pipeline	Welders	Diesel	Average	3.00	8.00	48.0	0.45
Pipeline	Tractors/Loaders/Backhoes	Diesel	Average	2.00	8.00	67.0	0.37
Pipeline	Excavators	Diesel	Average	2.00	8.00	172	0.38
Pipeline	Other Construction Equipment	Diesel	Average	2.00	8.00	226	0.42
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	232	0.36
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	125	0.36
Pipeline	Rollers	Diesel	Average	1.00	8.00	33.0	0.38

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Pipeline	Welders	Diesel	Average	3.00	8.00	48.0	0.45
Pipeline	Tractors/Loaders/Backhoes	Diesel	Average	2.00	8.00	67.0	0.37
Pipeline	Excavators	Diesel	Average	2.00	8.00	172	0.38
Pipeline	Other Construction Equipment	Diesel	Average	2.00	8.00	226	0.42
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	232	0.36
Pipeline	Rubber Tired Loaders	Diesel	Average	1.00	8.00	125	0.36
Pipeline	Rollers	Diesel	Average	1.00	8.00	33.0	0.38

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Pipeline	—	—	—	—
Pipeline	Worker	20.0	45.0	LDA,LDT1,LDT2
Pipeline	Vendor	0.00	10.6	HHDT,MHDT
Pipeline	Hauling	0.00	20.0	HHDT
Pipeline	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Pipeline	—	—	—	—
Pipeline	Worker	20.0	45.0	LDA,LDT1,LDT2
Pipeline	Vendor	0.00	10.6	HHDT,MHDT
Pipeline	Hauling	0.00	20.0	HHDT
Pipeline	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.
Construction: Trips and VMT	Construction equipment provided by Applicant.

CCS - Demolition Custom Report

5.18.2.1. Unmitigated

5.18.2.2. Mitigated

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	CCS - Demolition
Construction Start Date	1/30/2025
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.70
Precipitation (days)	16.2
Location	35.453174, -119.708967
County	Kern-San Joaquin
City	Unincorporated
Air District	San Joaquin Valley APCD
Air Basin	San Joaquin Valley
TAZ	2947
EDFZ	5
Electric Utility	Pacific Gas & Electric Company
Gas Utility	Southern California Gas
App Version	2022.1.1.14

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
User Defined Industrial	1.00	User Defined Unit	40.0	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-10-A	Water Exposed Surfaces
Construction	C-11	Limit Vehicle Speeds on Unpaved Roads

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

5. Activity Data

5.1. Construction Schedule

Phase Name	Phase Type	Start Date	End Date	Days Per Week	Work Days per Phase	Phase Description
Demolition	Demolition	1/30/2025	3/26/2025	5.00	40.0	—

5.2. Off-Road Equipment

5.2.1. Unmitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Demolition	Excavators	Diesel	Average	2.00	8.00	172	0.38
Demolition	Graders	Diesel	Average	1.00	8.00	259	0.41
Demolition	Off-Highway Trucks	Diesel	Average	1.00	8.00	407	0.38
Demolition	Rubber Tired Loaders	Diesel	Average	1.00	8.00	232	0.36

Demolition	Crawler Tractors	Diesel	Average	1.00	8.00	585	0.43
Demolition	Other Construction Equipment	Diesel	Average	1.00	8.00	425	0.42
Demolition	Generator Sets	Diesel	Average	2.00	8.00	18.0	0.74

5.2.2. Mitigated

Phase Name	Equipment Type	Fuel Type	Engine Tier	Number per Day	Hours Per Day	Horsepower	Load Factor
Demolition	Excavators	Diesel	Average	2.00	8.00	172	0.38
Demolition	Graders	Diesel	Average	1.00	8.00	259	0.41
Demolition	Off-Highway Trucks	Diesel	Average	1.00	8.00	407	0.38
Demolition	Rubber Tired Loaders	Diesel	Average	1.00	8.00	232	0.36
Demolition	Crawler Tractors	Diesel	Average	1.00	8.00	585	0.43
Demolition	Other Construction Equipment	Diesel	Average	1.00	8.00	425	0.42
Demolition	Generator Sets	Diesel	Average	2.00	8.00	18.0	0.74

5.3. Construction Vehicles

5.3.1. Unmitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Demolition	—	—	—	—
Demolition	Worker	22.5	17.3	LDA,LDT1,LDT2
Demolition	Vendor	—	10.6	HHDT,MHDT
Demolition	Hauling	0.00	20.0	HHDT
Demolition	Onsite truck	—	—	HHDT

5.3.2. Mitigated

Phase Name	Trip Type	One-Way Trips per Day	Miles per Trip	Vehicle Mix
Demolition	—	—	—	—
Demolition	Worker	22.5	17.3	LDA,LDT1,LDT2
Demolition	Vendor	—	10.6	HHDT,MHDT
Demolition	Hauling	0.00	20.0	HHDT
Demolition	Onsite truck	—	—	HHDT

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Non-applicable. No control strategies activated by user.

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)
Demolition	0.00	0.00	0.00	—	—

5.6.2. Construction Earthmoving Control Strategies

Non-applicable. No control strategies activated by user.

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Industrial	0.00	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	0.00	204	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.1.2. Mitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

5.18.2.2. Mitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

8. User Changes to Default Data

Screen	Justification
Land Use	Project acreage is 2,636 but disturbed land would be 40 acres per Applicant.
Construction: Construction Phases	Work Days per Phase provided by Applicant.
Construction: Off-Road Equipment	Construction equipment provided by Applicant.

APPENDIX C. CARB 2020 AND 2025 ESTIMATED EMISSION INVENTORIES

2016 SIP Emission Projection Data

2020 Estimated Annual Average Emissions

KERN COUNTY

All emissions are represented in Tons per Day and reflect the most current data provided to ARB.

B.2 AQIA Addendum April 2024: Well Abandonment

This page intentionally left blank.

Trinity Consultants

MEMORANDUM

To: AERA Energy LLC

From: Matthew Daniel

Date: March 15, 2024

RE: Air Quality Impact Analysis CarbonFrontier Project – Well Re-abandonment

The Air Quality Impact Analysis (AQIA) associated with the proposed CarbonFrontier Project (Project) by Aera Energy LLC (Aera Energy) was completed in December 2023. A subsequent request has been made to add impacts from legacy well re-abandonments associated with the Project to the already analyzed Project. At the direction of the Kern County Planning and Natural Resources Department, the impacts of the well re-abandonments have been provided in this supplemental memo to the AQIA.

This memorandum provides the revised criteria pollutant emissions and health risk analysis (HRA) based on the additional impacts from well re-abandonments associated with the Project.

Construction Emissions Impacts

The AQIA analyzed the CO_2 capture facility and infrastructure construction occurring over a period of approximately three years, starting with the Pre-C facility construction at GP 32. The AQIA analyzed sequential construction occurring for construction of the Post-C facilities located at COGEN 32 and the two SGSs. The AQIA also analyzed other construction activities which would start concurrently with the facility construction and included pipeline construction, injection well pad construction, well drilling, well plugging and abandonment activities. Additionally, installation of CO_2 distribution pipelines, intra-field electrical distribution, and well hookups occurring throughout the three-year period was also analyzed.

The addition of the well re-abandonments would increase potential construction emissions from on-site equipment due to additional exhaust emissions. Criteria pollutant emissions were estimated using the California Emissions Estimator Model (CalEEMod) version 2020.4.0. There will be two types of re-abandonments, based on the scope of work to be performed – type A and type B. Type A re-abandonments will entail standard activities that can be performed with a workover rig and last approximately 19 days/well, while Type B re-abandonments will require a drilling rig to remove existing cement and casing from legacy wells and will last roughly 35 days/well. This analysis looks at 6 Type A and 26 Type B re-abandonments. Anticipated manpower, equipment and schedule associated with each type of re-abandonment is listed below.

<u>Type A Re-abandonments:</u>

- One shift per day with 10 workers per shift
- Workover Rig - 10 hours per day for 14 days
- Mud Pump - 10 hours per day for 14 days
- Power Swivel - 10 hours per day for 14 days
- Tool Truck - 10 hours per day for 14 days
- Coiled Tubing Unit – 10 hours per day for 5 days

4900 California Ave, Ste 420A, Bakersfield, CA 93309
P 661.282.2200 / F 661.427.0703

- Bulk Truck – 10 hours per day for 5 days
- Vac Truck - 10 hours per day for 5 days
- Cement Pump Truck - 10 hours per day for 5 days

Type B Reabandonments:

- Two shifts per day with 10 workers per shift
- Drilling Rig – 24 hours per day for 30 days
- Coiled Tubing Unit – 10 hours per day for 5 days
- Bulk Truck – 10 hours per day for 5 days
- Vac Truck - 10 hours per day for 5 days
- Cement Pump Truck - 10 hours per day for 5 days

Well re-abandonments are assumed to begin in January 2026. To be conservative, all well re-abandonment activities were analyzed as occurring within a one-year period; however, it is recognized that completion of all the well abandonments could take up to approximately three years. The proposed Project's construction emissions from the AQIA and well re-abandonments for the year 2026 are shown in **Table 1**. Two additional CalEEMod runs were conducted, one for each re-abandonment type. Emissions associated with each type were multiplied by the anticipated number of each re-abandonment type and summed together. The output from the additional CalEEMod runs for the well re-abandonment activities are available in Appendix A.

Table 1. Short-Term Project Emissions

Emissions Source	Pollutant (tons/year)					
	ROG	NO_X	CO	SO_2	PM_{10}	$PM_{2.5}$
Year 2026 - Total	***10.37***	***93.21***	***72.07***	***0.18***	***6.07***	***4.47***
Facilities Pad Grading - SGS2972	*0.06*	*0.56*	*0.47*	*0.00*	*0.07*	*0.04*
GP32 - CO2 Capture Facility	*2.30*	*16.24*	*14.41*	*0.03*	*1.41*	*1.03*
32 Cogen - CO2 Capture Facility	*2.30*	*16.24*	*14.41*	*0.03*	*1.41*	*1.03*
SGS2868 - CO2 Capture Facility	*2.30*	*16.24*	*14.41*	*0.03*	*1.41*	*1.03*
SGS2972 - CO2 Capture Facility	*1.86*	*13.13*	*11.64*	*0.02*	*1.14*	*0.83*
CO2 Main Pipeline	*0.44*	*3.51*	*3.43*	*0.01*	*0.25*	*0.19*
Intra-Field Electrical Distribution	*0.11*	*1.03*	*0.78*	*0.00*	*0.05*	*0.04*
Well Re-abandonments	*1.00*	*26.27*	*12.53*	*0.06*	*0.32*	*0.27*

Health Risk Impacts

The revised Project impacts would result in emission increases of Hazardous Air Pollutants (HAPs) of Deisel Particulate Matter (DPM) from on-site equipment over what was evaluated in the AQIA. The AQIA concluded that the health risk impacts of the Project from cancer and chronic risk were less than the significant threshold. The addition of the DPM emissions associated with the well re-abandonments have little effect on the overall maximum health risks associated with the Project. The location of the overall potential maximum impact (PMIs) did not change. Well re-abandonment emissions were equally divided amongst the potential location of the re-abandonments and were analyzed for a one-year exposure utilizing the same modeling parameters of the original HRA in the AQIA. Since the only additional HAP associated with well re-abandonments is DPM

only cancer and chronic risk was reevaluated. **Table 2** shows the risk impacts from the original Project and well re-abandonments of the PMIs.

Table2. Potential Maximum Impacts Predicted by HARP2

	Maximum Lifetime Excess Cancer Risk	Maximum Non-Cancer Chronic Hazard Index
AQIA	6.65E-06	1.55E-02
Well Re-abandonments	2.77E-08	2.81E-05
Total	6.68E-06	1.55E-02
UTM Easting (m)	251003.06	251950.08
UTM Northing (m)	3926087.12	3925329.29

Based on the conclusion of the HRA performed for the AQIA and the HRA from the increase in HAP emissions associated with the well re-abandonments it is concluded that the proposed Project would continue to have a *less than significant* health risk impact. Electronic modeling files can be found in Appendix B.

Ambient Air Quality Impacts

As stated in the GAMAQI (2015, p 96-97), SJVAPCD has developed screening levels for requiring an Ambient Air Quality Analysis (AAQA). The SJVAPCD recommends that an AAQA be performed for all criteria pollutants when emissions of any criteria pollutant resulting from project construction or operational activities exceed the 100 pounds per day screening level, after compliance with Rule 9510 requirements and implementation of all enforceable mitigation measures.

The Project will be entering into a VERA which will reduce average daily emissions for construction and operational activities associated with this Project to a no net increase level. Therefore, an AAQA is not required for this Project.

Impacts to Greenhouse Gases and Climate Change

The proposed Project will have GHG emissions from construction and operation. These GHG emissions include emissions from area, energy, mobile, water, and waste sources. New regulations and new technologies in the future, and phase out of old equipment over time, will lead to a reduction of GHG emissions, but the reduction is not currently quantifiable. Additionally, the Project, as proposed, has the capacity to capture and sequester up to roughly 1.6 million metric tons of CO_2 per year, with a total sequestration capacity up to 40 million metric tons of CO_2. The installed capture facilities will have a capture efficiency of 95% at the pre-combustion facility and 90% at the post-combustion facilities. Even with the addition of GHG emissions from well re-abandonment, the Project will continue to achieve net negative GHG emissions impact.

Conclusions

As demonstrated above the addition of 18 truck trips to the proposed Project would result in an increase of construction emissions for the year 2026, however, it would not significantly impact the health risk, ambient air quality impacts or GHG impacts associated with the proposed Project.

B.3 Failure Investigation Report

This page intentionally left blank.

DOT	US Department of Transportation
PHMSA	Pipeline and Hazardous Materials Safety Administration
OPS	Office of Pipeline Safety – Accident Investigation Division

Principal Investigator	Wesley Mathews
Acting Accident Investigation Director	Chris Ruhl
Date of Report	May 26, 2022
Subject	Failure Investigation Report - Denbury Gulf Coast Pipelines, LLC – Pipeline Rupture/ Natural Force Damage

Operator, Location, & Consequences

Date of Failure	February 22, 2020
Commodity Released	Carbon Dioxide
City, County and State	Satartia, Yazoo County, MS
OpID and Operator Name	32545, Denbury Gulf Coast Pipelines, LLC
Unit # and Unit Name	75379 – MS-2
WMS Activity ID	20-176125
Milepost (MP) / Location	MP 6.6 / Pipeline Stationing 348+63
Type of Failure	Natural Force Damage
Fatalities	None
Injuries	None
Description of Area Impacted	Rural, “Could Affect” High Consequence Area (HCA) - Other Populated Area
Total Costs	$ 3,947,009

Key Points

- On February 22, 2020, a carbon dioxide (CO_2) pipeline operated by Denbury Gulf Coast Pipelines LLC (Denbury) ruptured in proximity to the community of Satartia, Mississippi. The rupture followed heavy rains that resulted in a landslide, creating excessive axial strain on a pipeline weld.
- Carbon dioxide is considered minimally toxic by inhalation and is classified as an asphyxiant, displacing the oxygen in air. Symptoms of CO_2 exposure may include headache and drowsiness. Individuals exposed to higher concentrations may experience rapid breathing, confusion, increased cardiac output, elevated blood pressure, and increased arrhythmias. Extreme CO_2 concentrations can lead to death by asphyxiation.
- When CO_2 in a super-critical phase (which is common for CO_2 pipelines) releases into open air, it naturally vaporizes into a heavier than air gas and dissipates. During the February 22 event, atmospheric conditions and unique topographical features of the accident site significantly delayed dissipation of the heavier-than-air vapor cloud. Pipeline operators are required to establish atmospheric models to prepare for emergencies—Denbury's model did not contemplate a release that could affect the Village of Satartia.
- Local emergency responders were not informed by Denbury of the rupture and the nature of the unique safety risks of the CO_2 pipeline. As a result, responders had to guess the nature of the risk, in part making assumptions based on reports of a "green gas" and "rotten egg smell" and had to contemplate appropriate mitigative actions. Fortunately, responders decided to quickly isolate the affected area by shutting down local highways and evacuating people in proximity to the release. Denbury reported on its PHMSA F 7000.1 accident report that 200 residents surrounding the rupture location were evacuated, and forty-five people were taken to the hospital. Denbury also reported that to the company's knowledge, one individual was admitted to the hospital for reasons unrelated to the pipeline failure. No fatalities were reported.
- This event demonstrated the need for:
    - Pipeline company awareness and mitigation efforts directed at addressing integrity threats due to changing climate, geohazards, and soil stability issues.
    - Improved public engagement efforts to ensure public and emergency responder awareness of nearby CO_2 pipeline and pipeline facilities and what to do if a CO_2 release occurs. This is especially important for communities in low-lying areas, with certain topographical features such as rivers and valleys.

Executive Summary

On February 22, 2020, at 7:06 p.m. Central Standard Time (CST[1]), Denbury's 24-inch Delhi (Delhi) Pipeline ruptured, releasing liquid CO_2 that immediately began to vaporize at atmospheric conditions. The site of the rupture was on the northeast side of Highway 433 (HWY 433), approximately one mile southeast of Satartia, Mississippi. Denbury subsequently reported the rupture released an estimated total of 31,405[2] barrels of CO_2. Following the accident, investigators from the Pipeline and Hazardous Material Safety Administration's (PHMSA's) Accident Investigation Division (AID) and Southwest Regional Office, conducted an investigation, including an onsite investigation.

Liquid CO_2 vaporizes when released to the atmosphere. Carbon dioxide vapor is 1.53 times heavier than air, and displaces oxygen, so it can act as an asphyxiant to humans and animals. The National Institute for Occupational Safety and Health has established that concentrations of 40,000 parts per million (ppm) are immediately dangerous to life and health. The Occupational Safety and Health Administration has established 5000 ppm as a permissible exposure limit, which is an 8-hour time-weighted average. The weather conditions and unique topography of the accident site prevented the CO_2 vapor from rapidly dispersing and allowing a plume to form that migrated toward Satartia. Upon learning of the pipeline rupture, Yazoo County Office of Emergency Management (Yazoo County OEM) shut down HWY 433 to all traffic and evacuated the area. Local authorities evacuated approximately 200 people near the rupture, including the entire town of Satartia (around 50 residents), and three homes across the Yazoo River. According to Denbury's PHMSA F 7000.1 accident report, forty-five people sought medical attention at local hospitals, including individuals who were caught in the vapor cloud while driving a vehicle. One individual was admitted to the hospital for reasons unrelated to the pipeline failure. There were no fatalities.

The pipeline failed on a steep embankment adjacent to HWY 433, which had recently subsided. Heavy rains are believed to have led to a landslide, which created axial strain on the pipeline and resulted in a full circumferential girth weld failure. After the accident, Denbury, under PHMSA's oversight, cut out the failed sections of pipe and sent them to Det Norske Veritas' (DNV) Columbus, Ohio laboratory for metallurgical analysis. DNV confirmed the initial onsite observations of a girth weld failure.

PHMSA's investigation also revealed several contributing factors to the accident, including but not limited to, Denbury not addressing the risks of geohazards in its plans and procedures, underestimating the potential affected areas that could be impacted by a release in its CO_2 dispersion model, and not notifying local responders to advise them of a potential failure.

System Details

Denbury's Delhi Pipeline, on which the failure occurred, consists of 77 miles of 24-inch diameter pipeline, the majority of which is located within Mississippi. The entire Delhi Pipeline system flows east to west, beginning at the Jackson Dome in Mississippi and terminating in Delhi, Louisiana. Denbury primarily uses the CO_2 for enhanced oil recovery (EOR) for Denbury Resources Inc. onshore oil wells. The pipeline is controlled from the Denbury control room located in Plano, Texas.

[1] All times are reported in CST unless otherwise noted.

[2] Denbury reported a total release volume of 31,405 barrels in Form PHMSA F-7000.1, Accident Report – Hazardous Liquid Pipeline Systems, dated November 25, 2020. The actual release volume likely exceeded this amount due to a valve operation error, however, Denbury has not confirmed and reported any new release volume to PHMSA.

Following the Delhi Pipeline rupture, two of Denbury's local oilfields were cut off from its CO_2 supply and assumed non-EOR operation while the pipeline remained out of service. One oilfield returned to full EOR operation before repairs were made to the Delhi Pipeline as the oilfield had an alternate supply of CO_2. The other oilfield conducted non-EOR operations until the pipeline was repaired and returned to service in October 2020.

Stupp Corporation manufactured the pipe in 2007 and Denbury installed it in 2009. The pipe was manufactured to API 5L X80 grade, with an electric resistance welded (ERW) longitudinal weld seam, a 0.469-inch wall thickness on the mainline pipe, 0.540-inch wall thickness on the bored pipe section under roads, which was 240 feet in length and more than 30 feet below HWY 433. The pipe is coated with fusion bonded epoxy (FBE) and was installed by horizontal directional drill. During construction, Denbury welded the pipe joints using an API 1104 qualified welding procedure. The procedure specified using an E6010 electrode root pass, followed by an E9018 electrode hot pass, then E10045 electrode for subsequent passes.

The maximum operating pressure of the Delhi Pipeline is 2160 pounds per square inch gauge (psig). At the time of the rupture, Denbury was operating the Delhi Pipeline at an estimated pressure of 1400 psig, which was above the 1070 psig needed to maintain CO_2 in a supercritical state.

Denbury's control room isolated the failed pipeline section by remotely operating the mainline block valves (MLBVs) at Redwood, Satartia, and Tinsley. There is approximately 9.55 miles of pipe between the Tinsley and Satartia MLBVs, which are the two MLBVs closest to the rupture.

Events Leading up to the Failure

According to the National Weather Service (NWS), accumulated rainfall data between January 1, 2020, through February 29, 2020 (60 days) for each of the cities of Greenville, Greenwood, Vicksburg, and Jackson, Mississippi – which form a relative square (Figure 1) around Satartia and Yazoo County[3] – was 17.43 inches, 19.41 inches, 23.2 inches, and 23.36 inches of rain, respectively. The amount of rain recorded in these four cities was between 7.44 and 13.63 inches above the annual historical average for the same 60-day timespan. Significant variations in environmental/climate conditions such as ambient temperatures and rainfall can impact soil stability and erosion patterns. Landslides are typically associated with periods of heavy rain, particularly in susceptible areas with the right combination of slope and soil-type. On May 26, 2022, PHMSA issued an updated Advisory Bulletin to remind operators of gas and hazardous liquid pipelines of the importance of identifying and mitigating risks caused by changes in environmental and geological conditions on their pipeline facilities.

[3] Neither Yazoo City, Satartia, nor Yazoo County had historic NWS data for the desired date range.

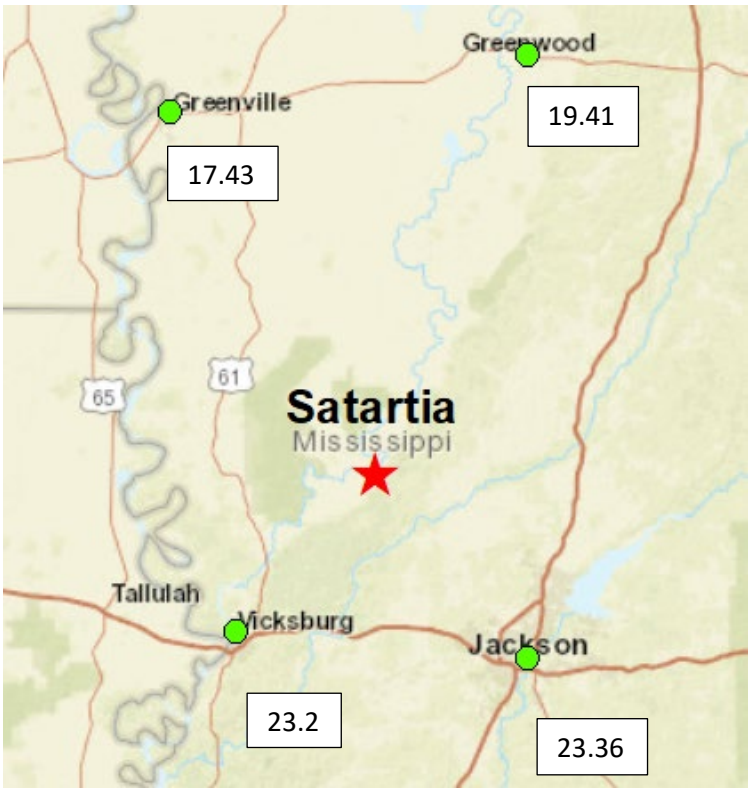

Figure 1: Map of Cities Relative to Satartia and Their Respective Rain Totals Between January 1, 2020, and February 29, 2020

On November 9, 2018, the Delhi Pipeline experienced a girth weld rupture at a valve location during pipeline reloading activities, and not attributed to natural force damage. Laboratory analysis indicated the release was the result of large thermal differential stresses being exerted on the pipeline from CO_2 loading at two different locations at the same time. The pipe between the two loading points shrank due to chilling from the CO_2, causing the girth weld connecting the pipeline to the valve body to rupture. The report found no evidence of inadequate mechanical properties or chemical composition anomalies in the ruptured weld. Denbury updated their procedure to prevent similar occurrences.

Prior to the accident, on November 8, 2019, Yazoo County first responders practiced a full-scale county response during a drill for a rail accident, however Denbury was not a participant in the drill. Local responders believe that the drill prepared them to respond to this event. Denbury had not conducted any drills with local responders since Denbury's modeling had not identified that Satartia would be impacted by a rupture of the pipeline.

Emergency Response

The Delhi Pipeline was operating normally prior to the February 22, 2020 accident.

Approximated Timeline

The following timeline was developed utilizing information provided by the Yazoo County OEM, [4] Denbury, and PHMSA investigator notes.

On February 22, 2020:

- 7:06 p.m. – Denbury's 24-inch pipeline ruptured.
- 7:07 p.m. – Denbury's control room was alerted by its supervisory control and data acquisition (SCADA) system of a pressure drop.
- 7:14 p.m. – Denbury control room remotely closed three MLBVs (one MLBV at Tinsley Station, which is upstream of the rupture site, and two MLBVs at Satartia and Redwood, which are downstream of the rupture).
- 7:15 p.m. – Denbury control room received SCADA confirmation that the MLBVs were closed.
- 7:15 p.m. – Yazoo County OEM dispatcher received an initial report of a "foul smell and green fog across the highway." Based on that information, responders responded under the assumption there was a possible chlorine leak and began contacting people from the local water utility company.
- 7:17 p.m. – Yazoo County OEM dispatcher received a call regarding a person possibly having a seizure. Responders began contacting personnel responsible for a nearby water well as the description of the report indicated chlorine gas.
- 7:19 p.m. – Denbury dispatched personnel to attempt to confirm MLBVs were closed successfully and to identify the location of the release.
- 7:26 p.m. – HWY 433 was ordered closed by local officials due to belief a chlorine leak was occurring.
- 7:30 p.m. – A responder commented that it sounded like a gas line had erupted. It was around this same time that another responder fielded a call from someone in the area who could hear a loud roar. This led the responders to believe that the accident was not chlorine gas related. First responders redirected their efforts to a possible CO_2 and hydrogen sulfide release, based on the initial first-hand reports from community members.
- 7:30 p.m. – First responders accessed a plume model generated by the NWS correlating local meteorological data with product type which indicated the CO_2 would move from the release site directly toward Satartia. Responders then called for the evacuation of Satartia. The scope of the response expanded as the CO_2 cloud dispersed, requiring an Incident Command (IC), commanded by the Chief of the District Three Volunteer Fire Department.
- 7:39 p.m. – Yazoo County OEM closed Highway 3 to traffic (intersection with HWY 433 is about 2/3-mile northwest of the rupture site).
- 7:43 p.m. – IC confirmed Denbury's CO_2 pipeline had ruptured; however, no one could get close to the release site due to the ongoing release of CO_2.
- 7:48 p.m. – Denbury's Tinsley Station Manager was contacted by IC and informed that Denbury's pipeline had ruptured. IC made Denbury aware of the response measures being taken. Denbury informed the IC that the Jackson Dome formation was shut down and that company personnel had been dispatched to check that the MLBVs were closed.

[4] The events entered in the Yazoo County OEM recording system are time stamped upon entry and may be delayed by seconds or minutes from the actual time of the event.

- 7:57 p.m. – Yazoo County OEM blocked off Mechanicsburg Road (around two miles southeast of the rupture site; intersects with HWY 433).
- 7:58 p.m. – According to Yazoo County OEM records, the Mississippi Department of Environmental Quality (MDEQ) contacted the Center for Toxicology & Environmental Health (CTEH) requesting technicians be dispatched to the rupture site with air monitoring equipment.
- 8:06 p.m. – The first Denbury representative arrived near the rupture site after confirming MLBV closures.
- 8:24 p.m. – Yazoo County OEM dispatch confirmed the second Denbury representative arrived near the rupture site.
- 9:06 p.m. – A Denbury representative from the Plano, Texas office called the National Response Center (NRC) to report their Delhi Pipeline had ruptured, releasing an estimated 222 barrels of liquid carbon dioxide (Report No. 1271847).
- 9:25 p.m. – Representatives from the CTEH and Denbury's environmental contractor E3 Environmental (E3) arrived on scene to conduct air monitoring to support the IC.
- 10:25 p.m. – Tinsley MLBV was completely closed.[5]
- 10:30 p.m. – CTEH initiated real-time air monitoring.

On February 23, 2020:

- 1:49 a.m. – The IC established a warming shelter at a local middle school for evacuees.
- 8:00 a.m. – Evacuees were allowed to return home. Air monitoring services were extended to anyone who requested the service. Evacuees were encouraged to vent their homes by opening doors and windows. The closure of HWY 433 was lifted after heavy equipment was used to clear mud that was deposited by the rupture.
- 11:34 a.m. – Real-time air monitoring concluded.

On February 24, 2020:

- 6:56 p.m., Denbury called the NRC and made the PHMSA required 48-hour update (Report No. 1272001). The update stated 21,873 barrels of liquid CO_2 had been released.[5]

Personnel from the Vicksburg Fire Department, including paramedics, District Three Volunteer Fire Department, Pafford EMS, Mississippi Emergency Management Agency, CF Industries, MDEQ, Madison County Fire Department, Warren County Fire Department, NWS, Local Police Departments, Yazoo County OEM, CTEH, E3, and Denbury participated in the emergency response efforts.

Local emergency responders utilized regular media, social media posts, phone calls, and door-to-door checks to notify homeowners and affected individuals of the CO_2 release.

A total of approximately 200 people were evacuated, which included those who were evacuated out of the area and those who were not allowed to pass through the area. During post-accident interviews, PHMSA learned that individuals on HWY 433 and in the area nearest to the migrating CO_2 vapor cloud experienced vehicle engine issues. This included individuals in a vehicle off of HWY 433, who succumbed to the effects of exposure to the released CO_2 and required emergency assistance to be evacuated. PHMSA also learned that one of two residents living in a dwelling in closest proximity to the pipeline rupture

[5] Denbury reported an updated estimate of 31,405 barrels to PHMSA on November 25, 2020.

passed out upon investigating the cloud. She later came-to and was able to evacuate to safety with her partner. Denbury reported a total of forty-five people sought medical attention at local hospitals.

Emergency Response Air Monitoring Plan

CTEH (Denbury's third-party contractor) in consultation with the IC developed an air monitoring plan to ensure the safety of response personnel, the community, and site characterization. CTEH implemented the plan to monitor for concentrations of CO_2, hydrogen-sulfide (H_2S), and oxygen (O_2) using handheld real-time instrumentation throughout the community and within homes of residents who requested monitoring. Air monitoring was conducted from 10:30 p.m. on February 22, 2020, until approximately 11:30 a.m. on February 23, 2020. Monitoring was performed using calibrated RAE Systems instruments made by Honeywell.

Carbon dioxide is considered minimally toxic by inhalation, unless in higher concentrations. CO_2 is classified as an asphyxiant, displacing the oxygen in breathing air. Symptoms of CO_2 exposure may include headache and drowsiness. Those exposed to higher concentrations may experience rapid breathing, confusion, increased cardiac output, elevated blood pressure, and increased arrhythmias. Extreme CO_2 concentrations can lead to death by asphyxiation.

In the hours after the rupture, after outdoor ambient air CO_2 levels continuously measured below 5,000 ppm, responders performed initial indoor assessment monitoring within residences and church buildings potentially impacted by the accident. During initial indoor assessments, CO_2 concentrations ranged from 200 through 28,000 ppm, with six detections exceeding 5,000 ppm. In these instances, occupants of these structures were advised to open doors and windows to allow ventilation to dissipate the concentration of CO_2 and not to enter prior to re-assessment. No subsequent CO_2 readings in the hours after the accident were recorded above 3,500 ppm during re-assessments.

According to firsthand accounts, as well as secondhand accounts from first responders, there was a "rotten eggs" odor associated with the CO_2 release and gas plume. A rotten eggs odor can be attributed to the presence of H_2S, which is naturally occurring in the geologic formation that serves as a source of the CO_2 in the pipeline. PHMSA reviewed the CTEH air monitoring results and did not identify any observed readings of H_2S by monitoring equipment. The monitoring equipment's detection limit for H_2S was 0.1 ppm.

Summary of Return-to-Service

Prior to repairing the pipeline, Denbury contracted an engineering firm to develop plans to cutout the failed section of pipe and to mitigate potential future land movement. Denbury installed soil shoring along HWY 433 to stabilize the area. PHMSA evaluated the repair plan and monitored its execution.

On September 1, 2020, Denbury began replacing the failed pipe section, and on September 26, Denbury welded the new sections of pipe into the pipeline at the accident location. Mannesmann Line Pipe manufactured the newly installed 80-foot section of 24-inch nominal diameter pipe in 2019. The pipe is API 5L X70 grade, has 0.562-inch wall thickness and an ERW longitudinal weld seam, and is coated with FBE.

Denbury restarted the pipeline on October 26, 2020. Prior to the restart of the pipeline, Denbury provided PHMSA with a proposed restart plan for review and approval. Concurrently with Denbury's repair and restart efforts, PHMSA conducted an inspection of Denbury's pipeline operations, which resulted in the

issuance of various enforcement actions, including a Notice of Probable Violation in connection with this accident.[6]

Investigation Details

On February 23, 2020, at 10:09 a.m., a PHMSA AID investigator from Oklahoma City arrived at the intersection of HWY 433 and Highway 3 to meet with Denbury representatives and emergency response organizations. The group then proceeded to the site of the rupture (Figure 2). By that time, the IC had demobilized, and roadblocks had been removed. Denbury crews were in the process of setting up caution fencing and slowing traffic on HWY 433 for public and worker safety. The rupture crater was on the northeast side of HWY 433 (Figure 2).

Figure 2: Vehicle is Parked on HWY 433 - The White is Ice Generated by the Release of CO_2 - The Blue Arrow Points North (Aerial Drone Photograph Courtesy of the Mississippi Emergency Management Agency)

[6] CPF 4-2022-017-NOPV, dated May 26, 2022.

The topography along the pipeline right-of-way (ROW) in this area is a steep hill that rises from the valley containing the Big Black River to the east, goes relatively flat across the crest of the hill containing HWY 433, and then slopes downward toward the valley containing the Yazoo River to the west.

Figure 3: Crater Created by the Rupture Containing Fallen Debris (dry ice, and the failed pipe sections) (Blue Arrow is Pointing at the Pipeline Separation)

The pipeline separated at a girth weld. The pipeline self-excavated due to the discharge of CO_2. The auto refrigeration generated by the CO_2 discharge and accompanying chance in phase covered the area with a thick layer of ice (Figures 2, 3, and 4). The upstream section of pipe was not covered in ice, and a slightly jagged edge was observed on the rupture edge (Figure 4). The crater was an estimated 40-feet-deep on the downstream (HWY 433) side and about four-feet-deep on the upstream side.

Figure 4: The failed pipe sections shown separated by a few inches.

Upon release, the CO_2 transitioned from a liquid to a gaseous phase resulting in a refrigeration effect. Although the pipeline was shut down by 7:15 pm, the remaining contents of the pipe continued to vent to the atmosphere for several hours. The CO_2 was heavier than air[7] and followed a path downhill. CO_2 moved down the slope to the east and remained in the bowl of the crater. As the discharged volume increased, and without significant winds to disperse the CO_2, the CO_2 moved over the crest of the hill then west into the valley, reaching Satartia.

Plume Model

First responders utilized a plume model generated by the NWS to base the decision to evacuate Satartia (Figure 5).

[7] CO_2 has a density approximately 1.53 times that of air in standard atmospheric conditions.

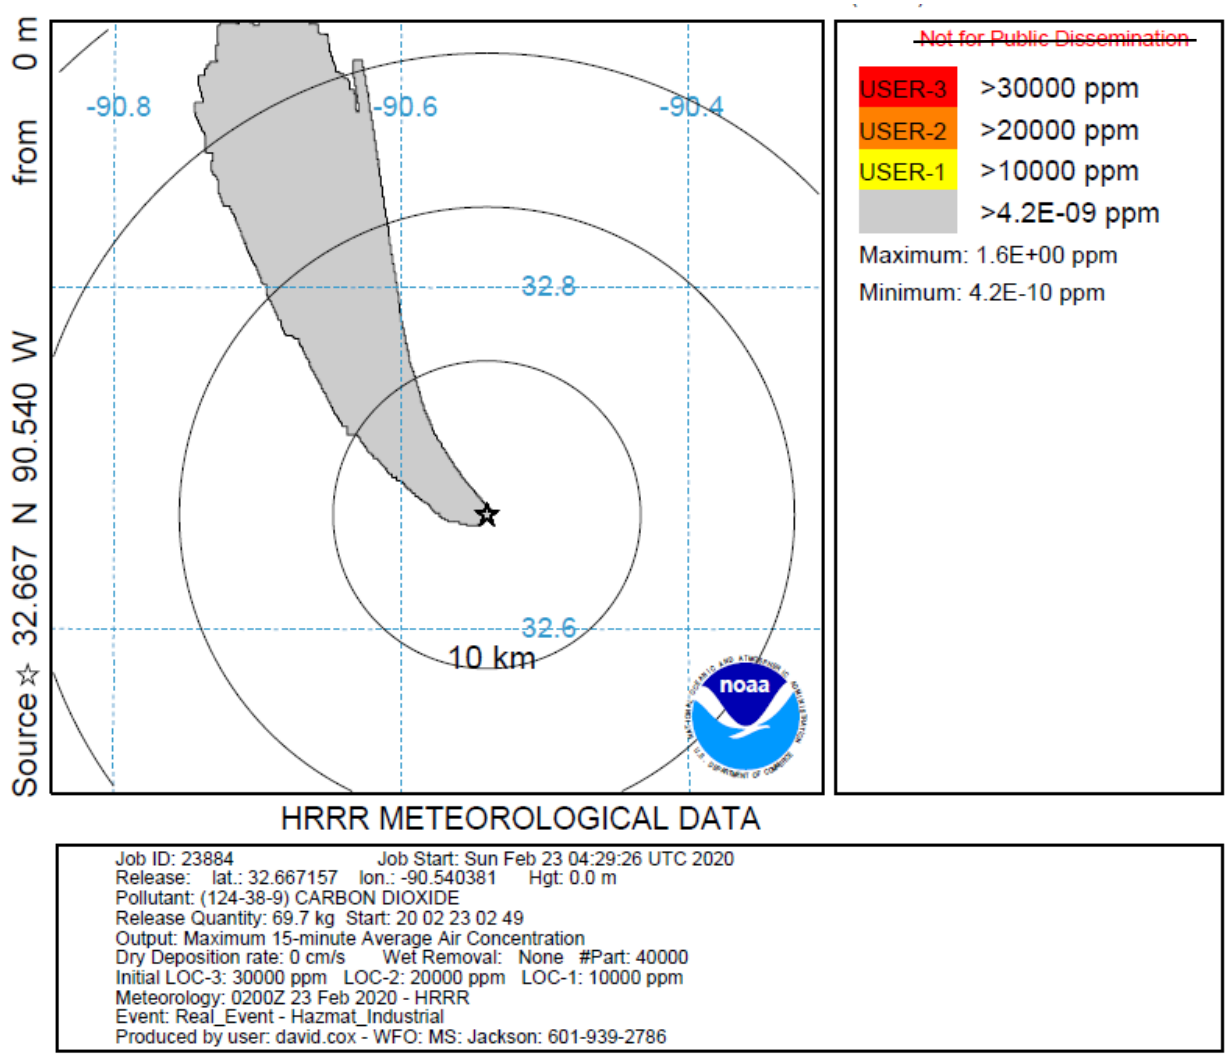

Figure 5: This Chart Shows the Plume Model Data Generated by the National Weather Service/NOAA - The Model Indicates the Direction a Plume or Cloud of CO_2 Would Have Followed from Ground Level While Dissipating, According to Atmospheric Data at the Time of the Release - Each Ring is 10 Kilometers (Satartia is Less Than Two Kilometers Northwest of Release Site, Indicated by the Star)[8]

Prior to the accident in 2011, Denbury had contracted a third-party company to generate an affected radius model for a potential CO_2 release. Denbury used the model to generate a zone along the pipeline ROW to identify pipeline segments which were within or "could affect" an HCA and to develop its Public Awareness Program (PAP).[9] The model established a zone for the Delhi Pipeline (Figure 6) that left Satartia outside of the affected radius, and therefore the pipeline segment was not identified by Denbury as a "could affect" HCA. Additionally, Satartia was not included in Denbury's PAP or considered in any local

[8] The NWS approved inclusion of the chart within this report and clarified that "Not for Public Dissemination" (in the upper right-hand corner) pertains to real-time emergency response utilization, due to inherent uncertainties with several variables.
[9] Required by 49 CFR § 195.440.

emergency response plans. The rupture location was one mile from the center of Satartia, where the entire town was evacuated.

Figure 6: Topographical Map Showing the Delhi Pipeline (Green) and Denbury's Buffer Zone (Red) on Either Side of the Pipeline and the Proximity to Satartia (Blue Star Indicates the Rupture Site)

Soil and Geohazards

The soil at the failure location is identified as a loess soil typical to the area and was relatively saturated due to the recent heavy rainfall. Dry patches of the soil observed later were powdery, confirming the loess to be silty and clayey, indicating the soil would be prone to absorb water as well as collapse or slump under the right conditions.[10] Vertical erosion of the steeply sloped hillside, made heavier by water saturation, produced enough axial loading on the pipeline to cause the girth weld to fail.

On February 23, 2020, representatives from the Mississippi Department of Transportation assessed the condition of the crater's edge along HWY 433. They determined the highway was at risk of further land movement due to current and future soil saturation from rainfall, the weight of the trees at the edge of the crater, and the HWY 433 ROW was impinged upon by the rupture. Crews were dispatched to cut down the trees and mitigate the risk of additional land movement. Soil instability along roads is not unusual in the region. The PHMSA AID investigator observed road damage from unstable soil slumping away from a road along roadways leading to the accident site. Denbury representatives mentioned that, along the Delhi pipeline, they experience two to three issues per year involving land movement. Denbury's Integrity Management Program (IMP)[11] identified "geo-technical hazards" (geohazards) as a potential risk to its pipelines but lacked additional details concerning threat assessment or preventative/mitigative measures for its operational pipelines such as: using in-line inspection tools with inertial measurement unit sensors, conducting bending strain analysis, or conducting geohazard assessments. Denbury's operations and

[10] Loess soil has a relatively high porosity (typically around 50-55%) and often contains vertical capillaries that allow the sediment to fracture and form vertical bluffs. The loess bluffs tend to erode vertically.
[11] Required by 49 CFR § 195.452.

maintenance (O&M) procedures also lacked substantive information regarding geohazard identification, assessment, remediation, and training for employees. Additionally, Denbury's pipeline patrolling program to address federal regulations[12] was commonly performed by aerial patrol. Records indicate that patrols were made at regular intervals, but no geohazards were identified at the rupture location.

In response to this rupture, PHMSA initiated a specialized review of Denbury's IMP and O&M activities. PHMSA's investigation identified that Denbury did not address the risk of geohazards to the pipeline and take adequate preventive and mitigative measures prior to the accident. PHMSA has made specific recommendations for the development of the company's geohazards program, which the company has initiated.

Welding Procedure

Denbury hired DNV prior to the construction of the pipeline to develop its welding procedure. The welding procedure was developed to API 1104, 20th edition and was qualified. The procedure utilized an E6010 electrode root pass, an E9018G electrode hot pass and E10045 electrode filler and cap pass. In 2009, a welding procedure utilizing an E10045 electrode was a pipeline construction industry leading development. Prior industry practice was to utilize cellulosic-type electrodes.

Laboratory and Root Cause Analyses

Once shoring was installed at the rupture site, the upstream pipe was excavated, and two failed pipe sections were cut out. On March 11, 2020, the two failure samples were secured and shipped to DNV's laboratory in Columbus, Ohio for metallurgical analysis. Denbury worked with Mears to provide DNV with a testing protocol to facilitate analysis. Mott MacDonald performed a site-specific soil movement analysis to estimate soil loading on the pipeline and perform a stress analysis. Mears performed a Root Cause Analysis utilizing the above information, coupled with information from original construction documentation, site observations, operating and maintenance records, and related information.

Denbury reported the results of the metallurgical findings and stress evaluations in a written accident report on the PHMSA Form 7000.1 and indicated soil movement upstream of the failure location induced axial stresses sufficient to cause an overload condition, and the soil movement was promoted by unusually heavy rainfall. There were no material defects observed with the pipe or the failed weld which could have contributed to the failure.

PHMSA notes the failed girth weld exhibited both ductile and brittle fracture appearances. A typical overload condition in these circumstances is expected to be ductile, unless the grain structure of the steel is susceptible to brittle failure, or the material has been chilled below its transition temperature from ductile to brittle behavior. A failure scenario whereby a leak initiates, and the refrigeration effect associated with vaporization of the liquid CO_2 results in a brittle failure is plausible, although a distinct failure origin within the girth weld was not identified.

Findings and Contributing Factors

PHMSA has determined that the failure of the Delhi Pipeline was a result of soil movement which caused excessive axial loading leading to failure at the girth weld. Area topography, soil type, and large amounts of rain over the preceding months saturated and vertically eroded the loess soil on the side of the hill above the pipeline. It is unclear whether prevalent warmer temperatures in the two months preceding the heavy rainfall could have contributed to the soil instability as well.

[12] Required by 49 CFR § 195.412.

Contributing factors include:

- Denbury's O&M procedures did not appear to address the potential for pipeline damage due to soil instability despite having prior experience with and knowledge of land movement risks.
- Denbury's IMP did not appear to address integrity threat identification and/or assessment for geohazards or preventative or mitigative measures.
- Denbury's aerial patrols did not identify a geohazard at the failure location prior to the accident.
- Denbury's CO_2 dispersion model underestimated the potential affected area that could be impacted by a release. As a result, the pipeline segment was not identified as a "could affect" HCA, and Satartia was not included in Denbury's PAP.
- Denbury did not notify local responders advising them of a potential failure. Local responders contacted Denbury approximately 40-minutes after the rupture. This led to confusion in understanding circumstances associated with the emergency and hindered the ability of first responders and community members to safely navigate the emergency.

DESCRIPTION OF INCIDENT
///THIS IS A PHMSA 48HR UPDATE TO NRC REPORT 1271847///

UPDATE: THE CORRECT LAT/LONG FOR THE INCIDENT IS 32.65785 NORTH AND
-90.53695 WEST.
TWO HUNDRED PRIVATE CITIZENS WERE EVACUATED FROM THEIR HOMES IN THE

AREA OF THE RELEASE.
FORTY FIVE PEOPLE WERE TAKEN TO A HOSPITAL. THE NUMBER OF PEOPLE TAKEN TO A HOSPITAL DUE TO INJURIES IS UNKNOWN
TWO PEOPLE ARE STILL AT THE HOSPITAL AS OF 24-FEB-20. THE RELEASE WAS COMPLETELY SECURED AT 23:08HRS ON SATURDAY THE 22-FEB-20. ROAD CLOSURES AND EVACUATION ORDER WAS LIFTED AT 08:00AM ON SUNDAY FEBRUARY 23RD. THE TOTAL AMOUNT OF THE RELEASE WAS DETERMINED TO BE 21,873 BARRELS OF CARBON DIOXIDE GAS. THE EVACUATION RADIUS WAS .25 MILES. TV NEWS AND POSSIBLY NEWSPAPERS IN THE LOCAL AREA AS WELL AS NATIONAL NEWS REPORTED THE INCIDENT. RELEASE DURATION WAS 4 HOURS. PHMSA, MS OIL AND GAS, MS DEQ WERE NOTIFIED. MS DEQ, STATE POLICE, LOCAL FD, LOCAL PD, EMS AND HWY PATROL WERE ALL ON SCENE.

ORIGINAL REPORT: CARBON DIOXIDE RELEASED FROM A 24 INCH PIPELINE DUE TO AN UNKNOWN CAUSE AT THIS TIME. ACCIDENT REPORT - HAZARDOUS LIQUID PIPELINE SYSTEMS

A federal agency may not conduct or sponsor, and a person is not required to respond to, nor shall a person be subject to a penalty for failure to comply with a collection of information subject to the requirements of the Paperwork Reduction Act unless that collection of information displays a current valid OMB Control Number. The OMB Control Number for this information collection is 2137-0047. All responses to the collection of information are mandatory. Send comments regarding this burden or any other aspect of this collection of information, including suggestions for reducing the burden to: Information Collection Clearance Officer, PHMSA, Office of Pipeline Safety (PHP-30) 1200 New Jersey Avenue, SE, Washington, D.C. 20590.

INSTRUCTIONS

Important: *Please read the separate instructions for completing this form before you begin. They clarify the information requested and provide specific examples. If you do not have a copy of the instructions, you can obtain one from the PHMSA Pipeline Safety Community Web Page at http://www.phmsa.dot.gov/pipeline/library/forms.*

PART A - KEY REPORT INFORMATION

Report Type: *(select all that apply)*	**Original:**	**Supplemental:**	**Final:**
		Yes	**Yes**
Last Revision Date:	11/25/2020		
1. Operator's OPS-issued Operator Identification Number (OPID):	32545		
2. Name of Operator	DENBURY GULF COAST PIPELINES, LLC		
3. Address of Operator:			
3a. Street Address	5851 LEGACY CIRCLE SUITE 1200		
3b. City	PLANO		
3c. State	Texas		
3d. Zip Code	75024		
4. Local time *(24-hr clock)* and date of the Accident:	02/22/2020 19:07		
5. Location of Accident:			
Latitude / Longitude	32.65785, -90.53695		
6. National Response Center Report Number (if applicable):	1271847		
7. Local time *(24-hr clock)* and date of initial telephonic report to the National Response Center (if applicable):	02/22/2020 20:51		
8. Commodity released: *(select only one, based on predominant volume released)*	CO2 (Carbon Dioxide)		
- Specify Commodity Subtype:			
- If "Other" Subtype, Describe:			
- If Biofuel/Alternative Fuel and Commodity Subtype is Ethanol Blend, then % Ethanol Blend:			
- If Biofuel/Alternative Fuel and Commodity Subtype is Biodiesel, then Biodiesel Blend e.g. B2, B20, B100			
9. Estimated volume of commodity released unintentionally (Barrels):	9,532.00		
10. Estimated volume of intentional and/or controlled release/blowdown (Barrels):	21,873.00		
11. Estimated volume of commodity recovered (Barrels):			
12. Were there fatalities?	No		
- If Yes, specify the number in each category:			
12a. Operator employees			
12b. Contractor employees working for the Operator			
12c. Non-Operator emergency responders			
12d. Workers working on the right-of-way, but NOT associated with this Operator			
12e. General public			
12f. Total fatalities (sum of above)			
13. Were there injuries requiring inpatient hospitalization?	No		
- If Yes, specify the number in each category:			
13a. Operator employees			
13b. Contractor employees working for the Operator			
13c. Non-Operator emergency responders			
13d. Workers working on the right-of-way, but NOT associated with this Operator			
13e. General public			
13f. Total injuries (sum of above)			

14. Was the pipeline/facility shut down due to the Accident?	Yes
- If No, Explain:	
- If Yes, complete Questions 14a and 14b: *(use local time, 24-hr clock)*	
14a. Local time and date of shutdown:	02/22/2020 19:15
14b. Local time pipeline/facility restarted:	10/26/2020 12:30
- Still shut down? (* Supplemental Report Required)	
15. Did the commodity ignite?	No
16. Did the commodity explode?	No
17. Number of general public evacuated:	200
18. Time sequence *(use local time, 24-hour clock)*:	
18a. Local time Operator identified Accident - effective 7- 2014 changed to "Local time Operator identified failure":	02/22/2020 20:20
18b. Local time Operator resources arrived on site:	02/22/2020 20:20

PART B - ADDITIONAL LOCATION INFORMATION

1. Was the origin of the Accident onshore?	Yes
If Yes, Complete Questions (2-12)	
If No, Complete Questions (13-15)	
- If Onshore:	
2. State:	Mississippi
3. Zip Code:	39194
4. City	Not Within a Municipality
5. County or Parish	Yazoo County
6. Operator-designated location:	Milepost/Valve Station
Specify:	6.6
7. Pipeline/Facility name:	Delhi
8. Segment name/ID:	Delhi
9. Was Accident on Federal land, other than the Outer Continental Shelf (OCS)?	No
10. Location of Accident:	Pipeline Right-of-way
11. Area of Accident (as found):	Underground
Specify:	Under soil
- If Other, Describe:	
Depth-of-Cover (in):	360
12. Did Accident occur in a crossing?	No
- If Yes, specify type below:	
- If Bridge crossing –	
Cased/ Uncased:	
- If Railroad crossing –	
Cased/ Uncased/ Bored/drilled	
- If Road crossing –	
Cased/ Uncased/ Bored/drilled	
- If Water crossing –	
Cased/ Uncased	
- Name of body of water, if commonly known:	
- Approx. water depth (ft) at the point of the Accident:	
- Select:	
- If Offshore:	
13. Approximate water depth (ft) at the point of the Accident:	
14. Origin of Accident:	
- In State waters - Specify:	
- State:	
- Area:	
- Block/Tract #:	
- Nearest County/Parish:	
- On the Outer Continental Shelf (OCS) - Specify:	
- Area:	
- Block #:	
15. Area of Accident:	

PART C - ADDITIONAL FACILITY INFORMATION

1. Is the pipeline or facility:	Interstate
2. Part of system involved in Accident:	Onshore Pipeline, Including Valve Sites
- If Onshore Breakout Tank or Storage Vessel, Including Attached Appurtenances, specify:	
3. Item involved in Accident:	Weld, including heat-affected zone
- If Pipe, specify:	
3a. Nominal diameter of pipe (in):	24
3b. Wall thickness (in):	.540

3c. SMYS (Specified Minimum Yield Strength) of pipe (psi):	80,000
3d. Pipe specification:	API 5L
3e. Pipe Seam , specify:	Longitudinal ERW - High Frequency
- If Other, Describe:	
3f. Pipe manufacturer:	Stupp Corporation
3g. Year of manufacture:	2007
3h. Pipeline coating type at point of Accident, specify:	Field Applied Epoxy
- If Other, Describe:	
- If Weld, including heat-affected zone, specify. If Pipe Girth Weld, 3a through 3h above are required:	Pipe Girth Weld
- If Other, Describe:	
- If Valve, specify:	
- If Mainline, specify:	
- If Other, Describe:	
3i. Manufactured by:	
3j. Year of manufacture:	
- If Tank/Vessel, specify:	
- If Other - Describe:	
- If Other, describe:	
4. Year item involved in Accident was installed:	2009
5. Material involved in Accident:	Carbon Steel
- If Material other than Carbon Steel, specify:	
6. Type of Accident Involved:	Other
- If Mechanical Puncture – Specify Approx. size:	
in. (axial) by	
in. (circumferential)	
- If Leak - Select Type:	
- If Other, Describe:	
- If Rupture - Select Orientation:	
- If Other, Describe:	
Approx. size: in. (widest opening) by	
in. (length circumferentially or axially)	
- If Other – Describe:	Guillotine Type Failure

PART D - ADDITIONAL CONSEQUENCE INFORMATION

1. Wildlife impact:	No
1a. If Yes, specify all that apply:	
- Fish/aquatic	
- Birds	
- Terrestrial	
2. Soil contamination:	No
3. Long term impact assessment performed or planned:	No
4. Anticipated remediation:	No
4a. If Yes, specify all that apply:	
- Surface water	
- Groundwater	
- Soil	
- Vegetation	
- Wildlife	
5. Water contamination:	No
5a. If Yes, specify all that apply:	
- Ocean/Seawater	
- Surface	
- Groundwater	
- Drinking water: *(Select one or both)*	
- Private Well	
- Public Water Intake	
5b. Estimated amount released in or reaching water (Barrels):	
5c. Name of body of water, if commonly known:	
6. At the location of this Accident, had the pipeline segment or facility been identified as one that "could affect" a High Consequence Area (HCA) as determined in the Operator's Integrity Management Program?	No
7. Did the released commodity reach or occur in one or more High Consequence Area (HCA)?	Yes
7a. If Yes, specify HCA type(s): *(Select all that apply)*	
- Commercially Navigable Waterway:	
Was this HCA identified in the "could affect" determination for this Accident site in the Operator's Integrity Management Program?	

- High Population Area:	
Was this HCA identified in the "could affect" determination for this Accident site in the Operator's Integrity Management Program?	
- Other Populated Area	Yes
Was this HCA identified in the "could affect" determination for this Accident site in the Operator's Integrity Management Program?	No
- Unusually Sensitive Area (USA) - Drinking Water	
Was this HCA identified in the "could affect" determination for this Accident site in the Operator's Integrity Management Program?	
- Unusually Sensitive Area (USA) - Ecological	
Was this HCA identified in the "could affect" determination for this Accident site in the Operator's Integrity Management Program?	
8. Estimated cost to Operator – effective 12-2012, changed to "Estimated Property Damage":	
8a. Estimated cost of public and non-Operator private property damage paid/reimbursed by the Operator – effective 12-2012, "paid/reimbursed by the Operator" removed	$ 225,899
8b. Estimated cost of commodity lost	$ 11,130
8c. Estimated cost of Operator's property damage & repairs	$ 3,504,518
8d. Estimated cost of Operator's emergency response	$ 205,462
8e. Estimated cost of Operator's environmental remediation	$ 0
8f. Estimated other costs	$ 0
Describe:	
8g. Estimated total costs (sum of above) – effective 12-2012, changed to "Total estimated property damage (sum of above)"	$ 3,947,009

PART E - ADDITIONAL OPERATING INFORMATION

1. Estimated pressure at the point and time of the Accident (psig):	1,402.00
2. Maximum Operating Pressure (MOP) at the point and time of the Accident (psig):	2,160.00
3. Describe the pressure on the system or facility relating to the Accident (psig):	Pressure did not exceed MOP
4. Not including pressure reductions required by PHMSA regulations (such as for repairs and pipe movement), was the system or facility relating to the Accident operating under an established pressure restriction with pressure limits below those normally allowed by the MOP?	No
- If Yes, Complete 4.a and 4.b below:	
4a. Did the pressure exceed this established pressure restriction?	
4b. Was this pressure restriction mandated by PHMSA or the State?	
5. Was "Onshore Pipeline, Including Valve Sites" OR "Offshore Pipeline, Including Riser and Riser Bend" selected in PART C, Question 2?	Yes
- If Yes - (*Complete 5a. – 5f below)* effective 12-2012, changed to *"(Complete 5.a – 5.e below)"*	
5a. Type of upstream valve used to initially isolate release source:	Remotely Controlled
5b. Type of downstream valve used to initially isolate release source:	Remotely Controlled
5c. Length of segment isolated between valves (ft):	50,406
5d. Is the pipeline configured to accommodate internal inspection tools?	Yes
- If No, Which physical features limit tool accommodation? (*select all that apply)*	
- Changes in line pipe diameter	
- Presence of unsuitable mainline valves	
- Tight or mitered pipe bends	
- Other passage restrictions (i.e. unbarred tee's, projecting instrumentation, etc.)	
- Extra thick pipe wall (applicable only for magnetic flux leakage internal inspection tools)	
- Other -	
- If Other, Describe:	
5e. For this pipeline, are there operational factors which significantly complicate the execution of an internal inspection tool run?	Yes
- If Yes, Which operational factors complicate execution? (*select all that apply*)	
- Excessive debris or scale, wax, or other wall buildup	

- Low operating pressure(s)	
- Low flow or absence of flow	Yes
- Incompatible commodity	
- Other -	
- If Other, Describe:	
5f. Function of pipeline system:	> 20% SMYS Regulated Trunkline/Transmission
6. Was a Supervisory Control and Data Acquisition (SCADA)-based system in place on the pipeline or facility involved in the Accident?	Yes
If Yes -	
6a. Was it operating at the time of the Accident?	Yes
6b. Was it fully functional at the time of the Accident?	Yes
6c. Did SCADA-based information (such as alarm(s), alert(s), event(s), and/or volume calculations) assist with the detection of the Accident?	Yes
6d. Did SCADA-based information (such as alarm(s), alert(s), event(s), and/or volume calculations) assist with the confirmation of the Accident?	Yes
7. Was a CPM leak detection system in place on the pipeline or facility involved in the Accident?	No
- If Yes:	
7a. Was it operating at the time of the Accident?	
7b. Was it fully functional at the time of the Accident?	
7c. Did CPM leak detection system information (such as alarm (s), alert(s), event(s), and/or volume calculations) assist with the detection of the Accident?	
7d. Did CPM leak detection system information (such as alarm (s), alert(s), event(s), and/or volume calculations) assist with the confirmation of the Accident?	
8. How was the Accident initially identified for the Operator?	CPM leak detection system or SCADA-based information (such as alarm(s), alert(s), event(s), and/or volume calculations)
- If Other, Specify:	
8a. If "Controller", "Local Operating Personnel", including contractors", "Air Patrol", or "Ground Patrol by Operator or its contractor" is selected in Question 8, specify:	
9. Was an investigation initiated into whether or not the controller(s) or control room issues were the cause of or a contributing factor to the Accident?	Yes, specify investigation result(s): (select all that apply)
- If No, the Operator did not find that an investigation of the controller(s) actions or control room issues was necessary due to: *(provide an explanation for why the operator did not investigate)*	
- If Yes, specify investigation result(s): *(select all that apply)*	
- Investigation reviewed work schedule rotations, continuous hours of service (while working for the Operator), and other factors associated with fatigue	Yes
- Investigation did NOT review work schedule rotations, continuous hours of service (while working for the Operator), and other factors associated with fatigue	
Provide an explanation for why not:	
- Investigation identified no control room issues	Yes
- Investigation identified no controller issues	Yes
- Investigation identified incorrect controller action or controller error	
- Investigation identified that fatigue may have affected the controller(s) involved or impacted the involved controller(s) response	
- Investigation identified incorrect procedures	
- Investigation identified incorrect control room equipment operation	
- Investigation identified maintenance activities that affected control room operations, procedures, and/or controller response	
- Investigation identified areas other than those above:	
Describe:	

PART F - DRUG & ALCOHOL TESTING INFORMATION

1. As a result of this Accident, were any Operator employees tested under the post-accident drug and alcohol testing requirements of DOT's Drug & Alcohol Testing regulations?	No
- If Yes:	
1a. Specify how many were tested:	

1b. Specify how many failed:	
2. As a result of this Accident, were any Operator contractor employees tested under the post-accident drug and alcohol testing requirements of DOT's Drug & Alcohol Testing regulations?	No
- If Yes:	
2a. Specify how many were tested:	
2b. Specify how many failed:	

PART G – APPARENT CAUSE

Select only one box from PART G in shaded column on left representing the APPARENT Cause of the Accident, and answer the questions on the right. Describe secondary, contributing or root causes of the Accident in the narrative (PART H).

Apparent Cause:	G2 - Natural Force Damage

G1 - Corrosion Failure - only one **sub-cause** can be picked from shaded left-hand column

Corrosion Failure – Sub-Cause:	
- If External Corrosion:	
1. Results of visual examination:	
- If Other, Describe:	
2. Type of corrosion: *(select all that apply)*	
- Galvanic	
- Atmospheric	
- Stray Current	
- Microbiological	
- Selective Seam	
- Other:	
- If Other, Describe:	
3. The type(s) of corrosion selected in Question 2 is based on the following: *(select all that apply)*	
- Field examination	
- Determined by metallurgical analysis	
- Other:	
- If Other, Describe:	
4. Was the failed item buried under the ground?	
- If Yes :	
4a. Was failed item considered to be under cathodic protection at the time of the Accident?	
If Yes - Year protection started:	
4b. Was shielding, tenting, or disbonding of coating evident at the point of the Accident?	
4c. Has one or more Cathodic Protection Survey been conducted at the point of the Accident?	
If "Yes, CP Annual Survey" – Most recent year conducted:	
If "Yes, Close Interval Survey" – Most recent year conducted:	
If "Yes, Other CP Survey" – Most recent year conducted:	
- If No:	
4d. Was the failed item externally coated or painted?	
5. Was there observable damage to the coating or paint in the vicinity of the corrosion?	
- If Internal Corrosion:	
6. Results of visual examination:	
- Other:	
7. Type of corrosion *(select all that apply)*: -	
- Corrosive Commodity	
- Water drop-out/Acid	
- Microbiological	
- Erosion	
- Other:	
- If Other, Describe:	
8. The cause(s) of corrosion selected in Question 7 is based on the following *(select all that apply)*: -	
- Field examination	
- Determined by metallurgical analysis	
- Other:	
- If Other, Describe:	
9. Location of corrosion *(select all that apply)*: -	
- Low point in pipe	
- Elbow	
- Other:	

- If Other, Describe:	
10. Was the commodity treated with corrosion inhibitors or biocides?	
11. Was the interior coated or lined with protective coating?	
12. Were cleaning/dewatering pigs (or other operations) routinely utilized?	
13. Were corrosion coupons routinely utilized?	
Complete the following if any Corrosion Failure sub-cause is selected AND the "Item Involved in Accident" (from PART C, Question 3) is Tank/Vessel.	
14. List the year of the most recent inspections:	
14a. API Std 653 Out-of-Service Inspection	
- No Out-of-Service Inspection completed	
14b. API Std 653 In-Service Inspection	
- No In-Service Inspection completed	
Complete the following if any Corrosion Failure sub-cause is selected AND the "Item Involved in Accident" (from PART C, Question 3) is Pipe or Weld.	
15. Has one or more internal inspection tool collected data at the point of the Accident?	
15a. If Yes, for each tool used, select type of internal inspection tool and indicate most recent year run: -	
- Magnetic Flux Leakage Tool	
Most recent year:	
- Ultrasonic	
Most recent year:	
- Geometry	
Most recent year:	
- Caliper	
Most recent year:	
- Crack	
Most recent year:	
- Hard Spot	
Most recent year:	
- Combination Tool	
Most recent year:	
- Transverse Field/Triaxial	
Most recent year:	
- Other	
Most recent year:	
Describe:	
16. Has one or more hydrotest or other pressure test been conducted since original construction at the point of the Accident?	
If Yes -	
Most recent year tested:	
Test pressure:	
17. Has one or more Direct Assessment been conducted on this segment?	
- If Yes, and an investigative dig was conducted at the point of the Accident::	
Most recent year conducted:	
- If Yes, but the point of the Accident was not identified as a dig site:	
Most recent year conducted:	
18. Has one or more non-destructive examination been conducted at the point of the Accident since January 1, 2002?	
18a. If Yes, for each examination conducted since January 1, 2002, select type of non-destructive examination and indicate most recent year the examination was conducted:	
- Radiography	
Most recent year conducted:	
- Guided Wave Ultrasonic	
Most recent year conducted:	
- Handheld Ultrasonic Tool	
Most recent year conducted:	
- Wet Magnetic Particle Test	
Most recent year conducted:	
- Dry Magnetic Particle Test	
Most recent year conducted:	
- Other	
Most recent year conducted:	
Describe:	

G2 - Natural Force Damage - only one **sub-cause** can be picked from shaded left-handed column

Natural Force Damage – Sub-Cause:	Heavy Rains/Floods
- If Earth Movement, NOT due to Heavy Rains/Floods:	
1. Specify:	

- If Other, Describe:	
- If Heavy Rains/Floods:	
2. Specify:	Other
- If Other, Describe:	,Soil movement, promoted by unusually high rainfall averages and not a singular event, induced axial stresses sufficient to cause an overload condition.,,
- If Lightning:	
3. Specify:	
- If Temperature:	
4. Specify:	
- If Other, Describe:	
- If Other Natural Force Damage:	
5. Describe:	
Complete the following if any Natural Force Damage sub-cause is selected.	
6. Were the natural forces causing the Accident generated in conjunction with an extreme weather event?	No
6a. If Yes, specify: *(select all that apply)*	
- Hurricane	
- Tropical Storm	
- Tornado	
- Other	
- If Other, Describe:	
G3 - Excavation Damage - only one **sub-cause** can be picked from shaded left-hand column	
Excavation Damage – Sub-Cause:	
- If Previous Damage due to Excavation Activity: Complete Questions 1-5 ONLY IF the "Item Involved in Accident" (from PART C, Question 3) is Pipe or Weld.	
1. Has one or more internal inspection tool collected data at the point of the Accident?	
1a. If Yes, for each tool used, select type of internal inspection tool and indicate most recent year run: -	
- Magnetic Flux Leakage	
Most recent year conducted:	
- Ultrasonic	
Most recent year conducted:	
- Geometry	
Most recent year conducted:	
- Caliper	
Most recent year conducted:	
- Crack	
Most recent year conducted:	
- Hard Spot	
Most recent year conducted:	
- Combination Tool	
Most recent year conducted:	
- Transverse Field/Triaxial	
Most recent year conducted:	
- Other	
Most recent year conducted:	
Describe:	
2. Do you have reason to believe that the internal inspection was completed BEFORE the damage was sustained?	
3. Has one or more hydrotest or other pressure test been conducted since original construction at the point of the Accident?	
- If Yes:	
Most recent year tested:	
Test pressure (psig):	
4. Has one or more Direct Assessment been conducted on the pipeline segment?	
- If Yes, and an investigative dig was conducted at the point of the Accident:	
Most recent year conducted:	
- If Yes, but the point of the Accident was not identified as a dig site:	
Most recent year conducted:	
5. Has one or more non-destructive examination been conducted at the point of the Accident since January 1, 2002?	
5a. If Yes, for each examination, conducted since January 1, 2002, select type of non-destructive examination and indicate most recent year the examination was conducted:	
- Radiography	
Most recent year conducted:	
- Guided Wave Ultrasonic	

Most recent year conducted:	
- Handheld Ultrasonic Tool	
Most recent year conducted:	
- Wet Magnetic Particle Test	
Most recent year conducted:	
- Dry Magnetic Particle Test	
Most recent year conducted:	
- Other	
Most recent year conducted:	
Describe:	
Complete the following if Excavation Damage by Third Party is selected as the sub-cause.	
6. Did the operator get prior notification of the excavation activity?	
6a. If Yes, Notification received from: *(select all that apply)* -	
- One-Call System	
- Excavator	
- Contractor	
- Landowner	
Complete the following mandatory CGA-DIRT Program questions if any Excavation Damage sub-cause is selected.	
7. Do you want PHMSA to upload the following information to CGA-DIRT (www.cga-dirt.com)?	
8. Right-of-Way where event occurred: *(select all that apply)* -	
- Public	
- If "Public", Specify:	
- Private	
- If "Private", Specify:	
- Pipeline Property/Easement	
- Power/Transmission Line	
- Railroad	
- Dedicated Public Utility Easement	
- Federal Land	
- Data not collected	
- Unknown/Other	
9. Type of excavator:	
10. Type of excavation equipment:	
11. Type of work performed:	
12. Was the One-Call Center notified?	
12a. If Yes, specify ticket number:	
12b. If this is a State where more than a single One-Call Center exists, list the name of the One-Call Center notified:	
13. Type of Locator:	
14. Were facility locate marks visible in the area of excavation?	
15. Were facilities marked correctly?	
16. Did the damage cause an interruption in service?	
16a. If Yes, specify duration of the interruption (hours)	
17. Description of the CGA-DIRT Root Cause *(select only the one predominant first level CGA-DIRT Root Cause and then, where available as a choice, the one predominant second level CGA-DIRT Root Cause as well):*	
Root Cause:	
- If One-Call Notification Practices Not Sufficient, specify:	
- If Locating Practices Not Sufficient, specify:	
- If Excavation Practices Not Sufficient, specify:	
- If Other/None of the Above, explain:	
G4 - Other Outside Force Damage - *only one **sub-cause** can be selected from the shaded left-hand column*	
Other Outside Force Damage – Sub-Cause:	
- If Damage by Car, Truck, or Other Motorized Vehicle/Equipment NOT Engaged in Excavation:	
1. Vehicle/Equipment operated by:	
- If Damage by Boats, Barges, Drilling Rigs, or Other Maritime Equipment or Vessels Set Adrift or Which Have Otherwise Lost Their Mooring:	
2. Select one or more of the following IF an extreme weather event was a factor:	
- Hurricane	
- Tropical Storm	
- Tornado	
- Heavy Rains/Flood	
- Other	
- If Other, Describe:	
- If Previous Mechanical Damage NOT Related to Excavation: Complete Questions 3-7 ONLY IF the "Item Involved in Accident" (from PART C, Question 3) is Pipe or Weld.	

3. Has one or more internal inspection tool collected data at the point of the Accident?	
3a. If Yes, for each tool used, select type of internal inspection tool and indicate most recent year run:	
- Magnetic Flux Leakage	
Most recent year conducted:	
- Ultrasonic	
Most recent year conducted:	
- Geometry	
Most recent year conducted:	
- Caliper	
Most recent year conducted:	
- Crack	
Most recent year conducted:	
- Hard Spot	
Most recent year conducted:	
- Combination Tool	
Most recent year conducted:	
- Transverse Field/Triaxial	
Most recent year conducted:	
- Other	
Most recent year conducted:	
Describe:	
4. Do you have reason to believe that the internal inspection was completed BEFORE the damage was sustained?	
5. Has one or more hydrotest or other pressure test been conducted since original construction at the point of the Accident?	
- If Yes:	
Most recent year tested:	
Test pressure (psig):	
6. Has one or more Direct Assessment been conducted on the pipeline segment?	
- If Yes, and an investigative dig was conducted at the point of the Accident:	
Most recent year conducted:	
- If Yes, but the point of the Accident was not identified as a dig site:	
Most recent year conducted:	
7. Has one or more non-destructive examination been conducted at the point of the Accident since January 1, 2002?	
7a. If Yes, for each examination conducted since January 1, 2002, select type of non-destructive examination and indicate most recent year the examination was conducted:	
- Radiography	
Most recent year conducted:	
- Guided Wave Ultrasonic	
Most recent year conducted:	
- Handheld Ultrasonic Tool	
Most recent year conducted:	
- Wet Magnetic Particle Test	
Most recent year conducted:	
- Dry Magnetic Particle Test	
Most recent year conducted:	
- Other	
Most recent year conducted:	
Describe:	
- If Intentional Damage:	
8. Specify:	
- If Other, Describe:	
- If Other Outside Force Damage:	
9. Describe:	

G5 - Material Failure of Pipe or Weld - only one **sub-cause** can be selected from the shaded left-hand column

Use this section to report material failures ONLY IF the "Item Involved in Accident" (from PART C, Question 3) is "Pipe" or "Weld."	
Material Failure of Pipe or Weld – Sub-Cause:	
1. The sub-cause shown above is based on the following: *(select all that apply)*	
- Field Examination	
- Determined by Metallurgical Analysis	
- Other Analysis	
- If "Other Analysis", Describe:	
- Sub-cause is Tentative or Suspected; Still Under Investigation	

(Supplemental Report required)	
- If Construction, Installation, or Fabrication-related:	
2. List contributing factors: *(select all that apply)*	
- Fatigue or Vibration-related	
Specify:	
- If Other, Describe:	
- Mechanical Stress:	
- Other	
- If Other, Describe:	
- If Environmental Cracking-related:	
3. Specify:	
- If Other - Describe:	
Complete the following if any Material Failure of Pipe or Weld sub-cause is selected.	
4. Additional factors: (*select all that apply*):	
- Dent	
- Gouge	
- Pipe Bend	
- Arc Burn	
- Crack	
- Lack of Fusion	
- Lamination	
- Buckle	
- Wrinkle	
- Misalignment	
- Burnt Steel	
- Other:	
- If Other, Describe:	
5. Has one or more internal inspection tool collected data at the point of the Accident?	
5a. If Yes, for each tool used, select type of internal inspection tool and indicate most recent year run:	
- Magnetic Flux Leakage	
Most recent year run:	
- Ultrasonic	
Most recent year run:	
- Geometry	
Most recent year run:	
- Caliper	
Most recent year run:	
- Crack	
Most recent year run:	
- Hard Spot	
Most recent year run:	
- Combination Tool	
Most recent year run:	
- Transverse Field/Triaxial	
Most recent year run:	
- Other	
Most recent year run:	
Describe:	
6. Has one or more hydrotest or other pressure test been conducted since original construction at the point of the Accident?	
- If Yes:	
Most recent year tested:	
Test pressure (psig):	
7. Has one or more Direct Assessment been conducted on the pipeline segment?	
- If Yes, and an investigative dig was conducted at the point of the Accident -	
Most recent year conducted:	
- If Yes, but the point of the Accident was not identified as a dig site -	
Most recent year conducted:	
8. Has one or more non-destructive examination(s) been conducted at the point of the Accident since January 1, 2002?	
8a. If Yes, for each examination conducted since January 1, 2002, select type of non-destructive examination and indicate most recent year the examination was conducted: -	
- Radiography	
Most recent year conducted:	
- Guided Wave Ultrasonic	
Most recent year conducted:	
- Handheld Ultrasonic Tool	

Most recent year conducted:	
- Wet Magnetic Particle Test	
Most recent year conducted:	
- Dry Magnetic Particle Test	
Most recent year conducted:	
- Other	
Most recent year conducted:	
Describe:	
G6 – Equipment Failure - only one **sub-cause** can be selected from the shaded left-hand column	
Equipment Failure – Sub-Cause:	
- If Malfunction of Control/Relief Equipment:	
1. Specify: *(select all that apply)* -	
- Control Valve	
- Instrumentation	
- SCADA	
- Communications	
- Block Valve	
- Check Valve	
- Relief Valve	
- Power Failure	
- Stopple/Control Fitting	
- ESD System Failure	
- Other	
- If Other – Describe:	
- If Pump or Pump-related Equipment:	
2. Specify:	
- If Other – Describe:	
- If Threaded Connection/Coupling Failure:	
3. Specify:	
- If Other – Describe:	
- If Non-threaded Connection Failure:	
4. Specify:	
- If Other – Describe:	
- If Other Equipment Failure:	
5. Describe:	
Complete the following if any Equipment Failure sub-cause is selected.	
6. Additional factors that contributed to the equipment failure: *(select all that apply)*	
- Excessive vibration	
- Overpressurization	
- No support or loss of support	
- Manufacturing defect	
- Loss of electricity	
- Improper installation	
- Mismatched items (different manufacturer for tubing and tubing fittings)	
- Dissimilar metals	
- Breakdown of soft goods due to compatibility issues with transported commodity	
- Valve vault or valve can contributed to the release	
- Alarm/status failure	
- Misalignment	
- Thermal stress	
- Other	
- If Other, Describe:	
G7 - Incorrect Operation - only one **sub-cause** can be selected from the shaded left-hand column	
Incorrect Operation – Sub-Cause:	
- If Tank, Vessel, or Sump/Separator Allowed or Caused to Overfill or Overflow	
1. Specify:	
- If Other, Describe:	

- If Other Incorrect Operation	
2. Describe:	
Complete the following if any Incorrect Operation sub-cause is selected.	
3. Was this Accident related to *(select all that apply)*: -	
- Inadequate procedure	
- No procedure established	
- Failure to follow procedure	
- Other:	
- If Other, Describe:	
4. What category type was the activity that caused the Accident?	
5. Was the task(s) that led to the Accident identified as a covered task in your Operator Qualification Program?	
5a. If Yes, were the individuals performing the task(s) qualified for the task(s)?	

G8 - Other Accident Cause - only one **sub-cause** can be selected from the shaded left-hand column

Other Accident Cause – Sub-Cause:	
- If Miscellaneous:	
1. Describe:	
- If Unknown:	
2. Specify:	

PART H - NARRATIVE DESCRIPTION OF THE ACCIDENT

On 2/22/2020 at 19:07, the Denbury Control Center (DCC) observed a low-pressure alarm at the Satartia motor operated valve (MOV) location on the Delhi segment. The Control Center Supervisor was notified and at 19:15 the upstream MOV, downstream MOV, and the Satartia MOV were closed by the DCC. Denbury operations personnel were immediately notified by the DCC of low-pressure alarms and valve closures and were mobilized to the area in addition to emergency response contractors. While mobilization of personnel occurred, the DCC closed all CO2 sources to Delhi segment between 19:26 and 19:28. At 19:54, a Denbury representative contacted the Tri-Community Fire Chief, who was on-site and identified himself as the Incident Commander on location acknowledging the incident was being managed in the Unified Command. Denbury personnel arrived on-site at 20:20 to confirm the Delhi segment had experienced a pipeline failure upstream of the Hwy 433 road crossing. At 20:21, a Denbury representative contacted the Yazoo County EMA, who was directing the Yazoo County Sheriffs Department, MS Highway Patrol, and MDOT. The Yazoo County EMA confirmed that they began facilitating the evacuation of residence near Satartia, MS at approximately 19:20. MSDEQ was notified at 19:58. Both MSDEQ and MEMA were on-scene and performing supporting agency roles during the emergency phase of the response (4 hours). At 20:51, the NRC was notified, and the CO2 leak was reported (NRC #1271847). At 21:36 emergency response contractors arrived on-site and began conducting preliminary air-monitoring for response personnel. At 21:55 additional emergency response contractors arrived on-site and began conducting community air monitoring and atmospheric testing in and around the failure site and the City of Satartia and the surrounding area. Air monitoring and atmospheric testing continued throughout the night. At 23:06, Denbury personnel observed no product coming from the failure location. At 0:00 on 2/23/2020, an Operation Period Briefing was conducted by the Unified Command. During the briefing, the incident command team instructed responders to continue air monitoring, conduct reconnaissance within the evacuated areas to ensure no people were left behind, clear the debris and soil off of HWY 433, and begin developing a plan to lift the evacuation. At 06:00 a planning meeting was conducted by the Unified Command. The recon team confirmed all personnel had been evacuated and reported seeing live cows, dogs, and cats throughout the evacuated area. The air monitoring team also reported that CO2 levels were down to ambient levels and the evacuation could be lifted. At 08:00 the Unified Command gave the All Clear, and the roads were opened and residents in the surrounding area were allowed to return to their homes. Personnel and a toxicologist from CTEH were made available to inspect homes prior to the residence re-entry. At 18:39 on 2/24/2020, the NRC was contacted and given a 48-hour update report (NRC #1272001). A total of 200 residents were evacuated and 45 residents were taken to the hospital. To Denburys knowledge, one individual was admitted to the hospital for reasons unrelated to the pipeline failure.

On 3/9/2020 pipeline samples of the failure location were removed, prepared for shipment, and sent to a testing laboratory on 3/11/2020. The results from the laboratory testing were received and shared with PHMSA on 6/26/2020.

Based on the findings of metallurgical and stress evaluations and the evidence of a code compliant pipeline, it is concluded that soil movement upstream of the failure location induced axial stresses sufficient to cause an overload condition and resulted in the pipeline rupture. Soil movement was promoted by unusually high rainfall averages and not a singular rainfall event.

The pipeline segment was repaired and on 10/26/2020 at 12:30 the pipeline was restarted with no issues.

Subject: Denbury Delhi 24-inch Transmission Line failure Root Cause Analysis – Final Report, Revised 9/02/2021

Thank you for the opportunity to provide Denbury Resources with root cause investigation and analysis for the Denbury Delhi 24-inch transmission line near Satartia, Mississippi. This revision includes additional appendices providing supporting information and responses to questions provided to Mears 4/7/2021. If you have any questions or comments, please call me at (614) 832-3896.

Sincerely,

Kevin Garrity

Executive Summary

Mears Group, Inc. (Mears) was retained by Denbury Resources (Denbury) to support investigation efforts and provide a Root Cause Analysis (RCA) in coordination with their response to a pipeline failure on the Delhi 24-inch Transmission Line near Satartia, Mississippi. The failure is reported to have occurred February 22, 2020, with a rupture approximately 6.59 miles (stationing 348+26) downstream of the Tinsley, MS station.

The investigation into the cause and contributing factors to the Delhi 24-inch failure has been undertaken through the following activities:

- In-Situ investigations at the incident location,
- Corrosion and coating related assessments,
- A review of available documents and information associated with the design, specification, construction, operation and maintenance of the pipeline infrastructure, and
- Laboratory Analysis of the Failure.

Metallurgical Testing and Failure Analysis was performed on three samples of pipe from the failure site. The metallurgical testing laboratory completed the following tests and examinations:

- Physical examination,
- Photographic documentation and videography,
- Magnetic Particle Inspection,
- Scanning electron microscopy,
- Metallographic analysis,
- Hardness testing,
- Mechanical testing, and
- Chemical analysis.

The results of the metallurgical testing have been analyzed for the purposes of this report and are relied upon in the formulation of the opinions and conclusions expressed in this report.

□□□□d □□ □□□ □□d□□□□ □r□□□□□d□□□□ pipeline failure occurred at the girth weld due to an overload of axial stress on the weld. A possible contributing factor to the failure may have been axial stresses introduced by movement. These □□d□□□□ □r□ □□□□□r□d □□ □□□ □□□□□ □□□□

1. The brittle failure originated at a girth weld. The presence of soft regions with dimples (ductile mode) and cleavage facets (brittle mode) are characteristics typical of a failure from overload conditions.
2. The failure occurred due to axial stresses. There was no indication of a pre-existing defect and a specific failure initiation site was not apparent.
3. The weld metal for both the failed girth weld and the intact weld was found to have lower hardness values than the surrounding pipe materials indicating the weld metal was weaker than the pipe material and thus, more susceptible to overload under axial stress conditions. The findings do not suggest the failure resulted from a welding quality issue.
4. There was no evidence of internal or external corrosion that may have contributed to the failure mode.
5. The mechanical and chemical testing results were in accordance with the requirements for API 5L X-80M PSL 2 line pipe.
6. The microstructure of the pipe material U/S and D/S of the failed girth weld are consistent with modern X-80M PSL 2 line pipe steel.

1.0 INTRODUCTION

Mears Group, Inc. (Mears) was retained by Denbury Resources (Denbury) to support investigation efforts and provide a Root Cause Analysis (RCA) in coordination with their response to a pipeline failure on the Delhi 24-inch Transmission Line near Satartia, Mississippi. The incident is reported to have occurred on February 22, 2020, when a failure occurred on the 24-inch Delhi Transmission Line, resulting a rupture of the pipeline.

The information, material and documentation reviewed and relied upon in the formation of the findings expressed include:

- Pipe and coating data,
- Alignment Sheets,
- Indirect inspection results,
- Google Earth™ imagery,
- As-built drawings and sketches,
- Onsite inspections,
- Field and laboratory test results,
- Metallurgical examination reports,
- Welding Procedures,
- Stress Analysis Report, and
- Personnel interviews.

The findings expressed are based upon the information reviewed to date and analyses performed to date and may be modified as new or additional information/analysis are considered.

2.0 BACKGROUND

The Delhi 24-inch Transmission Line serves as a carrier of carbon dioxide and is approximately 77.4 miles in length. The pipeline segment begins at the Denbury Tinsley Station in Yazoo County, Mississippi and continues to a meter station near Delhi, Louisiana. An overview of the pipeline segment is provided in Figure 1.

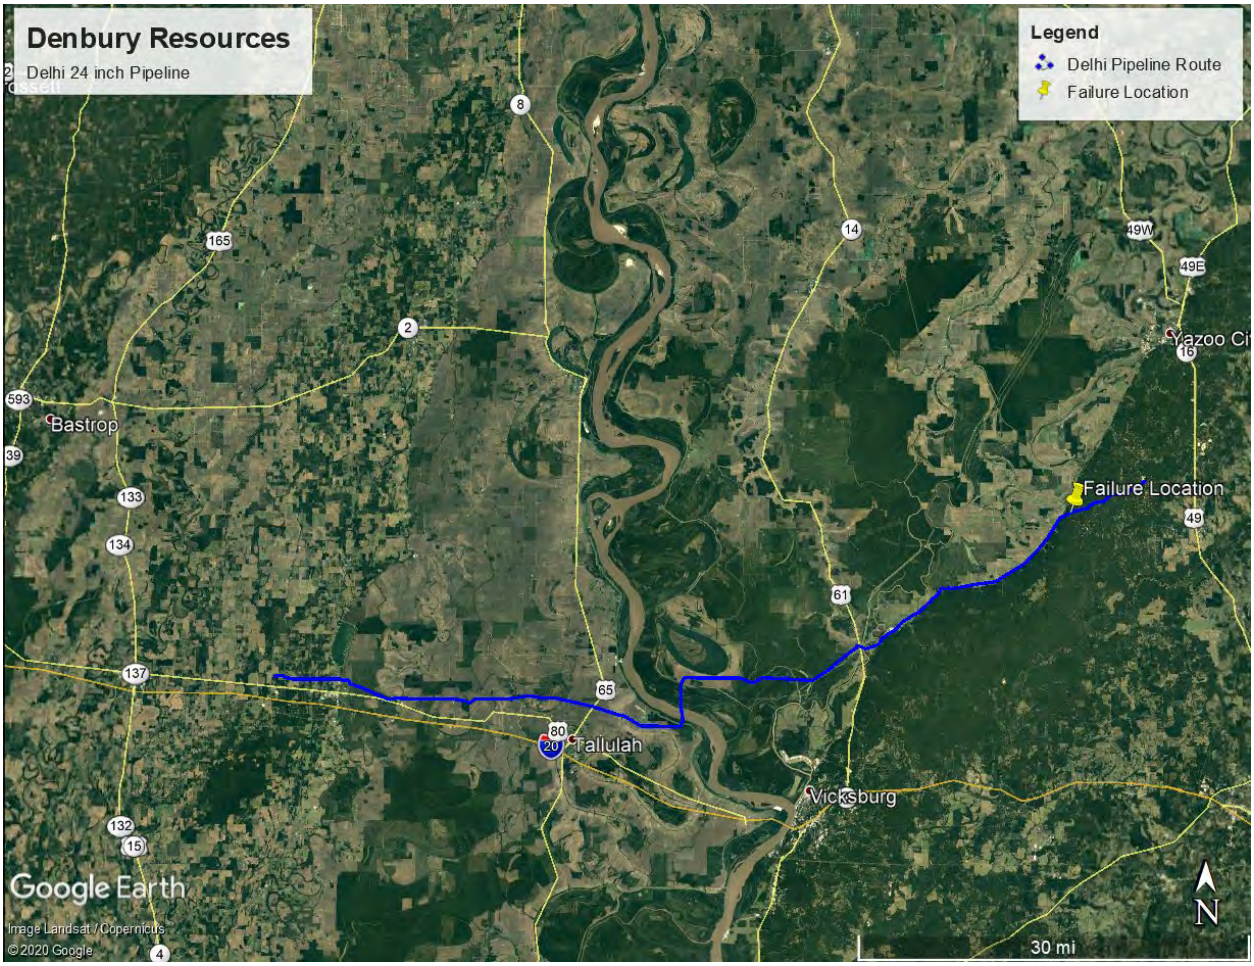

Figure 1. Delhi 24-inch Transmission Pipeline Route

2.1 Pipeline Construction Data

The Delhi 24-inch Transmission Line is documented as installed in 2009, primarily of 0.469-inch wall thickness, API 5L Grade X-80M PSL 2 piping, with a high frequency electric resistance welded (HF-ERW) seam, coated with fusion-bonded epoxy (FBE). Sections of piping installed using slick bore were constructed of 0.540-inch X-80 coated with FBE and an additional layer of abrasion-resistant overcoat (ARO). The pipeline has a diameter of 24 inches. A simplified overview of the pipeline segment is provided in Figure 2.

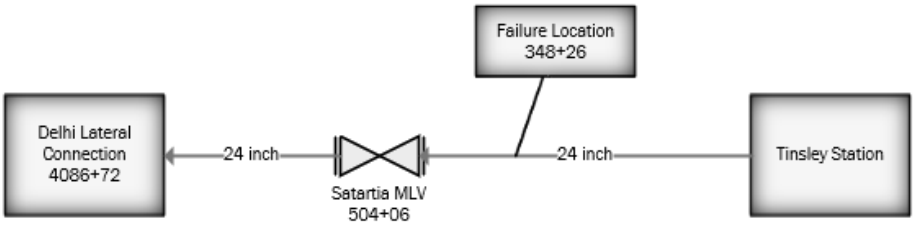

Figure 2. Simplified Delhi 24-inch Transmission Line Diagram

A summary of pipeline information for the Delhi 24-inch Transmission Line in included in Table 1.

Table 1. Pipeline Data

Pipeline Information	Delhi 24-inch Transmission Line
Line Length (miles)	77.4
Pipe Outside Diameter (inches)	24
Pipe Wall Thickness (inches)	0.469, 0.540
Pipe Grade	X-80
Maximum Allowable Operating Pressure (MAOP, psi)	2,160
Normal Operating Stress Level (psi)	1,200-1,450
Pressure at Time of Failure (psi)	1,336
Pipe Seam Type	ERW
Product Carried	Carbon Dioxide (dry)
Pipe Construction Date	2009
Pipe Coatings (type/thickness)	FBE 14-16 mils and ARO 40 mils
Girth Weld Coatings	Liquid Epoxy – SPC-2888

A post-construction hydrostatic pressure test was reported to have been conducted on the piping in January 2009 to a minimum test pressure of 2,908 psig at the Dead Weight Location for 8 hours.

The pipeline is reported to have had impressed current cathodic protection applied since the date of construction with no interference bonds and two continuity bonds at the start and end of the pipeline section.

2.2 Incident Summary

The incident is reported to have occurred after 7:00 p.m. local time, based on resident reports and an evacuation order, on February 22, 2020 near Satartia Mississippi, when a failure occurred at a girth weld, resulting in a rupture of the pipe near a crossing of Mississippi Highway 433 approximately 1 mile southeast of Satartia. The line was shut down and valves closed at approximately 7:17 p.m. as reported by Denbury.

The failure occurred on a pipe section consisting of 24-inch diameter by 0.540-inch wall thickness API 5L Grade X-80M PSL 2 line pipe with a high frequency electric resistance welded (HF ERW) seam. The pipe at the site of the failure was installed using slick bore, coated with FBE/ARO on the pipe and liquid epoxy coating applied on the girth welds. The failure occurred at approximate stationing 348+26, about 6.59 miles downstream of the Tinsley Station at the base of a hill, significantly lower in elevation than the surface of Highway 433. The pipeline normally operates between 1,200 psig and 1,450 psig. At the time of the failure, the pressure at the Tinsley Meter Station (0+00) was 1,336 psig.

A Google Earth™ overview of the failure location is provided in Figure 3.

Figure 3. Delhi 24-inch Transmission Failure Location

A photo of the failure location post-incident is included in Figure 4.

Figure 4. Post-Incident Photo of Failure Location (Downstream to Upstream)

3.0 ROOT CAUSE ANALYSIS PROCESS

A failure action sequence was used for the purposes of performing the Root Cause Analysis.

The basic role of a root cause analysis is as follows:

- Collect information.
- Understand what happened.
- Identify the problems that caused the incident.
- Analyze each problem's root causes.
- Look beyond root causes for systemic, cultural, and organizational factors.
- Develop recommendations for remediation to improve performance and prevent repeat incidents.

Since root cause analyses are normally associated with incidents or accidents, much of the existing terminology in use refers to "incidents".

A typical Failure Action Response Sequence adapted from Guidance for Plant Personnel on Gathering Data and Samples for Materials Failure Analysis MTI catalog MTI 9539 is shown in Figure 5.

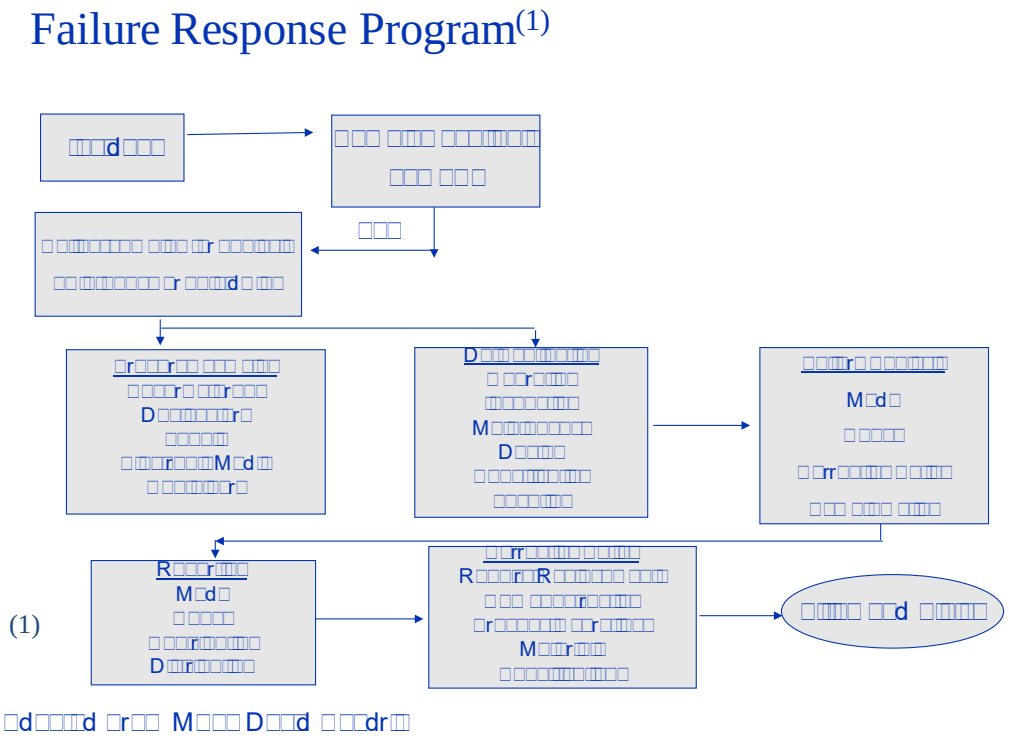

Figure 5. Failure Response Sequence

The root cause analysis focused on identifying the root cause(s) of the pipeline failure and contributing factors.

4.0 DESCRIPTION OF INVESTIGATIVE PROCESS

The investigation into the cause and contributing factors to the Delhi 24-inch Transmission line failure has been undertaken through the following activities:

1. In-Situ investigations at the release location,
2. Corrosion and coating related assessments,
3. A review of available documents and information associated with the design, specification, construction, operation and maintenance of the pipeline infrastructure, and
4. Laboratory failure analysis of the failure.

Metallurgical testing and a failure analysis were performed on three samples of pipe from the release site. The metallurgical testing lab completed the following tests and examinations:

- Physical examination,
- Photographic documentation and videography,
- Magnetic Particle Inspection,
- Scanning electron microscopy,
- Metallographic analysis,
- Hardness testing,
- Mechanical testing, and
- Chemical analysis.

The results of the metallurgical testing have been analyzed for the purposes of this report and are relied upon in the formulation of the opinions and conclusions expressed in this report.
