# Accreditation/Certification Summary

Client: Haley & Aldrich, Inc.
Job ID: 570-167861-1
Project/Site: Rosemead PCB Sampling / 209476-003

## Laboratory: Eurofins Calscience

Unless otherwise noted, all analytes for this laboratory were covered under each accreditation/certification below.

| Authority | Program | Identification Number | Expiration Date |
|---|---|---|---|
| California | State | 3082 | 07-31-24 |

The following analytes are included in this report, but the laboratory is not certified by the governing authority. This list may include analytes for which the agency does not offer certification.

| Analysis Method | Prep Method | Matrix | Analyte |
|---|---|---|---|
| 2540G | | Solid | Percent Moisture |
| 9045D | | Solid | Temperature |

| Authority | Program | Identification Number | Expiration Date |
|---|---|---|---|
| Oregon | NELAP | 4175 | 02-02-24 |

The following analytes are included in this report, but the laboratory is not certified by the governing authority. This list may include analytes for which the agency does not offer certification.

| Analysis Method | Prep Method | Matrix | Analyte |
|---|---|---|---|
| 9045D | | Solid | Temperature |

## Laboratory: Eurofins Cleveland

All accreditations/certifications held by this laboratory are listed. Not all accreditations/certifications are applicable to this report.

**To:** Virendra Patel
**Subject:** RE: 570-167861-1 Rosemead PCB Sampling / 209476-003 sample confirmation files from Eurofins Southwest
**Attachments:** 2024_0111_HAI_Revised COC.pdf

**CAUTION:** EXTERNAL EMAIL - Sent from an email domain that is not formally trusted by Eurofins.

Do not click on links or open attachments unless you recognise the sender and are certain that the content is safe.

Virendra,

The B-S samples referenced on COC page 1 of 6 should be B-5. PCB and moisture content needs to be removed from the LV-15 samples on page 6 of 6. A revised COC is attached.

Thanks,
Chris

---

Hello,

Attached please find the sample confirmation files for job 570-167861-1; Rosemead PCB Sampling / 209476-003

Please feel free to contact me if you have any questions.

Thank you.

**Virendra Patel**

# Login Sample Receipt Checklist

Client: Haley & Aldrich, Inc.

Job Number: 570-167861-1

**Login Number: 167861**
**List Number: 1**
**Creator: Le, Sunny**

**List Source: Eurofins Calscience**

| Question | Answer | Comment |
|---|---|---|
| Radioactivity wasn't checked or is </= background as measured by a survey meter. | N/A | |
| The cooler's custody seal, if present, is intact. | True | |
| Sample custody seals, if present, are intact. | True | |
| The cooler or samples do not appear to have been compromised or tampered with. | True | |
| Samples were received on ice. | True | |
| Cooler Temperature is acceptable. | True | |
| Cooler Temperature is recorded. | True | |
| COC is present. | True | |
| COC is filled out in ink and legible. | True | |
| COC is filled out with all pertinent information. | True | |
| Is the Field Sampler's name present on COC? | True | |
| There are no discrepancies between the containers received and the COC. | True | |
| Samples are received within Holding Time (excluding tests with immediate HTs) | True | |
| Sample containers have legible labels. | True | |
| Containers are not broken or leaking. | True | |
| Sample collection date/times are provided. | True | |
| Appropriate sample containers are used. | True | |
| Sample bottles are completely filled. | True | |
| Sample Preservation Verified. | True | |
| There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs | True | |
| Containers requiring zero headspace have no headspace or bubble is <6mm (1/4"). | True | |
| Multiphasic samples are not present. | True | |
| Samples do not require splitting or compositing. | True | |
| Residual Chlorine Checked. | N/A | |

# ANALYTICAL REPORT

## PREPARED FOR

Attn: Chris Tsiatsios
Haley & Aldrich, Inc.
3187 Red HIll Avenue
Suite 155
Costa Mesa, California 92626

Generated 1/29/2024 9:13:47 AM

## JOB DESCRIPTION

Rosemead Holding, LLC/ 0209476-002

## JOB NUMBER

570-168182-1

Eurofins Calscience
2841 Dow Avenue, Suite 100
Tustin CA 92780

See page two for job notes and contact information.

myEOL

## Job Notes

This report may not be reproduced except in full, and with written approval from the laboratory. The results relate only to the samples tested. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

The test results in this report relate only to the samples as received by the laboratory and will meet all requirements of the methodology, with any exceptions noted. This report shall not be reproduced except in full, without the express written approval of the laboratory. All questions should be directed to the Eurofins Calscience Project Manager.

## Authorization

Project/Site: Rosemead Holding, LLC/ 0209476-002

## Qualifiers

### Metals

| Qualifier | Qualifier Description |
|---|---|
| J | Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value. |

### General Chemistry

| Qualifier | Qualifier Description |
|---|---|
| F1 | MS and/or MSD recovery exceeds control limits. |

## Glossary

| Abbreviation | These commonly used abbreviations may or may not be present in this report. |
|---|---|
| ¤ | Listed under the "D" column to designate that the result is reported on a dry weight basis |
| %R | Percent Recovery |
| CFL | Contains Free Liquid |
| CFU | Colony Forming Unit |
| CNF | Contains No Free Liquid |
| DER | Duplicate Error Ratio (normalized absolute difference) |
| Dil Fac | Dilution Factor |
| DL | Detection Limit (DoD/DOE) |
| DL, RA, RE, IN | Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample |
| DLC | Decision Level Concentration (Radiochemistry) |
| EDL | Estimated Detection Limit (Dioxin) |
| LOD | Limit of Detection (DoD/DOE) |
| LOQ | Limit of Quantitation (DoD/DOE) |
| MCL | EPA recommended "Maximum Contaminant Level" |
| MDA | Minimum Detectable Activity (Radiochemistry) |
| MDC | Minimum Detectable Concentration (Radiochemistry) |
| MDL | Method Detection Limit |
| ML | Minimum Level (Dioxin) |
| MPN | Most Probable Number |
| MQL | Method Quantitation Limit |
| NC | Not Calculated |
| ND | Not Detected at the reporting limit (or MDL or EDL if shown) |
| NEG | Negative / Absent |
| POS | Positive / Present |
| PQL | Practical Quantitation Limit |
| PRES | Presumptive |
| QC | Quality Control |
| RER | Relative Error Ratio (Radiochemistry) |
| RL | Reporting Limit or Requested Limit (Radiochemistry) |
| RPD | Relative Percent Difference, a measure of the relative difference between two points |
| TEF | Toxicity Equivalent Factor (Dioxin) |
| TEQ | Toxicity Equivalent Quotient (Dioxin) |
| TNTC | Too Numerous To Count |

## Job ID: 570-168182-1 Eurofins Calscience

**Job Narrative**
**570-168182-1**

**Receipt**
The samples were received on 1/15/2024 4:52 PM. Unless otherwise noted below, the samples arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was 4.1º C.

**GC Semi VOA**
Method 8015B:

Method 8082A: The continuing calibration verification (CCV) associated with batch 240-601326 recovered above the upper control limit for the surrogate Decachlorobiphenyl. The Aroclors in the opening CCVs met criteria and all the samples met surrogate criteria. After careful evaluation the data is reported.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

**Metals**
Method 6010B: The post digestion spike % recovery for Arsenic associated with batch 570-402830 was outside of control limits. The associated sample is: (570-168445-C-6-A PDS ^2).

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

**General Chemistry**
Method 7196A: The matrix spike / matrix spike duplicate (MS/MSD) recoveries for preparation batch 570-402542 and analytical batch 570-403047 were outside control limits for one or more analytes. See QC Sample Results for detail. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample (LCS) recovery is within acceptance limits.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

**Organic Prep**
Method 3550C: Batch preparation batch 570-401907 is reported without a matrix spike/matrix spike duplicate (MS/MSD). The batch MS/MSD was originally performed on another client's sample, and this test was canceled at client request. This MS/MSD result does not have immediate bearing on any samples except for the actual sample spiked. The associated laboratory control sample (LCS) met acceptance criteria and provides long-term precision and accuracy for this batch.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

# Detection Summary

# Accreditation/Certification Summary

Client: Haley & Aldrich, Inc.
Job ID: 570-168182-1
Project/Site: Rosemead Holding, LLC/ 0209476-002

## Laboratory: Eurofins Calscience

Unless otherwise noted, all analytes for this laboratory were covered under each accreditation/certification below.

| Authority | Program | Identification Number | Expiration Date |
|---|---|---|---|
| California | State | 3082 | 07-31-24 |

The following analytes are included in this report, but the laboratory is not certified by the governing authority. This list may include analytes for which the agency does not offer certification.

| Analysis Method | Prep Method | Matrix | Analyte |
|---|---|---|---|
| 2540G | | Solid | Percent Moisture |

| | | | |
|---|---|---|---|
| Oregon | NELAP | 4175 | 02-02-24 |

## Laboratory: Eurofins Cleveland

The accreditations/certifications listed below are applicable to this report.

| Authority | Program | Identification Number | Expiration Date |
|---|---|---|---|
| California | State | 2927 | 02-27-24 |
| Oregon | NELAP | 4062 | 02-27-24 |

Note: Since laboratory accreditations are subject to change, Eurofins Calscience places the ownership of method, analyte & accreditation compliance upon our subcontract laboratories. This sample shipment is forwarded under chain-of-custody. If the laboratory does not currently maintain accreditation in the State of Origin listed above for analysis/tests/matrix being analyzed, the samples must be shipped back to the Eurofins Calscience laboratory or other instructions will be provided. Any changes to accreditation status should be brought to Eurofins Calscience attention immediately. If all requested accreditations are current to date, return the signed Chain of Custody attesting to said compliance to Eurofins Calscience.

# Data Usability Summary Report

**Project Name: Rosemead South El Monte**

**Project Description: Soil Samples**

**Sample Date(s): 4 through 15 January 2024**

**Analytical Laboratory: Eurofins Calscience – Tustin, CA**

**Validation Performed by: Raul Tenorio**

**Validation Reviewed by: Katherine Miller**

**Validation Date: 1 February 2024**

---

Haley & Aldrich, Inc. prepared this Data Usability Summary Report (DUSR) to summarize the review and validation of the analytical results for Sample Delivery Group(s) (SDGs) listed. This DUSR is organized into the following sections:

1. **Sample Delivery Group Numbers**
2. **Precision and Accuracy [for SDG(s) above]**
3. **Explanations**
4. **Glossary**
5. **Abbreviations**
6. **Qualifiers**

**References**

This data validation and usability assessment was performed per the guidance and requirements established by the United States Environmental Protection Agency (USEPA) using the following reference materials:

- National Functional Guidelines (NFG) for Inorganic Data Review.
- National Functional Guidelines (NFG) for Organic Data Review.

Data reported in this sampling event were reported to the laboratory method detection limit (MDL). Results found between the MDL and RL are flagged J as estimated.

Sample data were qualified in accordance with the laboratory's standard operating procedures (SOPs). The results presented in each laboratory report were found to be compliant with the data quality objectives (DQOs) for the project and are therefore usable; any exceptions are noted in the following pages.

# 1. Sample Delivery Group Numbers

## 1.1 SAMPLE MANAGEMENT

This DUSR summarizes the review of SDG numbers:

- 570-166963-1, dated 17 January 2024;
- 570-167110-1, dated 22 January 2024;
- 570-167861-1, dated 28 January 2024; and
- 570-168182-1, dated 29 January 2024

Samples were collected, preserved, and shipped following standard chain of custody (COC) protocols.

Samples were also received appropriately, identified correctly, and analyzed according to the COC.

Analyses were performed on the following samples in Tables 1 and 2.

## 1.2 CASE NARRATIVE

The laboratory report case narrative lists various quality control exceedances (e.g., continuing calibration verification) not evaluated by this review thus, no qualifiers were applied to the reported results.

The laboratory report case narratives included the following issues:

- SDG 570-166963-1, Method SW8082A: The following samples required a tetrabutylammonium sulfite (TBA) cleanup to reduce matrix interferences caused by sulfur: LV-9-2.0-010424-01 (570-166963-12), HA-SB-10-0.5-010424-01 (570-166963-13), HA-SB-07-0.5-010424-01 (570-166963-15), HA-SB-07-1.0-010424-01 (570-166963-16), HA-SB-07-2.0-010424-01 (570-166963-17), HA-SB-06-1.0-010424-01 (570-166963-19), HA-SB-06-2.0-010424-01 (570-166963-20), and HA-SB-05-0.5-010424-01 (570-166963-21).
- SDG 570-167110-1, Method SW8082A: The following samples required a tetrabutylammonium sulfite (TBA) cleanup to reduce matrix interferences caused by sulfur: (570-167861-B-3-A), (570-167861-B-3-B MS), and (570-167861-B-3-C MSD).
- SDG 570-167861-1, Method SW8082A: The following samples required a tetrabutylammonium sulfite (TBA) cleanup to reduce matrix interferences caused by sulfur: HA-SB-01-1.0-011124-01 (570-167861-3), HA-SB-08-1.0-011124-02 (570-167861-6), B-5-7.0--011124-01 (570-167861-7), HA-SB-03-4.0-011124-01 (570-167861-13), HA-SB-05-4.0-011124-01 (570-167861-19), HA-SB-05-3.0-011124-01 (570-167861-20), and HA-SB-05-3.0-011124-02 (570-167861-21), HA-SB-01-1.0-011124-01 (570-167861-3[MS]), and HA-SB-01-1.0-011124-01 (570-167861-3[MSD]).
- SDG 570-167861-1, Method SW8082A: The following sample required a Silica Gel cleanup, via EPA Method 3630C, to reduce matrix interferences: HA-SB-08-1.0-011124-01 (570-167861-5), HA-SB-08-1.0-011124-02 (570-167861-6), HA-SB-05-3.0-011124-01 (570-167861-20), HA-SB-10-4.0-011124-02 (570-167861-32), HA-SB-09-1.0-011124-02 (570-167861-35), LV-8-4.0-011124-01 (570-167861-42), and LV-8-4.0-011124-02 (570-167861-43).

- SDG 570-167861-1, Method SW8082A preparation: A portion of the following sample was used for analysis, rather than testing the entire sample amount in the original container, due to the sample container not being the appropriate size: EB-011124-01 (570-167861-49). As such, the required solvent rinse of the original container could not be performed.

### 1.3 HOLDING TIMES/PRESERVATION

The samples arrived at the laboratory at the proper temperature and were prepared and analyzed within the holding time and preservation criteria specified per method protocol, with the following exceptions:

| Method | Matrix | Holding Time | Preservation | Sample ID, Violation, Qualification |
|---|---|---|---|---|
| SW9045D | Soil | 15 minutes, unpreserved | None | The following samples were analyzed outside the holding time and qualified J: 570-167861-1, -2, -3, -4, -7, -20, -33, -36, -38 |

### 1.4 REPORTING LIMITS AND SAMPLE DILUTIONS

All sample dilutions were reviewed and found to be justified. Dilution of the project samples were required to bring calibration of target analytes within calibration range, matrix interference, foaming at the time of purging, or abundance of non-target analytes.

### 1.5 REPORTING BASIS (WET/DRY)

Refer to Section E 1.1. Soil data in this DUSR were reported on a dry weight basis for method SW8082A. Soil data in this DUSR were reported on a wet weight basis for methods SW6010B, SW7196A, SW8015D, and SW9045D.

Where reported, percent moisture results were reviewed and found to be within limits.

### 1.6 SURROGATE RECOVERY COMPLIANCE

Refer to Section E 1.2. The percent recovery (%R) for each surrogate compound added to each project sample were determined to be within the laboratory-specified quality control (QC) limits, with the following exceptions:

| Method | Sample ID | Surrogate | Dilution | %R | Qualification |
|---|---|---|---|---|---|
| 8082A | HA-SB-07-0.5-010424-01 | DCB Decachlorobiphenyl | 10x | 178% | None, dilution > 5x |

## 1.7 LABORATORY CONTROL SAMPLES

Refer to Section E 1.3. Compounds associated with the laboratory control sample/laboratory control sample duplicate (LCS/LCSD) analyses associated with client samples exhibited recoveries and relative percent differences (RPDs) within the specified limits.

## 1.8 MATRIX SPIKE SAMPLES

Refer to Section E 1.4. The sample(s) below were used for matrix spike/matrix spike duplicate (MS/MSD):

| Lab Sample Number | Matrix Spike/Matrix Spike Duplicate Sample Client ID | Method(s) |
|---|---|---|
| 570-166963-1 | HA-SB-13-0.5-010424-01 | SW8082A |
| 570-166963-6 | HA-SB-15-1.0-010424-01 | SW6010B |
| 570-167110-1 | HA-SB-02-0.5-010524-01 | SW8082A |
| 570-167861-9 | B-5-5.0-011124-01 | SW8082A |
| 570-167861-30 | HA-SB-10-3.0-011124-01 | SW8082A |
| 570-167861-33 | HA-SB-09-0.5-011124-01 | SW8082A |
| 570-167861-3 | HA-SB-01-1.0-011124-01 | SW8082A, SW6010B |
| 570-168182-1 | SB-13-1.0-011524-01 | SW8082A |
| 570-168182-14 | LV-15-01-W-5.0-011524-01 | SW6010B |

The MS/MSD recoveries and the relative percent difference (RPD) between the MS and MSD results were within the specified limits, with the following exceptions:

| Sample Type | Method | Parent Sample | Analyte | %R/RPD | Qualifier | Affected Samples |
|---|---|---|---|---|---|---|
| MS/MSD | SW6010B | HA-SB-15-1.0-010424-01 | Lead | 181%/-323% | NA | None, native sample > 4x the spike added |
| MS/MSD | SW8082A | HA-SB-02-0.5-010524-01 | Aroclor-1260 | 7%/41% | J/R | 570-167110-1 |
| MS/MSD | SW8082A | HA-SB-09-0.5-011124-01 | Aroclor-1016 | 87%/41%, RPD=72 | J/None | None, samples are ND |
| MS/MSD | SW8082A | HA-SB-09-0.5-011124-01 | Aroclor-1260 | 104%/42%, RPD=84 | J/None | None, samples are ND |

## 1.9 BLANK SAMPLE ANALYSIS

Refer to Section E 1.5. Method blank samples had no detections, indicating that no contamination from laboratory activities occurred.

The analysis of the blank samples for field quality control was free of target compounds, with the following exceptions:

| Blank Type | Date of Blank | Analyte Detected in Blank | Concentration (µg/L) | Qualifier | Affected Samples |
|---|---|---|---|---|---|
| Equipment blank | 1/11/24 | Aroclor-1254 | 0.57 | RL U | 570-167861-37 |
| Equipment blank | 1/11/24 | Aroclor-1254 | 0.57 | J+ | 570-167861-38 |

## 1.10 DUPLICATE SAMPLE ANALYSIS

Refer to Section E 1.6. The following sample(s) were used for laboratory duplicate analysis and the RPDs were all below 20 percent (or the absolute difference rule was satisfied if detects were less than 5 times the RL).

| Lab Sample Number | Laboratory Duplicate Sample Client ID | Method(s) |
|---|---|---|
| 570-167861-3 | HA-SB-01-1.0-011124-01 | SW9045D |
| 570-167861-33 | HA-SB-09-0.5-011124-01 | SW9045D |

The following sample(s) were used for field duplicate analysis. RPDs were all below 50 percent for soil (or the absolute difference rule was satisfied if detects were less than 5 times the RL). Any exceptions are noted below and qualified.

| Primary Sample ID | Duplicate Sample ID | Method(s) |
|---|---|---|
| HA-SB-05-3.0-011124-01 | HA-SB-05-3.0-011124-02 | EPA 8082A |
| HA-SB-08-1.0-011124-01 | HA-SB-08-1.0-011124-02 | EPA 8082A |
| HA-SB-09-1.0-011124-01 | HA-SB-09-1.0-011124-02 | EPA 8082A |
| LV-8-4.0-011124-01 | LV-8-4.0-011124-02 | EPA 8082A |
| SB-14-3.0-011124-01 | SB-14-3.0-011124-02 | EPA 8082A |
| HA-SB-24-2.0-011524-01 | HA-SB-24-2.0-011524-02 | EPA 6010B |
| HA-SB-29-1.0-011524-01 | HA-SB-29-1.0-011524-02 | EPA 6010B |
| B-5-7.0--011124-01 | B-5-7.0--011124-02 | EPA 8082A |
| HA-SB-10-2.0-011124-01 | HA-SB-10-2.0-011124-02 | EPA 8082A |
| HA-SB-10-4.0-011124-01 | HA-SB-10-4.0-011124-02 | EPA 8082A |

**Field Duplicate RPD Calculations:**

| Method | Analyte | Units | Primary Sample ID | Duplicate Sample ID | % RPD | Qualification |
|---|---|---|---|---|---|---|
| | | | HA-SB-08-1.0-011124-01 | HA-SB-08-1.0-011124-02 | | |
| SW8082A | Aroclor-1254 (PCB-1254) | µg/kg | 2,900 | 7,800 | NA | J/UJ, Abs. Diff. > RL |

| Method | Analyte | Units | Primary Sample ID | Duplicate Sample ID | % RPD | Qualification |
|---|---|---|---|---|---|---|
| | | | HA-SB-24-2.0-011524-01 | HA-SB-24-2.0-011524-02 | | |
| SW6010B | Lead | mg/kg | 146 | 443 | 101 | J/UJ, RPD>50 |
| **Method** | **Analyte** | **Units** | **Primary Sample ID** | **Duplicate Sample ID** | **% RPD** | **Qualification** |
| | | | **HA-SB-29-1.0-011524-01** | **HA-SB-29-1.0-011524-02** | | |
| SW6010B | Lead | mg/kg | 48.6 | 8.98 | NA | J/UJ, Abs. Diff. > RL |

## 1.11 CONFIRMATION COLUMN REVIEW

Refer to Section E 1.8. All relative percent differences (RPDs) were within control limits, with the following exceptions:

| Method | Analyte | Sample | RPD | Action |
|---|---|---|---|---|
| SW8082A | Aroclor-1254 | 570-166963-13 | > 40% | Qualify data estimated J/UJ |

## 1.12 SYSTEM PERFORMANCE AND OVERALL ASSESSMENT

The results presented in this report were found to comply with the DQOs for the project and the guidelines specified by the analytical method. Based on the review of this report, the data are useable and acceptable, as no data was rejected. A summary of qualifiers applied to this dataset is shown in Table 3.

## 2. Precision and Accuracy [for SDG(s) above]

Refer to Section E 1.7. Where required by the method, some measurement of analytical accuracy and precision was reported for each method with the site samples.

## 3. Explanations

The following explanations include more detailed information regarding each of the sections in the DUSR above. Not all sections in the Explanations are represented:

- E 1.1 Reporting Basis (Wet/Dry)
  - Soil samples can be reported on either a wet (as received) or dry weight basis. Dry weight data indicate calculations were made to compensate for the moisture content of the soil sample.
  - Percent (%) solids should be appropriately considered when evaluating analytical results for non-aqueous samples. Sediments with high moisture content may or may not be successfully analyzed by routine analytical methods. Samples should have greater than or equal to 30 percent solids to be appropriately quantified.
- E 1.2 Surrogate Recovery Compliance
  - Surrogates, also known as system monitoring compounds, are compounds added to each sample prior to sample preparation to determining the efficiency of the extraction procedure by evaluating the percent recovery (%R) of the compounds.
- E 1.3 Laboratory Control Samples
  - The laboratory control sample/laboratory control sample duplicate (LCS/LCSD) analyses are used to assess the precision and accuracy of the analytical method independent of matrix interferences.
- E 1.4 Matrix Spike Samples
  - Matrix spike/matrix spike duplicate (MS/MSD) data are used to assess the precision and accuracy of the analytical method and evaluate the effects of the sample matrix on the sample preparation procedures and measurement methodologies.
  - For inorganic methods, when a matrix spike recovery falls outside of the control limits and the sample result is less than four times the spike added, a post-digestion spike (PDS) is performed.
- E 1.5 Blank Sample Analysis
  - Method blanks are prepared by the analytical laboratory and analyzed concurrently with the project samples to assess possible laboratory contamination.
  - Field blanks are prepared to identify contamination that may have been introduced during field activity. Equipment blanks are prepared to identify contamination that may have been introduced while decontaminating sampling equipment. Trip blanks are prepared when volatile analysis is requested to identify contamination that may have been introduced during transport.
- E 1.6 Laboratory and Field Duplicate Sample Analysis
  - The laboratory duplicate sample analysis is used by the laboratory at the time of the analysis to demonstrate acceptable method precision. The RPD or absolute difference was evaluated for each duplicate sample pair to monitor the reproducibility of the data.

- The field duplicate sample analysis is used to assess the precision of the field sampling procedures and analytical method. The relative percent difference (RPD) or absolute difference was evaluated for each duplicate sample pair to monitor the reproducibility of the data.

- E 1.7 Precision and Accuracy
  - Precision measures the reproducibility of repetitive measurements. In a laboratory environment, this will be measured by determining the relative percent difference (RPD) found between a primary and a duplicate sample. This can be an LCS/LCSD pair, a MS/MSD pair, a laboratory duplicate performed on a site sample, or a field duplicate collected and analyzed concurrently with a site sample.
  - Accuracy is a statistical measurement of the correctness of a measured value and includes components of random error (variability caused by imprecision) and systematic error. In a laboratory environment, this will be measured by determining the percent recovery (%R) of certain spiked compounds. This can be assessed using LCS, blank spike (BS), MS, and/or surrogate recoveries.
- E 1.8 Confirmation Column Review
  - When analyzing for pesticides and polychlorinated biphenyls (PCBs), compound identification based on single-column analysis should be confirmed on a second column or supported by at least one other qualitative technique. When confirmed on a second column, the relative percent difference (RPD) should not exceed 40 percent.

# 4. Glossary

Not all of the following symbols, acronyms, or qualifiers occur in this document.

- Sample Types:
  - EB Equipment Blank Sample
  - FB Field Blank Sample
  - FD Field Duplicate Sample
  - N Primary Sample
  - TB Trip Blank Sample
- Units:
  - µg/kg micrograms per kilogram
  - µg/L micrograms per liter
  - µg/$m^3$ micrograms per cubic meter
  - mg/kg milligrams per kilogram
  - mg/L milligrams per liter
  - ppb v/v parts per billion volume/volume
  - pCi/L picocuries per liter
  - pg/g picograms per gram
  - pg/L picograms per liter
- Matrices:
  - AA Ambient Air
  - GS Soil Gas
  - GW/WG Groundwater
  - QW Water Quality
  - IA Indoor Air
  - SE Sediment
  - SO Soil
  - SSV Sub-slab Vapor
  - WQ Water Quality control matrix
  - WS Surface Water
- Table Footnotes:
  - NA Not applicable
  - ND Non-detect
  - NR Not reported
- Common Symbols:
  - % percent
  - < less than
  - ≤ less than or equal to
  - > greater than
  - ≥ greater than or equal to
  - = equal
  - °C degrees Celsius
  - ± plus or minus
  - ~ approximately
  - x times (multiplier)

- Fractions:
  - N Normal (method cannot be filtered)
  - D Dissolved (filtered)
  - T Total (unfiltered)

# 5. Abbreviations

| | |
|---|---|
| %D | Percent Difference |

# 6. Qualifiers

The qualifiers below are from the USEPA National Functional Guidelines and the data in the DUSR may contain these qualifiers:

- Concentration (C) Qualifiers:

  U The compound was analyzed for but not detected. The associated value is either the compound quantitation limit if not detected by the analytical instrument or could be the reported or blank concentration if qualified by blank contamination. This can also be displayed as less than the associated compound quantitation limit (<RL or <MDL), or "ND".

  B The compound was found in the sample and its associated blank. Its presence in the sample may be suspect.

- Quantitation (Q) Qualifiers:

  E The compound was quantitated above the calibration range.

  D The concentration is based on a diluted sample analysis.

- Validation Qualifiers:

  J The compound was positively identified; however, the associated numerical value is an estimated concentration only.

  J+ The result is an estimated quantity, but the result may be biased high.

  J- The result is an estimated quantity, but the result may be biased low.

  J/UJ as listed in exception tables J applies to detected data and UJ applies to non-detected data as reported by the laboratory.

  UJ The compound was not detected above the reported sample quantitation limit; however, the reported limit is estimated and may or may not represent the actual limit of quantitation.

  NJ The analysis indicated the presence of a compound for which there is presumptive evidence to make a tentative identification; the associated numerical value is an estimated concentration only.

  R The sample results were rejected as unusable; the compound may or may not be present in the sample.

  S Result is suspect. See DUSR for details.

***Notes:***

*EBK = Equipment blank contamination.*

*FDP = Field duplicate qualifier due to an exceedance of the specified limits.*

*HTQ = Holding time exceedance.*

*MSD = Matrix spike/matrix spike duplicate percent recoveries or relative percent difference were outside the specified limits.*

*RPD = Pesticides and PCB confirmation column RPD Exceeded; or MSD/LCS RPD exceedance.*

*J = The compound was positively identified; however, the associated numerical value is an estimated concentration only.*

*J+ = The result is an estimated quantity, but the result may be biased high.*

*U = The compound was analyzed for but not detected.*

| PROJECT | Rosemead - PCBs sampling | H&A FILE NO. | |
| LOCATION | 7200 Rosemead BLVD | PROJECT MGR | Chris T. |
| CLIENT | | REPORT NO. | |
| CONTRACTOR | JHA | DATE | 01/04/2024 |
| WEATHER | Clear/Sunny | TEMPERATURE | |

0700 - Arrived onsite (HA)
- Arrived onsite (JHA)
0715 - Health and Safety + Scope of work
0730 - Use site keys and gps to mark out sampling locations
0800 - Mark out of sampling locations complete using spray paint
- Directed JHA to start coring through asphalt/concrete.
0830 - HASB-01 JHA began to hand auger
- Paved; hit concrete. Moved to LV-10 (2, 3, 4 ft bgs) Hand auger
0845 - HA-SB-13; JHA began to hand auger (0.5, 1, 2, 3, 4 ft bgs)
- Refusal at 1.5 ft bgs
0900 - HA-SB-14; JHA began to hand auger (1 ft bgs) & (0.5 ft bgs) ✓
0930 - HA-SB-15; JHA began to hand auger (0.5 ft bgs, 1 ft bgs) ✓
1000 - HA-SB-12; JHA began to hand auger (0.5, 1, 2, 3 ft bgs) ✓
1010 - HA-LV-9; JHA began to hand auger (1, 2 ft bgs) ✓
1030 - HA-[illegible]; JHA began to hand auger (2, 3, 4, 0.5, 1 ft bgs)
- Refusal at 1 ft bgs
1100 - HA-SB-07; JHA began to hand auger (0.5, 1, 2 ft bgs) ✓
1130 - JHA went to lunch.
1200 - HA-SB-06; JHA began to hand auger (0.5, 1, 2 ft bgs) ✓
1230 - HA-SB-16; JHA began to hand auger (3, 4 ft bgs)
1240 - ~~Refusal~~ Refusal at 1 ft bgs.
- HA-SB-05; JHA began to hand auger (0.5, 1, 2, 3, 4 ft bgs)
1250 - Refusal at 1 ft bgs
1300 - HA-LV-8; JHA began to hand auger (4 ft bgs)
- ~~HA-BS~~ Refusal at 1 ft bgs. • Dup samples collected at 1 foot.
- HA-BS; JHA began to hand auger (5, 6, 7 ft bgs)
- Refusal at 3 ft bgs
1310 - HA-SB-08; JHA began to hand auger (0.5, 1 ft bgs)
1320 - Refusal at 1 ft bgs
1330 - Backfilling
1400 - JHA cleaned and left the site
1430 - Eurofins picked up samples; left the site

# DAILY FIELD REPORT

Page of

| | | | |
|---|---|---|---|
| PROJECT | Rosemead - PCB Sampling | H&A FILE NO. | |
| LOCATION | 2200 Rosemead Blvd. | PROJECT MGR. | Christ |
| CLIENT | JHA | REPORT NO. | |
| CONTRACTOR | | DATE | 01/05/24 |
| WEATHER | Sunny/Clear skies | TEMPERATURE | |

0700 - H&A and JHA arrived onsite.
0730 - Health and Safety + Scope of Work
- JHA setting up equipment
0800 - JHA hand augering at HA-SB-04 (0.5, 1 ft bgs) ✓
0810 - JHA hand augering at HA-SB-02 (0.5, 1 ft bgs) ✓
0830 - JHA hand augering HA-SB-01 (0.5, 1, 2, 3, 4 ft bgs)
- Refusal at ~1 ft bgs.
0840 - JHA hand auger at SB-13 (1, 2, 3 ft bgs)
- Refusal at ~0.6 inches
0930 - JHA hand auger at SB-11 (3, 4 ft bgs)
- Refusal at ~0.6 inches
0945 - JHA hand auger at HA-SB-03 (0.5, 1, 2, 3, 4 ft bgs)
- Refusal at ~0.6 inches.
1010 - JHA hand auger at SB-14 (3, 4 ft bgs)
- Refusal at ~1.0 ft.
1040 - Jay arrived onsite to transfer equipment
1100 - JHA went to lunch; Jay left the site.
1200 - JHA returned to site
1210 - JHA hand augering at HA-SB-08 (0.5, 1 ft bgs) No samples taken
- Reached 1 ft bgs, however it is only composed of brick and stones.
1230 - JHA hand augering at HA-SB-13 (2, 3, 4 ft bgs. • Resuming from 01/04/24
1315 - JHA hand augering at HA-SB-11 (1, 2, 3, 4 ft bgs) - Stopped at 2 ft
- Stopped at 2 ft • Resuming from 01/04/24

SUBJECT: Evaluation and Development of a Site-Specific Soil Screening Level for Protecting Groundwater from Lead Impacts in Shallow Soil
Rosemead Holding LLC Properties
2200-2226 N. Rosemead Boulevard, South El Monte, California
(LARWQCB File No. 107.0266, Site ID No. 2040647)

This technical memorandum was prepared by Haley & Aldrich, Inc. (Haley & Aldrich) on behalf of Rosemead Holding LLC to document the evaluation and development of a site-specific soil screening level (SSL) that is protective of groundwater quality from the impacts of elevated lead concentrations found in shallow soil at the properties located at 2200, 2212, 2218, and 2226 North Rosemead Boulevard, South El Monte, California (the Site).

The memorandum documents the approach and methods used to determine an appropriate Site-specific SSL for lead in shallow soil, as well as the results of the evaluation. The primary conclusions obtained from this evaluation are summarized below:

- The use of the soil attenuation model developed by Connor et al. (1997) allows the incorporation of Site-specific conditions to develop a Site-specific SSL for protecting groundwater from lead impacts found in shallow soil at the Site. Using appropriate Site-specific input values, the calculated Site-specific SSL is 1,500 milligrams per kilogram (mg/kg).
- The sensitivity assessment demonstrates that a calculated SSL value can vary (i.e., ranging from 450 mg/kg up to 2,800 mg/kg), dependent on the level of conservatism incorporated into the site-specific parameters used to calculate the SSL. The calculated range is considerably higher than the US Environmental Protection Agency's (USEPA's) Regional Screening Levels (RSLs) for

lead for the protection of groundwater of 14 mg/kg. As a result, the sensitivity assessment further demonstrates that a remedial action goal (RAG) of 14 mg/kg for lead is not applicable nor appropriate for this Site.

- Site soil pH conditions favors the formation of lead precipitation. This attenuation mechanism is not accounted for through the adsorption-based soil attenuation model developed by Connor et al. (1997), and thus this mechanism is expected to provide additional protection to groundwater quality. As a result, the Site-specific SSL of 1,500 mg/kg is conservative.

The remainder of the memorandum provides the following elements: (1) Background, (2) Objective of this evaluation, (3) Evaluation approach, (4) Evaluation outcomes, (5) Sensitivity scenario assessment, (6) Additional attenuation processes, and (6) Conclusions.

## Background

The Los Angeles Regional Water Quality Control Board (LARWQCB) is evaluating risk posed to groundwater by lead in soil at the Site in reference to Resolution 92-49 and Section 2550.4 of Title 23 of the California Code of Regulations. During a 23 May 2023 meeting, the LARWQCB suggested that an appropriate RAG for lead in soil sufficiently protective of groundwater is 14 mg/kg, which is based on USEPA's RSLs for lead for the protection of groundwater.

A 20 July 2023 technical memorandum evaluating the leaching potential for lead to groundwater at the Site was prepared by Leighton Consulting Inc. and submitted to the LARWQCB for review. This 20 July 2023 technical memorandum presented multiple lines of evidence supporting that a RAG of 14 mg/kg for lead for the protection of groundwater is not applicable nor appropriate for the Site.[1] The multiple lines of evidence include:

- Relatively elevated concentrations of lead in soil are limited to the upper 5 feet below ground surface (bgs) (often the upper 1 to 2 feet bgs); Site lead soil data are presented in Plate 1.
- Lead-impacted soil in the upper 5 feet bgs is planned for remediation.
- Although elevated lead is present in shallow soil, historical and recent Site groundwater data indicates that lead is not present in groundwater above laboratory detection limits.

At the 11 October 2023 meeting with the LARWQCB, Haley & Aldrich presented the model and Site-specific parameter assumptions used to develop a Site-specific SSL of 1,500 mg/kg for protecting groundwater from lead impacts in shallow soil. The LARWQCB requested a technical memorandum summarizing the model and Site-specific parameter assumptions used in calculating the Site-specific SSL for lead be prepared and submitted to the LARWQCB for review.

[1] The technical memorandum is dated 20 July 2023, from Robin J. Ferber and Matt Himmelstein, with the subject: *"Evaluation of Leaching Potential for Lead to Groundwater, Former Pacific Drum Company, 2200-2226 N. Rosemead Boulevard, South El Monte, California."*

## Objective

The objective of this technical memorandum is to present an appropriate Site-specific SSL for lead in soil for groundwater protection, using representative hydrogeological and geochemical data collected at the Site or obtained from relevant literature sources and USEPA guidance.

## Evaluation Approach

The USEPA's RSL for the protection of groundwater for lead of 14 mg/kg is based on several key conservative assumptions which do not apply to the Site, including:

- An infiltration rate of 0.18 meter per year (or 18 centimeters per year [cm/yr]): This rate is significantly higher than typical average infiltration rates determined using the Los Angeles Basin watershed model (LABWM) developed by the United States Geological Survey (USGS).[2]
- No consideration for the effects of leachate dilution in groundwater: The RSL is developed assuming that no dilution occurs when soil leachate is mixed with groundwater (i.e., the dilution attenuation factor [DAF] is 1). Note that the USEPA's RSL calculator allows for site-specific parameter inputs for the calculation of a site-specific leachate-groundwater dilution factor, as shown in Panel A of Figure 1 below.
- No consideration of attenuation resulting from unimpacted soil beneath impacted shallow soil to the groundwater table: Lead concentration data collected at the Site show that lead surface impacts generally have not mobilized through the subsurface beyond 5 feet bgs. Based on Site investigation data, lead concentrations in subsurface beyond 5 feet bgs are within regional background levels (i.e., concentrations up to 23.9 mg/kg).[3] The groundwater table is at 50 feet bgs based on boring logs for monitoring wells MW-4, MW-5, and MW-6 installed in December 2022 (EEC Environmental 2023). Further note that the depth to water measured during the two sampling events for these three monitoring wells in January and May 2023 ranged from 48.3 feet bgs up to 56.1 feet bgs, with an average depth to water of 51.9 feet bgs.
- A very conservative soil-water partitioning coefficient (Kd) for lead: SSL is a function of Kd value, as shown in Panel B of Figure 1. A higher Kd value results in a higher SSL. The lead RSL of

[2] Hevesi, J. and Johnson, T. D., 2016. Estimating Spatially and Temporally Varying Recharge and Runoff from Precipitation and Urban Irrigation in the Los Angeles Basin, California, Scientific Investigations Report 2016–5068. The report can be accessed at the URL: https://pubs.usgs.gov/sir/2016/5068/sir20165068_.pdf. The Site is located near the Montebello Forebay basin area, which has an estimated average direct recharge of 4.3 cm/yr (Page 76). The estimated average direct recharge for the whole Los Angeles groundwater study area is 3.5 cm/yr. Note that direct recharge includes recharge from net infiltration of precipitation, irrigation, and surface water through root zone in the basin area (Page 79). Because the Site is covered by asphalt pavement, the net infiltration at the Site is expected to be noticeably lower than 4.3 cm/yr.

[3] The technical memorandum is dated 20 July 2023, from Robin J. Ferber and Matt Himmelstein, with the subject: *"Evaluation of Leaching Potential for Lead to Groundwater, Former Pacific Drum Company, 2200-2226 N. Rosemead Boulevard, South El Monte, California."*

14 mg/kg is based on the Kd value of 900 liters per kilogram (L/kg).[4] Kd for lead increases as pH increases (Figure 2). As shown in Figure 2, the Kd value of 900 L/kg is more appropriate for acidic soil conditions (soil pH < 6). When soil pH is higher than 7, the Kd value of 3,000 L/kg is more representative. As shown on Figure 2 below, the Site-specific Kd value of 3,000 L/kg corresponds to the pH value of 7.4. The pH value of 7.4 is at the lower end of the Site-specific soil pH value range of 7.4 to 11.3 from shallow soil pH data collected at the Site by Leighton in 2023 (Leighton Geotechnical Exploration Update Report, 11 May 2023) and by Haley & Aldrich in January 2024 to further delineate chemical of concern in soil (January 2024 pH data presented Plate 1). The Site-specific pH value range is further supported by the reported likely representative pH value of 7.9 for shallow soil in the area where the Site is located, based on publicly available soil properties data from the U.S. Department of Agriculture (USDA).

Because the nature of the RSLs for the protection of groundwater is for the purpose of general screening, they are very conservative in order to avoid a false conclusion that no groundwater threat exists at a given soil contaminated site. It is not intended for establishing a site-specific cleanup goal.

The soil attenuation model (SAM), developed by Connor et al. (1997), provides a mathematical framework to estimate a site-specific soil screening level with the flexibility of: [5]

- Using site-specific infiltration rate and Kd value;
- Incorporating contamination depth effects in the vadose zone by accounting for the sportive redistribution of a contaminant from the initial impacted depth intervals to the underlying unimpacted soil; and
- Calculating the DAF, which accounts for the leachate-groundwater dilution effects as described in USEPA's soil screening guidance, published in 1996.[6]

[7] Source URL: https://www.epa.gov/risk/regional-screening-levels-rsls-equations

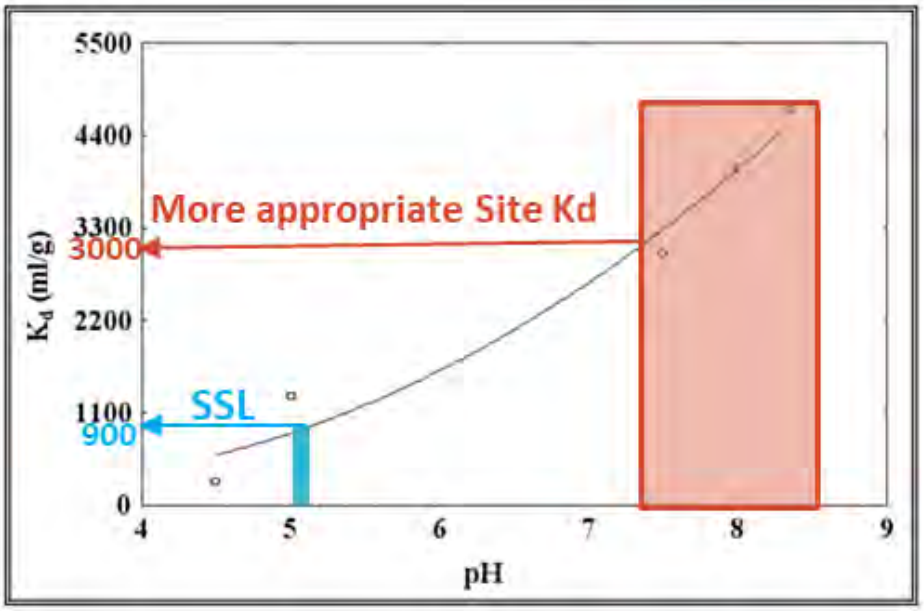

*Figure 2: Lead Kd value as a function of soil pH.*[8]

Because the SAM can account for various site-specific data and the effects of the contaminated soil profile (i.e., a layer of contaminated soil overlying a layer of unimpacted soil), it was used to estimate the Site-specific SSL for lead. Figure 3 illustrates a conceptual diagram of the SAM. The SAM can account for the following contaminant transport processes of lead from the vadose zone to groundwater:

- Chemical partitioning between vadose zone porewater and aquifer solids follows a linear adsorption relationship that can be characterized through an equilibrium adsorption constant Kd value.
- Infiltration leads to lead mobilization in the vadose zone as porewater percolates downward.
- The impact on groundwater quality by the leachate from the vadose zone can be approximated by the mixing between the porewater downward flow rate from the vadose zone source and the flow rate of shallow groundwater over an estimated mixing depth interval in the saturated zone.

The publication of Connor et al. (1997) is provided in Appendix A for more detailed information, such as equations used for cleanup level calculation and a parameter selection guide.

August. The figure is adapted from Figure F.1 of Appendix F of the report. Source URL: https://www.epa.gov/sites/default/files/2015-05/documents/402-r-99-004b.pdf

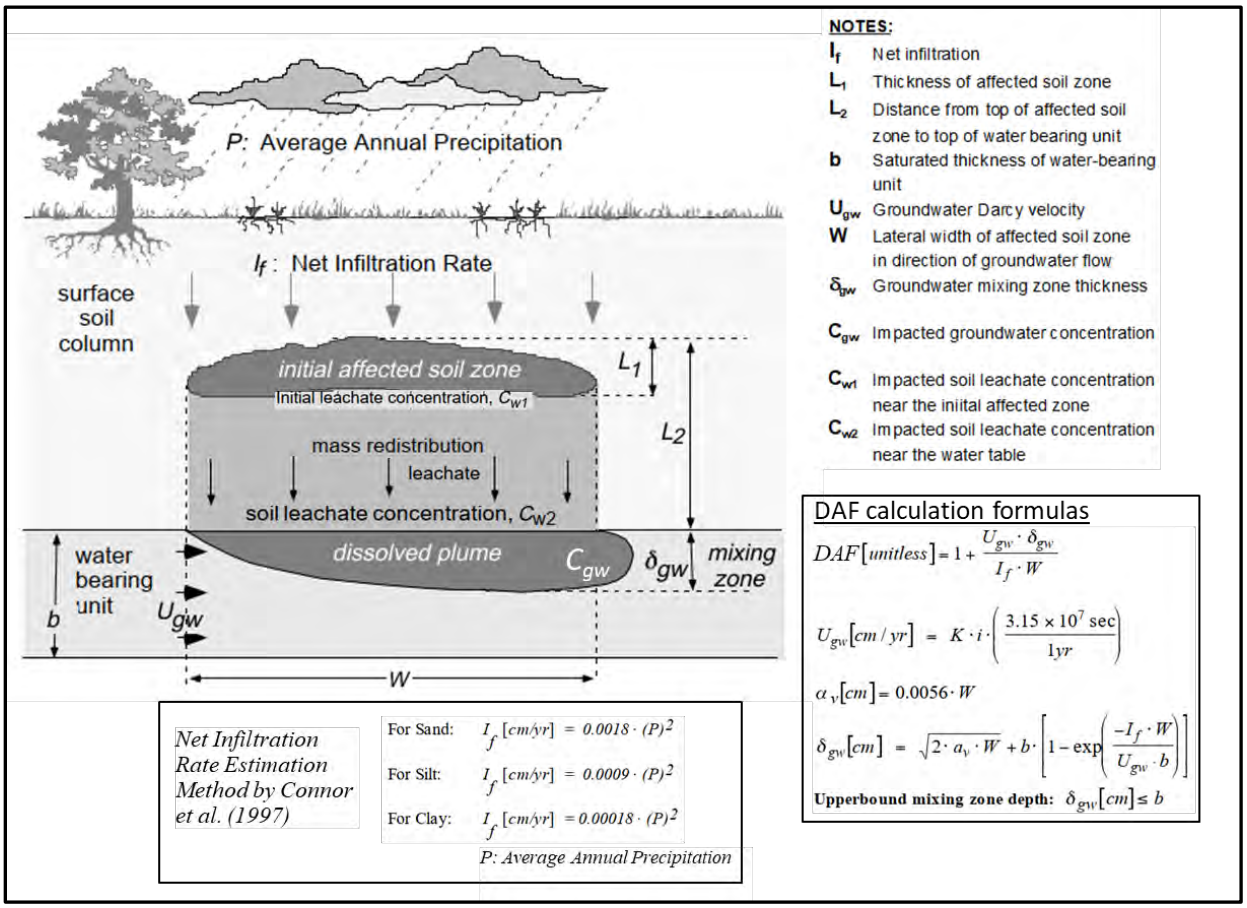

*Figure 3: Conceptual diagram of soil attenuation model developed by Connor et al. (1997).*

The procedure used to estimate the Site-specific SSL for lead is described below:

- Use 15 micrograms per liter (µg/L) (the USEPA Action Level in water for lead) as the target groundwater concentration ($C_{gw}$);
- Estimate a site-specific net infiltration rate ($I_f$) that is more appropriate for the Site location and conservative enough to not underestimate the rate; a method to estimate $I_f$ using site-specific average annual precipitation is provided by Connor et al. (1997) and shown in Figure 3;
- Calculate the site-specific DAF value using site-specific hydraulic parameters and $I_f$; the formulas used to estimate the DAF are shown in Figure 3.
- Calculate the target vadose zone leachate concentration ($C_{w2}$) near the water level, which occurs after lead mass redistribution from the initial affected zone (the top 5 feet of the vadose zone) to the whole vadose zone thickness (50 feet), by the formula below:
  - $C_{w2} = C_{gw} \times DAF$
- Calculate the target vadose zone leachate concentration ($C_{w1}$) right below the initial affected zone using the formula below:
  - $C_{w1} = C_{w2} \times L_2 / L_1$ (the definitions of $L_1$ and $L_2$ are shown in Figure 3)
- Estimate an appropriate site-specific Kd value for lead;

- Calculate the site-specific SSL ($C_T$) using the formulas below:
  - $C_T = C_{w1} \times (Kd + \Theta_w/\rho_b)$
    where $\Theta_w$ is volumetric water content in affected soil and $\rho_b$ is the soil bulk density.

The Site-specific parameter values obtained from the previous Site investigations or from the publicly available database are provided in Table 1. The rationale for each parameter value selected is provided in the final column in Table 1.

## Evaluation Results

The calculated Site-specific DAF value, using Site-specific hydraulic parameters and net infiltration rate, is 3.3, meaning the leachate concentration ($C_{w2}$ = 49.5 µg/L) at the bottom of the vadose zone is no more than 3.3 times higher than the target groundwater concentration ($C_{gw}$ = 15 µg/L). Accounting for the sportive redistribution of a contaminant from the initial impacted depth intervals to the underlying unimpacted soil ($L_2$/ $L_1$) and a Site-specific Kd, the calculated Site-specific SSL for lead for groundwater protection is 1,500 mg/kg.

## Sensitivity Scenario Assessment

While the parameters used to calculate Site-specific SSL for lead are either representative of Site conditions or protective in terms of not likely overestimating the SSL, heterogeneity in physical and chemical properties of both the vadose zone and saturated zone may result in variations of the calculated SSL value. Therefore, a sensitivity assessment was conducted. The parameters and their values used for this assessment, as well as corresponding SSL results are described below. Note that for each sensitivity test scenario, only one parameter was adjusted, and the remaining parameter values remain the same as the values presented in Table 1.

- Shallow Aquifer Thickness (b): A shallow aquifer thickness of 70 feet was used in the calculation of the Site-Specific SSL. Three additional shallow aquifer thickness values, 10 feet, 20 feet and 35 feet, were tested. The resulting SSL values are 720 mg/kg, 990 mg/kg, and 1,400 mg/kg, respectively.
- Hydraulic Conductivity for Shallow Groundwater (K): Two additional K values were tested. They are 3 times or one-third the value in Table 1 (=0.00064 centimeters per second [cm/s]). The resulting SSL values are 2,800 mg/kg and 990 mg/kg, respectively.
- Length between Top of the Impacted Zone to Water Table (L2): A length between top and the impacted zone to water table of 50 feet was used in the calculation of the Site-Specific SSL. The thickness of the vadose zone may vary due to the water table fluctuation. According to the Phase I Environmental Site Assessment prepared by Ramboll US Corporation, groundwater was encountered at approximately 32 feet to 34 feet bgs in 2002 at an adjacent property to the

south.[9] During a Phase II subsurface investigation performed at the Site by EEC Environmental in October 2020, groundwater was encountered beneath the Site at a depth of approximately 45 feet bgs.[10] The depth to water measured during the two sampling events for these three monitoring wells in January and May 2023 ranged approximately from 48 feet bgs up to 56 feet bgs. Therefore, two additional L2 values, 35 feet and 55 feet, are tested. The resulting SSL values are 1,000 mg/kg and 1,600 mg/kg, respectively.

- Net Infiltration Rate ($I_f$): The $I_f$ of 3.98 cm/yr (or 1.57 inches per year [in/yr]) was used in the calculation of the Site-specific SSL, which is 10% of the average annual precipitation (15.67 in/yr) based on a weather station near the Site (San Gabriel Fire Department, California). This value is between the recharge estimates for the Montebello Forebay basin area (4.3 cm/yr) and the whole Los Angeles groundwater study area (3.5 cm/yr). Because the Site will be covered by asphalt pavement and buildings, the net infiltration at the Site is expected to be noticeably lower than 4.3 cm/yr.

  Two additional $I_f$ values were tested. The lower bound $I_f$ value of 1.43 cm/yr was estimated using the average annual precipitation for South El Monte and the net infiltration rate estimation method for silt provided by Connor et al. (1997) (or see Figure 3). This lower bound value may be more representative to account for additional infiltration resistance due to the presence of fresh asphalt pavement and buildings after Site redevelopment. The upper bound $I_f$ value of 4.3 cm/yr is the estimated rate for the Montebello Forebay basin area (see comment/ rationale for $I_f$ in Table 1; Hevesi and Johnson 2016). The resulting SSL values using the lower bound and upper bound $I_f$ values above are 2,700 mg/kg and 1,400 mg/kg, respectively.

- Lead adsorption partitioning coefficient (Kd): As discussed previously, a Kd of 3,000 L/kg is more representative of Site conditions based on Site-specific soil pH and was used in the calculation of the Site-Specific SSL. Two additional Kd values were tested. They are 900 L/kg (RSL default value) and 1,500 L/kg. The resulting SSL values are 450 mg/kg and 750 mg/kg, respectively. The SSL values are linearly proportional to the Kd values.

The results of sensitivity assessment demonstrates that an SSL value can vary (i.e., ranging from 450 mg/kg up to 2,800 mg/kg), dependent on the level of conservatism incorporated into the site-specific parameters used to calculate the SSL. Note, however, the resulting SSLs calculated in this sensitivity assessment are considerably higher than the RSL of 14 mg/kg. The sensitivity analysis further demonstrates that a RAG of 14 mg/kg for lead is not appliable nor appropriate for this Site.

## Additional Attenuation Processes for Lead in Shallow Soil

The Site-specific lead SSL calculated above only account for the adsorption process. In an aerobic, alkaline soil environment where unsaturated zone porewater is rich in inorganic carbon (e.g.,

[9] Ramboll US Corporation, 2020. Phase I Environmental Site Assessment, 2212, 2218, and 2226 North Rosemead Blvd, South El Monte, California. 21 July.
[10] EEC Environmental, 2020. Technical Memorandum: Results of Phase II Subsurface Investigation in August and September 2020, South El Monte Parcels – 2200, 2212, 2218, and 2226 N. Rosemead Blvd. 19 October.

bicarbonate and carbonate resulting from dissolution of carbonate minerals), lead mobility is further reduced. Between pH = 7 and pH = 10, important lead bearing minerals under aerobic conditions are cerussite ($PbCO_3$) and hydrocerussite ($Pb_3(CO_3)_2(OH)_2$), as shown in Figure 4. The equilibrium solubility of lead is expected to be below 50 µg/L when a lead bearing mineral is the solubility-controlling phase (USEPA 2007). In general, when pH is higher than 8, precipitation of insoluble carbonates under aerobic conditions can drive precipitation reactions resulting in lead concentrations below the USEPA Action Level in water (15 µg/L) (see USEPA 2007 - EPA/600/R-07/140, Table 2.1 and Figure 2.4).

The measured Site soil pH values ranges from pH = 7.4 to pH = 11.3 (Leighton Geotechnical Exploration Update Report, 11 May 2023 and Haley & Aldrich January 2023 delineation sampling event) and the predominated soil pH is likely approximately 7.9 based on the USDA database. Therefore, the leachate lead concentration from the vadose zone before being mixed with groundwater is likely very close or below 15 µg/L. Given that Site soil is naturally rich in calcium carbonate (see Table 1), lead precipitation in situ is a significant attenuation process beside adsorption.

## Conclusions

The evaluation has reached the following conclusions:

- The use of the soil attenuation model developed by Connor et al. (1997) allows the incorporation of Site-specific conditions to develop a Site-specific SSL for protecting groundwater from lead impacts found in shallow soil at the Site. Using appropriate Site-specific input values, the Site-specific SSL is 1,500 mg/kg.
- The sensitivity assessment demonstrates that an SSL value can vary (i.e., ranging from 450 mg/kg up to 2,800 mg/kg), dependent on the level of conservatism incorporated into the site-specific parameters used to calculate the SSL. The calculated range is considerably higher than the RSL of 14 mg/kg. As a result, the sensitivity assessment further demonstrates that a RAG of 14 mg/kg for lead is not applicable nor appropriate for this Site.
- Site soil pH conditions favor the formation of lead precipitation. This attenuation mechanism is not accounted for through the adsorption-based soil attenuation model developed by Connor et al. (1997), and thus this mechanism is expected to provide additional protection to groundwater quality. As a result, the Site-specific SSL of 1,500 mg/kg is conservative.

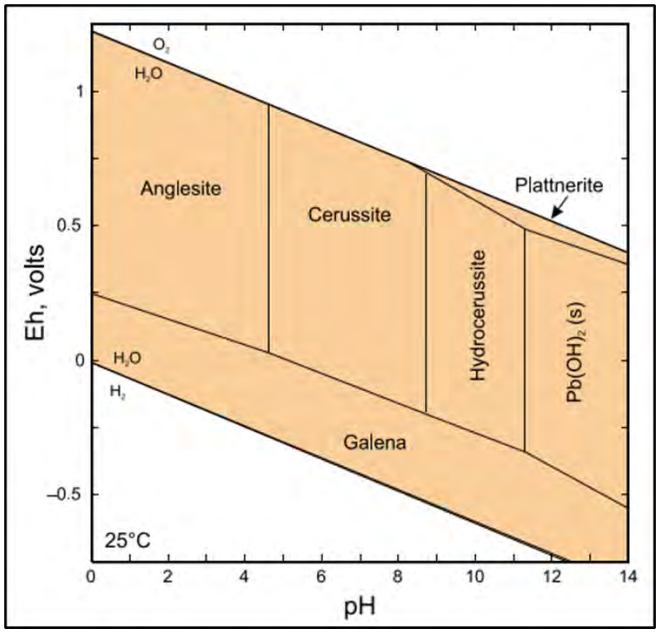

*Figure 4: Eh-pH diagram for lead (total Pb = $10^{-5}$ molal, total Carbon = $10^{-3}$ molal, total Sulfur = $10^{-3}$ molal; all organic lead complexes are suppressed; activity coefficients for all species are set equal to 1).*[11]

TABLE

**TABLE 1**
INPUT PARAMETERS TO THE SOIL ATTENUATION MODEL
ROSEMEAD HOLDINGI LLC PROPERTIES
2200-2226 N. ROSEMEAD BOULEVARD, SOUTH EL MONTE, CA

| Parameter Type | Parameter Name | Value | Unit | Comment/Rationale |
|---|---|---|---|---|
| Aquifer Characteristics | Shallow Aquifer Thickness (b) | 2134<br>70 | cm<br>ft | Based on the data presented in Figure 3-4 of the Gilbane, November, 2019, Supplemental Remedial Investigation Report, South El Monte Operable Unit, San Gabriel Valley Area 1 Superfund Site. Also see Appendix B. |
| | Hydraulic Conductivity for Shallow Groundwater Aquifer (K) | 0.00064<br>1.8 | cm/sec<br>ft/d | This value is based on the site-specific hydraulic conductivity value estimated using the well development data of MW-6. Note that an aquifer hydraulic conductivity value of 300 ft/d was estimated for the shallow aquifer throughout most of the Witter Narrow, as reported in the Geosystem Consultants, Inc., April, 1999 Feasibility Study Report, Interim Remedial Investigation/Feasibility Study, South El Monte Operable Unit. Therefore, 1.8 ft/d is likely a very conservative value. Also see Appendix C. |
| | Hydraulic Gradient (i) | 0.0027 | unitless | Based on the difference in groundwater gradients (0.0075 and 0.0048) measured in January 2023 and May 2023, as reported in the June, 2023, EEC Environmental Groundwater Well Installation and Sampling Report. Also see Appendix D. |
| Impact Zone Size | Contamination Zone Length along GW Flow Direction (W) | 6858<br>225 | cm<br>ft | Source length was estimated at 225 feet (69 m) based on the Limited Soil Remediation Work Plan developed for the site. Also see Appendix E. |
| | Current Impacted Soil Thickness (L1) | 152.4<br>5 | cm<br>ft | Site-specific data; the lead impact is predominately within the top 5 feet of the vadose zone. Also see Appendix F. |
| | Length between Top of the Impacted Zone to Water Table (L2) | 1524<br>50 | cm<br>ft | Site-specific vadose zone thickness. The water table is at 50 feet bgs. Also see Appendix G. |
| | Soil Bulk Density ($\rho_b$) | 1.5 | g/cm3 | Conservative default value used to calculate USEPA's SSL. Not a sensitive parameter. |
| | Water Filled Porosity ($\Theta_w$) | 0.3 | unitless | Default value used to calculate USEPA's SSL. Not a sensitive parameter. |
| Infiltration Estimation | Infiltration Rate ($I_f$) | 1.57<br>3.98 | in/yr<br>cm/yr | 1.57 in/yr or 3.98 cm/yr is 10% of the average annual precipitation (15.67 in/yr) based on a weather station near the Site (San Gabriel Fire Department, California). This value is between the recharge estimates for the Montebello Forebay basin area (4.3 cm/yr) and the whole Los Angeles groundwater study area (3.5 cm/yr). Because the Site will be covered by asphalt pavement and buildings, the net infiltration at the Site is expected to be noticeably lower than 4.3 cm/yr. Also see Appendix H. |
| Chemical Properties | Partitioning Coefficient (Kd) for Lead (Pb) | 3000 | L/kg | The Kd value for lead is a function of soil pH. Site-specific Kd value is based on the shallow soil pH data collected at the Site (between pH = 7.4 and pH = 11.3 (Leighton Geotechnical Expiration Update Report, 11 May 2023 and Haley & Aldrich January 2024 delineation sampling event) and further supported by the reported soil pH (=7.9) and calcium carbonate (a mineral that increase soil pH) content in shallow soil from the USDA database (approximately 2% weight percentage) for the area where the Site is located. The Kd value was selected based on the pH dependent Kd relationship for lead provided in Figure F.1 of the USEPA 402-R-99-004B document. Note that, beside adsorption, lead tends to precipitation under alkaline pH conditions. Also see Figure 2 in the memorandum and Appendix I. |
| Target Groundwater Concentration | Groundwater Protection Standard | 15 | µg/L | USEPA action level for lead in water. |
| Estimated Soil Screening Level | Bulk lead (Pb) concentration in the vase zone soil (mg/Kg) | **1500** | **mg/kg** | Estimated value based on the parameters above and according to formulas in Conor et al. (2007). |

**Notes:** cm = centimeters; in = inches; ft = feet; sec = second; d = day; yr = year; L = liter; kg = kilogram; mg = milligram; µg = microgram; cm3 = cubic centimeter; GW = groundwater

## 1.0 Overview of Soil Attenuation Model (SAM)

Under a risk-based corrective action (RBCA) process, soils and groundwater impacted by a chemical release are to be remediated or controlled to concentration levels such that further migration will not expose human or environmental receptors to unsafe levels of hazardous constituents. For this purpose, site-specific target levels (SSTLs) must be established for the affected soil mass such that subsequent soil leachate migration to an underlying water-bearing unit does not cause exceedance of applicable exposure limits for groundwater. To derive such groundwater protection standards, a new Soil Attenuation Model (SAM) has been developed to provide a conservative estimate of soil-to-groundwater contaminant release based on readily available information regarding annual rainfall, soil type, depth to groundwater, and the hydrogeologic properties of the underlying water-bearing unit. Using either site-specific or generic site properties, this analytical model can be used either to i) predict upperbound constituent concentrations in groundwater, based on an observed soil concentration, or ii) back-calculate a lower-bound soil SSTL value, based on the applicable risk-based screening level (RBSL) at the groundwater point of exposure (POE). The model is applicable to analysis of porous media soils impacted by either organic and inorganic constituents, in the absence of mobile non-aqueous phase liquids (NAPLs).

The SAM represents a modification to the soil-leachate equations presented in Appendix X.2 of ASTM E-1739 *Standard Guide for Risk-Based Corrective Action Applied at Petroleum Release Sites* (ASTM, 1995). These modifications are directed toward providing a more rigorous characterization of the soil-to-groundwater leachate process and assisting the user in estimation of critical input parameters. However, to accommodate use in Tiers 1 and 2 of the risk-based site evaluation effort, the SAM retains the format of a simple, screening-level analytical expression requiring limited site-specific data input. The model includes empirical relationships to assist the user in characterization of net infiltration and equilibrium soil moisture content parameters based on annual site rainfall and the predominant soil type overlying the groundwater unit. The soil-to-groundwater leachate process is characterized as a three-step procedure, beginning with i) equilibrium partitioning of soil contaminants from a finite source mass to infiltrating rainwater, followed by ii) sorptive redistribution of contaminants from the leachate onto underlying clean soils, and iii) subsequent leachate dilution within the receiving groundwater flow system. In the base version of this model, contaminant loss through the processes of volatilization and biodegradation are neglected for purpose of conservatism and simplicity.

This paper reviews the principal components of the Soil Attenuation Model (SAM) and presents detailed background information regarding model derivation and key assumptions. The SAM model has recently been specified for incorporation in the proposed Texas Risk Reduction Program (TRRP) (see TNRCC 1996). Sample default values to be used in Tier 1 and Tier 2 of the Texas process are also discussed herein. Summary guidelines regarding calculation procedures and input parameter selection are provided on Figure 2 and Table 4, respectively.

# 2.0 Model Description

### AMENDMENTS TO ASTM RBCA SOIL LEACHATE EQUATION

Appendix X.2 of ASTM E-1739 presents analytical equations for estimation of a soil leachate factor (LF), corresponding to a steady-state ratio between contaminant concentrations in affected soils and the resultant concentrations in an underlying water-bearing unit. Intended as example screening-level models, the ASTM soil leachate equations have been widely adopted for use in calculation of risk-based soil remediation standards under Tiers 1 and 2 of the ASTM RBCA planning process. In the ASTM model, the soil leachate process is characterized as a simple two-step process, involving: i) dissolution of soil contaminants into infiltrating rainwater (estimated using an equilibrium partitioning relationship), followed by ii) leachate dilution within the underlying groundwater (estimated using a simple box model).

The ASTM leachate factor equations meet the Tier 1 and Tier 2 objectives of conservatism, simplicity, and reproducibility; however, practical application of this leachate model has been complicated by difficulties associated with proper estimation of key input parameters and overly conservative characterization of the soil leachate process. Specifically, given the complexity of obtaining site-specific infiltration measurements, upperbound default values have been applied to rainfall infiltration rates (e.g., 30 cm/yr), providing worst-case estimates of soil leachate impacts. Furthermore, a simple two-step characterization of the leachate generation and migration process (ignoring the effect of contaminated soil mass and soil column thickness on leachate mass flux) can prove overly conservative for deep groundwater conditions.

To address these concerns, the SAM augments the existing ASTM soil leachate equation with features intended to assist in characterization of critical input parameters and more accurately simulate rainfall infiltration and leachate migration. A comparison of the SAM and ASTM models with respect to the key elements of the soil-to-groundwater contaminant release process is provided on Table 1. As shown, the SAM differs from the earlier leachate equations published in ASTM E-1739 by addition of the following features:

- *Net Infiltration Estimate*: SAM incorporates an empirical relationship for estimation of net rainfall infiltration based on mean annual rainfall and soil type.
- *Finite Source Mass*: The SAM assumes a finite contaminant source mass based on the mass of affected soil and the representative concentration of each constituent of concern (COC).

- *Sorptive Mass Redistribution*: The SAM incorporates depth effects by accounting for the sorptive redistribution of contaminants from the leachate onto soils underlying the affected soil zone. This sorptive mass loss reduces contaminant concentrations delivered to the underlying groundwater.

- *Default Soil Moisture Parameters*: SAM employs default soil moisture parameters ($\theta_{as}$, $\theta_{ws}$) consistent with the predominant soil type in the surface soil column.

- *Leachate-Groundwater Dilution*: The SAM estimates leachate dilution in the groundwater flow system using the same box model incorporated in the ASTM expression. However, a supplementary algorithm, published as part of the EPA Soil Screening Level Guide (U.S. EPA, 1996), has been added to assist the user in estimation of the groundwater mixing zone depth.

**TABLE 1: SUMMARY OF SAM AMENDMENTS TO ASTM SOIL LEACHATE EQUATIONS**

| | | SAM FEATURE | |
|---|---|---|---|
| **ELEMENT OF SOIL LEACHING PROCESS** | **ASTM LEACHATE MODEL FEATURE** | **REVISED?** | **DESCRIPTION** |
| **1) Net Rainfall Infiltration** | Uses upperbound estimate of annual infiltration (e.g., 30 cm/yr). | ***Yes*** | ***Net Infiltration Calculator***: Estimates net infiltration as function of rainfall and soil type. |
| **2) Soil Moisture/Air Contents** | Uses conservative default values. | ***Yes*** | ***Soil-Dependent Default Values***: Employs equilibrium soil moisture parameters consistent with soil type. |
| **3) Contaminant Source Mass** | Assumes infinite source mass in affected soil zone. | ***Yes*** | ***Finite Source Mass***: Contaminant source mass assumed to be finite (i.e., affected soil mass times representative contaminant concentration ). See also "Time Averaging" below. |
| **4) Equilibrium Partitioning: Soil to Leachate** | Assumes equilibrium relation-ship based on soil-water sorption, chemical properties. | No | ***Equilibrium Partitioning***: Equilibrium assumption retained as conservative, simplifying measure. |
| **5) Contaminant Loss via Volatilization and Biodegradation** | Not considered. | No | ***No Biodegradation or Volatilization***: These processes neglected in base model as conservative, simplifying measure. Biodegradation may be applied as optional measure based on site-specific data. |
| **6) Sorptive Redistribution of Contaminant on Underlying Soil (Depth Effect)** | Not considered. | ***Yes*** | *Sorptive Mass Redistribution*: Accounts for mass loss due to redistribution of leachable contaminants onto underlying soils. |
| **7) Leachate Dilution in Groundwater System** | Estimated using simple box dilution model. | No/Yes | ***Leachate-Groundwater Dilution***: Box model retained as simplifying measure. Supplementary algorithm provided for estimation of mixing zone depth. |
| **8) Time-Averaging of Groundwater Concentrations** | Not considered. | No | ***No Time Averaging***: Averaging of exposure concentrations over an exposure duration neglected in base model as conservative measure. May be applied as optional measure for carcinogenic constituents under Tier 3 evaluation. |

The SAM is consistent with the ASTM model in the use of an equilibrium partitioning relationship for estimation of soil pore water concentrations and in neglecting contaminant loss

via volatilization or biodegradation. In addition, neither the SAM nor the ASTM leachate model presently accounts for the gradual loss of source mass to leachate over time and the resultant decrease in contaminant flux to groundwater over a 30-year period of exposure. In each case, these measures represent conservative, simplifying assumptions consistent with the model application as a Tier 1 or Tier 2 screening-level tool. However, as noted on Table 1, biodecay and time averaging may be applied as optional modeling measures based on site-specific considerations under a Tier 2 or Tier 3 evaluation. If such options are to be utilized, biodegradation rates must be based on measured site-specific data. For carcinogenic constituents, time averaging may be applied to consider average chronic effects over the exposure duration.

**KEY COMPONENTS OF SAM**

The Soil Attenuation Model (SAM) can be used to derive a steady-state soil-to-groundwater contaminant leachate factor (LF) based on available information regarding site soil and groundwater conditions. The model can be used to predict contaminant flux from affected soils to underlying groundwater for either organic or inorganic constituents, in the absence of mobile, free-phase soil contaminants.

For the purpose of this analysis, shallow site geology is idealized as two principal stratigraphic components: i) a *surface soil column* consisting of unsaturated and saturated soils, wherein pore water flow is primarily vertical (downward), underlain by ii) a saturated, transmissive *water-bearing unit*, wherein pore water flow is principally horizontal (see Figure 1). The boundary of these two flow zones corresponds to the top of the uppermost water-bearing stratum beneath the site. Contaminant transfer from affected soils in the surface soil column to the underlying water-bearing unit occurs via vertical leachate migration. After entering the water-bearing unit, the leachate fluids mix with the lateral groundwater flow stream and spread horizontally from the point of entry in the downgradient direction of shallow groundwater flow (see Figure 1).

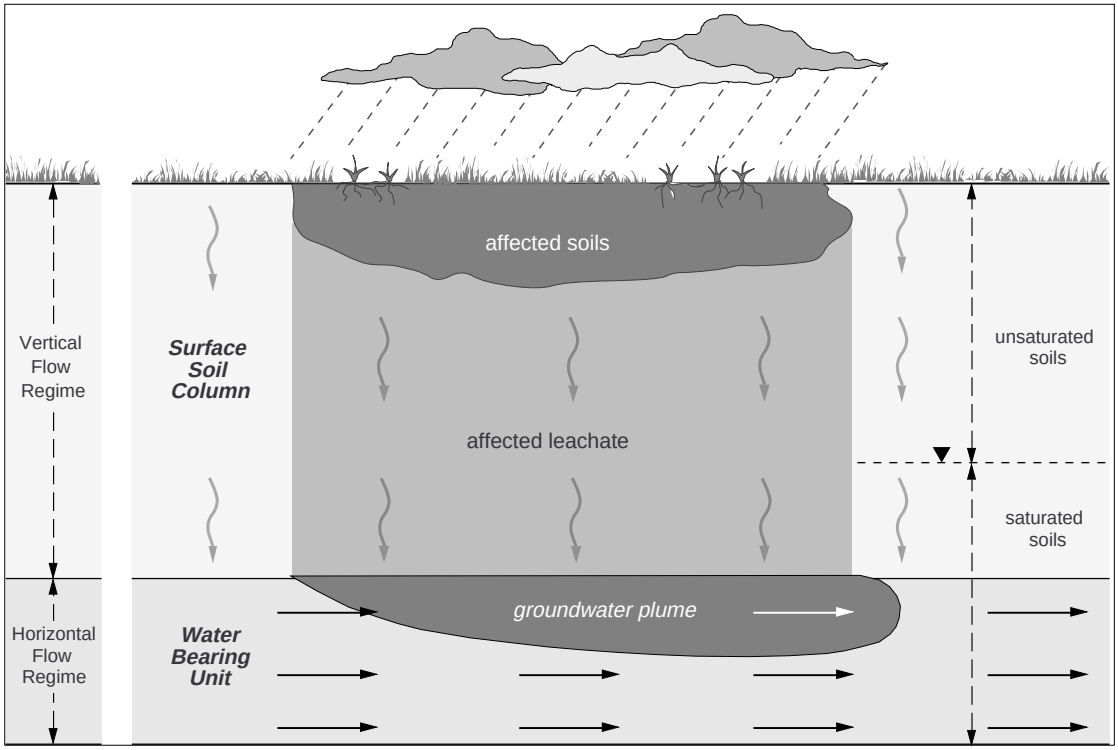
The SAM simulates this soil leachate process from the initial infiltration of rainfall through the affected soil zone to final mixing of the contaminated soil leachate with underlying groundwater. Principal components of this soil leachate model are illustrated on Figure 2 and discussed in further detail below. Background information regarding model derivation is provided in Attachments A through D.

### 1) Estimation of Net Infiltration

- ***Method Description***: Net infiltration corresponds to total infiltration (precipitation minus runoff) minus the additional loss associated with evapotranspiration. The net infiltration term ($I_f$) thereby represents the deep percolation flow (cm/year) through the affected soil zone which could result in contaminated leachate release to underlying groundwater. In the SAM, net infiltration is estimated as a function of average annual rainfall (cm/year) and the predominant soil type (sand, silt, or clay) using the empirical relationships plotted on Figure 3 (or using Equations 1a - 1c on Figure 2). Given the predominant soil type in the surface soil column, the curves and accompanying equations

can be used to obtain a conservative estimate of net annual infiltration (cm/year), based on a grass ground cover (i.e., no pavement). For highly stratified soil columns composed of multiple soil types (e.g., interbedded sand and clay), the lower permeability soil (i.e., clay) will control vertical infiltration.

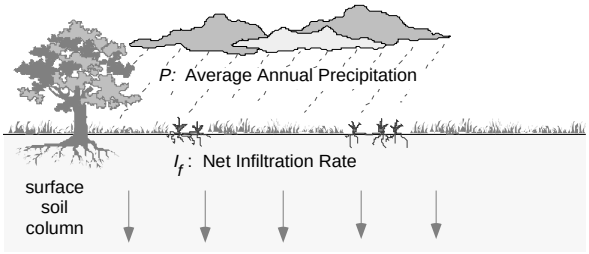
**FIGURE 1: IDEALIZED SCHEMATIC OF SOIL LEACHATE MIGRATION**



- ***Key Assumptions***: The sand soil curve shown on Figure 3 represents an 80% envelope line for rainfall infiltration data from over 100 sandy soil sites in 18 geographic regions in the United States, as compiled by Stephens & Associates (API, 1996). This curve provides a conservative (upper-range) estimate of deep percolation for over 80% of the sand or gravel soil sites reported in this database. Curves for silty and clayey soils were then derived from the empirical sandy soil curve based on the relative percent infiltration described by Viessman *et al* (1989) for the parameters of the Horton infiltration relationship. Detailed information regarding development of these empirical curves is provided in Attachment A. The net infiltration curves shown on Figure 3 correspond to a grass-covered site and will prove highly conservative for soils overlain by pavement (e.g., 100x overestimate of $I_f$).

## FIGURE 2: SCHEMATIC DIAGRAM OF SOIL ATTENUATION MODEL (SAM)

### 1. Estimation of the Net Infiltration Rate



Eqn. 1a: For Sand: $I_f\ [cm/yr] = 0.0018 \cdot (P)^2$

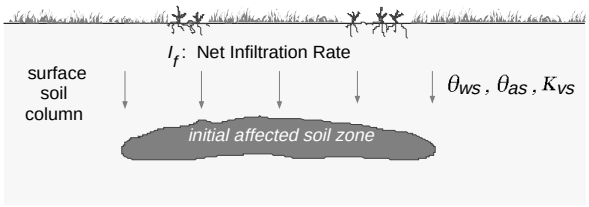
Eqn. 1b: For Silt: $I_f\ [cm/yr] = 0.0009 \cdot (P)^2$

Eqn. 1c: For Clay: $I_f\ [cm/yr] = 0.00018 \cdot (P)^2$

Eqn. 1d: Upperbound net infiltration limit:

$$I_f\ [cm/yr] \le I_{f_{max}} = K_{vs} \cdot \left[\frac{3.15x10^7\ sec}{1\ yr}\right]$$

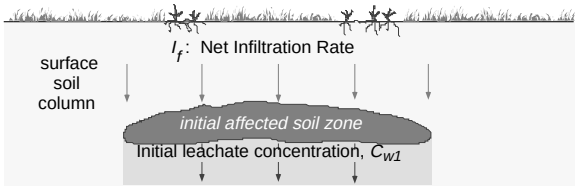
### 2. Equilibrium Volumetric Water and Air Contents



Option 2a) ***Default Values:*** Select default soil moisture parameters ($\theta_{as}$, $\theta_{ws}$) and saturated hydraulic conductivity based on soil type (see Table 2).

Option 2b) ***Site Measurements:*** Conduct site-specific measurements of $\theta_{as}$, and $\theta_{ws}$ on sufficient number of representative soil samples from surface soil column. Conduct field measurements of $K_{vs}$.

### 3, Equilibrium Partitioning: Affected Soil to Leachate



Eqn. 3a: $C_{w1}[mg/L] = K_{sw} \cdot C_T$

where:

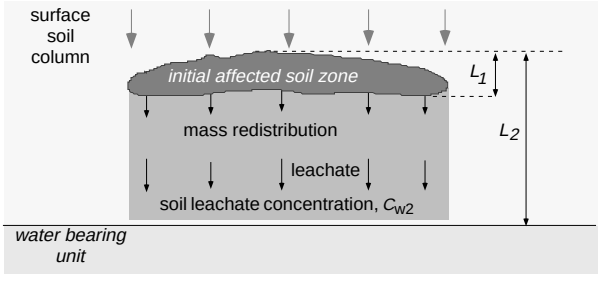
Eqn. 3b: $$K_{sw}\left[\frac{mg/L - H_20}{mg/Kg - soil}\right] = \frac{\rho_s}{B_w}$$

Eqn. 3c: $$B_w = \theta_{ws} + k_s \cdot \rho_s + H \cdot \theta_{as}$$

Eqn. 3d: $$k_s\left[\frac{cm^3 - H_20}{g - soil}\right] = k_{oc} \cdot foc \quad (Organics)$$

Eqn. 3e: $$k_s\left[\frac{cm^3 - H_20}{g - soil}\right] = k_d \quad (Inorganics)$$

### 4. Sorptive Mass Redistribution: Leachate to Underlying Clean Soil



Eqn. 4a: $$C_{w2}[mg/L] = C_{w1} \cdot \frac{L_1}{L_2}$$

Eqn. 4b: Upperbound leachate concentration for mass conservation:

$$C_{w2}[mg/L] \le \frac{C_T \cdot \rho_s \cdot L_1}{I_f \cdot ED}$$

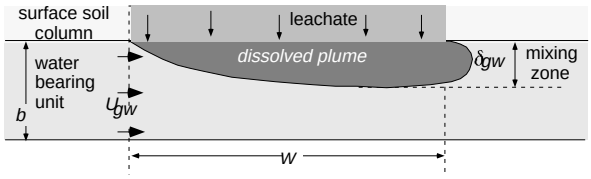
Eqn. 4c: Upperbound leachate concentration for solubility limit:

$$C_{w2}[mg/L] \le X \cdot S$$

***Continued***

## FIGURE 2: SCHEMATIC DIAGRAM OF SOIL ATTENUATION MODEL (SAM) *continued*

### 5. Leachate/Groundwater Dilution



Eqn. 5a: $$LDF\,[unitless] = 1 + \frac{U_{gw} \cdot \delta_{gw}}{I_f \cdot W}$$

where:

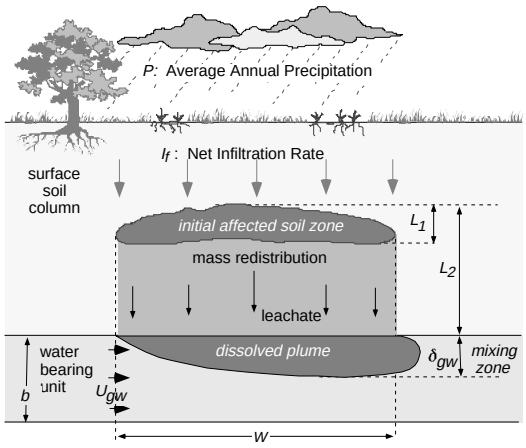
Eqn. 5b: $$U_{gw}[cm/yr] = K \cdot i \cdot \left( \frac{3.15 \times 10^7 \sec}{1yr} \right)$$

Eqn. 5c: $$\alpha_v[cm] = 0.0056 \cdot W$$

Eqn. 5d: $$\delta_{gw}[cm] = \sqrt{2 \cdot a_v \cdot W} + b \cdot \left[ 1 - \exp\left( \frac{-I_f \cdot W}{U_{gw} \cdot b} \right) \right]$$

Eqn. 5e: **Upperbound mixing zone depth:** $\delta_{gw}[cm] \le b$

### 6. Summary Calculations



Eqn. 6a: **Groundwater Exposure Concentration:**

$$C_{gw}[mg/L] = C_{w2} \cdot \frac{1}{LDF} \cdot \left( BDF^* \cdot TAF^* \right)$$

Eqn. 6b: **Soil Target Concentration:**

$$^{GW}Soil_{Ing.}[mg/Kg] = {}^{GW}RBSL \cdot LDF \cdot \frac{L_2}{L_1} \cdot \frac{1}{K_{sw}} \cdot \left( \frac{1}{BDF^* \cdot TAF^*} \right)$$

where:

*Eqn. 6c: **Optional Biodecay Factor:**

$$BDF[dim] = \exp\left[ -\lambda \cdot (L_2 - L_1) \cdot \left( \frac{B_w}{I_f} \right) \right]$$

*Eqn. 6d: **Optional Time Averaging Factor:**

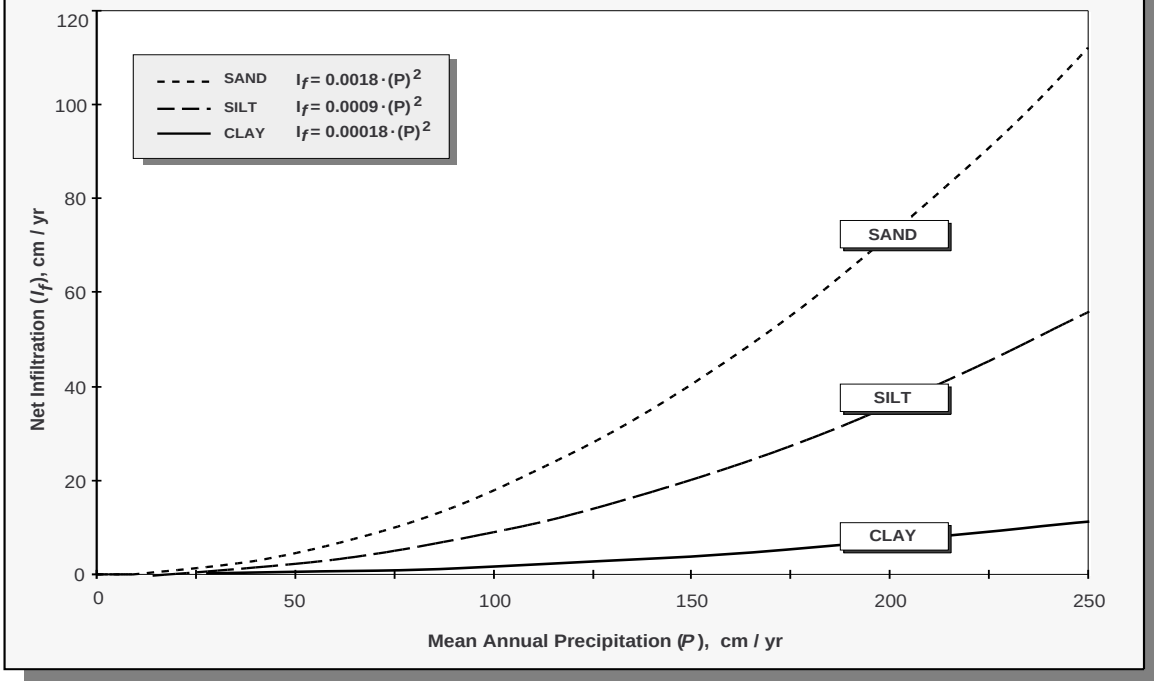
$$TAF[dim] = \frac{L_2 \cdot B_w}{I_f \cdot ED} \cdot \left[ 1 - \exp\left( \frac{-I_f \cdot ED}{L_2 \cdot B_w} \right) \right]$$

### Model Parameters

| | | TEXAS TIER 1 DEFAULT |
|---|---|---|
| b | Saturated thickness of water-bearing unit (cm) | SS |
| $B_w$ | Bulk water partioning coefficient (unitless) | CS |
| $C_{gw}$ | Concentration of COC in groundwater (mg/L) | SS |
| COC | Constituent of Concern | SS |
| $C_T$ | Bulk COC concentration on the soil mass (mg/Kg) | SS |
| $C_{w1}$ | Concentration of COC in soil leachate in the initial affected soil zone (mg/L) | SS/CS |
| $C_{w2}$ | Concentration of COC in soil leachate discharged to underlying water-bearing unit (mg/L) | SS/CS |
| ED | Exposure duration (yr) | 30 |
| foc | Fraction of organic carbon (g-C/g-soil) | 0.006 |
| H | Henry's Law constant for COC ($cm^3$-$H_20$/$cm^3$-air) | CS |
| i | Hydraulic gradient in water-bearing unit (cm/cm) | SS |
| $I_f$ | Net infiltration (cm/yr) | 10 |
| $I_{f\,max}$ | Upperbound infiltration limit (cm/yr) | (see above) |
| K | Hydraulic conductivity of water-bearing unit (cm/sec) | SS |
| $k_d$ | Inorganic soil-water sorption coefficient for COC ($cm^3$-$H_2O$/g-soil) | CS |
| $k_{oc}$ | Organic carbon partition coefficient for COC ($cm^3$-$H_2O$/g-C) | CS |
| $k_s$ | Soil-water sorption coefficient ($cm^3$-$H_2O$/g-soil) | CS |
| $K_{sw}$ | Soil-leachate partition factor for COC (mg/L-$H_2O$/mg/Kg-soil) | CS |
| $K_{vs}$ | Saturated hydraulic conductivity of vadose zone soils (cm/sec) | (see Table 2) |
| $L_1$ | Thickness of affected soil zone (cm) | 60 |
| $L_2$ | Distance from top of affected soil zone to top of water bearing unit (cm) | 60 |
| LDF | Leachate-groundwater dilution factor (unitless) | SS |
| P | Mean annual precipitation (cm/yr) | SS |
| $^{GW}RBSL$ | Risk-Based Screening Level in groundwater zone (mg/L) | CS |
| S | Aqueous solubility of COC (mg/L) | CS |
| $^{GW}Soil_{Ing}$ | Source Area Concentration Limit for soils (mg/Kg) | CS |
| $U_{gw}$ | Groundwater Darcy velocity (cm/yr) | 2,500 |
| W | Lateral width of affected soil zone in direction of GW flow (cm) • 0.5-acre site<br>• 3.0-acre site | 4,500<br>34,800 |
| X | Initial mole fraction of COC in source material (unitless) | 1.0 |
| $\alpha_v$ | Vertical groundwater dispersivity (cm) | (see above) |
| $\delta_{gw}$ | Groundwater mixing zone thickness (cm) | 200 |
| $\lambda$ | Biodecay rate of COC in vadose zone ($yr^{-1}$) | 0 |
| $\theta_{as}$ | Volumetric air content of surface soils ($cm^3$-air/$cm^3$-soil) | 0.13 |
| $\theta_T$ | Total porosity of surface soils ($cm^3$-pore-space/$cm^3$-soil) | 0.43 |
| $\theta_{ws}$ | Volumetric water content of surface soils ($cm^3$-$H_2O$/$cm^3$-soil) | 0.30 |
| $\rho_s$ | Soil bulk density (g-soil/ $cm^3$-soil) | 1.5 |

NOTE: SS = Site-specific parameter CS = Chemical-specific parameter

**FIGURE 3: ESTIMATION OF NET INFILTRATION BASED ON MEAN ANNUAL RAINFALL & SOIL TYPE**



**NOTES:**

1) Net rainfall infiltration through surface soils estimated based on empirical relationship of mean rainfall and predominant soil type in surface soil column. See Attachment A for derivation of empirical formulas.
2) $I_f$ = Net infiltration (i.e., total infiltration corrected for evapotranspiration loss), cm / yr
   P = Mean annual rainfall at site, cm / yr
3) Soil type classified per Unified Soil Classification System (USCS). See Lambe et al., 1969.

## 2) Volumetric Air and Water Contents

- ***Method Description***: For typical soil types, conservative default values for each of the input parameters required in these equations are provided on Table 2. To employ these defaults, the user must first determine the appropriate soil classification for soils within the surface soil column, using either the Unified Soil Classification System (USCS, Lambe et al, 1969) or USDA textural classification method (Peck et al, 1974), based on the predominant soil type observed in site boring logs. Note that for highly stratified systems composed of multiple soil types of roughly equivalent volumes, the lowest permeability soil will control the rate of infiltration and the resulting average moisture content. If desired, site-specific values for volumetric air and water content and saturated hydraulic conductivity can be developed based on measurements conducted on multiple soil samples spatially distributed throughout the surface soil column. However, as the model is not highly sensitive to these parameters, the expense of site-specific analyses may not be warranted in most cases.

**TABLE 2:DEFAULT SOIL PARAMETERS FOR ESTIMATION OF EQUILIBRIUM SOIL MOISTURE CONTENT (USCS SOIL TYPES)**

| USCS SOIL TYPE | | DEFAULT SOIL MOISTURE PARAMETERS | | | DEFAULT HYDRAULIC CONDUCTIVITY |
|---|---|---|---|---|---|
| SYMBOL | DESCRIPTION | $\theta_T$ | $\theta_{ws}$ | $\theta_{as}$ | $K_{vs}$ (cm/s) |
| SW | SAND, clean, well-graded | 0.41 | 0.08 | 0.33 | $10^{-2}$ |
| SP | SAND, clean, poorly-graded | 0.41 | 0.08 | 0.33 | $10^{-2}$ |
| SM | SAND, silty | 0.41 | 0.12 | 0.29 | $10^{-3}$ |
| SC | SAND, clayey | 0.38 | 0.23 | 0.15 | $10^{-5}$ |
| ML | SILT, sandy | 0.43 | 0.26 | 0.17 | $10^{-5}$ |
| ML | SILT | 0.46 | 0.30 | 0.16 | $10^{-5}$ |
| MH | SILT, clayey | 0.36 | 0.24 | 0.12 | $10^{-5}$ |
| CL | CLAY, sandy, low plasticity | 0.38 | 0.31 | 0.07 | $10^{-6}$ |
| CL | CLAY, silty, low plasticity | 0.36 | 0.34 | 0.02 | $10^{-7}$ |
| CH | CLAY, high-plasticity | 0.38 | 0.38 | 0 | $10^{-8}$ |

NOTES:
1) Default values for volumetric water ($\theta_{ws}$) and volumetric air ($\theta_{as}$) contents are to be matched to predominant soil type in surface soil column. See Attachment B for derivation of default values.
2) Typical saturated hydraulic conductivity ($K_{vs}$) values matched to median values reported by Freeze and Cherry (1979) and Rawls and Brakensiek (1985).
3) Unified Soil Classification System (USCS) described in Lambe et al (1969) and ASTM Standard D-2487.

- ***Model Derivation***: The default soil moisture values shown on Table 2 represent equilibrium levels associated with an annual rainfall of 30 inches (U.S. median), derived using the Brooks-Corey (1964) soil characteristic model and the Burdine (1953) equations for the relative permeability of unsaturated soils. Sensitivity analyses show that use of default soil moisture values based on a median rainfall level provides model results that are on average within $\pm$ 5% of those obtained using the site-specific, rainfall-dependent, soil moisture values derived using the Brooks-Corey model. Consequently, use of default soil moisture values represents a reasonable, simplifying measure in the SAM. Attachment B provides detailed information regarding the derivation of these tabulated default values.

Note that the *surface soil column* as defined in this model may consist of an upper unsaturated soil zone as well as a lower saturated soil zone, through which pore water flow is predominantly vertical (downward) toward an underlying water-bearing unit (see Figure 1). In the lower saturated portion of this soil column, the actual volumetric air content ($\theta_{as}$) of the soils will be zero. However, through use of default soil moisture values as listed on Table 2, the SAM characterizes the soil column as a uniform unsaturated soil zone (i.e., $\theta_{as} > 0$). For sites wherein the surface soil column is predominately saturated (e.g., clay stratum overlying confined water-

bearing with high confining head), these equilibrium soil moisture values will prove relatively conservative, contributing to an overestimation of soil leachate concentrations (i.e., higher $K_{sw}$ value; see Equation 3b).

**3) Equilibrium Partitioning**

- ***Method Description***: The transfer of soil contaminants to infiltrating rainwater is characterized on the basis of a conventional equilibrium partitioning relationship among the soil, pore water, and pore vapor phases of the surface soil matrix (see Equations 3a and 3b on Figure 2). Using these equilibrium relationships, the fraction of the soil contaminant mass partitioning to the soil leachate (i.e., soil-leachate partition factor, $K_{sw}$) is defined on the basis of site soil properties ($\rho_s$, $\theta_{ws}$, $\theta_{as}$, foc) and the chemical characteristics of the constituent of concern (H, $k_{oc}$, pH-dependent $k_d$ function). The soil-water sorption coefficient ($k_s$) for each constituent is calculated using separate functions for organic and inorganic constituents, as indicated on Figure 2. Guidelines for derivation of $k_s$ values are provided in the EPA Soil Screening Level (SSL) Document (U.S. EPA, 1996). Multiplying the representative COC concentration in the affected soil mass ($C_T$) by the soil-leachate partition factor ($K_{sw}$) yields an upperbound estimate of the resultant COC concentration in the soil leachate ($C_{w1}$). Under Tier 1, RBSLs can be derived on the basis of fixed default values for the site soil properties, as specified on Figure 2.

- ***Key Assumptions***: The soil-leachate partition factor ($K_{sw}$, see Equation 3b) used in the SAM represents the conventional three-phase equilibrium partitioning relationship for affected environmental media, which has been previously incorporated in both the ASTM E-1739 Appendix X.2 examples (ASTM, 1995) and in the EPA Soil Screening Level Document (U.S. EPA, 1996). The equation assumes instantaneous partitioning at equilibrium levels and thereby provides an upperbound estimate of contaminant release from soils to infiltrating rainwater and subsequently to underlying groundwater. The model neglects the effects of immobile residual non-aqueous phase liquids (NAPLs) that may be present within the affected soil mass. If such NAPL materials are present, many organics partition strongly to this fourth phase (i.e., immobile residual NAPL), reducing the mass fraction available for leachate release. (Note the SAM is not applicable to sites where mobile NAPL is actively percolating from the soil column to the underlying water-bearing unit.) In the SAM, such four-way partitioning has been neglected as a conservative, simplifying measure. As shown on Table 3, for BTEX constituents, neglecting such NAPL partitioning effects results in a conservative overprediction of leachate concentrations by a factor of 1.3x to 4.2x, depending on the assumed residual NAPL concentration in the soil pores (see Cases 1 and 2 on Table 3).

**4) Sorptive Mass Redistribution**

- ***Method Description***: The SAM corrects the equilibrium soil leachate concentration for the effect of sorptive mass loss as the leachate percolates downward toward the underlying

water-bearing unit. This adjustment can prove significant in deep groundwater systems, wherein a significant thickness of unaffected soils underlies the affected soil zone. For the SAM, the affected soil zone is characterized as a finite source mass equivalent to the affected soil mass times the representative constituent concentration. Prior to reaching groundwater, percolating rainwater serves to redistribute this finite source mass among soil, air, and pore fluids throughout the full thickness of the surface soil column.

As a result of this sorptive redistribution of contaminant mass onto intervening soils, the initial equilibrium leachate concentration ($C_{w1}$, as defined by Equation 3a) will be reduced by the ratio of the affected soil zone thickness ($L_1$), divided by the total soil column thickness from the top of the affected soils to the top of the saturated water-bearing unit ($L_2$). These depth parameters can be determined on a site-specific basis from soil boring logs and soil test results. The adjusted leachate concentration ($C_{w2}$) calculated using Equation 4a (see Figure 2) represents the maximum dissolved contaminant concentration in leachate entering the groundwater at any time (i.e., initial leachate front). This maximum leachate concentration can be expected to diminish over time, as the leachate process continually removes source mass from the affected soil zone. However, as a conservative measure, the SAM assumes this initial leachate concentration to remain constant for the full duration of the groundwater exposure period. Note that this upperbound leachate concentration ($C_{w2}$) must be adjusted for mass conservation considerations (Equation 4b) and effective solubility limits (Equation 4c). In each case, the lowest concentration determined by Equations 4a, 4b, and 4c will apply. For derivation of Tier 1 RBSL values, the affected soil unit can be assumed to be in contact with the water-bearing unit (i.e., $L_2/L_1 = 1$) thereby neglecting sorptive redistribution effects. Alternatively, Tier 1 soil RBSL charts can be provided for various ratios of $L_1/L_2$.

- ***Key Assumptions***: Attachment C details the derivation of the sorptive redistribution expression (Equation 4). The equation is based upon an assumption of COC mass conservation as the leachate front moves downward through the surface soil column, with the equilibrium partitioning of contaminants from the leachate to the encountered soil, vapor, and pore liquid phases characterized per Equation 3b. This model corresponds to movement of dissolved constituents through porous media and does not apply to cases involving downward migration of mobile NAPL materials. The equation determines the maximum leachate concentration reaching the depth of groundwater, neglecting the effects of the diminishing source concentration ($C_T$) over time as the leachate process continues. As shown on Table 3 (see Cases 7 and 8), using this maximum leachate concentration rather than a time-averaged value results in a conservative overprediction of chronic groundwater exposure concentrations by a factor of 1.1x to 1.4x, depending on soil column thickness.

**TABLE 3: EFFECT OF KEY ASSUMPTION ON SAM RESULTS**

| SAM MODEL ASSUMPTION | CALCULATED SOIL BENZENE LIMIT (mg/Kg) | | EFFECT OF BASE CASE ASSUMPTION ON CALCULATED SOIL LIMIT | |
|---|---|---|---|---|
| | SENSIVITY RUN RESULTS | BASE CASE RESULT | BASE CASE | SOIL LIMIT MULTIPLIER |
| **No NAPL Partitioning Effect** | | | | |
| • **Case 1: Four-way Partitioning:** Benzene $\theta_{or}$ = 0.01 | 1.94 | 0.46 | Conservative | 4.2x |
| • **Case 2: Four-way Partitioning:** Benzene $\theta_{or}$ = 0.001 | 0.60 | 0.46 | Conservative | 1.3x |
| **No Biodegradation** | | | | |
| • **Case 3: First-Order Decay:** Benzene Half-Life = 160 days; depth to GW: 5 ft | 644 | 0.46 | Conservative | 1400x |
| • **Case 4: First-Order Decay:** Benzene Half-Life = 1600 days; depth to GW: 5 ft | 0.92 | 0.46 | Conservative | 2x |
| **No Competitive Sorption Effects** | | | | |
| • **Case 5: Competitive Sorption:** Equal BTEX concentrations | 0.16 | 0.46 | Non-Conservative | 2.8x |
| • **Case 6: Competitive Sorption:** Benzene concentration = 10% of TEX | 0.11 | 0.46 | Non-Conservative | 4.1x |
| **No Time-Averaging of Groundwater Exposure Levels** | | | | |
| • **Case 7: Time Averaging** ED = 30 yrs; depth to GW: 0 ft | 0.62 | 0.46 | Conservative | 1.4x |
| • **Case 8: Time Averaging:** ED = 30 yrs; depth to GW: 5 ft | 1.38 | 1.23 | Conservative | 1.1x |

NOTES:

1) To evaluate impact of simplifying assumptions on SAM results, sensitivity runs were conducted for the various cases identified above. Sensitivity run results compared to standard model output (base case) to determine net effect (increase/decrease) on calculated soil cleanup standard.

2) **Base Case Input Parameters:**
Thickness of affected soil = 3 ft
Width of affected soil = 15 ft
Lateral Darcy velocity = 0.25 ft/day
Saturated thickness of water-bearing unit = 10 ft
Surface Soil Type: Silty Sand (SM)
Base Case Decay Rate: 0
Soil bulk density = 1.65 kg/L
Organic carbon partition coefficient = 83 L/kg (benzene)
Henry's Law coefficient = 0.23 (benzene)
Fraction organic carbon = 0.005
Soil Moisture Parameters: See SM, Table 2

3) $\theta_{or}$ = Residual saturation of NAPL in soil pores
Depth to GW = Distance from base of affected soils to top of water-bearing unit

The equilibrium partitioning relationship incorporated in the SAM (Equation 3b) also neglects the effects of competitive sorption of dissolved organic constituents onto the free organic carbon (foc) fraction of the soil matrix. In the derivation of the soil-leachate partition factor ($K_{sw}$) for each COC, the full foc mass is assumed to be available for sorption of each constituent. In reality, in the presence of multiple dissolved constituents, the soil-water sorption coefficient ($k_s$) for each COC will be a function of the relative concentration of that COC in the dissolved phase and its binding energy to the soil carbon sorbate. Such competitive sorption relationships have been characterized using Langmuir-type isotherms for filtration design, but are not well understood at the field level. Therefore, for purpose of simplicity, competitive sorption processes have been neglected in the SAM. This measure

can prove unconservative by overestimating soil sorption and consequently underestimating leachate concentrations. As shown on Table 3 (Cases 5 and 6), the degree of error involved depends upon the relative concentrations of the dissolved COCs. For BTEX mixtures, given equal source concentrations of each compound, leachate concentrations are underestimated by a factor of 2.8x to 4.1x. However, in conjunction with the other conservative elements of this model, this simplifying measure does not compromise the conservative nature of the SAM equation (see Item 6 below).

**5) Leachate/Groundwater Dilution**

- ***Model Description***: The SAM incorporates a leachate dilution factor (LDF) to account for dilution of dissolved COC concentrations as leachate mixes with lateral groundwater flow in the underlying water-bearing unit (see Equation 5a on Figure 2). This dilution factor is based upon a simple box model used to estimate mass dilution within a *mixing zone* located in the water-bearing unit directly beneath the affected soil mass (see Figure 2). Dividing the incoming leachate concentration ($C_{w2}$) by the LDF value yields a steady-state groundwater concentration within the mixing zone area.

  The infiltration rate $I_f$ used in Equation 5a can be estimated using the empirical relationships of Equations 1a - 1c or determined from direct site measurements. The lateral groundwater Darcy velocity within the water-bearing unit ($U_{gw}$) can be based on default values (Tier 1) or on site-specific measurements of the hydraulic conductivity and lateral flow gradient of the water-bearing unit (Tier 2). To assist in estimation of mixing zone thickness, the SAM incorporates an equation relating mixing zone dimensions to the saturated thickness of the water-bearing unit and the relative magnitudes of the leachate infiltration and lateral groundwater flowrates (Equations 5b and 5c). This expression can be used to obtain a reasonable estimate of mixing zone thickness in the absence of a measured vertical plume dimension. Alternatively, for an unconfined water-bearing unit, the estimated plume thickness may be matched to the range of water table fluctuation observed at the site. Under Tier 1, the LDF can be derived on the basis of the fixed default plume thickness and groundwater flow parameters, per the example Texas values specified on Figure 2.

- ***Key Assumptions***: The LDF equation used in the SAM (Equation 5a) assumes uniform mixing of groundwater and soil leachate within the area of the mixing zone, estimated to extend over only the upper portion of the water-bearing unit. Given that the screened interval of a water supply well would typically extend below this mixing zone depth, this dilution equation will provide a conservative (upper-range) estimate of potential COC concentrations in groundwater produced from a well drilled in the immediate vicinity of the affected soil zone. The LDF expression and the associated mixing zone equations shown on Figure 2 (Equations 5a - 5c) are the same as those used for development of EPA Soil Screening Level (SSL) values. Detailed discussion of these calculation methods can be found in the SSL Technical Background Document (U.S. EPA, 1996).

### 6) Summary Calculations

- ***Method Description***: Equations 6a and 6b on Figure 2 summarize the calculation methods for i) a groundwater exposure concentration ($C_{gw}$), associated with a given affected soil concentration and ii) a soil target concentration (SSTL value), associated with a given groundwater risk-based exposure limit. These expressions incorporate each of the SAM components described above. Under Tier 2, site-specific input parameters are to be employed as outlined on Table 4. Tier 1 RBSL values can be based on the fixed default parameters specified on Figure 2.

- ***Key Assumptions***: The net effects of the various modeling assumptions noted above on the calculated soil PCL value are indicated on Table 3. As noted previously, neglecting the effects of NAPL-phase partitioning and time-averaged exposure concentrations introduces a conservative factor of roughly 1.5x - 4x into the model results, reducing the calculated soil SSTL value in each case (see Cases 1, 2, 7, and 8). For constituent mixtures, ignoring competitive sorption may contribute a non-conservative factor of 3x - 4x to the model (see Cases 5 and 6). The absence of biodegradation effects may represent the most conservative assumption in the SAM. As shown on Table 3 (Cases 3 and 4), use of first-order decay half-lives of 160 days or 1600 days for benzene (equivalent to 10x and 100x slower decay rates than the published half-life for benzene in soils; see Howard et al, 1991) would increase the allowable soil SSTL value by factors of 1200x and 2x, respectively, above the no-biodegradation case assumed in the SAM.

  As noted previously, the various modeling assumptions itemized on Table 3 have been incorporated in the SAM for purpose of simplicity. Their sum effect is a likely under-estimate of allowable soil SSTL levels and an over-estimate of potential groundwater impacts associated with soil leachate release. Consequently, this modeling approach should prove appropriate for use as a screening-level model under Tiers 1 and 2 of the site evaluation process.

# 3.0 Application of SAM

#### SELECTION OF INPUT PARAMETERS FOR TIERS 1 AND 2

The SAM may be employed for either i) prediction of groundwater exposure concentrations associated with a given affected soil concentration (Equation 6a) or ii) calculation of a soil SSTL value associated with a given groundwater exposure limit (Equation 6b). Applicable input parameters for each component of the SAM are identified on Figure 2. General guidelines for selection of the model input values required for each step of the calculation process are provided on Table 4.

Under Tier 1 of the site evaluation process, soil concentration limits for each COC can be defined on the basis of default values for all model input parameters, including a default soil type (sand) and a fixed or variable ratio of $L_2/L_1$. Example Tier 1 default values for all SAM input parameters proposed for use in the Texas Risk Reduction Program are shown on Figure 2.

Under Tier 2, site-specific values may be employed for the various site parameters used in the SAM. Each of these inputs may be characterized on the basis of actual site measurements, given adequate field and laboratory data. However, given the difficulty of obtaining representative measurements of certain site parameters (e.g., $I_f$, $\theta_{ws}$, etc.), a combination of parameter estimates and direct site measurements may be applied as described below.

**Reasonable Parameter Estimates Under Tier 2**

Under Tier 2, reasonable estimates for the following model input parameters can be derived on the basis of general site information or published references, as follows:

- ***Net Infiltration ($I_f$)***: Estimate using Equations 1a - 1c based on i) predominant soil type in surface soil column and ii) mean annual rainfall in site vicinity.
- ***Estimated Soil Properties ($\theta_{as}$, $\theta_{ws}$, $\rho_s$, foc)***: Volumetric air and water contents ($\theta_{as}$, $\theta_{ws}$) in the surface soil column may be obtained from Table 2 based on the relevant soil type. Soil bulk density ($\rho_s$) and free organic carbon (foc) can be matched to default values (e.g., 1.5 g/cm3 and 0.006, respectively) or measured on a site-specific basis.
- ***Chemical Reference Properties ($K_{oc}$, H)***: Use the chemical property values provided by the regulatory agency or other relevant source (e.g. RBCA Toolkit Software).
- ***Estimated Mixing Zone Thickness ($\delta_{gw}$)***: In lieu of directly measuring the groundwater plume thickness beneath the affected soil zone, Equations 5b and 5c can be used to establish a reasonable estimate of the groundwater-leachate mixing zone thickness. If the saturated thickness (b) of the water-bearing unit has not been determined to date, the user may estimate saturated thickness as the maximum measured vertical extent of the water-bearing unit (i.e., from top of water-bearing unit to base of deepest well or boring) plus some fixed distance. All other parameters required for Equations 5b and 5c should be determined from site-specific measurements under Tier 2. Alternatively, the groundwater-leachate mixing zone thickness may be estimated as the maximum rage of documented annual water table fluctuations within an unsaturated water-bearing unit.

**Direct Site Parameter Measurements Under Tier 2**

For a Tier 2 evaluation, the following site parameters will typically require direct measurement to ensure accurate model results:

- ***Soil Properties (W, $L_1$, $L_2$, $C_s$)***: The lateral (W) and vertical ($L_1$) dimensions of the affected soil zone should be delineated on the basis of soil sampling and testing. For use in the SAM, $L_1$ for each COC should be matched to the maximum thickness of the affected soils containing the COC at levels in excess of Tier 1 limits. To provide a reasonable prediction of potential groundwater impacts, the COC concentration in the affected soil zone ($C_s$) should then be matched to the *average* value measured within soil samples from locations evenly distributed over the depth interval $L_1$.The distance from the top of the

**TABLE 4: SAM MODEL CALCULATION STEPS AND INPUT DATA REQUIREMENTS**

| | MODEL INPUT REQUIREMENTS | | | |
|---|---|---|---|---|
| SAM MODEL EQN. NO. | EQUATION PARAMETER | ESTIMATION METHOD | REQUIRED INPUT DATA | TIER 2 MEASUREMENT OR ESTIMATION GUIDELINES |
| **Step 1: Soil-Leachate Partition Coefficient ($K_{sw}$)** | | | | |
| **Eqn. 3b** | $p_s$ | D or SS | soil type | Use default value (e.g., 1.5 g/cm$^3$) or measure average value directly. |
| | $\theta_{ws}$, $\theta_{as}$ | Eqns. 2a and 2b | soil type | Use default $\theta_{as}$ and $\theta_{ws}$ values from Table 2 based on predominant USCS soil type. Define $I_f$ per Step 3 below. |
| | $k_s$ | Eqns. 3c and 3d | foc, pH, $k_{oc}$, $K_d$-metals | Measure foc or use default value (e.g., 0.006) for vadose zone. Determine $k_{oc}$ for each COC from chemical reference. For metals, measure soil pH and determine $K_d$-pH function from reference literature. |
| **Step 2: Sorptive Redistribution Factor ($L_2/L_1$)** | | | | |
| ---- | $L_1$ | SS | $L_1$ | Define maximum vertical thickness of affected soil zone exceeding Tier 1 limits based on field or laboratory analyses of soil cores |
| | $L_2$ | SS | $L_2$ | Define vertical distance from top of affected soil zone to top of water-bearing unit based on soil boring logs and soil test results. If depth to groundwater is unknown, either set $L_2$ equal to $L_1$ or estimate $L_2$ based on depth to same water-bearing unit at another site in the immediate vicinity. |
| **Step 3: Leachate-Groundwater Dilution Factor (LDF)** | | | | |
| Eqn. 5a | $I_f$ | Eqns. 1a - 1c | P, soil type | Measure directly or estimate using Equations 1a, 1b, or 1c per relevant soil type. For estimation, base P on local climatic records. Match soil type to site boring logs. |
| | $U_{gw}$ | Eqn. 5b | K, i | Measure i for groundwater using appropriate field methods. Based on soil classification tests (ASTM D-422 and D-2487), use default K value from Table 2 for corresponding USCS classification or conduct field measurement of K. |
| | W | SS | W | Parallel to groundwater flow, measure width of soil zone exceeding Tier 1 limit. |
| | $\delta_{gw}$ | Eqn. 5c | b, $\alpha_v$, W, $I_f$, $U_{gw}$ | Measure plume thickness beneath source or use Eqn. 5c. For Eqn. 5c, determine b from boring logs or estimate as maximum known thickness plus fixed distance (e.g., 10 ft). Use default value for $\alpha_v$ (see Eqn. 5c). Alternatively, estimate $\delta_{gw}$ as maximum range of documented annual water table fluctuation. Define all other input parameters as above. |
| **Step 4: Summary Calculations** | | | | |
| Eqn. 6a | $C_s$ | SS | $C_s$ | From field and lab test data, determine average COC concentration (mg/kg) within full affected soil zone corresponds to depth interval $L_1$. |
| Groundwater Exposure Concentration | $K_{sw}$, LDF, $L_1$, $L_2$ | ---- | ---- | Define per Steps 1 - 3 above. |
| Eqn. 6b | $^{GW}RBSL_{Ing.}$ | ---- | ---- | Identify applicable groundwater exposure limit (mg/L), for relevant exposure pathway (e.g., groundwater ingestion or dermal contact). |
| Soil Site-Specific Target Level (SSTL) | $K_{sw}$ LDF, $L_1$, $L_2$ | ---- | ---- | Define per Steps 1 - 3 above. |

**Parameter Definitions:**

| | |
|---|---|
| b | Saturated thickness of water-bearing unit (cm) |
| D | Default value |
| E | Exponent from Burdine relative permeability model (unitless) |
| foc | Free organic carbon content of surface soils [g-C / g-soil] |
| H | Henry's Law constant for constituent [cm$^3$-$H_2O$ / cm$^3$-air] |
| i | Lateral groundwater flow gradient in water-bearing unit (cm/cm) |
| $I_f$ | Net rainfall infiltration through affected soil zone (cm/yr) |
| $k_{oc}$ | Carbon-water sorption coefficient for constituent [g-$H_2O$ / g-C] |
| K | Hydraulic conductivity of underlying water-bearing unit (cm/sec) |
| $K_{sw}$ | Soil-leachate partition coefficient [(mg/L-$H_2O$) / (mg/Kg-soil)] |
| $K_{vs}$ | Saturated hydraulic conductivity of surface soils (cm/sec) |
| $L_1$ | Thickness of affected soil zone (cm) |
| $L_2$ | Thickness of soil column from top of affected soil zone to top of water-bearing unit (cm) |
| P | Average annual rainfall precipitation (cm/yr) |
| $p_s$ | Soil bulk density [g/cm$^3$] |
| SS | Site-specific measure |
| $U_{gw}$ | Darcy velocity (cm/sec) ($U_{gw} = K \cdot I$) |
| W | Width of affected soil zone parallel to groundwater flow direction (cm) |
| $\theta_{as}$ | Volumetric air content of surface soils [cm$^3$ - air/cm$^3$ - soil] |
| $\delta_{gw}$ | Leachate-groundwater mixing zone thickness (cm) |
| $\theta_T$ | Total soil porosity [cm$^3$-pore space / cm$^3$-soil] |
| $\theta_{ws}$ | Volumetric water content of surface soils [cm$^3$-water / cm$^3$-soil] |

affected soil zone to the top of the underlying water-bearing unit ($L_2$) can be determined from on-site boring logs or from data obtained from a separate location in close proximity to the site under evaluation.

- ***Groundwater Flow Properties ($U_{gw}$, K, i)***: For estimation of the leachate-dilution factor (LDF) and mixing zone depth ($\delta_{gw}$), the groundwater Darcy velocity within the underlying water-bearing unit ($U_{gw}$) should be calculated on the basis of site-specific lateral hydraulic flow gradient (i) value and an estimated or measured hydraulic conductivity (K) value. Determination of the lateral hydraulic flow gradient within the water-bearing unit involves triangulation among static water levels measured in at least 3 site wells or piezometers, per standard guidelines. If the soil type of the water-bearing unit has been classified in the laboratory in accordance with ASTM Standards D-422 and D-2487 (ASTM), the hydraulic conductivity of the unit may be estimated using the default values listed on Table 2. Alternatively, K can be directly measured in the field by means of rising-head slug tests or constant-rate pumping tests conducted on properly completed wells or piezometers.

**EXAMPLE APPLICATION OF SAM**

Table 5 presents example soil cleanup standards calculated using the SAM for a range of soil types, depths, and annual rainfall levels. Assumed site conditions are illustrated on Figure 4. In each case, the source area SSTL for the affected soil zone was back-calculated using Equation 6b, based on a 0.005 mg/L benzene exposure limit in the underlying water-bearing unit. For purpose of comparison, benzene soil limits calculated using the soil leachate equations and default infiltration rate (30 cm/yr) listed in ASTM E-1739 are also shown on Table 5.

For the cases analyzed, the ASTM soil concentration limit is a constant (i.e., 0.069 mg/kg benzene on soil). However, the SAM results vary according to annual rainfall, soil type, and thickness of the underlying soils. As shown on Table 5, allowable benzene soil concentrations vary by roughly one order of magnitude between an arid climate condition (e.g., Albuquerque, New Mexico) and a high rainfall area (e.g., Houston, Texas) for a given soil type. For a given rainfall and soil thickness, the allowable benzene level in sand versus clay soils also differs by roughly 10-fold. For each site and each soil type, the soil benzene limit increases with increasing thickness of underlying soils (at a rate that is linear with respect to the ratio $L_2/L_1$, as defined in Equation 6b). Please note that the soil concentration limits listed on Table 5 are example model results for a given set of site conditions and **do not** represent generic cleanup values. Site-specific soil SSTL values must be derived using appropriate model input parameters, per the procedures outlined on Table 4.

**TABLE 5: EXAMPLE SOIL CLEANUP LEVELS CALCULATED USING SAM AND ASTM SOIL LEACHING MODELS**

| SOIL ZONE DIMENSIONS | | | SOIL CONCENTRATION LIMIT FOR BENZENE (MG/KG) | | | | | |

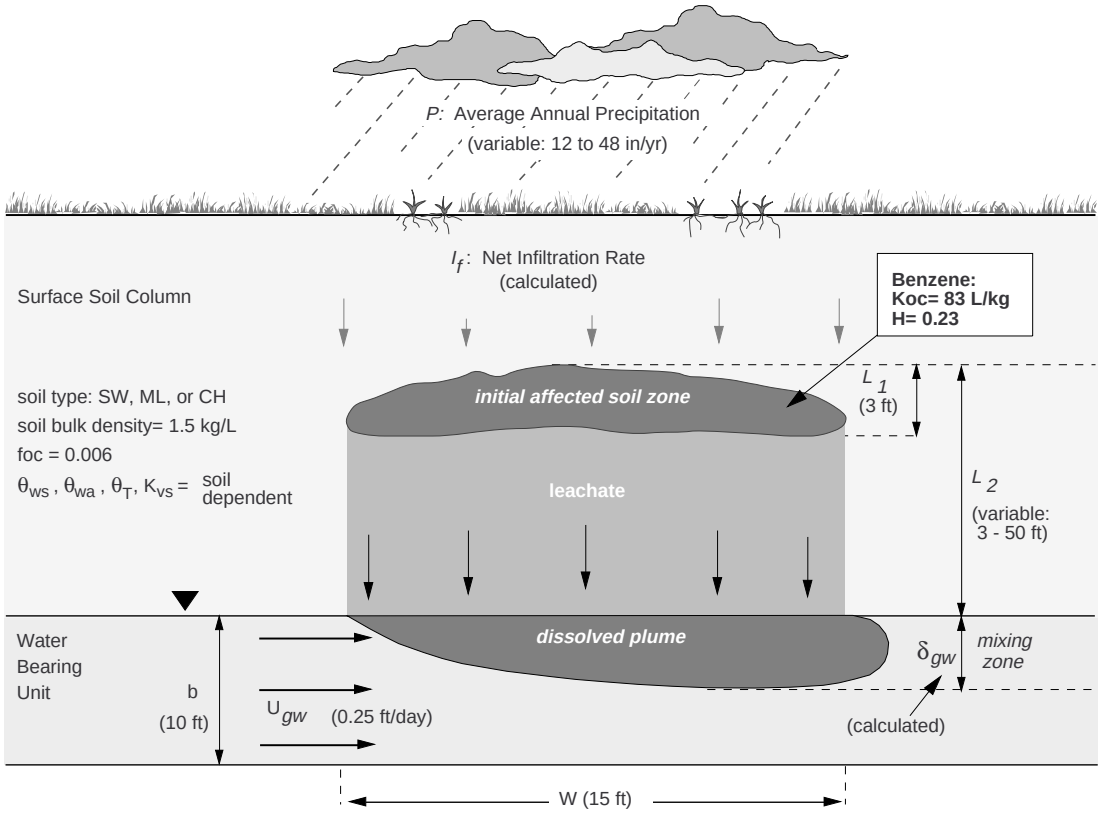
NOTES:

1) Soil concentration limits protective of 0.005 mg/L benzene exposure level in underlying groundwater were calculated using both the SAM (Equation 6b) and the ASTM E-1739 soil leaching equation (ASTM, 1995). ASTM value (0.069 mg/Kg) was based on default infiltration rate listed in Appendix X.2 of ASTM E-1739 (i.e., 30 cm/yr). SAM input varied according to soil type, annual rainfall, and depth of underlying soil. See Figure 4 for case study illustration.

2) Input Parameters:
   Thickness of affected soil = 3 ft
   Width of affected soil = 15 ft
   Lateral Darcy's velocity = 0.25 ft/day
   Saturated thickness of water-bearing unit = 10 ft
   Soil bulk density = 1.7 kg/L
   Organic carbon partition coefficient =38 L/kg (benzene)
   Henry's Law coefficient = 0.23 (benzene)
   Fraction organic carbon = 0.006

3) P = Mean annual precipitation
   Depth to Groundwater = Distance from base of affected soils to top of water-bearing unit ($L_2$ - $L_1$).
   L1 = Thickness of affected soils exceeding Tier 1 limits.
   L2 = Distance from top of affected soils to top of water-bearing unit.

**FIGURE 4: ASSUMED SITE CONDITIONS FOR EXAMPLE SAM MODEL CALCULATION**



NOTES: See Table 5 for calculation results.

See Attachment B for soil-dependent parameter values.

# ATTACHMENT A
# ESTIMATION OF ANNUAL NET INFILTRATION AS A FUNCTION OF MEAN ANNUAL PRECIPITATION AND SOIL TYPE

## Overview of Estimation Method

Net infiltration corresponds to total rainfall infiltration minus the loss associated with evapotranspiration. The net infiltration term ($I_f$) thereby represents the deep percolation flow (in cm/year) through the affected soil zone which could result in leachate release to underlying groundwater. In the SAM, net infiltration is estimated as a function of average annual rainfall (cm/year) and the predominant soil type in the vadose zone (sand, silt, or clay) using the empirical relationships plotted on Figure 2. Derivation of these empirical relationships is detailed below.

The sand soil curve shown on Figure 2 represents an 80% envelope based on rainfall infiltration data for over 100 sandy soil sites in 18 geographic regions in the United States, as compiled by Stephens & Associates (API, 1996). This regression curve provides a conservative (upper-range) estimate of deep percolation for over 80% of the sand or gravel soil sites reported in this database. Curves for silty and clayey soils were derived from this empirical sandy soil curve based on the relative percent infiltration occurring in a 2-hour storm event, as characterized using the Horton infiltration relationship (Viessman et al., 1989). Derivation procedures are detailed below.

## Net Infiltration as a Function of Precipitation for a Sandy Soil

The empirical relationship between net infiltration and annual rainfall in sandy soils was based upon a database of 140 sites from 18 different geographic regions compiled by Stephens & Associates (API, 1996). Among these, 101 sites consisting of sandy or gravelly soils were selected for characterization of sand infiltration rates. Many of the data points included in this subset contain soils much more permeable than sand, such as glacial outwash and other soils containing high percentages of gravel. Consequently, the dataset likely represents a high-range estimate for infiltration through sand.

A plot of percent annual net infiltration vs. mean annual precipitation for these 101 selected data points (see FigureA-1) indicates considerable scatter, but confirms a general trend of increasing percent infiltration with increased annual rainfall. The purpose of this net infiltration model is to provide a reasonable high-range estimate of infiltration rates. Therefore, as shown on FigureA-1, an envelope line for sandy soil infiltration exceeding actual reported infiltration rates for 80% of the site population has been selected as the characteristic curve for net infiltration. This relationship is conservative in that: i) approximately 80% of the representative data fall below the line, and ii) a majority of the data points plotted pertain to soil types more permeable than a sandy soil. Consequently, this curve can be relied upon to provide a conservative over-estimate of infiltration rates and leachate impacts in most sandy soil conditions.

The 80% envelope line for a sandy soil yields the following relationship between percent annual net infiltration and mean annual precipitation (see Figure 1.1):

A) $I_f$ [as % $P$]= 0.018 • ($P$)

where: $I_f$ = mean annual net infiltration as a percentage of precipitation
$P$ = mean annual precipitation, mm/yr

Converting this formula to determine net infiltration in cm/year for an input of annual precipitation in cm/year for a sandy soil yields:

B) $I_f$ [cm/year]= 0.0018 • $(P)^2$

where: $I_f$ = mean annual net infiltration in cm/year
$P$ = mean annual precipitation in cm/year

## Estimation of the Net Infiltration Relationships for Clay and Silt Soils

In order to establish infiltration vs. rainfall relationships for clay and silt soils comparable to that shown on Figure A-1, Horton's infiltration method can be used to estimate infiltration into clay and silt soils as a percentage of infiltration into sandy soils. These infiltration ratios may then be applied to Equation B above to derive clay and silt soil infiltration curves.

*Horton's equation:*

C) $f_p = f_c + (f_o - f_c) \cdot e^{-kt}$

where: $f_p$ = the infiltration capacity (depth/time) at some time (t), in/hr
$k$ = a constant representing the rate of decrease in f capacity, 1/hr
$f_c$ = a final or equilibrium capacity, in/hr
$f_o$ = the initial infiltration capacity, in/hr

The Horton infiltration method is a three-parameter model relating the infiltration capacity at any time ($f_p$) during a storm event to the initial infiltration rate ($f_o$), the final or equilibrium infiltration rate ($f_c$), and an exponential constant representing the decrease in infiltration capacity over time (k) (see Maidment, 1993). The model indicates that in a storm event, as rainfall intensity exceeds infiltration capacity, infiltration tends to decrease in an exponential manner. Based on the use of typical default parameters for various soil types, this model can be used to define infiltration rates in clay and silt soils as a percentage of the rate in sand for a given rainfall. Viessman *et al.* (1989) present typical infiltration curves and Horton parameter values for infiltration through sands, silts, and clays. Maximum parameter values for each given range are shown on Table A-1.

**Table A-1: Typical Parameters for Horton's Method**

| | Infiltration Rate (in/hr) | | |
|---|---|---|---|
| **Soil Group** | **$f_o$ @ t=0** | **$f_1$ @ t=1** | **$f_c$ @ t=∞** |
| **High (Sandy Soils)** | 5.0 | 1.0 | 0.85 |
| **Intermediate (Silty Soils)** | 2.5 | 0.5 | 0.425 |
| **Low (Clayey Soils)** | 0.5 | 0.1 | 0.085 |

From: Viessman et al., 1989

Note that the ratios among sand, silt, and clay are the same (100%, 50%, 10%) for any time. Therefore, the empirical relationship of net infiltration vs. annual rainfall for a sandy soil (Figure A-1) may simply be adjusted by the relative infiltration ratios used for the Horton infiltration method. This yields:

D) i) For **Sand**:

$$I_f = (0.0018) \cdot (P)^2$$

ii) For **Silt**:

$I_f = (50\%) \cdot (0.0018) \cdot (P)^2$

$$I_f = (0.0009) \cdot (P)^2$$

iii) For **Clay**:

$I_f = (10\%) \cdot (0.0018) \cdot (P)^2$

$$I_f = (0.00018) \cdot (P)^2$$

where: $I_f$ = mean annual net infiltration, cm/year
$P$ = mean annual precipitation, cm/year

# ATTACHMENT B
# DERIVATION OF DEFAULT SOIL MOISTURE PARAMETERS

## Overview of Methodology

The Brooks and Corey relationship (1964) combined with the Burdine equations (1959) can be used to derive volumetric air and water content values for vadose zone soils that are in equilibrium with the net annual rainfall infiltration rate. For use in the Soil Attenuation Model (SAM), these relationships have been used to establish default soil moisture volumes for various soil types, based on a median annual rainfall. Model sensitivity runs indicate that use of these median values in place of site-specific equilibrium moisture levels does not significantly affect model results. On this basis, these default values have been incorporated in SAM as a simplifying measure.

## Relationships of Soil Moisture to Rainfall Infiltration

Vertical infiltration under equilibrium conditions is related to the vertical hydraulic gradient and the unsaturated hydraulic conductivity at the ambient water content of the vadose zone soil. Unsaturated hydraulic conductivity is commonly expressed as the product of saturated hydraulic conductivity and the relative permeability, yielding the following vertical flow equation:

A) $I_f = i \bullet K_{vs} \bullet k_{rw}$

where:
- $I_f$ = net infiltration
- $i$ = hydraulic gradient
- $k_{rw}$ = relative permeability of the soil, unitless
- $K_{vs}$ = saturated hydraulic conductivity of vadose zone soils

By assuming that infiltration occurs under an average unit hydraulic gradient and solving for the relative permeability, this relationship converts to:

B) $$k_{rw} = \frac{I_f}{K_{vs}}$$

Studies have shown that the relative permeability is a function of the volumetric water content. Using the Brooks and Corey (1964) soil characteristic model combined with the Burdine equations (1959), the relative permeability function is given by:

C) $$k_{rw} = \left[ \frac{\theta_{ws} - \theta_{wr}}{\theta_T - \theta_{wr}} \right]^{\varepsilon}$$

where:
- $k_{rw}$ = relative permeability of the soil, unitless
- $\theta_{ws}$ = volumetric water content soil
- $\theta_T$ = total soil porosity
- $\theta_{wr}$ = irreducible soil water content
- $\varepsilon$ = $3 + 2/\lambda_{BC}$
- $\lambda_{BC}$ = pore size distribution index, unitless (Brooks and Corey, 1964)

Substituting Equation B into Equation C yields the following equation for volumetric water content as a function of annual rainfall infiltration, $I_f$:

$$D) \quad \theta_{ws} = \theta_{wr} + \left[\theta_T - \theta_{wr}\right] \bullet \left[\frac{I_f}{K_{vs}}\right]^{\frac{1}{\varepsilon}}$$

The volumetric air content of the soil can then be derived as:

$$E) \quad \theta_{as} = \theta_T - \theta_{ws}$$

## Derivation of Default Values for Volumetric Water and Air Content

### Default Brooks-Corey Parameters

Equations D and E can be used to estimate equilibrium soil moisture parameters ($\theta_{ws}$, $\theta_{as}$) for a given soil type based on default values of $\theta_T$, $\theta_{wr}$, and $K_{vs}$ for that soil type. For USDA soil types, default values for $\theta_T$ and $\theta_{wr}$ have been established by Carsel and Parrish (1988) using the multiple regression method of Rawls and Brakensiek (1985). Results of the Carsel and Parrish analyses are provided on Table B-1. To develop comparable values for Unified Soil Classification System (USCS) soils, USCS soil types were first correlated to USDA textural classifications as shown on Figure B-1. In most cases, the USCS soil type was found to overlap multiple USDA classifications. Therefore, to establish conservative values for USCS soils, the most conservative value (with respect to leachate concentration) among the overlapped USDA classifications was selected to represent the USCS soil type. For each USCS soil type, Table B-2 provides the resulting $\theta_T$ and $\theta_{wr}$ values. The saturated hydraulic conductivity ($K_{vs}$) of the surface soil column can also be characterized based on predominant soil type. Representative default values obtained from research literature are listed on Table B-3.

**Table B-1: Default Brooks-Corey Parameter Values for USDA Textural Classifications**

| USDA Textural Classification | $\theta_T$ | $\theta_{wr}$ | $\lambda_{BC}$ |
|---|---|---|---|
| Clay | 0.38 | 0.068 | 0.09 |
| Clay loam | 0.41 | 0.095 | 0.31 |
| Loam | 0.43 | 0.078 | 0.56 |
| Loamy sand | 0.41 | 0.057 | 1.28 |
| Silt | 0.46 | 0.034 | 0.37 |
| Silt loam | 0.45 | 0.067 | 0.41 |
| Silt clay | 0.36 | 0.070 | 0.09 |
| Silty clay loam | 0.43 | 0.089 | 0.23 |
| Sand | 0.43 | 0.045 | 1.68 |
| Sandy clay | 0.38 | 0.100 | 0.23 |
| Sandy clay loam | 0.39 | 0.100 | 0.48 |
| Sandy loam | 0.41 | 0.065 | 0.89 |

| CL: Sandy Clay | $10^{-6}$ |
| CL: Silty Clay | $10^{-7}$ |
| CH: Clay | $10^{-8}$ |

*Note: Typical saturated hydraulic conductivity values represent median values reported by Freeze and Cherry (1979), Rawls and Brakensiek (1985).*

## Derivation of Default Volumetric Air and Water Content Values

Using Equations D and E in combination with the default parameters on Tables B-1 through B-3, equilibrium soil moisture values ($\theta_{ws}$, $\theta_{as}$) can be derived as a function of soil type and annual rainfall infiltration ($I_f$). To evaluate the sensitivity of the SAM equation to the use of rainfall-dependent soil moisture values, soil leachate concentrations have been calculated for each soil type to compare the use of i) site-specific, rainfall-dependent, soil moisture values (derived using Equations D and E for site-specific rainfall level) and ii) default soil moisture values, derived using

Equations D an E for a fixed rainfall level matched to the U.S. Median level of 30 in/yr (Geraghty-Miller, 1973). Table B-4 summarizes the results of this analysis. As shown, the use of default values instead of site-specific soil moisture values at these rainfall levels produces an average variation of only 5% in the soil leachate concentration predicted by SAM. Consequently, fixed default soil moisture values based upon a median rainfall (i.e., 30 in/yr) can be used in place of the rainfall-dependent values (Equations D and E) with very little error. Default values for volumetric water content ($\theta_{ws}$) and volumetric air content ($\theta_{as}$) for each USCS soil type are provided on Table B-5.

**Table B-4: Comparison of Soil Leachate Concentrations Calculated Using Both Site Specific and Default Soil Moisture Values ($\theta_{ws}$, $\theta_{as}$) for Two Different Rainfall Levels**

| USCS Soil Classification | Predicted Leachate Concentration (mg/L-Benzene) | | | | | | |
|---|---|---|---|---|---|---|---|
| | Low Rainfall (P = 9 in/yr) | | | High Rainfall (P = 55 in/yr) | | | Maximum Difference |
| | Site-Specific $\theta_{ws}$ and $\theta_{as}$ | Default $\theta_{ws}$ and $\theta_{as}$ | Percent Difference | Site-Specific $\theta_{ws}$ and $\theta_{as}$ | Default $\theta_{ws}$ and $\theta_{as}$ | Percent Difference | |
| SW/SP: Clean Sand | 0.715 | 0.695 | 3% | 0.130* | 0.130* | 0% | 3% |
| SM: Silty Sand | 0.682 | 0.655 | 4% | 0.130* | 0.130* | 0% | 4% |
| SC: Clayey Sand | 0.618 | 0.571 | 8% | 0.130* | 0.130* | 0% | 8% |
| ML: Sandy Silt | 0.579 | 0.540 | 7% | 0.260* | 0.260* | 0% | 7% |
| ML: Silt | 0.555 | 0.510 | 8% | 0.260* | 0.260* | 0% | 8% |

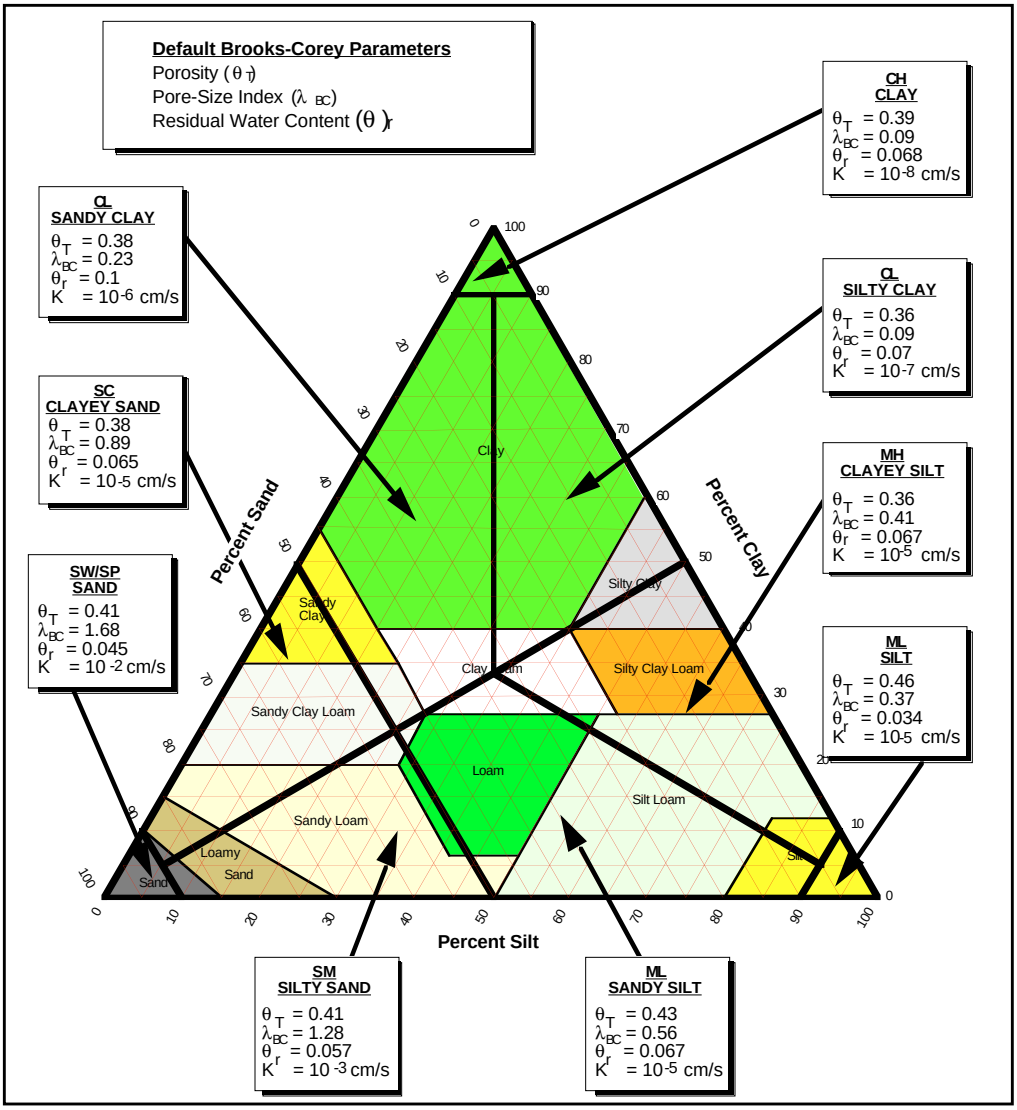
**FIGURE B-1: GENERALIZED CORRELATION OF USCS AND USDA SOIL TYPES AND DEFAULT BROOKS-COREY PARAMETERS**



Notes:

1) Correlations between USDA and USCS soil classification categories are approximate, based on the general range of soil grain size. Parameter values for USCS Classification were chosen as the most conservative values from corresponding USDA estimates (Carsel and Parrish, 1988; Rawls & Brakensiek, 1985). See Table B-1 for parameter values corresponding to USDA soil types.
2) See Peck et al., 1974 for USDA soil classifications. See Lambe et al., 1969 or USCS soil classifications.

# ATTACHMENT C
# SORPTIVE MASS REDISTRIBUTION: LEACHATE TO UNDERLYING CLEAN SOIL

## Overview

In the SAM model, contaminant transfer from the affected soil to the infiltrating porewater is characterized on the basis of a conventional equilibrium partitioning relationship (see Equations 3b and 3c on Figure 2). The model then corrects this initial leachate concentration for the effect of sorptive mass loss as the leachate percolates downward through the soil column toward the underlying groundwater zone. As a result of sorptive redistribution of contaminant mass from the leachate onto intervening soils, the initial equilibrium leachate concentration will be reduced prior to reaching the depth of the water-bearing unit. This adjustment can prove significant in deep groundwater systems, wherein a significant thickness of unaffected soils may underlie the affected soil zone.

This Attachment derives a simple expression for this sorptive redistribution effect, based on a finite source mass and equilibrium partitioning of leachate onto underlying soils.

## Sorptive Mass Redistribution

As indicated on Figure C-1, the source zone for contaminated leachate release to groundwater can be characterized as a discrete area ($A$) and thickness ($L_1$) of affected soils within the surface soil column overlying the uppermost water-bearing unit beneath the site. This source zone represents a finite source mass (equivalent to the bulk mass of affected soil times the representative COC concentration) that is spread downward through the soil column via leachate percolation. If, as a conservative measure, the processes of contaminant biodegradation and volatilization are neglected, the total mass of contaminants in the soil column remains constant as the leachate front moves toward the underlying water-bearing unit.

*Assuming equilibrium partitioning among the soil solid, pore liquid, and vapor phases as the contaminants spread over a soil depth (L) yields the following expression:*

A) $$A \cdot B_w \cdot C_w \cdot L = \text{Constant}$$

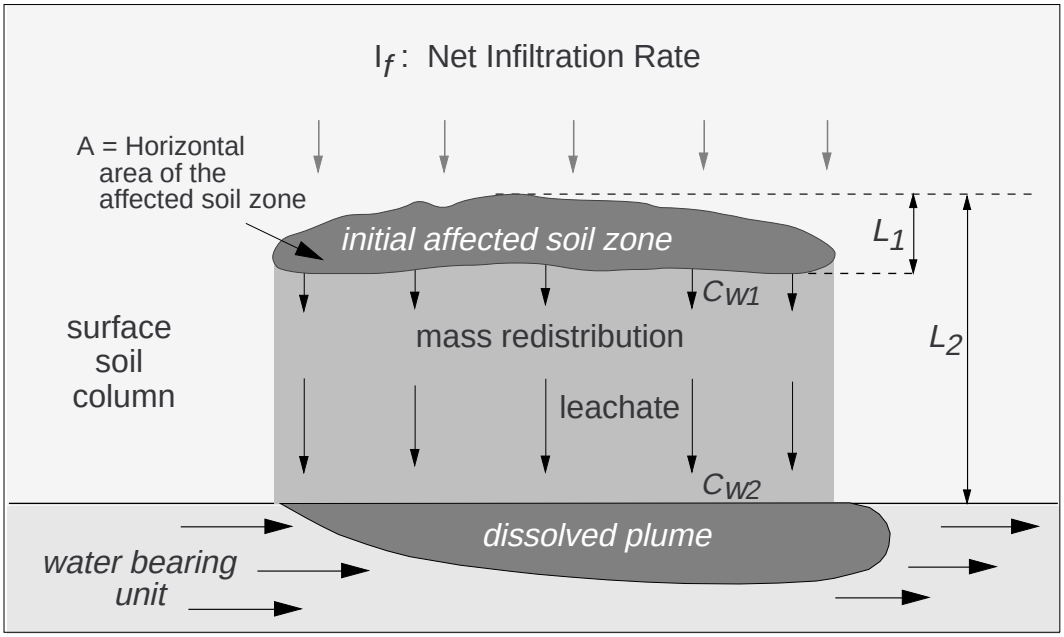
where: $A$ = area of affected soil zone
$B_w$ = bulk water partitioning coefficient
$C_w$ = COC concentration in the soil pore water
$L$ = distance from the top of the affected soil zone to depth of leachate front

*Given equilibrium partitioning, the bulk water partitioning coefficient ($B_w$) is expressed as:*

B) $$B_w = \theta_{ws} + H \cdot \theta_{as} + \rho_s \cdot k_s$$

where: $\theta_{ws}$ = volumetric water content of soil column
$\theta_{as}$ = volumetric air content of soil column
$H$ = Henry's law constant for COC
$p_s$ = bulk soil density

**FIGURE C-1: MASS REDISTRIBUTION PARAMETERS**



The affected soil area *(A)* and the bulk partitioning coefficient *($B_w$)* remain constant as the finite contaminant mass is redistributed to soils below the initial source zone. Prior to leachate release into the underlying water-bearing unit, the total contaminant mass is a constant for any soil depth *L*. Therefore:

*Mass in the redistributed source zone can be expressed as a function of its length and concentration and is equal the original source zone mass:*

C) $A \cdot B_w \cdot C_{w_1} \cdot L_1 = A \cdot B_w \cdot C_{w2} \cdot L_2$, or

D) $C_{w2} \cdot L_2 = C_{w1} \cdot L_1$

*Solving for the leachate concentration ($C_{w2}$) immediately prior to leachate release to the water-bearing unit yields:*

E) $$C_{w2} = C_{w1} \cdot \frac{L_1}{L_2}$$

where: $C_{w2}$ = COC concentration in the leachate at the depth of the water-bearing unit
$C_{w1}$ = COC concentration in the leachate at the base of the initial affected soil zone
$L_1$ = thickness of the original source zone
$L_2$ = distance from the top of the affected soil zone to the top of the saturated water-bearing unit

As the leachate process continues, contaminant mass will be released to underlying lateral groundwater flow, resulting in a net reduction in contaminant mass in the soil column and a consequent reduction in the soil leachate concentration $(C_{w2})$ entering the groundwater unit over time. In the SAM model, this diminishing source concentration is neglected as a conservative measure. The influent soil leachate concentration is assumed to remain constant over time, equal to the initial concentration in the leachate front (i.e., $C_{w2}$ as calculated per Equation E above).

# ATTACHMENT D
# TIME AVERAGING FACTOR: DIMINISHING LEACHATE SOURCE TO GROUNDWATER

## Overview of Source Depletion Process

In the SAM, a constant finite contaminant mass is redistibuted downward through the vertical soil column via equilibrium partitioning between the advancing leachate and the clean underlying soils. Upon reaching the water-bearing unit, the contaminant mass in the vertical soil column will decrease with time as the leachate process continually removes mass from the affected soil. However, as a conservative measure, the SAM assumes this initial leachate concentration to remain constant for the full duration of the groundwater exposure period. This assumption may prove to be overly conservative for carcinogenic compounds, where chronic effects are dependant on average COC concentrations over a particular exposure duration (e.g., typically 25 or 30 years for residential and industrial exposure scenarios, respectively). As an optional meaure for use with the SAM, a time averaging factor (TAF) has been derived to account for the diminishing leachate source to groundwater for a Tier 3 evaluation of carcinogenic COCs.

This Attachment derives a simple expression for a 30-year time averaging factor starting with the time the leachate first reaches the water bearing zone at an initial concentration ($C_{w0}$). This derivation is based on a mass balance of the vertical soil column between the top of the affected soil zone and the water table. The control volume has a discrete cross-sectional area ($A$) and thickness ($L$)

## Time Averaging Factor (TAF) Derivation

*C(t) is the leachate concentration in the control volume at any time, t. Assuming equilibrium partitioning, the total contaminant mass is given by*

A) $$M(t) = A \bullet L \bullet B_w \bullet C(t)$$ and

B) $$B_w = \theta_{ws} + H \bullet \theta_{as} + \rho_s \bullet k_s$$

where:
- $B_w$ = bulk water partitioning coefficient
- $\theta_{ws}$ = volumetric water content of soil column
- $\theta_{as}$ = volumetric air content of soil column
- $H$ = Henry's law constant for COC
- $p_s$ = bulk soil density
- $k_s$ = soil-water sorption coefficient for COC

*The time rate of change of contaminant mass in the control volume is equivalent to the advective contaminant flux via leachate to the groundwater. This is expressed as:*

C) $$\frac{dM}{dt} = A \bullet L \bullet B_w \bullet \frac{dC}{dt} = -A \bullet I_f \bullet C(t)$$

where: $I_f$ = net infiltration rate

*and rearranging yields:*

D) $$\frac{dC}{C(t)} = \frac{-I_f}{L \bullet B_w} dt$$

*For $C(t)=C_{w0}$ at $t=0$, this expression is integrated to yield:*

E) $$C(t) = C_{w0} \bullet \exp\left[\frac{-I_f \bullet t}{L \bullet B_w}\right]$$

*The TAF is the normalized average concentration $C_{avg}/C_{w0}$ over the exposure duration (ED) from $t=0$ to $t= ED$. This is expressed by:*

F) $$TAF = \frac{C_{avg}}{C_{w0}} = \frac{1}{ED} \bullet \int_0^{ED} \exp\left[\frac{-I_f \bullet t}{L \bullet B_w}\right] dt = \frac{L \bullet B_w}{I_f \bullet ED} \bullet \left[1 - \exp\left[\frac{-I_f \bullet ED}{L \bullet B_w}\right]\right]$$

# APPENDIX B
# Basis for Shallow Aquifer Thickness

## Appendix B – Basis for Shallow Aquifer Thickness

The value of 70 feet was used for the parameter, shallow aquifer thickness (b), in Table 1. This aquifer thickness is based on the regional shallow aquifer thickness reported in Figure 3-4 of the following report – "Supplemental Remedial Investigation Report, San Gabriel Valley Area 1 Superfund Site, South El Monte Operable Unit, Los Angeles County, California," dated November 2019, prepared by Gilbane.

# APPENDIX C
# Basis for Hydraulic Conductivity for Shallow Groundwater

## Appendix C – Basis for Hydraulic Conductivity for Shallow Groundwater

The value of 1.8 feet per day (or 0.00064 centimeter/second) was used for the parameter, hydraulic conductivity for shallow groundwater aquifer (K), in Table 1. This value is based on the site-specific hydraulic conductivity value estimated using the well development data of MW-6 and the aquifer testing software - AQTESOLV. The well development log for MW-6 is shown below.

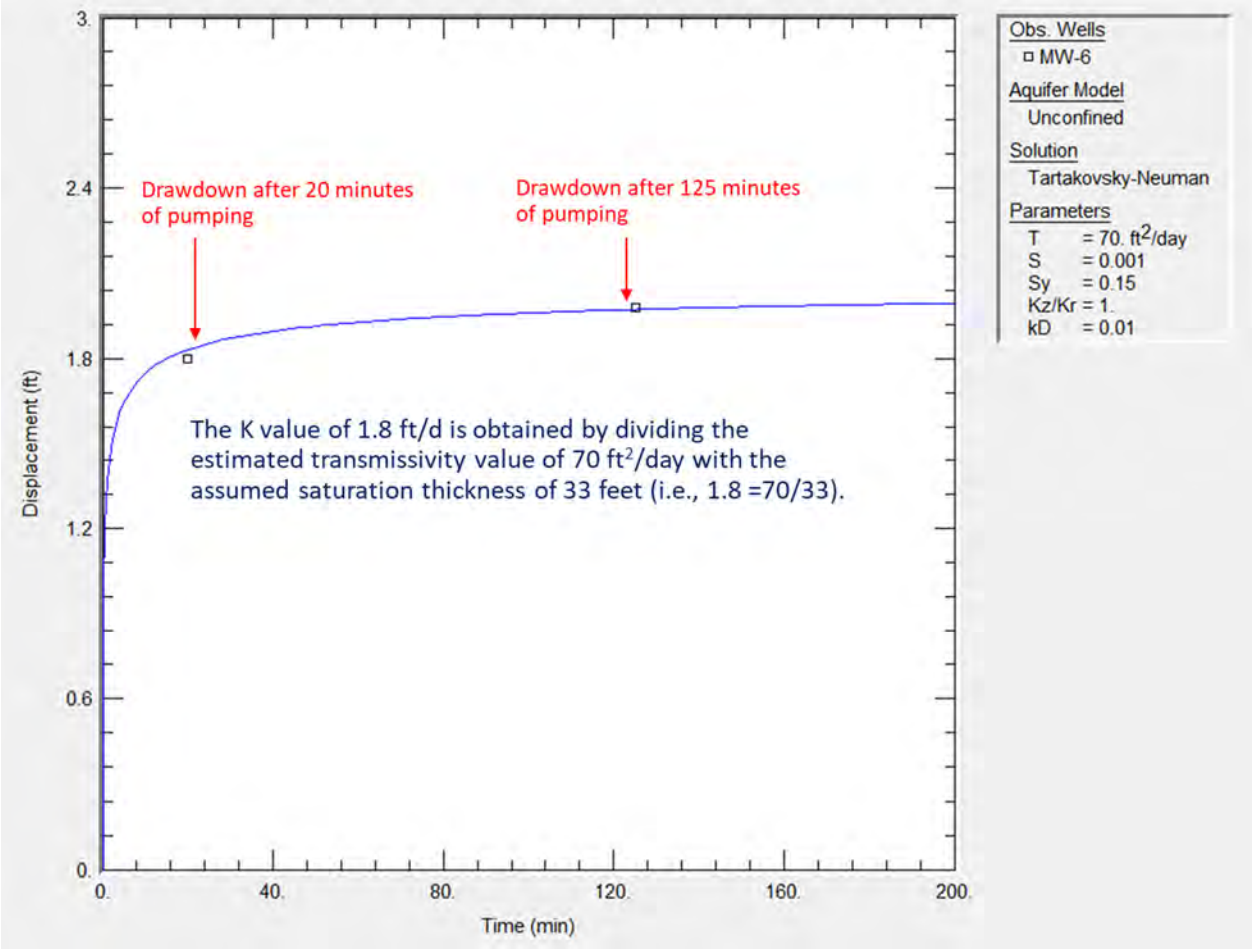
Pg 1 OF 1

The results of the AQTESOLV analysis are shown in the figure below.



Note that the K value for the shallow aquifer is much higher based on the hydraulic conductivity value reported in Page A-5 of the following report – "Feasibility Study Report, South El Monte Operable Unit, Interim Remedial Investigation/Feasibility Study, San Gabriel Basin, Los Angeles County, California," dated April 1999, prepared by Geosystem (see the image on the next page). Therefore, the use of 1.8 feet per day obtained from well development data of Site monitoring well MW-6 is likely very conservative.

A.1.6.1 Hydraulic Conductivity

In the CFEST model, hydraulic conductivity is considered isotropic in the horizontal plane. The areas of different horizontal hydraulic conductivity in each of the eight model layers are shown in Figures A-4 through A-11. It should be noted that the layers are not numbered sequentially from the top of the model mesh to the bottom. Rather, new layers incorporated into the model as new data became available were assigned sequential layer numbers irrespective of their depth.

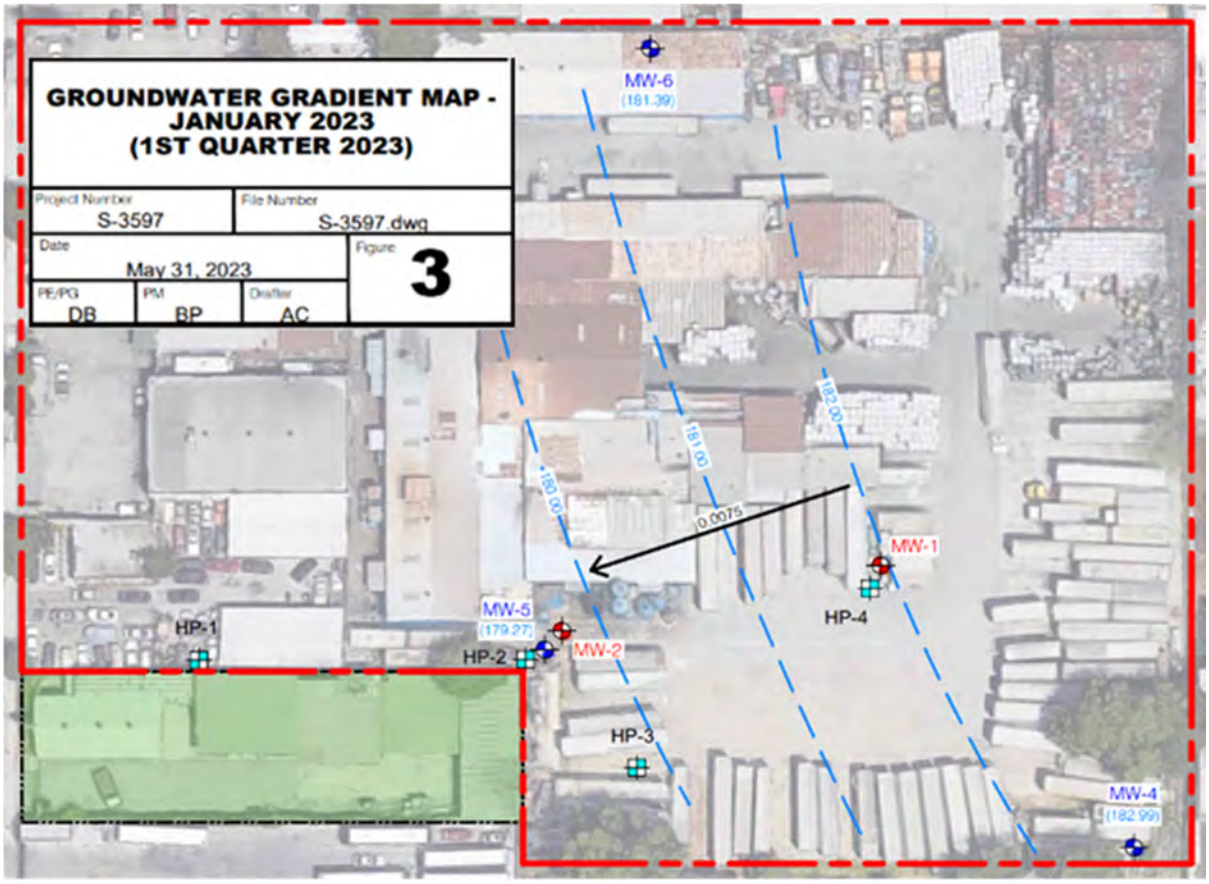
Figure A-4 shows shallow zone (Layer 1) conductivities ranging from 25 to 200 ft/day in the SEMOU and 300 ft/day throughout most of the Whittier Narrows. A low hydraulic conductivity value (0.1 ft/day) has been assigned to part of Layer 2 of the model in the vicinity of the SEMOU (Figure A-5) to simulate the "separating sequence" between the shallow and intermediate water-bearing zones in that area. The thickness of the separating sequence has been set to 100 feet, occurring between 100 and 200 feet below the top of the model. Layer 3 is representative of the intermediate zone within SEMOU. The intermediate zone horizontal conductivity has been set at 50 ft/day in the western SEMOU and 100 ft/day in the eastern SEMOU.

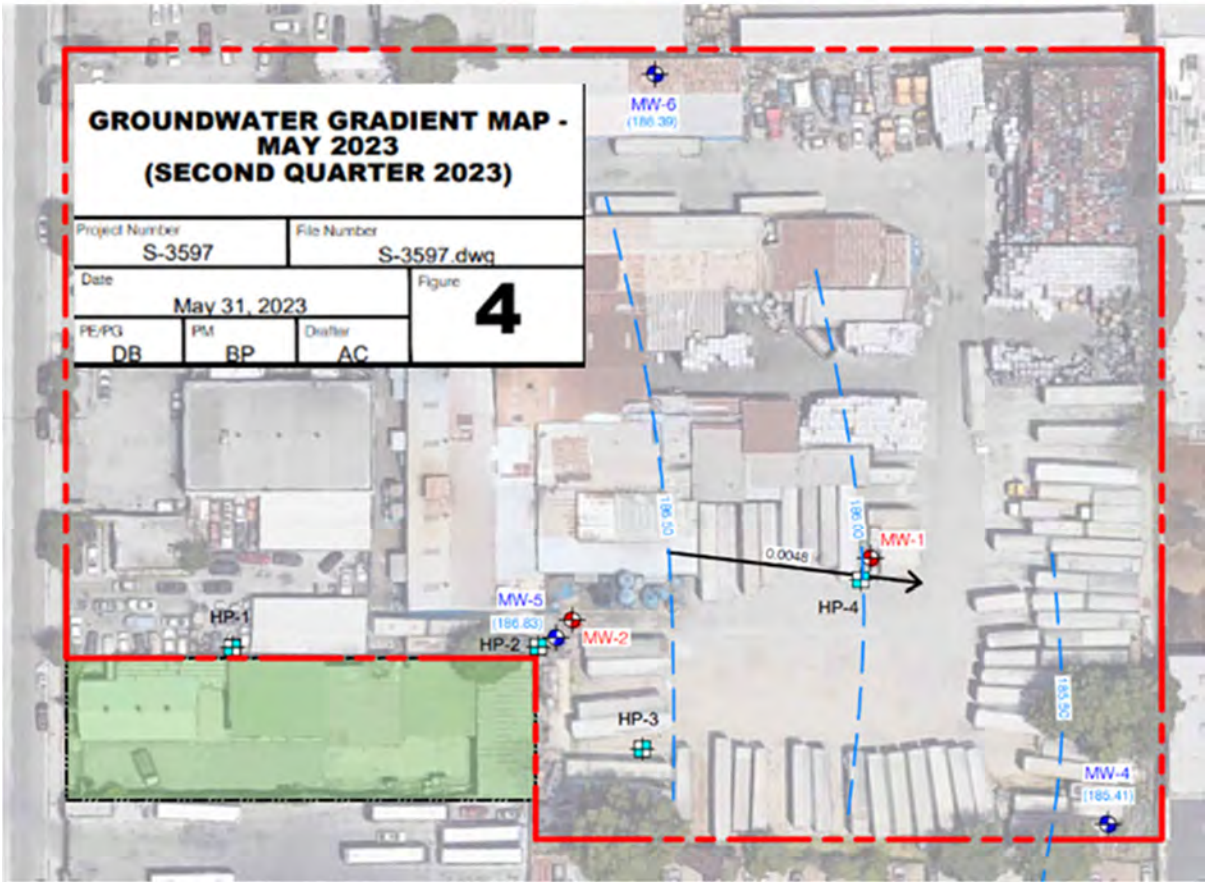
The ratio of horizontal to vertical hydraulic conductivity was initially set by EPA at 10:1 throughout most of the basin-wide model. However, during model calibration, EPA modified the conductivity ratios within the SEMOU, WNOU, and Montebello Forebay. For

# APPENDIX D
# Basis for Hydraulic Gradient

## Appendix D – Basis for Hydraulic Gradient

The value of 0.0027 was used for the parameter, hydraulic gradient (i), in Table 1. This value is based on the difference in groundwater gradients (0.0075 and 0.0048) measured in January 2023 and May 2023, as reported in the June 2023, EEC Environmental Groundwater Well Installation and Sampling Report (see the image on the next page). Because the groundwater flow direction at the Site is not constant, the use of the difference in the measured hydraulic gradients for the two monitoring events is considered more appropriate to not overestimate the extent of the groundwater flow beneath the Site.



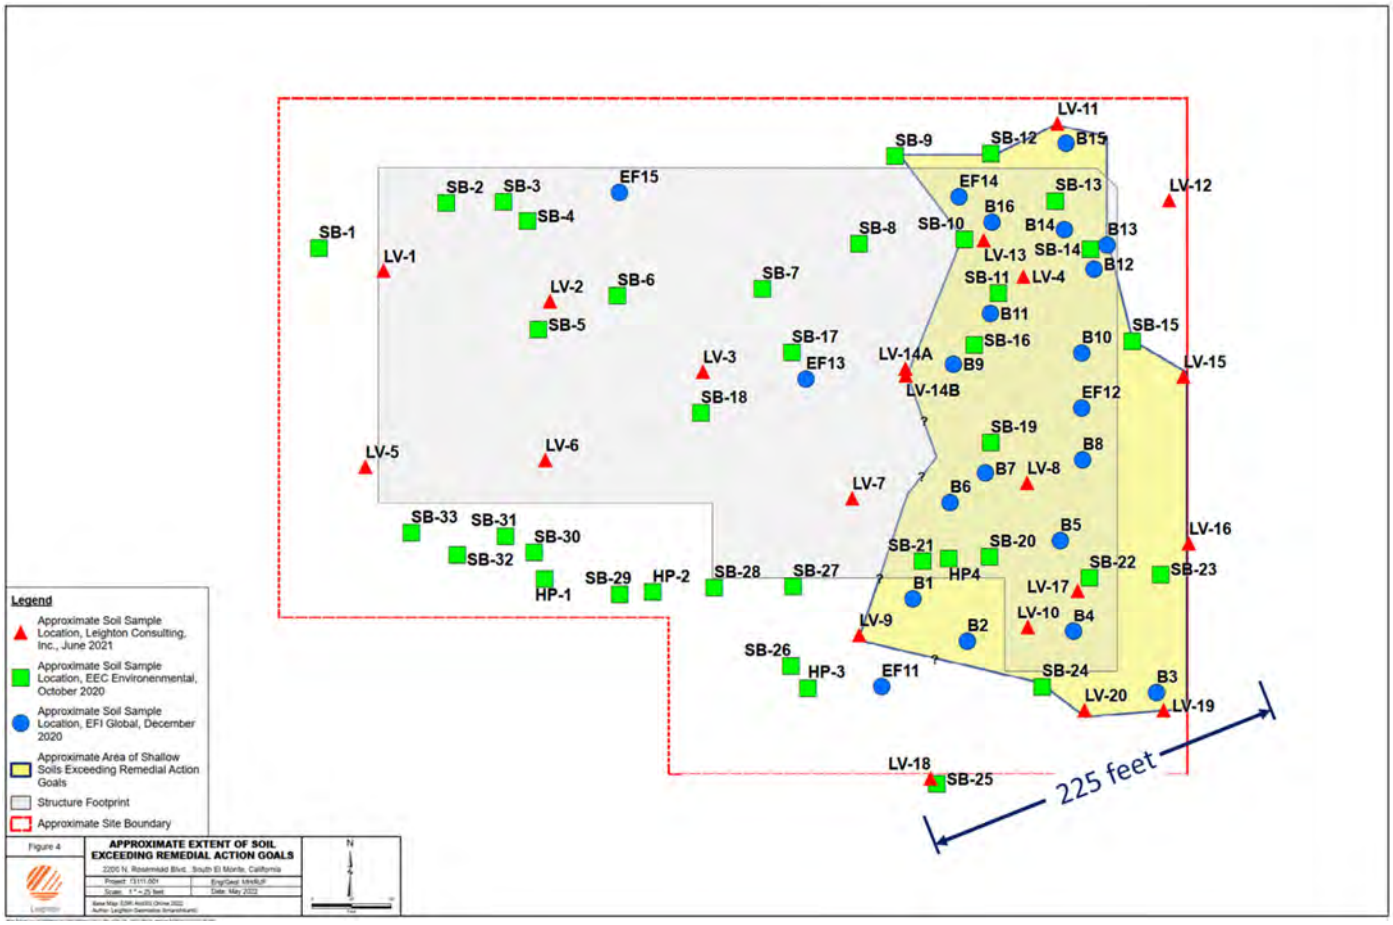


HALEY ALDRICH

# APPENDIX E
# Basis for Contamination Zone Length along Groundwater Flow Direction

## Appendix E – Basis for Contamination Zone Length along Groundwater Flow Direction

The value of 225 feet was used for the parameter, contamination zone length along groundwater flow direction (W), in Table 1. This value is based on the lead concentration distribution delineated (using the proposed lead remedial action goal of 500 mg/kg), shown in Figure 4 of the report, titled "Limited Soil Remediation Work Plan, for the Eastern Portion of 2200 North Rosemead Boulevard, South El Monte, California 91773," dated 25 April 2023, prepared by Leighton Consulting, LLC (also see the image below).



HALEY ALDRICH

# APPENDIX F
## Basis for Current Impacted Thickness

## Appendix G – Basis for Current Impacted Thickness

The value of 5 feet was used for the parameter, current impacted thickness (L1), in Table 1. This value is conservatively selected based on the lead concentration distributions found in numerous soil borings. Some data are reported in Table 1 of the report, titled "Preliminary Endangerment Assessment, Rosemead Holding LLC Property. 2200 North Rosemead Boulevard, South El Monte, California," dated 18 November 2022, prepared by Enviro-Tox Services, Inc. The lead concentration data in Table 1 is summarized below.

# APPENDIX G
# Basis for Length between Top of the Impacted Zone to Water Table

# Appendix G – Basis for Length between Top of the Impacted Zone to Water Table

The value of 50 feet was used for the parameter, length between top of the impacted zone to groundwater table (L2), in Table 1. This value is based on the representative vadose zone thickness reported from the boring logs of MW-4, MW-5, and MW-6 in the report, titled "Groundwater Well Installation and Sampling Report for Former Pacific Drum Company, 2200, 2212, 2218, and 2226 North Rosemead Boulevard, South El Monte, California," dated 19 June 2023, prepared by EEC Environmental. The portions of the boring logs showing the detection of groundwater are provided below.

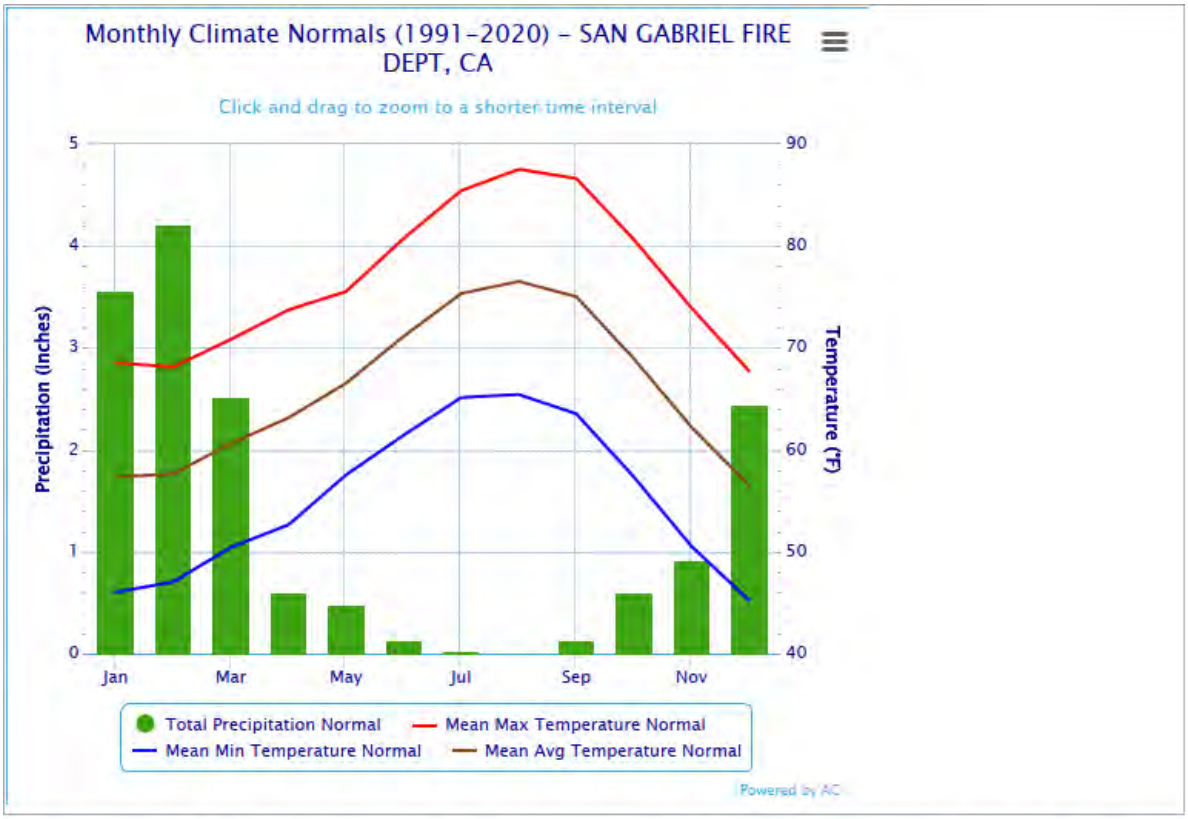
# APPENDIX H
## Basis for Infiltration Rate

## Appendix H – Basis for Infiltration Rate

The value of 3.98 centimeters per year (cm/yr) was used for the parameter, infiltration rate ($I_f$), in Table 1. This value is based on 10% of the average annual precipitation (15.67 inches per year or 39.8 cm/yr) based on a weather station near the Site (San Gabriel Fire Department, California) through the National Weather Service website (https://www.weather.gov/). The data are shown below.



| Month | Total Precipitation Normal (inches) | Mean Max Temperature Normal (°F) | Mean Min Temperature Normal (°F) | Mean Avg Temperature Normal (°F) |
|---|---|---|---|---|
| January | 3.56 | 68.6 | 46.1 | 57.4 |
| February | 4.22 | 68.2 | 47.1 | 57.7 |
| March | 2.53 | 70.9 | 50.5 | 60.7 |
| April | 0.61 | 73.8 | 52.7 | 63.2 |
| May | 0.48 | 75.6 | 57.6 | 66.6 |
| June | 0.13 | 80.8 | 61.5 | 71.2 |
| July | 0.04 | 85.5 | 65.2 | 75.4 |
| August | 0.00 | 87.6 | 65.5 | 76.6 |
| September | 0.13 | 86.7 | 63.6 | 75.1 |
| October | 0.61 | 80.7 | 57.4 | 69.0 |
| November | 0.92 | 74.0 | 50.6 | 62.3 |
| December | 2.44 | 67.8 | 45.3 | 56.6 |
| Annual | 15.67 | 76.7 | 55.3 | 66.0 |

This value is between the recharge estimates for the Montebello Forebay basin area (4.3 cm/yr) and the whole Los Angeles groundwater study area (3.5 cm/yr) based on the USGS report, titled "Estimating Spatially and Temporally Varying Recharge and Runoff from Precipitation and Urban Irrigation in the Los Angeles Basin, California, Scientific Investigations Report 2016–5068," published in 2016, authored by Hevesi and Johson (Source URL: https://pubs.usgs.gov/sir/2016/5068/sir20165068_.pdf). The relevant information taken from the report is shown in the images below. Because the Site is covered by asphalt pavement and buildings, the net infiltration at the Site is expected to be noticeably lower than 4.3 cm/yr.

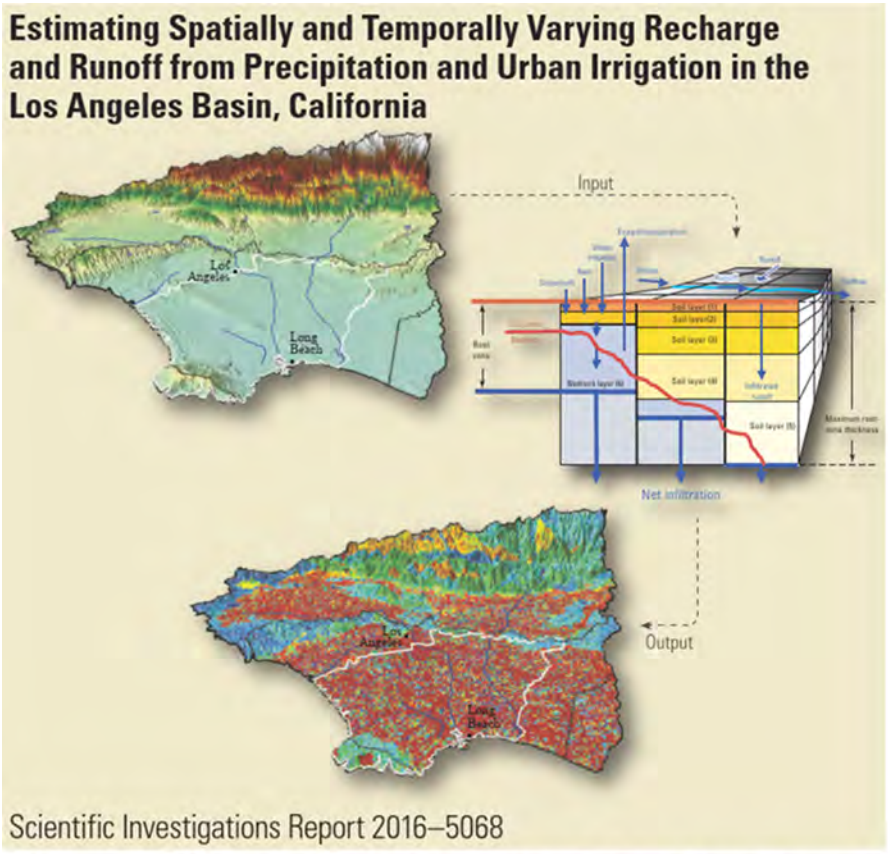


**Table 12.** Summary of average inflows, outflows, and changes in storage for the Los Angeles groundwater basins and Los Angeles groundwater study area, water years 1915–2014, Los Angeles Basin watershed model (LABWM), California.

[ET, evapotranspiration; ha-m/yr, hectare-meter per year; mm/yr, millimeter per year; nc, not collected]

| Area name | Units | Potential ET | Inflows | | | Generated runoff | Outflows | | | Change in storage | Potential mountain-front recharge | Total potential recharge |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | Precipitation | Surface water | Urban irrigation | | ET | Direct recharge | Surface water | | | |
| Los Angeles groundwater study area (LAGSA) | mm/yr | 1,258 | 336 | 24 | 135 | 140 | 297 | 35 | 164 | –1 | 18 | 53 |

# APPENDIX I
# Basis for Partitioning Coefficient (Kd) for Lead (Pb)

## Appendix I – Basis for Partitioning Coefficient (Kd) for Lead (Pb)

The value of 3000 L/kg was used for the parameter, partitioning coefficient (Kd) for lead, in Table 1. The Kd value for lead is a function of soil pH. Site specific Kd value is based on reported Site soil pH (=7.9) and calcium carbonate (a mineral that increases soil pH) content in shallow soil from the USDA database (approxiamtely 2% weight percentage). The information obtained from the USDA soil database (through the web soil survey website - https://websoilsurvey.nrcs.usda.gov/app/) are shown below.

**Tables – pH (1 to 1 Water) – Summary By Map Unit**

Summary by Map Unit – Los Angeles County, California, Southeastern Part (CA696)

| Map unit symbol | Map unit name | Rating |
|---|---|---|
| 1007 | Urban land-Biscailuz-Pico complex, 0 to 2 percent slopes | 7.9 |
| Totals for Area of Interest | | |

Site soil pH

**Tables – Calcium Carbonate (CaCO3) – Summary By Map Unit**

Summary by Map Unit – Los Angeles County, California, Southeastern Part (CA696)

| Map unit symbol | Map unit name | Rating (percent) |
|---|---|---|
| 1007 | Urban land-Biscailuz-Pico complex, 0 to 2 percent slopes | 2 |
| Totals for Area of Interest | | |

Site soil CaCO3 content

Two site-specific soil pH measurements are provided in the report, titled "Geotechnical Exploration Update, proposed Warehouse/Commercial Building, 2222 Rosemead Boulevard, South El Monte, Los Angeles County, California," dated 11 May 2023, prepared by Leighton Consulting, LLC. The two measurements are pH = 7.4 and pH = 9.8, as shown below.

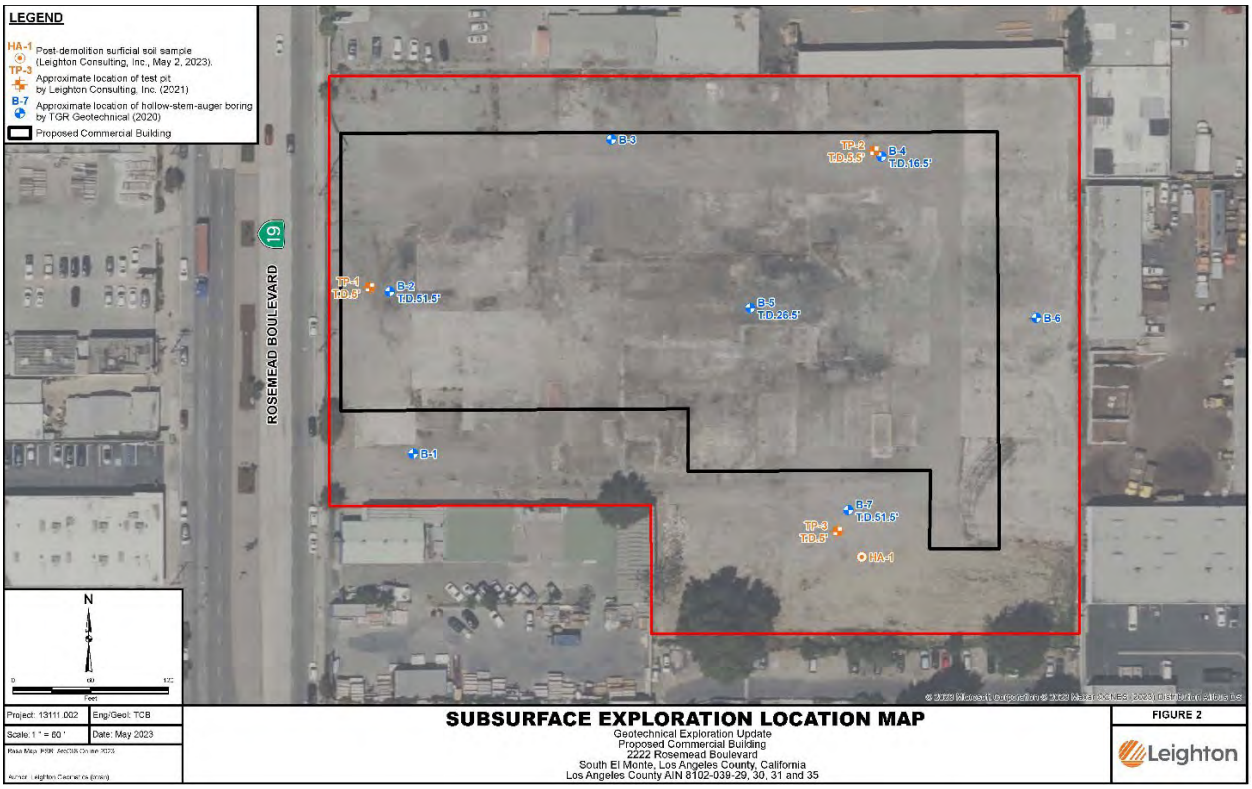
3.8.3. **Corrosivity Test Results**: To evaluate corrosion potential of soils sampled from this site, we tested a bulk soil sample for soluble sulfate content, soluble chloride content, pH and resistivity. Results of these tests (and TGR's 2020 results) are summarized below:

**Table 8. Results of Corrosivity Testing**

| Test Pit Number | Sample Depth (feet) | Sulfate (ppm) | Chloride (ppm) | pH | Minimum Resistivity (ohm-cm) |
|---|---|---|---|---|---|
| TGR-B-5 | 0 to 5 | 641 | 118 | 9.8 | 2,000 |
| HA-1 | 0 to 3 | 230 | 207 | 7.4 | 307 |

Note: mg/kg = milligrams per kilogram, or parts-per-million (ppm)

Samples TRG-B-5 (i.e., location B-5) and HA-1 were collected at the center and southeast portion of the site as shown in the figure below.



Additional pH data were collected from the site by Haley & Aldrich, Inc. in January 2024 during the delineation sampling event for chemicals of concern at the site. The January 2024 pH data is summarized in the following table.

**TABLE I**

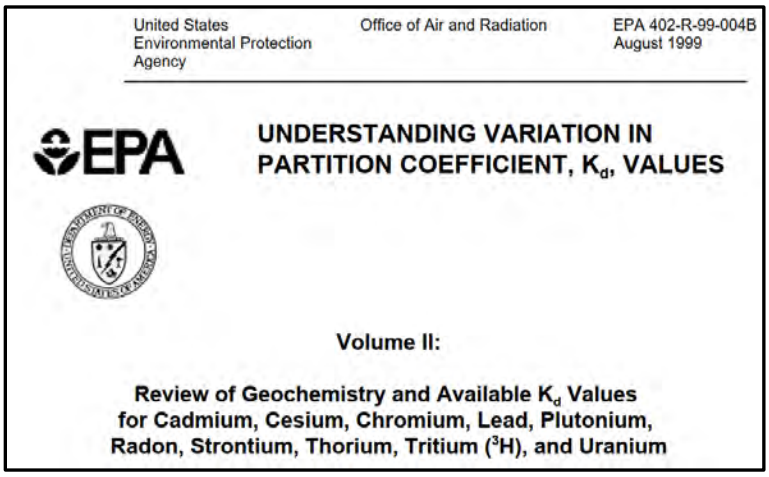
*J - Estimated value*

HALEY ALDRICH

Based on the knowledge of site-specific soil pH data above, the Kd value was selected based on the pH dependent Kd value for lead published in the USEPA 402-R-99-004B document (see the images below).



United States Environmental Protection Agency | Office of Air and Radiation | EPA 402-R-99-004B August 1999

EPA

**UNDERSTANDING VARIATION IN PARTITION COEFFICIENT, $K_d$, VALUES**

**Volume II:**

**Review of Geochemistry and Available $K_d$ Values for Cadmium, Cesium, Chromium, Lead, Plutonium, Radon, Strontium, Thorium, Tritium ($^3H$), and Uranium**

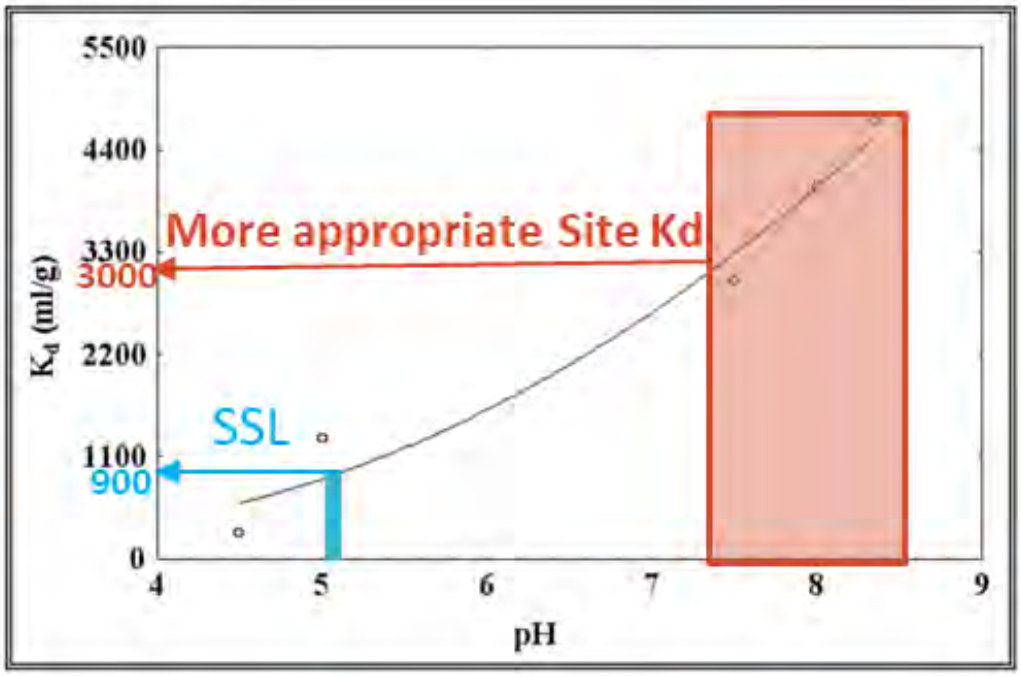


**Figure F.1**. Correlative relationship between $K_d$ and pH.

Note that, beside adsorption, lead tends to precipitation under alkaline pH conditions. The USEPA EPA/600/R-07/140 document indicates that lead leaching is generally not a concern when pH is above 8.

# 1. Introduction and Objectives

This human health risk evaluation was prepared by Haley & Aldrich, Inc. (Haley & Aldrich) on behalf of Rosemead Holding, LLC for the property located at 2200-2226 Rosemead Boulevard in South El Monte, California (Site; Figures 1 and 2). Rosemead Holding, LLC has entered into a voluntary Site Cleanup Program agreement with the Los Angeles Regional Water Quality Control Board (LARWQCB) with the objective of determining what actions, if any, are required as part of Site redevelopment.

The Site comprises approximately 5.1 acres of industrial land that was formerly developed with five structures, all of which have been demolished as of February 2022. The building slabs and pavement currently remain in place, with limited areas of exposed soil and vegetation in the southern portion of the Site. Future development plans for the Site consist of one three-story building which includes warehouse, retail, and office space. Only surface parking is planned in the areas surrounding the building. The proposed development plan is shown in Appendix A.

## 1.1 SITE BACKGROUND AND SCOPE

A risk assessment for the Site was previously submitted to the LARWQCB on 18 November 2022, as part of a Preliminary Endangerment Assessment (PEA) Report (ENVIRO-TOX Services, Inc., 2022). This human health risk evaluation was prepared to address specific comments regarding the PEA Report that were provided by the Office of Environmental Health Hazard Assessment (OEHHA) on 12 July 2023. The OEHHA comments and responses to those comments are provided in Appendix B.

As described in the PEA Report previously prepared for the Site (ENVIRO-TOX Services, Inc., 2022), environmental investigations at the Site date back to the 1980s, with multiple soil, soil vapor, and groundwater investigations being conducted between 1986 and 1998. The LARWQCB issued a No Further Requirement (NFR) letter in March 1998 related to groundwater at the Site. As such, consistent with the 2022 PEA Report, groundwater is not evaluated as part of this human health risk evaluation. Additional soil and soil vapor investigations were conducted in 2020 and 2021 to evaluate Site conditions in advance of the planned demolition and industrial redevelopment. Consistent with previous investigations that resulted in the NFR determination, these Site investigation activities indicated the presence of chemicals of potential concern (COPCs), including metals, polychlorinated biphenyls (PCBs), petroleum hydrocarbons, and volatile organic compounds (VOCs) in soil, in addition to polycyclic aromatic hydrocarbons (PAHs). Additionally, as indicated by soil vapor sampling conducted at the Site between 2020 and 2023, VOCs in soil vapor are widely distributed over the Site. The primary COPCs in soil vapor are chlorinated VOCs, specifically tetrachloroethylene (PCE), trichloroethylene (TCE), and vinyl chloride.

A soil vapor extraction (SVE) system designed to focus on the remediation of chlorinated VOCs in the subsurface was installed at the Site and operated from July 2022 to December 2022. Data related to the operation of the system was reported to the LARWQCB in the EEC Environmental (EEC) Fourth Quarter 2022 Remedial Progress Report, dated 31 January 2023 (EEC, 2023a). The SVE system was turned off in December 2022 for the purposes of evaluating its effectiveness with additional soil vapor sampling completed in March 2023. Soil samples were also collected at each soil vapor probe location during boring advancement.

The primary purpose of the human health risk evaluation is to determine whether the levels of chemicals detected in soil and soil vapor at the Site would pose a potential risk to human health based on the current and potential future property uses of the Site. The human health risk evaluation for the Site includes potential subsurface excavation scenarios and reasonably anticipated future land use scenarios. The results of the risk evaluation will be used to assist in identifying areas of the Site where remediation, or other forms of risk management, may be appropriate, with the overall goal of long-term protection of human health and the environment.

The methodology used in this human health risk evaluation is consistent with risk assessment guidelines provided by the United States Environmental Protection Agency's (USEPA's) "Risk Assessment Guidance for Superfund, Volume I, Human Health Evaluation Manual (Part A), Interim Final" (USEPA, 1989) and by the California Department of Toxic Substances Control's (DTSC's) "Preliminary Endangerment Assessment Manual" (DTSC, 2015). Human health risks were evaluated for hypothetical future on-Site receptors, which include construction workers assumed to be involved in the redevelopment of the Site and on-Site non-intrusive workers assumed to be present following such redevelopment.

According to the USEPA (1989), and as summarized below, there are four basic steps in the quantitative human health risk assessment process: (1) data collection and analysis; (2) exposure assessment; (3) toxicity assessment; and (4) risk characterization. These steps are summarized as follows:

- **Data Collection and Analysis:** For this human health risk evaluation, all Site environmental soil and soil vapor sampling data were reviewed to identify the COPCs and their representative concentrations to which populations could be exposed. The dataset for the human health risk evaluation was obtained from previous and recent Site investigations (as summarized in Section 2.1).
- **Exposure Assessment:** Site uses and physical features were evaluated to develop a conceptual site model (CSM), which identifies the pathways by which current and potential future receptors could be exposed to COPCs. The magnitude of the potential human exposures was also estimated.
- **Toxicity Assessment:** This phase of the risk assessment presents the relationship between the magnitude of exposure and potential adverse effects (dose-response assessment). As a part of the toxicity assessment, toxicity values were identified from the California Environmental Protection Agency (Cal/EPA)-recommended sources, and were then used to estimate the likelihood of adverse effects which could potentially occur at different exposure levels.
- **Risk Characterization:** The exposure and toxicity assessments were combined to characterize and quantify the potential for adverse health effects as a result of potential Site-specific exposures. The risk characterization estimates the likelihood that the estimated potential exposures to COPCs at the Site will result in either cancer or other non-cancer adverse health effects.

The remaining sections of this report are as follows:

- **Section 2 – Data Evaluation and Selection of Chemicals of Potential Concern:** Presents an evaluation of the data used in the human health risk evaluation and identifies the COPCs that have been included in the human health risk evaluation.

- **Section 3 – Exposure Assessment:** Identifies the populations that may potentially be exposed to Site COPCs, the pathways by which potential exposures may occur, and the exposure assumptions used to quantify potential exposures. Section 3.0 also presents the methodology for estimating representative exposure point concentrations (EPCs) for chemicals present in soil and soil vapor.
- **Section 4 – Toxicity Assessment:** Presents the quantitative toxicity criteria used in the calculation of the incremental lifetime excess cancer risks (ILECRs) and non-cancer hazard indices (HIs). Section 4.0 also presents the methodology for evaluating health effects associated with the lead detected in soil.
- **Section 5 – Risk Characterization:** Presents the methodology used to calculate the ILECRs and non-cancer HIs and presents the results of the cancer risk and non-cancer hazard assessments.
- **Section 6 – Summary and Conclusions:** Summarizes the results of the human health risk evaluation.
- **Section 7 – Development of Risk- and Ambient-Based Screening Concentrations (ABSCs):** Presents the methodology used to derive the risk-based screening concentrations (RBSCs) for each of the COPCs evaluated in the human health risk evaluation, and the ABSC for arsenic that may be used to guide upcoming remedial efforts.

The references used in this human health risk evaluation are presented at the end of the document. There are eight appendices that accompany this Report. Appendix A presents the proposed development for the Site. Appendix B presents the comments provided by OEHHA on 12 July 2023 and responses to comments. Appendix C presents the soil and soil vapor data included in the human health risk evaluation, Appendix D presents the output sheets of the USEPA ProUCL statistical program, Appendix E discusses the uncertainties inherent in the human health risk evaluation, Appendix F presents a sample volatilization factor (VF) calculation, Appendix G presents estimated vapor intrusion ILECRs and non-cancer hazard quotients (HQs)/HIs for COPCs in soil vapor, and Appendix H presents a sample RBSC calculation for naphthalene in soil.

# 2. Data Evaluation and Selection of Chemicals of Potential Concern

Data evaluation is the process of analyzing site characteristics and analytical data to identify constituents that are potentially related to the Site and for which there are data of sufficient quality to be used in a quantitative risk assessment (USEPA, 1989). This section summarizes: (1) the soil and soil vapor data considered relevant for the human health risk evaluation; and (2) the COPCs identified by medium for inclusion in the human health risk evaluation.

## 2.1 DEVELOPMENT OF THE RISK EVALUATION DATASETS

As mentioned in Section 1.1 above, environmental investigations at the Site date back to the 1980s, with multiple soil, soil vapor, and groundwater investigations being conducted between 1986 and 1998. These investigations were followed by additional soil and soil vapor investigations in 2020 and 2021 to evaluate Site conditions in advance of planned demolition and industrial redevelopment. These Site investigation data, as presented in the previous PEA Report for the Site, were included in the human health risk evaluation, in addition to soil and soil vapor data collected as part of the 2023 groundwater and soil vapor investigations that were completed in March / April 2023 and January 2024. Data collected during these investigations were included in the datasets used in the human health risk evaluation with the following exceptions:

- **Soil data collected at depths below 10 feet below ground surface (bgs)**. Soil data considered relevant for a human health risk evaluation for the Site (including potential subsurface excavation scenarios and reasonably anticipated future land use scenarios) typically include data for soil samples from depths up to and including 10 feet bgs, as 10 feet is generally considered the maximum depth for excavation activities associated with subsurface maintenance work or site redevelopment.
- **Non-detect soil sample results for certain sample locations.** Site soil datasets were provided in summary tables with results reported only for VOCs that were detected in soil at the Site. Therefore, non-detect VOC results for certain soil samples collected between October 2020 and February 2023 were not included in the human health risk evaluation.
- **Soil vapor data no longer considered representative of current conditions**. Historical soil vapor data was reviewed in the context of more current soil vapor data, where available, to determine if historical results were no longer representative of current subsurface soil vapor conditions. All soil vapor data collected prior to the 2020 sampling event are no longer considered representative of current conditions and were not used in the human health risk evaluation. In addition, because targeted soil vapor extraction was conducted by EEC, the following soil vapor sample results collected in October 2020 or June 2021 from within the radius of influence of the SVE system (i.e., within approximately 60 feet) are not considered to be representative of current subsurface soil vapor conditions and were not included in the human health risk evaluation. These include HP-1, HP-2, HP-3, SB-26, SB-27, SB-28, SB-29, SB-30, SB-33, LV-3, LV-5, LV-6, LV-7, and LV-9.
- **Soil vapor data collected at depths greater than 15 feet bgs**. Soil vapor data collected within the shallow vadose zone down to 15 feet bgs are more representative of soil vapor conditions under a future commercial building for the potential vapor intrusion pathway. VOC concentrations in samples collected at depths greater than 15 feet, assuming the source of VOCs

is deeper than 15 feet, should have greater attenuation to the surface than VOC concentrations in shallow vadose zone samples.

Analytical results included in the risk evaluation are presented in Appendix C.

## 2.2 SELECTION OF CHEMICALS OF POTENTIAL CONCERN

The selection of COPCs for the human health risk evaluation was based on guidance provided by the USEPA (1989) and DTSC (1997, 2015). In general, all chemicals detected in soil and soil vapor, excluding the data identified above in Section 2.1, were included in the quantitative human health risk evaluation.

### 2.2.1 Metals

DTSC guidance (1997, 2015) calls for the exclusion of inorganic compounds, specifically metals, from the quantitative risk assessment if they are detected at levels within the local background/ambient concentrations (hereafter referred to as simply "background"). As described in the PEA Report previously prepared for this Site (2022), the background metal dataset was obtained from soil metal data collected from California Air Force facilities (Hunter, Davis, and Roach, 2004). Maximum detected soil metal concentrations at the Site were compared to the 95th percentile concentration obtained from the California Air Force facilities. Any metal detected in soil at concentrations higher than the 95th percentile background concentration was retained as a COPC. As a result, antimony, arsenic, barium, cadmium, total chromium, hexavalent chromium, cobalt, copper, mercury, molybdenum, nickel, silver, and zinc were included as COPCs in the human health risk evaluation. The selection of metal COPCs is presented in Table 1.

### 2.2.2 Summary of Chemicals of Potential Concern

Chemicals that are included in the human health risk evaluation for soil and soil vapor are summarized below:

- The chemicals detected in on-Site soil (0 to 10 feet bgs) included in the human health risk evaluation as COPCs consist of: various VOCs; total petroleum hydrocarbons (TPH)-diesel, TPH-gasoline, TPH-motor oil, various PAHs, metals determined to be above background/ambient levels, and the PCBs Aroclor-1248, Aroclor 1254, and Aroclor 1260 (Table 1); and
- VOCs detected in soil vapor (Table 2).

# 3. Exposure Assessment

Exposure assessment is the process of describing, measuring, or estimating the intensity, frequency, and duration of potential human exposure to COPCs in environmental media (e.g., soil, water, and air). This section discusses the mechanisms by which people (receptors) might come into contact with the COPCs present in soil and soil vapor at the Site. It includes the characterization of the exposure setting (physical environment and potential receptors), identification of exposure pathways (potential sources, points of release, and exposure routes), and quantification of pathway-specific exposures (EPCs and intake assumptions) based on reasonably anticipated future land uses.

An exposure assessment is best conducted within the context of a risk-based CSM (Figure 3). The CSM is used to show the relationships between a chemical source, exposure pathway, and potential receptor.

The CSM identifies chemical sources, potentially impacted media, migration pathways, exposure routes, and possible exposure scenarios (USEPA, 1988). These source-pathway-receptor relationships provide the basis for the quantitative exposure assessment. Only potentially complete source-pathway-receptor relationships are included in the human health risk evaluation.

## 3.1 CONCEPTUAL SITE MODEL

Potential exposure to COPCs at a site depends on a number of factors related to the physical characteristics of a site and its surroundings. These factors include location, surrounding land use, surface topography, hydrogeology, meteorology, and vegetation. They also include factors related to the current and possible future uses of the site, which determine the types of activities that might occur at the site, the degree to which the site is accessible to the general public, and the mechanisms that might result in migration of COPCs to on- and off-site populations.

This section provides a brief description of the current Site setting and features, consistent with the PEA Report prepared previously by Enviro-Tox Services, Inc. (2022).

### 3.1.1 Site Setting

The Site currently comprises approximately 5.1 acres (223,987 square feet) of industrial land. The Site is unoccupied and concrete- and asphalt-paved, with limited areas of exposed soil and vegetation in the southern portion of the Site. The easternmost portion of the Site was previously occupied by Ditty Container, Inc. (Ditty), which subleased the property from Pacific Coast Drum Company (PCD) since 1996 and has recently vacated the Site. Beginning in the 1940s, both PCD and Ditty cleaned, refurbished, and repainted drums and refurbished plastic tote containers, primarily for the food industry. The former westernmost buildings at the Site were previously used for automotive repair and tire services.

The proposed development for the Site consists of one three-story building, which includes warehouse, retail, and office space. Only surface parking is planned in the areas surrounding the building. The proposed development plan is shown in Appendix A.

Based on the groundwater monitoring event conducted by EEC in January 2023, depth to groundwater beneath the subject property is approximately 53 to 56 feet below the top of casing in the monitoring wells. The groundwater flow direction was measured to the west-southwest (EEC, 2023b).

### 3.1.2 Identification of Potential Receptors

As described in Sections 1.1 and 3.1.1, the Site is currently unoccupied and is located within an industrialized area of South El Monte, California. Proposed industrial development of the Site consists of one three-story building, with a total building footprint of approximately 122,555 square feet. Planned future use of the first floor includes approximately 112,405 square feet of warehouse space, 8,200 square feet of retail space, and 1,950 square feet of office space. Based on the proposed development plans, hypothetical future land use at the Site is assumed to consist only of commercial/industrial use. Potential on-Site receptors therefore include the following:

- Full-time workers. Full-time workers may include administrative and operations staff that work at a commercial/industrial facility at the Site. These employees work 40-hour weeks and about 250 days per year.
- Part-time workers. Part-time workers may include specialized maintenance and operations personnel. Part-time workers may be present at the Site in response to sporadic labor and specialized personnel needs. These workers are assumed to operate from temporary on-Site offices and are not limited to 40-hour weeks.
- Visitors. Visitors are likely to be at the Site for no more than a few hours per week.

Given the above potential on-Site receptors, potentially exposed hypothetical future on-Site receptors identified for this human health risk evaluation include the following:

**Hypothetical future on-Site non-intrusive workers.** Full-time on-Site workers who may occupy future on-Site buildings and come into contact with chemical-impacted surface soil and dust while at work (Figure 3). However, these workers are not assumed to conduct earth-moving activities and/or dig trenches. Hence these workers are referred to as non-intrusive workers.

**Hypothetical future on-Site construction workers.** Hypothetical future intrusive on-Site outdoor construction workers are assumed to be involved in the redevelopment of the Site and/or short-term intrusive activities associated with utility-line work and were therefore included in the human health risk evaluation.

As stated above, part-time workers and visitors could also be exposed to Site-related chemicals while at the Site. However, exposures for these two types of sporadic receptors are likely to be much lower than those potentially experienced by full-time workers. Therefore, consistent with the PEA Report previously prepared by Enviro-Tox Services, Inc. (2022), only the on-Site, full-time worker exposure scenario was evaluated in this human health risk evaluation. Similarly, only the on-Site receptors were quantitatively evaluated in the human health risk evaluation, as off-Site receptor exposures are likely to be much lower than those estimated for on-Site receptors.

### 3.1.3 Identification of Exposure Pathways

An exposure pathway is a description of the mechanism by which an individual may come into contact with COPCs in the environment. An exposure pathway is defined by four elements (USEPA, 1989):

1. A source and mechanism of COPC release to the environment.
2. An environmental receiving or transport medium (e.g., air, soil) for the released COPC.

3. A point of potential contact with the medium of concern.
4. A potential exposure route (e.g., ingestion) at the contact point.

An exposure pathway is considered "complete" if all elements are present. The characterization of the potential exposure pathways based on existing information is presented in the CSM in Figure 3. Potential receptors may be exposed to COPCs in soil and outdoor or indoor air. Further discussion of potential exposure pathways is presented in the following subsections.

#### *3.1.3.1 Chemical Sources and Potential Release Mechanisms*

Historical environmental Site assessment activities indicated the presence of COPCs, including some metals, PCBs, petroleum hydrocarbons, and VOCs, in soil.

Once the chemicals are released into the surface and subsurface soil, the potential secondary release mechanisms include the following:

- Volatilization and dispersion of constituents in soil into indoor or outdoor air;
- Wind erosion and atmospheric dispersion of particulate-bound constituents;
- Migration of constituents from the subsurface soil down into groundwater;
- Migration of constituents in groundwater to neighboring surface water bodies; and
- Off-Site transport of chemicals in soil through surface water runoff.

The mechanisms listed above represent the theoretically complete mechanisms through which chemicals at the Site can be released and transported from one environmental medium to another. A discussion of each of these transport mechanisms and resulting human exposure routes, including those that are considered to be incomplete, is incorporated into the subsequent sections.

#### *3.1.3.2 Potentially Complete Exposure Pathways*

As previously indicated, complete exposure pathways require chemical sources, migration routes, an exposure point for contact, and human exposure routes. The complete exposure pathways through which hypothetical future on-Site receptor workers were assumed to be potentially exposed to Site COPCs are identified and discussed below.

Hypothetical future commercial/industrial use of the Site was evaluated given the planned future development of the Site to include commercial/industrial warehouse, retail, and office space. For this scenario, it was assumed that existing ground cover, including all hardscape, would be removed, and that redevelopment of the Site could result in significant disturbance of the existing topography in which excavated soil is left at the surface, such that hypothetical future receptors would be potentially exposed to COPCs in on-Site soil (0 to 10 feet bgs). As indicated on Figure 3, the potentially complete pathways through which hypothetical future on-Site populations may be exposed to COPCs in on-Site soil (0 to 10 feet bgs) or on-Site soil vapor include the following:

***Hypothetical Future On-Site Non-Intrusive Worker***

- incidental soil ingestion;

- dermal contact with soil;
- inhalation of particulates in outdoor air; and
- inhalation of volatiles migrating from soil up through the soil column (as soil vapor) into indoor and outdoor air.

***Hypothetical Future On-Site Construction Worker***

- incidental soil ingestion;
- dermal contact with soil;
- inhalation of particulates in outdoor air; and
- inhalation of volatiles migrating from soil up through the soil column into outdoor air.

#### *3.1.3.3 Incomplete/Insignificant Exposure Pathways*

Exposure pathways considered incomplete and/or insignificant were not included in the risk evaluation. The exposure pathways considered incomplete and/or insignificant are discussed below:

- **Exposures related to groundwater:** The LARWQCB issued a NFR letter in March 1998 related to groundwater at the Site. As such, consistent with the 2022 PEA Report, potential exposure to groundwater is not evaluated as part of this human health risk evaluation; and
- **Exposures related to the surface water runoff pathway:** Surface water runoff from the Site flows into a stormwater collection system before discharging to a city storm drain; therefore, it presents no exposure opportunities. Thus, the surface water runoff pathway is considered incomplete under current or future conditions and is not evaluated in the human health risk evaluation.

## 3.2 ESTIMATION OF REPRESENTATIVE EXPOSURE POINT CONCENTRATIONS

The following section presents the methods used to estimate the representative concentration of the COPCs in the soil and air to which hypothetical future non-intrusive worker and construction worker populations at the Site could be exposed.

### 3.2.1 Estimation of COPC Concentrations in Soil

The USEPA defines EPCs as the representative chemical concentrations a receptor may contact at an exposure area over the exposure period (USEPA, 1989). The concept is that individuals contact the impacted medium on a periodic and random basis. Because of the repeated and random nature of such contact, human exposure does not occur at a fixed point, but rather at a variety of points with equal likelihood that any given point within the exposure area will be the contact location on any given day. Thus, the EPCs should be based on the average chemical concentration within the exposure area (USEPA, 1989). To account for the uncertainty in estimating the average concentration, USEPA recommends that a UCL be used to represent the EPCs (USEPA, 2002a).

The calculation of EPCs for each COPC dataset includes an initial evaluation of the distribution of the data as a predecessor step to employing the best statistical methodology for determination of a concentration that estimates the mean of the dataset with a prescribed level of confidence. This means

that the average has been bounded by a statistically determined concentration to afford a percent level of confidence in the "true" mean of the dataset. The "95 percent upper confidence limit (UCL)" of the mean, for example, is considered a reasonable maximum exposure (RME) level (USEPA, 1989) so that there is confidence that the mean concentration of each COPC has been bounded at least 95 percent of the time. The USEPA's ProUCL 5.2.00 statistical program (USEPA, 2022a) was used to determine UCL concentrations of the COPCs in soil within 0- to 10-foot bgs depth interval (ProUCL outputs provided in Appendix D). The representative EPCs for COPCs used in the human health risk evaluation are summarized in Table 3.

In accordance with USEPA guidance (USEPA, 2022b), UCLs were not calculated for datasets with less than four detections or less than 10 samples. Although USEPA guidance (USEPA, 2022b) recommends the use of the mean or median when there are insufficient detections or number of samples in the dataset, the maximum detected concentration was conservatively used as the representative EPC in these cases in this human health risk evaluation.

### 3.2.2 Estimation of Air Concentrations Resulting from Emissions from Soil and Groundwater

#### *3.2.2.1 Volatile Organic Compounds*

##### 3.2.2.1.1 Indoor Air

Volatile compounds have the potential to volatilize from soil and/or groundwater into soil vapor and migrate up through the soil column and into the indoor air space of an overlying building. This process is referred to as "vapor intrusion." Building occupants could then be exposed via inhalation to these volatile compounds present in indoor air. The COPCs considered to be volatile are those COPCs that have a Henry's Law constant greater than $10^{-5}$ atmosphere-cubic meter per mole or a vapor pressure in excess of 1 millimeter of mercury (DTSC, 2015 and 2022a). Physicochemical properties of the COPCs in soil and soil vapor are presented in Table 4.

In general, soil vapor data, rather than soil or groundwater data, are preferred for use in transport modeling of volatile chemicals to indoor air, because soil vapor data represent a direct measurement of the gas-phase constituents that may migrate to indoor air. Thus, soil vapor data were used to evaluate the vapor intrusion pathway.

Although vapor intrusion is considered an incomplete transport/exposure pathway under current on-Site land use (given the lack of any current on-Site receptors or regularly occupied, enclosed structures), planned development of the Site consists of a three-story commercial/industrial building, which will occupy the majority of the Site (Appendix A). Potential vapor intrusion into the future on-Site commercial/industrial building was therefore evaluated on an individual sample basis considering the results of all soil vapor samples collected from across the Site.

In summary, the vapor intrusion pathway is evaluated for hypothetical future on-Site non-intrusive workers who may occupy the future commercial/industrial building. Potential vapor intrusion was evaluated using recommended approaches outlined by currently available DTSC, California State Water Resources Control Board (SWRCB), and USEPA guidance documents, specifically:

- *Final Guidance for the Evaluation and Mitigation of Subsurface Vapor Intrusion to Indoor Air* (Vapor Intrusion Guidance; DTSC, 2011);

- *OSWER Technical Guide for Assessing and Mitigating the Vapor Intrusion Pathway from Subsurface Vapor Sources to Indoor Air* (USEPA, 2015); and
- *Supplemental Guidance: Screening and Evaluating Vapor Intrusion. Final Draft.* (DTSC and SWRCB, 2023).

A range of default attenuation factors (AFs) was used in the vapor intrusion evaluation for the Site as follows:

- The DTSC default AF of 0.0005 for future commercial buildings (DTSC, 2011) was used for all COPCs detected in soil vapor at the Site. The default AF was derived by DTSC as the average of chemical-specific AFs modeled for 16 VOCs and commercial buildings using the USEPA Johnson and Ettinger Model (DTSC, 2011).
- The DTSC and SWRCB default AF of 0.03 (DTSC and SWRCB, 2023), which was derived entirely from data on chlorinated solvent compounds and for residential buildings (USEPA, 2012) and recommended by USEPA (2015a), was used for all COPCs detected in soil vapor at the Site.

A detailed discussion of DTSC-recommended default attenuation factors is presented in Appendix E. The results of the vapor intrusion evaluation are discussed in further detail in Section 5.0, Risk Characterization.

#### 3.2.2.1.2 Ambient Air

As presented in the CSM (Figure 3), it was assumed that all receptor populations included in the human health risk evaluation could be exposed to volatile chemicals present in outdoor air as a result of transport from soil. Exposure to volatile constituents present in outdoor air could occur via the inhalation pathway.

The transport of volatile COPCs from soil to outdoor air is modeled as two distinct processes: the volatilization of chemicals from soil to the ground surface, and the dispersion of the chemicals from the ground surface into the ambient air. These two processes are accounted for in the development of volatilization factors.

The transport of volatile COPCs from soil into outdoor air is modeled using the approach recommended in the USEPA soil screening guidance (USEPA, 1996) for infinite sources:

$$VF = \frac{Q/C_{vol} \times (3.14 \times D_A \times T)^{1/2} \times 10^{-4}\ (m^2/cm^2)}{2 \times \rho_b \times D_A}$$

where:

$$D_A = \frac{[(\theta_a{}^{10/3} D_i H') + (\theta_w{}^{10/3} D_w)]/\eta^2}{\rho_b K d + \theta_w + \theta_a H'_{TS}} \qquad \text{(Eq. F-13)}$$

And where:

VF = volatilization factor (cubic meters per kilogram [$m^3/kg$]);

| | | |
|---|---|---|
| $Q/C_{vol}$ | = | dispersion factor (grams per square meter per second [$g/m^2/s$] per kilogram per cubic meter [$kg/m^3$]); |
| $D_A$ | = | apparent diffusivity (chemical-specific; in square centimeters per second [$cm^2/s$]); |
| T | = | exposure interval (based on exposure duration; s); |
| $\rho_b$ | = | dry soil bulk density (grams per cubic centimeter [$g/cm^3$]); |
| $\eta$ | = | total soil porosity (cubic centimeters pore [$cm^3$pore]/$cm^3$soil); |
| $\theta_a$ | = | air-filled soil porosity ($cm^3$air/$cm^3$soil – calculated, $\eta$-$\theta_w$); |
| $D_i$ | = | diffusivity in air (chemical-specific, $cm^2/s$); |
| $\theta_w$ | = | water-filled soil porosity ($cm^3$water/$cm^3$soil); |
| $D_w$ | = | diffusivity in water (chemical-specific, $cm^2/s$); |
| $K_d$ | = | soil-water partition coefficient (chemical specific, $g/cm^3$); and |
| $H'_{TS}$ | = | Henry's Law Constant (chemical-specific, unitless). |

Where:

$$K_d = K_{oc} \times f_{oc} \qquad \text{(Eq. F-14)}$$

And where:

| | | |
|---|---|---|
| $K_{oc}$ | = | soil organic carbon partition coefficient (chemical-specific, $g/cm^3$); and |
| $f_{oc}$ | = | fraction organic carbon in soil (grams per gram [g/g]). |

Chemical-specific physiochemical properties and default soil properties for vadose zone soil are used in calculating the infinite source VFs. The chemical-specific physiochemical properties for the volatile COPCs in soil are presented in Table 6 of the human health risk evaluation. The default soil properties for vadose zone soil are presented in Appendix F as part of a sample VF calculation for naphthalene for hypothetical future on-Site non-intrusive workers. Consistent with the PEA Report previously prepared for the Site, the dispersion factor estimated for a default Site area of 0.5 acres, 68.18 $g/m^2/s$ per $kg/m^3$, was used to calculate the infinite source VFs for all receptors. Table 3 presents the calculated VFs for all volatile COPCs in Site soil.

#### *3.2.2.2 Non-Volatile Chemicals*

The human health risk evaluation assumes that the non-intrusive worker populations could be exposed to particulate-phase chemicals present in outdoor air as a result of transport from Site soil (i.e., chemicals adhered to airborne dust particles). In general, the concentration of a particulate-phase chemical in air (CA) is the product of the concentration of dust in air (CD) and the concentration of the chemical in soil (CS):

$$\text{CA}\ (mg/m^3) = CD\ (mg/m^3) \times\ \text{CS}\ (mg/kg)\ \times\ 10^{-6}\ (kg/mg)$$

Thus, for a given CS, a determination of the CA requires a determination of the CD. In the context of modeling chemical transport from soil to outdoor air, the concentration of dust in air is expressed

through the particulate emission factor (PEF). As defined by the USEPA Soil Screening Guidance (USEPA, 1996; 2002b), the PEF has units of cubic meters of air per kilogram of dust ($m^3$/kg), and is therefore equal to the reciprocal of the dust concentration:

$$\text{PEF } (m^3/kg) = \frac{1}{\text{CD } (mg/m^3)} \times 10^{+6} \ (mg/kg)$$

Combining the preceding two equations, the concentration of a particulate-phase chemical in outdoor air may be expressed as a function of the chemical concentration in soil and the PEF:

$$\text{CA } (mg/m^3) = \frac{\text{CS } (mg/kg)}{\text{PEF}(m^3/kg)}$$

The CS used to estimate the CA for a receptor is the EPC in soil for the non-intrusive worker receptor.

The default PEF for an industrial scenario recommended by the Cal/EPA DTSC Note number 1 (DTSC, 2019b) was used to estimate the particulate-phase chemical concentrations in outdoor air.

For construction worker populations, the dust concentration in air is assumed to be attributable to mechanical disturbance; therefore, the value is much higher than if attributable solely to wind erosion. As recommended by DTSC (2019b) for a construction worker scenario, it is conservatively assumed that construction worker populations are exposed to an 8-hour average dust concentration of 1 milligram per cubic meter (mg/$m^3$). This dust concentration corresponds to a PEF of one in one million ($1 \times 10^6$) $m^3$/kg (*i.e.*, 1 / [(1 mg/$m^3$) × ($1 \times 10^{-6}$ kg/mg)]).

The calculated particulate-phase chemical concentrations in outdoor air for COPCs are presented in Table 5.

### 3.3 HUMAN INTAKE ASSUMPTIONS

The route-specific assumptions used to estimate exposure to the COPCs in soil and soil vapor are presented in Table 5. Exposure assumptions are taken from DTSC and USEPA guidance documents, wherever possible, and are cited in Table 3. Standard DTSC-recommended RME assumptions for industrial worker and construction worker exposure scenarios (DTSC, 2019b) were used to evaluate hypothetical future on-Site non-intrusive workers and construction workers, respectively.

As described in subsequent sections, the various exposure assumptions are combined to estimate the intake of a chemical through a given route of exposure (e.g., soil ingestion). The route-specific intakes are then combined in order to calculate the total intake, with all exposure pathways combined. The route-specific equations used to calculate chemical intake are presented in Table 6 for the non-intrusive worker and construction worker scenarios.

# 4. Toxicity Assessment

The toxicity assessment characterizes the relationship between the magnitude of exposure to a chemical and the potential for adverse effects. More specifically, the toxicity assessment identifies or derives toxicity values that can be used to estimate the likelihood of adverse effects occurring in humans at different exposure levels. The human health risk evaluation assesses adverse carcinogenic and non-carcinogenic health effects resulting from chemical exposures. The hierarchy of sources for the toxicity criteria used for this human health risk evaluation corresponds to the State's guidelines (DTSC, 2015; 2019a) and are consistent with the DTSC's Toxicity Criteria Regulation (California Code of Regulations, 2018). Carcinogenic and non-carcinogenic toxicity values used in the human health risk evaluation are presented in Table 7.

## 4.1 TOXICITY ASSESSMENT FOR CARCINOGENIC EFFECTS

Current health risk assessment practice for carcinogens is based on the assumption that, for most substances, there is no threshold dose below which carcinogenic effects do not occur. This current "no-threshold" assumption for carcinogenic effects is based on an assumption that the carcinogenic processes are the same at high and low doses. This approach has generally been adopted by regulatory agencies as a conservative practice to protect public health, and the "no-threshold" assumption has been used in the agency-derived cancer slope factors (CSFs) and unit risk factors (URFs) used in this human health risk evaluation. Although the magnitude of the risk declines with decreasing exposure, the risk is believed to be zero only at zero exposure.

The toxicity values used to quantify the response potency of a potential carcinogen are the following:

- The CSF, used in assessing the oral route of exposure, represents the excess lifetime cancer risk due to a continuous, constant lifetime exposure to a specified level of a carcinogen generally reported as excess incremental cancer risk per milligram of chemical per kilogram body weight per day [$(mg/kg\text{-}day)^{-1}$].
- The URF, used to assess the inhalation route of exposure, represents the excess lifetime cancer risk due to a continuous, constant lifetime exposure to a specified level of a carcinogen in the air, generally reported as excess incremental cancer risk per microgram of chemical per cubic meter of air [$(\mu g/m^3)^{-1}$]. URFs are reported as excess incremental cancer risk per milligram of chemical per cubic meter of air [$(mg/m^3)^{-1}$] in Table 7 for risk calculation purposes.

The Cal/EPA and USEPA have published a list of CSFs and URFs recommended for use in risk assessments. The Cal/EPA-recommended CSFs and URFs are maintained on the Cal/EPA OEHHA's online toxicity criteria database (OEHHA, 2024). Table 7 presents the CSFs and URFs for COPCs used in this human health risk evaluation. As indicated in Table 7, the COPCs at the Site that are currently regulated as carcinogens are 1,1,2,2-tetrachloroethane, 1,1-dichloroethane, 1,2,4-trichlorobenzene, 1,2-dichloroethane, 1,2-dichloropropane, 1,4-dichlorobenzene, benzene, chloroethane, ethylbenzene, methyl tert-butyl ether, methylene chloride, naphthalene, tert-butyl alcohol, PCE, TCE, vinyl chloride, carcinogenic polycyclic aromatic hydrocarbons (CPAHs; benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[k]fluoranthene, chrysene, dibenz[a,h]anthracene, and indeno[1,2,3-cd]pyrene), arsenic, cadmium, hexavalent chromium, cobalt, and nickel. Consistent with DTSC guidance (DTSC, 2022a), the potential cancer and non-cancer health effects of individual CPAHs

are included in the estimate of cumulative cancer risk and non-cancer hazard from COPCs in soil at the Site.

## 4.2 TOXICITY ASSESSMENT FOR NON-CARCINOGENIC EFFECTS

The toxicity assessment for non-carcinogenic effects requires the estimation of an exposure level below which no adverse health effects in humans are expected to occur. USEPA refers to these levels as reference doses (RfDs) for oral exposures and reference concentrations (RfCs) for inhalation exposures (USEPA, 1989). The non-cancer RfD represents a dose, given in mg/kg-day, that would not be expected to cause adverse non-cancer health effects in potentially exposed populations. The non-cancer RfD is often referred to as the "acceptable dose." The non-cancer RfC represents the airborne concentration (in units of $mg/m^3$) that would not be expected to cause adverse non-cancer health effects in populations exposed through the inhalation pathway. OEHHA refers to these "acceptable dose or concentrations" as reference exposure levels (RELs). As the inhalation RfCs/RELs are derived from inhalation toxicity studies, they are used for evaluating inhalation exposures (USEPA, 1989). Consistent with the DTSC's Toxicity Criteria Regulation (California Code of Regulations, 2018), non-cancer toxicity values used (i.e., RfDs and RfCs) correspond to those listed and recommended by Cal/EPA and USEPA.

DTSC-recommended RfDs and RfCs (DTSC, 2019a) from the Integrated Risk Information System online database (USEPA, 2024) are used in this human health risk evaluation. Table 7 presents the non-carcinogenic toxicity values used in this human health risk evaluation COPCs at the Site.

## 4.3 TOXICITY ASSESSMENT FOR LEAD

The traditional RfD approach to the evaluation of chemicals is not applied to lead because most human health effects data are based on blood lead concentrations, rather than external doses (DTSC, 2022b). To evaluate this endpoint, DTSC developed the LeadSpread model. The latest version of the LeadSpread mathematical model, version 9 (DTSC, 2022b), estimates blood lead levels that would result from regular contact with lead in soil assuming exposure via incidental ingestion, dermal contact, and dust inhalation. In an industrial setting, the most sensitive receptor to potential lead exposure is a female worker of child-bearing age given the sensitivity of fetuses and neonates to the adverse effects of lead on development. The OEHHA has established 1 microgram per deciliter (µg/dL) as a benchmark for source-specific incremental change in blood lead levels for the protection of school children and fetuses (OEHHA, 2007). Using LeadSpread Version 9, DTSC developed a health-based soil screening level for lead in industrial land use scenarios of 500 milligrams per kilogram (mg/kg). This value represents the concentration in soil corresponding to a 90th percentile estimate of blood lead in the fetus of a pregnant adult worker equal to 1 µg/dL and is used in the human health risk evaluation to evaluate non-intrusive worker and construction worker exposures to lead in Site soil.

# 5. Risk Characterization

This section of the human health risk evaluation presents the quantitative characterization of risks posed by the COPCs identified in on-Site soil and on-Site soil vapor, and a discussion of uncertainties associated with the projected risks.

This section is divided into two parts. The first part discusses the methodology used in calculating potential health risks to potentially exposed populations posed by the presence of chemicals in on-Site soil and on-Site soil vapor. The second part presents the estimated cumulative potential ILECR and non-cancer hazard posed by the presence of COPCs in on-Site soil and on-Site soil vapor. The quantitative estimates of ILECRs and non-cancer hazards provide the basis for mitigation measures that may be appropriate to reduce risks to levels that would be fully protective of human health and the environment.

## 5.1 METHODOLOGY

Estimating ILECRs and non-cancer HIs for exposures to chemicals in soil and soil vapor requires information regarding chemical concentrations in the various media, the level of intake of the chemical, and the relationship between intake of the chemical and its toxicity as a function of human exposure to the chemical. The methodology used to derive the ILECRs and non-cancer HIs for the selected COPCs is based principally on guidance provided in the regulatory documents listed below.

- USEPA, 1989. *Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual (Part A). Interim Final*. Office of Emergency and Remedial Response. EPA/540/1-89/002. Washington, D.C. December.
- USEPA, 1991. *Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual. Supplemental Guidance. Standard Default Exposure Factors.* Office of Emergency and Remedial Response. 25 March.
- USEPA, 2009. *Risk Assessment Guidance for Superfund. Volume 1: Human Health Evaluation Manual (Part F, Supplemental Guidance for Inhalation Risk Assessment). Final.* OSWER Directive 9285.7-82. EPA-540-R1-070-002. January.
- DTSC, 2015. *Preliminary Endangerment Assessment Manual*. October.
- DTSC, 2019. *Recommended DTSC Default Exposure Factors for Use in Risk Assessment at California Hazardous Waste Sites and Permitted Facilities.* Human Health Risk Assessment (HHRA) Note Number: 1. Office of Human and Ecological Risk (HERO). 9 April.

The sections below present the equations used to derive the ILECRs and non-cancer HIs for the selected COPCs.

### 5.1.1 Carcinogenic Health Effects

The equations below describe the established relationship between estimated intake, toxicity, and risk for carcinogenic health effects. For exposures occurring via incidental soil ingestion and dermal contact with soil, the relationship for carcinogenic effects is given by the following equation (USEPA, 1989):

$$ILECR = CDI \times CSF$$

Where:

| | | |
|---|---|---|
| ILECR | = | Incremental lifetime excess cancer risk; the incremental probability of an individual developing cancer as a result of exposure to a particular cumulative dose of a potential carcinogen (unitless); |
| CDI | = | Chronic daily intake of a chemical (mg chemical/kg body weight-day); and |
| CSF | = | Cancer slope factor; the toxicity value which indicates the upper limit on ILECR per unit of dose of chemical (mg chemical/kg body weight-day)$^{-1}$. |

For inhalation pathways, the relationship for carcinogenic effects is given by the following equation (USEPA, 2009):

$$ILECR = EC \times URF$$

Where:

| | | |
|---|---|---|
| ILECR | = | Incremental lifetime excess cancer risk; the incremental probability of an individual developing cancer as a result of exposure to a particular cumulative concentration of a potential carcinogen (unitless); |
| EC | = | Exposure concentration of a chemical (mg chemical/m$^3$ air); and |
| URF | = | Unit Risk Factor; the toxicity value which indicates the upper limit on ILECR per unit of concentration of chemical (mg chemical/m$^3$ air)$^{-1}$. |

The formulas for developing the CDIs and ECs for the worker scenarios are presented in Table 4. The calculated CDIs and ECs for the populations evaluated in this human health risk evaluation for exposure to carcinogenic COPCs in soil are presented in Tables 8A and 8B. Estimated ILECRs associated with exposure to carcinogenic COPCs in soil for exposure scenarios evaluated in this human health risk evaluation are presented in Tables 10A and 10B.

ILECRs estimated on an individual sample basis for the vapor intrusion pathway for exposure scenarios evaluated in this human health risk evaluation are presented in Appendix H and summarized in Table 12A and 12B using soil-to-indoor AFs of 0.0005 and 0.03, respectively.

As a point of reference, the National Contingency Plan (NCP) (40 Code of Federal Regulations [CFR] 300) indicates that total ILECRs posed by a site should not exceed a range of $1 \times 10^{-6}$ to one hundred in a million ($1 \times 10^{-4}$). The Cal/EPA's point of departure for total ILECR for all receptor groups is $1 \times 10^{-6}$, and risk management decisions may raise this criterion depending on site-specific conditions (e.g., $1 \times 10^{-5}$ for commercial settings). OEHHA's benchmark risk level for total ILECRs is $1 \times 10^{-5}$.

### 5.1.2 Non-carcinogenic Health Effects

The equations below describe the established relationship between estimated intake, toxicity, and non-carcinogenic hazard. For exposures occurring via incidental soil ingestion and dermal contact with soil, the relationship for non-carcinogenic effects is given by the following equation (USEPA, 1989):

$$\text{Hazard Quotient} = \text{CDI}/\text{RfD}$$

$$\text{Hazard Index} = \sum \text{Hazard Quotient}$$

Where:

| | | |
|---|---|---|
| Hazard Quotient | = | Hazard quotient (HQ); an expression of the potential for a chemical to cause non-carcinogenic effects, which relates the allowable amount of a chemical (RfD) to the estimated Site-specific intake (unitless); |
| Hazard Index | = | Hazard index (HI); the sum of the chemical-specific HQs, which represents the cumulative potential for predicted exposures to result in non-carcinogenic effects (unitless); |
| CDI | = | Chronic daily intake of a chemical (mg chemical/kg body weight-day); and |
| RfD | = | Reference dose; the toxicity value indicating the threshold amount of chemical contacted below which no adverse health effects are expected (mg chemical/kg body weight-day). |

For inhalation pathways, the relationship for non-carcinogenic effects is given by the following equation (USEPA, 2009):

$$\text{Hazard Quotient} = \text{EC}/\text{RfC}$$

$$\text{Hazard Index} = \sum \text{Hazard Quotient}$$

Where:

| | | |
|---|---|---|
| Hazard Quotient | = | HQ; an expression of the potential for a chemical to cause non-carcinogenic effects, which relates the allowable concentration |

| | | |
|---|---|---|
| | | of a chemical (RfC) to the estimated site-specific exposure concentration (unitless); |
| Hazard Index | = | HI; the sum of the chemical-specific HQs, which represents the cumulative potential for predicted exposures to result in non-carcinogenic effects (unitless); |
| EC | = | Exposure Concentration of a chemical (mg chemical/$m^3$ air); and |
| RfC | = | Reference concentration; the toxicity value indicating the threshold concentration of chemical contacted below which no adverse health effects are expected (mg chemical/$m^3$ air). |

The formulas for developing the CDIs and ECs for the worker scenarios are presented in Table 4. The calculated CDIs and ECs for the populations evaluated in this human health risk evaluation for exposure to non-carcinogenic COPCs in soil are presented in Tables 9A and 9B. Estimated non-cancer HIs associated with exposure to non-carcinogenic COPCs in soil for exposure scenarios evaluated in this human health risk evaluation are presented in Tables 11A and 11B.

Non-cancer HIs estimated on an individual sample basis for the vapor intrusion pathway for exposure scenarios evaluated in this human health risk evaluation are presented in Appendix H and summarized in Table 12A and 12B using soil-to-indoor AFs of 0.0005 and 0.03, respectively.

For non-cancer health effects, a HQ of less than or equal to 1 implies that the intake for a given population and chemical is less than or equal to levels where adverse non-cancer health effects could occur. For non-cancer health hazards, a HQ of 1 is identified as the target level of concern. Chemical exposures that yield HIs of less than or equal to 1 are not expected to result in adverse non-cancer health effects (USEPA, 1989).

A HI that is calculated by summing the HQs for all COPCs, which is termed a Screening Hazard Index, generally provides an overestimation of potential risk. This is because the critical effects upon which the RfD and RfC values are derived are not necessarily the same for all COPCs. For example, the critical effect for TPH-diesel and TPH-gasoline is based on adverse effects to the general toxicity, nervous system, respiratory, and kidney while the critical effect for Aroclor-1242 is based on adverse effects to the skin, eyes, and immune system. Thus, summing HQs for TPH-diesel and TPH-gasoline is appropriate because the summation of HQs provides a HI for effects to the nervous system, respiratory, and kidney. Conversely, summing TPH-diesel and Aroclor-1242 HQs with the arsenic HQ does not provide an accurate estimate of total HI for one effect or the other. Rather, it provides an overestimate of general risk.

Consequently, a total HI that is above 1 and is based on exposures to multiple COPCs does not necessarily indicate that the potential for adverse health effects is unacceptable if the risks for the COPCs are not additive. Therefore, when HI values exceed 1, and the HQ values associated with any given COPC do not exceed 1, it is appropriate to conduct an additional evaluation to review the hazard quotient for each COPC individually, taking into consideration the effect of individual COPCs on target organs. Separate HI values for specific target organ effects may then be calculated and evaluated against the USEPA goal of a HI of 1. Hazard index values for hypothetical future on-Site non-intrusive worker and construction worker exposure to Site soil (0 to 10 feet bgs) were segregated by target organ effect, as shown on Tables 11A and 11B, respectively.

## 5.2 RESULTS OF CANCER RISK AND NON-CANCER HAZARD ASSESSMENT

This section presents the results of the ILECR and non-cancer hazard estimates for exposures to COPCs in on-Site soil and on-Site soil vapor under hypothetical future land use scenarios. Hypothetical future on-Site receptors evaluated include non-intrusive workers and construction workers.

As previously indicated, the ILECRs and non-cancer hazards estimated under the exposure scenarios evaluated in this human health risk evaluation are presented in Tables 10A through 12B.

### 5.2.1 On-Site Non-Intrusive Worker

The estimated cumulative ILECRs and non-cancer HIs associated with potential exposures to COPCs in on-Site soil (0 to 10 feet bgs) and on-Site soil vapor for the hypothetical future on-Site non-intrusive workers are summarized in the table below:

| Media | Cumulative ILECR | Non-cancer HI |
|---|---|---|
| On-Site Soil (0 to 10 feet bgs) | $6\times10^{-5}$ | 5 |
| On-Site Soil Vapor (Vapor Intrusion)[1] | $1\times10^{-4}$ / $7\times10^{-3}$ | 1 / 62 |

***Notes:***

*[1] The cumulative ILECR and non-cancer HI presented for the vapor intrusion pathway are the maximum values estimated on an individual sample basis for all soil vapor samples collected. Estimates based on the DTSC default attenuation factor of 0.0005 for future commercial buildings (DTSC, 2011) are presented followed by estimates based on the DTSC and SWRCB default attenuation factor for residential buildings of 0.03 (DTSC and SWRCB, 2023).*

#### *5.2.1.1 On-Site Soil (0 to 10 feet bgs)*

As indicated in Table 10A, the cumulative ILECR estimated for hypothetical future on-Site non-intrusive worker exposure to COPCs in on-Site soil (0 to 10 feet bgs) is $6 \times 10^{-5}$, which is within the acceptable risk range of $1 \times 10^{-6}$ to $1 \times 10^{-4}$, but above the Cal/EPA's point of departure of $1 \times 10^{-6}$ and OEHHA's benchmark cancer risk level of $1 \times 10^{-5}$. The estimated cumulative ILECR is predominantly attributable to arsenic ($2 \times 10^{-5}$; 36 percent), followed by Aroclor-1242 ($2 \times 10^{-5}$; 31 percent), hexavalent chromium ($1 \times 10^{-5}$; 19 percent), Aroclor-1248 ($2 \times 10^{-6}$; 3 percent), and Aroclor-1254 ($2 \times 10^{-6}$; 3 percent) via incidental ingestion and dermal contact (Table 10a). No other COPCs contribute chemical-specific ILECRs greater than $1 \times 10^{-6}$.

As indicated in Table 11A, the non-cancer HI estimated for hypothetical future on-Site non-intrusive worker exposure to COPCs in on-Site soil (0 to 10 feet bgs) is 5, which is above the acceptable HI of 1. The estimated HI is predominantly attributable to arsenic (HI of 2; 40 percent), Aroclor-1242 (HI of 1; 29 percent), TPH-diesel (HI of 0.7; 14 percent), TPH-gasoline (HI of 0.3; 5 percent), Aroclor-1248 (HI of 0.1; 3 percent), and Aroclor-1254 (HI of 0.1; 3 percent) contributing incrementally to a HI above 1. Excluding arsenic and Aroclors-1242, -1248, and -1254, the estimated non-cancer HI for hypothetical future on-Site non-intrusive workers does not exceed 1. The HIs for TPH-diesel and TPH-gasoline are likely overestimated, particularly the HI via the vapor inhalation pathway (HI of 0.6 and 0.2, respectively) due to the use of the VF approach to estimate outdoor air concentrations of COPCs that tend to overestimate emissions of VOCs from soils. As such, the HIs for TPH-diesel and TPH-gasoline are likely lower than what is presented in this risk evaluation.

When HI values for hypothetical future on-Site non-intrusive worker exposure to COPCs in on-Site soil (0 to 10 feet bgs) are summed by target organ effect, HI values exceed 1 (target organ HI of 1). HI segregation is shown in Table 10B. Note that the target organ-specific HI values that exceed 1 are predominately attributable to arsenic and Aroclor-1242.

#### *5.2.1.2 Lead in On-Site Soil (0 to 10 feet bgs)*

The EPC for lead in on-Site soil (0 to 10 feet bgs), 941 mg/kg (Table 6), is above the DTSC-SL for industrial soil of 500 mg/kg. Potential exposure for hypothetical future on-Site non-intrusive workers to lead in on-Site soil (0 to 10 feet bgs) may therefore result in an increase in blood lead level for the fetus of a hypothetical future on-Site non-intrusive worker above the OEHHA's benchmark value of 1 µg/dL.

#### *5.2.1.3 On-Site Soil Vapor: Vapor Intrusion*

As shown in Table 12A, using the DTSC default attenuation factor for future commercial buildings of 0.0005 (DTSC, 2011), estimated non-cancer HIs associated with vapor intrusion for hypothetical future on-Site non-intrusive workers are at or below the acceptable HI of 1; however, estimated cumulative ILECRs are at or above $1 \times 10^{-6}$ at several locations, ranging from $1 \times 10^{-6}$ to $1 \times 10^{-4}$ (SB-21 at 5 feet bgs; 22 August 2020 sample; Table 12A). ILECRs are above $1 \times 10^{-6}$ at eight locations and are driven by the following VOCs:

- benzene and ethylbenzene at two locations, HP-4 at 5 feet bgs and SB-21 at 5 feet bgs;
- PCE at four locations, HP-4 at 5 feet bgs, HP-9 at 5 and 15 feet bgs, and LV-10 at 6 feet bgs;
- TCE at one location, LV-4 at 14 feet bgs; and
- vinyl chloride at seven locations, HP-4 at 5 and 15 feet bgs, LV-4 at 14 feet bgs, LV-8 at 5 and 15 feet bgs, LV-10 at 6 feet bgs, SB-17 at 5 feet bgs, SB-18 at 5 feet bgs, and SB-21 at 5 and 15 feet bgs.

Seven of the eight locations with ILECRs are above $1 \times 10^{-6}$ are located within the footprint of the proposed future commercial building at the Site (Figure 2 and Appendix A).

As shown in Table 12B, using the DTSC and SWRCB default attenuation factor of 0.03 (DTSC and SWRCB, 2023), which was derived entirely from data on chlorinated solvent compounds and for residential buildings (USEPA, 2012), estimated non-cancer HIs associated with vapor intrusion for hypothetical future on-Site non-intrusive workers are at or above the acceptable HI of 1 at several locations, ranging from 2 to 62 (Table 12B). Estimated non-cancer HIs above 1 are driven primarily by detected concentrations of benzene, cis-1,2-dichloroethene, PCE, toluene, TCE, vinyl chloride, and/or xylenes in the following soil vapor samples:

- HP-4 (5 feet bgs),
- HP-9 (5 and 15 feet bgs),
- LV-3 (10 feet bgs),
- LV-4 (5 and 14 feet bgs),
- LV-8 (5 and 15 feet bgs),
- LV-10 (6 and 15 feet bgs),
- SB-5 (15 feet bgs),
- SB-8 (15 feet bgs),
- SB-10 (5 and 15 feet bgs),
- SB-13 (5 and 15 feet bgs),
- SB-14 (5 and 15 feet bgs),
- SB-16 (5 and 15 feet bgs),
- SB-17 (5 feet bgs),
- SB-18 (5 and 15 feet bgs),
- SB-20 (5 feet bgs)
- SB-21 (5 and 15 feet bgs),
- SB-22 (15 feet bgs), and
- SB-23 (15 feet bgs).

Estimated cumulative ILECRs are above $1 \times 10^{-6}$ at all locations, ranging from $2 \times 10^{-6}$ to $7 \times 10^{-3}$ (Table 12B). Cumulative ILECR estimates above $1 \times 10^{-6}$ are driven primarily by detected concentrations of 1,1-dichloroethane, 1,2-dichloroethane, 1,4-dioxane, benzene, bromodichloromethane, chloroform, ethylbenzene, methylene chloride, PCE, TCE, and/or vinyl chloride.

### 5.2.2 On-Site Construction Worker

The estimated cumulative ILECRs and non-cancer HIs associated with potential exposures to COPCs in on-Site soil (0 to 10 feet bgs) for the hypothetical future on-Site construction worker are summarized in the table below:

| Media | Cumulative ILECR | Non-cancer HI |
|---|---|---|
| On-Site Soil (0 to 10 feet bgs) | $4 \times 10^{-5}$ | 17 |

As indicated in Table 10B, the cumulative ILECR estimated for hypothetical future on-Site construction worker exposure to COPCs in on-Site soil (0 to 10 feet bgs) is $4 \times 10^{-5}$, which is within the acceptable risk range of $1 \times 10^{-6}$ to $1 \times 10^{-4}$, but above the Cal/EPA point of departure of $1 \times 10^{-6}$ and OEHHA's benchmark cancer risk level of $1 \times 10^{-5}$. The estimated cumulative ILECR is predominantly attributable to hexavalent chromium ($4 \times 10^{-5}$; 83 percent) via particulate inhalation ($4 \times 10^{-5}$) and incidental ingestion ($1 \times 10^{-6}$), arsenic ($3 \times 10^{-6}$; 7 percent) via incidental ingestion ($2 \times 10^{-6}$) and dermal contact ($1 \times 10^{-6}$), and Aroclor-1242 ($3 \times 10^{-6}$; 6 percent) via incidental ingestion ($1 \times 10^{-5}$) and dermal contact ($2 \times 10^{-5}$). No other COPCs contribute chemical-specific ILECRs greater than $1 \times 10^{-6}$.

Estimated ILECRs via the particulate inhalation pathway are based on an assumption of exposure to elevated dust levels of 1 mg/m$^3$ in air sustained over the entire 8-hour workday period over 250 days in one year during redevelopment soil disturbance construction activities at the Site. This assumption is overly conservative given that best management practices will likely be implemented during construction activities to minimize/mitigate dust emission levels to below the California Air Resources Board 24-hour particulate matter with a diameter less than or equal to 10 microns ($PM_{10}$) standard of 50 µg/m$^3$ for protection of surrounding communities and soil disturbance activities during redevelopment, such as grading and trenching for utilities would likely occurring the initial phases of redevelopment and over a small portion of a year. Therefore, the estimated ILECRs for the hypothetical future on-Site construction worker are overestimated and are likely lower than those presented in this risk evaluation, particularly for hexavalent chromium, where the estimated cumulative ILECR is predominantly attributable to the particulate inhalation pathway ($4 \times 10^{-5}$).

As indicated in Table 11B, the non-cancer HI estimated for hypothetical future on-Site construction worker exposure to COPCs in on-Site soil (0 to 10 feet bgs) is 17, which is above the acceptable HI of 1. The estimated HI is predominantly attributable to arsenic (41 percent) and Aroclor-1242 (31 percent) with estimated non-cancer HIs of 7 and 5, respectively. Other COPCs with HIs below 1 that contribute approximately 5, 4, 3, 3, 3, and 2 percent to the total HI include TPH-diesel (HI of 0.9), total chromium (HI of 0.6), Aroclor-1248 (HI of 0.5), Aroclor-1254 (HI of 0.5), cobalt (HI of 0.4), and Aroclor-1260 (HI of 0.3), respectively. Similarly for hexavalent chromium, the estimated non-cancer HIs for total chromium and cobalt are predominantly attributable to the particulate inhalation pathway (i.e., HIs via the particulate inhalation pathway for total chromium and cobalt are 0.6 and 0.3, respectively); therefore, they are overestimated and are likely lower than those presented in this risk evaluation. The HI for TPH-diesel is also overestimated, particularly the HI via the vapor inhalation pathway (HI of 0.6) as it is based on the assumption that the entire soil concentration of TPH-diesel is volatile. This assumption is overly

conservative given the weathering of the TPH in soil and only a portion of the lower end of carbon chain range of petroleum constituents that comprise TPH-diesel mixture is considered volatile.

When HI values for hypothetical future on-Site construction worker exposure to COPCs in on-Site soil (0 to 10 feet bgs) are summed by target organ effect, HI values exceed 1 (target organ HI of 1). HI segregation is shown in Table 11B. Note that the target organ-specific HI values that exceed 1 is predominately attributable to arsenic and Aroclor-1242.

#### *5.2.2.1 Lead in On-Site Soil (0 to 10 feet bgs)*

The EPC for lead in on-Site soil (0 to 10 feet bgs) of 941 mg/kg (Table 5) is above the DTSC-SL for industrial soil of 500 mg/kg. Potential exposure for hypothetical future on-Site construction workers to lead in on-Site soil (0 to 10 feet bgs) may therefore result in an increase in the blood lead level for the fetus of a hypothetical future on-Site non-intrusive worker above the OEHHA's benchmark value of 1 µg/dL.

### 5.3 UNCERTAINTIES IN THE RISK CHARACTERIZATION

The risk evaluation includes several uncertainties that warrant discussion. Many of the assumptions used in this risk assessment, regarding the representativeness of the sampling data, potential human exposures, fate and transport modeling, and chemical toxicity are conservative, follow agency guidance, and reflect a 90th or 95th percentile value, rather than a typical or average value. The use of several conservative exposure assumptions and toxicity estimates can introduce considerable uncertainty into the risk assessment. By using conservative exposure assumptions or toxicity estimates, the assessment can develop a significant conservative bias that may result in the calculation of significantly higher cancer risks or non-cancer hazards than are actually posed by the chemicals present in soil. A discussion of the key uncertainties used in this evaluation for the Site is discussed in Appendix E.

# 6. Summary and Conclusions

This human health risk evaluation was conducted to determine whether the levels of chemicals detected at the Site would pose a potential risk to human health based on the current and potential future property uses at the Site. The results of the human health risk evaluation will be used to assist in identifying areas of the Site where remediation, or other forms of risk management, may be appropriate to reduce risks to levels that would be fully protective of human health and the environment.

The risk evaluation was intended to be conservative, resulting in projected estimates of health risks that are likely higher than the actual risks that may be posed by the Site. The human receptors that could potentially be impacted through use of the Site were identified and included in the evaluation. Soil and soil vapor data collected during Site investigations were included in the datasets used in the quantitative human health risk evaluation, with the exceptions discussed in Section 3.1. Chemicals detected in soil within the top 10 feet were included in the evaluation under the assumption that a UCL represents the EPC to which human populations may be exposed. For VOCs detected in soil vapor, potential vapor intrusion was evaluated on an individual sample basis (*i.e.*, transport of COPCs from each probe location and sample depth was evaluated separately).

Summaries of the estimated total ILECRs and non-cancer HIs associated with potential exposures to COPCs in soil and soil vapor for the receptor populations evaluated in the human health risk evaluation are presented in the sections below. These sections discuss the quantitative risk results and corresponding conclusions for hypothetical future on-Site receptors.

## 6.1 HYPOTHETICAL FUTURE ON-SITE NON-INTRUSIVE WORKERS

The results of the human health risk evaluation indicate that the estimated cumulative ILECR associated with COPCs in on-Site soil (0 to 10 feet bgs) for hypothetical future on-Site non-intrusive workers is within the acceptable risk range of $1 \times 10^{-6}$ to $1 \times 10^{-4}$, but above the Cal/EPA point of departure of $1 \times 10^{-6}$ and OEHHA's benchmark cancer risk level of $1 \times 10^{-5}$. The non-cancer HI estimated for hypothetical future on-Site non-intrusive worker exposure to COPCs in on-Site soil (0 to 10 feet bgs) is 5, which is above the acceptable HI of 1. The estimated cumulative ILECR is driven by arsenic, hexavalent chromium, and Aroclors-1242, -1248, and -1254, that are also contributing chemical-specific ILECRs greater than $1 \times 10^{-6}$. The estimated HI is predominantly attributable to arsenic and Aroclors-1242, -1248, and -1254 contributing incrementally to a HI above 1. Excluding arsenic and Aroclors-1242, -1248, and -1254, the estimated non-cancer HI for hypothetical future on-Site non-intrusive workers does not exceed 1.

The EPC for lead in on-Site combined surface and subsurface soil (0 to 10 feet bgs) of 941 mg/kg, is above the DTSC-SL for industrial soil of 500 mg/kg. Potential exposure for hypothetical future on-Site non-intrusive workers to lead in on-Site soil (0 to 10 feet bgs) may therefore result in an increase in the blood lead level for the fetus of a hypothetical future on-Site non-intrusive worker above the OEHHA's benchmark value of 1 µg/dL.

Using the DTSC default attenuation factor of 0.0005 for future commercial buildings, estimated non-cancer HIs associated with vapor intrusion for hypothetical future on-Site non-intrusive workers are at or below the acceptable HI of 1; however, estimated cumulative ILECRs are above $1 \times 10^{-6}$ at eight locations; seven locations are within the footprint the proposed future commercial building at the Site.

Cumulative ILECR estimates above $1 \times 10^{-6}$ are driven primarily by detected concentrations of benzene, ethylbenzene, TCE, PCE, and/or vinyl chloride detected at the following eight soil vapor sample locations: HP-4 (5 and 15 feet bgs), HP-9 (5 and 15 feet bgs), LV-4 (14 feet bgs), LV-8 (5, and 15 feet bgs), LV-10 (6 feet bgs), SB-17 (5 feet bgs), SB-18 (5 feet bgs), and SB-21 (5 and 15 feet bgs).

Using the DTSC and SWRCB default attenuation factor of 0.03 (DTSC and SWRCB, 2023), which was derived entirely from data on chlorinated solvent compounds and for residential buildings (USEPA, 2012), estimated non-cancer HIs associated with vapor intrusion for hypothetical future on-Site non-intrusive workers are above the acceptable HI of 1 at 18 locations, ranging from 2 to 62. Estimated non-cancer HIs above 1 are driven primarily by detected concentrations of benzene, cis-1,2-dichloroethene, PCE, toluene, TCE, vinyl chloride, and/or xylenes detected in soil vapor. Estimated cumulative ILECRs are above $1 \times 10^{-6}$ at all locations, ranging from $2 \times 10^{-6}$ to $7 \times 10^{-3}$. Cumulative ILECR estimates above $1 \times 10^{-6}$ are driven primarily by detected concentrations of 1,1-dichloroethane, 1,2-dichloroethane, 1,4-dioxane, benzene, bromodichloromethane, chloroform, ethylbenzene, methylene chloride, PCE, TCE, and/or vinyl chloride.

In summary, the results of the human health risk evaluation support the following:

- VOCs detected in soil vapor may require some remediation, mitigation, or other form of risk management (e.g., institutional controls) prior to the redevelopment of the Site for future commercial/ industrial land use purposes.
- Aroclors, arsenic, hexavalent chromium, and lead in soil may require some remediation, mitigation, or other form of risk management (e.g., institutional controls) prior to the redevelopment of the Site for future commercial/industrial land use purposes.

## 6.2 HYPOTHETICAL FUTURE CONSTRUCTION WORKERS

The results of the human health risk evaluation indicate that the estimated cumulative ILECR associated with COPCs in on-Site soil (0 to 10 feet bgs) for hypothetical future on-Site construction workers is within the acceptable risk range of $1 \times 10^{-6}$ to $1 \times 10^{-4}$, but above the Cal/EPA's point of departure of $1 \times 10^{-6}$ and OEHHA's benchmark cancer risk level of $1 \times 10^{-5}$. The estimated non-cancer HI for hypothetical future on-Site construction worker exposure to COPCs in on-Site soil (0 to 10 feet bgs) is above the acceptable HI of 1. The estimated cumulative ILECR is driven by arsenic, hexavalent chromium, and Aroclor-1242. The estimated HI is driven by arsenic, with Aroclor-1242, TPH-diesel, Aroclor-1248, total chromium, cobalt, Aroclor-1260, and Aroclor-1254 contributing incrementally to a HI above 1.

Estimated ILECRs and/or HIs for the hypothetical future on-Site construction worker are overestimated and likely lower than presented in this risk evaluation, particularly for hexavalent chromium, total chromium, and cobalt, given the overly conservative exposure assumptions of sustained elevated dust levels during the entire workday for 250 days over a one-year period during redevelopment construction activities at the Site. Furthermore, the HI for TPH-diesel for the hypothetical future on-Site construction worker is overestimated and likely lower than presented in this risk evaluation, given the overly conservative assumption that the entire soil concentration of TPH-diesel is volatile and does not account for the weathering of the TPH in soil and only a portion of the lower end of carbon chain range of petroleum constituents that comprise a TPH-diesel mixture is considered volatile.

The EPC for lead in on-Site combined surface and subsurface soil (0 to 10 feet bgs) of 941 mg/kg, is above the DTSC-SL for industrial soil of 500 mg/kg. Potential exposure for hypothetical future on-Site

non-intrusive workers to lead in on-Site soil (0 to 10 feet bgs) may therefore result in an increase in the blood lead level for the fetus of a hypothetical future on-Site construction worker above the OEHHA's benchmark value of 1 µg/dL.

In summary, the results of the human health risk evaluation support that levels of arsenic, hexavalent chromium, Aroclors, and lead in soil at the Site may require some remediation, mitigation, or other form of risk management to protect the health of hypothetical future on-Site construction workers involved in the redevelopment of the Site for commercial/industrial land use purposes.

# 7. Development of Risk-Based and Ambient-Based Screening Concentrations

The overall remedial action goal is to ensure that residual concentrations of chemicals remaining at the Site are protective of human health and the environment. The following section presents the RBSCs and ABSCs that can be used in the upcoming remedial planning to identify detected concentrations of those chemicals in soil or soil vapor and areas of the Site that may warrant some form of remedial or risk management action.

Based on results of the human health risk evaluation, remediation or other forms of risk management (e.g., institutional controls) is not necessary under current conditions, as the Site is currently unoccupied. However, concentrations of several COPCs in soil or soil vapor exceed levels that would be considered acceptable for future on-Site commercial/industrial land use. Some form of remediation or other forms of risk management (e.g., institutional controls) may be required in order for the Site to be developed for such use in the future. Furthermore, concentrations of arsenic, hexavalent chromium, TPH, Aroclors, total chromium, and cobalt in Site soil may also require remediation or other forms of risk management (e.g., institutional controls) prior to redevelopment of the Site.

RBSCs have been developed for the COPCs evaluated in soil in this risk evaluation to assist in making remedial and risk management decisions for the Site. When developing remedial action goals under state and federal regulatory programs, the NCP (40 CFR 300) is commonly cited as the basis for determining an acceptable incremental risk for humans. According to the NCP, ILECRs posed by a remediated site should not exceed $1 \times 10^{-6}$ to $1 \times 10^{-4}$, and non-carcinogenic chemicals should not be present at levels expected to cause adverse health effects. RBSCs, concentrations of individual chemicals that correspond to an ILECR of $1 \times 10^{-6}$ or a non-cancer HQ of 1 for the receptors evaluated, are presented for both carcinogenic and non-carcinogenic effects in Table 13 for the COPCs in soil for the hypothetical future on-Site populations evaluated. The RBSCs will be used to identify and target those areas of the Site that may warrant some form of remedial or risk management action.

For lead, the RBSC will be based on DTSC's health-based soil screening level for lead in industrial land use scenarios of 500 mg/kg.

Ambient (or "background") soil concentrations of arsenic commonly exceed concentrations corresponding to ILECRs of $1 \times 10^{-6}$. Because it is not usually possible or practical to reduce concentrations below background levels, the risk management objective normally imposed by regulatory agencies in these situations is to remediate a site to ambient levels. The ABSC for arsenic is 11 mg/kg based on (i.e., rounded up from) the upper bound of the Site-specific soil arsenic concentration of 10.63 mg/kg developed in the PEA Report (ENVIRO-TOX Services, Inc., 2022).

The methodologies used to derive the RBSCs for soil are presented in Section 7.1.

## 7.1 DEVELOPMENT OF RISK-BASED CLEANUP LEVELS

This section presents methodology used to derive the range of chemical-specific RBSCs for soil that would be protective of hypothetical future on-Site populations, and chemical-specific RBSCs for soil vapor that would be protective of hypothetical future on-Site non-intrusive workers. These RBSCs can then be used to identify those areas of the Site that could either be targeted for remediation or which should be subjected to other forms of long-term risk management. As described above, the NCP (40 CFR

300) indicates that ILECRs posed by a site should not exceed a range of $1 \times 10^{-6}$ to $1 \times 10^{-4}$ and non-carcinogenic chemicals should not be present at levels expected to cause adverse health effects (i.e., a HI greater than 1). As a starting point, the target cancer risk level used in the calculation of the RBSCs for carcinogens is set at the lower end of the risk range of $1 \times 10^{-6}$. The target HQ used in the calculation of the RBSCs for non-carcinogens is 1. These RBSCs may then be compared to the on-Site soil concentrations to identify those chemicals and specific areas that may be the focus of upcoming remedial planning.

### 7.1.1 Methodology

Section 5.2 presented the ILECRs and non-cancer hazards posed by a given chemical at a concentration in on-Site soil under the on-Site exposure scenarios evaluated. Rearranging the equations used to estimate the ILECRs and non-cancer hazards and using the target ILECR of $1 \times 10^{-6}$ and the target non-cancer HQ of 1, the concentration of each chemical associated with the target ILECR and HQ levels can be determined. This is the common method used to estimate RBSCs for a site, where the results of the risk assessment indicate that some form of remediation or risk management is warranted.

#### *7.1.1.1 Soil Risk-Based Screening Concentrations*

The soil RBSCs presented in Table 13 are developed using the equations below. For carcinogenic effects, the following equation is used to derive the soil RBSC:

$$\mathrm{RBSC}_{\mathrm{a,carcinogen}} = \frac{\text{Target Risk Level}}{\left(\left[\frac{\mathrm{Risk}_{\mathrm{a,inhv}}}{\mathrm{Conc}_{\mathrm{inhv}}}\right] + \left[\frac{\mathrm{Risk}_{\mathrm{a,inhp}}}{\mathrm{Conc}_{\mathrm{a,inhp}}}\right] + \left[\frac{\mathrm{Risk}_{\mathrm{a,ing}}}{\mathrm{Conc}_{\mathrm{a,ing}}}\right] + \left[\frac{\mathrm{Risk}_{\mathrm{a,der}}}{\mathrm{Conc}_{\mathrm{a,der}}}\right]\right)}$$

Where:

| | | |
|---|---|---|
| $\mathrm{RBSC}_{\mathrm{a,carcinogen}}$ | = | Risk-based Screening Concentration, chemical a, for carcinogenic effects (mg/kg); |
| Target Risk Level | = | Target Cancer Risk Level (unitless); |
| $\mathrm{Risk}_{\mathrm{a,inhv}}$ | = | Calculated Cancer Risk for Chemical a for the vapor inhalation pathway, developed as described above (unitless); |
| $\mathrm{Risk}_{\mathrm{a,inhp}}$ | = | Calculated Cancer Risk for Chemical a for the particulate inhalation pathway, developed as described above (unitless); |
| $\mathrm{Risk}_{\mathrm{a,ing}}$ | = | Calculated Cancer Risk for Chemical a for the soil ingestion pathway, developed as described above (unitless); |
| $\mathrm{Risk}_{\mathrm{a,der}}$ | = | Calculated Cancer Risk for Chemical a for the dermal contact pathway, developed as described above (unitless); |
| $\mathrm{Conc}_{\mathrm{a,inhv}}$ | = | Representative Exposure Concentration of Chemical a for the vapor inhalation pathway (mg/kg); |
| $\mathrm{Conc}_{\mathrm{a,inhp}}$ | = | Representative Exposure Concentration of Chemical a for the particulate inhalation pathway (mg/kg); |
| $\mathrm{Conc}_{\mathrm{a,ing}}$ | = | Representative Exposure Concentration of Chemical a for the soil ingestion pathway (mg/kg); and |

| | | |
|---|---|---|
| $Conc_{a,der}$ | = | Representative Exposure Concentration of Chemical a for the dermal contact pathway (mg/kg). |

For non-carcinogenic effects, the following equation is used to derive the soil RBSC:

$$RBSC_{a,non-carcinogen} = \frac{\text{Target HQ}}{\left(\left[\frac{HQ_{a,inhv}}{Conc_{a,inhv}}\right] + \left[\frac{HQ_{a,inhp}}{Conc_{a,inhp}}\right] + \left[\frac{HQ_{a,ing}}{Conc_{a,ing}}\right] + \left[\frac{HQ_{a,der}}{Conc_{a,der}}\right]\right)}$$

Where:

| | | |
|---|---|---|
| $RBSC_{a,non-carcinogen}$ | = | Risk-based Screening Concentration, chemical a, for non-carcinogenic effects, (mg/kg); |
| Target HQ | = | Target Hazard Quotient Level (unitless); |
| $HQ_{a,inhv}$ | = | Calculated Hazard Quotient for Chemical a for the vapor inhalation pathway, developed as described above (unitless); |
| $HQ_{a,inhp}$ | = | Calculated Hazard Quotient for Chemical a for the particulate inhalation pathway, developed as described above (unitless); |
| $HQ_{a,ing}$ | = | Calculated Hazard Quotient for Chemical a for the soil ingestion pathway, developed as described above (unitless); |
| $HQ_{a,der}$ | = | Calculated Hazard Quotient for Chemical a for the dermal contact pathway, developed as described above (unitless); |
| $Conc_{a,inhv}$ | = | Representative Exposure Concentration of Chemical a for the vapor inhalation pathway (mg/kg); |
| $Conc_{a,inhp}$ | = | Representative Exposure Concentration of Chemical a for particulate inhalation pathway (mg/kg); |
| $Conc_{a,ing}$ | = | Representative Exposure Concentration of Chemical a for soil ingestion pathway (mg/kg); and |
| $Conc_{a,der}$ | = | Representative Exposure Concentration of Chemical a for dermal contact pathway (mg/kg). |

An example soil RBSC calculation for naphthalene is provided in Appendix H.

As presented in Table 13, the lowest of the RBSCs based on the cancer or non-cancer endpoint for the hypothetical future construction worker is lower than lower RBSC for the hypothetical future on-Site non-intrusive worker for several COPCs due to the overly conservative exposure assumptions used in the particulate inhalation pathway evaluation for the hypothetical future construction worker scenario, particularly for hexavalent chromium, total chromium, and cobalt. The RBSCs for hexavalent chromium, total chromium, and cobalt are driven by the particulate inhalation pathway. Best management practices will likely be implemented during construction activities to minimize/mitigate dust emission levels to below the California Air Resources Board 24-hour $PM_{10}$ standard of 50 µg/$m^3$ for protection of surrounding communities. Soil disturbance activities during redevelopment, such as grading and trenching for utilities, would likely occur during the initial phases of redevelopment and over a small portion of a year; therefore, soil remediation to the RBSCs for the hypothetical future on-Site non-

intrusive worker for these compounds would be protective of the hypothetical future construction worker.

**TABLE 1**
**SUMMARY OF CHEMICALS INCLUDED IN THE RISK ASSESSMENT: SOIL (0 TO 10 FEET BGS)**
ROSEMEAD HOLDING, LLC PROPERTY
SOUTH EL MONTE, CALIFORNIA

**Abbreviations:**

-- = Not analyzed for
bgs = Below ground surface
mg/kg = Milligrams per kilogram
NC = Not calculated. For upper confidence limits (UCLs), in order for ProUCL Version 5.1.002 to reliably evaluate a specific data population (e.g., dataset of concentrations of a particular chemical measured at the Site), the population must include at least ten results including at least four detections (United States Environmental Protection Agency [USEPA], 2022).
ND = Not detected

**Notes:**

[a] Arithmetic means derived using one-half the reporting limit values for non-detect results.
[b] UCLs derived using ProUCL Version 5.2.00 (USEPA 2022); ProUCL output is presented in Attachment D.
[c] Inorganics were included in the risk assessment if the maximum detected concentration of the Site data are above the respective maximum detected concentration in the background data set. Per Cal/EPA PEA guidance, lead is included regardless of background levels. As described in the PEA Report previously prepared for this Site, with the exception of arsenic, the background metal data set was obtained from soil metal data collected from California Air Force facilities (Hunter, Davis, and Roach, 2004). A Site-specific arsenic background concentration was developed in the PEA Report for the Site (Enviro-Tox Services, Inc., 2022). All other chemicals were included in the risk assessment if they were ever detected in soil.
[d] Naphthalene was analyzed as both a VOC and a PAH. The UCL calculated for naphthalene as a VOC was used as the exposure point concentration (EPC) in the risk calculations as it is a more robust and an equivalent EPC value compared to the dataset for naphthalene as a PAH.
[e] CPAH
[f] The 95th percentile concentration in the background data set obtained from the Air Force facilities (Hunter, Davis, and Roach, 2004).

**Abbreviations:**

bgs = Below ground surface

$m^3/kg$ = Cubic meters per kilogram

mg/kg = Milligrams per kilogram

$mg/m^3$ = Milligrams per cubic meter

**Notes:**

[a] Exposure point concentrations (EPCs) for on Site soil (0 to 10 feet bgs) are used for the evaluation of direct contact exposure pathways (i.e., ingestion and dermal contact) and inhalation of outdoor air particulates. Unless otherwise indicated, the upper confidence limit (UCL) of the arithmetic mean concentrations are used as the representative EPCs. UCLs derived using ProUCL 5.2.00 (USEPA, 2022); ProUCL output is presented in Attachment D. In cases where more than one UCL was suggested by ProUCL, the higher UCL was used. Where too few detections (<4) were available to calculate a UCL (USEPA, 2015), the maximum detected concentration was used. Maximum detected concentrations are bolded and italicized.

[b] Outdoor airborne particulate concentration is calculated by dividing the soil EPCs by the particulate emission factor (PEF). For hypothetical future on-Site non-intrusive workers, a default PEF of $1.36\times10^9$ $m^3/kg$ recommended by the California Environmental Protection Agency (Cal/EPA) Department of Toxic Substances Control (DTSC) for industrial scenario was used. For hypothetical future on-Site construction workers and maintenance workers, the default PEF of $1.0\times10^6$ $m^3/kg$ recommended by the DTSC for construction scenarios was used.

[c] Outdoor vapor concentration is calculated by dividing the soil EPCs by the chemical-specific volatilization factor (VF).

**Abbreviations:**
J&E = Johnson and Ettinger Model (Source 1; USEPA, 2017)
NA = Not applicable

**Notes:**
[a] Csat = the contaminant concentration in soil at which the absorptive limits of the soil particles, the solubility limits of the soil pore water, and saturation of soil pore air have been reached (USEPA, 2018). The equation used to calculate Csat is:
Csat = S / ρb × (Kd × ρb + θw + H' × θa), where:
S = solubility in water;
ρb = dry bulk density (1.66 g/cm3, default value; USEPA, 2017);
Kd = soil-water partition coefficient (Koc × foc, where foc = 0.006 g/g [default value; USEPA, 2017]);
θw = water-filled soil porosity (0.054 cm3/cm3, default value; USEPA, 2017);
H' = dimensionless Henry's Law constant; and
θa = air-filled soil porosity (0.321 cm3/cm3, default value; USEPA, 2017).

[b] Benzo(a)pyrene values used as surrogate.

**TABLE 5**
**EXPOSURE PARAMETERS**
ROSEMEAD HOLDING, LLC PROPERTY
SOUTH EL MONTE, CALIFORNIA

**Abbreviations:**

cm2/day = Centimeters squared per day
days/yr = Days per year
hrs/day = Hours per day
kg/mg = Kilograms per milligram
$m^3$/kg = Meters cubed per kilogram
mg/$cm^2$ = Milligrams per centimeters squared
mg/day = Milligrams per day
NA = Not applicable; parameter not applicable to evaluated receptor
ROW = Rights-of-way

**Notes:**

[a] . The particulate emission factors (PEF) for the on-Site non-intrusive and on-Site construction workers are recommended by the Department of Toxic Substances Control (DTSC) for industrial scenario and for receptors involved in soil excavation or other intrusive activities (DTSC, 2019), respectively.

[b] The area of exposed skin recommended by DTSC (2019) for industrial worker and construction worker populations.

[c] Soil adherence factors recommended by DTSC (2019) for industrial worker and construction worker populations.

[d] Dermal absorption factors for specific compound classes from DTSC (2015).

[e] DTSC default incidental soil ingestion rate for industrial workers (DTSC, 2019) used for on-Site non-intrusive workers. DTSC default incidental soil ingestion rate for construction workers (DTSC, 2019) used for on-Site construction workers.

[f] Exposure time for on-Site non-intrusive workers and construction workers corresponds to the DTSC default value for worker populations (8 hours per day; DTSC, 2019).

[g] Exposure frequency for on-Site non-intrusive workers and on-Site construction workers corresponds to the DTSC default values for industrial worker and construction worker populations, respectively (DTSC, 2019).

[h] Exposure duration of 25 years for on-Site non-intrusive workers is the DTSC default value for industrial worker populations (DTSC, 2019), which represents an upper-bound estimate of the total amount of time an individual may work in one location. Exposure duration of 1 year for on-Site construction workers is DTSC default value for construction worker populations (DTSC, 2019).

[i] Body weight values correspond to DTSC default values for adult receptors (DTSC, 2019).

[j] Averaging times correspond to DTSC default values (70 year lifetime × 365 days/year for carcinogens; exposure duration × 365 days/year for noncarcinogens; DTSC, 2019).

**TABLE 7**

**CARCINOGENIC AND NONCARCINOGENIC TOXICITY VALUES FOR CHEMICALS OF POTENTIAL CONCERN IN SOIL AND SOIL VAPOR**

ROSEMEAD HOLDING, LLC PROPERTY

SOUTH EL MONTE, CALIFORNIA

**Abbreviations**

ECP = Expedited Cancer Potency Factors

$(mg/m^3)^{-1}$ = Per milligrams per cubic meter

$(mg/kg\text{-}day)^{-1}$ = Per milligrams per kilogram per day

$mg/m^3$ = Milligrams per cubic meter

mg/kg-day = Milligrams per kilogram per day

na = Not applicable. Potential exposure to lead is evaluated using health-based screening levels derived using California Environmental Protection Agency (Cal/EPA) Department of Toxic Substances Control's (DTSC) LeadSpread model or United States Environmental Protection Agency's (USEPA) Adult Lead Methodology (ALM). Please see Section 4.3 of the human health risk assessment (HHRA) for discussion.

NC = Not considered to be a carcinogen by either USEPA or Cal/EPA

**Notes:**

Surrogate = In the absence of available reference doses (RfDs) or reference concentrations (RfCs) for chemicals of potential concern, surrogate chemicals were chosen based on structural similarity to avoid underestimating potential noncarcinogenic hazards:

- Cymene was represented by cumene.
- Ethanol was represented by 2-propanol.
- Potential noncarcinogenic effects of the CPAHs, benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, and indeno(1,2,3-cd)pyrene were represented by pyrene.
- Benzo(g,h,i)perylene was represented by pyrene.
- Dibenz(a,h)anthracene was represented by benzo(a)pyrene.
- Phenanthrene was represented by anthracene.
-TPH (C9-C40) was represented by TPH-diesel.
- Aroclor-1242, Aroclor-1248, and Aroclor-1260 were represented by Aroclor-1254.

Route = Route-to-route extrapolation from RfDs or RfCs using the following equations:

RfC = RfD / (InhR / BW) or RfD = RfC / (BW / Inhr), where:

Adult daily inhalation rate (InhR) = 20 m3/day (Cal/EPA, 2014); and

Adult body weight (BW) = 80 kg (Cal/EPA, 2014).

[a] The RfD for copper is based on a drinking water standard of 1.3 mg/L.

**Abbreviations:**
bgs = Below ground surface
CDI = Chronic daily intake
EC = Exposure concentration
$mg/m^3$ = Milligrams per cubic meter
mg/kg-day = Milligrams per kilogram per day
NA = Not applicable. No dermal absorption factor available for Chromium VI.
na = Not applicable. Potential exposure to lead is evaluated using the California Environmental Protection Agency (Cal/EPA) Department of Toxic Substances Control (DTSC) health-based screening levels (DTSC-SLs) for commercial/industrial soil (for hypothetical future on-Site commercial/industrial workers). Please see Section 4.3 of the human health risk assessment for discussion.
NC = Not considered a carcinogen
NV = Not volatile

| Aroclor-1268 (PCB-1268) | 8.9E-12 | NV | 2.9E-07 | 1.6E-07 | 4.5E-07 |
| **Cumulative ILECR** | **6.6E-07** | **1.9E-06** | **2.3E-05** | **3.7E-05** | **6E-05** |

**Abbreviations:**

bgs = Below ground surface

ILECR = Incremental lifetime excess cancer risk

NA = Not applicable. No dermal absorption factor available for Chromium VI.

na = Not applicable. Potential exposure to lead is evaluated using the California Environmental Protection Agency (Cal/EPA) Department of Toxic Substances Control (DTSC) health-based screening levels (DTSC-SLs) for commercial/industrial soil (for hypothetical future on-Site commercial workers). Please see Section 5.2 of the human health risk assessment for discussion.

NC = Not considered a carcinogen

NV = Not volatile

| Risk Drivers | Primary Target Organ |
|---|---|
| TPH-diesel | General Toxicity, Nervous System, Respiratory, Kidney |
| TPH-gasoline | General Toxicity, Nervous System, Respiratory |
| Arsenic | Nervous System, Respiratory, Cardiovascular, Skin, Reproductive |
| Aroclor-1242 (PCB-1242) | Skin, Ocular, Immune System |

| Target Organ-Specific HI | |
|---|---|
| General Toxicity | 0.9 |
| Nervous System | 3 |
| Respiratory | 3 |
| Kidney | 0.7 |
| Cardio-vascular | 2 |
| Skin | 3 |
| Reproductive | 2 |
| Ocular | 1 |
| Immune System | 1 |

**Abbreviations:**
bgs = Below ground surface
NA = Not applicable. No dermal absorption factor available for Chromium VI.

na = Not applicable. Potential exposure to lead is evaluated using the California Environmental Protection Agency (Cal/EPA) Department of Toxic Substances Control (DTSC) health-based screening levels (DTSC-SLs) for commercial/industrial soil (for hypothetical future on-Site commercial/industrial workers). Please see Section 5.2 of the human health risk assessment for discussion.
NC = Not calculated
NV = Not volatile

**ESTIMATED VAPOR INTRUSION ILECRs AND NONCANCER HQs/HIs FOR CHEMICALS OF POTENTIAL CONCERN IN SOIL VAPOR: HYPOTHETICAL FUTURE ON-SITE NON-INTRUSIVE WORKERS - AF OF 0.0005**

ROSEMEAD HOLDING, LLC PROPERTY
SOUTH EL MONTE, CALIFORNIA

**Abbreviations:**

bgs = below ground surface

HI = hazard index

ILECR = incremental lifetime excess cancer risk

**Notes:**

[a] ILECRs and HIs calculated using default attenuation factors published by the California Environmental Protection Agency Department of Toxic Substances Control (DTSC). Specifically, the DTSC-recommended value of 0.0005 for commercial buildings (DTSC, 2011) was used for the scenario evaluated (future on-Site non-intrusive workers).

**TABLE 13**
**SOIL RISK-BASED SCREENING CONCENTRATIONS**
ROSEMEAD HOLDING, LLC PROPERTY
SOUTH EL MONTE, CALIFORNIA

**Notes:**

BG () = The value indicated in parentheses corresponds to the background values (BG) of 11 mg/kg for arsenic. The cancer and/or noncancer risk-based screening concentrations (RBSCs) presented the following table for the hypothetical future on-Site non-intrusive worker and hypothetical future construction worker are below the BG concentrations for arsenic where shown. Units are in mg/kg.

| | Hypothetical Future On-Site Worker | | | |
|---|---|---|---|---|
| | Non-Intrusive | | Construction | |
| COPC | Cancer | Noncancer | Cancer | Noncancer |
| Arsenic | 0.25 | 3.0 | 1.8 | 0.85 |

mg/kg = Milligrams per kilogram

NC = Not considered a carcinogen

NA = Not applicable. Potential carcinogenic polyaromatic hydrcarbons (CPAHs; benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-c,d)pyrene) are evaluated using benzo(a)pyrene equivalents. Potential noncarcinogenic effects of the CPAHs are evaluated for each of the CPAHs individually, not using benzo(a)pyrene equivalents.

SC() = The risk-based screening concentrations (RBSCs) indicated in parentheses represent an RBSC that is greater than the theoretical soil saturation limit for that compound or the theoretical ceiling limit of 100,000 mg/kg (United States Environmental Protection Agency [USEPA], 2018). The theoretical soil saturation limit is the contaminant concentration in soil at which the absorptive limits of the soil particles, the solubility limits of the soil pore water, and saturation of soil pore air have been reached. Calculated soil saturation limits are presented in Table 6. The theoretical ceiling limit of 100,000 mg/kg is equivalent to a chemical representing 10 percent by weight of the soil sample. At this contaminant concentration (and higher), the assumptions for soil contact may be violated (for example, soil adherence and wind-borne dispersion assumptions) due to the presence of the foreign substance itself.

[a] Cancer RBSCs correspond to a target incremental lifetime excees cancer risk (ILECR) of 1×10-6. RBSCs corresponding to target ILECRs of 10-5 and 10-4 would be 10 times and 100 times higher, respectively, than the RBSCs presented in this table.

[b] Noncancer hazard RBSCs correspond to a target chemical-specific hazard quotient (HQ) of 1.

[c] RBSCs presented for lead are the health-based screening levels used to evaluate potential exposures and increases in blood lead levels for: a) the fetus of hypothetical future on-Site non-intrusive workers and construction workers (500 mg/kg), as described in Section 4.3.

# APPENDIX B
# OEHHA Response to Comments

| OEHHA COMMENTS DATED JULY 12, 2023 | HALEY & ALDRICH, INC. RESPONSE |
|---|---|
| **Chemical of Potential Concern (COPCs)**<br><br>Environmental assessments indicated the presence of metals, polychlorinated biphenyls (PCBs), petroleum hydrocarbons (TPH) , and volatile organic compounds (VOCs) in soil. COPCs are organic compounds detected in soil at concentrations above laboratory reporting limits and inorganic compounds detected at concentrations exceeding both background levels and screening levels. OEHHA does not recommend comparisons with screening levels as a basis for exclusion of chemicals as COPCs.<br><br>The only elements selected in soil as COPCs were antimony, arsenic, hexavalent chromium (Cr+6), cobalt, lead, and molybdenum. In addition to these, barium, cadmium, chromium, copper, mercury, nickel, silver, and zinc also exceeded background levels and should be evaluated as COPCs. | Comment noted. Barium, cadmium, chromium, copper, mercury, nickel, silver, and zinc along with antimony, arsenic, hexavalent chromium (Cr+6), cobalt, lead, and molybdenum shall be evaluated as soil COPCs in an updated health risk screening evaluation that will be included in an addendum to the Limited Soil Remediation Work Plan. |
| **Exposure Concentrations (EPCs)**<br><br>For arsenic and molybdenum, all Arochlors, and TPH-g, the reported 95% upper confidence limits (UCLs) are less than the mean concentrations for detects. | Comment noted. |
| **Conceptual Site Model**<br><br>Leighton evaluated soil exposure and associated risks and hazards to onsite outdoor workers and onsite construction workers. Soil gas exposure was not evaluated. | Comment noted. An evaluation of soil gas exposure will be included in an updated health risk screening evaluation that will be included in an addendum to the Limit Soil Remediation Work Plan. |

**Soil Risk Assessment**

Leighton

In their baseline soil risk assessment, Leighton used the UCL as the exposure concentration when it could be calculated, otherwise the maximum detected concentration. Exposure parameters were standard values from HHRA Note 1 (DTSC, 2019a) except that the exposure duration for the construction worker was 91 days rather than the usual 1 year, resulting in a four-fold reduction in risk. No site-specific basis for this departure from standard exposure parameters was provided. This

The calculated risk for outdoor workers exposed to contaminants in soil and dust through the ingestion, dermal, and inhalation pathways was 2E-5, exceeding the benchmark of 1E-5. The calculated risk for construction workers exposed to contaminants in soil and dust through these pathways was 1E-5, equaling the benchmark of 1E-5. The risk driver identified in soil was Cr+6. Although not widely dispersed throughout the site, Cr+6 contributed 97% and 67% of the estimated cancer risk for construction workers and outdoor workers, respectively. The hazard index (HI) for construction workers exceeded the benchmark of 1. The lead UCL was 1443 mg/kg, exceeding the DTSC screening level of 500 mg/kg.

Table 1: Leighton Risk and Hazard Estimates

| Exposure Scenarios | Estimated Risk | Estimated HI |
|---|---|---|
| Construction Worker | 1E-5 | 2 |
| Outdoor Worker | 2E-5 | 0.6 |

Table Notes: Risk estimates are presented in scientific notation. For example, a cancer risk of 1 in a million (0.000001) is written as 1E-6. HI is the estimated hazard index.

Comment noted.

OEHHA

To calculate cumulative risk and hazard for chemicals in soil, OEHHA used the equations from DTSC's Preliminary Endangerment Assessment Manual (DTSC 2015, Section 2.5). Values for exposure parameters were taken from DTSC's HERO Note 1 (DTSC 2019a) and toxicity values were from Note 10 (DTSC 2019b). This was done for all metals detected, except lead. Exposure concentrations were the UCLs. OEHHA entered the petroleum hydrocarbon data as TPH gasoline, TPH diesel, and TPH motor oil, rather than converting these values to assumed fractions. OEHHA's results differed from Leighton's results, as shown in Table 2:

Table 2: OEHHA's Partial Risk and Hazard Estimates

| Exposure Scenarios | Estimated Risk | Estimated HI |
|---|---|---|
| Construction Worker | 3.4E-6 | 6.8 |
| Outdoor Worker | 2.3E-5 | 1.9 |

Table Notes: Risk estimates are presented in scientific notation. For example, a cancer risk of 1 in a million (0.000001) is written as 1E-6. HI is the estimated hazard index. The modifier "partial" is in the title to indicate that some COPCs were omitted due to lack of statistical analysis.

OEHHA Both Leighton and OEHHA predicted construction worker risks below 1E-5 and outdoor worker risks exceeding 1E-5. Both Leighton and OEHHA predicted HIs above 1 for construction workers. OEHHA's HI for outdoor workers exceeded 1. Risk drivers were arsenic, Arochlor 1248, tetrachloroethene, and naphthalene. OEHHA did not assess the metals that were rejected as COPCs because no statistics were supplied for these metals. Risk and hazard estimates would be higher if all the metals that were detected above background were included.

| OEHHA COMMENTS DATED JULY 12, 2023 | HALEY & ALDRICH, INC. RESPONSE |
|---|---|
| **Risk-based Concentrations (RBCs)**<br><br>Leighton's Table 13 lists RBCs five metals five Arochlors, and six TPH ranges plus a background-based goal for arsenic. OEHHA has the following comments:<br>• OEHHA agrees that the RBCs for antimony, cobalt, hexavalent chromium, molybdenum, and the Arochlors yield risk estimates of 1E-5 or hazard quotients (HQs) of 1 when used as EPCs in a one-at-a-time forward calculation. But see comment below regarding additivity.<br>• The TPH RBCs yield HQs ranging from 0.41 to 1200. Only the RBC for TPH aliphatic high is less than 1.<br>• The construction worker risk estimates at the RBCs meet the target of 1E-5 only because of the shorter-than-usual exposure duration. If the standard exposure duration is used the RBC for hexavalent chromium would be 21 mg/kg.<br>• The Work Plan does not state what exposure metric (e.g. UCL or maximum) will be compared to the RBCs. This should be discussed with the Water Board.<br>• Since the RBC for arsenic (10.63 mg/kg) is based on the 95th percentile of background, the 95th percentile of current and post-remedial arsenic concentrations should be the metric to be compared to the clean-up goal for comparison, not the UCL. | Comment noted for all bullets listed in comment. |

| OEHHA COMMENTS DATED JULY 12, 2023 | HALEY & ALDRICH, INC. RESPONSE |
|---|---|
| • The RBCs should be applied in an additive manner, i.e., the ratios of the exposure concentrations to the respective RBCs for all carcinogens and other chemicals that may act in an additive manner should be added and the total compared to 1 (unity). An example follows:<br>o Risk index = EPCa/RBCa + EPCb/RBCb + EPCn/RBCn<br>o Risk index should be less than or equal to 1.<br>o Hazard index = EPCa/RBCa + EPCb/RBCb + EPCn/RBCn<br>o Hazard index should be less than or equal to 1.<br>• Lead is considered separately; it may be compared directly to the DTSC (2022) screening level of 500 mg/kg.<br>• Verification of post-remedial risk and hazards should be conducted in a manner similar to baseline risk assessment, i.e., the assessment should include all chemicals remaining on-site, not just those that were COPCs. Risk should be the cumulative risk from remaining concentrations of all carcinogens. The hazard index should be the combined HQs of all compounds that have the same target organ or the same mechanism of action. | |
| **Risk Management**<br>The request notes that the USEPA lead RSL for protection of groundwater is 14 mg/kg, lower than the San Francisco Bay Regional Water Quality Control Board's 320 mg/kg Environmental Screening Level (ESL, SFBRWQCB, 2019) for direct exposure to soil for protection | Comment noted. |

| OEHHA COMMENTS DATED JULY 12, 2023 | HALEY & ALDRICH, INC. RESPONSE |
|---|---|
| of human health. OEHHA defers to the Los Angeles Regional Water Quality Control Board regarding protection of groundwater. Leighton proposes to remove contaminated soil until the lead UCL concentration is 500 mg/kg or less. OEHHA agrees with this approach.<br><br>Leighton discusses risk management in Section 7.0 of Appendix B. OEHHA defers to the Los Angeles Regional Water Quality Control Board regarding risk management. | |
| **Conclusions**<br>• OEHHA cannot support Leighton's baseline risk assessment because it does not include all metals that were detected above background. Risk and hazard estimates would be higher if all the metals that were detected above background were included.<br>• RBCs will be needed for all metals detected above background. DTSC (2022) Note 3 screening levels may be used.<br>• Leighton should provide the basis for the reduced exposure duration for construction workers if this value is to be used in the verification assessment.<br>• OEHHA cannot support Leighton's RBCs for TPH.<br>• RBCs should be employed in an additive manner as noted above.<br>• Verification of post-remedial risk and hazards should include all remaining chemicals, not just those that were COPCs and should be based on cumulative risk and hazard indices. | An updated health risk screening evaluation that will be included in an addendum to the Limit Soil Remediation Work Plan and will address these comments as follows:<br>• All metals detected above background will be included as COPCs in the risk evaluation.<br>• RBCs will be developed for all metals above background.<br>• The basis for the reduced exposure duration for the construction worker will be provided.<br>• TPH will be evaluated as a mixture (i.e., TPH as gasoline, diesel, and motor oil) and RBCs will be developed for TPH as a mixture.<br>• It will be clarified that RBCs will be employed in an additive manner.<br>• It will be clarified that verification of post-remedial risk and hazards will include all remaining chemicals and will be based on cumulative risks and hazard indices. |

**Notes:**
Results in milligrams per kilogram (mg/kg)
Detected results are presented in bold
-- = results not available or sample not analyzed
< = Analyte was not detected at the given reporting limit
bgs = below ground surface
J = estimated value

**TABLE C-1**
**ANALYTICAL DATA INCLUDED IN THE HHRA: VOLATILE ORGANIC COMPOUNDS IN SOIL**
ROSEMEAD HOLDING, LLC PROPERTY
SOUTH EL MONTE, CALIFORNIA

| Sample Location | Sample Depth (feet bgs) | Sample Date | Sample Type | 4-Isopropyltoluene | 4-Methyl-2-pentanone (MIBK) | Acetone | Benzene | Bromobenzene | Bromodichloromethane | Bromoform | Bromomethane | Butylbenzene | Carbon Disulfide | Carbon Tetrachloride | Chlorobenzene | Chlorobromomethane | Chloroethane | Chloroform | Chloromethane | cis-1,2-Dichloroethene | cis-1,3-Dichloropropene | Dibromochloromethane | Dibromomethane | Dichlorodifluoromethane (Freon 12) | Ethanol | Ethyl tert-Butyl Ether (ETBE) | Ethylbenzene | Isopropyl ether | Isopropylbenzene (Cumene) |

**Notes:**
Results in milligrams per kilogram (mg/kg)
Detected results are presented in bold
-- = results not available or sample not analyzed
< = Analyte was not detected at the given reporting limit
bgs = below ground surface
J = estimated value

**TABLE C-1**
**ANALYTICAL DATA INCLUDED IN THE HHRA: VOLATILE ORGANIC COMPOUNDS IN SOIL**
ROSEMEAD HOLDING, LLC PROPERTY
SOUTH EL MONTE, CALIFORNIA

| Sample Location | Sample Depth (feet bgs) | Sample Date | Sample Type | m,p-Xylenes | Methyl tert-butyl ether (MTBE) | Methylene Chloride | Naphthalene | o-Xylene | Propylbenzene | sec-Butylbenzene | Styrene | Tert-Amyl Methyl Ether (TAME) | tert-Butyl Alcohol (TBA) | tert-Butylbenzene | Tetrachloroethene | Toluene | trans-1,2-Dichloroethene | trans-1,3-Dichloropropene | Trichloroethene | Trichlorofluoromethane (Freon 11) | Vinyl Acetate | Vinyl Chloride | Xylenes |

**Notes:**
Results in milligrams per kilogram (mg/kg)
Detected results are presented in bold
-- = results not available or sample not analyzed
< = Analyte was not detected at the given reporting limit
bgs = below ground surface
J = estimated value
J+ = estimated value, high biased

**TABLE C-6**
**ANALYTICAL DATA INCLUDED IN THE HHRA: VOLATILE ORGANIC COMPOUNDS IN SOIL VAPOR**
ROSEMEAD HOLDING, LLC PROPERTY
SOUTH EL MONTE, CALIFORNIA

| Sample Location | Sample Date | Sample Depth (feet bgs) | Sample Type | 1,1,1,2-Tetrachloroethane | 1,1,1-Trichloroethane | 1,1,2,2-Tetrachloroethane | 1,1,2-Trichloroethane | 1,1,2-Trichlorotrifluoroethane (Freon 113) | 1,1-Dichloroethane | 1,1-Dichloroethene | 1,1-Dichloropropene | 1,1-Difluoroethane | 1,2,3-Trichlorobenzene | 1,2,3-Trichloropropane | 1,2,4-Trichlorobenzene | 1,2,4-Trimethylbenzene | 1,2-Dibromo-3-Chloropropane (DBCP) | 1,2-Dibromoethane (EDB) | 1,2-Dichlorobenzene | 1,2-Dichloroethane | 1,2-Dichloropropane | 1,3,5-Trimethylbenzene | 1,3-Dichlorobenzene | 1,3-Dichloropropane | 1,4-Dichlorobenzene | 1,4-Dioxane | 2,2-Dichloropropane | 2-Butanone (MEK) | 2-Chlorotoluene | 2-Hexanone | 2-Propanol | 4-Chlorotoluene | 4-Ethyltoluene | 4-Isopropyltoluene | 4-Methyl-2-pentanone (MIBK) | Acetone | Benzene | Bromobenzene | Bromodichloromethane | Bromoform | Bromomethane | Butylbenzene | Carbon Disulfide | Carbon Tetrachloride | Chlorobenzene | Chlorobromomethane |

**TABLE C-6**
**ANALYTICAL DATA INCLUDED IN THE HHRA: VOLATILE ORGANIC COMPOUNDS IN SOIL VAPOR**
ROSEMEAD HOLDING, LLC PROPERTY
SOUTH EL MONTE, CALIFORNIA

**Notes:**

All analytical results for volatile organic compounds are presented in micrograms per cubic meter ($\mu g/m^3$).
Samples from depth interval greater than 15 feet bgs are not used in the HHRA.
Detected results are presented in **bold**.
- = Not analyzed for
< = Analyte was not detected at the given detection limit.
bgs = Below ground surface

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

| | | | |
|---|---|---|---|

**Nonparametric Distribution Free UCL Statistics**

**Detected Data appear Approximate Gamma Distributed at 5% Significance Level**

**Suggested UCL to Use**

| | |
|---|---|
| 95% KM Adjusted Gamma UCL | 0.63 |

**The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.**
**Please verify the data were collected from random locations.**
**If the data were collected using judgmental or other non-random methods,**
**then contact a statistician to correctly calculate UCLs.**

When a data set follows an approximate distribution passing only one of the GOF tests,
it is suggested to use a UCL based upon a distribution passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

DL/2 is not a recommended method, provided for comparisons and historical reasons

**Nonparametric Distribution Free UCL Statistics**

Detected Data appear Lognormal Distributed at 10% Significance Level

**Suggested UCL to Use**

KM H-UCL 9.1104E-4

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.
Please verify the data were collected from random locations.
If the data were collected using judgmental or other non-random methods,
then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Result (1,2,4-trichlorobenzene)**

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

DL/2 is not a recommended method, provided for comparisons and historical reasons

**Nonparametric Distribution Free UCL Statistics**

Detected Data appear Normal Distributed at 1% Significance Level

**Suggested UCL to Use**

95% KM (t) UCL 0.277

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.
Please verify the data were collected from random locations.
If the data were collected using judgmental or other non-random methods,
then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

ROSEMEAD HOLDING, LLC PROPERTY

SOUTH EL MONTE, CALIFORNIA

Detected Data appear Approximate Lognormal Distributed at 10% Significance Level

**Suggested UCL to Use**

KM H-UCL 0.104

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.
Please verify the data were collected from random locations.
If the data were collected using judgmental or other non-random methods,
then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

**Nonparametric Distribution Free UCL Statistics**

Detected Data appear Approximate Lognormal Distributed at 10% Significance Level

**Suggested UCL to Use**

KM H-UCL 1.029

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.

Please verify the data were collected from random locations.

If the data were collected using judgmental or other non-random methods,

then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Suggested UCL to Use**

| | |
|---|---|
| 95% Student's-t UCL | 172.7 |

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.
Please verify the data were collected from random locations.
If the data were collected using judgmental or other non-random methods,
then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

**Nonparametric Distribution Free UCL Statistics**

Data do not follow a Discernible Distribution

**Suggested UCL to Use**

95% KM (t) UCL 0.28

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.

Please verify the data were collected from random locations.

If the data were collected using judgmental or other non-random methods,

then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

**Nonparametric Distribution Free UCL Statistics**

Data do not follow a Discernible Distribution

**Suggested UCL to Use**

| | |
|---|---|
| 95% KM (t) UCL | 0.724 |

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.
Please verify the data were collected from random locations.
If the data were collected using judgmental or other non-random methods,
then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Suggested UCL to Use**

95% Student's-t UCL 154.7

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.
Please verify the data were collected from random locations.
If the data were collected using judgmental or other non-random methods,
then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

| | | | |

**Nonparametric Distribution Free UCL Statistics**

Detected Data appear Approximate Gamma Distributed at 5% Significance Level

**Suggested UCL to Use**

| | |
|---|---|
| 95% KM Adjusted Gamma UCL | 0.563 |

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.
Please verify the data were collected from random locations.
If the data were collected using judgmental or other non-random methods,
then contact a statistician to correctly calculate UCLs.

When a data set follows an approximate distribution passing only one of the GOF tests,
it is suggested to use a UCL based upon a distribution passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

DL/2 is not a recommended method, provided for comparisons and historical reasons

**Nonparametric Distribution Free UCL Statistics**

Data do not follow a Discernible Distribution

**Suggested UCL to Use**

95% KM (t) UCL 909.9

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.
Please verify the data were collected from random locations.
If the data were collected using judgmental or other non-random methods,

then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

| Mean (detects) | 35.39 | | |

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

DL/2 is not a recommended method, provided for comparisons and historical reasons

**Nonparametric Distribution Free UCL Statistics**

Detected Data appear Approximate Lognormal Distributed at 10% Significance Level

**Suggested UCL to Use**

| | |
|---|---|
| KM H-UCL | 1.894 |

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.
Please verify the data were collected from random locations.
If the data were collected using judgmental or other non-random methods,
then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Suggested UCL to Use**

| | |
|---|---|
| 95% Student's-t UCL | 16.69 |

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.
Please verify the data were collected from random locations.
If the data were collected using judgmental or other non-random methods,
then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

**Nonparametric Distribution Free UCL Statistics**

Data do not follow a Discernible Distribution

**Suggested UCL to Use**

| | |
|---|---|
| 95% KM (t) UCL | 0.325 |

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.
Please verify the data were collected from random locations.
If the data were collected using judgmental or other non-random methods,
then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Nonparametric Distribution Free UCL Statistics**

Data do not follow a Discernible Distribution

**Suggested UCL to Use**

95% KM (t) UCL 0.0252

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.
Please verify the data were collected from random locations.
If the data were collected using judgmental or other non-random methods,
then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

| KM Standard Error of Mean (logged) | 0.199 | | |

Note: KM UCLs may be biased low with this dataset. Other substitution method recommended

**DL/2 Statistics**

| **DL/2 Normal** | | **DL/2 Log-Transformed** | |
|---|---|---|---|
| Mean in Original Scale | 1.788 | Mean in Log Scale | -6.173 |
| SD in Original Scale | 12.62 | SD in Log Scale | 2.478 |
| 95% t UCL (Assumes normality) | 3.482 | 95% H-Stat UCL | 0.0985 |

DL/2 is not a recommended method, provided for comparisons and historical reasons

**Nonparametric Distribution Free UCL Statistics**

Data do not follow a Discernible Distribution

**Suggested UCL to Use**

| | |
|---|---|
| 95% KM (t) UCL | 3.484 |

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.
Please verify the data were collected from random locations.
If the data were collected using judgmental or other non-random methods,
then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

DL/2 is not a recommended method, provided for comparisons and historical reasons

**Nonparametric Distribution Free UCL Statistics**

Detected Data appear Approximate Gamma Distributed at 5% Significance Level

**Suggested UCL to Use**

95% KM Approximate Gamma UCL 486

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.
Please verify the data were collected from random locations.
If the data were collected using judgmental or other non-random methods,
then contact a statistician to correctly calculate UCLs.

When a data set follows an approximate distribution passing only one of the GOF tests,
it is suggested to use a UCL based upon a distribution passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

**Gamma ROS Statistics using Imputed Non-Detects**

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.
Please verify the data were collected from random locations.
If the data were collected using judgmental or other non-random methods,
then contact a statistician to correctly calculate UCLs.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

# APPENDIX E
# Uncertainties in the Human Health Risk Evaluation

# APPENDIX E – UNCERTAINTIES IN THE RISK EVALUATION

## 1. Introduction

Risk assessment includes several uncertainties that warrant discussion. Many of the assumptions used in this human health risk evaluation regarding the representativeness of the sampling data, human exposures, fate and transport modeling, and chemical toxicity are conservative, following agency guidance, and reflect a 90th or 95th percentile value, rather than a typical or average value. The use of several conservative exposure and toxicity assumptions can introduce considerable uncertainty into the risk evaluation. By using conservative exposure or toxicity estimates, the evaluation can develop a significant conservative bias that may result in the calculation of significantly higher cancer risks or non-cancer hazards than are actually posed by the chemicals present in soil and soil gas at the subject property located at 2200-2226 Rosemead Boulevard in South El Monte, California (Site). A discussion of the key uncertainties used in this evaluation for the Site is presented below.

## 2. Uncertainties in the Data Evaluation

Data evaluation and the selection of Site-related chemicals of potential concern (COPCs) to be included in the human health risk evaluation were based on the results of the sampling and analytical program. The factors that contribute to the uncertainties associated with the identification of COPCs are inherent in the data collection and data evaluation processes, including appropriate sample locations, adequate sample quantities, laboratory analyses, data validation, and treatment of validated samples.

As described in the PEA Report previously prepared for the Site (ENVIRO-TOX Services, Inc., 2022), environmental investigations at the Site date back to the 1980s, with multiple soil, soil gas, and groundwater investigations being conducted between 1986 and 1998. Additional soil and soil gas investigations were conducted in 2020 and 2021 to evaluate site conditions in advance of planned demolition and industrial redevelopment. Further Site-wide soil, soil gas, and groundwater sampling was completed in March and April 2023 to characterize current Site conditions and evaluate the effectiveness of a soil vapor extraction system that was installed at the Site and operated from July 2022 to December 2022. In June 2023, additional soil samples were collected to further characterize polychlorinated biphenyls (PCBs). Additional soil delineation of PCBs, lead, arsenic, and hexavalent chromium sampling was conducted by Haley & Aldrich in January 2024. More than 700 soil, soil gas, and groundwater samples have been collected at the 5-acre Site. As such, the datasets for the human health risk evaluation were developed from a very robust and comprehensive sampling program.

Soil data were reported on a wet-weight basis for samples collected prior to the June 2023 sampling event. California Environmental Protection Agency (Cal/EPA) guidance recommends the use of dry weight concentrations for data to be included in a human health risk evaluation (2015). A dry-weight conversion evaluation was performed based on percent moisture content data from the samples collected in January 2024. The sample depth-specific minimum, maximum, and average values for those samples are presented in the table below. Percent moisture content results for individual samples are shown in the laboratory reports in Appendix B of the Limited Soil Remediation Workplan Addendum.

| Sample Depth (ft bgs) | Number of Samples | Percent Moisture Content | | |
|---|---|---|---|---|
| | | Minimum Value | Maximum Value | Average Value |
| 0.5 | 14 | 7.7 | 18.3 | 11.1 |
| 1 | 17 | 5.2 | 19.3 | 11.7 |
| 2 | 14 | 2.2 | 21.1 | 11.4 |
| 3 | 13 | 8 | 36.1 | 19.0 |
| 4 | 12 | 12.5 | 35.7 | 19.8 |
| 5 | 2 | 10.2 | 16.5 | 13.4 |
| 6 | 1 | 15.3 | 15.3 | 15.3 |
| 7 | 1 | 9 | 9 | 9 |

The percent moisture content values varied in samples collected at each depth, as well as between depths. As such, depth-specific average percent moisture content values were used in the dry weight conversion evaluation. Wet weight to dry weight conversion using average moisture content values of between 9 and 19.8 percent would result in a 1.1- to 1.2-fold increase in soil concentrations, indicating that dry weight correction would not materially affect the conclusions of the human health risk evaluation.

# 3. Uncertainties in the Exposure Assessment

As described below, numerous assumptions must be made in order to estimate potential human exposure to the COPCs at the Site.

## 3.1 EXPOSURE ASSUMPTIONS AND PATHWAYS

Consistent with recommended California Environmental Protection Agency (Cal/EPA) Department of Toxic Substances Control (DTSC) default exposure assumptions (DTSC, 2019), it was assumed that exposures for hypothetical future on-Site non-intrusive worker populations, would be potentially complete on a daily basis, for a continual 25-year exposure period. This assumed exposure duration represents an upper-bound estimate of the total amount of time that an individual may be working in one location. As the average worker exposure duration in one location is actually less than 25 years, the cumulative exposures and risks presented in this risk evaluation likely represent overestimates of the more typical exposures that might be incurred in a commercial/industrial setting.

Additionally, the estimates of potential health risks for hypothetical future on-Site non-intrusive workers do not account for potential clean soil cover, concrete, asphalt, or other covering that actually would reduce exposure below that assumed in this analysis. Thus, the actual exposures to soil at the Site under possible future commercial/industrial land use would probably be much lower than what has been estimated in this assessment.

The selection of complete exposure pathways is another area of uncertainty in all risk assessments. In general, this risk evaluation has quantified all potentially complete exposure pathways through which individuals could become exposed to chemicals present in on-Site soil and on-Site soil gas. Accordingly, the exposure pathways quantified in this risk evaluation are believed to capture the range of theoretical

current and future exposures, and thus provide a conservative estimate of long-term exposures that could occur at the Site.

## 3.2 BIOAVAILABILITY OF CHEMICALS IN SOIL

Another exposure factor that has not been taken into account in this assessment is the bioavailability of chemicals in soil. Studies support that certain organic compounds, particularly highly lipophilic compounds, such as polycyclic aromatic hydrocarbons (PAHs), tend to be tightly bound to soil (Kelsey et al., 1997). This phenomenon can substantially reduce the bioavailability of chemicals to people exposed to chemicals in soil. A reduction in the bioavailability of the chemicals adsorbed to soil would reduce the projected health risk associated with exposure to soil. Low bioavailability could substantially reduce estimated risks below levels calculated using the default assumption that all chemicals are 100 percent bioavailable.

## 3.3 CALCULATION OF SOIL EXPOSURE POINT CONCENTRATIONS (EPCs)

As recommended by United States Environmental Protection Agency (USEPA) guidance (USEPA, 1989), EPCs should be based on the average chemical concentration within the exposure area. To account for the uncertainty in estimating the average concentration, USEPA recommends that an upper confidence limit (UCL) of the mean concentration be used to represent the EPCs rather than the arithmetic mean (USEPA, 2002).

The calculation of the UCL for each COPC dataset includes an initial evaluation of the distribution of the data as a predecessor step to employing the best statistical methodology for determination of a concentration that estimates the mean of the dataset with a prescribed level of confidence. This means that the average has been bounded by a statistically determined concentration to afford a percent level of confidence in the "true" mean of the dataset. The "95 percent UCL" of the mean, is considered a reasonable maximum exposure level (USEPA, 1989) so that there is confidence that the "true" mean concentration of each COPC has been bounded at least 95 percent of the time. USEPA's ProUCL 5.2.00 statistical program (USEPA, 2022) was used in the human health risk evaluation to calculate UCL concentrations for COPCs in soil. ProUCL output for each COPC (Appendix D) provides a summary of all UCLs that can be calculated using the statistical program in addition to recommended UCLs based on the initial evaluation of the distribution of each dataset. The ProUCL-recommended UCLs were used as representative EPCs for COPCs in soil (0 to 10 feet bgs) included in the human health risk evaluation.

As noted in the ProUCL output files for the Site (Appendix D), the use of the Kaplan Meier (KM) estimation method is recommended for some of these UCLs with a message that states "KM UCLs may be biased low with this dataset. Other substitution method recommended." The ProUCL technical guidance document further states that although the use of the KM estimation method is a preferred method for calculating UCLs for datasets with multiple detection limits, such as the data included in the human health risk evaluation, this method may underestimate the UCL and "should be used with caution in cases where the KM UCL is less than the mean using substitution of half the DL." As shown in Table E-1, several COPCs included in the risk assessment fall into this category, with arithmetic mean concentrations greater than the respective ProUCL-recommended UCL calculated using the KM estimation method. Alternative UCLs, such as the 95% KM Chebyshev UCL, may be selected for datasets with non-detects and multiple detection limits and were previously recommended in ProUCL Version 5.1. However, as described in the ProUCL technical guidance, Chebyshev UCLs are no longer recommended for use in ProUCL Version 5.2.00 because they tend to overestimate the mean (i.e., may provide an "unrealistically high" estimate of the mean concentration; USEPA, 2022). However, to evaluate the effect of using the KM estimation method recommended by ProUCL Version 5.2.00, which

provided UCLs less than arithmetic mean concentrations (potentially underestimating the "true" mean of these datasets), cancer risk and non-cancer hazard estimates were calculated using the 95% KM Chebyshev UCL for risk-drivers with arithmetic mean concentrations greater than the KM UCL (i.e., Aroclor-1254).

As shown in Table E-1, the KM H UCL of 0.65 mg/kg was used as the EPC for Aroclor-1254 in the human health risk evaluation. The 95% KM Chebyshev UCL calculated for Aroclor-1254 is 2.9 mg/kg (Appendix D), approximately 4 times higher than the KM H UCL and greater than the arithmetic mean for the dataset of 1.6 mg/kg. The use of the 95% KM Chebyshev UCL would therefore result in a corresponding four-fold increase in cancer risk and non-cancer hazard estimates for non-intrusive worker and construction worker exposure to Aroclor-1254 in on-Site soil. A four-fold increase in the EPC for Aroclor-1254 does not materially affect the conclusion that concentrations of Aroclor-1254, along with other PCBs, in soil may require some remediation or other form of risk management (e.g., institutional controls) prior to the redevelopment of the Site for future commercial/industrial land use purposes and to protect the health of hypothetical future on-Site construction workers involved in the redevelopment of the Site.

It should be noted, that for these datasets, with a large percentage of non-detects and elevated reporting limits, the calculated arithmetic mean concentration may also be biased high when calculated using substitution of half the DL for non-detects.

In accordance with USEPA guidance (2022), UCLs of the mean were not calculated for datasets with fewer than four detections or fewer than ten samples. Although the USEPA guidance (2022) recommends either the use of the mean or the median in these cases, the maximum detected concentration was conservatively used as the representative EPC. The use of maximum concentrations of COPCs detected in soil as the representative EPC will result in an overestimate of cancer risks and non-cancer hazards.

## 3.4 CALCULATION OF SOIL GAS EXPOSURE POINT CONCENTRATIONS (EPCs)

As discussed in Section 3.2.2 of the human health risk evaluation, vapor intrusion into the future on-Site building was conservatively modeled on a point-by-point soil gas sample basis (e.g., each sample location/depth). Vapor intrusion incremental lifetime excess cancer risks (ILECRs) and non-cancer hazard indices (HIs) presented for the hypothetical future receptors are then the maximum estimates for all soil gas samples evaluated. Use of the maximum vapor intrusion estimates from the point-by-point analysis likely results in an overestimate of ILECRs and non-cancer HIs for hypothetical future receptors as individuals inside a building are more likely exposed to average concentrations (e.g., UCLs) of the volatile organic compounds (VOCs) detected underneath and/or in the vicinity of the subject building. Therefore, potential health risks to hypothetical future on-Site non-intrusive workers associated with vapor intrusion exposure to the COPCs present in soil gas are overestimated and are likely lower than presented in this human health risk evaluation.

## 3.5 FATE AND TRANSPORT MODELING ASSOCIATED WITH VOLATILE COMPOUNDS IN SOIL AND SOIL GAS

### 3.5.1 Soil Gas to Indoor Air

As discussed in Section 3.2.2 of the human health risk evaluation, default attenuation factors were used to estimate potential vapor intrusion risks for the future on-Site non-intrusive worker exposure scenario. Specifically, the DTSC-derived value of 0.0005 for vapor intrusion to future commercial buildings (DTSC,

2011) and the USEPA-derived default attenuation factor of 0.03 (USEPA, 2015) were used to estimate a range of future potential health risks for future on-Site non-intrusive worker exposure to VOCs in indoor air. Various uncertainties are associated with the use of these default attenuation factors in this risk evaluation. Notably:

- The default attenuation factor of 0.0005 from the DTSC Vapor Intrusion Guidance (2011) is not Site-specific, nor chemical-specific. It is an estimated average of attenuation factors calculated (using the Johnson & Ettinger [J&E] vapor intrusion model) for 16 volatile organic compounds using default soil physical property values (dry bulk density, total porosity, and water-filled porosity), which are not characteristic of geophysical conditions at the Site.
- The modeling on which the default attenuation factor of 0.0005 is based assumes that the source of contamination is infinite, which is conservative for soil sources. First, the actual source of contamination is likely finite and will deplete over time, as volatile chemicals migrate upward through the soil column. This depletion can be further accelerated by biodegradation. Second, as the contamination is depleted, the distance between the source and the building will increase, resulting in decreased transport into the indoor environment. Thus, the actual long-term exposures that may occur at the Site are likely significantly lower than assumed in the calculation of future potential health risks, especially if biodegradation is occurring.
- The USEPA-derived default attenuation factor of 0.03 is based on paired sub-slab/indoor air data, not subsurface soil gas data as collected from the Site and evaluated in the human health risk evaluation. Further, this value represents the 95th percentile from the USEPA Vapor Intrusion Screening Level (VISL) database (USEPA, 2012), which means that 95 percent of the time the use of 0.03 is too conservative. The median value in the USEPA VISL database is 0.003, and order of magnitude lower than 0.03.
- The default attenuation factor of 0.03 is largely based on data collected from sites outside of California and is therefore not adequately representative of attenuation affected by California climates.

For the reasons listed above, the use of the default attenuation factors of 0.03 or 0.0005 may not provide a representative range of theoretical vapor intrusion risks for the Site.

### 3.5.2 Soil to Outdoor Air

In addition, many of the uncertainties associated with the fate and transport modeling conducted to estimate the predicted outdoor air concentrations for VOCs are similar to those associated with modeling of indoor air concentrations. As with indoor air modeling, the modeling used default soil properties which are not representative of site-specific geophysical conditions and assume that VOCs in soil are not undergoing biodegradation. In addition, the modeling is based on the assumption that there is an infinite source of contamination. The modeling of outdoor air concentrations is based on the assumption that only a single chemical is present in the subsurface. When many chemicals are present, these chemicals can interact in ways that reduce the vapor pressure of VOCs available for transport through the vadose zone. These assumptions are all likely conservative.

These assumptions are particularly conservative for the evaluation of total petroleum hydrocarbons (TPH)-diesel, which is evaluated as a VOC in the human health risk evaluation to estimate predicted outdoor air concentrations to which on-Site receptors may be exposed. The assumption that the entire soil concentration of TPH-diesel is volatile is overly conservative given that only a portion of the lower end of carbon chain range of petroleum constituents that comprise a TPH-diesel mixture is considered

volatile and that it is likely that a portion of the volatile fraction of the measured TPH-diesel has been further reduced by weathering in soil. Therefore, potential non-cancer health hazards associated with inhalation exposure to the volatile fraction of TPH-diesel migrating from soil into outdoor air may be overestimated and are likely lower than those presented in this risk assessment.

## 4. Uncertainties in the Toxicity Assessment

Uncertainty in the toxicity assessment arises for those chemicals which rely on animal studies as the basis for determining the appropriate toxicity value. All risk assessments assume that adverse effects observed in animal toxicity experiments would also be observed in humans (animal-to-human extrapolation), and that the toxic effect observed after exposure by one route would occur following exposure by a different route (route-to-route extrapolation).

In order to adjust for uncertainties that arise from the use of animal data, regulatory agencies often base the reference dose (RfD) for non-carcinogenic effects on the most sensitive animal species (i.e., the species that experiences adverse effects at the lowest dose) and adjust the dose via the use of safety or uncertainty factors. The adjustment compensates for the lack of knowledge regarding interspecies extrapolation and possibility that humans are more sensitive than the most sensitive experimental animal species tested. The use of uncertainty factors is considered to be health protective.

Second, when route-specific toxicity data are unavailable, data are often derived by route-to-route extrapolation, and equal absorption rates for both routes are assumed (i.e., oral to inhalation and inhalation to oral). This may or may not reflect the actual differences in toxicity that can be associated with the route of exposure but is considered to be a conservative and health-protective assumption. For dermal exposure to soil, chemical-specific absorption data generally are not available. Instead, dermal absorption rates, which are based on the default assumptions provided by the DTSC (2015), are assumed.

Cal/EPA has published a cancer potency factor for naphthalene. The cancer potency factor is based on inhalation studies with rats, conducted by the National Toxicology Program (NTP). According to Cal/EPA, the results of these inhalation studies show clear evidence of respiratory epithelial adenomas and olfactory epithelial neuroblastomas in male and female rats. As the studies are focused on the inhalation route of exposure, and as the cancers observed in these studies are associated with the respiratory system, it is possible that the observed carcinogenicity is route-specific and would not be observed if exposures were to occur via the oral route. Nonetheless, as a conservative screening-level approach, and consistent with recommendations from Cal/EPA, the cancer potency factor for naphthalene developed by Cal/EPA has been applied to the oral and dermal routes of exposure in this human health risk evaluation. Accordingly, the cancer risk for naphthalene estimated in this human health risk evaluation is based on the assumption that inhalation, oral and dermal exposure to naphthalene present in soil could result in cancer effects.

Cal/EPA Office of Environmental Health Hazard Assessment (OEHHA) published a chronic inhalation reference exposure level (REL) for trivalent chromium in August 2022 (OEHHA, 2022). The basis for the REL is exposure to inorganic water-soluble trivalent chromium compounds and is not applicable to water-insoluble trivalent compounds or elemental chromium. As a conservative screening-level approach, the REL for water-soluble trivalent chromium was applied to the inhalation route of exposure for the evaluation of total chromium. The assumption that total chromium detected at the Site is made up entirely of water-soluble trivalent chromium is a conservative and health-protective assumption that results in an overestimate of the non-cancer hazard index for inhalation exposures to total chromium in soil.

# 5. Uncertainties in the Risk Characterization

One source of uncertainty that is unique to risk characterization is the assumption that the total risk associated with exposure to multiple chemicals is equal to the sum of the individual risks for each chemical (i.e., the risks are additive). Other possible interactions include synergism, where the total risk is higher than the sum of the individual risks, and antagonism, where the total risk is lower than the sum of the individual risks. Relatively little data are available regarding potential chemical interactions following environmental exposure to chemical mixtures. Some studies have been carried out in rodents given simultaneous doses of multiple chemicals. The results of these studies indicated that no interactive effects were observed for mixtures of chemicals affecting different target organs (i.e., each chemical acted independently), whereas antagonism was observed for mixtures of chemicals affecting the same target organ, but by different mechanisms (Presidential/Congressional Commission of Risk Assessment and Risk Management [Risk Commission], 1997).

While there are no data on chemical interactions in humans to chemical mixtures at the dose levels typically observed in environmental exposures, animal studies suggest that synergistic effects will not occur at levels of exposure below their individual effect levels (Seed et al., 1995). As exposure levels approach the individual effect levels, a variety of interactions may occur, including those that are additive, synergistic, and antagonistic (Seed et al., 1995).

Current USEPA guidance for risk assessment of chemical mixtures (USEPA, 1989) recommends assuming an additive effect following exposure to multiple chemicals. Subsequent recommendations by other parties, such as the National Research Council (1988) and the Presidential/Congressional Commission on Risk Assessment and Risk Management (Risk Commission, 1997) have also advocated a default assumption of additivity. As currently practiced, risk assessments of chemical mixtures generally sum cancer risks regardless of tumor type, and sum non-cancer HIs regardless of toxic endpoint or mode of action. Given the available experimental data, this approach likely overestimates potential risks associated with simultaneous exposure to multiple chemicals.

**Abbreviations:**
mg/kg = milligrams per kilogram
UCL = upper confidence limit

**Notes:**
[a] Arithmetic means derived using one-half the reporting limit values for non-detect results
[b] UCLs derived using ProUCL Version 5.2.00 (USEPA 2022); ProUCL output is presented in Appendix D

# APPENDIX F
# Volatilization Calculations

**TABLE F-1**

**SOIL TO OUTDOOR AIR VOLATILIZATION FACTOR EQUATIONS AND SAMPLE CALCULATION**

ROSEMEAD HOLDING, LLC PROPERTY

SOUTH EL MONTE, CALIFORNIA

*Outdoor Air Volatilization Factor (VF) Calculated for Naphthalene, (USEPA, 2002, Equation 4-8)*
*Future Commercial Scenario*

$$VF = \frac{Q/C_{vol} \times (3.14 \times D_A \times T)^{1/2} \times 10^{-4}\ (m^2/cm^2)}{2 \times \rho_b \times D_A} = \mathbf{4.6E+04}\ m^3/kg$$

where:

$$D_A = \frac{[(\theta_a^{3.33} D_i H') + (\theta_w^{3.33} D_w)]/\eta^2}{\rho_b K_d + \theta_w + \theta_a H'_{TS}}$$

and:

| | | | |
|---|---|---|---|
| $Q/C_{vol}$ | 68.18 | $(g/m^2\text{-}s) / (kg/m^3)$ | dispersion factor (calculated, see Table F-2) |
| $D_A$ | 6.0E-06 | $cm^2/s$ | apparent diffusivity (calculated using equation cited above) |
| T | 7.9E+08 | s | exposure interval (based on commercial exposure duration of 25 years) |
| $\rho_b$ | 1.50 | $g/cm^3$ | dry soil bulk density (default; USEPA, 2002) |
| $\eta$ | 0.43 | $cm^3_{pore}/cm^3_{soil}$ | total soil porosity (default; USEPA, 2002) |
| $\theta_a$ | 0.28 | $cm^3_{air}/cm^3_{soil}$ | air-filled soil porosity (calculated, n-$\theta_w$) |
| $D_i$ | 6.0E-02 | $cm^2/s$ | diffusivity in air (chemical-specific, see Table 6 of the HHRA) |
| $\theta_w$ | 0.15 | $cm^3_{water}/cm^3_{soil}$ | water-filled soil porosity (default; USEPA, 2002) |
| $D_w$ | 8.4E-06 | $cm^2/s$ | diffusivity in water (chemical-specific, see Table 6 of the HHRA) |
| $K_d = K_{oc} \times f_{oc}$ | 9.3E+00 | $cm^3/g$ | soil-water partition coefficient (calculated using equation provided) |
| $K_{oc}$ | 1544 | $cm^3/g$ | soil organic carbon partition coefficient (chemical-specific, see Table 6 of HHRA) |
| $f_{oc}$ | 0.0060 | g/g | fraction organic carbon in soil (default; USEPA, 2002) |
| $H'_{TS}$ | 1.8E-02 | unitless | Henry's Law Constant (chemical-specific, see Table 6 of HHRA) |

United States Environmental Protection Agency (USEPA). 2002. Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites. Office of Solid Waste and Emergency Response. Washington, D.C., December.

**TABLE F-2**

**DISPERSION FACTOR CALCULATION FOR VOLATILE COMPOUNDS**

ROSEMEAD HOLDING, LLC PROPERTY

SOUTH EL MONTE, CALIFORNIA

***Site-specific Dispersion Factor for Volatiles (USEPA 2002, Equation D-1)***

$Q/C_{vol} = A \exp[(\ln A_{site} - B)^2 (1/C)]$ = **68.18** $(g/m^2\text{-}s) / (kg/m^3)$

where:

| | | | |
|---|---|---|---|
| $A_{site}$ | 0.50 | acres | areal extent of the Site |
| Location | Los Angeles | -- | General location (USEPA 2002) |
| A | 11.9110 | -- | constant, default value presented in Exhibit D-3 (USEPA, 2002) |
| B | 18.4385 | -- | constant, default value presented in Exhibit D-3 (USEPA, 2002) |
| C | 209.7845 | -- | constant, default value presented in Exhibit D-3 (USEPA, 2002) |

**References:**

USEPA. 2002. Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites. Office of Solid Waste and Emergency Response. Washington, D.C., December.

**TABLE G-1**
**ESTIMATED VAPOR INTRUSION ILECRs AND NONCANCER HQs/HIs FOR CHEMICALS OF POTENTIAL CONCERN IN SOIL VAPOR USING DEFAULT ATTENUATION FACTOR OF 0.0005: ON-SITE NON-INTRUSIVE WORKERS**
ROSEMEAD HOLDING, LLC PROPERTY
SOUTH EL MONTE, CALIFORNIA

**Abbreviations:**

bgs = below ground surface

HI = hazard index

HQ = hazard quotient

ILECR = incremental lifetime excess cancer risk

NC = Not considered to be a carcinogen.

$mg/m^3$ = milligrams per cubic meter

**Notes:**

[a] Measured chemical concentration in subsurface soil gas. Detected results are presented in bold. Non-detect results are represented by one-half the laboratory reporting limit; non-detect results are included if the chemical was detected in at least one Site soil gas sample. In the case of non-detect results in both duplicate and primary samples, one-half of the lower of the two reporting limits was evaluated.

[b] The attenuation factor represents the relationship between the chemical concentration in soil gas and the chemical concentration in indoor air (resulting from volatilization from soil gas*i.e.* , vapor intrusion). A default attenuation factor published by the California Department of Toxic Substances Control was used to calculate ILECRs and HIs. Specifically, the DTSC-recommended value of 0.0005 for commercial buildings (DTSC, 2011) was used for the scenario evaluated (future on-Site non-intrusive workers).

[c] The exposure point concentration (EPC) in indoor air is the predicted estimated indoor air concentration the receptor may be exposed to (EPC = soil gas concentration × attenuation factor).

[d] Exposure concentrations (ECs) were calculated using equations presented in Table 4 and exposure parameters presented in Table 3.

[e] Incremental lifetime excess cancer risks (ILECRs) and noncancer hazard quotients (HQs) calculated from ECs as follows:
ILECR = EC (cancer effects) × URF
HQ = EC (noncancer effects) / RfC
Unit risk factors (URFs) and reference concentrations (RfCs) presented in Table 7.
ILECRs greater than $1\times10^{-6}$ and HQs/HIs greater than 1 are bolded and shaded.

**ESTIMATED VAPOR INTRUSION ILECRs AND NONCANCER HQs/HIs FOR CHEMICALS OF POTENTIAL CONCERN IN SOIL VAPOR USING DEFAULT ATTENUATION FACTOR OF 0.03: ON-SITE NON-INTRUSIVE WORKERS**

ROSEMEAD HOLDING, LLC PROPERTY

SOUTH EL MONTE, CALIFORNIA

**Notes:**

bgs = below ground surface

HI = hazard index

HQ = hazard quotient

ILECR = incremental lifetime excess cancer risk

NC = Not considered to be a carcinogen.

$mg/m^3$ = milligrams per cubic meter

[a] Measured chemical concentration in subsurface soil gas. Detected results are presented in bold. Non-detect results are represented by one-half the laboratory reporting limit; non-detect results are included if the chemical was detected in at least one Site soil gas sample. In the case of non-detect results in both duplicate and primary samples, one-half of the lower of the two reporting limits was evaluated.

[b] The attenuation factor represents the relationship between the chemical concentration in soil gas and the chemical concentration in indoor air (resulting from volatilization from soil gas*i.e.* , vapor intrusion). Default attenuation factors published by the USEPA (2012) and the California Department of Toxic Substances Control and State Water Resources Control Board (2023) were used. Specifically, the USEPA-derived value of 0.03 for chlorinated volatile organic compounds (VOCs) and residential buildings (USEPA, 2015) was used for the scenario evaluated (future on-Site non-intrusive workers).

[c] The exposure point concentration (EPC) in indoor air is the predicted estimated indoor air concentration the receptor may be exposed to (EPC = soil gas concentration × attenuation factor).

[d] Exposure concentrations (ECs) were calculated using equations presented in Table 5 and exposure parameters presented in Table 4.

[e] Incremental lifetime excess cancer risks (ILECRs) and noncancer hazard quotients (HQs) calculated from ECs as follows:

ILECR = EC (cancer effects) × URF

HQ = EC (noncancer effects) / RfC

Unit risk factors (URFs) and reference concentrations (RfCs) presented in Table 7.

ILECRs greater than $1 \times 10^{-6}$ and HQs/HIs greater than 1 are bolded and shaded.

# APPENDIX H
# Risk-Based Screening Concentration Example Calculation

**TABLE H-1**
**SAMPLE RISK-BASED SCREENING CONCENTRATION CALCULATION FOR NAPHTHALENE IN SOIL**
ROSEMEAD HOLDING, LLC PROPERTY
SOUTH EL MONTE, CALIFORNIA

For carcinogens, the following equation is used to derive the soil RBSC for residents:

$$RBSC_{a,carcinogen} = \frac{Target\ Risk\ Level}{\left(\left[\frac{Risk_{a,inhv}}{Conc_{inhv}}\right] + \left[\frac{Risk_{a,inhp}}{Conc_{a,inhp}}\right] + \left[\frac{Risk_{a,ing}}{Conc_{a,ing}}\right] + \left[\frac{Risk_{a,der}}{Conc_{a,der}}\right]\right)} = 6.1$$

| Parameter | Definition | Parameter Values (for Naphthalene) |
|---|---|---|
| $RBSC_{a,carcinogen}$ | Risk-Based Screening Concentration, chemical a, for carcinogenic effects, (mg/kg) | See calculated value above |
| Target Risk Level | Target Cancer Risk Level (unitless) | 1.0E-06 |
| $Risk_{a,inhv}$ | Calculated Cancer Risk for Chemical a for the vapor inhalation pathway (unitless) | 2.5E-08 |
| $Risk_{a,inhp}$ | Calculated Cancer Risk for Chemical a for the particulate inhalation pathway (unitless) | 8.4E-13 |
| $Risk_{a,ing}$ | Calculated Cancer Risk for Chemical a for the soil ingestion pathway (unitless) | 1.5E-08 |
| $Risk_{a,der}$ | Calculated Cancer Risk for Chemical a for the dermal contact pathway (unitless) | 2.7E-08 |
| $Conc_{a,inhv}$ | Representative Exposure Point Concentration of Chemical a for the vapor inhalation pathway (mg/kg) | 0.41 |
| $Conc_{a,inhp}$ | Representative Exposure Point Concentration of Chemical a for the particulate inhalation pathway (mg/kg) | 0.41 |
| $Conc_{a,ing}$ | Representative Exposure Point Concentration of Chemical a for the soil ingestion pathway (mg/kg) | 0.41 |
| $Conc_{a,der}$ | Representative Exposure Point Concentration of Chemical a for the dermal contact pathway (mg/kg) | 0.41 |

# TECHNICAL MEMORANDUM

Date: October 19, 2020 S3537

TO: Mr. Carl Middleton
Northgate Gonzalez RE, LLC
1201 North Magnolia Avenue
Anaheim, California 92801

FROM: Ms. Vanessa Layne
EEC Environmental

PROJECT: South El Monte Parcels - 2200, 2212, 2218, and 2226 N. Rosemead Blvd

SUBJECT: Results of Phase II Subsurface Investigation in August and September 2020

EEC Environmental (EEC) is providing this Technical Memorandum (Tech Memo) to summarize the results of the subsurface investigation activities conducted at 2200, 2212, 2218, and 2226 N. Rosemead Blvd in South El Monte, California (the Site) (see Figure 1, Site Vicinity Map) in August and September 2020. The purpose of the investigation is to assess current subsurface conditions at the Subject Properties in order to provide baseline environmental data in advance of a property transaction.

## SCOPE OF WORK

The Site investigation was conducted in two mobilizations. The first mobilization targeted current and historic areas of concerns associated with the parcels. The second mobilization was a more focused investigation to delineate areas of elevated contaminants of concern (COCs) encountered during the first mobilization. The following describes the activities associated with investigations in August and September 2020:

- Conducting geophysical surveys of the Site to identify possible feature(s) related to prior site activities and to identify subsurface utilities that may have been in conflict with proposed drilling locations.
- Advancing 33 borings using the direct-push drilling method to approximately 15 feet below ground surface (bgs).
- Collecting soil samples at 2, 5, 10, and 15 feet bgs in each of the 33 soil borings. Samples were analyzed as presented in Table 1, *Sampling Matrix* and as summarized below.
- Installing dual-nested soil-vapor probes at 22 of the 33 direct-push boring locations at depths of 5 and 15 feet bgs.
- Collecting soil-vapor samples from each vapor probe and analyzing the samples for volatile organic compounds (VOCs) by United States Environmental Protection Agency (USEPA) Method TO-15.
- Advancing four additional borings to 48 feet bgs using a limited access hollow stem auger (HSA) drill rig to collect groundwater samples in areas of concern.

- Collecting soil samples at 10, 20, 30, and 40 feet bgs in each of the four additional borings.
- Collecting groundwater samples at each additional boring for analysis of VOCs by USEPA Method 8260B/5035.
- Installing multi-nested soil vapor probes each additional boring at depths of 5, 15, 30, and 40 feet bgs.
- Utilizing a mobile laboratory for the collection of soil-vapor samples at each vapor probe for the analysis of VOCs by USEPA Method 8260B.

This Tech Memo documents the methods, procedures, and results of the Site investigation activities. The scope of work outlined above was completed under the supervision of a California licensed Professional Geologist (PG).

## BACKGROUND

A more detailed description of the Site history is provided in the Phase I Environmental Site Assessments (ESA) developed by Ramboll Environmental[1,2]. The following are concerns that formed the basis for the subsurface investigation scopes of work.

The Site has been utilized for multiple industrial uses since the 1940s. The current site use is summarized below.

- 2200 N. Rosemead Blvd – Auto Center (front of parcel), Ditty Drum Company (back of parcel)
- 2212 N. Rosemead Blvd – Auto Body Repair shop
- 2218 N. Rosemead Blvd – BJ's Tire Spot
- 2226 N. Rosemead Blvd – Ditty Container Company

Numerous subsurface investigations were conducted at the Site since the 1980s under the jurisdiction of the Los Angeles Regional Water Quality Control Board's Wells Inestigation program and it was involved in the South El Monte operable unit of the San Gabriel Valley Superfund Site. In 1997, the Regional Water Quality Control Board issued a no further action letter based on several rounds of groundwater, soil gas, and soil testing. Subsequently, a settlement was reached with the United States Environmental Protection Agency (USEPA) and Pacific Drum Company (2200 N. Rosemead Blvd) in 2012. At the time, no government agency is involved with subsurface investigation at the Site or ordering remediation.

Based on previous investigation the following current and historic areas of concern have been identified at the Site:

- drum cleaning and storage areas
- tote storage areas
- hazard materials storage area
- clarifiers and interceptors
- trench drain
- paint storage areas
- above-ground storage tanks
- underground storage tanks

1 Ramboll US Corporation (Ramboll), 2020a. Phase I Environmental Site Assessment for 2200 North Rosemead Boulevard, South El Monte, California. July 21

2 Ramboll, 2020b. Phase I Environmental Site Assessment for 2212, 2218, and 2226 North Rosemead Boulevard, South El Monte, California. July 21

## SITE INVESTIGATION ACTIVITIES

Site investigation activities initially took place on August 21, 22, and 26, 2020. The investigation activities consisted of drilling and sampling 33 borings and installing and sampling dual-nested soil-vapor probes in 22 of the borings at the Subject Property (Figure 2*, Sample Location Map*). Based on the findings during that investigation, additional activities were performed on September 18, 19, 24, and 25, 2020 and included the drilling and sampling of four deeper borings, the collection of groundwater sample, and installation of multi-nested soil vapor probes.

### Pre-Drilling Activities

Prior to drilling, EEC prepared a site-specific health and safety plan, marked the proposed boring locations with white paint, and contacted Underground Service Alert (USA) to identify any subsurface utilities underlying the proposed drilling locations.

EEC obtained a permit for the installation of the soil borings from the Los Angeles County, Department of Health Services (LACDPH) prior to the beginning of the work. The permit is provided in Appendix A, *Boring Permit*.

### Site Clearance

On August 21, 2020 and again on September 18, 2020, Pacific Coast Locators (PCL) conducted geophysical surveys of the Site to confirm there were no conflicts with potential underground utilities at the proposed boring locations. Several geophysical methods were employed, including high-sensitivity metal detection, shallow-focus terrain conductivity, ground-penetrating radar (GPR), and electromagnetic utility locating. No anomalous subsurface structures were identified during the geophysical investigation.

### Drilling Activities

All boring locations are shown on Figure 2. Soil boings SB-1 through SB-33 were installed using limited access track-mounted direct push drill rigs. Deeper borings HP-1 through HP-2 were installed

#### *Direct-Push Drilling and Soil Sampling*

During the first mobilization, limited-access direct-push drill rigs were utilized to advance 33 soil borings to 15 feet bgs. Direct-push drill rigs are hydraulically powered soil probing machines that use both static force and percussion to drive steel boring rods into the subsurface. Soil samples were collected as the core barrel was advanced and soil is driven into an inner 1.75-inch diameter, 4-foot long clear acetate sampling sleeve. Each soil boring was continuously sampled and logged from the direct-push sleeves pursuant to the Unified Soil Classification System (USCS) (ASTM D-2488-00). Soil samples were examined in the field for soil type, physical characteristics, and field evidence of contamination (staining, elevated organic vapor readings, etc.). Soil was screened for organic vapors using a photo-ionization detector (PID) as the boring was advanced and the readings were recorded on a field boring log (Appendix B, *Soil Boring Logs*). After decontamination of the sampling core barrel, a new acetate sleeve was inserted into the barrel and lowered back into the boring annulus, and the sampling process was repeated to the total boring depth.

Soil samples were collected at 2, 5, 10, and 15 feet bgs in each boring. At the designated depth interval, a 6-inch soil sample was cut from the acetate sleeve and capped with Teflon™ lined end caps. Soil samples were labeled with a unique identification number, sealed in a plastic bag, and placed in a chilled

cooler. The soil samples were transferred under proper chain-of-custody protocols to Enthalpy Analytical, a California State-certified analytical laboratory for analysis. Soil samples were analyzed as presented in Table 1 and as described below:

- All soil samples collected at 2 and 5 feet bgs were analyzed for VOCs by USEPA Method 8260B and for total petroleum hydrocarbons (TPH) carbon chain by USEPA 8015B.
- Select soil samples collected at 2 feet bgs were also analyzed for the following:
    - Polychlorinated biphenyls (PCBs) by USEPA 8082;
    - Polycyclic aromatic hydrocarbons (PAHs) by USEPA Method 8270 SIM; and
    - California Title 22 Metals (CAM-17) by USEPA Methods 6010B/7471A;
- Depending on results of the samples listed above, additional depths were analyzed for vertical delineation.

### *Hollow-Stem Auger Drilling and Soil Sampling*

During the second mobilization, four deeper borings were advanced using a limited access HSA drill rig. Prior to drilling, each boring was cleared by hand auger to a depth of 5 ft bgs. Then the boring was drilled with using 8-inch-diameter, continuous-flight, hollow-stem augers. Borings were advanced to a total depth of approximately 48 ft bgs. Groundwater was encountered at depths of approximately 45 ft bgs.

During hollow-stem-auger drilling activities, split-spoon samples were collected at 10-foot intervals and examined for soil type and major lithological changes. Soils were visually examined by a field geologist and observations logged in accordance with American Society for Testing and Materials standard D2487-11 using the Unified Soil Classification System (USCS) under the supervision of a California licensed Professional Geologist. In addition, a portion of soil from each 5-foot depth interval was collected from the sampling equipment and placed in re-sealable plastic bags. The bags were sealed for at least 10 minutes to allow any VOC vapors to volatilize into the headspace of the bag. A photoionization detector (PID) was used to measure VOC concentrations within the headspace of the bag, and measurements recorded on boring logs. Soil samples were collected and preserved for laboratory analysis in accordance with United States Environmental Protection Agency (USEPA) Method 5035 using laboratory-provided field preservation kits. Soil samples were labeled with an identification number, sealed in a plastic bag, and placed into a chilled cooler. The collected soil samples were transferred under proper chain-of-custody protocols to Enthalpy Analytical Enthalpy, a California State–certified analytical laboratory, for analyses of VOCs by USEPA Method 8260B. The soil boring logs are provided in Appendix B.

### *Groundwater Sampling*

At borings HP-1 Through HP-4, once groundwater was encountered, a Hydropunch-type sampling device was driven to a depth of 3 feet below the groundwater table. The rod was withdrawn to expose the screen of the sampling device. A bailer was lowered into the sampler to collect a groundwater sample. Groundwater was encountered at approximately 45 feet bgs at each boring. Groundwater samples were submitted to Enthalpy for the analysis of VOCs in accordance with USEPA Method 8260B.

### *Soil Vapor Probe Installation*

At 22 boring locations, after completion of drilling to 15 feet bgs, dual-nested vapor probes were constructed in the boring annulus. Each of the dual-nested vapor probes was constructed from the

bottom up and consists of vapor probes set at approximately 5 and 15 feet bgs. Each vapor probe was constructed of 0.25-inch-diameter polyetheretherketone (PEEK) tubing fitted with a 1.75-inch vapor inlet filter at the bottom of the tubing. The vapor probe inlet filter was installed in the middle of a one-foot filter pack of clean, kiln-dried #3 Monterey sand with one-foot of dry bentonite chips placed above the sand. Hydrated bentonite was then installed above the dry bentonite chips. The process was repeated for each probe with the bentonite above the 5-foot probe extending to just below the base of the existing pavement. Soil-vapor probes were designed and constructed in accordance with the California Environmental Protection Agency (CalEPA) and Department of Toxic Substance Control's (DTSC) 2015 *Soil Gas Advisory (Soil Gas Advisory)*.

After completion of drilling and collection of groundwater samples at the four Hydropunch borings, multi-nested probes were constructed in the boring annulus. The probes were installed at depths of 5, 15, 30, and 40 feet bgs. The probe construction is similar to the description provided above, with the exception being the tubing was fastened to a one-inch diameter PVC stabilizer pipe. Each boring was completed with an 8-inch traffic rated well box.

## Soil Vapor Sample Collection and Analysis

During the first mobilization, the soil vapor probes were sampled on August 21, 22, and 26, 2020. The soil vapor probes installed during the second mobilization were sampled on September 24 and 25, 2020.

EEC allowed direct-push installations to equilibrate over a minimum period of 2-hours prior to initiating sampling activities. HSA-installed probes were allowed seven days to equilibrate.

After the equilibration period was observed, each vapor probe was purged in accordance with standards set in the *Soil Gas Advisory*, where three (3) purge volumes of stagnant air were removed using a vacuum pump at a rate of 200 mL/min. During the first mobilization, soil vapor samples were collected using a 1-liter laboratory certified clean Summa canister equipped with a laboratory calibrated flow regulator set at a rate of approximately 200 mL/min. After collection, soil vapor samples were transferred under proper chain-of-custody protocols to Enthalpy Analytical, a California State-certified analytical laboratory for VOC analysis by USEPA Method TO-15.

During the second mobilization, soil vapor samples were collected in clean, 50-milliliter (ml) glass syringes and transferred to the onsite mobile laboratory for direct injection into a gas chromatograph (GC) for analysis of VOCs in accordance with USEPA Method 8260 by Environmental Support Technologies (EST) onsite mobile laboratory.

## Waste Disposal

Investigation-derived waste (IDW) included soil cuttings generated during drilling and were stored onsite in ten U.S. Department of Transportation (DOT) approved 55-gallon drums. The drums were labeled with the accumulation start date, description of contents, and applicable contact information. The IDW was profiled, manifested, and will be disposed of within 90 days of generation. Manifests signed by the disposal facility were not available for inclusion in this report and can be provided under separate cover upon request.

# RESULTS

Detectable concentrations of VOCs, TPH, PCBs, PAHs, and metals were compared against the San Francisco Bay Regional Water Quality Control Board (SFRWQCB) Environmental Screening Levels (ESLs) for commercial/industrial direct exposure. The ESLs are the most current and generally most

conservative set of screening values; however, individual screening levels have not been developed for all constituents. If an ESL has not been developed for a constituent, the USEPA Regional Screening Levels (RSLs) for commercial/industrial soils were applied. In the case of arsenic, the background level of 12 mg/kg established for the Department of Toxic Substances Control (DTSC) was applied. Laboratory analytical results are summarized in Tables 2 through 8. Laboratory reports are provided in Appendix C, *Soil and Groundwater Laboratory Analytical Reports* and Appendix D, *Soil Vapor Laboratory Analytical Report*. Results for each constituent class are summarized below.

## Soil Analytical Results

### *Volatile Organic Compounds*

Eighty-four soil samples were analyzed for VOCs from the 33 shallow soil borings the four deep borings. VOC constituents were detected in all samples, with PCE, TCE, and BTEX compounds being the dominant VOCs detected. VOC results are summarized in *Table 2, Summary of Volatile Organic Compounds and Total Petroleum Hydrocarbons in Soil* and Table 7, *Summary of Volatile Organic Compounds in Additional Samples.* Estimated values (J), detected below the reporting limit and above the laboratory method detection limit, and are included in the summary tables for each constituent class. Soil laboratory results for all analytes are provided in Appendix C. VOCs exceeded the ESLs at one location (SB-21).

### *Total Petroleum Hydrocarbons*

Soil samples were analyzed for TPH carbon chain by USEPA 8015 from the 33 shallow soil borings. TPH was speciated into C6-C12 (gasoline range), C13-C22 (diesel range), and C23-C44 (motor oil range). TPH as gasoline was detected in six of the 33 borings. TPH as diesel was detected in 16 of the 33 borings, and TPH as motor oil was detected in 29 of the 33 borings. TPH results are summarized in Table 2 *Summary of Volatile Organic Compounds and Total Petroleum Hydrocarbons in Soil.*

TPH-gasoline was detected above the ESL at one location (SB-23 at 2 feet bgs). TPH-gasoline was not detected in the sample collected at 5 feet bgs. TPH-diesel was detected above the ESL at four locations (SB-14, SB-16, and SB-23 at 2 feet bgs and in SB-21 at 5 feet bgs). Concentrations of TPH-diesel were below either non-detect (ND) or below the ESL in samples collected at the next depth interval. TPH-motor oil concentrations were below the SFRWQCB ESL in all borings.

### *Polychlorinated Biphenyls (PCBs)*

Twenty soil samples were analyzed for PCBs by USEPA Method 8082. PCB isomers were all below detection limits except for PCB-1254 in five samples. Three of the five samples exceeded the SFRWQCB ESL. PCB results are summarized in Table 3*, Summary of Polychlorinated Biphenyls in Soil.*

### *Polycyclic Aromatic Hydrocarbons (PAHs)*

Thirty-three soil samples were analyzed for PAHs by USEPA Method 8270-SIM. PAH results are summarized in Table 4*, Summary of Polycyclic Aromatic Hydrocarbon in Soil.* Benzo(a)pyrene was detected above the SFRWQCB ESL in SB-14 at 2 feet bgs.

### *Metals*

Soil samples were analyzed for Title 22 metals from 33 soil borings by USEAP Method 6010B/7471A. Metal results are summarized in Table 5*, Summary of Metals in Soil.* Metal results were compared against the SFRWQCB ESLs, except for arsenic, which was compared against the background level of 12 mg/kg established by the DTSC. Concentrations of antimony, arsenic, and lead were detected above

their respective screening levels in various boring locations. Samples analyzed at the next depth intervals were below the screening levels.

## Soil Vapor Analytical Results

Detectable concentrations of VOCs in soil vapor were compared against the SFRWQCB ESLs for commercial/industrial subslab/soil gas vapor intrusion risk. The ESLs are the most current and generally most conservative set of screening values; however, individual screening levels have not been developed for all constituents. If an ESL has not been developed for a constituent, the USEPA RSLs for indoor industrial air were divided by a sub-slab attenuation factor of 0.03 to achieve adjusted RSL for soil vapor. The constituents without established ESLs are not the main risk drivers at the Site.

The soil-vapor laboratory results are summarized in Table 6, *Summary of Volatile Organic Compounds in Soil Vapor* and Table 8, *Summary of Volatile Organic Compounds in Additional Soil Vapor.* VOC concentrations were compared to the commercial/industrial ESLs and adjusted RSLs as warranted. Results elevated concentrations of VOCs throughout the site, with the highest concentrations located along the southern portion of the 2200 Rosemead parcel (Ditty Container Company property), in samples collected adjacent to the clarifier, the waste treatment area, and the waste storage area.

## Groundwater Analytical Results

Four groundwater samples were analyzed for VOCs by USEPA Method 8260B. Results were compared to their respective maximum contaminant levels (MCLs) and are summarized Table 7. Results indicated that shallow groundwater is impacted with VOCs slightly above the MCLs, but concentrations are not at levels that typically require remediation.

## SUMMARY

### Soil

Based on the results for the Site investigations, impacted soil is limited to the shallower depths. During Site redevelopment activities, focused excavations should be sufficient to address any residual levels of contamination that could interfere with operations or pose health and safety risks.

### Groundwater

Although groundwater is impacted with VOCs, the low concentrations are manageable and should not trigger any requirements for active remediation. These levels also may be impacted by the regional groundwater contamination that currently is being remediated by the USEPA as part of the 2012 Consent Agreements.

### Soil Vapor

Several VOCs, including PCE, TCE, cis-1,2-DCE, BTEX, methylene chloride, vinyl chloride, and 1,2-DCA exceed SFRWQCB Industrial/Commercial Subslab/Soil Gas risk levels. Vapor intrusion risk is present, particularly in the southern portion of the Ditty Container Company property. Mitigation of soil vapor will be necessary for future development but is manageable with the installation of targeted soil vapor extraction. EEC is developing a proposed scope of work and remediation budget for consideration.

## CONCLUSION

Extensive Site investigations were undertaken in August and September 2020, including 37 borings from which soil and soil gas samples were taken and four groundwater Hydropunch samples. Based upon our evaluation of the current and historic site data and the proposed development plans, EEC believes the contamination encountered at the Site is manageable and will not prevent commercial development of the properties. Soil vapor contamination requiring remediation appears to be limited along the southern boundary of the 2200 Parcel. Soil Vapor Extraction is the recommended technology to address the subsurface vapor contamination and would not interfere with any proposed industrial/commercial development of the property. VOC contamination was also identified in groundwater at levels below which, in EEC's experience, would not require remediation by the Regional Water Quality Control Board. EEC recommends that a detailed Scope of Work and Remediation Plan be developed to address areas of contamination identified exceeding commercial/industrial standards

# Table 5, Summary of Metals in Soil Samples
# South El Monte Parcels

**Key:**
-- = not analyzed
(a) =San Francisco Bay Regional Water Quality Control Board Environmental Screening Levels
(b) = Department of Toxic Substances Control (DTSC) Screening Level
J = Estimated value; concentration above the method detection limit but below the reporting limit
mg/kg = milligrams per kilogram
mg/L = milligrams per liter
ND<"X" = not detected above the method detection limit or reporting limit "X"
**RED** = at or exceeds screening level
