the 12-inch-diameter potable water line to the NASA-JPL property. The following would also be installed: a new 12-inch-diameter line along the relocated access road to serve a future groundwater well beside Basin F; a 16-inch-diameter utility line to serve existing wells in the Arroyo and the existing Monk Hill Treatment Plant; and a 12-inch diameter discharge main for the existing Arroyo Booster. Exhibit 3-3d, Area 3 – Basin J and Piping Plan, depicts the location and size of the proposed Basin J spreading basin and the access road alignment. The Piping Plan depicts the inlet/outlet connections between spreading basins and the Project's various pipelines.

Table 3.1-1 compares the improvements proposed in and near Area 3 as contained in the adopted HWMP and the improvements analyzed in the Final Master EIR for the Arroyo Seco Master Plan (ASMP) with those proposed by the Arroyo Seco Canyon Project.

TABLE 3.1-1
AREA 3 IMPROVEMENTS

Area 3 Improvements	Description of Improvements		
	Hahamongna Watershed Park Master Plan	**Final Master EIR for Arroyo Seco Master Plan* (Master EIR section)**	**Arroyo Seco Canyon Project**
JPL East Parking Lot	Relocate JPL parking, remove southern ¾ of parking lot and convert northern ¼ into public parking.	6-story, 1,200-space parking structure on JPL west parking lot (2.3.1.11.1 and 3.1.4.1.1).	*(Note: This parking structure is under construction by JPL and is not part of the Project.)*
		Convert JPL parking to 200-space public parking (2.3.1.15.1).	Up to 100-space decomposed granite recreational parking lot. (*Note: This is 100 parking spaces fewer than the parking lot analyzed in the Master EIR.)*
New public restroom	New restroom (with 1 urinal and 1 stall for men and 2 stalls for women) at northern end of parking lot, with storage area, public telephone, underground power connection, and sewage lift station and force main leading to the JPL line across the JPL bridge.	New restroom (with 1 urinal and 1 stall for men and 2 stalls for women) at northern end of parking lot, with storage area, trash enclosure, emergency phone, sewage lift station, and force main leading to the sewer line at the JPL campus through JPL bridge (2.3.1.15.2).	New restroom at northern end of parking lot with 2 gender-neutral stalls and sewage lift station and sewer connection leading to the JPL sewer line across JPL bridge. *(Note: This is 1 urinal and 1 stall fewer than the restroom analyzed in the Master EIR.)*
Bridge Crossing	New bridge crossing for the North Perimeter Trail, vehicles, and utilities.	Northern Bridge Crossing across Arroyo Seco that is 12 feet wide and 150 feet long (2.3.1.16.3).	Not proposed, but the existing pedestrian access path across the JPL bridge will be maintained and will connect to the new parking lot.
Spreading Basins	Expand 4 existing basins.	Expand 4 existing basins into the JPL parking lot (2.3.1.4.5).	Expand 4 existing basins.
	Relocate 2 sludge ponds.	Relocate and expand 2 sludge basins (2.3.1.4.5).	Replace 2 sludge ponds with 2 new spreading basins.
	Build 2 new basins.	Build 2 new basins (2.3.1.4.5).	Construct 2 sedimentation basins and 2 spreading basins. (*Note: This is 2 basins more than analyzed in the Master EIR. While the basins would be located in the same area, the area would have a different basin configuration.)*
		Convert 2 basins into a lake (2.3.1.4.5 and 2.3.1.13).	Not proposed.

TABLE 3.1-1
AREA 3 IMPROVEMENTS

Area 3 Improvements	Description of Improvements		
	Hahamongna Watershed Park Master Plan	**Final Master EIR for Arroyo Seco Master Plan* (Master EIR section)**	**Arroyo Seco Canyon Project**
Trails	New trail that runs from the north end of the JPL parking lot to the Gabrielino Trail.	4 trail connections from East Rim Trail to Perimeter Trail, including a new trail at the north end of the parking lot (2.3.1.16.5).	Potential future pedestrian pathway from the north end of the parking lot through the slope area to Gabrielino Trail
	Extend East Rim Trail from Arroyo Well to VOC Water Treatment Plant and from Arroyo Well to both the Altadena Crest Trail and the Gabrielino Trail (along back of JPL parking lot).	East Rim Trail is approximately 2,600 linear feet of new trail that runs from the VOC Water Treatment Plant through Johnson Field to the Arroyo Well before ending at the Altacrest Trail on backside of the existing parking lot (2.3.1.16.4).	Pedestrian pathway/trail along the eastern edge of the parking lot, with a potential future extension north to join the Gabrielino Trail north of Area 3.
	Relocate existing trail to the maintenance road.	Relocate the existing trail to the maintenance road (2.3.1.18.2).	Proposed maintenance roads around new spreading basins will be open for public use.
Trailhead	Gabrielino Trailhead area with a new restroom, picnic tables, public parking, and interpretive signage.	Interpretive and picnic area at the intersection of the Arroyo Well and Johnson Field Road, with parking spaces (2.3.1.12.7).	Restroom, pet waste station, and signage proposed at the Gabrielino Trailhead area.
Habitat restoration	Realign stream corridor and restore habitat on banks west of the parking lot and basins.	Move, expand, and restore the stream corridor by the Altadena drain (2.3.1.18.1.1).	No improvements are proposed on the banks west of the parking lot.
	Establish habitat at spreading basins.	Habitat establishment at spreading basins (2.3.1.18.1.3).	Not proposed.
	Establish habitat at the East Entrance.	Habitat establishment at the East Entrance and at Sunset Overlook (2.3.1.18.1.5).	Not proposed.
Pipeline Relocation and Demolition	None specified.	None specified.	Replace and realign Hume line from the north end of parking lot to the spreading basins.
			Relocate the JPL water line to the new access road.
			Demolish a portion of the influent and effluent line from the Behner Water Treatment Plant
			Relocate the 12-inch diameter Arroyo Booster pipeline to the new access road.
			Remove sludge lines.

TABLE 3.1-1
AREA 3 IMPROVEMENTS

Area 3 Improvements	Description of Improvements		
	Hahamongna Watershed Park Master Plan	**Final Master EIR for Arroyo Seco Master Plan* (Master EIR section)**	**Arroyo Seco Canyon Project**
Storm Drain Improvements	Shorten the Altadena storm drain and armor embankment to reduce erosion and restore habitat.	Shorten the Altadena drain and restore the stream corridor (2.3.1.4.6).	Not proposed.
	Extend the Altacrest storm drain as an underground pipe into the stream with inlets from the access road and the parking lot.	Extend the Altacrest drain as an underground drain between basins and that empties into the stream, with inlets to receive runoff from the parking lot (2.3.1.4.7).	Altacrest drain extension is not proposed
			County Storm Drain remains in place.
Overlook	Construct Sunset Overlook with interpretive signage and park amenities north of the East entrance.	Construct Sunset Overlook with picnic tables, seating, signage, and parking near east park entrance (2.3.1.14).	Not proposed.
Park Entrance	Relocate and improve the park entrance at Windsor/Explorer/Ventura intersection to Windsor/Mountain View.	Relocate the park entrance to Windsor/Mountain View, add a retaining wall, and restore habitat (2.3.1.3.1).	Not proposed.
	Relocate the parking area south of the entrance to the JPL parking lot	Relocate the parking area to the northern end of the JPL parking lot (2.3.1.3.1).	Not proposed.
		Reconstruct Windsor/Ventura intersection; add an interpretive area and a parking area (2.3.1.3.3)	Not proposed.
Access Road	Realign to the east side of the basins.	Realign along eastern edge of the parking lot (2.3.1.3.2).	Realign along eastern side of the basins and south and west of the new parking lot.
	Widen the road to Johnson Field.	Widen the Johnson Field Road to 2 lanes (2.3.1.3.3).	Not proposed.
Pump-Back system	Inlet at dam; pipe at the bottom eastern slope; and outlet at the highest east side basin and across the new bridge to the west side basins	Inlet, pump, and pipes to basins and lakes (2.3.1.4.2).	Not proposed.
Water line	Water line connections to new restrooms, campsite sinks, drinking fountains, and buildings.	None specified.	Connect the restroom and parking lot irrigation system to a metered service from the relocated JPL water main.

TABLE 3.1-1
AREA 3 IMPROVEMENTS

Area 3 Improvements	Description of Improvements		
	Hahamongna Watershed Park Master Plan	**Final Master EIR for Arroyo Seco Master Plan* (Master EIR section)**	**Arroyo Seco Canyon Project**
Overhead power and communication lines	Relocate to the North Bridge crossing or within the utility easement.	Relocate power and communication lines.	Not proposed.
	Power connections to new restrooms and pump-back system.	None specified.	Connect the restroom, irrigation controls, and basin metering structure to a new service drop using an existing overhead line in Area 3 (where the biggest load will come from the lift station).
	Underground PWP overhead distribution lines from the VOC Water Treatment Plant to Arroyo Well and from the VOC Water Treatment Plant to Johnson Field.	Underground 3,000 feet of power and communication lines from the VOC Water Treatment Plant to Arroyo Well and from the VOC Water Treatment Plant to Johnson Field (2.3.1.19.1).	Not proposed.
	Relocate SCE lines running from the JPL substation to the Windsor/Ventura intersection.	Realign the SCE power line across the basins to the North Bridge, Gabrielino Trail, Ventura Street, and ultimately to the existing line on Altadena Drive (2.3.1.19.2).	Not proposed.
Septic Tanks and Sewer lines	Abandon all septic tanks and construct a sewer collection system.	Connect a new restroom near Johnson Field to the sewer line on Lehigh Street (2.3.1.12.3) and connect a new restroom at the JPL parking lot to the sewer line in JPL campus (2.3.1.15.2).	Connect a restroom to sewer line in JPL campus.
Security gates	Add security gates at all vehicular entries and at the tunnel from the dam parking lot.	Add gates and fencing at the East Entrance and along west side of Windsor Avenue (2.3.1.20).	Not proposed.
		Add fencing at end of Altadena Drive (2.3.1.20).	Not proposed.
			Add security gates at the north end of the parking lot, with a roundabout and a guard house

TABLE 3.1-1
AREA 3 IMPROVEMENTS

Area 3 Improvements	Description of Improvements		
	Hahamongna Watershed Park Master Plan	**Final Master EIR for Arroyo Seco Master Plan* (Master EIR section)**	**Arroyo Seco Canyon Project**
Lighting	Add lighting on built structures and at major park entrances only.	Add safety lights at the new parking lots and at the new restrooms (3.1.4.1.1).	Add restroom interior and exterior lighting.
Public telephones	Add near improved restrooms and recreation amenities.	Add at the new restroom at north end of the public parking lot (2.3.1.15.2).	Not proposed.

JPL: Jet Propulsion Laboratory; VOC: volatile organic compounds; PWP: City of Pasadena Water and Power; SCE: Southern California Edison.

* Based on the Final Master EIR that includes Draft Master EIR and Clarifications and Revisions to Draft Master EIR (Section 12.0 of the Final Master EIR).

As shown, the Project would implement some of the improvements proposed by the HWMP and analyzed in the Final Master EIR for the Arroyo Seco Master Plan. However, the Project proposes a recreational parking lot and a restroom that are smaller than those analyzed in the Final Master EIR. There is also a variation to the spreading basin configuration within the same location and area. Other proposed improvements in Area 3 (e.g., proposed trails, walkway, hume line relocation, JPL water line relocation, utility line demolition in the proposed basin area, water line connection, security gates, roundabout, and guard station at north end of parking lot) are not discussed in the HWMP or the Final Master EIR. At the same time, the Project does not preclude the future implementation of other improvements in Area 3 (e.g., storm drain improvements, trail relocation, pumpback system, and utility line relocations) as contained in the HWMP or analyzed by the Final Master EIR but not proposed by the Project. Accordingly, this IS/MND is a stand-alone document and does not tier off of the Master EIR.

3.2 PROJECT DEMOLITION AND CONSTRUCTION

Construction of the permanent Project improvements is anticipated to take approximately 16 months, starting in Summer 2015 with construction of the temporary bridges beginning one month before the start of construction activities in Areas 1 and 2. Designated staging areas will be fenced to prevent safety hazards, as well as deter to vandalism and theft. Project completion is expected by Fall 2016, with temporary bridge demolition occurring at the end of construction activities in Areas 1 and 2. Planned construction activities are broken out by Area below.

During grading activities in Area 3, a total of approximately 23,000 cy of cut materials is anticipated. In the interest of minimizing export from the Project site, the City may implement a mechanical shaker to sort and sift through excavated soils. The shaker would separate finer soils from larger rocks, thereby allowing for the beneficial reuse of the excavated soils as engineered fill materials during the construction of the spreading basins. The shaker would be in operation for 8-hour days over the last 2 months of grading activities. If the City utilizes the shaker option, approximately 23,000 cy of cut materials would be processed through the shaker, resulting in approximately 21,000 cy of material for fill (to be used on-site) and approximately 2,000 cy of larger rock materials. These 2,000 cy of rock materials may be used on-site for decorative/landscaping purposes throughout the Project study area, or may be exported off-site. For the sake of providing a conservative analysis, both the Air Quality, Noise and Traffic sections of the IS/MND assume export of these materials.

Table 3.2-1, Construction Activity Assumptions, summarizes the anticipated construction activities for each area.

sf: square feet; ac: acres; cy: cubic yards; N/A: not applicable.

[a] Assumes 2 temporary bridges will be built, with a temporary bridge over Bridge No. 1 and another temporary bridge over Bridge No. 3.

[b] In addition to the listed equipment, the following equipment would be shared among any 1 of the 3 work areas: medium-duty trucks (<10), all-terrain forklift (1), front-end loader (1), water truck, portable generator, and hand tools (e.g., grinders, drills, compressors).

[c] In order to provide a conservative assessment to account for the unknown variation in the amount of soil that could be re-used onsite for engineered fill versus exported off-site, the number of truck trips was increased by assuming the use of 10 cy trucks instead of the standard 16 cy trucks.

Source: Carollo 2013.

Trucks hauling soils and debris to Scholl Canyon Landfill are expected to come to the site from I-210 at the Windsor Avenue off-ramp and head north on Windsor Avenue to Explorer Road into Area 3. From Area 3, trucks would turn southeast and north to the access road (North Arroyo Boulevard) to reach Areas 1 and 2. From these areas, the trucks would head south and pass through Area 3, Explorer Road, Windsor Avenue, and onto the westbound on-ramp on I-210. From I-210, trucks would head west on SR-134; exit at the Figueroa Street/Scholl Canyon Road off-ramp; head north-northeast toward the landfill. Trucks would come back from the landfill entering the eastbound on-ramp on the SR-134 at Figueroa Street and head east; trucks would then go west on I-210 to Windsor Avenue to Explorer Road and, ultimately, to the site.

3.2.1 AREA 1 – ARROYO SECO HEADWORKS

Temporary bridges would be constructed in Summer 2015 over Bridge No. 3 across the Arroyo Seco and over Bridge No. 1 across Millard Creek to allow heavy equipment to reach Areas 1 and 2 during construction. These temporary bridges would accommodate construction vehicles and prevent any damage to Bridge No. 1 and Bridge No. 3. The assembly process will be executed in such a way to ensure that the bridges are set upon disturbed trail areas only and would not extend into the creek or adjacent vegetated areas. These bridges would be removed after construction of the proposed improvements in Areas 1 and 2.

At the start of construction, a temporary cofferdam (temporary enclosure to keep water out) would be placed across the stream at the upstream end of Area 1, with a sump pump that would convey water through a pipe along the western edge of Area 1 and discharge water downstream of Area 1, when necessary. Portions of the Headworks structure and an existing slab are proposed to be removed from the streambed and banks with the use of hammers and breakers. Some portions of the structure that are below the proposed finish grade or that extend into the regraded canyon walls may not be removed. The channel would be recontoured within the two- to five-year floodplain areas to allow the Arroyo Seco to flow naturally through the area.

Site preparation for Area 1 would start in Summer 2015, with clearing, grubbing, and demolition of the Headworks structure starting in Fall 2015. Grading activities on approximately eight acres would start in the Fall of the same year for two months of rough grading and two months of fine grading and embankment revetment; these activities would be completed by Winter 2016. The planting and seeding task in Area 1 could involve volunteers from the community through coordination with the ASF. For safety reasons, planting and seeding activities (which would be completed by volunteers) would be performed when construction equipment is not in operation.

3.2.2 AREA 2 – ARROYO SECO INTAKE

The temporary bridges that would be constructed across the Arroyo Seco and Millard Creek to allow heavy equipment to reach Area 1 would also be used during construction in Area 2. In addition, a temporary cofferdam would be installed in the Arroyo Seco upstream of Area 2 using on-site materials to divert flows away from the construction area and from construction equipment. A sump pump and temporary pipeline would allow water flows to temporarily bypass the stream in Area 2.

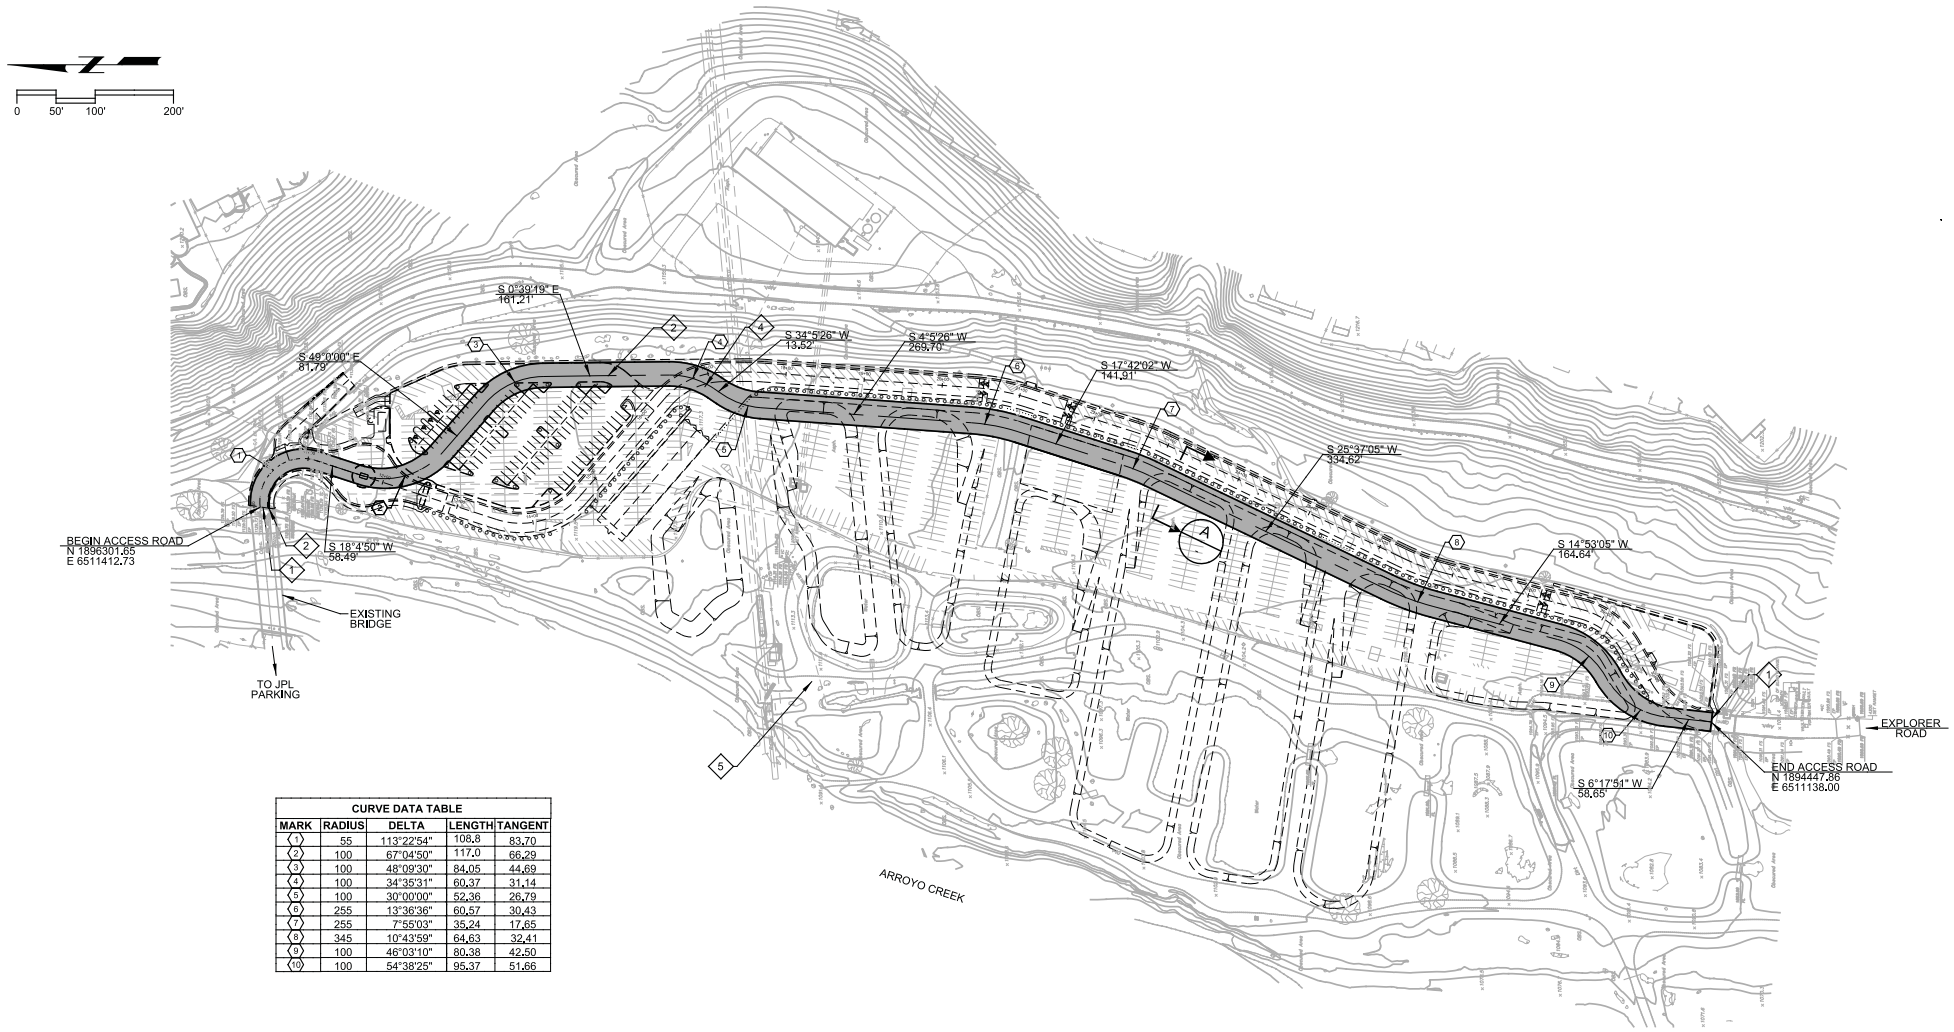
The Project would involve the removal of sediment and debris that has accumulated upstream and downstream of the existing weir and the demolition of the top two feet of the weir. In the same location and alignment, a new reinforced concrete sill would be cast with an integral cutoff wall on the downstream edge. The sill's upstream, downstream, and right and left abutments would be protected from erosion by a combination of heavy riprap stone and reinforced concrete. A pneumatic or electric operated spillway gate or a crest gate would be placed on the sill.

The existing concrete training wall on the east side of the streambed would remain in place but would be bolstered by the addition of riprap and concrete. In several locations, additional steel surfaces would be installed to protect the concrete from scour. The existing intake trash rack and gate slot guides would be removed and, as an option, the valve ahead of the pipeline may also be removed. A new trash rack with horizontal bars would be installed over the intake opening. The downstream end of the trash rack would be left partially open so that debris would have some opportunity to pass without requiring manual cleaning. Behind the trash rack would be a fine screen made of heavy wedge wire screen with 0.125- to 0.25-inch openings that are vertically oriented. The fine screen would be manually cleaned and would serve to keep all but the smallest debris out of the conveyance system. Immediately behind the screen would be an isolation gate

that can be automatically closed during high flow events. The gate would prevent the fine screen and downstream facilities from being filled with sediment.

Existing K-rails would be removed along an approximate 150-foot-long segment of the existing access road between Bridge No. 3 and the intake structure. The access road would be stabilized through reconstruction of the stream embankment and provision of riprap protection, with a rock wall extension above the road at the streamside to provide fall protection for users of the trail/access road. The road would be repaved with asphalt and would be sloped to direct surface runoff away from the stream towards the hillside.

Site preparation for Area 2 would also start in Summer 2015, with clearing, grubbing, and demolition of the diversion weir and retaining wall starting in Fall 2015. Grading activities on approximately 9,000 square feet of area near the diversion structure and on the access road would start in the Fall of the same year. Approximately 180 cubic yards (cy) of road base materials would be disposed of off-site (requiring a maximum of 36 truck trips with half loads). Infrastructure construction (e.g., formwork and concrete work, new weir gates, trash racks, valving, and embankment improvements) would occur for 3 months starting in Fall 2015. Construction of the control equipment enclosure would begin in Summer 2016, and access road paving would occur for 1 month starting in Spring 2016.



After Area 1 and Area 2 improvements are constructed, the temporary bridges would be demolished. This demolition work is expected to take approximately 4 weeks and a total of 20 truck trips in Fall 2016.

3.2.3 AREA 3 – JPL EAST PARKING LOT

Parking Lot Removal by JPL

As a part of the City's termination of the lease agreement for the JPL East Parking Lot, and not as a component of the proposed Project, JPL is required to remove all constructed improvements on the parking lot site, unless otherwise directed by the City (JPL 2012). As such, all existing facilities—including bus stops, fencing, bollards, signs, lighting, JPL overhead power lines, and the paved parking lot—are expected to be removed by JPL after completion of the JPL On-Site Parking Structure at the JPL campus in August 2014 as a part of this existing lease agreement. Of the 9.58 acres (417,305 square feet) that JPL is leasing from the City, approximately 357,347 square feet is currently paved. Of this, approximately 47,164 square feet of paving would remain in place for a 26-foot-wide temporary access roadway that would provide vehicle access for JPL employees to the new JPL On-Site Parking Structure. Dedicated access times during commuting hours may be enforced during construction activities in Area 3. JPL employees and visitors would have to use JPL's West Entrance during restricted access hours (i.e., outside peak commute hours).

JPL would remove all other paving and base materials and return the site to existing grade. As such, at the time that Project construction begins in Summer 2015, it is expected that the JPL East Parking Lot would no longer exist and is therefore not considered part of the baseline condition; only 47,164 square feet of paving on the temporary access road would remain as an existing, and therefore baseline, condition on the Project site. This temporary access road would be aligned and maintained in accordance with the Standard Specifications for Public Works Construction (Greenbook) and the City's Supplements and Modifications to the Greenbook (RR TRA-1) and, therefore, would not pose hazards to those using the road. Exhibit 3-4, Temporary Access Road Plan, shows the alignment of the temporary access road that will remain in place until the final roadway alignment is completed.

Construction Activities

Area 3 construction would begin with the removal of existing pipelines, except JPL's 12-inch-diameter potable main. This main would remain in place and in service until the new replacement main is installed, pressure tested, disinfected, and ready for connection to the existing water meter. The new JPL 12-inch-diameter potable water pipeline, the 12-inch-diameter JPL well line, the 16-inch-diameter utility service line, and the 12-inch-diameter Arroyo Booster line would be installed beneath the alignment of the new access road along the eastern edge of Area 3. The existing 30-inch-diameter hume line would stop at the northern section of Area 3 and would connect to the new 30-inch-diameter concrete, mortar-lined, and coated steel pipe along the eastern edge and across the new parking lot to sedimentation basins (Basins A and B); there would also be another direct connection to two spreading basins (Basins C and G). Portions of the Behner Water Treatment Plant's influent and effluent lines between the future access road and the existing 30-inch-diameter hume line would be removed, as these lines are not in use. The 8-inch-diameter sludge line from the Behner Water Treatment Plant would also be removed in Area 3. The County storm drain line would remain in place.

As the pipeline work is being completed, excavation for the new spreading basins would begin, especially in the areas abutting the new roadway alignment. The amount of excavated soils (from the spreading basin construction) to be hauled off site would be minimized by creating shallow embankments around proposed basins and raising the elevation of the access road and the new parking lot. This would consist of excavating approximately one foot below the existing grade and constructing two-foot-high berms around the basins. The electrical building near the sludge ponds would also be removed.

After the pipeline work, the new JPL access road would be built along the eastern edge of Area 3. When this road is completed, the temporary access road would be removed and construction of the spreading basins would continue. The decomposed granite parking lot would also be constructed at the northern end of Area 3 after the pipeline work. During these improvements, JPL employees and their visitors would have access through Area 3 to enter JPL using the temporary access road or the new access road (when it is completed) in Area 3.

Fencing, gates, a roundabout, a guard station, a restroom, a trail pathway, signs, and other improvements at the northern end of the parking lot would be constructed and/or installed. The proposed restroom would be constructed either on site or using a pre-fabricated building. The restroom would be connected to the relocated JPL potable line upstream of JPL's service meter.

Wastewater from the proposed restroom would be conveyed to an existing sewer line on the JPL campus through a new lift station and a new sewer line within the JPL Bridge. The sewer line will extend from the restroom; will be placed into the JPL Bridge's support structure; and will connect to the larger sewer trunk line within the JPL campus. A new lift station would be constructed in association with the restroom. Construction for the sewer line extension would involve trenching within the existing roadway on the eastside of the JPL Bridge and excavating through the existing asphalt approach to the bridge's sub-structure. There would be no access required from the creekbed or surrounding vegetated slopes. This temporary disturbance of the bridge would require detours for JPL employees to a single-lane crossing over the bridge.

Construction in Area 3 would also start in Summer 2015, with site preparation, clearing, and grubbing occurring in the same month. Approximately 150 truckloads of debris, dirt, and vegetation would be removed and disposed of at Scholl Canyon Landfill. Demolition activities for a maintenance shed, concrete vaults, head gates, and asphalt paving from the asphalt access road would begin in Fall 2015 and would extend for two weeks. Grading activities on approximately 20 acres for the spreading basins would continue for 5 months, with approximately

2,000 cubic yards of rock and/or excess soils requiring off-site disposal at Scholl Canyon Landfill. If the rocks are not beneficially reused on the Project site, a total of approximately 125 truck trips would be needed to haul the materials to Scholl Canyon Landfill, assuming use of a 16-cy truck. Because it is unknown exactly how much soils will be able to be beneficially reused on the Project site, and how much may be required for off-site disposal, a total of 210 truck trips was assumed in the Air Quality, Noise, and Traffic analyses within this IS/MND.

Infrastructure construction would occur for four months starting in Fall 2015. Building construction would start in Summer 2016. Access road paving (67,000 square feet) and parking lot paving with decomposed granite (72,000 square feet) would occur for approximately 2 months starting in Spring 2016. Project construction would be completed by Fall 2016.

3.3 LONG-TERM OPERATIONS

A 20 to 25 percent increase in the number of trail users and recreational visitors are conservatively anticipated with the Project, such that up to approximately 150 users per day on weekdays (an increase of 25 users per day) and 500 people per day on weekends (an increase of 100 users per weekend day) are expected to use the recreational facilities located in the Project area. As many as 1,000 people per day (an increase of 200 users per weekend day) may use the proposed improvements and nearby recreational facilities and trails during major holidays (e.g., Memorial Day weekend).

3.3.1 AREA 1 – ARROYO SECO HEADWORKS

The rest area/picnic area in Area 1 would serve users of the existing trail system. The picnic tables are expected to accommodate 4 persons per table (assuming a total of 3 proposed tables), or 12 people at any time. Therefore, there could be a slight increase in the number of people using recreational facilities in Area 1 due to the proposed picnic amenities. Trash collection would be conducted at least once a week by existing City personnel.

3.3.2 AREA 2 – ARROYO SECO INTAKE

The PWP typically does not divert water for recharge during large storm events (when flows are greater than 25 cfs) due to high total suspended solids (TSS) in the water. If water with high TSS levels is used for recharge, the ground surface in the basins can be “blinded” or plugged by fine material such as clays and silts. This would then reduce recharge rates and require removal of the top layer of fine material in order to recover the basins’ original recharge rates. Letting water with high TSS levels bypass without recharge is not preferred from a water supply perspective, but helps reduce maintenance issues associated with excessive cleanup of the basins.

The new diversion structure would capture all flows during small storm events and dry weather flows in the Arroyo Seco and up to 25 cfs during large storm. During larger storm events when the water is too turbid, the stream (with its associated sediment load) will bypass the structure. Operation during high flows would be facilitated by the adjustable height weir or crest gate. At low flows, the gate would start in the ‘up’ position and as flows increase, the gate would be lowered to maintain a constant water surface level in the diversion pool.

The existing intake is protected by a trash rack that withstands approach velocities of approximately 2.1 ft/sec and has openings of approximately 2 inches. This current arrangement does little to protect fish. The improved intake would have an approach velocity of 1.4 ft/sec and fine screens with openings of 3/32-inches. This proposed arrangement is expected to reduce the potential for fish to enter the intake. Additionally, the new intake is designed to be easily cleaned to prevent regions of high velocity on portions of the intake associated with debris build-up. Lastly,

the removal of the headworks in Area 1 would eliminate an impediment to fish movement and would re-establish the feasibility of fish passage through this area. As a result, Project effects on fish species are expected to be potentially beneficial.

City personnel would continue to provide maintenance of the diversion and intake structures as occurs under existing conditions.

3.3.3 AREA 3 – JPL EAST PARKING LOT

Once the parking structure on the JPL campus is completed and in use, JPL will no longer be running the shuttle buses from Area 3 to the JPL campus. Parking in Area 3 would be reduced from 1,132 spaces to a maximum of 100 spaces for recreational users in the Arroyo Seco Canyon area. Prior to the start of Project construction, no JPL employee or JPL visitor parking would occur in Area 3. JPL employees and JPL visitors would pass through Area 3 (through an access easement from the City) and over the JPL Bridge to access the new JPL On-Site Parking Structure at the JPL campus (on the west side of the Arroyo Seco). Thus, no change in JPL traffic volumes would occur in Area 3.

With the Project, vehicle access to the recreational parking lot and to the JPL Bridge would be provided from the south by the new two-lane asphalt road that would be located east of the new spreading basins. The road would then run northerly and divert to the western edge of the new recreational parking lot and connect to the new JPL security guardhouse before providing access across the bridge by JPL employees and visitors. A roundabout would be provided at the JPL guardhouse for vehicles not cleared for entry into the JPL property to allow vehicles to turn around and return to Windsor Avenue.

The new recreational parking lot, pet waste station, and restroom in Area 3 would be available for use by visitors of the Hahamongna Watershed Park and the ANF. Approximately 2,000 gallons per day of wastewater from the proposed restroom would be directed into the JPL sewer line. Restroom cleaning would be provided at least twice a week and trash would be collected at least once a week by existing City personnel.

The upper two new sedimentation basins (Basins A and B) would be operated independently or in parallel as surface water flows into the sedimentation basins prior to entering the spreading basins. The sedimentation basins would only be operated during storm events or when the water is too turbid to bypass the sedimentation basins. However, if one of the sedimentation basins is taken offline for maintenance, the entire flow would be received by the other basin. Sediments in Basins A and B would be periodically removed and hauled off to a disposal site, with the amount of sediment varying based on hydrology. The sediment volume is estimated to require off-site disposal at approximately 100 truckloads per year. This would replace the majority of sediment removal in the existing and new spreading basins.

Under normal operations when the water is clear, the sedimentation basins would be bypassed and surface water would be directed into the first spreading basin (Basin C). The new spreading basins would operate in series by filling the top-most basin and having water cascade down to the lower basin as each upper basin reaches its operating level. Approximately 3.1 acres of recharge area within the existing 4 spreading basins would be replaced with 8 spreading basins with 7.2 acres of recharge area. The increase in the recharge area by 4.1 acres would supplement the existing 2,300 ace-feet per year (afy) of recharge by an estimated additional 1,100 afy.

The frequency in which the spreading basins are cleaned would depend on the rate at which percolation degrades due to silts and clays in the diverted water. The City typically scrapes and tills the existing basins about once per year so the incremental maintenance needs for the

additional recharge area would not be significantly more, considering the benefit of the new sedimentation basins. When necessary, cleaning of the basins would continue to be accomplished by mechanically scraping the top layer of soil using front-end loaders, graders, or scrapers. Following removal, the surface would be disked or harrowed to loosen any soil compaction caused by cleaning. An estimated 100 truckloads of soil from the existing and proposed spreading basins would have to be disposed of off-site every 5 years.

3.4 FUNDING

The City of Pasadena and the ASF obtained a Proposition 84 grant in the amount of $3.271 million from the California Department of Water Resources for the Hahamongna Multi-Use Basin Project. The funds were awarded through an Integrated Regional Water Management Program Implementation Grant to the Greater Los Angeles Region. The Project is one of a suite of projects that were rolled up into a single grant agreement for the region that is being managed by the Los Angeles County Flood Control District. This grant would be used for the replacement of the intake structure to increase its capacity and for the construction of recreational amenities in the HWP.

The PWP would be funding the rest of the proposed improvements (i.e., Headworks removal, habitat restoration, and expansion of spreading basins).

3.5 AGENCY APPROVALS AND PERMITS

This IS/MND is intended to serve as the primary environmental document pursuant to CEQA for the Arroyo Seco Canyon Project, including discretionary approvals requested or required to implement the Project. In addition, this is the primary reference document for the formulation and implementation of a mitigation monitoring program for the Project.

As the Lead Agency, the Hearing Officer may adopt the IS/MND if it finds, on the basis of the whole record, that there is no substantial evidence that the Project would have a significant effect on the environment.

The Arroyo Seco is under the jurisdiction of various resource agencies, including the United States Army Corps of Engineers (USACE), the Los Angeles RWQCB, and the California Department of Fish and Wildlife (CDFW). Additionally, Area 1 includes land located within the ANF on property owned by the City of Pasadena. Also, the JPL campus is located on federal land in the City of La Cañada Flintridge.

Table 3.5-1 lists all the agencies that are known or expected to have permit or approval authority over the Project. Moreover, this IS/MND covers all federal, state, local government, and quasi-government approvals that may be needed to construct, implement, or operate the project, whether or not they are specifically identified in Table 3.5-1 or elsewhere in this IS/MND.

TABLE 3.5-1
AGENCY APPROVALS AND REQUIREMENTS

Agency	Approval/Permit Required	Purpose	Notes
City of Pasadena	Project approval	Approve the proposed Project and allocate City funds.	Including use of Proposition 84 grant funds.
	Easement	Authorize easement for JPL use of City land for vehicle access, guard shack, security fencing, utilities, and roundabout in Area 3	JPL access through Area 3 and use of access road, guard shack and roundabout
	Easement Amendment	Allow public access and utilities across JPL Bridge	Including public access on the JPL bridge sidewalk and allowing for sewer, electrical, and communications utilities and other public utility purposes in the JPL bridge
	Other agreement(s) to convey interest	Allow for agreement(s) with JPL as needed to construct and/or implement project	Agreement(s) may be needed for maintenance, right of entry, etc. to construct and/or operate project components
	Design Review	Approve the design of the proposed restroom building	In compliance with the Arroyo Seco Design Guidelines
	Conditional Use Permit	Allow for park and recreational facilities in the Open Space zone	In compliance with the City's Zoning Code
	Tree removal authorization	Allow removal of trees in areas to be disturbed.	In compliance with City Trees and Tree Protection Ordinance
USACE	Section 404 Nationwide Permit	Allow the discharge of dredge and fill material into "waters of the U.S.".	Nationwide Permit (NWP) required for stream and wetland restoration in Areas 1 and 2, and for maintenance of existing water diversion facilities in Area 2.
Los Angeles RWQCB	Section 401 Water Quality Certification	Protect water quality within "waters of the U.S.".	Water Quality Certification required for discharges to the Arroyo Seco associated with construction activities in Areas 1 and 2 and maintenance activities in Area 2.
CDFW	Section 1600 Streambed Alteration Agreement	Authorize changes to the natural flow or the bed, channel, or bank of any river, stream, or lake and associated impacts to biological resources.	Streambed Alteration Agreement required for habitat restoration in Area 1, disturbance of the stream channel during construction, and maintenance in Area 2 (existing permit expired in 2005).
USFS	Agreement	Allow water line connection	Water line connection from USFS Ranger Station to horse water trough and temporary irrigation system in Area 1
ASF	Approval	Use of Proposition 84 grant.	Must approve project as a Proposition 84 co-grantee with the City of Pasadena.

TABLE 3.5-1
AGENCY APPROVALS AND REQUIREMENTS

Agency	Approval/Permit Required	Purpose	Notes
JPL/NASA	Agreement(s) to convey interest	Allow for agreement(s) with City of Pasadena as needed to construct and/or implement project	Agreement(s) may be needed for maintenance, right of entry, etc. to construct and/or operate project components
	Easement Amendment	Allow public access and utilities across JPL Bridge	Including public access on the JPL bridge sidewalk and allowing for sewer, electrical, and communications utilities and other public utility purposes in the JPL bridge
	Easement Acceptance	Accept easement from City for JPL use of City land for vehicle access, guard shack, security fencing, utilities for power and communication, and roundabout in Area 3	JPL access through Area 3 and use of access road, guard shack and roundabout
Los Angeles County Sanitation Districts	Sewer Service Connection	Allow for the discharge of wastewater into the Sanitation District's wastewater treatment system.	The City or JPL shall consult with the District to determine if sewer service to the restroom in Area 3 requires a permit; payment of a connection fee; and/or an annual service fee.

USACE: U.S. Army Corps of Engineers; NWP: Nationwide Permit; Los Angeles RWQCB: Los Angeles Regional Water Quality Control Board; CDFW: California Department of Fish and Wildlife; USFS: United States Forest Service; ASF: Arroyo Seco Foundation; JPL: Jet Propulsion Laboratory; NASA: National Aeronautics and Space Administration.

SECTION 4.0 ENVIRONMENTAL ASSESSMENT

This section includes the completed CEQA environmental checklist form, as provided in Appendix G of the State CEQA Guidelines, as well as substantiation and clarification for each checklist response. The checklist form is used to assist in evaluating the potential environmental impacts of the Arroyo Seco Canyon Project and identifies whether the Project is expected to have potentially significant adverse impacts.

1. Project Title:	**ARROYO SECO CANYON PROJECT**
2. Lead Agency Name and Address:	City of Pasadena Planning and Community Development 175 North Garfield Avenue Pasadena California 91101-1704
3. Contact Person and Phone Number:	Jose Daniel Jimenez (626) 744-7137
4. Project Location:	In and along the Upper Arroyo Seco, upstream of Devil's Gate Dam and north of the intersection of Windsor Avenue and Ventura Street in Pasadena, Los Angeles County, CA: Area 1 – Arroyo Seco Headworks; Area 2 – Arroyo Seco Intake; and Area 3 – JPL East Parking Lot
5. Project Sponsor's Name and Address:	City of Pasadena Department of Water and Power 150 South Los Robles Avenue, Suite 200 Pasadena, California 91101
6. General Plan Designation/Zoning:	Open Space/Open Space and Planned Development-16

7. Description of Project: Restoration of a portion of the Arroyo Seco, reconstruction of surface water diversion facilities; expansion of spreading basins; and construction of recreational and educational amenities. See Section 3.0 for details.

8. Surrounding land uses and setting: The areas included in the Arroyo Seco Canyon Project are bound by residential uses in Pasadena and the community of Altadena to the east and south; open spaces in the ANF to the north; Devil's Gate Dam and Reservoir to the southwest; and the Arroyo Seco stream corridor, Oak Grove Park, and other recreational areas, the JPL campus, and residential areas in the City of La Cañada Flintridge on the west.

9. Other public agencies whose approval is required: USACE; Los Angeles RWQCB; CDFW; USFS; ASF; JPL; and Los Angeles County Sanitation Districts (See Table 3.5-1 above)

ENVIRONMENTAL FACTORS POTENTIALLY AFFECTED:

The environmental factors checked below would be potentially affected by this Project, involving at least one impact that requires mitigation, as indicated on the following pages.

- ☐ Aesthetics
- ☐ Air Quality
- ☒ Cultural Resources
- ☐ Geology and Soils
- ☒ Hazards and Hazardous Materials
- ☐ Land Use and Planning
- ☒ Noise
- ☐ Public Services
- ☒ Transportation/Traffic
- ☒ Mandatory Findings of Significance
- ☐ Agriculture and Forest Resources
- ☒ Biological Resources
- ☐ Energy
- ☐ Greenhouse Gas Emissions
- ☐ Hydrology and Water Quality
- ☐ Mineral Resources
- ☐ Population and Housing
- ☒ Recreation
- ☐ Utilities and Service Systems

DETERMINATION:

On the basis of this initial evaluation:

☐ I find that the proposed project COULD NOT have a significant effect on the environment, and a NEGATIVE DECLARATION will be prepared.

☒ I find that although the proposed project could have a significant effect on the environment, there will not be a significant effect in this case because revisions in the project have been made by or agreed to by the project proponent. A MITIGATED NEGATIVE DECLARATION will be prepared.

☐ I find that the proposed project MAY have a significant effect on the environment, and an ENVIRONMENTAL IMPACT REPORT is required.

☐ I find that the proposed project MAY have a "potentially significant impact" or "potentially significant unless mitigated" impact on the environment, but at least one effect (1) has been adequately analyzed in an earlier document pursuant to applicable legal standards, and (2) has been addressed by mitigation measures based on the earlier analysis as described on attached sheets. An ENVIRONMENTAL IMPACT REPORT is required, but it must analyze only the effects that remain to be addressed.

☐ I find that although the proposed project could have a significant effect on the environment, because all potentially significant effects (a) have been analyzed adequately in an earlier EIR or NEGATIVE DECLARATION pursuant to applicable standards, and (b) have been avoided or mitigated pursuant to that earlier EIR or NEGATIVE DECLARATION, including revisions or mitigation measures that are imposed upon the proposed project, nothing further is required.

EVALUATION OF ENVIRONMENTAL IMPACTS:

1) A brief explanation is required for all answers except "No Impact" answers that are adequately supported by the information sources a lead agency cites in the parentheses following each question. A "No Impact" answer is adequately supported if the referenced information sources show that the impact simply does not apply to projects like the one involved (e.g., the project falls outside a fault rupture zone). A "No Impact" answer should be explained where it is based on project-specific factors as well as general standards (e.g., the project will not expose sensitive receptors to pollutants, based on a project-specific screening analysis).

2) All answers must take account of the whole action involved, including off-site as well as on-site, cumulative as well as project-level, indirect as well as direct, and construction as well as operational impacts.

3) Once the lead agency has determined that a particular physical impact may occur, then the checklist answers must indicate whether the impact is potentially significant, less than significant with mitigation, or less than significant. "Potentially Significant Impact' is appropriate if there is substantial evidence that an effect is significant. If there are one or more "Potentially Significant Impact" entries when the determination is made, an EIR is required.

4) "Negative Declaration: Less Than Significant With Mitigation Incorporated" applies where the incorporation of mitigation measures has reduced an effect from "Potentially Significant Unless Mitigation Incorporated" applies where the incorporation of mitigation measures has reduced an effect from "Potentially Significant Impact" to a "Less than Significant Impact." The Lead Agency must describe the mitigation measures and briefly explain how they reduce the effect to a less than significant level (mitigation measures from Section 21, "Earlier Analysis," may be cross-referenced).

5) Earlier analysis may be used where, pursuant to the tiering, program EIR, or other CEQA process, an effect has been adequately analyzed in an earlier EIR or negative declaration. See CEQA Guidelines Section 15063(c)(3)(D). Earlier analyses are discussed in Section 21 at the end of the checklist.

   a) Earlier Analysis Used. Identify and state where they are available for review.

   b) Impacts Adequately Addressed. Identify which effects from the above checklist were within the scope of and adequately analyzed in an earlier document pursuant to applicable legal standards, and state whether such effects were addressed by mitigation measures based on the earlier analysis.

   c) Mitigation Measures. For effects that are "less than Significant with Mitigation Measures Incorporated," describe the mitigation measures which were incorporated or refined from the earlier documents and the extent to which address site-specific conditions for the project.

6) Lead agencies are encouraged to incorporate into the checklist references to information sources for potential impacts (e.g., general plans, zoning ordinances). Reference to a previously prepared or outside document should, where appropriate, include a reference to the page or pages where the statement is substantiated.

7) Supporting Information Sources: A source list should be attached, and other sources used or individuals contacted should be cited in the discussion.

8) The explanation of each issue should identify:

   a) The significance criteria or threshold, if any, used to evaluate each question; and

   b) The mitigation measure identified, if any, to reduce the impact to less than significant

4.1 AESTHETICS	Potentially Significant Impact	Less than Significant with Mitigation	Less than Significant Impact	No Impact
Would the project:				
a) Have a substantial adverse effect on a scenic vista?	☐	☐	☒	☐
b) Substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway?	☐	☐	☒	☐
c) Substantially degrade the existing visual character or quality of the site and its surroundings?	☐	☒	☐	☐
d) Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area?	☐	☐	☒	☐

4.1.1 EXISTING CONDITIONS

General Visual Character

The Project site is in an area that offers views of the San Gabriel Mountains and Arroyo Seco. The Upper Arroyo Seco is an open space area that features developed (mostly passive) recreational areas and a reservoir just north of Devil's Gate Dam and within the HWP. The area upstream of the dam transitions into a more natural environment, with the Arroyo Seco flowing through the canyon near the base of the San Gabriel Mountains. Water is perennial in the braided stream, with a large amount of cobbles and boulders. The Project site has views of the Arroyo Seco and is part of the natural landscape of the Upper Arroyo Seco.

Area 1 is defined by a bend in the stream channel with a damaged Headworks structure across the channel; a slightly raised terrace where the sedimentation basins were once located; and a paved/dirt Gabrielino Trail/access road along the eastern edge of the terrace. This area is flanked by vegetated hillsides to the east and west; and the USFS Ranger Station with three residences to the southeast.

Area 2 is a portion of the Arroyo Seco with a diversion structure across the channel; a training wall along the east side of the stream, upstream of the diversion structure; an intake structure at the southern end of the training wall; the Gabrielino Trail/access road along the eastern edge; and a bridge crossing the stream at the southern end. This area is also flanked by vegetated hillsides to the east and west. Two historic bridges (Bridge No. 2 and Bridge No. 3) cross the Arroyo Seco at the southern end of Area 2.

Area 3 is an elongated paved parking lot surrounded by a chain-link fence, with a rising slope to the east and large open sludge ponds/spreading basins to the west. Dirt roads surround the ponds/basins. The Arroyo Seco stream channel is west of the ponds/basins and is not within the Area 3 boundary. There are overhead power and communication lines that cross Area 3 to serve the various developments in the surrounding area and the light poles in the parking lot. A concrete bridge goes over the Arroyo Seco at the northern end of Area 3, leading into the JPL campus. An access road (Explorer Road) extends south from the southern end of Area 3 along a slope and ends at the intersection of Windsor Avenue and Ventura Street.

Due to the minimal amount of aboveground structures, views of the areas where improvements are proposed are generally confined to viewers on nearby roads and trails. These viewers include hikers; bicyclists; equestrians; maintenance personnel; public service responders; residents near Area 1; employees and visitors of JPL that park in Area 3; and other visitors that specifically go to these areas.

Scenic Resources

Several freeways and highways have been included in the California Scenic Highway System as "Officially Designated Scenic Highways" or "Eligible State Scenic Highways". The nearest Officially Designated Scenic Highway is SR-2, which runs through the San Gabriel Mountains from I-210 in La Cañada Flintridge to the San Bernardino County line (Caltrans 2013a). SR-2 is located approximately 1.2 miles northwest of Area 1 at its nearest point, but does not have views of the Arroyo Seco Canyon or HWP due to distance, slopes, and intervening vegetation.

The California Scenic Highway Program also designates I-210 as an Eligible Scenic Highway from the I-5 to the SR-134 (Caltrans 2013a). This freeway runs along the southern edge of Devil's Gate Dam. Travelers on the I-210 can see some of the vegetation within the Devil's Gate Reservoir and the distant mountains, but the spreading basins and parking lot in Area 3 and the more distant Arroyo Seco Canyon are not visible to travelers on I-210.

The Pasadena Comprehensive General Plan includes a Scenic Highways Element that seeks to provide an aesthetic visual experience for travelers on the City's street system. It includes objectives and policies to preserve the aesthetic qualities of streets and highways in Pasadena. The Scenic Highways Element does not designate any roads or highways in the City as Scenic Highways or Scenic Corridors. The Element provides guidelines for the development of a scenic corridor plan and includes a map that shows a portion of the Angeles Crest Highway (in the City) as an Official State Scenic Highway and two "Los Angeles County Recommended Scenic Highways (Unofficial): Linda Vista Avenue and Highland Drive (south of the I-210) and Huntington Drive (from Fremont Street to I-210).[3] These roads do not offer views of the Upper Arroyo Seco.

4.1.2 IMPACT ANALYSIS

Project Design Features

PDF AES-1 Public improvements in Areas 1 and 2 will be designed to comply with the Arroyo Seco Design Guidelines that address habitat restoration and landscaping using high value native plant species that would contribute to the genetic material of the Arroyo Seco, walls, signs, and site furnishings that are consistent with those found in the Hahamongna Watershed Park (HWP), subject to design review and approval by the City's Planning Division.

Regulatory Requirements

RR AES-1 The proposed improvements in Area 3 are required to be designed to comply with applicable criteria in the Arroyo Seco Design Guidelines, subject to design review and approval by the City's Planning Division.

[3] These roads are designated in the 1974 Los Angeles County Scenic Highways Element as Second Priority Routes proposed for further study. The Scenic Highways map in the 2014 Draft Conservation and Natural Resources Element no longer shows these roads as adopted or eligible Scenic Highways.

Impact Discussion

a) Would the project have a substantial adverse effect on a scenic vista?

c) Would the project substantially degrade the existing visual character or quality of the site and its surroundings?

Less Than Significant Impact.

Area 1 and Area 2 Impacts. Views of the Arroyo Seco and surrounding natural areas from the Gabrielino Trail can be considered a scenic vista. The visual character of the area can generally be described as including a relatively undisturbed natural stream and associated vegetation in a heavily-wooded canyon setting. The beauty of the area provides an important amenity for many recreational users. The Project proposes to restore a portion of the Upper Arroyo Seco in Area 1 in order to provide a more natural riparian corridor with native vegetation and natural elements. A nature trail through the riparian corridor would be provided, leading to a rest area/picnic area that would be constructed beside the stream. The Project would not involve the removal of any unique natural features. However, the Project would disturb vegetative cover, including riparian thickets and oak and sycamore woodlands. A total of 17 trees that are protected by the City's Tree Ordinance and the California Fish and Game Code are also expected to be removed. Removal of vegetation and trees is discussed further in Section 4.4, Biological Resources.

The proposed revegetation efforts and preliminary planting palette include four main restoration areas: Riparian Floodplain, Natural Uplands, Irrigated Picnic Area, and Willow Baffles. The trees to be planted would include coast live oak, California sycamore, Fremont cottonwood, California bay laurel, or other suitable native trees, with an associated irrigation system to support the tree establishment. The picnic tables, benches, signs, and horse water trough would utilize natural materials and/or be designed to blend with the landscape in accordance with the Arroyo Seco Design Guidelines (see PDF AES-1) and would not degrade the visual quality of the Arroyo Seco Canyon. The proposed improvements would create a more natural landscape for Area 1 and would provide greater opportunities to enjoy the area's natural open space. Aesthetic impacts related to long-term operations in Area 1 would be less than significant.

A new weir/sluice gate would span the width of the stream in Area 2, along with wing walls; riprap on both sides of the weir/sluice gate; and a control equipment enclosure near the Gabrielino Trail. The eroded portion of the Gabrielino Trail/access road would also be rebuilt to include riprap protection and a rock wall. While these structures would not complement the surrounding landscape, the man-made training wall, intake structure, diversion structure, chain-link fence, and control equipment enclosure in Area 2 have been in place for a long time. The new facilities are replacements for existing damaged infrastructure and are not new structures in a pristine setting. As such, flood control facilities are a component of the existing setting in Area 2 and the proposed Project would not result in an impact that could adversely affect a scenic vista or substantially degrade the visual character of the area. Additionally, the Project would reconstruct and improve these facilities, and the public facilities (e.g., signs, walls, fences, etc.) would be designed in accordance with the Arroyo Seco Design Guidelines (see PDF AES-1). Aesthetic impacts related to long-term operations within Area 2 would be less than significant.

Construction activities would detract from the natural setting, albeit not pristine, as construction equipment, staging areas, excavation, grading activities, demolition, and construction work would be visible to persons near the disturbed areas during the construction phase. Construction equipment and activities are a temporary visual nuisance that are commonplace; however, this impact is more noticeable in the context of the natural setting in Area 1, which is visited by people wishing to experience a natural non-urban setting. Construction activities would temporarily

diminish the visual quality of the areas being disturbed, and possibly the scenic vistas from portions of the Gabrielino Trail. However, this impact would be a short-term visual nuisance. Also, security fencing that may be provided around construction work areas would shield views of construction activities. The security fencing would also be located around equipment staging areas, which includes parking for vehicles/equipment when not in use and stockpiled materials. Impacts would be less than significant.

Views of the historic bridges along the Gabrielino Trail (Bridge No. 2 and Bridge No. 3) would also be affected during construction. These bridges would be protected during construction activities through the construction of a temporary bridge over Bridge No. 3 and the placement of plywood along the railing and balustrades of Bridge No. 2. The temporary bridge and plywood cover would protect and preserve these bridges from damage from passing construction equipment and trucks and would be removed at the end of construction activities. Short-term impacts on views of the bridges would be less than significant. No long-term impacts related to views of the historic bridges would occur.

The visual impacts of construction activities in Area 1 and Area 2 would be short-term and less than significant.

Area 3 Impacts. Area 3 is not considered a scenic vista or a scenic resource. This area consists of a developed parking lot, sludge ponds and spreading basins. However, the area does allow for views of the surrounding scenic areas, including the reservoir behind Devil's Gate, the Arroyo Seco, and the foothills of the San Gabriel Mountains. The creation of a small parking lot for recreational users, a restroom, and a JPL security guard house, as well as expansion of the spreading basins, would lead to a change in visual quality of Area 3.

As stated above in Section 3.2, Project Demolition and Construction, at the time that Project construction begins in Summer 2015, it is anticipated that the JPL East Parking Lot would no longer exist; only 47,164 square feet of paving on the temporary access road would remain as an existing condition on the Project site. The ground surface would be scraped clear of the parking lot and substrate, leaving exposed soils upon removal of the JPL East Parking Lot. The creation of the spreading basins would expand views of open ground and open water, which would be more natural than the existing paved parking lot or the base ground that would remain after JPL removes the parking lot pavement. This could be interpreted by some to be a beneficial visual impact, as there may be the potential for increased use of the open water by waterfowl.

The proposed restroom would feature wood, stone, and earth-tone colors to match its natural surroundings. As required under RR AES-1, the proposed improvements, including trails, would be designed to comply with the Arroyo Seco Design Guidelines. Although these would be new facilities, they would be relatively small, and compliance with RR AES-1 would reduce the potential for visual conflict between proposed structures and the natural setting by reflecting the natural surroundings and cultural heritage of the Arroyo Seco. Aesthetic impacts related to long-term operations within Area 3 would be less than significant.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified significant adverse impacts related to aesthetics in the HWP due to the increase in parking areas, parking lot lighting, new restrooms, active recreation areas, and the equestrian refuse disposal area. The Master EIR stated that planned park entrance improvements, widening of the spreading basins, flood management, lakes, overlooks, trails, bicycle routes, habitat conservation, utility improvements, security fencing, and gates are not expected to degrade the visual qualities of the site.

The Project does not propose an expansion of parking areas, parking lot lighting, or active recreation areas, but does include the construction of a new restroom at the northern end of Area 3.

The Master EIR provided mitigation measures to reduce significant adverse aesthetic impacts. The mitigation measures for construction sites from the Master EIR (Measure Aesthetic-1 and Measure Aesthetic-2) are similar to the proposed screening of construction areas and the maintenance of staging areas for safety and security reasons. The mitigation measures in the Master EIR related to new structures and improvements (Measure Aesthetic-6 and Measure Aesthetic-7) are similar to RR AES-1, which would be implemented by the Project. The Master EIR stated that impacts on aesthetics would be less than significant after mitigation.

b) Would the project substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway?

Less Than Significant Impact.

Areas 1, 2 and 3 Impacts. The proposed improvements in Areas 1, 2, and 3 would not be visible from SR-2 (an Officially Designated Scenic Highway) or I-210 (an Eligible Scenic Highway). The Project site is not located within the viewsheds of SR-2 or I-210. Thus, no impacts on scenic resources along these scenic highways would occur.

There are no City-designated Scenic Corridors, and the unofficial Scenic Corridors on Huntington Drive, Highland Drive, and Linda Vista Avenue do not offer views of the Upper Arroyo Seco or the Project site. The Project does not propose a scenic corridor plan and would not affect unofficial scenic corridors or the City's traditional urban design form and historic character.

As discussed above, the Arroyo Seco would be disturbed by construction activities. However, improvements in Area 1 would improve the riparian corridor and natural setting of stream. While a number of mature trees would be removed as part of Project construction, which would affect views of the natural landscape along the Upper Arroyo Seco, replacement of these trees would be provided under PDF BIO-1 and RR BIO-2 (see Section 4.4, Biological Resources).

Views of the historic bridges along the Gabrielino Trail would also be affected during construction as temporary bridges are built over Bridge No. 1 and Bridge No. 3 and as plywood is placed along the railings and balustrades of Bridge No. 2. This impact would be short term and less than significant.

Thus, impacts on scenic resources in the Upper Arroyo Seco would be temporary and less than significant. No mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that no impacts to scenic vistas and scenic highways would occur with implementation of the Arroyo Seco Master Plan, including the HWMP.

d) Would the project create a new source of substantial light or glare which would adversely affect day or nighttime views in the area?

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. No new lighting is proposed in Areas 1 or 2. In Area 3, the existing JPL East Parking Lot is lighted; however, JPL would remove the parking lot improvements, including the light poles prior to the start of construction activities for the Project analyzed herein.

No lighting is proposed in the new recreational parking lot, along the access road, or near the spreading basins or trails; also, there would not be any reflective surfaces that could result in glare. The proposed guard station and restroom in Area 3 would have interior and exterior lighting, but these structures are relatively small and would be surrounded by the access road, the new parking lot, the existing slopes, and the trails. In compliance with the Arroyo Seco Design Guidelines (RR AES-1), no lighting is proposed in natural areas; all proposed lighting fixtures would be focused downward and include appropriate shields; and proposed lights would serve both safety and aesthetic purposes. Also, no construction activities are proposed during the nighttime hours. Therefore, there would be less than significant impacts related to light and glare and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that parking lot lighting would result in significant adverse impacts. The Master EIR included mitigation measures (Measure Aesthetic-3 and Measure Aesthetic-4) to reduce significant impacts related to new sources of light. With compliance with the design standards for lighting in the Arroyo Seco Design Guidelines, Measure Aesthetic-3 and Measure Aesthetic-4 would not be necessary to further reduce the impacts of proposed lighting in Area 3 to below a level of significance.

4.1.3 MITIGATION MEASURE

Impacts on aesthetics would be less than significant; therefore, no mitigation measures are required.

4.2 AGRICULTURE AND FOREST RESOURCES	Potentially Significant Impact	Less than Significant with Mitigation	Less than Significant Impact	No Impact
Would the project:				
a) Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland), as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Resources Agency, to non-agricultural use?	☐	☐	☐	☒
b) Conflict with existing zoning for agricultural use, or a Williamson Act contract?	☐	☐	☐	☒
c) Conflict with existing zoning for, or cause rezoning of, forest land (as defined in Public Resources Code section 12220[g]), timberland (as defined by Public Resources Code section 4526), or timberland zoned Timberland Production (as defined by Government Code section 51104[g])?	☐	☐	☐	☒
d) Result in the loss of forest land or conversion of forest land to non-forest use?	☐	☐	☐	☒
e) Involve other changes in the existing environment which, due to their location or nature, could result in conversion of Farmland, to non-agricultural use or conversion of forest land to non-forest use?	☐	☐	☐	☒

4.2.1 EXISTING CONDITIONS

The California Department of Conservation administers the Farmland Mapping and Monitoring Program (FMMP) pursuant to Section 65570 of the *California Government Code.* Due to the predominance of urban development in the southern and central sections of Los Angeles County (which includes the City of Pasadena), this area was not included in the mapping effort by the FMMP (FMMP 2011). As such, there are no designated farmlands in or near the Arroyo Seco Canyon. Also, there are no existing or ongoing agricultural activities in or near the Arroyo Seco Canyon.

The Upper Arroyo Seco is designated and zoned as Open Space and a portion of Area 3 is zoned Planned Development – 16 in the City of Pasadena's Land Use Plan and Zoning Map (Pasadena 2009, 2012b). The Arroyo Seco originates in the ANF, and Area 1 is located within the boundaries of the ANF, while Areas 2 and 3 are located just south of the ANF. Area 1 is designated in the USFS Land Management Plan as Non-Forest System Land (USFS 2005a).

4.2.2 IMPACT ANALYSIS

Impact Discussion

a) Would the project convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland), as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Resources Agency, to non-agricultural use?

b) Would the project conflict with existing zoning for agricultural use, or a Williamson Act contract?

e) Would the project involve other changes in the existing environment which, due to their location or nature, could result in conversion of Farmland to non-agricultural use or conversion of forest land to non-forest use?

No Impact.

Areas 1, 2 and 3 Impacts. As discussed above, there is no designated Farmland or Farmland Soils within or near the Upper Arroyo Seco where the Project is proposed. Thus, no impacts on Farmland or Farmland Soils would occur. The Arroyo Seco Canyon and the surrounding area are not zoned for agricultural use, and there are no Williamson Act contracts in the City. Therefore, the Project would not conflict with an agricultural zone or Williamson Act contract. Also, there are no agricultural activities in or near the Upper Arroyo Seco, and no farmland conversion or impacts to agricultural uses would accompany the Project. Therefore, no impacts on agricultural resources would occur and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not address impacts on agricultural resources since the Initial Study for the Arroyo Seco Master Plan had determined earlier that no significant impacts to agricultural resources are anticipated.

c) Would the project conflict with existing zoning for, or cause rezoning of, forest land (as defined in Public Resources Code, Section 12220[g]), timberland (as defined by Public Resources Code, Section 4526), or timberland zoned Timberland Production (as defined by Government Code, Section 51104[g])?

d) Would the project result in the loss of forest land or conversion of forest land to non-forest use?

e) Would the project involve other changes in the existing environment which, due to their location or nature, could result in conversion of Farmland to non-agricultural use or conversion of forest land to non-forest use?

No Impact.

Areas 1, 2 and 3 Impacts. There are no timberland or timberland production zones in the City. The Open Space designation and zone for the Upper Arroyo Seco applies to active and passive public recreational facilities and natural open spaces that are environmentally and ecologically significant, while the Planned Development zone applies to sites developed with a particular mix of uses, appearance, land use compatibility, or special sensitivity to neighborhood character (Pasadena 2004). The proposed improvements would occur along the Arroyo Seco, where no forest or timberland resources have been identified in the City of Pasadena Comprehensive General Plan.

While Area 1 is located within the ANF, it is designated as Non-Forest System Land. The Project would not conflict with the adjacent Low Density Residential (LD) or the Open Space-National Forest (O-NF) designation of unincorporated County land to the north and east of Area 1 (LACDRP 2009). The Project would not conflict with the Back Country Motorized Use Restricted (BCMUR) zone north of Area 1, as designated in the ANF's Land Management Plan. The BCMUR zone considers the restoration of vegetation condition as a suitable activity or use and supports non-motorized dispersed recreational opportunities, including camping, hiking, biking, hunting and fishing (USFS 2005b).

No loss of forest resources or conversion of forest land to non-forest use will occur with the Project as the improvements in Area 1 would restore the riparian habitats to protect native plant and animal species and would provide recreational amenities to support recreational uses in the area. Long-term recreational activities in the Arroyo Seco Canyon and operation and maintenance activities on the PWP facilities would not adversely affect nearby forest resources. No impact on forest resources would occur with the Project and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not address impacts on forest resources.

4.2.3 MITIGATION MEASURES

There would be no impacts on agriculture and forest resources; therefore, no mitigation measures are required.

4.3 AIR QUALITY	Potentially Significant Impact	Less than Significant with Mitigation	Less than Significant Impact	No Impact
Would the project:				
a) Conflict with or obstruct implementation of the applicable air quality plan?	☐	☐	☐	☒
b) Violate any air quality standard or contribute substantially to an existing or projected air quality violation?	☐	☐	☒	☐
c) Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is in non-attainment under an applicable federal or state ambient air quality standard (including releasing emissions which exceed quantitative thresholds for ozone precursors)?	☐	☐	☒	☐
d) Expose sensitive receptors to substantial pollutant concentrations?	☐	☐	☒	☐
e) Create objectionable odors affecting a substantial number of people?	☐	☐	☒	☐

4.3.1 EXISTING CONDITIONS

The Project site is located in the Los Angeles County portion of the South Coast Air Basin (SoCAB) and, for air quality regulation and permitting, is under the jurisdiction of the South Coast Air Quality Management District (SCAQMD). Both the State of California (State) and the U.S. Environmental Protection Agency (USEPA) have established health-based Ambient Air Quality Standards (AAQS) for air pollutants, which are known as “criteria pollutants”. The AAQS are designed to protect the health and welfare of the populace within a reasonable margin of safety.

The AAQS for ozone (O_3), carbon monoxide (CO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), inhalable particulate matter with a diameter of 10 microns or less (PM10), fine particulate matter with a diameter of 2.5 microns or less (PM2.5), and lead are shown in Table 4.3-1.

TABLE 4.3-1
CALIFORNIA AND NATIONAL AMBIENT AIR QUALITY STANDARDS

Pollutant	Averaging Time	California Standards	Federal Standards	
			Primary[a]	Secondary[b]
O_3	1 Hour	0.09 ppm (180 µg/m^3)	–	–
	8 Hour	0.070 ppm (137 µg/m^3)	0.075 ppm (147 µg/m^3)	Same as Primary
PM10	24 Hour	50 µg/m^3	150 µg/m^3	Same as Primary
	AAM	20 µg/m^3	–	Same as Primary
PM2.5	24 Hour	–	35 µg/m^3	Same as Primary
	AAM	12 µg/m^3	12.0 µg/m^3	Same as Primary
CO	1 Hour	20 ppm (23 mg/m^3)	35 ppm (40 mg/m^3)	–
	8 Hour	9.0 ppm (10 mg/m^3)	9 ppm (10 mg/m^3)	–
	8 Hour (Lake Tahoe)	6 ppm (7 mg/m^3)	–	–
NO_2	AAM	0.030 ppm (57 µg/m^3)	0.053 ppm (100 µg/m^3)	Same as Primary
	1 Hour	0.18 ppm (339 µg/m^3)	0.100 ppm (188 µg/m^3)	–
SO_2	24 Hour	0.04 ppm (105 µg/m^3)	–	–
	3 Hour	–	–	0.5 ppm (1,300 µg/m^3)
	1 Hour	0.25 ppm (655 µg/m^3)	0.075 ppm (196 µg/m^3)	–
Lead	30-day Avg.	1.5 µg/m^3	–	–
	Calendar Quarter	–	1.5 µg/m^3	Same as Primary
	Rolling 3-month Avg.	–	0.15 µg/m^3	
Visibility Reducing Particles	8 hour	Extinction coefficient of 0.23 per km – visibility ≥ 10 miles (0.07 per km – ≥30 miles for Lake Tahoe)	**No Federal Standards**	
Sulfates	24 Hour	25 µg/m^3		
Hydrogen Sulfide	1 Hour	0.03 ppm (42 µg/m^3)		
Vinyl Chloride	24 Hour	0.01 ppm (26 µg/m^3)		

O_3: ozone; µg/m^3: micrograms per cubic meter; PM10: large particulate matter; AAM: Annual Arithmetic Mean; PM2.5: fine particulate matter; CO: carbon monoxide; mg/m^3: milligrams per cubic meter; NO_2: nitrogen dioxide; SO_2: sulfur dioxide; ppm: parts per million; km: kilometer; –: No Standard.

[a] *National Primary Standards:* The levels of air quality necessary, within an adequate margin of safety, to protect the public health.

[b] *National Secondary Standards:* The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.

Note: More detailed information in the data presented in this table can be found at the CARB website (www.arb.ca.gov).

Source: CARB 2013b.

Regional air quality is defined by whether the area has attained State and federal air quality standards, as determined by air quality data from various monitoring stations. Areas that are considered in "nonattainment" are required to prepare plans and implement measures that will bring the region into "attainment". When an area has been reclassified from nonattainment to attainment for a federal standard, the status is identified as "maintenance", and there must be a plan and measures established that will keep the region in attainment for the next ten years.

For the California Air Resources Board (CARB), an "unclassified" designation indicates that the air quality data for the area are incomplete and there are no standards to support a designation of attainment or nonattainment. Table 4.3-2 summarizes the attainment status of the SoCAB for the criteria pollutants.

TABLE 4.3-2
DESIGNATIONS OF CRITERIA POLLUTANTS IN THE SOUTH COAST AIR BASIN

Pollutant	State	Federal
O_3 (1-hour)	Nonattainment	No Standard
O_3 (8-hour)		Extreme Nonattainment
PM10	Nonattainment	Attainment/Maintenance
PM2.5	Nonattainment	Nonattainment
CO	Attainment	Attainment/Maintenance
NO_2	Nonattainment[a]	Attainment/Maintenance
SO_2	Attainment	Attainment
Lead	Nonattainment/Attainment[a,b]	Nonattainment/Attainment
All others	Attainment/Unclassified	No Standards

O_3: ozone; PM10: respirable particulate matter with a diameter of 10 microns or less; PM2.5: fine particulate matter with a diameter of 2.5 microns or less; CO: carbon monoxide; NO_2: nitrogen dioxide; SO_2: sulfur dioxide.

[a] CARB Executive Order R-14-001 (February 25, 2014) reclassifies the SoCAB to Attainment for NO_2 and Lead. The redesignation will become effective July 1, 2014.

[b] Los Angeles County is classified as nonattainment for lead; the remainder of the SoCAB is in attainment of the State and federal standards.

Sources: CARB 2014a, 2014b; USEPA 2013c.

The nearest sensitive receptors (i.e., residential homes) to the Project site include the USFS Ranger Station, which includes three dwelling units providing housing for USFS Rangers; these are located just east of the Gabrielino Trail in Area 1. The nearest sensitive receptors to Area 2 include single-family residences located along Canyon Dell Drive and Aralia Road approximately 800 feet to the east in the community of Altadena. The nearest sensitive receptors to Area 3 include single-family residences located along Ridgeview Drive, approximately 225 feet to the east in the community of Altadena.

4.3.2 IMPACT ANALYSIS

Regulatory Requirements

RR AQ-1 During construction, the Contractor is required to comply with the South Coast Air Quality Management District's (SCAQMD's) Rule 403, Fugitive Dust, which requires the implementation of best available control measures (BACM) for any activity or man-made condition capable of generating fugitive dust including, but not limited to, earth-moving activities, construction/demolition activities, disturbed surface area, or heavy- and light-duty vehicular movement. The BACMs include stabilizing soil; watering surface soils and crushed materials; covering hauls or providing freeboard; preventing track-out; and limiting vehicle speeds and wind barriers, among others.

RR AQ-2 In accordance with Section 2449(d)(3) of the California Air Resources Board's (CARB's) Regulation for In-Use Off-Road Diesel-Fueled Fleets, construction equipment and vehicles are required to limit idling times to no more than five consecutive minutes.

Impact Discussion

a) Would the project conflict with or obstruct implementation of the applicable air quality plan?

No Impact.

Areas 1, 2 and 3 Impacts. The SCAQMD develops rules and regulations; establishes permitting requirements for stationary sources; inspects emissions sources; and enforces such measures through educational programs or fines, when necessary. It is directly responsible for reducing emissions from stationary (area and point), mobile, and indirect sources and has prepared an Air Quality Management Plans (AQMP) that establishes a program of rules and regulations directed at attaining the National Ambient Air Quality Standards (NAAQS) and California Ambient Air Quality Standards (CAAQS).

On December 7, 2012, the SCAQMD adopted the 2012 AQMP, which is a regional and multi-agency effort (SCAQMD, CARB, Southern California Association of Governments [SCAG], and USEPA). The 2012 AQMP incorporates the latest scientific and technical information and planning assumptions, including the 2012 Regional Transportation Plan/Sustainable Communities Strategy (RTP/SCS); updated emission inventory methodologies for various source categories; and SCAG's latest growth forecasts. On December 20, 2012, the 2012 AQMP was submitted to CARB and the USEPA for concurrent review and approval for inclusion in the SIP (SCAQMD 2013a). The 2012 AQMP was approved by the CARB on January 25, 2013 (CARB 2014c).

The main purpose of an AQMP is to bring an area into compliance with the requirements of federal and State air quality standards. For a project to be consistent with the AQMP, the pollutants emitted from the project should not (1) exceed the SCAQMD CEQA air quality significance thresholds or (2) conflict with or exceed the assumptions in the AQMP. As shown in Threshold 4.3(b) below, pollutant emissions from the proposed Project would be less than the SCAQMD thresholds and would not result in a significant impact. The Project is consistent with the Zoning and General Plan Land Use designations for the site and is therefore consistent with the growth expectations for the region. Further, the proposed Project would not result in development or new land uses that have not been anticipated in the AQMP. No conflict with the 2012 AQMP would occur with the proposed Project. No impact is expected and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not identify a potential conflict with the AQMP.

b) Would the project violate any air quality standard or contribute substantially to an existing or projected air quality violation?

Less Than Significant Impact.

Areas 1, 2 and 3 Impacts. The SCAQMD has adopted significance thresholds to assess the regional impact of air pollutant emissions in the SoCAB. Table 4.3-3, SCAQMD Criteria Pollutant Mass Emissions Significance Thresholds, summarizes the SCAQMD's mass emissions thresholds, which are presented for both short-term construction and long-term operational emissions. A project with emissions rates below these thresholds is considered to have a less than significant effect on air quality.

TABLE 4.3-3
SCAQMD CRITERIA POLLUTANT SIGNIFICANT MASS EMISSIONS SIGNIFICANCE THRESHOLDS (LBS/DAY)

Criteria Pollutant	Construction	Operation
VOC	75	55
NOx	100	55
CO	550	550
SOx	150	150
PM10	150	150
PM2.5	55	55

SCAQMD: South Coast Air Quality Management District; lbs/day: pounds per day; VOC: volatile organic compounds; NOx: oxides of nitrogen; CO: carbon monoxide; SOx: oxides of sulfur; PM10: respirable particulate matter with a diameter of 10 microns or less; PM2.5: fine particulate matter with a diameter of 2.5 microns or less.

Source: SCAQMD 2011.

Regional Construction Impacts

The SCAQMD has established methodologies to quantify air pollutant emissions associated with construction activities, such as air pollutant emissions generated by operation of on-site construction equipment; fugitive dust emissions related to trenching and earthwork activities; and mobile (tailpipe) emissions from construction worker vehicles and haul/delivery truck trips. Emissions would vary from day to day, depending on the level of activity; the specific type of construction activity occurring; and, for fugitive dust, prevailing weather conditions.

A construction-period mass emissions inventory was compiled based on an estimate of construction equipment as well as scheduling and Project phasing assumptions. More specifically, the mass emissions analysis takes into account the following:

- Combustion emissions from operating on-site stationary and mobile construction equipment.
- Fugitive dust emissions from demolition, site preparation, and grading phases.
- Mobile-source combustion emissions and fugitive dust from worker commute and truck travel.

For the purposes of estimating emissions associated with construction activities, a conservative timeframe of March 2015 through April 2016 was applied to the modelling (as later dates would generally result in less emissions). Emissions were calculated using the California Emissions Estimator Model (CalEEMod) emissions inventory model (SCAQMD 2013b). CalEEMod is a computer program accepted by the SCAQMD that can be used to estimate anticipated emissions associated with land development projects in California. CalEEMod has separate databases for specific counties and air districts, and the Los Angeles County database was used for the proposed Project. Consistent with the requirements of SCAQMD Rule 403 (RR AQ-1), watering for dust control is assumed in the emissions calculations.

The mass emissions thresholds (see Table 4.3-3) are based on the rate of emissions (i.e., pounds of pollutants emitted per day). Therefore, the quantity, duration, and the intensity of construction activities are important in ensuring analysis of worst-case (i.e., maximum daily emissions) scenarios. Project activities (e.g., demolition, grading, building construction) are identified by start date and duration, as described in Table 3.2-1. Each activity has associated off-road equipment (e.g., dozers, backhoes, cranes) and on-road vehicles (e.g., haul trucks, concrete trucks, worker

commute vehicles). The City may choose to add a shaker during the grading of Area 3 to separate excavated aggregate and an additional front-end loader to support the shaker. The emissions calculations assume the shaker and loader would be operating. Detailed construction assumptions and CalEEMod inputs and outputs can be found in Appendix A.

Maximum daily emissions during the peak work day are shown in Table 4.3-4, Estimated Maximum Daily Construction Emissions. Actual emissions could be less than those forecasted due to the conservative nature of the assumptions incorporated into the CalEEMod program regarding phasing. If construction is delayed or occurs over a longer time period, emissions could be reduced because of (1) a more modern and cleaner-burning construction equipment fleet mix and/or (2) a less intensive buildout schedule (i.e., fewer daily emissions occurring over a longer time interval). As shown, all criteria pollutant emissions from Project construction would be less than their respective thresholds. Thus, impacts would be less than significant and no mitigation is required.

TABLE 4.3-4
ESTIMATED MAXIMUM DAILY CONSTRUCTION EMISSIONS
(LBS/DAY)

	VOC	NOx	CO	SOx	PM10	PM2.5
Maximum daily emissions in 2015	8	53	68	<0.5	7	4
Maximum daily emissions in 2016	7	60	48	<0.5	5	3
SCAQMD Daily Thresholds	***75***	***100***	***550***	***150***	***150***	***55***
Exceeds SCAQMD Thresholds?	**No**	**No**	**No**	**No**	**No**	**No**

lbs/day: pounds per day; VOC: volatile organic compound(s); NOx: nitrogen oxides; CO: carbon monoxide; SOx: sulfur oxides; PM10: respirable particulate matter with a diameter of 10 microns or less; PM2.5: fine particulate matter with a diameter of 2.5 microns or less; SCAQMD: South Coast Air Quality Management District.

Source: SCAQMD 2011 (thresholds).

Localized Construction Impacts

The localized effects from the on-site portion of daily emissions were evaluated at sensitive receptor locations that would be potentially impacted by the Project; these were evaluated according to the SCAQMD's localized significance threshold (LST) methodology, which utilizes on-site mass emissions rate look up tables and Project-specific modeling, where appropriate. LSTs are applicable to the following criteria pollutants: NO_2, CO, PM10, and PM2.5.[4] LSTs represent the maximum emissions from a project that are not expected to cause or contribute substantially to an exceedance of the most stringent applicable federal or State ambient air quality standard. These are developed based on the ambient concentrations of that pollutant for each source receptor area and distance to the nearest sensitive receptor. For PM10 and PM2.5, LSTs were derived based on requirements in SCAQMD's Rule 403 regarding Fugitive Dust (RR AQ-1). The mass rate look-up tables were developed for each source receptor area and can be used to determine whether or not a project may generate significant adverse localized air quality impacts. The SCAQMD provides LST mass rate look-up tables for projects that are less than or equal to five acres. For projects that exceed five acres, the five-acre LST look-up values can be used as a screening tool to determine which pollutants require detailed analysis. This approach is conservative as it assumes that all on-site emissions would occur within a five-acre area and over-predicts potential localized impacts (i.e., more pollutant emissions occurring within a smaller area and within closer proximity to potential sensitive receptors).

[4] NO_2 impacts are addressed by evaluating nitrogen oxide (NOx) emissions.

When quantifying mass emissions for localized analysis, only emissions that occur on site are considered. Consistent with the SCAQMD's LST methodology guidelines, emissions related to off-site delivery/haul truck activity and employee trips are not considered in the evaluation of localized impacts.

As shown in Table 4.3-5, localized construction emissions for all criteria pollutants would be less than their respective SCAQMD LST significance thresholds. Thus, impacts would be less than significant and no mitigation is required.

TABLE 4.3-5
MAXIMUM LOCALIZED CONSTRUCTION POLLUTANT EMISSIONS

Exceeds SCAQMD Thresholds?	**No**	**No**	**No**	**No**

lbs/day: pounds per day; NOx: nitrogen oxides; CO: carbon monoxide; PM10: respirable particulate matter with a diameter of 10 microns or less; PM2.5: fine particulate matter with a diameter of 2.5 microns or less; SCAQMD: South Coast Air Quality Management District; LST: Local Significance Threshold; SRA: Source Receptor Area.

[a] Thresholds are for 5-acre site with receptors located within 25 meters in SRA 8.
[b] Thresholds are for 1-acre site with receptors located within 200 meters.
[c] Thresholds are for 5-acre site with receptors located within 50 meters in SRA 8.

Source: SCAQMD 2009 (LSTs).

Toxic Air Contaminants Impacts

The greatest potential for toxic air contaminant (TAC) emissions during construction would be related to diesel particulate emissions associated with heavy equipment operations during site grading activities. The SCAQMD does not consider diesel-related cancer risks from construction equipment to be an issue due to the short-term nature of construction activities. Construction activities associated with the proposed Project would be short term (14 months at Area 3, less at Areas 1 and 2). The assessment of cancer risk is typically based on a 70-year exposure period. Because exposure to diesel exhaust would be well below the 70-year exposure period, construction of the proposed Project is not anticipated to result in an elevated cancer risk to exposed persons. As such, Project-related TAC impacts during construction would be less than significant and no mitigation is required.

Long-Term Operational Impacts

Operational emissions are comprised of area, energy, and mobile (i.e., vehicle) source emissions. The primary source of operational criteria pollutant emissions from the proposed Project would be vehicles used by the increased number of trail users and visitors to the Arroyo Seco Canyon that would utilize the improvements associated with the Project. In order to estimate vehicle emissions, it was assumed that trail users and visitors would increase by up to 25 vehicles on weekdays and 200 vehicles on holiday weekends. Other mobile sources include haul truck trips

for the regular removal of sediment from the sedimentation and spreading basins (estimated at 100 truckloads every year for sedimentation basin cleanup and 100 truckloads every 5 years for spreading basins cleanup) and trips for maintenance of the restrooms, trash cans, and pet waste stations (assumed to be at least weekly removal of trash and twice weekly cleaning of the restroom). Energy consumption for the Project was based on data for the same activity in city parks land use. Area source emissions include reapplication of architectural coatings and landscaping activities. Emissions were calculated with the CalEEMod model, as discussed above.

Estimated peak daily operational emissions from the Project, as shown in Table 4.3-6, would be substantially below the SCAQMD regional thresholds of significance. Therefore, the impact would be less than significant.

TABLE 4.3-6
PEAK DAILY OPERATIONAL EMISSIONS

Emissions Source	Emissions (lbs/day)				
	VOC	**NOx**	**CO**	**PM10**	**PM2.5**
Area sources	<0.5	<0.5	<0.5	<0.5	<0.5
Energy sources	<0.5	<0.5	<0.5	<0.5	<0.5
Mobile sources	1	2	8	1	<0.5
Total Operational Emissions	**1**	**2**	**8**	**1**	**<0.5**
SCAQMD Significance Thresholds	55	55	550	150	55
Exceeds Threshold?	**No**	**No**	**No**	**No**	**No**

lbs/day: pounds per day; VOC: volatile organic compounds; NOx: nitrogen oxides; CO: carbon monoxide; PM10: respirable particulate matter with a diameter of 10 microns or less; PM2.5: fine particulate matter with a diameter of 2.5 microns or less.

Totals may not add due to rounding

Notes: Emissions are higher of summer or winter seasons.
SOx and lead emissions are not shown; these emissions would be negligible for the Project.
CalEEMod model data sheets are included in Appendix A.

Source: SCAQMD 2011 (thresholds).

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that no significant air quality impacts from regional or local operational emissions would occur, but NOx and PM10 emissions during construction activities would be significant and unavoidable during the peak day and the peak quarter. The Master EIR identified 11 mitigation measures to reduce these impacts but determined that peak day and peak quarter NOx and PM10 emissions would still exceed SCAQMD thresholds and would remain significant even after mitigation.

The Project would implement RR AQ-1, which requires the implementation of the same best available control measures (BACMs) outlined in Measures Air-1 to Air-9 of the Master EIR. Measure Air-10 is not applicable since the Project would not exceed SCAQMD thresholds and the Project would implement RR AQ-2, which is similar to Measure Air-11. However, no mitigation measures are required to reduce these impacts to below a level of significance.

c) Would the project result in a cumulatively considerable net increase of any criteria pollutant for which the project region is in non-attainment under an applicable federal or state ambient air quality standard (including releasing emissions which exceed quantitative thresholds for ozone precursors)?

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. The SCAQMD's approach for assessing cumulative impacts is based on the AQMP forecasts of attainment of ambient air quality standards in accordance with the requirements of the Federal and State Clean Air Acts. As discussed earlier in Threshold 4.3(a), the proposed Project would be consistent with the AQMP, which is intended to bring the SoCAB into attainment for all criteria pollutants.[5] In addition, the mass regional emissions calculated for the proposed Project (Tables 4.3-5 and 4.3-6) would be less than SCAQMD's daily significance thresholds that are designed to assist the region in attaining the applicable CAAQS and NAAQS.

Short-term cumulative impacts related to air quality could occur if Project construction and nearby construction activities were to be near or exceed the thresholds for significance and would occur simultaneously. In particular, with respect to local impacts, cumulative construction particulate (i.e., fugitive dust) impacts are considered when projects are located within a few hundred yards of each other. As described in Section 4.18, Mandatory Findings of Significance, there is one project, sediment removal at the Devil's Gate Reservoir, which could have overlapping construction with the Project. However, as shown in Table 4.3-4, Project construction emissions would be well below the SCAQMD regional significance thresholds; particularly, particulate matter emissions would be less than ten percent of the thresholds. The Project's relatively minor contribution to short-term air quality emissions would not result in a cumulatively considerable net increase of any criteria pollutant. Therefore, the incremental effect of Project-related construction emissions of nonattainment pollutants would not be cumulatively considerable and Project impacts would be less than significant.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that no significant air quality impacts from regional or local operational emissions would occur, but NOx and PM10 emissions during construction activities would be significant and unavoidable during the peak day and the peak quarter. The Master EIR identified 11 mitigation measures to reduce these impacts, but determined that peak day and peak quarter NOx and PM10 emissions during construction would still exceed SCAQMD thresholds and would remain significant even after mitigation.

As stated above, the Project would implement RR AQ-1, which requires the implementation of the same BACMs outlined in Measures Air-1 to Air-9, and RR AQ-2, which is similar to Measure Air-11. However, no mitigation measures are required to reduce these impacts to below a level of significance.

[5] Section 15064(h)(3) of the State CEQA Guidelines states "A lead agency may determine that a project's incremental contribution to a cumulative effect is not cumulatively considerable if the project will comply with the requirements in a previously approved plan or mitigation program which provides specific requirements that will avoid or substantially lessen the cumulative problem (e.g., water quality control plan, air quality plan, integrated waste management plan) within the geographic area in which the project is located. Such plans or programs must be specified in law or adopted by the public agency with jurisdiction over the affected resources through a public review process to implement, interpret, or make specific the law enforced or administered by the public agency".

d) Would the project expose sensitive receptors to substantial pollutant concentrations?

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. As described in Threshold 4.3(b), the proposed Project would not result in any substantial TAC air pollution impacts, and construction criteria pollutant emissions would be less than the conservative LSTs. Therefore, Project construction would not expose any nearby sensitive receptors to substantial pollutant concentrations.

A CO hotspot is an area of localized CO pollution that is caused by severe vehicle congestion on major roadways, typically near intersections. If a project increases average delay at signalized intersections that are operating at level of service (LOS) E or F or causes an intersection that would operate at LOS D or better without the project to operate at LOS E or F with the project, there is a potential for a CO hotspot.

As discussed in Section 4.16, Transportation and Traffic, under Threshold a), the Project is expected to generate relatively small amounts of new traffic in the long term, most of which will be generated during non-peak hours (for trail use and inspection and maintenance of the proposed improvements) and on weekends (for trail use). During construction, vehicle trips generated by the Project would also not create a CO hotspot since construction vehicle trips would be restricted to non-peak hours, as outlined in MM TRA-1. Therefore, the Project would not increase congestion at major signalized intersections.

There would be no impact and no exposure of sensitive receptors to Project-generated local CO emissions. As such, the proposed Project would have a less than significant impact and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that no significant impact to local CO concentrations would occur and that traffic increases would not be sufficient to increase CO levels above SCAQMD's allowable increase.

e) Would the project create objectionable odors affecting a substantial number of people?

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. According to the SCAQMD's *CEQA Air Quality Handbook,* land uses associated with odor complaints typically include agricultural uses, wastewater treatment plants, food processing plants, chemical plants, composting, refineries, landfills, dairies, and fiberglass molding (SCAQMD 1993). The proposed Project does not propose any of these land uses and would not otherwise produce objectionable long-term operational odors.

Short-term construction equipment and activities would generate odors, such as diesel exhaust emissions from construction equipment and paving activities. There may be situations where construction activity odors would be noticeable by persons on the Gabrielino Trail, but these odors would not be unfamiliar or necessarily objectionable. The odors would be temporary and would dissipate rapidly from the source with an increase in distance. Therefore, the impacts would be short-term; would not be objectionable to a substantial number of people; and would be less than significant. All Project-related odors are construction related and short term in nature; no long-term operational odors would be created. As such, the proposed Project would have no impact in regards to objectionable odors.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that there are no known sources of odors in the Project area that will be released during construction.

4.3.3 MITIGATION MEASURES

There would be no significant adverse impacts related to air quality with compliance with RR AQ-1 and RR AQ-2; therefore, no mitigation measures are required.

4.4 BIOLOGICAL RESOURCES	Potentially Significant Impact	Less than Significant with Mitigation	Less than Significant Impact	No Impact
Would the project:				
a) Have a substantial adverse effect, either directly or through habitat modification, on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Wildlife or U.S. Fish and Wildlife Service?	☐	☒	☐	☐
b) Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations, or by the California Department of Fish and Wildlife or U.S. Fish and Wildlife Service?	☐	☒	☐	☐
c) Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means?	☐	☒	☐	☐
d) Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites?	☐	☐	☒	☐
e) Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance?	☐	☐	☒	☐
f) Conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan?	☐	☐	☐	☒

Vegetation mapping, general plant and wildlife surveys, habitat assessments for special status species, focused surveys, a tree report, and a jurisdictional delineation have been completed to determine the presence of biological resources that may be impacted by the Project. The findings of these studies are summarized below and the studies are provided in Appendix B.

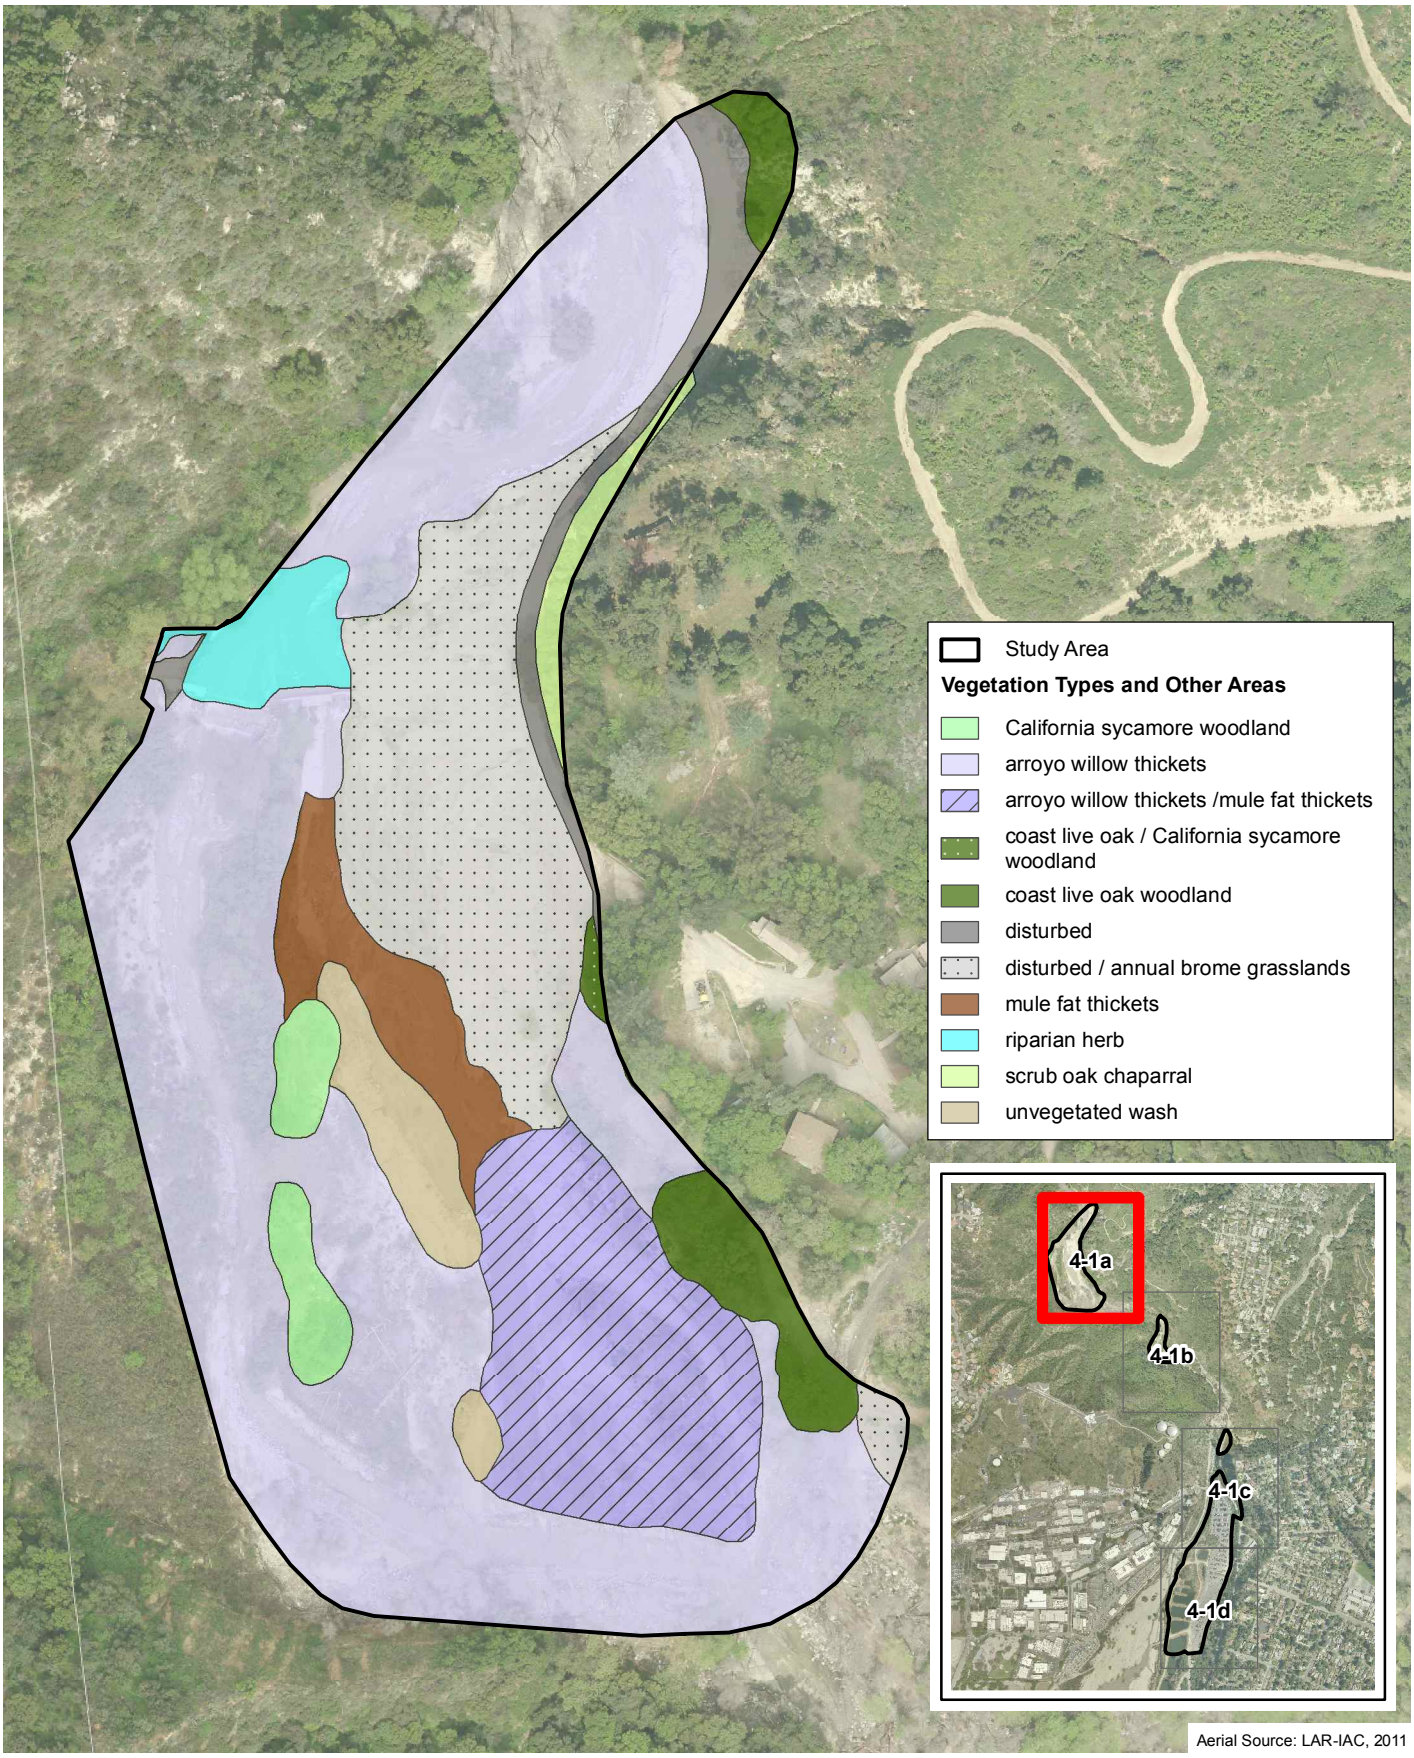
4.4.1 EXISTING CONDITIONS

The Project site is located within Arroyo Seco Canyon on the southern front of the San Gabriel Mountains. This Canyon represents one of the largest in the area and drains a large portion of the Angeles National Forest north of the Project site. The Canyon has a north-south alignment with steep east and west facing slopes. Chaparral and coastal sage scrub/sumac scrub are the dominant vegetation types on these steep slopes, although there are pockets of coast-live oak woodlands on the east facing slopes. A perennial stream with pool and riffles meanders through the canyon bottom and supports a dense riparian woodland before exiting the Canyon and crossing alluvial flats towards the Devil's Gate Dam.

The survey area included four locations: Area 1 – Arroyo Seco Headworks; Area 2 – Arroyo Seco Intake; Area 3 – JPL East Parking Lot; and a Temporary Staging Site. These four locations are connected together by the Gabrielino Trail, which serves as a recreational trail, as well as a

vehicular access road to the Arroyo Seco Canyon for the City of Pasadena and the USFS. This area supports a variety of plant and wildlife species.

Twenty-two vegetation types and other areas (i.e., unvegetated areas) occur in the Project's study area and are depicted in the Vegetation Map included in Exhibits 4-1a, 4-1b, 4-1c, and 4-1d. Where one vegetation type overlaps another type of mapping unit (e.g., a tree canopy over water or roads), the area was mapped according to the uppermost canopy of vegetation. Nomenclature for vegetation types generally follows that of *The Vegetation Classification and Mapping Program: List of California Terrestrial Natural Communities Recognized by the California Natural Diversity Database*.



Vegetation types within the project site disturbance limits include California buckwheat scrub, California buckwheat scrub/annual brome grasslands, California buckwheat scrub/laurel sumac scrub, coast-live oak woodland, California sagebrush scrub/laurel sumac scrub, California sagebrush scrub/California buckwheat scrub, disturbed, disturbed/annual brome grasslands, mule fat thickets, annual brome grasslands, coast live oak/California sycamore woodland, poison oak scrub, riparian herb, riparian herb/unvegetated wash, scrub oak chaparral, arroyo willow thickets, laurel sumac scrub, California sycamore woodland; white alder grove/California sycamore woodland, and arroyo willow thickets/mule fat thickets. Area 1 is dominated by arroyo willow thicket and white alder grove/California sycamore woodlands; Area 2 is dominated by white alder grove/California sycamore woodland, Area 3 is dominated by developed and disturbed/annual brome grasslands; and the temporary staging site is dominated by California sagebrush scrub/California buckwheat scrub. Vegetation on the project site primarily consists of native trees and plants (as indicated by the vegetation types above), though minimal amounts of non-native vegetation such as eupatory (*Ageratina adenophora*), giant reed (*Arundo donax*), cape ivy (*Delairea oderata*), and tree tobacco (*Nicotiana glauca*) were observed in the disturbed portions of Area 1.

Wildlife

The native vegetation types discussed above combined with the presence of naturally occurring pooled and running water give the site potential to support many wildlife species. The following discussion is intended to provide a general description of wildlife species observed or expected to occur on the Project site.

Fish within the Project area are predominantly non-native mosquito fish (*Gambusia affinis*). One native fish, rainbow trout (*Oncorhynchus mykiss*) is known to occur in upstream and downstream pockets, although its genetic origin is unclear due to stocking which occurred for many years in the Arroyo Seco. One other native fish, arroyo chub (*Gila orcuttii)*, was recently reintroduced within the Devil's Gate Dam area and may persist at that location. Although habitat is potentially suitable, with pooling and flowing water in portions of the site year-round, native species have largely been extirpated from the project area. Post-Project conditions are expected to enhance suitability for fish occupation as a result of removing structures and diversions in Area 1 and the new weir design will reduce potential fish mortality and increase potential for passage throughout the area when and where flows are sufficient.

Amphibians spend at least part of their life cycle in water. Amphibians are expected on the Project site due to the presence of water. Amphibians observed or expected to occur on the Project site include the coast range newt (*Taricha torosa torosa*), California chorus frog (*Pseudacris cadaverina*), Pacific chorus frog (*Pseudacris regilla*), and western toad (*Anaxyrus boreas*).

Reptiles generally favor habitats with boulders, rocks, cobble and sand. These elements offer protection from predators and thermal insulation. The Project site contains these elements in the upland areas and the unvegetated portions of the stream. Reptiles observed or expected to occur on the Project site include western fence lizard (*Sceloporus occidentalis*), Western whiptail (*Cnemidophorus tigris*), side-blotched lizard (*Uta stansburiana*), gopher snake (*Pituophis catenifer*), and western rattlesnake (*Crotalus oreganus*).

The Project site contains and is contiguous with a large open space area. This association with a large open space area and a perennial source of water on the Project site is expected to draw a multitude of bird species (residents and migrants). Bird species that were observed or expected to occur on the Project site include residents such as the California quail (*Callipepla californica*), western screech-owl (*Megascops kennicottii*), great horned owl (*Bubo virginianus*), Anna's hummingbird (*Calypte anna*) acorn woodpecker (*Melanerpes formicivorus*), western scrub-jay (*Aphelocoma californica*), oak titmouse (*Baeolophus inornatus*), bushtit (*Psaltriparus minimus*), house wren (*Troglodytes aedon*), California towhee (*Melozone crissalis*), lesser goldfinch (*Spinus psaltria*), and migrants such as black-chinned hummingbird (*Archilochus alexandri*), western wood-pewee (*Contopus sordidulus*), Pacific-slope flycatcher (*Empidonax difficilis*), cliff swallow (*Petrochelidon pyrrhonota*), black-throated gray warbler (*Setophaga nigrescens*), Wilson's warbler (*Cardellina pusilla*), white-crowned sparrow (*Zonotrichia leucophyrys*), and Bullock's oriole (*Icterus bullockii*).

Mammals are also expected to utilize the Project site for the same reasons mentioned above. The Project site is expected to have a high abundance of small and large mammals. Mammals observed or expected to occur on the Project site include large mammals such as the mule deer (*Odocoileus hemionus*), coyote (*Canis latrans*), mountain lion (*Puma concolor*), American black bear (*Ursus americanus*), bobcat (*Lynx rufus*), small mesopredators such as striped skunk (*Mephitis mephitis*), raccoon (*Procyon lotor*), and Virginia opossum (*Didelphis virginiana*); and small herbivores like the desert cottontail (*Sylvilagus audubonii*),California ground squirrel (*Otospermophilus beecheyi*), and Botta's pocket gopher (*Thomomys bottae*). A variety of bats are also expected to occur on the Project site including the California bat (*Myotix californicus*), hoary bat (*Lasiurus cinereus*), big brown bat (*Eptesicus fuscus*), and Brazilian free-tailed bat (*Tadarida brasiliensis*).

Special Status Resources

A number of special status resources have the potential to occur on the Project site. These include the least Bell's vireo (*Vireo bellii pusillus*), southwestern willow flycatcher (*Empidonax traillii extimus)*, California red-legged frog (*Rana draytonii*), arroyo toad (*Bufo californicus*), special status plants, regulated trees, jurisdictional waters and their associated habitats, and nesting birds. Other special status species are known to occur or may potentially occur but are not expected to be impacted by the Project.

Least Bell's Vireo/Willow Flycatcher

The least Bell's vireo and willow flycatcher are Endangered species that have the potential to occur in the willow riparian woodlands along the Arroyo Seco drainage. Historically, the breeding habitat of the least Bell's vireo and southwestern willow flycatcher is primarily riparian dominated by willows with dense understory vegetation. The southwestern willow flycatcher differs from least Bell's vireo in that it shows a stronger dependency on willow thickets and surface water for all its requirements. According to findings by the U.S. Fish and Wildlife Service, the Project site is not located in designated critical habitat for the least Bell's vireo or southwestern willow flycatcher.

Protocol surveys for the least Bell's vireo and the southwestern willow flycatcher indicated that no breeding least Bell's vireos or southwestern willow flycatchers were present on or near the Project site. Also, no migrant least Bell's vireo or willow flycatchers were observed during the surveys. The survey report is provided in Attachment F of Appendix B.

California Red-Legged Frog

The California red-legged frog is an Endangered species that has the potential to occur in the open water of the Arroyo Creek that runs through the Project site. The California red-legged frog was a common native frog in parts of Los Angeles, San Bernardino, Orange, Riverside, and San Diego Counties. This frog historically occurred in the San Gabriel Wilderness Area of the ANF; until 1999, there were no post-1970 observations in this area or nearby parts of the ANF. In 1999, a population of California red-legged frogs was located on the ANF in the San Francisquito Drainage in the Santa Clarita area. Current population estimates suggest that there are between 15 and 25 adults. This population, however, is threatened by non-native predators, disease, and parasites. The nearest recorded population is located on the north side of the San Gabriel Mountains approximately 15 miles away from the Project site. The Project site is not located within designated critical habitat for this species.

Focused surveys for the California red-legged frog indicated that no red-legged frog was present on or near the Project site. The survey report is provided in Attachment E of Appendix B.

Arroyo Toad

The arroyo toad is a federally Endangered species that has the potential to occur in the open water of the Arroyo Seco stream that runs through the project site. The arroyo toad is found from northern San Luis Obispo County south to Baja California, with an elevational range that extends up to 1,950 meters. This species is found in semi-arid regions near washes or intermittent streams. Habitats used include valley-foothill and desert riparian as well as a variety of more arid habitats including desert wash, palm oasis, and Joshua tree, mixed chaparral, and sagebrush. Adults are active from March to July. Arroyo toads are found near rivers with sandy banks, willows, cottonwoods, and sycamores in valley-foothill areas, desert riparian habitats, and in loose gravelly areas of streams in drier portions of its range. The nearest recorded population is located near the center of the Angeles National Forest, over 12 miles away from the Project site.

Focused surveys for the arroyo toad indicated that no arroyo toad was present on or near the Project site. The survey report is provided in Attachment E of Appendix B.

Special Status Plants

Special status plants have the potential to occur in many of the Project site's activity areas. Various plants are considered to be special status by State and federal resource agencies, academic institutions, and various conservation groups. Determination of the sensitivity level is based on the Nature Conservancy Heritage Program Status Ranks, which ranks special status plants on a global and statewide basis according to the number and size of remaining occurrences and recognized threats.

Botanical surveys conducted in and near the Project site indicate that no special status plants were observed on site. Two special status plants listed on the California Rare Plant Rank (CRPR) Watch List (i.e. Southern California black walnut [*Juglans californica*] trees), were recorded near the site. One is adjacent to the Area 3 boundaries (slope to the east of the impact area) and the other is adjacent to the staging area. These two trees are not located within the Project's disturbance limits and would not be impacted by Project implementation.

The special status plant survey report is provided in Attachment C of Appendix B.

Jurisdictional Waters and Associated Habitats

Vegetation types found in the Project area may be subject to permit requirements, as regulated by the USACE, the CDFW, and the RWQCB pursuant to Section 404 of the Clean Water Act and Sections 1600 et seq. of the *California Fish and Game Code.* The USACE takes jurisdiction over areas considered "waters of the U.S.", which can consist of wetland and non-wetland areas. Non-wetland jurisdictional waters (identified in the table below as open water and other non-wetland "waters of the U.S.") are typically defined by the ordinary high water mark and other specific criteria. Wetlands, a subset of jurisdictional "waters of the U.S.", are defined as those that possess the following three parameters: (1) hydrology that provides permanent or periodic inundation by groundwater or surface water; (2) hydric soils; and (3) hydrophytic vegetation. RWQCB jurisdictional limits equal those of the USACE, but can also include "isolated waters" that do not have a connection to a traditional navigable waterway. CDFW jurisdictional limits extend to the top of bank and generally exceed the USACE jurisdictional limits. CDFW jurisdictional areas also include riparian habitat supported by a river, stream, or lake regardless of the presence or absence of hydric soils and saturated soil conditions. The limits of CDFW jurisdiction are often defined by riparian vegetation.

Table 4.4-1 shows the amount of jurisdictional resources that occur within Project study area. The jurisdictional report is provided in Attachment G of Appendix B.

TABLE 4.4-1
JURISDICTIONAL RESOURCES FOR EACH PROJECT AREA

	Jurisdictional Resources (acres)					
	USACE Jurisdiction					
	Open Water	Other Non-Wetland "Waters of the U.S."	Total	Isolated Waters	Total RWQCB Jurisdiction[a]	Total CDFW Jurisdiction
Area 1	0.52	5.26	5.78	0.00	5.78	6.90
Area 2	0.17	0.40	0.57	0.00	0.57	1.32
Area 3	0.00	0.00	0.00	3.87	3.87	3.87
Total	*0.69*	*5.66*	**6.35**	**3.87**	**10.22**	**12.09**

USACE: U.S. Army Corps of Engineers; RWQCB: Regional Water Quality Control Board; CDFW: California Department of Fish and Wildlife.

[a] RWQCB jurisdiction generally matches that of the USACE, but also includes "isolated waters".

Source: BonTerra Psomas 2014a.

Nesting Birds

The Migratory Bird Treaty Act (MBTA) protects the nests of all native bird species, including common species such as mourning dove (*Zenaida macroura*), Anna's hummingbird (*Calypte anna*), and house finch (*Carpodacus mexicanus*). Nesting birds and raptors are also protected by Fish and Game Code. A variety of birds were observed during biological surveys and nesting birds have potential to occur in vegetation throughout the Project area.

Regulated Trees

Various trees are protected by the City of Pasadena's City Trees and Tree Protection Ordinance, as well as State resource agencies in conjunction with jurisdictional waters regulatory permits. Regulated trees have the potential to occur in many of the project site activity areas. Areas 1 and 2 occur within wooded riparian areas and support many native trees while Area 3 is less wooded and has lower potential for regulated trees. A total of 147 trees were documented within the survey area that met the minimum size requirement described in the City Trees and Tree Protection Ordinance and/or the *California Fish and Game Code*. Of the 147 trees included in this survey, 122 trees are "native" trees and 2 are categorized as "specimen" trees as described in the Ordinance (described above in Section 1.2). None of the trees in the survey area are "landmark" trees as described in the Ordinance. The native tree survey report is provided in Attachment D of Appendix B.

4.4.2 IMPACT ANALYSIS

Project Design Features

PDF BIO-1 Habitat restoration in Area 1 will utilize native plant species, in accordance with the Plant Palettes set forth in Appendix A of the Arroyo Seco Design Guidelines, which allow for substitutions with the concurrence of the Project's biologist/restoration specialist.

Regulatory Requirements

RR BIO-1 The City of Pasadena Department of Water and Power is required to obtain all necessary permits for impacts to "waters of the United States" and "waters of the State" from applicable resource agencies, including the United States Army Corps of Engineers (USACE), the Los Angeles Regional Water Quality Control Board (RWQCB), and the California Department of Fish and Wildlife (CDFW).

RR BIO-2 Tree pruning, removal, relocation, and replacement is required to be made in compliance with the City of Pasadena "City Trees and Tree Protection Ordinance" (Section 8.52 of the Pasadena Municipal Code), which requires that mature, public, landmark, landmark-eligible, native and specimen trees be protected and preserved. Work on protected trees must be approved by the City Manager or his/her designated personnel.

Impact Discussion

For the purposes of the impact discussions below, all Project impacts are categorized as being either permanent or temporary. Permanent impact areas are defined as changes to or removal of an existing vegetation type or "other areas," including disturbed or developed (e.g. paved areas) that are permanent as a result of Project implementation. Temporary access/impact areas are defined as areas that may be subject to traversing vehicles or other mobile equipment, staging of equipment, stockpiles of soil, and minor soil disturbance where there is no permanent alteration to the existing grade (e.g. no permanent holes, trenches, or berms), and no vegetation or tree removal is proposed.

a) Would the project have a substantial adverse effect, either directly or through habitat modification, on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Wildlife or U.S. Fish and Wildlife Service?

Less Than Significant With Mitigation.

Areas 1, 2 and 3 Impacts. The Project area provides potentially suitable habitat for the following seven federally and/or State Threatened and Endangered species: Braunton's milkvetch (*Astragalus brauntonii*), Nevin's barberry (*Mahonia nevinii*), San Fernando Valley spineflower (*Chorizanthe parryi* var. *Fernandina*), arroyo toad (*Anaxyrus californicus*), California red-legged frog (*Rana draytonii*), southwestern willow flycatcher (*Empidonax traillii extimus*), and least Bell's vireo (*Vireo bellii pusillus*). The results of the 2013 focused surveys were negative for all seven species; therefore, Project implementation is not expected to impact these species (BonTerra Psomas 2014c; BonTerra Consulting 2013a, 2013b). The southwestern willow flycatcher and least Bell's vireo are migratory bird species, however, that have the potential to occur in each spring/summer breeding season. Project activities occurring during future breeding seasons for these two bird species have the potential for impacts that would be considered potentially significant. Implementation of MM BIO-1 and MM BIO-2 would reduce this potential impact to less than significant because if these species are found during the pre-clearing sweep, work will temporarily be halted within 200 feet of the detected occupied habitat until the City can consult with the USFWS and CDFW and the City shall comply with any approvals and/or conditions imposed by these agencies.

The 2013 focused surveys identified two individuals of one special status plant species, Southern California black walnut (*Juglans californica* var. *californica*), in the Project area (BonTerra Psomas 2014c). The two Southern California black walnuts trees are located outside the impact areas for the Project; therefore Project implementation would not impact this species or any other special status plant. No mitigation is required.

The 2013 focused surveys and constraints analysis survey observed three additional non-listed special status wildlife species: coast range newt (*Taricha torosa torosa),* two-striped garter snake (*Thamnophis hammondii*), and yellow warbler (*Setophaga petechia*) (BonTerra Consulting 2013a, 2013b). All three species potentially occur within impact areas and may be adversely affected by Project implementation. The coast range newt and two-striped garter snake are aquatic species that may incur direct mortality of one or more individuals during the course of Project activities. However, due to the regional population size and distribution, and the relatively small number expected to be present at the Project site, these impacts are considered less than significant. Although not significant, implementation of the pre-clearing sweeps under MM BIO-1 would further reduce the potential for impacts to unlisted special status species.

Other special status species, such as the silvery legless lizard, may also occur in the Project area. Similar to the impacts on special status species described above, impacts are expected to be less than significant due to the limited extent and duration of disturbance and the relative regional population of this species. Potential impacts would be further reduced by the pre-construction sweeps conducted as part of MM BIO-1.

Project implementation would not be expected to result in the loss of individual yellow warblers; however, active nests of this species as well as all other native bird species are protected by the Migratory Bird Treaty Act (MBTA) and *California Fish and Game Code* and the loss of an active nest would be considered a potentially significant impact. Implementation of MM BIO-2, which requires pre-construction nesting bird surveys, and avoidance if applicable, would reduce this impact to a less than significant level.

Special status bat species, including silver-haired bat (*Lasionycteris noctivagans*), western red bat (*Lasiurus blossevillii*), and hoary bat (*Lasiurus cinereus*), potentially occur in the study area and may roost on the Project site. Potential roost sites for these species include tree cavities and exfoliating bark. Project construction has the potential for impacts to these species as a result of mortality of one or more individuals during tree removal activities. Due to the regional population size and distribution of these species, these impacts are considered less than significant. However, MM BIO-3, which requires a bat habitat assessment and a two-step tree removal process, will further minimize impacts on these species and ensure less than significant impacts.

Reduced Stream Flows

Project objectives include restoring the diversion capacity to its pre storm-damage level, as well as increasing diversions to capture an additional 1,100 acre-feet annually. As a result, Project flows downstream from the diversion point in Area 2 will be reduced to some degree relative to both current and historic conditions.

As described above, the Arroyo Seco stream continues downstream from the diversion as a mountainous boulder and riffle system shaded by a mixed riparian woodland canopy. Adjacent uplands are undeveloped and vegetated with native scrub and chaparral plant communities with dense oak woodlands on north- and northeast-facing slopes. Millard Canyon converges with the Arroyo Seco in this area, bringing additional flow throughout most of the year. Continuing downstream, the drainage exits the mouth of the canyon near the northern edge of Area 3. From this point moving south, the drainage changes dramatically as the creek flows across alluvial deposits with limited vegetation until reaching a large (0.25 mile by 0.40 mile) riparian woodland that occupies the occasionally flooded alluvial deposits in the reservoir behind Devil's Gate Dam in Hahamongna Watershed Park. The stream meanders through the willow woodland, creating braided channels that frequently shift as sediments fill the active channels. Large flood flows occasionally result in impounded water and filling of the reservoir. This occasional flooding is likely to be the primary source allowing for the large riparian woodland in the reservoir area. Low flows during most of the year persist on the surface for short distances beyond the canyon mouth before infiltrating the alluvium and flowing underground.

Plant and wildlife resources between the diversion point and the canyon mouth are expected to be very similar to those described for Areas 1 and 2. Due to the abundance of native vegetation, undeveloped lands, and riparian resources, the area is generally rich in native wildlife species diversity and abundance. A large portion of these species is likely to be dependent specifically on the stream and riparian habitat as a core resource. Exiting the canyon and crossing approximately 0.75 mile of mostly unvegetated sandy wash, plant and wildlife diversity is expected to drop off substantially as the area is suitable for fewer species and lower numbers of individuals. Reaching the riparian woodland of the reservoir, the species richness and population size is expected to increase substantially. Although the mostly developed surrounding area limits access of many species to only the more ubiquitous of the suburban setting, bird species are likely to be highly diverse as such a large riparian woodland area is rare in the region.

Continuing further downstream beyond Devil's Gate Dam, the Arroyo Seco stream flows through an urban landscape and is channelized for nearly the entire length to the Los Angeles River flood-control channel. Due to the lack of riparian habitat and difficulty of access, the lower Arroyo Seco is not expected to support riparian-dependent communities and is likely to be occupied by common wildlife in suburban environments in the region.

Based on a review of USGS gauging station data upstream of the Project site, City of Pasadena diversion records, and the Project Conceptual Design Report (Carollo 2013), diversion amounts have been highly variable through the years. Many factors appear to contribute to this variability,

such as available stream flows, season of availability, recharge basin saturation, flow volume, water rights thresholds, and others. As a result, consistent patterns in diversion are difficult to glean from the data. Adding to the complexity is the Station Fire sediment flows in late fall and winter of 2009, which damaged the diversion structure and altered the diversion regime due to the loss of design capacity. As a result, no water was diverted for many consecutive months in 2010. In general, diversions are highest, if available, from late fall through winter and into early spring. This corresponds with what is typically Southern California's wet season and highest stream flows. Due to the higher flows, the diversions represent a smaller percentage of the total stream flow compared with other times of the year. Conversely, stream flows taper off in early spring through summer and early fall. Although the diversion quantities appear to be generally lower at this time of the year, they represent a greater portion of the stream total. The average diversion is approximately 50 acre-feet per month for this period, which results in the diversion of 100 percent of stream flows in most months historically and rarely goes below 70 percent.

The post-Project diversions are expected to be similar in variation and complexity of factors involved in water management. The new diversion structure would allow for diverting up to 25 cfs (same as existing conditions). At the start of the rainy season, larger storm events have resulted in water that was too turbid and City staff avoided diverting stream flow to minimize transporting fine sediment into the spreading basins. Typically these stream flows were greater than the City's surface water rights of 25 cfs. When the water became less turbid, it was diverted and historically averaged 2,532 acre-feet per year (Table 2.2, Carollo 2013).

With the proposed improvements, post-Project diversions are estimated to result in an average increase of 17 percent under average year hydrologic conditions. Over a 10-year hydrologic period, the Project is estimated to divert on average an additional 1,100 acre-feet per year, which would reduce flows below the diversion point to some extent. It is assumed that the diversions would occur in a manner consistent with past diversions but with a greater amount of water diverted when available. Given that the late spring through early winter often resulted in high diversion percentages of the total stream flow, including many 100 percent diversions, it is probable that additional diversion would be experienced to a greater extent within the late Fall through mid-Spring months when greater flows are available. However, major storm flows exceeding 25 cfs would only allow up to 25 cfs of diversion with the Project, where major flows were historically passed through without diversion during the rainy season (Carollo 2013).

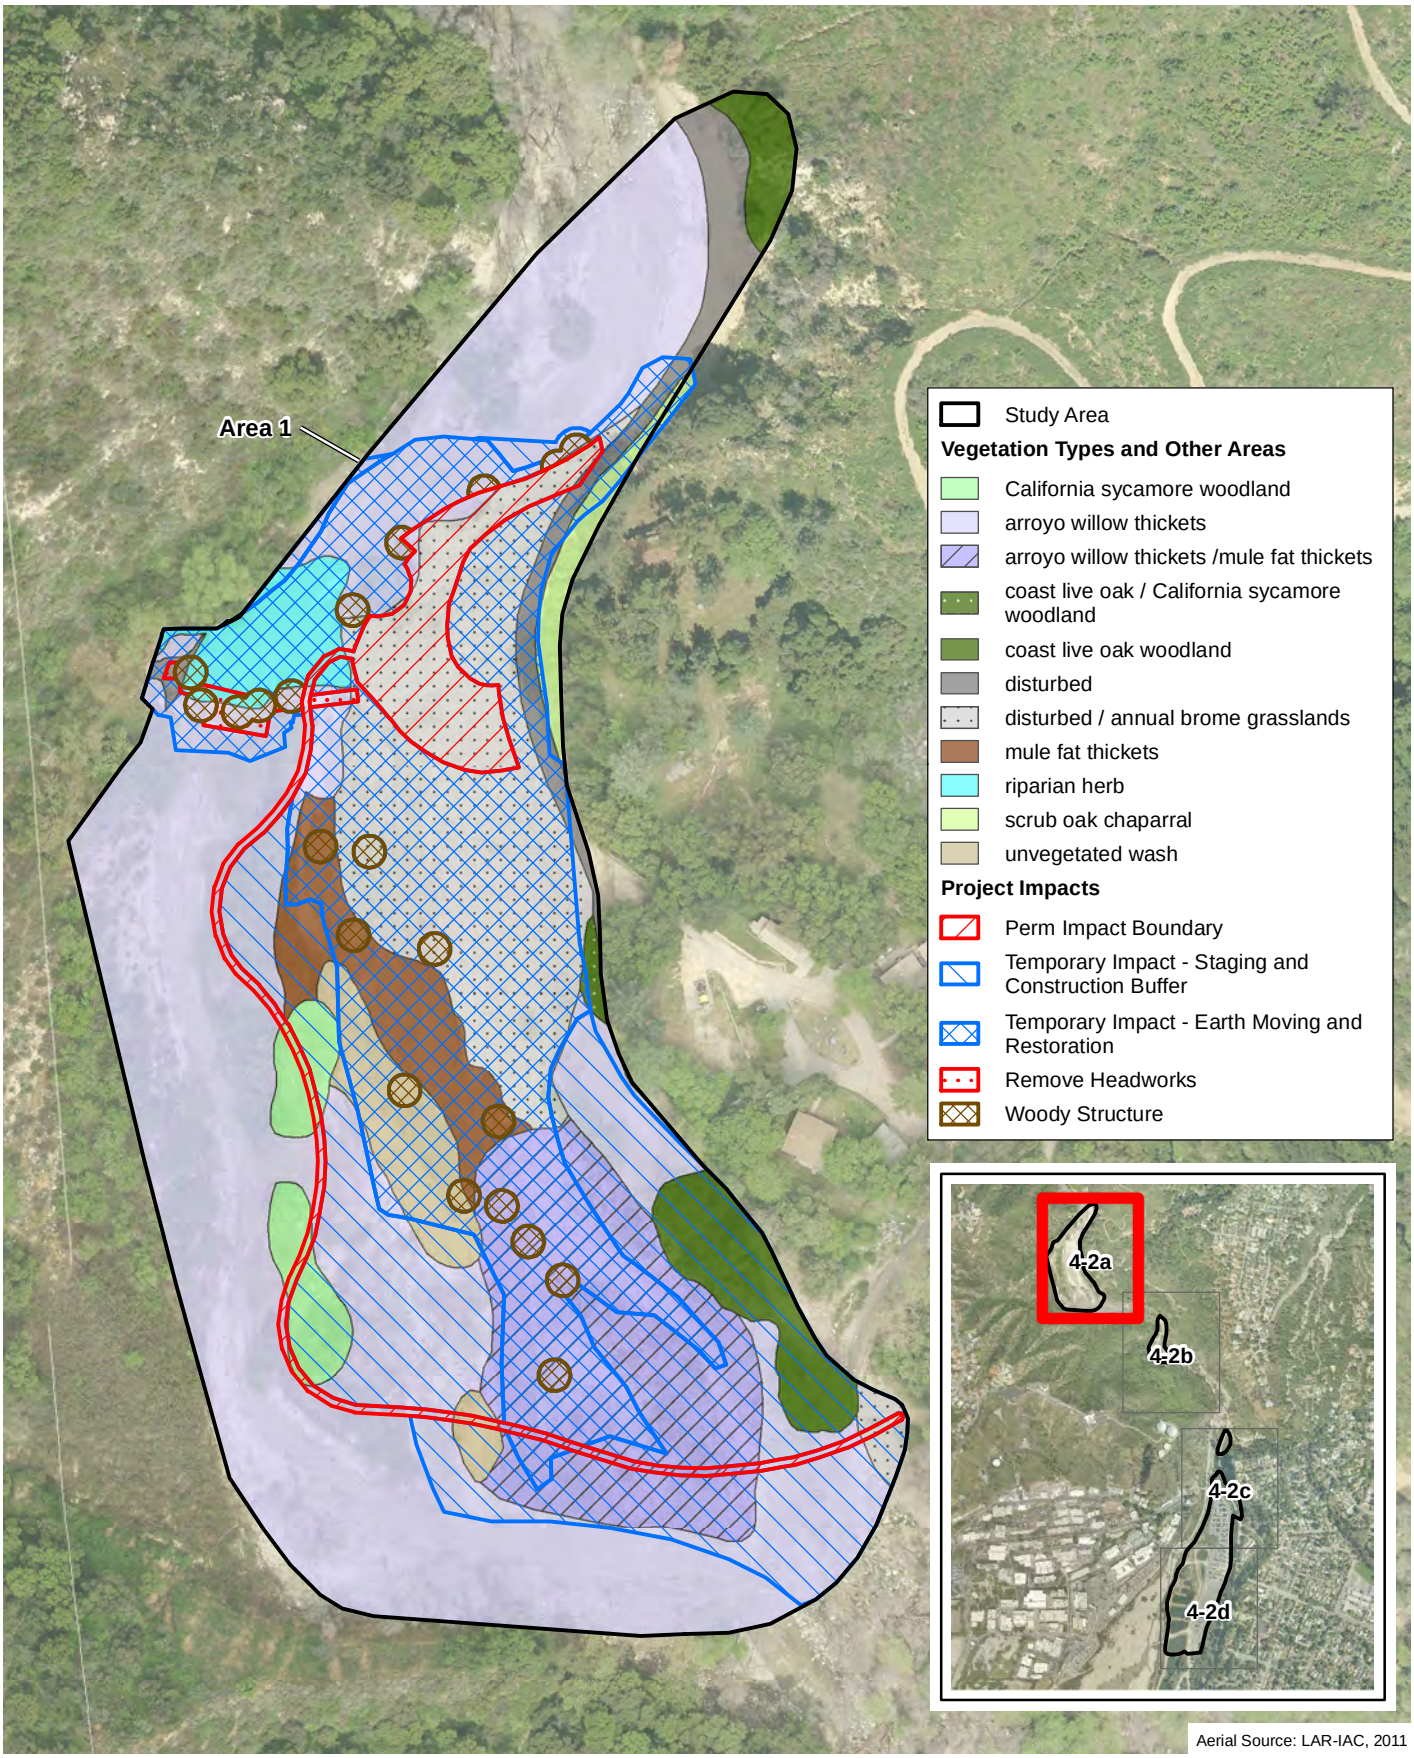
The effect of these reduced flows on biological communities downstream is difficult to measure. Reduced flows in general can cause shorter distances of available surface water; shorter duration of pooling; reduced extent of moist soils moving away from the streambed; and reduced stream velocities resulting in reduced sediment transport. These and other effects may impact species and vegetation communities dependent on such resources and processes.

Based on the Project's increased future diversions, reduced flows are expected as described. Although the damaged diversion structure has limited diversion in recent years, diversions have occurred historically prior to 1914 and it is expected that resources downstream have adapted to the flow regime with these diversions. However, the effects of a 17 percent increase in diversions above historical practice are uncertain. Given the uncertainty in the Project's level of effect, the impact on biological resources, including vegetation types and special status species potentially occurring, is considered potentially significant. Implementation of MM BIO-6, which requires monitoring the Arroyo Seco stream and associated riparian habitat from the intake structure (i.e. diversion point) downstream to Devil's Gate Dam and subsequent compensatory mitigation or corrective action to avoid or reduce any identified downstream impacts of the Project, would reduce this impact to a level considered less than significant.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified potentially significant impacts to sensitive plant species, riparian habitats, wetlands, and the arroyo southwestern toad. The Master EIR included mitigation measures to reduce significant impacts related to sensitive biological resources. Measure Biological-1 requires surveys to be conducted to determine the presence of sensitive plant species. (BonTerra Psomas 2014c). Also, directed surveys of the Arroyo toad (Measure Biological-3) have been implemented and the Arroyo toad was not observed and is not expected to be present in the areas proposed for disturbance (BonTerra Consulting 2013a). Measure Biological-4 requires surveys for the Nevin's barberry in the Central Arroyo Seco and is not applicable to the Project.

b) Would the project have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations, or by the California Department of Fish and Wildlife or U.S. Fish and Wildlife Service?

Less Than Significant With Mitigation.



Areas 1, 2 and 3 Impacts. Project implementation would result in a total impact of 24.95 acres (permanent impact of 18.17 acres and temporary impact of 6.77 acres) of riparian habitat, as summarized in Table 4.4-2 below and shown in Exhibits 4-2a, 4-2b, 4-2c, and 4-2d. Riparian and other special status vegetation types are italicized in Table 4.4-2 and are discussed below.

TABLE 4.4-2

The proposed Project would affect 6.37 acres (4.30 acres temporary; 2.07 acres permanent) of sensitive natural communities (or vegetation types) consisting of arroyo willow thickets, arroyo willow thickets/mule fat thickets, California sycamore woodland, coast live oak woodland, and white alder grove/California sycamore woodland. These vegetation types have been significantly reduced in acreage and are threatened by additional loss. Impacts on these vegetation types are considered potentially significant because of their high biological value. Impacts on these vegetation types would be reduced to less than significant levels with implementation of MM BIO-4, which requires restoration or replacement of sensitive natural communities.

Additionally, riparian vegetation may potentially be regulated as components of the streambed and riparian areas which are regulated by California Department of Fish and Wildlife (CDFW) per the *California Fish and Game Code* (§§1600–1616). Impacts to vegetation types in this regard are addressed under Threshold 4.3(c) below, which deals with impacts to federally protected wetlands.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified potentially significant impacts to riparian habitats: southern willow scrub and mule fat scrub. Proposed restoration projects would mitigate impacts to southern sycamore riparian woodland and streambed riparian plant communities and would be beneficial to wildlife for food and shelter. The Master EIR included Measure Biological-2 to prevent significant impacts associated with the loss of wetlands and riparian habitats. As discussed above, a Jurisdictional Delineation has been completed to identify riparian habitats and wetlands that would be affected by the Project. Permits would be obtained from resource agencies and compensatory mitigation provided, as required under MM BIO-5, which is similar to Measure Biological-2.

c) Would the project have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means?

Less Than Significant With Mitigation.

Areas 1, 2 and 3 Impacts. Approximately 6.35 acres of non-wetland "waters of the U.S.", 10.22 acres of RWQCB jurisdictional "waters of the State", and 12.09 acres of CDFW jurisdictional waters exist on the Project site. As summarized in Table 4.4-3, the proposed Project would permanently impact a total of 0.48 acre of non-wetland "waters of the U.S.", (of which 0.02 acre is open water) as well as 0.60 acre of CDFW jurisdiction. In addition, the proposed Project would impact 3.87 acres of spreading basins that are considered "isolated waters", which are under the jurisdiction of the RWQCB but not the USACE.

Approximately 3.67 acres of non-wetland "waters of the U.S." would be temporarily impacted during construction activities associated with the removal of the Headworks structure, streambed restoration activities, and replacement of the diversion weir and inlet structure. Approximately 7.54 acres of RWQCB "waters of the State" and 7.88 acres of CDFW jurisdictional waters will be similarly impacted on a temporary basis during construction. Table 4.4-3 shows the amount of temporary and permanent impacts to jurisdictional resources that would occur with Project implementation.

TABLE 4.4-3
JURISDICTIONAL RESOURCES IMPACTED FOR EACH PROJECT IMPROVEMENT

	Jurisdictional Resources					
	USACE Jurisdiction					
	Open Water	Other Non-Wetland "Waters of the U.S."	Total	Isolated Waters	Total RWQCB Jurisdiction[a]	Total CDFW Jurisdiction
Existing Jurisdictional Resources (acres)

USACE: U.S. Army Corps of Engineers; RWQCB: Regional Water Quality Control Board; CDFW: California Department of Fish and Wildlife.

[a] RWQCB jurisdiction generally matches that of the USACE, but also includes "isolated waters".

[b] These impacts should not result in a loss of ecological/hydrological functioning of the streambed and should not require compensatory mitigation.

Source: BonTerra Psomas 2014a

It is worthwhile to note that three of the proposed activities (removal of the Headworks structure, placement of woody structures, and trail construction) are considered permanent impacts but are self-mitigating aspects of the Project. This is because the jurisdictional areas will benefit from these proposed activities and compensatory mitigation is not required. The establishment of an at-grade pedestrian trail within Area 1 also does not require compensatory mitigation because it is not expected to affect the ecological or hydrological functioning of the area. Similarly, the temporary impact areas will be restored to their original condition at the conclusion of the Project and will not require compensatory mitigation.

Therefore, the permanent impacts to "waters of the U.S." that will negatively affect these resources is confined to the bank stabilization for the establishment of the picnic area in Area 1 and the construction of a new diversion weir and inlet structure in Area 2. These permanent impacts total 0.11 acre of USACE/RWQCB jurisdiction.

Aspects of the Project that will permanently impact CDFW jurisdiction and will require compensatory mitigation include the picnic area bank stabilization in Area 1 and the diversion weir/inlet structure and roadway/stream embankment construction in Area 2. Additionally, the proposed trail in Area 1 will be maintained free of vegetation on an ongoing basis. Therefore, this is considered to be a permanent impact on the riparian vegetation in the area. In all, a total of 0.38 acre of impacts to CDFW jurisdiction will likely require mitigation.

Compliance with RR BIO-1 requires obtaining the necessary permits for impacts to jurisdictional resources. Implementation of MM BIO-5—which requires obtaining regulatory permits from agencies, including a Section 404 Permit from the USACE, a Section 401 Permit from the Los Angeles RWQCB, and a Section 1600 Streambed Alteration Agreement from the CDFW and complying with the permits requirements for mitigating for the loss of jurisdictional resources—would reduce impacts to wetlands to less than significant levels.

As part of the Project, the PWP proposes to create an additional low-flow channel and restore riparian habitat in Area 1. As described in Section 3.1.1, this aspect of the Project will restore approximately 0.98 acre of riparian habitat and is expected to fully mitigate Project impacts to jurisdictional waters.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified potentially significant impacts to wetlands. The Master EIR included Measure Biological-2 to prevent significant impacts associated with the loss of wetlands and riparian habitats. As discussed above, permits would be obtained from resource agencies and compensatory mitigation provided, as required under MM BIO-5, which is similar to Measure Biological-2.

d) Would the project interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites?

Less Than Significant Impact.

Areas 1, 2 and 3 Impacts. The Project site is located just south of the southern edge of the Angeles National Forest. Development is located to the east, west, and south. Therefore wildlife is expected to move relatively freely between the Project site and open space areas to the north, but are not expected to move regularly into the developed areas west, east, or south of the Project site (with the exception of urban-tolerant species such as coyotes and striped skunks). For species that travel along riparian corridors, development to the south (JPL campus, Devil's Gate Dam, and the I-210) is a barrier to movement between the Upper Arroyo Seco and the Lower

Arroyo Seco. As a result, the Project site is not expected to serve as a regional corridor link between regional open space areas. It is expected, however, to support a relatively large amount of the local wildlife movement due to the existing topography, including the presence of a perennial creek.

Arroyo Seco Canyon is naturally very steep sided and restricts many species to traveling either up the canyon bottom or along the ridgelines. Local movement on the Project site is expected to include wildlife species with low mobility (e.g., amphibians, reptiles) and those with high mobility (e.g., birds, large mammals). Project implementation may affect movement of these wildlife species differently. The more mobile species would be expected to move through upland areas or along the periphery of the Project site through habitats not impacted by Project activities. Most mammalian wildlife movement occurs at night when construction would not be active; therefore, these species would still be expected to use the Gabrielino Trail for movement at night, and they would still able to use the ridgelines that would not be affected by the Project. Species with lower mobility may be adversely affected by Project implementation. These impacts, however, are expected to be short-term and not significant. Therefore, no mitigation would be required. Furthermore, Project implementation will restore native riparian habitat in the upstream portion of the Project area (PDF BIO-1), which is expected to have a beneficial effect on wildlife by creating an increase in native vegetation cover and habitats. Therefore, any adverse impacts on local wildlife movement would be further reduced by this PDF. Impacts on wildlife movement are considered less than significant and no mitigation is required.

In addition, the new diversion weir would be operated such that the pool level at the intake would be at a constant level of approximately 4 ft in depth, except during flooding conditions. This higher pool level would provide cover and refuge areas for existing fish populations and for potential re-established native fish populations. The deeper pool would also reduce water temperatures and increase the diversity of food supply. The upper end of the pool may also create a modest increase in spawning habitat as the stream changes from high gradient to low gradient over a short reach. The new weir design would also allow for a more gradual change in stream depth, which would be less harmful to fish when water is available.

The existing intake is protected by a trash rack that withstands approach velocities of approximately 2.1 ft/sec and has openings of approximately 2 inches. This current arrangement does little to protect fish. The improved intake would have an approach velocity of 1.4 ft/sec and fine screens with openings of 3/32-inches. In addition, the new screen consists of two screens – an outer and inner whereby the inner is smaller openings to avoid smaller fishes from becoming trapped. This proposed arrangement is expected to reduce the potential for fish to enter the intake. Additionally, the new intake is designed to be easily cleaned, which prevents regions of high velocity on portions of the intake associated with debris build-up. Lastly, the removal of the headworks in Area 1 would eliminate an impediment to fish movement and would re-establish the feasibility of fish passage through this area. As a result, project effects on fish species are expected to be potentially beneficial and no mitigation would be required.

The federal MBTA protects the nests of all native bird species, including common species such as mourning dove (*Zenaida macroura*), Anna's hummingbird (*Calypte anna*), and house finch (*Carpodacus mexicanus*). Nesting birds and raptors have the potential to occur in vegetation throughout the Project area. Besides the MBTA, Sections 3503 and 3503.5 of the *California Fish and Game Code* protect nesting migratory birds and raptors. As described by MM BIO-2—surveys for nesting birds—vegetation removal should be planned during the non-breeding season if possible. If vegetation removal would occur during the breeding season, a pre-construction nesting bird/raptor survey would be required prior to clearing to ensure compliance with the MBTA, in compliance with MM BIO-2.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan indicated that improvements proposed in the HWP would not impact the movement of native migratory fish and wildlife species and no significant impacts to known migratory wildlife corridors would occur. As discussed, Project impacts on wildlife movement would also be less than significant.

e) Would the project conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance?

Less Than Significant Impact.

Areas 1, 2 and 3 Impacts. A tree survey was conducted to identify trees within the project area that are potentially regulated by the City of Pasadena's City Trees and Tree Protection Ordinance (Chapter 8.52 of the Pasadena Municipal Code). Of the 147 trees included in this survey, 122 trees are "native" trees and 2 are categorized as "specimen" trees as described in the Ordinance (described above in Section 1.2). None of the trees in the survey area are "landmark" trees as described in the Ordinance. Of these 124 trees covered by the City Ordinance, a total of 17 are expected to be removed in order to construct the project. These consist of 13 white alders, 1 coast live oak, and 3 arroyo willows.

Of the 147 trees documented within the Project's study area, a total of 102 meet the requirements for protection by the CDFW. A total of 16 of these trees are expected to be removed to construct the project. These include 13 white alders and 3 arroyo willows.

In all, a total of 17 trees are expected to be removed. Of these 17 trees that are proposed for removal, 16 of them meet the requirements for protection under both the City Tree Ordinance and the *Fish and Game Code*. One coast live oak occurs in the middle of the parking lot in Area 3 that qualifies for protection under the City Tree Ordinance but not the *Fish and Game Code*. A summary of trees included in the survey that are regulated by the City Tree Ordinance and the *Fish and Game Code* is provided in Tables 4.4-4 and 4.4-5. The quantity of trees within each survey area is shown with the number of expected removals represented in parentheses.

TABLE 4.4-4
TREES WITHIN SURVEY AREA REGULATED UNDER PASADENA TREE ORDINANCE

Species	Quantity of Trees (Expected Removals)

Source: BonTerra Psomas 2014a.

As a result of Project construction, it is anticipated that a total of 17 trees would be removed. All of these trees are regulated by the City Tree Ordinance and 16 are regulated under Section 1602 of the *California Fish and Game Code.* It is possible that construction activity may be able to avoid a portion of these trees, thus lowering the overall impacts. However, because the removal of these trees is a clear possibility, they should be included in all tree removal permits that are acquired. If project construction is able to avoid some of these trees, project approvals and regulatory permits could later be amended and the overall mitigation/replacement requirements would be reduced accordingly.

According to guidelines adopted by the City of Pasadena in January 2010 (Pasadena 2010), tree replacement ratios are determined based on the size of the tree to be removed (i.e., larger trees require a higher replacement ratio). However use of larger sized replacement trees will, in turn, reduce the required number of replacement trees.

Removal of public trees require review and advice by the Urban Forestry Advisory Committee. Compliance with RR BIO-2 requires tree pruning, removal, relocation, and replacement to be made in compliance with the City of Pasadena "City Trees and Tree Protection Ordinance" (Section 8.52 of the Pasadena Municipal Code), which requires that mature, public, landmark, landmark-eligible, native and specimen trees be protected and preserved. Work on protected trees must be approved by the City Manager or his/her designated personnel.

A total of 13 trees were documented in the vicinity of the temporary staging site though none are located within the boundaries of that area. Because none of these trees are located within the boundaries of the temporary staging site, no impacts to these trees are anticipated. Additionally, there are several trees that appear to be located within or immediately adjacent to impact areas that are not included in the impact assessment. Such trees include those located adjacent to features whose footprint that can be adjusted shortly before and during construction in order to

avoid these trees. Impacts to trees that are not considered in accordance with RR BIO-2 and/or CDFW permit requirements, would be significant. In order to protect trees that are not anticipated to be impacted, MM BIO-7 requires that protective fencing be erected outside of the outer canopy of any tree whose root zone may be indirectly affected by construction activities, including soil stockpiles or equipment storage. Additionally, during Project construction, a biological monitor will be periodically present to record the number of trees actually impacted. If project construction can avoid impacting oak trees, the number of replacement trees will be reduced accordingly. Compliance with MM BIO-7, which requires tree protection during construction, would ensure that impacts to trees would be less than significant.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan indicated that projects that incorporate tree replacements are considered to be mitigated below the threshold of significance. The Project would comply with the City Trees and Tree Protection Ordinance, as RR BIO-2.

f) Would the project conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan?

No Impact.

Areas 1, 2 and 3 Impacts. There is no adopted Habitat Conservation Plan (HCP); Natural Community Conservation Plan (NCCP); or other approved local, regional, or State habitat conservation plan in the City of Pasadena.

There are two NCCPs in Los Angeles County. The Palos Verdes Peninsula NCCP covers 8,661 acres and provides a reserve system of 1,428 acres at the southwestern end of the County (nearly 30 miles southwest of Area 3) (CDFW 2013b). The West Mojave Plan covers 9.3 million acres of the western portion of the Mojave Desert, which includes the Antelope Valley area of Los Angeles County (northeastern section of Los Angeles County and nearly 20 miles northeast of Area 1) (BLM 2012). There are several HCPs in Los Angeles County but the HCP that is located nearest the HWP is the Newhall HCP along the Santa Clara River, west of I-5 (San Marino Environmental Associates 2004). Area 1 is located over 30 miles southeast of the Newhall HCP area.

The Project would not affect these conservation plans. Therefore, the Project would not conflict with the provisions of an adopted HCP, NCCP, or other approved local, regional, or State habitat conservation plan. No impact would occur and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that the Arroyo Seco Master Plan would not conflict with any habitat conservation plan, natural community conservation plan, or other local or regional habitat conservation plan; that the HWP is not included in any habitat conservation plan; and the HWP is not located in a designated sensitive ecological area.

4.4.3 MITIGATION MEASURES

MM BIO-1 A Biological Monitor shall be on site during vegetation clearing activities in Project work areas (i.e., areas of disturbance). Prior to the start of activities, the Biological Monitor shall confirm that the limits of Project work areas are clearly marked. In addition, the Biological Monitor shall conduct a pre-clearing sweep of the Project work area and shall flush and/or move common and unlisted special status wildlife to nearby suitable habitat outside the Project work area to the extent practicable.

The Biological Monitor shall also be familiar with least Bell's vireo and shall conduct pre-clearing non-protocol surveys for this species while onsite. If a least Bell's vireo or other State of federally listed species is detected, work activity within 200 feet of the detected occupied habitat will be temporarily halted and the City will consult with the USFWS and CDFW. With authorization from these agencies, which may include a 'take' permit, the project will proceed in accordance with conditions developed in the consultation. Conditions will include avoidance and minimization measures to prevent or minimize impacts on the listed species(s) occurring on or adjacent to the site.

MM BIO-2 Project construction shall be conducted in compliance with the conditions set forth in the Migratory Bird Treaty Act (MBTA) and *California Fish and Game Code* with methods approved by the U.S. Fish and Wildlife Service (USFWS) and California Department of Fish and Wildlife (CDFW) to protect active bird/raptor nests. To the maximum extent feasible, vegetation removal shall occur during the non-breeding season for nesting birds (generally late September to early March) and nesting raptors (generally early July to late January) to avoid impacts to nesting birds and raptors. If the Project requires that work be initiated during the breeding season for nesting birds (March 1–September 30) and nesting raptors (February 1–June 30), in order to avoid direct impacts on active nests, a pre-construction survey shall be conducted by a qualified Biologist for nesting birds and/or raptors within 3 days prior to clearing of any vegetation and/or any work near existing structures (i.e., within 300 feet for nesting birds and within 500 feet for nesting raptors). If the Biologist does not find any active nests within or immediately adjacent to the impact areas, the vegetation clearing/construction work shall be allowed to proceed.

If the Biologist finds an active nest within or immediately adjacent to the construction area and determines that the nest may be impacted or breeding activities substantially disrupted, the Biologist shall delineate an appropriate buffer zone around the nest depending on the sensitivity of the species and the nature of the construction activity. Any nest found during survey efforts shall be mapped on the construction plans. The active nest shall be protected until nesting activity has ended. To protect any nest site, the following restrictions to construction activities shall be required until nests are no longer active, as determined by a qualified Biologist: (1) clearing limits shall be established within a buffer around any occupied nest (the buffer shall be 100–300 feet for nesting birds and 300–500 feet for nesting raptors), unless otherwise determined by a qualified Biologist and (2) access and surveying shall be restricted within the buffer of any occupied nest, unless otherwise determined by a qualified Biologist. Encroachment into the buffer area around a known nest shall only be allowed if the Biologist determines that the proposed activity would not disturb the nest occupants. Construction can proceed when the qualified Biologist has determined that fledglings have left the nest or the nest has failed.

MM BIO-3 A Biological Monitor shall conduct a pre-construction bat habitat assessment of buildings and~~the~~ trees marked for potential removal. Potential for roosting shall be categorized by 1) potential for solitary roost sites 2) potential for colonial roost sites (10 bats or more). If the potential for colonial roosting is determined, those trees shall not be removed during the bat maternity roost season (March 1 – July 31). Trees potentially supporting colonial roosts outside of maternity roost season, and trees potentially supporting solitary roosts may be removed via a two-step removal process, whereby some level of disturbance (such as trimming of lower branches)

(at the direction of the Biological Monitor) is applied to the tree on day one to allow bats to escape during the darker hours, and the roost tree shall be removed two days later~~the following day~~ (i.e., there shall be no less or more than two~~one~~ nights between initial disturbance and the grading or tree removal). When feasible, trees will be dropped slowly and a Biological Monitor will monitor the activity. If buildings are determined to be occupied, one-way exclusionary devices will be placed over bat access points and left in place for two nights prior to building removal.

MM BIO-4 Prior to habitat disturbing activities of any Project component, a detailed restoration program shall be developed and implemented for any special status vegetation type identified within the Project disturbance limits that is removed. These special status vegetation types shall be restored within the project disturbance limits at a ratio of not less than 1:1, or as agreed to by the City of Pasadena in consultation with the CDFW. If the 1:1 ratio cannot be achieved within the project disturbance limits, then the balance shall be achieved by identifying additional areas for restoration or conservation within the Arroyo Seco or adjacent watersheds. Restoration shall consist of seeding and container plantings of appropriate species. A Restoration Program shall be submitted to the City of Pasadena for review by a qualified Biologist and approval by the resource agencies (USACE, RWQCB, CDFW) prior to issuance of grading permits. The Restoration Program shall include, at a minimum, the following elements:

a. **Responsibilities and qualifications of the personnel to implement and supervise the plan.** The responsibilities of the landowner, specialists, and maintenance personnel that will supervise and implement the plan shall be specified.

b. **Site selection.** The site(s) for mitigation shall be determined in coordination with the City of Pasadena and the resource agencies. Restoration required outside the Project disturbance limits shall be located in dedicated open space areas (i.e. preserved in perpetuity as open space) and shall be contiguous with other natural open space areas.

c. **Site preparation and planting implementation.** The site preparation shall include (1) protection of existing native species; (2) trash and invasive non-natives removal; (3) native species salvage and reuse (i.e., duff); (4) soil treatments (i.e., imprinting, decompacting); (5) erosion-control measures (i.e., rice or willow wattles); and (6) native seed mix application and plantings.

d. **Schedule.** Establishment of restoration/revegetation sites shall be conducted between October 1 and January 30. Seeding and planting of container plants shall take place immediately after preparation of the restoration sites.

e. **Maintenance plan/guidelines.** The maintenance plan shall include (1) invasive non-natives control, (2) herbivory control, (3) trash removal, (4) irrigation system maintenance, (5) maintenance training, and (6) replacement seeding and/or planting.

f. **Monitoring Plan.** The monitoring plan shall include (1) site preparation and implementation activities; (2) performance criteria as approved by the City of Pasadena and resource agencies; (3) long-term monitoring requirements and methods to determine compliance with performance criteria; (4) goals and methods of site maintenance (e.g., weed removal, erosion control); (5) preparation of regular progress reports to document site progress; and (6) preparation of annual reports which shall be submitted to the City of

Pasadena and resources agencies for three to five years. The monitoring shall be conducted for three to five years, depending upon the performance standard requirements for the vegetation type at the mitigation site.

g. **Long-term preservation.** Long-term preservation of the restoration site shall be outlined in the conceptual mitigation plan to ensure the mitigation site is not impacted by future development.

h. **Performance standards will be identified and will apply for each special status vegetation type.** Revegetation shall be considered successful at three years if the percent cover and species diversity of the restored and/or created habitat areas are similar to percent cover and species diversity of adjacent existing habitats, as determined by quantitative testing of existing, restored, and created habitat areas.

In addition, earth-moving equipment shall avoid maneuvering in areas outside the construction limits in order to avoid disturbing adjacent habitats. Prior to grading, the construction limits shall be identified on the grading plan and established at the Project site with appropriate staking and flagging materials. The Contractor shall submit a letter to the City of Pasadena verifying that the construction limits have been staked and flagged at the Project site.

MM BIO-5 Mitigation for the loss of jurisdictional resources shall be negotiated with the resource agencies during the regulatory permitting process (see RR BIO-1) and shall ensure that mitigation to compensate for permanent impacts on jurisdictional resources is equivalent or superior to biological functions and values impacted by the Project. Potential mitigation options may include: (1) removal of exotic species from the Arroyo Seco Canyon or Hahamongna Watershed Park; (2) payment to a mitigation bank or regional riparian enhancement program (e.g., invasive plant or wildlife species removal); and/or (3) restoration of riparian habitat either on site or off site at a ratio of no less than 1:1, determined through consultation with the USACE, the RWQCB, and the CDFW. The restoration plan shall detail the methodology and performance standards, which shall be prepared in accordance with requirements specified in permits/agreements issued by the USACE, the RWQCB, and the CDFW.

MM BIO-6 A team of qualified specialists in hydrology and plant and wildlife biology will monitor the Arroyo Seco stream and associated riparian habitat from the intake structure (i.e. diversion point) downstream to Devil's Gate Dam. The extent of the riparian habitat, including aquatic habitat, will be defined based on field observations during the initial site visit. Monitoring will begin with an initial baseline assessment to be conducted within six months prior to start of increased diversions. Thereafter, monitoring shall continue quarterly for a duration of five years. Data will be gathered at fixed points along the stream, and general descriptive notes and photos will be taken of the entire stretch. Data will include surface flow measurements; subsurface hydrology; surface water extent mapping; vegetation mapping; a vegetation health assessment; active channel location mapping; and a plant and wildlife habitat suitability assessment (including protocol surveys if warranted and necessary to determine presence or absence of species). Data from four quarterly visits will be compiled in an annual report. The initial report will include a summary of available biological and hydrological historic data for the site. Annual reports will also include U.S. Geological Survey (USGS) stream gauge data from the Arroyo Seco (upstream of the Project site) and City of Pasadena data on diversion amounts within the year. These reports will consider all potential

contributing factors, including precipitation and hydrologic conditions, flows from other managed tributaries, as well as potential maintenance and sediment removal activities behind the Devil's Gate Dam, and focus the reports on that which is attributable to the Project to the maximum extent feasible. Annual reports will conclude with an assessment on the effects of increased diversion and will provide recommendations for corrective actions, if deemed necessary to avoid or reduce downstream impacts attributable to the Project. Reports will be submitted to the City of Pasadena for review and approval of recommended corrective measures, if any.

Alternatively, if the City chooses not to take corrective measures, the City may mitigate for any loss of vegetation at a minimum 1:1 replacement ratio. The City shall only be required to mitigate for those impacts attributable to the City's increased diversions. Replacement vegetation shall be in kind; shall be equal to or greater than biological value prior to diversion; and shall be located within the Arroyo Seco watershed. Vegetation replacement shall mitigate for plant and wildlife impacts of the impacted community. Re-vegetated riparian communities within Area 1 established as part of the Project may potentially qualify towards credit for reduced flow impacts, if credit is available.

MM BIO-7 Prior to commencement of construction activities, trees not expected to be impacted by construction shall be enclosed by barriers such as chain-link fencing or orange snow fencing. At a minimum, the barriers will be placed at the outer canopy of each tree to be protected in place, and no grade changes will be made within the barriers without prior approval by the City. During Project construction, a biological monitor will be periodically present to record the number of trees actually impacted. If project construction can avoid impacting oak trees, the number of replacement trees will be reduced accordingly.

4.5 CULTURAL RESOURCES	Potentially Significant Impact	Less than Significant with Mitigation	Less than Significant Impact	No Impact
Would the project:				
a) Cause a substantial adverse change in the significance of a historical resource as defined in Section 15064.5?	☐	☒	☐	☐
b) Cause a substantial adverse change in the significance of an archaeological resource pursuant to Section 15064.5?	☐	☒	☐	☐
c) Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature?	☐	☒	☐	☐
d) Disturb any human remains, including those interred outside of formal cemeteries?	☐	☐	☒	☐

A Phase I Cultural Resources Assessment was prepared for the Project, which is summarized below and provided in its entirety in Appendix C.

4.5.1 EXISTING CONDITIONS

Prehistory

At the time of Spanish contact, the Arroyo Seco Canyon area is believed to have been inhabited by the Gabrielino, or *Tongva*. The name "Gabrielino" identifies those people who came under the control of Mission San Gabriel Arcángel and included the inhabitants of most of current-day Los Angeles and Orange counties and portions of Riverside and San Bernardino counties. McCawley reports that the Arroyo Seco was known to the Gabrielino as *M'kat*. The name means "rocky or something like that". According to McCawley, no people lived in Pasadena during late Prehistoric times, as the area was prairie (BonTerra Psomas 2014b).

History

Over 20 years before a group of settlers met at Reservoir Hill near the Arroyo Seco to create the Pasadena colony north of the Los Angeles settlement, gold miners had searched the headwaters of that seasonal creek in the San Gabriel Mountains. In 1853, gold was found in the placer diggings of miners exploring the Arroyo Seco Canyon, and quartz mines in the San Gabriel Mountains continued to be mined up to 1883.

El Prieto Canyon, which feeds into the Arroyo Seco Canyon in Section 32 of Township 2 North, Range 12 West, had originally been known as Negro Canyon or Negro Creek, so named after an African-American freeman by the name of Robert Owen, who sold firewood harvested off the hillsides of the lands held by the U.S. Government in the 1850s and 1860s to residents of the Los Angeles settlement.

Millard Canyon had originally been known by the Mexican residents of the area as Blanco Canyon because of the geology of the canyon walls in some places. Millard, whose first name is unknown, established a homesite at the mouth of the canyon in 1862. He was an illegal squatter on the land in Section 5 of Township 1 North, Range 12 West, who is said to have made his income by raising bees and hauling wood to Los Angeles. Millard lived in the canyon until 1872 when he moved to the Downey settlement after his wife and a child died.

In the 1880s, the U.S. Government opened up a limited amount of land in Sections 31 and 32 of Township 2 North, Range 12 West of the San Gabriel Mountain foothills for private ownership. John Hartwell, Eugene and Clara Giddings, and Jason and Owen Brown all received patents for acreage in Section 32 wherein lay Fern Canyon, El Prieto Canyon, and Millard Canyon, from 1883 to 1891. The eastern half of the southeast quarter of Section 31 was owned primarily by Will D. and Mary L. Gould, a lawyer and his wife from Los Angeles.

The Giddings settled into a residence at the mouth of Millard Canyon and reported to local historian Hiram Reid, that they would find evidence of pre-historic peoples in the canyon when they worked the land with plows and hoes. The Giddings had constructed a wagon toll-road up to the falls on Millard Creek, creating a destination for persons seeking out-of-doors entertainment by hiking and picnicking. Owen and Jason Brown, descendants of the Kansas abolitionist John Brown, constructed a homestead in a canyon named after them located just south of El Prieto Canyon in 1886.

The most ambitious operation on the Arroyo Seco in the San Gabriel Mountains was that of C. Perry Switzer. The "Commodore", as he was known, built a tourist-resort camp far into the mountains that was accessible from a trail that followed the Arroyo Seco. An improved road ran up the canyon from Millard Creek to a halfway house, and then the remaining six miles to Switzer's Camp would be reached by riding burros.

The location of Commodore Switzer's camp is still accessible on the Gabrielino Trail. Some of the cabins were destroyed in a fire in the late 1890s, and the great flood of 1938 removed over a mile of the road that connected the camp to the Angeles Crest Highway. The owner of the camp in the 1950s was not able to keep the camp operating, and the site fell into ruins. The USFS removed the stone chapel that had been designed by the architect Arthur Benton due to its deteriorating condition.

The Altadena topographic map of the area in 1924 shows that a large number of buildings, most probably small, recreational cabins, were situated along the Arroyo road north of where Millard Creek joins the Arroyo Seco. By 1939, there were still scattered buildings situated along the Arroyo Road to Oak Wilde, where the road connected by dirt road with the Angeles Crest Highway. With the completion of the Angeles Crest Highway in 1956, the Arroyo Boulevard (Highway) became obsolete and fell into disrepair.

Archaeological Resources

A cultural resources survey was conducted by Patrick O. Maxon, M.A., RPA and Mark A. Roeder on May 1, 2013, and completed by Mr. Maxon alone on November 21, 2013. The survey did not identify any archaeological resources on the Project site. While it is likely that native populations used the Arroyo Seco Canyon area in prehistoric times; previous disturbance of the ground surface and the creek's dynamic, fluvial environment have resulted in much of the area being disturbed. Any archaeological resources that may have been present have likely been washed away or buried by alluvial processes.

Eighteen cultural resources studies have been conducted within a one-mile radius of the Project site, with two of the studies including a portion of the Project site. These studies did not identify any resources on the Project site. However, eight previously recorded resources are located within one mile of the Project site. Table 4.5-1 lists these known cultural resources.

TABLE 4.5-1
CULTURAL RESOURCES WITHIN
ONE MILE OF THE PROJECT SITE

Site Number	Recorder (Year)	Comment
19-342	Cowper (1965)	Cogstone and millingstones
19-2189	McKenna (1993)	Jet Propulsion Laboratory
19-3086	Romani (2002)	Teddy's Outpost Picnic Area
19-3090	McIntyre (1998)	Lower Sam Merrill Trail
19-186870	Schmidt and Schmidt (2003)	Southern California Edison Eagle Rock-Laguna Bell Transmission Line Corridor
19-189942	McKenna (2012)	Hahamongna Watershed Park
19-150023	Stone (1992)	Arroyo Seco Ranger Station No. 1
19-150024	Stone (1992)	Arroyo Seco Ranger Station No. 2
Source: BonTerra Psomas 2014b.		

Paleontological Resources

The Project area is underlain by several geological rock units with varying paleontological sensitivity. Quartz Diorite (qd), found in the eastern edge of Area 1 and between Areas 2 and 3, has no potential to yield paleontological resources. Leucocratic Granitic Rocks (gr) that are present west of Area 1 and west and east of Area 2 have no potential to yield paleontological resources. Quaternary Older Alluvium Fan Deposits (Qoa) east of Area 1 and south of Area 2 have moderate potential to yield paleontological resources. Quaternary Older Alluvial Fan Sediments (Qof) east of Area 3 have low potential to yield paleontological resources. Quaternary Stream Deposits (Qg) in the stream course of the Arroyo Seco in Areas 1 and 2 and found in Area 3 have low potential to yield paleontological resources.

Native American Sacred Lands File Review

On March 20, 2013, an inquiry was made of the Native American Heritage Commission (NAHC) in Sacramento to request a review of the Sacred Lands File database regarding the possibility of Native American cultural resources and/or sacred places in the Project vicinity that are not documented on other databases. The NAHC responded on March 21, 2013, with its Sacred Lands File Search and contacts list of Native American groups and individuals who may have knowledge regarding Native American cultural resources not formally listed on any database. Each of these groups and individuals were mailed an informational letter March 21, 2013, describing the Project and requesting any information regarding resources that may exist on or near the Project site.

One response has been received to date. Robert Dorame, Tribal Chair/Cultural Resources for the Gabrielino Tongva Indians of California Tribal Council, replied via email that (1) several Indian villages were present along the Arroyo Seco in 1769, when Spanish occupation of California began; (2) the Sheldon Reservoir site, located south of Devil's Gate Dam on the east side of Arroyo Seco, contained 53 sets of human remains associated with a prehistoric village site; (3) the ethnohistoric village of *Hahamongna* is located one mile due north of JPL; and (4) Mr. Dorame's grandmother and great-grandmother lived in the San Pasqual Rancho beginning in the late 19th Century. The Rancho is located adjacent to the site (BonTerra Psomas 2014b).

Historical Resources

There are no structures on the Project site that are currently listed, individually or collectively, in either the National Register of Historic Places (NRHP) or the California Register of Historical Resources (CRHR). In assessing the historical significance of built-environment structures located in Areas 1, 2, and 3, as evaluated in the Historic Resources Assessment Report prepared by Daly & Associates (see Appendix C), federal, State, and local significance criteria were applied.

The PWP had water rights to the Arroyo Seco prior to 1914. Water diversion and control structures (e.g., the Headworks, water diversion structure, intake system, debris basins) began to be constructed in the canyon in 1914. Bridges No. 1 and 2 appear to date from the 1920s when Arroyo Boulevard was paved for use as a county highway, while Bridge No. 3 was constructed in 1939 by the Civilian Conservation Corps (CCC) to replace an earlier bridge destroyed in the flood of 1938. Over the years, floods and other high water events have caused permanent damage to water diversion structures in the canyon, and some were replaced as needed. Resources in and near the Project site include:

Area 1. The configuration of the Headworks in Area 1 has been in use for many years. The fact that this headwork has been manually operated for over 50 years points to its design longevity and ease of operation. The headworks facility is not a significant engineering or technological structure.

Area 2. Due to the extensive damage suffered by the diversion dam and intake system, the water diversion and control structures in Area 2 have lost their physical integrity of design, workmanship, and materials. Water diversion systems such as these have been in use for many years and usually do not present significant engineering or technological innovation.

Bridge No. 3. This bridge was constructed in 1939 by the CCC Company 903 assigned to the USFS, a team from the local CCC that had been working on various projects in the Arroyo Seco Canyon and San Gabriel Mountains since 1933. Besides this bridge, the Arroyo Seco through this section and south to Bridge No. 2 is lined with river rock masonry walls, which were most probably constructed by the CCC at the same time as Bridge No 3. Bridge No. 3 was designed using one of the oldest truss-bridge forms; is constructed of wood timbers; and was constructed by a group that is associated with events that made a significant contribution to the history of the United States and California. Bridge No. 3 appears to be a property that meets the criterion to be listed in the NRHP and in the CRHR.

Bridge No. 2. This bridge is situated on the Gabrielino Trail/Arroyo Boulevard, between Areas 2 and 3. This reinforced, poured-concrete arch bridge may have been constructed in the 1920s when Arroyo Boulevard was paved for use as a county highway. It has distinctive decorative elements (e.g., the urn-shaped cast concrete balustrade railings, bas-relief panels below the balusters on the stream sides of the bridge, and the arched support structure) that would not be found on a utility road for service vehicles. The bridge appears to have been constructed to provide a formal entrance to the Upper Arroyo Seco Forest and Arroyo Boulevard. Stone masonry walls that line the east side of the creek at Bridge No. 3 continue downstream and are present at Bridge No. 2. Bridge No. 2 appears to be a property that meets the criterion to be listed as a historical resource in the CRHR and in the City of Pasadena as a landmark.

Bridge No. 1. This bridge is situated on the Gabrielino Trail/Arroyo Boulevard, between Areas 2 and 3. Bridge No. 1 was constructed in 1939 to carry Arroyo Boulevard over the runoff from Millard Canyon Creek, before the creek intersects with the Arroyo Seco creek. The bridge slab was replaced in 1979 with a similar reinforced concrete span. Bridge No. 1 does not appear eligible for listing in the NRHP, CRHR, or as a City of Pasadena landmark.

Area 3. The sludge and spreading basins, water diversion structures, and water conduits situated in Area 3 were all designed using common engineering techniques for moving, diverting, and controlling water. In an effort to protect lives and property and to capture runoff from the western slopes of the San Gabriel Mountains, many water diversion structures are located not only in the Upper Arroyo Seco, but throughout the canyons in Los Angeles County. The spreading basins, sludge basins, and water diversion structures in Area 3 are not significant engineering or technically innovative structures.

4.5.2 IMPACT ANALYSIS

Project Design Features

PDF CUL-1 A temporary bridge will be constructed over Bridge No. 3 prior to the start of construction activities in Areas 1 and 2. The temporary bridge will be used for all construction vehicles and equipment and will be removed after construction activities are completed.

Regulatory Requirements

RR CUL-1 If human remains are encountered during excavation activities, all work is required to halt in the immediate vicinity of the discovery and the County Coroner must be notified (*California Public Resources Code* §5097.98). The Coroner is required to determine whether the remains are of forensic interest. If the Coroner, with the aid of an Archaeologist, determines that the remains are prehistoric, s/he is required to contact the Native American Heritage Commission (NAHC). The NAHC is responsible for designating the most likely descendant (MLD), who is responsible for the ultimate disposition of the remains, as required by Section 7050.5 of the *California Health and Safety Code.* The MLD is required to make his/her recommendation within 48 hours of being granted access to the site. The MLD's recommendation is required to be followed if feasible, and may include scientific removal and non-destructive analysis of the human remains and any items associated with Native American burials (*California Health and Safety Code* §7050.5). If the landowner rejects the MLD's recommendations, the landowner is required to rebury the remains with appropriate dignity on the property in a location that will not be subject to further subsurface disturbance (*California Public Resources Code* §5097.98).

Impact Discussion

a) Would the project cause a substantial adverse change in the significance of a historical resource as defined in Section 15064.5?

Less Than Significant Impact with Mitigation.

Areas 1, 2, and 3 Impacts. There are no historic resources in the Areas 1 or 3 that will be substantially changed as a result of the Project. Bridge No. 3 is situated within the boundary of Area 2, and Bridge No. 2 is located on the Gabrielino Trail (Arroyo Boulevard) between Areas 2 and 3. Project construction vehicles would cross/utilize Bridge No. 2 and have the potential to damage the structure and result in substantial changes/alterations of historic character-defining features that are components of Bridge No. 2. Additionally, the proposed Project has the potential to substantially change/alter a historic resource with the construction of a temporary bridge to

protect Bridge No. 3 and its associated features such as concrete abutments, railings, and stone walls.

PDF CUL-1 proposes a temporary bridge over Bridge No. 3 for use during construction. This will avoid use of the existing bridge and prevent damage from construction vehicles, equipment, and haul trucks. However, construction of the temporary bridge may affect the concrete abutments, railings, and stone walls. The design and construction (and eventual removal) of the temporary bridge will need to be prepared in accordance with the Secretary of the Interior's Standards for the Treatment of Historic Properties (MM CUL-1) so that the character defining features of any affected portions of the bridge remain intact after construction.

In addition, potential damage to the baluster railing of Bridge No. 2 could occur from construction equipment and trucks passing on the bridge. Each baluster railing, from the bridge deck to the top of the railing, will be protected by solid plywood panels secured without damaging the balusters or railing (MM CUL-2). The design and construction of the protective barriers will be prepared in accordance with the Secretary of the Interior's Standards for the Treatment of Historic Properties (MM CUL-2). Accordingly, the railings would not be adversely affected by construction traffic.

Impacts on historical resources would be less than significant after implementation of MM CUL-1 and MM CUL-2.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified potential impacts to historic resources and their settings and included mitigation measures to reduce significant impacts to historical resources. Measure Cultural-6 for impacts to Devil's Gate Dam, Measure Cultural-7 for impacts to features in the Central Arroyo Seco, and Measure Cultural-8 for impacts to the casting pond in the Lower Arroyo Seco are not applicable to the Project.

b) Would the project cause a substantial adverse change in the significance of an archaeological resource pursuant to Section 15064.5?

Less Than Significant Impact with Mitigation.

Areas 1, 2, and 3 Impacts. Several cultural resources have been recorded near the Project site. Teddy's Outpost picnic area (LAN-3086) is located just north of the Headworks near Area 1. Buildings 1015 and 1016 of the Arroyo Seco Ranger Station (19-150023 and 19-150024) are located just east of Area 1. JPL (LAN-2189) is located west of the Arroyo Seco and Area 3. The Hahamongna Watershed Park (19-189942) lies south of JPL and north of the I-210 Freeway on both sides of the Arroyo Seco. Area 3 is located within this park. A significant prehistoric site (LAN-342) was recorded at Millard Canyon, in the neighborhood north and east of the site, but was likely destroyed by development. No disturbance is proposed by the Project at these recorded resources.

It is likely that native populations used the Arroyo Seco Canyon area in prehistoric times. However, the dynamic, fluvial nature of the creek and surrounding floodplain have likely washed away archaeological resources or buried them by alluvial and colluvial processes. Previous disturbance during construction activities of existing facilities (e.g., Headworks, diversion and intake structures, Gabrielino Trail/access road, bridges, parking lot, and spreading basins) makes it unlikely that significant cultural resources are present in these areas. While unlikely, buried resources could exist in the Project site and be damaged by excavation and grading activities for Project construction, which would be a significant impact. As stated under MM CUL-3, a qualified Archaeologist must be retained to monitor earthmoving activities and to evaluate and develop a

mitigation plan for any discovered unique archaeological resource or historical resource. Impacts on archaeological resources would be less than significant with implementation of MM CUL-3.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified potentially significant impacts to known and unknown archaeological resources and included mitigation measures (Measure Cultural-2 and Measure Cultural-3) to reduce significant impacts to these resources. Measure Cultural-2 calls for monitoring around CA-LAN-26, which is located in the Central Arroyo Seco, and thus, this measure would not be applicable to the Project. Measure Cultural-3 requires archaeological monitoring during grading of native soils during construction of the surface parking areas, restrooms, Johnson Field expansion, and new trails in the HWP. Since the parking lot in Area 3 would have been removed before construction of the new parking lot occurs, no monitoring is proposed. However, MM CUL-3 will be implemented for improvements in Area 3 and this MM is similar to and therefore replaces Measure Cultural-3.

The Master EIR for the Arroyo Seco Master Plan also identified potential impacts to unknown Native American resources from grading activities associated with construction of the surface parking areas, restrooms, and Johnson Field expansion in the HWP. The Master EIR included Measure Cultural-4 for a Native American Monitor to observe grading activities. The Phase I Cultural Resources Assessment for this Project indicates that the Project site is highly disturbed due to continuous flows in the Arroyo Seco and past disturbance of adjacent areas; the field survey did not uncover archaeological resources; but due to cultural sensitivity within the area, archeological monitoring is recommended. Consultation with Native American tribes was conducted as part of the Phase I Cultural Resources Assessment and the response from the Gabrielino Tongva Indians of California Tribal Council did not express the need for a Native American Monitor. However, MM CUL-3 is recommended and requires monitoring of earthmoving activities for archaeological resources. The City has the option to have a Native American Monitor observe grading and excavation activities in Area 3, if local tribes express a need or deem it appropriate.

c) Would the project directly or indirectly destroy a unique paleontological resource or site or unique geologic feature?

Less Than Significant Impact with Mitigation.

Areas 1, 2 and 3 Impacts. Ground disturbance would occur at the stream bottom, which is overlain by recent alluvial material deposited by stream flows and generally does not contain fossil resources. The areas underlain by granitic bedrock also have no paleontological sensitivity. At the edges of the stream is older alluvium that may have limited potential for paleontological resources.

While no paleontological resources were observed on the surface of the Project site, underlying older Quaternary fluvial deposits may well contain significant vertebrate fossils. Thus, while excavation less than five feet in depth is not likely to disturb paleontological resources, deeper excavations (over five feet in depth), which are associated with excavation of the spreading basins, could expose paleontological resources that have the potential to be damaged by heavy equipment, which would be a significant impact. In order to avoid impacts to paleontological resources, MM CUL-4 requires that a qualified Paleontologist (one with training in the recognition of paleontological resources) shall be retained to observe grading activities in paleontologically sensitive sediments and conduct salvage excavation of paleontological resources as necessary. Any discovered resources would be evaluated for significance and appropriate exploration, salvage, and curation. Impacts on paleontological resources would be less than significant after mitigation.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified potentially significant impacts to cultural resources and included Measure Cultural-1 to reduce significant impacts to paleontological resources from construction of the Flint Wash Bridge, the north bridge, and public restrooms in the HWP. While the Project does not propose Flint Wash bridge or the north bridge, it includes construction of a restroom in Area 3. MM CUL-4 will be implemented during construction activities and includes the same requirements outlined in Measure Cultural-1.

d) Would the project disturb any human remains, including those interred outside of formal cemeteries?

Less Than Significant Impact.

Areas 1, 2, and 3 Impacts. While human remains have been found in the Project area, the records search and field survey indicate no evidence of human remains on or near the Arroyo Seco. In the unlikely event of an unanticipated encounter with human remains, the *California Health and Safety Code* and the *California Public Resources Code* require that any activity in the area of a potential find be halted and the Los Angeles County Coroner be notified, as described in RR CUL-1. There would be less than significant adverse impacts to human remains with compliance with RR CUL-1. No mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified potential impacts to human remains during construction activities for surface parking areas, public restrooms, and Johnson Field expansion in the HWP. The Master EIR included Measure Cultural-5 for the construction briefing of the foreman and all personnel regarding the need to notify the County Coroner and stop excavation and disturbance of the site in accordance with Section 5097.98 of the *California Public Resources Code.* As discussed above, the Project would comply with RR CUL-1, which is equivalent to Measure Cultural-5.

4.5.3 MITIGATION MEASURES

MM CUL-1 Prior to the start of construction activities in Areas 1 and 2, the cast concrete baluster railing of Bridge No. 2 shall be protected from construction activities that include the movement of heavy and large motor vehicles and machinery over it to gain access to Areas 1 and 2. Each baluster railing, from the bridge deck to the top of the railing, shall be clad with solid plywood panels, with a minimum thickness of ¾ inches (or equally effective measures shall be installed) to protect against unintentional impacts from passing over the bridge. The plywood barriers shall be secured without damaging the balusters or railing.

The design and construction (and eventual removal) of the protective barriers at Bridge No. 2 shall be prepared in accordance with the Secretary of the Interior's Standards for the Treatment of Historic Properties. The plans for the temporary barriers shall be reviewed by an architectural historian, historic architect, and structural or civil engineer who has experience with the physical components of historic bridges. A qualified architectural historian (who meets the Secretary of Interior's Professional Qualification Standards) shall be retained to monitor the proposed installation and removal of the protective barriers on Bridge No. 2, prior to construction. An installation/construction/repair methodology to protect the historic resources shall be developed prior to construction activities to ensure that the protective measures adequately safeguard Bridge No. 2.

A pre-construction and a post-construction survey shall be prepared to ensure that adverse effects or significant impacts have not occurred to the bridge. The installation/construction methodology and post-construction survey shall be submitted to the City of Pasadena Department of Planning – Historic Preservation.

MM CUL-2 Prior to commencement of construction activities within Areas 1 and 2, the design and construction (and eventual removal) of the temporary bridge over Bridge No. 3 shall be prepared in accordance with the Secretary of the Interior's Standards for the Treatment of Historic Properties. The plans for temporary bridge shall be reviewed by an architectural historian, historic architect, and structural or civil engineer who has experience with the physical components of historic bridges and stone walls. A qualified architectural historian (who meets the Secretary of Interior's Professional Qualification Standards) shall be retained to monitor the proposed installation/construction and removal plan documents for the temporary bridge on Bridge No. 3, prior to the start of construction activities.

A pre-construction and a post-construction survey shall be prepared to ensure that adverse effects or significant impacts have not occurred to the bridge. The installation/construction methodology and post-construction survey shall be submitted to the City of Pasadena Department of Planning and Community Development, Design and Historic Preservation.

MM CUL-3 Prior to commencement of earthmoving activities, the City shall retain a qualified Archaeologist to observe grading activities. The Archaeologist shall be present at the pre-grade conference; shall establish procedures for archaeological resource surveillance; and shall establish, in cooperation with the Contractor, procedures for temporarily halting or redirecting work to permit the sampling, identification, and evaluation of the artifacts, as appropriate. Should archaeological resources be found during ground-disturbing activities for the Project, the Archaeologist shall first determine whether it is a "unique archaeological resource" pursuant to the California Environmental Quality Act (CEQA, i.e., Section 21083.2[g] of the *California Public Resources Code*) or a "historical resource" pursuant to Section 15064.5(a) of the State CEQA Guidelines. If the archaeological resource is determined to be a "unique archaeological resource" or a "historical resource", the Archaeologist shall formulate a mitigation plan in consultation with the City of Pasadena that satisfies the requirements of the above-referenced sections. The Archaeologist shall prepare a report of the results of any study prepared as part of a testing or mitigation plan, following guidelines of the California Office of Historic Preservation, and s/he shall record the site and submit the recordation form to the City of Pasadena and the California Historic Resources Information System (CHRIS) at the South Central Coastal Information Center (SCCIC) at California State University, Fullerton. Work may proceed in other areas of the site, subject to the direction of the Archaeologist.

MM CUL-4 Prior to commencement of earthmoving activities, a qualified Paleontologist shall be retained to observe grading activities in native soils that are 5 feet below the ground surface or deeper, in paleontologically sensitive sediments, and to conduct salvage excavation of paleontological resources, as necessary. The Paleontologist shall be present at the pre-grading conference; shall establish procedures for paleontological resources surveillance; and shall establish, in cooperation with the Contractor, procedures for temporarily halting or redirecting work to permit the sampling, identification, and evaluation of any fossils discovered, as appropriate. If paleontological resources are discovered, the Paleontologist shall report such

findings to the City of Pasadena. If paleontological resources are found to be significant, the Paleontologist shall determine appropriate actions, in cooperation with the City, for exploration and/or salvage. These actions, as well as final mitigation and disposition of the resources, shall be subject to the approval of the City. All recovered fossils shall be deposited in an accredited institution or museum, such as the Natural History Museum of Los Angeles County.

4.6 ENERGY	Potentially Significant Impact	Less than Significant with Mitigation	Less than Significant Impact	No Impact
Would the project:				
a) Conflict with adopted energy conservation plans	☐	☐	☐	☒
b) Use non-renewable resources in a wasteful and inefficient manner?	☐	☐	☐	☒

4.6.1 EXISTING CONDITIONS

The Project site currently uses minimal energy, with no energy use in Areas 1 and 2. Area 3 is developed with the JPL East Parking Lot and lights at the parking lot utilize electrical energy when in use during the nighttime hours. There is also an electrical charging station in Area 3 for electric vehicles. However, JPL will be removing these lights and all on-site improvements as part of their lease termination, except for the asphalt on a temporary access road through Area 3. Electrical energy is also used for the basin metering in the spreading basins.

4.6.2 IMPACT ANALYSIS

Impact Discussion

a) Would the project conflict with adopted energy conservation plans?

No Impact.

Areas 1, 2 and 3 Impacts. The Project would have minimal demand for electrical energy. Sources of new energy demands resulting from Project implementation include the proposed control equipment enclosure and weir in Area 2 and the proposed restroom, guard station, irrigation system for planters within the parking lot, and basin metering in Area 3. Electricity would be provided to Area 2 via an existing electrical connection at an existing equipment building, so no new infrastructure is required. Electricity would be provided to Area 3 via the existing electrical infrastructure formerly used to power the parking lot lighting, and no new infrastructure is required. The temporary irrigation system in Area 1 would utilize a battery system. No demand for natural gas would be created by the Project. The elimination of the existing JPL East Parking Lot lighting and reductions in demand for State Water Project water deliveries due to increased groundwater recharge would help partially off-set new Project-related electrical demand. Therefore, although the Project would result in a slight increase in overall electrical usage, no new infrastructure would be required and any new electrical connections would be constructed in accordance with the City's Building Code (RR GEO-1). There would be no conflict with an adopted energy conservation plan would occur and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not address impacts related to Energy.

b) Would the project use non-renewable resources in a wasteful and inefficient manner?

No Impact.

Areas 1, 2 and 3 Impacts. Energy use during construction would include the use of fossil fuels for construction equipment, material deliveries, demolition waste disposal, and construction crew travel. Also, maintenance and inspection activities will generate vehicle trips that would utilize fossil fuels. This would be minimal when compared to fossil fuel use from total vehicle miles travelled in the City on a daily basis and would be short-term for construction activities and intermittent for maintenance activities. Also, this energy use would not be considered wasteful or inefficient.

Energy use in Area 1 for the temporary irrigation system would be provided by a battery system. Electrical energy would be needed in Area 2 for the proposed control equipment enclosure and weir. Electrical energy use in Area 3 would be needed for the proposed guard station, restroom, and irrigation system and the basin metering. The proposed Project will not create a high enough demand for energy to require development of new energy sources. With the relatively small sizes of the proposed facilities, energy needs would also be limited and would not be considered wasteful or inefficient. The Project would utilize surface water resources in the Arroyo Seco to increase groundwater recharge and, in turn, would have beneficial impacts on the PWP's water supply, including decreased demand for State Water Project water deliveries. The increase in groundwater recharge due to the Project will require an incremental increase in energy use for groundwater well pumping. However, with decreased reliance upon imported water sources, the net effect would be a reduction in boosting and conveying imported water to the City's water system. No adverse impact on non-renewable resources would occur and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not address impacts related to Energy.

4.6.3 MITIGATION MEASURES

There would be no significant adverse impacts on energy; therefore, no mitigation measures are required.

4.7 GEOLOGY AND SOILS	**Potentially Significant Impact**	**Less than Significant with Mitigation**	**Less than Significant Impact**	**No Impact**
Would the project:				
a) Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:				
i) Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault? Refer to Division of Mines and Geology Special Publication 42.	☐	☐	☒	☐
ii) Strong seismic ground shaking?	☐	☐	☒	☐
iii) Seismic-related ground failure, including liquefaction?	☐	☐	☒	☐
iv) Landslides?	☐	☐	☒	☐
b) Result in substantial soil erosion or the loss of topsoil?	☐	☐	☒	☐
c) Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in onsite or offsite landslide, lateral spreading, subsidence, liquefaction, or collapse?	☐	☐	☒	☐
d) Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property?	☐	☐	☒	☐

A Geotechnical Feasibility Study Report was prepared for the Project in August 2013 by Converse Consultants. The findings of this report are summarized below, with the report provided in Appendix D.

4.7.1 EXISTING CONDITIONS

The Arroyo Seco Canyon is located on the south-facing slopes of the San Gabriel Mountains. The San Gabriel Mountains are part of the Transverse Ranges physiographic province of Southern California. After the Devil's Gate Dam was constructed in 1920, sediments from the canyon accumulated behind the dam and raised the ground surface between the canyon walls. The areas around the dam and reservoir are relatively flat, but areas to the north feature moderately steep foothills. The lower hills north of the JPL campus rise to 1,560 feet above mean sea level (msl), but the San Gabriel Mountains rise up to heights of 6,200 to 8,400 feet above msl.

The Sierra Madre Fault is a 47-mile zone of deformation close to the base of the San Gabriel Mountains; it extends from the San Fernando Pass to the San Antonio Canyon in the eastern San Gabriel Mountains. Trenching at a site in Altadena indicated that the most recent earthquake on the fault segment near the Arroyo Seco occurred in the past 10,000 years. Peak ground

accelerations of between 0.47 gravity (g) and 0.75g are estimated in the City as a result of a magnitude 7.0 earthquake along the Sierra Madre Fault.

Ground elevations in Area 1 range from 1,210 to 1,260 feet above msl. The Headworks structure crosses where the stream elevation is approximately 1,222 feet above msl in Area 1, with slopes to the east rising to 1,231 feet above msl. This area is overlain by stream deposits and older alluvium consisting of primarily light brown silty sand, underlain by cobbles and boulders. The stream deposits and older alluvium are generally moderately dense to very dense. Based on the large amount of cobbles and boulders encountered during exploratory borings, difficult drilling conditions are expected during construction. Water was not encountered at a depth of seven feet but seasonal high groundwater is anticipated to be shallow. Soils are not corrosive to metal or concrete.

Ground elevations in Area 2 range from 1,170 to 1,200 feet above msl. The diversion structure in Area 2 is located in the stream at an elevation of 1,176 feet above msl. The eroded scarp along the access road in Area 2 is approximately 12 feet higher and has exposed older alluvium consisting of brown silty sand with cobbles and boulders that is underlain by very hard, massive granitic rock. The older alluvial soil is three feet thick over granitic bedrock. The upper one foot of bedrock is highly weathered but, below one foot, the bedrock is very hard and massive. Water was not encountered at a depth of 3.5 feet but, with the roadway adjacent to the stream channel, seasonal high groundwater is anticipated to be shallow.

Ground elevations in Area 3 range from 1,100 feet above msl at the southern end to 1,130 feet above msl at the northern end. The former parking lot in Area 3 was overlain by four to five inches of asphalt over a seven- to eight-inch-thick base over stream deposits. The spreading basins are underlain by stream deposits and terrace deposits, both consisting of primarily light brown silty sand, underlain by numerous cobbles and boulders. The stream deposits and terrace deposits are both moderately dense to very dense. Groundwater was not encountered in exploratory borings to a maximum depth of 21 feet.

The California Geological Survey's (CGS's) Inventory of Landslide Areas shows that the HWP, Areas 1 and 2, and adjacent areas have not been subject to landslides (CGS 2007).

4.7.2 IMPACT ANALYSIS

Regulatory Requirements

RR GEO-1 Grading, excavation, and construction is required to comply with the City's Building Code (Title 14 of the Pasadena Municipal Code, which incorporates the 2010 California Building Code), as they relate to site preparation and construction; alteration; moving; demolition; repair; use and occupancy of buildings; structures and building service equipment within the City. The California Building Code requires the preparation of engineering geologic reports, supplemental ground-response reports, and/or geotechnical reports for all new construction; new structures on existing sites; and alterations to existing buildings. It also includes seismic design criteria and requirements for use in the structural design of buildings (i.e., based on seismic hazard maps and the seismic design category) and specifies building components that require special seismic certification.

RR GEO-2 Proposed improvements must be designed and constructed in accordance with the recommendations of the Geotechnical Feasibility Report that has been prepared for the Project, as required by the City's Building Code.

Impact Discussion

a) Would the project expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:

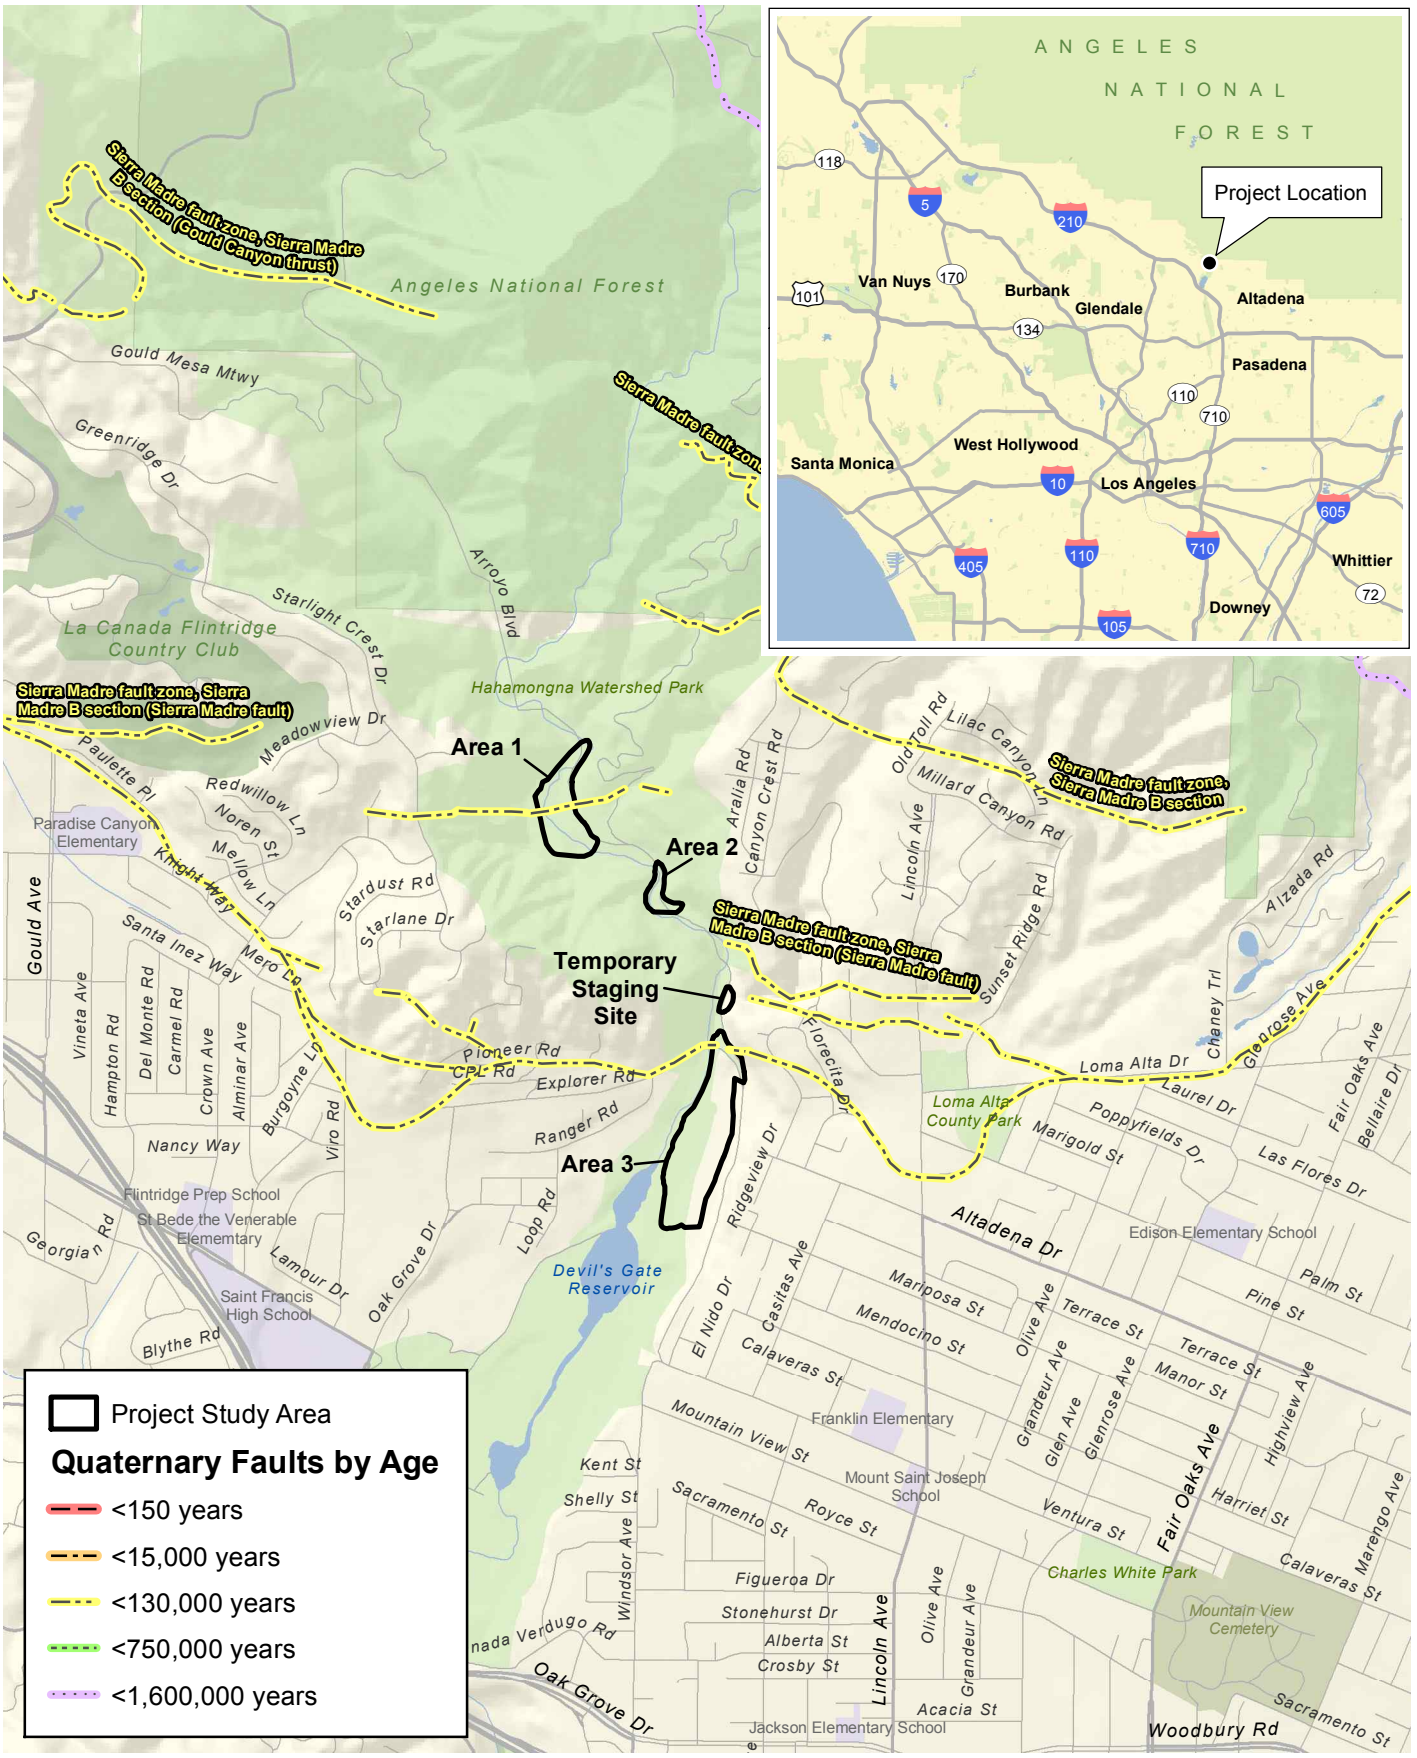
i) Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault? Refer to Division of Mines and Geology Special Publication 42.

ii) Strong seismic ground shaking?

iii) Seismic-related ground failure, including liquefaction?

iv) Landslides?

Less Than Significant Impact.



Areas 1, 2 and 3 Impacts. The Sierra Madre Fault (Tujunga segment) crosses the Arroyo Seco, north of the JPL Bridge. However, there is no designated Alquist-Priolo Special Studies Zone for the fault in the Upper Arroyo Seco.

Area 1 is not located within a designated Earthquake Fault Zone, but as shown in Exhibit 4-3, Faults, a splay of the Sierra Madre Fault runs through the center of Area 1. The stream is located within a Seismic Hazard Zone for liquefaction, with adjacent steep slopes susceptible to landslides. However, the Geotechnical Feasibility Study Report states that Area 1 has very dense gravelly sand with cobbles and boulders, and the site is not susceptible to liquefaction. Seismically induced settlement is also expected to be negligible.

Area 2 is not located within a designated Earthquake Fault Zone, but as shown in Exhibit 4-3, the traces of the Sierra Madre Fault are located approximately 1,000 feet south and approximately 1,000 feet north of Area 2. The stream is located within a Seismic Hazard Zone for liquefaction, with adjacent steep slopes susceptible to landslides. The Geotechnical Feasibility Study Report states that the presence of shallow granitic bedrock along the access road indicates that it is not susceptible to liquefaction hazards and seismically induced settlement would be negligible. While the slope just east of the access road is stable, small rock fall hazards are expected.

Area 3 is not located within a designated Earthquake Fault Zone, but as shown in Exhibit 4-3, a section of the Sierra Madre Fault runs though the northern portion of Area 3. Area 3 is located within a Seismic Hazard Zone for liquefaction.

Since portions of the Sierra Madre fault run through two of the three Project areas, the Project would be potentially exposed to fault rupture hazards. While structures sitting directly on top of the ruptured fault could be damaged in an earthquake event along the fault, the Project does not include any habitable structures or structures that are critical for public safety. Additionally, seismic shaking could be significant during an earthquake along other earthquake faults in the region. Ground shaking would not pose major safety hazards to the habitat restoration area and rest area/picnic area in Area 1. The new diversion and weir structures and the reconstructed access road in Area 2 could sustain damage during an earthquake event. Ground shaking would not pose major safety hazards to the spreading basins and parking lot in Area 3 but could damage the restroom, guardhouse, and pipelines proposed in this area. Design and construction in compliance with pertinent building code regulations (RR GEO-1) and in accordance with the recommendations of the Geotechnical Feasibility Report, including seismic design parameters (RR GEO-2), would ensure that the structural integrity of the proposed structures and improvements can withstand seismic shaking. The potential for liquefaction of bedrock is low, but

Faults

Exhibit 4-3

Arroyo Seco Canyon Project

N W E S

2,000 1,000 0 2,000 Feet

BonTerra PSOMAS

(Rev: 5-19-2014 CJS) R:\Projects\Carollo\J041\Graphics\MND\Ex_faults.pdf

D:\Projects\Carollo\J041\MXD\InHouse\faults_20140515.mxd

liquefaction in the stream channel is expected to be high. The restored habitat area in Area 1 and the diversion structure in Area 2 would be located within the stream and may be exposed to liquefaction hazards. Slopes in Areas 1 and 2 have a potential for small rock fall hazards, and slopes that would be created could be unstable. The proposed parking lot, access road, restroom, guardhouse, and pipelines in Area 3 could also be exposed to liquefaction hazards that may lead to ground settlement and foundation cracks. Design and construction of the proposed improvements would have to address liquefaction and slope stability in accordance with the recommendations of the Geotechnical Feasibility Report (RR GEO-2).

The temporary bridges in and near Area 2 would also have to be designed and constructed in accordance with the City's Building Code and the recommendations of the geotechnical investigation that would be prepared for the bridges (RR GEO-1). This will prevent the creation of risks associated with seismic and geologic hazards in the area.

Through compliance with RR GEO-1 and RR GEO-2, impacts related to seismic hazards would be less than significant. No mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified potential impacts related to strong ground motion and liquefaction on the Flint Wash Bridge, the north bridge, Sunset Overlook, and embankments in the HWP. Measure Geology-1, Measure Geology-4, and Measure Geology-5 call for compliance with existing building codes and regulations by the Flint Wash Bridge, the north bridge, Sunset Overlook, and embankments. The Project does not propose the construction of these facilities and thus, these measures are not applicable.

Proposed improvements would be built in accordance with existing building codes and regulations (RR GEO-1), which would reduce seismic hazards.

b) Would the project result in substantial soil erosion or the loss of topsoil?

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. Erosion within the Arroyo Seco has occurred due to loose soils in upstream areas, especially after the 2009 Station Fire. The proposed habitat restoration in Area 1 is expected to create a more natural riparian corridor that would reduce stream bank erosion through native planting, bank stabilization, woody debris clusters, and a meandering stream. The area around the diversion structure and the slopes along the access road in Area 2 would be stabilized with riprap protection. The new recreational parking lot in Area 3 would be covered in decomposed granite and the spreading basins would have compacted earth slope sides to reduce erosion. Therefore, the Project would reduce erosion in the long term.

During construction, erosion-control measures would be implemented as part of the Storm Water Pollution Prevention Plan (SWPPP) for the Project (RR HYD-1). Implementation of the erosion control best management practices (BMPs) in the SWPPP would reduce erosion, and impacts would be less than significant. No mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified the potential risk of damage from geologic hazards, including erosion. The Master EIR included mitigation measures to reduce geologic hazards to proposed improvements in the HWP. Measures Geology-1, Geology-4, and Geology-5 are for improvements that are not proposed by the Project and Measures Geology-6, Geology-7, and Geology-8 are for improvements in the Central or Lower Arroyo Seco; thus, these measures would not be applicable to the Project. The Master EIR stated that minor improvements (e.g., minor improvements to

existing structures, restrooms, surface parking areas, passive recreation facilities, and habitat restoration projects) would not expose people or property to significant risk for geologic hazards.

c) Would the project be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in onsite or offsite landslide, lateral spreading, subsidence, liquefaction, or collapse?

d) Would the project be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property?

Less Than Significant Impact.

Areas 1, 2 and 3 Impacts. The Project site may contain collapsible soils due to its location within and near the Arroyo Seco stream channel. Groundwater extraction wells in the general vicinity of Area 3 may also make this area susceptible to subsidence, although no significant regional subsidence has occurred in the City. The proposed spreading basins in Area 3 would increase recharge of the Monk Hill Subbasin of the Raymond Groundwater Basin. With only 60 percent of the recharge water pumped out, the Project would decrease the potential for subsidence.

To determine geologic hazards at the Project site, soil borings were made at the three areas to identify surface and subsurface soils and their characteristics. The Geotechnical Feasibility Study Report summarizes the findings of the soil analyses, which include geologic, seismic, and flood hazards, percolation testing, and slope stability. The report states that near surface soils in Areas 1 and 3 have a "Very Low" expansion potential (no soil expansion analysis was made for near surface soils in Area 2). The report includes seismic design parameters and recommendations for retaining walls, foundations, slabs-on-grade, soil corrosivity, site drainage, earthwork and site grading, pipeline backfill, temporary excavations, pavements, and other geotechnical considerations. Compliance with these recommendations (RR GEO-2) would address the geologic hazards that are present on the site.

The temporary bridges in and near Area 2 are required to be designed and constructed in accordance with the City's Building Code (RR GEO-1) and the recommendations of the geotechnical investigation that would be prepared for the bridges (RR GEO-2). This would avoid hazards associated with unstable soils, collapsible soils, expansive soils and/or other geologic hazards. Impacts would be less than significant and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified geologic hazards, including liquefaction, that may affect the water conservation pool, spreading basins, lakes, and utility line replacement and relocation proposed in the HWP. Measure Geology-2 called for the conservation pool, spreading basins, and lakes in the HWP to comply with all existing pertinent building codes and regulations; for geologic and geotechnical investigations for these improvements; and for remediation measures to minimize risks. Measure Geology-3 called for the replacement and relocation of utilities in the HWP to comply with all existing pertinent building codes and regulations; for geologic and geotechnical investigations for these improvements; and for remediation measures to minimize risks. RR GEO-1 and RR GEO-2 (similar to Measure Geology-2 and Measure Geology-3) would be implemented as part of the proposed spreading basins and utility improvements in Area 3.

e) Would the project have soils incapable of adequately supporting the use of septic tanks or alternative waste water disposal systems where sewers are not available for the disposal of waste water?

No Impact.

Areas 1, 2 and 3 Impacts. The proposed restroom in Area 3 would not include the construction of septic tanks or seepage pits/fields. Instead, the restroom would be connected to an existing sewer line on the JPL campus. The construction crew would be served by portable toilets that would be brought to the site at the start of Project construction. These portable toilets would be regularly cleaned out and removed at the end of construction. Therefore, no impacts related to the use of septic tanks or alternative wastewater disposal systems would occur with the Project and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan included mitigation that called for the construction of a wastewater system to serve the HWP to be completed prior to the construction and renovation of restrooms. However, the Master EIR considered the connection of the new restroom in Area 3 to the sewer line at the JPL campus, which is being proposed by the Project.

4.7.3 MITIGATION MEASURES

There would be no significant adverse impacts related to geology and soils with compliance with RR GEO-1 and RR GEO-2; therefore, no mitigation measures are required.

4.8 GREENHOUSE GAS EMISSIONS	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
Would the project:				
a) Generate greenhouse gas emissions, either directly or indirectly, that may have a significant impact on the environment?	☐	☐	☒	☐
b) Conflict with an applicable plan, policy or regulation adopted for the purpose of reducing the emissions of greenhouse gases?	☐	☐	☐	☒

4.8.1 EXISTING CONDITIONS

Climate change refers to any significant change in temperature, precipitation, or wind patterns over a period of time. Climate change may result from natural factors, natural processes, and human activities that change the composition of the atmosphere and alter the surface and features of the land. Significant changes in global climate patterns have recently been associated with global warming, which is an average increase in the temperature of the atmosphere near the Earth's surface; this is attributed to an accumulation of greenhouse gas (GHG) emissions in the atmosphere. GHGs trap heat in the atmosphere which, in turn, increases the Earth's surface temperature. Some GHGs occur naturally and are emitted to the atmosphere through natural processes, while others are created and emitted solely through human activities. The emission of GHGs through fossil fuel combustion in conjunction with other human activities appears to be closely associated with global warming.

GHGs, as defined under California's Assembly Bill (AB) 32, include carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6). General discussions on climate change often include water vapor, ozone, and aerosols in the GHG category. Water vapor and atmospheric ozone are not gases that are formed directly in the construction or operation of development projects, nor can they be controlled in these projects. Aerosols are not gases. While these elements have a role in climate change, they are not considered by either regulatory bodies, such as CARB, or climate change groups, such as the Climate Registry, as gases to be reported or analyzed for control. Therefore, no further discussion of water vapor, ozone, or aerosols is provided.

GHGs vary widely in the power of their climatic effects; therefore, climate scientists have established a unit called global warming potential (GWP). The GWP of a gas is a measure of both potency and lifespan in the atmosphere as compared to CO_2. For example, since CH_4 and N_2O are approximately 25 and 298 times more powerful than CO_2, respectively, in their ability to trap heat in the atmosphere, they have GWPs of 25 and 298, respectively (CO_2 has a GWP of 1). Carbon dioxide equivalent (CO_2e) is a quantity that enables all GHG emissions to be considered as a group despite their varying GWPs. The GWP of each GHG is multiplied by the prevalence of that gas to produce CO_2e. The atmospheric lifetime and GWP of selected GHGs are summarized in Table 4.8-1, Global Warming Potentials and Atmospheric Lifetimes.

TABLE 4.8-1
GLOBAL WARMING POTENTIALS AND ATMOSPHERIC LIFETIMES

Greenhouse Gas	Atmospheric Lifetime (years)	Global Warming Potential (100-year time horizon)
Carbon Dioxide (CO_2)	50.0–200.0	1
Methane (CH_4)	12.0	25
Nitrous Oxide (N_2O)	114.0	298
HFC-134a	14	1,430
PFC: Tetrafluoromethane (CF_4)	50,000.0	7,390
PFC: Hexafluoroethane (C_2F_6)	10,000.0	12,200
Sulfur Hexafluoride (SF_6)	3,200.0	22,800
HFC: hydrofluorocarbons; PFC: perfluorocarbons Source: IPCC 2007.		

Assembly Bill 32 – the California Global Warming Solutions Act of 2006

AB 32, the California Global Warming Solutions Act of 2006, recognizes that California is the source of substantial amounts of GHG emissions. The statute states that:

> Global warming poses a serious threat to the economic well being, public health, natural resources, and the environment of California. The potential adverse impacts of global warming include the exacerbation of air quality problems, a reduction in the quality and supply of water to the state from the Sierra snowpack, a rise in sea levels resulting in the displacement of thousands of coastal businesses and residences, damage to marine ecosystems and the natural environment, and an increase in the incidences of infectious diseases, asthma, and other human health-related problems.

In order to avert these consequences, AB 32 establishes a State goal of reducing GHG emissions to 1990 levels by the year 2020, which is a reduction of approximately 16 percent from forecasted emission levels, with further reductions to follow (CARB 2011).

City of Pasadena General Plan

The City is in the process of updating its General Plan, and adopted the Open Space and Conservation Element in January 2012. The Open Space and Conservation Element summarizes greenhouse gas issues and outlines goals and policies that will reduce greenhouse gas emissions. It states, “In the City of Pasadena, the primary tool to address greenhouse gases is the Mobility Element of the General Plan. The City is in the midst of a major update to the Mobility Element. The updated plan will introduce sustainable transportation and circulation goals and policies to encourage non-automotive alternatives for residents and visitors to move about the City” (City of Pasadena 2012a).

4.8.2 IMPACT ANALYSIS

Impact Discussion

a) Would the project generate greenhouse gas emissions, either directly or indirectly, that may have a significant impact on the environment?

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. In developing methods for GHG impact analysis, there have been suggestions of quantitative thresholds, often referred to as screening levels, which define an emissions level below which it may be presumed that climate change impacts would be less than significant. Neither the SCAQMD, the City of Pasadena, nor the County of Los Angeles has adopted a significance threshold for the GHG emissions from non-industrial development projects. Consequently, the City of Pasadena has determined, pursuant to the discretion afforded by Sections 15064.4(a) and 15064.4(b) of the State CEQA Guidelines, that the impact of the Project's GHG emissions be assessed based on the methodologies proposed by SCAQMD's GHG CEQA Significance Threshold Working Group.

On December 5, 2008, the SCAQMD Governing Board adopted the staff proposal for a tiered threshold approach wherein Tier 1 determines if a project qualifies for an applicable CEQA exemption; Tier 2 determines consistency with GHG reduction plans; and Tier 3 proposes a numerical screening value as a threshold. At their September 28, 2010, meeting, the Working Group suggested a Tier 3 threshold of 3,000 metric tons of carbon dioxide equivalent ($MTCO_2e$) per year for all land use types. Although the Project is not a residential or commercial development, in the absence of adopted thresholds, the City of Pasadena has decided to assess the significance of the Project's GHG emissions using this SCAQMD proposed Tier 3 screening threshold (SCAQMD 2010). It is noted that the use of the Tier 3 threshold was selected for the proposed Project because it is located in the South Coast Air Basin and these thresholds are based on the best available information and data at the time of preparation of this document. The development of project-level thresholds in accordance with CEQA is an ongoing effort at the State, regional, and County levels, and significance thresholds may differ for future projects based on new or additional data and information that may be available at that time for consideration.

Construction

Construction GHG emissions are generated by vehicle engine exhaust from construction equipment, on-road hauling trucks, vendor trips, and worker commuting trips. Construction GHG emissions were calculated by using CalEEMod. The model and construction assumptions are described in Section 4.3, Air Quality, and are included in Appendix A. The results are output in $MTCO_2e$ for each year of construction. The estimated construction GHG emissions for the Project are shown in Table 4.8-2.

GHG emissions generated from construction activities are finite and occur for a relatively short-term period of time. Unlike the numerous opportunities available to reduce a project's long-term GHG emissions through design features, operational restrictions, use of green-building materials, or other methods, GHG-reduction measures for construction equipment are relatively limited. Therefore, SCAQMD staff recommends that construction emissions be amortized over a 30-year project lifetime so that GHG-reduction measures will address construction GHG emissions as part of the operational GHG-reduction strategies (SCAQMD 2008). As shown in Table 4.8-2, Estimated GHG Emissions From Construction, the 30-year amortized construction emissions of the Project would be 22 $MTCO_2e$/yr.

TABLE 4.8-2
ESTIMATED ANNUAL GHG EMISSIONS FROM CONSTRUCTION

Year	Emissions ($MTCO_2e$)
2015	587
2016	85
Total	**672**
Annual Emissions*	**22**

$MTCO_2e$: metric tons of carbon dioxide equivalent

* Combined total amortized over 30 years.

Operations

Operational GHG emissions for the proposed Project are estimated by including purchased electricity; the energy associated with solid waste disposal; and mobile source emissions. CalEEMod incorporates local energy emission factors and mitigation measures based on the California Air Pollution Control Officers Association's (CAPCOA's) publication *Quantifying Greenhouse Gas Mitigation Measures* (CAPCOA 2010) and the *California Climate Action Registry General Reporting Protocol* (CCAR 2009). Estimated annual CO_2e emissions are presented in Table 4.8-3.

TABLE 4.8-3
ESTIMATED ANNUAL GHG EMISSIONS

Year	Emissions $MTCO_2e$
Operational Emissions	
Area	<0.5
Energy	<0.5
Mobile	100
Waste	1
Water	3
Total	**104**
Amortized Construction Emissions (Table 4-13)	**22**
Annual Emissions	**126**

$MTCO_2e$: metric tons of carbon dioxide equivalent

Note: totals may not add due to rounding.

As shown in Table 4.8-3, the estimated increase in annual GHG emissions, including amortized construction emissions, would be 126 $MTCO_2e$/yr. This value may be compared with and is less than the proposed SCAQMD Tier 3 screening threshold of 3,000 $MTCO_2e$/yr for all land use types. It is very unlikely that any individual development project would have GHG emissions of a magnitude to directly impact global climate change; therefore, any impact would be considered on a cumulative basis. Because the proposed Project's GHG emissions would be less than 3,000 $MTCO_2e$/yr, the emissions would not be cumulatively considerable. This impact would be less than significant; no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not address GHG emissions.

b) Would the project conflict with an applicable plan, policy or regulation adopted for the purpose of reducing the emissions of greenhouse gases?

No Impact.

Areas 1, 2 and 3 Impacts. As discussed above, the principal State plan and policy adopted for the purpose of reducing GHG emissions is AB 32. The quantitative goal of AB 32 is to reduce GHG emissions to 1990 levels by 2020. Plans and regulations (e.g., GHG emissions standards for vehicles and the Low Carbon Fuel Standard) are being implemented at the statewide level, and compliance at the project level is not addressed. The proposed Project does not conflict with these plans and regulations.

As previously discussed, the increase in GHG emissions would be much less than SCAQMD's recommended significance threshold for all land use projects. The Project would result in a slight increase in electrical use for increased groundwater well pumping to recover the water infiltrated through the spreading basins; however, this would be entirely offset by the corresponding reduced need for Colorado River Aqueduct (CRA) and State Water Project (SWP) water, which requires electricity for conveyance and boosting. Implementation of the proposed Project would not conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing GHG emissions. There would be no impact.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not address GHG emissions.

4.8.3 MITIGATION MEASURES

There would be no significant adverse impacts related to GHG emissions; therefore, no mitigation measures are required.

4.9 HAZARDS/HAZARDOUS MATERIALS	Potentially Significant Impact	Less than Significant with Mitigation	Less than Significant Impact	No Impact
Would the project:				
a) Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials?	☐	☐	☒	☐
b) Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment?	☐	☒	☐	☐
c) Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter-mile of an existing or proposed school?	☐	☐	☒	☐
d) Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would it create a significant hazard to the public or the environment?	☐	☒	☐	☐
e) For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project result in a safety hazard for people residing or working in the project area?	☐	☐	☐	☒
f) For a project within the vicinity of a private airstrip, would the project result in a safety hazard for people residing or working in the project area?	☐	☐	☐	☒
g) Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan?	☐	☒	☐	☐
h) Expose people or structures to a significant risk of loss, injury, or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands?	☐	☒	☐	☐

4.9.1 EXISTING CONDITIONS

The Project site includes Area 1 where the Headworks structure and sedimentation basins are located; Area 2 where the diversion and weir structures, intake structure, access road, and Bridge No. 3 are located; and Area 3 where the JPL East Parking Lot and spreading basins are located. No hazardous material use, storage, or generation occurs in these three areas.

The California Department of Toxic Substance Control (DTSC) maintains the EnviroStor Database, which compiles hazardous material sites and generators that have been identified for clean up or that are permitted to handle hazardous materials by various regulatory agencies. Hazardous material sites or generators in and near the HWP, as listed in the EnviroStor Database, include the JPL, Flintridge Riding Club, and Oak Grove Ranger Station (DTSC 2007). These facilities are located on the west side of the Arroyo Seco and would not be affected by the Project.

The USEPA maintains the Envirofacts Database, which compiles lists of facilities subject to permitting for their potential environmental hazards to air, water, waste, land, toxics, radiation, facility, regulatory compliance, and other. Facilities on the Envirofacts Database that are located in or near the HWP, include JPL, LA Steelcraft Products, Pacific Bell, Audubon Elementary School, Rite Cleaners, and several industrial and commercial uses south of Area 3 (USEPA 2013b).

The facility with the highest potential to affect the Project site is JPL, a 181.2-acre federally funded research and development center operated by the California Institute of Technology (Caltech) under a contract with NASA. JPL is involved in planning, advocacy, and execution of unmanned exploratory scientific flight through the solar system. The campus has 138 buildings and ancillary structures, including 19 underground storage tanks, immediately west of the Arroyo Seco in the City of La Cañada Flintridge. JPL generates laboratory chemical wastes that are brought to the Hazardous Waste Accumulation Facility (Building 305) for off-site disposal. Over 1,000 kilograms (kg, i.e., 2,204 pounds) of hazardous wastes are generated at JPL per year and this facility is considered a large quantity generator. Hazards material and waste handling at JPL is currently made in accordance with its Pollution Prevention Plan and applicable State and federal hazardous waste regulations (JPL 2012).

Past waste handling activities at JPL involved the disposal of waste solvents, solid rocket fuel propellants, cooling tower chemicals, sulfuric acid, freon, mercury, and chemical laboratory wastes into on-site seepage pits, settling chambers, and dumps. These waste-handling activities have led to soil and groundwater contamination, such that volatile organic compounds (VOCs) and perchlorate, which have been detected in local wells east and southeast of the JPL campus. The groundwater contamination is located beneath a portion of the JPL campus and has travelled east and southeast of the campus. This contamination has affected four water wells of the PWP in the Monk Hill Subbasin and two water wells of the Lincoln Avenue Water Company (LAWC) (USEPA 2013a). The nearest groundwater monitoring wells to Area 3 of the Project site include MW-3 (deep multi-port monitoring well) and MW-9 (shallow monitoring well). The depths to groundwater contamination at MW-3 are over 200 feet below the ground surface (NASA 2013a).

A number of studies and investigations under a Work Plan have been completed and a Removal Action Plan is being implemented that includes three water treatment facilities to remove perchlorate and VOCs from the groundwater. The Monk Hill Treatment System (located southeast of Area 3) removes VOCs and perchlorate from four City wells (Arroyo Well, Well 52, Ventura Well, and Windsor Well) located in and near Area 3 (JPL 2011).

The Arroyo Seco Canyon and adjacent areas are designated as a Very High Fire Hazard Severity Zone by the California Department of Forestry and Fire Protection (CalFire 2011). In August 2009, the Station Fire burned nearly 252 square miles in the ANF. This included a fire station, administration buildings, lookout tower, campgrounds, picnic areas, water systems, communication sites, roads, and trails. Subsequent to the fire, the USFS has implemented a restoration strategy that includes tree planting, invasive species removal, trail repair, and recreation sites clean up (USFS 2011).

Several Southern California Edison (SCE) and PWP power lines run through the HWP. However, there are no gas transmission pipelines or hazardous liquid pipelines running in or near the HWP, as mapped by the National Pipeline Mapping System (PHMSA 2012).

4.9.2 IMPACT ANALYSIS

Regulatory Requirements

RR HAZ-1 Construction activities are required to comply with existing federal, State, and local regulations regarding hazardous material use, storage, disposal, and transport to prevent risks to public health and safety. Construction wastes that meet hazardous waste criteria must be stored, manifested, transported, and disposed of in accordance with the *California Code of Regulations* (Title 22) and to the satisfaction of the Los Angeles County Fire Department, which serves as the local Certified Unified Program Agency (CUPA).

RR HAZ-2 The City shall continue to implement its Emergency Operations Plan, which outlines the City's responses to emergencies associated with natural disasters, technological incidents, and national security emergencies.

Impact Discussion

a) Would the project create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials?

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. No manufacturing or industrial activities are proposed by the Project and no aboveground storage tanks, underground storage tanks, natural gas transmission lines, or other hazardous material storage facilities/conduits would be built as part of the Project. No hazardous materials use, storage, waste generation, or disposal would occur during long-term use and operation of the proposed improvements.

Construction activities would utilize hazardous materials on a short-term basis, and compliance with RR HAZ-1 would prevent the creation of significant hazards to the public or the environment. Impacts would be less than significant and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified potential hazards associated with the release of hazardous materials (e.g., asbestos-containing materials and lead-based paint) into the environment. RR HAZ-1 (similar to Measure Hazards-1 and Measure Hazards-2) would be implemented for the proper handling and disposal of hazardous materials and wastes as part of construction activities for the Project.

b) Would the project create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment?

Less than Significant With Mitigation.

Areas 1, 2 and 3 Impacts. JPL currently utilizes hazardous materials and generates hazardous wastes, but its compliance with existing regulations would prevent the creation of hazards to adjacent land uses, including Area 3.

No long-term hazardous materials use or generation would occur with the Project, as discussed above. During construction, hazardous materials that would be in use would include oil and grease, solvents, diesel gasoline, and other chemicals in vehicles, trucks, and heavy equipment. These hazardous materials could pose risks to construction workers or lead to soil and water

contamination, if not properly stored, used, or disposed. Due to the presence of surface water in construction sites on the Arroyo Seco, the potential for water contamination and the likelihood that accidentally contaminated soils would enter the Arroyo Seco may create a public health and safety hazard. This would be considered a significant adverse impact.

To prevent environmental hazards, the handling of hazardous materials used in equipment would have to be made in accordance with existing regulations (RR HAZ-1) with regard to the transport of hazardous materials; on-site storage and use of hazardous materials; and procedures to implement in the event of a spill. In addition, under RR HYD-1, the Project would implement a SWPPP, as discussed in Section 4.9, Hydrology and Water Quality, which would include hazardous waste management BMPs and a sampling and analysis plan, which require the contractor to report and mitigate any hazardous material discharges that may contaminate the soil, surface water, and/or groundwater.

In addition, MM HAZ-1 includes specific measures to avoid impacts associated with hazardous material spills and accidents in and near the Arroyo Seco. These include inspecting trucks for oil, gasoline, or other vehicle fluid leaks; locating fueling areas and storage of hazardous materials away from water bodies and drainages; creating a plan for refueling; removing hazardous material spills and contaminated soils; controlling and containing hazardous materials spills; and ensuring cleanup kits are available. Implementation of MM HAZ-1 would reduce potential impacts associated with the use and reasonably foreseeable upset of hazardous materials to a less than significant level.

There is groundwater contamination beneath Area 3. Construction activities within Area 3 would involve excavations into native soils to create the spreading basins. However, construction activities are not anticipated to encounter any contaminated groundwater due to the depths of the contamination, which is over 200 feet below the ground surface. Dewatering of any groundwater within the construction areas may be required and would result in the need to discharge and dispose of the recovered water. RR HYD-3 requires compliance with Los Angeles RWQCB Order No. R4-2013-0095 for discharges of treated or untreated groundwater into surface waters. The order requires dischargers to file a Notice of Intent with the Los Angeles RWQCB prior to discharging into surface waters; to complete water sampling and analysis; to implement BMPs to prevent water quality degradation; and/or to treat groundwater prior to discharge. Coverage under the permit requires compliance with effluent limitations, discharge prohibitions, receiving water limitations, and other conditions/provisions in the permit, along with implementation of a monitoring and reporting program.

Due to the presence of contaminated groundwater in the Project area, there is the potential for earthmoving activities to disturb contaminated soils. Should discolored or odorous soils be encountered, MM HAZ-2 requires the soils be sampled and analyzed for contamination and remediated and/or disposed of in accordance with existing regulations, as necessary.

Compliance with applicable regulations (RR HAZ-1, RR HAZ-2, RR HYD-1, and RR HYD-3) and implementation of MM HAZ-1 and MM HAZ-2 would ensure that the use, storage, transport, and disposal of hazardous materials would not create hazards to public health and safety. Impacts would be less than significant after mitigation.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified potential hazards associated with the release of hazardous materials into the environment and discussed hazards associated with contaminated soils and groundwater from historic uses at the JPL campus. MM HAZ-2 (which is similar to Measure Hazards-3) would be implemented during excavation activities in Area 3. The Master EIR stated that construction activities would not require grading below 1,040.5 feet above msl (e.g., the east side park access,

east side parking area, sunset overlook, trails, bicycle routes and fencing) and would not expose people to contaminated soil or groundwater.

c) Would the project emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter-mile of an existing or proposed school?

Less than Significant Impact.

Areas 1 and 2 Impacts There are no schools within 0.25 mile of Areas 1 and 2. The proposed rest area/picnic area and restored habitat in Area 1 and the new diversion and weir structures and improved access road in Area 2 would not generate toxic emissions that may affect nearby trail users and residents. Construction activities would utilize hazardous materials in the short-term, but these would be handled in accordance with existing regulations (RR HAZ-1).

Area 3 Impacts. Sycamores School, located at 2933 El Nido Drive, is located approximately 600 feet southeast of Area 3. Odyssey Charter School, located at 725 Altadena Drive, is located 0.25 mile east of Area 3. Franklin Elementary School, located at 527 West Ventura Street, is located 0.5 mile southeast of Area 3. A number of other schools are located in Altadena east of the Arroyo Seco and in La Cañada Flintridge west of the Arroyo Seco.

The proposed spreading basins and the recreational parking lot in Area 3 would not generate toxic emissions that may affect students at nearby schools. Construction equipment and trucks coming to and from the Project site would utilize Windsor Avenue and I-210, and would not pass along area schools. Construction activities would utilize hazardous materials, but these would be handled in accordance with existing regulations (RR HAZ-1). No hazards to the construction crew or to nearby residents, students, or employees would occur from hazardous materials use on the site. Section 4.3, Air Quality, also discusses toxic air contaminants and determined that the Project would not expose any nearby sensitive receptors to substantial pollutant concentrations.

Impacts would be less than significant and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified schools as sensitive receptors that may be exposed to air contaminants, but no specific discussion of hazards to schools is provided in the Master EIR.

d) Would the project be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would it create a significant hazard to the public or the environment?

Less than Significant With Mitigation.

Areas 1 and 2 Impacts Areas 1 and 2 are not located on or near a site included in the list of hazardous material sites. Land uses utilizing hazardous materials are located downstream of Areas 1 and 2. The proposed rest area/picnic area and restored habitat in Area 1 would not pose hazards to adjacent land uses. Similarly, the new diversion and weir structures in Area 2 would not pose hazards.

Area 3 Impacts. The JPL campus, west of Area 3 and the Arroyo Seco, has been designated as a Superfund site pursuant to the federal Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and has been listed on the National Priority List (NPL) (USEPA 2013a). While the HWP is not a source of hazardous material contamination, past waste

handling activities at the JPL campus has led to groundwater contamination that has migrated to the east and southeast beneath the HWP, including Area 3.

The spreading basins and recreational parking lot proposed in Area 3 would not utilize hazardous materials or pose hazards to adjacent land uses. These improvements would not add to the underlying groundwater contamination. Also, contaminated groundwater has been found more than 200 to 300 feet beneath Area 3 (JPL 2013a) and, thus, would not be disturbed by excavation activities associated with construction of the sedimentation basins and expansion of the spreading basins. Impacts would be less than significant.

The increase in spreading area would increase percolation by as much as 1,100 afy of water into the ground, increasing the groundwater resources beneath Area 3. Modeling simulations conducted in 2005 using the NASA JPL's groundwater flow model for the Monk Hill Subarea were conducted to assess the potential impacts on existing groundwater contamination from increased groundwater recharge from the spreading basins anticipated in the Arroyo Seco Master Plan. The analysis assumed an increase in the spreading area from 13.1 acres to 21 acres; increasing recharge by 2,443 afy; and pumping from local production wells and JPL's extraction and injection wells. The simulations suggest that increased spreading would have the most significant effect on the uppermost aquifer layer, where an additional 5 to 10 feet of mounding could occur beneath the new spreading area. No significant change in flow patterns would occur. Also, only a minor change would occur in the capture zone of the deeper aquifer layers, where existing groundwater contamination is present. The modeling indicated that groundwater cleanup would not be significantly impacted by the expanded spreading grounds. With less groundwater recharge proposed by the Project (1,100 afy), impacts on the contaminated groundwater would likely be less than the 2005 modeling results.

As discussed above, compliance with RR HYD-3 would require implementation of water sampling and analysis; implementation of BMPs to prevent water quality degradation; and/or treatment of groundwater prior to discharge. A monitoring and reporting program would also have to be implemented to ensure that dewatering activities do not affect water quality in surface waters. In addition, compliance with MM HAZ-2 would ensure that encounters with potentially contaminated soils are remediated and/or disposed of in accordance with existing regulations.

Compliance with applicable regulations (RR HAZ-2 and RR HYD-1) and implementation of MM HAZ-2 would ensure that existing groundwater contamination in Area 3 does not pose hazards to public health and safety. Impacts would be less than significant after mitigation.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan discussed hazards associated with contaminated soils and groundwater from historic uses at the JPL campus, located west of Area 3. It indicated that water conservation and flood management activities, proposed lakes, Gabrielino Trail area, habitat conservation, and relocation/replacement of utilities that involve grading below 1040.5 feet above msl may expose contaminated soils and require mitigation. MM HAZ-2 (which is similar to Measure Hazards-3) would be implemented during excavation activities in Area 3.

The Master EIR stated that construction activities that would not require grading below 1,040.5 feet above msl (e.g., the east side park access, east side parking area, sunset overlook, trails, bicycle routes and fencing) would not expose people to contaminated soil or groundwater.

e) For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project result in a safety hazard for people residing or working in the project area?

f) For a project within the vicinity of a private airstrip, would the project result in a safety hazard for people residing or working in the project area?

No Impact.

Areas 1, 2 and 3 Impacts. There are no airports or airstrips within two miles of the Arroyo Seco Canyon. The nearest airports are the Burbank Bob Hope Airport and the El Monte Airport, which are both approximately 11 miles from the site. There is a heliport and a helipad near the Arroyo Seco. The Project would not involve the construction of high-rise structures or involve activities that could pose a safety hazard to helicopter or aircraft operations or airport activities, nor would it conflict with an airport land use plan. There would be no impact to airports or airstrips from the Project.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that the HWP is not located within an airport land use plan or within two miles of a public airport or private airstrip. Therefore, no hazards related to airport or aircraft operations would occur and no mitigation is required.

g) Would the project impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan?

Less than Significant With Mitigation.

Areas 1 and 2 Impacts. No improvements are proposed on the Gabrielino Trail/access road in Area 1, except for removal of a section of the chain-link fencing along its western edge. Improvement of the Gabrielino Trail/access road in Area 2 would result in a temporary partial obstruction of this road, which may affect emergency response and evacuation of the USFS Ranger Station and other areas in the ANF farther north. Compliance with the Standard Specifications for Public Works Construction (Greenbook) and the City's Supplements and Modifications to the Greenbook (RR TRA-1 in Section 4.16, Transportation/Traffic) regarding maintenance of access at all times would mean closure of only half of the access road; the use of a flagperson to direct traffic, as necessary; and allowing for the public use of the Gabrielino Trail/access road at times when construction is not ongoing. This RR also requires that the Gabrielino Trail/access road be made passable at the end of each workday. Thus, access to Areas 1 and 2 (including the USFS Ranger Station) would be made available during construction activities, but short-term closures may occur.

The process of assembling the temporary bridges over Bridge No. 1 near Area 1 and over Bridge No. 3 in Area 2 would block access across the bridges and areas farther north when the access road is connected to temporary bridges. Similarly, RR TRA-1 would ensure that access would be available to the USFS Ranger Station and the ANF during bridge construction, as required by the Greenbook.

Access would be maintained for vehicles coming to and from the USFS Ranger Station in accordance with the Greenbook (as discussed above); however, there would be short time periods during the day when both the temporary bridge and Bridge No. 1 or the other temporary bridge and Bridge No. 3 are closed. There would also be times when construction equipment and vehicles would be on the access road and would slow down other vehicles that need to pass through the area. While the bridges and access road do not provide access to a hospital, fire or police station, emergency operations center, communications center, emergency shelter or other critical or essential facilities, they do serve as the only access to the USFS Ranger Station and the ANF to the north. Temporary bridge closure would be considered a significant adverse impact on emergency access and evacuation.

MM HAZ-3 requires the Contractor to shorten the closures of the access road and bridges to the extent feasible and to inform the PWP, Pasadena Fire Department, Pasadena Police Department, Los Angeles County Fire Department, and the USFS at least one week prior to the start of construction of the times when work on the access road is planned; and when both Bridge No. 1 and the temporary bridge or Bridge No. 3 and the temporary bridge would be closed off. This will facilitate emergency response and evacuation that may be necessary when the bridges are not accessible or when the access road is partially blocked.

Compliance with RR TRA-1 and implementation of MM HAZ-3 would reduce impacts to emergency access and evacuation to less than significant levels after mitigation.

Area 3 Impacts. A temporary access road would be retained through Area 3 while construction of the new access road is ongoing. Also, the Gabrielino Trail to the east of Area 3 may serve as an additional emergency access road during construction activities. Thus, emergency access through Area 3 would be maintained at all times. Continued implementation of the City's Emergency Operations Plan (RR HAZ-2) would provide emergency access and evacuation in the HWP, as necessary. Impacts would be less than significant.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated no changes to the existing fire camp operated by the Los Angeles County Fire Department (located west of the Arroyo Seco) and the helicopter landing area operated by the Pasadena Police Department (south of Oak Grove Avenue and west of Windsor Avenue) would occur. Also, no encroachment into support areas for emergency evacuation plans was anticipated. Therefore, no increase in exposure to hazards related to emergency evacuation and air support operations and no impacts to emergency access would occur.

h) Would the project expose people or structures to a significant risk of loss, injury, or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands?

Less than Significant with Mitigation.

Areas 1, 2 and 3 Impacts. The Arroyo Seco Canyon is located in an area designated as a Very High Fire Hazard Severity Zone, which includes Areas 1 and 2 (CalFire 2011). The proposed habitat restoration and increased water diversion would not increase fire hazards in the Arroyo Seco Canyon and surrounding areas. The proposed recreational amenities would encourage the increase in trail users and visitors, who may accidentally cause fires in the canyon. While native plants would be combustible, they would not present fire hazards.

The proposed restroom would have fire-retardant shingles. The guard station, picnic table, benches, pet waste stations, trash receptacles, fencing, and signs would not utilize explosive or flammable materials; however, woody debris clusters, picnic tables and benches, and other improvements that utilize wood would be combustible. In the absence of a fire source, these improvements would not increase the potential for wildfire in the area.

The proposed control equipment enclosure, guard station and restroom would have electrical systems that may lead to fire. However, compliance with the City's Fire Prevention Code (RR PS-1 from Section 4.14, Public Services) would prevent the creation of a fire hazard. Also, the Project would not involve construction or operation of habitable structures that may expose people to wildfire hazards in the area. Users of the recreational facilities and maintenance workers that would come to the area would be in the area for limited time periods (from a few minutes to a few hours during each visit) and could readily avoid the area in the event of wildfires. Residents

of the USFS Ranger Station are exposed to wildfire hazards due to their employment, but this exposure would not increase with the Project.

Construction workers would be exposed to potential injury in the event of wildfire or an accidental fire at the construction sites. Potential sources of fire from the Project include sparks from construction equipment and vehicles and from electrical systems at the control equipment enclosure, guard station, and restroom. The City's Fire Prevention Code includes fire safety measures that need to be followed during construction and demolition. The use of various construction equipment with combustion engines could also increase the potential for fire at the Project sites. MM HAZ-4 requires the use of spark arrestors and other measures to prevent accidental fires. Compliance with MM HAZ-4 and RR PS-1 from Section 4.14, Public Services, would reduce the potential for fire. Therefore, wildfire hazards during construction would be less than significant.

With compliance with RR PS-1 from Section 4.14, Public Services, impacts related to wildfires would be less than significant and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan indicated that recreational improvements would not increase fire hazards or change the potential for fire hazard.

4.9.3 MITIGATION MEASURES

MM HAZ-1 The City shall require the Construction Contractors to implement the following measures:

- Trucks and equipment entering the site shall be inspected to be free from oil, gasoline, or other vehicle fluid leaks.
- Equipment fueling areas shall be located outside jurisdictional waters as identified by the USACE and CDFW.
- Hazardous materials shall not be stored within the 50-year floodplain for the Arroyo Seco. Instead, hazardous materials shall be stored within staging areas located away from the Arroyo Seco and shall be removed prior to the start of the storm season.
- All hazardous material spills and contaminated soils shall be excavated immediately upon discovery to minimize soil and water contamination and the potential of wildlife being poisoned or otherwise harmed.
- The Contractor shall maintain hazardous materials spill control, containment, and cleanup kits of adequate size and materials for potential accidental instream spills and releases.

MM HAZ-2 Should discolored or odorous soils be encountered during grading and excavation activities in Area 3, the Contractor shall have a sample of the soils analyzed for the presence of contamination. If the results of the testing show that chemical levels are present below regulatory levels, grading and excavation activities may proceed accordingly. Otherwise, remediation and/or removal of the contaminated soils shall be completed prior to continued ground disturbance if chemical levels are above regulatory standards. Remediation and/or disposal shall be conducted with the oversight of applicable regulatory agencies such as the Los Angeles County Fire Department [operating as the CUPA], the South Coast Air Quality Management District (SCAQMD), the California Department of Toxic Substances Control

(DTSC), and/or the U.S. Environmental Protection Agency in compliance with established maximum contaminant levels (MCLs).

MM HAZ-3 The Contractor shall schedule the temporary bridge construction and the access road reconstruction in Area 2 so as to shorten the necessary closures of the bridges and access road to the extent feasible. The Contractor shall also inform the Pasadena Department of Water and Power (PWP), the Pasadena Fire Department, the Pasadena Police Department, the Los Angeles County Fire Department, and the United States Forest Service (USFS) at least one week in advance of the start of construction of the times when work on Bridge No. 1/temporary bridge; Bridge No. 3/temporary bridge; and the Gabrielino Trail/access road are planned. Any major changes to the schedule shall be forwarded to these agencies at least one week prior to the bridge or trail closures.

MM HAZ-4 The Contractor shall not use, operate, or cause to be operated any internal combustion engine that uses hydrocarbon fuel, unless the engine is equipped with a spark arrestor and is maintained in effective working order, or the engine is constructed, equipped and maintained for the prevention of fire.

4.10 HYDROLOGY AND WATER QUALITY	**Potentially Significant Impact**	**Less than Significant with Mitigation**	**Less than Significant Impact**	**No Impact**
Would the project:				
a) Violate any water quality standards or waste discharge requirements?	☐	☒	☐	☐
b) Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted)?	☐	☐	☒	☐
c) Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation onsite or offsite?	☐	☐	☒	☐
d) Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding onsite or offsite?	☐	☐	☒	☐
e) Create or contribute runoff water which would exceed the capacity of existing or planned storm water drainage systems or provide substantial additional sources of pollutant runoff?	☐	☐	☐	☒

h) Place within a 100-year flood hazard area structures which would impede or redirect flood flows?	☐	☐	☐	☒
i) Expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam?	☐	☐	☐	☒
j) Inundation by seiche, tsunami, or mudflow?	☐	☐	☐	☒

4.10.1 EXISTING CONDITIONS

The Upper Arroyo Seco is located on the south-facing slopes of the San Gabriel Mountains. The watershed for the Upper Arroyo Seco (north of the Devil's Gate Dam) covers 32 square miles of the San Gabriel Mountains and surrounding areas. Several drainage streams (flows from canyons) and storm drains convey runoff into the Arroyo Seco. Stream flows depend on rainfall in the mountains during the winter and spring seasons, with urban runoff from local storm drains contributing very limited flows.

Devil's Gate Dam is a flood control facility owned and operated by the Los Angeles County Department of Public Works on land owned by the City of Pasadena. The County has an easement for the area upstream of the dam to the 1,075-foot elevation. This facility was built in 1920 for flood control and water conservation purposes. In 1948, the County constructed the spreading basins, which were subsequently transferred to the City of Pasadena for operation.

The Raymond Basin underlies an alluvial valley that covers approximately 40 square miles and that is bordered by the San Gabriel Mountains on the north; the San Rafael Hills on the west; and the Raymond Fault on the south and east. The general east-west trend of the San Gabriel Mountains, the north-south trend of the San Rafael Hills, and northeast trend of the Raymond Fault result in the basin having a triangular form. The basin is divided into the Monk Hill Subbasin to the west, the Santa Anita Subbasin to the east, and the Pasadena Subbasin in the central portion; these designations are based on differences in elevation and groundwater flow. Groundwater elevation east of the Arroyo Seco was estimated at 1,000 feet above msl in 2005 (MWD 2007).

The California Department of Water Resources estimates the Raymond Basin's storage capacity at about 1,450,000 acre-feet (af), with about 1,000,000 af of water remaining in storage in 1970. The Raymond Basin is recharged by the Arroyo Seco, a tributary to the Los Angeles River, and by Eaton Wash, Santa Anita Wash, and other streams in the watershed (DWR 2004).

Pumping rights to the Raymond Basin are adjudicated and the Raymond Basin Management Board administers the provisions of the adjudication decree. The Board coordinates the pumping rights and the groundwater storage accounts of public and private water agencies, including the PWP.

The spreading basins in Area 3 overlie the Monk Hill Subbasin, which has a natural safe yield of 7,489 afy. The MWD estimates that 11 wells in this subbasin provided 17,500 afy of water in 2004/2005. Valley Water Company has two aquifer storage and recovery (ASR) wells and PWP has no ASR wells in the Monk Hill Subbasin. The wells injected 10,500 afy of water in 2005. The Arroyo Seco spreading basins cover approximately 24 acres, with 12 acres of wetted area and a recharge capacity of 18 cfs and 13,000 afy (MWD 2007 and PWP 2014).

Groundwater quality is hard (high levels of calcium bicarbonate) and fluoride levels are occasionally high. Nitrate, perchlorate, and VOCs have been detected in wells in the Monk Hill Subbasin and along the Arroyo Seco (MWD 2007). The Monk Hill Treatment System (located on Windsor Avenue southeast of Area 3) removes VOCs and perchlorate from four City wells (Arroyo Well, Well 52, Ventura Well, and Windsor Well) located in and near Area 3 (NASA JPL 2011).

The floodplains for the 50-, 100- and 500-year storm events are generally confined to the stream channel in Areas 1 and 2. While the floodplains include portions of the access road in Area 1, the USFS Ranger Station is outside the 500-year floodplain (Carollo 2013). The Flood Insurance Rate Maps of the Federal Emergency Management Agency (FEMA) show that Areas 1 and 2 are located in Zone D (areas in which flood hazards are undetermined, but possible) and Area 3 is located in Zone X (areas determined to be outside the 0.2 percent annual chance floodplain) (FEMA 2008).

The Upper Arroyo Seco is not listed as an impaired water body under Section 303(d) of the Clean Water Act (SWRCB 2012).

4.10.2 IMPACT ANALYSIS

Project Design Features

PDF HYD-1 Habitat restoration proposed in Area 1 will create a more natural riparian corridor for the Arroyo Seco and will include recontouring the stream channel; stabilizing the bank; revegetating with native plants; creating planting islands; and placing woody debris clusters at scattered locations.

PDF HYD-2 Replacement of the diversion and weir structures in Area 2 and additional spreading basins and expansion of the spreading basins in Area 3 will increase groundwater recharge using the City's surface water rights from the Arroyo Seco.

PDF HYD-3 The proposed restroom in Area 3 will be located outside the 50-year floodplain and would be connected to the public sewer system. In addition, trash cans and pet waste stations will be provided in Areas 1 and 3 to reduce pollutants that may enter the Arroyo Seco.

Regulatory Requirements

RR HYD-1 Prior to the start of construction activities, the Contractor is required to file a Permit Registration Document (PRD) with the State Water Resources Control Board (SWRCB) in order to obtain coverage under the National Pollutant Discharge Elimination System (NPDES) General Permit for Storm Water Discharges Associated with the Construction and Land Disturbance Activities (Order No 2009-009-DWQ, NPDES No. CAS000002) or the latest approved general permit. This permit is required for construction activities (including demolition, clearing, grading, and excavation) and other land disturbance activities that result in the disturbance of one acre or more of total land area. The PRD consists of a Notice of Intent (NOI); a Risk Assessment; a Site Map; a Storm Water Pollution Prevention Program (SWPPP); an annual fee; and a signed certification statement. Pursuant to permit requirements, the Contractor must implement Best Management Practices (BMPs) in the SWPPP into the Project to reduce or eliminate construction-related pollutants in the runoff.

RR HYD -2 The Contractor is required to comply with SWRCB Order No. 2003-0017-DWQ, "General Waste Discharge Requirements for Dredge and Fill Discharges That Have Received State Water Quality Certification", which requires compliance with all conditions of the Water Quality Certification issued by the Regional Water Quality Control Board (RWQCB). Compliance with the Water Quality Certification issued by the RWQCB would ensure that any discharge does not conflict with the applicable provisions of Sections 301 (Effluent Limitations), 302 (Water Quality Related Effluent Limitations), 303 (Water Quality Standards and Implementation Plans), 306 (National Standards of Performance), or 307 (Toxic and Pretreatment Effluent Standards) of the Clean Water Act, or any other applicable requirements of State law.

RR HYD-3 Construction activities that will result in discharges of groundwater and dewatering that could result in discharges to surface waters are required to comply with the effluent limitations, discharge prohibitions, receiving water limitations, and other provisions outlined in the Los Angeles RWQCB Order No. R4-2013-0095. This Order requires that an NOI be filed with the Los Angeles RWQCB prior to dewatering activities and discharge into surface waters; water sampling and

analysis; implementation of BMPs to prevent water quality degradation; and/or treatment of groundwater prior to discharge. The Los Angeles RWQCB reviews the NOI and the proposed discharge; authorizes the discharge subject to the requirements in the Order; and prescribes an appropriate monitoring and reporting program.

RR HYD-4 The Contractor is required to comply with the City's Stormwater Management and Discharge Control Ordinance (Chapter 8.7 of the Pasadena Municipal Code), which prohibits illicit discharges and connections to the municipal storm water system; requires that storm water pollutants be reduced through litter control, natural water course protection, and containment of spills; and calls for the implementation of BMPs during construction through SWPPPs and standard urban storm water mitigation plans (SUSMPs) for new development and major redevelopment.

RR HYD-5 All new construction and improvements in flood-prone areas are required by the City's Floodplain Management Regulations Ordinance (Chapter 14.27 of the Pasadena Municipal Code) to be adequately anchored to prevent flotation, collapse, or lateral movement; to be constructed with materials and equipment resistant to flood damage; to have utility and service facilities designed and located to prevent water from entering; and to provide adequate drainage to reduce exposure to flood hazards.

Impact Discussion

a) Would the project violate any water quality standards or waste discharge requirements?

f) Would the project otherwise substantially degrade water quality?

Less than Significant with Mitigation.

Areas 1, 2 and 3 Impacts. The restoration of riparian habitat in Area 1 would reduce pollutants in the stream channel (PDF HYD-1) by diverting flows in the Arroyo Seco through a meandering high-flow channel featuring seasonal wetlands, planting islands, and sandbars that would allow for the settlement of soils and sediments. The improvements in Area 2 include a diversion structure and screens in the intake structure that would prevent sediments from entering into the diverted water. In addition, the sedimentation basins proposed in Area 3 (PDF HYD-2) would also allow for the settlement of silts and fine sediments, preventing these from entering the spreading basins. Since overflows from the high-flow channel and spreading basins would go back into the Arroyo Seco, these PDFs would have beneficial impacts on water quality in the Arroyo Seco.

Pollutants that may impact storm water quality and water quality in the Arroyo Seco would be reduced by the Project. The recreational parking lot in Area 3 would be constructed of decomposed granite and would not generate runoff pollutants that may enter the Arroyo Seco. Oil, grease, and other vehicle fluids that may leak from parked vehicles in the proposed recreational parking lot would be absorbed into the ground surface and would be in limited amounts. The proposed trash receptacles and pet waste stations (PDF HYD-3) would allow trail users and visitors to properly dispose of these wastes; this would discourage others from throwing wastes on the ground, thereby preventing their potential conveyance by runoff into the Arroyo Seco. The proposed restroom would also provide a convenience to trail users and visitors, thereby reducing the occurrence for human waste and contact in the streambed or canyon and improving the water quality in the Arroyo Seco. The restroom is estimated to generate 2,000 gallons of

wastewater per day that would be conveyed to an existing sewer line at the JPL campus (PDF HYD-3); this sewer line, in turn, would convey wastewater to the Los Angeles County Sanitation Districts' Whittier Narrows Water Reclamation Plant or the Joint Water Pollution Control Plant. No wastewater would be directed into the Arroyo Seco. Thus, the proposed restroom would reduce water pollutants in the Arroyo Seco. No long-term storm water pollutant generation would occur with the Project.

While the Upper Arroyo Seco is not an impaired water body, construction activities within and near the Arroyo Seco in Areas 1 and 2 would temporarily result in pollutants in the stream that may degrade water quality. Compliance with RR HYD-1 and RR HYD-4, which require implementation of BMPs during construction, would reduce the amount of these pollutants that enter the Arroyo Seco. In addition, the Project requires a Water Quality Certification from the Los Angeles RWQCB (MM BIO-5 from Section 4.4, Biological Resources), and implementation of the Waste Discharge Requirements (WDRs) and other conditions of the Water Quality Certification (RR HYD-2) would reduce pollutants in the stream.

Dewatering activities associated with excavation of the spreading basins in Area 3 may also lead to the temporary discharge of water into the Arroyo Seco that may affect water quality in the stream. Compliance with the provisions outlined in the Los Angeles RWQCB Order No. R4-2013-0095 relating to the discharge of groundwater into surface water (RR HYD-3) would reduce adverse impacts to water quality.

As discussed earlier, hazardous materials use, storage, and disposal (i.e., equipment and refueling activities) may lead to hazardous materials entering or being washed down into the Arroyo Seco. Compliance with MM HAZ-1 from Section 4.8, Hazards and Hazardous Materials, regarding hazardous materials handling at the construction sites would prevent these impacts.

Impacts on water quality would be less than significant during construction with compliance RR HYD-1, RR HYD-2, RR HYD-3, RR HYD-4, MM BIO-5 from Section 4.4, Biological Resources, and MM HAZ-1 from Section 4.8, Hazards and Hazardous Materials. No other mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified potential impacts to water quality from construction activities and increases in vehicles, horses, and park and trail users at the HWP. The Project would comply with RR HYD-1 and RR HYD-4 for the implementation of BMPs during construction as part of the SWPPP. These RRs are similar to the Master EIR's Measure Hydro-1. The Project's proposed trash cans and decomposed granite parking lot are comparable to BMPs called out in Measure Hydro-2.

The Master EIR also discussed potential microbial contamination of surface water from waterfowl and the use of wetlands for filtration. The Project does not propose habitat restoration in Area 3, which is located within the HWP and was analyzed in the Master EIR. However, the Project proposes wetland and habitat restoration in Area 1, which would provide filtration of water in the Arroyo Seco.

b) Would the project substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted)?

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. The Project does not involve direct extraction of groundwater from the Raymond Groundwater Basin's underlying Monk Hill Subbasin. The PWP owns the rights to divert up to 25 cfs of stream flow from the Arroyo Seco, but currently only utilizes up to 18 cfs for spreading at existing basins. The LAWC has surface water rights to 6.59 cfs of surface water flows on Millard Creek.

The new diversion and weir structures in Area 2 and the expanded spreading basins in Area 3 (PDF HYD-2) would allow for the capture and recharge of as much as 25 cfs. With the increased ability to divert water during storm events and the larger recharge area provided by additional spreading basins, the Project would allow for the recharge of an additional 1,100 af of water annually, which would supplement the PWP's local water supplies. This is a beneficial impact on PWP's water resources.

With the improved diversion, less surface water would flow in the portion of the Arroyo Seco downstream of Area 2 and towards the Devil's Gate Reservoir and more surface water would be conveyed to the spreading basins for groundwater recharge. The Upper Arroyo Seco, Devil's Gate Reservoir, and the spreading basins are underlain by the same Monk Hill Subbasin of the Raymond Groundwater Basin. Where surface water now percolates in Devil's Gate Reservoir to reach the groundwater or is released through the dam by the County prior to storm events, the Project would divert an estimated 1,100 afy into spreading basins, allowing for a 60 percent extraction (i.e., 660 afy) of the amount of groundwater infiltrated. Depending on the amount of surface water currently percolating at Devil's Gate Reservoir, the Project could alter the amount of water percolating into the underlying groundwater subbasin, as well as the amount of groundwater extraction. The Raymond Basin Management Board adjudicates water resources in this groundwater basin by setting the pumping rights and managing the groundwater storage accounts of public and private water agencies, including the PWP. Continued management of the Raymond groundwater basin would prevent adverse impacts to underlying groundwater resources, and impacts would be less than significant.

Construction activities would require water for dust control, equipment cleaning, and incidental uses, but this water demand would be provided by water trucks and would not directly impact underlying groundwater supplies. While recharge at existing spreading basins may be temporarily disrupted during the construction phases of the diversion and weir structures, the intake structure, and the spreading basins, and the long-term increase in recharge brought on by the Project would have a beneficial impact on groundwater supplies. Impacts on the spreading basins would be short-term and less than significant; no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that the improvement of spreading basins would have positive impacts on the Raymond groundwater basin.

c) Would the project substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation onsite or offsite?

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. Recontouring of Area 1 would change stream flows in the Arroyo Seco; however, the proposed flow diversion, floodplain islands, riparian planting, and woody debris clusters in Area 1 would reduce flow velocities in the Upper Arroyo Seco, while the bank stabilization (e.g., rock revetment and coconut fiber bundles) would reduce erosion and scour.

The addition of woody structures and revetment would slightly alter the course of the Arroyo Seco within Area 1; however, this portion of the creek is subject to variations in flows through the braided stream area.

Flows over the ten-year base flow may go into the proposed rest area/picnic area. Improvements in this area would be bolted into concrete foundations to withstand flooding and erosion hazards. If the proposed nature trail is submerged in flows and wiped out, it is anticipated that trail users would create a new trail alignment. Erosion due to changes in stream flows would be less than significant.

Increases in surface water diversion at Area 2 would not change drainage patterns, but would redirect some of the surface water flows currently entering the Devil's Gate Reservoir to the new spreading basins in Area 3. The area around the diversion structure and the slopes along the access road in Area 2 would also be stabilized with riprap protection to reduce erosion. The new recreational parking lot in Area 3 would be covered in decomposed granite, and the maintenance roadway around the spreading basins would be compacted to reduce erosion. Therefore, the Project would reduce erosion in the long term. No major change in drainage patterns or erosion and siltation would occur with the Project.

During construction, erosion control measures would be implemented as part of the Project's SWPPP (as RR HYD-1). BMPs proposed include cofferdams that would be placed at the upstream ends of Areas 1 and 2, with a sump pump to direct water through a pipeline to the downstream ends of the construction areas. This alteration of flows would be temporary, but would avoid construction materials and debris from entering the stream flow. A silt fence would also be installed around Area 1 to reduce erosion and sedimentation into the construction area. Compliance with the BMPs in the SWPPP would reduce erosion, and impacts would be less than significant. No mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that storm drain improvements, channel widening, and habitat establishment would reduce erosion along the Arroyo Seco. Erosion and sedimentation controls were called out for the water conservation pool, spreading basins, lakes, bridges, and utility relocation/replacement (Measures Geology-1 through Geology-5). Measures Geology-1, Geology-3, and Geology-4 are not applicable to the Project. The Project would comply with RR HYD-1, which includes implementation of erosion-control measures as part of the SWPPP for the Project. This is similar to Measures Geology-2 and Geology-5.

d) Would the project substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding onsite or offsite?

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. The proposed improvements would not change drainage patterns in a way that could cause flooding. The Project does not involve the construction of new impervious cover that would impede storm water absorption into soils, or cause new sheetflow runoff. In Area 1, the footings and legs for the proposed picnic tables, benches, horse water trough, pet waste stations, trash cans, and signs would be relatively small and scattered, and would have no impact on floodwater flows. These recreational and educational amenities in Area 1 will be placed outside the five-year floodplain to minimize the amount of maintenance or repair needed following storm events. Bank revetment and the addition of woody debris clusters and a high flow channel

would slightly alter the course of the Arroyo Seco within Area 1; however, they would not alter flows in such a way that could increase flooding.

The diversion and weir structures in Area 2 would be placed above the existing diversion sill, and no changes to existing drainage patterns would occur. Flooding in Area 2 would not change, although water impoundment during high flows would be greater.

The area near Area 3 that is most frequently inundated is located behind the Devil's Gate Dam, below the elevation of the spillway (at 1,040.5 feet above msl). When the water level reaches the top of the dam at an elevation 1,075 feet above msl, water flows downstream and does not rise further. Since Area 3 is above this downstream elevation (at 1,100 to 1,130 feet above msl), it is not subject to flooding. Flooding of the proposed spreading basins, which may be excavated below 1,100 feet above msl, would not present an adverse impact. Since the proposed recreational parking lot and restroom would be at an elevation near 1,130 feet above msl and above the height of the dam, these facilities would not be subject to flooding.

Changes in drainage patterns due to Project implementation would be confined to small areas and would not cause flooding. Impacts would be less than significant and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that floodplain features and flood water elevations would not be impacted significantly since no significant fill or dredging activities are planned and no major structures that may affect flow resistance and conveyance are proposed. Minor encroachments would not cause significant changes to flood water stages or erosion/sedimentation trends.

e) Would the project create or contribute runoff water which would exceed the capacity of existing or planned storm water drainage systems or provide substantial additional sources of pollutant runoff?

No Impact.

Areas 1, 2 and 3 Impacts. There are no storm drain systems that receive storm water flows from Areas 1 and 2. All storm water flows enter the Arroyo Seco. In Area 3, storm water flows will be reduced when compared to the existing condition due to the elimination of the JPL East Parking Lot and the expansion of the spreading basins. There would be no impact to storm water drainage systems. No long-term storm water pollutants would be generated by the Project, as previously discussed under Thresholds a) and f).

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified potential impacts to water quality from construction activities and increases in vehicles, horses, and park and trail users at the HWP. The Project would comply with RR HYD-1 and RR HYD-4 for the implementation of BMPs during construction as part of the SWPPP. These RRs are similar to the Master EIR's Measure Hydro-1. The Project's proposed trash cans and decomposed granite parking lot are comparable to BMPs called out in Measure Hydro-2.

g) Would the project place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map?

h) Would the project place within a 100-year flood hazard area structures which would impede or redirect flood flows?

No Impact.

Areas 1, 2 and 3 Impacts. The proposed Project would not involve the construction of any permanent housing that may be exposed to flood hazards. The improvements in Area 1 (e.g., habitat restoration, nature trail, and rest area/picnic area) would be located within the 100-year floodplain for the Arroyo Seco, but would be built to withstand flooding (RR HYD-5). Their small and scattered locations would not impede flood flows.

The proposed diversion and weir structures in Area 2 would impede low flows for diversion into the spreading basins in Area 3, but this is not considered an adverse impact. During extremely high-flow rain events, the proposed diversion and weir structures may be partially or fully bypassed, depending on streamflow turbidity or the potential for large debris damaging the weir, thus allowing flows to continue downstream. Area 3 is located outside the floodplain, and improvements in Area 3 would not impede flood flows.

An increase in the number of trail users in the Arroyo Seco Canyon may occur but, as in the existing condition, signage would be posted regarding the hazards associated with stream flows. No impacts related to flooding would occur and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that floodplain features and flood water elevations would not be impacted significantly since no significant fill or dredging activities are planned and no major structure that may affect flow resistance and conveyance is proposed. Minor encroachments would not cause significant changes to flood water stages or erosion/sedimentation trends.

i) Would the project expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam?

No Impact.

Areas 1, 2 and 3 Impacts. The proposed improvements would be located upstream of Devil's Gate Dam. The top of this dam is at an elevation of 1,075 feet above msl. The lowest ground elevation is at Area 3 and is 1,100 feet above msl. Thus, when waters behind the dam reach 1,075 feet above msl, they will overtop the dam and would not affect areas at higher elevations, including Area 3. Also, failure of the dam will release waters downstream into the Central and Lower Arroyo Seco (Pasadena 2011) and would not affect the proposed improvements in Areas 1, 2, or 3.

There are reservoirs on the ridge north of JPL and failure of these reservoirs may release waters into Areas 2 and 3. The new diversion and weir structures, the improved access road in Area 2, and the proposed parking lot and spreading basins in Area 3 would not be damaged by waters from these reservoirs. Also, the proposed restroom and guard station in Area 3 are unlikely to sustain any significant damage from reservoir failure and are not habitable structures with a permanent population.

The proposed diversion structure would impound low flows, but would allow flows above 25 cfs to pass through; thus, it would not lead to flooding of Area 2. Overflows in the spreading basins in Area 3 would flow back into the Arroyo Seco. The Project would not expose people or structures to flooding due to levee failure or dam inundation. No impacts would occur and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not identify inundation hazards in the HWP.

j) Would the project cause inundation by seiche, tsunami, or mudflow?

No Impact.

Areas 1, 2 and 3 Impacts. The City of Pasadena is located inland and is not subject to tsunami (sea waves) hazards. The Project would not expose people or structures to tsunami hazards due to distance from the Pacific Ocean. There is no large open water body near the Arroyo Seco that may pose seiche hazards. The existing and proposed spreading basins would not hold water for long periods, but would allow water to percolate into the ground within several hours. The basins would also have at least two feet of freeboard; spillways, pipes and outlets for water to flow into lower basins; and overflow pipes to direct water back into the Arroyo Seco. Thus, no seiche hazards would be created by the Project, and the Project would not be exposed to seiche hazards.

Mudflows in the Arroyo Seco Canyon occur during large storm events, with large amounts of debris and sediment deposited in the Devil's Gate Reservoir. The proposed flow diversion, floodplain islands, riparian planting, and woody debris clusters in Area 1 would reduce flow velocities in the Upper Arroyo Seco, while bank stabilization (e.g., rock revetment and coconut fiber bundles) would reduce erosion and scour. The diversion structure that would be rebuilt in Area 2 would allow large flows to pass through to prevent sediment build up behind the weir and intake structure; it would also slow down flow velocities and reduce downstream erosion and the potential for mudflows. In addition, stabilizing the roadway slope with riprap will reduce erosion that could add to sediment loads in the stream flow. The proposed sedimentation basins in Area 3 would remove fine sediments from the diverted water. Thus, the Project would reduce sediment loads and mudflow hazards in the Arroyo Seco. No adverse impacts related to tsunami, seiche, or mudflow would occur.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not identify hazards associated with tsunamis or mudflows. It did indicate that the Devil's Gate Reservoir poses seiche hazards, although no seiches have been reported and the dam does not impound water on a continuous basis.

4.10.3 MITIGATION MEASURES

Implementation of PDF HYD-1 and PDF HYD-2 and compliance with RRs HYD-1 to HYD-5 would reduce impacts to hydrology and water quality to less than significant levels; therefore, no mitigation measures are required.

4.11 LAND USE AND PLANNING	Potentially Significant Impact	Less than Significant with Mitigation	Less than Significant Impact	No Impact
Would the project:				
a) Physically divide an established community?	☐	☐	☐	☒
b) Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect?	☐	☐	☒	☐
c) Conflict with any applicable habitat conservation plan or natural community conservation plan?	☐	☐	☐	☒

4.11.1 EXISTING CONDITIONS

The Arroyo Seco Canyon Project proposes improvements at three separate areas along the Upper Arroyo Seco. Existing improvements in each area are discussed in Section 2.2 of this IS/MND.

The Upper Arroyo Seco and adjacent lands are designated and zoned as Open Space and Planned Development in the City of Pasadena's Land Use Plan and Zoning Map (Pasadena 2009, 2012b). The Open Space designation and zone applies to City-owned land with active and passive public recreational facilities and natural open spaces and the Planned Development zone applies to sites developed with a particular mix of uses, appearance, land use compatibility, or special sensitivity to neighborhood character (Pasadena 2004). The area north and east of Area 1, within the unincorporated community of Altadena, is designated as Low Density Residential and Open Space-National Forest (LACDRP 2009).

As discussed in Section 2.2, the Hahamongna Watershed Park Master Plan (HWMP) is a land use plan for approximately 330 acres of Hahamongna Watershed Park (HWP), which extends northward from the Devil's Gate Dam to the mouth of the Arroyo Seco Canyon. A number of improvements proposed for Area 3 are in the HWMP.

The ANF is managed by the USFS for the protection of open space and natural resources within the San Gabriel Mountains. Area 1 is located within the boundaries of the ANF and is designated in the USFS Land Management Plan as Non-Forest System Land (USFS 2005a) and is located on land owned by the City. Land farther north of Area 1 is designated as Back Country, Motorized Use Restricted (BCMUR). The BCMUR zone considers the restoration of vegetation condition as a suitable activity or use and supports non-motorized dispersed recreational opportunities, including camping, hiking, biking, hunting, and fishing (USFS 2005b).

4.11.2 IMPACT ANALYSIS

Regulatory Requirements

RR LU-1 The proposed improvements in Area 3 must be designed and constructed in compliance with the *Hahamongna Watershed Park Master Plan* (HWMP) and the proposed restroom building will require Design Review Approval.

RR LU-2 The proposed Project will require a Conditional Use Permit (CUP) for developing/improving recreational facilities in the Open Space zone.

Impact Discussion

a) Would the project physically divide an established community?

No Impact.

Areas 1, 2 and 3 Impacts. The proposed Arroyo Seco Canyon Project does not involve the displacement of existing residences or the construction of barriers through the developed areas located east and west of the Arroyo Seco. Therefore, the Project would not divide an established community. No impacts would occur and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not address impacts on land use and planning since the Initial Study for the Arroyo Seco Master Plan had determined earlier that no division or disruption of an established community would occur.

b) Would the project conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect?

Less Than Significant Impact.

Areas 1, 2 and 3 Impacts. The Project would not conflict with the City's Open Space designation and zone for the area since the restored habitat areas, improved water diversion facilities, expanded spreading basins, and new recreational amenities would be consistent with the Open Space designation. However, recreational elements in the Open Space zone require a conditional use permit (CUP) from the City. Therefore, the Project includes obtaining a CUP for developing/improving recreational facilities in the Open Space zone. The proposed recharge basins in Area 3 would not conflict with the Planned Development zone.

Chapter 3.32 of the City's Municipal Code is the Arroyo Seco Public Lands Ordinance, which outlines the City's regulations for publicly owned lands within the Arroyo Seco. This ordinance only applies to the Central and Lower Arroyo Seco and does not pertain to the Upper Arroyo Seco. The Project would not conflict with the Arroyo Seco Public Lands Ordinance, as the proposed improvements would be located north of the Devil's Gate Dam as defined in the ordinance.

The proposed improvements include the recreational parking lot at the northern end of Area 3; construction of spreading basins; expansion of the spreading basins; and the provision of a restroom, interpretive signs, and potential future trail connection at the north end of Area 3. These are consistent with the HWMP, which proposes the spreading basin expansion and a new trailhead north of the JPL East Parking Lot. The HWMP proposes other facilities in or near Area 3 (e.g., a sunset overlook, bridge for North Perimeter Trail, East park entrance, East Rim Trail, Johnson Field improvements, pumpback system, storm drain improvements, utility line relocation and undergrounding) that would not be implemented by the Project but, at the same time, would not be precluded from future implementation. No conflict with the HWMP would occur. Thus, the Project would comply with RR LU-1.

The habitat restoration, water diversion, and recreational amenities that would be provided by the Project in Area 1 would not conflict with the goals of the USFS for the protection of open space and natural resources within the San Gabriel Mountains. The Project would also not conflict with the BCMUR zone to the north, which considers the restoration of vegetation condition as a suitable activity or use and supports non-motorized dispersed recreational opportunities, including camping, hiking, biking, hunting and fishing.

Since no urban development is proposed and no change to the open space use of the land would occur with the Project, no conflict or inconsistency with regional plans (i.e., SCAG's Regional Comprehensive Plan, Regional Housing Needs Assessment, Regional Transportation Plan/Sustainable Communities Strategy, and Compass Blueprint) or with the growth forecasts used in the development of these regional plans would occur. Impacts would be less than significant.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not address impacts on land use and planning since the Initial Study for the Arroyo Seco Master Plan had determined earlier that no significant impact on applicable land use plan or policies would occur and no significant impacts to land use and planning are anticipated.

c) Would the project conflict with any applicable habitat conservation plan or natural community conservation plan?

No Impact.

Areas 1, 2 and 3 Impacts. As discussed under Section 4.4, Biological Resources, there is no adopted habitat conservation plan or natural community conservation plan in the City of Pasadena or near the City and the Arroyo Seco. The Arroyo Seco Canyon is located in the Altadena Foothills and Arroyos Significant Ecological Area (SEA) under the County's SEA program (LACDRP 2011). The Project site is not subject to the SEA Program because it is not located within an unincorporated County area. Still, the Project consists of habitat restoration, water diversion, and recreational amenities that would not conflict with the objectives of the SEA for species conservation, biotic diversity, or habitat linkages. Impacts on biological resources are discussed in Section 4.4 above. No impacts related to habitat conservation plans or natural community conservation plans would occur with the Project. No mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not address impacts on land use and planning since the Initial Study for the Arroyo Seco Master Plan had determined earlier that no habitat conservation plans or natural community conservation plans are applicable to the Arroyo Seco Master Plan since no such plans exist in the area.

4.11.3 MITIGATION MEASURES

There would be no significant adverse impacts related to land use and planning with compliance with RR LU-1 and RR LU-2; therefore, no mitigation measures are required.

4.12 MINERAL RESOURCES	Potentially Significant Impact	Less than Significant with Mitigation	Less than Significant Impact	No Impact
Would the project:				
a) Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state?	☐	☐	☒	☐
b) Result in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan, or other land use plan?	☐	☐	☐	☒

4.12.1 EXISTING CONDITIONS

Mineral resources are naturally occurring chemicals, elements, or compounds such as bituminous rock, gold, sand, gravel, clay, crushed stone, limestone, diatomite, salt, borate, potash, geothermal, petroleum, and natural gas resources. Construction aggregate refers to sand and gravel (natural aggregates) and crushed stone (rock) that are used as Portland-cement-concrete aggregate, asphaltic-concrete aggregate, road base, railroad ballast, riprap, fill, and the production of other construction materials.

The California Geological Survey (CGS) has identified deposits of regionally significant aggregate resources in the State in accordance with the Surface Mining and Reclamation Act (SMARA). Clusters or belts of mineral deposits are designated as Mineral Resources Zone 2 (MRZ-2), which include areas that require special management due to the presence of mineral resources important to the State. The Devil's Gate Reservoir is designated as an MRZ-2 zone. The reservoir was mined by eight operators and by the County for channel maintenance until 1994. The MRZ-2 zone in the reservoir covers 204 acres and contains sand and gravel deposits up to 100 feet below the ground surface. This zone encompasses Area 3. However, there is no active mining operation in this MRZ-2 zone (CDOC 2010).

Review of maps prepared by the California Department of Conservation shows that there are no oil, gas or geothermal fields in or near the Upper Arroyo Seco (CDOC 2001). Additionally, there are no active or idle oil wells in or near the canyon. The nearest well is a plugged and inactive well located approximately six miles southwest of Area 3 (DOGGR 2013).

4.12.2 IMPACT ANALYSIS

Project Design Features

PDF MIN-1 Large cobbles and boulders exposed in Area 2 will be collected and stockpiled at a designated area for future use as trail markers, signs, and other decorative purposes.

Regulatory Requirements

RR MIN-1 Excavation activities in Area 3 is required to include the collection of arroyo stone for use in structures, signs, walls, and other improvements in accordance with the Arroyo Seco Design Guidelines, subject to design review and approval by the City's Planning Division.

Impact Discussion

a) Would the project result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state?

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. The sand and gravel resources within Devil's Gate Reservoir, as identified by CGS (CDOC 2010), would not be affected by the Project, since no excavation, grading, or paving is proposed within the reservoir.

The proposed improvements in Areas 1 and 2, upstream of the reservoir, would restore habitat and increase water diversion, but would not affect the availability of sand and gravel resources in the reservoir. However, there are large cobbles and boulders in these areas that would be disturbed by the Project. Improvements in Area 1 would place these boulders along the edges of the stream and the nature trail, and in the proposed rest area/picnic area. Improvements in Area 2 may use boulders depending on integrity, shapes, and sizes for the rock wall and riprap protection. Improvements in Area 3 may also utilize cobbles and boulders (e.g., structure facades, walkway/trail edges, signs, etc.). In addition, as stated in PDF MIN-1, large cobbles and boulders in Area 2 would be moved away from active construction areas and stockpiled for future decorative uses, to conserve these resources.

The CGS has identified sand and gravel resources in Area 3 (CDOC 2010). The improvements in Area 3 would not extract the underlying sand, gravel, or arroyo stone resources, but may expose these resources during utility line excavation and as part of grading activities for the sedimentation basins and expansion of the spreading basins. The amount of excavated soils requiring off-site disposal would be minimized by creating shallow embankments around the proposed basins and raising the elevation of the access road and the new parking lot. Still, approximately 2,000 cubic yards of excess soils would be disposed of offsite. The HWMP and Arroyo Seco Design Guidelines call for the use of local arroyo stone in structures, walls, fences, signs, entries, and along trails to reflect the culture and style that is present along the Arroyo Seco. In compliance with the HWMP and Arroyo Seco Design Guidelines, RR MIN-1 requires the collection of arroyo stones during excavation activities in Area 3. This would allow for the reuse of the stones for the restroom, trail, drinking fountain, signs, or other site improvements, as well as to reduce the off-site disposal of excavated soils and materials.

The improvements for Area 3 would include some impervious surfaces (e.g., foundations for restroom, access road, and guard station), but the majority of the area would remain pervious as a decomposed granite parking lot and open sedimentation and spreading basins. Thus, the Project would maintain the availability of these mineral resources and would not preclude future mining operations in this area.

Impacts on regionally important mineral resources would be less than significant, and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan acknowledged the presence of mineral resources, such as arroyo stone, behind Devil's Gate Dam and includes a mitigation measure for the collection of the arroyo stone for use in other areas of the HWP. To allow for continued collection and reuse of the arroyo stone in the HWP, RR MIN-1 (similar to Measure Minerals-1) would be implemented in Area 3.

b) Would the project result in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan, or other land use plan?

No Impact.

Areas 1, 2 and 3 Impacts. There are no identified oil, gas, or geothermal resources or ongoing mining/extraction activities in the Upper Arroyo Seco. The City of Pasadena Comprehensive General Plan does not identify any mineral resources in the City (Pasadena 2004). The HWMP talks about the removal of sand and gravel from the Devil's Gate Reservoir in the past but does not identify aggregate or other mineral resources in and around the reservoir that should be protected or preserved (Pasadena 2003a).

The Project would not require mineral resources, nor would it change the availability of resources within Devil's Gate Reservoir. The diversion of water into the spreading basins would not affect sand and gravel resources in the reservoir. Additionally, no new structures or facilities would be constructed as part of the Project that could potentially restrict or obstruct future mineral resource recovery activities within Devil's Gate Reservoir. As discussed above, construction activities in Areas 2 and 3 would include collection of arroyo stones (PDF MIN-1 and RR MIN-1). Long-term recreational activities in the Arroyo Seco Canyon and operation and maintenance activities on the PWP facilities would not require mineral resources. Thus, there would be no impacts to locally important mineral resources. No mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan acknowledged the presence of mineral resources, such as arroyo stone, behind Devil's Gate Dam and includes a mitigation measure for the collection of the arroyo stone for use in structures, walls, fences, signs, entries, and along trails. The Project would implement RR MIN-1 in Area 3, which is similar to Measure Minerals-1 in the Master EIR.

4.12.3 MITIGATION MEASURES

There would be no significant adverse impacts related to mineral resources, with implementation of PDF MIN-1 and RR MIN-1. No mitigation is required.

4.13 NOISE	Potentially Significant Impact	Less than Significant with Mitigation	Less than Significant Impact	No Impact
Would the project result in:				
a) Exposure of persons to or generation of noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies?	☐	☐	☒	☐
b) Exposure of persons to or generation of excessive groundborne vibration or groundborne noise levels?	☐	☐	☒	☐
c) A substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project?	☐	☐	☒	☐
d) A substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project?	☐	☐	☒	☐
e) For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project expose people residing or working in the project area to excessive noise levels?	☐	☐	☐	☒
f) For a project within the vicinity of a private airstrip, would the project expose people residing or working in the project area to excessive noise levels?	☐	☐	☐	☒

4.13.1 EXISTING CONDITIONS

Noise-Sensitive Receptors

Noise-sensitive receptors include land uses where an excessive amount of noise would interfere with normal operations or activities and where a high degree of noise control may be necessary. Examples include schools, hospitals, and residential areas. Recreational areas may be considered noise-sensitive where quiet and solitude may be an important aspect of the specific recreational experience (Pasadena 2004).

Area 1. The USFS Ranger Station, which includes three dwelling units providing housing for USFS Rangers, is located just east of the trail in Area 1 (See aerial photograph of Area 1 in Exhibit 2-3a). The USFS Ranger Station is located in the City of Pasadena. The closest residences to the west in La Cañada Flintridge are on Gleneagles Place, approximately 0.2 mile west of Area 1. Residential neighborhoods to the east in Altadena are approximately 0.25 mile from Area 1.

Area 2. The closest homes to Area 2 are approximately 0.15 mile to the east on Canyon Dell Drive in Altadena. Residential neighborhoods to the west in La Cañada Flintridge are more than 0.25 mile from Area 2.

Area 3. There are single-family residential neighborhoods to the east of Area 3. Some homes are in the City of Pasadena and others are in Altadena. The closest homes to Area 3 are on Ridgeview Drive in Altadena, approximately 225 feet from the eastern edge of the JPL parking lot, and are approximately 100 feet higher in elevation than the parking lot.

North Windsor Avenue, between I-210 and Explorer Drive, would be used by traffic generated by the proposed Project. There are homes adjacent to North Windsor Avenue in the City of Pasadena and in the community of Altadena.

Passive and active recreational areas, including the Gabrielino Trail, are near all Project areas and are described in Section 4.15, Recreation.

Existing Noise Levels

Areas 1 and 2 are located in rural settings approximately 0.25 mile from suburban development. Local noise sources include occasional vehicles, recreational visitors, wind, and other natural sounds. Average hourly daytime noise levels (L_{eq}) are estimated to be 40 to 45 A-weighted decibels (dBA) L_{eq}.

Area 3 is located within a developed area and includes the JPL East Parking Lot. The principal local noise sources in the surrounding area are (1) industrial activities, including material handling equipment at the JPL campus to the west and (2) vehicles coming to, using, and leaving the parking lot. Average hourly daytime noise levels are estimated to be 50 to 55 dBA L_{eq}.

Ambient noise level measurements were taken near the residential receptors east of Area 3 on November 14, 2013, using a Larson Davis Laboratories Model 831 integrating sound level meter (LD 831). The LD 831 sound level meter and microphone was mounted on a tripod four to five feet above the ground and equipped with a windscreen during all measurements. The LD 831 was calibrated before and after use. Four short-term noise level measurements were made. The monitoring locations are shown in Exhibit 4-4, Noise Monitoring Locations. Each short-term measurement was taken for a period of 20 minutes to provide representative average daytime noise levels. The average, maximum, and minimum (L_{eq}, L_{max}, and L_{min}) values taken at each noise measurement location are shown in Table 4.13-1, Ambient Noise Level Measurements. The complete noise monitoring results are included in Appendix E.

TABLE 4.13-1
AMBIENT NOISE LEVEL MEASUREMENTS

Location No.	Location	Start Time (Duration)	Noise Levels (dBA)			Primary Noise Source(s)	Notes
			L_{eq}	L_{max}	L_{min}		
1	West end of Altadena Dr	12:01 PM (20 min)	46	55	41	Hum and material handling equipment at JPL. Occasional traffic.	Occasional hikers and their dogs.
2	West end of Mariposa St	12:32 PM (20 min)	45	60	40	Hum and material handling equipment at JPL.	One helicopter pass. Occasional dog bark.
3	Intersection of N Windsor Ave and Ventura St	1:07 PM (20 min)	53	65	44	Traffic on Windsor Ave and Ventura St	JPL noise; 105 cars on Windsor Ave and Ventura St; 35 cars on JPL access road.
4	West end of Kent St	1:59 PM (20 min)	47	56	42	Residential sounds. Traffic on Windsor Ave.	I-210 traffic noise audible.

dBA: A-weighted decibel; L_{eq}: average noise level over a period of minutes or hours expressed as the equivalent noise level for that time period; L_{max} and L_{min}: the highest and lowest (respectively) A-weighted sound level that occurs during that noise event; min: minutes; JPL-Jet Propulsion Laboratory; I: Interstate

As shown in Table 4.13-1, the daytime noise levels in the residential area east of Area 3 ranged from an average noise level of 45 to 53 dBA. The existing background noise environment (i.e., ambient noise) in the Project area is primarily influenced by occasional vehicle traffic on the roads adjacent to the Project site.

The area in the City of La Cañada Flintridge west of Areas 1 and 2 includes developed residential areas, but no major roadways. Average hourly daytime noise levels are estimated to be 45 to 50 dBA L_{eq}.

Applicable Noise Standards

While the Project would be located in the City of Pasadena, there are nearby noise-sensitive receptors in Cities of Pasadena and La Cañada Flintridge and the unincorporated community of Altadena. The applicable noise standards of all three jurisdictions are provided below.

City of Pasadena

The City of Pasadena has established guidelines and standards in its General Plan and Municipal Code. The Noise Element recognizes that construction activity is a source of occasional temporary nuisance noise throughout the City and that these and other such nuisance noises are common to cities and, because of their unpredictable nature, must be addressed on a case-by-case basis.

The following policies are applicable to the Project:

Policy 7b: The City will encourage limitations on construction activities adjacent to sensitive noise receptors.

Policy 7c: The City will encourage construction and landscaping activities that employ techniques to minimize noise.

The City Municipal Code (Title 9, article IV, Chapter 9.36, Noise Restrictions) is the City's Noise Ordinance. It is the City's policy ". . . to prohibit unnecessary, excessive and annoying noises from all sources . . . Noise at certain levels is detrimental to the health and welfare of the general public". The following sections of the Noise Ordinance are applicable to the Project:

Section 9.36.050 – General Noise Sources

This is applicable for long-term, operational noise and states "It is unlawful for any person to create, cause, make or continue to make or permit to be made or continued any noise or sound which exceeds the ambient noise level at the property line of any property by more than 5 decibels". In accordance with Section 9.36.040, adjustments are made to the allowable noise level for steady audible tones, repeated impulsive noise, and noise occurring for limited time periods.

Section 9.36.070 – Construction Projects

This section is applicable for Construction Projects and states:

A. No person shall operate any pile driver, power shovel, pneumatic hammer, derrick power hoist, forklift, cement mixer or any other similar construction equipment within a residential district or within a radius of 500 feet therefrom at any time other than as listed below:

    1. From 7:00 AM to 7:00 PM Monday through Friday;
    2. From 8:00 AM to 5:00 PM on Saturday; and
    3. Operation of any of the listed construction equipment is prohibited on Sundays and holidays.

B. No person shall perform any construction or repair work on buildings, structures or projects within a residential district or within a radius of 500 feet there from in such a manner that a reasonable person of normal sensitiveness residing in the area is caused discomfort or annoyance at any time other than as listed below:

    1. From 7:00 AM to 7:00 PM Monday through Friday;
    2. From 8:00 AM to 5:00 PM on Saturday; and
    3. Performance of construction or repair work is prohibited on Sundays and holidays.

C. For purposes of this section, holidays are New Year's Day, Martin Luther King Jr. Day, Lincoln's Birthday, Washington's Birthday, Memorial Day, Independence Day, Labor Day, Veterans Day, Thanksgiving Day, Day after Thanksgiving, and Christmas.

Section 9.36.080 – Construction Equipment.

This section states that "It is unlawful for any person to operate any powered construction equipment if the operation of such equipment emits noise at a level in excess of 85 dBA when measured within a radius of 100 feet from such equipment".

Los Angeles County

The Los Angeles County noise restrictions are applicable to the properties within the Altadena community. Section 12.08 of the County of Los Angeles Code (County Code) contains the County Noise Ordinance. The County sets maximum construction noise levels "at residential structures." As shown in Table 4.13-2 below, the daytime noise level limit at single-family residences for mobile construction equipment is 75 dBA.

TABLE 4.13-2
COUNTY OF LOS ANGELES CONSTRUCTION EQUIPMENT NOISE LIMITS

Time Interval	Single-Family Residential (dBA)	Multi-Family Residential (dBA)	Semi-Residential or Commercial (dBA)
Mobile Equipment			
Daily, except Sundays and legal holidays, 7:00 AM to 8:00 PM	75	80	85
Daily, 8:00 PM to 7:00 AM, and all day Sunday and legal holidays	60	64	70
Stationary Equipment			
Daily, except Sundays and legal holidays, 7:00 AM to 8:00 PM	60	65	70
Daily, 8:00 PM to 7:00 AM, and all day Sunday and legal holidays	50	55	60
dBA: A-weighted decibels Source: Los Angeles County 2013b.			

The County's Noise Ordinance requirements are not applicable to mobile noise sources such as automobiles or heavy trucks when traveling in a legal manner on public roadways or on private property. Mobile noise source control is preempted by federal and State laws.

City of La Cañada Flintridge

The City of La Cañada Flintridge does not have quantitative standards for construction noise.

Applicable Vibration Standards

Neither the City of Pasadena nor the City of La Cañada Flintridge has vibration standards. Section 12.08.560 of the Los Angeles County Code states, "Operating or permitting the operation of any device that creates vibration which is above the vibration perception threshold of any individual at or beyond the property boundary of the source if on private property, or at 150 feet (46 meters) from the source if on a public space or public right-of-way is prohibited. The perception threshold shall be a motion velocity of 0.01 in/sec over the range of 1 to 100 Hertz".

4.13.2 IMPACT ANALYSIS

Regulatory Requirements

RR NOI-1 In accordance with Section 9.36.070 of the City of Pasadena Municipal Code, the Contractor is required to limit noise-generating construction activities to between the hours of 7:00 AM and 7:00 PM Monday through Friday and between the hours of 8:00 AM and 5:00 PM Saturday in or within 500 feet of a residential district. No noise-generating construction activities shall be conducted on Sundays and federal holidays.

Impact Discussion

a) Would the project result in exposure of persons to or generation of noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies?

d) Would the project result in a substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project?

Less than Significant Impact.

Noise impacts associated with the proposed Project would be largely limited to the construction phase. The primary noise sources during construction of a project are the diesel engines of construction equipment and noise from operations such as pile driving, blasting, and jackhammering. No pile driving or blasting activities are proposed; jackhammering, hoe-rams, and concrete saws may be used for some demolition work.

Construction noise is related primarily to the use of heavy equipment. Construction equipment can be considered to operate in two modes: stationary and mobile. Stationary equipment operates in one location for one or more days at a time, with either a fixed-power operation (such as pumps, generators and compressors) or a variable noise operation (such as rock drills and pavement breakers). Mobile equipment moves around the construction site with power applied in cyclic fashion, such as bulldozers, graders, and loaders. Noise impacts from stationary equipment are assessed from the location of the specific equipment, while noise impacts from mobile construction equipment are assessed from the center of the equipment activity or construction site. The noise level at a receptor is dependent on the distance from the source to the receptor and the intervening topography and groundcover.

Variation in power is also a factor in characterizing the noise source levels from construction equipment. Power variation is accounted for by describing the noise at a reference distance from equipment operating at full power and adjusting it based on the duty cycle of the activity to determine the L_{eq} of the operation.[6] Typical duty cycles and noise levels generated by representative pieces of equipment are listed in Table 4.13-3, Typical Maximum Construction Equipment Noise Levels.

[6] The duty cycle is the percentage of time that the equipment is typically at full power.

TABLE 4.13-3
TYPICAL MAXIMUM CONSTRUCTION
EQUIPMENT NOISE LEVELS

Equipment	Noise Level (dBA) at 50 ft	Typical Duty Cycle
Auger Drill Rig	85	20%
Backhoe	80	40%
Blasting	94	1%
Chain Saw	85	20%
Clam Shovel	93	20%
Compactor (ground)	80	20%
Compressor (air)	80	40%
Concrete Mixer Truck	85	40%
Concrete Pump	82	20%
Concrete Saw	90	20%
Crane (mobile or stationary)	85	20%
Dozer	85	40%
Dump Truck	84	40%
Excavator	85	40%
Front End Loader	80	40%
Generator (25 KVA or less)	70	50%
Generator (more than 25 KVA)	82	50%
Grader	85	40%
Hydra Break Ram	90	10%
In situ Soil Sampling Rig	84	20%
Jackhammer	85	20%
Mounted Impact Hammer (hoe ram)	90	20%
Paver	85	50%
Pile Driver, Impact (diesel or pneumatic)	95	20%
Pile Driver, Vibratory	95	20%
Pneumatic Tools	85	50%
Pumps	77	50%
Rock Drill	85	20%
Scraper	85	40%
Tractor	84	40%
Vacuum Excavator (vac-truck)	85	40%
Vibratory Concrete Mixer	80	20%
dBA: A-weighted decibels; ft: feet; KVA: kilovolt amps Source: Thalheimer 2000.		

Each phase of construction has a specific equipment mix, depending on the work to be accomplished during that phase. Each phase also has its own noise characteristics; some would have higher continuous noise levels than others, and some have high-impact noise levels. The L_{eq} of each phase is determined by combining the Leq contributions from each piece of equipment used in that phase. Construction of the Project is anticipated to start in Summer 2015.

Typical heavy construction equipment would include bulldozers, excavators, dump trucks, front-end loaders, graders, and industrial/concrete saws. Because of the effects of noise attenuation, the distance from the noise source to a receptor is a primary consideration in determining the noise level experienced at the receptor. Because different construction stages involve different pieces of equipment and may involve only localized portions of a site, each construction stage can result in different noise levels being generated depending on the distance to sensitive receptors.

Area 1 Impacts. The noisiest construction work in Area 1 would be the demolition of the Headworks structure, which is located at the north end of Area 1, approximately 500 feet from the nearest Ranger Station residence. Assuming that a concrete saw or a hoe-ram has a maximum noise level of 90 dBA at 50 feet and a 20 percent duty cycle (as shown in Table 4.13-3), the maximum noise level at the Ranger Station more than 500 feet, which would occur intermittently, would be approximately 65 dBA. The average noise level would be less than 60 dBA L_{eq}. Grading in Area 1 would occur at distances of approximately 100 to 500 feet from the closest Ranger Station residence. Because equipment would move around the site, average noise levels are calculated for the average distance of 250 feet. Assuming the simultaneous operation of two pieces of equipment (e.g., an excavator and dump truck), average noise levels at the nearest receptor would be approximately 67 dBA L_{eq}. The noise would be audible at the Ranger Station and could occasionally interfere with normal speech of persons outside and close to the construction work. The duration of the demolition and grading phases would be relatively short at approximately four months; noise levels would vary throughout the day and from day to day. The Contractor shall also comply with construction time limits in the City's Noise Ordinance (RR NOI-1). This impact would be less than significant.

Residential neighborhoods to the east in Altadena and to the west in La Cañada Flintridge would experience noise levels at 51 dBA L_{eq} because of distance; there likely would also be additional noise reduction because of topographical features. The noise may be heard occasionally, but would not be substantial or significant. The City of Pasadena's Noise Ordinance is also more restrictive than the County's noise regulations and the City of La Canada Flintridge has no standards for construction noise. Thus, Project construction will comply with the City's Noise Ordinance (RR NOI-1).

Although no mitigation is required, MM NOI-1 would be incorporated into the Project to minimize noise impacts and to support Policies 7b and 7c of the Pasadena Comprehensive General Plan's Noise Element. MM NOI-1 specifies noise-control measures to minimize noise effects upon sensitive receptors.

Area 2 Impacts. The noisiest construction work in Area 2 would be the demolition of a portion of the diversion weir. Assuming that a concrete saw or a hoe-ram has a maximum noise level of 90 dBA at 50 feet and a 20 percent duty cycle (as shown in Table 4.13-3), the maximum noise level at the closest homes on Canyon Dell Drive in Altadena (approximately 800 feet to the east), which would occur intermittently, would be approximately 60 dBA; this is less than the County standard of 75 dBA. The average noise level would be less than 60 dBA L_{eq}. During grading in Area 2, assuming the simultaneous operation of two pieces of equipment, such as an excavator and dump truck, average noise levels at the nearest receptor in Altadena would be approximately 54 dBA L_{eq}. The noise may be occasionally audible, but would not interfere with normal speech of persons outside. This impact would be less than significant.

Construction noise from Area 2 to residential neighborhoods to the west in La Cañada Flintridge would be reduced to less than 55 dBA L_{eq} because of distance, with additional noise reduction likely occurring because of topographical features. The noise may be heard occasionally but

would not be substantial or significant; no mitigation is required. However, RR NOI-1 and MM NOI-1 would be implemented during construction activities.

Area 3 Impacts. The noisiest construction work in Area 3 would be the demolition of paved areas, concrete vaults, and other structures. Assuming that a concrete saw or a hoe-ram has a maximum noise level of 90 dBA at 50 feet and a 20 percent duty cycle (as shown in Table 4.13-3), the maximum noise level at the closest homes on Ridgeview Drive in Altadena, which would occur intermittently, would be approximately 73 dBA, which is less than the County standard of 75 dBA. The closest homes to Area 3 are located on a bluff approximately 100 feet above the elevation of Area 3. The noise from Area 3 to the closest homes would be reduced by distance and by the bluff edge, which would break the line of sight between the noise sources and the receptors. The average noise level would be approximately 65 dBA L_{eq}. During grading in Area 3, assuming the simultaneous operation of two pieces of equipment, such as an excavator and dump truck, average noise levels at the nearest Altadena receptors would be approximately 67 dBA L_{eq}. The noise would be audible and could occasionally interfere with normal speech of persons outside.

Project construction would not require pile driving or blasting. All equipment planned for use on the Project site would be anticipated to have noise levels not exceeding 90 dBA at a distance of 50 feet, which would be 84 dBA at a distance of 100 feet. This noise level would be less than the limit of 85 dBA at 100 feet stated in Section 9.36.080 of the City of Pasadena Noise Ordinance. All construction activities would also be limited to between the hours of 7:00 AM and 7:00 PM Monday through Friday and between 8:00 AM and 5:00 PM on Saturday, as required by the City's Noise Ordinance (RR NOI-1). As stated above, MM NOI-1 would also be implemented by the Contractor.

Roadway Noise

The Project would generate construction traffic on North Windsor Avenue. Traffic would include workers commuting to and from Areas 1, 2, and 3; vendors bringing materials; and haul trucks removing demolished structural and vegetative materials from the three site areas. The existing average daily weekday traffic volumes (ADT) in 2011 on North Windsor Avenue ranged from 6,361 to 10,097 ADT between Ventura Street and Figueroa Drive and from 10,258 to 13,928 south of Figueroa Drive to Oak Grove Avenue (Los Angeles County 2013a). CalEEMod assumptions for the mix of construction equipment assumed during construction activities result in an estimated maximum number of daily workers during Project construction of 366 ADT. Since a doubling of traffic volume is needed to increase noise levels by 3 dBA and since it takes a 5-dBA increase for noise level changes to become discernible, the increase in roadway noise would not be discernible and would be considered less than significant.

Truck passbys would be heard at residences adjacent to the roads used; the noise would be similar to the occasional noise of waste collection trucks, which would be approximately 73 to 77 dBA at a distance of 50 feet from the road centerline, depending on the speed of the truck. The maximum number of heavy truck trips would occur during demolition activities in Area 3. There would be approximately 52 passbys (26 round trips per day), which is fewer than 7 passbys per hour. During this period, the hourly average noise increase would be less than 2 dBA. During other Project phases, the number of heavy truck trips would be considerably less. This noise impact would not be substantial and impacts would be less than significant.

Hikers, bicyclists, and equestrians could come near construction activities in Areas 1, 2, and 3 while using the Gabrielino Trail. However, these recreational users would have the option of modifying their activities to avoid exposure to undesirable noise levels. Impacts on trail users and visitors would be less than significant.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that noise from operational and construction activities at the HWP would not create significant noise impacts. The Master EIR identified potential noise impacts from short-term construction activities in the Central Arroyo Seco and Lower Arroyo Seco and included mitigation measures to reduce construction noise. The Project would comply with RR NOI-1 for the scheduling of construction activities in accordance with City regulations. This RR is similar to Measure Noise-1. Although Measure Noise-2 and Measure Noise-3 are not applicable to the Project, these mitigation measures call for similar noise-control measures as those outlined in MM NOI-1.

b) Would the project result in exposure of persons to or generate excessive groundborne vibration or groundborne noise levels?

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. Vibration affects structures and persons located relatively close to the source of the vibration. For heavy construction equipment operations, vibration would not be perceptible and would be less than the 0.1 inch per second (in/sec) threshold of perception defined by Los Angeles County at distances of 200 feet and greater. There are no residential neighborhoods in Altadena/Los Angeles County within 200 feet of construction areas. At Area 1, heavy equipment may occasionally work at distances within 100 to 200 feet of a USFS Ranger Station residence, and vibration may be perceptible. However, neither the frequency, the duration of vibration, nor the magnitude of vibration would be substantial. The impact would be less than significant and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not identify any vibration impacts from proposed improvements or facilities in the HWP.

c) Would the project result in a substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project?

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. Permanent increases in noise associated with operations and maintenance of the proposed improvements would come from new vehicles trips from trail users and visitors and from maintenance crews.

Visitors. Existing maximum visitor use is estimated at 125 persons on weekdays and 800 persons on holiday weekend days, with fewer visitors on non-holiday weekend days. The proposed Project could increase visitor use by 25 persons on weekdays and 200 persons on holiday weekend days. A very conservative analysis assumes each visitor drives separately, resulting in an additional 50 one-way trips (25 round trips) on weekdays and 400 one-way trips (200 round trips) on holiday weekend days. As discussed previously, weekday traffic volumes on North Windsor Avenue north of Oak Grove Avenue ranged from 6,361 to 13,928 ADT. Weekend volumes are less, ranging from 4,680 to 9,044 ADT (Los Angeles County 2013a). The increase in weekday traffic would increase traffic noise levels by less than 0.1 dBA; the increase in weekend traffic would increase traffic noise levels by less than 0.5 dBA. These increases in noise levels would not be discernible; would be less than the City of Pasadena's 5-dBA standard; and would be less than significant. No mitigation is required.

Maintenance. There would be no substantial long-term changes to maintenance activities. Maintenance in Area 1 would be the same due to the elimination of maintenance for the Headworks and sedimentation basins but the need to maintain the proposed rest area/picnic area

and collect wastes from the pet waste station and trash cans. Maintenance in Area 2 would be reduced by automation of the diversion structure and the improved Gabrielino Trail/access road. Maintenance of the restroom, pet waste station, and trash can in Area 3 would require restroom cleaning twice per week and waste collection once a week. The reduced size of the parking lot would require less maintenance. The expanded spreading basins are expected to have the same maintenance needs due to the use of sedimentation basins, which would reduce the need for sediment removal in the spreading basins. Changes in noise resulting from maintenance activities would be negligible and less than significant; no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that operational components and recreational uses at the HWP would not create significant noise impacts.

e) For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project expose people residing or working in the project area to excessive noise levels?

f) For a project within the vicinity of a private airstrip, would the project expose people residing or working in the project area to excessive noise levels?

No Impact.

Areas 1, 2 and 3 Impacts. There are no airports or airstrips within two miles of the Arroyo Seco Canyon. The nearest airports are the Burbank Bob Hope Airport and the El Monte Airport, which are both approximately 11 miles from the site. The Project would not subject persons in the area to noise from public or private airports, nor would the Project generate aircraft noise. There is a heliport and a helipad near the Arroyo Seco but no change in helicopter noise would occur with the Project. There would be no impact.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that the HWP is not located within two miles of a public airport or private airstrip. Therefore, users of the HWP are not exposed to noise from airport or aircraft operations.

4.13.3 MITIGATION MEASURES

There would be no significant adverse impacts related to noise with compliance with RR NOI-1. However, MM NOI-1 would be implemented to further minimize noise impacts on adjacent land uses.

MM NOI-1 The Contractor shall implement the following noise reduction measures during all construction activities:

- Equip all construction equipment (fixed or mobile) with properly operating and maintained mufflers, consistent with or exceeding manufacturers' standards.
- Ensure that construction equipment engine enclosures and covers as provided by manufacturers shall be in place during operation.
- Place all stationary construction equipment so that the equipment is as far as feasible from noise-sensitive receptors and so that the emitted noise is directed away from the noise-sensitive receptors.

- Locate equipment and materials staging in areas that will create the greatest distance between staging area noise sources and noise-sensitive receptors during Project construction.
- Ensure that construction equipment is shut down when not in use.
- Limit haul truck deliveries to the same hours specified for the operation of construction equipment.

4.14 POPULATION AND HOUSING	Potentially Significant Impact	Less than Significant with Mitigation	Less than Significant Impact	No Impact
Would the project:				
a) Induce substantial population growth in an area, either directly (for example, by proposing new homes and businesses) or indirectly (for example, through the extension of roads or other infrastructure)?	☐	☐	☐	☒
b) Displace substantial numbers of existing housing, necessitating the construction of replacement housing elsewhere?	☐	☐	☐	☒
c) Displace substantial numbers of people, necessitating the construction of replacement housing elsewhere?	☐	☐	☐	☒

4.14.1 EXISTING CONDITIONS

The Arroyo Seco Canyon does not support a residential community nor contain residential land uses, except for the USFS Ranger Station near Area 1, which is developed with three dwelling units that are occupied by three households of USFS Rangers. There are nearby residential uses to the east of the Arroyo Seco, within the community of Altadena; to the east and southeast in the City of Pasadena; and to the west in the City of La Cañada Flintridge.

4.14.2 IMPACT ANALYSIS

Impact Discussion

a) Would the project induce substantial population growth in an area, either directly (for example, by proposing new homes and businesses) or indirectly (for example, through the extension of roads or other infrastructure)?

No Impact.

Areas 1, 2 and 3 Impacts. The Project does not propose the construction of new homes or businesses that may induce population growth in the area. Also, no extension of infrastructure to unserved areas is proposed. The presence of the construction crew would be temporary and would not generate a measurable demand for housing, goods, or services in the area.

No major change in the PWP's operational or maintenance activities would occur that would lead to new employees or which would induce growth and development in the area. The Project would improve the PWP's surface water diversion facilities and increase groundwater recharge. This would, in turn, reduce the PWP's reliance on imported water resources and would reduce its operating costs, but would not promote development in the City or the surrounding area.

The increase in the number of trail users/visitors due to the proposed recreational parking lot and the recreational and educational amenities that would be provided by the Project would not lead to a permanent population in the area. These trail users and visitors would be present in the Arroyo Seco Canyon for a few hours during each visit and would not create a permanent demand for housing, goods, or services in the area.

No growth-inducing impacts would occur and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not address impacts on population and housing since the Initial Study for the Arroyo Seco Master Plan had determined earlier that no new residential homes are planned and no significant impacts to population and housing are anticipated.

b) Would the project displace substantial numbers of existing housing, necessitating the construction of replacement housing elsewhere?

c) Would the project displace substantial numbers of people, necessitating the construction of replacement housing elsewhere?

No Impact.

Areas 1, 2 and 3 Impacts. Construction activities for the Project would be confined to the parcels owned by the City of Pasadena and located within the City. These activities would not affect the residences located within the USFS Ranger Station near Area 1 or the single-family residences to the east and west of the Arroyo Seco. No housing demolition or household displacement is proposed with the Project as the USFS Ranger Station near Area 1 would not be displaced, demolished, or rehabilitated. Long-term recreational activities in the Arroyo Seco Canyon and operation and maintenance activities on the PWP facilities would not displace existing housing or households. Thus, no displacement impacts would occur and no replacement housing is needed. No mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not address impacts on population and housing since the Initial Study for the Arroyo Seco Master Plan had determined earlier that no housing displacement or demand for additional housing would occur.

4.14.3 MITIGATION MEASURES

There would be no impacts related to population and housing; therefore, no mitigation measures are necessary.

4.15 PUBLIC SERVICES	Potentially Significant Impact	Less than Significant with Mitigation	Less than Significant Impact	No Impact
Would the project:				
a) Would the project result in substantial adverse physical impacts associated with the provision of new or physically altered government facilities, need for new or physically altered government facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for any of the public services:				
Fire protection?	☐	☐	☒	☐
Police protection?	☐	☐	☒	☐
Schools?	☐	☐	☐	☒
Parks?	☐	☐	☐	☒
Other public facilities?	☐	☐	☒	☐

4.15.1 EXISTING CONDITIONS

Public services in the Upper Arroyo Seco area are provided by the Pasadena Fire Department, the Pasadena Police Department, the Pasadena Unified School District, the City of Pasadena Parks and Natural Resources Division, the Pasadena Library, and other City departments. The Los Angeles County Fire Department and the USFS also provide wildfire protection services, particularly related to the ANF.

Fire Protection Services

The Pasadena Fire Department provides fire protection services to the City and operates eight fire stations. Pasadena Fire Station 38 at 1150 Linda Vista is located 2.4 miles south of Area 3. However, the Los Angeles County Fire Station #12 at 2760 North Lincoln Avenue in Altadena is located only 0.6 mile east of Area 3. County Fire Camp #2 is located southwest of the JPL campus and is a helicopter standby location during the fire season, with a crew of ten firefighters. County Fire Station #82 is located one mile southwest of Area 3 but is on the west side of the Arroyo Seco.

The Los Angeles County Fire Department has automatic aid agreements with 33 cities in the County, including the City of Pasadena, to provide fire protection services during a fire or medical emergency regardless of territory. Thus, City and County firefighters would provide emergency response to the Upper Arroyo Seco in the event of a fire incident.

In the ANF, the USFS provides fire prevention and preparedness; hazardous fuels reduction; wildfire suppression; and emergency support. Under the California Fire Assistance Agreement, local fire departments provide fire protection and suppression services to State and federal agencies. Under the Cooperative Fire Protection Agreement, the California Department of Forestry and Fire Protection (CalFire) and federal agencies (e.g., the USFS, the National Parks Service) assist each other to suppress wildland fires on lands adjacent to each other (Firescope 2009).

Police Protection Services

The Pasadena Police Department provides police protection and law enforcement services in the City. The Police Department has a Park Safety Specialist Team that is assigned to patrol City parks, including Hahamongna Watershed Park. In addition, the Police Department has a Volunteer Mounted Unit that consists of volunteers on horses who provide patrol services in the remote park areas of the City, such as Hahamongna Watershed Park (Pasadena 2013b).

The Pasadena Police Department also participates in the California Law Enforcement Mutual Aid Plan and the California Disaster and Civil Defense Master Mutual Aid Agreement, which allow the City to request mutual aid from and to provide mutual aid to adjacent police protection and law enforcement agencies.

The USFS provides law enforcement of federal laws within the ANF. The Pasadena Police Department is responsible for the enforcement of State and local laws on City lands (within the ANF) and at PWP facilities.

School Services

The Pasadena Unified School District (PUSD) provides school services to the Upper Arroyo Seco area through Franklin Elementary School, Eliot Middle School, and Muir High School (PUSD 2005, 2006, 2010).

Parks

The Upper Arroyo Seco provides recreational opportunities for area residents and visitors. Area 1 is located within the ANF and the Gabrielino Trail runs along the east side of Areas 1 and 2. Area 3 is located within Hahamongna Watershed Park, which is developed with a variety of active and passive recreational facilities. This park is maintained by the Pasadena Parks and Natural Resources Division.

Other Public Facilities

There are ten City libraries, with the Linda Vista Branch Library located nearest the Upper Arroyo Seco at 1281 Bryant Street, approximately two miles south of Area 3.

The Headworks structure in Area 1, the diversion and intake structures in Area 2, and the spreading basins in Area 3 are subject to inspection and maintenance by PWP personnel.

4.15.2 IMPACT ANALYSIS

Regulatory Requirements

RR PS-1 Proposed improvements are required to be designed and constructed in accordance with the Pasadena Fire Prevention Code (Chapter 14.28 of the City's Municipal Code), which adopts the California Fire Code with changes and additions to the adopted code.

Impact Discussion

a) Would the project result in substantial adverse physical impacts associated with the provision of new or physically altered government facilities, need for new or physically altered government facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for any of the public services:

- **Fire protection?**
- **Police protection?**
- **Schools?**
- **Parks?**
- **Other public facilities?**

Fire Protection

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. The proposed habitat restoration, increased water diversion, and new recreational and educational amenities would not introduce habitable structures, operational activities, or people into the area that could generate a long-term demand for fire protection services. Also, the Project does not propose any new land uses in or near the Arroyo Seco. Thus, the Project would not result in a need for new or physically altered fire protection facilities.

The restored habitat area, new diversion and intake structures, improved access road, new sedimentation/spreading basins, and new decomposed granite parking lot would not be susceptible to fire. The proposed restroom would have fire-retardant shingles. The woody structures proposed in Area 1 would be located along the water's edge and would be damp much of the time, substantially reducing any fire hazards. The proposed picnic tables and benches would be made of heavy duty wood with weatherproofing and would not be highly flammable. MM HAZ-4 would reduce the potential for fire from combustion engines used during construction. Project improvements would be constructed in accordance with the Pasadena Fire Prevention Code (Chapter 14.28 of the City's Municipal Code) as RR PS-1. The improved access road in Area 2 and the new access road in Area 3 would also be constructed in accordance with the emergency access requirements in the City's Fire Prevention Code (RR PS-1). Compliance with MM HAZ-4 and RR PS-1 will minimize the potential for fire and, therefore, the Project's demand for fire protection services.

Construction activities would temporarily create an increased demand for fire-protection services due to the use of equipment, electricity, fuels, and other fire sources that may ignite flammable and combustible materials. As discussed under Section 4.8, Hazards and Hazardous Materials, the Project has the potential to increase the risks associated with wildfires due to the presence of heavy construction equipment, including the use of flammable liquids and the presence of combustion engines, which could result in accidental fire.

During construction, emergency response by the Pasadena Fire Department to the HWP, the USFS Ranger Station, and the Upper Arroyo Seco may be affected while construction on or near the access road and at the Gabrielino Trail is ongoing. The existing trail/access road may be partially closed while improvements in Areas 1 and 2 are under construction. The existing bridges may also be closed while the temporary bridges over them are under construction. Since the Gabrielino Trail/access road to Areas 1 and 2 provide access to three households and a number

of hikers, bicyclists, equestrians and maintenance personnel, access would have to be maintained at all times in accordance with the Standard Specifications for Public Works Construction (Greenbook) (RR TRA-1 in Section 4.17, Transportation/Traffic). Also, MM HAZ-3 from Section 4.8, Hazards and Hazardous Materials, requires the contractor to inform public service agencies of the construction schedule and times when Bridge No. 3 and the access road would be closed. This will facilitate emergency response to the area in the event of a fire.

A temporary access road would be maintained in Area 3 while the new two-lane access road is under construction to provide continued access to the JPL campus through the JPL Bridge and to areas farther north (e.g., USFS Ranger Station). In addition, the Gabrielino Trail/North Arroyo Boulevard east of Area 3 may serve as an alternate emergency access to the JPL Bridge and ANF while improvements in Area 3 are under construction.

The City also implements an Emergency Operations Plan (RR HAZ-2 from Section 4.8, Hazards and Hazardous Materials) that outlines emergency procedures that would be followed in the event of a local, regional or national emergency.

Compliance with RR PS-1 and RR TRA-1 from Section 4.17, Transportation and Traffic, and RR HAZ-2 from Section 4.8, Hazards and Hazardous Materials would also facilitate fire protection services to the Project. No new or physically altered fire protection facilities would be needed to serve the Project and, thus, impacts on fire protection services would be less than significant and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified significant impacts on police, fire and emergency services during construction and operation of game fields, lakes, equestrian facilities, restrooms, and parking areas. Several mitigation measures were provided to reduce impacts on public services. The Arroyo Seco Canyon Project would comply with the City's Fire Prevention Code as RR PS-1, which is similar to Measure Public Services-3 and Measure Public Services-5. Implementation of MM HAZ-3, which is similar to Measure Public Services–1, would inform the Pasadena Fire Department of the construction schedule and the potential need to use alternative routes for emergency response.

Police Protection

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. The Project does not involve the development of habitable structures or operational activities that could increase demands for long-term police protection services. The restored habitat area, new diversion and intake structures, improved access road, new sedimentation basins, and expanded spreading basins are not new land uses that could attract criminal elements or criminal activities into the area. However, the new recreational parking lot, picnic tables, benches, signage and restroom may increase trail users/visitors and provide greater opportunities for vandalism, graffiti, littering, and theft.

The Park Safety Specialist Team and the Volunteer Mounted Unit of the Pasadena Police Department would continue to patrol the area and provide police protection services in the Upper Arroyo Seco, and PWP personnel would continue inspection and maintenance activities at the diversion structures and spreading basins. If any additional resources are required to patrol the area, the City of Pasadena can adjust staffing accordingly. Any increase in demand for police protection services would be less than significant and would not result in a need for new or physically altered police facilities.

Construction activities may provide opportunities for crime (e.g., theft and vandalism). However, construction areas and staging areas would be screened/fenced, which would prevent theft and vandalism during the construction phase. During construction, emergency response by the Pasadena Police Department to the HWP, USFS Ranger Station, and Upper Arroyo Seco may be affected when construction on or near the access road and at the Gabrielino Trail is ongoing. Similar to fire protection services, this impact would be temporary and less than significant since no new or physically altered police facilities would be needed or required. In addition, impacts on police services are further reduced with compliance with the Greenbook (see RR TRA-1 from Section 4.16, Transportation and Traffic) and advance notification of service providers under MM HAZ-3 (see Section 4.8, Hazards and Hazardous Materials).

Impacts on police protection services would be less than significant and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified significant impacts on police, fire and emergency services during construction and operation of various facilities in the HWP. The Arroyo Seco Canyon Project would implement MM HAZ-3, which is similar to Measure Public Services–1, to inform the Pasadena Police Department of the construction schedule and the potential need to use alternative routes for emergency response.

The Master EIR included Measure Public Services-2, which calls for additional sworn and non-sworn officers commensurate with the increase in park attendees. The majority of the anticipated increase in trail users (20 to 25 percent or as many as 200 additional trail users/visitors per day during a holiday weekend) would likely be using facilities in Areas 1 and 2 and would not be in Area 3 or the HWP. The improvements in Area 3 alone are not expected to require additional sworn and non-sworn officers.

Since the City regularly evaluates the need for police officers as part of its annual budgeting process, this mitigation is being implemented by the City. Also, emergency response and evacuation plans under Measure Public Services–4 have been established for the City for various types of emergencies and incidents (RR HAZ-2 from Section 4.8, Hazards and Hazardous Materials), and is implemented by the City and its various departments and personnel.

Schools

No Impact.

Areas 1, 2 and 3 Impacts. The Project would be located in areas designated as Open Space. The proposed habitat restoration, increased water diversion, and new recreational amenities would not induce residential development. Also, the Project would not generate a demand for school services because no residential land uses that may be occupied by households with school-aged children are proposed. Long-term recreational activities in the Arroyo Seco Canyon and operation and maintenance activities on the PWP facilities would not create a demand for school services. No impact on schools would occur with the Project and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that positive impacts on students would be provided by the HWP as an extended recreational, educational and cultural venue for area residents.

Parks

No Impact.

Areas 1, 2 and 3 Impacts. The Project would not generate a demand for parks or recreational facilities because the Project does not propose residential development that may be occupied by households that would utilize local parks and recreational areas. Rather, the Project includes the construction of recreational amenities along the Gabrielino Trail to serve the existing and future users of the HWP and the ANF. The Project would provide greater opportunities for recreation in Area 1 and would improve the recreational experience in the area with the rest area/picnic area, interpretive signage, trash can, horse water trough, and pet waste station. The proposed restroom, potential future trail connection, pet waste station, signage, and recreational parking lot in Area 3 would also improve the recreational experience. These amenities would not result in adverse impacts on parks and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that the expansion and improvement of existing active and passive recreational facilities in the HWP would accommodate additional visitors and would not have impacts on other parks in the area.

Other Public Facilities

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. The Project would not generate a demand for libraries because the Project does not propose residential development that may be occupied by households, nor would the Project bring in other land uses that may require library services or facilities. No impact on existing library services would occur with the Project.

Long-term operation and maintenance for the proposed recreational amenities and improved PWP facilities would be largely similar to existing services. Maintenance of the proposed restroom, trash cans, and pet waste stations would slightly increase over existing levels, but would be provided by the same City personnel. The improved surface water diversion and intake facilities would reduce maintenance activities from the PWP. The larger area for spreading basins may increase inspection and maintenance needs, but the proposed sedimentation basins would reduce the need for maintenance of the downstream spreading basins. The needed maintenance would not require new PWP personnel or new public facilities. Impacts related to park maintenance and groundwater recharge maintenance services would be less than significant. No mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that increases in public facility maintenance, landscape maintenance, public transportation, and park operation services to the HWP would be needed from the City Department of Public Works and Transportation. The Project would increase maintenance activities for the proposed recreational amenities but this impact is considered less than significant.

4.15.3 MITIGATION MEASURES

There would be no significant adverse impacts related to public services, with compliance with RR PS-1; therefore no mitigation measures are required.

4.16 RECREATION	Potentially Significant Impact	Less than Significant with Mitigation	Less than Significant Impact	No Impact
Would/does the project:				
a) Would the project increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated?	☐	☒	☐	☐
b) Does the project include recreational facilities or require the construction or expansion of recreational facilities which might have an adverse physical effect on the environment?	☐	☐	☒	☐

4.16.1 EXISTING CONDITIONS

The Hahamongna Watershed Park is developed with active and passive recreational areas on both sides of the Arroyo Seco, upstream of Devil's Gate Dam. East of the Arroyo Seco are several trails and Johnson Field (a softball field with picnic tables, a barbecue pit, and a restroom that have not been in use) that has been used by the County to temporarily stockpile sediments that were removed from the reservoir since 2011. The City's spreading basins and the JPL East Parking Lot in Area 3 are also located east of the Arroyo Seco. The parking lot was leased by the City to JPL until June 2013, with an extension until a new JPL On-Site Parking Structure is built on the JPL campus (expected to be completed in August 2014). West of the Arroyo Seco are multi-purpose play fields, picnic areas, an equestrian facility, an equestrian staging area, trails, trailheads, an overlook, a disc golf course, a fire camp, an amphitheater, a youth camp, restrooms, a maintenance yard, and parking lots.

The Arroyo Seco Trail runs along both sides of the Arroyo Seco and is part of the Rim of the Valley Trail Corridor that connects the Santa Monica Mountains and the San Gabriel Mountains through trails in the San Fernando and La Crescenta Valleys. This trail also continues south along the Central and Lower Arroyo Seco to connect with the Los Angeles River Trail. North of Devil's Gate Dam, there are several local trails on both sides of the Arroyo Seco, including the East Rim Trail, the West Rim Trail, the Mountain View Trail, the Flint Wash Trail, the Gould Canyon Trail, the Altadena Crest Trail, and the Gabrielino Trail.

North Arroyo Seco Road shares its alignment with the Gabrielino Trail, which is an easement from the City to the USFS that begins at the intersection Windsor Avenue and Ventura Street and extends 1.5 miles north along the eastern edge of the JPL parking lot toward the Arroyo Seco Canyon and the ANF. An existing dirt path runs east-west through the middle of the parking lot connecting the spreading basins on the west to the Gabrielino Trail on the east. This pathway is currently used by both pedestrians and equestrians.

4.16.2 IMPACT ANALYSIS

Impact Discussion

a) Would the project increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated?

Less Than Significant With Mitigation.

Areas 1, 2 and 3 Impacts. The Project would not induce population growth directly or indirectly, which could generate a need for or increase the use of parks and recreational facilities. Rather, the Project includes a rest area/picnic area and nature trail in Area 1; an improved Gabrielino Trail/access road in Area 2; and a potential future trail connection and restroom in Area 3. These recreational amenities would add to existing recreational facilities at the HWP and in the ANF to serve existing and future trail users and recreational visitors. These amenities would improve the recreational experience of existing users (through the provision of a restroom, picnic tables, benches, trash cans, pet waste stations, potential future trail connection, a drinking fountain, and signage along the existing trail) and may increase use of the adjacent trails. This increase is not expected to be large enough to attract a large number of new users into the area. Rather, it is anticipated that a 20 to 25 percent increase in use may occur, such that approximately 150 people would use the trail and adjacent recreational facilities on the weekdays (or 25 people more than existing) and 500 to 1,000 trail users/visitors would use them on weekends (as many as 200 users more per day during a holiday weekend). This increase in use is not expected to result in the deterioration of existing and proposed recreational facilities.

However, during construction within Areas 1, 2, and 3, there may be times when portions of the Arroyo Seco Trail, Altacrest Trail and Gabrielino Trail/access road would be closed to the public. While the trails would be kept open during construction to the extent possible, there would be days when equipment and construction activities would be on and/or near the trails, making recreational trail use hazardous for the general public. During these times, the trails would be closed.

Without proper noticing, it is possible that trail users would go into the HWP or the canyon only to find that the trails are closed. They would then have to turn back and find a nearby trail or move to another location (e.g., west side of the Arroyo Seco), while others may forego their planned recreational activity. Since the Gabrielino Trail is heavily used (estimated at 125 current trail users per weekday; 400 trail users on weekends; and 800 trail users on holiday weekends), intermittent closure of this and other nearby trails during the construction period would inconvenience a number of trail users. This would be a potentially significant but mitigable impact on recreation, especially during holiday weekends when trail use is highest.

MM REC-1 requires advanced notification to trail users of closures dates and alternative trails prior to the closure of the trails in and near the Project site. Periods of closure would be restricted to no more than 5 consecutive days during non-emergency closures, and notices would be posted at the parking lots and trail entrance stating the closure times and dates. There are a number of other existing trails and recreation areas in the vicinity of the Project that could be used during any trail closures. The southern segments of the Arroyo Seco Trail that run through Hahamongna Watershed Park and the Central and Lower Arroyo Seco would not be affected by Project construction and would be available for recreational use. In addition, there are a number of other access points that provide connections to regional trailheads that run through the ANF, including the Gould Canyon, Cross Town Trail, and the Lukens Connection Trail, which have trailheads off the Angeles Crest Highway in the City of La Canada Flintridge, as well as nearby Eaton Canyon and Loma Alta trails.

Use of alternative nearby trails on the days when the Arroyo Seco Trail, Altacrest Trail and Gabrielino Trail/access road are closed would be temporary and would not lead to any significant deterioration of these other trails. Impacts on nearby trails associated with the partial and temporary closure of trails near Areas 1, 2 and 3 would be short-term and less than significant. No mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified significant impacts on existing recreational facilities during construction activities and provided several mitigation measures. The Arroyo Seco Canyon Project would not require the closure of existing recreational facilities, appurtenant facilities (such as restrooms), playfields, or parking spaces.[7] Thus, mitigation measures (Measure Recreation-1 through Recreation-4) for the temporary closure of these facilities are not applicable. However, the Arroyo Seco Canyon Project would require the temporary closure of trails, and thus, would implement MM REC-1, which is similar to Measure Recreation-5.

b) Does the project include recreational facilities or require the construction or expansion of recreational facilities which might have an adverse physical effect on the environment?

Less Than Significant Impact.

Areas 1, 2 and 3 Impacts. The proposed recreational amenities in Areas 1 and 3 would add to existing recreational facilities in the Hahamongna Watershed Park to serve existing and future trail users and recreational visitors in the park but is not anticipated to increase the use of other recreational facilities in the City nor require the construction of other facilities. The proposed amenities include a new recreational parking lot, restroom, picnic tables, benches, trash cans, pet waste stations, and signage along an existing trail. These would improve the recreational experience of existing users and may increase the use of the adjacent trails although they are not expected to attract a large number of new users into the area. As discussed earlier, the Project is anticipated to lead to a 20 to 25 percent increase in use, such that 25 new trail users/visitors per weekday (over the current 125 trail users/visitors) and 100 to 200 new trail users/visitors on weekends (over the estimated 500 to 1,000 trail users/visitors) may be present per day. This increase in trail use is not expected to result in significant impacts on other recreational facilities in the HWP.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified significant impacts on trails during construction activities and provided several mitigation measures. The Arroyo Seco Canyon Project would require temporary closure of trails and would implement MM REC-1 (which is similar to Measure Recreation-5) to reduce impacts related to the unavailability of trails in the HWP. The Master EIR stated that play fields, new park entrances, lakes, security fencing and utility improvements would not affect recreation.

4.16.3 MITIGATION MEASURES

MM REC-1 Prior to the closure of recreational trails for public use, the Construction Contractor shall post signs at the parking lots and trail entrances providing at least one week of advanced notice of the dates and times of planned trail closures. The trails shall be closed no more than 5 consecutive days in non-emergency circumstances. In addition to the closure notice, the Contractor shall provide directions to the nearest trails in the surrounding areas that would be open for public use at the times when the trails are closed.

[7] It is anticipated that the new JPL parking structure would be in use by the time construction in Area 3 occurs.

4.17 TRANSPORTATION/TRAFFIC	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
Would the project:				
a) Conflict with an applicable plan, ordinance or policy establishing measures of effectiveness for the performance of the circulation system, taking into account all modes of transportation including mass transit and non-motorized travel and relevant components of the circulation system. Including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit?	☐	☒	☐	☐
b) Conflict with an applicable congestion management program, including, but not limited to level of service standards and travel demand established by the county congestion management agency for designated roads or highways?	☐	☐	☒	☐
c) Result in a change in air traffic patterns, including either an increase in traffic levels or change in location that results in substantial safety risks?	☐	☐	☐	☒

e) Result in inadequate emergency access?	☐	☒	☐	☐
f) Conflict with adopted policies, plans, or programs regarding public transit, bicycle, or pedestrian facilities, or otherwise decrease the performance or safety of such facilities?	☐	☐	☒	☐

4.17.1 EXISTING CONDITIONS

Regional Access

The Foothill Freeway (I-210) starts at the Golden State Freeway (I-5) in the northern portion of the San Fernando Valley, and generally runs in a southeasterly and easterly direction near the southern base of the San Gabriel and San Bernardino Mountains to the I-10 in Redlands. The I-210 has eight travel lanes as it passes along the southern edge of Devil's Gate Dam. Caltrans estimates the 2012 traffic volumes on the I-210 in this area (between Berkshire Place and Arroyo Boulevard) during the peak hour at 10,600 vehicles, with a peak month volume of 122,000 vehicles per day and an average daily traffic volume of 118,000 vehicles (Caltrans 2013b).

Local Roadway Network

Access to the Arroyo Seco Canyon is provided by the I-210's Arroyo Boulevard/Windsor Avenue off-ramp. Windsor Avenue is a two-lane road that runs north and ends at its intersection with Ventura Street and Explorer Road. Explorer Road continues northerly toward the JPL East Parking Lot and turns west across the Arroyo Seco (onto the JPL Bridge) and southwesterly onto the JPL campus. Oak Grove Drive is a four-lane road extending westerly from Windsor Avenue,

just north of the I-210, and passing along Devil's Gate Dam and the southwest edge of the reservoir before turning north toward the JPL campus.

In 2011, the average daily traffic (ADT) volumes on North Windsor Avenue from Ventura Street to Figueroa Drive ranged from 6,361 to 10,097 ADT on weekdays and from 4,680 to 6,458 ADT on the weekends. Farther south (between Figueroa Drive and Oak Grove Avenue), 2011 ADT ranged from 10,258 to 13,928 ADT on weekdays and 7,965 to 9,044 ADT on weekends (Los Angeles County 2013a).

Most of the existing vehicle trips on Windsor Avenue and Explorer Road in Area 3 are associated with employee travel to and from the JPL East Parking Lot during the morning and afternoon peak hours. In addition, there are paved and unpaved access roads that are also used by visitors to the HWP and maintenance workers to access the spreading basins, reservoir, and dam.

The Gabrielino Trail/access road is a paved road that runs on top of the slope east of the JPL East Parking Lot and goes into the Arroyo Seco Canyon, crossing the stream at several locations as it heads into the ANF. It becomes unpaved in Area 1 and farther north. This trail is used by hikers, bicyclists, and equestrians going into Arroyo Seco Canyon; it is also used by City, County, and USFS inspection and maintenance vehicles.

Transit Services

The Los Angeles County Metropolitan Transportation Authority (Metro) provides regional bus and passenger train services in the County. Metro Bus routes 177 and 268 run along Oak Grove Avenue and into the JPL campus, south and west of Area 3. The Glendale Beeline Route 3 also runs from Downtown Glendale to JPL (Metro 2013).

The Pasadena Area Rapid Transit System (ARTS) provides local bus services within the City. Route 52 goes into the JPL campus three times daily on weekdays from as far south as the intersection of Glenarm Street and Raymond Avenue (Pasadena 2013a). JPL also operates a shuttle from 7:00 AM to 9:00 AM and 3:00 PM to 5:00 PM that stops in the JPL East Parking Lot and at internal streets within the JPL campus (JPL 2012).

4.17.2 IMPACT ANALYSIS

Project Design Features

PDF TRA-1 During the construction phase, a temporary access road will be maintained in Area 3 prior to the availability of the permanent access road, to provide continued vehicle access to the Jet Propulsion Laboratory (JPL) campus via the JPL Bridge. During construction activities in Area 3, the temporary access road will be available for use by JPL employees and visitors during working weekdays, but the access road will be restricted at other times.

Regulatory Requirements

RR TRA-1 Construction activities are required to be conducted in accordance with the Standard Specifications for Public Works Construction (Greenbook) and the City's Supplements and Modifications to the Greenbook to maintain access to all parcels in and near the construction sites. This includes notification of residents and businesses affected by the road work; utility agencies with facilities in the area; the Pasadena Fire and Police Departments; and other emergency service providers.

The Greenbook also requires that access be made available at the end of each workday.

RR TRA-2 Temporary traffic control devices and methods used during construction are required to conform to the requirements of the latest edition of the Manual on Uniform Traffic Control Devices (MUTCD) and the California Supplement to the MUTCD. The contractor shall provide traffic tapers, traffic control devices, barricading, and signs necessary to ensure driver awareness and safety in construction areas and to assist fire and law enforcement personnel.

Impact Discussion

a) Would the project conflict with an applicable plan, ordinance or policy establishing measures of effectiveness for the performance of the circulation system, taking into account all modes of transportation including mass transit and non-motorized travel and relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit?

Less than Significant Impact with Mitigation.

Areas 1, 2 and 3 Impacts. Visitors to the Project site are expected to increase by a maximum of 20 to 25 percent with the Project. Weekday use at a current estimated average of 125 visitors could increase by 25 visitors to 150 visitors per weekday. These trips will be scattered throughout the day and would likely be outside peak hours. Weekly trash collection and twice weekly restroom cleaning would add minimal trips on a daily basis in the long-term. Intermittent sedimentation basin maintenance is estimated to generate approximately 100 truck trips every year and spreading basin maintenance would generate approximately 100 truck trips once every five years. While these truck trips can be spread out during the day and extended over several days, increases in AM and PM peak traffic volumes may occur.

Construction activities will also generate new vehicle trips from construction equipment and construction crews coming to the site; trucks bringing in building materials; trucks taking out excavated soils and other debris for off-site disposal; and construction equipment leaving the site after each construction phase. As shown in Table 3.2-1, Construction Assumptions, between 10 to 210 truckloads from one area would be hauling soils and debris to Scholl Canyon Landfill during each phase of construction.

Trucks would come to the site off I-210 at the Windsor Avenue off-ramp and head north on Windsor Avenue and on Explorer Road into Areas 3, 2, and 1. From the site, the trucks would head south on Windsor Avenue and onto the westbound on-ramp on I-210. From the I-210, trucks would head west on SR-134 and exit using the Figueroa Street/Scholl Canyon Road off-ramp before heading north-northeast toward the landfill. Trucks would come back from the landfill by entering the eastbound on-ramp on the SR-134 at Figueroa Street and heading east and then west on I-210 to Windsor Avenue, Explorer Road, and, ultimately, the site.

Roadway network performance is generally measured by the capacity of roadway intersections, including the ability of each leg of the intersection to handle traffic volumes and the average wait times of vehicles. Since AM and PM peak hours during weekdays handle the greatest amount of traffic at most intersections, the level of service (LOS) at intersections during the AM and PM peak hours is primarily used to evaluate the efficiency of the roadway system.

Project-related vehicle trips could increase AM and PM traffic volumes on Windsor Avenue, I-210, and other streets. Although construction-related vehicle trips are relatively small and not expected to significantly impact traffic or the circulation system along the truck route, restrictions on Project site construction activities to avoid adding new construction truck trips to local roads, arterials, and freeways during the AM and PM peak hours would further minimize impacts. MM TRA-1 would require Contractors to schedule the arrival and departure of the construction equipment and construction trucks outside the AM peak hours of 7:30 AM to 8:30 AM and the PM peak hours of 4:30 PM to 5:30 PM. In addition, trucks transporting debris from the site would be required to travel to and from the site outside the AM and PM peak hours. This would avoid adverse impacts to the peak hour operation of streets and intersections near the Project site.

There would be no impact on the use of mass transit systems with the Project because the Project site is not directly served by a public transportation system and is too far from public streets to encourage bicycle use or walking to the site by construction workers. Increase in trail users and visitors to the HWP and ANF will occur with the Project, which would be mainly recreational in nature. Impacts on non-motorized travel or pedestrian and bicycle paths are discussed under Section 4.15, Recreation, above. Impacts on the AM and PM peak hour operations of streets and intersections would be less than significant after mitigation.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan anticipated significant impacts on transportation and traffic and identified a number of intersection improvements as mitigation measures. The restriping of the I-210 westbound off-ramp at Windsor Avenue (Measure Transportation-1) has been implemented. Measures Transportation-2 and Transportation-3 call for a traffic control officer during large special events. The Arroyo Seco Canyon Project would result in approximately 25 additional visitors on weekdays and 100 additional visitors on weekends, with as much as 200 additional visitors on holiday weekends. These mitigation measures, when deemed appropriate by the City, are necessary for large special events, and the Project would not interfere with the implementation of these measures. Measure Transportation-4 calls for a wayfinding program for the Central Arroyo Seco and is not applicable to the Project.

b) Would the project conflict with an applicable congestion management program, including, but not limited to level of service standards and travel demand established by the county congestion management agency for designated roads or highways?

Less Than Significant Impact.

Areas 1, 2 and 3 Impacts. The Los Angeles County Congestion Management Program (CMP) calls for monitoring of the highway and roadway system in the County and a multi-modal system performance analysis. It sets a Level of Service (LOS) standard of E for the CMP Highway System. The program also promotes alternative modes of transportation; requires monitoring of land use and roadway performance by individual jurisdictions; and provides guidelines for conducting a Traffic Impact Analysis (TIA). The CMP TIA guidelines require analysis of freeway segments, ramps, and intersections if a proposed project would add 50 or more trips to a CMP arterial intersection or 150 or more trips (in either direction) during either the AM or PM weekday peak periods at a mainline freeway monitoring location.

The 2010 CMP includes I-210 as part of the CMP Highway System. The segment of I-210 between SR 134 and SR 2 operated at LOS D or better northbound during the AM peak hour and at LOS F southbound during the AM peak hour in 2009. During the PM peak hour, it operated at LOS D or better in both directions (MTA 2010). Caltrans does not identify this segment of I-210 as being a “Congested Urban Area” (Caltrans 2010).

The Project would not generate 50 or more trips that would be added to any one intersection during the AM or PM peak hours on weekdays, as only 25 additional visitors per day are anticipated; therefore, no TIA is required. During the weekends, approximately 100 to 200 visitors per day would be added by the Project when the traffic volumes on local roads, arterials, and freeways are less (e.g., weekend daily traffic volumes are 1,681 to 3,636 vehicles less on Windsor Avenue north of Figueroa Drive and 2,293 to 4,884 vehicles less south of Figueroa Drive). The addition of weekend trips is not expected to adversely affect the CMP Highway System; conflict with CMP LOS standards; or require a TIA.

During construction, the I-210 freeway and major roadways in the County's CMP would be utilized by trucks and vehicles coming to and from the Project site. These vehicle trips would be highly variable depending on the construction phase, with 20 to 30 pieces of construction equipment coming to the site during each stage (e.g., clearing/grubbing, demolition, grading, infrastructure, and paving stages). With the addition of the construction crew and trucks traveling to and from the site to dispose of debris at Scholl Canyon Landfill, more than 50 vehicle trips may be generated daily during Project construction.

Implementation of MM TRA-1, as discussed above, would avoid adding 50 or more trips to local roads, arterials, and freeways during the AM and PM peak hours. Therefore, traffic increases from the Project during peak hours would be less than 50 trips; would not affect peak hour LOS; and thus, no TIA is needed. Impacts on the Los Angeles County CMP would be less than significant and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan included a traffic impact analysis and a transit impact review in accordance with the CMP guidelines.

c) Would the project result in a change in air traffic patterns, including either an increase in traffic levels or change in location that results in substantial safety risks?

No Impact.

Areas 1, 2 and 3 Impacts. There are no airports or airstrips within two miles of the Upper Arroyo Seco. The nearest airports are the Burbank Bob Hope Airport and the El Monte Airport, which are both approximately 11 miles from Area 3. There is a heliport and a helipad near the Arroyo Seco but the Project would not affect nearby helicopter operations at the helipad or heliport. The Project would have no impact on air traffic patterns, because the proposed habitat restoration, increased surface water diversion and groundwater recharge, and recreational and educational amenities would not generate a demand for air transportation. No impacts on air traffic patterns would occur with the Project.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not identify any adverse impacts to air traffic patterns or air transportation.

d) Would the project substantially increase hazards due to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment)?

Less than Significant Impact with Mitigation.

Areas 1, 2 and 3 Impacts. The Project would not result in any new roadway features or alignments, with the exception of the temporary and final access road through Area 3 (PDF TRA-1). As a part of the termination of the lease agreement with the City for the JPL East

Parking Lot, and not as a component of the proposed Project, JPL is required to remove all constructed improvements on the parking lot site. It is anticipated that the City will request approximately 47,164 square feet of paving to remain in place for a 26-foot wide temporary access roadway that would provide vehicle access for JPL employees to the new JPL Parking Structure on the JPL property. Dedicated access times during commuting hours may be enforced during construction activities in Area 3, and JPL employees and visitors would have to use JPL's West Entrance during restricted access hours (outside peak commute hours). This temporary access road would remain in place during construction activities in Area 3 until the completion of the permanent access road. This temporary access road would be aligned and maintained in accordance with the Standard Specifications for Public Works Construction (Greenbook) and the City's Supplements and Modifications to the Greenbook (RR TRA-1) and would not increase hazards for users of the road.

Temporary bridges would be constructed over Bridge No. 1 and Bridge No. 3 in and near Area 2 to provide access for construction equipment and vehicles to reach Areas 1 and 2. The Gabrielino Trail/access road in Area 2 would also be reconstructed to prevent further slope erosion. During construction, there may be hazards from construction activities and the use of construction equipment near trail users and vehicles passing through construction areas. In Area 1, fencing around the construction area would prevent public access into Area 1, but would maintain public access on the Gabrielino Trail/access road adjacent to Area 1. Construction of the new diversion and weir structures in Area 2 would be located away from the Gabrielino Trail/access road. However, construction of the temporary bridges and access road reconstruction would be on or near the Gabrielino Trail/access road and could create temporary safety hazards to hikers, bicyclists, and equestrians. Because of the high number of recreational users on the Gabrielino Trail, any potential hazards along the trail would be a significant impact.

In order to protect the safety of trail users, MM TRA-2 requires that non-vehicular access, including hikers, bicyclists and equestrians, shall be limited or prohibited when work on the bridge and Gabrielino Trail/access road in Area 2 is ongoing, and that flagpersons shall be used as necessary to ensure the safety of recreational users.

An increase in the number of construction vehicles and trucks on Windsor Avenue during Project implementation would increase opportunities for traffic hazards. Flagpersons, signs, and traffic control devices would be provided at the intersection of Ventura Street and Windsor Avenue in accordance with the Greenbook (RR TRA-1) and MUTCD (RR TRA-2) to prevent hazards associated with construction vehicles merging with or diverging from vehicle traffic on Windsor Avenue. Compliance with RR TRA-1 and RR TRA-2 and with MM TRA-2 would reduce impacts to less than significant levels.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not identify any adverse impacts related to traffic hazards or incompatible uses.

e) Would the project result in inadequate emergency access?

Less than Significant Impact with Mitigation.

Areas 1 and 2 Impacts. The existing Gabrielino Trail/access road in Area 1 would be maintained, while portions of the access road in Area 2 would be improved. Thus, beneficial impacts on emergency access would occur in the long-term.

Construction activities on the Gabrielino Trail/access road would affect access to Areas 1 and 2, adjacent areas (including the USFS Ranger Station), and areas farther north in the ANF. Improvements to the Gabrielino Trail/access road, movement of heavy equipment, and the

installation of temporary bridges over Bridge No. 1 and Bridge No. 3 would result in short-term and partial obstruction of vehicular access, which would affect the ability of emergency responders to access the area.

Compliance with the Standard Specifications for Public Works Construction (Greenbook) and the City's Supplements and Modifications to the Greenbook (RR TRA-1) regarding maintenance of emergency access at all times would mean closure of only half of the access; the use of a flagperson to direct traffic, as necessary; and allowing for the public use of the Gabrielino Trail/access road at times when construction is not ongoing. Temporary traffic control devices are also required to be provided in conformance with the MUTCD and the California Supplement to the MUTCD (RR TRA-2).

However, there would still be times during the construction workday when very short-term closures of the temporary bridges and/or the access road would occur. Examples of temporary road closures include times when large equipment is in motion, requiring the full width of the Gabrielino Trail/access road, and when temporary bridges are being installed. If these activities would hinder emergency access to the USFS Ranger Station, impacts would be significant.

MM TRA-3 requires that prior to the start of construction, the Construction Contractor must provide written notice to the USFS and residences at the Ranger Station of the anticipated construction schedule, stating that access may be temporarily obstructed on an intermittent basis and providing a schedule of anticipated closures. In order to ensure that emergency vehicles would not be obstructed at any time, the measure also requires that any temporary obstructions to the Gabrielino Trail/access road that could hinder emergency vehicular access be mobile and able to be removed from the roadway immediately upon notice from emergency responders.

As discussed in Section 4.8, Hazards and Hazardous Materials, MM HAZ-3 requires that closures of the access road and bridge be shortened to the extent feasible and that the contractor inform the PWP, the Pasadena Fire Department, the Pasadena Police Department, the Los Angeles County Fire Department, and the USFS of the construction schedule and planned closures. This will allow for timely emergency response and evacuation of the USFS Ranger Station and areas farther to the north. Compliance with RR TRA-1, RR TRA-2, MM TRA-3, and MM HAZ-3 (from Section 4.8) would reduce impacts to emergency access to less than significant levels after mitigation.

Area 3 Impacts. Emergency access to the HWP and Devil's Gate Dam and Reservoir would not be affected by improvements in Area 3. Emergency access to the JPL campus would be provided by Oak Grove Avenue from the west. Secondary access from the east would continue to be provided by the temporary access road through Area 3 (PDF TRA-1) and by the Gabrielino Trail during construction activities in Area 3. Access to the existing spreading basins would also remain available from roads south of Area 3. Access to Areas 1 and 2 would remain available through the Gabrielino Trail along the east side of Area 3. Impacts on emergency access in Area 3 would be less than significant.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not identify any adverse impacts related to emergency access.

f) Would the project conflict with adopted policies, plans, or programs regarding public transit, bicycle, or pedestrian facilities, or otherwise decrease the performance or safety of such facilities?

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. Proposed habitat restoration, increased water diversion and groundwater recharge, and additional recreational and educational amenities would not affect existing public transit services, policies, plans, or programs.

The proposed nature trail, rest area/picnic area, horse water trough, and other improvements would provide beneficial recreational amenities that would support hiking, biking, and equestrian use on the Gabrielino Trail and in the ANF. The reconstruction/improvement of the access road in Area 2 would increase public safety for users of the access road, which would also benefit hikers, bicyclists, and equestrians using this Gabrielino Trail/access road. The proposed parking lot, restroom, signs, and potential future trail connection at the north end of Area 3 would improve facilities available to hikers, pedestrians, equestrians or bicyclists visiting the Arroyo Seco Canyon.

Shuttle service from the JPL East Parking Lot to the JPL campus will be discontinued when the new JPL On-Site Parking Structure is completed (JPL 2012). This impact is not related to the proposed Project but is a result of the new JPL On-Site Parking Structure that is currently under construction.

During construction, use of the Gabrielino Trail in Areas 1 and 2 may be temporarily restricted as recreational amenities are constructed in Area 1 and the access road is reconstructed in Area 2. Similarly, use of the existing trail that crosses Area 3 may be temporarily obstructed during excavation of the spreading basins. As discussed in Section 4.15, Recreation, temporary trail closure would occur during construction. MM REC-1 from Section 4.15, Recreation, requires the contractor to post signs to provide advanced notice of the dates and times of planned trail closures, along with directions to the nearest trails in the surrounding areas.

After construction, the trails will become available for long-term use at the same locations. Therefore, the Project would have less than significant impacts on public transit, bicycle, and pedestrian facilities and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not identify any adverse impacts related to alternative transportation policies, plans, or programs.

4.17.3 MITIGATION MEASURES

MM TRA-1 During construction activities in Areas 1, 2 and 3, all Contractors shall schedule the arrival and departure of the construction equipment, and construction trucks outside the AM peak hours of 7:30 AM to 8:30 AM and the PM peak hours of 4:30 PM to 5:30 PM. In addition, trucks transporting sediment and debris from the site shall travel to and from the site outside the AM and PM peak hours.

MM TRA-2 During construction activities in Areas 1 and 2, use of Bridge No. 1, Bridge No. 3, and the Gabrielino Trail/access road by hikers, bicyclists and equestrians shall be limited or prohibited when work on the temporary bridges and Gabrielino Trail/access road is ongoing. Flagpersons and/or other safety procedures shall be used as necessary to ensure the safety of recreational users.

MM TRA-3 Prior to the start of construction, the Construction Contractor shall provide written notice to the USFS and residences at the Ranger Station of the anticipated construction schedule, stating that access may be temporarily obstructed on an intermittent basis and providing a schedule of anticipated closures. In order to ensure that emergency vehicles would not be obstructed at any time, any temporary obstructions to the Gabrielino Trail/access road that could hinder emergency vehicular access shall be mobile and able to be removed from the roadway immediately upon notice from emergency responders.

4.18 UTILITIES AND SERVICE SYSTEMS	**Potentially Significant Impact**	**Less than Significant with Mitigation**	**Less than Significant Impact**	**No Impact**
Would the project:				
a) Exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board?	☐	☐	☒	☐
b) Require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?	☐	☐	☒	☐
c) Require or result in the construction of new storm water drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?	☐	☐	☐	☒
d) Have sufficient water supplies available to serve the project from existing entitlements and resources, or are new or expanded entitlements needed?	☐	☐	☒	☐
e) Result in a determination by the wastewater treatment provider which serves or may serve the project that it has inadequate capacity to serve the project's projected demand in addition to the provider's existing commitments?	☐	☐	☒	☐
f) Be served by a landfill with sufficient permitted capacity to accommodate the project's solid waste disposal needs?	☐	☐	☒	☐
g) Comply with federal, state, and local statutes and regulations related to solid waste?	☐	☐	☒	☐

4.18.1 EXISTING CONDITIONS

There are several groundwater wells owned by PWP in and near Area 3. The Arroyo Well is located beside Basin 5 (at the southern end of Area 3) and Well 52 is located beside Basin 7. The Ventura Well is located beside Basin 10 (south of Area 3). PWP also has three water lines crossing Area 3. There are two 24-inch pipelines (influent and effluent) from the Behner Water Treatment Plant to the 30-inch hume line in Area 3. This water treatment plant was previously used to treat surface water as part of PWP's domestic supply but is no longer in use. A 30-inch diameter hume line conveys surface water from the intake structure in Area 2 to the spreading basins in Area 3. Another water line extends from the Calaveras pressure zone at Kent Street and runs north across Area 3 to the JPL Bridge and into the JPL campus. In addition, there are two monitoring wells owned by JPL located east of Area 3.

A number of storm drain lines from Altadena, La Cañada Flintridge, JPL and the HWP discharge into the Arroyo Seco. The outfalls of three lines are located east of Area 3 and cross the JPL parking lot and spreading basins toward the Arroyo Seco (Pasadena 2003a).

There are no sewer lines serving Areas 1, 2 or 3. Wastewater in the area is conveyed to the main trunks of the Los Angeles County Sanitation Districts (LACSD) for treatment at various treatment plants.

A Southern California Edison (SCE) overhead transmission line runs across the HWP to Ventura Street. There are PWP power and communication lines that serve PWP's wells near Area 3; along Johnson Field Road; and along the Gabrielino Trail.

4.18.2 IMPACT ANALYSIS

Regulatory Requirements

RR UTIL-1 The Contractor shall comply with the City's Construction and Demolition Waste Management Ordinance (Chapter 8.62 of the Pasadena Municipal Code), which requires preparation and implementation of a Waste Management Plan that shows how at least 50 percent of construction and demolition debris would be diverted away from landfills. The Waste Management Plan shall be subject to City approval prior to the start of construction activities, and the Contractor shall provide monthly reports to demonstrate compliance during the construction phase.

Impact Discussion

a) Would the project exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board?

b) Would the project require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?

e) Would the project result in a determination by the wastewater treatment provider which serves or may serve the project that it has inadequate capacity to serve the project's projected demand in addition to the provider's existing commitments?

Less Than Significant Impact.

Areas 1, 2 and 3 Impacts. No restroom or other wastewater generating facilities are proposed in Areas 1 or 2. The restroom proposed in Area 3 would generate wastewater that would be conveyed into an existing sewer line at the JPL campus for treatment and disposal at the Whittier Narrows Water Reclamation Plant (WNWRP) or the Joint Water Pollution Control Plant (JWPCP) of the LACSD. Based on an assumption of 20 gallons per day per parking stall, an estimated 2,000 gallons per day of wastewater would be generated by the restroom, which is a minimal amount. This wastewater generation would come from the toilets and sink in the restroom. The majority of this wastewater generation would occur during the weekend when visitors to the Project area are highest. JPL operations are limited on the weekends and capacity of the existing trunk sewer line in JPL would be adequate to accommodate the additional flows. Wastewater discharges from the proposed restroom would increase the amount of wastewater, but would be similar to wastewater from other common restroom and bathroom facilities. This wastewater would not exceed wastewater treatment requirements of the LACSD or the Los Angeles RWQCB. The WNWRP has capacity to treat 12 million gallons per day (mgd) of wastewater, with excess flows directed to the JWPCP, which has capacity to treat 280 mgd. The JWPCP treated 265 mgd of wastewater in 2012; thus, there is as much as 15 mgd of available wastewater treatment capacity to serve the proposed restroom in Area 3.

During construction, portable toilets would be provided at the site for the construction crew, and these portable toilets would be regularly cleaned and their contents disposed of off-site by an outside company. Wastewater from these portable toilets would not exceed Los Angeles RWQCB treatment requirements. Also, an insignificant amount of wastewater would be generated by these portable toilets, and the Project would not need new or expanded treatment facilities. Capacity at existing wastewater treatment plants would not be exceeded during construction or operation of the proposed Project. Impacts related to wastewater facilities would be less than significant. No mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified potential impacts to wastewater and included Measure Utilities and Service Systems-1 for the construction of a sewage collection system to serve the HWP prior to the renovation and construction of restrooms. The Master EIR considered the connection of the new restroom in Area 3 to the sewer line at the JPL campus, which is being proposed by the Project. Thus, Measure Utilities and Service Systems-1 is not applicable to the Project.

b) Would the project require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?

d) Would the project have sufficient water supplies available to serve the project from existing entitlements and resources, or are new or expanded entitlements needed?

Less than Significant Impact.

Areas 1, 2 and 3 Impacts. Temporary irrigation of the landscaping at the rest area/picnic area in Area 1 would be provided until native plants are established. Irrigation and horse water trough in Area 1 would be served by the water line at the USFS Ranger Station. The proposed restroom, drinking fountain, and parking lot landscaping in Area 3 would be served by the relocated water line in Area 3. As estimated above, approximately 2,000 gallons per day (gpd) would be used by the restroom.

The new diversion and weir structures in Area 2 and the expanded spreading basins in Area 3 would increase the PWP groundwater recharge by approximately 1,100 acre-feet per year (afy). With the PWP allowed to extract 60 percent this volume, its water supply could increase by over 580,000 gpd. Water use by the Project (associated with the proposed restroom, landscape irrigation, drinking fountain, and horse water trough) is expected to be minimal and would be substantially less than the projected increase in PWP supplies due to the Project.

The proposed Project would require water for the control of fugitive dust during grading and excavation activities. A water truck would come to the construction sites, with water obtained from off-site sources, as needed. This water demand would be short-term and minimal.

Surface water flows in the Arroyo Seco in Area 1 would be diverted away from the construction area when grading activities occur in the stream channel. Surface water in the Arroyo Seco in Area 2 would also be diverted from the diversion and weir structures and may be directed into the intake structure for conveyance into the spreading basins if basin excavation in Area 3 has not started. Stream flows in the Arroyo Seco would be uninterrupted during construction in Area 3. However, the spreading basins would be decommissioned while the new basins are being excavated and existing basins are expanded. During these times, the intake structure would be closed and PWP would not be recharging surface waters. Instead, stream flows in Area 2 would be diverted away from the construction area and discharged into the Arroyo Seco downstream of Area 2. However, PWP maintains a groundwater storage reserve and is capable of making up

the temporary interruption in spreading. Therefore, PWP would not require more imported water sources during Project construction.

The Project would not affect water wells located near Area 3, but it would be necessary to relocate the JPL water line that crosses Area 3. The new relocated line would be installed prior to removing the existing line to avoid disruption in water service to the JPL campus. Once the new water line is ready for use, the existing line would be removed. The hume line would be relocated and water conveyance would be disrupted during construction of the new line and the spreading basins. This impact would be temporary and would not cut off water services to existing PWP customers.

After construction, as much as 1,100 afy more water would be diverted and recharged due to the expanded basins and the improved diversion structure. This would allow the PWP to use less imported water sources in the long term. Impacts on water supplies would be temporary and less than significant. No mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan did not identify any adverse impacts on water supplies or services.

c) Would the project require or result in the construction of new storm water drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?

No Impact.

Areas 1, 2 and 3 Impacts. The Project does not propose impervious areas that would increase runoff volumes and/or require new or expanded storm drainage. Improvements in Area 1 would retain storm water flows in the Arroyo Seco. Improvements in Area 2 would impound more water behind the new diversion and weir structures but would not affect the capacity of the Arroyo Seco. Instead, less surface water would flow in the Arroyo Seco downstream of the diversion structure and towards the Devil's Gate Reservoir. This would not require new storm drainage facilities and impacts on storm drainage would be less than significant.

The direction of drainage on the improved access road in Area 2 would not change from the existing as it would flow away from the stream and toward the eastern slope for discharge to the south. This would only affect the drainage pattern on the road but flows would still enter the Arroyo Seco downstream. Improvements in Area 3 would direct runoff into the spreading basins for recharge; and runoff from area storm drains would continue to discharge into the Arroyo Seco. The Project would not require any storm drainage facilities. Impacts on storm drainage would be less than significant, and no mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan stated that storm drain improvements would have beneficial impacts on storm runoff control but construction of these improvements would result in temporary impacts requiring mitigation. The Project does not proposed any of the storm drain improvements outlined in the Master Plan.

f) Would the project be served by a landfill with sufficient permitted capacity to accommodate the project's solid waste disposal needs?

g) Would the project comply with federal, state, and local statutes and regulations related to solid waste?

Less Than Significant Impact.

Areas 1, 2 and 3 Impacts. Trash cans and pet waste stations in Areas 1 and 3 would be subject to weekly maintenance and waste removal by City personnel. Solid wastes in these receptacles are expected to be minimal, although disposal is expected to slightly increase over existing conditions due to the presence of picnic tables in Area 1 and additional trail users, as discussed in Section 4.16, Recreation. The types of wastes generated would not change, but the amount would be slightly increased. Recycling bins at the restroom would also reduce demand for landfill space. Disposal of trash would continue through the City's current waste disposal and would not affect landfill capacity. Long-term impacts would be less than significant.

Temporary construction activities would generate solid wastes. Construction in Area 1 is estimated to generate 80 cubic yards (cy) of debris from clearing and grubbing activities and 64 cy of demolition wastes (with no excess cut soils) requiring disposal at Scholl Canyon Landfill.

Construction activities in Area 2 are estimated to generate 80 cy of debris from clearing and grubbing activities; 16 cy of demolition wastes; and 180 cy of cut soils requiring disposal at Scholl Canyon Landfill. Construction activities in Area 3 are estimated to generate 2,400 cy of debris from clearing and grubbing activities; 4,000 cy of demolition wastes; and 2,000 cy of excess cut soils requiring disposal at Scholl Canyon Landfill. It is anticipated that the 2,000 cy of excess cut soils would consist of larger rocks recovered through the use of an on-site shaker. It is the City's intention to utilize this recovered material on-site rather than disposing of the materials. However, in order to provide a conservative assessment of impacts, disposal at Scholl Canyon is considered. As such, a total of approximately 8,820 cy of soils and debris from Project construction would require off-site disposal.

The City's Construction and Demolition Waste Management Ordinance requires diversion of at least 50 percent of the total weight of construction and demolition debris away from landfills (RR UTIL-1). Compliance with this RR will reduce landfill demand from the Project.

The Scholl Canyon Landfill has a daily allowance to accept 3,400 tons per day and has 4.8 million tons of remaining capacity as of December 2010, and at current rates of disposal per day (approximately 1,400 tons/day), the landfill would reach its currently permitted capacity in the year 2021 (LACSD 2014). Additionally, the City of Glendale is currently considering ways to expand the capacity of the landfill, thereby extending its useful life by 13 to 19 years (LACSD 2014). There is adequate capacity (4.8 million tons) at Scholl Canyon Landfill to serve construction waste disposal needs (8,820 cy) of Project construction.

Hazardous materials would be disposed of in accordance with existing regulations (RR HAZ-1), as discussed in Section 4.8, Hazards and Hazardous Materials. Impacts related to landfill capacity and solid waste regulations would be less than significant. No mitigation is required.

Impact Comparison with Arroyo Seco Master EIR. The Master EIR for the Arroyo Seco Master Plan identified potential impacts on solid waste disposal capacity due to construction activities and additional park use; it included Measure Utilities and Service Systems-2 for the implementation of waste minimizing and recycling measures during construction activities. The Project would comply with RR UTIL-1, which is similar to Measure Utilities and Service Systems-2, for the recycling of construction wastes and debris. The Project would also comply with PDF MIN-1 and RR MIN-1 from Section 4.12, Mineral Resources, for the collection of arroyo stone

during excavation activities, which would reduce the need for solid waste disposal during construction.

The Project does not propose to relocate or replace electrical and communication lines. Thus, Measure Utilities and Service Systems-4, which calls for the undergrounding of utility lines, is not applicable.

4.18.3 MITIGATION MEASURES

There would be no significant impacts related to utilities and service systems with compliance with RR UTIL-1; therefore, no mitigation measures are required.

4.19 MANDATORY FINDINGS OF SIGNIFICANCE	Potentially Significant Impact	Less than Significant with Mitigation	Less than Significant Impact	No Impact
Does the project:				
a. Does the project have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, reduce the number or restrict the range of rare or endangered plant or animal, or eliminate important examples of the major periods of California history or prehistory?	☐	☒	☐	☐
b. Does the project have impacts that are individually limited, but cumulatively considerable? ("Cumulatively considerable" means that the incremental effects of a project are considerable when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects)?	☐	☒	☐	☐
c. Does the project have environmental effects which will cause substantial adverse effects on human beings, either directly or indirectly?	☐	☒	☐	☐

4.19.1 MANDATORY FINDINGS OF SIGNIFICANCE ANALYSIS

a) Does the project have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, reduce the number or restrict the range of rare or endangered plant or animal, or eliminate important examples of the major periods of California history or prehistory?

Less than Significant With Mitigation. As discussed above in Section 4.4, Biological Resources, and Section 4.5, Cultural Resources, the Project would lead to the disturbance of existing plant, aquatic, and animal habitats on and near the Arroyo Seco, as well as have potential impacts to cultural resources in the Project area. Mitigation measures have been developed to reduce potential environmental impacts on biological and cultural resources to less than significant levels.

Implementation of the mitigation measures would ensure that the Project does not degrade the quality of the environment; does not substantially reduce the habitat of fish or wildlife species; does not cause a fish or wildlife population to drop below self-sustaining levels; does not threaten to eliminate a plant or animal community; does not reduce the number or restrict the range of Rare or Endangered plant or animal; and does not eliminate important examples of the major periods of California history or prehistory. Impacts would be less than significant after mitigation.

In addition, beneficial impacts on biological resources would occur through the proposed restoration and revegetation of Area 1 and compliance with the Arroyo Seco Design Guidelines would promote the cultural heritage of the area.

b) Does the project have impacts that are individually limited, but cumulatively considerable? ("Cumulatively considerable" means that the incremental effects of a project are considerable when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects)?

Less than Significant Impact After Mitigation. A number of projects are ongoing and are proposed in the Hahamongna Watershed Park and adjacent areas. These cumulative projects include, but are not limited to those listed and described below.

1. The Los Angeles County Department of Public Works is planning to implement sediment removal activities in the Devil's Gate Reservoir. Temporary stockpiling at Johnson's Field occurred in 2011, 2012, and 2013, and the permanent sediment removal activities are currently being finalized. Sediment would be excavated and disposed off-site, including approximately 2.9 million cubic yards (cy) of sediment from a 120.42-acre area behind the dam; approximately 15,725 cy at the Johnson's Field stockpile; and additional sediment received by the dam during sediment removal. Sediment will be disposed at the Waste Management Facility in Azusa, the Vulcan Materials Reliance Facility in Irwindale, the Manning Pit Sediment Placement Site in Irwindale, and other secondary sites in Sun Valley. Vegetation and organic materials will be hauled to Scholl Canyon Landfill in Glendale. Sediment removal is expected to occur between Fall 2015 and Fall 2020, with annual reservoir management after 2020.

2. A new JPL On-Site Parking Structure is currently under construction on the west side of the Arroyo Seco, within the JPL campus, to replace the parking spaces in Area 3. When the City notified JPL of its intent not to renew the lease for the parking lot, JPL started to plan for a new parking structure and requested that its lease not be terminated until the JPL On-Site Parking Structure is built (expected to be completed in 2014). Removal of the existing parking pavement and associated improvements (e.g., bus stop, signs, light poles, fencing) at Area 3 is part of JPL's parking structure project. This project is anticipated to be completed before the Arroyo Seco Canyon Project begins construction.

3. The HWMP outlines the improvements for the HWP that include habitat establishment and restoration areas, spreading basins, an overnight camping area, park facilities, picnic areas, improved and new trails, restrooms, parking areas, overlooks, bicycle routes, storm drain improvements, flood management and water conservation facilities, trailheads, and bridges. None of the improvements proposed on the east side of the Arroyo Seco are planned for construction at the same time as the Project.

4. The HWMP Addendum for the Hahamongna Annex proposes improvements to a 30-acre site formerly owned by the Metropolitan Water District of Southern California that is developed with an abandoned USFS station, equestrian facilities, a fire camp, and open space. This site is west of the Arroyo Seco and south of the JPL campus. The HWMP Addendum calls for an education and conference facility, an equestrian facility, park offices, a fire camp (existing), passive recreational facilities, and open space. No timeline for construction of these improvements has been finalized.

5. The Hahamongna Multi-Benefit/Multi-Use Project proposes improvements at the Hahamongna Watershed Park on the west side of the Arroyo Seco, including: Westside Perimeter Trail; restoration of Berkshire Creek; Oak Grove Field restroom; Foothill drain improvements; and habitat restoration.

6. The Los Angeles County Flood Control District is planning a water conservation project at Devil's Gate Dam that involves the installation of a pump and intake structure at the upstream face of the dam, along with a five-mile pipeline from the pump easterly to Eaton Wash. This project will divert water from the dam for recharge at Eaton Wash and is in the conceptual design phase.

7. Pasadena Water and Power is currently planning for a recycled water project which would take recycled water from the Los Angeles Glendale Water Reclamation Plant (LAG). The proposed point of connection is at Scholl Canyon. The project proposes a pipeline from Scholl Canyon to the City near the intersection of Washington Blvd. and West Drive. The primary customers would be the Art Center College, Brookside Golf Course, Brookside Park, and Rose Bowl Stadium. PWP is currently preparing the environmental impact report. The goal is to begin construction in early 2016.

The Project would not lead to any significant long-term adverse impacts due to the type and size of the proposed improvements. The Project's environmental impacts would mainly be associated with construction activities and would be mitigated to levels considered less than significant, which would reduce the Project's contribution to cumulative impacts.

Construction of the Project would not contribute to cumulatively significant adverse impacts with the cumulative projects that would generally be located on the west side of the Arroyo Seco in the HWP or that would be constructed before the Project (e.g., JPL On-Site Parking Structure) or after the Project's construction schedule (e.g., Hahamongna Annex and Hahamongna Multi-Benefit/Multi-Use Project), or those that have not been specifically scheduled for construction (e.g., some HWMP improvements and Devil's Gate Dam/Eaton Wash water conservation project). However, the sediment removal activities in the Devil's Gate Reservoir are anticipated to begin in the Fall of 2015, during which the Project would have started construction. This construction schedule overlap would occur from Fall 2015 until Fall 2016, when Project construction would be completed (except for 5 months between December 2015 and April 2016 when the sediment removal project would not be ongoing). Thus, the Project's construction-related impacts (i.e., aesthetics, construction emissions, noise, recreation, and traffic) could cumulatively add to construction-related impacts of proposed sediment removal activities for approximately 8 months, assuming all projects move forward on their anticipated schedules. (The Draft EIR for the sediment removal activities considers the Arroyo Seco Canyon Project as a cumulative project and analyzes the cumulative impacts of both projects and other projects proposed in the surrounding area.)

Cumulative Impact Analysis

Aesthetics. As discussed in Section 4.1, Aesthetics, the Project would have no impacts on scenic highways and less than significant impacts related to new sources light and glare. Thus, the Project would not contribute to cumulative impacts on these issues. The Project would not lead to major permanent changes in the visual quality of the Arroyo Seco Canyon and the HWP with the design of public improvements in Areas 1 and 2 in accordance with the Arroyo Seco Design Guidelines (PDF AES-1) and the design of improvements in Area 3 in compliance with the Arroyo Seco Design Guidelines (RR AES-1). However, temporary changes in visual quality and scenic views would occur during the construction phase. Construction areas and staging areas would provide views of construction equipment, construction activities, disturbed soils, and building material stockpiles that would be visible to residents, employees and visitors in the area. The screening of construction sites and staging areas would limit these views.

Construction activities within Areas 1 and 2 would not be within the same viewshed as the sediment removal activities associated with the Devil's Gate Sediment Removal Project because they are upstream and obscured from view by topography and vegetation. However, construction activities within Area 3 would be within the same viewshed. Additionally, some truck traffic for the two projects would be using similar haul routes (i.e., Windsor Avenue for incoming trucks and I-210, SR 134, Scholl Canyon Road for outgoing trucks) when trees, vegetation and other organic materials from the reservoir are disposed of at the Scholl Canyon Landfill[8]. Therefore, cumulative projects in other areas of the HWP and sediment removal activities in the Devil's Gate Reservoir would expand views of construction equipment and activities that would detract from views of the natural open space and recreational areas in the HWP. This cumulative impact would be temporary and Project screening of construction areas and staging areas and MM TRA-1 (restrictions to non-peak hours) would reduce its contribution to cumulative short-term construction impacts on aesthetics to less than significant levels.

Agriculture and Forest Resources. As discussed in Section 4.2, Agriculture and Forest Resources, the Project would have no impact on agriculture and forest resources. Thus, the Project would not contribute to cumulative impacts on these resources.

Air Quality. As discussed in Section 4.3, the SCAQMD's approach for assessing cumulative impacts is based on the AQMP forecasts of attainment of ambient air quality standards in accordance with the requirements of the Federal and State Clean Air Acts. As discussed earlier in Threshold 4.3(a), the proposed Project would be consistent with the AQMP, which is intended to bring the SoCAB into attainment for all criteria pollutants. In addition, the mass regional emissions calculated for the proposed Project (Tables 4.3–4 and 4.3–6) would be less than SCAQMD's daily significance thresholds that are designed to assist the region in attaining the applicable State and national ambient air quality standards.

Short-term cumulative impacts related to air quality could occur if Project construction and nearby construction activities were to occur simultaneously. In particular, with respect to local impacts, cumulative construction particulate (i.e., fugitive dust) impacts are considered when projects are located within a few hundred yards of each other. As described above, sediment removal at the Devil's Gate Reservoir could have overlapping construction schedules with the Project. However, as shown in Table 4.3–5, Project construction emissions would be below the SCAQMD regional significance thresholds; particularly, particulate matter emissions would be less than ten percent of the thresholds. Therefore, the incremental effect of Project-related construction emissions of nonattainment pollutants would not be cumulatively considerable and Project impacts would be less than significant.

Biological Resources. As discussed in Section 4.4, Biological Resources, the Project would have potentially significant adverse impacts on biological resources. Several mitigation measures (MM BIO-1 through MM BIO-6) would be implemented to avoid and/or reduce these impacts to less than significant levels. The cumulative projects listed above would also have impacts on biological resources in the HWP and the Upper Arroyo Seco that could adversely change biodiversity and affect a number of sensitive species and their habitats; however, mitigation by individual projects and compliance with the permit conditions imposed by resource agencies are expected to mitigate project-specific impacts. Because all biological resources that would be impacted by the cumulative projects would be subject to mitigation to the satisfaction of the resource agencies and the lead agencies, and because the proposed Project would also mitigate all impacts to less than significant and would not alter the availability of open space or biological

[8] The proposed sediment removal activities at Devil's Gate Reservoir would utilize a number of disposal sites in the Cities of Azusa and Irwindale and other sites east and west of the reservoir, in addition to the Scholl Canyon Landfill.

resources in the Project area, incremental impacts would not be cumulatively considerable and no additional mitigation is required.

Cultural Resources. As discussed in Section 4.5, Cultural Resources, the Project would have potentially significant adverse impacts on historical resources, archaeological resources, and paleontological resources that are present within or near the construction sites. Mitigation measures (MMs CUL-1 through MM CUL-4) would be implemented to avoid and/or reduce these impacts to less than significant levels. The Project would also comply with RR CUL-1 in the event of discovery of human remains.

Since cultural resources are site-specific and since the Project site is not located within a historic district, no cumulative significant adverse impacts are expected from the Project with implementation of site-level surveys and mitigation outlined as part of cultural resource studies for individual development projects. Implementation of the proposed Project and the mitigation measures outlined above would prevent adverse impacts on cultural resources on the site. Thus, the Project would not have a cumulative contribution to the disturbance and/or destruction of cultural resources in the surrounding area.

Energy. The proposed Project would have a limited demand for energy when compared to the energy demand of the cumulative projects listed above or to the existing energy supplies that PWP provides to existing development in the City. The elimination of the existing JPL East Parking Lot lighting and reductions in demand for State Water Project water deliveries due to increased groundwater recharge would help partially off-set new Project-related electrical demand. Therefore, although the Project would result in a slight increase in overall electrical usage, no new infrastructure would be required and any new electrical connections would be constructed in accordance with the City's Building Code (RR GEO-1). Energy use by the Project would not be cumulatively considerable and cumulative impacts would be less than significant.

Geology and Soils. As discussed in Section 4.6, Geology and Soils, Project impacts associated with seismic and geologic hazards in the area would be less than significant with compliance with the City's Building Code (RR GEO-1) and the recommendations of the Project's Geotechnical Feasibility Report (RR GEO-2). Similarly, the cumulative projects would have to comply with the City's Building Code and the recommendations of geotechnical investigations prepared for individual projects. Geology and soils impacts are generally site specific and there is typically little, if any, cumulative relationship between the development of a proposed Project and development within a larger cumulative area. For example, development at the Project site would not alter geologic events or soil features/characteristics (such as ground shaking, seismic intensity, or soil expansion) at other locations; therefore, the Project would not result in cumulatively considerable impacts.

Greenhouse Gas (GHG) Emissions. As discussed in Section 4.7, Greenhouse Gas Emissions, it is very unlikely that any individual development project would have GHG emissions of a magnitude to directly impact global climate change; therefore, any impact would be considered on a cumulative basis. Because the proposed project's GHG emissions would be 126 $MTCO_2e$/yr and considerably less than 3,000 $MTCO_2e$/yr screening threshold recommended by SCAQMD, the Project's GHG emissions would not be cumulatively considerable. Cumulative impacts would be less than significant.

Hazards/Hazardous Materials. As discussed in Section 4.8, Hazards and Hazardous Materials, the Project's use, storage, transport, and disposal of hazardous materials will be made in accordance with existing regulations (RR HAZ-1). Similarly, the cumulative projects would have to comply with pertinent hazardous materials regulations. Compliance with existing regulations would reduce hazards to nearby schools, residences, and other land uses.

The Project would also implement MM HAZ-1, which includes measures to avoid adding to existing groundwater contamination, and MM HAZ-2, which requires sampling and remediation of discolored or odorous soils, as necessary, to avoid the dispersion of existing groundwater contamination. Neither the Project nor the cumulative projects are expected to interfere with the existing groundwater contamination, assuming compliance with existing regulations and applicable mitigation measures. Additionally, JPL's ongoing groundwater remediation and monitoring would continue to reduce these existing hazards over time.

There are no airports or airstrips within two miles of the Arroyo Seco Canyon, and the Project would not contribute to cumulative impacts on airport and aircraft operations. The Project and cumulative projects would be exposed to wildfire hazards present to the north, west, and south of the Reservoir, but with compliance with the City's Fire Prevention Code (RR PS-1), Project impacts would be less than significant. Thus, it would not contribute to cumulative impacts relate to wildfire hazards.

The Project may affect emergency response and evacuation due to temporary closure of the Gabrielino Trail/access road to the USFS Ranger Station and the ANF. Compliance with the Greenbook (RR TRA-1) and implementation of MM HAZ-3 (notification of public service agencies) would reduce the Project's contribution of cumulative impacts related to emergency response and evacuation. Continued implementation of the City's Emergency Operations Plan (RR HAZ-2) would also provide emergency access and evacuation in the HWP, as necessary. Cumulative impacts would be less than significant.

Hydrology and Water Quality. As discussed in Section 4.9, Hydrology and Water Quality, the Project would have beneficial impacts on hydrology and water quality by improving the riparian habitat in the Arroyo Seco (PDF HYD-1); increasing groundwater recharge (PDF HYD-1); and providing trash cans, pet waste stations, and a restroom (PDF HYD-3). Construction activities would result in pollutants in storm water and in the Arroyo Seco that would be reduced by compliance with the NPDES General Construction Permit (RR HYD-1), the City's Stormwater Management and Discharge Control Ordinance (RR HYD-4), and the SWRCB's Waste Discharge Requirements (RR HYD-2). Dewatering may also lead to the release of contaminated groundwater and would require compliance with the Los Angeles RWQCB's dewatering regulations (RR HYD-3). Cumulative projects would also have to comply with these regulations, as needed. Thus, cumulative impacts on storm water quality during the construction of individual projects would be less than significant.

Changes in drainage patterns due to habitat restoration in Area 1; surface water diversion in Area 2; and changes in drainage patterns in Area 3 would be less than significant. Changes in drainage patterns from cumulative projects are also expected to be confined to individual sites and would maintain flows into and in the Arroyo Seco. Cumulative impacts would be less than significant. No inundation hazards from dam or levee failure, seiche, tsunami, or mudflow would affect the Project, nor would they be created by the Project. Thus, no cumulative impacts related to these issues would occur.

Land Use and Planning. As discussed in Section 4.10, Land Use and Planning, the Project would not divide an established community and would not conflict with the City's Open Space designation and zoning. The Project would also comply with the HWMP (RR LU-1) and Arroyo Seco Design Guidelines (RR AES-1). Thus, the Project would not contribute to cumulative impacts related to land use and planning.

Mineral Resources. As discussed in Section 4.11, Mineral Resources, sand and gravel resources exist within the Devil's Gate Reservoir (although there are no active mining operations in the area), but the Project would not affect these resources. However, large cobbles and

boulders in and near the Arroyo Seco would be disturbed by the Project. These boulders would be reused for improvements in Areas 1, 2, and 3, and large cobbles and boulders in Area 2 would be stockpiled for future decorative uses (PDF MIN-1). Also, the Arroyo Seco Design Guidelines require the collection of arroyo stones during excavation activities in Area 3 (RR MIN-1). These would maintain the availability of local mineral resources. Improvements in Area 3 would not preclude future mining operations in this area. Also, long-term recreational activities in Arroyo Seco Canyon and operation and maintenance of the PWP facilities would not require mineral resources. Thus, the Project would not have a significant cumulative adverse impact on mineral resources.

Noise. As discussed in Section 4.12, Noise, changes in noise levels from Project construction and operation would be less than significant. The Project would comply with the City's Noise Ordinance (RR NOI-1) and would implement noise-control measures (MM NOI-1) to further reduce noise on adjacent land uses. While construction noise would be added to the construction noise impacts of the cumulative projects that are under construction at the same time (such as the sediment removal activities), noise levels generally dissipate rapidly from the source and would affect different receptors due to different construction site locations. Traffic noise impacts would occur on roadways used by construction equipment and haul trucks, but changes in noise levels would be intermittent and are not expected to increase by 5 dBA such that they will become discernible (since it would take a doubling of traffic volumes to increase noise levels by 3 dBA) and the Project would not lead to traffic increases equal to existing traffic volumes on Windsor Avenue, which ranged from 6,361 to 10,097 ADT on weekdays and from 4,680 to 6,458 ADT on the weekends in 2011. Additionally, MM TRA-1 requires construction equipment, construction vehicles, and the construction crew to avoid arrivals and departures during the AM peak hours (7:30 AM to 8:30 AM) and the PM peak hours (4:30 PM to 5:30 PM). Impacts on noise would be temporary and would not be cumulatively significant.

Population and Housing. As discussed in Section 4.13, Population and Housing, the Project would not introduce households or businesses, nor would it extend infrastructure that may induce growth in the area. It would also not displace existing housing or households in the area. Thus, the Project would not have cumulative impacts related to Population and Housing.

Public Services. As discussed in Section 4.14, Public Services, the Project would not create demands for school, library, or park services. Demands for fire and police protection services would be limited to the construction phase, and compliance with the City's Fire Prevention Code (RR PS-1) would reduce the incidence of fire and its associated demand for fire protection services. Similarly, the cumulative projects would comply with these City regulations and would not result in significant cumulative adverse impacts.

The Project's demand for police protection services would be reduced by screening construction areas and staging areas; complying with the Greenbook (RR TRA-1); and notifying public service providers (MM HAZ-3). While the Project would contribute to the cumulative demand for police protection services, its contribution would be minimal and would not be cumulatively considerable requiring new facilities. Long-term operation and maintenance for the proposed recreational amenities and improved PWP facilities would be largely similar to existing services. These impacts would be less than significant and would not be cumulatively considerable requiring new facilities.

Recreation. As discussed in Section 4.15, Recreation, the Project would improve recreational facilities in the Arroyo Seco Canyon, the ANF, and the HWP. This would result in beneficial impacts on Recreation in the long-term.

Concurrent construction of the Project and the cumulative projects would lead to the closure of some trails in the HWP and the ANF. Specifically, the sediment removal project would lead to the short-term closure of portions of the Altadena Crest Trail, Arroyo Seco Trail, and West Rim Trail. These closures may occur concurrent with closures of portions of the Gabrielino Trail, Altadena Crest Trail, and Arroyo Seco Trail that would occur during construction of the Project. MM REC-1 requires the Contractor to post signs at the parking lots and trail entrances providing at least one week of advanced notice of the dates and times of planned trail closures, along with directions to the nearest trails in the surrounding areas. To avoid directing trail users to nearby trails that would be closed due to other cumulative projects, this mitigation includes a provision that alternative trails be those that are not closed at the same times as the trails that would be closed by the Project. Impacts would be temporary and less than significant after mitigation. Thus, the Project would not contribute to significant cumulative impacts on Recreation.

Transportation/Traffic. As discussed in Section 4.16, Transportation and Traffic, the long-term increase in the number of vehicle trips associated with increases in trail users and visitors and maintenance vehicles would contribute to cumulative increases in existing traffic volumes on local streets and freeways. However, this increase is not considered cumulatively significant due to the limited number of trips expected during the AM and PM peak hours on weekdays.

During construction of the Project (Summer 2015 to Fall 2016), sediment removal activities at the Devil's Gate Reservoir would also be ongoing south of Area 3. While other cumulative projects may also be under construction at the same time, they are located on the other side of the Arroyo Seco and are likely to use a different set of roadways.

The I-210 off-ramps at Windsor Avenue and the segment of Windsor Avenue north to Oak Grove Drive would be used by construction equipment and trucks for the reservoir sediment removal and the Arroyo Seco Canyon Project. Sediment-removal trucks would turn left on Oak Grove Drive to enter the reservoir, while Arroyo Seco Canyon Project trucks would continue farther north. Departing trucks from the reservoir would use Oak Grove Drive and the Berkshire Place on-ramps to the I-210, while trucks departing from the Project would use Windsor Avenue south to the I-210 on-ramps.

Since arriving trucks from both the proposed Project and the Devil's Gate Project would use the same I-210 off-ramp and the segment of Windsor Avenue to Oak Grove Avenue throughout the work day, cumulative traffic impacts could occur. With the implementation of MM TRA-1 (which would restrict construction vehicles, construction equipment, and truck trips from the Project site to hours outside the AM and PM peak hours), the Project would not contribute to the significant adverse impacts of sediment removal haul trucks going to and from Devil's Gate Reservoir during the AM and PM peak hours. This would avoid cumulative impacts during AM and PM peak hours from the Project.

The sediment-removal activities at the Reservoir would also dispose of vegetation and organic materials at the Scholl Canyon Landfill, similar to the Project. Thus, the same route would be affected: I-210 east to SR-134 west and exit on Figueroa Street, north to Scholl Canyon Road. A maximum of 425 truck round trips per day (or 50 truck round trips per hour) are expected for sediment removal, with approximately 50 percent of the total going to Scholl Canyon Landfill during the first 3 weeks; and the remaining 50 percent to the other disposal sites. In subsequent years, 25 percent of the total trucks will go to Scholl Canyon Landfill during the first week; and the remaining 75 percent will go to other disposal sites.

In addition to MM TRA-1, the following mitigation is recommended to reduce cumulative impacts related to truck traffic near Scholl Canyon Landfill:

MM CUM-1 The Contractor for the Arroyo Seco Canyon Project shall coordinate with the Los Angeles County Department of Public Works and their contractor for the sediment removal activities at Devil's Gate Reservoir on the schedule of trucks coming to and from Scholl Canyon Landfill, such that the Project's truck traffic avoids the AM and PM peak hours to reduce conflict with local traffic and so that truck arrival times are staggered between the two projects to avoid queuing on Figueroa Street and on the State Route 134 on- and off-ramps.

The Project's contribution to cumulative traffic impacts would be temporary and less than significant after mitigation.

Utilities and Service Systems. As discussed in Section 4.17, Utilities and Service Systems, wastewater generation from the proposed restroom in Area 3 could be accommodated by wastewater treatment plants that would serve the Project. Cumulative impacts would be mitigated by the payment of connection and service fees by individual projects.

Long-term water use for the horse water trough, drinking fountain, restroom, and landscape irrigation and short-term construction site watering for dust control would be minimal and would not require new water supplies. Interruption of water diversion and groundwater recharge during construction would be temporary and would be compensated by the permanent increase in water diversion and recharge that would be provided by the improved diversion and weir structures in Area 2 and the expanded spreading basins in Area 3. No cumulative adverse impacts on water services and supplies would occur with the Project.

No storm drainage facilities are required by the Project; thus, no cumulative impacts on storm drainage would occur. Solid waste generation would be minimal in the long term and would be reduced during construction through compliance with the City's Construction and Demolition Waste Management Ordinance (RR UTIL-1). Cumulative projects would also have to comply with this ordinance during construction, and the Project's cumulative impacts on landfill capacity and solid waste regulations would be less than significant.

c) Does the project have environmental effects which will cause substantial adverse effects on human beings, either directly or indirectly?

Less than Significant With Mitigation. The proposed Project would have environmental effects that could cause substantial adverse effects on human beings, either directly or indirectly, as they relate to Aesthetics, Air Quality, Hazards and Hazardous Materials, Recreation, and Transportation/Traffic (as previously discussed under these environmental issues). Mitigation measures have been provided to reduce these impacts to less than significant levels. The Project's significant adverse effects on human beings would be less than significant after mitigation. Implementation of the Project would also have beneficial impacts on Hydrology and Water Quality by restoring riparian habitat along the Arroyo Seco and by increasing groundwater recharge; there would also be beneficial impacts on Recreation since additional recreational and educational facilities would be provided in the HWP and the Arroyo Seco Canyon.

1 BACKGROUND AND PURPOSE

The City of Pasadena Department of Water and Power (PWP) is conducting a project for improvement of the diversion and groundwater recharge system in Arroyo Seco Canyon. The Arroyo Seco Canyon Project includes work in three distinct areas for removal of a non-operational headworks structure, modification of the storm-damaged diversion structure, and improvements to the groundwater recharge system. A design for the project was completed in 2017 (Carollo Engineers, 2017). The California Environmental Quality Act (CEQA) Mitigated Negative Declaration (MND) was challenged, and PWP initiated an environmental compliance process for preparation of an Environmental Impact Report (EIR), which is now in progress.

A California Department of Fish and Wildlife (CDFW) Streambed Alteration Agreement was drafted during the project development and review process (CDFW, 2017a). CDFW also provided additional comments (CDFW, 2017b) from engineering review of the project regarding HEC-RAS hydraulic modeling, planted riprap revetment, grouted riprap, fish screens, fish passage, flows below the dam, and the geotechnical report.

PWP retained Kennedy/Jenks and subcontractor Northwest Hydraulic Consultants (NHC) to develop conceptual designs to address the topics raised in the draft agreement and CDFW comments and to develop modifications to the design of the diversion in Area 2 of the project. NHC was assisted in the fisheries review by Dr. Camm Smith, a leading authority on native fish in the Southern California region. The modified design must also consider maintaining the yield of the diversion to the extent feasible for recharge of groundwater resources, operational safety and reliability, and achievement of other environmental objectives.

1.1 PWP Diversion Operation

PWP currently diverts most of the flow from Arroyo Seco upstream of the diversion weir, when stream flows are below their full water right of 25 cfs. PWP plans to divert 25 cfs up to a higher threshold of streamflow before lowering an operable weir and allowing more turbid flow to pass downstream. Diversion during flood flows is not anticipated due to high turbidity levels and risk to diversion facilities. A primary benefit of the modified diversion will be to allow diversion during higher flows, at least during periods when turbidity and suspended sediment concentrations are considered acceptably low.

1.2 Environmental Process

PWP has completed an Initial Study for the project (Dudek, 2019) and conducted a public scoping meeting on 21 November 2019. Environmental analysis to evaluate potential impacts identified in the Initial Study, including assessment of biological resources in the area of the diversion, is in progress. The design of the diversion is being coordinated with the environmental evaluation to identify and minimize potential impacts.

1.3 Purpose of this Basis of Design Report

The purpose of this report is to present the design criteria and basis of design for the proposed modified diversion and intake system. A key objective of this report is to provide detailed information that can be reviewed with CDFW and other stakeholders to confirm the specific design direction for the project.

2 HYDROLOGIC SETTING

2.1 Hydrology of Arroyo Seco

Arroyo Seco is a tributary to the Los Angeles River that drains approximately 18 square miles of the Angeles National Forest in the San Gabriel Mountains at the site of the diversion. The diversion is located in the Arroyo Seco canyon approximately one-half mile upstream of the canyon mouth and the head of the alluvial fan now occupied by the reservoir area behind Devil's Gate Dam. The dam was constructed in 1920 and is owned and operated by Los Angeles County Flood Control District. A bridge crosses the stream at the Jet Propulsion Laboratory (JPL) east gate and is approximately located at the transition between confinement of the stream in the canyon and the unconfined alluvial fan and reservoir deposits downstream. Three other bridges are located between the JPL bridge and the diversion intake, and the Millard Creek tributary joins Arroyo Seco approximately 600 feet upstream of the JPL bridge.

2.1.1 Flow Frequency and Duration Characteristics

Deere and Ault (2017) used the USGS stream gage 11098000 on Arroyo Seco to assess hydrologic characteristics of the stream, adjusting the gage values by about 10 percent to account for additional watershed area between the gage and the diversion, which is located about one mile downstream of the gage. Estimated flow frequencies are shown in **Table 2.1.**

The flood of record at the gage occurred in the 1938 Water Year with a peak flow of approximately 8,600 cubic feet per second (cfs). A peak of approximately 8,500 cfs occurred in the 1969 Water Year. Since that time, no flood larger than 5,400 cfs has occurred. The most recent large flood events occurred in January 2005 (3,540 cfs), February 2010 (4,620 cfs) and Dec 2011 (2,260 cfs). The 2010 event followed the 2009 Station Fire that burned 160,000 acres, including much of the upper Arroyo Seco watershed. The 2010 event carried high sediment and debris loads, removed much of the riparian vegetation along the stream corridor, and damaged the diversion and access road. Flood flows and debris in the 2010 event overtopped the diversion intake vault and access road.

Table 2.1 Flow frequencies at Arroyo Seco diversion based on annual peaks at USGS Gage 11098000 for period 1914 to 2015 (from Deere and Ault, 2017)

Recurrence Interval, years	Peak Flow, cfs
2	613
5	1,878
10	3,204
50	7,543
100	9,962

Flow duration characteristics were also compiled by Deere and Ault from mean daily flow gage records for the full annual record and for specific months. The annual flow duration curve is shown in **Figure 2.1**.

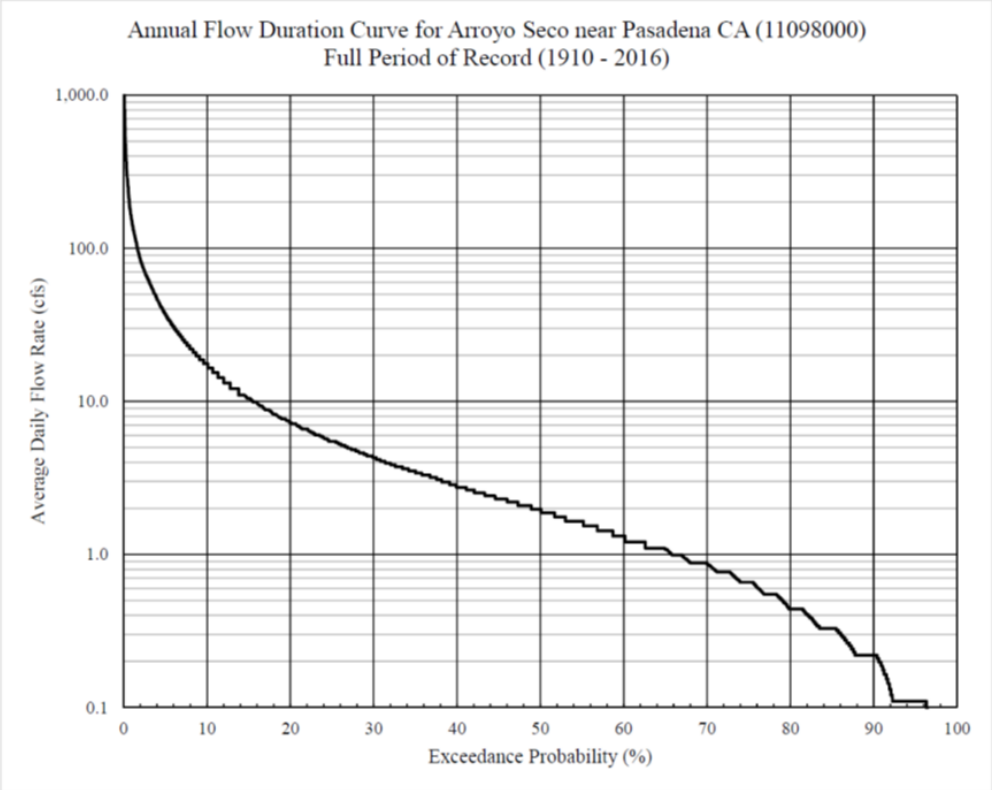

FIGURE B-13 – Annual flow duration curve for Arroyo Seco.

Figure 2.1 Annual flow duration curve for Arroyo Seco at USGS Gage 11098000 (from Deere and Ault, 2017)

On an annual basis, flows below 1 cfs occur about 35 percent of the time and flows above 25 cfs occur only about 7 percent of the time. The flow duration analysis indicated that the wettest months are typically February (**Figure 2.2**) and March, with flows above 1 cfs about 95 percent of the time and flows above 10 cfs about 35 percent of the time. The lowest flows occur in summer and fall months and the gage analysis indicates that zero flow occurs at the gage 24 percent of the time in August and 26 percent of the time in September (**Figure 2.3**). Flows less than 1 cfs occur 70 and 75 percent of the time in August and September, respectively. The gage record shows significant diurnal variation in summer months, presumably due to evapotranspiration by stream vegetation.

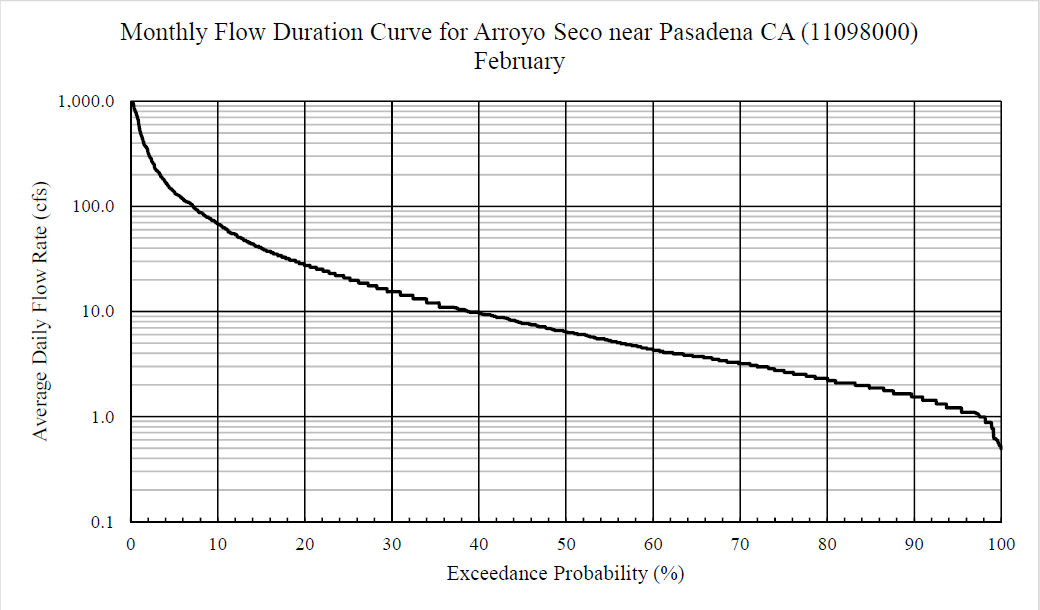

FIGURE B-5 – February flow duration curve for Arroyo Seco.

Figure 2.2 February flow duration curve for Arroyo Seco at USGS Gage 11098000 (from Deere and Ault, 2017)

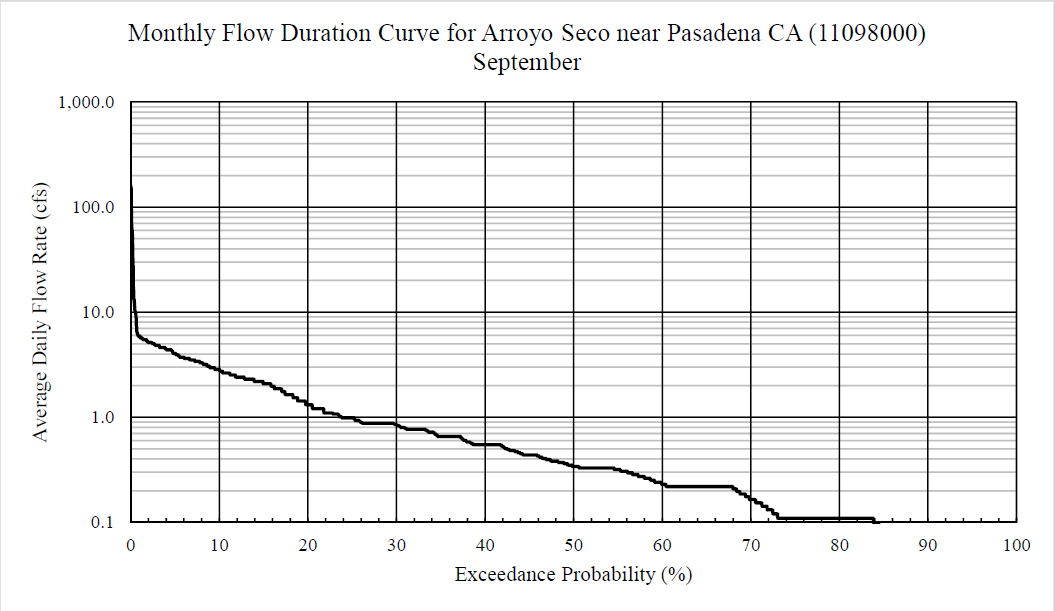

FIGURE B-12 – September flow duration curve for Arroyo Seco.

Figure 2.3 September flow duration for Arroyo Seco at USGS Gage 11098000 (from Deere and Ault, 2017)

Adjustments to gage values for watershed area differences are reasonable for flow frequency estimates but the accuracy of area-based adjustments such as the one applied in the Deere and Ault study may be less accurate for flow duration analysis because of large variations in lower flows that may occur with geology, stream substrate, vegetation, and other factors. On 17 August 2019 NHC made rough estimates of flow at the diversion of about 1 cfs and the gage recorded about 0.8 cfs on the same day, indicating that for at least one observation, little gain or loss was evident between the gage and the diversion at low flows. The median mean daily flow for this date according to the USGS gaging statistics is 0.4 cfs.

Under existing conditions, PWP diverts all flow in the creek at the diversion during periods of low flow, except for an amount that leaks or seeps past the dam. Millard Creek contributes flow downstream, but likely does not contribute perennial flow. On 17 August 2019, about 0.4 cfs of flow was estimated below Millard Creek, with about one third coming from Millard Creek and two thirds from Arroyo Seco. This flow estimate is very rough due to the difficulty in estimating shallow flow rates over a rough streambed and is only a single observation that may not be representative of typical conditions.

Flow frequency and flow duration information are relevant to fish passage design and instream flow objectives, as described in subsequent sections.

2.1.2 Storm Event Characteristics

The Arroyo Seco watershed generates relatively high unit runoff rates due to its geology, hypsography, and climatic setting. The computed 100-year recurrence peak flow corresponds to a unit flow rate of

about 550 cfs per square mile. Although high runoff may be generated by convective storms, the largest peaks in the record are generally associated with multi-day frontal storms and atmospheric river events from the Pacific Ocean. The steepness of the watershed and the potential for intense rainfall rates associated with some frontal storms produces very rapid increases in flow. **Figure 2.4** shows the hydrographs associated with the 2010 and 2005 annual peak events from USGS Gage 11098000. Differences in hydrograph shapes are due to antecedent conditions and precipitation patterns, but in both cases, flows increase and decrease rapidly in response to precipitation. In the 2010 event, flows increased from about 5 cfs on 5 February to the peak of 4,620 cfs only 24 hours later on 6 February and receded to about 30 cfs another 24 hours later on 7 February. Rapid changes in stage and flow can be expected to produce large sediment and debris loads and adjustment of channel beds and banks.

The most productive periods for diversion are associated with prolonged wet periods that are associated with light or moderate rainfall, such that flows remain above 5 to 10 cfs for prolonged periods of time and turbidity levels are not excessive.

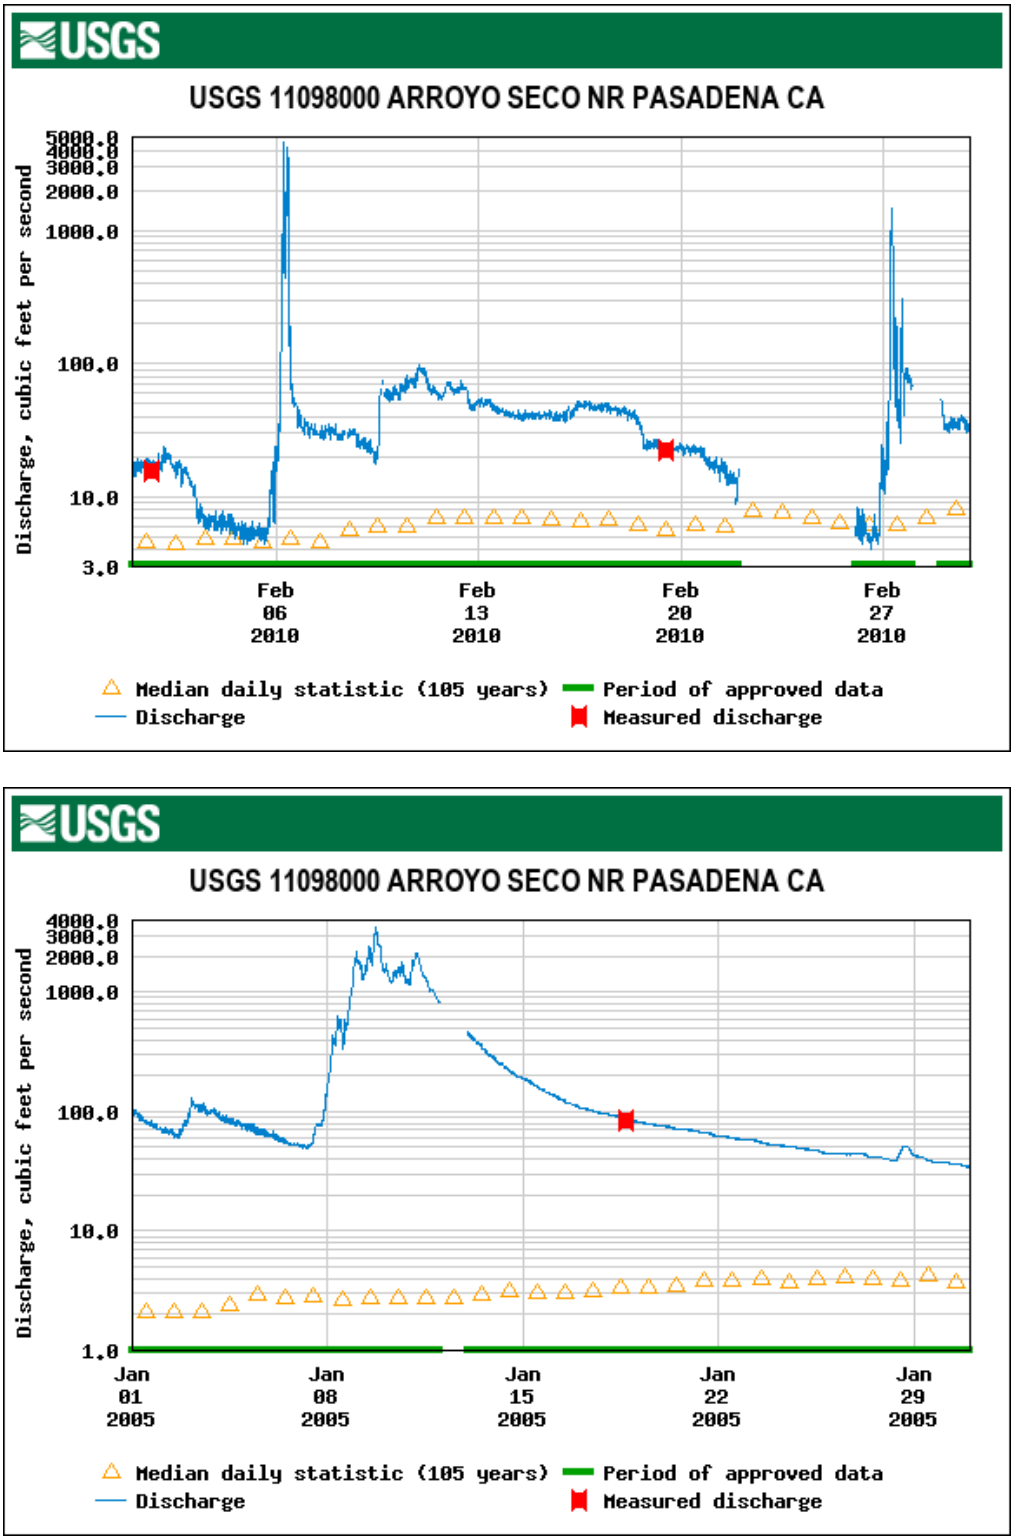

Figure 2.4 Storm hydrographs for 2010 (top) and 2005 (bottom) events

2.2 Geomorphic Characteristics

The streambed in the project area is generally comprised of coarse sediments ranging from sand to boulders. During an NHC site reconnaissance, bedrock exposure was noted in several locations between JPL bridge and the diversion in the banks and bed of the channel. Active streambed widths vary between about 20 and 40 feet. The channel varies between step-pool and plane bed morphology, with step-pools associated with steeper reaches and very coarse (cobble to boulder) bed material and bedrock exposures. These two channel morphologies are consistent with the overall slope of the channel of about 2.5 to 3 percent.

The watershed was severely burned in the 2009 Station Fire and was subject to elevated sediment debris and sediment loads in the years following the fire. As noted above, peak flows of approximately 4,600 cfs and 2,300 cfs were recorded at the gage in Water Years 2010 and 2011, respectively. At the present time, there is very little fine-grained material (silt or clay) in the present bed material in the reach between the JPL bridge and the diversion.

The channel between JPL and the diversion is densely vegetated, with willow dominant in some segments of the banks and alder dominant in others. There are numerous areas where alders of the same age class occur in stands along the bank, potentially indicating cycles of scouring and regrowth. The latest cycle may be associated with post-Station Fire flows. Aerial photography from March 2011 shows a scoured channel and vegetation mostly removed in a swath 60 to 100 feet wide between the headworks and JPL. Given the magnitude of the scour and deposition areas in 2011, the recovery of riparian vegetation along this reach of channel in less than 10 years is remarkable. **Figure 2.5** and **Figure 2.6** show typical sections of stream bed in this reach in August 2019. Vegetation characteristics upstream of the diversion to the headworks in Area 1 of the project area are similar. Riparian vegetation likely plays a role in channel stability during some flood flows, but due to the steepness of the channel and high sediment and debris loads, may be partially or nearly entirely lost in the largest events.

The diversion dam forms a small high point in the bed to facilitate flow into the intake. **Figure 2.7** shows a plot of the stream profile taken from aerial topography developed by PWP in 2015. **Figure 2.8** shows a similar plot in the immediate vicinity of the diversion. The stream slope is flattened upstream of the diversion but maintains a continuous positive slope of about 1.5 percent.

Figure 2.5 Arroyo Seco streambed and small bedrock drop between Millard Creek and diversion

Figure 2.6 Arroyo Seco streambed and small boulder drop downstream of first bridge upstream of Millard Creek

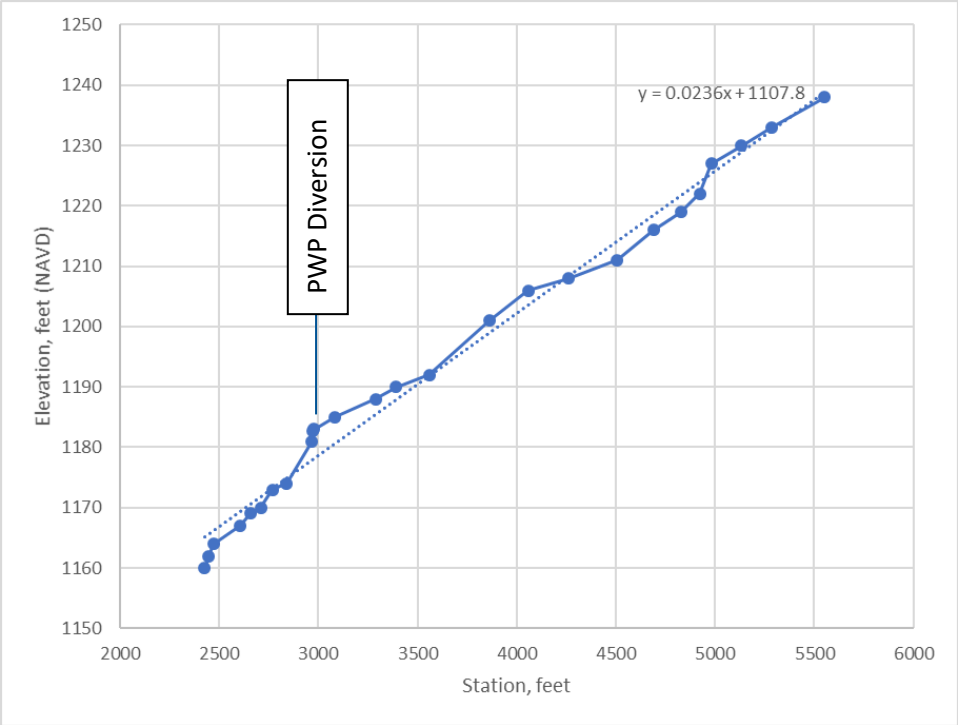

Figure 2.7 Profile of Arroyo Seco near PWP diversion, 2015 topography

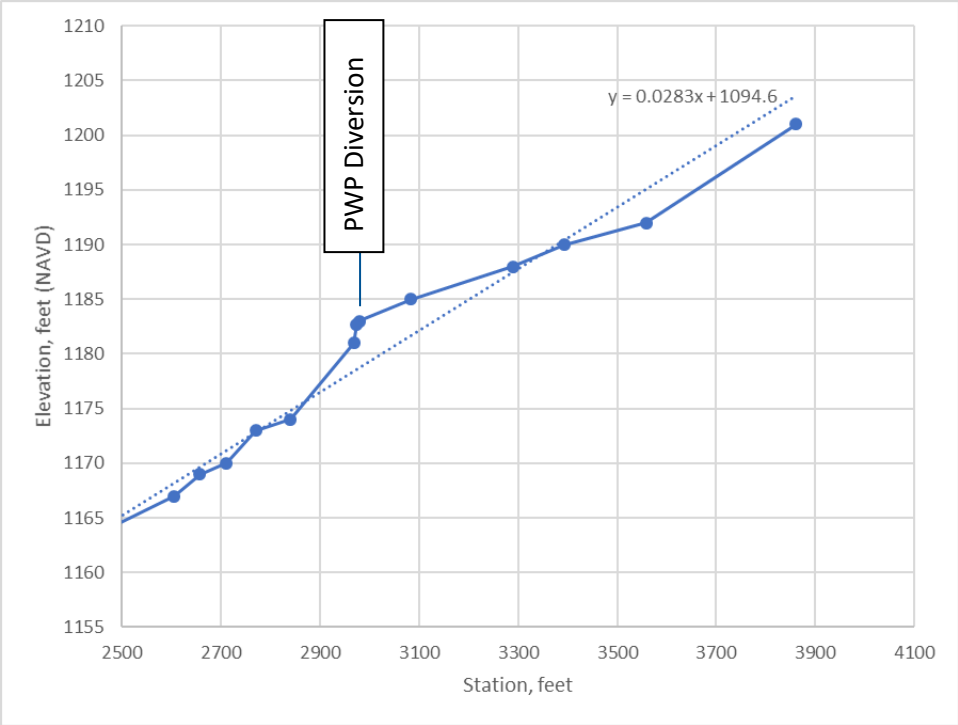

Figure 2.8 Stream slope in immediate vicinity of diversion, 2015 topography

Numerous barriers to aquatic organism passage are present in Arroyo Seco and Los Angeles River downstream of the project area. In the vicinity of the project, Devil's Gate Dam is a complete barrier and the reservoir stream segment above the dam is subject to deposition, channel shifting, and frequent dry conditions due to loss of flow into the alluvium as the channel emerges from the canyon. Upstream of the JPL bridge, partial temporal barriers may be present during low flows due to steep channel segments and step-pool or bedrock drops. An anthropogenic barrier exists at the road crossing approximately 500 feet downstream of the diversion at a channel spanning weir that apparently was the site of a historical stream gage. A drop of approximately three feet occurs at this concrete structure, shown in **Figure 2.9.**

At the diversion, a drop of approximately 2 feet occurs from the base of the flashboard notch to the water surface in the scour pool downstream. The top of the diversion dam is approximately 2.5 feet higher than the notch. A photo of the diversion dam and sluice notch is shown in **Figure 2.10.**

Figure 2.9 Barrier approximately 500 feet downstream of diversion

Figure 2.10 Diversion dam and sluice notch looking upstream

2.3 Fish and Aquatic Habitat

NHC retained Camm C. Swift, PhD, an expert in southern California native fish, to provide input on fisheries conditions in the project reach. The discussion below primarily summarizes information from a review letter provided by Dr. Smith, which is also included as Appendix A (Swift, 2019).

2.3.1 Historical Fish Habitat and Presence

The Arroyo Seco historically provided habitat for seven species of native freshwater fish, namely Pacific brook lamprey, *Lampetra spp.;* Pacific lamprey, *Entosphenus tridentata;* rainbow trout/steelhead, *Oncorhynchus mykiss;* arroyo chub, *Gila orcutti;* Santa Ana speckled dace, *Rhinichthys cf osculus;* Santa Ana sucker, *Catostomus santaanae;*and unarmored threespine stickleback, *Gasterosteus aculeatus williamsoni*. Judging by their occurrences elsewhere in the Los Angeles and Santa Ana rivers, only the dace and trout would have been common in Arroyo Seco from JPL upstream and the others would have primarily been in the lower reaches in habitats with lower gradients.

None except rainbow trout have been recorded as present in Arroyo Seco upstream of Devil's Gate Dam for at least 50 years and probably much longer due to major modifications to the watercourse downstream (Swift, et al, 1993). The rainbow trout is essentially the freshwater resident population of the species; if and when some go to sea to mature and return to the natal stream, they become steelhead. Rainbow Trout were present in upper Arroyo Seco for a long time and the stream was

accessible to steelhead at some time in the past. A population had maintained itself there more or less, possibly augmented by hatchery fish planted intermittently over time, but several surveys since the 2009 Station Fire by CDFW and NOAA biologists have not detected any fish.

No non-native species are known above Devil's Gate Dam except for possibly the descendants of introduced trout. Historical records exist of brown trout being placed in upper Arroyo Seco but there are no recorded observations of brown trout.

2.3.2 Present Conditions

Given the historical presence and successful reproduction of rainbow trout in the watershed upstream of the diversion, the Arroyo Seco watershed is assumed to include habitat in at least some locations that is potentially suitable for future establishment/recurrence of rainbow trout. Vegetation and undercut boulders or rock provide cover, and groundwater upwelling and extensive canopy keeps the water cool enough for them. Even in the dry season a few large pools may provide refuge to support a small population.

In the reach downstream of the diversion, recent observations indicate a few deeper pools with protection of undercut boulders and/or woody debris. However, many reaches are very shallow and exposed and the bulk of suitable habitat is likely upstream of the diversion, as it has been for a long time. The habitat currently present downstream of the diversion could support a small number of trout but clearly only a few tens of small fish, if that. In addition, this habitat is only suitable if pools are maintained during the summer months and it is not clear from recent observations (in a relatively wet water year) whether this is typically the case in late summer and fall. In addition, limited pool areas receive significant recreational use for swimming/bathing, and this disturbance would be adverse for fish in the limited areas available.

The flow duration curve in **Figure 2.3** indicates that flows at the gage upstream are less than 1 cfs almost 80 percent of the time in September, and the gage records indicate that zero flow occurs a large fraction of the time in August and September. Any trout downstream of the diversion would presently be unable to migrate upstream during drying conditions due to long areas of shallow flow and the barrier at the bridge downstream of the diversion. Migration downstream would be impossible due to dry conditions at the head of the reservoir. No fish have been observed in this reach in recent biological surveys.

Very high flows may wash fish downstream to the reservoir where they will likely perish under current conditions and remove riparian vegetation, as noted in recent observations of single age class stands of riparian trees. In addition, sediment delivery associated with mass wasting processes or wildfire may bury suitable substrates and vegetation, eliminate cover, and change turbidity and temperatures in the stream. The observations of fish in the Arroyo Seco watershed before the Station Fire and no observations almost a decade later are indicative of the significance of these types of events to fish populations.

Although suitable habitat may be present for reestablishment of rainbow trout in the upper watershed, anadromy is currently prevented for steelhead trout by multiple significant barriers downstream,

including the Los Angeles River flood control channel and Devil's Gate Dam. Access to upstream spawning and rearing habitat may also be limited by Brown Mountain Dam, located about 3 miles upstream of the diversion.

2.3.3 Future Conditions

The Southern California Steelhead Recovery Plan (NOAA, 2012) describes priority actions for recovery of steelhead in the region, including the Los Angeles River basin. The Los Angeles River is listed as a Core 3 population, indicating lower priority than some other regional streams with Core 1 and Core 2 populations. The Recovery Plan lists removal of barriers at dams, diversions, roads, and other structures as a priority action in the Los Angeles River biogeographic region. Steelhead recovery in Arroyo Seco would involve modification of multiple flood control facilities and removal of multiple barriers between the project area and the ocean, but efforts are underway to investigate the potential of restoring anadromous access in the Los Angeles River. For example, the Council for Watershed Health is currently working under a grant from the Wildlife Conservation Board to investigate and design passage and habitat features in a portion of the Los Angeles River. Access to tributaries and headwater areas for spawning and rearing would be a vital part of any recovery strategy for steelhead in the watershed. Speckled dace or arroyo chub might also be considered for re-establishment on lower gradient portions of the stream but are considered unlikely to survive in the mountainous conditions of the upper Arroyo Seco.

3 DESIGN OBJECTIVES AND CRITERIA

3.1 Diversion Flows

The proposed surface diversion is intended to provide a reliable source of surface water diversion throughout the year and over a range of flows. Diversion during flood flows is not anticipated due to high turbidity levels and risk to diversion facilities. PWP currently diverts most of the flow when flows are below their full water right of 25 cfs and is planning to divert 25 cfs up to a higher threshold before shutting down the diversion and allowing more turbid flow to pass downstream. Potential thresholds considered have included 50 cfs, 100 cfs and higher values. For the purposes of this report, a threshold of 100 cfs is referenced, but this may be adjusted in the future based on a better understanding of the relationship between turbidity and stream flow, and refinement of the fish protection and sediment management design approaches. A primary benefit of the modified diversion will be to allow diversion during higher flows, at least during periods when turbidity and suspended sediment concentrations are considered acceptably low. The previous design for the diversion (Deere and Ault, 2017) utilized an operable weir in a modified diversion structure, and this basic configuration was retained for the current design effort.

3.1.1 Instream Flow

CDFW draft permit conditions and comments on the previous design refer to the need to maintain instream flows downstream of the diversion, but do not provide specific targets. PWP conducted a study to address CDFW concerns and concluded that the diversion does not impact habitat in the downstream reach such as to require a release of surface water for instream flow, as long as the flow of groundwater remains unobstructed (Psomas, 2018). The present condition of seepage past the dam was intended to be maintained by constructing a modified structure at similar depth. No instream flow release criteria have been used in the preliminary design, but the diversion design includes gates and piping that would allow for release of surface water for instream flow in the future, if such requirements are developed. Instream flow releases would not, however, prevent flows from becoming very low or zero when natural inflows are low. Based on the flow duration analysis, this occurs during most years in the summer and fall.

3.2 Operation of the Diversion Weir

The proposed design for the diversion uses an operable weir to pond water at the intake during flows below an operating threshold. The proposed diversion weir will be operated to divert up to 25 cfs through the intake and pass all remaining flow downstream. The weir will be fully raised during low flows and will modulate during stream flows between 25 cfs and 100 cfs to maintain 25 cfs through the intake. Once the high flow threshold of 100 cfs stream flow is reached, the weir will be fully lowered. Operating criteria will need to be established for lowering the weir at a controlled rate to avoid rapid changes in upstream water surface that might result in stranding or other adverse conditions for aquatic organisms, and rapid increases in flow downstream that exceed the naturally high rates due to storm events.

The operable weir concept has advantages for managing sediment and minimizing effects on the channel morphology. Flow in the channel is relatively shallow at the diversion flow rates and a small range of streamside operating water levels is desirable to manage sediment, minimize drop to the downstream channel, and minimize the size of the operable weir required. It is desirable to set the open weir crest elevation slightly below the intake invert to allow for some sediment accumulation upstream of the dam without entraining it in the diversion and screens. During periods of high flows, lowering the weir would allow removal of accumulated sediment by erosion and transport downstream, to restore the streambed elevation to the crest of the notch. An operational plan is needed to turn the diversion out and flush accumulated sediment, if needed prior to stream flows reaching the threshold at which the crest gate would be lowered. The crest gate can be divided into sections to facilitate level control and sediment removal. An objective of the design is to provide operational flexibility with the crest gates to avoid the need to excavate sediment out of the stream bed in the vicinity of the intake.

3.3 Stream Habitat

In NHC's August 2019 site observations in the reach downstream of the diversion, flows on the order of 0.5 cfs were maintaining isolated pool habitats and relatively cool water. However, this is based on a

single site observation and may not be characteristic of all years. The physical habitat associated with the channel bed and banks includes a mixture of coarse sediments and riparian vegetation that could support aquatic species, including fish. Limiting factors for fish include low or zero flows in the late summer and fall, associated loss of connectivity and isolation of pools, and numerous bedrock and boulder drops that would prevent mobility during low flows.

Upstream of the diversion, physical habitat conditions appear to be similar and dry weather flows are higher, although still subject to low or zero flows in late summer.

3.4 Fish Protection

Fish are typically protected from entrainment in diversion flows using a screening system. CDFW (2002) and NMFS (1997) have published screen design criteria for anadromous salmonids. The criteria established by the two agencies are similar, and include requirements for screen size opening, screen approach velocity, and sweeping velocity. CDFW guidance expresses a preference for on-channel screens but provides criteria for off-channel screens as well. Numerous screen types and configurations have been used for exclusion of fish including end of pipe screens, cone screens, cylinder screens, drum screens, vertical screens, and horizontal screens.

A key criterion for screen sizing is approach velocity, the velocity vector component perpendicular to the screen, as this determines the screen area required. CDFW and NMFS criteria for salmonid fry set design approach velocity at 0.33 fps for on-channel screens and 0.4 fps for off-channel screens. Much lower values apply if the screens are not self-cleaning (passive). Sweeping velocity, the velocity vector component parallel to the screen, is typically designed to be greater than the approach velocity.

Although off-channel screens are considered less desirable in the CDFW guidance, potential advantages include lower potential for damage during floods and better control over depth and velocity distribution on the screens.

Based on the review of fisheries conditions in the project area, the screens will be designed for approach velocities consistent with protection of salmonid fry as described in the CDFW and NMFS guidance.

3.5 Aquatic Organism Passage

The existing diversion structure presents a barrier to passage due to the drop height, limited flow width through the flashboard slots, and high velocities during high flows.

Passage of fish downstream during diversion operations would result in fish being transported to the downstream reach and reservoir area in low flows. Under current conditions, fish may perish in this reach due to isolation or stranding in low or zero flow periods. The preliminary design focuses on excluding fish from the diversion and downstream reach while considering potential for future downstream passage during diversions if connectivity is re-established for passage through Devil's Gate Dam and downstream channels to the ocean.

The diversion weir will be lowered during periods of higher flows, and some passage of fish downstream may occur during these periods. The preliminary design will include features to allow upstream passage when the weir is lowered, and diversions are not occurring.

CDFW (2002) and NMFS (2019) standards for adult salmonid high fish passage design flows are typically the 1 percent exceedance flow or 50 percent of the 2-year flow. Juvenile salmonid high fish passage design flow is typically the 10 percent exceedance flow or 10 percent of the 2-year flow. **Table 3.1** shows potential fish passage design flows based on these criteria and analysis of the stream flow records for Arroyo Seco. It should be noted that low design flows provided by the criteria may not be passable in adjacent stream reaches due to the natural bed morphology. Additional analysis may be necessary to establish appropriate low fish passage design flows based on hydraulic characteristics of critical riffles or drops in adjacent reaches, but preliminary designs were evaluated based on the standard criteria listed.

Table 3.1 Potential fish passage design flows

High Design Flows	**% 2-Year**	**Q, cfs**
Adult Anadromous Salmonid	50	306.5
Juvenile Salmonid	10	61.3
Low Design Flows		**Q, cfs**
Adult Anadromous Salmonid		3
Juvenile Salmonid		1

As noted above, the design considers the need for potential downstream passage at the diversion if safe passage to the ocean is re-established downstream. The design should also consider the potential need for future upstream passage at the facility during diversions, if connectivity from the Pacific Ocean is re-established and steelhead are able to ascend the stream.

3.6 Flood and Erosion Protection

The design should allow flood flows to pass the intake, while minimizing potential for substantial damage to the facilities, and without significant adverse impact on the roadway or other infrastructure compared to existing conditions.

Very high velocities occur during flood flows and native bed materials include large rock, boulders, and bedrock. Some use of rock is needed in the design to stabilize the bed and bank against future flood events. Assuming an ample source of native rock, natural materials can be used to design fish and wildlife friendly biotechnical bed and bank stabilization that matches natural conditions in the stream as much as possible and minimizes the use of structural concrete and grouted rock. However, because of the high velocities during flood flows, some use of these materials is anticipated.

Where feasible, vegetation should be incorporated into the design to reduce velocities and boundary shear stresses, especially in areas adjacent to the main channel such as the left overbank downstream of the diversion. The design will be based on hydraulic model output, geomorphic assessment of potential profile and lateral adjustments, computation of stability for various material types, and incorporation of scour protection.

4 BASIS OF DESIGN

4.1 Project Elements

All project elements are shown on the preliminary (30%) plans included in Appendix B and are described in the following sections. It should be noted that final design plans will include a survey map showing current topography, existing structures and trees within the project area. Project elements include the following: diversion weir, downstream roughened channel, diversion intake and fish screens, gates and controls, the intake service building, and potential future elements including instream flow release, fish bypass and fishway.

4.2 Diversion Weir

4.2.1 Structure and Gate Type

The proposed diversion control structure spans the entire width of the existing channel in the same general location as the existing structure. A 30-foot long operable weir crest gate is located in a notch section of the structure. The diversion weir may be designed to operate using cable, hydraulic, or inflatable operating mechanisms. The design is investigating the potential for the weir to be split into two crest gate sections, 10 feet and 20 feet in length, so that the shorter section can be used for normal operations. The invert of the gated notch section is set at an elevation of 1177.8 feet, approximately 4 feet lower than the existing diversion weir, and the crest gates will raise to a maximum elevation of approximately 1183.0 feet. The structure section is 7.5 feet wide in the stream longitudinal direction and has a top elevation of 1183 feet.

The lowered crest elevation of the structure is based on review of stream profile and existing diversion information. The lowered crest is intended to reduce the structure's effects on hydraulics and sediment transport in the stream when the gate is lowered, while allowing diversion to the existing pipeline that conveys flows to the recharge facilities. The notch width in the diversion structure was set by estimating the active bed width of the stream upstream and downstream of the diversion and by evaluation of two-dimensional (2D) hydraulic modeling results to attempt to provide a velocity distribution similar to adjacent stream reaches.

Additional geotechnical investigation is required to support the design of the new diversion structure, including the foundation for the structure, effect of the structure on seepage flows, foundation for the right abutment, and the tie-in to the existing valley slope to prevent flanking.

4.2.2 Operation and Controls

Operation of the crest gates will be controlled by water depth measurements from a transducer located immediately upstream of the diversion. The transducer will communicate with a programmable logic controller (PLC) housed in the Intake Service Building. The PLC will control the modulation of the diversion weir gates to accurately deliver flow through the intake.

The diversion weirs will remain fully raised until the total streamflow reaches 25 cfs at an upstream water surface elevation of 1183.45 feet. The diversion weirs can then be modulated to maintain this water surface elevation, and the full 25 cfs diversion, up to a total streamflow of 100 cfs, at which point the weirs will be fully lowered and the intake will be isolated from the stream.

A diversion gate on the downstream side of the screens has the capability for automatic and remote operation such that the diversion flows can be fully shut down when the crest gates lower. Full isolation of the intake would be accomplished by manual installation of bulkhead flashboards upstream of the screens.

4.2.3 Effects of Flood Flows

A preliminary evaluation of hydraulic characteristics of Arroyo Seco in the project vicinity under existing and proposed conditions was completed using the HEC-RAS computational package developed by the Hydrologic Engineering Center of the U.S. Army Corps of Engineers (USACE). A 2D model of existing conditions was developed using 2016 LiDAR topography, and was modified for proposed conditions. For purposes of preliminary comparison, the Manning's roughness value for both models was set to 0.06 for all cells in the 2D flow area, representing the composite roughness of the floodplain vegetation and channel bed material. In the next phase of design, 2D modeling will be refined to include additional land surface categories with varying roughness values.

Peak 2-year, 10-year and 100-year peak velocities through the project vicinity for existing and proposed conditions are shown in **Figures 4.1** through **4.6** (flow direction is from top to bottom). These results indicate that under proposed conditions, when the gates are fully down and the crest elevation is approximately 4 feet lower than the existing weir elevation, flood water surface elevations (indicated by extent of inundation in the figures) are at or below existing conditions and maximum velocities are similar to existing condition. The figures show flood flows greater than about the 10-year flow spilling out of the channel under existing conditions, and 100-year flows spilling out of the channel in both existing and proposed conditions. These results will be refined as the design progresses but are generally consistent with observed behavior in the 2010 event.

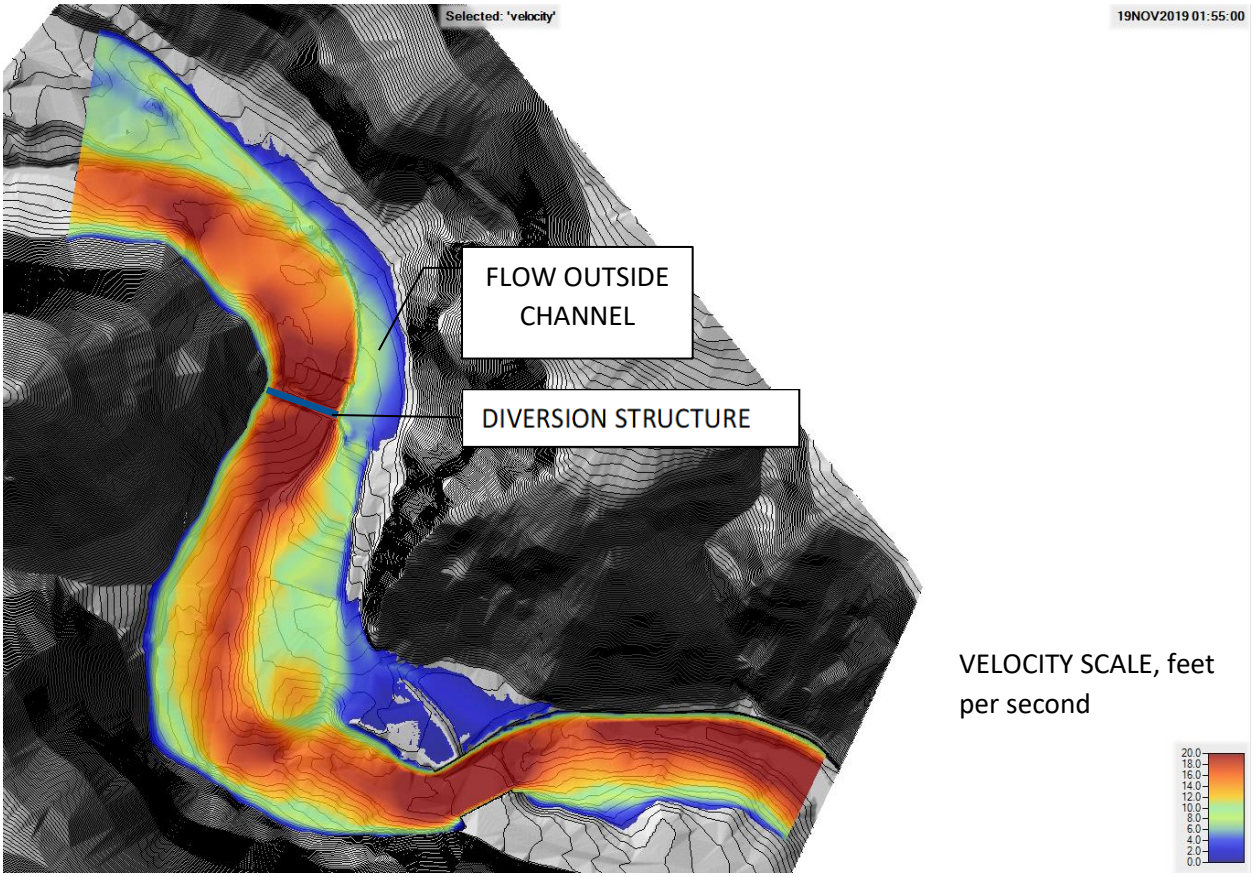

Figure 4.6 100-year flood extent and peak velocities, proposed conditions

4.3 Roughened Channel

The existing diversion structure creates a drop in stream profile and is a barrier to aquatic organism passage under most flows. In the proposed design, a roughened channel section downstream of the diversion structure is proposed to allow upstream passage when the weir crest gates are lowered.

Roughened channels are an accepted method of providing passage for steelhead trout in CDFW's Salmonid Stream Restoration Manual (CDFW, 2010), requiring site specific design and review. The roughened channel configuration proposed is a channel approximately the width of the active channel in adjacent stream segments, with an asymmetric v-shaped cross section to concentrate lower flows and provide adequate depth. Compared to other potential types of upstream passage features, the roughened channel type has the advantage of providing a range of velocities and depths at a given flow rate. Thus, smaller or weaker swimming native fish and other aquatic organisms can pass along the margins of the channel or near the bottom, using spaces in the bed material for hydraulic cover.

The roughened channel design follows the depth and velocity criteria established by CDFW (2002) and NMFS (2019) guidance for fish passage at road crossings, shown in **Table 4.1**. These criteria are typically

assumed relevant for design at features other than road crossings, but roughened channel designs are considered on a case-by-case basis for specific sites.

Table 4.1 Depth and velocity criteria from CDFW and NMFS road crossing guidelines

Species	Min Depth, ft	Max Velocity, fps (<60 ft passage length)	Max Hydraulic Drop, ft	Notes
Adult Anadromous Salmonid	1.0	6	1	
Juvenile Salmonid	0.5	1 1 (2 short distance)	0.5 1	CDFW NMFS

The proposed roughened channel profile slope downstream of the diversion weir is 4%. This is about twice the average bed slope and thus would be reasonably similar to a natural steep section or chute in the adjacent reaches of channel. The proposed typical channel section is an asymmetrical v-section with dimensions as shown in **Figure 4.7**.

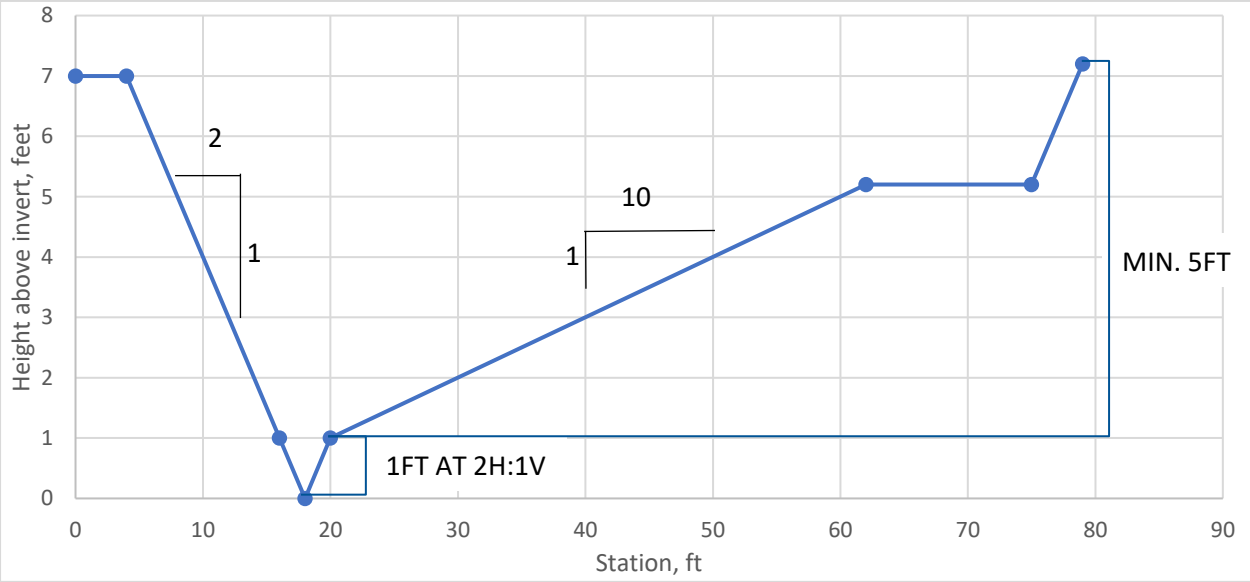

Figure 4.7 Typical Roughened Channel Section

Potential passage conditions were assessed using HEC-RAS over a range of flows based on channel cross sections constructed of Engineered Streambed Material (ESM). The size of a stable ESM was estimated using the CDFW guidance (2009) for roughened channels. The CDFW equation is based on the USACE (EM 1110-2-1601 Hydraulic Design of *Flood Control Channels*, 1994) equation for steep slopes, but is modified to produce a well-graded mixture of rock, gravel and sand similar to natural streambeds. One of the key parameters in the CDFW equation is slope. Using the bed slope (4%), the D84 rock size to resist motion in the 100-year flood event was estimated at approximately 6 feet, and the D50 at 2 to 3 feet. These sizes are probably impractical or at least very costly for construction, and extremely large

rock will potentially make fish passage difficult at lower flows. However, at the 100-yr flow, the slope of the energy grade line is approximately 2.6%, which is closer to the overall slope of Arroyo Seco. Using the energy grade slope, the D84 rock size was estimated at approximately 4.7 feet, and the D50 at approximately 2 feet. These sizes are more practical for use in construction and were adopted for the preliminary design. It should be noted that some potential for damage during extreme events will remain, and maintenance of the roughened channel may be required after large events to repair damage and maintain conditions for fish passage. Details for the ESM sizing calculations, gradations and assumptions can be found in Appendix C.

A one-dimensional (1D) HEC-RAS model was used to simulate the high and low design flows for juvenile and adult anadromous salmonid fish passage for cross sections representing the roughened channel. For this assessment, depth-dependent roughness values were estimated using the Mussetter equation, following methods provided in the CDFW (2009) guidance.

Figures 4.8 and 4.9 show the depth of flow and velocity distributions from the 1D model in a typical channel section representing the roughened channel under high design flow conditions for juvenile salmonids and adult anadromous salmonids. Maximum channel velocities under proposed conditions are approximately 4 fps for the juvenile high design flow and 8 fps for the adult passage flow. The velocity plots indicate the potential importance of channel margins for passage at higher flows, where lower velocity zones meeting the passage design criteria are maintained.

Figures 4.10 and 4.11 show the depth of flow and velocity under minimum low design flow conditions for juvenile salmonids and adult anadromous salmonids. The 1D model does not fully represent the complex shape of the low flow portion of the channel formed by intersecting rock surfaces, but the roughness estimate is intended to approximate the effect of an irregular flow path. Results indicate that depth and velocity conditions consistent with design criteria could be met.

At flows above 25 cfs, there is some potential that fish would pass over the weir, and a cushion pool downstream of the weir at the head of the roughened channel would be desirable to prevent injury.

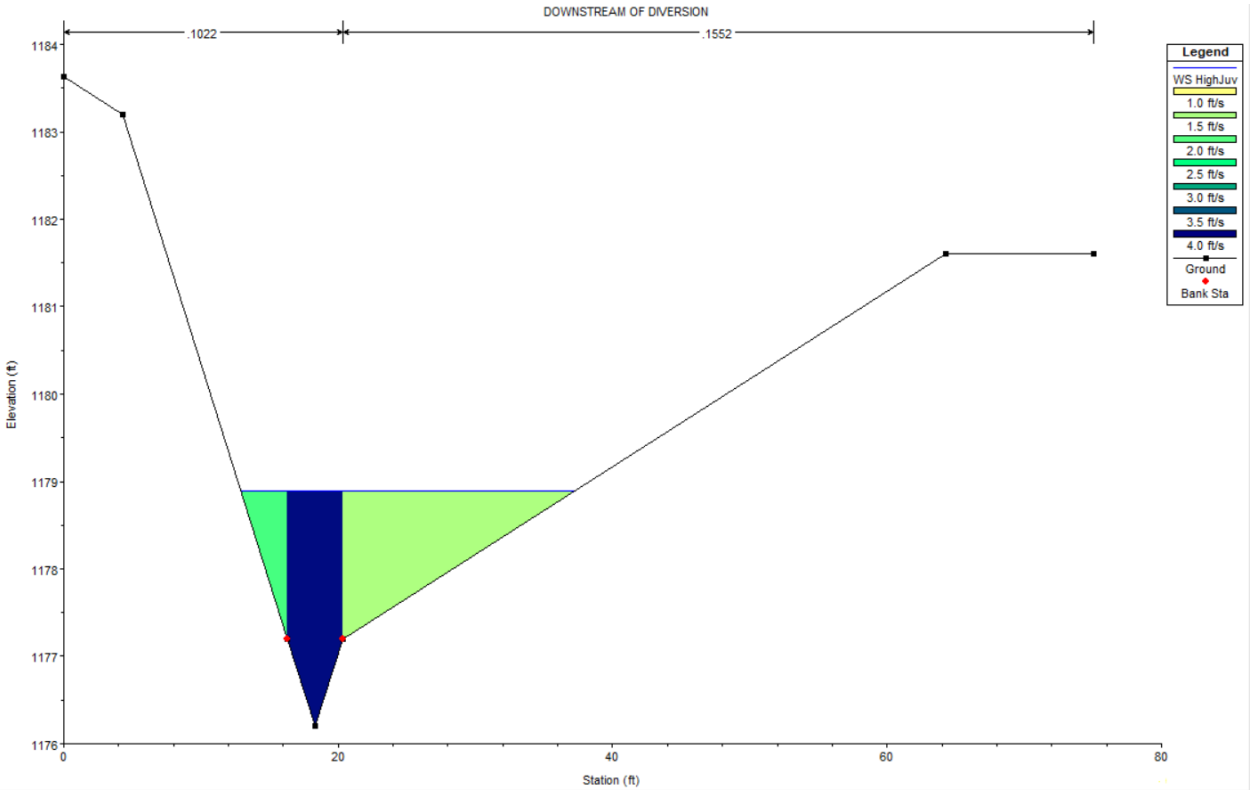

Figure 4.8 Hydraulic model proposed roughened channel cross section showing flow depth and velocity distribution at high design flow for juvenile fish passage (61.3 cfs)

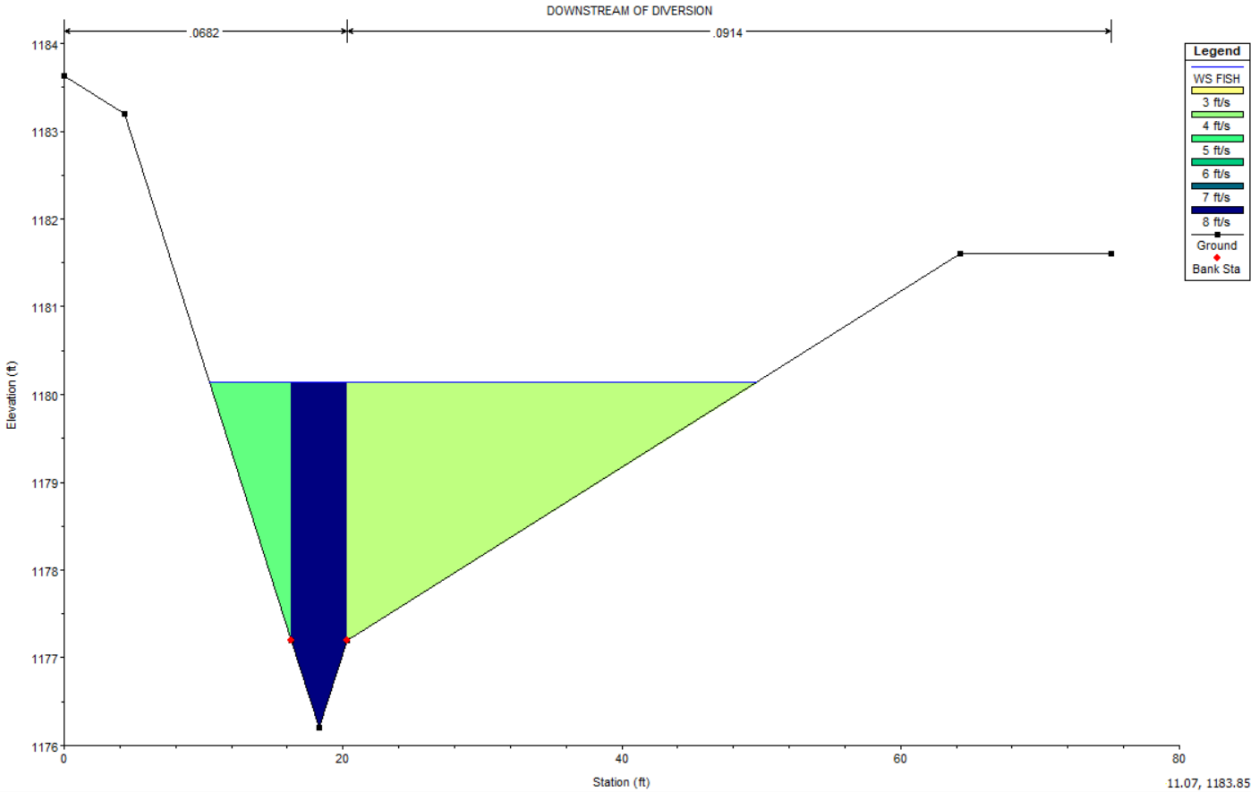

Figure 4.9 Hydraulic model proposed roughened channel cross section showing flow depth and velocity distribution at high design flow for adult anadromous salmonid fish passage (306.5 cfs)

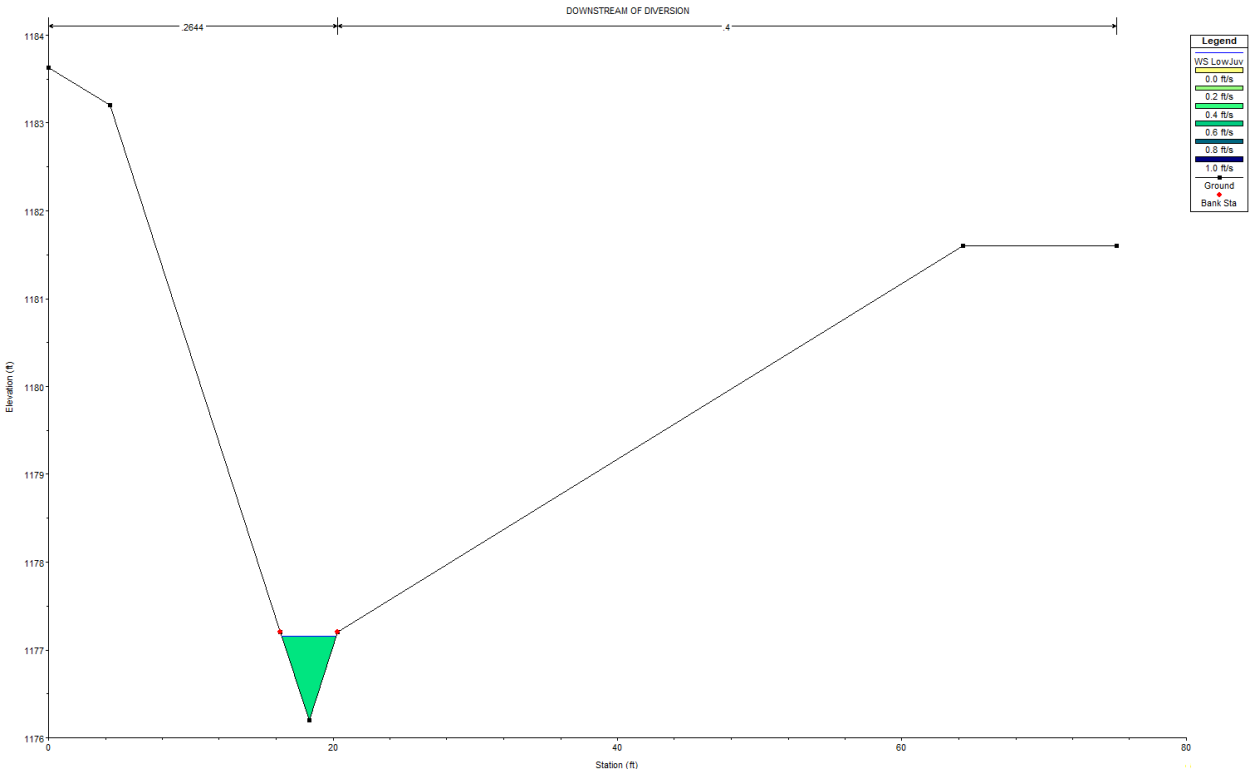

Figure 4.10 Hydraulic model proposed roughened channel cross section showing flow depth and velocity distribution at low design flow for juvenile fish passage (1 cfs)

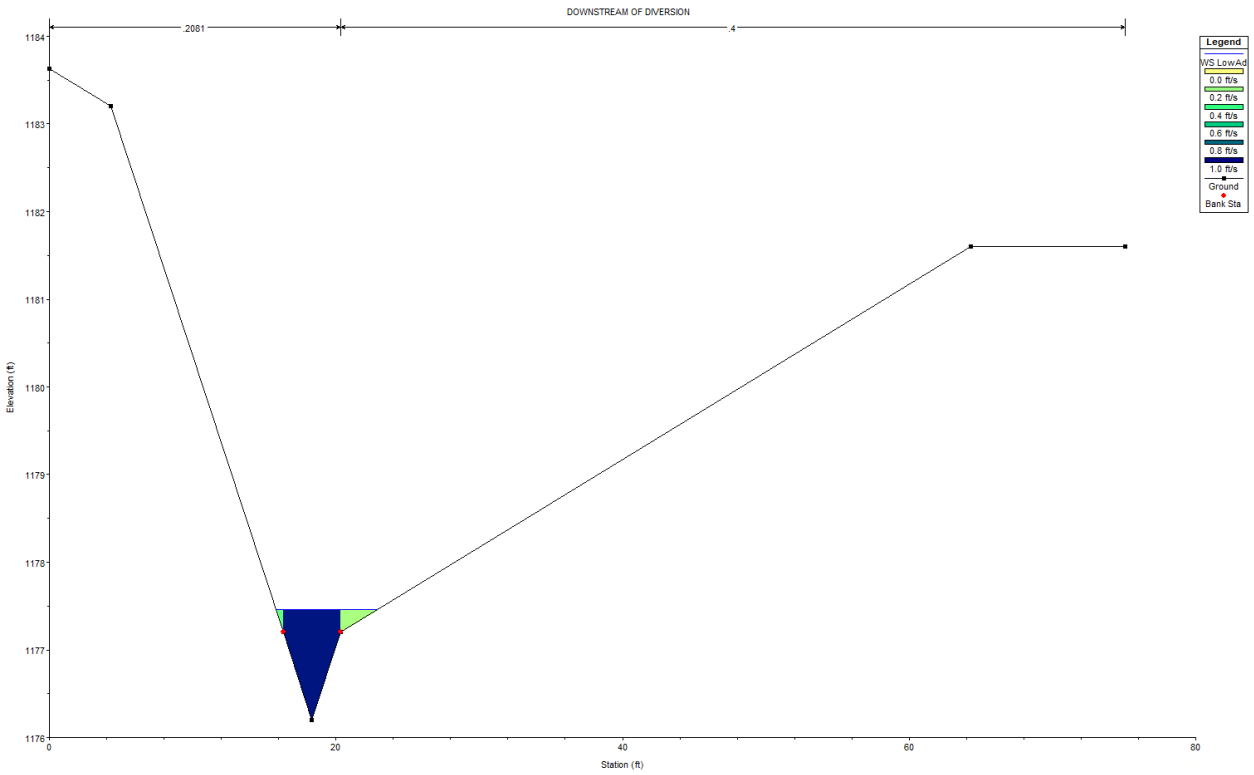

Figure 4.11 Hydraulic model proposed roughened channel cross section showing flow depth and velocity distribution at low design flow for adult anadromous salmonid fish passage (3 cfs)

The crest gate sill elevation was selected to more closely represent the general profile of the stream without the influence of the existing diversion. This will promote sediment transport continuity through the diversion reach during larger flows when bed material is mobilized and when the crest gate will be down. Grading upstream of the structure during construction will be limited to the immediate area of the diversion, and some evolution of the stream profile can be expected after construction. Bed material that has aggraded upstream of the structure is expected to be transported downstream, establishing a more uniform profile upstream of the diversion.

4.4 Intake Components

The proposed diversion intake is located on the left bank of the stream immediately upstream of the diversion weir. The intake is equipped with a trash rack mounted parallel to the stream flow and a bulkhead, allowing the diversion to be shut off during flood flows. Two configurations for the intake and screen bay were developed. The first configuration places the screens along the left bank of the stream immediately behind the trash rack. The second configuration uses an intake angled upstream and a tapered off-channel screen bay. **Figure 4.12** shows the conceptual layout for the two options. After review with the City, the tapered screen bay option was selected for use in the preliminary plans for its ability to flush sediments through the bay, protection of the screens, and potential adaptability in future

conditions for passage of fish downstream. Potential disadvantages are that any fish that enter the screen bay under present conditions would be further from the stream and might not find their way back to the channel as easily. The tapered bay would ultimately allow a sweeping velocity to meet design criteria when used with a downstream fish bypass, but prior to that time the sweeping velocity would decrease through the bay. Review with CDFW is anticipated prior to advancing the design.

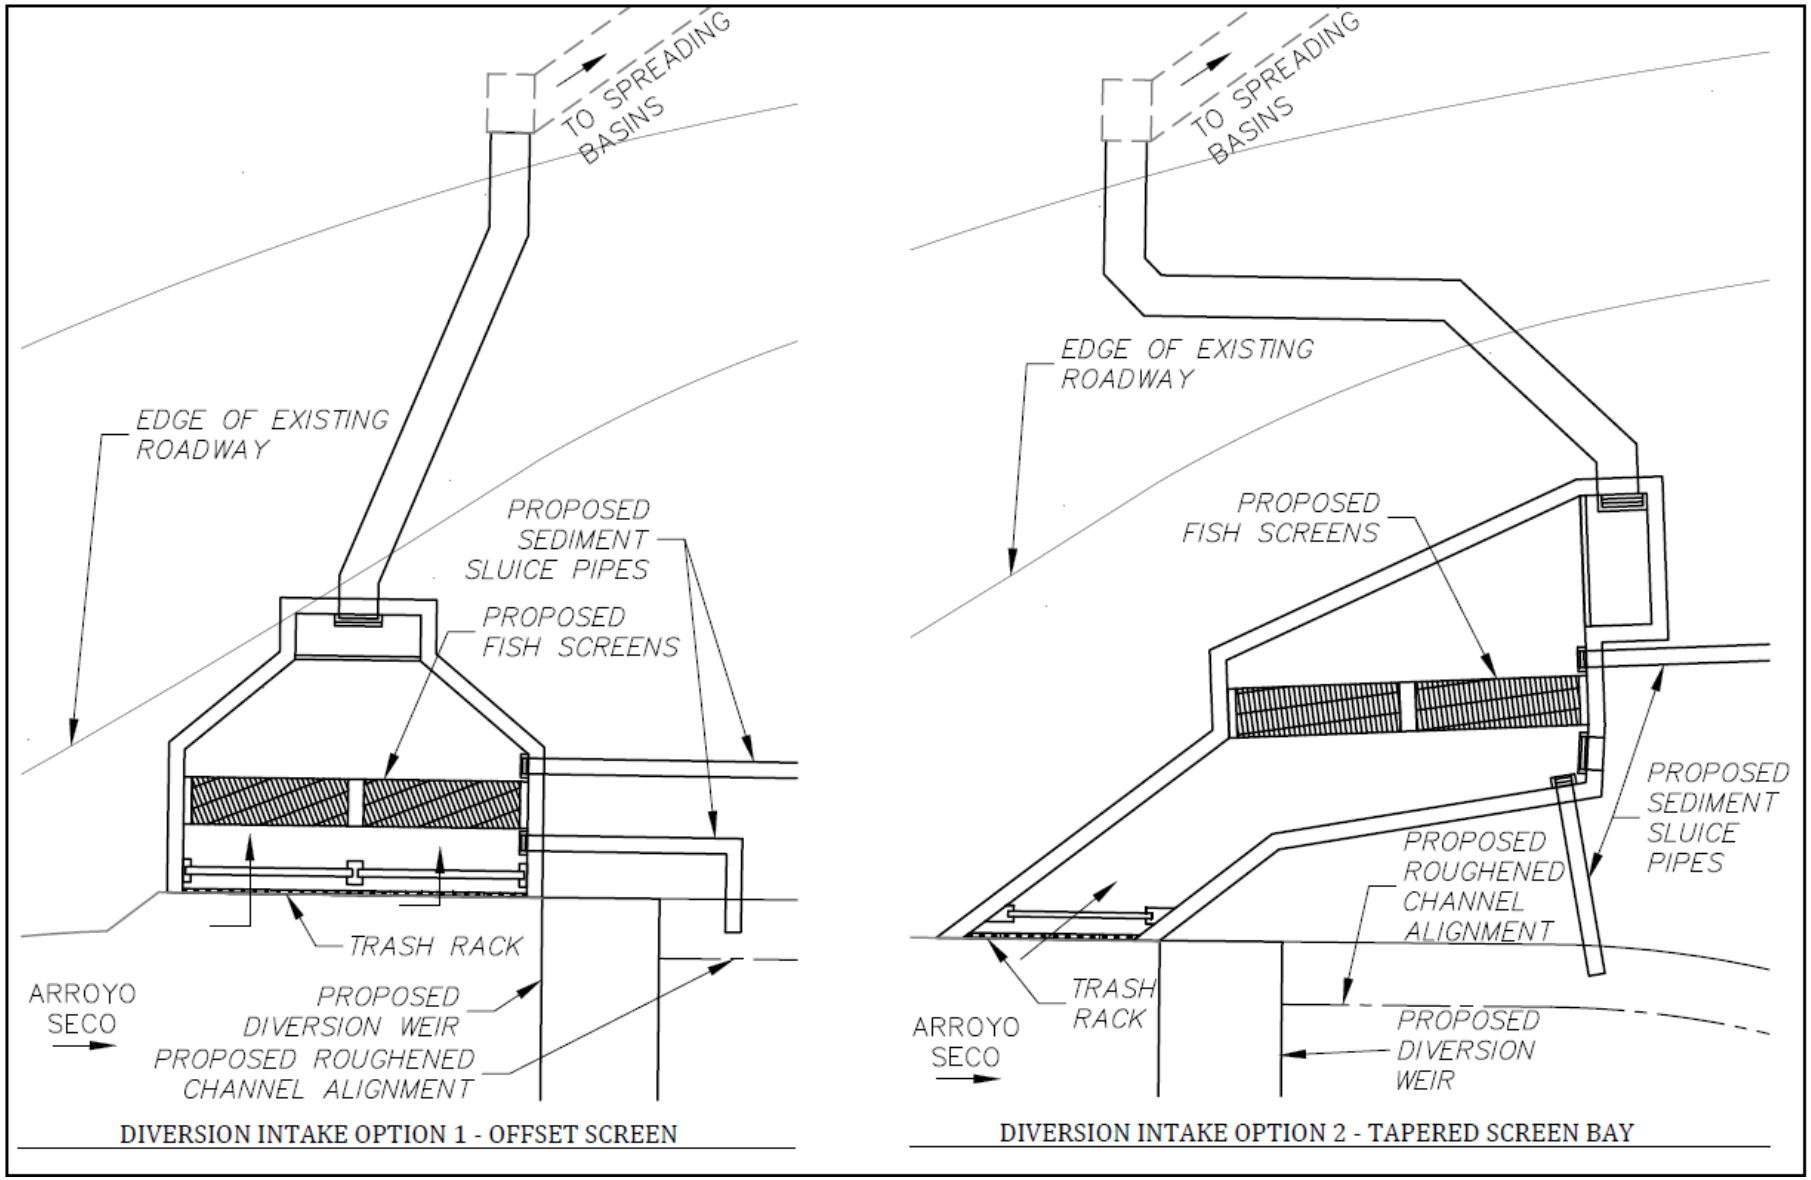

Figure 4.12 Screen bay configuration options (not to scale)

The intake shown in the drawings in Appendix B is an angled approach channel to a tapered fish screen bay. The tapered bay ends at a 12-inch diameter slide gate and flushing pipe for removing sediment and small debris build-up in front of the screens. Potential for future fish bypass at this location is described in Section 4.6.

The screening system will be designed to meet current NMFS and CDFW design guidelines for approach velocity. For a 4-foot diameter drum screen and a maximum approach velocity of 0.4 fps at the maximum diversion flow of 25 cfs, the minimum screen length required is approximately 20 feet. For ease of fabrication, installation and maintenance, two 10-foot-long drum screens are proposed.

Vertical screens and drum screens were considered for use at the site, and the preliminary design is laid out for use of drum screens. Drum screens are frequently used in small irrigation diversions and consist of a cylinder of screen material that rotates in the flow. The rotating action is used to clean small debris from the screen. The drum screen was initially conceived based on the configuration with the screens immediately behind the trash rack but was retained for use in the tapered screen bay. Additional review with the screen manufacturers and CDFW will influence the final selection of screen type.

Under current conditions, no flow would normally be bypassed from the upstream side of the screen bay and sweeping velocity will decrease along the screens. In this configuration, sweeping velocity is not relevant to downstream passage, as fish would be excluded from the downstream reach. At the 25 cfs design flow, sweeping velocity is approximately 1 fps at the bay inlet, and approximately 0.4 fps after traveling three-quarters of the length of the screens. See Appendix C for sweeping velocities along the length of the screen across a range of design flows without a bypass flow.

A second 12-inch diameter slide-gated cleanout pipe is located at the back of the fish screens to remove any sediment build-up behind the screens. This pipe could also be used to convey any future instream flows determined to be needed, as described in Section 4.8.

The final component of the intake structure is the outlet weir, located behind the fish screens. The drums screens must be designed to operate with submergence of 65 to 85 percent of diameter, and tailwater control is needed for this purpose. The design uses an 8-foot-long outlet weir that would be fitted with an adjustable weir plate set at an elevation of approximately 1182.5 feet. In conjunction with the diversion weir, this height maintains a minimum depth on the screens of 2.5 feet, or approximately 70% of the total diameter. Flow over the weir spills to a small vault and a 30-inch diameter slide-gated outlet pipe that conveys the diverted flow to existing Tunnel #4 and the spreading basins downstream.

The hydraulic profile of the system is shown in **Figure 4.13** below. This figure displays the calculated water surface elevation profile over a range of design flows.

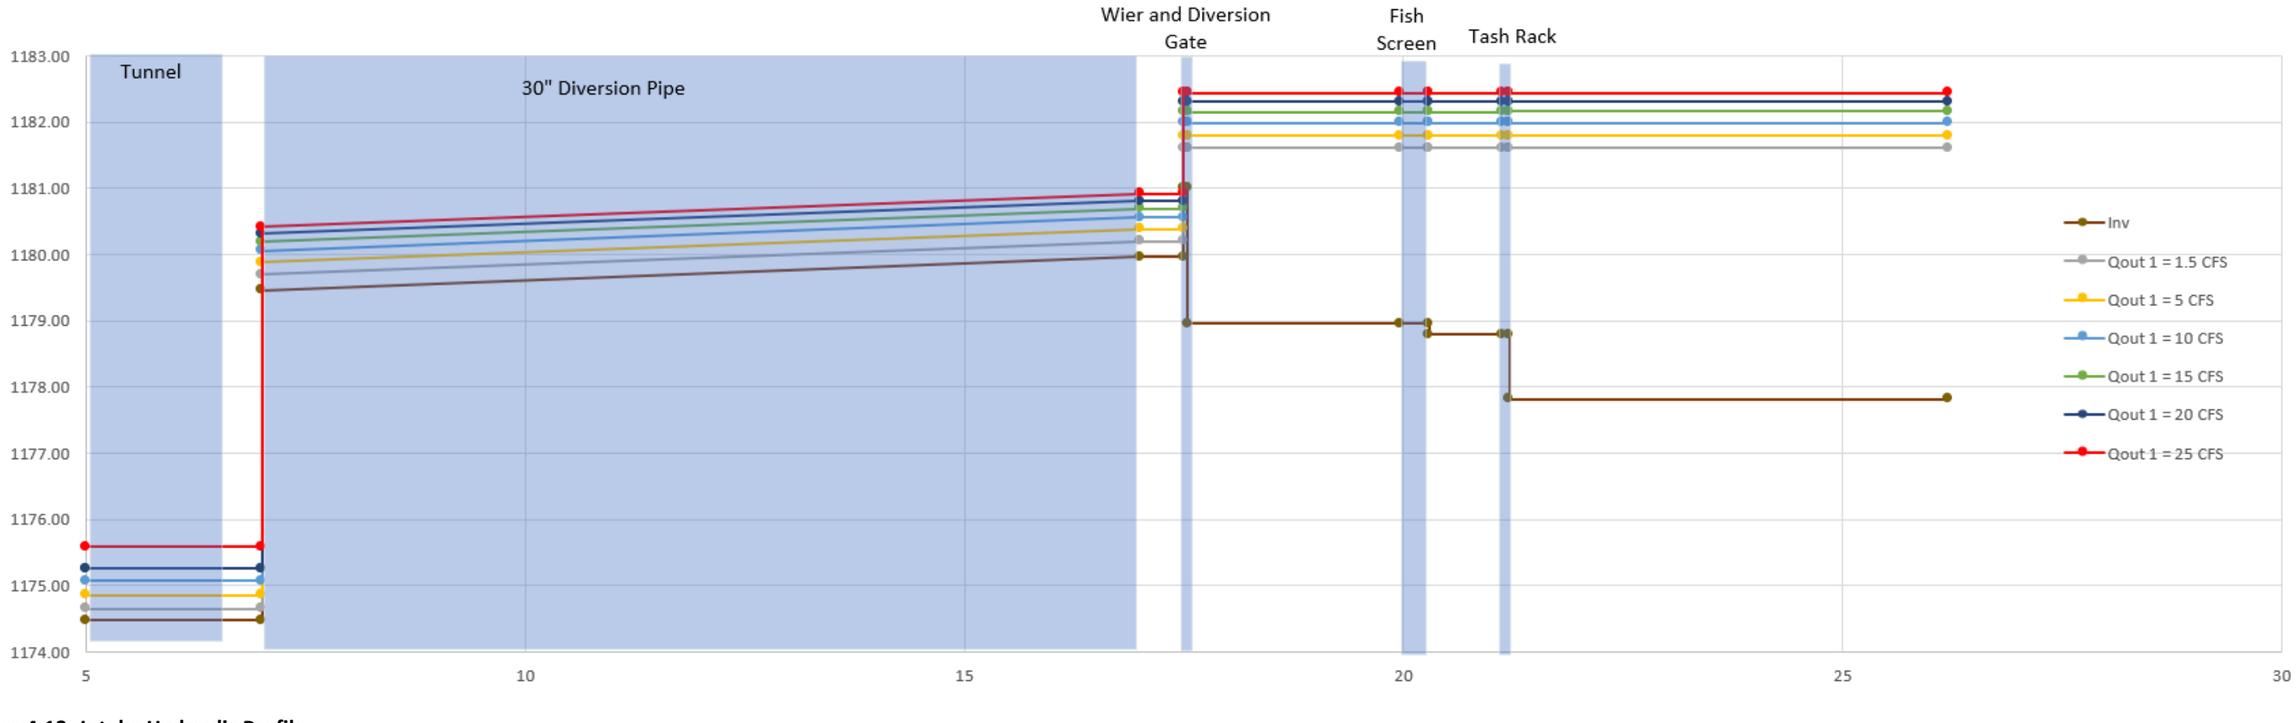

Figure 4.13 Intake Hydraulic Profile

4.5 Gates and Controls

The gate on the 30-inch diameter outlet pipe will be controlled by the PLC and automated based on water surface level readings immediately upstream of the diversion. The gate will close once stream flow reaches the 100 cfs threshold. High flow events will be forecasted and flow into the intake structure will be shut off pre-emptively and manually, using the bulkhead behind the trash rack, to prevent damage and large amounts of sediment and debris from entering the structure. The two 12-inch diameter cleanout pipes will be manually operated for the removal of sediment build-up, during routine maintenance of the intake.

4.6 Road Stabilization

The methods described in USACE Engineer Manual 1110-2-1601 were followed to develop the gradation of rock slope protection for the road stabilization on the left overbank (USACE, 1994). This rock slope protection will protect the roadway and shoulder and will be separated from the roughened channel by a regraded and replanted area. To the extent feasible, this overbank area would be stabilized by vegetative or biotechnical methods, but additional hydraulic analysis will be required to establish design parameters in subsequent design phases.

For the preliminary design of the road stabilization, velocity, depth, and channel curve radius to width ratio were developed from the preliminary 2D modeling results and applied in the USACE rock sizing equation for D30. A previous geotechnical report (Converse Consultants, 2013) recommended use of a Cast-In-Drilled-Hole (CIDH) pile-supported retaining wall along the west side of the road and included general recommendations for rock slope protection. However, this protection was associated with grading that created a slope set back from the stream adjacent to the road. The proposed design would fill the area between the roughened channel to restore vegetated floodplain. This area is proposed to be stabilized by biotechnical methods, with additional rock slope protection along the road, with a toe down into the fill to protect against scour. The geotechnical report included a boring near the southern end of this area that encountered granitic bedrock at less than 5 feet of depth, but site observations indicate that the road is located on a greater depth of alluvial material for most of its length. Additional subsurface exploration may be needed to define the limits of shallow bedrock.

2D modeling for 100-year flow conditions show a depth of approximately 3 feet and a velocity of approximate 9 fps on the left bank. The road stabilization is relatively straight, however the overall channel curves at a radius to width ratio of 4/1, which will direct flows toward the left bank. Using the USACE equation and these input parameters, the D30 rock size to resist motion in the 100-year flood event was estimated at approximately 1.85 feet. See Appendix C for additional details on the sizing calculations. This sizing falls within the range for the USACE typical 42” riprap gradation, shown in **Table 4.2** below. Although this rock could be vegetated, the slope protection is very close to the road and vegetation might reduce roadway clearance. Instead of joint planting the rock, dense planting or biotechnical stabilization is recommended along the toe and transverse to flow between the rock slope protection and the roughened channel.

Although the preliminary modeling indicates depths and velocities that can be addressed using vegetated floodplain and rock slope protection along the road, more detailed 2D modeling will be performed as the design progresses to represent the floodplain area and consider potential risks of erosion during extreme events. Additional measures such as subsurface groins or a return to the retaining wall concept might be considered if the risks are considered excessive.

Table 4.2 Riprap Sizing for Road Stabilization

	Rock Size (ft)
D30 min	1.70
D50 min	2.47
D90 min	2.04
D100 min	2.57
D100 max	3.46

4.7 Intake Service Building

The Intake Service building will house electrical and control equipment and potentially a compressor for operation of the crest gates. The structure could potentially be a prefabricated metal building, concrete masonry unit structure, or wood frame structure. Concrete masonry construction may offer the most protection from vandalism. The need for elevation above the roadway grade or floodproofing will be evaluated in subsequent phases of design.

4.8 Potential Future Components

4.8.1 Optional Bypass Pipe

Downstream fish passage is not considered beneficial in low flows under current conditions. However, the intake design can accommodate an optional 24" diameter slide-gated pipe from the screen bay to bypass fish downstream of the diversion while the diversion is in operation, if safe passage is re-established downstream to the ocean. If a bypass is required in the future, the design would conform to CDFW and NMFS criteria.

4.8.2 Instream Flow

PWP has determined that instream flow releases beyond seepage and leakage at the diversion are not needed to maintain stream habitat downstream. If instream flows are determined beneficial in the future, the proposed design can accommodate release of surface water for instream flows from the downstream side of the screens.

4.8.3 Optional Fishway

Under existing conditions, no fish have been observed in the downstream reach and anadromous passage from the ocean is not possible due to various infrastructure barriers. However, the proposed design can accommodate a future bypass fishway to allow for upstream passage while the diversion is operating, if access for steelhead should be re-established. Preliminary hydraulic calculations for the sizing of a bypass roughened channel pool and chute fishway with a maximum flow of 10 cfs was used to size and develop a preliminary layout for a potential future fishway. Adequate length is provided if the fishway begins immediately upstream of the intake structure and runs to the east, around the outside of the structure, then along the left bank and down the hillslope to connect with the stream at the end of the proposed roughened channel section. Other types of fishways may be considered in the future, but layout of this fishway type provides a conservative check on space requirements. The fishway is not proposed to be designed at this time.

5 CONSTRUCTION CONSIDERATIONS

5.1 Construction Timing

The project will require instream work and will benefit from construction during the lowest flows possible, which would be in late summer and early fall. Some work is outside the limits of the channel and could be performed earlier in the year if other environmental protections are in place in accordance with project permits and mitigation measures. A key schedule constraint may be surveys and monitoring for nesting birds. To the extent feasible, vegetation removal outside the nesting bird season may reduce the risk of delays. Except for potential vegetation removal phasing, the project is expected to be constructed in a single construction season. Some mechanical components, such as fish screens and crest gates may have long lead times for preparation of shop drawings, submittals, and fabrication which should be considered in construction scheduling. Coordination between construction activities in Areas 1 and 3 may also influence construction timing and scheduling and could provide some construction and cost efficiencies in shared or phased use of equipment, materials, and staging areas.

5.2 Elements of Construction

5.2.1 Instream Construction

A temporary stream bypass system, via gravity or pump, will need to be implemented to isolate the project reach from streamflow prior to and throughout construction. If the instream portion of the work is conducted in late summer, typical flows would be feasible to pump around the excavation with a portable pump. Monitoring of weather forecasts and provision for a larger gravity bypass may be needed to address the potential for higher flows that could occur due to rain events as part of a rain event action plan. Dewatering will likely be required for excavation and installation of the diversion structure. Water quality protection measures will be needed for control of turbidity in the dewatering flows and release back to the stream or adjacent infiltration area.

5.2.2 Grading

Grading for the roughened channel design and roadway/hillslope protection is estimated at approximately 2000 CY of cut and 2010 CY of fill. A portion of the cut may be suitable for reuse in the ESM or as other fill on the site. However, because the ESM requires a specific gradation, some or most of this material may be required to be imported. For the purpose of preliminary estimation of haul quantities, approximately 20 percent of the excavated material was assumed to be reused as fill, resulting in a preliminary estimate for import material of 1,600 cubic yards and export of about the same amount. A portion of the export may be used for other areas of the project.

5.2.3 Structures

The intake and diversion structures will be constructed of reinforced concrete. Structural design will be performed in subsequent design steps and wall and footing thicknesses and configurations shown in the drawings are approximate. The intake structure will be designed for access from the ground level adjacent to the roadway, similar to the existing intake vault, and the top is anticipated to be partly solid and partly constructed as removable grating or access cover.

A geotechnical investigation will be required to support design of the diversion structure and intake. A previous geotechnical assessment (Converse Consultants, 2013) addressed stabilization of the roadway at the site but did not include exploration or recommendations for the diversion structure and intake.

5.2.4 Piping

Installation of new piping from the intake vault to the conveyance line is anticipated. The new piping would extend from the outlet vault downstream of the screen bay to an existing vault at the head of the tunnel section of conveyance piping on the east side of the road. Additional piping will be required for flushing pipes from the screen bay and for electrical and control lines. The deepest trenching will likely be associated with the outlet pipe, which is estimated to be about ten feet deep based on the profile in **Figure 4.13**.

5.2.5 Electrical and Controls

Electrical power will be required to operate the crest gates and outlet slide gate. The other small gates and bulkhead are expected to be operated manually. Overhead power supply presently exists to the location of the former traveling screen site and would need to be extended to the diversion site. Automatic control is anticipated for the crest gates and remote control for the crest gates and pipeline outlet gate will be investigated during subsequent phases of design. Methods for providing site security and protection of mechanical and control equipment will also be investigated.

5.2.6 Revegetation

Revegetation for the project would include riparian planting on the left and right banks along the roughened channel and right bank key for the diversion structure. The left overbank area is vulnerable to

erosion during large floods and more intensive biotechnical stabilization may be needed in this area. The preliminary design would restore this area as high vegetated floodplain between the roughened channel and the roadway stabilization slope protection. Revegetation species will be selected based on native species present in the project vicinity, including willow, alder, and sycamore. Willow species may be emphasized in areas with high erosion potential to take advantage of high roughness, low stature, and extensive root systems for reduction of flood velocities and increased stability of bank and floodplain surfaces. Revegetation plans would also consider trees and species that are required to be removed for construction to mitigate these losses.

5.3 Temporary Construction Effects

5.3.1 Access and Public Safety

Construction access to and from the project site will be exclusively via the paved roadway of Gabrieleno Trail, a route used heavily by hikers, equestrians and bikers year-round. Due to the limited width of the existing trail and the intake area, temporary closures and use restrictions may be required during construction. However, the roadway is not anticipated to be fully closed during the entire construction period, and daily access to the USFS residential area should be feasible to maintain. The roadway/trail can be open during times when construction is not active, such as weekends, and when construction activities do not require equipment to be positioned in the roadway. Construction activities would be isolated with construction fencing, and temporary traffic control may be required for some activities. An access plan and project schedule will be required as part of construction contract administration to minimize closure and restrictions on use of the roadway.

5.3.2 Control of Water and Water Quality Protection

As noted above, a temporary stream bypass and dewatering facilities with water quality protection for discharges back to the stream will be required. In addition, the project will require development and implementation of a Storm Water Pollution Prevention Plan (SWPPP) for construction Best Management Practices (BMPs) for erosion control and water quality protection.

5.3.3 Material Import and Export

Hauling of import and export materials is anticipated to be in conventional road legal dump trucks with loads not to exceed standard highway limits. Approximately 1600 yards each of import and export is currently estimated, which may require approximately 200 truck trips. This estimate will be refined in subsequent phases of design. Stockpiling area is very limited at the site and the opportunity for back hauling to reduce truck trips and cost may be limited.

5.3.4 Dust Control and Noise

Sweeping and watering will need to be used for dust control during construction. Construction activities should be limited to normal working hours on weekdays, unless otherwise approved by PWP, and noise levels from construction equipment would be limited to 85 dBA at 100 feet as provided in the City

Municipal Code. If a pumped stream bypass is used, night operation of a generator and pumps may be needed, and a sound enclosure should be considered for this application in the subsequent phases of design.

5.3.5 Operations and Maintenance

A detailed operations and maintenance plan will be developed during the detailed design phase to address normal operation of the crest gate, fish screens, sediment management, mechanical components, control system, security, structural integrity, and other elements of the project. The operations plan will include procedures for shutting down the diversion during high flows and for post-flood inspections and repairs.

FISHERIES REVIEW LETTER, DR. CAMM SWIFT

October 29, 2019

To: Ed Wallace

Northwest Hydraulics Consultants

200 S Los Robles Avenue, Suite 405

Pasadena, CA 91101

From: Camm C. Swift, PhD, 6465 Elmo Road, Cumming, Georgia 30028

Subject: Fish and fish passage related to Pasadena Water and Power Department diversion on Arroyo Seco above Pasadena.

Pasadena Water and Power Department (PWP) has a water diversion on Arroyo Seco that requires upgrading and repair. Part of this work involves consideration of possible protection of, and accommodation for, potential native fishes of the Arroyo Seco, tributary to the Los Angeles River. The following assessment/analysis is based on extensive knowledge of the original fish fauna of the area as well as review of the recent plans for upgrading this diversion, comments from the California Department of Fish and Wildlife (CDFW), and communications with National Marine Fisheries Service (NMFS) and CDFW biologists specifically working with the fishes in the area.

The section of Arroyo Seco from the narrowing at the Jet Propulsion Laboratory (JPL) bridge upstream, including the PWP diversion, is a relatively small upland extent of the entire Arroyo Seco, a major tributary of the Los Angeles River. The whole Los Angeles River system is identified as one of the core populations of steelhead in the Mojave Rim Biogeographic Population Group identified in the NMFS Southern California Steelhead Recovery Plan. As such, the Los Angeles River system is considered essential for recovery of the Southern California Distinct Population Segment of Steelhead, a federally endangered species. Planning efforts by several agencies are underway to promote steelhead recovery. The Bureau of Reclamation has done a preliminary study of modifying the concrete portion of the Los Angeles River to facilitate steelhead and other anadromous fish passage. The (State of California) Wildlife Conservation Board recently awarded a grant to the Council for Watershed Health for design of channel modifications to the Los Angeles River. The City of Los Angeles and project partners are working with multiple agencies to increase biodiversity and restore native fish habitat and fish passage migration corridors to upper tributaries with high intrinsic potential spawning and rearing habitat for not only steelhead/ rainbow trout, but also arroyo chub, speckled dace, unarmored threespine stickleback, and Santa Ana sucker. This native fish project is aligned with approved and ongoing plans for the Los Angeles River watershed and tributaries (http://lariver.org/) including the City of Los Angeles Biodiversity Motion (Mayor's Sustainability Plan, LA Olympics 2028 biodiversity implementation), Greater LAR IRWMP, CDFW native fish habitat priorities and limiting factors analyses, minimum stream flow and water temperature studies, and related multi-benefit projects with ecosystem restoration components.

Seven species of native freshwater fishes historically occurred in Arroyo Seco as documented by Culver and Hubbs (1917): Pacific Brook Lamprey, *Lampetra spp.*, Pacific Lamprey, *Entosphenus tridentata*, Rainbow Trout/Steelhead, *Oncorhynchus mykiss*, Arroyo Chub, *Gila orcutti*, (California species of special concern), Santa Ana Speckled Dace, *Rhinichthys cf osculus*, Santa Ana Sucker, *Catostomus santaanae* (federally threatened), and Unarmored Threespine Stickleback, *Gasterosteus aculeatus williamsoni* (federally endangered). The Speckled Dace ostensibly occurs widely over much of the western United

States, but the Los Angeles basin populations are among the most distinctive genetically and may be a distinct and separate species (Smith et al. 2017). The seven native fish species identified by Culver and Hubbs constitute a distinct, endemic part of the aquatic fauna in the Los Angeles River basin, as part of what was called the Santa Ana system of streams which also included the San Gabriel and Santa Ana River basins and a few nearby areas. The fish were widespread from the base of the mountains to the ocean in the originally relatively well-watered systems (Swift et al. 1993; Mendenhall 1908).

Based on historical information, observations, and studies on other streams in the Los Angeles River? Basin (Swift et al. 1993; Swift and Drill 2008), most of the seven species occurred largely downstream of the canyon mouths where gradients decreased, more consistent water supplies upwelled from the ground, and riparian habitat was more extensive. In the case of the Arroyo Seco, the species likely to have penetrated farther upstream in the steeper gradients of the canyon are the Rainbow Trout and Speckled Dace, and these would have been the only species consistently present in the Arroyo above the JPL bridge. Analogous situations apply across the Los Angeles Basin system of streams where Rainbow Trout and sometimes dace or Arroyo Chubs exist in the upper part of tributaries. These include the streams, above Pacoima and Tujunga dams, above Cogswell Reservoir in the west Fork San Gabriel River, above Seven Oaks Dam in the Santa Ana River, in the Santiago Creek drainage above Irvine Lake, and in upper Trabuco Creek and other tributaries of San Juan Creek. The dace legitimately inhabit such upstream areas, whereas the Arroyo Chub usually has established populations in the reservoirs, occasionally moving upstream in the lower gradient areas in and above the reservoir footprint. Arroyo Chubs usually do not penetrate upstream in higher gradient areas inhabited only by Rainbow Trout and Speckled Dace.

Upstream of the JPL bridge, partial temporal barriers may be present during low flows due to steep channel segments and step-pool or bedrock drops. An anthropogenic barrier exists at the road crossing approximately 500 feet downstream of the diversion at a channel spanning weir that may have been installed for flow measurement. A drop of approximately three feet occurs at this concrete structure. Chubs are less able to migrate through locally steep gradients and away from drying conditions than Rainbow Trout, and in the reach downstream of the diversion would be stranded in pools during low or zero flow periods.

In the project area only Rainbow Trout have been present within the last 50 years (Swift, et al 1993) and probably much longer due to major modifications to the watercourse downstream. Rainbow Trout were still surviving in the upper Arroyo Seco until the flooding and scouring of the canyon after the large 2009 Station Fire. Currently, however, no fish are known to inhabit the Arroyo Seco above Devils Gate Dam, according to surveys and observations made by NOAA Steelhead Recovery coordinator Mark Capelli In August, 2018 (email 22 August 2019) and by California Fish and Wildlife Fishery Biologist John O'Brien "…in the last few years." (email 22 August 2019). While Rainbow Trout/Steelhead are not currently present, the design of the diversion should concentrate on this species because it is the only one with a possibility to reoccur and survive until major restoration efforts occur.

The multi-agency plans and projections noted above for the restoration of aquatic habitats for fishes and other native fauna would necessarily involve removal of, or passage around, Devils Gate Dam to provide access for steelhead returning from the ocean. Returning to Arroyo Seco above Devils Gate Dam is now impossible. Such capability as well as actually making passage possible from Devils Gate Dam to the ocean will be a major undertaking to be accomplished many years in the future. The main strategy for the present would presumably be to re-establish genetically identified southern steelhead populations in the upper Arroyo Seco until such time as viable connectivity is established to the ocean.

Speckled Dace an Arroyo Chub might also be considered, but are unlikely to survive in the mountainous conditions of the upper Arroyo Seco. Several similar upper watershed areas are have been considered desirable for re-establishing native fishes because of their remaining natural features, despite the fact that the evidence indicates most of the target fish would not survive there very long. The fact that pushing these fish farther upstream is relatively easy compared to trying to bring back the original and more optimal habitat in the lowlands does not mean it will be beneficial to the fish in the long run and likely threatens the likelihood of success.

Currently, conditions below the diversion and out onto the surface of the sediment-filled basin behind Devils Gate Dam are marginal or non-existent to support fishes largely due to the very low flows in the Arroyo Seco above the diversion for much of the year. Lack of water is the primary deficiency from about the JPL bridge upstream where substrate and cover is good but water is lacking and barriers to upstream movement are present. Below the JPL bridge the flatter sediment load of the reservoir is open to solar heating, is dominated by finer substrates, and cover and pools are rare or absent. This means fish that get past the diversion due to screening facilities face poor conditions downstream and may not be helped by such passage. During winter high flows fish would go over Devils Gate Dam only to perish over the long concrete-lined channels of Arroyo Seco and Los Angeles River. Even if they reached the ocean (actually the upper end of Los Angeles Harbor) it is unlikely the harbor would provide the beneficial growth conditions provided by relatively natural estuaries and lagoons farther north. During the summer/dry periods of the year, sections of the Arroyo Seco run dry and would leave fish stranded in isolated pools. Also, if significant amounts of sediment were removed from behind Devils Gate, almost certainly the water body would intentionally or unintentionally become home to a variety of exotic aquatic species that adversely affect survival of the native species. This is already true at several other sites in the Los Angeles basin where native stream fish populations interface downstream with flood control reservoirs. Thus, any downstream passage in the next few years at least would send fish into suboptimal conditions and any survivors would need a way to return upstream as the conditions dry out downstream. Another barrier likely may develop when the sediment is removed and the flow into the reservoir area above Devils Gate Dam becomes more precipitous at the mouth of the canyon above the reservoir footprint.

In summary, the primary concern for the diversion should be for minimizing adverse effects on Rainbow Trout/Steelhead. This species would be protected by incorporating screens in the diversion/intake structure designed to prevent Rainbow Trout fry from being entrained with the intake of stream water, and without bypassing the fish downstream where their survival is unlikely. If the introduction of Arroyo Chub and Speckled Dace is to be given consideration in the future, despite the constraints to their existence as noted above, their juvenile and adult sizes are similar to steelhead and the screens would accommodate these later life stages as well. Some calculated loss of very small larvae of the minnows would likely result as is the case in many other places where minnows occur with larger salmonids. Dace larvae occupy margins of the flowing streams, whereas Arroyo Chub larvae drift downstream more and invade standing waters as well (Feeney and Swift 2008). Thus the Arroyo Chub larvae are more likely to be impinged in any diversion screen. As noted above, however, consideration should be given as to the overall likelihood of reintroducing chub in this area before designing to mitigate for a small loss that may not occur.

It is also advisable to provide passage at the diversion dam during higher flows when the diversion is not operating and the flow volume will enable fish to return upstream before flows decline. As much as possible, the diversion should be designed for potential future change in operations to accommodate actual anadromous steelhead arriving from the ocean.

GENERAL NOTES

1. THE CONTRACTOR SHALL ASSUME RESPONSIBILITY FOR THE JOB SITE DURING THE COURSE OF CONSTRUCTION OF THIS PROJECT, INCLUDING SAFETY OF ALL PERSONS AND PROPERTY. THIS REQUIREMENT SHALL APPLY CONTINUOUSLY AND NOT BE LIMITED TO NORMAL WORKING HOURS.

2. THE CONTRACTOR SHALL NOTIFY UNDERGROUND SERVICE ALERT (USA) AT (800) 227-2600 (www.usanorth.org) PRIOR TO START OF ANY CONSTRUCTION.

3. THE CONTRACTOR SHALL BE RESPONSIBLE FOR IDENTIFYING AND AVOIDING DAMAGE TO UNDERGROUND UTILITIES. THE CONTRACTOR SHALL LOCATE EXISTING UTILITIES AT LEAST 48 HOURS PRIOR TO EXCAVATION. ANY RELOCATIONS OR TEMPORARY OUTAGES SHALL BE COORDINATED WITH THE STATE. IF UTILITY CONFLICTS ARE IDENTIFIED, THE CONTRACTOR SHALL HALT ALL WORK IN THE AREA AFFECTED BY THE UTILITY CONFLICT AND SHALL IMMEDIATELY NOTIFY THE STATE. CONTRACTOR SHALL BE HELD RESPONSIBLE FOR ANY AND ALL DAMAGE TO EXISTING STRUCTURES AND UTILITIES DURING CONSTRUCTION.

4. THE CONTRACTOR SHALL BE RESPONSIBLE FOR THE PROTECTION OF ALL EXISTING MONUMENTS AND ANY OTHER SURVEY MARKERS DURING CONSTRUCTION. ALL SUCH MONUMENTS OR MARKERS DESTROYED DURING CONSTRUCTION SHALL BE REPLACED AT CONTRACTOR'S EXPENSE.

5. THIS PROJECT IS SUBJECT TO REQUIREMENTS OF PERMITS ISSUED BY VARIOUS REGULATORY AGENCIES, INCLUDING THE US ARMY CORPS OF ENGINEERS, CALIFORNIA DEPARTMENT OF FISH AND WILDLIFE, REGIONAL WATER QUALITY CONTROL BOARD. THE CONTRACTOR IS RESPONSIBLE TO UNDERSTAND AND PERFORM ALL WORK IN ACCORDANCE WITH THE REQUIREMENTS OF THE PERMITS FROM ALL AGENCIES.

6. THE CONTRACTOR IS RESPONSIBLE FOR COMPLETING, SUBMITTING, AND ADHERING TO THE PROJECT STORM WATER POLLUTION PREVENTION PLAN (SWPPP) FOR CONSTRUCTION ACTIVITIES.

7. TEMPORARY ISOLATION OF IN-STREAM WORK AND CONTROL OF WATER WILL BE REQUIRED. CONSTRUCTION OF WATER CONTROL AND ISOLATION FEATURES SHOWN IN THE PLANS ILLUSTRATES ONE POTENTIAL METHOD. OTHER METHODS MAY BE PROPOSED BY THE CONTRACTOR FOR APPROVAL BY THE STATE. CONTRACTOR SHALL SUBMIT A PLAN FOR CONTROL OF WATER, STREAM ISOLATION, AND DEWATERING, INCLUDING MAINTENANCE AND RELOCATION DURING CONSTRUCTION TO ACCOMMODATE GRADING ACTIVITIES. AT THE COMPLETION OF CONSTRUCTION, ALL MATERIALS USED FOR THE STREAM ISOLATION AND DEWATERING SYSTEMS SHALL BE COMPLETELY REMOVED. IF CONSTRUCTION EXTENDS OVER MORE THAN ONE SEASON, CONTRACTOR SHALL REMOVE TEMPORARY FACILITIES IN THE CREEK CHANNEL AND WINTERIZE THE SYSTEM AS PROVIDED IN THE SWPPP.

8. EXISTING PRIVATE PROPERTY SHALL BE PROTECTED IN PLACE.

9. EXISTING VEGETATION OUTSIDE THE WORK AREA LIMIT IS TO BE PROTECTED PER REQUIREMENTS OF THE AND SWPPP.

10. CONTRACTOR WILL VERIFY AND CHECK EXISTING CONDITIONS PRIOR TO CONSTRUCTION. CONTRACTOR SHALL VERIFY LOCATIONS, LEVELS, DISTANCES, AND FEATURES THAT MAY AFFECT THE WORK. SHOULD EXISTING CONDITIONS DIFFER FROM THOSE SHOWN OR INDICATED, CONTRACTOR SHALL NOTIFY THE STATE PRIOR TO CONTINUING WITH ANY RELATED WORK.

11. ALL MATERIALS SHALL BE FURNISHED AND INSTALLED BY THE CONTRACTOR UNLESS OTHERWISE NOTED.

12. THE NORMAL WORK WEEK FOR CONSTRUCTION AT THE PROJECT SITE SHALL BE MONDAY THROUGH FRIDAY, 8:00AM TO 5:00PM, UNLESS OTHERWISE DIRECTED BY THE STATE. ALL WORK SHALL BE ACCOMPLISHED IN A MANNER THAT CAUSES MINIMAL DISRUPTION TO LOCAL RESIDENTS.

13. A GEOTECHNICAL REPORT FOR THIS PROJECT WAS PREPARED AND IS PROVIDED FOR IN THE PROJECT MANUAL,

14. SHOULD ARCHEOLOGICAL REMAINS OR ARTIFACTS BE ENCOUNTERED DURING ANY PHASE OF CONSTRUCTION, LAND ALTERATION WORK IN THE GENERAL VICINITY OF THE FINDS SHALL BE HALTED AND A QUALIFIED ARCHEOLOGIST AND THE STATE SHALL BE NOTIFIED IMMEDIATELY. WORK ON THE PROJECT SHALL NOT BE RESUMED UNTIL A MITIGATION PLAN WITH ADEQUATE MEASURES FOR SITE PROTECTION IS REVIEWED AND APPROVED BY THE STATE.

15. CONTRACTOR SHALL PREPARE A TRAFFIC CONTROL PLAN FOR REVIEW AND APPROVAL BY THE TRAFFIC CONTROL PLAN SHALL BE SUBMITTED TO THE FOR APPROVAL. ENCROACHMENT PERMITS FOR WORK OR STORAGE OF MATERIALS IN CITY RIGHTS OF WAY ARE THE RESPONSIBILITY OF THE CONTRACTOR. CONTRACTOR SHALL COORDINATE WITH THE FOR CONTROL OF PUBLIC ACCESS TO THE SITE DURING CONSTRUCTION.

16. CONTRACTOR SHALL PROVIDE A WATER TRUCK TO WATER AREAS AS NECESSARY TO CONTROL DUST. SOIL AND CONSTRUCTION MATERIAL SHALL NOT BE TRACKED OFF THE CONSTRUCTION SITE. SEE SHEET G3 AND PROJECT SPECIFICATIONS FOR WATER SUPPLY CONNECTIONS.

17. ALL IN-WATER/IN-CHANNEL WORK SHALL BE COMPLETED BY OCT 1. ALL OTHER GRADING WORK AND SITE STABILIZATION SHALL BE COMPLETED BY OCT 15.

18. AREAS THAT WILL BE INACTIVE BETWEEN OCTOBER 15 AND MAY 1 SHALL BE WINTERIZED IN ACCORDANCE WITH THE SWPPP, INCLUDING:

1) TEMPORARY EROSION AND SEDIMENT CONTROLS SHALL BE INSTALLED
2) DISTURBED AREAS SHALL BE STABILIZED
3) ONSITE CONSTRUCTION SLASH AND DEBRIS SHALL BE CLEANED UP AND REMOVED
4) EXCESS MATERIAL SOIL SHALL BE REMOVED FROM THE SITE AND TRANSPORTED TO A DESIGNATED STOCKPILE OR DISPOSAL AREA.
5) TEMPORARY IRRIGATION FACILITIES, IF INSTALLED, SHALL BE REMOVED OR WINTERIZED.

19. THE PROJECT BASE MAP WAS PRODUCED FROM AND FIELD SURVEY ACTUAL TOPOGRAPHY IS SUBJECT TO MINOR DEVIATIONS FROM THE GRADES SHOWN, AND CHANNEL CHANGES MAY OCCUR BETWEEN THE TIME OF FINAL PLANS AND BEGINNING OF CONSTRUCTION. THE STATE WILL PROVIDE FIELD DIRECTION FOR ADJUSTMENTS IN PROJECT FEATURES, LINES, AND GRADES TO FIT ACTUAL CONDITIONS AT THE TIME OF CONSTRUCTION.

20. ALL ELEVATIONS SHOWN ARE IN THE NORTH AMERICAN VERTICAL DATUM OF 1988 (NAVD88). LOCAL CONVERSION FROM TO NAVD88 IS +2.88 FEET.

23. APPLICABLE BUILDING CODES: 2016 CALIFORNIA BUILDING CODE, CCR TITLE 24, PART 2, VOLUME 1 OF 2 (BASED ON THE 2015 IBC).

OVERALL AREA SITE LOCATION

NOTES
1. BRIDGE #1 AND BRIDGE #3 ARE TEMPORARY STRUCTURES WITH A 12'-WIDE DRIVE WIDTH AND HS-20 LOAD RATINGS.
2. BRIDGE #2 IS A HISTORICAL STRUCTURE TO BE PROTECTED WITH A 58,000 LB LOAD LIMIT.

GENERAL NOTES

1. THESE PLANS AND SPECIFICATIONS REPRESENT THE DESIGN INTENT OF THE ENGINEER, AS APPROVED BY THE OWNER, CITY OF PASADENA. THE CONTRACTOR IS RESPONSIBLE FOR ALL ITEMS SHOWN ON THESE PLANS AND SPECIFICATIONS AND SHALL BE RESPONSIBLE FOR ANY DEVIATIONS FROM THESE PLANS AND ASSOCIATED RISK AND EXPENSE. THE CONTRACTOR SHALL BE RESPONSIBLE FOR MAINTAINING A COPY OF THE APPROVED PLANS AND SPECIFICATIONS AND ANY ADDENDA AT THE JOB SITE AT ALL TIMES. THE CONTRACTOR SHALL IMMEDIATELY NOTIFY CITY OF PASADENA OF ANY UNFORESEEN CIRCUMSTANCES OR CONDITIONS THAT WOULD ALTER THESE PLANS AND SPECIFICATIONS FOR APPROVAL OF MODIFICATIONS TO THE INTENDED DESIGN.
2. THE CONTRACTOR SHALL TAKE ALL PRECAUTIONARY MEASURES NECESSARY TO PROTECT EXISTING FACILITIES AND UTILITIES SHOWN OR NOT SHOWN WHICH ARE TO REMAIN IN PLACE FROM DAMAGE. ALL FACILITIES DAMAGED BY THE CONTRACTOR'S OPERATIONS SHALL BE EXPEDITIOUSLY REPAIRED OR RECONSTRUCTED TO THE CITY'S SATISFACTION AT THE CONTRACTOR'S EXPENSE WITHOUT ADDITIONAL COMPENSATION.
3. PROVIDE A MINIMUM OF 42 INCHES COVER ON ALL PIPELINES UNLESS OTHERWISE NOTED OR DIRECTED. INSTALL ALL PIPING AND PAVEMENT PER CITY OF PASADENA STD. PLAN S-407.
4. STRAIGHT ALIGNMENT AND UNIFORM SLOPES OF PIPES SHALL BE MAINTAINED BETWEEN INVERTS SHOWN. EXISTING UTILITIES SHALL BE VERIFIED IN ADVANCE OF PIPELINE PLACEMENT. CITY SHALL BE NOTIFIED IMMEDIATELY OF ANY EXISTING UTILITIES AFFECTING PIPELINE ALIGNMENT OR SLOPE.
5. ADJUST ALL VALVE BOXES, VAULTS, PULL BOXES AND MANHOLES TO FINISHED GRADE UNLESS OTHERWISE SHOWN OR DIRECTED.
6. ALL DEBRIS FROM DEMOLITION TO BE DISPOSED OF PROPERLY OFFSITE. ANY SALVAGEABLE MATERIALS OR EQUIPMENTS SHALL BE THE PROPERTY OF THE CITY AND MOVED TO THE CITY OF PASADENA WATER AND POWER MAINTENANCE YARD.
7. CONTRACTOR SHALL PROVIDE A STORM WATER POLLUTION CONTROL PLAN (PREPARED BY A CALIFORNIA REGISTERED CIVIL ENGINEER) FOR WORK DURING CONSTRUCTION CONFORMING TO THE NPDES PERMIT REQUIREMENTS.
8. THE CONTRACTOR SHALL SHORE, SUPPORT AND PROTECT EXISTING STRUCTURES AND FACILITIES IN ACCORDANCE WITH SECTION 02260.
9. WHERE REPLACING EXISTING PAVEMENT, MATCH EXIST GRADE AT EXISTING STRUCTURES AND BUILDINGS, EXCEPT WHERE NOTED OTHERWISE.
10. CONTRACTOR SHALL USE MECHANICAL RESTRAINT SYSTEMS, NOT THRUST BLOCKS, UNLESS NOTED OTHERWISE.
11. ALL EXISTING VALVES TO BE OPERATED BY CITY PERSONNEL ONLY. NOTIFY CITY 24 HOURS PRIOR TO NEED FOR VALVE OPERATION.
12. FOR CONNECTIONS TO EXISTING PIPES, CUT EXISTING PIPES SQUARE AND REPAIR ANY DAMAGE TO THE EXISTING LINING AND COATING.
13. ALL PIPE DIAMETERS ARE NOMINAL ID.
14. CONTRACTOR IS RESPONSIBLE FOR PROVIDING ALL CONSTRUCTION SURVEYING AND STAKING. VERIFY ALL EXISTING HORIZONTAL AND VERTICAL INFORMATION PRIOR TO DOING ANY WORK.
15. CONTRACTOR SHALL WORK WITHIN LIMITS OF WORK.
16. ALL TRENCHING AND BACKFILL SHALL BE IN ACCORDANCE WITH CONTRACT DOCUMENTS.
17. ALL ABOVE GROUND PIPING SHALL BE SUPPORTED WHETHER EXPLICITLY NOTED OR NOT. PROVIDE PIPE SUPPORTS EVERY 2 FT UNLESS EXPLICITLY NOTED OTHERWISE ON THE PLANS.
18. ANY CONTRACTOR PERFORMING WORK ON THIS PROJECT SHALL FAMILIARIZE HIMSELF WITH THE SITE AND SHALL BE SOLELY RESPONSIBLE FOR ANY DAMAGE TO EXISTING FACILITIES RESULTING DIRECTLY OR INDIRECTLY FROM HIS OPERATIONS, WHETHER OR NOT SUCH FACILITIES ARE SHOWN ON THESE PLANS.
19. THE CONTRACTOR'S ATTENTION IS EXPRESSLY DIRECTED TO ALL THE REQUIREMENTS AND PROVISIONS OF THE STATE OF CALIFORNIA SAFETY REGULATIONS. CONFORMANCE SHALL BE STRICTLY ENFORCED DURING THE ENTIRE LIFE OF THE CONTRACT AND/OR PROJECT. AN EXCAVATION PERMIT WILL BE REQUIRED FOR TRENCHES IN EXCESS OF 5.0 FEET IN DEPTH FROM CAL-OSHA.
20. THE CONTRACTOR SHALL DISPOSE OF ALL SURPLUS EXCAVATION AND DEMOLITION DEBRIS CONFORMING TO LOCAL CODES AND REGULATION.
21. THE CONTRACTOR SHALL REPLACE IN KIND, TO THE SATISFACTION OF THE CITY, ANY PAVING, OR OTHER IMPROVEMENTS CUT, REMOVED OR DAMAGED IN CONJUNCTION WITH THIS PROJECT.
22. PIPE DELIVERED TO THE SITE SHALL BE PROTECTED BY THE CONTRACTOR FROM DUST OR CONTAMINATION PRIOR TO PLACING IN TRENCH, DURING INSTALLATION AND TESTING. PIPE IS TO BE STORED TO PREVENT DAMAGE IN ACCORDANCE WITH MANUFACTURING RECOMMENDATIONS AND PROCEDURES. RECEIVING, STORAGE, AND HANDLING OF ALL POTABLE WATER PIPE AND APPURTENANCES SHALL BE IN ACCORDANCE WITH AWWA STANDARDS AND PROCEDURES.
23. THE CONTRACTOR SHALL ENSURE THAT ALL OPENINGS INTO ALL PIPELINES ARE PROTECTED AND AT THE END OF EACH WORK DAY SECURELY PLUGGED AND STOPPED SO THAT NO ANIMAL, FOWL OR RODENT CAN ENTER THE PIPELINE.
24. NO PIPELINE SHALL BE INSTALLED ON FILL MATERIAL WITHOUT FIRST MEETING IN-PLACE DENSITY TESTS REQUIRED.
25. ALL PERMITS REQUIRED BY LAW SHALL BE ACQUIRED BY CONTRACTOR BEFORE COMMENCING WORK. THE CONTRACTOR SHALL COMPLY WITH ALL APPLICABLE RULES AND REGULATIONS. SAFETY IS THE SOLE RESPONSIBILITY OF THE CONTRACTOR.
26. PRIOR TO START OF CONSTRUCTION, THE CONTRACTOR SHALL LOCATE ALL EXISTING UTILITIES IN AND AROUND THE AREAS OF NEW CONSTRUCTION. THE CONTRACTOR SHALL SUBMIT POTHOLE LOCATION DRAWINGS TO THE CITY FOR REVIEW PRIOR TO SUBMITTAL OF SHOP DRAWINGS. SUBMITTAL OF PROPOSED POTHOLE LOCATIONS TO THE CITY SHALL NOT RELIEVE CONTRACTOR OF ITS DUTY AND RESPONSIBILITY FOR REPAIRING DAMAGE TO UTILITIES FROM CONTRACTOR'S WORK OR MAKING FIELD ADJUSTMENTS TO PROPOSED PIPELINE ALIGNMENTS AND CONNECTIONS PENDING WRITTEN APPROVAL BY THE CITY.
27. THE CONTRACTOR IS RESPONSIBLE FOR FIELD VERIFICATION OF THE PRESENCE AND LOCATION OF ALL EXISTING SURFACE FEATURES, WHETHER SHOWN OR NOT HEREIN.
28. PRIOR TO SUBMITTAL OF PIPE SHOP DRAWINGS, THE CONTRACTOR SHALL FIELD POTHOLE TO VERIFY THE INVERT ELEVATION, OUTSIDE DIAMETER, LOCATION AND MATERIAL OF ALL EXISTING PIPELINES TO WHICH NEW PIPELINES WILL BE CONNECTED, AND SUBMIT THE INFORMATION WITH THE PIPE SUBMITTAL.

GENERAL NOTES

29. PROVIDE CONCRETE ENCASEMENT FOR ALL PIPING BENEATH STRUCTURES, PADS, VAULTS, AND ANY OTHER FACILITIES PER TYPICAL DETAIL P040.
30. ALL BUILDING COORDINATES ARE TO OUTSIDE CORNER OF COLUMN OR BUILDING WALL, UNLESS OTHERWISE INDICATED.
31. SMALL YARD PIPING (10 INCHES AND LESS INSIDE DIAMETER) IS SHOWN AS A CENTERLINE ON THE PLANS TO SCALE BUT IS NOT DIMENSIONED. THE CONTRACTOR SHALL FIELD INSTALL THE SMALL YARD PIPING ON LINE AND GRADE WITH MINIMUM COVER UNLESS OTHERWISE INDICATED CONFLICTS BETWEEN PIPES SHALL BE RESOLVED AS FOLLOWS: GRAVITY LINES HAVE PRIORITY. PRESSURE PIPELINES SHALL BE ROUTED UNDER OR OVER GRAVITY LINES AS NECESSARY WITH SETBACKS AND INSTALLATION PER CDPH STANDARDS AND GUIDELINES.
32. PRIOR TO PAVING, ALL UNDERGROUND FACILITIES INCLUDING, BUT NOT LIMITED TO SEWER, WATER, TELEPHONE, CABLE, POWER, INSTRUMENTATION, AND GAS SHALL BE IN PLACE AND TESTED.
33. OVER EXCAVATE 5 FT (MIN) HORIZONTALLY FROM FOUNDATION FOR ALL NEW STRUCTURES. OVER EXCAVATE 3 FT (MIN) VERTICALLY BENEATH FOUNDATION FOR ALL NEW STRUCTURES.
34. PROVIDE CONCRETE EQUIPMENT BASE PAD UNDER ALL EQUIPMENT. REFER TO STRUCTURAL TYPICAL DETAILS.
35. THE CONTRACTOR SHALL BE RESPONSIBLE FOR CONTROLLING GROUNDWATER ENCOUNTERED AND SECURING APPROPRIATE DISCHARGE PERMITS. CONTRACTOR SHALL SUBMIT DEWATERING PLAN TO ENGINEER FOR APPROVAL. DEWATERING SHALL BE IN ACCORDANCE WITH SECTION 02240.
36. THE CONTRACTOR SHALL NOT SHUT OFF ANY WATER OR ELECTRICAL SERVICE AT THE CURB AT ANY TIME, SHOULD THE CONTRACTOR REQUIRE THE WATER OR ELECTRICAL SERVICE TO BE SHUT OFF TO THE PRIVATE PROPERTY, ARRANGEMENTS SHALL BE MADE SOLELY BY THE CONTRACTOR WITH THE PROPERTY OWNER AND THE CONTRACTOR SHALL PROVIDE THE PROPERTY OWNER WITH AT LEAST 48 HOURS PRIOR NOTICE.
37. USE CURRENT REVISIONS AND VERSIONS FOR ALL REFERENCED APWA STANDARD PLANS.
38. IF THE CONTRACTOR PROPOSES TO TRIM TREES OR SHRUBS THAT FACILITATE HIS CONSTRUCTION ACCESS, SUCH PROPOSALS SHALL BE SUBMITTED TO THE CITY FOR REVIEW AND WRITTEN APPROVAL TWO WEEKS IN ADVANCE OF THE WORK. TRIMMING WORK SHALL BE DESIGNED AND SUPERVISED BY A LICENSED ARBORIST. THE CONTRACTOR SHALL NOTIFY AND RECEIVE WRITTEN APPROVAL PRIOR TO REMOVING ANY TREES WITHIN THE PROJECT AREA. THE CONTRACTOR SHALL BE RESPONSIBLE FOR ALL DAMAGE TO EXISTING TREES OR SHRUBS AND SHALL REPLACE ANY DAMAGED LANDSCAPE IN ACCORDANCE WITH CITY OF PASADENA REQUIREMENTS.
39. THE CONTRACTOR SHALL ASSUME SOLE AND COMPLETE RESPONSIBILITY FOR JOB SITE CONDITIONS DURING THE COURSE OF THE PROJECT, INCLUDING THE SAFETY OF ALL PERSONS AND PROPERTY. THIS REQUIREMENT SHALL APPLY CONTINUOUSLY AND SHALL NOT BE LIMITED TO NORMAL WORKING HOURS. THE CONTRACTOR SHALL DEFEND, INDEMNIFY, AND HOLD THE CITY AND THE ENGINEER HARMLESS FROM ANY AND ALL LIABILITY, REAL OR ALLEGED, IN CONNECTION WITH THE PERFORMANCE OF WORK ON THIS PROJECT, EXCEPTING LIABILITY ARISING FROM THE SOLE NEGLIGENCE OF THE CITY OR THE ENGINEER.
40. THE CONTRACTOR SHALL MAINTAIN A CLEAN WORK SITE FOR THE DURATION OF THE CONTRACT.
41. CONTRACTOR IS RESPONSIBLE FOR DESIGN AND APPROVAL OF TRAFFIC CONTROL BY CITY OF PASADENA TRANSPORTATION DEPARTMENT.
42. A COPY OF ALL PERMITS MUST BE KEPT ON-SITE DURING ALL PERIODS OF OPERATION.
43. THE FOLLOWING NOTES APPLY TO THE STRUCTURAL AND/OR GRADING PERMITS:
    A. CONTRACTOR MUST SUBMIT FINAL EXCAVATION DETAILS OF AREA AND CROSS SECTION OF EXCAVATION INCLUDING CALCULATED AMOUNTS OF CUT, FILL, AND EXPORT IN CUBIC YARDS FOR APPROVAL BY CITY OF PASADENA, DEPARTMENT OF BUILDING AND SAFETY.
    B. CONTRACTOR MUST FULFILL ANY OTHER CONDITIONS THAT ARE REQUIRED FOR PERMIT APPROVAL BY THE CITY OF PASADENA.
44. FURNISH AND INSTALL TRACER WIRE AND WARNING TAPE FOR ALL BURIED PIPE.
45. CONTRACTOR SHALL COORDINATE WITH CITY OF PASADENA WATER AND POWER DURING THE DEMOLITION PHASE OF THIS PROJECT AND SALVAGE ALL MATERIALS AND EQUIPMENT AS REQUIRED. SALVAGED EQUIPMENT WILL BE DELIVERED TO THE OWNERS SPECIFIED LOCATION.
46. PROVIDE A MINIMUM OF 10-FEET HORIZONTAL SEPARATION BETWEEN POTABLE AND NON-POTABLE PIPELINES IN ACCORDANCE WITH CDPH REQUIREMENTS.
47. PRIOR TO BACK FILLING PIPE TRENCHES, CONTRACTOR SHALL FIELD SURVEY AND PROVIDE AS BUILT COORDINATES FOR ALL NEW STRUCTURES, PIPELINES, AND APPURTENANCES.
48. ALL PAVEMENT REPLACEMENT SHALL BE DONE IN ACCORDANCE WITH CITY OF PASADENA PUBLIC WORKS DEPARTMENT STANDARDS. REFER TO CITY OF PASADENA STD. PLANS S-415, S-416, AND S-417.
49. CONTRACTOR SHALL BE RESPONSIBLE TO POT HOLE AND FIELD VERIFY THE LOCATION AND DEPTH OF ALL EXISTING UTILITIES REMAINING IN SERVICE THAT WILL BE CROSSED, OR WITHIN 4-FEET HORIZONTALLY, OF THE PROPOSED PIPELINES.
50. CONTRACTOR SHALL PROVIDE AND MAINTAIN ACCESS FOR PEDESTRIANS AND TRAFFIC THROUGH AREAS 2 AND 3. CONTRACTOR IS RESPONSIBLE FOR PROVIDING ALL DELINEATION'S, BARRICADES, TEMPORARY SIGNAGE, FLAGGERS, ETC. AS REQUIRED IN ACCORDANCE WITH CITY AND MUTCD STANDARDS.
51. CONTRACTOR IS REQUIRED TO OBTAIN ALL PERMITS WITH THE CITY, COUNTY, AND STATE PRIOR TO STARTING CONSTRUCTION. THIS INCLUDES, BUT IS NOT LIMITED TO DEMOLITION, GRADING, PAVING, BUILDING, ELECTRICAL, AND MECHANICAL.
52. THE CONTRACTOR MUST RECEIVE APPROVAL FROM THE CITY OF PASADENA ARBORIST PRIOR TO TRIMMING ANY TREES WITHIN THE CONSTRUCTION AREA. CONTRACTOR SHALL ALLOW 3 TO 4 WEEKS FOR CITY APPROVAL. ALL WORK MUST BE IN ACCORDANCE WITH THE TREE PROTECTION PLAN APPROVED BY THE CITY FORESTRY ADVISORY COMMITTEE. ALL EXCAVATION WITHIN TREE DRIP LINES MUST BE DONE BY HAND.
53. IT IS ANTICIPATED THAT A SIGNIFICANT AMOUNT OF LARGE ROCKS "BOULDERS" MAY BE ENCOUNTERED DURING THE EXCAVATION AND CONSTRUCTION OF THIS PROJECT. CONTRACTOR SHALL MAKE SPECIAL PROVISIONS REUSING, STOCK PILING, OR DISPOSING AT AN OFF-SITE LOCATION.
54. SOME OF THE HILLSIDE SLOPES WITHIN THE PROJECT AREA ARE PRONE TO ROCK SLIDES. CONTRACTOR SHALL TAKE CAUTION AND PROVIDE SPECIAL PROTECTION WHEN WORKING IN THESE AREAS.
55. THERE ARE SPECIAL PROVISIONS AND WORK RESTRICTIONS TO PROTECT NESTING BIRD HABITATS WITHIN THE PROJECT AREA. REFER TO TECHNICAL SPECIFICATIONS SECTION 01140 FOR ADDITIONAL REQUIREMENTS.
56. CONTRACTOR SHALL PROVIDE BRIDGE PROTECTION AND TEMPORARY ACCESS PLAN FOR ALL BRIDGES WHICH MAY BE IMPACTED BY CONSTRUCTION EQUIPMENT.
57. CONTRACTOR MAY REUSE ALL COBBLE AND ROCK BOULDERS GREATER THAN 18" OD FOR RIP RAP IF APPROVED BY ENGINEER.
58. THE PROPOSED IMPROVEMENTS SHOWN ON THESE DRAWINGS ARE SUPERIMPOSED ON A BASE MAP. THIS BASE MAP IS COMPILED FROM AERIAL AND GROUND SURVEYS, AND OTHER DATA AS MADE AVAILABLE TO THE ENGINEER, WHO SHALL NOT BE HELD LIABLE FOR CHANGES, INACCURACIES, OMISSIONS OR OTHER ERRORS ON THESE DOCUMENTS. THE COMPOSITE BASE MAP IS PROVIDED AS AN AID ONLY AND THE CONTRACTOR SHALL BE RESPONSIBLE FOR REVIEWING THESE DOCUMENTS AND INCORPORATING/INTEGRATING ALL CONSTRUCTION AS REQUIRED TO ACCOMMODATE IT IN THE SAME. NONE OF THE INCLUDED DRAWINGS DEPICT A BOUNDARY SURVEY ALTHOUGH A PARTIAL ALTA SURVEY WAS PERFORMED ALONG A PORTION OF THE UP ROW. BOUNDARY LINES SHOWN ARE APPROXIMATE AND FOR INFORMATIONAL PURPOSES ONLY.
59. IN THE EVENT THAT SUBGRADE OBSTRUCTIONS ARE ENCOUNTERED OR DISCREPANCIES ARE FOUND BETWEEN THE DRAWINGS AND FIELD CONDITIONS, NOTIFY ENGINEER OR CITY OF PASADENA FOR DIRECTIONS. DO NOT PROCEED WITH THE WORK WITHOUT DIRECTION FROM THE ENGINEER.
60. CONTRACTOR SHALL NOTIFY ALL PUBLIC AND PRIVATE UTILITY COMPANIES IN THE PROJECT AREA A MINIMUM OF THREE (3 WORKING DAYS PRIOR TO COMMENCEMENT OF WORK. CONTRACTOR MUST INVESTIGATE AND VERIFY THE LOCATION OF ANY EXISTING UTILITIES WITHIN THE PROJECT AREA. IT SHALL BE THE RESPONSIBILITY OF THE CONTRACTOR TO IDENTIFY, LOCATE, AND PROTECT ALL UNDERGROUND UTILITIES, ANY UNDERGROUND UTILITIES SHOWN ON THE PLANS ARE CONSIDERED TENTATIVE AND APPROXIMATIONS AND THEREFORE, NO WARRANTY EXPRESSED OR IMPLIED IS MADE AS TO THE COMPLETENESS OR CORRECTNESS OF THEIR LOCATION. THE UTILITY COMPANIES ARE THOUGHT TO BE MEMBERS OF UNDERGROUND SERVICE ALERT (U.S.A.) ON-CALL PROGRAM. THE CONTRACTOR SHALL NOTIFY U.S.A. 72-HOURS IN ADVANCE OF PERFORMING EXCAVATION WORK AT 811 FROM 7:00 AM TO 5:00 PM, MONDAY THROUGH FRIDAY. EXISTING PUBLIC UTILITIES SHALL BE KEPT IN SERVICE AT ALL TIMES. UTILITIES THAT INTERFERE WITH THE WORK TO BE PERFORMED SHALL BE PROTECTED AS REQUIRED BY CITY OF PASADENA AND ALL OTHER AFFECTED ENTITIES. DAMAGE TO UTILITIES SHALL BE REPAIRED OR REPLACED AT NO ADDITIONAL COST TO CITY TO THE SATISFACTION OF THE ENGINEER AND OWNER. POTHOLING IS REQUIRED FOR ANY EXCAVATION WITHIN FIVE (5) FEET OF THE EXISTING GAS TRANSMISSION PIPE SHALL BE DUG BY HAND IN THE PRESENCE OF UTILITY INSPECTOR.
61. CITY OF PASADENA WILL PROVIDE A QUALIFIED BIOLOGICAL/ARCHEOLOGICAL MONITOR THAT WILL INITIALLY REVIEW SITE CONSTRUCTION PROTOCOLS WITH ALL CONSTRUCTION CONTRACTOR EMPLOYEES AT A PRE-CONSTRUCTION MEETING THAT WILL BE SPECIFICALLY HELD ON RESOURCE PROTECTION. EACH EMPLOYEE ASSIGNED TO THIS PROJECT MUST PARTICIPATE IN THIS PRE-CONSTRUCTION MEETING AND DISCUSSION OF ADJACENT SENSITIVE RESOURCES, AND SIGN A STATEMENT INDICATING THAT THEY HAVE READ AND UNDERSTOOD THE PROTOCOLS AND AGREE TO ADHERE TO THEM. SIGNIFICANT BREACHES OF PROTOCOL AND FAILURE TO ADEQUATELY PROVIDE THE DEGREE OF RESOURCE PROTECTION REQUIRED BY THIS PROJECT WILL RESULT IN THE ISSUANCE OF A STOP WORK ORDER BY THE ENGINEER OR BY THE MONITOR. CITY OF PASADENA PROVIDED MONITOR WILL CAREFULLY INSPECT ALL WORK AREAS FOR THE PRESENCE OF WILDLIFE OR CULTURAL RESOURCES PRIOR TO INSTALLATION OF PROTECTIVE BARRIER FENCING AND FIELD FENCING, AND PRIOR TO INITIATION OF CONSTRUCTION EACH DAY. CONTRACTOR SHALL BE RESPONSIBLE FOR ANY PENALTIES AND ALL REPAIRS AND MITIGATIONS IMPOSED DUE TO BREACH OF PROTOCOL.
62. BY ENTERING INTO THIS CONTRACT WITH CITY OF PASADENA, THE CONTRACTOR AGREES TO HAVING EXAMINED THE SITE, COMPARING THE SITE CONDITIONS WITH THE DRAWINGS AND SPECIFICATIONS AND HAS CAREFULLY EXAMINED ALL OF THE CONTRACT DOCUMENTS AND IS SATISFIED AS TO THE CONDITIONS UNDER WHICH THE WORK IS TO BE PERFORMED. NO ALLOWANCE SHALL BE MADE SUBSEQUENTLY ON BEHALF OF THE CONTRACTOR DUE TO FAILURE TO BE ACQUAINTED WITH THE CONDITIONS OF THE SITE. THE CONTRACTOR SHALL BE RESPONSIBLE FOR COORDINATION WITH SUBCONTRACTORS AS REQUIRED TO ACCOMPLISH ALL CONSTRUCTION OPERATIONS. CONTRACTOR SHALL PROTECT ALL EXISTING ON-SITE AND OFF-SITE IMPROVEMENTS AGAINST DAMAGE RESULTING FROM OPERATIONS. RESPONSIBILITY EXTENDS TO THE CONTRACTOR'S WORKERS, SUBCONTRACTORS AND OTHERS PROVIDING SERVICES. CONTRACTOR SHALL REPAIR AND/OR REPLACE DAMAGE AT THEIR OWN EXPENSE AND TO THE SATISFACTION OF THE ENGINEER AND CITY OF PASADENA. THE CONTRACTOR SHALL DEFEND, INDEMNIFY, AND HOLD CITY OF PASADENA AND THE ENGINEER (QUESTA ENGINEERING CORPORATION) HARMLESS FROM ANY AND ALL LIABILITY, REAL OR ALLEGED, IN CONNECTION WITH THE PERFORMANCE OF WORK ON THIS PROJECT, EXCEPT FROM LIABILITY ARISING FROM THE SOLE NEGLIGENCE OF CITY OF PASADENA OR THE ENGINEER. THIS REQUIREMENT SHALL APPLY CONTINUOUSLY AND NOT BE LIMITED TO NORMAL WORKING HOURS.
63. CONTRACTOR SHALL ASSUME SOLE AND COMPLETE RESPONSIBILITY FOR SITE CONDITIONS DURING THE COURSE OF CONSTRUCTION, INCLUDING THE SAFETY OF ALL PERSONS AND PROPERTY. TRAFFIC CONTROL, ACCESS TO AND FROM ADJOINING DRIVEWAYS AND STREETS, AND ANY LANE CLOSURES. TRASH GENERATED BY THIS WORK (CONSTRUCTION DEBRIS, PAPER, BOTTLES, CIGARETTES, ETC) SHALL BE REMOVED ON A DAILY BASIS. CONTRACTOR SHALL CONTROL DUST AT ALL TIMES WITH WATER.
64. ALL WORK SHALL BE IN COMPLIANCE WITH APPLICABLE OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION (OSHA) STANDARDS AS SET FORTH BY THE FEDERAL DEPARTMENT OF LABOR AND/OR THE STATE OF CALIFORNIA AND CITY OF PASADENA. ALL TRAFFIC CONTROL SHALL BE IN ACCORDANCE WITH THE LATEST EDITION OF THE CALTRANS MANUAL OF TRAFFIC CONTROLS FOR CONSTRUCTION AND MAINTENANCE OF WORK ZONES. ALL SIGNS SHALL BE APPROPRIATELY CONSTRUCTED WITH REFLECTIVE MATERIAL ON A BACKING OF METAL OR FABRIC (NO WOOD OR PLASTIC ALLOWED) AND SHALL BE MAINTAINED THROUGHOUT CONSTRUCTION TO PROVIDE PROPER VISIBILITY, PER SECTION 12 OF THE CALTRANS SPECIAL PROVISIONS. THE CONTRACTOR SHALL MAINTAIN REASONABLE ACCESS TO ALL ROADWAYS DURING CONSTRUCTION.
65. REFER TO THE SPECIFICATIONS THAT ARE A PART OF THESE CONTRACT DOCUMENTS, COMPLY WITH ALL REGULATIONS AND CODES GOVERNING WORK PERFORMED UNDER THIS CONTRACT. REFER TO CALTRANS STANDARD PLANS AND SPECIFICATIONS AS REQUIRED.
66. WRITTEN DIMENSIONS ALWAYS TAKE PRECEDENCE OVER SCALED DIMENSIONS IF THERE IS A CONFLICT, THE CONTRACTOR SHALL CONTACT CITY OF PASADENA TO OBTAIN ADDITIONAL CLARIFICATION. NO DEVIATION OR SUBSTITUTION SHALL BE ALLOWED WITHOUT OBTAINING PRIOR WRITTEN APPROVAL FROM CITY OF PASADENA AND THE ENGINEER.

GENERAL MATERIAL IN CROSS SECTION

- STEEL
- CAST IRON OR FIBERGLASS
- BRONZE OR ALUMINUM
- MASONRY
- INSULATION
- PLASTIC, RUBBER OR NEOPRENE
- GRAVEL
- CONCRETE
- SOIL
- SAND
- WOOD (FINISH)

GENERAL MATERIAL IN PLAN

- ALUMINUM OR METAL DECKING
- CHECKERED PLATE
- SPAN — GRATING

GENERAL PLUMBING - SINGLE LINE PIPING

- WCO — WALL CLEANOUT
- FCO — FLOOR CLEANOUT
- BLOW OFF ASSEMBLY
- HUB DRAIN
- FLOOR DRAIN
- FLOOR SINK
- DRAIN TRAP

MISCELLANEOUS

- CHANGE IN PIPING MATERIAL
- ROUND OR DIAMETER
- SQUARE
- AT
- ANGLE
- DRAIN - SCHEMATIC
- (1) NEW STRUCTURAL COLUMN LINE NUMBER
- SLG-1500 — EQUIPMENT CALLOUT (SEE EQUIPMENT SCHEDULE)
- 30" SW — PIPE CALLOUT (SEE PIPE SCHEDULE)

GENERAL EQUIPMENT - SINGLE LINE

- STOP GATE
- SLIDE GATE
- SLUICE GATE
- AIR VACUUM AND AIR RELEASE ASSEMBLY
- THERMOMETER
- INJECTOR OR EDUCTOR
- FA — FLAME ARRESTER
- CENTRIFUGAL PUMP OR FAN
- VERTICAL TURBINE PUMP (PLAN)
- METERING PUMP
- PROGRESSING CAVITY, POSITIVE DISPLACEMENT PUMP
- BLOWER OR COMPRESSOR
- FLOW TUBE
- M — MAGNETIC METER
- ORIFICE PLATE AND FLANGES
- ROTAMETER
- T — CONDENSATE TRAP
- PIPE SUPPORT (IN PLAN ONLY)
- PIPE ANCHOR
- PULSATION DAMPENER
- EXPANSION CHAMBER WITH RUPTURE DISC
- RUPTURE DISC
- (X) GAUGE: x = G - GENERIC; x = P - PRESSURE; x = V - VACUUM; x = C - COMBINATION; x = S - PRESSURE SWITCH
- (X) GAUGE WITH DIAPHRAGM SEAL: x = G - GENERIC; x = P - PRESSURE; x = V - VACUUM; x = C - COMBINATION; x = S - PRESSURE SWITCH

A AREA 3 - DEMOLITION PLAN

SCALE: 1" = 100'
FILE: FILE

GENERAL NOTES:

1. ALL KEY NOTES AND DEMO MARK ID TAGS MAY NOT BE APPLICABLE TO THIS DRAWING. REFER TO OTHER DEMO SHEETS
2. CONTRACTOR SHALL PROVIDE AND MAINTAIN TEMPORARY ACCESS FOR RECREATIONAL USERS DURING CONSTRUCTION. REFER TO SPEC SECTION 01140 FOR ADDTIONAL DETAIL.
3. ALL DEMOLITION QUANTITIES LISTED ON THIS PLAN ARE APPROXIMATE. CONTRACTOR SHALL FIELD VERIFY EXISTING CONDITIONS.
4. ALL EXISTING CONCRETE HAS REINFORCING STEEL.
5. (NOT USED)
6. TO PROVIDE CLARITY, NOT ALL AREAS TO BE DEMOLISHED ARE HATCHED IN EVERY VIEW, PHOTO, OR PLAN.

KEY NOTES:

1. SEE DRAWING 03C-05, 06, 07, AND 08 FOR ADDITIONAL DETAIL ON EXISTING PIPES.
2. NOT USED.
3. RETAIN AND PROTECT.
4. CONTRACTOR SHALL POTHOLE/TRENCH TO VERIFY LOCATION OF EXISTING 12" JPL POTABLE LINE, BEFORE DEMOLITION WORK.
5. CONTRACTOR SHALL PROTECT EXISTING 12" JPL POTABLE MAIN UNTIL NEW 12" JPL LINE IS INSTALLED, PRESSURE TESTED, DISINFECTED, BACTERIA TESTED, AND PWP VERIFIES THAT NEW MAIN IS READY FOE SERVICE, AFTER NEW JPL POTABLE MAIN IS IN SERVICE, CONTRACTOR SHALL REMOVE AND DISCARD EXISTING.
6. RETAIN AND PROTECT EXISTING OVERHEAD SCE POWER LINES. COORDINATE WITH SCE FOR ALL WORK AROUND AND UNDER POWER LINES. WORK SHALL NOT BE ALLOWED WITHIN 20 FT OF EXISTING POWER POLES AND GUY WIRES.

130	1896169.29	6511452.04	1129.00	FG CENTER OF GUARD STATION

GENERAL NOTES:

1. REFER TO ROAD PLAN AND PROFILE DRAWINGS FOR ADDITIONAL FINISHED GRADE ELEVATIONS.
2. REFER TO LANDSCAPE PLANS FOR ALL PLANTING SCHEDULES AND IRRIGATION DESIGN.

KEY NOTES:

1. PREFABRICATED RESTROOM. REFER TO SECTION 13100. CONCRETE FOUNDATION PAD SHALL BE DESIGNED BY RESTROOM MANUFACTURER AND INSTALLED BY CONTRACTOR.
2. LANDSCAPE AREA, REFER TO LANDSCAPE PLANS.
3. CONSTRUCT GRAVEL ACCESS DRIVE. 4" GRAVEL (THICKNESS=2") OVER ABC (THICKNESS=8").
4. PARKING FOR RECREATIONAL USE SIGN, TYP OF 10 IN PARKING AREA. COORDINATE FINAL LOCATION W/ CITY.
5. INSTALL ROCK BOULDER ALONG EDGE OF ROADWAY. EACH BOULDER SHALL BE APPROX 1/2 TON W / 6-FOOT SPACING ON CENTER.
6. NEW FENCING PER APWA 600 (H = 6').
7. INSTALL 6' WIDE RAMP PER CITY STD. PLAN S-414.
8. CONSTRUCT 10' WIDE DRIVEWAY APPROACH PER APWA STD. PLAN 110-1, TYPE B.
9. CONSTRUCT 6" VERTICAL CURB PER APWA STD. PLAN 120-1, TYPE A1.
10. INSTALL AC PAVEMENT OVER ENTIRE PARKING AREA PER THICKNESSES DETAILED IN SECTION J (DWG 03C-12)
11. PAINTED 8'-6" x 18' PARKING STALL.
12. NOT USED
13. INSTALL REMOVABLE GUARD POST. INSTALL 5 @ 4'-0" O.C. FOR 20-FEET.
14. INSTALL AREA SIDEWALK AROUND RESTROOM, LIFT STATION, AND ALONG ROAD PER CITY STD PLAN S-421 AND S-422.
15. FOUNDATION AND UTILITY STUB-UPS TO BE INCLUDED IN THIS CONTRACT.
16. CONSTRUCT RETAINING WALL, (L =) PER——.

Call before you Dig
Avoid cutting underground utility lines. It's costly.

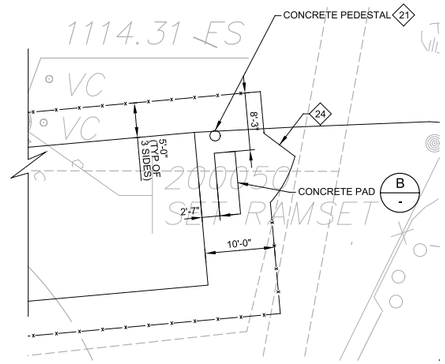
PLAN **B - SECTION**



B - CONCRETE SLAB
SCALE: NTS
FILE: 9137A1003C02

GENERAL NOTES:

1. REFER TO ROAD PLAN AND PROFILE DRAWINGS FOR ADDITIONAL FINISHED GRADE ELEVATIONS.
2. REFER TO LANDSCAPE PLANS FOR ALL PLANTING SCHEDULES AND IRRIGATION DESIGN.

KEY NOTES:

1. FURNISH AND INSTALL CHAIN LINK FENCE (H=8') AROUND PERIMETER OF BASIN A PER APWA STANDARD PLAN 600 AND ONE WALK GATE (WIDTH=10'), PROVIDE ONE DOUBLE LEAF DRIVE GATES (WIDTH = 20'). FIELD VERIFY FINAL DIMENSIONS.
2. PROVIDE 8% (APPROX) LONGITUDINAL SLOPE AND 2% CROSS SLOPE.
3. SPEED BUMP SIGN. REFER TO MUTCD W8-1. (QUANTITY 6)
4. EQUESTRIAN CROSSING AHEAD SIGN. REFER TO MUTCD W11-7. (QUANTITY 2)
5. SPEED BUMP PER PWS STANDARD.
6. "NO PARKING" SIGN. REFER TO MUTCD R7-1. (QUANTITY 3)
7. INSTALL ROCK BOULDER ALONG EDGE OF ROADWAY. EACH BOULDER SHALL BE APPROX 1/2 TON W / 6-FOOT SPACING ON CENTER.
8. NEW CHAIN LINK FENCING PER APWA 600 (H = 6').
9. RETAIN AND PROTECT EXISTING POWER POLE, GUY WIRES, AND OVER HEAD POWER LINES. REFER TO ALL SCE SAFETY REQUIREMENTS WHEN OPERATING AROUND SCE EQUIPMENT.
10. CONCRETE WING HEADWALL (SAN DIEGO RSD NO. D-35A, USE DIM FOR 42-INCH PIPE).
11. INSTALL REMOVABLE GUARD POST. INSTALL 13 @ 4'-0" O.C. FOR 72-FEET.
12. INSTALL REMOVABLE GUARD POST. INSTALL 9 @ 4'-0" O.C. FOR 36-FEET.
13. REFER TO PIPING PLANS (DWG 03C-06) FOR DETAIL ON INLET/OUTLET FOR EACH BASIN
14. CONTRACTOR LAY DOWN AND CONSTRUCTION TRAILER AREA. NO EQUIPMENT OR MATERIALS SHALL BE STORED ON TOP OF COUNTY STORM DRAIN BOX.
15. CONSTRUCT ACCESS DRIVE OF GRAVEL (THICKNESS = 2") AND ABC (THICKNESS = 8").
16. ALL BASIN RAMPS AND AREAS OUTSIDE OF BASINS SHALL BE COMPACTED NATIVE MATERIAL, UNLESS OTHERWISE NOTED OR SPECIFIED.
17. PROTECT AND RETAIN EXISTING TREES. FENCE OFF AREA UNDER TREE CANOPIES.
18. FLUME. REFER TO DWG 03C-06.
19. CONCRETE WING HEADWALL SIM TO SDRSD NO. D-35A, USE DIM FOR 42-INCH PIPE. PROVIDE REINFORCED CONCRETE SLAB (4' X 9') BETWEEN HEADWALLS, MATCH SLAB THICKNESS AND REINFORCING FOR HEADWALL SLAB.
20. RIP RAP ENERGY DISSIPATER, 800 SF AS DETAILED IN SAN DIEGO RSD D-40(1/4-TON).
21. FUTURE LOCATION FOR RADIO ANTENNA. REFER TO ELECTRICAL DWGS FOR ADDITIONAL DETAIL.
22. INSTALL REMOVABLE GUARD POST ON EITHER SIDE OF CONCRETE SLAB. HANG CHAIN BETWEEN POST WITH SWIVEL EYE BOLT SNAPS ON EITHER END. HANG "NO PARKING" SIGN IN MIDDLE OF CHAIN
23. DOUBLE-LEAF GATE
24. WALK GATE

SD4	1895945.79	6511389.60	RIM 1124.70	INV IN = 1121.93 INV OUT = 1121.85
SD5	NOT USED			
SD6	1895853.75	6511495.10	GRATE 1122.89	INV OUT = 1120.89

GENERAL NOTES:

1. CONTRACTOR TO FIELD VERIFY EXISTING UTILITY LOCATIONS AND TIE-IN CONNECTION POINTS. SUBMIT FIELD DATA TO ENGINEER.
2. CONTRACTOR SHALL NOT DISRUPT WATER SERVICE TO JPL AND PROTECT MAIN WHILE WORK OCCURS.
3. CONTRACTOR SHALL SUBMIT 2 WEEKS IN ADVANCE A SCHEDULE TO PWP WHEN THE NEW JPL POTABLE LINE IS READY FOR CONNECTION TO THE EXISTING JPL METER. CONNECTION TO THE METER SHALL BE PERMITTED FOLLOWING PASSING OF THE MAIN PRESSURE TEST, DISINFECTION, AND PASSING OF THE BACTERIOLOGICAL TESTING.
4. CONTRACTOR SHALL PROVIDE AT ALL TIMES NORTH BOUND AND SOUTH BOUND VEHICLE ACCESS IN AREA 3. CONTRACTOR SHALL SUBMIT A TRAFFIC CONTROL PLAN FOR APPROVAL THAT CONFORMS TO MUTCD AND THE CITY'S DEPARTMENT OF TRANSPORTATION.

KEY NOTES:

1. RETAIN AND PROTECT EXISTING PIPING.
2. INSTALL BACKFLOW PREVENTOR (ABOVE GROUND) PER PWP STD PLAN G-1209.
3. USE RESTRAINED JOINTS FROM TIE-IN TO END OF LINE.
4. INSTALL 1" COMBINATION AIR RELEASE AND VACUUM VALVE ASSEMBLY.
5. INSTALL FIRE HYDRANT PER PWP STD PLAN C-1327 WITH GUARD POST PER TYP DETAIL C160.
6. INSTALL 2" WATER SERVICE CONNECTION PER PWP STD PLAN W-102.
7. INSTALL IRRIGATION CONTROL BOX. REFER TO LANDSCAPING PLANS FOR ADDITIONAL DETAIL.
8. ROUTE 2" FORCE MAIN TO EDGE OF EXIST. BRIDGE. PROVIDE CAP AND MARK AT GROUND SURFACE FOR FUTURE CONNECTION TO CITY SEWER EXTENSION.
9. POTABLE AND NON-POTABLE PIPE CROSSING, PROVIDE AS REQUIRED PER CITY AND CDPH REQUIREMENTS.
10. (NOT USED).
11. (NOT USED).
12. HOT TAP EXISTING 12" WATER MAIN WITH SST TAPPING SLEEVE, INSTALL GATE VALVE W/ VALVE FIX PER PWP STD PLAN G-1224.
13. PROVIDE CONCRETE ENCASEMENT PER TYPICAL DETAIL P040 FROM MARK (152) TO (150).
14. INSTALL SEWER CLEANOUT PER TYPICAL DETAIL (TYPE 2). CLEANOUT LATERAL SHALL BE 6-INCH. PROVIDE REDUCER COUPLINGS AND SPOOL PIECES TO CONNECT 6-INCH CLENOUT W/ 2-INCH FORCE MAIN.
15. INSTALL SEWER CLEANOUT PER TYPICAL DETAIL P004 (TYPE 1).

COORDINATE LOCATION TABLE NOTES:

1. ELEVATIONS SHOWN FOR PIPE ARE AT PIPE INVERT, UNLESS NOTED OTHERWISE.
2. POTHOLED DATA HAS ACCURACY IN HORIZONTAL DATA OF ±3.3', CONTRACOTR TO FIELD VERIFY.
3. ± USED TO INDICATE APPROXIMATE DEPTH. CONTRACTOR TO FIELD VERIFY.
4. REFER TO ROAD/PIPE CROSS SECTION ON DWG 03C-12.
5. REFER TO BASIN PROFILE ON DWG 03C-13.
6. ALL BENDS ARE MADE BY DEFLECTION JOINTS ALONG LINE.
7. RESTRAINED LENGTHS DESIGNATED BY "R" AND CORRESPONDING DISTANCES FROM IDENTIFIED MARK.
8. DATA FOR EXISTING LINES ARE SCREENED.

GENERAL NOTES:

1. CONTRACTOR TO FIELD VERIFY EXISTING UTILITY LOCATIONS AND TIE-IN CONNECTION POINTS, SUBMIT FIELD DATA TO ENGINEER.
2. CONTRACTOR SHALL NOT DISRUPT WATER SERVICE TO JPL AND PROTECT MAIN WHILE WORK OCCURS.
3. ALL WORK ON THE POTABLE WATER SYSTEM SHALL BE IN ACCORDANCE WITH PWP STANDARDS.
4. CONTRACTOR SHALL PROVIDE AT ALL TIMES NORTH BOUND AND SOUTH BOUND VEHICLE ACCESS IN AREA 3.

KEY NOTES:

1. REFER TO DETAIL K ON DRAWING 03C-12 FOR PIPE SIZING/ MATERIAL.
2. USE RESTRAINED JOINTS FROM TIE-IN TO END OF LINE.
3. PROTECT EX 30" RW LINE IN PLACE WHEN GOING UNDERNEATH W/ 12" PW LINE.
4. CONTRACTOR SHALL BE RESPONSIBLE TO FIELD VERIFY AND CONFIRM LOCATION OF EXISTING JPL POTABLE WATER MAIN IN THIS AREA PRIOR TO REMOVING EXISTING DRAINS. THE CONTRACTOR SHALL CAREFULLY EXPOSE THE MAIN FOR PWP TO VISUALLY INSPECT. PWP WILL INITIALLY IDENTIFY AND MARK THE APPROXIMATE LOCATION OF THE JPL MAIN DURING THE UTILITY ALERT.
5. CUT AND CAP EXISTING 24" INFLUENT AND 24" EFFLUENT PIPELINE W / BLIND FLANGE AT WEST EDGE OF NEW MAINTENANCE ROAD.
6. CONNECT W/ EXISTING LINE USING FLANGES.
7. CONSTRUCT OUTLET SIMILAR TO DETAIL K ON SHEET 03C-12.
8. USE RESTRAINED JOINTS FOR 50 FT OF PIPE AT EACH TIE-IN.
9. PROTECT IN PLACE EXISTING LINE MAKE TIE-IN & ROUTE TO BASIN E.
10. CONCRETE ENCASE BOTH 90° ELBOWS PER TYP DETAIL P040. ENCASEMENT SHALL BE 10' MIN DEPTH.
11. PROVIDE 6" DEPRESSED AREA A MIN. OF 20' AROUND PIPE INLET. GRADE SHALL NOT EXCEED 5% MAX SLOPE FROM INISHED GRADE OF BASIN.
12. FURNISH AND INSTALL 8-INCH DRAIN (JOSAM SERIES 32300 OR EQUAL) W/ 15FT OF SST CHAIN TO ELEVATED DECK, SECURE CHAIN TO HOOK MOUNTED AT END OF DECK. PROVIDE FOUR-1/2" DIA SST HOOKS EQUALLY SPACED ACROSS THE END OF DECK.
13. REMOVE RISER/ CAP/ PIPING. EXTEND SIZE AS SHOWN.

GENERAL NOTES:

1. CONTRACTOR TO FIELD VERIFY EXISTING UTILITY LOCATIONS AND TIE-IN CONNECTION POINTS. SUBMIT FIELD DATA TO ENGINEER.
2. CONTRACTOR SHALL NOT DISRUPT WATER SERVICE TO JPL AND PROTECT MAIN WHILE WORK OCCURS.
3. CONTRACTOR SHALL SUBMIT 2 WEEKS IN ADVANCE A SCHEDULE TO PWP WHEN THE NEW JPL POTABLE LINE IS READY FOR CONNECTION TO THE EXISTING JPL METER. CONNECTION TO THE METER SHALL BE PERMITTED FOLLOWING PASSING OF THE MAIN PRESSURE TEST, DISINFECTION, AND PASSING OF THE BACTERIOLOGICAL TESTING.
4. CONTRACTOR SHALL PROVIDE AT ALL TIMES NORTH BOUND AND SOUTH BOUND VEHICLE ACCESS IN AREA 3. CONTRACTOR SHALL SUBMIT A TRAFFIC CONTROL PLAN FOR APPROVAL THAT CONFORMS TO MUTCD AND THE CITY'S DEPARTMENT OF TRANSPORTATION.

KEY NOTES:

1. INSTALL 12" CAP. DEMOLISH LINE NORTH OF CAP AS SHOWN ON DEMOLITION SHEETS.
2. REFER TO DETAIL K ON DRAWING 03C-12 FOR PIPE SIZING/ MATERIAL.
3. (NOT USED)
4. (NOT USED)
5. (NOT USED)
6. PROVIDE 6" DEPRESSED AREA A MIN. OF 20' AROUND PIPE INLET. GRADE SHALL NOT EXCEED 5% MAX SLOPE FROM FINISHED GRADE OF BASIN.

COORDINATE LOCATION TABLE NOTES:

1. ELEVATIONS SHOWN FOR PIPE ARE AT PIPE INVERT, UNLESS NOTED OTHERWISE.
2. POTHOLED DATA HAS ACCURACY IN HORIZONTAL DATA OF P3,3'. CONTRACOTR TO FIELD VERIFY.
3. ± USED TO INDICATE APPROXIMATE DEPTH. CONTRACTOR TO FIELD VERIFY.
4. NOT USED.
5. REFER TO BASIN PROFILE ON DWG 03C-13.
6. ALL BENDS ARE MADE BY DEFLECTION JOINTS ALONG LINE.
7. RESTRAINED LENGTHS DESIGNATED BY "R" AND CORRESPONDING DISTANCES FROM IDENTIFIED MARK.
8. DATA FOR EXISTING LINES ARE SCREENED.

COMBINATION STARTER
WITH CONTROL POWER TRANSFORMER
a = CIRCUIT BREAKER DISCONNECT, TYPE AS NOTED
b = STARTER TYPE
c = NEMA STARTER SIZE
d = OVERLOAD HEATERS

VARIABLE FREQUENCY DRIVE
WITH FEATURES AS SHOWN
a = INPUT CONTACTOR
b = OUTPUT CONTACTOR
c = BYPASS STARTER
d = INPUT CIRCUIT BREAKER
LR — LINE REACTOR
LL — LOAD REACTOR

REDUCED VOLTAGE SOLID STATE STARTER
WITH FEATURES AS SHOWN
BS = BYPASS STARTER

MISCELLANEOUS

HP — MOTOR
HP = HORSEPOWER RATING
FULL LOAD AMPS AS NOTED

PACKAGED EQUIPMENT
LOAD RATING AS INDICATED
a = RATED LOAD
b = UNIT(HP, KW, KVA) AS INDICATED

TRANSFORMER
a = DEVICE I.D.
b = KVA RATING
c = NUMBER OF PHASES
d = PRIMARY VOLTAGE
e = SECONDARY VOLTAGE
f,g = CONNECTION TYPE SYMBOL
h = IMPEDANCE

GROUNDED WYE CONNECTION

DELTA CONNECTION

G — ENGINE-GENERATOR RATINGS AS INDICATED ON THE DRAWINGS
a = KVA/KW
b = VOLTAGE/CONNECTION
c = PHASE
d = WIRE
e = PF

CURRENT TRANSFORMER WITH SHORTING TERMINAL BLOCK
a = QUANTITY
b = RATIO

POTENTIAL TRANSFORMER
a = QUANTITY
b = RATIO
c,d = CONNECTION TYPE SYMBOL

SSM — SOLID STATE MULTIFUNCTION METER

ATP — AMPERE TEST POINT

VTP — VOLTAGE TEST POINT

UTILITY METER

LIGHTNING ARRESTER

SPD — SURGE PROTECTIVE DEVICE

DRAWOUT CONNECTION

A	AMP
ABS	ABSOLUTE
AC	ALTERNATING CURRENT
ACK	ACKNOWLEDGE
ACTR	ACTUATOR
AF	AMP FRAME
AFC	AUTOMATIC FREQUENCY CONTROL
AIC	AMP INTERRUPTING CAPACITY
AM	AMMETER
ANN	ANNUNCIATOR
ANT	ANTENNA
APU	AUXILIARY POWER UNIT
ARM	ARMORED CABLE
AS	AMMETER SWITCH
ASYM	ASYMMETRICAL
AT	AMP TRIP
ATO	AUTOMATIC THROW OVER
ATP	AMMETER TEST POINT
ATS	AUTOMATIC TRANSFER SWITCH
AUTO XFMR	AUTOMATIC TRANSFORMER
AUX	AUXILIARY
AWG	AMERICAN WIRE GAGE
B	BELL
BAT	BATTERY
BFG	BELOW FINISHED GRADE
BHP	BRAKE HORSEPOWER
BKR	BREAKER
BRF	BELOW RAISED FLOOR
C	CONDUIT / CONTINUOUS LOAD
CB	CIRCUIT BREAKER
CCTV	CLOSED CIRCUIT TELEVISION
CCW	COUNTER CLOCKWISE
CKT	CIRCUIT
COAX	COAXIAL CABLE
COM	COMMON
COMM	COMMUNICATION
CPT	CONTROL POWER TRANSFORMER
CS	CONTROL SWITCH
CT	CURRENT TRANSFORMER
CV	CONTROL VALVE
CW	CLOCKWISE / COOL WHITE
DC	DIRECT CURRENT
DCS	DISTRIBUTED CONTROL SYSTEM
DCU - X	DISTRIBUTED CONTROL UNIT NO. X
DEMO	DEMOLITION
DISC	DISCONNECT SWITCH
DM	DEMAND METER
DPDT	DOUBLE POLE DOUBLE THROW
DPST	DOUBLE POLE SINGLE THROW
DS	DOOR SWITCH
E/G	EMERGENCY GENERATOR
EM	EMERGENCY
EMT	ELECTRICAL METALLIC TUBING
ENCL	ENCLOSURE
ENG	ENGINE
ENT	ELECTRICAL NON-METALLIC TUBING
EP	EXPLOSION PROOF
ETM	ELAPSED TIME METER
FA	FIRE ALARM
FACP	FIRE ALARM CONTROL PANEL
FDR	FEEDER
FLA	FULL LOAD AMPS
FLX	FLEXIBLE CONDUIT
FO	FIBER OPTIC
FRC	FIBERGLASS RIGID CONDUIT
FREQ	FREQUENCY
FU	FUSE
FU	SW FUSED SWITCH
FVNR	FULL VOLTAGE NON-REVERSING
FVR	FULL VOLTAGE REVERSING
FWD	FORWARD
G	GROUND / EQUIPMENT GROUND / GROUND FAULT
GEN	GENERATOR
GRC	GALVANIZED STEEL RIGID CONDUIT
GFCI	GROUND FAULT CIRCUIT INTERRUPTER (RECEPTACLE)
GFI	GROUND FAULT INTERRUPTER (BREAKER)
GFR	GROUND FAULT RELAY
H	HOT-LEG
HF	HIGH FREQUENCY
HP	HORSEPOWER
HPS	HIGH PRESSURE SODIUM
HR	HOUR
HSTAT	HUMIDISTAT
HV	HIGH VOLTAGE
HVAC	HEATING/VENTILATION/AIR CONDITIONING
HZ	HERTZ
I	INSTANTANEOUS LOAD
IC	INTERRUPTING CAPACITY
IJB	INSTRUMENT JUNCTION BOX
IMC	INTERMEDIATE METAL CONDUIT
INST	INSTANTANEOUS
INT	INTERLOCK
INTERCOM	INTERCOMMUNICATION
J	JUNCTION BOX
K	KEY INTERLOCK

LVL	LEVEL
M-X	MOTOR CONTROLLER NO. X
MA	MILLIAMPERE
MCA	MOTOR CIRCUIT AMPS
MCC - X	MOTOR CONTROL CENTER NO. X
MCP	MOTOR CIRCUIT PROTECTOR
MH	MANHOLE / MOUNTING HEIGHT
MLO	MAIN LUGS ONLY
MOD	MOTOR OPERATED DAMPER
MOV	METAL OXIDE VARISTOR
MRP	MOTOR PROTECTION RELAY
MS-X	MOTOR STARTER NO. X
MSP	MOTOR STARTING PANEL
MTO	MANUAL THROW OVER
MTR-X	MOTOR NO. X
MTS	MANUAL TRANSFER SWITCH
MV	MEGAVOLT
MVA	MEGAVOLT-AMPERES
MVS	MEDIUM VOLTAGE SWITCH
MW	MEGAWATT
N	NEUTRAL
NC	NORMALLY CLOSED
NEC	NATIONAL ELECTRICAL CODE
NFC	NONMETALLIC FLEXIBLE CONDUIT
NL	NIGHT LIGHT
NO	NORMALLY OPEN
NP	NAMEPLATE
O	OPEN OR OPENED
OH	OVERHEAD
OL	OVERLOAD RELAY
P	POLE
PA	PUBLIC ADDRESS
PB	PUSHBUTTON / PULL BOX
PCS	PVC COATED GALVANIZED STEEL CONDUIT
PCM	PROCESS CONTROL MODULE
PE	PHOTOCELL
PF	POWER FACTOR
PFCC	POWER FACTOR CORRECTION CAPACITOR
PFR	PHASE FAILURE RELAY
PH	PHASE
PNL	PANEL
PPX	POWER PANEL NO. X
PRI	PRIMARY
PT	POTENTIAL TRANSFORMER
PVC	POLYVINYL CHLORIDE RIGID PLASTIC CONDUIT
PW&P	PASADENA WATER & POWER
PWR	POWER
RAC	RIGID ALUMINUM CONDUIT
RECPT	RECEPTACLE
REV	REVERSE
RF	RADIO FREQUENCY
RMS	ROOT MEAN SQUARED
RVAT	REDUCED VOLTAGE AUTO TRANSFORMER
RVNR	REDUCED VOLTAGE NON-REVERSING
RVSS	REDUCED VOLTAGE SOLID STATE
S	SHIELD / SHORT-TIME
SA	SURGE ARRESTER
SC	SHORT CIRCUIT
SDBC	SOFT DRAWN BARE COPPER
SFL	SUB FEED LUGS
SLT	SEALTIGHT LIQUIDTIGHT FLEXIBLE CONDUIT
SM	SURFACE MOUNTED
SP	SINGLE POLE
SPD	SURGE PROTECTIVE DEVICE
SPDT	SINGLE POLE DOUBLE THROW
SPST	SINGLE POLE SINGLE THROW
SPKR	SPEAKER
SS	SOLID STATE
STB	SHORTING TERMINAL BLOCK
SW	SWITCH
SWBD	SWITCHBOARD
SWGR	SWITCHGEAR
SYM	SYMMETRICAL
TACH	TACHOMETER
TB - X	TERMINAL BLOCK - UNIT X
TC	THERMOCOUPLE / TIME CLOCK / TRAY CABLE
TD	TEMPERATURE DETECTOR RELAY
TE	TOTALLY ENCLOSED
TEFC	TOTALLY ENCLOSED FAN COOLED
TENV	TOTALLY ENCLOSED NON-VENTILATED
TERM	TERMINAL
TJB	TERMINAL JUNCTION BOX
TM	THERMAL MAGNETIC
TP	TWISTED PAIR
TS	TEMPERATURE SWITCH
TS1W	TWO SPEED CONSEQUENT POLE, ONE WINDING
TS2W	TWO SPEED SEPARATE WINDING
TSTAT	THERMOSTAT
UHF	ULTRA HIGH FREQUENCY
UNG	UNGROUNDED
UPS	UNINTERRUPTABLE POWER SUPPLY
UVR	UNDER VOLTAGE RELAY
V	VOLT
VA	VOLT AMPERE
VAR	VARMETER
VCP	VENDOR CONTROL PANEL
VFD	VARIABLE FREQUENCY DRIVE
VHF	VERY HIGH FREQUENCY
VM	VOLTMETER
VP	VAPORPROOF
VR	VOLTAGE REGULATOR
VS	VOTAGE SWITCH
VT	VOLTAGE TRANSFORMER
VTP	VOLTAGE TEST POINT
W	WATT / WEST
WT	WATER TIGHT
WP	WEATHER PROOF
XFMR	TRANSFORMER

NOTES:

1. REFER TO SPECIFICATIONS OTHER DRAWINGS FOR ADDITIONAL ABBREVIATIONS.

1 INTRODUCTION

1.1 Project Summary

Dudek has prepared this Biological Resources Technical Report (BRTR) for Pasadena Water and Power (PWP) in support of the City of Pasadena's (City) Arroyo Seco Canyon Project Areas 2 and 3 (proposed Project or Project). The Project is located in the northwest corner of the City of Pasadena in Los Angeles County, California as shown in Figure 1, Local Vicinity and Regional Location. Figure 1 also depicts the Project's 37.38-acre Study Area, which is defined as the following Project components (Area 2, Area 3, the Gabrielino Trail/Access Road between Area 2 and Area 3, and North Arroyo Boulevard[1] from Ventura Street), a 50-foot buffer around each component, and two staging areas. Figure 1 also identifies the municipal boundaries of the adjacent City of La Cañada Flintridge and the community of Altadena, as well as other nearby properties, including the Jet Propulsion Laboratory (JPL) and the Devil's Gate Reservoir and Dam.

The proposed Project consists of two primary action areas: a diversion dam and intake replacement in Area 2, and the spreading basin expansion in Area 3. These areas are connected by the Gabrielino Trail/Access Road, which serves as a recreational trail and the access road for the City of Pasadena and U.S. Forest Service vehicles heading into and out of the Angeles National Forest (ANF). No improvements are expected to the Gabrielino Trail/Access Road. The North Arroyo Boulevard connects with the Gabrielino Trail/Access Road and is included in the Study Area, as it connects Area 3 to the public road intersection of Ventura Street and Windsor Avenue.

This BRTR has been prepared to evaluate the potential impacts to biological resources pursuant to the California Environmental Quality Act (CEQA). This BRTR documents the vegetation communities, plants, wildlife; existing and potential special-status wildlife and plant species; wildlife movement; and jurisdictional waters within the Study Area. The biological significance of these resources and potential Project-related impacts are evaluated, and mitigation measures are recommended, if needed, to avoid or substantially lessen potentially significant environmental impacts.

This BRTR presents the findings of several biological surveys conducted at the Project site by Dudek, including a general biological reconnaissance survey conducted on April 23, 2019, focused special-status plant surveys conducted in May and July 2019, focused amphibian survey in May 3, 2019, focused special-status bird surveys from April to July 2019, jurisdictional delineation

[1] Also known as "Arroyo Seco Road".

update on July 5, 2019, focused fish survey conducted on October 14, 2019, and protected tree survey conducted on April 2 and 3, 2020.

1.1.1 Project Background

On October 9, 2014, PWP circulated the Arroyo Seco Canyon Project (ASCP) Initial Study/Mitigated Negative Declaration (IS/MND) and associated technical studies, State Clearinghouse Number 2014101022, for a 30-day public review period from October 9, 2014, to November 8, 2014. The PWP was seeking approval of a Conditional Use Permit (CUP) No. 6222 for the ASCP, which involved improvements to three areas, including Area 1, Arroyo Seco Headworks; Area 2, Arroyo Seco Intake; and Area 3, JPL East Parking Lot. The 2014 IS/MND included the following biological studies to support the analysis of the ASCP:

- Biological Technical Report, Arroyo Seco Canyon Project, dated September 2014 (BonTerra Psomas 2014a)
- Special Status Botanical Surveys for the Arroyo Seco Canyon Project, dated January 20, 2014 (BonTerra Psomas 2014b)
- Native Tree Survey, Arroyo Seco Canyon Project, dated September 2014 (BonTerra Psomas 2014c)
- Jurisdictional Delineation Report, Arroyo Seco Canyon Project, dated May 2014 (BonTerra Psomas 2014d)
- Results of the 2013 Amphibian Surveys for the Arroyo Seco Canyon Project, dated February 4, 2014 (BonTerra Psomas 2014e)
- Results of the 2013 Least Bell's Vireo/Southwestern Willow Flycatcher Survey for the Arroyo Seco Canyon Project Dated September 2013 (BonTerra Consulting 2013)

Figure 2, Study Area Comparison, shows a comparison of the areas studied in 2013 and 2014 documents listed above to the areas studied for this BRTR. As described below, the study areas are different to reflect the direction given through a Court judgement and associated Settlement Agreement related to the environmental review requirements of the proposed Project.

On January 12, 2015, the City's Hearing Officer made findings to approve the ASCP IS/MND for CUP No. 6222. On January 20, 2015, Spirit of the Sage Council, Project Soliton, and Hugh Bowles submitted an appeal of the Hearing Officer's decision to the Board of Zoning Appeals. The Board of Zoning Appeals hearing took place on March 4, 2015, and upheld the Hearing Officer's decision by a unanimous vote. The approval was again appealed to the City Council, and on June 1, 2015, the City Council voted to uphold the Board of Zoning Appeals decision by unanimous vote.

On July 2, 2015, a lawsuit (Court Case No. BS156207) was filed against the City by petitioners Spirit of the Sage Council and Project Soliton challenging the approval of the ASCP. On March 20, 2017, the Los Angeles Superior Court issued its decision and on June 26, 2017, entered a judgment that partially favored the petitioners. The Court found that the elements of the ASCP that related to increased diversions of surface water (i.e., greater taking of stream water from the Arroyo Seco beyond its current withdrawal) were inadequately analyzed under CEQA and required the preparation of an Environmental Impact Report (EIR).

The Court also ruled that the elements of the ASCP that did not relate to increased diversions were severable from the remainder of the ASCP and complied with CEQA. As such, the Court determined that CUP #6222 and its related findings and conditions of approval, and the ASCP IS/MND shall remain intact for these components, (Spirit of the Sage Council v. City of Pasadena 2017) and would be allowed to move forward without any additional environmental review pursuant to CEQA. These components include the following:

- Area 1, Arroyo Seco Headworks: All ASCP elements
- Area 2, Arroyo Seco Intake: Access road improvements and related slope reconstruction and protective riprap elements, except the diversion dam and intake replacement
- Area 3, JPL East Parking Lot: All ASCP elements, except the expansion of four existing spreading basins and the construction of two new spreading basins

As stated above, for Area 2, the demolition and replacement of the diversion dam and intake structure were required to be analyzed in an EIR. For Area 3, components of the ASCP IS/MND that would be allowed to proceed include the parking lot, access road, sedimentation basin, demolition of existing structures and pipelines, new pipelines, new public restroom, new security booth, and associated utility services (water, sewer, power, and communication lines), while the expansion of four existing spreading basins and the construction of two new spreading basins were required to be analyzed in an EIR.

In addition, a Settlement Agreement was negotiated, which stated that the City shall have the right to perform maintenance activities, including tilling and grading of the existing spreading basins to reestablish historical percolation rates and maintenance activities that involve negligible or no expansion of use as described in CEQA Guidelines Section 15301 for a Class 1 Categorical Exemption. The Settlement Agreement further clarified that the City may perform excavation and grading necessary for the temporary bridges as described in the ASCP IS/MND.

In accordance with the terms and provisions of the Writ of Mandate and Judgment, as modified by the Settlement Agreement, the City is preparing an EIR for the proposed Project in accordance with CEQA and the CEQA Guidelines. Because several components of the ASCP were allowed

to proceed without any additional environmental review pursuant to CEQA, the proposed Project boundaries of Area 2 and Area 3 have been refined from those shown in the ASCP IS/MND to reflect the activities subject to review under the EIR, as described below.

1.1.2 Report Format and Approach

This BRTR has been prepared to satisfy the requirements of CEQA and the terms and provisions of the Writ of Mandate and Judgment, as modified by the Settlement Agreement, regarding the biological impacts of Project implementation. As such, the Study Area for this BRTR is defined as Areas 2 and 3 as shown on Figure 1.

It is anticipated that this BRTR, in conjunction with the previous biological studies listed above that supported implementation of certain components of the ASCP (supported by the 2014 IS/MND and associated studies), would support the applications for a Section 404 Permit by the U.S. Army Corps of Engineers (USACE), a Section 1602 Streambed Alteration Agreement by the California Department of Fish and Wildlife (CDFW), and a Section 401 Water Quality Certification by the Los Angeles Regional Water Quality Control Board (RWQCB).

As such, it is anticipated that the future discretionary issuance of regulatory permits will be supported by the 2014 IS/MND and associated biological studies, as well as the 2019 EIR and this BRTR. Therefore, the Least Bell's Vireo/Southwestern Willow Flycatcher Focused Surveys Memorandum (Appendix A), California Red-Legged Frog/Arroyo Toad Survey Memorandum (Appendix B), and Focused Fish Survey Memorandum (Appendix C) are updated survey efforts that include areas of the ASCP that were allowed to proceed under the Settlement Agreement (e.g., Area 1 and portions of Areas 2 and 3), as well as the Study Area of the proposed Project (see Figure 1), to facilitate resource agency review of permit applications for the entirety of the ASCP

1.2 Project Description

1.2.1 Project Location

The Project site is located in the City of Pasadena within the Arroyo Seco Canyon, located in Township 1 North, Range 12 West on the Pasadena, California 7.5-inch U.S. Geologic Survey quadrangle map. The Project site can be accessed via Interstate (I) 210 by exiting Windsor Avenue and traveling northward for approximately 0.8-mile to the intersection of Windsor Avenue and Ventura Street. From this intersection, the City's open area (i.e., the former JPL East Parking Lot) is located approximately 0.3 miles north along Explorer Road, which constitutes the southern boundary of Area 3.

1.2.2 Project Purpose

The City owns the right to divert up to 25 cubic feet per second (cfs) of surface water from the Arroyo Seco and currently conveys this water to spreading basins for water pumping credits in the Raymond Basin. The City receives groundwater pumping credit between 60 to 80 percent of the amount of water recharged into the groundwater basin. In the two storm seasons following the 2009 Station Fire, excessive amounts of sediment washed down from the watershed. The debris flows damaged City structures, greatly reducing the City's capacity to divert water for spreading. As a result, PWP proposes to repair and replace damaged facilities in the Upper Arroyo Seco Canyon as a part of the proposed Project. The improvements would allow for increased utilization of the City's surface water rights from the Arroyo Seco and maximize the beneficial use of this important local water resource. The proposed Project would implement a multi-benefit approach to the repair and replacement of damaged infrastructure in the Arroyo Seco, with the overall Project objectives to increase the beneficial use of the surface water rights held by the City and to improve biological functions within the Arroyo Seco for both fish protection and through improved opportunities for fish passage.

The Project site consists of two primary areas, as shown on Figure 1: Area 2 (Diversion and Intake Replacement) and Area 3 (Spreading Basin Improvements), which are connected by the Gabrielino Trail/Access Road. The proposed Project would involve construction activity and facility improvements in both areas, as well as construction truck traffic along portions of the Gabrielino Trail/Access Road.

1.2.3 Project Components

1.2.3.1 Area 2: Diversion and Intake Replacement

Area 2 includes approximately 1.4 acres of the Study Area. Figure 3a, Area 2 Existing Conditions, identifies the primary existing structures in Area 2, including the concrete diversion weir and intake structure, and a historic bridge (Bridge No. 3) over the Arroyo Seco. The diversion weir directs water into the intake structure by obstructing the stream flow and creating a small pool of water that flows into the intake. The intake would be operated to divert the City's 25 cfs of water rights, while additional flows beyond 25 cfs would continue downstream. Due to sediment buildup trapped on the upstream side of the weir, the pooling capacity is reduced and the ability to collect water for spreading is limited. When water enters the intake, it is conveyed downstream through a combination of tunnels and pipelines to the PWP's spreading basins. The existing intake/diversion system consists of an approximate 9-foot high reinforced concrete training wall and intake with a trash rack on the east bank of the stream, and a reinforced concrete weir with stop logs in slots.

Under current conditions, the weir crest is approximately 2 feet above the streambed on the downstream side.

Improvements in Area 2 include the demolition and removal of the existing concrete weir and portions of the intake structure and the construction of a new diversion structure that would be operated to divert up to 25 cfs of stream flows into the existing conveyance system. The intake structure would be remodeled with new concrete walls and top deck to accommodate the replacement of a trash rack, gates and flushing line, and also a new screen configuration. An existing concrete slab that previously supported an equipment building located adjacent to the Gabrielino Trail/Access Road would be demolished. A new 106 square foot (11 feet 4 inches by 9 feet 4 inches) intake service building would be constructed to house the electrical and hydraulic controls for the diversion structure. Electric power for the operation of the diversion structure and control equipment enclosure would be supplied by an existing power line at the screen building (southeast of the intake structure). The locations of the proposed facilities and improvements are shown on Figure 3b, Area 2 Conceptual Design Overview.

The proposed new diversion/intake structure would capture flows up to PWP's surface water rights. Similar to existing operations, this would include all flows during small storm events and dry weather flows in the Arroyo Seco. However, the improvements will allow for diversion of flows during large storm events as well. During larger storms when the water is too turbid with suspended sediments (e.g., flows generally above 100 cfs), the stream with its associated sediment load would bypass the diversion/intake structure and continue downstream to Devil's Gate Reservoir. Operation of the weir during high flows would be facilitated by the adjustable height weir or crest gate. At low flows, the gate would start in the 'up' position and as flows increase, the gate would be lowered to maintain a constant water surface level in the diversion pool (a pool created behind the weir to allow for an appropriate water elevation to flow into the diversion intake). When the gate is fully lowered, flows would entirely bypass the diversion structure and carry all flows and sediment downstream.

The new diversion/intake structure would improve biological functions in the Arroyo Seco by allowing for fish passage if future fish populations are established, as well as other aquatic wildlife. The existing weir/diversion structure is a barrier to upstream fish passage due to the elevation drop downstream of the structure. The new diversion structure would be designed for the possibility that some future fish may pass downstream when the diversion is not operating (i.e., the gate is lowered to allow flows to continue downstream without diversion) or when the diversion is operating and flows are high enough to spill over the crest gate. A roughened channel would be constructed downstream of the new diversion structure and operable weir such that upstream passage for future fish populations may occur during periods when the diversion is not operating and flows are adequate to allow for passage. In the current condition, water passes through a trash rack to prevent debris from entering the conveyance system to the spreading basins. In addition to

filtering such debris, the proposed new intake structure would include a fish screening feature to prevent future fish populations from passing into the intake and conveyance system.

1.2.3.2 Area 3: Spreading Basin Improvements

Area 3 includes approximately 23.27 acres of the Study Area and is located approximately 0.3 miles downstream from Area 2. The Area 3 Study Area includes two existing spreading basins (Pasadena Ponds 1 and 2, formerly used as sludge ponds for the Behner Treatment Plant), Spreading Basins Nos. 1 and 2, a portion of Spreading Basin No. 3, the former JPL East Parking Lot removed in 2015 to accommodate the spreading basin expansion, and the adjacent Explorer Road. North Arroyo Boulevard is adjacent to Area 3 and would provide construction vehicle access to Area 2, while Explorer Road will be used to Access Area 3. Figure 4a, Area 3 Existing Conditions, identifies the primary structures and facilities in Area 3.

Improvements in Area 3 include the reconfiguration and expansion of the spreading basins in order to accommodate the increased diversion of stream flows for infiltration into the Raymond Basin. Spreading basins provide an additional means for recharge rather than losing this water to the ocean while allowing PWP to earn groundwater pumping credits for additional local water supply. Various facilities would be demolished, including inlet/outlet structures, dry vaults, woodsheds, utility light pole, pipes and valves, chain link fencing, corrugated metal pipes, and other small appurtenant structures, to allow for the reconstructed basins.

Figure 4b, Conceptual Site Plan, depicts the proposed spreading basin improvements. Stream flows from the existing conveyance system would outlet to the new sedimentation basin or to new spreading Basin E located over the existing Pasadena Pond 1. Basin F would be adjacent to mature trees to be preserved and would be located at the site of the existing Pasadena Pond 2. Basins G, H, and I would be located at the site of the existing Basins 1 and 2 and a portion of the City's open area (i.e., former JPL East Parking Lot). Each new basin would have an access ramp for maintenance. Rock boulders would be placed along the western edge of Explorer Road to separate the roadway from the adjacent basins. With the area's sloping terrain, depths of the basins would range from three feet to seven feet. When spreading water, the water depth in the basins would be approximately 1 foot. All basins would include inlets/outlets with 24-inch interconnection piping. Spillways, pipelines, culverts, and valves would be provided to connect the basins to each other. Basin J would be the last newly constructed basin located entirely within the former JPL East Parking Lot, which would include interconnection piping into the existing Basin 3. Other basins downstream of Basin 3 are not a part of the proposed Project, although Basin 4 may be temporarily impacted during construction.

1.2.3.3 Gabrielino Trail/Access Road

The Gabrielino Trail (i.e., North Arroyo Boulevard) runs generally parallel to the Arroyo Seco and along the eastern side of the former JPL East Parking Lot and serves as a recreation trail for hikers, bikers, and equestrian uses. The portion of the Gabrielino Trail that will be used for access constitutes 11.78 acres. It serves as a maintenance access road that leads to the Behner Water Treatment Plant and into the Arroyo Seco Canyon area to provide access for PWP and the USFS. During construction activities, the Gabrielino Trail/Access Road would provide for vehicular access to and from Area 2, and sometimes Area 3 (Explorer Road will be its primary access road). No changes will be made to the Gabrielino Trail as part of the Project.

1.2.4 Construction Activities

Construction of the Project improvements is anticipated to take approximately 16 months, starting in August 2021 with Project completion expected by January 2023. In the interest of minimizing the export of excavated materials from the Project site, the City may implement a mechanical shaker to sort and sift through excavated soils to separate finer soils from larger rocks, thereby allowing for the beneficial reuse of the materials as engineered fill materials during the construction of the spreading basins. Rock materials may be used on site for decorative/landscaping purposes throughout the Project study area, added to an existing stockpile that has been created by the City in an area along the west bank of the Arroyo for future uses, or may be exported off site.

Construction trucks hauling soils and debris to and from to Irwindale – Durbin Inert Debris Engineered Fill Site are expected to come to the site from I-210 at the Windsor Avenue off-ramp and head north on Windsor Avenue to the intersection with Ventura Street. At this intersection is a fork in the road, one leading to Explorer Road into Area 3 and the other leading to the gated North Arroyo Boulevard, which passes adjacent to residential properties and the Behner Treatment Plant. Near the JPL Bridge over the Arroyo Seco near the northern boundary of Area 3, North Arroyo Boulevard splits and provides access to the Gabrielino Trail/Access Road and to the JPL Bridge/Explorer Road. Construction trucks would use North Arroyo Boulevard to access Area 2 and Explorer Road would be used to access Area 3. From I-210, trucks would head east and then south on I-605; exit at Lower Azusa Road off-ramp; and head east onto Los Angeles Street to enter Irwindale – Durbin Inert Debris Engineered Fill Site. Trucks would come back from the landfill entering the northbound on-ramp of I-605at Los Angeles Street and head north; trucks would then go west on I-210 to Windsor Avenue to Explorer Road and, ultimately, to the site.

1.2.4.1 Staging Areas

The Screen Building adjacent to Area 2 and the Behner Water Treatment Plant adjacent to Area 3 would be used for temporary construction materials and equipment staging. The Screen Building staging area constitutes 0.09 acres of the Study Area and the Behner Treatment Plant Staging Area constitutes 0.84 acres.

1.2.5 Operational Activities

City personnel would continue to provide maintenance of the diversion and intake structures in Area 2 as occurs under existing conditions. When necessary, cleaning of the spreading basins in Area 3 would continue to be accomplished by mechanically scraping the top layer of soil using front-end loaders, graders, or scrapers. Following removal, the surface would be disked or harrowed to loosen any soil compaction caused by cleaning. An estimated 100 truckloads of soil from the existing and proposed spreading basins would have to be disposed of offsite every five years, which is reflective of current maintenance activities. As such, no substantive changes to ongoing operations and/or maintenance activities are anticipated.

INTENTIONALLY LEFT BLANK

2 REGULATORY SETTING

This chapter outlines the federal, state, and local regulations pertinent to the biological resources located on the Project site.

2.1 Federal

2.1.1 Federal Endangered Species Act

The federal Endangered Species Act (FESA) of 1973 (16 USC 1531 et seq.), as amended, is administered by the U.S. Fish and Wildlife Service (USFWS) for most plant and animal species and by the National Oceanic and Atmospheric Administration National Marine Fisheries Service for certain marine species. This legislation is intended to provide a means to conserve the ecosystems upon which endangered and threatened species depend and provide programs for the conservation of those species, thus preventing the extinction of plants and wildlife. The FESA defines an endangered species as "any species that is in danger of extinction throughout all or a significant portion of its range." A threatened species is defined as "any species that is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range." Under FESA, it is unlawful to "take" any listed species, and "take" is defined as, "harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct."

FESA allows for the issuance of incidental take permits for listed species under Section 7, which is generally available for projects that also require other federal agency permits or other approvals, and under Section 10, which provides for the approval of habitat conservation plans on private property without any other federal agency involvement.

2.1.2 Migratory Bird Treaty Act

The Migratory Bird Treaty Act (16 USC 703 et seq.), as amended, prohibits the intentional take of any migratory bird or any part, nest, or eggs of any such bird. Under the Migratory Bird Treaty Act, "take" is defined as pursuing, hunting, shooting, capturing, collecting, or killing, or attempting to do so. In December 2017, Department of the Interior Principal Deputy Solicitor Jorjani issued a memorandum (M-37050) that interprets the Migratory Bird Treaty Act's "take" prohibition to apply only to affirmative actions that have as their purpose the taking or killing of migratory birds, their nests, or their eggs. Unintentional or accidental take is not prohibited (DOI 2017). Additionally, Executive Order 13186, Responsibilities of Federal Agencies to Protect Migratory Birds, requires that any project with federal involvement address impacts of federal actions on

migratory birds with the purpose of promoting conservation of migratory bird populations (66 FR 3853–3856). The Executive Order requires federal agencies to work with USFWS to develop a memorandum of understanding. USFWS reviews actions that might affect these species.

2.1.3 Clean Water Act

The Clean Water Act provides guidance for the restoration and maintenance of the chemical, physical, and biological integrity of the nation's waters. Section 401 requires a project operator for a federal license or permit that allows activities resulting in a discharge to waters of the United States to obtain state certification, thereby ensuring that the discharge will comply with provisions of the Clean Water Act. The RWQCBs administer the certification program in California. Section 402 establishes a permitting system for the discharge of any pollutant (except dredged or fill material) into waters of the United States. Section 404 establishes a permit program administered by USACE that regulates the discharge of dredged or fill material into waters of the United States, including wetlands. USACE implementing regulations are found at 33 CFR 320 and 330. Guidelines for implementation are referred to as the Section 404(b)(1) Guidelines, which were developed by the U.S. Environmental Protection Agency in conjunction with USACE (40 CFR 230). The guidelines allow the discharge of dredged or fill material into the aquatic system only if there is no practicable alternative that would have less adverse impacts.

Wetlands and Other Waters of the United States

Aquatic resources, including riparian areas, wetlands, and certain aquatic vegetation communities, are considered sensitive biological resources and can fall under the jurisdiction of several regulatory agencies. USACE exerts jurisdiction over waters of the United States, including all waters that are subject to the ebb and flow of the tide; wetlands and other waters such as lakes, rivers, streams (including intermittent or ephemeral streams), mudflats, sandflats, sloughs, prairie potholes, vernal pools, wet meadows, playa lakes, or natural ponds; and tributaries of the above features.

The extent of waters of the United States is generally defined as that portion that falls within the limits of an ordinary high-water mark (OHWM). Typically, the OHWM corresponds to the water surface elevation of a 2-year flood event (USACE 2008a). In addition, waters of the United States may include wetlands, including swamps, bogs, seasonal wetlands, seeps, marshes, and similar areas, defined by USACE as "those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions" (33 CFR 328.3[b]; 40 CFR 230.3[t]). Indicators of three wetland parameters (i.e., hydric soils, hydrophytic vegetation,

and wetlands hydrology), as determined by field investigation, must be present for a site to be classified as a wetland by USACE (USACE 1987).

2.2 State

2.2.1 California Endangered Species Act

The California Endangered Species Act (CESA) (California Fish and Game Code, Section 2050-2068) provides protection and prohibits the take of plant, fish, and wildlife species listed by the State of California. Unlike FESA, under CESA state-listed plants have the same degree of protection as wildlife, but insects and other invertebrates may not be listed. Take is defined similarly to FESA and is prohibited for both listed and candidate species. Take authorization may be obtained by the project applicant from CDFW under CESA Section 2081, which allows take of a listed species for educational, scientific, or management purposes. In this case, private developers consult with CDFW to develop a set of measures and standards for managing the listed species, including full mitigation for impacts, funding of implementation, and monitoring of mitigation measures.

2.2.2 California Fish and Game Code

Fully Protected Species

Sections 3511, 4700, 5050, and 5515 of the California Fish and Game Code outline protection for fully protected species of mammals, birds, reptiles, amphibians, and fish. Species that are fully protected by these sections may not be taken or possessed at any time. CDFW cannot issue permits or licenses that authorize the "take" of any fully protected species, except under certain circumstances, such as scientific research and live capture and relocation of such species pursuant to a permit for the protection of livestock. Furthermore, it is the responsibility of the CDFW to maintain viable populations of all native species. Toward that end, the CDFW has designated certain vertebrate species as Species of Special Concern (SSC), because declining population levels, limited ranges, and/or continuing threats have made them vulnerable to extinction.

Section 5901

Section 5901 makes it unlawful to construct or maintain any device or contrivance that prevents, impedes, or tends to prevent or impede, the passing of fish up and down stream. Fish are defined in Section 45 as a wild fish, mollusk, crustacean, invertebrate, amphibian, or part, spawn, or ovum of any of those animals.

Section 5937

Section 5937 requires that the owner of any dam shall allow sufficient water at all times to pass through a fishway, or in the absence of a fishway, allow sufficient water to pass over, around or through the dam, to keep in good condition any fish that may be planted or exist below the dam. During the minimum flow of water in any river or stream, permission may be granted by the department to the owner of any dam to allow sufficient water to pass through a culvert, waste gate, or over or around the dam, to keep in good condition any fish that may be planted or exist below the dam, when, in the judgment of the department, it is impracticable or detrimental to the owner to pass the water through the fishway.

Section 1602

Under Section 1602 of the California Fish and Game Code, a project operator is required to notify CDFW prior to any project that would divert, obstruct, or change the natural flow, bed, channel, or bank of any river, stream, or lake. Pursuant to the code, a "stream" is defined as a body of water that flows at least periodically, or intermittently, through a bed or channel having banks and supporting fish or other aquatic life. Based on this definition, a watercourse with surface or subsurface flows that supports or has supported riparian vegetation is a stream and is subject to CDFW jurisdiction. Altered or artificial watercourses valuable to fish and wildlife are subject to CDFW jurisdiction. CDFW also has jurisdiction over dry washes that carry water during storm events.

Preliminary notification and project review generally occur during the environmental process. When an existing fish or wildlife resource may be substantially adversely affected, CDFW is required to propose reasonable project changes to protect the resource. These modifications are formalized in a Streambed Alteration Agreement, which becomes part of the plans, specifications, and bid documents for the project.

California Native Plant Protection Act

The Native Plant Protection Act of 1977 (see Section 1900 et seq. of the California Fish and Game Code) directed CDFW to carry out the Legislature's intent to "preserve, protect and enhance rare and endangered plants in this State." The Native Plant Protection Act gave the California Fish and Game Commission the power to designate native plants as "endangered" or "rare" and protect endangered and rare plants from take. CESA expanded on the original Native Plant Protection Act and enhanced legal protection for plants, but the Native Plant Protection Act remains part of the California Fish and Game Code. To align with federal regulations, CESA created the categories of "threatened" and "endangered" species. It converted all "rare" animals into the act as threatened species, but did not do so for rare plants. Thus, there are three listing categories for plants in California: rare, threatened, and endangered. Because rare plants are not included in CESA,

mitigation measures for impacts to rare plants are specified in a formal agreement between CDFW and the project proponent.

Nesting Birds

Section 3503 of the California Fish and Game Code states that it is unlawful to take, possess, or needlessly destroy the nests or eggs of any bird, except as otherwise provided by this code or any regulation made pursuant thereto. Section 3503.5 protects all birds of prey (raptors) and their eggs and nests. Section 3511 states that fully protected birds or parts thereof may not be taken or possessed at any time. Section 3513 states that it is unlawful to take or possess any migratory non-game bird as designated in the MBTA.

2.2.3 California Environmental Quality Act

CEQA requires identification of a project's potentially significant impacts on biological resources and ways that such impacts can be avoided, minimized, or mitigated. The act also provides guidelines and thresholds for use by lead agencies for evaluating the significance of proposed impacts.

CEQA Guidelines Section 15380(b)(1) defines endangered animals or plants as species or subspecies whose "survival and reproduction in the wild are in immediate jeopardy from one or more causes, including loss of habitat, change in habitat, overexploitation, predation, competition, disease, or other factors." A rare animal or plant is defined in Section 15380(b)(2) as a species that, although not presently threatened with extinction, exists "in such small numbers throughout all or a significant portion of its range that it may become endangered if its environment worsens; or … [t]he species is likely to become endangered within the foreseeable future throughout all or a significant portion of its range and may be considered 'threatened' as that term is used in the federal Endangered Species Act." Additionally, an animal or plant may be presumed to be endangered, rare, or threatened if it meets the criteria for listing, as defined further in CEQA Guidelines Section 15380(c).

CDFW has developed a list of "Special Species" as "a general term that refers to all of the taxa the California Natural Diversity Database (CNDDB) is interested in tracking, regardless of their legal or protection status." This is a broader list than those species that are protected under the FESA, CESA, and other California Fish and Game Code provisions, and includes lists developed by other organizations, including for example the Audubon Watch List Species. Guidance documents prepared by other agencies, including the Bureau of Land Management Sensitive Species and USFWS Birds of Special Concern, are also included on this CDFW Special Species list. Additionally, CDFW has concluded that plant species listed as California Rare Plant Rank (CRPR)

1 and 2 by the California Native Plant Society (CNPS), and potentially some CRPR 3 plants, are covered by CEQA Guidelines Section 15380.

Section IV, Appendix G (Environmental Checklist Form), of the CEQA Guidelines requires an evaluation of impacts to "any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by the California Department of Fish and Game or the U.S. Fish and Wildlife Service."

2.2.4 Porter–Cologne Water Quality Control Act

The intent of the Porter–Cologne Water Quality Control Act is to protect water quality and the beneficial uses of water, and it applies to both surface water and groundwater. Under this law, the State Water Resources Control Board develops statewide water quality plans, and the nine RWQCBs develop basin plans that identify beneficial uses, water quality objectives, and implementation plans. The RWQCBs have the primary responsibility to implement the provisions of both statewide and basin plans. Waters regulated under the Porter–Cologne Water Quality Control Act include isolated waters that are no longer regulated by USACE. Developments with impact to jurisdictional waters must demonstrate compliance with the goals of the act by developing stormwater pollution prevention plans, standard urban stormwater mitigation plans, and other measures to obtain an order of Waste Discharge Requirement (or, in cases where a Clean Water Act Section 401 certification is required, a waiver of Waste Discharge Requirement).

2.3 Local

City of Pasadena Trees and Tree Protection Ordinance

For this proposed Project, trees subject to City permit requirements include those defined by municipal code Chapter 8.52.020 (City of Pasadena 2010), as follows:

- "Public tree" means a tree located in a place or area under ownership or control of the city including but without limitation streets, parkways, open space, parkland and including city owned property under the operational control of another entity by virtue of a lease, license, operating or other agreement.

- "Protected tree" means a native, specimen, landmark, landmark-eligible, mature (except for the trees in RS or RM-12 zones), or public tree.

All surveyed trees are located in a City owned property, and therefore meet the definition of a "Public tree", which are considered a "Protected tree" by the City Municipal Code.

Tree replacement ratios are determined based on the size of the tree to be removed (i.e., larger trees require a higher replacement ratio). Tree replacement guidelines as specified in the City Tree Ordinance are as follows:

Trunk Diameter of Removed Tree	Replacement Ratio	Container Replacement Size
8.0–12.9 inches	6:1	15 gallons
	3:1	24-inch box
13.0–18.9 inches	8:1	15 gallons
	4:1	24-inch box
	2:1	36-inch box
19.0–36.9 inches	8:1	24-inch box
	4:1	36-inch box
>37 inches	12:1	24-inch box
	8:1	36-inch box

INTENTIONALLY LEFT BLANK

3 METHODS

Data regarding biological resources present within the Study Area was obtained through a review of pertinent literature, field reconnaissance, habitat assessments, and protocol/focused surveys, which are described in detail in this chapter.

3.1 Literature Review

Prior to conducting the field investigation, a literature review was conducted to evaluate the environmental setting of the Project site and identify potential special-status biological resources that may be found on the site. The following reports that encompass the Project site were reviewed and are referenced, as appropriate, in this BRTR:

- Arroyo Seco Canyon Diversions Biological Impacts Memorandum, dated November 8, 2018 (Psomas 2018)
- Fish and Fish Passage Related to Pasadena Water and Power Department Diversion on Arroyo Seco above Pasadena, dated October 29, 2019 (Swift 2019)
- Draft Basis of Design Report, Arroyo Seco Canyon Project – Intake/Diversion Design, dated May 2020 (Northwest Hydraulics Consultants 2020)
- Biological Technical Report, Arroyo Seco Canyon Project, dated September 2014 (BonTerra Psomas 2014a)
- Special Status Botanical Surveys for the Arroyo Seco Canyon Project, dated January 20, 2014 (BonTerra Psomas 2014b)
- Native Tree Survey, Arroyo Seco Canyon Project, dated September 2014 (BonTerra Psomas 2014c)
- Jurisdictional Delineation Report, Arroyo Seco Canyon Project, dated May 2014 (BonTerra Psomas 2014d)
- Jurisdictional Delineation Report, Arroyo Seco Canyon Project, dated April 2016 (BonTerra Psomas 2016a)
- Results of the 2013 Amphibian Surveys for the Arroyo Seco Canyon Project, dated February 4, 2014 (BonTerra Psomas 2014e)
- Results of the 2013 Least Bell's Vireo/Southwestern Willow Flycatcher Survey for the Arroyo Seco Canyon Project Dated September 2013 (BonTerra Consulting 2013)
- Results of the 2016 Least Bell's Vireo/Southwestern Willow Flycatcher Survey for the Arroyo Seco Canyon Project Dated August 2016 (BonTerra Psomas 2016b)

The following reports prepared for adjacent projects were also reviewed:

- Biological Technical Report for the Devil's Gate Reservoir Project Site in the City of Pasadena, Los Angeles County, California, dated November 2010, and appendices (Chambers Group 2010a)
- IS/MND for Berkshire Creek Area Improvements, dated May 2019 (Psomas 2019a)
- Upper Arroyo Seco Habitat Enhancement Plan, dated July 2019 (Psomas 2019b)

The following online databases and applications were queried:

- CNDDB (CDFW 2019a, 2019b)
- CNPS Inventory of Rare and Endangered Vascular Plants (CNPS 2019a)
- Calflora's What Grow Here (Calflora 2019)
- Biogeographic Information and Observation System (CDFW 2019d)
- USFWS Species Occurrence Data (USFWS 2019a)
- Information for Planning and Consultation (IPaC) occurrence data (USFWS 2019b)
- eBird's online database of bird distribution and abundance (eBird 2019)
- Critical Habitat online viewer (USFWS 2019c)
- Los Angeles County GIS Viewer (County of Los Angeles 2019)
- Historic aerials and topographic maps (Google Maps 2019; NETR 2019; USGS 2019)
- Wetland Mapper online viewer (USFWS 2019d)
- U.S. Department of Agriculture's Web Soil Survey (USDA 2019a)

The CNDDB and the CNPS Inventory were queried based on the U.S. Geological Survey (USGS) 7.5-minute quadrangle on which the Project site is located (Pasadena, California) and the eight surrounding quadrangles (Sunland, Condor Peak, Chilao Flat, Burbank, Mount Wilson, Hollywood, Los Angeles, and El Monte). The USFWS occurrence data and critical habitat databases were queried using geographic information system (GIS) software based on a 5-mile buffer around the Project site.

3.2 Resource Mapping

Dudek Senior Biologist Michael Cady performed a general reconnaissance-level biological survey on April 23, 2019, which was used to guide the schedule of surveys listed in Table 1, Schedule of

Surveys. The field effort for the Project also included vegetation mapping, a jurisdictional waters delineation, a focused special-status plant survey, and focused wildlife surveys.

Table 1
Schedule of Surveys

Date	Hours	Personnel	Focus	Conditions
4/23/2019	1300–1630	MC	General biological reconnaissance level survey	80°F–82°F, 0% cc, clear, 1–2 mph
5/3/2019	0700–1000	MC	Focused least Bell's vireo survey	59°F–68°F, 0%–100% cc, 1–2 mph
5/3/2019	1000–1200	MC	Non-protocol California red-legged frog and arroyo toad survey	68°F–71°F, 0% cc, 1–2 mph
5/15/2019	1030–1700	MC	Focused special-status plant survey/ vegetation mapping	62°F–67°F, 100% cc, 0–2 mph
5/22/2019	0558–1004	MB	Focused least Bell's vireo survey/focused southwestern willow flycatcher survey	52°F–64°F, 0%–45% cc, 0–4 mph
6/4/2019	0630–1018	MB	Focused least Bell's vireo survey/focused southwestern willow flycatcher survey	58°F–63°F, 100% cc, 0–2 mph
6/14/2019	0614–0934	MB	Focused least Bell's vireo survey/focused southwestern willow flycatcher survey	63°F–65°F, 100% cc, 0–3 mph
6/26/2019	0649–1003	MB	Focused least Bell's vireo survey/focused southwestern willow flycatcher survey	61°F–62°F, 100% cc, misty, 0–3 mph
7/5/2019	0800–1400	MC	Focused special-status plant survey/jurisdictional waters delineation	64°F–86°F, 0% cc, 0–5 mph
7/8/2019	0642–0935	MB	Focused least Bell's vireo survey/focused southwestern willow flycatcher survey	62°F–67°F, 100% cc, 0–1 mph
7/18/2019	0630–0900	MC	Focused least Bell's vireo survey	65°F–72°F, 100% cc, 0–1 mph
7/29/2019	0630–0900	MC	Focused least Bell's vireo survey	64°F–70°F, 5%-50% cc, 0 mph
10/14/2019	0900-1500	MC	Focused fish survey	61°F–73°F, 0% cc, 1–2 mph
4/2/2020	0800-1600	CL	Protected Tree Survey	NR
4/3/2020	0800-1600	CL	Protected Tree Survey	NR

Notes: cc = cloud cover; mph = miles per hour; NR = not recorded
Survey Personnel: CL = Christopher LaCroix; MB = Melissa Blundell; MC = Michael Cady.

Binoculars were used to survey areas that were not physically accessible due to terrain or dense vegetation. All plant and animal species detected by sight, calls, tracks, scat, or other sign were recorded, as well as a determination of potential wildlife linkages based on sign and track detection. Observable sensitive resources including flowering annual plants, shrubs, and trees, and conspicuous wildlife (i.e., birds and some reptiles) commonly accepted as regionally sensitive by CNPS, CDFW, or USFWS were also documented, if observed.

3.2.1 Vegetation Community and Land Cover Mapping

Vegetation communities and land uses within the Project site were mapped in the field directly onto a 200-scale (1 inch = 200 feet) color digital orthographic map of the property (Bing 2018). Following completion of the fieldwork, all vegetation polygons were digitized using ArcGIS software and GIS coverage was created. Vegetation communities within the Project site were mapped using A Manual of California Vegetation, Second Edition (Sawyer et al. 2009. Some modifications were incorporated to accommodate the lack of conformity of the observed communities to those included in these references.

3.2.2 Flora

Latin and common names for plant species with a CRPR (formerly CNPS List) follow the Inventory of Rare and Endangered Plants (CNPS 2019a). For plant species without a CRPR, Latin names follow the Jepson Interchange List of Currently Accepted Names of Native and Naturalized Plants of California (Jepson Flora Project 2019), and common names follow the California Natural Community list (CDFW 2019e) or the U.S. Department of Agriculture Natural Resources Conservation Service PLANTS Database (USDA 2019b).

3.2.2.1 Focused Special-Status Plant Survey

Dudek Senior Biologist Michael Cady conducted focused surveys for special-status plant species with a potential to occur within the two work areas, Gabrielino Trail/Access Road, and North Arroyo Boulevard, plus a 50-foot buffer surrounding each. Two surveys were conducted, one in the spring and one in the summer, in order to cover the blooming period of the target species. Prior to the start of focused surveys, nearby reference populations were checked to verify that target species were in bloom. The surveys conformed to CNPS Botanical Survey Guidelines (CNPS 2001); Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Natural Communities (CDFW 2018); and Guidelines for Conducting and Reporting Botanical Inventories for Federally Listed, Proposed, and Candidate Plants (USFWS 1996).

The Study Area was surveyed with meandering transects searching for federally and/or state-listed plants known to occur or with the potential to occur within the Study Area. Additionally, the Arroyo Seco streambed between Area 2 and the JPL Bridge was surveyed for special-status plant species associated with riparian habitats. All plant species encountered during the field surveys were identified to subspecies or variety, if applicable, to determine sensitivity status. Moreover, all plant species encountered in the field were recorded. If target species were encountered, data points were mapped in the field using a GPS unit.

3.2.3 Fauna

All wildlife species detected during the field surveys by sight, vocalizations, burrows, tracks, scat, and other signs were recorded. Binoculars (10 mm × 42 mm) were used to aid in the identification of observed wildlife. In addition to species observed on site, expected wildlife usage of the site was determined according to known habitat preferences and knowledge of relative distributions of regional wildlife in the area. Latin and common names of animals follow Crother (2012) for reptiles and amphibians, American Ornithologists' Union (AOU 2018) for birds, Wilson and Reeder (2005) for mammals, North American Butterfly Association (NABA 2016) for butterflies, and Moyle (2002) for fish.

3.2.3.1 Focused Least Bell's Vireo and Southwestern Willow Flycatcher Surveys

The surveys for least Bell's vireo (*Vireo bellii pusillus*) and southwestern willow flycatcher (*Empidonax traillii extimus*) were conducted according to USFWS (2001) and U.S. Geological Survey (Sogge et al. 2010) survey protocols. The surveys were conducted between May 3, 2019, and July 29, 2019. The focused surveys were conducted in any riparian habitats in the two work areas and along the Gabrielino Trail/Access Road. All southwestern willow flycatcher surveys were conducted by Dudek biologist Melissa Blundell, who holds a federal recovery permit (No. TE97717A) to survey for the species. Michael Cady conducted the surveys where only least Bell's vireo was the focus. The full methodology is included in Appendix A, Southwestern Willow Flycatcher and Least Bell's Vireo Survey Memorandum.

3.2.3.2 Non-Protocol California Red-Legged Frog and Arroyo Toad Survey

Dudek conducted a focused, but non-protocol, survey for California red-legged frog (*Rana draytonii*) and arroyo toad (*Anaxyrus californicus*) within the Study Area and within portions of Arroyo Seco from Area 2 to the JPL Bridge, and the spreading basins in Area 3 that had standing water. The purpose of the survey was to look for individuals of the two species and identify potential habitat. The survey was conducted on May 3, 2019 by Dudek Senior Biologist Michael Cady. The focused survey passes were conducted by walking along the stream. The full methodology is included in Appendix B, Non-Protocol California Red-Legged Frog and Arroyo Toad Survey Memorandum.

3.2.3.3 Focused Fish Survey

Dudek conducted a focused survey for fish within the Arroyo Seco from where the waters go sub-grade to the west of Area 3 (during drier periods of the year) and upstream to the Brown Mountain Dam; approximately 4.5 river miles. The focus of the survey was to determine if southern steelhead/rainbow trout (*Oncorhynchus mykiss*) and arroyo chub (*Gila orcuttii*) were present in

the survey area. The focused survey pass was conducted by walking along the stream. The full methodology is included in Appendix C, Focused Fish Survey Memorandum.

3.2.4 Jurisdictional Delineation

A jurisdictional delineation of waters of the United States, including wetlands, under the jurisdiction of the USACE, CDFW, and RWQCB was conducted by Dudek Senior Biologist Michael Cady to update potential jurisdictional waters in the Study Area in accordance with the 1987 USACE Wetland Delineation Manual: Arid West Region (USACE 2008b). The wetland delineation focused on identifying the changes to the extent of regulated resources within Arroyo Seco and the spreading basins that had been previously delineated (BonTerra Psomas 2014a, 2016a). This included the evaluation of the OHWM, surface water, and hydrophytic vegetation. Riparian habitat previously mapped was also checked to determine any changes. The previous jurisdictional delineation (BonTerra Psomas 2016a) was relied on to assess the potential presence of hydric soils.

Under current regulatory standards, an applicant under Section 404 of the Clean Water Act may request a Preliminary Jurisdictional Determination from USACE in which federal jurisdiction of aquatic resources is assumed. Alternatively, an Approved Jurisdictional Determination can be requested in which an assessment of surface water connectivity and/or significant nexus of aquatic resources within the Study Area with downstream navigable waters of the United States would be required to determine whether aquatic resources in the Study Area are "isolated" and can be excluded from federal jurisdiction. Since an assessment of surface water connectivity and/or significant nexus was not completed, aquatic resources within the Study Area are assumed to be under federal, as well as state, jurisdiction.

3.2.5 Protected Tree Survey

Dudek mapped tree locations for all trees located within the Area 2 and Area 3 Study Areas. Tree mapping was conducted using a Trimble Pathfinder Pro XH Global Positioning System (GPS) receiver with H-Star Technology. Since tree canopies can sometimes cause loss of satellite lock by blocking the line-of-sight to satellites, an electronic compass and reflectorless, electronic distance-measuring device were also used in mapping tree locations. The reflectorless, electronic distance-measuring device/compass combination operates in concert with the Pathfinder system to position offsets, and offset information is automatically attached to the GPS position data string. The electronic tree locations were then evaluated using ArcView 10.4 software to determine the position of the trees related to the project development footprint.

All inventoried and assessed protected trees were tagged with an aluminum tag bearing a unique identification number, which was placed on the trunk of each tree. Tree trunk diameters were measured using a diameter tape providing adjusted figures[2] for diameter measurements when wrapping the tape around an object's circumference. Diameter measurements were taken using protocol provided by the Council of Tree and Landscape Appraisers in the Guide for Plant Appraisal (ISA 2000). The trunk diameter measurement of each tree was taken at 4.5 feet above the ground along the trunk axis. Tree height was visually estimated by experienced tree surveyors. Tree canopy diameters were typically estimated by "pacing-off" the measurement based on the investigator's knowledge of their stride length or by visually estimating the canopy width. The crown diameter measurements were made along an imaginary line intersecting the tree trunk that best approximated the average canopy diameter. Additionally, Dudek arborists calculated composite trunk diameters for multiple-stem trees according to ISA standards. According to these standards, the sum of all stem diameters was calculated to ascertain composite trunk diameter values for multiple-stem trees.

Pursuant to the Guide for Plant Appraisal (ISA 2000), tree health and structure were evaluated with respect to five distinct tree components: roots, trunk, scaffold branches, small branches, and foliage. Each component of the tree was assessed with regard to health factors such as insect and pathogen damage, mechanical damage, presence of decay, presence of wilted or dead leaves, and wound closure. Tree health and structure were graded as good, fair, poor, and dead, with "good" representing no apparent problems, and "dead" representing a dying and/or dead tree. Good condition trees exhibit acceptable vigor, healthy foliage, and adequate structure, and lack any major maladies. Fair condition trees are typically those with few maladies but declining vigor. This method of tree condition rating is comprehensive and results in ratings that are useful for determining the status of trees based on common urban forestry standards.

3.2.6 Survey Limitations

The focused rare plant surveys were conducted in the spring and summer after a higher-than-normal rainy season. A weather station at Devil's Gate Dam has recorded 25.55 inches of precipitation since the beginning (October 1, 2018) of the current rainy season (LACDPW 2019), which is above the normal of 20.4 inches for Pasadena (City of Pasadena 2019a). This allowed for an above-average bloom from the plants in the region.

Climatic conditions during the survey generally were favorable for identification of wildlife. Potential limitations of the survey included seasonal constraints, a diurnal bias, and the absence of focused trapping for small mammals and reptiles. Surveys were conducted during the daytime to

[2] Inches divided by 3.14 (π) provide diameter measurement in inches.

maximize visibility for the detection of plants and most animals. Birds represent the largest component of the vertebrate fauna, and because they are active in the daytime, diurnal surveys maximize the number of observations of this portion of the fauna. In contrast, daytime surveys usually result in few observations of mammals, many of which may only be active at night. In addition, many species of reptiles and amphibians are secretive in their habits and are difficult to observe using standard meandering transects.

3.3 Special-Status Species Habitat Assessment

Endangered, rare, or threatened plant species as defined in Section 15380(b) of the CEQA Guidelines (14 CCR 15000 et seq.) are referred to as "special-status plant species" in this BRTR and include endangered or threatened plant species recognized in the context of CESA and FESA (CDFW 2019b) and plant species with a CRPR 1 through 4 (CNPS 2019a). Species with CRPR 3 or 4 may, but generally do not, qualify for protection under this provision. Species with CRPR 3 and 4 are those that require more information to determine status and plants of limited distribution. Thus, only CRPR 3 and 4 plant species that were also locally recognized by the City of Pasadena Trees and Tree Protection Ordinance were analyzed further.

Endangered, rare, or threatened wildlife species as defined in CEQA Guidelines, Section 15380(b) (14 CCR 15000 et seq.), are referred to as "special-status wildlife species" and, as used in this report, include (1) endangered or threatened wildlife species recognized in the context of CESA and FESA (CDFW 2019b); (2) California Species of Special Concern and Watch List species as designated by CDFW (2019c); (3) mammals and birds that are fully protected species as described in the California Fish and Game Code, Sections 4700 and 3511; and (4) Birds of Conservation Concern as designated by USFWS (2008).

The CNDDB and CNPS database queries conducted during the literature review resulted in a list of plant and wildlife species that have recorded occurrences within the Project vicinity. For each species evaluated, a determination was made regarding the potential for the species to occur in the Study Area based on information gathered during the field reconnaissance, including the location of the site, habitats present, current site conditions, known range, habitat associations, preferred soil substrate, life form, elevation, and blooming period.

4 ENVIRONMENTAL SETTING

The purpose of this chapter is to describe the general existing conditions within and adjacent to the Study Area to document the baseline conditions for the BRTR and subsequent analysis.

4.1 Climate

The Project vicinity has a Mediterranean climate, with typically hotter summers and slightly cooler winters than nearby coastal areas. The average temperature for the year is 63.9°F. The warmest month on average is August, with an average temperature of 74.7°F. The coolest month on average is January, with an average temperature of 54.4°F. The average amount of precipitation for the year in Pasadena is 20.4 inches. Its location relative to the San Gabriel Mountains means it receives orographic precipitation (precipitation produced when moist air is lifted as it moves over a mountain range), which adds several more inches of rainfall per year than nearby areas. Most of the precipitation occurs between October and April, with the most precipitation on average in February, with 4.6 inches (City of Pasadena 2019a).

4.2 Geology and Topography

The northern portion of the Study Area is mostly composed of steep slopes of the San Gabriel Mountains, with flat areas in the canyon bottom. The Arroyo Seco empties out into a broad piedmont plain that slopes downward from the base of the San Gabriel Mountains to Devil's Gate Reservoir, the lowest ground surface point of the Raymond Groundwater Basin within the Study Area. The Raymond Basin lies in the northwestern part of the San Gabriel Valley, bounded by the San Gabriel Mountains to the north, the San Rafael Hills to the west, and ending to the south and east at the Raymond Fault. The Raymond Fault separates the Raymond Basin from the Main San Gabriel Basin in the vicinity of the southeasterly boundary. The California Department of Water Resources characterized the water-bearing formations of the Raymond Basin as alluvial fill having characteristics of the coarse deposits found in the small basins near the mountain margins. The deposits are coarsest at the base of the mountains where they contain boulders several feet in diameter, but even in the southerly part of the basin, cobbles, stones, and boulders are not uncommon. There are practically no true sand beds in the northerly part of Raymond Basin. Recent alluvium occupies channels, washes, and flood plains of Arroyo Seco, Eaton Creek, and Big and Little Santa Anita Creeks, and to a lesser extent, exists as veneers scattered along the slope of the valley resulting from flood discharges of intermittent streams (Psomas 2018).

Area 2 is located approximately half a mile from the mouth of Arroyo Seco Canyon at an elevation of approximately 1,175 feet above mean sea level (AMSL). The canyon bottom is relatively narrow between Area 2 and the canyon mouth at the JPL bridge. Area 3 is within the piedmont

plain and has elevations that range between 1,130 feet AMSL in the north to 1,090 feet AMSL in the south. Area 3 is located approximately 20 to 30 feet above the current active floodplain of the Arroyo Seco (USGS 2018).

4.3 Soils

As shown in Figure 5, Soil Types, three soil types have been previously mapped for the Project site according to the U.S. Department of Agriculture Natural Resources Conservation Service Web Soil Survey (USDA 2019a): Hanford gravelly sandy loam, Ramona loam, and Ramona sandy loam.

Hanford Series

The Hanford series consists of very deep, well drained soils that formed in moderately coarse textured alluvium dominantly from granite. Hanford soils are on stream bottoms, floodplains and alluvial fans. The soils are well-drained, with negligible to low runoff and moderately rapid permeability. Vegetation in uncultivated areas is mainly annual grasses (USDA 2019c). Hanford soils are found in the northernmost portion of the Study Area and includes Area 2.

Ramona Series

The Ramona series are composed of fine sandy loam formed in alluvium derived mostly from granitic and related rock sources. Ramona soils are found on terraces and alluvial fans. The soils are well-drained, with slow to rapid runoff and moderately slow permeability. Uncultivated areas have a cover of annual grasses, forbs, chamise or chaparral. (USDA 2019c). Ramona soils are found in the remainder of the site and includes Area 3.

4.4 Surrounding Land Uses

The Arroyo Seco originates in the San Gabriel Mountains, with waters flowing south through the Cities of Pasadena, South Pasadena, and Los Angeles before joining the Los Angeles River just east of Elysian Park and west of the I-5/I-110 Interchange. Within the City of Pasadena, the Arroyo Seco passes through three distinct recreational areas: (1) Upper Arroyo Seco, containing the Hahamonga Watershed Park (HWP) and Devil's Gate Dam; (2) Central Arroyo Seco, containing the Brookside Golf Course and the Rose Bowl; and (3) Lower Arroyo Seco, containing an archery range, a casting pond, and Memorial Grove. HWP is bounded on the south by the Devil's Gate Dam and Oak Grove Drive. Oak Grove Drive and JPL mark the boundaries of the HWP to the west in the City of La Cañada Flintridge. To the east, HWP is bounded by the residential neighborhoods of Pasadena and Altadena. The HWP extends northward into the San Gabriel

Mountains and includes approximately 1,300 acres of open space and recreational amenities, including the Gabrielino Trail, which is heavily used for hiking/bicycling and equestrian activities.

Downstream of the JPL Bridge, the Arroyo Seco fans out into the alluvial system of the Devil's Gate Reservoir. In October 2018, the Los Angeles County Flood Control District (LACFCD) began preparing to start work on the Devil's Gate Sediment Removal Project, which plans to remove up to 1.7 million cubic yards of accumulated sediment located within 42 acres of the Devil's Gate Reservoir. In November 2018, the LACFCD began vegetation removal from within the sediment excavation footprint, and the sediment removal activities began in February of 2019.

The northernmost limit of the LACFCD's sediment removal area is located approximately 0.5-mile south of Area 3. Sediment removal would occur from that point southerly to the Devil's Gate Dam, which is located approximately 1.0-mile mile south of Area 3. The LACFCD's habitat restoration activities are planned adjacent to the sediment removal area as well as areas to the north, including along the slopes between the Arroyo Seco and the spreading basins as well as within the southernmost Spreading Basin No. 17 (i.e. Johnson Field). Sediment removal activities are anticipated to continue through 2022 with habitat restoration activities occurring through 2023 (Los Angeles County Public Works 2018).

Upstream of the Project's Study Area is the ANF, which is located within the San Gabriel Mountains. The ANF covers over 650,000 acres of primarily natural open space, which includes the upper portion of the Arroyo Seco watershed. Much of the ANF is covered with dense chaparral, which changes to pine- and fir-covered slopes near the mountain peaks at the higher elevations.

4.5 Watersheds and Hydrology

The Arroyo Seco watershed, a subwatershed of the Los Angeles River watershed, spans from mountainous headwaters through a mix of natural and urban lowlands where it converges with the Los Angeles River. Approximately 47 square miles drain into the Arroyo Seco watershed, approximately two-thirds of which are in the San Gabriel Mountains/ANF. The Arroyo Seco is a perennial stream, which means there is generally flowing water year-round, but the flow is below the surface (underground) in some locations at various times throughout the year. The Arroyo Seco flows through a deeply incised canyon through the San Gabriel Mountains before emptying into areas of open alluvium and incised channels downstream of the JPL Bridge to Devil's Gate Dam and Reservoir (USACE and LACDPW 2011). During high flow periods, surface flows can reach the Devil's Gate Reservoir area, but during low flow periods in the drier months of the year, water infiltrate into the sandy sediment at the uppermost portion of the Reservoir.

Also, during periods of high flow, the Arroyo Seco collects storm water from drains that either outlet directly into the stream, or indirectly from discharge points throughout the Hahamongna

Watershed Basin. The storm drains originate in the neighboring communities of Altadena and La Canada Flintridge, as well as JPL and Pasadena. Collectively, the amount of rainfall and storm water captured in the Arroyo Seco that finds its way to Devil's Gate Reservoir can exceed the natural percolation capacity of the streambed. When the water level behind the dam rises to a certain level, the LACFCD releases water that eventually flows to the ocean.

Below Devil's Gate Dam, Arroyo Seco is mostly channelized, with a stream bottom constructed of impervious materials and water flows restricted and controlled by the Dam (USACE and LACDPW 2011). The watershed outside of the San Gabriel Mountains consists primarily of urban lands where impervious surfaces dominate the land cover. Flow during the dry season, from May to October, consists primarily of nuisance urban runoff (USACE and LACDPW 2011).

The streambed in Area 2 is generally comprised of coarse sediments ranging from sand to boulders. Bedrock exposure was noted in several locations between the JPL bridge and the diversion in the banks and bed of the channel. Active streambed widths vary between about 20 and 40 feet. The channel varies between step-pool and plane bed morphology, with step-pools associated with steeper reaches and very coarse (cobble to boulder) bed material and bedrock exposures. These two channel morphologies are consistent with the overall slope of the channel of about 2.5 to 3 percent. The diversion dam in Area 2 forms a small high point in the bed to facilitate flow into the intake. The stream slope is significantly flattened upstream of the diversion but maintains a continuous positive slope of about 1.5 percent.

The watershed was severely burned in the 2009 Station Fire and was subject to elevated sediment debris and sediment loads in the years following the fire. Peak flows of approximately 4,600 cfs and 2,300 cfs were recorded at a gage upstream of Area 2 (USGS stream gage 11098000) in Water Years 2010 and 2011, respectively. At the present time, there is very little fine-grained material (silt or clay) in the present bed material in the reach between the JPL bridge and the diversion.

Numerous barriers to aquatic organism passage occur in Arroyo Seco and Los Angeles River downstream of the project area. In the vicinity of the project, Devil's Gate Dam is a complete barrier and the reservoir stream segment above the dam is subject to deposition, channel shifting, and frequent dry conditions due to loss of flow into the alluvium as the channel emerges from the canyon. Upstream of the JPL bridge, partial temporal barriers may be present during low flows due to steep channel segments and step-pool or bedrock drops. An anthropogenic barrier exists at the road crossing (Bridge 3) approximately 500 feet downstream of the diversion at a channel spanning weir that may have been installed for flow measurement. A drop of approximately three feet occurs at this concrete structure. At the diversion in Area 2, a drop of approximately two feet occurs from the base of the flashboard notch to the water surface in the scour pool downstream. The top of the diversion dam is approximately 2.5 feet higher than the notch.

4.6 Station Fire

In August 26, 2009, the Station Fire started in the ANF approximately 4 miles north of La Cañada Flintridge along the Angeles Crest Highway (SR-2). The fire was the largest fire in the recorded history of the ANF (est. 1892) and the 10th largest fire in California since 1933, as of 2019. The fire burned a total of 161,189 acres, 96% of which was on ANF lands. The fire burned almost the entire watershed of the Arroyo Seco in the ANF, which led to significant sediment flows following precipitation events. These sediments were deposited primarily in the Hahamongna alluvial plain and having significant effects on riparian communities, in some places completely burying them. (USACE and LACDPW 2011).

INTENTIONALLY LEFT BLANK

5 RESULTS

This chapter describes the results of the literature review, field surveys, and habitat assessments within the Study Area. Representative site photographs of the Project site are provided in Appendix D of this BRTR.

5.1 Vegetation Communities, Land Covers, and Floral Diversity

Ten vegetation communities and land cover types are identified within the approximately 34.57-acre Study Area during the biological resource evaluation: California sagebrush–California buckwheat scrub–laurel sumac scrub association, coast live oak woodland alliance, white alder–California sycamore woodland association, California sycamore woodlands alliance, arroyo willow–mulefat scrub association, laurel sumac scrub alliance, California sagebrush–California buckwheat scrub alliance, urban/developed, disturbed habitat, and parks and ornamental plantings. These vegetation communities and land cover types are described below, their acreages tabulated in Table 2, Vegetation Types, and their spatial distributions depicted on Figure 6, Vegetation Types (Sheets 1 and 2).

Notes: Numbers may not sum due to rounding.

[a] Unique codes assigned to alliances and associations.

[b] NatureServe Global and State rarity ranks per Faber-Langendoen et al. (2012). Natural communities with global or state ranks of 1–3 are considered Sensitive Natural Communities by CDFW and are to be addressed in the environmental review processes of CEQA (CDFW).

[c] Sensitive community

5.1.1 California Sagebrush–California Buckwheat–Laurel Sumac Scrub Association (32.110.06)

The California sagebrush–California buckwheat–laurel sumac scrub association consists of a codominance of California sagebrush (*Artemisia californica*), California buckwheat (*Eriogonum fasciculatum*), and laurel sumac (*Malosma laurina*). The association is part of the California Sagebrush–California Buckwheat scrub alliance (32.110.00) but is not considered a sensitive natural community (CDFW 2018). Laurel sumac is a large, large-leaved sclerophyllous shrub that grows to 16 feet in height. California sagebrush is a much-branched shrub up to 8 feet tall with shallow roots. California buckwheat is a semi-woody, multi-branched shrub with woody, many-branched roots. Many additional shrubs may be present in the community and the herbaceous layer is seasonally present (CNPS 2019b).

In the Study Area, California sagebrush–California buckwheat–laurel sumac scrub is found along North Arroyo Boulevard, on the slope adjacent to the eastern side of Area 3, and on the slopes above the riparian corridor within the canyon. Additional common shrubs found in the community in the Study Area include blue elderberry (*Sambucus nigra*), lemonade berry (*Rhus integrifolia*), deerweed (*Acmispon glaber*), white sage (*Salvia apiana*), black sage (*Salvia mellifera*), bush monkeyflower (*Diplacus aurantiacus*), hoary leaf ceanothus (*Ceanothus crassifolius*), and California coffee berry (*Frangula californica*). Common native herbaceous species included yellow pincushion (*Chaenactis glabriuscula*), small wirelettuce (*Stephanomeria exigua*), Clearwater cryptantha (*Cryptantha intermedia*), caterpillar phacelia (*Phacelia cicutaria*), and miniature lupine (*Lupinus bicolor*). Non-native species present include tree tobacco (*Nicotiana glauca*), Spanish broom (*Spartium junceum*), shortpod mustard (*Hirschfeldia incana*), and various grasses (*Avena* spp. and *Bromes* spp.).

5.1.2 Coast Live Oak Woodland Alliance (71.060.00)

Coast live oak woodland alliance is dominated by coast live oak (*Quercus agrifolia*), but it may include other tree species with less frequency. Coast live oak is a drought-resistant evergreen tree that grows to 80 feet in height. The canopy structure can be open to continuous and the shrub and herbaceous layers are sparse to intermittent. Coast live oak woodland are found on alluvial terraces, canyon bottoms, stream banks, slopes, flats. Soils are typically deep, sandy, or loamy with high organic matter (CNPS 2019b).

In the Study Area, coast live oak woodland is found along Gabrielino Trail/Access Road and Arroyo Boulevard. Additional tree species found in the community include canyon live oak (*Quercus chrysolepis*), California sycamore (*Platanus racemosa*), and bigleaf maple (*Acer macrophyllum*). The shrub component is sparse and consists of species also found in California sagebrush–California buckwheat–laurel sumac scrub. The understory was also sparse and common native herbaceous species include poison oak (*Toxicodendron diversilobum*), American black nightshade (*Solanum americanum*), golden currant (*Ribes aureum*), miner's lettuce (*Claytonia perfoliata*), and California polypody (*Polypodium californicum*).

5.1.3 White Alder–California Sycamore Woodland Association (61.420.11)

White alder–California sycamore woodland association is dominated by white alder (*Alnus rhombifolia*) and California sycamore. The association is part of the white alder groves alliance (61.420.00). White alder is a deciduous hardwood that attains 115 feet in height. California sycamore is a fast-growing, deciduous tree that attains 80 feet in height and is well adapted to intermittent flooding conditions. The community typically occurs in inland foothills and lower montane zones, usually as narrow strips along perennial stream courses throughout cismontane

California. It is well adapted to many flood regimes. White alder–California sycamore woodland is considered a sensitive vegetation community by CDFW (2018).

In the Study Area, white alder–California sycamore woodland is found in Area 2. The understory was very sparse and native herbaceous species include California blackberry (*Rubus ursinus*), and scarlet monkeyflower (*Erythranthe cardinalis*).

5.1.4 California Sycamore Woodlands Alliance (61.310.00)

California sycamore woodlands alliance is dominated by California sycamore, but it may include other tree species with less frequency. California sycamore is a fast-growing, deciduous tree that attains 80 feet in height and is well adapted to intermittent flooding conditions. The canopy structure can be open to continuous, the shrub layer is sparse to continuous, and the herbaceous layers is variable. California sycamore woodlands are found in gullies, intermittent streams, springs, seeps, stream banks, and terraces adjacent to floodplains that are subject to high-intensity flooding. Soils are typically rocky or cobbly alluvium with permanent moisture at depth (CNPS 2019b). California sycamore woodlands is considered a sensitive vegetation community by CDFW (CDFW 2019e).

In the Study Area, California sycamore woodlands are found within the Area 2 portion of the Study Area, on the west side of the Gabrielino Trail/Access Road and at the base of a steep slope. The understory consisted of poison oak and the non-native English ivy (*Hedera helix*).

5.1.5 Arroyo Willow–Mulefat Scrub Association (61.201.06)

Arroyo willow–mulefat scrub association is dominated by arroyo willow (*Salix lasiolepis*) and mulefat (*Baccharis salicifolia*). The association is part of the arroyo willow thickets alliance (61.201.00). Arroyo willow is a riparian tall shrub or tree that grows up to 26 feet in height. Mulefat is an evergreen shrub with willow-like leaves that have widely spaced, fine teeth and shiny upper surfaces. The canopy is open to continuous and the herbaceous layer is variable. The community is typically found on stream banks and benches, slope seeps, and stringers along drainages.

In the Study Area, arroyo willow–mulefat scrub association is located within the wash of the Arroyo Seco, adjacent to Area 3. Additional species present are similar to those found in the California sagebrush–California buckwheat–laurel sumac scrub association.

5.1.6 Laurel Sumac Scrub Alliance (45.455.00)

Laurel sumac scrub alliance is dominated by laurel sumac but may include other shrub species. Laurel sumac is a large, large-leaved sclerophyllous shrub that grows to 16 feet in height. The canopy of Laurel sumac scrub is open or continuous and the herbaceous layer is sparse or grassy. The community is typically found on steep slopes and soils are shallow and fine textured (CNPS 2019b).

In the Study Area, laurel sumac scrub is found in only one location on the western edge of Area 3. No other substantial shrub species are present. The understory is composed primarily of non-native vegetation that was dominated by shortpod mustard (*Hirschfeldia incana*) and various grasses (primarily *Avena* spp. and *Bromes* spp.).

5.1.7 California sagebrush–California Buckwheat Scrub Alliance (32.110.00)

California sagebrush–California buckwheat scrub alliance is dominated by California sagebrush and California buckwheat. California sagebrush is a much-branched shrub up to eight feet tall with shallow roots. California buckwheat is a semi-woody, multi-branched shrub with woody, many-branched roots. The herbaceous layer is seasonally present. The community is typically found on slopes that are steep and occurs on fine-textured soils developed from granitic or sedimentary rocks (CNPS 2019b). California sagebrush–California buckwheat scrub is considered a sensitive vegetation community by CDFW (CDFW 2019e).

In the Study Area, California sagebrush–California buckwheat scrub is found on the eastern slope adjacent to Area 2. Other species present are similar to those found in the California sagebrush–California buckwheat–laurel sumac scrub association.

5.1.8 Urban/Developed

Urban/developed land refers to areas that have been constructed upon or disturbed so severely that native vegetation is no longer supported (Holland 1986). Developed land includes areas with permanent or semi-permanent structures, pavement or hardscape, landscaped areas, and areas with a large amount of debris or other materials (Holland 1986). Developed areas are generally graded and compacted, sometimes covered with gravel road base or built, and have little to no vegetation present. Developed land dominates the majority of the Study Area for the project and refers to those areas supporting manmade structures or features including paved/compacted roadways, driveways, parking lots, residences, and commercial or industrial buildings. These areas support limited natural ecological processes, native vegetation, or habitat for wildlife species and thus are not considered sensitive by local, state, and/or federal agencies.

In the Study Area, the urban/developed land is primarily found in Area 3 and the Gabrielino Trail/Access Road. Non-native herbaceous species are present scattered throughout. Common species include redstem stork's bill (*Erodium cicutarium*), puncturevine (*Tribulus terrestris*), and various grasses (primarily *Avena* spp. and *Bromes* spp.).

5.1.9 Disturbed Habitat

Disturbed habitat refers to areas that are not developed yet, lack vegetation, and generally are the result of severe or repeated mechanical perturbation. Areas mapped as disturbed land may include unpaved roads, trails, and graded areas. Vegetation in these areas, if present at all, is usually sparse and dominated by non-native weedy herbaceous species (Jones & Stokes 1993).

In the Study Area, disturbed habitat is found within Area 3 and is primarily associated with the existing spreading basins. Routine maintenance of the basins keeps a vegetation community from becoming established. Dominant species found in disturbed habitat are non-native and include prickly lettuce (*Lactuca serriola*), shortpod mustard, wild radish (*Raphanus sativa*), tocalote (*Centaurea melitensis*), and various grasses (*Avena* spp. and *Bromes* spp.). Common native species include Canadian horseweed (*Erigeron canadensis*), common sunflower (*Helianthus annuus*), and telegraph weed (*Heterotheca grandiflora*). Components of California sagebrush–California buckwheat scrub are present, but native shrub cover is present in low abundance and density (i.e., less than 20% cover within minimum mapping units of 0.1 acres or more).

5.1.10 Parks and Ornamental Plantings

Parks and ornamental plantings consist of introduced trees, shrubs, flowers, and turf grass. Ornamental landscaping occurs in greenbelts, parks, and horticultural plantings throughout the county (Jones & Stokes 1993). In the Study Area, ornamental landscaping occurs at the southern end of North Arroyo Boulevard.

5.2 Plants

A total of 182 plant species were recorded in the Study Area, including 112 native species (61%) and 71 non-native species (39%). The more common plant species in the Study Area were identified in the description of the vegetation communities in Section 5.1, Vegetation Communities, Land Covers, and Floral Diversity. The majority of non-native species were found in Area 3. The cumulative list of plant species observed in the Study Area is provided in Appendix E to this BRTR. Special-status plant species are discussed in Section 5.5.1.

5.3 Wildlife

A total of 69 wildlife species were recorded in the Study Area, including 65 native species (94%) and four non-native species (6%), during the field effort for the Project. The cumulative list of wildlife species observed in the Study Area is provided in Appendix F to this BRTR. Special-status wildlife species are discussed in Section 5.5.2.

5.3.1 Fish

The Arroyo Seco historically provided habitat for seven species of native freshwater fish, namely Pacific brook lamprey (*Lampetra* spp.), Pacific lamprey (*Entosphenus tridentata*), rainbow trout/steelhead, arroyo chub, Santa Ana speckled dace (*Rhinichthys osculus*), Santa Ana sucker (*Catostomus santaanae*), and unarmored threespine stickleback (*Gasterosteus aculeatus williamsoni*). All occurred in Arroyo Seco and were recorded by Culver and Hubbs (1917). None, except rainbow trout, have been recorded as present in Arroyo Seco upstream of Devil's Gate Dam for at least 50 years (Swift and Seigel, 1993; Moyle, 2002) and probably much longer. Rainbow trout that have been observed in upper Arroyo Seco are believed to be present at least partly due to fish planting over the years. Rainbow trout were present in upper Arroyo Seco (upstream of the diversion) prior to the 2009 Station Fire but have not been detected since (Swift 2019).

Only three of these native species listed above remain elsewhere in the Los Angeles River drainage; Santa Ana sucker, arroyo chub, and Santa Ana speckled dace. They are present in the Los Angeles drainage only in Big Tujunga Wash above Hansen Dam and mostly below Big Tujunga dam, except that arroyo chub, which occurs above the Big Tujunga Dam as well. A few years ago a few hundred arroyo chub were moved from Big Tujunga to a couple of natural stretches of the Arroyo Seco below Devil's Gate Dam and under the Colorado Street Bridge, but these individuals did not survive beyond a second year; perhaps due to sediment deposition from the 2009 Station Fire. Judging by their occurrences elsewhere in the Los Angeles and Santa Ana rivers, only the Santa Ana speckled dace and rainbow trout would have been common in Arroyo Seco from the JPL bridge and upstream. The others would have primarily been in the lower reaches in habitats with lower gradients (Swift 2019).

No fish were observed during the 2019 surveys for the Project, including the focused fish survey (see Appendix C) that included all waters from the surface water terminus at the southern end in the Arroyo Seco wash adjacent to Area 3 to the Brown Mountain Dam. There was an incidental sighting of rainbow trout during the focused amphibian surveys conducted in 2013, but its provenance was not determined (BonTerra Psomas 2014e). The low flows and intermittent presence of surface water during a few to many months of the dry season means the habitat in the Study Area, while having desirable features, is very reduced and would temporarily support only

a few fish in the larger pools where some cover is present to deter predation. During dry years the pool habitat may be very limited or unsuitable due to lack of cover and temperature. This would account for the lack of fish other than a few small trout historically observed in the area of Area 2, probably strays from upstream. In addition, limited pool areas receive significant recreational use for swimming/bathing, and this disturbance would be adverse for fish in the limited areas available. (Northwest Hydraulic Consultants 2020)

The Arroyo Seco canyon is subject to occasional high flows and episodic disturbance associated with wildfire. Very high flows may wash fish downstream to the Devil's Gate Reservoir where they would likely perish under current conditions. These flows may also remove riparian vegetation, as noted in recent observations of single age class stands of riparian trees. In addition, sediment delivery associated with mass wasting processes or wildfire may bury suitable substrates and vegetation, eliminate cover, and change turbidity and temperatures in the stream. The observations of fish in the Arroyo Seco watershed before the Station Fire and few observations almost a decade later are indicative of the significance of these types of events to fish populations (Northwest Hydraulic Consultants 2020).

5.3.2 Amphibians

Three common amphibian species were observed in the Study Area: western toad (*Anaxyrus boreas*), California treefrog (*Pseudacris cadaverina*), and Baja California treefrog (*Pseudacris hypochondriaca*). These three species are primarily terrestrial, with predator avoidance, breeding activities, egg laying, and larval development occurring in the water. Numerous immature western toads were observed in the dried portions of the northern spreading basins in Area 3. Treefrog tadpoles were observed in the Arroyo Seco between Area 2 and the JPL Bridge during the California red-legged frog and arroyo toad non-protocol survey (Appendix B). Additional common amphibians with potential to occur in the Study Area are black-bellied slender salamander (*Batrachoseps nigriventris*) and garden slender salamander (*Batrachoseps major major*). These two species of slender salamander are terrestrial.

5.3.3 Reptiles

Three species of reptile were observed in the Study Area: San Diego alligator lizard (*Elgaria multicarinata webbii*), common side-blotched lizard (*Uta stansburiana*), and western fence lizard (*Sceloporus occidentalis*). Common species expected to occur include California striped racer (*Coluber lateralis lateralis*), San Diego nightsnake (*Hypsiglena ochrorhyncha klauberi*), California kingsnake (*Lampropeltis californiae*), gopher snake (*Pituophis catenifer*), and southern Pacific rattlesnake (*Crotalus oreganus helleri*).

5.3.4 Birds

Birds were the most common wildlife observed throughout the Study Area with 59 species observed. Common abundant species observed included bushtit (*Psaltriparus minimus*), house finch (*Haemorhous mexicanus*), lesser goldfinch (*Spinus psaltria*), Anna's hummingbird (*Calypte anna*), California scrub-jay (*Aphelocoma californica*), common raven (*Corvus corax*), mourning dove (*Zenaida macroura*), cliff swallow (*Petrochelidon pyrrhonota*), acorn woodpecker (*Melanerpes formicivorus*), Bewick's wren (*Thryomanes bewickii*), and dark-eyed junco (*Junco hyemalis*). The Study Area is expected to be used by many species during spring and fall migration.

5.3.5 Mammals

Four species of mammal were observed in the Study Area: western gray squirrel (Sciurus griseus), California ground squirrel (*Otospermophilus beecheyi*), coyote (*Canis latrans*), and mule deer (*Odocoileus hemionus*). Many mammal species are primarily nocturnal and would not have been seen during the surveys. Common species expected to occur include Virginia opossum (*Didelphis virginiana*), Audubon's Cottontail (*Sylvilagus audubonii*), Botta's pocket gopher (*Thomomys bottae*), big-eared woodrat (*Neotoma macrotis*), black bear (*Ursus americanus*), raccoon (*Procyon lotor*), striped skunk (*Mephitis mephitis*), mountain lion (*Puma concolor*), and bobcat (*Lynx rufus*). Bats are expected to forage over the Study Area, and potential day roost, but hibernation and maternal roosting is not expected due to the lack of physical structures (e.g., caves, mines, and abandoned buildings) that are associated with those activities.

5.4 Special-status Species Protocol/Focused Survey Results

Protocol surveys were conducted for least Bell's vireo and southwestern flycatcher, and focused surveys were conducted for arroyo chub, rainbow trout/southern steelhead, arroyo toad, and California red-legged frog. None of the focal species were observed. Table 3, Protocol/Focused Survey Special-Status Wildlife Species, summarizes the species status, habitat, and potential to occur.

Table 3
Protocol/Focused Survey Special-Status Wildlife Species

Scientific Name	Common Name	Status (Federal/State)	Habitat	Potential to Occur
Fish				
Gila orcuttii	arroyo chub	None/SSC	Warm, fluctuating streams with slow-moving or backwater sections of warm to cool streams at depths >40 centimeters (16 inches); substrates of sand or mud	Focused surveys for the species were negative in 2019. Not expected to occur in the Study Area or upstream and downstream from the Study Area. Habitat for the species is marginal in the Study Area. The species is considered to be extirpated from the Arroyo Seco.
Oncorhynchus mykiss irideus pop. 10	steelhead – Southern California DPS	FE/None	Clean, clear, cool, well-oxygenated streams; needs relatively deep pools in migration and gravelly substrate to spawn	Focused surveys for the species were negative in 2019. Not expected to occur in the Study Area or downstream from the Study Area. Population within Arroyo Seco are from historic stocking of hatchery-raised rainbow trout by CDFW. Access to the Study Area from downstream waters is blocked by Devil's Gate Dam.
Amphibians				
Anaxyrus californicus	arroyo toad	FE/SSC	Semi-arid areas near washes, sandy riverbanks, riparian areas, palm oasis, Joshua tree, mixed chaparral and sagebrush; stream channels for breeding (typically third order); adjacent stream terraces and uplands for foraging and wintering	Focused surveys for the species were negative in 2019. Not expected to occur in the Study Area or upstream and downstream from the Study Area. Habitat for the species is marginal in the Study Area. The species historically occurred in the Arroyo Seco but are considered extirpated due to the loss of habitat and the introduction of predators and competitors. Protocol surveys for the species conducted in 2013 for the Study Area were negative.

Table 3
Protocol/Focused Survey Special-Status Wildlife Species

Scientific Name	Common Name	Status (Federal/State)	Habitat	Potential to Occur
Rana draytonii	California red-legged frog	FT/SSC	Lowland streams, wetlands, riparian woodlands, livestock ponds; dense, shrubby or emergent vegetation associated with deep, still or slow-moving water; uses adjacent uplands	Focused surveys for the species were negative in 2019. Not expected to occur on the Study Area or upstream and downstream from the Study Area. Habitat for the species is marginal in the Study Area. The species is considered extirpated from the system due to the loss of habitat and the introduction of predators and competitors. Protocol surveys for the species conducted in 2013 for the Study Area were negative.
Birds				
Empidonax traillii extimus (nesting)	southwestern willow flycatcher	FE/SE	Nests in dense riparian habitats along streams, reservoirs, or wetlands; uses variety of riparian and shrubland habitats during migration	Low potential to occur. Protocol surveys for the species were negative in 2019. Marginal nesting habitat for the species does occur in the Study Area.
Vireo bellii pusillus (nesting)	least Bell's vireo	FE/SE	Nests and forages in low, dense riparian thickets along water or along dry parts of intermittent streams; forages in riparian and adjacent shrubland late in nesting season	Low potential to occur. Protocol surveys for the species were negative in 2019. Suitable nesting habitat for the species does occur in the Study Area.

Notes:
Status:
Federal
FE = Federal Endangered
FT = Federal Threatened
State
SE = State Endangered
SSC = Species of Special Concern

Arroyo Chub

Arroyo chub is a CDFW SSC. It occurs in slow-moving or backwater sections of warm to cool (10ºC to 24ºC) streams with mud or sand substrates; it thrives in low-gradient systems (Swift et al. 1993). This species may tolerate high temperatures and hypoxic conditions that occur in slow-

flowing or stagnant streams and backwater pools in dry summers. The arroyo chub feeds primarily on algae but also feeds on insects and small crustaceans.

Arroyo chub was not observed during the focused survey for fish conducted in 2019. Arroyo chub is not expected to occur in the Study Area, upstream of the Study Area, or immediately downstream from the Study Area. Suitable associated habitat is present, and the species was reintroduced to the Arroyo Seco below Devil's Gate Dam on August 25, 2008 (USACE and LACDPW 2011), but this species was not observed during fish-focused surveys conducted in 2012 (Chambers Group 2013). It is believed that the heavy sediment flow produced by rains following the Station Fire in 2009, which burned most of the watershed of the Arroyo Seco in the San Gabriel Mountains, may have removed the transplanted population (Scauzillo 2017).

Southern Steelhead

Southern steelhead (*Oncorhynchus mykiss irideus* pop. 10) is federally listed as endangered. In streams, the species use habitat consisting of relatively cool, well-oxygenated water with adequate depth and cover. Steelhead require relatively clean unconsolidated gravel and cobble for spawning. Steelhead have an ecological or migratory life cycle called anadromy, in which adults mature in the ocean and must return to freshwater to spawn. After their first year of life, steelhead may undergo physiological and morphological changes to smolts enabling them to survive in a marine environment. Downstream migration of juveniles usually occurs between March and June (Shapovalov and Taft 1954). In southern California, steelhead typically migrates to the ocean as one- or two-year olds (Moore 1980). Out-migrating steelhead in the Santa Clara River, for example, have been observed from January through early June, but the majority of steelhead smolt emigrate during the period from March through early May, and the timing of migration is strongly dependent on streamflows (ENTRIX 2000).

Genetically the native rainbow trout are the same as steelhead and usually can be distinguished genetically from various hatchery stocks. Thus genetic testing can determine if a population is native or not. Genetically identified native landlocked inland populations can be considered important for steelhead recovery if and when they regain access to the sea.

Historic stocking of Arroyo Seco with hatchery-raised rainbow trout by CDFW occurred; hence, there is some debate as to whether some of the trout seen in these currently landlocked areas are descendants of anadromous native *O. mykiss* (Friends of the Los Angeles River 2008). A recent genetic study of *O. mykiss* in southern California found that most populations have substantial genetic lineage from introduced hatchery rainbow trout, representing almost complete introgression or replacement of native fish by introduced hatchery trout (Jacobsen et al. 2014). Among the populations in tributaries of rivers that run through the highly urbanized areas of Southern California, only three groups of populations contained significant evidence of native

coastal steelhead ancestry: (1) populations from the San Gabriel River system, (2) Coldwater Canyon in the Santa Ana River, and (3) the San Luis Rey River; however, tissue sample were not collected from the Arroyo Seco, with only Santa Anita Stream (located 10 miles from the Study Area) representing the Los Angeles River watershed. The individuals from Santa Anita Stream had genetics that corresponded to rainbow trout raised at the Mount Whitney Fish Hatchery (Jacobsen et al. 2014).

Southern steelhead was not observed during the focused survey for fish conducted in 2019. Southern steelhead is not expected to occur in the Study Area or downstream from the Study Area. Access to the Study Area from downstream waters is blocked by impassable barriers of various types along the Los Angeles River and Arroyo Seco (e.g., Devil's Gate Dam, built in 1920, and an abandoned stream gage at Bridge 3). The species was not found during previous surveys conducted downstream from Devil's Gate Dam in the Arroyo Seco and Los Angeles River to the Pacific Ocean (Chambers Group 2010b). The Brown Mountain Dam is located approximately 3.5 miles upstream of the Study Area, which limits upstream movement. Additionally, the existing diversion dam and headworks structure in Area 1 are barriers to upstream movement.

The Southern California Steelhead Recovery Plan (NOAA 2012) describes priority actions for recovery of steelhead in the region, including the Los Angeles River basin. The Arroyo Seco watershed has a low ranking in relative viability for recovery. The Recovery Plan lists removal of barriers at dams, diversions, roads, and other structures as a priority action in the biogeographic region (NOAA 2012). Southern steelhead recovery in Arroyo Seco would involve modification of multiple flood control facilities and removal of multiple barriers between the project area and the ocean.

Arroyo Toad

Arroyo toad is federally listed as endangered and a CDFW SSC. The species is found in semi-arid areas near washes, sandy riverbanks, riparian areas, palm oasis, Joshua tree, mixed chaparral and sagebrush; stream channels for breeding (typically third order); adjacent stream terraces and uplands for foraging and wintering. Breeding habitat for the arroyo toad is created and maintained by the fluctuating hydrological, geological, and ecological processes operating in riparian ecosystems and the adjacent uplands. Periodic flooding that modifies stream channels, redistributes channel sediments, and alters pool location and form, coupled with upper terrace stabilization by vegetation, is required to keep a stream segment suitable for all life stages of the arroyo toad (66 FR 9413–9474). Periodic flooding helps maintain areas of open, sparsely vegetated, sandy stream channels and terraces (Sweet 1992; Griffin and Case 2001). During the day and other periods of inactivity, arroyo toads seek shelter by burrowing into sand (Sweet 1992). Thus, areas of sandy or friable (readily crumbled) soils are the most important habitat for the species, and these soils can be interspersed with gravel or cobble deposits (70 FR 19562–19633).

Arroyo toad was not observed during the focused survey for amphibians conducted in 2019 (see Appendix B). The species is not expected to occur in the Study Area, or upstream or immediately downstream from the Study Area. Marginal associated habitat is present and there is anecdotal evidence of arroyo toads along a small tributary of Arroyo Seco above Devil's Gate Reservoir in 1996 and in or near the settling ponds in the main channel above Devil's Gate Dam in 1997 and 1998 (USFWS 1999). The USFWS included this portion of the Arroyo Seco in the 2001 designation of critical habitat but it was not included in the 2005-revised designation of critical habitat, as there had been no sightings of the species since 1998. The population that historically occurred at this location are considered extirpated due to the loss of habitat and the introduction of predators and competitors (USFWS 2009). In addition, protocol surveys for the species conducted in 2013 for the majority of the Study Area were negative (BonTerra Psomas 2014e).

California Red-Legged Frog

California red-legged frog is federally listed as threatened and a CDFW SSC. The species is found in lowland streams, wetlands, riparian woodlands, livestock ponds; dense, shrubby, or emergent vegetation associated with deep, still or slow-moving water. It also uses adjacent uplands. Breeding must occur in aquatic habitats including streams, deep pools, backwaters within streams and streams, ponds, marshes, sag ponds, dune ponds, lagoons, and stock ponds. Red-legged frogs can occur in ephemeral ponds or permanent streams and ponds, but populations probably cannot persist in ephemeral streams (Jennings and Hayes 1985). Habitats with the highest densities of frogs are deep water ponds with dense stands of overhanging willows (*Salix* sp.) and a fringe of cattails (*Typha latifolia*) between the willow roots and overhanging willow limbs (Jennings 1988; Rathbun et al. 1993).

California red-legged frog was not observed during the focused survey for amphibians conducted in 2019 (see Appendix B). The species is not expected to occur in the Study Area, or upstream or immediately downstream from the Study Area. Marginal associated habitat is present, and the species was historically abundant in the Los Angeles River watershed, including Arroyo Seco, but it is considered extirpated from the system due to the loss of habitat and the introduction of predators and competitors (USFWS 2002). Protocol surveys for the species conducted in 2013 for the Study Area were negative (BonTerra Psomas 2014e).

Southwestern Willow Flycatcher

The willow flycatcher (*Empidonax traillii*), consisting of four or five subspecies, is the most widely distributed of the Empidonax flycatchers. It also has a sporadic breeding distribution throughout California, where three of the subspecies occur, including little willow flycatcher (*E. t. brewsteri*), *E. t. adastus* (which has no common name other than "willow flycatcher"), and southwestern willow flycatcher (*E. t. extimus*) (Craig and Williams 1998; Sedgwick 2000). The

different subspecies of willow flycatcher each occupy distinct breeding ranges and have subtle differences in color and morphology (Sogge et al. 1997), and possibly vocalizations.

Willow flycatchers are late spring migrants and have a breeding season of three months or less (Sedgwick 2000). The earliest spring arrival of the willow flycatcher in Southern California is typically between late April and early May. Along and near the California coast, migrations of *E. t. brewsteri* and *E. t. extimus* overlap, with *E. t. brewsteri* by far the more common subspecies. The numbers of E. t. brewsteri outweigh those of *E. t. extimus* so far that, unless detected at a known breeding site, it is almost certain that a willow flycatcher observed at a low elevation location in Southern California is *E. t. brewsteri,* although positive identification in the field to subspecies level may not be possible. When a willow flycatcher is observed in Southern California after about June 22, or if nesting activity is observed, it can be concluded that the individual is *E. t. extimus* (southwestern willow flycatcher). By this date, most migrant willow flycatchers have passed through Southern California; however, migrant willow flycatchers may again be observed—virtually always away from the coast—in late July as they pass through the region heading south to their wintering area (Sogge et al. 1997).

Southwestern willow flycatcher is a riparian-obligate species restricted to complex streamside vegetation. Four general habitat types are used by the species at its breeding sites: monotypic high elevation willow; exotic monotypes; native broadleaf-dominated riparian forest; and mixed native/exotic forests (Sogge et al. 1997). Of these, native broadleaf-dominated and mixed native/exotic are the primary habitats used by southwestern willow flycatcher in California. The native broadleaf-dominated habitat is composed of a single species, such as Goodding's willow (*Salix gooddingii*) or other willow (*Salix* spp.) species, or a mixture of broadleaf trees and shrubs, including cottonwood (*Populus* spp.), willow, box elder (*Acer negundo*), ash (*Fraxinus* spp.), and alder (*Alnus* spp.). Stands are usually three to 15 meters (10 to 50 feet) in height and are characterized by trees of different size classes, yielding multiple layers of canopy (Sogge et al. 1997). The vegetation of occupied nest sites includes dense patches interspersed with frequent small openings, open water, and a well-developed herbaceous layer, creating a habitat mosaic that is not uniformly dense (Sogge et al. 1997). Southwestern willow flycatcher nests typically occur in areas with multilayered vegetation and fairly closed (60% to 65%) tree canopy cover (Craig and Williams 1998).

There is marginal habitat for southwestern willow flycatcher in the Study Area; however, the species was not detected during the protocol surveys for the species conducted in 2019. Southwestern willow flycatcher was also not detected during protocol surveys in 2013 (BonTerra Consulting 2013) and 2016 (BonTerra Psomas 2016b). There are no CNDDB records for the species from the Arroyo Seco and only two for the species from Los Angeles County (Santa Clara River and Snow Spring) within the last 100 years (CDFW 2019a). Additionally, there are no eBird

records of *E. traillii* from the Arroyo Seco between late June and late July (eBird 2009), when southwestern willow flycatcher is known to nest in the region.

Least Bell's Vireo

Least Bell's vireo primarily occupies riverine riparian habitats along water, including dry portions of intermittent streams that typically provide dense cover within one to two meters (3.3 to 6.6 feet) of the ground, often adjacent to a complex, stratified canopy. Least Bell's vireo nesting habitats in cismontane and coastal areas include southern willow scrub, mulefat scrub, arroyo willow riparian forest edge, wild blackberry thickets, and, more rarely, cottonwood forest, sycamore alluvial woodland, and southern coast live oak riparian forest. Nests are typically built within approximately 1 meter (3.3 feet) of the ground in the forks of willows, wild rose (*Rosa* spp.), mulefat, or other understory vegetation (Franzreb 1989). Cover surrounding nests is moderately open mid-story with an overstory of willow, cottonwood (*Populus* spp.), western sycamore, or oak (*Quercus* spp.). Crown cover is usually more than 50% and contains occasional small openings. The most critical structural component to least Bell's vireo breeding habitat is a dense shrub layer at 0.6 to 3 meters (2 to 10 feet) above the ground (Goldwasser 1981; Franzreb 1989).

There is suitable habitat for least Bell's vireo in the Study Area and the species has been detected recently in the Hahamonga Wilderness Park to the south of the Study Area (eBird 2019). However, Least Bell's vireo was not detected during the protocol surveys for the species conducted in 2019. Least Bell's vireo flycatcher was also not detected during protocol surveys in 2013 (BonTerra Consulting 2013) and 2016 (BonTerra Psomas 2016b). The species does not have records within the Study Area or within the Arroyo Seco north of the Study Area (CDFW 2019a, eBird 2019).

5.5 Special-Status Species Habitat Assessment

The following describes the special-status plant and wildlife species that were observed or have been recorded in the vicinity of the Study Area during the surveys for the Project.

5.5.1 Special-Status Plant Species

No special-status plant species were documented in previous surveys of the Study Area. No special-status plants species were observed during Dudek's 2019 focused plant surveys, which were conducted during the blooming period and under conditions that would have allowed identification for species potentially present. Therefore, no special-status plant species were determined to have a moderate or high potential to occur in the Study Area. Appendix G of this BRTR, Special-Status Plant Species with Recorded Occurrences in the Project Vicinity, lists the special-status plants with

potential to occur at the Project site. Species that are either not expected to occur or have a low potential to occur are identified in Appendix G and are not analyzed further in this BRTR.

The dense canopy in Area 2 limits the understory development of herbaceous species. Area 3 has seen disturbances since at least 1952 related to the construction and maintenance of the spreading basins and parking lots for JPL (NETR 2019). This has removed much of the native habitats and disturbed the native soils and allowed for the introduction of numerous non-native plant species.

5.5.2 Special-Status Wildlife Species

One special-status wildlife species, yellow warbler (*Setophaga petechia*), was observed during the surveys in the Study Area. Four other species were recently observed during previous studies for the Project or adjacent projects: California newt (*Taricha torosa*), two-striped gartersnake (*Thamnophis hammondii*), southern California legless lizard (*Anniella stebbinsi*), and coastal whiptail (*Aspidoscelis tigris stejnegeri*) (BonTerra Psomas 2014a). One species has a moderate potential to occur in the Study Area: hoary bat (*Lasiurus cinereus*). Table 4, Special-Status Wildlife Species Present or with Medium or High Potential to Occur within the Study Area, summarizes the species that occur or have a moderate or high potential to occur. Species that are either not expected to occur or have a low potential to occur are indicated in Appendix H and are not analyzed further in this BRTR, with the exception of the subject fish, amphibians, and birds for which protocol or focused surveys were conducted for the project.

Table 4
Special-Status Wildlife Species Present or with Medium or High Potential to Occur within the Study Area

Scientific Name	Common Name	Status (Federal-State)	Habitat	Potential to Occur
		Amphibians		
Taricha torosa	California newt	None/SSC	Wet forests, oak forests, chaparral, and rolling grassland	Previously observed and assumed to be present. The species was observed during surveys for the Study Area in 2013 in the Arroyo Seco but was not observed in 2019. Suitable habitat is present within Area 2, and the species could be encountered on the Gabrielino Trail/Access Road to Area 2.

Table 4
Special-Status Wildlife Species Present or with Medium or High Potential to Occur within the Study Area

Scientific Name	Common Name	Status (Federal-State)	Habitat	Potential to Occur
Reptiles				
Anniella stebbinsi	Southern California legless lizard	None/SSC	Coastal dunes, stabilized dunes, beaches, dry washes, valley–foothill, chaparral, and scrubs; pine, oak, and riparian woodlands; associated with sparse vegetation and moist sandy or loose, loamy soils	Previously observed and assumed to be present. There are five recent (2017 and 2018) records from Study Area and adjacent areas of Hahamonga Park. Suitable habitat is present within Area 2 and Area 3, and it could be encountered on the Gabrielino Trail/Access Road to Area 2.
Aspidoscelis tigris stejnegeri	coastal whiptail	None/SSC	Hot and dry areas with sparse foliage, including chaparral, woodland, and riparian areas	Previously observed and assumed to be present. The species was observed during the 2013 surveys for the Study Area and suitable habitat for the species occurs throughout the Study Area and surrounding area.
Thamnophis hammondii	two-striped gartersnake	None/SSC	Streams, streams, pools, streams with rocky beds, ponds, lakes, vernal pools	Previously observed and assumed to be present. The species was observed during the 2013 surveys for the Study Area and suitable habitat for the species occurs throughout the Study Area and surrounding area.
Birds				
Setophaga petechia (nesting)	yellow warbler	None/SSC	Riparian plant associations in close proximity to water; frequently found nesting and foraging in willow shrubs and thickets, and in other riparian plants including cottonwoods, sycamores, ash, and alders	Present. Observed during the 2019 surveys in the Study Area near Area 2.

Table 4
Special-Status Wildlife Species Present or with Medium or High Potential to Occur within the Study Area

Scientific Name	Common Name	Status (Federal-State)	Habitat	Potential to Occur
Mammals				
Lasiurus cinereus	hoary bat	None/None	Forest, woodland riparian, and wetland habitats; also juniper scrub, riparian forest, and desert scrub in arid areas; generally roosts in dense foliage of medium to large trees; preferred sites are hidden from above, with few branches below, and have ground cover of low reflectivity; females and young tend to roost at higher sites in trees	Medium potential to occur. Suitable associated day/night roosting, maternity roosts, and foraging habitat for the individuals of the species occurs within the Study Area, and there are records of the species from other watersheds within the San Gabriel Mountains that have similar habitat to Arroyo Seco.

State
SSC = Species of Special Concern

5.6 Potential Jurisdictional Waters

With respect to USACE-jurisdictional waters of the U.S., including wetlands, the USACE makes the jurisdictional determination. The USACE issues two types of jurisdictional determinations: preliminary and approved.[3] Both types of determinations require a submittal of a formal jurisdictional delineation report. CDFW and RWQCB also may request a site visit to review the jurisdictional delineation and may potentially change the limits of delineation. Therefore, the jurisdiction determinations provided in this technical report are preliminary and only identify the potential for jurisdictional areas to be affected by the Project in accordance with the CEQA thresholds.

[3] The USACE issues two types of JDs—preliminary and approved. A preliminary JD is an expedited process typically initiated at the time that a 404 permit is requested for impacts to federal jurisdictional waters; the preliminary JD is non-binding and does not involve USACE review. This process is used when the permittee does not wish to request a determination that some or all of the potentially jurisdictional waters on the Project site are isolated (under the Rapanos decision) or otherwise not subject to federal jurisdiction. An approved JD is requested through submittal of a JD report and the accompanying form. It requires USACE review of the report and application of the criteria used to request a non-federal JD.

As shown in Figure 7, Potential Jurisdictional Waters (Sheets 1 and 2), no wetlands were identified within the Study Area. Potential non-wetland jurisdictional waters identified in the Study Area include the Arroyo Seco, Millard Canyon Stream (a tributary to Arroyo Seco), and the spreading basins. The delineation of the Study Area identified a total of 0.79 acres of waters of the United States; 4.66 acres under RWQCB jurisdiction; and 6.44 acres under the jurisdiction of the CDFW present in the Study Area. Table 5, Potential Jurisdictional Waters Delineated within the Study Area, summarizes the jurisdictional waters in each portion of the Study Area.

Table 5
Potential Jurisdictional Waters Delineated within the Study Area

Area	USACE Jurisdiction Non- Wetland Waters of the U.S. (acres)	RWQCB Jurisdiction (acres)	CDFW Jurisdiction (acres)
Area 2	0.25	0.25	0.79
Area 3	0.42	4.29	4.64
Gabrielino Trail/Access Road	0.11	0.11	1.01
Travelling Screen Building Staging Area	—	—	<0.01
Behner Treatment Plant Staging Area	—	—	—
Total	**0.79**	**4.66**	**6.44**

Notes: Numbers may not sum due to rounding.

Non-wetland waters of the U.S. regulated by the USACE are drainage features that conduct water at some point during the year, evidenced by the presence of an OHWM, but do not satisfy the criteria to be considered a wetland (wetland soils and/or vegetation is absent). In the Study Area, there were areas of waters of the U.S. that had open water during the surveys and delineations. The limits of non-wetland waters of the U.S. are defined by the presence of the OHWM. Evidence of the OHWM in the survey area includes surface relief, scour lines, flowing water, and breaks in bank slopes.

The RWQCB jurisdictional boundaries are defined as those determined for the USACE under waters of the U.S. However, the RWQCB takes jurisdiction over both connected and isolated waters. Isolated features (those that do not have a direct connection to an already determined waters of the U.S.) are under the jurisdiction of the RWQCB, but not the USACE. The spreading basins in Area 3 are considered isolated waters since they have no downstream connection with the Arroyo Seco; therefore, they are under the jurisdiction of the RWQCB, but not the USACE.

The CDFW jurisdiction extends from the top of the bank to the top of the bank, except where there is adjacent riparian vegetation. CDFW jurisdictional areas include the Arroyo Seco and the spreading basins in Area 3. Riparian habitats in the Study Area under CDFW jurisdiction include white alder–California sycamore woodland Area 2 and along the norther portions of the Gabrielino

Trail/Access Road and arroyo willow–mulefat scrub associated with the Arroyo Seco adjacent to Area 3. Additionally, the portions of the coast live oak woodlands and California sycamore woodlands in Area 2 and along the northern portions of the Gabrielino Trail/Access Road that contain the top of banks of the Arroyo Seco are also included under CDFW jurisdiction. The spreading basins in Area 3 are primarily devoid of native vegetation.

5.7 Wildlife Corridors and Habitat Linkages

Wildlife corridors are linear features that connect large patches of natural open space and provide avenues for dispersal or migration of animals and dispersal of plants (e.g., through wildlife vectors). Wildlife corridors contribute to population viability by assuring continual exchange of genes between populations, which helps maintain genetic diversity; providing access to adjacent habitat areas representing additional territory for foraging and mating; allowing for a greater carrying capacity; and providing routes for colonization of habitat lands following local population extinctions or habitat recovery from ecological catastrophes (i.e., the rescue effect).

Habitat linkages are small patches that join larger blocks of habitat and help reduce the adverse effects of habitat fragmentation. They serve as connections between habitat patches and help reduce the adverse effects of habitat fragmentation. Although individual animals may not move through a habitat linkage, the linkage is a potential route for gene flow and long-term dispersal. Habitat linkages may serve as both habitat and avenues of gene flow for small animals such as reptiles, amphibians, and rodents. Habitat linkages may be represented by continuous patches of habitat or by nearby habitat "islands" that function as steppingstones for dispersal and movement (especially for birds and flying insects). Wildlife corridors and habitat linkages provide avenues for dispersal or migration of animals that also contribute to population viability in several ways, including (1) ensuring continual exchange of genes between populations to aid in maintaining genetic diversity, (2) providing habitat for some species, (3) providing access to adjacent habitat areas representing additional territory for foraging and mating, (4) allowing for a greater carrying capacity, and (5) providing routes for colonization of habitat lands following local population extinctions or habitat recovery from ecological catastrophes.

The Study Area does not reside within any designated wildlife corridors and/or habitat linkages identified in the South Coast Missing Linkages analysis project (South Coast Wildlands 2008) or California Essential Habitat Connectivity project (Spencer et al. 2010). On a regional level, the Study Area and Hahamongna Watershed Park form an open space area that is located just south of the ANF, which has large, continuous natural habitats. Urban development is located to the east, west, and south of this area, which includes the artificial channelization of Arroyo Seco. Larger, urban-adapted terrestrial wildlife (e.g., coyotes) are expected to pass through the Study Area and Hahamongna Watershed Park to the urban environment, but the Study Area is not part of a regional

corridor or habitat linkage between another large open space. On a local level, terrestrial wildlife would be expected to move between the ANF and the Hahamongna Watershed Park using the Study Area and the portions of the Arroyo Seco outside of the Study Area and downstream of the JPL bridge.

For potential aquatic species, the Study Area is in between two impassable barriers: Devil's Gate Dam downstream and Brown Mountain Dam upstream, which prohibits regional movement of fish in the Arroyo Seco. The majority of the Arroyo Seco Channel and Los Angeles River downstream of the Devil's Gate Dam consists of a concrete-lined channel and the majority of it does not provide suitable habitat for fish or other sensitive species (Chambers Group 2013). On a local level, the portion of the Arroyo Seco between the two dams, including Area 2, does provide habitat for fish, and if occupied by fish (no fish were detected during the focused fish survey conducted in 2019), it would be expected that there would be local movement between the two dams; however, the current diversion structure in Area 2, an abandoned stream gage at Bridge 3, and several concrete structures upstream of Area 2, including the headworks structure in the previous studied Area 1, would inhibit upstream movement.

Semi-aquatic species (western toad, California treefrog, Baja California treefrog, and California newts) can move overland, traveling in the uplands in upstream and downstream directions, as juveniles and adults after an aquatic larval phase. Downstream drift due to the stream current is the primary movement during the larval phase of amphibians. The existing artificial barriers within the Study Area are not expected to impede movement for these amphibian species.

5.8 City of Pasadena Trees and Tree Protection Ordinance

A total of 93 trees were inventoried within the Area 2 and Area 3 Study Areas, of which 49 are in Area 2, and 44 in Area 3. No tree in the project area meets the City definition of a "Landmark Tree." Figure 8, Protected Trees (Sheet 1 and 2), presents the location of the individual trees mapped and assessed for the proposed project. Overall, the trees exhibit growth and structural conditions that are typical of their location in a native riparian watershed setting prone to drought and wildfires. The trees include various trunk and branch maladies and health and structural conditions. As presented in Appendix I, Protected Tree Report, 34% of the individually mapped trees (32 trees) exhibit good health; 64% (59 trees) are in fair health; 2% (2 trees) are in poor health. Structurally, 5% (5 trees) of the individually mapped trees are considered to exhibit good structure, 88% (82 trees) exhibit fair structure, 7% (6 trees) poor structure. The trees in good condition exhibit acceptable vigor, healthy foliage, and adequate structure, and lack any major maladies. Trees in fair condition are typical, with few maladies but declining vigor. Trees in poor condition exhibit declining vigor, unhealthy foliage, poor branch structure, and excessive lean. No pests or pathogens were observed on site.

6 PROJECT IMPACTS

This chapter addresses direct and indirect impacts to biological resources that would result from implementation of the proposed Project. The significance determinations for proposed or potential impacts are described in Chapter 7, Significant Impacts.

6.1 Definition of Impacts

6.1.1 Direct Permanent Impacts

Direct permanent impacts refer to the absolute and permanent physical loss of a biological resource due to clearing, grading, and/or construction of structures, which can be determined in four ways: (1) permanent loss of vegetation communities, land covers, and general wildlife and their habitat; (2) permanent loss of or harm to individuals of special-status plant and wildlife species; (3) permanent loss of suitable habitat for special-status species; and (4) permanent loss of wildlife movement and habitat connectivity.

6.1.2 Direct Temporary Impacts

Direct temporary impacts refer to a temporal loss of vegetation communities and land covers resulting from vegetation and land cover clearing. The main criterion for direct temporary impacts is that impacts would occur for a short period of time and would be reversible. Areas currently supporting native vegetation temporarily disturbed by construction activities would be restored and revegetated with a native species mix similar to that which existed prior to disturbance following completion of work in the area such that full biological function can be restored. Areas not currently supporting native vegetation would be adequately restored to prevent adverse effects such as erosion or establishment of invasive species following construction.

6.1.3 Indirect Impacts

Indirect impacts are reasonably foreseeable effects caused by Project implementation on remaining or adjacent biological resources outside the direct construction disturbance zone that may occur during construction (i.e., short-term construction related indirect impacts) or later in time as a result of the development (i.e., long-term, or operational, indirect impacts). Indirect impacts may affect areas within the defined Study Area, but outside the construction disturbance zone, including open spaces adjacent to the Gabrielino Trail/Access Road and to vegetation/wildlife habitats in downstream areas. Indirect impacts include short-term effects immediately related to construction activities and long-term or chronic effects related to the human occupation of

developed areas (i.e., development-related long-term effects) that are adjacent to naturalized areas.

For the proposed Project, it is assumed that the potential indirect impacts resulting from construction activities include fugitive dust from earthmoving activities, leaks or spills from construction equipment, noise from construction activities, and general human presence that may temporarily disrupt species and habitat vitality, as well construction-related soil erosion and runoff that could affect downstream resources.

6.1.4 Explanation of Findings of Significance

Impacts to sensitive vegetation communities or riparian habitat, special-status plant species, special-status wildlife species, wildlife corridors and habitat connectivity, and regional resource planning must be analyzed to determine whether such impacts are significant. CEQA Guidelines Section 15064(b) states that an ironclad definition of "significant" effect is not possible because the significance of an activity may vary with the setting. However, CEQA Guidelines Section 15065(a) lists impacts that are helpful in defining whether a project may have a significant effect on the environment. Mandatory findings of significance, which require preparation of an EIR, occur when there is substantial evidence that a project could: (1) substantially degrade the quality of the environment, (2) substantially reduce the habitat of a fish or wildlife species, (3) cause a fish or wildlife population to drop below self-sustaining levels, (4) threaten to eliminate a plant or animal community, or (5) reduce the number or restrict the range of a rare or endangered plant or animal.

The following are the significance thresholds for biological resources provided in the CEQA Appendix G environmental checklist, which states that a project would potentially have a significant effect if it:

- **Impact BIO-1**. Would the project have a substantial adverse effect, either directly or through habitat modifications, on any species identified as being a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFW or USFWS?
- **Impact BIO-2**. Would the project have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, or regulations, or by CDFW or USFWS?
- **Impact BIO-3**. Would the project have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including but not limited to marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means?

- **Impact BIO-4**. Would the project interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impedes the use of native wildlife nursery sites?
- **Impact BIO-5**. Would the project conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance?
- **Impact BIO-6**. Would the project conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan?

The evaluation of whether or not an impact to a particular biological resource is significant must consider both the resource itself and the role of that resource in a regional context. Substantial impacts are those that contribute to, or result in, permanent loss of an important resource, such as a population of a rare plant or animal. Impacts may be important locally because they result in an adverse alteration of existing site conditions but considered not significant because they do not contribute substantially to the permanent loss of that resource regionally. The severity of an impact and the offsetting benefits of mitigation are the primary determinants of whether or not that impact can be mitigated to a less-than-significant level.

6.2 Impacts to Special-Status Species

No special-status plant species were observed during the focused surveys and none have a medium or high potential to occur. Therefore, neither direct temporary or permanent impacts, nor indirect impacts, are expected and impacts would be less than significant. No mitigation is required.

Appendix H indicates the special-status wildlife species that were detected or have high or moderate potential to occur within the Study Area. Direct impacts to special-status wildlife species were quantified by comparing the limits of the proposed Project footprint with suitable habitat for these wildlife species and are further discussed below.

6.2.1 Direct Impacts

Special-Status Amphibians and Reptiles

One special-status amphibian (California newt) and three reptiles (two-striped gartersnake, Southern California legless lizard, and coastal whiptail) have occurred in the Study Area. These species are all designated as CDFW SSC. Due to the presence of suitable habitat, and/or documented occurrences for these species within the vicinity of the Project site, there is potential for these species to occur on site. If these species are determined to occur on the Project site prior

to construction, Project-related impacts could be considered significant if the impact causes the greater population of either species to drop below self-sustaining levels. These species are vulnerable to mortality or injury if struck by moving vehicles or equipment if present on-site during construction. These species are also vulnerable to mortality or injury during vegetation and ground disturbing activities associated with construction because they tend to be cryptic, slow moving, and below ground or under rocks or debris during cooler periods. It is highly unlikely that short-term construction activities could cause the greater population of these special-status species to drop below self-sustaining levels due to the relatively small area of construction activity and the short-term nature of the construction schedule.

No direct temporary impacts would occur; however, because habitat loss and/or mortality or injury to individual species is a reasonable possibility, direct permanent impacts would be considered potentially significant.

Project implementation of **MM-BIO-1** (Pre-Construction Survey and Relocation Plan) would reduce potential direct impacts to special-status wildlife (California newt, two-striped gartersnake, Southern California legless lizard, and coastal whiptail) to a less-than-significant level through pre-construction surveys, avoidance, and potential relocation.

Special-Status and Nesting Birds

One special-status bird species (yellow warbler) has a moderate potential to nest and forage within the open shrublands throughout the Project site. This species is a CDFW SSC and there is a potential for this species to nest and/or forage within or immediately adjacent to the proposed development footprint. If this species is determined to occur on the Project site prior to construction, Project-related direct impacts would occur particularly if construction would result in direct impacts to nesting and foraging habitat for yellow warbler.

Additionally, the trees and shrubs within the Project site provide suitable nesting habitat for bird species (i.e., yellow warbler and raptors) protected under the Migratory Bird Treaty Act (MBTA; 16 USC 703-712) and California Fish and Game Code Sections 3503.5, 3503, and 3513. Trimming, pruning, and/or removal of trees and shrubs may occur as a result of construction of the project, and could disrupt breeding activity. There would be no direct temporary impacts; however, there may be a potential for a direct permanent impact to occur to nesting birds (i.e., direct impacts to individuals, active nests, eggs, or young), particularly during the general nesting season of February 1 through August 31. Construction activities that could result in direct impacts to nesting birds include vegetation and tree removal during grading activities. Project implementation of **MM-BIO-2** (i.e., seasonal recommendations, pre-construction survey, avoidance buffers, and monitoring) would reduce potential direct impacts to a less-than-significant level.

Special-Status Mammals

One special-status bat species (hoary bat) has a moderate potential for day/night roosting, maternity roosts, and foraging habitat within the Study Area. If this species is determined to occur on the Project site prior to construction, it is highly unlikely that short-term construction activities could cause the greater population of this special-status species to drop below self-sustaining levels due to the relatively small area of construction activity and the short-term nature of the construction schedule. No direct temporary impacts would occur; however, because habitat loss and/or mortality or injury to individual species is a reasonable possibility, direct permanent impacts would be considered potentially significant.

Project implementation of **MM-BIO-3** (i.e., seasonal recommendations, pre-construction survey, avoidance buffers, and monitoring) would reduce potential direct impacts to a less-than-significant level. Direct impacts to day roosts occupied by individual special-status bat species would be less than significant as the impact would not be expected to reduce populations to below self-sustaining levels.

6.2.2 Indirect Impacts

Potential short-term indirect impacts to special-status wildlife could result from fugitive dust and increased human activity. Noise generated by construction activities, including vegetation removal and grading, that would be conducted during the avian breeding season (February 1 through August 31), could result in indirect impacts to nesting birds. Noise related to these activities has the potential to disrupt reproductive and feeding activities. Nighttime construction is not expected for the Project, so indirect impacts on potentially foraging special-status bats is not expected. Potential temporary indirect impacts during construction may cause mortality due to the abandonment of an active nest and would be considered significant, absent mitigation. Project implementation of MM-BIO-3 (i.e., seasonal recommendations, pre-construction survey, avoidance buffers, and monitoring) would reduce these potential indirect impacts to a less-than-significant level. Long-term indirect impacts to special-status wildlife are not expected.

6.3 Impacts to Vegetation Communities and Land Covers

6.3.1 Direct Impacts

Direct permanent and temporary impacts to vegetation communities within the Study Area are summarized in Table 6a-6f and illustrated on Figure 9, Impacts to Vegetation Types (Sheets 1 and 2). Direct impacts were quantified by calculating the Project impact area, which was delineated

based on engineering plans that identified the limits of grading, within the boundaries of the vegetation communities mapped in the Study Area. Direct impacts to vegetation communities would occur as a result of earthwork and/or vegetation removal activities. There would be no direct permanent or temporary impacts to the use of the Gabrielino Trail/Access Road or North Arroyo Boulevard. There would only be temporary impacts to the Travelling Screen Building Staging Area and the Behner Treatment Plant Staging Area.

Table 6a
Total Permanent and Temporary Direct Impacts to Vegetation Communities and Land Covers within the Study Area

The proposed Project would have direct permanent impacts to two CDFW sensitive vegetation communities—white alder-California sycamore woodland association (0.39 acres) and California sycamore woodlands alliance (0.01 acres)—due to the construction of the diversion and intake replacement in Area 2. The Project would have direct temporary impacts to two CDFW sensitive vegetation communities—white alder-California sycamore woodland association (0.11 acres) and California sycamore woodlands alliance (0.01 acres)—due to the construction of the diversion and intake replacement in Area 2. This is due to potential encroachment into the dripline of the woodland without removal of the trees.

The white alder–California sycamore woodland and California sycamore woodlands alliance vegetation communities are considered sensitive by CDFW due to their relative rarity and therefore, the loss of these vegetation communities (both permanent and temporary) would be considered significant, absent mitigation. Project implementation of **MM-BIO-4** (i.e., preparation and implementation of a Habitat Restoration Plan; see Section 7 for the mitigation measures) would reduce potential direct impacts to a less-than-significant level.

Other vegetation communities and land cover types (California sagebrush–California buckwheat–laurel sumac scrub association, laurel sumac scrub alliance, urban/developed, and disturbed habitat) are not considered sensitive by CDFW because they are relatively common; therefore, the loss of these additional vegetation communities (both permanent and temporary) would be less than significant.

6.3.2 Indirect Impacts

Short-Term Indirect Impacts

Potential short-term or temporary indirect impacts to sensitive vegetation communities in the Study Area would primarily result from construction activities and include impacts related to or resulting from the generation of fugitive dust, increased human activity, and the introduction of

pollutants from construction equipment. Excessive dust can decrease the vigor and productivity of vegetation through effects on light, penetration, photosynthesis, respiration, transpiration, increased penetration of phytotoxic gaseous pollutants, and increased incidence of pests and diseases. Erosion and chemical pollution (releases of fuel, oil, lubricants, paints, release agents, and other project-related materials) may affect sensitive vegetation communities. The use of chemical pollutants can decrease the number of plant pollinators, increase the existence of non-native plants, and cause damage to and destruction of native plants. These potential short-term, construction-related indirect impacts could affect the sensitive vegetation communities in the Study Area.

Potential construction-related indirect impacts to sensitive vegetation communities would be less than significant with the implementation of **MM-BIO-5** (i.e., demarcation of disturbance limits and biological monitoring during construction).

Long-Term Indirect Impacts

The current operation of the diversion weir and intake allows for moderate flows in the stream to be diverted during the wet season; however, operations bypass the diversion of surface water during storm events where flows are generally greater than approximately 25 cfs to prevent excessive sediment from entering the spreading basins. During dry summer months, surface flows in the upper Arroyo Seco are sufficiently low to allow the City to divert virtually all surface flows in the stream.

Psomas conducted an analysis (Psomas 2018, provided as Appendix J, Arroyo Seco Canyon Diversions Biological Impacts Memorandum [Memo], to this BRTR) of the indirect Project impacts to downstream habitats due to the increase in the amount of water diverted to the spreading basins. The study took the conservative approach of analyzing project impacts by comparing it to a "without diversion" scenario, rather than the current diversion operations. This approach reflects the maximum possible change from existing conditions. This Memo included a hydraulics, sediment transport, and groundwater analysis, which provided the baseline for an analysis of potential ecological effects of flow diversions on downstream willow habitat (potential habitat occupied by least Bell's vireo) conducted by the Southern California Coastal Water Research Project (SCCWRP).

The study area for the analysis includes a portion of the upper Arroyo Seco from Devil's Gate Dam extending upstream to Area 2 (see Appendix J: Exhibit 1, Study Area). As the Arroyo Seco flows in a southerly direction past the existing diversion weir and past the JPL Bridge, the channel morphology changes from a narrow canyon to a wide alluvial plain. During high flow periods, surface flows can reach the Devil's Gate Reservoir, but during low flow periods in the drier months of the year, water infiltrates into the sandy sediment at the uppermost portion of the Reservoir.

Therefore, a lack of observed surface water doesn't necessarily correlate to insufficient moisture within the substrate for the riparian vegetation in the Reservoir (Psomas 2018).

During the wet periods or during episodic storms, surface water will flow from the upper Arroyo Seco into the Reservoir. Ongoing surface flows from the Arroyo Seco will result in standing water in the Reservoir. A review of historic aerial photos from Google Earth shows at least some surface water in the lower portion of the Reservoir in May 2003, January 2005, November 2005, March 2006, October 2007, January 2008, November 2009, and March 2011. Surface water is not observed in aerial photos subsequent to 2011, which corresponds to the severe drought conditions experienced in California from 2011 through 2016 (Psomas 2018).

The dominant vegetation community in the Devil's Gate Reservoir is Black Willow Series (Sawyer et al. 2009), in which Goodding's black willow *(Salix gooddingii*) is the dominant species (Chambers Group 2010). This vegetation type occurs throughout the lower portion of Devil's Gate Reservoir, correlated with the wettest conditions observed in an aerial photo analysis conducted. In general, the spatial distribution of vegetation in Psomas' study area is correlated to the hydrology of the area. Modest dry season surface flows occur immediately downstream of the diversion weir, which encourages establishment of facultative wetland species such as California sycamore and white alder. As less water is available further downstream in the dry season, the vegetation is dominated by upland-riparian transitional species, such as mule fat and coast live oak. The greatest density and extent of facultative wetland species such as Goodding's black willow occurs in the downstream portion of Devil's Gate Reservoir, where Devil's Gate Dam blocks surface and subsurface flows, resulting in more available water to vegetation behind the Dam (Psomas 2018).

Hydraulics, Sediment Transport, and Groundwater Analysis

A hydraulics, sediment transport, and groundwater analysis (Hydraulics Analysis) was prepared for the study area and is included as Attachment A to the Memo (Appendix J). The purpose of the Analysis was to evaluate the relative impact of the City's proposed management of diversions from the Arroyo Seco on riparian resources located downstream of the diversion structure. Hydraulic modeling assumed 100 percent efficiency in diversions in order to reflect the maximum reduced flow and thereby the maximum potential downstream habitat impacts (Psomas 2018).

The maximum depth of the pooled water within the Reservoir pool for the with-diversion scenario is reduced by approximately 1.3 feet in a dry year in comparison to the without-diversion scenario (Appendix J: Attachment A, Exhibit 7). A review of Exhibit 5 of Appendix J, Attachment A indicates that the cause of the decrease in maximum depth is likely due to the fact that the total runoff for the representative dry year without-diversions is approximately 2,480 acre-feet (af), while the hydrograph with diversions for the representative dry year is approximately 550 af.

Therefore, the difference in runoff volume accounts for the difference in maximum depths shown in Exhibit 7 of the Hydraulics Analysis (Appendix J: Attachment A). It is important to note that the area of inundation is approximately the same between the two scenarios owing largely to the shape of the Reservoir upstream of the Dam (Psomas 2018).

The maximum Reservoir pool water surface elevation for the representative average year without-diversion and representative average year with-diversions are approximately equal, with the WSE (water surface elevation) = 1,035 feet (Appendix J: Attachment A, Exhibit 9). In these scenarios, the factor that controls the depth and WSE is the operation of Devil's Gate Dam. Despite the same maximum depths, the with-diversion scenario has greater inundation durations at the Reservoir fringes because the depth reaches the operational curve elevation more slowly than does the without-diversion scenario (Psomas 2018).

Like the representative average year scenarios, the representative wet year maximum depth is the same in the with- and the without-diversion scenarios because the Dam operational curve is controlling the maximum depth in the Reservoir, approximately WSE=1,035 feet (Appendix J: Attachment A, Exhibit 11). Like the average year scenarios, the with-diversion scenario has greater inundation durations at the Reservoir fringes because the with-diversion scenario Reservoir depth reaches the operational curve elevation more slowly than does the without-diversion scenario (Psomas 2018).

A review of regional groundwater data indicates that the distance to groundwater within the Reservoir area is substantially greater than the depth of the tree root zones and consequently would not be expected to have an effect on rootzones of the riparian habitat within the Reservoir. Studies associated with the Devil's Gate Sediment Removal Project support the reported groundwater elevation with measured average depth to ground water of over 100 feet and depth to a subsection of a perched aquifer greater than 20 feet (Psomas 2018).

Within the upstream section of Psomas' study area, between the diversion point and the JPL bridge, the model showed little or no measurable change in hydraulic conditions (such as depth, velocity, inundation area, and shear) with project diversions. However, factors influencing the hydraulics are markedly different in this high gradient mountainous section versus the low gradient downstream areas. The stream is much narrower and does not expand with increasing flows due to the constrictions of the hardened canyon walls and granite boulders in the mountainous section. Increasing volume of water from storms have a greater effect on flow velocity as water exits the mountains and less of an effect on increasing area of pooling or the duration of pooling. This is consistent with the model findings showing little change with project diversions in the upstream segment (Psomas 2018).

The upstream area also behaves differently during low flows. The hydraulic model assumptions limit the lowest modeled flow to 1 cfs. Therefore, flows below 1 cfs are not included in the modeling analysis, but are considered here. During times of low flow, the role of groundwater is substantially different between the low gradient downstream area and the high gradient upstream area. Within the upstream section of the Arroyo Seco, subsurface water (i.e. groundwater) is very shallow and often just below the streambed surface, even in areas that appear dry on the surface. Due to the steep gradient, this groundwater moves downstream through the substrate as a subsurface flow beneath the streambed. Furthermore, this section of the Arroyo Seco is considered a "gaining" stream indicating that surface flows increase moving downstream due to upwelling of subsurface flows. Upwelling occurs when subsurface flows move around less permeable sections of substrate and reach the surface to become surface pools or flows for segments of the stream and may penetrate more permeable substrate further downstream and return to subsurface flow or continue downstream as surface flow for long distances. Evidence of the intermingling of surface and subsurface flowing can often be seen from just below the diversion point downstream to an A-frame bridge (Bridge 3) where subsurface upwelling occurs at low points in the stream (Psomas 2018).

Groundwater within the low gradient portion of the study area, downstream of the JPL bridge, is very deep. The extensive alluvial deposits allow water to readily migrate through and downward until reaching the water table approximately 100 feet below the surface. Low flows that make it downstream and past the JPL bridge are only visible on the surface for short distances before penetrating the sediment to become subsurface flow and quickly dropping vertically. Consequently, low flow in the Psomas study area is not expected to be influenced by groundwater to any measurable degree due to the distance between surface flows and the groundwater table (Psomas 2018).

Ecological Modeling Study

An Ecological Modeling Study was prepared for Psomas' study area and is included as Attachment B to the Memo (Appendix J). The ecological effects of flow diversions were assessed based on modeled relationships between hydraulic changes described in the Analysis and the probability that the resultant physical conditions can support southern willow riparian habitat conditions conducive to occupancy by least Bell's vireo.

All hydraulic variables tested showed significant statistical differences (p value <0.001) in willow occurrence between predicted future conditions and historic flow characteristics. However, given the small sample size of vegetation polygons, inherent to the relatively small size of the Project (see Appendix J: Exhibit 2, Excavation Limits of the LACDPW Devil's Gate Sediment Removal Project), and the high number of hydraulic observations (over 18,000), it is believed the

significance estimates may be overestimated. The significant overlap in distributions of occurrence and the large AIC[4] value substantiate this suspicion (Psomas 2018).

As depicted in Figure 4 of the Ecological Modeling Study (Appendix J: Attachment B), the model predicts a negative correlation between increasing velocity and willow habitat presence. Expected changes in velocity are illustrated in Exhibits 3a-3f, Modeled Change in Maximum Velocity Due to Proposed Project, of the Memo (Appendix J). This is because willow habitat favors areas where water infiltrates the soil; higher velocities mean lower infiltration, and thus do not favor willow presence. A similar result is predicted for shear stress, so that as shear stress increases, the model predicts a decreased probability in willow occurrence. Depth shows an increase in willow probability as water depth increases. Due to implementation of the Project, willows may increase in the channel (narrow linear flow upstream of the Reservoir pool) and decrease in the Reservoir pool as water recedes and depth decreases. This translates into an increase in the probability of willow occurrence in areas where occurrence was high and a decrease in the probability of willow occurrence where the occurrence was low. The most pronounced decrease predicted is a 13.8% decline in probability of occurrence in the lower basin, near the spillway, associated with a slight decrease in depth and duration of inundation. This is offset by a 6.6% increase in probability of occurrence at the margins of the basin, also associated with change in depth and duration of inundation. This gives a net change in the probability of willow occurrence of less than 10%. (Psomas 2018).

Impact of Diversions on Vegetation/Habitat

Changes in the hydrological regime of stream systems have been shown to result in changes in vegetation structure and composition. The shifts in vegetation related to changes in hydrology is based upon: (1) the degree of fluctuations in groundwater levels; (2) the depth of root systems of existing vegetation; and (3) the resulting potential of invasive species establishment to displace native vegetation. The concept behind this relationship is that minor fluctuations in groundwater levels will not affect the presence of phreatophytic vegetation if the root systems of those plants are deep enough to access water in the phreatic zone (zone of saturation) or the capillary fringe (zone above the saturation area where water fills soil pore spaces through capillary motion and is available for plant uptake). However, if groundwater levels drop below the maximum depth of the root zone for a sufficient amount of time, then those plants are susceptible to be displaced by other species. Factors that affect the depth of roots include the genetic ability of each plant to produce deep roots, the soil type and the depth to which gas exchange is possible, and available water and nutrients. Additionally, root depth has been shown to be affected by fluctuations in the water table

[4] The Akaike Information Criterion [AIC] is an estimator of the relative quality of statistical models and provides a measure of the relative information not well represented by the model. It represents the balance between goodness of fit and model complexity (Psomas 2018).

as significant fluctuations encourage species to elongate deep roots to access waters (Psomas 2018).

Therefore, the principal question is whether the proposed Project's diversions would cause an increase in the depth to groundwater that is available for willows and cottonwoods. As shown in Exhibit 4, Baseline Hydrology Example, of the Memo (Appendix J), changes to groundwater levels should not extend beyond the maximum depths to groundwater within the root zone of phreatophytic species to maintain their presence (Psomas 2018).

Willow habitat in the Reservoir is characterized by persistent coverage of mature willow trees, though aerial photo analysis indicates that the extent of willow coverage varies over time, likely in response to annual variability in precipitation and inflows from the upper Arroyo Seco. Little change is observed in the lowest portions of the Reservoir (downstream end) while coverage appears to vary slightly at the upper portions of the Reservoir. Because the accumulated sediment in the Reservoir is mainly comprised of sandy material, the willow tree rhizosphere likely reaches the maximum root depth of approximately seven feet below grade. The lack of a persistent herbaceous understory suggests that the depth to groundwater for much of the year is at least two feet, since herbaceous species roots generally extend less than two feet below grade. Therefore, the depth to groundwater likely fluctuates in the range of two to seven feet in the lower end of the Reservoir. It should be noted that the groundwater at these elevations does not represent the upper limit of the groundwater aquifer, which occurs approximately 300 feet below the surface in the Reservoir riparian areas as described previously. Based on topography, the shallower groundwater is expected to result from subsurface flows from the San Gabriel Mountains, which flow south off the mountains and on to the Montrose/La Canada valley floor then to the east flowing downhill, towards the Arroyo Seco, until eventually reaching the deposited sediments within the Reservoir (Psomas 2018).

Generally, surface flows will reach the Reservoir area during and after significant rain events during the winter months. Vegetation in the Reservoir will utilize this water as it ponds and saturates the uppermost soil layers. The presence of Devil's Gate Dam is the dominant influence to the hydrology of Psomas' study area because it blocks surface and subsurface flows to downstream areas thus increasing the time that subsurface water is available to trees in the Reservoir. Additionally, the Reservoir is a collection area for subsurface water that flows from the upper Arroyo Seco area, as well as from the Montrose/La Canada slope to the west. Some of these inflows support the riparian tree species that occupy the Reservoir area (Psomas 2018).

Due to the highly variable precipitation in the region and the resulting variability in surface flows in the upper Arroyo Seco, identifying the typical flow regime is difficult. As discussed above, surface flow rates in the wet season can range from approximately 1 cfs to more than 200 cfs. The Analysis (Appendix J: Attachment A) categorizes precipitation data for the Psomas' study area as

either wet, average, or dry years. The maximum inundation zone in the Reservoir was shown to minimally fluctuate during wet, average, or dry years, (see Appendix J: Exhibits 5a-5c, Modeled Change in Maximum Inundation Due to Proposed Project). The maximum flood zone for the Reservoir is determined by the management of Devil's Gate Dam, as any water that would exceed the maximum surface elevation of 1,035 feet is released downstream. Areas that would not be flooded during maximum inundation levels consist of a narrow band along the margins of the inundation footprint that measures 2.1 acres. As discussed in the Hydraulics Analysis, while the footprint of the inundated area during dry years is less than average or wet years, the duration of inundation along these fringes is increased in the with-diversions scenario. Inundation duration in dry years is increased by diversions because the amount of runoff required to initiate dam operations is increased. Overall, the hydraulics model indicates that any reduction to the inundation footprint is infrequent (occurring only during dry years) and duration period is slightly increased on the fringes (Psomas 2018).

The Hydraulic Analysis also discusses the effect on water velocities. The Ecological Modeling Study indicates that increasing water velocities result in lower water infiltration into the soil, and this reduces the probability of willow establishment. However, the Hydraulic Analysis indicates that the effects of water diversion on velocity are small overall and in some cases the change in velocity from diversions is a decrease from existing conditions (see Appendix J: Exhibit 3a-3f). Therefore, no changes to the extent of willow habitat is expected to occur from modelled velocity changes (Psomas 2018).

The Hydraulic Analysis also indicates that proposed stream diversions are expected to be an unimportant factor to overall sediment transport potential because the controlling elements of sediment transport are geologic factors. Large runoff events typically drive sediment movement in southern California streams; since no diversions are proposed during peak events, the Project is not expected to affect stream sediment yield to the Reservoir. In fact, the design of the proposed crest gate diversion weir is expected to enhance sediment transport because the gate will be placed in the down position during peak flow events to prevent impediments to sediment transport, which occur presently by the diversion weir (Psomas 2018).

As described above, the hydrology of the Arroyo Seco is highly variable. The Ecological Modeling Study indicates that water depth and duration of inundation correlate most highly with changes in the extent of willow riparian habitat in the Reservoir. Because the rainfall and resulting stream flows can vary so dramatically in the Arroyo Seco and because willow riparian habitat is dependent on available water, it stands to reason that the extent of willow habitat would mirror the dynamics of the site hydrology. Therefore, changes in the willow habitat that may result from proposed diversion changes during dry year conditions would likely be temporary (due to the high growth rate of the species and the likelihood that dry year conditions would be followed by average or wet year conditions) and within the normal range of variability of the system (Psomas 2018).

Changing Existing Conditions

The Memorandum considered the change in existing conditions downstream due to the LACDPW Devil's Gate Dam Sediment Removal Project, which began after the completion of the study. A large portion of the riparian vegetation within areas potentially affected by the Project is not expected to exist when hydraulic changes resulting from Project diversions would occur. Additionally, the surface elevation of a large portion of the Reservoir area will be lowered as the LACDPW's sediment removal project excavates accumulated sediments over the course of the coming years. As a result, a much greater volume of water will be contained within a deeper pool in a smaller area of the Devil's Gate Dam Reservoir. It is expected that pool margins will recess accordingly towards the center of the pool and away from riparian habitat occurring at and beyond current maximum pool margins. Therefore, small changes in hydraulics at the margins of the pooled areas of the Reservoir resulting from Project diversions are not likely to occur within or adjacent to existing riparian woodland habitat at pool margins. In summary, the minimal potential effects on riparian habitat resulting from future Project diversions, as described in previous sections, are further reduced due to changing existing conditions that would occur due to the Devil's Gate Sediment Removal Project (Psomas 2018).

Conclusion

Downstream reduced flows associated with Project diversions are not expected to result in any measurable effects on downstream riparian habitat. Project studies examining existing conditions within Psomas' study area and potential changes in hydraulics, sediment transport, and ground water coupled with ecological modeling and habitat requirements all provide support of this conclusion (Psomas 2018). Additionally, changing future conditions further reduce potential Project effects. Mitigation would therefore not be required because there would be no impacts to hydrology or biological resources in the context of the CEQA.

6.4 Impacts to Potential Jurisdictional Wetlands and Waters

6.4.1 Direct Impacts

There are no potential jurisdictional wetlands on the Project site. Arroyo Seco and the spreading basins are potentially regulated by the USACE, RWQCB, and/or CDFW. The proposed Project would result in direct temporary and/or permanent impacts to these potentially jurisdictional waters, as summarized below. Direct impacts include discharge of fill (i.e., grading and construction/reconstruction of structures) to potentially jurisdictional waters, which would alter the size, scope, and character of these aquatic resources and therefore would be significant, absent mitigation. Table 7, Permanent and Temporary Direct Impacts to Jurisdictional Waters, includes

the acres of permanent and temporary impact, which are illustrated in Figure 10, Impacts to Jurisdictional Resources (Sheets 1 and 2).

Table 7
Permanent and Temporary Direct Impacts to Potential Jurisdictional Waters

Jurisdictional Waters	Direct Permanent Impacts (acres)	Direct Temporary Impacts (acres)
Area 2		
USACE waters of the United States	0.17	0.03
RWQCB waters of the state	0.17	0.03
CDFW streambed, bank, and riparian vegetation	0.38	0.09
Area 3		
USACE waters of the United States	—	—
RWQCB waters of the state	1.79	0.59
CDFW streambed and bank	1.81	0.60
Gabrielino Trail/Access Road		
USACE waters of the United States	—	—
RWQCB waters of the state	—	—

USACE waters of the United States	—	—
RWQCB waters of the state	—	—
CDFW streambed, bank, and riparian vegetation	—	—
Project Total		
USACE waters of the United States	**0.17**	**0.03**
RWQCB waters of the state	**1.96**	**0.62**
CDFW streambed and bank[a]	**2.19**	**0.69**

Note: Numbers may not sum due to rounding.
a. white alder–California sycamore woodland (0.45 acres) and coast live oak woodland (<0.01 acres)

Direct impacts to Area 3 as tabulated above include the existing spreading basins. However, the proposed Project design in Area 3 includes the reconfiguration and expansion of the spreading basins in order to accommodate the increased diversion of stream flows for infiltration. The new spreading basins are expected to have the same function as the basins being impacted. As such, the Project would result in a net increase of 3.64 acres for in-kind waters of the State and a net increase of 3.61 acres for in-kind CDFW jurisdictional areas in Area 3, as shown in Table 8, Jurisdictional Waters Created by Project Design. Maintenance of the new spreading basins would continue to be accomplished by mechanically removing the top layer of soil and disking or

harrowing the exposed surface to loosen any soil compaction caused by cleaning, which is reflective of current maintenance activities.

Table 8
Jurisdictional Waters Created by Project Design in Area 3

Jurisdictional Waters	Direct Permanent Impacts (acres)	Direct Temporary Impacts (acres)	Total Impacts (acres)	Created Jurisdictional Waters (acres)	Net Difference (acres)
Area 3					
USACE waters of the United States	—	—	—	—	—
RWQCB waters of the State	1.79	0.59	2.38	6.02	+3.64
CDFW streambed, bank	1.81	0.60	2.41	6.02	+3.61

Potential permanent and/or temporary direct impacts to potential jurisdictional waters in Area 2 would be reduced to less than significant with the implementation of MM-BIO-5 and **MM-BIO-6** (i.e., on-site restoration and/or land acquisition, mitigation program funding, and/or mitigation bank credits). Consultation with, and permit issuance from, USACE, RWQCB, and CDFW may result in higher mitigation ratios and specific criteria for restoration beyond the minimum standards presented in this mitigation.

6.4.2 Indirect Impacts

Potential temporary indirect impacts to potential jurisdictional waters in the Study Area would primarily result from construction activities and would include impacts from the generation of fugitive dust and the introduction of chemical pollutants (including herbicides). Excessive dust can decrease the vigor and productivity of vegetation through effects on light, penetration, photosynthesis, respiration, transpiration, increased penetration of phytotoxic gaseous pollutants, and increased incidence of pests and diseases. Erosion and chemical pollution (releases of fuel, oil, lubricants, paints, release agents, and other construction materials) may affect wetlands/jurisdictional waters. The release of chemical pollutants can reduce the water quality downstream and degrade adjacent habitats. However, during construction, erosion-control measures would be implemented as part of the Storm Water Pollution Prevention Plan (SWPPP) for the Project. Prior to the start of construction activities, the Contractor is required to file a Permit Registration Document (PRD) with the State Water Resources Control Board (SWRCB) in order to obtain coverage under the National Pollutant Discharge Elimination System (NPDES) General Permit for Storm Water Discharges Associated with the Construction and Land Disturbance Activities (Order No 2009-009-DWQ, NPDES No. CAS000002) or the latest

approved general permit. This permit is required for earthwork that results in the disturbance of one acre or more of total land area. The required SWPPP will mandate the implementation of best management practices (BMPs) to reduce or eliminate construction-related pollutants in the runoff, including sediment. Therefore, temporary indirect impacts would be less than significant due to compliance with regulations.

Please see the discussion in Section 6.2.2 regarding indirect long-term impacts to hydrology and vegetation due to the increased water diversion by the Project.

6.5 Impacts to Wildlife Corridors and Habitat Connectivity

Short-Term Construction Impacts

The proposed Project could potentially cause temporary direct and indirect impacts to the use of the Study Area by terrestrial wildlife moving from the ANF to the Hahamonga Watershed Park due to construction within Area 2 and Area 3. However, the impact would be less than significant since there are currently no fish within Arroyo Seco, as described in Section 5.3.1 of this BRTR, and semi-aquatic (amphibians) and terrestrial wildlife (reptiles and mammals) would still be able to use adjacent natural sloped areas along the Arroyo Seco and the Gabrielino Trail/Access Road to avoid construction areas. The Arroyo Seco wash would not be obstructed from Area 2 to Hahamonga Watershed Park, which would allow existing wildlife species to utilize the streambed and avoid the spreading basin construction in Area 3.

Long-Term Operational Impacts

Potential long-term operational impacts to movement of native resident or migratory fish or wildlife species or the use of native wildlife nursery sites may occur if the proposed Project includes substantial adverse effects, compared to current conditions, in one of the following areas:

1. Terrestrial species movement around the proposed diversion structure (in both upstream and downstream directions)

2. Aquatic and semi-aquatic movement over the diversion structure (in both upstream and downstream directions)

3. Aquatic and semi-aquatic movement through the diversion intake (in a downstream direction)

The proposed Project would not result in a substantial change to existing movement conditions for terrestrial wildlife, given that the proposed structures and other improvements are substantially similar in size and location to the existing condition.

Given that the current diversion structure does not include screens and the proposed Project includes a drum screen or vertical screen with automatic brush cleaning system at the intake structure, which would follow CDFW published design criteria to prevent aquatic and semi-aquatic wildlife from entering into the conveyance system, the proposed Project would not have an adverse effect on aquatic and semi-aquatic movement through the diversion intake.

Therefore, potential long-term operational impacts are related to aquatic and semi-aquatic movement over the diversion structure. Factors that affect suitability for movement include existing natural and proposed Project features such as, channel bank slope gradients, vegetative cover, surface flow conditions, subsurface (i.e., groundwater) conditions, the height of the diversion structure relative to stream elevations upstream and downstream of the diversion, and presence/absence of fish screens in the diversion intake.

Based on the data gathered from the USGS gaging station from 1990 through 2019, the average in-stream flows are 6,890 acre-feet/year (ft/yr). Using these years of data to represent the current condition of diverting when stream flows are 25 cubic feet per second (cfs) or less, the City diverts an average of 2,045 acre-ft/yr. Under the proposed Project, the City would be able to divert approximately 3,080 acre-ft/yr, resulting in approximately 1,035 acre-ft/yr of additional diverted flows into the spreading basins. These proposed increased diversions would result in a measurable increase in diversion only during larger wet-weather flows. There would be little to no difference in diversions between the current condition and the proposed Project during the drier periods of the year. Aquatic and semi-aquatic movement within surface waters would therefore only be affected during larger wet-weather flows. This impact is less than significant because the decreased wet-weather flow would remain sufficient to allow upstream and downstream movement by species currently occupying the Project Area (see additional discussion below regarding existing and future fish and amphibian species).

With regards to subsurface flows (i.e., groundwater), as previously described in Section 6.3.2 of this BRTR, within the upstream section of the Arroyo Seco, subsurface water is very shallow and often just below the streambed surface, even in areas that appear dry on the surface. Due to the steep gradient, this groundwater moves downstream through the substrate as a subsurface flow beneath the streambed. As such, although surface flows are not always present, subsurface flows can be assumed present. The present condition of subsurface flow below the diversion weir would be maintained by constructing a modified structure at similar depth to the current structure. Therefore, the proposed Project would not affect suitability of habitat for movement due to the lack of change the project would have to groundwater.

In addition, the current aged and ineffective diversion weir structure results in negligible seepage (or "weeping") of flows through the flashboards. During the drier periods of the year when low stream flows are fully diverted, the seepage has been estimated to be 0.1 to 0.2 cfs. While the current seepage is not sufficient to establish habitat for aquatic or semi-aquatic wildlife movement, the Project will allow for a similar release of flows through a valved bypass pipe from the intake structure. Therefore, there would be no change to this condition.

Fish Movement (Current Conditions)

As previously discussed in Section 5.3.1 of this BRTR, there are no fish present in the Arroyo Seco Canyon in the current condition. No fish were observed during the 2019 surveys for the Project, including the focused fish survey (see Appendix C) that included all waters from the surface water terminus at the southern end in the Arroyo Seco wash adjacent to Area 3 to the Brown Mountain Dam. There was an incidental sighting of rainbow trout during the focused amphibian surveys conducted in 2013, but its provenance was not determined (BonTerra Psomas 2014e). Therefore, the proposed Project replacement of the existing diversion structure and intake facility would not result in a substantial impediment to the movement of native resident or migratory fish species, because of the absence of fish in the current condition, and impacts would be less than significant.

If fish were present in the Study Area in the current condition, the current diversion operations which lacks a fish screen, would result in fish being transported downstream to be potentially stranded in isolated pools of water (the spreading basins or in the reach between the diversion and the JPL Bridge), or lost when passed into Devil's Gate Reservoir where flows spread out and habitat is unsuitable. The loss of connectivity and isolation of pools occurs primarily during the late summer/early fall months when there are periods of low to zero flows in the stream above the diversion (stream flows are below 1 cfs 35% of the year, and drop to zero about 10% of the time). This lack of water is the primary barrier for fish movement from about the JPL Bridge upstream where substrate and cover is good, but water is lacking. Below the JPL Bridge the flatter sediment load of the reservoir is open to solar heating, is dominated by finer substrates, and cover and pools are rare or absent. Also, the stream is subject to frequent dry conditions due to loss of aboveground flow as the channel emerges from the canyon into the alluvium, where water flow is primarily subterranean. During moderate flows, partial temporal barriers may be present in the canyon segment of the stream due to steep channel segments and step-pool or bedrock drops preventing upstream fish passage. Therefore, if fish were to be present, their movement would be restricted and they may perish due to isolation or stranding. The proposed Project will include fish screens to prevent isolation in the spreading basins and can be operated in a manner that excludes fish from the downstream reaches during diversion. The effects of the proposed Project related to downstream drift/movement are beneficial (i.e., no significant impact) due to inclusion of fish screens and proposed operations.

CDFW Coordination

The CDFW submitted a comment letter on the scope and content of the Draft EIR during the Notice of Preparation (NOP) public review period for this proposed Project and requested an evaluation to determine whether the Project would prevent or impede fish passage during low flow conditions. The cited Fish and Game Code section 5901 makes it unlawful to construct or maintain in any streams any device that prevents, impedes, or tends to prevent or impede the passing of fish up and downstream. In addition Fish and Game Code section 5937 is cited and requires the owner of any dam to allow sufficient water at all times to pass through a fishway or in the absence of a fishway, allow sufficient water to pass over, around or through the dam, to keep in good condition any fish that may be planted or existing below the dam.

While no fish are currently present, the City's general approach to the proposed Project is to plan for future conditions with the ability to operate the Project based on present conditions for fish. Under present conditions, an in-stream flow of about 0.5 cfs would be released to match the estimated leakage from the existing weir, and flows above this, up to the full 25 cfs water right, would be diverted when possible. The operation will exclude fish from the downstream reach under most conditions and from the diversion using fish screens designed to meet CDFW criteria for salmonid fry. Because, flows will pass over the crest gates when streamflow is greater than about 25 cfs and when the gates are lowered at higher flows, the City proposes that a monitoring program be developed to confirm that fish are not present in the reach downstream of the diversion after these conditions occur.

For a future condition where fish return or are reintroduced to the Arroyo Seco under present channel conditions, there are still several barriers to fish migration and survival that influence proposed operations. As such, operations would not be altered from those proposed under the present condition, i.e. fish would continue to be excluded from passing downstream the diversion and no minimum in-stream flows would be proposed. Under these conditions, the monitoring program would continue and would include a program to rescue fish between the diversion and JPL Bridge. During high flows when the gate is lowered, a roughened channel section downstream will allow upstream passage of future fish. Roughened channels are an accepted method of providing passage for steelhead trout in CDFW's Salmonid Stream Restoration Manual (CDFG 2010), requiring site specific design and review. The roughened channel configuration proposed is a channel approximately the width of the active channel in adjacent stream segments (upstream and downstream), with an asymmetric v-shaped cross section to concentrate lower flows and provide adequate depth. Compared to other potential types of upstream passage features, the roughened channel type has the advantage of providing a range of velocities and depths at a given flow rate. Thus, smaller or weaker swimming native fish and other aquatic organisms could pass along the margins of the channel or near the bottom, using spaces in the bed material for hydraulic cover. Additionally, revegetation for the Project would include biotechnical stabilization and

riparian planting on the west and east banks along the roughened channel providing coverage for wildlife. The combination of screening and monitoring/rescue would significantly reduce risk for any resident populations compared to existing diversion operations and would assist in maintaining populations upstream of the diversion

Under a future condition with restored anadromy, the City proposes to significantly alter diversion operations to allow for upstream and downstream fish passage (see Future Conditions for Fish section below).

Until such time, however, the proposed Project would result in an improvement to the existing condition and impacts related to potential aquatic and semi-aquatic species movement are less than significant.

Amphibian Movement (Current Conditions)

As discussed, in Section 5.3.2 of this BRTR, there are several amphibian species present in the Arroyo Seco, including western toad (*Anaxyrus boreas*), California treefrog (*Pseudacris cadaverina*), and Baja California treefrog (*Pseudacris hypochondriaca*). These amphibian species are primarily terrestrial and would not be hindered beyond the current condition with the implementation of the proposed Project. Importantly, amphibian populations would potentially benefit from the proposed Project due to the inclusion of the drum screen or a vertical screen with automatic brush cleaning system at the intake structure, which would follow CDFW published design criteria to prevent aquatic and semi-aquatic wildlife from entering into the conveyance system and becoming stranded in the spreading basins.

When the diversion is in operation during periods of low flow, downstream drift for larval amphibians would be prohibited and would prevent larva from being stranded downstream. When high flows spill over the raised gate, adult, juvenile, and larval amphibians would pass downstream, and adults and juveniles would be expected to move upstream along the western slope. The limits of the roughened channel would extend to the edge of the diversion structure to allow amphibians to pass along the side without leaving the stream corridor. When the weir is completely lowered its sill elevation will follow the stream's general profile, creating a smooth transition to the roughened channel section downstream and allowing for upstream passage. The maximum elevation of the weir when raised would not be higher in elevation than the existing diversion structure, and the elevation of the pool of water at the intake would not exceed existing levels. Therefore, the Project would not affect existing overland routes for semi-aquatic species in either upstream or downstream directions. Amphibians would continue to have the same routes for passage as in the existing condition.

Therefore, replacement of the existing diversion structure and intake facility with an enhanced facility in the same location would not result in a substantial change from existing conditions and would not substantially impede the movement of amphibians beyond the current pre-Project condition and impacts would be less than significant.

Future Conditions for Fish

The proposed Project has been designed in consideration of a future condition where fish are re-established in the Arroyo Seco. However, it is the City's position that under present conditions that includes periods of low to zero flows, the unsuitability of Devil's Gate Dam habitat and lack of passage, and barriers to upstream passage, downstream fish passage is undesirable. With the goal of excluding fish from the downstream reaches during diversions under present conditions, the proposed new diversion structure would be designed for the possibility that some future fish may pass downstream when the diversion is not operating (i.e., during periods of higher flows when the gate is lowered to allow flows to continue downstream without diversion) or when the diversion is operating and flows are high enough to spill over the crest gate. The roughened channel would allow for upstream passage when the weir crest gate is lowered.

A further condition for the future will occur when connectivity is re-established for passage through Devil's Gate Dam (i.e. removal of the dam or construction of a fish-ladder), connecting the upper and lower Arroyo Seco to the Los Angeles River and ultimately, the Pacific Ocean. This circumstance would potentially allow for the reintroduction of the southern steelhead (*Oncorhynchus mykiss irideus*), which is federally listed as endangered. In streams, the species uses habitat consisting of relatively cool, well-oxygenated water with adequate depth and cover. Steelhead require relatively clean unconsolidated gravel and cobble for spawning. Steelhead have an ecological or migratory life cycle called anadromy, in which adults mature in the ocean and must return to freshwater to spawn. However, until such time as safe connection to suitable downstream habitat or to the ocean can be provided, a bypass fishway is not proposed as part of the Project. If access for steelhead is re-established, however, the Project can accommodate a future bypass fishway and maintenance of minimum flow conditions to allow for upstream passage while the diversion is in operation.

As previously discussed, the Southern California Steelhead Recovery Plan (NOAA 2012) describes priority actions for recovery of steelhead in the region, including the Los Angeles River basin. The Arroyo Seco watershed has a low ranking in relative viability for recovery. The Recovery Plan lists removal of barriers at dams, diversions, roads, and other structures as a priority action in the biogeographic region (NOAA 2012). Southern steelhead recovery in Arroyo Seco would involve modification of multiple flood control facilities and removal of multiple barriers between the Project area and the ocean. Importantly, the removal of Devil's Gate Dam or modifications to allow fish passage both up and downstream would be a major undertaking.

Nevertheless, in this potential future scenario, the proposed Project design may not comply with Fish and Game Codes 5901 and/or 5937. Therefore, **MM-BIO-7** (Native Resident and Migratory Fish Monitoring Plan preparation and implementation) is recommended to be responsive to the CDFW comment letter received during the NOP review period for this Project to allow for the future use of the Study Area as a movement corridor for native resident or migratory fish species.

6.6 Impacts to City of Pasadena Protected Trees

6.6.1 Direct Impacts

Direct impacts to trees can be classified as a removal or encroachment. Trees are identified for removal when they are located within the permanent impact boundary. Trees are identified as encroachment if the tree canopy is within 5 feet of the permanent impact boundary, or if the tree trunk is within 15 feet of the permanent impact boundary. Direct impacts to encroachment trees include root damage, soil excavation and compaction, grade changes, loss of canopy, and trunk wounds, among others.

Direct tree impacts would result in the removal of 19 protected trees in total, of which all are located in Area 2. A total of 15 protected trees are expected to be encroached upon (11 trees in Area 2 and 4 trees in Area 3). No trees are anticipated to be removed in Area 3. See Table 9, Area 2 - Protected Trees Direct Permanent Impacts, Table 10, Area 3 - Protected Trees Direct Permanent Impacts, and Figure 11, Impacts to Protected Trees (Sheets 1 and 2) for direct permanent impacted protected tree locations.

Table 9
Area 2 - Protected Trees Direct Permanent Impacts

Native Tree Species		**Number of Trees**	
Scientific Name	*Common Name*	*Removal*	*Encroachment*
Alnus rhombifolia	white alder	15	5
Platanus racemosa	California sycamore	0	2
Populus trichocarpa	*black cottonwood*	0	1
Quercus agrifolia	coast live oak	3	2
Quercus chrysolepis	canyon live oak	0	1
Salix nigra	black willow	1	0
Total		**19**	**11**

Table 10
Area 3 - Protected Trees Direct Permanent Impacts

Native Tree Species		Number of Trees	
Scientific Name	*Common Name*	*Removal*	*Encroachment*
Platanus racemosa	California sycamore	0	1
Quercus agrifolia	coast live oak	0	3
Total		**0**	**4**

Impacts to these trees would be significant, absent mitigation, in accordance with the City's Tree Ordinance (Chapter 8.52 of the Pasadena Municipal Code). Project implementation of **MM-BIO-8** (i.e., i.e., tree replacement and protection) would reduce potential direct impacts to a less-than-significant level. Additionally, the City will follow the City's Tree Protection Guidelines established for projects subject to Chapter 8.52 and prepared by the City Manager (City of Pasadena 2019b). Applicable mandatory measures from the Guidelines that would be applied to construction of the proposed Project are generally summarized below to include, but not be limited to:

P-313-1.5 Protection of Trees on City Property

> (1) A tree protection zone (TPZ) shall be defined as the drip line of the tree plus four (4) radial feet;
>
> (2) Protective (6-foot high minimum) chain-link fencing with an access gate of minimal width should be installed around the TPZ to the extent practicable subject to approval by staff prior to the commencement of any grading, construction, or demolition. Fencing must also include 8 ½" x 11" (minimum) signage that includes the following information: Tree Protection Zone; name and contact information of project owner or authorized representative; and "Please contact the Pasadena Citizen Service Center to report any concerns (626) 744-7311;
>
> (3) All work conducted in the ground within the TPZ of any protected tree should be accomplished with hand tools, unless an air spade is utilized. Trenches in the TPZ should be tunneled or completed with an air spade to avoid damage to roots within the TPZ.
>
> (4) Any required trenching should be routed in such a manner as to minimize root damage. Radial trenching (radial to the tree trunk) is preferred as it is less harmful than tangential trenching. Construction activity should be diverted from the TPZ. Cutting of roots should be avoided (i.e. place pipes and cables below uncut roots). Wherever possible and in

accordance with applicable code requirements, the same trench should be used for multiple utilities.

(5) No construction staging or disposal of construction materials or byproducts including but not limited to paint, plaster, or chemical solutions is allowed in the TPZ.

6.7.2 Indirect Impacts

Indirect impacts to trees are the result of changes to the site that may cause tree decline, even when the tree is not directly injured. Site-wide changes affecting trees include diverting runoff and stormwater, creating retention and detention ponds, relocating streams or making improvements to streams, lowering or raising water tables, altering the capacity for soil moisture recharge, removing vegetation, or damming underground water flow (Matheny and Clark 1998). Indirect tree impacts may potentially occur to 13 additional protected trees.

Indirect impacts could potentially result in tree mortality adjacent to the Project work areas, which would be significant, absent mitigation, under the City's Tree Ordinance. Project implementation of MM-BIO-7 would reduce potential indirect impacts to a less-than-significant level.

6.7 Impacts to Regional Resource Planning

6.7.1 Direct Impacts

The Study Area does not occur within any proposed or approved HCPs or NCCPs, and outside the ANF boundaries. Therefore, the proposed Project would not result in a significant direct temporary or permanent impacts to any HCPs/NCCPs or other biological resources protected by regional resource planning. No impacts would occur and no mitigation is required.

6.7.2 Indirect Impacts

Due to the lack of mapped HCPs/NCCPs, within and immediately adjacent to the Study area, there would be no significant indirect temporary or permanent impacts to any HCPs/NCCPs. The Study Area is located near the ANF, which is managed by the Angeles National Forest Land Management Plan (ANF 2005), but since the Study Area is downstream, no indirect impacts to the ANF are expected and no mitigation is required.

INTENTIONALLY LEFT BLANK

7 MITIGATION

The following mitigation measures shall be implemented during the proposed Project to reduce the significant impacts identified in Chapter 6 to a less-than-significant level.

7.1 Impact BIO-1: Special-Status Species

Significant direct and indirect impacts to special-status species can be mitigated to less than significant with implementation of the following measures:

MM-BIO-1 Direct Impacts to Terrestrial Special-Status Wildlife.

Special-Status Wildlife Relocation Plan. Prior to commencement of any earthmoving activities or the pre-construction staging of equipment on the Project site, the City shall develop a Preconstruction Survey and Relocation Plan for terrestrial reptiles, including the California newt, two-striped gartersnake, Southern California legless lizard, and coastal whiptail. The Preconstruction Survey and Relocation Plan shall be submitted to the California Department of Fish and Wildlife (CDFW) for review prior to any ground-disturbing activities within potentially occupied habitat.

The Plan shall include at a minimum, the following: (1) protocols for pre-construction surveys to flush out and/or move identified special status wildlife within the study area, as feasible; (2) the timing, frequency, and locations where surveys should be conducted; (3) the habitat and conditions in the proposed relocation site(s); (4) the methods that would be used for trapping and relocating identified species; (5) protocols for documentation/recordation of the species and number of animals relocated; and (6) protocols for notifying CDFW in the event that identified species cannot be relocated.

The Plan shall require that a Biological Monitor be present during initial vegetation clearance activities within Areas 2 and 3, as well as twice weekly until ground disturbing activities are completed. The Biological Monitor shall also be familiar with least Bell's vireo and shall conduct pre-clearing non-protocol surveys for this species while onsite. If a least Bell's vireo or other State of federally listed species is detected, work activity within 200 feet of the detected occupied habitat will be temporarily halted and the City will consult with the appropriate wildlife agencies. With authorization from these agencies, which may include a 'take' permit, the project will proceed in accordance with conditions developed in the consultation. Conditions will include avoidance and

minimization measures to prevent or minimize impacts on the listed species(s) occurring on or adjacent to the site.

The Plan shall require that any individual special-status terrestrial wildlife species observed within the study area during the pre-construction survey(s) shall be flushed out and/or moved out of harm's way to avoid direct impacts to these species, and if special-status species are detected, the Biological Monitor shall capture and relocate individuals to nearby undisturbed areas with suitable habitat outside of the construction area, but as close to their origin as possible. The final recordation/documentation of any wildlife relocated during Project activities shall be made available to CDFW for confirmation that construction activities were executed in compliance with the approved Preconstruction Survey and Relocation Plan.

MM-BIO-2 Direct and Indirect Impacts to Special-Status and Nesting Birds.

Nesting Bird Avoidance. Project construction shall be conducted in compliance with the conditions set forth in the Migratory Bird Treaty Act (MBTA) and California Fish and Game Code with methods approved by California Department of Fish and Wildlife (CDFW) to protect active bird/raptor nests. To the maximum extent feasible, vegetation removal shall occur during the non-breeding season for nesting birds (generally late September to early March) and nesting raptors (generally early July to late January) to avoid impacts to nesting birds and raptors. If the Project requires that work be initiated during the breeding season for nesting birds (March 1–September 30) and nesting raptors (February 1–June 30), in order to avoid direct impacts on active nests, a pre-construction survey shall be conducted by a qualified Biologist for nesting birds and/or raptors within 3 days prior to clearing of any vegetation and/or any work near existing structures (i.e., within 300 feet for nesting birds and within 500 feet for nesting raptors). If the Biologist does not find any active nests within or immediately adjacent to the impact areas, the vegetation clearing/construction work shall be allowed to proceed.

If the Biologist finds an active nest within or immediately adjacent to the construction area and determines that the nest may be impacted or breeding activities substantially disrupted, the Biologist shall delineate an appropriate buffer zone around the nest depending on the sensitivity of the species and the nature of the construction activity. Any nest found during survey efforts shall be mapped on the construction plans. The active nest shall be protected until

nesting activity has ended. To protect any nest site, the following restrictions to construction activities shall be required until nests are no longer active, as determined by a qualified Biologist: (1) clearing limits shall be established within a buffer around any occupied nest (the buffer shall be 100–300 feet for nesting birds and 300–500 feet for nesting raptors), unless otherwise determined by a qualified Biologist and (2) access and surveying shall be restricted within the buffer of any occupied nest, unless otherwise determined by a qualified Biologist. Encroachment into the buffer area around a known nest shall only be allowed if the Biologist determines that the proposed activity would not disturb the nest occupants. Construction can proceed when the qualified Biologist has determined that fledglings have left the nest or the nest has failed.

MM-BIO-3 Direct and Indirect Impacts to Special-Status Bats

Bat Roost Avoidance. A Biological Monitor shall conduct a pre-construction bat habitat assessment of buildings and trees marked for potential removal. Potential for roosting shall be categorized by 1) potential for solitary roost sites, 2) potential for colonial roost sites (10 bats or more). If the potential for colonial roosting is determined, those trees shall not be removed during the bat maternity roost season (March 1 – July 31). Trees potentially supporting colonial roosts outside of maternity roost season, and trees potentially supporting solitary roosts may be removed via a two-step removal process, whereby some level of disturbance (such as trimming of lower branches) (at the direction of Biological Monitor) is applied to the tree on day one to allow bats to escape during the darker hours, and the roost tree shall be removed two days later (i.e., there shall be no less or more than two nights between initial disturbance and the grading or tree removal). When feasible, trees will be dropped slowly and a Biological Monitor will monitor the activity. If buildings are determined to be occupied, one-way exclusionary devices will be placed over bat access points and left in place for two nights prior to building removal.

7.2 Impact BIO-2: Sensitive Vegetation Communities

Significant direct and indirect impacts to sensitive vegetation communities can be mitigated to less than significant with implementation of the following measures:

MM BIO-4 Direct Impacts to Sensitive Vegetation Communities.

Direct impacts to sensitive communities (white alder–California sycamore woodland association and California sycamore woodlands alliance) shall be mitigated through a combination of on-site and/or off-site measures. Mitigation for impacts to sensitive vegetation communities shall consider and overlap with compensation for jurisdictional waters (MM-BIO-6) since the sensitive vegetation is associated with the jurisdictional limits of Arroyo Seco. Mitigation for direct impacts to sensitive vegetation communities shall be implemented through on-site creation/enhancement, program funding, mitigation bank credits, and/or creation/enhancement of native vegetation communities on City lands. Mitigation acreages shall be implemented as shown in Table 11, Mitigation for Direct Impacts to Sensitive Vegetation Communities.

Table 11
Mitigation for Direct Impacts to Sensitive Vegetation Communities

Sensitive Vegetation Community	Direct Impacts (acres)	Mitigation Ratio	Mitigation (acres)
white alder–California sycamore woodland association	0.47	3:1	1.41
California sycamore woodlands alliance	0.04	3:1	0.12
Totals:	**0.51**	**—**	**1.53**

On-site Mitigation. Prior to the issuance of a grading permit or any earthwork on the Project site, PWP shall prepare a Habitat Mitigation and Monitoring Plan (HMMP) for habitat enhancement and creation activities. The HMMP shall at a minimum include a feasible implementation structure, salvage/seeding details, invasive species eradication methods, irrigation system and schedule, a monitoring schedule, performance standard of success, estimated costs, and identification of responsible entities. The HMMP shall include restoration of the following habitats:

Riparian Woodlands. Impacted areas of white alder–California sycamore woodland association and California sycamore woodlands alliance shall be created/restored within and adjacent to the same on-site areas that the woodland currently existed prior to Project implementation, as well as other areas deemed to have appropriate soils and topography for successful establishment. Understory areas shall be revegetated with a diversity of locally collected seeds.

Temporary irrigation shall be established and maintained, with irrigation suspensions in times of rainfall. Successful establishment of the woodland shall be determined only after removal of irrigation system and confirmed ability of the woodland to survive in the absence of irrigation.

It is anticipated that a one-time restoration effort followed by monitoring and invasive weed removal for a minimum of five (5) years would be required. The HMMP shall be submitted to the City, CDFW, USACE, and RWQCB for review and comment, and revised to the satisfaction of the City and the three agencies.

Off-site Mitigation. If mitigation is implemented through mitigation program funding and/or mitigation bank credits, the Project Applicant shall work with the City, CDFW, USACE, and RWQCB to ensure the mitigation program funding and/or mitigation bank credits are appropriate to offset permanent impacts. Mitigation lands shall be comprised of similar or higher quality riparian woodland and preferably located in the vicinity of the site or watershed.

If mitigation is implemented through offsite enhancement of City-owned lands, PWP shall prepare a HMMP that details the location and existing conditions of the offsite lands. The HMMP shall at a minimum include a feasible implementation structure, salvage/seeding details, invasive species eradication methods, irrigation system and schedule, a monitoring schedule, performance standard of success, estimated costs, and identification of responsible entities. It is anticipated that a one-time restoration effort followed by monitoring and invasive weed removal for a minimum of five (5) years would be required. The HMMP shall be submitted to the City, CDFW, USACE, and RWQCB for review and comment, and revised to the satisfaction of the City and the three agencies.

MM-BIO-5 Indirect Impacts to Sensitive Vegetation Communities.

Demarcation of Disturbance Limits. To prevent inadvertent disturbance to sensitive vegetation communities outside the limits of work, the construction limits shall be clearly demarcated (e.g., installation of flagging or temporary high visibility construction fence) prior to ground disturbance activities. All construction activities including equipment staging and maintenance shall be conducted within the marked disturbance limits.

Monitoring. A qualified biologist shall be present during initial ground-disturbing activities within the Project Site to ensure that Project activities stay within the demarcated limits.

7.3 Impact BIO-3: Jurisdictional Wetlands and Waters

Significant direct and indirect impacts to jurisdictional waters can be mitigated to less than significant with implementation of the following measures and MM-BIO-5:

MM-BIO-6 Direct and Indirect Impacts to Jurisdictional Waters

Mitigation for direct impacts to jurisdictional waters shall be implemented through on-site enhancement of remaining jurisdictional waters and/or off-site acquisition, program funding, and/or mitigation bank credits. Mitigation ratios for each type of jurisdictional waters is shown in Table 12, Mitigation for Direct Impacts to Potential Jurisdictional Waters. Mitigation for temporary and permanent impacts to jurisdictional wetlands and waters shall consider and overlap with compensation for sensitive vegetation communities (MM-BIO-4).

Table 12
Mitigation for Direct Impacts to Potential Jurisdictional Waters

Jurisdictional Waters Type	Direct Impacts (acres)	Mitigation Ratio	Mitigation (acres)[a]
USACE waters of the United States	0.18	1:1	0.18
RWQCB waters of the state	2.57	1:1	2.57
CDFW streambed and bank, with riparian vegetation[b]	0.48	3:1	1.35
CDFW streambed and bank, with non-riparian habitat[c]	2.41	1:1	2.41

Notes:

a Mitigation areas for each jurisdictional type may overlap

b white alder–California sycamore woodland (0.48 acres) and coast live oak woodland (<0.01 acres)

c California sagebrush–California buckwheat–laurel sumac scrub (<0.001 acres); urban/developed (0.03 acres); disturbed habitat (2.38 acres); laurel sumac scrub (<0.01 acres)

On-site Mitigation. Prior to the issuance of a grading permit or any earthwork on the Project site, PWP shall prepare a HMMP for habitat enhancement and creation activities. The HMMP shall at a minimum include a feasible implementation structure, salvage/seeding details, invasive species eradication methods, irrigation system and schedule, a monitoring schedule, performance standard of success, estimated costs, and identification of responsible entities. The HMMP shall include restoration of the following habitats:

Riparian Woodlands. Impacted areas of white alder–California sycamore woodland association and coast live oak woodland shall be created/restored within and adjacent to the same on-site areas that the woodland currently

existed prior to Project implementation, as well as other areas deemed to have appropriate soils and topography for successful establishment. Understory areas shall be revegetated with a diversity of locally collected seeds. Temporary irrigation shall be established and maintained, with irrigation suspensions in times of rainfall. Successful establishment of the woodland shall be determined only after removal of irrigation system and confirmed ability of the woodland to survive in the absence of irrigation.

It is anticipated that a one-time restoration effort followed by monitoring and invasive weed removal for a minimum of five (5) years would be required. The HMMP shall be submitted to the CDFW, USACE, and RWQCB for review and comment, and revised to the satisfaction of the three agencies.

Off-site Mitigation. If mitigation is implemented through mitigation program funding and/or mitigation bank credits, PWP shall work with the CDFW, USACE, and RWQCB to ensure the mitigation program funding and/or mitigation bank credits are appropriate to offset permanent impacts. Mitigation lands shall be comprised of similar or higher quality riparian woodland and preferably located in the vicinity of the site or watershed.

If mitigation is implemented through offsite enhancement of City-owned lands, PWP shall prepare a HMMP that details the location and existing conditions of the offsite lands. The HMMP shall at a minimum include a feasible implementation structure, salvage/seeding details, invasive species eradication methods, irrigation system and schedule, a monitoring schedule, performance standard of success, estimated costs, and identification of responsible entities. It is anticipated that a one-time restoration effort followed by monitoring and invasive weed removal for a minimum of five (5) years would be required. The HMMP shall be submitted to the CDFW, USACE, and RWQCB for review and comment, and revised to the satisfaction of the three agencies.

7.4 Impact BIO-4: Habitat Linkages and Wildlife Corridors

Project design features in Area 2 would improve the ability of existing aquatic and semi-aquatic species to move up and downstream at the location from the current conditions. To determine if there are changes to future use of the Study Area as a movement corridor for native resident or migratory fish species, the following measure would be implemented:

MM-BIO-7 Direct and Indirect Impacts to Habitat Linkages and Wildlife Corridors

Native Resident and Migratory Fish Monitoring Plan. Prior to the commencement of earthmoving within Area 2 for the demolition of the existing diversion/weir structure, the City shall develop a Native Resident and Migratory Fish Monitoring Plan (Monitoring Plan), in consultation with CDFW. This Monitoring Plan shall set forth annual monitoring requirements to determine if native fish species or migratory fish populations are present within an approximate 3,500-foot section of the stream (about 1,500 feet upstream of the diversion/weir structure to the abandoned headworks (Area 1) and 2,000 feet downstream to the JPL Bridge at the mouth of the canyon). Annual survey protocols shall be established to the satisfaction of CDFW and set forth in the Monitoring Plan. If the results of the annual surveys reveal a positive presence of native fish, the Monitoring Plan shall set forth thresholds for determining the permanency of the population, and whether or not connectivity both upstream and downstream of the diversion structure is appropriate and in the best interest of the long-term survival of an established native or migratory fish population, given hazards associated with stranding downstream. Until passage for steelhead is restored to the Arroyo Seco, the City shall implement a program to rescue fish between the diversion structure and the JPL Bridge. If rescue is determined to be ineffective or impractical, then the City shall modify its operations to accommodate passage. At such time as steelhead passage is restored, the City shall alter either the design of the diversion/weir structure, the operational methods of the diversion/weir structure, or both to satisfy Fish and Game Code Sections 5901 and 5937.

7.5 Impact BIO-5: Local Policies or Ordinances

Significant direct and indirect impacts to City protected trees can be mitigated to less than significant with implementation of the following measures:

MM-BIO-8 Direct and Indirect to City of Pasadena Protected Trees

Tree Replacement and Protection. A qualified biologist shall be present during initial ground-disturbing activities within the Project site to ensure that Project activities stay within the demarcated limits, as required in MM-BIO-5. This qualified biologist shall identify the number of City-protected trees that are removed as a result of Project construction activities, as well as trees that would be encroached upon. This inventory of trees shall be used to determine an appropriate tree replacement program that shall be, at a minimum, consistent with the City's

Tree Ordinance (Chapter 8.52 of the Pasadena Municipal Code) and the Ordinance's administrative guideline replacement matrix, as it relates to tree replacement of protected trees. as it relates to tree replacement of protected trees.

Trees within approximately 15 feet of proposed construction activity shall be temporarily fenced with chain-link fencing in accordance with the City's Tree Ordinance and Tree Protection Guidelines. The fencing shall be installed to the extent of the tree's dripline plus four (4) radial feet and be minimum six (6) feet high with an access gate of minimal width. The fenced area shall be considered the TPZ unless proximate construction required temporary removal.

All trees that have been substantially root pruned (30% or more of their root zone) during construction within the TPZ shall be monitored by an International Society of Arboriculture Certified arborist for the first five years after construction completion. The arborist shall submit an annual report, photograph each tree and compare tree health and condition to the original, pre-construction baseline. For trees that do not survive the five-year monitoring period, such trees shall be replaced in accordance with the requirements of this measure.

7.6 Impact BIO-6: Habitat Conservation Plan

Because no significant impacts would occur as a result of the proposed project (see Section 6.7), no mitigation is required.

7.7 Level of Significance After Mitigation

Implementation of these mitigation measures will reduce potential impacts to biological resources to below a level of significance.

One special-status amphibian (California newt) and three special-status reptiles (two-striped gartersnake, Southern California legless lizard, and coastal whiptail) have occurred in the Study Area. Construction activities associated with the proposed Project could cause direct mortality of these species. MM-BIO-1 requires the development of a special-status wildlife relocation plan, pre-construction focused special-status wildlife surveys, and monitoring during initial ground-disturbing activities. Potential direct impacts to California newt, two-striped gartersnake, Southern California legless lizard, and coastal whiptail would be less than significant with implementation of MM-BIO-1.

Construction activities associated with the proposed project could result in a loss of suitable habitat or direct take of birds, and are considered less than significant. MM-BIO-2 requires nesting bird surveys within 300 feet (500 feet for raptors) of the proposed impact areas and if active nests are found, the biologist shall establish buffers and/or implement monitoring to avoid impacting avian nesting success. Potential direct impacts to protected nesting birds would be less than significant with implementation of MM-BIO-2.

One special-status bat (hoary bat) has a moderate potential to occur in the Study Area. Construction activities associated with the proposed Project could cause direct mortality of these species. MM-BIO-3 requires seasonal avoidance, pre-construction roost survey, and roost monitoring. Potential direct impacts to hoary bat would be less than significant with implementation of MM-BIO-3.

Significant direct and indirect temporary and permanent impacts to sensitive vegetation communities (coast live oak woodland alliance and white alder–California sycamore woodland association) would occur due to implementation of the Project. MM-BIO-4 requires that temporary impacts to sensitive vegetation communities be completed through on-site rehabilitation. MM-BIO-4 requires that permanent impacts sensitive vegetation communities be completed by the purchase of credits from a mitigation bank, the purchase of in lieu credits from an in-lieu fee program, and/or through the enhancement of native vegetation communities on City lands. MM-BIO-5 avoids indirect impacts to sensitive vegetation communities by requiring the demarcation of the disturbance limits. Impacts to sensitive vegetation communities and jurisdictional waters would be less than significant with implementation of MM-BIO-4 and MM-BIO-5.

Significant direct and indirect temporary and permanent impacts to potential jurisdictional waters would occur due to implementation of the Project. MM-BIO-6 requires that temporary impacted jurisdictional waters be restored and permanent impact compensation be completed by the purchase of credits from an agency-approved mitigation bank or purchase of in lieu credits from an in-lieu fee program and/or through the preparation and implementation of habitat restoration plan. MM-BIO-5 avoids indirect impacts to jurisdictional waters by requiring the demarcation of the disturbance limits. Impacts to jurisdictional waters would be less than significant with implementation of MM-BIO-5 and MM-BIO-6.

Significant direct and permanent impacts to potential wildlife corridors for fish if fish are ever reestablished within the Arroyo Seco. MM-BIO-7 would require the preparation and implementation of a Native Resident and Migratory Fish Monitoring Plan. Impacts to fish movement would be less than significant with implementation of MM-BIO-7.

Direct impacts would occur, and indirect impacts may occur, to trees protected by the City of Pasadena Trees and Tree Protection Ordinance. MM-BIO-8 requires the replacement of the removed trees per a City-defined ratio and the fencing to shield protected trees located in close

proximity to construction activities and requires monitoring of trees that have sustained substantial root zone pruning. Impacts to protected trees would be less than significant with implementation of MM-BIO-8.

Subject: 2019 Southwestern Willow Flycatcher and Least Bell's Vireo Survey Results for Arroyo Seco Canyon Project, Pasadena, California

Dear Recovery Permit Coordinator,

This report documents the results of five protocol-level presence/absence surveys for the state- and federally-listed endangered southwestern willow flycatcher (*Empidonax traillii extimus*; flycatcher) and eight protocol-level presence/absence surveys for the state- and federally-listed endangered least Bell's Vireo (*Vireo bellii pusillus*; vireo). The surveys were conducted in all areas of suitable flycatcher and vireo habitat within and surrounding the proposed Arroyo Seco Canyon Project (proposed project), located in the City of Pasadena, California (Figure 1).

The flycatcher and vireo are closely associated with riparian habitats, especially densely vegetated willow scrub and riparian forest vegetation. These species are threatened primarily by loss, degradation, and fragmentation of riparian habitats. Brown-headed cowbird (*Molothrus ater*) nest parasitism also poses an important threat. As per U.S. Fish and Wildlife Service (USFWS) permit requirements, a notification to conduct surveys for the southwestern willow flycatcher was submitted electronically to the Carlsbad USFWS Office on May 2, 2019 and flycatcher surveys commenced on May 22, 2019.

PROJECT BACKGROUND

On October 9, 2014, Pasadena Water and Power (PWP) circulated the Arroyo Seco Canyon Project (ASCP) Initial Study/Mitigated Negative Declaration (IS/MND) and associated technical studies, State Clearinghouse Number 2014101022, for a 30-day public review period from October 9, 2014, to November 8, 2014. The PWP was seeking approval of a Conditional Use Permit (CUP) No. 6222 for the ASCP, which involved improvements to three areas, including Area 1, Arroyo Seco Headworks; Area 2, Arroyo Seco Intake; and Area 3, JPL East Parking Lot. The 2014 IS/MND included the following biological studies to support the analysis of the ASCP:

- Biological Technical Report, Arroyo Seco Canyon Project, dated September 2014 (BonTerra Psomas 2014)
- Results of the 2013 Least Bell's Vireo/Southwestern Willow Flycatcher Survey for the Arroyo Seco Canyon Project Dated September 2013 (BonTerra Consulting 2013)

Figure 1 shows a comparison of the areas studied in 2013 and 2014, and the areas surveyed for the 2019 flycatcher and vireo surveys. As described below, the study areas are different to reflect the direction given through a Court judgement and associated Settlement Agreement related to the environmental review requirements of the proposed project.

On January 12, 2015, the City's Hearing Officer made findings to approve the ASCP IS/MND for CUP No. 6222. On January 20, 2015, Spirit of the Sage Council, Project Soliton, and Hugh Bowles submitted an appeal of the Hearing Officer's decision to the Board of Zoning Appeals. The Board of Zoning Appeals hearing took place on March 4, 2015, and upheld the Hearing Officer's decision by a unanimous vote. The approval was again appealed to the City Council, and on June 1, 2015, the City Council voted to uphold the Board of Zoning Appeals decision by unanimous vote.

On July 2, 2015, a lawsuit (Court Case No. BS156207) was filed against the City by petitioners Spirit of the Sage Council and Project Soliton challenging the approval of the ASCP. On March 20, 2017, the Los Angeles Superior Court issued its decision and on June 26, 2017, entered a judgment that partially favored the petitioners. The Court found that the elements of the ASCP that related to increased diversions of surface water (i.e., greater taking of stream water from the Arroyo Seco beyond its current withdrawal) were inadequately analyzed under CEQA and required the preparation of an Environmental Impact Report (EIR).

The Court also ruled that the elements of the ASCP that did not relate to increased diversions were severable from the remainder of the ASCP and complied with CEQA. As such, the Court determined that CUP #6222 and its related findings and conditions of approval, and the ASCP IS/MND shall remain intact for these components, and would be allowed to move forward without any additional environmental review pursuant to CEQA. These components include the following:

- Area 1, Arroyo Seco Headworks: All ASCP elements
- Area 2, Arroyo Seco Intake: Access road improvements and related slope reconstruction and protective riprap elements, except the diversion dam and intake replacement

- Area 3, JPL East Parking Lot: All ASCP elements, except the expansion of four existing spreading basins and the construction of two new spreading basins

As stated above, for Area 2, the demolition and replacement of the diversion dam and intake structure were required to be analyzed in an EIR. For Area 3, components of the ASCP IS/MND that would be allowed to proceed include the parking lot, access road, sedimentation basin, demolition of existing structures and pipelines, new pipelines, new public restroom, new security booth, and associated utility services (water, sewer, power, and communication lines), while the expansion of four existing spreading basins and the construction of two new spreading basins were required to be analyzed in an EIR.

In addition, a Settlement Agreement was negotiated, which stated that the City shall have the right to perform maintenance activities, including tilling and grading of the existing spreading basins to reestablish historical percolation rates and maintenance activities that involve negligible or no expansion of use as described in CEQA Guidelines Section 15301 for a Class 1 Categorical Exemption. The Settlement Agreement further clarified that the City may perform excavation and grading necessary for the temporary bridges as described in the ASCP IS/MND.

In accordance with the terms and provisions of the Writ of Mandate and Judgment, as modified by the Settlement Agreement, the City is preparing an EIR for the proposed Project in accordance with CEQA and the CEQA Guidelines. Because several components of the ASCP were allowed to proceed without any additional environmental review pursuant to CEQA, the proposed project boundaries of Area 2 and Area 3 have been refined from those shown in the ASCP IS/MND to reflect the activities subject to review under the EIR.

LOCATION AND EXISTING CONDITIONS

The proposed project is located in Pasadena, California beginning at the spreading basins adjacent to the Devil's Gate Reservoir and continues intermittently upstream along the Arroyo Seco within the San Gabriel Mountains. The proposed project consists of three areas: Area 1 (Headworks), Area 2 (Diversion and Intake Replacement) and Area 3 (Spreading Basin Improvements). These areas are connected by the Gabrielino Trail/Access Road, which serves as a recreational trail and the access road for City of Pasadena and United States Forest Service vehicles heading into the Arroyo Seco Canyon. The proposed project would involve construction activity and facility improvements in both areas, as well as construction truck traffic along portions of the Gabrielino Trail/Access Road. The proposed project will increase the utilization of surface water rights held by the City of Pasadena Water and Power Department by restoring and improving the intake facilities (Area 2), modifying the existing sediment removal

mechanism (Area 1 and Area 3), naturalizing the Arroyo Seco streambed (Area 1), and expanding recharge operations by creating additional spreading basins (Area 3). In addition, the project is planned to include a new public restroom facility, recreational and educational amenities near the Headworks structure (Area 1), and a new reduced-size parking lot at the former Jet Propulsion Laboratory parking site for those using the Arroyo Seco Canyon and Hahamongna Watershed Park area (Area 3).

Elevation of the Survey Area ranges from approximately 1,095 feet above mean sea level (amsl) in the southern portion of Survey Area 3 to approximately 1,250 feet amsl at the top of the Survey Area. Human disturbance in the Survey Area is moderate in the southern portion and light in the north. Human disturbance includes foot traffic and light recreation with most recreational activities (e.g., equestrian, hiking, vehicle access) occurring on the Gabrielino Trail/Access Road. Four soil types occur in the Survey Area: Hanford gravelly sandy loam, Ramona loam, Ramona sandy loam, and upper Los Angeles River.

VEGETATION COMMUNITIES

Vegetation communities and land uses within the Survey Area were mapped in the field directly onto a 200-scale (1 inch = 200 feet) color digital orthographic map of the property (Bing 2018). Following completion of the fieldwork, all vegetation polygons were digitized using ArcGIS software and GIS coverage was created. Vegetation communities within the Survey Area were mapped using A Manual of California Vegetation, Second Edition (MCV2; Sawyer et al. 2009).

A total of 12 vegetation communities and land covers were mapped by Dudek in the Survey Area (Figure 2) including California sagebrush-California buckwheat-laurel sumac scrub association, California sagebrush-ashy buckwheat scrub association, coast live oak woodland alliance, white alder-California sycamore woodland association, California sycamore woodlands alliance, arroyo willow-mulefat scrub association, arroyo willow thicket alliance, laurel sumac scrub alliance, California sagebrush-California buckwheat scrub alliance, urban/developed, disturbed habitat, and parks and ornamental plantings.

The following five vegetation communities in the Survey Area potentially provide suitable habitat for flycatcher and vireo: arroyo willow-mulefat scrub association, arroyo willow thicket alliance, white alder-California sycamore woodland association, California sycamore woodlands alliance, and coast live oak woodland alliance (where associated with the Arroyo Seco). The acreage for these vegetation communities are listed in Table 1, mapped on Figure 2, and described below.

Table 1
Summary of Suitable Riparian Vegetation Communities in the Survey Area

Vegetation Community or Land Cover	Acres
Arroyo Willow Thicket Alliance	5.44
Arroyo Willow-Mulefat Scrub Association	0.17
White Alder-California Sycamore Woodland Association	4.32
California Sycamore Woodlands Alliance	0.69
Coast Live Oak Woodland Alliance (where associated with Arroyo Seco)	7.03
Total	**17.65**

Suitable Riparian Vegetation

Arroyo willow thicket alliance (61.201.01) is dominated by arroyo willow (*Salix lasiolepis*) Arroyo willow is a riparian tall shrub or tree that grows up to 26 feet in height. Arroyo willow thickets occur along stream banks and on stream benches throughout much of California except the desert regions. This alliance is also associated with slope seeps and stringers along drainages (Sawyer et al. 2009). Arroyo willow thicket alliance is considered a sensitive vegetation community by CDFW (CDFW 2018).

In the Survey Area, this alliance is located in the northern portion of the survey (Figure 2). Some species associated with arroyo willow thickets include coyotebrush (*Baccharis pilularis*), mule-fat (*B. salicifolia*), redosier dogwood (*Cornus sericea*), California sycamore (*Platanus racemosa*), and cottonwoods (*Populus* spp.) (Sawyer et al. 2009).

Arroyo willow-mulefat scrub association is dominated by arroyo willow and mulefat. The association is part of the arroyo willow thickets alliance (61.201.00). Arroyo willow is a riparian tall shrub or tree that grows up to 26 feet in height. Mulefat is an evergreen shrub with willow-like leaves that have widely spaced, fine teeth and shiny upper surfaces. The canopy is open to continuous and the herbaceous layer is variable. The community is typically found on stream banks and benches, slope seeps, and stringers along drainages.

In the Survey Area, this association is located within the wash of the Arroyo Seco, adjacent to Survey Area 3. Additional common shrubs found in the community in the Study Area include blue elderberry (*Sambucus nigra*), lemonade berry (*Rhus integrifolia*), deerweed (*Acmispon glaber*), white sage (*Salvia apiana*), black sage (*Salvia mellifera*), bush monkeyflower (*Diplacus aurantiacus*), hoary leaf ceanothus (*Ceanothus crassifolius*), California coffee berry (*Frangula californica*).

White alder-California sycamore woodland association is dominated by white alder (*Alnus rhombifolia*) and California sycamore. The association is part of the white alder groves alliance (61.420.00). White alder is a deciduous hardwood that attains 115 feet in height. California sycamore is a fast-growing, deciduous tree that attains 80 feet in height and is well adapted to intermittent flooding conditions. The community typically occurs in inland foothills and lower montane zones, usually as narrow strips along perennial stream courses throughout cismontane California. It is well adapted to many flood regimes. White alder-California sycamore woodland is considered a sensitive vegetation community by CDFW (2018).

In the Survey Area, white alder-California sycamore woodland is found in Area 2. The understory was very sparse and native herbaceous species include California blackberry (*Rubus ursinus*), and scarlet monkeyflower (*Erythranthe cardinalis*).

California sycamore woodlands alliance (61.310.00) is dominated by California sycamore, but it may include other tree species with less frequency. California sycamore is a fast-growing, deciduous tree that attains 80 feet in height and is well adapted to intermittent flooding conditions. The canopy structure can be open to continuous, the shrub layer is sparse to continuous, and the herbaceous layers is variable. California sycamore woodlands are found in gullies, intermittent streams, springs, seeps, stream banks, and terraces adjacent to floodplains that are subject to high-intensity flooding. Soils are typically rocky or cobbly alluvium with permanent moisture at depth (CNPS 2019). California sycamore woodlands is considered a sensitive vegetation community by CDFW (CDFW 2018)

In the Survey Area, California sycamore woodlands are found within the Area 2 portion of the Survey Area, on the west side of the Gabrielino Trail/Access Road and at the base of a steep slope. The understory consisted of poison oak and the non-native English ivy (*Hedera helix*).

Coast live oak woodland alliance (71.060.02) is dominated by coast live oak (*Quercus agrifolia*), but it may include other tree species with less frequency. Coast live oak is a drought-resistant evergreen tree that grows to 80 feet in height. The canopy structure can be open to continuous and the shrub and herbaceous layers are sparse to intermittent. Coast live oak woodland are found on alluvial terraces, canyon bottoms, stream banks, slopes, flats. Soils are typically deep, sandy, or loamy with high organic matter (CNPS 2019). In the Survey Area, coast live oak woodland is found along Gabrielino Trail/Access Road and Arroyo Boulevard.

Although the understory of this vegetation community would provide little to no opportunities for vireo nesting, flycatchers have been known to nest in oak woodlands associated with the upper San Luis Rey River in San Diego County. As a conservative approach, the oak woodlands

associated with the Arroyo Seco were included in the surveys for flycatcher for this proposed project.

Additional tree species found in the community include canyon live oak (*Quercus chrysolepis*), California sycamore, and bigleaf maple (*Acer macrophyllum*). The shrub component is sparse and consists of species also found in California sagebrush-California buckwheat-laurel sumac scrub. The understory was also sparse and common native herbaceous species include poison oak (*Toxicodendron diversilobum*), American black nightshade (*Solanum americanum*), golden currant (*Ribes aureum*), miner's lettuce (*Claytonia perfoliata*), and California polypody (*Polypodium californicum*).

METHODS

Approximately 17.65 acres of suitable habitat within the approximately 50.67 acre Survey Area were surveyed for the flycatcher and vireo (Figures 2). The areas within the Survey Area were surveyed five times by Dudek biologist Melissa Blundell (#TE-97717A) and three times by Dudek senior biologist Michael Cady (Table 2). Focused surveys for these species was initiated on May 3, 2019 and completed on July 29, 2019. Weather conditions, time of day, and season were appropriate for the detection of flycatcher and vireo (see Table 2).

Table 2
Survey Conditions

Date	Hours	Personnel[1]	Focused Species[2]	Conditions

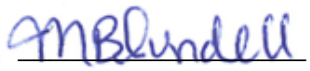
Notes:
[1]Biologists' Initials: MAB = Melissa Blundell; MC = Michael Cady
[2]LBVI = least Bell's vireo; SWFL = southwestern willow flycatcher

On days when surveys were conducted for both flycatcher and vireo, these surveys were conducted separately, with the initial pass through the habitat surveying for flycatcher and the return pass surveying for vireo. All surveys consisted of slowly walking a methodical transect within and adjacent to all suitable riparian habitat (Figure 2). An electronically based project map projected on an iPhone of the Survey Area was available to record the locations of any special-status species detected. Binoculars (8×40) were used to aid in detecting and identifying wildlife species. Biologists did not survey more than 3 linear kilometers of habitat on any given survey day.

A Section 10(a)(1)(A) permit is not required to conduct presence/absence surveys for vireo. The eight surveys for vireo followed the currently accepted *Least Bell's Vireo Survey Guidelines* (USFWS 2001), which states that a minimum of eight survey visits should be made to all riparian areas and any other potential vireo habitats during the period from April 10 to July 31. The site visits are required to be conducted at least 10 days apart to maximize the detection of early and late arrivals, females, non-vocal birds, and nesting pairs. Tape playback of vireo vocalizations were not used during the surveys. Surveys were conducted between dawn and 11:00 a.m. and were not conducted during periods of excessive or abnormal cold, heat, wind, rain, or other inclement weather.

The five surveys conducted for flycatcher followed survey methods described in accordance with *A Natural History Summary and Survey Protocol for the Southwestern Willow Flycatcher* (Sogge et al. 2010). Surveys within a site with a potential or foreseeable impact to the habitat due to a potential project or change in site management require five surveys. Since there is a project planned at this site, a total of five surveys were conducted, with one visit between May 15 and May 31, two visits between June 1 and June 24, and two visits between June 25 and July 17. The surveys during the final period were separated by more than 5 days, per protocol requirements. Recorded flycatcher vocalizations were played every 50–100 feet within suitable habitat, to induce flycatcher responses. If a flycatcher had been detected, playing of the tape would have ceased to avoid harassment.

RESULTS



No southwestern willow flycatchers or least Bell's vireos were observed during the focused surveys. One male brown-headed cowbird was detected near retention ponds in Survey Area 3 on June 4, 2019 (Figure 2 and 3). Five special-status species were observed during the surveys: Cooper's hawk (*Accipiter cooperii*, California Department of Fish and Wildlife [CDFW] Watch List [WL] for nesting), oak titmouse (*Baeolophus inornatus*, USFWS Bird of Conservation Concern [BCC] for nesting), yellow warbler (*Setophaga petechia,* CDFW Species of Special

Concern, USFWS BCC for nesting), and Lawrence's goldfinch (*Spinus lawrencei*, USFWS BCC for nesting). No evidence of reproduction (CDFW 2019) was documented for these species. Therefore, no California Natural Diversity Database (CNDDB) forms were submitted for these occurrences.

Overall, 59 bird species were observed during the focused surveys (Attachment A). Data forms (Sogge et al. 2010) for willow flycatcher surveys are included as Attachment B. Photo documentation of the Survey Area is provided in Attachment C.

I certify that the information in this survey report and attached exhibits fully and accurately represent my work. Please feel free to contact me at mblundell@dudek.com or (760) 214-1878 (cell) with questions or if you require additional information regarding this survey.

Sincerely,

Melissa Blundell
Biologist/#TE-97717A

ATTACHMENT A
Cumulative List of Bird Species Observed

BIRDS

ACCIPITRIDAE—HAWKS, KITES, EAGLES, & ALLIES

Accipiter cooperii—Cooper's hawk
Buteo jamaicensis—red-tailed hawk
Buteo lineatus—red-shouldered hawk

AEGITHALIDAE—LONG-TAILED TITS & BUSHTITS

Psaltriparus minimus—bushtit

ANATIDAE—DUCKS, GEESE, & SWANS

Anas platyrhynchos—mallard

APODIDAE—SWIFTS

Aeronautes saxatalis—white-throated swift

CARDINALIDAE—CARDINALS & ALLIES

Pheucticus melanocephalus—black-headed grosbeak
Piranga ludoviciana—western tanager

CATHARTIDAE—NEW WORLD VULTURES

Cathartes aura—turkey vulture

CHARADRIIDAE—LAPWINGS & PLOVERS

Charadrius vociferus—killdeer

COLUMBIDAE—PIGEONS & DOVES

Patagioenas fasciata—band-tailed pigeon
Zenaida macroura—mourning dove
Streptopelia decaocto—Eurasian collared-dove*

CORVIDAE—CROWS & JAYS

Aphelocoma californica—California scrub-jay
Corvus brachyrhynchos—American crow
Corvus corax—common raven

FRINGILLIDAE—FRINGILLINE & CARDUELINE FINCHES & ALLIES

Haemorhous mexicanus—house finch
Spinus lawrencei—Lawrence's goldfinch
Spinus psaltria—lesser goldfinch

Spinus tristis—American goldfinch

HIRUNDINIDAE—SWALLOWS

Hirundo rustica—barn swallow
Petrochelidon pyrrhonota—cliff swallow
Stelgidopteryx serripennis—northern rough-winged swallow
Tachycineta thalassina—violet-green swallow

ICTERIDAE—BLACKBIRDS

Icterus bullockii—Bullock's oriole
Icterus cucullatus—hooded oriole
* *Molothrus ater*—brown-headed cowbird

MIMIDAE—MOCKINGBIRDS & THRASHERS

Mimus polyglottos—northern mockingbird
Toxostoma redivivum—California thrasher

ODONTOPHORIDAE—NEW WORLD QUAIL

Callipepla californica—California quail

PARIDAE—CHICKADEES & TITMICE

Baeolophus inornatus—oak titmouse

PARULIDAE—WOOD-WARBLERS

Cardellina pusilla—Wilson's warbler
Oreothlypis celata—orange-crowned warbler
Setophaga petechia—yellow warbler

PASSERELLIDAE—NEW WORLD SPARROWS

Junco hyemalis—dark-eyed junco
Melospiza melodia—song sparrow
Melozone crissalis—California towhee
Pipilo maculatus—spotted towhee

PICIDAE—WOODPECKERS & ALLIES

Colaptes auratus—northern flicker
Melanerpes formicivorus—acorn woodpecker
Dryobates nuttallii—Nuttall's woodpecker
Dryobates pubescens—downy woodpecker
Dryobates villosus—hairy woodpecker

X Mixed native and exotic plants (mostly native, 50 - 90% native)

____ Mixed native and exotic plants (mostly exotic, 50 - 90% exotic)

____ Exotic/introduced plants (entirely or almost entirely, > 90% exotic)

Identify the 2-3 predominant tree/shrub species in order of dominance. Use scientific name.

Salix sp., *Alnus rhombifolia*

Average height of canopy (Do not include a range): **10** (meters)

Attach the following: 1) copy of USGS quad/topographical map (REQUIRED) of survey area, outlining survey site and location of WIFL detections;
2) sketch or aerial photo showing site location, patch shape, survey route, location of any detected WIFLs or their nests;
3) photos of the interior of the patch, exterior of the patch, and overall site. Describe any unique habitat features in Comments.

Comments (such as start and end coordinates of survey area if changed among surveys, supplemental visits to sites, unique habitat features. Attach additional sheets if necessary.

The Arroy Seco Canyon Project was last surveyed for southwestern willow flycatchers in 2013 and for least Bell's vireos in 2016. Surveys in 2019 included the same survey area boundaries (i.e., Survey Areas 1, 2, and 3; as in 2013 and 2016) plus additional study areas along access roads between these sites. The Arroyo Seco Canyon Project was last surveyed for southwestern willow flycatchers in 2013 and for least Bell's vireos in 2016. Surveys in 2019 included the same survey area boundaries (i.e., Survey Areas 1, 2, and 3) as in 2013 and 2016 plus additional study areas along access roads between these sites. The riparian habitat is dominated by willow species, including *Salix lasiolepis* and *Alnus rhombifolia* . Additional species included, but was not limited to, *Artemisia californi*a , *Artemisia douglasiana* , *Baccharis salicifolia, Eriogonum sp., Juglans californica, Malosma laurina, Platanus racemosa, Populus trichocarpa,Quercus agrifolia, Rubus* sp., *Salix gooddingii, Salix laevigata, Sambucus nigra* , and *Toxicodendron diversilobum* . Non-native species included, but was not limited to, *Delairea odorata, Hirschfeldia incana, Nicotiana glauca, Ricinus communis* , *Ulmus parvifolia* and non-native grasses.

Territory Summary Table. Provide the following information for each verified territory at your site.

Territory Number	All Dates Detected	UTM E	UTM N	Pair Confirmed? Y or N	Nest Found? Y or N	Description of How You Confirmed Territory and Breeding Status (e.g., vocalization type, pair interactions, nesting attempts, behavior)

MEMORANDUM

To:	Elisa Ventura
From:	Michael Cady
Subject:	Arroyo Seco Canyon – Non-Protocol California Red-Legged Frog and Arroyo Toad Survey
Date:	12/10/2019
Attachment(s):	A) Project and Survey Area Location; B) California Red-Legged Frog and Arroyo Toad Species Accounts

Dudek conducted a non-protocol survey for arroyo toad (*Anaxyrus californicus*) and California red-legged frog (*Rana draytonii*) for Pasadena Water and Power (PWP) in support of the proposed Arroyo Seco Canyon Project (proposed Project or Project). The Project is located in the in the northwest corner of the City of Pasadena in Los Angeles County, California, as shown in Attachment A, Project and Survey Area Location. For the proposed Project's Environmental Impact Report analysis, the proposed Project consists of two primary action areas: a diversion dam and intake replacement in Area 2, and the spreading basin expansion in Area 3. An additional area (Area 1; Arroyo Seco Headworks) was previously allowed under an Initial Study/Mitigated Negative Declaration for the project. This area was included in the non-protocol amphibian survey in support of the permits needed for impacts to jurisdictional waters for the project that will be for all three areas. These areas are connected by the Gabrielino Trail/Access Road, which serves as a recreational trail and the access road for City of Pasadena and U.S. Forest Service vehicles heading into and out of the Angeles National Forest.

Species accounts for arroyo toad and California red-legged frog are included in Attachment B, California Red-Legged Frog and Arroyo Toad Species Accounts.

Methods

Desktop Analysis

Prior to conducting the field investigation, a literature review was conducted to evaluate the environmental setting of the Project site and identify potential special-status biological resources that may be found on the site. The following reports that encompass the Project site were reviewed:

- Biological Technical Report, Arroyo Seco Canyon Project, dated September 2014 (BonTerra Psomas 2014a)
- Results of the 2013 Amphibian Surveys for the Arroyo Seco Canyon Project, dated February 4, 2014 (BonTerra Psomas 2014b)

The following online databases and reports were reviewed:

- California Department of Fish and Wildlife's (CDFW) California Natural Diversity Database (CNDDB) (CDFW 2019)

- U.S. Fish and Wildlife Service's (USFWS) Critical Habitat and Species Occurrence Data (USFWS 2019)
- Arroyo southwestern toad (*Bufo microscaphus californicus*) Recovery Plan (USFWS 1999)
- Arroyo Toad (*Bufo californicus* (=*microscaphus*)) 5-Year Review (USFWS 2009)
- Recovery Plan for the California Red-Legged Frog (*Rana aurora draytonii*) (USFWS 2002)

The CNDDB was queried based on the U.S. Geological Survey 7.5-minute quadrangle on which the Project site is located (*Pasadena, California*) and the eight surrounding quadrangles (*Sunland*, *Condor Peak*, *Chilao Flat*, *Burbank*, *Mount Wilson*, *Hollywood*, Los *Angeles*, and *El Monte*). The USFWS occurrence data and critical habitat databases were queried using geographic information system (GIS) software based on a 5-mile buffer around the Project site.

Field Survey

The purpose of the survey was to look for individuals of the two species and identify potential habitat. The survey was conducted on May 3, 2019 by Dudek Senior Biologist Michael Cady, as shown in Table 1, Survey Conditions. The survey was focused on the spreading basins with water and the Arroyo Seco from adjacent to Area 3 and upstream to Area 2, as shown in Attachment A. The focused survey passes were conducted by walking along the stream. Any pools, if present, where California red-legged frog could be present would be examined from a distance using binoculars before being approached.

Table 1
Survey Conditions

Date	Hours	Personnel	Conditions
5/3/2019	1000–1200	Michael Cady	68°F–71°F, 0% cc, 1–2 mph

Notes: cc = cloud cover; mph = miles per hour.

Results

No arroyo toad or California red-legged frog were observed during the survey of the survey area. No breeding habitat, overflow pools, old flood channels, and pools with shallow margins on streams with relatively open canopies (USFWS 1999), for the species was observed. No pools with substantial depth or with refugia (undercuts in banks or masses of tree roots were observed) that could support California red-legged frog were observed. Three common amphibian species were observed in the survey area: western toad (*Anaxyrus boreas*), California treefrog (*Pseudacris cadaverina*), and Baja California treefrog (*Pseudacris hypochondriaca*). Numerous immature western toads were observed associated with the northern spreading basins in Area 3. Treefrog tadpoles were observed in the Arroyo Seco between Area 2 and the JPL Bridge.

Arroyo Toad (Anaxyrus (=Bufo) californicus)

State: California Department of Fish and Game Species of Special Concern
Federal: Endangered

Status and Taxonomy

The arroyo toad was federally listed as endangered on December 16, 1994 (59 FR 64589–64867). Critical habitat for arroyo toad was designated on February 7, 2001 (66 FR 9414–9474). On October 30, 2002, the federal court of the District of Columbia set aside the 2001 critical habitat designation on the basis of a lawsuit challenging the designation of arroyo toad critical habitat, citing errors by the U.S. Fish and Wildlife Service (USFWS) in promulgating the rule (69 FR 23254–23328). On April 28, 2004, the USFWS proposed a new rule designating critical habitat that differed from the previous designation in regard to mapping grid size and new survey information for the arroyo toad. On April 13, 2005, the USFWS issued the final critical habitat designation for the arroyo toad (70 FR 19562–19633). The USFWS reduced the critical habitat area from the 95,655 acres proposed in February 2004 to 11,695 acres in the 2005 final designation (70 FR 19562–19633). Due to concerns about the scientific integrity of the 2005 designation the USFWS published a revised final critical habitat designation on February 9, 2011 that would include 98,366 acres of critical habitat for the arroyo toad (76 FR 7245–7467). This revised proposed designation incorporates new information for the arroyo toad collected since 2004 and uses a revised and more detailed mapping method. A 5-year review completed by the USFWS in 2009 recommended that the arroyo toad be reclassified to threatened (75 FR 28636–28642). Although not state-listed as threatened or endangered, arroyo toad is considered a California Department of Fish and Game Species of Special Concern.

At the time the arroyo toad was federally listed in 1994, it was classified as a subspecies (*Bufo microscaphus californicus*) of the southwestern toad (*B. microscaphus*). Based on the results of genetic studies, Gergus (1998) reclassified the arroyo toad as a separate species, *Bufo californicus* (66 FR 9414–9474). In addition, the long-standing genus *Bufo* in North America was replaced with *Anaxyrus* (Crother 2008), and therefore, the arroyo toad *Bufo californicus* was renamed *Anaxyrus californicus*.

The arroyo toad is a small (4.6 to 8.6 centimeters (1.8 to 3.4 inches)), stocky, dark-spotted toad, usually with a "V"-shaped, light-colored stripe across its head between the eyes (Stebbins 2003; USFWS 2009) and lacking a light-colored mid-dorsal stripe down its back. A detailed description of the species' physical characteristics can be found in USFWS (1999).

Habitat Description

The arroyo toad is found along low-gradient streams in coastal and desert drainages as well as high-elevation valleys in Southern California and northern Baja California, Mexico. It uses aquatic, riparian, and upland habitats to different degrees, depending on an individual's stage of development, the time of year, and the weather. Breeding and larval development occur within aquatic habitats; foraging may occur within drying stream beds, terraces adjacent to breeding sites, and nearby uplands, where aestivation and overwintering also occur. Breeding habitat for the arroyo toad is created and maintained by the fluctuating hydrological, geological, and ecological processes operating in riparian ecosystems and the adjacent uplands. Periodic flooding that modifies stream channels, redistributes channel sediments, and alters pool location and form, coupled with upper terrace stabilization by

vegetation, is required to keep a stream segment suitable for all life stages of the arroyo toad (66 FR 9414–9474). Periodic flooding helps maintain areas of open, sparsely vegetated, sandy stream channels and terraces (Sweet 1992; Griffin and Case 2001). During the day and other periods of inactivity, arroyo toads seek shelter by burrowing into sand (Sweet 1992). Thus, areas of sandy or friable (readily crumbled) soils are the most important habitat for the species, and these soils can be interspersed with gravel or cobble deposits (70 FR 19562–19633). Radiotelemetry studies at near-coastal locations (Griffin 1999) and montane sites (Ramirez 2002) documented extensive instream movements of adult and juvenile toads during their extended activity season. Arroyo toads may also seek temporary shelter under rocks or debris and have occasionally been found in mammal burrows (Griffin 1999). However, the use of burrows is not well understood and is believed to be an uncommon event (Haas 2005a).

Outside of the breeding season, juvenile and adult arroyo toads are terrestrial and spend most of their lives on open terraces and in riparian habitats, typically adjacent to breeding locations and, less commonly, moving into upland habitats. Riparian areas used by juveniles and adults for foraging and burrowing include sand bars, alluvial terraces, and streamside benches that lack vegetation or are sparsely to moderately vegetated (Sweet 1992; Holland and Sisk 2001). Upland habitats occupied by the arroyo toad include alluvial scrubs, sage scrubs, open chaparral, grassland, and oak woodland (Griffin and Case 2001). Friable sandy soils used for burrowing are the common factor in these occupied habitats. Arroyo toads also have been found in agricultural fields (Griffin 1999), but these lands may be habitat sinks (areas where mortality rates are higher than reproduction rates, and thus lead to population declines over the long term) due to soil type, tilling, pesticide and fertilizer applications, and heavy equipment use (Griffin and Case 2001).

Life History

Breeding generally occurs from late March until mid-June (Sweet 1989); however, depending on climatological and hydrologic conditions, breeding may commence as early as mid-February (Haas 2004) and extend into July. Arroyo toads move within streams and rivers to find suitable breeding and foraging habitats, as well as potential mates. In years when breeding conditions are poor, male advertisement may persist for extremely short periods, and the species' presence may be difficult to detect in the absence of frequent, early season surveys (Haas 2005a). Females rarely choose breeding sites under closed canopies; heavily shaded pools are generally unsuitable for eggs and larval arroyo toads because of lower water and soil temperatures and poor algal mat development (66 FR 9413–9474). Eggs are deposited in shallow aquatic habitats characterized by sandy and/or gravelly substrates and where silt deposition is minimal. These hatch in 4 to 5 days, and the immobile larvae sit for another 5 to 6 days before dispersing through the water (USFWS 2009). The filter-feeding arroyo toad tadpoles require algal mats for development. Breeding sites are typically located adjacent to sandy terraces (59 FR 64589–64866); at or near the edge of shallow pools, low-flow stream channels, and ox-bows; and along in-stream sand bars with minimal current (0 to 2 kilometers (1.24 miles) per hour) and little or no emergent vegetation. After metamorphosis, which typically occurs after 10 weeks (USFWS 2009) in the period from May to July, neonate toads remain along or very near breeding sites, in order to take advantage of available forage and ambient moisture—especially the moist, sandy substrate of drying pools. Over a period of 8 to 12 weeks, the neonates mature in size, and they leave wet or moist stream areas and river edges once they are physically capable of burying themselves in local substrates (Sweet 1992).

In many drainages, the arroyo toad does not breed annually, and metapopulations may persist for 7 years or more between breeding events (Haas 2005b). Moreover, early season breeding attempts may be unsuccessful if surface flows do not persist for the approximately 60 to 75 days necessary to support larvae to metamorphosis.

Thus, early season surveys are necessary to determine presence/absence status of the arroyo toad, especially in years of below-average rainfall (Haas 2004). In years when heavy rains (or planned water releases) affect breeding sites, arroyo toad larvae may swim or be flushed downstream due to heavy currents (Griffin 1999). Survivorship of these individuals has never been documented; thus, the effects of such events are unknown.

Subadults and adults may range widely into the surrounding uplands; however, most individuals remain on sandy terraces adjacent to breeding habitat. Smaller numbers of juveniles and adults range widely into surrounding upland habitats, and may move up to 1 kilometer (0.6 mile) or more from breeding sites (Holland and Sisk 2001). In some cases, adults have been found at distances greater than 1 kilometer from riparian areas, such as in upper Cristianitos Canyon in southern Orange County, where at least one individual was detected 3.4 kilometers (2.1 miles) from the nearest breeding population (Bloom Biological 2007). The distance traveled from a breeding site depends on topography (e.g., mild slopes are more easily traversed than steeper slopes) and presence of navigable pathways (e.g., roads, game trails, open habitats). Movements into uplands may facilitate foraging and dispersal; however, areas with extremely compact soils may act as habitat sinks, the use of which may result in desiccation and increased predator pressure.

Range and Distribution

The arroyo toad is endemic to the coastal plains, coastal slopes, mountains, and desert slopes of California and northern Baja California in habitats ranging in elevation from near sea level to 8,000 feet. Historically, the species was known to occur in coastal drainages in Southern California, from San Luis Obispo County to San Diego County, and in Baja California. According to the USFWS (2009), populations of arroyo toad are now reported in Monterey, San Luis Obispo, Santa Barbara, Ventura, Los Angeles, Orange, San Bernardino, Riverside, and San Diego Counties. Arroyo toads may also occur in Imperial County; however, this singular population needs verification (USFWS 2009).

Within the Plan Area, arroyo toads were historically found in the upper Salinas River basin near Santa Margarita, San Luis Obispo County. However, surveys during the 1980s and 1990s did not detect arroyo toads at this site. The habitat was potentially negatively affected by the construction of Santa Margarita Dam, approximately 16 kilometers (10 miles) upstream from the site (USFWS 1999). A Recovery Plan for the arroyo toad was published by the USFWS in 1999, establishing three recovery units for the species, with the Plan Area being included in the Northern Recovery Unit (USFWS 1999). The Northern Recovery Unit identifies seven populations or metapopulations on federal lands including one population at Fort Hunter Liggett Army Reserve Training Center, four populations within the Los Padres Nationals Forest and two populations within Angeles National Forest (USFWS 2009). However, none of these seven populations fall within the Plan Area. There are no historic or recent California Natural Diversity Database (CNDDB) records for arroyo toad within the Plan Area (Figure A-2) (CDFG 2012).

Population Status and Trends

Arroyo toads have disappeared from approximately 75% of the species' historically occupied habitat in California (USFWS 2009). Arroyo toads now survive primarily in the headwaters of coastal streams as small, isolated populations, having been extirpated from much of their historic habitat (USFWS 2009). At the time the arroyo toad was federally listed in 1994, only 22 populations of the species in the coastal and desert areas of nine counties were thought to remain in California. Since the listing of the arroyo toad, new locations in areas that were not previously known to be occupied by arroyo toads have been discovered as a result of site-specific surveys including a new population at Fort Hunter Liggett Army Reserve Training Center in Monterey County. Presently, there are 23

known populations of arroyo toad in California, and the area known to be occupied by the original 22 populations has expanded as a result of new arroyo toad localities (USFWS 2009).

Threats

In addition to the direct loss of aquatic, riparian, and upland habitat, other factors associated with urban development that contribute to declining arroyo toad populations were identified in the 2001 final designation of critical habitat (66 FR 9414–9474). The natural flow of streams can be altered by surface runoff from urban development and agricultural uses. Water pollution, in the form of fertilizers, biocides, chlorine, and other pollutants, adversely affects amphibian development, survival, and habitat. Further, the introduction of exotic predators (e.g., bullfrog (*Lithobates catesbeiana*), African clawed frog (*Xenopus laevis*), and green sunfish (*Lepomis cyanellus*)) and increases in mesopredators (e.g., raccoons (*Procyon lotor*) and skunks (*Mephitis mephitis*)) often associated with urban development can threaten or eliminate toad populations (69 FR 23254–23328). Exotic plant species (e.g., tamarisk, giant reed (*Arundo donax*), iceplant (Hottentot fig) (*Carpobrotus edulis*), and pampas grass (*Cortaderia selloana*)) may also degrade arroyo toad habitat by contributing to altered hydrology, eliminating sandbars and breeding pools, and restricting access to and quality of upland habitats (69 FR 23254–23328). Other factors that may adversely affect the species include livestock grazing and recreational activities in riparian areas and human-related increases in fire frequency and light and noise levels that may affect the species' nocturnal foraging and breeding behavior (Barrass and Cohn 1984). Increased water flow rates have been shown to negatively affect arroyo toad larvae swimming ability when compared to more common toad species (Wilson 2012). Feral pigs have been shown to negatively affect arroyo toads (76 FR 7245–7467). Additional threats include water management activities (including dams), road construction, maintenance and use, and mining.

Within the Northern Recovery Unit, the main threats to arroyo toad are non-native species, feral pigs, recreation, water management activities and diversions. The nearest known populations of arroyo toad to the Plan Area are on Fort Hunter Liggett Military Reservation on the Sisquoc River, Santa Maria River Basin, Santa Barbara. On Fort Hunter Liggett Military Reservation, the habitat in which the population exists is in a relatively natural state, but there are bullfrogs present. In addition, non-native beavers (*Castor canadensis*) are present, which are also considered a threat to arroyo toads because they build dams that alter the natural stream flow, which can impact breeding habitat for arroyo toad (USFWS 2009). Additionally, the resulting ponds are more likely to be occupied by bullfrogs. On the Sisquoc River, there is inadequate survey information available to determine the main threats (USFWS 2009).

Conservation and Management

The Arroyo Southwestern Toad Recovery Plan was published by the USFWS on July 24, 1999 (USFWS 1999). The recovery strategy for the arroyo toad consists of five parts: (1) stabilize and maintain populations through the range of the arroyo toad in California by protecting sufficient breeding and nonbreeding habitat; (2) monitor the status of existing populations to ensure recovery actions are successful; (3) identify and secure, by appropriate management and monitoring, additional suitable arroyo toad habitat and populations; (4) conduct research to determine the population dynamics and ecology of the species to guide management efforts and determine the best methods for reducing threats; and (5) develop and implement an outreach program.

A number of integrated natural resource management plans (INRMPs) on military lands, developed as part of compliance under the Sikes Act Improvement Act of 1977, have provided additional arroyo toad conservation

and protection measures, including the 2007 INRMP for Fort Hunter Liggett Military Reservation, which includes conservation measures for arroyo toad such as reducing bullfrog populations and identifying and reducing areas of noxious weeds (USFWS 2009).

The U.S. Forest Service has developed land management plans that provide additional guidance and protection for arroyo toad (USFWS 2009). Specific guidelines from the land management plans include the following: (1) standards and guidelines with measures to protect arroyo toad habitat that are incorporated into projects for managing vegetation, soil, water, and riparian areas; (2) identification of the arroyo toad as a Management Indicator Species to be used to track the health of aquatic habitat; (3) specific requirements for monitoring and monitoring activities that may affect arroyo toad habitat; (4) a five-step project screening process to minimize impacts to riparian arroyo toad habitat; and (5) guidelines for use of retardant and foams in aquatic environments to minimize the impacts of these chemicals to the arroyo toad and its habitat during fire suppression activities (USFWS 2009).

Multiple Habitat Conservation Plans (HCPs) provide additional protection for arroyo toad and suitable habitat on private lands. The Western Riverside Multiple Habitat Conservation Plan (MSHCP) identified a large Conservation Area where lands will be conserved. It also requires that areas outside of the Conservation Area will be surveyed for arroyo toad prior to development. The MSHCP also recognizes the importance of habitat connectivity and provides measures to ensure habitat conserved for arroyo toad will be connected to other areas of suitable habitat. The MSHCP also provides for the management and monitoring of populations of arroyo toad (USFWS 2009).

Additionally, a study by Miller et al (2012) indicates that periodic disturbance to water flows within stream segments are beneficial to arroyo toads and detrimental to non-native predators. Arroyo toads are able to persist in the adjacent upland areas while drought occurs, and are able to quickly reoccupy water once they return. Their non-native predators are unable to do so; therefore, recolonization of these resources takes longer for them.

California Red-Legged Frog (*Rana draytonii*)

State: California Department of Fish and Game Species of Special Concern
Federal: Threatened

Status and Taxonomy

California red-legged frog was originally described in 1852 as two distinct species *R. aurora* (northern red-legged frog) and *R. draytonii* (California red-legged frog), but was later reclassified as a single, polytypic species with two geographically contiguous subspecies, *R. a. aurora* and *R. a. draytoni*, whose ranges overlap over a broad zone spanning several hundred kilometers from Marin to Humboldt Counties (Schaffer et al. 2004). The results of genetic studies by Conlon et al. (2006) concluded that the two subspecies are actually separate species. The classification of the California red-legged frog as a distinct species has now been accepted by the scientific community (Crother 2008). The final critical habitat designation for California red-legged frog published in 2010 recognizes the California red-legged frog as a distinct species (75 FR 12816–12959).

The California red-legged frog was federally listed as threatened in 1996 (61 FR 25813–25833). On April 13, 2006, final critical habitat was designated for the California red-legged frog (71 FR 19244–19346). As a result of concern about scientific integrity and litigation (Center for Biological Diversity v. Kempthorne et al.) regarding the 2006 designation of critical habitat, the U.S. Fish and Wildlife Service (USFWS) published final revised critical habitat for the California red-legged frog on March 17, 2010 (75 FR 12816–12959). Although California red-legged frog is not state-listed as threatened or endangered, it is a California Department of Fish and Game Species of Special Concern.

The California red-legged frog is the largest native frog in the western United States (116 to 138 millimeters (4.6 to 5.4 inches)). The posterior abdomen and hind legs of adults are often red or salmon pink; the back is characterized by small black flecks and larger irregular dark blotches with indistinct outlines on a brown, gray, olive, or reddish-brown background color. A full description of the physical characteristics of the California red-legged frog can be found in the *Recovery Plan for the California Red-legged Frog (*Rana aurora draytonii*)* (USFWS 2002).

Habitat Description

California red-legged frogs use a variety of different habitats including riparian, aquatic, and upland habitats during their life cycle. The species may complete its cycle in one particular habitat or it may utilize a number of habitat types depending on climatic conditions or distance between, and the availability of, wetland and other moist environments (75 FR 12816–12959). Although the California red-legged frog can utilize multiple habitat types, breeding must occur in aquatic habitats including streams, deep pools, backwaters within streams and creeks, ponds, marshes, sag ponds, dune ponds, lagoons, and stock ponds. Red-legged frogs can occur in ephemeral ponds or permanent streams and ponds, but populations probably cannot persist in ephemeral streams (Jennings and Hayes 1985). Red-legged frogs generally avoid large river channels with widely fluctuating flows because such habitat does not permit successful reproductive activity (Hayes and Jennings 1988). Breeding adults often use deep, still, or slow-moving water and dense, shrubby riparian or emergent vegetation (Hayes and Jennings 1988), but frogs have been observed in shallow sections of streams and ponds that are devoid of vegetative cover. Habitats with the highest densities of frogs are deep water ponds with dense stands of overhanging willows (*Salix* sp.) and

a fringe of cattails (*Typha latifolia*) between the willow roots and overhanging willow limbs (Jennings 1988; Rathbun et al. 1993). The California red-legged frog uses riparian and upland habitats for shelter, foraging, cover, and non-dispersal movement (75 FR 12816–12959).

Life History

California red-legged frogs breed during the winter and early spring from as early as late November through April and May. Larvae remain in breeding ponds until metamorphosis in the summer months (Storer 1925; Wright and Wright 1949; 75 FR 12816–12959). There is no evidence to suggest that they lay more than one clutch per year like some eastern ranids (Emlen 1977). Males appear at breeding sites approximately 2 to 4 weeks before females. Males call in groups of two to seven individuals with females attracted to the calling males (Jennings and Hayes 1994; USFWS 2002). Egg masses containing approximately 2,000 to 6,000 dark reddish eggs are attached to emergent vegetation such as bulrushes (*Scirpus* spp.) and cattails. Eggs require 20 to 22 days to develop into tadpoles, and tadpoles require 4 to 5 months to attain metamorphosis, which usually occurs between July and September. However, not all tadpoles develop into frogs the first year since overwintering tadpoles have been observed by a number of studies (USFWS 2002). Sexual maturity can be attained at 2 years of age by males and 3 years of age by females (USFWS 2002).

Red-legged frogs also use non-aquatic terrestrial habitats for refuge and dispersal. They rest and feed in riparian vegetation, and the moisture and cover of the riparian zone may facilitate dispersal. During periods when water is absent, red-legged frogs may take refuge in moist areas within riparian habitats and small mammal burrows in surrounding upland areas. California red-legged frogs may aestivate in small mammal burrows and moist leaf litter up to 98 feet from water in adjacent dense riparian vegetation for up to 77 days (Rathbun et al. 1993).

California red-legged frog dispersal patterns appear to depend on habitat availability and environmental conditions (75 FR 12816–12959). In non-aquatic habitats, dispersal may be limited, although California red-legged frogs have been documented to disperse over 2 miles under certain conditions (Bugler et al. 2003). Fellers and Kleeman (2007) found that the average dispersal distance of California red-legged frogs in their survey was 492 feet away from breeding habitat, and they concluded that although most frogs move from their breeding habitat, most only disperse as far as the nearest non-breeding habitat.

Hayes and Tennant (1985) found that most frequent prey groups for adult red-legged frogs were carabid and tenebrionid beetles, water striders (Gerridae), lycosid spiders, and larval neuropterans. Tadpoles probably feed on algae (Jennings et al. 1992). Small vertebrates such as Northern Pacific treefrog (*Pseudacris regilla*) and California mouse (*Peromyscus californicus*) comprised more than 50% of the prey mass taken by larger frogs and were the largest prey items in the Hayes and Tennant (1985) study.

Range and Distribution

The California red-legged frog formerly occurred from Shasta County, California, to Baja California, Mexico, west of the mountains, in habitats ranging in elevation from sea level to approximately 1,500 meters (4,921feet). The current geographic range extends from southern Mendocino County south to Baja California (Shaffer et al. 2004). It is now known from isolated localities in the Sierra Nevada Mountains, northern Coast, and northern Transverse Ranges while it is believed to be extirpated from the southern Transverse and Peninsular Ranges (USFWS 2002).

There is one historic (pre-1990) occurrence record of California red-legged frog within the Plan Area at Grant's Lake, west of Bitterwater Valley Road. There are six recent occurrence records for the species within the Plan Area. These include three records from a small drainage and ponds located between 2 and 4 miles east of the intersection of Highway 41 and Antelope Grade, east of Cholame Valley. One record is from the Cuyama River, downstream from Miranda Canyon to an unnamed road crossing, and one record from 1 mile south of Ortega Spring, in the Temblor Ranges (CDFG 2012) (Figure A-3).

Population Status and Trends

According to the USFWS (61 FR 25813–25833), the species has been extirpated from 70% of its former range and is now found primarily in wetlands and streams in coastal drainages of central California from Marin County to Ventura County. Historically, the species was known from 46 counties, but it has been extirpated from 24 of these (USFWS 2002). It has nearly been extirpated from California's inland regions, including the foothills of the Sierra Nevada and coastal areas south of Ventura County (Jennings and Hayes 1994). In 2002, the USFWS listed the species as common in the San Francisco Bay area and along the central coast (USFWS 2002). Within the Plan Area, California red-legged frogs were once widespread in the inner Coast Ranges between the Salinas River system and the San Joaquin Valley but have been extirpated from more than 90% of historic localities.

Threats

Habitat loss and degradation have been primary factors in the decline of the California red-legged frog. Other factors contributing to declining red-legged frog populations, directly related to urban development, include the introduction and spread of exotic predators (e.g., bullfrog (*Lithobates catesbeianus*), African clawed-frog (*Xenopus laevis*), green sunfish (*Lepomis cyanellus*), and crayfish) and increases in mesopredators (e.g., raccoons (*Procyon lotor*), skunks (*Mephitis mephitis*), and opossums (*Didelphis marsupialis*)) (Jennings 1988; Jennings and Hayes 1985; Moyle et al. 1986; Hayes and Jennings 1986). Additionally, water pollution, in the form of fertilizers, biocides, chlorine, and other pollutants, adversely affect amphibian development, survival, and habitat. Further, exotic plant species (e.g., tamarisk, giant reed (*Arundo donax*), iceplant (Hottentot fig) (*Carpobrotus edulis*), and pampas grass (*Cortaderia selloana*)) may also degrade red-legged frog habitat by contributing to altered hydrology, eliminating breeding pools, and restricting access to and quality of upland habitat. Other factors that may adversely affect the species include livestock grazing and recreational activities in riparian areas, and human-related increases in fire frequency (Jennings 1988).

In 2010, the USFWS designated critical habitat for the California red-legged frog, including one critical habitat area (SLO-1) that overlaps with the northeast corner of the Plan Area. This area of critical habitat includes locations in the Cholame Creek drainage and portions of the following watersheds: the southern portion of Blue Point, the western portion of Jack Canyon, and the eastern portion of Palo Prieto Canyon. The USFWS (75 FR 12816–12959) lists the following threats within this area of critical habitat: highway construction, overgrazing, and water diversions and recommends that the following issues across all suitable habitat for California red-legged frog may require special management considerations: disease; impacts from recreational activities, water diversions, mining, and flood-control maintenance activities; dredging; sedimentation; water chemistry; sedimentation; water chemistry or temperature alterations; pesticide application; overgrazing; competition and predation by non-native animal species; and habitat removal and alteration by urbanization, timber activities, and nonnative plant introduction.

Conservation and Management

The *Recovery Plan for the Red-legged Frog (*Rana aurora draytonii*)* was published by the USFWS on May 28, 2002 (USFWS 2002). The Plan Area overlaps with the Diablo Range and Salinas Valley Recovery Unit and the Northern Transverse Ranges and Tehachapi Mountains Recovery Unit. The recovery strategy for the California red-legged frog consists of four parts: (1) protect existing populations by reducing threats, (2) restore and create habitat that will be protected and managed in perpetuity, (3) survey and monitor populations and conduct research on the biology of and threats to the subspecies, and (4) reestablish populations of the subspecies within its historical range.

Jennings and Hayes (1994) recommend that riparian habitats need greater protection, especially areas of dense vegetation associated with deep water habitats. They also recommend that water quality standards and water flow regimes need to be maintained.

The 2010 final revised critical habitat rule designates 1,636,609 acres of critical habitat in 48 critical habitat units within 27 California counties (75 FR 12816–12959). The USFWS states that the proposed fourfold expansion of critical habitat over the 2006 designation better reflects areas that contain the primary constituent elements of red-legged frog habitat, including aquatic habitat for breeding activities; aquatic habitat for non-breeding activities; and upland habitat for shelter, foraging, predator avoidance, and dispersal (75 FR 12816–12959). In addition, 34 core areas that were described in the *Recovery Plan for the Red-legged Frog (*Rana aurora draytonii*)* (USFWS 2002) were used to focus on critical habitat areas, and areas within the 2006 designation were expanded to include habitat that is adjacent to areas with documented occurrences of red-legged frogs.

The California red-legged frog is covered under 22 habitat conservation plans (USFWS 2012).

MEMORANDUM

To:	Elisa Ventura
From:	Michael Cady
Subject:	Arroyo Seco Canyon – Focused Fish Survey
Date:	December 15, 2019
Attachment(s):	A) Project and Survey Area Location; B) Southern Steelhead/Rainbow Trout and Arroyo Chub Species Accounts

Dudek conducted a focused fish survey for the City of Pasadena (City) Pasadena Water and Power (PWP) in support of Arroyo Seco Canyon Project Areas 2 and 3 (proposed Project or Project). The focus of the survey were southern steelhead/rainbow trout *Oncorhynchus mykiss*) and arroyo chub (*Gila orcuttii*). The Project is located in the in the northwest corner of the City of Pasadena in Los Angeles County, California, as shown in Attachment A, Project and Survey Area Location. For the proposed Project's Environmental Impact Report analysis, the proposed Project consists of two primary action areas: a diversion dam and intake replacement in Area 2, and the spreading basin expansion in Area 3. An additional area (Area 1; Arroyo Seco Headworks) was previously allowed under an Initial Study/Mitigated Negative Declaration for the project. This area was included in the focused fish survey in support of the permits needed for impacts to jurisdictional waters for the project that will be for all three areas. These areas are connected by the Gabrielino Trail/Access Road, which serves as a recreational trail and the access road for City of Pasadena and U.S. Forest Service vehicles heading into and out of the Angeles National Forest.

Species accounts for southern steelhead/rainbow trout and arroyo chub are included in Attachment B, Southern Steelhead/Rainbow Trout and Arroyo Chub Species Accounts.

Methods

Desktop Analysis

Prior to conducting the field investigation, a literature review was conducted to evaluate the environmental setting of the Project site and identify potential special-status biological resources that may be found on the site. The following reports that encompass the Project site were reviewed:

- Biological Technical Report, Arroyo Seco Canyon Project, dated September 2014 (BonTerra Psomas 2014a)

The following online databases and reports were reviewed:

- California Department of Fish and Wildlife's (CDFW) California Natural Diversity Database (CNDDB) (CDFW 2019)
- U.S. Fish and Wildlife Service's (USFWS) Critical Habitat and Species Occurrence Data (USFWS 2019)

- National Oceanic and Atmospheric Administration's (NOAA). Southern California Steelhead Recovery Plan (NOAA 2012)
- Inland Fishes of California (Moyle 2002)
- The Status and Distribution of the Freshwater Fishes of Southern California (Swift et al. 1993)
- Fish Species of Special Concern Of California (Moyle et al. 2015)

The CNDDB was queried based on the U.S. Geological Survey 7.5-minute quadrangle on which the Project site is located (*Pasadena, California*) and the eight surrounding quadrangles (*Sunland*, *Condor Peak*, *Chilao Flat*, *Burbank*, *Mount Wilson*, *Hollywood*, Los *Angeles*, and *El Monte*). The USFWS occurrence data and critical habitat databases were queried using geographic information system (GIS) software based on a 5-mile buffer around the Project site.

Field Survey

The focused survey area was within the Arroyo Seco from where the waters go sub-grade to the west of Area 3 and upstream to the Brown Mountain Dam; approximately 4.5 river miles, as shown in Attachment A. The purpose of the survey was to look for individuals of the two species and identify potential habitat. The survey was conducted on May 3, 2019 by Dudek Senior Biologist Michael Cady, as shown in Table 1, Survey Conditions. The focused survey passes were conducted by walking along and within the stream. Any pools, if present, where southern steelhead/rainbow trout could be present would be examined from a distance using binoculars before being approached.

Table 1
Survey Conditions

Date	Hours	Personnel	Conditions
10/14/2019	0900-1500	Michael Cady	61°F–73°F, 0% cc, 1–2 mph

Notes: cc = cloud cover; mph = miles per hour.

Results

No fish were observed during the survey. No suitable habitat, characterized by slow-moving water, mud or sand substrate, and depths greater than 40 centimeters (Moyle et al. 2015), for arroyo chub was observed in the survey area. No large, deep pools were observed that are preferred by the species during the summer and early fall (NOAA 2012), prior to the onset of the wet season.

Southern Steelhead/Rainbow Trout and Arroyo Chub Species Accounts

INTENTIONALLY LEFT BLANK

Southern Steelhead (*Oncorhynchus mykiss*)

State: None
Federal: Endangered

Life History

The southern steelhead (*Oncorhynchus mykiss*) and the rainbow trout are the same species, but the steelhead is anadromous (migrating from salt to freshwater) and the rainbow trout is confined to freshwater habitats. It is common to find populations exhibiting both life history strategies within the same river system, and individuals that exhibit one life history strategy can produce offspring that exhibit the other strategy (62 FR 43937–43954). Southern steelhead are lightly to heavily spotted with small black spots on a lighter background; the dorsal, caudal, and adipose fins have these spots as well. Juvenile and larger freshwater resident trout have a red to pink stripe down the mid-sides, hence the name 'rainbow" for the freshwater populations. Anadromous fish are larger, lack the pink stripe of the rainbow trout, and exhibit an overall silvery appearance with a "steely" blue-grey color dorsally. The inside of the mouth is entirely white in contrast to the other Pacific salmonid species, and they have a stronger tail stock and smaller anal fin than the other native Pacific salmon. The adipose fin separates them from all other native freshwater fish in anadromous streams in coastal southern California (Moyle 2002).

The range of the southern steelhead is from the Santa Maria River along the San Luis Obispo–Santa Barbara County line in the north to the Tijuana River just north of the United States–Mexico border in the south. The southern steelhead's historic range within many of these coastal streams was limited by natural barriers, above which no known southern California populations of native rainbow trout or steelhead previously existed. Definitive records of southern steelhead are not available for many of the small coastal streams within the Southern California Evolutionarily Significant Unit (ESU); however, it is believed that most of the streams were inhabited by southern steelhead. The distribution of southern steelhead within the ocean is not well known, but some evidence indicates that they stay relatively close to the coast and even near the mouths of their natal streams, in contrast to other Pacific salmonid species that range widely in the ocean (NMFS 2007).

Since the late 1990s southern steelhead have been recorded in the following watersheds:

- Santa Barbara County – the Santa Maria River, Santa Ynez River, Gaviota Creek, Arroyo Honda, Mission Creek, and Carpinteria Creek;
- Ventura County – the Ventura River and Santa Clara River;
- Los Angeles County – Malibu Creek and Topanga Creek;
- Orange County – San Juan Creek; and
- San Diego County – San Mateo Creek.

Migration and life history patterns of southern steelhead depend on rainfall and streamflow. In the highly variable conditions of the watersheds along the south central California coast, populations may commonly decline to extremely low numbers in some years. In most southern California streams sandbars at the mouth of the estuaries during periods of low river flow may block migration from the ocean. Adult steelhead congregate in the Pacific Ocean

off the mouth of the River and migrate upstream after the sandbar is breached from seasonal tidal influences and/or when triggered by rising streamflows from storm events (Moyle 2002; Shapovalov and Taft 1954).

In some river systems such as the Santa Clara River, steelhead appear to use winter freshets (a rise or overflowing of a stream resulting from heavy rain or snow melt) as a means to move from the sea to the upper areas of the watershed. These winter freshets may provide enough surface flow to break through the sandbar that builds up at the River–estuary interface during the low flow summer months.

Downstream migration of juveniles usually occurs between March and June (Shapovalov and Taft 1954). In southern California, steelhead typically migrates to the ocean as one- or two-year olds (Moore 1980). Outmigrating steelhead in the Santa Clara River, for example, have been observed from January through early June, but the majority of steelhead smolt emigrate during the period from March through early May, and the timing of migration is strongly dependent on streamflows (ENTRIX 2000).

Steelhead in the ocean feed on a variety of pelagic organisms, primarily anchovies and crustaceans. In streams, they overwhelmingly feed on aquatic insects in both the benthos and stream drift. They also consume available non-insects, including amphipods, isopods, oligochaete worms, and terrestrial insects that fall into streams. Larger steelhead in freshwater streams also take fish, such as sculpin, tidewater gobies, and small minnows and suckers. Larger juveniles in lagoons may feed on mysid shrimp, amphipods, and isopods, as well as a smaller variety of insects available in lagoons (Moyle 2002).

In streams, steelhead use habitat consisting of relatively cool, well-oxygenated water with adequate depth and cover. Temperature tolerances and preferences of steelhead vary among life stages. Eggs mortality may occur at water temperatures in excess of 55° F (13.3° C) (McEwan and Jackson 1996). At water temperatures greater than 70° F (21.1° C), steelhead appear to have difficulty obtaining sufficient oxygen from the water (McEwan and Jackson 1996). However, Carpanzano (1996) found trout living in Sespe Creek with a water temperature of 82.4° F (28° C). Cover provided by gravel, cobble, boulder, undercut banks, large and small woody debris, and overhanging vegetation is important for survival.

Steelhead require relatively clean unconsolidated gravel and cobble for spawning. Females excavate oval nests and lay their eggs while one or more attending males fertilize the eggs as they fall among the gravel. Unlike other Pacific salmonid species, steelhead can survive spawning and return to reproduce multiple times. Eggs hatch within three to four weeks, but the alevins (yolk-sac fry) cannot swim because they still have a large yolk attached. The alevins remain in the gravel for two additional weeks and then emerge when their yolk is used up. At this point, the alevins become free swimming juveniles. The juveniles spend one to two years in freshwater, reaching five to 10 inches in length before attempting to migrate to the ocean (Moyle 2002). Fish that descend to larger river habitats or coastal lagoons often attain larger sizes than stream-reared fish. It has been shown in the Santa Cruz, for example, that larger fish survive much better in the ocean than smaller fish. After their first year of life, steelhead may undergo physiological and morphological changes to smolts enabling them to survive in a marine environment. These smolts then migrate to the ocean, typically from March to May (Moyle 2002). Steelhead spend two to three years in the ocean and can grow to approximately 35 inches in length and weigh up to 22 pounds, although most are smaller (Moyle 2002). Studies of central California steelhead indicate that most individuals return to their natal stream, but some individuals do stray to other streams. This aspect of southern California populations is little studied and is an area of active current research.

Regulatory History

The southern steelhead was federally-listed as endangered in 1997 in the Southern California ESU that extends from the Santa Maria River in the north southward to Malibu Creek without critical habitat (62 FR 43937–43954). In 2002 the range of the Southern California ESU was extended south to the United States–Mexico Border (67 FR 21586–21598). On January 5, 2006, the federal endangered status of the southern steelhead was re-affirmed for 10 Distinct Population Segments (DPS) of West Coast Steelhead (71 FR 834).

Critical Habitat

The NMFS designated final critical habitat for five steelhead ESUs on September 2, 2005, (70 FR 52488–52586). The NMFS identified the following primary constituent elements (PCEs) in designating steelhead critical habitat (70 FR 52521):

1. Freshwater spawning sites with water quantity and quality conditions and substrate supporting spawning, incubation and larval development.
2. Freshwater rearing sites with water quantity and floodplain connectivity to form and maintain physical habitat conditions and support juvenile growth and mobility; water quality and forage supporting juvenile development; and natural cover such as shade, submerged and overhanging large wood, log jams and beaver dams, aquatic vegetation, large rocks and boulders, side channels, and undercut banks.
3. Freshwater migration corridors free of obstruction with water quantity and quality conditions and natural cover such as submerged and overhanging large wood, aquatic vegetation, large rocks and boulders, side channels, and undercut banks supporting juvenile and adult mobility and survival.
4. Estuarine areas free of obstruction with water quality, water quantity, and salinity conditions supporting juvenile and adult physiological transitions between fresh- and saltwater; natural cover such as submerged and overhanging large wood, aquatic vegetation, large rocks and boulders, and side channels; and juvenile and adult forage, including aquatic invertebrates and fishes, supporting growth and maturation.
5. Nearshore marine areas free of obstruction with water quality and quantity conditions and forage, including aquatic invertebrates and fishes, supporting growth and maturation; and natural cover such as submerged and overhanging large wood, aquatic vegetation, large rocks and boulders, and side channels.
6. Offshore marine areas with water quality conditions and forage, including aquatic invertebrates and fishes, supporting growth and maturation.

Recovery Plan

Presently, a Recovery Plan required by the federal ESA has not been published. However, a Southern California ESU recovery team has been formed and is currently working on a draft Recovery Plan for southern steelhead within the Santa Clara River and the Southern California ESU. In September 2007, a Federal Recovery Outline for the DPS of southern steelhead was released (NMFS 2007).

Threats

The primary threats to southern steelhead include loss of important portions of habitat range and deterioration of habitats due to artificial barriers that limit upstream migration, diversion of water from natural channels, and introduction of non-native species. The following provides a brief summary of the threats to southern steelhead based on the five listing factors that are used to assess species for listing as threatened or endangered under the federal ESA: (1) alteration of flow regimes from construction of dams and diversions; (2) decreased water quality (particularly higher water temperatures); (3) recreational fishing; (4) predation from birds and other fishes; and (5) competition and introduction of disease from trout and exotic species such as channel catfish, black bullhead, green sunfish, and largemouth bass.

ARROYO CHUB

State: California Department of Fish and Wildlife Species of Special Concern
Federal: None

Life History

The arroyo chub (Gila orcutti) is native to the Los Angeles, San Gabriel, San Luis Rey, Santa Ana, and Santa Margarita rivers and San Juan and Malibu creeks (CDFG 1995B). Arroyo chub are now rare within their native range and are only common in the upper Santa Margarita River and its tributary De Luz Creek in northern San Diego County; Trabuco Creek below O'Neill Regional Park and San Juan Creek (San Juan Creek drainage) in southern Orange County; and Malibu Creek (Swift et al. 1993) and West Fork San Gabriel River below Cogswell Reservoir in Los Angeles County (CDFG 1995). The arroyo chub's range was artificially expanded as bait with trout or mosquitofish in the 1930s and 1940s (Swift et al. 1993). The arroyo chub was successfully introduced into the Santa Ynez, Santa Maria, Cuyama, and Mojave rivers, and is considered to be introduced within the Santa Clara River watershed (Swift et al. 1993; CDFG 1995). If not for the introduced populations, the arroyo chub would likely be considered a threatened or endangered species (NatureServe 2007).

The arroyo chub is a small fish, typically about 70 to 100 millimeters in size. It occurs in slow-moving or backwater sections of warm to cool (10ºC to 24ºC) streams with mud or sand substrates; it thrives in low-gradient systems (Swift et al. 1993). This species may tolerate high temperatures and hypoxic conditions that occur in slow-flowing or stagnant streams and backwater pools in dry summers. The arroyo chub feeds primarily on algae but also feeds on insects and small crustaceans.

The arroyo chub can successfully reproduce after one year (CDFG 1995). Arroyo chubs are fractional spawners that will breed from May to August, with the majority of breeding events taking place in June and July (CDFG 1995), although others report spawning in March to April or May (NatureServe 2007). The arroyo chub breeding habitat requires slow-moving areas of water or pools. After hatching, the young spend the next three to four months in areas of quiet water, usually among vegetation or areas with cover (CDFG 1995).

Threats

The arroyo chub is subject to various threats, including urbanization and associated habitat fragmentation, degradation, and reduction of suitable habitat for necessary for survival and breeding (CDFG 1995). The red shiner (*Cyprinella lutrensis*), an introduced minnow, can competitively exclude the arroyo chub from many areas it would be expected to occur. The arroyo chub can also be the victim of predation by various species, including green sunfish (*Lepomis cyanellus*) and salmonids. Other threats include lowering of the water level by dewatering, diversions, and water quality effects of waste and storm waters. The genetic integrity of introduced arroyo chub populations is at risk because as the species may hybridize in areas where other species of the *Cyprinidae* family occur (NatureServe 2007).

EUDICOTS

VASCULAR SPECIES

ADOXACEAE—MUSKROOT FAMILY

Sambucus nigra—blue elderberry

AMARANTHACEAE—AMARANTH FAMILY

* *Amaranthus albus*—prostrate pigweed

ANACARDIACEAE—SUMAC OR CASHEW FAMILY

Malosma laurina—laurel sumac
Rhus integrifolia—lemonade berry
Rhus ovata—sugarbush
* *Schinus molle*—Peruvian peppertree
Toxicodendron diversilobum—poison oak

APIACEAE—CARROT FAMILY

* *Anthriscus caucalis*—bur chervil
* *Conium maculatum*—poison hemlock

APOCYNACEAE—DOGBANE FAMILY

* *Nerium oleander*—oleander
* *Vinca major*—bigleaf periwinkle

ARALIACEAE—GINSENG FAMILY

* *Hedera helix*—English ivy

ASTERACEAE—SUNFLOWER FAMILY

Achillea millefolium—common yarrow
Ambrosia acanthicarpa—flatspine bur ragweed
Ambrosia psilostachya—western ragweed
* *Anthemis cotula*—stinking chamomile
Artemisia californica—California sagebrush
Artemisia douglasiana—Douglas' sagewort
Artemisia dracunculus—wild tarragon
Baccharis pilularis—coyote brush
Baccharis salicifolia—mulefat
Bidens frondosa—devil's beggartick

* *Bidens pilosa*—hairy beggarticks
* *Carduus pycnocephalus*—Italian plumeless thistle
* *Centaurea melitensis*—Maltese star-thistle
Chaenactis glabriuscula—yellow pincushion
* *Delairea odorata*—Cape-ivy
Encelia californica—California brittle bush
Erigeron canadensis—Canadian horseweed
Erigeron foliosus—leafy fleabane
Eriophyllum confertiflorum—golden-yarrow
Helianthus annuus—common sunflower
* *Helminthotheca echioides*—bristly oxtongue
Heterotheca grandiflora—telegraphweed
* *Lactuca serriola*—prickly lettuce
Lepidospartum squamatum—scale broom
* *Logfia gallica*—narrowleaf cottonrose
Malacothrix saxatilis—cliff desertdandelion
* *Pseudognaphalium luteoalbum*—Jersey cudweed
Rafinesquia californica—California plumeseed
* *Sonchus asper*—spiny sowthistle
* *Sonchus oleraceus*—common sowthistle
Stephanomeria exigua—small wirelettuce
Stephanomeria virgata—rod wirelettuce

BETULACEAE—BIRCH FAMILY
Alnus rhombifolia—white alder

BORAGINACEAE—BORAGE FAMILY
Cryptantha intermedia—Clearwater cryptantha
Cryptantha micromeres—pygmyflower cryptantha
Eriodictyon crassifolium—thick leaf yerba santa
Eucrypta chrysanthemifolia—spotted hideseed
Pectocarya penicillata—sleeping combseed
Phacelia cicutaria—caterpillar phacelia
Phacelia tanacetifolia—lacy phacelia

BRASSICACEAE—MUSTARD FAMILY
* *Brassica nigra*—black mustard
* *Brassica rapa*—field mustard
* *Capsella bursa-pastoris*—shepherd's purse
Cardamine oligosperma—little western bittercress
Descurainia pinnata—western tansymustard

* *Hirschfeldia incana*—shortpod mustard
Lepidium virginicum—Virginia pepperweed
Nasturtium officinale—watercress
* *Raphanus sativus*—cultivated radish
* *Sisymbrium irio*—London rocket
* *Sisymbrium officinale*—hedgemustard
* *Sisymbrium orientale*—Indian hedgemustard

CACTACEAE—CACTUS FAMILY
* *Opuntia ficus-indica*—Barbary fig
Opuntia oricola—chaparral pricklypear

CARYOPHYLLACEAE—PINK FAMILY
Silene laciniata—cardinal catchfly

CHENOPODIACEAE—GOOSEFOOT FAMILY
* *Chenopodium album*—lambsquarters
* *Salsola tragus*—prickly Russian thistle

CONVOLVULACEAE—MORNING-GLORY FAMILY
Calystegia macrostegia—island false bindweed
Cuscuta californica—chaparral dodder

CRASSULACEAE—STONECROP FAMILY
Dudleya cymosa—canyon liveforever

CUCURBITACEAE—GOURD FAMILY
Marah fabacea—California man-root
Marah macrocarpa—Cucamonga manroot

EUPHORBIACEAE—SPURGE FAMILY
Euphorbia albomarginata—whitemargin sandmat
* *Ricinus communis*—castorbean

FABACEAE—LEGUME FAMILY
Acmispon americanus—Spanish clover
Acmispon glaber—deer weed
Acmispon maritimus—coastal bird's-foot trefoil
* *Colutea arborescens*—bladder senna
Lathyrus vestitus—Pacific pea
Lupinus bicolor—miniature lupine
Lupinus hirsutissimus—stinging annual lupine

* *Medicago polymorpha*—burclover
* *Melilotus indicus*—annual yellow sweetclover
Pickeringia montana—chaparral pea
* *Spartium junceum*—Spanish broom

FAGACEAE—OAK FAMILY
Quercus agrifolia—coast live oak
Quercus berberidifolia—scrub oak
Quercus chrysolepis—canyon live oak

GERANIACEAE—GERANIUM FAMILY
* *Erodium botrys*—longbeak stork's bill
* *Erodium cicutarium*—redstem stork's bill
* *Geranium molle*—dovefoot geranium

GROSSULARIACEAE—GOOSEBERRY FAMILY
Ribes amarum—bitter gooseberry
Ribes aureum—golden currant
Ribes malvaceum—chaparral currant

JUGLANDACEAE—WALNUT FAMILY
Juglans californica—Southern California black walnut

LAMIACEAE—MINT FAMILY
* *Marrubium vulgare*—horehound
Salvia apiana—white sage
Salvia mellifera—black sage

LAURACEAE—LAUREL FAMILY
Umbellularia californica—California bay

MALVACEAE—MALLOW FAMILY
* *Malva parviflora*—cheeseweed mallow

MONTIACEAE—MONTIA FAMILY
Claytonia perfoliata—miner's lettuce

MORACEAE—MULBERRY FAMILY
* *Ficus carica*—edible fig

MYRTACEAE—MYRTLE FAMILY
* *Eucalyptus camaldulensis*—river redgum

OLEACEAE—OLIVE FAMILY

Fraxinus velutina—velvet ash

ONAGRACEAE—EVENING PRIMROSE FAMILY

Camissoniopsis bistorta—southern suncup
Camissoniopsis confusa—San Bernardino suncup
Camissoniopsis micrantha—miniature suncup
Clarkia purpurea—winecup clarkia
Epilobium canum—hummingbird trumpet
* *Oenothera laciniata*—cutleaf evening primrose

OROBANCHACEAE—BROOM-RAPE FAMILY

Castilleja affinis—coast Indian paintbrush

PAPAVERACEAE—POPPY FAMILY

Eschscholzia californica—California poppy

PHRYMACEAE—LOPSEED FAMILY

Diplacus aurantiacus—bush monkeyflower
Erythranthe cardinalis—scarlet monkeyflower

PLANTAGINACEAE—PLANTAIN FAMILY

Keckiella cordifolia—heartleaf keckiella
* *Plantago arenaria*—sand plantain
* *Plantago lanceolata*—narrowleaf plantain
* *Plantago major*—common plantain
* *Veronica anagallis-aquatica*—water speedwell

PLATANACEAE—PLANE TREE, SYCAMORE FAMILY

Platanus racemosa—California sycamore

POLEMONIACEAE—PHLOX FAMILY

Allophyllum glutinosum—sticky false gilyflower

POLYGONACEAE—BUCKWHEAT FAMILY

Eriogonum fasciculatum—California buckwheat
* *Rumex crispus*—curly dock

RANUNCULACEAE—BUTTERCUP FAMILY

Clematis lasiantha—pipestem clematis

RHAMNACEAE—BUCKTHORN FAMILY

Ceanothus crassifolius—hoary leaf ceanothus
Ceanothus leucodermis—chaparral whitethorn
Ceanothus oliganthus—hairy leaf ceanothus
Frangula californica—California coffee berry
Rhamnus crocea—redberry buckthorn
Rhamnus ilicifolia—hollyleaf redberry

ROSACEAE—ROSE FAMILY

Cercocarpus betuloides—birch leaf mountain mahogany
Heteromeles arbutifolia—toyon
Prunus ilicifolia—holly leaf cherry
Rosa californica—California rose
Rubus ursinus—California blackberry

RUBIACEAE—MADDER FAMILY

Galium angustifolium—narrowleaf bedstraw
Galium aparine—stickywilly

SALICACEAE—WILLOW FAMILY

Populus fremontii—Fremont cottonwood
Salix exigua—sandbar willow
Salix gooddingii—black willow
Salix laevigata—red willow
Salix lasiolepis—arroyo willow

SAPINDACEAE—SOAPBERRY FAMILY

Acer macrophyllum—bigleaf maple
* *Acer saccharinum*—silver maple

SCROPHULARIACEAE—FIGWORT FAMILY

* *Verbascum blattaria*—moth mullein
* *Verbascum virgatum*—wand mullein

SIMAROUBACEAE—QUASSIA OR SIMAROUBA FAMILY

* *Ailanthus altissima*—tree of heaven

SOLANACEAE—NIGHTSHADE FAMILY

Datura wrightii—sacred thorn-apple
* *Nicotiana glauca*—tree tobacco
Solanum americanum—American black nightshade
Solanum douglasii—greenspot nightshade

Solanum xanti—chaparral nightshade

URTICACEAE—NETTLE FAMILY

* *Urtica dioica*—stinging nettle

ZYGOPHYLLACEAE—CALTROP FAMILY

* *Tribulus terrestris*—puncturevine

FERNS AND FERN ALLIES

VASCULAR SPECIES

DRYOPTERIDACEAE—WOOD FERN FAMILY

* *Dryopteris arguta*—coastal woodfern

POLYPODIACEAE—POLYPODY FAMILY

Polypodium californicum—California polypody

PTERIDACEAE—BRAKE FAMILY

Pellaea andromedifolia—coffee cliffbrake

GYMNOSPERMS AND GNETOPHYTES

VASCULAR SPECIES

CUPRESSACEAE—CYPRESS FAMILY

Calocedrus decurrens—incense cedar

PINACEAE—PINE FAMILY

Pinus coulteri—Coulter pine

* *Pinus halepensis*—Aleppo pine

MONOCOTS

VASCULAR SPECIES

AGAVACEAE—AGAVE FAMILY

* *Agave americana*—American century plant

Hesperoyucca whipplei—chaparral yucca

ARECACEAE—PALM FAMILY

* *Washingtonia robusta*—Washington fan palm

POACEAE—GRASS FAMILY

* *Avena barbata*—slender oat
* *Avena fatua*—wild oat
* *Bromus diandrus*—ripgut brome
* *Bromus hordeaceus*—soft brome
* *Bromus madritensis* ssp. *rubens*—red brome
  Elymus condensatus—giant wild rye
* *Festuca myuros*—rat-tail fescue
* *Festuca perennis*—perennial rye grass
* *Hordeum murinum*—mouse barley
* *Lamarckia aurea*—goldentop grass
* *Pennisetum setaceum*—fountain grass
* *Phalaris minor*—littleseed canarygrass
* *Polypogon monspeliensis*—annual rabbitsfoot grass
* *Polypogon viridis*—beardless rabbitsfoot grass
* *Schismus barbatus*—common Mediterranean grass
* *Stipa miliacea*—no common name

INTENTIONALLY LEFT BLANK

* Denotes non-native species.

AMPHIBIAN

FROGS

HYLIDAE—TREEFROGS

Pseudacris cadaverina—California treefrog
Pseudacris hypochondriaca—Baja California treefrog

TOADS

BUFONIDAE—TRUE TOADS

Anaxyrus boreas—western toad

BIRD

BLACKBIRDS, ORIOLES, AND ALLIES

ICTERIDAE—BLACKBIRDS

Icterus bullockii—Bullock's oriole
Icterus cucullatus—hooded oriole
* *Molothrus ater*—brown-headed cowbird

BUSHTITS

AEGITHALIDAE—LONG-TAILED TITS AND BUSHTITS

Psaltriparus minimus—bushtit

CARDINALS, GROSBEAKS, AND ALLIES

CARDINALIDAE—CARDINALS AND ALLIES

Pheucticus melanocephalus—black-headed grosbeak
Piranga ludoviciana—western tanager

FINCHES

FRINGILLIDAE—FRINGILLINE AND CARDUELINE FINCHES AND ALLIES

Haemorhous mexicanus—house finch
Spinus lawrencei—Lawrence's goldfinch
Spinus psaltria—lesser goldfinch
Spinus tristis—American goldfinch

FLYCATCHERS

TYRANNIDAE—TYRANT FLYCATCHERS

Contopus sordidulus—western wood-pewee
Empidonax difficilis—Pacific-slope flycatcher
Myiarchus cinerascens—ash-throated flycatcher
Sayornis nigricans—black phoebe
Tyrannus vociferans—Cassin's kingbird

HAWKS

ACCIPITRIDAE—HAWKS, KITES, EAGLES, AND ALLIES

Accipiter cooperii—Cooper's hawk
Buteo jamaicensis—red-tailed hawk
Buteo lineatus—red-shouldered hawk

HUMMINGBIRDS

TROCHILIDAE—HUMMINGBIRDS

Calypte anna—Anna's hummingbird
Selasphorus sasin—Allen's hummingbird

JAYS, MAGPIES, AND CROWS

CORVIDAE—CROWS AND JAYS

Aphelocoma californica—California scrub-jay
Corvus brachyrhynchos—American crow
Corvus corax—common raven

MOCKINGBIRDS AND THRASHERS

MIMIDAE—MOCKINGBIRDS AND THRASHERS

Mimus polyglottos—northern mockingbird
Toxostoma redivivum—California thrasher

NEW WORLD QUAIL

ODONTOPHORIDAE—NEW WORLD QUAIL

Callipepla californica—California quail

NEW WORLD VULTURES

CATHARTIDAE—NEW WORLD VULTURES

Cathartes aura—turkey vulture

OLD WORLD WARBLERS AND GNATCATCHERS

SYLVIIDAE—SYLVIID WARBLERS

Polioptila caerulea—blue-gray gnatcatcher

PIGEONS AND DOVES

COLUMBIDAE—PIGEONS AND DOVES

Patagioenas fasciata—band-tailed pigeon

Zenaida macroura—mourning dove

* *Streptopelia decaocto*—Eurasian collared-dove

SHOREBIRDS

CHARADRIIDAE—LAPWINGS AND PLOVERS

Charadrius vociferus—killdeer

SILKY FLYCATCHERS

PTILOGONATIDAE—SILKY-FLYCATCHERS

Phainopepla nitens—phainopepla

STARLINGS AND ALLIES

STURNIDAE—STARLINGS

* *Sturnus vulgaris*—European starling

SWALLOWS

HIRUNDINIDAE—SWALLOWS

Hirundo rustica—barn swallow

Petrochelidon pyrrhonota—cliff swallow

Stelgidopteryx serripennis—northern rough-winged swallow

Tachycineta thalassina—violet-green swallow

SWIFTS

APODIDAE—SWIFTS

Aeronautes saxatalis—white-throated swift

TITMICE

PARIDAE—CHICKADEES & TITMICE

Baeolophus inornatus—oak titmouse

VIREOS

VIREONIDAE—VIREOS

Vireo gilvus—warbling vireo

WATERFOWL

ANATIDAE—DUCKS, GEESE, AND SWANS

Anas platyrhynchos—mallard

WOOD WARBLERS AND ALLIES

PARULIDAE—WOOD-WARBLERS

Cardellina pusilla—Wilson's warbler
Oreothlypis celata—orange-crowned warbler
Setophaga petechia—yellow warbler

WOODPECKERS

PICIDAE—WOODPECKERS AND ALLIES

Colaptes auratus—northern flicker
Melanerpes formicivorus—acorn woodpecker
Dryobates nuttallii—Nuttall's woodpecker
Dryobates pubescens—downy woodpecker
Dryobates villosus—hairy woodpecker

WRENS

TROGLODYTIDAE—WRENS

Catherpes mexicanus—canyon wren
Thryomanes bewickii—Bewick's wren
Troglodytes aedon—house wren

WRENTITS

TIMALIIDAE—BABBLERS

Chamaea fasciata—wrentit

PARROTS

PSITTACIDAE—AFRICAN AND NEW WORLD PARROTS

* *Amazona viridigenalis*—red-crowned parrot

NEW WORLD SPARROWS

PASSERELLIDAE—NEW WORLD SPARROWS

Junco hyemalis—dark-eyed junco
Melospiza melodia—song sparrow
Melozone crissalis—California towhee
Pipilo maculatus—spotted towhee

MAMMAL

CANIDS

CANIDAE—WOLVES AND FOXES

Canis latrans—coyote

SQUIRRELS

SCIURIDAE—SQUIRRELS

Sciurus griseus—western gray squirrel
Spermophilus (Otospermophilus) beecheyi—California ground squirrel

UNGULATES

CERVIDAE—DEERS

Odocoileus hemionus—mule deer

REPTILE

LIZARDS

PHRYNOSOMATIDAE—IGUANID LIZARDS

Sceloporus occidentalis—western fence lizard
Uta stansburiana—common side-blotched lizard

ANGUIDAE—ALLIGATOR LIZARDS

Elgaria multicarinata—southern alligator lizard

INTENTIONALLY LEFT BLANK

APPENDIX G

Special-Status Plant Species with Recorded Occurrences in the Project Vicinity

INTENTIONALLY LEFT BLANK

APPENDIX G
Special-Status Plant Species with Recorded Occurrences in the Project Vicinity

Scientific Name	Common Name	Status[1] (Federal/State/CRPR)	Primary Habitat Associations/ Life Form/ Blooming Period/ Elevation Range (feet)	Potential to Occur
Arctostaphylos glandulosa ssp. *gabrielensis*	San Gabriel manzanita	None/None/1B.2	Chaparral (rocky)/perennial evergreen shrub/Mar/1950–4920	Not expected to occur. The Study Area is outside the range of the species.
Arenaria paludicola	marsh sandwort	FE/SE/1B.1	Marshes and swamps (freshwater or brackish); sandy, openings/perennial stoloniferous herb/May–Aug/5–560	Not expected to occur. Suitable associated habitat is not present in the Study Area.
Astragalus brauntonii	Braunton's milk-vetch	FE/None/1B.1	Chaparral, Coastal scrub, Valley and foothill grassland; recent burns or disturbed areas, usually sandstone with carbonate layers/perennial herb/Jan–Aug/10–2100	Low potential to occur. Marginal habitat (coastal scrub) is present, but the species distribution is very limited in the San Gabriel Mountains (Monrovia Canyon). The species was not observed during the focused special-status plant species surveys in the Study Area.
Astragalus pycnostachyus var. lanosissimus	Ventura marsh milk-vetch	FE/SE/1B.1	Coastal dunes, Coastal scrub, Marshes and swamps (edges, coastal salt or brackish)/perennial herb/(June)Aug–Oct/0–115	Not expected to occur. Marginal habitat is present (coastal sage scrub), but the species typically occurs closer to the coast and is currently only known from Ventura County. Los Angeles County occurrences believed to be extirpated.
Atriplex parishii	Parish's brittlescale	None/None/1B.1	Chenopod scrub, Playas, Vernal pools; alkaline/annual herb/June–Oct/80–6235	Not expected to occur. Suitable associated habitat is not present in the Study Area.
Atriplex serenana var. *davidsonii*	Davidson's saltscale	None/None/1B.2	Coastal bluff scrub, Coastal scrub; alkaline/annual herb/Apr–Oct/30–655	Not expected to occur. Marginal habitat (coastal scrub) is present, but Los Angeles County occurrences believed to be extirpated. Recent records (<50 years) are primarily closer to the coast or located in areas with alkaline soils.
Berberis nevinii	Nevin's barberry	FE/SE/1B.1	Chaparral, Cismontane woodland, Coastal scrub, Riparian scrub; sandy or gravelly/perennial evergreen shrub/(Feb)Mar–June/225–2705	Low potential to occur. Suitable associated habitat present and recent local records occur, but the conspicuous shrub was not observed during the focused special-status plant species survey in the Study Area.
Calochortus clavatus var. *gracilis*	slender mariposa lily	None/None/1B.2	Chaparral, Coastal scrub, Valley and foothill grassland/perennial bulbiferous herb/Mar–June(Nov)/1045–3280	Low potential to occur. Suitable associated habitat is present, but no records from within the Arroyo Seco watershed. The species was not observed during the focused special-status plant species surveys in the Study Area.

Scientific Name	Common Name	Status[1] (Federal/State/CRPR)	Primary Habitat Associations/ Life Form/ Blooming Period/ Elevation Range (feet)	Potential to Occur
Calochortus palmeri var. *palmeri*	Palmer's mariposa lily	None/None/1B.2	Chaparral, Lower montane coniferous forest, Meadows and seeps; mesic/perennial bulbiferous herb/Apr–July/2325–7840	Not expected to occur. Suitable associated habitat is not present and the Study Area is outside the elevation range of the species.
Calochortus striatus	alkali mariposa lily	None/None/1B.2	Chaparral, Chenopod scrub, Mojavean desert scrub, Meadows and seeps; alkaline, mesic/perennial bulbiferous herb/Apr–June/225–5235	Not expected to occur. Suitable associated habitat is not present and the Study Area is outside the range of the species (western Mojave Desert).
Calochortus weedii var. *intermedius*	intermediate mariposa lily	None/None/1B.2	Chaparral, Coastal scrub, Valley and foothill grassland; rocky, calcareous/perennial bulbiferous herb/May–July/340–2805	Low potential to occur. Marginal habitat (coastal scrub) is present, but the species has a single record from the San Gabriel Mountains. Records for the species are primarily associated with the Puente Hills, the Santa Ana Mountains, and the Perris Basin. The species was not observed during the focused special-status plant species surveys in the Study Area.
Calystegia felix	lucky morning-glory	None/None/1B.1	Meadows and seeps (sometimes alkaline), Riparian scrub (alluvial); historically associated with wetland and marshy places, but possibly in drier situations as well; possibly silty loam and alkaline/annual rhizomatous herb/Mar–Sep/95–705	Not expected to occur. Only one record within the last 100 years in Los Angeles County, with the remaining recent occurrences from Chino in San Bernardino County.
Castilleja gleasoni	Mt. Gleason paintbrush	None/SR/1B.2	Chaparral, Lower montane coniferous forest, Pinyon and juniper woodland; granitic/perennial herb (hemiparasitic)/May–June(Sep)/2180–7120	Not expected to occur. Suitable associated habitat is not present and the Study Area is outside the elevation range of the species.
Centromadia parryi ssp. *australis*	southern tarplant	None/None/1B.1	Marshes and swamps (margins), Valley and foothill grassland (vernally mesic), Vernal pools/annual herb/May–Nov/0–1575	Not expected to occur. Suitable associated habitat is not present in the Study Area.
Centromadia pungens ssp. *laevis*	smooth tarplant	None/None/1B.1	Chenopod scrub, Meadows and seeps, Playas, Riparian woodland, Valley and foothill grassland; alkaline/annual herb/Apr–Sep/0–2100	Low potential to occur. Marginal habitat is present (riparian woodland), but the species has only one historic record (>100 years) within the Los Angeles River watershed. The species was not observed during the focused special-status plant species surveys in the Study Area.

Scientific Name	Common Name	Status[1] (Federal/State/CRPR)	Primary Habitat Associations/ Life Form/ Blooming Period/ Elevation Range (feet)	Potential to Occur
Chorizanthe parryi var. *fernandina*	San Fernando Valley spineflower	FC/SE/1B.1	Coastal scrub (sandy), Valley and foothill grassland/annual herb/Apr–July/490–4005	Low potential to occur. Marginal habitat is present, but the species has no local records within the last 100 years. The species was not observed during the focused special-status plant species surveys in the Study Area.
Chorizanthe parryi var. *parryi*	Parry's spineflower	None/None/1B.1	Chaparral, Cismontane woodland, Coastal scrub, Valley and foothill grassland; sandy or rocky, openings/annual herb/Apr–June/900–4005	Low potential to occur. Suitable habitat (coastal scrub) is present and the species has a historical record (1919) upstream of the Study Area; however, the species was not observed during the focused special-status plant species surveys in the Study Area.
Cladium californicum	California sawgrass	None/None/2B.2	Meadows and seeps, Marshes and swamps Alkaline or Freshwater/perennial rhizomatous herb/June–Sep/195–5250	Not expected to occur. Suitable associated habitat is not present in the Study Area.
Cuscuta obtusiflora var. *glandulosa*	Peruvian dodder	None/None/2B.2	Marshes and swamps (freshwater)/annual vine (parasitic)/July–Oct/45–920	Not expected to occur. Suitable associated habitat is not present in the Study Area.
Dodecahema leptoceras	slender-horned spineflower	FE/SE/1B.1	Chaparral, Cismontane woodland, Coastal scrub (alluvial fan); sandy/annual herb/Apr–June/655–2495	Low potential to occur. Suitable associated habitat (coastal scrub) is present and the species has a historical record (1920) upstream of the Study Area; however, the focused special-status plant surveys were negative for the species in the Study Area.
Dudleya multicaulis	many-stemmed dudleya	None/None/1B.2	Chaparral, Coastal scrub, Valley and foothill grassland; often clay/perennial herb/Apr–July/45–2590	Not expected to occur. Suitable associated habitat (coastal scrub) is present, but the species has no records west of the San Gabriel River in the San Gabriel Mountains.
Galium grande	San Gabriel bedstraw	None/None/1B.2	Broadleafed upland forest, Chaparral, Cismontane woodland, Lower montane coniferous forest/perennial deciduous shrub/Jan–July/1390–4920	Not expected to occur. Suitable associated habitat is not present in the Study Area.
Helianthus nuttallii ssp. *parishii*	Los Angeles sunflower	None/None/1A	Marshes and swamps (coastal salt and freshwater)/perennial rhizomatous herb/Aug–Oct/30–5005	Not expected to occur. Suitable associated habitat is not present and the species is presumed extinct.

Scientific Name	Common Name	Status[1] (Federal/State/CRPR)	Primary Habitat Associations/ Life Form/ Blooming Period/ Elevation Range (feet)	Potential to Occur
Horkelia cuneata var. *puberula*	mesa horkelia	None/None/1B.1	Chaparral (maritime), Cismontane woodland, Coastal scrub; sandy or gravelly/perennial herb/Feb–July(Sep)/225–2655	Low potential to occur. Suitable associated habitat (coastal scrub) is present and the species has been previously found in the Study Area area, but the record is greater than 100 years old. The species was not observed during the focused special-status plant species surveys in the Study Area.
Imperata brevifolia	California satintail	None/None/2B.1	Chaparral, Coastal scrub, Mojavean desert scrub, Meadows and seeps (often alkali), Riparian scrub; mesic/perennial rhizomatous herb/Sep–May/0–3985	Low potential to occur. Suitable associated habitat (coastal) is present, but the species has only been found within the Big Tujunga Creek portion of the Los Angeles River watershed. The species was not observed during the focused special-status plant species surveys in the Study Area.
Lasthenia glabrata ssp. *coulteri*	Coulter's goldfields	None/None/1B.1	Marshes and swamps (coastal salt), Playas, Vernal pools/annual herb/Feb–June/0–4005	Not expected to occur. Suitable associated habitat is not present in the Study Area.
Linanthus concinnus	San Gabriel linanthus	None/None/1B.2	Chaparral, Lower montane coniferous forest, Upper montane coniferous forest; rocky, openings/annual herb/Apr–July/4985–9185	Not expected to occur. Suitable associated habitat is not present and the Study Area is outside the elevation range of the species.
Linanthus orcuttii	Orcutt's linanthus	None/None/1B.3	Chaparral, Lower montane coniferous forest, Pinyon and juniper woodland; openings/annual herb/May–June/3000–7035	Not expected to occur. Suitable associated habitat is not present and the Study Area is outside the elevation range of the species.
Lupinus peirsonii	Peirson's lupine	None/None/1B.3	Joshua tree woodland, Lower montane coniferous forest, Pinyon and juniper woodland, Upper montane coniferous forest; gravelly or rocky/perennial herb/Apr–June/3280–8200	Not expected to occur. Suitable associated habitat is not present and the Study Area is outside the elevation range of the species.
Malacothamnus davidsonii	Davidson's bush-mallow	None/None/1B.2	Chaparral, Cismontane woodland, Coastal scrub, Riparian woodland/perennial deciduous shrub/June–Jan/605–3740	Low potential to occur. Suitable habitat is present (coastal scrub), but the conspicuous shrub was not observed during the focused special-status plant species surveys in the Study Area.
Nasturtium gambelii	Gambel's water cress	FE/ST/1B.1	Marshes and swamps (freshwater or brackish)/perennial rhizomatous herb/Apr–Oct/15–1085	Not expected to occur. Suitable associated habitat is not present in the Study Area.
Navarretia prostrata	prostrate vernal pool navarretia	None/None/1B.1	Coastal scrub, Meadows and seeps, Valley and foothill grassland (alkaline), Vernal pools; Mesic/annual herb/Apr–July/5–3970	Not expected to occur. The species is almost exclusively associated with vernal pools in southern California, which are not found onsite.

Scientific Name	Common Name	Status[1] (Federal/State/CRPR)	Primary Habitat Associations/ Life Form/ Blooming Period/ Elevation Range (feet)	Potential to Occur
Opuntia basilaris var. *brachyclada*	short-joint beavertail	None/None/1B.2	Chaparral, Joshua tree woodland, Mojavean desert scrub, Pinyon and juniper woodland/perennial stem succulent/Apr–June(Aug)/1390–5905	Not expected to occur. Suitable associated habitat is not present and the Study Area is outside the range of the species (northern slopes of the San Gabriel and San Bernardino mountains.
Orobanche valida ssp. *valida*	Rock Creek broomrape	None/None/1B.2	Chaparral, Pinyon and juniper woodland; granitic/perennial herb (parasitic)/May–Sep/4100–6560	Not expected to occur. Suitable associated habitat is not present and the Study Area is outside the elevation range of the species.
Phacelia stellaris	Brand's star phacelia	None/None/1B.1	Coastal dunes, Coastal scrub/annual herb/Mar–June/0–1310	Not expected to occur. Suitable associated habitat (coastal scrub) is present, but the species is only known from one record in the Los Angeles River watershed (Downey) and no records less than 75 years old in Los Angeles County.
Pseudognaphalium leucocephalum	white rabbit-tobacco	None/None/2B.2	Chaparral, Cismontane woodland, Coastal scrub, Riparian woodland; sandy, gravelly/perennial herb/(July)Aug–Nov(Dec)/0–6890	Low potential to occur. Suitable habitat (coastal scrub and riparian woodland) is present, but the species has only one record within the last 75 year within the Los Angeles River watershed (Big Tujunga Creek). The species was not observed during the focused special-status plant species surveys in the Study Area.
Quercus dumosa	Nuttall's scrub oak	None/None/1B.1	Closed-cone coniferous forest, Chaparral, Coastal scrub; sandy, clay loam/perennial evergreen shrub/Feb–Apr(May–Aug)/45–1310	Low potential to occur. Suitable habitat (coastal scrub) is present, but the conspicuous shrub was not observed during the focused special-status plant species surveys in the Study Area.
Ribes divaricatum var. *parishii*	Parish's gooseberry	None/None/1A	Riparian woodland/perennial deciduous shrub/Feb–Apr/210–985	Not expected to occur. Suitable habitat (riparian woodland) is present, but the species is presumed extinct.
Scutellaria bolanderi ssp. *austromontana*	southern mountains skullcap	None/None/1B.2	Chaparral, Cismontane woodland, Lower montane coniferous forest; mesic/perennial rhizomatous herb/June–Aug/1390–6560	Not expected to occur. Suitable associated habitat is not present in the Study Area.
Sidalcea neomexicana	salt spring checkerbloom	None/None/2B.2	Chaparral, Coastal scrub, Lower montane coniferous forest, Mojavean desert scrub, Playas; alkaline, mesic/perennial herb/Mar–June/45–5020	Not expected to occur. Suitable soil conditions are not present in the Study Area.
Spermolepis lateriflora	western bristly scaleseed	None/None/2A	Sonoran desert scrub; Rocky or sandy/annual herb/Mar–Apr/1195–2200	Not expected to occur. Suitable associated habitat is not present in the Study Area.

Scientific Name	Common Name	Status[1] (Federal/State/CRPR)	Primary Habitat Associations/ Life Form/ Blooming Period/ Elevation Range (feet)	Potential to Occur
Symphyotrichum defoliatum	San Bernardino aster	None/None/1B.2	Cismontane woodland, Coastal scrub, Lower montane coniferous forest, Meadows and seeps, Marshes and swamps, Valley and foothill grassland (vernally mesic); near ditches, streams, springs/perennial rhizomatous herb/July–Nov(Dec)/5–6695	Low potential to occur. Suitable habitat (coastal scrub and streams) is present, but the species has no records within the last 100 year within the Los Angeles River watershed. The species was not observed during the focused special-status plant species surveys in the Study Area.
Symphyotrichum greatae	Greata's aster	None/None/1B.3	Broadleafed upland forest, Chaparral, Cismontane woodland, Lower montane coniferous forest, Riparian woodland; mesic/perennial rhizomatous herb/June–Oct/980–6595	Low potential to occur. Suitable habitat (riparian woodland) is present in Area 2 and there a recent (1991) local records upstream of the Study Area; however, the species was not observed during the focused special-status plant species surveys in the Study Area.
Thelypteris puberula var. *sonorensis*	Sonoran maiden fern	None/None/2B.2	Meadows and seeps (seeps and streams)/perennial rhizomatous herb/Jan–Sep/160–2000	Low potential to occur. Suitable habitat is present (streams) and there is a local record from 1967; however, the species was not observed during the focused special-status plant species surveys in the Study Area.

Notes:

[1] Status abbreviations:

FE: Federally Endangered

FT: Federally Threatened

SE: State Endangered

SR: State Rare

ST: State Threatened

CRPR: California Rare Plant Rank

1A: Plants presumed extirpated in California and either rare or extinct elsewhere

1B: Plants rare, threatened, or endangered in California and elsewhere

2A: Plants presumed extirpated in California but common elsewhere

2B: Plants rare, threatened, or endangered in California but more common elsewhere

Special-Status Wildlife Species with Recorded Occurrences in the Project Vicinity

INTENTIONALLY LEFT BLANK

APPENDIX H
Special-Status Wildlife Species with Recorded Occurrences in the Project Vicinity

Scientific Name	Common Name	Status[1] (Federal/State)	Habitat[1]	Potential to Occur
Fish				
Catostomus santaanae	Santa Ana sucker	FT/None	Small, shallow, cool, clear streams less than 7 meters (23 feet) in width and a few centimeters to more than a meter (1.5 inches to more than 3 feet) in depth; substrates are generally coarse gravel, rubble, and boulder	Not expected to occur on the Study Area or upstream and downstream from the Study Area. Suitable associated habitat is present and the Santa Ana sucker was historically documented throughout the upper and lower areas of the Los Angeles River watershed including the main stem Los Angeles River near Universal City and Los Feliz Boulevard and the tributaries Big Tujunga Creek and Arroyo Seco Creek. However, the species has been extirpated throughout most of this watershed.[2] The species was not found during previous surveys conducted downstream from Devil's Gate Dam in the Arroyo Seco and Los Angeles River to the Pacific Ocean.[3]
Gila orcuttii	arroyo chub	None/SSC	Warm, fluctuating streams with slow-moving or backwater sections of warm to cool streams at depths >40 centimeters (16 inches); substrates of sand or mud	Not expected to occur on the Study Area or upstream and downstream from the Study Area. Marginal habitat is present and the species was reintroduced to the Arroyo Seco below Devil's Gate Dam on August 25, 2008[4], but this species was not observed during fish-focused surveys conducted in 2012.[3] It is believed that the heavy sediment flow produced by rains following the Station Fire in 2009, which burned most of the watershed of the Arroyo Seco in the San Gabriel Mountains, may have removed the transplanted population[5]. Focused surveys for the species were negative in 2019.

Scientific Name	Common Name	Status[1] (Federal/State)	Habitat[1]	Potential to Occur
Oncorhynchus mykiss irideus pop. 10	steelhead - southern California DPS	FE/None	Clean, clear, cool, well-oxygenated streams; needs relatively deep pools in migration and gravelly substrate to spawn	Not expected to occur on the Study Area or downstream from the Study Area. Suitable associated habitat is present and the Arroyo Seco supports rainbow trout (*O. mykiss*) within the upper portions of the watershed, but historic stocking of Arroyo Seco with hatchery-raised rainbow trout by CDFW occurred; hence, there is some debate as to whether some of the trout seen in these currently landlocked areas are descendants of anadromous native *O. mykiss*.[6]. A recent genetic study of *O. mykiss* in southern California found that most populations have substantial genetic lineage from introduced hatchery rainbow trout, representing almost complete introgression or replacement of native fish by introduced hatchery trout.[7] Among the populations in tributaries of rivers that run through the highly urbanized areas of Southern California, only three groups of populations contained significant evidence of native coastal steelhead ancestry: (1) populations from the San Gabriel River system, (2) Coldwater Canyon in the Santa Ana River, and (3) the San Luis Rey River; however, tissue sample were not collected from the Arroyo Seco, with only Santa Anita Creek (located 10 miles from the Study Area) representing the Los Angeles River watershed. The individuals from Santa Anita Creek had genetics that corresponded to rainbow trout raised at the Mount Whitney Fish Hatchery. Access to the Study Area from downstream waters is blocked by impassable barriers (e.g., Devil's Gate Dam, built in 1920) of various types along the Los Angeles River and Arroyo Seco. The species was not found during previous surveys conducted downstream from Devil's Gate Dam in the Arroyo Seco and Los Angeles River to the Pacific Ocean.[3] Focused surveys for the species were negative in 2019.

Scientific Name	Common Name	Status[1] (Federal/State)	Habitat[1]	Potential to Occur
Rhinichthys osculus ssp. 3	Santa Ana speckled dace	None/SSC	Headwaters of the Santa Ana and San Gabriel Rivers; may be extirpated from the Los Angeles River system	Not expected to occur on the Study Area or upstream and downstream from the Study Area. Suitable associated habitat is present and the species historically inhabited streams in the upland areas of the Santa Ana, San Gabriel and Los Angeles rivers systems, but have since been extirpated from many parts of their range, including the middle reaches of the Santa Ana River, Strawberry Creek (Santa Ana River), Mill Creek (Santa Ana River), and most of the Los Angeles River (except Big Tujunga Creek) and San Jacinto River basins.[8] The species was not found during previous surveys conducted downstream from Devil's Gate Dam in the Arroyo Seco and Los Angeles River to the Pacific Ocean.[3]
Amphibians				
Anaxyrus californicus	arroyo toad	FE/SSC	Semi-arid areas near washes, sandy riverbanks, riparian areas, palm oasis, Joshua tree, mixed chaparral and sagebrush; stream channels for breeding (typically third order); adjacent stream terraces and uplands for foraging and wintering	Not expected to occur on the Study Area or upstream and downstream from the Study Area. Marginal habitat is present and there is anecdotal evidence of arroyo toads along a small tributary of Arroyo Seco above Devil's Gate Reservoir in 1996 and in or near the settling ponds in the main channel above Devil's Gate Dam in 1997 and 1998[9]. The USFWS included this portion of the Arroyo Seco in the 2001 designation of critical habitat but it was not included in the 2005 revised designation of critical habitat, as there had been no sightings of the species since 1998. The population that historically occurred at this location are considered extirpated due to the loss of habitat and the introduction of predators and competitors [10]. Protocol surveys for the species conducted in 2013 for the Study Area were negative.[11] Focused surveys for the species were negative in 2019.

Scientific Name	Common Name	Status[1] (Federal/State)	Habitat[1]	Potential to Occur
Rana draytonii	California red-legged frog	FT/SSC	Lowland streams, wetlands, riparian woodlands, livestock ponds; dense, shrubby or emergent vegetation associated with deep, still or slow-moving water; uses adjacent uplands	Not expected to occur on the Study Area or upstream and downstream from the Study Area. Marginal habitat is present and the species was historically abundant in the Los Angeles River watershed, including Arroyo Seco, but it is considered extirpated from the system due to the loss of habitat and the introduction of predators and competitors.[12] Protocol surveys for the species conducted in 2013 for the Study Area were negative.[11] Focused surveys for the species were negative in 2019.
Rana muscosa	mountain yellow-legged frog	FE/SE, WL	Lakes, ponds, meadow streams, isolated pools, and open riverbanks; rocky canyons in narrow canyons and in chaparral	Not expected to occur on the Study Area or upstream and downstream from the Study Area. Marginal habitat is present and the species was historically known from the Arroyo Seco watershed, but those populations are considered extirpated.[13] Additionally, the Arroyo Seco watershed was not included in the San Gabriel Mountains Management Unit as described in the USFWS prepared recovery plan for the species.[14] Protocol surveys for the species conducted in 2013 for the Study Area were negative.[11]
Taricha torosa	California newt	None/SSC	Wet forests, oak forests, chaparral, and rolling grassland	Present. The species was observed during surveys for the Study Area in 2013 in the Arroyo Seco, suitable habitat is present within Area 2, and the species could be encountered on the access road to Area 2.
Reptiles				
Emys marmorata	western pond turtle	None/SSC	Slow-moving permanent or intermittent streams, ponds, small lakes, and reservoirs with emergent basking sites; adjacent uplands used for nesting and during winter	Low potential to occur on the Study Area and upstream. Not expected to occur downstream from the Study Area. There is marginal habitat present and the species was historically known from the Arroyo Seco, but the last available record of the species is from 1971 and the species may be extirpated from the watershed.[1]
Anniella stebbinsi	southern California legless lizard	None/SSC	Coastal dunes, stabilized dunes, beaches, dry washes, valley–foothill, chaparral, and scrubs; pine, oak, and riparian woodlands; associated with sparse vegetation and moist sandy or loose, loamy soils	Previously observed and assumed to be present. There are five recent (2017 and 2018) records[1] in the Study Area and adjacent areas of Hahamonga Park. Suitable habitat is present within Area 2 and Area 3, and it could be encountered on the access road to Area 2.

Scientific Name	Common Name	Status[1] (Federal/State)	Habitat[1]	Potential to Occur
Arizona elegans occidentalis	California glossy snake	None/SSC	Arid scrub, rocky washes, grasslands, chaparral. Appears to prefer microhabitats of open areas and areas with soil loose enough for easy burrowing.	Low potential to occur. Marginal associated habitat is present in Area 3, but there are few recent records of the species in Los Angeles County.[1]
Aspidoscelis tigris stejnegeri	coastal whiptail	None/SSC	Hot and dry areas with sparse foliage, including chaparral, woodland, and riparian areas.	Previously observed and assumed to be present. The species was observed during the 2013 surveys for the Study Area and suitable habitat for the species occurs throughout the Study Area and surrounding area.
Phrynosoma blainvillii	Blainville's horned lizard	None/SSC	Open areas of sandy soil in valleys, foothills, and semi-arid mountains including coastal scrub, chaparral, valley–foothill hardwood, conifer, riparian, pine–cypress, juniper, and annual grassland habitats	Low potential to occur. While suitable habitat for the species occurs in Area 3 and along the access road to Area 1 and Area 2, the high level of human activity and vehicle traffic has likely negatively affected the presence of the species in the area due to direct impacts or the introduction of non-native ants
Thamnophis hammondii	two-striped gartersnake	None/SSC	Streams, creeks, pools, streams with rocky beds, ponds, lakes, vernal pools	Previously observed and assumed to be present. The species was observed during the 2013 surveys for the Study Area and suitable habitat for the species occurs throughout the Study Area and surrounding area.
Birds				
Athene cunicularia (burrow sites & some wintering sites)	burrowing owl	BCC/SSC	Nests and forages in grassland, open scrub, and agriculture, particularly with ground squirrel burrows	Low potential to occur. There is marginal associated habitat species and there is only one wintering record for the species within Hahamonga Watershed Park[15].
Buteo swainsoni (nesting)	Swainson's hawk	BCC/ST	Nests in open woodland and savanna, riparian, and in isolated large trees; forages in nearby grasslands and agricultural areas such as wheat and alfalfa fields and pasture	Not expected to occur (nesting). Suitable associated nesting habitat for the species does not occur in the Study Area or within the immediate vicinity. Species may be transient in the Study Area vicinity during migration.
Coccyzus americanus occidentalis (nesting)	western yellow-billed cuckoo	FT, BCC/SE	Inhabits extensive deciduous riparian thickets or forests, with dense, low-level understory foliage, and abuts slow-moving watercourses, backwaters, or seeps; willow usually a dominant component of the vegetation; densely foliaged, deciduous trees and shrubs, especially willows, required for roosting/nesting sites	Not expected to occur. Suitable associated nesting habitat for the species does not occur in the Study Area or within the immediate vicinity. The species is a rare visitor to Los Angeles County

Scientific Name	Common Name	Status[1] (Federal/State)	Habitat[1]	Potential to Occur
Coturnicops noveboracensis	yellow rail	BCC/SSC	Nesting requires wet marsh/sedge meadows or coastal marshes with wet soil and shallow, standing water	Not expected to occur. Suitable associated nesting and foraging habitat for the species does not occur in the Study Area or within the immediate vicinity.
Cypseloides niger (nesting)	black swift	BCC/SSC	Nests in moist crevices, caves, and cliffs behind or adjacent to waterfalls in deep canyons; forages over a wide range of habitats	Not expected to occur. Suitable associated nesting habitat for the species does not occur in the Study Area or within the immediate vicinity.
Empidonax traillii extimus (nesting)	southwestern willow flycatcher	FE/SE	Nests in dense riparian habitats along streams, reservoirs, or wetlands; uses variety of riparian and shrubland habitats during migration	Not expected to occur. Marginal nesting habitat for the species does occur in the Study Area; however, the protocol survey for the species was negative for the Study Area.
Falco peregrinus anatum (nesting)	American peregrine falcon	FDL, BCC/FP, SDL	Nests on cliffs, buildings, and bridges; forages in wetlands, riparian, meadows, croplands, especially where waterfowl are present	Not expected to occur. Suitable associated nesting habitat for the species does not occur in the Study Area or within the immediate vicinity.
Polioptila californica californica	coastal California gnatcatcher	FT/SSC	Nests and forages in various sage scrub communities, often dominated by California sagebrush and buckwheat; generally avoids nesting in areas with a slope of greater than 40%; majority of nesting at less than 1,000 feet above mean sea level	Not expected to occur. Marginal associated habitat for the species is present in Area 3, but the species does not have any records in the Study Area or at Hahamonga Watershed Park and it has few records from the southern slopes of the San Gabriel Mountains.[1, 15] Protocol surveys for the species were conducted for the Devil's Gate Reservoir Sediment Removal Project located just to the south of the Study Area and the surveys were negative for the species.[16]
Riparia riparia (nesting)	bank swallow	None/ST	Nests in riparian, lacustrine, and coastal areas with vertical banks, bluffs, and cliffs with sandy soils; open country and water during migration	Not expected to occur. Suitable nesting habitat for the species does not occur in the Study Area or within the immediate vicinity.
Setophaga petechia (nesting)	yellow warbler	None/SSC	Riparian plant associations in close proximity to water. Also nests in montane shrubbery in open conifer forests in Cascades and Sierra Nevada. Frequently found nesting and foraging in willow shrubs and thickets, and in other riparian plants including cottonwoods, sycamores, ash, and alders.	Present. Observed during the surveys in the Study Area near Area 2.

Scientific Name	Common Name	Status[1] (Federal/State)	Habitat[1]	Potential to Occur
Vireo bellii pusillus (nesting)	least Bell's vireo	FE/SE	Nests and forages in low, dense riparian thickets along water or along dry parts of intermittent streams; forages in riparian and adjacent shrubland late in nesting season	Not expected to occur. Suitable nesting habitat for the species does occur in the Study Area; however, the focused survey for the species was negative for the Study Area.
Mammals				
Antrozous pallidus	pallid bat	None/SSC	Grasslands, shrublands, woodlands, forests; day roosts are in caves, crevices, mines, and occasionally in hollow trees and buildings; night roosts may be in more open sites, such as porches and open buildings; few hibernation and maternity sites are known, but probably uses rock crevices	Low potential to occur. Suitable associated day/night roosts and foraging habitat for the individuals of the species occurs within the Study Area, but hibernation and maternity sites are not expected to occur.
Corynorhinus townsendii	Townsend's big-eared bat	None/SSC	Mesic habitats characterized by coniferous and deciduous forests and riparian habitat, but also xeric areas; requires caves, mines, tunnels, buildings, or other human-made structures for day and night roosting; hibernation sites are cold, but not below freezing; maternity roosts are found in caves, tunnels, mines, and buildings	Low potential to occur. Suitable associated day/night roosts and foraging habitat for the individuals of the species occurs within the Study Area, but hibernation and maternity sites are not expected to occur.
Eumops perotis californicus	western mastiff bat	None/SSC	Chaparral, coastal and desert scrub, coniferous and deciduous forest and woodland; day and night roosts in crevices in rocky canyons and cliffs where the canyon or cliff is vertical or nearly vertical, trees, and tunnels; nursery roosts described as tight rock crevices	Low potential to occur. Suitable associated day/night roosts and foraging habitat for the individuals of the species occurs within the Study Area, but hibernation and maternity sites are not expected to occur.
Lasionycteris noctivagans	silver-haired bat	None/None	Primarily a coastal and montane forest dweller; hibernates in hollow trees, rock crevices, buildings, mines, caves, and under sloughing bark; forages in or near coniferous or mixed deciduous forest, stream or river drainages; females may form nursery colonies or occur as solitary individuals in dense foliage or hollow trees	Low potential to occur. Suitable associated day/night roosting, hibernation roosting, and foraging habitat for the individuals of the species occurs within the Study Area; however, there are few records of the species from southern California, with most occurring in the Sierra Nevada and Cascade ranges.[1]

Scientific Name	Common Name	Status[1] (Federal/State)	Habitat[1]	Potential to Occur
Lasiurus blossevillii	western red bat	None/SSC	Roosting habitat includes forests and woodlands from sea level up through mixed conifer forests; feeds over a wide variety of habitats including grasslands, shrublands, open woodlands and forests, and croplands; day/night/maternal roosts primarily in trees, less often in shrubs and are often in edge habitats adjacent to streams, fields, or urban areas; usually solitary, although nursery colonies occasionally are found	Low potential to occur. Suitable associated day/night roosts, maternity roosts, and foraging habitat for the individuals of the species occurs within the Study Area; however, there are few records of the species from the San Gabriel Mountains.[1]
Lasiurus cinereus	hoary bat	None/None	Forest, woodland riparian, and wetland habitats; also juniper scrub, riparian forest, and desert scrub in arid areas; generally roosts in dense foliage of medium to large trees; preferred sites are hidden from above, with few branches below, and have ground cover of low reflectivity; females and young tend to roost at higher sites in trees	Medium potential to occur. Suitable associated day/night roosting, maternity roosts, and foraging habitat for the individuals of the species occurs within the Study Area, and there are records of the species from other watersheds within the San Gabriel Mountains that have similar habitat as the Arroyo Seco.[1]
Lasiurus xanthinus	western yellow bat	None/SSC	Valley–foothill riparian, desert riparian, desert wash, and palm oasis habitats; below 2,000 feet above mean sea level; day/night roosts in riparian trees and palms; may form small maternity groups in trees and palms	Low potential to occur. Suitable associated day/night roosts, maternity roosts, and foraging habitat for the individuals of the species occurs within the Study Area; however, there are few records of the species from the San Gabriel Mountains.[1]
Lepus californicus bennettii	San Diego black-tailed jackrabbit	None/SSC	Arid habitats with open ground; grasslands, coastal scrub, agriculture, disturbed areas, and rangelands	Low potential to occur. Area 3 has suitable, open habitat for the species, but the species few records from the vicinity.[1]
Macrotus californicus	Californian leaf-nosed bat	None/SSC	Riparian woodlands, desert wash, desert scrub; day/night roosts in mines and caves, occasionally buildings and bridges; maternity colonies found in tunnels and caves	Low potential to occur. Suitable associated day/night roosts and foraging habitat for the individuals of the species occurs within the Study Area, but maternity roosts habitat is not present. Former populations have disappeared from coastal basins, from Los Angeles to San Diego.[17]
Microtus californicus stephensi	south coast marsh vole	None/SSC	Tidal marshes along the coast	Not expected to occur on the Study Area or upstream and downstream from the Study Area. Suitable associated habitat is not present in the Study Area, upstream, or downstream of the Study Area.

Scientific Name	Common Name	Status[1] (Federal/State)	Habitat[1]	Potential to Occur
Neotoma lepida intermedia	San Diego desert woodrat	None/SSC	Coastal scrub, desert scrub, chaparral, cacti, rocky areas	Low potential to occur. Marginal habitat is located within the Study Area, but the species is expected to occur in the uplands areas of the Arroyo Seco Canyon slopes within rocky areas or densely vegetated areas.
Nyctinomops macrotis	big free-tailed bat	None/SSC	Rocky areas; roosts in caves, holes in trees, buildings, and crevices on cliffs and rocky outcrops; forages over water; probably does not breed in California. In other areas, small nursery colonies are formed in rocky crevices in high cliffs.	Low potential to occur. Suitable associated day/night roosts and foraging habitat for the individuals of the species occurs within the Study Area, but maternity roosts habitat is not present.
Onychomys torridus ramona	southern grasshopper mouse	None/SSC	Common in arid desert habitats of the Mojave Desert and southern Central Valley of California. Alkali desert scrub and desert scrub habitats are preferred, with somewhat lower densities expected in other desert habitats, including succulent shrub, wash, and riparian areas. Also occurs in coastal scrub, mixed chaparral, sagebrush, low sage, and bitterbrush habitats. Uncommon in valley foothill and montane riparian, and in a variety of other habitats.	Low potential to occur. Marginal habitat is located within the Study Area within Area 3; however there are few records of this species the Los Angeles Basin.[1]

1 INTRODUCTION

This protected tree report provides an inventory and evaluation of the protected trees located on the Arroyo Seco Canyon Project Areas 2 and 3 (project). The project site is located in the City of Pasadena, California (Figure 1). As such, this protected tree report covers the regulations and requirements for the protection and removal of protected trees within the jurisdiction of the City of Pasadena (City).

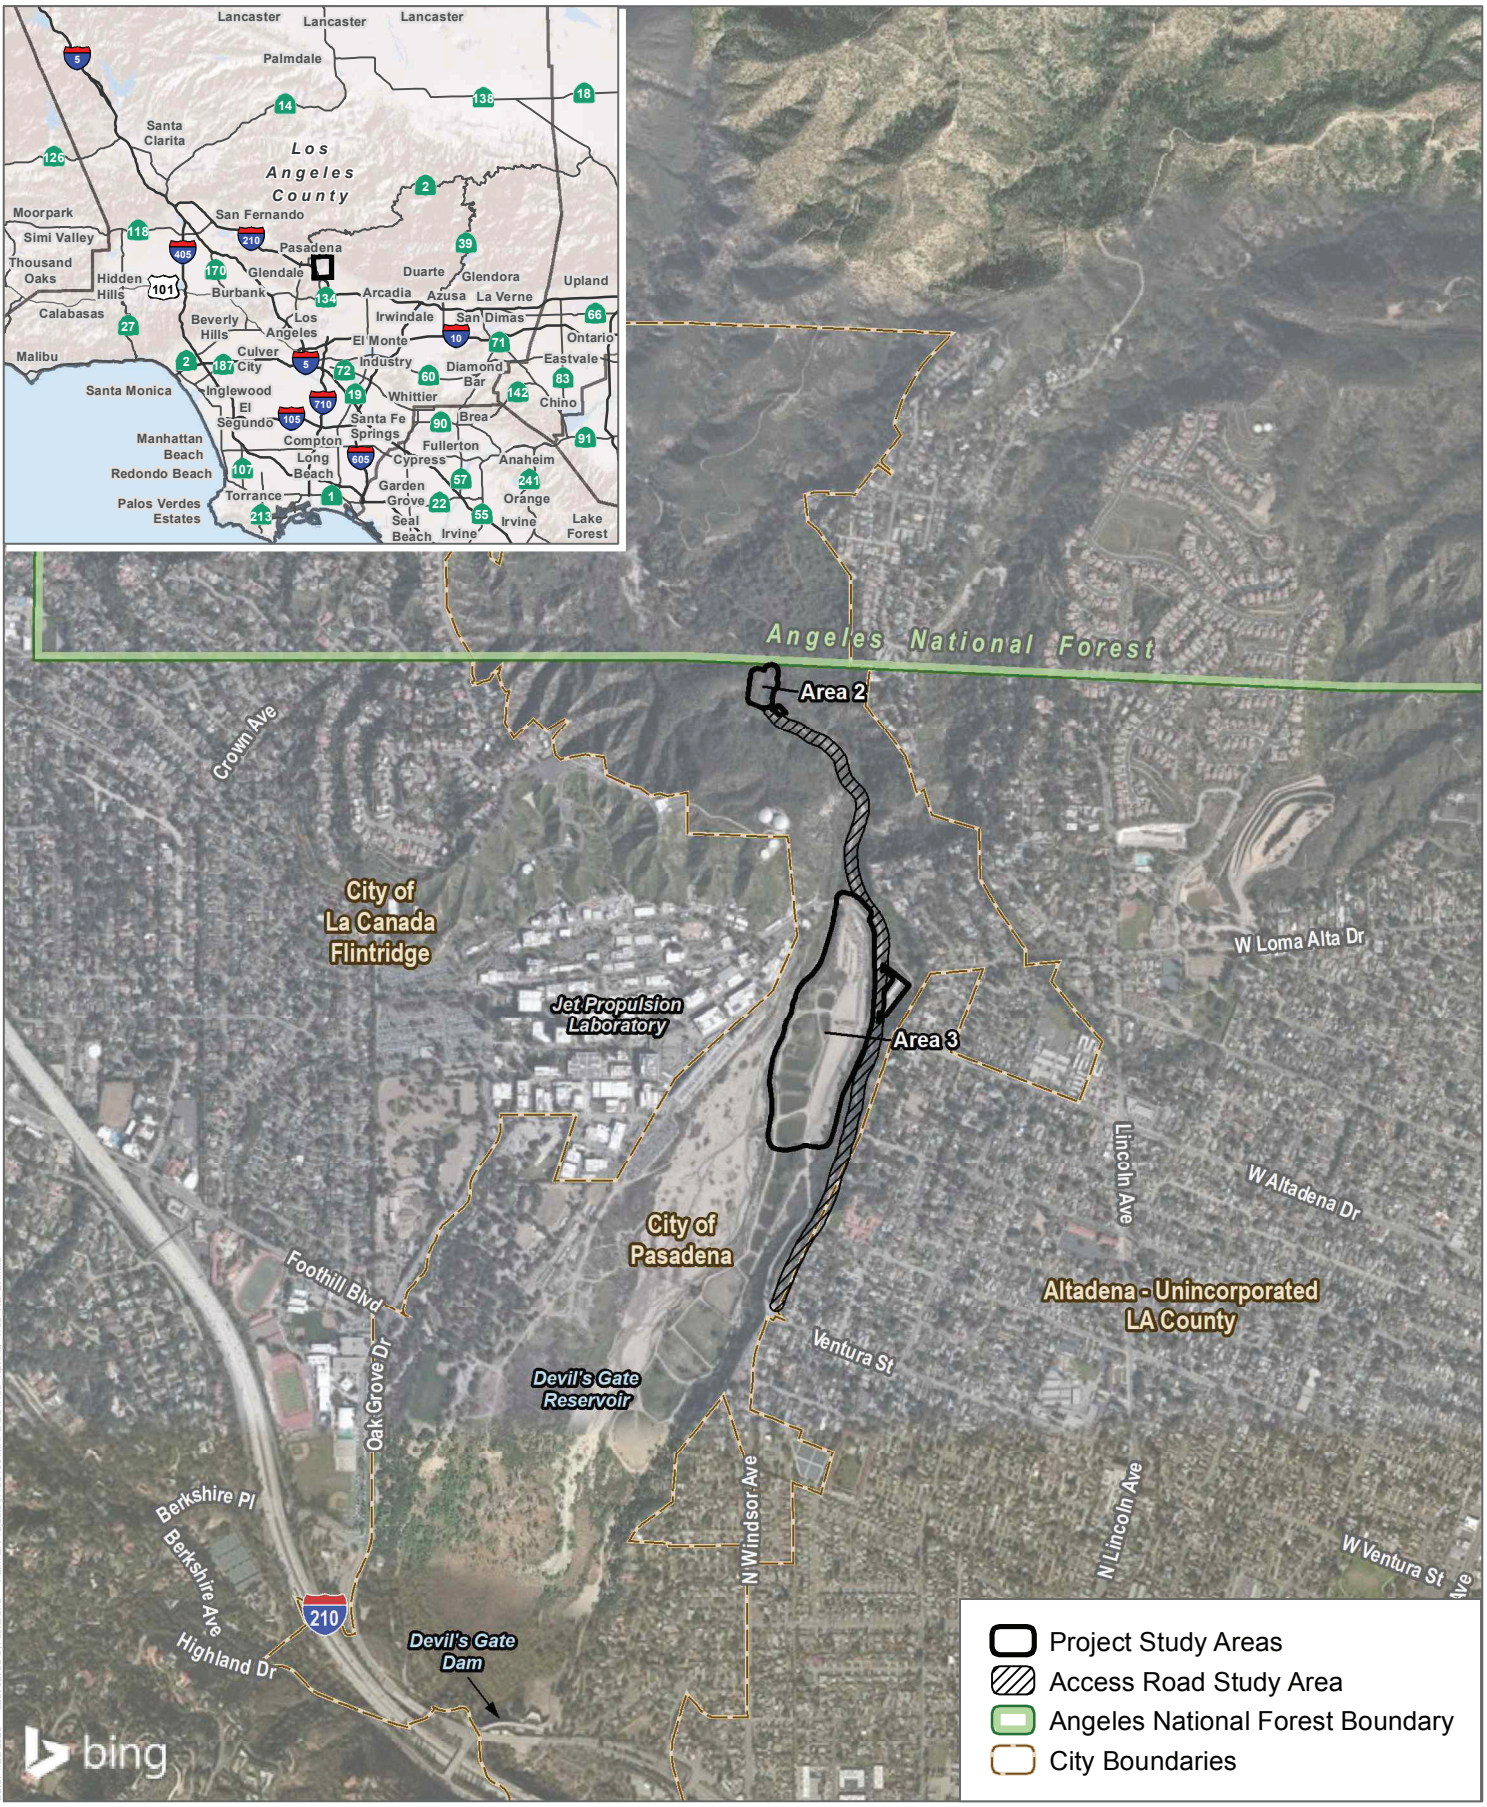
The City retained Dudek to conduct a tree inventory and assessment for the project site. The project site includes Area 2, Diversion and Intake Replacement and Area 3, Spreading Basin Improvements, which are connected by the North Arroyo Boulevard (i.e. Gabrielino Trail/Access Road). A Dudek International Society of Arboriculture (ISA)-Certified Arborist performed various functions associated with surveying, inventorying, and evaluating the condition of all protected trees located within the project site to meet the requirements of the municipal code Chapter 8.52 – City Trees and Tree Protection. This protected tree report addresses protected and non-protected trees.

The purpose of this protected tree report is to present the physical characteristics and mapped locations of the site's protected trees that are to be removed or protected in place during the proposed grading and construction-related activities, which are limited to Areas 2 and 3 of the project site. No earthmoving is anticipated to occur within the Gabrielino Trail/Access Road or the staging areas.

1.1 Project Location

The project site is located in the City within the Arroyo Seco Canyon at 3420 and 3500 Arroyo Seco Road, City of Pasadena. The project site is located in within Township 1 and 2 North, Range 12 West, of the Pasadena, California 7.5-minute USGS quadrangle. As shown on Figure 1, Explorer Road provides vehicular access to the southernmost boundary of Area 3 (approximately 0.3-mile from the intersection of Windsor Avenue and Ventura Street) and continues northward along the eastern boundary of Area 3. Area 2 is located approximately 0.34-mile north of Area 3, and just south of the boundary of the Angeles National Forest. The project site lies within Los Angeles County, just east of the City of La Canada Flintridge and west of the City of Altadena.

1.2 Site Characteristics



The project site has one paved access road on the south end of the property that extends into the spreading basin. The site continues further along the Gabrielino Trail on the north end of the property. The remaining land within the project site is best characterized as undeveloped native riparian land consisting of native tree species.

1.3 Project Description

The project site consists of two primary areas, as shown on Figure 1, Local Vicinity and Regional Location, including Area 2, Diversion and Intake Replacement and Area 3, Spreading Basin Improvements, which are connected by the North Arroyo Boulevard (i.e., Gabrielino Trail/Access Road). The proposed project involves construction activity and facility improvements in Areas 2 and 3, as well as construction truck traffic along portions of the Gabrielino Trail/Access Road. The former Travelling Screen and Chlorine Building (Screen Building) adjacent to Area 2 and the Behner Water Treatment Plant adjacent to Area 3 would be used for temporary construction materials and equipment staging only.

Improvements in Area 2 include the demolition and removal of the existing diversion weir and intake structure, and construction of a new diversion weir/intake structure that would allow for the diversion of up to 25 cubic feet per second (cfs) of flows from the Arroyo Seco for conveyance into the spreading basins in Area 3. Improvements in Area 3 include the reconfiguration and expansion of the spreading basins in order to accommodate the increased diversion of creek flows for infiltration into the Raymond Basin.

2 METHODS

2.1 Individual Tree Evaluation

Dudek mapped tree locations for all trees located on the project site. Tree mapping was conducted using a Trimble Pathfinder Pro XH GPS receiver with H-Star Technology. Since tree canopies can sometimes cause loss of satellite lock by blocking the line-of-sight to satellites, an electronic compass and reflectorless, electronic distance-measuring device were also used in mapping tree locations. The reflectorless, electronic distance-measuring device/compass combination operates in concert with the Pathfinder system to position offsets, and offset information is automatically attached to the GPS position data string. The electronic tree locations were then evaluated using ArcView 10.4 software to determine the position of the trees related to the project development footprint.

All inventoried and assessed protected trees were tagged with an aluminum tag bearing a unique identification number, which was placed on the trunk of each tree. These numbers correspond to the tree attribute information presented in Appendix A, Tree Information Matrix. Tree trunk diameters were measured using a diameter tape providing adjusted figures[1] for diameter measurements when wrapping the tape around an object's circumference. Diameter measurements were taken using protocol provided by the Council of Tree and Landscape Appraisers in the Guide for Plant Appraisal (ISA 2000). The trunk diameter measurement of each tree was taken at 4.5 feet above the ground along the trunk axis, with common exceptions. For example, in cases where a tree's trunk was located on a slope, the 4.5-foot distance was approximated as the average of the shortest and longest sides of the trunk (i.e., the uphill side and downhill side of a tree's trunk, respectively), and the measurement was made at this point. Tree height was visually estimated by experienced tree surveyors. Tree canopy diameters were typically estimated by "pacing-off" the measurement based on the investigator's knowledge of their stride length or by visually estimating the canopy width. The crown diameter measurements were made along an imaginary line intersecting the tree trunk that best approximated the average canopy diameter. Additionally, Dudek arborists calculated composite trunk diameters for multiple-stem trees according to ISA standards. According to these standards, the sum of all stem diameters was calculated to ascertain composite trunk diameter values for multiple-stem trees.

Pursuant to the Guide for Plant Appraisal (ISA 2000), tree health and structure were evaluated with respect to five distinct tree components: roots, trunk, scaffold branches, small branches, and foliage. Each component of the tree was assessed with regard to health factors such as insect and pathogen damage, mechanical damage, presence of decay, presence of wilted or dead leaves, and wound closure. Tree health and structure were graded as good, fair, poor, and dead, with "good" representing no apparent problems, and "dead" representing a dying and/or dead tree. Good

[1] Inches divided by 3.14 (π) provide diameter measurement in inches.

condition trees exhibit acceptable vigor, healthy foliage, and adequate structure, and lack any major maladies. Fair condition trees are typically those with few maladies but declining vigor. This method of tree condition rating is comprehensive and results in ratings that are useful for determining the status of trees based on common urban forestry standards.

Individual tree attribute data is presented in Appendix A, and protected tree locations are presented in Appendix B, Protected Tree Locations and Proposed Impacts Exhibit. Representative protected tree photographs are presented in Appendix C.

2.2 Tree Impact Analysis

Dudek's ISA-certified arborists determined tree impacts by conducting a spatial analysis of individual tree locations and canopy extents visible in project site aerial imagery in relation to the proposed development plan. The tree dataset, digital aerial imagery, and site development planning data were evaluated using geographic information system (GIS) software to determine where individual trees were located in relation to proposed development areas. Trees are considered impacted when anticipated disturbance to the tree is either 5 feet outside the dripline, or 15 feet from the trunks of a tree, whichever distance is greater. Trees with project-related construction activity occurring within their driplines are considered encroached upon for the purposes of this report. The impact analysis results were used to determine overall tree impacts for the project site.

2.3 Scope of Work Limitations

No root crown excavations or investigations, internal probing, or aerial canopy inspections were performed during the tree assessments. Therefore, the presence or absence of internal decay or other hidden or inaccessible inferiorities in individual trees could not be confirmed. It is recommended that any large tree proposed for preservation or relocation in an urban setting be thoroughly inspected for internal or subterranean decay by a qualified arborist before finalizing preservation or relocation plans.

3 OBSERVATIONS

3.1 Individual Trees

A total of 93 City-protected trees were inventoried within biological study areas for Areas 2 and 3. No tree in the project area meets the City definition of a "Landmark tree".

- A total of 49 protected trees were identified within Area 2.
- A total of 44 protected trees were identified within Area 3.

Appendix B presents the location of the individual trees mapped and assessed for the proposed project. Overall, the trees exhibit growth and structural conditions that are typical of their location in a native riparian watershed setting prone to drought and wildfires. The trees include various trunk and branch maladies and health and structural conditions. As presented in Appendix A, 34% of the individually mapped trees (32 trees) exhibit good health; 64% (59 trees) are in fair health; 2% (2 trees) are in poor health. Structurally, 5% (5 trees) of the individually mapped trees are considered to exhibit good structure, 88% (82 trees) exhibit fair structure, 7% (6 trees) poor structure. The trees in good condition exhibit acceptable vigor, healthy foliage, and adequate structure, and lack any major maladies. Trees in fair condition are typical, with few maladies but declining vigor. Trees in poor condition exhibit declining vigor, unhealthy foliage, poor branch structure, and excessive lean. No pests or pathogens were observed on site.

Trees within biological study areas for Areas 2 and 3 vary in size and stature according to species and available growing space. The site's trees are composed of single- and multi-stemmed trees, with single-stemmed trunk diameters that range from 1 to 70 inches, and multi-stemmed trunk diameters that range from 9 to 135 inches. Tree heights vary from 12 to 60 feet. Tree canopy extents range from 9 feet to approximately 50 feet.

INTENTIONALLY LEFT BLANK

4 REGULATORY DEFINITIONS AND REQUIREMENTS

A tree inventory and assessment of the project site was performed pursuant to City municipal code Chapter 8.52 – City Trees and Tree Protection. The following is an outline of the key aspects of the ordinance.

4.1 Definitions

Municipal Code Chapter 8.52.020 – City Trees and Tree Protection

For this project, trees subject to City permit requirements include those defined by municipal code Chapter 8.52.020, as follows:

- "Public tree" means a tree located in a place or area under ownership or control of the city including but without limitation streets, parkways, open space, parkland and including city owned property under the operational control of another entity by virtue of a lease, license, operating or other agreement.

- "Protected tree" means a native, specimen, landmark, landmark-eligible, mature (except for the trees in RS or RM-12 zones), or public tree.

For the purposes of this report, all trees are located in a City owned property, and therefor meet the definition of a “Public tree”, which are considered a “Protected tree” by the City Municipal Code. Determining tree impacts, trees that have protected zones that have been encroached upon would also be considered impacted. The tree protection zone is considered the area within the dripline of a tree and extending from there to a point at least five feet outside the dripline, or 15 feet from the trunks of a tree, whichever distance is greater.

4.2 Regulations

City of Pasadena – City Trees and Tree Protection

The City’s, City Trees and Tree Protection municipal code was in part established to:

- Preserve and grow Pasadena's canopy cover by protecting landmark, native and specimen trees on specified areas of private property and expanding the protection of street trees and trees on public property.
- Safeguard the City's urban forest by providing for the regulation of the protection, planting, maintenance and removal of trees in the city.
- Protect the visual and aesthetic character of the city.

- Improve and enhance property values by conserving and adding to the distinctive and unique aesthetic character of the many areas of Pasadena.
- Improve the quality of life for residents, visitors and wildlife.
- Create favorable conditions for the protection of designated landmark, native and specimen trees, for the benefit of current and future residents of Pasadena.
- Maintain and enhance the general health, safety and welfare of the city and its residents by assisting in counteracting air pollution and in minimizing soil erosion and other related environmental damage.
- Protect and maintain healthy trees in the land use planning processes as set forth herein.
- Establish procedures and practices for fulfilling the purposes of this city tree and tree protection ordinance.

Under the City municipal code, "No permits will be issued to any person or entity for pruning or removal of public trees, and all pruning and removal of public trees shall be undertaken by employees or contractors of the city pursuant to Section 8.52.080."

5 IMPACTS

Tree impacts were determined using GIS software and spatial locations of trees relative to the project's impact areas (development footprint). Impacts were further determined based on Dudek's experience with native and non-native trees and their typical reactions to root disturbances from construction activities, such as soil compaction, excavation, and grading. The impact analysis results presented herein were used for developing appropriate mitigation measures for the proposed project.

For the purposes of this report, direct impacts to trees can be classified as a removal or encroachment. Trees are identified for removal when they are located within the permanent impact boundary, as shown in Appendix B, which presents the location of the individual trees mapped and assessed for the proposed project. Trees are identified as encroachment if the tree canopy is within 5' of the permanent impact boundary, or if the tree trunk is within 15' of the permanent impact boundary. Direct impacts to encroachment trees include root damage, soil excavation and compaction, grade changes, loss of canopy, and trunk wounds, among others.

In general, there is a great deal of variation in tolerance to construction impacts among tree species, ages, and conditions. It is important to know how a certain tree, based on its species, age, and condition, would respond to different types of disturbance. The trees on the project site are of varying ages and conditions. Mature specimens are typically more sensitive to root disturbance and grade changes. In general, healthy trees will respond better to changes in their growing environment. Trees of poor health or stressed conditions may not be vigorous enough to cope with direct or indirect impacts from construction activities.

Impact totals presented are based on conceptual disturbance limits and development plans as of the date of this report. As such, the actual number of trees subject to direct impacts may change as the detailed site planning process proceeds. Actual tree impact numbers may be lower than anticipated and as presented in this report once detailed plans are developed. Measures to reduce impacts are encouraged and would be implemented in the field during grading operations. Following completion of construction-related disturbances, actual protected tree impact totals would be updated and provided, along with revised mitigation totals.

5.1 Direct Tree Impacts

For the purposes of this protected tree report, direct impacts are those associated with tree removal or earth-moving encroachment activities within the tree-protected zone (canopy dripline plus 5 feet or 15 feet from trunk, whichever is greater). Tree removal is expected to be required when the trunk is located inside the permanent impact boundary. Encroachment is expected when soil and roots are disturbed within the tree protected zone. Table 1 summarizes the number of trees by species that are expected to be directly impacted by construction.

Direct tree impacts would result in the removal of 19 protected trees in total, of which all are located in Area 2. A total of 15 protected trees are expected to be encroached upon (11 trees in Area 2 and 4 trees in Area 3). No trees are anticipated to be removed in Area 3. The locations of impacted trees are presented by impact type on the map in Appendix B. Measures to minimize the extent of impacts to encroached trees are provided in Chapter 6, Tree Protection Measures.

Table 1
Summary of Direct Tree Impacts in Area 2

Species		Protected Trees	
Scientific Name	*Common Name*	*Removal*	*Encroachment*
Alnus rhombifolia	white alder	15	5
Platanus racemosa	Ca. sycamore	0	2
Populus trichocarpa	black cottonwood	0	1
Quercus agrifolia	coast live oak	3	2
Quercus chrysolepis	canyon live oak	0	1
Salix nigra	black willow	1	0
	Total	**19**	**11**

Table 2
Summary of Direct Tree Impacts in Area 3

Species		Protected Trees	
Scientific Name	*Common Name*	*Removal*	*Encroachment*
Platanus racemosa	Ca. sycamore	0	1
Quercus agrifolia	coast live oak	0	3
	Total	**0**	**4**

INTENTIONALLY LEFT BLANK

6 TREE PROTECTION MEASURES

A total of 15 protected trees located on the project site are anticipated to be encroached upon and have direct impacts from construction-related activities. As such, tree protection is required for those trees that would have encroachment, in accordance with section 8.52 of the Pasadena Municipal Code, Tree Protection Ordinance. Construction related activities should be monitored by a qualified certified arborist to ensure tree protection measures are followed, and assess tree impacts.

Other trees on the project site are located within the temporary construction zone (see Appendix B), and indirect impacts to trees may result from changes to the site that may cause tree decline, even when the tree is not directly injured. Indirect impacts include potential damage due to temporary staging of equipment. Any additional City-protected tree that is within the Project's study area and is not identified as a removal or encroachment should follow the tree protection standards of the City's Tree Protection Ordinance.

INTENTIONALLY LEFT BLANK

7 CONCLUSION

The project site contains 93 protected trees, of which 49 are in Area 2, and 44 in Area 3. A total of 19 protected trees will be removed due to project implementation, all of which are located within Area 2. According to the City Tree Protection Ordinance, replacement totals for removed trees are determined by the "tree replacement matrix", which means the table of requirements for replanting replacement trees on private property when removing protected trees. As the City's Tree Protection Ordinance does not dictate a replacement ratio for removed 'public trees', the tree replacement requirement and the approved tree replacement ratio is at the discretion of the City and subject to a final tree impact analysis. As such, the final tree numbers associated with tree replacement may vary from that presented in this tree inventory and assessment.

15 trees will have encroachment (11 in Area 2, and 4 in Area 3). All protected trees not removed should be subject to the tree protection standards of the City's Tree Protection Ordinance. Construction related activities around the 15 encroachment trees should be monitored by a qualified certified arborist to ensure tree protection measures are followed, and to assess tree impacts.

INTENTIONALLY LEFT BLANK

8 ARBORIST'S DISCLOSURE STATEMENT

This oak tree report provides conclusions and recommendations based only on a visual examination of the trees and surrounding site by an ISA-certified arborist and reasonable reliance on the completeness and accuracy of the information provided to the arborist. The examination did not include subterranean or internal examination of the trees.

Arborists are tree specialists who use their education, knowledge, training, and experience to examine trees; recommend measures to enhance the beauty and health of trees; and attempt to reduce the risk of living near them. Although trees provide many benefits to those who live near them, they also include inherent risks from breakage or failure that can be minimized but not eliminated.

Arborists cannot detect every condition that could possibly lead to the failure of a tree. Trees are living organisms subject to attack by disease, insects, fungi, weather, and other forces of nature, and conditions that lead to failure are often hidden within trees and belowground. There are some inherent risks with trees that cannot be predicted with any degree of certainty, even by a skilled and experienced arborist. Arborists cannot predict acts of nature, including, without limitation, storms of sufficient strength, which can cause an apparently healthy tree to fail. Additionally, arborists cannot guarantee that a tree will be healthy or safe under all circumstances or for any specific period of time. A tree's condition could change over a short or long period of time due to climatic, cultural, and/or environmental conditions. Further, there is no guaranty or certainty that recommendations or efforts to correct unsafe conditions will prevent future breakage or failure of a tree.

To live or work near trees is to accept some degree of risk. Neither the author of this oak tree report nor Dudek assume any responsibility for or will be liable for any claims, losses, or damages for damage to any tree, death or injury to any person, or any loss of or damage to any personal or real property.

Arroyo Seco Canyon Diversions
Biological Impacts Memorandum

INTENTIONALLY LEFT BLANK

MEMORANDUM

November 8, 2018

To:
Elisa Ventura, PE, Principal Engineer
Pasadena Water and Power

From:
Marc T. Blain
Senior Project Manager

Subject: Arroyo Seco Canyon Diversions Biological Impacts Memorandum

---

The purpose of this Memorandum is to describe methods and results of an analysis of the potential impacts on biological resources in the Upper Arroyo Seco, including the Devil's Gate Reservoir (Reservoir) area that may result from proposed water diversions associated with the implementation of the Pasadena Water and Power (PWP) proposed Arroyo Seco Canyon Project (ASCP). The ASCP would repair, replace and/or rehabilitate the diversion and intake structures in the Arroyo Seco in order to maximize the capture of PWP's surface water rights. The improvements, including a new sedimentation basin in the vicinity of the spreading basins, would facilitate management of sediment for diversion and spreading operations that were in the past managed with a headworks structure and settling basins further upstream. The ASCP also includes the expansion of PWP's spreading basins. The facilities and improvements that would be constructed as part of the ASCP would be located at three areas along the Arroyo Seco: Area 1 – Arroyo Seco Headworks; Area 2 – Arroyo Seco Intake; and Area 3 – Former PL Jet Propulsion Laboratory (JPL) East Parking Lot/Spreading Basins.

This Memorandum includes: (1) a summary of ASCP activities in the upper Arroyo Seco; (2) a description of current biological conditions in the study area; (3) background information on the biology and ecology of the dominant vegetation in the study area; (4) a summary of the findings of the recent Hydraulic, Sediment Transport, and Groundwater Analysis of the study area prepared by Psomas and included as Appendix A; (5) a summary of the methods and results of an ecological modeling study prepared by Southern California Coastal Water Research Project and included as Appendix B; (6) an analysis of the potential effect Project diversions may have on downstream vegetation communities and habitat; and (7) potential mitigation options with associated cost estimates to reduce diversion impacts.

PROJECT DESCRIPTION

PWP currently operates several structures in the upper Arroyo Seco Canyon that capture and convey water to a series of groundwater recharge (spreading) basins that are located along the eastern boundary of Devil's Gate Reservoir. The City of Pasadena (City) owns the right to divert up to 25 cubic feet per second (cfs) of surface water into their spreading basins, but heavy rain events in 2010 and 2011 washed down excessive amounts of sediment from the watershed that was destabilized due to the 2009 Station Fire. These debris flows damaged the diversion structure and prevented the City from diverting their allowed surface water rights into their spreading basins.

As a result, PWP proposes to repair and replace damaged facilities in the upper Arroyo Seco Canyon as a part of the ASCP. The improvements will allow for increased utilization of the City's surface water rights from the Arroyo Seco and maximize the beneficial use of this historically important local water resource. Specifically, modifications to the facilities in Area 2 will allow for increased diversion by capturing stream flows during storm events that in the past have been bypassed.

The proposed new diversion structure would capture all flows during small storm events and dry weather flows in the Arroyo Seco and would also capture up to PWP's surface water rights during large storm events. During larger storms when the water is too turbid (i.e. flows generally above 100 cfs), the stream with its associated sediment load would bypass the diversion structure and continue downstream to Devil's Gate Reservoir. Operations during high flows would be facilitated by the adjustable height weir or crest gate. At low flows, the gate would start in the 'up' position and as flows increase, the gate would be lowered to maintain a constant water surface level in the diversion pool (a pool created behind weir to allow for elevation appropriate to flow into diversion intake). When the gate is fully lowered, flows would entirely bypass the diversion structure and carry sediment downstream unabated.

PROJECT LOCATION

The survey area for this Memorandum includes a portion of the upper Arroyo Seco from Devil's Gate Dam extending upstream to the existing diversion weir and intake structure (to be replaced as part of the ASCP). The survey area is located in the City of Pasadena, in Hahamongna Watershed Park, south and east of the JPL (see Exhibit 1, Study Area).

EXISTING CONDITIONS

Climate and Hydrology

The Arroyo Seco upstream of the diversion weir is a perennial stream that contains surface water flow throughout the year. Currently, the City captures most dry season (approximately May through October) surface flows in the intake structure and transports this water to spreading basins that are located along the eastern boundary of Devil's Gate Reservoir. Wooden boards are placed in the diversion weir to direct flowing water into the intake structure. A small amount of water (e.g. less than 0.1 cfs) passes around the wooden boards and some limited pooling is often visible in the stream extending approximately 350 linear feet downstream of the diversion weir where a wooden A-frame bridge crosses over the stream. The stream gradient is generally flat immediately upstream of the bridge. There is a concrete footing for the bridge in the stream and downstream of that footing, there is an immediate four-foot drop in elevation of the stream bottom. This footing impedes the flow of water during the dry season, so that any surface flows do not generally extend past the bridge during the dry season.

The survey area is in a region that is subject to a Mediterranean climate, characterized by warm, dry summers and mild winters with intermittent rain that falls from November through April, usually peaking from December through March. Therefore, the region is subject to long periods without precipitation followed by wet winter months. In addition to significant variability in rainfall within any given year, rainfall amounts vary significantly from year to year. As shown in Table 1, total annual rainfall in recent years has ranged from as little as 6.24 inches in the 2006-2007 water year to 56.47 inches in the 2004-2005 water year.

The extreme range in rainfall totals results in wide variations in the amount of surface flows in the Arroyo Seco. For example, the monthly rainfall for Pasadena in January 2005 was 15.89 inches, which resulted in a mean stream flow in the Arroyo Seco of 268 cfs (Psomas 2018). That January 2005 data in the context of the mean monthly stream flow for Arroyo Seco in January (19.6 cfs), February (31.6 cfs), and March (25.8 cfs) is illustrative of the wide range of stream flows in the wet season months. Notably, the mean stream flow in the peak of the dry season (July through October) averaged less than 2.0 cfs.

Source: WRCC 2018. Rainfall totals provided in inches

During the wet periods or during episodic storms, surface water will flow from the upper Arroyo Seco into Devil's Gate Reservoir. Ongoing surface flows from the Arroyo Seco will result in standing water in the Reservoir. A review of historic aerial photos from Google Earth shows at least some surface water in the lower portion of the Reservoir in May 2003, January 2005, November 2005, March 2006, October 2007, January 2008, November 2009, and March 2011. Surface water is not observed in aerial photos subsequent to 2011, which corresponds to the severe drought conditions experienced in California from 2011 through 2016.

As the Arroyo Seco flows in a southerly direction past the existing diversion weir and past the JPL bridge, the channel morphology changes from a narrow canyon to a wide alluvial plain. During high flow periods, surface flows can reach the Devil's Gate Reservoir area, but at other times, water quickly infiltrates into the sandy sediment at the uppermost portion of the Reservoir. Therefore, a lack of observed surface water doesn't necessarily correlate to insufficient moisture within the substrate for the riparian vegetation in the Reservoir.

Existing Vegetation

The dominant vegetation community in the survey area is Black Willow Series, in which Goodding's black willow (*Salix gooddingii*) is the dominant species (Chambers Group 2010). Other native species associated with this vegetation community in the survey area include mule fat (*Baccharis salicifolia*), Fremont cottonwood (*Populus fremontii*), black cottonwood (*Populus trichocarpa*), and red willow (*Salix laevigata*). Non-native species such as gum trees (*Eucalyptus* sp.) and tree tobacco (*Nicotiana glauca*) were also observed. This vegetation type occurs throughout the lower portion of Devil's Gate Reservoir, correlated with the wettest conditions observed in the aerial photo analysis described above.

In somewhat drier areas in the upper Reservoir, a patchy distribution of mule fat scrub occurs intermixed with areas of unvegetated wash (Chambers 2010). These patches consist of dense stands of mule fat with occasional willow trees. Other species observed in these patches are various herbaceous non-native species such as Italian thistle (*Carduus pycnocephalus*), poison hemlock (*Conium maculatum*), and short-pod mustard (*Hirschfeldia incana*).

Further upstream, at the transition area from the narrow Arroyo Seco Creek to the wide alluvial system of Devil's Gate Reservoir (near the JPL bridge), the habitat consists of California sycamore woodland (BonTerra Psomas 2017). This vegetation community consists of California sycamore (*Platanus racemosa*) with occasional white alder (*Alnus rhombifolia*) and mule fat.

Continuing upstream, the vegetation is generally dominated by coast live oak (*Quercus agrifolia*) with patches of mule fat and occasional California sycamores. Immediately downstream of the diversion weir, vegetation is dominated by a mix of California sycamores and white alders with occasional Goodding's black willows and arroyo willows (*Salix lasiolepis*) (BonTerra Psomas 2014). Understory vegetation downstream of the diversion weir consists of riparian species such as tall umbrella sedge (*Cyperus eragrostis*), crofton weed (*Ageratina adenophora*), and water cress (*Nasturtium officinale*). As stream conditions become drier downstream of the existing diversion weir, understory vegetation is dominated by upland species such as smilo grass (*Stipa miliacea*) and poison oak (*Toxicodendron diversilobum*).

In general, the spatial distribution of vegetation in the study area is correlated to the hydrology of the area. Modest dry season surface flows occur immediately downstream of the diversion weir, which encourages establishment of facultative wetland species such as California sycamore and white alder (Lichvar and Kartesz 2009). As less water is available further downstream in the dry season, the vegetation is dominated by upland-riparian transitional species, such as mule fat and coast live oak. The greatest density and extent of facultative wetland species such as Goodding's black willow occurs in the downstream portion of Devil's Gate Reservoir, where Devil's Gate Dam blocks surface and subsurface flows, resulting in more available water to vegetation behind the Dam. No obligate wetland vegetation species (species that require wetlands) were described in the Chambers (2010) report, which is consistent with the highly variable surface flows that occur in the study area.

SPECIES BACKGROUND INFORMATION

Plant Species

Vegetation in the study area generally varies from facultative wetland plant species that can occur in perennially wet to intermittently wet areas, to drier species that are adapted to intermittent or ephemerally flowing water and/or to upland conditions. This section summarizes the general characteristics of the dominant facultative wetland species in the study area, as these are assumed to be the most sensitive to changes in the hydrological regime.

Goodding's Black Willow

Goodding's black willow is a phreatophyte, in other words, a deep-rooted species that is adapted to absorbing available groundwater for survival (Bush et al 1992). It is a deciduous tree species that is common to riparian areas throughout the southwestern United States (Hatch 2007). Goodding's black willow is a fast-growing species with a life span of approximately 50 years (Karrenberg et al 2002). They produce small wind-dispersed seeds that are short-lived (Stella et al 2006) and germinate within hours of landing (Karrenberg et al 2002). Peak seed production for this species occurs from April to July (Boland 2014). Seed germination requires moist sand that has some sun exposure, though long-term inundation of an area will greatly reduce seed germination (Tallent-Halsell and Walker 2002). Goodding's black willow is a potentially deep-rooted species with a maximum rooting depth of approximately seven feet (Stromberg 2013).

Fremont Cottonwood

Fremont cottonwood is a deep-rooted phreatophyte tree that is one of the most common trees in riparian areas of central and southern California (Hatch 2007). It is a fast-growing, deciduous tree that can grow up to 60 feet in height and has a life span of up to 130 years. Reproduction is similar to willows in that Fremont cottonwoods produce large amounts of small wind-dispersed seeds that are short-lived and typically germinate within 24 to 48 hours of landing on suitable sites (Fenner et al 1984). Seeds are covered with tiny hairs that aid in wind dispersal and allow them to float on water. Peak seed production for this species occurs in the later winter and early spring from February to April (Fenner et al 1984). Fremont cottonwood root depth is similar to Goodding's black willow potentially reaching seven feet below grade (Stromberg 2013).

Wildlife Species

Riparian habitats in southern California provide essential refuge, food, and water for a wide variety of wildlife. Certain species, such as the song sparrow (*Melospiza melodia*), are obligate riparian species and require riparian zones for their life cycle. Riparian zones are characterized by a unique set of physical ecological factors in comparison to the surrounding regional landscape (Gregory et al. 1991). Ecological factors inherent to riparian zones include flooding, rich soils, a water table within reach of plant roots (discussed further in the Impact of Diversions on Vegetation/Habitat section below); and fluvial events such as sediment transport, scouring, and channel movement (Griggs 2009). Species that require riparian zones for any portion of their life cycle are adapted to the associated fluvial events. The dynamic nature of riparian zones due to fluvial events disrupts habitat structure; therefore, various structural forms such as forest, woodland, shrubland, meadow and grassland, evolve over time. The heterogeneity of riparian zones creates many habitat features, and in turn, they support a greater diversity of wildlife than any other habitat type (Smith 1980). Riparian zones also function as important migration routes for many species.

Special status bird species that may potentially breed in riparian habitats in the Project's zone of influence include the State and federally-listed Endangered southwestern willow flycatcher (*Empidonax traillii extimus*) and least Bell's vireo (*Vireo bellii pusillus*); the yellow-breasted chat (*Icteria virens*), a California Species of Special Concern; and the yellow warbler (*Setophaga petechia*) a California Species of Special Concern. Non-special status bird species that may occur for breeding in the riparian habitats include the red-shouldered hawk (*Buteo lineatus*), red-tailed hawk (*Buteo jamaicensis*), cooper's hawk (*Accipiter cooperii*), warbling vireo (*Vireo gilvus*), common yellowthroat (*Geothlypis trichas*), and song sparrow among others. Preserving habitat for Endangered species has an indirect effect of preserving habitat for a host of other species that utilize the same habitat. In the study area, the least Bell's vireo, a State and federally-listed Endangered species, has been documented. Due to its regulatory status and its use as the key species for the ecological modeling (discussed in the Ecological Modeling Study section below), a detailed description of the vireo's life history, habitat requirements, and the study area's potential for supporting the vireo are discussed below.

Least Bell's Vireo

Bell's vireo is a Neotropical migrant that breeds in central and southwestern North America from northern Mexico to Southern California, Nevada, and Utah; east to Louisiana; and north to North Dakota, Wisconsin, and Indiana in the central United States (AOU 1998). There are four recognized subspecies of Bell's vireo (*Vireo bellii*) including *V. b. belli*; V. *b. medius*; *V. b. arizonae*; and *V. b. pusillus*, the least Bell's vireo (AOU 1998). Of the four Bell's vireo subspecies, only two breed in California: the least Bell's vireo and the Arizona Bell's vireo which breeds in the Colorado River Valley (Garrett and Dunn 1981; Rosenberg et al. 1991). The least Bell's vireo breeds in cismontane southern California and on the western edge of the deserts (Garrett and Dunn 1981). This subspecies winters in southern Baja California, and on the Pacific slope of mainland Mexico from Sonora south through northern Nicaragua (Brown 1993), and on the Atlantic slope from Veracruz Mexico south to Honduras (AOU 1998). The least Bell's vireo is a federally and State-listed Endangered Species. On February 2, 1994, the USFWS issued their final determination of critical habitat for the least Bell's vireo (USFWS 1994), identifying approximately 37,560 acres as critical habitat in Santa Barbara, Ventura, Los Angeles, San Bernardino, Riverside, and San Diego counties. These areas account for nearly 49 percent of the least Bell's vireo population in the United States (USFWS 1994). The Project area is not located in the designated critical habitat area for this species.

The least Bell's vireo population has increased tenfold from 291 territories in the early 1980s to an estimated 2,968 territories 35 years later (USFWS 2006). After a decade or more of absence in Los Angeles County, the least Bell's vireo returned by the mid-1980s with a pair reported from Whittier Narrows in 1985 and 1986 (Long 1993). Numbers of least Bell's vireo have continued to increase since that time, and it is now known to occur at several other locations in Los Angeles County such as the San Fernando (Van Norman) Dam; the San Gabriel River at Fish Canyon and Van Tassel Canyon; the Sepulveda Basin Wildlife Area; and the Castaic Lagoon Recreation Area (CDFW 2018). The two largest populations in the county are at Hansen Dam in the northeastern corner of the San Fernando Valley where 44 least Bell's vireo territories were present in 2009 (Griffith Wildlife Biology 2009) and on the Santa Clara River from I-5 downstream to the Las Brisas Bridge where 56 least Bell's vireo territories were present in 2007 (Bloom Biological, Inc. 2007).

This small olive-gray passerine occurs in riparian habitats. Breeding habitat consists of willow riparian woodland dominated by willows (*Salix* spp.), with western sycamore (*Platanus racemosa*), and cottonwoods (*Populus* spp.), with dense understory vegetation. Understory shrubs such as mule fat (*Baccharis salisifolia*) and California rose (*Rosa californica*) are often a component of the understory (Goldwasser 1981). The least Bell's vireo generally nests in early successional stages of riparian habitats, with nest sites predominantly located in willows, and more specifically willows that are between four and ten feet high (Franzreb 1989). The most critical factor in breeding habitat structure is the presence of a dense understory shrub layer from approximately two to ten feet above ground (Goldwasser 1981; Salata 1983; Franzreb 1989). The least Bell's vireo arrives on its breeding grounds mid-March with males arriving slightly before females (Barlow 1962; Brown 1993; Nolan 1960). Most individuals depart breeding grounds by September (Brown 1993). The vireo shows a high degree of site fidelity[1] (Greaves 1987). This species has two broods per season and its territory size is approximately 0.5-4.2 acres (Franzreb 1989). Nests are constructed from grass, plant fibers, leaves, paper, and strips of park fashioned with spider silk and lined with fine grass, down, and hair and are shaped like an open bag or basket (Barlow 1962; Nolan 1960). Nests are suspended from a fork in a low branch of a tree or shrub (Barlow 1962; Nolan 1960). Insects and spiders comprise 99 percent of the Bell's vireo diet, but some fruit may be taken after July (Barlow 1962; Brown 1993; Nolan 1960).

Conditions suitable for this species are present in riparian vegetation in the study area within the Devil's Gate Reservoir. Least Bell's vireo has been detected in the Reservoir during 2013 focused surveys for the Devil's Gate Sediment Removal Project, and by civilian birders in 2017 and 2018 (Chambers Group 2013; eBird 2018). During the 2013 focused surveys, one un-pared male was detected singing frequently, apparently defending a territory, on April 29, May 23, June 5, and 17. In 2017, one observation was reported to eBird on April 1 (no details given in the observation). Two least Bell's vireo, thought to be the same bird, were reported from the Reservoir in 2018 by the same individual (eBird 2018). On July 1, 2018 a singing male was recorded and uploaded to eBird; and on August 12, 2018 recordings of a singing male and multiple photographs showing the vireo clearly were uploaded (eBird 2018). No nesting in the Arroyo Seco has been documented to date.

The least Bell's vireo observations that include location data (2013 and August 2018 observations) place them in the black willow woodland within the Devil's Gate Reservoir within 0.5 miles of the Devil's Gate Dam, south of the Project area (see Exhibit 2, Modeled Change in Maximum Inundation Due to Proposed Project). The description of the black willow woodland from 2013 describes this area as containing large and small patches of black willow dominant habitat with mule fat, Fremont cottonwood (*Populus fremontii*), black cottonwood (*Populus trichocarpa*), white alder (*Alnus rhombifolia*), red alder (*Alnus rubra*), red willow (*Salix laevigata*) gum (*Eucalyptus* sp.), and tree tobacco (*Nicotiana glouca*) (Chambers Group 2013). It is also noted that portions of this community are lacking secondary structure (dense understory) due to unstable sediment accumulation and subsequent scouring from storm events (Chambers Group 2013). The July 2018 observer noted that the vireo was observed in a fairly open willow forest containing cottonwoods and eucalyptus, with a thick weedy understory about 3-6 feet high. This description is consistent with the breeding habitat requirements for the vireo as described above.

Upstream of the diversion point, potentially suitable habitat for the southwestern willow flycatcher and least Bell's vireo occurs in the arroyo willow thickets, arroyo willow thickets/mule fat thickets, and mule fat thickets habitat types. Focused surveys for the flycatcher and vireo have been negative to date in this area (BonTerra Consulting 2013, BonTerra Psomas 2016).

[1] Site fidelity refers to the tendency to return each season to the same nest site or breeding colony.

A drastic change in the Arroyo Seco habitat occurred as storms washed down large volumes of sediment from the canyon after the 2009 Station Fire, as is evidenced from historical aerial imagery. Sediment was deposited in the stream and washed down and settled in the Reservoir just above the Dam (refer to the 2014 Biological Technical Report for the Arroyo Seco Canyon Project for Area locations). Riparian habitat in these areas was knocked down or covered by sediment effectively removing the habitat over large areas. Habitat is slowly recovering, although, in the Reservoir large patches of low stature vegetation, free of mature willows are still visible.

The least Bell's vireo observations in the Reservoir occurred after this sediment inundation and associated habitat degradation. Although no pairing of vireo has been detected, it is not conclusive that breeding has not occurred. The least Bell's vireo is notoriously cryptic when breeding, and a female may have gone undetected. Additionally, multiple vireo were detected recently (2017 and 2018) in nearby Eaton Canyon approximately 4.75 miles south east of the study area, indicating that there is regional potential for a female to pair with a male defending a territory in the Reservoir (eBird 2018).

The vireo will nest in in the openings in between thickets, within thickets, and within closed canopied woodlands (Greaves 1989), and because of this, the dynamic nature of the habitat in the Reservoir remains potentially suitable for this species so long as a portion of the habitat remains unaffected long enough to generate a thick understory. A thick, tangled understory of mule fat, California rose, or other shrub species could potentially provide suitable habitat within 2-3 years if conditions were appropriate for growth.

HYDRAULIC, SEDIMENT TRANSPORT, AND GROUNDWATER STUDIES

A Hydraulics, Sediment Transport, and Groundwater Analysis was prepared for the study area and is included in Attachment A to this Memorandum (Psomas 2018). The purpose of the Analysis was to evaluate the relative impact of the City's proposed management of diversions from the Arroyo Seco on riparian resources located downstream of the diversion structure. Hydraulic modeling assumed 100 percent efficiency in diversions in order to reflect the maximum reduced flow and thereby the maximum potential downstream habitat impacts. A summary of the results of the Analysis is presented below.

The ***maximum depth*** of the Reservoir pool "with-diversion" is reduced by approximately 1.3 feet in a dry year in comparison to the "without-diversion" scenario (Exhibit 7, Attachment A). A review of Exhibit 5 of Attachment A indicates that the cause of the decrease in maximum depth is likely due to the fact that the total runoff for the representative dry year without-diversions is approximately 2,480 acre-feet (af), while the hydrograph with diversions for the representative dry year is approximately 550 af. Therefore, the difference in runoff volume accounts for the difference in maximum depths shown in Exhibit 7, Attachment A. It is important to note that the area of inundation is approximately the same between the two scenarios owing largely to the shape of the Reservoir upstream of the Dam.

The ***maximum Reservoir pool water surface elevation*** for the representative average year without-diversion and representative average year with-diversions are approximately equal, with the WSE (water surface elevation) = 1,035 feet (Exhibit 9, Attachment A). In these scenarios, the factor that controls the depth and WSE is the operation of Devil's Gate Dam. Despite the same maximum depths, the with-diversion scenario has greater inundation durations at the Reservoir fringes because the depth reaches the operational curve elevation more slowly than does the without-diversion scenario.

Like the representative average year scenarios, the representative wet year maximum depth is the same in the with- and the without-diversion scenarios because the Dam operational curve is controlling the maximum depth in the Reservoir, approximately WSE=1,035 feet (Exhibit 11, Attachment A). Like the average year scenarios, the with-diversion scenario has greater inundation durations at the Reservoir fringes because the with-diversion scenario Reservoir depth reaches the operational curve elevation more slowly than does the without-diversion scenario.

A review of regional groundwater data indicates that the distance to groundwater within the Reservoir area is substantially greater than the depth of the tree root zones and consequently would not be expected to have an effect on rootzones of the riparian habitat within the Reservoir. Studies associated with the Devil's Gate Sediment Removal Project support the reported groundwater elevation with measured average depth to ground water of over 100 feet and depth to a subsection of a perched aquifer greater than 20 feet (LACDPW 2018).

Within the upstream section of the study area, between the diversion point and the JPL Bridge, the model showed little or no measurable change in hydraulic conditions (such as depth, velocity, inundation area, and shear) with project diversions. However, factors influencing the hydraulics are markedly different in this high gradient mountainous section versus the low gradient downstream areas. The stream is much narrower and does not expand with increasing flows due to the constrictions of the hardened canyon walls and granite boulders in the mountainous section. Increasing volume of water from storms have a greater effect on flow velocity as water exits the mountains and less of an effect on increasing area of pooling or the duration of pooling. This is consistent with the model findings showing little change with project diversions in the upstream segment.

The upstream area also behaves differently during ***low flows***. Thethe hydraulic model assumptions limit the lowest modeled flow to 1 cfs; therefore. Therefore, flows below 1 cfs are not included in the modeling analysis but are considered here. During times of low flow, the role of groundwater is substantially different between the low gradient downstream area and the high gradient upstream area. Within the upstream section of the Arroyo Seco, subsurface water (i.e. groundwater) is very shallow and often just below the creekbed surface, even in areas that appear dry on the surface. Due to the steep gradient, this groundwater moves downstream through the substrate as a subsurface flow beneath the stream bed. Furthermore, this section of the Arroyo Seco is considered a "gaining" stream indicating that surface flows increase moving downstream due to upwelling of subsurface flows. Upwelling occurs when subsurface flows move around less permeable sections of substrate and reach the surface to become surface pools or flows for segments of the stream and may penetrate more permeable substrate further downstream and return to subsurface flow or continue downstream as surface flow for long distances. Evidence of the intermingling of surface and subsurface flowing can often be seen from just below the diversion point downstream to the A-frame bridge where subsurface upwelling occurs at low points in the stream.

As mentioned previously, groundwater within the low gradient portion of the study area, downstream of the JPL Bridge, is very deep. The extensive alluvial deposits allow water to readily migrate through and downward until reaching the water table approximately 100 feet below the surface. Low flows that make it downstream and past the JPL bridge are only visible on the surface for short distances before penetrating the sediment to become subsurface flow and quickly dropping vertically. Consequently, low flow in the lower study area is not expected to be influenced by groundwater to any measurable degree due to the distance between surface flows and the groundwater table.

ECOLOGICAL MODELING STUDY

An Ecological Modeling Study was prepared for the study area and is included as Attachment B. The ecological effects of flow diversions were assessed based on modeled relationships between hydraulic changes described in the Hydraulics, Sediment Transport, and Groundwater Analysis and the probability that the resultant physical conditions can support southern willow riparian habitat conditions conducive to occupancy by least Bell's vireo.

For this Study, the statistical approach, rather than a mechanistic approach, was used to estimate the probability of occurrence of vireo under physical conditions associated with flow diversion scenarios. This statistical approach was used because: (1) it is a more efficient approach for evaluating ecological effects in a relatively small area over relatively short periods of time; (2) it can be more directly related to available species observation data; (3) it produces a probability estimate that provides flexibility in setting management thresholds (i.e. managers can select a probability of effect that triggers a management decision); and (4) the hydraulic modeling does not provide a long-enough time series of output (due to the computational complexity of the model) to support a mechanistic approach.

All hydraulic variables tested showed significant statistical differences (p value <0.001) in willow occurrence between predicted future conditions and historic flow characteristics. However, given the small sample size of vegetation polygons, inherent to the relatively small size of the Project (see Exhibit 2, Excavation Limits of the LACDPW Devil's Gate Sediment Removal Project), and the high number of hydraulic observations (over 18,000), it is believed the significance estimates may be overestimated. The significant overlap in distributions of occurrence and the large AIC[2] value substantiate this suspicion.

As depicted in Figure 4 of the Ecological Modeling Study (Attachment B), the model predicts a negative correlation between increasing velocity and willow habitat presence. Expected changes in velocity are illustrated in Exhibits 3a-3f, Modeled Change in Maximum Velocity Due to Proposed Project, of this Memorandum. This is because willow habitat favors areas where water infiltrates the soil; higher velocities mean lower infiltration, and thus do not favor willow presence. A similar result is predicted for shear stress, so that as shear stress increases, the model predicts a decreased probability in willow occurrence. Depth shows an increase in willow probability as water depth increases. Due to implementation of the ASCP, willows may increase in the channel (narrow linear flow upstream of the Reservoir pool) and decrease in the Reservoir pool as water recedes and depth decreases.

Upstream areas showed little to no change consistent with the hydraulic model which forms its basis.

IMPACT OF DIVERSIONS ON VEGETATION/HABITAT

Changes in the hydrological regime of stream systems have been shown to result in changes in vegetation structure and composition (Stromberg et al 1996). Though much of the research on this topic has occurred in the desert southwest (Stromberg 2013; Tallent-Halsell and Walker 2002) and the Sierra Nevada (Smith et al 1991), these studies have generally documented the responses of species that occur in the study area for this Memorandum, namely Goodding's black willow and Fremont cottonwood. The shifts in vegetation related to changes in hydrology is based upon: (1) the degree of fluctuations in groundwater levels; (2) the depth of root systems of existing vegetation; and (3) the resulting potential of invasive

[2] The Akaike Information Criterion [AIC] is an estimator of the relative quality of statistical models and provides a measure of the relative information not well represented by the model. It represents the balance between goodness of fit and model complexity.

species establishment to displace native vegetation (Leenhouts et al 2006; Horton and Clark 2001). The concept behind this relationship is that minor fluctuations in groundwater levels will not affect the presence of phreatophytic vegetation if the root systems of those plants are deep enough to access water in the phreatic zone (zone of saturation) or the capillary fringe (zone above the saturation area where water fills soil pore spaces through capillary motion and is available for plant uptake). However, if groundwater levels drop below the maximum depth of the root zone for a sufficient amount of time, then those plants are susceptible to be displaced by other species. Factors that affect the depth of roots include the genetic ability of each plant to produce deep roots, the soil type and the depth to which gas exchange is possible, and available water and nutrients (Foxx et al 1982). Additionally, root depth has been shown to be affected by fluctuations in the water table as significant fluctuations encourage species to elongate deep roots to access waters (Horton and Clark 2001).

Therefore, the principal question is whether the proposed ASCP diversions would cause an increase in the depth to groundwater that is available for willows and cottonwoods. As shown in Exhibit 4, Baseline Hydrology Example, changes to groundwater levels should not extend beyond the maximum depths to groundwater within the root zone of phreatophytic species to maintain their presence.

Leenhouts et al (2006) studied Goodding's black willow-Fremont cottonwood woodlands and their relation to groundwater depth. They categorized the riparian corridor in three classes: (1) intermittent-dry flow regimes with average groundwater depth in excess of 3.5 meters; (2) intermittent-wet flow regimes with average groundwater depth between 2.5 and 3.5 meters; and (3) perennially flowing areas with average groundwater depth of less than 2.5 meters. Willow-cottonwood forests were dense and multi-aged in Class 3 areas; drought-tolerant species such as salt cedar (*Tamarix ramosissima*) were subdominant and a dense and diverse herbaceous layer was present. Willows and cottonwoods were still dominant at Class 2 sites, but salt cedar presence increased, the herbaceous layer was diminished, and the productivity of willows and cottonwoods was decreased. Class 1 sites became dominated by salt cedar as native species were presumably unable to access sufficient groundwater for survival.

Willow habitat in Devil's Gate Reservoir is characterized by persistent coverage of mature willow trees, though aerial photo analysis indicates that the extent of willow coverage varies over time, likely in response to annual variability in precipitation and inflows from the upper Arroyo Seco. Little change is observed in the lowest portions of the Reservoir (downstream end) while coverage appears to vary slightly at the upper portions of the Reservoir. Because the accumulated sediment in Devil's Gate Reservoir is mainly comprised of sandy material, the willow tree rhizosphere likely reaches the maximum root depth of approximately seven feet below grade. The lack of a persistent herbaceous understory suggests that the depth to groundwater for much of the year is at least two feet, since herbaceous species roots generally extend less than two feet below grade. Therefore, the depth to groundwater likely fluctuates in the range of two to seven feet in the lower end of the Reservoir. It should be noted that the groundwater at these elevations does not represent the upper limit of the groundwater aquifer (the MHSA), which occurs approximately 300 feet below the surface in the Reservoir riparian areas as described previously. Based on topography, the shallower groundwater is expected to result from subsurface flows from the from San Gabriel Mountains, which flow south off the mountains and on to the Montrose/La Canada valley floor then to the east flowing downhill, towards the Arroyo Seco, until eventually reaching the deposited sediments within the Reservoir.

The current operation of the diversion weir and intake structure allows surface water during large storm events to flow downstream unimpeded as the intake structure is closed during peak flows (greater than approximately 100 cfs) to prevent damage to the pipe that delivers water to the spreading basins. Therefore, no changes to the hydrology will occur during times when the highest surface flows are

present. When moderate flows are present in the stream during the wet season, some water is diverted and a portion of the stream water bypasses the intake and continues downstream. During dry summer months, surface flows in the upper Arroyo Seco are sufficiently low to allow PWP to divert virtually all surface flows in the stream.

The impact of the ASCP is assessed based on changes to the current operation of the intake structure. The ASCP will continue to allow peak flows during the wet season to bypass the intake structure and will continue to capture most or all dry season flows. Therefore, the ASCP's potential to affect downstream vegetation communities is assessed based on the maximum allowed diversion of 25 cfs, which would presumably result in diversion of flows for a longer time due to extended periods of surface flow in the wet season, as well as diversion beyond those captured in the existing condition.

Generally, surface flows will reach the Reservoir area during and after significant rain events during the winter months. Vegetation in the Reservoir will utilize this water as it ponds and saturates the uppermost soil layers. The presence of Devil's Gate Dam is the dominant influence to the hydrology of the study area because it blocks surface and subsurface flows to downstream areas thus increasing the time that subsurface water is available to trees in the Reservoir. Additionally, the Reservoir is a collection area for subsurface water that flows from the upper Arroyo Seco area, as well as from the Montrose/La Canada slope to the west. Some of these inflows support the riparian tree species that occupy the Reservoir area.

Due to the highly variable precipitation in the region and the resulting variability in surface flows in the upper Arroyo Seco, identifying the typical flow regime is difficult. As discussed above, surface flow rates in the wet season can range from approximately 1 cfs to more than 200 cfs. The Hydraulics, Sediment Transport, and Groundwater Analysis (Attachment A) categorizes precipitation data for the study area as either wet, average, or dry years. The maximum inundation zone in the Reservoir was shown to minimally fluctuate during wet, average, or dry years (see Exhibits 5a-5c, Modeled Change in Maximum Inundation Due to Proposed Project). The maximum flood zone for the Reservoir is determined by the management of Devil's Gate Dam, as any water that would exceed the maximum surface elevation of 1,035 feet is released downstream. Areas that would not be flooded during maximum inundation levels consist of a narrow band along the margins of the inundation footprint that measures 2.1 acres. As discussed in the Hydraulic Analysis, while the footprint of the inundated area during dry years is less than average or wet years, the duration of inundation along these fringes is increased in the with-diversions scenario. Inundation duration in dry years is increased by diversions because the amount of runoff required to initiate Dam operations is increased. Overall, the hydraulics model indicates that any reduction to the inundation footprint is infrequent (occurring only during dry years) and duration period is slightly increased on the fringes. Furthermore, the model's conservative assumption of 100 percent efficiency in diversions is highly unlikely to be achieved. Diversions would therefore be less than modeled and impacts less than depicted in modeling results.

The Hydraulic Analysis also discusses the effect on water velocities. The Ecological Modeling Study indicates that increasing water velocities result in lower water infiltration into the soil, and this reduces the probability of willow establishment. However, the Hydraulic Analysis indicates that the effects of water diversion on velocity are small overall and in some cases the change in velocity from diversions is a decrease from existing conditions (see Exhibit 3a–3f, Modeled Change in Maximum Velocity Due to Proposed Project). Therefore, no changes to the extent of willow habitat is expected to occur from modelled velocity changes.

The Hydraulic Analysis also indicates that proposed stream diversions are expected to be an unimportant factor to overall sediment transport potential because the controlling elements of sediment transport are geologic factors. Large runoff events typically drive sediment movement in southern California streams; since no diversions are proposed during peak events, the ASCP is not expected to affect stream sediment yield to Devil's Gate Reservoir. In fact, the design of the proposed crest gate diversion weir is expected to enhance sediment transport because the gate will be placed in the down position during peak flow events to prevent impediments to sediment transport, which occur presently by the diversion weir.

As described above, the hydrology of the Arroyo Seco is highly variable. The ecological modelling study indicates that water depth and duration of inundation correlate most highly with changes in the extent of willow riparian habitat in the Reservoir. Because the rainfall and resulting stream flows can vary so dramatically in the Arroyo Seco and because willow riparian habitat is dependent on available water, it stands to reason that the extent of willow habitat would mirror the dynamics of the site hydrology. Therefore, changes in the willow habitat that may result from proposed diversion changes during dry year conditions would likely be temporary (due to the high growth rate of the species and the likelihood that dry year conditions would be followed by average or wet year conditions) and within the normal range of variability of the system.

To further illustrate the Reservoir vegetation's lack of dependency on dry season flows from the upper Arroyo Seco, the drought conditions that persisted earlier this decade provided an excellent test to the resiliency of the willow habitat. From April 2011 through April 2016, only eight of those months had rainfall totals in excess of two inches. Therefore, for a five-year period, surface water likely flowed past the diversion weir for only brief and infrequent periods. Though inflows to the Reservoir were exceptionally small, the depth to groundwater appeared to remain within the rhizosphere of the willow trees in the Reservoir since the extent of those trees remained largely the same. This also provides support of the concept of subsurface flow contribution coming largely from the La Canada/Montrose valley slope and into upper limits of the sediments in the Reservoir allowing willow riparian persistence.

An additional factor considered in assessing the potential impacts is the relative contribution of the Arroyo Seco from the diversion point to the total inflow to the Devil's Gate Reservoir. The watershed area of the Reservoir, above the dam, is 18,070 acres while the area of the watershed from the diversion point is 12,010 acres. The watershed and approximate flow contribution from the diversion point is 66 percent of the total watershed and approximate inflow of the Devil's Gate Reservoir. The model results reflect the change in flows from the relative contribution at the diversion point. The additional flows from other tributaries within the remaining 33 percent of the watershed contribute to the total inflow. Consequently, the actual effect of the downstream diversions is likely to be less impactful than model results would indicate.

With respect to the vegetation that is immediately downstream of the diversion weir and upstream of the JPL bridge, water regularly flows through this area in the wet season and, as described above, a small amount of water passes through the wooden boards of the diversion weir in the dry season. The upper Arroyo Seco, above the JPL bridge and within granite-based mountains, has a high water table (Attachment A) so that the riparian vegetation downstream of the diversion weir is likely supported by subsurface flows that pass under the diversion weir and often resurface at various points. Construction of the new crest gate diversion weir may be a slightly deeper than the current diversion weir, depending on the ultimate design of the structure. Minor changes in the depth of the structure are not anticipated to substantially block subsurface flows from passing through the area and continuing downstream as subsurface and resurfacing flow based on the typical depth of groundwater in the area and the steepness of the stream gradient which provides additional force or 'head.'

Further evidence of the upstream area's lack of dependency on surface flows is indicated by the maturity of the vegetation. Riparian vegetation in this area is dominated by sycamore and alder riparian trees which have persisted in the area even when surface flows are minimal. The maturity of this habitat suggests a stable amount of water in the root zone of these trees even in the dry season. As such, impacts to riparian or other vegetation communities in the upper study area are unlikely to result from the increased proposed water diversions.

Project studies examining existing conditions within the study area and potential changes in hydraulics, sediment transport, and ground water coupled with ecological modeling and habitat requirements indicate that downstream reduced flows associated with ASCP diversions are not expected to result in any measurable effects on downstream riparian vegetation/habitat.

CHANGING EXISTING CONDITIONS

Existing conditions within the study area are expected to change significantly within the near future. Beginning in fall of 2018, a large portion of riparian vegetation within the Devil's Gate Reservoir section of the study area, as shown in Exhibit 2, Excavation Limits of the LACDPW Devil's Gate Sediment Removal Project, will be removed as part of Los Angeles County Department of Public Work's sediment removal project (LACDPW 2018). Consequently, a large portion of the riparian vegetation within areas potentially affected by the ASCP is not expected to exist when hydraulic changes resulting from Project diversions would occur. Additionally, the surface elevation of a large portion of the Reservoir area will be lowered as the County's sediment removal project excavates accumulated sediments over the course of the coming years. As a result, a much greater volume of water will be contained within a deeper pool in a smaller area of the Reservoir. It is expected that pool margins will recess accordingly towards the center of the pool and away from riparian habitat occurring at and beyond current maximum pool margins. Therefore, small changes in hydraulics at the margins of the pooled areas of the Reservoir resulting from ASCP diversions are not likely to occur within or adjacent to existing riparian woodland habitat at pool margins. In summary, the minimal potential effects on riparian habitat resulting from future ASCP diversions, as described in previous sections above, are further reduced due to changing existing conditions.

CONCLUSIONS

Downstream reduced flows associated with ASCP diversions are not expected to result in any measurable effects on downstream riparian habitat. Project studies examining existing conditions within the study area and potential changes in hydraulics, sediment transport, and ground water coupled with ecological modeling and habitat requirements all provide support of this conclusion. Additionally, changing future conditions further reduce potential ASCP effects. Mitigation would therefore not be required because there would be no significant impacts to hydrology or biological resources in the context of the California Environmental Quality Act (CEQA). Also, to ensure the diversions are implemented as proposed and modeled in the aforementioned studies, a series of design features and monitoring measures are recommended. Recommendations include:

1. All flows exceeding approximately 100 cfs will be allowed to pass through the weir structure without diversions. A monitoring protocol shall be developed to accurately measure the stream flows at the point of diversion in a timely manner during and immediately following significant rain fall events (1 or more inches within a 24-hour period). Monitoring data shall be logged on an annual basis. If modeling data determines that flows exceeding 100 cfs are being partially diverted, immediate evaluation of operational and/or structural changes shall be conducted and implemented.

2. Accurate records of weir operations shall be kept and made available upon request to regulatory agencies. Records shall include diversion methods implemented and diversion quantities over a given period of time.
3. If the proposed weir structure design exceeds the subsurface depth of the existing weir structure, the City shall evaluate the design to confirm that no measurable interference of subsurface groundwater flows would result when compared to the existing conditions.

1.0 INTRODUCTION

Pasadena Water and Power (PWP) operates a diversion structure located approximately 0.25-mile north of Millard Creek on the Arroyo Seco. PWP has surface water rights of 25 cfs and and diverts streamflows into an intake structure. Upon entering the intake, the water is piped downstream approximately 3,000 feet to the PWP's spreading basins for groundwater recharge. The diversion structure and intake structure were damaged due to the debris flows following the 2009 Station Fire. Since then, the structures have operated at a reduced capacity.

The proposed Arroyo Seco Canyon Project (ASCP) would repair, replace and/or rehabilitate the diversion and intake structures in the Arroyo Seco in order to maximize the capture of PWP's surface water rights. The improvements, including a new sedimentation basin in the vicinity of the spreading basins, would facilitate management of sediment for diversion and spreading operations that were in the past managed with a headworks structure and settling basins further upstream. The ASCP also includes the expansion of PWP's spreading basins. The facilities and improvements that would be constructed as part of the Arroyo Seco Canyon Project would be located at three areas along the Arroyo Seco: Area 1 – Arroyo Seco Headworks; Area 2 – Arroyo Seco Intake; and Area 3 – Former JPL East Parking Lot/Spreading Basins (refer to Exhibit 2). This Hydraulics, Sediment Transport, and Groundwater Analysis (Report) analyzes one component of the larger Arroyo Seco Canyon Project: water diversions from the Arroyo Seco Intake structure in Area 2 (proposed Project).

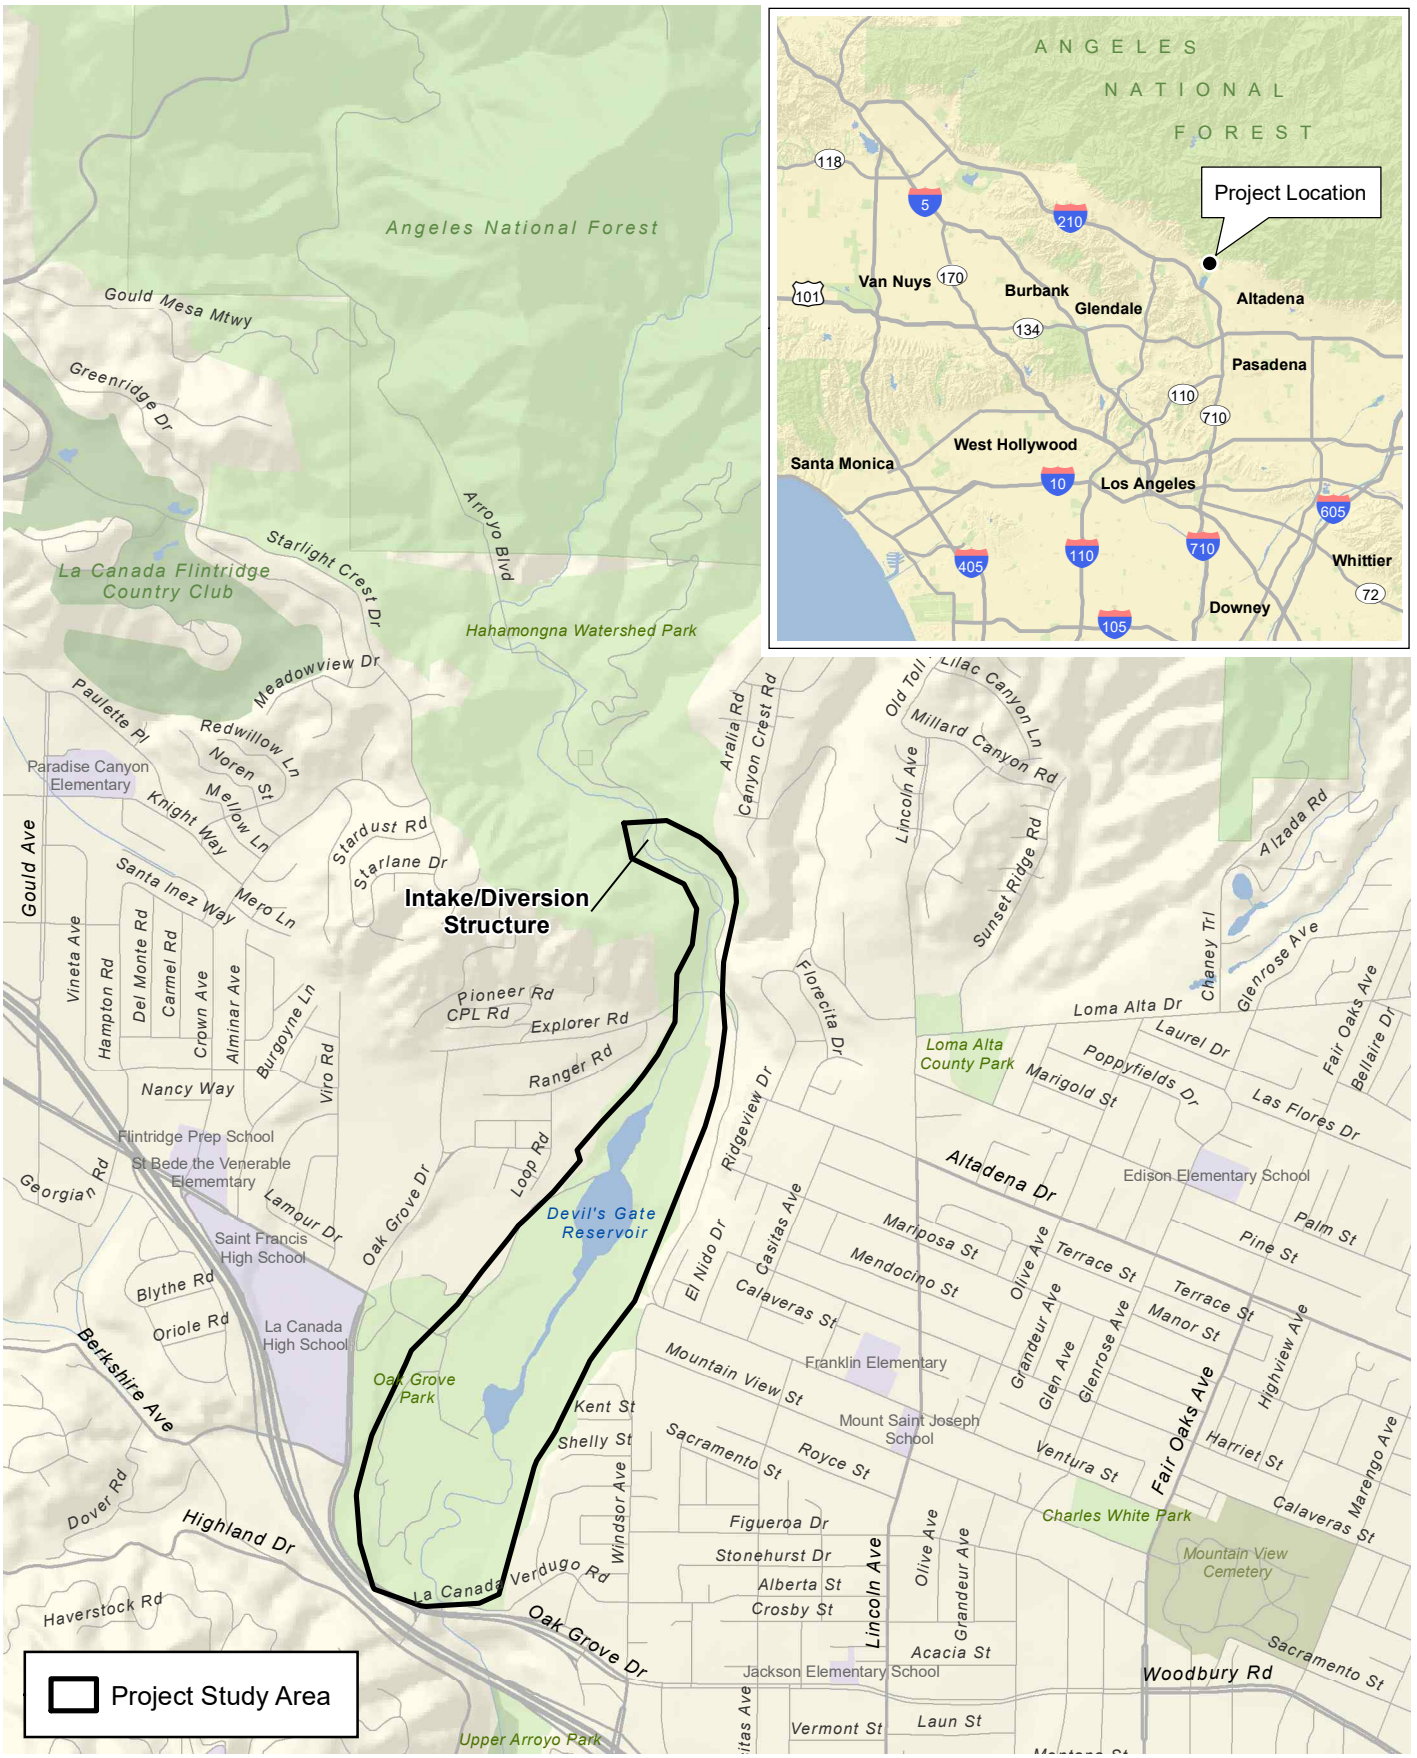
Changes to riparian habitats in the Project area can result from several potential sources, including changes in discharge patterns into the Devil's Gate Reservoir associated with water use practices (i.e. urban runoff) and diversions; infiltration of water in the existing spreading basins; alterations in sediment deposition and ponding patterns associated with the operation of Devil's Gate Dam; variation in sediment yield associated with fires in the upper watershed, such as the 2009 Station Fire; and long-term climate changes (including changes in drought cycles).

The purpose of this analysis is to evaluate the relative impact of the City's proposed management of diversions from the Arroyo Seco on riparian resources located downstream of the diversion structure. The goal of this Report is to identify the changes specifically concerning sediment transport, hydraulics, and groundwater that may affect down-stream riparian habitats. The results shall provide the baseline for further ecological modeling to assess biological impacts of the project on riparian resources.

2.0 PROJECT SETTING

2.1 PROJECT LOCATION

The Project site is located within the Arroyo Seco Watershed, which is a subwatershed of the larger Los Angeles River Watershed. The Arroyo Seco is a perennial creek, which means there is generally flowing water year-round, but the flow is below the surface (underground) in some locations. Creek flows that originate in the San Gabriel Mountains continue to flow south through the cities of Pasadena, South Pasadena and Los Angeles, before joining the Los Angeles River just east of Elysian Park and west of the Interstate (I) 5/I-110 Interchange. Within the City of Pasadena, the Arroyo Seco passes through three distinct recreational areas: (1) Upper Arroyo Seco, containing Hahamongna Watershed Park and Devil's Gate Dam; (2) Central Arroyo Seco, containing the Brookside Golf Course and Rose Bowl; and (3) Lower Arroyo Seco, containing an archery range, casting pond, and Memorial Grove. The proposed Project involves the construction of a new diversion structure in the Upper Arroyo Seco (in the City of Pasadena on land owned by the City). Exhibit 1, Regional Location and Local Vicinity, shows the location of the Arroyo Seco in the City of Pasadena, as well as the boundaries of the Project Study Area.



The locations of the Areas 1, 2, and 3, as identified in the larger Arroyo Seco Canyon Project, are shown in Exhibit 2, Location of Areas 1, 2, and 3. These areas are connected by the Gabrielino Trail, which serves as a recreational trail and the access road for City of Pasadena and United States Forest Service (USFS) vehicles heading into the Arroyo Seco Canyon. This Hydraulics, Sediment Transport, and Groundwater Analysis (Report) analyzes one component of the larger Arroyo Seco Canyon Project: water diversions from the Arroyo Seco Intake structure in Area 2 to the spreading grounds in Area 3.

The Project site can be accessed via I-210 by exiting Windsor Avenue and traveling northward for approximately 0.8 mile to its intersection with Ventura Street. From this intersection, the former JPL East Parking Lot is located approximately 0.27 mile north along Explorer Road, which can be accessed by walking, bicycling, driving, or by horse.

2.2 EXISTING CONDITIONS

The Arroyo Seco is an important source of water supply for the City of Pasadena. The City owns the right to divert up to 25 cubic feet per second (cfs) of surface water from the Arroyo Seco into the City's spreading basins located along the east side of the Devil's Gate Reservoir, upstream of Devil's Gate Dam.. PWP uses the surface water to recharge the underlying Monk Hill Subbasin (a sub-aquifer of the Raymond Basin) for groundwater well extraction.

PWP currently operates several structures in the Arroyo Seco Canyon that capture and convey stream water to a series of groundwater recharge (spreading) basins that are located adjacent to the National Aeronautics and Space Administration's (NASA's) Jet Propulsion Laboratory (JPL) campus. These facilities include the Arroyo Seco Headworks structure and adjacent sedimentation basins, the Arroyo Seco Intake Dam, and the associated pipelines that convey water to the existing spreading basins. A large number of these facilities were entirely or severely damaged due to debris flows in 2010 and 2011, subsequent to the 2009 Station Fire.

3.0 PROJECT DESCRIPTION

3.1 PROJECT PURPOSE AND NEED

PWP proposes the ASCP to repair and replace damaged facilities in Arroyo Seco Canyon. The improvements will allow for increased utilization of the City's surface water rights from the Arroyo Seco and maximize the beneficial use of this historically important local water resource. Specifically, modifications to the facilities in Area 2 will allow for increased diversion by capturing stream flows during storm events that in the past have been bypassed. PWP typically does not divert the stream water for recharge during large storm events (i.e. flows greater than approximately 100 cfs) due to the high total suspended solids (TSS) in the water. If water with high TSS levels is used for recharge, the ground surface in the spreading basins can be "blinded" or plugged by fine material, such as clays and silts, which would then reduce percolation and groundwater recharge rates. This reduced efficacy of the spreading basins is counterproductive in terms of groundwater recharge, and requires more maintenance to remove the top layer of fine materials at the spreading basins in order to recover the original recharge rates. Letting water with high TSS levels bypass without recharge is not preferred from a water supply perspective, but helps reduce maintenance issues associated with excessive cleanup of the basins. For the purposes of the present analysis, a maximum discharge in the Arroyo Seco must be defined to represent the upper limit at which water can be withdrawn. This flow rate is assumed to be 100 cfs.

3.2 PROJECT COMPONENTS

The proposed new diversion structure would capture all flows during small storm events and dry weather flows in the Arroyo Seco, and up to PWP's surface water rights during large storm events. During larger storms when the water is too turbid, the stream (with its associated sediment load) would bypass the structure and continue downstream in the creekbed. Operation during high flows would be facilitated by the adjustable height weir or crest gate. At low flows, the gate would start in the 'up' position and as flows increase, the gate would be lowered to maintain a constant water surface level in the diversion pool. When the gate is fully lowered, flows will be bypassed and carry sediment downstream.

City personnel would continue to provide maintenance of the diversion and intake structures as occurs under existing conditions.

4.0 PREVIOUS STUDIES

Two studies were reviewed to enhance the background understanding of the Project area hydraulics. A summary of each relative to the analysis in this Report is provided below.

PHILLIP WILLIAMS & ASSOCIATES (2000) – The purpose of the Phillip Williams & Associates (PWA) study was to provide supplemental analysis of hydrology and geomorphology to the development of a master plan for the Hahamongna Watershed Park. The study specifically examined hydrology, geomorphology, flood hazards, water resources history, sediment transport and maintenance, and groundwater recharge. Pertinent to the proposed Project are the hydrology, flood hazards and sediment transport analyses.

The hydrology element of the study examined precipitation gages near the Project site, including USGS stream gage #11098000. A flood frequency analysis of the gage data was conducted. Additional analysis of a Los Angeles County Department of Public Works stream gage (F277-R) was also completed. A review of the stream gage data showed that several major floods have occurred during the period of record for the stream gage and as recently as 1983. (It should be noted that the 1998 peak discharge was greater than the 1983 peak discharge, however, a vetted data set may not have been available at the time.) Interestingly, none of the major floods were preceded by a wildfire within three years. The PWA study also followed Waanan & Crippen (1977) in developing a relationship between the discharge at the gage and the discharge below the gage based on tributary area. The base relationship takes the form:

$$Q_d = Q_{gage}\left(A_d/A_{gage}\right)^n$$

where Q_d and Q_{gage} are the discharge rates at a location downstream of the gage and at the gage, respectively, A_d and A_{gage} are the watershed areas at a location downstream of the gage and at the gage, respectively, and n is an exponent based on the return frequency of the discharge being scaled. It is important to note that PWA assumed that all discharges are bulked, which appears to be reasonable for the study area and the USGS gage data.

Hydraulic numerical modeling was completed for the study using the MIKE11 model for a combination of the 2- 10- and 50-year annual return frequency events. The model was limited to the stretch of Arroyo Seco between the Jet Propulsion Laboratory (JPL) Bridge and the Devil's Gate Dam. MIKE modeling focused on flood management.

The sediment transport analysis included geomorphology and hydraulics. The geomorphic analysis noted the importance of floods, fires and debris flows within the watershed, and noted that these types of events play an important role in the frequency and magnitude of watershed and stream sediment yield in the study area. The study examines the many published rates of watershed debris yield and notes the alluvial fan-like environment of the lower portion of the study area. PWA also presents the record of sediment management within the Devil's Gate Reservoir.

Historical aerial photograph analysis was performed to determine the historical extent of the active bed and erosional patterns. The analysis found that the limits of erosion are topographically controlled and that the upper portion of the reservoir has typically been braided where the lower portion exhibits ponding.

A two-dimensional FLO-2D numerical model was run for the 2-, 10-, and 50-year hydrographs. The purpose of the model was to determine the debris flow in the reservoir. The model extents were the same as the MIKE model. Historical sectional and longitudinal analysis was also completed within the reservoir. Additional empirical analysis was completed to estimate sediment yield for discrete events. The study found what is commonly accepted as the basis for sediment

yield in southern California watersheds: yield scales with volume of precipitation. Therefore, the smallest, most frequent runoff events or the driest years will transport little or no sediment to the reservoir, while high volume, infrequent events or wet years may potentially transport relatively large volumes of sediment within the study area. The MIKE model was also updated to analyze sediment transport within the study area using sediment data collected within the reservoir. The model was calibrated against historical section data. The model results appear to over-predict bed change during the 2-year event with up to 9.5 feet of aggradation in the model bed at the most upstream cross section. The authors attribute this to the rapid expansion of channel width immediately downstream of the entrance to the reservoir.

JET PROPULSION LABORATORY (2003) – The Jet Propulsion Laboratory (JPL) study describes the development and calibration of the JPL groundwater model as part of the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) site. Of interest to the present work, the JPL study found no constant loss from Arroyo Seco to Raymond Basin, the underlying groundwater basin, nor any regular and consistent contribution from Raymond Basin to the Arroyo Seco. This indicates that water from the aquafer is not at a depth shallow enough to provide water to sustain vegetation.

5.0 HYDRAULIC MODEL

5.1 MODEL DESCRIPTION

Hydraulic modeling was completed using the U.S. Army Corps of Engineers' (USACE) Hydraulic Engineering Center River Analysis System (HEC-RAS). The HEC-RAS numerical model was designed to calculate water surface profiles in channels assuming a steady flow and uniform discharge based on site hydrology. The HEC-RAS model was run in two-dimensional mode. A description of the model and the model set-up follows.

5.1.1 Equations of Motion

Multi-Dimensional shallow water models can be used to resolve depth and depth-averaged velocities in the horizontal directions x and y. The shallow water equations appear in integral form as (Chaudhry 1993):

$$\frac{\partial}{\partial t}\int_{\Omega} \mathrm{U}d\Omega + \oint_{\partial\Omega} (Fdy - Gdx) = \int_{\Omega} Sd\Omega$$

The dependent variables, U, fluxes F and G, and the source terms are defined as,

$$U = \begin{pmatrix} h \\ uh \\ vh \end{pmatrix} F = \begin{pmatrix} uh \\ u^2h + \frac{gh^2}{2} \\ uvh \end{pmatrix} G = \begin{pmatrix} vh \\ uvh \\ v^2h + \frac{gh^2}{2} \end{pmatrix} S = \begin{pmatrix} 0 \\ gh(s_{ox} - s_{fx}) \\ gh(s_{oy} - s_{fy}) \end{pmatrix}$$

where u and v are the depth averaged flow velocities in the x (easterly) and y (northerly) directions, respectively. The terms in S account for the bed and friction slopes and are given as,

$$s_{ox} = -\frac{\partial z}{\partial x}\ s_{oy} = -\frac{\partial z}{\partial y}$$

and

$$s_{sf} = \frac{n^2 u\sqrt{u^2 + v^2}}{h^{3/4}}\ s_{fy} = \frac{n^2 v\sqrt{u^2 + v^2}}{h^{3/4}}$$

where z=z(x,y) is the bed elevation above an arbitrary datum. Finally, Ω represent the domain of two-dimensional control, and $\partial\Omega$ is its boundary.

5.2 TOPOGRAPHIC REPRESENTATION AND MODEL EXTENT

The HEC-RAS model domain for the study area (as identified on Exhibit 1) was developed in RAS Mapper, a subroutine of HEC-RAS, using topographic 2015 information (tested at an accuracy of 1.25' at 95% confidence level) provided by the City of Pasadena. The topographic data is found in Attachment A. A Manning's coefficient was applied to the study reach and hydrographs were developed for analysis, both described below. As shown in Exhibit 3, HEC-RAS Model Extent, the model extends from upstream of the proposed diversion point to Devil's Gate Dam to upstream of the diversion. The upstream extent was selected because it is the upstream limit of potential impacts to the stream since diversions will not impact hydraulics or hydrology upstream of this location. The downstream limit was chosen because it represents the downstream limits of impacts to the stream because of the presence of Devil's Gate Dam. Numerical hydraulic models are made up of individual computational cells (units of area analyzed) which can vary in size. This model includes approximately 22,250 computational cells with an 18-square foot cell size.

5.3 MANNING'S VALUES

HEC-RAS uses Manning's Equation to represent friction loss in the model, as described above. Manning's values were selected based on aerial (Google Earth) and site photography. The Manning's values range from 0.065 to 0.085. In the present analysis, Manning's value of 0.065 is representative of sandy bottom, wide, braided channel sections with vegetation, while a Manning's value of 0.085 is representative of relatively narrow, steep canyon sections with trees, brush and variable bed section. These values follow guidance for the selection of Manning's values as presented in Barnes (1967) and Chow (1959).

A sensitivity analysis was determined to be unnecessary. The majority of habitat of concern within the study area is generally within the reservoir and the velocities that will be experienced by this vegetation in the reservoir's pool area is at or near zero feet per second. Changing the Manning's value will not change the velocity experienced by the vegetation. Moreover, changing the velocity in the stream by modifying the Manning's values will not alter the velocities experienced by the vegetation in the reservoir. Finally, the largest discharges that occur in the study's numerical modeling are not altered by the proposed project so the roughness values that control the depth and velocities that vegetation experiences during these large events is the same in both the existing and proposed conditions. Alteration of roughness will not change the outcome during these events.

5.4 BOUNDARY CONDITIONS

The down-stream model boundary condition is set to normal depth, while the inflowing boundary condition is set to an inflowing hydrograph, described below. Model outflow is based on the operational curve of Devil's Gate Dam. Generally, there is no outflow from the model for water surface elevations below 1,025 feet. Between 1,025 feet and 1,030 feet the outflow from the Dam is 100 cfs; between 1,030 feet and 1,035 feet the outflow from the Dam is 300 cfs; above 1,035 feet the outflow is 800 cfs. The greatest observed elevation in the reservoir during the representative wet year without diversion is 1,035 feet.

5.5 HYDROLOGY

All hydraulic modeling is based on USGS daily gage data at stream gage #11098000. Daily average discharge data is utilized for the period 1989 to 2014, which is the vetted stream gage data available at the time of writing and is not strongly influenced by drought. Individual water year hydrographs representing dry, average and wet years are selected for modeling, as described below. The hydrologic record at the gage for the period is shown in Exhibit 4, USGS Stream Gage Data for the 1989/1990 to 2013/2014 Water Years.

It is important to recognize that the area of the watershed contributing to the stream at the gage location is smaller than the area of the watershed contributing to the stream at the proposed diversion location. To account for the difference in watershed area the gage data has been scaled as a function of the watershed area to account for the difference. The scaling follows the approach of Waanan and Crippen (1977), which was also used by PWA (1990) in their flood frequency analysis of Arroyo Seco. The scaling is computed as:

$$Q_{diversion} = Q_{gage}(A_{diversion}/A_{gage})^n$$

where *Q* is the flow rate at a given location on the stream, *A* is the area of the watershed at a location corresponding to the respective flow rate, and *n* is an empirical value that is a function of the return period of the discharge being scaled. In the present study all daily discharges in the wet, average and dry hydrographs fall within the range of the 2-year peak discharge, therefore the exponent *n* is set to 0.72 after PWA (1990). The watershed areas were calculated using GIS-based tools and topography provided by the City. The watershed areas at the gage and proposed diversion are 16.0 square miles and 18.8 square miles, respectively.

To develop representations of wet, average and dry years the relative deviation percent was calculated for each year (Gao et al. 2018). The relative deviation percent was calculated by comparing the average annual runoff volume to the annual runoff volume for each year. Years where annual runoff was less than the average are considered dry, while years where the annual runoff was greater than the average are considered wet. Approximately 28% and 72% of annual runoff volumes were determined to be wet and dry, respectively. The years selected to represent wet and dry hydrographs were taken as the median wet and dry annual runoff volumes, respectively. The average runoff year was taken to be the year where annual runoff was closest to the average. The relative deviation percent data for all years is shown in Table 1.

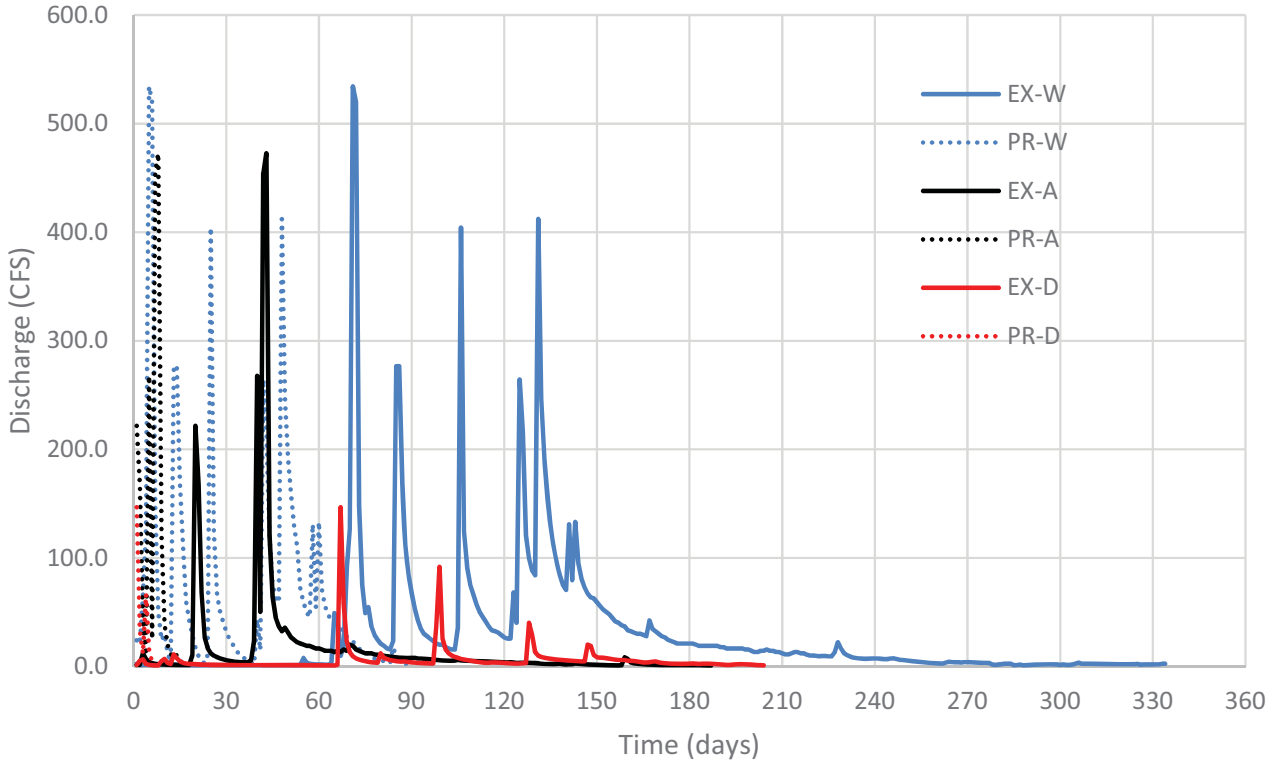
TABLE 1
WET AND DRY ANNUAL RUNOFF VOLUME BY RELATIVE DEVIATION PERCENT AT USGS GAGE #11098000

WATER YEAR		ANNUAL RUNOFF (AF)	RELATIVE DEVIATION %	WET OR DRY?
1989	1990	752	-90.2	DRY
1990	1991	3,499	-54.6	DRY
1991	1992	13,876	80.2	WET
1992	1993	31,231	305.5	WET
1993	1994	2,307	-70.0	DRY
1994	1995	17,957	133.1	WET
1995	1996	5,040	-34.6	DRY
1996	1997	3,867	-49.8	DRY
1997	1998	20,330	164.0	WET
1998	1999	2,094	-72.8	DRY
1999	2000	2,965	-61.5	DRY
2000	2001	3,224	-58.1	DRY
2001	2002	472	-93.9	DRY
2002	2003	2,314	-70.0	DRY
2003	2004	1,290	-83.3	DRY
2004	2005	37,888	391.9	WET
2005	2006	5,239	-32.0	DRY
2006	2007	616	-92.0	DRY
2007	2008	5,754	-25.3	DRY
2008	2009	1,857	-75.9	DRY
2009	2010	9,713	26.1	WET
2010	2011	14,804	92.2	WET
2011	2012	2,759	-64.2	DRY
2012	2013	1,305	-83.1	DRY
2013	2014	1,398	-81.9	DRY
	AVERAGE=	7702		
	MEDIAN=	3224	DRY % =	0.72
			WET % =	0.28
			WET MEDIAN=	17,957
			DRY MEDIAN=	2,311

For modeling purposes, the 1994-1995 water year is used to represent a wet year's runoff volume, the 2007-2008 water year is used to represent an average year's runoff volume, and the 2002-2003 water year is used to represent a dry year's runoff volume.

To develop hydrograph input for modeling, the hydrograph data was limited to daily average discharges greater than 1 cfs. Therefore, no days without runoff are represented in the model. This approach is undertaken because discharges lower than 1 cfs will not reach the Dam owing largely to frictional attenuation within the model. Moreover, the model does not consider infiltration, and is very conservative with respect to the volume of water (more than actual) reaching the dam. It is likely that discharges less than 1 cfs not fully attenuated by friction will be infiltrated before reaching the Dam. Finally, the diversion is being modeled as capable of collecting all the water in the stream, which is unlikely since diversion structures are "leaky" by their nature and at present we cannot account for the leaky loss. Like the modeling approach to

infiltration, this approach is also very conservative with respect to the volume of water that reaches the Dam.



The proposed operational curve of the diversions includes three elements : 1) the diversion will remove all water from the stream up to 25 cfs; 2) diversions will cease for discharges above 100 cfs; and 3) all diverted water is assumed to infiltrate in the spreading basins regardless of the total volume of diversion. Curve elements 1 and 3 are conservative statements. Curve element 1 simplifies modeling because it doesn't consider the leaky nature of diversions, and it is conservative in approach since the constructed system will not be able to capture 100 percent of all discharges, which is typical for operations of diversion structures in natural systems, as noted above (NRC 1939). Curve element 3 is conservative because it states that all of the water to which the City has legal rights can be infiltrated, and that infiltration basins (will have sufficient capacity for all of the diverted water as designed. Factor 2 is represented in modeling since the turbidity of 100 cfs discharges typically represents the upper limit of turbidity that can be successfully managed by the proposed diversion system (City of Pasadena pers comm).

Diversions are represented in the model by subtracting 25 cfs from the daily average discharge values in the modeled hydrographs for discharge values less than 100 cfs. Durations of the discharges remain unchanged (one day), and all days with no discharge are removed from the hydrograph. The without diversion and proposed (with diversion) hydrographs for wet, average and dry years are shown in Exhibit 5, Existing and Proposed Modeling Hydrographs for the Wet, Average, and Dry Runoff Years.

Note that the "without diversion" scenario is used as the most conservative approach to reflect the maximum possible change from existing conditions. Currently there are some diversions of unspecified rates and durations, but they are well below PWP's surface water rights.

5.6 HYDRAULIC ASSUMPTIONS

Modeling used in the present study is uncalibrated hydraulically because no data exists with which to calibrate the model. That is, there does not exist any data that compares discharge to depth, velocity or other hydraulic parameters. It is assumed that the present modeling is conservative, as it doesn't consider evaporation, infiltration, evapotranspiration or other forms of loss besides friction. Attenuation in the model is only a function of friction, and both direct and anecdotal evidence exist to indicate that stream flows in the Arroyo Seco reach the Dam and reservoir.

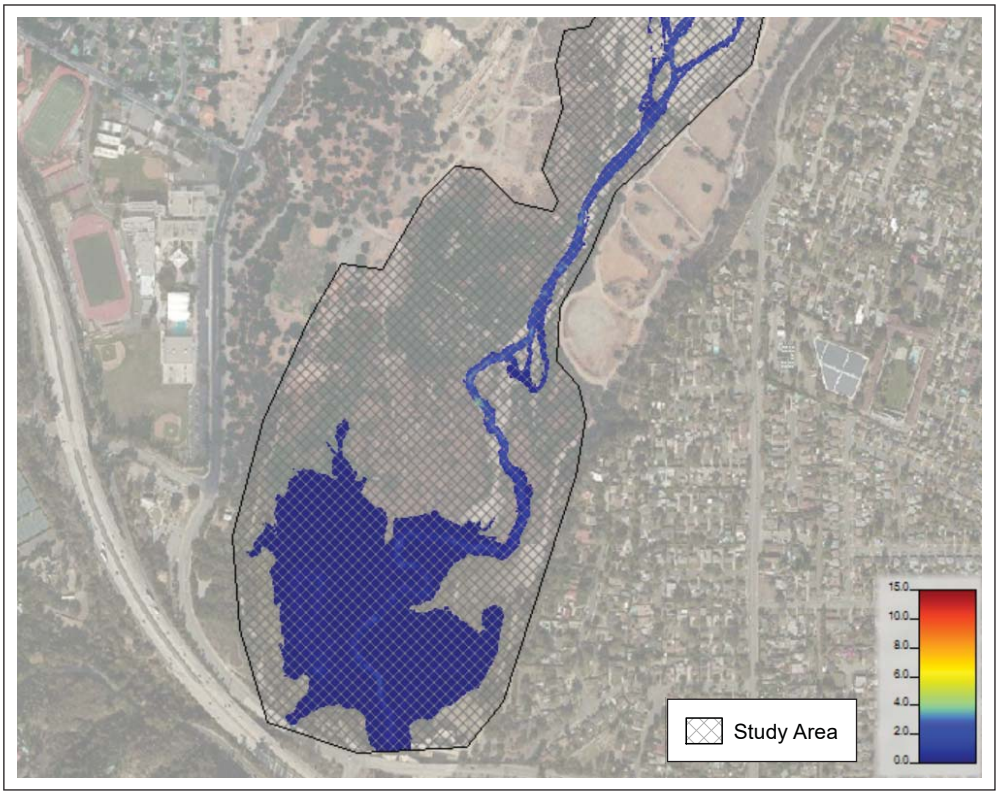
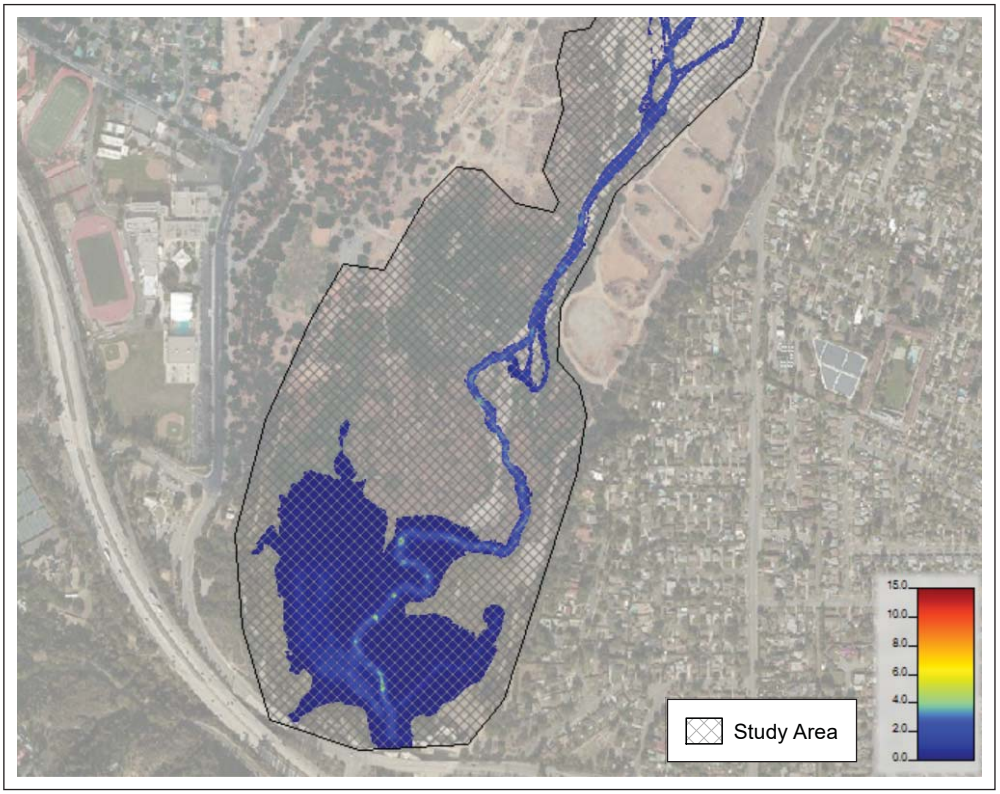
6.0 HYDRAULIC MODEL OUTPUT.;

The HEC-RAS model was run for three representative water years as described above: wet, average and dry total runoff volumes. The HEC-RAS model was also run for the three representative years with proposed Project diversions, also described above. What follows is a comparison of maximum depth and maximum velocity for each representative water year for both the hydrology with and without diversions.



6.1 DRY YEAR VELOCITY

The representative dry year and representative dry year with diversions maximum velocity are shown in Exhibit 6, Representative Dry Year Maximum Velocity. Comparing the two graphics reveals that the maximum velocity in the with-diversion scenario is higher than in the without-diversion scenario in some locations immediately upstream of the Dam. In the primary stream channel upstream of the Dam the maximum velocity doubles from approximately 2.5 feet per second (fps) in the without-diversion condition to approximately 4.2 fps in the with-diversion scenario. In addition, there is an approximate doubling of velocity in some portions of the backwater area upstream and to the west of the Dam from approximately 0.3 fps in the without-diversion scenario to approximately 0.6 fps in the with-diversion scenario.



A review of Exhibit 5 indicates what the driver is for the increase in velocity. In the without-diversion scenario small discharge events (Q<25 cfs) begin to fill the reservoir prior to a significant event (Q>>25 cfs). When the smaller events pond upstream of the Dam, the larger events maximum velocity is lower because of backwatering from the Dam due to ponding. In contrast, when water has not ponded upstream of the Dam, no backwatering will occur during a more significant event and velocities will be higher in the main stream and in some of the backwatering areas. It is important to note that these higher velocities can occur in a dry, average or wet year regardless of whether diversions occur if an early runoff event in the season is relatively large and little or no backwatering has occurred prior to the runoff event. It is also important to note that the total change in velocity is relatively low and occurs well below (v=0.6 fps) or just below (v=4.0 fps) a typical velocity (i.e. 4.5 fps) for initiation of sediment transport in sandy bed, vegetated streams.

6.2 DRY YEAR DEPTH

The representative dry year without-diversions and representative dry year with-diversions maximum depth are shown in Exhibit 7, Representative Dry Year Maximum Depth. The graphics show that the maximum depth between the without-diversion and with-diversion scenarios drops by approximately 1.3 feet. A review of Exhibit 5 indicates the cause of the decrease in maximum depth. In the without-diversion conditions, the total runoff for the representative dry year is approximately 2,480 acre-feet (af), while the hydrograph with-diversions for the representative dry year is approximately 550 af. Therefore, the difference in runoff volume accounts for the difference in maximum depths shown in Exhibit 7. It is important to note that the area of inundation is approximately the same between the two scenarios owing largely to the shape of the reservoir upstream of the Dam.

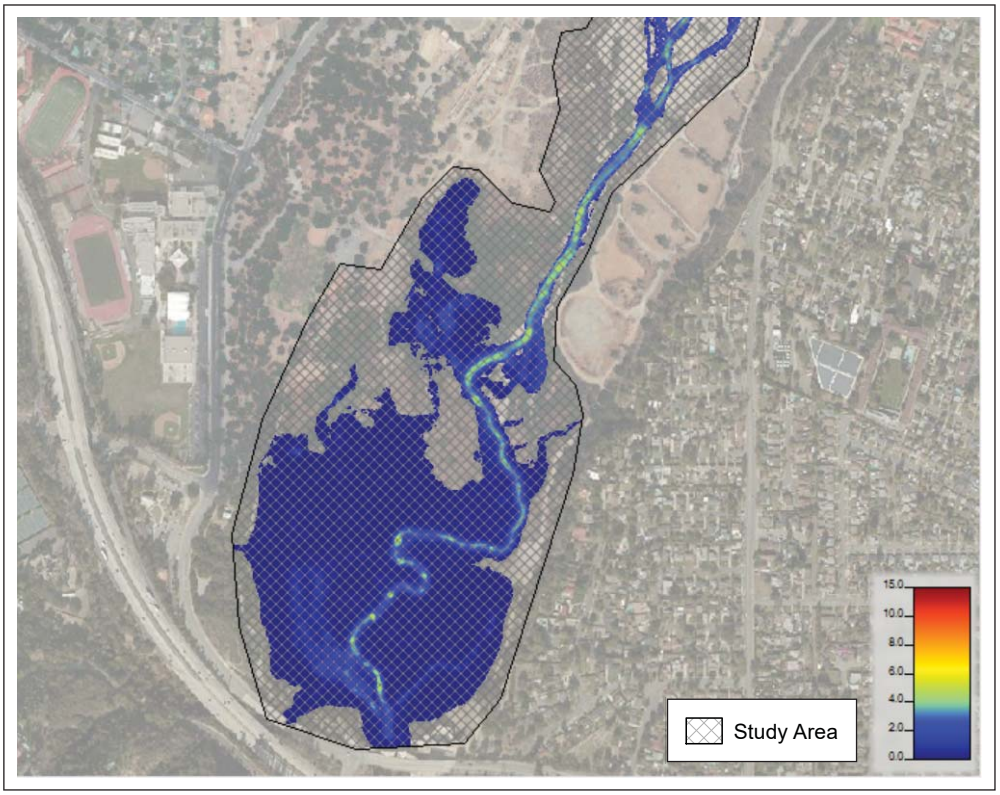
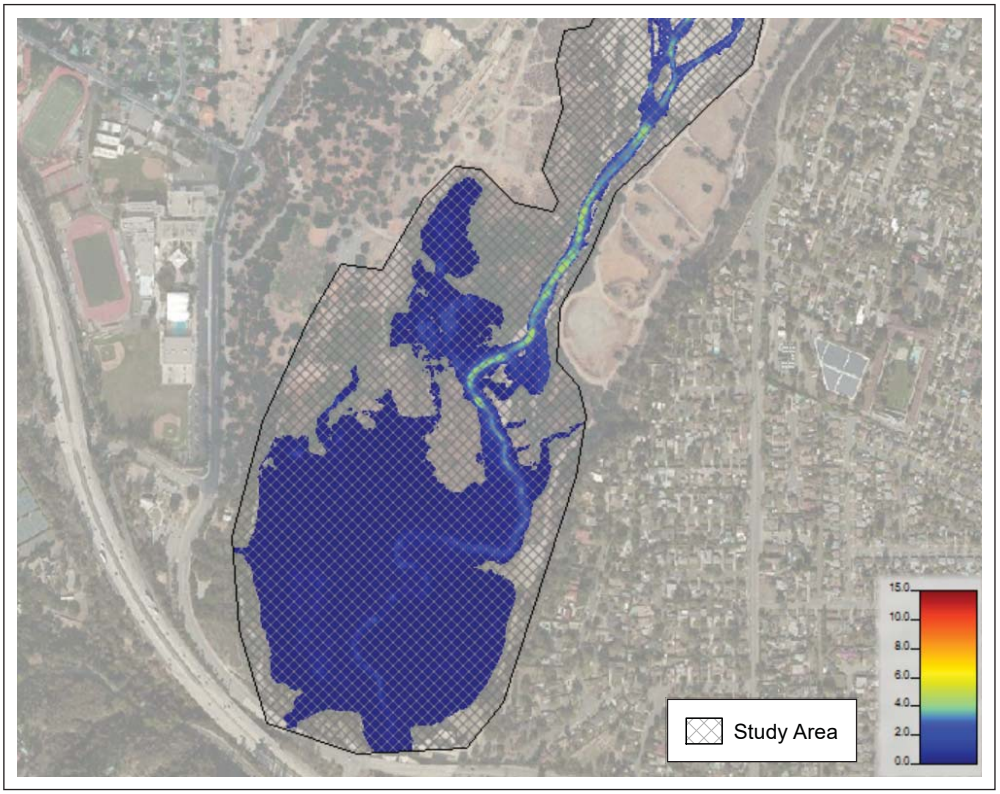
6.3 AVERAGE YEAR VELOCITY

The representative average year and representative average year with-diversions maximum velocity are shown in Exhibit 8, Representative Average Year Maximum Velocity. Unlike the dry scenarios, the maximum velocity in the without-diversion scenario is higher than in the with-diversion scenario in some locations immediately upstream of the Dam. In the primary stream channel upstream of the Dam, the maximum velocity doubles from approximately 2.5 fps in the with-diversion condition to approximately 5.5 fps in the without-diversion scenario. In addition, this is an approximate doubling of velocity in some portions of the backwater area upstream of the Dam from approximately 0.6 fps in the with-diversion scenario to approximately 1.0 fps in the without-diversion scenario.



The reason for these differences is similar to that in the representative dry year scenarios, except that the reservoir has relatively high ponding in the with-diversion scenario compared to the without-diversion scenario before a significant (Q>>25 cfs) event occurs. In the representative average year scenario, the resulting maximum velocities are relatively higher than in the representative dry year scenario (5.5 fps vs. 4.2 cfs, respectively). It appears from Exhibit 5 that the difference in modeled maximum velocity in this location is a function of hydrograph shape (rate of flow versus time) as opposed to other hydraulic or hydrologic factors.

6.4 AVERAGE YEAR DEPTH



The representative average year without diversion and representative average year with diversions maximum depth is shown in Exhibit 9, Representative Average Year Maximum Depth.. The images are indistinguishable from one another because the maximum water surface elevation is the same, approximately WSE (water surface elevation) = 1,035 feet. In these scenarios, the factor that controls the depth and WSE is the operation of Devil's Gate Dam. Despite the same maximum depths, the with-diversion scenario has greater inundation durations at the reservoir fringes because the with-diversion scenario reservoir depth reaches the operational curve elevation more slowly than does the without-diversion scenario.

6.5 WET YEAR VELOCITY

The representative wet year without diversion and representative wet year with diversions maximum velocity is shown in Exhibit 10, Representative Wet Year Maximum Velocity.. Like the other representative scenarios, there are differences in maximum velocity upstream of the reservoir. The difference between the representative wet year without-diversion and with-diversion maximum velocity is lower in magnitude than in the similar representative dry and average scenarios. This appears to be a function of the rate at which the reservoir fills in the represented wet year scenarios. In the wet year scenarios, the difference in maximum velocity in the channel upstream of the reservoir is approximately 3.0 cfs and 1.5 cfs for the with-diversion and without-diversion scenarios, respectively. One interesting difference between the representative wet year scenarios and other scenarios is how far upstream the differences are observed. In the case of the wet year scenarios, the differences in velocity are observed in the channel upstream of the ponded reservoir, while in the representative average scenarios the differences are confined to downstream of the infiltration basins on the east bank. A review of the model output indicates that the difference in extent of impacts is a function of the extent of ponding and ponded elevation in the reservoir, which alters the backwatering further upstream than in the average scenario conditions. The difference is not attributable to change in hydrology resulting from diversions since the largest discharges (Q>100 cfs) are not impacted by the diversions.

6.6 WET YEAR DEPTH

The representative wet year without-diversions and representative wet year with-diversions maximum depth is shown in Exhibit 11, Representative Wet Year Maximum Depth. Like the representative average year scenarios, the representative wet year maximum depth exhibits are indistinguishable because the Dam operational curve is controlling the maximum depth in the reservoir, approximately WSE=1,035 feet. Like the average year scenarios, the with-diversion scenario has greater inundation durations at the reservoir fringes because the with-diversion scenario reservoir depth reaches the operational curve elevation more slowly than does the without diversion scenario.

7.0 SEDIMENT TRANSPORT MODEL

7.1 MODEL DESCRIPTION

General adjustment was estimated in this study using the U.S. Army Corps of Engineers (USACE) SAM steady-state numerical model. Here, SAM was employed to provide a first calculation of sediment transport potential within Arroyo Seco. The SAM Sediment Hydraulic Package is an integrated system of programs developed through the Flood Damage Reduction and Stream Restoration Research Program to aid in the analyses associated with designing, operating, and maintaining flood control channels and stream restoration projects. SAM combines the hydraulic information and the bed material gradation information to compute the sediment transport capacity for a given channel or floodplain hydraulic cross-section for a given discharge at a single point in time. Several sediment transport functions are available for this analysis and SAM can assist in selecting the most appropriate sediment transport equation.

The three primary fluvial components of SAM are SAM.HYD, SAM.SED and SAM.AID. SAM.HYD provides a steady state, normal-depth, one-dimensional representation of channel hydraulics. The SAM.SED module combines the hydraulic parameters with the bed material gradation curve to compute bed material discharge rating curves by size classification. The SAM.AID module provides the user with recommended sediment transport equations based on the best matches between hydraulic parameters and grain size distribution of the study reach with parameters from widely accepted and published research.

The SAM numerical model is built upon hydraulic and fluvial components. The hydraulic components include representations of river bed characteristics that are input into an analytical procedure. The fluvial component includes representation of bed gradation as percent finer statistics and a selection of up to twenty sediment transport equations. SAM's hydraulic component will accept either average reach parameters or cross-section data imported from HEC-2/HEC-RAS/HEC-6 models. Hydraulic modeling is based on a uniform flow equation where discharge is the dependent variable such that,

$$Q = f(D, n, W, z, S)$$

where Q is discharge in cfs, D is flow depth in feet, n is the Manning's number, W is bottom width in feet, z is the channel side slope, and S is the energy slope. The bottom width is representative of the total moveable bed width of the channel and Manning's number is a composite value. Normal depth is calculated using Manning's equation, and effective values of width and depth are calculated following normal depth calculations.

The fluvial component is based on sediment transport functions to calculate the bed portion of the sediment discharge-rating curve. The sediment transport equations are of the form,

$$GS_i = f(V, D, S_e, B_e, d_e, \rho_s, G_{sf}, d_s, i_b, \rho_f, T)$$

where GS_i is the transport rate for sediment size class i; the hydraulic terms V, D, S_e, and B_e, are the average velocity, effective flow depth, energy slope, and effective flow width, respectively; the sediment particle parameters d_e, ρ_s, and G_{sf} are the effective particle size, particle density, and grain size shape factor, respectively; the sediment mixture properties, d_s and i_b are the geometric mean particle size of sediment class i and fraction of class i in the bed, respectively; and the fluid properties ρ_f, and T, the water density and temperature, respectively. Twenty well known, published, peer-reviewed transport equations are available including Ackers-White, Colby, Laursen-Copeland, Laursen–Madden, MPM, Toffaleti, Yang, Van Rijn and others. Once the data assembly is complete, the SAM.SED module can be used to create a sediment discharge-rating

curve based on grain size distribution. The reader is referred to the SAM user's documentation for further reference.

It is important to note that the SAM model is a zero-dimensional computational package that is only based on a single cross-section at a point in time. As such, SAM simulations can only represent a reach average during a steady state discharge. Because SAM applies sediment transport to a point, no variability in size distribution in either space or time is calculated. With these limitations in mind, in this study SAM is intended to provide a first approximation to sediment transport to which other more sensitive calculations can be compared.

7.2 MODEL INPUT

In this study, hydraulic representation of the streambed is accomplished in several distinct steps. First, the HEC-RAS numerical model is used to develop a representative cross section for analysis. Second, the HEC-RAS geometry is combined with hydraulic data for the representative cross section. Next, the hydraulic data and cross section are entered into the SAM.HYD subroutine and the model is run. The sediment data, described below, is entered into the model, the SAM.AID subroutine is run, and a transport equation is selected. Once the equation is selected the SAM.SED subroutine is run.

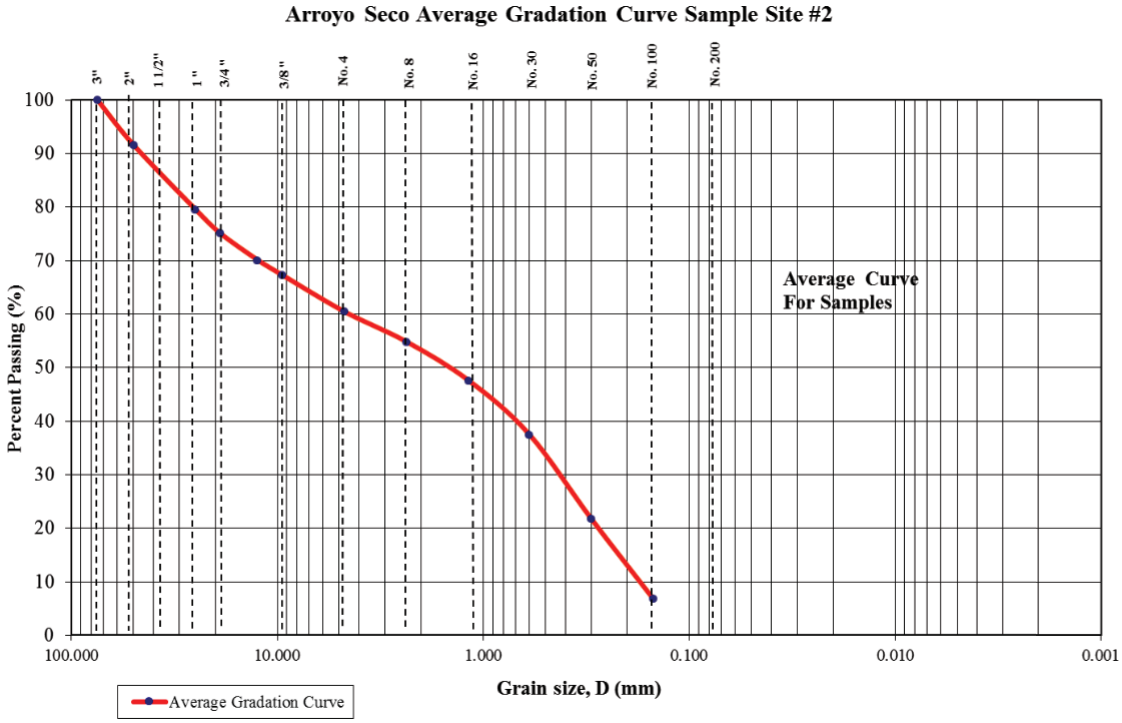
7.3 SEDIMENT DATA

To characterize the sediment of the streambed and by extension, the possible bed load of sediment during discharge events, a sediment grain size analysis was conducted. The goal of the analysis is to gain a statistical representation of the size distribution of soil components of the streambed. Grain size distribution analysis is a powerful tool because the results can represent both a qualitative description of soil make up as well as quantitative input for further predictive measures, such as fluvial modeling.

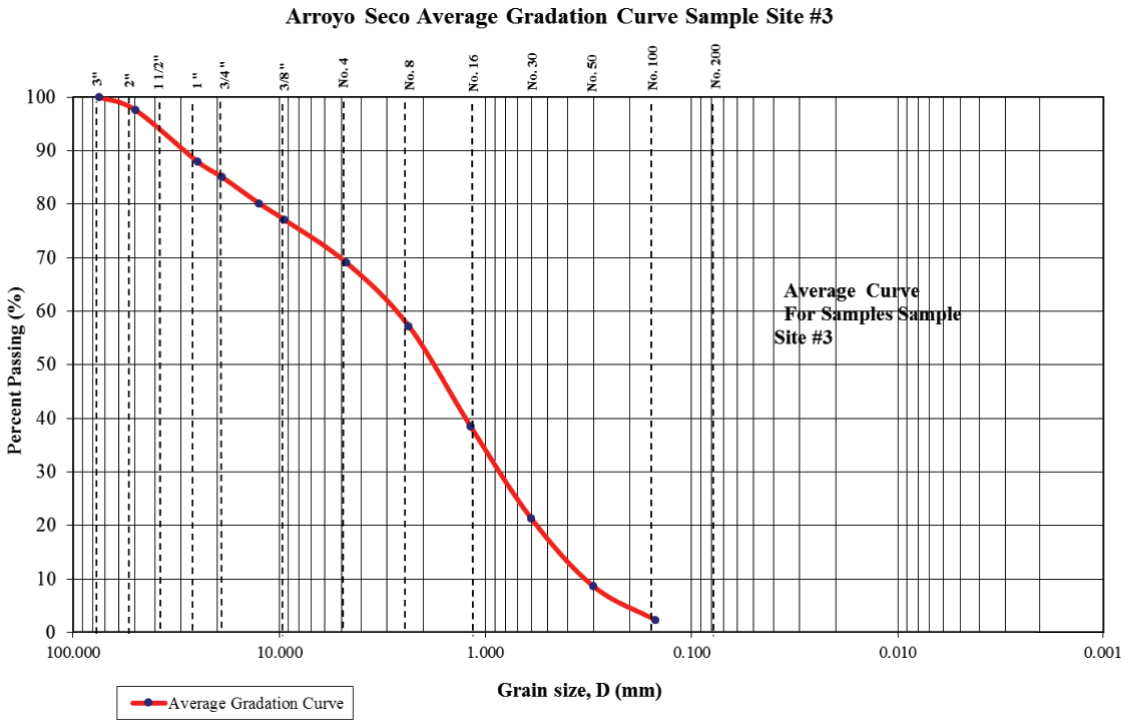
Sediment sampling was conducted by R. T. Frankian & Associates (2018). Sampling was conducted at a total of 6_locations, approximately every 2,000 feet within the stream bed from 200 feet upstream of the existing diversion structure to 200 feet upstream of the Dam face, which is a distance of approximately two miles. A total of three samples were taken within the stream bed at each of the proposed sample locations; each sample location was taken from a depth of approximately 18 inches. Samples were only obtained in surface-dry areas of the stream bed. Access to each of the sample locations was limited to foot traffic from various access points. The excavation and sampling of sediments were limited to the use of hand-operated equipment. Excavated sediments were stockpiled on heavy tarps during the process of excavation, sampling, and classification. The remnant excavated sediments were used to backfill each of the sample locations. Field samples obtained from each of the test pits were laboratory sieved for grain size distribution testing in general accordance with ASTM Test Method D422. The portions of the samples tested were limited to that portion of each sample greater than the No. 200 Sieve.

Since SAM is a single point model, two specific locations were chosen for modeling. The first model location is approximately 200 feet upstream of the JPL Bridge, while the second model location is approximately 1,100 feet downstream from the bridge. Both locations are relatively distant from the influence of confluences and structures, and neither is located in the reservoir, which is not appropriate for modeling with SAM. Sample Location No. 2 and No. 3 were taken at these sites, respectively, and the average grainsize distribution at each location was used for SAM modeling. The average grainsize distribution of Sample Location No. 2 and No. 3 is shown in Exhibit 12. One benefit for selecting these sites is that the upstream location is within the more confined channel reach, while the downstream location is below the grade break in the stream where Arroyo Seco begins to widen and acquires characteristics of an alluvial surface. Therefore,

these two locations are representative of the two primary stream morphologies found in the study area. All Frankian sediment data is presented in Attachment C.



7.4 TRANSPORT EQUATION SELECTION



Sediment transport equations used in all SAM modeling were chosen with the assistance of the U.S. Army Corps of Engineers' (USACE's) SAM.AID subroutine. The SAM.AID subroutine determines the most representative transport function based on the hydraulic parameters and soil gradation data for a section of Arroyo Seco by comparing model data with the results of 20 peer-reviewed and widely acknowledged sediment transport studies. To accomplish the task of guiding the user in selecting an appropriate transport function, SAM.AID assumes that the function that best represents sediment transport in a gauged stream would also best represent transport in an ungauged stream with similar sediment and hydraulic characteristics. SAM.AID begins by comparing study parameters (V, D, S_e, B_e, D_{50}) with parameters in the transport function database. Comparison begins by determining if D_{50} falls within one of the ranges identified in the database. Once the initial matches have been made in the database, the three best-matched sediment transport functions for the study reach are listed along with the parameters that matched the data set. Once the best transport equation matches have been determined by SAM.AID, the most representative equations are run in SAM.SED.

The Yang and Ackers-White equations were found to be the representative transport equation for a discharge of 25 cfs, the proposed diversion discharge. A discussion of sediment transport applicability (Yang and Huang 2001) suggests that Ackers-White is more appropriate for sand transport than is the Yang equation. Therefore, all analysis is based on Ackers-White, but the Yang equation results are included for completeness. All SAM model input and output can be found in Attachment C.

7.5 SAM MODEL RUNS

The SAM model was run at Sample Location No. 2 and No. 3 for 25 cfs, the proposed diversion discharge. The SAM runs were intended to indicate the possible change in sediment transport potential at the two model locations resulting from the proposed diversions. Representative hydraulics from each location were taken from the HEC-RAS model and sediment data was taken from Frankian sieve data, as described above.

8.0 SEDIMENT TRANSPORT MODEL OUTPUT

The sediment transport potential at Sample Location No. 2 and No. 3 are, respectively, 37,680 and 169 tons per day for the Ackers-White equation and 3,788 and 148 tons per day for the Yang equation. A large portion of the difference appears to be related to Location No. 2's ability to generate sufficient transport potential in the 2.828 mm size class for Ackers-White, which does not occur at Location No. 3. Additionally, the transport potential for all size classes is approximately one order of magnitude greater at Location No. 2 than Location No. 3 for Ackers-White for almost all grain size classes. Similar results are observed for Yang's equation, although Yang predicts sediment transport potential up to 5.657 mm at Location No. 2, but only up to 2.828 mm at Location No. 3.

A review of the hydraulics at each location identifies the cause of the disparity in transport potential between the two locations. The steeper, narrower Location No. 2 has higher velocity, steeper slope and narrower top width relative to Location No. 3, which is below the channel's grade break. This finding matches the finding of PWA (2000) that significant sediment deposition occurs in what is referred to as the "upper reservoir." The implication for this finding is that the lower portion of the Arroyo Seco study area behaves in a similar way to an alluvial fan below the hydrographic apex whereby sediment is deposited in patterns associated with flow path uncertainty, and sediment transport below the grade break is strongly a function of local hydraulics (e.g. Leopold et al. 1992).

9.0 HYDRAULIC AND SEDIMENT MODELING CONCLUSIONS

In dry, average, and wet representative years, modeled diversions from Arroyo Seco have an effect on velocity in select areas of the reservoir upstream of Devil's Gate Dam. The effects on velocity are small in absolute terms ($\Delta v_{maximum} < 3$ *fps*), and in some cases the change in velocity represents a decrease from the existing conditions. Numerical modeling indicates that the factors that control change in velocity in the reservoir are the magnitude (peak discharge) and shape (number of peaks and duration of individual runoff hydrographs) of the earliest storms in a given season and the extent to which ponded water fills the lower reservoir. In cases where diversions do not effect early-season large runoff events, differences in maximum velocity can be expected to be negligible between the without and with diversion scenarios for any representative year. In contrast, the extent which the reservoir is full in either the without or with diversion scenario may affect the change in velocity by creating a backwater condition in the reservoir. Modeling suggests that the direct effect on velocity from diversions is for events where the maximum discharge is near or below 25 cfs. However, as was identified by Inman and Jenkins (1999), the dominant driver of runoff in coastal southern California is large winter storms. Therefore, only in years where the primary source of water to the Devil's Gate Reservoir is runoff events near or below 25 cfs are velocities expected to be affected by diversions. It should be noted that the representative dry year is only minimally affected in this manner.

Effects on maximum depth in dry, average, and wet representative years in Arroyo Seco are largely mediated by the amount of ponding in Devil's Gate Reservoir. Ultimately, the ponding in the reservoir is a function of the rate, frequency and volume of inflow, and the dam operation outflow. In representative average and wet years, the modeled extent of ponding is a function primarily of dam operations for both the without and with diversions. In represented dry years, numerical modeling indicates that maximum depth is primarily driven by the volume of water entering the reservoir in the absence of reaching the dam operational curve elevation. In representative dry years, diversions may have an effect on maximum water depth in the reservoir, and modeling indicates that maximum depth in these years is partially a function of when in the season the largest runoff events occur. That is, representative dry years with diversions and a few relatively large runoff events will have a similar maximum depth in the reservoir compared to representative dry years without diversions. In contrast, in representative dry years without a few relatively large events, modeling predicts that the difference in reservoir maximum depth will be greater. Finally, in representative wet and average years the duration of inundation can be impacted on the fringes of the reservoir by diversions. Diversions in these years appear to increase the inundation duration somewhat by increasing the volume of runoff required to initiate dam operations.

The numerical modeling presented here indicates that relatively small effects on maximum velocity and maximum depth occur from proposed diversions upstream. These effects (change in velocity) are limited generally to the stream channel within the lower reservoir and the backwater area immediately upstream and to the west of the dam. Additional minor effects (change in duration of inundation) are indicated at the reservoir edge and appear to be strongly a function of dam operations as well as diversions.

SAM modeling of two locations within the study area indicates that there is greater sediment transport potential at 25 cfs in upper portions of Arroyo Seco, which are steep and narrow, compared to portions below the topographic break, which are wider and flatter. This finding echoes that of PWA (2000) that found that significant sediment deposition occurs in the "upper reservoir." **The implication for the present study is that for low discharges in Arroyo Seco, the reduction in discharge of 25 cfs is expected to be unimportant to overall sediment transport potential because the controlling elements of sediment transport are geologic factors.** Moreover, in large runoff events that are typically the dominant delivery mechanism of

sediment in southern California (Inman and Jenkins 1999) no diversions are presently proposed and are therefore not expected to be impactful to stream sediment yield to the reservoir.

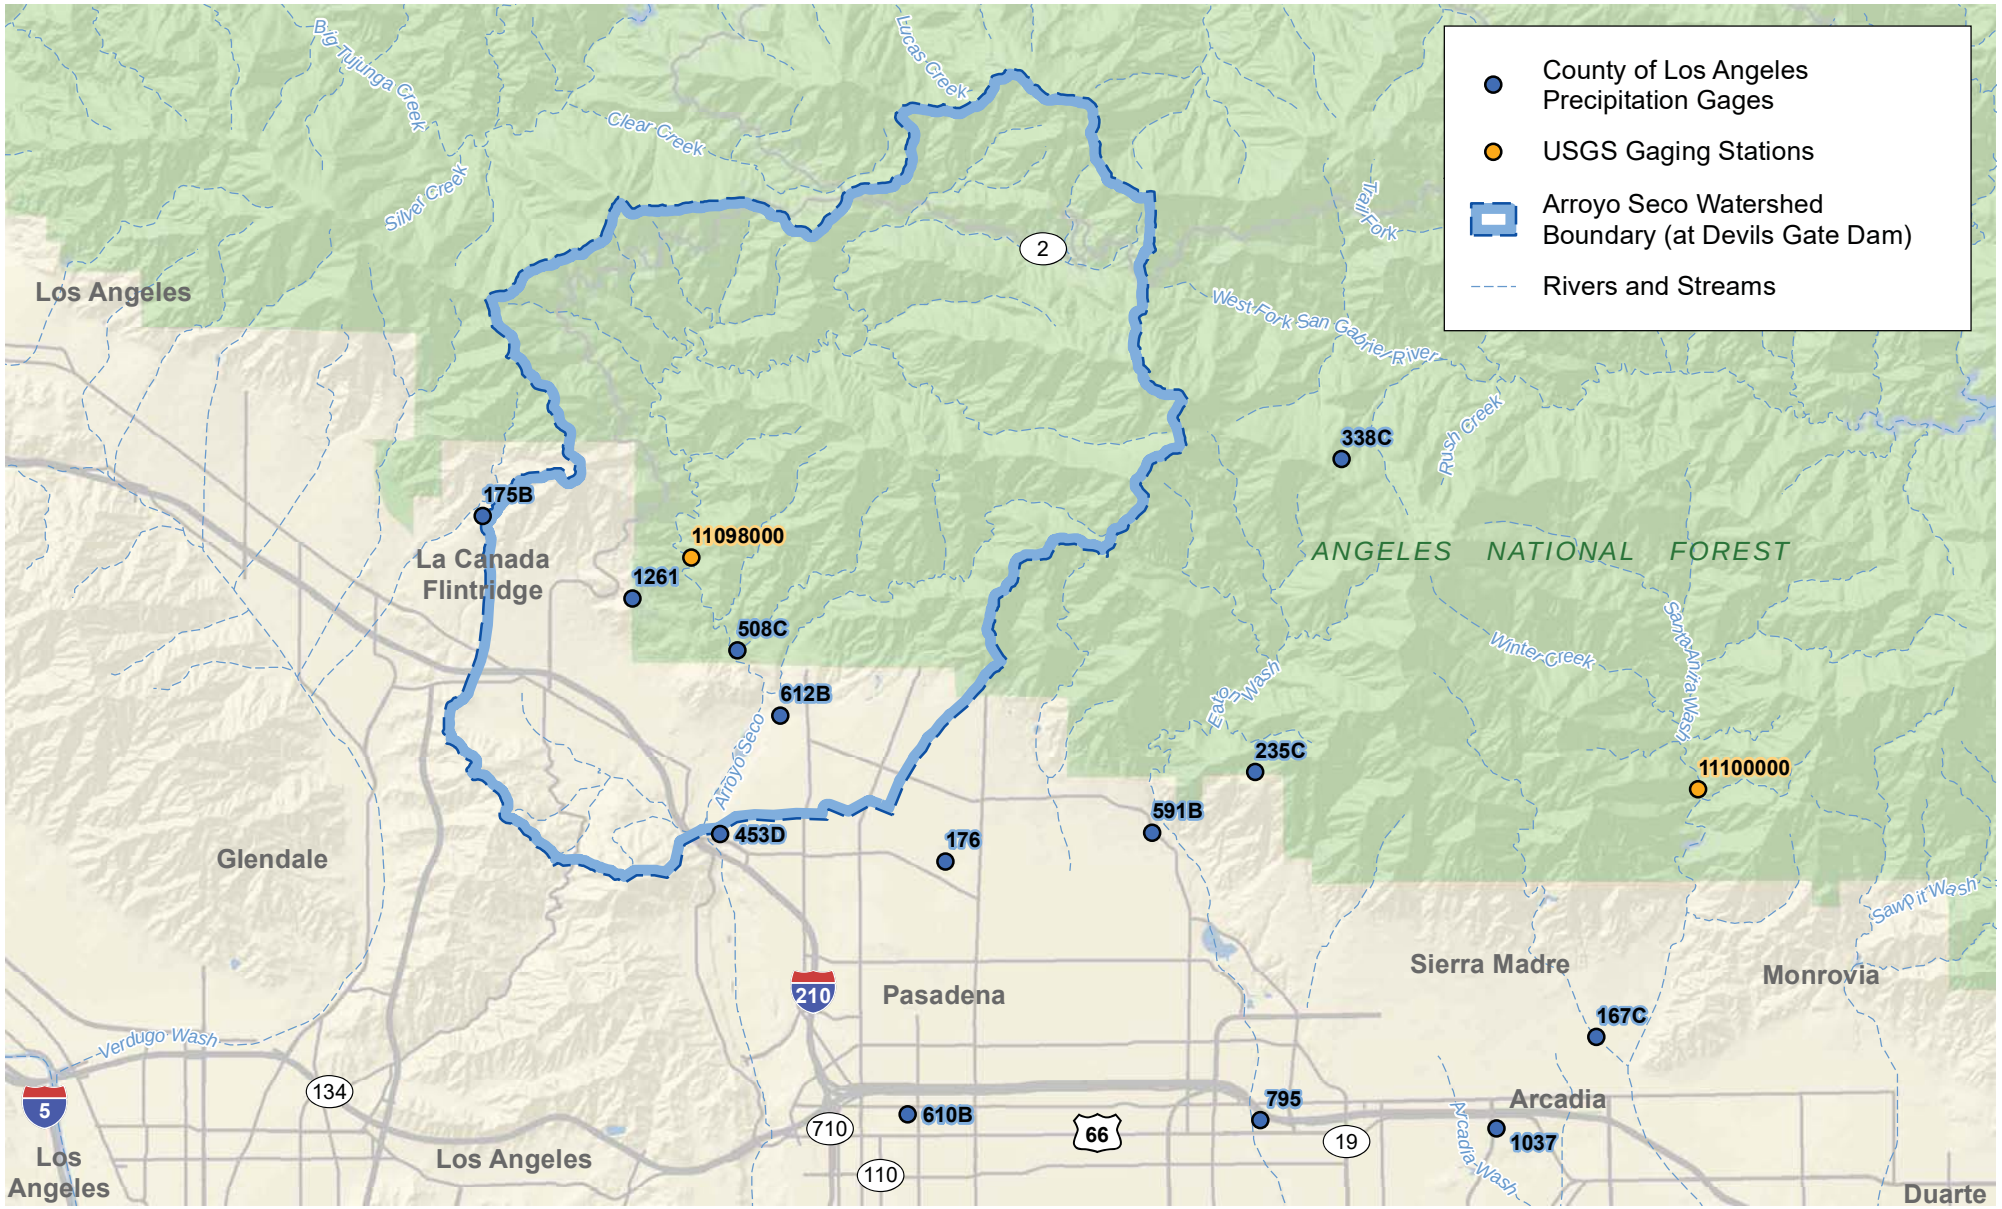
10.0 GROUNDWATER ASSESSMENT

10.1 PHYSIOGRAPHY

The Arroyo Seco Watershed is bounded on the north by the San Gabriel Mountains, which consist of steep, rocky ridges broken by numerous irregular canyons. The elevations of these mountains vary from about 1,200 feet along their base to a maximum of more than 6,000 feet above sea level at the headwaters of the Arroyo Seco.

The Arroyo Seco stream empties out into a broad piedmont plain that slopes downward from the base of the San Gabriel Mountains to Devil's Gate Reservoir, the lowest ground surface point of the Raymond Groundwater Basin within the Project area (see Exhibit 13). The Arroyo Seco continues south until it empties into the Los Angeles River near the intersection of the 5 and 110 freeways. The Raymond Basin (see Hydrogeology Section) forms along the southern flank of the San Gabriel Mountains and extends into the project area beneath Devil's Gate Reservoir.

10.2 GEOLOGY



10.2.1 General Geology

The Raymond Basin lies in the northwestern part of the San Gabriel Valley, bounded by the San Gabriel Mountains to the north, the San Rafael Hills to the west, and ending to the south and east at the Raymond Fault. The San Gabriel Mountains, along with the San Bernardino Mountains to the east and the Santa Monica Mountains to the west, make up a major portion of the east-west trending Transverse Range geologic province of California. The San Gabriel Mountains are primarily composed of Cretaceous to Tertiary crystalline rocks, including diorites, granites, monzonites, and granodiorites, with a complex history of intrusion and metamorphism. The Sierra Madre fault system separates the San Gabriel Mountains to the north from the San Gabriel Valley to the south. Within the valley lies Quaternary alluvium, made up of sand, gravel, clay, or some mixture of each. Underlying the alluvium is the crystalline basement complex, comprised of the same general rock types that are exposed in the San Gabriel Mountains to the north (Foster Wheeler Environmental Corporation [FWEC], 1999).

Raymond Fault, the southern boundary of the triangle, crosses the San Gabriel Valley floor for a distance of about nine miles, connecting a granitic spur from the San Gabriel Mountains at the eastern end of the Raymond Basin with Tertiary sediments outcropping in its southwestern corner. The Raymond Fault separates the Raymond Basin from the Main San Gabriel Basin in the vicinity of the southeasterly boundary. The fault zone is not impervious and groundwater can flow across this boundary into the Main Basin (NASA 2003). The general geology of the Raymond Basin is shown in Exhibit 14.

The low water-bearing formations in the project area include the Basement Complex rocks and Tertiary sediments of the Topanga, Modelo and Puente formations (Exhibit 14 and Attachment D).

The Basement Complex is comprised of pre-Cretaceous series of crystalline rocks that comprise the basal formation of the region. These are chiefly igneous plutonic rocks of granitic type, together with their metamorphic phases, such as schists, gneisses, and also various intrusive dikes. The Basement Complex comprises the majority of San Gabriel Range to the north and the San Rafael Hills to the west. The Basement Complex protrudes above the alluvium at Monk Hill

and near the head of Eaton Wash demonstrating that it is continuous beneath the area. The Topanga Formation, Tertiary age sedimentary rocks, is represented in the Raymond Basin by fairly well bedded shales, sandstones, and conglomerates that are well consolidated. The exposed Topanga beds are limited to the southwesterly corner of the area along a fault block where the formation is exposed for a mile in the channel of Arroyo Seco just north of the Raymond Fault and for about one and one-quarter miles easterly from the Arroyo Seco to Raymond Hill (RBMB, 2016).

The CDWR (1966) characterized the water-bearing formations of the Raymond Basin as alluvial fill having characteristics of the coarse deposits found in the small basins near the mountain margins. The deposits are coarsest at the base of the mountains where they contain boulders several feet in diameter, but even in the southerly part of the basin, cobbles, stones, and boulders are not uncommon. There are practically no true sand beds in the northerly part of Raymond Basin. The average sand content in the basin sediments as determined from well logs is only 2.8 percent. The deposits are characterized throughout by an abundance of weathered material. Decomposed yellowish gravels, clayey yellow and red gravels, and red or brown residual soil clays are the typical deposits.

The older alluvium found within the area is nearly continuous along the entire southerly flank of San Gabriel Range with little change in composition or structure. Within the Raymond Basin, it constitutes practically all of the water-bearing series and is not only dominant at the surface but appears to continue with depth to bedrock, although at depth, it may be in contact with some of the late Tertiary sediments. The older alluvial fill consists of a small portion of sand and almost equal proportions of gravel and clay. Older alluvial fill is of great thickness and its deposition has occurred through a long period. Weathering, disintegration, and cementation have been continuous and the results have varied with local conditions and there is considerable spatial variation in the water yielding characteristics of this formation (RBMB, 2016).

Recent alluvium occupies channels, washes, and flood plains of Arroyo Seco, Eaton Creek, and Big and Little Santa Anita Creeks, and to a lesser extent, exists as veneers scattered along the slope of the valley resulting from flood discharges of intermittent streams (Exhibits 13 and 14). For the most part, the recent alluvium is believed to be shallow, but in the upper portions of Little Santa Anita Wash, the indications are that the recent alluvium may extend to a depth of about 150 feet. These sediments are similar to those found in the older alluvium but contain a much smaller proportion of clay and are unconsolidated.

10.2.2 Structural Features and Faults

According to the CDWR (1943), the geologic structure of Raymond Basin is complicated. The rough surface topography of the Basement Complex outside the area indicates that the bedrock floor beneath the alluvium undulates, although the present mountain block undoubtedly exhibits a more rugged topography due to its recent rejuvenation with accompanying accentuation of erosive forces, then the old erosion surface was buried and protected by alluvial deposits of the area. However, within the area, except at the boundaries, and the granitic protrusions at Monk Hill and near the north end of Eaton Wash, there is no surface expression of undulations of bedrock which might indicate possible impediments to groundwater movement.

The San Gabriel Fault cuts through the central portion of San Gabriel Mountains and has an east-west trend. It is one of the main faults in the mountain block but is so distant that its effect upon the Raymond Basin area is only indirect (RBMB, 2016).

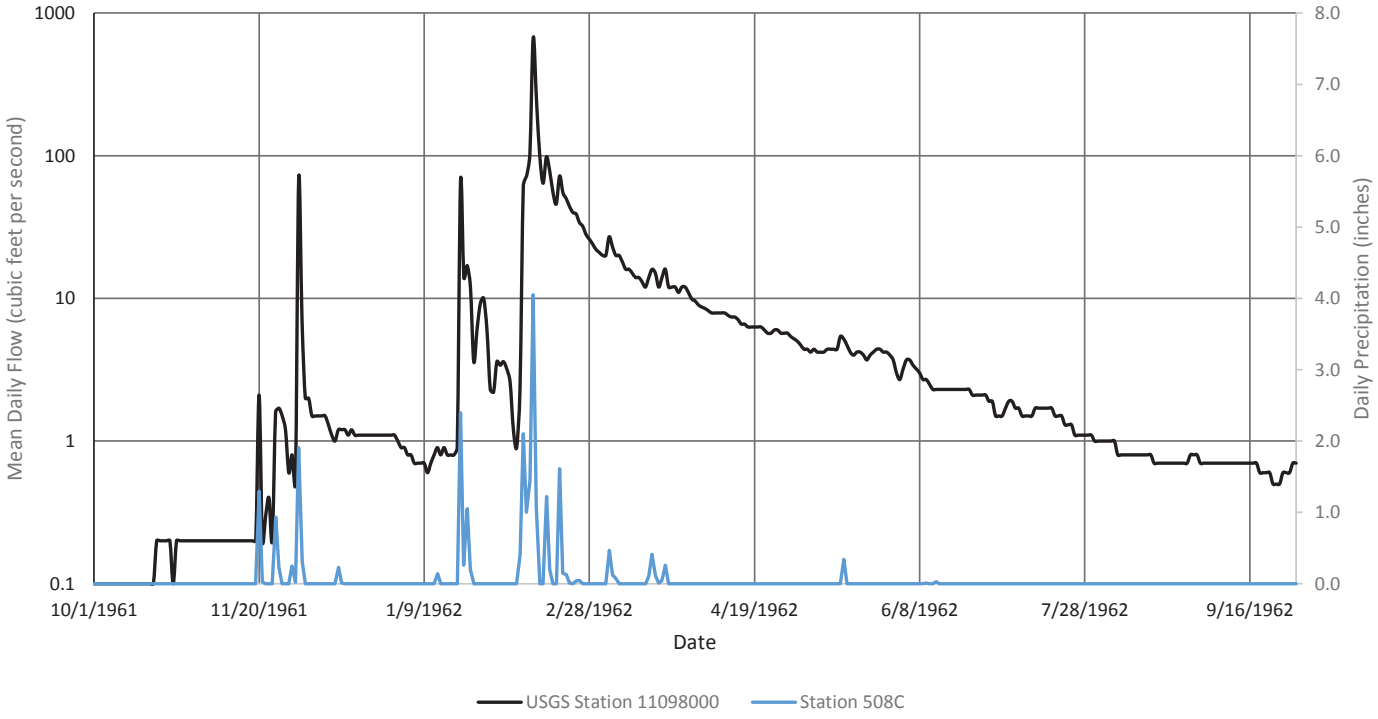
The Sierra Madre Fault system is a broad zone of faulting with an east-west trend roughly parallel to the southern edge of the San Gabriel Mountains, swinging to the northwest in the vicinity of the City of Sierra Madre. The main trace of this zone leaves the southern edge of the foothills at a

point west of the mouth of Eaton Wash, penetrating the mountain block in a north-westerly direction for some distance before it again swings to the west. The bedrock contours as a result of the geophysical survey indicate a uniform northerly slope of the buried bedrock surface from San Rafael Hills (RBMB, 2016).

Hydrogeologic investigations and groundwater modeling work at the Jet Propulsion Lab (JPL) (NASA, 2003) identified a thrust fault crossing Arroyo Seco just as Arroyo Seco enters the Raymond Basin. Preliminary work indicated that the fault was a partial barrier to groundwater flow.

The Raymond fault forms the boundary between the Raymond Basin and the Main San Gabriel Basin from the City of South Pasadena on the west to the City of Monrovia on the east. It is likely a thin, impervious gouge formed in alluvium because it creates a several hundred-foot difference in water level elevation in approximately 2,700 feet between Del Mar Well of California American Water Company and Well No. 3 of San Gabriel County Water District (RBMB, 2016). In addition to the difference in water level elevation, the barrier effect of the Raymond fault is indicated by the presence of artesian conditions during periods of high water levels, and by the creation of ponds and swampy areas north of the fault line. The Raymond fault appears to impede groundwater movement southward from the Raymond Basin into the Main San Gabriel Basin (RBMB, 2016).

10.3 WATER RESOURCES



10.3.1 Precipitation

The Raymond Basin is located within a region of both semiarid and Mediterranean climate, with warm, dry summers and mild winters with intermittent rain. The majority of the annual rainfall occurs between December and March. Precipitation in the Arroyo Seco area has been monitored by a network of precipitation stations operated by Los Angeles County, Department of Public Works (LACDPW). Annual precipitation within the Raymond Basin is more variable in the mountain watershed than in the valley floor. The mountain watershed (28.40 inches) averages about 7 inches more annual precipitation than the valley floor (21.33 inches) (RBMB, 2016).

As previously indicated, RBMB (2016) conducted an evaluation of precipitation in both the mountain areas and the valley floor areas and noted about 7 inches of more precipitation in the mountain region. No existing operational precipitation gages are located in the upper portion of Arroyo Seco, however an historic gage was located at the Arroyo Seco Ranger Station (LA County gage 508C) and operated from 1914 to 1974 (see Exhibit 13). A comparison was made with LA County gage 175 (La Canada Irrigation District) to find an average year for precipitation during the same period that LA County gage 508C was operational. The period selected was October 1961 to September 1962 where LA County gage 175 recorded 26.00 inches (20-year average was 26.96 [as reported by RBMB, 2016]) and LA County gage 508C recorded 24.75 inches and is presented in Exhibit 15.

10.3.2 Surface Water

The entire Raymond Basin area lies within the watershed of the Los Angeles River (CDWR, 1966), and surface runoff from the San Gabriel Mountains enters the area through numerous streams, principally the Arroyo Seco, Eaton Wash, and Santa Anita Wash. About one-third of the surface runoff is conveyed by the Arroyo Seco, the largest of the streams, which flows across the Monk Hill Subarea and the Pasadena Subarea, and joins the Los Angeles River by cutting through the San Rafael Hills. Outflow from the western portion of the Monk Hill Subarea reaches the Los Angeles River through the Verdugo Wash. The balance of the surface runoff primarily flows in

Eaton Wash and the Santa Anita Wash to the Rio Hondo and ultimately drains to the Los Angeles River.

The U.S. Geological Survey (USGS) maintains a surface water gaging station no. 11098000 and referred to as Arroyo Seco near Pasadena, CA (see Exhibit 13). Table 2 provides the mean monthly flow, measured by the USGS gage at the Arroyo Seco site.

Source: Derived from USGS, 2018.

The majority of the runoff occurs between December and May with the remainder of the period with average monthly flows generally less than 5 cubic feet per second (cfs). The maximum flow measured with the USGS gage, for the period of record (1911 through 2017), was 8,620 cfs (on March 2, 1938) (USGS, 2018). While the largest responses to flow generally occur from precipitation events, the stream maintains flows during non-rainfall periods indicating that it derives some of its flow from springs, groundwater inflow and other sources, such as storm drain outlets.

A comparison was made for an average precipitation period (see Precipitation section) with the daily mean streamflow for USGS station 11098000, Arroyo Seco near Pasadena, CA and presented in Exhibit 15. The comparison indicates the Arroyo Seco quickly responds to precipitation events in excess of 0.5 inches per day which occur between mid-October through February. By mid-March, the stream goes into a baseflow condition declining from 10-20 cfs to

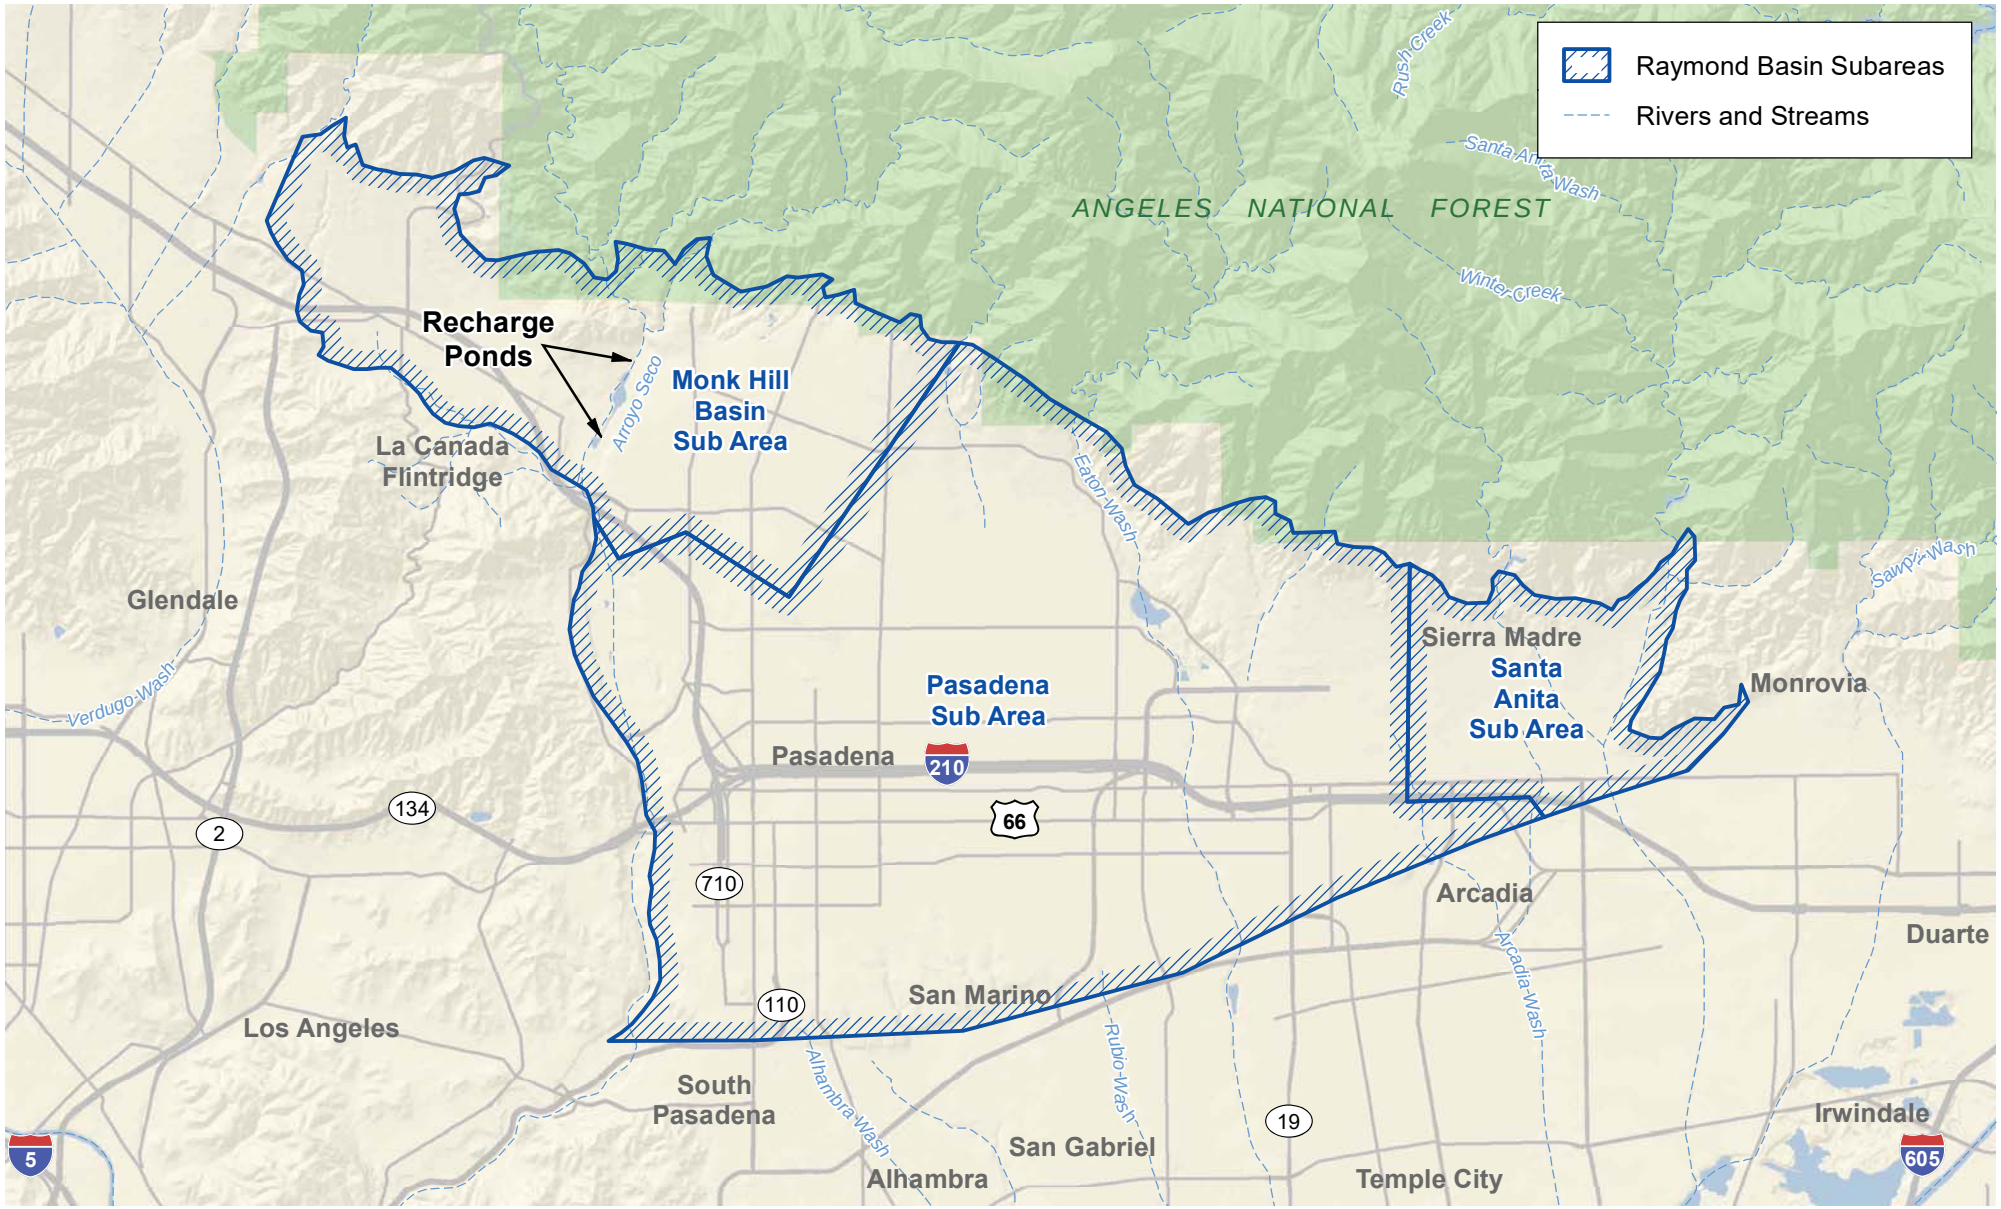
approximately 1 cfs in late summer. This is probably related to the delayed discharge from the fractured bedrock groundwater discharging to the shallow alluvium found in the mountainous portion of Arroyo Seco.

10.3.3 Groundwater

The Raymond Basin is a structural basin filled with permeable alluvial deposits, which is underlain and surrounded by relatively impermeable rock. The Basin aquifer is stratified in some areas by confining or semi-confining layers consisting of impermeable or less-permeable materials such as clay or silt. In these areas, the Basin aquifer is an aquifer system that may include an unconfined or water-table aquifer overlying individual confined or artesian aquifers separated by semi-confining or confining layers. In general, the Basin aquifer is classified as an unconfined to semi-confined aquifer system because the semi-confining or confining layers are not continuous across the Basin (RBMB, 2016).

The base of the water bearing zones is considered bedrock with elevations ranging from approximately 500 feet below sea level to 2,000 feet above mean sea level. The Raymond Basin is divided into three separate hydrologic sub-areas: the Pasadena Subarea, the Santa Anita Subarea, and the Monk Hill Subarea (MHSA) (see Exhibit 16, Groundwater Subareas within the Raymond Groundwater Basin). The diversion point lies just outside of the MHSA while the spreading grounds lie just inside the eastern edge of the MHSA adjacent to the City of Pasadena production wells. Downgradient of the MHSA, groundwater elevations range from 500 to 900 feet above mean sea level (msl) and have a southern flow direction, which then curves to the southeast in the southern part of the basin. The direction of groundwater flow within the basin varies depending on the subarea. Estimates of regional hydraulic gradient range between 40 and 200 feet per mile (0.008- to 0.04-foot/foot) (RBMB, 1985). The total storage capacity of the Raymond Basin is estimated to be approximately 1.37 million acre feet (maf). The amount of water in storage in 2003 was approximately 800,000 af with an unused storage space of about 570,000 (RBMB, 2016).

The Raymond Groundwater Basin is an adjudicated groundwater basin managed by Raymond Basin Management Board. The adjudication (originally completed in 1944 and amended over the years) determined who had a right to extract water and the maximum annual amount of water allowed to be pumped by each producer. This “safe yield” concept allows an annual fixed amount of water to be used by the 16 water producers served by the Raymond Basin (RBMB, 2016 and 2018).



Groundwater Levels and Flow

Groundwater levels in the Raymond Basin range from about 350 feet above Mean Sea Level (MSL) in Santa Anita Subarea to more than 1,050 feet above MSL in the MHSA. Groundwater generally flows southeast from the MHSA in the northwest to the Raymond fault in the southeast (RBMB, 2016).

Monk Hill Subarea

Groundwater levels in the MHSA have fluctuated, but remained relatively stable since 2000 (RBMB, 2016). In general, groundwater flows from the MHSA into the Pasadena subarea (RBMB, 2016).

NASA (2003) reported that the water table elevation varies significantly over the JPL site, which is located immediately west of Arroyo Seco, by as much as 130 feet. The groundwater elevation high point was measured in MW-1, located at the mouth of the Arroyo Seco. The significant

change in average hydraulic head between the monitoring wells located near the mouth of the Arroyo Seco and the monitoring wells to the southwest and west of the mouth of the Arroyo Seco. The change in flow regime across this area, significant difference in water levels over the relatively short distance, and lack of response of water levels near the mouth of the Arroyo Seco to pumping suggests the presence of either a very low conductivity area within the mouth of the Arroyo Seco or a hydraulic barrier that affects groundwater flow from this area (NASA, 2003).

Subsurface Flow

CDWR (1966) addresses subsurface inflow from the Raymond Basin into the Main Basin and states in part "…*Underflow into San Gabriel Valley across the Raymond fault varied from 2,000 to 12,000 acre-feet per year during the base period [from 1943-44 to 1959-60]. This subsurface flow did not occur at the same rate along the length of the fault, but varied from west to east. The lowest rates occurred near the western edge of the basin where the Raymond fault constitutes a nearly impervious barrier to groundwater movement, and the highest rates occurred near Santa Anita where the barrier effect is negligible. Estimates of underflow across the Raymond fault were based on values of groundwater gradients between water levels north of the fault."*

Monk Hill Subarea

Subsurface inflow from the Verdugo Basin into the MHSA has ranged from 890 acre-feet to 3,990 acre-feet over the period from 1994-95 to 2011-12. The long-term (31-year) average annual subsurface inflow has been 2,270 acre-feet. Subsurface outflow from the MHSA into the Pasadena Subarea has ranged from 5,750 acre-feet to 7,270 acre-feet over the period 1994-95 through 2011-12. The mean subsurface outflow to the Pasadena Subarea was 6,700 acre-feet (RBMB, 2016).

Groundwater Recharge

Monk Hill Subarea

Artificial recharge of the MHSA historically has occurred as a result of infiltration of stormwater runoff and, to a lesser degree, injection of treated imported water. Artificial recharge (through the spreading grounds) has ranged from 450 acre-feet to 9,700 acre-feet during the period of 1994-95 through 2011-12. Injection of treated imported water has ranged from zero acre-feet to 1,480 acre-feet during the period of 1994-95 through 2011-12. Average combined annual recharge from artificial recharge and injection has been 3,400 acre-feet (RBMB, 2016).

Accordingly, the diversion of water from Arroyo Seco north of the MHSA into the spreading grounds that are located inside of the MHSA has caused a mounding effect in the groundwater table in the MHSA (NASA, 2003).

10.4 GROUNDWATER CONCLUSIONS

Both surface water of Arroyo Seco and groundwater in the underlying alluvium of Arroyo Seco drainage north of the MHSA eventually discharge into the Monk Hill Subarea. The diversion of water upgradient of the MHSA from Arroyo Seco and placement into the Arroyo Seco spreading grounds (in the MHSA) adjacent to the existing Pasadena production wells is essentially assisting in the enhancement of groundwater replenishment and management of the Raymond Basin which is consistent with the requirements of the adjudicated Raymond Groundwater Basin. **As a result, it is unlikely that groundwater levels within close proximity of riparian resources would have any measurable effect on rootzones because of the relative depth of the groundwater.**

INTRODUCTION

The Los Angeles 30’ x 60’ quadrangle covers approximately 5,000 km^2 including much of the densely populated urban and suburban areas of the southern California megalopolis. The quadrangle is about 90 km east-west and about 55 km north-south, extending from Fillmore and Thousand Oaks in the west to Acton in the northeast and Montebello in the southeast. It covers the urban San Gabriel Valley and San Gabriel Mountain foothill communities from Monrovia to Pasadena, as well as Glendale, downtown Los Angeles, Hollywood, Santa Monica, Malibu, and all the communities in the San Fernando Valley, Simi Valley, and the upper Santa Clara River Valley. Population of these urban and suburban areas, as listed in the 2000 Census, totals approximately 5.6 million, and property value is estimated to total hundreds of billions of dollars. The quadrangle also includes large areas of wilderness in the Angeles and Los Padres National Forests, the Santa Monica Mountains National Recreation Area, and the Sespe Condor Sanctuary. The relief in the quadrangle ranges from about a hundred meters subsea (in Santa Monica Bay) to more than 2,000 meters above sea level at Pacifico Mountain in the high San Gabriel Mountains. Residents and visitors are subject to potential hazards from earthquakes, debris flows and other landslides, floods, wildfires, subsidence from ground water and petroleum withdrawal, and swelling soils; and coastal areas are exposed to flooding and erosion by storm and tsunami waves. This geologic map is intended to illustrate the distribution of the rocks and surficial deposits of the area and their structural and stratigraphic relations to one another. It provides a regional geologic framework as an aid to better evaluations of the potential for hazard from active earth processes. As a digital product it includes some areas mapped in greater detail than others; however, it is not sufficiently detailed to serve as a basis for site-specific evaluations.

SOURCES OF GEOLOGIC MAPPING

The map has been compiled from many scientific studies in different parts of the quadrangle, and represents the work of many geologists. Compilation of the Los Angeles 30’ x 60’ quadrangle was completed by Yerkes and Campbell (2005) and published by the U.S. Geological Survey. That map, which can be considered version 1.0 of the digital geologic map of the Los Angeles 30’ x 60’ quadrangle, involved digitization of original field mapping, and digitization and assembly of numerous published and unpublished source geologic maps. This effort, led by Robert Yerkes between 1985 and completion of the map in 2005, provides a foundation for the additions and further refinement presented here.

This map, version 2.0 of the digital geologic map of the Los Angeles 30’ x 60’ quadrangle, represents an update of the map by Yerkes and Campbell with extensive revisions and additions. Many of these revisions and additions resulted from studies by the California Geological Survey to define Seismic Hazard Zones, where development must consider the potential hazards from liquefaction and earthquake-induced landslides. The listing of sources of geologic mapping below includes geologic maps that were used by Yerkes and Campbell (2005), additional geologic maps included in this compilation, and reports describing the liquefaction zoning and earthquake-induced landslide zoning for each quadrangle. Although the Seismic Hazard Zone Reports referenced below are focused on the details of delineation of the hazard zones, virtually all reports resulted in revised mapping of some geologic units. Revised mapping of younger Quaternary units, including the contact between late Quaternary alluvium and

bedrock, was a focus of the seismic hazard zoning effort because these contacts can define the boundaries of Liquefaction Hazard Zones. New mapping of Quaternary units was generally based on geomorphic expression, supplemented by descriptions of the subsurface materials in numerous boreholes from throughout the valley areas (Wills and Hitchcock, 1999, Hitchcock and others, 1999). Quaternary units are designated using the terminology of Matti and Cossette (2007).

The process of creating earthquake-induced landslide zoning resulted in compilation of bedrock units that in some cases differed from the compilation of Yerkes and Campbell (2005). This effort also included re-mapping of landslides for the region, except for areas within National Forests. In preparing this compilation, we have used the compilations from the Seismic Hazard Zonation Program, reconciled those with the source maps used by Yerkes and Campbell (2005), added additional detail based on source maps not used by either the Seismic Hazard Zonation Program or Yerkes and Campbell (2005) and added selected landslides mapped by the Seismic Hazard Zonation Program. Due to the scale of this map, most small landslides and all landslides considered "questionable" in the original landslide inventories are not shown. CGS landslide inventory maps, and related 1:24,000-scale maps, show a more complete depiction of landslides. Landslides that are too small to show on 1:24,000-scale maps can be hazardous and damaging, so no regional map should be used to evaluate the landslide hazard to a particular location or parcel.

In addition to revisions to geologic contacts based on the Seismic Hazard Zonation Program, this map includes extensive revisions to the crystalline bedrock of the San Gabriel Mountains. Yerkes and Campbell (2005) completed a generalized compilation of the San Gabriel Mountains. In their compilation, they modified the nomenclature of the basement rock units to conform with the IUGA Subcommission on Systematics of Igneous Rocks (Streckheisen, 1973), and to provide continuity with the compilation in the San Bernardino 30' x 60' quadrangle (Morton and Miller, 2003), which adjoins the Los Angeles 30' x 60' quadrangle on the east. They did not, however, attempt to reconcile the various more detailed maps of this area. For this compilation, we have attempted to use as much detailed original mapping as possible and describe the units in as much detail as possible. Where the detailed mapping and unit descriptions are from a single source, such as within the anorthosite complex described by Carter (1980, 1982), this map represents a complete, consistent interpretation. In other areas, detailed mapping and description of map units are lacking or are provided by different authors who had differing interpretations. In some cases, we have extended units described by one author based on contacts by another. Although the resulting compilation is more detailed than that by Yerkes and Campbell (2005), there are significant areas where map unit boundaries, descriptions, and correlations could be improved by new mapping.

In addition to the major updates noted above, CGS has updated numerous other local areas based on map sources not used in the map by Yerkes and Campbell (2005). These more local updates include new mapping of parts of the active Hollywood, San Cayetano, and Simi Faults, updates to mapping and stratigraphy of the Plio-Pleistocene sedimentary rocks of the Ventura basin (see Appendix A), and updates to the Tertiary units in the Soledad basin.

The major sources of mapping are listed below by the 7.5-minute quadrangles shown in Figure 1. Sources are underlined if they are a major source of geologic unit boundaries shown on this compilation, and in italics if they were not used in the compilation by Yerkes and Campbell (2005). Seismic Hazard

Zone (SHZ) Reports for each quadrangle are also listed, along with landslide inventory maps that resulted from the Seismic Hazard Zonation Program, which are published as part of the CGS Landslide Inventory Map Series (LSIM).

THE TRANSVERSE RANGES AND THE SAN ANDREAS FAULT

Nearly all of the Los Angeles quadrangle lies within the south-central part of the Transverse Ranges geomorphic province, a band of west-trending mountain ranges and valleys, varying from 50 km to 130 km in width that extends about 400 km from Point Arguello on the west to the eastern San Bernardino Mountains on the east (Fig. 2). The east-west grain of the Transverse Ranges Province presents a stark and abrupt interruption of the general northwesterly trends of the Peninsular Ranges Province (including the California Continental Borderland) to the south and the northwesterly to northerly grain of the California Coast Ranges, the Great Valley, the Sierra Nevada, and the Mojave Provinces to the north. The southeastern corner of the Los Angeles quadrangle includes the northern part of the Los Angeles basin, which lies at the northern end of the Peninsular Ranges Province. The northwestern quarter of the Los Angeles quadrangle includes the eastern part of the Ventura basin and its southeastern extension, the San Fernando basin. These basins were the sites of very thick accumulations of marine sediments in the late Miocene and Pliocene. The southern boundary of Transverse Range structures is commonly placed at the Anacapa-Santa Monica-Hollywood-Raymond-Cucamonga zone of interconnected north-dipping thrust faults. West of Santa Monica, the southern limit of Transverse Range structures is the offshore Anacapa Fault, which lies a few kilometers south of the southern boundary of the quadrangle. Northwesterly trending faults in the Peninsular Ranges Province, such as the Newport-Inglewood zone, the Elsinore-Whittier Fault, and several faults in the offshore Continental Borderland, appear to be truncated by the east-west zone of interconnected faults, although the apparent step between the Hollywood and Santa Monica Fault zones along the projection of the Newport-Inglewood Fault suggests that the boundary has been modified locally.

The Transverse Ranges are a major anomaly embedded across the general grain of the North American Continent and, although middle Miocene and younger tectonism is responsible for much of the present rock distribution and physiographic relief, the distributions of different crystalline basement rocks, and their Cretaceous and Paleogene superjacent strata, suggest the influence of earlier tectonic episodes. The geologic history remains imperfectly understood, and many interpretations concerning specific aspects are actively disputed among earth scientists (e.g., Campbell and others, 1966; Dibblee and Ehrenspeck, 1993). The distinctive physiographic and structural characteristics of the provinces are superimposed on a preexisting framework of Proterozoic through early Cretaceous igneous and metamorphic basement rocks, which occur chiefly in fault-bounded blocks. This simple relationship has been modified in places so that rocks that are commonly associated with one province can be found in an adjacent province. For example, strata found south of the Malibu Coast Fault and west of the Newport-Inglewood zone of faulting and folding include probable Catalina Schist basement overlain by Miocene volcanics and Monterey facies sedimentary strata in a sequence best correlated with that of the Palos Verdes Peninsula-Santa Catalina Island area of the northern Peninsular Ranges. Although Catalina Island and the Palos Verdes Peninsula are dominated by northwesterly trending structures, and are included in the Peninsular Ranges Province, an east-trending band, bounded by the Malibu Coast Fault on the north and the offshore Anacapa-Santa Monica Fault, is characterized by east-trending folds and north-over-south thrust faults and, therefore, is included in the Transverse Ranges province. Some province-bounding faults take advantage of pre-existing structures in places, but not everywhere.

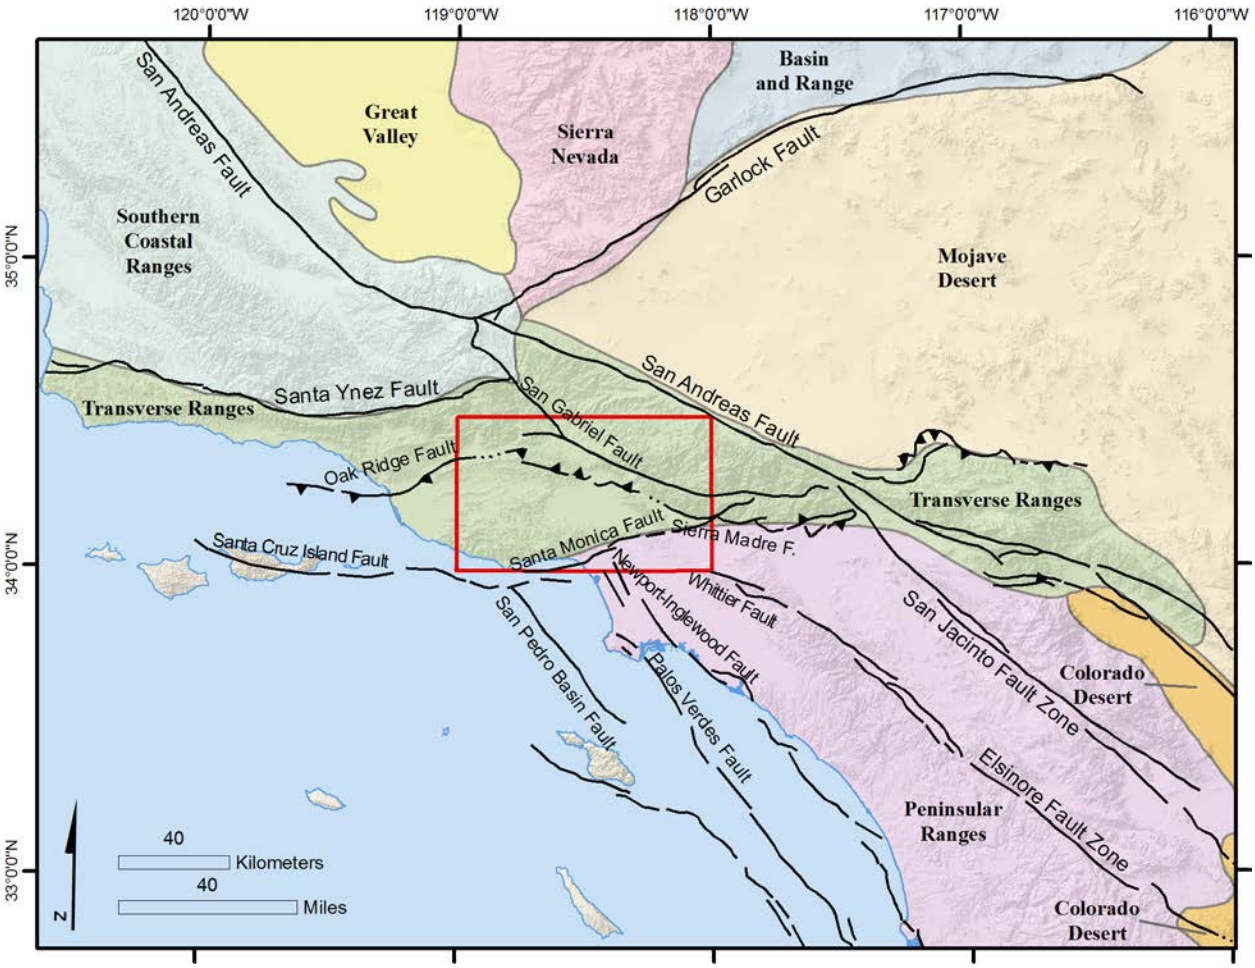

Figure 2. Area of the Los Angeles 30' x 60' quadrangle in reference to geomorphic provinces of southern California.

Major basement rock boundaries are not confined to the margins of the Transverse Ranges, but are also found within the province. For example, the northwest-trending Verdugo Fault separates the cratonic Precambrian to Cretaceous crystalline basement of the San Gabriel Mountains from the oceanic Jurassic metasedimentary basement of the Santa Monica Mountains. Similarly, the Raymond-Cucamonga segment of the southern frontal fault system of the Transverse Ranges approximates the boundary between the San Gabriel Mountains crystalline basement and the oceanic Jurassic basement in the Santa Ana Mountains (northern Peninsular Ranges). The Santa Monica Slate resembles similar Jurassic rocks in the Santa Ana Mountains. Although Jones and others (1976) note that sparse Jurassic fossils from the Santa Monica Mountains are younger than Jurassic fossils from the Santa Ana Mountains, both sections are very thick and represent millions of years of accumulation of pelitic sediment in abyssal to bathyal environments, and they are probably broadly correlative. This relatively simple pattern is further complicated by evidence that the cratonic rocks of the San Gabriel Mountains have been thrust over the Pelona Schist, for which the protolith is inferred to be Jurassic oceanic crust (Ehlig, 1981).

Many workers have attempted to reconstruct the rock distribution in the region as it was before the middle Miocene beginning of major structural deformation (e.g., Campbell and Yerkes, 1976; Crouch, 1979; Hornafius and others, 1986; Powell, 1993; Wright, 1991; Yeats, 2004) using recognized

translations and rotations of fault-bounded blocks. The paleomagnetic evidence that the western Transverse Ranges were rotated approximately 60 degrees clockwise in Miocene time (Kamerling and Luyendyk, 1979) should be kept in mind with regard to descriptions of pre-Pliocene sedimentary and structural trends. For example, northeasterly-trending faults that are truncated by the base of the Modelo and older units have been rotated from initial northwesterly orientations after their last movements. Similarly, north-trending shorelines and pinch-outs in Paleogene and Miocene strata (Yerkes and Campbell, 1976) have been rotated from westerly trends (McCulloh and others, 2002; McCulloh and Beyer, 2004). It seems logical that reconstruction should result in an unbroken western margin for the North American Continent that connects the rocks and structure to the north with those to the south of the Transverse Ranges. However, the pre-middle Miocene positions of individual fault blocks have not been comprehensively established. Partial reconstructions using extensive subsurface data, precise age dating, and well-established minimum fault movements and rotations have demonstrated the difficulty in accurately modeling the early Miocene margin of the North American continent (McCulloh and Beyer, 2004).

The San Andreas Fault crosses the Transverse Ranges Province with an east-southeasterly trend, in sharp contrast to its northwesterly trends to the north, in central California, and to the south, along the east side of the Salton Sea and the Imperial Valley. From Tejon Pass to Wrightwood, the San Andreas approximates the northern boundary of the Transverse Ranges (San Gabriel Mountains), and a short segment of the fault crosses the extreme northeastern corner of the Los Angeles quadrangle. Farther east it separates the San Gabriel Mountains from the San Bernardino Mountains, emerging from the south side of Cajon Pass to mark (approximately) the southern boundary of the Transverse Ranges (San Bernardino Mountains), and continues on that trend for another 45 km (approximately) southeasterly to the vicinity of North Palm Springs.

The presently recognized trace of the San Andreas Fault was probably not a single continuous fault before the end of the (Miocene-Pleistocene) tectonism that resulted in the modern Transverse Ranges Province. Some segments that are now connected show displacements that probably predate the late Miocene. The San Gabriel Fault probably was a major strand of the San Andreas in late Miocene through early Pliocene time that is now much less active (Crowell, 1952). The modern through-going San Andreas Fault consists of connected segments of varying ages and tectonic origins, and may be linked by fault segments that did not exist before the opening of the Gulf of California in the late Pliocene. Although the San Andreas Fault is seen only in the extreme northeast corner of the Los Angeles quadrangle, it is an important component of the geologic structure in the quadrangle, and is probably the principal control for the north-south compressive stress field presently imposed on the central Transverse Ranges. The ongoing deformation and associated earthquakes (Working Group on California Earthquake Probabilities, 2008) are generally considered to be the result of the northwest-trending right-lateral movement of the North American Plate relative to the Pacific Plate as constrained in upper crustal rocks by the geometry of the modern San Andreas Fault.

GEOLOGIC UNITS IN DEPOSITIONAL BASINS AND STRUCTURAL BLOCKS

The geologic map units are divided into several columns in the explanation and brief description of map units on the map sheet, reflecting different sequences of units in different depositional basins. The

units are arranged in a single sequence in the “Description of Map Units” below. The designations of different units in different areas is partly semantic; that is, different authors may have used different names for correlative strata in different parts of the quadrangle; or have used the same names for map units that may be only partly correlative. However, real differences in lithologic character are also represented by the use of different names for strata of correlative ages. We have not been able to identify all the map unit names that should be extended and those that should be restricted. However, it seems clear that the present distribution of rock units is the result of the convergence of tectonic elements of diverse geologic histories. The subdivision of the unit abbreviations and brief descriptions into different columns on the map sheet is our attempt to illustrate the spatial diversity as objectively as possible, while retaining the stratigraphic elements shared in common.

Rocks of the Transverse Ranges Province are subdivided into geographic areas where similar rock sequences are exposed, these geographic areas reflect, at least in part, fault-bounded structural blocks: (1) Topatopa Mountains and the eastern Santa Ynez Range, (2) Oak Ridge, Santa Susana Mountains, Simi Hills, and Santa Monica Mountains, (3) Castaic Valley-Soledad Canyon and western San Gabriel Mountains (Figure 3). The rocks of the northern Peninsular Ranges Province are described in a frame of two middle Miocene and older structural blocks: (1) eastern Los Angeles basin, and (2) western Los Angeles basin. Within the Oak Ridge, Santa Susana Mountains, Simi Hills, Santa Monica Mountains block, middle Miocene and older strata are described separately for the Santa Susana Mountains-Simi Hills area and the central and western Santa Monica Mountains, chiefly because of large changes in thickness of the Conejo Volcanics and nomenclatural differences that represent relatively minor facies changes in the middle Miocene and older rocks. In the central Santa Monica Mountains, the strata in the upper plate of the Malibu Bowl Detachment Fault include a number of tongues of the Conejo Volcanics that have not been specifically correlated with the lithologic subdivisions of that unit in the lower plate. The eastern and western Los Angeles basin blocks correspond to the Northwestern and Central structural blocks of Yerkes and others (1965).

The bedrock units of the area are commonly described in two principal groups: 1) Basement rocks – early Cretaceous and older, crystalline metamorphic and igneous rocks; and 2) The superjacent sequence of late Cretaceous and Tertiary strata. The greatest contrast in basement character is at the boundaries of the San Gabriel Mountains-Soledad basin block. The San Gabriel Mountains form a basement massif that includes components of Proterozoic, Paleozoic, and pre-middle-Cretaceous Mesozoic metamorphic and plutonic rocks. These are the oldest basement rocks in the Los Angeles quadrangle and appear to represent old continental crust at the western margin of the North American craton that has been thrust over Jurassic oceanic crust of a different metamorphic facies than is found in adjacent blocks. In the eastern Los Angeles basin, to the south of the San Gabriel Mountains, and in the Santa Monica Mountains, to the west of the San Gabriel Mountains, the basement rocks are metasedimentary and metavolcanic rocks of Jurassic age that were probably deposited on a Jurassic oceanic crust and accreted to the margin of the North American craton. They have been intruded by early Cretaceous granitic bodies of the same age as similar rocks in the San Gabriel Mountains, but the relationship between these granite bodies is not clear. The basement rocks of the western Los Angeles basin also are associated with a Jurassic oceanic crust; however, their metamorphic character is significantly different, including blueschist facies schists that represent metamorphism in a subduction zone. The basement in the Topatopa Mountains block is unknown, but in the Santa Ynez Mountains, a

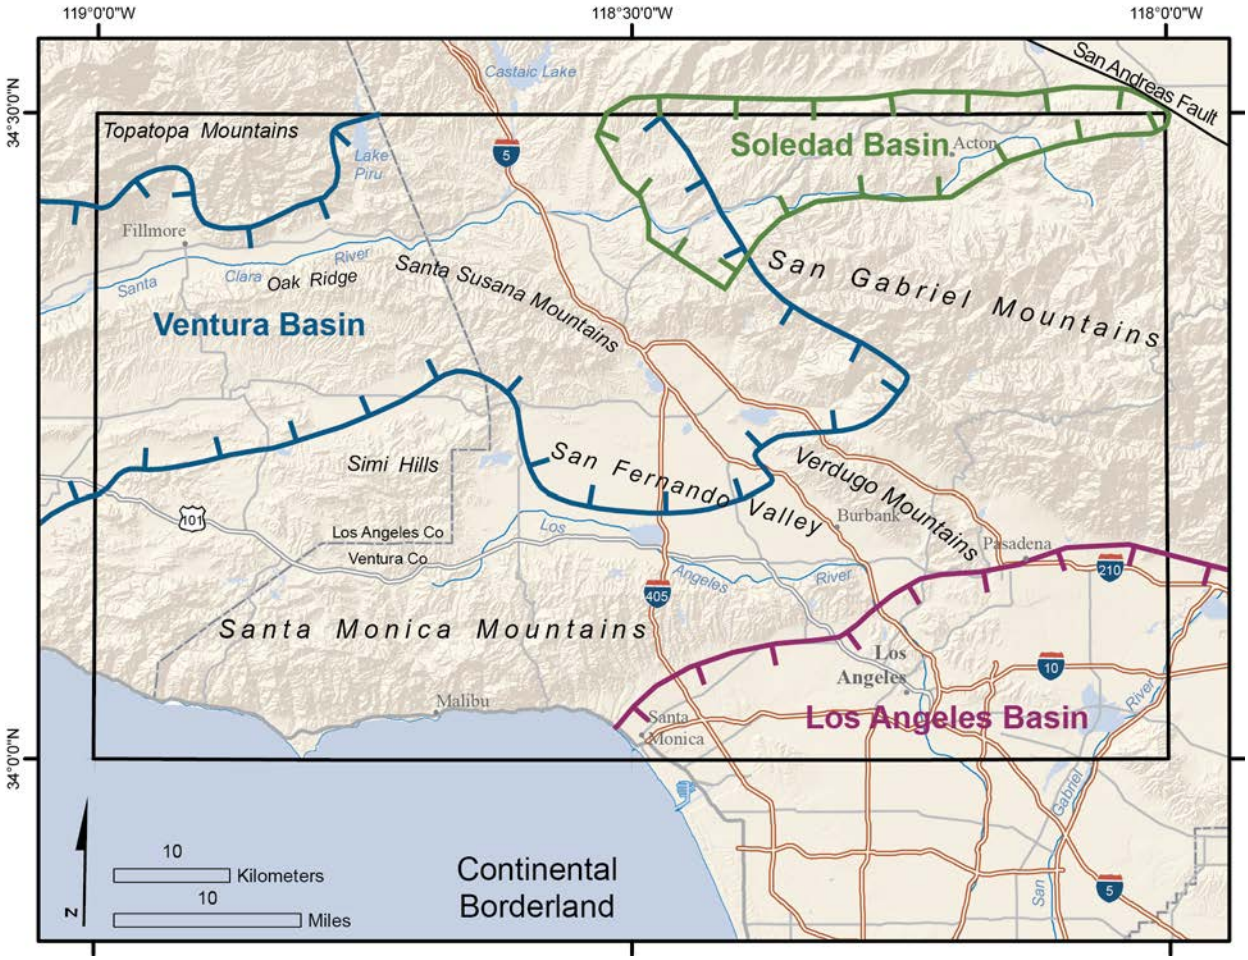

Figure 3. Principal late Tertiary to Quaternary depositional basins and upland areas where bedrock units are exposed within the Los Angeles 30'x60' quadrangle. The Soledad basin is represented by Miocene strata, which are truncated to the southwest by the San Gabriel Fault and subsequently overlapped by Pleistocene deposits of the Ventura basin; the Ventura and Los Angeles basin boundaries represent the limits of associated Pliocene and Pleistocene formations.

few miles to the west, the basement is Franciscan Formation, including schists very much like those of the western Los Angeles basin basement rocks.

The superjacent sequence consists of Upper Cretaceous and Tertiary sedimentary and volcanic strata that rest unconformably on the crystalline basement. The regional unconformity at the base of the Upper Cretaceous is expressed only in the central Santa Monica Mountains, where the Trabuco Formation overlies basement rocks. Another regional unconformity, at the base of the Paleogene section, can be seen in the western Santa Monica Mountains and the Simi Hills where the Simi Conglomerate overlies the Upper Cretaceous sequence. The middle Miocene disruption of the pre-middle Miocene sequence and the formation of more localized basins is expressed by more restricted unconformities at the bases of late-middle Miocene and younger strata and extreme variations in thickness of late Miocene and younger units.

DESCRIPTION OF MAP UNITS

The arrangement of map unit descriptions on the map sheet illustrates the correlation of map units among different depositional basins. The map area straddles two major physiographic provinces, the Transverse Ranges and the Peninsular Ranges, and the southwest margin includes rocks commonly associated with the Southern California Borderland. The modern provinces are largely the products of Neogene tectonics, volcanism, and sedimentation, but each province contains fault-bounded blocks of Paleogene and older rocks that correlate over a larger area.

Similarities and differences among rock units are incompletely reflected in the nomenclature and labeling of the rock units, which evolved from many geologic investigations over the past century. The majority of the units on this map have been adopted from the source maps used in compilation. Named Formations of sedimentary strata are made up of multiple episodes of individual depositional events and each event need not be distributed over exactly the same area. This can lead to significant differences in the age range of a rock stratigraphic unit from one area to another.

Map labels are abbreviations that indicate age and origin of surficial deposits, or age and formally recognized names of formations and members. Where stratigraphic assignment is tentative, a query (?) is added to the label in the database. Where informal subunits are represented by subscripted numbers, numbers increase with decreasing age (i.e., of subunits 1-4, 4 is the youngest and 1 is the oldest). Quaternary deposits are found in all provinces and subareas; however they are relatively local in extent, and deposits are commonly associated with distinctive geomorphic features such as fans, flood plains and terraces. For a complete listing of geologic units and the 7.5’ quadrangles on which they occur, refer to Appendix B.

af **Artificial fill (late Holocene)—**Deposits of sand silt and gravel resulting from human construction, mining or quarrying activities; includes compacted engineered and noncompacted nonengineered fill. Only large deposits are shown. Fills emplaced after source maps were completed are generally not shown.

Qa **Alluvium (late Holocene)**—Unconsolidated gravel, sand and silt in active or recently active floodplains, locally including related alluvial fans and streambeds where those are not mapped separately; chiefly stream deposited, but includes some debris-flow deposits. Locally corresponds with or encompasses areas of historic flooding, including deposits behind flood-control structures.

Qw **Wash deposits (late Holocene)**—Unconsolidated gravel, sand and silt in active or recently active streambeds; chiefly stream deposited, but includes some debris-flow deposits; episodes of bank-full stream flow are frequent enough to inhibit growth of vegetation.

Qb **Beach deposits (late Holocene)**—Loose fine- and medium-grained sand of active beaches chiefly between elevations of lower-low water and storm strands).

Qe **Eolian deposits (late Holocene)**—Loose, fine- to medium- grained sand, silty sand and silt; forms transitory dunes against beach-facing cliff.

Qf **Alluvial fan (Holocene)**—Unconsolidated bouldery, cobbly, gravelly, sandy, or silty alluvial deposits on active and recently active alluvial fans and in some connected headward channel segments.

Qls **Landslide deposits (Holocene and late Pleistocene?)**—Only selected landslide deposits shown on this map as described below. Deposits represent rock detritus from bedrock and surficial materials, broken in varying degrees from relatively coherent large blocks to disaggregated small fragments, deposited by landslide processes. Most deposits are Holocene, some dissected landslides may be as old as late Pleistocene. Landslide deposits shown on this map were compiled primarily from landslide inventories prepared by CGS for the Seismic Hazard Zonation Program. For this map, only landslides described as definite or probable and larger than 50,000 square meters are shown to preserve the clarity of the underlying bedrock geology. Selected historically active landslides between 10,000 and 50,000 square meters are shown, but no landslides smaller than 10,000 square meters are shown on this map. Exceptions to these rules include small or questionable landslides surrounded by larger probable or definite landslides.

Qya **Young alluvium, undivided (Holocene and late Pleistocene)**—Unconsolidated, generally friable, stream-deposited silt, sand and gravel on flood plains, locally including related alluvial fans and streambeds where those are not mapped separately. Deposits are clearly related to depositional processes that are still on-going. Subunits are distinguished by relative ages based on geomorphic relationships, relative degree of surface dissection and soil formation. Includes:

Qya_4 **Young alluvium, Unit 4 (Holocene)**—Youngest of as many as 4 subunits of Qya that can be distinguished in some areas.

Qya_3 **Young alluvium, Unit 3 (Holocene and late Pleistocene)**—Older young alluvium, older than Unit 4, younger than Unit 2.

Qya_2 **Young alluvium, Unit 2 (late Pleistocene)**—Older young alluvium, older than Unit 3, younger than Unit 1.

Qya_1 **Young alluvium, Unit 1 (late Pleistocene)**—Oldest young alluvium.

Qyf **Young fan deposits, undivided (Holocene and late Pleistocene)**—Unconsolidated gravel, sand and silt, bouldery along mountain fronts; deposited chiefly from flooding streams and debris flows. Deposits are clearly related to depositional processes that are still on-going. Subunits are distinguished by relative ages based on geomorphic relationships, relative degree of surface dissection and soil formation. Includes:

Qyf_5 **Young alluvial-fan deposits, Unit 5 (Holocene)**—Youngest of four subunits of Qyf that can be distinguished in some areas. Designated Qyf_5 because of continuity with young alluvial fan designated Qyf_5 on map of San Bernardino 30’x60’ quadrangle to east.

Qyf_3 **Young alluvial-fan deposits, Unit 3 (Holocene to late Pleistocene)**—Young fan deposits, older than Unit 5, younger than Unit 2.

Qyf_2 **Young alluvial-fan deposits, Unit 2 (Holocene to late Pleistocene)**—Older young fan deposits, older than Unit 3, younger than Unit 1.

Qyf_1 **Young alluvial-fan deposits, Unit 1 (Holocene to late Pleistocene)**—Oldest of as many as four subunits of Qyf that can be distinguished in some areas.

Qoa **Old alluvium undivided (late to middle Pleistocene)**—Unconsolidated to moderately indurated gravel, sand and silt deposited on flood plains, locally including related alluvial fans and streambeds where those are not mapped separately. Deposits have been uplifted or otherwise removed from the locus of recent sedimentation. Surfaces may be dissected in varying degrees; and can show moderately to well-developed pedogenic soils. Subunits are distinguished by relative ages based on geomorphic relationships, relative degree of surface dissection and soil formation. Includes:

Qoa_3 **Old alluvium, Unit 3 (late Pleistocene)**—Youngest of as many as three subunits of Qoa that can be distinguished in some areas.

Qoa_2 **Old alluvium, Unit 2 (late Pleistocene)**—Intermediate of as many as three subunits of Qoa that can be distinguished in some areas.

Qoa_1 **Old alluvium, Unit 1 (middle Pleistocene)**—Oldest of as many as three subunits of Qoa that can be distinguished in some areas.

Qof **Old fan deposits, undivided (late to middle Pleistocene)**—Slightly to moderately consolidated silt, sand and gravel deposits on alluvial fans. Deposits have been uplifted or otherwise removed from the locus of recent sedimentation. Morphology of original alluvial fan surface usually well preserved, though dissected in varying degrees; surfaces can show moderately to well-developed pedogenic soils. Subunits are distinguished by relative ages based on geomorphic relationships, relative degree of surface dissection and soil formation. Includes:

Qof_4 **Old fan deposits, Unit 4 (late Pleistocene)**—Youngest of as many as four subunits of Qof that can be distinguished in some areas.

Qof_3 **Old fan deposits, Unit 3 (late Pleistocene)**—Intermediate subunit of Qof that can be distinguished in some areas, older than Qof_4 and younger than Qof_2.

Qof_2 **Old fan deposits, Unit 2 (late Pleistocene)**—Intermediate subunit of Qof that can be distinguished in some areas, older than Qof_3 and younger than Qof_1.

Qof_1 **Old fan deposits, Unit 1 (late Pleistocene)**—Oldest of at least four subunits of Qof that can be distinguished in some areas.

Qoft **Alluvial fan deposits on wave-cut surface (late Pleistocene to Holocene)**—Unconsolidated to moderately indurated, clay, silt, sand, and angular gravel including clasts to boulder size; chiefly debris-flow deposits, but probably includes some stream-deposited material; surfaces can show slight to moderate pedogenic soil development. Overlies elevated wave-planed bedrock and marine terrace deposits along the coast.

Qom **Old shallow marine deposits on wave-cut surface (late Pleistocene)**—Unconsolidated (but with small areas locally calcite-cemented) sand, silty sand and gravel; commonly overlies wave-cut bedrock surfaces at two or more altitudes above present sea level; surfaces can show slight to moderate pedogenic soil development; locally carries molluscan fauna referred to the late Pleistocene (Addicott, 1964).

Qoab **Old alluvium and breccia (late Pleistocene to Holocene)**—Deposit of angular shale chips and colluvium derived from Modelo Fm. Mapped adjacent to San Fernando Fault, age relationships with other alluvial units unknown.

Qob **Old breccia, (late Pleistocene to Holocene)**—Fine to coarse sand with well-rounded pebble gravel and shale chips and colluvium derived from Modelo Fm. Mapped adjacent to San Fernando Fault, age relationships with other alluvial units unknown.

Qvoa **Very old alluvium, undivided (middle to early Pleistocene)**—Slightly to moderately consolidated silt, sand and gravel deposits. Deposits have been uplifted or otherwise removed from the locus of recent sedimentation. Environment of deposition may include axial valley, floodplain or alluvial fan, but morphology of original deposit may not be preserved. Surfaces may be significantly dissected and show well-developed pedogenic soils. Subunits are distinguished by relative ages based on geomorphic relationships, relative degree of surface dissection and soil formation.

$Qvoa_2$ **Very old alluvium, (middle to early Pleistocene)**—Younger subunit of Qvoa that can be distinguished in some areas.

$Qvoa_1$ **Very old alluvium, (middle to early Pleistocene)**—Older subunit of Qvoa that can be distinguished in some areas.

Qvof **Very old alluvial-fan deposits (middle to early Pleistocene)**—Slightly to moderately consolidated silt, sand and gravel deposits on alluvial fans. Deposits have been uplifted or otherwise removed from the locus of recent sedimentation. Morphology of original alluvial fan surface preserved to some extent. Surfaces may be significantly dissected and show well-developed pedogenic soils. Subunits are distinguished by relative ages based on geomorphic relationships, relative degree of surface dissection and soil formation.

$Qvof_2$ **Old alluvial-fan deposits, Unit 3 (late Pleistocene)**—Subunit of Qvof with distinct alluvial fan morphology, overlies and is therefore younger than $Qvoa_1$.

Qpa **Pacoima Formation (middle Pleistocene)**—Fanglomerate or sedimentary breccia with a dark-brown to reddish-brown clayey sand matrix; weakly indurated; crudely bedded; poorly sorted with angular, pebble- to boulder-size clasts composed primarily of crystalline rock locally derived from the San Gabriel Mountains, as described in the type area at the mouth of Pacoima Canyon. The Pacoima Formation exposed in the Mint Canyon quadrangle contains more rounded clasts than the type area and the color varies to light yellowish brown; farther west in the Newhall quadrangle the overall clast size decreases and clast composition varies as a result of facies changes associated with greater distance from the San Gabriel Mountain source area and influx of sedimentary clasts shed from the uplifting Santa Susana Mountains to the south (Treiman and Saul, 1986). The Pacoima Formation is an unconformity bounded unit deposited in the eastern Ventura basin that is typically gently inclined; distinguished from the underlying Saugus Formation by poorer bedding and sorting, clast angularity, and angular discordance in most areas; distinguished from younger terrace deposits and overlying older alluvium primarily by degree of erosion and weathering, and the occurrence of locally intense folding and faulting.

The maximum thickness is about 500 to 1,000 ft. (152 to 305 m). The Pacoima Formation was initially described by Oakeshott (1952) and subsequently mapped by Oakeshott (1958) and Barrows and others (1974) in the northern San Fernando Valley and south of the San Gabriel Fault in the eastern Santa Clarita Valley area. Saul (1979, 1990) and Saul and Wootton (1983) followed this usage in mapping of the Mint Canyon quadrangle, and Treiman (1986, 1987a) extended the formation into the Newhall quadrangle in place of older alluvial deposits mapped by Kew (1924) and Winterer and Durham (1962). The Pacoima Formation is younger than about 0.4 Ma based on the estimated youngest age of the underlying Saugus Formation studied in the Santa Clarita Valley by Levi and others (1986) and Treiman and Saul (1986) estimated that deposition of the Pacoima Formation was essentially completed by about 0.3 Ma.

Eastern Ventura Basin, including San Fernando Basin

QTs/Qs **Saugus Formation, undivided (late? Pleistocene to late Pliocene)**—Weakly to moderately cemented, medium- to coarse-grained, light-gray to yellowish-gray sandstone and pebble conglomerate and light greenish-gray sandy siltstone deposited in the Ventura basin; moderately sorted; commonly cross bedded and channeled; interbedded with moderate-brown to reddish-brown poorly sorted sandy mudstone and local claystone seams in the type area and other portions of the eastern Ventura basin, reflecting overbank deposits and paleosols; fluvial near the basin axis, transitioning to alluvial fan environment near the basin margins; interfingers with shallow marine sands to the west. The Saugus Formation is chiefly nonmarine as defined by Hershey (1902b) and Winterer and Durham (1962), but mapping compiled herein may locally include shallow marine interbeds. Transitional to brackish water deposits at the base of the section observed in the eastern Ventura basin are assigned to the Sunshine Ranch Member. This formation has a gradational to interfingering conformable contact with underlying shallow marine strata of the Pico Formation near the axis of the Ventura basin, but the contact is time transgressive and is progressively younger to the west. Near the basin margins, the base is unconformable with the Pico Formation and locally overlaps older strata and basement rock. The upper contact shows distinct angular discordance with the overlying Pacoima Formation in most areas, but discordance is more subtle west of Valencia and middle Pleistocene deposition in this area may be nearly continuous. The thickness varies greatly across the Ventura basin; Kew (1924) reports a thickness of 2,000 ft. (610 m) but Winterer and Durham (1962) report that up to 12,000 ft. (3,660 m) of Saugus strata were encountered in a well southeast of San Fernando Pass; a thickness of 2,000 m is reported in the western Ventura basin below the Santa Clara River, but DeVecchio and others (2012b) report a thickness of only 40 to 60 m in the Camarillo area near the southwest margin of the basin. In the eastern Ventura basin, the base of the Saugus is estimated at about 2.3 Ma west of Valencia and in the Mission Hills (Levi and Yeats, 1993) to about 2.6 Ma near Gold Canyon in the northern San Fernando Valley (Beyer and others, 2009). Unfossiliferous deltaic deposits mapped as Saugus in the Elsmere Canyon area by Dibblee (1991d, 1992c) and Squires (2012) may be significantly older based on their position below Sunshine Ranch strata and mapped interfingering relationships with older Pico and Towsley Formation strata. The top of the Saugus in the eastern Ventura basin is estimated at about 0.5 Ma by Levi and Yeats (1993) and is younger to the west. North

of Ventura, Lajoie and others (1982) report an age of 0.2 Ma in marine sands underlying the Saugus and an age of 85 ka in overlying marine terrace deposits. In the Moorpark area, Wagner and others (2007) report an age of 780 to 850 ka at a Mammoth fossil site. In the Camarillo and Las Posas Hills area, DeVecchio and others (2012a, 2012b) report that Saugus strata overlie marine sands as young as about 125 ka and may be as young as 25 ka south of the Camarillo Hills based on OSL dating. Based on reported ages, Saugus strata west of Fillmore and west of the Tapo Canyon area are considered post-Pliocene in age and therefore mapped as Qs rather than QTs. Clasts within the Saugus Formation are typically plutonic, metamorphic and volcanic rocks, derived primarily from the San Gabriel Mountains, and transported westward by the ancestral Santa Clara River; however, distinctive clast assemblages have locally been recognized and mapped as informal members or facies by various workers. These include upper Saugus (QTsu); volcaniclastic breccia-conglomerate (Qsv) and Camarillo member (Qsc); additional facies are defined by Weber (1982) in the Santa Clarita area based on the presence or absence of San Francisquito Formation sandstone, Pelona Schist, or anorthosite clasts. The Saugus Formation was initially defined by Hershey (1902b) as the "Saugus division" for continental strata exposed in railroad cuts east of Bouquet Junction near Saugus (type area). These deposits were subsequently lumped into the Fernando Formation by Eldridge and Arnold (1907). Kew (1923, 1924) formally adopted the term Saugus Formation for the upper section of the Fernando Group and extended usage into the western Ventura basin. Kew generally followed Hershey's nonmarine definition except that he also included underlying coarse-grained shallow marine deposits within the Saugus Formation. The unit was redefined and remapped by Winterer and Durham (1962) in the eastern Ventura basin, who reassigned most of the shallow marine strata to the Pico Formation, conforming to Hershey's nonmarine definition of the Saugus. This nonmarine definition has been adopted by most workers in the eastern Ventura basin (e.g. Saul, 1975, 1979; Weber, 1982; Yeats and others, 1985; Saul and Wootton, 1983; Treiman, 1986, 1987a; Dibblee Foundation maps; Squires and others, 2006; Squires, 2012). Maps covering areas south and west of the area mapped by Winterer and Durham commonly include marine deposits as part of the Saugus based on Kew's definition (e.g. Weber and others, 1973; White, 1985; Squires and White, 1983; Groves, 1991). The restricted usage of Winterer and Durham (1962) in the type area is adopted herein and shallow marine strata formerly assigned to the Saugus Formation in the Santa Susana Mountains and Oak Ridge located east of, and down section of, the Grimes deltaic unit (QTpg) are reassigned as an upper informal member of the Pico Formation (QTpcu) (see Appendix A for details). Nonmarine strata of similar age are mapped as the La Habra Formation in the Los Angeles basin (Eckis, 1934), and as the Casitas Formation in the Santa Barbara basin (Upson, 1951). Mapped members include:

QTsu **Saugus Formation, upper member (middle Pleistocene)**—On the south flank of the Santa Susana Mountains this unit consists of nonmarine sandstone and conglomerate with clasts composed primarily of shale and sandstone derived from the Modelo and Towsley Formations (Oat Mountain 7.5' quadrangle); the most representative section is at Horse Flats. This clast assemblage is interpreted to represent uplift, emergence and initial erosion of the Santa Susana Mountains, as described in Saul (1975), Shields (1977a), Saul (1979), and Levi and Yeats

(1993); Qt of Bishop (1950) and Jennings (1957). Strata mapped as upper Saugus west of Valencia and southwest of Castaic Junction consist of moderately sorted, yellowish-gray to light yellowish-brown sandstone, conglomerate and silty sandstone, and poorly sorted sandy mudstone beds; the conglomerate beds also contain clasts derived from the Santa Susana Mountains; less lithified and sorted than underlying Saugus Formation strata. Most of this section was assigned to the Saugus Formation by Winterer and Durham (1962) and by Dibblee (1996d), but was assigned to the Pacoima Formation by Treiman (1986). This unit appears to be a transitional facies between the two formations, both structurally and lithologically; angular discordance with the underlying Saugus varies from locally distinct along the southeastern portion of the contact, where it coincides with a monoclinal warp, to negligible to the northwest at the Santa Clara River. The contact with the overlying Pacoima Formation is a subtle angular unconformity or disconformity. This unit may correlate with the upper Saugus strata on the south flank of the Santa Susana Mountains based on the appearance of clasts derived from the newly emergent Santa Susana Mountains.

Qsc **Saugus Formation, Camarillo member (late Pleistocene)**—Thickly bedded, reddish, pebble-bearing siltstone; paleosols with carbonate-cemented rhizoliths common; clasts are dominantly composed of locally derived Miocene shale and volcanic clasts, with subordinate granitic and metamorphic clasts. Defined informally by DeVecchio and others (2012b) for their chronostratigraphic units Qs_2 and Qs_3 exposed in the Camarillo and Las Posas Hills area; locally derived clast assemblage distinguishes this member from older sections of the Saugus Formation to the north and is interpreted by DeVecchio and others (2012b) to indicate that uplift of South Mountain and Oak Ridge had diverted the ancestral Santa Clara River to the north, thereby preventing crystalline clasts derived from the San Gabriel Mountains from reaching this area; DeVecchio and others (2012b) report IRSL dates of 78 ± 6 ka to 125 ± 9 ka for this member; thickness 40 to 60 m.

Qsv **Saugus Formation, volcaniclastic breccia-conglomerate (Pleistocene)**—Massive to crudely bedded, breccia-conglomerate composed of angular to subrounded, pebble- to boulder-size, weathered and fresh clasts of Conejo Volcanics in a poorly consolidated matrix of caliche, clay, silt and sand. Amount of matrix material is variable; some exposures consist only of angular, monolithologic volcanic clasts coated with caliche and contain little or no other matrix material. Previously mapped as part of the Conejo Volcanics. May represent remnants of debris shed from Conejo Volcanics highland into local basin during deposition of Saugus Formation (T. F. Blake, pers. com., 1993). (Dibblee, 1992a and 1992b; Irvine, 1995).

QTsg **Saugus Formation, conglomerate (early Pleistocene)**—Conglomerate mapped at the base of the formation. Clasts are predominantly crystalline igneous and metamorphic rocks recognizable as presently exposed in the northwestern San Gabriel Mountains. (Saul and Wootton, 1983).

QTsr **Saugus Formation, Sunshine Ranch Member, undivided (early Pleistocene to late Pliocene)**—Sulfur-yellow to light-brown and light-gray sandstone, conglomerate and silty sandstone, greenish-gray sandy siltstone and mudstone, and local limestone beds; sandstone and conglomerate commonly cross bedded or channeled; considered primarily paralic

nonmarine or transitional brackish lagoon or estuary deposits with local interfingering marine beds; the greenish-gray fine-grained interbeds are considered the most characteristic lithologic type of the member (exposed in the Oat Mountain, San Fernando, Newhall, and Mint Canyon 7.5' quadrangles). The thickness of the Sunshine Ranch Member is estimated to be about 3,000 ft. (915 m) in the type area. This member is primarily late Pliocene in age based on fossil horse teeth, but likely early Pleistocene in part based on revised time scale of Gibbard and others (2010). It was initially named informally by Hazzard (1940) in an unpublished report as the "Sunshine Ranch formation" for distinctive transitional strata at Sunshine Ranch in the Mission Hills area of the northern San Fernando Valley. Oakeshott (1950, 1958) published formal descriptions and mapping of this unit, which he assigned as an upper member of the Pico Formation; subsequently reassigned as a lower member of the Saugus Formation by Winterer and Durham (1958, 1962) and this usage has been adopted by most subsequent workers in the area (e.g. Barrows and others, 1974; Saul, 1975; Treiman 1987b; Dibblee Foundation maps); Saul and Wootton (1983) excluded all fossiliferous marine beds and subdivided the Sunshine Ranch into an upper and lower facies. Diagnostic greenish-gray mudstone and peaty siltstone occur locally in the lower Saugus Formation south and east of Newhall, leading Treiman (1987b) and Dibblee (1991d, 1992c) to map these outcrops as the Sunshine Ranch Member. The diagnostic beds are uncommon and laterally discontinuous, however. Winterer and Durham (1962) concluded that it is not practical to delineate this member in this area. These possible areas of the Sunshine Ranch Member are shown as queried.

QTsru **Saugus Formation, Sunshine Ranch Member, upper facies**—Nonmarine, poorly consolidated grayish-green clayey sandy siltstone and mudstone, light-brown silty sandstone, light-gray to yellowish-gray pebbly arkosic sandstone and sandy conglomerate, and thin beds of white sandy and nodular limestone; thickness as much as 300 m. Saul and Wootton (1983) note that this facies best characterizes the member and is mapped by them north of the San Gabriel Fault (southwest part of Mint Canyon 7.5' quadrangle).

QTsrl **Saugus Formation, Sunshine Ranch Member, lower facies**—Nonmarine sulfur-yellow, brown or gray arkosic sandstone, silty sandstone, pebbly sandstone, and conglomerate (Saul and Wooton, 1983); thickness about 120 m; occurs on both sides of the San Gabriel Fault (southwest part of Mint Canyon 7.5' quadrangle).

QTse **Saugus Formation, Elsmere Canyon delta plain facies (Pliocene)**—Sandstone and conglomerate with subordinate siltstone and sandy siltstone interbeds; typically weathers light gray and gray to light greenish gray but is locally brown on fresh surfaces due to oil impregnation; light-brown to brown iron-oxide staining locally common; clasts pebble to local boulder size, subrounded to rounded, and composed primarily of crystalline rock derived from the adjacent San Gabriel Mountains; small-scale, low-angle to larger-scale trough cross bedding and channels with erosive bases common (Squires, 2012); foreset beds locally apparent; commonly forms resistant exposures and cliffs in the Elsmere Canyon area; over 450 m thick. Squires (2012) interprets this unit as a braid delta where a braided river flowing from the ancestral San Gabriel Mountains entered the ocean; strata in the Elsmere Canyon area are interpreted as braided river deposits on the delta plain that interfinger to the southwest with

delta front and offshore marine deposits of the Pico and Towsley Formations west and south of the Antelope Valley (14) Freeway. This facies may interfinger with Sunshine Ranch-like mudstone beds northeast of Whitney Canyon and is overlain to the northwest by possible Sunshine Ranch member strata per Treiman (1987b). Squires (2012) notes a possible marine transgression at the top of this unit. This section previously mapped as Pico Formation by Winterer and Durham (1962) and Treiman (1987b), but assigned to the Saugus Formation by Dibblee (1991d, 1992c) and by Squires (2012) based primarily on the lack of marine fossils. This unit is assigned here to the Saugus Formation following the definitions of Winterer and Durham (1962) based on the lack of marine fossils and interpreted nonmarine depositional environment (Squires, 2012); however, differentiation of the lateral transition from marine to nonmarine aspects of the delta is problematic in this area and some unfossiliferous marine delta front deposits may be included west of Highway 14. This facies is mapped because of the unique combination of its nonmarine character and stratigraphic position below Sunshine Ranch member strata; based on this position and interfingering relationships with the Pico and possibly even the Towsley Formations, this unit is likely entirely Pliocene in age.

Qlp **Las Posas Formation (middle to late early Pleistocene)**—Shallow marine, light-gray to light yellowish-gray, fine- to locally coarse-grained sandstone, silty sandstone and pebbly sandstone with greenish-gray mudstone and subordinate conglomerate interbeds in the type area; invertebrate fossils and bivalve-dominated hash beds locally common; sands commonly quartz rich; pebbles composed of well-rounded plutonic, metamorphic and volcanic clasts derived primarily from the San Gabriel Mountains; moderately well sorted; medium bedded to locally laminated; poorly cemented. The Las Posas Formation crops out on either side of the Las Posas Valley in the Las Posas Hills and on the south side of South Mountain/Oak Ridge west of Long Canyon, and west of Fillmore on the north side of the Santa Clara River (western Ventura basin). A prominent basal conglomerate is commonly present in the South Mountain area (Lung, 1958) and northwest of the Santa Clara River at Adams Canyon (basal Saugus of Driver, 1928; Irvine, unpublished mapping 1991). It overlies or interfingers with the Mudpit shale north of the Santa Clara River. In the South Mountain area, it conformably overlies or locally interfingers with upper Pico Formation siltstone and is distinguished from older shallow marine strata of the upper Pico Formation (QTpcu) to the east by its stratigraphic position above the Grimes Canyon deltaic unit (QTpg), whereas QTpcu is generally below QTpg; to the south, it unconformably overlies the Sespe Formation and Conejo Volcanics in the Las Posas Hills. The Las Posas Formation is up to 300 m thick below Las Posas Valley (Dibblee, 1992g). Its age is estimated at 450 ka to 750 ka based on amino acid racemization (Wehmiller, 2010 in DeVecchio and others, 2012b), but DeVecchio and others (2012b) report an OSL date of 141 ± 10 ka near the base of the section in the Las Posas Hills. Sarna-Wojcicki and others (1984) estimate the base of the shallow marine sands (their “San Pedro”) is at about 1.0 Ma in the South Mountain area, but also report an age of about 0.4 Ma in the Ventura area. This unit was originally mapped as Fernando Formation by McLaughlin and Waring (1914) after the definition of Eldridge and Arnold (1907) and subsequently assigned to the Saugus Formation by Kew (1924). The Las Posas “formation” was coined by Pressler (1929) for sands in the Las Posas Hills type area, and nearby South Mountain, Oak Ridge and Camarillo Hills that are

stratigraphically above the “Santa Barbara horizon” and contain warm water “Saugus” fauna of Kew (1924) and Waterfall (1929). Pressler subdivided this unit into a lower Kalorama member (which Bailey, 1935 subsequently included in his Santa Barbara Formation) and an upper Long Canyon member. Subsequent workers referred to this section either as a marine member of the Saugus following Kew, 1924 (e.g. Pasta, 1958; Lung, 1958; Jakes, 1979), as the San Pedro Formation (e.g. Grant and Gale, 1931; Bailey, 1943, 1951;State Water Resources Board, 1953; Weber and others, 1973), or as the Las Posas Sand or Formation (e.g. Dibblee Foundation Maps; DeVecchio and others, 2012a and b); the term Las Posas Formation is adopted because the term San Pedro is restricted to the Los Angeles basin and the term Saugus Formation is restricted to nonmarine deposits following the original definitions of Hershey (1902b) and Winterer and Durham (1962).

Los Angeles Basin

Qsp **San Pedro Formation (middle Pleistocene)**—Unconsolidated sand with local gravelly sand, silty sand and silt interbeds; shallow marine invertebrate fossils common. Woodring and others (1946) report a maximum stratigraphic thickness of about 300 ft. (90 m). The San Pedro Formation has an estimated age range of 200 to 500 ka, as summarized in Jacobs, (2007). The San Pedro Formation was defined at San Pedro Hill (Palos Verdes Peninsula) and extended to other portions of the Los Angeles basin. Fossils were noted at San Pedro Hill by early workers (e.g. Trask, 1855b; Lawson, 1893) but Dall (1898) is credited as the first to use the term “San Pedro beds” (Wilmarth, 1938). Arnold and Arnold (1902) and Arnold (1903) distinguished a “lower” and “upper” San Pedro series and the “lower series” was subsequently assigned the name San Pedro “formation” by Kew *in* Tieje (1926). Terminology for the San Pedro Formation was formalized by Woodring and others (1946) and their usage is adopted herein. This term was extended into the subsurface by Poland and others (1956, 1959) and additional background is summarized by Powell and Ponti (2007). The term San Pedro has also been extended by some workers in the past to granular Pleistocene strata in the western Ventura basin based on molluscan fauna (e.g. Grant and Gale, 1931; Bailey, 1935); however, this extended usage is not used here, as suggested by Ponti (pers. comm., 2012), based on the presence of an intervening depositional basin boundary.

Qi **Inglewood Formation (early Pleistocene)**—Shallow marine, well-consolidated clay-siltstone and interbedded very fine-grained sandstone, commonly with calcareous, limonitic concretions; relatively dense and moderately expansive where weathered. This unit is now recognized as one from which most of the landslides in the Baldwin Hills are derived (Hsu and others, 1982).

QTms **Sedimentary rocks of the Pacific Palisades area (early Pleistocene to late Pliocene)**—A few small exposures of marine siltstone and very fine-grained silty sandstone; very soft and slightly indurated, locally very fossiliferous, fossils referred to the late Pliocene or early Pleistocene; maximum thickness about 120 m (Hoots, 1931; McGill, 1989).

Soledad Basin and San Andreas Fault Zone

QTjh **Juniper Hills Formation (early Pleistocene to late Pliocene) undifferentiated**—Pink, buff', light-brown, or red, pebbly to cobbly, coarse, arkosic sandstone, silty sandstone, lesser conglomerate, and thin-bedded shale. Mapped by Barrows and others (1985) in the San Andreas Fault zone. Sandstone and conglomerate represent fluvial and other continental deposits. Sandstone is poorly to moderately indurated, typically well bedded and poorly sorted. Clasts are sub-angular to well-rounded and include abundant yellow-brown sandstone and a variety of very well-rounded. tough metavolcanic cobbles recycled from the San Francisquito Fm.; abundant volcanic rocks probably recycled from the Punchbowl fm.; leucocratic granitic rocks; silver, gray and spotted Pelona Schist; ferruginous syenite; and medium- to coarse-grained blue-Quartz granite and leucogneiss. This unit is typically folded and internally deformed.

QTjhc **Juniper Hills Formation (early Pleistocene to late Pliocene) Clay shale member**—Greenish-gray, light brown, and black silty clay shale with very thin maroon sandstone layers. Mapped by Barrows and others (1985) in San Andreas Fault zone. Shale is thin-bedded, gypsiferous, with local iron oxide stained bedding. Also contains minor beds of finely laminated gray- to light grayish-brown silty sandstone, white arkose, and white chalky calcareous beds. Clay shale member probably represents lake deposits that are interbedded with other continental deposits. This unit is typically folded and internally deformed. Clay rich units are locally expansive with typical “popcorn” weathering.

QTjhr **Juniper Hills Formation (early Pleistocene to late Pliocene) Red arkose member**—Red to dark-red pebbly arkose and minor white and gray silty sandstone. Localized along Northern Nadeau Fault and is stained, deformed, crushed, and contains fractured clasts. Clasts are predominantly subrounded, light-colored granitic rocks and lesser varicolored volcanic rocks. Strongly resembles Punchbowl Fm. and may have been derived exclusively from a Punchbowl terrane.

QTjhm **Juniper Hills Formation (early Pleistocene to late Pliocene) Mixed clast member**—White to buff, coarse, poorly sorted and locally chaotic, pebbly, arkosic sandstone· and angular cobble to boulder conglomerate with abundant, rounded, leucocratic granitic-rock cobbles; subangular to subrounded clasts of gray mica schist, thinly laminated quartzite, and white quartz from Pelona Schist; yellowish rusty-brown, rounded sandstone cobbles and recycled, tough, metavolcanic clasts from San Francisquito Fm.; and scarce, maroon, fine-grained sandstone pebbles from Vasquez Fm. (?). Volcanic clasts (other than recycled San Francisquito Fm. cobbles) not seen. The presence of abundant (locally 80-90%) large clasts of Pelona Schist is distinctive.

Ventura Basin, including San Fernando Basin

QTp **Pico Formation (middle Pleistocene to Pliocene)**—Thick marine sequence composed of siltstone, sandstone and subordinate conglomerate deposited in the Ventura basin; coarser-grained sediments deposited primarily by turbidity currents and are commonly the dominant lithology along the axis of the basin, in feeder channels on the adjacent basin slopes (Yeats,

1979a; Sylvester and Brown, 1988), and at the eastern margin of the basin south of Newhall (Winterer and Durham, 1962); hemipelagic clayey siltstone is interbedded or interfingering with the turbidity deposits and is locally the dominant lithology; deposited primarily at bathyal depths exceeding 4,500 ft. (1400 m) at the base of the section (Natland, 1967), but grades or interfingers up section into upper bathyal to neritic mudstone (see Mudpit shale - QTpms) and shallow water shelf and delta sandstone, conglomerate, and siltstone, with locally prominent fossil hash beds (see QTpcu and QTpg). The siltstone is typically bluish gray where fresh and olive gray with limonite stains or nodules where weathered; coarse-grained units range from light olive gray to light gray and light brown; compact but typically not well cemented. Siltstone beds typically contain abundant foraminifers and local invertebrate fossils. The upper shallow water deposits also contain locally abundant molluscan fossils and ostracodes. The Pico Formation is widely exposed in the eastern Ventura basin; it is exposed in the central Ventura basin on either side of the Santa Clara River Valley, but is thickest below this valley along the Ventura basin axis, where it is largely concealed by alluvium and faulting. Winterer and Durham (1962) report a maximum thickness of about 5,000 to 6,000 ft. (1500 to 1800 m) in the eastern Ventura basin; however, Bailey (1952) reports a thickness of about 13,900 to 15,400 ft. (4200 to 4700 m) west of the map area in the Ventura area. The lower basinal section pinches out to the south and Pico deposits along the northern margin of the Ventura basin are missing in the upper reaches of the mountains on the north due to uplift and erosion. The basal portion of the formation was reportedly deposited during the Repettian stage in both the western and eastern Ventura basin (e.g. Dibblee, 1988; Beyer and others, 2009), and overlies the Modelo Formation to the west and overlies or interfingers with the Towsley Formation to the east in the type area. The top of the formation is time transgressive and is progressively younger to the west. Near the type section west of Valencia, the Pico Formation is reportedly older than about 2.5 Ma, the age of the base of the Saugus Formation estimated by Levi and others (1986). However, Winterer and Durham (1962) report the presence of the benthic foraminifera *Uvigerina peregrina* and *Bulimina subacuminata* within Pico siltstone, which characterize the early Pleistocene Wheelerian and Venturian stages respectively (Natland, 1952; Squires and others, 2006). McDougall and others (2012) report that these species also occur in the upper Repettian stage. In the western Ventura basin the upper Pico Formation includes early to middle Pleistocene ash beds, and alternatively underlies or includes the 0.6 Ma Lava Creek ash (see QTpms). This section was initially assigned to the Fernando Formation as defined by Eldridge and Arnold (1907) and as mapped by McLaughlin and Waring (1914). Kew (1924) subsequently assigned the lower, marine strata of the Fernando to the Pico Formation (except for coarse-grained shallow marine deposits), with the type section at Pico Canyon. Winterer and Durham (1962) remapped and redefined the formation in the type area and assigned the coarse-grained shallow marine units to the Pico Formation. This usage has been adopted by most workers in the eastern Ventura basin and is adopted here and extended to the Santa Susana Mountains and Oak Ridge. Strata in the Ventura basin containing Repettian-age fauna that are lithologically similar to the type Pico section are included within the Pico Formation. The term Repetto is abandoned entirely as a lithologic formation per the recommendation of Durham and Yerkes (1964). The term Pico is abandoned as a lithologic

formation in the Los Angeles basin following the recommendation of Durham and Yerkes (1959, 1964). The term Fernando Formation is not used in the Ventura basin based on differences in lithologic facies reported between the type Pico section and Pliocene strata in the Los Angeles basin (Durham and Yerkes, 1959, 1964) (see Appendix A for details). Lithologic facies have been mapped locally, including:

QTpg **Pico Formation, Grimes Canyon deltaic facies**—Medium- to coarse-grained sandstone, pebbly sandstone, and pebble conglomerate; cross bedding common to pervasive and foreset beds locally apparent; channeling common as well; weakly cemented to uncemented, clasts typically crystalline and derived from the San Gabriel Mountains, and rounded to well-rounded and smooth; moderately to well sorted; conglomerate locally clast supported; typically light gray; light-brown iron-oxide staining varies from local to prominent; generally unfossiliferous; uncommon greenish-gray sandy siltstone to rare thin claystone interbeds with local invertebrate fossils. This unit is well exposed along Grimes Canyon road and at quarries to the east and west of the road (Moorpark and Simi Valley West quadrangles). It is equivalent to a unit interpreted by Dibblee (1992b) as a delta deposit from west-flowing streams and expanded eastward into Happy Camp Canyon on this map based on additional field mapping. It interfingers with and is underlain by Pico siltstone to the west; underlain by and likely grades into or interfingers with fossiliferous shallow marine sands to the east that are assigned here to the upper coarse-grained marine member of the Pico Formation (QTpcu). Overlain by Las Posas Formation or undifferentiated Saugus Formation. Maximum thickness is about 315 m per Dibblee (1992b) cross section. This section historically assigned either to the Saugus or San Pedro Formations; designated herein as an informal member of the Pico Formation based on the definition of Winterer and Durham (1962) and the interpretation that most of this unit is marine; This interpretation is based on mapped interfingering relationships with offshore marine siltstone of the Pico Formation to the west, the presence of uncommon fossiliferous interbeds, the presence of marine sands up section of this unit near Grimes Canyon Road, the prevalence of well-rounded and nearly polished clasts indicative of extensive abrasion in a littoral environment, and foreset bedding suggestive of a delta front environment; however, differentiation of unfossiliferous marine sands from nonmarine sands is problematic in some areas and some nonmarine paralic strata are likely included in the unit as currently mapped. This unit stratigraphically separates and distinguishes older, shallow marine sands to the east, assigned herein as an informal upper facies of the Pico Formation (QTpcu), from younger, shallow marine sands to the west assigned herein to the Las Posas Formation.

QTpcu **Pico Formation, coarse-grained upper facies**—Sandstone, conglomerate and locally prominent fossil hash/coquina beds overlying Pico offshore deposits; locally cross bedded and channeled; gradational with or underlying the Grimes deltaic unit (QTpg); onlaps older formations to the south; overlain conformably or unconformably by nonmarine Saugus or transitional Sunshine Ranch Member strata in most areas; invertebrate fossils locally common. This facies is interpreted as shallow marine shelf, delta or embayment deposits (White, 1983, 1985; Groves, 1991). This section was initially mapped as the lower portion of the Saugus Formation by Kew (1924), but was reassigned to the upper Pico Formation in the eastern Ventura basin by Winterer and Durham (1962). Shallow marine strata previously assigned to

the lower marine Saugus Formation in the Santa Susana Mountains are reassigned here to this facies following the usage of Winterer and Durham and subsequent workers in the type localities of the Saugus and Pico Formations (see Appendix A for details).

QTpms **Pico Formation, Mudpit shale member (middle to early Pleistocene)**—Marine mudstone and siltstone with locally common sandstone interbeds and conglomerate lenses and rare, thin ash beds; conglomerate beds with hard siliceous clasts common at base; foraminifers common; local invertebrate fossils; typically bluish gray when fresh, weathering to olive gray; poorly bedded to locally laminated; 3,500 ft. (1067 m) thick north of Ventura (Natland, 1967). This member was deposited in the western Ventura basin (Fillmore quadrangle) at bathyal to neritic depths (Natland, 1967). Lower contact is conformable with the underlying Pico Formation. Correlative strata in the South Mountain/Balcom Canyon/Oak Ridge area are not lithologically distinctive relative to typical Pico Formation strata (Lung, 1958) and therefore the Mudpit shale member is not distinguished in this area. The upper contact is reportedly time transgressive and interfingers with shallow marine (Las Posas) sands to the east of Ventura (Bailey 1935; Hopps, 1995). Natland (1967) reports this unit contains lower Hallian and upper Wheelerian benthic foraminifers. Contains the 0.73 to 0.78 Ma Bishop ash and 0.8 to 1.1 Ma Glass Mountain ashes and spans the 0.78 Ma transition from reverse (Matuyama) to normal (Brunhes) polarity. The base occurs in proximity to the 1.2 Ma Bailey ash and the top is alternatively shown either above or below the 0.6 Ma Lava Creek ash (Wehmiller and others, 1978, Lajoie and others, 1982; Sarna-Wojcicki and others, 1984). Mudpit shale strata were originally assigned to the Fernando Formation of Eldridge and Arnold (1907), as mapped by McLaughlin and Waring (1914). These strata were subsequently included in the Pico Formation by Kew (1924) and described as upper Pico Formation by Cartwright (1928) and Driver (1928). Waterfall (1929) noted the similarity of molluscan fauna in this section with the fauna at Bath House beach in Santa Barbara and many subsequent workers assigned this section to the Santa Barbara Formation based on this faunal criteria (e.g. Bailey, 1935, 1951; usage adopted by Weber and others, 1973). Early workers in the Ventura Avenue/Rincon/San Miguelito oil fields referred to this section more informally as the Mudpit shale and Dibblee (1990) assigned it to the informal Mudpit shale member of the Pico Formation. This usage is adopted here (see Appendix A for details).

QTpc **Pico Formation, sandstone and conglomerate**—Sandstone and conglomerate interbeds within typical Pico siltstone (Val Verde quadrangle and Moorpark 7.5’ quadrangles).

Los Angeles Basin

Durham and Yerkes (1964) described two members, upper and lower, in the Puente Hills:

QTfu **Fernando Formation, Upper Member (early Pleistocene to Pliocene)**—In general, the Fernando Formation consists of massive light-gray siltstone, light yellowish-brown fine- to medium-grained sandstone, and light-brown to reddish-brown pebbly conglomerate in the Los Angeles basin; primarily marine but nonmarine conglomerate beds are reportedly included in the upper part of the section (Lamar, 1970); exposed primarily in the Los Angeles and El Monte quadrangles. Name introduced by Eldridge and Arnold (1907) based on unpublished

mapping of Homer Hamlin in the San Fernando Valley and initially extended to Pliocene strata from southern Los Angeles County to Santa Maria. The term Fernando was elevated to group status by Kew (1923, 1924), but was subsequently reclassified back to formational rank to name Pliocene strata of the Los Angeles basin by Durham and Yerkes (1964). See Appendix A for nomenclature details. Locally contains Repettian-Wheelerian (early Pleistocene to early Pliocene per McDougall and others, 2012) foraminiferal zone boundary (Lamar, 1970).

The upper member on this map includes Fernando Formation members 2 and 3 of Lamar (1970): **QTfuc**—pebbly sandstone and conglomerate; **QTfuf**—fossiliferous.

QTfl **Fernando Formation, Lower Member (Pliocene)**—Interbedded silty sandstone and massive pebble conglomerate of the Los Angeles basin. Includes Fernando Formation member 1 of Lamar (1970). See QTfu above and Appendix A for discussion of nomenclature **QTflc**—conglomerate.

Ventura Basin

Tw **Towsley Formation, undivided (early Pliocene to late Miocene)**—Interbedded sandstone, conglomerate, and sandy siltstone and mudstone; the coarse-grained facies is light-colored and commonly lenticular, and is interpreted as turbidity current deposits in a submarine fan; the fine-grained facies is characteristically brown weathering and represents deposition between the fan lobes (Fritsche, pers. comm. 2011). Winterer and Durham (1962) report the presence of numerous transported fossil invertebrates that suggest a depositional water depth in excess of 600 ft. (180 m), and possible depths of 3,000 ft. (900 m) or more based on foram assemblages Strata, up to 4,000 ft. (1200 m) thick, form widespread exposures in eastern Ventura County; overlies Modelo Formation strata in the Topatopa Mountains. The Towsley Formation overlies and interfingers with the Modelo Formation in the Santa Susana Mountains and overlaps Modelo strata to rest directly on basement rocks near and east of San Fernando Pass. Its base is distinguished from the Modelo Formation at the first thick bedded pebbly sandstone. The generally conformable, locally interfingering upper contact with the Pico Formation is chosen at the transition from diagnostic brown-weathering siltstone of the Towsley to olive-gray siltstone with common limonite nodules typical of the Pico. The Towsley Formation is early Pliocene to late Miocene (Winterer and Durham, 1962; Squires and others 2006, fig. 2). This section was initially included in the Modelo Formation by Kew (1924); the section in the Elsmere Canyon area was assigned to the “Repetto formation” by Oakeshott (1950); a new, unnamed formation was proposed by Winterer and Durham (1951), was subsequently named the Towsley Formation in Winterer and Durham (1954), and was formally described and mapped by Winterer and Durham (1962) based on the type section at Towsley Canyon, southwest of Valencia. In the northern San Fernando Valley, east of Pacoima Canyon, a band of strata was shown as Pico Formation by Yerkes and Campbell (2005); Hill (1930) also mapped this section as Pico, but Oakeshott (1958) mapped it as “Repetto formation” and several early Caltech theses note the presence of brown weathering siltstone, which is typical of the Towsley Formation of Winterer and Durham (1962); Barrows and others (1974) mapped it as undifferentiated Towsley/Pico Formation; Dibblee (1991e) maps it as Towsley Formation. This

unit is mapped here as Towsley Formation based on Dibblee and the noted lithology, but is queried due to the possible inclusion of undifferentiated Pico Formation strata. Mapped subunits and members include:

Tws **Towsley Formation, siltstone**—Brown mudstone and siltstone, locally carries foraminifera referred to the Mohnian Stage (late Miocene) of Kleinpell (1938).

Twc **Towsley Formation, conglomerate**—Pale pebble conglomerate and sandstone in lenticular beds.

Twhc **Towsley Formation, Hasley Conglomerate Member**—Basal conglomerate member.

Los Angeles Basin

Tpn **Puente Formation, undivided (early Pliocene and late Miocene)**—Marine siltstone, sandstone, and shale; mostly a Los Angeles basin temporal equivalent of the Modelo Formation, but partly younger; named by Eldridge (*in* Eldridge and Arnold, 1907) from exposures in the Puente Hills; strata are associated with the Los Angeles basin (El Monte, Los Angeles and Hollywood 7.5' quadrangles) as contrasted with Modelo strata, which are associated with the eastern Ventura basin. In the Los Angeles and Hollywood 7.5' quadrangles Lamar (1970) mapped four non-sequential, interbedded, informal lithologic subunits, which have not been specifically correlated with the formal members recognized by Shoellhamer and others (1954).

Tpsl **Puente Formation, siltstone (early Pliocene)**—Well-bedded, light gray siltstone; thickest beds at top of section, also interbeds lower in section (Lamar, 1970, fig. 14).

Tpsh **Puente Formation, siliceous shale (early Pliocene)**—Well-bedded, light gray, siliceous shale and siltstone; regularly interbedded with thin, fine- to coarse-grained sandstone beds; most common in a few discontinuous zones, chiefly in upper-central part of formation (Lamar, 1970, fig. 14).

Tpds **Puente Formation, diatomaceous shale (early Pliocene)**—Well-bedded, dull white diatomaceous shale; a discontinuous single zone in central part of formation (Lamar, 1970, fig. 14).

Tpss **Puente Formation, sandstone (late Miocene)**—Well-bedded, very fine- to very coarse-grained sandstone; medium to light brown and light gray; mostly well cemented but less so in uppermost parts; local discoidal concretions; most abundant in lower part of formation (Lamar, 1970, fig. 14).

Tpnsc **Puente Formation, Sycamore Canyon Member (late Miocene)**—Predominantly sandstone and pebble conglomerate, laterally variable; sandstone is thick-bedded to massive, medium- to coarse-grained, friable; siltstone is massive- to thin-bedded, siliceous; conglomerate is massive, contains pale to brownish-gray pebbles and cobbles; siltstone locally contains bathyl-depth foraminiferal faunas; **Tpnscc** - conglomerate bed. Member named by Schoellhamer and others (1954).

Tpny **Puente Formation, Yorba Member (late Miocene)**—Predominantly siltstone, with sandstone interbeds; named for Yorba Bridge over the Santa Ana River, east of Atwood; white to gray, thin-bedded, micaceous and siliceous siltstone; upper part contains large boulders "floating" in much fine-grained material – interpreted to be a turbidity current deposit. Named by Schoellhamer and others (1954).

Tpnsq **Puente Formation, Soquel Member (late Miocene)**—Predominantly sandstone, minor interbedded siltstone; sandstone is gray to yellowish-gray, massive- to well-bedded, medium- to coarse-grained, poorly sorted; interbedded pebbly sandstone; many such beds are graded, locally pebbly to cobbley conglomeratic; lower part of unit contains ellipsoidal, calcite-cemented boulders as large as 1.5 m. Named by Schoellhamer and others (1954).

Eastern Ventura Basin

Tcs **Castaic Formation, undivided (late Miocene)**—Marine tuffaceous or diatomaceous shale, interbedded pebbly sandstone, sparse limestone concretions with well-preserved foraminifera. Named by Winterer and Durham (1954) for marine sandstone strata of late Miocene age (equivalent in age to the Modelo Formation), north of the San Gabriel Fault and east of Newhall; name extended to north for late Miocene shale with interbedded sandstone and minor pebble conglomerate in Soledad-Ridge basin area by Crowell (1954).

Tm **Modelo Formation, undivided (late and middle Miocene)**—Predominantly gray to brown thin-bedded mudstone, diatomaceous clay shale, or siltstone, with interbeds of very fine-grained to coarse-grained sandstone; proportion and thickness of sandstone interbeds allows lithofacies to be mapped in some areas; generally unconformable on older rocks around northern, eastern and southern margins of the Ventura basin. The base of the Modelo is generally unconformable on middle Miocene and older rocks. The name, Modelo, was introduced by Eldridge and Arnold (1907) for strata exposed in the Topatopa Mountains, north of Piru and further described in the Santa Susana Mountains and San Fernando Pass areas by Winterer and Durham (1962); extended to the eastern Santa Monica Mountains and described in detail by Hoots (1931) where further noted for turbidite features indicating submarine fan deposition (Sullwold, 1960); Along the north flank of the Santa Monica Mountains the unconformity mapped by Hoots (1931) in the eastern part of the range, where Modelo locally overlies Santa Monica Slate, has been mapped continuously westward (Yerkes and Campbell, 1980; Weber, 1984; and unpublished 1:12,000-scale mapping by Yerkes and Campbell, 1965-1974, in the Canoga Park and Calabasas 7.5' quadrangles) as far as the north side of the Ventura Freeway (U.S. 101) at the west side of Las Virgenes Creek, to the west of which it becomes accordant with (and apparently conformable on) subjacent strata of the Calabasas Formation (Weber, 1984); further west, the Modelo and subjacent parts of the Calabasas appear to grade progressively westward into more diatomaceous, clayey, Monterey-like lithofacies. Many of the sandstone and shale beds below (south of) the unconformity (and its westward conformable extension) and above (north) of the Conejo Volcanics are lithologically similar to the Modelo but more intensely folded and faulted; these have been assigned to the Calabasas Formation by Yerkes and Campbell (1979). Fellbaum and Fritsche (1993) include them in the

Modelo Formation; however, their stratigraphic position below the unconformity mapped by Hoots (1931) as the base of the Modelo, and the predominance of middle Miocene foraminifera (Luisian or Relizian?) in the Calabasas, suggests their correlation with Modelo strata is questionable. In the eastern Santa Monica Mountains the Modelo was mapped and described in detail by Hoots (1931), and Kleinpell (1938) used the unconformity at the base, well exposed near Mohn Springs in Topanga Canyon, where it is underlain by predominantly middle Miocene Topanga strata, as the base for his type Mohnian (foraminiferal) Stage (late Miocene). Widespread in eastern Ventura basin; locally extended to include some strata along the south flank of the Santa Monica Mountains in the Pacific Palisades-Westwood area. Five members were described by Cemen (1977) in the Topatopa Mountains and four of them have been mapped as far south as the north flanks of Oak Ridge and the Santa Susana Mountains. Age-correlative strata in the Los Angeles basin are generally referred to the Puente Formation or, west of the Newport-Inglewood zone, to the Monterey Shale. Mapped facies of the Modelo Formation include:

Tmsu **Modelo Formation, upper sandstone unit at Laskey Mesa**—Weber (1984) assigned strata at Laskey Mesa to the Towsley Formation, as shown by Yerkes and Campbell (2005); Truex and Hall (1969) previously assigned most of this section to the Modelo Formation and the uppermost portion to the Santa Margarita Formation, and Brown (1957) mapped it as Modelo Formation; Dibblee (1992b) mapped this section as Tertiary unnamed shale and sandstone; Yeats (1979) reported that Towsley Formation does not occur south of the Santa Susana Fault. Field review of this area did not reveal any brown mudstone or coarse-grained turbidite beds typical of the Towsley Formation and this unit has been reassigned to the upper Modelo Formation herein based on lithologic similarity to Modelo strata to the west and previous usage.

Tm_5 **Modelo Formation, member 5**—Upper shale and siltstone unit; dark brown to gray, moderately to well compacted, thin-bedded to laminated silty shale and siltstone, locally siliceous near base; contains foraminifera assigned to the upper Mohnian and lower Delmontian Stages of Kleinpell (1938); thickness locally exceeds 458 m. (Cemen, 1977) Includes units mapped as Sisquoc Formation by Dibblee (1991).

Tm_4 **Modelo Formation, member 4**—Upper sandstone unit; white to gray, fine to coarse-grained arkosic sandstone, with subordinate thin partings and lenticular interbeds of silty clay shale, locally siliceous; thickness variable, locally as much as 825 m. (Cemen, 1977).

Tm_3 **Modelo Formation, member 3**—Middle shale unit; porcelaneous and calcareous shale and porcelaneous mudstone, brown to buff, thin-bedded to laminated, moderately to well indurated, with thick lenses of gray calcareous sandstone locally; thickness variable but may exceed 763 m.; foraminifera referred to lower part of the Mohnian Stage of Kleinpell (1938) (Cemen, 1977).

Tm_2 **Modelo Formation, member 2—**Lower sandstone unit; grayish white to dark brown, fine to medium-grained sandstone, locally interbedded with dark brown siltstone and claystone; locally as much as 915 m. thick, thins westward and pinches out between the middle and lower shale units (Cemen, 1977).

Tm_1 **Modelo Formation, member 1—**Lower shale unit; cherty to porcelaneous shale and mudstone, locally calcareous, locally diatomaceous, moderately to well indurated, thin-bedded to laminated, generally dark gray to brown; contains foraminifera referred to the Relizian and Luisian Stages of Kleinpell (1938), indicating the unit is age-correlative with the Calabasas Formation and, possibly the upper part of the Topanga Canyon Formation in the Santa Monica Mountains; thickness 214-794 m. (Cemen, 1977).

Tmd **Modelo Formation, diatomaceous shale**—Diatomaceous shale; includes outcrops on the south side of the San Fernando Valley at Pierce College shown as Pico Formation by Yerkes and Campbell (2005), based on the presence of Repettian stage benthic foraminifers (Ingle, 1967; Yerkes and Campbell, 1993); previously assigned to the Modelo Formation by Hoots (1931). Review of these exposures indicates that much of this unit is lithologically more consistent with the Modelo Formation than the Pico Formation. This section is assigned here to the Modelo Formation based on the noted lithology and presence of Modelo Formation mapped on strike to the east and west, but is queried based on the reported presence of Repettian stage fauna.

Tms **Modelo Formation, sandstone**—Sandstone and conglomerate.

Tmb **Modelo Formation, "burnt shale"**—Unusual slag and scoriaceous- to obsidian-like material found within the upper part of the Modelo Formation in the Grimes Canyon area, Big Mountain/Happy Camp Canyon, and upper Las Virgenes Canyon area. It is composed of red, yellowish-orange, purple, brown, and black mudstone, siltstone, and diatomite that has been altered by in-situ combustion of natural gas in layers containing abundant organic material, as described and mapped by Irvine (1995), Brown (1957), and Jestes (1958).

Soledad Basin and San Andreas Fault Zone

Tpbc **Punch Bowl Formation, clay shale member (late Miocene)**—Gray, poorly indurated clayey shale with local gypsum. (Dibblee, 2001).

Tpbv **Punch Bowl Formation, volcanic clast member (late Miocene)**—White to pink, coarse, pebbly to cobbly, arkosic sandstone, thin-bedded silty sandstone, and minor thin-bedded, white, nodular limestone. Si1ty layers range from yellowish tan through greenish brown to red. Sandstone is well-indurated, well-stratified and was probably deposited in alluvial fan and floodplain environments. Clasts are predominately light-colored granitic rock pebbles and cobbles with lesser (up to 40%) tuffaceous and porphyritic volcanic .rocks ranging in composition from rhyolite to andesite. (Barrows and others, 1985).

Tmc **Mint Canyon Formation, undivided (late and middle Miocene)**—First described by Hershey (1902b), named by Kew (1924), mapped in detail by Saul and Wootton (1983) and Saul (1985), who recognized three intertonguing lithofacies. Includes a variety of semi-consolidated nonmarine sediments deposited in fluvial and lacustrine environments. Jahns and Muehlberger (1954) describe two informal members: a lower member including reddish-brown basement rock breccia, conglomerate, sandstone, siltstone and mudstone (thickness ~ 335 m); and an

upper member consisting of thin-bedded brownish or greenish siltstone and interbedded tuff (thickness ~ 790 m).

Tmcd **Mint Canyon Formation, Lacustrine deltaic (foreset) facies**—Predominantly fine- to coarse-grained, sparsely-concretionary, cross-bedded, arkosic sandstone, interbedded with conglomeratic sandstone, gray to brown sandy siltstone and claystone; tuff and tuffaceous sedimentary beds; marly and nodular carbonate. Sparsely fossiliferous: small clam and snail shells, vertebrate bones and teeth. (Saul and Wootton, 1983).

Tmcl **Mint Canyon Formation, Lacustrine bottomset facies**—Interbedded sandstone, silty sandstone, siltstone, claystone and thin beds and lenses of limestone; a few lenses of turbidite sandstone and coarse conglomerate; tuffaceous beds; ostracod shells; bedding planes commonly darkened by finely divided lignite; graded beds common. (Saul and Wootton, 1983).

Tmcm **Mint Canyon Formation, Lacustrine and lake-marginal fluvial facies**—Deposits of arkosic sandstone and conglomeratic sandstone, with interbedded siltstone and mudstone; some nodular carbonate in siltstone; thin beds of limestone common in mudstone. (Saul and Wootton, 1983).

Ttk **Tick Canyon Formation, undivided (middle to early Miocene)**—Reddish, fluvial and lacustrine sandstone, siltstone and claystone, and gray, tan, and reddish, well-cemented and well-bedded conglomerates (Mint Canyon, Agua Dulce and San Fernando 7.5’ quadrangles; Oakeshott, 1958). Named by Jahns (1940), and separated from the overlying lower part of the Mint Canyon Formation on the basis of a distinctively older vertebrate fauna. Includes area east of Tick Canyon and in upper Agua Dulce Canyon mapped by Oakeshott (1958) as Mint Canyon Formation but shown by Jahns and Muehlberger (1954) and Dibblee (1996b,c) as Tick Canyon Fm. Ehlert (2003) found no lithologic differences or unconformity between Tick Canyon and overlying Mint Canyon Formations and suggests that units mapped as Tick Canyon Formation should be considered basal sediments of the Mint Canyon Formation. Original usage retained, but question regarding validity of Tick Canyon Formation noted.

Ttkc **Tick Canyon Formation, conglomerate (middle to early Miocene)**—Dark gray, coarse, poorly-bedded conglomerate, Oakeshott, 1958), Dibblee (1996b,c).

Los Angeles Basin and Continental Borderland

Tmt **Monterey Shale, undivided (late, middle, and early Miocene)**—Marine clay shale, thin interbedded siltstone, minor sandstone and pebble conglomerate, and glassy tuff; siltstone is commonly diatomaceous, locally bituminous, siliceous, or dolomitic; sandstone is commonly quartz arenite; some conglomerates contain clasts of glaucophane schist. Shale is gray to dark brownish gray where fresh, weathers quickly to chalky white; contains foramifera referred to the Relizian, Luisian, or Mohnian Stages (early middle, late middle, or early late Miocene respectively) of Kleinpell (1938). Monterey strata are exposed only south of the Malibu Coast Fault and west of the Newport-Inglewood zone of faulting and folding; rocks of equivalent age north of the Malibu Coast Fault are referred to the Topanga Group and the Modelo Formation; east of the Newport Inglewood zone, strata of equivalent age are referred to the Puente Formation and the Topanga Group. The Monterey is generally considered a distal, deep-basin

facies of the more-proximal Modelo, Puente and other formations of the equivalent age range. Name extended into southern California from type area in Monterey County, central California (Woodring and others, 1936). The upper part of the unit in some areas (chiefly along the Pacific Coast Highway) is late Mohnian in age and locally overlies the early Miocene Trancas Formation unconformably; its relation to middle Miocene Monterey strata on Point Dume is obscured, but could be an intraformational unconformity. The (mostly middle Miocene) section exposed on Point Dume is about 1000 m thick. The Monterey Shale in the northern Los Angeles basin is unconformably overlain by unconsolidated Pliocene, Pleistocene and Holocene deposits; *includes*:

Tmtd **Monterey Shale, deformed (middle and early Miocene)**—Intensely deformed shale, siltstone, and sandstone, commonly dolomitic, locally siliceous, locally very cherty; contains foraminifera referred to the Relizian or Luisian (middle Miocene) Stages of Kleinpell (1938). In upper plate of Escondido thrust fault beds are tightly folded, with vertical limbs and gently east-plunging axes; thickness across folded beds is at least 650 m.

Ventura Basin and Los Angeles Basin

Tt **Topanga Group, undivided (middle and early Miocene)**—First called the Topanga Formation by Kew (1923) for exposures in the central Santa Monica Mountains that include the type locality for the "Topanga Canyon fauna" (about 50 molluscan species) of Arnold (1907a). Durrell (1954) recognized that the three subdivisions identified by Kew (1923) are contiguous westward with extensive units of formation rank, labeling them the Lower Topanga, Middle Topanga and Upper Topanga Formations. Subsequent publication of the North American Stratigraphic Code led Yerkes and Campbell (1979) to change the names to conform, and designated the set of three formations as the Topanga Group, consisting of the Calabasas Formation, the Conejo Volcanics, and the Topanga Canyon Formation, each with two or more members. Elsewhere, middle Miocene strata with similar lithologic and biologic facies have been informally divided: in the eastern Ventura basin and the northern Los Angeles basin beds containing Luisian BFZ foraminifera (late middle Miocene), that are labeled **Tt** are chiefly age-equivalent to the Calabasas Formation; beds containing a "Temblor" or "Topanga" molluscan fauna have also been labeled **Tt**. Middle Miocene volcanic rocks that may be related to the Conejo Volcanics, but are spatially separated, are labeled **Ttb**. The distribution and nomenclature history of the Topanga Group has been reviewed by Campbell and others (2007).

In the Santa Susana Mountains, informal subunits include:

Tt_4 **Topanga Group, Oat Mountain unit 4**—Upper sandstone with interbedded siltstone and local pebble conglomerate; sandstone, medium- to coarse-grained arkose, locally contains *Amusium lompocensis*; thickness about 140 m; (Saul, 1979).

Tt_3 **Topanga Group, Oat Mountain unit 3**—Shale, foram-bearing siltstone, and mudstone, about 122 m thick (Saul, 1979).

Tt_2 **Topanga Group, Oat Mountain unit 2**—Sandstone, fine- to coarse-grained, arkosic, well indurated, massive, about 244 m thick (Saul, 1979).

Tt_1 **Topanga Group, Oat Mountain unit 1**—Shaly siltstone, massive- to well-bedded, minor lenses of conglomeratic sandstone; siltstone locally contains microfauna assigned to the Luisian Stage of Kleinpell (1938) suggesting it is an age-correlative of the Calabasas Formation (Saul, 1979).

In the eastern Santa Monica Mountains informal subunits include:

Ttss **Topanga Group, sandstone**—Sandstone, medium- to coarse-grained, well-bedded, light brown and gray (Lamar, 1970).

Ttsl **Topanga Group, siltstone**—Siltstone, well bedded, medium to dark brown, with interbedded sandstone, shale and chert (Lamar, 1970).

Ttcg **Topanga Group, conglomerate**—Conglomerate, massive- to well-bedded, light brown; includes basal breccia locally (Lamar, 1970).

Ttb **Intrusive and extrusive volcanic rocks**—Chiefly basaltic, interlayered with sandstone and shale assigned to the Topanga Group. In part, may be correlative with Conejo Volcanics of central and western Santa Monica Mountains and adjacent areas to the northwest; but includes rocks that are dated as older than the oldest contiguous Conejo (McCulloh and others, 2002). (eastern Santa Monica Mountains, Hoots, 1931; Santa Susana Mountains, Evans and Miller, 1978; northeastern Verdugo Mountains, Oakeshott, 1958).

In the central and western Santa Monica Mountains divisions include:

Tcb **Calabasas Formation, undivided (early late Miocene and late middle Miocene)**—Interbedded impure, clayey to silty sandstone and silty shale, with local beds of sedimentary breccia; sandstone is thin-, medium- and thick-bedded, mostly medium to coarse grained, poorly sorted, commonly with wacke texture, commonly shows graded bedding; shale, locally diatomaceous; may have small phosphatic pellets, locally abundant fish scales, sparse Foraminifera and rust-colored plant casts, some thicker beds contain zones of large ovoid dolomitic concretions; sedimentary breccia, olistostromes incorporating cobble- to large boulder-size clasts of recognizable older Tertiary strata, some as fossil-bearing clasts of Paleocene, Eocene, early Miocene, and middle Miocene strata. Many of the sandstones are lithologically similar to those in the overlying, less-deformed Modelo Formation. Total thickness is about 1,200 m in the type area. The Modelo is unconformable on the Calabasas in the name area, however, west of Malibu Junction and north of the Ventura Freeway the two formations are accordant, the Calabasas is greatly thinned, and grades westward into finer-grained clayey siltstone and shale much like that of the Modelo in the area, and the two formations are distinguished only by differences in foraminiferal fauna. (The Calabasas there contains foraminifera referred to the Luisian Stage of Kleinpell, 1938; the Modelo contains foraminifera referred to the Mohnian Stage of Kleinpell, 1938). The contact relationships with the underlying Conejo Volcanics are marked by extreme variability, ranging from unconformable to accordant and intertonguing, apparently reflecting marine sedimentation, at least partly contemporaneous with the development of a submarine volcanic edifice and associated tectonic disturbance. Intraformational deformation west of Liberty Canyon, the

angular unconformity east of Medea Creek, and the abruptly thinner Calabasas section near and west of Agoura reflect local tectonic activity during deposition; and the volcanic conglomerate is probably significantly younger than most of the Calabasas section to the east. In the west-central Santa Monica Mountains the Calabasas Formation and older strata are involved in major pre-Modelo deformation that includes detachment faulting. Well-defined upper-plate ramps in Trancas and Topanga Canyons show offsets exceeding many hundreds of feet on faults that bend to follow bedding planes, along which intervening beds are missing or thinned, and establish a style of younger-over-older faulting as a significant structural feature. Outcrops where contact relations can be observed in macroscopic detail, and confirm depositional or shear-surface relations, are extremely rare, but where found indicate little discordance at stratigraphic hiatus or local unconformity contacts between pre-Conejo Tertiary Formations. The Paleogene sequence is similar to that in the adjacent Simi Hills and the more distant Santa Ana Mountains, where variations in depositional environments appear to represent epeiric transgressions and regressions. Therefore, we conclude that contacts lacking local exposures of diagnostic depositional character, where significant parts of the section are missing or dramatically thinned, are one or more of a set of detachment faults. The alternative is to infer Paleogene orogenic deformation on a scale not recognized elsewhere in southern California.

Tcbvc **Calabasas Formation, Volcanic conglomerate (late middle Miocene)**—Volcanic conglomerate, mapped by Weber (1984) as basal Calabasas Formation where it rests unconformably on the Chatsworth Formation (Cretaceous) along the south flank of the Simi Hills, and extends northwestward across the Cretaceous-Paleogene sequence at the west end of the Simi Hills. This conglomerate is probably correlative with volcanic conglomerates that locally forms the base of the Calabasas Formation sandstone and shale exposed along and north of the Ventura Freeway in the Agoura area (Blackerby, 1965), and overlying volcanic strata in the Thousand Oaks area (Weber, 1984). In addition to the informal volcanic conglomerate member, five members were named by Yerkes and Campbell (1979).

Tcbs **Calabasas Formation, Stokes Canyon Breccia Member (late middle Miocene)**—Sedimentary breccia consisting of angular boulders and cobbles of redeposited well-cemented sandstone with molluscan faunas diagnostic of the "Martinez" (Paleocene) and "Domengine" (middle Eocene) Stages; the breccia bed is locally as thick as 60 m; underlain and overlain conformably by Calabasas sandstone and siltstone; locally overlain unconformably by basal conglomerate of the Modelo Formation. Thinner, less continuous breccia beds are present at two other horizons nearby. (Stokes Canyon area, northern Malibu Beach and southern Calabasas 7.5’ quadrangles; Yerkes and Campbell, 1979, p. E22; Yerkes and Campbell, 1980).

Calabasas subunits in the upper plate of Malibu Bowl Detachment Fault include:

Tcbmp **Calabasas Formation, Mesa Peak Breccia Member**—Sedimentary breccia consisting of angular boulders and cobbles of volcanic rock in a very coarse-grained sandstone matrix; maximum thickness approximately 288 m. Overlies the Newell Sandstone Member of the Calabasas Formation in the upper plate of the Malibu Bowl Detachment Fault, west central

Malibu Beach 7.5' quadrangle (Yerkes and Campbell, 1979, p. E23; Yerkes and Campbell, 1980).

Tcbn **Calabasas Formation, Newell Sandstone Member**—Poorly sorted turbidite sandstone and interbedded shaly siltstone with large dolomitic concretions; overlies and wedges out westward into Malibu Bowl Tongue of the Conejo Volcanics; maximum thickness approximately 244 m. (Yerkes and Campbell, 1979, p. E23; Yerkes and Campbell 1980).

Tcbd **Calabasas Formation, Dry Canyon Sandstone Member**—Sandstone (proximal turbidites) and subordinate interbedded siltstone, many thin turbidites, locally prominent dolomitic concretions in siltstone; overlies and tongues eastward into Solstice Canyon Tongue of the Conejo Volcanics; underlies and intertongues westward into Escondido Canyon Shale Member of the Calabasas Formation; overlain by, and locally intertongues with, the Malibu Bowl Tongue of the Conejo Volcanics, and locally overlain by the Newell Sandstone member of the Calabasas Formation; locally overlain by Latigo Canyon Breccia Member of the Calabasas Formation; underlain by Ramera Canyon Tongue of Conejo Volcanics; approximate maximum thickness 686 m (Campbell and others, 1996; Yerkes and Campbell, 1979, p. E24; Yerkes and Campbell, 1980).

Tcbl **Calabasas Formation, Latigo Canyon Breccia Member**—Sedimentary breccia, large angular boulders of Sespe Sandstone and fossiliferous Vaqueros sandstone in sandy, tuffaceous or volcanic breccia; intertongues with epiclastic volcanic breccia; approximate maximum thickness 91 m; underlies the Solstice Canyon Tongue of the Conejo Volcanics and overlies the Escondido Canyon shale member of the Calabasas formation (Yerkes and Campbell, 1979, p. E23; Campbell and others, 1996).

Tcbe **Calabasas Formation, Escondido Canyon Shale Member**—Siltstone, mudstone, shale and minor interbedded thin sandstone turbidites; locally prominent dolomitic concretions; tongues eastward into Dry Canyon Sandstone Member of the Calabasas Formation; westward laps onto and intertongues with Ramera Canyon Tongue of the Conejo Volcanics; approximate maximum thickness 276 m; (Yerkes and Campbell, 1979, p. E24; Campbell and others, 1996).

Tco **Conejo Volcanics, undivided (middle Miocene)**—Basalt, andesitic basalt, basaltic andesite, andesite, and dacite in a thick sequence of extrusive volcanic flows, flow-breccias, agglomerates, and epiclastic volcanic breccias, volcanic sandstones and siltstones; thickest (probably in excess of 3 km) where it underlies the north flank of the western Santa Monica Mountains, and thinning eastward to as little as 200 m of interbedded flows and volcaniclastic sedimentary rocks on the nose of the Topanga Anticline; further east the volcanic rocks are thin and discontinuous, and the name has not been extended eastward for more than a mile east of Topanga Canyon Road. The thick sequence shows a crude compositional layering: pillow basalts, pillow breccias, aquagene tuffs, black volcanic sandstones and interbedded black siltstones are common in the basal part of the Conejo, associated with basalt, andesitic basalt, and basaltic andesite flows, breccias, and agglomerates; andesite and basaltic andesite predominate in the central part of the sequence with interlayered andesitic basalt; and an upper zone, dominated by andesitic and basaltic andesite but including dacite flows in some areas as

well as epiclastic volcanic conglomerates containing andesite and dacite clasts. The map by Durrell (1954) called the volcanics that intervene between lower Miocene and upper-middle Miocene sedimentary strata the “Middle Topanga Formation”; but his students Sonneman (1956) and Blackerby (1965) adopted the name "Conejo Formation” and “Conejo Volcanics", following the usage of Taliaferro (1924) for rocks in the Conejo Mountain area. This usage was formalized by Yerkes and Campbell (1979). In the vicinity of boundary between the Triunfo Pass and Point Dume quadrangles the contact with the upper part of the underlying Topanga Canyon and Vaqueros Formations is a buttress unconformity against a degraded half graben or caldera wall that laps eastward conformably onto shelf sediments at a higher stratigraphic level. Weigand and Savage (1993) have summarized the geochemistry of the Conejo Volcanics, comparing them with other southern California Miocene volcanic suites. The range in initial $^{87}Sr/^{86}Sr$ is reported as 0.60294-0.70320, indicating parent magmas derived from the upper mantle without important crustal rock contamination (Weigand and Savage, 1993, p. 105,106). K-Ar ages on plagioclases from basalt and andesite, reported by Turner and Campbell (1979), range from 15.5±0.8 m.y. near the base of the Conejo to 13.9±0.4 m.y. near the top. McCulloh and others (2002, p. 3) have recalculated the older date using updated decay constants to yield a 15.9±0.8 m.y. age.

Along the north flank of the Santa Monica Mountains, lithologic subunits include:

Tcode **Conejo Volcanics, dacite-bearing epiclastic lenses**—Epiclastic volcanic rocks, but including basalt, andesite and dacite pyroclastic flows and flow breccia; forms relatively thin layers and lenses interbedded in lower part of Calabasas Formation, which locally includes volcanic sandstone and volcanic conglomerate (north of Ventura Freeway, Thousand Oaks 7.5’ quadrangle; after Blackerby, 1965).

Tcod **Conejo Volcanics, dacite-bearing upper zone**—Interlayered dacite (including trachytic dacite), andesite and basalt flows and pyroclastics; minor volcanic sandstone. Malibu Junction Member of Conejo Volcanics of Blackerby (1965) (south of Ventura Freeway, Thousand Oaks 7.5’ quadrangle).

Tcoa **Conejo Volcanics, andesitic central zone**—Interlayered porphyritic and microporphyritic andesite, andesitic basalt, and basaltic andesite flows, agglomerates and flow breccias; includes some crystal tuff, vesicular andesite, pyroclastics and volcanic sandstone; includes Ladyface Member and Medea Member of Blackerby (1965), as well as Potrero and Triunfo Members of Sonneman (1956) and Guynes (1959). (Blackerby, 1965 and unpublished mapping 1965-1973; Campbell and others, 1996, and unpublished mapping 1962-1976; Sonneman, 1956; Guynes, 1959; and Weber, 1984). Lithologically recognized subunits, which occur at various stratigraphic levels, and do not form a consistent stratigraphic sequence, include:

Tcoaf **Conejo Volcanics, andesitic central zone, andesitic flows**—Andesite flows, mapped as Potrero Member of the Conejo Formation by Sonneman (1956) and Guynes (1959).

Tcoaa **Conejo Volcanics, andesitic central zone, andesitic agglomerate**—Andesite agglomerate and tuff, mapped as part of Potrero Member of the Conejo Formation by Guynes (1959).

Tcoab **Conejo volcanics, andesitic central zone, andesite breccia**—Andesitic and basaltic breccia and some agglomerate; mostly equivalent to rocks mapped as the Triunfo Member by Sonneman (1956) and Guynes (1959), and includes rocks mapped as Medea Member by Blackerby (1965). (Yerkes and Campbell, 1980; Campbell and others, 1970; Sonneman, 1956; Guynes, 1959; Weber, 1984; and unpublished 1:12,000-scale mapping by R. H. Campbell and B. A. Blackerby, 1967-1972).

Tcob **Conejo Volcanics, basaltic lower zone, basalt and andesitic basalt**—Chiefly basalt, olivine basalt, basaltic andesite, and andesitic basalt; ranges from trachytic olivine basalt to porphyritic quartz andesite; as flows, breccias, agglomerates, pillow basalts, pillow breccias, and basaltic sand and silt; includes Olivine Basalt and Seminole Members of Blackerby (1965); (Malibu Beach, Point Dume, Triunfo Pass, and Thousand Oaks 7.5' quadrangles; Yerkes and Campbell, 1980; Campbell and others, 1996; Blackerby, 1965; Sonneman, 1956; Guynes, 1959; Weber, 1984; and unpublished 1:12,000-scale mapping by R. H. Campbell and B. A. Blackerby, 1962-1976). Lithologically recognized subunits (flows and breccias) are interlayered at various stratigraphic levels in the upper part of the zone, and do not form a consistent stratigraphic sequence; however pillow basalt, pillow breccia, and volcanic sand predominate in the lower part of the zone. Subunits include:

Tcobf **Conejo Volcanics, basaltic lower zone, basalt and andesitic basalt, basalt flows**—Basalt, andesitic basalt and basaltic andesite flows (Blackerby, 1965; Yerkes and Campbell, 1979, 1980; Campbell and others, 1996; Weber, 1984).

Tcobb **Conejo Volcanics, basaltic lower zone, basalt and andesitic basalt, basaltic breccia**—Basalt, andesitic basalt and basaltic andesite breccias; can include some pillow breccia; in part, mapped as Serrano member of Conejo Volcanics by Sonneman (1956) and Guynes (1959). (Sonneman, 1956; Guynes, 1959; Blackerby, 1965; Yerkes and Campbell, 1980; Weber, 1984; Campbell and others, 1996).

Tcop **Conejo Volcanics, basaltic lower zone, pillow basalt**—Basalt pillow lavas, pillow breccias and probable aquagene tuffs; included in Seminole Member mapped by Blackerby, 1965, and Serrano Member mapped by Sonneman, 1956, and by Guynes, 1959. (Sonneman, 1956; Guynes, 1959; Blackerby, 1965; Yerkes and Campbell, 1980; Campbell and others, 1996).

Tcobz **Conejo Volcanics, basaltic lower zone, basaltic sand**—Black basaltic sand and siltstone; included in Seminole Member of Blackerby, 1965. (Blackerby, 1965; Yerkes and Campbell, 1980; Campbell and others, 1996).

In the upper plate of Malibu Bowl Detachment Fault, three stratigraphically distinct tongues of volcanic rocks are interbedded with members of the Calabasas Formation:

Tcom **Conejo Volcanics, Malibu Bowl Tongue**—Andesitic and basaltic flows and flow breccias; underlies and tongues eastward into the Newell Sandstone Member of the Calabasas Formation and overlies the Dry Canyon Sandstone Member of the Calabasas Formation; as much as 143 m thick (Yerkes and Campbell, 1979; Yerkes and Campbell, 1980).

Tcos **Conejo Volcanics, Solstice Canyon Tongue**—Basaltic and andesitic flows, breccias, and tuffs; local water-laid volcanic sandstone; underlies and intertongues eastward into the upper part of the Dry Canyon Sandstone Member of the Calabasas Formation, overlies Latigo Canyon Breccia Member of the Calabasas Formation; as much as 143 m thick (Campbell and others, 1970; Yerkes and Campbell, 1979; Yerkes and Campbell, 1980; Campbell and others, 1996).

Tcor **Conejo Volcanics, Ramera Canyon Tongue**—Basaltic and andesitic breccias, tuff-breccias, and flows(?); minor volcanic sandstone; underlies, and upper part intertongues with lower part of Escondido Canyon Shale Member of the Calabasas Formation; underlain in some areas by shallow marine strata of the Topanga Canyon Formation which is cut out locally by the Malibu Bowl Detachment Fault; as much as 518 m thick. (Campbell and others, 1970; Yerkes and Campbell, 1979; Yerkes and Campbell, 1980; Campbell and others, 1996).

Ti **Intrusive rocks, undivided (middle Miocene)**—Dikes, sills and irregularly shaped intrusive bodies of diabase, basalt, and andesite; commonly pervasively altered and easily eroded, undercutting slopes and, therefore, commonly spatially associated with toes of landslides; sills are larger and more abundant in the Topanga Canyon Formation at shallow stratigraphic depths below the base of the Conejo Volcanics; intrusive along the Malibu Bowl Detachment Fault only where Topanga Canyon Formation and younger strata are carried in the upper plate; (widespread in central and western Santa Monica Mountains; Yerkes and Campbell, 1980; Campbell and others, 1996; Yerkes and Campbell, 1994. In the central and western Santa Monica Mountains these are related to the Conejo Volcanics; however, in the eastern Santa Monica Mountains and elsewhere they may be related to other volcanic centers of roughly the same age (for example, small dikes mapped by Saul (1976) in the Mount Wilson 7.5' quadrangle).

Tid **Intrusive rocks, dacite (middle Miocene)**—Dacite dikes, irregular intrusive bodies in older Conejo rocks, and a plug intrusive into Topanga Canyon Formation; (Dibblee and Ehrenspeck, 1993, p. 89).

Tia **Intrusive rocks, andesitic (middle Miocene)**—Andesitic dikes, sills and irregular intrusive bodies, chiefly sills in Topanga Canyon and Vaqueros Formations, and dikes in older rocks.

Tib **Intrusive rocks, basaltic (middle Miocene)**—Basaltic, diabasic, and gabbroic dikes, sills and irregular intrusive bodies, chiefly sills in Topanga Canyon Formation and following detachment faults, and dikes in older rocks.

Tim **Mixed rocks (middle Miocene and early or early middle Miocene)**—Very fine- to fine-grained basalt, pervasively intrusive into black siltstone and very fine-grained sandstone of the Topanga Canyon Formation on a spacing too intimate to map separately at 1:12,000-scale; (Campbell, unpublished mapping, 1967-1976).

Ttc **Topanga Canyon Formation (middle and early Miocene)**—Marine sandstone, commonly arkosic, with interbedded siltstone, pebbly sandstone and pebble-cobble conglomerate; generally well indurated; recognized only in the central and western Santa Monica Mountains, where it is overlain unconformably by the Conejo Volcanics, and conformably overlies lithologically similar older Miocene and Oligocene strata of the Vaqueros Formation;

elsewhere, correlative strata are included in the undivided Topanga Group, **Tt**. Yerkes and Campbell (1979) formalized the name “Topanga Canyon Formation” and described as members lithologic facies that indicate an eastward shoaling of depositional environments from deeper shelf on the west to shoreface, estuarine, and fluvial deposits, wedging out just east of Santa Ynez Canyon. (Note that the deposition precedes post-volcanic tectonic rotation, so in early middle Miocene time the direction of shoaling was nearly north). North of Castro Peak, where the formation is undivided (**Ttc**), it is as much as 1,070 m thick. West of Santa Ynez Canyon to Malibu Canyon three members are recognized: the Cold Creek (**Ttcc**), Fernwood (**Ttcf**), and Saddle Peak (**Ttcs**) Members (Yerkes and Campbell, 1960). The Fernwood Member represents an estuarine and fluvial depositional environment, and separates shelf marine strata of the underlying Saddle Peak and overlying Cold Creek Members, both of which pinch out west of Topanga Canyon. The Fernwood Member wedges out westward and the two nearshore marine members coalesce just east of Malibu Canyon; therefore, the Formation is undivided from Malibu Canyon west to Zuma Canyon. Interbeds of siltstone and mudstone, suggestive of deepening offshore shelf depositional environments, become progressively thicker westward, and siltstone strata of the Encinal Canyon Member (**Ttce**) predominate west of Zuma Canyon. In and west of Arroyo Sequit some thick sandstone beds become prominent in the upper part of the Topanga Canyon Formation, and are here called the Big Sycamore Member (**Ttcb**).

Ttcc **Topanga Canyon Formation, Cold Creek Member**—Marine sandstone, siltstone, and minor pebbly sandstone; sandstone commonly medium grained, moderately to well sorted arkosic arenite, in laminated and graded beds as much as two meters thick, and locally biotitic. About 707 m thick in the northeast corner of the Malibu Beach 7.5’ quadrangle. Locally abundant molluscan fauna referred to "Temblor Stage" of Weaver and others (1944), including the locality for the “Topanga Canyon fauna” (about 50 molluscan species) of Arnold (1907a); named as a member of the Topanga Canyon Formation by Yerkes and Campbell (1979). Conformably overlies the Fernwood member of the Topanga Canyon formation; overlain, in most places conformably, by Conejo Volcanics. In a few localities in upper Topanga Canyon the Conejo is missing and the Cold Creek Member is accordantly overlain by the Calabasas Formation. Foraminifera from siltstone in upper part assigned to Relizian BFZ. (Yerkes and Campbell, 1980; Campbell, unpublished 1:12,000-scale mapping, 1965-1972).

Ttcf **Topanga Canyon Formation, Fernwood Member**—Paralic, fluvial, estuarine, and marine sandstone, pebbly sandstone, and mudstone, with minor tuff and limestone; interbedded with grayish-red or olive-gray mudstone and, locally, minor vitric rhyolite tuff and algal(?) limestone; fluvial sandstone forms thick lenticular ledge-forming beds and is complexly channeled and crossbedded; locally abundant closely spaced borings normal to sandstone bedding (ophiomorpha?), and rare fragments of bone occur; the shallow-water gastropod Melongena, known only from the provincial middle Miocene, occurs in sandstone on a ridge west of Topanga Canyon (in the Fernwood area) (Yerkes and Campbell, 1979; Yerkes and Campbell, 1980). The Fernwood is overlain conformably by and intertongues into the Cold Creek Member of the Topanga Canyon Formation. The Fernwood overlies the Saddle Peak Member conformably and may intertongue with it. In several parts of the Topanga Canyon drainage area Fernwood strata are cut off down dip by Sespe Formation redbeds along the

Malibu Bowl Detachment Fault or by basalt and diabase intrusive into the fault. Fritsche (1993) and Flack (1993) propose that the Fernwood member should be assigned to the Sespe Formation. However, the Fernwood has nowhere been observed to be in direct depositional contact with Sespe strata (even though short segments of approximately located contact are shown on the map, there is no outcrop exposure of unfaulted contact relationships). Nor does the Fernwood contain any red sandstone, which is characteristic of (though not always present in) the Sespe Formation. Therefore, the usage of the source maps is retained. (Yerkes and Campbell, 1979; Yerkes and Campbell, 1980; Yerkes and Campbell, 1994).

Ttcs **Topanga Canyon Formation, Saddle Peak Member**—Thick-bedded to massive, medium-to coarse grained marine sandstone, pebbly sandstone, and hackly fracturing sandy siltstone, over a 1/2-m-thick basal pebble conglomerate; conformably overlain by the Fernwood Member of the Topanga Canyon Formation; conformably overlies the Piuma Member of the Sespe Formation or its' marine correlative Vaqueros Formation; in places faulted against Sespe and older rocks, or strata of the Calabasas Formation, chiefly along the Malibu Bowl Detachment Fault. A resistant sandstone near the base of the Saddle Peak Member contains an abundant "Temblor" megafauna that includes the gastropod *Antillophos dumbleanus* (Anderson), that is apparently restricted to the middle Miocene; immediately above this bed is a 10-cm thick layer of well-preserved, in part articulated valves of the giant pectinid *Vertipecten nevadanus* (Conrad) (also called *V. bowersi*); the entire fauna is referred to the middle Miocene "Temblor" provincial Stage. Fritsche (1993) has proposed that the Saddle Peak Member be included with the Vaqueros Formation because some elements of the fauna are long ranging and are also found in the Vaqueros, and because closely similar lithofacies are found in both units. However, detailed mapping can carry continuous and overlapping stratigraphic horizons in most areas where the Saddle Peak Member is in contact with underlying Vaqueros, and the two units are mappable separately. Therefore, the usage of the source maps is retained. The unit is about 220 m thick along Piuma Road on the west shoulder of Saddle Peak. (Yerkes and Campbell, 1979; Yerkes and Campbell, 1980).

Ttcb **Topanga Canyon Formation, Big Sycamore Member**—Alternating gray sandstone and dark gray siltstone or silty mudstone, commonly platy to shaly; chiefly mudstone with interbedded thin- to thick-bedded lenticular sandstone in sets that locally coalesce to massive beds; sandstone grain size variable, with local rip-up clasts of shale, and pebbly sandstone with polished, rounded chert pebbles; mudstone interbeds commonly thin-bedded to shaly. A rare occurrence of detrital glaucophane in sandstone is the earliest known north of the Malibu Coast Fault. Sonneman (1954) estimated a total thickness of 2,400 ft. (732 m) to 3,500 ft. (1,066 m). Mapped as the "Upper Member of the Sycamore Formation" by Sonneman (1956); mapped as individual sandstone beds in the "Undivided Topanga Canyon Formation" by Dibblee and Ehrenspeck (1990); here called "Big Sycamore Member of the Topanga Canyon Formation" to follow rules of the North American Code. Fossils include: locally common *Vertipectin Nevandus* at Point Mugu; rare *Turritella Temblorensis* (Sonneman, 1954); and Relizian foraminifera (Sonneman, 1954).

Ttce **Topanga Canyon Formation, Encinal Member**—Chiefly dark gray siltstone or silty mudstone, commonly platy to shaly, but at many localities bedding fissility is obscured by a dominant conchoidal fracture, possibly indicating bioturbation; lenticular dolomitic concretions locally abundant, particularly along locally restricted stratigraphic zones as thick as 60 cm; rare medium-and fine-grained sandstone beds in the Encinal Canyon area (western Point Dume 7.5' quadrangle) increase in abundance somewhat westward in the Triunfo Pass 7.5' quadrangle. The siltstone rests conformably on sandstone of the underlying San Nicholas Member of the Vaqueros Formation, but there is apparent discordance in some places where lack of exposure prevents clear discrimination. The Encinal Canyon Member intertongues with and is overlapped conformably by the Big Sycamore Member of the Topanga Canyon Formation, and unconformably overlain by Conejo Volcanics (see discussion of base of Conejo, above). Poorly preserved foraminifera in two collections from the Encinal Canyon Road exposures reported by Yerkes and Campbell (1979) are assigned to the Relizian(?) stage and Saucesian or Relizian stages of Kleinpell (1938), respectively. Further west, in the Triunfo Pass and Point Mugu quadrangles Sonneman (1956) reports that the "Lower Member of the Sycamore Formation", which is contiguous with the Encinal Canyon Member of the Topanga Canyon Formation (Yerkes and Campbell, 1980), also contained foraminifera assignable to the Relizian Stage. A subsequent collection reported by Flack (1993) is also assigned a late Saucesian to early Relizian age. Flack (1993, p. 46) considers the Encinal Member, as well as the entire Topanga Canyon Formation, to be late early Miocene rather than early middle Miocene. (Campbell and others, 1996; Campbell, unpublished 1:12,000-scale mapping, 1965-1975; Sonneman, 1956; Dibblee and Ehrenspeck, 1990).

Western Los Angeles Basin-Continental Borderland

Tr **Trancas Formation, undivided (middle and early Miocene)**—Marine mudstone, silty shale, claystone, sandstone, and locally prominent sedimentary breccia on Lechusa Point and Point Dume; the breccias are distinctive for their abundant detritus of the Mesozoic Catalina Schist, including glaucophane schist (San Onofre breccia of Woodford and Bailey, 1928). The Trancas has been much deformed in the zone south of the Malibu Coast Fault, and no complete section is known. The Sovereign Oil Company Malibu 1 exploratory well on Point Dume drilled through 290 m of marine sandstone, mudstone, claystone, and sedimentary breccia (San Onofre Breccia) between the base of the Monterey Shale and the underlying Zuma Volcanics, assigned to the Trancas formation by Yerkes and Campbell (1979); (Point Dume and Triunfo Pass 7.5' quadrangles; Campbell and others, 1996; Campbell, 1965-1975, unpublished 1:12,000-scale mapping). The siltstones locally contain abundant foraminiferal assemblages assigned to the Saucesian (lower Miocene) and Relizian or Luisian (middle Miocene) stages of Kleinpell (1938). **Tra**—quartz-bearing calcarenites in the western part of the Point Dume 7.5' quadrangle and eastern part of the Triunfo Pass 7.5' quadrangle are distinctive for the pervasive intergranular disruption that causes original bedding to be completely masked; further west, at Sequit Point, the sandstones are seen to be coarse-grained, cross-laminated calcarenites, composed chiefly of barnacle plates and oyster fragments, with significant areas intruded by sandstone of similar composition but in which the original fabric is no longer visible (inferred

to be a result of liquefaction). An exposure of San Onofre Breccia overlying Zuma Volcanics on the tip of Point Dume, south of the Point fault, is assumed to represent the base of the Trancas Formation in that area. The Trancas may intertongue with both the Zuma Volcanics and the lower part of the Monterey Shale, but is locally unconformably overlain by upper (late Miocene) beds of the Monterey Shale.

Tz **Zuma Volcanics (middle and early Miocene)**—Basaltic, andesitic and dacitic flows, flow breccias, pillow lavas, aquagene tuffs, mudflow breccias, volcanic sand and interbedded mudstone, siltstone, sandstone, minor breccia-conglomerate; all probably deposited in a marine environment; no igneous rocks south of the Malibu Coast Fault are recognizably intrusive into the associated sedimentary rocks; sedimentary interbeds carry foraminifera referred to the Relizian or Luisian Stages (middle Miocene) of Kleinpell (1938). Weigand and Savage (1993), from a study of major element analyses, showed that most of the analyzed samples of Zuma Volcanics fall in the dacite field of the classification of LeBas and others (1986). Plagioclase phenocrysts from basalt near the tip of Point Dume have been dated at 14.6 ± 1 my (Berry and others, 1976). Base not exposed, but an equivalent section in the exploratory well, Sovereign Malibu 1 on Point Dume, is about 430 m (stratigraphic) thick above probable metamorphic basement (Catalina Schist). Although the Zuma and Conejo Volcanics fall within the same range of ages, the overlying and underlying sedimentary strata, and the basement rocks, are significantly different, suggesting that they could be related to different extrusive centers. (Campbell and others, 1970, 1996; Yerkes and Campbell, 1980; and Campbell, unpublished 1:12,000-scale mapping, 1967-1971).

Soledad Basin and San Andreas Fault Zone

Tvz **Vasquez Formation, undivided (early Miocene to Oligocene?)**—Yellowish and reddish sandstone, conglomerate, and interbedded andesite-basalt, lying on pre-Tertiary crystalline basement rocks and unconformably below strata of Tick Canyon Formation; total thickness as much as 3,810 m (Jahns and Muehlberger, 1954). Includes numerous beds and lenses of megabreccia, many monolithologic. Named by Sharp (1936); further described by Jahns (1939). (Dibblee, 1996a,b).

Tvza **Vasquez Formation, andesitic volcanic rocks (early Miocene? to late Oligocene)**—Dark-gray to dark reddish-brown andesite and basaltic andesite, hard, very fine-grained matrix with fine- to medium euhedral phenocrysts of plagioclase feldspar. Occasional flow banding, conglomeratic layering, and some silica-filled amygdules. Outcrops locally exhibit sub-parallel sheet jointing.

Tvzb **Vasquez Formation, basaltic volcanic rocks (early Miocene? to late Oligocene)**—Dark-gray, basaltic to andesitic volcanic rocks. Unit contains small phenocrysts of augite and olivine. Outcrop exposures are highly jointed and resistant, with weathered surfaces dark-gray to dark-brown.

Tvzc **Vasquez Formation, non-marine conglomerate (early Miocene? to late Oligocene)**—Pebble- to cobble fluvial conglomerate and red clayey siltstone. Unit consists of sub-rounded to

rounded clasts of gray, tan, pink, and lavender volcanic rocks. Also contains quartz monzonitic to granodioritic clasts.

Tvzs **Vasquez Formation, sedimentary rocks (early Miocene? to late Oligocene)**—Pebble- to cobble fluvial conglomerate and red clayey siltstone. Unit consists of sub-rounded to rounded clasts of gray, tan, pink, and lavender volcanic rocks. Also contains quartz monzonitic to granodioritic clasts.

Topatopa Mountains and eastern Santa Ynez Range

Trn **Rincon Formation (early Miocene and late Oligocene)**—Marine shale and mudstone with dolomitic and limonitic concretions as much as 0.65 m in diameter (Fillmore 7.5’ quadrangle); foraminiferal faunas referred to the Zemorrian and Saucesian Stages (early Miocene) of Kleinpell (1938); thickness about 275 m. Overlain, apparently accordantly, by shale and mudstone assigned to the lower part of the Modelo formation (which, in this area, is designated middle and upper Miocene), and conformably overlies Vaqueros Formation strata. The type section for the Rincon Formation is approximately 30 mi. to the west in the vicinity of Rincon Point where the name, Rincon Shale, was suggested by Kerr (1931) (south flank of Santa Ynez Mountains, Fillmore and Piru 7.5’ quadrangles; Eschner, 1969). Fritsche (1993) proposed that similar rocks within a similar age-range in the western Santa Monica Mountains (the Encinal Member of the Topanga Canyon Formation and the Danielson Member of the Vaqueros Formation) should be termed "tongues" of the Rincon Formation; however, we have retained the nomenclature of the source maps

Western Santa Monica Mountains, Oak Ridge and eastern Ventura Basin

Tv **Vaqueros Formation, undivided (early Miocene and Oligocene)**—A heterogeneous sequence of thick- and medium-bedded sandstone and interbedded siltstone and mudstone; sandstone ranges from coarse- to very fine-grained, chiefly biotitic arkosic arenites and wackes; siltstone and mudstone interbeds commonly dark gray, but can be greenish or reddish in color; commonly carries *Turritella inezana* and other elements of the "Vaqueros fauna". Although the name was first used in central California (Hamlin, 1904) and subsequently extended on the basis of faunal elements, it has long been used in coastal Southern California, and is used consistently throughout intervening areas, to refer to a well-recognized and widespread, predominantly marine sequence that contains a distinctive molluscan fauna (Loel and Corey, 1932). Since Addicott (1972) noted that the range of the Temblor fauna included the range of the Vaqueros fauna in the Temblor Range type area, some authors (Fritsche, 1993; Dibblee, 1989a) have proposed abandoning the name, Vaqueros, and combining the pre-Conejo post-Sespe strata into a single unit. However, in nearly all the problematical areas there are sufficient continuous or overlapping beds, as well as differences in fauna, to provide a realistic basis for mapping separate formations. In the Santa Monica Mountains a complete section in the vicinity of Castro Peak, where the Vaqueros accordantly overlies the nonmarine Sespe formation, is as much as 760 m thick; east of Malibu Canyon however, shoreface facies intertongue with nonmarine strata of the Sespe Formation, and Vaqueros strata are not present in and east of Topanga Canyon. Along the north side of Simi Valley, Vaqueros strata about 600 m thick lie

accordantly above Sespe redbeds and are overlain by Conejo Volcanics; the Vaqueros wedges-out to the east in the Simi Valley West 7.5' quadrangle. In the Simi Valley area, Squires and Filewicz (1983, Fig. 2) show the Vaqueros as approximately 310 m in thickness, intertonguing with and overlying the Sespe Formation; it pinches out eastward beneath the unconformably overlying Conejo Volcanics. North of Fillmore, the easternmost Vaqueros is about 183 m thick. (Cemen, 1977; Eschner, 1969; Bailey, 1951). Oborne (1993) has described the several interbedded lithofacies that are present to the west of Topanga Canyon and interprets them to represent deposition during a rapid marine transgression from west to east over nonmarine strata of the Sespe. This compilation retains the usage and nomenclature of Yerkes and Campbell, 2005. (western Santa Monica Mountains, western Topatopa Mountains, and north side of Simi Valley; Yerkes and Campbell, 1979; Yerkes and Campbell, 1980; Campbell and others, 1996; Eschner, 1969; Bailey, 1951; Cemen, 1977; Squires, 1983a; Sonneman, 1956; Durrell, 1954). Includes:

Tvn **Vaqueros Formation, San Nicholas Member**—Very thick bedded to massive cliff- and ledge-forming marine sandstone, generally very light gray to pale bluish gray; rare interbeds and partings of siltstone and shale, commonly dark gray. Sandstone, very fine- to very coarse-grained arenite, locally pebbly; thick beds show internal cross lamination, parallel, lamination, and disturbed (burrowed?), laminations; local common barnacle detritus. Generally conformably underlain by the Danielson Member of the Vaqueros Formation; however, locally thinned where it rests on older rocks beneath the Zuma Detachment Fault, as in Encinal Canyon. Conformably overlain by the Encinal Member of the Topanga Canyon Formation. Mapped as "Nicholas Formation" by Sonneman (1956), named for exposures in the vicinity of San Nicholas Canyon (Triunfo Pass 7.5' quadrangle); formalized as a member of the Vaqueros Formation by Yerkes and Campbell (1979). (Campbell and others, 1996; Campbell, unpublished 1:12,000-scale mapping, 1967-1975).

Tvd **Vaqueros Formation, Danielson Member**—Grayish black, very fine-grained, marine sandy siltstone or mudstone, in medium and thin beds, generally with indistinct parallel lamination; fractures commonly conchoidal or irregularly subparallel to bedding, but locally platy or shaly. In San Nicholas Canyon, several prominent interbeds, 1/3 to 1 m thick, of calcareous very fine-grained sandstone and sandy mudstone contain fossil remains of *Turritella inezana* Conrad in such numbers as to locally form biostromes (Yerkes and Campbell, 1979, p. E12). Mapped as "Danielson Formation" by Sonneman (1956), named for exposures on the Danielson Ranch in Big Sycamore Canyon (Triunfo Pass 7.5' quadrangle); formalized as a member of the Vaqueros Formation by Yerkes and Campbell (1979). (Sonneman, 1956; Campbell and others, 1996; Campbell, unpublished 1:12,000-scale mapping, 1967-1975).

Western Santa Monica Mountains, Oak Ridge and eastern Ventura Basin

Ts **Sespe Formation, undivided (early Miocene, Oligocene, and late Eocene)**—A nonmarine "redbed" sequence of sandstone, pebbly sandstone, varicolored mudstone, and pebble-cobble conglomerate; sandstone beds commonly very thick to massive, with strong internal cross lamination; and rare thin interbeds varicolored reddish, greenish and grayish mudstone. The

sandstone beds are characteristically red in color, chiefly as a result of intergranular hematized biotite; several sections include beds that lack the characteristic red color. The only complete section of the Sespe exposed in the Santa Monica Mountains is in the Solstice Canyon-Castro Peak area, where about 1000 m of the nonmarine strata are in depositional contact on (and accordant with) the underlying marine Llajas Formation, and accordantly beneath the overlying marine Vaqueros Formation. Elsewhere in the Santa Monica Mountains, both to the east and to the west, the Sespe is in fault contact with underlying older strata, chiefly along the Zuma Detachment Fault. At the west end of the Simi Hills about 1365 m of Sespe strata lie accordantly above the marine Llajas and unconformably below Conejo Volcanics. Along the north side of Simi Valley, Sespe exposures total as much as 1656 m in thickness in the west (Simi Valley West 7.5' quadrangle), but wedges out to the east, north of Santa Susana Pass (Simi Valley East 7.5' quadrangle). Along the north flank of Oak Ridge the Sespe can be as much as 2135 m thick, based in part on drill-hole data. In the western Topatopa Mountains, north of Fillmore, the Sespe is about 430 m thick between the underlying marine Coldwater Formation and overlying marine strata assigned to the Vaqueros Formation (Fillmore 7.5' quadrangle). The name, Sespe Formation, was introduced by Watts (1897) and further described by Bailey (1947) for exposures in the vicinity of Sespe Creek, north of Fillmore, and has been extended over large parts of coastal southern California by various workers. Generally, it has been applied to a thick nonmarine sandstone, conglomeratic sandstone and siltstone sequence that is underlain by marine Eocene strata and overlain by marine Miocene beds.

Tsp **Sespe Formation, Piuma Member (early Miocene)**—In contrast to the thicker bedded, more coarsely grained sandstone and conglomerate of the undivided Sespe Formation below, the Piuma Member is distinguished by thinner individual beds, sandstone of generally finer grain size, absence of pebble and cobble conglomerate, and greater abundance of interbedded lacustrine or lagoonal siltstone. The member name was formalized by Yerkes and Campbell (1979) for the upper of two tongues of the Sespe that can be easily distinguished where strata of the marine Vaqueros Formation separate them; the Vaqueros wedges out eastward, but the contact between the Piuma Member and the undivided Sespe below can be carried some distance eastward beyond the Vaqueros wedge-out. (Yerkes and Campbell, 1980).

Topatopa Mountains and eastern Santa Ynez Range

Tcw **Coldwater Formation (late Eocene)**—Marine arkosic sandstone and shale, with lenses of pebble conglomerate and oyster reefs; thickness about 390 m. Earliest use of "Coldwater Sandstone Member" by Kew (1924); referred to "Coldwater Formation" by Bailey (1947). (Eschner, 1969).

Tcz **Cozy Dell Formation (late to middle Eocene)**—Well-bedded brown clay shale and mudstone; thickness as much as 600 m. Earliest use of "Cozy Dell Shale " member of the Tejon Formation by Kerr and Schenk (1928); described as "Cozy Dell Shale" by Dibblee (1950). (Eschner, 1969).

Tma **Matilija Formation, undivided (middle to early Eocene)**—Marine sandstone, arkosic, very well indurated, and interbedded mudstone and siltstone. Conformable beneath Cozy Dell Formation; base not exposed in the map area; total thickness exceeds 1 km. Molluscan fossils are of the Tejon Stage (late Eocene); however, interbedded shale contains foraminifera referred to the Ulatisian and Narizian (early to middle Eocene) Stages of Mallory (1959). "Matilija sandstone" member of the Tejon Formation defined by Kerr and Schenk (1928), described as Matilija Sandstone by Dibblee (1950). (Eschner, 1969). Includes:

Tmasl **Matilija Formation, siltstone and shale**—Micaceous shale with thin sandstone interbeds; Foraminifera referred to the Ulatisian and Narizian (middle to early Eocene) Stages of Mallory (1959). (Eschner, 1969).

Santa Susana Mountains, Simi Hills and Santa Monica Mountains

Tl **Llajas Formation (middle to early Eocene)**—Shallow marine, light-gray to yellowish-gray, very fine- to medium-grained sandstone, laminated siltstone and local mollusk coquina beds; interfingers with alluvial conglomerate (Tlc) at the base; sandstone is laminated to bioturbated; moderately indurated (Irvine, 1990, 1991; Squires, 1983b); section is about 1,800 ft. (550 m) thick. Locally contains fossil mollusks assigned to the "Domengine Stage" (Weaver and others, 1944); Figure 3 of Squires (1983b) suggests the basal portion corresponds to the upper "Capay Stage". As summarized by Squires (1983b), the Llajas section in the Simi Valley area was originally assigned to the "Tejon" or "Meganos" Formations (e.g. Kew, 1919, 1924); subsequently assigned informally to the Llajas Formation by Schenck (1931) and McMasters (1933); more formally named by Cushman and McMasters (1936) for surface outcrops at the type section on the northwest side of the north branch of Llajas Canyon (now known as Chivo Canyon and formerly known as "Oil Canyon"), and from corehole data obtained from the nearby Tapo No. 42 oil well, all located on the northeast side of Simi Valley) (Simi Valley East, Oat Mountain, Thousand Oaks 7.5' quadrangles, and correlative strata in the Point Dume, Malibu Beach, and Topanga 7.5' quadrangles). Includes:

Tlc **Llajas Formation, basal conglomerate**—Alluvial to shallow marine, light-brown to reddish-brown conglomerate interbedded with subordinate, poorly sorted, generally massive sandstone (Irvine, 1990); conglomerate is typically unstratified, ungraded, clast supported, and poorly sorted; clasts are typically well rounded, cobble size, and composed dominantly of quartzite with lesser amounts of granitic, volcanic and metamorphic rocks (Squires, 1983b). Squires (1983b) interprets this facies as a coastal alluvial fan or fan delta deposit. This unit defines the base of Llajas strata relative to the underlying Santa Susana Formation in the area northeast of Simi Valley (Evans and Miller, 1978).

San Gabriel Mountains

Tj **Juncal Formation (late early Eocene)**—Marine, brown amalgamated sandstone beds with interbedded conglomeratic sandstone, conglomerate and siltstone exposed in Elsmere Canyon (San Fernando 7.5' quadrangle); moderately to well cemented; clasts include exotic purple volcanic porphyry and local large siltstone rip-up clasts, and range up to boulder size. The coarse-

grained units are interpreted as turbidity current deposits in a middle- to upper-fan submarine fan depositional environment (Squires, 2008). The Elsmere Canyon section has a measured thickness of about 520 m (Squires, 2008) and it locally contains fossil mollusks originally assigned to the "Domengine Stage" of late early to early middle Eocene age (Weaver and others, 1944); however, detailed studies by Squires (2008) suggest the section at Elsmere Canyon represents the transition from the "Domengine Stage" to the underlying "Capay" Stage, at an age of about 50.5 Ma. The Eocene strata at Elsmere Canyon were first assigned to the "Domengine formation" by Brown and Kew (1932) and this usage was followed by early workers in the area (e.g. Oakeshott, 1950, 1958), and this usage was followed on Version 1.0 of the Los Angeles 30'x60' geologic map (Yerkes and Campbell, 1995). The Elsmere section was left unnamed by Winterer and Durham (1962), Kern (1973), and Dibblee (1991). Some subsequent workers assigned the name "Llajas Formation" to this section (e.g. Seedorf, 1983 and Yeats and others, 1994). Squires (2008) re-evaluated the past nomenclature and conducted additional field studies, and concluded the Elsmere Eocene section is more consistent lithologically with exposures of Juncal Formation mapped to the northwest in the Piru Creek area (Squires, 1987) rather than the type Llajas section, and the Piru and Elsmere sections may have originally been contiguous (Yeats and others, 1994).

The term "Martinez Formation" was previously retained on Version 1.0 of the Los Angeles 30x60' sheet for coarse-grained marine greenish-black to light olive-gray sandstone, with thin interbeds of black shale, and lenticular beds of well-cemented conglomerate of Eocene or Paleocene age mapped as fault-bounded slivers along the San Gabriel Fault between Bear Divide and Tujunga Canyon on the Sunland and San Fernando 7.5' quadrangles (Oakeshott, 1958; Yerkes and Campbell, 2005); clasts reportedly include exotic volcanic porphyry. The term "Martinez Formation" was imported from a type locality in the San Francisco Bay area; the term "Martinez" now generally refers to a Paleocene molluscan stage. Assignment of this section to the "Martinez Formation" was reportedly based on lithologic similarity with "Martinez" strata mapped in the Tejon quadrangle (Oakeshott, 1958) and on the discovery of the age-diagnostic fossil *Turritella pachecoënsis* (Clements and Oakeshott, 1935); however, use of the term "Martinez" has generally been abandoned as a lithologic formation name in southern California. Squires (pers. comm. 2014) notes that the reported specimens of fossil *Turritella* cannot be located for review and additional specimens could not be found during recent field studies; based on field observations of the stratigraphy and presence of exotic volcanic porphyry clasts, Squires suggests that the fault-bounded slivers may actually be part of the Juncal Formation; the fault-bounded slivers are therefore queried as Juncal Formation herein.

Santa Susana Mountains, Simi Hills and Santa Monica Mountains

Tss **Santa Susana Formation (early Eocene to late Paleocene)**—Marine clay shale and conchoidally fractured mudstone and siltstone with interbeds of fine- to medium-grained sandstone and lenses of pebble-cobble conglomerate; gray limestone concretions common in shale; locally contains foraminifera; locally abundant mollusks diagnostic of the "Meganos" and "Martinez" Stages (Saul, 1983); thickness as much as 1,000 m in the Simi Hills; unit thickness varies laterally and rapid lateral facies changes are common across map area. Named by Nelson (1925) for exposures in the Simi Hills near the town of Santa Susana. As

summarized by Parker (1983, 1985), lower Tertiary strata in the Simi Hills were originally correlated and assigned to the "Martinez and/or Meganos Formations" by early workers, including Waring (1914, 1917), Kew (1919, 1924), and Clark (1921). Nelson (1925) raised the "Martinez Formation" to group status and subdivided it into the Simi Conglomerate, Las Virgenes Sandstone, and the Martinez marine member, overlain by the Santa Susana Formation. Most literature published to date follows some form of Nelson's terminology, but the placement of contacts varies considerably among different authors. Parker (1983, 1985) modified Nelson's Santa Susana Formation to include the underlying Martinez marine member, thereby encompassing all strata above the Simi Conglomerate and Las Virgenes Sandstone and below the Llajas Formation in the Simi Hills and northeastern Simi Valley. Parker and other authors abandoned "Martinez Group" and "Martinez marine member" because "Martinez" is a molluscan Stage name, imported from a central California type locality, and no longer considered appropriate to use as a formation name for this interval. Colburn and others (1988) and Colburn and Novak (1989) extended Parker's nomenclature to correlative rocks in the Santa Monica Mountains and included beds mapped as Coal Canyon Formation by Yerkes and Campbell (1979, 2005) in the Santa Susana Formation. Distribution of lower Tertiary strata in the Simi Valley area on this map is based on Squires (1983a), which includes Parker's nomenclature and contacts. Parker described the lower Tertiary units in terms of western and eastern facies based on the location of the stratigraphic sections relative to the "Runkle Canyon fault" (Squires, 1983a). The western facies of the Santa Susana Formation in the Simi Valley area (Simi Valley East, Calabasas and Thousand Oaks 7.5'quadrangles) overlies the Las Virgenes Sandstone with a gradational to sharp contact and is disconformably overlain by the Llajas Formation. It generally consists of a lower unit of densely bioturbated, fossiliferous, fine- to medium-grained sandstone and an upper unit dominated by poorly fossiliferous fractured mudstone and siltstone interbedded with subordinate sandstone and minor conglomerate. The lower unit represents transition zone and offshore to shelf deposits and the upper unit represents deposition within a slope environment. The eastern facies overlies the Simi Conglomerate with a gradational or sharp contact and is overlain disconformably by the Llajas Formation. The eastern facies is more variable, but generally consists of fractured mudstone and siltstone similar to the western facies with discontinuous interbeds of sandstone and conglomerate. East of Meier Canyon, mudstone and siltstone are present in the lower half and sandstone and conglomerate present in the upper half. Sandstone occurs as discontinuous lenses in conglomerate and in beds up to 20 meters thick. Near Runkle Canyon, sandstone occurs as thin interbeds within the mudstone and siltstone and in tongues up to 150 m with locally abundant megafossils occurring in layers within concretionary beds. Northeast of Simi Valley in Poison Oak Canyon, beds are dominantly mudstone interbedded with minor sandstone above two tongues of Simi Conglomerate. These beds represent inner fan deposits. Interbedded sandstone and conglomerate near Meier Canyon represent the coarse portion of an inner fan and slope deposits. The uppermost portion of the Santa Susana Formation in both the western and eastern facies consists of sandstone with megafossils and microfauna indicative of a shelf environment and may record a basin filling and shoaling event prior to the deposition of the nonmarine basal Llajas conglomerate., In the Santa Monica Mountains, Santa Susana strata

include marine sandstone, pebble conglomerate, siltstone and algal limestone. Sandstone is very fine to medium grained, poorly to well sorted, consisting of subrounded quartz and feldspar grains in a sparse clay matrix, locally biotitic; locally contains abundant mollusks; beds commonly are thick and locally have graded upper parts and sharp upper contacts. Siltstone and silty claystone are present locally in the upper part of the formation; closely jointed, conchoidal fracture, and containing abundant biotite; local partings of fine-grained silty biotitic sandstone, and calcareous beds or concretions as thick as 15 cm and as long as 1 m. Pebble-cobble conglomerate forms resistant steep slopes in Carbon and Topanga Canyons; in beds as much as 7 m thick with scattered pebbles, boulders, slabs, and interbeds of mudstone and medium-to coarse-grained sandstone. The Yerkes and Campbell (2005) map shows the Coal Canyon Formation to be about 335 m thick in Solstice Canyon, the only complete section exposed in the Santa Monica Mountains. The thickness summed from incomplete sections in the Carbon Canyon-Topanga Canyon area is as much as 450 m. Commonly carries a molluscan fauna that includes the Martinez-Stage gastropods *Turitella pachecoensis* and *Mesalia martinezensis* (Gabb, 1869). Colburn and others (1988) and Colburn and Novak (1989) prepared five stratigraphic columns and detailed geologic maps of the section localities along the axis of the Santa Monica Mountains from Solstice Canyon in the west to Runyon Canyon near Hollywood and correlated Simi Conglomerate, Las Virgenes Sandstone, and Santa Susana Formation strata. The Las Virgenes Sandstone and Simi Conglomerate are not separately delineated on the current version of the Los Angeles compilation map in the central and eastern Santa Monica Mountains (Malibu Beach, Topanga, Beverly Hills, and Hollywood 7.5’ quadrangles) and Simi Conglomerate and Las Virgenes Sandstone strata mapped by Colburn and Novak (1989) are included in Santa Susana Formation in these areas. Yerkes and Campbell (1979) mapped the Simi Conglomerate in Solstice Canyon (Point Dume 7.5’ quadrangle), but did not recognize the Las Virgenes Sandstone in the Solstice Canyon section, and included most of that interval in the Simi Conglomerate. In the Santa Monica Mountains, the Santa Susana Formation overlies and interfingers with the nonmarine Las Virgenes Sandstone (included in Simi Conglomerate on this map) or overlies the late Cretaceous Tuna Canyon Formation; the relations are generally accordant but locally unconformable. In Solstice Canyon, the Santa Susana Formation is overlain disconformably(?) by marine strata of Eocene age. (Squires, 1983a; Yerkes and Campbell, 1980; Campbell and others, 1996). Includes:

Tssl **Santa Susana Formation, limestone**—Algal limestone occurs as scattered lenses and pods in siltstone sequences east of Topanga Canyon, most prominently in the eastern wall of Santa Ynez Canyon.

Santa Susana Mountains, Simi Hills and Santa Monica Mountains

Tlv **Las Virgenes Sandstone (early(?) Paleocene)**—Nonmarine to marine light-gray to yellowish orange, predominantly medium- to coarse-grained weakly to moderately indurated sandstone with green interbedded mudstone and red-bed mudstone, and minor pebble conglomerate; megafossils and burrows are present in the upper part of the section at Bus Canyon; thin sequence, locally as thick as 195 m near Bus Canyon in the Simi Hills, but thins westward to zero; originated as sandy, braided alluvial and meandering stream deposits on a coastal plain;

upper part represents nearshore marine deposits (Parker, 1983); conformably overlies Simi Conglomerate and is overlain by and interfingers with the Santa Susana Formation. Named by Nelson (1925) for exposures near Las Virgenes Canyon in the Simi Hills. Colburn and others (1988) and Colburn and Novak (1989) correlated Las Virgenes Sandstone from the Simi Hills to five localities in the Santa Monica Mountains. These strata are included in the Santa Susana Formation on the current Los Angeles compilation map in the central and eastern Santa Monica Mountains (Malibu Beach, Topanga, Beverly Hills, and Hollywood 7.5' quadrangles). Yerkes and Campbell (1979, 2005) did not recognize the Las Virgenes Sandstone in the Solstice Canyon section (Point Dume 7.5' quadrangle), and included most of that interval in the Simi Conglomerate, including distinctive pisolite-bearing beds that Colburn assigned to the Las Virgenes Sandstone. Pisolite-bearing red beds are also mapped in the Bus Canyon section in the Simi Hills by Parker (1985), but he included the beds in the Simi Conglomerate. (Squires, 1983a).

Tsi **Simi Conglomerate, undivided (Paleocene)**—Thin, predominantly nonmarine cobble-boulder conglomerate mapped at the base of the Tertiary sequence in the Simi Hills, the Santa Monica Mountains, and northeast of Simi Valley. The conglomerate is poorly bedded, weakly to moderately indurated and contains abundant well-rounded, polished cobbles and boulders of quartzite, granitic, rhyolitic, and gneissic rocks in conglomeratic, coarse-grained sandstone. Distribution of lower Tertiary strata in the Simi Valley area shown on this map is based on Squires (1983a), which includes Parker's (1983, 1985) nomenclature and contacts. Parker described the lower Tertiary units in terms of western and eastern facies based on the location of the stratigraphic sections relative to the "Runkle Canyon fault" (Squires, 1983a). According to Parker, Simi Conglomerate west of the Runkle Canyon fault (Squires, 1983a) represents alluvial fan and braided river deposits and Simi Conglomerate east of the Runkle Canyon fault in Runkle and Meier Canyons and northeast of the Simi Valley represents channel and inner fan facies of a deep-sea fan, based on observed sedimentary structures and microfaunal studies summarized by Parker (1983, 1985). The marine conglomerate included by Parker in the Simi Conglomerate is considered by other authors to be part of the Santa Susana Formation or an unnamed Paleocene marine unit (Hanson, 1981).Yerkes and Campbell (1979) tentatively correlated beds described in the Simi Hills by Nelson (1925) as the Simi Conglomerate with lithologically similar beds in the Solstice Canyon area of the Santa Monica Mountains, and the correlation is supported in subsequent detailed petrographic work by Colburn and Novak (1989). In Solstice Canyon (eastern Point Dume 7.5' quadrangle) the conglomerate includes a 1-m-thick bed of brick-red pisolitic clayey sandstone, which Colburn and Novak (1989) include in the Las Virgenes Sandstone. Simi Conglomerate beds mapped by Colburn and Novak (1989) in the central and eastern Santa Monica Mountains (Malibu Beach, Topanga, Beverly Hills, and Hollywood 7.5' quadrangles) are included in the Santa Susana Formation on the current Los Angeles compilation map. Correlative strata in the Santa Susana Mountains, mapped as "Martinez Formation" by Evans and Miller (1978), are here included with the Simi Conglomerate. Evans and Miller (1978) recognized three local lithologic members.

Tsic **Simi Conglomerate, conglomeratic member**—Massive, yellowish brown pebble to cobble conglomerate with numerous brownish sandstone lenses as much as 1 m thick and continuous

for a few tens of meters along strike. Locally contains molluscan fauna referred to the Martinez Stage (Paleocene) (Evans and Miller, 1978).

Tsis **Simi Conglomerate, shale member**—Light olive gray micaceous siltstone, silty shale, and shale with local thin interbeds of brown, medium- to coarse-grained sandstone. Dark gray limestone occurs in the shale as thin, discontinuous beds as well as small pods and lenses (Evans and Miller, 1978).

Tsia **Simi Conglomerate, sandstone member**—Massive, gray to brownish, coarse- to very coarse-grained sandstone, cemented by silica and hydrous iron oxides, with thin interbeds of micaceous siltstone and lenses of boulder, cobble and pebble conglomerate; locally strongly cemented by calcite (Evans and Miller, 1978).

Santa Susana Mountains, Simi Hills and central and western Santa Monica Mountains

Kc **Chatsworth Formation (late Cretaceous)**—Dominantly turbidite sandstone, massive, thick-bedded, medium- to coarse-grained, well-cemented; conglomeratic sandstone with rounded, polished clasts of quartzite, porphyry and granitic rocks; with minor siltstone and conglomerate. Molluscan faunas include the ammonite *Metaplacenticeras californicum* and the gastropod *Tuttitella pescaderosensis*, referred to the Campanian or Maestrictian (late Cretaceous) Stages (Popenoe, 1973; Saul and Alderson, 1981); benthic foramifera from mudstones in the lower-middle part of the sequence are referred to the late Campanian. Exposed thickness exceeds 1830 m; base not exposed nor drilled; overlain with slight unconformity by Paleocene strata along north side of the Simi Hills, elsewhere, as along the south flank of the Simi Hills, unconformably overlain by Miocene beds. The name, Chatsworth Formation was introduced and defined by Colburn and others (1981) for rocks in the eastern Simi Hills near Chatsworth, that were previously mapped as “Chico Formation” or as unnamed “Upper Cretaceous Rocks” (“Chico” is a molluscan Stage name imported from central California). (Weber, 1984).

Central and western Santa Monica Mountains

Kt **Tuna Canyon Formation, undivided (late Cretaceous)**—Marine sandstone, siltstone and conglomerate. Sandstone, thick-bedded to very thick-bedded, laminated and graded arkosic wacke (turbidite); locally containing abundant fragments of black slate(?); convolute lamination in some beds, load casts, low-angle cross-lamination, or concentrations of carbonized plant fragments or mica. Fossiliferous sandstone and siltstone are present locally as interbeds or thick lenses; in Las Flores Canyon, contains several beds of olive-gray siltstone that locally contain foramifera. The Tuna Canyon Formation is nowhere completely exposed in the Santa Monica Mountains; the maximum exposed thickness, in the Pena Canyon-Tuna Canyon area, is nearly 800 m. East of Santa Ynez Canyon rests on nonmarine red conglomerate (Trabuco Formation, late Cretaceous) and the Santa Monica Slate (late Jurassic). The formation is overlain disconformably (?) by the Simi Conglomerate in Solstice Canyon, and elsewhere by a basal conglomerate of the Coal Canyon Formation (Paleocene). In several places it contains the Campanian ammonite *Metaplacenticeras sp.*; foramifera faunas are referred to zones D-2, E, and F-1 (Maestrictian or Campanian - late Cretaceous) of Goudkoff (1945). Named by Yerkes

and Campbell (1979) to replace the name “Chico”, which was imported from central California and used on earlier maps in the Santa Monica Mountains. (central and eastern Santa Monica Mountains; Campbell and others, 1996; Yerkes and Campbell, 1980; Alderson, 1988; Hoots, 1931). East of Santa Ynez Canyon the formation was subdivided by Alderson (1988) into four informal members:

Kte **Tuna Canyon Formation, informal member 'e'**—Greenish-gray shale with interbedded coarse-grained sandstone in the upper part.

Ktd **Tuna Canyon Formation, informal member 'd'**—Fine-grained, thick-bedded, fossiliferous sandstone.

Ktc **Tuna Canyon Formation, informal member 'c'**—Pebble-cobble conglomerate and minor sandstone.

Ktb **Tuna Canyon Formation, informal member 'b'**—sandstone with minor conglomerate and black shale, carrying Turonian and Coniacian ammonites.

Ktr **Trabuco Formation (late Cretaceous)**—Conglomerate with well-rounded, polished pebbles, cobbles and boulders of varicolored quartzite, porphyry, granite, basalt, and with angular chips of black slate in a matrix of soft, clayey, coarse-grained to pebbly grit. Thickness estimated at 225 m; unconformably overlies Santa Monica Slate. Name applied by Durrell (1954) for rocks of similar composition and stratigraphic position in the type area in the Santa Ana Mountains, where it was named by Packard (1916); correlation reiterated by Colburn (1973). (Yerkes and Campbell, 1980; Hoots, 1931).

Kgr **Granitic rocks (late Cretaceous)**—Includes a variety of plutonic igneous rocks ranging from quartz monzonite and granodiorite to tonalite, quartz diorite, and diorite; chiefly quartz diorite: intrudes Santa Monica Slate in the eastern Santa Monica Mountains (Durrell, 1954).

San Gabriel and Verdugo Mountains

Kgl **Granitic rocks, leucocratic granodiorite (late Cretaceous)**—Light gray to buff, fine- to medium- grained granodiorite; intrudes all other crystalline rocks in area south of south branch of the San Gabriel Fault (Smith, 1982).

Kgd **Granodiorite (Cretaceous)**—Light-gray to dark-gray, medium-grained granodiorite. Unit includes well-foliated, gneissic mafic enclaves. In thin section, samples have some hornblende, apatite, euhedral zircons, and biotite although much is altered to chlorite. Some myrmekitic texture observed in plagioclase feldspars. Exposed in northeast Pacifico Mountain quadrangle. Mapped as qd by Barrows and others (1985) and Dibblee (1997); described by Olson and Hernandez (2013) on map of adjacent Palmdale quadrangle.

Kto **Tonalite (late Cretaceous)**—Mapped by Jahns and Muehlberger (1954) as “granite and other quartz-bearing plutonic rocks”; these rocks are compositionally tonalite (D. M. Morton, oral communication, 2003) in the IUGA classification (Streckheisen, 1973).

Ktoqd **Tonalite and quartz diorite (late Cretaceous)**—Mapped by Morton (1973) as predominantly quartz diorite, grading to granodiorite, quartz monzonite and diorite; compositionally mostly

tonalite (D. M. Morton, oral communication, 2003) in the IUGA classification (Streckheisen, 1973).

Ktowd **Tonalite (Wilson Diorite of Miller, 1934) (late Cretaceous)**—Designated granodiorite and quartz diorite on source maps; identified as mostly tonalite (D. M. Morton, oral communication, 2003) in the IUGA classification (Streckheisen, 1973).

Kgrd **Granodiorite**—Gray medium to coarse grained granodiorite with quartz diorite and granite. Described as Granodiorite by Oakeshott (1958). Includes rocks mapped as the Mt Josephine Granodiorite by Carter (1980). Mostly massive, but commonly gneissoid near contacts with older rocks; locally carries large inclusions and pendants of gneiss and Placerita metasediments. (Oakeshott, 1958, Carter, 1980).

Kp **Pelona Schist (Late Cretaceous to Paleocene?)**—Greenish-gray chlorite-albite, actinolite-albite, quartz-albite, and albite-talc schists, locally interbedded with metavolcanics and brown to black quartzites; a thick, isoclinally(?) folded sequence. The protolith of the Pelona and its correlative Orocopia Schist was presumably deposited during the mid-Mesozoic, recrystallized during burial to depths of 25-35 km, and later thrust beneath western North America at rates > 4 mm/y on the Vincent thrust. Named by Hershey (1902a) for outcrops on the Sierra Pelona ridge. (Ehlig, 1981, p. 266; Jacobson, 1990; northern Mint Canyon 7.5' quadrangle, map after Jahns and Muehlberger, 1954).

Jeg **Echo granite (Jurassic)**—Coarse-grained, pinkish-orange granite and monzogranite; medium-grained, xenomorphic, inequigranular, and showing protoclastic granulation in thin section (Miller, 1946). Determined to be Jurassic in age by Barth (2008). Named by Miller (1934). (Smith, 1986).

Eastern Santa Monica Mountains

Jsm **Santa Monica Slate, undivided (late Jurassic)**—Black slate, sheared metasiltstone, and fine-grained metagraywacke; intensely jointed, isoclinally(?) folded; intruded by Cretaceous granitic pluton forming contact auriole zones of phyllite and spotted cordierite slate; rare pelecypod fragments indicate a late Jurassic age in part (Imlay, 1963). Named by Hoots (1931, p. 88) (Hoots, 1931). Includes:

Jsms **Santa Monica Slate, spotted slate**—Spotted with large crystals of cordierite; outer zone of contact aureole with nearby granitic intrusive rocks; grades to unspotted slate through a zone in which individual spots become progressively smaller outward (Hoots, 1931).

Jsmp **Santa Monica Slate, phyllite**—Chiefly mica schist and dark gray phyllite; forms inner zone of contact aureole with adjacent granitic intrusive (Hoots, 1931).

San Gabriel and Verdugo Mountains

Mzdbh **Biotite-hornblende diorite (Mesozoic?)**—Medium- to dark-gray, medium-grained biotite-hornblende monzodiorite; includes scattered small bodies of older brownish-gray coarse-grained weakly gneissic biotite quartz monzonite; intruded by leucocratic granodiorite (Smith, 1986).

Mzdhb **Hornblende-biotite diorite (Mesozoic?)**—Medium-gray, medium-grained hornblende- biotite diorite; intruded by coarse-grained hornblende diorite and younger leucocratic granodiorite (Smith, 1986).

Mzqdb **Biotite-quartz diorite (Mesozoic?)**—Medium- to dark gray, medium grained quartz diorite; slightly gneissic. Locally contains inclusions of coarse-grained quartz diorite a few m across, and small elongate bodies of marble, quartzite, and schist of Paleozoic (?) age (Smith, 1986).

Mzmg **Biotite Monzogranite (Mesozoic)**—Light gray fine to coarse grained generally non-porphyritic monzogranite. Locally includes granodiorite. Foliated to locally gneissic. Mapped by Smith (1986) as leucogranitic and metamorphic complex. (Smith, 1986; Powell and others 1983).

Mzmgp **Porphyritic Biotite Monzogranite (Mesozoic)**—Light gray fine to coarse grained generally non-porphyritic Monzogranite. Locally includes granodiorite. Foliated to locally gneissic. Mapped by Smith (1986) as leucogranitic and metamorphic complex. (Smith, 1986; Powell and others 1983).

Mzd **Biotite-Hornblende Quartz Diorite, Diorite, and Gabbro (Mesozoic)**—Dark gray fine to coarse grained diorite. Locally includes tonalite and granodiorite. Foliated. Mapped by Saul (1976) as diorite. (Saul, 1986; Powell and others 1983).

Mzhd **Hornblende Diorite (Mesozoic)**—Gray, medium- to coarse-grained hypidiomorphic granular diorite. (Smith, 1986).

Mza **Alaskite (Mesozoic?)**—Salmon-pinkish-gray, medium-grained, mildly gneissic syenogranite. Forms long thin klippe over a much larger mass of granitic rock (Smith, 1986).

Mzh **Hornblendite (Mesozoic)**—Melanocratic coarse-grained hornbledite (Powell and others, 1983).

Mzm **Mylonite (Mesozoic)**—Gray fine-grained to microcrystalline mylonite. Mapped by Smith (1986) as siliceous metasedimentary rock. (Powell and others, 1983; Smith 1986).

Mzdg **Diorite gneiss (early to middle Mesozoic)**—Dark-colored gneisses including metadiorites, massive hornblende diorite, and amphibolite and biotite schists (60-80% plagioclase, 5-15% quartz, 5% or less potassium feldspar, locally as much as 30% biotite and locally as much as 10% brown hornblende); intrudes the Placerita Formation and intruded by Cretaceous granitic rocks; (Oakeshott, 1958).

TRlgd **Mount Lowe intrusive suite, undivided (Triassic)**—A compositionally layered pluton exposed over a large area in the western San Gabriel Mountains and northeastern Soledad basin (studied and described by Ehlig, 1981); varies from hornblende diorite and quartz diorite near the base to albite-rich granite and syenite in the upper part; large phenocrysts of hornblende, orthoclase and garnet contribute to distinctive appearance (pebbles and cobbles are readily recognizable as clasts in younger gravel deposits); metamorphosed to lower amphibolite facies and upper amphibolite facies (grade apparently varies with proximity to Cretaceous intrusive rocks); average composition 60-90% feldspar, of which plagioclase (oligoclase to albite) is

most abundant and orthoclase occurs chiefly as phenocrysts, quartz ranges from a trace to as much as 25 %, averages about 10% (Ehlig, 1981). Initially named Mount Lowe Granodiorite by Miller (1926 abstract), subsequently termed Lowe Granodiorite by Miller (1934, 1946); renamed Mount Lowe intrusion by Barth and Ehlig (1988). The common usage of most source maps has been retained in this map compilation. A U-Pb age on zircon is reported as 220 ± 10 my (Silver, 1971), and a Rb-Sr whole rock age of 208 ± 14 my reported by Joseph and others (1982). Joseph and others (1982) also report a high (800-1,100 ppm) Sr content, a low initial ^{87}Sr-^{86}Sr ratio of 0.70456 ± 0.00003, and a high alkali content ($Na_2O = K_2O \sim 10$ wt.%). More recently, Barth and others (1990) report a U-Pb zircon age of 218 my. Subunits include:

TRlgb **Mount Lowe intrusive suite, biotite-orthoclase facies**—As much as 10 percent biotite in a nearly white granular plagioclase and subordinate (less than 25 percent) quartz matrix. Has orthoclase phenocrysts; hornblende phenocrysts prominent in other subunits are absent, although a few hornblende-bearing layers occur in the lower part of this subunit (Dibblee 1996, 2001; Ehlig, 1981 and unpublished).

TRlgdp **Mount Lowe intrusive suite, Porphyritic facies**—Orthoclase phenocrysts in granular matrix of plagioclase and subordinate quartz; garnet also occurs as small crystals concentrated in veinlets (Dibblee 1996, 2001; Ehlig, 1981 and unpublished).

TRlgdh **Mount Lowe intrusive suite, orthoclase-hornblende facies**—Light gray hornblende diorite (Dibblee 1996, 2001; Ehlig, 1981 and unpublished).

TRlgm **Metamorphosed Mount Lowe intrusive suite (Cretaceous and Triassic)**—Relatively uniform light-colored orthogneiss containing porphyroblasts (relict phenocrysts) of hornblende and, less commonly, potassium feldspar in a plagioclase and quartz matrix. Parent plutonic rock is (Triassic) Lowe Granodiorite and was metamorphosed during a Cretaceous orogenic event (Morton, 1973a, p. 9; and D. M. Morton, oral communication, 2003).

TRhdg **Hornblende diorite gabbro**—dark to very dark gray, medium-grained hornblende diorite gabbro. Massive to locally foliated. (Dibblee 1996, 2001; Ehlig, 1981 and unpublished).

MzPzsp **Serpentinite (Mesozoic or Paleozoic)**—Light to dark green, well foliated, sheared and slickensided serpentinite, altered peridotite (chiefly augite and olivine); slickensided fragments up to boulder size; boundaries intensely sheared and relations to adjacent rocks obscure (Barrows and others, 1975).

Pzgn **Gneiss complex (Paleozoic?)**—Feldspathic gneisses, including granitic to granodioritic augen gneisses, gneissic intrusive rocks of granitic to dioritic composition, amphibole-rich gneiss, and local interlayered schist, quartzite, amphibolite, and marble; according to Jahns and Muehlberger (1954), many of the gneisses are of hybrid origin, and some may be parts of the Placerita Formation that have been intimately injected by younger igneous material.

Pzp **Placerita Formation (Paleozoic)**—Metamorphosed sedimentary rocks, including marble, dolomite, feldspathic gneisses, graphitic marble, quartzite, calcic pyroxene hornfels and a variety of schists including feldspar-tremolite, graphite-tremolite, graphite-biotite-feldspar, and tremolite-talc; the various schists and gneisses occur as septa and pendants of all sizes in a

granodioritic host rock, along with diorite gneisses and migmatites. The best-preserved section may be as much as 600 m thick. Named by Miller (1934), for exposures in Placerita Canyon, the type locality. The age indicated by Oakeshott (1958) is pre-Cretaceous; however, Morton (oral communication, 2003) indicates the age is Paleozoic. (Central Sunland 7.5' quadrangle, Oakeshott, 1958; southern Mint Canyon 7.5' quadrangle, Saul and Wooton, 1983).

Pgn **Gneiss (Proterozoic?)**—Alternating discontinuous dark brown biotite-rich and light-colored quartz-feldspar-rich layers and lenses; layers generally about an inch thick; sheared, as expressed by an intricate structure of gneiss lenses with common local small microscopic tight flow-type folds. Described by Morton (1973) and by Crook and others (1987) as Cretaceous or older, but recently described by Morton (oral communication, 2003) as Precambrian. (Morton, 1973; Crook and others, 1987).

Anorthosite-gabbro complex of Oakeshott (1958) probably a result of differentiation of a single parent magma. Anorthosite and gabbro are pervasively shattered, sheared and brecciated. Barth and others (1995) indicate a general age of 1,200 Ma on the basis of dated zircons and thermobarometry, substantially older than 930 ± 90 Ma and 810 ± 80 Ma lead-alpha zircon ages determined by Neuerburg and Gottfried (1954).Unit is composed of sub-units mapped and described by Carter (1980) including:

Pan **Anorthosite-gabbro complex, anorthosite (Proterozoic)**—Composed of medium- to very coarse-grained plagioclase; light gray and white; contains more than 90 percent plagioclase (andesine) and less than 10 percent mafic minerals (mostly hypersthene); grain size ranges from less than 1 mm to more than 30 cm.

Pagb **Anorthosite-gabbro complex, anorthosite with gabbro (Proterozoic)**—Composed of anorthosite as above with layers or zones of gabbro or diorite.10 to 50% mafic minerals, mostly hornblende, white to gray, medium to coarse grained (Carter, 1980, 1982).

Psy **Anorthosite-gabbro complex, syenite (Proterozoic)**—Composed of plagioclase feldspar (andesine) with lesser potassium feldspar (Microcline-perthite). Has minute black specks of magnetite which may be altered from augite. Rock is generally tan, stained rusty tan to brown by limonite where weathered. (Jahns and Muehlberger, 1954; Oakeshott, 1958; Carter, 1980, 1982).

Pfgb **Anorthosite-gabbro complex, ferro-gabbro (Proterozoic)**—Composed mostly of ferro-magnesian minerals with lesser feldspars dark greenish brown. Contains sub-metallic molecules of iron ilmenite (magnetite-titanite). Intrusive into Pan and Psy. (Carter, 1980, 1982).

Plgb **Anorthosite-gabbro complex, leucogabbro (Proterozoic)**—Light gray compositionally layered gabbro, leucogabbro and anorthosite (Carter, 1980, 1982).

Pjgb **Anorthosite-gabbro complex, jotunitic gabbro (Proterozoic)**—Light gray compositionally layered gabbro with antiperthitic andesine. (Carter, 1980, 1982).

Pjgba **Anorthosite-gabbro complex, jotunite-norite-gabbro-diorite (Proterozoic)**—Composed of hornblende, chlorite, biotite, and actinolite (altered from pyroxene) and limonite-magnetite,

dark greenish brown, locally compositionally layered, contains inclusions of anorthosite (Carter, 1980, 1982).

Pggn **Anorthosite-gabbro complex, gabbroic to anorthositic gneiss (Proterozoic)**—Rocks of the anorthosite-syenite complex that were strongly deformed and in part recrystallized during emplacement of the Triassic Mt Lowe Intrusive suite (Carter, 1980, 1982).

Pgb **Anorthosite-gabbro complex, gabbro (Proterozoic)**—Gray, mottled with greenish or brownish black, and solid dark greenish and brownish black; mafic mineral content ranges from 35 percent to 65 percent of rock; compositionally ranging from gabbroic anorthosite to norite, diorite, pegmatitic hornblende gabbro, and olivine gabbro. Chiefly xenomorphic granular texture; alternating felsic and mafic bands, from a few inches to several feet in thickness are common, but generally discontinuous. Feldspar is mostly calcic andesine (labradorite in more mafic rocks), in many places partly altered to albite or albite-oligoclase. Pyroxenes (and subordinate amphiboles) commonly altered to chlorite, antigorite and biotite (Oakeshott, 1958). (Carter, 1980, 1982, Oakeshott, 1958).

Phbgb **Anorthosite-gabbro complex, hornblende bytownite gabbro (Proterozoic)**—Fine to medium grained foliated, layered, hornblende-chlorite gabbro with labradorite to bytwonite plagioclase. Some layers of anorthosite (Carter, 1980, 1982).

Pgbla **Anorthosite-gabbro complex, anorthosite inclusion-rich gabbro (Proterozoic)**—Strongly layered gabbro with numerous inclusions of anorthosite, some of which are up to 50 feet in length (Carter, 1980, 1982).

Pmgn **Mendenhall Gneiss (Proterozoic)**—Layered migmatitic felsic gneiss and mafic granulite, having rare interlayered augen gneiss and aluminous gneiss. Gneiss is characterized by large-scale foliation, fracturing, jointing, and blocky shattering. Dikes of anorthosite and associated rocks cut gneiss, and centimeter- to meter-scale fragments of gneiss are scattered through the anorthosite. Most distinctive rock is dark gneiss with tint imparted by blue quartz (Oakeshott, 1958). Named by Oakeshott (1958, p. 21), who designated type locality on Mendenhall Peak. Age of Mendenhall Gneiss is greater than 1,200 Ma age of anorthosite sequence (Silver and others, 1963; Barth and others, 1995).

SYMBOL EXPLANATION

Contact between map units - Solid where accurately located or approximately located; short dash where inferred; dotted where concealed; queried where identity or existence is uncertain

Gradational contact between map units

Fault - Solid where accurately located; long dash where approximately located; short dash where inferred; dotted where concealed; queried where identity or existence is uncertain

Thrust Fault - Barbs on upper plate; solid where accurately located; short dash where inferred; dotted where concealed; queried where identity or existence is uncertain

Detachment fault - Solid where accurately located; long dash where approximately located; short dash where inferred; dotted where concealed; queried where identity or existence is uncertain

Syncline - Solid where accurately located; long dash where approximately located; dotted where concealed

Anticline - Solid where accurately located; long dash where approximately located; dotted where concealed

Overturned anticline - Solid where accurately located

Dike - Solid where accurately located; long dash where approximately located; dotted where concealed

Tuff marker bed

Strike and dip of sedimentary beds. Number indicates dip angle in degrees:

ANALYSIS OF POTENTIAL ECOLOGICAL EFFECTS OF FLOW DIVERSIONS ON WILLOW HABITAT

TECHNICAL MEMO

From: Eric Stein and Jenny Taylor – Southern California Coastal Water Research Project (SCCWRP)

To: Marc Blain, David Jaffe - Psomas

Re: Analysis of Potential Ecological Effects of Flow Diversions on Willow Habitat

Date: September 14, 2018

Background and Approach

The ecological effects of flow diversions were assessed based on modeled relationships between hydraulic changes and probability that the resultant physical conditions can support southern willow riparian habitat conditions conducive to occupancy by least Bell's vireo.

There are two general approaches that can be used to relate physical changes (e.g. changes in streambed elevation or substrate composition) to biological effects (e.g. ability to support vireo). The first involves creating a mechanistic model that predicts species occupancy through a series of equations that relate physical changes to specific life history needs of the species. For example, predicting the expected recruitment, growth, and scour of riparian habitat based on a time series of modeled patterns of velocity and scour. The second approach involves establishing statistical relationships between physical conditions and probability of a species occurring using a combination of output of hydraulic models and presence vs. absence data of vireo over time.

For this study we used the statistical approach to estimate the probability of occurrence of vireo under physical conditions associated with flow diversion scenarios. We chose this approach because 1) it is a more efficient approach for evaluating ecological effects in a relatively small area over relatively short periods of time; 2) it can be more directly related to available species observation data; 3) it produces a probability estimate that provides flexibility in setting management thresholds (i.e. managers can select a probability of effect that triggers a management decision); and 4) the hydraulic modeling does not provide a long-enough time series of output (due to the computational complexity of the model) to support a mechanistic approach.

The probability of effects on least Bell's vireo were assessed using the following steps. Data preparation was done in ArcGIS and analysis was completed in RStudio:

1. Physical properties in the study area were based on the hydraulic model output provided by Psomas. We focused on depth, extent and duration of inundation, velocity, and shear stress as the key output variables as these are the ones most likely to influence presence or absence of willow riparian habitat preferred by the least Bell's vireo. We focus primarily on the dry year model output as the greatest differences were observed under dry conditions, and therefore, any effects, if they occur, would be under dry conditions.

2. Initially, we planned to use vireo occurrence data as an indicator of suitable habitat. However, despite a thorough literature review, we were only able to find a few instances of vireo nesting and a few confirmed absences. Therefore, we decided to use willow presence as an indicator of suitable habitat, which has been documented extensively in the literature.

3. Vegetation coverage of the study area was digitized for a representative wet year (2010) and dry year (2014) using digital aerial imagery provided through the USDA National Agriculture Imagery Program (NAIP). NAIP provides seamless georectified images with four color bands (red, green, blue and near infrared) with known vintage. NAIP imagery is acquired at a one-meter ground sample distance with a horizontal accuracy that matches within six meters of photo-identifiable ground control points, which are used during image inspection. An unsupervised object classification was used to attribute riparian trees and shrubs vs. non-target habitats, and raster images were converted to polygons. Straggler trees and shrubs were manually deleted or produced the final shape files.

4. Water velocity, percent of time inundated, water depth, shear stress, and arrival time variables were used from the *dry* year hydraulic modeling. We focused on the dry year, because results of the hydraulic modeling comparing the historical with predicted flows differed most significantly for the dry year. These hydraulic parameters were selected because they are known to influence recruitment, growth, and survival of riparian habitat. These variables were provided to us in raster format, with approximately 18,000 pixels. We converted each pixel to a point and spatially joined the hydraulic variable values to the vegetation layer. This created a dataset that related the presence of willow with each of the hydraulic variables.

5. To begin to explore the relationship between each of the hydraulic variables and the occurrence of willow, we compared the distribution of each variable for areas where willows were present and areas where willows were absent using a two-sided t-test. Arrival time showed the least difference between groups (p>0.1) and because the distributions looked so similar, we did not include this variable in further analysis. The other four hydraulic variables did display a significant difference between the two groups and were all significant at the α=0.001 level: Depth, shear stress, velocity, and percent of year inundated. A correlation matrix (
6. Figure 1) was calculated for the remaining four hydraulic variables and shear stress was removed based on its significant correlation with velocity (r=0.79).

7. Data were split randomly into 25% testing data and 75% training data. Initially a multinomial regression was used to predict vegetation classes including coast live oak, riparian herbaceous, and willow. However, this model severely overpredicted willow occurrence. Because we are concerned with the potential reduction in willow habitat, we decided this model would not provide a reliable answer to that question. Logistic regression analysis (eq. 1) was the next model used to develop relationships between the three hydraulic properties and the presences or absence of willow habitat. We used a binomial logistic regression model because it allows for estimation of the probability of a binomial response (in this case presence vs. absence of willow habitat) based on one or more predictor variables (in this case hydraulic properties). The resulting plots allow for an estimation of the probability of vireo habitat occurrence based on a continuous range of hydraulic variables (e.g. inundation time, water velocity).

Eq. (1): $\text{logit}(\text{willow presence}) = \beta_0 + \beta_1(\text{depth}) + \beta_2(\text{velocity}) + \beta_3(\text{annual inundation})$

8. The validation of the model with the testing data showed an overall accuracy of 81.9%. The model was very good at predicting areas where willows were absent (specificity=89.9%) and much less effective at predicting areas where willows are present (sensitivity = 13.5%). From an ecological perspective, this makes sense because we can accurately predict areas where we know willows are unlikely to occur. In contrast, there are other areas that are unlikely to support willows, but where absence may be explained by a variety of factors beyond channel hydraulics (See Attachment A). This suggests that our predictions of willow occurrence will be much less accurate than our predictions of willow absence.

9. The dry year logistic regression model was used to predict willow occurrence with the modelled hydraulic output under the proposed water diversion scenario. Dry wear model output was used because the greatest differences in channel conditions were observed during the simulated dry year. The same method was used to prepare the data as described above for the training data: the velocity, percent inundation, and depth variables were converted to points and joined together.

Results

All hydraulic variables tested showed significant differences ($p < 0.001$) in willow occurrence between predicted future conditions and historic flow characteristics. However, given the small sample size of vegetation polygons and the high number of hydraulic observations (>18,000), we believe the significance estimates may be overestimated.

The basic logistic regression models are provided in Figure through 4 and show the probability of willow occurrence for depth, annual percentage inundation time, and velocity, respectively. The range on the x-axes are bounded by the values observed in the data and their associated probability estimates. We see an increase in probability of willow occurrence with increasing depth and percent annual inundation. These trends in depth and annual inundation percentage suggest that the some persistent inundation is important for suitable willow habitat, which agrees with the literature. Lastly, we see a steep decline in occurrence of willow habitat as the velocity increases. This suggests that willows will not be present in active channels where velocity is highest.

Our models predict a slight decrease in probability of occurrence of willow habitat in dry years with the proposed diversion compared to without the diversion. Changes in probability of occurrence vary spatially and are most pronounced near the outlet to the spillway and at the margins of the basin (Figure 5). In general, we see exaggeration of extreme values; increases in the probability of willow occurrence in areas where occurrence was high and decreases in the probability of willow occurrence where the occurrence was low. The most pronounced decrease predicted is a 13.8% decline in probability of occurrence in the lower basin, near the spillway, associated with a slight decrease in depth and duration of inundation. This is offset by a 6.6% increase in probability of occurrence at the margins of the basin, also associated with change in depth and duration of inundation.

It is important to note that difference in velocity in the reservoir is not a driver of impacts to habitat since the velocity is essentially zero for most of the ponded areas. The biggest influencing factor appears to be the duration of inundation which is driven by a combination of hydrologic events and the operational curve of the dam. Only in a statistically dry year with high flow events that occur late in the storm season (as opposed to the average) do we see durational impacts to ponding extents in the model. This change in duration of inundation also influences change in probability of willow

occurrence along the margins of the basin. However, as stated above, net changes in probability of willow occurrence are less than 10%. As previously noted, we see no effects in the main portion of the stream channel or during wet years. Finally, it is important to note, that this analysis only speaks to the probability that willow habitat will or will not occur, it does not speak to health or vigor of the community.

Caveats of Analysis

1. Pseudoreplication is an issue when observations are not random or independent. Our observations were based on the pixel size of the hydraulic modeling, as opposed to randomly selecting plots as our samples. Consequently, pseudoreplication may have introduced additional uncertainty into our results.

2. The hydraulic variables that went into this analysis were averaged values based on wet and dry years, therefore, they do not show the true extent of water inundation. We are not considering that some areas do get inundated in dry years, or that some areas do not get inundated in dry years. This likely is the reason the model had trouble finding differences between the areas that do have willows and those that do not.

3. The presence of vegetation is a function of the current year's precipitation, which we considered, but also the precipitation and resulting hydraulics of many years prior, which we did not consider.

4. The vegetation classification was completed because the original vegetation map which was part of the EIR was too coarse (it was used in the multinomial regression which ultimately over predicted willow). This vegetation classification was not ground-truthed, and it is likely that other types of trees and shrubs, such as coast live oak, were included in what we designated willow habitat.

5. Results of the statistical analysis are limited by the small area of analysis and low data density. A regional analysis would have provided the opportunity to develop the logistic regression model using a larger more robust data set, which would have improved confidence and resolution in the model.

Figures

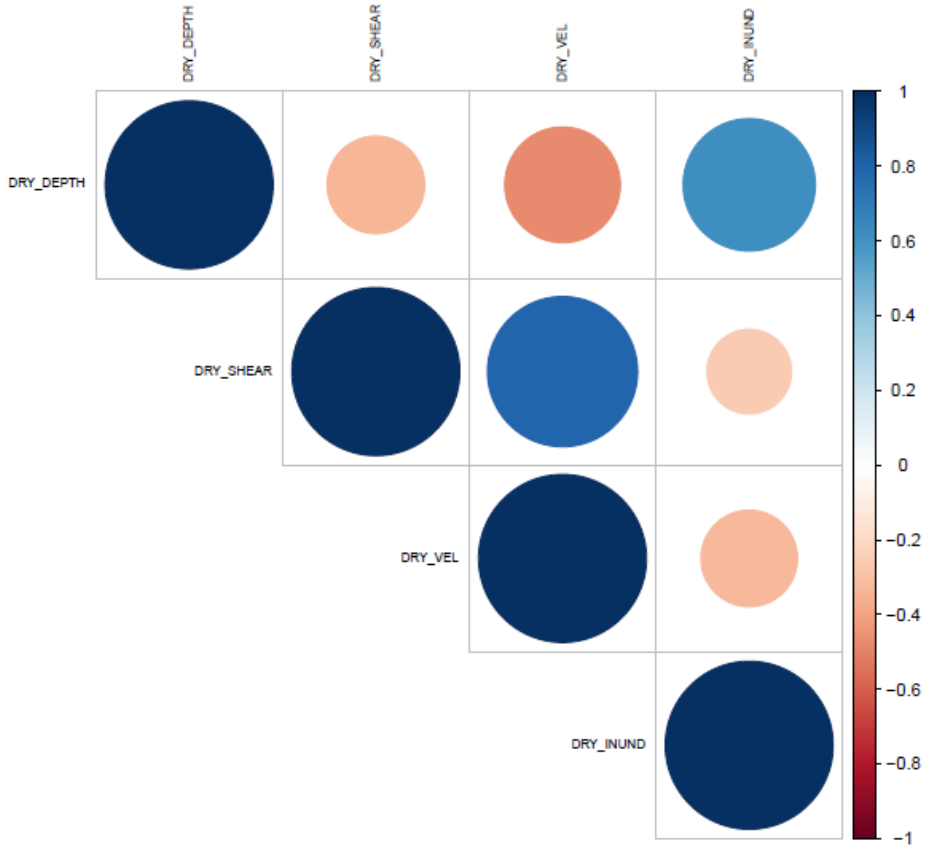

Figure 1: Dry year correlation plot of depth, shear stress, velocity, and annual inundation percentage. The correlation between shear and velocity was above 0.7.

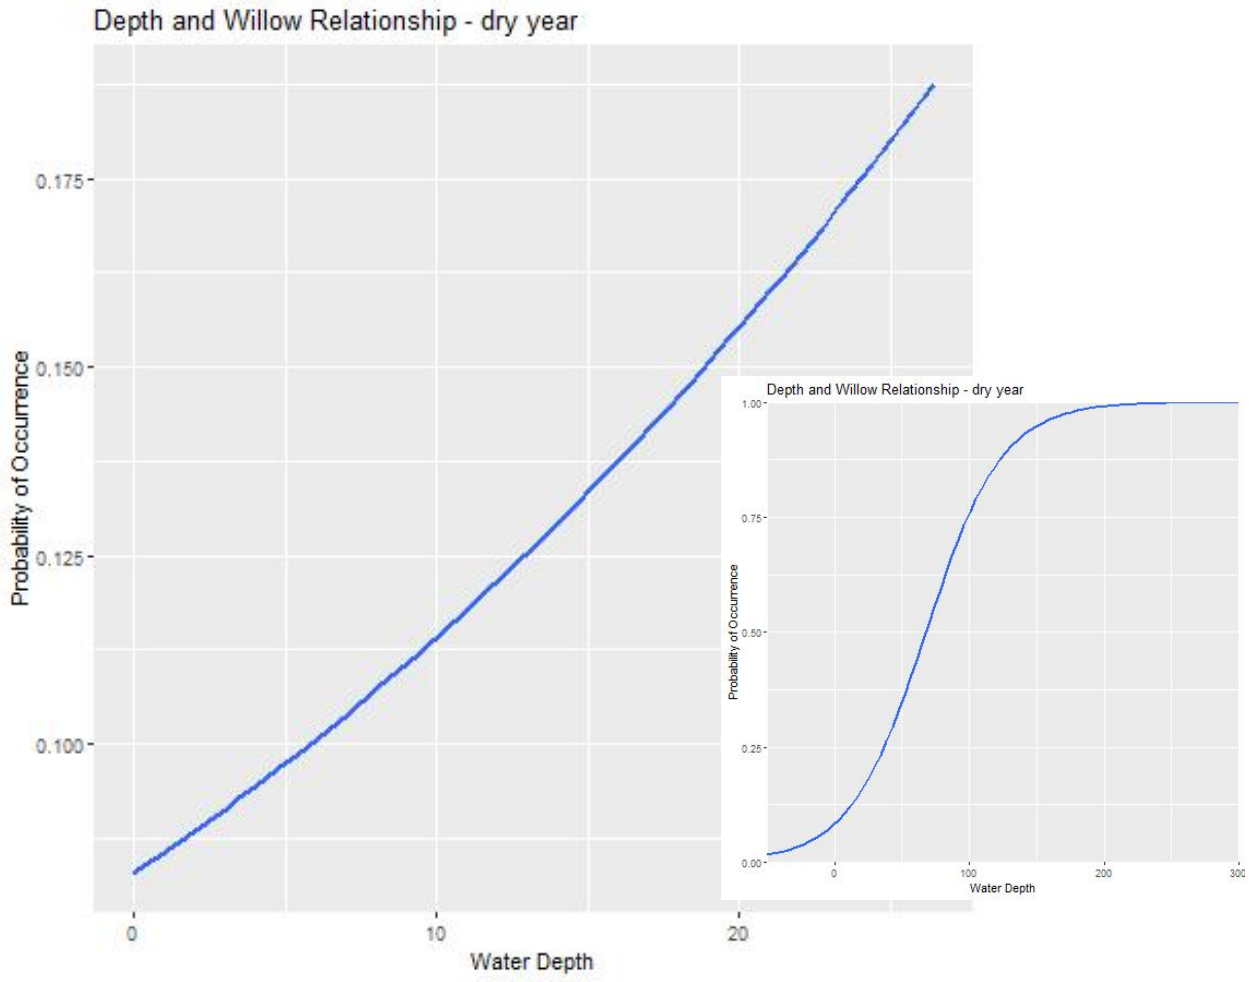

Figure 2: The relationship between water depth (ft) and the probability of occurrence of willow. Inset graph shows the full logistic regression. Larger graph focuses on the range of depth values in the dry year hydraulic data set and the associated estimates of probability of willow occurrence.

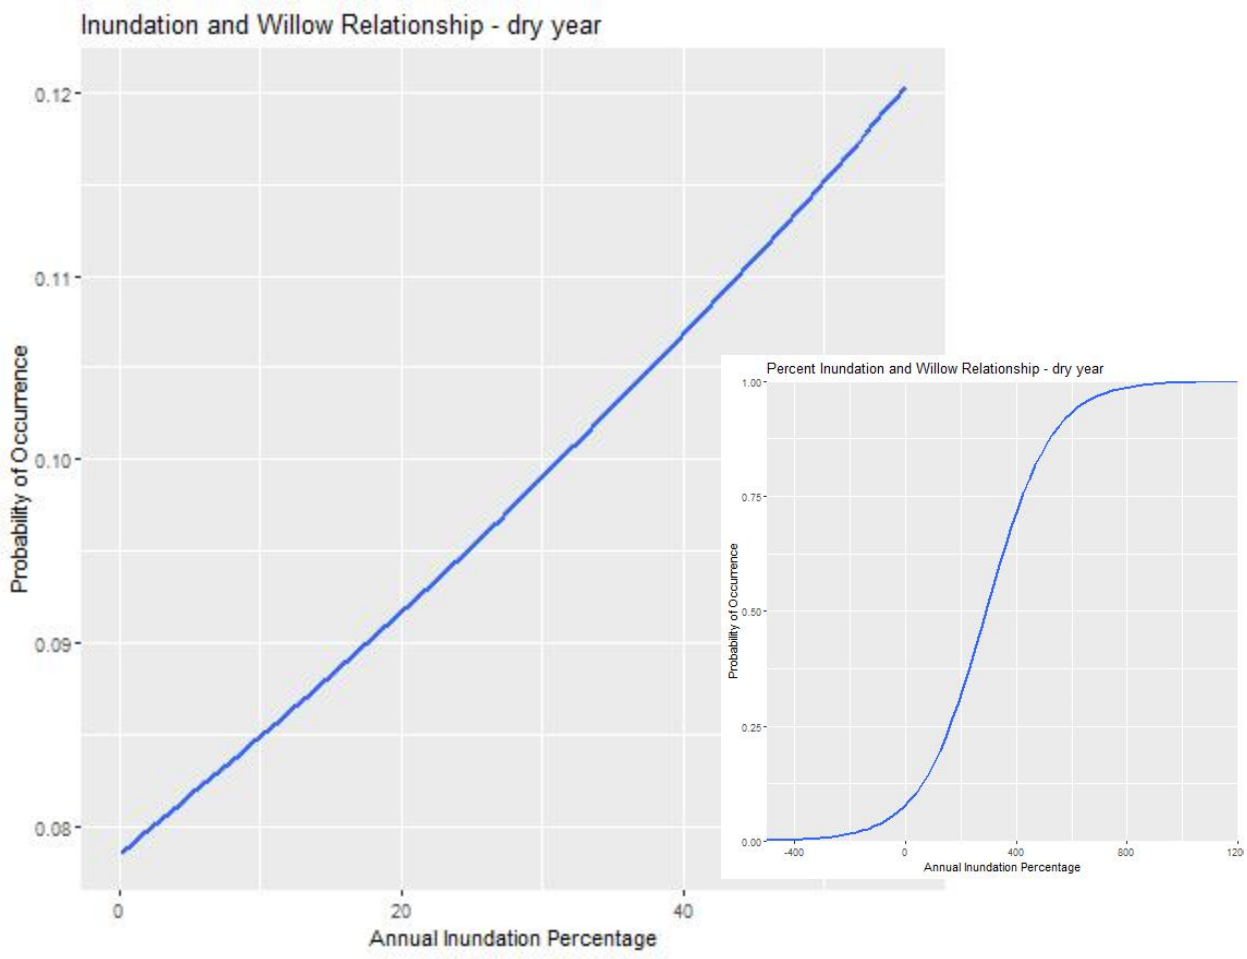

Figure 3: The relationship between average annual inundation percentage and the probability of occurrence of willow. Inset graph shows the full logistic regression. Larger graph focuses on the range of inundation values in the dry year hydraulic data set and the associated estimates of probability of willow occurrence.

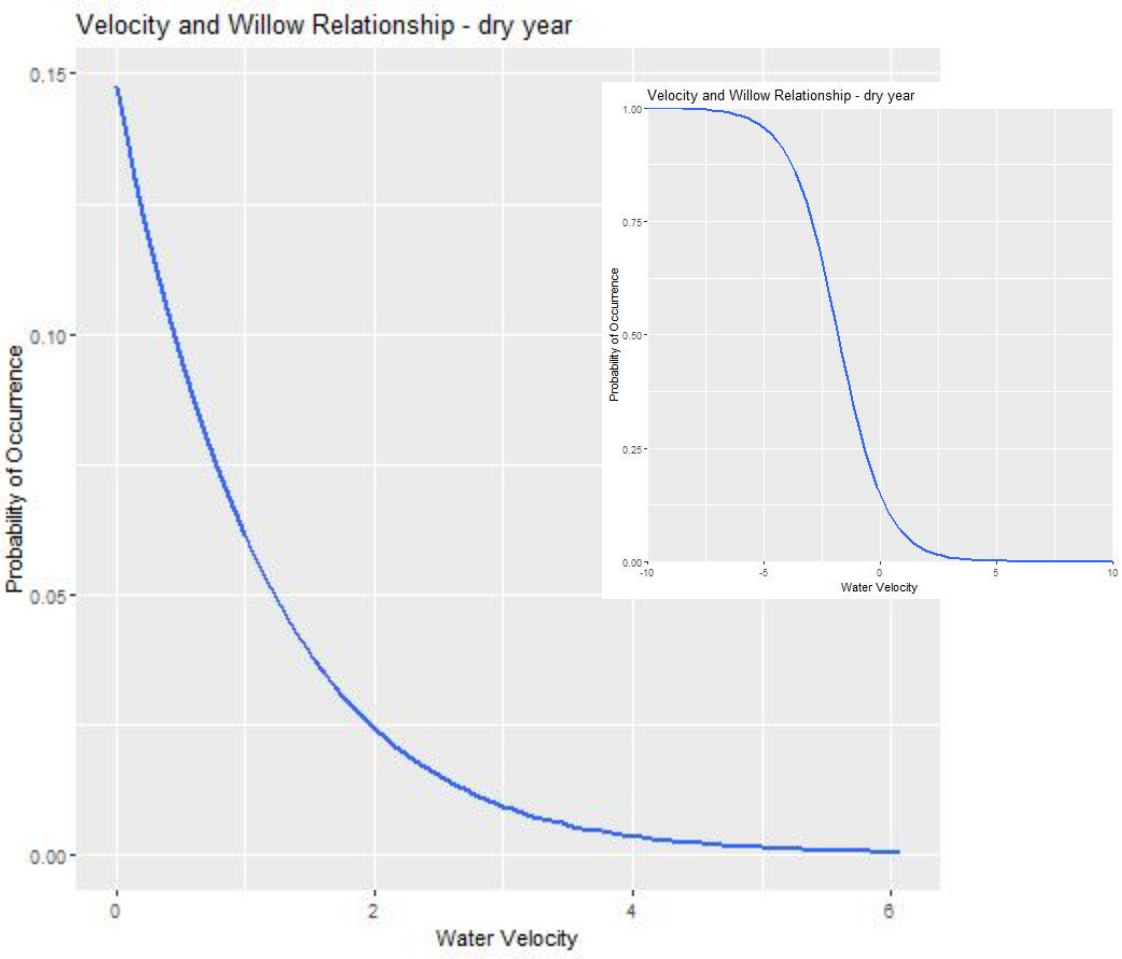

Figure 4: The relationship between water velocity (ft/s) and the probability of occurrence of willow. Inset graph shows the full logistic regression. Larger graph focuses on the velocity range in the dry year hydraulic data set and the associated estimates of probability of willow occurrence.

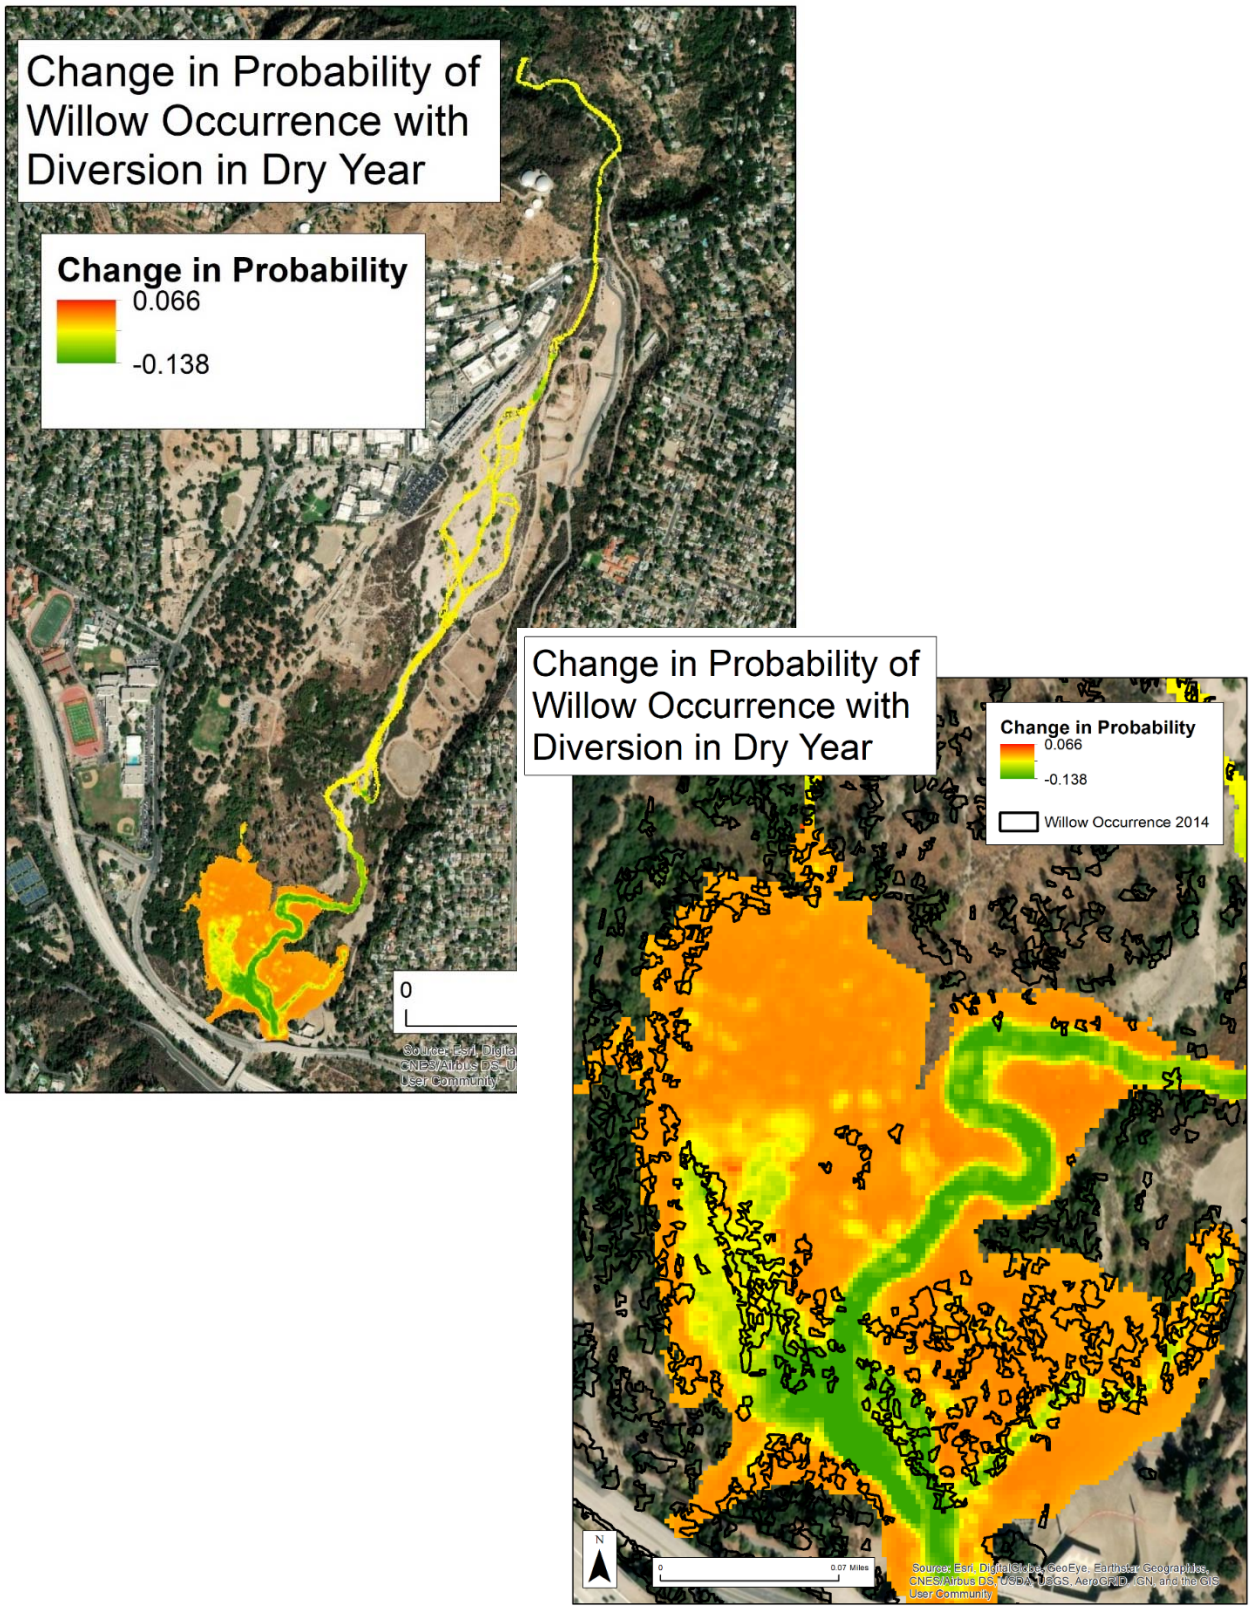

Figure 1: Change in probability of willow with the diversion in a dry year, compared to a dry year with no diversion. Green shows a decrease in probability, yellow is roughly no change, and red signifies an increase in probability. Note that green is a decrease of 13.8% and red is an increase of 6.6%. Lower graphic shows a zoomed in view of the lower basin.

Attachment A: Box plots showing differences in ranges of hydraulic variables in areas where willows were present (1) vs. absent (0)

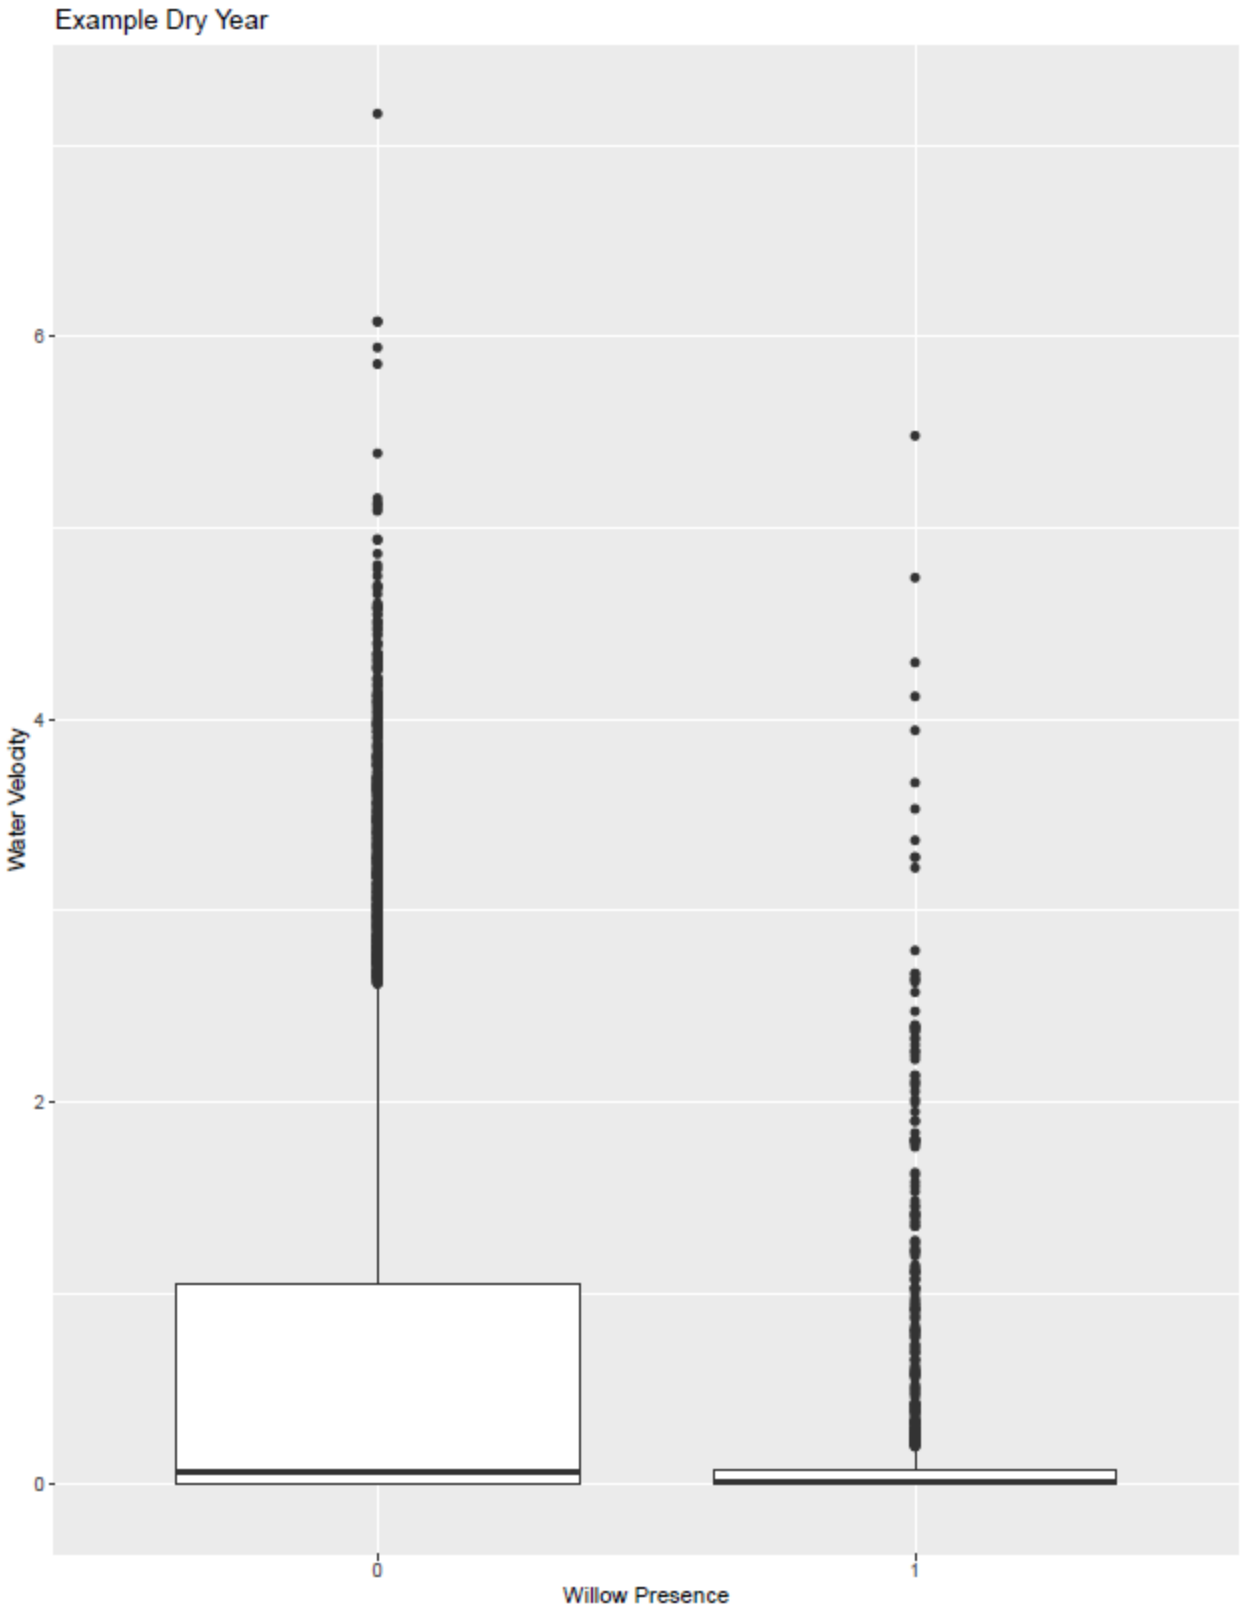

Figure A-1: Boxplot showing water velocity (ft/s) values for observations where willow shrub was and was not present.

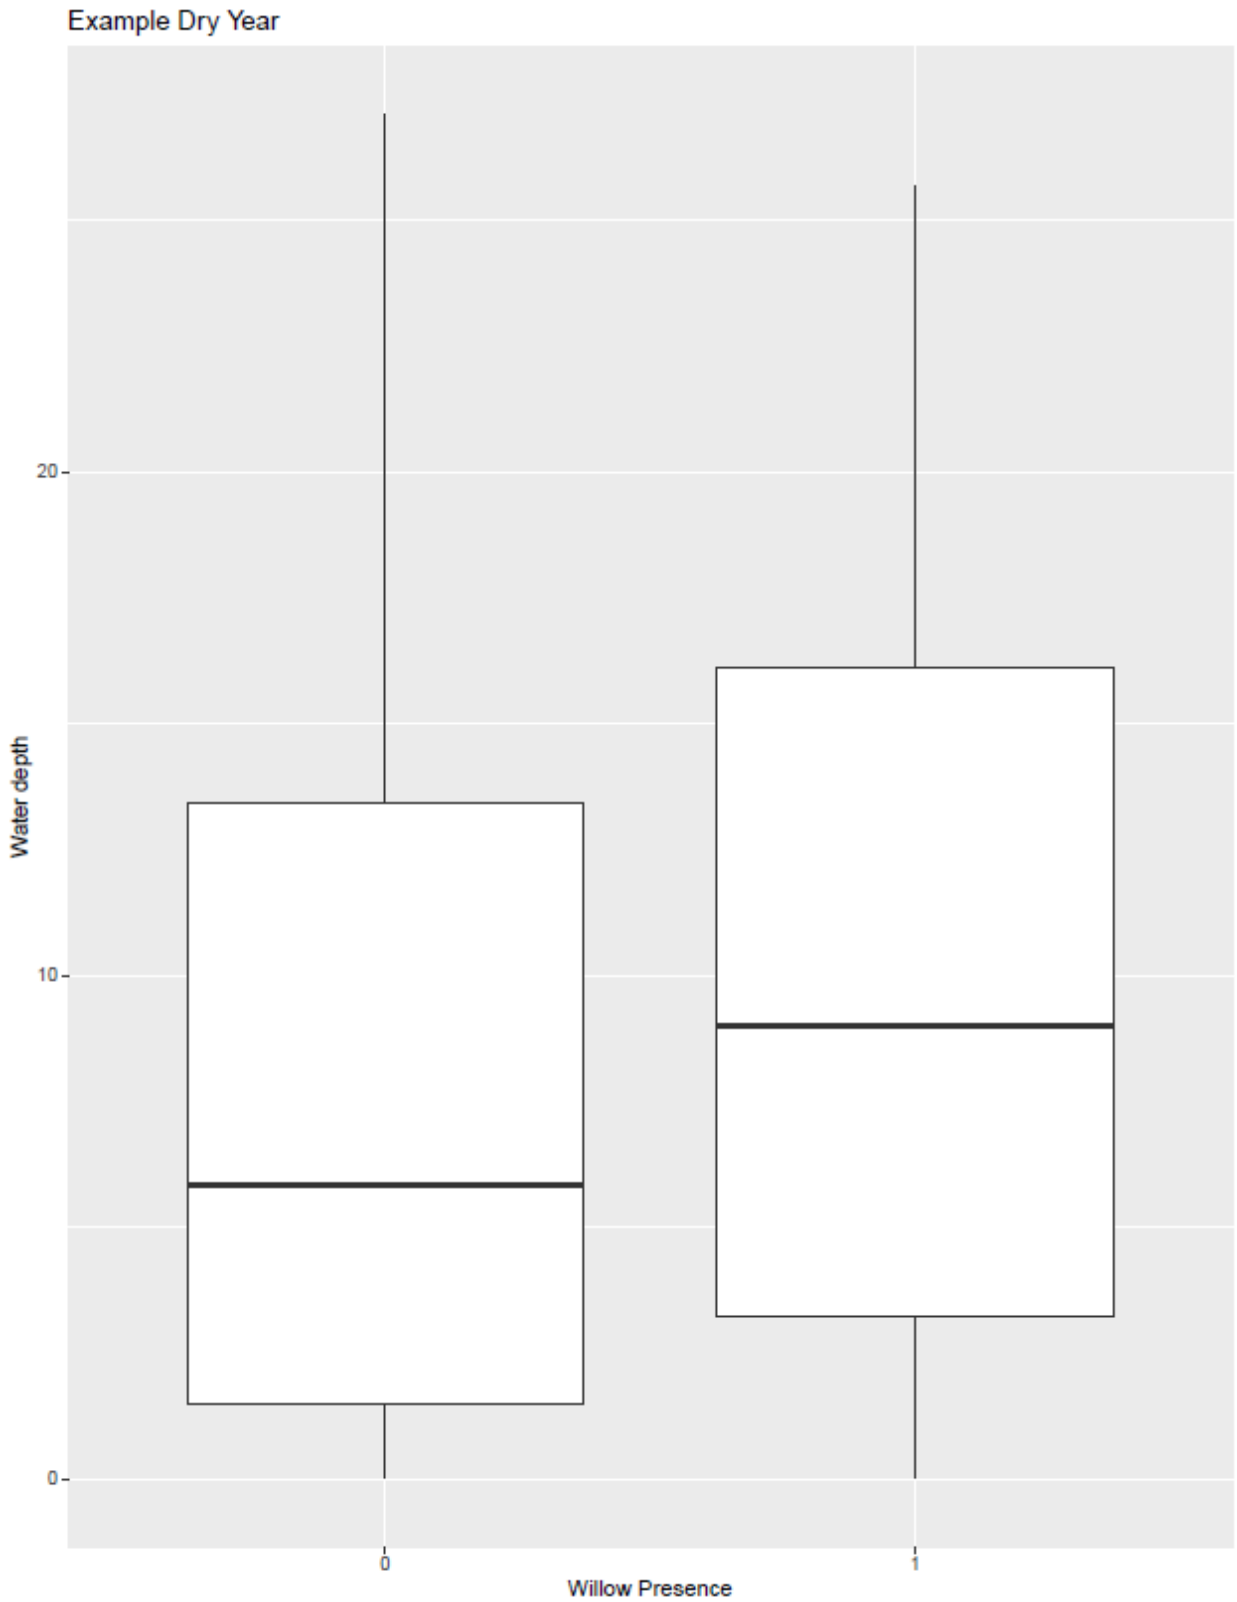

Figure A-2: Boxplot showing water depth (ft) values for observations where willow shrub was and was not present.

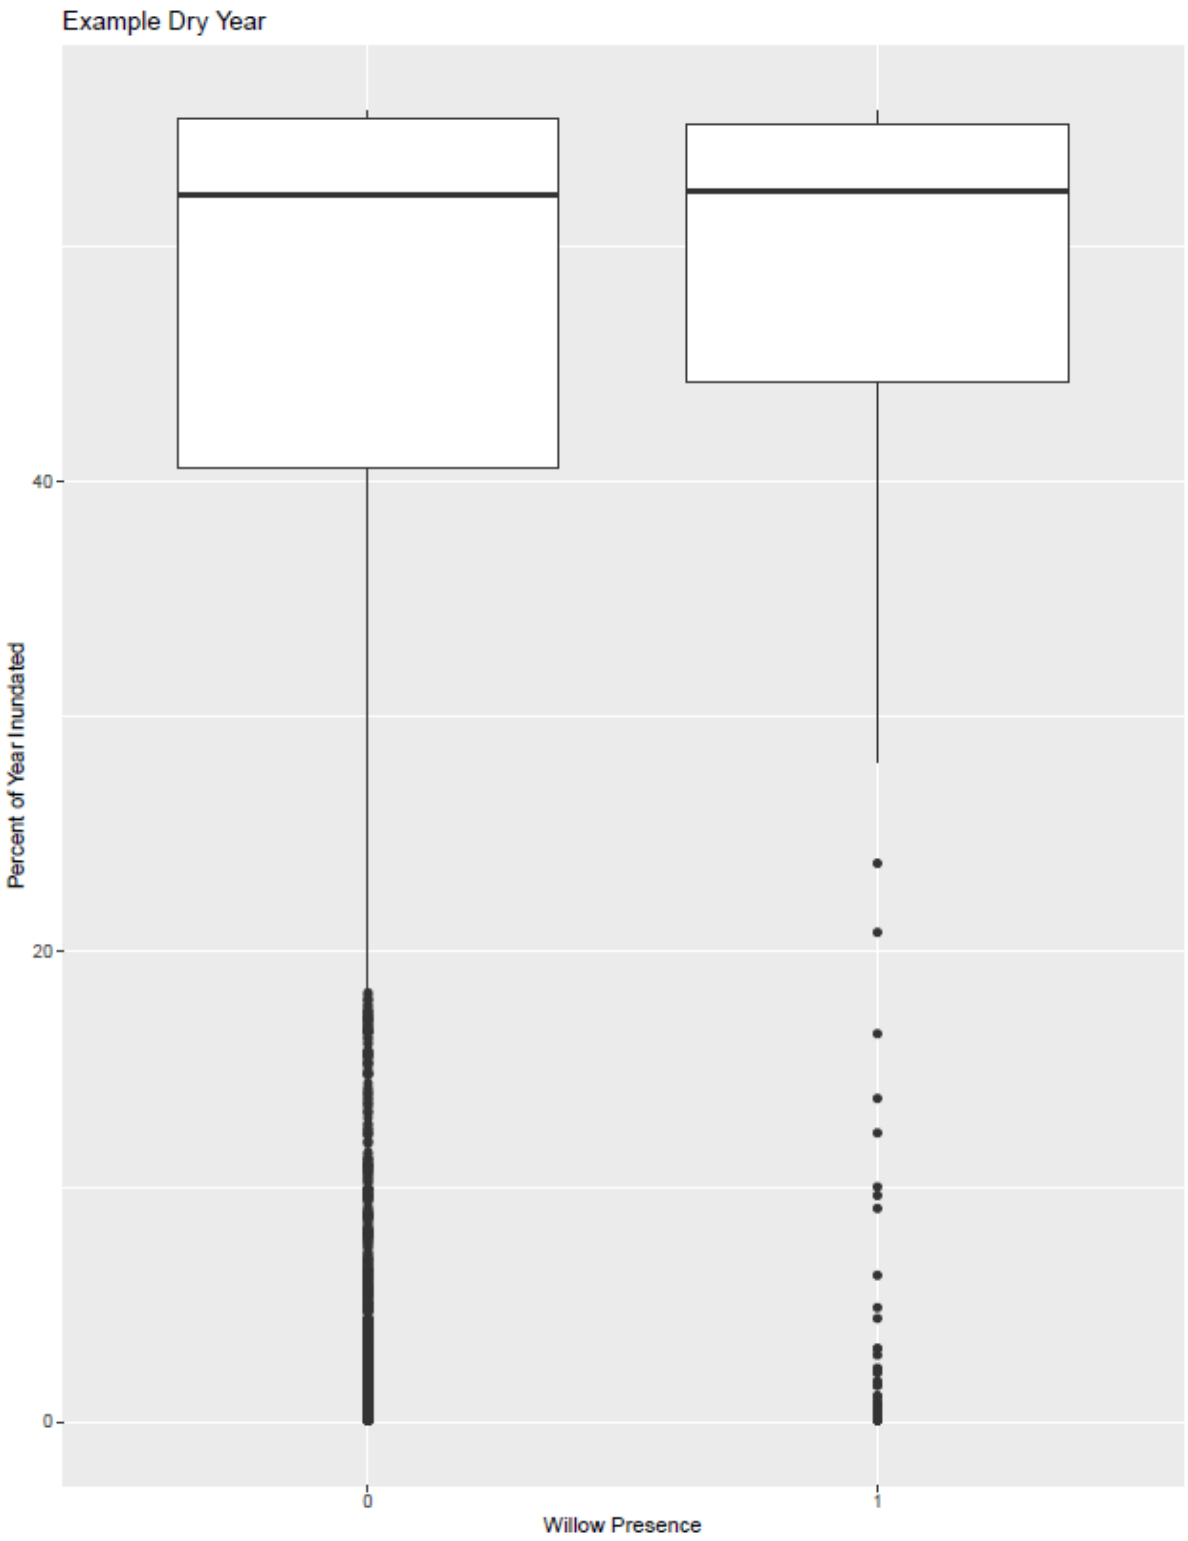

Figure A-3: Boxplot showing percentage of year with water inundation values for observations where willow shrub was and was not present.

INTENTIONALLY LEFT BLANK

Executive Summary

Dudek was retained by the City of Pasadena (City) to complete a cultural resources technical report for the Arroyo Seco Canyon Project Areas 2 and 3 (Project) in the City of Pasadena, California. This report includes the results of a California Historical Resources Information System (CHRIS) records search; coordination with the Native American Heritage Commission (NAHC) and tribal contacts; pedestrian survey of the Project site by a qualified architectural historian; building development and archival research; development of an appropriate historic context for the Project site; and recordation and evaluation of built environment resources over 45 years old for historical significance and integrity in consideration of National Register of Historic Places (NRHP), California Register of Historical Resources (CRHR), and City of Pasadena designation criteria and integrity requirements. This report was prepared in conformance with California Environmental Quality Act (CEQA) Guidelines Section 15064.5 for historical resources and all applicable local guidelines and regulations.

Dudek conducted a CHRIS records search at the South Central Coastal Information Center (SCCIC) on October 3, 2019. The records search results indicate that 14 previously recorded cultural resources exist within the surrounding 0.5-mile search radius. However, only one resource, the Hahamongna Watershed Park and associated recreational facilities (P-19-189942), overlaps the Project site. This resource was previously found ineligible for the CRHR and is not considered an historical resource under CEQA.

Dudek contacted the NAHC on September 16, 2019, and requested a review of the Sacred Lands File (SLF). The NAHC replied via email on October 7, 2019 stating that the result of the SLF search was positive. Moreover, the NAHC recommended contacting the Gabrieleno Band of Mission Indians – Kizh Nation for more information. The NAHC also provide contact information for an additional four Native American individuals and/or tribal organizations who may have direct knowledge of cultural resources in or near the Project site; however, the additional four Native American individuals and/or tribal organizations have not, as of the preparation of this technical report, contacted the City requesting that the lead agency (City) provide notification to the tribe of projects in the tribe's area of traditional and cultural affiliation. No additional tribal outreach was conducted by Dudek; however, in compliance with Assembly Bill (AB) 52, the City has contacted tribal representatives that have requested to be notified of projects in Pasadena. Details of the SLF request and results including the tribal outreach process are presented in Section 2.2 and provided in Appendix C. The proposed Project is subject to compliance with Assembly Bill (AB) 52. Native American consultation pursuant to AB 52 is on-going.

The following resources within the Project Area of Potential Effect (APE) were identified as historical resources under CEQA and historic properties under Section 106 of the National Historic Preservation Act (NHPA):

- John L. Behner Water Treatment Plant (3S/3CS/5S3)
- Bridge No. 2 (3S/3CS/5S3)
- Bridge No. 3 (3S/3CS/5S3)

Additionally, five (5) stone wall features were identified within the APE that are considered character-defining features of the larger Arroyo Seco, and should be avoided/protected as part of the proposed Arroyo Seco Canyon Project in accordance with the Arroyo Seco Design Guidelines (City of Pasadena 2003a).

The remaining built environment identified within the APE, including the Screen Building Complex, Bridge No. 1, and the PWP/LACFCD flood control and water conservation infrastructure, do not appear eligible for NRHP, CRHR, or City designation due to a lack of significant historical associations and architectural merit. Therefore, these properties are not considered historical resources under CEQA or historic properties under Section 106 of the NHPA.

Implementation of MM-CUL-1 through -5 (Section 6.3), will reduce impacts to the John L. Behner WTP, Bridge No. 2, and the Arroyo Seco stone wall features to a less than significant level. However, impacts will remain significant and unavoidable for Bridge No. 3 since the structural overlay bridge installed in 2017 is not in conformance with the Secretary of the Interior's Standards for the Treatment of Historic Properties in consideration of its proposed permanency. The overlay structure, characterized by a steel deck supported by steel I-beam girders, poured-in-place concrete ramps, and tubular metal railings, does not conform to the Secretary of the Interior's Standards for Rehabilitation of a 1930s timber bridge built by the CCC. As a potentially permanent design feature (or at least into the foreseeable future), the continued presence of the overlay structure on Bridge No. 3 is considered a significant impact to historical resources, as the overlay detracts from nearly all of its important character-defining features and introduces incompatible, highly visible, modern materials.

Because there are no plans for the future reconstruction/replacement of Bridge No. 3 at this time, it is anticipated that the existing bridge may continue to deteriorate. Therefore, this Draft EIR anticipates the environmental impacts of the continued use of the temporary bridge structure over Bridge No. 3, and the continued deterioration of the existing Bridge No. 3, into the foreseeable future. Whether and when reconstruction/replacement of Bridge No. 3 will be undertaken is unknown, and it is unknown whether the new bridge would be constructed in such a manner that would allow for its preservation as a historical resource. Therefore, impacts to historical resources under CEQA are considered significant and unavoidable, even with implementation of archival documentation mitigation (MM-CUL-2).

Section 106 of NHPA requires federal agencies to take into account the effects of their undertakings on historic properties, assess the effects, and seek ways to avoid, minimize, or mitigate any adverse effects on such properties (36 CFR 800.1[a]). In consideration of the discussion above for Bridge No. 3, the proposed project would result in adverse effects to historic properties that cannot be mitigated in a way that would eliminate or reduce effects.

1 Introduction

Dudek was retained by the City of Pasadena to complete a Cultural Resources Technical Report to support the required California Environmental Quality Act (CEQA) Section 15064.5 for historical resources and Section 106 of the National Historic Preservation Act (NHPA) documentation for the Arroyo Seco Canyon Project (Project) in the City of Pasadena, California. This report includes the results of a California Historical Resources Information System (CHRIS) records search; coordination with the California Native American Heritage Commission (NAHC) and tribal contacts; pedestrian survey of the Project site by a qualified architectural historian and archaeologist; building development and archival research; development of an appropriate historic context for the Project site; and recordation and evaluation of five (5) properties over 45 years old for historical significance and integrity in consideration of National Register of Historic Places (NRHP), California Register of Historical Resources (CRHR), and City of Pasadena designation criteria and integrity requirements.

This report and associated property significance evaluations was prepared by Dudek Architectural Historians Kate G. Kaiser, MSHP; Kara R. Dotter, MSHP; and Nicole Frank, MSHP. Dudek Archaeologist Adriane Dorrler, BA, completed the CHRIS records search, the NAHC Sacred Lands File (SLF) request, and coordinated Native American outreach, in addition to contributing to the report. This report was reviewed for quality assurance/quality control by Dudek Principal Architectural Historian Samantha Murray, MA, Dudek Senior Archaeologist Heather McDaniel McDevitt, MA, RPA and Dudek Lead Archaeologist Linda Kry, BA. Resumes for all key personnel are provided in Appendix A. Ms. Murray meets the Secretary of the Interior's Professional Qualification Standards (36 CFR 61) for both an Architectural History and Archaeological Principal Investigator.

1.1 Project Location and Description

Project Location

The Project site is located in the City of Pasadena within the Arroyo Seco Canyon at 3420 and 3500 Arroyo Seco Road, City of Pasadena. The Project site is located within Township 1 and 2 North, Range 12 West, of the Pasadena, California 7.5-minute USGS quadrangle. The Project site encompasses portions of two separate parcels, specifically Assessor Parcel Numbers (APNs) 5830-001-906 and 5823-015-902. The Project site can be accessed via Interstate (I) 210 by exiting Windsor Avenue and traveling northward for approximately 0.8-mile to the intersection of Windsor Avenue and Ventura Street. From this intersection, the City's open area (i.e., former Jet Propulsion Laboratory [JPL] East Parking Lot) is located approximately 0.3-mile north along Explorer Road, which constitutes the southern boundary of Area 3.

The proposed Project consists of two primary areas, as shown on Figure 1, Project Location Map, including Area 2, Diversion and Intake Replacement and Area 3, Spreading Basin Improvements. These areas are connected by the Arroyo Seco Road[1] (i.e. Gabrielino Trail/Access Road), which serves as a recreational trail and the access road for City of Pasadena and U.S. Forest Service (USFS) vehicles heading into the Arroyo Seco Canyon. As shown on Figure 1, the proposed Project would involve construction activity and facility improvements in both areas, as well as construction truck traffic along portions of the Gabrielino Trail/Access Road. The former Travelling Screen and

[1] Formerly North Arroyo Boulevard

Chlorine Building (Screen Building) adjacent to Area 2 and the Behner Water Treatment Plant adjacent to Area 3 would be used for temporary construction materials and equipment staging.

The Arroyo Seco is a creek that begins in the San Gabriel Mountains and passes through three distinct recreational areas within the City: (1) Upper Arroyo Seco, containing the Hahamongna Watershed Park (HWP) and Devil's Gate Reservoir and Dam; (2) Central Arroyo Seco, extending south of the Devil's Gate Dam to the Colorado Street Bridge; and (3) Lower Arroyo Seco, from the Colorado Street Bridge to the southern boundary of the City. The Project proposes new facilities and improvements only in the Upper Arroyo Seco, as shown on Figure 1.

Project Summary

Pursuant to Section 15367 of the State CEQA Guidelines, the City of Pasadena (City) Department of Water and Power (PWP) is the Lead Agency for the Project, as it has the principal responsibility for carrying out the Project and has the authority for approving the Project and its accompanying environmental documentation. The following provides a breakdown of all major Project areas/components:

Area 2: Diversion and Intake Replacement

Figure 2 (Area 2 Existing Conditions), identifies the primary existing structures in Area 2, including the concrete diversion weir and intake structure, a fenced area with a screening building and access to sections of the conveyance system, the Gabrielino Trail/Access Road, and a historic bridge (Bridge No. 3) over the Arroyo Seco. The diversion weir directs water into the intake structure by obstructing the stream flow and creating a small pool of water that flows into the intake. The intake would be operated to divert the City's 25 cfs of water rights, while additional flows beyond 25 cfs would continue downstream. Due to sediment buildup trapped on the upstream side of the weir, the pooling capacity is reduced and the ability to collect water for spreading is limited. When water enters the intake, it is conveyed downstream through the conveyance system to the PWP's spreading basins. The existing intake/diversion system consists of an approximate 9-foot-high reinforced concrete training wall and intake structure with a trash rack on the east bank of the stream, and a reinforced concrete weir with stop logs in slots. Under current conditions, the weir crest is approximately 2 feet above the streambed on the downstream side.

Improvements in Area 2 include the demolition and removal of the existing concrete weir and portions of the intake structure and the construction of a new diversion structure that would be operated to divert up to 25 cfs of creek flows into the existing conveyance system. The intake structure would be remodeled with new concrete walls and top deck to accommodate a new screen configuration. An existing concrete slab that previously supported an equipment building located adjacent to the Gabrielino Trail/Access Road would be demolished. A new 106-square-foot (11 feet 4 inches by 9 feet 4 inches) intake service building would be constructed to house the electrical and hydraulic controls for the diversion structure. Electric power for the operation of the diversion structure and control equipment enclosure would be supplied by an existing power line at the screen building (southeast of the intake structure). The locations of the proposed facilities and improvements are shown on Figure 3 (Area 2 Conceptual Design Overview).

The proposed new diversion/intake structure would capture flows up to PWP's surface water rights. This would include all flows during small storm events and dry weather flows in the Arroyo Seco, and a portion of flows during large storm events. During larger storms when the water is too turbid with suspended sediments (e.g., flows generally above 100 cfs), the stream with its associated sediment load would bypass the diversion/intake structure and continue downstream to Devil's Gate Reservoir. Operation of the weir during high flows would be facilitated by

the adjustable height weir or crest gate. At low flows, the gate would start in the 'up' position and as flows increase, the gate would be lowered to maintain a constant water surface level in the diversion pool (a pool created behind the weir to allow for an appropriate water elevation to flow into the diversion intake). When the gate is fully lowered, flows would entirely bypass the diversion structure and carry all flows and sediment downstream.

Under existing conditions, the weir/diversion structure is a barrier to upstream fish passage due to the elevation drop downstream of the structure. The new diversion/intake structure would improve biological functions in the Arroyo Seco by allowing for fish (and other aquatic wildlife) passage in the event that fish populations are established in the future. The new diversion structure would be designed for the possibility that some future fish may pass downstream when the diversion is not operating (i.e., the gate is lowered to allow flows to continue downstream without diversion) or when the diversion is operating and flows are high enough to spill over the crest gate. A roughened channel would be constructed downstream of the new diversion structure and operable weir such that upstream passage for future fish populations may occur during periods when the diversion is not operating and flows are adequate to allow for passage. In the current condition, water passes through a trash rack to prevent debris from entering the conveyance system to the spreading basins. In addition to filtering such debris, the proposed new intake structure would include a fish screening feature to prevent future fish populations from passing into the intake and conveyance system.

Area 3: Spreading Basin Improvements

As shown in Figure 4 (Area 3 Existing Conditions), Area 3 is located approximately 0.3-mile downstream from Area 2 and includes two existing spreading basins that are known as Pasadena Ponds 1 and 2 (formerly used as sludge ponds for the Behner Treatment Plant) and Spreading Basins No. 1 through 4, the former JPL Parking Lot and adjacent Explorer Road, and the Arroyo Seco Road (i.e. Gabrielino Trail/Access Road), which would provide construction vehicle access to Area 2 of the Project site. Figure 4 identifies the primary structures and facilities in Area 3.

As shown in Figure 5, Area 3 Conceptual Design Overview, improvements in Area 3 include the reconfiguration and expansion of the spreading basins in order to accommodate the increased diversion of creek flows for infiltration into the Raymond Basin. Various facilities would be demolished, including inlet/outlet structures, dry vaults, woodsheds, utility light pole, pipes and valves, chainlink fencing, corrugated metal pipes, and other small appurtenant structures, to allow for the reconstructed basins.

Figure 5 (Area 3 Conceptual Design Overview), depicts the proposed spreading basin improvements. Creek flows from the existing conveyance system would outlet to the new sedimentation basin or to new spreading Basin E located over the existing Pasadena Pond 1. Basin F would be adjacent to mature trees to be preserved and would be located at the site of the existing Pasadena Pond 2. Basins G, H, and I would be located at the site of the existing Basins 1 and 2 and a portion of the City's open area (i.e., former JPL East Parking Lot, vacated in 2015 for the purpose of expanding the spreading basins). Each new basin would have an access ramp for maintenance. Rock boulders would be placed along the western edge of Explorer Road to separate the roadway from the adjacent basins. With the area's sloping terrain, depths of the basins would range from 3 feet to 7 feet. When spreading water, the water depth in the basins would be approximately 1 foot. All basins would include inlets/outlets with 24-inch interconnection pipelines. Spillways, pipelines, culverts, and valves would be provided to connect the basins to each other. Basin J would be the last newly constructed basin located entirely within the former JPL East Parking Lot, which would include interconnection pipelines into the existing Basin 3. Other basins downstream of Basin 3 are not a part of the proposed Project, although Basin 4 may be temporarily impacted during construction.

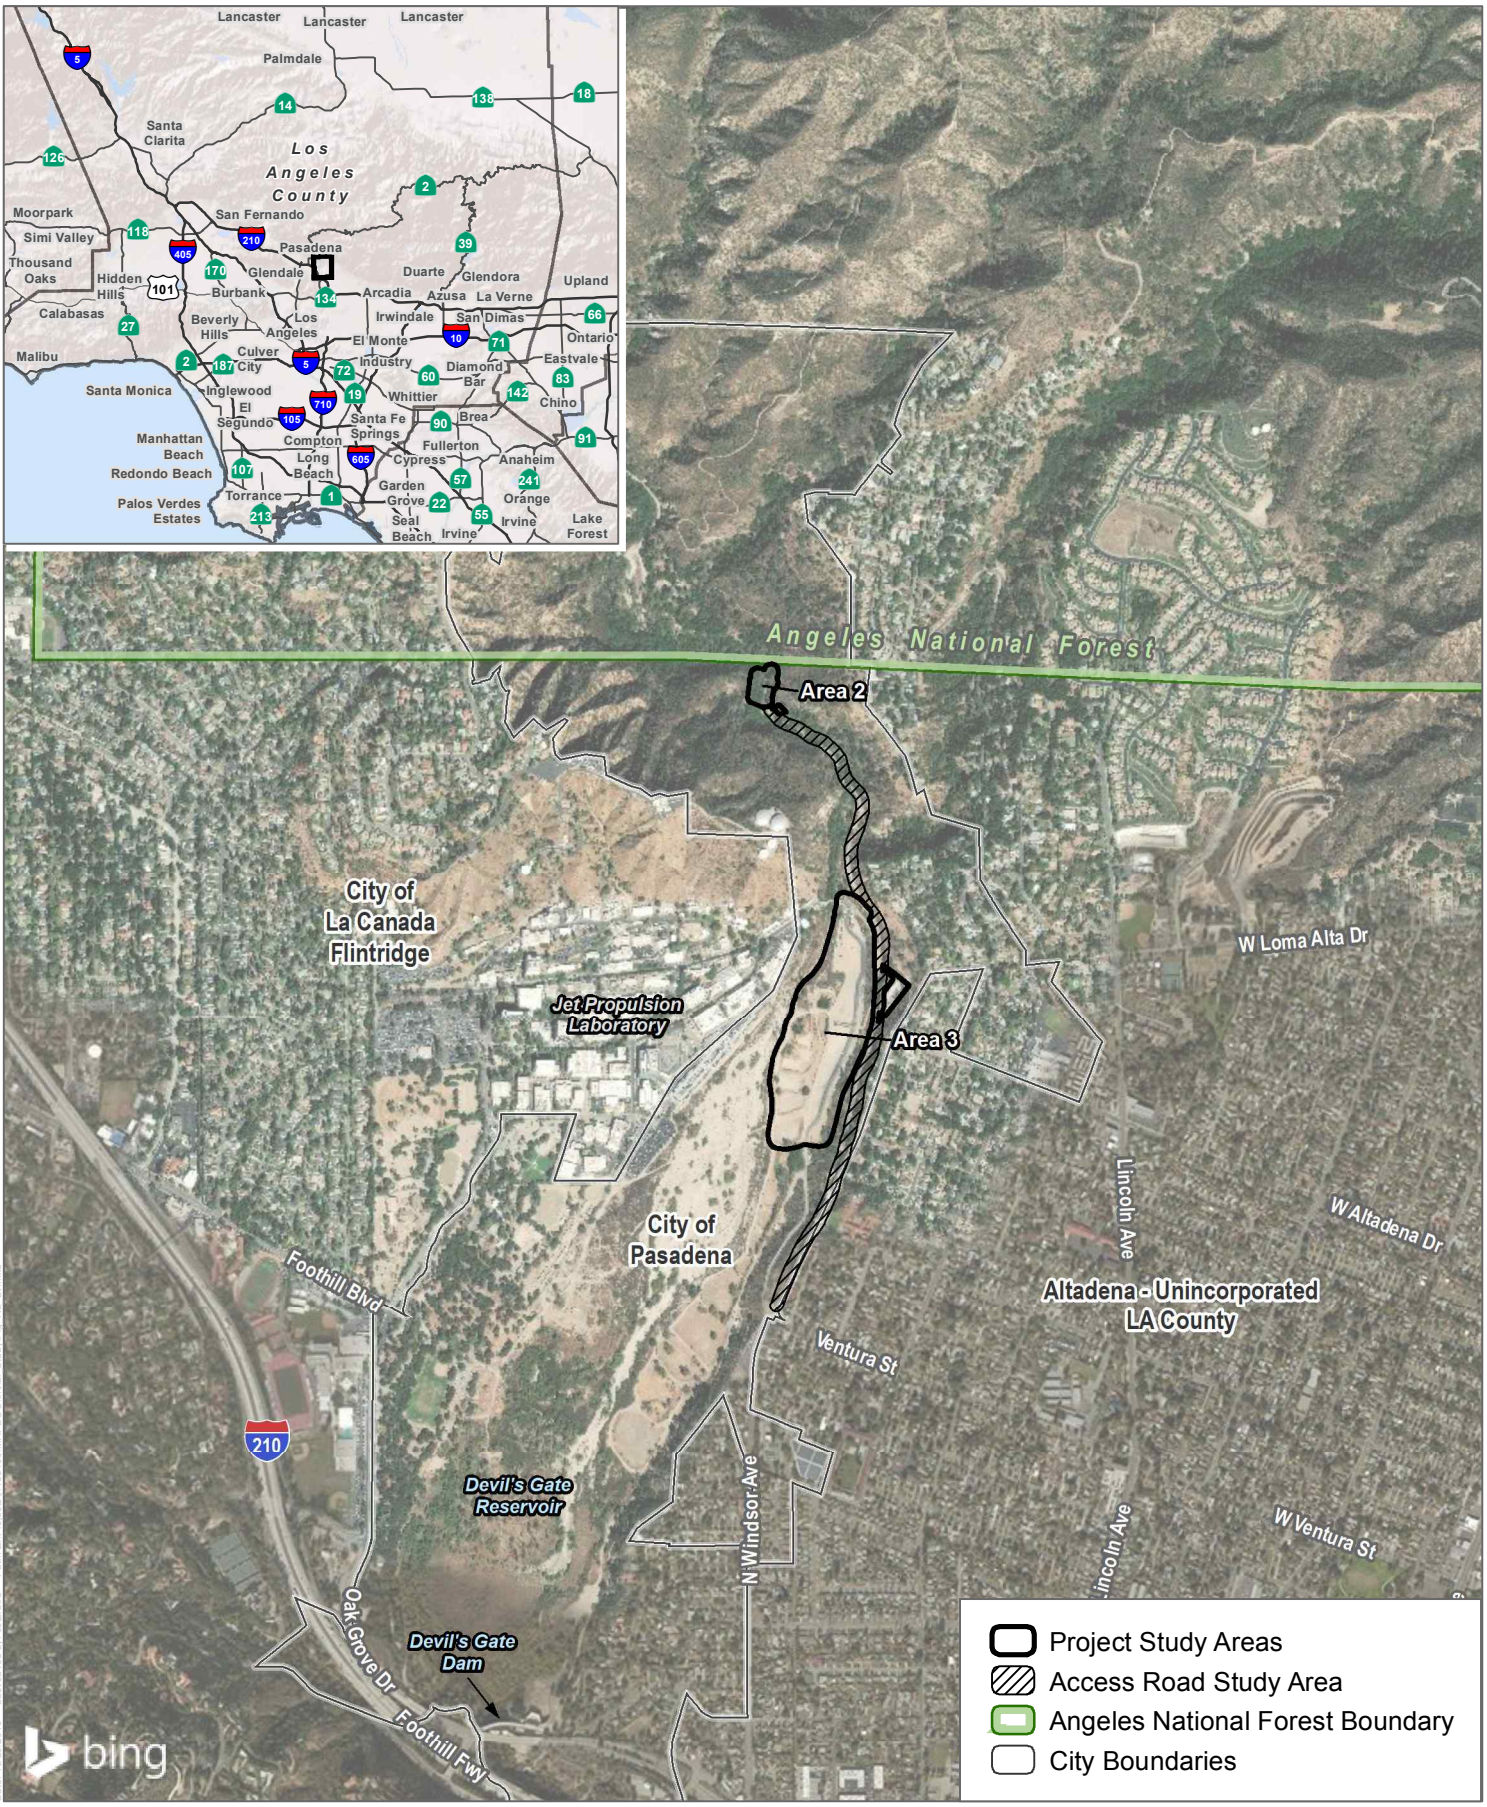
Gabrielino Trail and Bridge Crossings

As shown in Figure 6 (Gabrielino Trail and Bridge Crossings Map), the Gabrielino Trail (i.e., Arroyo Seco Road) runs generally parallel to the Arroyo Seco and along the eastern side of the former JPL East Parking Lot and serves as a recreation trail for hikers, bikers, and equestrian uses. It also serves as a maintenance access road that leads to the Behner Water Treatment Plant and into the Arroyo Seco Canyon area to provide access for PWP and the USFS. During construction activities, the Gabrielino Trail/Access Road would provide for vehicular access to and from Area 2, and sometimes Area 3 (Explorer Road will be its primary access road).

Along the Gabrielino Trail/Access Road, three bridges cross portions of the Arroyo Seco. Bridge Nos. 1, 2, and 3 are located between Areas 2 and 3, respectively. Bridge No. 1 is a culvert-style bridge with concrete slab deck over Millard Creek, approximately 0.13-mile north of the JPL Bridge. A July 2015 Bridge Condition Assessment found that the bridge abutments were being undermined due to scouring and that the Gabrielino Trail/Access Road had sloughed off in sections. A structural overlay bridge spanning the length of this bridge was constructed in 2017 to provide additional support for large/heavy vehicle travel and to protect the structure from further damage. Bridge No. 2 is located approximately 130 feet north of Bridge No. 1 and is a reinforced concrete arch bridge with decorative cast-concrete railing. Bridge No. 2 was likely constructed to provide a formal entrance to the Upper Arroyo Seco and the ANF; Bridge No. 2 meets the required criteria to be listed as a historical resource in the California Register of Historic Resources (CRHR) and in the City of Pasadena as a landmark (BonTerra Psomas 2015).

Bridge No. 3 is located approximately 0.34-mile north of the JPL Bridge within Area 2 and was constructed with truss-bridge forms using wood timbers. It was constructed by the Civilian Conservation Corps (CCC) in 1939 and is associated with events that made a significant contribution to the history of the United States and California. Bridge No. 3 is eligible for inclusion in the NRHP and in the CRHR. The bridge was heavily damaged by the 2010/2011 storm events following the 2009 Station Fire. A structural overlay bridge spanning the entire length of Bridge No. 3 was constructed in 2017 to provide additional support for large/heavy vehicle travel and to protect the structure from further damage. A structural evaluation of Bridge No. 3 subsequent to the structural overlay, however, shows that the condition of Bridge No. 3 continues to deteriorate and is no longer safe for use (TJC 2018).. Structural repairs, including replacement of its timber members, will be required to restore its use.

Upon completion of the proposed Project, the City intends to keep the Bridge No. 3 overlay structure as-is, with the understanding that the reconstruction/replacement of Bridge No. 3 will eventually be required, although such replacement is not yet planned, if the City wishes to maintain the bridge. Although the temporary structural bridge overlay was constructed to allow transport of heavy equipment and materials during the ASCP construction, its continued presence provides for the safe passage of vehicles, pedestrians, and equestrians along the Gabrielino Trail/Access Road and to the USFS facilities. Additionally, the temporary structure allows access to large vehicles, including fire trucks, that were previously restricted due to the loading limitations of the original bridge even before it was damaged. The temporary structure spans the existing bridge abutments; therefore, its structural integrity is not impacted by the deteriorating structural integrity of Bridge No. 3. Since the temporary structure is constructed of steel elements and concrete, and will experience relatively light traffic, its expected service life is estimated to exceed 50 years. There may be safety risks associated with the continued deterioration of Bridge No. 3 if structural members fail and fall; in which case the City may decide to affirmatively deconstruct some or all of the bridge to protect public safety.



Because there are no plans for the future reconstruction/replacement of the Bridge No. 3 at this time, it is anticipated that the existing bridge may continue to deteriorate, and although not anticipated at this point, may even be removed to protect public safety. Therefore, this Draft EIR anticipates the environmental impacts of the continued use of the temporary bridge structure over Bridge No. 3, and the continued deterioration of the existing Bridge No. 3, into the foreseeable future (and perhaps even its eventual removal). Whether and when reconstruction/replacement of Bridge No. 3 will take place is unknown, and it is unknown whether the new bridge would be constructed in such a manner that would allow for its preservation as a historical resource.

Additionally, stone masonry walls (which are considered local historical resources that contribute to the character of the larger Arroyo Seco) line the east side of the Arroyo Seco at Bridge No. 2 and continue upstream to Bridge No. 3. The stone masonry walls would not be altered by Project activities, but will require protection.

Construction Staging Areas

As depicted on Figures 3 and 5, during construction activities, the former Travelling Screen and Chlorine Building (Screen Building) adjacent to Area 2 and the Behner Water Treatment Plant adjacent to Area 3 would be used for temporary construction materials and equipment staging.

1.2 Area of Potential Effects

In consideration of the Project's requirement to address Section 106 of the NHPA, an Area of Potential Effects (APE) has been defined for the Project. The APE is the geographic area or areas within which an undertaking may directly or indirectly cause changes in the character or use of historic properties. Determination of the APE is influenced by a project's setting, the scale and nature of the undertaking, and the different kinds of effects that may result from the undertaking (36 CFR 800.16(d)). The proposed Project APE (Figure 7) includes consideration of the potential direct and indirect effects of the project/undertaking.

The APE is where ground disturbance is expected to occur, representing the proposed Project footprint, and includes the following components:

- Area 2, which will entail the demolition and removal of the existing concrete weir and portions of the intake structure and the construction of a new diversion structure
- Area 3, which will entail the reconfiguration and expansion of the existing spreading basins and demolition of facilities, including inlet/outlet structures, dry vaults, woodsheds, utility light pole, pipes and valves, chainlink fencing, corrugated metal pipes, and other small appurtenant structures, to allow for the reconstructed basins
- Gabrielino Trail and Bridge Crossings, which will provide for vehicular access to and from Area 2, and sometimes Area 3.
- During construction activities, the Screen Building adjacent to Area 2 and the Behner Water Treatment Plant adjacent to Area 3 would be used for temporary construction materials and equipment staging.

The vertical extent of the APE for the proposed Project is defined as the depth of soils disturbed during Project construction that have the potential to contain intact cultural deposits. The amount of disturbed soils varies according to the topography and construction needs, but is anticipated to be roughly up to 10 feet below grade where trenching is anticipated.

1.3 Regulatory Setting

Federal

The NRHP is the United States' official list of districts, sites, buildings, structures, and objects worthy of preservation. Overseen by the National Park Service under the U.S. Department of the Interior, the NRHP was authorized under the NHPA, as amended. Its listings encompass all National Historic Landmarks and historic areas administered by the National Park Service.

NRHP guidelines for the evaluation of historic significance were developed to be flexible and to recognize the accomplishments of all who have made significant contributions to the nation's history and heritage. Its criteria are designed to guide state and local governments, federal agencies, and others in evaluating potential entries in the NRHP. For a property to be listed in or determined eligible for listing, it must be demonstrated to possess integrity and to meet at least one of the following criteria:

- The quality of significance in American history, architecture, archaeology, engineering, and culture is present in districts, sites, buildings, structures, and objects that possess integrity of location, design, setting, materials, workmanship, feeling, and association; and

    A. That are associated with events that have made a significant contribution to the broad patterns of our history; or

    B. That are associated with the lives of persons significant in our past; or

    C. That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction; or

    D. That have yielded, or may be likely to yield, information important in prehistory or history.

"Integrity" is defined in NRHP guidance, How to Apply the National Register Criteria, as "the ability of a property to convey its significance. To be listed in the NRHP, a property must not only be shown to be significant under the NRHP criteria, but it also must have integrity" (NPS 1990). NRHP guidance further states that properties be completed at least 50 years ago to be considered for eligibility. Properties completed fewer than 50 years before evaluation must be proven to be "exceptionally important" (criteria consideration G) to be considered for listing.

A historic property is defined as "any prehistoric or historic district, site, building, structure, or object included in, or eligible for inclusion in, the NRHP maintained by the Secretary of the Interior. This term includes artifacts, records, and remains that are related to and located within such properties. The term includes properties of traditional religious and cultural importance to an Indian tribe or Native Hawaiian organization and that meet the NRHP criteria" (36 CFR Sections 800.16(i)(1)).

Effects on historic properties under Section 106 of the NHPA are defined in the assessment of adverse effects in 36 CFR Sections 800.5(a)(1) as follows:

> An adverse effect is found when an undertaking may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the National Register in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. Consideration shall be given to all qualifying characteristics of a historic property, including those that may have been identified subsequent to the original evaluation of the property's eligibility for the National Register. Adverse effects may include reasonably foreseeable effects caused by the undertaking that may occur later in time, be farther removed in distance or be cumulative.

Adverse effects on historic properties are clearly defined and include the following (36 CFR 800.5(2)):

(i) Physical destruction of or damage to all or part of the property;

(ii) Alteration of a property, including restoration, rehabilitation, repair, maintenance, stabilization, hazardous material remediation and provision of handicapped access, that is not consistent with the Secretary's Standards for the Treatment of Historic Properties (36 CFR Part 68) and applicable guidelines;

(iii) Removal of the property from its historic location;

(iv) Change of the character of the property's use or of physical features within the property's setting that contributes to its historic significance;

(v) Introduction of visual, atmospheric or audible elements that diminish the integrity of the property's significant historic features;

(vi) Neglect of a property which causes its deterioration, except where such neglect and deterioration are recognized qualities of a property of religious and cultural significance to an Indian tribe or Native Hawaiian organization; and

(vii) Transfer, lease, or sale of property out of Federal ownership or control without adequate and legally enforceable restrictions or conditions to ensure long-term preservation of the property's historic significance.

To comply with Section 106 of the NHPA, the criteria of adverse effect are applied to historic properties that exist in the area of potential effects (APE), pursuant to 36 CFR Section 800.5(a)(1). If no historic properties are identified in the APE, a finding of "no historic properties affected" are made for a project. If there are historic properties in the APE, application of the criteria of adverse effect will result in project-related findings of either "no adverse effect" or "adverse effect," as described above. A finding of no adverse effect may be appropriate when the undertaking's effects do not meet the thresholds in criteria of adverse effect 36 CFR Section 800.5(a)(1), in certain cases when the undertaking is modified to avoid or lessen effects, or if conditions were imposed to ensure review of rehabilitation plans for conformance with the Secretary of the Interior's Standards for the Treatment of Historic Properties (codified in 36 CFR Part 68).

If adverse effects findings were expected to result from a project, mitigation is required, as feasible, and resolution of those adverse effects by consultation may occur to avoid, minimize, or mitigate adverse effects on historic properties, pursuant to 36 CFR Section 800.6(a).

State

California Register of Historical Resources

In California, the term "historical resource" includes but is not limited to "any object, building, structure, site, area, place, record, or manuscript which is historically or archaeologically significant, or is significant in the architectural, engineering, scientific, economic, agricultural, educational, social, political, military, or cultural annals of California" (California Public Resources Code Section 5020.1(j)). In 1992, the California legislature established the CRHR "to be used by state and local agencies, private groups, and citizens to identify the state's historical resources and to indicate what properties are to be protected, to the extent prudent and feasible, from substantial adverse change" (California Public Resources Code Section 5024.1(a)). The criteria for listing resources on the CRHR were expressly developed to be in accordance with previously established criteria developed for listing in the NRHP, enumerated below. According to California Public Resources Code Section 5024.1(c)(1–4), a resource is considered historically significant if it (i) retains "substantial integrity," and (ii) meets at least one of the following criteria:

(1) Is associated with events that have made a significant contribution to the broad patterns of California's history and cultural heritage.

(2) Is associated with the lives of persons important in our past.

(3) Embodies the distinctive characteristics of a type, period, region, or method of construction, or represents the work of an important creative individual, or possesses high artistic values.

(4) Has yielded, or may be likely to yield, information important in prehistory or history.

In order to understand the historic importance of a resource, sufficient time must have passed to obtain a scholarly perspective on the events or individuals associated with the resource. A resource less than 50 years old may be considered for listing in the CRHR if it can be demonstrated that sufficient time has passed to understand its historical importance (see 14 CCR 4852(d)(2)).

The CRHR protects cultural resources by requiring evaluations of the significance of prehistoric and historic resources. The criteria for the CRHR are nearly identical to those for the NRHP, and properties listed or formally designated as eligible for listing in the NRHP are automatically listed in the CRHR, as are the state landmarks and points of interest. The CRHR also includes properties designated under local ordinances or identified through local historical resource surveys.

California Environmental Quality Act

As described further below, the following CEQA statutes and CEQA Guidelines are of relevance to the analysis of archaeological, historic, and tribal cultural resources:

- California Public Resources Code Section 21083.2(g) defines "unique archaeological resource."
- California Public Resources Code Section 21084.1 and CEQA Guidelines Section 15064.5(a) define "historical resources." In addition, CEQA Guidelines Section 15064.5(b) defines the phrase "substantial adverse change in the significance of an historical resource." It also defines the circumstances when a project would materially impair the significance of an historical resource.

- California Public Resources Code Section 21074(a) defines "tribal cultural resources."

- California Public Resources Code Section 5097.98 and CEQA Guidelines Section 15064.5(e) set forth standards and steps to be employed following the accidental discovery of human remains in any location other than a dedicated ceremony.

- California Public Resources Code Sections 21083.2(b)-(c) and CEQA Guidelines Section 15126.4 provide information regarding the mitigation framework for archaeological and historic resources, including examples of preservation-in-place mitigation measures; preservation-in-place is the preferred manner of mitigating impacts to significant archaeological sites because it maintains the relationship between artifacts and the archaeological context and may also help avoid conflict with religious or cultural values of groups associated with the archaeological site(s).

More specifically, under CEQA, a project may have a significant effect on the environment if it may cause "a substantial adverse change in the significance of an historical resource" (California Public Resources Code Section 21084.1; CEQA Guidelines Section 15064.5(b).) If a site is either listed or eligible for listing in the CRHR, or if it is included in a local register of historic resources or identified as significant in a historical resources survey (meeting the requirements of California Public Resources Code Section 5024.1(q)), it is a "historical resource" and is presumed to be historically or culturally significant for purposes of CEQA (California Public Resources Code Section 21084.1; CEQA Guidelines Section 15064.5(a)). The lead agency is not precluded from determining that a resource is an historical resource even if it does not fall within this presumption (California Public Resources Code Section 21084.1; CEQA Guidelines Section 15064.5(a)).

A "substantial adverse change in the significance of an historical resource" reflecting a significant effect under CEQA means "physical demolition, destruction, relocation, or alteration of the resource or its immediate surroundings such that the significance of an historical resource would be materially impaired" (CEQA Guidelines Section 15064.5(b)(1); California Public Resources Code Section 5020.1(q)). In turn, CEQA Guidelines section 15064.5(b)(2) states the significance of an historical resource is materially impaired when a project:

1. Demolishes or materially alters in an adverse manner those physical characteristics of an historical resource that convey its historical significance and that justify its inclusion in, or eligibility for, inclusion in the California Register of Historical Resources; or

2. Demolishes or materially alters in an adverse manner those physical characteristics that account for its inclusion in a local register of historical resources pursuant to section 5020.1(k) of the Public Resources Code or its identification in an historical resources survey meeting the requirements of section 5024.1(g) of the Public Resources Code, unless the public agency reviewing the effects of the project establishes by a preponderance of evidence that the resource is not historically or culturally significant; or

3. Demolishes or materially alters in an adverse manner those physical characteristics of a historical resource that convey its historical significance and that justify its eligibility for inclusion in the California Register of Historical Resources as determined by a lead agency for purposes of CEQA.

Pursuant to these sections, the CEQA inquiry begins with evaluating whether a project site contains any "historical resources," then evaluates whether that project will cause a substantial adverse change in the significance of a historical resource such that the resource's historical significance is materially impaired.

If it can be demonstrated that a project will cause damage to a unique archaeological resource, the lead agency may require reasonable efforts be made to permit any or all of these resources to be preserved in place or left in an undisturbed state. To the extent that they cannot be left undisturbed, mitigation measures are required (California Public Resources Code Section 21083.2[a], [b], and [c]).

California Public Resources Code Section 21083.2(g) defines a unique archaeological resource as an archaeological artifact, object, or site about which it can be clearly demonstrated that without merely adding to the current body of knowledge, there is a high probability that it meets any of the following criteria:

1. Contains information needed to answer important scientific research questions and that there is a demonstrable public interest in that information.

2. Has a special and particular quality such as being the oldest of its type or the best available example of its type.

3. Is directly associated with a scientifically recognized important prehistoric or historic event or person.

Impacts to non-unique archaeological resources are generally not considered a significant environmental impact (California Public Resources Code section 21083.2(a); CEQA Guidelines Section 15064.5(c)(4)). However, if a non-unique archaeological resource qualifies as tribal cultural resource (California Public Resources Code Section 21074(c), 21083.2(h)), further consideration of significant impacts is required. CEQA Guidelines Section 15064.5 assigns special importance to human remains and specifies procedures to be used when Native American remains are discovered. As described below, these procedures are detailed in California Public Resources Code Section 5097.98.

Local

City of Pasadena Historic Preservation Ordinance (Chapter 17.62)

This study was completed in consideration of all sections of the Pasadena Historic Preservation Ordinance (Chapter 17.62). Sections most relevant to this study are provided below.

17.62.010 - Purpose of Chapter

The purpose of this Chapter is to specify significance criteria for the designation of historic resources, procedures for designation, and review procedures to:

A. Encourage and promote the adaptive reuse of the City's historic resources;

B. Enhance, perpetuate, and preserve architecturally and historically significant structures and promote revitalization of historic neighborhoods and commercial areas;

C. Ensure that the rights of the owners of historic resources and owners of properties adjacent to historic resources are safeguarded;

D. Foster civic pride in the beauty and noble accomplishments of the past by promoting private stewardship of historic resources that represent these accomplishments;

E. Fulfill the City's responsibilities:

1. As a Certified Local Government under Federal preservation laws; and

2. For Federal Section 106 reviews and for the California Environmental Quality Act regarding historic resources.

F. Promote the identification, documentation, and evaluation of the significance of individual historic resources and districts;

G. Implement the historic preservation goals, policies, and programs of the General Plan;

H. Promote the City as a destination for tourists and as a desirable location for business;

I. Promote public awareness of the value of rehabilitation, restoration, and maintenance of the existing building stock as a means to conserve reusable material and energy resources;

J. Recognize the City's historic resources as economic assets; and

K. Stabilize and improve property values, and enhance the aesthetic and visual character and environmental amenities of the City's historic properties and areas.

17.62.040 - Criteria for Designation of Historic Resources

A. Evaluation of Historic Resources.

When considering applications to designate a historic monument, landmark, historic sign, landmark tree or landmark district, the Historic Preservation Commission shall apply the criteria below according to applicable National Register of Historic Places Bulletins for evaluating historic properties, including the seven aspects of integrity: location, design, setting, materials, workmanship, feeling and association (National Register of Historic Places Bulletin #15: "How to Apply the National Register Criteria for Evaluation").

B. Historic monuments.

1. A historic monument shall include all historic resources previously designated as historic treasures before adoption of this Chapter, historic resources that are listed in the National Register at the State-wide or Federal level of significance (including National Historic Landmarks) and any historic resource that is significant at a regional, State, or Federal level, and is an exemplary representation of a particular type of historic resource and meets one or more of the following criteria:

   a. It is associated with events that have made a significant contribution to the broad patterns of the history of the region, State, or nation.

   b. It is associated with the lives of persons who are significant in the history of the region, State, or nation.

   c. It is exceptional in the embodiment of the distinctive characteristics of a historic resource property type, period, architectural style, or method of construction, or that is an exceptional representation

of the work of an architect, designer, engineer, or builder whose work is significant to the region, State, or nation, or that possesses high artistic values that are of regional, State-wide or national significance.

d. It has yielded, or may be likely to yield, information important in prehistory or history of the region, State, or nation.

2. A historic monument designation may include significant public or semi-public interior spaces and features.

C. Landmarks.

1. A landmark shall include all properties previously designated a landmark before adoption of this Chapter and any historic resource that is of a local level of significance and meets one or more of the criteria listed in Subparagraph 2., below.

2. A landmark may be the best representation in the City of a type of historic resource or it may be one of several historic resources in the City that have common architectural attributes that represent a particular type of historic resource. A landmark shall meet one or more of the following criteria:

a. It is associated with events that have made a significant contribution to the broad patterns of the history of the City, region, or State.

b. It is associated with the lives of persons who are significant in the history of the City, region, or State.

c. It embodies the distinctive characteristics of a type, architectural style, period, or method of construction, or represents the work of an architect, designer, engineer, or builder whose work is of significance to the City or, to the region or possesses artistic values of significance to the City or to the region.

d. It has yielded, or may be likely to yield, information important locally in prehistory or history.

D. Historic signs.

1. A historic sign shall include all signs in the sign inventory as of the date of adoption of this Zoning Code and any sign subsequently designated historically significant by the Historic Preservation Commission that possesses high artistic values. A historic sign shall meet one or more or the following criteria:

a. The sign is exemplary of technology, craftsmanship or design of the period when it was constructed, uses historic sign materials and means of illumination, and is not significantly altered from its historic period. Historic sign materials shall include metal or wood facings, or paint directly on the façade of a building. Historic means of illumination shall include incandescent light fixtures or neon tubing on the exterior of the sign. If the sign has been altered, it must be restorable to its historic function and appearance.

b. The sign is integrated with the architecture of the building.

c. A sign not meeting criteria a or b above may be considered for inclusion in the inventory if it demonstrates extraordinary aesthetic quality, creativity, or innovation.

2. All other regulations relating to signs shall comply with Chapter 17.48 (Signs).

E. Landmark trees.

A tree shall qualify to be of historic or cultural significance and of importance to the community if it meets any one of the following criteria:

1. It is one of the largest or oldest trees of the species located in the City;

2. It has historical significance due to an association with a historic event, person, site, street, or structure; or

3. It is a defining landmark or significant outstanding feature of a neighborhood.

F. Landmark districts.

1. A landmark district shall include all landmark districts previously designated before adoption of this Chapter and any grouping of contiguous properties that also meet the following criteria:

   a. Within its boundaries, a minimum of 60 percent of the properties qualify as contributing; and

   b. The grouping represents a significant and distinguishable entity of Citywide importance and one or more of a defined historic, cultural, development and/or architectural context(s) (e.g., 1991 Citywide historic context, as amended, historic context prepared in an intensive-level survey or historic context prepared specifically for the nominated landmark district).

   2. When determining the boundaries of a landmark district, the Historic Preservation Commission shall use the National Register of Historic Places Bulletin #21: "Defining Boundaries for National Register Properties".

Arroyo Seco Master Plan

The Arroyo Seco Master Plans are a set of documents defining the community vision for the Arroyo Seco Natural Park. The set is comprised of four separate planning documents: the Lower Arroyo Master plan, Central Arroyo Master Plan, Hahamonga Watershed Park Master Plan, and Design Guidelines. The Hahamongna Watershed Park Master Plan and Design Guidelines are both relevant to this report.

The Hahamongna Watershed Park Master Plan (City of Pasadena 2003b) illustrates a vision for the 300-acres of open space that extends from Devil's Gate Dam north and into the Arroyo Seco Canyon, on the northwestern edge of the city. The Hahamongna Watershed Park Master Plan was adopted to establish a framework for recreation, water resources, flood management, habitat restoration, and cultural resources in this area. The Hahamonga Watershed Park Master Plan promotes the use of decorative Arroyo stone walls, gates, and fences, reflecting the historic heritage of the Arroyo Seco in Pasadena. They are established in this Master Plan as major enhancing and contributing to the unique setting of the natural habitats that are focal areas throughout the park.

Arroyo Seco Design Guidelines

The Arroyo Seco Design Guidelines (City of Pasadena 2003a) provide a unifying set of criteria for the site development improvements set forth in the Arroyo Seco Master Plan for on-going, long-range improvements for the Arroyo Seco. These guidelines will lead to a unified park design that reflects the heritage of the Arroyo Seco and its relationship to the tradition of the City of Pasadena. The Arroyo Seco Design Guidelines provide specific site design solutions that are consistent with the existing Arroyo Seco Ordinance and a vehicle by which practical inputs for ongoing improvements can take place. The Design Guidelines document gives more specific instances dictating how decorative cobblestone walls, gates, and fences should be utilized.

In the Architectural Design Concepts section guidelines, the "use of natural materials" and "arroyo stone" should be incorporated whenever appropriate. The guidelines also call for the preservation of stone walls in the Arroyo, when culturally significant. The arroyo stone walls and steps throughout the City of Pasadena and especially in the Arroyo Seco are considered an historic resource because many of them were built during the WPA years and in some locations designed by notable architects (City of Pasadena 2003a). See below:

7.2 General Guidelines

7.2.1 Walls

1. Where appropriate, vines and/or shrubs can be located against walls in areas where vandalism (graffiti) is a problem.

2. The stone walls in the Arroyo are culturally significant and shall be preserved.

3. Wall improvements in the Arroyo Seco shall primarily consist of walls that are faced in arroyo stone.

4. Walls constructed of split-faced block may be allowed in appropriate situations as determined by the Design Commission.

5. Wall improvements shall use the historic masonry style of the Arroyo by using a variety of sizes of stone, with large stones and boulders at the base of the wall including dry-stack techniques.

6. See the Wall Restoration Standards in Appendix E for improvements being considered to an existing stone wall or the construction of a new arroyo stone wall.

7. Where an existing stone retaining wall is in need of repair and posing a threat to the further degradation of the wall or to the public, the wall will be improved to ensure structural stability. See Appendix E, Wall Restoration Standards.

8. Wall improvements will consider drainage patterns immediate to the wall and provide weep holes at regular intervals and/or the appropriate drainage solution to protect the longevity of the wall.

9. Improvements to arroyo stone walls will be made by a qualified craftsman in the masonry trade with demonstrable experience with similar work.

10. Low stone walls will be finished so that the top of the wall is smooth, flat, and comfortable enough to be used as seating.

11. A well-crafted and proportionately sized cantilevered concrete cap atop an arroyo stone wall or pilaster is an acceptable design.

12. All construction and repair of the arroyo stone walls and steps shall be done in accordance with the current City of Pasadena's "Standard Specifications for Public Works Construction" (popularly known as the "Greenbook").

13. Arroyo stone walls along neighborhood trails shall be restored.

2 Background Research

2.1 CHRIS Records Search

A California Historical Resources Information System (CHRIS) records search was conducted for the Project site and surrounding 0.5-mile records search area at the South Central Coastal Information Center (SCCIC), located on the campus of California State University, Fullerton on October 3, 2019. This search included their collections of mapped prehistoric, historic, and built environment resources, Department of Parks and Recreation Site Records, technical reports, and ethnographic references. Additional consulted sources include historical maps of the study area, the National Register of Historic Places (NRHP), the California Register of Historical Resources (CRHR), the California Historic Property Data File, the lists of California State Historical Landmarks, California Points of Historical Interest, and the Archaeological Determinations of Eligibility. The confidential records search results are also provided in Confidential Appendix B.

Previously Conducted Cultural Resources Studies

The SCCIC records indicate that 35 cultural resources investigations have been conducted within 0.5-mile of the Project site. Of these, six studies were conducted within a portion of the Project site, (LA-01903, LA-06948, LA-08927, LA-11042, LA-11193, and LA-11194), and one study (LA-01312) was adjacent to the Project site. Table 1, below, summarizes all 35 previous cultural resources studies followed by a brief summary of each study that overlaps or is adjacent to the Project.

Table 1. Previous Cultural Resources Investigations Within 0.5-Mile of the Project Site

LA-01312

In 1976, John Bridgewater of the Saugus Ranger District conducted an Archaeological Reconnaissance Report (ARR) for Crest-Millard Fuel Management Unit on locations in Arroyo Seco and Tujunga Districts. The resulting report, *Fuel Break System for the Crest-Millard Fuel Management System* (Bridewater 1976), studied dispersed sections of the Angeles National Forest potentially affected by the maintenance and expansion of a fuel break system. The study area included an APE that extended to the first major ridge in the San Gabriel Mountain north of the area between the foothill cities of Tujunga and Pasadena, roughly adjacent to the current Project site. One prehistoric site was identified within the vicinity of the APE (P-19-000342) as a result of the records search and field survey, however, it was determined that it would only be impacted if future plans pushed construction north of the Vasquez Break. A site survey record from 1965 for P-19-000342 was attached to Mr. Bridgewater's report which included surface survey of a general village site, identification of a cogstone, milling stones, and interviews of the property owners who attested to a purported village having existed according to the local cultural memory.

LA-01903

In 1987, Leslie Blodgett was contracted by Cotton/Beland and Associates to prepare an Archaeological Survey Report in support of repair and reuse of the Devil's Gate Reservoir, in the City of Pasadena. The study area consisted of the reservoir property located directly north of the I-210 Foothill Freeway and directly south of the Cal Tech Jet Propulsion Laboratory. The study area overlapped a portion of the current Project site at Area 3. The resulting report, *Preliminary Assessment of the Prehistoric Cultural Resources of the Devil's Gate Reservoir, Pasadena, California* (Blodgett 1987), consisted of a records search and pedestrian survey. No prehistoric cultural resources were identified within the study area as a result of the archival review and field inspection. However, the records search identified two prehistoric sites within 1-mile of the study area: the aforementioned P-19-000342 purported village site, and P-19-000026, known as the Sheldon Reservoir site, which consists of a multi-level prehistoric graveyard. As a result of these findings, the study area was determined archaeologically sensitive given the close proximity of these sites to the study area.

LA-06948

In 2002, Southern California Edison Company (SCE) retained Compass Rose Archaeological, Inc. to conduct a Phase I Inventory in support of the proposed replacement and relocation of two deteriorated H-frame structures on the Seco 16 kV circuit. One structure location is within the current Project site. The study impact areas consisted of individual structure locations and a 30-meter diameter surrounding each structure. No prehistoric or historic-age cultural resources were identified within the impact areas as a result of the CHRIS records search and pedestrian survey. The resulting letter report, *Southern California Edison Seco 16 kV Circuit Edison Company Circuit Deteriorated Pole Replacement Project* (Romani 2002), stated that no further cultural resources considerations were warranted for the project aside from standard management recommendations for the unanticipated discovery of cultural resources uncovered during construction activities.

LA-08927

In 2007, Willdan retained McKenna et. al. to conduct a cultural resources study in support of the Arroyo Seco Master Plan Project with improvements to the Sunset Overlook Trailhead area located at Windsor Avenue within the Hahamongna Watershed Park in the City of Pasadena. The project consisted of improvements to the parking lot, as well as the widening of the trailhead, extending to where the Gabrieleno Trail meets the Sunset Overlook,

overlapping the southern portion of the current Project site. The study consisted of a CHRIS records search, Native American coordination, and a pedestrian survey. No cultural resources were identified within the study area as a result of the records search and pedestrian survey. However, based on communications with the Gabrielino/Tongva Tribe, the Tribe considers the area of Arroyo Seco sensitive for the presence of cultural resources of Native American origin. The resulting letter report, *A Phase I (CEQA) and Class III (NEPA) Cultural Resources Investigation for the Sunset Overlook Trailhead Area of the Hahamongna Watershed Park in the City of Pasadena, Los Angeles County, California* (McKenna et.al. 2007), stated that the study area should be considered moderately sensitive for the presence of prehistoric archaeological resources and provided recommendations for archaeological monitoring during construction.

LA-11042

In 2009, Willdan retained McKenna et. al. to conduct a cultural resources study in support of the Eastside Neighborhood and JPL Connector Trail Project with improvements to all trail-ways north of Devil's Gate Reservoir in the Arroyo Seco area west of the City of Pasadena. Specifically, the study area included approximately 1619 linear feet of trail improvements between the City of Altadena (from the terminus of Altadena Drive) and Hahamongna Watershed Park, overlapping a portion of Area 3 within the current Project site. The study consisted of a CHRIS records search, Native American coordination, and a pedestrian survey. No cultural resources were identified within the study area as a result of the records search and pedestrian survey. However, based on communications with the Gabrielino/Tongva Tribe, the Tribe considers the area of Arroyo Seco sensitive for the presence of cultural resources of Native American origin. The resulting letter report, *A Phase I (CEQA) and Class III (NEPA) Cultural Resources Investigation for the Eastside Neighborhood and JPL Connector Trail Improvements Project Area in the Hahamongna Watershed Park, City of Pasadena, Los Angeles County, California* (McKenna et.al. 2009), stated that the study area should be considered moderately sensitive for the presence of prehistoric archaeological resources and provided recommendations for archaeological monitoring during construction.

LA-11193

In 2007, the City of Pasadena, Parks and Natural Resources Division prepared a Master EIR Initial Study in support of the Sunset Overlook Trailhead Area in Hahamongna Watershed Park. Details of this project were discussed above in SCCIC report LA-08927. The Initial Study published the results of the McKenna et.al. 2007 study, which determined that the study area is sensitive for the presence of Native American cultural resources, and provided mitigations for archaeological monitoring.

LA-11194

In 2002, the City of Pasadena, Parks and Natural Resources Division prepared the Hahamongna Watershed Park Master Plan. The Hahamongna Watershed Park overlaps the southern portion of the current Project site. The document referenced the Blodgett (1987) study discussed above in SCCIC report LA-01903, which stated that although no prehistoric cultural resources were identified within the Hahamongna Watershed Park as a result of a records search and pedestrian survey, the presence of two known prehistoric sites within the vicinity of the park suggests that the area is sensitive for the presence of prehistoric cultural resources.

Previously Recorded Cultural Resources

The CHRIS records indicate that one previously recorded resource (P-19-189942) overlaps the Project site, and one resource (P-19-186535) is adjacent to the Project site. Resource P-19-189942 consists of the Hahamongna

Watershed Park and associated recreational facilities. The resource was previously found ineligible for the CRHR. Resource P-19-186535 consists of the Angeles National Forest, a registered California Historical Landmark. The Project does not overlap the forest and is not anticipated to impact this resource.

Thirteen additional previously recorded cultural resources are within 0.5-mile of the Project site. Of these, two consist of prehistoric archaeological resources, including P-19-000342, the purported village site discussed above in SCCIC report LA-01312, and an isolated granitic discoidal recovered from fill material. There is one multi-component resource consisting of multiple loci of sparse prehistoric lithic scatters, as well as a historic-era domestic refuse scatter and purported historic-era burial from the late 1800s. There are two historic-era archaeological resources consisting of a granite headstone fragment from 1865, which is associated with the multi-component site, and the remnants of an early twentieth century campground known as Teddy's Outpost. None of these prehistoric or historic-era archaeological resources have been evaluated for the NRHP or CRHR.

Additionally, there are eight built environment resources within 0.5-mile of the Project site. These resources include the Jet Propulsion Laboratory campus, the registered National Historic Landmark Space Flight Operations Facility and the NRHP eligible Space Simulator, which are both within the Jet Propulsion Laboratory campus; the USDA Forest Service Oak Grove administrative site; two individual buildings within the Arroyo Seco Ranger Station administration site; a USDA Forest Service road; and the CRHR listed single-family property built in 1924 known as the Buffum House. Table 2, below, provides further details of all previously recorded cultural resources within the records search area.

Table 2. Previously Recorded Cultural Resources Within 0.5-Mile of the Project Site

Primary Number	Trinomial	Age and Type	Description	NRHP/CRHR Eligibility	Recorded By and Year	Proximity to Project Site
P-19-000342	CA-LAN-000342	Prehistoric: Site	Suspected location of prehistoric village site known as the Millard Canyon Site. Information gathered from informal interviews conducted with the property owners in the 1960s. A cogged stone and metate fragment were identified on the property. No archaeological testing was conducted at the site.	7R: Not evaluated	Cowper, D. (1965); Eberhart, H. (1965); King, C. (1989)	Outside

Table 2. Previously Recorded Cultural Resources Within 0.5-Mile of the Project Site

Primary Number	Trinomial	Age and Type	Description	NRHP/CRHR Eligibility	Recorded By and Year	Proximity to Project Site
P-19-001599	CA-LAN-001599	Multi-component Prehistoric and Historic-age: Site	Four loci consisting of sparse prehistoric scatters of ground and chipped stone tools and a historic-age scatter of early twentieth century domestic refuse. A historic-era burial is purported in the vicinity, though no remains were identified (see P-19-002679 below).	7R: Not evaluated	King, C. (1989); Bissell, R. (1992); King, C. (1992)	Outside
P-19-002189	CA-LAN-002189	Built Environment: Government campus	Remnants of the Jet Propulsion Laboratory campus constructed in 1936.	7R: Not evaluated	McKenna, J. (1993)	Outside
P-19-002679	CA-LAN-002679	Historic-age: Feature	Partial headstone identified within previously recorded site P-19-001599. Granite headstone engraved with "M/1865" and a Christian cross.	7R: Not evaluated	Maxon, P. (1998)	Outside
P-19-003086	CA-LAN-003086	Historic-age: Site	Former location of Teddy's Outpost, an early twentieth century tourist camp site razed in 1925. None of the original buildings remain. Site is currently used as a picnic area.	7R: Not evaluated	Romani, G. (2002)	Outside
P-19-100276	—	Prehistoric: Isolate	Discoidal, granitic. Recovered from a disturbed context within fill material.	7R: Not evaluated	Maxon, P. (1998)	Outside

Table 2. Previously Recorded Cultural Resources Within 0.5-Mile of the Project Site

Primary Number	Trinomial	Age and Type	Description	NRHP/CRHR Eligibility	Recorded By and Year	Proximity to Project Site
P-19-150023	—	Built Environment: Government building	Building #1015 within the Arroyo Seco Ranger Station administration site constructed in 1934.	7R: Not evaluated	Stone, M. (1992)	Outside
P-19-150024	—	Built Environment: Government building	Building #1016 within the Arroyo Seco Ranger Station administration site constructed in 1934.	7R: Not evaluated	Stone, M. (1992)	Outside
P-19-180710	—	Built Environment: Government building	Space Flight Operations Facility built 1963 within the Jet Propulsion Laboratory campus.	3S: Appears eligible for NRHP (1984); National Historic Landmark (1985)	Butowsky, H. (1984)	Outside
P-19-180711	—	Built Environment: Government building	Space Simulator built 1961 within the Jet Propulsion Laboratory campus.	3S: Appears eligible for NRHP (1984)	Butowsky, H. (1984)	Outside
P-19-186535	—	Cultural Resource: Forest	Angeles National Forest declared in 1892.	California Historical Landmark No. 717 (1960)	Arbuckle, J. (1979)	Adjacent
P-19-186872	—	Built Environment: Road	USDA Forest Service Road 2N66 depicted on maps as early as 1926.	7R: Not evaluated	Schmidt, J. and J. Schmidt (2005)	Outside

Table 2. Previously Recorded Cultural Resources Within 0.5-Mile of the Project Site

Primary Number	Trinomial	Age and Type	Description	NRHP/CRHR Eligibility	Recorded By and Year	Proximity to Project Site
P-19-186878	—	Built Environment: Government facility	USDA Forest Service facility known as the Oak Grove Administrative Site constructed in 1941.	7R: Not evaluated	Vance, D. (2000)	Outside
P-19-188157	—	Built Environment: Single-family property	Buffum House (built 1924) located at 711 West Calaveras Street.	1CS: Listed in the CRHR (2007)	Merchell, A. (2007)	Outside
P-19-189942	—	Built Environment: Park	Hahamongna Watershed Park, formerly Oak Grove Park, in use as open-space park area since the 1880s.	6Z: found ineligible for the CRHR (2012)	McKenna, J. (2012)	Overlaps

P-19-189942 (Hahamongna Watershed Park)

The Hahamonga Watershed Park overlaps the southern portion of the Project area at Area 3 and the Gabrielino Trail/ Access Road area. The park consists of picnic areas, hiking trails, ball fields, a golf course, disc golf course, equestrian trails, parking lots, support facilities, Devil's Gate Dam and improvements, flood control reservoir, and an open recreational landscape. According to the record, Hahamongna Watershed Park has been used for recreation, to varying extents, since the 1880s. In more recent years, the park became strongly associated with the sport of disc golf in the 1970s, as one of the first courses in the Los Angeles area. In 2003, The Hahamongna Watershed Park was adopted in the Arroyo Seco Master Plan. However, according to the site record, the Hahamongna Watershed Park the Disc Golf Course did not meet the minimum age requirements for consideration as historic period resources. Though the park has had recreation related activities dating back to the 1880s, the park itself, as currently established, is a modern, post-1988 facility that has evolved since its opening to meet the demands of users and citizens. As such, the park fails to meet any of the requirements for federal or state level listings as a historical resource. The Oak Grove Disc Golf Course is a feature within the park that, in and of itself, has a unique history and recognition. However, since the original course is no longer intact and the existing course has enlarged, adapted, and reconfigured to accommodate changes in the game, rules, and levels of participation, it does not meet the basic integrity requirements for consideration in the NRHP or CRHR. The Disc Golf Course, however, was recommended eligible by the record author as a local resource "for its inception in the City of Pasadena, the development of the game, and its association with world-wide competitions and recognition by fans of the game. The Disc Golf Course does not overlap the current Project site.

2.2 Native American Coordination

Sacred Lands File and Tribal Outreach

Dudek contacted the NAHC on September 16, 2019, and requested a review of the Sacred Lands File (SLF). The NAHC replied via email on October 7, 2019 stating that the result of the SLF search was positive. Moreover, the NAHC recommended contacting the Gabrieleno Band of Mission Indians – Kizh Nation for more information. The NAHC also provide contact information for an additional four Native American individuals and/or tribal organizations who may have direct knowledge of cultural resources in or near the Project site; however, the additional four Native American individuals and/or tribal organizations have not, as of the preparation of this technical report, contacted the City requesting that the lead agency (City) provide notification to the tribe of projects in the tribe's area of traditional and cultural affiliation. No additional tribal outreach was conducted by Dudek; however, in compliance with Assembly Bill (AB) 52, the City has contacted tribal representatives that have requested to be notified of projects in Pasadena. Details of the SLF request and results including the tribal outreach process are presented in Appendix C.

The City sent notification of the proposed Project, pursuant to AB 52 on November 7, 2019, to all California Native American tribal representatives that have requested to be notified of projects within the City. The notification letter included a Project map and description inquiring if the tribe entities would like to request formal consultation in order to discuss the Project and the potential to impact any TCRs. AB 52 allows tribes 30 days after receiving notification to request consultation. If a response is not received within the allotted 30 days, it is assumed that consultation is declined. To date, one response to the City's notification letters has been received and one formal consultation has been requested. In a letter from Andrew Salas, Chairperson of the Gabrieleño Band of Mission Indians – Kizh Nation (Tribe) received by the City on November 15, 2019, Mr. Salas stated that the Project site is located within the Tribe's ancestral territory and that formal consultation was requested of the City by the Tribe.

Formal consultation was conducted over the phone on April 2, 2020 with three representatives from the City and two representatives from the Tribe present. After a description of the Project, history of water improvements and the nature of soils in the Project area were provided by the City, the Tribal representatives presented their knowledge of cultural resources in the area as well as their concerns regarding what the Tribe believes to be potential impacts to unknown cultural resources as a result of the proposed Project. The Tribal representatives stated that they request monitoring of soils during ground disturbing activities and that the Tribe is not requesting any Project alternatives or avoidance. The City contacted the Tribe via email on April 29, 2020 and provided proposed mitigation language developed based on the Tribe's input during the April 2, 2020 consultation. Within the email, the City stated that the consultation process will be considered complete absent of further communication to the contrary from the Tribe on or before May 15, 2020. On May 12, 2020, the Tribe emailed the City and provided further language and documentation supporting their request for mitigation measures stating, "we have provided to the Lead Agency substantial evidence that the proposed project may have a significant impact on our TCRs." The Tribe attached to the email specific mitigation language approved by their Tribal Government and requested the mitigation measures be incorporated into the EIR. Table 3 summarizes the results of the AB 52 process for the proposed Project. Documentation of the City's AB-52 efforts with Native American groups and/or individuals is provided in Appendix C.

Table 3. Summary of Project AB-52 Notification and Outreach

Native American Tribal Representatives	Method of Notification/Date	Response Received
Andrew Salas, Chairperson Gabrieleno Band of Mission Indians - Kizh Nation	Certified Mail; November 7, 2019	Tribe requested formal consultation, via email, regarding the proposed Project on November 15, 2019. Consultation meeting between the City and the Tribe occurred on April 2, 2020. The Tribe requested monitoring of ground disturbance during the April 2, 2020 consultation meeting. The City contacted the Tribe via email on April 29, 2020 and provided proposed mitigation language. On May 12, 2020 the Tribe emailed the City and provided further language supporting their request for mitigation measures as well as specific mitigation language approved by their Tribal Government. In response to the Tribe's request, the City revised the mitigation language to be consistent with the Tribe's requested mitigation measures via email on June 8, 2020. The Tribe responded to this email on the same day and proposed a different revised measure. This revised language is set forth in MM-TCR-1 and MM-TCR-2 of this Draft EIR. This email signifies the conclusion of the consultation pursuant to AB-52.
Sam Dunlap Gabrielino – Tongva Tribe	Certified Mail; November 7, 2019	No response received

Assembly Bill 52 Consultation

The proposed Project is subject to compliance with AB 52 (PRC 21074), which requires consideration of impacts to TCRs as part of the CEQA process, and that the lead agency notify California Native American Tribal representatives (that have requested notification) who are traditionally or culturally affiliated with the geographic area of the proposed Project. All NAHC-listed California Native American Tribal representatives that have requested project notification pursuant to AB 52 were sent letters by the City on November 7, 2019. The letters contained a project description, outline of AB 52 timing, request for consultation, and contact information for the appropriate lead agency representative. Documents related to AB 52 consultation are on file with the City. Tribal cultural resources are discussed in Section 4.9, Tribal Cultural Resources of the Draft Environmental Impact Report (EIR) for the proposed Project.

2.3 CHRID Review

Dudek also conducted a review of the California Historical Resources Inventory Database (CHRID), specifically for properties entered by the City of Pasadena. The CHRID promotes and protects cultural heritage through documenting and sharing information on historical resources. CHRID was developed through the California State Office of Historic Preservation's Certified Local Government (CLG) Grant Program and partially funded through the Federal Historic Preservation Fund Program.

All properties within the Project site were searched in the online CHRID. As a result, none of the properties located within the Project site are listed in the online CHRID and therefore have not been previously evaluated. A review of Pasadena's Historic and Landmark Districts indicates that the Project site does not fall within any existing historic districts. NASA's Space Flight Operations Facility (Jet Propulsion Laboratory), which is listed in the NRHP, is adjacent

to the Project area on the western side. A review of the CHRID confirmed that no properties within the Project site have been previously evaluated for historical significance.

Although not listed in the CHRID, 3139 Ridgeview Drive (APN 5829-026-053) is adjacent to the Project area on the eastern side. The property contains an historic house designed by Frank Lloyd Wright, Jr., and is eligible for listing in the CRHR.

2.4 Building Development and Archival Research

Building development and archival research were conducted for the Project site in an effort to establish a thorough and accurate historic context for the significance evaluations, and to confirm the building development history of the Project site and associated parcels.

Los Angeles County Office of the Assessor

On November 15, 2019, Dudek researched property characteristic records for the Project site in order to establish APNs and dates of construction.

Historical Newspaper Search

Dudek reviewed historical newspapers for the City of Pasadena and City Los Angeles in an effort to understand the development of the Project site. Sources were collected from the Pasadena Public Library, Los Angeles Public Library and online newspaper repository Newspapers.com. All information obtained from the historical newspaper search was incorporated into the historic context.

Pasadena Digital History Collaboration

Dudek reviewed historical photographs, newspaper clippings, maps, and directories held by the PDHC (Pasadena Digital History Collaboration), available online through the PDHC website. The PDHC is a cooperative partnership with Pasadena City College Shatford Library, Pasadena Museum of History, Pasadena Public Library, and other community partners. All information obtained from PDHC was incorporated into the historic context.

Historical Aerial Photographs

Historic aerial photographs of the Project site were available from Nationwide Environmental Title Research LLC (NETR) maps for the years 1952, 1953, 1954, 1964, 1972, 1977, 1978, 1980, 1982, 1994, 2002, 2003, 2004, 2005, 2009, 2010, 2012, 2014, and 2016 and from the University of California, Santa Barbara (UCSB), FrameFinder Maps for the years 1927, 1935, 1938, 1944, 1952, 1956, 1960, 1968, 1976, 1981, and 1982 (NETR 2019; UCSB 2019).

The earliest aerial photograph dates from 1927 and indicates that the Project site was a relatively undeveloped watershed, with evidence of flood damage within the canyon and at the mouth of the canyon. Informal trails and unpaved formal roads are visible in the canyon, including a short, unpaved road spur near the Bridge No. 1 location which leads to a turnaround area and a small square-plan building. This building was outside the Project site, but appears to be a square-plan, river cobble-clad building on a concrete platform, still located at the end of the spur road. Bridge No. 2 is also visible in the 1927 photograph (NETR 2019; UCSB 2019).

In the next available photograph from 1935, a king truss bridge at the canyon mouth, a bridge where Bridge No 1 (southernmost) is located, a potential above ground pipeline near Bridge No. 1, Bridge No. 2, the rock retaining walls between Bridge No. 2 and the screen building are all present, and the weir intake structure are all visible. A single structure and retaining wall are visible where the screen building is located, but it is not clear if this is the same structure (NETR 2019; UCSB 2019).

The next photograph from 1938 was taken in July 1938, and still shows extensive flood damage from the January and February 1938 floods. All bridges except Bridge No. 2 appear to have been destroyed. The Arroyo Seco Road appears to be washed out in several locations, including where the rock retaining walls were located. All buildings near the weir/intake, as well as the weir/intake have been destroyed. The structures identified as a pipeline in the original 1935 photograph appear to have been destroyed by the 1938 photograph and do not reappear in subsequent photographs until 1980 (NETR 2019; UCSB 2019).

In 1944, the Arroyo Seco Road appears repaired and paved. Bridge No 2 is visible, as well as the improved road, rock retaining walls, screen building, and a new weir intake structure, spanning the drainage. Bridge No. 3, the CCC-built king truss bridge, is obscured from view by vegetation and shadow (NETR 2019; UCSB 2019).

In 1952, the spreading basins, then-owned by Los Angeles County Flood Control District (LACFCD) first appear, as well as the LACFCD-owned flow control dams, Altadena Storm Drain, and sheds associated with the spreading basins. The gated Pasadena Water and Power (PWP)-owned sludge basins do not appear yet. The Jet Propulsion Laboratory (JPL) has begun using the basin area as an informal parking lot accessed by a bailey bridge across the creek bed, parking vehicles northeast of the spreading basins. Arroyo Seco Road is now accessed via a single switchback from the canyon floor and spreading basins. Further up-canyon, new buildings at the screen building appear. Bridge No. 3 is visible in 1952, due to vegetation changes. Bridge No. 2 and the rock retaining walls are in place and visible (NETR 2019; UCSB 2019).

There are no visible changes to the Project site in the 1956 photograph, but in the 1960 photograph the JPL parking lot has expanded and replaced the access bridge, removing the switchback access road. The gated, PWP sludge basins are still not present. By the 1968 photograph, the JPL parking lot has expanded south several hundred feet, south to the fourth spreading basin (NETR 2019; UCSB 2019).

In the 1976 photograph, Bridge No. 1, the simple slab bridge appears for the first time. Behner Wastewater Treatment Plant also first appears in the 1976 aerial photograph. The two sludge basins also appear, between the intake structure and the north-most spreading basin, in the 1976 photograph; however they do not yet have gates around them. Between the 1977 and 1980 aerial photograph, a pipeline appears just west of Bridge No. 1, and southwest of Bridge No. 2, before taking a sharp turn due west and up a steep slope. No changes were noted in 1981 or 1982 aerials. The sludge basins appear gated for the first time in 2002. No other changes were noted (NETR 2019; UCSB 2019).

INTENTIONALLY LEFT BLANK

3 Cultural Setting

3.1 Prehistoric Overview

Evidence for continuous human occupation in Southern California spans the last 10,000 years. Various attempts to parse out variability in archaeological assemblages over this broad period have led to the development of several cultural chronologies; some of these are based on geologic time, most are based on temporal trends in archaeological assemblages, and others are interpretive reconstructions. To be more inclusive, this research employs a common set of generalized terms used to describe chronological trends in assemblage composition: Paleoindian (pre-5500 BC), Archaic (8000 BC–AD 500), Late Prehistoric (AD 500–1769), and Ethnohistoric (post-AD 1769).

Paleoindian Period (pre-5500 BC)

Evidence for Paleoindian occupation in the region is tenuous. Our knowledge of associated cultural pattern(s) is informed by a relatively sparse body of data that has been collected from within an area extending from coastal San Diego, through the Mojave Desert, and beyond. One of the earliest dated archaeological assemblages in the region is located in coastal Southern California (though contemporaneous sites are present in the Channel Islands) derives from SDI-4669/W-12 in La Jolla. A human burial from SDI-4669 was radiocarbon dated to 9,590–9,920 years before present (95.4% probability) (Hector 2006). The burial is part of a larger site complex that contained more than 29 human burials associated with an assemblage that fits the Archaic profile (i.e., large amounts of ground stone, battered cobbles, and expedient flake tools). In contrast, typical Paleoindian assemblages include large stemmed projectile points, high proportions of formal lithic tools, bifacial lithic reduction strategies, and relatively small proportions of ground stone tools. Prime examples of this pattern are sites that were studied by Emma Lou Davis (1978) on Naval Air Weapons Station China Lake near Ridgecrest, California. These sites contained fluted and unfluted stemmed points and large numbers of formal flake tools (e.g., shaped scrapers, blades). Other typical Paleoindian sites include the Komodo site (MNO-679)—a multi-component fluted point site, and MNO-680—a single component Great Basined Stemmed point site (see Basgall et al. 2002). At MNO-679 and -680, ground stone tools were rare while finely made projectile points were common.

Warren et al. (2004) claimed that a biface manufacturing tradition present at the Harris site complex (SDI-149) is representative of typical Paleoindian occupation in the region that possibly dates between 10,365 and 8,200 BC (Warren et al. 2004). Termed San Dieguito (see also Rogers 1945), assemblages at the Harris site are qualitatively distinct from most others in the region because the site has large numbers of finely made bifaces (including projectile points), formal flake tools, a biface reduction trajectory, and relatively small amounts of processing tools (see also Warren 1968). Despite the unique assemblage composition, the definition of San Dieguito as a separate cultural tradition is hotly debated. Gallegos (1987) suggested that the San Dieguito pattern is simply an inland manifestation of a broader economic pattern. Gallegos's interpretation of San Dieguito has been widely accepted in recent years, in part because of the difficulty in distinguishing San Dieguito components from other assemblage constituents. In other words, it is easier to ignore San Dieguito as a distinct socioeconomic pattern than it is to draw it out of mixed assemblages.

The large number of finished bifaces (i.e., projectile points and non-projectile blades), along with large numbers of formal flake tools at the Harris site complex, is very different than nearly all other assemblages throughout the region, regardless of age. Warren et al. (2004) made this point, tabulating basic assemblage constituents for key early Holocene sites. Producing finely made bifaces and formal flake tools implies that relatively large amounts of time were spent for tool manufacture. Such a strategy contrasts with the expedient flake-based tools and cobble-core reduction strategy that typifies non-San Dieguito Archaic sites. It can be inferred from the uniquely high degree of San Dieguito assemblage formality that the Harris site complex represents a distinct economic strategy from non-San Dieguito assemblages.

San Dieguito sites are rare in the inland valleys, with one possible candidate, RIV-2798/H, located on the shore of Lake Elsinore. Excavations at Locus B at RIV-2798/H produced a toolkit consisting predominately of flaked stone tools, including crescents, points, and bifaces, and lesser amounts of groundstone tools, among other items (Grenda 1997). A calibrated and reservoir-corrected radiocarbon date from a shell produced a date of 6630 BC. Grenda (1997) suggested this site represents seasonal exploitation of lacustrine resources and small game and resembles coastal San Dieguito assemblages and spatial patterning.

If San Dieguito truly represents a distinct socioeconomic strategy from the non-San Dieguito Archaic processing regime, its rarity implies that it was not only short-lived, but that it was not as economically successful as the Archaic strategy. Such a conclusion would fit with other trends in Southern California deserts, where hunting-related tools were replaced by processing tools during the early Holocene (see Basgall and Hall 1990).

Archaic Period (8000 BC – AD 500)

The more than 2,500-year overlap between the presumed age of Paleoindian occupations and the Archaic period highlights the difficulty in defining a cultural chronology in Southern California. If San Dieguito is the only recognized Paleoindian component in the coastal Southern California, then the dominance of hunting tools implies that it derives from Great Basin adaptive strategies and is not necessarily a local adaptation. Warren et al. (2004) admitted as much, citing strong desert connections with San Dieguito. Thus, the Archaic pattern is the earliest local socioeconomic adaptation in the region (see Hale 2001, 2009).

The Archaic pattern, which has also been termed the Millingstone Horizon (among others), is relatively easy to define with assemblages that consist primarily of processing tools, such as millingstones, handstones, battered cobbles, heavy crude scrapers, incipient flake-based tools, and cobble-core reduction. These assemblages occur in all environments across the region with little variability in tool composition. Low assemblage variability over time and space among Archaic sites has been equated with cultural conservatism (see Basgall and Hall 1990; Byrd and Reddy 2002; Warren 1968; Warren et al. 2004). Despite enormous amounts of archaeological work at Archaic sites, little change in assemblage composition occurred until the bow and arrow was adopted around AD 500, as well as ceramics at approximately the same time (Griset 1996; Hale 2009). Even then, assemblage formality remained low. After the bow was adopted, small arrow points appear in large quantities and already low amounts of formal flake tools are replaced by increasing amounts of expedient flake tools. Similarly, shaped millingstones and handstones decreased in proportion relative to expedient, unshaped ground stone tools (Hale 2009). Thus, the terminus of the Archaic period is equally as hard to define as its beginning because basic assemblage constituents and patterns of manufacturing investment remain stable, complemented only by the addition of the bow and ceramics.

Late Prehistoric Period (AD 500-1769)

The period of time following the Archaic and before Ethnohistoric times (AD 1769) is commonly referred to as the Late Prehistoric (Rogers 1945; Wallace 1955; Warren et al. 2004); however, several other subdivisions continue to be used to describe various shifts in assemblage composition. In general, this period is defined by the addition of arrow points and ceramics, as well as the widespread use of bedrock mortars. The fundamental Late Prehistoric assemblage is very similar to the Archaic pattern, but includes arrow points and large quantities of fine debitage from producing arrow points, ceramics, and cremations. The appearance of mortars and pestles is difficult to place in time because most mortars are on bedrock surfaces. Some argue that the Ethnohistoric intensive acorn economy extends as far back as AD 500 (Bean and Shipek 1978). However, there is no substantial evidence that reliance on acorns, and the accompanying use of mortars and pestles, occurred before AD 1400. Millingstones and handstones persisted in higher frequencies than mortars and pestles until the last 500 years (Basgall and Hall 1990); even then, weighing the economic significance of millingstone-handstone versus mortar-pestle technology is tenuous due to incomplete information on archaeological assemblages.

3.2 Ethnographic Overview

The history of the Native American communities prior to the mid-1700s has largely been reconstructed through later mission-period and early ethnographic accounts. The first records of the Native American inhabitants of the region come predominantly from European merchants, missionaries, military personnel, and explorers. These brief, and generally peripheral, accounts were prepared with the intent of furthering respective colonial and economic aims and were combined with observations of the landscape. They were not intended to be unbiased accounts regarding the cultural structures and community practices of the newly encountered cultural groups. The establishment of the missions in the region brought more extensive documentation of Native American communities, though these groups did not become the focus of formal and in-depth ethnographic study until the early twentieth century (Bean and Shipek 1978; Boscana 1846; Geiger and Meighan 1976; Harrington 1934; Laylander 2000; Sparkman 1908; White 1963). The principal intent of these researchers was to record the precontact, culturally specific practices, ideologies, and languages that had survived the destabilizing effects of missionization and colonialism. This research, often understood as “salvage ethnography,” was driven by the understanding that traditional knowledge was being lost due to the impacts of modernization and cultural assimilation. Alfred Kroeber applied his “memory culture” approach (Lightfoot 2005: 32) by recording languages and oral histories within the region. Ethnographic research by Dubois, Kroeber, Harrington, Spier, and others during the early twentieth century seemed to indicate that traditional cultural practices and beliefs survived among local Native American communities.

It is important to note that even though there were many informants for these early ethnographies who were able to provide information from personal experiences about native life before the Europeans, a significantly large proportion of these informants were born after 1850 (Heizer and Nissen 1973); therefore, the documentation of pre-contact, aboriginal culture was being increasingly supplied by individuals born in California after considerable contact with Europeans. As Robert F. Heizer (1978) stated, this is an important issue to note when examining these ethnographies, since considerable culture change had undoubtedly occurred by 1850 among the Native American survivors of California.

Based on ethnographic information, it is believed that at least 88 different languages were spoken from Baja California Sur to the southern Oregon state border at the time of Spanish contact (Johnson and Lorenz 2006, p.

34). The distribution of recorded Native American languages has been dispersed as a geographic mosaic across California through six primary language families (Golla 2007).

Victor Golla has contended that one can interpret the amount of variability within specific language groups as being associated with the relative "time depth" of the speaking populations (Golla 2007: 80) A large amount of variation within the language of a group represents a greater time depth then a group's language with less internal diversity. One method that he has employed is by drawing comparisons with historically documented changes in Germanic and Romantic language groups. Golla has observed that the "absolute chronology of the internal diversification within a language family" can be correlated with archaeological dates (2007:71). This type of interpretation is modeled on concepts of genetic drift and gene flows that are associated with migration and population isolation in the biological sciences.

The tribes of this area have traditionally spoken Takic languages that may be assigned to the larger Uto–Aztecan family (Golla 2007, p. 74). These groups include the Gabrielino (alternately Gabrieleño), Cahuilla, and Serrano. Golla has interpreted the amount of internal diversity within these language-speaking communities to reflect a time depth of approximately 2,000 years. Other researchers have contended that Takic may have diverged from Uto–Aztecan ca. 2600 BC–AD 1, which was later followed by the diversification within the Takic speaking tribes, occurring approximately 1500 BC–AD 1000 (Laylander 2000).

Gabrielino (Gabrieleño)/Tongva

The archaeological record indicates that project site and vicinity was occupied by the Gabrieleño, who arrived in the Los Angeles Basin around 500 B.C. Surrounding cultural groups included the Chumash and Tataviam to the northwest, the Serrano and Cahuilla to the northeast, and the Juaneño and Luiseño to the southeast.

The name "Gabrieliño" or "Gabrieleño" denotes those people who were administered by the Spanish from the San Gabriel Mission, which included people from the Gabrieleño area proper as well as other social groups (Bean and Smith 1978; Kroeber 1925). Therefore, in the post-Contact period, the name does not necessarily identify a specific ethnic or tribal group. The names by which Native Americans in southern California identified themselves have, in some cases, been lost. Many modern Gabrieleño identify themselves as the Tongva (King 1994), within which there are a number of regional bands. Though the names "Tongva" or "Gabrieleño" are the most common names used by modern Native American groups, and are recognized by the Native American Heritage Commission, there are groups within the region that self-identify differently, such as the Gabrielino Band of Mission Indians - Kizh Nation. In order to be inclusive of the majority of tribal entities within the region, the name "Tongva" or "Gabrieleño" are used within this report.

Tongva lands encompassed the greater Los Angeles Basin and three Channel Islands, San Clemente, San Nicolas, and Santa Catalina. The Tongva established large, permanent villages in the fertile lowlands along rivers and streams, and in sheltered areas along the coast, stretching from the foothills of the San Gabriel Mountains to the Pacific Ocean. A total tribal population has been estimated of at least 5,000 (Bean and Smith 1978), but recent ethnohistoric work suggests a number approaching 10,000 (O'Neil 2002). Houses constructed by the Tongva were large, circular, domed structures made of willow poles thatched with tule that could hold up to 50 people (Bean and Smith 1978). Other structures served as sweathouses, menstrual huts, ceremonial enclosures, and probably communal granaries. Cleared fields for races and games, such as lacrosse and pole throwing, were created adjacent to Tongva villages (McCawley 1996). Archaeological sites composed of villages with various sized structures have been identified.

The largest, and best documented, ethnographic Tongva village in the vicinity was that of *Yanga* (also known as Yaangna, Janga, and Yabit), which was in the vicinity of the downtown Los Angeles (McCawley 1996:56-57; NEA and King 2004). This village was reportedly first encountered by the Portola expedition in 1769. In 1771, Mission San Gabriel was established. Yanga provided a large number of the recruitments to this mission; however, following the founding of the Pueblo of Los Angeles in 1781, opportunities for local paid work became increasingly common, which had the result of reducing the number of Native American neophytes from the immediately surrounding area (NEA and King 2004). Mission records indicate that 179 Gabrieleno inhabitants of Yanga were recruited to San Gabriel Mission (King 2000; NEA and King 2004: 104). Based on this information, Yanga may have been the most populated village in the Western Gabrieleno territory. Second in size, and less thoroughly documented, the village of Cahuenga was located slightly closer, just north of the Cahuenga Pass.

Father Juan Crespi passed through the area near Yanga on August 2-3, 1769. The pertinent sections from his translated diary are provided here:

> Sage for refreshment is very plentiful at all three rivers and very good here at the Porciúncula [the Los Angeles River]. At once on our reaching here, eight heathens came over from a good sized village encamped at this pleasing spot among some trees. They came bringing two or three large bowls or baskets half-full of very good sage with other sorts of grass seeds that they consume; all brought their bows and arrows but with the strings removed from the bows. In his hands the chief bore strings of shell beads of the sort that they use, and on reaching the camp they threw the handfuls of these beads at each of us. Some of the heathens came up smoking on pipes made of baked clay, and they blew three mouthfuls of smoke into the air toward each one of us. The Captain and myself gave them tobacco, and he gave them our own kind of beads, and accepted the sage from them and gave us a share of it for refreshment; and very delicious sage it is for that purpose.
>
> We set out at a half past six in the morning from this pleasing, lush river and valley of Our Lady of Angeles of La Porciúncula. We crossed the river here where it is carrying a good deal of water almost at ground level, and on crossing it, came into a great vineyard of grapevines and countless rose bushes having a great many open blossoms, all of it very dark friable soil. Keeping upon a westerly course over very grass-grown, entirely level soils with grand grasses, on going about half a league we came upon the village belonging to this place, where they came out to meet and see us, and men, women, and children in good numbers, on approaching they commenced howling at us though they had been wolves, just as before back at the spot called San Francisco Solano. We greeted them and they wished to give us seeds. As we had nothing at hand to carry them in, we refused [Brown 2002:339-341, 343].

The Tongva subsistence economy was centered on gathering and hunting. The surrounding environment was rich and varied, and the tribe exploited mountains, foothills, valleys, deserts, riparian, estuarine, and open and rocky coastal eco-niches. Like that of most native Californians, acorns were the staple food (an established industry by the time of the early Intermediate Period). Acorns were supplemented by the roots, leaves, seeds, and fruits of a wide variety of flora (e.g., islay, cactus, yucca, sages, and agave). Fresh water and saltwater fish, shellfish, birds, reptiles, and insects, as well as large and small mammals, were also consumed (Bean and Smith 1978: 546; Kroeber 1925; McCawley 1996).

A wide variety of tools and implements were used by the Tongva to gather and collect food resources. These included the bow and arrow, traps, nets, blinds, throwing sticks and slings, spears, harpoons, and hooks.

Groups residing near the ocean used oceangoing plank canoes and tule balsa canoes for fishing, travel, and trade between the mainland and the Channel Islands (McCawley 1996).

Tongva people processed food with a variety of tools, including hammerstones and anvils, mortars and pestles, manos and metates, strainers, leaching baskets and bowls, knives, bone saws, and wooden drying racks. Food was consumed from a variety of vessels. Catalina Island steatite was used to make ollas and cooking vessels (Blackburn 1963; Kroeber 1925; McCawley 1996).

At the time of Spanish contact, the basis of Tongva religious life was the Chinigchinich cult, centered on the last of a series of heroic mythological figures. Chinigchinich gave instruction on laws and institutions, and also taught the people how to dance, the primary religious act for this society. He later withdrew into heaven, where he rewarded the faithful and punished those who disobeyed his laws (Kroeber 1925). The Chinigchinich religion seems to have been relatively new when the Spanish arrived. It was spreading south into the Southern Takic groups even as Christian missions were being built and may represent a mixture of native and Christian belief and practices (McCawley 1996).

Deceased Tongva were either buried or cremated, with inhumation more common on the Channel Islands and the neighboring mainland coast and cremation predominating on the remainder of the coast and in the interior (Harrington 1942; McCawley 1996). Cremation ashes have been found in archaeological contexts buried within stone bowls and in shell dishes (Ashby and Winterbourne 1966), as well as scattered among broken ground stone implements (Cleland et al. 2007). Archaeological data such as these correspond with ethnographic descriptions of an elaborate mourning ceremony that included a wide variety of offerings, including seeds, stone grinding tools, otter skins, baskets, wood tools, shell beads, bone and shell ornaments, and projectile points and knives. Offerings varied with the sex and status of the deceased (Johnston 1962; McCawley 1996; Reid 1926). At the behest of the Spanish missionaries, cremation essentially ceased during the post-Contact period (McCawley 1996).

3.3 Historic Period Overview

Post-Contact history for the State of California is generally divided into three periods: the Spanish Period (1769–1821), Mexican Period (1821–1848), and American Period (1846–present). Although Spanish, Russian, and British explorers visited the area for brief periods between 1529 and 1769, the Spanish Period in California begins with the establishment in 1769 of a settlement at San Diego and the founding of Mission San Diego de Alcalá, the first of 21 missions constructed between 1769 and 1823. Independence from Spain in 1821 marks the beginning of the Mexican Period, and the signing of the Treaty of Guadalupe Hidalgo in 1848, ending the Mexican–American War, signals the beginning of the American Period when California became a territory of the United States.

Spanish Period

Spanish explorers made sailing expeditions along the coast of southern California between the mid-1500s and mid-1700s. In search of the legendary Northwest Passage, Juan Rodríquez Cabríllo stopped in 1542 at present-day San Diego Bay. With his crew, Cabríllo explored the shorelines of present Catalina Island as well as San Pedro and Santa Monica Bays. Much of the present California and Oregon coastline was mapped and recorded in the next half-century by Spanish naval officer Sebastián Vizcaíno. Vizcaíno's crew also landed on Santa Catalina Island and at San Pedro and Santa Monica Bays, giving each location its long-standing name. The Spanish crown laid claim to California based on the surveys conducted by Cabríllo and Vizcaíno (Bancroft 1885; Gumprecht 1999).

More than 200 years passed before Spain began the colonization and inland exploration of Alta California. The 1769 overland expedition by Captain Gaspar de Portolá marks the beginning of California's Historic period, occurring just after the King of Spain installed the Franciscan Order to direct religious and colonization matters in assigned territories of the Americas. With a band of 64 soldiers, missionaries, Baja (lower) California Native Americans, and Mexican civilians, Portolá established the Presidio of San Diego, a fortified military outpost, as the first Spanish settlement in Alta California. In July of 1769, while Portolá was exploring southern California, Franciscan Fr. Junípero Serra founded Mission San Diego de Alcalá at Presidio Hill, the first of the 21 missions that would be established in Alta California by the Spanish and the Franciscan Order between 1769 and 1823.

The Portolá expedition first reached the present-day boundaries of Los Angeles in August 1769, thereby becoming the first Europeans to visit the area. Father Crespi named "the campsite by the river Nuestra Señora la Reina de los Angeles de la Porciúncula" or "Our Lady the Queen of the Angels of the Porciúncula." Two years later, Friar Junípero Serra returned to the valley to establish a Catholic mission, the Mission San Gabriel Arcángel, on September 8, 1771 (Hoover et al 2002). In 1795 Fr. Fermin Lasuen ordered a new report on possible mission sites, and the Francisco Reyes Rancho was ultimately chosen as the new mission site, with Mission San Fernando Rey de España being formally founded in 1797 (Perkins 1957). Shortly thereafter, many of the local Gabrielino and Tataviam people were removed from their homeland, relocated to the mission, and their native lifeways taken away.

Mexican Period

A major emphasis during the Spanish Period in California was the construction of missions and associated presidios to integrate the Native American population into Christianity and communal enterprise. Incentives were also provided to bring settlers to pueblos or towns, but just three pueblos were established during the Spanish Period, only two of which were successful and remain as California cities (San José and Los Angeles). Several factors kept growth within Alta California to a minimum, including the threat of foreign invasion, political dissatisfaction, and unrest among the indigenous population. After more than a decade of intermittent rebellion and warfare, New Spain (Mexico and the California territory) won independence from Spain in 1821. In 1822, the Mexican legislative body in California ended isolationist policies designed to protect the Spanish monopoly on trade, and decreed California ports open to foreign merchants (Dallas 1955).

Extensive land grants were established in the interior during the Mexican Period, in part to increase the population inland from the more settled coastal areas where the Spanish had first concentrated their colonization efforts. Rancho San Vicente y Santa Monica, where the project site is located, was granted by Governor Juan Alvarado to Francisco Sepulveda in 1838. The Rancho encompasses present day Santa Monica, Brentwood, Mandeville Canyon, portions of the Santa Monica Mountains, and parts of West Los Angeles (Hoffman 1862: 63).

During the supremacy of the ranchos (1834–1848), landowners largely focused on the cattle industry and devoted large tracts to grazing. Cattle hides became a primary southern California export, providing a commodity to trade for goods from the east and other areas in the United States and Mexico. The number of nonnative inhabitants increased during this period because of the influx of explorers, trappers, and ranchers associated with the land grants. The rising California population contributed to the introduction and rise of diseases foreign to the Native American population, who had no associated immunities.

American Period

War in 1846 between Mexico and the United States precipitated the Battle of Chino, a clash between resident Californios and Americans in the San Bernardino area. The Mexican-American War ended with the Treaty of Guadalupe Hidalgo in 1848, ushering California into its American Period.

California officially became a state with the Compromise of 1850, which also designated Utah and New Mexico (with present-day Arizona) as U.S. Territories (Waugh 2003). Horticulture and livestock, based primarily on cattle as the currency and staple of the rancho system, continued to dominate the southern California economy through 1850s. The Gold Rush began in 1848, and with the influx of people seeking gold, cattle were no longer desired mainly for their hides but also as a source of meat and other goods. During the 1850s cattle boom, rancho vaqueros drove large herds from southern to northern California to feed that region's burgeoning mining and commercial boom. Cattle were at first driven along major trails or roads such as the Gila Trail or Southern Overland Trail, then were transported by trains when available. The cattle boom ended for southern California as neighbor states and territories drove herds to northern California at reduced prices. Operation of the huge ranchos became increasingly difficult, and droughts severely reduced their productivity (Cleland 2005).

Historical Overview of the City of Pasadena

Like many cities in the San Gabriel Valley, the City of Pasadena's history is linked to the Mission San Gabriel and the subsequent privatization of ranchos once owned by the Mission in the eighteenth and nineteenth centuries. By 1827, the Mission ranchos were being partitioned, sold, and developed independent of the Mission. The first rancho sold was Rancho San Pasqual in 1827 (Figure 8), followed by Rancho Santa Anita and Rancho San Rafael. Portions of these three ranchos would later become the City of Pasadena (HRG 2007).

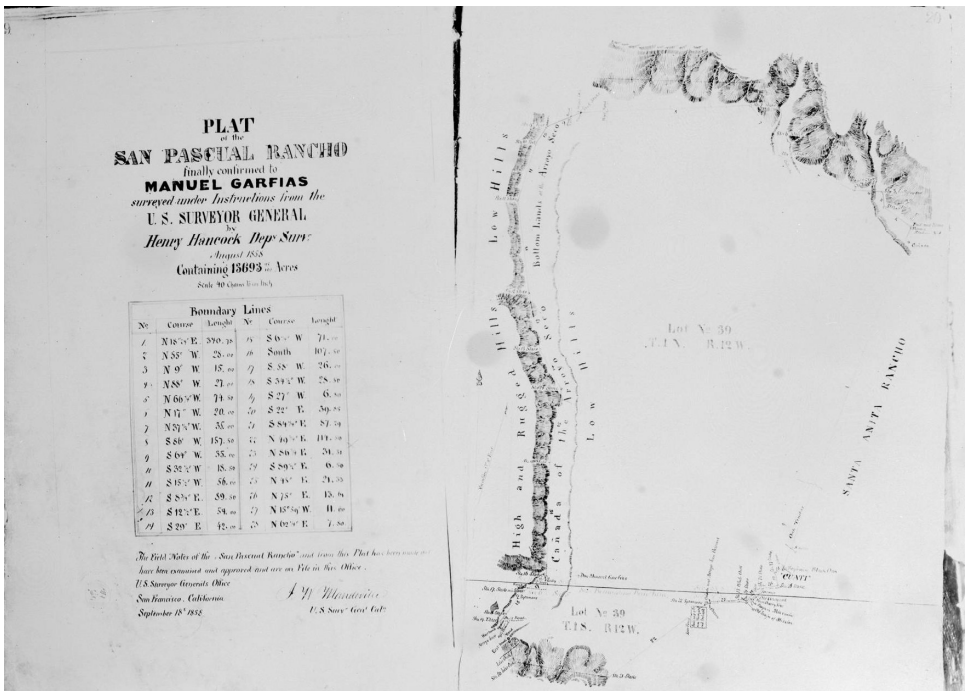

Figure 8. San Pasqual Rancho, 1858 (C.C. Pierce Collection of Photographs, Huntington Digital Library)

In 1874 Benjamin Davis Wilson, owner of a portion of the Rancho San Pasqual, negotiated a deal with Daniel Berry from Indiana. Berry, like many Americans at the time, was caught up in the concept of Manifest Destiny and sought land in the west with his fellow farmers from Indiana. He hoped to cultivate the warm climate crops that were not possible to grow in his home state. Berry secured a deal with Wilson for a portion of the Rancho San Pasqual and immediately surveyed and subdivided the property into 100 parcels. Quick development of the parcels and the establishment of a water conveyance system made the area conducive to farming and development. By 1875, the name Pasadena was chosen for the area. Growth and development continued rapidly in Pasadena and by 1880 the population had reached 383 (HRG 2007).

Growth and development continued in Pasadena throughout the 1880s and like other areas of Southern California, Pasadena experienced a land speculation boom. The land speculation boom was a result of the development of the railroad in Southern California and cities like Pasadena saw increases in land values with land selling for $1,000 per acre in 1886. The boom of the 1880s gave way to huge property subdivisions and population increases in Pasadena, as evidenced by the fact that more than 400 new buildings were constructed during this time (Grimes 2010; O'Conner 1993).

During the 1880s, Pasadena also became a desirable destination and greatly benefited from the tourism industry and grew to support temporary visitors. Pasadena was a particularly attractive climate, and health tourism was also a major component of its early economy. Events like the Tournament of Roses parade and East-West football game, which began in 1902 as the first of its kind in the nation introduced visitors to a mild winter climate and the beauty of the city. By 1900, Pasadena was supporting approximately 60,000 visitors during the winter months. The once-agricultural community quickly became a tourist destination, which led to the development of the commercial center, but also the hotel industry and other supporting service industries for seasonal visitors (Bricker et. al. 1992; HRG 2007; O'Conner 1993).

In addition to becoming a tourist destination, advancements in transportation including rail and trolley lines, made Pasadena a desirable place to live outside of the city of Los Angeles. Although the population boom precipitated the need for residential buildings, it also created a need for a more substantial commercial district in Pasadena. Colorado Boulevard became the main commercial thoroughfare with subsequent development on streets intersecting Colorado Boulevard like Fair Oaks Avenue and Raymond Avenue (Grimes 2010; HRG 2007).

By the 1890s, the population of the City reached 4,882 and expansion from the central city core led to development in all directions. Population increases and continued increases in tourism led to expanded cultural and social services in the city including an opera house, firehouse, and public library. The most remarkable institutions from the 1890s however, were the Tournament of Roses in 1890 and California Institute of Technology in 1891 (which became known as Caltech). Transportation also improved greatly during the 1890s with the electric streetcar service from Los Angeles to Pasadena established in 1895. The social and technological growth of the City in the 1890s led to the annexation of East Pasadena in 1904 and North Pasadena in 1906 (Grimes 2010; HRG 2007; O'Conner 1993).

Architectural history development patterns in Pasadena ran parallel to the population growth and development going on in the late 1800s. By the 1880s, large mansions began to emerge and prominent architects began to design homes for the wealthy residents of the City. One of the most significant movements of the time seen in Pasadena is the Arts and Crafts Movement, which dominated the architectural development of Southern California for years to come. Leading the movement in Pasadena were Charles and Henry Greene, who revolutionized the architectural development of Southern California with their high style California Bungalows. Population growth and

development also warranted a switch in Pasadena from only single-family residential living to higher density urban options. Pulling from the traditions of Greene and Greene, the Bungalow Court emerged to meet the growing housing needs of Pasadena. The Bungalow Court became a model for middle class architecture throughout Southern California and provided solutions to housing issues for many years to come (Grimes 2010; HRG 2007; Makinson 1977).

Technology was also increasingly important at the turn of the century and Pasadena like other cities saw the influence of the motor vehicle start to change the City's landscape and development. Pasadena embraced the automobile and by 1915 there was one automobile for every four residents of the City, which was significantly higher than other cities in the United States. Growing dependency on automobiles led to major thoroughfares like Colorado Boulevard developing to support the new industry with numerous car dealerships and related services. Infrastructure projects also began during the early years of the twentieth century with large-scale projects like the Colorado Street Bridge in 1913, the first of several Beaux Arts-style bridges which spanned the Arroyo Seco, connecting Pasadena to the towns of Eagle Rock and Glendale. Subsequent road constructions and bridge constructions continued in the 1920s and 1930s to support the influx of people to Pasadena and California (HRG 2007; O'Conner 1993).

Like other cities in the 1920s, Pasadena saw another population boom. The population of the city began the decade at 45,000 and ended the decade in 1930 with a population of 76,000. Pasadena's development at this time was largely influenced by the City Beautiful Movement and this period of growth led to the erection of the City Hall building. As seen in the previous population boom, Pasadena also experienced cultural expansion during this time with the erection of the Pasadena Playhouse in 1925 and the Rose Bowl Stadium in 1922. Despite these grand additions to the City in the 1920s, the City was also effected by the Great Depression and experienced a brief economic downturn. The Great Depression marked a slower economic period in Pasadena, but the city favored well in comparison to other cities throughout California. One of the hardest hit industries in Pasadena at the time was the tourism industry, as many people lacked the money for extravagant vacations and resorts. By the late 1930s the tourism industry was devastated and most of the resort hotels and amenities were closed (O'Conner 1993).

Although the post-war and depression years marked a bleak time in American history, the shift in architectural design during this period forever changed the American landscape. The work of early Modernists like Richard Neutra and Rudolph M. Schindler set the stage for Modernism to grow in Los Angeles with their use of International Style. The International Style combined economical materials, forward thinking and innovation. Important architects like Irving Gill, Frank Lloyd Wright, and Harwell Hamilton Harris made significant contributions to the Modernist movement in California (HRG 2007; O'Conner 1993).

The importance of innovation and forward thinking worked well for Pasadena once the United States entered World War II. Resort-era hotels remaining in the city were converted to military functions and with Caltech and Jet JPL research and development going toward the war effort, Pasadena was revived. Innovation and forward thinking also became a huge factor in the housing market once the war concluded as there was an influx of returning soldiers who required housing. Government agencies like the Federal Housing Administration (FHA) provided instructions for developers and builders for the best ways to deal with the population boom. They stressed the importance of proper planning, mass produced materials, and small house types. Following the war, these ideas were heavily implemented throughout the United States (HRG 2007).

Victory in World War II also ushered in a new era of hope and prosperity for the United States and from an architectural perspective, designers and architects embraced this optimism and saw it as a chance to move design

forward. The focus on economical materials started by the early Modernists had a resurgence, as did the mass production of materials perfected during the war years. The other factor that became so important was the relationship between the automobile and commercial and residential living. New technologies and population increases made automobiles more prevalent than ever, and architectural development moved ahead, making Pasadena a key location for these modern movements (HRG 2007).

In the 1940s and 1950s, new industries including manufacturing and science companies came to the city, the population continued to boom, and the city developed at a rapid speed. Culture remained a high priority in Pasadena during this time of growth and development with the Pasadena Playhouse and the Pasadena Art Museum. However, this growth and development came with a host of logistical problems as the city began to run out of space and experienced major issues with traffic congestion. For these reasons, many industries felt they could no longer grow and expand in Pasadena and they sought land elsewhere (HRG 2007).

The City of Pasadena responded to this industrial exodus with the establishment of the Chamber of Commerce in 1959 and the formation of a redevelopment agency. Attracting new forms of business was key for Pasadena and the first step in preserving the vast historical resources of the city. The primary business district moved east of Fair Oaks and Colorado leaving the downtown full of vacant storefronts and dilapidation. In 1969, the Pasadena Art Museum of Modern Art (now the Norton Simon Museum of Art) opened while the renowned Pasadena Playhouse closed and was sold at auction (HRG 2007; City of Pasadena 2019).

Pasadena began to experience a period of economic revitalization at the start of the 1970s. Plans were made for the construction of the Foothill and Long Beach Freeways that would link Pasadena to other major freeways to the east, west, and south. Old Pasadena was slated for demolition in 1971 under the city's Central District Improvement Plan despite strong opposition to save it. Groups like the Pasadena Development Agency and Pasadena Heritage worked to protect the architectural history of the city, including Old Pasadena, and bring back economic stability. Large corporations began to relocate their headquarters to Pasadena. Development restarted with the construction of the Conference Center, the Plaza Pasadena Mall, condominiums, office space, and commercial buildings. In 1979, the city passed the Urban Conservation Overlay Zone, which saved the historic structures of Old Pasadena from demolition (City of Pasadena 2019b; Old Pasadena 2016).

Between 1980 and 1990, the population of Pasadena increased by 11% and with the increase in population came a surge in development and ethnic diversity. In 1980, a charter amendment approved by voters changed Pasadena's election system to district only elections allowing for more diversity in the local government. In 1993, the Board of Directors changed their name to the City Council and a mayor was elected on a rotating basis from the senior City Councilmembers. Throughout the 1990s, Pasadena continued to experience civic beautification campaigns including the 1993 Old Pasadena Streetscape and Alleyways Project. Newly installed parking meters in Old Pasadena and a borrowed $5 million payed for the construction of new sidewalks, street furniture, trees, and lighting. The city turned the alleys info functional walkways that granted easy access to restaurants and shops. Old Pasadena boomed and encouraged other business districts to install parking meters in order to finance public improvements. In 2002, the Los Angeles County Metro's Gold Line light rail reopened Pasadena for rapid transit. High-density condominiums began to be constructed throughout the city, which increased the city's population (Shoup 2018; City of Pasadena 2019b; Old Pasadena 2016).

3.4 Project Site History

Arroyo Seco Canyon Developments (1887-present)

The Project site is located within the Hahamongna Watershed Master Plan Area, within the larger Arroyo Seco which also includes the Central and Lower Arroyo Seco Master Plan Areas. Arroyo Seco Canyon is an important watershed which begins in the San Gabriel Mountains at Mount Wilson, continues west of the cities of Pasadena and Altadena, and extends south to join the Los Angeles River. The canyon was used as a prehistoric through-route for the Hahamong'nas (a band of native Tongva people), connecting the area that is now Hahamongna Watershed Park to trade partners to the north. The canyon continued to be a source of water, recreation, and travel route well into the nineteenth century. As early as 1887, the City of Pasadena and citizens were recognizing the Arroyo Seco as a whole for its benefits as a park. Locals swam at the pools at Devil's Gate, hiked to the waterfall at Millard Canyon, and took pack animal trips to Mount Wilson. At the turn of the twentieth century, Arroyo Seco enjoyed a long period of recreational development, such as at Camp Oakwilde, a rustic resort constructed in 1911, and several private and public cabins throughout the canyon. In 1911, the City of Pasadena annexed the lower and middle sections of the Arroyo Seco, and in 1919, the area now known as Hahamongna Watershed Park was annexed to the city (City of Pasadena 2019b).

With the recreation movement taking hold in the Arroyo Seco, and the Arts and Crafts Movement (1895-1920) influencing building and landscape architecture at large in southern California, the area within and around the Arroyo Seco developed several unifying features that were consistently used throughout the Arroyo Seco canyon area, including parks, trails, landscaping features, neighborhoods, and civic structures. These included the emphasis on the natural environment and use of native cobblestone in walls, gates, and fences, especially as accents to pedestrian walkways and roads that might otherwise have a utilitarian appearance. Native rock cobblestone walls also complemented the larger Arts and Crafts-style residential architecture of Pasadena. Even after the Arts and Crafts Movement waned in popularity, the use of native cobblestone persisted as a unifying landscape feature in the Arroyo Seco (Bricker et al. 1992; Pasadena 2003a).

A road through Arroyo Seco Canyon has been visible on maps since the 1894 "Los Angeles, Calif." topographical map of the area. This earliest topographical map of the area shows the road extending between the Los Angeles Terminal Railroad Line and a mountain hamlet called Las Casitas before looping back west and south to La Cañada, following an older trail forged by the native Gabrielinos. The road was subjected to several floods over the years, damaging the road bed, bridges, dams and other infrastructure placed along it. Arroyo Seco Canyon Road, also known as Arroyo Boulevard, was paved for use as a county highway c. 1920, during which time Bridge No. 2 was constructed as a necessary improvement along the Arroyo Boulevard/Gabrielino Trail. Bridge No. 2 appears on the very first available aerial map from 1927, as well as other smaller bridges along the road and at the mouth of the canyon. A secondary spur road, leading east from the Bridge No. 1 crossing location, is also present on aerial photos as early as 1927. At the end of this spur road was a square-plan, river cobble-clad building on a concrete platform and a small, concrete diversion dam. Both of these structures are located outside of the Project site (LAT 1919; USGS 2019).

Arroyo Seco Road appears improved by bridges in the earliest available aerial photograph from 1927; however, subsequent floods in 1934 and 1938 appear to obliterate the road and bridges in the canyon, with the exception of Bridge No. 2. The road between Devil's Gate Dam and Oak Wilde, a forest community some 4 miles up Arroyo Seco Road, remained closed until 1939, the same year local Civilian Conservation Corps (CCC) Company 903

constructed Bridge No. 3. Despite the CCC improvements, the City of Pasadena road section outside of U. S. Forest Service lands was not officially repaired until 1941 (LAT 1938, 1940a, 1940b; Pasadena Star News 1939).

Local CCC Company 903 was assigned to the U.S. Forest Service in 1933 to work on projects within Arroyo Seco Canyon and San Gabriel Mountains. One of Roosevelt's more successful New Deal programs, the CCC was a work relief program focused on environmental projects, providing employment to young men during the Great Depression. By June 1, 1933, over 1,400 working camps were established, employing more than 300,000 men, representing the most rapid peace-time mobilization in U.S history. Working on projects for the U.S. Forest Service, the National Park Service, and the Departments of Agriculture and Interior, CCC workers fought forest fires, planted trees, cleaned and maintained access roads, re-seeded grazing lands, implemented soil erosion controls, and built wildlife refuges, fish-rearing facilities, animal shelters, and water storage basins. Roosevelt also authorized the CCC to build bridges and campground facilities in an effort to encourage people to go enjoy America's natural resources. Although focused on providing employment for young unskilled men between 18 and 25 years of age, the CCC also employed WW1 army veterans, skilled foresters and craftsmen, and approximately 88,000 Native Americans from Indian reservations. The CCC reached its largest employment in August 1935, with more than 500,000 men working in 2,900 camps. Estimates indicate that approximately five percent of the US male population, about three million men, participated in the CCC.

The CCC planted more than three billion trees and constructed facilities in more than 800 parks nationwide during the nine years which the group was in existence, helping shape our modern national and state park systems (History.com 2010). In 1941, the Arroyo Seco Project, part of a Los Angeles River watershed upstream work project, began with the Millard Canyon channel and road improvement project. A joint effort between Forest Service and the City of Pasadena engineers, the improvements in Millard Canyon entailed channel improvements and creating a new road cut above the channel bed with a "seven foot wall of native rock" (Pasadena Post 1941:17). The stretch of road to be improved by the retaining walls and barriers was described as above Devil's Gate Dam, and below the Brown Mountain truck trail turn off. The road improvements were in support of the larger goal of the watershed upstream work project: to build the Brown Mountain Dam near Arroyo Seco headwaters as a means of flood control. When the upstream project was completed, the City entered into a contract with the Forest Service to share costs of maintenance and patrols for the sections of Arroyo Seco and Millard Canyon that were in City of Pasadena Land, but adjacent to Forest Service land. Improvements are also visible in aerial photographs between 1938 and 1944, such as the construction of Bridge No. 1, road pavement, and the construction of native rock retaining walls and barriers (Pasadena Post, 1941a, 1941b; Pasadena Star News 1941, 1944; UCSB 2019).

Screen Building Complex (c. 1932-1944)

The Screen Building Complex consists of the screen building (formerly known as the Chlorine Plant, per as-built drawings), intake structure, and a flashboard dam/weir. The screen building is identified on 1932 as-built plans for the Arroyo Seco Headworks (Work Order 2802, Pasadena Water Department 1932), indicating that it was constructed around this time. As such, it is likely that these components were constructed by the CCC during their Arroyo Seco improvements campaign in the 1930s. A flashboard dam/weir was also part of this as-built drawing set, and was constructed at this location in 1932. It is possible that an earlier weir, dam, or pipeline preceded its construction, but this could not be verified in archival research, including aerial photographs or historical maps. An image of the weir from March 5, 1937, shows that there was a modest concrete structure with angled buttresses and a paved horizontal surface downstream, leading to a short drop off to the natural streambed (Figure 9). The drop off aligns with retaining walls on either end. A concrete wing wall lines the cut bank side of the stream where the weir meets it, and a small concrete platform (the top deck of the intake structure) rests adjacent to the wing

wall on mounded soil. The 1938 historic aerial image shows the devastation wrought by flooding that year; the screen building is visible, but the c. 1932 weir appears to have been destroyed. In the next 1944 historic aerial image clearly shows the screen building, intake structure, and a new weir. The new weir, visible in the 1944 aerial photograph, is of a different design than the 1932 weir, and a cobblestone wall is visible rising from the original retaining wall on the right (east or cutbank) side of the weir. The cobblestone wall supports a concrete platform, of which the original rectangular concrete platform is incorporated, indicating extensive repairs and/or additional damage during later flood events.

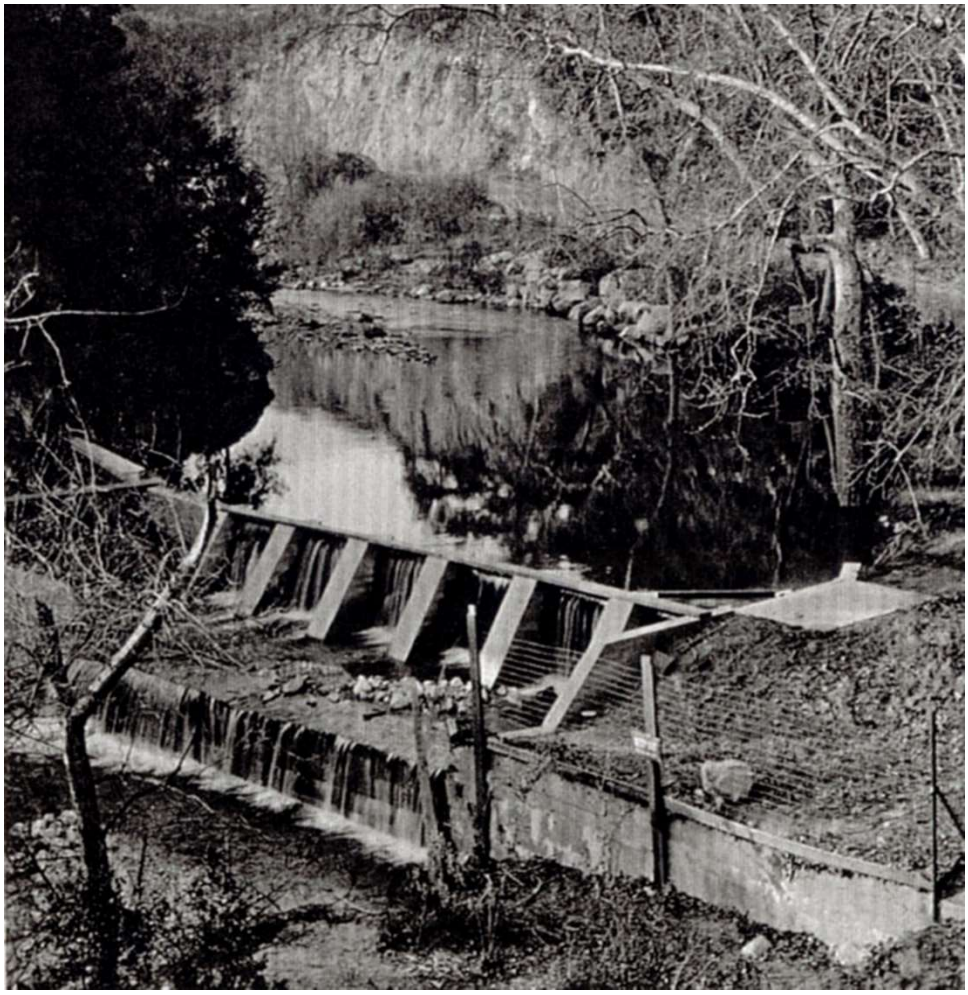

Figure 9. Weir and intake structure, dated March 5, 1937, view looking upstream (ASF 2019)

Debris basins and flood control infrastructure (1948)

Flood control in Arroyo Seco began after the especially costly 1914 and 1916 floods damaged large portions of Los Angeles County farmland and urban areas. In 1915, the LACFCD was established in response to the in 1914 flood, and would protect an area of 2,760 square miles. Investment was initially delayed by the onset of World War I, but the first flood control feature built in the Arroyo Seco was the Devil's Gate Dam: designed in 1916, funded by bonds in 1917, and erected by Los Angeles County Department of Public Works by 1920 (Brick 2011; Pasadena Star News 1916; SB&C 1919; Van Wormer 1991).

The City of Pasadena, which had water rights to Arroyo Seco, began a spreading program in Arroyo Seco in 1914 to replenish the Raymond Basin aquifer; however, the program was abandoned in 1924 due to drought. The remnants of the 1914 spreading basins were washed out in 1936 when the Arroyo Seco stream changed its course to the east side of the Arroyo. Historic aerial photographs and maps indicate that the LACFCD-owned spreading grounds were installed in 1948, as a result of a 1940 push to build upstream flood control features in the Angeles National Forest. $1.17 million was used towards the establishment of silt and debris check dams on the upstream side of the Devil's Gate reservoir and the Brown Mountain Dam. The first funding installment was approved in 1941 and another in 1944, resulting from the 1944 storm and subsequent flood. Federal funds also went to the channelization of Arroyo Seco Canyon further downstream of Devil's Gate Dam By 1952, the Los Angeles County-owned Altadena Storm Drain and sheds were completed as well (Figure 10). The PWP-owned sludge basins were added in the 1970s, after the construction of the Behner Water Treatment Plant (Brown and Taylor 1982; City of Pasadena 2003b; ETA 1941; LAT 1940c, 1946; SCPR 2016; UCSB 2019; Van Wormer 1991).

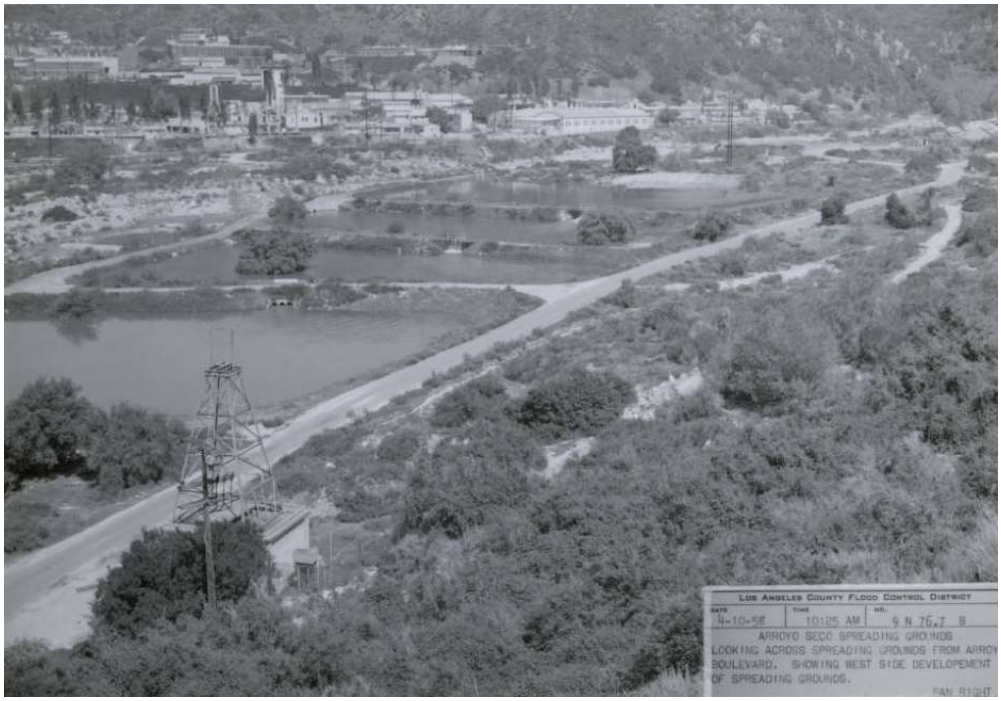

Figure 10. Arroyo Seco Spreading Basins, 1958 (Los Angeles County Flood Control District File Copy Prints Collection, Los Angeles County Library)

John L. Behner Water Treatment Plant (1971)

The John L. Behner Water Treatment Plant (WTP) was named after the first General Manager of the consolidated Pasadena Water and Power Department (PWP). Located in the Arroyo Seco Canyon east of JPL, the plant had a capacity of 5 million gallons per day. The project, which began as the result of a PWP feasibility study in 1967 decided on the current location. Originally, the Metropolitan Water District (MWD) identified the Upper Arroyo Seco as a location for their new MWD water treatment plant; however, they received backlash from Pasadena citizens using the area as a park. As a result, the City of Pasadena moved forward with their plan for a smaller water treatment plant facility, and a county regional park at the same time. The push was successful, and the PWP's plant was designed by Pasadena-based engineering firm James M. Montgomery, Consulting Engineers Inc. and constructed by the Margate Construction Company in 1970 and dedicated in 1971. However, new water treatment

regulations imposed as a result of the Surface Water Treatment Rule meant that the treatment plant was shut down in June 1993. Another feasibility study on the potential for upgrading the facility was conducted in 1995, but the Behner WTP remains offline to this day (City of Pasadena 2010, 2012; LAT 1968; PI 1971).

3.5 Architectural Styles

Only one resource within the Project site was designed in a clear architectural style: the Behner WTP, which exhibits numerous character-defining features of the Brutalist style.

Brutalism

The term "Brutalism" derives from the French *béton brut*, which translates as raw concrete, and describes concrete that displays the patterns, seams, and bug holes caused by formwork and concrete emplacement. The Brutalist architectural style is characterized by its use of raw building materials in a very direct and imposing way, emphasizing bulky forms and sharp angles with limited visible glass surfaces. A popular style between the 1950s and 1970s, Brutalism favored heavy, solid shapes cast with highly detailed and textured reinforced concrete. Often associated with High Modernism, a style emphasizing austere and abstract forms rooted in science and technology, the bold, unapologetic design and monumentality of Brutalism makes it an easy target for criticism, and it is thought to be one of the most divisive styles of architecture to emerge since the beginning of the twentieth century (Lowder 2013, McAlester 2013, Mindel 2016).

The best known early Brutalist architecture was that of Swiss architect Le Corbusier in the early 1950s. Brutalism gained popularity in the United Kingdom in the mid-century as war-torn communities actively sought inexpensive construction and design techniques in order to create affordable government buildings, housing, and shopping centers. However, Brutalism was also popular among those without budget constraints, as the style came to be artistically appreciated for its honest expression of materials, sculptural qualities, and anti-bourgeois aesthetic.

Brutalism was a popular style of architecture for educational buildings, particularly university buildings, but was relatively rare for corporate and single-family residential projects. It was also favored for civic projects, high-rise apartments, and shopping centers, as the style emulated strength, functionality, and an appreciation for material simplicity (Brutalism Online 2016).

Character-defining features of Brutalism include (City of San Diego 2007, HRG 2007):

- Exposed, expressive structural system
- Rough, unadorned concrete construction
- Monumental massing
- Heavy blockish shapes
- Angular and rectilinear forms
- Prefabricated concrete panels with exposed joinery
- Windows as voids in an otherwise solid volume
- Repetitive patterns
- Avoidance of traditional elements or ornament
- Raised plazas and base articulation

3.6 Engineer: James M. Montgomery, Consulting Engineers, Inc. (1945-1990)

The Behner WTP was designed by engineer James M. Montgomery (1896-1969). Montgomery was born in Ohio in 1896, and moved to Los Angeles California by 1910. He briefly served in the military during World War I, and was honorably discharged in October 1918. Montgomery returned to Newark, Ohio for a few years, but eventually moved back to Los Angeles Between 1935 and 1940. Montgomery launched his engineering firm in 1941, after having some success in helping design the F.E. Weymouth Memorial Water Softening and Filtration Plant in 1936 with MWD. This early connection with water infrastructure led to a career of consulting, studies, reports, and designing water infrastructure systems for Southern California and the greater West Coast of the United States for the next five decades. The firm was based in Pasadena for the first few decades. James Montgomery himself passed away in 1969, but his firm continued consulting work focused on water infrastructure. In 1990, the James M. Montgomery, Consulting Engineers, Inc. firm merged with Watson Hawksley, Ltd of the United Kingdom to become Montgomery-Watson. In 2001, Montgomery Watson merged with Harza Engineering and became Montgomery Watson Harza. This name was shortened to MWH Global in 2003. In 2016, MWH was acquired by Stantec Consulting, Inc. (Ancestry 2019).

Known works by Montgomery include:

- F.E. Weymouth Memorial Water Softening and Filtration Plant, Metropolitan Water District, City of La Verne, 1936-1941
- Arcadia Plant improvements, City of Santa Monica, 1958
- William B. Cater Filtration Plan, City of Santa Barbara, 1962
- Arcadia Plant improvements, City of Santa Monica, 1966
- Water Softening System, Alameda County Water District, 1966
- South San Diego Reservoir, City of San Diego, 1968
- Anaheim Lake Demonstration Desalination Plant, Orange County Water District, 1973
- Warner Ave Sewer Pump Station, City of Huntington Beach, 1986

INTENTIONALLY LEFT BLANK

4 Field Survey

4.1 Methods

Built Environment Survey

Dudek Architectural Historian Kate Kaiser, MSHP and Nicole Frank, MSHP, conducted a pedestrian survey of the Project site for historic built environment resources on October 23, 2019. The survey entailed walking to each affected property in the Project area: the PWP spreading basins, the LACFCD flood control infrastructure, Southern California Edison (SCE) transmission line route, PWP Behner Wastewater Treatment Plant, the Arroyo Seco road bed within and between all proposed Project areas, the three bridge sites, the screen building, and the intake structure and weir. Dudek staff documented each building and structure with notes and photographs, specifically noting character-defining features, spatial relationships, observed alterations, and examining any historic landscape features in the proposed project area. Dudek documented the fieldwork using field notes, digital photography, close-scale field maps, and aerial photographs. Photographs of the subject property were taken with a digital camera. All field notes, photographs, and records related to the current study are on file at Dudek's Pasadena, California, office.

Archaeological Survey

An intensive-level archaeological survey of Project APE was completed by Samantha Murray, MA, Registered Professional Archaeologist (RPA) on April 23, 2019. The survey entailed opportunistically inspecting any portions of the APE with exposed sediment, including unpaved portions of the access road, Area 2, and Area 3. The northernmost portion of Area 2 that encompasses areas beyond the access road exhibited almost no ground surface visibility due to low-lying vegetation, including poison oak in the area beneath Bridge No. 3. Nearly all portions of Area 3 were surveyed with the exception of a few small areas with restricted access surrounding the flood control infrastructure. Ground visibility surrounding the flood control infrastructure was approximately 50% due to presence of dry grasses and shrubs. Much of the area surrounding the JPL parking is regularly disturbed by vehicles and has no potential for intact resources.

4.2 Results

Built Environment Survey

During the course of the pedestrian survey, Dudek identified six (6) built environment resources over 45 years old requiring recordation and evaluation for historical significance, including the Behner WTP, Screen Building Complex, Bridges No. 1, 2 and 3, spreading basins, and various flood control infrastructure. Section 5 (Significance Evaluations) provides a detailed physical description of each resource and associated significance evaluations under all applicable national, state, and local designation criteria and integrity requirements. DPRs for all evaluated resources are located in Appendix D.

Dudek also identified several features associated with the larger Arroyo Seco. These features include cobblestone and concrete retaining walls that date between 1938 and 1940. These walls vary in length and height, but were typically constructed of smooth, round river cobbles, in semi-coursed layers, with a thick Portland cement mortar:

- rock retaining wall on northeast side of Arroyo Seco Canyon roadbed (Figures 11 and 12);
- rock retaining wall supporting the east-most canyon wall (Figure 13);
- rock retaining wall near screen building (Figure 14);
- rock wall barrier on side of road near intake/weir structure (also Figure 14); and
- rock wall barrier on south side of Bridge No. 2 (Figure 15).

In addition to the above-mentioned resources, Dudek also identified two wooden H-frame structures associated with an SCE transmission line (the Seco 16 kV Circuit) that overlaps a portion of the Project APE (Figures 16 and 17), identified on maps as an SCE easement near the spreading basins. A third structure associated with this line was identified just outside the western boundary of the APE near JPL on the east side of Arroyo Road. Two other SCE lines (Gorge 16kV and Tola 16kV) also intersect the APE in roughly the same area. Records search results indicate that at least one of the Seco 16kV towers within the APE was previously recorded in 2002 as part of an archaeological survey report prepared for SCE for the Seco 16 kV Circuit Deteriorated Pole Replacement Project. This report indicates that the structure near the spreading basins was replaced and that the structure outside the western boundary of the APE was moved. The proposed Project will avoid the SCE infrastructure that intersect the APE and will result in no permanent physical changes to the SCE easement. As such, no SCE infrastructure within the Project site was evaluated for historical significance.

Figure 16. Overview of SCE infrastructure in APE above Explorer Road, view looking southwest (IMG-2635)

Figure 17. Overview of SCE infrastructure in APE near spreading basins, view looking southwest (IMG_2613)

Archaeological Survey

No archaeological resources were identified within the Project site as a result of the intensive-level pedestrian survey.

5 Significance Evaluations

In order to determine if the proposed Project will impact historical resources under CEQA or historic properties under Section 106 of the NHPA, identified resources within the APE were evaluated for historical significance and integrity in consideration of NRHP, CRHR, and City of Pasadena designation criteria and integrity requirements. A detailed physical description of each resource and associated photographs are also provided.

5.1 John L. Behner Water Treatment Plant

Property Description

The John L. Behner Water Treatment Plant is a one-story Brutalist-style civic building, rectangular in shape, with a flat roof, designed by James M. Montgomery, Consulting Engineer, Inc. of Pasadena, and built in 1971. Exterior walls are exposed concrete with limited fenestration. The design emphasizes horizontality in form, but with strong vertical accents: simple, unadorned, rectangular concrete pilasters flank each narrow window/panel; broad concrete pilasters flank the entry door; and repetitive patterns of vertically-oriented rectilinear forms. A tall, monolithic concrete wall, with a broad band of vertically-oriented rectilinear forms creating a repetitive pattern, blocks view of the southern portion of external water treatment facilities to the east of and adjacent to the building. The external water treatment facilities comprise a series of open concrete tanks, with water flow controlled by a pair of wood flood gates, and a pair of moderately-sized, cylindrical above-ground tanks.

The main (northwest) elevation (Figure 18) presents as two sections: the left (northern) two-thirds consists of regularly-spaced narrow, vertical windows or panels, topped with louvered rectangular vents, and a double-leaf flush entry door with a flat panel inset above. The door is accessed by three broad, shallow concrete steps, bordered to the left (north) by a square integral concrete planter. Another narrower, shallower integral concrete planter runs along the base of the wall. The right (southern) third projects forward about three feet and is about two feet taller, with a repetitive pattern of vertically-oriented rectilinear forms. Three rows of patinated metal letters in a simple modern font are attached to the upper center of the wall and read “City of Pasadena John L. Behner Water Treatment Plant.”

The southwest elevation (Figure 19) presents as a monolithic wall with a repetitive pattern of vertically-oriented rectilinear forms. A near-full-height, flush, double-leaf loading door sits off-center, and a painted metal I-beam projects outwards from the top between the two leaves. The tall, monolithic concrete wall begins at the eastern end of this elevation, effectively continuing in line from the southeast elevation, and is pierce by a corrugated metal door.

The southeast elevation (Figure 20) presents as two sections: the left (southern) third is about two feet taller and predominantly exposed concrete masonry units (CMUs) laid in running bond, with a vertical and horizontal panel decorated in the repetitive pattern of vertically-oriented rectilinear forms; a half-lite painted metal door pierces the wall near the left edge. The right (northern) two-thirds of the elevation consists of exposed CMUs laid in running bond, with a vented half-lite door accessed via a concrete walkway and five evenly-spaced narrow, horizontally-oriented louvered vents located near the base of the wall.

The northeast elevation is monolithic concrete with four full-length rectangular concrete pilasters flanking a centered single-width roll-up garage door. Short portions of two rectangular concrete pilasters project above the door.

Figure 20. Behner Treatment Plant: southeast elevation, view looking southwest (DSC02274)

NRHP/CRHR Statement of Significance

Criterion A/1: That are associated with events that have made a significant contribution to the broad patterns of our history.

Archival research did not find any associations with events that have made a significant contribution to the broad patterns of our history. The subject property was completed in 1971, during a period of economic downturn that that began in the late 1960s, and taken offline in 1993 after passage of the Surface Water Treatment Rule. Although the property is generally representative of the City's mid-century growth, it has no direct association with events that made a significant contribution to the history of the City of Pasadena, the State of California, or the Nation. Therefore, the property does not appear eligible under Criterion A of the NRHP or Criterion 1 of the CRHR.

Criterion B/2: That are associated with the lives of persons significant in our past.

Archival research did not indicate that any previous property owners or people who have worked at this property are known to be historically significant figures at the national, state, or local level. As such, this property is not known to have any historical associations with people important to the nation's or state's past. Furthermore, to be found eligible under B/2 the property has to be directly tied to an important person and the place where that individual conducted or produced the work for which he or she is known. This property does not appear to be associated with any individual's important historic work and does not appear eligible for the NRHP under Criterion B or CRHR under Criterion 2.

Criterion C/3: That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction.

The John L. Behner Water Treatment Plant is a good example of Brutalist civic architecture as expressed in the context of a utilitarian building designed for practicality. Designed by local Pasadena engineering firm James M. Montgomery, Consulting Engineer Inc. and built in 1971, the building displays several character-defining features of the Brutalist architectural style, including an exposed, expressive structural system; rough, unadorned concrete construction; monumental massing; heavy blockish shapes; angular and rectilinear forms; prefabricated concrete panels with exposed joinery; windows as voids in an otherwise solid volume; repetitive patterns; and avoidance of traditional elements or ornament. While smaller in scale than the more monumental, hulking Brutalist buildings often seen in civic centers and on college campuses, the building still conveys the essential character-defining features of the Brutalist design aesthetic and exhibits a high level of integrity. The designing engineering firm, James M. Montgomery, Consulting Engineer, Inc., is a local, Pasadena-based firm that regularly constructed water infrastructure projects for local cities and water districts, such as MWD, Santa Monica, and Huntington Beach. There are no known alterations to the exterior of the building. Although the engineer does not rise to the level of a "master," the building embodies the distinctive characteristics of the Brutalist architectural style and possesses artistic values of significance to the City or to the region. Consideration was also given to the fact that Brutalism is a relatively rare architectural style in Pasadena, with few noteworthy examples. The Pasadena CHRID lists only two eligible Brutalist properties: a public library and a private residence. According to the Los Angeles Conservancy, "The Lamanda Park Branch of the Pasadena Public Library is a rare Brutalist building in an area of modest suburban homes in east Pasadena." (LAC 2019) The same may be said of the Behner WTP, as it remains relatively hidden from view, tucked away behind a suburban neighborhood**. As such, the property appears eligible for the NRHP under Criterion C and CRHR under Criterion 3 at the local level of significance.**

Criterion D/4: That have yielded, or may be likely to yield, information important in prehistory or history.

The property is not significant under Criterion D of the NRHP or Criterion 4 of the CRHR as a source, or likely source, of important historical information nor does it appear likely to yield important information about historic construction methods, materials or technologies.

Pasadena Statement of Significance

The City of Pasadena's landmark designation criteria is based on the NRHP/CRHR designation criteria and integrity requirements. Therefore, for all of the reasons identified in the discussion of NRHP and CRHR eligibility, **the subject property appears eligible as a landmark under local designation criteria 2c.**

Integrity Discussion

The John L. Behner Water Treatment Plant maintains integrity of location, as it remains in its original location. The building retains integrity of design as it has not undergone any large-scale exterior alterations since its construction and maintains the essential features of form, plan, space, structure, and style. The building retains integrity of setting, as upon its construction, the Arroyo Seco Canyon area had already attained the majority of JPL-related development, residential suburban development, and undeveloped Forest Service and parkland observed today. The building maintains integrity of materials and workmanship due to the retention of the physical elements that date from its construction. The windows sport metal security screens, but the majority of the building's original

materials are extant. The building retains integrity of feeling and association, as the property retains the ability to express itself as a water treatment plant. In summary, the building retains the requisite integrity for designation, and appears eligible for listing under NRHP Criterion C, CRHR Criterion 3, and City of Pasadena Landmark criterion 2c at the local level of significance.

5.2 Screen Building Complex

Property Description

The Screen Building Complex (formerly known as the Chlorination Plant) consists of the screen building built c. 1932, a weir built c. 1938, and an intake structure built c. 1938. The screen building (Figure 21) is an L-shaped, flat-roofed concrete building of utilitarian design. A narrow drip edge runs along the walls below what appears to be a short parapet wall. Fenestration includes two flush single-leaf entry doors, a roll-up garage door, and five windows obscured by metal screens. A vertical metal ladder attached near one of the entry doors provides access to the roof. An elevated rectangular concrete open-air tank structure, with a large piece of mechanical equipment bolted over half of the structure and accessed by three metal steps, sits to the left of and slightly in front of the screen building. A rectangular arch constructed from metal I-beams, with the two uprights supported with angled I-beams on the front and back of the arch, is located in front of the garage door. The weir (Figure 22) is a combination of mortared stone and poured-in-place concrete with at least one wood sluice gate, although access was limited during survey due to vegetation and debris. A cobblestone wall rises from the original retaining wall on the right (east or cutbank) side of the weir and supports a concrete platform, the top deck of the intake structure, into which the original rectangular concrete platform is incorporated and expanded (Figure 23).

Figure 21. Screen building, view looking south (IMG_2767)

Figure 22. Weir, eastern end with wood sluice gate, view looking upstream (IMG_2797)

Figure 23. Weir detail, view looking upstream (IMG_2791)

NRHP/CRHR Statement of Significance

Criterion A/1: That are associated with events that have made a significant contribution to the broad patterns of our history.

Archival research did not find any associations with events that have made a significant contribution to the broad patterns of our history. The complex was completed c. 1932, most likely by the CCC during their improvements campaign in the Arroyo Seco Canyon. The extant weir was replaced after a major flooding event in 1938, and a newer cobblestone wall rises from the original retaining wall on the right (east or cutbank) side of the weir. The cobblestone wall supports a concrete platform, into which the original rectangular concrete platform is incorporated, indicating extensive repairs and/or additional damage during later flood events. The Screen Building Complex is no longer visibly recognizable as dating to its original c. 1932 construction date due to the extensive damage and subsequent repairs. Further, it does not have a direct association with events that made a significant contribution to the history of the City of Pasadena, the State of California, or the Nation. Therefore, the property does not appear eligible under Criterion A of the NRHP or Criterion 1 of the CRHR.

Criterion B/2: That are associated with the lives of persons significant in our past.

Archival research did not indicate that any previous property owners or people who have worked at this property are known to be historically significant figures at the national, state, or local level. As such, this property is not known to have any historical associations with people important to the nation's or state's past. Furthermore, to be found eligible under B/2 the property has to be directly tied to an important person and the place where that individual conducted or produced the work for which he or she is known. This property does not appear to be associated with any individual's important historic work and does not appear eligible for the NRHP under Criterion B or CRHR under Criterion 2.

Criterion C/3: That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction.

The Screen Building Complex comprises a screen building, a weir, and an intake structure. The individual components are modest utilitarian structures built with common materials using common techniques and with no artistic value. They do not embody the distinctive characteristics of a type, period, or method of construction, nor do they represent the work of a master, nor does the complex represent a significant and distinguishable entity whose components may lack individual distinction. Furthermore, the Screen Building Complex is no longer visibly recognizable as dating to its original c. 1932 construction date due to the extensive damage and subsequent repairs. For these reasons, the Screen Building Complex does not appear eligible for listing in the NRHP under Criterion C or CRHR under Criterion 3.

Criterion D/4: That have yielded, or may be likely to yield, information important in prehistory or history.

The property is not significant under Criterion D of the NRHP or Criterion 4 of the CRHR as a source, or likely source, of important historical information nor does it appear likely to yield important information about historic construction methods, materials or technologies.

Pasadena Statement of Significance

The City of Pasadena's landmark designation criteria is based on the NRHP/CRHR designation criteria and integrity requirements, Therefore, for all of the reasons identified in the discussion of NRHP and CRHR eligibility, the subject property does not appear eligible under any local designation criteria, either individually or as part of a district.

Integrity Discussion

The Screen Building Complex retains integrity of location, as it remains in its original location. The Complex lacks integrity of design as it was subjected to large-scale exterior alterations since its original construction in 1932 and no longer maintains the essential features of form, plan, space, structure, and style. The Complex retains integrity of setting, as it still rests within a natural environment along the Arroyo Seco. The Complex lacks integrity of materials and workmanship due to the extensive damage and subsequent repairs to the physical elements that date from its construction. The Complex retains integrity of feeling, as it is still nestled within the Arroyo Seco surrounded by a mixture of natural environment and water infrastructure. Finally, while the screen building still reads as a grouping of structures related to water infrastructure in Pasadena, this association is not significant. In summary, the Screen Building Complex does not retain the requisite integrity for designation, nor does it rise to the level of significance required for designation at the national, state or local levels.

5.3 Bridge No. 1

Property Description

Bridge No. 1 appears to be a two-span box culvert bridge, with the bridge supported on either end by a cobblestone abutment wall and in the middle by a cobblestone wall (Figure 24). The abutments and center wall may be concrete clad with mortared cobblestones, or built as load-bearing cobblestone masonry walls. The bridge deck appears to be supported by a metal plate(s) that rests upon the cobblestone walls (Figure 25). An approximately 18-inches-tall band of mortared cobblestone rests on the upstream and downstream edges of the metal plate(s), with the bridge deck coated in tarmac. A new temporary bridge with concrete access ramps passes across the deck of Bridge No.1. Aerial images indicate a bridge crossing over Millard Canyon existed at the same location prior to 1927. Archival research indicates that the original bridge was either damaged or destroyed by the 1938 floods, and replaced with the existing two-span box culvert bridge either during a CCC repair campaign in 1939 or as part of the 1941 Arroyo Seco Program. A previous report identified the bridge deck as being replaced with a "similar reinforced concrete span" in 1979, and that river rock was applied to both sides of the deck at the time to "visually integrate it with the existing river rock-clad bridge components" (Daly 2014). Comparison of photographs taken in 2019 during the site visit with those included in a 2015 report indicate that the bridge deck was coated with a layer of tarmac c. 2017, prior to installing the temporary bridge (TJC & Associates 2015). Two pipelines emerge from the ground near the southern end of Bridge No. 1 and run along the west side of the Arroyo Boulevard/Gabrielino Trail (Figure 26). The larger metal pipe is wrapped with what appears to be disintegrating asphalt rolled material, and continues underground near the southern end of Bridge No. 2. The smaller pipeline appears to be concrete and dives underground north of Bridge No. 2, just after a bolted metal pipe connection between two runs of concrete pipe (Figures 27 and 28).

Figure 24. Bridge No. 1 with temporary bridge in place, view looking south (DSC02332)

Figure 25. Bridge No. 1, detail of cobblestone edge and central supporting wall (DSC02336)

Figure 26. View of pipelines, near Bridge No. 1 (DSC02327)

Figure 27. View of pipelines, near Bridge No. 1 (DSC02323)

Figure 28. Pipeline near Bridge No. 2, view looking southeast (DSC02367)

NRHP/CRHR Statement of Significance

Bridge No. 1 does not meet any of the criteria for listing in the NRHP or CRHR, either individually or as part of an existing historic district.

Criterion A/1: That are associated with events that have made a significant contribution to the broad patterns of our history.

Archival research did not find any associations with events that have made a significant contribution to the broad patterns of our history. Archival research indicates that the original bridge was either damaged or destroyed by the 1938 floods, and replaced with the existing two-span box culvert bridge either during a CCC repair campaign in 1939 or as part of the 1941 Arroyo Seco Program. Bridge No. 1 was completed c. 1940, replacing the original bridge, and is a simple utilitarian design. Even if the bridge was constructed as part of the CCC repair campaign in 1939, it does not maintain any significant physical features that convey this association. Further, evidence suggests that the bridge deck was replaced in 1979 (Daly 2014). It has no direct association with events that have made a significant contribution to the history of the City of Pasadena, the State of California, or the Nation. Therefore, the property does not appear eligible under Criterion A of the NRHP or Criterion 1 of the CRHR.

Criterion B/2: That are associated with the lives of persons significant in our past.

Archival research did not indicate that any previous property owners or people who have worked at this property are known to be historically significant figures at the national, state, or local level. As such, this property is not known to have any historical associations with people important to the nation's or state's past. Furthermore, to be found eligible under B/2 the property has to be directly tied to an important person and the place where that

individual conducted or produced the work for which he or she is known. This property does not appear to be associated with any individual's important historic work and does not appear eligible for the NRHP under Criterion B or CRHR under Criterion 2.

Criterion C/3: That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction.

Bridge No. 1 is a two-span box culvert bridge of simple utilitarian design completed c. 1940, replacing an older bridge damaged or destroyed by the 1938 floods. Although parts of it are cobblestone, the material was popular during the early 20th C. due to the influence of Greene and Greene and the Arts & Crafts style, and it was inexpensive and readily available from the Arroyo Seco stream bed. Additionally, a previous evaluation of the bridge (Daly 2014) indicates that the bridge deck was replaced in 1979 with reinforced concrete, and subsequently topped with at least one layer of tarmac (c. 2017). The bridge itself is not characteristic of a type, period, or method of construction, nor does it represent the work of a master, nor does it possess high artistic values, and it is not part of a significant and distinguishable entity whose components may lack individual distinction. For these reasons, Bridge No. 1 does not appear eligible for listing in the NRHP under Criterion C or CRHR under Criterion 3.

Criterion D/4: That have yielded, or may be likely to yield, information important in prehistory or history.

The property is not significant under Criterion D of the NRHP or Criterion 4 of the CRHR as a source, or likely source, of important historical information nor does it appear likely to yield important information about historic construction methods, materials or technologies.

Pasadena Statement of Significance

The City of Pasadena's landmark designation criteria is based on the NRHP/CRHR designation criteria and integrity requirements, Therefore, for all of the reasons identified in the discussion of NRHP and CRHR eligibility, the subject property does not appear eligible under any local designation criteria, either individually or as part of a district.

Integrity Discussion

Bridge No. 1 maintains integrity of location, as it remains in its original location. The bridge does not retain integrity of design as its deck was replaced in 1979. The bridge retains diminished integrity of setting, as it still rests within a natural environment along the Arroyo Seco. The bridge also lacks integrity of materials and workmanship due to replacement of the bridge deck and other features. The bridge's simple design does not convey the feeling or association with a CCC-built bridge as it lacks major visible character-defining features and associated materials. In summary, Bridge No. 1 does not retain the requisite integrity for designation, nor does it rise to the level of significance required for designation at the national, state or local levels.

5.4 Bridge No. 2

Property Description

Bridge No. 2 is a board-formed concrete arch bridge, with board-formed concrete abutments and a subtle four-point arch, spanning the Arroyo Seco, constructed circa 1920 (Figure 29). Rectangular concrete railings border the upstream and downstream edges of the bridge deck, with openings between upper and lower rails sporting a row of classically shaped single balusters resembling the form of a flower bud from a pomegranate tree (Figure 30). The bridge deck is covered with tarmac.

Figure 29. Bridge No. 2, view looking downstream (IMG_2730)

Figure 30. Bridge No. 2, detail of deck and railing with balusters (DSC02361)

NRHP/CRHR Statement of Significance

Criterion A/1: That are associated with events that have made a significant contribution to the broad patterns of our history.

Archival research did not find any associations with events that have made a significant contribution to the broad patterns of our history. Bridge No. 2 was constructed c. 1920 as a necessary improvement along the Arroyo Boulevard/Gabrielino Trail, around the time Arroyo Boulevard was paved for use as a county highway. However, the road no longer functions as a county highway or a major thoroughfare, and has no direct association with events that made a significant contribution to the history of the City of Pasadena, the State of California, or the Nation. Therefore, Bridge No.2 does not appear eligible under Criterion A of the NRHP or Criterion 1 of the CRHR.

Criterion B/2: That are associated with the lives of persons significant in our past.

Archival research did not indicate that any previous property owners or people who have worked at this property are known to be historically significant figures at the national, state, or local level. As such, this property is not known to have any historical associations with people important to the nation's or state's past. Furthermore, to be found eligible under B/2 the property has to be directly tied to an important person and the place where that individual conducted or produced the work for which he or she is known. This property does not appear to be associated with any individual's important historic work and does not appear eligible for the NRHP under Criterion B or CRHR under Criterion 2.

Criterion C/3: That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction.

Built c. 1920, around the time Arroyo Boulevard was paved for use as a county highway, Bridge No. 2 exhibits classical design elements in the rows of classically shaped single balusters resembling the form of a flower bud from a pomegranate tree, as well as the subtle four-point shape of the arch. The bridge also displays the pattern of board-formed concrete, a method of construction popular for civil works during the early 20th Century. The designed structure successfully relied on massed reinforced concrete with a broad arched opening to withstand the destructive forces of periodic floods down Arroyo Seco. As such, the bridge embodies distinctive characteristics of a type, period, and method of construction. **Therefore, Bridge No. 2 appears eligible for listing under Criterion C of the NRHP and Criterion 3 of the CRHR at the local level of significance.**

Criterion D/4: That have yielded, or may be likely to yield, information important in prehistory or history.

The property is not significant under Criterion D of the NRHP or Criterion 4 of the CRHR as a source, or likely source, of important historical information nor does it appear likely to yield important information about historic construction methods, materials or technologies.

Pasadena Statement of Significance

The City of Pasadena's landmark designation criteria is based on the NRHP/CRHR designation criteria and integrity requirements, Therefore, for all of the reasons identified in the discussion of NRHP and CRHR eligibility, **the subject property appears eligible as a landmark under local designation criterion 2c.**

Integrity Discussion

Bridge No. 2 maintains integrity of location, as it remains in its original location. The bridge retains integrity of design as it has not undergone any large-scale exterior alterations since its construction and maintains the essential features of form, plan, space, structure, and style. The bridge retains integrity of setting, as it still rests within a natural environment along the Arroyo Seco. The bridge retains integrity of materials and workmanship due to the retention of the physical elements that date from its construction. The bridge no longer retains integrity of feeling and association, since Arroyo Boulevard/Gabrielino Trail no longer serves as an important thoroughfare. In summary, Bridge No. 2 retains the requisite integrity for designation, and appears eligible for listing under NRHP Criterion C, CRHR Criterion 3, and City of Pasadena Landmark criterion 2c.

5.5 Bridge No. 3

Property Description

Bridge No. 3 is a wooden kingpost truss bridge, with heavy timber supports braced by a vertical metal rod and angled wood beam braced on a cantilevered timber girder (Figure 31). Timber railings line both side of the bridge deck, and board-formed concrete retaining walls support either end of the bridge. A metal plaque attached to one end of the southern retaining wall indicates the wood bridge was erected in 1939 by "C.C.C. Company 903 – U.S.F.S. in cooperation with Pasadena Water Department." A temporary bridge deck is positioned directly above the original wood bridge. The temporary bridge was initially installed to accommodate the loading from heavy equipment

needed during construction of the Arroyo Seco Canyon Project that would be beyond the capacity of the original Bridge 3. However, as the condition of the original bridge has continued to deteriorate and is no longer safe for use, the temporary structure allows for continued passage into the canyon and access to the USFS compound by isolating traffic weight and movement from affecting the older wood bridge. The temporary bridge deck is built with anti-skid steel decking supported by steel I-beam girders, and is bolted through wood sill plates into the top of the original bridge's concrete retaining walls. Sloped, poured-in-place concrete ramps provide access to the temporary bridge deck at either end. Tubular metal railings line each side of the temporary bridge deck and concrete access ramps (Figure 32).

Figure 31. Bridge No. 3, view looking downstream (IMG_2761)

Figure 32. Bridge No. 3, view looking north-northwest (IMG_2749)

NRHP/CRHR Statement of Significance

Criterion A/1: That are associated with events that have made a significant contribution to the broad patterns of our history.

Archival research indicates that Bridge No. 3 was constructed in 1939 by the CCC, after the 1938 flood destroyed the original bridge. Local CCC Company 903 was assigned to the USFS in 1933 to work on projects within Arroyo Seco Canyon and San Gabriel Mountains. One of Roosevelt's more successful New Deal programs, the CCC was a work relief program focused on environmental projects, providing employment to young men during the Great Depression. They planted more than three billion trees and constructed facilities in more than 800 parks nationwide during the nine years which the group was in existence, helping shape our modern national and state park systems. As such, Bridge No. 3 was constructed by a group associated with events that made a significant contribution to the broad patterns of our history. **Therefore, Bridge No. 3 appears eligible under Criterion A of the NRHP and Criterion 1 of the CRHR.**

Criterion B/2: That are associated with the lives of persons significant in our past.

Archival research did not indicate that any previous property owners or people who have worked at this property are known to be historically significant figures at the national, state, or local level. As such, this property is not known to have any historical associations with people important to the nation's or state's past. Furthermore, to be found eligible under B/2 the property has to be directly tied to an important person and the place where that individual conducted or produced the work for which he or she is known. This property does not appear to be

associated with any individual's important historic work and does not appear eligible for the NRHP under Criterion B or CRHR under Criterion 2.

Criterion C/3: That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction.

Bridge No. 3 is a wooden kingpost truss bridge, with heavy timber supports braced by a vertical metal rod and angled wood beam braced on a cantilevered timber girder. Timber railings line both side of the bridge deck, and board-formed concrete retaining walls support either end of the bridge. The kingpost design harkens back to timber-framed roof construction in Roman buildings, and was common in medieval architecture. The kingpost made its way into timber bridge design via Palladio, the first known personage to promote timber trusses for bridge design, and is the oldest timber truss design used for bridges. The kingpost truss is comprised of a stringer, a kingpost (vertical beam), and two diagonal beams designed primarily for short spans of approximately 20 to 30 feet. As such, the bridge embodies the distinctive characteristics of a type and method of construction. **Therefore, Bridge No. 3 appears eligible under Criterion C of the NRHP and Criterion 3 of the CRHR.**

Criterion D/4: That have yielded, or may be likely to yield, information important in prehistory or history.

The property is not significant under Criterion D of the NRHP or Criterion 4 of the CRHR as a source, or likely source, of important historical information nor does it appear likely to yield important information about historic construction methods, materials or technologies.

Pasadena Statement of Significance

The City of Pasadena's landmark designation criteria is based on the NRHP/CRHR designation criteria and integrity requirements, Therefore, for all of the reasons identified in the discussion of NRHP and CRHR eligibility, **the subject property appears eligible as a landmark under local designation criteria 2a and 2c.**

Integrity Discussion

Bridge No. 3 maintains integrity of location, as it remains in its original location. The bridge retains integrity of design as it has not undergone any large-scale exterior alterations since its construction and maintains the essential features of form, plan, space, structure, and style. The bridge retains integrity of setting, as it still rests within a natural environment along the Arroyo Seco. The bridge retains integrity of materials and workmanship due to the retention of the physical elements that date from its construction. Finally, the bridge retains the feeling of an early 20th century timber bridge constructed by the CCC and it maintains its essential character-defining features to convey its association with the CCC building campaign in the 1930s. In summary, Bridge No. 3 retains the requisite integrity for designation, and appears eligible for listing under NRHP Criteria A and C, CRHR Criteria 1 and 3, and City of Pasadena Landmark criteria 2a and 2c.

5.6 Flood Control Infrastructure

Property Description

Flood control infrastructure at the upstream end of the spreading basins consists of two LACFCD-owned sheds to either side of a County-owned concrete storm drain box structure, called the Altadena Storm Drain, with pulley operated components and a concrete and metal check dam. Each shed is a square plan gable fronted building, with horizontal wood board cladding, and rolled composition roofing, on a concrete slab foundation. The doors are both located on the south elevations and consist of vertical wood board doors, braced on the interior. Other fenestration consists of screened window openings and a louvered vent in the gable end. The two sheds are to either side of the storm drain box structure with three openings on the top side, and letting out via culvert into the Arroyo Seco (Figure 33).

Figure 33. Altadena Storm Drain structure, pulley mechanism, and west-most shed, View looking west (IMG_2606)

The PWP spreading basins consist of, two spreading basins (Pasadena Ponds 1 and 2) formerly used as sludge ponds during operation of the Behner WTP, and 14 additional spreading basins (originally developed by LACFCD) separated by check dams completed between 1948 and 1952. Spreading basin features are engineered earthen ponds separated by soil embankments and small wood and concrete flow control dams. Each basin varies in total size and depth (Figure 34). The Pasadena Ponds 1 and 2 also have buried concrete culverts between them and the Parshall Flume, as well as chain link fence surrounding them (Figure 35).

Figure 34. Overview to spreading basins; View looking south (IMG_2631)

Figure 35. Overview to PWP sludge basins, now Pasadena Ponds 1 and 2; View looking southwest (IMG_2608)

A flow control dam is located west of the westernmost shed. Situated in a naturalized channel, west of the Altadena Storm Drain, the flow control dam consists of two walls of wood cribbing, and a wood board dam in the center, with removable boards in a metal track in order to control flow in the narrow channel (Figure 36). The downstream side of the channel has had a gunite mixture applied to the channel walls. On the east side of the dam, is a concrete platform, stair and metal handrail. On the west side of the dam, are two corrugated metal canisters, one lidded with flat metal and the other with conical metal.

Figure 36. Dam, View looking northwest (IMG_2600)

Finally, downstream of the flow control dam, there is a culvert and vehicle bridge through which water is measured (via a Parshall Flume) before it flows into the spreading basins (Figure 37). The culvert has two 18-inch openings in the channel basin. The roadbed is filled with gravel, but the culvert is constructed of board-formed concrete, with metal lining, and metal guard rails on top for safety. There is also a corrugated galvanized steel tank with a conical lid placed on a concrete platform on the upstream side of the culvert. The tank is currently used to house the controls for the Parshall Flume's metering device.

Figure 37. Culvert and Vehicle bridge, looking southwest (IMG_2612)

Identified Alterations

The following alterations were observed during the field visit:

- windows removed from shed (date unknown)
- LACFCD signs added to both shed exteriors (date unknown)
- metal railing replacing older wood handrail on flow control dam structure (date unknown)

NRHP/CRHR Statement of Significance

Criterion A/1: That are associated with events that have made a significant contribution to the broad patterns of our history.

Archival research did not find any associations with events that have made a significant contribution to the broad patterns of our history. The spreading basins were completed in 1948, and the Altadena Storm Drain, sheds, culverts, and check dams completed between 1948 and 1952. These date have no bearing on the industrial, commercial, and institutional growth of Pasadena nor is it directly related to a historical natural disaster such as a specific flood. The flood control infrastructure appears to have no direct association with events that have made a significant contribution to the history of the City of Pasadena, or Los Angeles County, the State of California, or the Nation. Therefore, the property does not appear eligible under Criterion A of the NRHP or Criterion 1 of the CRHR.

Criterion B/2: That are associated with the lives of persons significant in our past.

Archival research did not indicate that any previous property owners or people who have worked on these structures are known to be historically significant figures at the national, state, or local level. The structures have been owned

by PWP or LACFCD since construction, and as such is not associated with the life of a specific person significant to the past. Furthermore, to be found eligible under B/2 the property has to be directly tied to an important person and the place where that individual conducted or produced the work for which he or she is known. The structures do not appear to be associated with any individual's important historic work and does not appear eligible for the NRHP under Criterion B or CRHR under Criterion 2.

Criterion C/3: That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction.

The flood control structures, including spreading basins completed in 1948, and the Altadena Storm Drain, sheds, culverts and checkdams completed between 1948 and 1952, are utilitarian in construction and lack association to a specific architectural style or method of construction. They have no specific character-defining features, do not represent the work of a master engineer, do not possess high artistic value and are not significant as contributing features of an entity whose components may lack individual distinction. Therefore the structures do not appear eligible for listing in the NRHP under Criterion C or CRHR under Criterion 3.

Criterion D/4: That have yielded, or may be likely to yield, information important in prehistory or history.

The structures are not significant under Criterion D of the NRHP or Criterion 4 of the CRHR as a source, or likely source, of important historical information nor does it appear likely to yield important information about historic construction methods, materials or technologies.

Pasadena Statement of Significance

The City of Pasadena's landmark designation criteria is based on the NRHP/CRHR designation criteria and integrity requirements, Therefore, for all of the reasons identified in the discussion of NRHP and CRHR eligibility, the flood control structures do not appear eligible under any local designation criteria, either individually or as part of a district.

Integrity Discussion

The spreading basins, Altadena Storm Drain, checkdams, culverts, and sheds, as a collective engineered structure retain integrity of location and have not been moved since their construction in 1948. They maintain integrity of design as it has not undergone any large-scale exterior alterations since its construction and maintains the essential features of form, structure, and function. The structures retain integrity of setting, as they remain in the Arroyo Seco floodplain north of the Devil's Gate Dam, structures retain between a steep hillside and the campus of JPL. The structures retain integrity of materials and workmanship due to the retention of the physical elements that date from its construction. The structures retain integrity of feeling and association, as they can still express their purpose as water and flood related infrastructure. In summary, while the structures retain the requisite integrity, it does not rise to the level of significance required for designation at the national, state or local levels.

5.7 Summary of Evaluation Findings

Table 4 provides a summary of all resources evaluated for historical significance within the Project site. Six (6) built environment resources were identified as a result of the background research and pedestrian survey. Of these, three resources (the Behner WTP, Bridge No. 2, and Bridge No. 3) were found eligible for NRHP, CRHR and local designation. The remaining three resources (the Screen Building Complex, Bridge No. 1, and the flood control and water conservation Infrastructure) were found not eligible under all designation criteria due to a lack of historical associations and integrity.

Table 4. Summary of Resource Evaluation Findings

Resource Name	Description	Built Date	Evaluation Findings
John L. Behner WTP	Brutalist-style water treatment plant building and related infrastructure	1971	Appears eligible under NRHP/CRHR Criteria C/3 at local level, and City Criterion 2c (3S/3CS/5S3)
Screen Building Complex	Complex consisting of screen building, a weir, and intake structure	c. 1932	Appears not eligible under all designation criteria (6Z)
Bridge No. 1	Two-span box culvert bridge spanning Millard Canyon tributary creek	c. 1938-1941	Appears not eligible under all designation criteria (6Z)
Bridge No. 2	Concrete arch bridge spanning the Arroyo Seco	c. 1920	Appears eligible under NRHP/CRHR Criteria C/3 at local level, and City Criterion 2c (3S/3CS/5S3)
Bridge No. 3	King truss bridge spanning the Arroyo Seco erected by the CCC	1939	Appears eligible under NRHP/CRHR Criteria A/1 and C/3, and City Criteria 2a and 2c (3S/3CS/5S3)
Flood Control Structures (PWP/LACFCD)	Complex of utilitarian sheds, Altadena Storm Drain, culvert, flow control dam, Parshall Flume, Pasadena Ponds 1 and 2, and 14 spreading basins	c. 1948-1952	Appears not eligible under all designation criteria (6Z)

INTENTIONALLY LEFT BLANK

6 Impacts Analysis

6.1 Historical Resources Identified within the APE

The following historical resources/historic properties were identified within the Project APE as a result of the property significance evaluations (Section 5):

- John L. Behner Water Treatment Plant (3S/3CS/5S3)
- Bridge No. 2 (3S/3CS/5S3)
- Bridge No. 3 (3S/3CS/5S3)

Additionally, five (5) features were identified within the APE that are considered character-defining features of the larger Arroyo Seco, and should be avoided/protected as part of the current Project. The Arroyo Seco is considered "a unique environmental, recreational and cultural resource of the city surrounded by residential neighborhoods" and "must be preserved, protected and properly maintained." (Arroyo Seco Public Lands Ordinance 3.32.020). The arroyo stone walls and steps throughout the City of Pasadena and especially in the Arroyo Seco are considered an historical resource because many of them were built during the WPA years and in some locations designed by notable architects. Rehabilitation, including maintenance and repair, shall be focused on conservation of this historic resource (City of Pasadena 2003). Contributing design features of the Arroyo Seco identified in the Project APE include cobblestone and concrete retaining walls that date between 1938 and 1940:

- rock retaining wall for on northeast side of Arroyo Seco Canyon roadbed (Figures 11 and 12);
- rock retaining wall supporting the east-most canyon wall (Figure 13);
- rock retaining wall near screen building (Figure 14);
- rock wall barrier on side of road near intake/weir structure (also Figure 14);
- rock wall barrier on south side of Bridge No. 2 (Figure 15).

These walls vary in length and height, but are typically constructed of smooth, round river cobbles, in semi-coursed layers, with a thick Portland cement mortar. The use of semi-coursed, smooth river cobble in concrete mortar is a common feature seen throughout Pasadena and the Arroyo Seco. The Arroyo Seco Design Guidelines (Pasadena 2003a) document is one of four separate planning documents produced as part of The Arroyo Seco Master Plans. The design guidelines provide a unifying set of criteria for the site development improvements set forth in the Arroyo Seco Master Plan for on-going, long-range improvements for the Arroyo Seco. The purpose of these guidelines is to maintain a unified park design that reflects the heritage of the Arroyo Seco and its relationship to the tradition of the City of Pasadena. The Arroyo Seco Design Guidelines provide specific site design solutions that are consistent with the existing Arroyo Seco Ordinance and a vehicle by which practical inputs for ongoing improvements can take place (Pasadena 2003).

6.2 Analysis of Potential Project Impacts

Area 2 Diversion and Intake Replacement

Table 5 provides an analysis of all proposed Project activities associated with the Area 2 Diversion and Intake Replacement. No historical resources were identified in Area 2.

Table 5. Area 2 Impacts Analysis

Proposed Activity	Potential to Impact?	Recommendations to Reduce Impacts?	Level of Significance
Demolition and removal of the existing concrete weir and portions of the intake structure	No. The Screen Building Complex and related infrastructure (including the weir and intake structure) was found ineligible and is not an historical resource.	None required	Less than significant
Construction of a new diversion structure that would be operated to divert up to 25 cfs of creek flows into the existing conveyance system.	No. Construction of a new diversion structure would not directly impact or indirectly alter the setting or character of any adjacent resources.	None required	Less than significant
Remodel intake structure with new concrete walls and top deck to accommodate a new screen configuration.	No. The Screen Building Complex and related infrastructure (including the weir and intake structure) was found ineligible and is not an historical resource.	None required	Less than significant
Demolish an existing concrete slab that previously supported an equipment building located adjacent to the Gabrielino Trail/Access Road.	No. The Screen Building Complex and related infrastructure (including the existing concrete slab) was found ineligible and is not an historical resource.	None required	Less than significant

Table 5. Area 2 Impacts Analysis

Proposed Activity	Potential to Impact?	Recommendations to Reduce Impacts?	Level of Significance
Construct a new 106-square-foot intake service building to house the electrical and hydraulic controls for the diversion structure.	No. Construction of a new intake service building would not directly impact or indirectly alter the setting or character of any adjacent resources.	None required	Less than significant

Area 3 Spreading Basin Improvements

Table 6 provides an analysis of all proposed Project activities associated with the Area 3 Spreading Basin Improvements. No historical resources were identified in Area 3. Although the proposed Project's construction activities will intersect the existing SCE Easement, all associated SCE infrastructure (i.e., poles and wires) will be avoided by the Project and protected in coordination with SCE.

Table 6. Area 3 Impacts Analysis

Proposed Activity	Potential to Impact?	Recommendations to Reduce Impacts?	Level of Significance
Reconfiguration and expansion of the spreading basins.	No. All PWP/LACFCD flood control and water conservation infrastructure, including the spreading basins, were found ineligible and are not historical resources.	None required	Less than significant
Demolition of various facilities, including inlet/outlet structures, dry vaults, woodsheds, utility light pole, pipes and valves, chainlink fencing, corrugated metal pipes, and other small appurtenant structures, to allow for the reconstructed basins.	No. All PWP/LACFCD flood control and water conservation infrastructure was found ineligible and is not considered an historical resource.	None required	Less than significant

Table 6. Area 3 Impacts Analysis

Proposed Activity	Potential to Impact?	Recommendations to Reduce Impacts?	Level of Significance
Construction of proposed spreading basin improvements include new spreading Basins E, F, G, H, I and J. Each new basin would have an access ramp for maintenance. All basins would include inlets/outlets with 24-inch interconnection pipelines. Spillways, pipelines, culverts, and valves would be provided to connect the basins to each other.	No. All PWP/LACFCD flood control and water conservation infrastructure, including the spreading basins, were found ineligible and are not historical resources.	None required	Less than significant
Rock boulders would be placed along the western edge of Explorer Road to separate the roadway from the adjacent basins.	No. There are no historical resources that would be impacted by the placement of rock boulders along the western edge of Explorer Road, Further, the use of natural materials as a barrier is in conformance with the existing Arroyo Seco Design Guidelines: "Boulders are preferred in establishing perimeter barriers. Typically, they are placed to keep motorized vehicles out of an area." (City of Pasadena 2003:9-3)	It is recommended that boulder placement follow the Arroyo Seco Design Guidelines: "They should be randomly spaced…and slightly buried to look natural and prevent rolling." (City of Pasadena 2003:9-3)	Less than significant

Gabrielino Trail and Bridges 2 and 3

Table 7 provides an analysis of all proposed Project activities associated with the Gabrielino Trail and Bridge Crossings in consideration of the historical resources identified in and around this portion of the APE (Section 6.1), including: Bridge No. 2, Bridge No. 3, and the Arroyo Seco rock wall features.

Table 7. Gabrielino Trail and Bridge Impacts Analysis

Proposed Activity	Potential to Impact?	Recommendations to Reduce Impacts?	Level of Significance
During construction, the Gabrielino Trail/Access Road would provide for vehicular access to and from Area 2, and sometimes Area 3 (Explorer Road will be its primary access road).	**Yes.** Activity along the access road has the potential to impact the concrete railings of Bridge No. 2 and the adjacent Arroyo Seco stone wall features (as described in Section 6.1). These are design features of the larger Arroyo Seco and should be protected from inadvertent damage during construction activities.	**MM-CUL-1**	Less than significant with incorporation of **MM-CUL-1**
The structural overlay bridges spanning the entire length of Bridge Nos. 1 and 3 would remain in place throughout the duration of construction.	No. These structural overlays are already in-place and have been determine essential to safely support vehicles during construction. Bridge No. 1 is not an historical resource under CEQA. With regard to Bridge No. 3, an historical resources impact assessment was prepared for the temporary bridge overlays in conformance with the required 2015 MND mitigation. The analysis states that "although temporary protective measures would be installed for 1-2 years, these protective measures are removable and reversible." (Jerabek 2015)	None required	Less than significant
Upon completion of the proposed Project, the City intends to remove the Bridge No. 1 structure.	No. Bridge No. 1 is not an historical resource and removal of the temporary structure would not impact historical resources.	None required.	Less than significant

Upon completion of the proposed Project, the City intends to keep the Bridge No. 3 structure as-is, complete with additional structural overlay bridge spanning the entire length of Bridge No. 3, into the foreseeable future. To protect public safety, certain elements of the bridge may need to be removed.	**Yes.** Bridge No. 3 is an historical resource under CEQA/historic property under Section 106 of the NHPA. The structural overlay bridge installed in 2017 that spans the entire length of Bridge No. 3 is not in conformance with the Secretary of the Interior's Standards for the Treatment of Historic Properties in consideration of its proposed permanency. The overlay structure, characterized by a steel deck supported by steel I-beam girders, poured-in-place concrete ramps, and tubular metal railings, does not conform to the Secretary of the Interior's Standards for Rehabilitation of a 1930s timber bridge built by the CCC. Nor does the current bridge overlay conform to the City's Arroyo Seco Design Guidelines for Open Structures and Bridges. Now that the overlay is proposed to remain on Bridge No. 3 into the foreseeable future, the existing bridge overlay should be reviewed for conformance with the Arroyo Seco Design Guidelines. As a potentially permanent design feature, the continued presence of the overlay structure on Bridge No. 3 is considered a significant impact to historical resources, as the overlay detracts from nearly all of its important character-defining features and introduces incompatible, highly visible, modern materials. It is anticipated that Bridge No. 3 will continue to deteriorate, and as a result, PWP will need to remove dangerous elements of the bridge (damaged joists, for example) and even partially or fully demolish the bridge to protect public safety as it continues to deteriorate.	**MM-CUL-2** will lessen impacts but will not reduce impacts below a level of significance	Significant even with implementation of **MM-CUL-2**

Table 7. Gabrielino Trail and Bridge Impacts Analysis

Proposed Activity	Potential to Impact?	Recommendations to Reduce Impacts?	Level of Significance
	Whether and when reconstruction/replacement of Bridge No. 3 will take place is unknown, and it is unknown whether the new bridge would be constructed in such a manner that would allow for its preservation as a historical resource.		

Construction Staging Areas

Table 8 provides an analysis of all proposed Project construction staging areas in consideration of the historical resources identified in and around this portion of the APE (Section 6.1), including the Behner WTP.

Table 8. Construction Staging Impacts Analysis

Proposed Activity	Potential to Impact?	Recommendations to Reduce Impacts?	Level of Significance
During construction activities, the Screen Building adjacent to Area 2 would be used for temporary construction materials and equipment staging.	No. The Screen Building Complex and related infrastructure is not an historical resource.	None required	Less than significant
During construction activities, the Behner Water Treatment Plant adjacent to Area 3 would be used for temporary construction materials and equipment staging.	**Yes**. The Behner WTP is considered an historical resource under CEQA/historic property under Section 106 of the NHPA and has the potential to be inadvertently damaged by construction equipment and materials.	**MM-CUL-3**	Less than significant with incorporation of **MM-CUL-3**

Project-wide Impacts

No archaeological resources were identified within the Project site as a result of the current study. Based on the results provided above, the potential of encountering and impacting unknown archaeological resources during Project implementation is low; however, it is always possible that unanticipated discoveries could be encountered during ground-disturbing activities associated with the proposed Project. If such unanticipated discoveries were encountered, impacts to encountered resources could be potentially significant. However, with implementation of MM-CUL-4, which requires that all construction work occurring within 100 feet of the find shall immediately stop until a qualified archaeologist, meeting the Secretary of the Interior's Professional Qualification Standards for Archaeology, can evaluate the significance of the find, potentially significant impacts to archaeological resources would be reduced to less-than-significant levels. With incorporation of **MM-CUL-4**, the Project's potential to cause a substantial adverse change in the significance of an archaeological resource pursuant to §15064.5 would be reduced to a level less than significant.

6.3 Regulations and Mitigation Measures

Implementation of the following mitigation measures will reduce potential project-related impacts to historical and archaeological resources below a level of significance, and would result in no adverse effects to historic properties.

MM-CUL-1. Protection Measures for Bridge No. 2 and Arroyo Stone Features

Prior to the commencement of construction vehicle and truck traffic along the Gabrielino Trail/Access Road north of the JPL Bridge, the City shall ensure that Bridge No. 2 and all identified arroyo stone wall features along the affected portions of the Gabrielino Trail/Access Road are properly protected for the duration of construction activities, as follows: The City shall install temporary protective barriers in the form of concrete k-rails along the decorative railings of Bridge No. 2 on both sides of the road to protect the railings from further deterioration and damage from vehicles. The concrete k-rails shall be removed once the Project is completed leaving Bridge No. 2 intact. The concrete k-rails shall be installed parallel to the Bridge's existing baluster railings, with approximately 2 feet of separation between the k-rail and the resource. The k-rails shall be positioned to ensure that the Bridge railings are protected from daily construction traffic. The k-rails shall not be permanently attached to the bridge. All arroyo stone wall features adjacent to the access road shall be protected by concrete k-rails wherever feasible, however, in areas where k-rails would create an impassable situation for vehicles, the City shall utilize other reasonable protections, including cones and flagging, to ensure that the arroyo stone walls are not inadvertently damaged during construction. The plans for the temporary barriers shall be reviewed by a qualified architectural historian prior to project implementation. In order to ensure that the bridge and stone walls are adequately protected during Project activities, the City shall ensure completion of pre-construction and post-construction surveys by a qualified historic preservation consultant to ensure that adverse effects or significant impacts have not occurred to Bridge No. 2. The installation/construction methodology and post-construction survey shall be submitted to the City of Pasadena Department of Planning – Historic Preservation for review and approval.

MM-CUL-2. Bridge No. 3 Mitigation

Prior to project construction completion, the City shall ensure preparation of Historic American Engineering Record (HAER) documentation for Bridge No. 3 in accordance with the *Secretary of the Interior's Standards for Architectural and Engineering Documentation*. Documentation shall be completed by a qualified historic preservation professional who meets the Secretary of the Interior's Professional Qualifications Standards for architectural

history. The documentation shall capture the physical description of the existing bridge with: 1) existing as-builts/drawings (where/if available); 2) a written narrative that includes a detailed history and architectural description of the bridge and a discussion of its historical significance; 3) photographs of the bridge with large format negatives to demonstrate its current condition; and 4) provide other photographs of the bridge prior to installation of the current overlay. Upon approval of the final HAER package, the City shall offer one original copy of the final HAER package to the City of Pasadena Historic Preservation Program, the South Central Coastal Information Center at California State University, Fullerton, and the Angeles National Forest Administrative Office.

Prior to project construction completion, the City shall conduct a review of the bridge overlay design on Bridge No. 3 and construction materials used in the bridge overlay to determine improvements that can be made to conform with the City's Arroyo Seco Design Guidelines. Examples of potential improvements include, but are not limited to, evaluation of appropriate paint colors that reflect the natural character of the Arroyo Seco, and replacement of components with more natural materials (e.g. wood, concrete, brick, arroyo stone piers, unpainted weathering steel or other natural materials, such as copper and wrought iron). The proposed design improvements shall be submitted to the City of Pasadena Department of Planning – Historic Preservation for review and approval.

MM-CUL-3. Protect Behner WTP Building During Construction

Prior to commencement of Project construction activities that would require equipment staging at the Behner Water Treatment Plant (WTP), the City shall ensure that the exterior of the Behner Water Treatment Plant (WTP) building is adequately protected from equipment and vehicle staging activities. The northwest and southwest exterior elevations of the WTP shall, at a minimum, be protected by construction fencing and signage to ensure that none of the major exterior character-defining features of the building are inadvertently damaged. Fencing shall be placed at a minimum distance of five (5) feet from the exterior of the building, and crews working in the immediate vicinity should be alerted to the presence of an historical resource and instructed to avoid it. The City shall ensure that Project-related equipment and materials are not in contact with the exterior or the building, including absolute avoidance of leaning materials and equipment against exterior walls. The temporary fencing, signage, and barriers shall be removed at the conclusion of construction activities.

MM-CUL-4. Unanticipated Discovery of Cultural Resources

Prior to commencement of earthmoving activities, the City shall retain a qualified Archaeologist meeting the Secretary of the Interior's Professional Qualification Standards for Archaeology. The Archaeologist shall be present at the pre-grade conference; shall establish procedures for archaeological resource surveillance; and shall establish, in cooperation with the Contractor, procedures for temporarily halting or redirecting work to permit the sampling, identification, and evaluation of the artifacts, as appropriate. At a minimum, in the event archaeological resources are exposed during construction activities, all construction work occurring within 100 feet of the find shall immediately stop until a qualified archaeologist can evaluate the significance of the find and determine whether or not additional study is warranted. The Archaeologist shall first determine whether it is a "unique archaeological resource" pursuant to the California Environmental Quality Act (CEQA, i.e., Section 21083.2[g] of the California Public Resources Code) or a "historical resource" pursuant to Section 15064.5(a) of the State CEQA Guidelines. If the archaeological resource is determined to be a "unique archaeological resource" or a "historical resource", the Archaeologist shall formulate a mitigation plan in consultation with the City of Pasadena that satisfies the requirements of the above-referenced sections. The Archaeologist shall prepare a report of the results of any study prepared as part of a testing or mitigation plan, following guidelines of the California Office of Historic Preservation, and s/he shall record the site and submit the recordation form to the City of Pasadena and the

California Historic Resources Information System (CHRIS) at the South Central Coastal Information Center (SCCIC) at California State University, Fullerton. Work may proceed in other areas of the site, subject to the direction of the Archaeologist.

Regulatory Compliance: Unanticipated Discovery of Human Remains

The discovery of human remains would require handling in accordance with California Public Resources Code. In accordance with Section 7050.5 of the California Health and Safety Code, if human remains are found within the Project site, the County Coroner must be notified of the discovery within 24 hours. No further excavation or disturbance of the site or any nearby area reasonably suspected to overlie adjacent remains can occur until the County Coroner has determined, within two (2) working days of notification of the discovery, the appropriate treatment and disposition of the human remains. If the County Coroner determines that the remains are, or are believed to be, Native American, he or she must notify the NAHC in Sacramento within 24 hours. In accordance with California Public Resources Code, Section 5097.98, the NAHC must immediately notify those persons it believes to be the most likely descendant of the deceased Native American. The most likely descendant must complete his/her inspection within 48 hours of being granted access to the site. The designated most likely descendant would then determine, in consultation with the property owner, the disposition of the human remains.

INTENTIONALLY LEFT BLANK

7 Findings and Conclusions

7.1 Summary of Findings

The following resources within the Project APE were identified as historical resources under CEQA and historic properties under Section 106 of the NHPA:

- John L. Behner Water Treatment Plant (3S/3CS/5S3)
- Bridge No. 2 (3S/3CS/5S3)
- Bridge No. 3 (3S/3CS/5S3)

Additionally, five (5) features were identified within the APE that are considered character-defining features of the larger Arroyo Seco, and should be avoided/protected as part of the current project, including:

- rock retaining wall for on northeast side of Arroyo Seco Canyon roadbed (Figures 11 and 12);
- rock retaining wall supporting the east-most canyon wall (Figure 13);
- rock retaining wall near screen building (Figure 14);
- rock wall barrier on side of road near intake/weir structure (also Figure 14);
- rock wall barrier on south side of Bridge No. 2 (Figure 15).

The remaining resources identified within the APE, including the Screen Building Complex, Bridge No. 1, and the LACFCD infrastructure do not appear eligible for NRHP, CRHR, or City designation due to a lack of significant historical associations and architectural merit. Therefore, these properties are not considered historical resources under CEQA or historic properties under Section 106 of the NHPA.

7.2 Conclusions

CEQA requires a lead agency to determine whether a project may have a significant effect on historical resources (PRC section 21084.1; CEQA Guidelines section 15064.5(b)). All historical resources identified within the APE have the potential to be impacted by the proposed project. Implementation of MM-CUL-1 through -5 (Section 6.3), will reduce impacts to the John L. Behner WTP, Bridge No. 2, and the Arroyo Seco stone wall features to a less than significant level. However, impacts will remain significant and unavoidable for Bridge No. 3 since the structural overlay bridge installed in 2017 is not in conformance with the Secretary of the Interior's Standards for the Treatment of Historic Properties or the Arroyo Seco Design Guidelines in consideration of its proposed permanency. The overlay structure, characterized by a steel deck supported by steel I-beam girders, poured-in-place concrete ramps, and tubular metal railings, does not conform to the Secretary of the Interior's Standards for Rehabilitation of a 1930s timber bridge built by the CCC. As a potentially permanent design feature, the continued presence of the overlay structure on Bridge No. 3 is considered a significant impact to historical resources, as the overlay detracts from nearly all of its important character-defining features and introduces incompatible, highly visible, modern materials.

It is anticipated that Bridge No. 3 will continue to deteriorate, and as a result, PWP will need to remove dangerous elements of the bridge (damaged joists, for example) and even partially or fully demolish the bridge to protect public safety as it continues to deteriorate. Whether and when ultimate reconstruction/replacement of Bridge No. 3 will be undertaken is unknown, and it is unknown whether the new bridge would be constructed in such a manner that would allow for its preservation as a historical resource. Therefore, impacts to historical resources under CEQA are considered significant and unavoidable, even with implementation of MM-CUL-2.

Section 106 of NHPA requires federal agencies to take into account the effects of their undertakings on historic properties, assess the effects, and seek ways to avoid, minimize, or mitigate any adverse effects on such properties (36 CFR 800.1[a]). In consideration of the discussion above for Bridge No. 3, the proposed project would result in adverse effects to historic properties that cannot be mitigated in a way that would eliminate or reduce effects.

Appendix A

Preparers' Qualifications

Kara R. Dotter, MSHP, MS

Senior Historic Preservation Specialist, Architectural Historian

Kara R. Dotter, Senior Historic Preservation Specialist and Architectural Historian with Dudek, brings with her over 15 years of experience in historic preservation and architectural materials conservation. Initially based in Austin, Texas, where she worked for WJE Associates as an Historic Preservation Specialist, she worked overseas in Northern Ireland before moving to San Diego, where she worked for IS Architecture before joining Dudek. Her recent work as Project Lead concentrates on supporting NEPA and CEQA compliance for the Built Environment component of Construction Package 2-3 of the Fresno to Bakersfield project section of the California High-Speed Rail Project.

Relevant Project Experience

Environmental Preconstruction Services for Construction Package 2 and 3, California High-Speed Rail Authority, Fresno to Bakersfield Section, California. Served as project lead for the Built Environment component of the environmental preconstruction services. The work involves conducting cultural resources assessments for a proposed 65-mile-long segment of the Fresno to Bakersfield high-speed rail alignment as directed by the California High-Speed Rail Authority and Federal Transit Administration (FTA) in order to comply with NEPA and CEQA regulations. Contributions include architectural history field surveys; documenting and updating the CRHR-designated 7,040-acre Washington Irrigated Colony Rural Historic Landscape; completion of over 150 California Department of Parks and Recreation (DPR) forms for the evaluation of built environment resources; conducting research for and producing HASRs and supplemental Findings of Effect (sFOEs); development of Protection and Stabilization Plans and Response Plans for Unanticipated Effects and Unintended Damage; managing structural and vibration engineering consultants; and overseeing vibration monitoring of sensitive historic resources.

Environmental Compliance Services for the Caltrain Modernization (Calmod) Peninsula Corridor Electrification Project (PCEP). Ms. Dotter is the project lead for the Built Environment component of the environmental compliance services. The work involves cultural resources documentation in order to comply with NEPA and CEQA regulations relating to the electrification and increased capacity of the Caltrain Corridor from San Francisco's 4th and King Caltrain Station to approximately the Tamien Caltrain Station. Ms. Dotter's contributions include architectural history field surveys; managing subconsultants; conducting research for and producing documentation to HABS level III standards; and reviewing design plans and equipment placement for conformance with the Secretary of the Interior Standards for Rehabilitation.

SDSU West Campus Project EIR, San Diego, California. Dudek was retained by the San Diego State University (SDSU) to conduct an Initial Study and EIR for the proposed West Campus expansion project located in San Diego, California. Part of the work included evaluating potential impacts to historical resources located on the project

site, which include the SDCCU Stadium, originally known as the San Diego Stadium. The historic resources technical memorandum provided the results of that evaluation, as well as an impacts analysis and recommended mitigation measures. Ms. Dotter conducted the site survey and archival research, and authored the memorandum.

Jacumba Valley Solar Project, San Diego County, California. The project proposes a 100 megawatt solar farm that included photovoltaic solar panels, a 1,500-volt DC underground collection system, a 34.5 kilovolt overhead and underground collection system, and a 20 megawatt energy storage facility. Served as architectural historian and lead author of the historical resources constraints analysis to comply with CEQA and of the resulting Historical Resources Technical Report conducted for the Environmental Impact Report. The constraints analysis identified one potential historical resource, the remains of an early 20th century dairy operation, for which a Historical Resources Technical Report and DPR forms was completed in compliance with CEQA.

Department of General Services Historical Resource Evaluation for the Normal Street Department of Motor Vehicles Site at 3960 Normal Street, San Diego, California. Dudek was retained by the State of California Department of General Services to complete a Historical Resources Technical Report for a project that proposes demolition and replacement of the Department of Motor Vehicles (DMV) building located at 3960 Normal Street in the City of San Diego. To comply with Public Resources Code Section 5024(b), DGS must submit to the State Historic Preservation Officer (SHPO) an inventory of all structures over 50 years of age under DGS's jurisdiction that are listed in or that may be eligible for inclusion in the National Register of Historic Places (NRHP), or that may be eligible for registration as a California Historical Landmark (CHL). The DMV was found not eligible. Authored the Historical Resources Technical Report, as well as recording and evaluating the Normal Street DMV building for Federal, State, and local level criteria and integrity considerations, completion of DPR forms, and responding to SHPO comments.

Historical Resources Evaluation of Public Utilities Department Reservoir Structures, City of San Diego, California. The project proposes upgrades to ten historic-era dams, an historic-era flume, and various attendant structures, within the San Diego water supply network. Serving as architectural historian and co-author of a multiple-property historical resources evaluation report. Project includes development of a network-wide historical context, as well as contexts for each contributor; multiple field surveys; archival research; consideration of potential impacts to historical resources under CEQA; appropriate mitigation measures; and review for conformance with the SOI's Standards for the Treatment of Historic Properties.

Municipal Waterways Maintenance Plan, City of San Diego, San Diego County, California. Dudek was retained by the City of San Diego and the Bureau of Reclamation to initiate the processing of a joint EIR and EIS. The proposed WMP is intended to establish an effective and streamlined program that allows for waterway facilities (channels, ditches, sumps) to be maintained, while minimizing impacts and potential adverse effects of maintenance. The proposed WMP will outline specific activities, maintenance methods, and procedures that will guide future maintenance and repair activities. Served as lead author of the Historical Resources Inventory and Analysis Report, conducting archival research; identifying potential historical resources; and analyzing the proposed WMP maintenance activities to determine their potential to impact historical resources.

North County Pure Water Project, City of San Diego, California. Served as architectural historian and lead author of the Historical Resource Technical Report for the proposed pipeline route as part of the EIR/EIS. Preparation of the report involved conducting building development and archival research on historic-era structures along the 56-mile-long route, development of historic contexts, historical significance evaluations for each historic-era structure in consideration of local, state, and national designation criteria requirements, and determining appropriate mitigation measures, in addition to responding to comments on the EIR/EIS from the public.

Kate Kaiser, MSHP

Architectural Historian

Kate Kaiser is an architectural historian with 8 years' professional experience as a cultural resource manager specializing in California Environmental Quality Act (CEQA) compliance, National Historic Preservation Act Section 106 compliance, reconnaissance and intensive level surveys, archival research, cultural landscapes, and GIS. Ms. Kaiser meets the Secretary of the Interior's Professional Qualification Standards for architectural history and archaeology.

Relevant Dudek Project Experience

Gilroy City-wide Historic Resource Inventory, City of Gilroy, Santa Clara County, California. Served as architectural historian and co-author for the citywide historic context statement. Preparation of the historical context statement involved extensive archival research, coordination with the City of Gilroy and archival repositories, and developing the historical narrative and themes for the City. The project also involved creation and editing of a GIS database of over 3,400 properties in order to create the building records and State of California Department of Parks and Recreation Series 523 forms (DPR forms) for each property surveyed. Ms. Kaiser assisted in the creation, editing, and data management of the DPR forms produced for each building as well as historic districts.

Olympic Well Field Restoration and Arcadia Water Treatment Plant Expansion Project, City of Santa Monica, Los Angeles County, California. Served as architectural historian and author of the Historic Resources Technical Report. The report evaluated the Arcadia Water Treatment Plant and a well along Olympic Boulevard. The project proposed to demolish several underutilized buildings and structures as part of a multi-component project to add new wells to the Olympic Well Field, construct a new 16-inch pipeline connecting the Olympic Well Field to a new Olympic Advanced Water Treatment Facility, and expand the Arcadia water Treatment.

Modelo Project Environmental Impact Report, City of Commerce, Los Angeles County, California. Served as architectural historian and co-authorfor the Cultural Resources Technical Report and EIR cultural resources chapter. The report evaluated the Veterans Memorial Park located within the proposed Project area. The project proposed to demolish and redevelop the Project site to accommodate a mixed-use development and park.

Arroyo Seco Canyon Project, City of Pasadena, Los Angeles County, California. Served as architectural historian and co-author for the Cultural Resources Technical Report. The report evaluated six historic-aged engineering buildings and infrastructure systems within the proposed project area. Dudek recommended that all buildings and structures were ineligible for listing in the NRHP or CRHR with the exception of the Behner Water Treatment Plant, and provided impacts analysis for City of Pasadena Arroyo Seco Stone Wall design elements present in the proposed Project Area.

Silent Ranch Hillside Subdivision Project, City of Glendora, Los Angeles County, California. Served as architectural historian and author of the Historic Resources Technical Report. The report evaluated Charles Silent's Rancho Los Alisos property, Girl Scout Camp Aventura, Forest Service flood control dams, and a segment of the MWD Upper Feeder Pipeline. The project proposed indirect impacts to the setting of the pipeline and provided for protection against damage or overloading as the pipeline is an MWD public utility.

City of Irwindale Speculative Concrete Tilt-Up Building Project. Irwindale, Los Angeles County, California. Kaiser served as architectural historian and author of the Cultural Resources Technical Report. The report evaluated a hollow-core concrete panel manufacturing plant in southeast Irwindale. The project proposed to demolish all buildings and structures in the project site and construct a 528 710 s.f., tilt-up concrete warehouse on the parcel.

LADWP Valley Generating Station Project, Los Angeles Department of Water and Power, California. Served as architectural historian and author of the Cultural Resources Technical Report for the Valley Generating Station Project. The report evaluated the historical significance for each building and structure in the study area. The project proposed to remove the 1953 steam generating plant, as well as the four stacks, SPRR rail spur, and underground fuel tanks.

Judicial Council of California Historical Resource Evaluation Report for the Stanley Mosk Courthouse, City of Los Angeles, Los Angeles County, California. Served as architectural historian and author of the Historical Resource Evaluation Report. Dudek was retained by the Judicial Council of California (JCC) to prepare an evaluation of the Stanley Mosk Los Angeles County Courthouse building, located at 111 N. Hill Street in the City of Los Angeles, California, in order to comply with Public Resources Code Section 5024(b). The report concluded the Stanley Mosk Courthouse was eligible for designation as a historic property in the NRHP, CHL, CRHR, and Los Angeles Historic Cultural Monument list under Criterion A/1 and C/3.

Phillips 66 and Kinder Morgan Relocation Project, Berths 150-151, Marine Oil Terminal Engineering and Maintenance Standards (MOTEMS), Port of Los Angeles, California. Served as architectural historian and co-author of the Updated Historical Resources Evaluation. Preparation of the report involved reviewing previous evaluations for Union Oil Terminal Berths 150-151 and writing an updated significance evaluation. The project proposed to remove and replace the original wharfs with new concrete loading platform, mooring and breasting dolphins, access ramps, catwalks, and an underwater bulkhead.

Globemaster Corridor Specific Plan, City of Long Beach, Los Angeles County, California. Served as architectural historian and author of the Draft EIR-EIS Cultural Resources Chapter. The project includes rezoning portions of the GCSP area, and a mobility plan that implements new streets and pedestrian connectors. Since the GCSP does not directly propose changes to the buildings or structures in the Plan area, the cultural resources report takes a programmatic overview and offers potential impacts analysis and mitigation measures for future development.

LADWP De Soto Tanks Project, Los Angeles Department of Water and Power, California. Served as architectural historian and author of the Historic Properties Identification Report. The report evaluated a 1941 reservoir and associated buildings. The project proposed to replace them with modern underground storage tanks, as well as connections to other trunk lines. The project also analyzed the potential project impacts to the Chatsworth Momonga/Mission Trail, a City of Los Angeles Historic-Cultural Monument (HCM) adjacent to the Project area.

Campus-wide Historic Context Statement for California State University Long Beach, City of Long Beach, Los Angeles County, California. Served as architectural historian and co-author of the historic context statement analyzing the effect of master architect Edward Killingsworth on the development of the campus. Preparation of the historic context statement involved extensive archival research, in-person interviews of architects who worked on-campus, review of CSU Long Beach building and landscape records, and coordination with local heritage groups.

Kaiser Permanente Los Angeles Medical Center Project, Los Angeles, Los Angeles County, California. Served as architectural historian and co-author of the Draft EIR Cultural Resources Chapter and the author of the cultural resources technical report. The report evaluated six buildings greater than 45 years in age that are proposed for demolition as part of the multiphase project. The DEIR chapter also analyzed potential indirect impacts on two other National Register listed or eligible sites: the Aline Barnsdall Complex and the Hollywood Presbyterian Medical Center.

Samantha Murray, MA

Historic Built Environment Lead / Senior Architectural Historian

Samantha Murray is a senior architectural historian with 14 years' professional experience in in all elements of cultural resources management, including project management, intensive-level field investigations, architectural history studies, and historical significance evaluations in consideration of the California Register of Historical Resources (CRHR), the National Register of Historic Places (NRHP), and local-level evaluation criteria. She meets the Secretary of the Interior's Professional Qualification Standards for both Architectural History and Archaeology.

Education

California State University, Los Angeles
MA, Anthropology, 2013

California State University, Northridge
BA, Anthropology, 2003

Professional Affiliations

California Preservation Foundation

Society of Architectural Historians

National Trust for Historic Preservation

Registered Professional Archaeologist

Ms. Murray is skilled in the recordation, evaluation, and mitigation of adverse effects to historic water resource infrastructure throughout California, including dams, reservoirs, pumping stations, channels, and culverts. Understanding the scale and complexity of this unique resource type, Ms. Murray has guided architects and engineers through the process of adjusting plans to conform with the Secretary of the Interior's Standards for Rehabilitation, and understands the need to strike a balance between preservation and functionality. In addition to her expertise with water resource infrastructure, she has prepared hundreds of historical resource evaluations and developed detailed historic context statements for a multitude of property types and architectural styles, including private residential, commercial, industrial, educational, medical, ranching, mining, airport, and cemetery properties. Ms. Murray also has a strong understanding of consultation with the State Historic Preservation Officer (SHPO), and regularly receives SHPO concurrence with no comments. She has also provided expertise on numerous projects requiring conformance with the *Secretary of the Interior's Standards for the Treatment of Historic Properties*.

Finally, Ms. Murray has extensive experience preparing environmental compliance documentation in support of projects that fall under the California Environmental Quality Act (CEQA)/National Environmental Policy Act (NEPA), and Sections 106 and 110 of the National Historic Preservation Act (NHPA). She also regularly works with local governments and historic preservation ordinance requirements. Ms. Murray has also served as a third-party reviewer and expert witness in court proceedings concerning interpretation and treatment of historical resources under CEQA and local municipal code.

Select Water Infrastructure Project Experience

San Diego PUD Citywide Historic Context Statement and Evaluation of Dam Infrastructure (in progress). Dudek is currently in the process of preparing a citywide historic context statement and significance evaluation of all dam and reservoir infrastructure owned/operated by the City's Public Utilities Department. Dudek is also preparing detailed impacts assessments for proposed modification to dams, as required by DSOD. The project involves evaluation of 10 dams and a flume for historical significance in consideration of NRHP, CRHR, and City designation criteria and integrity requirements, and requires extensive archival research and pedestrian survey. Upon completion of the project, the City will have a streamlined document for the management of their historic dam

and reservoir infrastructure. To date, Dudek has completed a draft historic context statement and multiple dam historical significance evaluations.

City of Santa Cruz Newell Creek Dam Inlet Outlet Replacement Project (2019). Dudek worked with the City of Santa Cruz. The Newell Creek Dam is an earthen dam approximately 195 feet high with a crest length of about 750 feet. Built in 1961, the dam forms Loch Lomond Reservoir (Reservoir), which has a maximum storage capacity of approximately 8,646 acre-feet. The proposed Project would consist of replacement of the existing aging inlet/outlet works in new locations at the Reservoir and other associated improvements. Dudek completed an historical resource evaluation of the dam and associated infrastructure in consideration of NRHP, CRHR, and City designation criteria and integrity requirements and prepare a detailed impacts assessment. Ms. Murray oversaw completion of the dam site evaluation and technical report.

Floriston Springs Filtration Project, Floriston, Nevada County, California (2018). Kennedy/Jenks Consultants Inc. retained Dudek to complete a cultural resources study. The Floriston Property Owners Association seeks to renovate the Floriston Water Treatment Plant and pipeline, as the existing facilities do not meet the water supply, water treatment conditions, and water pressure demand of Floriston. Dudek's cultural resources study included a pedestrian survey of the project site for cultural resources, building development and archival research, recordation and evaluation of several buildings on the project site over 45 years of age, and an assessment of project-related impacts to historical resources in conformance with the CEQA and all applicable local municipal code and planning documents. The Floriston Schoolhouse, constructed circa 1900, was found not eligible under all NRHP and CRHR designation criteria. Ms. Murray oversaw the built environment components of the final cultural resources report.

Morena Reservoir Outlet Tower Replacement Project, City of San Diego, California (2016). Ms. Murray evaluated the 1912 Morena Dam and Outlet Tower for NRHP, CRHR, and local level eligibility and integrity requirements. The project entailed conducting extensive archival research and development research at City archives, libraries, and historical societies, and preparation of a detailed historic context statement on the history of water development in San Diego County.

Los Angeles Department of Water and Power (LADWP) As-Needed Environmental Compliance Services (2016-ongoing). Dudek provides on-call environmental services to the LADWP. As part of this contract, Dudek has prepared CEQA+ documentation (CEQA and Section 106 of the NHPA) for a range of infrastructure projects, including groundwater treatment facilities, power plants, electrical transmission and distribution facilities, reservoirs, pipelines, roadways, and other related infrastructure. This documentation typically includes completion of a California Historical Resources Information System records search, Native American consultation, intensive pedestrian survey, identification of historical resources/historic properties, and an assessment of project-related impacts/effects. Some of Dudek's recent task orders that required cultural resources technical reports include:

- City Trunk Line Project
- Western Trunk Line Project
- De Soto Trunk Line Project
- Coronado Trunk Line Project
- West Los Angeles District Yard Project
- Haynes Generating Station Units 3-6 Demolition Project
- Tujunga Spreading Grounds Enhancement Project
- Upper Stone Canyon Reservoir Water Quality Improvement Project
- Power Plant (PP) 1 and 2 Transmission Line Conversion Project

Adriane Dorrler

As-Needed Archaeologist

Adriane Dorrler is a field archaeologist with more than 14 years' experience in cultural resource management specializing in cultural resource studies with private, state, and federal regulatory agencies including National Historic Preservation Act (NHPA) Sections 106 and 110 and California Environmental Quality Act (CEQA) compliance extending primarily throughout Southern California. Ms. Dorrler has worked directly with Bureau of Land Management, the California Public Utilities Commission, California State Parks, and various military installations including the Marine Corps Air Ground Combat Center at Twentynine Palms, Marine Corps Base (MCB) Camp Pendleton, Naval Base Coronado, and Navy Installation San Clemente Island. She has experience in all aspects of project development from initial research, planning, and development to interpreting and synthesizing data in technical reports. Ms. Dorrler has acted as project manager and field director on complex data recovery programs, managed multiple archaeology laboratories, worked as liaison between Native American tribes and clients, and engaged in education and public outreach programs. In addition to Southern California, Ms. Dorrler has worked as a consulting archaeologist in the southwestern United States, the Mid-Atlantic region, and New England.

Project Experience

Development

Cannon Road, Caruso Affiliated, City of Carlsbad, San Diego County, California. Served as field director for a cultural resources constraints study of a 203-acre property for a proposed commercial retail center and open space easement in the City of Carlsbad. Conducted an intensive-level cultural resources survey.

Solana Highlands Revitalization, City of Solana Beach, San Diego County, California. Served as staff archaeologist during the preparation of an Environmental Impact Report (EIR) for a proposed 13.4-acre multifamily residential development with usable open space in Solana Beach. Authored Tribal Information Request letters in accordance with CEQA guidelines.

Murrieta 180, City of Murrieta, California. Served as field director for archaeological survey of a 10.9-acre property for a proposed multifamily residential development in Murrieta. Conducted a Phase I cultural resources inventory including a pedestrian survey and records search review of the California Historical Resources Information System.

Homestead South Cultural Resources, Newhall Land and Farming Company, Unincorporated Los Angeles County, California. Served as field director for archaeological survey of approximately 4,000-acre subdivision directly adjacent to the City of Santa Clarita. Conducted an intensive-level cultural resources survey.

Sand Canyon Plaza, JSB Development, City of Santa Clarita, California. Served as staff archaeologist during a Phase I cultural resources inventory for a proposed commercial and residential planning development in Santa Clarita. Performed a records search review of the California Historical Resources Information System.

Newland Sierra, Newland Land Co., San Diego, California. Served as staff archaeologist for the Phase I cultural resources inventory and Phase II significance evaluation of 1,983 acres of a proposed residential development within the North County Metro Subregion. Conducted a pedestrian survey, performed a records search review of the California Historical Resources Information System, and was a contributing author in the technical report.

As-Needed Environmental Planning Consultant Support Services, City of San Diego, California. Served as archaeological and paleontological monitor for underground conduit system installation in the neighborhood of Encanto. Tasks include environmental compliance monitoring.

Cultural Resources Evaluation for Rancho Jamul Estates, Rancho Jamul Estates, San Diego County, California. Served as archaeologist responsible for surveying and testing for 20 historic and prehistoric resources for an approximately 400-acre development project in Jamul, California. Recorded and tested prehistoric and historic resources for significance and eligibility to local and state registers. Assisted in preparation and data analysis of technical report.

Cultural Resource Mitigation for Robertson Ranch, San Diego County, California. Served as archaeologist responsible for data recovery, controlled grading, and mass grading phases for an approximately 400-acre development project in Carlsbad, California. Assisted in preparation and data analysis of technical report.

Centre City Development Corporation Downtown San Diego Mitigation and Monitoring Reporting Program, Centre City Development Corporation, San Diego, California. Served as field director/archaeology and paleontology monitor for numerous commercial projects in downtown San Diego subject to the Centre City Development Corporation mitigation measures and mitigation monitoring requirements. Examples of projects include:

- The Q Project
- Lofts @ 707 10th Avenue Project
- South Block Lofts Project
- Vista Colina Project
- 6th and Market Project
- Carnation Building/Icon LLC Project
- Electra Project
- Park Terrace Project
- Pointe of View Project
- Vantage Pointe Project
- West Park Project
- Q Street Lofts Project
- The Mark

Cultural and Paleontological Resource Monitoring for the Towne Center Industrial Plaza Project, Imperial County, California. Served as archaeological and paleontological monitor for the mass grading and utility trenching of 125 acres of commercial/industrial land in Calexico, California.

Cultural Resource Survey for the Ketchum Ranch Project, San Diego County, California. Served as archaeologist responsible for field survey and eligibility review for prehistoric and historic sites for an approximately 208-acre development project in Jacumba, California.

Cultural Resource Survey for the Yuma Sector Project, BLM, Yuma County, Arizona. Served as archaeology crew chief responsible for in field survey and National Register eligibility review for ten prehistoric sites and three historic objects.

Cultural Resource Survey and Evaluation for the Otay Business Park Project, San Diego County, California. Served as archaeologist responsible for surveying and testing programs for an approximately 160-acre development

Linda Kry

Archaeologist

Linda Kry is an archaeologist with 13 years' experience in cultural resource management specializing in various aspects of cultural resources investigations within Los Angeles County, Orange County, San Bernardino County, Kern County, Imperial County, Inyo County, Riverside County, and the Mojave Desert. Ms. Kry's experience includes archival research, reconnaissance surveys, artifact analysis, assisting CEQA lead agencies with AB-52 notification and consultation process, and authoring technical reports pursuant to CEQA and Section 106 of the NHPA. Ms. Kry's extensive experience includes the management of cultural resources specialists in support of various aspects of cultural resources compliance, construction monitoring, Native American consultation, archaeological testing and treatment, and prehistoric and historical resource significance evaluations.

Education

University of California, Los Angeles
BA, Anthropology, 2006
Cerritos College
AA, Anthropology, 2004

Project Experience

De Soto Trunk Line Project, Los Angeles Department of Water and Power, Los Angeles, California. Archaeological lead for a cultural resources study pursuant to CEQA and Section 106 of the National Historic Preservation Act (NHPA). Los Angeles Department of Water and Power LADWP is proposing to replace the portions of the De Soto Trunk Line located in West San Fernando Valley. The proposed project would increase the safety, capacity and reliability of LADWP's water system in the western San Fernando Valley.

Haynes Generating Station Demolition Project, Los Angeles County Department of Public Works, Malibu, California. Archaeological lead and monitoring coordinator. The project included the demolition of Units 3, 4, 5, and 6 at the Haynes Generating Station (HnGS), which were originally constructed more than five decades ago, to minimize health and safety risks and reduce future maintenance.

Old Topanga Road Over Old Topanga Creek Bridge Maintenance Repair Project, Los Angeles County Department of Public Works, Val Verde Area of Unincorporated Los Angeles County, California. Archaeological lead for a cultural resources study pursuant to CEQA in support of a Mitigated Negative Declaration. Tasks include Assembly Bill (AB) 52 consultation support to identify known tribal cultural resources within the project's proposed Area of Potential Effect (APE) to analyze the potential impacts to cultural resources and provide mitigation to a less than significant level.

Compton Boulevard over Compton Creek and Wilmington Avenue over Compton Creek Bridge Replacement Projects, Compton, California. Archaeological lead for a cultural resources study pursuant to CEQA and Section 106 of the NHPA and in conformance with Caltrans requirements. As archaeological lead, tasks include coordination for a cultural resources study, including AB 52 consultation support, and preparation of Archaeological Survey Reports (ASRs) for each proposed project.

City Trunk Line South Project, Los Angeles Department of Water and Power, Los Angeles, California. Archaeological lead for a cultural resources study pursuant to CEQA and Section 106 of the NHPA. Los Angeles Department of Water and Power LADWP is proposing to replace an old and deteriorating trunk line that was built in 1914 and has a history of leaks and breaks. The proposed trunk link will improve capacity, reliability, and flexibility in the water system.

February 2019 Storm Repair Project, Los Angeles County Department of Public Works, Malibu, California. Archaeological lead responsible for managing the cultural resources inventory and assessment of cultural resources

within the project area in support of emergency guardrail replacement work in the Woolsey Fire burn area. Responsibilities also include coordinating Native American monitoring needs for the project.

FLOR 401 E 7th Street Construction Monitoring, Skid Row Housing Trust, Los Angeles, California. Project manager for construction monitoring for the development of 99 units of permanent supportive housing for homeless veterans and/or special needs populations, and affordable housing for low-income individuals in Downtown Los Angeles.

Woolsey Fire Guardrails Replacement Project, Los Angeles County Department of Public Works, Malibu, California. Archaeological lead responsible for managing the cultural resources inventory and assessment of cultural resources within the project area in support of emergency guardrail replacement work in the Woolsey Fire burn area. Responsibilities also include coordinating Native American monitoring needs for the project.

Coronado Trunk Line Project, Los Angeles Department of Water and Power, Los Angeles, California. Archaeological lead for a Phase I cultural resources study pursuant to CEQA and Section 106 of the NHPA. Los Angeles Department of Water and Power is proposing to construct a new 30-inch diameter welded steel pipe, approximately 7,200 feet in length, along with a regulating and relief station vault and flow master vault. The proposed trunk line would add reliability and redundancy to the system.

River Supply Conduit Unit 7 Project, Los Angeles Department of Water and Power, Los Angeles and Burbank, California. Archaeological lead and monitoring coordinator for archaeological and paleontological services in support of the River Supply Conduit (RSC) Unit 7 Project. The existing River Supply Conduit (RSC) is a major transmission pipeline in the LADWP water distribution system. The Project is critical to meet safety of water supplies, reliability of water infrastructure, and sustainability of water supply.

8th, Grand and Hope Project, Eyestone Environmental, Los Angeles, California. Archaeological lead providing management oversight and reporting for tribal cultural resources (TCRs) and archaeological studies in support of a proposed 45-story mixed-use project in Downtown Los Angeles.

Bellwood Avenue Project, Eyestone Environmental, Los Angeles, California. Archaeological lead providing management oversight and reporting for a TCR study for a project that proposes to develop a new eldercare facility on a 2.22-acre site in the West Los Angeles Community Plan are of the City of Los Angeles.

313-333 San Vicente Boulevard Project, Eyestone Environmental, Los Angeles, California. Archaeological lead providing management oversight and reporting for a TCR study for a project that proposes to develop a 19-story, multi-family residential building and the deconstruction, reassembly, rehabilitation and limited alteration of the existing cathedral of Our Lady of Mount Lebanon – Saint Maronite Catholic Cathedral.

Relevant Previous Experience

Los Angeles International Airport (LAX) Midfield Satellite Concourse, Los Angeles, California. Served as field director for archaeological and paleontological monitoring project associated with the creation of a new aircraft passenger concourse and associated elements at LAX. Responsibilities included coordinating with company personnel and project contractors, scheduling, and recordation and collection of field data.

Los Angeles Metropolitan Transportation Authority Compliance Monitoring, Los Angeles, California. Served as archaeological and paleontological monitoring coordinator for the multiyear and multisite project within the greater Los Angeles area, including the Crenshaw rail transit corridor and the 1.9-mile Regional Connector subway. Responsibilities included coordinating and scheduling various contractors and archaeologists; developing and providing cultural resources training for new contractors and archaeologists; monthly project updates to client; invoice and budget reviews; lab analysis of all resources collected and preparation of those resources for curation.

Heather McDaniel McDevitt, RPA

Archaeologist and Human Osteologist

Heather McDaniel McDevitt is an archaeologist and Cultural Resources Lead for Dudek's Santa Barbara office with over 13 years of cultural resource management (CRM) experience throughout California and Baja California. Ms. McDaniel McDevitt also serves as Dudek Lead Human Osteologist providing on-call osteological services corporate-wide. Ms. McDaniel McDevitt has served as a field supervisor, lab director, principal investigator and project manager on Phase I, Extended Phase I, Phase II, and Phase III projects conducting surveys, testing, site significance evaluations and recordation, data recovery and laboratory analysis. Her education encompasses archaeology, biological anthropology, and GIS. As a bioarchaeologist, Ms. McDaniel McDevitt combines physical anthropology and archaeology in the study of faunal and human remains to reveal ancient lifeways. Her specific area of GIS research is the use of predictive modeling and remote sensing to better understand settlement and subsistence patterns, which can be used to forecast areas of potential impacts and assist in mitigating damage to cultural resources more efficiently.

Ms. McDaniel McDevitt has worked on projects for the National Park Service, U.S. Environmental Protection Agency (EPA), National Aeronautics and Space Administration, U.S. Bureau of Land Management, the Smithsonian Institute, California State Parks, California Department of Transportation, and various private CRM and environmental firms. Ms. McDaniel McDevitt's professional experience in CRM provides significant knowledge and practical experience with state and federal regulations such as the National Environmental Policy Act (NEPA), Section 106 of the National Hictoric Preservation Act, and the California Environmental Quality Act (CEQA). Ms. McDaniel McDevitt has also served as an adjunct professor at community and state institutions for courses in physical and cultural anthropology, archaeology, and GIS.

Selected Project Experience

Chatsworth Reservoir Mitigation Feasibility Study, Chatsworth, Los Angeles County. Provided senior review and support for LADWP on-call contract task order for potential compensatory mitigation projects on LADWP property and facilities located within the Chatsworth Reservoir, previously nominated as a Historic-Cultural Monument with the City of Los Angeles. Efforts included constraints analysis considering archaeological, historic built resources and paleontological resources both unknown and previously identified through literature review, NAHC Sacred Land

Files records search, paleontological records search. Results were summarized in a report memo in including a discussion of the potential constraints and mitigation measures necessary should the project proceed.

Agoura Village East Multi-Use Complex Cultural Resource Studies, Agoura Hills, Los Angeles County. As Principal Investigator designed and implemented research design involving previously recorded archaeological site CA-LAN-41. Supervised and conducted excavations intended to delineate horizontal and vertical extent of the site, site significance, and analysis on recovered remains, Native American consultation and preparation of final reports including avoidance/mitigation strategies. Currently devising research design and methodology for data recovery of unavoidable impacts to site and supporting Native American consultation efforts for City of Agoura Hills.

1225 Cliff Drive Archaeological and Paleontological Study, Laguna Beach, Los Angeles County. Provided senior review and support for archaeological and paleontological resources studies for a private development. Tasks to determine sensitivity of project site included Paleontological and archaeological records searches and literature reviews, NAHC Sacred Land Files search and coordination of informal tribal outreach, pedestrian survey and report preparation.

February 2019 Storm Repair Project, Los Angeles County Department of Public Works, Malibu, California. Provided senior review and support for LADPW on-call contract task order to provide cultural resources services in for construction activities of storm repair project located in Santa Monica Coastal Zone. Involves cultural resource survey of project impact areas, management of monitoring staff, providing recommendations to construction and project management staff, assisting with implementing mitigation plan, providing field visit verification reports and assisting in Native American consultation efforts.

Pacific Palisades Village Initial Study/Mitigated Negative Declaration, Los Angeles, California. As project archaeologist, conducted Phase 1 Archaeological Investigation, prepared technical report and portions of the MND including a Cultural Landscape Study and Construction Mitigation and Monitoring Treatment Plan. As field director, duties included project management, facilitation of Pre-Construction Meeting, coordination and supervision of archaeological and paleontological technician crew, as well as document preparation.

Regulatory Compliance for Proposed Development within NRHP Archaeological Site CA-LAN-41, Agoura Hills, Los Angeles County, California. As project manager, Principal Investigator and Field Director, design and implement all necessary regulatory compliance and treatment of the archaeological site CA-LAN-41, in accordance with CEQA and local agency regulations. Serve as lead project analyst and on-call human osteologist, developing methodology for research design, crew supervision of all aspects of the investigative efforts. Project is on-going.

Palmdale CalVet REN Project, Los Angeles County, Californa. (11150) Provided senior review and support for archaeological resources study for a private development. Project proposes to build 56 duplex condominiums on a 9.9-acre site, to provide permanent, affordable housing to veterans (Condominium Project or project).

5-Year On-Call Archaeological Services, City of Ventura, California. As project Manager, currently manages Dudek's contract for the City of Ventura on-call archaeological services including archaeological, historical, and Native American services, including but not limited to monitoring, archaeological record searches, historical research, architectural history, surveys for both prehistoric and historical resources, extended Phase I surveys, test excavations, data recovery, Native American coordination, coordination with the Native American Heritage Commission, AB-52 support, treatment protocols, feasibility/concept plan studies and recommendations, hiring and managing applicable sub consultants and specialty disciplines as required, preparation of management plans, design and implementation of mitigation methods. Potential projects include municipal infrastructure improvements such as domestic water distribution system, sanitary sewer collection system, storm drainage collection system and other undertakings as determined.

Dear NAHC,

Please find attached the NAHC Sacred Lands File Search request and project location map for the proposed Arroyo Seco Canyon Project (Dudek #11884). Dudek is requesting a NAHC search for any sacred sites, tribal cultural resources, or other places of Native American community value that may fall within a one-mile radius of the proposed Project site.

Please let me know if you have any questions regarding this project. You can email the results to me at adorrler@dudek.com.

Thank you in advance,

Adriane Gusick
Associate Archaeologist

Email: adorrler@dudek.com

Project Description:
The City of Pasadena (City) owns the right to divert up to 25 cubic feet per second of surface water from the Arroyo Seco into their spreading basins for pumping credits in the Raymond Basin. In the two storm seasons following the 2009 Station Fire, excessive amounts of sediment washed down from the watershed. The debris flows damaged City structures, greatly reducing the City's capacity to divert water for spreading. As a result, the City of Pasadena Department of Water and Power proposes to repair and replace damaged facilities in the Upper Arroyo Seco Canyon as a part of the proposed Project. The improvements would allow for increased utilization of the City's surface water rights from the Arroyo Seco and maximize the beneficial use of this important local water resource.

The proposed Project consists of three primary areas, including Area 1, Headworks Removal; Area 2, Diversion and Intake Replacement; and Area 3, Spreading Basin Improvements. These areas are connected by the Gabrielino Trail/Access Road. The proposed Project would involve construction activity and facility improvements in all three areas, as well as along portions of the Gabrielino Trail/Access Road. Additionally, portions of the 30-inch hume line, which is a pipeline that conveys water from the diversion weir to the spreading basins, may also be improved/replaced.

RE: Arroyo Seco Canyon Project, Los Angeles County

Dear Ms. Gusick:

A record search of the Native American Heritage Commission (NAHC) Sacred Lands File (SLF) was completed for the information you have submitted for the above referenced project. The results were positive. Please contact the Gabrieleno Band of Mission Indians - Kizh Nation on the attached list for more information. Other sources of cultural resources should also be contacted for information regarding known and recorded sites.

Attached is a list of Native American tribes who may also have knowledge of cultural resources in the project area. This list should provide a starting place in locating areas of potential adverse impact within the proposed project area. I suggest you contact all of those indicated; if they cannot supply information, they might recommend others with specific knowledge. By contacting all those listed, your organization will be better able to respond to claims of failure to consult with the appropriate tribe. If a response has not been received within two weeks of notification, the Commission requests that you follow-up with a telephone call or email to ensure that the project information has been received.

If you receive notification of change of addresses and phone numbers from tribes, please notify the NAHC. With your assistance, we can assure that our lists contain current information. If you have any questions or need additional information, please contact me at my email address: steven.quinn@nahc.ca.gov.

Sincerely,

Steven Quinn
Associate Governmental Program Analyst

The John L. Behner Water Treatment Plant is a one-story Brutalist-style civic building, rectangular in shape, with a flat roof, designed by James M. Montgomery, Consulting Engineer, Inc. of Pasadena, and built in 1971. Exterior walls are exposed concrete with limited fenestration. The design emphasizes horizontality in form, but with strong vertical accents: simple, unadorned, rectangular concrete pilasters flank each narrow window/panel; broad concrete pilasters flank the entry door; and repetitive patterns of vertically-oriented rectilinear forms. The John L. Behner Water Treatment Plant (WTP), named after the first General Manager of the consolidated Pasadena Water and Power Department (PWP). Located in the Arroyo Seco Canyon east of JPL, the plant had a capacity of 5 million gallons per day. The project, which began as the result of a PWP feasibility study in 1967 decided on the current location. Originally, the Metropolitan Water District (MWD) identified the Upper Arroyo Seco as a location for their new MWD water treatment plant, however they received backlash from Pasadena citizens using the area as a park. As a result, the City of Pasadena moved forward with their plan for a smaller water treatment plant facility, and a county regional park at the same time. The push was successful, and the PWP's plant was designed by Pasadena-based engineering firm James M. Montgomery, Consulting Engineers Inc. and constructed by the Margate Construction Company in 1970 and dedicated 1971. (*see continuation sheet*)

***P3a. Description: (continued)**

A tall, monolithic concrete wall, with a broad band of vertically-oriented rectilinear forms creating a repetitive pattern, blocks view of the southern portion of external water treatment facilities to the east of and adjacent to the building. The external water treatment facilities comprise a series of open concrete tanks, with water flow controlled by a pair of wood flood gates, and a pair of moderately-sized, cylindrical above-ground tanks.

The main (northwest) elevation presents as two sections: the left (northern) two-thirds consists of regularly-spaced narrow, vertical windows or panels, topped with louvered rectangular vents, and a double-leaf flush entry door with a flat panel inset above. The door is accessed by three broad, shallow concrete steps, bordered to the left (north) by a square integral concrete planter. Another narrower, shallower integral concrete planter runs along the base of the wall. The right (southern) third projects forward about three feet and is about two feet taller, with a repetitive pattern of vertically-oriented rectilinear forms. Three rows of patinated metal letters in a simple modern font are attached to the upper center of the wall and read “City of Pasadena John L. Behner Water Treatment Plant.”

The southwest elevation presents as a monolithic wall with a repetitive pattern of vertically-oriented rectilinear forms. A near-full-height, flush, double-leaf loading door sits off-center, and a painted metal I-beam projects outwards from the top between the two leaves. The tall, monolithic concrete wall begins at the eastern end of this elevation, effectively continuing in line from the southeast elevation, and is pierce by a corrugated metal door.

The southeast elevation presents as two sections: the left (southern) third is about two feet taller and predominantly exposed concrete masonry units (CMUs) laid in running bond, with a vertical and horizontal panel decorated in the repetitive pattern of vertically-oriented rectilinear forms; a half-lite painted metal door pierces the wall near the left edge. The right (northern) two-thirds of the elevation consists of exposed CMUs laid in running bond, with a vented half-lite door accessed via a concrete walkway and five evenly-spaced narrow, horizontally-oriented louvered vents located near the base of the wall.

The northeast elevation is monolithic concrete with four full-length rectangular concrete pilasters flanking a centered single-width roll-up garage door. Short portions of two rectangular concrete pilasters project above the door.

Figure 1. Behner Treatment Plant: southwest elevation, view looking northeast (IMG_2660)

Figure 2. Behner Treatment Plant: southeast elevation, view looking southwest (DSC02274)

***B10. Significance: (continued)**

John L. Behner Water Treatment Plant (1971)

The John L. Behner Water Treatment Plant (WTP) was named after the first General Manager of the consolidated Pasadena Water and Power Department (PWP). Located in the Arroyo Seco Canyon east of JPL, the plant had a capacity of 5 million gallons per day. The project, which began as the result of a PWP feasibility study in 1967 decided on the current location. Originally, the Metropolitan Water District (MWD) identified the Upper Arroyo Seco as a location for their new MWD water treatment plant; however, they received backlash from Pasadena citizens using the area as a park. As a result, the City of Pasadena moved forward with their plan for a smaller water treatment plant facility, and a county regional park at the same time. The push was successful, and the PWP's plant was designed by Pasadena-based engineering firm James M. Montgomery, Consulting Engineers Inc. and constructed by the Margate Construction Company in 1970 and dedicated in 1971. However, new water treatment regulations imposed as a result of the Surface Water Treatment Rule meant that the treatment plant was shut down in June 1993. Another feasibility study on the potential for upgrading the facility was conducted in 1995, but the Behner WTP remains offline to this day (City of Pasadena 2010, 2012; LAT 1968; PI 1971).

Architectural style: Brutalism

The term "Brutalism" derives from the French béton brut, which translates as raw concrete, and describes concrete that displays the patterns, seams, and bug holes caused by formwork and concrete emplacement. The Brutalist architectural style is characterized by its use of raw building materials in a very direct and imposing way, emphasizing bulky forms and sharp angles with limited visible glass surfaces. A popular style between the 1950s and 1970s, Brutalism favored heavy, solid shapes cast with highly detailed and textured reinforced concrete. Often associated with High Modernism, a style emphasizing austere and abstract forms rooted in science and technology, the bold, unapologetic design and monumentality of Brutalism makes it an easy target for criticism, and it is thought to be one of the most divisive styles of architecture to emerge since the beginning of the twentieth century (Lowder 2013, McAlester 2013, Mindel 2016).

The best known early Brutalist architecture was that of Swiss architect Le Corbusier in the early 1950s. Brutalism gained popularity in the United Kingdom in the mid-century as war-torn communities actively sought inexpensive construction and design techniques in order to create affordable government buildings, housing, and shopping centers. However, Brutalism was also popular among those without budget constraints, as the style came to be artistically appreciated for its honest expression of materials, sculptural qualities, and anti-bourgeois aesthetic.

Brutalism was a popular style of architecture for educational buildings, particularly university buildings, but was relatively rare for corporate and single-family residential projects. It was also favored for civic projects, high-rise apartments, and shopping centers, as the style emulated strength, functionality, and an appreciation for material simplicity (Brutalism Online 2016).

Character-defining features of Brutalism include (City of San Diego 2007, HRG 2007):

- Exposed, expressive structural system
- Rough, unadorned concrete construction
- Monumental massing
- Heavy blockish shapes
- Angular and rectilinear forms
- Prefabricated concrete panels with exposed joinery
- Windows as voids in an otherwise solid volume

- Repetitive patterns
- Avoidance of traditional elements or ornament
- Raised plazas and base articulation

Engineer: James M. Montgomery, Consulting Engineers, Inc. (1945-1990)

The Behner WTP was designed by engineer James M. Montgomery (1896-1969). Montgomery was born in Ohio in 1896, and moved to Los Angeles California by 1910. He briefly served in the military during World War I, and was honorably discharged in October 1918. Montgomery returned to Newark, Ohio for a few years, but eventually moved back to Los Angeles Between 1935 and 1940. Montgomery launched his engineering firm in 1941, after having some success in helping design the F.E. Weymouth Memorial Water Softening and Filtration Plant in 1936 with MWD. This early connection with water infrastructure led to a career of consulting, studies, reports, and designing water infrastructure systems for Southern California and the greater West Coast of the United States for the next five decades. The firm was based in Pasadena for the first few decades. James Montgomery himself passed away in 1969, but his firm continued consulting work focused on water infrastructure. In 1990, the James M. Montgomery, Consulting Engineers, Inc. firm merged with Watson Hawksley, Ltd of the United Kingdom to become Montgomery-Watson. In 2001, Montgomery Watson merged with Harza Engineering and became Montgomery Watson Harza. This name was shortened to MWH Global in 2003. In 2016, MWH was acquired by Stantec Consulting, Inc. (Ancestry 2019).

Known works by Montgomery include:

- F.E. Weymouth Memorial Water Softening and Filtration Plant, Metropolitan Water District, City of La Verne, 1936-1941
- Arcadia Plant improvements, City of Santa Monica, 1958
- William B. Cater Filtration Plan, City of Santa Barbara, 1962
- Arcadia Plant improvements, City of Santa Monica, 1966
- Water Softening System, Alameda County Water District, 1966
- South San Diego Reservoir, City of San Diego, 1968
- Anaheim Lake Demonstration Desalination Plant, Orange County Water District, 1973
- Warner Ave Sewer Pump Station, City of Huntington Beach, 1986

NRHP/CRHR Statement of Significance

Criterion A/1: That are associated with events that have made a significant contribution to the broad patterns of our history.

Archival research did not find any associations with events that have made a significant contribution to the broad patterns of our history. The subject property was completed in 1971, during a period of economic downturn that that began in the late 1960s, and taken offline in 1993 after passage of the Surface Water Treatment Rule. Although the property is generally representative of the City's mid-century growth, it has no direct association with events that made a significant contribution to the history of the City of Pasadena, the State of California, or the Nation. Therefore, the property does not appear eligible under Criterion A of the NRHP or Criterion 1 of the CRHR.

Criterion B/2: That are associated with the lives of persons significant in our past.

Archival research did not indicate that any previous property owners or people who have worked at this property are known to be historically significant figures at the national, state, or local level. As such, this property is not known to have any historical associations with people important to the nation's or state's past. Furthermore, to be found eligible under B/2 the property has to be directly tied to an important person and

the place where that individual conducted or produced the work for which he or she is known. This property does not appear to be associated with any individual's important historic work and does not appear eligible for the NRHP under Criterion B or CRHR under Criterion 2.

Criterion C/3: That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction.

The John L. Behner Water Treatment Plant is a good example of Brutalist civic architecture as expressed in the context of a utilitarian building designed for practicality. Designed by local Pasadena engineering firm James M. Montgomery, Consulting Engineer Inc. and built in 1971, the building displays several character-defining features of the Brutalist architectural style, including an exposed, expressive structural system; rough, unadorned concrete construction; monumental massing; heavy blockish shapes; angular and rectilinear forms; prefabricated concrete panels with exposed joinery; windows as voids in an otherwise solid volume; repetitive patterns; and avoidance of traditional elements or ornament. While smaller in scale than the more monumental, hulking Brutalist buildings often seen in civic centers and on college campuses, the building still conveys the essential character-defining features of the Brutalist design aesthetic and exhibits a high level of integrity. The designing engineering firm, James M. Montgomery, Consulting Engineer, Inc., is a local, Pasadena-based firm that regularly constructed water infrastructure projects for local cities and water districts, such as MWD, Santa Monica, and Huntington Beach. There are no known alterations to the exterior of the building. Although the engineer does not rise to the level of a "master," the building embodies the distinctive characteristics of the Brutalist architectural style and possesses artistic values of significance to the City or to the region. Consideration was also given to the fact that Brutalism is a relatively rare architectural style in Pasadena, with few noteworthy examples. The Pasadena CHRID lists only two eligible Brutalist properties: a public library and a private residence. According to the Los Angeles Conservancy, "The Lamanda Park Branch of the Pasadena Public Library is a rare Brutalist building in an area of modest suburban homes in east Pasadena." (LAC 2019) The same may be said of the Behner WTP, as it remains relatively hidden from view, tucked away behind a suburban neighborhood. ***As such, the property appears eligible for the NRHP under Criterion C and CRHR under Criterion 3 at the local level of significance.***

Criterion D/4: That have yielded, or may be likely to yield, information important in prehistory or history.

The property is not significant under Criterion D of the NRHP or Criterion 4 of the CRHR as a source, or likely source, of important historical information nor does it appear likely to yield important information about historic construction methods, materials or technologies.

Pasadena Statement of Significance

The City of Pasadena's landmark designation criteria is based on the NRHP/CRHR designation criteria and integrity requirements. Therefore, for all of the reasons identified in the discussion of NRHP and CRHR eligibility, ***the subject property appears eligible as a landmark under local designation criteria 2c.***

Integrity Discussion

Integrity Discussion
The John L. Behner Water Treatment Plant maintains integrity of location, as it remains in its original location. The building retains integrity of design as it has not undergone any large-scale exterior alterations since its construction and maintains the essential features of form, plan, space, structure, and style. The building retains integrity of setting, as upon its construction, the Arroyo Seco Canyon area had already attained the majority of JPL-related development, residential suburban development, and undeveloped Forest Service and parkland observed today. The building maintains integrity of materials and workmanship due to the retention of the physical elements that date from its construction. The windows sport metal security screens, but the majority of the building's original materials are extant. The building retains integrity of feeling and association, as the property retains the ability to express itself as a water treatment plant. In summary, the building retains the requisite integrity for designation, and appears eligible for listing under NRHP Criterion C, CRHR Criterion 3, and City of Pasadena Landmark criterion 2c at the local level of significance.

(Discuss importance in terms of historical or architectural context as defined by theme, period, and geographic scope. Also address integrity.)

The Screen Building Complex consists of the screen building (formerly known as the Chlorine Plant, per as-built drawings), intake structure, and a flashboard dam/weir. The screen building is identified on 1932 as-built plans for the Arroyo Seco Headworks (Work Order 2802, Pasadena Water Department 1932), indicating that it was constructed around this time. As such, it is likely that these components were constructed by the CCC during their Arroyo Seco improvements campaign in the 1930s. A flashboard dam/weir was also part of this as-built drawing set, and was constructed at this location in 1932. It is possible that an earlier weir, dam, or pipeline preceded its construction, but this could not be verified in archival research, including aerial photographs or historical maps. An image of the weir from March 5, 1937, shows that there was a modest concrete structure with angled buttresses and a paved horizontal surface downstream, leading to a short drop off to the natural streambed. The drop off aligns with retaining walls on either end. (*see continuation sheet*)

***Date of Evaluation:** December 27, 2019

(This space reserved for official comments.)

***P3a. Description: (continued)**

A vertical metal ladder attached near one of the entry doors provides access to the roof. An elevated rectangular concrete open-air tank structure, with a large piece of mechanical equipment bolted over half of the structure and accessed by three metal steps, sits to the left of and slightly in front of the screen building. A rectangular arch constructed from metal I-beams, with the two uprights supported with angled I-beams on the front and back of the arch, is located in front of the garage door. The weir is a combination of mortared stone and poured-in-place concrete with at least one wood sluice gate, although access was limited during survey due to vegetation and debris. A cobblestone wall rises from the original retaining wall on the right (east or cutbank) side of the weir and supports a concrete platform, the top deck of the intake structure, into which the original rectangular concrete platform is incorporated and expanded.

Figure 1. Screen building, view looking south (IMG_2767)

Figure 2. Weir, eastern end with wood sluice gate, view looking upstream (IMG_2797)

Figure 3. Weir detail, view looking upstream (IMG_2791)

***B10.Significance: (continued)**

A concrete wing wall lines the cut bank side of the stream where the weir meets it, and a small concrete platform (the top deck of the intake structure) rests adjacent to the wing wall on mounded soil. The 1938 historic aerial image shows the devastation wrought by flooding that year; the screen building is visible, but the c. 1932 weir appears to have been destroyed. In the next 1944 historic aerial image clearly shows the screen building, intake structure, and a new weir. The new weir, visible in the 1944 aerial photograph, is of a different design than the 1932 weir, and a cobblestone wall is visible rising from the original retaining wall on the right (east or cutbank) side of the weir. The cobblestone wall supports a concrete platform, of which the original rectangular concrete platform is incorporated, indicating extensive repairs and/or additional damage during later flood events.

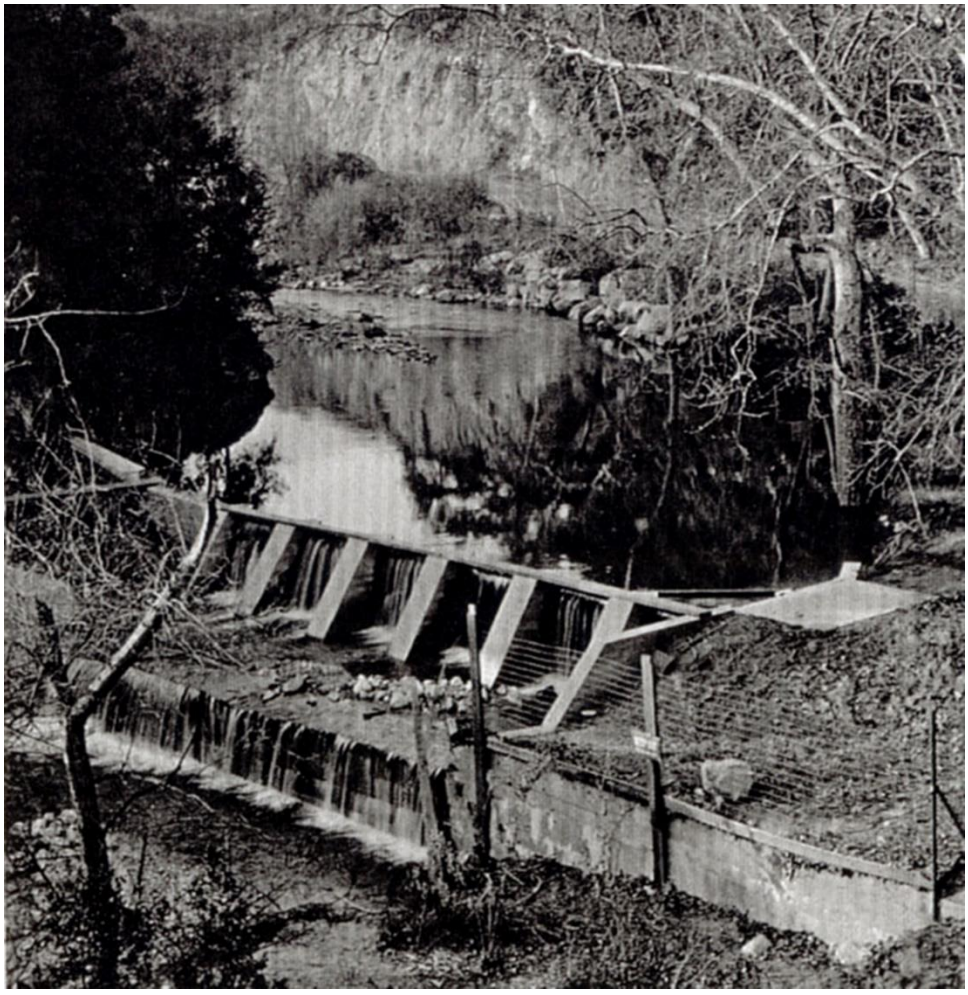

Figure 4. Weir and intake structure, dated March 5, 1937, view looking upstream (ASF 2019)

NRHP/CRHR Statement of Significance

Criterion A/1: That are associated with events that have made a significant contribution to the broad patterns of our history.

Archival research did not find any associations with events that have made a significant contribution to the broad patterns of our history. The complex was completed c. 1932, most likely by the CCC during their improvements campaign in the Arroyo Seco Canyon. The extant weir was replaced after a major flooding event in 1938, and a newer cobblestone wall rises from the original retaining wall on the right (east or cutbank) side of the weir. The cobblestone wall supports a concrete platform, into which the original rectangular concrete platform is incorporated, indicating extensive repairs and/or additional damage during later flood events. The Screen Building Complex is no longer visibly recognizable as dating to its original c. 1932 construction date due to the extensive damage and subsequent repairs. Further, it does not have a direct association with events that made a significant contribution to the history of the City of Pasadena, the State of California, or the Nation. Therefore, the property does not appear eligible under Criterion A of the NRHP or Criterion 1 of the CRHR.

Criterion B/2: That are associated with the lives of persons significant in our past.

Archival research did not indicate that any previous property owners or people who have worked at this property are known to be historically significant figures at the national, state, or local level. As such, this property is not known to have any historical associations with people important to the nation's or state's past. Furthermore, to be found eligible under B/2 the property has to be directly tied to an important person and the place where that individual conducted or produced the work for which he or she is known. This property does not appear to be associated with any individual's important historic work and does not appear eligible for the NRHP under Criterion B or CRHR under Criterion 2.

Criterion C/3: That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction.

The Screen Building Complex comprises a screen building, a weir, and an intake structure. The individual components are modest utilitarian structures built with common materials using common techniques and with no artistic value. They do not embody the distinctive characteristics of a type, period, or method of construction, nor do they represent the work of a master, nor does the complex represent a significant and distinguishable entity whose components may lack individual distinction. Furthermore, the Screen Building Complex is no longer visibly recognizable as dating to its original c. 1932 construction date due to the extensive damage and subsequent repairs. For these reasons, the Screen Building Complex does not appear eligible for listing in the NRHP under Criterion C or CRHR under Criterion 3.

Criterion D/4: That have yielded, or may be likely to yield, information important in prehistory or history.

The property is not significant under Criterion D of the NRHP or Criterion 4 of the CRHR as a source, or likely source, of important historical information nor does it appear

likely to yield important information about historic construction methods, materials or technologies.

Pasadena Statement of Significance

The City of Pasadena's landmark designation criteria is based on the NRHP/CRHR designation criteria and integrity requirements, Therefore, for all of the reasons identified in the discussion of NRHP and CRHR eligibility, the subject property does not appear eligible under any local designation criteria, either individually or as part of a district.

Integrity Discussion

The Screen Building Complex retains integrity of location, as it remains in its original location. The Complex lacks integrity of design as it was subjected to large-scale exterior alterations since its original construction in 1932 and no longer maintains the essential features of form, plan, space, structure, and style. The Complex retains integrity of setting, as it still rests within a natural environment along the Arroyo Seco. The Complex lacks integrity of materials and workmanship due to the extensive damage and subsequent repairs to the physical elements that date from its construction. The Complex retains integrity of feeling, as it is still nestled within the Arroyo Seco surrounded by a mixture of natural environment and water infrastructure. Finally, while the screen building still reads as a grouping of structures related to water infrastructure in Pasadena, this association is not significant. In summary, the Screen Building Complex does not retain the requisite integrity for designation, nor does it rise to the level of significance required for designation at the national, state or local levels.

Arroyo Seco Canyon Developments (1887-present)

The Project site is located within the Hahamongna Watershed Master Plan Area, within the larger Arroyo Seco which also includes the Central and Lower Arroyo Seco Master Plan Areas. Arroyo Seco Canyon is an important watershed which begins in the San Gabriel Mountains at Mount Wilson, continues west of the cities of Pasadena and Altadena, and extends south to join the Los Angeles River. The canyon was used as a prehistoric through-route for the Hahamong'nas (a band of native Tongva people), connecting the area that is now Hahamongna Watershed Park to trade partners to the north. The canyon continued to be a source of water, recreation, and travel route well into the nineteenth century. As early as 1887, the City of Pasadena and citizens were recognizing the Arroyo Seco as a whole for its benefits as a park. Locals swam at the pools at Devil's Gate, hiked to the waterfall at Millard Canyon, and took pack animal trips to Mount Wilson. At the turn of the twentieth century, Arroyo Seco enjoyed a long period of recreational development, such as at Camp Oakwilde, a rustic resort constructed in 1911, and several private and public cabins throughout the canyon. ***P3a. Description: (continued)**

A new temporary bridge with concrete access ramps passes across the deck of Bridge No.1. Aerial images indicate a bridge crossing over Millard Canyon existed at the same location prior to 1927. Archival research indicates that the original bridge was either damaged or destroyed by the 1938 floods, and replaced with the existing two-span box culvert bridge either during a CCC repair campaign in 1939 or as part of the 1941 Arroyo Seco Program. A previous report identified the bridge deck as being replaced with a "similar reinforced concrete span" in 1979, and that river rock was applied to both sides of the deck at the time to "visually integrate it with the existing river rock-clad bridge components" (Daly 2014). Comparison of photographs taken in 2019 during the site visit with those included in a 2015 report indicate that the bridge deck was coated with a layer of tarmac c. 2017, prior to installing the temporary bridge (TJC & Associates 2015). Two pipelines emerge from the ground near the southern end of Bridge No. 1 and run along the west side of the Arroyo Boulevard/Gabrielino Trail. The larger metal pipe is wrapped with what appears to be disintegrating asphalt rolled material, and continues underground near the southern end of Bridge No. 2. The smaller pipeline appears to be concrete and dives underground north of Bridge No. 2, just after a bolted metal pipe connection between two runs of concrete pipe.

Figure 2. Bridge No. 1, detail of cobblestone edge and central supporting wall (DSC02336)

Figure 3. View of pipelines, near Bridge No. 1 (DSC02327)

Figure 4. View of pipelines, near Bridge No. 1 (DSC02323)

***B10.Significance: (continued)**

In 1911, the City of Pasadena annexed the lower and middle sections of the Arroyo Seco, and in 1919, the area now known as Hahamongna Watershed Park was annexed to the city (City of Pasadena 2019b).

With the recreation movement taking hold in the Arroyo Seco, and the Arts and Crafts Movement (1895-1920) influencing building and landscape architecture at large in southern California, the area within and around the Arroyo Seco developed several unifying features that were consistently used throughout the Arroyo Seco canyon area, including parks, trails, landscaping features, neighborhoods, and civic structures. These included the emphasis on the natural environment and use of native cobblestone in walls, gates, and fences, especially as accents to pedestrian walkways and roads that might otherwise have a utilitarian appearance. Native rock cobblestone walls also complemented the larger Arts and Crafts-style residential architecture of Pasadena. Even after the Arts and Crafts Movement waned in popularity, the use of native cobblestone persisted as a unifying landscape feature in the Arroyo Seco (Bricker et al. 1992; Pasadena 2003a).

A road through Arroyo Seco Canyon has been visible on maps since the 1894 "Los Angeles, Calif." topographical map of the area. This earliest topographical map of the area shows the road extending between the Los Angeles Terminal Railroad Line and a mountain hamlet called Las Casitas before looping back west and south to La Cañada, following an older trail forged by the native Gabrielinos. The road was subjected to several floods over the years, damaging the road bed, bridges, dams and other infrastructure placed along it. Arroyo Seco Canyon Road, also known as Arroyo Boulevard, was paved for use as a county highway c. 1920, during which time Bridge No. 2 was constructed as a necessary improvement

along the Arroyo Boulevard/Gabrielino Trail. Bridge No. 2 appears on the very first available aerial map from 1927, as well as other smaller bridges along the road and at the mouth of the canyon. A secondary spur road, leading east from the Bridge No. 1 crossing location, is also present on aerial photos as early as 1927. At the end of this spur road was a square-plan, river cobble-clad building on a concrete platform and a small, concrete diversion dam. Both of these structures are located outside of the Project site (LAT 1919; USGS 2019).

Arroyo Seco Road appears improved by bridges in the earliest available aerial photograph from 1927; however, subsequent floods in 1934 and 1938 appear to obliterate the road and bridges in the canyon, with the exception of Bridge No. 2. The road between Devil's Gate Dam and Oak Wilde, a forest community some 4 miles up Arroyo Seco Road, remained closed until 1939, the same year local Civilian Conservation Corps (CCC) Company 903 constructed Bridge No. 3. Despite the CCC improvements, the City of Pasadena road section outside of U. S. Forest Service lands was not officially repaired until 1941 (LAT 1938, 1940a, 1940b; Pasadena Star News 1939).

Local CCC Company 903 was assigned to the U.S. Forest Service in 1933 to work on projects within Arroyo Seco Canyon and San Gabriel Mountains. One of Roosevelt's more successful New Deal programs, the CCC was a work relief program focused on environmental projects, providing employment to young men during the Great Depression. By June 1, 1933, over 1,400 working camps were established, employing more than 300,000 men, representing the most rapid peace-time mobilization in U.S history. Working on projects for the U.S. Forest Service, the National Park Service, and the Departments of Agriculture and Interior, CCC workers fought forest fires, planted trees, cleaned and maintained access roads, re-seeded grazing lands, implemented soil erosion controls, and built wildlife refuges, fish-rearing facilities, animal shelters, and water storage basins. Roosevelt also authorized the CCC to build bridges and campground facilities in an effort to encourage people to go enjoy America's natural resources. Although focused on providing employment for young unskilled men between 18 and 25 years of age, the CCC also employed WW1 army veterans, skilled foresters and craftsmen, and approximately 88,000 Native Americans from Indian reservations. The CCC reached its largest employment in August 1935, with more than 500,000 men working in 2,900 camps. Estimates indicate that approximately five percent of the US male population, about three million men, participated in the CCC.

The CCC planted more than three billion trees and constructed facilities in more than 800 parks nationwide during the nine years which the group was in existence, helping shape our modern national and state park systems (History.com 2010). In 1941, the Arroyo Seco Project, part of a Los Angeles River watershed upstream work project, began with the Millard Canyon channel and road improvement project. A joint effort between Forest Service and the City of Pasadena engineers, the improvements in Millard Canyon entailed channel improvements and creating a new road cut above the channel bed with a "seven foot wall of native rock" (Pasadena Post 1941:17). The stretch of road to be improved by the retaining walls and barriers was described as above Devil's Gate Dam, and below the Brown Mountain truck trail turn off. The road improvements were in support of the larger goal of the watershed upstream work project: to build the Brown Mountain Dam near Arroyo Seco headwaters as a means of flood control. When the upstream project was completed, the City entered into a contract with the Forest Service to share costs of maintenance and patrols for the sections of Arroyo Seco and Millard Canyon that were in City of Pasadena Land, but adjacent to Forest Service land. Improvements are also visible in aerial photographs between 1938 and 1944, such as the construction of Bridge No. 1, road pavement, and the construction of native rock retaining walls and barriers (Pasadena Post, 1941a, 1941b; Pasadena Star News 1941, 1944; UCSB 2019).

NRHP/CRHR Statement of Significance

Bridge No. 1 does not meet any of the criteria for listing in the NRHP or CRHR, either individually or as part of an existing historic district.

Criterion A/1: That are associated with events that have made a significant contribution to the broad patterns of our history.

Archival research did not find any associations with events that have made a significant contribution to the broad patterns of our history. Archival research indicates that the original bridge was either damaged or destroyed by the 1938 floods, and replaced with the existing two-span box culvert bridge either during a CCC repair campaign in 1939 or as part of the 1941 Arroyo Seco Program. Bridge No. 1 was completed c. 1940, replacing the original bridge, and is a simple utilitarian design. Even if the bridge was constructed as part of the CCC repair campaign in 1939, it does not maintain any significant physical features that convey this association. Further, evidence suggests that the bridge deck was replaced in 1979 (Daly 2014). It has no direct association with events that have made a significant contribution to the history of the City of Pasadena, the State of California, or the Nation. Therefore, the property does not appear eligible under Criterion A of the NRHP or Criterion 1 of the CRHR.

Criterion B/2: That are associated with the lives of persons significant in our past.

Archival research did not indicate that any previous property owners or people who have worked at this property are known to be historically significant figures at the national, state, or local level. As such, this property is not known to have any historical associations with people important to the nation's or state's past. Furthermore, to be found eligible under B/2 the property has to be directly tied to an important person and the place where that individual conducted or produced the work for which he or she is known. This property does not appear to be associated with any individual's important historic work and does not appear eligible for the NRHP under Criterion B or CRHR under Criterion 2.

Criterion C/3: That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction.

Bridge No. 1 is a two-span box culvert bridge of simple utilitarian design completed c. 1940, replacing an older bridge damaged or destroyed by the 1938 floods. Although parts of it are cobblestone, the material was popular during the early 20th C. due to the influence of Greene and Greene and the Arts & Crafts style, and it was inexpensive and readily available from the Arroyo Seco stream bed. Additionally, a previous evaluation of the bridge (Daly 2014) indicates that the bridge deck was replaced in 1979 with reinforced concrete, and subsequently topped with at least one layer of tarmac (c. 2017). The bridge itself is not characteristic of a type, period, or method of construction, nor does it represent the work of a master, nor does it possess high artistic values, and it is not part of a significant and distinguishable entity whose components may lack

individual distinction. For these reasons, Bridge No. 1 does not appear eligible for listing in the NRHP under Criterion C or CRHR under Criterion 3.

Criterion D/4: That have yielded, or may be likely to yield, information important in prehistory or history.

The property is not significant under Criterion D of the NRHP or Criterion 4 of the CRHR as a source, or likely source, of important historical information nor does it appear likely to yield important information about historic construction methods, materials or technologies.

Pasadena Statement of Significance

The City of Pasadena's landmark designation criteria is based on the NRHP/CRHR designation criteria and integrity requirements, Therefore, for all of the reasons identified in the discussion of NRHP and CRHR eligibility, the subject property does not appear eligible under any local designation criteria, either individually or as part of a district.

Integrity Discussion

Bridge No. 1 maintains integrity of location, as it remains in its original location. The bridge does not retain integrity of design as its deck was replaced in 1979. The bridge retains diminished integrity of setting, as it still rests within a natural environment along the Arroyo Seco. The bridge also lacks integrity of materials and workmanship due to replacement of the bridge deck and other features. The bridge's simple design does not convey the feeling or association with a CCC-built bridge as it lacks major visible character-defining features and associated materials. In summary, Bridge No. 1 does not retain the requisite integrity for designation, nor does it rise to the level of significance required for designation at the national, state or local levels.

Bridge No. 2 is a board-formed concrete arch bridge, with board-formed concrete abutments and a subtle four-point arch, spanning the Arroyo Seco, constructed circa 1920 (Figure 29). Rectangular concrete railings border the upstream and downstream edges of the bridge deck, with openings between upper and lower rails sporting a row of classically shaped single balusters resembling the form of a flower bud from a pomegranate tree (Figure 30). The bridge deck is covered with tarmac. (*see continuation page*)

***P3a. Description: (continued)**

Figure 1. Bridge No. 2, detail of deck and railing with balusters (DSC02361)

***B10. Significance: (continued)**

In 1911, the City of Pasadena annexed the lower and middle sections of the Arroyo Seco, and in 1919, the area now known as Hahamongna Watershed Park was annexed to the city (City of Pasadena 2019b).

With the recreation movement taking hold in the Arroyo Seco, and the Arts and Crafts Movement (1895-1920) influencing building and landscape architecture at large in southern California, the area within and around the Arroyo Seco developed several unifying features that were consistently used throughout the Arroyo Seco canyon area, including parks, trails, landscaping features, neighborhoods, and civic structures. These included the emphasis on the natural environment and use of native cobblestone in walls, gates, and fences, especially as accents to pedestrian walkways and roads that might otherwise have a utilitarian appearance. Native rock cobblestone walls also complemented the larger Arts and Crafts-style residential architecture of Pasadena. Even after the Arts and Crafts Movement waned in popularity, the use of native cobblestone persisted as a unifying landscape feature in the Arroyo Seco (Bricker et al. 1992; Pasadena 2003a).

A road through Arroyo Seco Canyon has been visible on maps since the 1894 "Los Angeles, Calif." topographical map of the area. This earliest topographical map of the area shows the road extending between the Los Angeles Terminal Railroad Line and a mountain hamlet called Las Casitas before looping back west and south to La Cañada, following an older trail forged by the native Gabrielinos. The road was subjected to several floods over the years, damaging the road bed, bridges, dams and other infrastructure placed along it. Arroyo Seco Canyon Road, also known as Arroyo Boulevard, was paved for use as a county

highway c. 1920, during which time Bridge No. 2 was constructed as a necessary improvement along the Arroyo Boulevard/Gabrielino Trail. Bridge No. 2 appears on the very first available aerial map from 1927, as well as other smaller bridges along the road and at the mouth of the canyon. A secondary spur road, leading east from the Bridge No. 1 crossing location, is also present on aerial photos as early as 1927. At the end of this spur road was a square-plan, river cobble-clad building on a concrete platform and a small, concrete diversion dam. Both of these structures are located outside of the Project site (LAT 1919; USGS 2019).

Arroyo Seco Road appears improved by bridges in the earliest available aerial photograph from 1927; however, subsequent floods in 1934 and 1938 appear to obliterate the road and bridges in the canyon, with the exception of Bridge No. 2. The road between Devil's Gate Dam and Oak Wilde, a forest community some 4 miles up Arroyo Seco Road, remained closed until 1939, the same year local Civilian Conservation Corps (CCC) Company 903 constructed Bridge No. 3. Despite the CCC improvements, the City of Pasadena road section outside of U. S. Forest Service lands was not officially repaired until 1941 (LAT 1938, 1940a, 1940b; Pasadena Star News 1939).

Local CCC Company 903 was assigned to the U.S. Forest Service in 1933 to work on projects within Arroyo Seco Canyon and San Gabriel Mountains. One of Roosevelt's more successful New Deal programs, the CCC was a work relief program focused on environmental projects, providing employment to young men during the Great Depression. By June 1, 1933, over 1,400 working camps were established, employing more than 300,000 men, representing the most rapid peace-time mobilization in U.S history. Working on projects for the U.S. Forest Service, the National Park Service, and the Departments of Agriculture and Interior, CCC workers fought forest fires, planted trees, cleaned and maintained access roads, re-seeded grazing lands, implemented soil erosion controls, and built wildlife refuges, fish-rearing facilities, animal shelters, and water storage basins. Roosevelt also authorized the CCC to build bridges and campground facilities in an effort to encourage people to go enjoy America's natural resources. Although focused on providing employment for young unskilled men between 18 and 25 years of age, the CCC also employed WW1 army veterans, skilled foresters and craftsmen, and approximately 88,000 Native Americans from Indian reservations. The CCC reached its largest employment in August 1935, with more than 500,000 men working in 2,900 camps. Estimates indicate that approximately five percent of the US male population, about three million men, participated in the CCC.

The CCC planted more than three billion trees and constructed facilities in more than 800 parks nationwide during the nine years which the group was in existence, helping shape our modern national and state park systems (History.com 2010). In 1941, the Arroyo Seco Project, part of a Los Angeles River watershed upstream work project, began with the Millard Canyon channel and road improvement project. A joint effort between Forest Service and the City of Pasadena engineers, the improvements in Millard Canyon entailed channel improvements and creating a new road cut above the channel bed with a "seven foot wall of native rock" (Pasadena Post 1941:17). The stretch of road to be improved by the retaining walls and barriers was described as above Devil's Gate Dam, and below the Brown Mountain truck trail turn off. The road improvements were in support of the larger goal of the watershed upstream work project: to build the Brown Mountain Dam near Arroyo Seco headwaters as a means of flood control. When the upstream project was completed, the City entered into a contract with the Forest Service to share costs of maintenance and patrols for the sections of Arroyo Seco and Millard Canyon that were in City of Pasadena Land, but adjacent to Forest Service land. Improvements are also visible in aerial photographs between 1938 and 1944, such as the construction of Bridge No. 1, road pavement, and the construction of native rock retaining walls and barriers (Pasadena Post, 1941a, 1941b; Pasadena Star News 1941, 1944; UCSB 2019).

NRHP/CRHR Statement of Significance

Criterion A/1: That are associated with events that have made a significant contribution to the broad patterns of our history.

Archival research did not find any associations with events that have made a significant contribution to the broad patterns of our history. Bridge No. 2 was constructed c. 1920 as a necessary improvement along the Arroyo Boulevard/Gabrielino Trail, around the time Arroyo Boulevard was paved for use as a county highway. However, the road no longer functions as a county highway or a major thoroughfare, and has no direct association with events that made a significant contribution to the history of the City of Pasadena, the State of California, or the Nation. Therefore, Bridge No.2 does not appear eligible under Criterion A of the NRHP or Criterion 1 of the CRHR.

Criterion B/2: That are associated with the lives of persons significant in our past.

Archival research did not indicate that any previous property owners or people who have worked at this property are known to be historically significant figures at the national, state, or local level. As such, this property is not known to have any historical associations with people important to the nation's or state's past. Furthermore, to be found eligible under B/2 the property has to be directly tied to an important person and the place where that individual conducted or produced the work for which he or she is known. This property does not appear to be associated with any individual's important historic work and does not appear eligible for the NRHP under Criterion B or CRHR under Criterion 2.

Criterion C/3: That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction.

Built c. 1920, around the time Arroyo Boulevard was paved for use as a county highway, Bridge No. 2 exhibits classical design elements in the rows of classically shaped single balusters resembling the form of a flower bud from a pomegranate tree, as well as the subtle four-point shape of the arch. The bridge also displays the pattern of board-formed concrete, a method of construction popular for civil works during the early 20th Century. The designed structure successfully relied on massed reinforced concrete with a broad arched opening to withstand the destructive forces of periodic floods down Arroyo Seco. As such, the bridge embodies distinctive characteristics of a type, period, and method of construction. **Therefore, Bridge No. 2 appears eligible for listing under Criterion C of the NRHP and Criterion 3 of the CRHR at the local level of significance.**

Criterion D/4: That have yielded, or may be likely to yield, information important in prehistory or history.

The property is not significant under Criterion D of the NRHP or Criterion 4 of the CRHR as a source, or likely source, of important historical information nor does it appear

likely to yield important information about historic construction methods, materials or technologies.

Pasadena Statement of Significance

The City of Pasadena's landmark designation criteria is based on the NRHP/CRHR designation criteria and integrity requirements, Therefore, for all of the reasons identified in the discussion of NRHP and CRHR eligibility, the subject property **appears eligible as a landmark under local designation criterion 2c**.

Integrity Discussion

Bridge No. 2 maintains integrity of location, as it remains in its original location. The bridge retains integrity of design as it has not undergone any large-scale exterior alterations since its construction and maintains the essential features of form, plan, space, structure, and style. The bridge retains integrity of setting, as it still rests within a natural environment along the Arroyo Seco. The bridge retains integrity of materials and workmanship due to the retention of the physical elements that date from its construction. The bridge no longer retains integrity of feeling and association, since Arroyo Boulevard/Gabrielino Trail no longer serves as an important thoroughfare. In summary, Bridge No. 2 retains the requisite integrity for designation, and appears eligible for listing under NRHP Criterion C, CRHR Criterion 3, and City of Pasadena Landmark criterion 2c.

Arroyo Seco Canyon Developments (1887-present)

The Project site is located within the Hahamongna Watershed Master Plan Area, within the larger Arroyo Seco which also includes the Central and Lower Arroyo Seco Master Plan Areas. Arroyo Seco Canyon is an important watershed which begins in the San Gabriel Mountains at Mount Wilson, continues west of the cities of Pasadena and Altadena, and extends south to join the Los Angeles River. The canyon was used as a prehistoric through-route for the Hahamongnas (a band of native Tongva people), connecting the area that is now Hahamongna Watershed Park to trade partners to the north. The canyon continued to be a source of water, recreation, and travel route well into the nineteenth century. As early as 1887, the City of Pasadena and citizens were recognizing the Arroyo Seco as a whole for its benefits as a park. Locals swam at the pools at Devil's Gate, hiked to the waterfall at Millard Canyon, and took pack animal trips to Mount Wilson. At the turn of the twentieth century, Arroyo Seco enjoyed a long period of recreational development, such as at Camp Oakwilde, a rustic resort constructed in 1911, and several private and public cabins throughout the canyon. (*see continuation sheet*)

(This space reserved for official comments.)

***P3a. Description: (continued)**

The temporary bridge was initially installed to accommodate the loading from heavy equipment needed during construction of the Arroyo Seco Canyon Project that would be beyond the capacity of the original Bridge 3. However, as the condition of the original bridge has continued to deteriorate and is no longer safe for use, the temporary structure allows for continued passage into the canyon and access to the USFS compound by isolating traffic weight and movement from affecting the older wood bridge. The temporary bridge deck is built with anti-skid steel decking supported by steel I-beam girders, and is bolted through wood sill plates into the top of the original bridge's concrete retaining walls. Sloped, poured-in-place concrete ramps provide access to the temporary bridge deck at either end. Tubular metal railings line each side of the temporary bridge deck and concrete access ramps.

Figure 1. Bridge No. 3 with temporary bridge in place, view looking north-northwest (IMG_2749)

***B10. Significance: (continued)**

In 1911, the City of Pasadena annexed the lower and middle sections of the Arroyo Seco, and in 1919, the area now known as Hahamongna Watershed Park was annexed to the city (City of Pasadena 2019b).

With the recreation movement taking hold in the Arroyo Seco, and the Arts and Crafts Movement (1895-1920) influencing building and landscape architecture at large in southern California, the area within and around the Arroyo Seco developed several unifying features that were consistently used throughout the Arroyo Seco canyon area, including parks, trails, landscaping features, neighborhoods, and civic structures. These included the emphasis on the natural environment and use of native cobblestone in walls, gates, and fences, especially as accents to pedestrian walkways and roads that might otherwise have a utilitarian appearance. Native rock cobblestone walls also complemented the larger Arts and Crafts-style residential architecture of Pasadena. Even after the Arts and Crafts

Movement waned in popularity, the use of native cobblestone persisted as a unifying landscape feature in the Arroyo Seco (Bricker et al. 1992; Pasadena 2003a).

A road through Arroyo Seco Canyon has been visible on maps since the 1894 "Los Angeles, Calif." topographical map of the area. This earliest topographical map of the area shows the road extending between the Los Angeles Terminal Railroad Line and a mountain hamlet called Las Casitas before looping back west and south to La Cañada, following an older trail forged by the native Gabrielinos. The road was subjected to several floods over the years, damaging the road bed, bridges, dams and other infrastructure placed along it. Arroyo Seco Canyon Road, also known as Arroyo Boulevard, was paved for use as a county highway c. 1920, during which time Bridge No. 2 was constructed as a necessary improvement along the Arroyo Boulevard/Gabrielino Trail. Bridge No. 2 appears on the very first available aerial map from 1927, as well as other smaller bridges along the road and at the mouth of the canyon. A secondary spur road, leading east from the Bridge No. 1 crossing location, is also present on aerial photos as early as 1927. At the end of this spur road was a square-plan, river cobble-clad building on a concrete platform and a small, concrete diversion dam. Both of these structures are located outside of the Project site (LAT 1919; USGS 2019).

Arroyo Seco Road appears improved by bridges in the earliest available aerial photograph from 1927; however, subsequent floods in 1934 and 1938 appear to obliterate the road and bridges in the canyon, with the exception of Bridge No. 2. The road between Devil's Gate Dam and Oak Wilde, a forest community some 4 miles up Arroyo Seco Road, remained closed until 1939, the same year local Civilian Conservation Corps (CCC) Company 903 constructed Bridge No. 3. Despite the CCC improvements, the City of Pasadena road section outside of U. S. Forest Service lands was not officially repaired until 1941 (LAT 1938, 1940a, 1940b; Pasadena Star News 1939).

Local CCC Company 903 was assigned to the U.S. Forest Service in 1933 to work on projects within Arroyo Seco Canyon and San Gabriel Mountains. One of Roosevelt's more successful New Deal programs, the CCC was a work relief program focused on environmental projects, providing employment to young men during the Great Depression. By June 1, 1933, over 1,400 working camps were established, employing more than 300,000 men, representing the most rapid peace-time mobilization in U.S history. Working on projects for the U.S. Forest Service, the National Park Service, and the Departments of Agriculture and Interior, CCC workers fought forest fires, planted trees, cleaned and maintained access roads, re-seeded grazing lands, implemented soil erosion controls, and built wildlife refuges, fish-rearing facilities, animal shelters, and water storage basins. Roosevelt also authorized the CCC to build bridges and campground facilities in an effort to encourage people to go enjoy America's natural resources. Although focused on providing employment for young unskilled men between 18 and 25 years of age, the CCC also employed WW1 army veterans, skilled foresters and craftsmen, and approximately 88,000 Native Americans from Indian reservations. The CCC reached its largest employment in August 1935, with more than 500,000 men working in 2,900 camps. Estimates indicate that approximately five percent of the US male population, about three million men, participated in the CCC.

The CCC planted more than three billion trees and constructed facilities in more than 800 parks nationwide during the nine years which the group was in existence, helping shape our modern national and state park systems (History.com 2010). In 1941, the Arroyo Seco Project, part of a Los Angeles River watershed upstream work project, began with the Millard Canyon channel and road improvement project. A joint effort between Forest Service and the City of Pasadena engineers, the improvements in Millard Canyon entailed channel improvements and creating a new road cut above the channel bed with a "seven foot wall of native rock" (Pasadena Post 1941:17). The stretch of road to be improved by the retaining walls and barriers was described as above Devil's Gate Dam, and below the Brown Mountain

truck trail turn off. The road improvements were in support of the larger goal of the watershed upstream work project: to build the Brown Mountain Dam near Arroyo Seco headwaters as a means of flood control. When the upstream project was completed, the City entered into a contract with the Forest Service to share costs of maintenance and patrols for the sections of Arroyo Seco and Millard Canyon that were in City of Pasadena Land, but adjacent to Forest Service land. Improvements are also visible in aerial photographs between 1938 and 1944, such as the construction of Bridge No. 1, road pavement, and the construction of native rock retaining walls and barriers (Pasadena Post, 1941a, 1941b; Pasadena Star News 1941, 1944; UCSB 2019).

NRHP/CRHR Statement of Significance

Criterion A/1: That are associated with events that have made a significant contribution to the broad patterns of our history.

Archival research indicates that Bridge No. 3 was constructed in 1939 by the CCC, after the 1938 flood destroyed the original bridge. Local CCC Company 903 was assigned to the USFS in 1933 to work on projects within Arroyo Seco Canyon and San Gabriel Mountains. One of Roosevelt's more successful New Deal programs, the CCC was a work relief program focused on environmental projects, providing employment to young men during the Great Depression. They planted more than three billion trees and constructed facilities in more than 800 parks nationwide during the nine years which the group was in existence, helping shape our modern national and state park systems. As such, Bridge No. 3 was constructed by a group associated with events that made a significant contribution to the broad patterns of our history. **Therefore, Bridge No. 3 appears eligible under Criterion A of the NRHP and Criterion 1 of the CRHR.**

Criterion B/2: That are associated with the lives of persons significant in our past.

Archival research did not indicate that any previous property owners or people who have worked at this property are known to be historically significant figures at the national, state, or local level. As such, this property is not known to have any historical associations with people important to the nation's or state's past. Furthermore, to be found eligible under B/2 the property has to be directly tied to an important person and the place where that individual conducted or produced the work for which he or she is known. This property does not appear to be associated with any individual's important historic work and does not appear eligible for the NRHP under Criterion B or CRHR under Criterion 2.

Criterion C/3: That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction.

Bridge No. 3 is a wooden kingpost truss bridge, with heavy timber supports braced by a vertical metal rod and angled wood beam braced on a cantilevered timber girder. Timber railings line both side of the bridge deck, and board-formed concrete retaining walls support either end of the bridge. The kingpost design harkens back to timber-framed roof construction in Roman buildings, and was common in medieval architecture. The kingpost made its way into timber bridge design via Palladio, the first known personage to promote timber trusses for bridge design, and is the oldest timber truss design used for bridges.

The kingpost truss is comprised of a stringer, a kingpost (vertical beam), and two diagonal beams designed primarily for short spans of approximately 20 to 30 feet. As such, the bridge embodies the distinctive characteristics of a type and method of construction. **Therefore, Bridge No. 3 appears eligible under Criterion C of the NRHP and Criterion 3 of the CRHR.**

Criterion D/4: That have yielded, or may be likely to yield, information important in prehistory or history.

The property is not significant under Criterion D of the NRHP or Criterion 4 of the CRHR as a source, or likely source, of important historical information nor does it appear likely to yield important information about historic construction methods, materials or technologies.

Pasadena Statement of Significance

The City of Pasadena's landmark designation criteria is based on the NRHP/CRHR designation criteria and integrity requirements, Therefore, for all of the reasons identified in the discussion of NRHP and CRHR eligibility, the subject property **appears eligible as a landmark under local designation criteria 2a and 2c.**

Integrity Discussion

Bridge No. 3 maintains integrity of location, as it remains in its original location. The bridge retains integrity of design as it has not undergone any large-scale exterior alterations since its construction and maintains the essential features of form, plan, space, structure, and style. The bridge retains integrity of setting, as it still rests within a natural environment along the Arroyo Seco. The bridge retains integrity of materials and workmanship due to the retention of the physical elements that date from its construction. Finally, the bridge retains the feeling of an early 20th century timber bridge constructed by the CCC and it maintains its essential character-defining features to convey its association with the CCC building campaign in the 1930s. In summary, Bridge No. 3 retains the requisite integrity for designation, and appears eligible for listing under NRHP Criteria A and C, CRHR Criteria 1 and 3, and City of Pasadena Landmark criteria 2a and 2c.

Debris basins and flood control infrastructure (1948)

Flood control in Arroyo Seco began after the especially costly 1914 and 1916 floods damaged large portions of Los Angeles County farmland and urban areas. In 1915, the LACFCD was established in response to the in 1914 flood, and would protect an area of 2,760 square miles. Investment was initially delayed by the onset of World War I, but the first flood control feature built in the Arroyo Seco was the Devil's Gate Dam: designed in 1916, funded by bonds in 1917, and erected by Los Angeles County Department of Public Works by 1920 (Brick 2011; Pasadena Star News 1916; SB&C 1919; Van Wormer 1991) (*see continuation sheet*)

***P3a. Description: (continued)**
The doors are both located on the south elevations and consist of vertical wood board doors, braced on the interior. Other fenestration consists of screened window openings and a louvered vent in the gable end. The two sheds are to either side of the storm drain box structure with three openings on the top side, and letting out via culvert into the Arroyo Seco.

Figure 1. Altadena Storm Drain structure, pulley mechanism, and west-most shed, View looking west (IMG_2606)

The PWP spreading basins consist of, two spreading basins (Pasadena Ponds 1 and 2) formerly used as sludge ponds during operation of the Behner WTP, and 14 additional spreading basins (originally developed by LACFCD) separated by check dams completed between 1948 and 1952. Spreading basin features are engineered earthen ponds separated by soil embankments and small wood and concrete flow control dams. Each basin varies in total size and depth. The Pasadena Ponds 1 and 2 also have buried concrete culverts between them and the Parshall Flume, as well as chain link fence surrounding them.

Figure 2. Overview to spreading basins; View looking south (IMG_2631)

Figure 3. Overview to PWP sludge basins, now Pasadena Ponds 1 and 2; View looking southwest (IMG_2608)

A flow control dam is located west of the westernmost shed. Situated in a naturalized channel, west of the Altadena Storm Drain, the flow control dam consists of two walls of wood cribbing, and a wood board dam in the center, with removable boards in a metal track in order to control flow in the narrow channel. The downstream side of the channel has had a gunite mixture applied to the channel walls. On the east side of the dam, is a concrete platform, stair and metal handrail. On the west side of the dam, are two corrugated metal canisters, one lidded with flat metal and the other with conical metal.

Figure 4. Dam, View looking northwest (IMG_2600)

Finally, downstream of the flow control dam, there is a culvert and vehicle bridge through which water is measured (via a Parshall Flume) before it flows into the spreading basins. The culvert has two 18-inch openings in the channel basin. The roadbed is filled with gravel, but the culvert is constructed of board-formed concrete, with metal lining, and metal guard rails on top for safety. There is also a corrugated galvanized steel tank with a conical lid placed on a concrete platform on the upstream side of the culvert. The tank is currently used to house the controls for the Parshall Flume's metering device.

Figure 5. Culvert and Vehicle bridge, looking southwest (IMG_2612)

Identified Alterations

The following alterations were observed during the field visit:

- windows removed from shed (date unknown)
- LACFCD signs added to both shed exteriors (date unknown)
- metal railing replacing older wood handrail on flow control dam structure (date unknown)

***B10.Significance: (continued)**

The City of Pasadena, which had water rights to Arroyo Seco, began a spreading program in Arroyo Seco in 1914 to replenish the Raymond Basin aquifer; however, the program was abandoned in 1924 due to drought. The remnants of the 1914 spreading basins were washed out in 1936 when the Arroyo Seco stream changed its course to the east side of the Arroyo. Historic aerial photographs and maps indicate that the LACFCD-owned spreading grounds were installed in 1948, as a result of a 1940 push to build upstream flood control features in the Angeles National Forest. $1.17 million was used towards the establishment of silt and debris check dams on the upstream side of the Devil's Gate reservoir and the Brown Mountain Dam. The first funding installment was approved in 1941 and another in 1944, resulting from the 1944 storm and subsequent flood. Federal funds also went to the channelization of Arroyo Seco Canyon further downstream of Devil's Gate Dam By 1952, the Los Angeles County-owned Altadena Storm Drain and sheds were completed as well. The PWP-owned sludge basins were added in the 1970s, after the construction of the Behner Water Treatment Plant (Brown and Taylor 1982; City of Pasadena 2003b; ETA 1941; LAT 1940c, 1946; SCPR 2016; UCSB 2019; Van Wormer 1991).

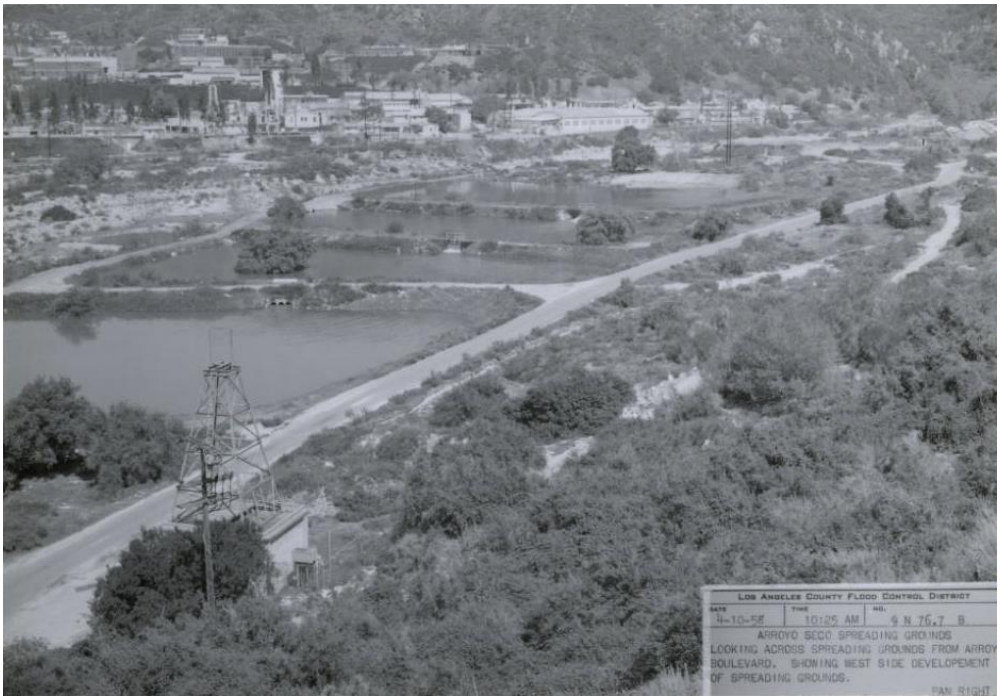

Figure 6. Arroyo Seco Spreading Basins, 1958 (Los Angeles County Flood Control District File Copy Prints Collection, Los Angeles County Library)

NRHP/CRHR Statement of Significance

Criterion A/1: That are associated with events that have made a significant contribution to the broad patterns of our history.

Archival research did not find any associations with events that have made a significant contribution to the broad patterns of our history. The spreading basins were completed in 1948, and the Altadena Storm Drain, sheds, culverts, and check dams completed between 1948 and 1952. These date have no bearing on the industrial, commercial, and institutional growth of Pasadena nor is it directly related to a historical natural disaster such as a specific flood. The flood control infrastructure appears to have no direct association with events that have made a significant contribution to the history of the City of Pasadena, or Los Angeles County, the State of California, or the Nation. Therefore, the property does not appear eligible under Criterion A of the NRHP or Criterion 1 of the CRHR.

Criterion B/2: That are associated with the lives of persons significant in our past.

Archival research did not indicate that any previous property owners or people who have worked on these structures are known to be historically significant figures at the national, state, or local level. The structures have been owned by PWP or LACFCD since construction, and as such is not associated with the life of a specific person significant to the past. Furthermore, to be found eligible under B/2 the property has to be directly tied to an important person and the place where that individual conducted or produced the work for which he or she is known. The structures do not appear to be associated

with any individual's important historic work and does not appear eligible for the NRHP under Criterion B or CRHR under Criterion 2.

Criterion C/3: That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction.

The flood control structures, including spreading basins completed in 1948, and the Altadena Storm Drain, sheds, culverts and checkdams completed between 1948 and 1952, are utilitarian in construction and lack association to a specific architectural style or method of construction. They have no specific character-defining features, do not represent the work of a master engineer, do not possess high artistic value and are not significant as contributing features of an entity whose components may lack individual distinction. Therefore the structures do not appear eligible for listing in the NRHP under Criterion C or CRHR under Criterion 3.

Criterion D/4: That have yielded, or may be likely to yield, information important in prehistory or history.

The property is not significant under Criterion D of the NRHP or Criterion 4 of the CRHR as a source, or likely source, of important historical information nor does it appear likely to yield important information about historic construction methods, materials or technologies.

Pasadena Statement of Significance

The City of Pasadena's landmark designation criteria is based on the NRHP/CRHR designation criteria and integrity requirements, Therefore, for all of the reasons identified in the discussion of NRHP and CRHR eligibility, the flood control structures do not appear eligible under any local designation criteria, either individually or as part of a district.

Integrity Discussion

The spreading basins, Altadena Storm Drain, checkdams, culverts, and sheds, as a collective engineered structure retain integrity of location and have not been moved since their construction in 1948. They maintain integrity of design as it has not undergone any large-scale exterior alterations since its construction and maintains the essential features of form, structure, and function. The structures retain integrity of setting, as they remain in the Arroyo Seco floodplain north of the Devil's Gate Dam, structures retain between a steep hillside and the campus of JPL. The structures retain integrity of materials and workmanship due to the retention of the physical elements that date from its construction. The structures retain integrity of feeling and association, as they can still express their purpose as water and flood related infrastructure. In summary, while the structures retain the requisite integrity, it does not rise to the level of significance required for designation at the national, state or local levels.

Attn: Michael J. Williams, Ph.D., Senior Paleontologist

re: Vertebrate Paleontology Records Check for paleontological resources for the proposed Arroyo Seco Project, Dudek Project # 11884, in the City of Pasadena, Los Angeles County, project area

Dear Michael:

I have conducted a thorough search of our paleontology collection records for the locality and specimen data for the proposed Arroyo Seco Project, Dudek Project # 11884, in the City of Pasadena, Los Angeles County, project area as outlined on the portion of the Pasadena USGS topographic quadrangle map that you sent to me via e-mail on 17 September 2019. We do not have any vertebrate fossil localities that lie directly within the proposed project area boundaries, but we do have localities nearby from the sedimentary deposits that occur in the proposed project area, either at the surface or at depth.

In the elevated terrain of the San Gabriel Mountains around the northern parcel of the proposed project area the bedrock is composed of plutonic igneous rocks that will not contain recognizable fossils. Most of the proposed project area, though, has surficial deposits that consist predominantly of younger Quaternary gravels in the Arroyo Seco Canyon drainage, but with older Quaternary Alluvium, derived as alluvial fan deposits from the San Gabriel Mountains to the northeast, on the northeastern side of the southern parcel of the proposed project area. These sedimentary deposits typically do not contain significant vertebrate fossils, at least in the uppermost layers, but underlying older and perhaps finer-grained Quaternary deposits may well contain significant vertebrate fossils.

Our closest vertebrate fossil locality in older Quaternary deposits is LACM 2027, southeast of the proposed project area, south of Washington Boulevard and west of Allen Avenue near the western end of Brigden Road, that produced a fossil specimen of mastodon, *Mammut*, at unstated depth. Further to the southwest of the proposed project area, in Eagle Rock east of the Pasadena Freeway (I-110) and Eagle Rock Boulevard just south of York Boulevard, our older Quaternary locality LACM (CIT) 342 produced fossil specimens of turkey, *Parapavo californicus*, and mammoth, *Mammuthus*, at a depth of 14 feet below the surface. The fossil turkey specimen from locality LACM (CIT) 342 was published in the scientific literature by L.H. Miller in 1942 (A New Fossil Bird Locality. Condor, 44(6):283-284) and the mammoth specimen was a rare, nearly complete skeleton and was published in the scientific literature by V.L. Roth in 1984 (How Elephants Grow: Heterochrony and the Calibration of Developmental Stages in Some Living and Fossil Species. Journal of Vertebrate Paleontology, 4(1):126-145).

Excavations in the igneous bedrock exposed in the elevated terrain in the northern part of the proposed project area will not encounter recognizable fossils. Shallow excavations in the younger Quaternary gravels exposed in the Arroyo Seco drainage, as well as the older Quaternary Alluvium on the eastern portion of the souther parcel of the proposed project area, are unlikely to uncover significant vertebrate fossils. Deeper excavations that extend down into older and perhaps finer-grained Quaternary deposits, however, may well uncover significant fossil vertebrate specimens. Any substantial excavations in the proposed project area, therefore, should be monitored closely to quickly and professionally recover any fossil remains discovered while not impeding development. Also, sediment samples should be collected and processed to determine the small fossil potential in the proposed project area. Any fossils recovered during mitigation should be deposited in an accredited and permanent scientific institution for the benefit of current and future generations.

This records search covers only the vertebrate paleontology records of the Natural History Museum of Los Angeles County. It is not intended to be a thorough paleontological survey of the proposed project area covering other institutional records, a literature survey, or any potential on-site survey.

Sincerely,

Samuel A. McLeod, Ph.D.
Vertebrate Paleontology

1.0 INTRODUCTION

Pasadena Water and Power (PWP) operates a diversion structure located approximately 0.25-mile north of Millard Creek on the Arroyo Seco. PWP has surface water rights of 25 cfs and and diverts streamflows into an intake structure. Upon entering the intake, the water is piped downstream approximately 3,000 feet to the PWP's spreading basins for groundwater recharge. The diversion structure and intake structure were damaged due to the debris flows following the 2009 Station Fire. Since then, the structures have operated at a reduced capacity.

The proposed Arroyo Seco Canyon Project (ASCP) would repair, replace and/or rehabilitate the diversion and intake structures in the Arroyo Seco in order to maximize the capture of PWP's surface water rights. The improvements, including a new sedimentation basin in the vicinity of the spreading basins, would facilitate management of sediment for diversion and spreading operations that were in the past managed with a headworks structure and settling basins further upstream. The ASCP also includes the expansion of PWP's spreading basins. The facilities and improvements that would be constructed as part of the Arroyo Seco Canyon Project would be located at three areas along the Arroyo Seco: Area 1 – Arroyo Seco Headworks; Area 2 – Arroyo Seco Intake; and Area 3 – Former JPL East Parking Lot/Spreading Basins (refer to Exhibit 2). This Hydraulics, Sediment Transport, and Groundwater Analysis (Report) analyzes one component of the larger Arroyo Seco Canyon Project: water diversions from the Arroyo Seco Intake structure in Area 2 (proposed Project).

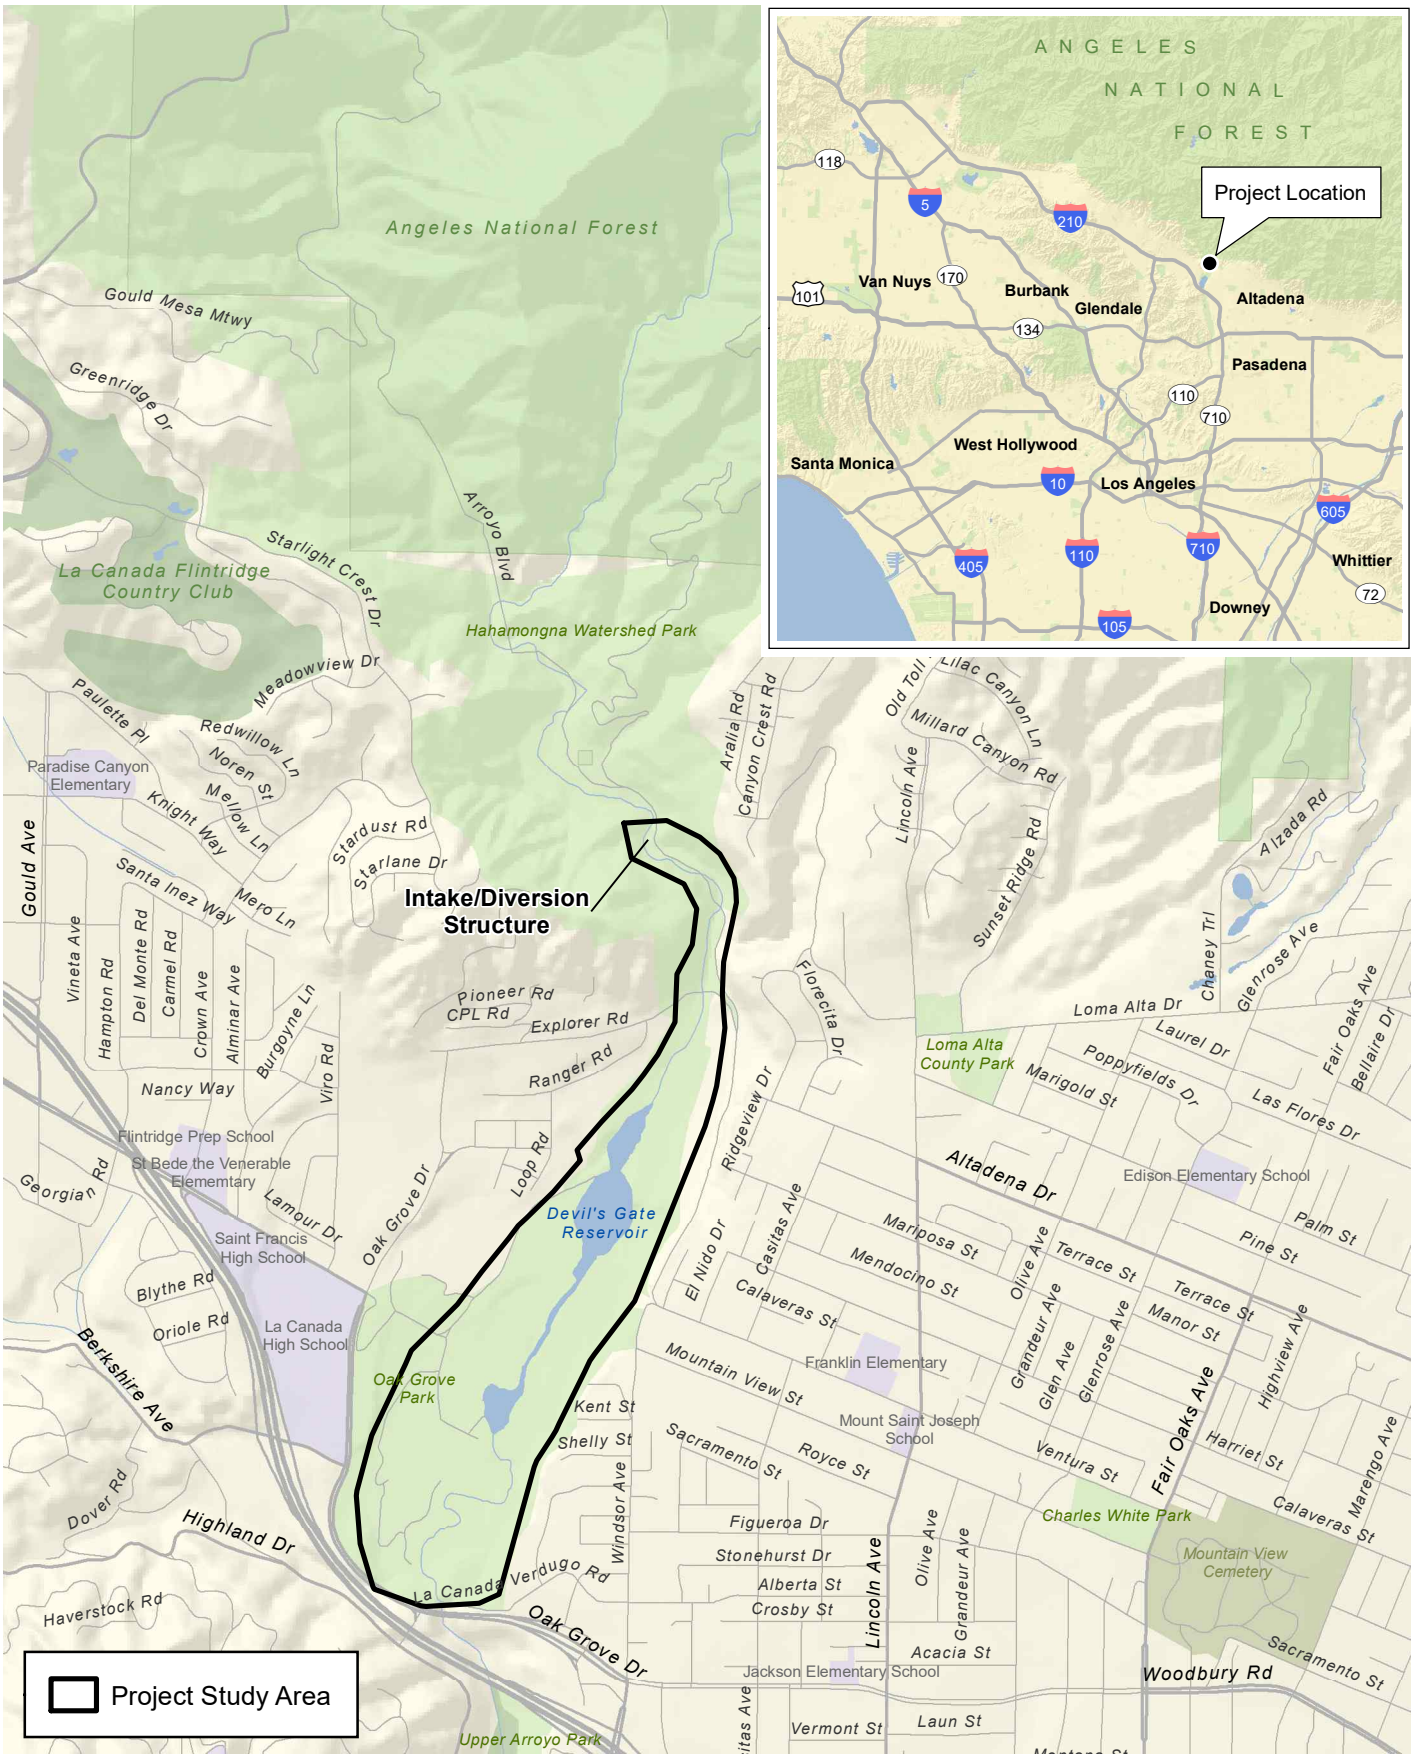
Changes to riparian habitats in the Project area can result from several potential sources, including changes in discharge patterns into the Devil's Gate Reservoir associated with water use practices (i.e. urban runoff) and diversions; infiltration of water in the existing spreading basins; alterations in sediment deposition and ponding patterns associated with the operation of Devil's Gate Dam; variation in sediment yield associated with fires in the upper watershed, such as the 2009 Station Fire; and long-term climate changes (including changes in drought cycles).

The purpose of this analysis is to evaluate the relative impact of the City's proposed management of diversions from the Arroyo Seco on riparian resources located downstream of the diversion structure. The goal of this Report is to identify the changes specifically concerning sediment transport, hydraulics, and groundwater that may affect down-stream riparian habitats. The results shall provide the baseline for further ecological modeling to assess biological impacts of the project on riparian resources.

2.0 PROJECT SETTING

2.1 PROJECT LOCATION

The Project site is located within the Arroyo Seco Watershed, which is a subwatershed of the larger Los Angeles River Watershed. The Arroyo Seco is a perennial creek, which means there is generally flowing water year-round, but the flow is below the surface (underground) in some locations. Creek flows that originate in the San Gabriel Mountains continue to flow south through the cities of Pasadena, South Pasadena and Los Angeles, before joining the Los Angeles River just east of Elysian Park and west of the Interstate (I) 5/I-110 Interchange. Within the City of Pasadena, the Arroyo Seco passes through three distinct recreational areas: (1) Upper Arroyo Seco, containing Hahamongna Watershed Park and Devil's Gate Dam; (2) Central Arroyo Seco, containing the Brookside Golf Course and Rose Bowl; and (3) Lower Arroyo Seco, containing an archery range, casting pond, and Memorial Grove. The proposed Project involves the construction of a new diversion structure in the Upper Arroyo Seco (in the City of Pasadena on land owned by the City). Exhibit 1, Regional Location and Local Vicinity, shows the location of the Arroyo Seco in the City of Pasadena, as well as the boundaries of the Project Study Area.



The locations of the Areas 1, 2, and 3, as identified in the larger Arroyo Seco Canyon Project, are shown in Exhibit 2, Location of Areas 1, 2, and 3. These areas are connected by the Gabrielino Trail, which serves as a recreational trail and the access road for City of Pasadena and United States Forest Service (USFS) vehicles heading into the Arroyo Seco Canyon. This Hydraulics, Sediment Transport, and Groundwater Analysis (Report) analyzes one component of the larger Arroyo Seco Canyon Project: water diversions from the Arroyo Seco Intake structure in Area 2 to the spreading grounds in Area 3.

The Project site can be accessed via I-210 by exiting Windsor Avenue and traveling northward for approximately 0.8 mile to its intersection with Ventura Street. From this intersection, the former JPL East Parking Lot is located approximately 0.27 mile north along Explorer Road, which can be accessed by walking, bicycling, driving, or by horse.

2.2 EXISTING CONDITIONS

The Arroyo Seco is an important source of water supply for the City of Pasadena. The City owns the right to divert up to 25 cubic feet per second (cfs) of surface water from the Arroyo Seco into the City's spreading basins located along the east side of the Devil's Gate Reservoir, upstream of Devil's Gate Dam.. PWP uses the surface water to recharge the underlying Monk Hill Subbasin (a sub-aquifer of the Raymond Basin) for groundwater well extraction.

PWP currently operates several structures in the Arroyo Seco Canyon that capture and convey stream water to a series of groundwater recharge (spreading) basins that are located adjacent to the National Aeronautics and Space Administration's (NASA's) Jet Propulsion Laboratory (JPL) campus. These facilities include the Arroyo Seco Headworks structure and adjacent sedimentation basins, the Arroyo Seco Intake Dam, and the associated pipelines that convey water to the existing spreading basins. A large number of these facilities were entirely or severely damaged due to debris flows in 2010 and 2011, subsequent to the 2009 Station Fire.

3.0 PROJECT DESCRIPTION

3.1 PROJECT PURPOSE AND NEED

PWP proposes the ASCP to repair and replace damaged facilities in Arroyo Seco Canyon. The improvements will allow for increased utilization of the City's surface water rights from the Arroyo Seco and maximize the beneficial use of this historically important local water resource. Specifically, modifications to the facilities in Area 2 will allow for increased diversion by capturing stream flows during storm events that in the past have been bypassed. PWP typically does not divert the stream water for recharge during large storm events (i.e. flows greater than approximately 100 cfs) due to the high total suspended solids (TSS) in the water. If water with high TSS levels is used for recharge, the ground surface in the spreading basins can be "blinded" or plugged by fine material, such as clays and silts, which would then reduce percolation and groundwater recharge rates. This reduced efficacy of the spreading basins is counterproductive in terms of groundwater recharge, and requires more maintenance to remove the top layer of fine materials at the spreading basins in order to recover the original recharge rates. Letting water with high TSS levels bypass without recharge is not preferred from a water supply perspective, but helps reduce maintenance issues associated with excessive cleanup of the basins. For the purposes of the present analysis, a maximum discharge in the Arroyo Seco must be defined to represent the upper limit at which water can be withdrawn. This flow rate is assumed to be 100 cfs.

3.2 PROJECT COMPONENTS

The proposed new diversion structure would capture all flows during small storm events and dry weather flows in the Arroyo Seco, and up to PWP's surface water rights during large storm events. During larger storms when the water is too turbid, the stream (with its associated sediment load) would bypass the structure and continue downstream in the creekbed. Operation during high flows would be facilitated by the adjustable height weir or crest gate. At low flows, the gate would start in the 'up' position and as flows increase, the gate would be lowered to maintain a constant water surface level in the diversion pool. When the gate is fully lowered, flows will be bypassed and carry sediment downstream.

City personnel would continue to provide maintenance of the diversion and intake structures as occurs under existing conditions.

4.0 PREVIOUS STUDIES

Two studies were reviewed to enhance the background understanding of the Project area hydraulics. A summary of each relative to the analysis in this Report is provided below.

PHILLIP WILLIAMS & ASSOCIATES (2000) – The purpose of the Phillip Williams & Associates (PWA) study was to provide supplemental analysis of hydrology and geomorphology to the development of a master plan for the Hahamongna Watershed Park. The study specifically examined hydrology, geomorphology, flood hazards, water resources history, sediment transport and maintenance, and groundwater recharge. Pertinent to the proposed Project are the hydrology, flood hazards and sediment transport analyses.

The hydrology element of the study examined precipitation gages near the Project site, including USGS stream gage #11098000. A flood frequency analysis of the gage data was conducted. Additional analysis of a Los Angeles County Department of Public Works stream gage (F277-R) was also completed. A review of the stream gage data showed that several major floods have occurred during the period of record for the stream gage and as recently as 1983. (It should be noted that the 1998 peak discharge was greater than the 1983 peak discharge, however, a vetted data set may not have been available at the time.) Interestingly, none of the major floods were preceded by a wildfire within three years. The PWA study also followed Waanan & Crippen (1977) in developing a relationship between the discharge at the gage and the discharge below the gage based on tributary area. The base relationship takes the form:

$$Q_d = Q_{gage}\left(A_d/A_{gage}\right)^n$$

where Q_d and Q_{gage} are the discharge rates at a location downstream of the gage and at the gage, respectively, A_d and A_{gage} are the watershed areas at a location downstream of the gage and at the gage, respectively, and n is an exponent based on the return frequency of the discharge being scaled. It is important to note that PWA assumed that all discharges are bulked, which appears to be reasonable for the study area and the USGS gage data.

Hydraulic numerical modeling was completed for the study using the MIKE11 model for a combination of the 2- 10- and 50-year annual return frequency events. The model was limited to the stretch of Arroyo Seco between the Jet Propulsion Laboratory (JPL) Bridge and the Devil's Gate Dam. MIKE modeling focused on flood management.

The sediment transport analysis included geomorphology and hydraulics. The geomorphic analysis noted the importance of floods, fires and debris flows within the watershed, and noted that these types of events play an important role in the frequency and magnitude of watershed and stream sediment yield in the study area. The study examines the many published rates of watershed debris yield and notes the alluvial fan-like environment of the lower portion of the study area. PWA also presents the record of sediment management within the Devil's Gate Reservoir.

Historical aerial photograph analysis was performed to determine the historical extent of the active bed and erosional patterns. The analysis found that the limits of erosion are topographically controlled and that the upper portion of the reservoir has typically been braided where the lower portion exhibits ponding.

A two-dimensional FLO-2D numerical model was run for the 2-, 10-, and 50-year hydrographs. The purpose of the model was to determine the debris flow in the reservoir. The model extents were the same as the MIKE model. Historical sectional and longitudinal analysis was also completed within the reservoir. Additional empirical analysis was completed to estimate sediment yield for discrete events. The study found what is commonly accepted as the basis for sediment

yield in southern California watersheds: yield scales with volume of precipitation. Therefore, the smallest, most frequent runoff events or the driest years will transport little or no sediment to the reservoir, while high volume, infrequent events or wet years may potentially transport relatively large volumes of sediment within the study area. The MIKE model was also updated to analyze sediment transport within the study area using sediment data collected within the reservoir. The model was calibrated against historical section data. The model results appear to over-predict bed change during the 2-year event with up to 9.5 feet of aggradation in the model bed at the most upstream cross section. The authors attribute this to the rapid expansion of channel width immediately downstream of the entrance to the reservoir.

JET PROPULSION LABORATORY (2003) – The Jet Propulsion Laboratory (JPL) study describes the development and calibration of the JPL groundwater model as part of the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) site. Of interest to the present work, the JPL study found no constant loss from Arroyo Seco to Raymond Basin, the underlying groundwater basin, nor any regular and consistent contribution from Raymond Basin to the Arroyo Seco. This indicates that water from the aquafer is not at a depth shallow enough to provide water to sustain vegetation.

5.0 HYDRAULIC MODEL

5.1 MODEL DESCRIPTION

Hydraulic modeling was completed using the U.S. Army Corps of Engineers' (USACE) Hydraulic Engineering Center River Analysis System (HEC-RAS). The HEC-RAS numerical model was designed to calculate water surface profiles in channels assuming a steady flow and uniform discharge based on site hydrology. The HEC-RAS model was run in two-dimensional mode. A description of the model and the model set-up follows.

5.1.1 Equations of Motion

Multi-Dimensional shallow water models can be used to resolve depth and depth-averaged velocities in the horizontal directions x and y. The shallow water equations appear in integral form as (Chaudhry 1993):

$$\frac{\partial}{\partial t}\int_{\Omega} \mathrm{U}d\Omega + \oint_{\partial\Omega} (Fdy - Gdx) = \int_{\Omega} Sd\Omega$$

The dependent variables, U, fluxes F and G, and the source terms are defined as,

$$U = \begin{pmatrix} h \\ uh \\ vh \end{pmatrix} F = \begin{pmatrix} uh \\ u^2h + \frac{gh^2}{2} \\ uvh \end{pmatrix} G = \begin{pmatrix} vh \\ uvh \\ v^2h + \frac{gh^2}{2} \end{pmatrix} S = \begin{pmatrix} 0 \\ gh(s_{ox} - s_{fx}) \\ gh(s_{oy} - s_{fy}) \end{pmatrix}$$

where u and v are the depth averaged flow velocities in the x (easterly) and y (northerly) directions, respectively. The terms in S account for the bed and friction slopes and are given as,

$$s_{ox} = -\frac{\partial z}{\partial x}\ s_{oy} = -\frac{\partial z}{\partial y}$$

and

$$s_{sf} = \frac{n^2 u\sqrt{u^2 + v^2}}{h^{3/4}}\ s_{fy} = \frac{n^2 v\sqrt{u^2 + v^2}}{h^{3/4}}$$

where z=z(x,y) is the bed elevation above an arbitrary datum. Finally, Ω represent the domain of two-dimensional control, and $\partial\Omega$ is its boundary.

5.2 TOPOGRAPHIC REPRESENTATION AND MODEL EXTENT

The HEC-RAS model domain for the study area (as identified on Exhibit 1) was developed in RAS Mapper, a subroutine of HEC-RAS, using topographic 2015 information (tested at an accuracy of 1.25' at 95% confidence level) provided by the City of Pasadena. The topographic data is found in Attachment A. A Manning's coefficient was applied to the study reach and hydrographs were developed for analysis, both described below. As shown in Exhibit 3, HEC-RAS Model Extent, the model extends from upstream of the proposed diversion point to Devil's Gate Dam to upstream of the diversion. The upstream extent was selected because it is the upstream limit of potential impacts to the stream since diversions will not impact hydraulics or hydrology upstream of this location. The downstream limit was chosen because it represents the downstream limits of impacts to the stream because of the presence of Devil's Gate Dam. Numerical hydraulic models are made up of individual computational cells (units of area analyzed) which can vary in size. This model includes approximately 22,250 computational cells with an 18-square foot cell size.

5.3 MANNING'S VALUES

HEC-RAS uses Manning's Equation to represent friction loss in the model, as described above. Manning's values were selected based on aerial (Google Earth) and site photography. The Manning's values range from 0.065 to 0.085. In the present analysis, Manning's value of 0.065 is representative of sandy bottom, wide, braided channel sections with vegetation, while a Manning's value of 0.085 is representative of relatively narrow, steep canyon sections with trees, brush and variable bed section. These values follow guidance for the selection of Manning's values as presented in Barnes (1967) and Chow (1959).

A sensitivity analysis was determined to be unnecessary. The majority of habitat of concern within the study area is generally within the reservoir and the velocities that will be experienced by this vegetation in the reservoir's pool area is at or near zero feet per second. Changing the Manning's value will not change the velocity experienced by the vegetation. Moreover, changing the velocity in the stream by modifying the Manning's values will not alter the velocities experienced by the vegetation in the reservoir. Finally, the largest discharges that occur in the study's numerical modeling are not altered by the proposed project so the roughness values that control the depth and velocities that vegetation experiences during these large events is the same in both the existing and proposed conditions. Alteration of roughness will not change the outcome during these events.

5.4 BOUNDARY CONDITIONS

The down-stream model boundary condition is set to normal depth, while the inflowing boundary condition is set to an inflowing hydrograph, described below. Model outflow is based on the operational curve of Devil's Gate Dam. Generally, there is no outflow from the model for water surface elevations below 1,025 feet. Between 1,025 feet and 1,030 feet the outflow from the Dam is 100 cfs; between 1,030 feet and 1,035 feet the outflow from the Dam is 300 cfs; above 1,035 feet the outflow is 800 cfs. The greatest observed elevation in the reservoir during the representative wet year without diversion is 1,035 feet.

5.5 HYDROLOGY

All hydraulic modeling is based on USGS daily gage data at stream gage #11098000. Daily average discharge data is utilized for the period 1989 to 2014, which is the vetted stream gage data available at the time of writing and is not strongly influenced by drought. Individual water year hydrographs representing dry, average and wet years are selected for modeling, as described below. The hydrologic record at the gage for the period is shown in Exhibit 4, USGS Stream Gage Data for the 1989/1990 to 2013/2014 Water Years.

It is important to recognize that the area of the watershed contributing to the stream at the gage location is smaller than the area of the watershed contributing to the stream at the proposed diversion location. To account for the difference in watershed area the gage data has been scaled as a function of the watershed area to account for the difference. The scaling follows the approach of Waanan and Crippen (1977), which was also used by PWA (1990) in their flood frequency analysis of Arroyo Seco. The scaling is computed as:

$$Q_{diversion} = Q_{gage}(A_{diversion}/A_{gage})^n$$

where *Q* is the flow rate at a given location on the stream, *A* is the area of the watershed at a location corresponding to the respective flow rate, and *n* is an empirical value that is a function of the return period of the discharge being scaled. In the present study all daily discharges in the wet, average and dry hydrographs fall within the range of the 2-year peak discharge, therefore the exponent *n* is set to 0.72 after PWA (1990). The watershed areas were calculated using GIS-based tools and topography provided by the City. The watershed areas at the gage and proposed diversion are 16.0 square miles and 18.8 square miles, respectively.

To develop representations of wet, average and dry years the relative deviation percent was calculated for each year (Gao et al. 2018). The relative deviation percent was calculated by comparing the average annual runoff volume to the annual runoff volume for each year. Years where annual runoff was less than the average are considered dry, while years where the annual runoff was greater than the average are considered wet. Approximately 28% and 72% of annual runoff volumes were determined to be wet and dry, respectively. The years selected to represent wet and dry hydrographs were taken as the median wet and dry annual runoff volumes, respectively. The average runoff year was taken to be the year where annual runoff was closest to the average. The relative deviation percent data for all years is shown in Table 1.

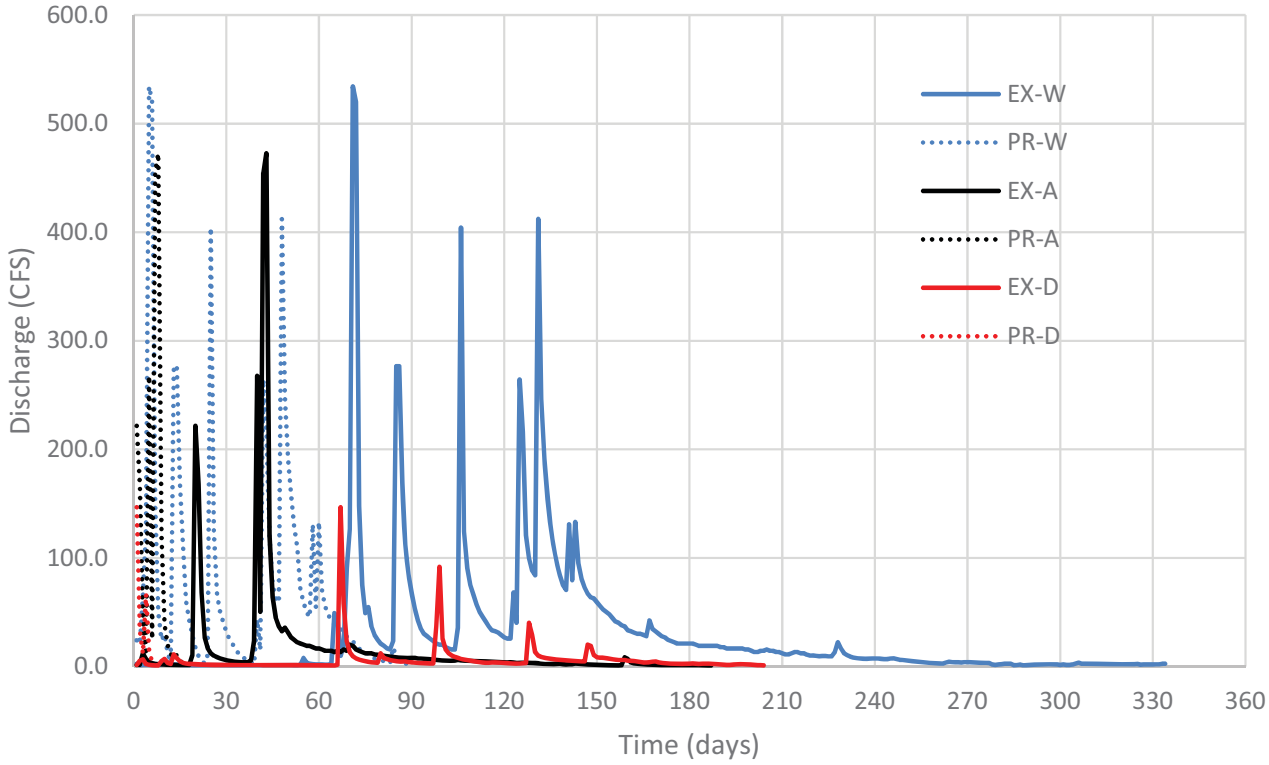
TABLE 1
WET AND DRY ANNUAL RUNOFF VOLUME BY RELATIVE DEVIATION PERCENT AT USGS GAGE #11098000

WATER YEAR		ANNUAL RUNOFF (AF)	RELATIVE DEVIATION %	WET OR DRY?
1989	1990	752	-90.2	DRY
1990	1991	3,499	-54.6	DRY
1991	1992	13,876	80.2	WET
1992	1993	31,231	305.5	WET
1993	1994	2,307	-70.0	DRY
1994	1995	17,957	133.1	WET
1995	1996	5,040	-34.6	DRY
1996	1997	3,867	-49.8	DRY
1997	1998	20,330	164.0	WET
1998	1999	2,094	-72.8	DRY
1999	2000	2,965	-61.5	DRY
2000	2001	3,224	-58.1	DRY
2001	2002	472	-93.9	DRY
2002	2003	2,314	-70.0	DRY
2003	2004	1,290	-83.3	DRY
2004	2005	37,888	391.9	WET
2005	2006	5,239	-32.0	DRY
2006	2007	616	-92.0	DRY
2007	2008	5,754	-25.3	DRY
2008	2009	1,857	-75.9	DRY
2009	2010	9,713	26.1	WET
2010	2011	14,804	92.2	WET
2011	2012	2,759	-64.2	DRY
2012	2013	1,305	-83.1	DRY
2013	2014	1,398	-81.9	DRY
	AVERAGE=	7702		
	MEDIAN=	3224	DRY % =	0.72
			WET % =	0.28
			WET MEDIAN=	17,957
			DRY MEDIAN=	2,311

For modeling purposes, the 1994-1995 water year is used to represent a wet year's runoff volume, the 2007-2008 water year is used to represent an average year's runoff volume, and the 2002-2003 water year is used to represent a dry year's runoff volume.

To develop hydrograph input for modeling, the hydrograph data was limited to daily average discharges greater than 1 cfs. Therefore, no days without runoff are represented in the model. This approach is undertaken because discharges lower than 1 cfs will not reach the Dam owing largely to frictional attenuation within the model. Moreover, the model does not consider infiltration, and is very conservative with respect to the volume of water (more than actual) reaching the dam. It is likely that discharges less than 1 cfs not fully attenuated by friction will be infiltrated before reaching the Dam. Finally, the diversion is being modeled as capable of collecting all the water in the stream, which is unlikely since diversion structures are "leaky" by their nature and at present we cannot account for the leaky loss. Like the modeling approach to

infiltration, this approach is also very conservative with respect to the volume of water that reaches the Dam.



The proposed operational curve of the diversions includes three elements : 1) the diversion will remove all water from the stream up to 25 cfs; 2) diversions will cease for discharges above 100 cfs; and 3) all diverted water is assumed to infiltrate in the spreading basins regardless of the total volume of diversion. Curve elements 1 and 3 are conservative statements. Curve element 1 simplifies modeling because it doesn't consider the leaky nature of diversions, and it is conservative in approach since the constructed system will not be able to capture 100 percent of all discharges, which is typical for operations of diversion structures in natural systems, as noted above (NRC 1939). Curve element 3 is conservative because it states that all of the water to which the City has legal rights can be infiltrated, and that infiltration basins (will have sufficient capacity for all of the diverted water as designed. Factor 2 is represented in modeling since the turbidity of 100 cfs discharges typically represents the upper limit of turbidity that can be successfully managed by the proposed diversion system (City of Pasadena pers comm).

Diversions are represented in the model by subtracting 25 cfs from the daily average discharge values in the modeled hydrographs for discharge values less than 100 cfs. Durations of the discharges remain unchanged (one day), and all days with no discharge are removed from the hydrograph. The without diversion and proposed (with diversion) hydrographs for wet, average and dry years are shown in Exhibit 5, Existing and Proposed Modeling Hydrographs for the Wet, Average, and Dry Runoff Years.

Note that the "without diversion" scenario is used as the most conservative approach to reflect the maximum possible change from existing conditions. Currently there are some diversions of unspecified rates and durations, but they are well below PWP's surface water rights.

5.6 HYDRAULIC ASSUMPTIONS

Modeling used in the present study is uncalibrated hydraulically because no data exists with which to calibrate the model. That is, there does not exist any data that compares discharge to depth, velocity or other hydraulic parameters. It is assumed that the present modeling is conservative, as it doesn't consider evaporation, infiltration, evapotranspiration or other forms of loss besides friction. Attenuation in the model is only a function of friction, and both direct and anecdotal evidence exist to indicate that stream flows in the Arroyo Seco reach the Dam and reservoir.

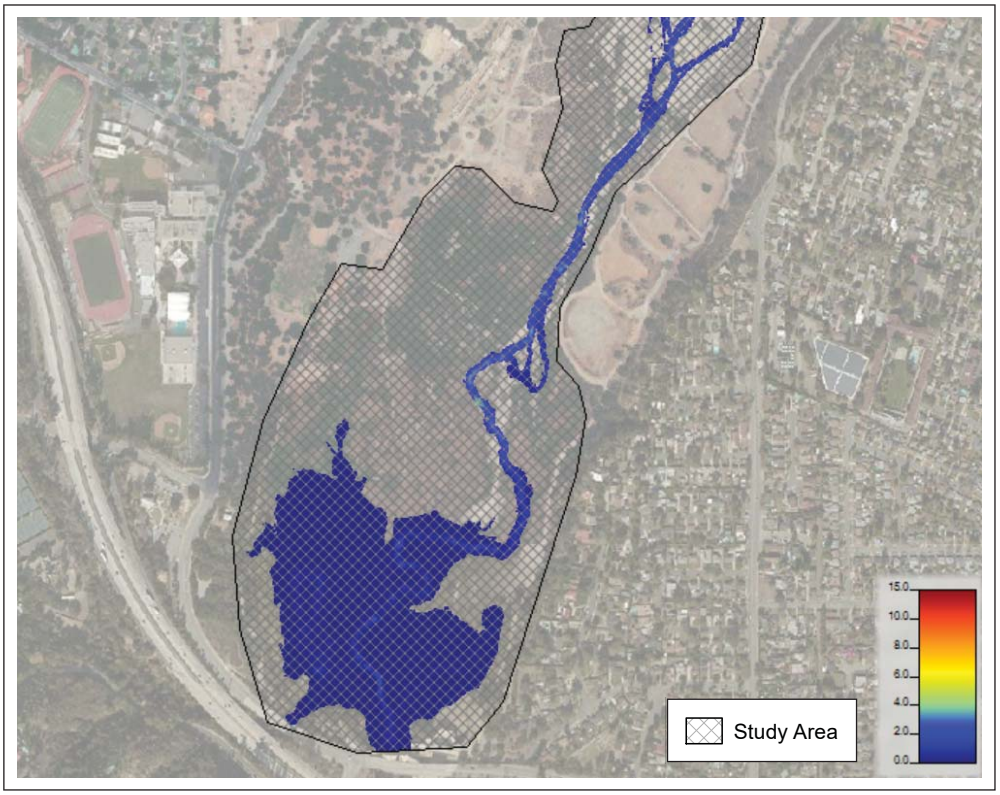
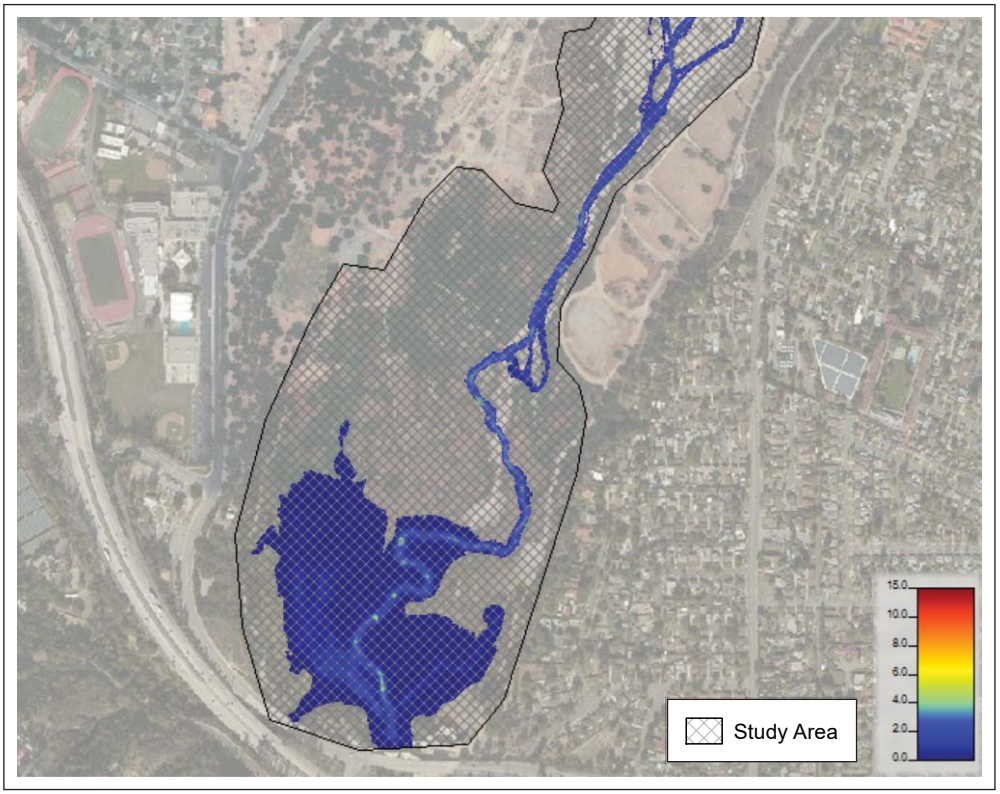
6.0 HYDRAULIC MODEL OUTPUT.;

The HEC-RAS model was run for three representative water years as described above: wet, average and dry total runoff volumes. The HEC-RAS model was also run for the three representative years with proposed Project diversions, also described above. What follows is a comparison of maximum depth and maximum velocity for each representative water year for both the hydrology with and without diversions.



6.1 DRY YEAR VELOCITY

The representative dry year and representative dry year with diversions maximum velocity are shown in Exhibit 6, Representative Dry Year Maximum Velocity. Comparing the two graphics reveals that the maximum velocity in the with-diversion scenario is higher than in the without-diversion scenario in some locations immediately upstream of the Dam. In the primary stream channel upstream of the Dam the maximum velocity doubles from approximately 2.5 feet per second (fps) in the without-diversion condition to approximately 4.2 fps in the with-diversion scenario. In addition, there is an approximate doubling of velocity in some portions of the backwater area upstream and to the west of the Dam from approximately 0.3 fps in the without-diversion scenario to approximately 0.6 fps in the with-diversion scenario.



A review of Exhibit 5 indicates what the driver is for the increase in velocity. In the without-diversion scenario small discharge events (Q<25 cfs) begin to fill the reservoir prior to a significant event (Q>>25 cfs). When the smaller events pond upstream of the Dam, the larger events maximum velocity is lower because of backwatering from the Dam due to ponding. In contrast, when water has not ponded upstream of the Dam, no backwatering will occur during a more significant event and velocities will be higher in the main stream and in some of the backwatering areas. It is important to note that these higher velocities can occur in a dry, average or wet year regardless of whether diversions occur if an early runoff event in the season is relatively large and little or no backwatering has occurred prior to the runoff event. It is also important to note that the total change in velocity is relatively low and occurs well below (v=0.6 fps) or just below (v=4.0 fps) a typical velocity (i.e. 4.5 fps) for initiation of sediment transport in sandy bed, vegetated streams.

6.2 DRY YEAR DEPTH

The representative dry year without-diversions and representative dry year with-diversions maximum depth are shown in Exhibit 7, Representative Dry Year Maximum Depth. The graphics show that the maximum depth between the without-diversion and with-diversion scenarios drops by approximately 1.3 feet. A review of Exhibit 5 indicates the cause of the decrease in maximum depth. In the without-diversion conditions, the total runoff for the representative dry year is approximately 2,480 acre-feet (af), while the hydrograph with-diversions for the representative dry year is approximately 550 af. Therefore, the difference in runoff volume accounts for the difference in maximum depths shown in Exhibit 7. It is important to note that the area of inundation is approximately the same between the two scenarios owing largely to the shape of the reservoir upstream of the Dam.

Representative Dry Year Maximum Depth

Exhibit 7

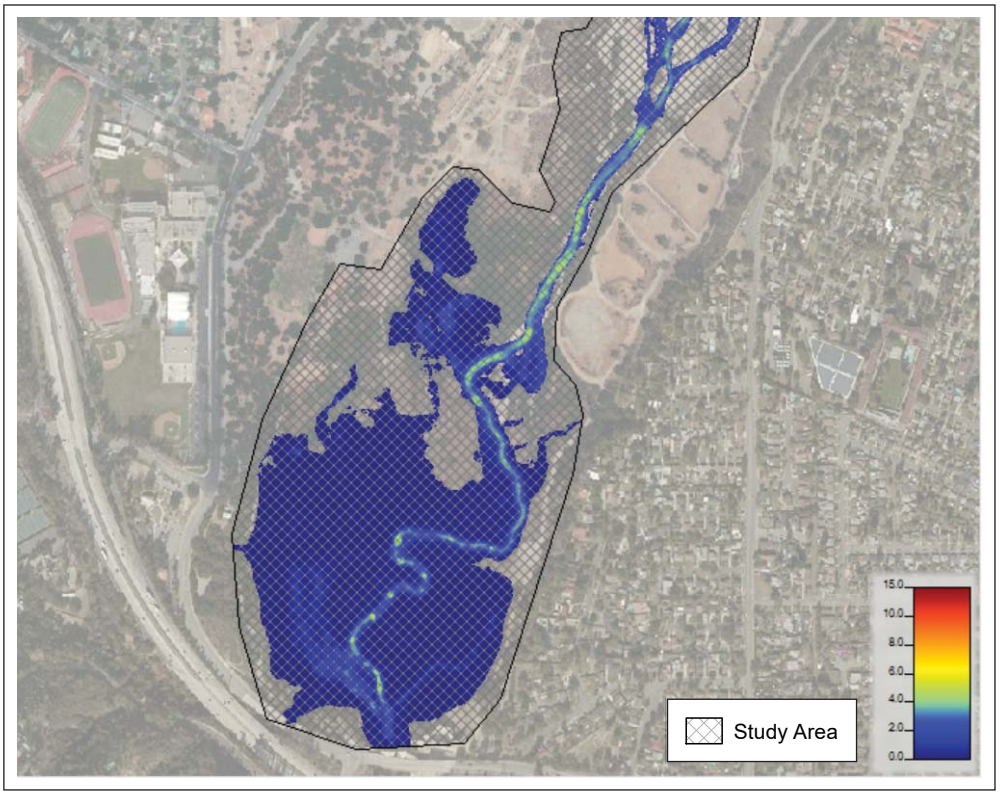
Arroyo Seco Diversion Hydraulics Analysis

PSOMAS

(2018-8-3 CJS) R:\Projects\PAS_Pasaden\3PAS010700\Graphics\Hydro_Rpt/

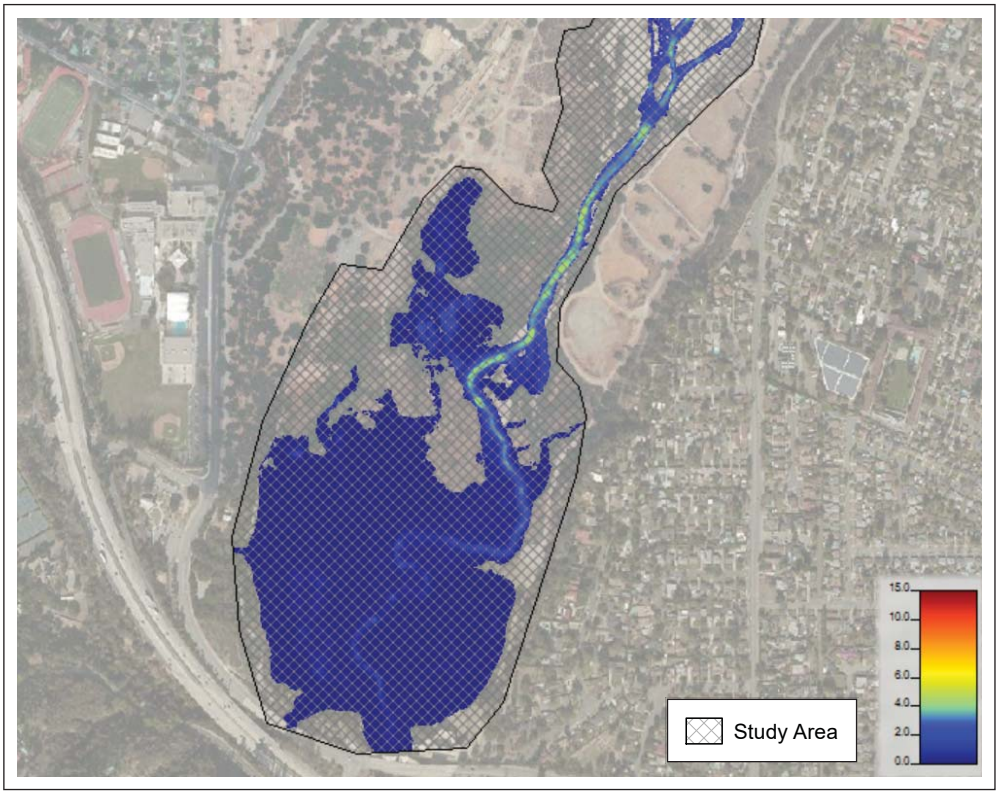
6.3 AVERAGE YEAR VELOCITY

The representative average year and representative average year with-diversions maximum velocity are shown in Exhibit 8, Representative Average Year Maximum Velocity. Unlike the dry scenarios, the maximum velocity in the without-diversion scenario is higher than in the with-diversion scenario in some locations immediately upstream of the Dam. In the primary stream channel upstream of the Dam, the maximum velocity doubles from approximately 2.5 fps in the with-diversion condition to approximately 5.5 fps in the without-diversion scenario. In addition, this is an approximate doubling of velocity in some portions of the backwater area upstream of the Dam from approximately 0.6 fps in the with-diversion scenario to approximately 1.0 fps in the without-diversion scenario.



The reason for these differences is similar to that in the representative dry year scenarios, except that the reservoir has relatively high ponding in the with-diversion scenario compared to the without-diversion scenario before a significant (Q>>25 cfs) event occurs. In the representative average year scenario, the resulting maximum velocities are relatively higher than in the representative dry year scenario (5.5 fps vs. 4.2 cfs, respectively). It appears from Exhibit 5 that the difference in modeled maximum velocity in this location is a function of hydrograph shape (rate of flow versus time) as opposed to other hydraulic or hydrologic factors.

6.4 AVERAGE YEAR DEPTH



The representative average year without diversion and representative average year with diversions maximum depth is shown in Exhibit 9, Representative Average Year Maximum Depth.. The images are indistinguishable from one another because the maximum water surface elevation is the same, approximately WSE (water surface elevation) = 1,035 feet. In these scenarios, the factor that controls the depth and WSE is the operation of Devil's Gate Dam. Despite the same maximum depths, the with-diversion scenario has greater inundation durations at the reservoir fringes because the with-diversion scenario reservoir depth reaches the operational curve elevation more slowly than does the without-diversion scenario.

6.5 WET YEAR VELOCITY

The representative wet year without diversion and representative wet year with diversions maximum velocity is shown in Exhibit 10, Representative Wet Year Maximum Velocity.. Like the other representative scenarios, there are differences in maximum velocity upstream of the reservoir. The difference between the representative wet year without-diversion and with-diversion maximum velocity is lower in magnitude than in the similar representative dry and average scenarios. This appears to be a function of the rate at which the reservoir fills in the represented wet year scenarios. In the wet year scenarios, the difference in maximum velocity in the channel upstream of the reservoir is approximately 3.0 cfs and 1.5 cfs for the with-diversion and without-diversion scenarios, respectively. One interesting difference between the representative wet year scenarios and other scenarios is how far upstream the differences are observed. In the case of the wet year scenarios, the differences in velocity are observed in the channel upstream of the ponded reservoir, while in the representative average scenarios the differences are confined to downstream of the infiltration basins on the east bank. A review of the model output indicates that the difference in extent of impacts is a function of the extent of ponding and ponded elevation in the reservoir, which alters the backwatering further upstream than in the average scenario conditions. The difference is not attributable to change in hydrology resulting from diversions since the largest discharges (Q>100 cfs) are not impacted by the diversions.

6.6 WET YEAR DEPTH

The representative wet year without-diversions and representative wet year with-diversions maximum depth is shown in Exhibit 11, Representative Wet Year Maximum Depth. Like the representative average year scenarios, the representative wet year maximum depth exhibits are indistinguishable because the Dam operational curve is controlling the maximum depth in the reservoir, approximately WSE=1,035 feet. Like the average year scenarios, the with-diversion scenario has greater inundation durations at the reservoir fringes because the with-diversion scenario reservoir depth reaches the operational curve elevation more slowly than does the without diversion scenario.

All model input and output can be found in Attachment B.

7.0 SEDIMENT TRANSPORT MODEL

7.1 MODEL DESCRIPTION

General adjustment was estimated in this study using the U.S. Army Corps of Engineers (USACE) SAM steady-state numerical model. Here, SAM was employed to provide a first calculation of sediment transport potential within Arroyo Seco. The SAM Sediment Hydraulic Package is an integrated system of programs developed through the Flood Damage Reduction and Stream Restoration Research Program to aid in the analyses associated with designing, operating, and maintaining flood control channels and stream restoration projects. SAM combines the hydraulic information and the bed material gradation information to compute the sediment transport capacity for a given channel or floodplain hydraulic cross-section for a given discharge at a single point in time. Several sediment transport functions are available for this analysis and SAM can assist in selecting the most appropriate sediment transport equation.

The three primary fluvial components of SAM are SAM.HYD, SAM.SED and SAM.AID. SAM.HYD provides a steady state, normal-depth, one-dimensional representation of channel hydraulics. The SAM.SED module combines the hydraulic parameters with the bed material gradation curve to compute bed material discharge rating curves by size classification. The SAM.AID module provides the user with recommended sediment transport equations based on the best matches between hydraulic parameters and grain size distribution of the study reach with parameters from widely accepted and published research.

The SAM numerical model is built upon hydraulic and fluvial components. The hydraulic components include representations of river bed characteristics that are input into an analytical procedure. The fluvial component includes representation of bed gradation as percent finer statistics and a selection of up to twenty sediment transport equations. SAM's hydraulic component will accept either average reach parameters or cross-section data imported from HEC-2/HEC-RAS/HEC-6 models. Hydraulic modeling is based on a uniform flow equation where discharge is the dependent variable such that,

$$Q = f(D, n, W, z, S)$$

where Q is discharge in cfs, D is flow depth in feet, n is the Manning's number, W is bottom width in feet, z is the channel side slope, and S is the energy slope. The bottom width is representative of the total moveable bed width of the channel and Manning's number is a composite value. Normal depth is calculated using Manning's equation, and effective values of width and depth are calculated following normal depth calculations.

The fluvial component is based on sediment transport functions to calculate the bed portion of the sediment discharge-rating curve. The sediment transport equations are of the form,

$$GS_i = f(V, D, S_e, B_e, d_e, \rho_s, G_{sf}, d_s, i_b, \rho_f, T)$$

where GS_i is the transport rate for sediment size class i; the hydraulic terms V, D, S_e, and B_e, are the average velocity, effective flow depth, energy slope, and effective flow width, respectively; the sediment particle parameters d_e, ρ_s, and G_{sf} are the effective particle size, particle density, and grain size shape factor, respectively; the sediment mixture properties, d_s and i_b are the geometric mean particle size of sediment class i and fraction of class i in the bed, respectively; and the fluid properties ρ_f, and T, the water density and temperature, respectively. Twenty well known, published, peer-reviewed transport equations are available including Ackers-White, Colby, Laursen-Copeland, Laursen–Madden, MPM, Toffaleti, Yang, Van Rijn and others. Once the data assembly is complete, the SAM.SED module can be used to create a sediment discharge-rating

curve based on grain size distribution. The reader is referred to the SAM user's documentation for further reference.

It is important to note that the SAM model is a zero-dimensional computational package that is only based on a single cross-section at a point in time. As such, SAM simulations can only represent a reach average during a steady state discharge. Because SAM applies sediment transport to a point, no variability in size distribution in either space or time is calculated. With these limitations in mind, in this study SAM is intended to provide a first approximation to sediment transport to which other more sensitive calculations can be compared.

7.2 MODEL INPUT

In this study, hydraulic representation of the streambed is accomplished in several distinct steps. First, the HEC-RAS numerical model is used to develop a representative cross section for analysis. Second, the HEC-RAS geometry is combined with hydraulic data for the representative cross section. Next, the hydraulic data and cross section are entered into the SAM.HYD subroutine and the model is run. The sediment data, described below, is entered into the model, the SAM.AID subroutine is run, and a transport equation is selected. Once the equation is selected the SAM.SED subroutine is run.

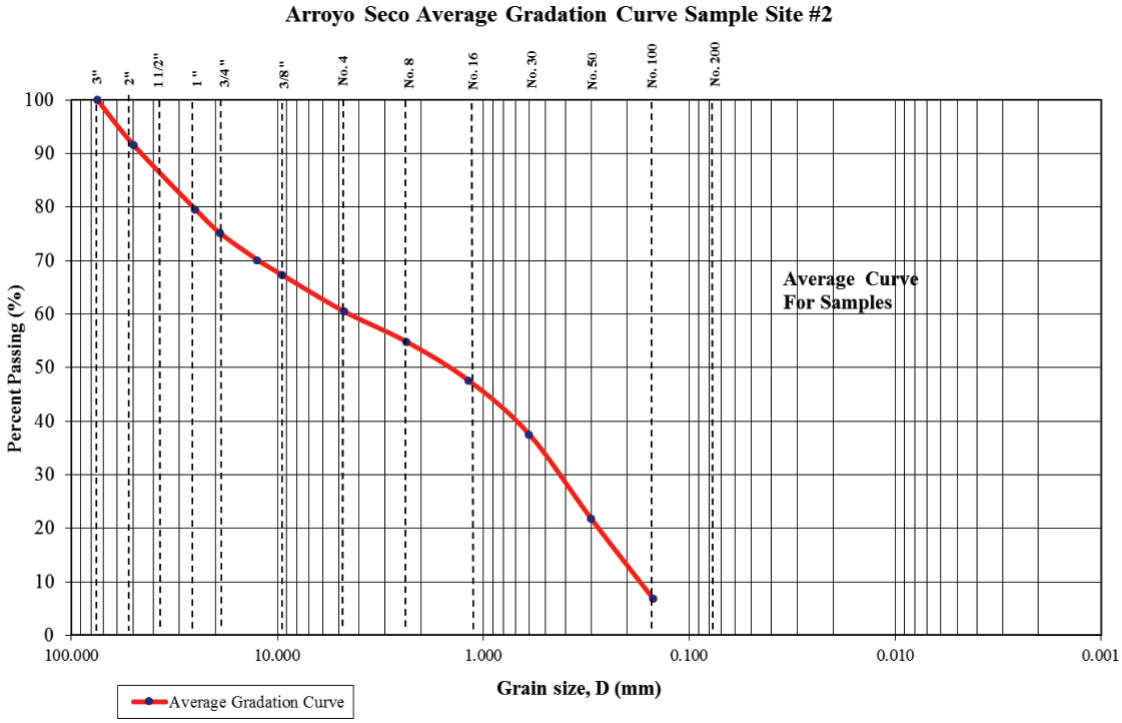
7.3 SEDIMENT DATA

To characterize the sediment of the streambed and by extension, the possible bed load of sediment during discharge events, a sediment grain size analysis was conducted. The goal of the analysis is to gain a statistical representation of the size distribution of soil components of the streambed. Grain size distribution analysis is a powerful tool because the results can represent both a qualitative description of soil make up as well as quantitative input for further predictive measures, such as fluvial modeling.

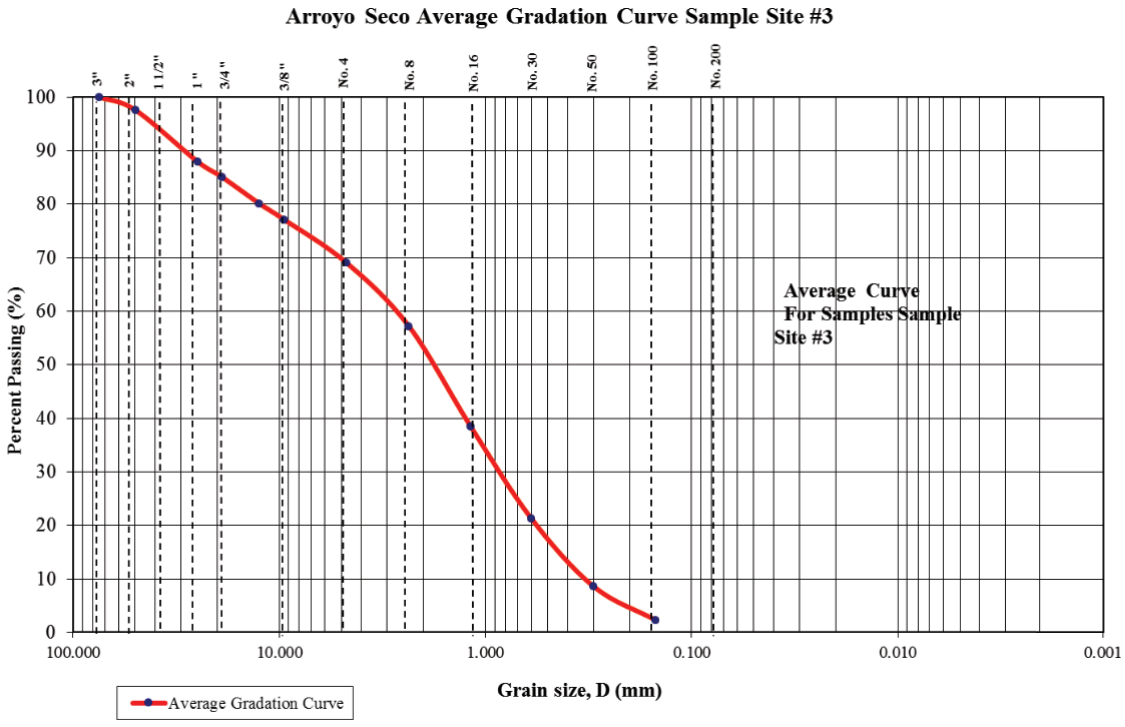
Sediment sampling was conducted by R. T. Frankian & Associates (2018). Sampling was conducted at a total of 6_locations, approximately every 2,000 feet within the stream bed from 200 feet upstream of the existing diversion structure to 200 feet upstream of the Dam face, which is a distance of approximately two miles. A total of three samples were taken within the stream bed at each of the proposed sample locations; each sample location was taken from a depth of approximately 18 inches. Samples were only obtained in surface-dry areas of the stream bed. Access to each of the sample locations was limited to foot traffic from various access points. The excavation and sampling of sediments were limited to the use of hand-operated equipment. Excavated sediments were stockpiled on heavy tarps during the process of excavation, sampling, and classification. The remnant excavated sediments were used to backfill each of the sample locations. Field samples obtained from each of the test pits were laboratory sieved for grain size distribution testing in general accordance with ASTM Test Method D422. The portions of the samples tested were limited to that portion of each sample greater than the No. 200 Sieve.

Since SAM is a single point model, two specific locations were chosen for modeling. The first model location is approximately 200 feet upstream of the JPL Bridge, while the second model location is approximately 1,100 feet downstream from the bridge. Both locations are relatively distant from the influence of confluences and structures, and neither is located in the reservoir, which is not appropriate for modeling with SAM. Sample Location No. 2 and No. 3 were taken at these sites, respectively, and the average grainsize distribution at each location was used for SAM modeling. The average grainsize distribution of Sample Location No. 2 and No. 3 is shown in Exhibit 12. One benefit for selecting these sites is that the upstream location is within the more confined channel reach, while the downstream location is below the grade break in the stream where Arroyo Seco begins to widen and acquires characteristics of an alluvial surface. Therefore,

these two locations are representative of the two primary stream morphologies found in the study area. All Frankian sediment data is presented in Attachment C.



7.4 TRANSPORT EQUATION SELECTION



Sediment transport equations used in all SAM modeling were chosen with the assistance of the U.S. Army Corps of Engineers' (USACE's) SAM.AID subroutine. The SAM.AID subroutine determines the most representative transport function based on the hydraulic parameters and soil gradation data for a section of Arroyo Seco by comparing model data with the results of 20 peer-reviewed and widely acknowledged sediment transport studies. To accomplish the task of guiding the user in selecting an appropriate transport function, SAM.AID assumes that the function that best represents sediment transport in a gauged stream would also best represent transport in an ungauged stream with similar sediment and hydraulic characteristics. SAM.AID begins by comparing study parameters (V, D, S_e, B_e, D_{50}) with parameters in the transport function database. Comparison begins by determining if D_{50} falls within one of the ranges identified in the database. Once the initial matches have been made in the database, the three best-matched sediment transport functions for the study reach are listed along with the parameters that matched the data set. Once the best transport equation matches have been determined by SAM.AID, the most representative equations are run in SAM.SED.

The Yang and Ackers-White equations were found to be the representative transport equation for a discharge of 25 cfs, the proposed diversion discharge. A discussion of sediment transport applicability (Yang and Huang 2001) suggests that Ackers-White is more appropriate for sand transport than is the Yang equation. Therefore, all analysis is based on Ackers-White, but the Yang equation results are included for completeness. All SAM model input and output can be found in Attachment C.

7.5 SAM MODEL RUNS

The SAM model was run at Sample Location No. 2 and No. 3 for 25 cfs, the proposed diversion discharge. The SAM runs were intended to indicate the possible change in sediment transport potential at the two model locations resulting from the proposed diversions. Representative hydraulics from each location were taken from the HEC-RAS model and sediment data was taken from Frankian sieve data, as described above.

8.0 SEDIMENT TRANSPORT MODEL OUTPUT

The sediment transport potential at Sample Location No. 2 and No. 3 are, respectively, 37,680 and 169 tons per day for the Ackers-White equation and 3,788 and 148 tons per day for the Yang equation. A large portion of the difference appears to be related to Location No. 2's ability to generate sufficient transport potential in the 2.828 mm size class for Ackers-White, which does not occur at Location No. 3. Additionally, the transport potential for all size classes is approximately one order of magnitude greater at Location No. 2 than Location No. 3 for Ackers-White for almost all grain size classes. Similar results are observed for Yang's equation, although Yang predicts sediment transport potential up to 5.657 mm at Location No. 2, but only up to 2.828 mm at Location No. 3.

A review of the hydraulics at each location identifies the cause of the disparity in transport potential between the two locations. The steeper, narrower Location No. 2 has higher velocity, steeper slope and narrower top width relative to Location No. 3, which is below the channel's grade break. This finding matches the finding of PWA (2000) that significant sediment deposition occurs in what is referred to as the "upper reservoir." The implication for this finding is that the lower portion of the Arroyo Seco study area behaves in a similar way to an alluvial fan below the hydrographic apex whereby sediment is deposited in patterns associated with flow path uncertainty, and sediment transport below the grade break is strongly a function of local hydraulics (e.g. Leopold et al. 1992).

9.0 HYDRAULIC AND SEDIMENT MODELING CONCLUSIONS

In dry, average, and wet representative years, modeled diversions from Arroyo Seco have an effect on velocity in select areas of the reservoir upstream of Devil's Gate Dam. The effects on velocity are small in absolute terms ($\Delta v_{maximum} < 3$ *fps*), and in some cases the change in velocity represents a decrease from the existing conditions. Numerical modeling indicates that the factors that control change in velocity in the reservoir are the magnitude (peak discharge) and shape (number of peaks and duration of individual runoff hydrographs) of the earliest storms in a given season and the extent to which ponded water fills the lower reservoir. In cases where diversions do not effect early-season large runoff events, differences in maximum velocity can be expected to be negligible between the without and with diversion scenarios for any representative year. In contrast, the extent which the reservoir is full in either the without or with diversion scenario may affect the change in velocity by creating a backwater condition in the reservoir. Modeling suggests that the direct effect on velocity from diversions is for events where the maximum discharge is near or below 25 cfs. However, as was identified by Inman and Jenkins (1999), the dominant driver of runoff in coastal southern California is large winter storms. Therefore, only in years where the primary source of water to the Devil's Gate Reservoir is runoff events near or below 25 cfs are velocities expected to be affected by diversions. It should be noted that the representative dry year is only minimally affected in this manner.

Effects on maximum depth in dry, average, and wet representative years in Arroyo Seco are largely mediated by the amount of ponding in Devil's Gate Reservoir. Ultimately, the ponding in the reservoir is a function of the rate, frequency and volume of inflow, and the dam operation outflow. In representative average and wet years, the modeled extent of ponding is a function primarily of dam operations for both the without and with diversions. In represented dry years, numerical modeling indicates that maximum depth is primarily driven by the volume of water entering the reservoir in the absence of reaching the dam operational curve elevation. In representative dry years, diversions may have an effect on maximum water depth in the reservoir, and modeling indicates that maximum depth in these years is partially a function of when in the season the largest runoff events occur. That is, representative dry years with diversions and a few relatively large runoff events will have a similar maximum depth in the reservoir compared to representative dry years without diversions. In contrast, in representative dry years without a few relatively large events, modeling predicts that the difference in reservoir maximum depth will be greater. Finally, in representative wet and average years the duration of inundation can be impacted on the fringes of the reservoir by diversions. Diversions in these years appear to increase the inundation duration somewhat by increasing the volume of runoff required to initiate dam operations.

The numerical modeling presented here indicates that relatively small effects on maximum velocity and maximum depth occur from proposed diversions upstream. These effects (change in velocity) are limited generally to the stream channel within the lower reservoir and the backwater area immediately upstream and to the west of the dam. Additional minor effects (change in duration of inundation) are indicated at the reservoir edge and appear to be strongly a function of dam operations as well as diversions.

SAM modeling of two locations within the study area indicates that there is greater sediment transport potential at 25 cfs in upper portions of Arroyo Seco, which are steep and narrow, compared to portions below the topographic break, which are wider and flatter. This finding echoes that of PWA (2000) that found that significant sediment deposition occurs in the "upper reservoir." **The implication for the present study is that for low discharges in Arroyo Seco, the reduction in discharge of 25 cfs is expected to be unimportant to overall sediment transport potential because the controlling elements of sediment transport are geologic factors.** Moreover, in large runoff events that are typically the dominant delivery mechanism of

sediment in southern California (Inman and Jenkins 1999) no diversions are presently proposed and are therefore not expected to be impactful to stream sediment yield to the reservoir.

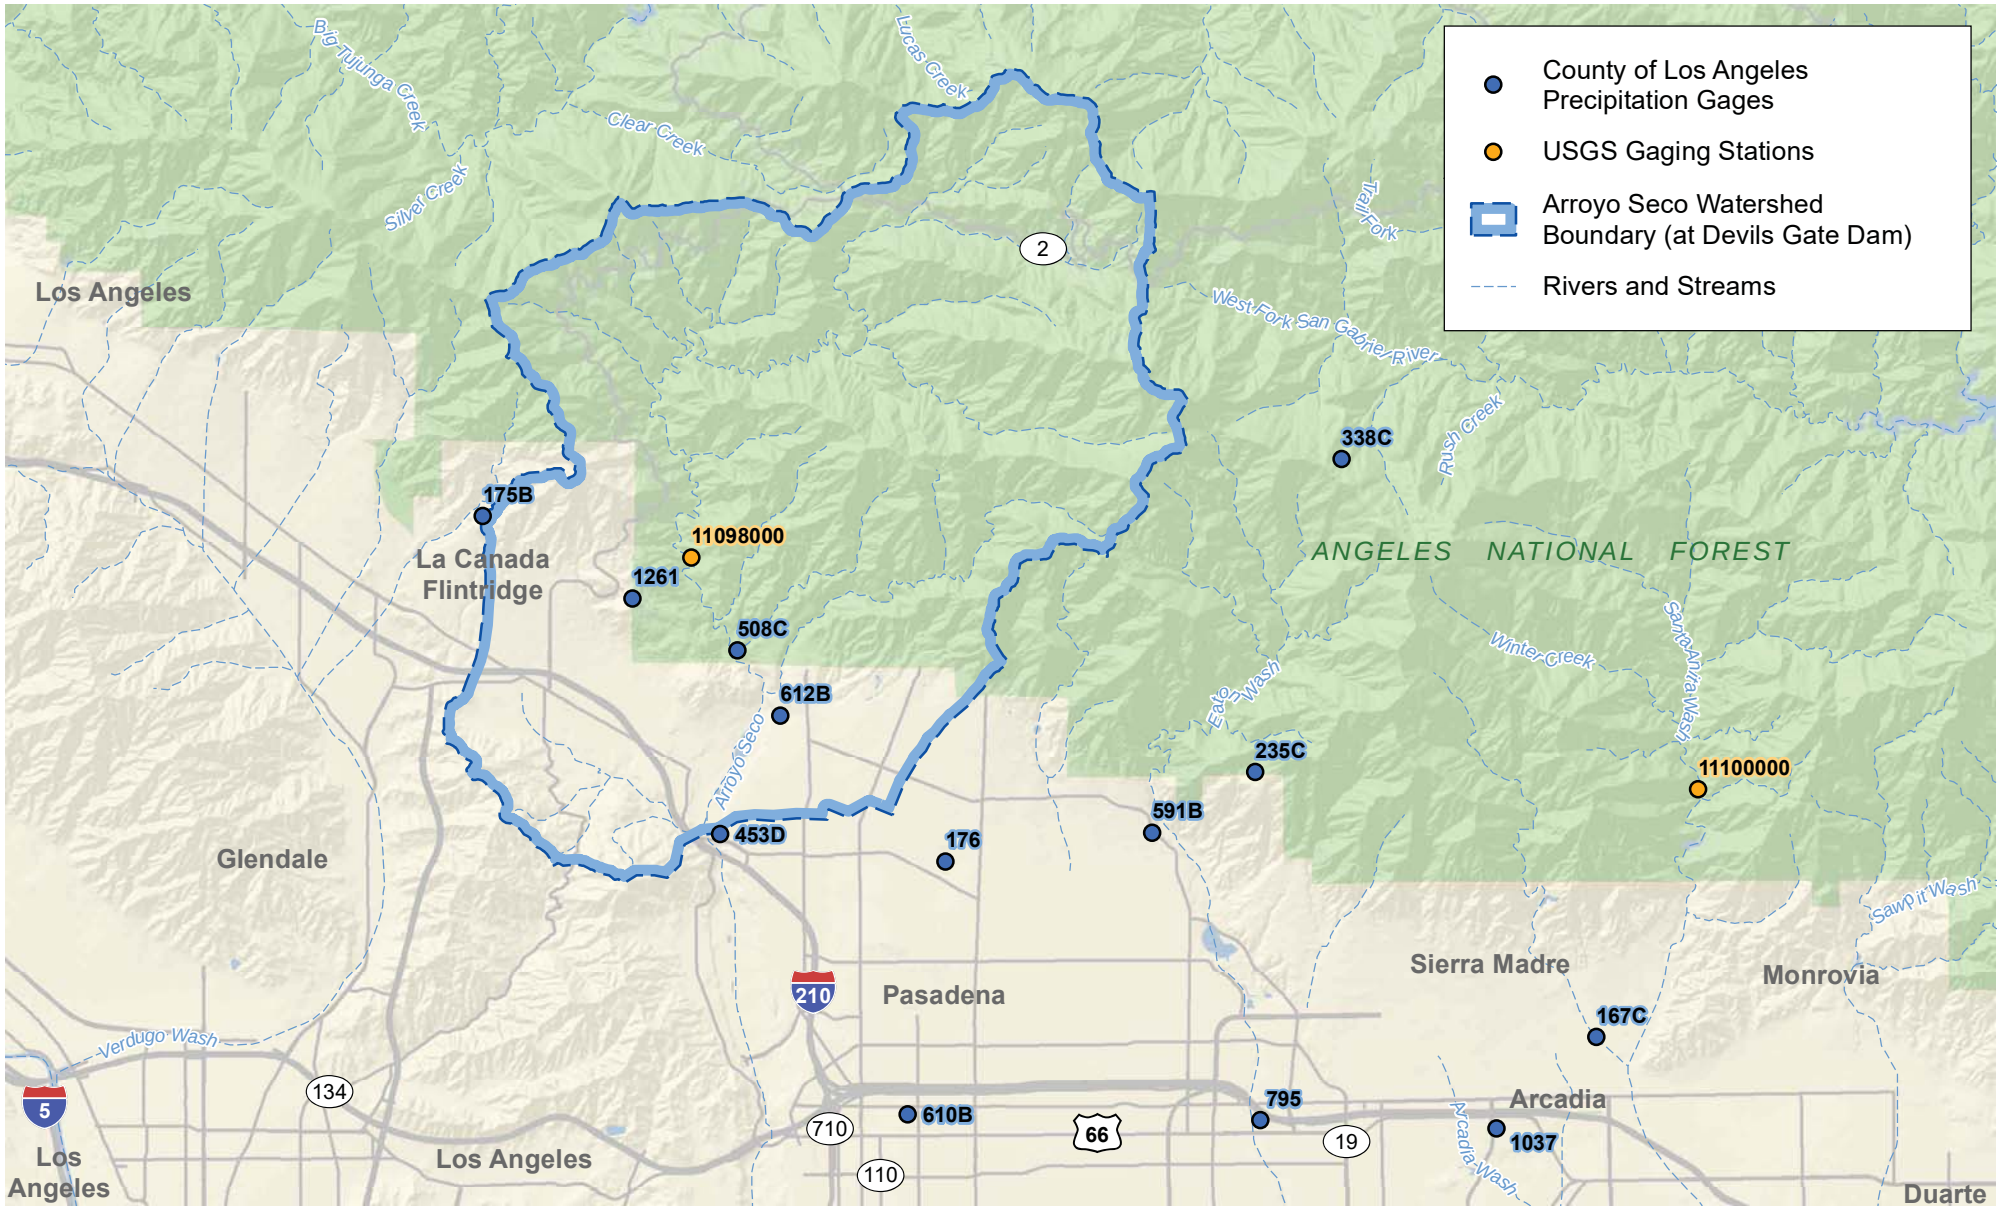
10.0 GROUNDWATER ASSESSMENT

10.1 PHYSIOGRAPHY

The Arroyo Seco Watershed is bounded on the north by the San Gabriel Mountains, which consist of steep, rocky ridges broken by numerous irregular canyons. The elevations of these mountains vary from about 1,200 feet along their base to a maximum of more than 6,000 feet above sea level at the headwaters of the Arroyo Seco.

The Arroyo Seco stream empties out into a broad piedmont plain that slopes downward from the base of the San Gabriel Mountains to Devil's Gate Reservoir, the lowest ground surface point of the Raymond Groundwater Basin within the Project area (see Exhibit 13). The Arroyo Seco continues south until it empties into the Los Angeles River near the intersection of the 5 and 110 freeways. The Raymond Basin (see Hydrogeology Section) forms along the southern flank of the San Gabriel Mountains and extends into the project area beneath Devil's Gate Reservoir.

10.2 GEOLOGY



10.2.1 General Geology

The Raymond Basin lies in the northwestern part of the San Gabriel Valley, bounded by the San Gabriel Mountains to the north, the San Rafael Hills to the west, and ending to the south and east at the Raymond Fault. The San Gabriel Mountains, along with the San Bernardino Mountains to the east and the Santa Monica Mountains to the west, make up a major portion of the east-west trending Transverse Range geologic province of California. The San Gabriel Mountains are primarily composed of Cretaceous to Tertiary crystalline rocks, including diorites, granites, monzonites, and granodiorites, with a complex history of intrusion and metamorphism. The Sierra Madre fault system separates the San Gabriel Mountains to the north from the San Gabriel Valley to the south. Within the valley lies Quaternary alluvium, made up of sand, gravel, clay, or some mixture of each. Underlying the alluvium is the crystalline basement complex, comprised of the same general rock types that are exposed in the San Gabriel Mountains to the north (Foster Wheeler Environmental Corporation [FWEC], 1999).

Raymond Fault, the southern boundary of the triangle, crosses the San Gabriel Valley floor for a distance of about nine miles, connecting a granitic spur from the San Gabriel Mountains at the eastern end of the Raymond Basin with Tertiary sediments outcropping in its southwestern corner. The Raymond Fault separates the Raymond Basin from the Main San Gabriel Basin in the vicinity of the southeasterly boundary. The fault zone is not impervious and groundwater can flow across this boundary into the Main Basin (NASA 2003). The general geology of the Raymond Basin is shown in Exhibit 14.

The low water-bearing formations in the project area include the Basement Complex rocks and Tertiary sediments of the Topanga, Modelo and Puente formations (Exhibit 14 and Attachment D).

The Basement Complex is comprised of pre-Cretaceous series of crystalline rocks that comprise the basal formation of the region. These are chiefly igneous plutonic rocks of granitic type, together with their metamorphic phases, such as schists, gneisses, and also various intrusive dikes. The Basement Complex comprises the majority of San Gabriel Range to the north and the San Rafael Hills to the west. The Basement Complex protrudes above the alluvium at Monk Hill

and near the head of Eaton Wash demonstrating that it is continuous beneath the area. The Topanga Formation, Tertiary age sedimentary rocks, is represented in the Raymond Basin by fairly well bedded shales, sandstones, and conglomerates that are well consolidated. The exposed Topanga beds are limited to the southwesterly corner of the area along a fault block where the formation is exposed for a mile in the channel of Arroyo Seco just north of the Raymond Fault and for about one and one-quarter miles easterly from the Arroyo Seco to Raymond Hill (RBMB, 2016).

The CDWR (1966) characterized the water-bearing formations of the Raymond Basin as alluvial fill having characteristics of the coarse deposits found in the small basins near the mountain margins. The deposits are coarsest at the base of the mountains where they contain boulders several feet in diameter, but even in the southerly part of the basin, cobbles, stones, and boulders are not uncommon. There are practically no true sand beds in the northerly part of Raymond Basin. The average sand content in the basin sediments as determined from well logs is only 2.8 percent. The deposits are characterized throughout by an abundance of weathered material. Decomposed yellowish gravels, clayey yellow and red gravels, and red or brown residual soil clays are the typical deposits.

The older alluvium found within the area is nearly continuous along the entire southerly flank of San Gabriel Range with little change in composition or structure. Within the Raymond Basin, it constitutes practically all of the water-bearing series and is not only dominant at the surface but appears to continue with depth to bedrock, although at depth, it may be in contact with some of the late Tertiary sediments. The older alluvial fill consists of a small portion of sand and almost equal proportions of gravel and clay. Older alluvial fill is of great thickness and its deposition has occurred through a long period. Weathering, disintegration, and cementation have been continuous and the results have varied with local conditions and there is considerable spatial variation in the water yielding characteristics of this formation (RBMB, 2016).

Recent alluvium occupies channels, washes, and flood plains of Arroyo Seco, Eaton Creek, and Big and Little Santa Anita Creeks, and to a lesser extent, exists as veneers scattered along the slope of the valley resulting from flood discharges of intermittent streams (Exhibits 13 and 14). For the most part, the recent alluvium is believed to be shallow, but in the upper portions of Little Santa Anita Wash, the indications are that the recent alluvium may extend to a depth of about 150 feet. These sediments are similar to those found in the older alluvium but contain a much smaller proportion of clay and are unconsolidated.

10.2.2 Structural Features and Faults

According to the CDWR (1943), the geologic structure of Raymond Basin is complicated. The rough surface topography of the Basement Complex outside the area indicates that the bedrock floor beneath the alluvium undulates, although the present mountain block undoubtedly exhibits a more rugged topography due to its recent rejuvenation with accompanying accentuation of erosive forces, then the old erosion surface was buried and protected by alluvial deposits of the area. However, within the area, except at the boundaries, and the granitic protrusions at Monk Hill and near the north end of Eaton Wash, there is no surface expression of undulations of bedrock which might indicate possible impediments to groundwater movement.

The San Gabriel Fault cuts through the central portion of San Gabriel Mountains and has an east-west trend. It is one of the main faults in the mountain block but is so distant that its effect upon the Raymond Basin area is only indirect (RBMB, 2016).

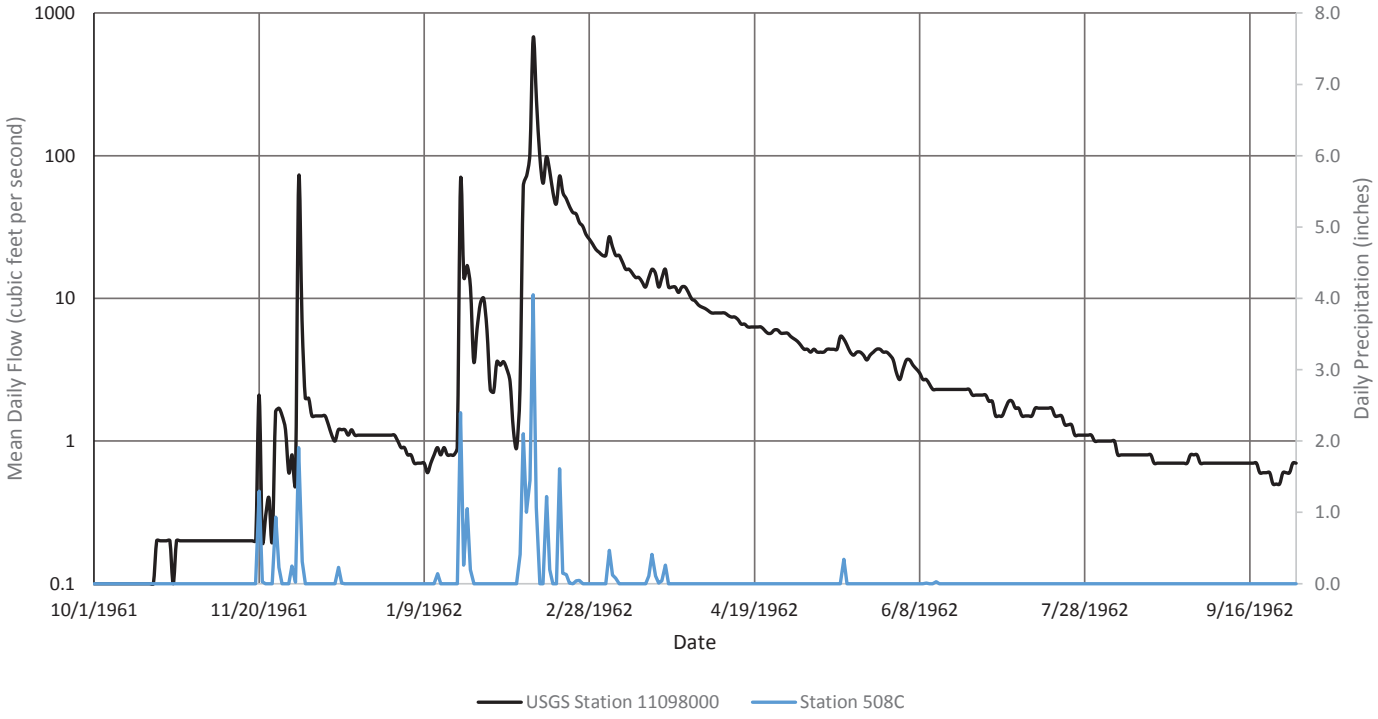
The Sierra Madre Fault system is a broad zone of faulting with an east-west trend roughly parallel to the southern edge of the San Gabriel Mountains, swinging to the northwest in the vicinity of the City of Sierra Madre. The main trace of this zone leaves the southern edge of the foothills at a

point west of the mouth of Eaton Wash, penetrating the mountain block in a north-westerly direction for some distance before it again swings to the west. The bedrock contours as a result of the geophysical survey indicate a uniform northerly slope of the buried bedrock surface from San Rafael Hills (RBMB, 2016).

Hydrogeologic investigations and groundwater modeling work at the Jet Propulsion Lab (JPL) (NASA, 2003) identified a thrust fault crossing Arroyo Seco just as Arroyo Seco enters the Raymond Basin. Preliminary work indicated that the fault was a partial barrier to groundwater flow.

The Raymond fault forms the boundary between the Raymond Basin and the Main San Gabriel Basin from the City of South Pasadena on the west to the City of Monrovia on the east. It is likely a thin, impervious gouge formed in alluvium because it creates a several hundred-foot difference in water level elevation in approximately 2,700 feet between Del Mar Well of California American Water Company and Well No. 3 of San Gabriel County Water District (RBMB, 2016). In addition to the difference in water level elevation, the barrier effect of the Raymond fault is indicated by the presence of artesian conditions during periods of high water levels, and by the creation of ponds and swampy areas north of the fault line. The Raymond fault appears to impede groundwater movement southward from the Raymond Basin into the Main San Gabriel Basin (RBMB, 2016).

10.3 WATER RESOURCES



10.3.1 Precipitation

The Raymond Basin is located within a region of both semiarid and Mediterranean climate, with warm, dry summers and mild winters with intermittent rain. The majority of the annual rainfall occurs between December and March. Precipitation in the Arroyo Seco area has been monitored by a network of precipitation stations operated by Los Angeles County, Department of Public Works (LACDPW). Annual precipitation within the Raymond Basin is more variable in the mountain watershed than in the valley floor. The mountain watershed (28.40 inches) averages about 7 inches more annual precipitation than the valley floor (21.33 inches) (RBMB, 2016).

As previously indicated, RBMB (2016) conducted an evaluation of precipitation in both the mountain areas and the valley floor areas and noted about 7 inches of more precipitation in the mountain region. No existing operational precipitation gages are located in the upper portion of Arroyo Seco, however an historic gage was located at the Arroyo Seco Ranger Station (LA County gage 508C) and operated from 1914 to 1974 (see Exhibit 13). A comparison was made with LA County gage 175 (La Canada Irrigation District) to find an average year for precipitation during the same period that LA County gage 508C was operational. The period selected was October 1961 to September 1962 where LA County gage 175 recorded 26.00 inches (20-year average was 26.96 [as reported by RBMB, 2016]) and LA County gage 508C recorded 24.75 inches and is presented in Exhibit 15.

10.3.2 Surface Water

The entire Raymond Basin area lies within the watershed of the Los Angeles River (CDWR, 1966), and surface runoff from the San Gabriel Mountains enters the area through numerous streams, principally the Arroyo Seco, Eaton Wash, and Santa Anita Wash. About one-third of the surface runoff is conveyed by the Arroyo Seco, the largest of the streams, which flows across the Monk Hill Subarea and the Pasadena Subarea, and joins the Los Angeles River by cutting through the San Rafael Hills. Outflow from the western portion of the Monk Hill Subarea reaches the Los Angeles River through the Verdugo Wash. The balance of the surface runoff primarily flows in

Eaton Wash and the Santa Anita Wash to the Rio Hondo and ultimately drains to the Los Angeles River.

The U.S. Geological Survey (USGS) maintains a surface water gaging station no. 11098000 and referred to as Arroyo Seco near Pasadena, CA (see Exhibit 13). Table 2 provides the mean monthly flow, measured by the USGS gage at the Arroyo Seco site.

Source: Derived from USGS, 2018.

The majority of the runoff occurs between December and May with the remainder of the period with average monthly flows generally less than 5 cubic feet per second (cfs). The maximum flow measured with the USGS gage, for the period of record (1911 through 2017), was 8,620 cfs (on March 2, 1938) (USGS, 2018). While the largest responses to flow generally occur from precipitation events, the stream maintains flows during non-rainfall periods indicating that it derives some of its flow from springs, groundwater inflow and other sources, such as storm drain outlets.

A comparison was made for an average precipitation period (see Precipitation section) with the daily mean streamflow for USGS station 11098000, Arroyo Seco near Pasadena, CA and presented in Exhibit 15. The comparison indicates the Arroyo Seco quickly responds to precipitation events in excess of 0.5 inches per day which occur between mid-October through February. By mid-March, the stream goes into a baseflow condition declining from 10-20 cfs to

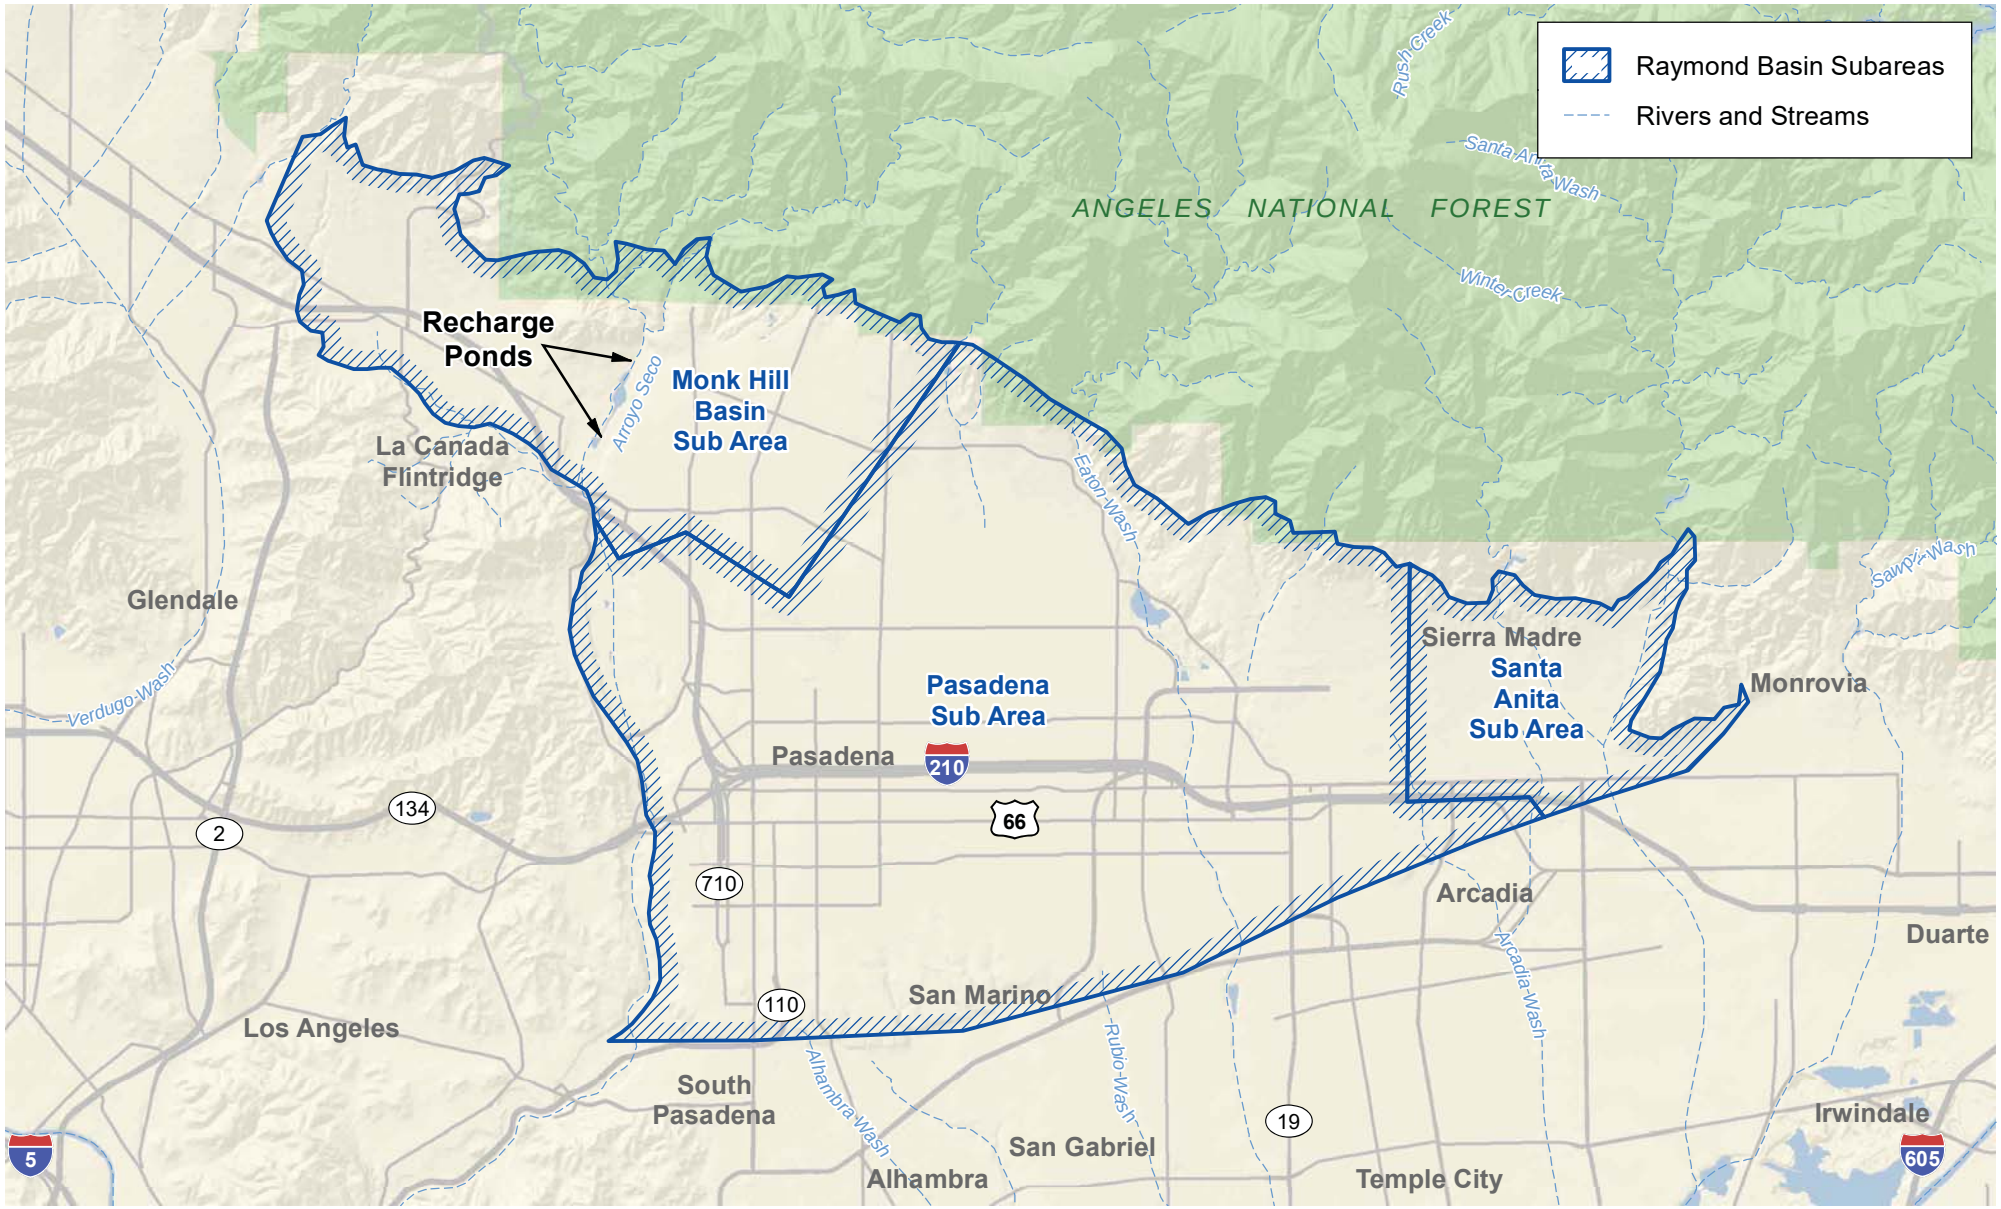
approximately 1 cfs in late summer. This is probably related to the delayed discharge from the fractured bedrock groundwater discharging to the shallow alluvium found in the mountainous portion of Arroyo Seco.

10.3.3 Groundwater

The Raymond Basin is a structural basin filled with permeable alluvial deposits, which is underlain and surrounded by relatively impermeable rock. The Basin aquifer is stratified in some areas by confining or semi-confining layers consisting of impermeable or less-permeable materials such as clay or silt. In these areas, the Basin aquifer is an aquifer system that may include an unconfined or water-table aquifer overlying individual confined or artesian aquifers separated by semi-confining or confining layers. In general, the Basin aquifer is classified as an unconfined to semi-confined aquifer system because the semi-confining or confining layers are not continuous across the Basin (RBMB, 2016).

The base of the water bearing zones is considered bedrock with elevations ranging from approximately 500 feet below sea level to 2,000 feet above mean sea level. The Raymond Basin is divided into three separate hydrologic sub-areas: the Pasadena Subarea, the Santa Anita Subarea, and the Monk Hill Subarea (MHSA) (see Exhibit 16, Groundwater Subareas within the Raymond Groundwater Basin). The diversion point lies just outside of the MHSA while the spreading grounds lie just inside the eastern edge of the MHSA adjacent to the City of Pasadena production wells. Downgradient of the MHSA, groundwater elevations range from 500 to 900 feet above mean sea level (msl) and have a southern flow direction, which then curves to the southeast in the southern part of the basin. The direction of groundwater flow within the basin varies depending on the subarea. Estimates of regional hydraulic gradient range between 40 and 200 feet per mile (0.008- to 0.04-foot/foot) (RBMB, 1985). The total storage capacity of the Raymond Basin is estimated to be approximately 1.37 million acre feet (maf). The amount of water in storage in 2003 was approximately 800,000 af with an unused storage space of about 570,000 (RBMB, 2016).

The Raymond Groundwater Basin is an adjudicated groundwater basin managed by Raymond Basin Management Board. The adjudication (originally completed in 1944 and amended over the years) determined who had a right to extract water and the maximum annual amount of water allowed to be pumped by each producer. This “safe yield” concept allows an annual fixed amount of water to be used by the 16 water producers served by the Raymond Basin (RBMB, 2016 and 2018).



Groundwater Levels and Flow

Groundwater levels in the Raymond Basin range from about 350 feet above Mean Sea Level (MSL) in Santa Anita Subarea to more than 1,050 feet above MSL in the MHSA. Groundwater generally flows southeast from the MHSA in the northwest to the Raymond fault in the southeast (RBMB, 2016).

Monk Hill Subarea

Groundwater levels in the MHSA have fluctuated, but remained relatively stable since 2000 (RBMB, 2016). In general, groundwater flows from the MHSA into the Pasadena subarea (RBMB, 2016).

NASA (2003) reported that the water table elevation varies significantly over the JPL site, which is located immediately west of Arroyo Seco, by as much as 130 feet. The groundwater elevation high point was measured in MW-1, located at the mouth of the Arroyo Seco. The significant

change in average hydraulic head between the monitoring wells located near the mouth of the Arroyo Seco and the monitoring wells to the southwest and west of the mouth of the Arroyo Seco. The change in flow regime across this area, significant difference in water levels over the relatively short distance, and lack of response of water levels near the mouth of the Arroyo Seco to pumping suggests the presence of either a very low conductivity area within the mouth of the Arroyo Seco or a hydraulic barrier that affects groundwater flow from this area (NASA, 2003).

Subsurface Flow

CDWR (1966) addresses subsurface inflow from the Raymond Basin into the Main Basin and states in part "…*Underflow into San Gabriel Valley across the Raymond fault varied from 2,000 to 12,000 acre-feet per year during the base period [from 1943-44 to 1959-60]. This subsurface flow did not occur at the same rate along the length of the fault, but varied from west to east. The lowest rates occurred near the western edge of the basin where the Raymond fault constitutes a nearly impervious barrier to groundwater movement, and the highest rates occurred near Santa Anita where the barrier effect is negligible. Estimates of underflow across the Raymond fault were based on values of groundwater gradients between water levels north of the fault."*

Monk Hill Subarea

Subsurface inflow from the Verdugo Basin into the MHSA has ranged from 890 acre-feet to 3,990 acre-feet over the period from 1994-95 to 2011-12. The long-term (31-year) average annual subsurface inflow has been 2,270 acre-feet. Subsurface outflow from the MHSA into the Pasadena Subarea has ranged from 5,750 acre-feet to 7,270 acre-feet over the period 1994-95 through 2011-12. The mean subsurface outflow to the Pasadena Subarea was 6,700 acre-feet (RBMB, 2016).

Groundwater Recharge

Monk Hill Subarea

Artificial recharge of the MHSA historically has occurred as a result of infiltration of stormwater runoff and, to a lesser degree, injection of treated imported water. Artificial recharge (through the spreading grounds) has ranged from 450 acre-feet to 9,700 acre-feet during the period of 1994-95 through 2011-12. Injection of treated imported water has ranged from zero acre-feet to 1,480 acre-feet during the period of 1994-95 through 2011-12. Average combined annual recharge from artificial recharge and injection has been 3,400 acre-feet (RBMB, 2016).

Accordingly, the diversion of water from Arroyo Seco north of the MHSA into the spreading grounds that are located inside of the MHSA has caused a mounding effect in the groundwater table in the MHSA (NASA, 2003).

10.4 GROUNDWATER CONCLUSIONS

Both surface water of Arroyo Seco and groundwater in the underlying alluvium of Arroyo Seco drainage north of the MHSA eventually discharge into the Monk Hill Subarea. The diversion of water upgradient of the MHSA from Arroyo Seco and placement into the Arroyo Seco spreading grounds (in the MHSA) adjacent to the existing Pasadena production wells is essentially assisting in the enhancement of groundwater replenishment and management of the Raymond Basin which is consistent with the requirements of the adjudicated Raymond Groundwater Basin. **As a result, it is unlikely that groundwater levels within close proximity of riparian resources would have any measurable effect on rootzones because of the relative depth of the groundwater.**

INTRODUCTION

The Los Angeles 30’ x 60’ quadrangle covers approximately 5,000 km^2 including much of the densely populated urban and suburban areas of the southern California megalopolis. The quadrangle is about 90 km east-west and about 55 km north-south, extending from Fillmore and Thousand Oaks in the west to Acton in the northeast and Montebello in the southeast. It covers the urban San Gabriel Valley and San Gabriel Mountain foothill communities from Monrovia to Pasadena, as well as Glendale, downtown Los Angeles, Hollywood, Santa Monica, Malibu, and all the communities in the San Fernando Valley, Simi Valley, and the upper Santa Clara River Valley. Population of these urban and suburban areas, as listed in the 2000 Census, totals approximately 5.6 million, and property value is estimated to total hundreds of billions of dollars. The quadrangle also includes large areas of wilderness in the Angeles and Los Padres National Forests, the Santa Monica Mountains National Recreation Area, and the Sespe Condor Sanctuary. The relief in the quadrangle ranges from about a hundred meters subsea (in Santa Monica Bay) to more than 2,000 meters above sea level at Pacifico Mountain in the high San Gabriel Mountains. Residents and visitors are subject to potential hazards from earthquakes, debris flows and other landslides, floods, wildfires, subsidence from ground water and petroleum withdrawal, and swelling soils; and coastal areas are exposed to flooding and erosion by storm and tsunami waves. This geologic map is intended to illustrate the distribution of the rocks and surficial deposits of the area and their structural and stratigraphic relations to one another. It provides a regional geologic framework as an aid to better evaluations of the potential for hazard from active earth processes. As a digital product it includes some areas mapped in greater detail than others; however, it is not sufficiently detailed to serve as a basis for site-specific evaluations.

SOURCES OF GEOLOGIC MAPPING

The map has been compiled from many scientific studies in different parts of the quadrangle, and represents the work of many geologists. Compilation of the Los Angeles 30’ x 60’ quadrangle was completed by Yerkes and Campbell (2005) and published by the U.S. Geological Survey. That map, which can be considered version 1.0 of the digital geologic map of the Los Angeles 30’ x 60’ quadrangle, involved digitization of original field mapping, and digitization and assembly of numerous published and unpublished source geologic maps. This effort, led by Robert Yerkes between 1985 and completion of the map in 2005, provides a foundation for the additions and further refinement presented here.

This map, version 2.0 of the digital geologic map of the Los Angeles 30’ x 60’ quadrangle, represents an update of the map by Yerkes and Campbell with extensive revisions and additions. Many of these revisions and additions resulted from studies by the California Geological Survey to define Seismic Hazard Zones, where development must consider the potential hazards from liquefaction and earthquake-induced landslides. The listing of sources of geologic mapping below includes geologic maps that were used by Yerkes and Campbell (2005), additional geologic maps included in this compilation, and reports describing the liquefaction zoning and earthquake-induced landslide zoning for each quadrangle. Although the Seismic Hazard Zone Reports referenced below are focused on the details of delineation of the hazard zones, virtually all reports resulted in revised mapping of some geologic units. Revised mapping of younger Quaternary units, including the contact between late Quaternary alluvium and

bedrock, was a focus of the seismic hazard zoning effort because these contacts can define the boundaries of Liquefaction Hazard Zones. New mapping of Quaternary units was generally based on geomorphic expression, supplemented by descriptions of the subsurface materials in numerous boreholes from throughout the valley areas (Wills and Hitchcock, 1999, Hitchcock and others, 1999). Quaternary units are designated using the terminology of Matti and Cossette (2007).

The process of creating earthquake-induced landslide zoning resulted in compilation of bedrock units that in some cases differed from the compilation of Yerkes and Campbell (2005). This effort also included re-mapping of landslides for the region, except for areas within National Forests. In preparing this compilation, we have used the compilations from the Seismic Hazard Zonation Program, reconciled those with the source maps used by Yerkes and Campbell (2005), added additional detail based on source maps not used by either the Seismic Hazard Zonation Program or Yerkes and Campbell (2005) and added selected landslides mapped by the Seismic Hazard Zonation Program. Due to the scale of this map, most small landslides and all landslides considered "questionable" in the original landslide inventories are not shown. CGS landslide inventory maps, and related 1:24,000-scale maps, show a more complete depiction of landslides. Landslides that are too small to show on 1:24,000-scale maps can be hazardous and damaging, so no regional map should be used to evaluate the landslide hazard to a particular location or parcel.

In addition to revisions to geologic contacts based on the Seismic Hazard Zonation Program, this map includes extensive revisions to the crystalline bedrock of the San Gabriel Mountains. Yerkes and Campbell (2005) completed a generalized compilation of the San Gabriel Mountains. In their compilation, they modified the nomenclature of the basement rock units to conform with the IUGA Subcommission on Systematics of Igneous Rocks (Streckheisen, 1973), and to provide continuity with the compilation in the San Bernardino 30' x 60' quadrangle (Morton and Miller, 2003), which adjoins the Los Angeles 30' x 60' quadrangle on the east. They did not, however, attempt to reconcile the various more detailed maps of this area. For this compilation, we have attempted to use as much detailed original mapping as possible and describe the units in as much detail as possible. Where the detailed mapping and unit descriptions are from a single source, such as within the anorthosite complex described by Carter (1980, 1982), this map represents a complete, consistent interpretation. In other areas, detailed mapping and description of map units are lacking or are provided by different authors who had differing interpretations. In some cases, we have extended units described by one author based on contacts by another. Although the resulting compilation is more detailed than that by Yerkes and Campbell (2005), there are significant areas where map unit boundaries, descriptions, and correlations could be improved by new mapping.

In addition to the major updates noted above, CGS has updated numerous other local areas based on map sources not used in the map by Yerkes and Campbell (2005). These more local updates include new mapping of parts of the active Hollywood, San Cayetano, and Simi Faults, updates to mapping and stratigraphy of the Plio-Pleistocene sedimentary rocks of the Ventura basin (see Appendix A), and updates to the Tertiary units in the Soledad basin.

The major sources of mapping are listed below by the 7.5-minute quadrangles shown in Figure 1. Sources are underlined if they are a major source of geologic unit boundaries shown on this compilation, and in italics if they were not used in the compilation by Yerkes and Campbell (2005). Seismic Hazard

Zone (SHZ) Reports for each quadrangle are also listed, along with landslide inventory maps that resulted from the Seismic Hazard Zonation Program, which are published as part of the CGS Landslide Inventory Map Series (LSIM).

THE TRANSVERSE RANGES AND THE SAN ANDREAS FAULT

Nearly all of the Los Angeles quadrangle lies within the south-central part of the Transverse Ranges geomorphic province, a band of west-trending mountain ranges and valleys, varying from 50 km to 130 km in width that extends about 400 km from Point Arguello on the west to the eastern San Bernardino Mountains on the east (Fig. 2). The east-west grain of the Transverse Ranges Province presents a stark and abrupt interruption of the general northwesterly trends of the Peninsular Ranges Province (including the California Continental Borderland) to the south and the northwesterly to northerly grain of the California Coast Ranges, the Great Valley, the Sierra Nevada, and the Mojave Provinces to the north. The southeastern corner of the Los Angeles quadrangle includes the northern part of the Los Angeles basin, which lies at the northern end of the Peninsular Ranges Province. The northwestern quarter of the Los Angeles quadrangle includes the eastern part of the Ventura basin and its southeastern extension, the San Fernando basin. These basins were the sites of very thick accumulations of marine sediments in the late Miocene and Pliocene. The southern boundary of Transverse Range structures is commonly placed at the Anacapa-Santa Monica-Hollywood-Raymond-Cucamonga zone of interconnected north-dipping thrust faults. West of Santa Monica, the southern limit of Transverse Range structures is the offshore Anacapa Fault, which lies a few kilometers south of the southern boundary of the quadrangle. Northwesterly trending faults in the Peninsular Ranges Province, such as the Newport-Inglewood zone, the Elsinore-Whittier Fault, and several faults in the offshore Continental Borderland, appear to be truncated by the east-west zone of interconnected faults, although the apparent step between the Hollywood and Santa Monica Fault zones along the projection of the Newport-Inglewood Fault suggests that the boundary has been modified locally.

The Transverse Ranges are a major anomaly embedded across the general grain of the North American Continent and, although middle Miocene and younger tectonism is responsible for much of the present rock distribution and physiographic relief, the distributions of different crystalline basement rocks, and their Cretaceous and Paleogene superjacent strata, suggest the influence of earlier tectonic episodes. The geologic history remains imperfectly understood, and many interpretations concerning specific aspects are actively disputed among earth scientists (e.g., Campbell and others, 1966; Dibblee and Ehrenspeck, 1993). The distinctive physiographic and structural characteristics of the provinces are superimposed on a preexisting framework of Proterozoic through early Cretaceous igneous and metamorphic basement rocks, which occur chiefly in fault-bounded blocks. This simple relationship has been modified in places so that rocks that are commonly associated with one province can be found in an adjacent province. For example, strata found south of the Malibu Coast Fault and west of the Newport-Inglewood zone of faulting and folding include probable Catalina Schist basement overlain by Miocene volcanics and Monterey facies sedimentary strata in a sequence best correlated with that of the Palos Verdes Peninsula-Santa Catalina Island area of the northern Peninsular Ranges. Although Catalina Island and the Palos Verdes Peninsula are dominated by northwesterly trending structures, and are included in the Peninsular Ranges Province, an east-trending band, bounded by the Malibu Coast Fault on the north and the offshore Anacapa-Santa Monica Fault, is characterized by east-trending folds and north-over-south thrust faults and, therefore, is included in the Transverse Ranges province. Some province-bounding faults take advantage of pre-existing structures in places, but not everywhere.

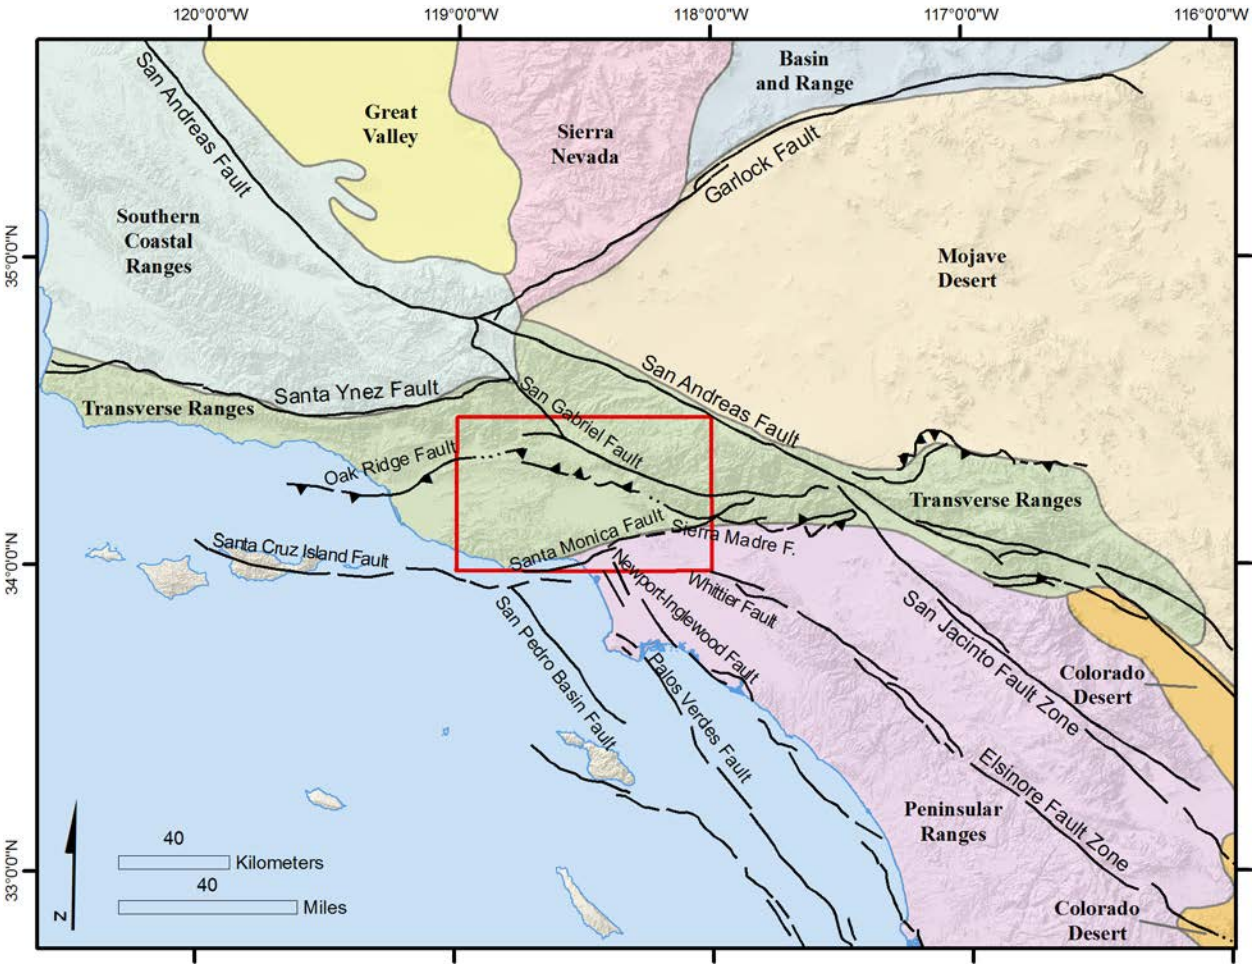

Figure 2. Area of the Los Angeles 30' x 60' quadrangle in reference to geomorphic provinces of southern California.

Major basement rock boundaries are not confined to the margins of the Transverse Ranges, but are also found within the province. For example, the northwest-trending Verdugo Fault separates the cratonic Precambrian to Cretaceous crystalline basement of the San Gabriel Mountains from the oceanic Jurassic metasedimentary basement of the Santa Monica Mountains. Similarly, the Raymond-Cucamonga segment of the southern frontal fault system of the Transverse Ranges approximates the boundary between the San Gabriel Mountains crystalline basement and the oceanic Jurassic basement in the Santa Ana Mountains (northern Peninsular Ranges). The Santa Monica Slate resembles similar Jurassic rocks in the Santa Ana Mountains. Although Jones and others (1976) note that sparse Jurassic fossils from the Santa Monica Mountains are younger than Jurassic fossils from the Santa Ana Mountains, both sections are very thick and represent millions of years of accumulation of pelitic sediment in abyssal to bathyal environments, and they are probably broadly correlative. This relatively simple pattern is further complicated by evidence that the cratonic rocks of the San Gabriel Mountains have been thrust over the Pelona Schist, for which the protolith is inferred to be Jurassic oceanic crust (Ehlig, 1981).

Many workers have attempted to reconstruct the rock distribution in the region as it was before the middle Miocene beginning of major structural deformation (e.g., Campbell and Yerkes, 1976; Crouch, 1979; Hornafius and others, 1986; Powell, 1993; Wright, 1991; Yeats, 2004) using recognized

translations and rotations of fault-bounded blocks. The paleomagnetic evidence that the western Transverse Ranges were rotated approximately 60 degrees clockwise in Miocene time (Kamerling and Luyendyk, 1979) should be kept in mind with regard to descriptions of pre-Pliocene sedimentary and structural trends. For example, northeasterly-trending faults that are truncated by the base of the Modelo and older units have been rotated from initial northwesterly orientations after their last movements. Similarly, north-trending shorelines and pinch-outs in Paleogene and Miocene strata (Yerkes and Campbell, 1976) have been rotated from westerly trends (McCulloh and others, 2002; McCulloh and Beyer, 2004). It seems logical that reconstruction should result in an unbroken western margin for the North American Continent that connects the rocks and structure to the north with those to the south of the Transverse Ranges. However, the pre-middle Miocene positions of individual fault blocks have not been comprehensively established. Partial reconstructions using extensive subsurface data, precise age dating, and well-established minimum fault movements and rotations have demonstrated the difficulty in accurately modeling the early Miocene margin of the North American continent (McCulloh and Beyer, 2004).

The San Andreas Fault crosses the Transverse Ranges Province with an east-southeasterly trend, in sharp contrast to its northwesterly trends to the north, in central California, and to the south, along the east side of the Salton Sea and the Imperial Valley. From Tejon Pass to Wrightwood, the San Andreas approximates the northern boundary of the Transverse Ranges (San Gabriel Mountains), and a short segment of the fault crosses the extreme northeastern corner of the Los Angeles quadrangle. Farther east it separates the San Gabriel Mountains from the San Bernardino Mountains, emerging from the south side of Cajon Pass to mark (approximately) the southern boundary of the Transverse Ranges (San Bernardino Mountains), and continues on that trend for another 45 km (approximately) southeasterly to the vicinity of North Palm Springs.

The presently recognized trace of the San Andreas Fault was probably not a single continuous fault before the end of the (Miocene-Pleistocene) tectonism that resulted in the modern Transverse Ranges Province. Some segments that are now connected show displacements that probably predate the late Miocene. The San Gabriel Fault probably was a major strand of the San Andreas in late Miocene through early Pliocene time that is now much less active (Crowell, 1952). The modern through-going San Andreas Fault consists of connected segments of varying ages and tectonic origins, and may be linked by fault segments that did not exist before the opening of the Gulf of California in the late Pliocene. Although the San Andreas Fault is seen only in the extreme northeast corner of the Los Angeles quadrangle, it is an important component of the geologic structure in the quadrangle, and is probably the principal control for the north-south compressive stress field presently imposed on the central Transverse Ranges. The ongoing deformation and associated earthquakes (Working Group on California Earthquake Probabilities, 2008) are generally considered to be the result of the northwest-trending right-lateral movement of the North American Plate relative to the Pacific Plate as constrained in upper crustal rocks by the geometry of the modern San Andreas Fault.

GEOLOGIC UNITS IN DEPOSITIONAL BASINS AND STRUCTURAL BLOCKS

The geologic map units are divided into several columns in the explanation and brief description of map units on the map sheet, reflecting different sequences of units in different depositional basins. The

units are arranged in a single sequence in the “Description of Map Units” below. The designations of different units in different areas is partly semantic; that is, different authors may have used different names for correlative strata in different parts of the quadrangle; or have used the same names for map units that may be only partly correlative. However, real differences in lithologic character are also represented by the use of different names for strata of correlative ages. We have not been able to identify all the map unit names that should be extended and those that should be restricted. However, it seems clear that the present distribution of rock units is the result of the convergence of tectonic elements of diverse geologic histories. The subdivision of the unit abbreviations and brief descriptions into different columns on the map sheet is our attempt to illustrate the spatial diversity as objectively as possible, while retaining the stratigraphic elements shared in common.

Rocks of the Transverse Ranges Province are subdivided into geographic areas where similar rock sequences are exposed, these geographic areas reflect, at least in part, fault-bounded structural blocks: (1) Topatopa Mountains and the eastern Santa Ynez Range, (2) Oak Ridge, Santa Susana Mountains, Simi Hills, and Santa Monica Mountains, (3) Castaic Valley-Soledad Canyon and western San Gabriel Mountains (Figure 3). The rocks of the northern Peninsular Ranges Province are described in a frame of two middle Miocene and older structural blocks: (1) eastern Los Angeles basin, and (2) western Los Angeles basin. Within the Oak Ridge, Santa Susana Mountains, Simi Hills, Santa Monica Mountains block, middle Miocene and older strata are described separately for the Santa Susana Mountains-Simi Hills area and the central and western Santa Monica Mountains, chiefly because of large changes in thickness of the Conejo Volcanics and nomenclatural differences that represent relatively minor facies changes in the middle Miocene and older rocks. In the central Santa Monica Mountains, the strata in the upper plate of the Malibu Bowl Detachment Fault include a number of tongues of the Conejo Volcanics that have not been specifically correlated with the lithologic subdivisions of that unit in the lower plate. The eastern and western Los Angeles basin blocks correspond to the Northwestern and Central structural blocks of Yerkes and others (1965).

The bedrock units of the area are commonly described in two principal groups: 1) Basement rocks – early Cretaceous and older, crystalline metamorphic and igneous rocks; and 2) The superjacent sequence of late Cretaceous and Tertiary strata. The greatest contrast in basement character is at the boundaries of the San Gabriel Mountains-Soledad basin block. The San Gabriel Mountains form a basement massif that includes components of Proterozoic, Paleozoic, and pre-middle-Cretaceous Mesozoic metamorphic and plutonic rocks. These are the oldest basement rocks in the Los Angeles quadrangle and appear to represent old continental crust at the western margin of the North American craton that has been thrust over Jurassic oceanic crust of a different metamorphic facies than is found in adjacent blocks. In the eastern Los Angeles basin, to the south of the San Gabriel Mountains, and in the Santa Monica Mountains, to the west of the San Gabriel Mountains, the basement rocks are metasedimentary and metavolcanic rocks of Jurassic age that were probably deposited on a Jurassic oceanic crust and accreted to the margin of the North American craton. They have been intruded by early Cretaceous granitic bodies of the same age as similar rocks in the San Gabriel Mountains, but the relationship between these granite bodies is not clear. The basement rocks of the western Los Angeles basin also are associated with a Jurassic oceanic crust; however, their metamorphic character is significantly different, including blueschist facies schists that represent metamorphism in a subduction zone. The basement in the Topatopa Mountains block is unknown, but in the Santa Ynez Mountains, a

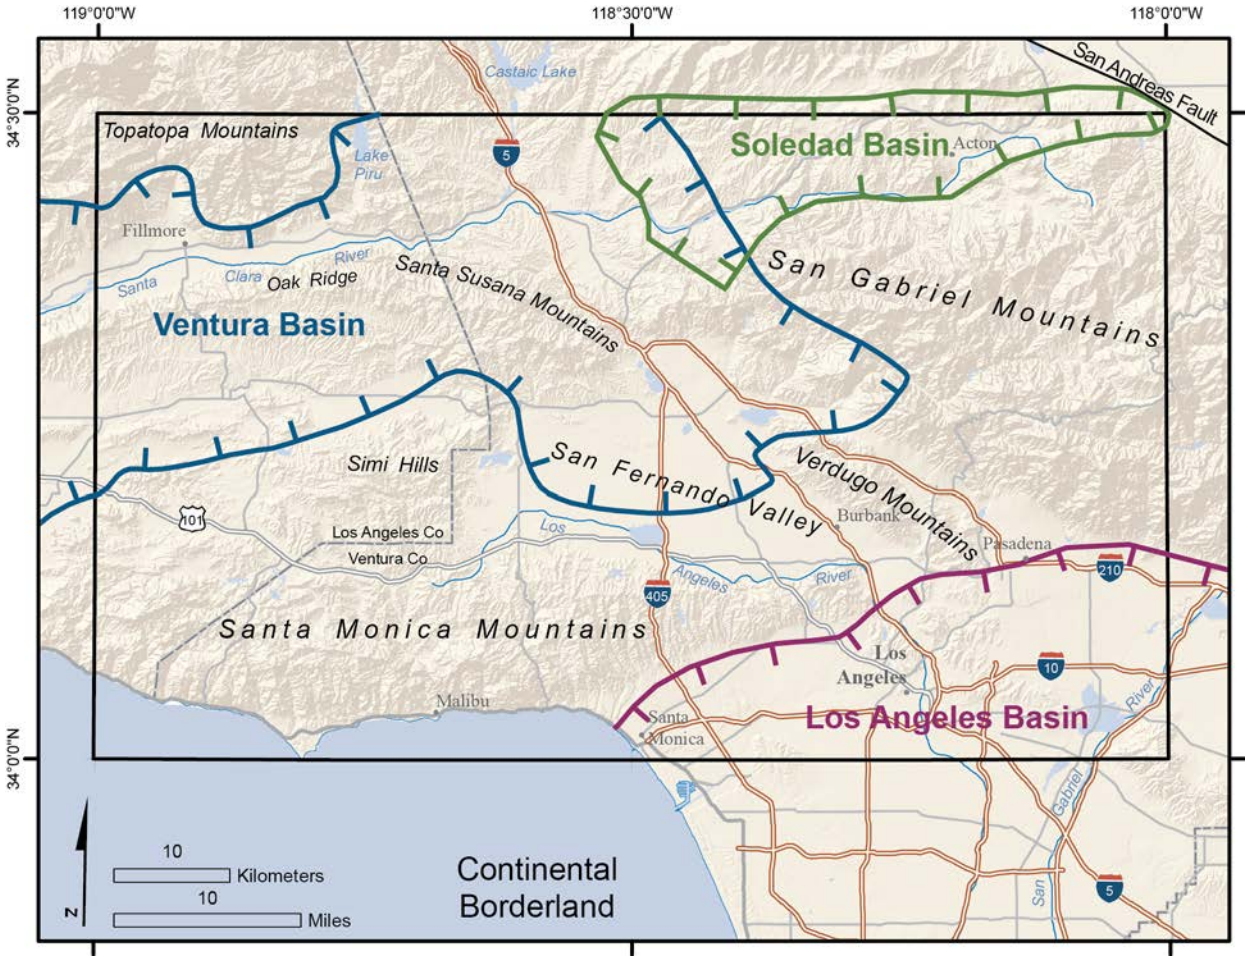

Figure 3. Principal late Tertiary to Quaternary depositional basins and upland areas where bedrock units are exposed within the Los Angeles 30'x60' quadrangle. The Soledad basin is represented by Miocene strata, which are truncated to the southwest by the San Gabriel Fault and subsequently overlapped by Pleistocene deposits of the Ventura basin; the Ventura and Los Angeles basin boundaries represent the limits of associated Pliocene and Pleistocene formations.

few miles to the west, the basement is Franciscan Formation, including schists very much like those of the western Los Angeles basin basement rocks.

The superjacent sequence consists of Upper Cretaceous and Tertiary sedimentary and volcanic strata that rest unconformably on the crystalline basement. The regional unconformity at the base of the Upper Cretaceous is expressed only in the central Santa Monica Mountains, where the Trabuco Formation overlies basement rocks. Another regional unconformity, at the base of the Paleogene section, can be seen in the western Santa Monica Mountains and the Simi Hills where the Simi Conglomerate overlies the Upper Cretaceous sequence. The middle Miocene disruption of the pre-middle Miocene sequence and the formation of more localized basins is expressed by more restricted unconformities at the bases of late-middle Miocene and younger strata and extreme variations in thickness of late Miocene and younger units.

DESCRIPTION OF MAP UNITS

The arrangement of map unit descriptions on the map sheet illustrates the correlation of map units among different depositional basins. The map area straddles two major physiographic provinces, the Transverse Ranges and the Peninsular Ranges, and the southwest margin includes rocks commonly associated with the Southern California Borderland. The modern provinces are largely the products of Neogene tectonics, volcanism, and sedimentation, but each province contains fault-bounded blocks of Paleogene and older rocks that correlate over a larger area.

Similarities and differences among rock units are incompletely reflected in the nomenclature and labeling of the rock units, which evolved from many geologic investigations over the past century. The majority of the units on this map have been adopted from the source maps used in compilation. Named Formations of sedimentary strata are made up of multiple episodes of individual depositional events and each event need not be distributed over exactly the same area. This can lead to significant differences in the age range of a rock stratigraphic unit from one area to another.

Map labels are abbreviations that indicate age and origin of surficial deposits, or age and formally recognized names of formations and members. Where stratigraphic assignment is tentative, a query (?) is added to the label in the database. Where informal subunits are represented by subscripted numbers, numbers increase with decreasing age (i.e., of subunits 1-4, 4 is the youngest and 1 is the oldest). Quaternary deposits are found in all provinces and subareas; however they are relatively local in extent, and deposits are commonly associated with distinctive geomorphic features such as fans, flood plains and terraces. For a complete listing of geologic units and the 7.5’ quadrangles on which they occur, refer to Appendix B.

af **Artificial fill (late Holocene)—**Deposits of sand silt and gravel resulting from human construction, mining or quarrying activities; includes compacted engineered and noncompacted nonengineered fill. Only large deposits are shown. Fills emplaced after source maps were completed are generally not shown.

Qa **Alluvium (late Holocene)**—Unconsolidated gravel, sand and silt in active or recently active floodplains, locally including related alluvial fans and streambeds where those are not mapped separately; chiefly stream deposited, but includes some debris-flow deposits. Locally corresponds with or encompasses areas of historic flooding, including deposits behind flood-control structures.

Qw **Wash deposits (late Holocene)**—Unconsolidated gravel, sand and silt in active or recently active streambeds; chiefly stream deposited, but includes some debris-flow deposits; episodes of bank-full stream flow are frequent enough to inhibit growth of vegetation.

Qb **Beach deposits (late Holocene)**—Loose fine- and medium-grained sand of active beaches chiefly between elevations of lower-low water and storm strands).

Qe **Eolian deposits (late Holocene)**—Loose, fine- to medium- grained sand, silty sand and silt; forms transitory dunes against beach-facing cliff.

Qf **Alluvial fan (Holocene)**—Unconsolidated bouldery, cobbly, gravelly, sandy, or silty alluvial deposits on active and recently active alluvial fans and in some connected headward channel segments.

Qls **Landslide deposits (Holocene and late Pleistocene?)**—Only selected landslide deposits shown on this map as described below. Deposits represent rock detritus from bedrock and surficial materials, broken in varying degrees from relatively coherent large blocks to disaggregated small fragments, deposited by landslide processes. Most deposits are Holocene, some dissected landslides may be as old as late Pleistocene. Landslide deposits shown on this map were compiled primarily from landslide inventories prepared by CGS for the Seismic Hazard Zonation Program. For this map, only landslides described as definite or probable and larger than 50,000 square meters are shown to preserve the clarity of the underlying bedrock geology. Selected historically active landslides between 10,000 and 50,000 square meters are shown, but no landslides smaller than 10,000 square meters are shown on this map. Exceptions to these rules include small or questionable landslides surrounded by larger probable or definite landslides.

Qya **Young alluvium, undivided (Holocene and late Pleistocene)**—Unconsolidated, generally friable, stream-deposited silt, sand and gravel on flood plains, locally including related alluvial fans and streambeds where those are not mapped separately. Deposits are clearly related to depositional processes that are still on-going. Subunits are distinguished by relative ages based on geomorphic relationships, relative degree of surface dissection and soil formation. Includes:

Qya_4 **Young alluvium, Unit 4 (Holocene)**—Youngest of as many as 4 subunits of Qya that can be distinguished in some areas.

Qya_3 **Young alluvium, Unit 3 (Holocene and late Pleistocene)**—Older young alluvium, older than Unit 4, younger than Unit 2.

Qya_2 **Young alluvium, Unit 2 (late Pleistocene)**—Older young alluvium, older than Unit 3, younger than Unit 1.

Qya_1 **Young alluvium, Unit 1 (late Pleistocene)**—Oldest young alluvium.

Qyf **Young fan deposits, undivided (Holocene and late Pleistocene)**—Unconsolidated gravel, sand and silt, bouldery along mountain fronts; deposited chiefly from flooding streams and debris flows. Deposits are clearly related to depositional processes that are still on-going. Subunits are distinguished by relative ages based on geomorphic relationships, relative degree of surface dissection and soil formation. Includes:

Qyf_5 **Young alluvial-fan deposits, Unit 5 (Holocene)**—Youngest of four subunits of Qyf that can be distinguished in some areas. Designated Qyf_5 because of continuity with young alluvial fan designated Qyf_5 on map of San Bernardino 30’x60’ quadrangle to east.

Qyf_3 **Young alluvial-fan deposits, Unit 3 (Holocene to late Pleistocene)**—Young fan deposits, older than Unit 5, younger than Unit 2.

Qyf_2 **Young alluvial-fan deposits, Unit 2 (Holocene to late Pleistocene)**—Older young fan deposits, older than Unit 3, younger than Unit 1.

Qyf_1 **Young alluvial-fan deposits, Unit 1 (Holocene to late Pleistocene)**—Oldest of as many as four subunits of Qyf that can be distinguished in some areas.

Qoa **Old alluvium undivided (late to middle Pleistocene)**—Unconsolidated to moderately indurated gravel, sand and silt deposited on flood plains, locally including related alluvial fans and streambeds where those are not mapped separately. Deposits have been uplifted or otherwise removed from the locus of recent sedimentation. Surfaces may be dissected in varying degrees; and can show moderately to well-developed pedogenic soils. Subunits are distinguished by relative ages based on geomorphic relationships, relative degree of surface dissection and soil formation. Includes:

Qoa_3 **Old alluvium, Unit 3 (late Pleistocene)**—Youngest of as many as three subunits of Qoa that can be distinguished in some areas.

Qoa_2 **Old alluvium, Unit 2 (late Pleistocene)**—Intermediate of as many as three subunits of Qoa that can be distinguished in some areas.

Qoa_1 **Old alluvium, Unit 1 (middle Pleistocene)**—Oldest of as many as three subunits of Qoa that can be distinguished in some areas.

Qof **Old fan deposits, undivided (late to middle Pleistocene)**—Slightly to moderately consolidated silt, sand and gravel deposits on alluvial fans. Deposits have been uplifted or otherwise removed from the locus of recent sedimentation. Morphology of original alluvial fan surface usually well preserved, though dissected in varying degrees; surfaces can show moderately to well-developed pedogenic soils. Subunits are distinguished by relative ages based on geomorphic relationships, relative degree of surface dissection and soil formation. Includes:

Qof_4 **Old fan deposits, Unit 4 (late Pleistocene)**—Youngest of as many as four subunits of Qof that can be distinguished in some areas.

Qof_3 **Old fan deposits, Unit 3 (late Pleistocene)**—Intermediate subunit of Qof that can be distinguished in some areas, older than Qof_4 and younger than Qof_2.

Qof_2 **Old fan deposits, Unit 2 (late Pleistocene)**—Intermediate subunit of Qof that can be distinguished in some areas, older than Qof_3 and younger than Qof_1.

Qof_1 **Old fan deposits, Unit 1 (late Pleistocene)**—Oldest of at least four subunits of Qof that can be distinguished in some areas.

Qoft **Alluvial fan deposits on wave-cut surface (late Pleistocene to Holocene)**—Unconsolidated to moderately indurated, clay, silt, sand, and angular gravel including clasts to boulder size; chiefly debris-flow deposits, but probably includes some stream-deposited material; surfaces can show slight to moderate pedogenic soil development. Overlies elevated wave-planed bedrock and marine terrace deposits along the coast.

Qom **Old shallow marine deposits on wave-cut surface (late Pleistocene)**—Unconsolidated (but with small areas locally calcite-cemented) sand, silty sand and gravel; commonly overlies wave-cut bedrock surfaces at two or more altitudes above present sea level; surfaces can show slight to moderate pedogenic soil development; locally carries molluscan fauna referred to the late Pleistocene (Addicott, 1964).

Qoab **Old alluvium and breccia (late Pleistocene to Holocene)**—Deposit of angular shale chips and colluvium derived from Modelo Fm. Mapped adjacent to San Fernando Fault, age relationships with other alluvial units unknown.

Qob **Old breccia, (late Pleistocene to Holocene)**—Fine to coarse sand with well-rounded pebble gravel and shale chips and colluvium derived from Modelo Fm. Mapped adjacent to San Fernando Fault, age relationships with other alluvial units unknown.

Qvoa **Very old alluvium, undivided (middle to early Pleistocene)**—Slightly to moderately consolidated silt, sand and gravel deposits. Deposits have been uplifted or otherwise removed from the locus of recent sedimentation. Environment of deposition may include axial valley, floodplain or alluvial fan, but morphology of original deposit may not be preserved. Surfaces may be significantly dissected and show well-developed pedogenic soils. Subunits are distinguished by relative ages based on geomorphic relationships, relative degree of surface dissection and soil formation.

$Qvoa_2$ **Very old alluvium, (middle to early Pleistocene)**—Younger subunit of Qvoa that can be distinguished in some areas.

$Qvoa_1$ **Very old alluvium, (middle to early Pleistocene)**—Older subunit of Qvoa that can be distinguished in some areas.

Qvof **Very old alluvial-fan deposits (middle to early Pleistocene)**—Slightly to moderately consolidated silt, sand and gravel deposits on alluvial fans. Deposits have been uplifted or otherwise removed from the locus of recent sedimentation. Morphology of original alluvial fan surface preserved to some extent. Surfaces may be significantly dissected and show well-developed pedogenic soils. Subunits are distinguished by relative ages based on geomorphic relationships, relative degree of surface dissection and soil formation.

$Qvof_2$ **Old alluvial-fan deposits, Unit 3 (late Pleistocene)**—Subunit of Qvof with distinct alluvial fan morphology, overlies and is therefore younger than $Qvoa_1$.

Qpa **Pacoima Formation (middle Pleistocene)**—Fanglomerate or sedimentary breccia with a dark-brown to reddish-brown clayey sand matrix; weakly indurated; crudely bedded; poorly sorted with angular, pebble- to boulder-size clasts composed primarily of crystalline rock locally derived from the San Gabriel Mountains, as described in the type area at the mouth of Pacoima Canyon. The Pacoima Formation exposed in the Mint Canyon quadrangle contains more rounded clasts than the type area and the color varies to light yellowish brown; farther west in the Newhall quadrangle the overall clast size decreases and clast composition varies as a result of facies changes associated with greater distance from the San Gabriel Mountain source area and influx of sedimentary clasts shed from the uplifting Santa Susana Mountains to the south (Treiman and Saul, 1986). The Pacoima Formation is an unconformity bounded unit deposited in the eastern Ventura basin that is typically gently inclined; distinguished from the underlying Saugus Formation by poorer bedding and sorting, clast angularity, and angular discordance in most areas; distinguished from younger terrace deposits and overlying older alluvium primarily by degree of erosion and weathering, and the occurrence of locally intense folding and faulting.

The maximum thickness is about 500 to 1,000 ft. (152 to 305 m). The Pacoima Formation was initially described by Oakeshott (1952) and subsequently mapped by Oakeshott (1958) and Barrows and others (1974) in the northern San Fernando Valley and south of the San Gabriel Fault in the eastern Santa Clarita Valley area. Saul (1979, 1990) and Saul and Wootton (1983) followed this usage in mapping of the Mint Canyon quadrangle, and Treiman (1986, 1987a) extended the formation into the Newhall quadrangle in place of older alluvial deposits mapped by Kew (1924) and Winterer and Durham (1962). The Pacoima Formation is younger than about 0.4 Ma based on the estimated youngest age of the underlying Saugus Formation studied in the Santa Clarita Valley by Levi and others (1986) and Treiman and Saul (1986) estimated that deposition of the Pacoima Formation was essentially completed by about 0.3 Ma.

Eastern Ventura Basin, including San Fernando Basin

QTs/Qs **Saugus Formation, undivided (late? Pleistocene to late Pliocene)**—Weakly to moderately cemented, medium- to coarse-grained, light-gray to yellowish-gray sandstone and pebble conglomerate and light greenish-gray sandy siltstone deposited in the Ventura basin; moderately sorted; commonly cross bedded and channeled; interbedded with moderate-brown to reddish-brown poorly sorted sandy mudstone and local claystone seams in the type area and other portions of the eastern Ventura basin, reflecting overbank deposits and paleosols; fluvial near the basin axis, transitioning to alluvial fan environment near the basin margins; interfingers with shallow marine sands to the west. The Saugus Formation is chiefly nonmarine as defined by Hershey (1902b) and Winterer and Durham (1962), but mapping compiled herein may locally include shallow marine interbeds. Transitional to brackish water deposits at the base of the section observed in the eastern Ventura basin are assigned to the Sunshine Ranch Member. This formation has a gradational to interfingering conformable contact with underlying shallow marine strata of the Pico Formation near the axis of the Ventura basin, but the contact is time transgressive and is progressively younger to the west. Near the basin margins, the base is unconformable with the Pico Formation and locally overlaps older strata and basement rock. The upper contact shows distinct angular discordance with the overlying Pacoima Formation in most areas, but discordance is more subtle west of Valencia and middle Pleistocene deposition in this area may be nearly continuous. The thickness varies greatly across the Ventura basin; Kew (1924) reports a thickness of 2,000 ft. (610 m) but Winterer and Durham (1962) report that up to 12,000 ft. (3,660 m) of Saugus strata were encountered in a well southeast of San Fernando Pass; a thickness of 2,000 m is reported in the western Ventura basin below the Santa Clara River, but DeVecchio and others (2012b) report a thickness of only 40 to 60 m in the Camarillo area near the southwest margin of the basin. In the eastern Ventura basin, the base of the Saugus is estimated at about 2.3 Ma west of Valencia and in the Mission Hills (Levi and Yeats, 1993) to about 2.6 Ma near Gold Canyon in the northern San Fernando Valley (Beyer and others, 2009). Unfossiliferous deltaic deposits mapped as Saugus in the Elsmere Canyon area by Dibblee (1991d, 1992c) and Squires (2012) may be significantly older based on their position below Sunshine Ranch strata and mapped interfingering relationships with older Pico and Towsley Formation strata. The top of the Saugus in the eastern Ventura basin is estimated at about 0.5 Ma by Levi and Yeats (1993) and is younger to the west. North

of Ventura, Lajoie and others (1982) report an age of 0.2 Ma in marine sands underlying the Saugus and an age of 85 ka in overlying marine terrace deposits. In the Moorpark area, Wagner and others (2007) report an age of 780 to 850 ka at a Mammoth fossil site. In the Camarillo and Las Posas Hills area, DeVecchio and others (2012a, 2012b) report that Saugus strata overlie marine sands as young as about 125 ka and may be as young as 25 ka south of the Camarillo Hills based on OSL dating. Based on reported ages, Saugus strata west of Fillmore and west of the Tapo Canyon area are considered post-Pliocene in age and therefore mapped as Qs rather than QTs. Clasts within the Saugus Formation are typically plutonic, metamorphic and volcanic rocks, derived primarily from the San Gabriel Mountains, and transported westward by the ancestral Santa Clara River; however, distinctive clast assemblages have locally been recognized and mapped as informal members or facies by various workers. These include upper Saugus (QTsu); volcaniclastic breccia-conglomerate (Qsv) and Camarillo member (Qsc); additional facies are defined by Weber (1982) in the Santa Clarita area based on the presence or absence of San Francisquito Formation sandstone, Pelona Schist, or anorthosite clasts. The Saugus Formation was initially defined by Hershey (1902b) as the "Saugus division" for continental strata exposed in railroad cuts east of Bouquet Junction near Saugus (type area). These deposits were subsequently lumped into the Fernando Formation by Eldridge and Arnold (1907). Kew (1923, 1924) formally adopted the term Saugus Formation for the upper section of the Fernando Group and extended usage into the western Ventura basin. Kew generally followed Hershey's nonmarine definition except that he also included underlying coarse-grained shallow marine deposits within the Saugus Formation. The unit was redefined and remapped by Winterer and Durham (1962) in the eastern Ventura basin, who reassigned most of the shallow marine strata to the Pico Formation, conforming to Hershey's nonmarine definition of the Saugus. This nonmarine definition has been adopted by most workers in the eastern Ventura basin (e.g. Saul, 1975, 1979; Weber, 1982; Yeats and others, 1985; Saul and Wootton, 1983; Treiman, 1986, 1987a; Dibblee Foundation maps; Squires and others, 2006; Squires, 2012). Maps covering areas south and west of the area mapped by Winterer and Durham commonly include marine deposits as part of the Saugus based on Kew's definition (e.g. Weber and others, 1973; White, 1985; Squires and White, 1983; Groves, 1991). The restricted usage of Winterer and Durham (1962) in the type area is adopted herein and shallow marine strata formerly assigned to the Saugus Formation in the Santa Susana Mountains and Oak Ridge located east of, and down section of, the Grimes deltaic unit (QTpg) are reassigned as an upper informal member of the Pico Formation (QTpcu) (see Appendix A for details). Nonmarine strata of similar age are mapped as the La Habra Formation in the Los Angeles basin (Eckis, 1934), and as the Casitas Formation in the Santa Barbara basin (Upson, 1951). Mapped members include:

QTsu **Saugus Formation, upper member (middle Pleistocene)**—On the south flank of the Santa Susana Mountains this unit consists of nonmarine sandstone and conglomerate with clasts composed primarily of shale and sandstone derived from the Modelo and Towsley Formations (Oat Mountain 7.5' quadrangle); the most representative section is at Horse Flats. This clast assemblage is interpreted to represent uplift, emergence and initial erosion of the Santa Susana Mountains, as described in Saul (1975), Shields (1977a), Saul (1979), and Levi and Yeats

(1993); Qt of Bishop (1950) and Jennings (1957). Strata mapped as upper Saugus west of Valencia and southwest of Castaic Junction consist of moderately sorted, yellowish-gray to light yellowish-brown sandstone, conglomerate and silty sandstone, and poorly sorted sandy mudstone beds; the conglomerate beds also contain clasts derived from the Santa Susana Mountains; less lithified and sorted than underlying Saugus Formation strata. Most of this section was assigned to the Saugus Formation by Winterer and Durham (1962) and by Dibblee (1996d), but was assigned to the Pacoima Formation by Treiman (1986). This unit appears to be a transitional facies between the two formations, both structurally and lithologically; angular discordance with the underlying Saugus varies from locally distinct along the southeastern portion of the contact, where it coincides with a monoclinal warp, to negligible to the northwest at the Santa Clara River. The contact with the overlying Pacoima Formation is a subtle angular unconformity or disconformity. This unit may correlate with the upper Saugus strata on the south flank of the Santa Susana Mountains based on the appearance of clasts derived from the newly emergent Santa Susana Mountains.

Qsc **Saugus Formation, Camarillo member (late Pleistocene)**—Thickly bedded, reddish, pebble-bearing siltstone; paleosols with carbonate-cemented rhizoliths common; clasts are dominantly composed of locally derived Miocene shale and volcanic clasts, with subordinate granitic and metamorphic clasts. Defined informally by DeVecchio and others (2012b) for their chronostratigraphic units Qs_2 and Qs_3 exposed in the Camarillo and Las Posas Hills area; locally derived clast assemblage distinguishes this member from older sections of the Saugus Formation to the north and is interpreted by DeVecchio and others (2012b) to indicate that uplift of South Mountain and Oak Ridge had diverted the ancestral Santa Clara River to the north, thereby preventing crystalline clasts derived from the San Gabriel Mountains from reaching this area; DeVecchio and others (2012b) report IRSL dates of 78 ± 6 ka to 125 ± 9 ka for this member; thickness 40 to 60 m.

Qsv **Saugus Formation, volcaniclastic breccia-conglomerate (Pleistocene)**—Massive to crudely bedded, breccia-conglomerate composed of angular to subrounded, pebble- to boulder-size, weathered and fresh clasts of Conejo Volcanics in a poorly consolidated matrix of caliche, clay, silt and sand. Amount of matrix material is variable; some exposures consist only of angular, monolithologic volcanic clasts coated with caliche and contain little or no other matrix material. Previously mapped as part of the Conejo Volcanics. May represent remnants of debris shed from Conejo Volcanics highland into local basin during deposition of Saugus Formation (T. F. Blake, pers. com., 1993). (Dibblee, 1992a and 1992b; Irvine, 1995).

QTsg **Saugus Formation, conglomerate (early Pleistocene)**—Conglomerate mapped at the base of the formation. Clasts are predominantly crystalline igneous and metamorphic rocks recognizable as presently exposed in the northwestern San Gabriel Mountains. (Saul and Wootton, 1983).

QTsr **Saugus Formation, Sunshine Ranch Member, undivided (early Pleistocene to late Pliocene)**—Sulfur-yellow to light-brown and light-gray sandstone, conglomerate and silty sandstone, greenish-gray sandy siltstone and mudstone, and local limestone beds; sandstone and conglomerate commonly cross bedded or channeled; considered primarily paralic

nonmarine or transitional brackish lagoon or estuary deposits with local interfingering marine beds; the greenish-gray fine-grained interbeds are considered the most characteristic lithologic type of the member (exposed in the Oat Mountain, San Fernando, Newhall, and Mint Canyon 7.5' quadrangles). The thickness of the Sunshine Ranch Member is estimated to be about 3,000 ft. (915 m) in the type area. This member is primarily late Pliocene in age based on fossil horse teeth, but likely early Pleistocene in part based on revised time scale of Gibbard and others (2010). It was initially named informally by Hazzard (1940) in an unpublished report as the "Sunshine Ranch formation" for distinctive transitional strata at Sunshine Ranch in the Mission Hills area of the northern San Fernando Valley. Oakeshott (1950, 1958) published formal descriptions and mapping of this unit, which he assigned as an upper member of the Pico Formation; subsequently reassigned as a lower member of the Saugus Formation by Winterer and Durham (1958, 1962) and this usage has been adopted by most subsequent workers in the area (e.g. Barrows and others, 1974; Saul, 1975; Treiman 1987b; Dibblee Foundation maps); Saul and Wootton (1983) excluded all fossiliferous marine beds and subdivided the Sunshine Ranch into an upper and lower facies. Diagnostic greenish-gray mudstone and peaty siltstone occur locally in the lower Saugus Formation south and east of Newhall, leading Treiman (1987b) and Dibblee (1991d, 1992c) to map these outcrops as the Sunshine Ranch Member. The diagnostic beds are uncommon and laterally discontinuous, however. Winterer and Durham (1962) concluded that it is not practical to delineate this member in this area. These possible areas of the Sunshine Ranch Member are shown as queried.

QTsru **Saugus Formation, Sunshine Ranch Member, upper facies**—Nonmarine, poorly consolidated grayish-green clayey sandy siltstone and mudstone, light-brown silty sandstone, light-gray to yellowish-gray pebbly arkosic sandstone and sandy conglomerate, and thin beds of white sandy and nodular limestone; thickness as much as 300 m. Saul and Wootton (1983) note that this facies best characterizes the member and is mapped by them north of the San Gabriel Fault (southwest part of Mint Canyon 7.5' quadrangle).

QTsrl **Saugus Formation, Sunshine Ranch Member, lower facies**—Nonmarine sulfur-yellow, brown or gray arkosic sandstone, silty sandstone, pebbly sandstone, and conglomerate (Saul and Wooton, 1983); thickness about 120 m; occurs on both sides of the San Gabriel Fault (southwest part of Mint Canyon 7.5' quadrangle).

QTse **Saugus Formation, Elsmere Canyon delta plain facies (Pliocene)**—Sandstone and conglomerate with subordinate siltstone and sandy siltstone interbeds; typically weathers light gray and gray to light greenish gray but is locally brown on fresh surfaces due to oil impregnation; light-brown to brown iron-oxide staining locally common; clasts pebble to local boulder size, subrounded to rounded, and composed primarily of crystalline rock derived from the adjacent San Gabriel Mountains; small-scale, low-angle to larger-scale trough cross bedding and channels with erosive bases common (Squires, 2012); foreset beds locally apparent; commonly forms resistant exposures and cliffs in the Elsmere Canyon area; over 450 m thick. Squires (2012) interprets this unit as a braid delta where a braided river flowing from the ancestral San Gabriel Mountains entered the ocean; strata in the Elsmere Canyon area are interpreted as braided river deposits on the delta plain that interfinger to the southwest with

delta front and offshore marine deposits of the Pico and Towsley Formations west and south of the Antelope Valley (14) Freeway. This facies may interfinger with Sunshine Ranch-like mudstone beds northeast of Whitney Canyon and is overlain to the northwest by possible Sunshine Ranch member strata per Treiman (1987b). Squires (2012) notes a possible marine transgression at the top of this unit. This section previously mapped as Pico Formation by Winterer and Durham (1962) and Treiman (1987b), but assigned to the Saugus Formation by Dibblee (1991d, 1992c) and by Squires (2012) based primarily on the lack of marine fossils. This unit is assigned here to the Saugus Formation following the definitions of Winterer and Durham (1962) based on the lack of marine fossils and interpreted nonmarine depositional environment (Squires, 2012); however, differentiation of the lateral transition from marine to nonmarine aspects of the delta is problematic in this area and some unfossiliferous marine delta front deposits may be included west of Highway 14. This facies is mapped because of the unique combination of its nonmarine character and stratigraphic position below Sunshine Ranch member strata; based on this position and interfingering relationships with the Pico and possibly even the Towsley Formations, this unit is likely entirely Pliocene in age.

Qlp **Las Posas Formation (middle to late early Pleistocene)**—Shallow marine, light-gray to light yellowish-gray, fine- to locally coarse-grained sandstone, silty sandstone and pebbly sandstone with greenish-gray mudstone and subordinate conglomerate interbeds in the type area; invertebrate fossils and bivalve-dominated hash beds locally common; sands commonly quartz rich; pebbles composed of well-rounded plutonic, metamorphic and volcanic clasts derived primarily from the San Gabriel Mountains; moderately well sorted; medium bedded to locally laminated; poorly cemented. The Las Posas Formation crops out on either side of the Las Posas Valley in the Las Posas Hills and on the south side of South Mountain/Oak Ridge west of Long Canyon, and west of Fillmore on the north side of the Santa Clara River (western Ventura basin). A prominent basal conglomerate is commonly present in the South Mountain area (Lung, 1958) and northwest of the Santa Clara River at Adams Canyon (basal Saugus of Driver, 1928; Irvine, unpublished mapping 1991). It overlies or interfingers with the Mudpit shale north of the Santa Clara River. In the South Mountain area, it conformably overlies or locally interfingers with upper Pico Formation siltstone and is distinguished from older shallow marine strata of the upper Pico Formation (QTpcu) to the east by its stratigraphic position above the Grimes Canyon deltaic unit (QTpg), whereas QTpcu is generally below QTpg; to the south, it unconformably overlies the Sespe Formation and Conejo Volcanics in the Las Posas Hills. The Las Posas Formation is up to 300 m thick below Las Posas Valley (Dibblee, 1992g). Its age is estimated at 450 ka to 750 ka based on amino acid racemization (Wehmiller, 2010 in DeVecchio and others, 2012b), but DeVecchio and others (2012b) report an OSL date of 141 ± 10 ka near the base of the section in the Las Posas Hills. Sarna-Wojcicki and others (1984) estimate the base of the shallow marine sands (their “San Pedro”) is at about 1.0 Ma in the South Mountain area, but also report an age of about 0.4 Ma in the Ventura area. This unit was originally mapped as Fernando Formation by McLaughlin and Waring (1914) after the definition of Eldridge and Arnold (1907) and subsequently assigned to the Saugus Formation by Kew (1924). The Las Posas “formation” was coined by Pressler (1929) for sands in the Las Posas Hills type area, and nearby South Mountain, Oak Ridge and Camarillo Hills that are

stratigraphically above the “Santa Barbara horizon” and contain warm water “Saugus” fauna of Kew (1924) and Waterfall (1929). Pressler subdivided this unit into a lower Kalorama member (which Bailey, 1935 subsequently included in his Santa Barbara Formation) and an upper Long Canyon member. Subsequent workers referred to this section either as a marine member of the Saugus following Kew, 1924 (e.g. Pasta, 1958; Lung, 1958; Jakes, 1979), as the San Pedro Formation (e.g. Grant and Gale, 1931; Bailey, 1943, 1951;State Water Resources Board, 1953; Weber and others, 1973), or as the Las Posas Sand or Formation (e.g. Dibblee Foundation Maps; DeVecchio and others, 2012a and b); the term Las Posas Formation is adopted because the term San Pedro is restricted to the Los Angeles basin and the term Saugus Formation is restricted to nonmarine deposits following the original definitions of Hershey (1902b) and Winterer and Durham (1962).

Los Angeles Basin

Qsp **San Pedro Formation (middle Pleistocene)**—Unconsolidated sand with local gravelly sand, silty sand and silt interbeds; shallow marine invertebrate fossils common. Woodring and others (1946) report a maximum stratigraphic thickness of about 300 ft. (90 m). The San Pedro Formation has an estimated age range of 200 to 500 ka, as summarized in Jacobs, (2007). The San Pedro Formation was defined at San Pedro Hill (Palos Verdes Peninsula) and extended to other portions of the Los Angeles basin. Fossils were noted at San Pedro Hill by early workers (e.g. Trask, 1855b; Lawson, 1893) but Dall (1898) is credited as the first to use the term “San Pedro beds” (Wilmarth, 1938). Arnold and Arnold (1902) and Arnold (1903) distinguished a “lower” and “upper” San Pedro series and the “lower series” was subsequently assigned the name San Pedro “formation” by Kew *in* Tieje (1926). Terminology for the San Pedro Formation was formalized by Woodring and others (1946) and their usage is adopted herein. This term was extended into the subsurface by Poland and others (1956, 1959) and additional background is summarized by Powell and Ponti (2007). The term San Pedro has also been extended by some workers in the past to granular Pleistocene strata in the western Ventura basin based on molluscan fauna (e.g. Grant and Gale, 1931; Bailey, 1935); however, this extended usage is not used here, as suggested by Ponti (pers. comm., 2012), based on the presence of an intervening depositional basin boundary.

Qi **Inglewood Formation (early Pleistocene)**—Shallow marine, well-consolidated clay-siltstone and interbedded very fine-grained sandstone, commonly with calcareous, limonitic concretions; relatively dense and moderately expansive where weathered. This unit is now recognized as one from which most of the landslides in the Baldwin Hills are derived (Hsu and others, 1982).

QTms **Sedimentary rocks of the Pacific Palisades area (early Pleistocene to late Pliocene)**—A few small exposures of marine siltstone and very fine-grained silty sandstone; very soft and slightly indurated, locally very fossiliferous, fossils referred to the late Pliocene or early Pleistocene; maximum thickness about 120 m (Hoots, 1931; McGill, 1989).

Soledad Basin and San Andreas Fault Zone

QTjh **Juniper Hills Formation (early Pleistocene to late Pliocene) undifferentiated**—Pink, buff', light-brown, or red, pebbly to cobbly, coarse, arkosic sandstone, silty sandstone, lesser conglomerate, and thin-bedded shale. Mapped by Barrows and others (1985) in the San Andreas Fault zone. Sandstone and conglomerate represent fluvial and other continental deposits. Sandstone is poorly to moderately indurated, typically well bedded and poorly sorted. Clasts are sub-angular to well-rounded and include abundant yellow-brown sandstone and a variety of very well-rounded. tough metavolcanic cobbles recycled from the San Francisquito Fm.; abundant volcanic rocks probably recycled from the Punchbowl fm.; leucocratic granitic rocks; silver, gray and spotted Pelona Schist; ferruginous syenite; and medium- to coarse-grained blue-Quartz granite and leucogneiss. This unit is typically folded and internally deformed.

QTjhc **Juniper Hills Formation (early Pleistocene to late Pliocene) Clay shale member**—Greenish-gray, light brown, and black silty clay shale with very thin maroon sandstone layers. Mapped by Barrows and others (1985) in San Andreas Fault zone. Shale is thin-bedded, gypsiferous, with local iron oxide stained bedding. Also contains minor beds of finely laminated gray- to light grayish-brown silty sandstone, white arkose, and white chalky calcareous beds. Clay shale member probably represents lake deposits that are interbedded with other continental deposits. This unit is typically folded and internally deformed. Clay rich units are locally expansive with typical “popcorn” weathering.

QTjhr **Juniper Hills Formation (early Pleistocene to late Pliocene) Red arkose member**—Red to dark-red pebbly arkose and minor white and gray silty sandstone. Localized along Northern Nadeau Fault and is stained, deformed, crushed, and contains fractured clasts. Clasts are predominantly subrounded, light-colored granitic rocks and lesser varicolored volcanic rocks. Strongly resembles Punchbowl Fm. and may have been derived exclusively from a Punchbowl terrane.

QTjhm **Juniper Hills Formation (early Pleistocene to late Pliocene) Mixed clast member**—White to buff, coarse, poorly sorted and locally chaotic, pebbly, arkosic sandstone· and angular cobble to boulder conglomerate with abundant, rounded, leucocratic granitic-rock cobbles; subangular to subrounded clasts of gray mica schist, thinly laminated quartzite, and white quartz from Pelona Schist; yellowish rusty-brown, rounded sandstone cobbles and recycled, tough, metavolcanic clasts from San Francisquito Fm.; and scarce, maroon, fine-grained sandstone pebbles from Vasquez Fm. (?). Volcanic clasts (other than recycled San Francisquito Fm. cobbles) not seen. The presence of abundant (locally 80-90%) large clasts of Pelona Schist is distinctive.

Ventura Basin, including San Fernando Basin

QTp **Pico Formation (middle Pleistocene to Pliocene)**—Thick marine sequence composed of siltstone, sandstone and subordinate conglomerate deposited in the Ventura basin; coarser-grained sediments deposited primarily by turbidity currents and are commonly the dominant lithology along the axis of the basin, in feeder channels on the adjacent basin slopes (Yeats,

1979a; Sylvester and Brown, 1988), and at the eastern margin of the basin south of Newhall (Winterer and Durham, 1962); hemipelagic clayey siltstone is interbedded or interfingering with the turbidity deposits and is locally the dominant lithology; deposited primarily at bathyal depths exceeding 4,500 ft. (1400 m) at the base of the section (Natland, 1967), but grades or interfingers up section into upper bathyal to neritic mudstone (see Mudpit shale - QTpms) and shallow water shelf and delta sandstone, conglomerate, and siltstone, with locally prominent fossil hash beds (see QTpcu and QTpg). The siltstone is typically bluish gray where fresh and olive gray with limonite stains or nodules where weathered; coarse-grained units range from light olive gray to light gray and light brown; compact but typically not well cemented. Siltstone beds typically contain abundant foraminifers and local invertebrate fossils. The upper shallow water deposits also contain locally abundant molluscan fossils and ostracodes. The Pico Formation is widely exposed in the eastern Ventura basin; it is exposed in the central Ventura basin on either side of the Santa Clara River Valley, but is thickest below this valley along the Ventura basin axis, where it is largely concealed by alluvium and faulting. Winterer and Durham (1962) report a maximum thickness of about 5,000 to 6,000 ft. (1500 to 1800 m) in the eastern Ventura basin; however, Bailey (1952) reports a thickness of about 13,900 to 15,400 ft. (4200 to 4700 m) west of the map area in the Ventura area. The lower basinal section pinches out to the south and Pico deposits along the northern margin of the Ventura basin are missing in the upper reaches of the mountains on the north due to uplift and erosion. The basal portion of the formation was reportedly deposited during the Repettian stage in both the western and eastern Ventura basin (e.g. Dibblee, 1988; Beyer and others, 2009), and overlies the Modelo Formation to the west and overlies or interfingers with the Towsley Formation to the east in the type area. The top of the formation is time transgressive and is progressively younger to the west. Near the type section west of Valencia, the Pico Formation is reportedly older than about 2.5 Ma, the age of the base of the Saugus Formation estimated by Levi and others (1986). However, Winterer and Durham (1962) report the presence of the benthic foraminifera *Uvigerina peregrina* and *Bulimina subacuminata* within Pico siltstone, which characterize the early Pleistocene Wheelerian and Venturian stages respectively (Natland, 1952; Squires and others, 2006). McDougall and others (2012) report that these species also occur in the upper Repettian stage. In the western Ventura basin the upper Pico Formation includes early to middle Pleistocene ash beds, and alternatively underlies or includes the 0.6 Ma Lava Creek ash (see QTpms). This section was initially assigned to the Fernando Formation as defined by Eldridge and Arnold (1907) and as mapped by McLaughlin and Waring (1914). Kew (1924) subsequently assigned the lower, marine strata of the Fernando to the Pico Formation (except for coarse-grained shallow marine deposits), with the type section at Pico Canyon. Winterer and Durham (1962) remapped and redefined the formation in the type area and assigned the coarse-grained shallow marine units to the Pico Formation. This usage has been adopted by most workers in the eastern Ventura basin and is adopted here and extended to the Santa Susana Mountains and Oak Ridge. Strata in the Ventura basin containing Repettian-age fauna that are lithologically similar to the type Pico section are included within the Pico Formation. The term Repetto is abandoned entirely as a lithologic formation per the recommendation of Durham and Yerkes (1964). The term Pico is abandoned as a lithologic

formation in the Los Angeles basin following the recommendation of Durham and Yerkes (1959, 1964). The term Fernando Formation is not used in the Ventura basin based on differences in lithologic facies reported between the type Pico section and Pliocene strata in the Los Angeles basin (Durham and Yerkes, 1959, 1964) (see Appendix A for details). Lithologic facies have been mapped locally, including:

QTpg **Pico Formation, Grimes Canyon deltaic facies**—Medium- to coarse-grained sandstone, pebbly sandstone, and pebble conglomerate; cross bedding common to pervasive and foreset beds locally apparent; channeling common as well; weakly cemented to uncemented, clasts typically crystalline and derived from the San Gabriel Mountains, and rounded to well-rounded and smooth; moderately to well sorted; conglomerate locally clast supported; typically light gray; light-brown iron-oxide staining varies from local to prominent; generally unfossiliferous; uncommon greenish-gray sandy siltstone to rare thin claystone interbeds with local invertebrate fossils. This unit is well exposed along Grimes Canyon road and at quarries to the east and west of the road (Moorpark and Simi Valley West quadrangles). It is equivalent to a unit interpreted by Dibblee (1992b) as a delta deposit from west-flowing streams and expanded eastward into Happy Camp Canyon on this map based on additional field mapping. It interfingers with and is underlain by Pico siltstone to the west; underlain by and likely grades into or interfingers with fossiliferous shallow marine sands to the east that are assigned here to the upper coarse-grained marine member of the Pico Formation (QTpcu). Overlain by Las Posas Formation or undifferentiated Saugus Formation. Maximum thickness is about 315 m per Dibblee (1992b) cross section. This section historically assigned either to the Saugus or San Pedro Formations; designated herein as an informal member of the Pico Formation based on the definition of Winterer and Durham (1962) and the interpretation that most of this unit is marine; This interpretation is based on mapped interfingering relationships with offshore marine siltstone of the Pico Formation to the west, the presence of uncommon fossiliferous interbeds, the presence of marine sands up section of this unit near Grimes Canyon Road, the prevalence of well-rounded and nearly polished clasts indicative of extensive abrasion in a littoral environment, and foreset bedding suggestive of a delta front environment; however, differentiation of unfossiliferous marine sands from nonmarine sands is problematic in some areas and some nonmarine paralic strata are likely included in the unit as currently mapped. This unit stratigraphically separates and distinguishes older, shallow marine sands to the east, assigned herein as an informal upper facies of the Pico Formation (QTpcu), from younger, shallow marine sands to the west assigned herein to the Las Posas Formation.

QTpcu **Pico Formation, coarse-grained upper facies**—Sandstone, conglomerate and locally prominent fossil hash/coquina beds overlying Pico offshore deposits; locally cross bedded and channeled; gradational with or underlying the Grimes deltaic unit (QTpg); onlaps older formations to the south; overlain conformably or unconformably by nonmarine Saugus or transitional Sunshine Ranch Member strata in most areas; invertebrate fossils locally common. This facies is interpreted as shallow marine shelf, delta or embayment deposits (White, 1983, 1985; Groves, 1991). This section was initially mapped as the lower portion of the Saugus Formation by Kew (1924), but was reassigned to the upper Pico Formation in the eastern Ventura basin by Winterer and Durham (1962). Shallow marine strata previously assigned to

the lower marine Saugus Formation in the Santa Susana Mountains are reassigned here to this facies following the usage of Winterer and Durham and subsequent workers in the type localities of the Saugus and Pico Formations (see Appendix A for details).

QTpms **Pico Formation, Mudpit shale member (middle to early Pleistocene)**—Marine mudstone and siltstone with locally common sandstone interbeds and conglomerate lenses and rare, thin ash beds; conglomerate beds with hard siliceous clasts common at base; foraminifers common; local invertebrate fossils; typically bluish gray when fresh, weathering to olive gray; poorly bedded to locally laminated; 3,500 ft. (1067 m) thick north of Ventura (Natland, 1967). This member was deposited in the western Ventura basin (Fillmore quadrangle) at bathyal to neritic depths (Natland, 1967). Lower contact is conformable with the underlying Pico Formation. Correlative strata in the South Mountain/Balcom Canyon/Oak Ridge area are not lithologically distinctive relative to typical Pico Formation strata (Lung, 1958) and therefore the Mudpit shale member is not distinguished in this area. The upper contact is reportedly time transgressive and interfingers with shallow marine (Las Posas) sands to the east of Ventura (Bailey 1935; Hopps, 1995). Natland (1967) reports this unit contains lower Hallian and upper Wheelerian benthic foraminifers. Contains the 0.73 to 0.78 Ma Bishop ash and 0.8 to 1.1 Ma Glass Mountain ashes and spans the 0.78 Ma transition from reverse (Matuyama) to normal (Brunhes) polarity. The base occurs in proximity to the 1.2 Ma Bailey ash and the top is alternatively shown either above or below the 0.6 Ma Lava Creek ash (Wehmiller and others, 1978, Lajoie and others, 1982; Sarna-Wojcicki and others, 1984). Mudpit shale strata were originally assigned to the Fernando Formation of Eldridge and Arnold (1907), as mapped by McLaughlin and Waring (1914). These strata were subsequently included in the Pico Formation by Kew (1924) and described as upper Pico Formation by Cartwright (1928) and Driver (1928). Waterfall (1929) noted the similarity of molluscan fauna in this section with the fauna at Bath House beach in Santa Barbara and many subsequent workers assigned this section to the Santa Barbara Formation based on this faunal criteria (e.g. Bailey, 1935, 1951; usage adopted by Weber and others, 1973). Early workers in the Ventura Avenue/Rincon/San Miguelito oil fields referred to this section more informally as the Mudpit shale and Dibblee (1990) assigned it to the informal Mudpit shale member of the Pico Formation. This usage is adopted here (see Appendix A for details).

QTpc **Pico Formation, sandstone and conglomerate**—Sandstone and conglomerate interbeds within typical Pico siltstone (Val Verde quadrangle and Moorpark 7.5’ quadrangles).

Los Angeles Basin

Durham and Yerkes (1964) described two members, upper and lower, in the Puente Hills:

QTfu **Fernando Formation, Upper Member (early Pleistocene to Pliocene)**—In general, the Fernando Formation consists of massive light-gray siltstone, light yellowish-brown fine- to medium-grained sandstone, and light-brown to reddish-brown pebbly conglomerate in the Los Angeles basin; primarily marine but nonmarine conglomerate beds are reportedly included in the upper part of the section (Lamar, 1970); exposed primarily in the Los Angeles and El Monte quadrangles. Name introduced by Eldridge and Arnold (1907) based on unpublished

mapping of Homer Hamlin in the San Fernando Valley and initially extended to Pliocene strata from southern Los Angeles County to Santa Maria. The term Fernando was elevated to group status by Kew (1923, 1924), but was subsequently reclassified back to formational rank to name Pliocene strata of the Los Angeles basin by Durham and Yerkes (1964). See Appendix A for nomenclature details. Locally contains Repettian-Wheelerian (early Pleistocene to early Pliocene per McDougall and others, 2012) foraminiferal zone boundary (Lamar, 1970).

The upper member on this map includes Fernando Formation members 2 and 3 of Lamar (1970): **QTfuc**—pebbly sandstone and conglomerate; **QTfuf**—fossiliferous.

QTfl **Fernando Formation, Lower Member (Pliocene)**—Interbedded silty sandstone and massive pebble conglomerate of the Los Angeles basin. Includes Fernando Formation member 1 of Lamar (1970). See QTfu above and Appendix A for discussion of nomenclature **QTflc**—conglomerate.

Ventura Basin

Tw **Towsley Formation, undivided (early Pliocene to late Miocene)**—Interbedded sandstone, conglomerate, and sandy siltstone and mudstone; the coarse-grained facies is light-colored and commonly lenticular, and is interpreted as turbidity current deposits in a submarine fan; the fine-grained facies is characteristically brown weathering and represents deposition between the fan lobes (Fritsche, pers. comm. 2011). Winterer and Durham (1962) report the presence of numerous transported fossil invertebrates that suggest a depositional water depth in excess of 600 ft. (180 m), and possible depths of 3,000 ft. (900 m) or more based on foram assemblages Strata, up to 4,000 ft. (1200 m) thick, form widespread exposures in eastern Ventura County; overlies Modelo Formation strata in the Topatopa Mountains. The Towsley Formation overlies and interfingers with the Modelo Formation in the Santa Susana Mountains and overlaps Modelo strata to rest directly on basement rocks near and east of San Fernando Pass. Its base is distinguished from the Modelo Formation at the first thick bedded pebbly sandstone. The generally conformable, locally interfingering upper contact with the Pico Formation is chosen at the transition from diagnostic brown-weathering siltstone of the Towsley to olive-gray siltstone with common limonite nodules typical of the Pico. The Towsley Formation is early Pliocene to late Miocene (Winterer and Durham, 1962; Squires and others 2006, fig. 2). This section was initially included in the Modelo Formation by Kew (1924); the section in the Elsmere Canyon area was assigned to the “Repetto formation” by Oakeshott (1950); a new, unnamed formation was proposed by Winterer and Durham (1951), was subsequently named the Towsley Formation in Winterer and Durham (1954), and was formally described and mapped by Winterer and Durham (1962) based on the type section at Towsley Canyon, southwest of Valencia. In the northern San Fernando Valley, east of Pacoima Canyon, a band of strata was shown as Pico Formation by Yerkes and Campbell (2005); Hill (1930) also mapped this section as Pico, but Oakeshott (1958) mapped it as “Repetto formation” and several early Caltech theses note the presence of brown weathering siltstone, which is typical of the Towsley Formation of Winterer and Durham (1962); Barrows and others (1974) mapped it as undifferentiated Towsley/Pico Formation; Dibblee (1991e) maps it as Towsley Formation. This

unit is mapped here as Towsley Formation based on Dibblee and the noted lithology, but is queried due to the possible inclusion of undifferentiated Pico Formation strata. Mapped subunits and members include:

Tws **Towsley Formation, siltstone**—Brown mudstone and siltstone, locally carries foraminifera referred to the Mohnian Stage (late Miocene) of Kleinpell (1938).

Twc **Towsley Formation, conglomerate**—Pale pebble conglomerate and sandstone in lenticular beds.

Twhc **Towsley Formation, Hasley Conglomerate Member**—Basal conglomerate member.

Los Angeles Basin

Tpn **Puente Formation, undivided (early Pliocene and late Miocene)**—Marine siltstone, sandstone, and shale; mostly a Los Angeles basin temporal equivalent of the Modelo Formation, but partly younger; named by Eldridge (*in* Eldridge and Arnold, 1907) from exposures in the Puente Hills; strata are associated with the Los Angeles basin (El Monte, Los Angeles and Hollywood 7.5' quadrangles) as contrasted with Modelo strata, which are associated with the eastern Ventura basin. In the Los Angeles and Hollywood 7.5' quadrangles Lamar (1970) mapped four non-sequential, interbedded, informal lithologic subunits, which have not been specifically correlated with the formal members recognized by Shoellhamer and others (1954).

Tpsl **Puente Formation, siltstone (early Pliocene)**—Well-bedded, light gray siltstone; thickest beds at top of section, also interbeds lower in section (Lamar, 1970, fig. 14).

Tpsh **Puente Formation, siliceous shale (early Pliocene)**—Well-bedded, light gray, siliceous shale and siltstone; regularly interbedded with thin, fine- to coarse-grained sandstone beds; most common in a few discontinuous zones, chiefly in upper-central part of formation (Lamar, 1970, fig. 14).

Tpds **Puente Formation, diatomaceous shale (early Pliocene)**—Well-bedded, dull white diatomaceous shale; a discontinuous single zone in central part of formation (Lamar, 1970, fig. 14).

Tpss **Puente Formation, sandstone (late Miocene)**—Well-bedded, very fine- to very coarse-grained sandstone; medium to light brown and light gray; mostly well cemented but less so in uppermost parts; local discoidal concretions; most abundant in lower part of formation (Lamar, 1970, fig. 14).

Tpnsc **Puente Formation, Sycamore Canyon Member (late Miocene)**—Predominantly sandstone and pebble conglomerate, laterally variable; sandstone is thick-bedded to massive, medium- to coarse-grained, friable; siltstone is massive- to thin-bedded, siliceous; conglomerate is massive, contains pale to brownish-gray pebbles and cobbles; siltstone locally contains bathyl-depth foraminiferal faunas; **Tpnscc** - conglomerate bed. Member named by Schoellhamer and others (1954).

Tpny **Puente Formation, Yorba Member (late Miocene)**—Predominantly siltstone, with sandstone interbeds; named for Yorba Bridge over the Santa Ana River, east of Atwood; white to gray, thin-bedded, micaceous and siliceous siltstone; upper part contains large boulders "floating" in much fine-grained material – interpreted to be a turbidity current deposit. Named by Schoellhamer and others (1954).

Tpnsq **Puente Formation, Soquel Member (late Miocene)**—Predominantly sandstone, minor interbedded siltstone; sandstone is gray to yellowish-gray, massive- to well-bedded, medium- to coarse-grained, poorly sorted; interbedded pebbly sandstone; many such beds are graded, locally pebbly to cobbley conglomeratic; lower part of unit contains ellipsoidal, calcite-cemented boulders as large as 1.5 m. Named by Schoellhamer and others (1954).

Eastern Ventura Basin

Tcs **Castaic Formation, undivided (late Miocene)**—Marine tuffaceous or diatomaceous shale, interbedded pebbly sandstone, sparse limestone concretions with well-preserved foraminifera. Named by Winterer and Durham (1954) for marine sandstone strata of late Miocene age (equivalent in age to the Modelo Formation), north of the San Gabriel Fault and east of Newhall; name extended to north for late Miocene shale with interbedded sandstone and minor pebble conglomerate in Soledad-Ridge basin area by Crowell (1954).

Tm **Modelo Formation, undivided (late and middle Miocene)**—Predominantly gray to brown thin-bedded mudstone, diatomaceous clay shale, or siltstone, with interbeds of very fine-grained to coarse-grained sandstone; proportion and thickness of sandstone interbeds allows lithofacies to be mapped in some areas; generally unconformable on older rocks around northern, eastern and southern margins of the Ventura basin. The base of the Modelo is generally unconformable on middle Miocene and older rocks. The name, Modelo, was introduced by Eldridge and Arnold (1907) for strata exposed in the Topatopa Mountains, north of Piru and further described in the Santa Susana Mountains and San Fernando Pass areas by Winterer and Durham (1962); extended to the eastern Santa Monica Mountains and described in detail by Hoots (1931) where further noted for turbidite features indicating submarine fan deposition (Sullwold, 1960); Along the north flank of the Santa Monica Mountains the unconformity mapped by Hoots (1931) in the eastern part of the range, where Modelo locally overlies Santa Monica Slate, has been mapped continuously westward (Yerkes and Campbell, 1980; Weber, 1984; and unpublished 1:12,000-scale mapping by Yerkes and Campbell, 1965-1974, in the Canoga Park and Calabasas 7.5' quadrangles) as far as the north side of the Ventura Freeway (U.S. 101) at the west side of Las Virgenes Creek, to the west of which it becomes accordant with (and apparently conformable on) subjacent strata of the Calabasas Formation (Weber, 1984); further west, the Modelo and subjacent parts of the Calabasas appear to grade progressively westward into more diatomaceous, clayey, Monterey-like lithofacies. Many of the sandstone and shale beds below (south of) the unconformity (and its westward conformable extension) and above (north) of the Conejo Volcanics are lithologically similar to the Modelo but more intensely folded and faulted; these have been assigned to the Calabasas Formation by Yerkes and Campbell (1979). Fellbaum and Fritsche (1993) include them in the

Modelo Formation; however, their stratigraphic position below the unconformity mapped by Hoots (1931) as the base of the Modelo, and the predominance of middle Miocene foraminifera (Luisian or Relizian?) in the Calabasas, suggests their correlation with Modelo strata is questionable. In the eastern Santa Monica Mountains the Modelo was mapped and described in detail by Hoots (1931), and Kleinpell (1938) used the unconformity at the base, well exposed near Mohn Springs in Topanga Canyon, where it is underlain by predominantly middle Miocene Topanga strata, as the base for his type Mohnian (foraminiferal) Stage (late Miocene). Widespread in eastern Ventura basin; locally extended to include some strata along the south flank of the Santa Monica Mountains in the Pacific Palisades-Westwood area. Five members were described by Cemen (1977) in the Topatopa Mountains and four of them have been mapped as far south as the north flanks of Oak Ridge and the Santa Susana Mountains. Age-correlative strata in the Los Angeles basin are generally referred to the Puente Formation or, west of the Newport-Inglewood zone, to the Monterey Shale. Mapped facies of the Modelo Formation include:

Tmsu **Modelo Formation, upper sandstone unit at Laskey Mesa**—Weber (1984) assigned strata at Laskey Mesa to the Towsley Formation, as shown by Yerkes and Campbell (2005); Truex and Hall (1969) previously assigned most of this section to the Modelo Formation and the uppermost portion to the Santa Margarita Formation, and Brown (1957) mapped it as Modelo Formation; Dibblee (1992b) mapped this section as Tertiary unnamed shale and sandstone; Yeats (1979) reported that Towsley Formation does not occur south of the Santa Susana Fault. Field review of this area did not reveal any brown mudstone or coarse-grained turbidite beds typical of the Towsley Formation and this unit has been reassigned to the upper Modelo Formation herein based on lithologic similarity to Modelo strata to the west and previous usage.

Tm_5 **Modelo Formation, member 5**—Upper shale and siltstone unit; dark brown to gray, moderately to well compacted, thin-bedded to laminated silty shale and siltstone, locally siliceous near base; contains foraminifera assigned to the upper Mohnian and lower Delmontian Stages of Kleinpell (1938); thickness locally exceeds 458 m. (Cemen, 1977) Includes units mapped as Sisquoc Formation by Dibblee (1991).

Tm_4 **Modelo Formation, member 4**—Upper sandstone unit; white to gray, fine to coarse-grained arkosic sandstone, with subordinate thin partings and lenticular interbeds of silty clay shale, locally siliceous; thickness variable, locally as much as 825 m. (Cemen, 1977).

Tm_3 **Modelo Formation, member 3**—Middle shale unit; porcelaneous and calcareous shale and porcelaneous mudstone, brown to buff, thin-bedded to laminated, moderately to well indurated, with thick lenses of gray calcareous sandstone locally; thickness variable but may exceed 763 m.; foraminifera referred to lower part of the Mohnian Stage of Kleinpell (1938) (Cemen, 1977).

Tm_2 **Modelo Formation, member 2—**Lower sandstone unit; grayish white to dark brown, fine to medium-grained sandstone, locally interbedded with dark brown siltstone and claystone; locally as much as 915 m. thick, thins westward and pinches out between the middle and lower shale units (Cemen, 1977).

Tm_1 **Modelo Formation, member 1—**Lower shale unit; cherty to porcelaneous shale and mudstone, locally calcareous, locally diatomaceous, moderately to well indurated, thin-bedded to laminated, generally dark gray to brown; contains foraminifera referred to the Relizian and Luisian Stages of Kleinpell (1938), indicating the unit is age-correlative with the Calabasas Formation and, possibly the upper part of the Topanga Canyon Formation in the Santa Monica Mountains; thickness 214-794 m. (Cemen, 1977).

Tmd **Modelo Formation, diatomaceous shale**—Diatomaceous shale; includes outcrops on the south side of the San Fernando Valley at Pierce College shown as Pico Formation by Yerkes and Campbell (2005), based on the presence of Repettian stage benthic foraminifers (Ingle, 1967; Yerkes and Campbell, 1993); previously assigned to the Modelo Formation by Hoots (1931). Review of these exposures indicates that much of this unit is lithologically more consistent with the Modelo Formation than the Pico Formation. This section is assigned here to the Modelo Formation based on the noted lithology and presence of Modelo Formation mapped on strike to the east and west, but is queried based on the reported presence of Repettian stage fauna.

Tms **Modelo Formation, sandstone**—Sandstone and conglomerate.

Tmb **Modelo Formation, "burnt shale"**—Unusual slag and scoriaceous- to obsidian-like material found within the upper part of the Modelo Formation in the Grimes Canyon area, Big Mountain/Happy Camp Canyon, and upper Las Virgenes Canyon area. It is composed of red, yellowish-orange, purple, brown, and black mudstone, siltstone, and diatomite that has been altered by in-situ combustion of natural gas in layers containing abundant organic material, as described and mapped by Irvine (1995), Brown (1957), and Jestes (1958).

Soledad Basin and San Andreas Fault Zone

Tpbc **Punch Bowl Formation, clay shale member (late Miocene)**—Gray, poorly indurated clayey shale with local gypsum. (Dibblee, 2001).

Tpbv **Punch Bowl Formation, volcanic clast member (late Miocene)**—White to pink, coarse, pebbly to cobbly, arkosic sandstone, thin-bedded silty sandstone, and minor thin-bedded, white, nodular limestone. Si1ty layers range from yellowish tan through greenish brown to red. Sandstone is well-indurated, well-stratified and was probably deposited in alluvial fan and floodplain environments. Clasts are predominately light-colored granitic rock pebbles and cobbles with lesser (up to 40%) tuffaceous and porphyritic volcanic .rocks ranging in composition from rhyolite to andesite. (Barrows and others, 1985).

Tmc **Mint Canyon Formation, undivided (late and middle Miocene)**—First described by Hershey (1902b), named by Kew (1924), mapped in detail by Saul and Wootton (1983) and Saul (1985), who recognized three intertonguing lithofacies. Includes a variety of semi-consolidated nonmarine sediments deposited in fluvial and lacustrine environments. Jahns and Muehlberger (1954) describe two informal members: a lower member including reddish-brown basement rock breccia, conglomerate, sandstone, siltstone and mudstone (thickness ~ 335 m); and an

upper member consisting of thin-bedded brownish or greenish siltstone and interbedded tuff (thickness ~ 790 m).

Tmcd **Mint Canyon Formation, Lacustrine deltaic (foreset) facies**—Predominantly fine- to coarse-grained, sparsely-concretionary, cross-bedded, arkosic sandstone, interbedded with conglomeratic sandstone, gray to brown sandy siltstone and claystone; tuff and tuffaceous sedimentary beds; marly and nodular carbonate. Sparsely fossiliferous: small clam and snail shells, vertebrate bones and teeth. (Saul and Wootton, 1983).

Tmcl **Mint Canyon Formation, Lacustrine bottomset facies**—Interbedded sandstone, silty sandstone, siltstone, claystone and thin beds and lenses of limestone; a few lenses of turbidite sandstone and coarse conglomerate; tuffaceous beds; ostracod shells; bedding planes commonly darkened by finely divided lignite; graded beds common. (Saul and Wootton, 1983).

Tmcm **Mint Canyon Formation, Lacustrine and lake-marginal fluvial facies**—Deposits of arkosic sandstone and conglomeratic sandstone, with interbedded siltstone and mudstone; some nodular carbonate in siltstone; thin beds of limestone common in mudstone. (Saul and Wootton, 1983).

Ttk **Tick Canyon Formation, undivided (middle to early Miocene)**—Reddish, fluvial and lacustrine sandstone, siltstone and claystone, and gray, tan, and reddish, well-cemented and well-bedded conglomerates (Mint Canyon, Agua Dulce and San Fernando 7.5’ quadrangles; Oakeshott, 1958). Named by Jahns (1940), and separated from the overlying lower part of the Mint Canyon Formation on the basis of a distinctively older vertebrate fauna. Includes area east of Tick Canyon and in upper Agua Dulce Canyon mapped by Oakeshott (1958) as Mint Canyon Formation but shown by Jahns and Muehlberger (1954) and Dibblee (1996b,c) as Tick Canyon Fm. Ehlert (2003) found no lithologic differences or unconformity between Tick Canyon and overlying Mint Canyon Formations and suggests that units mapped as Tick Canyon Formation should be considered basal sediments of the Mint Canyon Formation. Original usage retained, but question regarding validity of Tick Canyon Formation noted.

Ttkc **Tick Canyon Formation, conglomerate (middle to early Miocene)**—Dark gray, coarse, poorly-bedded conglomerate, Oakeshott, 1958), Dibblee (1996b,c).

Los Angeles Basin and Continental Borderland

Tmt **Monterey Shale, undivided (late, middle, and early Miocene)**—Marine clay shale, thin interbedded siltstone, minor sandstone and pebble conglomerate, and glassy tuff; siltstone is commonly diatomaceous, locally bituminous, siliceous, or dolomitic; sandstone is commonly quartz arenite; some conglomerates contain clasts of glaucophane schist. Shale is gray to dark brownish gray where fresh, weathers quickly to chalky white; contains foramifera referred to the Relizian, Luisian, or Mohnian Stages (early middle, late middle, or early late Miocene respectively) of Kleinpell (1938). Monterey strata are exposed only south of the Malibu Coast Fault and west of the Newport-Inglewood zone of faulting and folding; rocks of equivalent age north of the Malibu Coast Fault are referred to the Topanga Group and the Modelo Formation; east of the Newport Inglewood zone, strata of equivalent age are referred to the Puente Formation and the Topanga Group. The Monterey is generally considered a distal, deep-basin

facies of the more-proximal Modelo, Puente and other formations of the equivalent age range. Name extended into southern California from type area in Monterey County, central California (Woodring and others, 1936). The upper part of the unit in some areas (chiefly along the Pacific Coast Highway) is late Mohnian in age and locally overlies the early Miocene Trancas Formation unconformably; its relation to middle Miocene Monterey strata on Point Dume is obscured, but could be an intraformational unconformity. The (mostly middle Miocene) section exposed on Point Dume is about 1000 m thick. The Monterey Shale in the northern Los Angeles basin is unconformably overlain by unconsolidated Pliocene, Pleistocene and Holocene deposits; *includes*:

Tmtd **Monterey Shale, deformed (middle and early Miocene)**—Intensely deformed shale, siltstone, and sandstone, commonly dolomitic, locally siliceous, locally very cherty; contains foraminifera referred to the Relizian or Luisian (middle Miocene) Stages of Kleinpell (1938). In upper plate of Escondido thrust fault beds are tightly folded, with vertical limbs and gently east-plunging axes; thickness across folded beds is at least 650 m.

Ventura Basin and Los Angeles Basin

Tt **Topanga Group, undivided (middle and early Miocene)**—First called the Topanga Formation by Kew (1923) for exposures in the central Santa Monica Mountains that include the type locality for the "Topanga Canyon fauna" (about 50 molluscan species) of Arnold (1907a). Durrell (1954) recognized that the three subdivisions identified by Kew (1923) are contiguous westward with extensive units of formation rank, labeling them the Lower Topanga, Middle Topanga and Upper Topanga Formations. Subsequent publication of the North American Stratigraphic Code led Yerkes and Campbell (1979) to change the names to conform, and designated the set of three formations as the Topanga Group, consisting of the Calabasas Formation, the Conejo Volcanics, and the Topanga Canyon Formation, each with two or more members. Elsewhere, middle Miocene strata with similar lithologic and biologic facies have been informally divided: in the eastern Ventura basin and the northern Los Angeles basin beds containing Luisian BFZ foraminifera (late middle Miocene), that are labeled **Tt** are chiefly age-equivalent to the Calabasas Formation; beds containing a "Temblor" or "Topanga" molluscan fauna have also been labeled **Tt**. Middle Miocene volcanic rocks that may be related to the Conejo Volcanics, but are spatially separated, are labeled **Ttb**. The distribution and nomenclature history of the Topanga Group has been reviewed by Campbell and others (2007).

In the Santa Susana Mountains, informal subunits include:

Tt_4 **Topanga Group, Oat Mountain unit 4**—Upper sandstone with interbedded siltstone and local pebble conglomerate; sandstone, medium- to coarse-grained arkose, locally contains *Amusium lompocensis*; thickness about 140 m; (Saul, 1979).

Tt_3 **Topanga Group, Oat Mountain unit 3**—Shale, foram-bearing siltstone, and mudstone, about 122 m thick (Saul, 1979).

Tt_2 **Topanga Group, Oat Mountain unit 2**—Sandstone, fine- to coarse-grained, arkosic, well indurated, massive, about 244 m thick (Saul, 1979).

Tt_1 **Topanga Group, Oat Mountain unit 1**—Shaly siltstone, massive- to well-bedded, minor lenses of conglomeratic sandstone; siltstone locally contains microfauna assigned to the Luisian Stage of Kleinpell (1938) suggesting it is an age-correlative of the Calabasas Formation (Saul, 1979).

In the eastern Santa Monica Mountains informal subunits include:

Ttss **Topanga Group, sandstone**—Sandstone, medium- to coarse-grained, well-bedded, light brown and gray (Lamar, 1970).

Ttsl **Topanga Group, siltstone**—Siltstone, well bedded, medium to dark brown, with interbedded sandstone, shale and chert (Lamar, 1970).

Ttcg **Topanga Group, conglomerate**—Conglomerate, massive- to well-bedded, light brown; includes basal breccia locally (Lamar, 1970).

Ttb **Intrusive and extrusive volcanic rocks**—Chiefly basaltic, interlayered with sandstone and shale assigned to the Topanga Group. In part, may be correlative with Conejo Volcanics of central and western Santa Monica Mountains and adjacent areas to the northwest; but includes rocks that are dated as older than the oldest contiguous Conejo (McCulloh and others, 2002). (eastern Santa Monica Mountains, Hoots, 1931; Santa Susana Mountains, Evans and Miller, 1978; northeastern Verdugo Mountains, Oakeshott, 1958).

In the central and western Santa Monica Mountains divisions include:

Tcb **Calabasas Formation, undivided (early late Miocene and late middle Miocene)**—Interbedded impure, clayey to silty sandstone and silty shale, with local beds of sedimentary breccia; sandstone is thin-, medium- and thick-bedded, mostly medium to coarse grained, poorly sorted, commonly with wacke texture, commonly shows graded bedding; shale, locally diatomaceous; may have small phosphatic pellets, locally abundant fish scales, sparse Foraminifera and rust-colored plant casts, some thicker beds contain zones of large ovoid dolomitic concretions; sedimentary breccia, olistostromes incorporating cobble- to large boulder-size clasts of recognizable older Tertiary strata, some as fossil-bearing clasts of Paleocene, Eocene, early Miocene, and middle Miocene strata. Many of the sandstones are lithologically similar to those in the overlying, less-deformed Modelo Formation. Total thickness is about 1,200 m in the type area. The Modelo is unconformable on the Calabasas in the name area, however, west of Malibu Junction and north of the Ventura Freeway the two formations are accordant, the Calabasas is greatly thinned, and grades westward into finer-grained clayey siltstone and shale much like that of the Modelo in the area, and the two formations are distinguished only by differences in foraminiferal fauna. (The Calabasas there contains foraminifera referred to the Luisian Stage of Kleinpell, 1938; the Modelo contains foraminifera referred to the Mohnian Stage of Kleinpell, 1938). The contact relationships with the underlying Conejo Volcanics are marked by extreme variability, ranging from unconformable to accordant and intertonguing, apparently reflecting marine sedimentation, at least partly contemporaneous with the development of a submarine volcanic edifice and associated tectonic disturbance. Intraformational deformation west of Liberty Canyon, the

angular unconformity east of Medea Creek, and the abruptly thinner Calabasas section near and west of Agoura reflect local tectonic activity during deposition; and the volcanic conglomerate is probably significantly younger than most of the Calabasas section to the east. In the west-central Santa Monica Mountains the Calabasas Formation and older strata are involved in major pre-Modelo deformation that includes detachment faulting. Well-defined upper-plate ramps in Trancas and Topanga Canyons show offsets exceeding many hundreds of feet on faults that bend to follow bedding planes, along which intervening beds are missing or thinned, and establish a style of younger-over-older faulting as a significant structural feature. Outcrops where contact relations can be observed in macroscopic detail, and confirm depositional or shear-surface relations, are extremely rare, but where found indicate little discordance at stratigraphic hiatus or local unconformity contacts between pre-Conejo Tertiary Formations. The Paleogene sequence is similar to that in the adjacent Simi Hills and the more distant Santa Ana Mountains, where variations in depositional environments appear to represent epeiric transgressions and regressions. Therefore, we conclude that contacts lacking local exposures of diagnostic depositional character, where significant parts of the section are missing or dramatically thinned, are one or more of a set of detachment faults. The alternative is to infer Paleogene orogenic deformation on a scale not recognized elsewhere in southern California.

Tcbvc **Calabasas Formation, Volcanic conglomerate (late middle Miocene)**—Volcanic conglomerate, mapped by Weber (1984) as basal Calabasas Formation where it rests unconformably on the Chatsworth Formation (Cretaceous) along the south flank of the Simi Hills, and extends northwestward across the Cretaceous-Paleogene sequence at the west end of the Simi Hills. This conglomerate is probably correlative with volcanic conglomerates that locally forms the base of the Calabasas Formation sandstone and shale exposed along and north of the Ventura Freeway in the Agoura area (Blackerby, 1965), and overlying volcanic strata in the Thousand Oaks area (Weber, 1984). In addition to the informal volcanic conglomerate member, five members were named by Yerkes and Campbell (1979).

Tcbs **Calabasas Formation, Stokes Canyon Breccia Member (late middle Miocene)**—Sedimentary breccia consisting of angular boulders and cobbles of redeposited well-cemented sandstone with molluscan faunas diagnostic of the "Martinez" (Paleocene) and "Domengine" (middle Eocene) Stages; the breccia bed is locally as thick as 60 m; underlain and overlain conformably by Calabasas sandstone and siltstone; locally overlain unconformably by basal conglomerate of the Modelo Formation. Thinner, less continuous breccia beds are present at two other horizons nearby. (Stokes Canyon area, northern Malibu Beach and southern Calabasas 7.5’ quadrangles; Yerkes and Campbell, 1979, p. E22; Yerkes and Campbell, 1980).

Calabasas subunits in the upper plate of Malibu Bowl Detachment Fault include:

Tcbmp **Calabasas Formation, Mesa Peak Breccia Member**—Sedimentary breccia consisting of angular boulders and cobbles of volcanic rock in a very coarse-grained sandstone matrix; maximum thickness approximately 288 m. Overlies the Newell Sandstone Member of the Calabasas Formation in the upper plate of the Malibu Bowl Detachment Fault, west central

Malibu Beach 7.5' quadrangle (Yerkes and Campbell, 1979, p. E23; Yerkes and Campbell, 1980).

Tcbn **Calabasas Formation, Newell Sandstone Member**—Poorly sorted turbidite sandstone and interbedded shaly siltstone with large dolomitic concretions; overlies and wedges out westward into Malibu Bowl Tongue of the Conejo Volcanics; maximum thickness approximately 244 m. (Yerkes and Campbell, 1979, p. E23; Yerkes and Campbell 1980).

Tcbd **Calabasas Formation, Dry Canyon Sandstone Member**—Sandstone (proximal turbidites) and subordinate interbedded siltstone, many thin turbidites, locally prominent dolomitic concretions in siltstone; overlies and tongues eastward into Solstice Canyon Tongue of the Conejo Volcanics; underlies and intertongues westward into Escondido Canyon Shale Member of the Calabasas Formation; overlain by, and locally intertongues with, the Malibu Bowl Tongue of the Conejo Volcanics, and locally overlain by the Newell Sandstone member of the Calabasas Formation; locally overlain by Latigo Canyon Breccia Member of the Calabasas Formation; underlain by Ramera Canyon Tongue of Conejo Volcanics; approximate maximum thickness 686 m (Campbell and others, 1996; Yerkes and Campbell, 1979, p. E24; Yerkes and Campbell, 1980).

Tcbl **Calabasas Formation, Latigo Canyon Breccia Member**—Sedimentary breccia, large angular boulders of Sespe Sandstone and fossiliferous Vaqueros sandstone in sandy, tuffaceous or volcanic breccia; intertongues with epiclastic volcanic breccia; approximate maximum thickness 91 m; underlies the Solstice Canyon Tongue of the Conejo Volcanics and overlies the Escondido Canyon shale member of the Calabasas formation (Yerkes and Campbell, 1979, p. E23; Campbell and others, 1996).

Tcbe **Calabasas Formation, Escondido Canyon Shale Member**—Siltstone, mudstone, shale and minor interbedded thin sandstone turbidites; locally prominent dolomitic concretions; tongues eastward into Dry Canyon Sandstone Member of the Calabasas Formation; westward laps onto and intertongues with Ramera Canyon Tongue of the Conejo Volcanics; approximate maximum thickness 276 m; (Yerkes and Campbell, 1979, p. E24; Campbell and others, 1996).

Tco **Conejo Volcanics, undivided (middle Miocene)**—Basalt, andesitic basalt, basaltic andesite, andesite, and dacite in a thick sequence of extrusive volcanic flows, flow-breccias, agglomerates, and epiclastic volcanic breccias, volcanic sandstones and siltstones; thickest (probably in excess of 3 km) where it underlies the north flank of the western Santa Monica Mountains, and thinning eastward to as little as 200 m of interbedded flows and volcaniclastic sedimentary rocks on the nose of the Topanga Anticline; further east the volcanic rocks are thin and discontinuous, and the name has not been extended eastward for more than a mile east of Topanga Canyon Road. The thick sequence shows a crude compositional layering: pillow basalts, pillow breccias, aquagene tuffs, black volcanic sandstones and interbedded black siltstones are common in the basal part of the Conejo, associated with basalt, andesitic basalt, and basaltic andesite flows, breccias, and agglomerates; andesite and basaltic andesite predominate in the central part of the sequence with interlayered andesitic basalt; and an upper zone, dominated by andesitic and basaltic andesite but including dacite flows in some areas as

well as epiclastic volcanic conglomerates containing andesite and dacite clasts. The map by Durrell (1954) called the volcanics that intervene between lower Miocene and upper-middle Miocene sedimentary strata the “Middle Topanga Formation”; but his students Sonneman (1956) and Blackerby (1965) adopted the name "Conejo Formation” and “Conejo Volcanics", following the usage of Taliaferro (1924) for rocks in the Conejo Mountain area. This usage was formalized by Yerkes and Campbell (1979). In the vicinity of boundary between the Triunfo Pass and Point Dume quadrangles the contact with the upper part of the underlying Topanga Canyon and Vaqueros Formations is a buttress unconformity against a degraded half graben or caldera wall that laps eastward conformably onto shelf sediments at a higher stratigraphic level. Weigand and Savage (1993) have summarized the geochemistry of the Conejo Volcanics, comparing them with other southern California Miocene volcanic suites. The range in initial $^{87}Sr/^{86}Sr$ is reported as 0.60294-0.70320, indicating parent magmas derived from the upper mantle without important crustal rock contamination (Weigand and Savage, 1993, p. 105,106). K-Ar ages on plagioclases from basalt and andesite, reported by Turner and Campbell (1979), range from 15.5±0.8 m.y. near the base of the Conejo to 13.9±0.4 m.y. near the top. McCulloh and others (2002, p. 3) have recalculated the older date using updated decay constants to yield a 15.9±0.8 m.y. age.

Along the north flank of the Santa Monica Mountains, lithologic subunits include:

Tcode **Conejo Volcanics, dacite-bearing epiclastic lenses**—Epiclastic volcanic rocks, but including basalt, andesite and dacite pyroclastic flows and flow breccia; forms relatively thin layers and lenses interbedded in lower part of Calabasas Formation, which locally includes volcanic sandstone and volcanic conglomerate (north of Ventura Freeway, Thousand Oaks 7.5’ quadrangle; after Blackerby, 1965).

Tcod **Conejo Volcanics, dacite-bearing upper zone**—Interlayered dacite (including trachytic dacite), andesite and basalt flows and pyroclastics; minor volcanic sandstone. Malibu Junction Member of Conejo Volcanics of Blackerby (1965) (south of Ventura Freeway, Thousand Oaks 7.5’ quadrangle).

Tcoa **Conejo Volcanics, andesitic central zone**—Interlayered porphyritic and microporphyritic andesite, andesitic basalt, and basaltic andesite flows, agglomerates and flow breccias; includes some crystal tuff, vesicular andesite, pyroclastics and volcanic sandstone; includes Ladyface Member and Medea Member of Blackerby (1965), as well as Potrero and Triunfo Members of Sonneman (1956) and Guynes (1959). (Blackerby, 1965 and unpublished mapping 1965-1973; Campbell and others, 1996, and unpublished mapping 1962-1976; Sonneman, 1956; Guynes, 1959; and Weber, 1984). Lithologically recognized subunits, which occur at various stratigraphic levels, and do not form a consistent stratigraphic sequence, include:

Tcoaf **Conejo Volcanics, andesitic central zone, andesitic flows**—Andesite flows, mapped as Potrero Member of the Conejo Formation by Sonneman (1956) and Guynes (1959).

Tcoaa **Conejo Volcanics, andesitic central zone, andesitic agglomerate**—Andesite agglomerate and tuff, mapped as part of Potrero Member of the Conejo Formation by Guynes (1959).

Tcoab **Conejo volcanics, andesitic central zone, andesite breccia**—Andesitic and basaltic breccia and some agglomerate; mostly equivalent to rocks mapped as the Triunfo Member by Sonneman (1956) and Guynes (1959), and includes rocks mapped as Medea Member by Blackerby (1965). (Yerkes and Campbell, 1980; Campbell and others, 1970; Sonneman, 1956; Guynes, 1959; Weber, 1984; and unpublished 1:12,000-scale mapping by R. H. Campbell and B. A. Blackerby, 1967-1972).

Tcob **Conejo Volcanics, basaltic lower zone, basalt and andesitic basalt**—Chiefly basalt, olivine basalt, basaltic andesite, and andesitic basalt; ranges from trachytic olivine basalt to porphyritic quartz andesite; as flows, breccias, agglomerates, pillow basalts, pillow breccias, and basaltic sand and silt; includes Olivine Basalt and Seminole Members of Blackerby (1965); (Malibu Beach, Point Dume, Triunfo Pass, and Thousand Oaks 7.5' quadrangles; Yerkes and Campbell, 1980; Campbell and others, 1996; Blackerby, 1965; Sonneman, 1956; Guynes, 1959; Weber, 1984; and unpublished 1:12,000-scale mapping by R. H. Campbell and B. A. Blackerby, 1962-1976). Lithologically recognized subunits (flows and breccias) are interlayered at various stratigraphic levels in the upper part of the zone, and do not form a consistent stratigraphic sequence; however pillow basalt, pillow breccia, and volcanic sand predominate in the lower part of the zone. Subunits include:

Tcobf **Conejo Volcanics, basaltic lower zone, basalt and andesitic basalt, basalt flows**—Basalt, andesitic basalt and basaltic andesite flows (Blackerby, 1965; Yerkes and Campbell, 1979, 1980; Campbell and others, 1996; Weber, 1984).

Tcobb **Conejo Volcanics, basaltic lower zone, basalt and andesitic basalt, basaltic breccia**—Basalt, andesitic basalt and basaltic andesite breccias; can include some pillow breccia; in part, mapped as Serrano member of Conejo Volcanics by Sonneman (1956) and Guynes (1959). (Sonneman, 1956; Guynes, 1959; Blackerby, 1965; Yerkes and Campbell, 1980; Weber, 1984; Campbell and others, 1996).

Tcop **Conejo Volcanics, basaltic lower zone, pillow basalt**—Basalt pillow lavas, pillow breccias and probable aquagene tuffs; included in Seminole Member mapped by Blackerby, 1965, and Serrano Member mapped by Sonneman, 1956, and by Guynes, 1959. (Sonneman, 1956; Guynes, 1959; Blackerby, 1965; Yerkes and Campbell, 1980; Campbell and others, 1996).

Tcobz **Conejo Volcanics, basaltic lower zone, basaltic sand**—Black basaltic sand and siltstone; included in Seminole Member of Blackerby, 1965. (Blackerby, 1965; Yerkes and Campbell, 1980; Campbell and others, 1996).

In the upper plate of Malibu Bowl Detachment Fault, three stratigraphically distinct tongues of volcanic rocks are interbedded with members of the Calabasas Formation:

Tcom **Conejo Volcanics, Malibu Bowl Tongue**—Andesitic and basaltic flows and flow breccias; underlies and tongues eastward into the Newell Sandstone Member of the Calabasas Formation and overlies the Dry Canyon Sandstone Member of the Calabasas Formation; as much as 143 m thick (Yerkes and Campbell, 1979; Yerkes and Campbell, 1980).

Tcos **Conejo Volcanics, Solstice Canyon Tongue**—Basaltic and andesitic flows, breccias, and tuffs; local water-laid volcanic sandstone; underlies and intertongues eastward into the upper part of the Dry Canyon Sandstone Member of the Calabasas Formation, overlies Latigo Canyon Breccia Member of the Calabasas Formation; as much as 143 m thick (Campbell and others, 1970; Yerkes and Campbell, 1979; Yerkes and Campbell, 1980; Campbell and others, 1996).

Tcor **Conejo Volcanics, Ramera Canyon Tongue**—Basaltic and andesitic breccias, tuff-breccias, and flows(?); minor volcanic sandstone; underlies, and upper part intertongues with lower part of Escondido Canyon Shale Member of the Calabasas Formation; underlain in some areas by shallow marine strata of the Topanga Canyon Formation which is cut out locally by the Malibu Bowl Detachment Fault; as much as 518 m thick. (Campbell and others, 1970; Yerkes and Campbell, 1979; Yerkes and Campbell, 1980; Campbell and others, 1996).

Ti **Intrusive rocks, undivided (middle Miocene)**—Dikes, sills and irregularly shaped intrusive bodies of diabase, basalt, and andesite; commonly pervasively altered and easily eroded, undercutting slopes and, therefore, commonly spatially associated with toes of landslides; sills are larger and more abundant in the Topanga Canyon Formation at shallow stratigraphic depths below the base of the Conejo Volcanics; intrusive along the Malibu Bowl Detachment Fault only where Topanga Canyon Formation and younger strata are carried in the upper plate; (widespread in central and western Santa Monica Mountains; Yerkes and Campbell, 1980; Campbell and others, 1996; Yerkes and Campbell, 1994. In the central and western Santa Monica Mountains these are related to the Conejo Volcanics; however, in the eastern Santa Monica Mountains and elsewhere they may be related to other volcanic centers of roughly the same age (for example, small dikes mapped by Saul (1976) in the Mount Wilson 7.5' quadrangle).

Tid **Intrusive rocks, dacite (middle Miocene)**—Dacite dikes, irregular intrusive bodies in older Conejo rocks, and a plug intrusive into Topanga Canyon Formation; (Dibblee and Ehrenspeck, 1993, p. 89).

Tia **Intrusive rocks, andesitic (middle Miocene)**—Andesitic dikes, sills and irregular intrusive bodies, chiefly sills in Topanga Canyon and Vaqueros Formations, and dikes in older rocks.

Tib **Intrusive rocks, basaltic (middle Miocene)**—Basaltic, diabasic, and gabbroic dikes, sills and irregular intrusive bodies, chiefly sills in Topanga Canyon Formation and following detachment faults, and dikes in older rocks.

Tim **Mixed rocks (middle Miocene and early or early middle Miocene)**—Very fine- to fine-grained basalt, pervasively intrusive into black siltstone and very fine-grained sandstone of the Topanga Canyon Formation on a spacing too intimate to map separately at 1:12,000-scale; (Campbell, unpublished mapping, 1967-1976).

Ttc **Topanga Canyon Formation (middle and early Miocene)**—Marine sandstone, commonly arkosic, with interbedded siltstone, pebbly sandstone and pebble-cobble conglomerate; generally well indurated; recognized only in the central and western Santa Monica Mountains, where it is overlain unconformably by the Conejo Volcanics, and conformably overlies lithologically similar older Miocene and Oligocene strata of the Vaqueros Formation;

elsewhere, correlative strata are included in the undivided Topanga Group, **Tt**. Yerkes and Campbell (1979) formalized the name “Topanga Canyon Formation” and described as members lithologic facies that indicate an eastward shoaling of depositional environments from deeper shelf on the west to shoreface, estuarine, and fluvial deposits, wedging out just east of Santa Ynez Canyon. (Note that the deposition precedes post-volcanic tectonic rotation, so in early middle Miocene time the direction of shoaling was nearly north). North of Castro Peak, where the formation is undivided (**Ttc**), it is as much as 1,070 m thick. West of Santa Ynez Canyon to Malibu Canyon three members are recognized: the Cold Creek (**Ttcc**), Fernwood (**Ttcf**), and Saddle Peak (**Ttcs**) Members (Yerkes and Campbell, 1960). The Fernwood Member represents an estuarine and fluvial depositional environment, and separates shelf marine strata of the underlying Saddle Peak and overlying Cold Creek Members, both of which pinch out west of Topanga Canyon. The Fernwood Member wedges out westward and the two nearshore marine members coalesce just east of Malibu Canyon; therefore, the Formation is undivided from Malibu Canyon west to Zuma Canyon. Interbeds of siltstone and mudstone, suggestive of deepening offshore shelf depositional environments, become progressively thicker westward, and siltstone strata of the Encinal Canyon Member (**Ttce**) predominate west of Zuma Canyon. In and west of Arroyo Sequit some thick sandstone beds become prominent in the upper part of the Topanga Canyon Formation, and are here called the Big Sycamore Member (**Ttcb**).

Ttcc **Topanga Canyon Formation, Cold Creek Member**—Marine sandstone, siltstone, and minor pebbly sandstone; sandstone commonly medium grained, moderately to well sorted arkosic arenite, in laminated and graded beds as much as two meters thick, and locally biotitic. About 707 m thick in the northeast corner of the Malibu Beach 7.5’ quadrangle. Locally abundant molluscan fauna referred to "Temblor Stage" of Weaver and others (1944), including the locality for the “Topanga Canyon fauna” (about 50 molluscan species) of Arnold (1907a); named as a member of the Topanga Canyon Formation by Yerkes and Campbell (1979). Conformably overlies the Fernwood member of the Topanga Canyon formation; overlain, in most places conformably, by Conejo Volcanics. In a few localities in upper Topanga Canyon the Conejo is missing and the Cold Creek Member is accordantly overlain by the Calabasas Formation. Foraminifera from siltstone in upper part assigned to Relizian BFZ. (Yerkes and Campbell, 1980; Campbell, unpublished 1:12,000-scale mapping, 1965-1972).

Ttcf **Topanga Canyon Formation, Fernwood Member**—Paralic, fluvial, estuarine, and marine sandstone, pebbly sandstone, and mudstone, with minor tuff and limestone; interbedded with grayish-red or olive-gray mudstone and, locally, minor vitric rhyolite tuff and algal(?) limestone; fluvial sandstone forms thick lenticular ledge-forming beds and is complexly channeled and crossbedded; locally abundant closely spaced borings normal to sandstone bedding (ophiomorpha?), and rare fragments of bone occur; the shallow-water gastropod Melongena, known only from the provincial middle Miocene, occurs in sandstone on a ridge west of Topanga Canyon (in the Fernwood area) (Yerkes and Campbell, 1979; Yerkes and Campbell, 1980). The Fernwood is overlain conformably by and intertongues into the Cold Creek Member of the Topanga Canyon Formation. The Fernwood overlies the Saddle Peak Member conformably and may intertongue with it. In several parts of the Topanga Canyon drainage area Fernwood strata are cut off down dip by Sespe Formation redbeds along the

Malibu Bowl Detachment Fault or by basalt and diabase intrusive into the fault. Fritsche (1993) and Flack (1993) propose that the Fernwood member should be assigned to the Sespe Formation. However, the Fernwood has nowhere been observed to be in direct depositional contact with Sespe strata (even though short segments of approximately located contact are shown on the map, there is no outcrop exposure of unfaulted contact relationships). Nor does the Fernwood contain any red sandstone, which is characteristic of (though not always present in) the Sespe Formation. Therefore, the usage of the source maps is retained. (Yerkes and Campbell, 1979; Yerkes and Campbell, 1980; Yerkes and Campbell, 1994).

Ttcs **Topanga Canyon Formation, Saddle Peak Member**—Thick-bedded to massive, medium-to coarse grained marine sandstone, pebbly sandstone, and hackly fracturing sandy siltstone, over a 1/2-m-thick basal pebble conglomerate; conformably overlain by the Fernwood Member of the Topanga Canyon Formation; conformably overlies the Piuma Member of the Sespe Formation or its' marine correlative Vaqueros Formation; in places faulted against Sespe and older rocks, or strata of the Calabasas Formation, chiefly along the Malibu Bowl Detachment Fault. A resistant sandstone near the base of the Saddle Peak Member contains an abundant "Temblor" megafauna that includes the gastropod *Antillophos dumbleanus* (Anderson), that is apparently restricted to the middle Miocene; immediately above this bed is a 10-cm thick layer of well-preserved, in part articulated valves of the giant pectinid *Vertipecten nevadanus* (Conrad) (also called *V. bowersi*); the entire fauna is referred to the middle Miocene "Temblor" provincial Stage. Fritsche (1993) has proposed that the Saddle Peak Member be included with the Vaqueros Formation because some elements of the fauna are long ranging and are also found in the Vaqueros, and because closely similar lithofacies are found in both units. However, detailed mapping can carry continuous and overlapping stratigraphic horizons in most areas where the Saddle Peak Member is in contact with underlying Vaqueros, and the two units are mappable separately. Therefore, the usage of the source maps is retained. The unit is about 220 m thick along Piuma Road on the west shoulder of Saddle Peak. (Yerkes and Campbell, 1979; Yerkes and Campbell, 1980).

Ttcb **Topanga Canyon Formation, Big Sycamore Member**—Alternating gray sandstone and dark gray siltstone or silty mudstone, commonly platy to shaly; chiefly mudstone with interbedded thin- to thick-bedded lenticular sandstone in sets that locally coalesce to massive beds; sandstone grain size variable, with local rip-up clasts of shale, and pebbly sandstone with polished, rounded chert pebbles; mudstone interbeds commonly thin-bedded to shaly. A rare occurrence of detrital glaucophane in sandstone is the earliest known north of the Malibu Coast Fault. Sonneman (1954) estimated a total thickness of 2,400 ft. (732 m) to 3,500 ft. (1,066 m). Mapped as the "Upper Member of the Sycamore Formation" by Sonneman (1956); mapped as individual sandstone beds in the "Undivided Topanga Canyon Formation" by Dibblee and Ehrenspeck (1990); here called "Big Sycamore Member of the Topanga Canyon Formation" to follow rules of the North American Code. Fossils include: locally common *Vertipectin Nevandus* at Point Mugu; rare *Turritella Temblorensis* (Sonneman, 1954); and Relizian foraminifera (Sonneman, 1954).

Ttce **Topanga Canyon Formation, Encinal Member**—Chiefly dark gray siltstone or silty mudstone, commonly platy to shaly, but at many localities bedding fissility is obscured by a dominant conchoidal fracture, possibly indicating bioturbation; lenticular dolomitic concretions locally abundant, particularly along locally restricted stratigraphic zones as thick as 60 cm; rare medium-and fine-grained sandstone beds in the Encinal Canyon area (western Point Dume 7.5' quadrangle) increase in abundance somewhat westward in the Triunfo Pass 7.5' quadrangle. The siltstone rests conformably on sandstone of the underlying San Nicholas Member of the Vaqueros Formation, but there is apparent discordance in some places where lack of exposure prevents clear discrimination. The Encinal Canyon Member intertongues with and is overlapped conformably by the Big Sycamore Member of the Topanga Canyon Formation, and unconformably overlain by Conejo Volcanics (see discussion of base of Conejo, above). Poorly preserved foraminifera in two collections from the Encinal Canyon Road exposures reported by Yerkes and Campbell (1979) are assigned to the Relizian(?) stage and Saucesian or Relizian stages of Kleinpell (1938), respectively. Further west, in the Triunfo Pass and Point Mugu quadrangles Sonneman (1956) reports that the "Lower Member of the Sycamore Formation", which is contiguous with the Encinal Canyon Member of the Topanga Canyon Formation (Yerkes and Campbell, 1980), also contained foraminifera assignable to the Relizian Stage. A subsequent collection reported by Flack (1993) is also assigned a late Saucesian to early Relizian age. Flack (1993, p. 46) considers the Encinal Member, as well as the entire Topanga Canyon Formation, to be late early Miocene rather than early middle Miocene. (Campbell and others, 1996; Campbell, unpublished 1:12,000-scale mapping, 1965-1975; Sonneman, 1956; Dibblee and Ehrenspeck, 1990).

Western Los Angeles Basin-Continental Borderland

Tr **Trancas Formation, undivided (middle and early Miocene)**—Marine mudstone, silty shale, claystone, sandstone, and locally prominent sedimentary breccia on Lechusa Point and Point Dume; the breccias are distinctive for their abundant detritus of the Mesozoic Catalina Schist, including glaucophane schist (San Onofre breccia of Woodford and Bailey, 1928). The Trancas has been much deformed in the zone south of the Malibu Coast Fault, and no complete section is known. The Sovereign Oil Company Malibu 1 exploratory well on Point Dume drilled through 290 m of marine sandstone, mudstone, claystone, and sedimentary breccia (San Onofre Breccia) between the base of the Monterey Shale and the underlying Zuma Volcanics, assigned to the Trancas formation by Yerkes and Campbell (1979); (Point Dume and Triunfo Pass 7.5' quadrangles; Campbell and others, 1996; Campbell, 1965-1975, unpublished 1:12,000-scale mapping). The siltstones locally contain abundant foraminiferal assemblages assigned to the Saucesian (lower Miocene) and Relizian or Luisian (middle Miocene) stages of Kleinpell (1938). **Tra**—quartz-bearing calcarenites in the western part of the Point Dume 7.5' quadrangle and eastern part of the Triunfo Pass 7.5' quadrangle are distinctive for the pervasive intergranular disruption that causes original bedding to be completely masked; further west, at Sequit Point, the sandstones are seen to be coarse-grained, cross-laminated calcarenites, composed chiefly of barnacle plates and oyster fragments, with significant areas intruded by sandstone of similar composition but in which the original fabric is no longer visible (inferred

to be a result of liquefaction). An exposure of San Onofre Breccia overlying Zuma Volcanics on the tip of Point Dume, south of the Point fault, is assumed to represent the base of the Trancas Formation in that area. The Trancas may intertongue with both the Zuma Volcanics and the lower part of the Monterey Shale, but is locally unconformably overlain by upper (late Miocene) beds of the Monterey Shale.

Tz **Zuma Volcanics (middle and early Miocene)**—Basaltic, andesitic and dacitic flows, flow breccias, pillow lavas, aquagene tuffs, mudflow breccias, volcanic sand and interbedded mudstone, siltstone, sandstone, minor breccia-conglomerate; all probably deposited in a marine environment; no igneous rocks south of the Malibu Coast Fault are recognizably intrusive into the associated sedimentary rocks; sedimentary interbeds carry foraminifera referred to the Relizian or Luisian Stages (middle Miocene) of Kleinpell (1938). Weigand and Savage (1993), from a study of major element analyses, showed that most of the analyzed samples of Zuma Volcanics fall in the dacite field of the classification of LeBas and others (1986). Plagioclase phenocrysts from basalt near the tip of Point Dume have been dated at 14.6 ± 1 my (Berry and others, 1976). Base not exposed, but an equivalent section in the exploratory well, Sovereign Malibu 1 on Point Dume, is about 430 m (stratigraphic) thick above probable metamorphic basement (Catalina Schist). Although the Zuma and Conejo Volcanics fall within the same range of ages, the overlying and underlying sedimentary strata, and the basement rocks, are significantly different, suggesting that they could be related to different extrusive centers. (Campbell and others, 1970, 1996; Yerkes and Campbell, 1980; and Campbell, unpublished 1:12,000-scale mapping, 1967-1971).

Soledad Basin and San Andreas Fault Zone

Tvz **Vasquez Formation, undivided (early Miocene to Oligocene?)**—Yellowish and reddish sandstone, conglomerate, and interbedded andesite-basalt, lying on pre-Tertiary crystalline basement rocks and unconformably below strata of Tick Canyon Formation; total thickness as much as 3,810 m (Jahns and Muehlberger, 1954). Includes numerous beds and lenses of megabreccia, many monolithologic. Named by Sharp (1936); further described by Jahns (1939). (Dibblee, 1996a,b).

Tvza **Vasquez Formation, andesitic volcanic rocks (early Miocene? to late Oligocene)**—Dark-gray to dark reddish-brown andesite and basaltic andesite, hard, very fine-grained matrix with fine- to medium euhedral phenocrysts of plagioclase feldspar. Occasional flow banding, conglomeratic layering, and some silica-filled amygdules. Outcrops locally exhibit sub-parallel sheet jointing.

Tvzb **Vasquez Formation, basaltic volcanic rocks (early Miocene? to late Oligocene)**—Dark-gray, basaltic to andesitic volcanic rocks. Unit contains small phenocrysts of augite and olivine. Outcrop exposures are highly jointed and resistant, with weathered surfaces dark-gray to dark-brown.

Tvzc **Vasquez Formation, non-marine conglomerate (early Miocene? to late Oligocene)**—Pebble- to cobble fluvial conglomerate and red clayey siltstone. Unit consists of sub-rounded to

rounded clasts of gray, tan, pink, and lavender volcanic rocks. Also contains quartz monzonitic to granodioritic clasts.

Tvzs **Vasquez Formation, sedimentary rocks (early Miocene? to late Oligocene)**—Pebble- to cobble fluvial conglomerate and red clayey siltstone. Unit consists of sub-rounded to rounded clasts of gray, tan, pink, and lavender volcanic rocks. Also contains quartz monzonitic to granodioritic clasts.

Topatopa Mountains and eastern Santa Ynez Range

Trn **Rincon Formation (early Miocene and late Oligocene)**—Marine shale and mudstone with dolomitic and limonitic concretions as much as 0.65 m in diameter (Fillmore 7.5’ quadrangle); foraminiferal faunas referred to the Zemorrian and Saucesian Stages (early Miocene) of Kleinpell (1938); thickness about 275 m. Overlain, apparently accordantly, by shale and mudstone assigned to the lower part of the Modelo formation (which, in this area, is designated middle and upper Miocene), and conformably overlies Vaqueros Formation strata. The type section for the Rincon Formation is approximately 30 mi. to the west in the vicinity of Rincon Point where the name, Rincon Shale, was suggested by Kerr (1931) (south flank of Santa Ynez Mountains, Fillmore and Piru 7.5’ quadrangles; Eschner, 1969). Fritsche (1993) proposed that similar rocks within a similar age-range in the western Santa Monica Mountains (the Encinal Member of the Topanga Canyon Formation and the Danielson Member of the Vaqueros Formation) should be termed "tongues" of the Rincon Formation; however, we have retained the nomenclature of the source maps

Western Santa Monica Mountains, Oak Ridge and eastern Ventura Basin

Tv **Vaqueros Formation, undivided (early Miocene and Oligocene)**—A heterogeneous sequence of thick- and medium-bedded sandstone and interbedded siltstone and mudstone; sandstone ranges from coarse- to very fine-grained, chiefly biotitic arkosic arenites and wackes; siltstone and mudstone interbeds commonly dark gray, but can be greenish or reddish in color; commonly carries *Turritella inezana* and other elements of the "Vaqueros fauna". Although the name was first used in central California (Hamlin, 1904) and subsequently extended on the basis of faunal elements, it has long been used in coastal Southern California, and is used consistently throughout intervening areas, to refer to a well-recognized and widespread, predominantly marine sequence that contains a distinctive molluscan fauna (Loel and Corey, 1932). Since Addicott (1972) noted that the range of the Temblor fauna included the range of the Vaqueros fauna in the Temblor Range type area, some authors (Fritsche, 1993; Dibblee, 1989a) have proposed abandoning the name, Vaqueros, and combining the pre-Conejo post-Sespe strata into a single unit. However, in nearly all the problematical areas there are sufficient continuous or overlapping beds, as well as differences in fauna, to provide a realistic basis for mapping separate formations. In the Santa Monica Mountains a complete section in the vicinity of Castro Peak, where the Vaqueros accordantly overlies the nonmarine Sespe formation, is as much as 760 m thick; east of Malibu Canyon however, shoreface facies intertongue with nonmarine strata of the Sespe Formation, and Vaqueros strata are not present in and east of Topanga Canyon. Along the north side of Simi Valley, Vaqueros strata about 600 m thick lie

accordantly above Sespe redbeds and are overlain by Conejo Volcanics; the Vaqueros wedges-out to the east in the Simi Valley West 7.5' quadrangle. In the Simi Valley area, Squires and Filewicz (1983, Fig. 2) show the Vaqueros as approximately 310 m in thickness, intertonguing with and overlying the Sespe Formation; it pinches out eastward beneath the unconformably overlying Conejo Volcanics. North of Fillmore, the easternmost Vaqueros is about 183 m thick. (Cemen, 1977; Eschner, 1969; Bailey, 1951). Oborne (1993) has described the several interbedded lithofacies that are present to the west of Topanga Canyon and interprets them to represent deposition during a rapid marine transgression from west to east over nonmarine strata of the Sespe. This compilation retains the usage and nomenclature of Yerkes and Campbell, 2005. (western Santa Monica Mountains, western Topatopa Mountains, and north side of Simi Valley; Yerkes and Campbell, 1979; Yerkes and Campbell, 1980; Campbell and others, 1996; Eschner, 1969; Bailey, 1951; Cemen, 1977; Squires, 1983a; Sonneman, 1956; Durrell, 1954). Includes:

Tvn **Vaqueros Formation, San Nicholas Member**—Very thick bedded to massive cliff- and ledge-forming marine sandstone, generally very light gray to pale bluish gray; rare interbeds and partings of siltstone and shale, commonly dark gray. Sandstone, very fine- to very coarse-grained arenite, locally pebbly; thick beds show internal cross lamination, parallel, lamination, and disturbed (burrowed?), laminations; local common barnacle detritus. Generally conformably underlain by the Danielson Member of the Vaqueros Formation; however, locally thinned where it rests on older rocks beneath the Zuma Detachment Fault, as in Encinal Canyon. Conformably overlain by the Encinal Member of the Topanga Canyon Formation. Mapped as "Nicholas Formation" by Sonneman (1956), named for exposures in the vicinity of San Nicholas Canyon (Triunfo Pass 7.5' quadrangle); formalized as a member of the Vaqueros Formation by Yerkes and Campbell (1979). (Campbell and others, 1996; Campbell, unpublished 1:12,000-scale mapping, 1967-1975).

Tvd **Vaqueros Formation, Danielson Member**—Grayish black, very fine-grained, marine sandy siltstone or mudstone, in medium and thin beds, generally with indistinct parallel lamination; fractures commonly conchoidal or irregularly subparallel to bedding, but locally platy or shaly. In San Nicholas Canyon, several prominent interbeds, 1/3 to 1 m thick, of calcareous very fine-grained sandstone and sandy mudstone contain fossil remains of *Turritella inezana* Conrad in such numbers as to locally form biostromes (Yerkes and Campbell, 1979, p. E12). Mapped as "Danielson Formation" by Sonneman (1956), named for exposures on the Danielson Ranch in Big Sycamore Canyon (Triunfo Pass 7.5' quadrangle); formalized as a member of the Vaqueros Formation by Yerkes and Campbell (1979). (Sonneman, 1956; Campbell and others, 1996; Campbell, unpublished 1:12,000-scale mapping, 1967-1975).

Western Santa Monica Mountains, Oak Ridge and eastern Ventura Basin

Ts **Sespe Formation, undivided (early Miocene, Oligocene, and late Eocene)**—A nonmarine "redbed" sequence of sandstone, pebbly sandstone, varicolored mudstone, and pebble-cobble conglomerate; sandstone beds commonly very thick to massive, with strong internal cross lamination; and rare thin interbeds varicolored reddish, greenish and grayish mudstone. The

sandstone beds are characteristically red in color, chiefly as a result of intergranular hematized biotite; several sections include beds that lack the characteristic red color. The only complete section of the Sespe exposed in the Santa Monica Mountains is in the Solstice Canyon-Castro Peak area, where about 1000 m of the nonmarine strata are in depositional contact on (and accordant with) the underlying marine Llajas Formation, and accordantly beneath the overlying marine Vaqueros Formation. Elsewhere in the Santa Monica Mountains, both to the east and to the west, the Sespe is in fault contact with underlying older strata, chiefly along the Zuma Detachment Fault. At the west end of the Simi Hills about 1365 m of Sespe strata lie accordantly above the marine Llajas and unconformably below Conejo Volcanics. Along the north side of Simi Valley, Sespe exposures total as much as 1656 m in thickness in the west (Simi Valley West 7.5' quadrangle), but wedges out to the east, north of Santa Susana Pass (Simi Valley East 7.5' quadrangle). Along the north flank of Oak Ridge the Sespe can be as much as 2135 m thick, based in part on drill-hole data. In the western Topatopa Mountains, north of Fillmore, the Sespe is about 430 m thick between the underlying marine Coldwater Formation and overlying marine strata assigned to the Vaqueros Formation (Fillmore 7.5' quadrangle). The name, Sespe Formation, was introduced by Watts (1897) and further described by Bailey (1947) for exposures in the vicinity of Sespe Creek, north of Fillmore, and has been extended over large parts of coastal southern California by various workers. Generally, it has been applied to a thick nonmarine sandstone, conglomeratic sandstone and siltstone sequence that is underlain by marine Eocene strata and overlain by marine Miocene beds.

Tsp **Sespe Formation, Piuma Member (early Miocene)**—In contrast to the thicker bedded, more coarsely grained sandstone and conglomerate of the undivided Sespe Formation below, the Piuma Member is distinguished by thinner individual beds, sandstone of generally finer grain size, absence of pebble and cobble conglomerate, and greater abundance of interbedded lacustrine or lagoonal siltstone. The member name was formalized by Yerkes and Campbell (1979) for the upper of two tongues of the Sespe that can be easily distinguished where strata of the marine Vaqueros Formation separate them; the Vaqueros wedges out eastward, but the contact between the Piuma Member and the undivided Sespe below can be carried some distance eastward beyond the Vaqueros wedge-out. (Yerkes and Campbell, 1980).

Topatopa Mountains and eastern Santa Ynez Range

Tcw **Coldwater Formation (late Eocene)**—Marine arkosic sandstone and shale, with lenses of pebble conglomerate and oyster reefs; thickness about 390 m. Earliest use of "Coldwater Sandstone Member" by Kew (1924); referred to "Coldwater Formation" by Bailey (1947). (Eschner, 1969).

Tcz **Cozy Dell Formation (late to middle Eocene)**—Well-bedded brown clay shale and mudstone; thickness as much as 600 m. Earliest use of "Cozy Dell Shale " member of the Tejon Formation by Kerr and Schenk (1928); described as "Cozy Dell Shale" by Dibblee (1950). (Eschner, 1969).

Tma **Matilija Formation, undivided (middle to early Eocene)**—Marine sandstone, arkosic, very well indurated, and interbedded mudstone and siltstone. Conformable beneath Cozy Dell Formation; base not exposed in the map area; total thickness exceeds 1 km. Molluscan fossils are of the Tejon Stage (late Eocene); however, interbedded shale contains foraminifera referred to the Ulatisian and Narizian (early to middle Eocene) Stages of Mallory (1959). "Matilija sandstone" member of the Tejon Formation defined by Kerr and Schenk (1928), described as Matilija Sandstone by Dibblee (1950). (Eschner, 1969). Includes:

Tmasl **Matilija Formation, siltstone and shale**—Micaceous shale with thin sandstone interbeds; Foraminifera referred to the Ulatisian and Narizian (middle to early Eocene) Stages of Mallory (1959). (Eschner, 1969).

Santa Susana Mountains, Simi Hills and Santa Monica Mountains

Tl **Llajas Formation (middle to early Eocene)**—Shallow marine, light-gray to yellowish-gray, very fine- to medium-grained sandstone, laminated siltstone and local mollusk coquina beds; interfingers with alluvial conglomerate (Tlc) at the base; sandstone is laminated to bioturbated; moderately indurated (Irvine, 1990, 1991; Squires, 1983b); section is about 1,800 ft. (550 m) thick. Locally contains fossil mollusks assigned to the "Domengine Stage" (Weaver and others, 1944); Figure 3 of Squires (1983b) suggests the basal portion corresponds to the upper "Capay Stage". As summarized by Squires (1983b), the Llajas section in the Simi Valley area was originally assigned to the "Tejon" or "Meganos" Formations (e.g. Kew, 1919, 1924); subsequently assigned informally to the Llajas Formation by Schenck (1931) and McMasters (1933); more formally named by Cushman and McMasters (1936) for surface outcrops at the type section on the northwest side of the north branch of Llajas Canyon (now known as Chivo Canyon and formerly known as "Oil Canyon"), and from corehole data obtained from the nearby Tapo No. 42 oil well, all located on the northeast side of Simi Valley) (Simi Valley East, Oat Mountain, Thousand Oaks 7.5' quadrangles, and correlative strata in the Point Dume, Malibu Beach, and Topanga 7.5' quadrangles). Includes:

Tlc **Llajas Formation, basal conglomerate**—Alluvial to shallow marine, light-brown to reddish-brown conglomerate interbedded with subordinate, poorly sorted, generally massive sandstone (Irvine, 1990); conglomerate is typically unstratified, ungraded, clast supported, and poorly sorted; clasts are typically well rounded, cobble size, and composed dominantly of quartzite with lesser amounts of granitic, volcanic and metamorphic rocks (Squires, 1983b). Squires (1983b) interprets this facies as a coastal alluvial fan or fan delta deposit. This unit defines the base of Llajas strata relative to the underlying Santa Susana Formation in the area northeast of Simi Valley (Evans and Miller, 1978).

San Gabriel Mountains

Tj **Juncal Formation (late early Eocene)**—Marine, brown amalgamated sandstone beds with interbedded conglomeratic sandstone, conglomerate and siltstone exposed in Elsmere Canyon (San Fernando 7.5' quadrangle); moderately to well cemented; clasts include exotic purple volcanic porphyry and local large siltstone rip-up clasts, and range up to boulder size. The coarse-

grained units are interpreted as turbidity current deposits in a middle- to upper-fan submarine fan depositional environment (Squires, 2008). The Elsmere Canyon section has a measured thickness of about 520 m (Squires, 2008) and it locally contains fossil mollusks originally assigned to the "Domengine Stage" of late early to early middle Eocene age (Weaver and others, 1944); however, detailed studies by Squires (2008) suggest the section at Elsmere Canyon represents the transition from the "Domengine Stage" to the underlying "Capay" Stage, at an age of about 50.5 Ma. The Eocene strata at Elsmere Canyon were first assigned to the "Domengine formation" by Brown and Kew (1932) and this usage was followed by early workers in the area (e.g. Oakeshott, 1950, 1958), and this usage was followed on Version 1.0 of the Los Angeles 30'x60' geologic map (Yerkes and Campbell, 1995). The Elsmere section was left unnamed by Winterer and Durham (1962), Kern (1973), and Dibblee (1991). Some subsequent workers assigned the name "Llajas Formation" to this section (e.g. Seedorf, 1983 and Yeats and others, 1994). Squires (2008) re-evaluated the past nomenclature and conducted additional field studies, and concluded the Elsmere Eocene section is more consistent lithologically with exposures of Juncal Formation mapped to the northwest in the Piru Creek area (Squires, 1987) rather than the type Llajas section, and the Piru and Elsmere sections may have originally been contiguous (Yeats and others, 1994).

The term "Martinez Formation" was previously retained on Version 1.0 of the Los Angeles 30x60' sheet for coarse-grained marine greenish-black to light olive-gray sandstone, with thin interbeds of black shale, and lenticular beds of well-cemented conglomerate of Eocene or Paleocene age mapped as fault-bounded slivers along the San Gabriel Fault between Bear Divide and Tujunga Canyon on the Sunland and San Fernando 7.5' quadrangles (Oakeshott, 1958; Yerkes and Campbell, 2005); clasts reportedly include exotic volcanic porphyry. The term "Martinez Formation" was imported from a type locality in the San Francisco Bay area; the term "Martinez" now generally refers to a Paleocene molluscan stage. Assignment of this section to the "Martinez Formation" was reportedly based on lithologic similarity with "Martinez" strata mapped in the Tejon quadrangle (Oakeshott, 1958) and on the discovery of the age-diagnostic fossil *Turritella pachecoënsis* (Clements and Oakeshott, 1935); however, use of the term "Martinez" has generally been abandoned as a lithologic formation name in southern California. Squires (pers. comm. 2014) notes that the reported specimens of fossil *Turritella* cannot be located for review and additional specimens could not be found during recent field studies; based on field observations of the stratigraphy and presence of exotic volcanic porphyry clasts, Squires suggests that the fault-bounded slivers may actually be part of the Juncal Formation; the fault-bounded slivers are therefore queried as Juncal Formation herein.

Santa Susana Mountains, Simi Hills and Santa Monica Mountains

Tss **Santa Susana Formation (early Eocene to late Paleocene)**—Marine clay shale and conchoidally fractured mudstone and siltstone with interbeds of fine- to medium-grained sandstone and lenses of pebble-cobble conglomerate; gray limestone concretions common in shale; locally contains foraminifera; locally abundant mollusks diagnostic of the "Meganos" and "Martinez" Stages (Saul, 1983); thickness as much as 1,000 m in the Simi Hills; unit thickness varies laterally and rapid lateral facies changes are common across map area. Named by Nelson (1925) for exposures in the Simi Hills near the town of Santa Susana. As

summarized by Parker (1983, 1985), lower Tertiary strata in the Simi Hills were originally correlated and assigned to the "Martinez and/or Meganos Formations" by early workers, including Waring (1914, 1917), Kew (1919, 1924), and Clark (1921). Nelson (1925) raised the "Martinez Formation" to group status and subdivided it into the Simi Conglomerate, Las Virgenes Sandstone, and the Martinez marine member, overlain by the Santa Susana Formation. Most literature published to date follows some form of Nelson's terminology, but the placement of contacts varies considerably among different authors. Parker (1983, 1985) modified Nelson's Santa Susana Formation to include the underlying Martinez marine member, thereby encompassing all strata above the Simi Conglomerate and Las Virgenes Sandstone and below the Llajas Formation in the Simi Hills and northeastern Simi Valley. Parker and other authors abandoned "Martinez Group" and "Martinez marine member" because "Martinez" is a molluscan Stage name, imported from a central California type locality, and no longer considered appropriate to use as a formation name for this interval. Colburn and others (1988) and Colburn and Novak (1989) extended Parker's nomenclature to correlative rocks in the Santa Monica Mountains and included beds mapped as Coal Canyon Formation by Yerkes and Campbell (1979, 2005) in the Santa Susana Formation. Distribution of lower Tertiary strata in the Simi Valley area on this map is based on Squires (1983a), which includes Parker's nomenclature and contacts. Parker described the lower Tertiary units in terms of western and eastern facies based on the location of the stratigraphic sections relative to the "Runkle Canyon fault" (Squires, 1983a). The western facies of the Santa Susana Formation in the Simi Valley area (Simi Valley East, Calabasas and Thousand Oaks 7.5'quadrangles) overlies the Las Virgenes Sandstone with a gradational to sharp contact and is disconformably overlain by the Llajas Formation. It generally consists of a lower unit of densely bioturbated, fossiliferous, fine- to medium-grained sandstone and an upper unit dominated by poorly fossiliferous fractured mudstone and siltstone interbedded with subordinate sandstone and minor conglomerate. The lower unit represents transition zone and offshore to shelf deposits and the upper unit represents deposition within a slope environment. The eastern facies overlies the Simi Conglomerate with a gradational or sharp contact and is overlain disconformably by the Llajas Formation. The eastern facies is more variable, but generally consists of fractured mudstone and siltstone similar to the western facies with discontinuous interbeds of sandstone and conglomerate. East of Meier Canyon, mudstone and siltstone are present in the lower half and sandstone and conglomerate present in the upper half. Sandstone occurs as discontinuous lenses in conglomerate and in beds up to 20 meters thick. Near Runkle Canyon, sandstone occurs as thin interbeds within the mudstone and siltstone and in tongues up to 150 m with locally abundant megafossils occurring in layers within concretionary beds. Northeast of Simi Valley in Poison Oak Canyon, beds are dominantly mudstone interbedded with minor sandstone above two tongues of Simi Conglomerate. These beds represent inner fan deposits. Interbedded sandstone and conglomerate near Meier Canyon represent the coarse portion of an inner fan and slope deposits. The uppermost portion of the Santa Susana Formation in both the western and eastern facies consists of sandstone with megafossils and microfauna indicative of a shelf environment and may record a basin filling and shoaling event prior to the deposition of the nonmarine basal Llajas conglomerate., In the Santa Monica Mountains, Santa Susana strata

include marine sandstone, pebble conglomerate, siltstone and algal limestone. Sandstone is very fine to medium grained, poorly to well sorted, consisting of subrounded quartz and feldspar grains in a sparse clay matrix, locally biotitic; locally contains abundant mollusks; beds commonly are thick and locally have graded upper parts and sharp upper contacts. Siltstone and silty claystone are present locally in the upper part of the formation; closely jointed, conchoidal fracture, and containing abundant biotite; local partings of fine-grained silty biotitic sandstone, and calcareous beds or concretions as thick as 15 cm and as long as 1 m. Pebble-cobble conglomerate forms resistant steep slopes in Carbon and Topanga Canyons; in beds as much as 7 m thick with scattered pebbles, boulders, slabs, and interbeds of mudstone and medium-to coarse-grained sandstone. The Yerkes and Campbell (2005) map shows the Coal Canyon Formation to be about 335 m thick in Solstice Canyon, the only complete section exposed in the Santa Monica Mountains. The thickness summed from incomplete sections in the Carbon Canyon-Topanga Canyon area is as much as 450 m. Commonly carries a molluscan fauna that includes the Martinez-Stage gastropods *Turitella pachecoensis* and *Mesalia martinezensis* (Gabb, 1869). Colburn and others (1988) and Colburn and Novak (1989) prepared five stratigraphic columns and detailed geologic maps of the section localities along the axis of the Santa Monica Mountains from Solstice Canyon in the west to Runyon Canyon near Hollywood and correlated Simi Conglomerate, Las Virgenes Sandstone, and Santa Susana Formation strata. The Las Virgenes Sandstone and Simi Conglomerate are not separately delineated on the current version of the Los Angeles compilation map in the central and eastern Santa Monica Mountains (Malibu Beach, Topanga, Beverly Hills, and Hollywood 7.5’ quadrangles) and Simi Conglomerate and Las Virgenes Sandstone strata mapped by Colburn and Novak (1989) are included in Santa Susana Formation in these areas. Yerkes and Campbell (1979) mapped the Simi Conglomerate in Solstice Canyon (Point Dume 7.5’ quadrangle), but did not recognize the Las Virgenes Sandstone in the Solstice Canyon section, and included most of that interval in the Simi Conglomerate. In the Santa Monica Mountains, the Santa Susana Formation overlies and interfingers with the nonmarine Las Virgenes Sandstone (included in Simi Conglomerate on this map) or overlies the late Cretaceous Tuna Canyon Formation; the relations are generally accordant but locally unconformable. In Solstice Canyon, the Santa Susana Formation is overlain disconformably(?) by marine strata of Eocene age. (Squires, 1983a; Yerkes and Campbell, 1980; Campbell and others, 1996). Includes:

Tssl **Santa Susana Formation, limestone**—Algal limestone occurs as scattered lenses and pods in siltstone sequences east of Topanga Canyon, most prominently in the eastern wall of Santa Ynez Canyon.

Santa Susana Mountains, Simi Hills and Santa Monica Mountains

Tlv **Las Virgenes Sandstone (early(?) Paleocene)**—Nonmarine to marine light-gray to yellowish orange, predominantly medium- to coarse-grained weakly to moderately indurated sandstone with green interbedded mudstone and red-bed mudstone, and minor pebble conglomerate; megafossils and burrows are present in the upper part of the section at Bus Canyon; thin sequence, locally as thick as 195 m near Bus Canyon in the Simi Hills, but thins westward to zero; originated as sandy, braided alluvial and meandering stream deposits on a coastal plain;

upper part represents nearshore marine deposits (Parker, 1983); conformably overlies Simi Conglomerate and is overlain by and interfingers with the Santa Susana Formation. Named by Nelson (1925) for exposures near Las Virgenes Canyon in the Simi Hills. Colburn and others (1988) and Colburn and Novak (1989) correlated Las Virgenes Sandstone from the Simi Hills to five localities in the Santa Monica Mountains. These strata are included in the Santa Susana Formation on the current Los Angeles compilation map in the central and eastern Santa Monica Mountains (Malibu Beach, Topanga, Beverly Hills, and Hollywood 7.5' quadrangles). Yerkes and Campbell (1979, 2005) did not recognize the Las Virgenes Sandstone in the Solstice Canyon section (Point Dume 7.5' quadrangle), and included most of that interval in the Simi Conglomerate, including distinctive pisolite-bearing beds that Colburn assigned to the Las Virgenes Sandstone. Pisolite-bearing red beds are also mapped in the Bus Canyon section in the Simi Hills by Parker (1985), but he included the beds in the Simi Conglomerate. (Squires, 1983a).

Tsi **Simi Conglomerate, undivided (Paleocene)**—Thin, predominantly nonmarine cobble-boulder conglomerate mapped at the base of the Tertiary sequence in the Simi Hills, the Santa Monica Mountains, and northeast of Simi Valley. The conglomerate is poorly bedded, weakly to moderately indurated and contains abundant well-rounded, polished cobbles and boulders of quartzite, granitic, rhyolitic, and gneissic rocks in conglomeratic, coarse-grained sandstone. Distribution of lower Tertiary strata in the Simi Valley area shown on this map is based on Squires (1983a), which includes Parker's (1983, 1985) nomenclature and contacts. Parker described the lower Tertiary units in terms of western and eastern facies based on the location of the stratigraphic sections relative to the "Runkle Canyon fault" (Squires, 1983a). According to Parker, Simi Conglomerate west of the Runkle Canyon fault (Squires, 1983a) represents alluvial fan and braided river deposits and Simi Conglomerate east of the Runkle Canyon fault in Runkle and Meier Canyons and northeast of the Simi Valley represents channel and inner fan facies of a deep-sea fan, based on observed sedimentary structures and microfaunal studies summarized by Parker (1983, 1985). The marine conglomerate included by Parker in the Simi Conglomerate is considered by other authors to be part of the Santa Susana Formation or an unnamed Paleocene marine unit (Hanson, 1981).Yerkes and Campbell (1979) tentatively correlated beds described in the Simi Hills by Nelson (1925) as the Simi Conglomerate with lithologically similar beds in the Solstice Canyon area of the Santa Monica Mountains, and the correlation is supported in subsequent detailed petrographic work by Colburn and Novak (1989). In Solstice Canyon (eastern Point Dume 7.5' quadrangle) the conglomerate includes a 1-m-thick bed of brick-red pisolitic clayey sandstone, which Colburn and Novak (1989) include in the Las Virgenes Sandstone. Simi Conglomerate beds mapped by Colburn and Novak (1989) in the central and eastern Santa Monica Mountains (Malibu Beach, Topanga, Beverly Hills, and Hollywood 7.5' quadrangles) are included in the Santa Susana Formation on the current Los Angeles compilation map. Correlative strata in the Santa Susana Mountains, mapped as "Martinez Formation" by Evans and Miller (1978), are here included with the Simi Conglomerate. Evans and Miller (1978) recognized three local lithologic members.

Tsic **Simi Conglomerate, conglomeratic member**—Massive, yellowish brown pebble to cobble conglomerate with numerous brownish sandstone lenses as much as 1 m thick and continuous

for a few tens of meters along strike. Locally contains molluscan fauna referred to the Martinez Stage (Paleocene) (Evans and Miller, 1978).

Tsis **Simi Conglomerate, shale member**—Light olive gray micaceous siltstone, silty shale, and shale with local thin interbeds of brown, medium- to coarse-grained sandstone. Dark gray limestone occurs in the shale as thin, discontinuous beds as well as small pods and lenses (Evans and Miller, 1978).

Tsia **Simi Conglomerate, sandstone member**—Massive, gray to brownish, coarse- to very coarse-grained sandstone, cemented by silica and hydrous iron oxides, with thin interbeds of micaceous siltstone and lenses of boulder, cobble and pebble conglomerate; locally strongly cemented by calcite (Evans and Miller, 1978).

Santa Susana Mountains, Simi Hills and central and western Santa Monica Mountains

Kc **Chatsworth Formation (late Cretaceous)**—Dominantly turbidite sandstone, massive, thick-bedded, medium- to coarse-grained, well-cemented; conglomeratic sandstone with rounded, polished clasts of quartzite, porphyry and granitic rocks; with minor siltstone and conglomerate. Molluscan faunas include the ammonite *Metaplacenticeras californicum* and the gastropod *Tuttitella pescaderosensis*, referred to the Campanian or Maestrictian (late Cretaceous) Stages (Popenoe, 1973; Saul and Alderson, 1981); benthic foramifera from mudstones in the lower-middle part of the sequence are referred to the late Campanian. Exposed thickness exceeds 1830 m; base not exposed nor drilled; overlain with slight unconformity by Paleocene strata along north side of the Simi Hills, elsewhere, as along the south flank of the Simi Hills, unconformably overlain by Miocene beds. The name, Chatsworth Formation was introduced and defined by Colburn and others (1981) for rocks in the eastern Simi Hills near Chatsworth, that were previously mapped as “Chico Formation” or as unnamed “Upper Cretaceous Rocks” (“Chico” is a molluscan Stage name imported from central California). (Weber, 1984).

Central and western Santa Monica Mountains

Kt **Tuna Canyon Formation, undivided (late Cretaceous)**—Marine sandstone, siltstone and conglomerate. Sandstone, thick-bedded to very thick-bedded, laminated and graded arkosic wacke (turbidite); locally containing abundant fragments of black slate(?); convolute lamination in some beds, load casts, low-angle cross-lamination, or concentrations of carbonized plant fragments or mica. Fossiliferous sandstone and siltstone are present locally as interbeds or thick lenses; in Las Flores Canyon, contains several beds of olive-gray siltstone that locally contain foramifera. The Tuna Canyon Formation is nowhere completely exposed in the Santa Monica Mountains; the maximum exposed thickness, in the Pena Canyon-Tuna Canyon area, is nearly 800 m. East of Santa Ynez Canyon rests on nonmarine red conglomerate (Trabuco Formation, late Cretaceous) and the Santa Monica Slate (late Jurassic). The formation is overlain disconformably (?) by the Simi Conglomerate in Solstice Canyon, and elsewhere by a basal conglomerate of the Coal Canyon Formation (Paleocene). In several places it contains the Campanian ammonite *Metaplacenticeras sp.*; foramifera faunas are referred to zones D-2, E, and F-1 (Maestrictian or Campanian - late Cretaceous) of Goudkoff (1945). Named by Yerkes

and Campbell (1979) to replace the name “Chico”, which was imported from central California and used on earlier maps in the Santa Monica Mountains. (central and eastern Santa Monica Mountains; Campbell and others, 1996; Yerkes and Campbell, 1980; Alderson, 1988; Hoots, 1931). East of Santa Ynez Canyon the formation was subdivided by Alderson (1988) into four informal members:

Kte **Tuna Canyon Formation, informal member 'e'**—Greenish-gray shale with interbedded coarse-grained sandstone in the upper part.

Ktd **Tuna Canyon Formation, informal member 'd'**—Fine-grained, thick-bedded, fossiliferous sandstone.

Ktc **Tuna Canyon Formation, informal member 'c'**—Pebble-cobble conglomerate and minor sandstone.

Ktb **Tuna Canyon Formation, informal member 'b'**—sandstone with minor conglomerate and black shale, carrying Turonian and Coniacian ammonites.

Ktr **Trabuco Formation (late Cretaceous)**—Conglomerate with well-rounded, polished pebbles, cobbles and boulders of varicolored quartzite, porphyry, granite, basalt, and with angular chips of black slate in a matrix of soft, clayey, coarse-grained to pebbly grit. Thickness estimated at 225 m; unconformably overlies Santa Monica Slate. Name applied by Durrell (1954) for rocks of similar composition and stratigraphic position in the type area in the Santa Ana Mountains, where it was named by Packard (1916); correlation reiterated by Colburn (1973). (Yerkes and Campbell, 1980; Hoots, 1931).

Kgr **Granitic rocks (late Cretaceous)**—Includes a variety of plutonic igneous rocks ranging from quartz monzonite and granodiorite to tonalite, quartz diorite, and diorite; chiefly quartz diorite: intrudes Santa Monica Slate in the eastern Santa Monica Mountains (Durrell, 1954).

San Gabriel and Verdugo Mountains

Kgl **Granitic rocks, leucocratic granodiorite (late Cretaceous)**—Light gray to buff, fine- to medium- grained granodiorite; intrudes all other crystalline rocks in area south of south branch of the San Gabriel Fault (Smith, 1982).

Kgd **Granodiorite (Cretaceous)**—Light-gray to dark-gray, medium-grained granodiorite. Unit includes well-foliated, gneissic mafic enclaves. In thin section, samples have some hornblende, apatite, euhedral zircons, and biotite although much is altered to chlorite. Some myrmekitic texture observed in plagioclase feldspars. Exposed in northeast Pacifico Mountain quadrangle. Mapped as qd by Barrows and others (1985) and Dibblee (1997); described by Olson and Hernandez (2013) on map of adjacent Palmdale quadrangle.

Kto **Tonalite (late Cretaceous)**—Mapped by Jahns and Muehlberger (1954) as “granite and other quartz-bearing plutonic rocks”; these rocks are compositionally tonalite (D. M. Morton, oral communication, 2003) in the IUGA classification (Streckheisen, 1973).

Ktoqd **Tonalite and quartz diorite (late Cretaceous)**—Mapped by Morton (1973) as predominantly quartz diorite, grading to granodiorite, quartz monzonite and diorite; compositionally mostly

tonalite (D. M. Morton, oral communication, 2003) in the IUGA classification (Streckheisen, 1973).

Ktowd **Tonalite (Wilson Diorite of Miller, 1934) (late Cretaceous)**—Designated granodiorite and quartz diorite on source maps; identified as mostly tonalite (D. M. Morton, oral communication, 2003) in the IUGA classification (Streckheisen, 1973).

Kgrd **Granodiorite**—Gray medium to coarse grained granodiorite with quartz diorite and granite. Described as Granodiorite by Oakeshott (1958). Includes rocks mapped as the Mt Josephine Granodiorite by Carter (1980). Mostly massive, but commonly gneissoid near contacts with older rocks; locally carries large inclusions and pendants of gneiss and Placerita metasediments. (Oakeshott, 1958, Carter, 1980).

Kp **Pelona Schist (Late Cretaceous to Paleocene?)**—Greenish-gray chlorite-albite, actinolite-albite, quartz-albite, and albite-talc schists, locally interbedded with metavolcanics and brown to black quartzites; a thick, isoclinally(?) folded sequence. The protolith of the Pelona and its correlative Orocopia Schist was presumably deposited during the mid-Mesozoic, recrystallized during burial to depths of 25-35 km, and later thrust beneath western North America at rates > 4 mm/y on the Vincent thrust. Named by Hershey (1902a) for outcrops on the Sierra Pelona ridge. (Ehlig, 1981, p. 266; Jacobson, 1990; northern Mint Canyon 7.5' quadrangle, map after Jahns and Muehlberger, 1954).

Jeg **Echo granite (Jurassic)**—Coarse-grained, pinkish-orange granite and monzogranite; medium-grained, xenomorphic, inequigranular, and showing protoclastic granulation in thin section (Miller, 1946). Determined to be Jurassic in age by Barth (2008). Named by Miller (1934). (Smith, 1986).

Eastern Santa Monica Mountains

Jsm **Santa Monica Slate, undivided (late Jurassic)**—Black slate, sheared metasiltstone, and fine-grained metagraywacke; intensely jointed, isoclinally(?) folded; intruded by Cretaceous granitic pluton forming contact auriole zones of phyllite and spotted cordierite slate; rare pelecypod fragments indicate a late Jurassic age in part (Imlay, 1963). Named by Hoots (1931, p. 88) (Hoots, 1931). Includes:

Jsms **Santa Monica Slate, spotted slate**—Spotted with large crystals of cordierite; outer zone of contact aureole with nearby granitic intrusive rocks; grades to unspotted slate through a zone in which individual spots become progressively smaller outward (Hoots, 1931).

Jsmp **Santa Monica Slate, phyllite**—Chiefly mica schist and dark gray phyllite; forms inner zone of contact aureole with adjacent granitic intrusive (Hoots, 1931).

San Gabriel and Verdugo Mountains

Mzdbh **Biotite-hornblende diorite (Mesozoic?)**—Medium- to dark-gray, medium-grained biotite-hornblende monzodiorite; includes scattered small bodies of older brownish-gray coarse-grained weakly gneissic biotite quartz monzonite; intruded by leucocratic granodiorite (Smith, 1986).

Mzdhb **Hornblende-biotite diorite (Mesozoic?)**—Medium-gray, medium-grained hornblende- biotite diorite; intruded by coarse-grained hornblende diorite and younger leucocratic granodiorite (Smith, 1986).

Mzqdb **Biotite-quartz diorite (Mesozoic?)**—Medium- to dark gray, medium grained quartz diorite; slightly gneissic. Locally contains inclusions of coarse-grained quartz diorite a few m across, and small elongate bodies of marble, quartzite, and schist of Paleozoic (?) age (Smith, 1986).

Mzmg **Biotite Monzogranite (Mesozoic)**—Light gray fine to coarse grained generally non-porphyritic monzogranite. Locally includes granodiorite. Foliated to locally gneissic. Mapped by Smith (1986) as leucogranitic and metamorphic complex. (Smith, 1986; Powell and others 1983).

Mzmgp **Porphyritic Biotite Monzogranite (Mesozoic)**—Light gray fine to coarse grained generally non-porphyritic Monzogranite. Locally includes granodiorite. Foliated to locally gneissic. Mapped by Smith (1986) as leucogranitic and metamorphic complex. (Smith, 1986; Powell and others 1983).

Mzd **Biotite-Hornblende Quartz Diorite, Diorite, and Gabbro (Mesozoic)**—Dark gray fine to coarse grained diorite. Locally includes tonalite and granodiorite. Foliated. Mapped by Saul (1976) as diorite. (Saul, 1986; Powell and others 1983).

Mzhd **Hornblende Diorite (Mesozoic)**—Gray, medium- to coarse-grained hypidiomorphic granular diorite. (Smith, 1986).

Mza **Alaskite (Mesozoic?)**—Salmon-pinkish-gray, medium-grained, mildly gneissic syenogranite. Forms long thin klippe over a much larger mass of granitic rock (Smith, 1986).

Mzh **Hornblendite (Mesozoic)**—Melanocratic coarse-grained hornbledite (Powell and others, 1983).

Mzm **Mylonite (Mesozoic)**—Gray fine-grained to microcrystalline mylonite. Mapped by Smith (1986) as siliceous metasedimentary rock. (Powell and others, 1983; Smith 1986).

Mzdg **Diorite gneiss (early to middle Mesozoic)**—Dark-colored gneisses including metadiorites, massive hornblende diorite, and amphibolite and biotite schists (60-80% plagioclase, 5-15% quartz, 5% or less potassium feldspar, locally as much as 30% biotite and locally as much as 10% brown hornblende); intrudes the Placerita Formation and intruded by Cretaceous granitic rocks; (Oakeshott, 1958).

TRlgd **Mount Lowe intrusive suite, undivided (Triassic)**—A compositionally layered pluton exposed over a large area in the western San Gabriel Mountains and northeastern Soledad basin (studied and described by Ehlig, 1981); varies from hornblende diorite and quartz diorite near the base to albite-rich granite and syenite in the upper part; large phenocrysts of hornblende, orthoclase and garnet contribute to distinctive appearance (pebbles and cobbles are readily recognizable as clasts in younger gravel deposits); metamorphosed to lower amphibolite facies and upper amphibolite facies (grade apparently varies with proximity to Cretaceous intrusive rocks); average composition 60-90% feldspar, of which plagioclase (oligoclase to albite) is

most abundant and orthoclase occurs chiefly as phenocrysts, quartz ranges from a trace to as much as 25 %, averages about 10% (Ehlig, 1981). Initially named Mount Lowe Granodiorite by Miller (1926 abstract), subsequently termed Lowe Granodiorite by Miller (1934, 1946); renamed Mount Lowe intrusion by Barth and Ehlig (1988). The common usage of most source maps has been retained in this map compilation. A U-Pb age on zircon is reported as 220 ± 10 my (Silver, 1971), and a Rb-Sr whole rock age of 208 ± 14 my reported by Joseph and others (1982). Joseph and others (1982) also report a high (800-1,100 ppm) Sr content, a low initial ^{87}Sr-^{86}Sr ratio of 0.70456 ± 0.00003, and a high alkali content ($Na_2O = K_2O \sim 10$ wt.%). More recently, Barth and others (1990) report a U-Pb zircon age of 218 my. Subunits include:

TRlgb **Mount Lowe intrusive suite, biotite-orthoclase facies**—As much as 10 percent biotite in a nearly white granular plagioclase and subordinate (less than 25 percent) quartz matrix. Has orthoclase phenocrysts; hornblende phenocrysts prominent in other subunits are absent, although a few hornblende-bearing layers occur in the lower part of this subunit (Dibblee 1996, 2001; Ehlig, 1981 and unpublished).

TRlgdp **Mount Lowe intrusive suite, Porphyritic facies**—Orthoclase phenocrysts in granular matrix of plagioclase and subordinate quartz; garnet also occurs as small crystals concentrated in veinlets (Dibblee 1996, 2001; Ehlig, 1981 and unpublished).

TRlgdh **Mount Lowe intrusive suite, orthoclase-hornblende facies**—Light gray hornblende diorite (Dibblee 1996, 2001; Ehlig, 1981 and unpublished).

TRlgm **Metamorphosed Mount Lowe intrusive suite (Cretaceous and Triassic)**—Relatively uniform light-colored orthogneiss containing porphyroblasts (relict phenocrysts) of hornblende and, less commonly, potassium feldspar in a plagioclase and quartz matrix. Parent plutonic rock is (Triassic) Lowe Granodiorite and was metamorphosed during a Cretaceous orogenic event (Morton, 1973a, p. 9; and D. M. Morton, oral communication, 2003).

TRhdg **Hornblende diorite gabbro**—dark to very dark gray, medium-grained hornblende diorite gabbro. Massive to locally foliated. (Dibblee 1996, 2001; Ehlig, 1981 and unpublished).

MzPzsp **Serpentinite (Mesozoic or Paleozoic)**—Light to dark green, well foliated, sheared and slickensided serpentinite, altered peridotite (chiefly augite and olivine); slickensided fragments up to boulder size; boundaries intensely sheared and relations to adjacent rocks obscure (Barrows and others, 1975).

Pzgn **Gneiss complex (Paleozoic?)**—Feldspathic gneisses, including granitic to granodioritic augen gneisses, gneissic intrusive rocks of granitic to dioritic composition, amphibole-rich gneiss, and local interlayered schist, quartzite, amphibolite, and marble; according to Jahns and Muehlberger (1954), many of the gneisses are of hybrid origin, and some may be parts of the Placerita Formation that have been intimately injected by younger igneous material.

Pzp **Placerita Formation (Paleozoic)**—Metamorphosed sedimentary rocks, including marble, dolomite, feldspathic gneisses, graphitic marble, quartzite, calcic pyroxene hornfels and a variety of schists including feldspar-tremolite, graphite-tremolite, graphite-biotite-feldspar, and tremolite-talc; the various schists and gneisses occur as septa and pendants of all sizes in a

granodioritic host rock, along with diorite gneisses and migmatites. The best-preserved section may be as much as 600 m thick. Named by Miller (1934), for exposures in Placerita Canyon, the type locality. The age indicated by Oakeshott (1958) is pre-Cretaceous; however, Morton (oral communication, 2003) indicates the age is Paleozoic. (Central Sunland 7.5' quadrangle, Oakeshott, 1958; southern Mint Canyon 7.5' quadrangle, Saul and Wooton, 1983).

Pgn **Gneiss (Proterozoic?)**—Alternating discontinuous dark brown biotite-rich and light-colored quartz-feldspar-rich layers and lenses; layers generally about an inch thick; sheared, as expressed by an intricate structure of gneiss lenses with common local small microscopic tight flow-type folds. Described by Morton (1973) and by Crook and others (1987) as Cretaceous or older, but recently described by Morton (oral communication, 2003) as Precambrian. (Morton, 1973; Crook and others, 1987).

Anorthosite-gabbro complex of Oakeshott (1958) probably a result of differentiation of a single parent magma. Anorthosite and gabbro are pervasively shattered, sheared and brecciated. Barth and others (1995) indicate a general age of 1,200 Ma on the basis of dated zircons and thermobarometry, substantially older than 930 ± 90 Ma and 810 ± 80 Ma lead-alpha zircon ages determined by Neuerburg and Gottfried (1954).Unit is composed of sub-units mapped and described by Carter (1980) including:

Pan **Anorthosite-gabbro complex, anorthosite (Proterozoic)**—Composed of medium- to very coarse-grained plagioclase; light gray and white; contains more than 90 percent plagioclase (andesine) and less than 10 percent mafic minerals (mostly hypersthene); grain size ranges from less than 1 mm to more than 30 cm.

Pagb **Anorthosite-gabbro complex, anorthosite with gabbro (Proterozoic)**—Composed of anorthosite as above with layers or zones of gabbro or diorite.10 to 50% mafic minerals, mostly hornblende, white to gray, medium to coarse grained (Carter, 1980, 1982).

Psy **Anorthosite-gabbro complex, syenite (Proterozoic)**—Composed of plagioclase feldspar (andesine) with lesser potassium feldspar (Microcline-perthite). Has minute black specks of magnetite which may be altered from augite. Rock is generally tan, stained rusty tan to brown by limonite where weathered. (Jahns and Muehlberger, 1954; Oakeshott, 1958; Carter, 1980, 1982).

Pfgb **Anorthosite-gabbro complex, ferro-gabbro (Proterozoic)**—Composed mostly of ferro-magnesian minerals with lesser feldspars dark greenish brown. Contains sub-metallic molecules of iron ilmenite (magnetite-titanite). Intrusive into Pan and Psy. (Carter, 1980, 1982).

Plgb **Anorthosite-gabbro complex, leucogabbro (Proterozoic)**—Light gray compositionally layered gabbro, leucogabbro and anorthosite (Carter, 1980, 1982).

Pjgb **Anorthosite-gabbro complex, jotunitic gabbro (Proterozoic)**—Light gray compositionally layered gabbro with antiperthitic andesine. (Carter, 1980, 1982).

Pjgba **Anorthosite-gabbro complex, jotunite-norite-gabbro-diorite (Proterozoic)**—Composed of hornblende, chlorite, biotite, and actinolite (altered from pyroxene) and limonite-magnetite,

dark greenish brown, locally compositionally layered, contains inclusions of anorthosite (Carter, 1980, 1982).

Pggn **Anorthosite-gabbro complex, gabbroic to anorthositic gneiss (Proterozoic)**—Rocks of the anorthosite-syenite complex that were strongly deformed and in part recrystallized during emplacement of the Triassic Mt Lowe Intrusive suite (Carter, 1980, 1982).

Pgb **Anorthosite-gabbro complex, gabbro (Proterozoic)**—Gray, mottled with greenish or brownish black, and solid dark greenish and brownish black; mafic mineral content ranges from 35 percent to 65 percent of rock; compositionally ranging from gabbroic anorthosite to norite, diorite, pegmatitic hornblende gabbro, and olivine gabbro. Chiefly xenomorphic granular texture; alternating felsic and mafic bands, from a few inches to several feet in thickness are common, but generally discontinuous. Feldspar is mostly calcic andesine (labradorite in more mafic rocks), in many places partly altered to albite or albite-oligoclase. Pyroxenes (and subordinate amphiboles) commonly altered to chlorite, antigorite and biotite (Oakeshott, 1958). (Carter, 1980, 1982, Oakeshott, 1958).

Phbgb **Anorthosite-gabbro complex, hornblende bytownite gabbro (Proterozoic)**—Fine to medium grained foliated, layered, hornblende-chlorite gabbro with labradorite to bytwonite plagioclase. Some layers of anorthosite (Carter, 1980, 1982).

Pgbla **Anorthosite-gabbro complex, anorthosite inclusion-rich gabbro (Proterozoic)**—Strongly layered gabbro with numerous inclusions of anorthosite, some of which are up to 50 feet in length (Carter, 1980, 1982).

Pmgn **Mendenhall Gneiss (Proterozoic)**—Layered migmatitic felsic gneiss and mafic granulite, having rare interlayered augen gneiss and aluminous gneiss. Gneiss is characterized by large-scale foliation, fracturing, jointing, and blocky shattering. Dikes of anorthosite and associated rocks cut gneiss, and centimeter- to meter-scale fragments of gneiss are scattered through the anorthosite. Most distinctive rock is dark gneiss with tint imparted by blue quartz (Oakeshott, 1958). Named by Oakeshott (1958, p. 21), who designated type locality on Mendenhall Peak. Age of Mendenhall Gneiss is greater than 1,200 Ma age of anorthosite sequence (Silver and others, 1963; Barth and others, 1995).

SYMBOL EXPLANATION

Contact between map units - Solid where accurately located or approximately located; short dash where inferred; dotted where concealed; queried where identity or existence is uncertain

Gradational contact between map units

Fault - Solid where accurately located; long dash where approximately located; short dash where inferred; dotted where concealed; queried where identity or existence is uncertain

Thrust Fault - Barbs on upper plate; solid where accurately located; short dash where inferred; dotted where concealed; queried where identity or existence is uncertain

Detachment fault - Solid where accurately located; long dash where approximately located; short dash where inferred; dotted where concealed; queried where identity or existence is uncertain

Syncline - Solid where accurately located; long dash where approximately located; dotted where concealed

Anticline - Solid where accurately located; long dash where approximately located; dotted where concealed

Overturned anticline - Solid where accurately located

Dike - Solid where accurately located; long dash where approximately located; dotted where concealed

Tuff marker bed

Strike and dip of sedimentary beds. Number indicates dip angle in degrees:

- Horizontal bedding
- 35 — Inclined bedding
- Vertical bedding
- 75 — Overturned bedding
- 35 — Inclined bedding where top direction of beds is known
- 75 — Overturned bedding where top direction of beds is known
- 15 — Inclined crumpled bedding
- 35 — Approximate orientation of inclined bedding
- 60 — Inclined bedding as determined from aerial photographs

35 — Strike and dip of inclined cleavage. Number indicates dip angle in degrees

60 — Strike and dip of inclined igneous foliation. Number indicates dip angle in degrees

Strike and dip of metamorphic foliation. Number indicates dip angle in degrees:

- 35 — Inclined foliation
- Vertical foliation

30 — Strike and dip of inclined igneous joints. Number indicates dip angle in degrees

ANALYSIS OF POTENTIAL ECOLOGICAL EFFECTS OF FLOW DIVERSIONS ON WILLOW HABITAT

TECHNICAL MEMO

From: Eric Stein and Jenny Taylor – Southern California Coastal Water Research Project (SCCWRP)

To: Marc Blain, David Jaffe - Psomas

Re: Analysis of Potential Ecological Effects of Flow Diversions on Willow Habitat

Date: September 14, 2018

Background and Approach

The ecological effects of flow diversions were assessed based on modeled relationships between hydraulic changes and probability that the resultant physical conditions can support southern willow riparian habitat conditions conducive to occupancy by least Bell's vireo.

There are two general approaches that can be used to relate physical changes (e.g. changes in streambed elevation or substrate composition) to biological effects (e.g. ability to support vireo). The first involves creating a mechanistic model that predicts species occupancy through a series of equations that relate physical changes to specific life history needs of the species. For example, predicting the expected recruitment, growth, and scour of riparian habitat based on a time series of modeled patterns of velocity and scour. The second approach involves establishing statistical relationships between physical conditions and probability of a species occurring using a combination of output of hydraulic models and presence vs. absence data of vireo over time.

For this study we used the statistical approach to estimate the probability of occurrence of vireo under physical conditions associated with flow diversion scenarios. We chose this approach because 1) it is a more efficient approach for evaluating ecological effects in a relatively small area over relatively short periods of time; 2) it can be more directly related to available species observation data; 3) it produces a probability estimate that provides flexibility in setting management thresholds (i.e. managers can select a probability of effect that triggers a management decision); and 4) the hydraulic modeling does not provide a long-enough time series of output (due to the computational complexity of the model) to support a mechanistic approach.

The probability of effects on least Bell's vireo were assessed using the following steps. Data preparation was done in ArcGIS and analysis was completed in RStudio:

1. Physical properties in the study area were based on the hydraulic model output provided by Psomas. We focused on depth, extent and duration of inundation, velocity, and shear stress as the key output variables as these are the ones most likely to influence presence or absence of willow riparian habitat preferred by the least Bell's vireo. We focus primarily on the dry year model output as the greatest differences were observed under dry conditions, and therefore, any effects, if they occur, would be under dry conditions.

2. Initially, we planned to use vireo occurrence data as an indicator of suitable habitat. However, despite a thorough literature review, we were only able to find a few instances of vireo nesting and a few confirmed absences. Therefore, we decided to use willow presence as an indicator of suitable habitat, which has been documented extensively in the literature.

3. Vegetation coverage of the study area was digitized for a representative wet year (2010) and dry year (2014) using digital aerial imagery provided through the USDA National Agriculture Imagery Program (NAIP). NAIP provides seamless georectified images with four color bands (red, green, blue and near infrared) with known vintage. NAIP imagery is acquired at a one-meter ground sample distance with a horizontal accuracy that matches within six meters of photo-identifiable ground control points, which are used during image inspection. An unsupervised object classification was used to attribute riparian trees and shrubs vs. non-target habitats, and raster images were converted to polygons. Straggler trees and shrubs were manually deleted or produced the final shape files.

4. Water velocity, percent of time inundated, water depth, shear stress, and arrival time variables were used from the *dry* year hydraulic modeling. We focused on the dry year, because results of the hydraulic modeling comparing the historical with predicted flows differed most significantly for the dry year. These hydraulic parameters were selected because they are known to influence recruitment, growth, and survival of riparian habitat. These variables were provided to us in raster format, with approximately 18,000 pixels. We converted each pixel to a point and spatially joined the hydraulic variable values to the vegetation layer. This created a dataset that related the presence of willow with each of the hydraulic variables.

5. To begin to explore the relationship between each of the hydraulic variables and the occurrence of willow, we compared the distribution of each variable for areas where willows were present and areas where willows were absent using a two-sided t-test. Arrival time showed the least difference between groups (p>0.1) and because the distributions looked so similar, we did not include this variable in further analysis. The other four hydraulic variables did display a significant difference between the two groups and were all significant at the α=0.001 level: Depth, shear stress, velocity, and percent of year inundated. A correlation matrix (
6. Figure 1) was calculated for the remaining four hydraulic variables and shear stress was removed based on its significant correlation with velocity (r=0.79).

7. Data were split randomly into 25% testing data and 75% training data. Initially a multinomial regression was used to predict vegetation classes including coast live oak, riparian herbaceous, and willow. However, this model severely overpredicted willow occurrence. Because we are concerned with the potential reduction in willow habitat, we decided this model would not provide a reliable answer to that question. Logistic regression analysis (eq. 1) was the next model used to develop relationships between the three hydraulic properties and the presences or absence of willow habitat. We used a binomial logistic regression model because it allows for estimation of the probability of a binomial response (in this case presence vs. absence of willow habitat) based on one or more predictor variables (in this case hydraulic properties). The resulting plots allow for an estimation of the probability of vireo habitat occurrence based on a continuous range of hydraulic variables (e.g. inundation time, water velocity).

Eq. (1): $\text{logit}(\text{willow presence}) = \beta_0 + \beta_1(\text{depth}) + \beta_2(\text{velocity}) + \beta_3(\text{annual inundation})$

8. The validation of the model with the testing data showed an overall accuracy of 81.9%. The model was very good at predicting areas where willows were absent (specificity=89.9%) and much less effective at predicting areas where willows are present (sensitivity = 13.5%). From an ecological perspective, this makes sense because we can accurately predict areas where we know willows are unlikely to occur. In contrast, there are other areas that are unlikely to support willows, but where absence may be explained by a variety of factors beyond channel hydraulics (See Attachment A). This suggests that our predictions of willow occurrence will be much less accurate than our predictions of willow absence.

9. The dry year logistic regression model was used to predict willow occurrence with the modelled hydraulic output under the proposed water diversion scenario. Dry wear model output was used because the greatest differences in channel conditions were observed during the simulated dry year. The same method was used to prepare the data as described above for the training data: the velocity, percent inundation, and depth variables were converted to points and joined together.

Results

All hydraulic variables tested showed significant differences ($p < 0.001$) in willow occurrence between predicted future conditions and historic flow characteristics. However, given the small sample size of vegetation polygons and the high number of hydraulic observations (>18,000), we believe the significance estimates may be overestimated.

The basic logistic regression models are provided in Figure through 4 and show the probability of willow occurrence for depth, annual percentage inundation time, and velocity, respectively. The range on the x-axes are bounded by the values observed in the data and their associated probability estimates. We see an increase in probability of willow occurrence with increasing depth and percent annual inundation. These trends in depth and annual inundation percentage suggest that the some persistent inundation is important for suitable willow habitat, which agrees with the literature. Lastly, we see a steep decline in occurrence of willow habitat as the velocity increases. This suggests that willows will not be present in active channels where velocity is highest.

Our models predict a slight decrease in probability of occurrence of willow habitat in dry years with the proposed diversion compared to without the diversion. Changes in probability of occurrence vary spatially and are most pronounced near the outlet to the spillway and at the margins of the basin (Figure 5). In general, we see exaggeration of extreme values; increases in the probability of willow occurrence in areas where occurrence was high and decreases in the probability of willow occurrence where the occurrence was low. The most pronounced decrease predicted is a 13.8% decline in probability of occurrence in the lower basin, near the spillway, associated with a slight decrease in depth and duration of inundation. This is offset by a 6.6% increase in probability of occurrence at the margins of the basin, also associated with change in depth and duration of inundation.

It is important to note that difference in velocity in the reservoir is not a driver of impacts to habitat since the velocity is essentially zero for most of the ponded areas. The biggest influencing factor appears to be the duration of inundation which is driven by a combination of hydrologic events and the operational curve of the dam. Only in a statistically dry year with high flow events that occur late in the storm season (as opposed to the average) do we see durational impacts to ponding extents in the model. This change in duration of inundation also influences change in probability of willow

occurrence along the margins of the basin. However, as stated above, net changes in probability of willow occurrence are less than 10%. As previously noted, we see no effects in the main portion of the stream channel or during wet years. Finally, it is important to note, that this analysis only speaks to the probability that willow habitat will or will not occur, it does not speak to health or vigor of the community.

Caveats of Analysis

1. Pseudoreplication is an issue when observations are not random or independent. Our observations were based on the pixel size of the hydraulic modeling, as opposed to randomly selecting plots as our samples. Consequently, pseudoreplication may have introduced additional uncertainty into our results.

2. The hydraulic variables that went into this analysis were averaged values based on wet and dry years, therefore, they do not show the true extent of water inundation. We are not considering that some areas do get inundated in dry years, or that some areas do not get inundated in dry years. This likely is the reason the model had trouble finding differences between the areas that do have willows and those that do not.

3. The presence of vegetation is a function of the current year's precipitation, which we considered, but also the precipitation and resulting hydraulics of many years prior, which we did not consider.

4. The vegetation classification was completed because the original vegetation map which was part of the EIR was too coarse (it was used in the multinomial regression which ultimately over predicted willow). This vegetation classification was not ground-truthed, and it is likely that other types of trees and shrubs, such as coast live oak, were included in what we designated willow habitat.

5. Results of the statistical analysis are limited by the small area of analysis and low data density. A regional analysis would have provided the opportunity to develop the logistic regression model using a larger more robust data set, which would have improved confidence and resolution in the model.

Figures

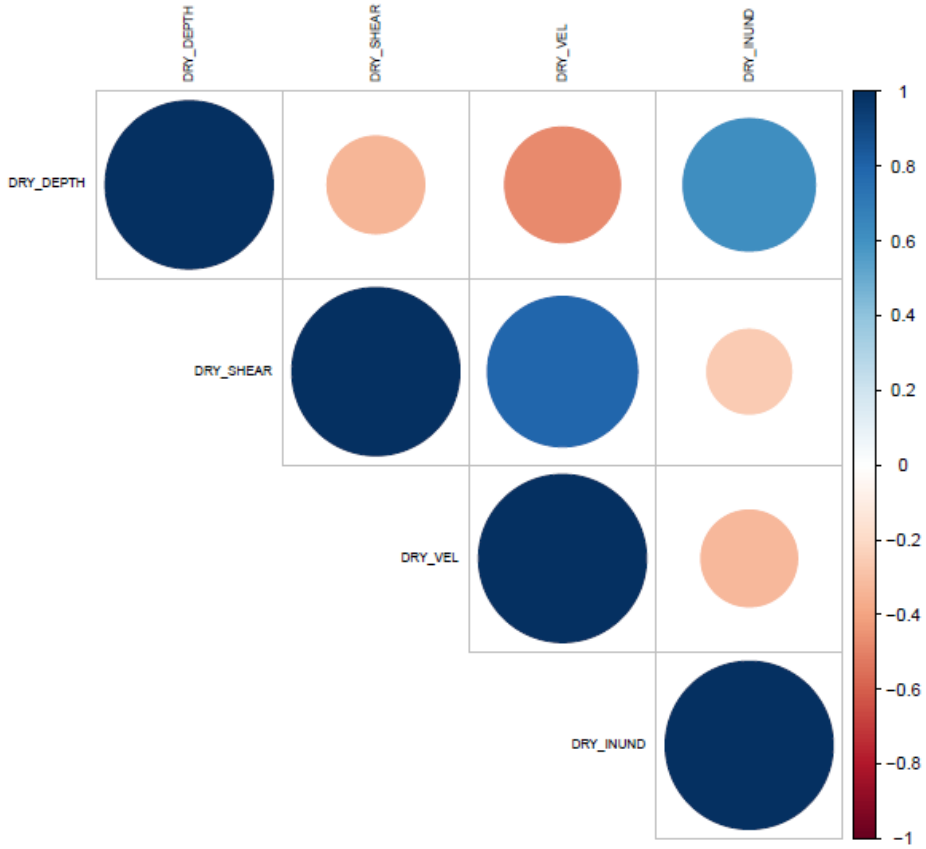

Figure 1: Dry year correlation plot of depth, shear stress, velocity, and annual inundation percentage. The correlation between shear and velocity was above 0.7.

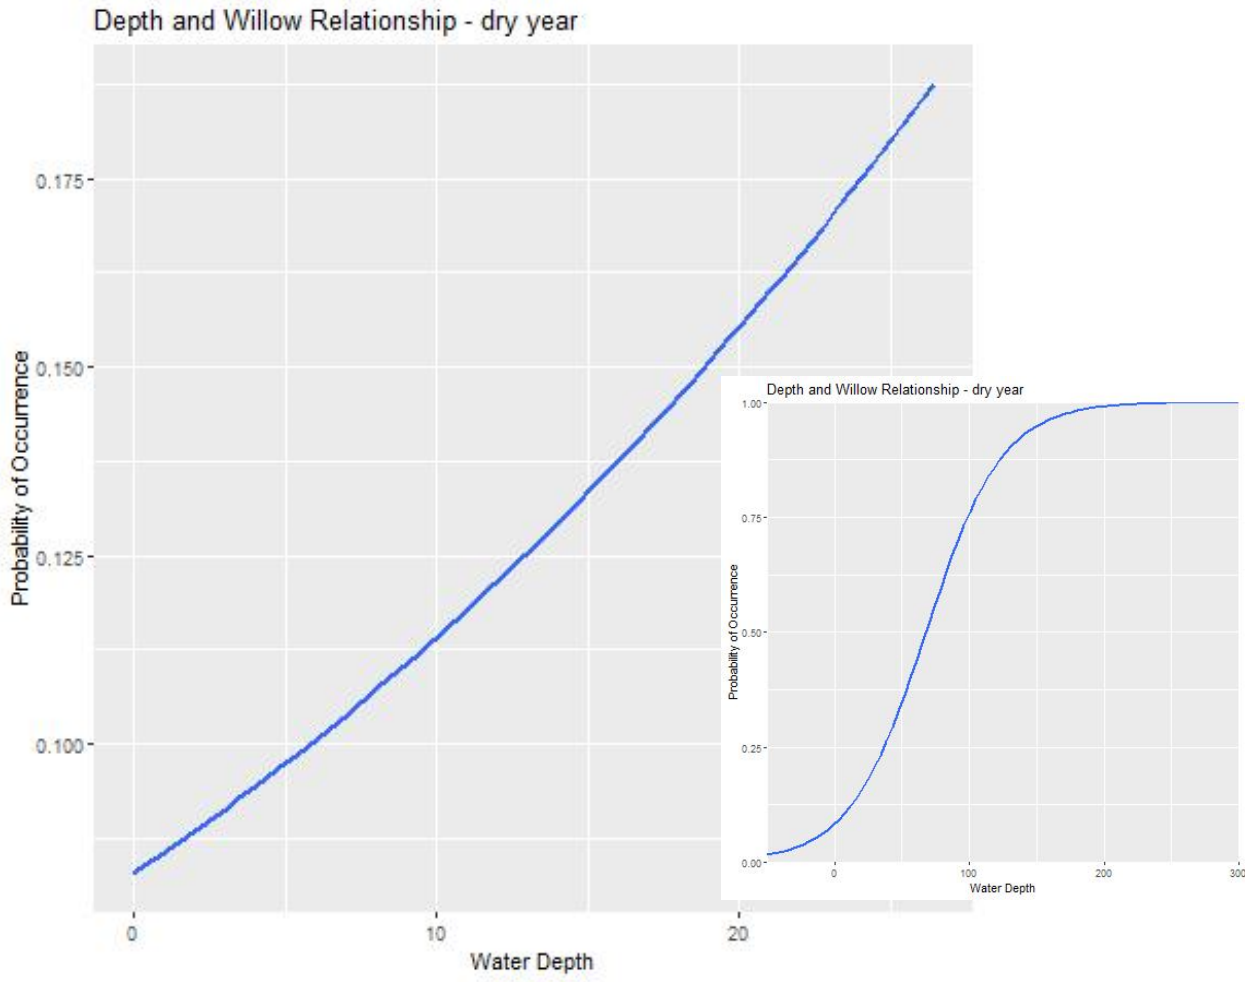

Figure 2: The relationship between water depth (ft) and the probability of occurrence of willow. Inset graph shows the full logistic regression. Larger graph focuses on the range of depth values in the dry year hydraulic data set and the associated estimates of probability of willow occurrence.

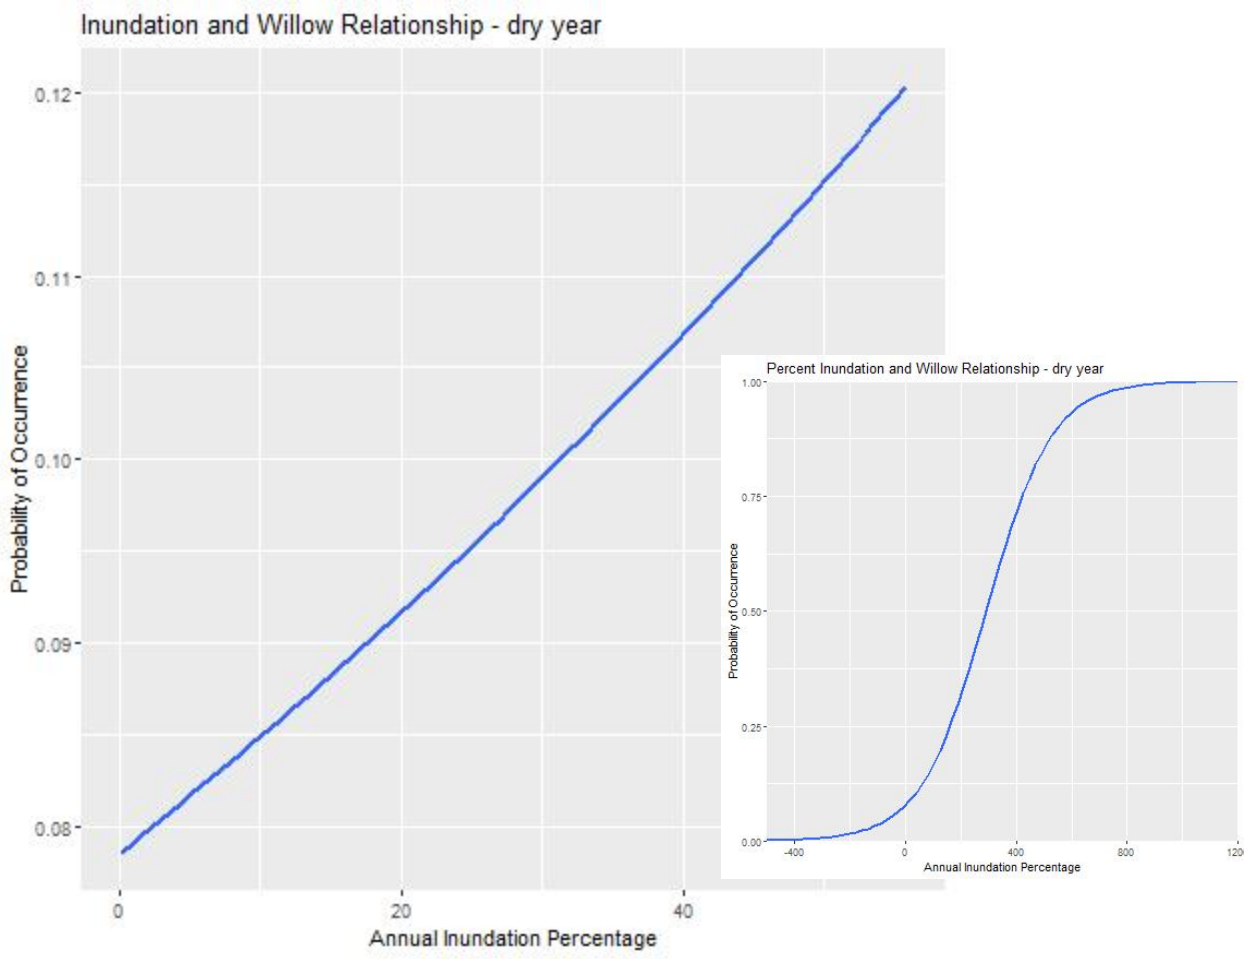

Figure 3: The relationship between average annual inundation percentage and the probability of occurrence of willow. Inset graph shows the full logistic regression. Larger graph focuses on the range of inundation values in the dry year hydraulic data set and the associated estimates of probability of willow occurrence.

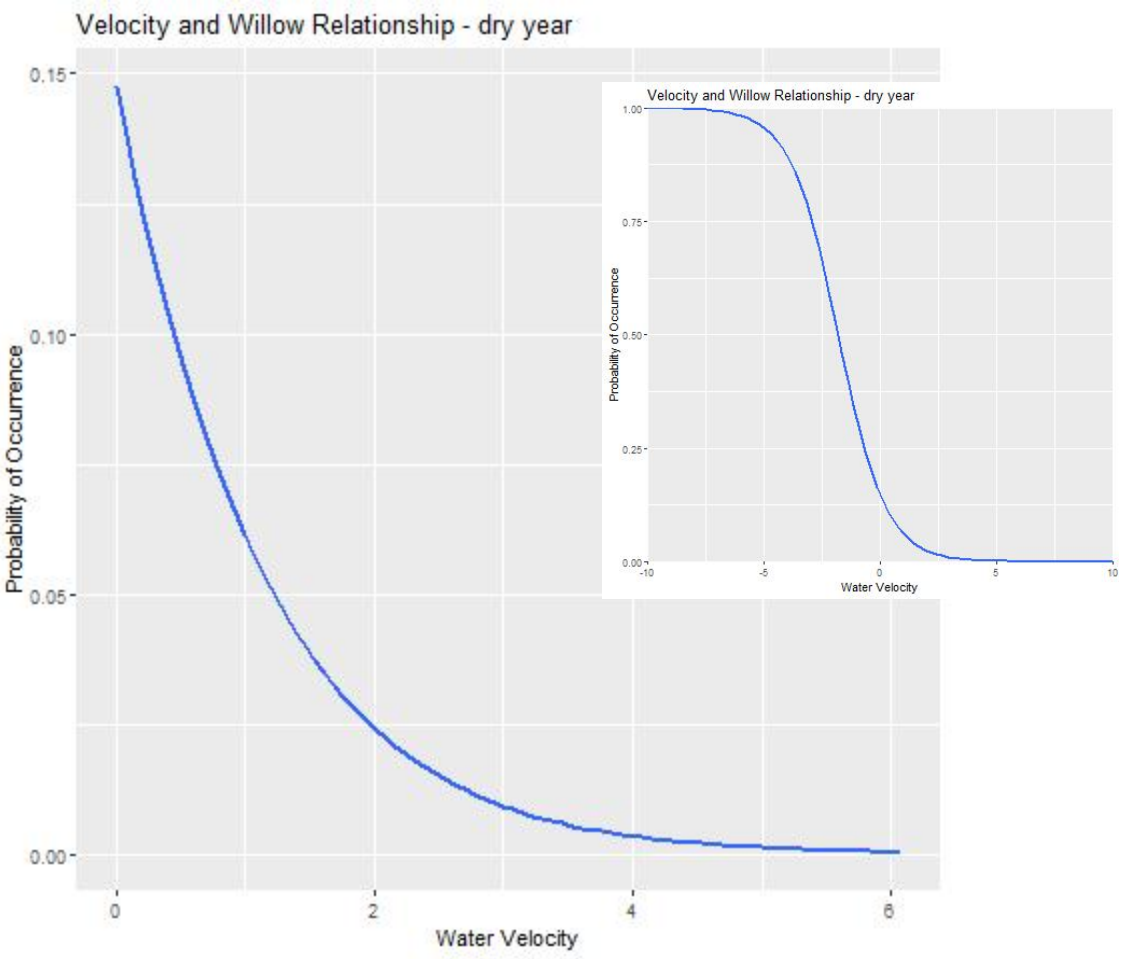

Figure 4: The relationship between water velocity (ft/s) and the probability of occurrence of willow. Inset graph shows the full logistic regression. Larger graph focuses on the velocity range in the dry year hydraulic data set and the associated estimates of probability of willow occurrence.

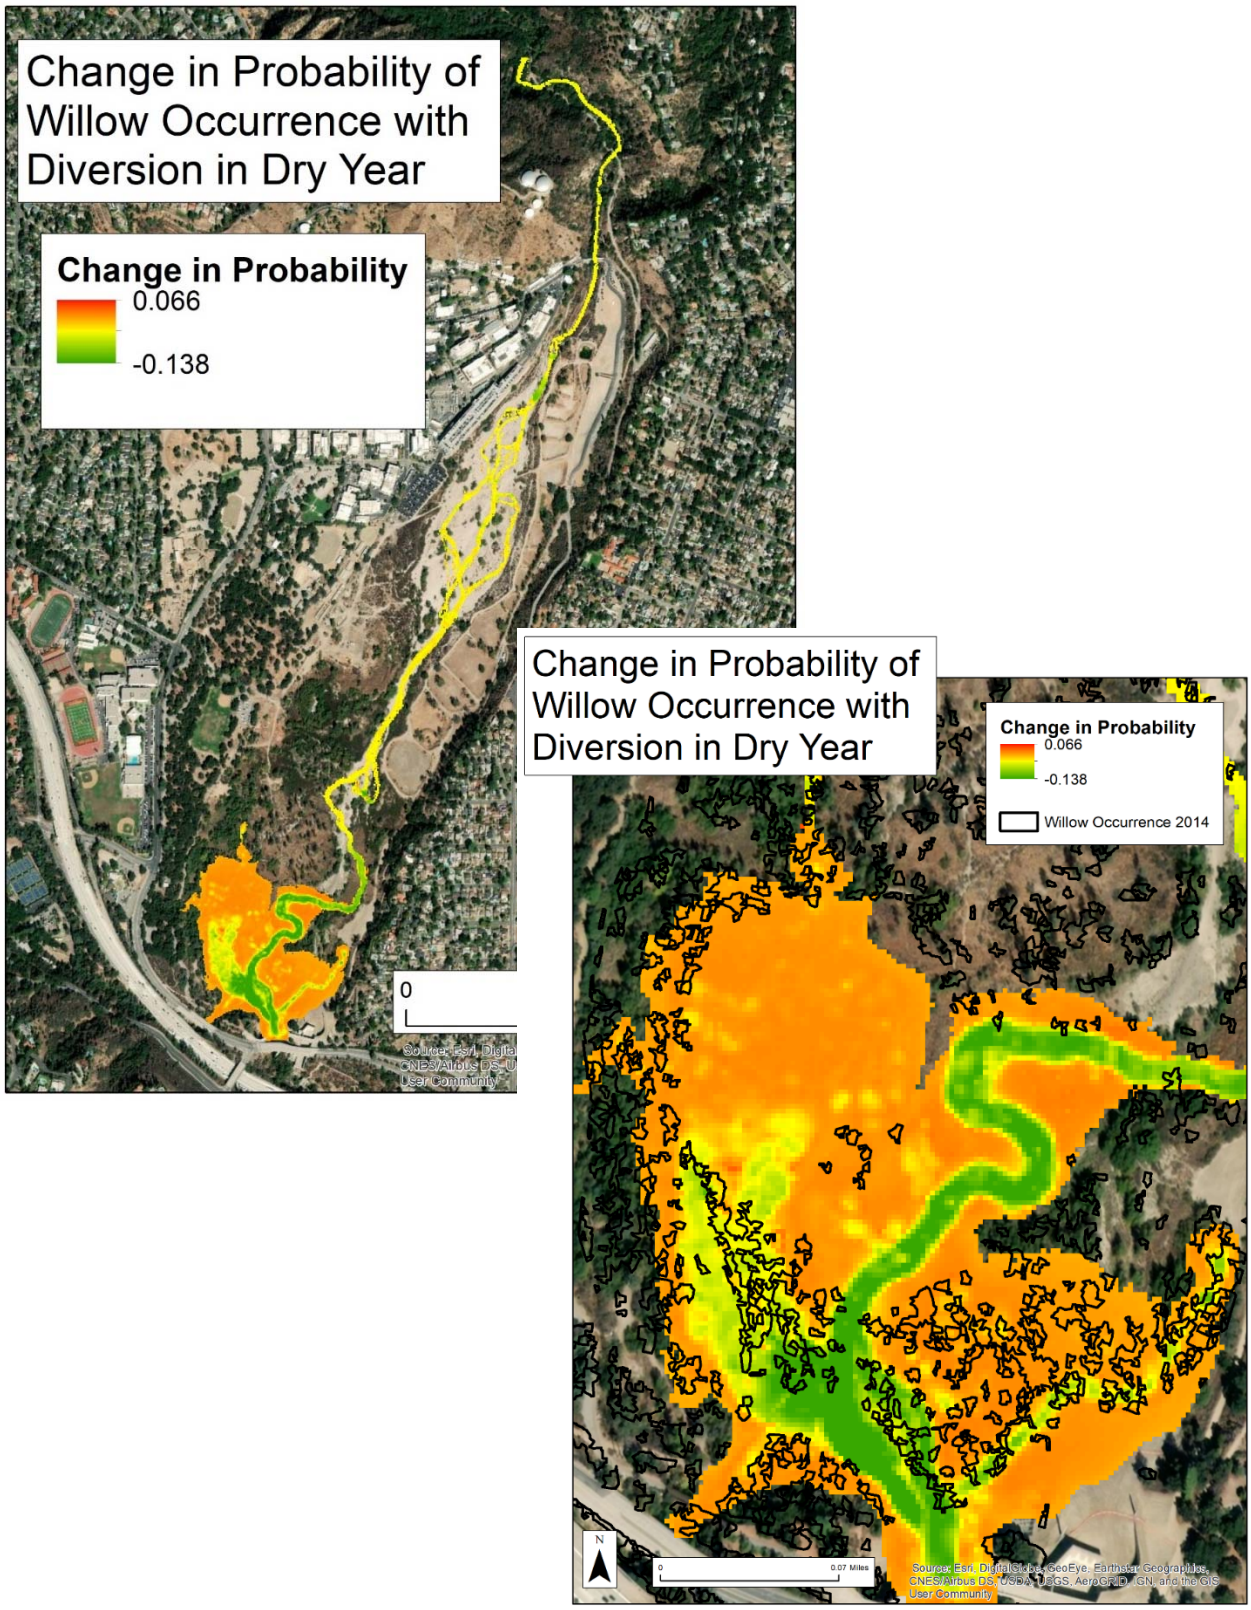

Figure 1: Change in probability of willow with the diversion in a dry year, compared to a dry year with no diversion. Green shows a decrease in probability, yellow is roughly no change, and red signifies an increase in probability. Note that green is a decrease of 13.8% and red is an increase of 6.6%. Lower graphic shows a zoomed in view of the lower basin.

Attachment A: Box plots showing differences in ranges of hydraulic variables in areas where willows were present (1) vs. absent (0)

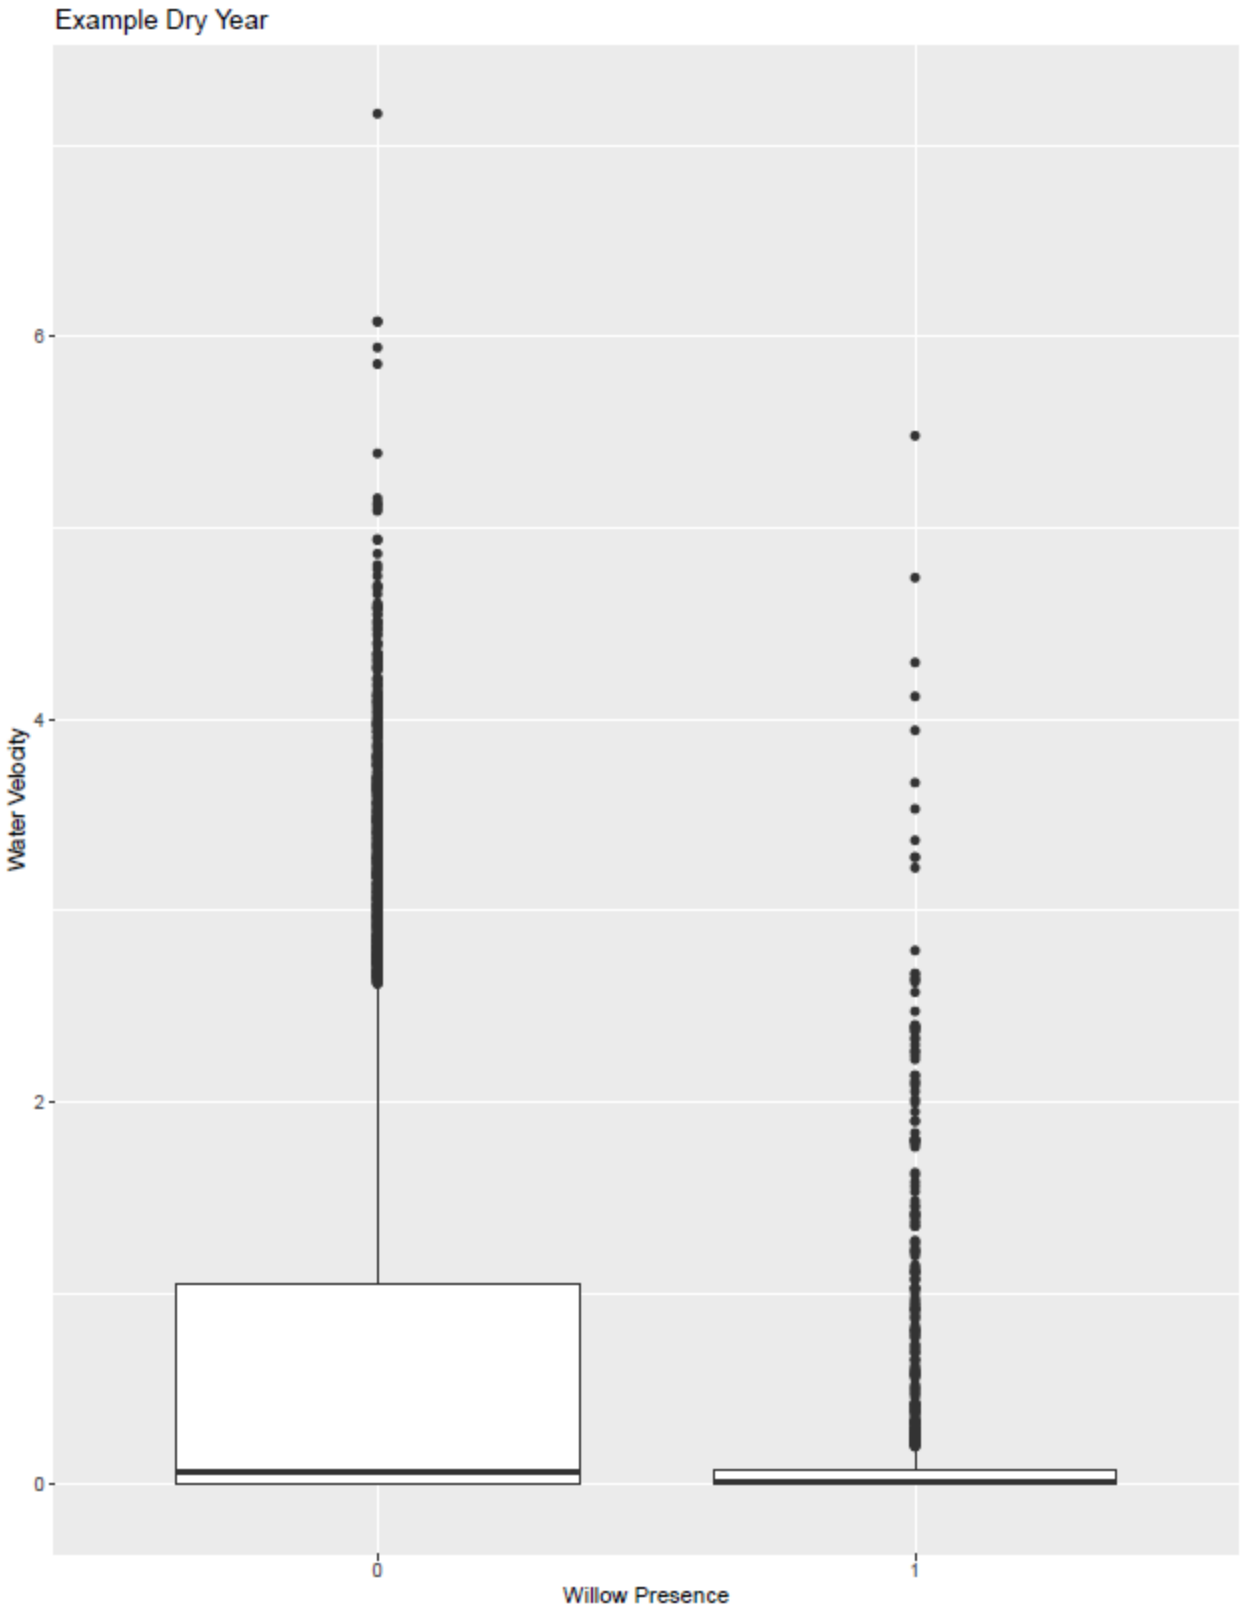

Figure A-1: Boxplot showing water velocity (ft/s) values for observations where willow shrub was and was not present.

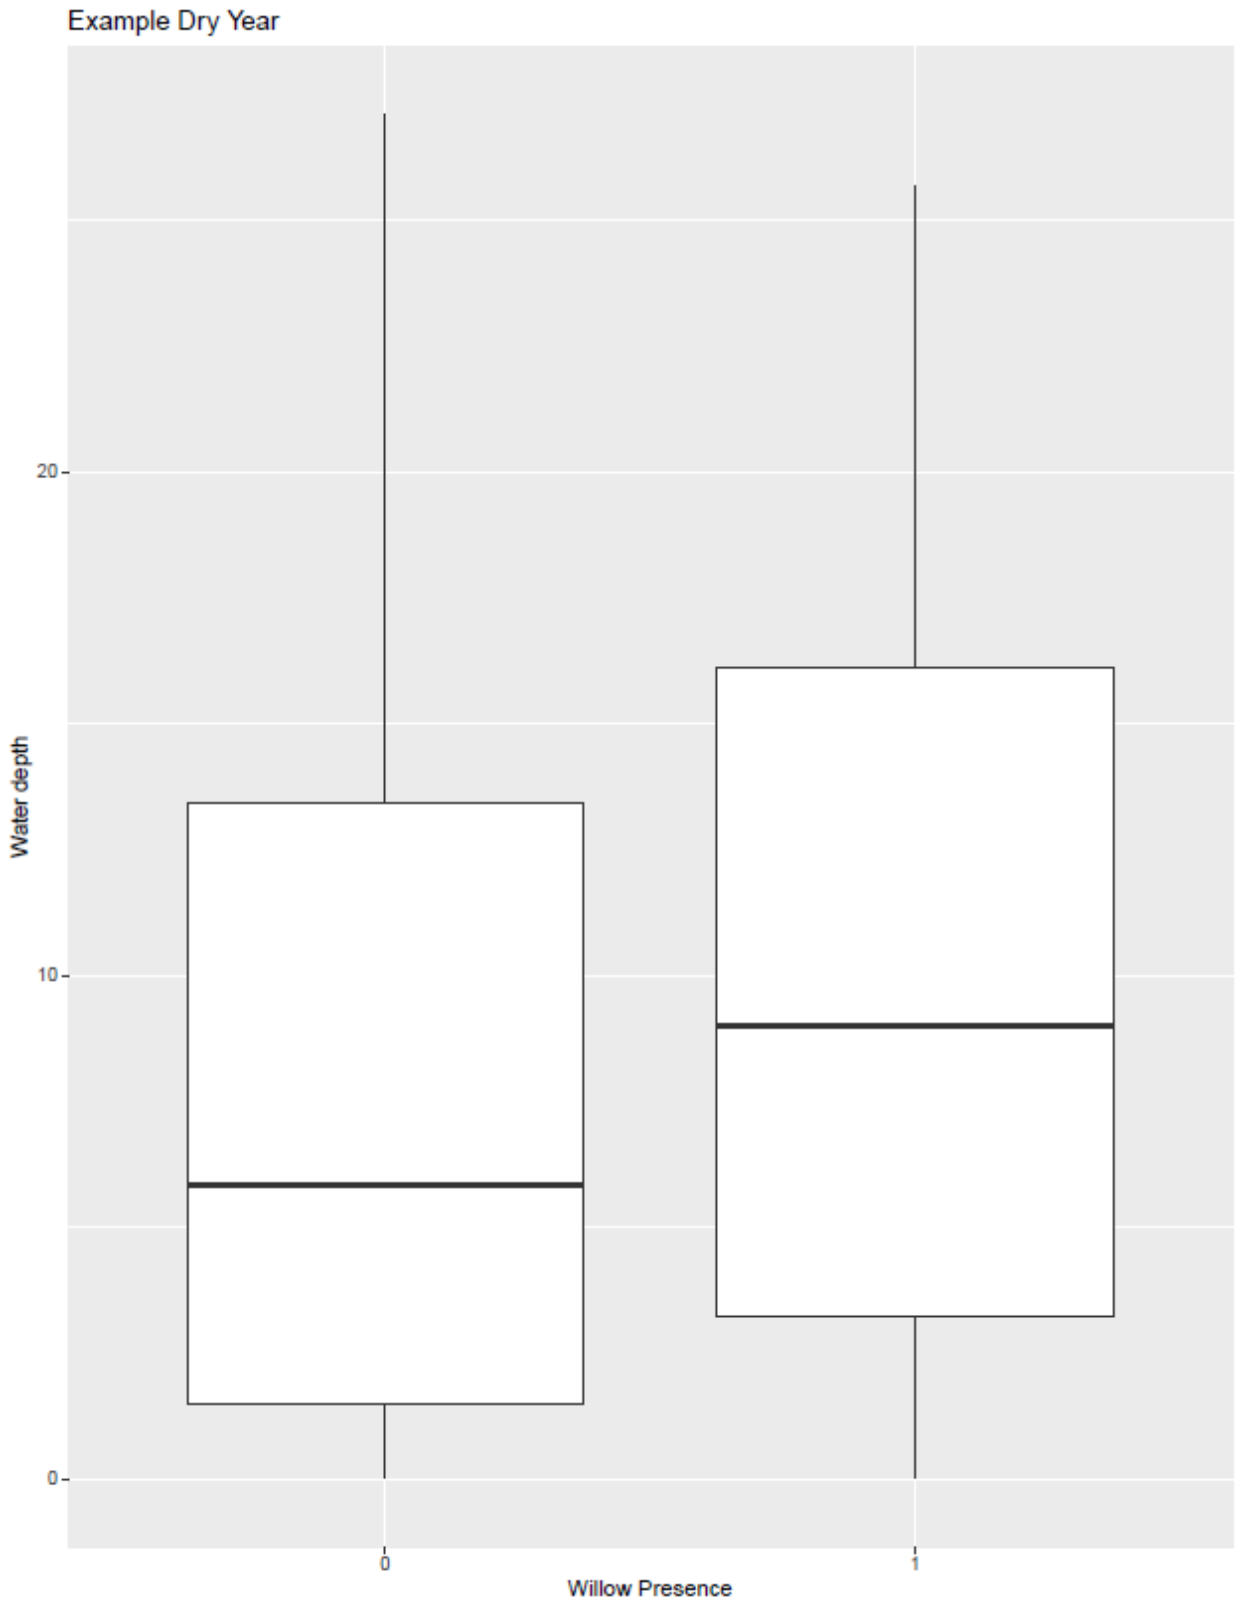

Figure A-2: Boxplot showing water depth (ft) values for observations where willow shrub was and was not present.

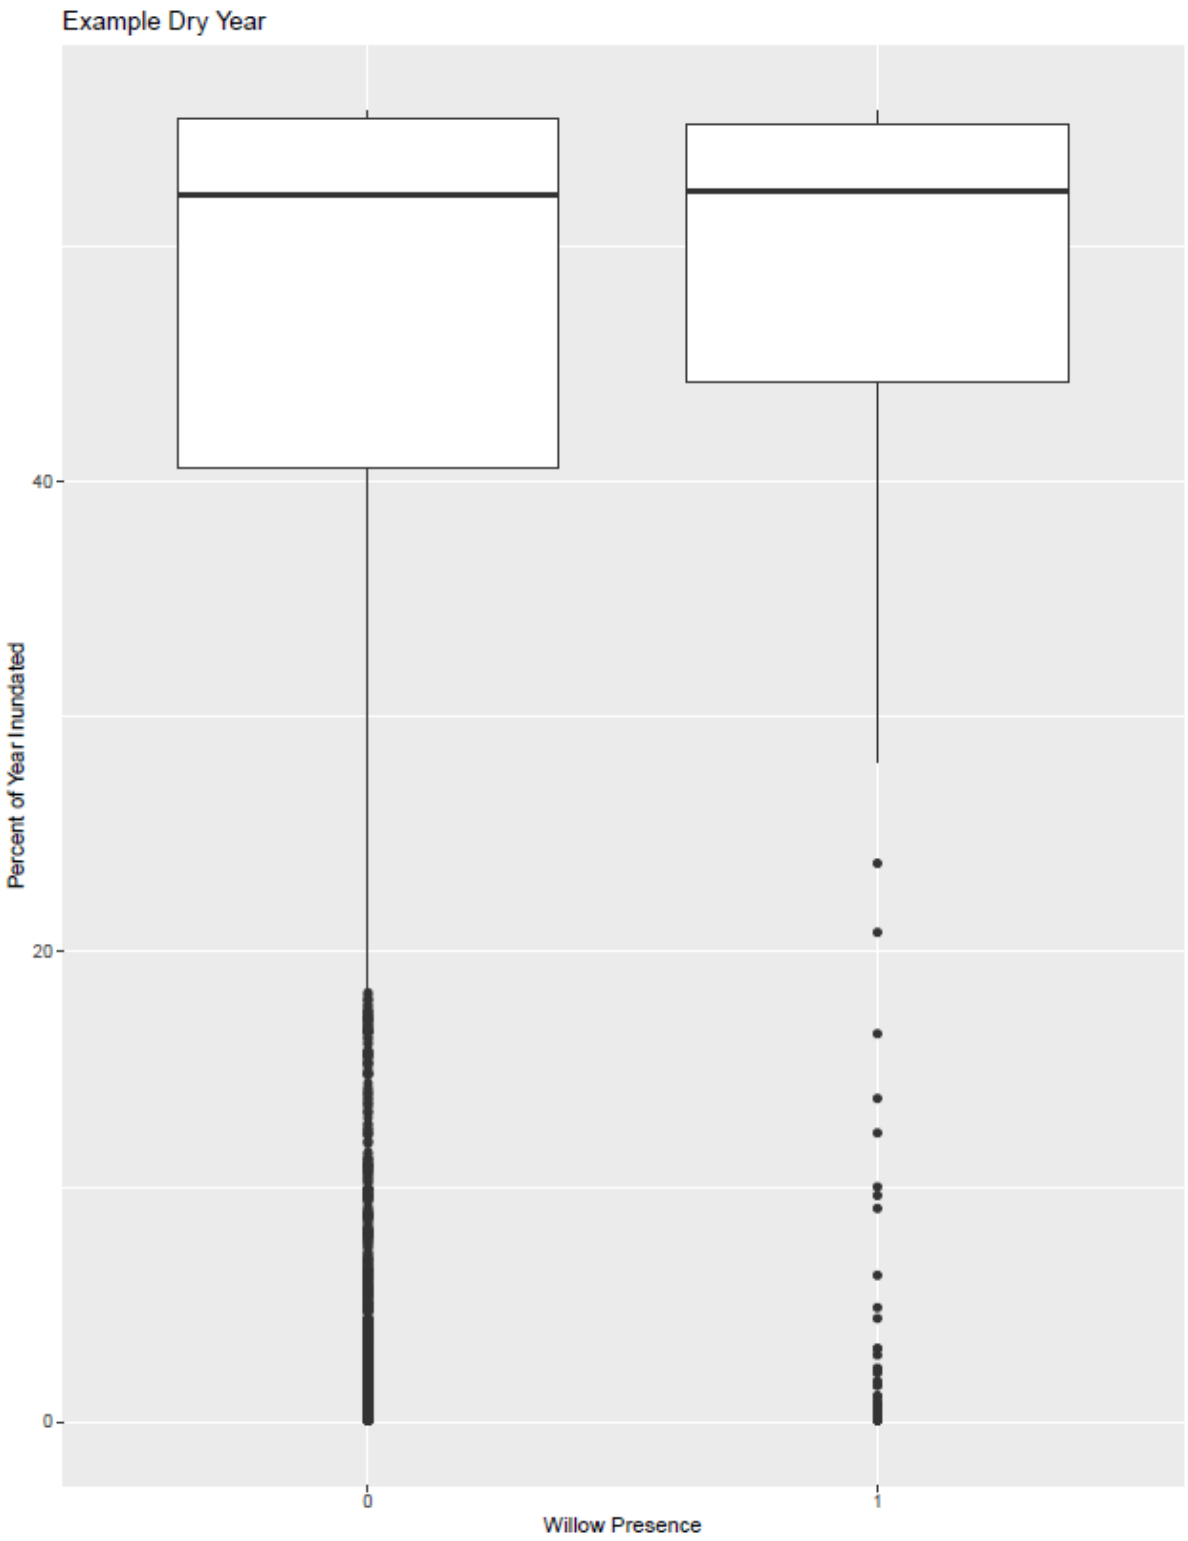

Figure A-3: Boxplot showing percentage of year with water inundation values for observations where willow shrub was and was not present.

Cc: Linda Kry
Subject: Request for a Sacred Lands File Search_Dudek (#11884)
Attachments: 11884_NAHC SLF_Request_PDF.pdf; Fig_records_search.pdf

Dear NAHC,

Please find attached the NAHC Sacred Lands File Search request and project location map for the proposed Arroyo Seco Canyon Project (Dudek #11884). Dudek is requesting a NAHC search for any sacred sites, tribal cultural resources, or other places of Native American community value that may fall within a one-mile radius of the proposed Project site.

Please let me know if you have any questions regarding this project. You can email the results to me at adorrler@dudek.com.

Thank you in advance,

Adriane Gusick
Associate Archaeologist

Project Description:
The City of Pasadena (City) owns the right to divert up to 25 cubic feet per second of surface water from the Arroyo Seco into their spreading basins for pumping credits in the Raymond Basin. In the two storm seasons following the 2009 Station Fire, excessive amounts of sediment washed down from the watershed. The debris flows damaged City structures, greatly reducing the City's capacity to divert water for spreading. As a result, the City of Pasadena Department of Water and Power proposes to repair and replace damaged facilities in the Upper Arroyo Seco Canyon as a part of the proposed Project. The improvements would allow for increased utilization of the City's surface water rights from the Arroyo Seco and maximize the beneficial use of this important local water resource.

The proposed Project consists of three primary areas, including Area 1, Headworks Removal; Area 2, Diversion and Intake Replacement; and Area 3, Spreading Basin Improvements. These areas are connected by the Gabrielino Trail/Access Road. The proposed Project would involve construction activity and facility improvements in all three areas, as well as along portions of the Gabrielino Trail/Access Road. Additionally, portions of the 30-inch hume line, which is a pipeline that conveys water from the diversion weir to the spreading basins, may also be improved/replaced.

☑ Project Location Map is attached

RE: Arroyo Seco Canyon Project, Los Angeles County

Dear Ms. Gusick:

A record search of the Native American Heritage Commission (NAHC) Sacred Lands File (SLF) was completed for the information you have submitted for the above referenced project. The results were positive. Please contact the Gabrieleno Band of Mission Indians - Kizh Nation on the attached list for more information. Other sources of cultural resources should also be contacted for information regarding known and recorded sites.

Attached is a list of Native American tribes who may also have knowledge of cultural resources in the project area. This list should provide a starting place in locating areas of potential adverse impact within the proposed project area. I suggest you contact all of those indicated; if they cannot supply information, they might recommend others with specific knowledge. By contacting all those listed, your organization will be better able to respond to claims of failure to consult with the appropriate tribe. If a response has not been received within two weeks of notification, the Commission requests that you follow-up with a telephone call or email to ensure that the project information has been received.

If you receive notification of change of addresses and phone numbers from tribes, please notify the NAHC. With your assistance, we can assure that our lists contain current information. If you have any questions or need additional information, please contact me at my email address: steven.quinn@nahc.ca.gov.

Sincerely,

Steven Quinn
Associate Governmental Program Analyst

PASADENA WATER AND POWER

November 7, 2019

Andrew Salas, Chairman
Gabrieleño Band of Mission Indians – Kizh Nation
PO Box 393
Covina, CA 91723
Email: admin@gabrielenoindians.org and gabrielenoindians@yahoo.com

Subject: Formal Notification of a Proposed Project Pursuant to AB 52 and Sections 21080.3.1 and 21080.3.2 of the California Environmental Quality Act (CEQA)

Project: Arroyo Seco Canyon Project Areas 2 and 3, City of Pasadena, California

Dear Mr. Salas:

Pursuant to Assembly Bill (AB) 52 and Section 21080.3.1 of the California Environmental Quality Act (CEQA), and in response to your associated request, the City of Pasadena is hereby providing formal notification of the proposed Arroyo Seco Canyon Project Areas 2 and 3. Enclosed please find a brief description of the proposed project and its location.

If you wish to begin consultation on this project pursuant to AB 52 and Sections 21080.3.1 and 21080.3.2 of CEQA, please request such consultation as soon as possible, but no later than 30 days from the date of this letter. The City of Pasadena's (lead agency's) contact person for this project is:

Elisa Ventura, P.E.
City of Pasadena Department of Water and Power
150 South Los Robles Avenue, Suite 200
Pasadena, California 91101
(626) 744-4465 eventura@cityofpasadena.net

Your comments and concerns are important to the City and we welcome the opportunity to consult with the Gabrieleño Band of Mission Indians – Kizh Nation, upon your request. If you have any questions regarding the project, please do not hesitate to contact Elisa Ventura at the contact information noted above.

Sincerely,

E. Ventura

Elisa Ventura, P.E.

Enclosure: Description of the Proposed Project and Location

DESCRIPTION OF THE PROPOSED PROJECT AND LOCATION

PROJECT NAME: Arroyo Seco Canyon Project Areas 2 and 3

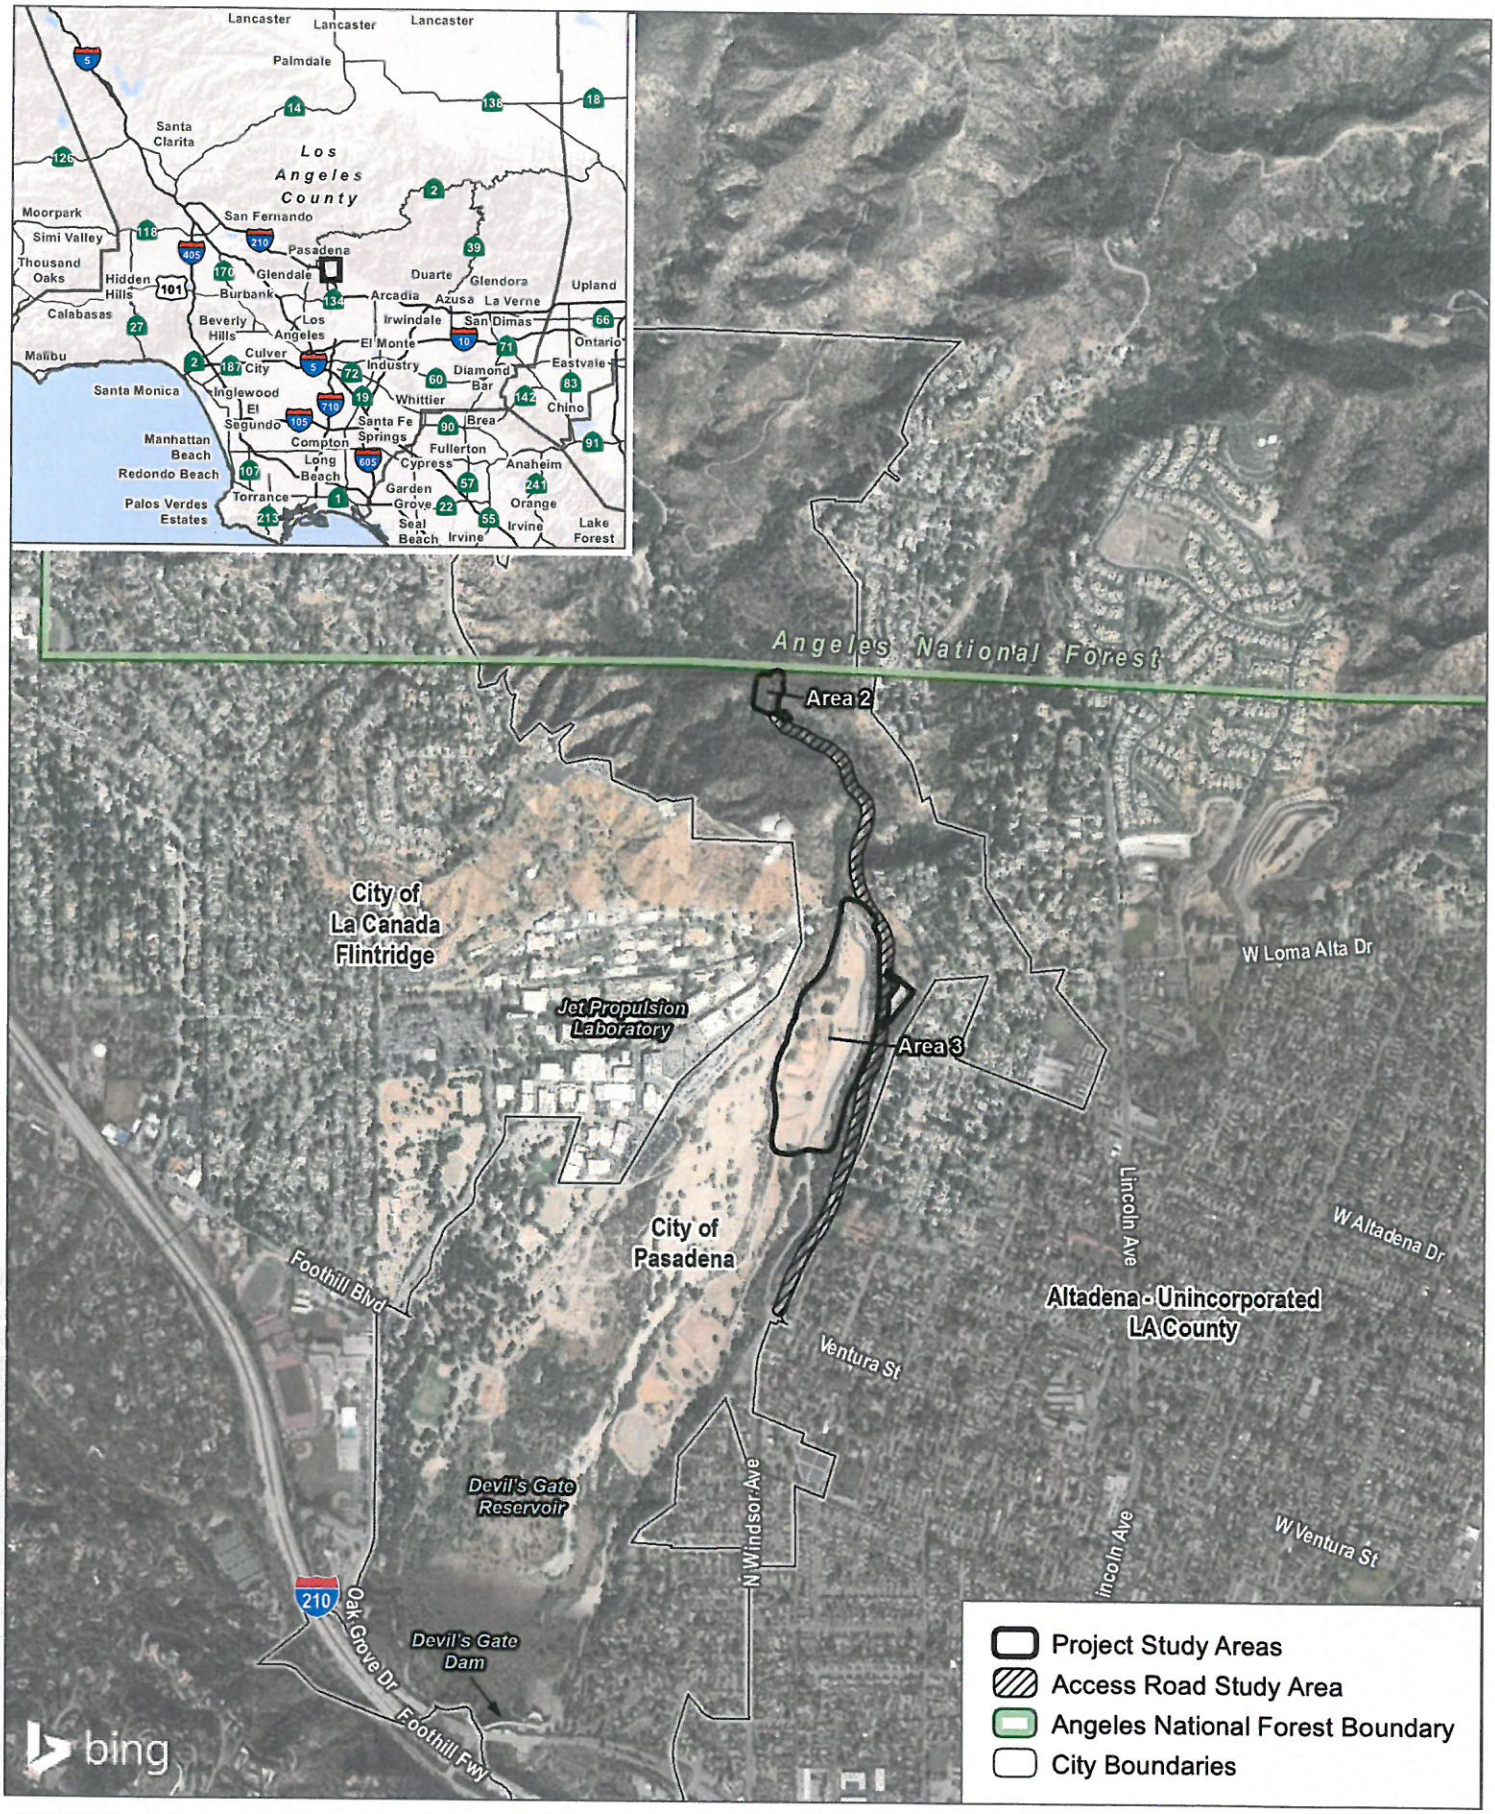
PROJECT LOCATION AND SETTING: As shown in the attached Figure 1, Local Vicinity and Regional Location, the proposed Project site is located within the Arroyo Seco Canyon adjacent to North Arroyo Boulevard and the Gabrielino Trail, located in Township 1 North, Range 12 West on the Pasadena, California 7.5′ USGS quadrangle map. The proposed Project is located at 3420 to 3500 North Arroyo Boulevard, City of Pasadena (City). The proposed Project site includes portions of Assessor Parcel Numbers 5830-001-906 and 5823-015-902. The proposed Project consists of two primary areas, including Area 2, Diversion and Intake Replacement and Area 3, Spreading Basin Improvements. These areas are connected by the Gabrielino Trail/Access Road, which serves as a recreational trail and the access road for City and United States Forest Service vehicles heading into the Arroyo Seco Canyon.

The proposed Project site is bound by residential uses in Pasadena and the community of Altadena to the east and south; open spaces in the Angeles National Forest (ANF) to the north; Devil's Gate Dam and Reservoir to the southwest; and the Arroyo Seco stream corridor, Oak Grove Park, and other recreational areas, the NASA-Jet Propulsion Laboratory (JPL) campus, and residential areas in the City of La Cañada Flintridge on the west.

ZONING: Open Space

GENERAL PLAN DESIGNATION: Open Space

PROJECT SUMMARY: The City owns the right to divert up to 25 cubic feet per second (cfs) of surface water from the Arroyo Seco for direct use or for spreading into its basins for water pumping credits in the Raymond Basin. The City receives between 60 to 80% groundwater pumping credit for the amount of water recharged into the groundwater basin. The City of Pasadena Department of Water and Power (PWP) proposes to repair and replace damaged facilities in the Upper Arroyo Seco Canyon, which would allow for increased utilization of the City's surface water rights from the Arroyo Seco and maximize the beneficial use of this important local water resource. The overall Project objectives to increase the beneficial use of the surface water rights held by the City and to improve biological functions within the Arroyo Seco.



The Project involves a requested modification to Conditional Use Permit #6222 in order to construct and operate proposed water infrastructure improvements in Areas 2 and 3. A description of the proposed Project is included in the Initial Study, and a brief summary of proposed Project components is provided below.

Area 2: Diversion and Intake Replacement- Improvements in Area 2 include the removal of the existing diversion/weir structure and the intake structure, which would be replaced with a new

diversion/weir structure that could be operated to divert up to 25 cfs of creek flows through the new intake structure and into the existing conveyance system (a combination of tunnels and pipelines). The new intake would include a fish screening feature to prevent future fish populations from passing into the intake and conveyance system. A roughened channel would be constructed directly downstream of the new weir to allow for future fish passage upstream during moderate flow periods. Other improvements include a new service building to house the electrical and hydraulic controls for the diversion structure and new engineered streambed material along the eastern creek slope to prevent erosion adjacent to the Gabrielino Trail/Access Road. (See Figure 2)

Area 3: Spreading Basin Improvements- Improvements in Area 3 include the reconfiguration and expansion of the spreading basins in order to accommodate the increased flows for infiltration into the Raymond Basin. Various facilities would be demolished, including inlet/outlet structures, pipes and valves, fencing, and other small appurtenant structures, to allow for the reconstructed basins. Creek flows from the existing conveyance system would outlet to the new sedimentation basin or to new spreading Basin E located at the site of the existing Pasadena Pond 1. Basin F would be adjacent to mature trees to be preserved and would be located at the site of the existing Pasadena Pond 2. Basins G, H, and I would be located at the site of the existing Basins 1 and 2 and a portion of the City's open area (i.e. former JPL East Parking Lot). New Basin J would be located between existing Basins 3 and 4, and Explorer Road. (See Figure 3)

During construction activities, the existing Gabrielino Trail/Access Road would provide for vehicular access to and from Areas 2 and 3, and Explorer Road would provide for vehicular access to and from Area 3. The former Travelling Screen and Chlorine Building adjacent to Area 2 and the Behner Water Treatment Plant adjacent to Area 3 would be used for temporary construction materials and equipment staging. No new habitable structures would be constructed, and no new employees would be generated by the proposed Project.
