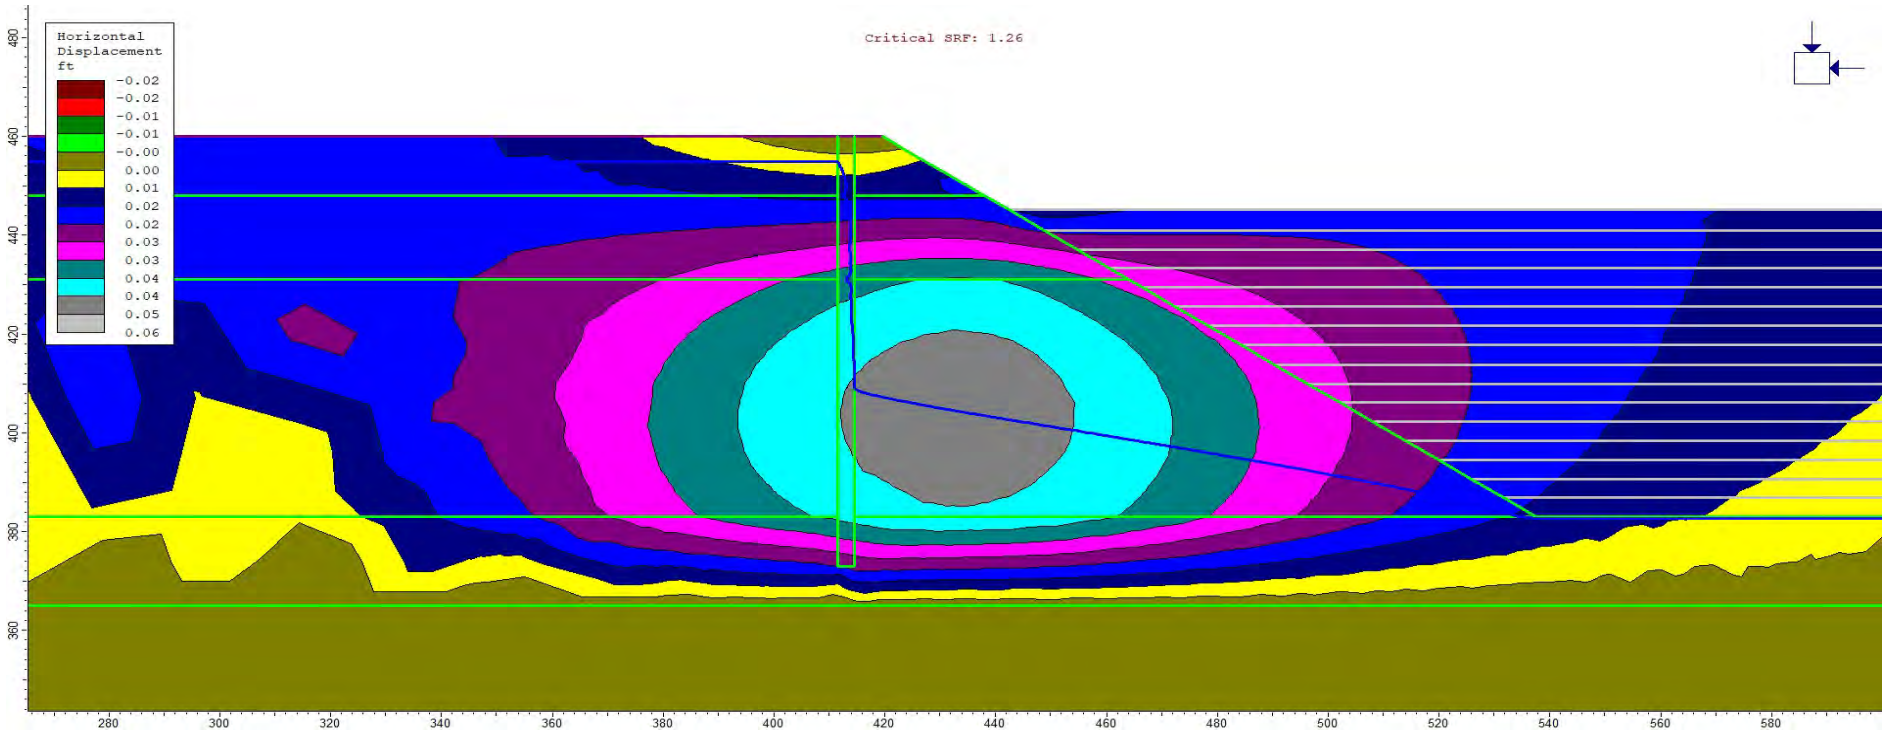
ESTIMATED DEFLECTIONS
1.5H:1V SLOPE & LOW STRENGTH SLURRY WALL

NOTES:

1. Deflection levels (ft) are color coded separately in each plot as shown in the insets.



2. The difference between the deflections under normal conditions (upper plot) and the simulated failure conditions (lower plot) is indicative of the safety margin.

ESTIMATED DEFLECTIONS
CORRESPONDING TO THE LIMIT OF STABILITY

1. INTRODUCTION

1.1. BACKGROUND

This document addresses potential CEQA relevant impacts on hydrology and water quality associated with the Project. Impacts on potential flooding, surface water drainage, groundwater flow, groundwater supply, and water quality are considered.

The hydrology and water quality conditions of the Project were assessed through review of Applicant-submitted documents, existing publicly available data and reports, and field observations. The Applicant has prepared documentation regarding groundwater conditions as presented in *Groundwater Conditions at and in the Vicinity of the Tulare Irrigation District Mackay's Point Project* (Schmidt, 2012) and *McKay Point Project*. Data from other publicly available documents were reviewed and evaluated as part of this assessment.

This document includes a discussion of the general Site conditions including environmental setting, climate, surface-water conditions, and groundwater conditions. The design and the construction stages of the Reservoir are described. Anticipated changes to the baseline conditions due to the Project are also evaluated. Finally, potential impacts to hydrology and water quality are evaluated based on the California Environmental Quality Act (CEQA) Appendix G significance criteria.

1.2. PROJECT OVERVIEW

The Tulare Irrigation District (TID), the Consolidated Peoples Ditch Company (CPDC) and the Visalia & Kaweah Water Company (VKWC) are joint owners (Owners) of approximately 500 acres of land adjacent to the Kaweah and St. Johns Rivers in Tulare County, California, commonly referred to as the McKay Point Project area or Site (Figures 1 and 2). Together, the Owners are the holders of pre-1914 and appropriative water rights on the Kaweah and/or the St. Johns Rivers, and they own storage capacity rights in Lake Kaweah formed by the impoundment of water behind the Terminus Dam.

The Owners are also members of the Kaweah and St. Johns Rivers Association (Association), which oversees the surface water rights and diversion operations on the Kaweah River. The Owners propose to develop approximately 200 acres of the total 500-acre McKay Point property on the north side of the divergence of the Kaweah and St. Johns Rivers into a surface water storage and reregulation reservoir (Reservoir) as shown on Figures 2 and 3. When completed, the Reservoir will serve as a surface water storage/re-regulation facility. The Owners will also use the Reservoir to optimize groundwater recharge in basins within the Kaweah subbasin.

West Coast Aggregate (WCA) will excavate the Reservoir in accordance with plans and specifications to be developed. WCA intends to process the resulting aggregate materials (i.e., rock, sand, and gravel) within the Project Site (Figures 2 and 3). WCA would then sell processed materials such as Portland Cement Concrete (PCC) grade aggregate, used by their customers

DRAFT

offsite to manufacture concrete and asphaltic concrete products. WCA will also recycle concrete construction debris at their facility.

The Reservoir capacity is expected to be 4,600-acre feet. Its depth is expected to range from approximately 60 to 80 feet locally, with a typical average depth of approximately of 75 feet. The material excavated during construction will consist of resource-grade aggregate and will be processed at the WCA facility to be established within the excavation area.

Upon completion of the Reservoir excavation, water will be periodically diverted from the Kaweah River and stored in the Reservoir to achieve the following objectives:

- Store winter runoff and release in summer when required downstream.
- Reduce flood peaks during periods of high flows.
- Store Kaweah River water when the Owners' systems are at capacity so that additional water can be released later to be used for groundwater recharge within the Owners' respective service areas.

The Reservoir will extend vertically below the groundwater levels, and the Applicant will implement dry mining methods to recover the aggregate and to create the Reservoir. Dewatering of the excavated area will be conducted, as necessary to allow for dry mining techniques.

The Reservoir phase of the Project will entail storage and release of surface water only. To minimize groundwater from entering the excavation and the Reservoir, a slurry wall will be installed around the perimeter to decrease groundwater seepage. While some amount of seepage inflow will occur during periods when the Reservoir is not full, this seepage will be pumped out and returned to nearby groundwater. The slurry wall will also minimize stored water losses from the Reservoir to groundwater when it is full.

DRAFT

2. ENVIRONMENTAL SETTING

2.1. REGIONAL SETTING

The Site is in California's Central Valley near the western boundary in the foothills of the Sierra Nevada Geomorphic Province of California (Figure 1). The southern San Joaquin Valley bounds this part of the Sierra Nevada to the west and the Great Basin to the east. The Central Valley is one of the most productive agricultural regions in the world.

The Site vicinity is drained by the Kaweah and St. Johns Rivers, which drain ultimately to the Tulare Lakebed in the southern end of the San Joaquin Valley (Figure 4). In 1962, Lake Kaweah, located upstream from the Site, was created by the construction of Terminus Dam on the Kaweah River. Renovations of this dam in 2004 significantly reduced flooding at the Site and the surrounding area.

The Site is in the eastern portion of Kaweah Sub-basin of the San Joaquin Valley Groundwater Basin. This area is underlain by young and old unconsolidated fluvial deposits (sandy and silty gravels, clayey sand and cobbles, and silty and clayey sands) that originated from the nearby Sierra-Nevada Mountains. These moderately to highly permeable silts, sands and gravels extend to depths of several hundred feet or more.

2.2. LOCAL SETTING

The Site is currently undeveloped and has been used for cattle grazing under lease arrangements. Most of the Site is vegetated with native grasses.

The surface soil at the Site primarily consists of loose, medium-grained sand with occasional gravel and cobbles. Site surface drainage east of the river split is generally to the south and southeast toward the Kaweah River and west of the river split generally to the south and southwest toward the St. Johns River. The Site elevation slopes from approximately 472 feet above mean sea level (msl) at the northeastern end of the property, downward to approximately 454 feet above msl at the southwestern end.

2.3. CLIMATE

2.3.1. CURRENT CONDITIONS

Climate in the Site vicinity is typical of the foothill region of the central valley, with cool rainy winters having a mean daily temperature ranging from 40° to 50° F and hot dry summers when daytime temperatures can exceed 100° F (Table 1). During the summer months, a high-pressure system off the west coast of California prevents precipitation from occurring in the area. During the winter, this high-pressure system is intermittent, allowing Pacific storms to bring rainfall to the foothills. Rainfall increases with elevation in the foothills and the ranges. Most of the precipitation occurs from November through April.

2.3.2. CLIMATE CHANGE

Based on studies conducted for the Greater Kaweah Groundwater Sustainability Agency (GEI/GSI, 2020) the following changes to the precipitation, evapotranspiration, and runoff in the East Kaweah Basin are projected for 2030 and 2070 respectively. These projections are compared to current, or baseline conditions determined for the period 1981 to 2010.

Precipitation

Annual precipitation is projected to change very little, by approximately 0.5% either up or down. However, the seasonal distribution of precipitation will change with increases projected for Winter and late Summer and decreases in Spring. Specific projected changes are:

- 2030 Precipitation:
  - Annual increase of 0.06 inches or 0.4%
  - Increases in the November to April period; maximum increase in March (0.25 inches or 10%)
  - Decrease in the May through July period; maximum decrease in May (-0.08 inches or -14%)
  - Increase in the August to September period; maximum increase in August (negligible or 9%)
- 2070 Precipitation:
  - Annual decrease of -0.09 inches or -0.6%.
  - Increases in the December to March period; maximum increase in January (0.46 inches or 17%).
  - Decrease in the April through June period; maximum decrease in May (-0.18 inches or -31%).

DRAFT

- Increase in the July to September period; maximum increase in September (0.05 inches or 25%).

Evapotranspiration

Annual evapotranspiration is projected to increase, by approximately 3.2% to 8.2%. Maximum increases are projected to occur in the Winter and Spring periods. Specific projected changes are:

- 2030 Evapotranspiration:
  - Annual increase of 2.1 inches or 3.2% measured as pan evaporation.
  - Maximum relative increases occur in January (0.06 inches or 4.3%) and June (0.35 inches or 3.8%).
- 2070 Evapotranspiration:
  - Annual increase of 5.3 inches or 8.2% as pan evaporation.
  - Maximum relative increases occur in December (0.18 inches or 12.8%) and May (0.58 inches or 8.0%).

Under these conditions it can be expected that the crop demands for water will generally increase in proportion to the increased evapotranspiration estimates; by approximately 3% to 8% over time.

Runoff

Annual runoff is projected to be reduced by approximately -5% by and after 2030. A significant change is projected to occur in the seasonal distribution of runoff. Under current and the projected 2030 conditions the peak inflows occur, and are projected to occur, in May each year, i.e., in mid Spring. By 2070 inflows are predicted to peak in late Winter, two months earlier than March.

Strom Precipitation

As part of California's Fourth Climate Change Assessment, the California Energy Commission sponsored a study of the projected changes to California's precipitation intensity-duration-frequency curves which evaluated how the intensity and frequency of 1-to-7-day precipitation events would change for extreme storms such as the 25-year to 100-year events, compared to those experienced in from 1950 to 1999. The projections were made for the period 2050 to 2099 (50-years). The work was undertaken by the University of California, Irvine (UCI, 2018).

The general conclusions of the study are that extreme precipitation is expected to increase across most cities in California. Climate model simulations under the RCP8.5[1] project that in the future, the frequency of what is currently a 50-year event could double in both Southern and Northern California. This means that areas across California may experience extreme precipitation that is more intense and twice as frequent, relative to historical records.

[1] A Representative Concentration Pathway (RCP) is a greenhouse gas (GHG) concentration trajectory generally adopted by the Intergovernmental Panel on Climate Change (IPCC) for climate change forecasting. The RCPs describe the possible changes in future anthropogenic (i.e., human) GHG emissions. RCP 4.5 is described by the IPCC as an intermediate scenario. Emissions peak occurs around 2040, and then declines. RCP 8.5 emissions continue to rise throughout the 21st century and this pathway is generally taken as the basis for worst-case climate change scenarios.

DRAFT

He closest city to the Project that was analyzed is Fresno. Evaluation of the climate change effect on one-day storm precipitation frequencies for Fresno indicates, for example, that the precipitation values for a return period of 100-years would increase by 14% to 19% for the RCP4.5 and RCP8.5 scenarios respectively for the 50-year future projection period. The current storm precipitation amounts would occur more frequently. For example, the annual probability of occurrence of the current 100-year precipitation which is 1% could be increased to between 1.4% and 1.9% respectively, i.e., this storm event would become nearly twice as likely.

DRAFT

3. BASELINE CONDITIONS

This section contains descriptions of the existing (baseline) Site geologic and hydrologic conditions.

3.1. REGIONAL AND LOCAL GEOLOGY

The Central Valley has been formed by millions of years of deposition of Quaternary sediments derived from the uplifted Sierra Nevada and Coast Ranges, which bound the Central Valley on its east and west sides (Figure 1). The Central Valley is an alluvial plain, approximately 50 miles wide and 400 miles long (north south). Sediments have been deposited into the Central Valley for the last 160 million years and are thousands of feet thick in certain areas.

Numerous rivers and streams originating in the higher elevations of the Sierra Nevada, including the Kaweah River, flow westward into the Central Valley, depositing Quaternary alluvial sediments upon which the Site is located (Mathews and Burnett, 1965). This alluvium is underlain by a sequence of marine and continental sedimentary rocks consisting of shale, siltstone, and sandstone and locally granitic rock. Beneath the sedimentary rocks lie an impermeable basement complex of igneous and metamorphic rocks that extend as deep as 13,000 feet bgs. These basement rocks are a subsurface extension of the same rocks that occur in the Sierra Nevada (Faunt et al., 2009). A geologic map of the region is included as Figure 5

A total of 6 soil borings were conducted at the Site in November 2011 (BSK, 2011). Based on these borings and hydrogeologic interpretations by Schmidt (2012), the thickness of fluvial sediments within the Reservoir area ranges between approximately 40 and 100 feet. Alluvial deposits at the Site consist of sand that is about 15-20 feet thick. Luhrdorff and Scalmanini (1995) describe these sediments as Younger Alluvium. Below this sand interval, cobbles, boulders with sand, clay and silt are common. These deposits extended to a depth of about 40 feet on the eastern portion of the Site, and to about 100 feet on the western portion. Luhrdorff and Scalmanini (1995) describe these sediments as Older Alluvium. Geologic cross-sections for the Site have been prepared by Schmidt (2012) and for this study, which are included in Attachment A.

Weathered bedrock was not encountered in borings on the western portion of the Site but was encountered at approximately 77 ft bgs in two borings drilled at the eastern portion of the Site. The bedrock encountered is likely Mesozoic granitic rocks of the Sierra-Nevada batholith, which has been mapped as outcrops at higher elevations within a few miles to the north, east and south of Site. The weathered bedrock is presumed to underlie the entire Site but is apparently present at various depths (Attachment A). Discontinuous intrusions of clay or clayey sand were also occasionally encountered.

3.2. GROUNDWATER

The shallow aquifer at the Site is composed of the alluvial fan deposits associated with the local rivers. In some areas near the Site where overlying sediments are relatively thin, such as the Lemon Cove and Lindmore areas south of the Site, weathered bedrock forms the predominant aquifer. For example, one Lemon Cove public supply well is screened in the bedrock aquifer.

Most of the groundwater production south of the Kaweah River is from the bedrock interval (Schmidt, 2012).

Regionally, groundwater flows generally toward the west from the recharge areas of the Sierra Nevada mountains to the center of the valley (Figure 6). Groundwater elevations in the region vary from around 460 feet amsl near the Site, to around 250 ft amsl near the City of Visalia (DWR, 2014). Groundwater is pumped in the area for agricultural and urban uses.

The Site is in the Kaweah Subbasin, within the Tulare Lake Hydrologic Region (DWR, 2003). The Site is also near the eastern boundary of the Kaweah Delta Water Conservation District (KDWCD) (District; Figure 7). Approximately 265,000 acres of the district is irrigated for agriculture, and about 45,000 acres is urbanized. Numerous public and private entities within the district boundaries divert water from the river and its distributaries mainly for irrigation. In addition, almost all the land within the KDWCD receives some irrigation water obtained from groundwater, often as a supplement to surface water (Groundwater Sustainability Plan - GWSP, GKGSA, 2020).

KDWCD and surrounding areas have been in long-term groundwater overdraft. The KDWCD wide overdraft for the period 2007 to 2017 was estimated at approximately 78,000 AF/yr. Most of the overdraft occurs in the western portion of the district; not the Project vicinity (GKGSA, 2020).

In January 2020, the Greater Kaweah Sustainability Agency (GKGSA) published its “Groundwater Sustainability Plan” (GWSP). The purpose of the GWSP, is among others, to identify and describe Minimum Thresholds and Measurable Objectives for each monitoring location for each applicable Sustainability Indicator, as required to achieve the Sustainability Goal, and to define and identify Projects and Management Actions proposed by the GKGSA to achieve the Sustainability Goal. The Sustainability Plan area and its jurisdictional boundaries are shown on Figure 8. The Reservoir will be in Hydrogeologic Zone 10 within these boundaries. For this zone, the Minimum Threshold and Measurable Objective groundwater levels have been established for Well KSB-2822 (also referred to as 18S27E05J001M), located between the St. Johns and Kaweah Rivers (Figure 9), as 421 and 420 feet amsl respectively. The levels at KSB-2822 are at the Minimum Threshold and Measurable Objective levels established by the GKGSA).

The shallow aquifer in the Site vicinity is unconfined (Schmidt, 2012) and water levels are significantly higher than the Minimum Threshold and Measurable Objective levels. The long-term water level measurements for wells in the region surrounding the Site indicate stable water levels, except for temporary declines during drought periods (Figure 9). Seasonal water level fluctuations in the Site vicinity have generally varied by less than 20 feet for the last 50 years (Fugro, 2007). Within the Site, approximate water level elevations ranged from 463 feet amsl near the east edge of the Lemon Cove Facility, to just under than 430 feet amsl in the western part of the Site in December 2011 (Figure 10) based on six borings sampled during the site investigation program. The CEMEX excavations located immediately to the north of the Site, have exposed groundwater because of the permitted surface mining on that site. As presented in Attachment B, groundwater level elevations have ranged from about 438 to 443 feet amsl in the area immediately northwest of the Site, to between 456 to 460 feet to the northeast of the Site in the 2008 to 2010 period.

The main source of recharge to the aquifers in the Site area is groundwater flow form the east. Localized groundwater gradients suggests that the St. Johns and Kaweah Rivers lose some of their flow to infiltration, and that these rivers are sources of groundwater recharge. Other sources

DRAFT

of groundwater recharge in the Site vicinity include infiltration of water used for irrigation, and infiltration from local irrigation ditches in the area and from seasonal surface water flow.

3.3. GROUNDWATER WATER QUALITY

Groundwater in the region is generally considered suitable for beneficial uses, including municipal/domestic, industrial, and agricultural purposes except for a few instances that are discussed below. In the project vicinity, groundwater quality is favorable with respect to physical parameters (total dissolved solids, pH, and specific conductivity), and other major constituents related to potability (such as chloride, and sulfate, and nitrate). Groundwater in the project area generally reflects the properties of local surface water runoff, which serves as a replenishment source. While there are localized occurrences of high dissolved minerals or high nitrate levels due to the influence of land use (e.g., infiltration of irrigation tailwater), groundwater generally satisfies Title 22 Drinking Water Standards and is utilized as a drinking water source for municipalities, small community systems, and individual households. High concentrations of iron and manganese are also known to occur in the region, which in some instances may exceed secondary drinking water standards (Luhdorff and Scalmanini, 2004).

Consistent with the regional characteristics, groundwater quality at the project site is characterized by relatively low conductance and is of calcium-bicarbonate to calcium-sodium bicarbonate in composition. Samples collected from monitoring wells completed in the younger alluvium and the older alluvium at the project site had specific conductance values of 120 to 260 mhos/cm and total dissolved solids (TDS) levels of 95 to 170 mg/l (Jones & Stokes, 1998). Calcium and bicarbonate are the predominant cation and anion. Compared with sources to the west, the groundwater in the project area exhibits lower mineralization due to the apparent influences of surface waters in the Kaweah and St. Johns Rivers (Bookman-Edmonston 1972). ·

Several locations surrounding the project vicinity have experienced degraded groundwater quality in the shallower aquifers due to agricultural practices in the area. Examples include the Lemon Cove area, the areas immediately south of Wutchumna Hill and west of the Reservoir, which have elevated levels of nitrate in groundwater, up to approximately 100 mg/L (Schmidt, 2001).

The City of Woodlake has also reported problems with elevated nitrate concentrations and is concerned with any project that may increase degradation (Jones & Stokes, 1998). Other than nitrate, groundwater and surface water in the Site vicinity appear suitable for existing beneficial uses (Fugro, 2007).

3.4. SURFACE WATER

3.4.1. CURRENT CONDITIONS

The east side of the San Joaquin Valley consists of a broad plain formed by coalescing alluvial fans associated with streams draining the western slopes of the Sierra Nevada (Figure 4). The southern end of the San Joaquin Valley is known as the Tulare Basin. The Tulare Basin is hydrologically closed. Instead of flowing to the ocean, streams from the Sierra Nevada flowing into the Tulare Basin terminate at depressions, the largest of which is the Tulare Lakebed.

DRAFT

The primary natural surface water bodies in the Site vicinity are the Kaweah and St. Johns Rivers, which form the eastern and southern Site boundaries. The Kaweah River flows westward from its headwaters in the Sierra Nevada. Along the southern Site perimeter at a location referred to as McKay Point, the Kaweah River diverges into two rivers, forming the St. Johns River and the Lower Kaweah River. Several ponds are located just north of the Site at the adjacent CEMEX operation (Figure 2). A pond is also located on the Kaweah River Rock property to the west of the Site. These ponds consist of exposed groundwater, created by previous mining beneath the groundwater elevation.

Downstream of the Site, the Kaweah River historically branched into 8 or 10 shallow channels that overflowed during high flows, creating marshlands. These shallow channels were later integrated into irrigation canals and ditches for the delivery of irrigation water in support of agriculture irrigation. These channels still carry non-irrigation flow to Tulare Lakebed but only during periods of extraordinary precipitation or snow melt (Figure 4; Army Corps, 1990).

In 1962, Lake Kaweah (the Lake), located approximately 3 miles upstream of the Site, was created by the construction of Terminus Dam (Figure 4). Construction of this dam provided storage of irrigation water and flood protection for downstream areas. The Lake has a capacity of approximately 185,630 AF. Flood control considerations require that, between November and March, a portion of the Lake volume be reserved to store runoff in high rainfall or snowmelt events. Therefore, during a wet year the Lake typically releases most of the water to maintain low levels. In a dry years Lake outflow is typically very low in winter with sporadic increases in response to significant precipitation or snowmelt conditions.

Storage for water supply begins in late winter and releases occur in late spring and early summer. In wetter years, releases may begin in late winter and remain high (above 1,500 to 2,000 cfs) through spring and late summer (EPA, 2005; US Army Corp. 2005, Kaweah, and St. Johns Rivers Association - Water Master Reports though 2007). Water released from the Terminus Dam serves multiple local water districts such as the Tulare Irrigation District (TID) and Kaweah Delta Water Conservation District (KDWCD) as well as several small ditch companies. The dam also discharges water to generate hydroelectricity.

During a typical average year streamflow upstream from McKay Point (gauge Kaweah River at McKay Point) is intermittent for about 8 months during late summer through late winter (September through April (Watermaster Reports). When they occur, flows can typically range up to 1,000 to 2,000 cfs. During June and July flows are more consistent with maximum flows still ranging up to approximately 2,000 cfs or higher (Table 2 below).

DRAFT

TABLE 2: KAWEAH RIVER AT MCKAY POINT – MONTHLY FLOWS – (PERIOD 2001-2020)													
	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEP	OCT	NOV	DEC	ANNUAL
Average (cfs)	313	355	298	314	731	1,359	1,265	525	94	15	61	127	455
Minimum monthly (cfs)	-	-	-	-	8	454	207	15	-	-	-	-	61
Maximum monthly (cfs)	1,862	2,071	2,241	1,709	2,241	2,303	2,135	1,609	701	178	668	723	1,274
Average (AF)	19,261	19,701	18,301	18,665	44,939	80,854	77,805	32,286	5,577	907	3,637	7,832	329,765
Streamflow data from the annual Water Master Reports (Kaweah & St. Johns Rivers Association) for the period of record 2001 to 2020.													

The annual flows vary significantly and since 2001 have ranged from 43,815 AF/year to 922,247 AF/year. The gauged values are summarized in Table 3 below. In approximately 30% of the years the flow is above average, and in the remaining 70% of the years, below average.

TABLE 3: KAWEAH RIVER AT MCKAY POINT – ANNUAL FLOWS IN AF/YEAR – (PERIOD 2001-2020) – BOLD VALUES ARE YEARS WITH ABOVE AVERAGE FLOWS										
Year	2000-01	-02	-03	-04	-05	-06	-07	-08	-09	-10

Flow	**746,509**	200,737	99,523	52,893	43,813	287,178	**922,247**	202,334	**631,189**	156,873
Streamflow data from the annual Water Master Reports (Kaweah & St. Johns Rivers Association) for the period of record 2001 to 2020. Year is based on the October to September time frame.										

Flows arriving at McKay point are divided between the St. John and Kaweah Rivers by the McKay Point Structure which consists of two flow control structures, one in the St. Johns and one in the Kaweah River. These water control facilities are owned and operated by the Kaweah Delta Water Conservation District and the Kaweah & St. Johns Rivers Association. Both check structures are located immediately downgradient of McKay Point (Figure 3). The check structures can be closed or opened to control flow rates in the St. Johns and Kaweah Rivers.

Dry Creek flows into the Kaweah between Terminus Dam and McKay Point and is the largest source of runoff below Terminus Dam (Figure 4). Dry Creek flows southward from its headwaters and joins the Kaweah approximately one mile down from Terminus Dam. Water supply diversions begin immediately downstream of the dam through Hawkeye, Lemon Cove, and Foothill Ditches, and flows diverted are less than 10,000 AF/yr. total. Farther downstream, Wutchumna Ditch Company diverts water into Bravo Lake, a 4,000 AF Reservoir (U. S. Army Corps of Engineers, 1990).

DRAFT

Spills from the irrigation systems of the Kaweah and St. Johns Rivers are limited to the above average years as shown by the measured flows in Table 4.

TABLE 4: SPILLAGES FROM THE KAWEAH AND ST. JOHNS RIVER IRRIGATION AREAS MEASURED AT (1) ELK BAYOU BELOW ROAD 96 AND (2) CROSS CREEK AT HIGHWAY 43 TO TULARE LAKE – ANNUAL FLOWS IN AF/YEAR – (PERIOD 2001-2020)

Streamflow data from the annual Water Master Reports (Kaweah & St. Johns Rivers Association) for the period of record 2001 to 2020. Year is based on the October to September time frame.

3.5. FLOODING

Before the Terminus Dam was constructed, extraordinary storm events in December 1955 resulted in an estimated peak flood discharge at McKay Point of 87,000 cfs, which is the largest peak runoff from the Kaweah River watershed in the 20th century. Since the construction of Terminus Dam in 1962, most flooding concerns for areas downstream of the dam were greatly alleviated. For example, the peak average daily inflow to Lake Kaweah during the 1966 flood was 105,000 cfs, whereas the maximum release from the dam was 5,666 cfs. Lake Kaweah is operated with an objective of maintaining a flow of less than 5,500 cfs at McKay Point, which includes flow from undammed tributaries such as Dry Creek. Above this flow rate, flood damage can occur to downstream properties, infrastructure, and municipalities (U. S. Army Corps of Engineers, 1990).

The Terminus Dam height was increased by approximately 21 feet in 2004, which further reduced flooding in the area (U. S. Army Corps of Engineers, 2005). It is estimated that currently the dam provides protection for a design flood event of 50-year return period (FEMA, 2009).

FEMA has prepared a flood hazard map for the area including the Site (Figure 11). FEMA has calculated base flood elevations for the Kaweah and St. Johns Rivers, but only for stretches downstream of McKay Point. The map indicates that the 100-year flood level near the Site along the St. Johns River is approximately 465 feet amsl. During most flooding conditions, major and minor flooding in the area is dissipated by diversions to the network of irrigation ditches, irrigation diversions, channel percolation, and evapotranspiration (U. S. Army Corps of Engineers, 1990).

DRAFT

3.6. SURFACE WATER QUALITY

Surface water near the project Site is generally considered suitable for beneficial uses including municipal, domestic, agricultural and groundwater recharge purposes. Virtually all municipal and industrial water supply in the region is derived from groundwater and surface water is essentially used exclusively for agricultural purposes. As such, the surface water quality is classified as Class I for irrigation by the Department of Water Resources. The water is characterized by relatively low conductance and dissolved solids and is of calcium-bicarbonate to calcium-sodium bicarbonate in composition (Luhdorff & Scalmanini, 2004)

DRAFT

4. PROJECT DISCUSSION

4.1. INTRODUCTION

This section describes the reservoir objectives, includes a discussion of the initial excavation and final construction of the Reservoir, the design of the excavation, slurry wall, and final Reservoir. It provides the water balance analyses for both the excavation and Reservoir operational stages and describes how the reservoir would be operated. The section concludes with an analysis of the water supply and flood control benefits that would be achieved.

4.2. RESERVOIR OBJECTIVES

Once the Reservoir is completed, the Owners will utilize the Reservoir and its facilities to manage their surface water supplies to increase the long-term availability of irrigation supplies, groundwater recharge supplies, and to provide for additional flood flow reductions by temporarily storing high flood waters. Its purpose is to provide multiple benefits including:

- Capturing and re-regulating water made available to the Owners during flood releases from Terminus Dam.
- Capturing and re-regulating water entitlements belonging to the Owners released from Terminus.
- Capturing and re-regulating any other water sources on the Kaweah River, such as Dry Creek, that may be made available to the Owners.
- Allowing other entities with water rights on the Kaweah River to capture and/or re-regulate flows when designated by the Owners.
- Allowing other entities to capture and/or re-regulate flows of the Lower Kaweah River and St. Johns River for purposes of storm water runoff and flood prevention with permission of the Owners and Kaweah/St. Johns water rights interests.
- Effectively extending the Owners' irrigation and/or groundwater recharge season by storing additional Kaweah River water during events in which the Owners' delivery systems are at capacity.

The Reservoir would be constructed in such a way that revenue can be obtained to offset the construction and development costs. Locating the Reservoir adjacent to the Kaweah River allows for easy connection between the river and the Reservoir, thus minimizing the need for pipelines. The elevation of the water surface above McKay Point in the Kaweah River will be used to divert water into the reservoir by gravity.

4.3. RESERVOIR CONSTRUCTION

4.3.1. APPROACH

The proposed Reservoir would occupy a surface area of approximately 130 acres, have an average water depth of 60 to 80 feet, and would have storage capacity of approximately 4,600

DRAFT

acre-feet (Figures 3 and 12). Final side slopes will be approximately 3:1, horizontal: vertical (H:V), to maximize stability and minimize bank erosion from wind, water, and waves. The upper portions of the Reservoir slopes for several feet above and below the full Reservoir water level will be covered with suitable riprap from natural stone sources or processed construction concrete debris to prevent wave action from eroding the surface.

4.3.2. EXCAVATION

Over the estimated approximate 15- to 23-year excavation phase, excavation is expected to proceed at annual rates of up to approximately 920,000 gross tons per year of silts, sands, and gravels, although this rate will likely vary in any given year. The excavation equipment, the material processing plant and associated settling pond would be located within the Reservoir perimeter as shown in Figure 13. Different areas of the excavation bottom would be lowered in stages and the process equipment relocated as appropriate. The excavated materials would be processed to produce a specified range of granular construction materials and sold. The work would be done by WCA. WCA would also receive, stockpile, and recycle concrete construction debris materials.

During the initial excavation and material processing stage, an impermeable slurry wall will be constructed around the exaction area to limit the amount of groundwater flow into the excavation as excavation progresses below the water table.

The WCA excavation phase (Figure 13) would include the following key facilities:

- A security fence that surrounds the excavation and eventual Reservoir area.
- A controlled access gate along the west side of the excavation area.
- A scale hose near the entrance gate to provide for weighing recycle materials coming into the site and construction materials being shipped from the site.
- A haul truck unloading and loading area.
- Portable crusher and recycle plant.
- Portable diesel fuel tank for onsite equipment (4,000 gallon).
- An aggregated production (wash/screen) plant.
- A stockpile area, or areas.
- A slurry wall.
- A settling pond for clarifying/recycling process and wash water for reuse.

As shown on Figure 13 the excavations would occur within the footprint of the total area and be expanded and deepened over time. The initial excavation area shown in Figures 13 and 14, is approximately sufficient for a 6-month supply of processed material. Typically, the side slopes of the excavation will be 1.5 to 1 (Horizontal: Vertical). It should be noted that the layout and facilities shown on the figure are for illustrative purpose and WCA will refine and adjust these as necessary at the start of the excavation program, keeping all the operations within the excavation footprint.

During excavation phase, the area would be dewatered, as needed, by a series of wells constructed within the excavation area to draw down the water table to below the excavation floor. Seepage calculations (Attachment D) indicate these extraction rates would initially be minimal and increase to their maximum as the excavation is deepened to the maximum depth, i.e.

DRAFT

- Initial rate: 0 gpm
- Final rate: approximately 220 gpm

The water extracted to dewater the excavation would be pumped to the northern edge of the excavation and re-injected into a gravel fill infiltration gallery along and outside of the northern border of the slurry wall as shown on Figures 3, 13 and 14. This groundwater pumping would therefore not result in a consumptive loss of water.

The slurry wall will be designed by a qualified professional and constructed by a qualified contractor with experience in installing similar facilities. Construction would include the following facilities:

- A perimeter access road that would also serve as a leveling surface for the construction of the slurry wall. The road would vary in width from approximately 30 to 50 feet and be built on fill up to 8 foot in height.
- An approximately 60- to 80-foot-deep slurry wall surrounding the excavation/Reservoir area. Its actual depth will be determined during design and verified during construction based on subsurface information, to provide the required reduction in groundwater inflow. As shown on Figure 15, the slurry wall would be constructed through the perimeter road and capped off with a durable gravel layer.
- An approximately 5-foot-deep water infiltration trench along the northern border of the ultimate Reservoir area (Figures 15 and 16).

It is anticipated construction would take approximately 6 months and would include the following on-site facilities as shown on Figure 13. After completion of the slurry wall these facilities would be demobilized from the site:

- Vehicle and equipment parking areas.
- A fill material stockpile area.
- Equipment storage area.
- A bentonite slurry mixing pond (see further discussion below on the slurry wall construction activities).
- A slurry wall backfill mixing area that would be moved along with the construction of the slurry wall, so it is always adjacent to the segment being excavated.

The general sequence of slurry wall construction activities would include:

- Surface clearing, grading, and filling to create a sufficiently long section of the perimeter road.
- Excavation of the slurry wall trench (Figure 15) through the road which also provides a relatively level surface to contain the slurry in the excavation. The trench is first excavated to its full depth and then extended in length.
- Filling the trench with a bentonite slurry (bentonite clay and water mix) to support the sides of the excavation and prevent them from collapsing. The bentonite slurry is mixed in the above referenced bentonite slurry mix pond and pumped by pipeline into the excavated trench.
- The excavated soils from the trench are placed in an adjacent prepared slurry wall backfill mixing area for use in preparing the backfill, or if unsuitable for hauling the soil back to the WCA operations for processing as appropriate. The crushed concrete from offsite recycling may also be used as final riprap protection on the Reservoir slopes.

DRAFT

- As the trench is extended in length, backfilling is commenced. This is accomplished by first preparing the backfill material which typically includes granular soils mixed in with bentonite and water to create a low permeability material in the slurry wall backfill mixing area. Either suitable durable excavated granular material will be used, or suitable material will be obtained from the WCA operations or imported from offsite.
- Once mixed, the backfill is pushed into the trench by a dozer, or equivalent, from the narrow end, opposite to the end of the trench that is still being excavated. The backfill material displaces the bentonite slurry in the trench and eventually settles and forms a low permeability wall. The ultimate length of the slurry wall is approximately 13,400 feet and its width is typically 3 feet.
- As the wall is completed and gravel cap is placed over the top of the backfilled trench, it will form part of the perimeter road as shown on Figure 15.
- A road safety berm will also be constructed along the inside of the road facing the excavation area.
- As the excavation of the reservoir is deepened an access ramp as shown on Figure 16 will be constructed in the excavated slope to provide for equipment access.

It should be noted the above discussion is for illustration purposes and actual construction techniques will vary based on the approved means and methods the contractor selects, and possible future technology advances in slurry wall construction.

The longitudinal section through the initial and final excavation is shown on Figure 14. The excavation configuration is relatively shallow compared to its length (horizontal to vertical dimensions are of the order of 100 to 1).

The material balance is as follows:

- Excavated to a 1.5 to 1 slope: 16.4 million tons (11,050,000 cy)
- Use of excavated materials:
    - Exported as product: 11.5 million tons
    - Use for 3 to 1 fill: 2.4 million tons (based on a 75% usability factor)
    - Use for road construction 0.1 million tons
    - Other uses 2.5 million tons

Compared to the above volumes the volume of the slurry wall is much less, at approximately 112,000 cy (0.2 million tons).

4.3.3. RESERVOIR

Construction of the Reservoir would be initiated during the final stages of the excavation and material processing, or if necessary, at a later stage. It would include two major construction activities:

- Backfilling of the excavation slopes to flatten them from 1.5 to 1 to 3.0 to 1. This is shown on Figures 14, 15 and 16. The backfill would be of suitable materials that has both sufficient strength and is relatively free draining. It would be constructed from the bottom up in compacted layers of suitable thickness. Figure 16 shows the first layer of the backfill being placed along the east side of the excavation.

DRAFT

- The second major activity would include construction of the following components (Figure 17):
    - Inflow Channel - controlled by gates
    - Electrically operated slide gates in the Inflow Channel.
    - Inflow Chute – with rip-rap erosion protection.
    - Energy Dissipation Pool - Based upon the drilling logs, it is expected bedrock will be encountered at the proposed final elevation of the Inflow Chute. However, if the excavation does not get down to bedrock, installation of an energy dissipation pool at the base of the Inflow Chute would prevent potential scouring of the excavation slope by water entering the Reservoir.
    - Floating Barge Pump and Discharge Pipeline to deliver into the Kaweah River upstream of the existing McKay Point Structures.
    - Above-Ground Diesel Tank, Generators and Generator Building.
    - Outflow Channel into the St. Johns River.
    - Electrically Operated Weir for the Outflow Channel.
    - Supervisory Control and Data Acquisition (SCADA) equipment would be used to monitor Reservoir levels and conditions, and to operate the Inflow Channel, Outflow Channel, and Floating Barge Pump.

4.4. DESIGN

Conceptual level designs have been completed for the purposes of this report. These are described in the Geology and Soils Technical Study (SLR, 2021), and are at a level of detail that allows for the evaluation of the impacts and benefits associated with the proposed facilities. A brief discussion is also provided of the typical detailed design activities that would be performed before the facilities are constructed.

Conceptual designs of the various reservoir components discussed in Section 4.3.3 above are provided by Provost and Pritchard.

4.5. WATER BALANCE

4.5.1. DURING EXCAVATION

Processing will include both crushing and screening as well as washing. A total water flow rate of up to 1,500 gpm will be required for these processes. The used water will be collected and conveyed to a settling pond in the bottom of the excavation where the washed-out fine material would settle, and the clarified water would be recycled back to the processing plant with the remainder infiltrating back into groundwater under the excavation area. A much smaller amount of makeup water would be required to replace the water lost in the processing and water used for dust control at the Site. This water would be extracted from several wells located within the excavation area, the same wells that are used to dewater the excavation. Estimated makeup water requirements (or consumptive use of water during the construction period) amount to:

DRAFT

- Losses in the processing: 110 AF/year
- Settling pond evaporation: 1 AF/year
- Dust control water: 30 AF/year

  Total: 141 AF/year

The processing will also result in the accumulation of fine silt which collects in the bottom of the settling pond, some of which may be used as a soil amendment onsite in association with revegetation activities, and in construction of safety and slope stabilization berms.

During excavation the groundwater extracted to maintain dry conditions would be pumped back into the infiltration trench so would not represent a consumptive use.

4.5.2. DURING RESERVOIR OPERATIONS

Water balance analyses have been performed to assess how the Reservoir would typically be operated and how much consumptive use is associated with these operations. Water loss would occur form:

- Evaporative loss from the moist surface of the Reservoir when it is maintained in an empty condition.
- Evaporative loss from the Reservoirs surface when it is full, or partially full.

Estimated consumptive use during a year when the reservoir is operating is approximately 200 AF. During years when the reservoir is not used, net evaporation losses range from insignificant for the case where the Reservoir is maintained empty by continuous pumping of the inflowing groundwater into the infiltration trench, to approximately 340 AF for the case when the Reservoir is maintained in a filled condition, thus saving the pumping energy consumption.

4.6. ANTICIPATED RESERVOIR OPERATIONS

4.6.1. INFLOW CHANNEL MANAGEMENT

The Inflow and Outflow Channels will be constructed perpendicular to the Kaweah and St. Johns Rivers (Figures 3 and 17). The Inflow Channel will provide flow into the Reservoir via a reinforced concrete control structure. The control structure would include an approach apron, reinforced concrete floor, flow/level control gates, walls, and a deck on top of the structure. The existing check structures downstream of McKay Point and the proposed inlet gates would control the flow rate into the Reservoir (Provost and Pritchard, 2014).

To divert river water into the Reservoir, when the river water level is higher than that of the Reservoir, the Electrically Operated Weir on the Inflow Channel would be opened. Water would flow by gravity into the Reservoir up to a maximum flow capacity of up to 3,500 cfs and an average of approximately 2,400 cfs as the Reservoir fills up. Upon achieving water level equilibrium between Reservoir and river, the Electrically Operated Weir would be closed. As the level of the river recedes, the Electrically Operated Weir would serve to hold water in the Reservoir.

DRAFT

4.6.2. OUTFLOW CHANNEL MANAGEMENT

Gravity-Flow Water Delivery into The St. Johns River and Kaweah River

The gravity Outflow Channel for the Reservoir is located downstream of the St. John's check structure (Figures 3 and 17). The discharge capacity of the outlet is currently estimated to be approximately 900 cubic feet per second. The outlet could gravity drain up to approximately 1,100-acre feet of the Reservoir into the St. Johns River. A proposed floating pump would empty the remaining 3,500 acre-feet stored in the Reservoir. Discharge capacity of the floating pump is currently estimated to be 160 cubic feet per second and would discharge upstream of McKay's Point allowing for diversions into either the St. Johns or the Lower Kaweah River (Provost and Pritchard, 2014).

When the St. Johns River water level is lower than that of the Reservoir, lowering the Electrically Operated Weir on the Outflow Channel would deliver water by gravity flow into the St. Johns River up to a maximum flow capacity of 900 cfs. The average flow rate will be approximately 350 cfs because the flow rate would reduce gradually to zero as the level of the Reservoir approaches the level of the Outflow Channel.

The Outflow Channel will include a riprap or concrete apron, constructed across the riverbed of the St. Johns River when dry. This apron will prevent the potential scouring effects of the water entering the river.

The Inflow Channel could also be used as an Outflow Channel to deliver releases to the Kaweah River. It also includes riprap protection in the river. When the Kaweah River water level is lower than that of the Reservoir, lowering the Electrically Operated Weir on the Inflow Channel would deliver water by gravity flow into the Kaweah River at a flow capacity of 500 cfs (the Inflow Channel could be used for inflow or outflow). The average flow rate of return will approximate 200 cfs because the flow rate would reduce gradually to zero as the level of the Reservoir approaches the level of the Inflow Channel.

Water delivery in this manner is limited by the amount of water being stored at a level higher than that of the Inflow Channel (i.e., approximately 15 feet of additional storage). Once the level of the Reservoir falls below that of the Inflow Channel, the Floating Barge Pump will be used.

Pumped Water Delivery into The St. Johns and Lower Kaweah River

To release water to the St. Johns River or the Lower Kaweah River when the river water levels are higher than that of the Reservoir, the Floating Barge Pump will pump water from the Reservoir, via the Floating Barge Pump Discharge, into the Kaweah River, upstream of the McKay Point Structure.

DRAFT

4.6.3. RESEVOIR OPERATIONS

The Reservoir would be operated in one of the following modes:

- *Water Conservation Mode* during which excess water would be stored in the Reservoir for later release downstream for irrigation use or groundwater recharge.
- *Flood Control Mode* during which the Reservoir would be used to store flood peaks to alleviate downstream flood damage.
- *Dual Use Mode* during which the Reservoir would be operated either for conservation or flood control.

From mid-April through the end of October, the Reservoir would be in *Water Conservation Mode* for water supply re-regulation. It is anticipated that the Reservoir would fill for the final time with flood water or otherwise storable Owner entitlement. Before the end of the irrigation season the Reservoir would be emptied to meet Owner irrigation demand and would remain empty for the upcoming flood season.

From the beginning of November to the end of January the Reservoir would be in *Flood Control Mode*. Flood peaks resulting from Terminus dam release and flood flows in the unregulated Dry Creek which exceed a stipulated flow rate would be diverted into the Reservoir to decrease downstream flood flows. Further discussion of this control mode is provided in Section 4.6.5 below.

From early February through mid-April approximately, the Reservoir would be in a *Dual Use Mode* which involves the overlapping of two operational drivers: *Flood Control* and Water *Conservation Modes*. During this period the Reservoir would be filled based on the availability of refused floodwater and the need to have an empty Reservoir for flood mitigation given forecasted weather conditions.

The Reservoir could be filled in a few days, depending on the flow in the Kaweah River and would decrease the peak flood flows. The quickest the Reservoir could be completely dewatered would be in approximately 12 days.

4.6.4. WATER SUPPLY BENEFITS (*CONSERVATION MODE* OPERATION)

Tulare Irrigation District (TID) has established a water balance model that simulates the irrigation water system from the outflow from Terminus Dam and Dry Creek down to the spill areas Cross Creek at Highway 43 into Tulare Lake, including supplies from, and exchanges with the Central Valley Project (CVP) and the Friant-Kern Canal, and the demands of the TID and the Consolidated Peoples Ditch Company (CPDC) and the Visalia and Kaweah Water Company (VKWC). The model incorporates the Reservoir operation. This model has been used to illustrate Reservoir operations for the climatic conditions observed for ten years from 2010 to 2019. The results of these simulations are shown in Figures 18A through 18E, and the associated agricultural water gains are summarized in Table 5[2]. These results indicate that the Reservoir benefits occur when the mean annul flow conditions exceed approximately 50% of the long-term mean annual flow, or in 6 out of the 11 years simulated. In these years, it would have benefited agencies to put Kaweah

[2] Note that the year 2017-18 is not plotted in the Figure 18 series since the additional water provided is very small.

DRAFT

water into the Reservoir to be able to take Central Valley Project (CVP) water during events in which Owners' delivery systems were at capacity due to a combination of Kaweah and CVP water and there was surplus CVP water available which had to be refused to avoid additional spill on the Kaweah system.

As shown on Figure 18A for example, the solid red line indicates the period of the *Flood Control Mode*, the dashed red line indicates the duration of the *Dual Use Mode,* and the remaining period corresponds to the *Conservation Mode*. As noted from this figure there were no diversions for flood control purposes. During the *Dual Use* and *Conservation Mode* periods water was transferred into the Reservoir in the April and May, and smaller amounts in June and August as indicated by the green dashed line. This stored water would have been used in May and again in July and August as indicated by the dotted blue line. The corresponding Reservoir volumes are indicated by the solid blue line

TABLE 5 SUMMARY OF ANNUAL AGRICULTURAL BENEFITS

Year	Annual Precipitation at Terminus Reservoir		Annual Runoff of Kaweah River at McKay Point		Agricultural Benefit	
	Inches	% Of Long-Term Mean	Acre Feet	% Of Long-Term Mean	Additional Water Provided for D/S Use (AF)	Number Of Major Water Supply Events
2009-10	18.96	127%	454,670	122%	7,092	2
2010-11	22.38	150%	746,509	201%	6,910	2
2011-12	12.23	82%	200,737	54%	4,600	1
2012-13	6.77	45%	99,523	27%	-	
2013-14	6.15	41%	52,893	14%	-	
2014-15	8.97	60%	43,813	12%	-	
2015-16	18.39	123%	287,178	77%	-	
2016-17	19.89	133%	922,247	248%	5,842	1
2017-18	8.93	60%	202,334	54%	61	1
2018-19	17.33	116%	631,189	170%	11,445	2
AVERAGE ANNUAL	14.94	100%	371,790	371,790	3,595	1.5

The benefits of the *Conservation Mode* operations are expected to increase for climate change scenarios. While the total annual runoff changes are minor (a reduction of up to 5%, Section 2.3.2) the higher seasonal flows are projected to occur earlier in the year likely resulting in increased flood releases from Terminus Dam. With the Reservoir in place these earlier releases could be stored and then used to increase the CVP water by a like amount later in the year. Furthermore, use of the Reservoir will more critical since overall, less runoff will be available, making it more important to reduce any spillage of unused water by storing it in the Reservoir.

4.6.5. FLOOD MANAGEMENT BENEFITS (*FLOOD CONTROL MODE* OPERATIONS)

The Terminus Dam and Kaweah Project is operated so that flows do not exceed 5,500 cfs in the Kaweah at McKay Point to protect the downstream municipalities, rural communities, and agricultural lands in the Tulare Lakebed from flood damage. (USACOE, Revised 2005). Dry Creek is the major uncontrolled tributary to the Kaweah River below Terminus Dam and upstream of the Reservoir. This tributary can produce high magnitude flows that require rapid release changes from the dam if the impact is to be reduced, since there are no flood control measures in place for these flows.

Flood attenuation benefits were assessed by considering the three largest instantaneous flood peak flows that were recorded on Dry Creek between 1960 and 1997. As shown on Table 6, these include:

- December 6, 1966 (peak flow = 14,500 cfs).
- January 25, 1969 (6,070 cfs).
- January 2, 1997 (4,380 cfs).

Operations of Terminus Dam allowed for low release rates on these flood days to compensate for the higher Dry Creek flows as shown by the measured average daily flows in Table 6 (column 3). However even with these reduced discharges the flood peak flows in the Kaweah River at McKay point were still elevated as shown in the 4th column of Table 6, i.e., 4,508, 6,646 and 15,549 cfs respectively. In extremely wet years such as 2017, it would be desirable to have the Reservoir absorb the Dry Creek flows so that Terminus can keep releasing as opposed to reducing releases from Terminus, thereby keeping storage available for flood inflow to Terminus (Watermaster of the Kaweah Delta).

Flood routing simulations were conducted to assess how much the Reservoir, had it been in pace, could have reduced these flood peaks. For these simulations it was assumed that once the Kaweah River at McKay Point flows exceed 2,500 cfs, the excess flows up to the maximum capacity of the inlet to the Reservoir (3,500 cfs[3]) are diverted into the Reservoir. As shown by the results listed in Table 6 (column 5), it would have been possible to reduce the flows to below approximately 3,000 cfs in the river, except for the very large December 1966 flood. Even for this event the flood peak would have been reduced to 12,472 cfs, a reduction of 3,068 cfs.

Figure 19 shows which day of the year the measured annual maximum flood peaks occurred in Dry Creek, and these can be considered to cover the periods during which future large floods may occur and during which the Reservoir could potentially be used for flood control purposes. The solid lines in the chart indicate the approximate starts and finishes to the *Flood Control Mode* period that could be considered. These periods would include:

- November 1 would be the start of the flood control operations during which the Reservoir would exclusively be used for flood control purposes and emptied after each flood storage event in anticipation of the next flood event. The released water could be used for recharge in a variety of basins around TID ranging from several acres to 150 acres in size.
- January 31 would be considered the end of the *Flood Control Mode* period.

[3] This assumes the gates will all be opened to provide for the maximum inflow capacity during a flood event. During normal operations inflow rates would be less.

DRAFT

- February 1 through April 15 would be considered a *Dual Use Mode* period during which water from a projected large flood would be stored in the Reservoir, but after the flood the water would only be released in accordance the which agricultural demand as discussed in Section 4.6.4.

TABLE 6: KAWEAH RIVER AT MCKAY POINT – ANNUAL FLOWS						
HISTORIC FLOOD FLOW DATA				SIMULATED EFFECT OF STORING FLOOD FLOWS ABOVE 2,500 CFS[4] IN RESERVOIR		
DATE	MEASURED INSTANTANEOUS PEAK DRY CREEK FLOW RATE (CFS)	MEASURED AVERAGE SAME DAY DAILY OUTFLOW FROM TERMINUS DAM (CFS)[5]	CALCULATED MAXIMUM INSTANTANEOUS PEAK FLOW IN KAWEAH AT McKAY POINT (CFS)[6]	REDUCED FLOOD FLOWS TO DOWNSTREAM OF RESERVOIR (CFS)[7]	REDUCTION IN KAWEAH RIVER AT McKAY POINT FLOW BY STORING FLOOD WATER IN THE RESERVOIR (CFS)	RESERVOIR STORAGE UNTILIZED (AF)
December 6, 1966	14,500	1,040	15,540	12,472	3,068[8]	4,600
January 25, 1969	6,070	576	6,646	3,146	3,500	2,429
January 2, 1997	4,380	128	4,508	2,628	1,880	939

The flood routing was repeated for the estimated 10-year to 100-year flood peaks at McKay Point developed by FEMA and discussed in Section 3.5 above. The results are provided in Table 7 showing the reductions that could be achieved. It is evident that the Reservoir could reduce flood peaks to below the target 5,500 cfs for flood events up to approximately the one in 50-year event. For larger floods, it would still be possible to reduce the flood peaks, however it would not be possible to meet the 5,500 cfs target at McKay Point.

In conclusion the Reservoir would have the ability to capture some of the floodwater from large floods in Dry Creek, where it would be held until it can be safely returned to the Kaweah and St. Johns rivers for direct use or recharge. The Reservoir has the capacity to reduce flood peak up to approximately the 50-year return period event to below the Target 5,5000 cfs. There would still be a benefit during still larger floods in reducing the peak flow rates.

[4] The 2,500 cfs has been set as a threshold above which water is diverted into the Reservoir. During floods in Dry Creek of this magnitude the flood peaks could be potentially further reduced if necessary.
[5] Based on the difference between the measured average daily flows at "Dry Creek" from "Total Kaweah River at McKay Point" as recorded in the Water Master Reports.
[6] Sum of the measured instantaneous Dry Creek flow and the average daily outflow from the Terminus Dam
[7] Based on flood routing through the Reservoir.
[8] It was not possible to reduce the flood peak by the capacity of the inlet structure because the reservoir was filled with flood water before the actual peak river flow occurred.

TABLE 7 SIMULATED EFFECT OF STORING FLOOD FLOWS ABOVE 2,500 CFS[9] IN RESERVOIR				
DATE	ESTIMATED MAXIMUM INSTANTANEOUS PEAK FLOW IN KAWEAH AT McKAY POINT (CFS)[10]	REDUCED FLOOD FLOWS TO DOWNSTREAM OF RESERVOIR (CFS)	REDUCTION IN KAWEAH RIVER AT McKAY POINT FLOW BY STORING FLOOD WATER IN THE RESERVOIR (CFS)	RESERVOIR STORAGE UNTILIZED (AF)
100-year	18,456	16,706	1,750	4,600
50-year	8,725	5,225	3,500	3,998
10-year	4,400	2,500	1,900	955

Since climate change is expected to result in increased intensities of flood events, more frequent flood events, and earlier arrival of high winter flows. Under these conditions the Reservoir would provide for increased flood control benefits. For example, as discussed in Section 2.3.2, flood peaks for the current frequencies are expected to occur almost twice as often. This would mean that instead of the Reservoir contribution to flood reductions for storms exceeding the 10-year event, it would be more useful and would be able to provide for reductions in flood flows for storms exceeding the 5-year event. This means that over a Project life of 50-year say, instead of the Reservoir being used approximately 5 times, it would be used approximately 10 times.

DRAFT

[9] The 3,500 cfs has been set as a threshold above which water is diverted into the Reservoir. During floods in Dry Creek of this magnitude the flood peaks could be potentially further reduced if necessary.

[10] Based on FEMA estimates

5. POTENTIAL IMPACTS

5.1. CEQA SIGNIFICANCE CRITERIA

Hydrology and water quality impacts are described in subsequent sections based on an evaluation of existing Site surface and groundwater hydrology and water quality conditions, and consideration of Project water consumption and potential changes to surface and groundwater hydrology and quality due to Project ground disturbance and land uses. A hydrology or water quality impact is considered significant if it would result in any of the following, adapted from the CEQA Guidelines, Appendix G:

a) Violate any water quality standards or waste discharge requirements or otherwise substantially degrade surface or groundwater water quality.

b) Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of preexisting nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted).

c) Substantially alter the existing drainage pattern of the Site or area, including through the alteration of the course of a stream or river, in a manner which would result in substantial erosion or siltation on- or off-site.

d) Substantially alter the existing drainage pattern of the Site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or off-Site.

e) Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems, cause flooding on- /or off-Site, or provide substantial additional sources of polluted runoff.

f) Place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map.

g) Place within a 100-year flood hazard area structures which would impede or redirect flood flows.

h) Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding because of the failure of a levee or dam; or

i) Inundation by seiche, tsunami, or mudflow.

Regarding item “f”, the Project does not include the construction of housing. As a result, this criterion has been eliminated from further consideration.

DRAFT

5.2. IMPACT HWQ 1 (CRITERION "a"): THE PROJECT COULD RESULT IN IMPACTS TO WATER QUALITY

The potential for water quality impacts to be caused by the Project due to the use and storage of fuels and chemicals, and possibly due to runoff from the Project Area, is evaluated below.

Any unacceptable impacts due to suspended sediment entrainment in surface water would be prevented by the appropriate engineering measures and regulated under the State Water Resources Control Board's (SWRCB's) General Storm Water Permit. These measures are discussed further below.

5.2.1. USE OF FUELS AND OTHER CHEMICALS FOR EQUIPMENT OPERATION AND MAINTENANCE

The use of hazardous materials during Reservoir construction and operation would mainly include fuels, lubricants, and fluids associated with vehicles and equipment. Hazardous materials used as part of construction operations on onsite equipment and vehicles would primarily include fuels and lubricants. Any spill from vehicles or equipment would likely be small and would be promptly and easily cleaned up and disposed of in accordance with State and County regulations.

During Reservoir excavation and construction, hazardous materials will not be stored onsite. Only minor maintenance of equipment and vehicles would be conducted onsite, and vehicles would be fueled by a mobile fuel truck. These activities would be done within the excavation area (Figure 13) where the receipt, storage, handling, use and disposition of these materials in compliance with the requirements of the approved Business Plan, Hazardous Materials Inventory.

Construction will include the installation of an above-ground diesel storage tank, diesel generators, and a generator building near the Inflow Channel. Except for the fluids stored in or on the vehicles and equipment, and, during operations, one AST containing diesel fuel (see below), hazardous materials will not be stored within the Project site. The AST will be used to operate a floating pump in connection with Reservoir operations and will not be used for fueling of vehicles or equipment. Therefore, dispenser-related spillage will not occur

The AST will be dual walled for leak protection. Filling of the AST will only occur in a designated area underlain by concrete paving or a protected flexible membrane liner to facilitate spill cleanup and to inhibit migration of fuel contaminants into the soil column. The Diesel AST will be managed in accordance with a Spill Prevention, Control and Countermeasure (SPCC) Plan. Storage, transfer, spill avoidance, and spill response procedures will be documented in the SPCC Plan.

The AST will not be in an area predicted to be inundated by a 100-year flood, as described in subsequent sections, and as shown on Figure 11. Therefore, damage of the AST because of flooding is not anticipated.

DRAFT

5.2.2. STORM WATER RUNOFF

The SWRCB (Board) has jurisdiction throughout California. Created by the State Legislature in 1967, the Board protects water quality by setting statewide policy, coordinating, and supporting the Regional Water Board efforts, and reviewing petitions that contest Regional Board actions. Nine Regional Water Quality Control Boards exercise rule making and regulatory activities by basins. Tulare County falls within the jurisdiction of the Central Valley Regional Water Quality Control Board (CVRWQCB). As such, the Project is subject to the requirements of the *Water Quality Control Plan for the Tulare Lake Basin*, revised January 2004.

The SWRCB issued a statewide Industrial General Storm Water Permit (Permit) that applies to all industrial storm water discharges. The SWRCB adopted a new Permit that took effect July 1, 2020.

The Owners will obtain coverage under the Permit, as required. Storm water runoff from the Project Area would be managed through proper implementation of Best Management Practices (BMPs such as sediment and erosion control measures) as described in the Stormwater Pollution Prevention Plan (SWPPP). The primary objective of the SWPPP and BMPs is to ensure that polluted runoff, including runoff containing suspended solids and sediment, does not leave the Site and degrade other water bodies. The SWPPP will contain descriptions of aspects such as potential discharge areas, significant materials, and BMPs. BMPs also include non-structural elements such as employee training, documented operating procedures, and general housekeeping. Compliance with applicable storm water regulations will prevent impacts to water quality.

The Project is designed to divert water from the Kaweah River and store this water for later release downstream for use by irrigation water customers. The Project design incorporates engineering measures such as concrete slabs and riprap to prevent erosion and entrainment of suspended solids at the inlets and outlets to the Reservoir where higher water velocities are expected to occur. The Project will not create large areas of impermeable surfaces and will not result in increased rates of surface runoff. In fact, the Project will serve to capture rainfall, thereby reducing surface runoff compared to baseline conditions. Geologic materials exposed in the Reservoir will consist of natural sediments which do not contain deleterious materials or chemical constituents capable of degrading groundwater. Process water will not be generated or discharged to groundwater or surface water as part of the Project. Therefore, the Project is not expected to produce additional runoff, or convey pollutants to surrounding waterbodies.

During the construction phase, energy dissipaters such as sediment catchment basins or sumps, rock dams, and berms, will reduce erosion, trap sediment, and minimize the potential for off-site transport of pollutants. During the excavation phase of the construction, activities will take place inside the excavation itself, thereby preventing any runoff from these activities from entering the rivers. Operations will minimize the extent of disturbed areas. Discharges of storm water runoff from the Site will decrease. Runoff will be directed into the Reservoir or local detention areas to the extent practical.

The final side slopes for the reservoir will be protected from erosion by wind-wave action by the placement of suitable granular material including riprap to armor these surfaces. The perimeter

DRAFT

road will be graded to direct runoff into the Reservoir or onsite detention areas instead of toward the rivers. Also, the road will continue to be inspected and maintained regularly. Inspections of the road condition and the status of sediment and erosion control measures will be integrated with regular required storm water inspection pursuant to the Permit.

5.2.3. DISCHARGES FROM RESERVOIR COULD CONTAIN SUSPENDED SOLIDS

The Owners may choose to fill the Reservoir during high flow conditions, which may occur in response to periods of extraordinary precipitation. High flow conditions will naturally entrain soil particles from the banks or bottom of the river. As a result, water diverted into the Reservoir may contain elevated concentrations of sediments. Releases from the Reservoir containing excessive sediments could violate the Basin Plan water quality objectives (WQOs), and adversely affect beneficial uses that are designated for the St. John River.

During the time water is stored within the Reservoir, sufficient time will be allowed for settlement of sediments to occur to assure that the discharged water will meet the WQOs with respect to suspended sediment and turbidity.

5.2.4. CONCLUSION

The Project is not expected to cause increased siltation or degrade water quality of surface waters or groundwater, or cause violations of water quality criteria. The Site will be subject to conditions of the SWPPP and SPCC Plan, including provisions for inspections, monitoring, and reporting. The Project involves creation of a Reservoir, which is a topographic depression that will reduce runoff discharges from the Site and vicinity. As a result of proper implementation of sediment and erosion control measures, the Project is not expected to exacerbate the pollutant load of St. Johns or Kaweah Rivers.

Major maintenance of the trucks and equipment will be conducted at approved facilities located outside of the Project area, both during the excavation. construction and operational phases. During the excavation and construction of the Reservoir trucks and equipment will be fueled onsite with mobile fuel trucks within the excavation area. Since the AST will be constructed, operated, and maintained in accordance with applicable regulations, the probability of an onsite spill is minimized. As a result of the factors discussed above, this analysis concludes that the Project would have a less than significant impact on water quality under criterion “a” above.

Level of Significance Before Mitigation: Less than significant
Mitigation Measures: None Required

DRAFT

5.3. IMPACT HWQ2 (b): THE PROJECT COULD IMPACT GROUNDWATER SUPPLIES, GROUNDWATER LEVELS, AND/OR RECHARGE

5.3.1. SLURRY WALL INSTALLATION

As noted above, a slurry wall, installed initially during excavation of the Reservoir, will decrease the flux of groundwater between the Reservoir/excavation and surrounding aquifer. Slurry walls are underground walls made of bentonite (clay) mixtures that are installed to inhibit groundwater flow. In this case, the slurry wall would be installed around the Reservoir perimeter to decrease groundwater seepage flowing into the Reservoir during excavation and construction phases, and to keep the Reservoir in a relatively dry condition when not being used for storage. The slurry wall would be installed from elevations above the groundwater levels and extend upwards into the Reservoir's perimeter berm as needed to contain water stored in the Reservoir above groundwater levels and downwards into natural lower permeability materials as discussed in Section 4.1.

The slurry wall would be a permanent fixture of the Reservoir and would serve as an essential feature to achieve the following:

- Assist in maintaining dewatered storage capacity to receive surface water diversions.
- Keep groundwater out of the Reservoir to minimize aquifer impacts and provide maximum space to receive Kaweah River water; and
- Inhibit losses of surface water stored in the Reservoir to the surrounding aquifer when the Reservoir is full.

It is recognized that even with the slurry wall installed there will be groundwater seepage into the Reservoir from under the slurry wall when the Reservoir is empty and some leakage of stored water to groundwater when the Reservoir is full. How this seepage/leakage is managed is described in Section 4.1 and in the discussion below.

5.3.2. DRY RESERVOIR CONDITIONS

Dry reservoir conditions will exist during construction after slurry wall installation. Dry Reservoir conditions will also exist during Reservoir operations during time periods in which the Owners wish to reserve storage for anticipated dam releases or precipitation events. Under these conditions, the Owners would intend to keep groundwater out of the Reservoir.

The slurry wall will not eliminate flow of groundwater into the Reservoir when the Owners wish to keep it dry. Dewatering will still be required because the bottom of the Reservoir will be at a lower elevation than the surrounding groundwater, creating a hydraulic gradient toward the Reservoir. Therefore, some groundwater seepage into the Reservoir will occur under the slurry wall and is estimated at approximately 220 gpm when the Reservoir is being kept dry (Attachment D). This is the maximum estimated range of groundwater seepage into the Reservoir, which would occur at the end of the excavation and construction phases and is estimated to occur during the entire Reservoir operations phase when the Reservoir is kept empty. At the end of excavation and construction, the bottom of the Reservoir will be approximately 60 - 75 feet below ground surface,

DRAFT

the maximum amount of pit wall will be exposed, and the maximum amount of groundwater head surrounding the Reservoir will be realized.

Reservoir operations do not involve storage of groundwater. Therefore, when dry Reservoir conditions are desired, seepage will be captured in a sump at a designated location within the Reservoir and will pumped back and reintroduced into the local aquifer via an infiltration trench located along the north side of the Reservoir, between the slurry wall and the adjacent CEMEX property. (Figure 12).

As stated above, groundwater in the Site vicinity generally flows toward the northwest (Schmidt, 2012). Based on this gradient, the Kaweah and St. Johns Rivers contribute to groundwater recharge for much of the time, and together with groundwater inflow from the east appear to be primary factors in driving the direction of groundwater flow.

After the slurry wall is installed, the general direction of groundwater flow is not expected to change since it is driven by recharge from the east and from the river channels. This northwest flow is expected to flow around the slurry wall to the north and south. This is not expected to significantly inhibit groundwater flow to areas west or north (downgradient) of the Site because the abundant coarse-grained soils of the alluvium and the fractured rock of the aquifer in the area is expected to accommodate flow around (to the north and south) and underneath the Site (Attachment A).

Groundwater is not expected to significantly mound (accumulate vertically) on the upgradient side of the Site or cause a “shadow” of depressed groundwater levels downgradient of the Site. Parcels located adjacent west of the Site will continue to receive recharge as groundwater flows around the slurry wall.

As stated above, seepage into the excavation will be collected and infiltrated back into to the aquifer, so the seepage will not constitute a loss and is not expected to affect groundwater supplies or levels.

The St. Johns and Kaweah Rivers create a significant hydraulic divide in the groundwater system. In general, any changes occurring on one side of a hydraulic divide are unlikely to affect conditions on the other side. Therefore, it is unlikely that potential groundwater related impacts, if any, would occur at sites located south of the St. Johns River or east of the Kaweah River. Because of the hydraulic divide and because the Project will not affect the fractured rock groundwater unit, groundwater levels in wells south of the Kaweah River such as the Lemon Cove municipal supply well are not expected to be affected by the Project.

The Reservoir, when pumped out, is not expected to impact the Minimum Threshold and Measurable Objective groundwater levels that have been established for Well KSB-2822 (also referred to as 18S27E05J001M), located between the St. Johns and Kaweah Rivers – Figure 9). The modeled changes to the groundwater levels around the outside of the slurry wall are provided in Attachment D which indicates these are insignificant, i.e., less than 3 to 3 feet.

DRAFT

5.3.3. OPERATING RESERVOIR CONDITIONS

An estimated approximately 200 AF/yr. ((approximately 124 gpm as a continuous flow) of net evaporation will occur during a typical year of operation during which the Reservoir remains full or partially full, during the months of May through September and for short periods of days or weeks in the November through January period when used for flood control (se Section 4.5.2). This compares to the additional annual average 3,129 AF of additional agricultural water that would be made available by operating the Reservoir (Section 4.6.3). This evaporation rate amounts to 6% of the added water generated.

On a basin wide scale, the evaporation rate is minimal (less than 0.02%) compared to the 862,000 AF (699,000 AF of which is groundwater) delivered annually for irrigation purposes in the district (Fugro, 2007). Furthermore, since the Reservoir would be frequently emptied (likely 2 or more times per year) this would prevent any buildup of dissolved constituent that may be caused by evaporative concentration.

It is not anticipated that the reservoir will remain in a full condition for an entire year; however, if for some reason this were to occur, the annual evaporative loss is expected to be approximately 340 AF (Section 4.5.2).

During Reservoir operations, when the Reservoir is filled with diverted surface water, the water surface elevation will be up to approximately 460 feet elevation which exceeds the groundwater elevation at several locations within the Reservoir footprint. Although the slurry wall will have been installed to inhibit groundwater flux into and out of the Reservoir, aquifer recharge will occur under full Reservoir conditions because the Reservoir level will be higher than the surrounding groundwater. The recharge rate is expected to be minor due to the presence of the low-permeability slurry wall. The recharge volume depends on how much time the Reservoir water level remains above the groundwater levels in the vicinity. This recharge volume is not further evaluated because it is small and, in any event, constitutes a source of groundwater recharge no more than the recharge from the rivers.

5.3.4. CONSUMPTION WATER USE DURING EXCAVATION AND CONSTRUCTION

During excavation, the amount of water consumption will be relatively minor. As discussed in Section 4.1 it is estimated be approximately 141 AF/year.

Water for these purposes would be obtained from wells installed in the bottom of the excavation. These wells would also be used for maintaining the excavation in a dry enough state for the excavation and processing activities. These consumptive uses from the existing source constitute a minimal impact over baseline conditions. These consumptive uses are not expected to affect groundwater levels or supplies in the Site vicinity.

5.3.5. CONCLUSIONS

Negligible losses to groundwater are anticipated. The slurry wall will be in place, which will form a flow barrier in the alluvial groundwater system. As a result, in the Site area, groundwater flow

DRAFT

directions will change as groundwater flows around the slurry wall through the alluvium and fractured rocks that surround the Site. Groundwater that seeps into the excavation through the slurry wall or through the bottom of the excavation will be collected and re-infiltrated back to the aquifer using infiltration drains. The infiltration gallery will be located north of the excavation, which will minimize changes to the current direction of groundwater flow in this area. Because recharge would not be significantly interrupted and offsite groundwater elevations are not expected to change noticeably, the excavation phase would therefore result in less than significant impacts under criterion “b” above.

Reservoir operations are expected to result in less impact to groundwater than the excavation and construction phases described above. The slurry wall will reduce impacts to groundwater supply by inhibiting groundwater from entering the Reservoir, where it would be subjected to evaporation. Seepage into the Reservoir through the slurry wall during dry-Reservoir periods will be returned to the aquifer. Reservoir operations impacts therefore are considered less than significant under criterion “b”.

Level of Significance Before Mitigation: Less than Significant
Mitigation Measures: None Required

5.4. IMPACT HWQ3 (c): CHANGES TO SITE OR AREA DRAINAGE PATTERNS COULD RESULT IN EROSION OR SILTATION IMPACTS

This section describes an evaluation of the potential for drainage pattern changes to cause erosion or siltation impacts. Drainage system changes associated with the Project include installation and use of the Inlet and Outlet Channel. As described above, the Project involves creation of a topographic depression that will capture precipitation and some storm water runoff. However, there are no identifiable creeks or water bodies that will be disturbed by the Project. The Project will not involve placing structures in the St. Johns or Kaweah River channels. The only changes to the river channels will be placement of riprap at the Inflow and Outflow Channels, and construction of the Inflow and Outflow Channels. The riprap will be placed below the elevation of the surrounding channel, and the Inflow/Outflow Channels will be set back from the main river channels; these structures are designed to avoid impedance of river flows.

To evaluate scouring, SLR reviewed historical aerial photos. Previous aerial photos from the years 1954, 1956, 1969, 1974, 1984, 1989, and 1994 were reviewed to determine if major scouring or changes in morphology of the Kaweah and St. Johns Rivers have historically occurred near the Site. Based on review of these aerial photographs, no significant changes have occurred since the 1954 photograph. Terminus Dam, constructed in 1962, regulates flows and flooding and rapid changes in river morphology and scouring will therefore be minimized.

The potential for scouring to occur during delivery of water from Reservoir to the St. Johns and Kaweah Rivers will be minimized. The Outflow and Inflow Channels would include a riprap and concrete aprons, constructed across the riverbed of the Kaweah River (Figure 3). These aprons will prevent the potential scouring effects of the water being delivered to the rivers. In addition, the aprons will be installed so they do not protrude into the stream, so that they will not affect river flow rates or patterns.

DRAFT

After a flood storage event in the Reservoir, water stored in the upper portion of the Reservoir would be released at flows ranging up to 900 cfs. The erosion protection measured installed in the Reservoir will prevent erosion in the outflow structure and the 900 cfs flow rate is significantly lower than the prior natural flood flows that have occurred in the rive channels and will not result in any changes to the natural erosion patterns in these.

To release water to the St. Johns River or the Kaweah River when the river water levels are higher than that of the Reservoir, a Floating Barge Pump (electrically powered) will pump water from the Reservoir into the Kaweah River, upstream of the McKay Point Structure. The Floating Barge Pump, or series of pumps, would have an approximate maximum flow rate of 160 cfs. Erosion control features will be constructed in the Floating Barge Pump discharge area so that the channel of the Kaweah River is not scoured.

In addition to review of aerial photos, SLR conducted sediment transport modeling using a computer application. The HEC-RAS computer application was utilized to evaluate the potential for sediment transport in the channels of the Kaweah River east of McKay Point, St. Johns River, and the Lower Kaweah River. The potential for sediment transport is dependent on the grain size distribution of channel materials, riverbed gradient, flow rate, and water flow regime. Further details regarding this evaluation are provided in Attachment C.

The sediment transport analysis was conducted based on the average maximum monthly flow of 1,500 cfs. This value consists of the highest average monthly flow rate measured between 2001 and 2007 documented in annual Watermaster reports (Watermaster, 2007). In other words, the flow rate used is considered the higher range of typical flow rates that occur in the Kaweah River in the Site vicinity.

Results of the HEC-RAS sediment transport analysis are presented in Attachment C. These results include profile views of the riverbeds, which illustrate a minimal potential for scour and transport at the flow rate applied.

Based on the results of the analyses the Project is not anticipated to alter the natural flow rates or conditions in the river. During Reservoir operations, flow rates in the St. Johns and Kaweah Rivers will remain within the existing range of typical flow rates that are currently managed through outflows of Terminus Dam. Use of the Reservoir for flood storage may cause flow rates in the Kaweah and St. Johns Rivers to decrease during periods of high precipitation, thereby actually reducing the scour potential.

Aerial photograph review and HEC-RAS sediment transport evaluation both suggest that, under typical conditions, there is insignificant potential for sediment transport in the river channels along the Site southern boundary. Terminus Dam is used extensively to manage flow rates in the rivers, and to avoid flow rates that would result in extensive scouring. The Project does not involve features or facilities that will change these conditions and may reduce flow rates during periods of extraordinary precipitation by providing flood storage. Based on these factors, siltation and erosion impacts associated with the Project are less than significant with respect to criterion “c” above.

Level of Significance Before Mitigation: Less than Significant
Mitigation Measures: None Required

DRAFT

5.5. IMPACT HWQ5 (d): CHANGES TO ON-SITE DRAINAGE PATTERNS, INCLUDING ALTERING THE COURSE OF RIVERS, OR SUBSTANTIALLY INCREASE THE RATE OR AMOUNT OF SURFACE RUNOFF, RESULTING IN FLOODING IMPACTS

Reservoir excavation and construction would not alter the course of rivers. The Project would, however, change onsite drainage patterns because construction of a topographic depression will reduce the amount of storm water runoff flowing out of the Reservoir area. Releases from the Reservoir will not cause river flows to exceed their normal flow rate range and will not cause flooding. In fact, the Reservoir will be used for flood storage, which will decrease river flow rates during periods of extraordinary precipitation. Based on these factors, the Project would not increase the potential for flooding on- or off-site and therefore would not result in significant impacts under criterion “d” above.

Level of Significance Before Mitigation: Less than Significant
Mitigation Measures: None Required

5.6. IMPACT HWQ5 (e): CREATE OR CONTRIBUTE RUNOFF WATER WHICH WOULD EXCEED THE CAPACITY OF EXISTING OR PLANNED STORMWATER DRAINAGE SYSTEMS, CAUSE FLOODING ON- OR OFF - SITE, OR PROVIDE SUBSTANTIAL ADDITIONAL SOURCES OF POLLUTED RUNOFF

Since both during the excavation and Reservoir phases the Project would store any rainfall that falls within the Project area, there would be no increases in flood flows outside of the Project area so the capacity of existing or planned stormwater drainage systems would not be affected. Since stormwater in the Project area would also be collected with either the excavation or Reservoir, there would be no offsite sources of polluted runoff. Discharges from the Reservoir for agricultural purposes would be subject to appropriate water quality standards.

Level of Significance Before Mitigation: Less than Significant
Mitigation Measures: None Required

5.7. IMPACT HWQ4 (g): PLACE HOUSING IN 100-YEAR FLOOD HAZARD AREA, OR STRUCTURES THAT WOULD IMPEDE OR REDIRECT FLOOD FLOWS

The Federal Emergency Management Agency (FEMA) flood map for the area including the Site indicates that the eastern portion of the proposed Reservoir is located within the 100-Year Flood Hazard Zone (Figure 9). FEMA has established base flood elevations for the St. Johns and Lower Kaweah Rivers downstream of McKay Point, but not for the Kaweah River upstream of McKay Point and the portion of the proposed Reservoir within the 100-year Flood Hazard Zone. This

DRAFT

situation is common because FEMA tends to apply its resources to conducting detailed flood mapping in populated areas (such as near the City of Visalia) rather than rural areas.

FEMA's work on the eastern portion of the Site was not conducted in sufficient detail to establish base flood elevations, and it follows that the accuracy of the flood hazard zone presented by FEMA could be improved if flood mapping in greater detail was conducted. Therefore, SLR conducted flood modeling for this area in greater detail to establish base flood elevations, and to delineate the 100-year flood inundation area.

The HEC-RAS hydraulic software package, released by the United States Army Corps of Engineers, was used to simulate the 100-year flood flow at the Kaweah River east of McKay Point. The flow is based upon the raised spillway at the Terminus dam. The peak flow at McKay Point is 18,220 cfs, as calculated by the United States Army Corps of Engineers. Details regarding this flood modeling are included in Attachment C.

The topographic data used for flood modeling consisted of the LiDAR survey conducted for the Tulare and Visalia basin in 2004. These topographic data were part of the same dataset used by FEMA for the flood mapping conducted downstream of McKay Point as documented in FEMA (2009). A total of 12 cross sections, spaced at a maximum of 1,000 feet apart, were created along the length of 7,600 feet east of the McKay Point junction of the Kaweah River. For purposes of model stability, cross sections were interpolated throughout the reach with sections positions at distances no larger than 75 feet apart.

SLR conducted a steady state flow analysis to calculate the based flood elevations for the peak flow of the 100-year flood for the Kaweah River east of McKay Point. The analysis was calibrated to tie into the water surface elevations calculated in the prior analyses conducted by FEMA for stretches of the St. Johns and Kaweah Rivers downstream of McKay Point.

Figure 11 presents the water surface elevations and floodway for the 100-year flood peak flow. Based on SLR's detailed flood modeling evaluation, the floodway for the 100-year flood peak flow will only encroach minimally on the proposed Reservoir footprint. Although the eastern end of proposed Reservoir footprint is in the areas subject to inundation as sated by FEMA, no significant quantities of water will be present in these areas. Therefore, since the Project is not expected to place structures in the 100-year flood hazard zone and is not expected to redirect flood flows this potential impact is considered less than significant under criterion "g".

Level of Significance Before Mitigation: Less than Significant
Mitigation Measures: None Required

5.8. MPACT HWQ6 (h): POTENTIAL IMPACTS OF LEVEE OR DAM FAILURE

This section considers both a levee and dam failure from a facility in the vicinity of the Project, as well as a potential failure of the Project facilities.

Levee or dam failure from a facility in the vicinity of the Project

The Terminus Dam is considered a High Hazard dam where failure or mis-operation could cause loss of human life. It has an Emergency Action Plan (EAP) which describes actions to be taken

DRAFT

to reduce the potential for property damage and loss of life in an area affected by the dam failure of the dam (https://nid.sec.usace.army.mil/#/dams/system/549835/summary). The EAP was last revised on September 19, 2016 and exercised (tested) on October 21, 2020.

A hypothetical failure of the Terminus Dam located upstream of the Project, likely by a dam breach, would result in a flood of released water. In the event of such a failure, the Project would not alter the extent of downstream flooding since it provides no impediment to the dam breach flood wave. Since some of the flood wave would be stored in the reservoir, the Project may slightly reduce the downstream flooding.

Workers at the Project during both the excavation and Reservoir phases would likely be exposed to flooding from a Terminus Dam failure and would need to be made aware of the EAP and be trained to comply with its requirements.

Based on the discussion above, risk associated with the unlikely scenario of a Terminus Dam failure will be minimized by the EAP. Thus, the Project would not result in significant impacts under criterion “h" above.

Potential failure of the Project facilities

The Project involves construction of a perimeter berm that may be as much as approximately 8 feet above surrounding topography in some areas. However, as described in Section 4.7, the Project only includes the placement of a berm at the edge of the predicted area to be inundated by the 100-year flood. In addition, the Project does not involve construction of housing or work areas that will be occupied on a regular basis. As described above, most of the Reservoir operations will be conducted remotely. Construction operations will also be conducted outside of the 100-year flood inundation area. Therefore, the Project is not expected to be affected by a 100-year flood.

The water elevation in the Reservoir may extend above the current natural surface elevation. Water will be withheld in some areas of the Reservoir by a berm that contains a slurry wall. The berm will be designed and constructed, to an appropriate factor of safety, to withhold the hydraulic forces necessary to store surface waters at the desired elevation. Regular inspections of the Reservoir structures and facilities, including the berm, will be conducted. Failures of berms such as the one proposed typically display early signs of an impending failure, such as slumping, appearance of seepage, or settlement, so that corrective actions will be taken by the Owners as appropriate to avoid the failure.

Even if failure occurs, the entire Reservoir volume would not flow out. A maximum of up to approximately 1,000 AF could drain from the Reservoir without pumping, compared to the total Reservoir volume of approximately 4,600 AF. In that unlikely case, the Owners would have multiple response options. The Reservoir level could be quickly lowered in a controlled fashion using the Inlet and/or Outlet Channels. Also, the McKay Point structure immediately downstream could be used to limit the extent to which river levels are raised. Similarly, the additional flow could be accommodated by multiple downstream watercourses, including the Lower Kaweah, St. Johns, and the multiple related irrigation ditches.

DRAFT

Based on the discussion above, the Project is not expected to cause significant loss, injury, or death by dam or dike failure. Thus, the Project would not result in significant impacts under criterion “h" above.

Conclusion

Level of Significance Before Mitigation: Less than Significant
Mitigation Measures: None Required

5.9. IMPACT HWQ7(i): POTENTIAL IMPACTS FROM SEICHE, TSUNAMI, OR MUDFLOW

The Project is not near the coast, so it is not susceptible to inundation by a tsunami. In addition, the Project is surrounded by relatively flat topography, and calculations conducted by SLR suggest that proposed Reservoir slopes are within acceptable factors of safety. Therefore, the Site is not expected to be affected by a mudflow.

A seiche is a standing wave that can occur in small water bodies such as basins, swimming pools, and lakes. The wave can reduce water levels at one end of the water body and increase the water level on the other, like the “sloshing” of water back and forth.

The potential for seismic ground shaking to generate a seiche in the proposed Reservoir was evaluated. The risk associated with a seiche is overtopping of the Reservoir if the amplitude of the wave exceeds the freeboard included in the design by an amount large enough to generate a force that could be detrimental to the facility.

The occurrence of a seiche and the amplitude of the wave are controlled by the natural period of the Reservoir and that of the earthquake. If the two periods are similar, resonance can occur, thus amplifying the wave.

The natural period of the Reservoir can be calculated using the Merian formula assuming a rectangular basin (USNRC, 2011).

$$\mathrm{T} = \frac{2\,L}{\sqrt{gh}}$$

Where L is the length of the basin, g the acceleration of gravity (32.2 cm/sec^2), and h the depth of water. Combining a representative value of 600 ft as the average width of the basin and a depth of water h of 70 ft, the natural period of the Reservoir is estimated to be:

$$T = \frac{(2)(600)}{\sqrt{(32.2)(70)}} = 25\ s$$

This natural period is to be compared to that of the earthquake that may shake the Site. The typical range of period for strong ground motion is between 0 and 5.0 seconds, with the dominant period for the site-specific event being on the order of 0.2 second (USGS, http://geohazards.usgs.gov/hazardtool/application.php). Therefore, the difference in period between the Reservoir and the design earthquake is two orders of magnitude.

DRAFT

An empirical formula is provided in HAZUS (FEMA, 2003) to estimate the peak wave height of the seiche as:

$$H = \sqrt{\frac{A}{L\,(\pi f)^2}}$$

Where H is the peak height, A is the acceleration (in g's), f is the frequency of the lake, and L is the wavelength (5.12/ft^2). Using the PGA calculated for the 2,475-year event of 0.20 g, the maximum wave height of a seiche is estimated to be 0.06 cm.

The estimated value of the peak wave for the seiche at the Site is extremely low and for practical purposes, insignificant. In addition, the ratio between the Reservoir and the natural period of the seismic event that could occur on Site is on the order of 125:1 (25/0.2), which indicates a possible resonance condition is unlikely.

Given the size of the Reservoir and the anticipated earthquake dominant period, resonance will not occur at the Site between the Reservoir and ground shaking, therefore the risk of a damaging seiche is insignificant and any seismic generated wave will be controlled by the design freeboard. Thus, the Project would not result in significant impacts under criterion "i" above.

Level of Significance Before Mitigation: Less than Significant
Mitigation Measures: None Required

DRAFT

6. CONCLUSIONS

As described in previous sections, SLR has conducted a review of baseline and Project related conditions and has evaluated potential Project related impacts relating to Hydrology and Water Quality based on CEQA Appendix G criteria. Based on our evaluation, we have identified no significant impacts.

LIMITATIONS

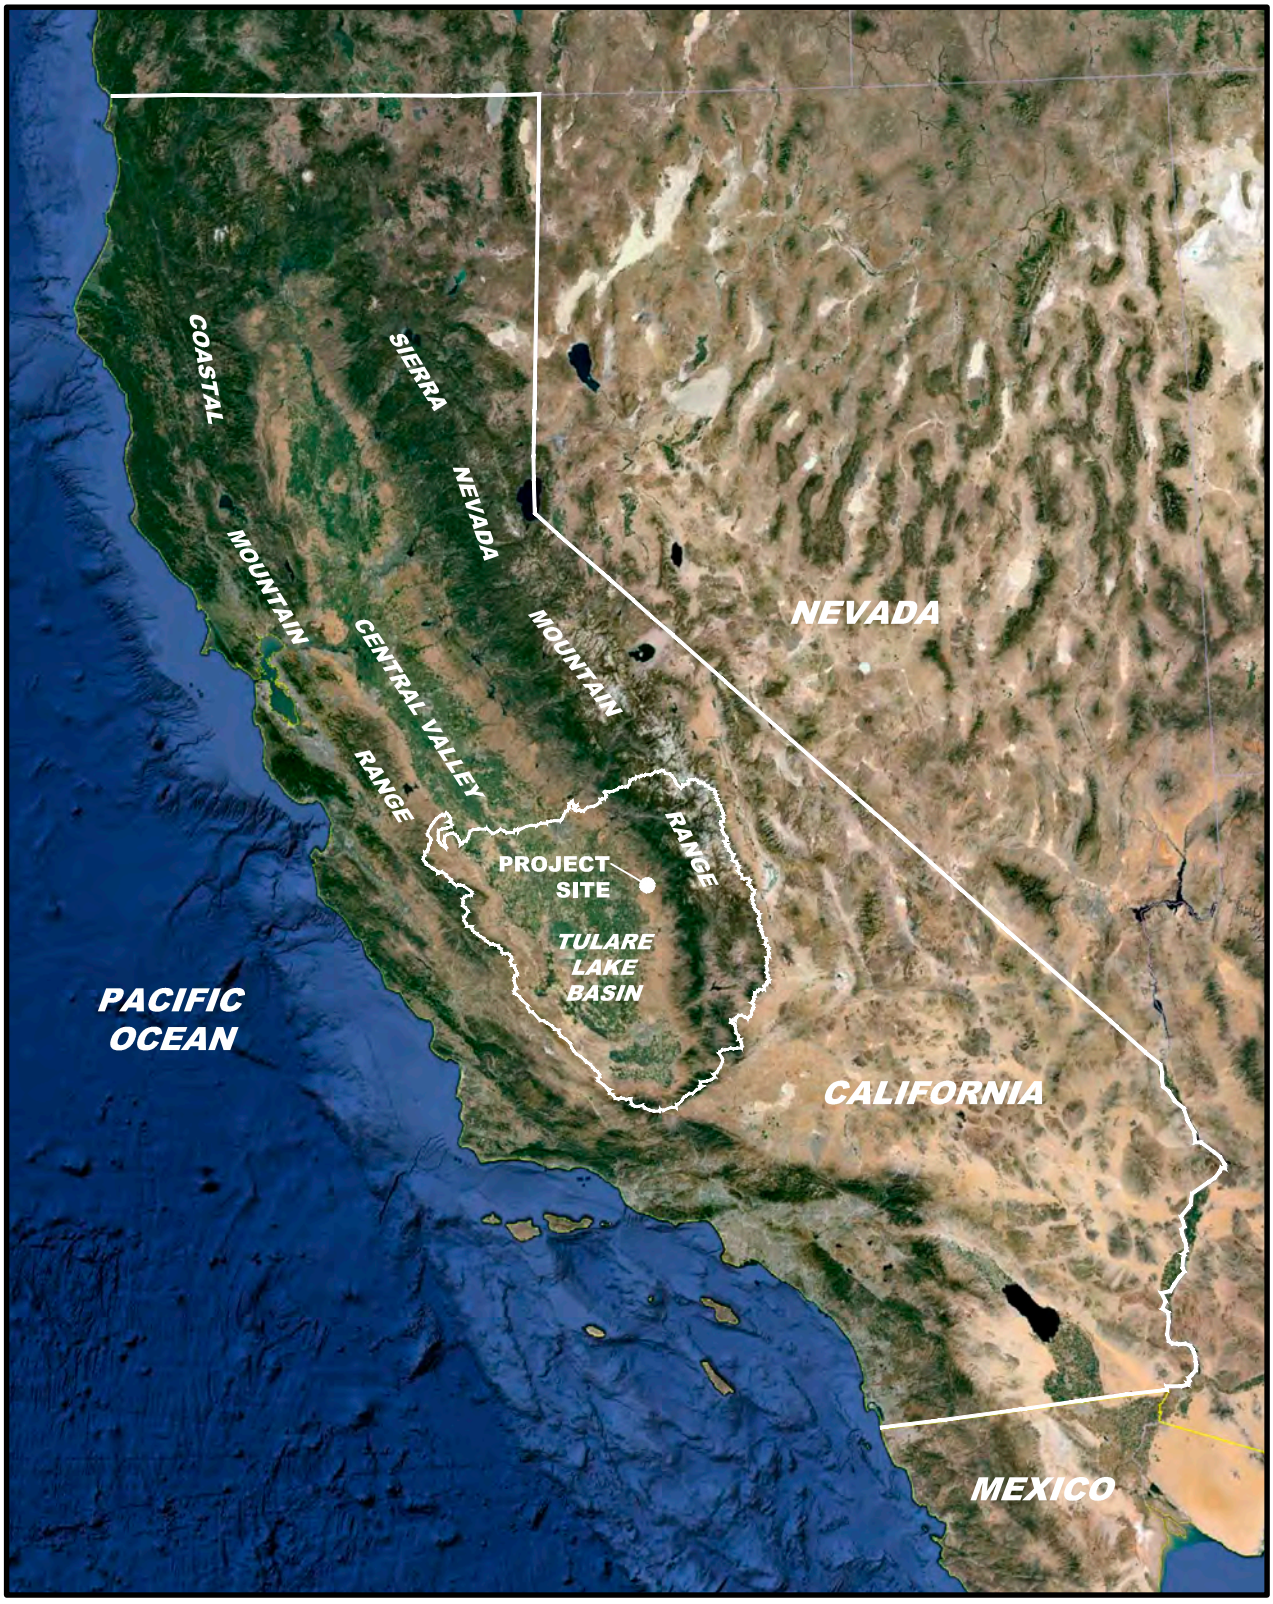
The services described in this work product were performed in accordance with generally accepted professional consulting principles and practices. No other representations or warranties, expressed or implied, are made. These services were performed consistent with our agreement with our client. This work product is intended solely for the use and information of our client unless otherwise noted. Any reliance on this work product by a third party is at such party's sole risk.

Opinions and recommendations contained in this work product are based on conditions that existed at the time the services were performed and are intended only for the client, purposes, locations, time frames, and project parameters indicated. The data reported and the findings, observations, and conclusions expressed are limited by the scope of work. We are not responsible for the impacts of any changes in environmental standards, practices, or regulations after the performance of our services. We do not warrant the accuracy of information supplied by others, or the use of segregated portions of this work product.

The purpose of an environmental assessment is to reasonably evaluate the potential for, or actual impact of, past practices on a given site area. When performing an environmental assessment, it is understood that a balance must be struck between a reasonable inquiry into the environmental issues and an appropriate level of analysis for each conceivable issue of potential concern. The following paragraphs discuss the assumptions and parameters under which such an opinion is rendered.

No investigation can be thorough enough to exclude the presence of hazardous materials at a given site. If hazardous conditions have not been identified during the assessment, such a finding should not therefore be construed as a guarantee of the absence of such materials on the Site, but rather as the result of the services performed within the scope, practical limitations, and cost of the work performed.

Environmental conditions that are not apparent may exist at the Site. Our professional opinions are based in part on interpretation of data from a limited number of discrete sampling locations and therefore may not be representative of the actual overall Site environmental conditions.



The passage of time, manifestation of latent conditions, or occurrence of future events may require further study at the Site, analysis of the data, and/or reevaluation of the findings, observations, and conclusions in the work product.

This work product presents professional opinions and findings of a scientific and technical nature. The work product shall not be construed to offer legal opinion or representations as to the requirements of, nor the compliance with, environmental laws, rules, regulations, or policies of federal, state, or local governmental agencies.

RIVER ANALYSIS

MCKAY POINT RESERVOIR, CALIFORNIA

1. PURPOSE AND SCOPE

This computation package documents the river analysis conducted for the Kaweah River east of McKay Point at the proposed McKay Point Reservoir Project Site. Maximum 1% flood peak flows were used to calculate the maximum water surface elevation. A sediment transport analysis of the river bottom was conducted under average maximum monthly flow.

2. ANALYSIS

The Federal Emergency Management Agency (FEMA) in 2009 and 2012 created Flood Insurance Rate Maps for the 1% flood (Attachment 1). The maps show the extents of areas subject to inundation, the floodway which can contain the 1% flood flow, and (for some areas) the flood water elevation contours. The extents of areas subject to inundation were calculated by FEMA for the Kaweah River and the St. Johns River only for the Kaweah River and the St. Johns River west of McKay Point. FEMA did not calculate such flood elevations for areas east of McKay Point, as they often tend to devote their resources to areas with larger populations.

The HEC-RAS hydraulic software package, released by the United States Army Corps of Engineers, was used to simulate the 1% flood flow at the Kaweah River east of McKay Point. The flow is based upon the raised spillway at the Terminus dam. The peak flow at McKay Point is 18,220 cfs. The peak flow was calculated by the United States Army Corps of Engineers.

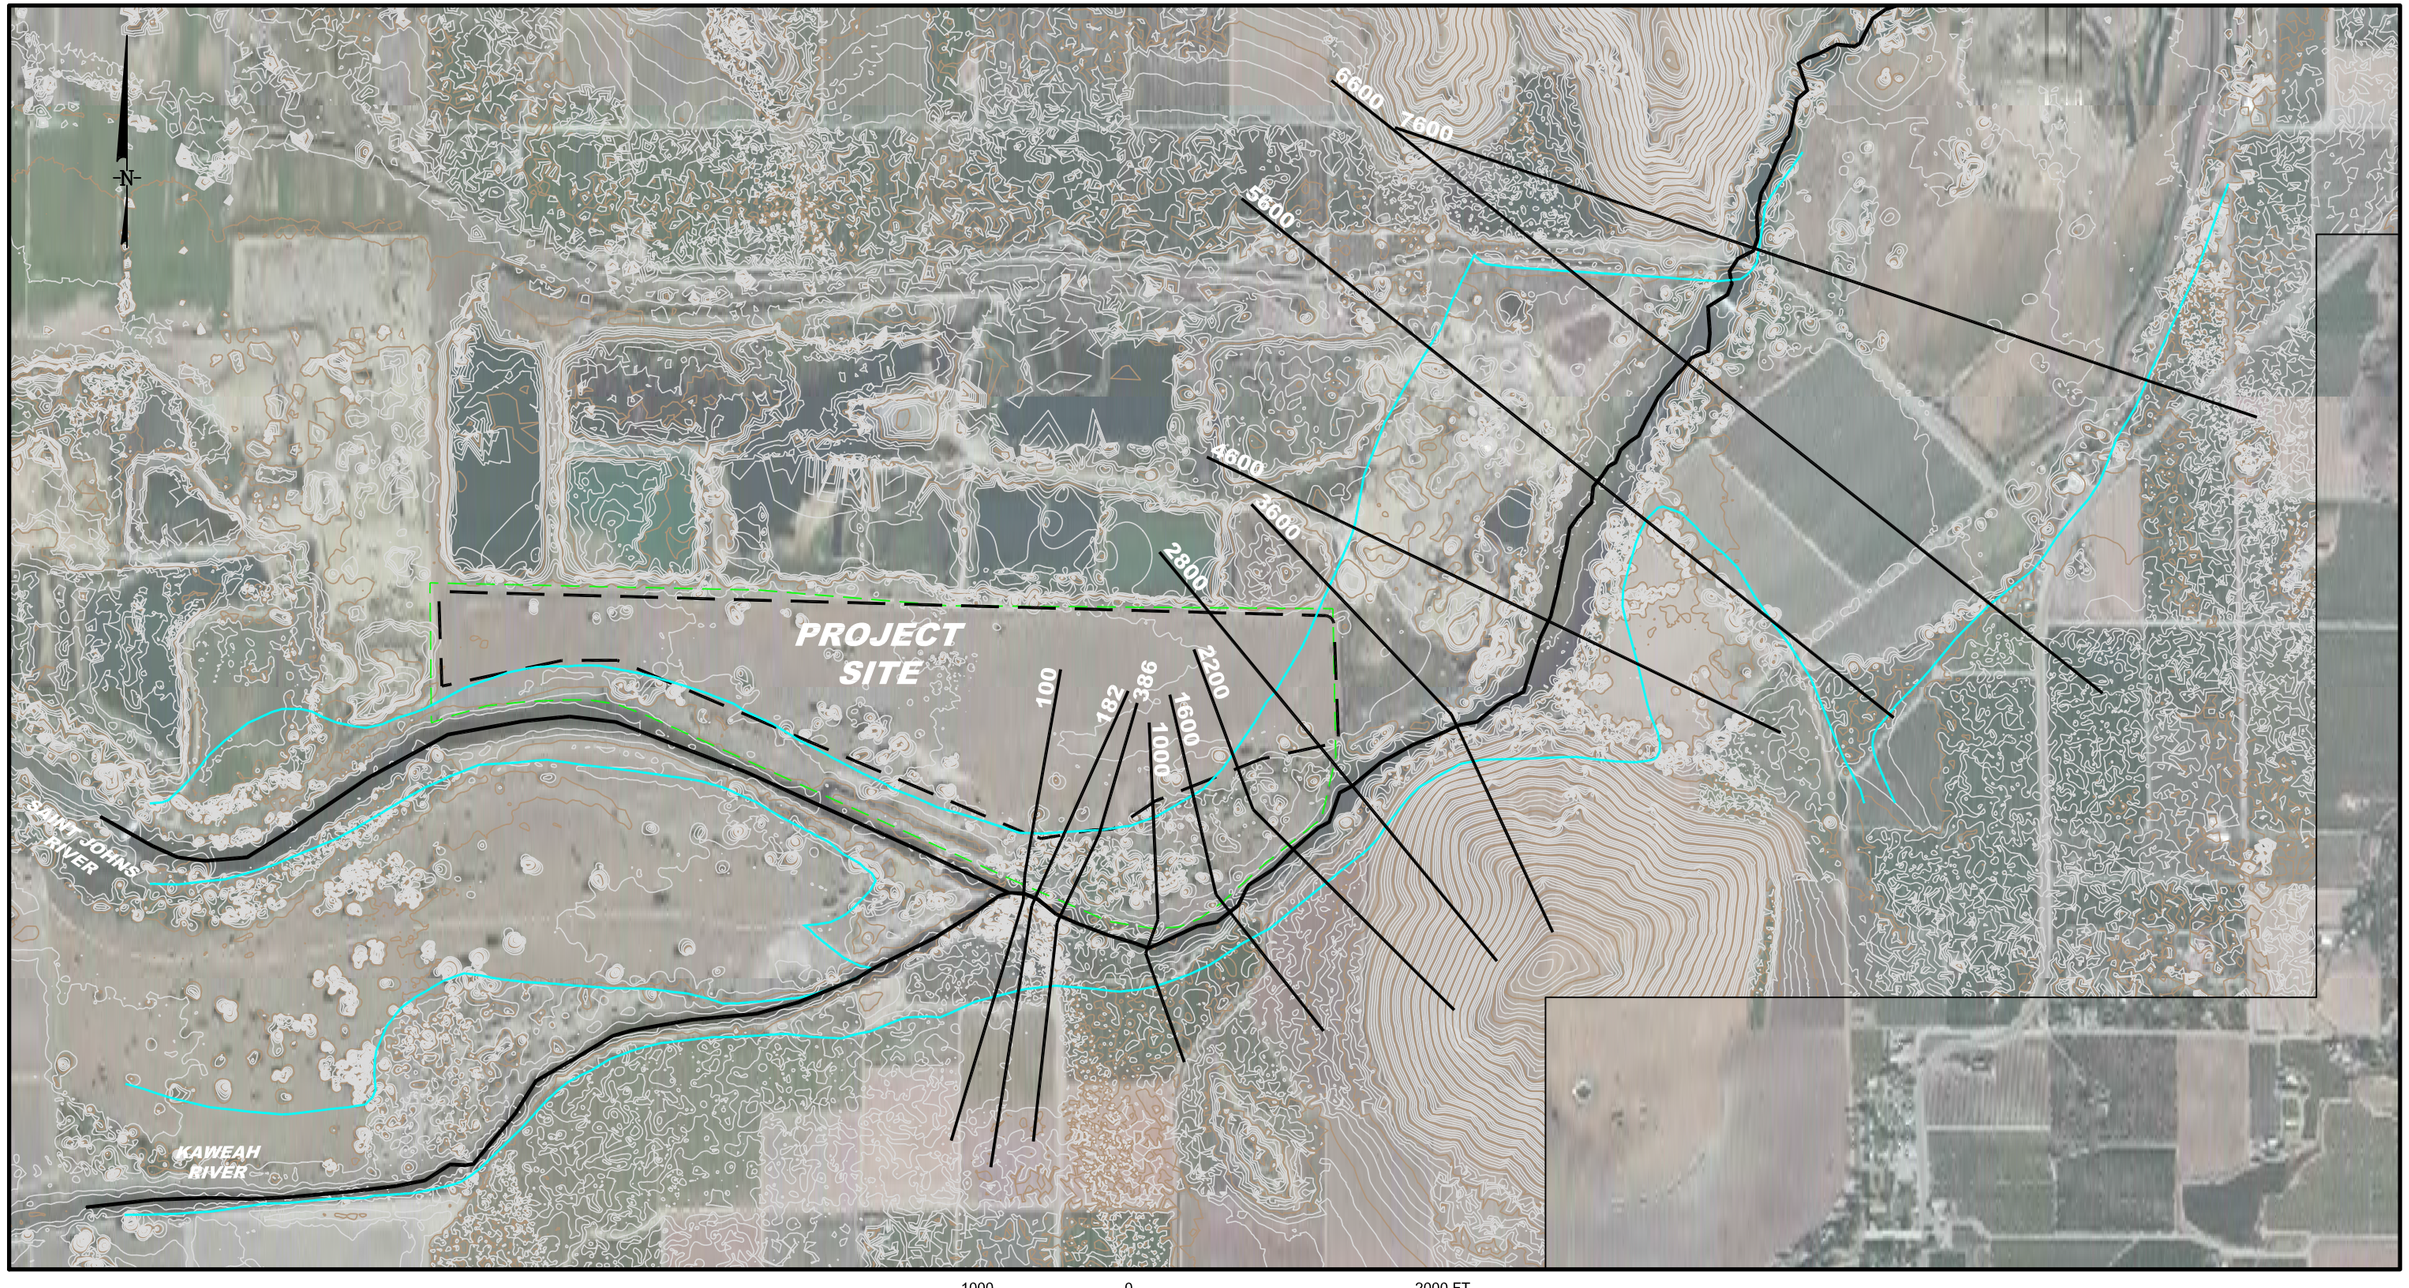
The topographic data used was from the LiDAR survey conducted for the Tulare and Visalia basin in 2004. A total of 12 cross sections, spaced at a maximum of 1,000 feet apart, were created along the length of 7,600 feet east of McKay Point of the Kaweah River. For purposes of model stability, cross sections were interpolated throughout the reach with sections positions at distances no larger than 75 feet apart. See Figure 1 for the HEC-RAS cross section locations.

A steady state flow analysis was conducted to calculate the water surface elevations for the peak flow of the 1% flood for the Kaweah River east of McKay Point. This analysis was calibrated to tie into the water surface elevations calculated in the prior analyses

conducted by FEMA in 2009. Therefore, SLR's river analysis supplements the analyses conducted by FEMA west of McKay Point.

Roughness coefficients (Manning's "n" values) utilized in the flow analysis were based on similar values from the 2009 FEMA analyses for the Lower Kaweah River just downstream of McKay Point. The channel "n" value of 0.035 and the overbank "n" value of 0.05 were used in SLR's river analysis.

3. SUMMARY AND CONCLUSIONS



The results of the HEC-RAS steady-state river analysis pre-project are presented in Attachment 2. The results of the HEC-RAS steady-state river analysis post-project are presented in Attachment 3. Results include a summary table and cross section plots of the 12 cross sections.

Figure 2 presents the post-project water surface elevations and floodway for the 1% flood peak flow. SLR's flood calculation results suggest that the floodway for the 1% flood peak flow will not encroach on the proposed reservoir footprint.

FEMA FLOOD INSURANCE RATE MAPS

NOTES TO USERS

This map is for use in administering the National Flood Insurance Program. It does not necessarily identify all areas subject to flooding, particularly from local drainage sources of small size. The **community map repository** should be consulted for possible updated or additional flood hazard information.

To obtain more detailed information in areas where **Base Flood Elevations** (BFEs) and/or **floodways** have been determined, users are encouraged to consult the Flood Profiles and Floodway Data and/or Summary of Stillwater Elevations tables contained within the Flood Insurance Study (FIS) report that accompanies this FIRM. Users should be aware that BFEs shown on the FIRM represent rounded whole-foot elevations. These BFEs are intended for flood insurance rating purposes only and should not be used as the sole source of flood elevation information. Accordingly, flood elevation data presented in the FIS report should be utilized in conjunction with the FIRM for purposes of construction and/or floodplain management.

Coastal Base Flood Elevations shown on this map apply only landward of 0.0' North American Vertical Datum of 1988 (NAVD 88). Users of this FIRM should be aware that coastal flood elevations are also provided in the Summary of Stillwater Elevations tables in the Flood Insurance Study report for this jurisdiction. Elevations shown in the Summary of Stillwater Elevations tables should be used for construction and/or floodplain management purposes when they are higher than the elevations shown on this FIRM.

Boundaries of the **floodways** were computed at cross sections and interpolated between cross sections. The floodways were based on hydraulic considerations with regard to requirements of the National Flood Insurance Program. Floodway widths and other pertinent floodway data are provided in the Flood Insurance Study report for this jurisdiction.

Certain areas not in Special Flood Hazard Areas may be protected by **flood control structures**. Refer to Section 2.4 "Flood Protection Measures" of the Flood Insurance Study report for information on flood control structures for this jurisdiction.

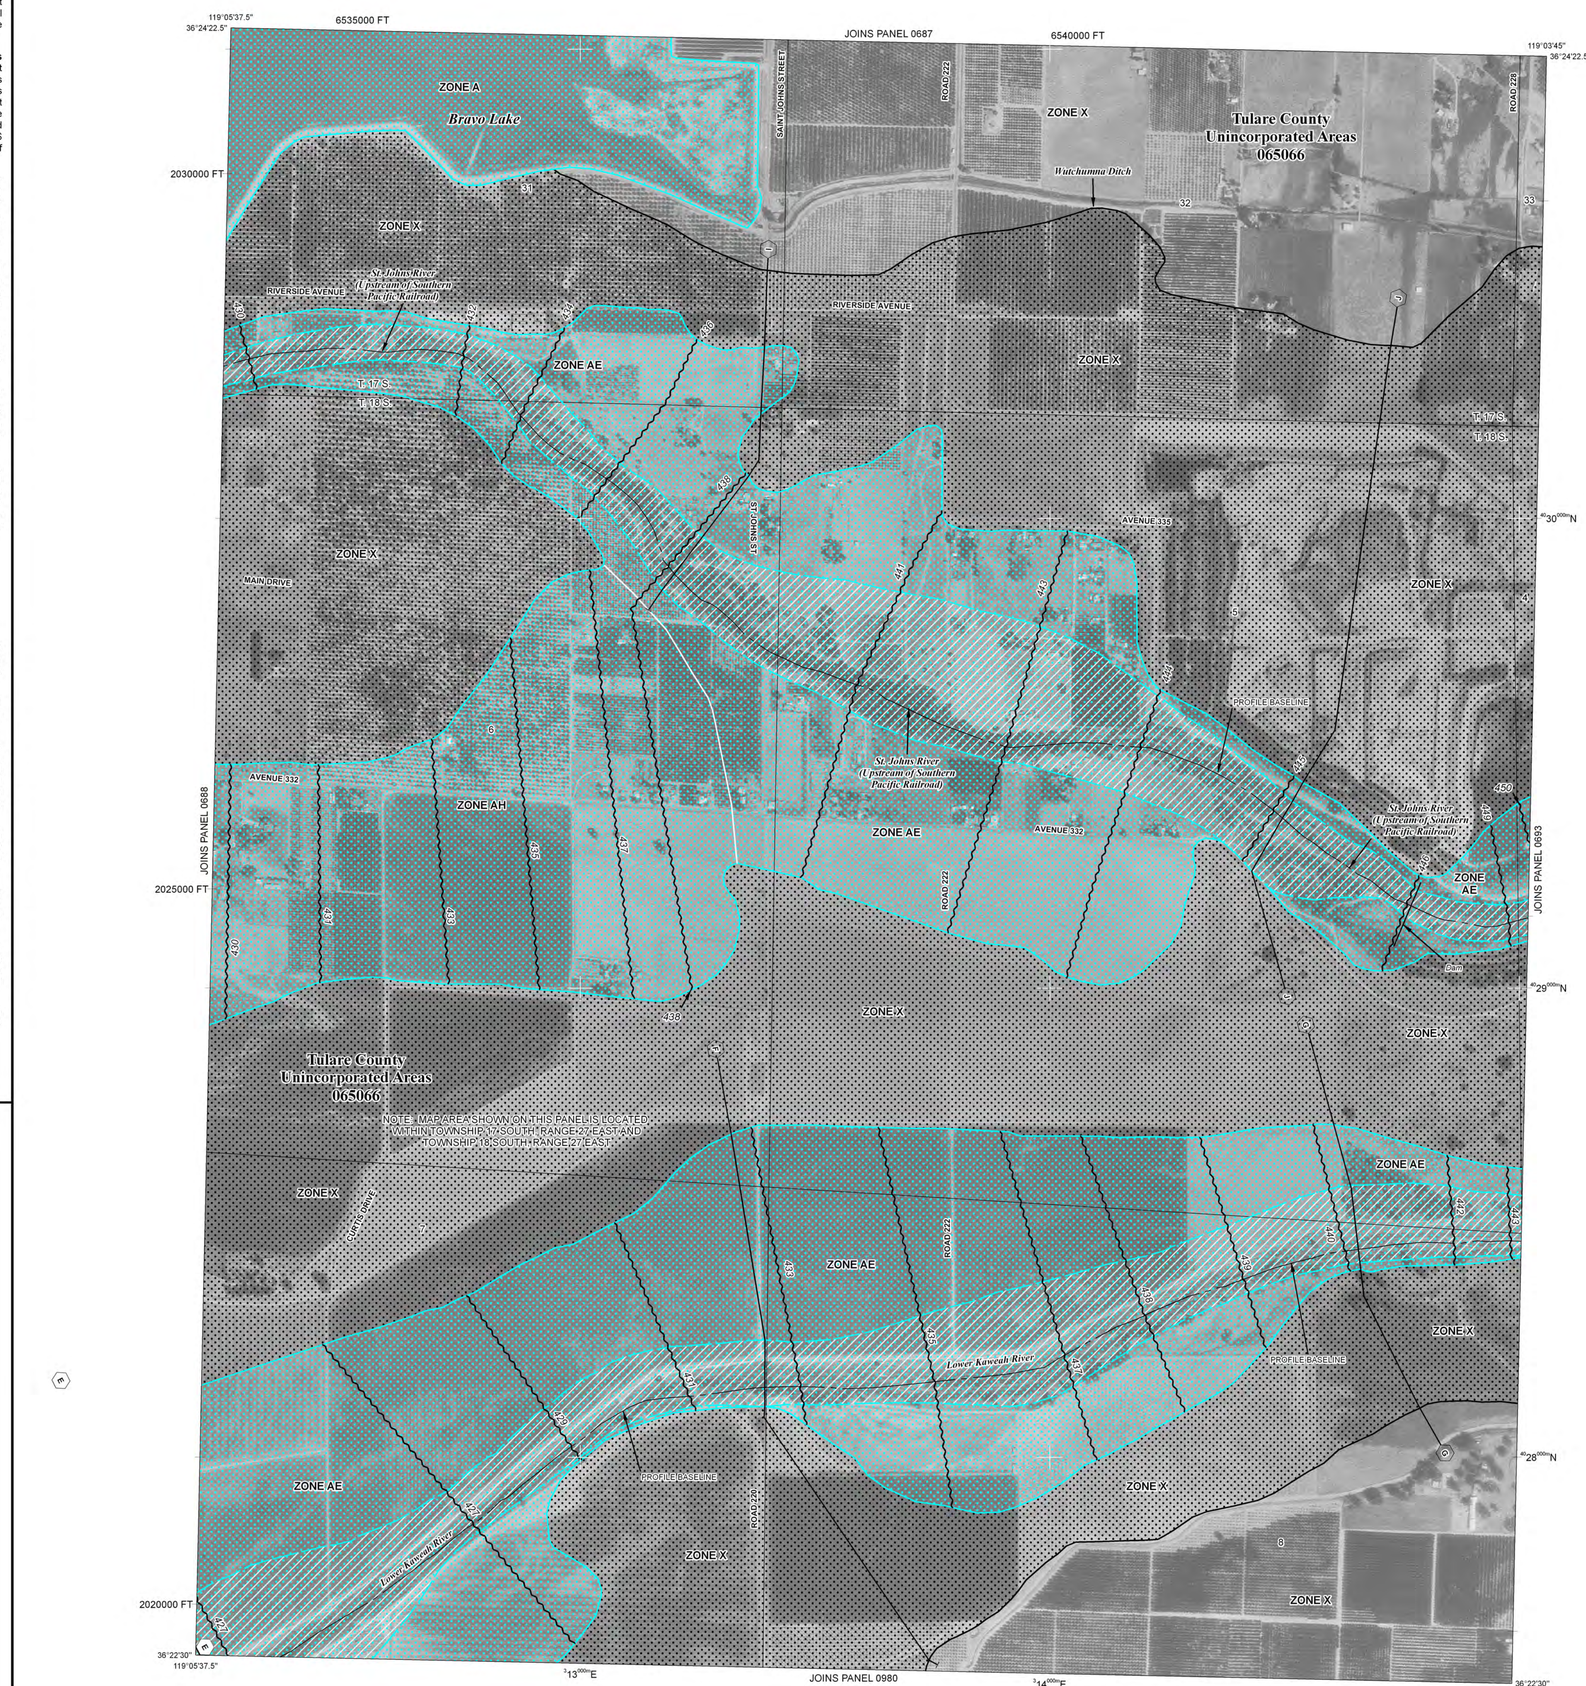
The **projection** used in the preparation of this map was Universal Transverse Mercator (UTM) Zone 11. The **horizontal datum** was NAD 83, GRS80 spheroid. Differences in datum, spheroid, projection or UTM zones used in the production of FIRMs for adjacent jurisdictions may result in slight positional differences in map features across jurisdiction boundaries. These differences do not affect the accuracy of this FIRM.

Flood elevations on this map are referenced to the North American Vertical Datum of 1988. These flood elevations must be compared to structure and ground elevations referenced to the same **vertical datum**. For information regarding conversion between the National Geodetic Vertical Datum of 1929 and the North American Vertical Datum of 1988, visit the National Geodetic Survey website at http://www.ngs.noaa.gov or contact the National Geodetic Survey at the following address:

NGS Information Services
NOAA, N/NGS12
National Geodetic Survey
SSMC-3, #9202
1315 East-West Highway
Silver Spring, Maryland 20910-3282
(301) 713-3242

To obtain current elevation, description, and/or location information for **bench marks** shown on this map, please contact the Information Services Branch of the National Geodetic Survey at **(301) 713-3242**, or visit its website at http://www.ngs.noaa.gov.

Base map information shown on this FIRM was derived from U.S. Geological Survey Digital Orthophoto Quadrangles produced at a scale of 1:12,000 from photography dated 1987 or later.



This map reflects more detailed and up-to-date **stream channel configurations** than those shown on the previous FIRM for this jurisdiction. The floodplains and floodways that were transferred from the previous FIRM may have been adjusted to conform to these new stream channel configurations. As a result, the Flood Profiles and Floodway Data tables in the Flood Insurance Study Report (which contains authoritative hydraulic data) may reflect stream channel distances that differ from what is shown on this map.

Corporate limits shown on this map are based on the best data available at the time of publication. Because changes due to annexations or de-annexations may have occurred after this map was published, map users should contact appropriate community officials to verify current corporate limit locations.

Please refer to the separately printed **Map Index** for an overview map showing the layout of map panels; community map repository addresses; and a Listing of Communities table containing National Flood Insurance Program dates for each community as well as a listing of the panels on which each community is located.

Contact the **FEMA Map Service Center** at 1-800-358-9616 for information on available products associated with this FIRM. Available products may include previously issued Letters of Map Change, a Flood Insurance Study report, and/or digital versions of this map. The FEMA Map Service Center may also be reached by Fax at 1-800-358-9620 and its website at http://msc.fema.gov.

If you have **questions about this map** or questions concerning the National Flood Insurance Program in general, please call **1-877-FEMA MAP** (1-877-336-2627) or visit the FEMA website at http://www.fema.gov.

LEGEND

SPECIAL FLOOD HAZARD AREAS SUBJECT TO INUNDATION BY THE 1% ANNUAL CHANCE FLOOD

The 1% annual flood (100-year flood), also known as the base flood, is the flood that has a 1% chance of being equaled or exceeded in any given year. The Special Flood Hazard Area is the area subject to flooding by the 1% annual chance flood. Areas of Special Flood Hazard include Zones A, AE, AH, AO, AR, A99, V, and VE. The Base Flood Elevation is the water-surface elevation of the 1% annual chance flood.

ZONE A	No Base Flood Elevations determined.
ZONE AE	Base Flood Elevations determined.
ZONE AH	Flood depths of 1 to 3 feet (usually areas of ponding); Base Flood Elevations determined.
ZONE AO	Flood depths of 1 to 3 feet (usually sheet flow on sloping terrain); average depths determined. For areas of alluvial fan flooding, velocities also determined.
ZONE AR	Special Flood Hazard Area formerly protected from the 1% annual chance flood by a flood control system that was subsequently decertified. Zone AR indicates that the former flood control system is being restored to provide protection from the 1% annual chance or greater flood.
ZONE A99	Area to be protected from 1% annual chance flood by a Federal flood protection system under construction; no Base Flood Elevations determined.
ZONE V	Coastal flood zone with velocity hazard (wave action); no Base Flood Elevations determined.
ZONE VE	Coastal flood zone with velocity hazard (wave action); Base Flood Elevations determined.

FLOODWAY AREAS IN ZONE AE

The floodway is the channel of a stream plus any adjacent floodplain areas that must be kept free of encroachment so that the 1% annual chance flood can be carried without substantial increases in flood heights.

OTHER FLOOD AREAS

ZONE X	Areas of 0.2% annual chance flood; areas of 1% annual chance flood with average depths of less than 1 foot or with drainage areas less than 1 square mile; and areas protected by levees from 1% annual chance flood.

OTHER AREAS

ZONE X	Areas determined to be outside the 0.2% annual chance floodplain.
ZONE D	Areas in which flood hazards are undetermined, but possible.

COASTAL BARRIER RESOURCES SYSTEM (CBRS) AREAS

OTHERWISE PROTECTED AREAS (OPAs)

CBRS areas and OPAs are normally located within or adjacent to Special Flood Hazard Areas.

- 1% annual chance floodplain boundary
- 0.2% annual chance floodplain boundary
- Floodway boundary
- Zone D boundary
- CBRS and OPA boundary
- Boundary dividing Special Flood Hazard Area Zones and boundary dividing Special Flood Hazard Areas of different Base Flood Elevations, flood depths or flood velocities.

NOTES TO USERS

This map is for use in administering the National Flood Insurance Program. It does not necessarily identify all areas subject to flooding, particularly from local drainage sources of small size. The **community map repository** should be consulted for possible updated or additional flood hazard information.

To obtain more detailed information in areas where **Base Flood Elevations** (BFEs) and/or **floodways** have been determined, users are encouraged to consult the Flood Profiles and Floodway Data and/or Summary of Stillwater Elevations tables contained within the Flood Insurance Study (FIS) report that accompanies this FIRM. Users should be aware that BFEs shown on the FIRM represent rounded whole-foot elevations. These BFEs are intended for flood insurance rating purposes only and should not be used as the sole source of flood elevation information. Accordingly, flood elevation data presented in the FIS report should be utilized in conjunction with the FIRM for purposes of construction and/or floodplain management.

Coastal Base Flood Elevations shown on this map apply only landward of 0.0' North American Vertical Datum of 1988 (NAVD 88). Users of this FIRM should be aware that coastal flood elevations are also provided in the Summary of Stillwater Elevations tables in the Flood Insurance Study report for this jurisdiction. Elevations shown in the Summary of Stillwater Elevations tables should be used for construction and/or floodplain management purposes when they are higher than the elevations shown on this FIRM.

Boundaries of the **floodways** were computed at cross sections and interpolated between cross sections. The floodways were based on hydraulic considerations with regard to requirements of the National Flood Insurance Program. Floodway widths and other pertinent floodway data are provided in the Flood Insurance Study report for this jurisdiction.

Certain areas not in Special Flood Hazard Areas may be protected by **flood control structures**. Refer to Section 2.4 "Flood Protection Measures" of the Flood Insurance Study report for information on flood control structures for this jurisdiction.

The **projection** used in the preparation of this map was Universal Transverse Mercator (UTM) Zone 11. The **horizontal datum** was NAD 83, GRS80 spheroid. Differences in datum, spheroid, projection or UTM zones used in the production of FIRMs for adjacent jurisdictions may result in slight positional differences in map features across jurisdiction boundaries. These differences do not affect the accuracy of this FIRM.

Flood elevations on this map are referenced to the North American Vertical Datum of 1988. These flood elevations must be compared to structure and ground elevations referenced to the same **vertical datum**. For information regarding conversion between the National Geodetic Vertical Datum of 1929 and the North American Vertical Datum of 1988, visit the National Geodetic Survey website at http://www.ngs.noaa.gov or contact the National Geodetic Survey at the following address:

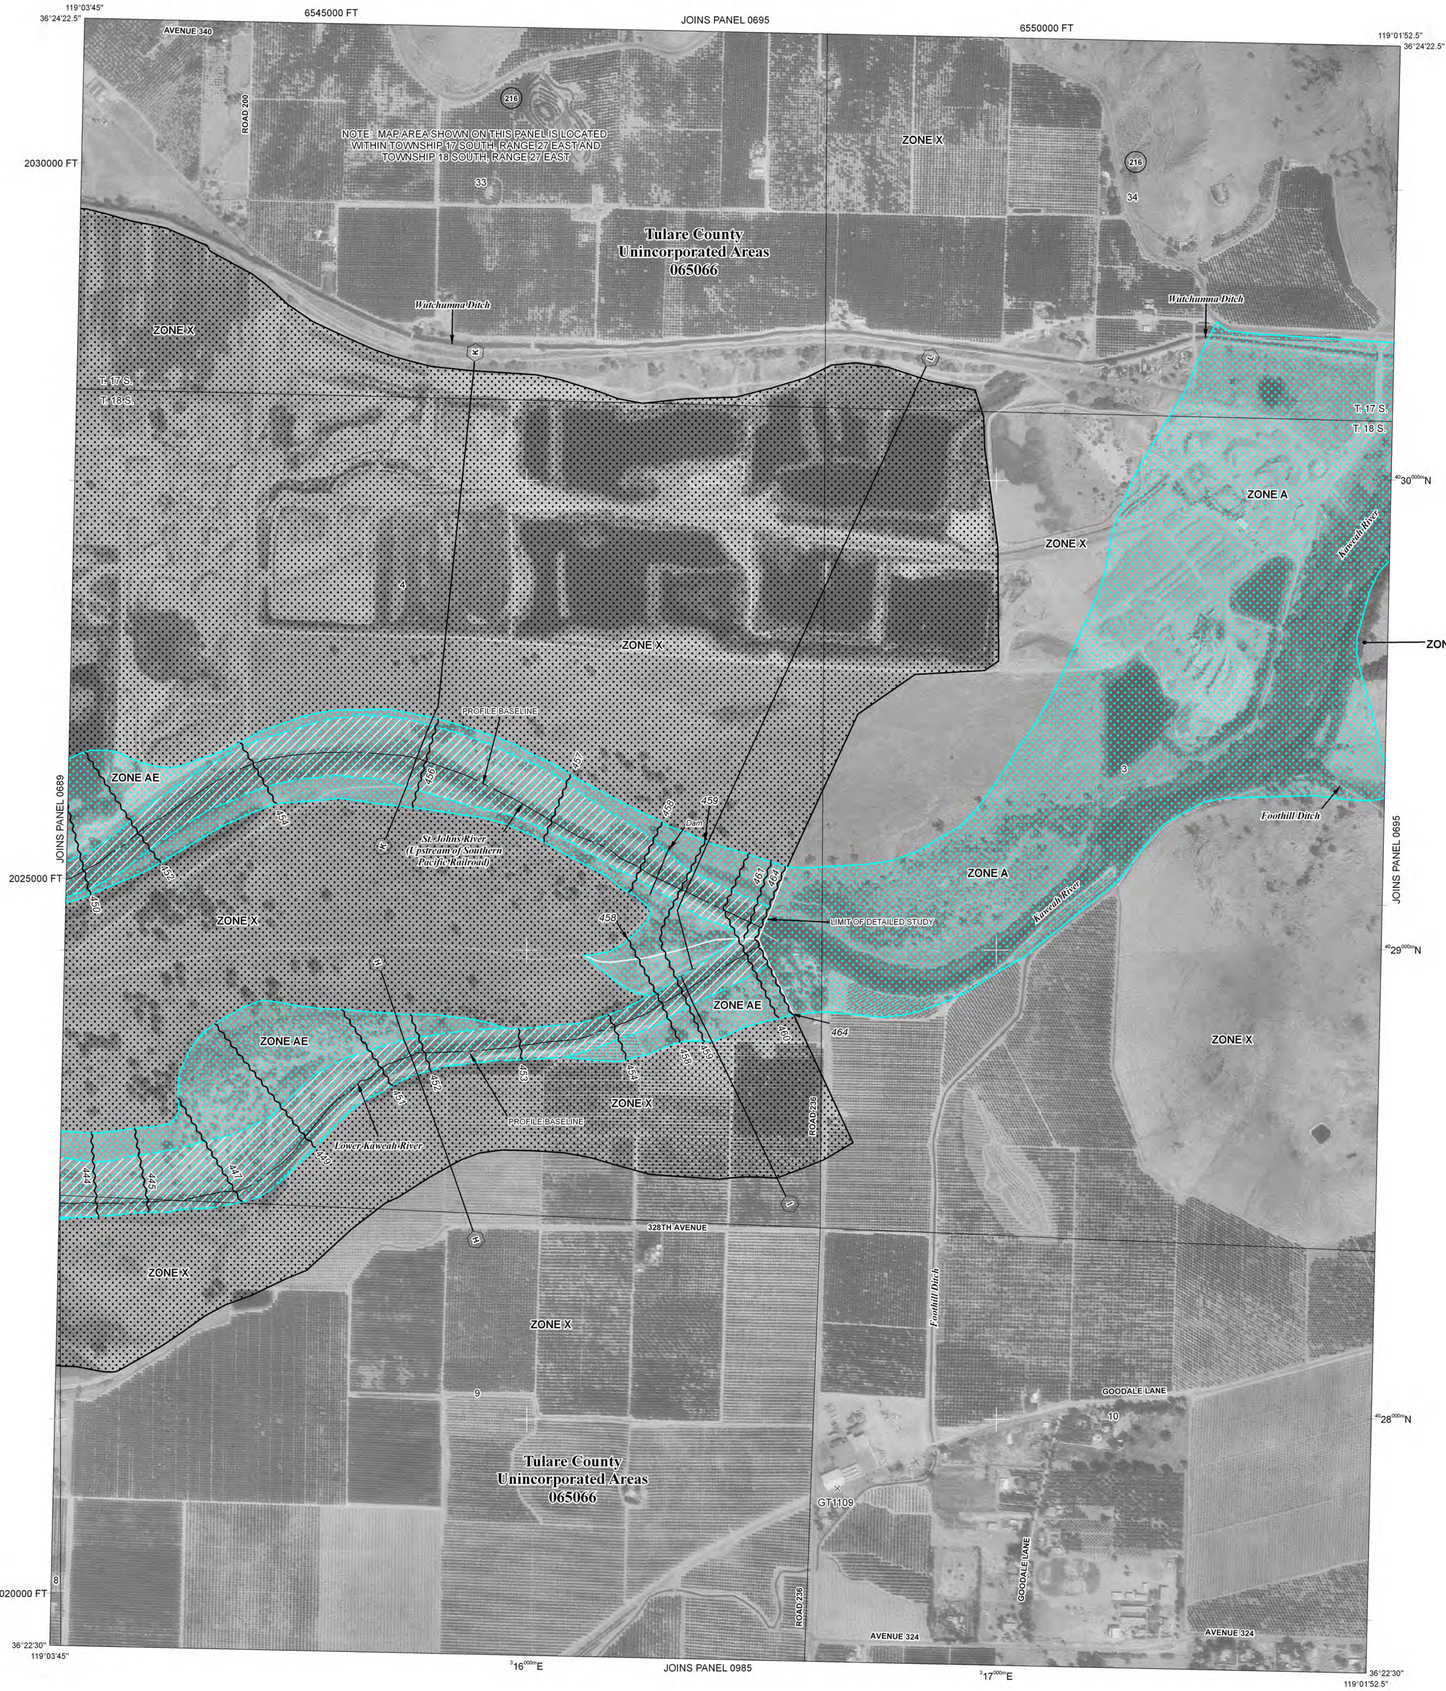
(301) 713-3242

To obtain current elevation, description, and/or location information for **bench marks** shown on this map, please contact the Information Services Branch of the National Geodetic Survey at **(301) 713-3242**, or visit its website at http://www.ngs.noaa.gov.

Base map information shown on this FIRM was derived from U.S. Geological Survey Digital Orthophoto Quadrangles produced at a scale of 1:12,000 from photography dated 1987 or later.



This map reflects more detailed and up-to-date **stream channel configurations** than those shown on the previous FIRM for this jurisdiction. The floodplains and floodways that were transferred from the previous FIRM may have been adjusted to conform to these new stream channel configurations. As a result, the Flood Profiles and Floodway Data tables in the Flood Insurance Study Report (which contains authoritative hydraulic data) may reflect stream channel distances that differ from what is shown on this map.

Corporate limits shown on this map are based on the best data available at the time of publication. Because changes due to annexations or de-annexations may have occurred after this map was published, map users should contact appropriate community officials to verify current corporate limit locations.

Please refer to the separately printed **Map Index** for an overview map showing the layout of map panels; community map repository addresses; and a Listing of Communities table containing National Flood Insurance Program dates for each community as well as a listing of the panels on which each community is located.

Contact the **FEMA Map Service Center** at 1-800-358-9616 for information on available products associated with this FIRM. Available products may include previously issued Letters of Map Change, a Flood Insurance Study report, and/or digital versions of this map. The FEMA Map Service Center may also be reached by Fax at 1-800-358-9620 and its website at http://msc.fema.gov.

If you have **questions about this map** or questions concerning the National Flood Insurance Program in general, please call **1-877-FEMA MAP** (1-877-336-2627) or visit the FEMA website at http://www.fema.gov.

LEGEND

SPECIAL FLOOD HAZARD AREAS SUBJECT TO INUNDATION BY THE 1% ANNUAL CHANCE FLOOD

The 1% annual flood (100-year flood), also known as the base flood, is the flood that has a 1% chance of being equaled or exceeded in any given year. The Special Flood Hazard Area is the area subject to flooding by the 1% annual chance flood. Areas of Special Flood Hazard include Zones A, AE, AH, AO, AR, A99, V, and VE. The Base Flood Elevation is the water-surface elevation of the 1% annual chance flood.

ZONE A	No Base Flood Elevations determined.
ZONE AE	Base Flood Elevations determined.
ZONE AH	Flood depths of 1 to 3 feet (usually areas of ponding); Base Flood Elevations determined.
ZONE AO	Flood depths of 1 to 3 feet (usually sheet flow on sloping terrain); average depths determined. For areas of alluvial fan flooding, velocities also determined.
ZONE AR	Special Flood Hazard Area formerly protected from the 1% annual chance flood by a flood control system that was subsequently decertified. Zone AR indicates that the former flood control system is being restored to provide protection from the 1% annual chance or greater flood.
ZONE A99	Area to be protected from 1% annual chance flood by a Federal flood protection system under construction; no Base Flood Elevations determined.
ZONE V	Coastal flood zone with velocity hazard (wave action); no Base Flood Elevations determined.
ZONE VE	Coastal flood zone with velocity hazard (wave action); Base Flood Elevations determined.

FLOODWAY AREAS IN ZONE AE

The floodway is the channel of a stream plus any adjacent floodplain areas that must be kept free of encroachment so that the 1% annual chance flood can be carried without substantial increases in flood heights.

OTHER FLOOD AREAS

ZONE X	Areas of 0.2% annual chance flood; areas of 1% annual chance flood with average depths of less than 1 foot or with drainage areas less than 1 square mile; and areas protected by levees from 1% annual chance flood.

OTHER AREAS

ZONE X	Areas determined to be outside the 0.2% annual chance floodplain.
ZONE D	Areas in which flood hazards are undetermined, but possible.

COASTAL BARRIER RESOURCES SYSTEM (CBRS) AREAS

OTHERWISE PROTECTED AREAS (OPAs)

CBRS areas and OPAs are normally located within or adjacent to Special Flood Hazard Areas.

	1% annual chance floodplain boundary
	0.2% annual chance floodplain boundary
	Floodway boundary
	Zone D boundary
	CBRS and OPA boundary
	Boundary dividing Special Flood Hazard Area Zones and boundary dividing Special Flood Hazard Areas of different Base Flood Elevations, flood depths or flood velocities.

NOTES TO USERS

This map is for use in administering the National Flood Insurance Program. It does not necessarily identify all areas subject to flooding, particularly from local drainage sources of small size. The **community map repository** should be consulted for possible updated or additional flood hazard information.

To obtain more detailed information in areas where **Base Flood Elevations** (BFEs) and/or **floodways** have been determined, users are encouraged to consult the Flood Profiles and Floodway Data and/or Summary of Stillwater Elevations tables contained within the Flood Insurance Study (FIS) report that accompanies this FIRM. Users should be aware that BFEs shown on the FIRM represent rounded whole-foot elevations. These BFEs are intended for flood insurance rating purposes only and should not be used as the sole source of flood elevation information. Accordingly, flood elevation data presented in the FIS report should be utilized in conjunction with the FIRM for purposes of construction and/or floodplain management.

Coastal Base Flood Elevations (BFEs) shown on this map apply only landward of 0.0' North American Vertical Datum of 1988 (NAVD 88). Users of this FIRM should be aware that coastal flood elevations are also provided in the Summary of Stillwater Elevations table in the Flood Insurance Study report for this jurisdiction. Elevations shown in the Summary of Stillwater Elevations table should be used for construction and/or floodplain management purposes when they are higher than the elevations shown on this FIRM.

Boundaries of the **floodways** were computed at cross sections and interpolated between cross sections. The floodways were based on hydraulic considerations with regard to requirements of the National Flood Insurance Program. Floodway widths and other pertinent floodway data are provided in the Flood Insurance Study report for this jurisdiction.

Certain areas not in Special Flood Hazard Areas may be protected by **flood control structures**. Refer to Section 2.4 "Flood Protection Measures" of the Flood Insurance Study report for information on flood control structures for this jurisdiction.

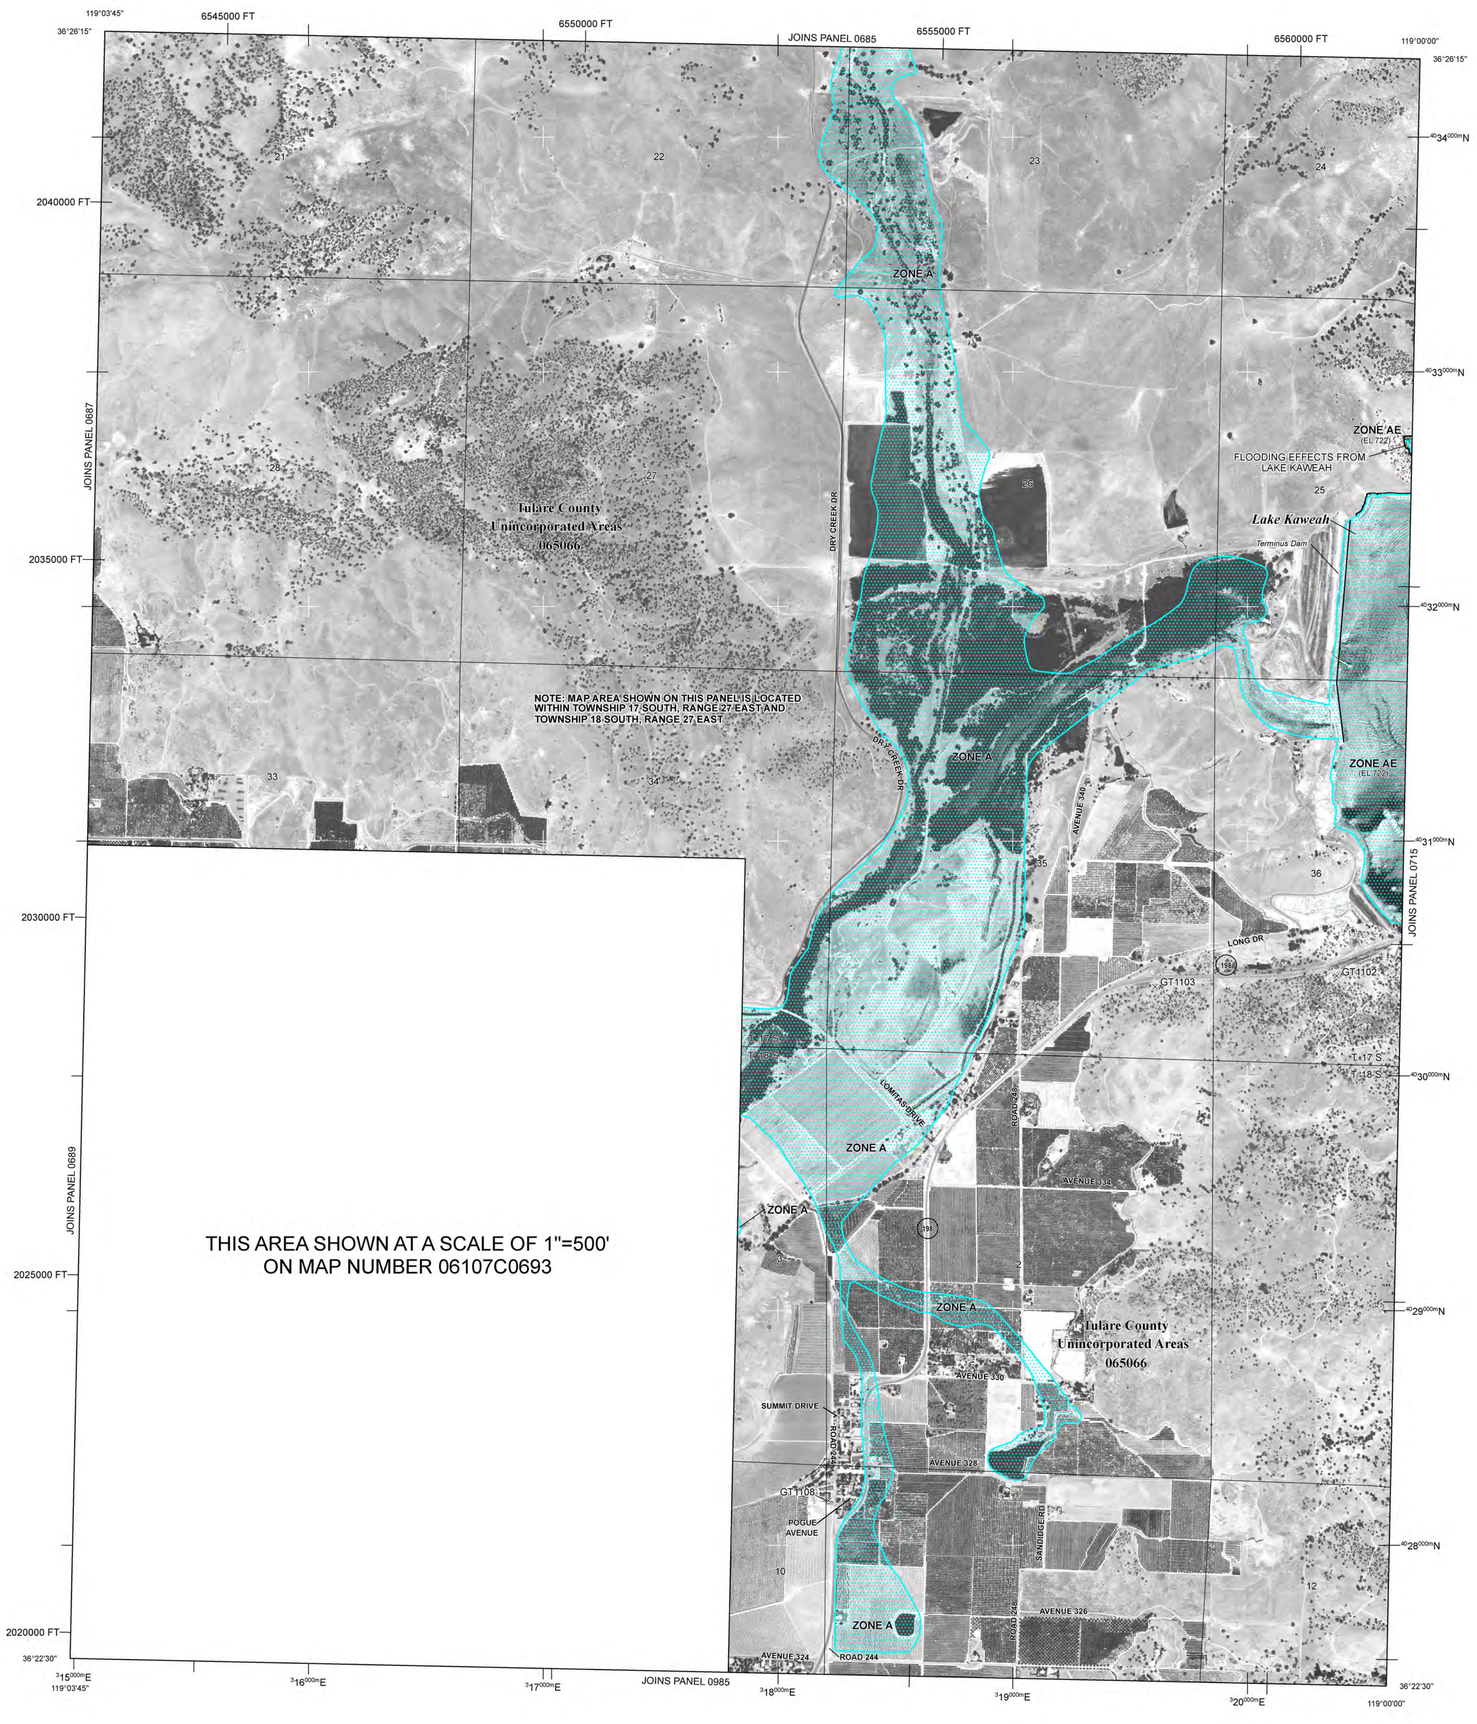
The **projection** used in the preparation of this map was Universal Transverse Mercator zone 11. The **horizontal datum** was NAD83, GRS1980 spheroid. Differences in datum, spheroid, projection or UTM zones used in the production of FIRMs for adjacent jurisdictions may result in slight positional differences in map features across jurisdiction boundaries. These differences do not affect the accuracy of this FIRM.

Flood elevations on this map are referenced to the North American Vertical Datum of 1988. These flood elevations must be compared to structure and ground elevations referenced to the same **vertical datum**. For information regarding conversion between the National Geodetic Vertical Datum of 1929 and the North American Vertical Datum of 1988, visit the National Geodetic Survey website at http://www.ngs.noaa.gov/ or contact the National Geodetic Survey at the following address:

NGS Information Services
NOAA, N/NGS12
National Geodetic Survey
SSMC-3, #9202
1315 East-West Highway
Silver Spring, Maryland 20910-3282
(301) 713-3242

To obtain current elevation, description, and/or location information for **bench marks** shown on this map, please contact the Information Services Branch of the National Geodetic Survey at **(301) 713-3242** or visit its website at http://www.ngs.noaa.gov/.

Base map information shown on this FIRM was derived from U.S. Geological Survey Digital Orthophoto Quadrangles produced at a scale of 1:12,000 from photography dated 1987 or later.



This map reflects more detailed and up-to-date **stream channel configurations** than those shown on the previous FIRM for this jurisdiction. The floodplains and floodways that were transferred from the previous FIRM may have been adjusted to conform to these new stream channel configurations. As a result, the Flood Profiles and Floodway Data tables *in the Flood Insurance Study report (which contains authoritative hydraulic data)* may reflect stream channel distances that differ from what is shown on this map.

Corporate limits shown on this map are based on the best data available at the time of publication. Because changes due to annexations or de-annexations may have occurred after this map was published, map users should contact appropriate community officials to verify current corporate limit locations.

Please refer to the separately printed **Map Index** for an overview map of the county showing the layout of map panels; community map repository addresses; and a Listing of Communities table containing National Flood Insurance Program dates for each community as well as a listing of the panels on which each community is located.

For information and questions about this map, available products associated with this FIRM including historic versions of this FIRM, how to order products or the National Flood Insurance Program in general, please call the FEMA Map Information eXchange at 1-877-FEMA-MAP (1-877-336-2627) or visit the FEMA Map Service Center website at http://msc.fema.gov. Available products may include previously issued Letters of Map Change, a Flood Insurance Study Report, and/or digital versions of this map. Many of these products can be ordered or obtained directly from the website. Users may determine the current map date for each FIRM panel by visiting the FEMA Map Service Center website or by calling the FEMA Map Information eXchange.

The "profile base lines" depicted on this map represent the hydraulic modeling baselines that match the flood profiles in the FIS report. As a result of improved topographic data, the "profile base line", in some cases, may deviate significantly from the channel centerline or appear outside the SFHA.

LEGEND

SPECIAL FLOOD HAZARD AREAS SUBJECT TO INUNDATION BY THE 1% ANNUAL CHANCE FLOOD

The 1% annual chance flood (100-year flood), also known as the base flood, is the flood that has a 1% chance of being equaled or exceeded in any given year. The Special Flood Hazard Area is the area subject to flooding by the 1% annual chance flood. Areas of Special Flood Hazard include Zones A, AE, AH, AO, AR, A99, V, and VE. The Base Flood Elevation is the water-surface elevation of the 1% annual chance flood.

ZONE A	No Base Flood Elevations determined.
ZONE AE	Base Flood Elevations determined.
ZONE AH	Flood depths of 1 to 3 feet (usually areas of ponding); Base Flood Elevations determined.
ZONE AO	Flood depths of 1 to 3 feet (usually sheet flow on sloping terrain); average depths determined. For areas of alluvial fan flooding, velocities also determined.
ZONE AR	Special Flood Hazard Area formerly protected from the 1% annual chance flood by a flood control system that was subsequently decertified. Zone AR indicates that the former flood control system is being restored to provide protection from the 1% annual chance or greater flood.
ZONE A99	Areas to be protected from 1% annual chance flood event by a Federal flood protection system under construction; no Base Flood Elevations determined.
ZONE V	Coastal flood zone with velocity hazard (wave action); no Base Flood Elevations determined.
ZONE VE	Coastal flood zone with velocity hazard (wave action); Base Flood Elevations determined.

FLOODWAY AREAS IN ZONE AE

The floodway is the channel of a stream plus any adjacent floodplain areas that must be kept free of encroachment so that the 1% annual chance flood can be carried without substantial increases in flood heights.

OTHER FLOOD AREAS

ZONE X	Areas of 0.2% annual chance flood; areas of 1% annual chance flood with average depths of less than 1 foot or with drainage areas less than 1 square mile; and areas protected by levees from 1% annual chance flood.

OTHER AREAS

ZONE X	Areas determined to be outside the 0.2% annual chance floodplain.
ZONE D	Areas in which flood hazards are undetermined, but possible.

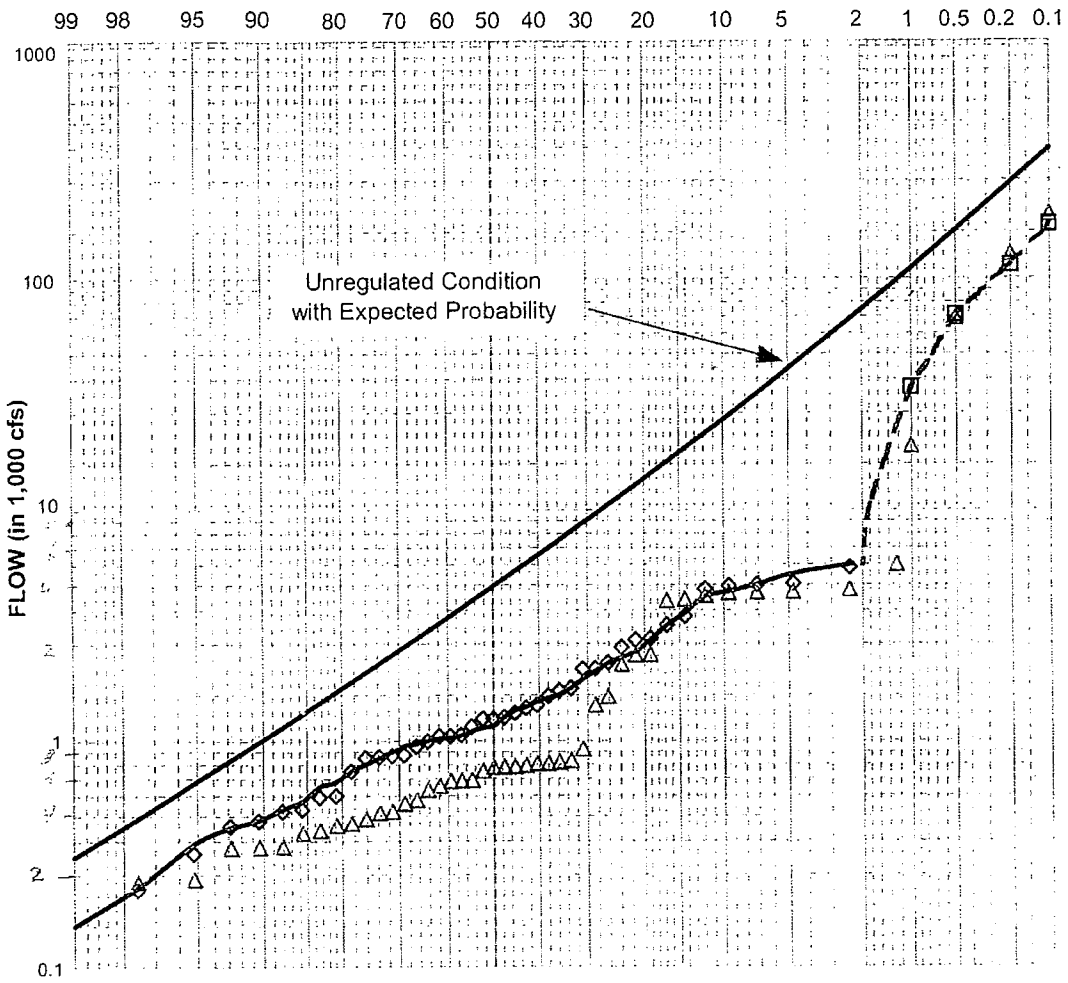
2975 North Farmerville Blvd.
Farmersville, CA 93223-2303

Dear Mr. George:

This is in response to the request to provide the revised flow at McKay Point for the 1% flood. The revised flow is based upon the raise spillway at the dam. The peak release from the reservoir during this event is 17,900 cfs. The peak flow at McKay Point, including local flow from Dry, Mehrtens, and Yokohl Creeks is 18,220 cfs.

Enclosed is the hourly data for the routing along with 2 plots that show the operation and flows.

If you have any questions, please contact Mr. Wayne Johnson at (916) 557-7139.



Sincerely,

Wayne L Johnson FOR

Paul E Pugner, PE

RIVERBED ANALYSIS

Written by: SB Date: 2016 / 06/ 24 (YY MM DD) Reviewed by: TP Date: 2016 / 06/ 24 (YY MM DD)

Client: SESPE Project: McKay Point Reservoir Project No: 117.00981 Task No.: 01

RIVERBED ANALYSIS

MCKAY POINT RESERVOIR, CALIFORNIA

1. PURPOSE AND SCOPE

This attachment documents the riverbed analysis conducted for the Kaweah River and the St. Johns River at the proposed McKay Point Reservoir Project site. The McKay Point Reservoir Project involves the creation of a topographic depression that will capture precipitation and some storm water runoff. The Project will not involve placing structures in the St. Johns or Kaweah River channels and will not alter the course of either river. The only changes to the river channels will be placement of rip rap at the Inflow and Outflow Channels, and construction of the Inflow and Outflow Channels. The rip rap will be placed below the elevation of the main river channels, and the Inflow/Outflow Channels will be set back from the main river channels. These structures are designed to avoid impedance of river flows.

2. ANALYSIS

SLR reviewed historical aerial photos of the riverbeds of the Kaweah and St. Johns Rivers and the surrounding areas. The aerial photos from the years 1954, 1956, 1969, 1974, 1984, 1989, 1994, and 2002 were obtained from Environmental Data Resources, Inc. (EDR, 2014). The aerial photos from the years 2003, 2004, 2005, 2006, 2009, 2010, 2011, 2012, and 2014 were obtained from Google Earth. The photos were reviewed to determine if major scouring or changes to the morphology of the Kaweah and St. Johns Rivers had occurred near the McKay Point Reservoir Project site in the past. The 1954 and 1956 photos show that the size and shape of the river channels varied with the weather conditions and the corresponding flow volumes that occurred at the time. However, starting with the 1969 photo, no significant changes can be observed. Terminus Dam was constructed in 1962, and regulates flows and flooding, and thus river morphology and scouring. Rapid changes in river morphology and scouring have therefore been minimized. Terminus Dam is used extensively to manage flow rates in the rivers and to avoid flow rates that would result in extensive scouring.

3. SUMMARY AND CONCLUSIONS

SLR has conducted a review of historical aerial photographs of the McKay Point Reservoir Project site and the surrounding areas to identify whether the Kaweah and St. Johns Rivers have moved or changed course significantly in the past sixty years. The results of this riverbed analysis are presented in a series of figures in which the 2014 aerial image is overlaid by sketches of the historical outlines of the river channels from the selected years of 1956, 1969,

1974, 1984, 1994, 2002, 2005, and 2014. Based on this evaluation, SLR concludes that the riverbeds of the Kaweah and St. Johns Rivers have not moved significantly since construction of Terminus Dam in 1962.

It is anticipated that during reservoir operations, flow rates in the St. Johns and Kaweah Rivers will remain within the existing range of typical flow rates that are currently managed through outflows of Terminus Dam. Use of the reservoir for flood storage may actually cause flow rates in the Kaweah and St. Johns Rivers to decrease during periods of high precipitation, thereby reducing scour potential. Thus, SLR also concludes that the riverbeds of both the Kaweah and St. Johns Rivers would not move as a result of the McKay Point Reservoir Project.

ATTACHMENT D

SEEPAGE CALCULATIONS

DRAFT

D.1 INTRODUCTION

Seepage calculations were performed to determine the amount of groundwater inflow into the excavated reservoir, both with and without the proposed slurry wall. These analyses were conducted using two methods, i.e.:

- Simplified Two-dimensional (2-D) analyses; and
- A conceptual level Three-dimensional (3-D) analysis as a check on the 2-D modleing and also to assess the likely impacts of the project on the groundwater levels surrounding the Reservoir.

Tw sets of analyses were performed as a check on the range of potential values that could be generated. The details of the modeling work and the results are provided in Sections D.2 and D.3 bellow. The overall key results are as follows:

Table D1-1 Summary of Excavation and Reservoir Inflow Rates

PROJECT STAGE	CONDITIONS	SLURRY WALL	INFILTRATION TRENCH	2-D MODELLING (GPM)	3-D MODELLING (GPM)	RECOMMENDED FOR USE IN ENVIRONMENTAL ANALYSES (GPM)	RATIONAL
Excavation / Reservoir	Final Excavation Empty Reservoir	No	No	0	0	0	
	Initial Excavation Full Reservoir	No	No	659	830	800	Reasonable average value

D.2 TWO DIMENSIONAL ANALYSES

D.2.1 INTRODUCTION

Two geologic cross sections across the reservoir were developed based on the boring logs available and a review of available information about the site. These two geologic cross sections are presented in Attachment A of the Technical Memorandum prepared by SES (SES, 2012). Based on these geologic cross sections and the layout of the reservoir developed by Provost and Pritchard (February 18, 2014), three representative cross sections were developed for seepage analysis. The locations of the three cross sections are shown on Figure D2-1. Each cross section represents the geologic conditions, width of the reservoir, and the hydrogeologic regime in the various areas of the reservoir. The depth of the reservoir at each cross section was taken from the layout developed by Provost and Pritchard.

The seepage analyses consist of evaluating the flow of water into the reservoir during and at the end of excavation. The analyses are performed for the following three scenarios:

1. The first scenario considered construction of the reservoir (i.e. excavation) without a perimeter slurry wall;

2. The second scenario includes a slurry wall installed around the perimeter of the reservoir approximately 50 ft away from the crest of the slopes and extending down to elevation 388 ft above mean sea level (amsl); and

3. The third scenario consists of augmenting scenario two by adding a reinjection/recirculation trench north of the slurry wall to recirculate influent water back into the natural groundwater system.

The seepage analyses presented in this attachment were performed with the finite element programs SEEP/W (GeoStudio, 2012).

D.2.2 REPRESENTATIVE SECTIONS

D.2.2.1 SECTION 1

This section runs north to south and combines the information from geologic cross sections AA' and BB' (Attachment A in SES 2012) with an emphasis on the conditions observed at Boring B-1. Boring B-1 indicates a lack of the bedrock horizon unit that was observed at other boring locations. Consequently, groundwater flow underneath the reservoir will be within the SC/CL layer. Also, this section of the reservoir is triangular rather than trapezoidal.

D.2.2.2 SECTION 2

This section runs north to south and again combines the information from geologic cross sections AA' and BB' with emphasis on the conditions observed at Boring B-2. Boring B-2 indicates a lack of the bedrock horizon unit that was observed at other boring locations. Also, this section of the reservoir was modeled as a trapezoid.

D.2.2.3 SECTION 3

This section again runs from north to south and combines information from geologic cross sections AA' and BB' with an emphasis on the conditions observed at Borings B-3 and B-4. Borings B-3 and B-4 indicate a bedrock horizon existing at the final depth of excavation along with SC/CL and SP lenses. Also, this section of the reservoir was modeled as a trapezoid.

D.2.3 MATERIAL PROPERTIES

The hydraulic conductivities of the different stratigraphic layers were calculated using the results of the geotechnical testing carried out on samples recovered from the borings. A series of grain size analyses (ASTM D422) were performed on samples collected in the borings. The results of these tests were used together with correlations such as those developed by Hazen (1852, 1911), Kozeny (1927) and Carman (1938, 1956) to determine hydraulic conductivities. The details of the analyses are provided in Attachment B of SES (2012). The values estimated by SES were compared to those measured by Fugro (2002) at a nearby site and the values of transmissivity reported by Luhdorff and Scalmanini (1995) for a site west of the project site.

The hydraulic conductivity of the slurry wall is very low and a conductivity value was set based on engineering judgement. The selected hydraulic conductivity of the slurry wall is 3.3×10^{-11} ft/sec (1×10^{-9} cm/s).

The values of isotropic saturated hydraulic conductivities used in the analyses are presented in Table D2-1.

Analyses were performed considering isotropic as well as anisotropic conditions for the alluvium. This is the ratio of the horizontal to the vertical saturated hydraulic conductivity. Both conditions were analyzed as a sensitivity analysis to address the uncertainty in the depositional nature of the alluvium/unconsolidated materials in the upper layers. A coefficient of anisotropy of 5 was used. This coefficient was not applied to the bedrock or the slurry wall.

D.2.4 BOUNDARY CONDITIONS

The boundary conditions for the analysis were established based on the location of the reservoir with respect to the Kaweah River to the south, and the CEMEX ponds (former pits) north of the proposed reservoir.

D.2.4.1 CROSS SECTION 1

This section is the furthest from the Kaweah River at approximately 2,340 ft, and is not affected by its regime. The water table in Boring B-1 was observed at elevation 438 ft amsl. In their report, Luhdorff and Scalmanini have established that the ephemeral nature of the Saint Johns River has no significant effect on the water table in the area. Therefore, the southern boundary condition was set as a constant head of 438 ft amsl at a distance 2,340 ft south of the reservoir. For the northern boundary conditions, the groundwater elevations from Figure 6 of Kenneth Schmidt and Associates (November-December, 2011) were used. The groundwater elevation on the northern boundary was set at an elevation of 438 ft amsl 1000 feet north of the reservoir.

D.2.4.2 CROSS SECTION 2

Groundwater elevations in Borings B-5 and B-2 were used to establish the boundary in terms of total head for the north and south end of this section. The northern boundary condition was set at a constant head of 445 ft amsl at a distance 1000 ft north of the reservoir, and the boundary condition on the south was set as a constant head of 445 ft amsl at a distance 1,780 ft south of the reservoir.

D.2.4.3 CROSS SECTION 3

Section 3 is the most influenced by the Kaweah River. The groundwater elevation in Boring B-6 was used to establish the boundary conditions for the south end of this section and the groundwater elevation Figure 6 of Kenneth Schmidt and Associates was used for the north end of the section. The northern boundary condition was set as a constant head equal to 452 ft amsl at a distance 1000 ft north of the reservoir, whereas the southern boundary condition was set as a constant head of 460 ft amsl at a distance 370 ft south of the reservoir.

D.2.4.4 RADIUS OF INFLUENCE

The radius of influence for the alluvium typical of the area was established in the pump test performed by Luhdorff and Scalmanini. The radius of influence is on the order of 1,000 ft. Consequently, the model's boundary conditions were set at a minimum of 1,000 ft from the edges of the reservoir when applicable. This minimum of 1,000 ft was utilized for the southern boundaries of Sections 1 and 2. However, the southern boundary condition of Section 3 was exempt from the 1,000 ft minimum distance, as the edge of the reservoir is approximately 370 ft from the Kaweah River.

D.2.5 RECIRCULATION / REINJECTION OF INFLUENT GROUNDWATER

Scenario three utilizes an injection/recirculation trench to recirculate all influent water from the excavation back into the natural groundwater system. This injection/recirculation trench was modeled to have dimensions of 3 ft wide by 10 ft deep, and was assigned a material conductivity of $1x10^{-2}$ ft/sec (0.3 cm/sec). The injection/recirculation trench was placed 10 ft north of the slurry wall for scenario three.

As groundwater enters the excavation, it will be pumped into the injection/recirculation trench. The water added to the natural groundwater system from the injection/recirculation trench will consequently increase the flux into the excavation, thus requiring slightly greater pumping into the injection/recirculation trench to keep the excavation unsaturated. Groundwater inflow and required injection/recirculation rates will continue to rise as excavation proceeds, and must be accommodated for.

D.2.6 RESULTS

Analyses were performed for each scenario at each cross section using the representative values of saturated hydraulic conductivity listed in Table D2-1 for each formation assuming either isotropic or anisotropic conditions in the alluvium.

D.2.6.1 FLOWS AT EACH SECTION

The three sections analyzed are shown on Figures D2-2 through D2-4 for scenario one (no slurry wall), D2-5 through D2-7 for the scenario two (slurry wall), and D2-8 through D2-10 for scenario three (slurry wall and reinjection/recirculation). The results in the form of the pressure head and flux into the reservoir are shown on Figures D2-11 through D2-13 for scenario one, D2-14 through D2-16 for scenario 2, and D2-17 through D2-19 for scenario three.

The results for anisotropic conditions are similar, so are not shown herein. The results for isotropic versus anisotropic conditions indicate that the uncertainty in isotropy isn't a determining factor in the results.

The results are presented in Table D2-2 as the flow into the excavation in cubic feet per second (ft^3/s) and gallons per minute (gpm) for each representative section and each scenario analyzed.

D.2.6.2 TOTAL FLOW INTO RESERVOIR

The total flows into the reservoir were evaluated for each scenario by a weighted average of the length of reservoir perimeter best represented by each of the three sections. Those weighting lengths were established based on review of the geologic conditions, width of the reservoir, and the boundary conditions of each section. The lengths of pit modeled by each of the representative cross sections were established as:

- Section 1: 1,600 ft;
- Section 2: 2,200 ft; and
- Section 3: 2,000 ft.

For a total length of 5,800 ft.

The total flows into the reservoir for each scenario are reported in Table D2-3.

Table D2-1: Hydraulic Conductivity Values

LAYER #	SOIL DESCRIPTION	SOIL TYPE	K (cm/s)	K (ft/s)
1	Poorly Graded Sand	SP	$1.6x10^{-3}$	$5.3x10^{-5}$

D.3 THREE DIMENSIONAL ANALYSES

D.3.1 INTRODUCTION

This attachment describes the approach and assumptions used to estimate the seepage inflow rates through numerical and empirical methods. SLR used two methodologies to assess the inflow rates.

Firstly, a systematic groundwater pump and treat (P&T) method for capture zone analysis described by the USEPA was used (USEPA, 2008). The dewatering estimate assumes the groundwater inflows to the excavation can be represented by the saturated thickness and local gradient towards the planned reservoir (Table D3-1). This approach does not include the slurry wall and infiltration trench. However, the method is helpful as a screening tool to perform a basic assessment of the hydrogeologic conditions and as a check on the flow rates expected from the numerical modeling.

Secondly, a steady-state numerical model was developed for the Project to estimate the general groundwater condition around and seepage rate into the planned excavation for the following three scenarios.

1. The first scenario considered the construction of the planned excavation to its maximum depth (i.e., reservoir) without a perimeter slurry wall;

2. The second scenario includes slurry walls installed around the perimeter of the planned maximum excavation; and

3. The third scenario consists of augmenting scenario two by adding a reinjection/recirculation trench north of the slurry wall to recirculate the collected influent water back into the natural groundwater system.

D.3.2 BACKGROUND

The numerical assessment evaluates the anticipated changes to the baseline hydrogeologic conditions resulting from the Project. The source of lithological and hydrogeological data of the evaluation are previous studies conducted on the site, such as Kenneth D. Schmidt and Associates 2012, SLR 2021a, SLR 2021b, and Section D.2 above. Additional data from other publicly available documents were also reviewed and used as part of this assessment.

D.3.3 EXCAVATION DESIGN, SLURRY WALL, AND INFILTRATION TRENCH SETTING

The excavation design has about 5,700 ft length and variable-width ranges from 330 to 1,310 ft Figure 3D-2 and Figure 3D-11 (Provost & Pritchard Consulting Group via email, June 2021). The excavation depth ranges from 370 – 425 ft amsl from the ground surface (about 467 ft, amsl), generally overlying the clay unit and bedrock.

The slurry wall is designed to impede the inflow of water to the planned excavation from all dimensions. A thickness of one foot and hydraulic conductivity equal to that of the clay unit (0.0013 ft/day, or $5x10^{-7}$ cm/sec) was used in the model.

The infiltration trench was set to the north of the slurry wall, and the hydraulic conductivity was equal to that of the gravel (69 ft/da, or 2.5 x 10^{-2} cm/sec).

The existing ponds are represented by surface water that intercepts groundwater flow towards the reservoir. The ponds are treated in the model overlying a highly permeable material extending 10 feet below the local potentiometric surface. The impact of the ponds on the dewatering rate from the excavation was evaluated compared to the results of scenario 2.

D.3.4 METHODOLOGY

The conceptual site model (CSM) provides a framework for understanding site-specific features and physical processes that influence groundwater flow around the planned excavation. The conceptual site model (CSM) aims to organize the field data to simplify the field problem while maintaining its essential characteristics so that the system can be analyzed more readily. Of necessity simplification of site conditions is required when establishing a CSM (Anderson and Woessner, 1992).

A total of seventeen boring logs, six onsite (BSK, 2011), and eleven offsite, boring logs were used to build the CSM (Figure D3-1). The offsite boring logs were collected from the California Department of Water Resources (CA-DWR) website. The lithologic logs were reviewed for their quality, and poorly logged borings were excluded from further consideration. Based on these borings, the thickness of alluvial deposits at the Project site ranges between approximately 60 and 80 feet. The uppermost alluvial deposits at the Project site consist of sand, cobbles, boulders, silt, and clay (Luhdorff and Scalmanini, 1995). The contact between alluvial deposits and bedrock is shallower in the east and gets deeper towards the west (Kenneth D. Schmidt and Associates, 2012).

The CSM formulation involves synthesizing available hydrological, lithological, hydrogeological data contained in various reports. It includes consideration of the

hydrogeologic framework, water budget, and groundwater flow systems. Historical water levels indicate that the groundwater flows from the northeast towards the southwest **(**SLR, 2021b).

Hydrostratigraphic units of the CSM were developed using related strata that control the groundwater flow. There are six major geologic/hydrogeologic units generated from Leapfrog Works (Seequent Limited, 2020, version 4.0.1), consistent with the previous classifications presented in Figure D-2 (also Kenneth D. Schmidt and Associates, 2012; SLR, 2021a). These hydrostratigraphic units were exported from Leapfrog Works and imported into the Groundwater Vistas model grid.

D.3.5 EPA METHOD OF SEEPAGE RATE ESTIMATE

The groundwater inflow rate into the planned excavation was estimated using the following mathematical relationship (USEPA, 2008):

$$Q = K * (b * w) * i * factor$$

Where

Q = extraction rate (cubic feet per day)
K = hydraulic conductivity (ft/day)
b = saturated thickness (ft)
w = excavation width/length in this case (ft)
i = site-wide/regional hydraulic gradient
factor = 1.5 to 2.0, accounting for other contributions to the water in the reservoir, for example, horizontal flow from northeast, vertical flow from another water-bearing zone or ponds, etc.

SLR reviewed site-specific data such as:

- Range of hydraulic conductivities from seepage studies (Section D.2).
- Water levels (SLR, 2021b, CA-WDR's website)
- Site hydraulic gradient (SLR, 2021b, CA-WDR's website)
- Excavation design (surface area, width, depth, side slopes, etc. (SLR, 2021b, Provost & Pritchard Consulting Group via email, June 2021).

Using this information, SLR developed key inputs in Table D3-1, with detailed calculations and results presented in Table D3-3.

Table D3-1 – Key Inputs to the EPA Method of Dewatering Estimates

Excavation Design	
Excavation average depth (ft)	60
Unsaturated thickness around the planned excavation, b (ft)	20 - 25
Saturated thickness around the planned excavation, b (ft)	37 - 52
Length/Width/ of the planned excavation, b (ft)	5,709
Hydraulic properties, gravel (ft/day)	69
Hydraulic gradient (ft/ft) [Average of gradients]	0.012

Note:- The minimum and maximum of the saturated and unsaturated thicknesses are based on borings B1-B6 and all monitoring wells listed in Table D3-4, respectively.

Assumptions inherent to the method include:

- Homogenous, isotropic, confined aquifer of infinite extent;
- Uniform aquifer thickness;
- The saturated zone around the planned excavation represents the aquifer thickness;
- Uniform regional horizontal hydraulic gradient;
- Steady-state flow;
- Negligible vertical gradient;
- No net recharge or net recharge is accounted for in regional hydraulic gradient; and
- No other sources of water were introduced to the aquifer induced by excavation.

D.3.6 NUMERICAL MODEL SEEPAGE RATE ESTIMATE

The CSM is converted into a mathematical model by selecting a code, specifying boundary conditions, grids to represent the geologic formations, employing aquifer parameters, recharge, and discharge zones of the Site. Details of the model development are given below.

D.3.6.1 CODE SELECTION

The numerical model was constructed and calibrated in MODFLOW-USG, a new version of MODFLOW (McDonald and Harbaugh, 1988; Harbaugh, 2005) for unstructured grids (Panday et al., 2013). The modeling environment and pre-/post-processor is Groundwater Vistas version 8.03 (ESI, 2020).

The model cells can take on numerous shapes, such as triangles, octagons, and variable sizes, allowing refinement in areas of interest, i.e., the planned excavation. Unstructured grids do not necessarily require to be arranged on a row, and column bases and cells are linked together regardless of shape. The planned excavation was represented in the domain by “air” zones where high K values (assumed to be 5,000 ft/day) were assigned to let unrestricted water flow into it (Table D3-6). Groundwater Vistas was employed for a pre - and post-processing of input and output data, respectively. It also provides an extensive set of tools for developing, modifying, and calibrating numerical models.

D.3.6.2 MODEL DEVELOPMENT AND INPUT DATA

The three-dimensional geologic model domain was built in Leapfrog Works and exported to the Groundwater Vistas. Historical hydrogeological data were reviewed and processed to represent average conditions (Table D3-4). The model was developed to simulate the steady-state groundwater condition based on the average data of historical water levels. About fifteen monitoring wells, inside and outside the property, were used for calibration. Ten monitoring wells were used as target heads, and the remaining five wells were used to establish General Head Boundary conditions (Table D3-4).

D.3.6.3 MODEL GRID AND BOUNDARY CONDITIONS

No-flow boundaries were assigned to parts of the southern and northern edges of the domain to simulate the general northeast to southwest groundwater flow gradient. These boundaries were set at a sufficient distance from the planned excavation to allow the model to calculate the impact of dewatering the reservoir on groundwater levels surrounding it. General head conditions that allow groundwater flow into and out of the system were set on the northeast and southwest. Water level heads for the General Head Boundaries were set based on the average historical water levels collected from adjacent monitoring wells (Table D3-4). General head conductances were set high enough to permit flow into and out of the system depending on the surrounding heads. A river boundary was specified to imitate the Kaweah River to the south (Figure D3-5).

The model grid consists of 6 layers, 356 columns and 127 rows, with grid spacing ranging from 21 ft to 200 ft and 21 ft to 282 feet for columns and rows, respectively (Figure 3D-1). Finer grid spacing was applied around the planned excavation. The model domain has an active area of 77.7 million sq. ft.

D.3.6.4 AQUIFER PROPERTIES AND RECHARGE

For the steady-state model, the principal aquifer properties are hydraulic conductivities and recharge. The hydraulic conductivities of the major geologic units were determined

by geotechnical testing through grain size analyses (ASTM D422) and Section D.2. Hydraulic conductivity values set for the calibrated model are restricted to be between 95 % to 105 % of the values based on the above geotechnical testing and are presented in Table D3-6.

Recharge flux to the system was estimated from the average precipitation collected from the site vicinity, namely LEMON COVE (LMC). The annual precipitation data summarizes measurements collected from June 2019 to June 2021. The recharge flux applied to the calibrated model is roughly 10 % infiltration of the recharge estimated from LMC (Table D3-2).

Table D3-2. Calibrated Model Recharge

Precipitation Averages (Inches)	
January	2.73
February	2.52
March	2.08
April	1.45
May	0.49
June	0.15
July	0.01
August	0.03
September	0.2

November	1.4
December	2.26
Yearly Precipitation (in)	*14.03*
Recharge flux (ft/day) 20%	*0.000641*
Recharge flux (ft/day) 10%	*0.000320*
Recharge flux (ft/day) in the calibrated model	***0.000285***

D.3.7 MODEL CALIBRATION

Calibration of a numerical groundwater flow model is the process of adjusting model parameters to obtain a reasonable match between field-measured values and model predicted values of heads (groundwater levels) and fluxes (groundwater flows). There are two ways of finding model parameters to achieve calibration (Anderson and Woessner, 2002). (1) Manual trial and error adjustment of parameters and (2) automated parameter estimation. Groundwater Vistas (GV) assists model calibration in three ways (ESI, 2020):

(1) calculation of calibration statistics for a head, drawdown, or flux, (2) automated parameter sensitivity analysis, and (3) automatic model calibration using a nonlinear least-squares technique built into the GV interface or using external inverse models such as PEST (Doherty, 2010). All these methods have been applied to calibrate the steady-state model.

D.3.8 RESULTS

D.3.8.1 RESULTS OF EPA METHOD

The six boring logs and the resulting three-dimensional geologic model demonstrate that gravel and sand dominate the subsurface beneath the planned excavation. The inflow rate was estimated to be 750 (gpm). The estimate was based on calculations with limited site data, and the actual seepage rates may vary. Results are summarized below in Table D3-3.

Table D3-3. Estimation of Extraction Rates

					[1]Scenario 1 - Factor = 1.5		***[2] Scenario 2 - Factor = 2.0***	
Excavation Inflow Estimates	**K[1] (ft/day)**	**b[2] (ft)**	**W[3] (ft)**	**i[4] (ft/ft)**	**Q[5] (ft3/day)**	**Q[5] (gpm)**	**Q[6] (ft3/day)**	**Q[6] (gpm)**
Inflow Rate (Q)	6.9E+01	51.91	5,709	0.0035	108,418	564	144,383	750

Note
1 Scenario 1 represents inflows to the ponds that are coming from the north only.
2 Scenario 2 assumes a small component of inflows from the northeast.
3 The methodology and assumptions are provided in USEPA's "A Systematic Approach for Evaluation of Capture Zones at Pump and Treat Systems", EPA 600/R-08/003, January 2008.

D.3.8.2 RESULTS OF STEADY-STATE NUMERICAL MODEL

3.8.2.1 Calibration Results

The calibration process confirmed that hydraulic conductivities and recharge previously applied for SEEP/W simulation (Section D.2) are still valid. The final calibrated parameters are also within 95 % to 105 % of the previously determined or used to understand the hydrogeologic condition of the Project Site. Locations of targets are provided in Figure D-1. A summary of the calibration steady-state water level targets is provided in Table D3-4.

Table D3-4 Calibrated Water Level Comparison

No.	Target	Easting (UTM, m)	Northing (UTM, m)	Layer	Water Level, Observed (ft, amsl)	Water Level, Modelled (ft, amsl)	Remark
1	B-1	315652	4029539	2	438	441	Target well

3.8.2.2 Calibration Statistics

Table D3-5 presents a summary of the statistical measures for the steady-state calibration. A Scaled root mean square (SRMS) of less than 10% is desirable and less than 5% preferable. The model's SRMS is about 7.0% (Table D3-5).

Table D3-5 Calibration Statistics

Residual Mean (ft)	-0.47501
Absolute Residual Mean (ft)	1.769329
Residual Std. Deviation (ft)	2.098374
Sum of Squares (ft^2)	46.288088
RMS Error (ft)	2.151467
Min. Residual (ft)	-3.914231
Max. Residual (ft)	2.855395
Number of Observations	10

Scaled Residual Mean	-0.015473

Chart 3-1 Observed vs. Simulated Groundwater Levels (Steady-State)

3.8.2.3 Calibrated Hydraulic Conductivities

A summary of the final calibrated parameters used for the simulation of the above-mentioned three scenarios is provided in Table D3-6.

Table D3-6 Calibrated Conductivity and Storage Parameters

Parameter	Kx (ft/day)	Ky (ft/day)	Kz (ft/day)
Bedrock	0.3091331	0.3091331	0.00293969
Clay	0.001235	0.001235	0.0013
Silty/Sandy Clay	0.004515	0.004515	0.000371081
Silty/clayey sand	0.139555	0.139555	0.06556124
Gravel	69.3	69.3	6.6
Sand	4.75	4.75	0.5
Air	5000	5000	5000

Table D3-7 Calibrated Recharge Parameters

Parameter	Description	Rate ft/day	% Annual Rainfall
R1	Site-wide	0.000285	10.0%

D.3.8.3 WATER BALANCE

The water balance for the calibrated model is provided in Table D3-8. General Head Boundary comprises most of the total inflows and outflows.

The model is considered to have a good mass balance; flow rates entering and leaving the system are 303 gpm (58,167 ft^3/day) and 302 gpm (58,158 ft^3/day), respectively. The corresponding percent discrepancy is low, 0.02%.

Table D3-8 Summary of Water Balance (steady-state, non-project condition)

	In (ft^3/d)	Out (ft^3/d)
Constant Head	0	0
River	24,634	8,367
General Head	31,477	49,791
Recharge	2,057	0
Total	**58,167**	**58,158**
Discrepancy (In-Out)	8.8 ft3/d	0.02 %

The calibrated model's parameter distribution led to the best overall simulation of the hydrogeologic conditions predicted after the planned excavation placement under the three scenarios mentioned above (Figure 3D-3). Results of the predictive simulations are provided below.

D.3.8.4 RESULTS OF PREDICTIVE MODEL SIMULATION

The results of the predictive models for the three scenarios mentioned above are explained in detail in the following sections.

3.8.4.1 Results of the Frist Scenario- Excavation without Slurry Walls

As the excavation draws more water, the potentiometric surface around the excavation declines progressively to the bottom of the reservoir that ranges from 390 ft amsl to 424 ft amsl. When the resulting potentiometric levels are compared to the natural condition, the drawdown inside the excavation ranges from 43 ft amsl to 65 ft amsl. The shallower water level follows silty/sandy clay or bedrock within the planned reservoir, as the excavation halts at the clay or bedrock units (Figure D3-4).

Figures D3-3 through D3-5 demonstrate the natural condition, project-condition and comparison of the natural (existing) water level with the predicted water level after excavation.

The drain cells, set at 390 ft amsl within the reservoir, quantify the amount of water that needs to be dewatered. The steady-state model estimates the total inflows into the reservoir to be approximately 830 gpm (Table D3-9).

3.8.4.2 Results of the Second Scenario- Excavation with Slurry Walls

The placement of the slurry walls changes the inflow rate into the excavation significantly. When the slurry walls extend to the bottom of layer 2 (~ 378 ft amsl), the barrier diminishes the inflow into the excavation to 70 gpm a reduction of approximately 90% from the previous scenario (Figure D3-6).

To simulate the case where the slurry wall depth is less extensive, the second layer was divided into two and the slurry was set to layer one and half of layer two. It is then assumed, that the slurry wall is installed to a shallower depth, i.e., only through the upper half of layer 2. The inflow increased by two folds compared to the results of scenario two (i.e., from 70 gpm to 160 gpm).

The following figures compare the water level changes caused by excavation with the slurry walls (Figures D3-6 and D3-7).

The model results indicate limited groundwater depression compared to the natural condition. The placement of the reservoir still draws groundwater flow towards it despite the placement of slurry walls. The depression is proportional to the lower inflow rate (160 gpm) and occurs dominantly in layer two. The average depth to the water table in layer one is about 50 % of the thickness of the layer (~22 ft), and thus, a limited decline in the groundwater level. Layer two is fully saturated and experiences an increased decline in groundwater level due to a proportionally higher flow to the reservoir. Overall, the groundwater depression is significantly less when compared to scenario 1. The increased decline in Layer 2 indicates that the pre-excavation upward gradient is reduced. The excavation intercepts the groundwater flow; however, below the bottom of the reservoir, it remains significantly unchanged and is governed by a regional gradient.

3.8.4.3 Results of the Third Scenario- Excavation with Slurry Walls and Infiltration Trench

When scenario two is augmented by the infiltration trench, the estimated inflows into the planned excavation do not change significantly from the estimated rate of scenario two. A limited groundwater mounding is observed in layer one due to about 70 gpm of flux infiltrated through a trench (Figure D3-6 through D3-8). In layer two, like scenario two, depression of groundwater is observed due to the inflow to the excavation.

The results indicate that the slurry wall controls the flow around the excavation (Table D3-9) dominantly.

Table D3-9 Model Mass Balance

Condition	Flux (gpm)	Remarks
Planned Excavation in Layers 1 and 2 [No Slurry Wall]	**Scenario - 1**	Drain cells were set @ 390 ft, amsl, top elevation of L1 ~ 467 ft, amsl, bottom elevation of L2 ~ 380 ft. amsl
	830	
Planned Excavation surrounded by a Slurry wall in Layers 1 and 2 [Scenario 2 with a Slurry wall extended to layer 1 and part of layer 2]	**Scenario - 2**	Drain cells were set @ 390 ft, amsl, top elevation of L1 ~ 467 ft, amsl, bottom elevation of L2 ~ 380 ft. amsl. [Bottom elevation of sublayer 2-1 is ~ 400 ft amsl.]
	70	
	160	
Planned Excavation surrounded by a Slurry wall with Infiltration Trench on the North [Scenario 3 with a Slurry wall extended to layer 1 and part of layer 2]	**Scenario - 3**	Drain cells were set @ 390 ft, amsl, top elevation of L1 ~ 467 ft, amsl, bottom elevation of L2 ~ 380 ft. amsl [Bottom elevation of sublayer 2-1 is ~ 400 ft amsl.]
	74	
	174	

To further characterize inflow for the slurry wall scenario, a different completion depth as assumed. The slurry wall was set to layer one and half of layer two by dividing layer two into two sublayers. The results indicate this would increase the inflows slightly to 160 and 174 gpm respectively (Table D3-93, Figure D-9).

SLR notes that the results of the numerical simulations are based on simplifications of the actual field condition. The actual dewatering rates are expected to be around the approximated inflow rate but may be higher or lower by some amount.

D.3.9 SENSITIVITY ANALYSIS

Sensitivity analyses were conducted to understand how changing some conditions affects the inflow rates to the excavation. The changes made to evaluate the sensitivity of the model are the following.

1. Existing ponds to the North of the Reservoir, which vary in size in the Google Earth historical images, were set as high permeability subsurface material that intercepts groundwater. The “air” zone (5000 ft/day) was assumed up to 10 ft depth below the water level as measured by nearby monitoring wells. Its impact is evaluated by the resulting inflow rate towards the reservoir.
2. In addition, to assess the robustness of the slurry wall in minimizing inflows to the excavation, a simulation was performed assuming a worst-case failure of a segment of the wall, and inflow rates were estimated and compared with the results of scenario two.

D.3.9.1 SENSITIVITY ANALYSES

The following changes were made to analyze the sensitivity of the model to changes in the input parameters.

Existing Ponds to the north of the Reservoir. The pond’s water was treated as surface water intercepting groundwater through artificially high hydraulic conductivity (“air” zone (5000 ft/day)). The subsurface beneath the pond is assumed to be 10 ft below the local water level and is restricted to layer one (Table D3-10). The results indicate the inflows (65 gpm) would be like those with groundwater levels in the area. The slight decrease is due to the slightly differing heads assume in groundwater and the ponds respectively.

Slurry Wall failure. The failure mode analysis assumed that the slurry wall for scenario two was also assumed to fail using two different sizes. Failure of four columns in layers one and two (84 ft by the saturated thickness of layer one and 84 ft by 45 ft in layer two) resulted in an inflow increase by more than two-fold to 190 gpm (Table D3-10). The failure in the wall will occur over an area of 42 feet by 45 feet (i.e., two columns and layer one and half of layer two), the resultant inflows remain the same as scenario 2 (Table D3-10).

Table D3-10 Model Sensitivity Analyses

CONDITION	FLUX (GPM)	REMARKS
Ponds to the North of the Reservoir (Slurry walls set in Layer 1 and Layer 2)	65	The ponds intercept some groundwater flowing towards the reservoir
Slurry walls set in Layer 1 and Layer 2 assumed to fail in bigger section (26 ft by 45 ft)	Scenario - 2 (modified)	
	190	
Slurry walls set in Layer 1 and Layer 2 assumed to fail in smaller section (13 ft by 22.5 ft)	Scenario - 2 (modified)	The small crack does not change the results of Scenario 2.
	70	

3.9.1.1 Model Uncertainties

It is important to understand numerical models have their limitations and the results should be considered approximate at these stage two methods have essentially be applied, i.e. Both 2-D and 3-D analyses to increase the level of confidence in the results. For purposes of these analyses, it is anticipated that during the detailed design process, added field data will be made available and the modeling will be improved.

The calibrated steady-state flow model simulations reasonably match water levels and the groundwater inflow rate estimate through different methods is not significantly different.

Some of the limitations of the modeling work are as follows:

- Site specific lithological, well construction, water level data was limited, and additional data from other publicly available documents were also reviewed and used as presented without further validation.

- The steady-state model represents the general hydrogeologic conditions, and variation of input parameters, water levels and water budget with time is not considered in the numerical simulations.

D.3.10 CONCLUSIONS

The results of the model calibration for the steady-state model reasonably matched water levels and the groundwater flow budget measured or estimated for the site. The total inflows projected using the USEPA (USEPA, 2008) empirical method is not significantly different from the seepage rate estimated numerically. The total flow rates into the reservoir are assessed for each scenario and are reported in Table D3-8.

The results of the numerical simulations are based on simplifications of the actual field condition. The actual dewatering rates are expected to be around the approximated inflow rates but may be higher or lower by some amount.

Tulare Irrigation District
McKay Point Reservoir Project Biological Resources Evaluation,
Tulare County, California

Introduction

This report summarizes the results of year 2011 and 2013 reconnaissance-level biological resources surveys conducted within and immediately adjacent to the site of the proposed McKay Point Reservoir (i.e., project site) in Tulare County, California (Figure 1). The project site lies 2.5 miles southwest of Lake Kaweah; 1.5 miles southeast of Bravo Lake; 1.0 miles northwest of the community of Lemon Cove; and 2.5 miles southwest of the community of Woodlake.

The Tulare Irrigation District (TID), Consolidated Peoples Ditch Company (CPDC) and Visalia & Kaweah Water Company (VKWC)) are joint owners of the approximately 200 acres of land adjacent to the Kaweah and St. Johns rivers that comprise the project site. This land is commonly referred to as the McKay's Point property.

The joint owners propose to construct a new reservoir (i.e., McKay's Point Reservoir) on the north side of the divergence of the Kaweah and St. Johns rivers near McKay's Point. The McKay's Point Reservoir will serve as a surface water storage/re-regulation facility (i.e., surface water management tool). The reservoir would occupy a surface area of approximately 180 acres and would have storage capacity of approximately 4,000 acre-feet. Depths of approximately 60 feet below ground surface (bgs) are proposed. Final slopes would be 3:1, horizontal:vertical (h:v), in order to minimize any bank erosion from the wind and water.

The project site and immediately adjacent lands within 250 feet of the site were evaluated during the biological resources survey to identify evidence of special-status plants and wildlife, rare or sensitive vegetation communities, and potential jurisdictional waters or wetlands that could be affected by the proposed project.

Survey Methods

The project site and adjacent lands were surveyed by Michael Bumgardner (Bumgardner Biological Consulting) on May 16, 2011 and September 18, 2013. The surveys were conducted on foot as random meander transects such that all portions of the project site could be effectively evaluated. Gross-scale mapping of the plant communities on the project site was conducted given that only three discernible communities occur on the site. A search for special-status plant and wildlife species was conducted and focused on local taxa that have been recorded in the California Natural Diversity Data Base (CNDDB) or California Native Plant Society's (CNPS) Online Inventory of Rare and Endangered Plants. Lastly, a reconnaissance-level search for waters with regulatory jurisdiction under the Clean Water Act, California Fish and Game Code, and/or Porter-Cologne Water Quality Control Act was conducted within the site boundaries.

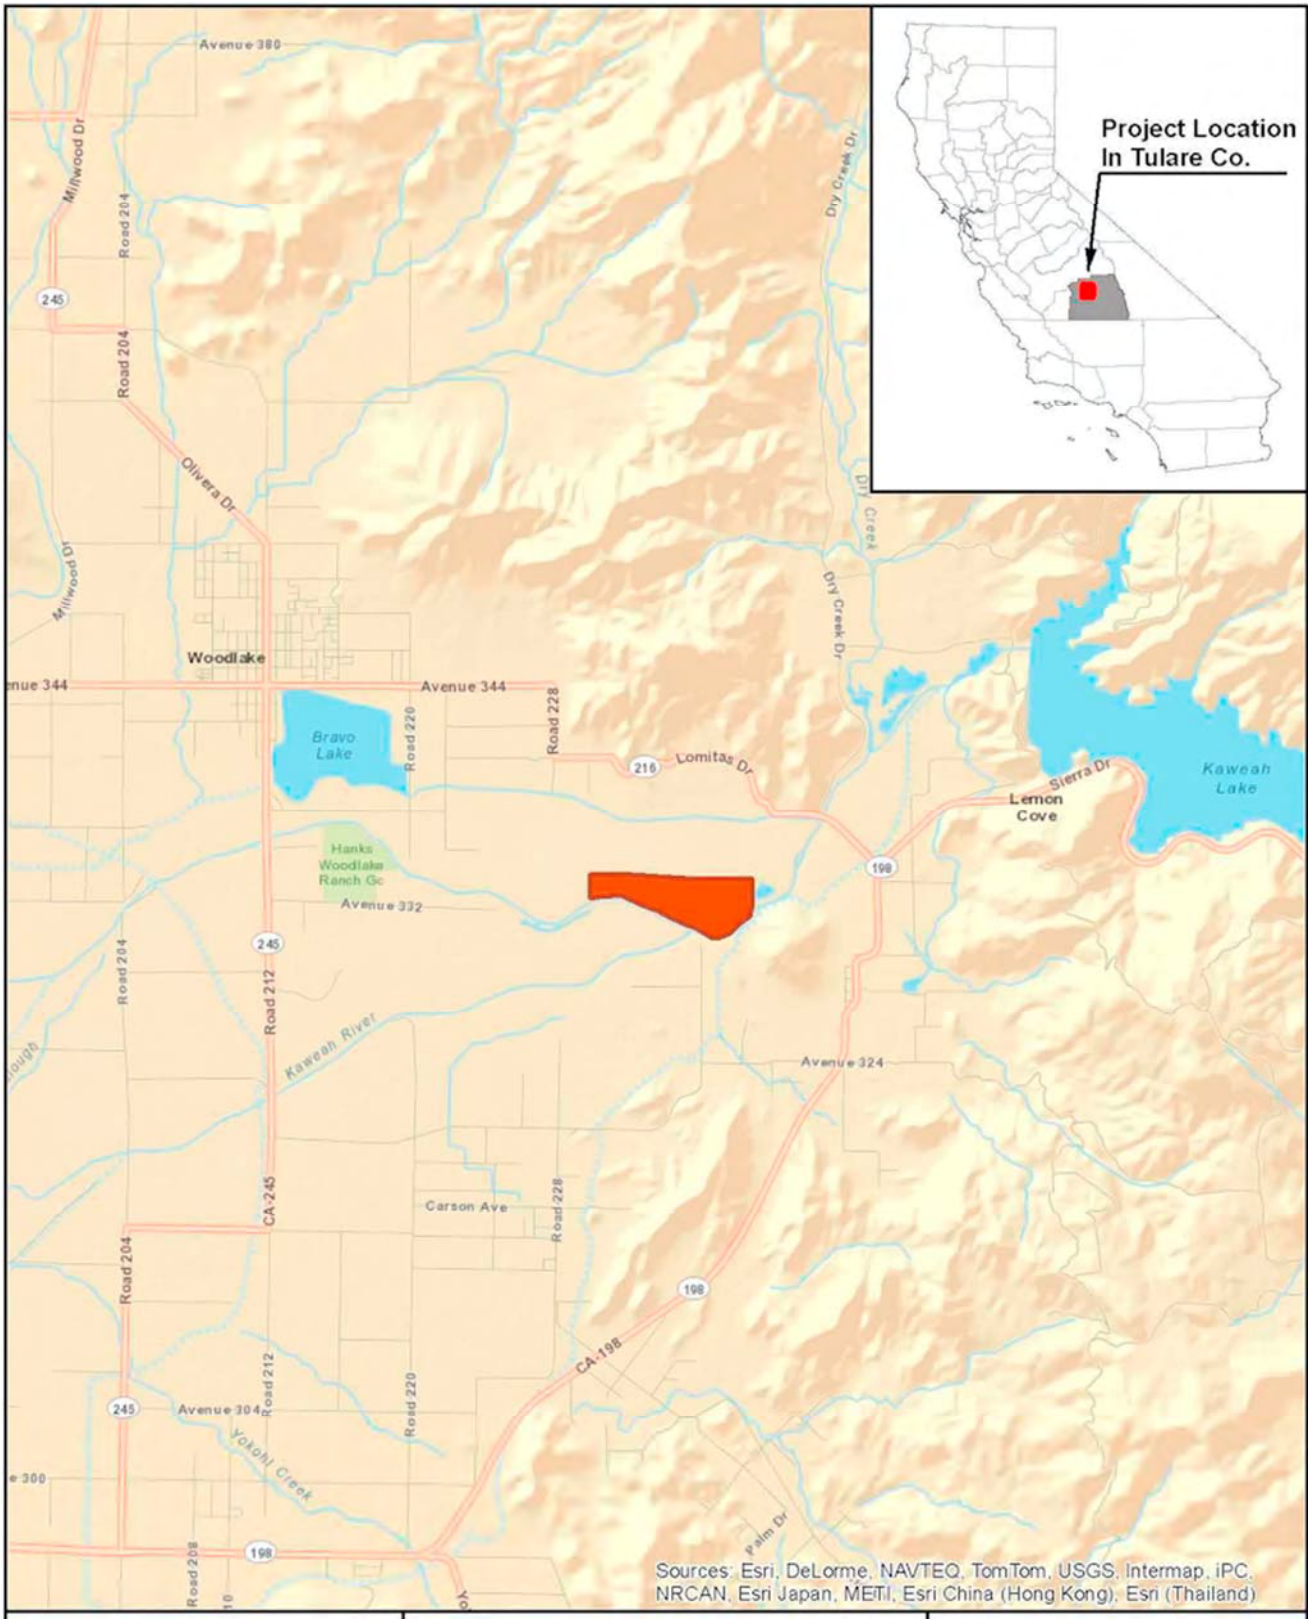

Figure 1
McKay Point Reservoir Project Site – Tulare County, California

Analytical Methods

A standard nine-quadrangle CNDDB/Rarefind 3 report was generated for the project site (i.e., query of the USGS 7.5-minute topographic quadrangle in which the project site is found as well as the immediate eight surrounding topographic quadrangles, viz. Woodlake and the surrounding Stokes Mtn., Ivanhoe, Exeter, Aukland, Rocky Hill, Shadequarter Mtn., Kaweah, and Chickencoop Canyon quads. The California Natural Diversity Data Base (CNDDB) contains records for special-status species, as well as sensitive natural communities, which have been reported to the California Department of Fish and Wildlife (CDFW). The Rarefind 3 report for the project site is provided in Appendix A. Each of the species identified in the Rarefind 3 report were then evaluated in terms of their likelihood of occurrence within and immediately adjacent to the project site. This evaluation considered the known distribution and habitat requirements of the species such that one of the following findings was prepared:

- Known to Occur – species was observed within or immediately adjacent to the project site during the May 16, 2011 survey or September 18, 2013 survey or has previously been documented within or immediately adjacent to the project site.
- High Potential – species has not been documented within or immediately adjacent to the project site, but should be expected on more than 50% of visits to suitable habitat in the project site during the appropriate season and time of day.
- Moderate Potential – species has not been documented within or immediately adjacent to the project site, but should be expected on less than 50% of visits to suitable habitat in the project site during the appropriate season and time of day.
- Low Potential – species has not been documented within or immediately adjacent to the project site nor is it likely to occur on the project site, but its presence cannot be completely discounted due to incomplete information on the taxon's distribution or habitat requirements.
- No Potential – species does not occur within the project site due to the lack of required habitat features for the species or the known range of the species is well defined and does not include the project site.

The findings for each of the species identified in the Rarefind 3 report are presented in this report.

Other sources of information on special-status species in California were subsequently reviewed given that the CNDDB is not inclusive of all special-status species that may occur in an area. A review of the CDFW's List of Special Animals (January 2011) and List of Special Plants (July 2013) was therefore conducted to determine if any special-status species not identified in the Rarefind 3 report have the potential to occur in the project site. This review was based on the professional experience of Michael Bumgardner within the region and elsewhere in California, but also included review of

other published sources of information on special-status species in California. These latter sources include the following:

- California Native Plant Society Inventory of Rare and Endangered Plants (online edition) (CNPS 2013).
- The Jepson Manual: Vascular Plants of California, 2nd edition (Baldwin and Goldman 2012).
- Amphibian and Reptile Species of Special Concern in California (Jennings and Hayes 1994).
- The Distribution of the Birds of California (Grinnell and Miller 1944).
- California Birds: Their Status and Distribution (Small 1994).
- California's Wildlife Volume II Birds (Zeiner et al. 1990).
- eBird Data Base (http://ebird.org/ebird/eBirdReports?cmd=Start) (2013).
- Mammalian Species of Special Concern in California (Williams 1986).
- Mammals of the Pacific States: California, Oregon, and Washington (Ingles 1978).
- Bat species accounts prepared as course materials for *Ecology and Conservation of California Bats* offered through San Francisco State University's Sierra Nevada Field Campus.
- Western Bat Working Group website (http://www.wbwg.org/species_accounts).

Species that are known or expected to occur in the vicinity of the project site were then further evaluated in this report.

Vegetation Communities and Site Characteristics

The project site is located immediately north of the divergence of the Kaweah and St. Johns rivers. The site is flat and has been used most recently to support cattle grazing. There are no developed uses on the site. Much of the onsite vegetation consists of non-native annual grassland (Figure 2). As such, most of the vegetation consists of non-native annual grasses [e.g., wild oat (*Avena fatua*)], but also includes herbaceous species such as lamb's-quarters (*Chenopodium album*), wild cucumber (*Marah* sp.), and deer weed (*Acmispon glaber*). Small, scattered stands of mule fat (*Baccharis salicifolia*) also occur within the non-native annual grassland. However, these latter stands are not significant enough in size to warrant mapping as a discernible vegetation community.

Mixed oak-riparian woodland occurs in the southeastern portion of the project site (Figure 2). Woody species that are associated with this stand of vegetation include willows (*Salix* spp.), Fremont's cottonwood (*Populus fremontii*), western sycamore (*Platanus racemosa*), tamarisk (*Tamarix* sp.), tree tobacco (*Nicotiana glauca*), blue elderberry (*Sambucus mexicana*), and interior live oak (*Quercus wislizeni*). California wild grape (*Vitis californica*) occurs as a liana growing into the canopy of the woody species. The canopy cover in this stand of vegetation varies between approximately 20 and 100 percent and is best described as interrupted woodland.

Figure 2
McKay Point Reservoir Project Site – Vegetation Communities

Approximately 39.8 acres of elderberry savannah-riparian woodland (a sensitive vegetation community tracked by the CDFW) occurs adjacent to the mixed oak-riparian woodland, but also extends west along the southern border of the project site (Figure 2). It should be noted that the depicted boundaries in Figure 2 are an approximation of the borders of this vegetation community and the mixed oak-riparian woodland as the two communities have no clearly discernible boundary where they occur adjacent to and grade into each other. The dominant species in the elderberry savannah-riparian woodland is blue elderberry. However, scattered Fremont's cottonwoods and willows also occur in this vegetation community. The onsite elderberry shrubs/clumps are large and old with many stems and likely represent the remnants of a formerly more contiguous community.

Jurisdictional Wetlands and Other Waters

Jurisdictional wetlands or other waters of the United States are areas that cannot be dredged or filled without a permit from the U.S. Environmental Protection Agency or U.S. Army Corps of Engineers (this latter permit is commonly referred to as a "Section 404" permit in reference to the section of the federal Clean Water Act that requires such permits). Actions that require issuance of a "Section 404" permit include earth-moving activities that result in fill of jurisdictional wetlands and other waters. It should be noted that such actions may also require the issuance of state permits (e.g., California Fish and Game Code Section 1603 streambed alteration agreement and/or Regional Water Quality Control Board Section (RWQCB) Section 401 clean water certification).

Wetlands or other waters of the United States are identified based on three criteria, viz. (1) soil characteristics, (2) hydrology, and (3) plant species. The U.S. Army Corps of Engineers (USACE) has developed a procedure and manual for delineating wetlands that requires comprehensive evaluation of these three criteria during field environmental assessments. A formal wetland delineation was not conducted for the purposes of this report. However, no waters that are subject to the jurisdiction of the USACE, CDFW, or RWQCB, other than the Kaweah and St. Johns rivers, occur on or immediately adjacent to the project site. The latter two rivers are jurisdictional waters and the placement of fill associated with the intake/outlet infrastructure of the McKay's Point Reservoir will be subject to the jurisdiction of the USACE, CDFW, and RWQCB.

Habitat Conservation Plans and Other Similar Habitat Management Plans

There are no Habitat Conservation Plans (HCPs), Natural Community Conservation Plans (NCCPs), or other approved local, regional, or state habitat conservation plans that apply to the project site.

Wildlife Diversity

The surveys within and adjacent to the project site resulted in the documentation of relatively low wildlife diversity (i.e., two species of amphibians, one species of reptile, 14 species of birds, and five species of mammals). However, it should be noted that no

comprehensive wildlife surveys were conducted for the project. The only amphibians that were found in and adjacent to the project site included Pacific treefrog (*Hyla regilla*) and bullfrog (*Rana catesbeiana = Lithobates catesbeianus*). Both of these species are relatively widespread in lower elevation drainages, ponds, and other waters in California. The only reptile species recorded within and adjacent to the project site was western fence lizard (*Sceloporus occidentalis*). This species is relatively widespread within the non-desert, lowland portions of California. The bird species recorded within and adjacent to the project site included phainopepla (*Phainopepla nitens*), northern mockingbird (*Mimus polyglottos*), Nuttall's woodpecker (*Picoides nuttallii*), American robin (*Turdus migratorius*), willow flycatcher (*Empidonax traillii*), Pacific-slope flycatcher (*E. difficilis*), house finch (*Haemorhous mexicanus*), western scrub-jay (*Aphelocoma californica*), Anna's hummingbird (*Calypte anna*), northern flicker (*Colaptes auratus*), turkey vulture (*Cathartes aura*), killdeer (*Charadrius vociferus*), black phoebe (*Sayornis nigricans*), and California quail (*Callipepla californica*). Most of these species are common and widespread year-round or winter residents within oak and riparian woodlands within the region. However, the willow flycatcher and Pacific-slope flycatcher are only migrants through the area and do not occur as a nesting or wintering species at the project site. Lastly, mammal species documented on and near the project site included California ground squirrel (*Otospermophilus beecheyi*) Botta's pocket gopher (*Thomomys bottae*) (mounds only), (burrows only), coyote (*Canis latrans*), mule deer (*Odocoileus hemionus*), and raccoon (*Procyon lotor*) (tracks only).

It should be noted that other wildlife species probably occur on or near the project site, but would not likely be found in one-day reconnaissance-level surveys. These other species include, but are not limited to, southern alligator lizard (*Elgaria multicarinata*), western skink (*Plestiodon skiltonianus*), common kingsnake (*Lampropeltis getula*), Pacific gopher snake (*Pituophis catenifer*), western rattlesnake (*Crotalus viridis*), several species of small mammals, several species of oak or riparian-associated passerines (i.e., songbirds), red-tailed hawk (*Buteo jamaicensis*), American kestrel (*Falco sparverius*), and great horned owl (*Bubo virginianus*).

Special-Status Plant Species

No special-status plant taxa were observed on or immediately adjacent to the project site during the surveys. In addition, no special-status plant taxa that have been documented in the project region (Table 1) are considered to have any potential to occur on the project site given the onsite conditions (i.e., lack of suitable habitat for and/or known distribution of the species).

Special-Status Wildlife Species

Only two special-status wildlife species were observed on the project site during the surveys. One of these species (i.e., Nuttall's woodpecker) is a likely year-round resident in the mixed oak-riparian woodland in the southeastern portion of the project site. The second species (i.e., willow flycatcher) was only observed during the September 18, 2013 survey and is considered a migrant that passes through the area (including the project

site). Furthermore, this latter species is only considered a special-status species when nesting (typically in dense willow scrub in the Sierra Nevada).

Sixteen special-status wildlife species that have been documented in the project region (Table 1) are considered to have some potential to occur on or near the project site. Three of these species are insects (i.e., moestan blister beetle, Morrison's blister beetle, and Tulare cuckoo wasp) that are not well known in terms of their life history and behavior, but that have been recorded in the project vicinity in habitats similar to those that occur on the project site. As such, they cannot be discounted and are considered to have some potential, albeit low, to occur on the project site. There is also suitable habitat on the project site for a fourth special-status insect species [i.e., valley elderberry longhorn beetle (VELB)]. However, the nearest known occurrences of the beetle, which occurs in and on elderberry, are more than 4.5 miles southwest and 8.5 miles northeast of the project site. Furthermore, the beetle is known to have poor dispersal abilities and does not occur in large sections of elderberry savannah or riparian habitat that is otherwise suitable for the species other than it is isolated by reaches of unsuitable habitat (i.e., gaps in the suitable habitat as small as 300 linear feet). Though no exit holes attributable to VELB were found during the reconnaissance-level surveys of the project site, it should be noted that focused surveys for VELB exit holes would need to be conducted to support a finding of absence. Consequently, the taxon is considered to have some potential, albeit low, to occur on the project site.

Only one special-status reptile is believed to have any potential to occur on the project site. This latter species [i.e., western pond turtle (*Emys marmorata*)] is known from occurrences upstream in the Kaweah River drainage. In addition, it has been known to occur in a wide variety of slow-moving waters throughout California. Thus, it is considered to have some potential, albeit low, to occur in the aquatic habitats of the adjacent Kaweah and St. Johns rivers and to nest in the upland portions of the project site.

Ten special-status birds are considered to have some potential to occur on the project site. Seven of these latter species [Cooper's hawk (*Accipiter cooperii*), white-tailed kite (*Elanus leucurus*), loggerhead shrike (*Lanius ludovicianus*), oak titmouse (*Baeolophus inornatus*), yellow-breasted chat (*Icteria virens*), lark sparrow (*Chondestes grammacus*), and Lawrence's goldfinch (*Spinus lawrencei*)] are known to nest in oak or riparian woodlands. Furthermore, each of these species has been recorded nesting within less than two miles of the project site. As such, each of these species, with the exception of oak titmouse is considered to have some potential, albeit low, to nest in the onsite mixed oak-riparian woodland. Given the presence of Nuttall's woodpecker in the mixed oak-riparian woodland, oak titmouse is considered to have a moderate potential to nest onsite since the species is a secondary cavity nester (i.e., nests in cavities/holes created by woodpeckers).

Other special-status bird species with some potential to occur on the project site include ferruginous hawk (*Buteo regalis*), merlin (*Falco columbarius*), and burrowing owl (*Athene cunicularia*). No evidence of burrowing owl was found on the project. In addition, no suitable burrows or burrow surrogates that could be used by the species were

found on the project site. However, California ground squirrel burrows were observed immediately offsite on the northern and eastern boundaries of the project site. As such, there is the potential for indirect impacts to the species at these off-site locations should they be occupied by the species. Ferruginous hawk and merlin do not occur in the project region as nesting species. However, they do occur in the area as wintering species and are considered special-status species when wintering. Given the presence of suitable habitat onsite (i.e., large tract of non-native grassland) and known winter occurrences within less than two miles, these two species are considered to have some potential, albeit low, to occur on the project site.

Only one special-status mammal is believed to have any potential to occur on the project site. Western red bat (*Lasiurus blossevillii*) is known to utilize large trees in riparian forest or orchards as roost sites. Therefore, the species is considered to have some potential, albeit low, to occur in the mixed oak-riparian woodland located on the project site.

Conclusions

Sensitive or special-status biological resources that could be adversely affected by the proposed McKay's Point Reservoir Project are limited to the following:

- elderberry savannah-riparian woodland (a sensitive vegetation community);
- Kaweah and St. Johns rivers (jurisdictional waters of the state and United States); and
- special-status wildlife species (up to 16 species).

Elderberry savannah is a sensitive vegetation community that is tracked by the CDFW. It is poorly represented in the CNDDB, but is known to occur throughout the Central Valley in small stands. Approximately 39.8 acres of this vegetation community would be adversely affected by the project.

Fill within the Kaweah and St. Johns rivers would occur with construction of each river's inflow and outflow channels and associated rip-rap or concrete aprons. This fill would require permitting from the USACE, CDFW, and RWQCB.

Adverse effects to up to 16 special-status wildlife species could occur with construction and operation of the project. Approximately half of these species are birds that may nest in the mixed oak-riparian woodland in the southeastern portion of the project site. The project would not result in direct effects to these species (i.e., loss of habitat), but could result in indirect effects (e.g., significant disturbance during nesting from nearby construction activities). The project could result in direct effects to burrowing owl even with no suitable roost sites on the project site since the loss of suitable foraging habitat could adversely affect individuals occupying adjacent lands. The project could also result in indirect effects to burrowing owls occupying adjacent offsite lands due to disturbance from nearby construction activities. The loss of foraging habitat for wintering merlin and ferruginous hawk would contribute to the cumulative loss of

suitable winter foraging habitat for these species. The remaining special-status species addressed by this report (i.e., insects and western pond turtle) could each experience adverse direct effects from loss of habitat. Furthermore, potential direct effects to western pond turtle could include loss of individuals (adults and eggs) during construction-related activities.

No other important, significant, sensitive, or regulated biological resources (including aquatic habitats, roost sites, staging areas, etc.) were found to be associated with the project site.

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
		PLANTS		
Atriplex cordulata var. *erecticaulis*	Earlimart orache	none/none/CNPS list 1B.2	This annual saltbush occurs on saline or alkaline soils in valley and foothill grassland. It is known from Kings, Kern, and Tulare counties. It blooms from August to November.	**No Potential.** No individuals of this taxon were observed within or near the project site. In addition, the taxon only occurs on saline or alkaline soils in valley and foothill grassland – conditions that do not exist within the project site. Therefore, the taxon has no potential to occur within the project site.
Atriplex minuscula	lesser saltscale	none/none/CNPS list 1B.1	This annual saltbush grows in sandy alkaline areas in chenopod scrub, playas, and valley and foothill grassland. It is known from Alameda, Butte, Fresno, Kern, Madera, Merced, Stanislaus, and Tulare counties. It blooms from May to October.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs on sandy alkaline soils in chenopod scrub, playas, and valley and foothill grassland – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
Atriplex persistens	vernal pool smallscale	none/none/CNPS list 1B.2	This annual saltbush occurs in claypan and alkaline vernal pools and alkaline grasslands. It has been recorded from	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only

Therefore, the species has no potential to occur within the project site.
Brodiaea insignis	Kaweah brodiaea	none/SE/CNPS list 1B.2	This perennial bulbiferous herb occurs on granitic or clay soils in cismontane woodland, meadows and seeps, and valley and foothill grassland. It is known only from the Tule and Kaweah river drainages in Tulare County. It blooms from April to June.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs on granitic or clay soils in cismontane woodland, meadows and seeps, and valley and foothill grassland – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
Chamaesyce hooveri	Hoover's spurge	FE/none/CNPS list 1B.2	This species occurs in vernal pools in valley and foothill grassland (mostly in the northern Sacramento Valley), but has been found in Butte, Glenn, Colusa, Merced, Stanislaus, Tehama, and Tulare counties. It blooms from July to October.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs vernal pools in valley and foothill grassland – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Leptosiphon serrulatus	Madera leptosiphon	none/none/CNPS list 1B.2	This annual herb occurs in cismontane woodland and lower montane coniferous forest. It is known from Fresno, Kern, Madera, Mariposa, and Tulare counties. It blooms from April to May.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs in cismontane woodland and lower montane coniferous forest – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
Mimulus norrisii	Kaweah monkeyflower	none/none/CNPS list 1B.3	This annual herb occurs on carbonate or rocky soils in chaparral and cismontane woodland. It has been found in Fresno and Tulare counties. It blooms from March to May.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs in cismontane woodland and chaparral – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
Mimulus pictus	calico monkeyflower	none/none/CNPS list 1B.2	This annual herb occurs on granitic soils (often in disturbed areas) in broadleafed upland forest and cismontane woodland. It has been found in Kern and Tulare counties. It blooms from March to May.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs in broadleafed upland forest – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Orcuttia inaequalis	San Joaquin Valley orcutt grass	FT/SE/CNPS list 1B.1	This grass occurs in vernal pools (typically larger or more persistent pools) within valley and foothill grassland. The remaining populations of this species occur mostly in the southeastern San Joaquin Valley (Fresno, Merced, Madera, and Tulare counties). Historically, the species also occurred in Stanislaus County. It blooms from April to September.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs in vernal pools in valley and foothill grassland – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
Pseudobahia bahiifolia	Hartweg's golden sunburst	FE/SE/CNPS list 1B.1	This species occurs in cismontane woodland and valley and foothill grassland (almost always on shallow, well-drained, fine-textured soils - typically on clay, acidic soils) on the north or northeast facing side of Mima mounds). It has been recorded in Fresno, Madera, Merced, Stanislaus, Tuolumne, and Yuba counties. Blooming occurs from March to April.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs in cismontane woodland and valley and foothill grassland on the north or northeast facing side of Mima mounds – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
Tuctoria greenei	Greene's tuctoria	FE/SR/CNPS list 1B.1	This grass occurs in the dry bottoms of vernal pools in valley and foothill grassland. It is currently known to occur in Butte, Colusa, Glenn, Merced,	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs in vernal pools in valley and foothill

It blooms from May to September.	grassland – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
INVERTEBRATES				
Branchinecta lynchi	Vernal pool fairy shrimp	FT/none/none	This species occurs primarily in vernal pools (sandstone depression, grass swale, earth slump, or basalt-flow depression pools) in grassland and oak savannah of the Central Valley. However, the species also occurs at a small number of locations in the central Coast Ranges from Monterey County to Santa Barbara County as well as Riverside County.	**No Potential.** There is no suitable vernal habitat within or adjacent (i.e., within 250 feet) to the project site for this species. Therefore, there is no potential for the species to be affected by the project.
Lepidurus packardi	Vernal pool tadpole shrimp	FE/none/none	This species inhabits clear to turbid vernal pools and swales in the Sacramento Valley and northern San Joaquin Valley.	**No Potential.** There is no suitable vernal habitat within or adjacent (i.e., within 250 feet) to the project site for this species. Therefore, there is no potential for the species to occur on the project site or be affected by the project.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Talanites moodyae	Moody's gnaphosid spider	none/SA/none	Little is known and published about this species. However, it has been found in grasslands under rocks (generally serpentine) on rocky mounts, buttes, and hilltops. Only six known occurrences are reported – all from Fresno and Tulare counties.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs on rocky mounts, buttes, or hilltops (usually under serpentine rocks) – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
Lytta moesta	moestan blister beetle	none/SA/none	The range of this species is not well known, but occurrences have been documented in Fresno, Kern, Madera, Santa Cruz, Stanislaus, and Tulare counties. The CDFW reports that very little is known about the life history and behavior of this species. However, it has been collected from March to September and has typically been found in association with its host species (i.e., the species' larvae feed on the pollen stores that ground-nesting solitary bees have provided for their own larvae).	**Low Potential.** Given that ground-nesting solitary bees (i.e., beetle's host species) are widely distributed in California and little is known about this species' life history and behavior, it cannot be discounted as occurring on the project site. Therefore, it is considered to have some potential, albeit low, to occur on the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Lytta morrisoni	Morrison's blister beetle	none/SA/none	The range of this species is not well known, but occurrences have been documented in the southern San Joaquin Valley in Kern, Fresno, Tulare, San Benito, and San Luis Obispo counties. The CDFW reports that life history and behavior information for the species does not exist. However, it has typically been found in association with its host species (i.e., the species' larvae feed on the pollen stores that ground-nesting solitary bees have provided for their own larvae).	**Low Potential.** Given that ground-nesting solitary bees (i.e., beetle's host species) are widely distributed in California and little is known about this species' life history and behavior, it cannot be discounted as occurring on the project site. Therefore, it is considered to have some potential, albeit low, to occur on the project site.
Desmocerus californicus dimorphus	valley elderberry longhorn beetle	FT/none/none	This subspecies occurs at scattered locations in the Central Valley and adjacent foothills of the Sierra Nevada and Coast Ranges. It is entirely dependent upon its host plant (i.e., elderberry spp.) and is only found where this shrub occurs (typically in riparian vegetation associations, but occasionally in single, isolated shrubs or stands of the plant).	**Low Potential.** A large number of old-growth elderryberry shrubs occur within the project site. Though no evidence of valley elderberry longhorn beetle exit holes was found during a reconnaissance-level survey of the project site, the subspecies cannot be discounted as occurring on the project site without more thorough surveys. Therefore, it is considered to have some potential, albeit low, to occur on the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Chrysis tularensis	Tulare cuckoo wasp	none/SA/none	This species is known only from a small series of specimens that have been collected in Amador, Fresno, Monterey, and Tulare counties. Cuckoo wasps are nest parasitoids of predatory wasps and sawflies. However, the host species of this species are unknown. Adults have been found from April to June in open, sunny habitats with abundant flowers and small shrubs, where they feed on nectar.	**Low Potential.** Given that predatory wasps and sawflies (i.e., wasp's host species) are widely distributed in California and little is known about this species' life history and behavior, it cannot be discounted as occurring on the project site. Furthermore, the nearest known record to the project site is from immediately north of the intersection of Road 212 and Avenue 344 (less than three miles from the project site). Therefore, it is considered to have some potential, albeit low, to occur on the project site.
AMPHIBIANS				
Ambystoma californiense	California tiger salamander	FT/ST/none	This species is found in annual grassland, oak savannah, and coastal sage scrub adjacent to vernal pools, stock ponds, and ponded reaches of ephemeral streams (aquatic breeding sites). The species is patchily distributed in the Central Valley from Yolo County to Kings County, but also occurs in Alameda and Contra Costa counties south through the interior	**No Potential.** No suitable aquatic breeding habitat for the species occurs within or immediately adjacent to the project site. Furthermore, the nearest known occurrences of the species (at and near the Stone Corral Ecological Reserve east of Yettem) are more than 11 miles west of the project site. Lastly, the onsite soils are very sandy and appear to preclude the creation of burrows by all species other than valley

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
			valleys of the Coast Ranges. Disjunct populations occur in Santa Barbara County and Sonoma County.	pocket gopher. Therefore, there are only marginal underground refugia for the species onsite and it is considered to have no potential to occur on the project site.
Batrachoseps regius	Kings River slender salamander	none/SA/none	This species has been found in Fresno County on the south and east sides of the North Fork of the Kings River and at Summit Meadow in the drainage of the South Fork of the Kings River. It has also been found in the drainage of the middle fork of the Kaweah River in Tulare County. It occurs in talus, under rocks and downed logs, and in leaf litter in chaparral, cismontane woodland, and montane coniferous forest above 1,100 and 8,100 feet in elevation.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species has only been recorded in talus, under rocks, under downed logs, and in leaf litter in chaparral, cismontane woodland, and montane coniferous forest between 1,100 and 8,100 feet – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
Rana boylii	foothill yellow-legged frog	none/CSC/none	This species was historically distributed throughout the foothill portions of the Sierra Nevada and Coast Ranges drainages from the Oregon border to the San Gabriel River (Los Angeles County). The species requires shallow, small to moderate streams (typically perennial waters	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species requires shallow, small to moderate streams (typically perennial waters with some cobble-sized substrate and riffle habitat above 600 feet in elevation and without bullfrogs – conditions that do not exist

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
			with some cobble-sized substrate and riffle habitat above 600 feet in elevation and without bullfrogs).	within the project site. Therefore, the species has no potential to occur within the project site.
Lithobates pipiens	northern leopard frog (native populations only)	none/CSC/none	Historical populations of this species in California existed in scattered locations below 6,500 feet in Siskiyou and Modoc counties and in the northern Owens Valley. Individuals of unknown origin were introduced into El Dorado, Kern, Los Angeles, Merced, San Francisco, Sierra, Tehama, and Tulare counties between 1905 and 1970. Several of these introduced populations experienced rapid growth and range expansions before completely disappearing. Except for a small population that is currently present in Merced County, all of these introduced populations have perished. It has been found in grassland, wet meadows, potholes, forests, woodland, brushlands, springs, canals, bogs, marshes, reservoirs (generally where there is permanent water with abundant aquatic vegetation).	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the population recorded near Orosi in Tulare County is considered to be an introduced population and is therefore not a special-status species. Therefore, native populations of this species have no potential to occur within the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Spea hammondii	Western spadefoot	none/CSC/none	This species is found in dry habitats (e.g., annual grassland, oak savannah and woodland, and coastal sage scrub) adjacent to vernal pools, stock ponds, and overflow channels of low-gradient drainages within the Central Valley and coastal California from Monterey County to San Diego County.	**No Potential.** No suitable aquatic breeding habitat for the species occurs within or immediately adjacent to the project site. Furthermore, the project site is relatively landlocked by semi-perennial rivers, sand and gravel mining operations, and agricultural uses that would preclude movement of the species onto the site from more suitable habitats located near the site (e.g., lands north of Highway 216). Consequently, the species is considered to have no potential to occur within the project site.
REPTILES				
Emys marmorata	Western pond turtle	none/CSC/none	This species historically occurred throughout most of the Pacific-slope drainages in California (below approximately 4,000 feet). The species now occurs at scattered locations throughout its former range (primarily in the central Sierra Nevada foothills, Central Valley, San Francisco Bay area, and north-central coast and Coast Ranges. It occurs in and adjacent to	**Low Potential.** Given that potentially suitable habitat is provided by the adjacent Kaweah and St. Johns rivers and the species has been recorded upstream in the Kaweah River, it cannot be discounted as occurring on the project site. Suitable aquatic habitat within the project site only occurs in the Kaweah and St. Johns rivers. However, individuals could also enter the upland portion of the site for egg-laying.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
			ponds, reservoirs, or other slow-moving perennial aquatic habitats (e.g., sloughs, streams, and rivers). The species may be active year-round in some parts of its range.	Therefore, it is considered to have some potential, albeit low, to occur on the project site.
BIRDS				
Ardea herodias	great blue heron (nesting colony)	none/SA/none	This species is fairly common throughout most of California where there are shallow estuaries, or freshwater or saltwater emergent wetlands. However, it is less common along riverine and rocky coastal shores and above the foothills in the mountains. Rookeries (i.e., nesting colonies) are typically active from February to late July and occur in the tops of secluded large snags or live trees. Rookeries are sometime shared with the great egret or other large wading birds.	**No Potential.** No nesting colonies of this species were observed within or near the project site. In addition, the nearest reported nesting colony is on Dry Creek, one mile north of the confluence of Dry Creek and the Kaweah River (more than two miles from the project site). Therefore, no nesting colonies of this species occur within or immediately adjacent to the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Gymnogyps californianus	California condor	FE/SE/none	This species occurs as a reintroduced species primarily in the mountains of Ventura, Santa Barbara, Los Angeles, Monterey, and San Benito counties. However, individuals are known to be wide-ranging and occasionally occur soaring over the Tehachapi Mountains and southern Sierra Nevada. The species is strictly a scavenger and may travel up to 35 miles or more from roost sites in search of carrion. Most foraging occurs in open habitats that facilitate landings and takeoffs. Traditional roost sites are on cliffs or ledges, but snags and trees in old growth coniferous forest may also be used.	**No Potential.** No suitable roost sites for this species occur within or near the project site. In addition, other potential attractors to the project site (e.g., large mammals and potential food sources) are not provided at or near the site. Lastly, the nearest known use areas for this species are located in more rugged country more than 13 miles southeast of the project site. Therefore, the species is considered to have no potential to occur within the project site.
Accipiter cooperii	Cooper's hawk (nesting)	none/SA/none	This species occurs as an uncommon breeding resident throughout most of the low to mid-elevation wooded portions of California where it inhabits open, interrupted, or marginal woodlands. It is seldom found in areas without dense tree stands. Nest sites are typically found in riparian or	**Low Potential.** There is suitable nesting habitat for the species (i.e., interrupted riparian woodland with dense stands of trees) located in the southeastern portion of the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than two miles from the project site along Dry Creek Drive

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
			deciduous trees in canyon bottoms or river flood plains.	upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to nest on the project site.
Buteo regalis	Ferruginous hawk (wintering)	none/none/BCC	This species is a winter resident of the Modoc Plateau, Central Valley, and Coast Ranges. It forages in large, open tracts of grasslands, sparse scrubland, and deserts.	**Low Potential.** There is suitable wintering habitat for the species (i.e., open grassland) on the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than 1.5 miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to winter on or immediately adjacent to the project site.
Elanus leucurus	white-tailed kite (nesting)	none/CFP/none	This species is found as a resident throughout the lower elevation portions of California in low rolling grasslands with scattered oaks and river bottomlands or marshes adjacent to deciduous woodland. It requires grasslands, meadows, or marshes (for foraging) located near dense-topped trees (for nesting and roosting).	**Low Potential.** There is suitable nesting habitat for the species (i.e., mixed oak and riparian woodland) located in the southeastern portion of the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than 1.5 miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to nest on the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Falco columbarius	Merlin (wintering)	none/SA/none	This species winters in California from September to May. It occurs in a variety of low elevation, relative flat habitats that include wooded areas, coastlines, open grasslands, savannah, and the periphery of lakes. It is less often found in open desert. It typically requires dense stands of trees for cover and roosting. It is most often found where there are substantial populations of small birds (the primary prey item).	**Low Potential.** There is suitable wintering habitat for the species (i.e., open grassland) on the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than 1.5 miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to winter on or immediately adjacent to the project site.
Athene cunicularia	Burrowing owl (burrow sites)	none/CSC/BCC	This species is found throughout the Central Valley, in the San Francisco Bay Area, at scattered locations along the coast, and in portions of the desert regions. It is a year-round resident in annual and perennial grasslands or other vegetation communities that support sparse or non-existent tree or shrub canopies.	**Low Potential.** Though the annual grassland on the project site provides suitable foraging habitat for the species, there is no evidence of suitable burrow sites on the project site (i.e., no California ground squirrels or their burrows, or other suitable burrow surrogates were observed on the project site). However, a small number of California ground squirrel burrows were observed in the spoils materials from the adjacent sand and gravel mining operations. Therefore, there is some potential for offsite individuals to be affected by activities on the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Picoides nuttallii	Nuttall's woodpecker (nesting)	none/none/BCC	This species occurs as a resident of low-elevation riparian deciduous and oak habitats (cismontane woodland) throughout much of California with the exception of the deserts, high Sierra Nevada, and redwood belt.	**Known to Occur.** There is suitable cismontane woodland for the species (i.e., mixed oak and riparian woodland) in the southeastern portion of the project site. Furthermore, the species was heard and observed in the adjacent woodland during reconnaissance-level surveys of the project site. Therefore, the species is known to occur on the project site.
Empidonax traillii	willow flycatcher (nesting)	none/SE/BCC	This species is a rare to locally uncommon, summer resident in wet meadow and montane riparian habitats at 2000 to 8000 feet in elevation in the Sierra Nevada and Cascade Range. It also occurs at scattered locations (at lower elevations) in southern California (including along the Kern, Santa Margarita, San Luis Rey, and Santa Ynez rivers). It most often occurs in broad, open river valleys or extensive mountain meadows with dense shrubby willows. Nesting occurs between mid-May and late August in northern California.	**No Potential.** Though a migrant individual was observed in the mixed oak and riparian woodland on the project site during reconnaissance-level surveys of the site, there is no suitable riparian habitat within or adjacent to the project site that could be used as nesting habitat by this species. Furthermore, there are no records in the CNDDB below 2,000 feet in elevation anywhere in the Sierra Nevada (mostly due to nest parasitism by brown-headed cowbird). Therefore, the species has no potential to occur within the project site or otherwise be affected during nesting by the project.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Lanius ludovicianus	loggerhead shrike (nesting)	none/CSC/BCC	This species is found as a resident and wintering species throughout the lower elevation portions of California in grasslands, saltbush scrub, chaparral, oak savannah, and other open woodland types (generally where there are trees with dense cover for nesting).	**Low Potential.** There is suitable nesting habitat for the species (i.e., mixed oak and riparian woodland with dense stands of trees) located in the southeastern portion of the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than two miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to nest on the project site.
Baeolophus inornatus	Oak titmouse (nesting)	none/none/BCC	This species occurs as a common resident throughout much of California other than the deserts, high Sierra Nevada, and redwood belt. It is generally found in cismontane woodland (particularly oak or riparian woodlands) where it nests in the cavities created by woodpeckers.	**Moderate Potential.** There is suitable cismontane woodland for the species (i.e., mixed oak and riparian woodland) in the southeastern portion of the project site. Furthermore, there are potential nest sites (i.e., woodpecker-created nest holes) in this woodland. Lastly, there are records from the project vicinity in the eBird data base (i.e., less than two miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have a moderate potential to occur on the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Icteria virens	yellow-breasted chat (nesting)	none/CSC/none	This species is found as a summer resident mostly in low to mid-elevation coastal, valley, foothill, and desert riparian habitats (up to 4,800 feet in foothill riparian and 6,500 feet east of the Sierra Nevada). Nesting typically occurs in dense vegetation near streams.	**Low Potential.** There is suitable nesting habitat for the species (i.e., interrupted riparian woodland with dense stands of trees) located in the southeastern portion of the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than two miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to nest on the project site.
Chondestes grammacus	lark sparrow (nesting)	none/SA/none	This species occurs as a resident in the lowlands and foothills throughout much of California where it is found in cismontane woodland (especially oaks), open mixed chaparral, and valley and foothill grasslands with scattered trees.	**Low Potential.** There is suitable cismontane woodland for the species (i.e., mixed oak and riparian woodland) located in the southeastern portion of the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than two miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to nest on the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Spinus lawrencei	Lawrence's goldfinch (nesting)	none/none/BCC	This species is found as a breeding species in oak woodlands, other arid woodlands, and chaparral in the lower elevations of northern California and in riparian woodland, pinyon-juniper woodland, and lower montane communities in southern California. A local water source and a source of abundant seeds are required habitat components.	**Low Potential.** There is suitable cismontane woodland for the species (i.e., mixed oak and riparian woodland) located in the southeastern portion of the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than two miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to nest on the project site.
MAMMALS				
Vulpes macrotis mutica	San Joaquin kit fox	FE/ST/none	This taxon is found in the San Joaquin Valley from Contra Costa County south to Kern County. It is also found in the dry interior valleys of the Coast Ranges (e.g., Salinas and Santa Clara valleys). It occurs in open, sparsely vegetated areas of low relief (typically in native or non-native grassland or alkali sink scrub).	**No Potential.** Though there is suitable habitat for the taxon on and adjacent to the project site (i.e., grassland), and it has been recorded 2.7 miles northwest and 4.8 miles southwest of the project site, there are no potential dens on the site that would be suitable for the taxon. The sandy onsite soils may preclude the creation and maintenance of larger burrows that do not collapse (hence the lack of California ground squirrel burrows). Therefore, the taxon is considered to have no potential to

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
				occur within the project site or otherwise be affected by the project.
Taxidea taxus	American badger	none/CSC/none	This species is found as a resident species at scattered localities throughout California (except in the coastal redwood region). Generally occurs in extensive, open habitats in the vicinity of abundant rodent populations.	**No Potential.** Though there is suitable habitat for the species on and adjacent to the project site (i.e., grassland), there are no potential dens on the site that would be suitable for the species. The sandy onsite soils may preclude the creation and maintenance of larger burrows that do not collapse (hence the lack of California ground squirrel burrows). Therefore, the species is considered to have no potential to occur within the project site or otherwise be affected by the project.
Antrozous pallidus	Pallid bat	none/CSC/none	This species is found as a resident in all desert, grassland, shrub, woodland, and forest habitats from sea level to approximately 6,000 feet. Day roosts are typically found in buildings, bridges, rocky outcrops, mines, caves, and trees. Night roosts are generally provided by bridges, mines, and caves.	**No Potential.** No suitable day or night roosts for the species occur on or immediately adjacent to the project site. Therefore, it has no potential to occur on the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Eumops perotis californicus	Western mastiff bat	none/CSC/none	This subspecies is found as an uncommon resident in southern California, but also occurs along the lower west slope of the Sierra Nevada and in the interior Coast Ranges as far north as the Tumey Hills (eastern San Benito County). Roosts are typically found in crevices in cliff faces, cracks in boulders, or occasionally in buildings (particularly where the roost allows for a large vertical drop).	**No Potential.** No suitable day or night roosts for the species occur on or immediately adjacent to the project site. Therefore, it has no potential to occur on the project site.
Lasiurus blossevillii	Western red bat	none/CSC/none	This species occurs at scattered locations throughout the lowland portions of California west of the Sierra Nevada crest and desert regions (typically in riparian forest or orchards). It is less abundant at low and middle elevations in coniferous forest. Roosting sites are found in tree or shrub foliage between 2 and 40 ft above ground (typically in large cottonwoods, sycamores, walnuts, and willows).	**Low Potential.** There is suitable cismontane woodland for the species (i.e., mixed oak and riparian woodland) located in the southeastern portion of the project site. The large trees associated with this woodland could serve as roost sites – particularly during migration. Therefore, there is some potential, albeit low, for the species to occur on the project site.

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site

LIKELIHOOD OF OCCURRENCE DEFINITIONS

Known to Occur	Taxon was observed within or immediately adjacent to the project site or has previously been documented within or immediately adjacent to the project site.
High Potential	Taxon has not been documented within or immediately adjacent to the project site, but should be expected on more than 50% of visits to suitable habitat on and near the project site during the appropriate season and time of day.
Moderate Potential	Taxon has not been documented within or immediately adjacent to the project site, but should be expected on less than 50% of visits to suitable habitat on and near the project site during the appropriate season and time of day.
Low Potential	Taxon has not been documented within or immediately adjacent to the project site nor is it likely to occur on or near the project site, but its presence cannot be completely discounted due to incomplete information on the taxon's distribution or habitat requirements.
No Potential	Taxon does not occur within or immediately adjacent to the project site due to the lack of required habitat features for the taxon, or the known range of the taxon is well defined and does not include the project vicinity.

Tulare Irrigation District
McKay Point Reservoir Project Biological Resources Evaluation,
Addendum No. 1
Tulare County, California
January 2021

Introduction

This report summarizes the results of year 2020 reconnaissance-level biological resources surveys, as well as other previous surveys (Bumgardner Biological Consulting 2011, 2013), conducted within and immediately adjacent to the site of the proposed McKay Point Reservoir Project (i.e., Project) in Tulare County, California (Figure 1). The Project site includes Assessor Parcel Numbers (APNs) 113-070-016 (in part), 113-080-005, 113-080-008, 113-090-001, and 113-100-002. The Project site lies 2.5 miles southwest of Lake Kaweah; 1.5 miles southeast of Bravo Lake; 1.0 miles northwest of the community of Lemon Cove; and 2.5 miles southwest of the community of Woodlake.

Project Description

The Tulare Irrigation District (TID), Consolidated Peoples Ditch Company (CPDC) and Visalia & Kaweah Water Company (VKWC)) are joint owners (Owners) of the approximately 200 acres of land adjacent to the Kaweah and St. Johns rivers that comprise the Project site. This land is commonly referred to as the McKay Point property.

The Owners propose to construct a new reservoir (i.e., McKay Point Reservoir) on the north side of the divergence of the Kaweah and St. Johns rivers near McKay Point. The McKay Point Reservoir would serve as a surface water storage/re-regulation facility (i.e., surface water management tool). The reservoir would occupy a surface area of approximately 180 acres and would have storage capacity of approximately 4,000 acre-feet. Depths of approximately 60 feet below ground surface (bgs) are proposed. Final slopes would be 3:1, horizontal:vertical (h:v), to minimize any bank erosion from wind and water.

The Project objectives include capturing and re-regulating water made available to the Owners Owners during flood releases from Lake Kaweah; capturing and re-regulating water entitlements belonging to the Owners released from Lake Kaweah; capturing and re-regulating water released for the Owners during peak power enhancement flows from the Terminus Hydropower Plant (Lake Kaweah); capturing and re-regulating any other water sources on the Kaweah River that may be made available to the Owners; allowing other entities with water rights on the Kaweah River to capture and/or re-regulate flows when designated by the Owners; allowing other entities to capture and/or re-regulate

flows of the Lower Kaweah River and St. Johns River for purposes of storm water runoff and flood prevention with permission of the Owners and Kaweah/St. Johns water rights interests; constructing the reservoir in such a way that revenue can be obtained to offset the construction and development costs; and locating the reservoir adjacent to the Kaweah River to allow for off-stream access to surface water storage, thus minimizing the need for pipelines.

Survey Methods

The Project site, the existing access road located on the adjacent Seaborn site, and other adjacent lands within approximately 250 feet of the sites are all considered part of the Project's biological study area (BSA) and were evaluated during the biological resources surveys in 2011, 2013, and 2020 to identify evidence of special-status plants and wildlife, rare or sensitive vegetation communities, and potential jurisdictional waters or wetlands that could be affected by the Project.

The Project was initially proposed in 2011 but was delayed. The proposed Project has since been reactivated and TID, as the lead CEQA agency, has requested that the biological surveys performed in 2011 and 2013 be updated since they are now several years old. The activities proposed for the Project site have not changed significantly since 2013. However, the sand and gravel removed from the Project site during construction of the reservoir would no longer be taken offsite to the CEMEX processing plant north of the Project site. The excavated aggregate would be processed on the Project site.

There is an existing haul road directly west of the Project site located on the Seaborn site. This road would provide ingress and egress to the Project site. Hence, in addition to updating the biological resources information for the Project site, the existing access road and the areas adjacent to it located on the Seaborn site are also addressed by this report and considered part of the BSA.

The Project site and adjacent lands were surveyed by me (Michael Bumgardner, Bumgardner Biological Consulting) on May 16, 2011 and September 18, 2013. A more recent survey of the Project site (i.e., on October 15, 2020) was again conducted by me. However, the latter survey also included the existing access road on the Seaborn site (as identified above). The surveys of the BSA were conducted on foot as random meander transects, where possible, such that all potentially affected lands could be effectively evaluated. Where random meander transects were not possible, portions of the BSA were surveyed from the nearest private property boundary or through "windshield surveys." Gross-scale mapping of the vegetation communities on the Project site was conducted given that only three discernible vegetation communities occur on the site. The latter

level of mapping of the extant vegetation communities was continued for the access road on the Seaborn site (Figure 2).

An onsite search for evidence of special-status plant and wildlife species was conducted and focused on local taxa that have been recorded in the California Natural Diversity Database (CNDDB) or California Native Plant Society's (CNPS) Online Inventory of Rare and Endangered Plants during the 2011 and 2013 surveys. This data was updated in 2020.

The October 15, 2020 survey of the Project and adjacent areas was conducted mostly as a "windshield survey" to achieve two purposes: (1) to confirm that no substantive changes had occurred to the Project site since the 2013 survey and (2) to identify the extant vegetation communities adjacent to the existing access road on the Seaborn site and evaluate their potential to support special-status plant and wildlife species. However, a more focused survey (i.e., linear transects on 100-foot centers) was conducted by me and Tulare Irrigation District (TID) staff Jeremy Barroll and Riley Nolan (under my direction) on October 15, 2020. The latter survey was focused on finding evidence of burrowing owl, San Joaquin kit fox, and American badger.

Lastly, a reconnaissance-level search for waters with regulatory jurisdiction under the Clean Water Act, California Fish and Game Code, and/or Porter-Cologne Water Quality Control Act was conducted within the Project site boundaries.

Analytical Methods

An updated nine-quadrangle CNDDB/Rarefind 5 report was generated for the Project site (i.e., query of the USGS 7.5-minute topographic quadrangle in which the Project site is found, as well as the immediate eight surrounding topographic quadrangles, viz. Woodlake and the surrounding Stokes Mountain, Ivanhoe, Exeter, Auckland, Rocky Hill, Shadequarter Mountain, Kaweah, and Chickencoop Canyon quads). The CNDDB contains records for special-status species, as well as sensitive natural communities, which have been reported to the California Department of Fish and Wildlife (CDFW). The Rarefind 5 report for the Project site is provided in Appendix A. Each of the species identified in the Rarefind 5 report were then evaluated in terms of their likelihood of occurrence within the BSA. This evaluation considered the known distribution and habitat requirements of the species such that one of the following findings was prepared:

- Known to Occur – species was observed within or immediately adjacent to the Project site during the May 16, 2011, September 18, 2013, or October 15, 2020 survey or has previously been documented within or immediately adjacent to the Project site.

- High Potential – species has not been documented within or immediately adjacent to the Project site but should be expected on more than 50% of visits to suitable habitat in the Project site during the appropriate season and time of day.
- Moderate Potential – species has not been documented within or immediately adjacent to the Project site but should be expected on less than 50% of visits to suitable habitat in the Project site during the appropriate season and time of day.
- Low Potential – species has not been documented within or immediately adjacent to the Project site nor is it likely to occur on the Project site, but its presence cannot be completely discounted due to incomplete information on the taxon's distribution or habitat requirements.
- No Potential – species does not occur within the Project site due to the lack of required habitat features for the species or the known range of the species is well defined and does not include the Project site.

The findings for each of the species identified in the Rarefind 5 report are presented in this report.

Other sources of information on special-status species in California were subsequently reviewed given that the CNDDB is not inclusive of all special-status species that may occur in an area. This review was based on my professional experience within the region and elsewhere in California, but also included review of other published sources of information on special-status species in California. These latter sources include the following:

- The Jepson Manual: Vascular Plants of California (Baldwin and Goldman 2012).
- California Native Plant Society (CNPS), Rare Plant Program. 2020. Inventory of Rare and Endangered Plants of California (online edition, v8-03 0.39). website http://www.rareplants.cnps.org (Accessed: October 26, 2020).
- Amphibian and Reptile Species of Special Concern in California (Jennings and Hayes 1994).
- California Herps - A Guide to the Amphibians and Reptiles of California. (Nafis 2020) available at: http://www.californiaherps.com/ (Accessed October 26, 2020).
- California Bird Species of Special Concern. Studies of Western Birds 1. Western Field Ornithologists, Camarillo, California and California Department of Fish and Game (Shuford and Gardali 2008).
- The Distribution of the Birds of California (Grinnell and Miller 1944).
- California Birds: Their Status and Distribution (Small 1994).

- California's Wildlife Volume II Birds (Zeiner et al. 1990).
- eBird. 2020. eBird: An online database of bird distribution and abundance [web application]. eBird, Ithaca, New York. Available: http://www.ebird.org. (Accessed: October 26, 2020).
- Mammalian Species of Special Concern in California (Williams 1986).
- Terrestrial Mammal Species of Special Concern in California (unfinished 1998 update) (Bolster 1998).
- Mammals of the Pacific States: California, Oregon, and Washington (Ingles 1978).
- Western Bat Working Group website (http://wbwg.org/western-bat-species/).
- Recovery Plan for Upland Species of the San Joaquin Valley, California (USFWS 1998).

Species that are known or expected to occur in the vicinity of the Project site were then further evaluated in this report.

Vegetation Communities and Site Characteristics

The description of the vegetation communities within the Project site, as described in the *Tulare Irrigation District, McKay Point Reservoir Project Biological Resources Evaluation, Tulare County, California* (Bumgardner Biological Consulting 2013), is still valid as the October 15, 2020 survey found no substantive changes in the type or distribution of the onsite vegetation communities have occurred since 2013. Hence, the description and mapping of the vegetation communities described in the *Tulare Irrigation District, McKay Point Reservoir Project Biological Resources Evaluation, Tulare County, California* (Bumgardner Biological Consulting 2013) are herein incorporated by reference.

The areas within the north/northeastern portion of the Seaborn site (adjacent to the existing access road) have been used most recently to support aggregate mining and processing. As such most of the northeastern portion of the property consists of developed land uses and is barren or supports no discernible vegetation communities (Figure 2). Scattered vegetation within this portion of the Seaborn site includes but is not limited to ruderal species such as lamb's-quarters [*Chenopodium album*], deer weed [*Acmispon glaber*], common bindweed [*Convolvulus arvensis*], telegraph weed [*Heterotheca grandiflora*] and various annual grasses.

The existing access road within the Seaborn site runs along the northern boundary of the site. Vegetation along the road consists almost entirely of non-native annual grassland. Though this vegetation community supports some weedy species (e.g., broadleaf filaree

[*Erodium botrys*] and common fiddleneck [*Amsinckia menziesii*]), most of the vegetative cover is composed of non-native annual grasses (e.g., wild oat [*Avena fatua*], rattail fescue [*Vulpia myuros*], bromes [*Bromus* spp.], etc.). This latter stand of vegetation encompasses approximately 41 acres.

All other land cover adjacent to the existing access road (i.e., within 250 feet of the road) is associated with various agricultural uses (orchard, row crops, etc.).

Jurisdictional Wetlands and Other Waters

Jurisdictional wetlands or other waters of the United States are areas that cannot be dredged or filled without a permit from the U.S. Environmental Protection Agency or U.S. Army Corps of Engineers (this latter permit is commonly referred to as a "Section 404" permit in reference to the section of the federal Clean Water Act that requires such permits). Actions that require issuance of a "Section 404" permit include earth-moving activities that result in fill of jurisdictional wetlands and other waters. It should be noted that such actions may also require the issuance of state permits (e.g., California Fish and Game Code Section 1602 lake and streambed alteration agreement and/or Regional Water Quality Control Board Section (RWQCB) Section 401 clean water certification).

Wetlands or other waters of the United States are identified based on three criteria, viz. (1) soil characteristics, (2) hydrology, and (3) plant species. The U.S. Army Corps of Engineers (USACE) has developed a procedure and manual for delineating wetlands that requires comprehensive evaluation of these three criteria during field environmental assessments. A formal wetland delineation was not conducted for the purposes of this report. However, no waters that are clearly subject to the jurisdiction of the USACE, CDFW, or RWQCB, other than the St. Johns and Kaweah Rivers, occur on or immediately adjacent to the Project or Seaborn sites. The only potential exception to this latter finding is that the "daylighted" groundwaters that occur within the Seaborn site may now be jurisdictional based on the Waters of the State regulations that were approved by the Office of Administrative Law and became effective on May 28, 2020. As such, a determination of whether jurisdictional waters occur within the Seaborn site is beyond the reach of this document and will be addressed elsewhere by individuals that are more familiar with the current law and regulations addressing this issue.

Habitat Conservation Plans and Other Similar Habitat Management Plans

There are no Habitat Conservation Plans (HCPs), Natural Community Conservation Plans (NCCPs), or other approved local, regional, or state habitat conservation plans that apply to the Project site.

Special-Status Plant Species

The likelihood of occurrence evaluation for special-status plants provided in the *Tulare Irrigation District, McKay Point Reservoir Project Biological Resources Evaluation, Tulare County, California* (Bumgardner Biological Consulting 2013), which did not address the Seaborn site, now addresses both the Project site, the areas adjacent to the existing access road on the Seaborn site, and other areas adjacent to the Project site (i.e., BSA). No special-status plant taxa, as described in Table 1, are associated with the BSA. Nor were any special-status plant taxa observed on or immediately adjacent to the BSA during the October 15, 2020 survey. All special-status plants that occur in the region have been discounted from having any potential to occur within the BSA due to lack of suitable habitat and/or the distribution of the taxon is well known and does not include the BSA.

Special-Status Wildlife Species

The likelihood of occurrence evaluation for special-status wildlife provided in the *Tulare Irrigation District, McKay Point Reservoir Project Biological Resources Evaluation, Tulare County, California* (Bumgardner Biological Consulting 2013), which did not address the Seaborn site, now addresses both the Project site, the areas adjacent to the existing access road on the Seaborn site, and other areas adjacent to the Project site . No special-status wildlife species were observed within the BSA during the October 15, 2020 survey. However, 16 special-status wildlife species that have been documented in the Project region (Table 1) are now considered to have some potential to occur in the BSA. Three (3) of these species are insects (i.e., Moestan blister beetle [*Lytta moesta*], Morrison's blister beetle [*Lytta morrisoni*], and Tulare cuckoo wasp [*Chrysis tularensis*]) that are not well known in terms of their life history and behavior, but that have been recorded in the Project vicinity in habitats like those that occur in the BSA. As such, they cannot be discounted and are considered to have some potential, albeit low, to occur in the BSA.

The previous biological resources evaluations for the Project site (Bumgardner Biological Consulting 2013, Entomological Consulting Services 2014) found evidence that a fourth special-status insect taxon (i.e., valley elderberry longhorn beetle [VELB] [*Desmocerus californicus dimorphus*]) occurs within the BSA. However, the U.S. Fish and Wildlife Service's (USFWS) review of records within the southern portion of the subspecies presumed historic range found that records for VELB's "sister subspecies" *Desmocerus californicus* had been inappropriately attributed to VELB. The USFWS subsequently removed Tulare, Kern, and Kings counties from the presumed historic range of the subspecies (USFWS 2014). VELB is therefore no longer considered a special-status species that may be affected by the Project.

Crotch bumble bee [*Bombus crotchii*] is another special-status insect species that is considered to have some potential to occur within the BSA. This finding is based on the species' historic distribution and presence of suitable habitat (e.g., relatively warm and dry sites in open grassland and scrub habitats) within the BSA. Nests of this species are often typically located underground in abandoned rodent nests, or above ground in tufts of grass, old bird nests, rock piles, or cavities in dead trees. As such, there are many places within the BSA that could be used for nesting by this species. However, given the species rapidly declining range it is not considered to have more than a low potential to occur within the BSA.

Two (2) special-status reptiles (i.e., western pond turtle [*Actinemys marmorata* formerly *Emys marmorata*] and Northern California legless lizard [*Anniella pulchra*]) are believed to have some potential, albeit low, to occur in the BSA. Regarding western pond turtle, it has been known to occur in a wide variety of still or slow-moving waters throughout California. The nearest known occurrences to the BSA are from upstream in the Kaweah River drainage. Thus, the species is considered to have some potential to occur in the aquatic habitats of the adjacent Kaweah and St. Johns rivers Lastly, the species could nest in various upland portions of the BSA.

The potential for California legless lizard to occur in the BSA is believed to be limited to the non-native annual grassland on the Project site, mainly due to the suitable soils (i.e., sands and sandy loam) that are located on the Project site. The nearest known location for the species, Kaweah Oaks Preserve, is less than 8 miles southwest of the Project site and connected via the Kaweah River corridor. Furthermore, the secretive nature of the species often results in failure to document extant occurrences. It may then occur at locations in the Project vicinity where searches for the species have simply not been conducted. As such, it is considered to have at least a low potential to occur within the BSA.

Nine (9) special-status birds are considered to have some potential to occur within the BSA. Five (5) of these latter species (Cooper's hawk [*Accipiter cooperii*], white-tailed kite [*Elanus leucurus*], loggerhead shrike [*Lanius ludovicianus*], oak titmouse [*Baeolophus inornatus*], and Lawrence's goldfinch [*Spinus lawrencei*]) are known to nest in oak or riparian woodlands. Furthermore, each of these species has been recorded nesting within less than 2 miles of the BSA. As such, each of these species, is considered to have either a low or moderate potential to nest or winter (e.g., white-tailed kite) within the BSA.

Other special-status bird species with some potential to occur in the BSA include ferruginous hawk [*Buteo regalis*], merlin [*Falco columbarius*], golden eagle [*Aquila chrysaetos*], and burrowing owl [*Athene cunicularia*].

Three (3) of the latter special-status avian species with some potential to occur within the BSA are strictly wintering species. These species (e.g., ferruginous hawk, merlin, and golden eagle) tend to be wide-ranging, often utilize fallow agricultural fields or similar open vegetation communities (e.g., annual grassland) and have substantial acreage of suitable wintering habitat within the Project vicinity. Winter occurrences of each of these species have been documented within less than 2 miles of the BSA. Therefore, these species can be expected to occur within the BSA on at least an occasional basis.

No evidence of burrowing owl (e.g., urates, regurgitated fur and feather pellets, feathers, prey remains, etc.) has been found in the BSA. In addition, no suitable burrows or burrow surrogates that could be used by the species were found within the BSA. However, California ground squirrel [*Otospermophilus beecheyi*] burrows were observed immediately offsite on the northern and eastern boundaries of the Project site. In addition, scattered California ground squirrel burrows were found in the non-native annual grassland adjacent to the existing access road along the northern boundary of the Seaborn site. However, most of these burrows had been abandoned by the ground squirrels and showed no use by any other large vertebrate species (i.e., most contained substantial cobwebs and plant debris). As such, there is potential for the species to occur adjacent to the existing access road at some point in the future and the species is considered to have at least a low potential to occur in the BSA.

Another special-status taxon that often utilizes California ground squirrel burrows is San Joaquin kit fox [*Vulpes macrotis mutica*]. The burrowing owl surveys found no evidence of this taxon in the BSA. However, this is not unexpected as the taxon does not normally range much north of Kern County on the east side of the San Joaquin Valley (i.e., it occurs principally in the “rain shadow” of the west side of the San Joaquin Valley). The nearest CNDDB occurrence of the taxon is attributed to Woodlake and is 1.5 miles northwest of the BSA. The next five nearest CNDDB occurrences are approximately 4 to 9 miles west of the BSA in the vicinity of Ivanhoe. Therefore, there is some potential for San Joaquin kit fox to occur in the BSA (mostly the western-most portions of the site), but the potential is considered low.

Designated Critical Habitat

When a species is proposed for listing as endangered or threatened under the Endangered Species Act, the USFWS and National Marine Fisheries Service (NMFS) must consider whether there are areas of habitat believed to be essential to the species' conservation. Those areas may be proposed for designation as critical habitat. Only activities that involve a federal permit, license, funding, or authorization (i.e., federal nexus) and are likely to destroy or adversely modify an area of critical habitat can be affected by the designation. In such a case, the USFWS and NMFS typically work with the appropriate federal lead agency, as well as private or other landowners (when appropriate), to amend

their project to allow it to proceed without adversely affecting the critical habitat. Thus, most projects with a federal nexus are likely to go forward, but some may be modified to minimize harm to critical habitat. Regarding the McKay Point Reservoir Project, there is no critical habitat that has been designated that includes the Project or Seaborn sites. Therefore, this issue is not addressed further in this biological resources evaluation.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
		PLANTS		
Atriplex cordulata var. *erecticaulis*	Earlimart orache	none/none/CNPS list 1B.2	This annual saltbush occurs on saline or alkaline soils in valley and foothill grassland. It is known from Kings, Kern, and Tulare counties. It blooms from August to November.	**No Potential.** No individuals of this taxon were observed within the BSA. In addition, the taxon only occurs on saline or alkaline soils in valley and foothill grassland – conditions that do not exist within the BSA. Therefore, the taxon has no potential to occur within the BSA.
Atriplex minuscula	lesser saltscale	none/none/CNPS list 1B.1	This annual saltbush grows in sandy alkaline areas in chenopod scrub, playas, and valley and foothill grassland. It is known from Alameda, Butte, Fresno, Kern, Madera, Merced, Stanislaus, and Tulare counties. It blooms from May to October.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs on sandy alkaline soils in chenopod scrub, playas, and valley and foothill grassland – conditions that do not exist within the BSA. Therefore, the species has no potential to occur within the BSA.
Atriplex persistens	vernal pool smallscale	none/none/CNPS list 1B.2	This annual saltbush occurs in claypan and alkaline vernal pools and alkaline	**No Potential.** No individuals of this species were observed within the BSA. In

			grasslands. It has been recorded from Colusa, Glenn, Madera, Merced, Solano, Stanislaus, and Tulare counties. It blooms from June to October.	addition, the species only occurs in claypan and alkaline vernal pools and alkaline grasslands – conditions that do not exist within the BSA. Therefore, the species has no potential to occur within the BSA.
Brodiaea insignis	Kaweah brodiaea	none/SE/CNPS list 1B.2	This perennial bulbiferous herb occurs on granitic or clay soils in cismontane woodland, meadows and seeps, and valley and foothill grassland. It is known only from the Tule and Kaweah river drainages in Tulare County. It blooms from April to June.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs on granitic or clay soils in cismontane woodland, meadows and seeps, and valley and foothill grassland – within the Tule and Kaweah river drainages. Therefore, the species has no potential to occur within the BSA.
Delphinium recurvatum	recurved larkspur	none/none/CNPS list 1B.2	This perennial herb occurs in alkaline areas in chenopod scrub, cismontane woodland, and valley and foothill grassland. It is known from Alameda, Butte, Contra Costa, Colusa, Fresno, Glenn, Kings, Kern, Madera, Merced, Monterey, San Joaquin, Solano, Sutter, San Luis Obispo, and Tulare counties. It blooms from March to June.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs in alkaline areas in chenopod scrub, cismontane woodland, and valley and foothill grassland – conditions that do not exist within the BSA. Therefore, the species has no potential to occur within the BSA.

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Diplacus pictus (formerly *Mimulus pictus*)	calico monkeyflower	none/none/CNPS list 1B.2	This annual herb occurs on granitic soils (often in disturbed areas) in broad-leafed upland forest and cismontane woodland. It has been found in Kern and Tulare counties. It blooms from March to May.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs on granitic soils in broad-leafed upland forest – conditions that do not exist within the BSA. Therefore, the species has no potential to occur in the BSA.
Eriogonum nudum var. *murinum*	mouse buckwheat	none/none/CNPS list 1B.2	This perennial herb occurs on sandy soils in chaparral, cismontane woodland, and valley and foothill grassland. It known from only 11 occurrences – all in Tulare County. It blooms from June to November.	**No Potential.** No individuals of this taxon were observed within the BSA. The taxon occurs on sandy soils in valley and foothill grassland – conditions that exist within the BSA. However, all known records are from the Three Rivers area well upstream in the Kaweah River drainage. Therefore, the taxon is considered to have no potential to occur within the BSA.
Eryngium spinosepalum	spiny-sepaled button-celery	none/none/CNPS list 1B.2	This perennial species occurs in and vernal pools, wet valley and foothill grassland, swales, and similar wetland habitats. Known occurrences have been documented in the San Joaquin	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs in alkaline areas in wet valley and foothill grassland and vernal pools – conditions that do not

			Valley (Kern to Stanislaus counties), along the Central Coast (Monterey and San Luis Obispo counties). Blooming occurs from April to May.	exist within the BSA. Therefore, the species has no potential to occur in the BSA.
Euphorbia hooveri (formerly *Chamaesyce hooveri*)	Hoover's spurge	FT/none/CNPS list 1B.2	This annual herb occurs in association with large vernal pools. It has been recorded in Merced, Stanislaus, Butte, Glenn, Tulare, and Tehama counties but may be extirpated in Tulare County. It blooms mostly during July, but sometimes into October if there is sufficient moisture.	**No Potential.** No individuals of this species were observed within the BSA. In addition, suitable habitat (i.e., large vernal pools) does not occur within or near the BSA. Therefore, the species has no potential to occur the BSA.
Fritillaria striata	striped adobe-lily	none/SE/CNPS list 1B.1	This perennial bulbiferous herb occurs in cismontane woodland and valley and foothill grassland (usually on clay soils). It is known from Kern and Tulare counties. It blooms from February to April.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs in cismontane woodland and valley and foothill grassland (usually on clay soils) – conditions that do not exist within the BSA. Therefore, the species has no potential to occur within the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Glyceria grandis	American manna grass	none/none/CNPS list 2.3	This perennial rhizomatous grass occurs in bogs and fens, meadows and seeps, and marshes and swamps. It is known from El Dorado, Fresno, Humboldt, Mendocino, Mono, Placer, and Tulare counties. It blooms from June to August.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs in bogs and fens, meadows and seeps, and marshes and swamps – conditions that do not exist within the BSA. Therefore, the species has no potential to occur in the BSA.
Helianthus winteri	Winter's sunflower	none/none/CNPS list 1B.2	This perennial shrub occurs in open, ungrazed foothill woodlands and annual grasslands on well-drained, granitic soils, generally on lower-elevation, south-facing foothill slopes. It is known from Fresno and Tulare counties where it blooms year-round.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs in open, ungrazed foothill woodlands and annual grasslands on well-drained, granitic soils, generally on lower-elevation, south-facing foothill slopes. Therefore, the species has no potential to occur in the BSA.
Lasthenia chrysantha	alkali-sink goldfields	none/none/CNPS list 1B.1	This annual herb occurs in vernal pools and on alkali flats. It has been found in Fresno, Kings, Kern, Lake, Madera, Merced, Placer, Solano, Stanislaus, and Tulare counties. It blooms from February to June.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs in vernal pools and on alkali flats. Therefore, the species has no potential to occur within the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Lasthenia glabrata ssp. *coulteri*	Coulter's goldfields	none/none/CNPS list 1B.1	This annual taxon is associated with heavy soils, vernal pools, low alkaline fields and hillsides, and alkaline marshes in Colusa, Kern, Los Angeles, Merced, Orange, Riverside, Santa Barbara, San Bernardino, San Diego, San Luis Obispo, Tehama, Tulare, Ventura, and Yolo counties. It blooms from February to June.	**No Potential.** No individuals of this species were observed within the BSA. In addition, suitable habitat for the taxon (alkaline marshes and other wet alkaline habitats) does not exist within the BSA. Therefore, the species has no potential to occur in the BSA.
Mimulus norrisii	Kaweah monkeyflower	none/none/CNPS list 1B.3	This annual herb occurs on carbonate or rocky soils in chaparral and cismontane woodland. It has been found in Fresno and Tulare counties. It blooms from March to May.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs on carbonate or rocky soils in cismontane woodland and chaparral – conditions that do not exist within the BSA. Therefore, the species has no potential to occur in the BSA.
Orcuttia inaequalis	San Joaquin Valley orcutt grass	FT/SE/CNPS list 1B.1	This grass occurs in vernal pools (typically larger or more persistent pools) within valley and foothill grassland. The remaining populations	**No Potential.** No individuals of this species were observed within the BSA. In addition, it only occurs in vernal pools in valley and foothill grassland – conditions

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			of this species occur mostly in the southeastern San Joaquin Valley (Fresno, Merced, Madera, and Tulare counties). Historically, the species also occurred in Stanislaus County. It blooms from April to September.	that do not exist within the BSA. Therefore, the species has no potential to occur in the BSA.
Pseudobahia bahiifolia	Hartweg's golden sunburst	FE/SE/CNPS list 1B.1	This species occurs in cismontane woodland and valley and foothill grassland (almost always on shallow, well-drained, fine-textured soils - typically on clay, acidic soils) on the north or northeast facing side of Mima mounds). It has been recorded in Fresno, Madera, Merced, Stanislaus, Tuolumne, and Yuba counties. Blooming occurs from March to April.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs in cismontane woodland and valley and foothill grassland on the north or northeast facing side of Mima mounds – conditions that do not exist within the BSA. Therefore, the species has no potential to occur in the BSA.
Pseudobahia peirsonii	San Joaquin adobe sunburst	FT/SE/CNPS list 1B.1	The species is known from a few mostly small occurrences along the southeastern side of the San Joaquin Valley in the interface with the Sierra Nevada foothills. It occurs on heavy clay soils in valley and foothill	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs on heavy adobe clay soils in oak woodland and valley and foothill grassland – conditions that do not exist within the BSA. Therefore, the

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			grassland and oak woodland. It has been recorded in Fresno, Tulare, Kern, and Los Angeles counties. Blooming occurs from February to April.	species has no potential to occur in the BSA.
Sagittaria sanfordii	Sanford's arrowhead	none/none/CNPS list 1B.2	This perennial species occurs in shallow, standing, fresh water and slow-moving waterways (e.g., marshes, ponds, vernal pools, lakes, reservoirs, sloughs, ditches, unlined canals, streams, and rivers) at elevations below 2000 feet. It blooms from late May to August.	**No Potential.** No individuals of this species were observed within the BSA. The species occurs in shallow, standing, fresh water and slow-moving waterways (e.g., marshes, ponds, vernal pools, lakes, reservoirs, sloughs, ditches, unlined canals, streams, and rivers). Such habitat (i.e., standing or slow-moving waters does not occur in the BSA. Therefore, the species has no potential to occur in the BSA.
Tuctoria greenei	Greene's tuctoria	FE/SR/CNPS list 1B.1	This grass occurs in the bottom of drying vernal pools in valley and foothill grassland. It is currently known from Butte, Colusa, Glenn, Merced, Modoc, Shasta, and Tehama counties, but has previously occurred in Fresno, Madera, San Joaquin, Stanislaus, and Tulare counties where	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs in vernal pools in valley and foothill grassland – conditions that do not exist within the BSA. Therefore, the species has no potential to occur in the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			it is now believed to be extirpated. It blooms from May to September.	
INVERTEBRATES				
Branchinecta lynchi	vernal pool fairy shrimp	FT/none/none	This species occurs primarily in vernal pools (sandstone depression, grass swale, earth slump, or basalt-flow depression pools) in grassland and oak savannah of the Central Valley. However, the species also occurs at a small number of locations in the central Coast Ranges from Monterey County to Santa Barbara County as well as Riverside County.	**No Potential.** There is no suitable vernal habitat within or adjacent to the BSA for this species. Therefore, there is no potential for the species to be affected by the Project.
Lepidurus packardi	vernal pool tadpole shrimp	FE/none/none	This species inhabits clear to turbid vernal pools and swales in the Sacramento Valley and northern San Joaquin Valley.	**No Potential.** There is no suitable vernal habitat within the BSA for this species. Therefore, there is no potential for the species to be affected by the Project.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Linderiella occidentalis	California fairy shrimp	none/SA/none	Occurs primarily in vernal pools and other seasonal wetlands in grassland and oak savannah of the Central Valley. However, the species has also been recorded at scattered locations in the Coast Ranges from Mendocino County south to Ventura County.	**No Potential.** There is no suitable vernal habitat within the BSA for this species. Therefore, there is no potential for the species to be affected by the Project.
Talanites moodyae	Moody's gnaphosid spider	none/SA/none	Little is known and published about this species. However, it has been found in grasslands under rocks (generally serpentine) on rocky mounts, buttes, and hilltops. Only six known occurrences are reported – all from Fresno and Tulare counties.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs on rocky mounts, buttes, or hilltops (usually under serpentine rocks) – conditions that do not exist within the BSA. Therefore, the species has no potential to occur within either of the two sites.
Lytta moesta	Moestan blister beetle	none/SA/none	The range of this species is not well known, but occurrences have been documented in Fresno, Kern, Madera, Santa Cruz, Stanislaus, and Tulare counties. The CDFW reports that little is known about the life history and	**Low Potential.** Given that ground-nesting solitary bees (i.e., beetle's host species) are widely distributed in California and little is known about this species' life history and behavior, it cannot be discounted as not occurring within the BSA. Therefore, it is

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			behavior of this species. However, it has been collected from March to September and has typically been found in association with its host species (i.e., the species' larvae feed on the pollen stores that ground-nesting solitary bees have provided for their own larvae).	considered to have some potential, albeit low, to occur on the BSA.
Lytta morrisoni	Morrison's blister beetle	none/SA/none	The range of this species is not well known, but occurrences have been documented in the southern San Joaquin Valley in Kern, Fresno, Tulare, San Benito, and San Luis Obispo counties. The CDFW reports that life history and behavior information for the species does not exist. However, it has typically been found in association with its host species (i.e., the species' larvae feed on the pollen stores that ground-nesting solitary bees have provided for their own larvae).	**Low Potential.** Given that ground-nesting solitary bees (i.e., beetle's host species) are widely distributed in California and little is known about this species' life history and behavior, it cannot be discounted as not occurring within the BSA. Therefore, the species has some potential, albeit low, to occur within either of the two sites.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Desmocerus californicus dimorphus	valley elderberry longhorn beetle	FT/none/none	This subspecies occurs at scattered locations in the Central Valley and adjacent foothills of the Sierra Nevada and Coast Ranges. It is entirely dependent upon its host plant (i.e., elderberry spp.) and is only found where this shrub occurs (typically in riparian vegetation associations, but occasionally in single, isolated shrubs or stands of the plant). The southern limit of its range in and near the San Joaquin Valley now only extends to Fresno County.	**No Potential.** Many old growth elderryberry shrubs occur within the Project site and observations of valley longhorn beetles and their exit holes at the site were tentatively assigned to the listed subspecies in 2014. However, review by the USFWS has subsequently resulted in the removal of Kings, Kern, and Tulare counties from the subspecies' presumed historic range. Therefore, the subspecies has no potential to occur within the BSA.
Chrysis tularensis	Tulare cuckoo wasp	none/SA/none	This species is known only from a small series of specimens that have been collected in Amador, Fresno, Monterey, and Tulare counties. Cuckoo wasps are nest parasitoids of predatory wasps and sawflies. However, the host species of this species are unknown. Adults have been found from April to June in open,	**Low Potential.** Given that predatory wasps and sawflies (i.e., wasp's host species) are widely distributed in California and little is known about this species' life history and behavior, it cannot be discounted from occurring within the BSA. Furthermore, the nearest known record to the Project site is from north of Road 212 and Avenue 344 (less than 3 miles from the Project site).

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			sunny habitats with abundant flowers and small shrubs, where they feed on nectar.	Therefore, it is considered to have some potential, albeit low, to occur within the BSA.
Bombus crotchii	Crotch bumble bee	none/SA/none	This species occurs from coastal California east to the Sierra Nevada-Cascade crest. It occurs at relatively warm and dry sites in open grassland and scrub habitats. Colonies are annual and only the new, mated queens overwinter. Nests are often located underground in abandoned rodent nests, or above ground in tufts of grass, old bird nests, rock piles, or cavities in dead trees.	**Low Potential.** Given this species' historic distribution and the lack of focused species-specific surveys, it cannot be discounted from occurring on the Project site. Therefore, it is considered to have some potential, albeit low, to occur within the BSA.
AMPHIBIANS				
Ambystoma californiense	California tiger salamander	FT/ST/none	This species is found in annual grassland, oak savannah, and coastal sage scrub adjacent to vernal pools, stock ponds, and ponded reaches of ephemeral streams (aquatic breeding	**No Potential.** No suitable aquatic breeding habitat for the species (i.e., vernal pools or other seasonal wetlands) occurs within the BSA. Furthermore, the nearest known occurrences of the species (at and near the

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			sites). The species is patchily distributed in the Central Valley from Yolo County to Kings County, but also occurs in Alameda and Contra Costa counties south through the interior valleys of the Coast Ranges. Disjunct populations occur in Santa Barbara County and Sonoma County.	Stone Corral Ecological Reserve east of Yettem) are more than 11 miles west of the Project site. Lastly, the BSA is landlocked by agricultural land uses that would preclude the species from reaching the two sites from offsite wetlands that could be used by the species. Therefore, it has no potential to occur within the BSA.
Batrachoseps regius	Kings River slender salamander	none/SA/none	This species has been found in Fresno County on the south and east sides of the North Fork of the Kings River and at Summit Meadow in the drainage of the South Fork of the Kings River. It has also been found in the drainage of the middle fork of the Kaweah River in Tulare County. It occurs in talus, under rocks and downed logs, and in leaf litter in chaparral, cismontane woodland, and montane coniferous forest above 1,100 and 8,100 feet in elevation.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species has only been recorded in talus, under rocks, under downed logs, and in leaf litter in chaparral, cismontane woodland, and montane coniferous forest between 1,100 and 8,100 feet in elevation– conditions that do not exist within the BSA. Therefore, the species has no potential to occur within the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Rana boylii	foothill yellow-legged frog (East/Southern Sierra Clade)	none/SE/none	This species was historically distributed throughout the foothill portions of the Sierra Nevada and Coast Ranges drainages from the Oregon border to the San Gabriel River (Los Angeles County). The species requires shallow, small to moderate streams (typically perennial waters with some cobble-sized substrate and riffle habitat above 600 feet in elevation and without bullfrogs). The East/Southern Sierra Clade extends from the South Fork American River Subbasin to where the Sierra Nevada meet the Tehachapi Mountains.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species requires shallow, small to moderate streams (typically perennial waters) with some cobble-sized substrate and riffle habitat above 600 feet in elevation and without bullfrogs – conditions that do not exist within the BSA. Therefore, the species has no potential to occur within the BSA.
Lithobates pipiens	northern leopard frog (native populations only)	none/CSC/none	Historical populations of this species in California existed in scattered locations below 6,500 feet in Siskiyou and Modoc counties and in the northern Owens Valley. Individuals of unknown origin were introduced into El Dorado, Kern, Los Angeles,	**No Potential.** No individuals of this species were observed within the BSA. In addition, the only known population in the region, recorded near Orosi in Tulare County, is an introduced population and is therefore not a special-status species. Hence, there is no available information to

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			Merced, San Francisco, Sierra, Tehama, and Tulare counties between 1905 and 1970. Several of these introduced populations experienced rapid growth and range expansions before completely disappearing. Except for a small population that is currently present in Merced County, all these introduced populations have perished. It has been found in grassland, wet meadows, potholes, forests, woodland, brushlands, springs, canals, bogs, marshes, reservoirs (generally where there is permanent water with abundant aquatic vegetation).	suggest that any native populations have the potential to occur within the BSA.
Spea hammondii	western spadefoot	none/CSC/none	This species is found in dry habitats (e.g., annual grassland, oak savannah and woodland, and coastal sage scrub) adjacent to vernal pools, stock ponds, and overflow channels of low-gradient drainages within the Central Valley and coastal California from Monterey	**No Potential.** No suitable aquatic breeding habitat for the species occurs within the BSA. Furthermore, the BSA is relatively landlocked by semi-perennial rivers, sand and gravel mining operations, and agricultural uses that would preclude movement of the species from more suitable habitats located in the Project

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			County to San Diego County.	vicinity (e.g., lands north of Highway 216). Consequently, the species is considered to have no potential to occur within the BSA.
REPTILES				
Actinemys marmorata formerly *Emys marmorata*	western pond turtle	none/CSC/none	This species historically occurred throughout most of the Pacific-slope drainages in California (below approximately 4,000 feet). The species now occurs at scattered locations throughout its former range (primarily in the central Sierra Nevada foothills, Central Valley, San Francisco Bay area, and north-central coast and Coast Ranges. It occurs in and adjacent to ponds, reservoirs, or other slow-moving perennial aquatic habitats (e.g., sloughs, streams, and rivers). The species may be active year-round in some parts of its range.	**Low Potential.** Given that potentially suitable habitat is provided by the adjacent Kaweah and St. Johns rivers and the species has been recorded upstream in the Kaweah River, it cannot be discounted from occurring within BSA. In addition, individuals could also occur in the upland portions of the BSA during egg-laying. Therefore, it is considered to have some potential, albeit low, to occur within the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Anniella pulchra	Northern California legless lizard	none/CSC/none	This species occurs as a fossorial species in sand, sandy loam, or leaf-mold substrates. It can be found in a variety of habitats that include coastal beach, chaparral, pine-oak woodland, and riparian habitats. Soil moisture is essential. It appears to be active mostly during the morning and evening, just beneath the surface of sunlight-warmed substrate. It may also be active on the surface at night when substrate temperatures remain warm for extended intervals. It should be noted that recent mitochondrial and nuclear DNA work has resulted in the species being split into five distinct species with the local species (*A. pulchra*) occurring only along the coast, in the Coastal Ranges as far south as northwestern Ventura County and in parts of the San Joaquin Valley.	**Low Potential.** No individuals of this species were observed during the reconnaissance-level surveys of the BSA. However, there is a relatively recent occurrence (2015) documented in the CNDDB from about 0.2 miles northwest of Highway 198 at Road 180, in the vicinity of Outside Creek and Johnson Slough, about 6.5 miles east of Visalia.in the Kaweah Oaks Preserve. Therefore, given the presence of suitable habitat (primarily on the Project site), the species is considered to have some potential, albeit low, to occur within the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			BIRDS	
Phalacrocorax auritus	double-crested cormorant (nesting)	none/SA/none	This species is found as a colonial nester on coastal cliffs and offshore islands, and along lake and river margins in the interior portions of California. It nests along the coast on sequestered islets, usually on ground with sloping surface, or in tall trees or snags along lake or river margins.	**No Potential.** A colonial nest site was found in a couple of snags between the southern access road and the mining pit pond on the Seaborn property (outside the BSA). It was not active at the time of the survey given the time of year (October). So, it could not be determined when it was last occupied. However, it is the only colonial nesting site for the species in the area and is outside the BSA. Therefore, the Project would not adversely affect nesting by this species.
Ardea herodias	great blue heron (nesting colony)	none/SA/none	This species is common throughout most of California where there are shallow estuaries, or freshwater or saltwater emergent wetlands. However, it is less common along riverine and rocky coastal shores and above the foothills in the mountains. Rookeries (i.e., nesting colonies) are	**No Potential.** No nesting colonies of this species have been observed within the BSA. In addition, the nearest reported nesting colony is on Dry Creek, one mile north of the confluence of Dry Creek and the Kaweah River (more than two miles from the Project site). Therefore, no known or potential nesting colonies of this species

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			typically active from February to late July and occur in the tops of secluded large snags or live trees. Rookeries are sometime shared with the great egret or other large wading birds.	occur within the BSA.
Gymnogyps californianus	California condor	FE/SE/none	This species occurs as a reintroduced species primarily in the mountains of Ventura, Santa Barbara, Los Angeles, Monterey, and San Benito counties. However, individuals are known to be wide-ranging and occasionally occur soaring over the Tehachapi Mountains and southern Sierra Nevada. The species is strictly a scavenger and may travel up to 35 miles or more from roost sites in search of carrion. Most foraging occurs in open habitats that facilitate landings and takeoffs. Traditional roost sites are on cliffs or ledges, but snags and trees in old growth coniferous forest may be used.	**No Potential.** No suitable roost sites for this species occur within the BSA. In addition, other potential attractors to the sites (e.g., large mammals and potential food sources) are not provided at or near the BSA. Lastly, the nearest known use areas for this species are in more rugged country more than 13 miles southeast of the BSA. Therefore, the species is considered to have no potential to occur within the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Accipiter cooperii	Cooper's hawk (nesting)	none/SA/none	This species occurs as an uncommon breeding resident throughout most of the low to mid-elevation wooded portions of California where it inhabits open, interrupted, or marginal woodlands. It is seldom found in areas without dense tree stands. Nest sites are typically found in riparian or deciduous trees in canyon bottoms or river flood plains.	**Moderate Potential.** There is suitable nesting habitat for the species (i.e., interrupted oak woodland with dense stands of trees within the BSA. However, there are only a small number of scattered nesting season records from the Project vicinity in the eBird data base. Nonetheless, this relatively secretive species is considered to have a moderate potential to nest within the BSA.
Buteo swainsoni	Swainson's hawk (nesting)	none/ST/none	Occurs as a breeding resident in the Central Valley (primarily in the southern Sacramento and northern San Joaquin valleys), Klamath Basin, and Modoc Plateau. However, nesting pairs are also occasionally found in the Mojave Desert, Lanfair Valley (San Bernardino County), Antelope Valley (Los Angeles County), and eastern San Luis Obispo County. In the Central Valley the species nests in riparian woodland or forest stands, or oak	**No Potential.** Though suitable nesting habitat for the species occurs within the BSA (i.e., interrupted oak woodland), the nearest known nesting records for the species are more than 17 miles west of these sites in the vicinity of Traver. As such, the species is considered to have no potential to nest within the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			savannah. Nest territories are located adjacent to suitable foraging habitat (e.g., grassland, suitable grain and row crop fields, alfalfa, and pastures).	
Buteo regalis	ferruginous hawk (wintering)	none/none/BCC	This species is a winter resident of the Modoc Plateau, Central Valley, and Coast Ranges. It forages in large, open tracts of grasslands, sparse scrubland, and deserts.	**Low Potential.** There is suitable wintering habitat for the species (i.e., open grassland) within the BSA. Furthermore, there are records from the Project vicinity in the eBird data base (i.e., less than 1.5 miles from the BSA along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to winter within the BSA.
Elanus leucurus	white-tailed kite (nesting and wintering)	none/CFP/none	This species is found as a resident throughout the lower elevation portions of California in low rolling grasslands with scattered oaks and river bottomlands or marshes adjacent to deciduous woodland. It requires grasslands, meadows, or marshes (for foraging) located near dense-topped	**Low Potential.** There is suitable nesting habitat for the species (i.e., mixed oak woodland) within the BSA. However, there is only one eBird record from the nesting season in the Project vicinity. Nonetheless, there are several eBird records from the Project vicinity during the winter months. Therefore, the species is considered to have

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			trees (for nesting and roosting).	some potential, albeit low, to occur on the BSA (but mostly during the winter months).
Haliaeetus leucocephalus	bald eagle (nesting and wintering)	none/SE/BCC	The species winters throughout California at lakes, reservoirs, rivers, and some rangelands and coastal wetlands. Nesting occurs mainly in mountain and foothill forests and woodlands near reservoirs, lakes, and rivers. Most current nest territories are in northern California, but the species also nests in various locations in the central and southern Sierra Nevada mountains and foothills, in several locations in the central Coast Ranges, inland southern California, and Santa Catalina Island. The nesting season lasts from January through August.	**No Potential.** No individuals of this species were observed during any of the reconnaissance-level surveys of the BSA. There are multiple winter eBird occurrences scattered around nearby Dry Creek and Bravo Lake (sites where public access allows for potential observations - unlike the BSA). However, the species is considered to have no potential to occur within the BSA due to the lack of suitable roost sites or abundant and suitable prey species (e.g., fish or waterfowl).
Aquila chrysaetos	golden eagle (nesting and wintering)	none/CFP/BCC	Found as a breeding resident throughout most of California (other than the valley floor of the Central Valley). Also found as a wintering species throughout most of California	**Low Potential.** There is suitable wintering habitat for the species (i.e., open grassland) within the BSA. Furthermore, there are records from the Project vicinity in the eBird data base (i.e., less than 1.5 miles

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			(other than the high Sierra Nevada). Species requires open terrain for hunting (e.g., grassland, oak savannah, and early successional stages of shrub and woodland habitats). Typically nests on secluded cliffs, but may also use large, isolated trees.	from the BSA along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to winter within the BSA.
Falco columbarius	merlin (wintering)	none/SA/none	This species winters in California from September to May. It occurs in a variety of low elevation, relative flat habitats that include wooded areas, coastlines, open grasslands, savannah, and the periphery of lakes. It is less often found in open desert. It typically requires dense stands of trees for cover and roosting. It is most often found where there are substantial populations of small birds (the primary prey item).	**Low Potential.** There is suitable wintering habitat for the species (i.e., open grassland) within the BSA. Furthermore, there are records from the Project vicinity in the eBird data base (i.e., less than 1.5 miles from the Project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to winter within the BSA.
Athene cunicularia	burrowing owl (burrow sites)	none/CSC/BCC	This species is found throughout the Central Valley, in the San Francisco Bay Area, at scattered locations along the coast, and in portions of the desert	**Low Potential.** The annual grassland within the BSA provides suitable foraging habitat for the species. In addition, scattered California ground squirrel burrows occur in

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			regions. It is a year-round resident in annual and perennial grasslands or other vegetation communities that support sparse or non-existent tree or shrub canopies.	the far western portion of the BSA. Though no evidence of occupation by burrowing owls was found at these burrows, it does not preclude their future use. Therefore, there is some potential, albeit low, for the species to occur within the far western portion of BSA.
Empidonax traillii	willow flycatcher (nesting)	none/SE/BCC	This species is a rare to locally uncommon, summer resident in wet meadow and montane riparian habitats (typically dense willow scrub) at 2000 to 8000 feet in elevation in the Sierra Nevada and Cascade Range. It also occurs at scattered locations (at lower elevations) in southern California (including along the Kern, Santa Margarita, San Luis Rey, and Santa Ynez rivers). It most often occurs in broad, open river valleys or extensive mountain meadows with dense shrubby willows. Nesting occurs between mid-May and late August in northern California.	**No Potential.** Though a migrant individual was observed in the mixed oak woodland on the Project site during the 2013 reconnaissance-level survey of the site, there is no suitable riparian habitat within the BSA that could be used as nesting habitat by this species (i.e., extensive, dense willow scrub). Furthermore, there are no records in the CNDDB below 2,000 feet in elevation anywhere in the Sierra Nevada (mostly due to nest parasitism by brown-headed cowbird). Therefore, the species has no potential to occur within the BSA as a nesting species.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Lanius ludovicianus	loggerhead shrike (nesting)	none/CSC/BCC	This species is found as a resident and wintering species throughout the lower elevation portions of California in grasslands, saltbush scrub, chaparral, oak savannah, and other open woodland types (generally where there are trees with dense cover for nesting).	**Moderate Potential.** There is suitable nesting habitat for the species (i.e., mixed oak and riparian woodland with dense stands of trees) located in the southeastern portion of the BSA. Furthermore, there are records from the Project vicinity in the eBird data base (i.e., less than two miles from the Project site along Dry Creek Drive). Therefore, the species is considered to have a moderate potential to nest within the BSA.
Vireo bellii pusillus	least Bell's vireo (nesting)	FE/SE/none	Found as a summer resident (late March to late August) in coastal valleys from Monterey County south through coastal southern California to San Diego County. Also occurs at scattered locations along the western border of the deserts. There have been recent records from the Central Valley given its recovery in southern California. It typically nests in dense willow riparian communities but is also	**No Potential.** Though there is no suitable nesting habitat for this subspecies within the BSA, and the subspecies had been extirpated from the Central Valley, it has recently been found sporadically again in the valley (e.g., one nesting record from Merced NWR in 2012). Nonetheless, the subspecies is considered to have no potential to occur within the BSA given the extremely limited number of records in the Central Valley and distance to those recent

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			occasionally found in live oak stands adjacent to drainages.	records.
Baeolophus inornatus	oak titmouse (nesting)	none/none/BCC	This species occurs as a common resident throughout much of California other than the deserts, high Sierra Nevada, and redwood belt. It is generally found in cismontane woodland (particularly oak or riparian woodlands) where it nests in the cavities created by woodpeckers.	**Moderate Potential.** There is suitable nesting habitat for the species (i.e., oak woodland) within the BSA. Furthermore, there are potential nest sites (i.e., woodpecker-created nest holes) in these woodlands. Lastly, there are records from the Project vicinity in the eBird data base (i.e., less than two miles from the Project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have a moderate potential to occur within the BSA.
Icteria virens	yellow-breasted chat (nesting)	none/CSC/none	This species is found as a summer resident mostly in low to mid-elevation coastal, valley, foothill, and desert riparian habitats (up to 4,800 feet in foothill riparian and 6,500 feet east of the Sierra Nevada). Nesting typically occurs in dense riparian vegetation near streams.	**No Potential.** There is no dense riparian vegetation within the BSA. Though there are records from the Project vicinity in the eBird data base (i.e., multiple records from along Dry Creek Drive in the vicinity of the Kaweah Gravel Pits and a couple of records from the riparian habitat associated with Bravo Lake), the BSA does not provide the

TABLE 1

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
				type of dense riparian habitat (e.g., willow scrub) used as nesting habitat by the species in the western United States. Therefore, the species has no potential to occur within the BSA as a nesting species.
Agelaius tricolor	tricolored blackbird (nesting)	none/CSE/BCC	The species is a resident species in annual grassland, oak savannah and freshwater marsh within the Central Valley and coastal California from Sonoma County to San Diego County. Nesting habitat typically involves emergent freshwater marsh, but may include tall, dense stands of willow, blackberry, thistle, nettles, or grasses. Grasslands or rangeland providing an abundant source of food (e.g., large numbers of grasshoppers or butterfly larvae) often are within at least three miles of nest colonies.	**No Potential.** There is a CNDDB occurrence from about 1.3 miles west-northwest of Lake Kaweah Dam, 2 miles north of the Highway 216 and 198 intersection, and 4 miles east of Woodlake. However, there is no suitable nesting habitat (e.g., vegetation that is flooded, spinous, or otherwise defended against easy access by mammalian predators) for the species within the BSA. Therefore, it is considered to have no potential to nest within the BSA.
Spinus lawrencei	Lawrence's goldfinch (nesting)	none/none/BCC	This species is found as a breeding species in oak woodlands, other arid woodlands, and chaparral in the lower	**Low Potential.** There is suitable nesting habitat for the species (i.e., mixed oak and riparian woodland) located in the

TABLE 1

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			elevations of northern California and in riparian woodland, pinyon-juniper woodland, and lower montane communities in southern California. A local water source and a source of abundant seeds are required habitat components.	southeastern portion of the Project site. Furthermore, there are records from the Project vicinity in the eBird data base (i.e., less than two miles from the Project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to nest in the BSA.
MAMMALS				
Vulpes macrotis mutica	San Joaquin kit fox	FE/ST/none	This taxon is found in the San Joaquin Valley from Contra Costa County south to Kern County. It is also found in the dry interior valleys of the Coast Ranges (e.g., Salinas and Santa Clara valleys). It occurs in open, sparsely vegetated areas of low relief (typically in native or non-native grassland or alkali sink scrub).	**Low Potential.** Though there is suitable habitat for the taxon within the BSA (i.e., non-native annual grassland), and it has been recorded 2.7 miles northwest and 4.8 miles southwest of the Project site, surveys of the annual grassland within the BSA found no potential dens or other evidence of the taxon to suggest it occurs within the BSA. In addition, the sandy soils on the Project site may preclude the creation and maintenance of burrows that do not easily collapse (hence the lack of California ground squirrel burrows). Therefore, the

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
				taxon is considered to have only a low potential to occur in the annual grassland associated with the easternmost and northernmost portions of the BSA.
Taxidea taxus	American badger	none/CSC/none	This species is found as a resident species at scattered localities throughout California (except in the coastal redwood region). Generally, occurs in extensive, open habitats in the vicinity of abundant rodent populations.	**No Potential.** Though there is suitable habitat for the species within the BSA (i.e., non-native annual grassland), surveys have found no evidence to suggest that the species occurs within the BSA (i.e., suitable dens or diggings). In addition, the BSA is fragmented from other habitat that could be occupied by the species. Therefore, the species is considered to have no potential to occur within the BSA or otherwise be affected by the Project.
Antrozous pallidus	pallid bat	none/CSC/none	This species is found in a variety of habitats from sea level to approximately 6,000 feet. Day roosts are typically found in buildings, bridges, rocky outcrops, mines, caves, and trees. Night roosts are generally provided by bridges, mines, and caves.	**No Potential.** No suitable day or night roosts for the species occur on or immediately adjacent to the BSA. Therefore, it has no potential to occur within the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Eumops perotis californicus	western mastiff bat	none/CSC/none	This subspecies is found as an uncommon resident in southern California, but also occurs along the lower west slope of the Sierra Nevada and in the interior Coast Ranges as far north as the Tumey Hills (eastern San Benito County). Roosts are typically found in crevices in cliff faces, cracks in boulders, or occasionally in buildings (particularly where the roost allows for a large vertical drop).	**No Potential.** No suitable day or night roosts for the species occur on or immediately adjacent to the BSA. Therefore, it has no potential to occur within the BSA.
Lasiurus blossevillii	western red bat	none/CSC/none	The species occurs throughout the lowland portions of California west of the Sierra Nevada crest and desert regions (typically in riparian forest or orchards). It is less abundant in coniferous forest. Roosting sites are found in tree or shrub foliage between 2- and 40-feet above ground (typically in large cottonwoods, sycamores, walnuts, and willows).	**No Potential.** Though suitable habitat and roosts for the species occur within the BSA, there are no known occurrences from Tulare County. The nearest records to the BSA (2 records) are from northwestern Fresno County. Therefore, the species is considered to have no potential to occur within the BSA.

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA

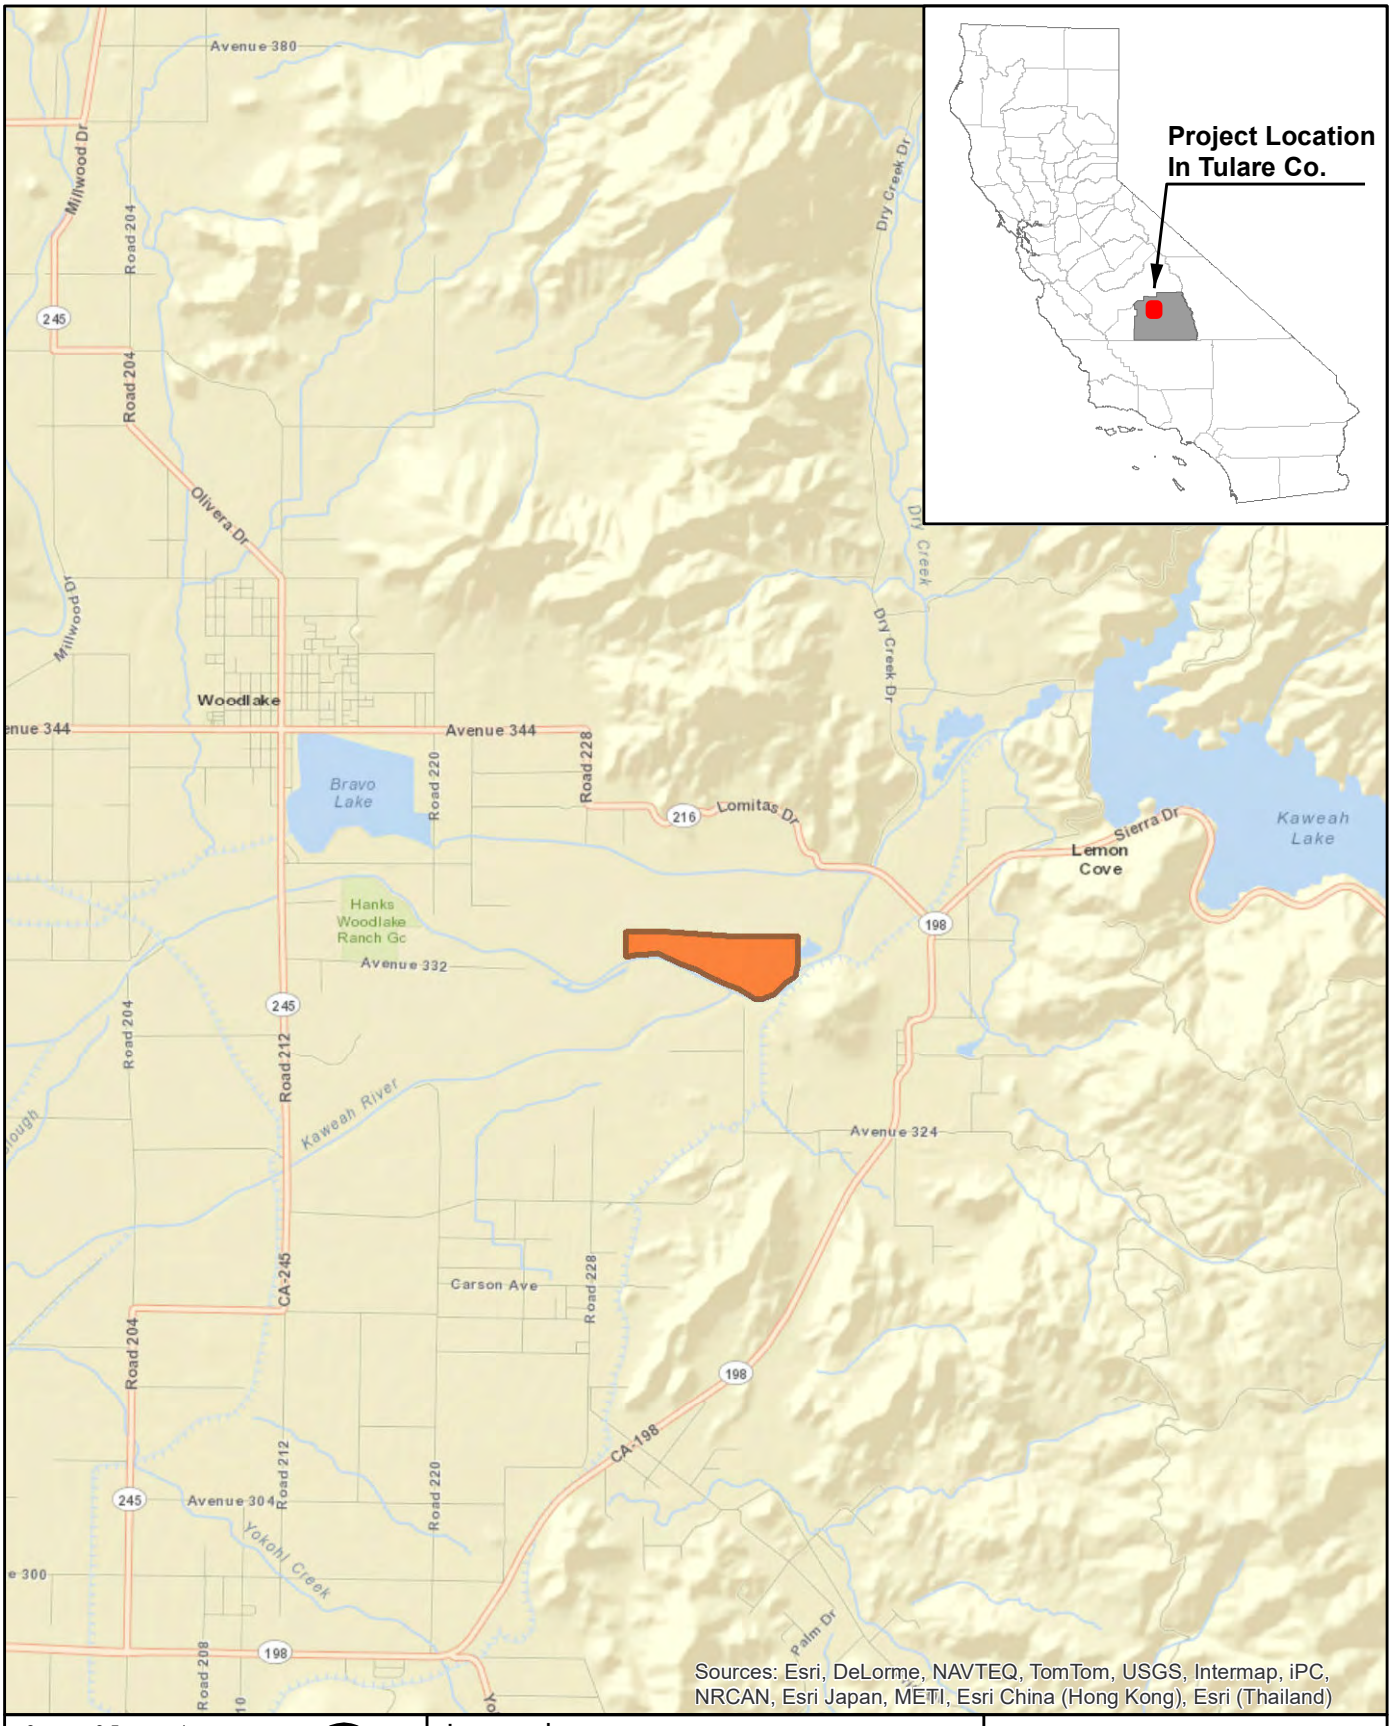
LIKELIHOOD OF OCCURRENCE DEFINITIONS

Known to Occur	Taxon was observed within or immediately adjacent to the Project site during the May 16, 2011, September 18, 2013, or October 15, 2020 surveys or has previously been documented within or immediately adjacent to the Project site.
High Potential	Taxon has not been documented within or immediately adjacent to the Project site but should be expected on more than 50% of visits to suitable habitat on and near the Project site during the appropriate season and time of day.
Moderate Potential	Taxon has not been documented within or immediately adjacent to the Project site but should be expected on less than 50% of visits to suitable habitat on and near the Project site during the appropriate season and time of day.
Low Potential	Taxon has not been documented within or immediately adjacent to the Project site nor is it likely to occur on or near the Project site, but its presence cannot be completely discounted due to incomplete information on the taxon's distribution or habitat requirements.
No Potential	Taxon does not occur within or immediately adjacent to the Project site due to the lack of required habitat features for the taxon, or the known range of the taxon is well defined and does not include the Project vicinity.



Note: This table has changed from that provided with the *Tulare Irrigation District McKay Point Reservoir Project Biological Resources Evaluation, Tulare County, California* (Bumgardner Biological Consulting 2013) given the following: (1) addition of special-status species that were previously undocumented in the query area, (2) addition of new occurrences of special-status species that had previously been document in the query area (3) changes to the state and/or federal regulatory status of species that had previously been documented in the query area., and (4) removal of some species from the CDFW Special Animals List. Hence, this table replaces Table 1 from the 2013 Biological Resources Evaluation.

AIR QUALITY, HEALTH RISK, AND CLIMATE CHANGE IMPACT ASSESSMENT

Tulare Irrigation District
McKay Point Reservoir Project

November 23, 2021

EXECUTIVE SUMMARY

This Air Quality, Health Risk, and Climate Change Impact Assessment (Report) has been prepared to quantify and determine the significance of air quality, health risk, and climate change impacts associated with the proposed excavation, construction, and operation of the McKay Point Reservoir (the Project). The Project location is provided in Figure 1 (Appendix A).

The following Project features would affect air emissions and were assessed.

- Excavation of approximately 110 acres, removal of approximately 16.5 million gross tons of material, and 11.55 net million tons during the excavation phase of the Project. The excavation phase also involves the installation of a slurry wall. For the purposes of this analysis, the excavation is assumed to last 23 years and have a maximum annual excavation rate of approximately 920,000 tons and an annual maximum production rate of approximately 650,000 tons finished product for offsite shipment.
- Construction of inflow and outflow channels, a weir (powered by electricity), and a floating barge pump (powered by a diesel generator).
- Operation of the reservoir, and the associated activities including off-road engine use, vehicle travel, and minor road/landscape maintenance.

Directly adjacent to the Project site there has been an aggregate mining and processing facility that has operated on the Seaborn site since the early 1950s (Figure 2, Appendix A). The emissions data provided by the previous operators was used to calculate the baseline for this Project. Project emissions were estimated by subtracting emissions occurring at the Seaborn site (baseline) from predicted emissions with the Project (future). Baseline emissions were estimated using historical aggregates production records. As a feature of the Project design, the processing rate of the excavated aggregate would be managed such that it would not exceed baseline activity levels.

This analysis uses San Joaquin Valley Unified Air Pollution Control District (SJVAPCD) approved methods in combination with current best practices, including methods from the Health Risk Assessment (HRA) Guidelines (OEHHA, 2015), to quantify the impacts associated with the Project. Methods or guidance provided by the San Diego Air Pollution Control District (SDPACD) and South Coast Air Quality

Management District (SCAQMD) were also used in cases where SJVAPCD guidance was outdated or inapplicable. Use of SDAPCD and SCAQMD guidelines are discussed in the Report Sections 2.4.2 and 3.1.4, respectively. Project emissions are compared to applicable significance thresholds and analyzed with EPA AERMOD and HARP2 HRA modeling software.

The Report has the following findings with respect to Air Quality and Greenhouse Gasses (GHG), which address the specific impact statements within the California Environmental Quality Act (CEQA) Guidelines Appendix G Environmental Checklist Form (California Code of Regulations, Title 14):

1. Air Quality

a) The Project would NOT conflict with or obstruct implementation of any applicable air quality plan. Potential conflicts with applicable air quality plans have been analyzed and ruled out (see Section 2.5.1).

The Project would be required to comply with regional air quality rules promulgated by the SJVAPCD and participate in reducing air pollutant emissions. Aggregate production, which would occur during the Project excavation phase, is proportional to population growth, which is a factor that is accounted for in air quality plans. The Project would not obstruct implementation of applicable SJVAPCD air quality plans and therefore be less than significant.

b) The Project would NOT result in a cumulatively considerable net increase of any criteria pollutant for which the Project region is non-attainment under an applicable Federal or State ambient air quality standard (see Section 2.5.2).

Table ES-1 presents Project annual emissions for each criteria pollutant and the associated significance criteria established by SJVAPCD. As required by CEQA, the level of significance is determined by the net change (or increment) between pre-project environmental conditions (baseline) and post-project (future) environmental conditions. Because regulatory requirements now require cleaner engines and the use of new technology, the Project source emission values shown in Table ES-1 are at times a negative value. Negative values represent a reduction in emissions from baseline due to cleaner engines or new technologies. This is a beneficial impact resulting from the Project. As shown in Table ES-1, Project emissions do not exceed the SJVAPCD significance criteria and are therefore less than significant.

Table ES-1 Annual Project Emissions and Comparison to APCD Significance Criteria

Criteria Pollutant	Project Permitted Sources (tons/yr)	Permitted Sources Significance Threshold (tons/yr)	Exceeds Permitted Sources Threshold?	Project Permit Exempt Sources (tons/yr)	Permit Exempt Sources Significance Threshold	Exceeds Permit Exempt Threshold?
ROG	-0.08	10	No	-0.35	10	**No**
CO	-0.27	100	No	2.20	100	**No**
NO_X	-0.66	10	No	-5.10	10	**No**

Criteria Pollutant	Project Permitted Sources (tons/yr)	Permitted Sources Significance Threshold (tons/yr)	Exceeds Permitted Sources Threshold?	Project Permit Exempt Sources (tons/yr)	Permit Exempt Sources Significance Threshold	Exceeds Permit Exempt Threshold?
PM_{10} (total)	-0.02	15	No	14.37	15	**No**
$PM_{2.5}$	-0.03	15	No	5.93	15	**No**
SO_X	-0.01	27	No	-0.10	27	**No**

Source: Appendix C.

Note: Negative values result when the Project emissions are less than the baseline emissions and represent emissions reductions due to newer technology and lower emission equipment.

Impact analysis for a project's potential to exceed or contribute to exceedance of an ambient air quality standard (AAQS) normally involves modeling emissions to predict the concentration of pollutant(s) at the property line. However, SJVAPCD has established a screening level of 100 lb/day that is considered overly conservative such that when emissions are below the screening level, it can be assumed that the emissions would not result in a significant impact. SJVAPCD allows emission reduction from the implementation of mitigation measures to be included in the screening analyses. Project emissions with mitigation measures, as necessary, are compared to the 100 lb/day screening level as shown in Table ES-2, and the necessary mitigation measures are discussed below.

Table ES-2 Project On-site Daily Emissions and Model Screening Level Comparison

Criteria Pollutant	CO lbs/day	NO_x lbs/day	PM_{10} lbs/day	$PM_{2.5}$ lbs/day	SO_x lbs/day
Baseline	163	457	260	80	3.2
Excavation	119	221	529	160	0.40
Project	-45	-236	269	80	-2.8
Screening Criteria	100	100	100	100	100
Exceeds Criteria?	**No**	**No**	**Yes**	**No**	**No**

Source: Appendix C.

As shown in Table ES-2, PM_{10} emissions increases associated with the Project may exceed the screening level for PM_{10}. Therefore, the following mitigation measure would be required in order to reduce PM_{10} emissions below the screening thresholds.

Mitigation Measure AQ-1: Unpaved Road Fugitive Dust Control: *Roads upon which material is hauled to the on-site plant for processing shall be controlled by methods that will achieve 90% reduction of fugitive dust. This can be achieved by frequent watering, use of chemical dust suppressants, or a combination of watering and chemical dust suppressants. Other methods which achieve 90% reduction of fugitive dust may be acceptable with Lead Agency approval.*

Mitigated analysis was performed assuming that unpaved roads were controlled at a level of 90% by application of chemical dust suppressants or other equivalent methods. Mitigated results are shown in Table ES-3.

Table ES-3 Mitigated On-site Daily Emissions and Model Screening Level Comparison

Criteria Pollutant	CO (lb/day)	NOx (lb/day)	PM_{10} (lb/day)	$PM_{2.5}$ (lb/day)	SOx (lb/day)
Baseline	163.1	457.1	260.1	79.8	3.2
Excavation	118.5	220.8	344.9	120.7	0.4
Project	-44.6	-236.3	84.8	40.8	-2.8
Screening Criteria	100	100	100	100	100
Exceeds Criteria?	**No**	**No**	**No**	**No**	**No**

Source: Appendix C

c) The Project would not expose sensitive receptors to substantial pollutant concentrations (see Section 2.5.3).

Table ES-4 presents health risk assessment results for the Project and compares them to applicable thresholds.

Health risk is determined based on the change in conditions associated with the implementation of the Project. Emissions sources present in the baseline cease to operate, and emissions from the Project are introduced. Therefore, baseline risk is modeled as negative risk (emissions going away), and Project risk is modeled as positive (new emissions). In many cases, Project emissions end up being lower than those in the baseline, due to newer technologies and updated regulations. In such cases, risk to receptors may be reduced, as the Project results in a reduction of emissions. In cases where risk to a receptor is greater in the baseline than in the Project, the risk is represented as a negative number.

Table ES-4 Project Health Risk Impacts and Comparison to Significance Thresholds

Receptor Figure Label – Type	Receptor Model ID #	Excess Cancer Cases per Million People Exposed	Chronic Hazard Index	Acute Hazard Index
1 – Residence	396	-22.1	0.0	0.000
2 – Residence	397	-16.4	0.0	0.020
3 – Residence	398	4.4	0.23	0.031
4 – Residence	399	3.9	0.14	0.059

Threshold Exceeded?	**N/A**	**No**	**No**	**No**

Source: Appendix E.

Note: These receptors represent locations of highest exposure. Discrepancies between table and appendix values may exist due to rounding. Negative values represent risk levels that when compared to baseline levels are less than the baseline level – resulting in a beneficial impact.
MEIR: Maximum Exposed Individual Receptor; MEIW: Maximum Exposed Individual Worker; PMI: Point of Maximum Impact

As demonstrated in Table ES-4, the Project does not result in exceedances of the significance thresholds and therefore the Project impacts would be less than significant.

d) The Project would not result in other emissions (such as those leading to odors) adversely affecting a substantial number of people (see Section 2.5.4).

Baseline conditions include similar sources to the Project sources that could cause odor. Based on SJVAPCD records, the previous operations did not receive complaints about odor in the past from a substantial number of people. The Project would have similar or upgraded emission controls compared to the Seaborn facility, and in general the Project is further away from receptors than the Seaborn facility. SJVACPD provides a screening table of facilities that are considered sources of significant odors. As seen in the Table 34, aggregate mining and processing facilities are not included in SJVAPCD for potential significant odor generating sources. In addition, SJVAPCD has regulations that require facilities not to present a nuisance to the adjacent areas. Odor complaints are addressed under the SJVAPCD nuisance rule (Rule 4102). The Project would comply with SJVAPCD rules and regulations. Therefore, Project impact related to odor is less than significant.

2. Greenhouse Gasses (GHGs)

a) The Project would not generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment (see Section 3.5.1).

"It is widely recognized that no single project could generate enough GHG emissions to noticeably change the global climate temperature. However, the combination of GHG emissions from past, present, and future projects could contribute substantially to global climate change. GHG emissions, and their associated contribution to climate change, are inherently a cumulative impact issue. Therefore, project-level impacts of GHG emissions are treated as one-in-the-same as cumulative impacts." (SJVAPCD, 2015, p. 111). As recognized by SJVAPCD in the preceding quote, climate change is a cumulative effect and no single project is large enough to impact climate change. Thus, the Project would not, by itself, either directly or indirectly result in a significant impact on the environment due to generation of GHG emissions.

This concept is also reflected in California Air Resources Board's (CARB's) 2017 Scoping Plan, which regulates fuels at a level in the supply chain above the Project, such that the Project has no choice but to use energy in California that is already regulated. The Project therefore does not have its own emissions, but is simply a location in which GHG emissions are taking place as a result of fuel that is already regulated. Therefore, the Project itself cannot have a significant impact on the environment.

b) The Project would not conflict with an applicable plan, policy or regulation adopted for the purpose of reducing the emissions of GHGs. Potential conflicts with applicable air quality plans have been analyzed and ruled out (see section 3.5.2).

Project emissions of GHGs are presented in Table ES-5 below, primarily for purposes of disclosure. SJVAPCD guidance on impact analysis and threshold determination for GHGs is outdated and the methods used in SCAQMD which are more recent were used to evaluate significance of Project GHG emissions. Specifically, SCAQMD excludes emissions from sectors that are required to participate in the Cap-and-Trade Program administered by the California Air Resources Board (CARB) as discussed in the *Final Negative Declaration for Phillips 66 Los Angeles Refinery Carson Plant - Crude Oil Storage Project* (SCAQMD, 12/12/2014).[1] The Project would emit GHGs from fuel burned in engines. Transportation fuel suppliers and importers are required to report emissions under the Cap-and-Trade which is designed to reduce GHG emissions as needed to achieve emissions reductions described in related planning documents which primarily consists of the Assembly Bill (AB) 32 Scoping Plan. Thus, the emissions reductions will occur at a level in the supply chain above the Project which will have no choice but to use fuels with GHG intensities that are consistent with the current Scoping Plan.

[1] http://www.aqmd.gov/home/research/documents-reports/lead-agency-permit-projects/permit-project-documents---year-2014

Table ES-5 Project GHG Emissions

Source	CO_2e (MT/yr)
Baseline Emissions	1,280
Future Emissions (Max Year)	2,283
Total Project Emissions	1,003
Screening Criteria (SCAQMD)	10,000
Project Exceeds Screening Criteria?	**No**

Source: Appendix C.

Note: http://www.aqmd.gov/home/rules-compliance/ceqa/air-quality-analysis-handbook/ghg-significance-thresholds.

In summary, GHG emissions from the Project are less than the SCAQMD GHG screening criteria. In addition, each Project source would emit GHGs in amounts consistent with the AB 32 Scoping Plan. Therefore, the Project impact related to GHG emissions is less than significant.

1.0 INTRODUCTION

This Air Quality and Climate Change Impact Assessment (AQCCIA) presents technical information and analysis describing reasonably foreseeable changes to the environment that would occur with the McKay Point Reservoir Project (Project) located near Lemon Cove, California (Figure 1, Appendix A).

The Project is within a mining resource zone of regional significance (CGS, 2018). Accordingly, there are aggregate mining operations in the immediate vicinity of the Project site. The CEMEX Lemon Cove aggregate facility is immediately to the north, and their Stillwell Aggregate Mine is approximately 1.0 miles to the northeast of the Project site. The Kaweah River Rock aggregate mining and processing facility was located immediately to the west on the Seaborn site, and the Kaweah South Project lies approximately 1.0 miles to the southwest of the Project site. See Figure 2 (Appendix A) which shows the regional Project site setting.

The potential air quality impacts are analyzed for the following three phases: excavation of the site for the reservoir (the excavation phase); construction of the reservoir (the construction phase); and, operation of the reservoir (the operation phase).

The Excavation Phase

The excavation phase would involve excavating approximately 110 acres in order to provide a pit of sufficient size to allow the reservoir to be constructed. The excavation is anticipated to occur up to approximately a 23-year period and approximately 16.5 million gross tons of raw material would be excavated. The raw aggregate material would be excavated and processed onsite by West Coast Aggregate (WCA). Processing of the raw material would include a wash/screen plant and a crush/recycle plant. The production of Portland Cement Concrete (PCC) grade aggregate would produce approximately a total 11.55 million net tons of PCC grade aggregate.

Sand and gravel (aggregate) mining and processing activities have been conducted at the adjacent Seaborn site since the late 1940's. During the ten-year period of 1997 to 2006, the average net tonnage produced on the Seaborn site was 535,903 tons. The peak year during that period was 2005, with 650,673 tons produced on the Seaborn site. Based on this historic data, 500,000 tons annually was chosen as a conservative representation of the average year in the baseline, and 650,000 tons annually was chosen to represent the maximum year in the baseline.

The excavation, storage and production of PCC grade aggregate would be managed by WCA such that the baseline maximum production rate of the processed aggregate by WCA would not exceed the baseline production rates previously being done at the mining operation located on the Seaborn site. Once processed, approximately 70 percent of the excavated materials would be of marketable quality, which is referred to as net tons. This means a year's excavation of 920,000 gross tons would produce approximately 650,000 net tons of processed marketable construction-grade aggregate. Therefore, the number of on-road trucks transporting the material offsite on public roads to WCA's customers would not result in an increase to the baseline number of trucks used at the Seaborn site.

The crush/recycle plant (powered by a diesel generator) would be used to break up oversized pieces of rock prior to processing in the wash/screen plant. The crush/recycle plant would also be used to recycle used concrete and asphalt brought in from offsite. WCA would also import materials to be blended with the aggregate if required by their customers. For the purposes of this analysis, it was assumed that when recycling and/or blending activities were taking place, the excavation and processing of aggregated would be reduced such that the total emissions associated with excavation/processing of aggregate combined with the emissions associated with the transport and processing/blending of recycled materials and additives would not result in an increase to baseline. The Project would be managed such that this would be the case.

A slurry wall, needed to minimize groundwater seepage into the pit, would also be installed around the perimeter of the site during the early stage of the excavation phase to allow for dry mining techniques during excavation. The slurry wall would remain after excavation and become part of the reservoir.

The Construction Phase

The reservoir construction phase would include installation of following:

- Inflow and outflow channels;
- Electrically operated weir;
- Floating barge pump (diesel);
- Energy dissipation pools;
- 10,000-gallon diesel fuel storage tank with secondary containment; and
- Two diesel-fired generators.

Due to the low volatility of diesel, the San Joaquin Valley Unified Air Pollution Control District (SJVAPCD) does not consider diesel tank emissions to be sufficiently consequential to require permitting; therefore, diesel storage tank emissions were not considered in this analysis (see Section 2.1.3.2).

The Operation Phase

The reservoir operation phase would involve the proposed basin being filled an average of two times per year for a total usable yearly volume of 9,100 acres-feet. Approximately 3,580 acres-feet would flow by gravity into the adjacent St. Johns River and the remaining 5,520 acres-feet could be pumped out at a maximum flow rate of 160 cubic feet per second (cfs). Operation phase emissions would result from the two diesel generators used by the pump, a backhoe used for site maintenance, and onsite trucks used for water spray, refueling of the diesel generator, other minor site or equipment maintenance.

2.0 AIR QUALITY

This AQCCIA was prepared using current best practices including the Guidance for Assessing and Mitigating Air Quality Impacts (GAMAQI) (SJVAPCD, 2015) and the Air Toxics Hot Spots Program Guidance Manual for Preparation of Health Risk Assessments (OEHHA, 2015). Methods or guidance provided by the San Diego Air Pollution Control District (SDPACD) and South Coast Air Quality Management District (SCAQMD) were also used in cases where SJVAPCD guidance was outdated or inapplicable. Use of SDAPCD and SCAQMD guidelines are discussed in Sections 2.4.2 and 3.1.4 respectively.

2.1 Regulatory Setting

Both the state and the federal government have established health-based criteria called Ambient Air Quality Standards (AAQS) for six air pollutants. These "criteria pollutants" are ozone (O_3), carbon monoxide (CO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), lead (Pb), and suspended particulate matter ($PM_{2.5}$ and PM_{10}), each of which is described more fully In Appendix B (Characteristics of Air Pollutants). The regulatory status of the criteria pollutants within the SJVAPCD and AAQS which are presented in Table 1. Many constituents in air emissions other than criteria pollutants result in health effects and are regulated as toxic air contaminants (TACs) using health risk assessment methods (i.e., as opposed to comparing concentration of criteria pollutant to an AAQS). Diesel particulate matter (DPM) and respirable crystalline silica (RCS) are two TACs of concern associated with Project sources and are also discussed in Appendix B.

2.1.1 Federal

2.1.1.1 Criteria Pollutants

The Clean Air Act (CAA) is the comprehensive Federal law that regulates air emissions from stationary and mobile sources. Congress established much of the basic structure of the CAA in 1970, and made major revisions in 1977 and 1990. "The Clean Air Act in a Nutshell: How It Works" (EPA, 2013) contains a thorough yet concise summary of how US EPA implements the CAA. Table 1 presents Federal and State AAQS. Table 2 identifies how the CAA applies to The Project.

Table 1 State and Federal Ambient Air Quality Standards

Pollutant	Averaging Time	California Standards[1]		National Standards [2]		
		Concentration [3]	Method [4]	Primary [3,5]	Secondary [3,6]	Method [7]
Ozone (O_3) [8]	1 Hour	0.09 ppm (180 µg/m^3)	Ultraviolet Photometry	—	Same as Primary Standard	Ultraviolet Photometry
	8 Hour	0.070 ppm (137 µg/m^3)		0.070 ppm (137 µg/m^3)		
Respirable Particulate Matter (PM_{10}) [9]	24 Hour	50 µg/m^3	Gravimetric or Beta Attenuation	150 µg/m^3	Same as Primary Standard	Inertial Separation and Gravimetric Analysis
	Annual Arithmetic Mean	20 µg/m^3		—		
Fine Particulate Matter ($PM_{2.5}$) [9]	24 Hour	—	—	35 µg/m^3	Same as Primary Standard	Inertial Separation and Gravimetric Analysis
	Annual Arithmetic Mean	12 µg/m^3	Gravimetric or Beta Attenuation	12.0 µg/m^3	15 µg/m^3	
	1 Hour	20 ppm (23 mg/m^3)		35 ppm (40 mg/m^3)	—	

Pollutant	Averaging Time	California Standards[1]		National Standards [2]		
		Concentration [3]	Method [4]	Primary [3,5]	Secondary [3,6]	Method [7]
Carbon Monoxide (CO)	8 Hour	9.0 ppm (10 mg/m^3)	Non-Dispersive Infrared Photometry (NDIR)	9 ppm (10 mg/m^3)	—	Non-Dispersive Infrared Photometry (NDIR)
	8 Hour (Lake Tahoe)	6 ppm (7 mg/m^3)		—	—	
Nitrogen Dioxide (NO_2)[10]	1 Hour	0.18 ppm (339 µg/m^3)	Gas Phase Chemi-luminescence	100 ppb (188 µg/m^3)	—	Gas Phase Chemi-luminescence
	Annual Arithmetic Mean	0.030 ppm (57 µg/m^3)		0.053 ppm (100 µg/m^3)	Same as Primary Standard	
Sulfur Dioxide (SO_2)[11]	1 Hour	0.25 ppm (655 µg/m^3)	Ultraviolet Fluorescence	75 ppb (196 µg/m^3)	—	Ultraviolet Flourescence; Spectro-photometry (Pararosaniline Method)
	3 Hour	—		—	0.5 ppm (1,300 µg/m^3)	
	24 Hour	0.04 ppm (105 µg/m^3)		0.14 ppm (for certain areas)[10]	—	
	Annual Arithmetic Mean	—		0.030 ppm (for certain areas)[10]	—	
Lead[12,13]	30 Day Average	1.5 µg/m^3	Atomic Absorption	—	—	High Volume Sampler and Atomic Absorption
	Calendar Quarter	—		1.5 µg/m^3 (for certain areas)[12]	Same as Primary Standard	
	Rolling 3-Month Average	—		0.15 µg/m^3		
Visibility Reducing Particles[14]	8 Hour	See footnote 13	Beta Attenuation and Transmittance through Filter Tape	**No National Standards**		
Sulfates	24 Hour	25 µg/m^3	Ion Chromatography			
Hydrogen Sulfide	1 Hour	0.03 ppm (42 µg/m^3)	Ultraviolet Fluorescence			
Vinyl Chloride[12]	24 Hour	0.01 ppm (26 µg/m^3)	Gas Chromatography			

Source: CARB, May 4, 2016.

Up to date as of December 9, 2020. See footnotes on following page.

1. California standards for ozone, carbon monoxide (except 8-hour Lake Tahoe), sulfur dioxide (1 and 24 hour), nitrogen dioxide, and particulate matter (PM_{10}, $PM_{2.5}$, and visibility reducing particles), are values that are not to be exceeded. All others are not to be equaled or exceeded. California ambient air quality standards are listed in the Table of Standards in Section 70200 of Title 17 of the California Code of Regulations.
2. National standards (other than ozone, particulate matter, and those based on annual arithmetic mean) are not to be exceeded more than once a year. The ozone standard is attained when the fourth highest 8-hour concentration measured at each site in a year, averaged over three years, is equal to or less than the standard. For PM_{10}, the 24-hour standard is attained when the expected number of days per calendar year with a 24-hour average concentration above 150 µ g/m3 is equal to or less than one. For $PM_{2.5}$, the 24-hour standard is attained when 98 percent of the daily concentrations, averaged over three years, are equal to or less than the standard. Contact the US EPA for further clarification and current National policies.
3. Concentration expressed first in units in which it was promulgated. Equivalent units given in parentheses are based upon a reference temperature of 25°C and a reference pressure of 760 torr. Most measurements of air quality are to be corrected to a reference temperature of 25°C and a reference pressure of 760 torr; ppm in this table refers to ppm by volume, or micromoles of pollutant per mole of gas.
4. Any equivalent measurement method, which can be shown to the satisfaction of the ARB to give equivalent results at or near the level of the air quality standard, may be used.

5. National Primary Standards: The levels of air quality necessary, with an adequate margin of safety, to protect the public health.
6. Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.
7. Reference method as described by the US EPA. An "equivalent method" of measurement may be used but must have a "consistent relationship to the reference method" and must be approved by the US EPA.
8. On October 1, 2015, the National 8-hour ozone primary and secondary standards were lowered from 0.075 to 0.070 ppm.
9. On December 14, 2012, the National annual $PM_{2.5}$ primary standard was lowered from 15 µg/m^3 to 12.0 µg/m^3. The existing National 24- hour $PM_{2.5}$ standards (primary and secondary) were retained at 35 µg/m^3, as was the annual secondary standard of 15 µg/m^3. The existing 24-hour PM_{10} standards (primary and secondary) of 150 µg/m^3 also were retained. The form of the annual primary and secondary standards is the annual mean, averaged over 3 years.
10. To attain the 1-hour National standard, the 3-year average of the annual 98th percentile of the 1-hour daily maximum concentrations at each site must not exceed 100 ppb. Note that the National 1-hour standard is in units of parts per billion (ppb). California standards are in units of parts per million (ppm). To directly compare the National 1-hour standard to the California standards the units can be converted from ppb to ppm. In this case, the National standard of 100 ppb is identical to 0.100 ppm.
11. On June 2, 2010, a new 1-hour SO_2 standard was established and the existing 24-hour and annual primary standards were revoked. To attain the 1-hour National standard, the 3-year average of the annual 99th percentile of the 1-hour daily maximum concentrations at each site must not exceed 75 ppb. The 1971 SO_2 National standards (24-hour and annual) remain in effect until one year after an area is designated for the 2010 standard, except that in areas designated nonattainment for the 1971 standards, the 1971 standards remain in effect until implementation plans to attain or maintain the 2010 standards are approved. Note that the 1-hour National standard is in units of parts per billion (ppb). California standards are in units of parts per million (ppm). To directly compare the 1-hour National standard to the California standard the units can be converted to ppm. In this case, the National standard of 75 ppb is identical to 0.075 ppm.
12. The CARB has identified lead and vinyl chloride as 'toxic air contaminants' with no threshold level of exposure for adverse health effects determined. These actions allow for the implementation of control measures at levels below the ambient concentrations specified for these pollutants.
13. The National standard for lead was revised on October 15, 2008 to a rolling 3-month average. The 1978 lead standard (1.5 µg/m^3 as a quarterly average) remains in effect until one year after an area is designated for the 2008 standard, except that in areas designated nonattainment for the 1978 standard, the 1978 standard remains in effect until implementation plans to attain or maintain the 2008 standard are approved.
14. In 1989, CARB converted both the general statewide 10-mile visibility standard and the Lake Tahoe 30-mile visibility standard to instrumental equivalents, which are "extinction of 0.23 per kilometer" and "extinction of 0.07 per kilometer" for the statewide and Lake Tahoe Air Basin standards, respectively.

Table 2 Applicability of US EPA Activities under the CAA to the Project

US EPA Activity	Applicable to Project Sources?
Establish air quality standards.	Yes, see **Impact AQ-2**.
Designate quality of air in attainment areas.	No, the Project is not an attainment area.
Administrate state implementation plans.	No, the Project is not a SIP.
Require additional programs in nonattainment areas.	Yes, the Project would comply with SJVAPCD programs and rules that address nonattainment.
Provide guidance on control techniques.	No, the Project would employ standard controls.
Regulate interstate air pollution.	No, the Project is not a state.
Require plans to maintain clean air after a nonattainment area meets the standard.	Yes, the Project would comply with SJVAPCD programs and rules that maintain attainment.
Preserve clean air in attainment areas.	Yes, the Project would comply with SJVAPCD programs and rules that preserve attainment.
Adopt National standards for new stationary sources.	Yes, new stationary sources at the Project that have an applicable New Source Performance Standard (NSPS) are discussed in this subchapter.

US EPA Activity	Applicable to Project Sources?
Adopt National standards or guidelines for consumer and commercial products.	No, the Project does not buy products that emit air pollutant from vendors outside the country.
Adopt National standards for new vehicles and engines, and fuels.	No, the Project does not manufacture vehicles, engines, or fuels.
Regulate emissions from oil drilling on the Outer Continental Shelf.	No, the Project is not drilling oil or located on the Outer Continental Shelf.
Regulate hazardous air pollutants.	Yes, the Project is subject to the NESHAP for engines as discussed in this subchapter.
Protect visibility in National parks by regulating regional haze.	No, the Project is approximately 10 miles from the boundary of Sequoia National Park but does not include a major stationary source.
Control acid rain by regulating NO_2 and SO_2 emissions from power plants.	No, the Project does not include a power plant or other major source of combustion pollutants.
Protect stratospheric ozone by regulating ozone-depleting compounds (e.g., chlorofluorocarbons).	No, the Project would purchase refrigerants and other classes of products from a U.S. vendor.
Regulate major sources of air pollution by administrating a Federal operating permit program.	No, the Project is a minor source that does not require a Federal operating permit.

New Source Performance Standards – Title 40, Code of Federal Regulations (CFR), Part 60

Subpart OOO (Nonmetallic Mineral Processing Plants) is applicable to new, modified, or reconstructed nonmetallic mineral processing facilities (with certain exceptions, such as fixed sand and gravel plants and crushed stone plants with capacities of 25 tons per hour or less, or portable sand and gravel plants and crushed stone plants with capacities of 150 tons per hour or less). Subpart OOO restricts emissions from affected facilities equipped with capture systems used to capture and transport particulate matter to a control device. Emissions are prohibited in excess of 0.032 grams per dry standard cubic meter (g/dscm) (0.014 grains per dry standard cubic feet [gr/dscf]), and from exhibiting visible emissions based on quarterly monitoring. Subpart OOO also prohibits the discharge of any fugitive emissions from affected facilities without capture systems and the discharge of fugitive emissions escaping capture systems that exhibit greater than 7 percent opacity (12 percent for crushers without capture systems).

Subpart IIII (Stationary Compression Ignition Internal Combustion Engines) is applicable to new, modified, or reconstructed stationary engines and would apply to the generators. However, the requirements would be superseded by application of the best available control technology (BACT) which will be more stringent, and particularly near 2030 when the generators are expected to be installed.

Regulations Affecting New Diesel Engines

US EPA regulates emissions from new non-road (i.e., off-road, portable, and stationary) internal combustion engines by tiered standards (e.g., compression-ignition engines in 40 CFR 89.112, 40 CFR 1039.101, and 40 CFR 1039.102). Emissions from new non-road engines are regulated using standards that apply by model year, class of vehicle, and fuel type (e.g., heavy-heavy duty diesel engines in 40 CFR 86.004-11, 40 CFR 86.007-11, and 40 CFR 86.099-11). These regulations affect manufacturers but are relevant to the Project because diesel engines are the primary source of Project emissions besides dust.

Engine tiers are emissions standards that were phased-in by size and model year between 1996 and 2015. Tier 0 engines are engines that were built before the applicable engine tier standard came into effect for each engine size. Although the regulations require Tier 4 Final engines in 2015, manufacturing has not kept up with demand in the 100 to 174 hp and 750+ hp size categories. Table 3 presents the emissions factors for each tier.

Table 3 Engine Tier Emissions Standards

Engine Tier	NOx + NMHC (g/hp-hr)	NMHC (g/hp-hr)	Nox (g/hp-hr)	CO (g/hp-hr)	PM (g/hp-hr)
1	Ns	1.0	6.9	8.5	0.40
2	4.9	Ns	Ns	2.6	0.15
3	3.0	Ns	Ns	2.6	0.15
4 Interim	3.0	Ns	Ns	2.6	0.015
4 Final	Ns	0.19	0.3	2.6	0.015

Notes: ns = no standard; and 1.341 hp/kW is used to convert kW in the regulation to hp in this table.

Regulations Affecting Sources of Hazardous Air Pollutants

The Federal Clean Air Act Amendments (CAAA) Section 112(k) requires the EPA to reduce hazardous air pollutant (HAP) risks in urban areas. The EPA's strategy for reducing these risks is discussed in the *Integrated Urban Air Toxics Strategy*. Among the major new programs are the operating permits program (Title V) and provisions to phase out ozone-depleting substances (Title VI). Existing programs that have seen major changes due to the amendments include attainment provisions for the National Emissions Standards for Hazardous Air Pollutants (NESHAP) program.

The provisions in Title I that address the control of HAP emissions, or air toxics, include provisions for the promulgation of NESHAP, or maximum achievable control technology (MACT) standards, as well as several related programs to enhance and support the NESHAP Program. The activities and responsibilities required under Section 112 directly affect not only the EPA but State and local regulatory agencies as well. In addition to air quality agencies administering the majority of Section 112, the storage of acutely hazardous materials above threshold quantities is administrated under Section 112® by the State Office of Emergency Management (OEM) through the local Certified Unified Permitting Agencies (CUPAs).

The Project's generators to be installed would be subject to the Reciprocating Internal Combustion Engine (RICE) NESHAP (40 CFR 63, Subpart ZZZZ). The engines would need to meet BACT when installed. Such engines would require monitoring and recordkeeping under this NESHAP.

2.1.2 State

The California Air Resources Board (CARB) coordinates and oversees both state and federal air pollution control programs in California. CARB oversees activities of local air districts and is responsible for incorporating air quality management plans developed by each air district into the State Implementation Plan (SIP) for Federal EPA approval. CARB maintains air quality monitoring stations throughout the State in conjunction with local air districts. Data collected at these stations are used by CARB and EPA to classify areas as "attainment" or "nonattainment" with respect to each pollutant and to monitor progress towards attaining air quality standards. ARB has divided the State into 15 air basins. Significant authority for air quality control is delegated to local air districts that regulate emissions from stationary sources and develop attainment plans.

2.1.2.1 Criteria Pollutants

The State of California began to set California ambient air quality standards (CAAQS) in 1969. The CAAQS are generally more stringent than the NAAQS. In addition to the six criteria pollutants covered by the NAAQS, there are CAAQS standards for sulfates, hydrogen sulfide, vinyl chloride, and visibility reducing particles. These standards are also listed in Table 1.

Originally, there were no deadlines for the air districts to meet the CAAQS, or to be in "attainment" with the CAAQS. However, the California Clean Air Act (CCAA) provided a timeframe and a planning structure to promote their attainment levels. The CCAA required air districts that did not have air quality in their air basins that met the standards (nonattainment areas) in the State to prepare attainment plans and proposed to classify each such area on the basis of the submitted plan. The attainment plans require a minimum 5 percent annual reduction in the emissions of nonattainment pollutants unless all feasible measures have been implemented. The Tulare County area of the San Joaquin Valley Air Basin (SJVAB) is currently classified as a nonattainment area for three criteria pollutants: O_3, PM_{10}, and $PM_{2.5}$.

2.1.2.2 Toxic Air Contaminants

The CARB Statewide comprehensive air toxics program was established in the early 1980s. The Toxic Air Contaminant Identification and Control Act (AB 1807, 1983) created California's program to reduce exposure to air toxics. The Air Toxics "Hot Spots" Information and Assessment Act (AB 2588, 1987) requires a Statewide air toxics inventory, notification of people exposed to a significant health risk, and facility plans to reduce these risks.

Under AB 1807, CARB is required to use certain criteria in the prioritization for the identification and control of air toxics. In selecting substances for review, CARB must consider criteria relating to "the risk of harm to public health, amount or potential amount of emissions, manner of, and exposure to, usage of the substance in California, persistence in the atmosphere, and ambient concentrations in the community." AB 1807 also requires CARB to use available information gathered from the AB 2588 program to include in the prioritization of compounds. The list of Toxic Air Contaminants (TACs) includes all federal HAPs plus the following pollutants: 1,2-dibromoethane, 1,2-dichloroethane, hexavalent chromium, cadmium, inorganic arsenic, nickel, inorganic lead, diesel particulate matter, and environmental tobacco smoke (17 CCR § 93000 and §93001).

Under AB 2588, facilities are required to report air toxic emissions, ascertain health risks and notify nearby residents of significant risks. In September 1992, the Hot Spots Act was amended by Senate Bill 1731, which required facilities that pose a significant health risk to reduce their risk through a risk management plan. The emissions inventory and risk assessment information from this program is incorporated into this AQCCIA as discussed in Section 3.4.

In July 2007, CARB adopted an airborne toxic control measure (ATCM) for in-use off-road diesel vehicles (13 CCR § 2449 et seq.). This regulation required that specific fleet average requirements be met for NO_x emissions and for particulate matter emissions. Where average requirements cannot be met, BACT requirements apply. The regulation also included several recordkeeping and reporting requirements.

After a series of revisions and amendments, the Final Regulation Order, effective November 30, 2018, establishes a tier-based phase out schedule that is outlined in Table 4 for small fleets (cumulative horsepower of up to 750) and large fleets (cumulative horsepower of greater than 750).

Table 4 Portable Engine ATCM Phase-Out Schedule

Engine Certification	Engines Rated 50 to 750 bhp		Engines Rated >750 bhp
	Large Fleet	Small Fleet	
Tier 1	1/1/2020	1/1/2020	1/1/2022
Tier 2 built prior to 1/1/2009	1/1/2022	1/1/2023	1/1/2025
Tier 2 built on or after 1/1/2009	NA	NA	1/1/2027
Tier 3 built prior to 1/1/2009	1/1/2025	1/1/2027	NA
Tier 3 built on or after 1/1/2009	1/1/2027	1/1/2029	NA
Tier 1, 2, and 3 flexibility engines	December 31 of the year 17 years after the date of manufacture. This provision shall not apply to any engine operation before the effective date of this regulation.		

Source: (CARB, 2018).

The CARB ATCM for Stationary Compression Ignition Engines (17CCR § 93115 et. seq.) contains tables of emissions standards that vary based on the size, use, and existence of the engine. Specifically, new engines have to meet emissions standards for all pollutants while existing engines comply by reducing emissions of DPM by 85% or more. Engines used in agricultural operations have separate requirements as well.

Because the Project is located on an alluvial deposit, and naturally occurring asbestos (NOA) is not found in alluvium, the following ATCM for construction, grading, quarrying and surface mining operations applies to the Project:

- Asbestos ATCM for Construction, Grading, Quarrying, and Surface Mining Operations (17 CCR § 93105) requires the implementation of mitigation measures to minimize emissions of asbestos-laden dust unless an exemption in the ATCM applies. Applicable to this Project, the ATCM states that the "APCO may provide an exemption for crushing, screening and conveying equipment, stockpiles, and off-site material transport at a sand and gravel operation if the operation processes only materials from an alluvial deposit."

On July 26, 2017, Governor Brown approved Assembly Bill No. 617 ("AB 617"). AB 617 added and amended various sections of the California Health and Safety Code. The intent of AB 617 is to develop a collaborative relationship between CARB and local air districts to facilitate community participation, provide a science-based foundation supporting the identification of communities with high cumulative exposure burdens, accelerate the development and use of advanced air monitoring methods and equipment, and support the use of new mobile and stationary source technology. Specific communities have been identified as priority disadvantage communities that are currently subject to AB 617 requirements. The Project is not located in an identified community at this point. If in the future it is identified as being in a disadvantaged community subject to AB 617, the Project would comply with the requirements set forth in AB 617, as applicable.

2.1.3 San Joaquin Valley Unified Air Pollution Control District

The 1976 Lewis Air Quality Management Act established the San Joaquin Valley Unified Air Pollution Control District (SJVAPCD or District) and other air districts throughout the state. The Federal Clean Air Act Amendments of 1977 required that each state adopt an implementation plan outlining pollution control measures to attain the federal standards in nonattainment areas of the state.

The CCAA provides the SJVAPCD with the authority to manage transportation activities and regulate stationary source emissions. Indirect sources of pollution are those sources related to a stationary facility or development project (see Rule 9510) but otherwise outside the Air District authority to regulate. An example of this would be the motor vehicles at an intersection, a mall, and on highways. As a State agency, CARB regulates motor vehicles and fuels for their emissions.

The SJVAPCD has adopted several attainment plans to achieve State and Federal air quality standards. The SJVAPCD continuously monitors the region's progress implementing attainment plans and periodically reports to CARB and the EPA. Finally, SJVAPCD periodically revises attainment plans to reflect new conditions and requirements in accordance with schedules mandated by the CCAA and Clean Air Act Amendments (CAAA).

2.1.3.1 Air Quality Management Plans

The following are State plans that have been adopted by the SJVAPCD.

Ozone Plans:

Extreme 1-Hour Ozone Attainment Demonstration Plan

This plan, adopted by the SJVAPCD board in 2004, sets forth measures and emission reduction strategies designed to attain the Federal 1-hour ozone standard by November 15, 2010. This plan was approved by the EPA on March 8, 2010; however, the EPA's approval was subsequently withdrawn effective November 26, 2012, in response to a decision issued by the U.S. Court of Appeals for the Ninth Circuit (Sierra Club v. EPA, 671 F.3d 955) remanding EPA's approval of these State Implementation Plan revisions. Concurrent with EPA's final rule, CARB is withdrawing the Plan. On May 6, 2014, the SJVAPCD submitted a formal request to the U.S. EPA, asking that the EPA determine the SJVAB has attained the Federal 1-hour ozone standard which was revoked in 1997.

2007 8-Hour Ozone Plan

This plan sets forth measures and a "dual path" strategy to attain the federal 8-hour ozone standard for the SJVAB by reducing emissions on ozone and particulate matter precursors. The plan also includes provisions for improved pollution control technologies for mobile and stationary sources, as well as an increase in State and federal funding for incentive-based measures to reduce emissions. All local measures were to be adopted by the SJVAPCD before 2012. This plan was approved by the EPA on March 1, 2012. On November 26, 2012, however, the EPA withdrew its determination that the plan satisfied the Clean Air Act requirements regarding emission growth caused by growth in vehicle-miles traveled. All other determinations in the EPA's March 1, 2012, rule approving the plan remain unchanged and in effect.

2016 Ozone Plan for 2008 8 Hour Ozone Standard

In order to meet the December 31st, 2031 deadline for attainment, this plan incorporates emissions reduction strategies for stationary sources including regulatory actions; incentive programs; technology advancement programs; policy and legislative activities; public outreach, education, and communication; and undefined strategies under "black box" provisions. The plan demonstrates that existing regulations go above and beyond the Federal Reasonably Available Control Technology (RACT) requirement. The plan also emphasizes that mobile source emissions, which fall under state and federal jurisdiction, make up over 85% of the Valley's NOx emissions. For this reason, the District requested that CARB and EPA adopt and implement strategies so that sources outside District authority would be controlled enabling the standard to be met without the need for "black box" provisions. Moreover, the plan states that CARB and EPA action will be essential to attainment with the AAQS.

2020 Reasonable Available Control Technology (RACT) Demonstration for the 2015 8-Hour Ozone Standard

The 2020 RACT Demonstration (The Demonstration) includes a comprehensive evaluation of all NOx and VOC District rules to ensure that each rule meets or exceeds RACT. District rules were reviewed and compared to federal, state, and local regulations. State suggested control measures and technology clearinghouses were revised to ensure major sources and EPA Control Technique Guidelines sources in the jurisdiction of the SJVAPCD were subject to RACT. The Demonstration fulfills the federal Clean Air Act requirements and demonstrates that all federal RACT requirements are satisfied by SJVAPCD rules.

Particulate Matter Plans:

2007 PM_{10} Maintenance Plan

On October 25, 2007, CARB approved the SJVAPCD's 2007 PM_{10} Maintenance Plan and Request for Redesignation with modifications to the transportation conformity budgets. On September 25, 2008, the EPA redesignated the SJVAB to attainment for the PM_{10} NAAQS and approved the PM_{10} maintenance plan.

2012 $PM_{2.5}$ Plan

The US EPA set the first $PM_{2.5}$ standard in 1997 and in 2005 designated the Valley as nonattainment for the 1997 standard. The 1997 standard has two limits of attainment: an annual average of 15 µg/m³ and a 24-hour average of 65 µg/m³. The SJVAPCD adopted the 2008 $PM_{2.5}$ Plan in April 2008 to demonstrate how the Valley

would come into attainment of the 1997 $PM_{2.5}$ standard by no later than April 2015. US EPA subsequently lowered the 24-hour standard to 35 µg/m³ in 2006 and re-issued the nonattainment designation for the San Joaquin Valley in 2009. Through continued implementation of the 2008 $PM_{2.5}$ Plan, the San Joaquin Valley was expected to be in attainment of the 1997 annual standard by 2015.

The 2012 $PM_{2.5}$ Plan builds on the prior $PM_{2.5}$ plans and demonstrates attainment of the newer 2006 24-hour $PM_{2.5}$ standard by the federal attainment deadline of 2019, with the majority of the Valley actually experiencing attainment ahead of 2019. The SJVAPCD, in collaboration with CARB, based this attainment demonstration on comprehensive analysis, careful evaluation, and a sound scientific foundation. Using the SJVAPCD Governing Board's guiding principles adopted in February 2012, this plan emphasizes public health as the number one priority in meeting federal ambient air quality standards (NAAQS).

The 2012 $PM_{2.5}$ Plan is a multifaceted strategy that utilizes a combination of conventional and innovative control strategies to reduce emissions of $PM_{2.5}$ and other pollutants that form $PM_{2.5}$. The San Joaquin Valley's successes in adopting regulations and other strategies that have improved the San Joaquin Valley's air quality provide the foundation for the Plan. In developing the Plan, the SJVAPCD claims to have left "no stone unturned" in evaluating all sources of emissions for potential strategies to reduce emissions.

In addition to reducing direct emissions of $PM_{2.5}$, the 2012 $PM_{2.5}$ Plan focuses on reducing oxides of nitrogen (NO_x) emissions, which is a predominant pollutant not only in the formation of $PM_{2.5}$ in the San Joaquin Valley, but is also the focus of SJVAPCD's ozone reduction strategies. This overlapping significance and emphasis on reducing NO_x emissions helps to address both of the San Joaquin Valley's biggest air quality challenges, $PM_{2.5}$ and ozone. Along with comprehensive efforts at the local level to reduce emissions, reducing mobile source emissions that are not under the direct authority of SJVAPCD are critical to attaining the standard, and the 2012 $PM_{2.5}$ Plan includes State and federal measures that will provide significant new emissions reductions in the coming years. As outlined below, the plan's comprehensive control strategy includes regulatory actions, incentive programs, technology advancement, policy and legislative positions, public outreach, participation and communication, and additional strategies.

2015 Plan for the 1997 $PM_{2.5}$ Standard

The 2015 Plan for the 1997 $PM_{2.5}$ Standard was adopted on April 16, 2015, and addresses the EPA annual $PM_{2.5}$ standard of 15 µg/m3 as well as the EPA 24-hour $PM_{2.5}$ standard of 65 µg/m3 both of which were established in 1997. The plan's strategy focuses on attaining the standard quickly, as well as prioritizing $PM_{2.5}$ emissions that pose the most health risk to residents.

2016 Moderate Area Plan for the 2012 $PM_{2.5}$ Standard

The 2016 Moderate Area Plan for the 2012 $PM_{2.5}$ Standard was adopted by the District on September 15, 2016. This plan addresses the $PM_{2.5}$ NAAQS of 12 µg/m³ with an attainment deadline of December 31, 2021, established in 2012. This plan demonstrates the impracticability of attainment before the deadline and requests the area be reclassified from moderate to serious nonattainment.

2018 Plan for the 1997, 2006 and 2012 $PM_{2.5}$ Standards

Adopted on November 15, 2018, the plan includes significant incentive-based control measures as well as control measures for stationary and area industrial sources. The plan also calls on CARB to act in order to achieve reductions of mobile sources.

SB 656 Particulate Matter Control Measure Implementation Schedule

Senate Bill (SB) 656 was enacted in 2003 and codified as Health and Safety Code Section 39614. SB 656 seeks to reduce exposure to PM_{10} and $PM_{2.5}$ and make further progress toward attainment of the NAAQS and CAAQS for PM_{10} and $PM_{2.5}$. SB 656 required CARB, in consultation with local air districts, to develop and adopt lists of "the most readily available, feasible, and cost-effective" particulate matter control measures. Subsequently, air districts were required to adopt implementation schedules for relevant control measures. In June 2005, the SJVAPCD adopted its SB 656 Particulate Matter Control Measure Implementation Schedule, and has adopted each relevant strategy into their rules.

2.1.3.2 SJVAPCD Rules and Regulations

The following SJVAPCD rules and regulations are applicable to Project sources. Rule summaries are provided to clarify applicability, and excludes rules that do not apply which are numerous and exhaustive.

Regulation I (General Provisions):

Rule 1160 (Emission Statements)

Rule 1160 requires owners/operators of stationary sources that emit NO_X or ROG to submit annual emission inventories. More information can be found in the Air Resources Board's "Instructions for the Emission Data System Review and Update Report" document (California Air Resources Board, 1988).

Regulation II (Permits):

Rule 2010 (Permits Required)

Rule 2010 requires, prior to construction, any newly proposed air-polluting facilities to first obtain an Authority to Construct from the Air Pollution Control Officer. Prior to operation of the new facility, the SJVAPCD also requires that any new facility obtain a Permit to Operate from the Air Pollution Control Officer. Permits to Operate must be posted and maintained on or near the source of the air pollution.

Rule 2201 (New and Modified Stationary Source Review)

Rule 2201 establishes SJVAPCD's program to limit emissions at new and modified sources so that there is no net increase in emissions within the SJVAB. Rule 2201 uses BACT and mechanisms such as emissions offsets, to ensure that AAQS are met or maintained. Criteria pollutants are regulated under this Rule, including VOC, NO_x, SO_x, PM_{10}, $PM_{2.5}$, and CO. Under Rule 2201, BACT is required if the emissions of a regulated pollutant would exceed two pounds per day. In addition, emission offsets to mitigate an increase in emissions from a new or modified stationary source would be required if the facility's emissions exceed the following amounts:

- 20,000 pounds per year of NO_x or VOC;

- 200,000 pounds per year of CO;
- 54,750 pounds per year of SO_x; or
- 29,200 pounds per year of PM_{10}.

Project equipment that would be subject to this rule includes stationary sources such as diesel engines and processing units of the aggregate plant, and stockpiles.

This rule also includes significance thresholds for Federal Major Modifications at Major Source facilities. The previous facility in the baseline was not a Major Source. This facility is functionally equivalent, and therefore there is no reason to believe this facility would be a Major Source. Additionally, the annual emissions of this facility in the Project do not exceed offset thresholds. Determination of Major or Non-Major Source is based on emissions calculated and discussed in Sections 2.4.6, 2.4.4, and 2.4.5.

Rule 2280 (Portable Equipment Registration)

Rule 2280 outlines the procedure and requirements associated with the registration of portable emissions units. Sand and gravel screening, rock crushing, and RAP crushing operations are among operations eligible for registration of portable equipment, if a portable diesel-fired engine will be used to power processing equipment. Rule 2280 would be applicable to the Project if temporary construction requires equipment (such as a generator set) under Rule 2280.

Regulation III (Fees):

Regulation III contains rules related to District fees. The Project may be subject to fees related to permitting, air toxics, dust, ozone, as well as others.

Regulation IV (Prohibitions):

Rule 4001 (New Source Performance Standards)

Rule 4001 codifies the SJVAPCD's adoption and incorporation of Federal New Source Performance Standards (NSPS) as set forth in 40 CFR Part 60. NSPS apply to a variety of stationary sources, including asphalt plants and aggregate processing plants. However, this Project does not trigger the thresholds to be subject to this rule. If subject to this rule, the regulation imposes emissions standards for relevant pollutants and requires that specified emission performance standards, control equipment, and monitoring devices be installed at all new, modified, or reconstructed facilities to limit emissions. The regulation includes test methods, monitoring, notification, and recordkeeping requirements. The aggregate plant is subject to 40 CFR Part 60, Subpart OOO, which is discussed above in Section 2.1.1.1.

Rule 4002 (National Emission Standards for Hazardous Air Pollutants)

Rule 4002 incorporates the National Emission Standards for Hazardous Air Pollutants (NESHAPs) as set forth in 40 CFR Part 61, and the NESHAPs for source categories as set forth in 40 CFR Part 63. 40 CFR Part 61 includes emission standards for several known toxic air pollutants, such as beryllium, mercury, and vinyl chloride. 40 CFR Part 63 regulates NESHAP by source categories. Both regulations also include test methods and

procedures, as well as monitoring, notification, and recordkeeping requirements. These requirements would be applicable to diesel engines used by the Project.

Rule 4101 (Visible Emissions)

Rule 4101 prohibits emissions of visible air contaminants from any potential source of air contaminants. The rule prohibits air contaminants, other than water vapor, from resulting in greater than Number 1 on Ringelmann Chart (i.e., 20 percent opacity) for a combined period of more than 3 minutes of any hour.

Rule 4102 (Nuisance)

To protect the public health, Rule 4102 prohibits any person from discharging such quantities of air contaminants that cause injury, detriment, nuisance, or annoyance to any considerable number of persons or to the public. Odors are typically addressed under this rule.

Rule 4201 (Particulate Matter Concentration)

To protect the ambient air quality, Rule 4201 establishes a particulate matter emission standard. A release or discharge of dust, fumes, or total suspended particulate matter emissions into the atmosphere from any single-source operation may not exceed 0.1 gr/dscf. Rule 4201 includes test methodology to determine the particulate concentration in an exhaust stream.

Rule 4202 (Particulate Matter Emission Rate)

Rule 4202 limits particulate matter emissions and applies to any source operation that emits or may emit particulate matter. The rule specifies allowable emissions rates based on process weight rate calculations.

Rule 4301 (Fuel Burning Equipment)

Rule 4301 limits the emission of air contaminants from fuel burning equipment. Included in this rule are requirements that fuel burning equipment not discharge:

- Combustion contaminants exceeding 0.1 gr/dscf at 12% carbon dioxide;
- Discharge greater than 200 lbs per hour of sulfur compounds;
- Discharge greater than 140 pounds per hour of nitrogen compounds; or,
- Discharge greater than 10 pounds per hour of combustion contaminants.

Rule 4623 (Storage of Organic Liquids)

Rule 4623 limits VOC emissions from the storage of organic liquids. The rule applies to any tank of organic liquid with a capacity of 1,100 gallons or greater, and requires that such tanks include VOC control systems. The rule includes maintenance, recordkeeping, and testing requirements. However, tanks exclusively receiving and/or storing an organic liquid with a true vapor pressure (TVP) less than 0.5 pound per square inch absolute (e.g., diesel fuel, lubricating and hydraulic oils) are exempt from all other requirements of the rule except for complying with the provisions for (1) TVP and API gravity testing, (2) recordkeeping, and (3) test methods.

Regulation VIII (Fugitive PM_{10} Prohibitions):

The rules under Regulation VIII are intended to reduce ambient concentrations of particulate matter (PM_{10} or larger) and were developed pursuant to EPA guidance for Serious PM_{10} Nonattainment Areas. These rules are applicable to specified anthropogenic sources. Applicability of each rule is discussed below and requirements are presented for rules that apply to the Project. Rule 8081 is omitted because it only applies to agricultural sources.

Rule 8011 (General Requirements)

Rule 8011 contains resources referenced by other rules in Regulation VIII including definitions of terms (74), exemptions (4), general requirements related to road dust controls (4), test methods for visual opacity (2) and surface stabilization (6) included as appendices to the Rule, a recordkeeping requirement, and provision allowing operators to implement a Fugitive PM_{10} Management Plan (FPMP) that is designed to achieve 50% control efficiency that has been approved by the APCO.

Rule 8021 (Construction, Demolition Excavation, Extraction, and Other Earthmoving Activities)

Rule 8021 prohibits construction, demolition, excavation, extraction, or other earthmoving activities unless the appropriate requirements are sufficiently implemented to limit visible dust emissions (VDE) to 20% opacity.

Rule 8031 (Bulk Materials)

Rule 8031 requires any facility that performs outdoor handling, storage, and transport of bulk materials to use appropriate methods as listed in Rule 8031 to limit VDE to 20 percent opacity or to comply with the conditions for a stabilized surface as defined in Rule 8011 (General Requirements). Appropriate methods to limit VDE listed in Rule 8031 include:

- Applying water or chemical/organic stabilizers/suppressants;
- Constructing and maintaining sufficient barriers to obstruct wind;
- Storing materials on stabilized surfaces; covering bulk materials with tarps, plastic, or other suitable material; limiting on-site vehicle speed;
- Loading haul trucks to limit VDE;
- Applying water on the top of loads to limit VDE;
- covering haul trucks with tarps or other covers to limit VDE; and
- Maintaining haul trucks to prevent spillage or loss of bulk materials.

Rule 8041 (Carryout and Trackout)

The purpose of Rule 8041 is to prevent or limit fugitive dust emissions from carryout and trackout on paved public roads or the paved shoulders of paved public roads. Facilities subject to Rules 8021, 8031, 8061, or 8071 must also comply with this rule. Rule 8041 requires that affected facilities prevent and/or clean up carryout and trackout at the end of each workday. Cleanup of carryout and trackout is accomplished by manually sweeping and picking up, operating a rotary brush or broom accompanied by sufficient wetting to limit VDE to 20% opacity, operating a PM_{10}-efficient street sweeper that has a pick-up efficiency of at least 80%, or flushing with water if curbs and gutters are not present and where the use of water will not result in a source of trackout material or other adverse impacts, such as a water quality violation under the National Pollutant Discharge

Elimination System program. Rule 8041 requires that owners/operators of sites with paved interior roads use a trackout control device to reduce carryout and trackout. Rule 8041 prohibits the use of blower devices, dry rotary brushes, or brooms for removal of carryout and trackout on public roads.

Rule 8051 (Open Areas)

The purpose of Rule 8051 is to limit fugitive dust emissions from open areas. The rule applies to any open area having 0.5 acre or more within urban areas, or 3.0 acres or more within rural areas, and that contains at least 1,000 square feet of disturbed surface area. Whenever open areas are disturbed or vehicles are used in open areas, an owner/operator must implement one or a combination of control measures to comply with the conditions of a stabilized surface at times and to limit VDE to 20 percent opacity. Control measures to be used include applying and maintaining water or dust suppressant(s) to unvegetated areas or establishing vegetation on previously disturbed areas; or paving, applying, and maintaining gravel, or applying and maintaining chemical/organic stabilizers/suppressants. Where open areas are disturbed due to trespass, such activities should be prevented by posting "No Trespassing" signs or installing physical barriers such as fences.

Rule 8061 (Paved and Unpaved Roads)

The purpose of Rule 8061 is to limit fugitive dust emissions from paved and unpaved roads by implementing control measures and design criteria. This rule applies to any new or existing public or private paved or unpaved road, road construction project, or road modification project. Rule 8061 requires that new or modified paved roads have certain specifications based on the road's existing or projected annual average daily trips (AADT). Requirements include minimum paved or stabilized shoulder widths, as well as curbing, intersection, and median specifications. The rule prescribes requirements for maintenance of public paved roads, including specifications for PM_{10}-efficient sweepers and road cleanup. Rule 8061 also includes requirements for unpaved road segments. Unpaved road segments with 26 or more AADT must stabilize road surfaces by application of water, chemical dust suppressant, washed gravel, or similar measures. In addition, the visible dust emissions associated with such areas is limited to 20 percent opacity. Unpaved roads with fewer than 26 AADT are exempt from some requirements of this rule.

Rule 8071 (Unpaved Vehicle/Equipment Traffic Areas)

This rule limits fugitive dust emissions from unpaved vehicle and equipment traffic areas. Unpaved vehicle and equipment traffic areas with 50 or more AADT must stabilize road surfaces by application of water, chemical dust suppressant, washed gravel, or similar measures. In addition, the visible dust emissions associated with such areas is limited to 20 percent opacity. Unpaved vehicle and equipment traffic areas with less than 50 AADT are exempt from Rule 8071.

2.1.3.3 CEQA Guidance

The SJVAPCD Air Quality Modeling: Permitting and CEQA webpage[2] links to documents prepared by the District and others and notes that modeling guidance provided by the SJVAPCD is dated and may not be the best approach if one is trying to use currently accepted methods such as those employed by OEHHA. For this reason,

[2] http://valleyair.org/busind/pto/Tox_Resources/AirQualityMonitoring.htm#modeling_guidance

the Report has been written with the Air Toxics Hotspots Program Guidance Manual for the Preparation of Risk Assessments (OEHHA, 2015).

2.1.4 Tulare County General Plan Air Quality Policies

The Tulare County General Plan has a number of policies for air quality. General Plan policies that apply to the Project are listed below.

AQ-1.1 Cooperation with Other Agencies

The County shall cooperate with other local, regional, Federal, and State agencies in developing and implementing air quality plans to achieve State and federal Ambient Air Quality Standards. The County shall partner with the SJVAPCD, Tulare County Association of Governments (TCAG), and the California Air Resource Board to achieve better air quality conditions locally and regionally.

AQ-1.2 Cooperation with Local Jurisdictions

The County shall participate with cities, surrounding counties, and regional agencies to address cross-jurisdictional transportation and air quality issues.

AQ-1.3 Cumulative Air Quality Impacts

The County shall require development to be located, designed, and constructed in a manner that would minimize cumulative air quality impacts. Applicants shall be required to propose alternatives as part of the State CEQA process that reduce air emissions and enhance, rather than harm, the environment.

AQ-1.4 Air Quality Land Use Compatibility

The County shall evaluate the compatibility of industrial or other developments, which are likely to cause undesirable air pollution with regard to proximity to sensitive land uses, and wind direction and circulation in an effort to alleviate effects upon sensitive receptors.

AQ-1.5 California Environmental Quality Act (CEQA) Compliance

The County shall ensure that air quality impacts identified during the CEQA review process are consistently and reasonable mitigated when feasible.

AQ-1.7 Support Statewide Climate Change Solutions

The County shall monitor and support the efforts of CalEPA, CARB, and the SJVAPCD, under AB 32 (Health and Safety Code § 38501 et seq.), to develop a recommended list of emission reduction strategies. As appropriate, the County will evaluate each new project under the updated General Plan to determine its consistency with the emission reduction strategies.

AQ-4.1 Air Pollution Control Technology

The County shall utilize the BACM and RACM as adopted by the County to support SJVAPCD air quality attainment plans to achieve and maintain healthful air quality and high visibility standards. These measures shall be applied to new development approvals and permit modifications as appropriate.

AQ-4.2 Dust Suppression Measures

The County shall require developers to implement dust suppression measures during excavation, grading, and site preparation activities consistent with SJVAPCD Regulation VIII – Fugitive Dust Prohibitions. Techniques may include, but are not limited to, the following:

1. Site watering or application of dust suppressants,
2. Phasing or extension of grading operations,
3. Covering of stockpiles,
4. Suspension of grading activities during high wind periods (typically winds greater than 25 miles per hour), and
5. Re-vegetation of graded areas.

AQ-4.3 Paving or Treatment of Roadways for Reduced Air Emissions

The County shall require that all new roads be paved or treated to reduce dust generation where feasible as required by SJVAPCD Regulation VIII, Rule 8061- Paved and Unpaved Roads. For new projects with unpaved roads, funding for roadway maintenance shall be adequately addressed and secured.

AQ-4.5 Public Awareness

The County shall promote public awareness of the seriousness and extent of the existing air quality problems

2.2 Environmental Setting

The environmental setting includes the physical setting against which changes that would occur with the Project are compared in order to determine the Project's potential air quality impact. The environmental setting also includes factors that influence the setting such as meteorology, geography, and the locations of emission sources and receptors. Frequency and severity of high pollutant concentrations in the air as well result in adverse health effects which are also part of the physical setting and the primary reason for regulating air pollutants. Air quality standards are set at levels where that will protect health, including the health of sensitive populations. Descriptions of regional and Project site air quality are provided in this section.

2.2.1 Regional Setting

The Project site is located in the San Joaquin Valley within the central portion of the San Joaquin Valley Air Basin (SJVAB) under the jurisdiction of the SJVAPCD. The SJVAPCD's jurisdictional area is shown on Figure 3 (Appendix A).

Air pollution is directly related to several factors including a region's topographic features. The SJVAB is defined by the Sierra Nevada Mountain range in the east (8,000 to 14,000 feet in elevation), the Coast Range in the

west (averaging 3,000 feet in elevation), and the Tehachapi Mountains in the south (6,000 to 8,000 feet in elevation). The valley is basically flat with a slight downward gradient to the northwest. The valley opens to the Pacific Ocean at the Carquinez Strait, where the San Joaquin-Sacramento Delta empties into San Francisco Bay.

Although marine air generally flows into the basin from the San Joaquin River delta, the region's topographic features restrict air movement within the basin. The Coast Range hinders wind access into the valley from the west, the Tehachapi Mountains prevent southerly passage of air, and the Sierra Nevada Mountain range to the east is a barrier to air movement. These topographic features result in weak air flow, which becomes blocked vertically by high barometric pressure over the valley. As a result, the SJVAB is susceptible to pollutant accumulation over time. Most of the surrounding mountains are above the normal height of summer inversion layers (1,500 to 3,000 feet).

During the summer season, wind usually originates at the north end of the Valley, through Tehachapi Pass into the Southeast Desert Air Basin (Figure 4, Appendix A). During the winter, wind occasionally originates in the south end of the Valley and flows in a north-northwesterly direction. Also, during the winter months, the Valley experiences light, variable winds, less than 10 miles per hour (mph). Low wind speeds combined with low inversion layers in the winter create a climate conducive to the accumulation of CO and PM_{10} (County of Fresno, 2011).

According to Western Regional Climate Center (WRCC), the Lemon Cove Station (044890) located within 1 mile from the Project site, is the nearest climatological monitoring station. Based on the period of record (1/1/1899 to 1/20/2015), average monthly temperature has ranged from a minimum of 36.9° Fahrenheit (F) to a maximum of 99.3° F. December and January are typically the coldest months with July and August the warmest (WRCC, 2015).

The annual rainfall totals approximately 14.4 inches and mostly occurs between November and April (WRCC, 2015). Summer rainfall is minimal and generally limited to scattered thundershowers over the Sierra Nevada Mountain range.

SJVAPCD, together with CARB, maintains ambient air quality monitoring stations in the Tulare County area. Data collected at permanent monitoring stations are used by the US EPA to classify regions as "attainment" or "nonattainment," depending on whether the regions met the requirements stated in the primary federal and state AAQS. The San Joaquin Valley is a single air quality nonattainment area. The attainment status in Tulare County area and the SJVAB is shown in Table 5.

Table 5 San Joaquin Valley Attainment Status

Pollutant	Federal Designation[a]	State Designation[b]
Ozone - One hour	No Federal Standard[f]	Nonattainment/Severe
Ozone - Eight hour	Nonattainment/Extreme[e]	Nonattainment
PM_{10}	Attainment[c]	Nonattainment
$PM_{2.5}$	Nonattainment[d]	Nonattainment

Pollutant	Federal Designation[a]	State Designation[b]
Carbon Monoxide	Attainment/Unclassified	Attainment/Unclassified
Nitrogen Dioxide	Attainment/Unclassified	Attainment
Sulfur Dioxide	Attainment/Unclassified	Attainment
Lead (Particulate)[h]	No Designation/Classification	Attainment
Hydrogen Sulfide	No Federal Standard	Unclassified
Sulfates	No Federal Standard	Attainment
Visibility Reducing Particles	No Federal Standard	Unclassified
Vinyl Chloride[h]	No Federal Standard	Attainment

Source: San Joaquin Valley Unified APCD (SJVAPCD, 2020)

a. See Code of Regulations (CFR) 40 CFR, Part 81
b. See CCR Title 17 Sections 60200-60210
c. On September 25, 2008, the EPA redesignated the San Joaquin Valley to attainment for the PM_{10} NAAQS and approved the PM_{10} Maintenance Plan.
d. The Valley is designated nonattainment for the 1997 federal $PM_{2.5}$ standards. The EPA released final designations for the 2006 $PM_{2.5}$ standards in December 2008 (effective in 2009), designating the Valley as nonattainment for the 2006 $PM_{2.5}$ standards.
e. Though the SJVAB was initially classified as "nonattainment/Serious" for the 1997 8-hour ozone standard, the EPA approved a reclassification to "extreme nonattainment" on May 5, 2010 (effective June 4, 2010).
f. Effective June 15, 2005, the EPA revoked the federal 1-hour ozone standard, including associated designations and classifications. However, the EPA had previously classified the SJVAB as extreme nonattainment for this standard. EPA approved the 2004 Extreme Ozone Attainment Demonstration Plan on March 8, 2010 (effective April 7, 2010). Many applicable requirements for extreme 1-hour ozone nonattainment areas continue to apply to the SJVAB.

2.2.2 Local Setting

McKay Point, the Project site, is approximately 200 acres located adjacent to where the Lower Kaweah River and St. Johns River diverge. The Project is approximately one mile northwest of the community of Lemon Cove and west of the intersection of State Routes 198 and 216 in Tulare County, California.

SJVAPCD maintains ambient air quality monitoring stations throughout the SJVAB in order to measure compliance with NAAQS/CAAQS. Not all air pollutants are monitored at each station; thus, data from the closest representative station that monitors a specific pollutant are used is reported in Table 6.

The closest ambient air quality monitoring station to the Project site is the Visalia station. This station is located approximately 13.6 miles west-southwest of the Project site and measures O_3, PM_{10}, and $PM_{2.5}$. The station is constructed to monitor at a "neighborhood scale", defined by the EPA as a station covering an area between 0.5 and 4.0 square kilometers (0.3 to 2.5 miles) in range. Data is collected for the purpose of observing a representative concentration for the neighborhood within which the monitoring station is located.

Air quality at the Project site is expected to be better than air quality at the Visalia monitoring station because the monitoring station is located within an urban area where there are more emissions sources. The Project site and surrounding lands are characterized as rural with few air emissions sources and so one would expect fewer hot spots and/or near field exposures as compared to more urban areas where there are many sources and where ambient measurements are collected. Regional pollutant (e.g., ozone and $PM_{2.5}$) concentrations measured at the Visalia station conservatively represent concentrations on-site because these amounts are

added to Project concentrations and to cumulative concentration is compared to the AAQS in order to determine the Project's impact.

Ambient concentrations and number of days when the primary air quality standards were exceeded are presented in Table 6 and Table 7. Carbon monoxide and sulfur dioxide are not presented in these tables because the pollutants are not currently monitored within Tulare County and concentrations measured at all monitoring stations within SJVAB have been less than State or Federal standards over the past five years. Ozone levels exceeded the State one-hour and eight-hour standards and the federal eight-hour standard in each of the past five years. PM_{10} levels exceeded only the state standard in the last five years. $PM_{2.5}$ levels exceeded the federal standard for the past five years. A summary of all ambient air quality standards is presented in Table 1.

Table 6 Ambient Air Quality in the Project Area

Concentration and Averaging Period	Ambient Air Quality Standard	2015	2016	2017	2018	2019
Ozone 1-hr	0.09 ppm (State, max.)	0.110	0.098	0.109	0.112	0.093
Ozone 8-hr	0.070 ppm (State, max.)	0.079	0.080	0.083	0.085	0.084
	0.070 ppm (Fed., 4th high)	0.091	0.083	0.092	0.095	0.082
NO_2 1-hr	0.18 ppm (State, max.)	0.0623	0.0575	0.0581	0.0692	0.0707
	0.100 ppm (Fed., 98th %ile)	0.0456	0.0459	0.0556	0.0529	0.055
NO_2 Annual	0.030 ppm (State) 0.053 ppm (Fed.)	0.009	NA	0.010	0.010	0.009
PM_{10} 24-hr	50 µg/m^3 (State, max.)	140.3	132.5	145.7	159.6	418.5
	150 µg/m^3 (Fed., 2nd high)	67.3	137.1	144.8	153.4	411.1
PM_{10} Annual	20 µg/m^3 (State)	NA	NA	46.9	52.0	46.3
$PM_{2.5}$ 24-hr	35 µg/m^3 (Fed., 98th %ile)	45.8	40.7	74.6	63.4	45.5
$PM_{2.5}$ Annual	12 µg/m^3 (State, max.)	NA	15.5	16.8	17.4	12.2
	12.0 µg/m^3 (Fed., 3 Yr Avg.)	17.6	16.2	15.7	16.1	15.5

*Data Not Available

Source: Trends Summary for O_3, PM_{10}, $PM_{2.5}$ and Top 4 Summary for NO_2. (CARB, 2020).

Max. = Maximum. Hr = Hour. Fed. = Federal. ppm = parts per million. µg/m3 = micrograms per cubic meter.

4th high = Annual fourth-highest daily maximum 8-hour concentration, averaged over 3 years.

2nd high = Not to be exceeded more than once per year on average over 3 years.

98th %ile = 98th percentile of: 1-hour daily maximum concentrations for the 1-hr NO_2 NAAQS; and of 24-hour average concentrations for PM_{10} and $PM_{2.5}$, averaged over 3 years.

ND – insufficient data available to determine. NA – data are not available from the listed sources.

Carbon monoxide and sulfur dioxide are not presented in these tables because the pollutants are not currently monitored within Tulare County and concentrations measured at all monitoring stations within the Air Basin have been less than State or federal standards over the past five years.

Table 7 Number of Days Exceeding Air Quality Standards

Monitoring Site	Year	Days Exceeding State 1-Hour O_3	Days Exceeding State 8-Hour O_3	Days Exceeding Federal 8-Hour O_3	Days Exceeding State 24-Hour PM_{10}[a]	Days Exceeding Federal 24-Hour $PM_{2.5}$[a]
Visalia	2015	9	52	49	59.4	ND
	2016	1	19	18	68.8	ND
	2017	9	65	61	89.3	135.9
	2018	8	58	53	94.0	164.4
	2019	0	26	22	ND	115.8

Source: Trends Summary (CARB, 2020).

[a] Measurements of PM_{10} and $PM_{2.5}$ are usually collected every 6 days and 3 days, respectively. "Numbers of days exceeding the standards" are mathematical estimates.

ND – insufficient data available to determine.

2.2.3 Health Effects Setting

NAAQS/CAAQS and Reference Exposure Levels (REL) that are used for health risk assessment are designated for each pollutant at a level where no "adverse health effect" would occur to sensitive populations. The OEHHA relies upon the definition of "adverse health effect" published by American Thoracic Society (ATS). ATS published a definition in 1985 and then amended the definition in 2000 to address issues not covered by the 1985 definition. From the 1985 definition, "adverse respiratory health effect" means:

> *Medically significant physiologic or pathologic changes generally evidenced by one or more of the following:*
> 1. *Interference with the normal activity of the affected person or persons;*
> 2. *Episodic respiratory illness;*
> 3. *Incapacitating illness;*
> 4. *Permanent respiratory injury; and/or*
> 5. *Progressive respiratory dysfunction* (OEHHA, 2004).

As discussed by OEHHA, the 2000 ATS publication (see copy in Appendix B) recommended that the following "dimensions" of adverse effects be considered when determining an adverse health effect:

1. *Biomarkers: These should be considered; however, it must be kept in mind that few biomarkers have been validated sufficiently to establish their use for defining a point at which a response becomes adverse, consequently, not all changes in biomarkers should necessarily be considered adverse.*
2. *Quality of life: In recent years, decreased health-related quality of life has become widely accepted as an adverse health effect. The review committee concluded that reduction in quality of life, whether in healthy persons or persons with chronic respiratory disease, should be considered as an adverse effect.*

3. *Physiological impact: The committee recommended that small, transient reductions in pulmonary function should not necessarily be regarded as adverse, although permanent loss of lung function should be considered adverse. The committee also recommended that reversible loss of lung function in conjunction with symptoms should be considered adverse.*
4. *Symptoms: Air pollution-related symptoms associated with reduced quality of life or with a change in clinical status (i.e., requiring medical care or a change in medications) should be considered adverse at the individual level. At the population level, the committee suggested that any detectable increase in symptom frequency should be considered adverse.*
5. *Clinical outcomes: Detectable effects of air pollution on clinical measures should be considered adverse. More specifically, the ATS committee cited as examples increases in emergency department visits for asthma or hospitalizations for pneumonia, at the population level, or an increased need to use bronchodilator medication, at the individual level. The committee recommended that: "no level of effect of air pollution on population-level clinical indicators can be considered acceptable."*
6. *Mortality: Increased mortality should clearly be judged as adverse.*
7. *Population health versus individual risk: The committee concluded that a shift in risk factor distribution, and hence the risk profile of an exposed population, should be considered adverse when the relationship between the risk factor and the disease is causal, even if there is no immediate occurrence of obvious illness* (OEHHA, 6/2004).

Based on these recommendations, many health outcomes found to be associated with criteria pollutants could be considered adverse, including pulmonary function changes accompanied by symptoms, pulmonary function changes and respiratory symptoms that reduce quality of life, large changes in pulmonary function, clinical outcomes such as emergency department visits for asthma, hospitalization for respiratory and cardiovascular disease, and mortality. In addition, outcomes such as increase in airway reactivity and inflammation may be considered adverse if they signify increases in the potential risk profile of the population.

> *With regard to sensitivity, the 1970 Clean Air Act recognized that some persons were so ill as to need controlled environments, e.g., persons in intensive care units or newborn infants in nurseries; the act stated that the standards might not necessarily protect such individuals. It further stated, however, that the standards should protect "particularly sensitive citizens such as bronchial asthmatics and emphysematics who in the normal course of daily activity are exposed to the ambient environment.* (ATS, 2000).

Finally, according to ATS, research now shows that some highly susceptible individuals may respond to common exposures at or close to natural background pollutant levels that are often unavoidable.

2.3 Significance Thresholds

Determination of whether impacts exceed the Significance Thresholds is performed using the threshold criteria and methodologies established by the lead agency and/or air district.

2.3.1 CEQA Guidelines Appendix G

As stated, in the Appendix G Environmental Checklist, where available, the significance criteria established by the applicable air quality management district or air pollution control district may be relied upon to make the following determinations:

Would the project:

a) *Conflict with or obstruct implementation of applicable air quality plan?*
b) *Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is non-attainment under an applicable Federal or State ambient air quality standard?*
c) *Expose sensitive receptors to substantial pollutant concentrations?*
d) *Result in other emissions (such as those leading to odors) adversely affecting a substantial number of people?*

The SJVAPCD guidelines, rules and regulations that were considered in the following determinations are discussed below in Section 2.3.2.

2.3.2 SJVAPCD Guidance

SJVAPCD recommends that application of the GAMAQI criteria when evaluating project specific impacts on air quality within the SJVAB. The SJVAPCD identifies threshold criteria that separate a project's short-term emissions from its long-term emissions. The short-term emissions are mainly related to the construction phase of a project and are recognized to be temporary. The long-term emissions are mainly related to the activities that will occur indefinitely as a result of project operations. In addition, CEQA states another condition that could establish a project as having a significant effect on the environment is effects that are considered "cumulatively considerable." Threshold criteria for Project construction impacts, Project operations, and cumulative impacts are discussed below.

SJVAPCD Rules and Regulations

SJVAPCD recommends that air quality assessments reflect emission reductions achieved through compliance with SJVAPCD rules and regulations. The applicable SJVAPCD rules and regulations are provided in Section 2.1.4.

Regional Impacts from Criteria Pollutant Emissions

The quantities of pollutants above which SJVAPCD believes would have a significant effect on air quality are presented in Table 8. Impacts from construction, operational non-permitted equipment and activities, and operational permitted equipment and activities are evaluated independently from one another. The threshold criteria are applied on a calendar year basis. For construction emissions, the annual emissions are evaluated on a rolling 12-month period.

Localized Impacts from Criteria Pollutants and Toxic Air Contaminants

The thresholds of significance for Ambient Air Quality are based on the CAAQS and NAAQS. A project would be considered to have a significant impact if its emissions are predicted to cause or contribute to a violation of

an ambient air quality standard by exceeding any CAAQS/NAAQS. The standards are listed above in Table 1. Significance thresholds used by SJVAPCD are presented in Table 8.

Table 8 SJVACPD Threshold Criteria for Assessing Impacts

Criteria Pollutants			
Pollutant	Construction Phase [b] (ton/yr)	Operation Phase Permit-Required [c] (ton/yr)	Operation Phase Permit-Exempt [c] (ton/yr)
CO	100	100	100
NOx	10	10	10
ROG	10	10	10
SOx	27	27	27
PM_{10}	15	15	15
$PM_{2.5}$	15	15	15
Recommended Toxic Air Contaminants (TACs), Odor Thresholds[b]			
TACs (including carcinogens and non-carcinogens)	Maximum Incremental Cancer Risk ≥ 20 in 1 million Chronic & Acute Hazard Index ≥ 1.0 (project increment)		
Odor	More than one confirmed complaint per year averaged over a three-year period, or three unconfirmed complaints per year averaged over a three-year period. (Screening distance is one mile for HMA plants.)		
Ambient Air Quality Standards [d]			
Screening Criteria	100 lb/day of any criteria pollutant after implementation of mitigation measures.		
Modeling Criteria	If modeling is required because emissions exceed the screening criteria (100 lb/day), then the project would have a significant impact on an AAQS if the project concentration plus background concentration measured at the closest air monitoring station exceeds the most stringent AAQS or Significant Impact Level (SIL) in cases where background concentration already exceeds or nearly exceeds the AAQS.		

a Based on SJVAPCD "Air Quality Thresholds of Significance – Criteria Pollutants". (San Joaquin Valley Air Pollution Control District, 2015)

b Based on SJVAPCD "Recommended Thresholds of Significant Impact". (San Joaquin Valley Air Pollution Control District, 2012)

c Based on SJVAPCD "Ambient Air Quality Standards & Valley Attainment Status" (San Joaquin Valley Air Pollution Control District, n.d.)

d Based on SJVAPCD "Guidance for Assessing and Mitigating Air Quality Impacts". (SJVAPCD, 2015)

Screening Threshold for On-Site Emissions

In addition to the CAAQS/NAAQS, the GAMAQI contains Ambient Air Quality Screening Tools. Impacts require a detailed assessment when on-site emission increases from construction activities or operational activities exceed the 100 pounds per day (lb/day) screening level for each criteria pollutant evaluated after implementation of enforceable mitigation measures. Under such circumstance, the SJVAPCD recommends that an ambient air quality analysis be performed. An ambient air quality analysis uses air dispersion modeling to determine if emission increases from a project will cause or contribute to a violation of the ambient air quality standards.

For stationary source projects, the GAMAQI states that on-site construction emissions, on-site operational emissions from permitted equipment and activities, and on-site operational emissions from non-permitted equipment and activities each would be screened separately by comparison the 100 lb/day threshold.

Odors

Due to the subjective nature of odor impacts, the number of variables that can influence the potential for an odor impact, and the variety of odor sources, there are no quantitative or formulaic methodologies to determine if potential odors would have a significant impact. Rather, projects must be assessed on a case-by-case basis.

SJVAPCD GAMAQI recommends that all available pertinent information should be considered in order to qualitatively determine if a significant impact is likely to occur. SJVAPCD recommends that applicable information regarding the characteristics of the odor source be disclosed. Consideration of such parameters assists in evaluating the potential for odor impacts as a result of the proposed Project.

SJVAPCD has identified some common types of facilities that have been known to produce odors in the SJVAB. These are presented in Table 9. Table 9 is used as a screening tool to qualitatively assess a project's potential to adversely affect area receptors. This list of facilities is not all-inclusive; however, aggregate mining and processing is not one of the facilities identified by the District as a potential source of significant odors.

Table 9 Screening Levels for Potential Odor Sources

Type of Facility	Distance (miles)
Wastewater Treatment Facilities	2
Sanitary Landfill	1
Transfer Station	1
Composting Facility	1
Petroleum Refinery	2
Asphalt Batch Plant	1
Chemical Manufacturing	1
Fiberglass Manufacturing	1
Painting/Coating Operations (e.g., auto body	1
Food Processing Facility	1
Feed Lot/Dairy	1
Rendering Plant	1

Source: (SJVAPCD, 2015, p. 103).

Cumulative Impacts

By its very nature, air pollution has a cumulative impact. No single project would be sufficient in size, by itself, to result in nonattainment of the regional air quality standards. Instead, a project's emissions may be

individually limited, but cumulatively considerable when taken in combination with past, present, and future development within the San Joaquin Valley Air Basin.

When assessing whether there is a new significant cumulative effect, SJVAPCD recommends that whether or not the incremental effects of the project are cumulatively considerable be evaluated. "Cumulatively considerable" means that the incremental effects of an individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects [14 CCR § 15064(h)(1)].

If the project will comply with the requirements in a previously approved plan or mitigation program, including, but not limited to an air quality attainment or maintenance plan that provides specific requirements that will avoid or substantially lessen the cumulative problem within the geographic area in which the project is located, then the project's incremental contribution to a cumulative effect is not cumulatively considerable (CEQA Guidelines §15064(h)(3)).

Cumulative Impacts Associated with Criteria Pollutants from Permitted Sources

SJVAPCD's attainment plans demonstrate that project-specific net emissions increase below NSR offset requirements will not prevent the District from achieving attainment. Consequently, emission impacts from sources permitted consistent with NSR requirements are not individually significant and are not cumulatively significant.

Cumulative Impacts Associated with Criteria Pollutants from Non-Permitted Sources

When determining cumulative significance, air quality impacts from all non-permitted equipment and activities emissions sources are to be considered when determining if project-specific emissions impacts would be individually significant. The SJVAPCD concludes that when activities and emissions from non-permitted sources are individually significant, they are also cumulatively significant.

Cumulative Impacts Associated with Toxic Air Contaminants

Impacts from TACs are localized impacts. SJVAPCD has established thresholds of significance for TACs that are extremely conservative and protective of health impacts on sensitive receptors. Because impacts from TACs are localized and the thresholds of significance for TACs have been established at such a conservative level, risks over the individual thresholds of significance are also considered cumulatively significant. No other cumulative risk thresholds apply.

2.4 Methodology

Guidelines and emissions thresholds established by the SJVAPCD in the GAMAQI (SJVAPCD, 2015) are used to assess impacts in this AQCCIA. The SJVAPCD also requires evaluation of cumulative air quality impacts, which are further discussed in Section 2.5.

2.4.1 Assumptions and Project Design Features

The impact assessment incorporated the following general assumptions:

- The excavation and associated equipment would operate in compliance with applicable air quality regulations.
    - Authorities to Construct and Permits to Operate would be obtained from the SJVAPCD for the portable crush/recycle and wash/screen plants at which time the equipment would be required to utilize Best Available Control Technology (BACT). It is anticipated that the plant would be equipped with water sprays at key emissions points.
    - Diesel engines would comply with applicable State regulations (i.e., air toxic control measures (ATCM)). This includes labeling of off-road equipment with registration numbers assigned by CARB, establishment of an idling policy, and limiting idle time to less than five minutes (13 CCR §2449).
    - A fugitive emission control plan would be implemented to comply with SJVAPCD Regulation VIII, "Fugitive PM_{10} Prohibition" and would include the following measures:
        i. The area to be excavated will be irrigated or sprayed by water trucks when visible dust is observed during excavation activities.
        ii. A water truck will be utilized to wet down the haul road from the excavation to the plant site as necessary to meet SJVAPCD fugitive dust requirements.
        iii. Records demonstrating compliance with fugitive dust requirements will be maintained for those days that a control measure was implemented and include the type of control measure(s) used, the location and extent of coverage, the date, the amount, and frequency of dust suppressant applied (Rule 8011, Section 6.2).
        iv. Limit visible dust emissions to 20 percent opacity for a period or periods aggregating more than three (3) minutes in any one (1) hour and comply with the conditions for stabilized surface areas (Rule 8021, Section 5.0; Rule 8031, Section 5.0).
        v. Stabilize disturbed areas that are greater than 0.5 acres in size and which remain inactive for seven (7) days (Rule 8021, Section 5.2).
        vi. Stabilize stockpile surfaces (Rule 8031, Section 5.0).
        vii. Maintain a stabilized surface on the unpaved haul road (Rule 8021, Section 5.2).
        viii. During high wind conditions, cease excavation and other earthmoving activities that disturb the soil whenever visible dust emissions exceed 20 percent opacity. Continue operation of water trucks/control devices when activities cease, unless unsafe to do so. (Rule 8021, Section 5.4).
        ix. Prevent unauthorized vehicle disturbance of open areas by posting signs or installing physical barriers such as fences, gates, posts, and/or other appropriate barriers to effectively prevent access to the area(s) (Rule 8051, Section 5.0).

- The portable crush/recycle plant / diesel generator would be eligible registration in the CARB Portable Equipment Registration Program (PERP).

- The Project is located in Tulare County, which is among the counties listed as containing serpentine and ultramafic rock (OPR, 2000). However, the Project site is located on an alluvial deposit which does not contain serpentine or ultramafic rock and no NOA has been found on the Project site or in the vicinity of the Project.

- The Project would not store hazardous substances or acutely hazardous substances in quantities that would be subject to chemical accident prevention provisions of the CAA or the implementing regulation (40 CFR Part 68).

- Electricity is currently provided to the Project site by Southern California Edison (SCE).

Project Design Features

Project design features are aspects/activities of the Project that are already included in the design of the Project and will be implemented. The impact assessment incorporated the following Project design features:

- The Project will be managed such that there will be no increase in the production rate of aggregates from the baseline level. Therefore, the number of trucks traveling offsite on public roads will not increase from baseline.
- The Project will be managed so that when recycling and/or blending activities were taking place, the excavation and processing of aggregated would be reduced such that the total emissions associated with excavation/processing of aggregate combined with the emissions associated with the transport and processing/blending of recycled materials and additives would not result in an increase to baseline.
- The number of employees will not exceed the number of employees required for previous aggregate operations (baseline).
- The number of delivery and other non-aggregate trucks would be included in the total number of trucks coming/going from the site such that the total number of trucks would not exceed baseline.
- A slurry wall would be constructed as early as feasible during the excavation phase of the Project, to facilitate dry mining techniques.
- Activities associated with the Project will comply with all applicable rules and regulations.

2.4.2 Emissions Calculations Methodologies

Emissions from combustion sources associated with the Project including on- and non-road diesel engines are calculated in Appendix C using the methods presented below.

Emissions from dust sources associated with excavation phase of the Project including excavation/grading activities, aggregates processing (screen/wash plant & crush/recycle plant), stockpile/loadout areas, travel on

onsite unpaved roads, and wind erosion of stockpile areas are calculated in Appendix C using the methods presented below.

Non-Road Engines

Non-road engine emissions in off-road vehicles and dewatering pumps were calculated using the CalEEMod default method and emissions factors. Engine emissions rates decrease over time as the fleet is turned over and controls are implemented to comply with CARB regulations (i.e., In-Use Off-Road and Portable Engine ATCMs). Appendix A of the CalEEMod User Manual contains the following equation for quantifying off-road engine emissions.

$$Emissions_{DieselEx} = \sum_{i} (EF_i \times Pop_i \times AvgHP_i \times Load_i \times Activity_i)$$

Where:

EF = Emission factor in grams per horsepower-hour (g/bhp-hr)
Pop = Population, or the number of pieces of equipment.
AvgHP = Maximum rated average horsepower.
Load = Load factor.
Activity = Hours of operation.
i = Equipment type.

Emissions factors for the baseline were estimated based CalEEMod Appendix D Table 3.4: Off-road Emissions Factors. Baseline emissions factors were based on the 2005 operating years, and future emissions factors were based on the 2020 operating year. These assumptions are conservative as the majority of the baseline period takes place prior to 2005 (when engines had higher emissions) and the future excavation takes place after 2020 (when engines will have lower emissions).

The Project would use electricity currently being provided by SCE to power the wash/screen plant and a diesel generator to power a portable crush/recycle plant. The generators would need to be large enough to start the plant which is the mode of operation when peak power is used. Once each unit is in motion, inertia of the moving parts reduce the power required to continue steady-state operation. In order to minimize power required for start-up, equipment would be started in stages.

It is common for generators servicing aggregates plants to operate normally at 50% load with near 100% load occurring only temporarily during start-up as discussed above. Similarly, the electric motor rating are peak power requirements during start-up. For instance, a crusher with a 400 horespower (hp) electric motor normally operates at half that power level.

Given the above observations, it is assumed that a 1,015-horsepower generator would be needed for the portable crush/recycle plant. Furthermore, it is assumed that a 1,015-horsepower generator would be eligible for initial registration in the CARB Portable Equipment Registration Program (PERP) as a minimum standard that must be achieved in order to obtain a stationary source permit from SJVAPCD. Current PERP eligibility requirements can be found here: http://www.arb.ca.gov/portable/portable.htm.

On-Road Engines

Travel emissions rates for on-road trucks (T7 tractor vehicle class) were calculated from the Tulare County fleet emissions inventory reported by the online version of EMFAC2021. Emissions reported in grams per vehicle miles traveled (VMT) were multiplied by total VMT to determine emissions. A vehicle speed of 15 miles per hour was used to determine emissions rates for on-road trucks traveling on-site. On-road emissions onsite were conservatively omitted from the baseline model, as a majority of the haul route utilized in the baseline will also be used in the future. Emissions from on-road engines were calculated using the equation from Appendix A of the CalEEMod User Manual presented below.

$$Emissions_{Pollutant} = VMT \times EF_{Running,Pollutant}$$

Where:

Emissions $_{Pollutant}$ = Emissions from vehicle running for each pollutant.
VMT = Vehicle miles traveled.
$EF_{Running, Pollutant}$ = Emission factor for running emissions for each pollutant.

Excavation

Fugitive dust emissions generated during excavation, material processing, and material handling were calculated using the following methods.

Quarrying fugitive emissions were estimated using the San Diego Air Pollution Control District (SDAPCD) Default quarrying emissions factor of 0.021 lbs PM_{10} per ton of material quarried, as the SJVAPCD does not specify an emissions factor for quarried material.

Material dropping from the excavator to haul trucks and from the haul trucks to the ground emit fugitive dust. Material drop emissions were calculated using the CalEEMod default methodology which is based on the following emissions factor equation from AP-42 Section 13.2.4.

$$EF = k(0.0032)\frac{\left(\frac{U}{5}\right)^{1.3}}{\left(\frac{M}{2}\right)^{1.4}}$$

Where: E = emission factor (lb/ton).
k = particle size multiplier (dimensionless: 0.35 for PM_{10}).
U = mean wind speed, (miles per hour [mph]).
M = material moisture content (%).

Moisture content of twelve percent (12%) is used which is the default value in CalEEMod and reflects the fact that materials are watered as necessary to control dust (i.e., no additional control efficiency for watering is applied to this source). The mean wind speed of 4.92 miles per hour (mph) is used based upon the mean wind speed for Tulare County in Table 1 of CalEEMod User's Guide Appendix D. Material drops from vehicles would continue to occur at the aggregate plant feed hopper in amounts equal to or less than those that occurred in

the baseline. Material drops also occur in processing plants and quantification of in-plant material drop emissions are discussed later in this subchapter.

Aggregates Processing Plants

Aggregates processing on the Project site would take place at an aggregate wash/screen plant, and as needed to crush larger pieces of aggregate at the crush/recycle plant. Plant equipment is briefly described below:

- Wash/Screen Plant (grid powered by SCE)
  - 1 hopper;
  - 1 wet screen;
  - 2 sand screws; and
  - 11 Conveyors.
- Crush/Recycle Plant (portable engine powered by diesel generator)
  - A hopper;
  - 2 crushers;
  - 2 screens; and
  - 15 conveyors.

Stockpile/Loadout Areas

Emissions from sources in these areas are calculated using the SJVAPCD's uncontrolled emissions factor of 5.27 lb-PM_{10}/acre-day and recommended 80% control efficiency for watering of stockpiles containing greater than one percent material smaller than 3/8-inch (SJVAPCD, 2013).

Travel on On-site Unpaved Roads

Road dust emissions are calculated using the CalEEMod and AP-42 emissions factor equations (Appendix E). AP-42 Section 13.2.2 (November 2006) contains the following emissions factor equation for vehicles traveling on unpaved roads at industrial sites:

$$E_{ext} = \left[k \left(\frac{s}{12} \right)^{0.9} \times \left(\frac{W}{3} \right)^{0.45} \right]$$

Where: E_{ext} = annual particulate emission factor (having units matching the units of k),
k = particle size multiplier units of interest (e.g., 1.5 lb/VMT for PM_{10}),
s = surface material silt content (%),
W = average weight (tons) of the vehicles traveling the road,

Unpaved road emissions were calculated for on-road trucks traveling on the Project site to haul material to the processing plants and processed product for export. The control efficiency for watering unpaved roads was assumed to be 80 percent based on AP-42 13.2.2 – Unpaved Roads, Figure 13.2.2-2 of AB-42. The silt content of the unpaved roads was assumed to be 4.8 percent per AP-42 Table 13.2.2-1 (Sand and Gravel Processing). Off-road truck weight (40 tons empty, 90 tons full) was obtained for a representative 50-ton capacity truck

from the Caterpillar Performance Handbook. On-road trucks were assumed to be 40 tons full and 15 tons empty with a capacity of 25 tons. Annual emissions were adjusted for rainfall, assuming 51 days a year exceeding 0.01 inch of rainfall (CAPCOA, 2013).

AP-42 Section 13.2.1 (January 2011) contains the following emissions factor equation for paved roads:

$$E_{ext} = [k(sL)^{0.91} \times (W)^{1.02}]$$

Where: E_{ext} = annual particulate emission factor (having units matching the units of k),
k = particle size multiplier units of interest (e.g., 0.0022 lb/VMT for PM_{10}),
sL = road surface silt loading (grams per square meter) (g/m2),
W = average weight (tons) of the vehicles traveling the road,

Processing and screening equipment emissions of PM_{10} and $PM_{2.5}$ were calculated using factors provided in Section 11.9.2 of AP-42 and the PM Calculator posted on the US EPA website. Emission factors for controlled sources were used because processing equipment would have water spray bars installed to reduce the particulate emissions.

Slurry Wall

The slurry wall would be installed during the excavation phase of the Project. The slurry wall will decrease the flux of groundwater between the reservoir/excavation pit and surrounding aquifer. Slurry walls are underground walls made of bentonite (clay) mixtures that are installed to inhibit groundwater flow. In this case, the slurry wall would be installed around the reservoir perimeter to decrease groundwater seepage flowing into the reservoir during excavation and construction phases, and to keep the reservoir in a relatively dry condition when not being used for storage. The slurry wall would be installed from elevations above the groundwater levels and extend upwards into the Reservoir's perimeter berm as needed to contain water stored in the Reservoir above groundwater levels and downwards into natural lower permeability material.

The slurry wall will be designed by a qualified professional and constructed by a qualified contractor with experience in installing similar facilities. The general sequence of slurry wall construction activities, which were analyzed as part of the Project excavation phase in this report, would include:

- Surface clearing, grading, and filling to create a sufficiently long section of the perimeter road.
- Excavation of the slurry wall trench through the road which also provides a relatively level surface to contain the slurry in the excavation. The trench is first excavated to its full depth and then extended in length.
- Filling the trench with a bentonite slurry (bentonite clay and water mix) to support the sides of the excavation and prevent them from collapsing. The bentonite slurry is mixed in the above referenced bentonite slurry mix pond and pumped by pipeline into the excavated trench.
- The excavated soils from the trench are placed in an adjacent prepared slurry wall backfill mixing area for use in preparing the backfill, or if unsuitable for hauling the soil back to the WCA operations for processing as appropriate.

- As the trench is extended in length, backfilling is commenced. This is accomplished by first preparing the backfill material which typically includes granular soils mixed in with bentonite and water to create a low permeability material in the slurry wall backfill mixing area. Suitable durable excavated granular material will be used, or more suitable material will be obtained from the WCA operations or imported from offsite.
- Once mixed, the backfill is pushed into the trench by a dozer, or equivalent, from the narrow end, opposite to the end of the trench that is still being excavated. The backfill material displaces the bentonite slurry in the trench and eventually settles and forms a low permeability wall. The ultimate length of the slurry wall is approximately 13,400 feet and its width is typically 3 feet.
- As the wall is completed and gravel cap is placed over the top of the backfilled trench, it will form part of the perimeter road.
- A road safety berm will also be constructed along the inside of the road facing the excavation area.
- As the excavation of the reservoir is deepened an access ramp will be constructed in the excavated slope to provide for equipment access.

It should be noted the above discussion is for illustration purposes and actual construction techniques will vary based on the approved means and methods the contractor selects, and possible future technology advances in slurry wall construction; however, emissions from source (mobile equipment, dust, etc.) required to construct the slurry wall were incorporated into the analysis of the excavation phase emissions.

2.4.3 CEQA Baseline for Excavation Phase

In the past, mining has occurred on the adjacent Seaborn facility. The excavated materials were hauled by truck to the onsite processing plant during 1997 to 2006, the facility baseline was conservatively estimated at 500,000 tons per year average and 650,000 tons per year maximum. This means that over the course of the 10-year period, the average net tonnage mined was 500,000, whereas the maximum year in this period involved the excavation of 650,000 net tons. Table 10 presents the equipment associated with baseline excavation.

Based of communications with the Seaborn site operators, the baseline number of employees was 7 to 12 and the equipment used was the standard equipment typically used for aggregate excavation and operations. The Project would have either the same or less employees and the same standard aggregate mining equipment would be used as in the baseline. Because the Project site aggregates processing plant would not increase production rate above baseline levels, the number of trips and Vehicle Miles Traveled (VMT) by on-road trucks delivering product to the market would not change from baseline levels and continued operation of these existing sources of air emissions would not be an effect of the Project. For the purposes of this analysis, the baseline emissions are the average annual baseline activity levels.

Baseline for Non-Road Engines

Baseline haul distance from the excavation to the processing plant was assumed to be 0.3 miles. This average trip length is half of the longest haul path on the Seaborn site. Loader, excavator and haul truck activity levels were based on haul distance and cycle time analysis (Appendix C). The skid steer, telehandler, de-watering

pumps, and water trucks were assumed to have fixed operational hours. Baseline equipment activity is summarized in Table 10.

Table 10 Baseline Equipment and Activity for Excavation

Equipment	HP	Annual Operating Hours	Max Daily Operating Hours
988 Loader	540	502	14
982 Loader	400	502	14
980 Loader	390	502	14
390 Excavator	530	511	14
Two Haul Trucks	600	1044	14
Skid Steer	65	626	2
Telehandler/Aerial Lift	402	626	2
Water Truck	402	2503	14
Recycle Generator Set	1015	148	14

Source: Appendix C.

Excavation equipment emission factors in the baseline were obtained from the CalEEMod Appendix D Table 3.4: Off-road Emissions Factors for the year 2005. Average annual emissions in the baseline are summarized in Table 11.

Table 11 Excavation Exhaust Emissions During the Baseline Period

Period	Units	ROG	CO	NO_X	SO_2	PM_{10} (diesel)	$PM_{2.5}$ (diesel)
Annual	Tons	1.7	6.1	17.5	0.13	0.67	0.67
Max Daily	lbs	43.7	163.1	457.1	3.24	16.63	16.63
Max Hourly	lbs	3.2	12.0	33.3	0.24	1.24	1.24

Source: Appendix C.

Baseline for On-Road Engines

The Production rate or the amount of material produced by the Project would remain unchanged from the baseline level. Thus, off-site haul trucks and associated emissions would not be increased above baseline.

In general, diesel engine emissions from all modes of operation decrease in the future due to phase-in of CARB engine regulations. This primarily affects cancer risk, which is a multi-year impact.

Baseline Emissions Summary

Table 12 presents baseline emissions for each emissions source associated with the baseline activity. Sources are broken out into two categories, Stationary Sources and Permit Exempt sources. PM_{10} and $PM_{2.5}$ emissions in Table 12 include both fugitive emissions and engine exhaust emissions.

Table 12 Baseline Annual Emissions Summary

Baseline Emissions (tons/yr)							
		ROG	**CO**	**NO_X**	**SO_2**	**PM_{10} Total**	**$PM_{2.5}$ Total**
Stationary Sources	Recycle Plant Fugitive Ems.					0.12	0.03
	Recycle Engine	0.12	0.45	1.26	0.0084	0.04	0.04
	Aggregates Plant Fugitive Ems.					0.03	0.01
	Aggregates Storage					0.38	0.11
Permit Exempt Sources	Excavation Fugitive Ems.					7.5	2.2
	Excavation Offroad Engines	0.86	3.21	8.74	0.06	0.34	0.34
	Aggregates Transfer/Drops					0.62	0.18
	Off-Road Vehicle Haul	0.72	2.48	7.49	0.055	5.6	1.4
	Total Emissions	**1.7**	**6.1**	**17.5**	**0.1**	**14.6**	**4.3**

Source: Appendix C.

2.4.4 Project Construction Phase Emissions

The construction phase of the Project would begin prior to excavation with installation of site security features. The remainder of reservoir features would be constructed approximately 15 to 23 years after the excavation begins.

- Site security features and on-site construction office (prefabricated trailer) including an access gate and perimeter road.
- Inflow channel consisting of a weir, chute, and dissipation pool and Outflow Channel consisting of a weir each requires an excavator, backhoe, water truck, loader, compactor, cement trucks, cement pumps, and cranes.
- Generator building and floating barge pump, including an aboveground diesel tank, would require an excavator, water truck, backhoe, compactor, trencher and cement trucks.

Combustion emission sources at the reservoir during construction consist of off-road mobile and portable diesel fueled equipment. The off-road equipment emissions were calculated using emissions factors in Appendix D of the CalEEMod User's Guide.

2.4.4.1 Site Security Features and On-site Office

Zero emissions are assessed for installation of site security fence and the on-site office (which is assumed to be prefabricated) because emissions from these activities are negligible.

2.4.4.2 Inflow and Outflow Channels

The engineering design of the reservoir was prepared by Provost & Pritchard Consulting Group (P&P). The following design information was obtained from P&P.

The inflow and outflow structures would require excavation and grading to prepare the sites for form installation. These structures are assumed to be constructed using the average units in the 2025 off-road fleet. Inflow/outflow grading consists of clearing and grubbing of approximately 3 acres, excavation of 20,000 cubic yards, and the placement of approximately 9,000 cubic yards of rip-rap. Excavated soils are assumed to be spread onsite. Table 13 lists the approximate equipment activity levels for grading of the in/out flow channels.

Table 13 In/Out-Flow Grading

Description	Equipment	HP	Rate	Quantity	# of 8-hour Days
Clear and Grub, Haul Roads	Dozer	165	1 hr/ac	3 ac	1
Canal Excavation and Spreading	Tractor	530	15 cy/load	20,000 cy @ 3 loads/hr	56
Final Shaping of Canal	Grader	200	0.5 hr/ac	3 ac	1
Placing of Rip-Rap	Excavator	184	1 cy/bucket	9,000 cy @ 20 buckets/hr	56
Hauling of Rip-Rap	Dump Truck	300	10 cy/Haul	9,000 cy @ 4 hauls/hr	28
Dust Control	Water Truck	230	2 hr/day	56 days	14

Source: Provost & Pritchard Consulting Group, 3/18/2015 (Appendix B).

Construction of the in/out-flow building would consist of finish grading and minor excavation of approximately 600 cubic yards and the placement of approximately 1,100 cubic yards of concrete. Excavated soils are assumed to be spread onsite. Table 14 lists the approximate equipment activity levels for construction.

Table 14 In/Out-Flow Building

Description	Equipment	HP	Rate	Quantity	# of 8 Hour Days
Minor Excavation, Structural Compaction	Excavator	184	1 cy/bucket	500 cy @ 20 buckets/hr	3
Minor Excavation and Moving of Materials	Backhoe	108	4 cy/hr	100 cy	3
Concrete Placement (Pump)	Generator	84	20 cy/hr	1,100 cy	7
Placing of Box Culvert	Crane	250	N/A	N/A	10

Source: Provost & Pritchard Consulting Group, 3/18/2015 (Appendix B).

2.4.4.3 Generator Building and Floating Barge Pump

Construction of the generator/barge pump would consist of finish grading and minor excavation as well as excavation and placement of the barge pump discharge pipes. Table 15 lists the approximate equipment activity levels for construction of the generator/barge pump.

Table 15 Generator/Barge Pump

Description	Equipment	HP	Rate	Quantity	# of 8 Hour Days
Minor Excavation and Moving of Materials	Backhoe	108	4 cy/hr	50 cy	2
Pipe Trench Excavation, Backfill, and Compaction	Excavator	184	200 ft/ 8 hr	1200 ft	6
Concrete Placement (Pump)	Diesel Generator	84	N/A	N/A	1
Dust Control, Soil Conditioning	Water Truck	230	1 hr/day	8 days	1

Source: Provost & Pritchard Consulting Group, 3/18/2015 (Appendix B).

2.4.4.4 Construction Phase Emissions Summary

Construction emissions were determined using CalEEMod version 2016.3.2. In order to account for various potential construction timelines, construction activities were assumed to take place within the same year. This assumption is conservative, as the Project is likely to spread out construction activities, reducing annual emissions from the estimate made in this analysis. Table 16 presents emissions from the construction phase of the Project.

Table 16 Project Construction Emissions

Activity	ROG (tpy)	CO (tpy)	NO_X (tpy)	SO_2 (tpy)	PM_{10} (tpy)	$PM_{2.5}$ (tpy)
Project Construction	0.048	0.29	0.49	0.001	0.022	0.018

Source: Appendix D.

2.4.5 Excavation Phase Emissions

For the purposes of this analysis, excavation was assumed to occur for approximately 23 years, and the maximum annual production rate (920,000 tons gross, 650,000 tons net) was assumed to occur in the first year of the Project. Slurry wall installation is also assumed to take place at the beginning of the excavation phase, and is expected to take 1 year. By modeling the maximum year and slurry wall installation in the first year of the excavation phase, the model is conservative, as modeled receptors are assumed to be infants and more sensitive to emissions. The average year (720,000 tons gross, 500,000 tons net) was modeled for every year after the first year.

2.4.5.1 Slurry Wall

The slurry wall will be designed by a qualified professional and installed by a qualified contractor. Slurry wall installation includes the following activities:

- Creation of a perimeter access road that would also serve as a leveling surface for the construction of the slurry wall.
- Creation of an approximately 60- to 80-foot-deep slurry wall surrounding the excavation/reservoir area. Its actual depth will be determined during design and verified during construction based on subsurface information, to provide the required reduction in groundwater inflow.
- An approximately 5-foot-deep water infiltration trench along the northern border of the ultimate reservoir area.

It is anticipated construction would take approximately 6 months and would include the following on-site facilities. After completion of the slurry wall these facilities would be demobilized from the site:

- Vehicle and equipment parking areas.
- A fill material stockpile area.
- Equipment storage area.
- A bentonite slurry mixing pond (see further discussion below on the slurry wall construction activities).
- A slurry wall backfill mixing area that would be moved along with the construction of the slurry wall so it is always adjacent to the segment being excavated.

The general sequence of slurry wall construction activities would include:

- Surface clearing, grading, and filling to create a sufficiently long section of the perimeter road.
- Excavation of the slurry wall trench through the road which also provides a relatively level surface to contain the slurry in the excavation. The trench is first excavated to its full depth and then extended in length.
- Filling the trench with a bentonite slurry (bentonite clay and water mix) to support the sides of the excavation and prevent them from collapsing. The bentonite slurry is mixed in the above referenced bentonite slurry mix pond and pumped by pipeline into the excavated trench.
- The excavated soils from the trench are placed in an adjacent prepared slurry wall backfill mixing area for use in preparing the backfill, or if unsuitable for hauling the soil back to the WCA operations for processing as appropriate.
- As the trench is extended in length, backfilling is commenced. This is accomplished by first preparing the backfill material which typically includes granular soils mixed in with bentonite and water to create a low permeability material in the slurry wall backfill mixing area. Suitable excavated granular material will be used, or more suitable material will be obtained from the WCA operations or imported from offsite.
- Once mixed, the backfill is pushed into the trench by a dozer, or equivalent, from the narrow end, opposite to the end of the trench that is still being excavated. The backfill materials displaces the bentonite slurry

in the trench and eventually settles and forms a low permeability wall. The ultimate length of the slurry wall is approximately 13,400 feet and its width is typically 3 feet.

- As the wall is completed and gravel cap is placed over the top of the backfilled trench, it will form part of the perimeter road.
- A road safety berm will also be constructed along the inside of the road facing the excavation area.
- As the excavation of the reservoir pit is deepened an access ramp will be constructed in the excavated slope to provide for equipment access.

It should be noted the above discussion is for illustration purposes and actual construction techniques will vary based on the approved means and methods the contractor selects, and possible future technology advances in slurry wall construction.

In summary, slurry wall installation consists of clearing and grubbing approximately 26 acres, excavating approximately 112,000 cubic yards of native soil, and pouring of the slurry wall into the excavated trench. For the purposes of this analysis, soil excavated and transported for the slurry wall construction would be considered part of the total excavated material, such that the average site tonnage excavated (including slurry wall excavation) does not exceed baseline levels in the max year. Slurry wall materials imported to the site would substitute for exported material such that haul truck activity on-site and off-site would also not increase above baseline levels. Table 17 lists the approximate equipment activity levels for construction.

Table 17 Slurry Wall Excavation and Installation

Description	Equipment	HP	Rate	Quantity	# of 8 Hour Days
Clear/Grub, Haul Road, Construction Ponds	Dozer	165	1 hr/ac	26 ac	4
Slurry Wall Excavation	Excavator	429	1.7 cy/bucket	109,000 cy @ 25 buckets/hr	321
Haul Excavated Soil to Mixing Site and Return with Slurry Mix	Dump Truck	300	10 cy/haul	119,000 cy @ 4 hauls/hour	372
Plug Mill for Sieving Native Soils	Generator	100	4 hr/day	401 days	201
Mixing and Moving Slurry Mix	Loader	349	3 cy/bucket	119,000 cy @ 20 buckets/hr	248
Construction Slurry Pump	Generator	84	N/A	N/A	321
Dust Control	Water Truck	230	2 hr/day	401 days	100
Material Imports	On-Road Trucks	n/a	14 trips/day at 14.7 VMT/trip	60,000 tons in 4,800 trips	372

Source: Provost & Pritchard Consulting Group, 9/15/2014 (Appendix B).

2.4.5.2 Excavation Activity

Excavation activity would be limited to historical levels in the baseline. Accordingly, dust emissions related to excavation would not increase. However, the excavation emissions would change locations from the Seaborn site to the Project site which is immediately adjacent to the Seaborn site. The HRA included this change in location.

Excavation Phase Non-Road Engines

Table 18 presents the size, type and hours of operation for equipment that would be involved in excavating the reservoir.

Table 18 Excavation Equipment

Equipment	HP	Operating Hours per Year	Max Daily Operating Hours
988 Loader	540	502	14
982 Loader	400	502	14
980 Loader	390	502	14
390 Excavator	530	511	14
Haul Truck	600	1044	14
Haul Truck	600	1044	14
Dewatering Pump	30	3754	12
Dewatering Pump	30	3754	12
Skid Steer	65	626	2
Telehandler/Aerial Lift	402	626	2
Water Truck	402	2503	14

Source: Appendix B.

Annual hours of operation for the loaders, excavator, and haul trucks were determined based upon cycle time analysis using methods in the Caterpillar Performance Handbook (Appendix C).

The skid steer, telehandler, water trucks and dewatering pumps were assumed to have fixed operational hours. Up to two portable pumps, with 30 hp diesel engines, would be used to dewater the excavations. The pumps would operate continuously to keep the excavation dry.

Excavation Phase On-Road Engines

The amount of material produced by the Project would remain unchanged from the baseline level. Thus, off-site travel activity levels and associated emissions would be unaffected by the Project. Emissions from engines in trucks traveling on-site to export and import materials were calculated and incorporated into the HRA.

The number of employees would be either be less or remain unchanged from baseline condition with the Project. In general, diesel engine emissions from all modes of operation decrease in the future due to phase-in of CARB engine regulations. This primarily affects cancer risk which is a multi-year impact.

Excavation Phase Aggregates Processing Plant

The aggregates processing plant emission rate were calculated for both the aggregate screen/wash plant and crush/recycle plant (Appendix C). The screen/wash plant consists mostly of wet screening and material handling, and therefore only has fugitive emissions associated with dry feed materials. The wash/screen plant is run on grid electricity. The crush/recycle plant would be run using a portable diesel generator, and the associated fugitive and engine emissions were calculated for incorporation in the HRA (Appendix C).

Excavation Phase Stockpile/Loadout Area

The stockpile area would not increase from baseline levels with the Project. Emissions from a stockpile area two acres in size was attributed to the stockpile area at the Seaborn site in the baseline and for the Project. Emissions were calculated using the emissions factor and control efficiency recommended in Stationary Source Policy 1610 (SJVAPCD, 2013).

Excavation Phase Travel on Roads

Emissions from travel on roads depend upon the number of trips, length of the road, weight and speed of the vehicle and road surface condition.

Road lengths in the baseline at the Seaborn site were determined based on aerial photography on Google Earth taken during the baseline period. Half of the longest haul path was chosen as a representative road length in the baseline. Similarly, half of the longest haul path on the McKay site was chosen as the average haul trip for the purposes of this analysis.

Excavation Phase Emissions Summary

For emissions calculations, the Project is assumed to operate within the annual maximum production rate of 650,000 tons/yr for the first year, and then the average production rate 500,000 tons/yr for the following 22 years. Although the length of the excavation phase would be between 15 to 23 years, the actual length of this phase of the Project is dependent on the amount of high-quality aggregate is located in the pit area and the market demand. For the emission calculations it was assumed that it would take 23 years for the excavation of the pit for the reservoir to be completed. Assuming 30 percent waste factor, the maximum amount of material that would be excavated is approximately 920,000 gross tons/yr. In order to conservatively model air quality impact, the maximum excavation rate is assessed in the first year, concurrently with the installation of the slurry wall. Slurry wall installation emissions and Project excavation maximum annual emissions are shown in Table 19 and Table 20 respectively.

2.4.6 Operation Phase Emissions

The following assumes that on average the proposed basin could be filled two times per year for a total usable yearly volume of 9,100 acres-feet. Approximately 3,580 acres-feet can flow by gravity into the St. Johns River and the remaining 5,520 acres-feet can be pumped out at a maximum flow rate of 160 cubic feet per second. Table 21 lists the approximate equipment activity levels for operations. Table 22 lists the resulting emissions totals from Project operation.

Table 21 Project Operations

Non-Road Sources	**Equipment**	**HP**	**Rate**	**Quantity**	**# of 8 Hour Days**
Pumping	Generator	600	160 cfs	7,700 ac-ft	73
Minor Site Maintenance	Backhoe	108	N/A	N/A	20
On-Road Sources	**Equipment**	**Vehicle Miles Traveled / Year**			
Support Trucks	Spray Truck	380			
Support Trucks	Pickup	2,080

2.4.7 Health Risk Assessment

A HRA was performed using current best practices including methods from the HRA Guidelines (OEHHA, 2015). The four steps involved in the risk assessment process are: 1) hazard identification, 2) exposure assessment, 3) dose-response assessment, and 4) risk characterization. These four steps were used to assess health risk for the Project and each is discussed in the sections below.

Hazard Identification and Quantification

For air toxics sources, hazard identification involves the pollutant(s) of concern emitted by a facility, and the types of adverse health effects associated with exposure to the chemical(s), including whether a pollutant is a potential human carcinogen or is associated with other types of adverse health effects. Appendix A of the HRA Guidelines includes a list of TACs that are used for HRA in California.

DPM is the primary toxic constituent emitted by mining projects. DPM has an assigned cancer potency factor (CPF) and a non-cancer reference exposure level (REL) that are used to evaluate the risk from the DPM concentration present.

Fugitive emissions were generally speciated into constituent TACs based on SJVAPCD speciation profiles. San Diego Air Pollution Control District (SDAPCD) speciation profiles were also used when speciation data was not available from SJVACPD. The resulting mass of each TAC was used as input along with the dispersion coefficients to predict the ground level concentration (GLC) of each TAC which could then be used to evaluate the dose received by each receptor along each exposure pathway and, in the case of non-cancer risk, on each target organ, which was performed using HARP2 as discussed in the following subsections.

TACs incorporated in the HRA can be found in Table 23. Specific speciation profiles for road-based emissions, aggregates processing emissions, storage emissions, and excavation emissions can be found in Appendix C. Diesel emissions were evaluated for diesel particulate matter.

The HRA considered whether health risk from asbestos should be quantified. It was determined based on review of available maps (California Department of Conservation, Division of Mines and Geology, 2000) and language in the Asbestos ATCM's (17CCR §93105 and §93106) that allows the APCO to exempt sand and gravel facilities operating in alluvial deposits, that asbestos is unlikely to exist within, or upstream from, the Project site. Therefore, asbestos was excluded from the HRA.

Exposure Assessment

The purpose of exposure assessment is to estimate the extent of public exposure to emitted substances. For the Hot Spots program, in practice this means estimating exposures for those emitted substances for which potential cancer risk or noncancer health hazards for acute, repeated 8-hour, and chronic exposures will be evaluated. This involves emission quantification, modeling of environmental transport, evaluation of environmental fate, identification of exposure routes, identification of exposed populations, and estimation of short-term (e.g., 1-hour maximum), 8-hour average, and long-term (annual) exposure levels.

Hot Spots Analysis and Reporting Program (HARP2) software developed by CARB can be used to model ground level concentrations at specific off-site locations. HARP2 incorporates the US EPA-approved dispersion model, American Meteorological Society/Environmental Protection Agency Regulatory Model (AERMOD). AERMOD is a steady-state plume model based on planetary boundary layer turbulence structure and scaling concepts, including treatment of both surface and elevated sources, and both simple and complex terrain. CARB recommends AERMOD for Hot Spots risk assessments (OEHHA, 2015).

In this HRA, the air dispersion modeling was performed separately from HARP2 using AERMOD View by Lakes Environmental, Version 10.0.1 running AERMOD executable Version 2112. Output from the Lakes software program were imported to HARP2 (dated 2021) which was then used to perform the risk characterization

portion of the HRA. The process of using air dispersion modeling results as the basis of HRA follows these four steps:

1. Air dispersion modeling is used to estimate annual average and maximum one-hour ground level concentrations (GLC). The air dispersion modeling results are expressed as an air concentration or in terms of (Chi over Q) for each receptor point. (Chi over Q) is the modeled downwind air concentration (Chi) based on an emission rate of one gram per second (Q). (Chi over Q) is expressed in units of micrograms per cubic meter per gram per second, or ($\mu g/m^3$)/(g/s). (Chi over Q) is sometimes written as (X/Q) and is sometimes referred to as the dilution factor.

2. When multiple substances are evaluated, the X/Q is normally utilized since it is based on an emission rate of one gram per second. The X/Q at the receptor point of interest is multiplied by the substance-specific emission rate (in g/s) to yield the substance-specific GLC in units of $\mu g/m^3$. The following equations illustrate this point.

   $$GLC = \left(\frac{X}{Q}\right) \times Q_{Substance}$$

   $$\frac{X}{Q} = (Chi\ over\ Q)\ in\ \left(\frac{{}^{\mu g}/_{m^3}}{{}^{g}/_{s}}\right), from\ model\ results\ with\ unit\ emission\ rate$$

   $$Q_{Substance} = substance\ emission\ rate\ \left({}^{g}/_{s}\right)$$

3. The applicable exposure pathways (e.g., inhalation, soil contact, fish consumption) are identified for the emitted substances, and the receptor locations are identified. This determines which exposure algorithms are ultimately used to estimate dose. After the exposure pathways are identified, the fate and transport algorithms are used to estimate concentrations in the applicable exposure media (e.g., soil or water) and the exposure algorithms are used to determine the substance-specific dose.

4. The dose is used with cancer and noncancer health values to calculate the potential health impacts for the receptor. An example calculation using the high-end point-estimates for the inhalation (breathing) exposure pathway can be found in Appendix I of the HRA Guidelines (OEHHA, 2015).

AERMOD was used as described above to calculate a X/Q for each source-receptor combination by setting the emission rate for each source in the model to one gram per second (1 g/s). Other parameters used in AERMOD describe overall control of the model domain and functionality (e.g., coordinate system, terrain, non-default options, etc.), receptors (e.g., location, height), sources (e.g., size, location, exhaust velocity, temperature, operating schedule), meteorology (files provided by SJVAPCD), and output file options.

The Control Pathway of AERMOD was set to provide output in units of concentration; and both wet and dry plume depletion were disabled. The non-regulatory default option of flat terrain was selected as well as the beta option “Adjusted Friction Velocity (u*) in AERMET (ADJ_U*)” as discussed above. Pollutant/averaging

options were set to PM_{10} with averaging times of 1-hour and the period of the meteorological data file (i.e., five years). The rural dispersion coefficient was used and exponential decay was excluded.

Receptors were modeled at a flagpole height of 1.5 m. Fourteen (14) discrete receptors, 441 grid receptors, and 179 plant boundary receptors were modeled for a total of 634 receptors. The discrete receptors are shown on Figure 7 (Appendix A) and Table 24. The receptor grid was used to make the contoured plots of health risk shown in Figure 7 Appendix A.

Sources that existed during the baseline period and those proposed by the Project are illustrated on Figure 6a and 6b (Appendix A) and source parameters are summarized in Table 25. Project and baseline sources were included in the model. Project sources were assigned positive emissions values and baseline sources were assigned negative values so that the HRA result represent the change in health risk with the Project.

A wind rose showing the frequency of direction and speed of wind at the Visalia Airport (2007 through 2010) was produced from wind data obtained from the SJVAPCD website (Figure 5, Appendix A). The U-star adjusted (ADJ_U*) wind data file was chosen from the SJVAPCD website for the Project because it is a mining project and similar to the project discussed in the EPA Memo on this topic (EPA, 2016). Visalia Airport (Station No. 93144) is about 19 miles west-southwest of the Project.

Output of the dispersion model in the form of plotfiles, one for each combination of source and averaging period, that contain X/Q values were then used in HARP2 with the emissions rates presented above and other human exposure parameters discussed below to predict the acute, non-cancer chronic, and cancer risk at each receptor. The modeling files are provided in Appendix F.

Note: Project is in UTM Zone 11N.

Once emissions exit the source, the substances emitted will be dispersed in the air. The emission plume may contain both vapor phase substances and particulates. A semivolatile organic toxicant can partition into both vapor and particulate phases. Particulates can deposit on vegetation, on soil, and in water at a rate that is dependent on the particle size. A deposition rate of 0.05 m/s is conservative and was used for the Project HRA. The following algorithms are used to estimate concentrations in environmental media including air, soil, water, vegetation, and animal products.

Table 25 Emissions Source Parameters for Baseline and Project

AERMOD ID	Description	Src Grp ID	Type	UTM	Size [a]	Other Parameters
BMINE	Baseline excavation area	1	Area Poly	314323.56 m E, 4030149.56 m N	365,208 m^2	Release Height = 0m Initial Vertical Dim. = 1.39m

[a] Flat terrain was used so each source has base elevation of zero meters.

[b] Haul road parameters by EPA methods (EPA, 2012).

[c] Initial dimensions by EPA methods (EPA, 1995).

Determination of the concentration in air is made using X/Q and the emissions rate (g/s) as discussed above. The concentration of the substance in soil (Cs) is a function of the deposition, accumulation period, chemical specific soil half-life, mixing depth, and soil bulk density. For simplicity and health protection, the Tier 1 default

assumes 70-year soil deposition for the accumulation period at end of 70-year facility lifetime. The water pathway is evaluated as if a standing water body (e.g., pond or lake) is impacted by facility emissions and is used as a source for drinking water by food-producing animals or humans, or is a source of angler-caught fish. The average concentration of the substance in water (Cw) is a function of direct deposition (material carried in by surface run-off may occur as well but is not modeled). Concentrations in vegetation, animal products, angler caught fish, and mother's milk are predicated on the concentrations estimate to be in the air, water, and soil. The Project HRA includes air, soil ingestion, home grown produce, and mother's milk as pathways of exposure. Detailed discussion of the methodologies used to determine the concentrations in various media to which receptors may be exposed is located in Subchapter 5.3 of the HRA Guidelines.

Once the concentrations of substances are estimated in air, soil, water, plants, and animal products, they are used to evaluate estimated exposure to people. Exposure is evaluated by calculating the daily dose in milligrams per kilogram body weight per day (mg/kg/d). The HRA Guidelines describe the algorithms used by HARP2 to calculate this dose for exposure through inhalation, dermal absorption, and ingestion pathways. All chemicals are assessed for exposure through inhalation. Emissions of semi-or non-volatile multi-pathway substances (e.g., earth metals in fugitive dust), the soil ingestion pathway and the dermal soil exposure pathway are also assessed. The mother's milk pathway is used depending on the multi-pathway substance released. The Project HRA assessed each of these pathways.

Inhalation Dose

The dose through the inhalation route is estimated for cancer risk assessment and noncancer hazard assessment. Both residential and offsite worker exposures are considered. Since residential exposure includes near-continuous long-term exposure at a residence and workers are exposed only during working hours (i.e., 8 hours/day), different breathing rate distributions are used.

Exposure through inhalation is a function of the breathing rate, the exposure frequency, and the concentration of a substance in the air. For residential exposure, the breathing rates are determined for specific age groups, so inhalation dose (Dose-air) is calculated for each of these age groups, 3rd trimester, 0<2, 2<9, 2<16, 16<30 and 16-70 years. OEHHA used the mother's breathing rates to estimate dose for the 3rd trimester fetus assuming the dose to the fetus during the 3rd trimester is the same as the mother's dose. These age-specific groupings are needed in order to properly use the age sensitivity factors for cancer risk assessment. Tier 1 evaluations and the Project HRA use the high-end point estimate (i.e., the 95th percentiles) breathing rates for the inhalation pathway in order to avoid underestimating cancer risk to the public, including children. The following equation is used to determine dose for the inhalation pathway.

$$Dose_{Air} = C_{Air} \times \left\{\frac{BR}{BW}\right\} \times A \times EF \times 10^{-6}$$

Where:

$Dose_{Air}$ = Dose through inhalation (mg/kg/d)

C_{Air} = Concentration in air (µg/m^3)

{BR/BW} = Daily breathing rate normalized to body weight (L/kg body weight-day)

A = Inhalation absorption factor (unitless)
EF = Exposure frequency (unitless), days/365 days
10^{-6} = Micrograms to milligrams conversion, liters to cubic meters conversion

As discussed above, recommended values for the breathing rate normalized to body weight term, {BR/BW}, are the 95th percentile high-end point estimate that is used for Tier 1 HRAs like the Project HRA. This term has several values that are needed to assess cancer risk for each age bins designated in the HRA Guidelines (i.e., third trimester, 0 to 2, 2 to 16 and 16 to 70 years). These values as well as parametric model distributions used for Tier 3 and Tier 4 stochastic analysis are provided in the HRA Guidelines. The inhalation absorption factor, A, is recommended to be assigned a value of one (i.e., 100% of dose is absorbed) but may also be assigned the value determined by the toxicological study upon which the REL for the substance is based. Exposure frequency is recommended to be 350 days for residential exposures. Table 26 presents the mean and high-end point estimates for residential intake rates that were assumed in the Project HRA.

For worker exposure, the HARP2 default assumes working age begins at 16 years, and that exposures to facility emissions occur during the work shift, typically up to 8 hours per day during work days. Breathing rates that occur over an 8-hour period vary depending on the intensity of the activity, and are used to estimate the inhalation dose. The 8-hour breathing rates may also be used for cancer risk assessment of children and teachers exposed at schools during school hours. The Project HRA used a more conservative approach and instead applied residential exposure characteristics at the nearby school, Sequoia Union Elementary School.

Table 26 Point Estimates of Residential Daily Breathing Rates by Age Group

Estimate	3rd Trimester[1] (L/kg BW-day)[2]	0<2 Years (L/kg BW-day)	2<16 Years (L/kg BW-day)	16<30 Years (L/kg BW-day)
Mean (65%ile)[3]	225	658	452	210
High-End (95%ile)	361	1090	745	335

Source: (OEHHA, 2015, pp. 5-25).

1 3rd trimester breathing rates based on breathing rate of pregnant women using the assumption that the dose to the fetus during the 3rd trimester is the same as that to the mother.

2 Values are in units of liters of air per kilogram of body weight per day.

3 Mean values were not used in the HRA and are provided for informational purposes only.

Exposed workers may be engaged in activities ranging from desk work, which would reflect breathing rates of sedentary/passive or light activities, to farm worker activities, which would reflect breathing rates of moderate intensity. OEHHA recommends default (Tier 1) point estimate 8-hour breathing rates in L/kg-8-hrs based on the mean and 95th percentile of moderate intensity activities, 170 and 230 L/kg-8-hrs, respectively, for adults 16-70 years old.

Non-cancer health risks were determined in HARP2 by dividing the GLC of each pollutant at each receptor by the corresponding reference exposure level (REL, units of µg/m^3) resulting a hazard index (HI). The HIs for pollutants affecting each target organ were then summed to determine the total HI for each target organ. The target organ with the greatest HI is reported as the non-cancer health risk at each receptor. Worker chronic non-cancer health risk results were multiplied by a Worker Adjustment Factor (WAF) of 4.2 which represents

the amount overlap between the Project operating schedule and the worker's work schedule; both of which are assumed to be 8 hr/day, 5 days/wk. The mean and high-end intake rates for workers were 170 and 230 liters per kilogram per 8-hours (L/kg-8-hrs). Workers were assumed to be exposed for 25 years as recommended in the HRA Guidelines (OEHHA, 2015, pp. 5-26).

Annual residential dose was calculated by HARP2 using the GLC (mg/m^3), the intake rate (L/kg-day), 350 days/yr exposure frequency, and an assumption that the entire mass of pollutants inhaled is absorbed into the body of the individual exposed (i.e., no pollutants are exhaled). A fraction of time at home (FAH) of 85% was applied for individuals of any age. Annual worker dose was calculated the same way and adjusted to 250 days/yr exposure frequency by multiplying the result by 0.68.

Inhalation dose of each pollutant at each receptor for each year was then multiplied in HARP2 by the inhalation cancer slope factor for the pollutant to estimate annual cancer risk in units of excess cancer cases per million individuals exposed. The total cancer risk from inhalation was then calculated by summing the annual risk from each pollutant and year of exposure. Residential cancer risk assumed exposure duration of 30 years as recommended by OEHHA (OEHHA, 2015, pp. 8-1) and the OEHHA Derived Method intake rate for all exposure pathways and all ages which is more conservative than the recommended Risk Management Policy (RMP) (95/80%ile combination for inhalation pathway and 65%ile for other pathways), and RMP Derived Method (95/80%ile combination for two dominant exposure pathways and 65%ile for other pathways). The RMP 95/80%ile combination refers to applying the 95^{th} percentile intake rate for ages less than two years and the 80^{th} percentile intake rate for ages over two years whereas the OEHHA Derived Method uses 95%ile intake rate for all ages and results in greater risk estimates which is conservative.

Ingestion Pathway

The average concentration of pollutants in soil is a function of the deposition, accumulation period, chemical specific half-life, mixing depth, and soil bulk density. For simplicity and health protection, the HARP2 default 70-year soil deposition for the accumulation period was assumed. As discussed above, the conservative deposition rate (0.05 m/s) was applied. Equations and parameters used to estimate the concentration of pollutant in the soil from the GLC can be found in the HRA Guidelines (p. 5-6 to 5-8).

The exposure dose through residential soil ingestion varies by age and was calculated for each age group. The dose is calculated by HARP2 based on the concentration in soil, pollutant specific gastrointestinal relative absorption fraction (GRAF, unitless), soil ingestion rate (mg/kg-day), and exposure frequency using the equation presented in the HRA Guidelines (p. 5-43). For simplicity, GRAF was assigned a value of one which represents the entire mass of pollutant being absorbed. Soil ingestion rates vary by age and the high-end point estimates shown in Table 27 were used.

Table 27 Soil Ingestion Rate Point Estimates by Age Group

Estimate	3rd Trimester[1] (mg/kg BW-yr)[2]	0<2 Years (mg/kg BW-yr)	2<16 Years (mg/kg BW-yr)	16<30 Years (mg/kg BW-yr)
Mean (65%ile)[3]	0.7	20	3	0.7
High-End (95%ile)	3	40	10	3

Source: (OEHHA, 2015, pp. 5-44).

1 3rd trimester is assumed to be the mother's soil ingestion rate.

2 Values are in units of milligrams of pollutant ingested per kilogram of body weight per year.

3 Geometric mean (GM) values were not used in the HRA and are provided for informational purposes only.

Dermal Pathway

Exposure through dermal absorption (dose-dermal) is a function of the soil or dust loading of the exposed skin surface, the amount of skin surface area exposed, and the concentration and availability of the pollutant. The annual dermal load (ADL) is a composite of the body surface area per kg body weight, exposure frequency, and soil adherence to the skin. High-end point estimates of ADL for individuals located in a mixed climate were used.

Table 28 Annual Dermal Loading Point Estimates by Age Group

Estimate	3rd Trimester[1] (mg/kg BW-yr)[2]	0<2 Years (mg/kg BW-yr)	2<16 Years (mg/kg BW-yr)	16<30 Years (mg/kg BW-yr)
Mean (65%ile)[3]	1,100	2,200	5,700	1,100
High-End (95%ile)	2,400	2,900	8,100	2,400

Source: (OEHHA, 2015, pp. 5-37).

1 3rd trimester based on ADL of mother normalized to body weight assuming exposure to the mother and feus are the same.

2 Values are in units of milligrams of pollutant on skin per kilogram of body weight per year.

3 Mean values were not used in the HRA and are provided for informational purposes only.

High-end ADL was combined with the concentration of pollutant in soil, the fraction absorbed across skin (pollutant-specific factor), the exposure duration (i.e., 70 years) and the averaging time (i.e., 70-year lifetime) using equations presented in the HRA Guidelines (p. 5-41) to estimate the dermal dose for each residential receptor. Worker receptors used the adult ADL and omitted exposure duration and averaging time from the calculation.

Mother's Milk Pathway

Estimates of the concentration of pollutants in a mother's milk require the use of the air, water, and soil environmental fate evaluations. Infants would be exposed to the pollutants in concentrations equal to the concentrations at which the mother is exposed from birth up to 25 years of age when the infant is born. The exposed infant is assumed to be fully breastfed for the first year of life. The summed average dose daily dose (mg/kg-day) from all pathways is calculated for the nursing mother using equations in the HRA Guidelines (p. 5-59). Breast milk intake rates of 101 and 139 g/kg-day are used by HARP2.

Dose-Response Assessment

Dose-response assessment is the process of characterizing the relationship between exposure to an agent and incidence of an adverse health effect in exposed populations. In quantitative carcinogenic risk assessment, the dose-response relationship is expressed in terms of a potency slope that is used to calculate the probability or risk of cancer associated with an estimated exposure. Cancer potency factors (CPF) are expressed as the 95th percent upper confidence limit of the slope of the dose response curve estimated assuming continuous lifetime exposure to a substance. Typically, potency factors are expressed as units of inverse dose (e.g., (mg/kg BW/day)$^{-1}$) or inverse concentration (e.g., (µg/m3)$^{-1}$). It is assumed in cancer risk assessments that risk is directly proportional to dose and that there is no threshold for carcinogenesis. (OEHHA, 2015).

For noncarcinogenic effects, dose-response data developed from animal or human studies are used to develop acute, 8-hour, and chronic noncancer Reference Exposure Levels (RELs). The acute, 8-hour and chronic RELs are defined as the concentration at which no adverse noncancer health effects are anticipated even in sensitive members of the general population, with infrequent one-hour exposures, repeated 8-hour exposures over a significant fraction of a lifetime, or continuous exposure over a significant fraction of a lifetime, respectively. The most sensitive health effect is chosen to develop the REL if the chemical affects multiple organ systems. Unlike cancer health effects, noncancer health effects are generally assumed to have thresholds for adverse effects. In other words, injury from a pollutant will not occur until exposure to that pollutant has reached or exceeded a certain concentration (i.e., threshold) and/or dose. The acute, 8-hour, and chronic RELs are air concentrations intended to be below the threshold for health effects for the general population (OEHHA, 2015).

The actual threshold for health effects in the general population is generally not known with any precision. Uncertainty factors are applied to the Lowest Observed Adverse Effects Level (LOAEL) or No Observed Adverse Effects Level (NOAEL) or Benchmark Concentration values from animal or human studies to help ensure that the chronic, 8-hour and acute REL values are below the threshold for human health for nearly all individuals. Table 29 summarizes the health values that were used in the dose-response assessment.

Note: Greyed cells contain values that were not used in the HRA. Specifically, DPM was used to assess chronic/cancer risk from exposure to diesel exhaust.

Risk Characterization

Risk characterization is the final step of the HRA. In this step, information developed through the exposure assessment is combined with information from the dose-response assessment to characterize risks to the general public from emissions. In the California, OEHHA conducts the dose-response assessment during the development of cancer potency factors and Reference Exposure Levels. These are used in conjunction with the exposure estimates to estimate cancer risk and evaluate hazard from noncancer toxicity of emitted chemicals. Under AB2588, risk characterizations present both individual and population-wide health risks. A general summary of the risk characterization components includes the following items and information.

- The locations of the point of maximum impact (PMI), the maximum exposed individual receptor (MEIR), and the maximum exposed individual worker (MEIW) are to be identified. The PMI, MEIW, and MEIR for cancer risk and for noncancer hazard indices (averaging times for acute 1-hour, repeated 8-hour, and chronic hazard indices) may not be the same location; all should be identified.
- The location of any specified sensitive receptors (e.g., schools, hospitals, daycare, or eldercare facilities -contact the District or reviewing authority for more information) should be identified.
- Estimates of population-wide cancer risk and noncancer hazard.

Cancer Risk

Cancer risk is calculated by multiplying the daily inhalation or oral dose, by a cancer potency factor, the age sensitivity factor, the frequency of time spent at home (for residents only), and the exposure duration divided by averaging time, to yield the excess cancer risk. As described below, the excess cancer risk is calculated separately for each age grouping and then summed to yield cancer risk at the receptor location. A brief description of the age sensitivity factors, exposure duration, and frequency of time spent at home are included below. These factors are discussed in various technical support documents to the HRA Guidelines.

OEHHA has determined that young animals are more sensitive than adult animals to exposure to many carcinogens. Therefore, OEHHA developed age sensitivity factors (ASFs) to take into account the increased sensitivity to carcinogens during early-in-life exposure. In the absence of chemical-specific data, OEHHA recommends a default ASF of 10 for the third trimester to age 2 years, and an ASF of 3 for ages 2 through 15

years to account for potential increased sensitivity to carcinogens during childhood. These values manifest in the intake parameters presented below.

FAH during the day can be used to adjust exposure duration and cancer risk from a specific facility's emissions, based on the assumption that exposures to the facility's emissions are not occurring away from home. From the third trimester to age <2 years, 85% of time is spent at home. From age 2 through <16 years, 72% of time is spent at home. From age 16 years and greater, 73% of time is spent at home. Facilities with a school within the 1×10^{-6} (or greater) isopleth are directed to use FAH = 1 for the child age groups (3rd Trimester, 0<2 years, and 2<16 years).

For residential inhalation exposure, cancer risk must be separately calculated for specified age groups because of age differences in sensitivity to carcinogens and age differences in intake rates (per kg body weight). Separate risk estimates for these age groups provide a health-protective estimate of cancer risk by accounting for greater susceptibility in early life, including both age-related sensitivity and amount of exposure. The following equation illustrates the formula for calculating residential inhalation cancer risk.

$$RISK_{inh-res} = DOSE_{air} \times CPF \times ASF \times \frac{ED}{AT} \times FAH$$

Where:

$RISK_{inh\text{-}res}$ = Residential inhalation cancer risk
$DOSE_{air}$ = Daily inhalation dose (mg/kg-day)
CPF = Cancer potency factor $(mg/kg\text{-}day)^{-1}$
ASF = Age sensitivity factor for a specified age group (unitless)
ED = Exposure duration (in years) for a specified age group
AT = Averaging time for lifetime cancer risk (years)
FAH = Fraction of time spent at home (unitless)

Cancer risks calculated for individual age groups are summed to estimate the total cancer risk over the period of interest and/or lifetime. Cancer risk is typically expressed in "chances per million" (cancer risk × 10^6) but may also be expressed in other ways, such as "chances per 100,000" or "chances per 10 million" (cancer risk × 10^7).

For assessment of off-site worker cancer risk at the MEIW, the default assumes working age begins at 16 years. The daily inhalation dose ($DOSE_{air}$) is based on the adjusted 8-hour concentration at the MEIW (for noncontinuous sources) and amount of time the offsite worker's schedule overlaps with the facility's emission schedule. The duration of exposure at the MEIW receptor is 25 years. Additional consideration for offsite worker cancer risk assessment is whether there are women of child bearing age at the MEIW location and whether the MEIW has a daycare center. Under most circumstances, cancer risk accumulated by inhalation is calculated using the following equation:

$$RISK_{inh-work} = DOSE_{air} \times CPF \times ASF \times \frac{ED}{AT}$$

Where:

$RISK_{inh\text{-}work}$ = Worker inhalation cancer risk
$DOSE_{air}$ = Daily inhalation dose (mg/kg-day)
CPF = Cancer potency factor $(mg/kg\text{-}day)^{-1}$
ASF = Age sensitivity factor for a specified age group (one for working age 16 to 70)
ED = Exposure duration (in years) for a specified age group (25 years)
AT = Averaging time for lifetime cancer risk (70 years)

As discussed previously, some substances (e.g., semi-volatile organics and metals) are carcinogenic regardless of how they enter the body. Exposures to these substances are called multi-pathway. HRA for a facility that emits a multi-pathway pollutant must, at a minimum, evaluate doses from soil ingestion and dermal exposure. If polycyclic aromatic hydrocarbons, lead, dioxins, furans, or polychlorinated biphenyls are emitted, then the breast-milk consumption pathway becomes mandatory for residential receptors. OEHHA has developed transfer coefficients for these chemicals from the mother to breast milk. The other exposure pathways (e.g., ingestion of homegrown produce or fish) are only evaluated for residential receptors if the facility impacts that exposure medium and the receptor under evaluation can be exposed to that medium or pathway.

Non-inhalation residential cancer risk is calculated using the same steps as inhalation cancer risk. The pathway under evaluation (e.g., soil ingestion) is multiplied by the substance-specific oral slope factor, expressed in units of inverse dose (i.e., $(mg/kg/day)^{-1}$), the appropriate ASF, and exposure duration divided by averaging time to yield the cancer risk for a specified age grouping. Cancer risk for each age group is summed as appropriate for the exposure duration.

If multiple substances are emitted, the substance-specific cancer risks for all exposure pathways are summed to give the (total) multi-pathway cancer risk at the receptor location. HARP2 displays the multi-pathway risk for each carcinogenic substance and a breakdown of the cancer risk from each exposure pathway.

This HRA evaluates mother's milk due to presence of lead in fugitive dust. The default assumption inherent in the intake rate is that the infant's only source of food is breast for the first year (e.g., is fully breastfed), which is one-half of the 0<2 year age group used in the Hot Spots program. Thus, the cancer risk by the mother's milk pathway is calculated with a slightly modified equation using a different exposure duration. Once the cancer risk is determined for the mother's milk pathway then it is summed with the other risks to calculate the total cancer risk for the receptor.

OEHHA recommends that exposure from projects longer than 2 months but less than 6 months be assumed to last 6 months (e.g., a 2-month project would be evaluated as if it lasted 6 months). Exposure from projects lasting more than 6 months should be evaluated for the duration of the project. In all cases, for assessing risk to residential receptors, the exposure should be assumed to start in the third trimester to allow for the use of the ASFs. Thus, for example, if one is evaluating a proposed 10-year project, the cancer risks for the residents would be calculated based on exposures starting in the third trimester through the first ten years of life.

Non-Cancer Risk

Estimates of noncancer inhalation health impacts are determined by dividing an airborne concentration at the receptor by the appropriate REL. This is termed the Hazard Index (HI) Approach. A REL is used as an indicator of potential noncancer health impacts and is defined as the concentration at which no adverse noncancer health effects are anticipated. When a health impact calculation is performed for a single substance, then it is called the hazard quotient (HQ). Each REL for a substance will have one or more target organ systems (e.g., respiratory system, nervous system, etc.) where the substance can have a noncancer health impact. Thus, all HQs have specified target organ systems associated with them. The sum of the Hazard HQs of all chemicals emitted that impact the same target organ is the HI. Inhalation RELs for noncancer health impacts have been developed for acute, 8-hour, and chronic exposures to a number of substances.

Acute RELs are designed to protect against the maximum 1-hour ground level concentration at the receptor. Chronic RELs protect against long-term exposure to the annual average air concentration spread over 24 hours/day, 7 days/week.

Eight-hour RELs are designed to protect people with daily 8-hour schedules, such as offsite workers, in an impacted zone. The 8-hour RELs are used for typical daily work shifts of 8-9 hours and represent concentrations at or below which health impacts would not be expected even for sensitive subpopulations in the general population with repeated daily 8-hour exposures over a significant fraction of a lifetime. The 8-hour RELs can be used to evaluate the potential for health impacts (including effects of repeated exposures) in offsite workers, and to children and teachers exposed during school hours.

Acute, 8-hour, and chronic RELs are needed because the dose metrics and even the health impact endpoints may be different with the different exposure durations of acute, daily 8-hour, and chronic exposures. Also, although chronic REL values are lower or set the same as 8-hour RELs, there are some cases such as special meteorological situations (e.g., significant diurnal-nocturnal meteorological differences) or intermittent exposures where the 8-hour REL may be more protective than the chronic REL.

As discussed above, in order to calculate the acute, 8-hour, or chronic HQ, the maximum ground-level concentration (in µg/m^3) during the appropriate period of time (i.e., 1-hour acute, 8-hour, and 1-year chronic) is divided by the corresponding REL (in µg/m^3) for the substance. If a receptor is exposed to multiple substances that target the same organ system, then the HQs for the individual substances are summed to obtain a Hazard Index (HI) for that target organ as shown in the following equations.

$$HI_{Organ1} = \frac{C_{air,1}}{REL_1} + \frac{C_{air,2}}{REL_2} + \cdots + \frac{C_{air,n,}}{REL_n}$$

or

$$HI_{Organ1} = HQ_1 + HQ_2 + \cdots + HQ_n$$

A HI of 1.0 or less indicates that adverse health effects are not expected to result from exposure to emissions of that substance. As the HI increases above one, the probability of human health effects increases by an undefined amount. However, HI above one is not necessarily indicative of health impacts due to the application of uncertainty factors in deriving the RELs.

There are non-cancer multi-pathway pollutants that are assessed for inhalation, ingestion, and other non-inhalation pathways. Nickel and arsenic are two that are found in fugitive dust and so the non-inhalation exposures to these metals are assessed for the corresponding target organs. Specifically, nickel effects the respiratory, hematologic, and alimentary systems while arsenic affects development; the nervous and cardiovascular systems; and the skin.

2.5 Project-Level Impacts and Mitigation Measures

2.5.1 Conflict with or Obstruction to the Implementation of an Air Quality Plan

Impact Statement

Impact AQ-1: *Would the Project conflict with or obstruct implementation of the applicable air quality plan?* **(Appendix G Threshold Criteria (a))**

Impact Analysis

The SJVAPCD is tasked with implementing programs and regulations required by the CAA and the CCAA. In that capacity, the SJVAPCD has prepared plans to attain Federal and State ambient air quality standards. The SJVAPCD has established thresholds of significance for criteria pollutant emissions, which are based on SJVAPCD NSR offset requirements for stationary sources. Stationary sources in the SJVAPCD are subject to some of the toughest regulatory requirements in the nation. Emission reductions achieved through implementation of SJVAPCD offset requirements are a major component of the SJVAPCD's air quality plans. Thus, projects with emissions below the thresholds of significance for criteria pollutants would be determined to "Not conflict or obstruct implementation of the SJVAPCD's air quality plan" (SJVAPCD, 2015, p. 65).

Planned and current measures to be implemented under the applicable air quality plans do not apply to the Project. Moreover, the Project operators, including WCA, would be required to comply with regional air quality rules promulgated by the SJVAPCD and participate in reducing air pollutant emissions. Lastly, aggregates production is proportional to population growth, which is a factor that is accounted for in air quality plans. Therefore, the Project would not obstruct implementation of the applicable SJVAPCD air quality plan. Project impacts were determined to be less than significant.

Level of Significance Before Mitigation

Less than significant.

Mitigation Measures

None required.

Level of Significance After Mitigation

Not applicable.

2.5.2 Net increase of any criteria pollutant

Impact Statement

Impact AQ-2: *Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is non-attainment under an applicable Federal or State ambient air quality standard?* **(Appendix G Threshold Criteria (b))**

Impact Analysis

CEQA defines cumulative impacts as two or more individual effects which, when considered together, are either significant or "cumulatively considerable", meaning they add considerably to a significant environmental impact. An adequate cumulative impact analysis considers a project over time and in conjunction with other past, present, and reasonably foreseeable future projects whose impacts might compound those of the project being assessed.

By its very nature, air pollution is largely a cumulative impact. The nonattainment status of regional pollutants is a result of past and present development. Future attainment of State and Federal ambient air quality standards is a function of successful implementation of the SJVAPCD's attainment plans. Consequently, the SJVAPCD's application of thresholds of significance for criteria pollutants is relevant to the determination of whether a project's individual emissions would have a cumulatively significant impact on air quality.

A CEQA Lead Agency may determine that a project's incremental contribution to a cumulative effect is not cumulatively considerable if the project will comply with the requirements in a previously approved plan or mitigation program, including but not limited to an air quality attainment or maintenance plan that provides specific requirements that will avoid or substantially lessen the cumulative problem within the geographic area in which the project is located (CCR §15064(h)(3)).

Thus, if project emissions (change from baseline) exceed thresholds for NOx, ROG, PM_{10} or $PM_{2.5}$, then the project would result in a cumulatively considerable net increase of a criteria pollutant for which the SJVAPCD is in non-attainment under applicable Federal or State ambient air quality standards. This does not imply that if the project impact is less than those significance criteria, it cannot be cumulatively significant. The significance criteria are presented in Table 8 and include thresholds that are applied separately to construction and operation phases of a project. Construction phase emissions are summarized and compared to applicable thresholds in Table 30.

Table 30 Construction Phase Criteria Pollutant Annual Emissions

	ROG (ton/yr)	CO (ton/yr)	NO_X (ton/yr)	PM_{10} (ton/yr)	$PM_{2.5}$ (ton/yr)	SOx (ton/yr)
Construction	0.048	0.29	0.49	0.022	0.018	0.001
Threshold	10	100	10	15	15	27
Significant?	**No**	**No**	**No**	**No**	**No**	**No**

Source: Appendix D.

Hourly and annual emissions were quantified for the excavation phase. Annual emissions thresholds apply separately for Permitted and Permit-Exempt sources. Table 31 and Table 32 present annual and hourly excavation phase emissions respectively, and compare the emissions to the applicable significance thresholds.

Table 31 Excavation Phase Criteria Pollutant Annual Emissions

Criteria Pollutant	Permitted Sources (tons/yr)	Permitted Sources Significance Threshold (tons/yr)	Exceeds Permitted Sources Threshold?	Permit-Exempt Sources (tons/yr)	Permit-Exempt Sources Significance Threshold	Exceeds Permit-Exempt Threshold?
ROG	-0.08	10	No	-0.35	10	No
CO	-0.27	100	No	2.20	100	No
NO_X	-0.66	10	No	-5.10	10	No
PM_{10} (total)	-0.02	15	No	14.37	15	No
$PM_{2.5}$	-0.03	15	No	5.93	15	No
SO_X	-0.01	27	No	-0.10	27	No

Source: Appendix C.

Table 32 Excavation Phase Criteria Pollutant Daily Emissions

Criteria Pollutant	CO lbs/day	NO_x lbs/day	PM_{10} lbs/day	$PM_{2.5}$ lbs/day	SO_x lbs/day
Baseline	163	457	260	80	3.24
Excavation	119	221	529	160	0.40
Project	-45	-236	269	80	-2.83
Screening Criteria	100	100	100	100	100
Exceeds Criteria?	**No**	**No**	**Yes**	**No**	**No**

Source: Appendix C.

Table 30, Table 31, and Table 32 show that except for PM_{10} the Project does not exceed thresholds.

The level of road dust control in the baseline is based upon watering two to three times per day. That level of watering is assigned 80% control efficiency. Increasing the control efficiency to 90% would result in an additional reduction of approximately 50%. As shown in EPA's AP-42 Figure 13.2.2-2 pertaining to unpaved

roads, watering alone can achieve up to 95% control. The certified Kaweah South Project EIR assigned 93% to the combination of "limiting vehicle speed to 15 mph, improving surfaces with aggregate, and watering" (Tulare County, 2006). Thus, 90% control is feasible and achieved in practice using water or a combination of water and chemical dust suppressants (e.g., magnesium chloride, lignin sulfonate, etc.). The excavation phase has maximum net emissions (Project minus baseline) of 269 lbs/day which would be reduced to 84.8 lbs/day with the additional control (Appendix C, Mitigated Emissions, Maximum Year). Therefore, with Mitigation Measure AQ-1, the Project would not result in a cumulatively considerable net increase of any criteria pollutant for which the project region is non-attainment under an applicable Federal or State ambient air quality standard and is therefore less than significant.

Level of Significance Before Mitigation

Daily PM_{10} emissions are potentially significant.

Mitigation Measures

Mitigation Measure AQ-1 is recommended to avoid causing or contributing to an existing or projected violation of an air quality standard.

Mitigation Measure AQ-1*:* *Roads upon which material is hauled to the on-site plant for processing shall be controlled by methods that will achieve 90% reduction of fugitive dust. This can be achieved by frequent watering, use of chemical dust suppressants, or a combination of watering and chemical dust suppressants. Other methods which achieve 90% reduction of fugitive dust may be acceptable with Lead Agency approval.*

Level of Significance After Mitigation

Less than significant.

2.5.3 Exposure of Sensitive Receptors to Substantial Pollutant Concentrations

Impact Statement

Impact AQ-3: *Would the Project expose sensitive receptors to substantial pollutant concentrations?* **(Appendix G Threshold Criteria (c))**

Impact Analysis

Determination of whether project emissions would expose sensitive receptors to substantial pollutant concentrations is a function of assessing potential health risks. Sensitive receptors are facilities that house or attract children, the elderly, people with illnesses, or others who are especially sensitive to the effects of air pollutants. Hospitals, schools, convalescent facilities, and residential areas are examples of sensitive receptors. When evaluating whether a development proposal has the potential to result in localized impacts, the nature of the air pollutant emissions, the proximity between the emitting facility and sensitive receptors, the direction of prevailing winds, and local topography must be considered (SJVAPCD, 2015, p. 66).

A Health Risk Assessment was performed as discussed in Section 2.4.7 to evaluate the effects of TACs including DPM from vehicles and other substances potentially found in fugitive dust emissions (i.e., metals and crystalline silica). Risk from excavation and operation of the reservoir are each incorporated into the values presented in Table 33 which shows the cancer risk at the closest residential and sensitive receptors including Sequoia Union Elementary School.

Health risk is determined based on the change in conditions associated with the implementation of the Project. Emissions sources present in the baseline cease to operate, and emissions from the Project are introduced. Therefore, baseline risk is modeled as negative risk (emissions going away), and Project risk is modeled as positive (new emissions). In many cases, Project emissions end up being lower than those in the baseline, due to newer technologies and updated regulations. In such cases, risk to receptors may be reduced, as the Project results in a reduction of emissions. In cases where risk to a receptor is greater in the baseline than in the Project, the risk is represented as a negative number.

Table 33 Health Risk Results

Receptor Figure Label – Type	Receptor Model ID Number	Excess Cancer Cases per Million People Exposed	Chronic Hazard Index	Acute Hazard Index
1 – Residence	396	-22.1	0.0	0.000
2 – Residence	397	-16.4	0.0	0.020
3 – Residence	398	4.4	0.23	0.031
4 – Residence	399	3.9	0.14	0.059

Significance Threshold	N/A	20	1.0	1.0
Threshold Exceeded?	**N/A**	**No**	**No**	**No**

Source: Appendix E.

Note: These receptors represent locations of highest exposure. Discrepancies between table and appendix values may exist due to rounding. Negative values represent risk reduction compared to baseline levels.
MEIR: Maximum Exposed Individual Receptor; MEIW: Maximum Exposed Individual Worker; PMI: Point of Maximum Impact

As shown in Table 33, health risk from the Project is less than significant.

Level of Significance Before Mitigation

Less than significant.

Mitigation Measures

None required.

Level of Significance After Mitigation

Not applicable.

2.5.4 Odors Affecting a Substantial Number of People

Impact Statement

Impact AQ-4: *Would the Project result in other emissions (such as those leading to odors) adversely affecting a substantial number of people?* **(Appendix G Threshold Criteria (d))**

Impact Analysis

Due to the subjective nature of odor impacts, the number of variables that can influence the potential for an odor impact, and the variety of odor sources, there are no quantitative or formulaic methodologies to determine the presence of a significant odor impact. Rather, the SJVAPCD recommends that odor analyses strive to fully disclose all pertinent information.

The intensity of an odor source's operations and its proximity to sensitive receptors influences the potential significance of odor emissions. The SJVAPCD has identified some common types of facilities that have been known to produce odors in the San Joaquin Valley. These are presented in Table 34 below along with a reasonable distance from the source within which, the degree of odors could possibly be significant (It should be noted that aggregate mining/processing facilities are not included on Table 34). If the proposed project would result in sensitive receptors being located closer than the screening level distances, a more detailed analysis should be provided and include information regarding odor complaints (SJVAPCD, 2015, p. 103).

Table 34 Odor Screening Distances

Type of Facility	Odor Screening Distance (miles)
Wastewater Treatment Facilities	2
Sanitary Landfill	1
Transfer Station	1
Composting Facility	1
Petroleum Refinery	2
Asphalt Batch Plant	1
Chemical Manufacturing	1
Fiberglass Manufacturing	1
Painting/Coating Operations (e.g., auto body shops)	1
Food Processing Facility	1
Feed Lot/Dairy	1

Type of Facility	Odor Screening Distance (miles)
Rendering Plant	1

Source: (SJVAPCD, 2015).

Diesel exhaust from mobile equipment/vehicles has a slight odor. Odor intensity would decrease rapidly with distance and is not expected to be frequently (or at all) detectable at locations outside of the Project site boundary. In addition, given the subjective nature of odors, such odors are generally only considered to be objectionable by residential receptors (i.e., not by occupational workers). Given the rural nature of the Project vicinity, there are few residences located within 1 mile of the reservoir where the majority of the on-site emissions of diesel exhaust from mobile equipment/vehicles would occur. Therefore, it is not anticipated that objectionable odors affecting a substantial number of people could result from the Project.

In addition, the Project is required to comply with the SJVAPCD nuisance rule (Rule 4102), which reads:

> *"A person shall not discharge from any source whatsoever such quantities of air contaminants or other materials which cause injury, detriment, nuisance or annoyance to any considerable number of persons or to the public or which endanger the comfort, repose, health or safety of any such person or the public or which cause or have a natural tendency to cause injury or damage to business or property."*

The Project will not result in other emissions (such as those leading to odors) adversely affecting a substantial number of people and therefore, the Project impacts were determined to be less than significant.

Level of Significance Before Mitigation

Less than significant.

Mitigation Measures

None required.

Level of Significance After Mitigation

Not applicable.

3.0 GREENHOUSE GASES

This section of the AQCCIA assesses potential GHG impacts of the Project. The methodologies used and the information provided in this section are supported by calculations in Appendices C and D.

3.1 Regulatory Setting

3.1.1 Characteristics of Greenhouse Gases - Climate Change Pollutants

The accumulation of GHGs in the atmosphere contributes to the regulation of the earth's temperature. Some GHGs can remain in the atmosphere for long periods of time (i.e., long-lived). There are six GHGs recognized under the Kyoto Protocol and have been found by the International Panel on Climate Change (IPCC) to have a "Long-lived" effect on global climate change. The primary one associated with the Project are Nitrous Oxides (N_2O). Also see Appendix B for additional detail.

3.1.1.1 Greenhouse Gases - Climate Change Pollutants

In general, there are six (6) compounds/classes of GHGs that are counted when emissions are inventoried. Each GHG exhibits a different global warming potential (GWP). The mass of emissions of each GHG is multiplied by its GWP to determine the carbon dioxide equivalent (CO_2e) potential for global warming. GWPs have changed over time by the Intergovernmental Panel on Climate Change (IPCC) which is considered an authority on GHGs and their effects. The CAP and CARB emissions inventories and plans use GWPs that are an iteration or two behind and the most recent IPCC publication. Characteristics of each long-lived GHG and the associated GWP is presented below.

Carbon Dioxide (CO_2) is an odorless, colorless natural GHG. CO_2 is emitted from natural and anthropogenic sources. Natural sources include the following: decomposition of dead organic matter; respiration of bacteria, plants, animals, and fungus; evaporation from oceans; and volcanic outgassing. Anthropogenic sources include burning coal, oil, natural gas, and wood. By definition, CO_2 has a GWP equal to one (1).

Methane (CH_4) is a flammable GHG. A natural source of CH_4 is from the anaerobic decay of organic matter. Geological deposits, known as natural gas fields, also contain CH_4, which is extracted for fuel. Other sources include landfills, fermentation of manure, and ruminants such as cattle. CH_4 has a GWP equal to 28.

Nitrous Oxide (N_2O) is a colorless GHG. N_2O is produced by microbial processes in soil and water, including those reactions that occur in fertilizer containing nitrogen. In addition to agricultural sources, some industrial processes (fossil fuel-fired power plants, nylon production, nitric acid production, and vehicle emissions) also contribute to its atmospheric load. N_2O has a GWP equal to 265.

Hydrofluorocarbons (HFCs) are synthetic chemicals that are used as a substitute for chlorofluorocarbons (CFCs). Of all the GHGs, they are one of three groups with the highest global warming potential. HFCs are human made for applications such as air conditioners and refrigerants. HFCs have GWPs that range from 124 (HFC 125a) to 14,300 (HFC 23).

Perfluorocarbons (PFCs) have stable molecular structures and do not break down through the chemical processes in the lower atmosphere; therefore, PFCs have long atmospheric lifetimes, between 10,000 and 50,000 years. The two main sources of PFCs are primary aluminum production and semiconductor manufacturing. PFCs have GWPs that range from 7,390 (PFC 14) to 12,200 (PFC 116).

Sulfur Hexafluoride (SF_6) is an inorganic, odorless, colorless, nontoxic, nonflammable gas. SF_6 is used for insulation in electric power transmission and distribution equipment, in the magnesium industry, in semiconductor manufacturing, and as a tracer gas for leak detection. SF_6 has a GWP equal to 22,800.

3.1.2 Federal

To date, there is no federal overarching law specifically related to climate change or the reduction of GHGs. The Environmental Protection Agency (EPA) authority to regulate GHG emissions stems from the U.S. Supreme Court decision in *Massachusetts v. EPA,* 549 US 497 (2007). The Supreme Court found that GHGs are air pollutants covered by the Clean Air Act, and the EPA Endangerment Findings concluded the elements CO_2, CH_4, N_2O, HFCs, PFCs, and SF_6 threatened public health for both current and future generations. In 2009, the U.S. EPA published a rule for the mandatory reporting of GHG from sources that in general emit 25,000 metric tons or more of carbon dioxide equivalent per year in the United States. Implementation of 40 CFR Part 98 is referred to as the Greenhouse Gas Reporting Program (GHGRP). This collection of comprehensive, nationwide emissions data is intended to provide a better understanding of the sources of GHGs and to guide development of policies and programs to reduce emissions (U.S. EPA, 2013). Additional federal actions have included the implementation of standards for vehicles, biofuel production, and power generation. Federal actions relating to GHG emissions are summarized and provided in Appendix B.

3.1.3 State

A more comprehensive list of the California legislation over the last approximately 32 years as well as a summary of GHG scoping plan goals and recent developments are provided in Appendix B. Table 35 provides al list of potentially relevant California regulations.

Table 35 California Climate Change Legislation

Date	Legislation	Description
September 10, 2018	Senate Bill 100 (De León, Chapter 312, Statues of 2018)	California Renewables Portfolio Standard Program: emissions of greenhouse gases. This bill establishes the 100 Percent Clean Energy Act of 2017 which increases the Renewables Portfolio Standard (RPS) requirement from 50 percent by 2030 to 60 percent, and creates the policy of planning to meet all of the state's retail electricity supply with a mix of RPS-eligible and zero-carbon resources by December 31, 2045, for a total of 100 percent clean energy.

Date	Legislation	Description
July 26, 2017	Assembly Bill 617 (Christina Garcia, Chapter 136, Statutes of 2017)	Companion to Cap-and-Trade Extension Establishes a groundbreaking program to measure and reduce air pollution from mobile and stationary sources at the neighborhood level in the communities most impacted by air pollutants. Requires the Air Resources Board to work closely with local air districts and communities to establish neighborhood air quality monitoring networks and to develop and implement plans to reduce emissions. The focus on community-based air monitoring and emission reductions will provide a national model for enhanced community protection.
July 25, 2017	Assembly Bill 398 (Eduardo Garcia, Chapter 135, Statutes of 2017)	Cap-and-Trade Extension Extends and improves the Cap and Trade Program, which will enable the state to meet its 2030 emission reduction goals in the most cost-effective manner. Furthermore, extending the Cap and Trade Program will provide billions of dollars in auction proceeds to invest in communities across California.
September 19, 2016	Senate Bill 1383 (Lara, Chapter 395, Statutes of 2016)	Short-lived Climate Pollutants Establishes statewide reduction targets for short-lived climate pollutants.
September 8, 2016	Assembly Bill 197 (Eduardo Garcia, Chapter 250, Statutes of 2016)	Greenhouse gas regulations Prioritizes direct emission reductions from large stationary sources and mobile sources.
September 8, 2016	Senate Bill 32 (Pavley, Chapter 249, Statutes of 2016)	Greenhouse Gas emission reduction target for 2030 Establishes a statewide greenhouse gas (GHG) emission reduction target of 40 percent below 1990 levels by 2030.

Source: California Air Quality and Climate Legislation | California Air Resources Board.

Table 36 California Climate Change Regulations

Regulation	Description
AB 32 Climate Change Scoping Plan	In June 2021, CARB began holding a Public Workshop Series to commence development of the 2022 Scoping Plan. The 2022 Scoping Plan Update will assess progress towards achieving the SB 32 2030 target of a 40% GHG reduction and lay out a path to achieve carbon neutrality by 2045.
Greenhouse Gas Reduction Fund	State program allocating proceeds from cap-and-trade auctions to support investments and projects that reduce greenhouse gas emissions throughout California.

Regulation	Description
Amendments to the Mandatory Greenhouse Gas Reporting Regulation	The CARB Regulation for the Mandatory Reporting of Greenhouse Gas Emissions was originally approved in 2007 and revised in 2010, 2012, 2013, 2014, 2016 and 2018. Amendments to MRR were approved on March 29, 2019 and became effective on April 1, 2019, for 2019 data. The 2019 amendments were implemented to: • Support California's Cap-and-Trade Regulation to ensure consistency with the calculation of compliance obligations • Ensure that reported GHG emissions and product data are accurate and complete in order to support California's GHG reduction programs
Cap & Trade Amendments	December 2018 amendments to the cap-and-trade regulation included: • New price containment points and a price ceiling • Limits on offset use • New industrial facility leakage assistance factors for 2018 and beyond • Clarifications on electric and gas utility use of allowance value • Compliance provisions for Energy Imbalance Market (EIM)-related GHG emissions • Offset invalidation clarifications • Streamlining implementation requirements • Adjustments to linkage reflecting Ontario's actions to revoke its participation in the cap-and-trade market. September 2016 amendments to the cap-and-trade regulation included: • Emission caps for the post-2020 program • Post-2020 continuation of the allowance price containment reserve • Linking with Ontario's cap-and-trade program • Compliance with the federal Clean Power Plan • Modifications to allowance allocation
Cap & Trade Offset Protocols	The Air Resources Board has adopted five protocols for offset compliance projects. In addition to the original four protocols adopted in 2011, ARB has adopted: Mine Methane Capture (MMC) Projects Compliance Offset Protocol, adopted April 2014
Cap & Trade Link with Quebec	California linked its cap-and-trade program with Quebec's program in January 2014. Linkage allows for the use of compliance instruments from Quebec's greenhouse gas emission trading system to meet compliance obligations pursuant to the California Cap-and-Trade Regulation, and the reciprocal approval of compliance instruments issued by California to meet compliance obligations in the external trading program.
Mandatory Commercial Recycling	This regulation addresses recycling requirements for businesses that generate 4 or more cubic yards of commercial solid waste per week and multifamily residential dwellings with 5 or more units, regardless of the amount of waste generated; local jurisdiction requirements for education, outreach, monitoring and reporting; and CalAsphalt and concrete recycling review. The regulations were approved on May 7, 2012.

Source: (Climate Change | California Air Resources Board, 2021).

On December 14, 2017, CARB approved the 2017 Climate Change Scoping Plan Update (Scoping Plan) which aims to reduce GHG emissions. The Scoping Plan "is a package of economically viable and technologically feasible actions to not just keep California on track to achieve its 2030 target, but stay on track for a low- to zero-carbon economy by involving every part of the state. Every sector, every local government, every region, every resident is part of the solution. The Plan underscores that there is no single solution but rather a balanced

mix of strategies to achieve the GHG target. This Plan highlights the fact that a balanced mix of strategies provides California with the greatest level of certainty in meeting the target at a low cost while also improving public health, investing in disadvantaged and low-income communities, protecting consumers, and supporting economic growth, jobs and energy diversity. Successful implementation of this Plan relies, in part, on long-term funding plans to inform future appropriations necessary to achieve California's long-term targets." (2017 Scoping Plan, p. ES4).

3.1.4 San Joaquin Valley Unified Air Pollution Control District

SJVAPCD GHG policy is established in the *District Policy Addressing GHG Emission Impacts for Stationary Source Projects Under CEQA When Serving as the Lead Agency* (SJVAPCD, 2009). The document outlines a methodology to determine if a project meets the Best Performance Standards (BPS) for GHG emissions. The Document states, "Projects implementing BPS would be determined to have a less than significant individual and cumulative impact on global climate change and would not require project specific quantification of GHG emissions". When serving as the lead agency, the District requires stationary sources that do not comport with a BPS to demonstrate GHG reductions of 29% as compared to Business-as-Usual. Business-as-Usual is defined by the District as "The emissions for a type of equipment or operation within an identified class and category projected for the year 2020, assuming no change in GHG emissions per unit of activity as established for the baseline period".

This policy, however, does not apply to the Project; CARB regulations adopted in 2010 established a cap-and-trade program for the largest sources of GHG emissions in the State. Included in cap-and-trade are the fuels that are utilized by the Project.

South Coast Air Quality Management District (SCAQMD) guidelines, which are more recent, were used to evaluate significance of GHG impacts. Specifically, SCAQMD excludes emissions from sectors that are required to participate in the Cap-and-Trade Program administered by the California Air Resources Board (CARB) as discussed in the *Final Negative Declaration for Phillips 66 Los Angeles Refinery Carson Plant - Crude Oil Storage Project* (SCAQMD, 12/12/2014).[3] The Project analysis therefore emits GHGs from fuel burned in vehicle engines and fuel burned in stationary equipment. Transportation fuel suppliers and importers are required to report emissions under the Cap-and-Trade which is designed to reduce GHG emissions as needed to achieve emissions reductions described in related planning documents which primarily consists of the AB 32 Scoping Plan.

3.1.5 Tulare County

The Tulare County Climate Action Plan (CAP) (Tulare County, 2012a) serves as a guiding document for County actions to reduce GHG emissions and adapt to the potential effects of climate change. The CAP is an implementation measure of the 2030 General Plan Update.

[3] http://www.aqmd.gov/home/research/documents-reports/lead-agency-permit-projects/permit-project-documents---year-2014

General Plan 2030

The Tulare County General Plan (Tulare County, 2012b) policies that relate to greenhouse gas emissions from the proposed Project are listed below.

AQ-1.5 California Environmental Quality Act (CEQA) Compliance

The County shall ensure that air quality impacts identified during the CEQA review process are consistently and reasonably mitigated when feasible.

AQ-1.7 Support statewide Climate Change Solutions

The County shall monitor and support the efforts of CalEPA, CARB, and the SJVAPCD, under AB 32 (Health and Safety Code §38501 et seq.), to develop a recommended list of emission reduction strategies. As appropriate, the County will evaluate each new project under the updated General Plan to determine its consistency with the emission reduction strategies.

AQ-1.8 Greenhouse Gas Emissions Reduction Plan/Climate Action Plan

The County will develop a Greenhouse Gas Emissions Reduction Plan (Plan) that identifies greenhouse gas emissions within the County as well as ways to reduce those emissions. The Plan will incorporate the requirements adopted by the California Air Resources Board specific to this issue. In addition, the County will work with the Tulare County Association of Governments and other applicable agencies to include the following key items in the regional planning efforts.

1. Inventory all known, or reasonably discoverable, sources of greenhouse gases in the County,
2. Inventory the greenhouse gas emissions in the most current year available, and those projected for year 2020, and
3. Set a target for the reduction of emissions attributable to the County's discretionary land use decisions and its own internal government operations.

AQ-1.9 Support Off-Site Measures to Reduce Greenhouse Gas Emissions

The County will support and encourage the use of off-site measures or the purchase of carbon offsets to reduce greenhouse gas emissions.

Climate Action Plan

The CAP describes itself as follows.

> *…a four-step process recommended by the Institute for Local Government.*
>
> *First, an inventory of greenhouse gas emission sources was developed for a base year (2007) to identify the most important categories and potential for emission reductions.*
>
> *Second, future year inventories for 2020 and 2030 were projected to illustrate what emissions would be in the future accounting for projected growth, but without controls on the sources. The future year inventory is referred to as a "business-as-usual scenario." The year 2020*

> *projection was used to allow comparison to the State's target year in CARB's Scoping Plan. The year 2030 projection was used to identify the growth in emissions that would occur by the General Plan planning horizon year. The 2020 inventory was projected by interpolating emissions growth predicted between 2007 and 2030.*
>
> *The third step was to identify and describe policies, regulations, and programs that apply to sources in the County's emission inventories and will achieve reductions by the target years. The policies, regulations, and programs considered in the CAP include those by federal, state, and local governments. These were then quantified to the extent possible using best available methodologies and data to determine the amount of reductions that are needed by the target years from Tulare County to achieve consistency with state targets.*
>
> *The last step was the development of a monitoring program that tracks implementation progress and emission reductions over time and identifies a process for taking corrective actions, if needed.* (Tulare County, 2012a, pp. 2-3).

The CAP describes the County's, the State's and the SJVAPCD's role in reducing GHGs as follows:

> *The County's focus is on emission sources within its regulatory authority, which are mainly related to land use and the local transportation system. To some extent, the County can influence activities that provide greenhouse gas reductions such as water conservation and solid waste diversion and recycling. The County also can require feasible mitigation measures for new projects as a Lead Agency under the CEQA… new projects are required to address greenhouse gas and climate impacts under CEQA during the approval process.*
>
> *…*
>
> *The CARB has the primary responsibility for the State's climate programs and regulations that would apply to mobile and industrial sources of greenhouse gases. The California Energy Commission has primary responsibility for energy efficiency standards related to buildings and certain consumer products. The San Joaquin Valley Air Pollution Control District (SJVAPCD) regulates stationary, areawide, and indirect sources of emissions that impact health. Many SJVAPCD regulations on health-based pollutant emissions also reduce greenhouse gas emissions. (Tulare County, 2012a, p. 3).*

Regarding CEQA, the CAP states:

> *One of the most important uses for a CAP is to establish significance thresholds for reviewing projects under CEQA. Greenhouse gas emissions from an individual project will not result in a perceptible impact on global climate. Impacts to global climate are caused by the cumulative impacts of greenhouse gases emitted anywhere and everywhere on Earth. The Office of Planning and Research CEQA Guidelines encourages use of a plan consistency threshold for cumulative impacts on climate change. Projects that demonstrate consistency with the policies, implementation measures, and emission reduction targets contained in the CAP would have a less than significant impact on climate change. (Tulare County, 2012a, p. 4).*

…

Although it is technologically possible to reduce greenhouse gases if cost is not considered, the potential exists that a locally implemented measure will only serve to relocate the emissions to another place that does not require the new technology. Therefore, even if emission rates are lower in one place, it could have no effect on global climate if the emission-producing activity is shipped out of State or overseas. (Tulare County, 2012a, p. 4).

…

Projects implementing the General Plan that are subject to CEQA will be required to demonstrate consistency with the CAP and achieve emission reductions that will enable the County to meet its greenhouse gas reduction target. The policies focus on the following:

- *Land Use and Transportation System Improvements*
- *Alternative, Non-automotive Travel Modes*
- *Building Energy Efficiency/Green Building Design*
- *Water Conservation*
- *Waste Reduction Program*

(Tulare County, 2012a, p. 11).

…

The CAP needs to provide a strategy that would result in the County achieving a 26-percent reduction in order for it to qualify for use in CEQA consistency findings. (Tulare County, 2012a, p. 12)

Based on the analysis conducted in preparing the CAP, an overall additional reduction of 1.1 percent from new and existing development is required to show consistency with the Scoping Plan target for development related sources of 26.2 percent. Achieving a 1.1-percent reduction from new development by 2020 will require an average project level reduction of 6 percent. (Tulare County, 2012a, p. 14).

The organizational boundary used for the CAP includes emissions that are reasonably attributable to the County's discretionary land use decisions and the County's internal government operations. As such, areas that are within incorporated cities are considered outside the County's organizational boundary. The CAP operational boundary includes emissions associated with operations owned or controlled by the County. These include direct and indirect emissions resulting from the energy (electricity and natural gas), mobile source (on- and off-road), agriculture (dairy/feedlots), and solid waste (landfills) sectors in unincorporated Tulare County and are summarized in Table 37.

Table 37 Operational Boundaries of Emissions in CAP

Sector	Source of Emissions	Data Source Used in CAP
Mobile Sources	On-road	TCAG, EMFAC Model (CARB)
	Offroad	OFFROAD2007 Model (CARB)

Sector	Source of Emissions	Data Source Used in CAP
Solid Waste	Trash	LandGEM Model, Tulare County Resource Management Agency
Natural Gas	Residential	The Gas Company
	Commercial	The Gas Company
	Industrial	The Gas Company
Dairy/Feedlot	Dairy/Feedlot	Jones and Stokes, 2006; EPA
Electricity	Residential	PG&E, SCE
	Commercial	PG&E, SCE
	Industrial	PG&E, SCE

Source: (Tulare County, 2012a, p. A6).

Notes: Tulare County Association of Governments (TCAG), Pacific Gas and Electric (PG&E), Southern California Edison (SCE).

Table 38 presents the list of emissions reductions that the CAP takes credit for in demonstrating consistency with the AB 32 Scoping Plan and objective to reduce GHG emissions to 1990 levels by 2020. The following discussion in the CAP is applicable to the Project. "*Commercial and industrial development in Tulare County during the 2020 and 2030 planning timeframes will be subject to conditions of approval and mitigation measures that will reduce GHG emissions beyond State regulations in most projects. For industrial projects where the SJVAPCD is a Responsible Agency, the project will be expected to implement Best Performance Standards included in the SJVAPCD Guidelines for Addressing Greenhouse Gas Emissions on the processes and stationary equipment that emit GHGs to levels that meet or exceed State targets*." (Tulare County, 2012a, p. 55). Other measures only applicable to commercial, residential and mixed uses (i.e., not industrial) are presented in Table 39 and Table 40 for completeness.

Table 38 Emission Reductions from State Regulations and Measures

Affected Emission Sources	California Legislation	Percent Reduction from 2020 GHG Inventory	Fraction Applicable to Tulare Co. Inventory	End Use Sector	Scaled Emission Reduction Credit
Mobile	AB 1493 Pavley	19.7	0.387	On-road passenger/ light truck transportation	7.62
	LCFS	7.2	0.387	On-road passenger/ light truck transportation	2.79
	LCFS	7.2	0.067	On-road Heavy/ Medium Duty transportation	0.48

Affected Emission Sources	California Legislation	Percent Reduction from 2020 GHG Inventory	Fraction Applicable to Tulare Co. Inventory	End Use Sector	Scaled Emission Reduction Credit
	Heavy Duty Efficiency	2.9	0.013	On-road Heavy Duty transportation	0.04
	Passenger Vehicle Efficiency	2.8	0.387	On-road passenger/ light truck transportation	1.08
Area	Energy Efficiency Measures	9.5	0.039	Natural Gas (Residential)	0.37
			0.12	Natural Gas (Non-Residential)	1.13
Indirect	Renewable Portfolio Standard	18.3	0.271	Electricity (excluding cogeneration)	4.96
	Energy Efficiency Measures	15.7	0.271	Electricity	4.25
	Solid Waste Methane	14.2	0.106	Solid Waste (10.6)	1.51
	Solar Roofs	1.5	0.271	Electricity (excluding cogeneration) (27.1)	0.41

3.2 Environmental Setting

Climate change refers to global changes in the average weather of the Earth measured by changes in wind patterns, storms, precipitation, and temperature. While climate change is global in scale, California-specific impacts to the climate may result in a loss of snow-pack, increased risk of large wildfires, and a potential reduction in the quality and quantity of certain agricultural products.

Gases that trap heat in the atmosphere are GHGs, analogous to the way a greenhouse retains heat. Consequently, these GHG emissions are believed to directly affect the global climate.

Emissions Inventories

CARB's most recent GHG emission inventory, the 2020 Edition, tracks the emissions of seven GHGs identified in the California Health and Safety Code for years 2000 to 2018. In 2018, total GHG emissions were 425 $MMTCO_2e$, an increase of 1.0 $MMTCO_2e$ compared to 2017. Emissions have decreased since peak levels in 2004. Overall trends in the inventory also demonstrate that the carbon intensity of California's economy (the amount of carbon pollution per million dollars of gross domestic product (GDP)) is declining, representing a 43% decline since 2000, while the State's GDP has grown 59% during this period (Trend Report, 2020, pp. 1-3).

The transportation sector remains the largest source of GHG emissions in the State, accounting for 40% of statewide emissions in 2018. Emissions from the electricity sector have increased slightly in 2018 and account for 15% of the inventory. Emissions from the remaining sectors have remained relatively constant, although emissions from high-GWP gases have continued to climb as they replace ozone depleting substances banned under the Montreal Protocol (Trend Report, 2020, p. 5).

3.3 Threshold Criteria

Determination of whether an impact is significant usually involves the comparison of Project impact levels to threshold criteria set by the lead agency. For air quality and GHG impacts, lead agencies often rely on guidance from a responsible agency. In this report, SCAQMD guidance is utilized, as discussed in Section 3.1.4.

3.3.1 CEQA Guidelines Appendix G

The Environmental Checklist Form in Appendix G of the CEQA Guidelines presents questions about projects that, if true for a particular project, would be considered a significant impact. This document considers the following Environmental Checklist Form questions to be the Significance Thresholds for GHG emissions from this Project.

Would the project:

a) Generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment?

b) Conflict with an applicable plan, policy or regulation adopted for the purpose of reducing the emissions of GHGs?

3.3.2 Additional Threshold Criteria

Tulare County

The CAP identifies the items in Table 41 as requirements for determining consistency of a project with the CAP.

Table 41 CEQA Project Requirements for Consistency with CAP

Item	Required for Consistency?
Percent reduction in greenhouse gas emissions	6%
Consistency with General Plan policies	Yes
Consistency with Rural Valley Land Plans or Foothill Growth Management Plan development criteria	Yes
Consistency with Urban Growth Boundary expansion criteria	Yes
Consistency for development within Rural Community Urban Development Boundaries and Hamlet Development Boundaries	Yes

Source: (Tulare County, 2012a, p. 58)

South Coast Air Quality Management District

This analysis utilizes SCAQMD guidelines as described in Section 3.1.4. With the new cap and trade policy, fuels used by the Project are regulated at a higher level, so GHG emissions associated with these fuels are calculated and summarized for disclosure purposes. SCAQMD uses a 10,000 MT/yr CO_2e for determining significant impacts for proposed projects. (SCQAMD, 2008) The SCAQMD threshold is compared to the Project GHG emissions for context and disclosure.

3.4 Methodology

3.4.1 CEQA Baseline

The baseline condition consists of emissions associated with excavation of materials at the Seaborn Site. The amount of work required to excavate and process material at the Seaborn site and for the Project is considered to be equal because of the similar topography of the sites, similar use of mining equipment, and the fact that the Project would not exceed the previous production rate nor would it increase the amount of offsite on-road haul truck or vehicle traffic. In addition, the Project's processing plants would move along with the excavation activities as it progresses through the site; therefore, reducing the amount of on-site travel by haul trucks or other equipment associated with transporting the aggregate to the processing plants. The maximum annual CO_2e emissions during the baseline period is conservatively represented by assuming average annual production rate 500,000 tons per year, and summarized in Table 42. Detailed calculations are provided in Appendix C.

Table 42 Baseline GHG Emissions at Maximum Historical Rate

Source	CO_2e (MT/yr)
Crush/Recycle Plant Engine	86
Excavation Off-Road Engines	645
Off-Road Vehicle Haul	549
Total	**1,280**

Source: Appendix C.

Notes: Average historical productionrate assumed to be 500,000 tons aggregate processed per year. The wash/screen plant operates on electricity provided by SCE.

Converted from App. C based on 2204.6 lb/MT. GWP of CH_4 assumed to be 28 per IPCC Fifth Assessment Report (AR5).

3.4.2 Project Excavation Phase

Equipment and activity levels for excavation in the baseline and for the Project are presented in Section 2.4 and the associated GHG emissions are summarized in Table 43 below. Detailed calculations are provided in Appendix C.

Table 43 Project Excavation Phase GHG Emissions at Proposed Maximum Annual Rate

Source	CO_2e (MT/yr)
Crush/Recycle Plant Engine	85
Excavation Off-Road Engines	638
Off-Road Vehicle Haul	598
Dewatering Pumps	95
On-Road Vehicle Haul	79
Slurry Wall Installation	613
Total	**2,108**

Source: Appendix C.

Notes: Maximum annual rate of 650,000 tons processed per year. The wash/screen plant operates on electricity provided by SCE

Converted from App. C based on 2204.6 lb/MT. GWP of CH_4 assumed to be 28 per IPCC Fifth Assessment Report (AR5).

3.4.3 Project Construction Phase

The construction phase consists of the following features:

- Site security features and on-site construction office (prefabricated trailer) including an access gate and perimeter road;
- Inflow channel consisting of a weir, chute, and dissipation pool and Outflow Channel consisting of a weir each requires an excavator, backhoe, water truck, loader, compactor, cement trucks, cement pumps, and cranes; and
- Generator building and floating barge pump, including an aboveground diesel tank, would require an excavator, water truck, backhoe, compactor, trencher and cement trucks.

As discussed previously in regard to criteria air pollutants, CO_2e emissions associated with off-road mobile equipment were calculated using CalEEMod. The estimated mass of GHGs that would be emitted during

construction phase of the Project was determined to be an annual maximum of 96.7 Metric tons of CO_2e per year (Appendix D), based on the activity levels provided by Provost and Pritchard Consulting Group (Appendix B).

3.4.4 Operation Phase

Calculated operation phase emissions include:

- Operation of the generators;
- Off-road engines for road maintenance;
- On-road support vehicles.

Operation phase emissions are presented in Table 44 and detailed calculations are provided in Appendix C.

Table 44 Operation Phase GHG Emissions

Source	CO_2e (MT/yr)
Reservoir Operation Pumps	147
Off-Road Engines	23
On-Road Vehicles	5
Total	**175**

Source: Appendix C.

3.5 Project-Level Impacts and Mitigation Measures

3.5.1 Generate GHG Emissions That May Have a Significant Impact on the Environment

Impact Statement

Impact GHG-1: *Would the Project generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment?* **(Appendix G Threshold Criteria (a)).**

Impact Analysis

"It is widely recognized that no single project could generate enough GHG emissions to noticeably change the global climate temperature. However, the combination of GHG emissions from past, present, and future projects could contribute substantially to global climate change. GHG emissions, and their associated contribution to climate change, are inherently a cumulative impact issue. Therefore, project-level impacts of GHG emissions are treated as one-in-the-same as cumulative impacts." (SJVAPCD, 2015, p. 111). As recognized by SJVAPCD in the preceding quote, climate change is a cumulative effect and no single project is large enough to impact climate change. Thus, the Project would not, by itself, either directly or indirectly result in a significant impact on the environment due to generation of GHG emissions.

This is reflected in the 2017 Scoping Plan, which regulates fuels at a level in the supply chain above the project, such that the project has no choice but to use energy in California that is already regulated. The Project therefore does not have its own emissions, but is simply a location in which GHG emissions are taking place as

a result of fuel that is already regulated. Therefore, the Project itself cannot have a significant impact on the environment.

Level of Significance Before Mitigation

Less than significant.

Mitigation Measures

None required.

Level of Significance After Mitigation

Not applicable.

3.5.2 Conflict with an Applicable Plan, Policy or Regulation that Reduces GHGs

Impact Statement

Impact GHG-2: *Would the Project conflict with an applicable plan, policy or regulation adopted for the purpose of reducing the emissions of GHGs?* **(Appendix G Threshold Criteria (b)).**

Impact Analysis

Project emissions of GHGs are presented in Table 45 below, primarily for purposes of disclosure. Portions of the SJVAPCD guidance on impact analysis for GHGs are outdated; therefore, the methods used in South Coast Air Quality Management District (SCAQMD) which are more recent were used to evaluate significance of GHG impacts. Specifically, SCAQMD excludes emissions from sectors that are required to participate in the Cap-and-Trade Program administered by the California Air Resources Board (CARB) as discussed in the *Final Negative Declaration for Phillips 66 Los Angeles Refinery Carson Plant – Crude Oil Storage Project* (SCAQMD, 12/12/2014).[4] The Project would emit GHGs from fuel burned in vehicle engines and fuel burned in stationary equipment. Transportation fuel suppliers and importers are required to report emissions under the Cap-and-Trade which is designed to reduce GHG emissions as needed to achieve emissions reductions described in related planning documents which primarily consists of the AB 32 Scoping Plan. Thus, the emissions reductions will occur at a level in the supply chain above the Project which will have no choice but to use fuels with GHG intensities that are consistent with the Scoping Plan.

[4] http://www.aqmd.gov/home/research/documents-reports/lead-agency-permit-projects/permit-project-documents---year-2014

Table 45 Project GHG Emissions

Source	CO_2e (MT/yr)
Baseline Emissions	1,280
Project (Future Emissions) (Max Year)	2,283
Net change between baseline and Project (Project Emissions) (Max Year)	1,003
Screening Criteria (SCAQMD) Threshold	10,000
Will the Project Exceed SCAQMD Screening Criteria?	**No**

This information is provided for disclosure purposes. Emissions are a result of sources already regulated by the Scoping Plan.
Source: Appendix C.
Note: http://www.aqmd.gov/home/rules-compliance/ceqa/air-quality-analysis-handbook/ghg-significance-thresholds.

In summary, The GHGs associated with the Project would be consistent with the AB 32 Scoping Plan. Therefore, the Project impact on GHG emissions is less than significant. Additionally, for context, emissions from the Project are less than the SCAQMD GHG screening criteria.

Level of Significance Before Mitigation

Less than significant.

Mitigation Measures

None required.

Level of Significance After Mitigation

Not applicable.

APPENDIX B

BACKGROUND INFORMATION

Appendix B
Characteristics of Air Pollutants

Ozone: Ozone (smog) is formed by photochemical reactions between oxides of nitrogen (NO_X) and volatile organic compounds (VOC), rather than being directly emitted. The San Joaquin Valley Air Pollution Control District (SJVAPCD) Health-Based Implementation Strategy prioritizes NOx reductions over VOC reductions because NOx reductions would have greater effect on reducing ozone concentrations and be more protective of public health.

O_3 is a pungent, colorless gas typical of photochemical smog. Elevated O_3 concentrations may result in reduced lung function, particularly during vigorous physical activity. This health effect is particularly acute in sensitive receptors such as the sick, the elderly, and young children. O_3 levels peak during summer and early fall.

Breathing ground-level ozone can result in a number of health effects that are observed in broad segments of the population. Some of these effects include:

- Induction of respiratory symptoms;
- Decrements in lung function; and
- Inflammation of airways.

Respiratory symptoms can include:

- Coughing;
- Throat irritation;
- Pain, burning, or discomfort in the chest when taking a deep breath; and
- Chest tightness, wheezing, or shortness of breath.

In addition to these effects, evidence from observational studies indicates that higher daily ozone concentrations are associated with increased asthma attacks, increased hospital admissions, increased daily mortality, and other markers of morbidity. The consistency and coherence of the evidence for effects upon asthmatics suggests that ozone can make asthma symptoms worse and can increase sensitivity to asthma triggers.

Carbon Monoxide: Carbon monoxide (CO) is formed by the incomplete combustion of fossil fuels, almost entirely from automobiles. It is a colorless, odorless gas that can cause dizziness, fatigue, and impairments to central nervous system functions.

The severity of symptoms due to CO exposure increases with the blood carboxyhemoglobin (COHb) level. The first signs of CO exposure include mild headache and breathlessness with moderate exercise. Continued exposure may lead to more severe headache, irritability, impaired judgment and memory, and rapid onset of fatigue.

Persons with cardiovascular disease, including those with angina, persons with chronic obstructive pulmonary disease, persons with anemia, and fetuses of pregnant women may be more sensitive to the adverse effects of carbon monoxide exposure. The fetuses of pregnant women, especially those expectant mothers exercising vigorously, may be especially vulnerable due to the much higher affinity of fetal hemoglobin for CO compared to adult hemoglobin.

Persons exposed to methylene chloride are more sensitive to the effects of CO exposure because CO is a metabolite of methylene chloride. Smokers may experience an additional burden of COHb since their carboxyhemoglobin levels are already elevated by smoking.

Nitrogen Oxides: Nitrogen dioxide is a generic term for the mono-nitrogen oxides which include nitric oxide (NO) and NO_2. NO is a colorless, odorless gas and NO_2 is a reddish-brown gas. NO_X is formed from fuel combustion under high temperature or pressure. NO_X is a primary component of the photochemical smog reaction. It also contributes to other pollution problems, including a high concentration of fine particulate matter, poor visibility, and acid deposition (i.e., acid rain). NO_X decreases lung function and may reduce resistance to infection.

Acute exposure to NO_2 may cause pulmonary edema, pneumonitis, and bronchitis. NO_2 is considered a relatively insoluble, reactive gas, such as phosgene and ozone. Once inhaled, NO_2 reaches the lower respiratory tract, affecting mainly the bronchioles and the adjacent alveolar spaces, where it may produce pulmonary edema within hours.

Sulfur Dioxide: Sulfur dioxide is a colorless, irritating gas formed primarily from combustion of fuels containing sulfur. Industrial facilities also contribute to gaseous SO_2 levels. SO_2 irritates the respiratory tract, can injure lung tissue when combined with fine particulate matter, and reduces visibility and the level of sunlight.

Both controlled laboratory studies and epidemiology studies have shown that people with asthma and children are particularly sensitive to and are at increased risk from the effects of SO_2 air pollution. Asthmatic subjects exposed to levels of SO_2 within regulatory standards have demonstrated increased respiratory symptoms such as shortness of breath, coughing and wheezing, and decrements in lung function.

Lead: Lead (Pb) was phased out of use in gasoline and paint. It is present at trace concentrations in a variety of other materials including most natural materials extracted from the earth's crust. Once in the bloodstream, Pb can cause damage to the brain, nervous system, and other body systems. Children are highly susceptible to the effects of Pb.

Particulate Matter: Particulate matter (PM) pollution consists of very small liquid and solid particles floating in the air. Some particles are large or dark enough to be seen as soot or smoke. Others are so small they can be detected only with an electron microscope. Particulate matter is a mixture of materials

that can include smoke, soot, dust, salt, acids, and metals. Particulate matter also forms when gases emitted from motor vehicles and industrial sources undergo chemical reactions in the atmosphere. PM_{10} refers to particles less than or equal to 10 microns in aerodynamic diameter. $PM_{2.5}$ refers to particles less than or equal to 2.5 microns in aerodynamic diameter and are a subset of PM_{10}.

There are sources of PM_{10} in both urban and rural areas. PM_{10} and $PM_{2.5}$ are emitted from stationary and mobile sources, including diesel trucks and other motor vehicles, power plants, industrial processing, wood burning stoves and fireplaces, wildfires, dust from roads, construction, landfills, and agriculture, and fugitive windblown dust. Because particles originate from a variety of sources, their chemical and physical compositions vary widely.

PM_{10} and $PM_{2.5}$ particles are small enough to be inhaled into, and lodge in, the deepest parts of the lung, evading the respiratory system's natural defenses. Health problems may occur as the body reacts to these foreign particles.

Acute and chronic health effects associated with high particulate levels include the aggravation of chronic respiratory diseases, heart and lung disease, and coughing, bronchitis, and respiratory illnesses in children. Recent mortality studies have shown a statistically significant direct association between mortality and daily concentrations of particulate matter in the air. Non-health-related effects include reduced visibility and soiling of buildings. PM_{10} can increase the number and severity of asthma attacks, cause or aggravate bronchitis and other lung diseases, and reduce the body's ability to fight infections. PM_{10} and $PM_{2.5}$ can aggravate respiratory disease, and cause lung damage, cancer, and premature death.

Although particulate matter can cause health problems for everyone, certain people are especially vulnerable to adverse health effects of PM_{10}. These "sensitive populations" include children, the elderly, exercising adults, and those suffering from chronic lung disease such as asthma or bronchitis. Of greatest concern are recent studies that link PM_{10} exposure to the premature death of people who already have heart and lung disease, especially the elderly. Acidic PM_{10} can also damage manmade materials and is a major cause of reduced visibility in many parts of the U.S.

Respirable Crystalline Silica: Respirable Crystalline Silica (RCS) means crystalline silicon dioxide with aerodynamic diameter less than four microns (0.0004 cm). Crystalline silica or quartz is ubiquitous in nature. Most dust generated by construction and mining activities including blasting produces dust particles larger than 4 microns. These particles are too large reach alveoli of the lungs which are the target organ. Thus, RCS constitutes a tiny fraction of the dust from these sources and does not represent a significant health risk to neighbors of these types of projects. In order to result in toxic effects, the silica needs to be crystalline, smaller than 4 microns, inhaled, and not exhaled.

Inhalation of RCS initially causes respiratory irritation and an inflammatory reaction in the lungs. Silicosis results from chronic exposure; it is characterized by the presence of histologically unique silicotic nodules and by fibrotic scarring of the lung. Lung diseases other than cancer associated with silica exposure include silicosis, tuberculosis/silicotuberculosis, chronic bronchitis, small airways disease, and

emphysema. Ambient air exposures do not cause concern but levels to which workers (e.g., miners, sandblasters) may be exposed have been shown to cause cancer.

Acute exposures to high concentrations cause cough, shortness of breath, and pulmonary alveolar lipoproteinosis (acute silicosis). In a report on the hazards of exposure to crystalline silica, the American Thoracic Society (1997) stated: "Studies from many different work environments suggest that exposure to working environments contaminated by silica at dust levels that appear not to cause roentgenographically visible simple silicosis can cause chronic airflow limitation and/or mucus hypersecretion and/or pathologic emphysema." Other researchers also concluded that "chronic levels of silica dust that do not cause disabling silicosis may cause the development of chronic bronchitis, emphysema, and/or small airways disease that can lead to airflow obstruction, even in the absence of radiological silicosis." Fibrotic lesions associated with crystalline silica have also been found at autopsy in the lungs of granite workers who lacked radiological evidence of silicosis (OEHHA, 2004).

Silicosis results from chronic exposure; it is characterized by the presence of histologically unique silicotic nodules and by fibrotic scarring of the lung. Lung diseases other than cancer associated with silica exposure include silicosis, tuberculosis/silicotuberculosis, chronic bronchitis, small airways disease, and emphysema. Silica exposure has been implicated in autoimmune diseases (rheumatoid arthritis, scleroderma, systemic lupus erythematosus) in gold miners and granite workers and in the causation of kidney disease in some occupations, possibly by an immune mechanism (OEHHA, 2004).

Diesel Particulate Matter: Diesel exhaust and many individual substances contained in it (including arsenic, benzene, formaldehyde, and nickel) have the potential to contribute to mutations in cells that can lead to cancer.

Long-term exposure to diesel exhaust particles poses the highest cancer risk of any toxic air contaminants (TAC) evaluated by the California Office of Environmental Health Hazard Assessment (OEHHA). The California Air Resources Board (CARB) has estimated that about 70 percent of the cancer risk that the average Californian faces from breathing TACs stems from diesel exhaust particles. In a comprehensive assessment of diesel exhaust, OEHHA analyzed more than 30 studies of people who worked around diesel equipment, including truck drivers, railroad workers, and equipment operators. The studies showed these workers were more likely than workers who were not exposed to diesel emissions to develop lung cancer. These studies provide strong evidence that long-term occupational exposure to diesel exhaust increases the risk of lung cancer.

Other researchers and scientific organizations, including the National Institute for Occupational Safety and Health, have calculated similar cancer risks from diesel exhaust as those calculated by OEHHA and CARB.

Exposure to diesel exhaust can have immediate health effects. Diesel exhaust can irritate the eyes, nose, throat and lungs, and it can cause coughs, headaches, lightheadedness, and nausea. In studies with human volunteers, diesel exhaust particles made people with allergies more susceptible to the materials

to which they are allergic, such as dust and pollen. Exposure to diesel exhaust also causes inflammation in the lungs, which may aggravate chronic respiratory symptoms and increase the frequency or intensity of asthma attacks.

Diesel engines are a major source of fine-particle pollution. The elderly and people with emphysema, asthma, and chronic heart and lung disease are especially sensitive to fine-particle pollution. Numerous studies have linked elevated particle levels in the air to increased hospital admissions, emergency room visits, asthma attacks, and premature deaths among people suffering from respiratory problems. Because children's lungs and respiratory systems are still developing, they are also more susceptible than healthy adults to fine particles. Exposure to fine particles is associated with increased frequency of childhood illnesses and can reduce lung function in children.

Appendix B
Greenhouse Gases – Characteristics of Climate Pollutants & Regulatory Setting

1.1 Regulatory Section

1.1.1 Characteristics of Climate Pollutants

The accumulation of greenhouse gases (GHGs) in the atmosphere contributes to the regulation of the earth's temperature. Some GHGs can remain in the atmosphere for long periods of time (i.e., long-lived). There are six GHGs recognized under the Kyoto Protocol and have been found by the International Panel on Climate Change (IPCC) to have a "Long-lived" effect on global climate change. In addition, California has identified "short-lived" climate pollutants. These are described below. The primary one associated with the Project are Nitrous Oxides (N_2O).

1.1.1.1 Long-Lived Climate Pollutants

In general, there are six (6) compounds/classes of GHGs that are counted when emissions are inventoried. Each GHG exhibits a different global warming potential (GWP). The mass of emissions of each GHG is multiplied by its GWP to determine the carbon dioxide equivalent (CO_2e) potential for global warming. GWPs have changed over time by the Intergovernmental Panel on Climate Change (IPCC) which is considered an authority on GHGs and their effects. The CAP and CARB emissions inventories and plans use GWPs that are an iteration or two behind and the most recent IPCC publication. Characteristics of each long-lived GHG and the associated GWP is presented below.

Carbon Dioxide (CO_2) is an odorless, colorless natural GHG. CO_2 is emitted from natural and anthropogenic sources. Natural sources include the following: decomposition of dead organic matter; respiration of bacteria, plants, animals, and fungus; evaporation from oceans; and volcanic outgassing. Anthropogenic sources include burning coal, oil, natural gas, and wood. By definition, CO_2 has a GWP equal to one (1).

Methane (CH_4) is a flammable GHG. A natural source of CH_4 is from the anaerobic decay of organic matter. Geological deposits, known as natural gas fields, also contain CH_4, which is extracted for fuel. Other sources include landfills, fermentation of manure, and ruminants such as cattle. CH_4 has a GWP equal to 28.

Nitrous Oxide (N_2O) is a colorless GHG. N_2O is produced by microbial processes in soil and water, including those reactions that occur in fertilizer containing nitrogen. In addition to agricultural sources, some industrial processes (fossil fuel-fired power plants, nylon production, nitric acid production, and vehicle emissions) also contribute to its atmospheric load. N_2O has a GWP equal to 265.

Hydrofluorocarbons (HFCs) are synthetic chemicals that are used as a substitute for chlorofluorocarbons (CFCs). Of all the GHGs, they are one of three groups with the highest global warming potential. HFCs are human made for applications such as air conditioners and refrigerants. HFCs have GWPs that range from 124 (HFC 125a) to 14,300 (HFC 23).

Perfluorocarbons (PFCs) have stable molecular structures and do not break down through the chemical processes in the lower atmosphere; therefore, PFCs have long atmospheric lifetimes, between 10,000 and 50,000 years. The two main sources of PFCs are primary aluminum production and semiconductor manufacturing. PFCs have GWPs that range from 7,390 (PFC 14) to 12,200 (PFC 116).

Sulfur Hexafluoride (SF_6) is an inorganic, odorless, colorless, nontoxic, nonflammable gas. SF_6 is used for insulation in electric power transmission and distribution equipment, in the magnesium industry, in semiconductor manufacturing, and as a tracer gas for leak detection. SF_6 has a GWP equal to 22,800.

1.1.1.2 Short-Lived Climate Pollutants

Short-lived climate pollutants are climate forcers that remain in the atmosphere for a much shorter period of time than longer-lived climate pollutants, such as carbon dioxide (CO_2). Their relative potency, when measured in terms of how they heat the atmosphere, can be tens, hundreds, or even thousands of times greater than that of CO_2. The impacts of short-lived climate pollutants are especially strong over the short term. Reducing these emissions can make an immediate beneficial impact on climate change.

Black carbon is a component of fine particulate matter, which has been identified as a leading environmental risk factor for premature death. It is produced from the incomplete combustion of fossil fuels and biomass burning, particularly from older diesel engines and forest fires. Black carbon warms the atmosphere by absorbing solar radiation, influences cloud formation, and darkens the surface of snow and ice, which accelerates heat absorption and melting. Diesel particulate matter (DPM) emissions are a major source of black carbon and are also toxic air contaminants that have been regulated and controlled in California for several decades in order to protect public health.

Fluorinated gases (F-gases) are the fastest growing source of greenhouse gas emissions in California and globally. They include ozone-depleting substances that are being phased out globally under the Montreal Protocol, and their primary substitute, hydrofluorocarbons (HFCs). Most F-gas emissions come from leaks of these gases in refrigeration and air-conditioning systems. Emissions also come from aerosol propellants, fire suppressants, and foam-expansion agents.

1.1.2 Federal

To date, there is no federal overarching law specifically related to climate change or the reduction of GHGs. The Environmental Protection Agency (EPA) authority to regulate GHG emissions stems from the U.S. Supreme Court decision in *Massachusetts v. EPA,* 549 US 497 (2007). The Supreme Court found that GHGs are air pollutants covered by the Clean Air Act, and the EPA Endangerment Findings concluded the elements CO_2, CH_4, N_2O, HFCs, PFCs, and SF_6 threatened public health for both current and future generations. In 2009, the U.S. EPA published a rule for the mandatory reporting of GHG from sources that in general emit 25,000 metric tons or more of carbon dioxide equivalent per year in the United States. Implementation of 40 CFR Part 98 is referred to as the Greenhouse Gas Reporting Program (GHGRP). This collection of comprehensive, nationwide emissions data is intended to provide a better understanding of the sources of GHGs and to guide development of policies and programs to reduce emissions. (U.S. EPA,

2013) Additional federal actions have included the implementation of standards for vehicles, biofuel production, and power generation. Federal actions relating to GHG emissions are summarized and provided in Table 1 below.

Table 1 – Federal Actions Relating to GHG Emissions

Date	Action	Description
April 2, 2007	*Massachusetts v. EPA*, 549 U.S. 497	Supreme Court found that GHGs are air pollutants covered by the Clean Air Act. (528-29.)
September 22, 2009	Mandatory Reporting Rule	This rule and subsequent rules which amend 40 CFR Part 98 require and govern the collection accurate and timely data on GHG emissions that can be used to inform future policy decisions.
December 7, 2009	EPA Endangerment Findings	• Elevated concentrations of GHGs—CO_2, CH_4, N_2O, HFCs, PFCs, and SF_6—in the atmosphere threaten the public health and welfare of current and future generations. This is referred to as the "endangerment finding." • Combined emissions of GHGs—CO_2, CH_4, N_2O, and HFCs—from new motor vehicles and new motor vehicle engines contribute to the GHG air pollution that endangers public health and welfare. This is referred to as the "cause or contribute finding." (*Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act* (Dec. 15, 2009) 74 Fed. Reg. 66496, 546.)
December 19, 2007	Energy Independence and Security Act (EISA)	• Increase the supply of alternative fuel sources by requiring fuel producers to use at least 36 billion gallons of biofuel in 2022. • Set a target of 35 miles per gallon (mpg) for the combined fleet of cars and light trucks by model year 2020 and establish a fuel economy program for medium and heavy duty vehicles. • Prescribe or revise standards affecting regional efficiency for heating and cooling products.
April 2010, September 2011, and August 2012	EPA and NHTSA Joint Final Rules for Vehicle Standards	• In 2010, established a National program consisting of new standards for light-duty vehicles model years 2012 through 2016 which achieve the 250 g CO_2/mile (35 mpg) target in the EISA beginning with the 2016 model year fleet. • In 2011, approved GHG emissions standards for medium and heavy duty trucks model years 2014 through 2018. • In 2012, approved standards for model year 2017 and beyond light duty vehicles to 163 g CO_2/mile (i.e., 54.5 mpg if achieved only by fuel efficiency) for model year 2025.
January 2, 2011	Clean Air Act Permitting for GHGs	On June 23, 2014, the U.S. Supreme Court issued its decision in Utility Air Regulatory Group v. EPA, 134 S. Ct. 2427 (2014) ("UARG"). The Court held that EPA may not treat GHGs as an air pollutant for purposes of determining whether a source is a major source required to obtain a PSD or title V permit. The Court also held that PSD permits that are otherwise required (based on emissions of other pollutants) may continue to require limitations on GHG emissions based on the application of Best Available Control Technology (BACT).

Date	Action	Description
August 3, 2015	Clean Power Plan	The Plan provides standards for power plants, customized goals for states to cut the carbon pollution from power plants, national consistency, accountability and a level playing field while reflecting each state's energy mix. On February 9, 2016, the Supreme Court stayed implementation of the Clean Power Plan pending judicial review. EPA claims "The Court's decision was not on the merits of the rule. EPA firmly believes the Clean Power Plan will be upheld when the merits are considered because the rule rests on strong scientific and legal foundations."

1.1.3 State

The following tables were copied from the California government website for climate change (climatechange.ca.gov) and list the California legislation (Table 2), regulations, (Table 3), and executive orders (Table 4) through 2018. More recent developments are discussed immediately following the tables.

Table 2 – California Climate Change Legislation

Date	Legislation	Description
September 10, 2018	Senate Bill 100 (De León, Chapter 312, Statues of 2018)	California Renewables Portfolio Standard Program: emissions of greenhouse gases. This bill establishes the 100 Percent Clean Energy Act of 2017 which increases the Renewables Portfolio Standard (RPS) requirement from 50 percent by 2030 to 60 percent, and creates the policy of planning to meet all of the state's retail electricity supply with a mix of RPS-eligible and zero-carbon resources by December 31, 2045, for a total of 100 percent clean energy.
July 26, 2017	Assembly Bill 617 (Christina Garcia, Chapter 136, Statutes of 2017)	Companion to Cap-and-Trade Extension Establishes a groundbreaking program to measure and reduce air pollution from mobile and stationary sources at the neighborhood level in the communities most impacted by air pollutants. Requires the Air Resources Board to work closely with local air districts and communities to establish neighborhood air quality monitoring networks and to develop and implement plans to reduce emissions. The focus on community-based air monitoring and emission reductions will provide a national model for enhanced community protection.
July 25, 2017	Assembly Bill 398 (Eduardo Garcia, Chapter 135, Statutes of 2017)	Cap-and-Trade Extension Extends and improves the Cap and Trade Program, which will enable the state to meet its 2030 emission reduction goals in the most cost-effective manner. Furthermore, extending the Cap and Trade Program will provide billions of dollars in auction proceeds to invest in communities across California.

Date	Legislation	Description
September 19, 2016	Senate Bill 1383 (Lara, Chapter 395, Statutes of 2016)	Short-lived Climate Pollutants Establishes statewide reduction targets for short-lived climate pollutants.
September 8, 2016	Assembly Bill 197 (Eduardo Garcia, Chapter 250, Statutes of 2016)	Greenhouse gas regulations Prioritizes direct emission reductions from large stationary sources and mobile sources.
September 8, 2016	Senate Bill 32 (Pavley, Chapter 249, Statutes of 2016)	Greenhouse Gas emission reduction target for 2030 Establishes a statewide greenhouse gas (GHG) emission reduction target of 40 percent below 1990 levels by 2030.
October 7, 2015	Senate Bill 350 (De León, Chapter 547, Statutes of 2015)	Clean Energy and Pollution Reduction Act of 2015 Establishes targets to increase retail sales of renewable electricity to 50 percent by 2030 and double the energy efficiency savings in electricity and natural gas end uses by 2030.
September 21, 2014	Senate Bill 605 (Lara, Chapter 523, Statutes of 2014)	Short-lived climate pollutants Requires the State Air Resources Board to complete a comprehensive strategy to reduce emissions of short-lived climate pollutants by January 1, 2016.
September 21, 2014	Senate Bill 1275 (De León, Chapter 530, Statutes of 2014)	Charge Ahead California Initiative Establishes a State goal of 1 million zero-emission and near-zero-emission vehicles in service by 2020. Amends the enhanced fleet modernization program to provide a mobility option. Establishes the Charge Ahead California Initiative requiring planning and reporting on vehicle incentive programs and increasing access to and benefits from zero-emission vehicles for disadvantaged, low-income, and moderate-income communities and consumers.
September 21, 2014	Senate Bill 1204 (Lara, Chapter 524, Statutes of 2014)	California Clean Truck, Bus, and Off-Road Vehicle and Equipment Technology Program Creates the California Clean Truck, Bus, and Off-Road Vehicle and Equipment Technology Program funded by the Greenhouse Gas Reduction Fund for development, demonstration, precommercial pilot, and early commercial deployment of zero- and near-zero emission truck, bus, and off-road vehicle and equipment technologies, with priority given to projects benefiting disadvantaged communities.

Date	Legislation	Description
September 28, 2013	Assembly Bill 8 (Perea, Chapter 401, Statutes of 2013)	Alternative fuel and vehicle technologies: funding programs Extends until January 1, 2024, extra fees on vehicle registrations, boat registrations, and tire sales in order to fund the AB 118, Carl Moyer, and AB 923 programs that support the production, distribution, and sale of alternative fuels and vehicle technologies and air emissions reduction efforts. The bill suspends until 2024 ARB's regulation requiring gasoline refiners to provide hydrogen fueling stations and appropriates up to $220 million, of AB 118 money to create a hydrogen fueling infrastructure in the State.
September 28, 2013	Assembly Bill 1092 (Levine, Chapter 410, Statutes of 2013)	Building standards: electric vehicle charging infrastructure Requires the Building Standards Commission to adopt mandatory building standards for the installation of future electric vehicle charging infrastructure for parking spaces in multifamily dwellings and nonresidential development.
September 30, 2012	Senate Bill 535 (De León, Chapter 830, Statutes of 2012)	Greenhouse Gas Reduction Fund and Disadvantaged Communities Requires the California Environmental Protection Agency to identify disadvantaged communities; requires that 25% of all funds allocated pursuant to an investment plan for the use of moneys collected through a cap-and-trade program be allocated to projects that benefit disadvantaged communities and 10 those 25% be use within disadvantaged communities; and requires the Department of Finance to include a description of how these requirements are fulfilled in an annual report.
September 30, 2012	Assembly Bill 1532 (J. Perez, Chapter 807, Statutes of 2012)	Greenhouse Gas Reduction Fund in the Budget Requires the Department of Finance to develop and submit to the Legislature an investment plan every three years for the use of the Greenhouse Gas Reduction Fund; requires revenue collected pursuant to a market-based compliance mechanism to be appropriated in the Annual Budget Act; requires the department to report annually to the Legislature on the status of projects funded; and specifies that findings issued by the Governor related to "linkage" as part of a market-base compliance mechanism are not subject to judicial review.
April 12, 2011	Senate Bill X1-2 (Simitian, Chapter 1, Statutes of 2011)	Governor Edmund G. Brown, Jr. signed Senate Bill X1-2 into law to codify the ambitious 33 percent by 2020 goal. SBX1-2 directs California Public Utilities Commission's Renewable Energy Resources Program to increase the amount of electricity generated from eligible renewable energy resources per year to an amount that equals at least 20% of the total electricity sold to retail customers in California per year by December 31, 2013, 25% by December 31, 2016 and 33% by December 31, 2020. The new RPS goals applies to all electricity retailers in the State including publicly owned utilities (POUs), investor-owned utilities, electricity service providers, and community choice aggregators. This new RPS preempts the California Air Resources Boards' 33 percent Renewable Electricity Standard.
September 29, 2011	Assembly Bill 1504 (Skinner, Chapter 534, Statutes of 2010)	Forest resources and carbon sequestration. Bill requires Department of Forestry and Fire Protection and Air Resources Board to assess the capacity of its forest and rangeland regulations to meet or exceed the State's greenhouse goals, pursuant to AB 32.

Date	Legislation	Description
September 30, 2008	Senate Bill 375 (Steinberg, Chapter 728, Statutes of 2008)	Sustainable Communities & Climate Protection Act of 2008 requires Air Resources Board to develop regional greenhouse gas emission reduction targets for passenger vehicles. ARB is to establish targets for 2020 and 2035 for each region covered by one of the State's 18 metropolitan planning organizations. For more information on SB 375, see the ARB Sustainable Communities page.
October 14, 2007	Assembly Bill 118 (Núñez, Chapter 750, Statutes of 2007)	Alternative Fuels and Vehicles Technologies The bill would create the Alternative and Renewable Fuel and Vehicle Technology Program, to be administered by the Energy Commission, to provide funding to public projects to develop and deploy innovative technologies that transform California's fuel and vehicle types to help attain the State's climate change policies.
August 24, 2007	Senate Bill 97 (Dutton, Chapter 187, Statutes of 2007)	Directs Governor's Office of Planning and Research to develop CEQA guidelines "for the mitigation of greenhouse gas emissions or the effects of greenhouse gas emissions." For more information see the OPR CEQA and Climate Change page.
July 18. 2006	Assembly Bill 1803 (Committee on Budget, Chapter 77, Statutes of 2006)	Greenhouse gas inventory transferred to Air Resources Board from the Energy Commission.
August 21, 2006	Senate Bill 1 (Murray, Chapter 132, Statutes of 2006)	California's Million Solar Roofs plan is enhanced by PUC and CEC's adoption of the California Solar Initiative. SB1 directs PUC and CEC to expand this program to more customers, and requiring the State's municipal utilities to create their own solar rebate programs. This bill would require beginning January 1, 2011, a seller of new homes to offer the option of a solar energy system to all customers negotiating to purchase a new home constructed on land meeting certain criteria and to disclose certain information.
September 26, 2006	Senate Bill 107 (Simitian, Chapter 464, Statutes of 2006)	SB 107 directs California Public Utilities Commission's Renewable Energy Resources Program to increase the amount of renewable electricity (Renewable Portfolio Standard) generated per year, from 17% to an amount that equals at least 20% of the total electricity sold to retail customers in California per year by December 31, 2010.
September 27, 2006	Assembly Bill 32 (Núñez, Chapter 488, Statutes of 2006)	California Global Warming Solutions Act of 2006. This bill would require Air Resources Board (ARB) to adopt a statewide greenhouse gas emissions limit equivalent to the statewide greenhouse gas emissions levels in 1990 to be achieved by 2020. ARB shall adopt regulations to require the reporting and verification of statewide greenhouse gas emissions and to monitor and enforce compliance with this program. AB 32 directs Climate Action Team established by the Governor to coordinate the efforts set forth under Executive Order S-3-05 to continue its role in coordinating overall climate policy. See more information on AB 32 at ARB.

Date	Legislation	Description
September 12, 2002	Senate Bill 1078 (Sher, Chapter 516, Statutes of 2002)	This bill establishes the California Renewables Portfolio Standard Program, which requires electric utilities and other entities under the jurisdiction of the California Public Utilities Commission to meet 20% of their renewable power by December 31, 2017 for the purposes of increasing the diversity, reliability, public health, and environmental benefits of the energy mix.
September 7, 2002	Senate Bill 812 (Sher, Chapter 423, Statutes of 2002)	This bill added forest management practices to the California Climate Action Registry members' reportable emissions actions and directed the Registry to adopt forestry procedures and protocols to monitor, estimate, calculate, report, and certify carbon stores and carbon dioxide emissions that resulted from the conservation-based management of forests in California.
July 22, 2002	Assembly Bill 1493 (Pavley, Chapter 200, Statutes of 2002)	The "Pavley" bill requires the registry, in consultation with ARB, to adopt procedures and protocols for the reporting and certification of reductions in greenhouse gas emissions from mobile sources for use by the ARB in granting the emission reduction credits. This bill requires the ARB to develop and adopt, by January 1, 2005, regulations that achieve the maximum feasible reduction of greenhouse gases emitted by passenger vehicles and light-duty trucks. For more information on AB 1493 Pavley I, see the ARB Clean Car Standards page.
October 11, 2001	Senate Bill 527 (Sher, Chapter 769, Statutes of 2001)	This bill revises the functions and duties of the California Climate Action Registry and requires the Registry, in coordination with CEC to adopt third-party verification metrics, developing GHG emissions protocols and qualifying third-party organizations to provide technical assistance and certification of emissions baselines and inventories. SB 527 amended SB 1771 to emphasize third-party verification.
September 30, 2000	Senate Bill 1771 (Sher, Chapter 1018, Statutes of 2000)	SB 1771 establishes the creation of the non-profit organization, the California Climate Action Registry and specifies functions and responsibilities to develop a process to identify and qualify third-party organizations approved to provide technical assistance and advice in monitoring greenhouse gas emissions, and setting greenhouse gas (GHG) emissions baselines in coordination with CEC. Also, the bill directs the Registry to enable participating entities to voluntarily record their annual GHG emissions inventories. Also, SB 1771 directs CEC to update the State's greenhouse gas inventory from an existing 1998 report and continuing to update it every five years.
September 28, 1988	Assembly Bill 4420 (Sher, Chapter 1506, Statutes of 1988)	The California Energy Commission (CEC) was statutorily directed to prepare and maintain the inventory of greenhouse gas emissions (GHG) and to study the effects of GHGs and the climate change impacts on the State's energy supply and demand, economy, environment, agriculture, and water supplies. The study also required recommendations for avoiding, reducing, and addressing related impacts - and required the CEC to coordinate the study and any research with federal, state, academic, and industry research projects.

Table 3 – California Climate Change Regulations

Regulation	Description
AB 32 Climate Change Scoping Plan	In June 2021, CARB began holding a Public Workshop Series to commence development of the 2022 Scoping Plan. The 2022 Scoping Plan Update will assess progress towards achieving the SB 32 2030 target of a 40% GHG reduction and lay out a path to achieve carbon neutrality by 2045.
Building Decarbonization/ Building Energy Efficiency Standards	Workshops commenced in February 2021 for developing the 2022 Building Energy Efficiency Standards (Energy Code). The 2022 Energy Code will improve upon the 2019 Energy Code for new construction of, and additions and alterations to, residential and nonresidential buildings. The California Energy Commission (CEC) updates the standards every three years. These CEC standards are part of a broad multi-agency "green building" approach to maximize energy efficiency, conserve water, reduce waste, minimize transportation emissions, and provide good indoor environmental quality to protect occupant health.
Greenhouse Gas Reduction Fund	State program allocating proceeds from cap-and-trade auctions to support investments and projects that reduce greenhouse gas emissions throughout California.
Amendments to the Mandatory Greenhouse Gas Reporting Regulation	The CARB Regulation for the Mandatory Reporting of Greenhouse Gas Emissions was originally approved in 2007 and revised in 2010, 2012, 2013, 2014, 2016 and 2018. Amendments to MRR were approved on March 29, 2019 and became effective on April 1, 2019, for 2019 data. The 2019 amendments were implemented to: • Support California's Cap-and-Trade Regulation to ensure consistency with the calculation of compliance obligations • Ensure that reported GHG emissions and product data are accurate and complete in order to support California's GHG reduction programs
Cap & Trade Amendments	December 2018 amendments to the cap-and-trade regulation included: • New price containment points and a price ceiling • Limits on offset use • New industrial facility leakage assistance factors for 2018 and beyond • Clarifications on electric and gas utility use of allowance value • Compliance provisions for Energy Imbalance Market (EIM)-related GHG emissions • Offset invalidation clarifications • Streamlining implementation requirements • Adjustments to linkage reflecting Ontario's actions to revoke its participation in the cap-and-trade market. September 2016 amendments to the cap-and-trade regulation included: • Emission caps for the post-2020 program • Post-2020 continuation of the allowance price containment reserve • Linking with Ontario's cap-and-trade program • Compliance with the federal Clean Power Plan • Modifications to allowance allocation
Low Carbon Fuel Standard	In September 2015, the Air Resources Board re-adopted the Low Carbon Fuel Standard, to settle issues arising from lawsuits. The requirement is still a 10 percent reduction in the carbon intensity of transportation fuels.
Cap & Trade Offset Protocols	The Air Resources Board has adopted five protocols for offset compliance projects. In addition to the original four protocols adopted in 2011, ARB has adopted: Mine Methane Capture (MMC) Projects Compliance Offset Protocol, adopted April 2014

Appendix B: Greenhouse Gases – Characteristics of Climate Pollutants & Regulatory Setting

Regulation	Description
Cap & Trade Link with Quebec	California linked its cap-and-trade program with Quebec's program in January 2014. Linkage allows for the use of compliance instruments from Quebec's greenhouse gas emission trading system to meet compliance obligations pursuant to the California Cap-and-Trade Regulation, and the reciprocal approval of compliance instruments issued by California to meet compliance obligations in the external trading program.
Building Energy Efficiency Standards	The Energy Commission's 2013 Building Energy Efficiency Standards are 25 percent more efficient than previous standards for residential construction and 30 percent better for nonresidential construction. The Standards, which took effect on January 1, 2014, offer builders better windows, insulation, lighting, ventilation systems and other features that reduce energy consumption in homes and businesses.
Advanced Clean Cars Standard	The Advanced Clean Cars Program, approved in January 2012, will achieve additional GHG reductions from passenger vehicles for model years 2017-2025. This Program represents a new approach to passenger vehicles (cars, light trucks) by combining the control of smog-causing pollutants and GHG emissions into a single coordinated package of standards known as Low Emission Vehicles (LEV) III. The new approach also includes efforts under the Zero-Emission Vehicle Program to support and accelerate the numbers of plug-in hybrids and zero-emission vehicles in California.
Water Appliance Standards	The Energy Commission's 2015 Water Appliance Standards are projected to save 10 billion gallons in the first year, increasing over time to 100 billion gallons of water per year. The energy efficiency and water standards require water appliances to consume less water thereby using less energy while performing the same function. The standards apply to toilets and urinals; residential lavatory faucets; kitchen faucets; public lavatory faucets.
Cap & Trade Rulemaking Activities	A proposed California cap on greenhouse gas emissions and a market-based compliance mechanisms, including compliance offset protocols. OAL approved the rulemaking and filed it with the Secretary of State on December 13, 2011. The regulation will become effective on the January 1, 2012.
Low Carbon Fuel Standards (LCFS)	The regulations are designed to reduce the carbon intensity (CI) of transportation fuels used in California by at least 10 percent by the year 2020. The Air Resources Board approved the LCFS regulation for adoption on April 23, 2009. The regulation entered into full effect on April 15, 2010. Based upon feedback from stakeholders, amendments to the regulations were proposed by the Board in December 2011.
33% Renewable Portfolio Standard	On May 5, 2011, the California Public Utilities Commission adopted the Order Instituting Rulemaking (R.) 11-05-005 to open a new proceeding for the implementation and administration of the 33% RPS Program. The primary focus of the R.11-05-005 proceeding was the implementation of the new 33% RPS law, Senate Bill (SB) 2 (1X) (Simitian), stats. 2011.
Mandatory Commercial Recycling	This regulation addresses recycling requirements for businesses that generate 4 or more cubic yards of commercial solid waste per week and multifamily residential dwellings with 5 or more units, regardless of the amount of waste generated; local jurisdiction requirements for education, outreach, monitoring and reporting; and CalAsphalt and concrete recycling review. The regulations were approved on May 7, 2012.

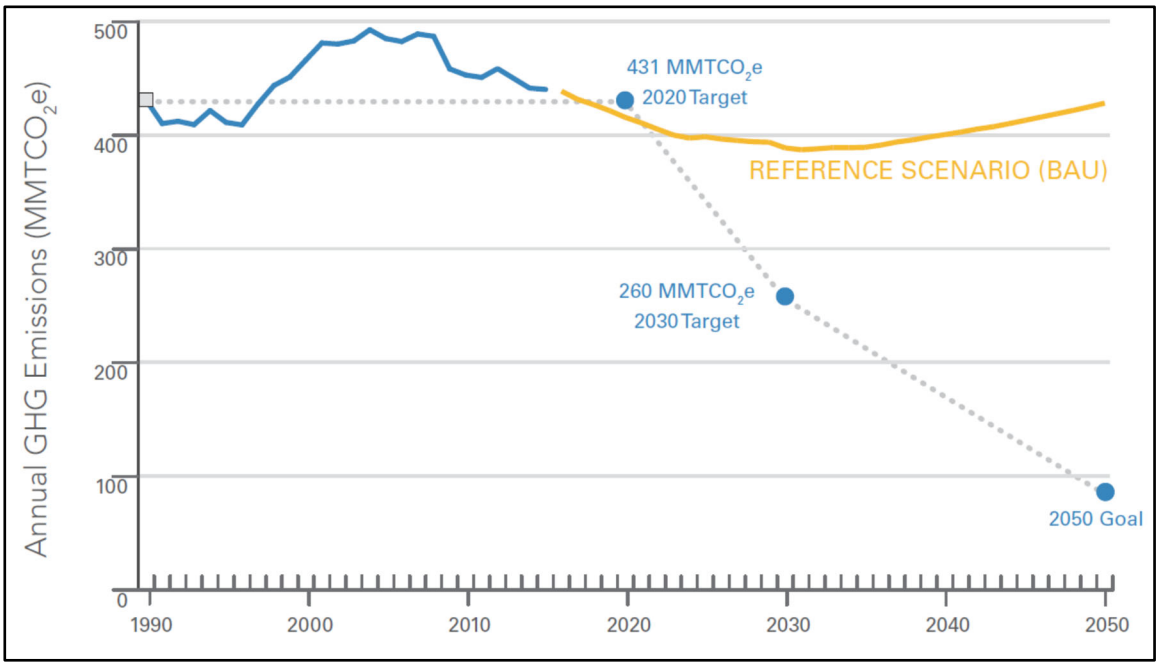
Table 4 – California Climate Change Executive Orders



Date	Executive Order	Description
September 23, 2020	N-79-20	EO-N-79-20 requires all California vehicles to be emissions free; cars and passenger trucks by 2035, medium and heavy duty trucks by 2045.
September 20, 2019	N-19-19	EO-N-19-19 requires various state agencies to leverage their existing investments, spending, or state-owned building to further CA's climate goals.
September 10, 2018	B-55-18	EO-B-55-18 establishes a new statewide goal to achieve carbon neutrality as soon as possible, and no later than 2045, and achieve and maintain net negative emissions thereafter.
July 17, 2015	B-32-15	EO-B-32-15 Sets goals for ZEVs in freight transportation
April 29, 2015	B-30-15	EO-B-30-15 sets an interim greenhouse gas (GHG) emissions target for 2030 at 40 percent below 1990 levels.
April 25, 2012	B-18-12	EO-B-18-12 calls for significant reductions in State agencies' energy purchases and GHG emissions. The Executive Order included a Green Building Action Plan, which provided additional details and specific requirements for the implementation of the Executive Order
March 23, 2012	B-16-12	EO-B-16-12 orders State agencies to facilitate the rapid commercialization of zero-emission vehicles (ZEVs). The Executive Order sets a target for the number of 1.5 million ZEVs in California by 2025. Also, the Executive Order sets as a target for 2050 a reduction of GHG emissions from the transportation sector equaling 80 percent less than 1990 levels.
September 15, 2009	S-21-09	EO-S-21-09 coordinates renewable energy efforts between CARB, CPUC, and Cal ISO.
November 17, 2008	S-14-08	EO-S-14-08 establishes renewable energy generation share for retail sellers of electricity in California.
November 14, 2008	S-13-08	EO-S-13-08 directs State agencies to plan for sea level rise and climate impacts through coordination of the State Climate Adaptation Strategy.
January 18, 2007	S-01-07	EO-S-01-07 establishes the 2020 target and Low Carbon Fuel Standard. The EO directs the Secretary of Cal/EPA as coordinator of 2020 target activities and requires the Secretary to report back to the Governor and Legislature biannually on progress toward meeting the 2020 target.
October 18, 2006	S-20-06	EO-S-20-06 establishes responsibilities and roles of the Secretary of Cal/EPA and State agencies in climate change.
April 25, 2006	S-06-06	EO-S-06-06 directs Secretary of Cal/EPA to participate in the Bio-Energy Interagency Working Group and addresses biofuels and bioenergy from renewable resources.
June 1, 2005	S-03-05	EO-S-3-05 establishes greenhouse gas emission reduction targets, creates the Climate Action Team, and directs the Secretary of Cal/EPA to coordinate efforts with meeting the targets with the heads of other State agencies. The EO requires the Secretary to report back to the Governor and Legislature biannually on progress toward meeting the GHG targets, GHG impacts to California, Mitigation and Adaptation Plans.
December 14, 2004	S-20-04	EO-S-20-04 (Green Buildings) directs State agencies to reduce energy use in State owned buildings by 20% by 2015 and increase energy efficiency.

Date	Executive Order	Description
April 20, 2004	S-07-04	EO-S-07-04 designates the 21 interstate freeways in California as the "California Hydrogen Highway Network" and directs state agencies to plan and build a network of hydrogen fueling stations along these routes by 2010.

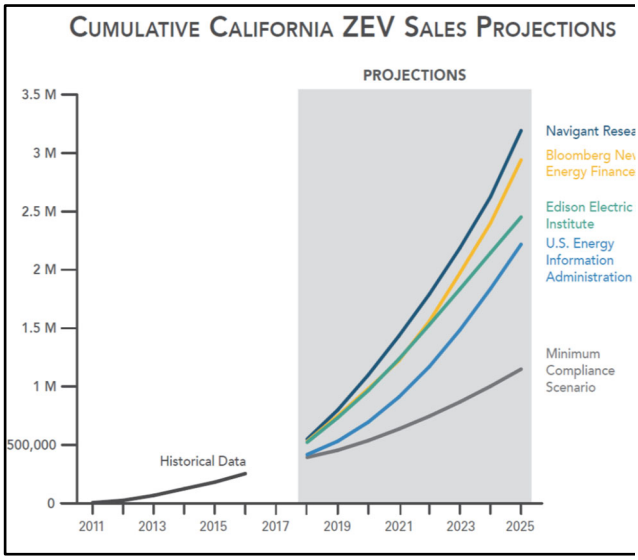
Source: (California Climate Executive Orders - Wikipedia, 2021)

On December 14, 2017, CARB approved the 2017 Climate Change Scoping Plan Update (Scoping Plan) which aims to reduce GHG emissions according to the following graphic. The Scoping Plan "is a package of economically viable and technologically feasible actions to not just keep California on track to achieve its 2030 target, but stay on track for a low- to zero-carbon economy by involving every part of the state. Every sector, every local government, every region, every resident is part of the solution. The Plan underscores that there is no single solution but rather a balanced mix of strategies to achieve the GHG target. This Plan highlights the fact that a balanced mix of strategies provides California with the greatest level of certainty in meeting the target at a low cost while also improving public health, investing in disadvantaged and low-income communities, protecting consumers, and supporting economic growth, jobs and energy diversity. Successful implementation of this Plan relies, in part, on long-term funding plans to inform future appropriations necessary to achieve California's long-term targets." (2017 Scoping Plan, p. ES4).

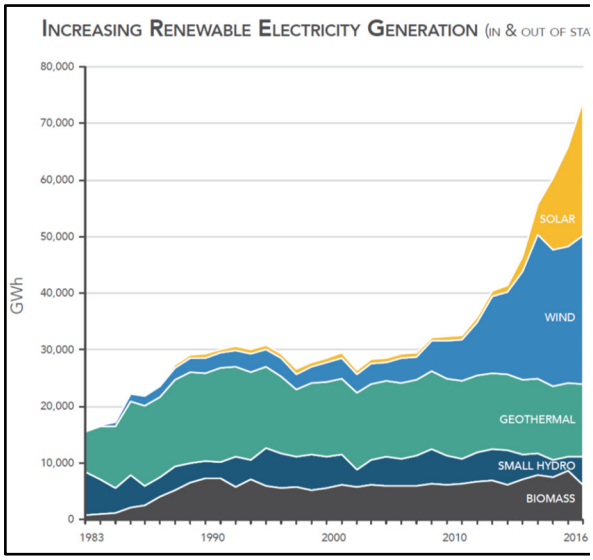
Chart 1 – 2030 Target Scoping Plan Reference Scenario

Source: Figure 6 (2017 Scoping Plan, p. 24)

The development of the Scoping Plan began by first modeling a Reference Scenario (BAU). The Reference Scenario is the forecasted statewide GHG emissions through 2030 with



> *existing policies and programs, but without any further action to reduce GHGs. [2017 Scoping Plan] Figure 6 [above] provides the modeling results for a Reference Scenario for this Scoping Plan. The graph shows the State is expected to reduce emissions below the 2020 statewide GHG target, but additional effort will be needed to maintain and continue GHG reductions to meet the mid- (2030) and long-term (2050) targets. Figure 6 depicts a linear, straight-line path to the 2030 target. It should be noted that in any year, GHG emissions may be higher or lower than the straight line. That is to be expected as periods of economic recession or increased economic activity, annual variations in hydropower, and many other factors may influence a single or several years of GHG emissions in the State. CARB's annual GHG reporting and inventory will provide data on progress towards achieving the 2030 target.*
> (2017 Scoping Plan, p. 23).



The Scoping Plan states that the California Legislature has shaped the State's climate change program, setting out clear policy objectives over the next decade including:

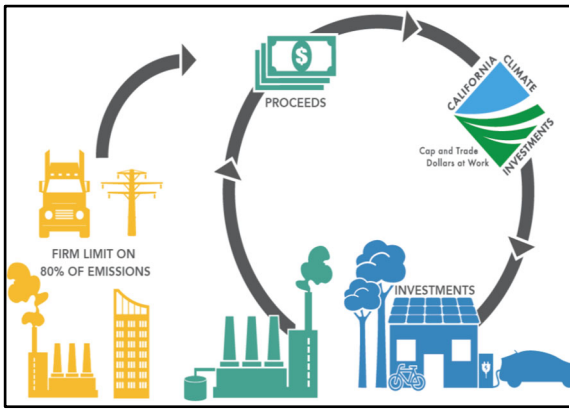
> - *40% reduction in GHG emissions by 2030;*
> - *50% renewable electricity;*
> - *Double energy efficiency savings;*
> - *Support for clean cars;*
> - *Integrate land use, transit, and affordable housing to curb auto trips;*
> - *Prioritize direct reductions;*
> - *Identify air pollution, health, and social benefits of climate policies;*
> - *Slash "super pollutants" (i.e., hydrofluorocarbons or HFCs);*
> - *Protect and manage natural and working lands;*
> - *Invest in disadvantaged communities; and*
> - *Strong support for Cap-and-Trade.*
>
> (2017 Scoping Plan, p. ES6).

Illustrations from the Scoping Plan that pertain to future emissions from the sectors representing the greatest GHG emissions, transportation and electricity use, are reproduced below.

Chart 2 – 2017 Scoping Plan GHG Exhibits

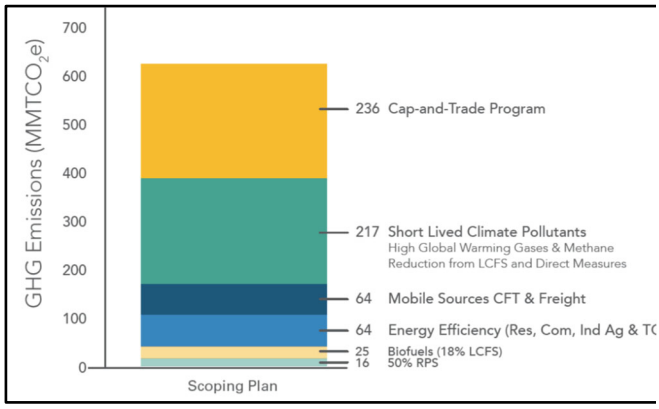
Source: (2017 Scoping Plan, p. ES5)

Source: (2017 Scoping Plan, p. ES9)



In addition to technology forcing and incentivizing regulations, the Cap-and-Trade Program is critical to meeting the Scoping Plan objectives. CARB states:

> *The Cap-and-Trade Program is fundamental to meeting California's long-range climate targets at low cost. The Cap-and-Trade Program includes GHG emissions from transportation, electricity, industrial, agricultural, waste, residential and commercial sources, and caps them while complementing the other measures needed to meet the 2030 GHG target. Altogether, the emissions covered by the Cap-and-Trade program total 80 percent of all GHG emissions in California. California's response to climate change has led to many innovative programs designed to reduce GHG emissions, including the Renewable Portfolio and Low Carbon Transportation Standards, but the Cap-and-Trade Program guarantees GHG emissions reductions through a strict overall emissions limit that decreases each year, while trading provides businesses with flexibility in their approach to reducing emissions. The Cap-and-Trade Program also generates revenue when the allowances to emit pollution are auctioned. Some of the revenue is returned directly to electricity ratepayers, and the rest is dedicated to reducing GHG emissions by making Legislatively directed investments in California with an emphasis on programs or projects that benefit disadvantaged and low-income communities.*
> (2017 Scoping Plan, p. ES16).



The following illustrations presents how CARB believes money will flow from the Cap-and-Trade program to enable state-funded investments and the amount of GHG emissions reduction that will be achieved

overall and from Cap-and-Trade which is required to cover the gap between reductions from other measures in the Scoping Plan and the 2030 Target.

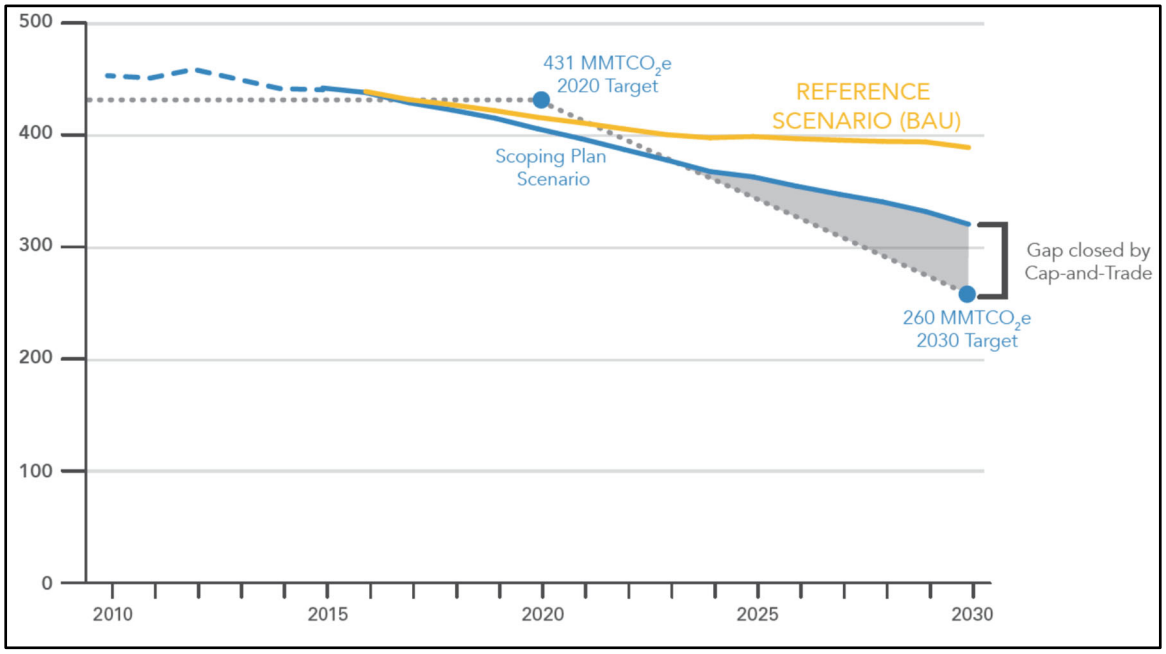


Chart 3 – 2017 Scoping Plan Cap-and-Trade Exhibits

Source: California's Carbon Pricing and Investment Overview (2017 Scoping Plan, p. ES16).

Source: Scoping Plan Scenario – Estimated Cumulative GHG Reductions by Measure (2021 – 2030) (2017 Scoping Plan, p. 28).

Source: 2017 Scoping Plan Reference Scenario (2017 Scoping Plan, p. 24).

Reference Scenario 2030 emissions estimate of 389 $MMTCO_2e$ to the 2030 target of 260 $MMTCO_2e$ and the level of 2030 emissions with the known commitments, estimated to be 320 $MMTCO_2e$. The known commitments are expected to result in emissions that are 60 $MMTCO_2e$ above the target in 2030, and have a cumulative emissions reduction gap of about 236 $MMTCO_2e$. This means the known commitments do not decline fast enough to achieve the 2030 target. The remaining 236 $MMTCO_2e$ of estimated GHG emissions reductions would not be achieved unless further action is taken to reduce GHGs. Consequently, for the Scoping Plan Scenario, the Post-2020 Cap-and-Trade Program would need to deliver 236 $MMTCO_2e$

cumulative GHG emissions reductions from 2021 through 2030. If the estimated GHG reductions from the known commitments are not realized due to delays in implementation or technology deployment, the post-2020 Cap-and-Trade Program would deliver the additional GHG reductions in the sectors it covers to ensure the 2030 target is achieved.

Table 5 – Climate Change Policies and Measures

Recommended Action	Applies to Project?
Implement SB 350 by 2030: • Increase the Renewables Portfolio Standard to 50 percent of retail sales by 2030 and ensure grid reliability. • Establish annual targets for statewide energy efficiency savings and demand reduction that will achieve a cumulative doubling of statewide energy efficiency savings in electricity and natural gas end uses by 2030. • Reduce GHG emissions in the electricity sector through the implementation of the above measures and other actions as modeled in IRPs to meet GHG emissions reductions planning targets in the IRP process. Load-serving entities and publicly- owned utilities meet GHG emissions reductions planning targets through a combination of measures as described in IRPs.	No, Project will purchase grid electricity, not administrate it.
Implement Mobile Source Strategy (Cleaner Technology and Fuels): • At least 1.5 million zero emission and plug-in hybrid light-duty electric vehicles by 2025. • At least 4.2 million zero emission and plug-in hybrid light-duty electric vehicles by 2030. • Further increase GHG stringency on all light-duty vehicles beyond existing Advanced Clean Cars regulations. • Medium- and heavy-duty GHG Phase 2. • Innovative Clean Transit: Transition to a suite of to-be-determined innovative clean transit options. Assumed 20 percent of new urban buses purchased beginning in 2018 will be zero emission buses with the penetration of zero-emission technology ramped up to 100 percent of new sales in 2030. Also, new natural gas buses, starting in 2018, and diesel buses, starting in 2020, meet the optional heavy-duty low-NO_X standard. • Last Mile Delivery: New regulation that would result in the use of low NO_X or cleaner engines and the deployment of increasing numbers of zero-emission trucks primarily for class 3-7 last mile delivery trucks in California. This measure assumes ZEVs comprise 2.5 percent of new Class 3–7 truck sales in local fleets starting in 2020, increasing to 10 percent in 2025 and remaining flat through 2030. • Further reduce VMT through continued implementation of SB 375 and regional Sustainable Communities Strategies; forthcoming statewide implementation of SB 743; and potential additional VMT reduction strategies not specified in the Mobile Source Strategy but included in the document "Potential VMT Reduction Strategies for Discussion."	No, Project vehicles are heavy-heavy duty and were not subject to heavy-duty GHG Phase 1 regulations. Thus, they would be unlikely to be subject to these measures.
Increase stringency of SB 375 Sustainable Communities Strategy (2035 targets).	No, Project does not affect SB 375 targets.
By 2019, adjust performance measures used to select and design transportation facilities. • Harmonize project performance with emissions reductions, and increase competitiveness of transit and active transportation modes (e.g., via guideline documents, funding programs, project selection, etc.).	No, Project does not affect viability of transit or active modes.

Recommended Action	Applies to Project?
By 2019, develop pricing policies to support low-GHG transportation (e.g., low-emission vehicle zones for heavy duty, road user, parking pricing, transit discounts).	No, Project does not affect government pricing policies.
Implement California Sustainable Freight Action Plan: • Improve freight system efficiency. • Deploy over 100,000 freight vehicles and equipment capable of zero emission operation and maximize both zero and near-zero emission freight vehicles and equipment powered by renewable energy by 2030.	No, Project does not affect whether Freight Action Plan can be implemented.
Adopt a Low Carbon Fuel Standard with a CI reduction of 18 percent.	No, Project does not affect CARB's ability to adopt standards.
Implement the Short-Lived Climate Pollutant Strategy by 2030: • 40 percent reduction in methane and hydrofluorocarbon emissions below 2013 levels. • 50 percent reduction in black carbon emissions below 2013 levels.	No, Project does not affect whether SLCP strategy can be implemented.
By 2019, develop regulations and programs to support organic waste landfill reduction goals in the SLCP and SB 1383.	No, Project does not affect CARB's ability to adopt regulations.
Implement the post-2020 Cap-and-Trade Program with declining annual caps.	No, Project does not affect CARB's ability to implement Cap-and-Trade.
By 2018, develop Integrated Natural and Working Lands Implementation Plan to secure California's land base as a net carbon sink: • Protect land from conversion through conservation easements and other incentives. • Increase the long-term resilience of carbon storage in the land base and enhance sequestration capacity • Utilize wood and agricultural products to increase the amount of carbon stored in the natural and built environments • Establish scenario projections to serve as the foundation for the Implementation Plan	No, Project does not affect ability to develop such a plan.
Establish a carbon accounting framework for natural and working lands as described in SB 859 by 2018.	No, Project does not affect ability to establish such a framework.
Implement Forest Carbon Plan	No, Project does not affect ability to implement such a plan.
Identify and expand funding and financing mechanisms to support GHG reductions across all sectors.	No, Project does not affect whether CARB can identify and expand funding.

Source: (CARB, 2017, pp. 103-104).

Table 6 shows the amount of change in GHG emissions by Scoping Plan sector. Note that Project sources mainly fall into the electric power and transportation sectors with exception of the portable generator which would be in the industrial sector but is likely to be owned and operated by a contractor.

Table 6 – Estimated Change in GHG Emissions by Sector

Scoping Plan Category	1990 ($MMTCO_2e$)	2030 Scoping Plan Ranges ($MMTCO_2e$)
Agriculture	26	24–25
Residential and Commercial	44	38–40
Electric Power	108	30–53
High GWP	3	8–11
Industrial	98	83–90
Recycling and Waste	7	8–9
Transportation (Including TCU)	152	103–111
Natural Working Lands Net Sink*	-7***	TBD
Sub Total	431	294–339
Cap-and-Trade Program	n/a	34–79
Total	**431**	**260**

Source: (2017 Scoping Plan, p. 31).

* Work is underway through 2017 to estimate the range of potential sequestration benefits from the natural and working lands sector.

** The SLCP will reduce emissions in this sector by 40 percent from 2013 levels. However, the 2030 levels are still higher than the 1990 levels as emissions in this sector have grown between 1990 and 2013.

*** This number reflects net results and is different than the intervention targets discussed in Chapter 4.

MEMORANDUM

To: Scott Cohen, SESPE Consulting, INC

From: Jan Bowen, Provost & Pritchard

Subject: McKay Point Project Construction

Date: 3/18/2015

This memo explains the assumptions that were used to estimate construction phase lengths and equipment, and yearly project operations and project operation equipment for the McKay Point Project.

Construction Phase:

The following assumes that the slurry wall would be constructed by an outside contractor and the in/out flow grading, in/out flow building and generator/barge pump would be constructed by Tulare Irrigation District (TID). A list of TID's current construction equipment is attached. Total operational times are reported in number of days assuming a day is eight hours of operation. If during construction the daily hours (or number of excavators, dozers, loaders, etc.) of operation were increased, then the actual days of construction would be reduced accordingly.

Slurry Wall

Slurry wall construction consists of clearing and grubbing approximately 26 acres, excavating approximately 109,000 cubic yards of native soil, and the poring of the slurry wall into the excavated trench. Excavated soils would be hauled to an onsite screening/mixing site and screened for use in the slurry wall mix. Approximately 4,000 dry tons of bentonite and 56,000 tons silty/clay fines would be delivered to the site for use in the slurry wall. Excess native soils would either be spread or stored on site. Construction slurry consisting of a bentonite-water slurry would be pumped into the trench to hold the sides of the trench open during construction. A mixture of bentonite, imported silty/clay fines and native soil would be used for the final slurry wall. The slurry wall would be hauled from the mixing site and placed into the trench. A final native soil cap consisting of approximately 10,000 cubic yards would be placed on top of the slurry wall. The following table lists the approximate equipment activity levels for construction:

Slurry Wall Excavation and Installation					
Description	*Equipment*	*HP*	*Rate*	*Quantity*	*# of 8 hour Days*
Clear/Grub, Haul Road, Construction Ponds	Dozer	165	1 hr/ac	26 ac	4
Slurry Wall Excavation	Excavator	429	1.7 cy/bucket	109,000 cy @ 25 bucket/hr	321
Haul Excavated Soil To Mixing Site and Return With Slurry Mix	Dump Truck	300	10 cy/haul	119,000 cy @ 4 hauls/hour	372
Plug Mill for Sieving Native Soils	Generator	100	4 hr/day	401 day	201
Mixing and Moving Slurry Mix	Loader	349	3 cy/bucket	119,000 cy @ 20 bucket/hr	248
Construction Slurry Pump	Generator	84	N/A	N/A	321
Dust Control	Water Truck	230	2 hr/day	401 days	100

In/Out Flow Grading

In/out flow grading consists of clearing and grubbing of approximately 3 acres, excavation of 20,000 cubic yards, and the placement of approximately 9,000 cubic yards of rip-rap. Excavated soils are assumed to be spread on site. The following table lists the approximate equipment activity levels for construction:

In/Out Flow Grading					
Description	*Equipment*	*HP*	*Rate*	*Quantity*	*# of 8 hour Days*
Clear and Grub, Haul Roads	Dozer	165	1 hr/ac	3 ac	1
Canal Excavation and Spreading	Tractor	530	15 cy/load	20,000 cy @ 3 load/hr	56
Final Shaping of Canal	Grader	200	0.5 hr/ac	3 ac	1
Placing of Rip-Rap	Excavator	184	1 cy/bucket	9,000 cy @ 20 bucket/hr	56
Hauling of Rip-Rap	Dump Truck	300	10 cy/Haul	9,000 cy @ 4 haul/hr	28
Dust Control	Water Truck	230	2 hr/day	56 day	14

In/Out Flow Building

Construction of the in/out flow building would consist of finish grading and minor excavation of approximately 600 cubic yards and the placement of approximately 1,100 cubic yards of concrete. Excavated soils are assumed to be spread on site. The following table lists the approximate equipment activity levels for construction:

In/Out Flow Building					
Description	*Equipment*	*HP*	*Rate*	*Quantity*	*# of 8 hour Days*
Minor Excavation, Structural Compaction	Excavator	184	1 cy/bucket	500 cy @ 20 bucket/hr	3
Minor Excavation and Moving of Materials	Backhoe	108	4 cy/hy	100 cy	3
Concrete Placement (Pump)	Generator	84	20 cy/hr	1,100 cy	7
Placing of Box Culvert	Crane	250	N/A	N/A	10
Dust Control, Soil Conditioning	Water Truck	230	1 hr/day	24	3

Generator/Barge Pump

Construction of the generator/barge pump would consist of finish grading and minor excavation, tank and building pad concrete slabs, and excavation and placement of the barge pump discharge pipes. The following table lists the approximate equipment activity levels for construction:

Generator/Barge Pump					
Description	*Equipment*	*HP*	*Rate*	*Quantity*	*# of 8 hour Days*
Minor Excavation and Moving of Materials	Backhoe	108	4 cy/hr	50 cy	2
Pipe Trench Excavation, Backfill, and Compaction	Excavator	184	200 ft/ 8 hr	1200 ft	6
Concrete Placement (Pump)	Generator	84	N/A	N/A	1
Dust Control, Soil Conditioning	Water Truck	230	1 hr/day	8 days	1

Project Operations:

The following assumes that on average the proposed basin could be filled two times per year for a total usable yearly volume of 9,200 acres-feet. Approximately 2,200 acres-feet can flow by gravity into the St. Johns River and the remaining 7,000 acres-feet can be pumped out at a maximum flow rate of 160 cubic feet per second. The following table lists the approximate equipment activity levels for operations:

Project Operations					
Description	*Equipment*	*HP*	*Rate*	*Quantity*	*# of 8 hour Days*
Pumping	Generator	600	160 cfs	7,700 ac-ft	73
Minor Site Maintenance	Backhoe	108	N/A	N/A	20
On Road Vehicles					
Description	*Equipment*	*Vehicle Miles Traveled / Year*			
Support Trucks	Spray Truck	380			
Support Trucks	Pickup	2,080			
Support Trucks	Fuel Truck	450			

American Thoracic Society

What Constitutes an Adverse Health Effect of Air Pollution?

THIS OFFICIAL STATEMENT OF THE AMERICAN THORACIC SOCIETY WAS ADOPTED BY THE ATS BOARD OF DIRECTORS, JULY 1999

PURPOSE OF THE STATEMENT

As the twentieth century ends, the health effects of outdoor air pollution remain a public health concern in developing and developed countries alike. In the United States, the principal pollutants monitored for regulatory purposes (carbon monoxide, nitrogen dioxide, sulfur dioxide, particles, ozone, and lead; see Table 1) show general trends of declining concentrations, although ozone pollution now affects many regions of the country besides southern California (1). Yet, even at levels of air pollution now measured in many cities of the United States, associations between air pollution levels and health indicators are being demonstrated at concentrations around those set by standards of the U.S. Environmental Protection Agency (2, 3). In many countries of the developing world, concentrations of air pollutants are rising with industrialization and the increasing numbers of motor vehicles (4, 5). Extremely large and densely populated urban areas, often referred to as "megacities," have the potential to generate unprecedented air quality problems.

There are common principles to air quality management throughout the world. Public health protection unifies all approaches, whether based on voluntary guidelines, mandated standards for concentrations, or source control. The intent is to limit or to avoid any impact of air pollution on the public's health. Air quality management is thus based on a scientific foundation built from the epidemiologic, toxicologic, and clinical evidence on health effects of air pollution. In interpreting this evidence for public health protection, there is a need to identify those effects that are considered "adverse" and to separate them from those effects not considered adverse.

The American Thoracic Society has previously provided guidance on the distinction between adverse and nonadverse health effects of air pollution in its 1985 statement, "Guidelines as to What Constitutes an Adverse Respiratory Health Effect" (6). Definitions of adverse effects have also been offered by the World Health Organization (7–10), but the guidance of the American Thoracic Society has received particular emphasis in the United States. Preparation of the original statement was intended to coincide with consideration of the passage of an amended Clean Air Act and to provide a framework for interpreting scientific evidence relevant to the mandate of the act. In particular, the Clean Air Act requires that the Administrator of the Environmental Protection Agency promulgate, for certain pollutants, standards that will be sufficient to protect against adverse effects of the air pollutants on health. The act is silent on the definition of "adverse effect" and, at the time of the 1985 statement, there was considerable controversy around the interpretation of this language as revision of the act was being considered. Recognizing the need of policy makers for expert guidance, the American Thoracic Society released the 1985 statement, which to date constitutes the sole set of recommendations on this issue from an expert panel convened by a health organization.

The American Thoracic Society has revised the 1985 statement because new scientific findings, published since the original statement, have again raised questions as to the boundary between adverse and nonadverse in considering health effects of air pollution. These new findings reflect improved sensitivity of research approaches and the application of biomarkers that can detect even subtle perturbations of biologic systems by air pollutants. Epidemiologic research designs have been refined and large sample sizes and increasingly accurate methods for exposure assessment have increased the sensitivity of epidemiologic data for detecting evidence of effects. New statistical approaches and advances in software and hardware have facilitated analyses of large databases of mortality and morbidity information. The design of clinical studies-including controlled exposures of volunteers-has also advanced and biologic specimens may be obtained after exposure, for example, by fiberoptic bronchoscopy, to identify changes in levels of markers of injury. Toxicologic studies have also gained in sophistication through incorporation of more sensitive indicators of effect and the careful tracing of the relationship between exposure and biologically relevant doses to target sites, which may now be considered at a molecular level.

New dimensions have been added to the array of outcome measures. Medical outcomes research now recognizes that patient well-being should be broadly conceptualized and measured rigorously, in addition to considering the biological process of the disease itself. As a result, health-related quality of life, the perception of well-being, is now considered a necessary component of outcomes research. Validated instruments have been developed to assess the impact of health-related symptoms and impairment on functional status and quality of life (11-14). The formalization of the concept of environmental justice acknowledges that the effects of specific pollutants cannot be evaluated in isolation without giving consideration to the overlapping exposures of populations, often minority group members of low socioeconomic status, who live in neighborhoods that are heavily exposed to multiple environmental contaminants (15).

This new statement, like the 1985 statement, is intended to provide guidance to policy makers and others who interpret the scientific evidence on the health effects of air pollution for the purpose of risk management. The statement does not offer strict rules or numerical criteria, but rather proposes principles to be used in weighing the evidence and setting boundaries between adverse and nonadverse health effects. Even if the technical tools were available for scaling the consequences of air pollution on the multiple relevant axes, the placement of dividing lines should be a societal judgment and consequently

* For detailed information on scientific bases and policy considerations underlying decisions establishing the NAAQS listed here, see the AQCDs, staff papers, and NAAQS Promulgation notices cited in text. Such information can also be obtained from several internet websites (e.g., http://www.epa.giv/airs/criteria.html; http://www.epa.gov/oar/oaqps/publicat.html; and http://www.epa.gov/ncea/biblio.htm).

TABLE 2

ADVERSE RESPIRATORY HEALTH EFFECTS

A. Increased mortality (*Increased* as used here and subsequently means significantly [$p < 0.05$] increased above that recorded in some standard, comparable population. In selected situation, $p < 0.1$ may be appropriate)
B. Increased incidence of cancer
C. Increased frequency of symptomatic asthmatic attacks
D. Increased incidence of lower respiratory tract infections
E. Increased exacerbations of disease in persons with chronic cardiopulmonary or other disease that could be reflected in a variety of ways
   1. Less able to cope with daily activities (i.e., shortness of breath or increased anginal episodes)
   2. Increased hospitalization, both frequency and duration
   3. Increased emergency ward or physician visits
   4. Increased pulmonary medication
   5. Decreased pulmonary function
F. Reduction in FEV_1 or FVC associated with clinical symptoms
   1. Chronic reduction in FEV, or FVC associated with clinical symptoms
   2. A significant increase in number of persons with FEV_1 below normal limits: chronically reduced FEV, is a 'predictor of increased risk of mortality. Transient or reversible reductions that are not associated with an asthmatic attack appear to be less important. It should be emphasized that a small but significant reduction in a population mean FEV, or $FEV_{.75}$ is probably medically significant, as such a difference may indicate an increase in the number of persons witn respiratory impairment in the population. In other words, a small part of the population may manifest a marked change that is medically significant to them, but when diluted with the rest of the population the change appears to be small
   3 An increased rate of decline in pulmonary function (FEV,) relative to the predicted value in adults with increasing age or failure of children to maintain their predicted FEV, growth curve. Such data must be standardized for sex, race, height, and other demographic and anthropometric factors
G. Increased prevalence of wheezing in the chest apart from colds, or of wheezing most days or nights. (The significance of wheezing with colds needs more study and evaluation.)
H. Increased prevalence or incidence of chest tightness
I. Increased prevalence or incidence of cough/phlegm production requiring medical attention
I. Increased incidence of acute upper respiratory infections that interfere with normal activity
K. Acute upper respiratory tract infections that do not interfere with normal activity
L. Eye, nose, and throat irritation that may interfere with normal activity (i.e., driving a car) if severe
M. Odors

this committee does not propose specific boundaries for separating adverse from nonadverse effects.

OVERVIEW OF THE 1985 STATEMENT

The 1985 statement of the American Thoracic Society was directed at respiratory health effects of air pollution and emphasized the interpretation of the epidemiologic evidence. The statement recognized the spectrum of responses to air pollution, which begins with exposure and evidence of exposure and ends at death. This spectrum has been characterized as a pyramid, based in the most common consequence-exposure-and having mortality, the least common and most severe consequence, at its tip. The statement included a table that lists adverse respiratory health effects, seemingly in order of declining severity (Table 2). The 1985 statement hinged the distinction between adverse and nonadverse effects on medical considerations. The committee recognized that the boundary is further influenced by societal considerations: "Where one draws the line to categorize it as an adverse health effect or an action level between pathophysiologic or physiologic change is probably best left to the individual or the community."

The committee's definition of adverse respiratory health effects was ". medically significant physiologic or pathologic changes generally evidenced by one or more of the following: (*1*) interference with the normal activity of the affected person or persons, (2) episodic respiratory illness, (3) incapacitating illness, (4) permanent respiratory injury, and/or (5) progressive respiratory dysfunction." The committee noted that all changes are not adverse, citing the example of carboxyhemoglobin. The level of carboxyhemoglobin, beyond that from endogenous production, is indicative of exposure but it is not predictive of adverse effects until reaching threshold levels, depending on the effect and the susceptibility of the exposed person. The statement recognized that a distinction should be drawn between effects to individuals and effects to populations and that populations are heterogeneous in their susceptibility. The comment was offered that a change in a population could be "medically significant" for that group. The statement also provides guidance on interpretation of'reversible effects and on interpreting irreversible effects. In acknowledging that research would continue to address uncertainties, the committee recommended that the guidelines should be periodically reviewed and updated.

METHODOLOGY FOR DEVELOPING THIS STATEMENT

Following the recommendation of the committee that authored the 1985 statement, the Environmental and Occupational Health Assembly of the American Thoracic Society recognized a need to reconvene a group to review and revise the prior statement. The statement had been used for more than a decade and new investigative approaches were being used to identify effects of air pollution that were not considered by the first committee. In addition, societal perspectives had shifted since the early 1980s and a forma1 concern for the impact of air

pollution on specific groups had been expressed through the environmental justice movement.

To revise the statement, a multidisciplinary committee was convened in 1997 that included expertise in pulmonary medicine, public health, epidemiology, both clinical and animal toxicology, biochemistry, and cellular and molecular biology. This committee conducted several planning meetings and consulted experts in environmental economics and in ethics. In addition, a multidisciplinary workshop was convened to gain input from the range of groups potentially interested in the statement and its application. The committee's approach was discussed at a symposium held at the 1999 Annual Meeting of the American Thoracic Society. After further revisions, the statement was reviewed and submitted to the Board of the American Thoracic Society.

BACKGROUND ON THE CLEAN AIR ACT

The preparation of the original statement was largely motivated by potential ambiguity in interpreting the language of the Clean Air Act, which addresses adverse effects of air pollution without providing clear guidance as to the distinction between adverse and nonadverse effects. In addition, questions regarding this distinction arise repeatedly in interpreting the findings of research studies, whether observational or experimental. Consequently, the 1985 statement has had broader application than just the interpretation of evidence on air pollution and health for the purpose of promulgating air quality regulations. Nonetheless, the committee found the legislative history of the Clean Air Act to be relevant to its charge.

The first national legislation on air pollution, the Air Pollution Control Act, was passed in the mid-1950s; the original Clean Air Act was passed in 1963 and last revised in 1990. The act is lengthy and complex in its provisions; most relevant to considerations in defining an adverse health effect are Sections 108 (Air Quality Criteria and Control Techniques), 109 (National Ambient Air Quality Standards), and 112 (Hazardous Air Pollutants). National Ambient Air Quality Standards (NAAQS) are set individually for six prevalent pollutants (Table 1), often referred to as "criteria pollutants." They are so designated because of the requirement for comprehensively reviewing relevant information in a criteria document. The primary NAAQS are to be set at a level that protects the public health with an adequate margin of safety, regardless of economic or technical feasibility of attainment. The secondary standards are concerned with welfare and environmental consequences.

The hazardous air pollutants, as defined in Section 112, are not covered under Sections 108 and 109 as criteria pollutants. In 1990, the Congress offered a list of 189 such pollutants and a process for listing and delisting substances. The 1990 Clean Air Act states: "The Administrator shall periodically review [and revise] the list [of 189 hazardous air pollutants] by. adding pollutants which present, or may present, through inhalation or other routes of exposure, a threat of adverse human health effects (including, but not limited to substances which are known to be, or may reasonably be anticipated to be, carcinogenic, mutagenic, teratogenic, neurotoxic, which cause reproductive dysfunction, or which are acutely or chronically toxic). ." Section 112(f)(2) further directs the Environmental Protection Agency to assess whether the emissions standards for the listed hazardous air pollutants required under other subsections "provide an ample margin of safety to protect public health" and if not, then the agency is to develop standards that will address the "remaining risk."

The historical record provides an indication of the intent of the Congress in framing the language of the Clean Air Act with regard to protection of the public's health. Research now shows that the most highly susceptible individuals may respond to common exposures that are often at or close to natural background pollutant levels.

With regard to sensitivity, the 1970 Clean Air Act recognized that some persons were so ill as to need controlled environments, e.g., persons in intensive care units or newborn infants in nurseries; the act stated that the standards might not necessarily protect such individuals. It further stated, however, that the standards should protect "particularly sensitive citizens such as bronchial asthmatics and emphysematics who in the normal course of daily activity are exposed to the ambient environment." The act further suggested that the adequacy of any standard could be tested in a statistically representative sample of sensitive individuals. The hearing record on the 1970 act is informative. Dr. Hon T. Middleton (Commissioner, National Air Pollution Control Administration, Department of Health, Education, and Welfare) addressed the Senate Subcommittee on Air and Water Pollution of the Committee on Public Works on May 27, 1970. He testified that the intent of any national air quality standard is to be "protective of health in all places" and set at a level below which effects have not been observed. Dr. Middleton recognized the difficulty of finding a demarcation point of exposure below which there is no effect and he noted that there may be subtle effects and evolving scientific understanding.

Further difficulties in the language of the Clean Air Act were later noted in ***A Legislative History of the Clean Air Act Amendments of 1977: A Continuation of the Clean Air Act Amendments of 1970.*** This document noted the difficulty of applying the margin of safety and the erosion of margins of safety by advancing scientific knowledge. The document also commented on the implicit assumption of a safe threshold in the language of the act and the implausibility of this assumption. The report questioned whether the NAAQS (I) protect against genetic mutations, birth defects, and cancer, (2) take sufficient account of the consequences of long-term low-level exposures or short-term peaks, and (3) sufficiently consider synergism among pollutants and the formation of secondary pollutants, e.g., sulfates, with their own toxicity. These considerations remain relevant more than 20 years later.

This selective review of the historical record indicates that Congress intended that the NAAQS would afford health protection not only to the general population but to subgroups with enhanced susceptibility to air pollution, including people with asthma and people with chronic obstructive lung disease. Nevertheless, it is also clear that some exquisitely susceptible individuals might remain outside the ambit of protection of the NAAQS. A margin of safety was to be provided but quantitative specification was not offered. The evolutionary nature of the supporting scientific evidence was repetitively acknowledged and the need to distinguish adverse from nonadverse effects was at least implicitly recognized. The current language of Section 112 explicitly acknowledges the possibility of shifting understanding of risks of specific hazardous air pollutants.

GENERAL CONSIDERATIONS

In preparing the statement, the committee identified several general considerations that are relevant to interpreting evidence on the health effects of air pollution. Each of these considerations and the committee's judgment as to their proper weighting are detailed below.

Population Health versus Individual Risk

The effects of air pollution can be viewed in the complementary contexts of the increment of an individual's risk for disease—the clinician's measure of impact-and of the additional risk incurred by a population, which is the public health perspectivc (16). Both perspectives arc relevant to interpreting research findings on air pollution and to regulations that are protective of the public's health. Any risk incurred by an exposed individual beyond some boundary, determined by the individual or on a societal basis, could be deemed unacceptable. For example. prolonged exposure to a respiratory carcinogen could result in an individual-level incremental risk of exposure of 10^{-4}, more than two orders of magnitude lower than the baseline lifetime individual risk in the United States. Nevertheless, among an exposed population of IO', the estimated number of cancer cases that might result from such an exposure would number 10^{3}, illustrating that minute individual risks may be significant from the standpoint of population exposures.

Exposure could also enhance risk for a population to an unacceptable degree, perhaps without shifting the risks of any particular individuals to an unacceptable level. Figure 1 illustrates the distinction. In Figure l A, the population's distribution of exposure shifts toward a higher level and some members of the population cross the boundary to an unacceptable risk. In Figure lB, the shift affects the position of the population distribution, but no individuals move to an unacceptable level of risk. Effects on persons with asthma are illustrative. A population of children with asthma could have a distribution of lung function such that no individual child has a level associated with significant impairment. Exposure to air pollution could shift the distribution toward lower levels without bringing any individual child to a level that is associated with clinically relevant consequences. Individuals within the population would, however, have diminished reserve function and are at potentially increased risk if affected by another agent, e.g., a viral infection. Assuming that the relationship between the risk factor and the disease is causal, the committee considered that such a shift in the risk factor distribution, and hence the risk profile of the exposed population. should be considered adverse, even in the absence of the immediate occurrence of frank illness.

Ethics and Equity

The past decade has brought increasing concern over the ethics of heterogeneous, inequitable distributions of environmental and occupational exposures (IS). Within the United States, some groups receive disproportionate exposures to environmental agents that arc injurious to health; the environmental justice movement seeks to redress these inequities. The exposures of concern originate in breathing polluted outdoor air, living in substandard housing with indoor air pollution problems, including exposures to certain bioacrosols and combustion products, and working in jobs with occupational respiratory risks. Groups encompassed by this movement in the United States include various racial and ethnic minority populations. particularly those living within urban areas, and the socioeconomically disadvantaged. In the developing world, such exposures can occur at substantially higher levels and may, in some instances, extend to a majority of a given nation's population. Limited access to care and medications may enhance susceptibility to pollution.

The concept of environmental equity had not been formally voiced when the 1985 statement was written. The present committee viewed inequities of exposure as potentially representing a form of susceptibility to air pollution. In other words, individuals within the target groups may be at increased risk of experiencing adverse effects from a given level of ambient air pollution because their baseline risk level may have been raised by other exposures. Moreover, in some instances there may be genetic and nutritional factors enhancing susceptibility as well. It should be noted, however, that there are other exposure scenarios and other subpopulations with increased baseline risks that are not formally included within the environmental justice movement. The heterogeneity of populations needs full acknowledgment, whether it reflects disproportionate noxious exposures or other factors. Observing that there have been few investigations of the effects of other exposures, genetics, or nutrition on susceptibility to air pollution-related effects, either in the United States or internationally, the committee issued a call for additional research in these areas.

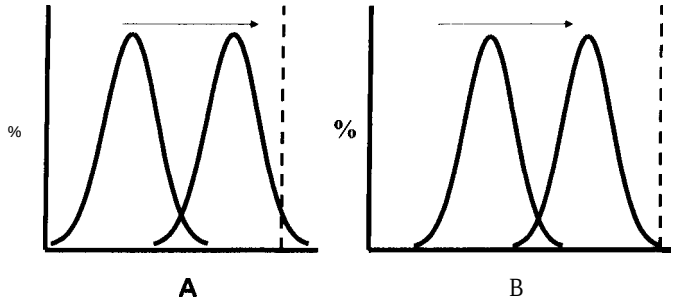

Figure 7. Hypothetical distributions **of exposure for two populations, *A* and *B*. (See text for explanation.)**

Economic Costs

Adverse health effects of air pollution incur costs, including direct costs of providing treatment for illness and indirect costs of lost work time and productivity. Cost-benefit analysis provides an estimate of the balancing of the costs of controls against the benefits; cost effectiveness analysis provides an indication of the level of control accomplished in relation to costs. Cost-benefit and cost-effectiveness analysis are assumption-laden tools now being used for policy-making purposes. Cost estimates depend on the valuation given to illness, lost work time and productivity, and even to lost life. It has been proposed that cost-benefit analysis may facilitate the process of deciding whether a given air pollution-related health impact should be considered adverse. The legislative history of the Clean Air Act explicitly excludes consideration of economic factors in setting ambient air quality standards or in developing emissions standards for hazardous air pollutants. In the context of air quality regulation, cost-benefit analysis is a multistep process involving the articulation of value judgments regarding potential costs (expenditures of public and private resources to reduce pollutant emissions and exposures) versus benefits (avoidance of specified adverse health impacts in a designated population). Benefits, in theory, should be quantified as the willingness of beneficiaries to pay to avoid the adverse impact. In practice, quantification of such health impacts from exposure to air pollution is often based on direct costs related to medical treatment and indirect costs such as school absenteeism, lost work time, decreased productivity, and, at the extreme, person-years of life lost. Valuations of a given effect may vary internationally, as differences in population age distributions, comorbidity, nutritional status, and other circumstances can affect this process. Ideally, cost–bene-

fit analysis should make explicit the value judgments underlying these assessments, highlighting distinctions among alternative pollution control strategies to achieve specific air quality standards. Willingness of individuals to pay to avoid adverse health effects is also estimated from responses to contingent valuation surveys and from market data concerning choices about employment that carries health risks.

Nevertheless, the committee concurred that the specification of which health effects should be considered adverse must precede the application of cost-benefit analysis for evaluation of air pollution control strategies. That is, once a given outcome is designated as adverse, this information can be used as input to cost-benefit analysis. Estimates of costs associated with a given health outcome. while useful from a public policy perspective, cannot be translated into any clinical or biological framework to distinguish adverse from nonadverse effects. Therefore, the committee concluded that however valuable this economists' tool may be for regulatory decision-making, cost-benefit analysis lay outside the scope of this position paper and, indeed, the expertise of the American Thoracic Society.

Susceptibility

The issue of susceptibility has been recognized throughout the history of our initiatives to regulate outdoor air pollution. Susceptibility, broadly defined, may include extrinsic factors, including the profile of exposures to other pollutants, for example, in the workplace or at home, and intrinsic factors, for example, genotype. The size of the population of individuals susceptible to indoor air pollution is large, potentially including infants and the elderly, persons with chronic heart and lung diseases, and the immunocompromised. Persons with multiple deleterious exposures may also be considered as having heightened susceptibility, particularly if the combined effects of the agents are synergistic. Even with the populations considered as susceptible there is a distribution of the degree of susceptibility. For example, levels of nonspecific airway responsiveness in persons with asthma span several orders of magnitude.

The current explosive growth in knowledge of the genetic basis of lung disease, including responses to environmental agents, will provide increasing insights into the mechanistic basis of susceptibility and provide markers of risk status. We already have evidence of between-person variation in the pulmonary function response to ozone and interstrain variation in the pulmonary effects of environmental exposures, including criteria pollutants, in rodent species. As we develop the capacity to more precisely identify those at risk, we may find it increasingly challenging to assure protection for all individuals against adverse health effects.

The present committee agreed with the principle espoused in the Clean Air Act: that regulations should extend protection to include those with enhanced susceptibility to air pollution, recognizing that some highly susceptible individuals may still respond to low-level exposures. Research now shows that some highly susceptible individuals may respond to common exposures that are often unavoidable. Furthermore, by definition, susceptible individuals cannot have the same margin of safety as the nonsusceptible groups within the population.

Heterogeneity of Perspectives

In society there is an extraordinary range of views on environmental issues and tolerance of risk. Looking more globally to other developed countries and to the developing countries, the range of perspectives is even broader. The committee acknowledges that any defined boundaries for distinguishing adverse health effects may not be embraced by all groups. This heterogeneity and the possibility that some may reject the committee's proposal challenged the committee to recommend in principle that control measures should maximize public health benefits while assuring equity.

DIMENSIONS OF ADVERSE EFFECTS

Biomarkers

Biomarkers are indicators of exposure, effect, or susceptibility that are measured in biologic materials, such as blood or bronchoalveolar lavage fluid. The concept of biomarkers has been formalized since the 1985 statement (17) and since then. a continuously increasing number of candidate indicators of exposure, effect, and susceptibility have been developed and applied in laboratory studies of humans and animals and in both occupational and environmental population studies. The progressive refinement of techniques in the field of cellular and molecular biology, and the burgeoning understanding of the complex chemical intracellular and cell-to-cell signaling pathways collectively termed "cytokines" (18), have rapidly expanded the spectrum of candidate markers of effects. It is now possible to detect very early, or initiating phases of responses at the molecular level, such as the production of mRNA for cytokines. Similarly, the progressive development of genetic assays and understanding of the human genome have provided numerous candidate markers of both effects and susceptibility (19).

Biomarkers relevant to air pollution have been measured in blood, exhaled air, urine, sputum, and in bronchoalveolar lavage fluids and tissue specimens collected by bronchoscopy. Bronchoalveolar lavage fluids, for example, are now frequently analyzed for cell numbers and types, cytokines (e.g., several interleukins and tumor necrosis factor α), enzymes (e.g., lactate dehydrogenasc and β-glucoronidase), fibronectin, protein, arachidonic acid metabolites, and reactive oxygen species. Because many of the epithelial cell types of the nasopharyngeal region are similar to epithelia and responses in the trachea, bronchi, and bronchioles, responses of nasal cells have been examined as potential biomarkers for their ability to predict parallel responses in lung airways, which are more difficult to sample.

Biomarkers have been extensively applied in toxicologic studies of air pollution, both in animals and in clinical studies involving exposures of human volunteers. The biomarkcrs are examined for their ability to provide evidence of "biologically effective" doses, including the earliest phases of homeostatic responses, the occurrence of injury, outcomes that are intermediate between injury and disease, and the presence of established disease processes. Genetic markers of susceptibility have begun to be applied to the respiratory system, and this application will undoubtedly expand rapidly. A frequent goal of biomarker development is the ability to readily measure changes that precede and predict continued or progressive events leading to clinical effects and disease (Figure 2).

To date, although biomarkers have proved informative about homeostatic adjustments to exposure and the mechanisms of injury and disease, lack of validation against previously established measures of effect. such as clinical status or even physiologic impairment, remains an important weakness. We do not know if elevations of biomarkers during short-term experimental exposures signal risk for ongoing injury and clinical effects or simply indicate transient responses that can provide insights into mechanisms of injury. The utility of some older biomarkers is well established, such as the relationships among carboxyhemoglobin. exposure to carbon monoxide,

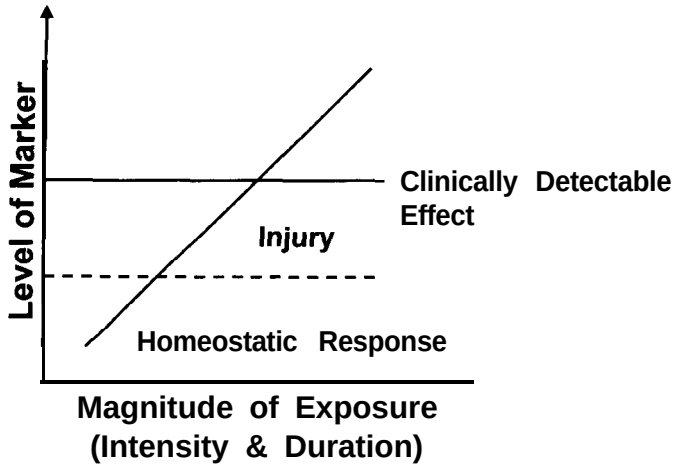

figure 2. Schema for considering biomarkers of response.

impairment of oxygen-carrying capacity, and the risk for angina in the presence of ischemic heart disease. However, the interpretative value for the majority of the many promising new cytokine and genetic biomarkers remains to be established. Not only is it difficult to assess the value of many biomarkers for distinguishing between physiological, homeostatic responses and injury, but it is also difficult to judge the value of changes during short-term exposures for predicting ongoing injury or risk for longer-term clinical effects.

The committee concluded that the continued development of biomarkers is an important need because of their considerable potential not only for detecting the adverse effects of air pollution exposure, but also for aiding the determination of the types and levels of response that should be considered adverse. We often do not know in a parallel, iterative manner, whether the exploration and validation of biomarkers will unquestionably advance our understanding of the mechanisms of homeostatic and injury responses. At this time, however, few of the rapidly growing list of candidate biomarkers have been validated to such an extent that their responses can be used with confidence to define the point at which a response should be equated to an adverse effect warranting preventive measures. Thus, we presently have only a very modest ability to translate evidence from biomarkers directly into a taxonomy of adverse health effects. Consequently, the committee cautions that not all changes in biomarkers related to air pollution should be considered as indicative of injury that represents an adverse effect.

Quality of Life

Health, in its broadest definition, includes not only the absence of disease but the attainment of well-being. Since the preparation of the 198.5 statement, the National Institutes of Health, the Centers of Disease Control, the Food and Drug Administration, and the World Health Organization have broadened their perspective of health to incorporate the concept of health-related quality of life as a valid and important health outcome. Health-related quality of life (HRQL) refers to the individual's perception of well-being, and includes such factors as self-care functioning, mental health, pain, and sense of overall well-being. Decreased health-related quality of life is widely accepted to be an adverse health effect. For this reason, measurable negative effects of air pollution on quality of life, whether for persons with chronic respiratory conditions or the population in general, were consequently considered by this committee to be adverse health effects. Air pollution exposure can adversely affect several domains of quality of life including physical functioning (particularly for persons with respiratory or cardiovascular conditions) and general well-being. Stinging, watery eyes resulting from air pollution not only reflect a chronic physical symptom but may decrease overall quality of life. Outdoor air pollution and odors have been associated with psychiatric symptoms, including anxiety and depression. Increased levels of some air pollutants have been reported to be associated with an increase in psychiatric admissions. The potential effects of air pollution and respiratory symptoms on different domains of quality of life are illustrated in Figure 3.

Measurement of the impact of air pollution on health-related quality of life can be accomplished either by measuring specific domains that may be influenced by air quality (e.g., anxiety, functional status), or by using specific quality of life instruments designed to measure multiple health-related domains (e.g., MOS-SF-36, St. George's Respiratory Questionnaire). The cost-benefits of improved air quality on health-related quality of life could also be measured by the use of quality of life measures that employ utility rating scales. The effects of air pollution of a magnitude considered to be clinically significant with these instruments should be regarded as adverse in interpreting evidence on the health effects of air pollution, regardless of the affected dimension. Additional research is needed to develop an information base for interpreting data from new and more sensitive instruments directed specifically at air pollution.

Physiological impact

The 198.5 statement acknowledged a distinction between reversible and irreversible effects. Healthy persons may sustain transient reductions in pulmonary function associated with air pollution exposure, e.g., reduction of the forced vital capacity (FVC) with exercise at times of higher levels of ozone pollution. However, the committee recommends that a small, transient loss of lung function, by itself, should not automatically be designated as adverse. In drawing the distinction between adverse and nonadverse reversible effects, this committee recommended that reversible loss of lung function in combination with the presence of symptoms should be considered as adverse. This recommendation is consistent with the 1985 statement. The Environmental Protection Agency has also needed to address the interpretation of such data. The Envi-

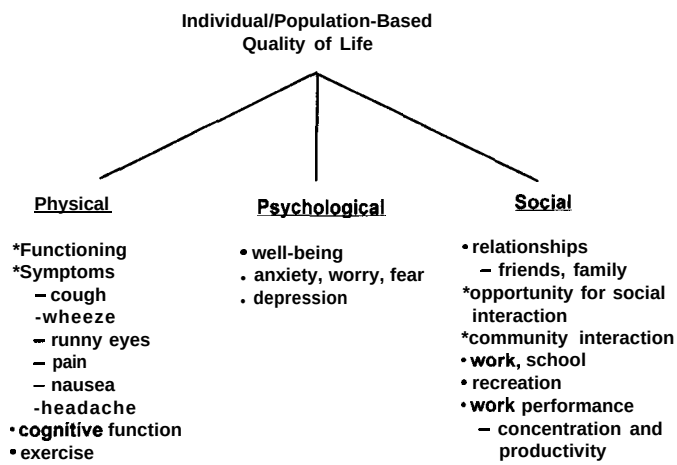

Figure 3. Quality of life domains vulnerable to the adverse health/respiratory effects of air pollution.

ronmental Protection Agency, in its 1989 review of ozone (20), offered a graded classification of lung function changes in persons with asthma. Reduction of the forced expiratory volume in 1 s (FEV_1) was graded as mild, moderate, or severe for reductions of less than 10%, 10–20%, and more than 20%, respectively. This classification has not been validated for acceptability or against other measures.

There is also epidemiologic evidence that air pollution may adversely affect lung growth or accelerate the age-related decline of lung function. Epidemiologic studies are limited in their power to detect such permanent effects and any evidence of association between air pollution exposure and permanent loss of function is indicative of an adverse effect at the population level. Some individuals may sustain clinically relevant, permanent losses of lung function. This committee considered that any detectable level of permanent lung function loss attributable to air pollution exposure should be considered as adverse.

Symptoms

Air pollution exposure can evoke symptoms in persons without underlying chronic heart or lung conditions and also provoke or increase symptom rates in persons with asthma and chronic obstructive lung disease. The Environmental Protection Agency also offered a scale for cough and pain on taking a deep breath in its 1989 ozone review (20). "Infrequent cough" was classified as "None/Normal."

Do all levels of increased symptom occurrence constitute an adverse health effect? The committee judged that air pollution-related symptoms associated with diminished quality of life or with a change in clinical status should be considered as adverse at the individual level. Characterizing the degree of symptomatology associated with diminished quality of life is an appropriate focus for research and a topic that could be investigated using new approaches for assessing quality of life. A change in clinical status can be appropriately set in a medical framework as one requiring medical care or a change in medication. At the population level, any detectable increment in symptom frequency should be considered as constituting an adverse health effect.

Clinical Outcomes

A wide range of clinical outcome measures has been considered in relation to air pollution, including population-level effects, such as increases in numbers of emergency room visits for asthma or hospitalizations for pneumonia, and individual-level effects, such as increased need for bronchodilator therapy. The present committee shared the view of the previous group: detectable effects of air pollution on clinical measures should be considered adverse.

At the population level, the magnitude of the detectable air pollution effect will depend on the extent of the data available for evaluation and methodological aspects of the data, including the degree of error affecting exposure and outcome variables. With large databases, seemingly modest effects may be detectable. However, the committee recommends that no level of effect of air pollution on population-level clinical indicators can be considered acceptable.

Mortality

Following the development of new approaches for the analysis of time-series data, extensive analyses have now been reported on the relationship between daily mortality counts and levels of air pollution on the same or prior days. Several prospective cohort studies have also addressed the effect of longer-term indicators of air pollution exposure on mortality, controlling for relevant individual factors, including age, sex, cigarette smoking, and occupational exposures, among others. Cross-sectional studies-comparing mortality across locations having different levels of air pollution while controlling for a variety of potential confounding factors-have also been conducted. The air pollution-associated mortality findings figured prominently in the recent revision of the U.S. NAAQS for particulate matter.

Associations between air pollution levels and daily mortality counts have been interpreted by some as reflecting the impact of air pollution on a pool of frail individuals with severe underlying heart or lung disease. One explanation for the day-to-day associations attributes them to a brief advancement of the time of death for extremely frail individuals who would have been expected to die soon even in the absence of an air pollution-related insult (21). Work has shown, however, that while this phenomenon of advancement, referred to as mortality displacement, may occur, it cannot provide a full explanation of the associations repeatedly found between daily fluctuations of air pollution and mortality (22, J. Schwartz, "Harvesting and long term exposure effects in the relationship between air pollution and mortality" [1999, unpublished manuscript]). In addition, some mortality time-series studies have found effects across all age strata, not just among the elderly or the very young, suggesting potentially substantial effects on person-years of life lost. Finally, studies of long-term exposures have shown a gradient of mortality risk from cardiopulmonary disease as well as differences in life expectancy across cities with different long-term pollution levels. Thus, although we still have little insight into the extent to which mortality displacement occurs, the evidentiary ensemble from several types of study designs consistently shows that air pollution can shorten the life span to an unacceptable degree.

Risk Assessment

Since the publication of the 1985 statement, quantitative risk assessment has emerged as a key tool for summarizing information on risks to health from environmental agents. Quantitative risk assessment offers a framework for organizing information on risks within its four elements: hazard identification, exposure assessment, dose-response assessment, and risk characterization. The findings of a risk assessment, encompassed in the risk characterization component, may include an overall assessment of impact, a description of the distribution of risk in the population, and an evaluation of risk for susceptible persons within the population. Quantitative risk assessment has been a cornerstone in evaluating risks of environmental carcinogens and we anticipate increasing application to non-carcinogenic health effects of environmental agents, including air pollution.

In interpreting the findings of risk assessments, guidance can be found in precedents offered by key interpretations of regulatory requirements, including the Supreme Court's decision on the benzene standard proposed by the Occupational Safety and Health Administration, and in pollutant-specific regulatory actions. Risks may be couched as the numbers of attributable events in the population and also as the level of risk incurred by individual members of the population.

The committee recognized the rising use and potential utility of quantitative risk assessment in characterizing the health effects of air pollution. However, the committee noted that the results of quantitative risk assessment can often be sensitive to assumptions regarding the distribution and magnitude of exposure, the choice of an appropriate dose-response relationship, and other input decisions. Judgments on acceptability of risk are societal and made through complex regulatory

processes involving extensive public input. The committee did not consider that its mandate extended to offering specific guidance on acceptable risk levels for populations or individuals, nor is risk assessment an appropriate basis for determining what constitutes an adverse effect.

CONCLUSIONS

Since the preparation of the 1985 statement of the American Thoracic Society, there have been tremendous advances in the scientific methods used to investigate the health effects of air pollution. These advances range from the molecular to the behavioral levels of inquiry. As a result, this statement covers topics that are new since the 1985 statement. Yet, this committee, like the 1985 group, was confronted by a lack of formal research or investigation on the very topic of this statement: the boundary between adverse and nonadverse effects. Consequently, the committee needed to exercise its collective judgment on matters that should be based in some broader, societal decision-making **process. Its recommendations are summarized below.**

- ***Biomarkers.*** Few of the rapidly growing list of candidate biomarkers have been validated sufficiently that their responses can be used with confidence to define the point at which a response should be equated to an adverse effect warranting preventive measures. The committee cautions that not all changes in biomarkers related to air pollution should be considered as indicative of injury that represents an adverse effect.
- ***Quality of life.*** Decreased health-related quality of life is widely accepted as an adverse health effect. For this reason, measurable negative effects of air pollution on quality of life, whether for persons with chronic respiratory conditions or for the population in general, were consequently considered to be adverse by this committee.
- ***Physiological impact.*** The committee recommends that a small, transient loss of lung function, by itself. should not automatically be designated as adverse. In drawing the distinction between adverse and nonadverse reversible effects, this committee recommended that reversible loss of lung function in combination with the presence of symptoms should be considered adverse. This committee considered that any detectable level of permanent lung function loss attributable to air pollution exposure should be considered adverse.
- ***Symptoms.*** The committee judged that air pollution-related symptoms associated with diminished quality of life or with a change in clinical status should be considered adverse at the individual level.
- ***Clinical outcomes.*** The present committee shared the view of the previous group: detectable effects of air pollution on clinical measures should be considered as adverse.
- ***Mortality.*** This committee agreed with the conclusion articulated by the 1985 group that any effect on mortality should be judged as adverse. In addition, we are now faced with the challenge of interpreting the findings of time-series studies of effects on short time frames. In interpreting this type of evidence, consideration needs to be given to the extent of life-shortening underlying the association.
- ***Population health versus individual risk.*** Assuming that the relationship between the risk factor and the disease is causal, the committee considered that such a shift in the risk factor distribution, and hence the risk profile of the exposed population, should be considered adverse, even in the absence of the immediate occurrence of frank illness.

This statement was prepared by an ad-hoc committee of the Assembly on Environmental and Occupational Health. Members of the committee are:

San Joaquin Valley
Air Pollution Control District

Zero Equivalency Policy
for
Greenhouse Gases

Approved By:	Signed David Warner Director of Permit Services	Date:	**March 24, 2010** **Revised January 24, 2012**

Purpose:

The purpose of this policy is to detail how small increases in greenhouse gas (GHG) emissions for permitted sources are handled during the application review process. This policy establishes a level below which project specific increases in greenhouse gas emissions are considered equivalent to zero for District permitting purposes. Establishment of this policy maximizes reductions in GHG emissions and improves efficiencies in the permitting process by identifying projects which have no potential to achieve substantial GHG emission reductions.

I. Applicability

This guidance is to be followed when processing Authority to Construct (ATC) applications for projects with potential increases in greenhouse gas emission and the District serves as Lead Agency for CEQA purposes.

II. Background

The California Environmental Quality Act (CEQA) and CEQA Guidelines require agencies to adopt procedures and guidelines for implementing CEQA. Consistent with those requirements, the District adopted its *Environmental Review Guidelines* (ERG), which provides District staff with guidance for streamlining the District's permitting process while assuring that environmental impacts related to District actions are thoroughly and consistently addressed. The ERG establishes specific District permitting actions which are ministerial approvals and not subject to CEQA; identifies specific permitting actions that have been determined to qualify for exemption under the "General Rule" that CEQA does not apply where it can be seen with certainty that there is no possibility that the activity in question may have a significant effect on the environment; and identifies certain classes of projects that are most frequently categorically exempt from the provisions of CEQA.

On December 17.2009, the Valley Air District's Governing Board adopted the adopted the *District Policy – Addressing GHG Emission Impacts for Stationary Source Projects Under CEQA When Serving as the Lead Agency*. The policy adopted December 17, 2009, applies to all District permitting projects that have an increase in GHG emissions, regardless of the magnitude of the increase. The adopted policy establishes the use of performance based standards (Best Performance Standards) as a means of determining the cumulative significance of project specific greenhouse gas emissions on global climate change. The policy requires District staff to establish Best Performance Standards (BPS) for each class and category of stationary source emissions and to evaluate the cumulative significance of project specific greenhouse gas emissions on global climate change. However, the policy also establishes that projects exempt from CEQA are not subject to further environmental review for greenhouse gas impacts.

It is conceivable that at least some projects which qualify for exemption per the District's adopted Environmental Review Guidelines will have some increase in greenhouse gas emissions. To ensure that these projects receive further environmental consideration and to ensure consistency in processing such ATC applications, this policy establishes a level of greenhouse emissions below which project specific increases in greenhouse gas emissions would be considered equivalent to zero for CEQA purposes. Projects with increases in greenhouse emissions that are non-zero would require further environmental review for greenhouse gas impacts.

To establish a zero equivalency level, the District considered greenhouse gas emissions associated with stationary sources that are so small that they are not subject to District prohibitory rules or District permit requirements. As indicated in the attached analysis, District staff evaluated greenhouse emissions from two permit-exempt emission sources; 5-mmbtu/hr gas-fired boilers and 50-horsepower diesel engines. The permit-exempt boiler has the potential to emit of more than 2,300 metric tons-CO_2e/year, while the permit-exempt internal combustion engine emitted slightly more than 230 metric tons-CO_2e/year

Therefore, choosing the more conservatively low of the two sources, the zero equivalency level is established at 230 metric tons-CO_2e/year.

III. Air District CEQA Implementation:

Greenhouse gas emissions of 230 metric tons-CO_2e/year or less are considered to be zero for District permitting purposes. When an Authority to Construct (ATC) application is received, and the District is the Lead Agency, District staff will follow established District policy and Environmental Review Guidelines to determine if the project is exempt from further environmental analysis. If the project would be exempt from further environmental review and if potential increases in stationary source greenhouse gas emissions are zero, the project will be determined to be exempt from further environmental review and the ATC will be processed consistent with existing District policies and procedures. Projects not meeting the above conditions will receive further environmental review, consistent with established District CEQA guidance.

Attachment A – GHG Emission Rate Evaluation for Two Permit-Exempt Equipment Categories

The District has evaluated potential greenhouse gas emissions from 1) internal combustion engines rated at 50 brake horsepower and 2) natural gas-fired boilers with a rated firing capacity of 5 MMBtu/hour.

50 bhp Internal Combustion Engine

Basis and Assumptions

- The engine is a compression-ignited unit fueled with diesel in agricultural equipment service.
- The engine operates at full rated power.
- Specific fuel consumption is 220 g/kWh (typical for engine type).
- Density of diesel fuel is 7.0 lb/gallon.
- Higher Heating Value (HHV) of diesel is 138,700 Btu/gallon.
- Engine operates 8,760 hours per year.
- Emission factors and global warming potentials (GWP) for diesel fuel are taken from the California Climate Change Action Registry (CCAR), Version 3.1, January, 2009 (Appendix C, Tables C.1, C.3 and C.6) :

  CO2 10.15 kg/gallon (22.3 lb/gallon)
  CH4 1.44 g/gallon (0.006 lb/gal)
  N2O 0.26 g/gallon (0.001 lb/gal)

  GWP for CH4 = 21 lb-CO_2e per lb-CH4
  GWP for N2O = 310 lb-CO_2e per lb-N2O

Calculations

Diesel fuel consumption rate at full rated horsepower:

$$\frac{50}{\text{bhp}} \times \frac{0.7456\ \text{kW}}{\text{hp}} \times \frac{220\ \text{g}}{\text{kWh}} \times \frac{1\ \text{lb}}{453.6\ \text{g}} \times \frac{\text{gal}}{7\ \text{lb}} = 2.58\ \text{gal/hour}$$

Hourly Emissions

CO2 Emissions = 2.58 gal/hr x 22.3 lb/gal = 57.5 lb-CO_2e/hour
CH4 Emissions = 2.58 gal/hr x 0.006 lb/gal x 21 lb-CO_2e per lb-CH4 = 0.3 lb-CO_2e/hour
N2O Emissions = 2.58 gal/hr x 0.001 lb/gal x 310 lb-CO_2e per lb-N2O = 0.8 lb-CO_2e/hour

Total = 57.5 + 0.3 + 0.8 = 58.6 lb-CO_2e/hour

Annual Emissions

58.6 lb-CO_2e/hour x 8,760 hr/year ÷ 2,000 lb/ton = 257 short tons-CO_2e/year

Metric Conversion

257 short tons-CO_2e/year x 0.9072 metric tons/short ton = **233 metric tons**

5 MMBtu/hour Boiler

Basis and Assumptions

- The boiler is fired with natural gas at a rate of 5 MMBtu/hour (HHV)
- The boiler operates 8,760 hours per year and is in commercial/institutional service
- Emission factors and global warming potentials (GWP) are taken from the California Climate Change Action Registry (CCAR), Version 3.1, January, 2009 (Appendix C, Tables C.7 and C.8):

  CO2 53.06 kg/MMBtu (HHV) natural gas (116.7 lb/MMBtu)
  CH4 0.005 kg/MMBtu (HHV) natural gas (0.011 lb/MMBtu)
  N2O 0.0001 kg/MMBtu (HHV) natural gas (0.00022 lb/MMBtu)

  GWP for CH4 = 21 lb-CO_2e per lb-CH4
  GWP for N2O = 310 lb-CO_2e per lb-N2O

Calculations

Hourly Emissions

CO2 Emissions = 5.0 MMBtu/hr x 116.7 lb/MMBtu = 583.5 lb-CO_2e/hour
CH4 Emissions = 5.0 MMBtu/hr x 0.011 lb/MMBtu x 21 lb-CO_2e per lb-CH4 = 1.2 lb-CO_2e/hour
N2O Emissions = 5.0 MMBtu/hr x 0.00022 lb/MMBtu x 310 lb-CO_2e per lb-N2O = 0.3 lb-CO_2e/hour

Total = 583.5 + 1.2 + 0.3 = 585.0 lb-CO_2e/hour

Annual Emissions

585.0 lb-CO_2e/hour x 8,760 hr/year ÷ 2,000 lb/ton = 2,562 tons-CO_2e/year

Metric Conversion

2,562 short tons-CO_2e/year x 0.9072 metric tons/short ton = **2,324 metric tons**

San Joaquin Valley
Air Pollution Control District

APR - 2025

CEQA Determinations of Significance for Projects Subject to ARB's GHG Cap-and-Trade Regulation

Approved By:	Arnaud Marjollet, Director of Permit Services	Date:	June 25, 2014

I. Purpose:

The District has a statutory obligation to fully comply with the provisions of CEQA before issuing an Authority to Construct (ATC). The purpose of this policy is to provide guidance to District staff on how to determine significance of greenhouse gas (GHG) emissions from projects subject to the California Air Resources Board Cap-and-Trade regulation or occurring at entities subject to the California Air Resources Board Cap-and-Trade regulation.

II. Applicability:

This policy is to be followed when processing ATC applications and when providing technical guidance to lead agencies and the public regarding significance of project specific GHG emissions.

III. Background:

Assembly Bill 32 (AB32)

Assembly Bill 32 (California Global Warming Solutions Act of 2006) is a key piece of California's effort to reduce its GHG emissions. AB32 requires the California Air Resources Board (ARB) to establish regulations designed to reduce California's GHG emissions to 1990 levels by 2020. On December 11, 2008, ARB adopted its AB32 Scoping Plan, setting forth a framework for future regulatory action on how California will achieve that goal through sector-by-sector regulation.

Cap-and-Trade

The AB 32 Scoping Plan identifies a Cap-and-Trade program as one of the strategies California will employ to reduce the greenhouse gas (GHG) emissions that cause climate change. The Cap-and-Trade program is implemented by the California Air Resources Board and caps GHG emissions from the industrial, utility, and transportation fuels sectors – which account for roughly 85% of the state's GHG emissions.

The program works by establishing a hard cap on about 85 percent of total statewide greenhouse gas emissions. The cap starts at expected business-as-usual emissions levels in 2012, and declines 2-3% per year through 2020. Fewer and fewer GHG emissions allowances are available each year, requiring covered sources to reduce their emissions or pay increasingly higher prices for those allowances. The cap level is set in 2020 to ensure California complies with AB 32's emission reduction target of returning to 1990 GHG emission levels.

The scope of GHG emission sources subject to Cap-and-Trade in the first compliance period (2013-2014), includes:

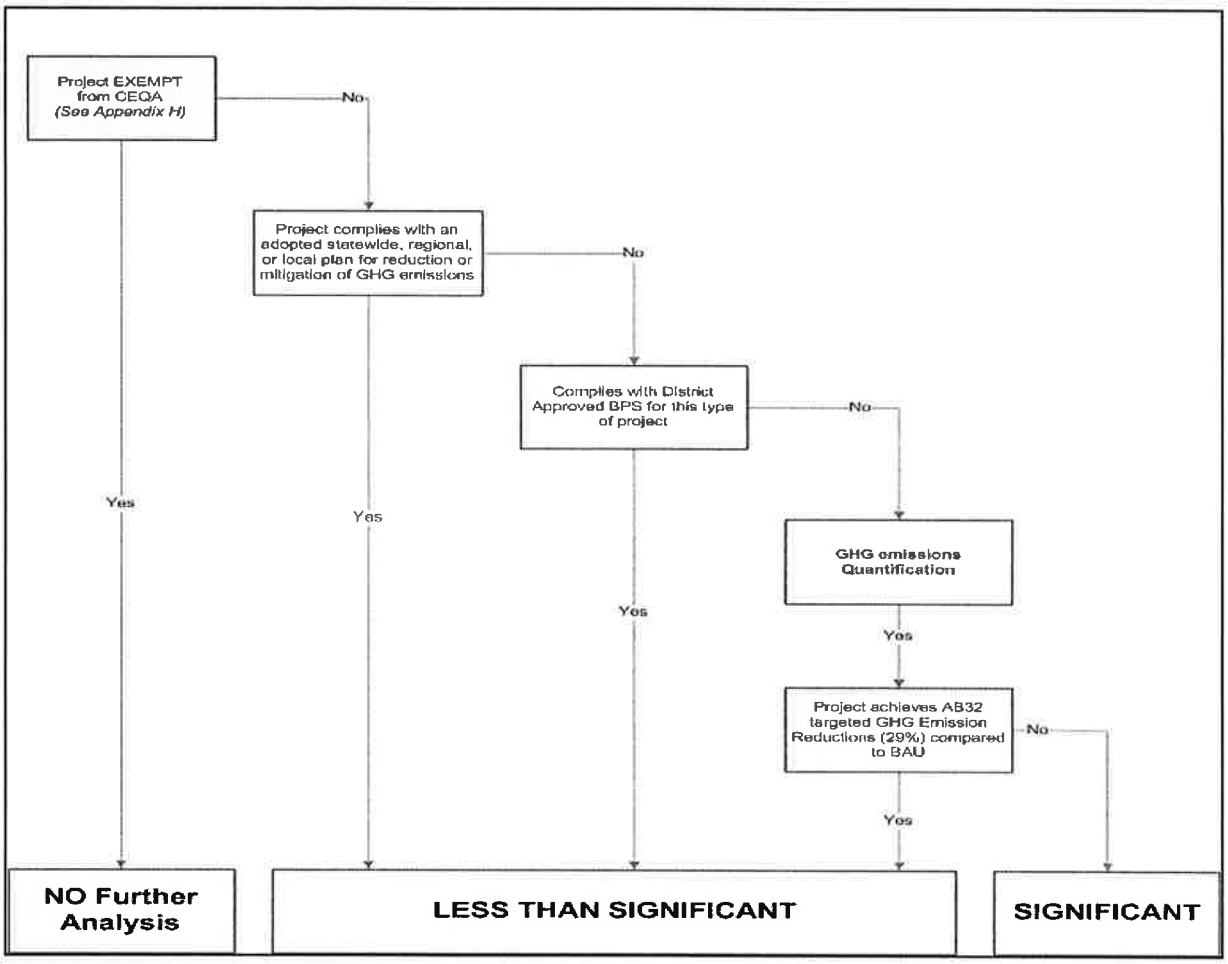
- All electricity generated and imported into California. The first deliverer of electricity into the state is the capped entity (the one that will have to purchase and surrender allowances).
- Large industrial facilities emitting more than 25,000 metric tons of GHG pollution/year. Examples include oil refineries and cement manufacturers.

The scope of GHG emission sources subject to Cap-and-Trade during the second compliance period (2015-2017), expands to include distributors of transportation fuels (including gasoline and diesel), natural gas, and other fuels. The regulated entity will be the fuel provider that distributes the fuel upstream (not the gas station). In total, the Cap-and-Trade program is expected to include roughly 350 large businesses, representing about 600 facilities. Individuals and small businesses will not be regulated.

Under the program, companies do not have individual or facility-specific reduction requirements. Rather, all companies covered by the regulation are required to turn in allowances in an amount equal to their total greenhouse gas emissions during each phase of the program. The program gives companies the flexibility to either trade allowances with others or take steps to cost-effectively reduce emissions at their own facilities. Companies that emit more will have to turn in more allowances. Companies that can cut their emissions will have to turn in fewer allowances. Furthermore, as the cap declines, total GHG emissions are reduced.

On October 20, 2011, ARB's Board adopted the final Cap-and-Trade regulation and Resolution 11-32. As part of finalizing the regulation, the Board considered the related environmental analysis and, consistent with CEQA requirements, approved ARB's functionally equivalent document (FED).

CEQA Requirements



In December, 2009, the California Natural Resources Agency (NRA) amended the CEQA Guidelines to include Global Climate Change (GCC), which is now generally accepted by the scientific community to be occurring and caused by Greenhouse Gases (GHG). The amendments address analysis and mitigation of the potential effects of GHG emissions in CEQA documents. In their *Final Statement of Reasons for Regulatory Action,* NRA recognizes that the analysis of GHG emissions in a CEQA document presents unique challenges to lead agencies. NRA amended section 15064(h)(3) of the CEQA guidelines to add compliance with plans or regulations for the reduction of greenhouse gas emissions to the list of plans and programs that may be considered in a cumulative impacts analysis. In their *Final Statement of Reasons for Regulatory Action*, NRA discusses that AB32 requires ARB to adopt regulations that achieve the maximum technologically feasible and cost effective GHG reductions to reach the adopted state-wide emissions limit. NRA goes on to state that a lead agency may consider whether ARB's GHG reduction regulations satisfy the criteria in existing subdivision (h)(3).

District CEQA Policy

CEQA requires each public agency to adopt objectives, criteria, and specific procedures consistent with CEQA Statutes and the CEQA Guidelines for administering its responsibilities under CEQA, including the orderly evaluation of projects and preparation of environmental documents. On December 17, 2009, the District's Governing Board adopted the District's policy, APR 2005, *Addressing GHG Emission Impacts for Stationary Source Projects Under CEQA When Serving as the Lead Agency,* for addressing GHG emission impacts when the District is Lead Agency under CEQA and approved the District's guidance document for use by other agencies when addressing GHG impacts as lead agencies under CEQA. Under this policy, the District's determination of significance of project-specific GHG emissions is founded on the principal that projects with GHG emission reductions consistent with AB 32 emission reduction targets are considered to have a less than significant impact on global climate change.

As illustrated in Figure 1, the District's board-adopted policy for determining significance of project-specific GHG emissions employs a tiered approach. Of specific relevance to Cap-and-Trade is the provision that: "Projects complying with an approved GHG emission reduction plan or GHG mitigation program, which avoids or substantially reduces GHG emissions within the geographic area in which the project is located, would be determined to have a less than significant individual and cumulative impact for GHG emissions. Such plans or programs must be specified in law or approved by the lead agency with jurisdiction over the affected resource and supported by a CEQA compliant environmental review document adopted by the lead agency. Projects complying with an approved GHG emission reduction plan or GHG mitigation program would not be required to implement best performance standards (BPS)". Projects that do not comply with such a plan or program must implement best performance standards or undergo a project-specific analysis demonstrating that GHG emissions would be reduced by at least 29%, as compared to business-as-usual.

Figure 1: Determination of Significance for Stationary Source Projects

IV. Determination of Significance of GHG Emissions for Projects Subject to ARB's GHG Cap-and-Trade Regulation:

Significant GHG Emission increases under CEQA

The District has determined that GHG emissions increases that are covered under ARB's Cap-and-Trade regulation cannot constitute significant increases under CEQA, for two separate and distinct reasons:

1. *Cap-and-Trade Regulation is an Approved GHG Emissions Reduction Plan:*

   As discussed above, ARB's Cap-and-Trade regulation is an adopted statewide plan for reducing or mitigating GHG emissions from targeted industries and is supported by an environmental review process that has been successfully defended in court as equivalent to, and compliant with, CEQA requirements.

   Consistent with CCR §15064(h)(3), the District finds that compliance with ARB's Cap-and-Trade regulation would avoid or substantially lessen the impact of

project-specific GHG emissions on global climate change. The District also finds that the ARB's Cap-and-Trade regulation was supported by an appropriate CEQA-equivalent analysis. The District therefore concludes that GHG emissions increases subject to ARB's Cap-and-Trade regulation would have a less than significant individual and cumulative impact on global climate change., and

2. *Cap-and-Trade Regulation Requires Mitigation of GHG Increases:*

   GHG emissions addressed by the Cap-and-Trade regulation are subject to an industry-wide cap on overall GHG emissions. As such, any growth in emissions must be accounted for under that cap, such that a corresponding and equivalent reduction in emissions must occur to allow any increase. Further, the cap decreases over time, resulting in an overall decrease in GHG emissions. Therefore, it is reasonable to conclude that implementation of the Cap-and-Trade program will and must fully mitigate project-specific GHG emissions for emissions that are covered by the Cap-and-Trade regulation.

Regardless of and independent to the significance determination made above, the District finds that, through compliance with the Cap-and-Trade regulation, project-specific GHG emissions that are covered by the regulation will be fully mitigated. The District therefore concludes that GHG emissions increases subject to ARB's Cap-and-Trade regulation would have a less than significant individual and cumulative impact on global climate change.

Entities Covered by this Policy

Industries covered by Cap-and-Trade are identified in the regulation under section 95811, *Covered Entities:*

1. *Group 1: Large industrial facilities*

   These types of facilities are subject to compliance obligations starting in 2013, and the specific companies covered are listed at http://www.arb.ca.gov/cc/capandtrade/capandtrade.htm, Section 95811 (a), under the "Publically Available Market Information" section (list maintained by the California Air Resources Board,).

2. *Group 2: Electricity generation facilities located in California, or electricity importers*

   These types of facilities are subject to Cap and Trade (section 95811, b), with compliance obligations starting in 2013 (section 95851, a).

3. *Group 3: Suppliers of Natural Gas, Suppliers of Reformulated Gasoline Blendstock for Oxygenate Blending and Distillate Fuel Oil, Suppliers of Liquefied Petroleum Gas, and Suppliers of Blended Fuels*

   These entities are subject to compliance obligations starting in 2015, which obligations must cover all fuels (except jet fuels) identified in section 95811 (c) through (f) of the Cap-and-Trade regulation delivered to end users in California, less the fuel delivered to covered entities (group 1 above).

Under Cap-and-Trade regulation, the program expands to also include fuel distributors. As a result, combustion of fossil fuels including transportation fuels used in California (on and off road including locomotives), not directly covered at large sources, are subject to Cap-and-Trade requirements, with compliance obligations starting in 2015.

Fuel Supplier/Distributor Applicability Threshold

The threshold for a fuel supplier/distributor (Group 3) to be subject to the Cap-and-Trade regulation is 25,000 MT CO2e per year from the emissions of GHG that would result from the combustion or oxidation of the quantities of the specific fuels imported and/or delivered to California by the individual fuel supplier. Consequently, entities supplying fuels that would result in less than 25,000 MT CO2 annual GHG emissions are not subject to the Cap-and-Trade regulation.

Based on ARB's Reporting and Verification Summary, in the year 2012, there were 219 fuel suppliers in California not subject to the Cap-and-Trade regulation. Based on this data, and using the applicability threshold, the District has conservatively estimated that the GHG emissions resulting from the combustion of all fuels supplied by those fuel suppliers not subject to the Cap-and-Trade regulation would represent less than 1.0 % of the State's total Annual GHG emissions. As did the ARB when excluding such sources from the Cap-and-Trade regulation, the District considers GHG emissions resulting from the combustion of all fuels supplied by those fuel suppliers not subject to the Cap-and-Trade regulation to be insignificant. Therefore, it is reasonable to apply this policy to GHG emissions resulting from the combustion of all fuels in the State of California.

GHG Baseline Emissions and GHG Emission Increases

The GHG baseline emission levels of covered entities identified in Cap-and-Trade were established with the original Cap-and-Trade regulation. In addition, under Cap-and-Trade requirements, in order to maintain their GHG emissions below the established cap, facilities identified under "covered entities" are subject to mitigation requirements. Therefore, for the intent of this policy, under Cap-and-Trade requirements, mitigation is required for all GHG emission increases from "covered facilities".

V. Conclusion:

In conclusion, all GHG emission increases resulting from the combustion of any fuel produced, imported and/or delivered in California are mitigated under Cap-and-Trade, either directly by facilities identified under groups 1 or 2 (*section 95811(a) and (b)*), or by fuel suppliers identified under the group 3 (*section 95811(c) through (f)*). Therefore, GHG emission increases caused by fuel use (other than jet fuels) are determined to have a less than significant impact on global climate change under CEQA.

HP estimated based on CalEEMod App D for equipment that does not h

Load Factor Based on CalEEMod App D Table 3.3

For Baseline period of 1997 - 2006, CalEEMod Default equipment is con

For Project period of 2021 - 2035, CalEEMod Defualt equipment is cons

* Assumed to operate on fixed operational hours. Other equipment ope

Average Emissions (Pre-mitigation)

Aggregates Fugitive Mining, Storage, and Sitewide Drop Emissions

Drops from stationary equipment (i.e., conveyors) are included in the plant emissions calculations.

Drop, Mining, and Storage Pile Emissions Factors

Material Drop Emission Factor from AP42 13.2.4:	
PM10 E.F. (lb/ton) = $k(0.0032)(U/5)^{1.3}/(M/2)^{1.4}$	
k = particle size multiplier =	0.35
U = mean wind speed[1] =	4.9
M = material moisture content =	3
PM10 EF (lb/ton) =	0.00062
PM2.5 EF[2] (lb/ton) =	0.00018

Bulldozing Emission Factor, CalEEMod User Manual, Appendix A:		
EF PM10 (lb/hr) = 1.0 * s^1.5 / 7.9 * 0.75 =	0.67	
EF PM2.5 (lb/hr) = 5.7 * s^1.2 / 7.9 * 0.105 =	0.09	
s (silt, %) =	6.9	
Watering C.E. =	61%	water every 3 hours if material is not already wet
days of rain =	51	

Quarry Operation Fugitive Emissions:	
lbs PM10 / Ton Quarried[3] =	0.021
lbs PM2.5/lbs PM10 =	0.292

Storage Pile Emissions Controlled Factor from SSP1610 - Aggregate Processing:

lb PM10/acre/day 1.054

	Area (acres)	lbs PM10/hr	lbs PM10/day	lbs PM10/yr
Baseline Storage	2	0.1	2.1	769.4
Project Storage	2	0.1	2.1	769.4

Notes:

[1] Mean wind speed based on data for Tulare in Table 1 of CalEEMod User Manual Appendix D which states 2.2 m/s (equvalent to 4.921 mph).

[2] PM2.5 emission factor assumed to be 29.2% of PM10 for material drops based on SCAQMD's *Updated CEIDARS Table with PM2.5 Fractions for mineral products - loading*

[3] Emission Factor from San Diego Air Pollution Control District, *Quarry Operations, General* (https://bit.ly/2XXNWUI)

Drop and Mining Emissions - Baseline

Particle size multiplier based on AP-42 Table 13.2.1-1
Silt Loading based on ADT of 500 - 5000 from AP-42 Table 13.1-2
Control efficiency for unpaved roads in baseline is 80% for watering.

Future Unpaved Road Emission Factors

Unpaved Road emissions factor from AP42 Section 13.2.2

EF (lb/VMT)= 4.9 * (S/12)$^{0.7}$ * (W/3)$^{0.45}$

	Mining Haul Trucks		On-road Trucks	
	PM10	PM2.5	PM10	PM2.5
S = silt content (%) =	4.8		4.8	
W_l = loaded truck wt (tons) =	90		40	
W_u = unloaded truck wt (tons) =	40		15	
W = avg truck weight	65		27.5	
EF (lb/VMT) =	10.30	2.18	6.99	1.48
Future C.E. =	80%	80%	80%	80%
Future EF (lb/VMT) =	**2.06**	**0.44**	**1.40**	**0.30**

Silt content based on mean Sand and Gravel Processing from AP-42 Table 13.2.2-1.
PM2.5 emissions are 21.2% of PM10 for unpaved roads (SCAQMD *Updated CEIDARS Table).*

Future Paved Road Emission Factors

Paved Road emissions factor from AP42 Section 13.2.1

EF (lb/VMT)= k * (sL)$^{0.91}$ * (W)$^{1.02}$

	Mining Haul Trucks		On-road Trucks	
	PM10	PM2.5	PM10	PM2.5
k= particle size multiplier (lb/vmt) =	0.0022	0.00054	0.0022	0.00054
sL = road surface silt loading (g/m^2) =	0.2	0.2	0.2	0.2
W_l = loaded truck wt (tons) =	90	120	40	40
W_u = unloaded truck wt (tons) =	40	50	15	15
W = avge truck weight	65.00	85.00	27.50	27.50
EF (lb/VMT) =	0.04	0.01	0.01	0.00
Future C.E. =	80%	80%	80%	80%
Future EF (lb/VMT) =	**0.0072**	**0.0023**	**0.0030**	**0.0007**

Particle size multiplier based on AP-42 Table 13.2.1-1
Silt Loading based on ADT of 500 - 5000 from AP-42 Table 13.1-2

Average Emissions (Pre-mitigation)

Off-Road Emissions Emissions Calculations - Cycle Time Analyses

Assumptions

Parameters	Truck Loading
Loader Model	980H Loader
Travel Distance (avg) (meters)	15
Bucket Payload[1] (yd^3)	7.00
Bucket Payload in Tons	10.5
Material Type[2]	Uniform Agg > 1"
Bucket Fill Factor[2]	85%
Job Efficiency[3] (work 50 min/hr)	83%
Grade Resistance[4]	0%
Rolling Resistance[4]	3%
Total Resistance[4]	3%

Cycle Time (mins)

Hydraulic Cycle Time [5]	Truck Loading	
Average Cycle Time [6]		0.65
Material Handler?	Yes	-0.05
Materials:	3/4" to 6"	0.00
Pile:	Conveyor piled >10'	0.00
Truck Ownership:	Common	-0.04
Operation Cycle:	Constant	-0.04
Target Type:	N/A	0.00
Total Hydraulic Cycle Time		**0.52**

Total Cycle Time (mins)	Truck Loading
Hydraulic Cycle Time (min/cycle)	0.52
Travel with load[7] (min/cycle)	0.08
Travel empty[7] (min/cycle)	0.07
Total Cycle Time (min/cycle)	**0.67**

Rate Calculations

Production Calculations	Truck Loading
Cycles per Hour	74.6
Production Rate (tph)	666

[1] Bucket payload ranges based on activity type and equipment size. In this case, heaped bucket capacity for the 980H is equal to the bucket capacity of a 988 that is equipped for digging. Thus, all three loaders (980, 982, 988) have similar e

[2] Material type and bucket fill factor from Caterpillar Performance Handbook Edition 41, January 2011

[3] Job efficiency accounts for operator skill, minor repairs and adjustments, personnel delays, and delays caused by job l CPH suggested 50 minutes (83%) (CPH page 12-80)

[4] Resisitance from CPH pg 22-5 and 22-6 and "Typical Rolling Resistance Factors" table on page 27-1

[5] Guidelines for "Selecting a Machine" on page 12-79 and 12-80 of CPH were used to determine the hydraulic cycle time

[6] Average cycle time for this type of equipment is tabulated on page 12-80 of CPH.

[7] Figures on pages 12-149 through 12-156 in the CPH were used to estimate the travel times for theloaders.

Excavator Cycle Time Analysis

Assumptions

Excavator Bucket Size =	4.3	yd^3
Material Type =	Sand and Gravel	
Sand and Gravel density =	1.5	$tons/yd^3$

Cycle Time

From the Caterpillar Performance Handbook, Edition 41 (2011)
page 4-183 "Cycle Time Estimating Chart"
Based on the low end of the typical range due to the loose configuration of material to be moved.

Cycle Time =	0.28	minutes

Production Estimate

Production Rate =	691	yd^3/hour
Production Rate =	1037	tons/hour
Job Efficiency* =	67%	
Production Rate =	691	tons/hour

* Job efficiency is estimated to be 40 minutes per hour to account for operator skill, minor delays, and periodic excavator transportation

Average Emissions (Mitigated)

Aggregates Fugitive Mining, Storage, and Sitewide Drop Emissions

Drops from stationary equipment (i.e., conveyors) are included in the plant emissions calculations.

Drop, Mining, and Storage Pile Emissions Factors

Material Drop Emission Factor from AP42 13.2.4:

PM10 E.F. (lb/ton) = $k(0.0032)(U/5)^{1.3}/(M/2)^{1.4}$

k = particle size multiplier =	0.35
U = mean wind speed[1] =	4.9
M = material moisture content =	3
PM10 EF (lb/ton) =	0.00062
PM2.5 EF[2] (lb/ton) =	0.00018

Bulldozing Emission Factor, CalEEMod User Manual, Appendix A:

EF PM10 (lb/hr) = 1.0 * s^1.5 / 7.9 * 0.75 =	0.67	
EF PM2.5 (lb/hr) = 5.7 * s^1.2 / 7.9 * 0.105 =	0.09	
s (silt, %) =	6.9	
Watering C.E. =	61%	water every 3 hours if material is not already wet
days of rain =	51	

Quarry Operation Fugitive Emissions:

lbs PM10 / Ton Quarried[3] =	0.021
lbs PM2.5/lbs PM10 =	0.292

Storage Pile Emissions Controlled Factor from SSP1610 - Aggregate Processing:

lb PM10/acre/day 1.054

	Area (acres)	lbs PM10/hr	lbs PM10/day	lbs PM10/yr
Baseline Storage	2	0.1	2.1	769.4
Project Storage	2	0.1	2.1	769.4

Notes:

[1] Mean wind speed based on data for Tulare in Table 1 of CalEEMod User Manual Appendix D which states 2.2 m/s (equvalent to 4.921 mph).

[2] PM2.5 emission factor assumed to be 29.2% of PM10 for material drops based on SCAQMD's *Updated CEIDARS Table with PM2.5 Fractions for mineral products - loading*

[3] Emission Factor from San Diego Air Pollution Control District, *Quarry Operations, General* (https://bit.ly/2XXNWUI)

Drop and Mining Emissions - Baseline

Max Year Emissions (Pre-mitigation)

Aggregates Fugitive Mining, Storage, and Sitewide Drop Emissions

Drops from stationary equipment (i.e., conveyors) are included in the plant emissions calculations.

Drop, Mining, and Storage Pile Emissions Factors

Material Drop Emission Factor from AP42 13.2.4:

PM10 E.F. (lb/ton) = $k(0.0032)(U/5)^{1.3}/(M/2)^{1.4}$

k = particle size multiplier =	0.35
U = mean wind speed[1] =	4.9
M = material moisture content =	3
PM10 EF (lb/ton) =	0.00062
PM2.5 EF[2] (lb/ton) =	0.00018

Bulldozing Emission Factor, CalEEMod User Manual, Appendix A:

EF PM10 (lb/hr) = 1.0 * s^1.5 / 7.9 * 0.75 =	0.67	
EF PM2.5 (lb/hr) = 5.7 * s^1.2 / 7.9 * 0.105 =	0.09	
s (silt, %) =	6.9	
Watering C.E. =	61%	water every 3 hours if material is not already wet
days of rain =	51	

Quarry Operation Fugitive Emissions:

lbs PM10 / Ton Quarried[3] =	0.021
lbs PM2.5/lbs PM10 =	0.292

Storage Pile Emissions Controlled Factor from SSP1610 - Aggregate Processing:

lb PM10/acre/day 1.054

	Area (acres)	lbs PM10/hr	lbs PM10/day	lbs PM10/yr
Baseline Storage	2	0.1	2.1	769.4
Project Storage	2	0.1	2.1	769.4

Notes:

[1] Mean wind speed based on data for Tulare in Table 1 of CalEEMod User Manual Appendix D which states 2.2 m/s (equvalent to 4.921 mph).

[2] PM2.5 emission factor assumed to be 29.2% of PM10 for material drops based on SCAQMD's *Updated CEIDARS Table with PM2.5 Fractions for mineral products - loading*

[3] Emission Factor from San Diego Air Pollution Control District, *Quarry Operations, General* (https://bit.ly/2XXNWUl)

Rate Calculations

Production Calculations	Truck Loading
Cycles per Hour	74.6
Production Rate (tph)	666

[1] Bucket payload ranges based on activity type and equipment size. In this case, heaped bucket capacity for the 980H is equal to the bucket capacity of a 988 that is equipped for digging. Thus, all three loaders (980, 982, 988) have similar e

[2] Material type and bucket fill factor from Caterpillar Performance Handbook Edition 41, January 2011

[3] Job efficiency accounts for operator skill, minor repairs and adjustments, personnel delays, and delays caused by job l CPH suggested 50 minutes (83%) (CPH page 12-80)

[4] Resisitance from CPH pg 22-5 and 22-6 and "Typical Rolling Resistance Factors" table on page 27-1

[5] Guidelines for "Selecting a Machine" on page 12-79 and 12-80 of CPH were used to determine the hydraulic cycle time

[6] Average cycle time for this type of equipment is tabulated on page 12-80 of CPH.

[7] Figures on pages 12-149 through 12-156 in the CPH were used to estimate the travel times for theloaders.

Excavator Cycle Time Analysis

Assumptions

Excavator Bucket Size =	4.3	yd^3
Material Type =	Sand and Gravel	
Sand and Gravel density =	1.5	$tons/yd^3$

Cycle Time

From the Caterpillar Performance Handbook, Edition 41 (2011)
page 4-183 "Cycle Time Estimating Chart"
Based on the low end of the typical range due to the loose configuration of material to be moved.

Cycle Time =	0.28	minutes

Production Estimate

Production Rate =	691	yd^3/hour
Production Rate =	1037	tons/hour
Job Efficiency* =	67%	
Production Rate =	691	tons/hour

* Job efficiency is estimated to be 40 minutes per hour to account for operator skill, minor delays, and periodic excavator transportation

	Baseline Tonnage		Project Tonnage		Recycle Plant Tonnage - Baseline and Excavation
	Gross	Net	Gross	Net

HP estimated based on CalEEMod App D for equipment that does not have Model # listed (Except Haul Truck HP, which is based on Cat 772 or equivalent truck v

Load Factor Based on CalEEMod App D Table 3.3

For Baseline period of 1997 - 2006, CalEEMod Default equipment is conservatively estimated based on the 2005 emission year (App D Table 3.4)

For Project period of 2021 - 2035, CalEEMod Defualt equipment is conservatively estimated based on 2020 emission year (App D Table 3.4)

* Assumed to operate on fixed operational hours. Other equipment operating hours are calculated based on cycle time calculations and tonnage throughput

Max Year Emissions (Mitigated)

Aggregates Fugitive Mining, Storage, and Sitewide Drop Emissions

Drops from stationary equipment (i.e., conveyors) are included in the plant emissions calculations.

Drop, Mining, and Storage Pile Emissions Factors

Material Drop Emission Factor from AP42 13.2.4:

PM10 E.F. (lb/ton) = $k(0.0032)(U/5)^{1.3}/(M/2)^{1.4}$

k = particle size multiplier =	0.35
U = mean wind speed[1] =	4.9
M = material moisture content =	3
PM10 EF (lb/ton) =	0.00062
PM2.5 EF[2] (lb/ton) =	0.00018

Bulldozing Emission Factor, CalEEMod User Manual, Appendix A:

EF PM10 (lb/hr) = 1.0 * s^1.5 / 7.9 * 0.75 =	0.67	
EF PM2.5 (lb/hr) = 5.7 * s^1.2 / 7.9 * 0.105 =	0.09	
s (silt, %) =	6.9	
Watering C.E. =	61%	water every 3 hours if material is not already wet
days of rain =	51	

Quarry Operation Fugitive Emissions:

lbs PM10 / Ton Quarried[3] =	0.021
lbs PM2.5/lbs PM10 =	0.292

Storage Pile Emissions Controlled Factor from SSP1610 - Aggregate Processing:

lb PM10/acre/day 1.054

	Area (acres)	lbs PM10/hr	lbs PM10/day	lbs PM10/yr
Baseline Storage	2	0.1	2.1	769.4
Project Storage	2	0.1	2.1	769.4

Notes:

[1] Mean wind speed based on data for Tulare in Table 1 of CalEEMod User Manual Appendix D which states 2.2 m/s (equvalent to 4.921 mph).

[2] PM2.5 emission factor assumed to be 29.2% of PM10 for material drops based on SCAQMD's *Updated CEIDARS Table with PM2.5 Fractions for mineral products - loading*

[3] Emission Factor from San Diego Air Pollution Control District, *Quarry Operations, General* (https://bit.ly/2XXNWUl)

Rate Calculations

Production Calculations	Truck Loading
Cycles per Hour	74.6
Production Rate (tph)	666

[1] Bucket payload ranges based on activity type and equipment size. In this case, heaped bucket capacity for the 980H is equal to the bucket capacity of a 988 that is equipped for digging. Thus, all three loaders (980, 982, 988) have similar e

[2] Material type and bucket fill factor from Caterpillar Performance Handbook Edition 41, January 2011

[3] Job efficiency accounts for operator skill, minor repairs and adjustments, personnel delays, and delays caused by job l CPH suggested 50 minutes (83%) (CPH page 12-80)

[4] Resisitance from CPH pg 22-5 and 22-6 and "Typical Rolling Resistance Factors" table on page 27-1

[5] Guidelines for "Selecting a Machine" on page 12-79 and 12-80 of CPH were used to determine the hydraulic cycle time

[6] Average cycle time for this type of equipment is tabulated on page 12-80 of CPH.

[7] Figures on pages 12-149 through 12-156 in the CPH were used to estimate the travel times for theloaders.

Excavator Cycle Time Analysis

Assumptions

Excavator Bucket Size =	4.3	yd^3
Material Type =	Sand and Gravel	
Sand and Gravel density =	1.5	$tons/yd^3$

Cycle Time

From the Caterpillar Performance Handbook, Edition 41 (2011)
page 4-183 "Cycle Time Estimating Chart"
Based on the low end of the typical range due to the loose configuration of material to be moved.

Cycle Time =	0.28	minutes

Production Estimate

Production Rate =	691	yd^3/hour
Production Rate =	1037	tons/hour
Job Efficiency* =	67%	
Production Rate =	691	tons/hour

* Job efficiency is estimated to be 40 minutes per hour to account for operator skill, minor delays, and periodic excavator transportation

1.3 User Entered Comments & Non-Default Data

McKay Point Reservoir Project Construction - Tulare County, Annual

Project Characteristics -

Land Use - The Owners propose to develop approximately 200 acres within the 500 acre McKay Point property.

Construction Phase - Construction timeline and activity levels based on Provost & Pritchard Consulting Group communication dated 3/18/2015 (Appendix B of Air Quality Report).

Off-road Equipment - Operational days conservatively based on equipment with longest construction timeline.

Off-road Equipment - See Appendix B

Off-road Equipment - See Appendix B

Road Dust - Site roads are conservatively assumed to be un-paved.

Construction Off-road Equipment Mitigation -

Operational Off-Road Equipment -

Off-road Equipment - See Appendix B
In/Out Flow Grading/Dozing is separated from In/Out-Flow Excavation in CalEEMod model but sourced from the same table of Provost & Pritchard Consulting Memo.

1.3 User Entered Comments & Non-Default Data

McKay Point Reservoir Project Construction - Tulare County, Summer

Project Characteristics -

Land Use - The Owners propose to develop approximately 200 acres within the 500 acre McKay Point property.

Construction Phase - Construction timeline and activity levels based on Provost & Pritchard Consulting Group communication dated 3/18/2015 (Appendix B of Air Quality Report).

Off-road Equipment - Operational days conservatively based on equipment with longest construction timeline.

Off-road Equipment - See Appendix B

Off-road Equipment - See Appendix B

Road Dust - Site roads are conservatively assumed to be un-paved.

Construction Off-road Equipment Mitigation -

Operational Off-Road Equipment -

Off-road Equipment - See Appendix B
In/Out Flow Grading/Dozing is separated from In/Out-Flow Excavation in CalEEMod model but sourced from the same table of Provost & Pritchard Consulting Memo.

1.3 User Entered Comments & Non-Default Data

McKay Point Reservoir Project Construction - Tulare County, Winter

Project Characteristics -

Land Use - The Owners propose to develop approximately 200 acres within the 500 acre McKay Point property.

Construction Phase - Construction timeline and activity levels based on Provost & Pritchard Consulting Group communication dated 3/18/2015 (Appendix B of Air Quality Report).

Off-road Equipment - Operational days conservatively based on equipment with longest construction timeline.

Off-road Equipment - See Appendix B

Off-road Equipment - See Appendix B

Road Dust - Site roads are conservatively assumed to be un-paved.

Construction Off-road Equipment Mitigation -

Operational Off-Road Equipment -

Off-road Equipment - See Appendix B
In/Out Flow Grading/Dozing is separated from In/Out-Flow Excavation in CalEEMod model but sourced from the same table of Provost & Pritchard Consulting Memo.

October 14, 2013

Tulare Irrigation District
McKay Point Reservoir Project Biological Resources Evaluation,
Tulare County, California

Introduction

This report summarizes the results of year 2011 and 2013 reconnaissance-level biological resources surveys conducted within and immediately adjacent to the site of the proposed McKay Point Reservoir (i.e., project site) in Tulare County, California (Figure 1). The project site lies 2.5 miles southwest of Lake Kaweah; 1.5 miles southeast of Bravo Lake; 1.0 miles northwest of the community of Lemon Cove; and 2.5 miles southwest of the community of Woodlake.

The Tulare Irrigation District (TID), Consolidated Peoples Ditch Company (CPDC) and Visalia & Kaweah Water Company (VKWC)) are joint owners of the approximately 200 acres of land adjacent to the Kaweah and St. Johns rivers that comprise the project site. This land is commonly referred to as the McKay's Point property.

The joint owners propose to construct a new reservoir (i.e., McKay's Point Reservoir) on the north side of the divergence of the Kaweah and St. Johns rivers near McKay's Point. The McKay's Point Reservoir will serve as a surface water storage/re-regulation facility (i.e., surface water management tool). The reservoir would occupy a surface area of approximately 180 acres and would have storage capacity of approximately 4,000 acre-feet. Depths of approximately 60 feet below ground surface (bgs) are proposed. Final slopes would be 3:1, horizontal:vertical (h:v), in order to minimize any bank erosion from the wind and water.

The project site and immediately adjacent lands within 250 feet of the site were evaluated during the biological resources survey to identify evidence of special-status plants and wildlife, rare or sensitive vegetation communities, and potential jurisdictional waters or wetlands that could be affected by the proposed project.

Survey Methods

The project site and adjacent lands were surveyed by Michael Bumgardner (Bumgardner Biological Consulting) on May 16, 2011 and September 18, 2013. The surveys were conducted on foot as random meander transects such that all portions of the project site could be effectively evaluated. Gross-scale mapping of the plant communities on the project site was conducted given that only three discernible communities occur on the site. A search for special-status plant and wildlife species was conducted and focused on local taxa that have been recorded in the California Natural Diversity Data Base (CNDDB) or California Native Plant Society's (CNPS) Online Inventory of Rare and Endangered Plants. Lastly, a reconnaissance-level search for waters with regulatory jurisdiction under the Clean Water Act, California Fish and Game Code, and/or Porter-Cologne Water Quality Control Act was conducted within the site boundaries.

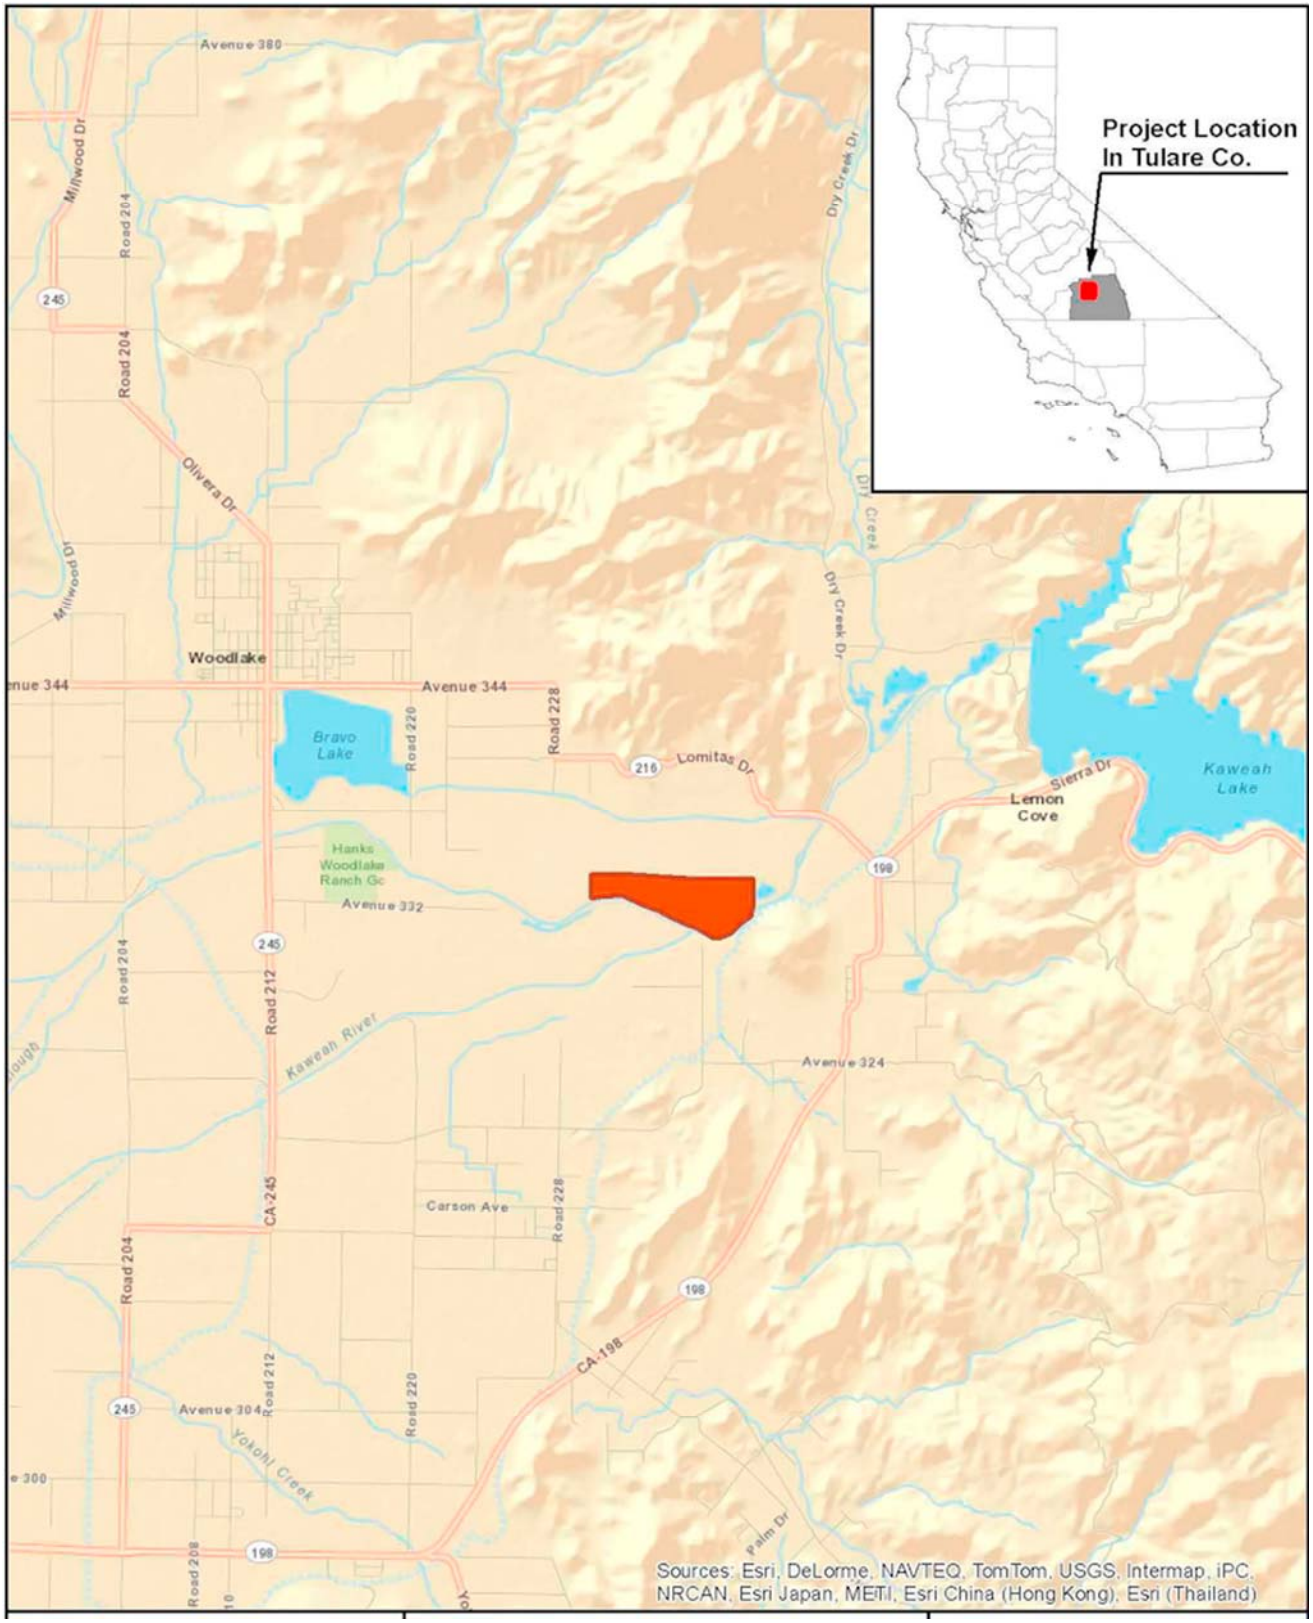

Figure 1
McKay Point Reservoir Project Site – Tulare County, California

Analytical Methods

A standard nine-quadrangle CNDDB/Rarefind 3 report was generated for the project site (i.e., query of the USGS 7.5-minute topographic quadrangle in which the project site is found as well as the immediate eight surrounding topographic quadrangles, viz. Woodlake and the surrounding Stokes Mtn., Ivanhoe, Exeter, Aukland, Rocky Hill, Shadequarter Mtn., Kaweah, and Chickencoop Canyon quads. The California Natural Diversity Data Base (CNDDB) contains records for special-status species, as well as sensitive natural communities, which have been reported to the California Department of Fish and Wildlife (CDFW). The Rarefind 3 report for the project site is provided in Appendix A. Each of the species identified in the Rarefind 3 report were then evaluated in terms of their likelihood of occurrence within and immediately adjacent to the project site. This evaluation considered the known distribution and habitat requirements of the species such that one of the following findings was prepared:

- Known to Occur – species was observed within or immediately adjacent to the project site during the May 16, 2011 survey or September 18, 2013 survey or has previously been documented within or immediately adjacent to the project site.
- High Potential – species has not been documented within or immediately adjacent to the project site, but should be expected on more than 50% of visits to suitable habitat in the project site during the appropriate season and time of day.
- Moderate Potential – species has not been documented within or immediately adjacent to the project site, but should be expected on less than 50% of visits to suitable habitat in the project site during the appropriate season and time of day.
- Low Potential – species has not been documented within or immediately adjacent to the project site nor is it likely to occur on the project site, but its presence cannot be completely discounted due to incomplete information on the taxon's distribution or habitat requirements.
- No Potential – species does not occur within the project site due to the lack of required habitat features for the species or the known range of the species is well defined and does not include the project site.

The findings for each of the species identified in the Rarefind 3 report are presented in this report.

Other sources of information on special-status species in California were subsequently reviewed given that the CNDDB is not inclusive of all special-status species that may occur in an area. A review of the CDFW's List of Special Animals (January 2011) and List of Special Plants (July 2013) was therefore conducted to determine if any special-status species not identified in the Rarefind 3 report have the potential to occur in the project site. This review was based on the professional experience of Michael Bumgardner within the region and elsewhere in California, but also included review of

other published sources of information on special-status species in California. These latter sources include the following:

- California Native Plant Society Inventory of Rare and Endangered Plants (online edition) (CNPS 2013).
- The Jepson Manual: Vascular Plants of California, 2nd edition (Baldwin and Goldman 2012).
- Amphibian and Reptile Species of Special Concern in California (Jennings and Hayes 1994).
- The Distribution of the Birds of California (Grinnell and Miller 1944).
- California Birds: Their Status and Distribution (Small 1994).
- California's Wildlife Volume II Birds (Zeiner et al. 1990).
- eBird Data Base (http://ebird.org/ebird/eBirdReports?cmd=Start) (2013).
- Mammalian Species of Special Concern in California (Williams 1986).
- Mammals of the Pacific States: California, Oregon, and Washington (Ingles 1978).
- Bat species accounts prepared as course materials for *Ecology and Conservation of California Bats* offered through San Francisco State University's Sierra Nevada Field Campus.
- Western Bat Working Group website (http://www.wbwg.org/species_accounts).

Species that are known or expected to occur in the vicinity of the project site were then further evaluated in this report.

Vegetation Communities and Site Characteristics

The project site is located immediately north of the divergence of the Kaweah and St. Johns rivers. The site is flat and has been used most recently to support cattle grazing. There are no developed uses on the site. Much of the onsite vegetation consists of non-native annual grassland (Figure 2). As such, most of the vegetation consists of non-native annual grasses [e.g., wild oat (*Avena fatua*)], but also includes herbaceous species such as lamb's-quarters (*Chenopodium album*), wild cucumber (*Marah* sp.), and deer weed (*Acmispon glaber*). Small, scattered stands of mule fat (*Baccharis salicifolia*) also occur within the non-native annual grassland. However, these latter stands are not significant enough in size to warrant mapping as a discernible vegetation community.

Mixed oak-riparian woodland occurs in the southeastern portion of the project site (Figure 2). Woody species that are associated with this stand of vegetation include willows (*Salix* spp.), Fremont's cottonwood (*Populus fremontii*), western sycamore (*Platanus racemosa*), tamarisk (*Tamarix* sp.), tree tobacco (*Nicotiana glauca*), blue elderberry (*Sambucus mexicana*), and interior live oak (*Quercus wislizeni*). California wild grape (*Vitis californica*) occurs as a liana growing into the canopy of the woody species. The canopy cover in this stand of vegetation varies between approximately 20 and 100 percent and is best described as interrupted woodland.

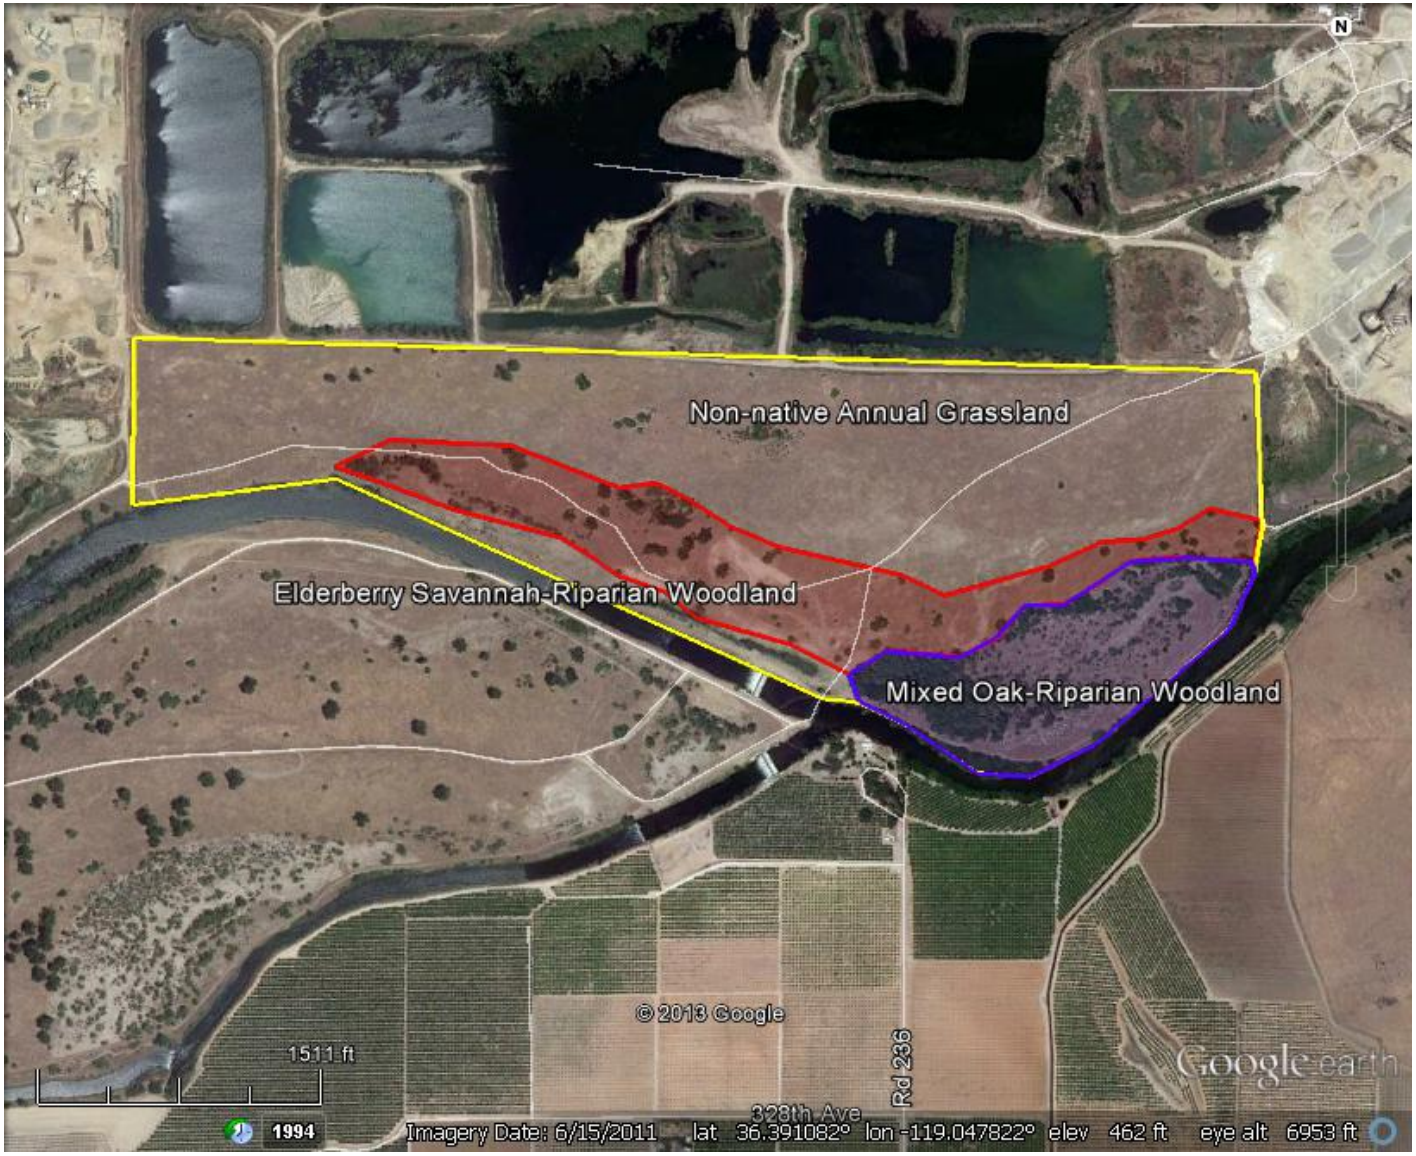

Figure 2
McKay Point Reservoir Project Site – Vegetation Communities

Approximately 39.8 acres of elderberry savannah-riparian woodland (a sensitive vegetation community tracked by the CDFW) occurs adjacent to the mixed oak-riparian woodland, but also extends west along the southern border of the project site (Figure 2). It should be noted that the depicted boundaries in Figure 2 are an approximation of the borders of this vegetation community and the mixed oak-riparian woodland as the two communities have no clearly discernible boundary where they occur adjacent to and grade into each other. The dominant species in the elderberry savannah-riparian woodland is blue elderberry. However, scattered Fremont's cottonwoods and willows also occur in this vegetation community. The onsite elderberry shrubs/clumps are large and old with many stems and likely represent the remnants of a formerly more contiguous community.

Jurisdictional Wetlands and Other Waters

Jurisdictional wetlands or other waters of the United States are areas that cannot be dredged or filled without a permit from the U.S. Environmental Protection Agency or U.S. Army Corps of Engineers (this latter permit is commonly referred to as a "Section 404" permit in reference to the section of the federal Clean Water Act that requires such permits). Actions that require issuance of a "Section 404" permit include earth-moving activities that result in fill of jurisdictional wetlands and other waters. It should be noted that such actions may also require the issuance of state permits (e.g., California Fish and Game Code Section 1603 streambed alteration agreement and/or Regional Water Quality Control Board Section (RWQCB) Section 401 clean water certification).

Wetlands or other waters of the United States are identified based on three criteria, viz. (1) soil characteristics, (2) hydrology, and (3) plant species. The U.S. Army Corps of Engineers (USACE) has developed a procedure and manual for delineating wetlands that requires comprehensive evaluation of these three criteria during field environmental assessments. A formal wetland delineation was not conducted for the purposes of this report. However, no waters that are subject to the jurisdiction of the USACE, CDFW, or RWQCB, other than the Kaweah and St. Johns rivers, occur on or immediately adjacent to the project site. The latter two rivers are jurisdictional waters and the placement of fill associated with the intake/outlet infrastructure of the McKay's Point Reservoir will be subject to the jurisdiction of the USACE, CDFW, and RWQCB.

Habitat Conservation Plans and Other Similar Habitat Management Plans

There are no Habitat Conservation Plans (HCPs), Natural Community Conservation Plans (NCCPs), or other approved local, regional, or state habitat conservation plans that apply to the project site.

Wildlife Diversity

The surveys within and adjacent to the project site resulted in the documentation of relatively low wildlife diversity (i.e., two species of amphibians, one species of reptile, 14 species of birds, and five species of mammals). However, it should be noted that no

comprehensive wildlife surveys were conducted for the project. The only amphibians that were found in and adjacent to the project site included Pacific treefrog (*Hyla regilla*) and bullfrog (*Rana catesbeiana = Lithobates catesbeianus*). Both of these species are relatively widespread in lower elevation drainages, ponds, and other waters in California. The only reptile species recorded within and adjacent to the project site was western fence lizard (*Sceloporus occidentalis*). This species is relatively widespread within the non-desert, lowland portions of California. The bird species recorded within and adjacent to the project site included phainopepla (*Phainopepla nitens*), northern mockingbird (*Mimus polyglottos*), Nuttall's woodpecker (*Picoides nuttallii*), American robin (*Turdus migratorius*), willow flycatcher (*Empidonax traillii*), Pacific-slope flycatcher (*E. difficilis*), house finch (*Haemorhous mexicanus*), western scrub-jay (*Aphelocoma californica*), Anna's hummingbird (*Calypte anna*), northern flicker (*Colaptes auratus*), turkey vulture (*Cathartes aura*), killdeer (*Charadrius vociferus*), black phoebe (*Sayornis nigricans*), and California quail (*Callipepla californica*). Most of these species are common and widespread year-round or winter residents within oak and riparian woodlands within the region. However, the willow flycatcher and Pacific-slope flycatcher are only migrants through the area and do not occur as a nesting or wintering species at the project site. Lastly, mammal species documented on and near the project site included California ground squirrel (*Otospermophilus beecheyi*) Botta's pocket gopher (*Thomomys bottae*) (mounds only), (burrows only), coyote (*Canis latrans*), mule deer (*Odocoileus hemionus*), and raccoon (*Procyon lotor*) (tracks only).

It should be noted that other wildlife species probably occur on or near the project site, but would not likely be found in one-day reconnaissance-level surveys. These other species include, but are not limited to, southern alligator lizard (*Elgaria multicarinata*), western skink (*Plestiodon skiltonianus*), common kingsnake (*Lampropeltis getula*), Pacific gopher snake (*Pituophis catenifer*), western rattlesnake (*Crotalus viridis*), several species of small mammals, several species of oak or riparian-associated passerines (i.e., songbirds), red-tailed hawk (*Buteo jamaicensis*), American kestrel (*Falco sparverius*), and great horned owl (*Bubo virginianus*).

Special-Status Plant Species

No special-status plant taxa were observed on or immediately adjacent to the project site during the surveys. In addition, no special-status plant taxa that have been documented in the project region (Table 1) are considered to have any potential to occur on the project site given the onsite conditions (i.e., lack of suitable habitat for and/or known distribution of the species).

Special-Status Wildlife Species

Only two special-status wildlife species were observed on the project site during the surveys. One of these species (i.e., Nuttall's woodpecker) is a likely year-round resident in the mixed oak-riparian woodland in the southeastern portion of the project site. The second species (i.e., willow flycatcher) was only observed during the September 18, 2013 survey and is considered a migrant that passes through the area (including the project

site). Furthermore, this latter species is only considered a special-status species when nesting (typically in dense willow scrub in the Sierra Nevada).

Sixteen special-status wildlife species that have been documented in the project region (Table 1) are considered to have some potential to occur on or near the project site. Three of these species are insects (i.e., moestan blister beetle, Morrison's blister beetle, and Tulare cuckoo wasp) that are not well known in terms of their life history and behavior, but that have been recorded in the project vicinity in habitats similar to those that occur on the project site. As such, they cannot be discounted and are considered to have some potential, albeit low, to occur on the project site. There is also suitable habitat on the project site for a fourth special-status insect species [i.e., valley elderberry longhorn beetle (VELB)]. However, the nearest known occurrences of the beetle, which occurs in and on elderberry, are more than 4.5 miles southwest and 8.5 miles northeast of the project site. Furthermore, the beetle is known to have poor dispersal abilities and does not occur in large sections of elderberry savannah or riparian habitat that is otherwise suitable for the species other than it is isolated by reaches of unsuitable habitat (i.e., gaps in the suitable habitat as small as 300 linear feet). Though no exit holes attributable to VELB were found during the reconnaissance-level surveys of the project site, it should be noted that focused surveys for VELB exit holes would need to be conducted to support a finding of absence. Consequently, the taxon is considered to have some potential, albeit low, to occur on the project site.

Only one special-status reptile is believed to have any potential to occur on the project site. This latter species [i.e., western pond turtle (*Emys marmorata*)] is known from occurrences upstream in the Kaweah River drainage. In addition, it has been known to occur in a wide variety of slow-moving waters throughout California. Thus, it is considered to have some potential, albeit low, to occur in the aquatic habitats of the adjacent Kaweah and St. Johns rivers and to nest in the upland portions of the project site.

Ten special-status birds are considered to have some potential to occur on the project site. Seven of these latter species [Cooper's hawk (*Accipiter cooperii*), white-tailed kite (*Elanus leucurus*), loggerhead shrike (*Lanius ludovicianus*), oak titmouse (*Baeolophus inornatus*), yellow-breasted chat (*Icteria virens*), lark sparrow (*Chondestes grammacus*), and Lawrence's goldfinch (*Spinus lawrencei*)] are known to nest in oak or riparian woodlands. Furthermore, each of these species has been recorded nesting within less than two miles of the project site. As such, each of these species, with the exception of oak titmouse is considered to have some potential, albeit low, to nest in the onsite mixed oak-riparian woodland. Given the presence of Nuttall's woodpecker in the mixed oak-riparian woodland, oak titmouse is considered to have a moderate potential to nest onsite since the species is a secondary cavity nester (i.e., nests in cavities/holes created by woodpeckers).

Other special-status bird species with some potential to occur on the project site include ferruginous hawk (*Buteo regalis*), merlin (*Falco columbarius*), and burrowing owl (*Athene cunicularia*). No evidence of burrowing owl was found on the project. In addition, no suitable burrows or burrow surrogates that could be used by the species were

found on the project site. However, California ground squirrel burrows were observed immediately offsite on the northern and eastern boundaries of the project site. As such, there is the potential for indirect impacts to the species at these off-site locations should they be occupied by the species. Ferruginous hawk and merlin do not occur in the project region as nesting species. However, they do occur in the area as wintering species and are considered special-status species when wintering. Given the presence of suitable habitat onsite (i.e., large tract of non-native grassland) and known winter occurrences within less than two miles, these two species are considered to have some potential, albeit low, to occur on the project site.

Only one special-status mammal is believed to have any potential to occur on the project site. Western red bat (*Lasiurus blossevillii*) is known to utilize large trees in riparian forest or orchards as roost sites. Therefore, the species is considered to have some potential, albeit low, to occur in the mixed oak-riparian woodland located on the project site.

Conclusions

Sensitive or special-status biological resources that could be adversely affected by the proposed McKay's Point Reservoir Project are limited to the following:

- elderberry savannah-riparian woodland (a sensitive vegetation community);
- Kaweah and St. Johns rivers (jurisdictional waters of the state and United States); and
- special-status wildlife species (up to 16 species).

Elderberry savannah is a sensitive vegetation community that is tracked by the CDFW. It is poorly represented in the CNDDB, but is known to occur throughout the Central Valley in small stands. Approximately 39.8 acres of this vegetation community would be adversely affected by the project.

Fill within the Kaweah and St. Johns rivers would occur with construction of each river's inflow and outflow channels and associated rip-rap or concrete aprons. This fill would require permitting from the USACE, CDFW, and RWQCB.

Adverse effects to up to 16 special-status wildlife species could occur with construction and operation of the project. Approximately half of these species are birds that may nest in the mixed oak-riparian woodland in the southeastern portion of the project site. The project would not result in direct effects to these species (i.e., loss of habitat), but could result in indirect effects (e.g., significant disturbance during nesting from nearby construction activities). The project could result in direct effects to burrowing owl even with no suitable roost sites on the project site since the loss of suitable foraging habitat could adversely affect individuals occupying adjacent lands. The project could also result in indirect effects to burrowing owls occupying adjacent offsite lands due to disturbance from nearby construction activities. The loss of foraging habitat for wintering merlin and ferruginous hawk would contribute to the cumulative loss of

suitable winter foraging habitat for these species. The remaining special-status species addressed by this report (i.e., insects and western pond turtle) could each experience adverse direct effects from loss of habitat. Furthermore, potential direct effects to western pond turtle could include loss of individuals (adults and eggs) during construction-related activities.

No other important, significant, sensitive, or regulated biological resources (including aquatic habitats, roost sites, staging areas, etc.) were found to be associated with the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
		PLANTS		
Atriplex cordulata var. *erecticaulis*	Earlimart orache	none/none/CNPS list 1B.2	This annual saltbush occurs on saline or alkaline soils in valley and foothill grassland. It is known from Kings, Kern, and Tulare counties. It blooms from August to November.	**No Potential.** No individuals of this taxon were observed within or near the project site. In addition, the taxon only occurs on saline or alkaline soils in valley and foothill grassland – conditions that do not exist within the project site. Therefore, the taxon has no potential to occur within the project site.
Atriplex minuscula	lesser saltscale	none/none/CNPS list 1B.1	This annual saltbush grows in sandy alkaline areas in chenopod scrub, playas, and valley and foothill grassland. It is known from Alameda, Butte, Fresno, Kern, Madera, Merced, Stanislaus, and Tulare counties. It blooms from May to October.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs on sandy alkaline soils in chenopod scrub, playas, and valley and foothill grassland – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
Atriplex persistens	vernal pool smallscale	none/none/CNPS list 1B.2	This annual saltbush occurs in claypan and alkaline vernal pools and alkaline grasslands. It has been recorded from	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Leptosiphon serrulatus	Madera leptosiphon	none/none/CNPS list 1B.2	This annual herb occurs in cismontane woodland and lower montane coniferous forest. It is known from Fresno, Kern, Madera, Mariposa, and Tulare counties. It blooms from April to May.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs in cismontane woodland and lower montane coniferous forest – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
Mimulus norrisii	Kaweah monkeyflower	none/none/CNPS list 1B.3	This annual herb occurs on carbonate or rocky soils in chaparral and cismontane woodland. It has been found in Fresno and Tulare counties. It blooms from March to May.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs in cismontane woodland and chaparral – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
Mimulus pictus	calico monkeyflower	none/none/CNPS list 1B.2	This annual herb occurs on granitic soils (often in disturbed areas) in broadleafed upland forest and cismontane woodland. It has been found in Kern and Tulare counties. It blooms from March to May.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs in broadleafed upland forest – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Orcuttia inaequalis	San Joaquin Valley orcutt grass	FT/SE/CNPS list 1B.1	This grass occurs in vernal pools (typically larger or more persistent pools) within valley and foothill grassland. The remaining populations of this species occur mostly in the southeastern San Joaquin Valley (Fresno, Merced, Madera, and Tulare counties). Historically, the species also occurred in Stanislaus County. It blooms from April to September.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs in vernal pools in valley and foothill grassland – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
Pseudobahia bahiifolia	Hartweg's golden sunburst	FE/SE/CNPS list 1B.1	This species occurs in cismontane woodland and valley and foothill grassland (almost always on shallow, well-drained, fine-textured soils - typically on clay, acidic soils) on the north or northeast facing side of Mima mounds). It has been recorded in Fresno, Madera, Merced, Stanislaus, Tuolumne, and Yuba counties. Blooming occurs from March to April.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs in cismontane woodland and valley and foothill grassland on the north or northeast facing side of Mima mounds – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
Tuctoria greenei	Greene's tuctoria	FE/SR/CNPS list 1B.1	This grass occurs in the dry bottoms of vernal pools in valley and foothill grassland. It is currently known to occur in Butte, Colusa, Glenn, Merced,	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs in vernal pools in valley and foothill

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
			Modoc, Shasta, and Tehama counties. Historically, it also occurred in Fresno, Madera, San Joaquin, Stanislaus, and Tulare counties. It blooms from May to September.	grassland – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
INVERTEBRATES				
Branchinecta lynchi	Vernal pool fairy shrimp	FT/none/none	This species occurs primarily in vernal pools (sandstone depression, grass swale, earth slump, or basalt-flow depression pools) in grassland and oak savannah of the Central Valley. However, the species also occurs at a small number of locations in the central Coast Ranges from Monterey County to Santa Barbara County as well as Riverside County.	**No Potential.** There is no suitable vernal habitat within or adjacent (i.e., within 250 feet) to the project site for this species. Therefore, there is no potential for the species to be affected by the project.
Lepidurus packardi	Vernal pool tadpole shrimp	FE/none/none	This species inhabits clear to turbid vernal pools and swales in the Sacramento Valley and northern San Joaquin Valley.	**No Potential.** There is no suitable vernal habitat within or adjacent (i.e., within 250 feet) to the project site for this species. Therefore, there is no potential for the species to occur on the project site or be affected by the project.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Talanites moodyae	Moody's gnaphosid spider	none/SA/none	Little is known and published about this species. However, it has been found in grasslands under rocks (generally serpentine) on rocky mounts, buttes, and hilltops. Only six known occurrences are reported – all from Fresno and Tulare counties.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species only occurs on rocky mounts, buttes, or hilltops (usually under serpentine rocks) – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
Lytta moesta	moestan blister beetle	none/SA/none	The range of this species is not well known, but occurrences have been documented in Fresno, Kern, Madera, Santa Cruz, Stanislaus, and Tulare counties. The CDFW reports that very little is known about the life history and behavior of this species. However, it has been collected from March to September and has typically been found in association with its host species (i.e., the species' larvae feed on the pollen stores that ground-nesting solitary bees have provided for their own larvae).	**Low Potential.** Given that ground-nesting solitary bees (i.e., beetle's host species) are widely distributed in California and little is known about this species' life history and behavior, it cannot be discounted as occurring on the project site. Therefore, it is considered to have some potential, albeit low, to occur on the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Lytta morrisoni	Morrison's blister beetle	none/SA/none	The range of this species is not well known, but occurrences have been documented in the southern San Joaquin Valley in Kern, Fresno, Tulare, San Benito, and San Luis Obispo counties. The CDFW reports that life history and behavior information for the species does not exist. However, it has typically been found in association with its host species (i.e., the species' larvae feed on the pollen stores that ground-nesting solitary bees have provided for their own larvae).	**Low Potential.** Given that ground-nesting solitary bees (i.e., beetle's host species) are widely distributed in California and little is known about this species' life history and behavior, it cannot be discounted as occurring on the project site. Therefore, it is considered to have some potential, albeit low, to occur on the project site.
Desmocerus californicus dimorphus	valley elderberry longhorn beetle	FT/none/none	This subspecies occurs at scattered locations in the Central Valley and adjacent foothills of the Sierra Nevada and Coast Ranges. It is entirely dependent upon its host plant (i.e., elderberry spp.) and is only found where this shrub occurs (typically in riparian vegetation associations, but occasionally in single, isolated shrubs or stands of the plant).	**Low Potential.** A large number of old-growth elderryberry shrubs occur within the project site. Though no evidence of valley elderberry longhorn beetle exit holes was found during a reconnaissance-level survey of the project site, the subspecies cannot be discounted as occurring on the project site without more thorough surveys. Therefore, it is considered to have some potential, albeit low, to occur on the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Chrysis tularensis	Tulare cuckoo wasp	none/SA/none	This species is known only from a small series of specimens that have been collected in Amador, Fresno, Monterey, and Tulare counties. Cuckoo wasps are nest parasitoids of predatory wasps and sawflies. However, the host species of this species are unknown. Adults have been found from April to June in open, sunny habitats with abundant flowers and small shrubs, where they feed on nectar.	**Low Potential.** Given that predatory wasps and sawflies (i.e., wasp's host species) are widely distributed in California and little is known about this species' life history and behavior, it cannot be discounted as occurring on the project site. Furthermore, the nearest known record to the project site is from immediately north of the intersection of Road 212 and Avenue 344 (less than three miles from the project site). Therefore, it is considered to have some potential, albeit low, to occur on the project site.
AMPHIBIANS				
Ambystoma californiense	California tiger salamander	FT/ST/none	This species is found in annual grassland, oak savannah, and coastal sage scrub adjacent to vernal pools, stock ponds, and ponded reaches of ephemeral streams (aquatic breeding sites). The species is patchily distributed in the Central Valley from Yolo County to Kings County, but also occurs in Alameda and Contra Costa counties south through the interior	**No Potential.** No suitable aquatic breeding habitat for the species occurs within or immediately adjacent to the project site. Furthermore, the nearest known occurrences of the species (at and near the Stone Corral Ecological Reserve east of Yettem) are more than 11 miles west of the project site. Lastly, the onsite soils are very sandy and appear to preclude the creation of burrows by all species other than valley

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
			valleys of the Coast Ranges. Disjunct populations occur in Santa Barbara County and Sonoma County.	pocket gopher. Therefore, there are only marginal underground refugia for the species onsite and it is considered to have no potential to occur on the project site.
Batrachoseps regius	Kings River slender salamander	none/SA/none	This species has been found in Fresno County on the south and east sides of the North Fork of the Kings River and at Summit Meadow in the drainage of the South Fork of the Kings River. It has also been found in the drainage of the middle fork of the Kaweah River in Tulare County. It occurs in talus, under rocks and downed logs, and in leaf litter in chaparral, cismontane woodland, and montane coniferous forest above 1,100 and 8,100 feet in elevation.	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species has only been recorded in talus, under rocks, under downed logs, and in leaf litter in chaparral, cismontane woodland, and montane coniferous forest between 1,100 and 8,100 feet – conditions that do not exist within the project site. Therefore, the species has no potential to occur within the project site.
Rana boylii	foothill yellow-legged frog	none/CSC/none	This species was historically distributed throughout the foothill portions of the Sierra Nevada and Coast Ranges drainages from the Oregon border to the San Gabriel River (Los Angeles County). The species requires shallow, small to moderate streams (typically perennial waters	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the species requires shallow, small to moderate streams (typically perennial waters with some cobble-sized substrate and riffle habitat above 600 feet in elevation and without bullfrogs – conditions that do not exist

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
			with some cobble-sized substrate and riffle habitat above 600 feet in elevation and without bullfrogs).	within the project site. Therefore, the species has no potential to occur within the project site.
Lithobates pipiens	northern leopard frog (native populations only)	none/CSC/none	Historical populations of this species in California existed in scattered locations below 6,500 feet in Siskiyou and Modoc counties and in the northern Owens Valley. Individuals of unknown origin were introduced into El Dorado, Kern, Los Angeles, Merced, San Francisco, Sierra, Tehama, and Tulare counties between 1905 and 1970. Several of these introduced populations experienced rapid growth and range expansions before completely disappearing. Except for a small population that is currently present in Merced County, all of these introduced populations have perished. It has been found in grassland, wet meadows, potholes, forests, woodland, brushlands, springs, canals, bogs, marshes, reservoirs (generally where there is permanent water with abundant aquatic vegetation).	**No Potential.** No individuals of this species were observed within or near the project site. In addition, the population recorded near Orosi in Tulare County is considered to be an introduced population and is therefore not a special-status species. Therefore, native populations of this species have no potential to occur within the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Spea hammondii	Western spadefoot	none/CSC/none	This species is found in dry habitats (e.g., annual grassland, oak savannah and woodland, and coastal sage scrub) adjacent to vernal pools, stock ponds, and overflow channels of low-gradient drainages within the Central Valley and coastal California from Monterey County to San Diego County.	**No Potential.** No suitable aquatic breeding habitat for the species occurs within or immediately adjacent to the project site. Furthermore, the project site is relatively landlocked by semi-perennial rivers, sand and gravel mining operations, and agricultural uses that would preclude movement of the species onto the site from more suitable habitats located near the site (e.g., lands north of Highway 216). Consequently, the species is considered to have no potential to occur within the project site.
REPTILES				
Emys marmorata	Western pond turtle	none/CSC/none	This species historically occurred throughout most of the Pacific-slope drainages in California (below approximately 4,000 feet). The species now occurs at scattered locations throughout its former range (primarily in the central Sierra Nevada foothills, Central Valley, San Francisco Bay area, and north-central coast and Coast Ranges. It occurs in and adjacent to	**Low Potential.** Given that potentially suitable habitat is provided by the adjacent Kaweah and St. Johns rivers and the species has been recorded upstream in the Kaweah River, it cannot be discounted as occurring on the project site. Suitable aquatic habitat within the project site only occurs in the Kaweah and St. Johns rivers. However, individuals could also enter the upland portion of the site for egg-laying.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
			ponds, reservoirs, or other slow-moving perennial aquatic habitats (e.g., sloughs, streams, and rivers). The species may be active year-round in some parts of its range.	Therefore, it is considered to have some potential, albeit low, to occur on the project site.
BIRDS				
Ardea herodias	great blue heron (nesting colony)	none/SA/none	This species is fairly common throughout most of California where there are shallow estuaries, or freshwater or saltwater emergent wetlands. However, it is less common along riverine and rocky coastal shores and above the foothills in the mountains. Rookeries (i.e., nesting colonies) are typically active from February to late July and occur in the tops of secluded large snags or live trees. Rookeries are sometime shared with the great egret or other large wading birds.	**No Potential.** No nesting colonies of this species were observed within or near the project site. In addition, the nearest reported nesting colony is on Dry Creek, one mile north of the confluence of Dry Creek and the Kaweah River (more than two miles from the project site). Therefore, no nesting colonies of this species occur within or immediately adjacent to the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Gymnogyps californianus	California condor	FE/SE/none	This species occurs as a reintroduced species primarily in the mountains of Ventura, Santa Barbara, Los Angeles, Monterey, and San Benito counties. However, individuals are known to be wide-ranging and occasionally occur soaring over the Tehachapi Mountains and southern Sierra Nevada. The species is strictly a scavenger and may travel up to 35 miles or more from roost sites in search of carrion. Most foraging occurs in open habitats that facilitate landings and takeoffs. Traditional roost sites are on cliffs or ledges, but snags and trees in old growth coniferous forest may also be used.	**No Potential.** No suitable roost sites for this species occur within or near the project site. In addition, other potential attractors to the project site (e.g., large mammals and potential food sources) are not provided at or near the site. Lastly, the nearest known use areas for this species are located in more rugged country more than 13 miles southeast of the project site. Therefore, the species is considered to have no potential to occur within the project site.
Accipiter cooperii	Cooper's hawk (nesting)	none/SA/none	This species occurs as an uncommon breeding resident throughout most of the low to mid-elevation wooded portions of California where it inhabits open, interrupted, or marginal woodlands. It is seldom found in areas without dense tree stands. Nest sites are typically found in riparian or	**Low Potential.** There is suitable nesting habitat for the species (i.e., interrupted riparian woodland with dense stands of trees) located in the southeastern portion of the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than two miles from the project site along Dry Creek Drive

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
			deciduous trees in canyon bottoms or river flood plains.	upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to nest on the project site.
Buteo regalis	Ferruginous hawk (wintering)	none/none/BCC	This species is a winter resident of the Modoc Plateau, Central Valley, and Coast Ranges. It forages in large, open tracts of grasslands, sparse scrubland, and deserts.	**Low Potential.** There is suitable wintering habitat for the species (i.e., open grassland) on the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than 1.5 miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to winter on or immediately adjacent to the project site.
Elanus leucurus	white-tailed kite (nesting)	none/CFP/none	This species is found as a resident throughout the lower elevation portions of California in low rolling grasslands with scattered oaks and river bottomlands or marshes adjacent to deciduous woodland. It requires grasslands, meadows, or marshes (for foraging) located near dense-topped trees (for nesting and roosting).	**Low Potential.** There is suitable nesting habitat for the species (i.e., mixed oak and riparian woodland) located in the southeastern portion of the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than 1.5 miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to nest on the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Falco columbarius	Merlin (wintering)	none/SA/none	This species winters in California from September to May. It occurs in a variety of low elevation, relative flat habitats that include wooded areas, coastlines, open grasslands, savannah, and the periphery of lakes. It is less often found in open desert. It typically requires dense stands of trees for cover and roosting. It is most often found where there are substantial populations of small birds (the primary prey item).	**Low Potential.** There is suitable wintering habitat for the species (i.e., open grassland) on the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than 1.5 miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to winter on or immediately adjacent to the project site.
Athene cunicularia	Burrowing owl (burrow sites)	none/CSC/BCC	This species is found throughout the Central Valley, in the San Francisco Bay Area, at scattered locations along the coast, and in portions of the desert regions. It is a year-round resident in annual and perennial grasslands or other vegetation communities that support sparse or non-existent tree or shrub canopies.	**Low Potential.** Though the annual grassland on the project site provides suitable foraging habitat for the species, there is no evidence of suitable burrow sites on the project site (i.e., no California ground squirrels or their burrows, or other suitable burrow surrogates were observed on the project site). However, a small number of California ground squirrel burrows were observed in the spoils materials from the adjacent sand and gravel mining operations. Therefore, there is some potential for offsite individuals to be affected by activities on the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Picoides nuttallii	Nuttall's woodpecker (nesting)	none/none/BCC	This species occurs as a resident of low-elevation riparian deciduous and oak habitats (cismontane woodland) throughout much of California with the exception of the deserts, high Sierra Nevada, and redwood belt.	**Known to Occur.** There is suitable cismontane woodland for the species (i.e., mixed oak and riparian woodland) in the southeastern portion of the project site. Furthermore, the species was heard and observed in the adjacent woodland during reconnaissance-level surveys of the project site. Therefore, the species is known to occur on the project site.
Empidonax traillii	willow flycatcher (nesting)	none/SE/BCC	This species is a rare to locally uncommon, summer resident in wet meadow and montane riparian habitats at 2000 to 8000 feet in elevation in the Sierra Nevada and Cascade Range. It also occurs at scattered locations (at lower elevations) in southern California (including along the Kern, Santa Margarita, San Luis Rey, and Santa Ynez rivers). It most often occurs in broad, open river valleys or extensive mountain meadows with dense shrubby willows. Nesting occurs between mid-May and late August in northern California.	**No Potential.** Though a migrant individual was observed in the mixed oak and riparian woodland on the project site during reconnaissance-level surveys of the site, there is no suitable riparian habitat within or adjacent to the project site that could be used as nesting habitat by this species. Furthermore, there are no records in the CNDDB below 2,000 feet in elevation anywhere in the Sierra Nevada (mostly due to nest parasitism by brown-headed cowbird). Therefore, the species has no potential to occur within the project site or otherwise be affected during nesting by the project.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Lanius ludovicianus	loggerhead shrike (nesting)	none/CSC/BCC	This species is found as a resident and wintering species throughout the lower elevation portions of California in grasslands, saltbush scrub, chaparral, oak savannah, and other open woodland types (generally where there are trees with dense cover for nesting).	**Low Potential.** There is suitable nesting habitat for the species (i.e., mixed oak and riparian woodland with dense stands of trees) located in the southeastern portion of the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than two miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to nest on the project site.
Baeolophus inornatus	Oak titmouse (nesting)	none/none/BCC	This species occurs as a common resident throughout much of California other than the deserts, high Sierra Nevada, and redwood belt. It is generally found in cismontane woodland (particularly oak or riparian woodlands) where it nests in the cavities created by woodpeckers.	**Moderate Potential.** There is suitable cismontane woodland for the species (i.e., mixed oak and riparian woodland) in the southeastern portion of the project site. Furthermore, there are potential nest sites (i.e., woodpecker-created nest holes) in this woodland. Lastly, there are records from the project vicinity in the eBird data base (i.e., less than two miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have a moderate potential to occur on the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Icteria virens	yellow-breasted chat (nesting)	none/CSC/none	This species is found as a summer resident mostly in low to mid-elevation coastal, valley, foothill, and desert riparian habitats (up to 4,800 feet in foothill riparian and 6,500 feet east of the Sierra Nevada). Nesting typically occurs in dense vegetation near streams.	**Low Potential.** There is suitable nesting habitat for the species (i.e., interrupted riparian woodland with dense stands of trees) located in the southeastern portion of the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than two miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to nest on the project site.
Chondestes grammacus	lark sparrow (nesting)	none/SA/none	This species occurs as a resident in the lowlands and foothills throughout much of California where it is found in cismontane woodland (especially oaks), open mixed chaparral, and valley and foothill grasslands with scattered trees.	**Low Potential.** There is suitable cismontane woodland for the species (i.e., mixed oak and riparian woodland) located in the southeastern portion of the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than two miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to nest on the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Spinus lawrencei	Lawrence's goldfinch (nesting)	none/none/BCC	This species is found as a breeding species in oak woodlands, other arid woodlands, and chaparral in the lower elevations of northern California and in riparian woodland, pinyon-juniper woodland, and lower montane communities in southern California. A local water source and a source of abundant seeds are required habitat components.	**Low Potential.** There is suitable cismontane woodland for the species (i.e., mixed oak and riparian woodland) located in the southeastern portion of the project site. Furthermore, there are records from the project vicinity in the eBird data base (i.e., less than two miles from the project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to nest on the project site.
MAMMALS				
Vulpes macrotis mutica	San Joaquin kit fox	FE/ST/none	This taxon is found in the San Joaquin Valley from Contra Costa County south to Kern County. It is also found in the dry interior valleys of the Coast Ranges (e.g., Salinas and Santa Clara valleys). It occurs in open, sparsely vegetated areas of low relief (typically in native or non-native grassland or alkali sink scrub).	**No Potential.** Though there is suitable habitat for the taxon on and adjacent to the project site (i.e., grassland), and it has been recorded 2.7 miles northwest and 4.8 miles southwest of the project site, there are no potential dens on the site that would be suitable for the taxon. The sandy onsite soils may preclude the creation and maintenance of larger burrows that do not collapse (hence the lack of California ground squirrel burrows). Therefore, the taxon is considered to have no potential to

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
				occur within the project site or otherwise be affected by the project.
Taxidea taxus	American badger	none/CSC/none	This species is found as a resident species at scattered localities throughout California (except in the coastal redwood region). Generally occurs in extensive, open habitats in the vicinity of abundant rodent populations.	**No Potential.** Though there is suitable habitat for the species on and adjacent to the project site (i.e., grassland), there are no potential dens on the site that would be suitable for the species. The sandy onsite soils may preclude the creation and maintenance of larger burrows that do not collapse (hence the lack of California ground squirrel burrows). Therefore, the species is considered to have no potential to occur within the project site or otherwise be affected by the project.
Antrozous pallidus	Pallid bat	none/CSC/none	This species is found as a resident in all desert, grassland, shrub, woodland, and forest habitats from sea level to approximately 6,000 feet. Day roosts are typically found in buildings, bridges, rocky outcrops, mines, caves, and trees. Night roosts are generally provided by bridges, mines, and caves.	**No Potential.** No suitable day or night roosts for the species occur on or immediately adjacent to the project site. Therefore, it has no potential to occur on the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
Eumops perotis californicus	Western mastiff bat	none/CSC/none	This subspecies is found as an uncommon resident in southern California, but also occurs along the lower west slope of the Sierra Nevada and in the interior Coast Ranges as far north as the Tumey Hills (eastern San Benito County). Roosts are typically found in crevices in cliff faces, cracks in boulders, or occasionally in buildings (particularly where the roost allows for a large vertical drop).	**No Potential.** No suitable day or night roosts for the species occur on or immediately adjacent to the project site. Therefore, it has no potential to occur on the project site.
Lasiurus blossevillii	Western red bat	none/CSC/none	This species occurs at scattered locations throughout the lowland portions of California west of the Sierra Nevada crest and desert regions (typically in riparian forest or orchards). It is less abundant at low and middle elevations in coniferous forest. Roosting sites are found in tree or shrub foliage between 2 and 40 ft above ground (typically in large cottonwoods, sycamores, walnuts, and willows).	**Low Potential.** There is suitable cismontane woodland for the species (i.e., mixed oak and riparian woodland) located in the southeastern portion of the project site. The large trees associated with this woodland could serve as roost sites – particularly during migration. Therefore, there is some potential, albeit low, for the species to occur on the project site.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site
FEDERAL				
	FE	Federally listed as Endangered		
	FT	Federally listed as Threatened		
	FPE	Federally proposed as Endangered		
	FPT	Federally proposed as Threatened		
	FC	Federal Candidate Species (former Category 1 candidates)		
	BCC	U.S. Fish and Wildlife Service designated “Birds of Conservation Concern” 2008		
STATE				
	SE	State listed as Endangered		
	ST	State listed as Threatened		
	SR	State listed as Rare		
	CFP	California Department of Fish and Game designated “Fully Protected”		
	CSC	California Department of Fish and Game designated “Species of Special Concern”		
	SA	California Department of Fish and Game designated “Special Animal”		
OTHER				
	CNPS List 1A	Plants presumed extinct in California		
	CNPS List 1B	Plants that are rare, threatened, or endangered in California and elsewhere		
	CNPS List 2	Plants that are rare, threatened, or endangered in California, but are more common elsewhere		
	CNPS List 3	Plants about which we need more information – a review list		
	CNPS List 4	Plants of limited distribution – a watch list		
	CNPS Threat Rank 0.1	Seriously threatened in California (high degree/immediacy of threat)		
	CNPS Threat Rank 0.2	Fairly threatened in California (moderate degree/immediacy of threat)		
	CNPS Threat Rank 0.3	Not very threatened in California (low degree/immediacy of threats or no current threats known)		

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT, TULARE COUNTY

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence on Project Site

LIKELIHOOD OF OCCURRENCE DEFINITIONS

Known to Occur	Taxon was observed within or immediately adjacent to the project site or has previously been documented within or immediately adjacent to the project site.
High Potential	Taxon has not been documented within or immediately adjacent to the project site, but should be expected on more than 50% of visits to suitable habitat on and near the project site during the appropriate season and time of day.
Moderate Potential	Taxon has not been documented within or immediately adjacent to the project site, but should be expected on less than 50% of visits to suitable habitat on and near the project site during the appropriate season and time of day.
Low Potential	Taxon has not been documented within or immediately adjacent to the project site nor is it likely to occur on or near the project site, but its presence cannot be completely discounted due to incomplete information on the taxon's distribution or habitat requirements.
No Potential	Taxon does not occur within or immediately adjacent to the project site due to the lack of required habitat features for the taxon, or the known range of the taxon is well defined and does not include the project vicinity.

APPENDIX D-2

McKay Point Reservoir – Biological Resources Report, Addendum No. 1
(Bumgardner Biological Consulting, 2021)

THIS PAGE IS INTENTIONALLY BLANK

Tulare Irrigation District
McKay Point Reservoir Project Biological Resources Evaluation,
Addendum No. 1
Tulare County, California
January 2021

Introduction

This report summarizes the results of year 2020 reconnaissance-level biological resources surveys, as well as other previous surveys (Bumgardner Biological Consulting 2011, 2013), conducted within and immediately adjacent to the site of the proposed McKay Point Reservoir Project (i.e., Project) in Tulare County, California (Figure 1). The Project site includes Assessor Parcel Numbers (APNs) 113-070-016 (in part), 113-080-005, 113-080-008, 113-090-001, and 113-100-002. The Project site lies 2.5 miles southwest of Lake Kaweah; 1.5 miles southeast of Bravo Lake; 1.0 miles northwest of the community of Lemon Cove; and 2.5 miles southwest of the community of Woodlake.

Project Description

The Tulare Irrigation District (TID), Consolidated Peoples Ditch Company (CPDC) and Visalia & Kaweah Water Company (VKWC)) are joint owners (Owners) of the approximately 200 acres of land adjacent to the Kaweah and St. Johns rivers that comprise the Project site. This land is commonly referred to as the McKay Point property.

The Owners propose to construct a new reservoir (i.e., McKay Point Reservoir) on the north side of the divergence of the Kaweah and St. Johns rivers near McKay Point. The McKay Point Reservoir would serve as a surface water storage/re-regulation facility (i.e., surface water management tool). The reservoir would occupy a surface area of approximately 180 acres and would have storage capacity of approximately 4,000 acre-feet. Depths of approximately 60 feet below ground surface (bgs) are proposed. Final slopes would be 3:1, horizontal:vertical (h:v), to minimize any bank erosion from wind and water.

The Project objectives include capturing and re-regulating water made available to the Owners Owners during flood releases from Lake Kaweah; capturing and re-regulating water entitlements belonging to the Owners released from Lake Kaweah; capturing and re-regulating water released for the Owners during peak power enhancement flows from the Terminus Hydropower Plant (Lake Kaweah); capturing and re-regulating any other water sources on the Kaweah River that may be made available to the Owners; allowing other entities with water rights on the Kaweah River to capture and/or re-regulate flows when designated by the Owners; allowing other entities to capture and/or re-regulate

flows of the Lower Kaweah River and St. Johns River for purposes of storm water runoff and flood prevention with permission of the Owners and Kaweah/St. Johns water rights interests; constructing the reservoir in such a way that revenue can be obtained to offset the construction and development costs; and locating the reservoir adjacent to the Kaweah River to allow for off-stream access to surface water storage, thus minimizing the need for pipelines.

Survey Methods

The Project site, the existing access road located on the adjacent Seaborn site, and other adjacent lands within approximately 250 feet of the sites are all considered part of the Project's biological study area (BSA) and were evaluated during the biological resources surveys in 2011, 2013, and 2020 to identify evidence of special-status plants and wildlife, rare or sensitive vegetation communities, and potential jurisdictional waters or wetlands that could be affected by the Project.

The Project was initially proposed in 2011 but was delayed. The proposed Project has since been reactivated and TID, as the lead CEQA agency, has requested that the biological surveys performed in 2011 and 2013 be updated since they are now several years old. The activities proposed for the Project site have not changed significantly since 2013. However, the sand and gravel removed from the Project site during construction of the reservoir would no longer be taken offsite to the CEMEX processing plant north of the Project site. The excavated aggregate would be processed on the Project site.

There is an existing haul road directly west of the Project site located on the Seaborn site. This road would provide ingress and egress to the Project site. Hence, in addition to updating the biological resources information for the Project site, the existing access road and the areas adjacent to it located on the Seaborn site are also addressed by this report and considered part of the BSA.

The Project site and adjacent lands were surveyed by me (Michael Bumgardner, Bumgardner Biological Consulting) on May 16, 2011 and September 18, 2013. A more recent survey of the Project site (i.e., on October 15, 2020) was again conducted by me. However, the latter survey also included the existing access road on the Seaborn site (as identified above). The surveys of the BSA were conducted on foot as random meander transects, where possible, such that all potentially affected lands could be effectively evaluated. Where random meander transects were not possible, portions of the BSA were surveyed from the nearest private property boundary or through "windshield surveys." Gross-scale mapping of the vegetation communities on the Project site was conducted given that only three discernible vegetation communities occur on the site. The latter

level of mapping of the extant vegetation communities was continued for the access road on the Seaborn site (Figure 2).

An onsite search for evidence of special-status plant and wildlife species was conducted and focused on local taxa that have been recorded in the California Natural Diversity Database (CNDDB) or California Native Plant Society's (CNPS) Online Inventory of Rare and Endangered Plants during the 2011 and 2013 surveys. This data was updated in 2020.

The October 15, 2020 survey of the Project and adjacent areas was conducted mostly as a "windshield survey" to achieve two purposes: (1) to confirm that no substantive changes had occurred to the Project site since the 2013 survey and (2) to identify the extant vegetation communities adjacent to the existing access road on the Seaborn site and evaluate their potential to support special-status plant and wildlife species. However, a more focused survey (i.e., linear transects on 100-foot centers) was conducted by me and Tulare Irrigation District (TID) staff Jeremy Barroll and Riley Nolan (under my direction) on October 15, 2020. The latter survey was focused on finding evidence of burrowing owl, San Joaquin kit fox, and American badger.

Lastly, a reconnaissance-level search for waters with regulatory jurisdiction under the Clean Water Act, California Fish and Game Code, and/or Porter-Cologne Water Quality Control Act was conducted within the Project site boundaries.

Analytical Methods

An updated nine-quadrangle CNDDB/Rarefind 5 report was generated for the Project site (i.e., query of the USGS 7.5-minute topographic quadrangle in which the Project site is found, as well as the immediate eight surrounding topographic quadrangles, viz. Woodlake and the surrounding Stokes Mountain, Ivanhoe, Exeter, Auckland, Rocky Hill, Shadequarter Mountain, Kaweah, and Chickencoop Canyon quads). The CNDDB contains records for special-status species, as well as sensitive natural communities, which have been reported to the California Department of Fish and Wildlife (CDFW). The Rarefind 5 report for the Project site is provided in Appendix A. Each of the species identified in the Rarefind 5 report were then evaluated in terms of their likelihood of occurrence within the BSA. This evaluation considered the known distribution and habitat requirements of the species such that one of the following findings was prepared:

- Known to Occur – species was observed within or immediately adjacent to the Project site during the May 16, 2011, September 18, 2013, or October 15, 2020 survey or has previously been documented within or immediately adjacent to the Project site.

- High Potential – species has not been documented within or immediately adjacent to the Project site but should be expected on more than 50% of visits to suitable habitat in the Project site during the appropriate season and time of day.
- Moderate Potential – species has not been documented within or immediately adjacent to the Project site but should be expected on less than 50% of visits to suitable habitat in the Project site during the appropriate season and time of day.
- Low Potential – species has not been documented within or immediately adjacent to the Project site nor is it likely to occur on the Project site, but its presence cannot be completely discounted due to incomplete information on the taxon's distribution or habitat requirements.
- No Potential – species does not occur within the Project site due to the lack of required habitat features for the species or the known range of the species is well defined and does not include the Project site.

The findings for each of the species identified in the Rarefind 5 report are presented in this report.

Other sources of information on special-status species in California were subsequently reviewed given that the CNDDB is not inclusive of all special-status species that may occur in an area. This review was based on my professional experience within the region and elsewhere in California, but also included review of other published sources of information on special-status species in California. These latter sources include the following:

- The Jepson Manual: Vascular Plants of California (Baldwin and Goldman 2012).
- California Native Plant Society (CNPS), Rare Plant Program. 2020. Inventory of Rare and Endangered Plants of California (online edition, v8-03 0.39). website http://www.rareplants.cnps.org (Accessed: October 26, 2020).
- Amphibian and Reptile Species of Special Concern in California (Jennings and Hayes 1994).
- California Herps - A Guide to the Amphibians and Reptiles of California. (Nafis 2020) available at: http://www.californiaherps.com/ (Accessed October 26, 2020).
- California Bird Species of Special Concern. Studies of Western Birds 1. Western Field Ornithologists, Camarillo, California and California Department of Fish and Game (Shuford and Gardali 2008).

- California Birds: Their Status and Distribution (Small 1994).

- California's Wildlife Volume II Birds (Zeiner et al. 1990).
- eBird. 2020. eBird: An online database of bird distribution and abundance [web application]. eBird, Ithaca, New York. Available: http://www.ebird.org. (Accessed: October 26, 2020).
- Mammalian Species of Special Concern in California (Williams 1986).
- Terrestrial Mammal Species of Special Concern in California (unfinished 1998 update) (Bolster 1998).
- Mammals of the Pacific States: California, Oregon, and Washington (Ingles 1978).
- Western Bat Working Group website (http://wbwg.org/western-bat-species/).
- Recovery Plan for Upland Species of the San Joaquin Valley, California (USFWS 1998).

Species that are known or expected to occur in the vicinity of the Project site were then further evaluated in this report.

Vegetation Communities and Site Characteristics

The description of the vegetation communities within the Project site, as described in the *Tulare Irrigation District, McKay Point Reservoir Project Biological Resources Evaluation, Tulare County, California* (Bumgardner Biological Consulting 2013), is still valid as the October 15, 2020 survey found no substantive changes in the type or distribution of the onsite vegetation communities have occurred since 2013. Hence, the description and mapping of the vegetation communities described in the *Tulare Irrigation District, McKay Point Reservoir Project Biological Resources Evaluation, Tulare County, California* (Bumgardner Biological Consulting 2013) are herein incorporated by reference.

The areas within the north/northeastern portion of the Seaborn site (adjacent to the existing access road) have been used most recently to support aggregate mining and processing. As such most of the northeastern portion of the property consists of developed land uses and is barren or supports no discernible vegetation communities (Figure 2). Scattered vegetation within this portion of the Seaborn site includes but is not limited to ruderal species such as lamb's-quarters [*Chenopodium album*], deer weed [*Acmispon glaber*], common bindweed [*Convolvulus arvensis*], telegraph weed [*Heterotheca grandiflora*] and various annual grasses.

The existing access road within the Seaborn site runs along the northern boundary of the site. Vegetation along the road consists almost entirely of non-native annual grassland. Though this vegetation community supports some weedy species (e.g., broadleaf filaree

[*Erodium botrys*] and common fiddleneck [*Amsinckia menziesii*]), most of the vegetative cover is composed of non-native annual grasses (e.g., wild oat [*Avena fatua*], rattail fescue [*Vulpia myuros*], bromes [*Bromus* spp.], etc.). This latter stand of vegetation encompasses approximately 41 acres.

All other land cover adjacent to the existing access road (i.e., within 250 feet of the road) is associated with various agricultural uses (orchard, row crops, etc.).

Jurisdictional Wetlands and Other Waters

Jurisdictional wetlands or other waters of the United States are areas that cannot be dredged or filled without a permit from the U.S. Environmental Protection Agency or U.S. Army Corps of Engineers (this latter permit is commonly referred to as a "Section 404" permit in reference to the section of the federal Clean Water Act that requires such permits). Actions that require issuance of a "Section 404" permit include earth-moving activities that result in fill of jurisdictional wetlands and other waters. It should be noted that such actions may also require the issuance of state permits (e.g., California Fish and Game Code Section 1602 lake and streambed alteration agreement and/or Regional Water Quality Control Board Section (RWQCB) Section 401 clean water certification).

Wetlands or other waters of the United States are identified based on three criteria, viz. (1) soil characteristics, (2) hydrology, and (3) plant species. The U.S. Army Corps of Engineers (USACE) has developed a procedure and manual for delineating wetlands that requires comprehensive evaluation of these three criteria during field environmental assessments. A formal wetland delineation was not conducted for the purposes of this report. However, no waters that are clearly subject to the jurisdiction of the USACE, CDFW, or RWQCB, other than the St. Johns and Kaweah Rivers, occur on or immediately adjacent to the Project or Seaborn sites. The only potential exception to this latter finding is that the "daylighted" groundwaters that occur within the Seaborn site may now be jurisdictional based on the Waters of the State regulations that were approved by the Office of Administrative Law and became effective on May 28, 2020. As such, a determination of whether jurisdictional waters occur within the Seaborn site is beyond the reach of this document and will be addressed elsewhere by individuals that are more familiar with the current law and regulations addressing this issue.

Habitat Conservation Plans and Other Similar Habitat Management Plans

There are no Habitat Conservation Plans (HCPs), Natural Community Conservation Plans (NCCPs), or other approved local, regional, or state habitat conservation plans that apply to the Project site.

Special-Status Plant Species

The likelihood of occurrence evaluation for special-status plants provided in the *Tulare Irrigation District, McKay Point Reservoir Project Biological Resources Evaluation, Tulare County, California* (Bumgardner Biological Consulting 2013), which did not address the Seaborn site, now addresses both the Project site, the areas adjacent to the existing access road on the Seaborn site, and other areas adjacent to the Project site (i.e., BSA). No special-status plant taxa, as described in Table 1, are associated with the BSA. Nor were any special-status plant taxa observed on or immediately adjacent to the BSA during the October 15, 2020 survey. All special-status plants that occur in the region have been discounted from having any potential to occur within the BSA due to lack of suitable habitat and/or the distribution of the taxon is well known and does not include the BSA.

Special-Status Wildlife Species

The likelihood of occurrence evaluation for special-status wildlife provided in the *Tulare Irrigation District, McKay Point Reservoir Project Biological Resources Evaluation, Tulare County, California* (Bumgardner Biological Consulting 2013), which did not address the Seaborn site, now addresses both the Project site, the areas adjacent to the existing access road on the Seaborn site, and other areas adjacent to the Project site . No special-status wildlife species were observed within the BSA during the October 15, 2020 survey. However, 16 special-status wildlife species that have been documented in the Project region (Table 1) are now considered to have some potential to occur in the BSA. Three (3) of these species are insects (i.e., Moestan blister beetle [*Lytta moesta*], Morrison's blister beetle [*Lytta morrisoni*], and Tulare cuckoo wasp [*Chrysis tularensis*]) that are not well known in terms of their life history and behavior, but that have been recorded in the Project vicinity in habitats like those that occur in the BSA. As such, they cannot be discounted and are considered to have some potential, albeit low, to occur in the BSA.

The previous biological resources evaluations for the Project site (Bumgardner Biological Consulting 2013, Entomological Consulting Services 2014) found evidence that a fourth special-status insect taxon (i.e., valley elderberry longhorn beetle [VELB] [*Desmocerus californicus dimorphus*]) occurs within the BSA. However, the U.S. Fish and Wildlife Service's (USFWS) review of records within the southern portion of the subspecies presumed historic range found that records for VELB's "sister subspecies" *Desmocerus californicus* had been inappropriately attributed to VELB. The USFWS subsequently removed Tulare, Kern, and Kings counties from the presumed historic range of the subspecies (USFWS 2014). VELB is therefore no longer considered a special-status species that may be affected by the Project.

Crotch bumble bee [*Bombus crotchii*] is another special-status insect species that is considered to have some potential to occur within the BSA. This finding is based on the species' historic distribution and presence of suitable habitat (e.g., relatively warm and dry sites in open grassland and scrub habitats) within the BSA. Nests of this species are often typically located underground in abandoned rodent nests, or above ground in tufts of grass, old bird nests, rock piles, or cavities in dead trees. As such, there are many places within the BSA that could be used for nesting by this species. However, given the species rapidly declining range it is not considered to have more than a low potential to occur within the BSA.

Two (2) special-status reptiles (i.e., western pond turtle [*Actinemys marmorata* formerly *Emys marmorata*] and Northern California legless lizard [*Anniella pulchra*]) are believed to have some potential, albeit low, to occur in the BSA. Regarding western pond turtle, it has been known to occur in a wide variety of still or slow-moving waters throughout California. The nearest known occurrences to the BSA are from upstream in the Kaweah River drainage. Thus, the species is considered to have some potential to occur in the aquatic habitats of the adjacent Kaweah and St. Johns rivers Lastly, the species could nest in various upland portions of the BSA.

The potential for California legless lizard to occur in the BSA is believed to be limited to the non-native annual grassland on the Project site, mainly due to the suitable soils (i.e., sands and sandy loam) that are located on the Project site. The nearest known location for the species, Kaweah Oaks Preserve, is less than 8 miles southwest of the Project site and connected via the Kaweah River corridor. Furthermore, the secretive nature of the species often results in failure to document extant occurrences. It may then occur at locations in the Project vicinity where searches for the species have simply not been conducted. As such, it is considered to have at least a low potential to occur within the BSA.

Nine (9) special-status birds are considered to have some potential to occur within the BSA. Five (5) of these latter species (Cooper's hawk [*Accipiter cooperii*], white-tailed kite [*Elanus leucurus*], loggerhead shrike [*Lanius ludovicianus*], oak titmouse [*Baeolophus inornatus*], and Lawrence's goldfinch [*Spinus lawrencei*]) are known to nest in oak or riparian woodlands. Furthermore, each of these species has been recorded nesting within less than 2 miles of the BSA. As such, each of these species, is considered to have either a low or moderate potential to nest or winter (e.g., white-tailed kite) within the BSA.

Other special-status bird species with some potential to occur in the BSA include ferruginous hawk [*Buteo regalis*], merlin [*Falco columbarius*], golden eagle [*Aquila chrysaetos*], and burrowing owl [*Athene cunicularia*].

Three (3) of the latter special-status avian species with some potential to occur within the BSA are strictly wintering species. These species (e.g., ferruginous hawk, merlin, and golden eagle) tend to be wide-ranging, often utilize fallow agricultural fields or similar open vegetation communities (e.g., annual grassland) and have substantial acreage of suitable wintering habitat within the Project vicinity. Winter occurrences of each of these species have been documented within less than 2 miles of the BSA. Therefore, these species can be expected to occur within the BSA on at least an occasional basis.

No evidence of burrowing owl (e.g., urates, regurgitated fur and feather pellets, feathers, prey remains, etc.) has been found in the BSA. In addition, no suitable burrows or burrow surrogates that could be used by the species were found within the BSA. However, California ground squirrel [*Otospermophilus beecheyi*] burrows were observed immediately offsite on the northern and eastern boundaries of the Project site. In addition, scattered California ground squirrel burrows were found in the non-native annual grassland adjacent to the existing access road along the northern boundary of the Seaborn site. However, most of these burrows had been abandoned by the ground squirrels and showed no use by any other large vertebrate species (i.e., most contained substantial cobwebs and plant debris). As such, there is potential for the species to occur adjacent to the existing access road at some point in the future and the species is considered to have at least a low potential to occur in the BSA.

Another special-status taxon that often utilizes California ground squirrel burrows is San Joaquin kit fox [*Vulpes macrotis mutica*]. The burrowing owl surveys found no evidence of this taxon in the BSA. However, this is not unexpected as the taxon does not normally range much north of Kern County on the east side of the San Joaquin Valley (i.e., it occurs principally in the "rain shadow" of the west side of the San Joaquin Valley). The nearest CNDDB occurrence of the taxon is attributed to Woodlake and is 1.5 miles northwest of the BSA. The next five nearest CNDDB occurrences are approximately 4 to 9 miles west of the BSA in the vicinity of Ivanhoe. Therefore, there is some potential for San Joaquin kit fox to occur in the BSA (mostly the western-most portions of the site), but the potential is considered low.

Designated Critical Habitat

When a species is proposed for listing as endangered or threatened under the Endangered Species Act, the USFWS and National Marine Fisheries Service (NMFS) must consider whether there are areas of habitat believed to be essential to the species' conservation. Those areas may be proposed for designation as critical habitat. Only activities that involve a federal permit, license, funding, or authorization (i.e., federal nexus) and are likely to destroy or adversely modify an area of critical habitat can be affected by the designation. In such a case, the USFWS and NMFS typically work with the appropriate federal lead agency, as well as private or other landowners (when appropriate), to amend

their project to allow it to proceed without adversely affecting the critical habitat. Thus, most projects with a federal nexus are likely to go forward, but some may be modified to minimize harm to critical habitat. Regarding the McKay Point Reservoir Project, there is no critical habitat that has been designated that includes the Project or Seaborn sites. Therefore, this issue is not addressed further in this biological resources evaluation.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
		PLANTS		
Atriplex cordulata var. *erecticaulis*	Earlimart orache	none/none/CNPS list 1B.2	This annual saltbush occurs on saline or alkaline soils in valley and foothill grassland. It is known from Kings, Kern, and Tulare counties. It blooms from August to November.	**No Potential.** No individuals of this taxon were observed within the BSA. In addition, the taxon only occurs on saline or alkaline soils in valley and foothill grassland – conditions that do not exist within the BSA. Therefore, the taxon has no potential to occur within the BSA.
Atriplex minuscula	lesser saltscale	none/none/CNPS list 1B.1	This annual saltbush grows in sandy alkaline areas in chenopod scrub, playas, and valley and foothill grassland. It is known from Alameda, Butte, Fresno, Kern, Madera, Merced, Stanislaus, and Tulare counties. It blooms from May to October.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs on sandy alkaline soils in chenopod scrub, playas, and valley and foothill grassland – conditions that do not exist within the BSA. Therefore, the species has no potential to occur within the BSA.
Atriplex persistens	vernal pool smallscale	none/none/CNPS list 1B.2	This annual saltbush occurs in claypan and alkaline vernal pools and alkaline	**No Potential.** No individuals of this species were observed within the BSA. In

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Diplacus pictus (formerly *Mimulus pictus*)	calico monkeyflower	none/none/CNPS list 1B.2	This annual herb occurs on granitic soils (often in disturbed areas) in broad-leafed upland forest and cismontane woodland. It has been found in Kern and Tulare counties. It blooms from March to May.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs on granitic soils in broad-leafed upland forest – conditions that do not exist within the BSA. Therefore, the species has no potential to occur in the BSA.
Eriogonum nudum var. *murinum*	mouse buckwheat	none/none/CNPS list 1B.2	This perennial herb occurs on sandy soils in chaparral, cismontane woodland, and valley and foothill grassland. It known from only 11 occurrences – all in Tulare County. It blooms from June to November.	**No Potential.** No individuals of this taxon were observed within the BSA. The taxon occurs on sandy soils in valley and foothill grassland – conditions that exist within the BSA. However, all known records are from the Three Rivers area well upstream in the Kaweah River drainage. Therefore, the taxon is considered to have no potential to occur within the BSA.
Eryngium spinosepalum	spiny-sepaled button-celery	none/none/CNPS list 1B.2	This perennial species occurs in and vernal pools, wet valley and foothill grassland, swales, and similar wetland habitats. Known occurrences have been documented in the San Joaquin	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs in alkaline areas in wet valley and foothill grassland and vernal pools – conditions that do not

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			Valley (Kern to Stanislaus counties), along the Central Coast (Monterey and San Luis Obispo counties). Blooming occurs from April to May.	exist within the BSA. Therefore, the species has no potential to occur in the BSA.
Euphorbia hooveri (formerly *Chamaesyce hooveri*)	Hoover's spurge	FT/none/CNPS list 1B.2	This annual herb occurs in association with large vernal pools. It has been recorded in Merced, Stanislaus, Butte, Glenn, Tulare, and Tehama counties but may be extirpated in Tulare County. It blooms mostly during July, but sometimes into October if there is sufficient moisture.	**No Potential.** No individuals of this species were observed within the BSA. In addition, suitable habitat (i.e., large vernal pools) does not occur within or near the BSA. Therefore, the species has no potential to occur the BSA.
Fritillaria striata	striped adobe-lily	none/SE/CNPS list 1B.1	This perennial bulbiferous herb occurs in cismontane woodland and valley and foothill grassland (usually on clay soils). It is known from Kern and Tulare counties. It blooms from February to April.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs in cismontane woodland and valley and foothill grassland (usually on clay soils) – conditions that do not exist within the BSA. Therefore, the species has no potential to occur within the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Glyceria grandis	American manna grass	none/none/CNPS list 2.3	This perennial rhizomatous grass occurs in bogs and fens, meadows and seeps, and marshes and swamps. It is known from El Dorado, Fresno, Humboldt, Mendocino, Mono, Placer, and Tulare counties. It blooms from June to August.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs in bogs and fens, meadows and seeps, and marshes and swamps – conditions that do not exist within the BSA. Therefore, the species has no potential to occur in the BSA.
Helianthus winteri	Winter's sunflower	none/none/CNPS list 1B.2	This perennial shrub occurs in open, ungrazed foothill woodlands and annual grasslands on well-drained, granitic soils, generally on lower-elevation, south-facing foothill slopes. It is known from Fresno and Tulare counties where it blooms year-round.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs in open, ungrazed foothill woodlands and annual grasslands on well-drained, granitic soils, generally on lower-elevation, south-facing foothill slopes. Therefore, the species has no potential to occur in the BSA.
Lasthenia chrysantha	alkali-sink goldfields	none/none/CNPS list 1B.1	This annual herb occurs in vernal pools and on alkali flats. It has been found in Fresno, Kings, Kern, Lake, Madera, Merced, Placer, Solano, Stanislaus, and Tulare counties. It blooms from February to June.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs in vernal pools and on alkali flats. Therefore, the species has no potential to occur within the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Lasthenia glabrata ssp. *coulteri*	Coulter's goldfields	none/none/CNPS list 1B.1	This annual taxon is associated with heavy soils, vernal pools, low alkaline fields and hillsides, and alkaline marshes in Colusa, Kern, Los Angeles, Merced, Orange, Riverside, Santa Barbara, San Bernardino, San Diego, San Luis Obispo, Tehama, Tulare, Ventura, and Yolo counties. It blooms from February to June.	**No Potential.** No individuals of this species were observed within the BSA. In addition, suitable habitat for the taxon (alkaline marshes and other wet alkaline habitats) does not exist within the BSA. Therefore, the species has no potential to occur in the BSA.
Mimulus norrisii	Kaweah monkeyflower	none/none/CNPS list 1B.3	This annual herb occurs on carbonate or rocky soils in chaparral and cismontane woodland. It has been found in Fresno and Tulare counties. It blooms from March to May.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs on carbonate or rocky soils in cismontane woodland and chaparral – conditions that do not exist within the BSA. Therefore, the species has no potential to occur in the BSA.
Orcuttia inaequalis	San Joaquin Valley orcutt grass	FT/SE/CNPS list 1B.1	This grass occurs in vernal pools (typically larger or more persistent pools) within valley and foothill grassland. The remaining populations	**No Potential.** No individuals of this species were observed within the BSA. In addition, it only occurs in vernal pools in valley and foothill grassland – conditions

TABLE 1

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			of this species occur mostly in the southeastern San Joaquin Valley (Fresno, Merced, Madera, and Tulare counties). Historically, the species also occurred in Stanislaus County. It blooms from April to September.	that do not exist within the BSA. Therefore, the species has no potential to occur in the BSA.
Pseudobahia bahiifolia	Hartweg's golden sunburst	FE/SE/CNPS list 1B.1	This species occurs in cismontane woodland and valley and foothill grassland (almost always on shallow, well-drained, fine-textured soils - typically on clay, acidic soils) on the north or northeast facing side of Mima mounds). It has been recorded in Fresno, Madera, Merced, Stanislaus, Tuolumne, and Yuba counties. Blooming occurs from March to April.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs in cismontane woodland and valley and foothill grassland on the north or northeast facing side of Mima mounds – conditions that do not exist within the BSA. Therefore, the species has no potential to occur in the BSA.
Pseudobahia peirsonii	San Joaquin adobe sunburst	FT/SE/CNPS list 1B.1	The species is known from a few mostly small occurrences along the southeastern side of the San Joaquin Valley in the interface with the Sierra Nevada foothills. It occurs on heavy clay soils in valley and foothill	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs on heavy adobe clay soils in oak woodland and valley and foothill grassland – conditions that do not exist within the BSA. Therefore, the

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			grassland and oak woodland. It has been recorded in Fresno, Tulare, Kern, and Los Angeles counties. Blooming occurs from February to April.	species has no potential to occur in the BSA.
Sagittaria sanfordii	Sanford's arrowhead	none/none/CNPS list 1B.2	This perennial species occurs in shallow, standing, fresh water and slow-moving waterways (e.g., marshes, ponds, vernal pools, lakes, reservoirs, sloughs, ditches, unlined canals, streams, and rivers) at elevations below 2000 feet. It blooms from late May to August.	**No Potential.** No individuals of this species were observed within the BSA. The species occurs in shallow, standing, fresh water and slow-moving waterways (e.g., marshes, ponds, vernal pools, lakes, reservoirs, sloughs, ditches, unlined canals, streams, and rivers). Such habitat (i.e., standing or slow-moving waters does not occur in the BSA. Therefore, the species has no potential to occur in the BSA.
Tuctoria greenei	Greene's tuctoria	FE/SR/CNPS list 1B.1	This grass occurs in the bottom of drying vernal pools in valley and foothill grassland. It is currently known from Butte, Colusa, Glenn, Merced, Modoc, Shasta, and Tehama counties, but has previously occurred in Fresno, Madera, San Joaquin, Stanislaus, and Tulare counties where	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs in vernal pools in valley and foothill grassland – conditions that do not exist within the BSA. Therefore, the species has no potential to occur in the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			it is now believed to be extirpated. It blooms from May to September.	
INVERTEBRATES				
Branchinecta lynchi	vernal pool fairy shrimp	FT/none/none	This species occurs primarily in vernal pools (sandstone depression, grass swale, earth slump, or basalt-flow depression pools) in grassland and oak savannah of the Central Valley. However, the species also occurs at a small number of locations in the central Coast Ranges from Monterey County to Santa Barbara County as well as Riverside County.	**No Potential.** There is no suitable vernal habitat within or adjacent to the BSA for this species. Therefore, there is no potential for the species to be affected by the Project.
Lepidurus packardi	vernal pool tadpole shrimp	FE/none/none	This species inhabits clear to turbid vernal pools and swales in the Sacramento Valley and northern San Joaquin Valley.	**No Potential.** There is no suitable vernal habitat within the BSA for this species. Therefore, there is no potential for the species to be affected by the Project.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Linderiella occidentalis	California fairy shrimp	none/SA/none	Occurs primarily in vernal pools and other seasonal wetlands in grassland and oak savannah of the Central Valley. However, the species has also been recorded at scattered locations in the Coast Ranges from Mendocino County south to Ventura County.	**No Potential.** There is no suitable vernal habitat within the BSA for this species. Therefore, there is no potential for the species to be affected by the Project.
Talanites moodyae	Moody's gnaphosid spider	none/SA/none	Little is known and published about this species. However, it has been found in grasslands under rocks (generally serpentine) on rocky mounts, buttes, and hilltops. Only six known occurrences are reported – all from Fresno and Tulare counties.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species only occurs on rocky mounts, buttes, or hilltops (usually under serpentine rocks) – conditions that do not exist within the BSA. Therefore, the species has no potential to occur within either of the two sites.
Lytta moesta	Moestan blister beetle	none/SA/none	The range of this species is not well known, but occurrences have been documented in Fresno, Kern, Madera, Santa Cruz, Stanislaus, and Tulare counties. The CDFW reports that little is known about the life history and	**Low Potential.** Given that ground-nesting solitary bees (i.e., beetle's host species) are widely distributed in California and little is known about this species' life history and behavior, it cannot be discounted as not occurring within the BSA. Therefore, it is

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			behavior of this species. However, it has been collected from March to September and has typically been found in association with its host species (i.e., the species' larvae feed on the pollen stores that ground-nesting solitary bees have provided for their own larvae).	considered to have some potential, albeit low, to occur on the BSA.
Lytta morrisoni	Morrison's blister beetle	none/SA/none	The range of this species is not well known, but occurrences have been documented in the southern San Joaquin Valley in Kern, Fresno, Tulare, San Benito, and San Luis Obispo counties. The CDFW reports that life history and behavior information for the species does not exist. However, it has typically been found in association with its host species (i.e., the species' larvae feed on the pollen stores that ground-nesting solitary bees have provided for their own larvae).	**Low Potential.** Given that ground-nesting solitary bees (i.e., beetle's host species) are widely distributed in California and little is known about this species' life history and behavior, it cannot be discounted as not occurring within the BSA. Therefore, the species has some potential, albeit low, to occur within either of the two sites.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Desmocerus californicus dimorphus	valley elderberry longhorn beetle	FT/none/none	This subspecies occurs at scattered locations in the Central Valley and adjacent foothills of the Sierra Nevada and Coast Ranges. It is entirely dependent upon its host plant (i.e., elderberry spp.) and is only found where this shrub occurs (typically in riparian vegetation associations, but occasionally in single, isolated shrubs or stands of the plant). The southern limit of its range in and near the San Joaquin Valley now only extends to Fresno County.	**No Potential.** Many old growth elderryberry shrubs occur within the Project site and observations of valley longhorn beetles and their exit holes at the site were tentatively assigned to the listed subspecies in 2014. However, review by the USFWS has subsequently resulted in the removal of Kings, Kern, and Tulare counties from the subspecies' presumed historic range. Therefore, the subspecies has no potential to occur within the BSA.
Chrysis tularensis	Tulare cuckoo wasp	none/SA/none	This species is known only from a small series of specimens that have been collected in Amador, Fresno, Monterey, and Tulare counties. Cuckoo wasps are nest parasitoids of predatory wasps and sawflies. However, the host species of this species are unknown. Adults have been found from April to June in open,	**Low Potential.** Given that predatory wasps and sawflies (i.e., wasp's host species) are widely distributed in California and little is known about this species' life history and behavior, it cannot be discounted from occurring within the BSA. Furthermore, the nearest known record to the Project site is from north of Road 212 and Avenue 344 (less than 3 miles from the Project site).

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			sunny habitats with abundant flowers and small shrubs, where they feed on nectar.	Therefore, it is considered to have some potential, albeit low, to occur within the BSA.
Bombus crotchii	Crotch bumble bee	none/SA/none	This species occurs from coastal California east to the Sierra Nevada-Cascade crest. It occurs at relatively warm and dry sites in open grassland and scrub habitats. Colonies are annual and only the new, mated queens overwinter. Nests are often located underground in abandoned rodent nests, or above ground in tufts of grass, old bird nests, rock piles, or cavities in dead trees.	**Low Potential.** Given this species' historic distribution and the lack of focused species-specific surveys, it cannot be discounted from occurring on the Project site. Therefore, it is considered to have some potential, albeit low, to occur within the BSA.
AMPHIBIANS				
Ambystoma californiense	California tiger salamander	FT/ST/none	This species is found in annual grassland, oak savannah, and coastal sage scrub adjacent to vernal pools, stock ponds, and ponded reaches of ephemeral streams (aquatic breeding	**No Potential.** No suitable aquatic breeding habitat for the species (i.e., vernal pools or other seasonal wetlands) occurs within the BSA. Furthermore, the nearest known occurrences of the species (at and near the

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			sites). The species is patchily distributed in the Central Valley from Yolo County to Kings County, but also occurs in Alameda and Contra Costa counties south through the interior valleys of the Coast Ranges. Disjunct populations occur in Santa Barbara County and Sonoma County.	Stone Corral Ecological Reserve east of Yettem) are more than 11 miles west of the Project site. Lastly, the BSA is landlocked by agricultural land uses that would preclude the species from reaching the two sites from offsite wetlands that could be used by the species. Therefore, it has no potential to occur within the BSA.
Batrachoseps regius	Kings River slender salamander	none/SA/none	This species has been found in Fresno County on the south and east sides of the North Fork of the Kings River and at Summit Meadow in the drainage of the South Fork of the Kings River. It has also been found in the drainage of the middle fork of the Kaweah River in Tulare County. It occurs in talus, under rocks and downed logs, and in leaf litter in chaparral, cismontane woodland, and montane coniferous forest above 1,100 and 8,100 feet in elevation.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species has only been recorded in talus, under rocks, under downed logs, and in leaf litter in chaparral, cismontane woodland, and montane coniferous forest between 1,100 and 8,100 feet in elevation– conditions that do not exist within the BSA. Therefore, the species has no potential to occur within the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Rana boylii	foothill yellow-legged frog (East/Southern Sierra Clade)	none/SE/none	This species was historically distributed throughout the foothill portions of the Sierra Nevada and Coast Ranges drainages from the Oregon border to the San Gabriel River (Los Angeles County). The species requires shallow, small to moderate streams (typically perennial waters with some cobble-sized substrate and riffle habitat above 600 feet in elevation and without bullfrogs). The East/Southern Sierra Clade extends from the South Fork American River Subbasin to where the Sierra Nevada meet the Tehachapi Mountains.	**No Potential.** No individuals of this species were observed within the BSA. In addition, the species requires shallow, small to moderate streams (typically perennial waters) with some cobble-sized substrate and riffle habitat above 600 feet in elevation and without bullfrogs – conditions that do not exist within the BSA. Therefore, the species has no potential to occur within the BSA.
Lithobates pipiens	northern leopard frog (native populations only)	none/CSC/none	Historical populations of this species in California existed in scattered locations below 6,500 feet in Siskiyou and Modoc counties and in the northern Owens Valley. Individuals of unknown origin were introduced into El Dorado, Kern, Los Angeles,	**No Potential.** No individuals of this species were observed within the BSA. In addition, the only known population in the region, recorded near Orosi in Tulare County, is an introduced population and is therefore not a special-status species. Hence, there is no available information to

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			Merced, San Francisco, Sierra, Tehama, and Tulare counties between 1905 and 1970. Several of these introduced populations experienced rapid growth and range expansions before completely disappearing. Except for a small population that is currently present in Merced County, all these introduced populations have perished. It has been found in grassland, wet meadows, potholes, forests, woodland, brushlands, springs, canals, bogs, marshes, reservoirs (generally where there is permanent water with abundant aquatic vegetation).	suggest that any native populations have the potential to occur within the BSA.
Spea hammondii	western spadefoot	none/CSC/none	This species is found in dry habitats (e.g., annual grassland, oak savannah and woodland, and coastal sage scrub) adjacent to vernal pools, stock ponds, and overflow channels of low-gradient drainages within the Central Valley and coastal California from Monterey	**No Potential.** No suitable aquatic breeding habitat for the species occurs within the BSA. Furthermore, the BSA is relatively landlocked by semi-perennial rivers, sand and gravel mining operations, and agricultural uses that would preclude movement of the species from more suitable habitats located in the Project

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			County to San Diego County.	vicinity (e.g., lands north of Highway 216). Consequently, the species is considered to have no potential to occur within the BSA.
REPTILES				
Actinemys marmorata formerly *Emys marmorata*	western pond turtle	none/CSC/none	This species historically occurred throughout most of the Pacific-slope drainages in California (below approximately 4,000 feet). The species now occurs at scattered locations throughout its former range (primarily in the central Sierra Nevada foothills, Central Valley, San Francisco Bay area, and north-central coast and Coast Ranges. It occurs in and adjacent to ponds, reservoirs, or other slow-moving perennial aquatic habitats (e.g., sloughs, streams, and rivers). The species may be active year-round in some parts of its range.	**Low Potential.** Given that potentially suitable habitat is provided by the adjacent Kaweah and St. Johns rivers and the species has been recorded upstream in the Kaweah River, it cannot be discounted from occurring within BSA. In addition, individuals could also occur in the upland portions of the BSA during egg-laying. Therefore, it is considered to have some potential, albeit low, to occur within the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Anniella pulchra	Northern California legless lizard	none/CSC/none	This species occurs as a fossorial species in sand, sandy loam, or leaf-mold substrates. It can be found in a variety of habitats that include coastal beach, chaparral, pine-oak woodland, and riparian habitats. Soil moisture is essential. It appears to be active mostly during the morning and evening, just beneath the surface of sunlight-warmed substrate. It may also be active on the surface at night when substrate temperatures remain warm for extended intervals. It should be noted that recent mitochondrial and nuclear DNA work has resulted in the species being split into five distinct species with the local species (*A. pulchra*) occurring only along the coast, in the Coastal Ranges as far south as northwestern Ventura County and in parts of the San Joaquin Valley.	**Low Potential.** No individuals of this species were observed during the reconnaissance-level surveys of the BSA. However, there is a relatively recent occurrence (2015) documented in the CNDDB from about 0.2 miles northwest of Highway 198 at Road 180, in the vicinity of Outside Creek and Johnson Slough, about 6.5 miles east of Visalia.in the Kaweah Oaks Preserve. Therefore, given the presence of suitable habitat (primarily on the Project site), the species is considered to have some potential, albeit low, to occur within the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			BIRDS	
Phalacrocorax auritus	double-crested cormorant (nesting)	none/SA/none	This species is found as a colonial nester on coastal cliffs and offshore islands, and along lake and river margins in the interior portions of California. It nests along the coast on sequestered islets, usually on ground with sloping surface, or in tall trees or snags along lake or river margins.	**No Potential.** A colonial nest site was found in a couple of snags between the southern access road and the mining pit pond on the Seaborn property (outside the BSA). It was not active at the time of the survey given the time of year (October). So, it could not be determined when it was last occupied. However, it is the only colonial nesting site for the species in the area and is outside the BSA. Therefore, the Project would not adversely affect nesting by this species.
Ardea herodias	great blue heron (nesting colony)	none/SA/none	This species is common throughout most of California where there are shallow estuaries, or freshwater or saltwater emergent wetlands. However, it is less common along riverine and rocky coastal shores and above the foothills in the mountains. Rookeries (i.e., nesting colonies) are	**No Potential.** No nesting colonies of this species have been observed within the BSA. In addition, the nearest reported nesting colony is on Dry Creek, one mile north of the confluence of Dry Creek and the Kaweah River (more than two miles from the Project site). Therefore, no known or potential nesting colonies of this species

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			typically active from February to late July and occur in the tops of secluded large snags or live trees. Rookeries are sometime shared with the great egret or other large wading birds.	occur within the BSA.
Gymnogyps californianus	California condor	FE/SE/none	This species occurs as a reintroduced species primarily in the mountains of Ventura, Santa Barbara, Los Angeles, Monterey, and San Benito counties. However, individuals are known to be wide-ranging and occasionally occur soaring over the Tehachapi Mountains and southern Sierra Nevada. The species is strictly a scavenger and may travel up to 35 miles or more from roost sites in search of carrion. Most foraging occurs in open habitats that facilitate landings and takeoffs. Traditional roost sites are on cliffs or ledges, but snags and trees in old growth coniferous forest may be used.	**No Potential.** No suitable roost sites for this species occur within the BSA. In addition, other potential attractors to the sites (e.g., large mammals and potential food sources) are not provided at or near the BSA. Lastly, the nearest known use areas for this species are in more rugged country more than 13 miles southeast of the BSA. Therefore, the species is considered to have no potential to occur within the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Accipiter cooperii	Cooper's hawk (nesting)	none/SA/none	This species occurs as an uncommon breeding resident throughout most of the low to mid-elevation wooded portions of California where it inhabits open, interrupted, or marginal woodlands. It is seldom found in areas without dense tree stands. Nest sites are typically found in riparian or deciduous trees in canyon bottoms or river flood plains.	**Moderate Potential.** There is suitable nesting habitat for the species (i.e., interrupted oak woodland with dense stands of trees within the BSA. However, there are only a small number of scattered nesting season records from the Project vicinity in the eBird data base. Nonetheless, this relatively secretive species is considered to have a moderate potential to nest within the BSA.
Buteo swainsoni	Swainson's hawk (nesting)	none/ST/none	Occurs as a breeding resident in the Central Valley (primarily in the southern Sacramento and northern San Joaquin valleys), Klamath Basin, and Modoc Plateau. However, nesting pairs are also occasionally found in the Mojave Desert, Lanfair Valley (San Bernardino County), Antelope Valley (Los Angeles County), and eastern San Luis Obispo County. In the Central Valley the species nests in riparian woodland or forest stands, or oak	**No Potential.** Though suitable nesting habitat for the species occurs within the BSA (i.e., interrupted oak woodland), the nearest known nesting records for the species are more than 17 miles west of these sites in the vicinity of Traver. As such, the species is considered to have no potential to nest within the BSA.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			savannah. Nest territories are located adjacent to suitable foraging habitat (e.g., grassland, suitable grain and row crop fields, alfalfa, and pastures).	
Buteo regalis	ferruginous hawk (wintering)	none/none/BCC	This species is a winter resident of the Modoc Plateau, Central Valley, and Coast Ranges. It forages in large, open tracts of grasslands, sparse scrubland, and deserts.	**Low Potential.** There is suitable wintering habitat for the species (i.e., open grassland) within the BSA. Furthermore, there are records from the Project vicinity in the eBird data base (i.e., less than 1.5 miles from the BSA along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to winter within the BSA.
Elanus leucurus	white-tailed kite (nesting and wintering)	none/CFP/none	This species is found as a resident throughout the lower elevation portions of California in low rolling grasslands with scattered oaks and river bottomlands or marshes adjacent to deciduous woodland. It requires grasslands, meadows, or marshes (for foraging) located near dense-topped	**Low Potential.** There is suitable nesting habitat for the species (i.e., mixed oak woodland) within the BSA. However, there is only one eBird record from the nesting season in the Project vicinity. Nonetheless, there are several eBird records from the Project vicinity during the winter months. Therefore, the species is considered to have

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			trees (for nesting and roosting).	some potential, albeit low, to occur on the BSA (but mostly during the winter months).
Haliaeetus leucocephalus	bald eagle (nesting and wintering)	none/SE/BCC	The species winters throughout California at lakes, reservoirs, rivers, and some rangelands and coastal wetlands. Nesting occurs mainly in mountain and foothill forests and woodlands near reservoirs, lakes, and rivers. Most current nest territories are in northern California, but the species also nests in various locations in the central and southern Sierra Nevada mountains and foothills, in several locations in the central Coast Ranges, inland southern California, and Santa Catalina Island. The nesting season lasts from January through August.	**No Potential.** No individuals of this species were observed during any of the reconnaissance-level surveys of the BSA. There are multiple winter eBird occurrences scattered around nearby Dry Creek and Bravo Lake (sites where public access allows for potential observations - unlike the BSA). However, the species is considered to have no potential to occur within the BSA due to the lack of suitable roost sites or abundant and suitable prey species (e.g., fish or waterfowl).
Aquila chrysaetos	golden eagle (nesting and wintering)	none/CFP/BCC	Found as a breeding resident throughout most of California (other than the valley floor of the Central Valley). Also found as a wintering species throughout most of California	**Low Potential.** There is suitable wintering habitat for the species (i.e., open grassland) within the BSA. Furthermore, there are records from the Project vicinity in the eBird data base (i.e., less than 1.5 miles

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			(other than the high Sierra Nevada). Species requires open terrain for hunting (e.g., grassland, oak savannah, and early successional stages of shrub and woodland habitats). Typically nests on secluded cliffs, but may also use large, isolated trees.	from the BSA along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to winter within the BSA.
Falco columbarius	merlin (wintering)	none/SA/none	This species winters in California from September to May. It occurs in a variety of low elevation, relative flat habitats that include wooded areas, coastlines, open grasslands, savannah, and the periphery of lakes. It is less often found in open desert. It typically requires dense stands of trees for cover and roosting. It is most often found where there are substantial populations of small birds (the primary prey item).	**Low Potential.** There is suitable wintering habitat for the species (i.e., open grassland) within the BSA. Furthermore, there are records from the Project vicinity in the eBird data base (i.e., less than 1.5 miles from the Project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to winter within the BSA.
Athene cunicularia	burrowing owl (burrow sites)	none/CSC/BCC	This species is found throughout the Central Valley, in the San Francisco Bay Area, at scattered locations along the coast, and in portions of the desert	**Low Potential.** The annual grassland within the BSA provides suitable foraging habitat for the species. In addition, scattered California ground squirrel burrows occur in

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
			regions. It is a year-round resident in annual and perennial grasslands or other vegetation communities that support sparse or non-existent tree or shrub canopies.	the far western portion of the BSA. Though no evidence of occupation by burrowing owls was found at these burrows, it does not preclude their future use. Therefore, there is some potential, albeit low, for the species to occur within the far western portion of BSA.
Empidonax traillii	willow flycatcher (nesting)	none/SE/BCC	This species is a rare to locally uncommon, summer resident in wet meadow and montane riparian habitats (typically dense willow scrub) at 2000 to 8000 feet in elevation in the Sierra Nevada and Cascade Range. It also occurs at scattered locations (at lower elevations) in southern California (including along the Kern, Santa Margarita, San Luis Rey, and Santa Ynez rivers). It most often occurs in broad, open river valleys or extensive mountain meadows with dense shrubby willows. Nesting occurs between mid-May and late August in northern California.	**No Potential.** Though a migrant individual was observed in the mixed oak woodland on the Project site during the 2013 reconnaissance-level survey of the site, there is no suitable riparian habitat within the BSA that could be used as nesting habitat by this species (i.e., extensive, dense willow scrub). Furthermore, there are no records in the CNDDB below 2,000 feet in elevation anywhere in the Sierra Nevada (mostly due to nest parasitism by brown-headed cowbird). Therefore, the species has no potential to occur within the BSA as a nesting species.

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Lanius ludovicianus	loggerhead shrike (nesting)	none/CSC/BCC	This species is found as a resident and wintering species throughout the lower elevation portions of California in grasslands, saltbush scrub, chaparral, oak savannah, and other open woodland types (generally where there are trees with dense cover for nesting).	**Moderate Potential.** There is suitable nesting habitat for the species (i.e., mixed oak and riparian woodland with dense stands of trees) located in the southeastern portion of the BSA. Furthermore, there are records from the Project vicinity in the eBird data base (i.e., less than two miles from the Project site along Dry Creek Drive). Therefore, the species is considered to have a moderate potential to nest within the BSA.
Vireo bellii pusillus	least Bell's vireo (nesting)	FE/SE/none	Found as a summer resident (late March to late August) in coastal valleys from Monterey County south through coastal southern California to San Diego County. Also occurs at scattered locations along the western border of the deserts. There have been recent records from the Central Valley given its recovery in southern California. It typically nests in dense willow riparian communities but is also	**No Potential.** Though there is no suitable nesting habitat for this subspecies within the BSA, and the subspecies had been extirpated from the Central Valley, it has recently been found sporadically again in the valley (e.g., one nesting record from Merced NWR in 2012). Nonetheless, the subspecies is considered to have no potential to occur within the BSA given the extremely limited number of records in the Central Valley and distance to those recent

			occasionally found in live oak stands adjacent to drainages.	records.
Baeolophus inornatus	oak titmouse (nesting)	none/none/BCC	This species occurs as a common resident throughout much of California other than the deserts, high Sierra Nevada, and redwood belt. It is generally found in cismontane woodland (particularly oak or riparian woodlands) where it nests in the cavities created by woodpeckers.	**Moderate Potential.** There is suitable nesting habitat for the species (i.e., oak woodland) within the BSA. Furthermore, there are potential nest sites (i.e., woodpecker-created nest holes) in these woodlands. Lastly, there are records from the Project vicinity in the eBird data base (i.e., less than two miles from the Project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have a moderate potential to occur within the BSA.
Icteria virens	yellow-breasted chat (nesting)	none/CSC/none	This species is found as a summer resident mostly in low to mid-elevation coastal, valley, foothill, and desert riparian habitats (up to 4,800 feet in foothill riparian and 6,500 feet east of the Sierra Nevada). Nesting typically occurs in dense riparian vegetation near streams.	**No Potential.** There is no dense riparian vegetation within the BSA. Though there are records from the Project vicinity in the eBird data base (i.e., multiple records from along Dry Creek Drive in the vicinity of the Kaweah Gravel Pits and a couple of records from the riparian habitat associated with Bravo Lake), the BSA does not provide the

				type of dense riparian habitat (e.g., willow scrub) used as nesting habitat by the species in the western United States. Therefore, the species has no potential to occur within the BSA as a nesting species.
Agelaius tricolor	tricolored blackbird (nesting)	none/CSE/BCC	The species is a resident species in annual grassland, oak savannah and freshwater marsh within the Central Valley and coastal California from Sonoma County to San Diego County. Nesting habitat typically involves emergent freshwater marsh, but may include tall, dense stands of willow, blackberry, thistle, nettles, or grasses. Grasslands or rangeland providing an abundant source of food (e.g., large numbers of grasshoppers or butterfly larvae) often are within at least three miles of nest colonies.	**No Potential.** There is a CNDDB occurrence from about 1.3 miles west-northwest of Lake Kaweah Dam, 2 miles north of the Highway 216 and 198 intersection, and 4 miles east of Woodlake. However, there is no suitable nesting habitat (e.g., vegetation that is flooded, spinous, or otherwise defended against easy access by mammalian predators) for the species within the BSA. Therefore, it is considered to have no potential to nest within the BSA.
Spinus lawrencei	Lawrence's goldfinch (nesting)	none/none/BCC	This species is found as a breeding species in oak woodlands, other arid woodlands, and chaparral in the lower	**Low Potential.** There is suitable nesting habitat for the species (i.e., mixed oak and riparian woodland) located in the

TABLE 1

			elevations of northern California and in riparian woodland, pinyon-juniper woodland, and lower montane communities in southern California. A local water source and a source of abundant seeds are required habitat components.	southeastern portion of the Project site. Furthermore, there are records from the Project vicinity in the eBird data base (i.e., less than two miles from the Project site along Dry Creek Drive upstream along the Kaweah River). Therefore, the species is considered to have some potential, albeit low, to nest in the BSA.
MAMMALS				
Vulpes macrotis mutica	San Joaquin kit fox	FE/ST/none	This taxon is found in the San Joaquin Valley from Contra Costa County south to Kern County. It is also found in the dry interior valleys of the Coast Ranges (e.g., Salinas and Santa Clara valleys). It occurs in open, sparsely vegetated areas of low relief (typically in native or non-native grassland or alkali sink scrub).	**Low Potential.** Though there is suitable habitat for the taxon within the BSA (i.e., non-native annual grassland), and it has been recorded 2.7 miles northwest and 4.8 miles southwest of the Project site, surveys of the annual grassland within the BSA found no potential dens or other evidence of the taxon to suggest it occurs within the BSA. In addition, the sandy soils on the Project site may preclude the creation and maintenance of burrows that do not easily collapse (hence the lack of California ground squirrel burrows). Therefore, the

TABLE 1

SPECIAL-STATUS SPECIES RECORDED OR POTENTIALLY OCCURRING WITHIN THE VICINITY OF THE MCKAY POINT RESERVOIR PROJECT SITE AND SEABORN SITE, BIOLOGICAL STUDY AREA, TULARE COUNTY, CALIFORNIA

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
				taxon is considered to have only a low potential to occur in the annual grassland associated with the easternmost and northernmost portions of the BSA.
Taxidea taxus	American badger	none/CSC/none	This species is found as a resident species at scattered localities throughout California (except in the coastal redwood region). Generally, occurs in extensive, open habitats in the vicinity of abundant rodent populations.	**No Potential.** Though there is suitable habitat for the species within the BSA (i.e., non-native annual grassland), surveys have found no evidence to suggest that the species occurs within the BSA (i.e., suitable dens or diggings). In addition, the BSA is fragmented from other habitat that could be occupied by the species. Therefore, the species is considered to have no potential to occur within the BSA or otherwise be affected by the Project.
Antrozous pallidus	pallid bat	none/CSC/none	This species is found in a variety of habitats from sea level to approximately 6,000 feet. Day roosts are typically found in buildings, bridges, rocky outcrops, mines, caves, and trees. Night roosts are generally provided by bridges, mines, and caves.	**No Potential.** No suitable day or night roosts for the species occur on or immediately adjacent to the BSA. Therefore, it has no potential to occur within the BSA.

TABLE 1

Genus/Species	Common Name	Status Federal/CA/Other	Habitats and Seasonal Distribution in California	Likelihood of Occurrence in the BSA
Eumops perotis californicus	western mastiff bat	none/CSC/none	This subspecies is found as an uncommon resident in southern California, but also occurs along the lower west slope of the Sierra Nevada and in the interior Coast Ranges as far north as the Tumey Hills (eastern San Benito County). Roosts are typically found in crevices in cliff faces, cracks in boulders, or occasionally in buildings (particularly where the roost allows for a large vertical drop).	**No Potential.** No suitable day or night roosts for the species occur on or immediately adjacent to the BSA. Therefore, it has no potential to occur within the BSA.
Lasiurus blossevillii	western red bat	none/CSC/none	The species occurs throughout the lowland portions of California west of the Sierra Nevada crest and desert regions (typically in riparian forest or orchards). It is less abundant in coniferous forest. Roosting sites are found in tree or shrub foliage between 2- and 40-feet above ground (typically in large cottonwoods, sycamores, walnuts, and willows).	**No Potential.** Though suitable habitat and roosts for the species occur within the BSA, there are no known occurrences from Tulare County. The nearest records to the BSA (2 records) are from northwestern Fresno County. Therefore, the species is considered to have no potential to occur within the BSA.

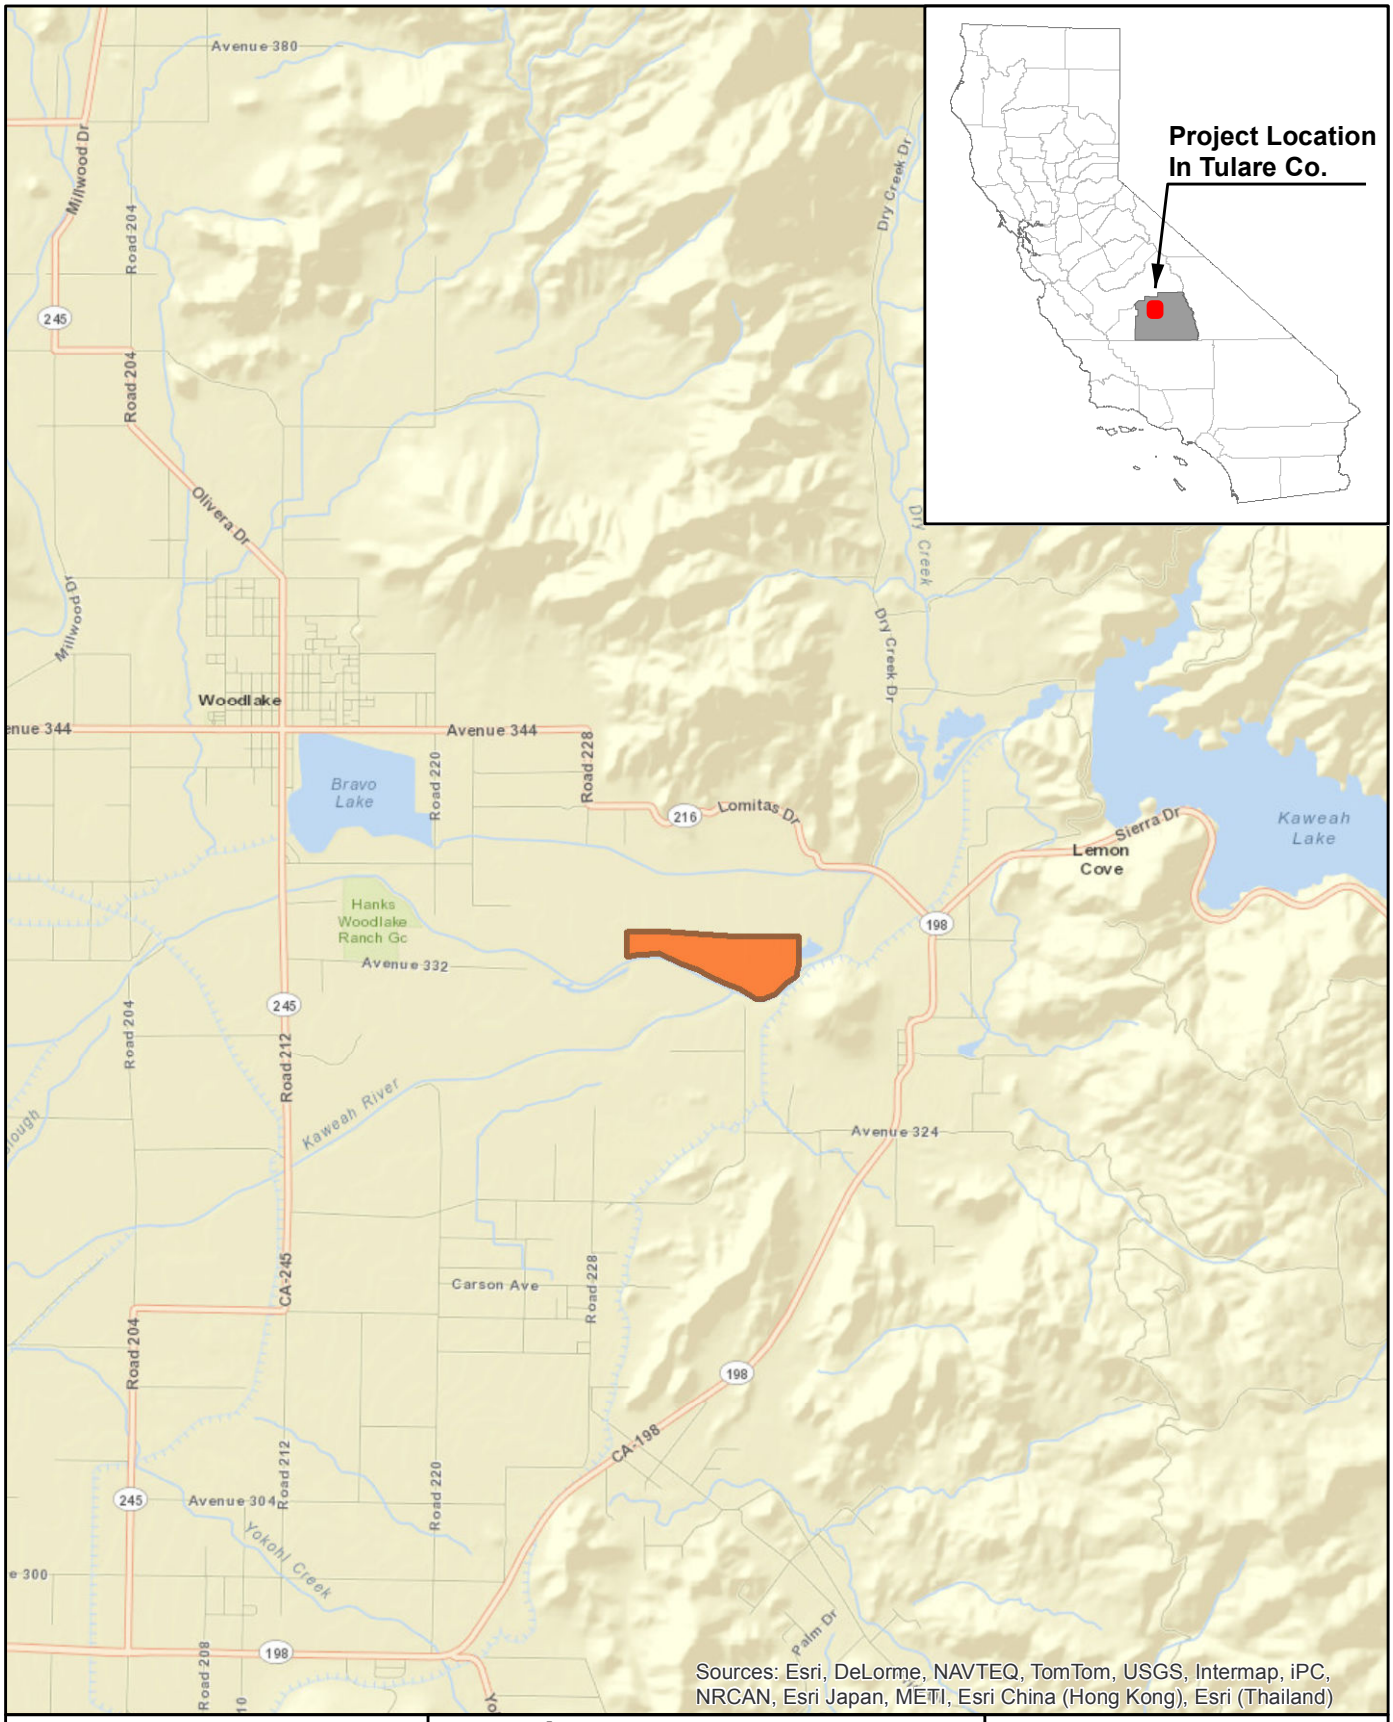
LIKELIHOOD OF OCCURRENCE DEFINITIONS

Known to Occur	Taxon was observed within or immediately adjacent to the Project site during the May 16, 2011, September 18, 2013, or October 15, 2020 surveys or has previously been documented within or immediately adjacent to the Project site.
High Potential	Taxon has not been documented within or immediately adjacent to the Project site but should be expected on more than 50% of visits to suitable habitat on and near the Project site during the appropriate season and time of day.
Moderate Potential	Taxon has not been documented within or immediately adjacent to the Project site but should be expected on less than 50% of visits to suitable habitat on and near the Project site during the appropriate season and time of day.
Low Potential	Taxon has not been documented within or immediately adjacent to the Project site nor is it likely to occur on or near the Project site, but its presence cannot be completely discounted due to incomplete information on the taxon's distribution or habitat requirements.
No Potential	Taxon does not occur within or immediately adjacent to the Project site due to the lack of required habitat features for the taxon, or the known range of the taxon is well defined and does not include the Project vicinity.



Note: This table has changed from that provided with the *Tulare Irrigation District McKay Point Reservoir Project Biological Resources Evaluation, Tulare County, California* (Bumgardner Biological Consulting 2013) given the following: (1) addition of special-status species that were previously undocumented in the query area, (2) addition of new occurrences of special-status species that had previously been document in the query area (3) changes to the state and/or federal regulatory status of species that had previously been documented in the query area., and (4) removal of some species from the CDFW Special Animals List. Hence, this table replaces Table 1 from the 2013 Biological Resources Evaluation.

May 2014

INTRODUCTION

The Tulare County Irrigation District is proposing to construct a new reservoir at McKay Point, immediately north of the confluence of the Kaweah and St. John's Rivers northeast of Visalia, CA (Figure 1). It is known as the McKay Point Reservoir. The proposed project site consists of five neighboring parcels (Figure 2), which collectively measure 194 acres. Blue elderberry (*Sambucus mexicana*: Caprifoliaceae) plants grow in various portions of the project site and many of them could be directly or indirectly impacted by construction of the proposed reservoir.

Blue elderberry is the sole food plant for the Valley Elderberry Longhorn beetle (VELB), *Desmocerus californicus dimorphus* (Coleoptera: Cerambycidae). The VELB is recognized as a threatened species pursuant to provisions of the federal Endangered Species Act of 1973, as amended. Removal of the beetle's elderberry food plant is interpreted as "take" of the threatened beetle's habitat as defined by the Endangered Species Act. Lawful removal of the elderberry food plant of the VELB can be performed after obtaining a permit for incidental take from the U.S. Fish & Wildlife Service (USFWS).

This report describes the findings of an inventory survey of the resident elderberry plants that was performed in April 2014 at the McKay Point Reservoir project site. The purpose of the inventory was to acquire information on the resident elderberry plant to determine appropriate mitigation measures that may be needed for the reservoir project.

Inventory data were collected at this site in accordance with the procedures described by the VELB conservation guidelines (USFWS 1999). Data from the inventory were used to perform a mitigation analysis for the elderberry plants that will be impacted by the project. The findings of the analysis were used to prepare a mitigation plan that discusses two alternative mitigation solutions, namely:

a) purchase VELB conservation credits from an USFWS-approved conservation bank, whose service territory includes the McKay Point Reservoir project site; or

b) protect a suitable mitigation site and revegetate it with the requisite number of elderberries and associated native plants and monitor it for a minimum of 10 years to demonstrate that the habitat restoration is successful.

BACKGROUND INFORMATION

In 1980, the USFWS recognized the VELB as a threatened species and designated two sites along the American River in the city of Sacramento as critical habitat (USFWS 1980). A recovery plan for the VELB was published by the USFWS in 1984 (USFWS 1984).

The VELB was recognized as a threatened species because of loss and alteration of its riparian habitat and because it naturally occurs at low population densities. This beetle is generally found along waterways and in floodplains that support remnant stands of riparian vegetation. In particular, elderberry must be present, as both larvae and adults feed on this shrub

or small tree. Larvae of the VELB feed internally on the pith of the trunk and larger branches, while adult beetles feed externally on elderberry flowers and foliage. Prior to metamorphosing into the adult life stage, VELB larvae chew an emergence or exit hole in the roots or trunk of the elderberry, through which the adult beetle later exits the plant. The VELB's exit hole is about the diameter of a standard wooden pencil and somewhat oval in shape. Often there is some swelling on the trunk where the exit hole is found. Exit holes in the lower trunk of elderberries are characteristic of past VELB infestations. Several studies (cited in USFWS 1984 and Barr 1991) have found that exit holes generally occur between ground level and about six feet in height. Similar appearing holes in the upper trunk and branches may be due to other wood-feeding insects.

Exit holes remain in the trunks of the elderberries even after the VELB has ceased to use a particular elderberry. For this reason, the exit hole can be used as an indicator of past infestation. Most exit holes that are observed on elderberries are older and difficult to date. However, recent holes can be readily distinguished based on the presence of larval frass or a pupal case of the VELB, fresh wood shavings, and non-oxidized wood. Unfortunately, these signs usually disappear within a few weeks after a VELB leaves the elderberry. As such, recent exit holes are detected rather infrequently. Several other types of insects make holes on elderberries and live in the stems. Others live in the tunnels created by the VELB larvae. These insects and insect-feeding birds often enlarge or modify older VELB exit holes to feed on these secondary insect inhabitants in the VELB tunnels.

Surveys conducted subsequent to the beetle's recognition as a threatened species have demonstrated that the VELB is more widespread than originally believed. Observations of exit holes and limited numbers of adults led the USFWS to believe that the beetle's geographic range included virtually all of the Central Valley and some surrounding foothill areas. This and various conservation efforts recently led the USFWS (2012) to propose delisting of the VELB. However, a scientific review panel (Atkins North America 2013) found that the USFWS was not aware of previously publishing findings by Chemsak (2005), which restricted the VELB's geographic range to only the Sacramento Valley and northern San Joaquin Valley. Adults observed in the southern San Joaquin Valley exhibited the phenotype of the non-threatened, nominate subspecies, *Desmocerus californicus californicus* rather than the VELB. This conclusion is further supported by specimens cited in Halstead and Oldham (2000). For these reasons, the peer reviewers concluded that the best available scientific data indicates that the VELB's geographic range is restricted to the Sacramento Valley and northern San Joaquin Valley and the perceived threats identified in the proposed rule to the listed beetle may actually be greater than portrayed by USFWS (2012). However, until USFWS publishes a final rulemaking it will undoubtedly consider the geographic range of the VELB to still include the southern San Joaquin Valley.

SURVEY METHODS

The McKay Point site was visited on April 9 and 10, 2014 to inventory the resident elderberry plants. This inventory was conducted in accordance with the Conservation Guidelines for Valley Elderberry Longhorn beetle (USFWS 1999). Based on this document, USFWS considers elderberries with a basal trunk diameter equal to or greater than (≥) 1.0 inch to be habitat for the VELB.

All portions of the McKay Point project site were inspected to determine the presence or absence of any elderberry plants. As individual elderberry plants were observed, positional coordinates were obtained using a mapping grade GPS unit manufactured by Trimble. My assistant and I inventoried the elderberries that would directly and indirectly (within 100 ft. of the reservoir's border) impacted by the project, per the aforementioned Conservation Guidelines for the VELB (USFWS 1999). The data dictionaries in our GPS units were programmed to record the following information for each elderberry plant location:

a) total number of elderberry plants;

b) number of trunks present for each of three basal diameter size categories;

c) presence of verifiable *Desmocerus* exit holes; and

d) whether or not the elderberry plant(s) grew in riparian habitat.

The McKay Point site was revisited on April 29, 2014 to search for adult beetles. Visual surveys were conducted in the mixed oak-riparian woodland portions of the site.

SURVEY RESULTS

As illustrated in Figure 3, plant communities at the McKay Point site include mixed oak-riparian woodland, elderberry savannah-riparian woodland, and non-native annual grassland. All three habitats are grazed by cattle, which can roam freely among the five parcels.

A total of 191 elderberry plants (Figure 4) were inventoried. Characteristics of the resident elderberries growing at these locations are summarized in Table 1. The vast majority of the elderberries, 176, grow in the two riparian plant communities, while only 15 were observed in the annual grassland. Within the footprint of the proposed reservoir, 140 elderberries were noted, while 51 were found growing within 100 ft. of the perimeter of the reservoir. A few of the elderberries within this 100-ft. buffer actually grow off-site on neighboring property (Figure 4).

Most of the elderberries growing at the project site are mature plants. Living stems less than one inch in basal diameter were uncommon as cattle were observed eating them during our inventory. A total of 143 stems exhibited basal diameters between 1 and 3 inches, 151 stems were between 3 and 5 inches, and 298 stems were greater than 5 inches (Table 1). Only a few plants exhibited solitary trunks, while the vast majority was characterized by multi-stemmed trunks. Bona fide exit holes of *Desmocerus* were observed on 13 (6.8%) elderberry plants.

No *Desmocerus* beetles were observed during our field work for the elderberry inventory. During my return visit on April 29th two males resembling the phenotype of the non-threatened *Desmocerus californicus californicus* were observed on elderberry plants growing in the mixed oak-riparian woodland located in the southeastern portion of the site. Unfortunately my recovery permit from USFWS does not allow me to collect living individuals as voucher specimens. Since both males were alive, neither was preserved as a voucher specimen.

ELDERBERRY MITIGATION ANALYSIS AND PLAN

The mitigation analysis and plan described in this section assumes that the beetle at the project site for the proposed McKay Pt. reservoir is the threatened VELB. However, as noted earlier, existing published information indicates that beetle in the greater Visalia area should be the non-threatened, nominate subspecies (*Desmocerus californicus californicus*). Also, two males observed there exhibited the phenotype of the nominate subspecies. If the USFWS adjusts the geographic range of the VELB in its final ruling to match information provided by Chemsak (2005) and Halstead and Oldham (2000), the reservoir project site would no longer be considered within the range of the VELB. Thus, none of the mitigation described herein would be necessary to satisfy any take of the threatened beetle under the Endangered Species Act.

Mitigation Analysis.

The data collected during this elderberry inventory was used to prepare a mitigation analysis in accordance with the USFWS's (1999) VELB conservation guidelines. Because the full extent of potential impacts due to the proposed reservoir project cannot be identified at this time, my mitigation analysis assumes that **all** elderberry plants growing within the footprint of the proposed reservoir and within 100 feet from the perimeter of the reservoir will be lost or otherwise affected. If project planning can avoid one or more of the elderberry plants, then the mitigation may be reduced accordingly.

In some instances, USFWS will allow work activities to occur as close as 20 feet from the dripline of elderberry plants, but this must be approved by USFWS after a review of descriptions of work procedures near the elderberries, access routes, laydown areas, equipment storage areas, and parking areas, plus the project's work schedule. Unfortunately, this information was not available at the time when this inventory was conducted. General protective measures are discussed in the next section of this report. If the protective measures are followed and USFWS approves, the mitigation requirements for this project could be substantially reduced from the scenario presented in this report.

The elderberry inventory information is used to:

a) identify the number of existing elderberries that will be transplanted to a secure mitigation site;

b) calculate the numbers of replacement elderberry seedlings that need to be propagated and planted at the mitigation site;

c) calculate the numbers of associated native trees and shrubs that need to be propagated and planted at the mitigation site; and

d) calculate the amount of acreage that needs to be secured to mitigate for the loss of VELB habitat.

The following points from the USFWS's (1999) VELB conservation guidelines were

considered in the mitigation analysis:

a) each trunk with a basal diameter $\geq$ 1.0 inch that is directly or indirectly impacted should be transplanted;

b) each stem with a basal diameter of 1.0 inch or greater that is impacted will be replaced with seedling elderberry plants using a replacement ratio of 1:1 to 8:1, and this ratio depends upon the type of habitat, sizes of basal stem diameters of affected elderberries, and the presence of VELB exit holes in the affected plants;

c) representative native tree and shrub species that grow in association with the elderberries will be planted at a ratio of one or two specimens for every replacement elderberry seedling (1:1 or 2:1 ratios);

d) 1800 square feet should be provided for every five replacement elderberry seedlings, five associated natives, and transplant; and

e) a mitigation site, which will serve as habitat for the VELB in perpetuity, must be secured for the transplants and replacement plantings, and the size of the site is determined by the total planting square footage required for all replacement elderberries and associated natives.

Using this inventory information, Table 1 presents the anticipated mitigation requirements for potential impacts to elderberries. The number of replacement plants necessary to compensate for the anticipated loss of 592 stems $\geq$ 1 inch is 2,087 elderberries and 664 associated native plants. The 191 resident elderberry plants with basal stem diameters > 1 inch must also be transplanted to the secure mitigation site. The required mitigation acreage for these replacement plants is a minimum of 343,800 $ft.^2$ or approximately 7.9 acres. Due to the large differential between the number of required seedlings for elderberry and associated natives, I suggest planting 11 elderberry seedlings with every transplant.

Depending upon the location of and characteristics of the mitigation site, various associated native trees and shrubs would be appropriate to plant in conjunction with the replacement elderberries to restore the riparian habitat. For example, Box Elder, Cottonwood, Willow, Valley Oak, and California Rose, are some riparian tree and vine species that often grow in close association with the elderberry food plant of the VELB in the greater Visalia area.

In addition, the findings of the aforementioned analysis are converted to an equivalent number of VELB conservation credits. Project sponsors may decide to satisfy their mitigation requirements through the purchase of such credits from a conservation bank approved by the USFWS to sell VELB conservation credits. This project will require 417 VELB conservation credits.

Mitigation Plan.

Assuming that all of the 191 aforementioned elderberries at the project site will be impacted by construction of the new reservoir, two alternatives are available to the project

sponsors to resolve their VELB mitigation requirements, including:

a) secure a mitigation site, protect it in perpetuity, revegetate it with the required numbers of elderberries and associated natives, and monitor it annually for a minimum period of 10 years to demonstrate that the habitat restoration is successful;

or

b) purchase VELB conservation credits at a USFWS-approved conservation bank whose service territory includes the project site.

The remainder of this section discusses each of these mitigation options in more detail.

Option #1 – Mitigation Site and Habitat Restoration: Under this option, the project sponsors would secure a mitigation site, protect it in perpetuity, revegetate it with the required numbers of elderberries and associated natives, and monitor it annually for a minimum period of 10 years to demonstrate that the habitat restoration effort is successful (i.e., at least 60 % survival of mitigation plantings at the end of 10 years). Specific features of this option for anticipated impacts to elderberries are detailed as follows:

a) at least 2,087 elderberry seedlings will need to be propagated and planted at a secure mitigation site;

b) at least 664 associated natives will need to be propagated and planted at a secure mitigation site;

c) 191 elderberry plants with stems $\geq$ 1 inch basal diameter that grow at the project site will be transplanted to a secure mitigation site; and

d) the mitigation site will need to include a minimum of 7.9 acres to insure adequate planting space for all of the mitigation plants.

The USFWS (1999) VELB conservation guidelines discuss additional measures that should be followed, including acceptable planting design standards, success criteria, monitoring, other implementation activities, and reporting requirements. Depending upon the location and characteristics of the mitigation site, the USFWS may provide additional recommendations for the habitat restoration effort.

This option may be the most expensive and lengthy of the two alternative mitigation solutions available to the project sponsors for the following reasons. First, a suitable mitigation site may need to be purchased if the sponsor does not currently own a site appropriate for restoration of VELB habitat. Because a property suitable for mitigation and measuring exactly 7.9 acres may not be available, the project sponsors may need to purchase a larger site to obtain the required acreage. Secondly, depending upon the condition of the mitigation site, the costs of site preparation, habitat restoration, and security may be considerable. Finally, annual monitoring and reporting to USFWS is required for a minimum of 10 years, or until all criteria

for successful restoration is actually achieved.

Option #2 – Purchase VELB Conservation Credits: For anticipated impacts at the reservoir project site, the project sponsor could purchase 417 VELB conservation credits (also referred to as "habitat units") from a USFWS-approved conservation bank whose service territory includes the project site. The 417 conservation credits are determined by dividing the total number of required mitigation elderberries by 5 (i.e., 2,087/5), which yields 417. No additional credits are needed for the associated native plants. Also, the 191 elderberries at the reservoir project site, whose basal stem diameters are > 1 inch, should also be transplanted to the conservation bank.

The service territory of at least one USFWS-approved conservation bank, the French Camp Conservation Bank, includes the McKay Point project site. Contact Mr. Darryl Foreman, Strata Habitat Foundation, 578 Riviera Circle, Larkspur, CA 94939, (415) 309-0646, for information about the availability of and fees for VELB credits. Transplanting of impacted elderberries may be an extra cost that will be estimated by the bank operator after visiting the project site. The USFWS (1999) VELB conservation guidelines provide information about the best time to transplant elderberries and recommended procedures for preparing the elderberries for transplant. These guidelines recommend transplanting the elderberries when they are dormant, usually between mid-November through mid-February. If transplanting occurs outside of this period, then the USFWS may impose higher mitigation ratios for elderberries and associated natives.

Advantages of this option are that the conservation bank assumes all responsibilities and liabilities for insuring that the required VELB mitigation is successful. Thus, once the project sponsor completes its purchase of the VELB credits, it will have fulfilled its mitigation obligation for the project.

PROTECTIVE MEASURES DURING AND AFTER CONSTRUCTION

If any elderberry plants remain at the reservoir project site during grading and construction activities, the following protective measures are recommended by USFWS (1999).

a) A buffer zone will be established around the perimeter of all elderberry plants that provide potential habitat for the VELB (i.e., $\geq$ 1 inch basal stem diameter). Preferably, the buffer zone should be at least 100 ft. wide and cannot include firebreaks, access routes, equipment storage areas, parking areas, or laydown areas. The perimeter of the buffer zone should be fenced during grading and construction activities.

b) All construction personnel will be briefed on the need to avoid damage to elderberries, as well as the penalties for non-compliance.

c) Warning signs will be erected every 50 feet along the edge of the buffer perimeter. The signs should state: "This area is habitat for the Valley Elderberry Longhorn Beetle, a threatened species, and must not be disturbed. This species is protected by

the Endangered Species Act of 1973, as amended. Violators are subject to prosecution, fines, and imprisonment." The signs should be clearly readable from a distance of 20 feet, and must be maintained for the duration of construction.

d) All construction personnel will receive training on the status of the VELB and the need to protect its elderberry food plant.

In some instances the USFWS may reduce the buffer width to 20 feet around the dripline of elderberries. Additional protective measures are required and must be approved by USFWS, but may include precautions such as:

a) avoid work during the adult flight period of the VELB, which is generally between March 1st and June 30th;

b) conduct earthwork and other dust generating activities during the dormant period of the elderberry, i.e., mid-November through mid-February;

c) implement stringent measures for dust control;

d) no use of insecticides or herbicides at the project site; and

e) increased frequency of biological monitoring, for example once per week, to insure that the elderberries are adequately protected during the work.

USFWS may also request other protective measures after reviewing the project.

Indirect impacts to the elderberry plants, such as the accumulation of dust on foliage and flowers of the elderberry, can also adversely affect the VELB. Thus appropriate dust control measures should be followed throughout the grading and construction periods. Dust may also be generated by vehicular and equipment operation along temporary roads. Appropriate dust control measures include:

a) sprinkle water on all active construction areas at least twice daily and more often when conditions warrant;

b) cover all trucks hauling soil, sand and other loose materials or require all trucks to maintain at least two feet of freeboard;

c) pave, apply water three times daily, or apply non-toxic soil stabilizers on all unpaved access roads, parking, areas, and staging areas at construction sites;

d) sweep streets daily if visible soil material is carried onto adjacent public streets;

e) hydroseed or apply non-toxic soil stabilizers to inactive construction areas;

f) enclose, cover, water twice daily, or apply non-toxic soil binders to exposed soil

stockpiles;

g) limit traffic speed on unpaved roads to 5 mph;

h) replant vegetation in disturbed areas as quickly as possible;

i) suspend grading activities when winds exceed 25 mph or when visible dust clouds cannot be prevented from extending beyond active construction area; and

j) limit the areas subject to excavation, grading, and other dust generating activities at any one time.

Similarly, appropriate erosion control measures should be implemented to prevent any damage to the elderberries. The particular erosion control measures that may be needed should be recommended by a soils engineer.

Finally, if any elderberry plants remain at these project sites after completion of these projects, they will need to be protected and monitored to insure that subsequent site maintenance or other activities do not adversely impact them. The USFWS (1999) VELB conservation guidelines discuss measures for restoration, maintenance, and protection of buffer areas in more detail. The requirements are generally similar to those for off-site mitigation areas. A written plan for the restoration, protection, and maintenance of buffer areas needs to be approved by USFWS.

OBTAINING THE INCIDENTAL TAKE PERMIT

As long as the USFWS includes the Visalia area within the geographic range of the VELB, this agency will require an incidental take permit to be acquired by a project proponent and mitigation to compensate for any potential impacts. Assuming that an incidental take permit is required, the project proponent may apply for an individual permit under Section 10(a) of the FESA, if no other federal permits are required for the project, or under Section 7 of this regulation if other federal permits are needed. For example, endangered species permits are frequently "piggybacked" on wetlands permits issued by the U.S. Army Corps of Engineers. In either case, mitigation requirements are generally the same.

CONCLUSIONS

Historical records of *Desmocerus californicus* from Tulare County based on adult beetles rather than exit holes are limited; however, all specimens have phenotypes resembling the non-threatened subspecies *californicus* rather than the threatened subspecies *dimorphus* (Barr 1991; Chemsak 2005; and Halstead and Olmstead 2000). During the field surveys described herein, two males resembling the non-threatened subspecies were observed at the McKay Point site. For these reasons, I conclude that the beetle present there is the non-threatened *Desmocerus californicus californicus* rather than the threatened VELB (*Desmocerus californicus dimorphus*).

At this time the USFWS is preparing its final rulemaking regarding its earlier proposed

delisting of the VELB. It was supposed to have been published within one year from the publication of the proposed delisting (fall of 2012), but is overdue. While it is possible that USFWS will follow through with its original plan to delist the VELB, another scenario is that USFWS will continue to recognize the VELB as a threatened or endangered species, but modify the beetle's geographic range to exclude the southern and central portions of the San Joaquin Valley. If either of these scenarios actually occurs, then the VELB mitigation measures described in this report should no longer be necessary for the McKay Point reservoir project since the project site would no longer occur within the VELB's geographic range. Since its final rulemaking is already overdue, USFWS should publish its findings in the near future.

MANAGEMENT SUMMARY

Tulare Irrigation District (TID), on behalf of the Visalia Water Company, and the Consolidated Peoples Ditch Company are proposing to build the McKay Reservoir Project (Project), a reservoir and associated intake and outlet structures, on land adjacent to the Kaweah and St. Johns Rivers in Tulare County, California. As the Lead Agency, TID is subject to Tulare County's regulations under the California Environmental Quality Act (CEQA).

To meet CEQA requirements, Applied EarthWorks, Inc. (*Æ*), on behalf of TID, conducted a cultural resources investigation to determine whether cultural resources are present within the Project area. The study included records searches at the California Historical Resources Information System Southern San Joaquin Valley Information Center (SSJVIC) at California State University, Bakersfield to identify previously recorded sites and prior studies in the Project area, a search of the Native American Heritage Commission's (NAHC) Sacred Lands File,, and a pedestrian archaeological survey of the Project area. The initial SSJVIC records search of the Project area and the surrounding 0.5-mile radius indicated that the Project area had not been previously surveyed and no archaeological or historical sites had been previously identified in the Project area.

As a result of the survey, *Æ* identified and recorded one historic-era isolate (P-54-005095/ AE-2193-2) and one prehistoric isolate (P-54-005096/AE-2193-3). P-54-005095 is a scatter of wood and metal that appears to be the remains of a historic wagon in the northwestern corner of the Project area. P-54-005096 is a basalt flake that lies outside of areas to be disturbed by the Project, as currently designed. Isolates lack association with other artifacts or features and cannot typically be associated with specific individuals or historic events. The ability of isolates to provide data regarding prehistory or history is limited and typically exhausted by the process of recording. Therefore, neither of the isolates is considered eligible for the California Register of Historical Resources.

Because of the high sensitivity of the Project area to contain buried archaeological deposits, *Æ* recommends limited subsurface testing in the immediate area of P-54-005096 and geoarchaeological analysis of the Project area to more fully understand the potential for Project ground-disturbing activities to cause adverse impacts to buried cultural resources. *Æ* advises that in the event archaeological remains are encountered during Project development or ground-moving activities in any portion of the Project, all work in the vicinity of the find should be halted until a qualified archaeologist can identify the discovery and assess its significance.

If human remains are uncovered during construction, the Tulare County Coroner is to be notified to arrange their proper treatment and disposition. If the remains are identified on the basis of archaeological context, age, cultural associations, or biological traits to be those of a Native American, California Health and Safety Code 7050.5 requires that the County Coroner notify the NAHC within 24 hours of discovery. The NAHC will then identify the Most Likely Descendant, who will be afforded the opportunity to recommend means for treatment of the human remains following protocols in California Public Resources Code 5097.98. A copy of the final version of

this report will be placed on file at the SSJVIC. Field notes and photographs are on file at *Æ*'s office in Fresno, California.

1
INTRODUCTION AND PROJECT DESCRIPTION

The Tulare Irrigation District (TID), on behalf of the Visalia Water Company, and the Consolidated Peoples Ditch Company are proposing to build the McKay Point Reservoir Project (Project), a water storage/reregulation facility in Tulare County, California (Figures 1-1 and 1-2). The Project lies in Township 18 South, Range 27 East, Sections 3 and 4 as shown on the U.S. Geological Survey (USGS) Woodlake 7.5-minute topographic quadrangle (Figure 1-3). The Project footprint occupies approximately 194 acres on the north side of the St. Johns River where it diverges from the Kaweah River at McKay Point.

Figure 1-1 Project area from the northeastern corner; view to the west-southwest.

The Project would require discretionary approvals and is therefore subject to the California Environmental Quality Act (CEQA). The TID is the Project applicant and the CEQA Lead Agency. The TID proposes the excavation, construction, and maintenance and operation of the McKay Point Reservoir (Project) on behalf of the Visalia and Kaweah Water Company and the Consolidated Peoples Ditch Company (Owners). The reservoir would provide surface water storage and reregulation to optimize groundwater recharge within the Owners' service areas. The Project area consists of 194 acres within the McKay Point property, including excavation of a 110-acre pit extending 60 feet below the ground surface (Figure 1-4). West Coast Sand and Gravel would be contracted to complete excavation of overburden and transform the aggregate

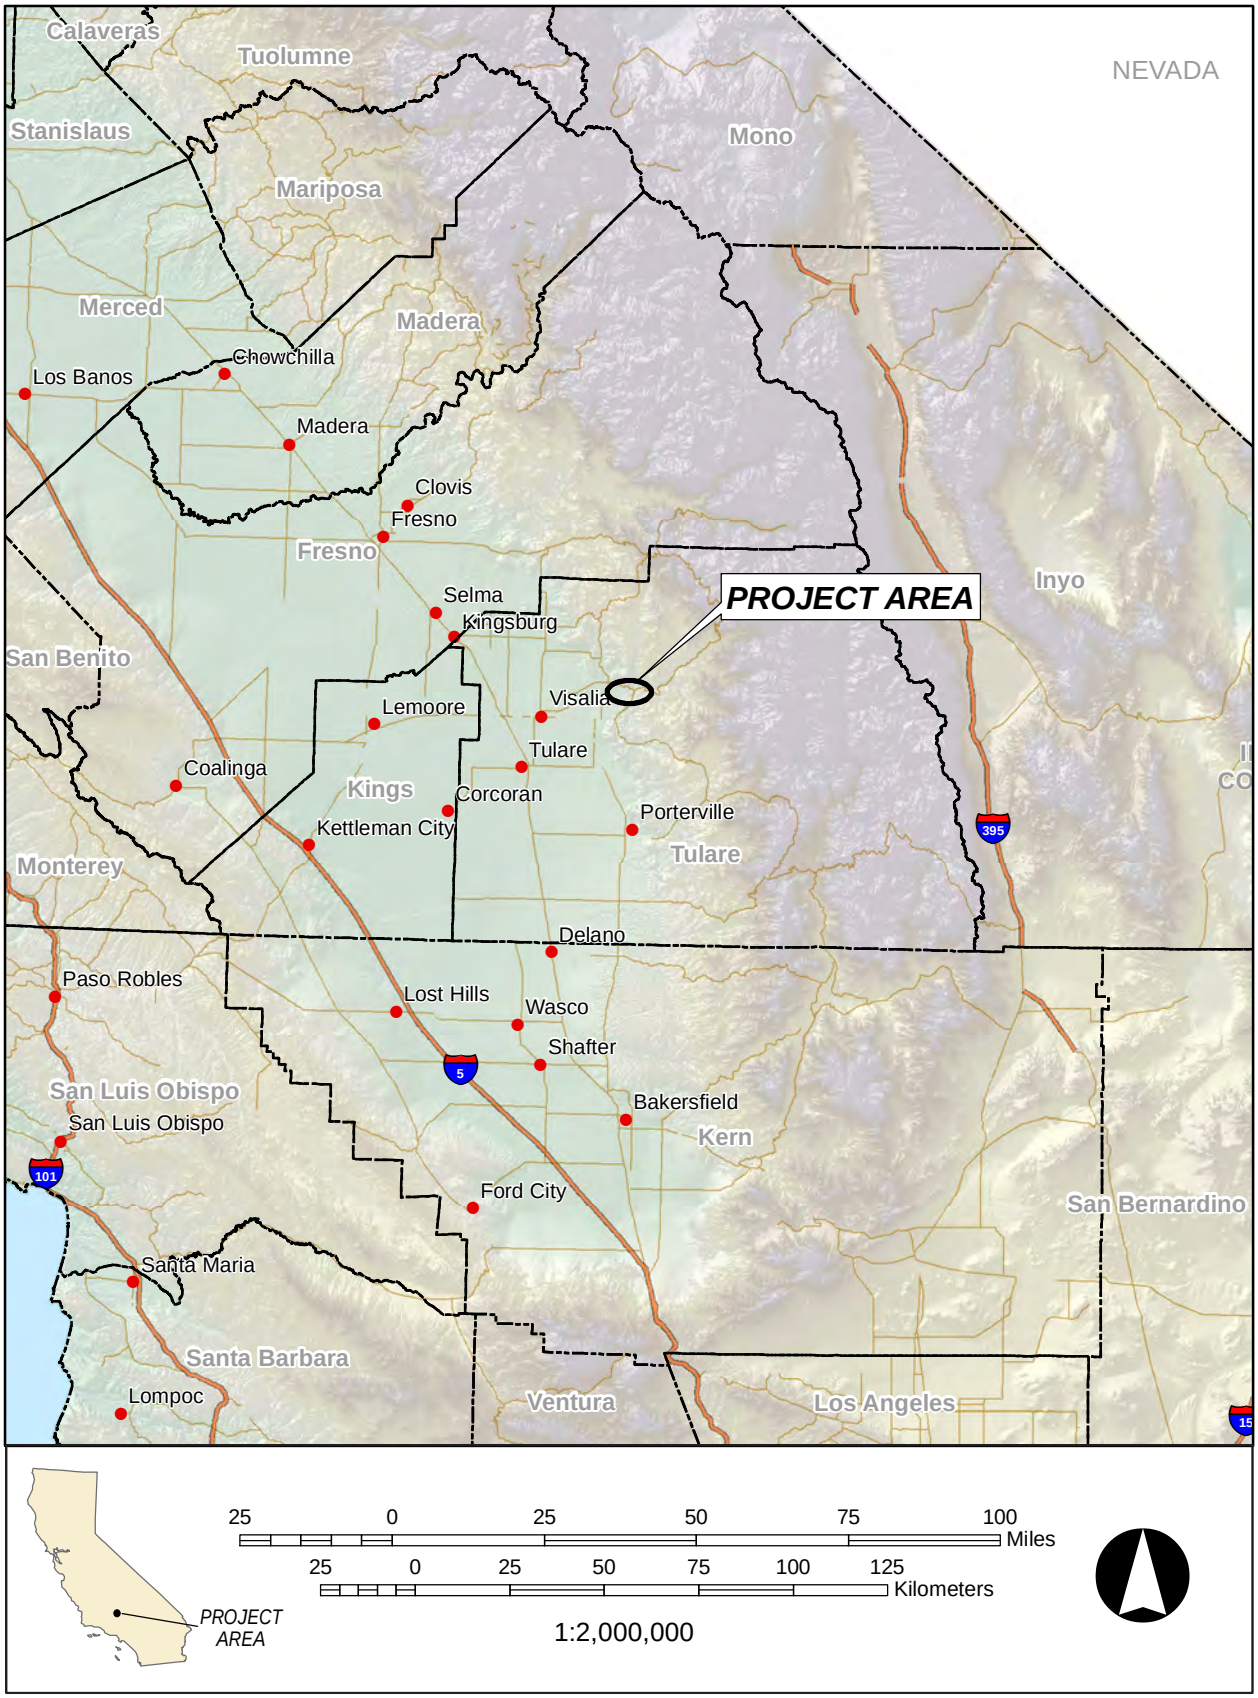

Figure 1-2 Project area in Tulare County.

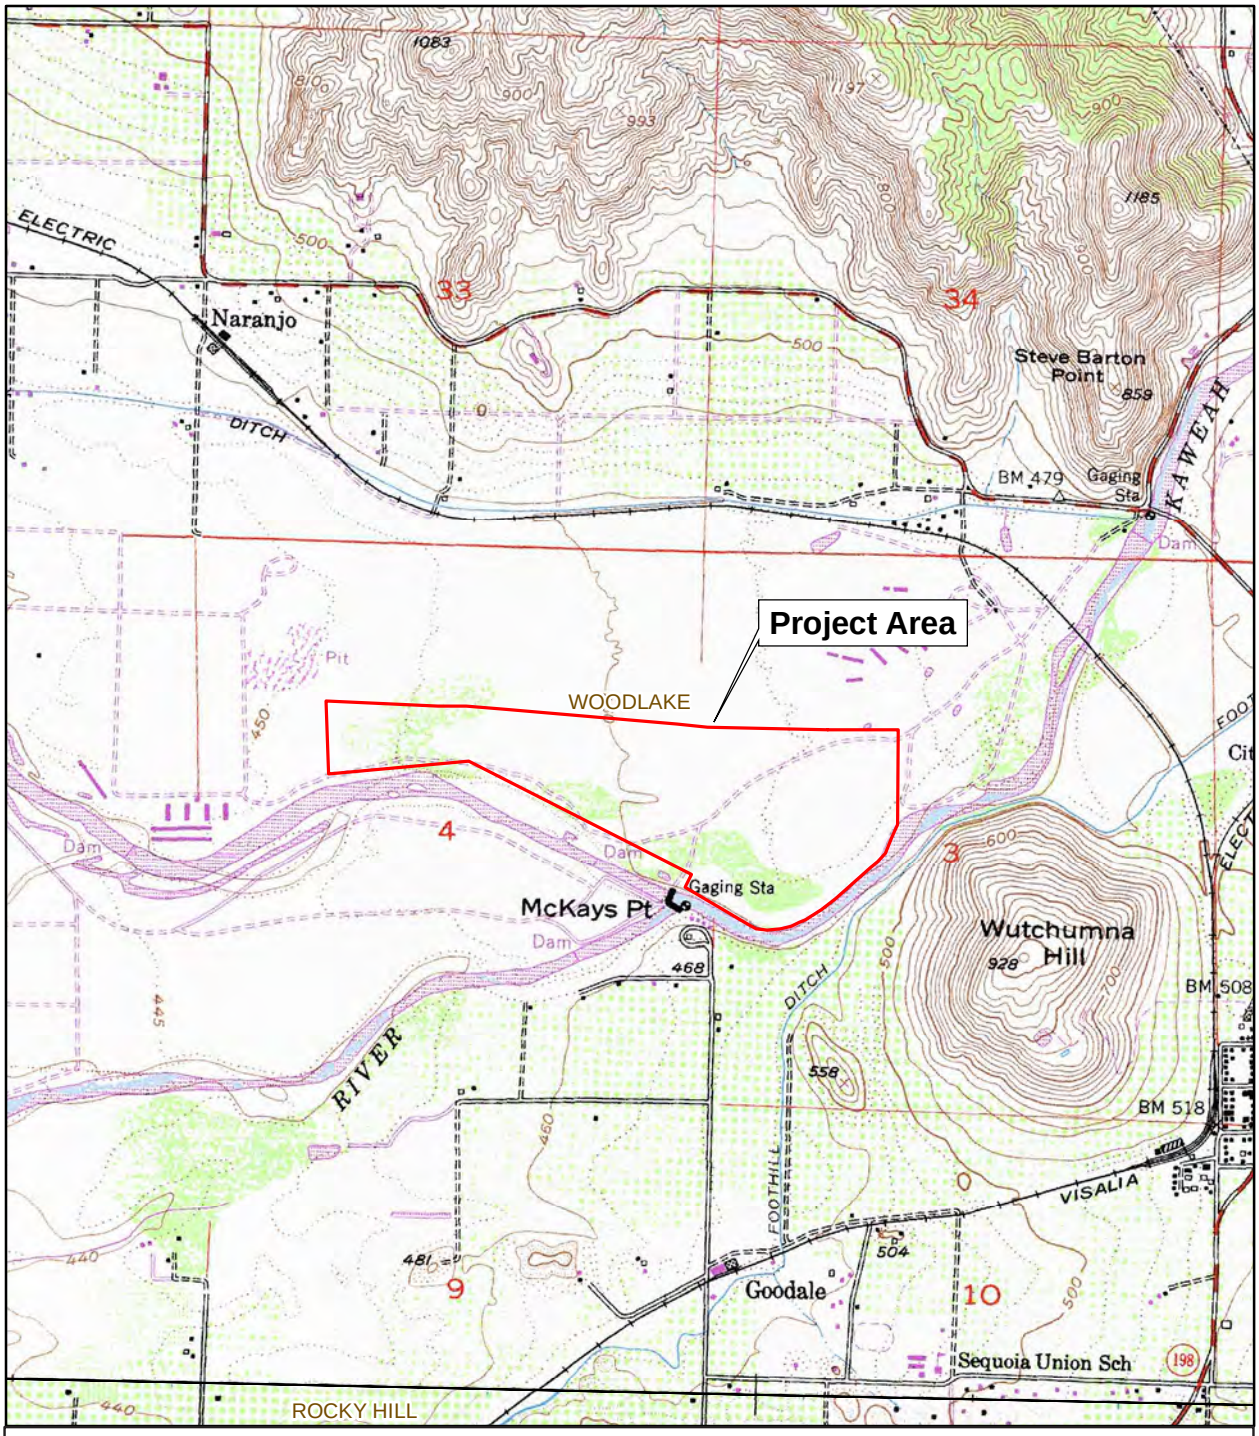

Figure 1-3 Project location on U.S. Geological Survey Woodlake 7.5-minute quadrangle.

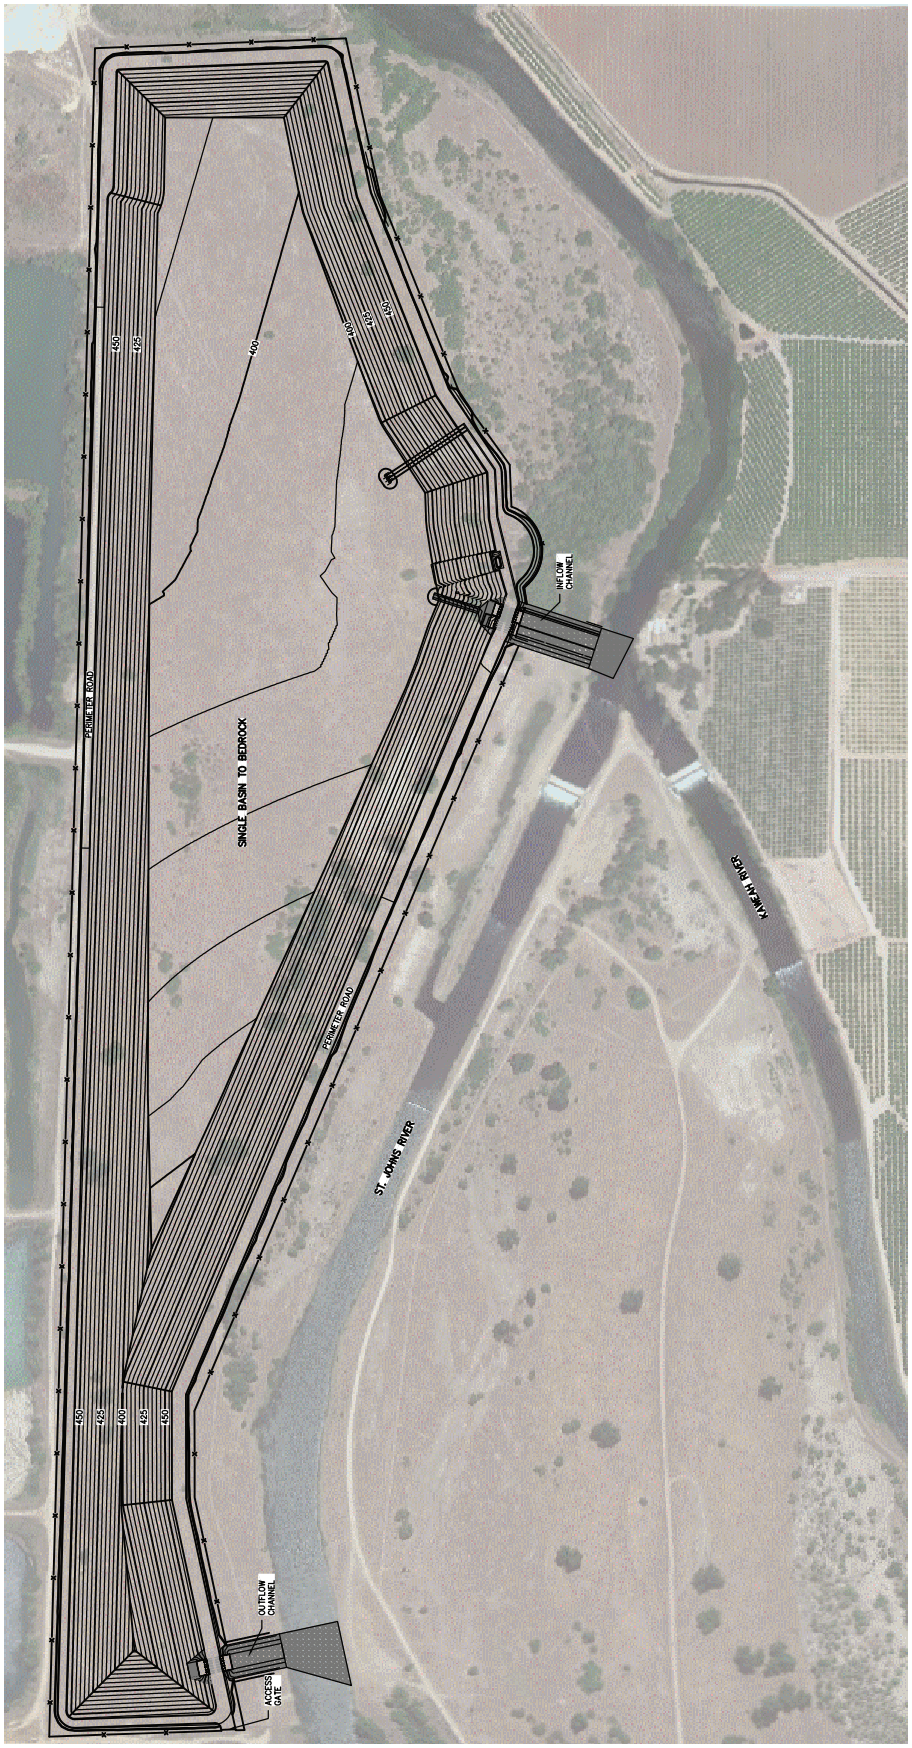

Figure 1-4 Proposed Project footprint.

into saleable material offsite. Other construction elements include inflow and outflow channels with reinforced concrete base and riprap, a flow/level control gate, an infiltration gallery made up of on-site ditches, a peripheral fence with access road, an entrance gate, and a generator building. The Project also includes a habitat area adjacent to the reservoir. This area will be preserved and not subjected to any ground-disturbing activity (Figure 1-4).

Tulare County will serve as Lead Agency under the California Surface Mining and Reclamation Act (SMARA) and, as such, the Project will be required to obtain County approval of a Surface Mining Permit for a SMARA-compliant Reclamation Plan and Financial Assurance Cost Estimate. TID is the Lead Agency for purposes of compliance with the CEQA, which mandates that public agencies consider whether their actions will have a significant impact on important cultural resources. Under CEQA, cultural resources require consideration if they are listed in or are eligible for listing in the California Register of Historical Resources (CRHR). A significant impact occurs if the project alters the qualities or properties of the resource that make it eligible for listing on the CRHR, although it should be noted that not all impacts are significant or adverse.

Under contract to Sespe Consulting, Inc. (Sespe), Applied EarthWorks, Inc. (Æ) performed a cultural resources investigation for the Project. The investigation included: (1) records searches, (2) Native American outreach, (3) a pedestrian archaeological surface survey completed in 2013 (Armstrong and Lloyd 2014), and (4) preparation of this technical report. The cultural resources work documented in this report was carried out in accordance with state regulations and standards, and the report has been prepared in accordance with the California Office of Historic Preservation (1990) standards outlined in *Archaeological Resource Management Reports (ARMR): Recommended Contents and Format*. Æ also has performed paleontological studies of the Project area, which are reported under separate cover (Clifford and DeBusk 2014; Macias 2021).

Æ Senior Archaeologists Jay Lloyd (M.A.), a Registered Professional Archaeologist (RPA) and D. Gail Bellenger (M.A., RPA), provided technical and administrative oversight for all aspects of the Project. Æ Principal Archaeologist Diana T. Dyste (M.A., RPA) contributed to the report and served as technical editor. Associate Archaeologist Matthew Armstrong (M.A., RPA) requested the records search, conducted Native American outreach, supervised the pedestrian survey, and prepared the technical report. Jessica Jones requested a supplementary records search and updated this technical report. Æ GIS Technician Elizabeth Rapp (B.A.) assisted with the intensive pedestrian survey and prepared the Project maps. Résumés for supervisory personnel are provided in Appendix A.

2
SETTING

This chapter describes the environmental and cultural setting of the Project area to provide a context for understanding archaeological resources in the region. The nature and distribution of past human activities in the Central Valley have been affected by topography, climate change, water availability, and access to biological resources. Therefore, prior to discussing the cultural setting, aspects of the regional environment are briefly summarized below.

2.1 ENVIRONMENTAL SETTING

The Project area is in the San Joaquin Valley, the southern half of an elongated trough called the Central Valley. The Central Valley is a 50-mile-wide lowland that extends approximately 500 miles from the Cascade Range to the Tehachapi Mountains (Norris and Webb 1990:412). The Central Valley is divided into two unequally sized lobes separated by the Stockton fault. The northern lobe is the Sacramento Valley, drained by the Sacramento River, whereas the southern lobe is the San Joaquin Valley, drained by the San Joaquin River. The southeastern end of the San Joaquin Valley contains the now dry Tulare–Buena Vista–Kern Lake basin.

The San Joaquin Valley is bound by the Sacramento/San Joaquin River Delta to the north, the Sierra Nevada to the east, the Coast Ranges to the west, and the Tehachapi Mountains to the south. The San Joaquin Valley comprises two distinct hydrologic subbasins: the San Joaquin and the Tulare. The San Joaquin subbasin is drained by the San Joaquin River. The Tulare subbasin has no regular surface outlet; it was formed by the merging of alluvial fans from the Kings River to the east and Los Gatos Creek to the west (Cone 1911). The Tulare subbasin rivers—the Kings, Kaweah, Tule, and Kern—flowed into the subbasin, forming large inland lakes. Tulare Lake, approximately 30 miles southeast of the Project area, was an extremely shallow seasonal lake that expanded horizontally across the flat landscape as it filled with winter and spring runoff. Its broad yet shallow dimensions resulted in wide fluctuations of the lake's shoreline during both prehistoric and historical times. As it filled beyond its natural alluvial barriers, water was channeled down the Fresno Slough into the San Joaquin River. Tulare Lake was the largest naturally occurring lake in California as recently as 1920 (Norris and Webb 1990:433). The size of the lake was gradually reduced by the historical development of irrigation systems and the reclamation of water from the Kings River and other sources. Today, Tulare Lake only exists in times of flooding, and the deep reserve of groundwater is tapped for private and public use.

The Project area is located on the north side of the confluence of the St. Johns River and the Lower Kaweah River, near Woodlake in Tulare County. The Kaweah River flows from a canyon in the Sierra Nevada approximately 3 miles to the northeast. The Kaweah is one of a number of rivers (including the Kern, Tule, and Kings) that deposit low-gradient fans along the eastern San Joaquin Valley and drain the western slopes of the Sierra Nevada range. Elevations in the Project area range between 450 and 470 feet above mean sea level.

Several branch streams (including the St. Johns River) diverge from the Kaweah River soon after it exits the canyon at the head of a large low-gradient alluvial fan commonly referred to as the

Kaweah Delta. The river is now dammed, and water flow is highly regulated; however, many of the formerly natural channels are still evident. Additionally, sloughs, abandoned channels, and overflow channels further connect or distribute water across the lower portion of the alluvial fan. Between channels are large masses of recently vegetated alluvium, rapidly aggrading due to the cohesive nature of fine particles and root binding by vegetation (Waters 1992). This hydrological system has been highly modified by channelization and water control in the valley, and some drainages (including the St. Johns River) flow only seasonally if at all.

The development of agriculture within the Project area resulted in the replacement of native plants and animals with domesticated species. Common native plants today include white, blue, and live oaks (*Quercus* sp.) as well as walnut (*Juglans* sp.), cottonwood (*Populus aegiros*), willow (*Salix* sp.), and tule (*Schoenoplectus* sp.). Also prominent is bulrush (*Cyperus* sp.) and cattail (*Typha* sp.), various grasses, flowers, and saltbrush. The previously swampy valley floor once provided a lush habitat for a variety of animals including mule deer (*Odocoileus hemionus*), tule elk (*Cervus* sp.), pronghorn (*Antilocapra americana*), grizzly bear (*Ursus arctos californicus*), black bears (*Ursus americanus*), and mountain lions (*Puma concolor*) (Preston 1981:245–247). Mammals commonly noted today are the valley coyote (*C. latrans*), bobcat (*Lynx rufus*), gray fox (*Urocyon cinereoargenteus*), kit fox (*Vulpes macrotis*), and rabbits (Leporidae). Birds in the area include American osprey (*Pandion haliaetus* sp.), redwing blackbird (*Agelaius phoeniceus*), marsh hawk (*Circus cyaneus*), willow and Nuttall woodpeckers (Picidae), western meadowlark (*Sturnella neglecta*), and quail (Phasianidae). The lakes, rivers, and streams throughout the vicinity provided rich habitat for an assortment of freshwater fish species (Preston 1981:249).

2.2 CULTURAL SETTING

2.2.1 Prehistory

Relatively few research-oriented archaeological investigations have been conducted in the Central Valley south of the Stockton area, and synthesized information on prehistoric events in the area is sparse (Moratto 1984:189, 191–193, 512, 573; Rosenthal et al. 2007). Nonetheless, archaeological work performed within the Kaweah River drainage, and specifically a few miles to the east at Lake Kaweah (Meighan et al. 1988) provides valuable information germane to regional prehistory. Further information comes from excavations performed in the mountains and hills to the south and southeast (Dillon 1992; Meighan et al. 1988; Wallace et al. 1989).

The first large-scale excavations in the southern San Joaquin Valley were conducted near Tulare and Kern Lakes by Gifford and Schenck (1926), who unearthed flexed burials, pottery, obsidian arrow points, milling stones and mortars, and intricately fashioned steatite artifacts. In the late 1940s, Riddell (1951) investigated a Yokuts cemetery (CA-KER-74) near the town of Delano. The graves contained Euro-American items along with shell ornamentation, flaked stone tools, and steatite artifacts. Less than 10 years later, a team of archaeologists from University of California, Los Angeles, excavated CA-TUL-90, another burial site at the edge of former Tulare Lake approximately 29 miles west of the Project. By comparing their findings at CA-TUL-90 with those of earlier studies, Warren and McKusick (1959) constructed a chronological sequence of mortuary practices, which could then be used to infer the age(s) of sites containing interments.

Later archaeological investigations at Kern and Tulare lakes revealed that occupation occurred possibly as early as 11,000 years before present (B.P.) (Sampson 1991). The Witt Site (CA-KIN-32) on the southwest shore of Tulare Lake contains fluted projectile points as well as later types, suggesting continuous occupation of the basin from Paleoindian times until historical contact (Fenenga 1993; Moratto 1984:81–82).

Excavation of CA-KER-116, a prehistoric site at Buena Vista Lake, found a deeply-buried component ascribed to the Western Pluvial Lakes Tradition that dated from circa 11,500–7500 B.P. (Fredrickson and Grossman 1977; Grossman 1968; Moratto 1984). Population density was low at that time, with a few settlements focused around the shores of ancient lakes. Between 8000 and 4000 B.P., the prehistoric economy centered on hunting and fishing, although mortars and pestles as well as *Olivella* and *Haliotis* shell beads and ornaments appear in some assemblages (Sutton 1997). Although populations may have centered on the lakes, there is some evidence for use of the mountains of eastern Tulare County as early as 6000 B.P. by small, highly mobile parties who repeatedly visited specific resource procurement areas (Dillon 1992).

Beginning about 4000 B.P., the subsistence base expanded to include seed processing. Sites dating to this period contain assemblages comparable to the roughly coeval Early Horizon components of the Sacramento–San Joaquin Delta region (e.g., extended burials with grave goods, Pinto series projectile points, time-diagnostic *Haliotis* and *Olivella* beads as well as ornaments and charmstones) (Moratto 1984; Riddell 1951; Walker 1947; Wedel 1941). It is difficult to clearly determine the ancestry of these early peoples, although artifact assemblages associated with occupations postdating 3000 B.P. may be linked to the ancestors of the ethnographic Yokuts. The latest period of occupation, from 1500 B.P. to historic contact, indicates a greater reliance on acorns and other plant foods as well as trade with the Central Coast region and Southern California interior (Moratto 1984:183, 188).

Chronological data from research conducted within the Kaweah River drainage to the east of the Project area is limited as few radiocarbon dates, obsidian hydration measurements, or time-diagnostic artifacts have been collected or reported (Meighan et al. 1988:140, 270–273). Available data suggest that occupation of the Lake Kaweah area began around 2500 B.P., although it is likely that earlier occupations are simply unrecognized (Meighan et al. 1988:273).

The Kaweah River drainage generally, and the location currently covered by Lake Kaweah specifically, was well-populated in late prehistory. Some ethnohistoric period estimates place the population as high as 2,400 individuals. The area supported a large variety of site types, including villages, cemeteries, bedrock milling stations, hunting blinds and traps, and rock art. The settlement system appears to have centered on villages, occupied most or all of the year, from which small groups (likely families) would radiate out to gather resources at seasonal camps and special-use sites (e.g. hunting locations, acorn gathering spots, etc.) (Meighan et al. 1988).

The identity of the prehistoric occupants of the Lake Kaweah area is open to some interpretation. Several sites indicate cemetery burials in keeping with late prehistoric and ethnohistoric Yokuts traditions. However, other sites contain cremations and burials in house floors. This may indicate retention of earlier burial practices within the Lake Kaweah area, or it may indicate that the area was occupied by both Yokuts and Mono peoples. This latter hypothesis is further supported by local rock art, which appears to be more similar to known Mono styles than to that of the Yokuts.

Moreover, pottery, an innovation often attributed to the Mono, is relatively abundant in Lake Kaweah sites, while steatite vessels more common in the western Yokuts sites are rare (Meighan et al. 1988). While, the ethnographic record indicates that the region was populated by Yokuts people, the aggregate data seem to suggest that either the Yokuts population regularly interacted with and shared many traits of the neighboring Mono population, or that the area prehistorically was used by both groups.

2.2.2 Ethnography

The Project area is within the homeland of the Gáwea (or Kaweah) Yokuts (Kroeber 1976: 480; Latta 1999:187–188), one of the many autonomous tribes that make up the Southern Valley Yokuts ethnolinguistic group. At the time of first contact with the Spanish missionaries, the Yokuts people, including northern valley and foothill groups, collectively inhabited the San Joaquin Valley as well as the eastern foothills of the Sierra Nevada from the Calaveras River southward to the Kern River (Wallace 1978a, 1978b). The Yokuts language belongs to the broader Penutian family, which subsumes a relatively diverse assemblage of languages, including Miwok, Costanoan, Maiduan, and Wintuan (Silverstein 1978). Compared to other Penutian languages, however, Yokuts shows considerable internal linguistic homogeneity, especially given the extent of its geographic distribution. Dialects differ minimally and were mutually intelligible, at least among individuals from contiguous groups. This relative lack of linguistic differentiation suggests that ancestors of the Yokuts entered California after the arrival and subsequent radiation of the more linguistically diverse Penutian groups such as the Miwok and Costanoan (Moratto 1984:554).

The basic unit of Yokuts society was the nuclear family, which was identified with a totem symbol specific to the paternal line. Within each tribe, lineage totems were further grouped into one of two moieties, designated by the overarching symbols of the eagle and coyote (Wallace 1978b:453). The basic political unit was the tribe or tribelet, which encompassed a single village or several settlements (Kroeber 1976).

Tulare Lake and its tributary rivers, including the Kaweah and the St. Johns, were a central part of Southern Valley Yokuts subsistence, providing food, building material, and avenues of travel for small watercraft. Not surprisingly, most Yokuts villages were situated near major waterways or around Tulare Lake (Wallace 1978b:448). For example, the main Gáwea village, also known as *Gáwea*, was situated on the north side of the Kaweah River at the current location of Terminus Dam (Latta 1999:188). The rivers provided fish, waterfowl, and other game attracted to the fresh water. The tule stalk was used in the manufacture of mats, baskets, and other goods (Wallace 1978b:451).

Most flaked stone artifacts were fashioned from obsidian and other imported material (Wallace 1978b:452). Ground stone artifacts, inclusive of handstones and milling slabs/slicks as well as mortars and pestles, were manufactured of granitic and metavolcanics rock. Where suitable outcrops were available, milling slicks and bedrock mortars were manufactured on bedrock. Where bedrock was not available, portable mortars and slabs manufactured from large cobbles and small boulders were used.

At the broader interregional level, the villages of the Southern Valley Yokuts profited from the east-west trade of goods that flowed between the Pacific coast and the high Sierra and Great

Basin (Davis 1961). The Yokuts bartered their local staples (e.g., freshwater fish, acorns, and tule reeds) to obtain such goods as Olivella beads and other shell material from the west as well as obsidian from the east.

As with other Indian groups in California, the lifeways of the Yokuts were dramatically altered as a result of contact with Spanish explorers and missionaries, miners, ranchers, and other immigrants who entered the San Joaquin Valley after 1700. In 1856, the Tule River Indian Reservation was established for the Koyeti and Yaudanchi tribes. The reservation was moved from its original site just east of Porterville, designated as State Historical Landmark #388, to its present location in 1873 (Tule River Indian Tribe 2011). As late as 1926, adobe ruins from the original reservation were still present (Small 1926:469). The introduction of European culture and new diseases proved devastating to the native population. In the 1860s, smallpox decimated Indians living at the Cobble Lodge site (CA-TUL-145) near Lake Kaweah (Moratto 1984:331).

There are several Native American tribal groups with ancestral ties to the Project area, including the Santa Rosa Rancheria Tachi Yokut Tribe, Tule River Indian Tribe, and the Wuksache Indian Tribe/Eshom Valley Band. Several Southern Valley Yokuts tribes have survived the effects of colonization. Yokuts today have developed language apprenticeship programs and early childhood education centers to serve tribal members, including the Wukchumne of the Tule-Kaweah near Porterville, Choynimni speakers of the Kings River tribes, Chukchansi at the Picayune and Table Mountain rancherias near Fresno, and Yawelmani speakers of the Tule River Reservation (Golla 2011:154). Several Yokuts tribal groups are governed by elders' councils and operate auxiliary departments that serve local tribal populations in areas of healthcare, education, and cultural resource management.

2.2.3 History

Government expeditions to the Tulare Lake basin during the mid to late 1840s resulted in recommendations for the development of agricultural settlements that would permanently alter the area (Preston 1981:62). After discovery of gold at Coloma in 1848, speculators began entering the San Joaquin Valley. The miners' needs for food and supplies subsequently facilitated the development of ranching in the Tulare Lake basin (Preston 1981:72). New roads and trails emerged throughout the area, and the ranching industry boomed when access to livestock markets to the north and south became available.

In 1853, Tulare County, which at the time included most of present-day Kings County, was established with the budding town of Visalia as the county seat. By the 1870s many Southern Pacific Railroad towns had emerged, including Hanford (1877), Lemoore (1877), and Tulare (1872) (Preston 1981:125). The coming of the railroad was by no means a boon for all residents. Numerous pioneers had settled on and improved railroad land, mistakenly believing that they would pay the low per-acre price advertised by the railroad for unimproved land. Instead, when homesteaders attempted to gain title to their land, they were given asking prices exceeding $30 per acre for their now-improved properties. The disgruntled settlers filed suits against the railroad but were stone-walled by railroad-backed politicians. Frustration erupted into violence on May 11, 1880 when homesteaders exchanged gunfire with a U.S. marshal and railroad representatives near Hanford. The incident—known as the Mussel Slough Tragedy—provided fodder for antirailroad sentiment in the press and served as the inspiration for the Frank Norris novel, *The Octopus: A California Story* (see Baloian [2009] and Hanson [2006]).

The pace of economic development in Tulare County greatly accelerated with the construction of irrigation systems. Several irrigation companies formed in the early and mid-1870s, and after overcoming initial financial and physical difficulties, the Lower Kings River, People's, and Last Chance ditches, among others, were delivering water to farms by the end of the decade (Menefee and Dodge 1913). Tulare irrigation concerns tapped the ample Kings River, although some canals draw water from the Kaweah River and its branches.

Citrus fruit, now a major crop in Tulare County, was initially thought "too exotic" for the San Joaquin Valley. Lemons, specifically, were thought to be ill-suited to the valley climate, until they were planted by James William Center Pogue in 1868. Initially planting nearer the Kaweah River, the Pogue family moved their orchards to the community of Lime Kiln. In addition to serving as the home base for Pogue's growing citrus operation, Lime Kiln also became the base for a large operation organized by Pogue, J. B. Wallace, and C. W. Crocker. The three also built the Pogue Hotel to serve travelers. In 1894, Pogue subdivided the land in and around Lime Kiln and sold residential lots, renaming the town Lemon Cove (Kaweah Commonwealth n.d.).

By 1910 the development of new towns and settlements had slowed dramatically, and improvements were initiated to construct better roads. Agricultural concerns continued to prosper, resulting in the intensification of local farming until the 1930s, when individual farmers emerging from the Great Depression no longer found agriculture to be a lucrative endeavor. Since that time farmland has increasingly been developed for commercial interests.

Despite the general slowdown in the development of new towns, Woodlake was founded in 1912 by land developer Gilbert F. Stevenson as a planned community surrounded by citrus orchards. Initial growth was rapid, and by 1913 Woodlake contained two schools, retail stores, two churches, a bank, and a newspaper. Stevenson further ensured the growth of the community by paying half of the cost to install a bridge across the St. Johns River, donating right-of-way to the railroad companies to bring trains (including the Visalia Electric Railroad) to the town, and building levees around Wood Lake (now known as Bravo Lake) to ensure that it remained a permanent year-round water feature (City of Woodlake 2013).

Stevenson's fortunes suffered with the onset of the Great Depression. However, Woodlake continued to grow, with agriculture remaining its primary source of income. The City of Woodlake was incorporated in 1940, making it the seventh city in Tulare County (City of Woodlake 2013).

3
METHODS

3.1 RECORDS SEARCH

Æ requested records searches from the California Historical Resources Information System Southern San Joaquin Valley Information Center (SSJVIC) at California State University, Bakersfield in October 2013 and November 16, 2020. These searches encompassed all land within a 0.5-mile radius of the Project area. Sources consulted included archaeological site and survey base maps, reports of previous investigations, cultural resource records, the listings of the National Register of Historic Places, the Historic Property Data File (3/18/13), the California Historical Landmarks, the California Register of Historical Resources, the California Inventory of Historic Resources, the California Points of Historical Interest, and the Built Environment Resources Directory (Appendix B).

3.2 NATIVE AMERICAN OUTREACH

On September 30, 2013, Æ contacted the Native American Heritage Commission (NAHC) on behalf of TID to request a search of its Sacred Lands File to identify any Native American cultural resources recorded in the Project area. Æ also requested a list of individuals and groups with whom TID may consult regarding resources of sacred or special cultural and spiritual significance in the Project area. On October 2, 2013, Æ sent letters describing the Project and its location to the contacts identified by the NAHC (listed below).

- Neil Peyron, Chairperson, Tule River Indian Tribe;
- Lalo Franco, Cultural Coordinator, Santa Rosa Tachi Rancheria;
- Kenneth Woodrow, Chairperson of the Wuksache Indian Tribe/Eshom Valley Band;
- John Sartuche of the Wuksache Tribe;
- Jennifer Malone; and
- Kerri Vera, Environmental Department, and Joey Garfield, Tribal Archaeologist, Tule River Indian Tribe.

On October 14, 2013, Æ sent a follow-up e-mail or made a phone call to those contacts that had not yet responded. A contact log and copies of the Native American outreach documentation are included in Appendix C.

3.3 FIELD SURVEY

Æ archaeologists Matthew Armstrong and Elizabeth Rapp conducted a pedestrian survey of the Project area using 15–20-meter transects on October 7–11, 2013. The approximately 175-acre survey area encompassed the 168 acres proposed for the Project, including the reservoir locations and habitat area (Figure 3-1). Æ also surveyed the banks of the St. Johns River adjacent to the Project's southern boundary.

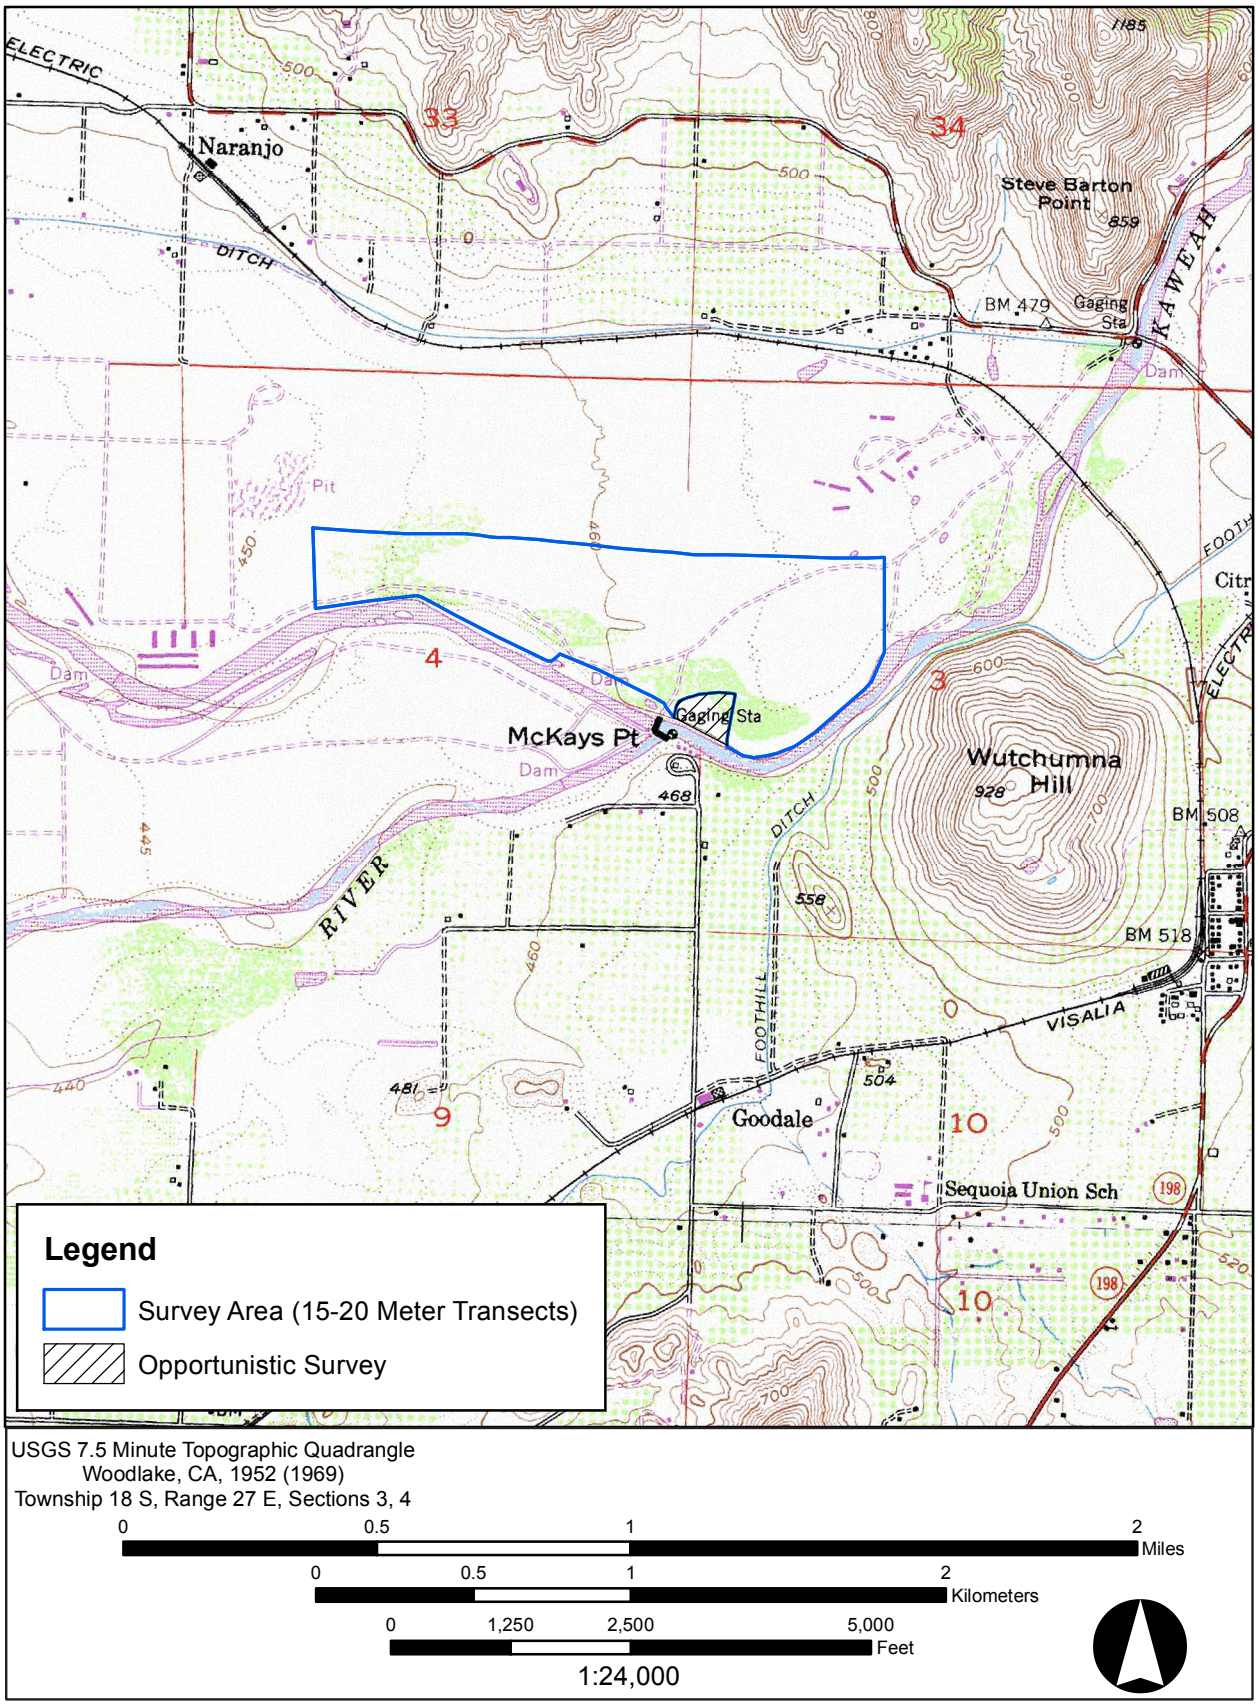

Figure 3-1 Cultural resources survey coverage.

When an artifact or feature was encountered that appeared to be of historic age (i.e., 45 years old or older), surveyors marked its position and closely examined the surrounding area for associated artifacts and/or features. Cultural resources identified within the Project area were mapped using a Trimble GeoXH hand-held Global Positioning System (GPS) and documented on California Department of Parks and Recreation (DPR) 523 series cultural resources inventory forms. Cultural resources and survey conditions were photographed using a Canon Powershot A810 digital camera. Methods and field observations were recorded on Æ Daily Work Record and Survey Field Record forms. All photographs and field notes are on file at Æ's Fresno office. Complete documentation of cultural resources, including confidential location maps, is included in Appendix D.

4
FINDINGS

4.1 RECORDS SEARCH AND BACKGROUND RESEARCH

Æ's first records search request was submitted to the SSJVIC on October 10, 2013, and results were returned on October 14, 2013 (RS# 13-403). Æ requested a supplementary records search to capture new resources or studies that have occurred in the Project vicinity since the 2013 investigations. The second records search was requested on November 16, 2020, and was returned on November 30, 2020. The results of both records searches are provided below. Until Æ's investigations in 2013 (TU-1668), no cultural resources studies had occurred within the Project area. Three cultural resource investigations have occurred within a 0.5-mile radius of the Project (Table 4-1), one of which (TU-01365) overlaps slightly with a portion of the survey area (see Section 3.3 for an explanation of the survey area versus the Project area).

Table 4-1
Previous Cultural Resources Studies within 0.5 Mile of the Project Area

SSJVIC Report No.	Report Author(s)	Report Date	Report Title
TU-01365	Pruett, Catherine	2009	A Cultural Resource Assessment for Approximately 30 Acres, Located Northeast of Visalia, Tulare County, California
TU-01394	Parr, Robert	2009	Cultural Resource Assessment for the Replacement of Eleven Deteriorated Power Poles on the Southern California Edison Company Bravo, Cairns, Campbell, Homer, Merryman, and Redbanks 12 kV Circuits, Tulare County, California
TU-01498	Leach-Palm, Laura; Brandy, Paul; King, Jay; Mikkelsen, Pat; Seil, Libby; Hartman, Lindsay; and Bradeen, Jill	2010	Cultural Resources Inventory of Caltrans District 6 Rural Conventional Highways in Fresno, Western Kern, Kings, Madera, and Tulare Counties

Until 2013, no resources had been recorded within the Project area, but five resources were identified within 0.5 miles of the Project area (Table 4-2): four historic-era resources (P-54-004034, -004587, -004615, and -004676) and one prehistoric habitation site located across the Kaweah River (P-54-000316). P-54-004676 was mistakenly mapped by the SSJVIC within the Project area, but a review of the site record found that it is on the St. Johns River, just outside both the Project area and the survey area. The site record describes P-54-000316 as a "village site" but provides no information regarding the site constituents. Documentation of the records searches is included in Appendix B.

Table 4-2
Previously Recorded Resources Within 0.5 Mile of the Project Area

Primary No.	Date Recorded	Prehistoric/ Historic	Description
P-54-004676	2008	Historic	Historic-era diversion dam (built in 1938)
P-54-004587	2008	Historic	Historic-era recreation area
P-54-000316	Unknown	Prehistoric	Probable habitation site
P-54-004034	2001	Historic	Historic-era electric railroad (built in 1905)
P-54-004615	1999	Historic	Historic-era ditch (built in 1878)

Æ also examined the historic USGS topographic maps of the Project area. The 1928 Lemon Cove and 1952 Woodlake 7.5-minute quadrangles (the name of the quadrangle was changed from Lemon Cove to Woodlake in 1952) show no infrastructure in the Project area itself, although the 1928 map shows a small dam on the St. Johns River downstream of the Project area. The 1952 map shows the current dam (P-54-004676) adjacent to the Project area and notes that the St. Johns River has gone dry. The 1969 revision to the 1952 map indicates water once again flowing in the St. Johns River and depicts dirt roads within the Project area (the same dirt roads still exist and were used by Æ during survey). The Project area is surrounded by the historic Visalia Electric Railroad, but this section of the electric railroad has not been formally recorded and does not intrude into the Project area.

4.2 NATIVE AMERICAN OUTREACH

On October 2, 2013, the NAHC responded to Æ's request and stated that the Sacred Lands File did not indicate the presence of sacred sites in the Project area. The NAHC provided Æ with a list of individuals and organizations to be contacted regarding information on Native American cultural resources in the Project area. Æ sent a letter soliciting concerns about the Project to the each of the individuals and tribes on October 2, 2013. Follow-up phone calls were made and emails sent on October 14, 2013. No further outreach was undertaken in 2020. The TID is responsible for government-to-government Native American consultation pursuant to CEQA and Assembly Bill 52.

To date, Æ has received responses from two of the seven individuals contacted (Table 4-3). A copy of Æ's Native American outreach log is provided in Appendix C.

Table 4-3
Excerpt from the Native American Outreach Log

Individual/Organization	Contact	Comments	Date Received
Santa Rosa Rancheria Tachi Yokut Tribe	Shana Brum	Brum stated that the Project is in a highly sensitive area and requested an on-site meeting and Native American monitoring during ground-disturbing activities. Brum further recommended that the Project proponent contact the Wukchumni Tribe.	10/7/13
Wuksache Tribe	Johnny Sartuche	Sartuche stated that the Project area is sensitive for cultural resources and requested that he be notified of any resources identified. He further recommended that the Project not proceed due to the sensitivity of the area.	10/14/13

4.3 FIELD SURVEY

The survey area is currently used as a cow pasture and is covered in seasonal grasses with a sparse scatter of live oaks, maples, and cottonwood trees. Cattle have recently eaten most of the grass cover, and mineral soil is visible throughout the proposed reservoir locations. Vegetation is dense in the reserved habitat area in the southeastern portion of the Project area. Approximately 90 percent of the survey area exhibited 60 percent or better ground visibility. The one exception is the westernmost end of the reserved habitat area, where dense berry vines and oak and maple trees resulted in poor ground visibility and prevented systematic transects. At these locations, the crew walked existing cattle trails, venturing into denser vegetation where feasible to look for features and artifacts. Ground visibility in the western portion of the reserved habitat area was approximately 10 percent.

Sediments within the survey area consist of poorly sorted coarse- to fine-grained sand and sandy loams, ranging from gray to light tan in color. Based on examination of rodent burrows and areas of disturbance, it appears that the soils are poorly developed, consistent with recent sediment deposition. During a visit to the Project area on October 7, 2013, TID Project Engineer Aaron Fukuda informed Æ's personnel that overflow water from the mines and reservoirs immediately north of the Project has washed over the Project area and into the river channels. It is possible that recent sediments overlie previously deposited cultural materials obscuring them from view.

4.3.1 Resources Within the Project Area

Æ's survey for the Project resulted in the discovery of two isolated artifacts—one from the historic era (P-54-005095/AE-2193-2) and one that is prehistoric P-54-005096 (AE-2193-3).

P-54-005095 is the collapsed remains of a wood object, likely a wagon. The majority of planks were too badly degraded to measure, but those that could be measured were 3.5 inches by 3.5 inches in cross section, and of unknown length due to decay and breakage (Figure 4-2). The hardware that held the planks together includes square nuts, round-headed nails, and metal rods of undetermined length (all were partially buried) that terminate in threaded nuts (Figure 4-3). The longer rods are consistent with cross rods of the sort that held the sides on wood wagons. None of the observed hardware is time diagnostic, but wood wagons would have been more common in the nineteenth and early twentieth centuries.

P-54-005096 is an isolated basalt flake (Figure 4-4). The flake is 4.5 centimeters long by 1.3 centimeters wide by 0.8 centimeters thick. It appears to be a secondary core reduction flake with no cortex. Three flake scars are present on its dorsal side.

4.3.2 Resources Immediately Outside the Project Area

Outside but immediately adjacent to the Project's eastern boundary are pieces of old machinery and a flatbed truck. These comprise a distinct scatter of unknown age and purpose. The bed, fenders, and cab of the truck are present, all other parts are missing (Figure 4-5). It appears to be a Ford flatbed truck, likely from the late 1930s to mid-1940s. It is not possible to determine when the truck was left at this location. The machinery appears to be parts of pulley and conveyor belt systems, consistent with equipment used in both mining and agriculture (Figures 4-6 and 4-7). The age of these objects is unknown, although their association with the

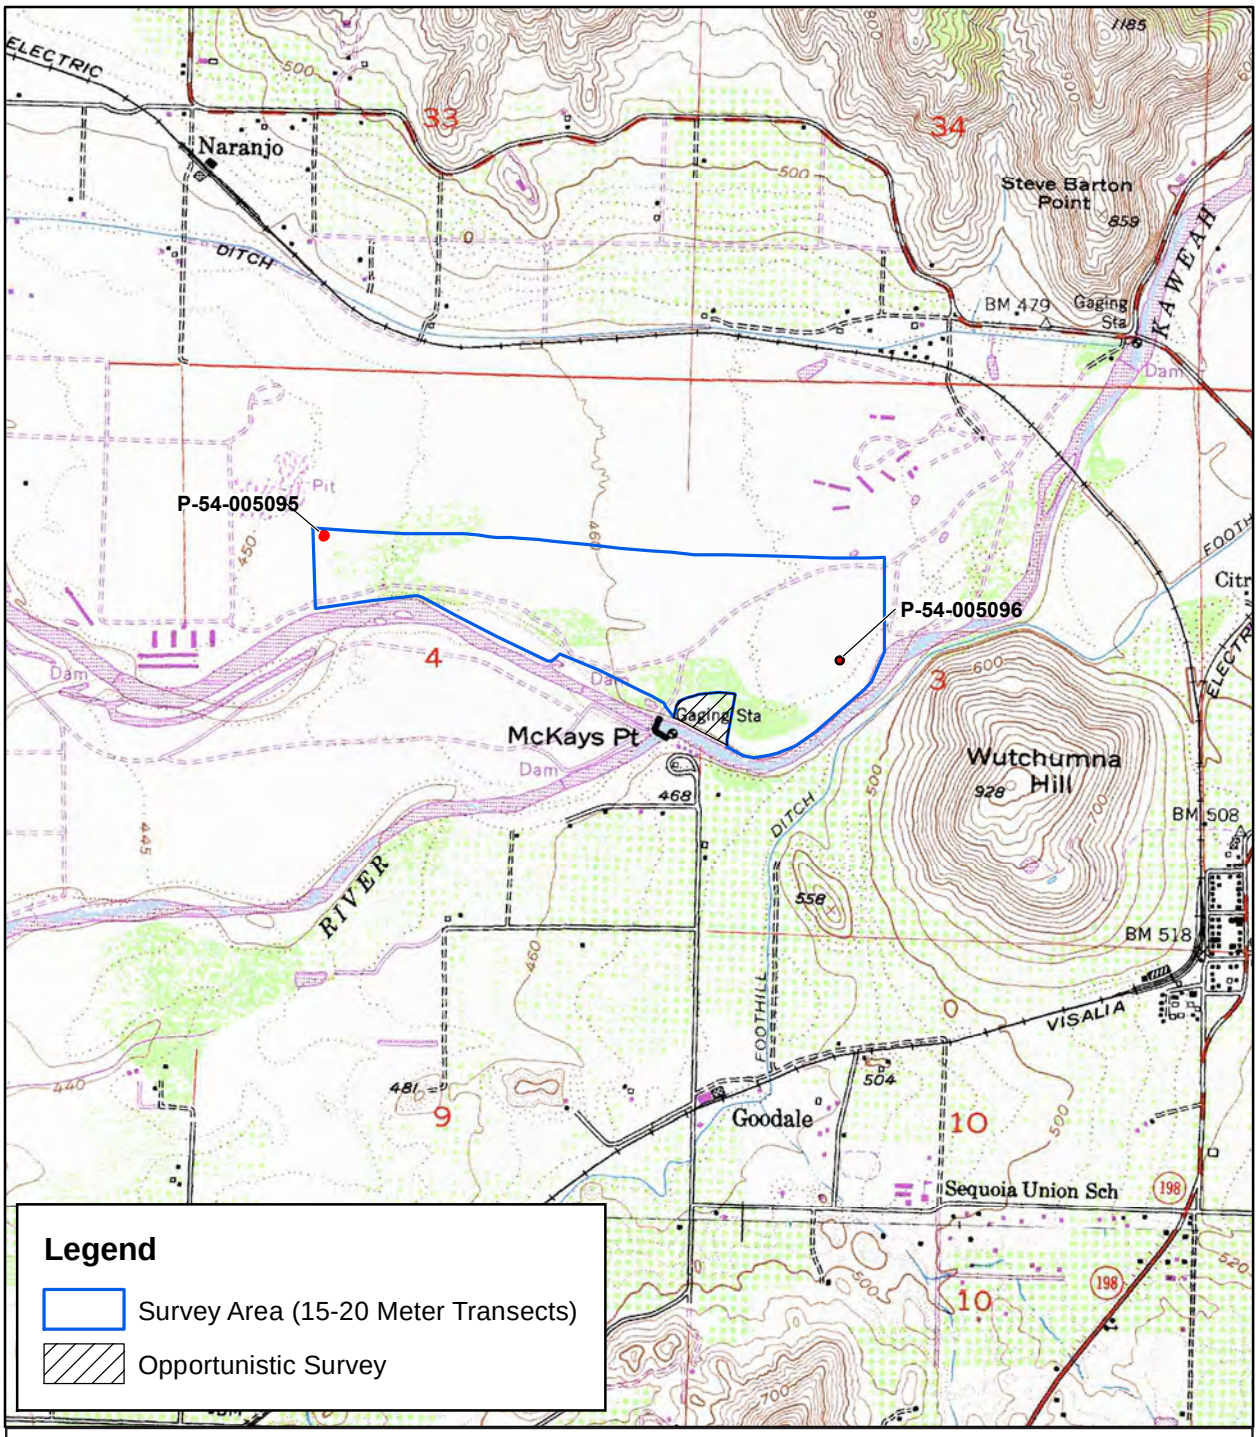

Figure 4-1 Location of cultural resources identified within the survey area.

Figure 4-2 Wood planks and hardware at AE-2193-2.

Figure 4-3 Close-up of long metal rods in AE-2193-2.

Figure 4-4 Ventral side of AE-2193-3.

Figure 4-5 Remains of truck near Project's eastern boundary; view to the east.

Figure 4-6 Machinery east of Project area; view to the east.

Figure 4-7 Machinery east of Project area; view to the north-northeast.

truck and the accumulation of sediments on parts of the machinery suggest that the truck and machinery were all deposited at or around the same time.

The Project, as currently designed, will not impact these objects, but their presence provides some information regarding the types of activities performed in the general vicinity of the Project. As such, they are worth noting, but they have not been formally recorded as cultural resources because they fall outside the Project area.

5
CONCLUSIONS AND RECOMMENDATIONS

TID, on behalf of the Visalia Water Company, and the Consolidated Peoples Ditch Company are proposing to build the McKay Point Reservoir Project in Tulare County. The construction of the Project requires compliance with the CEQA, which mandates that public agencies determine whether a proposed Project will have a significant effect on archaeological and historical resources, and, if so, whether the adverse effect can be avoided or mitigated.

As the first step in the CEQA process, Æ conducted a cultural resources inventory of the Project area. The purpose of the study was to identify cultural resources within the Project area and to assess whether additional studies are necessary. Subsequent phases of the CEQA process—which are not part of the scope of the current investigation—involve formally evaluating the significance and eligibility of identified cultural resources for inclusion in the CRHR, assessing potential Project impacts on significant resources, and applying mitigation measures to significant resources impacted by the development.

The following recommendations are based on the current understanding of both the Project and the resources. As additional information comes to light with regard to specific impacts associated with the Project, it may be necessary to revise, alter, or change the recommendations. As an alternative to additional studies, TID may elect to avoid potentially significant resources provided that such resources are protected from direct and incidental Project impacts.

5.1 SPECIFIC RECOMMENDATIONS

Æ discovered one historic-era isolate P-54-005095 and one prehistoric isolate P-54-005096 within the Project boundary. Isolates are objects lacking clear associations with other materials, time, or people, and as such can provide only limited information regarding history and prehistory. P-54-005095 and P-54-005096 are not unique, rare, or otherwise exceptional, and thus they are considered insignificant resources *a priori* under CRHR criteria because they lack important associations and scientific data potential. No further treatment of these resources is recommended.

However, isolated prehistoric artifacts may indicate the potential for significant buried archaeological deposits. There is high potential for the Project to uncover significant intact buried archaeological deposits given the Project's position on the landform and proximity to a meandering river environment that would have provided ideal habitat and rich sources for food and materials that would have sustained prehistoric Native American populations in the immediate area. Meandering river environments characterized by landforms that are subject to rapid alluvial deposition throughout time further increase the sensitivity of Project area. Further bolstering this point is the presence of an important Native American site across the Kaweah River southeast of the Project area.

Because of the high sensitivity for buried cultural resources in the Project area, Æ recommends two complimentary approaches to be completed prior to implementation of the Project: general Project area geoarchaeological testing and limited subsurface testing with shovels and augers at the location of P-54-005096. The latter would confirm if there is a larger intact buried archaeological deposit. If a more substantial deposit is identified, additional extended site testing would be needed to complete the CEQA-required assessment of the resource's significance and eligibility for inclusion in the CRHR. Geoarchaeological testing uses systems theory as a guiding framework to analyze patterns of geology, hydrology, sedimentology, and anthropogenic landscape use to interpret the potential for paleosols that may contain intact archaeological deposits within the study area (Schiffer 1987; Waters 1992). Subsurface coring or trenching then focuses on investigating key areas identified as having moderate to high potential for containing anthropogenic paleosols. Application of these recommendations would provide the CEQA Lead Agency with a more complete understanding of the potential for Project activities to cause adverse impacts to historical resources within the Project area.

5.2 GENERAL RECOMMENDATIONS

Consistent with state regulations, Æ advises that in the event archaeological resources are encountered during Project development or ground-disturbing activities within any portion of the Project area, all work within 100 feet (30 meters) of the find must be halted until a Secretary of the Interior qualified professional archaeologist can identify the discovery and assess its significance. Such finds include, but are not limited to, prehistoric stone grinding implements, stone tools, soapstone bowls, ornaments (e.g., beads, pendants), features such as burned soil, earthen ovens, and floors of shelters as well as intact historic-era building foundations and concentrations of historic artifacts.

If human remains are uncovered during construction, the Tulare County Coroner is to be notified immediately and must investigate the discovery. If the remains are identified on the basis of archaeological context, age, cultural associations, or biological traits to be those of a Native American, California Health and Safety Code 7050.5 requires that the coroner notify the NAHC within 24 hours of discovery. The NAHC will then identify the Most Likely Descendant, who will be afforded the opportunity to recommend means of treatment for the human remains pursuant to California Public Resources Code 5097.98.6.

APPENDIX A

Personnel Qualifications

DIANA TERESA DYSTE

Managing Principal/Principal Archaeologist

Areas of Expertise

- Cultural resource management
- Ethnography
- Tribal consultation
- Zooarchaeological, paleoethnobotanical, and ground stone analysis

Years of Experience

- 20

Education

Ph.D. candidate, Anthropology/ Feminist Studies, University of California, Santa Barbara

M.A., Anthropology (Archaeology/ Cultural Resource Management emphasis), University of California, Santa Barbara, 2010

B.A., Anthropology, University of California, Santa Barbara, 2002

A.A., Liberal Arts and Sciences, Ventura College, 1999

Registrations/Certifications

- Registered Professional Archaeologist 39362477

Permits/Licensure

- Principal Investigator, California BLM Statewide Cultural Resources Use Permit CA-18-22

Professional Affiliations

- American Anthropological Association
- American Cultural Resources Association
- Santa Barbara Museum of Natural History
- Society for American Archaeology
- Society for California Archaeology
- World Archaeological Congress

Professional Experience

2020–	Managing Principal/Principal Archaeologist, Applied EarthWorks, Inc., Fresno, California
2018–2020	Senior Archaeologist, Applied EarthWorks, Inc., Fresno, California
2015–2018	Interim Cultural Resources Supervisor and Senior Archaeologist/Ethnographer, Aspen Environmental Group
2007–2009	Archaeologist (GS-9), U.S. Department of Agriculture, Los Padres National Forest
2005–2007	Archaeologist (GS-7), U.S. Department of Agriculture, Los Padres National Forest
2004–2005	Archaeological Contractor, Padre, Inc., Ventura, California
2000–2005	Archaeologist (GS-4/5), U.S. Department of Agriculture, Los Padres National Forest

Technical Qualifications

Ms. Dyste has 20 years of experience in cultural resources management and meets the Secretary of the Interior's qualification criteria as an archaeologist. She has extensive experience preparing environmental documents and managing complex projects pursuant to applicable federal, state, and local regulations. Her work includes senior review or prime authorship of cultural resources documents for National Historical Preservation Act Section 106, National Environmental Policy Act, and California Environmental Quality Act compliance, including public and tribal comment and response; development of research designs; design and implementation of cultural resource plans. Ms. Dyste is qualified to conduct archaeological survey, as well as zooarchaeological, paleoethnobotanical, lithics, and ethnographic analyses. She is able to analyze cultural spatial patterns via use of Geographic Information Systems software. Ms. Dyste's Assembly Bill 52 and NHPA Section 106 tribal consultation services are informed by her knowledge and training in Native American jurisprudence, cultural sensitivity training, and graduate seminars in Native American environmental law, indigenous research methodologies, and community-based Participatory Action Research with tribal and special interest groups. She has project experience in coastal, highlands, grasslands, desert, and remote mountain settings across the state of California, although her academic region of specialty is in central and southern California with a focus on Salinan, Esselan, northern/interior/coastal Chumash prehistoric and modern political tribal groups. Ms. Dyste is a native Spanish speaker and assists clients with the translation of English to Spanish signage and public notices.

D. Gail Bellenger

Senior Archaeologist

Areas of Expertise

- Cultural resource management
- Prehistoric archaeology
- Native American outreach and tribal consultation
- Project management

Years of Experience

- 15

Education

M.A., Public Archaeology, California State University, Northridge, 2016

B.S., Environmental Resource Management, University of Nevada, Reno, 1996

B.A., Anthropology, University of Nevada, Reno, 1994

Registrations/Certifications

- Registered Professional Archaeologist 41587764

Professional Affiliations

- Society for California Archaeology

Professional Experience

2020–	Senior Archaeologist, Applied EarthWorks, Inc., Fresno, California
2018–2020	Archaeologist and Senior Biologist, EMC Planning Group, Monterey, California
2016–2018	Environmental Manager, Project Engineering Company, West Jordan, Utah
2001–2004	Environmental Scientist IV-Cultural Resources and Environmental Resources, Nevada Department of Transportation, Carson City, Nevada
1997–1999	Co-op Archaeologist, Bureau of Land Management, Battle Mountain, Nevada
1995–1997	Curatorial Assistant, Nevada State Museum Anthropology Department, Carson City, Nevada
1994–1995	Paleoclimatology Lab Intern, Desert Research Institute, Reno, Nevada

Technical Qualifications

Ms. Bellenger has 15 years of experience in cultural resource and environmental resource management and meets the Secretary of the Interior's qualification criteria as an archaeologist. Her areas of expertise include the prehistory of the central California coast and the Great Basin. She has prepared several National Register nominations and has experience preparing a variety of environmental documents. She has managed complex projects pursuant to applicable federal, state, and local regulations, including large- and small-scale projects requiring compliance with National Historical Preservation Act (NHPA) Section 106, National Environmental Policy Act (NEPA), and California Environmental Quality Act (CEQA). Ms. Bellenger is qualified to conduct archaeological surveys and construction monitoring. She has worked in desert, coastal, highlands, and remote locations throughout Nevada, Utah, and California. Her recent experience encompasses projects in central and central coastal California with a focus on Salinan, Esselen, and Ohlone tribes.

JESSICA JONES

Staff Archaeologist/Project Manager

Areas of Expertise

- Geographic Information Systems (GIS) in archaeology
- Computer-generated maps and graphics
- Archaeological survey and excavation

Years of Experience

- 7

Education

B.A., Anthropology, California State University, Sacramento, 2013

Archaeological Technician Certificate, Anthropology Department, Fresno City College, Fresno, California, 2011

Affiliations

Society for California Archaeology

Professional Experience

2020–	Staff Archaeologist/Project Manager, Applied EarthWorks, Inc. Fresno, California
2017–	Staff Archaeologist/GIS Specialist, Applied EarthWorks, Inc. Fresno, California
2015–2017	Geographic Information Systems (GIS) Technician, Applied EarthWorks, Inc., Fresno, California
2012–2013	Laboratory Technician (volunteer), Archaeological Research Center, California State University, Sacramento
2009–2010	Laboratory Technician (volunteer), Fresno City College, Fresno, California

Technical Qualifications

As a Staff Archaeologist, Ms. Jones performs Native American outreach, archival research, pedestrian archaeological and built environment survey, site recordation and evaluation, and partakes in archaeological excavation for projects throughout the Central Valley and Sierra Nevada foothills. She serves as a primary author or contributor for cultural resource inventory reports and is experienced in the preparation of California Department of Parks and Recreation (DPR) cultural resource record forms (523 series) and California Department of Transportation cultural resource documents. Ms. Jones has managed several water infrastructure improvement projects in the Central Valley and has working knowledge of Section 106 of the National Historic Preservation Act and California Environmental Quality Act regulatory frameworks. Her expertise also includes work as a Geographic Information Systems (GIS) technical specialist. She has extensive experience as a cartographer and spatial data manager for large and small projects involving both prehistoric and historic-era built environment cultural resources, particularly linear resources such as historic-era canal systems and related pumps, basins, and other components. Ms. Jones is a critical component of Æ's digital technology program, responsible for instructing cultural and paleontological staff in the use of ESRI ArcGIS software. Her background also includes extensive experience volunteering in archaeological repositories where she gained expertise in laboratory processing, cataloging, and management of archaeological collections.

CULTURAL RESOURCES RECORDS SEARCH

The following are the results of a search of the cultural resources site record files at the Southern San Joaquin Valley Information Center. These files include known and recorded archaeological and historic sites, inventories and excavation reports filed with this office, and properties listed on the National Register of Historic Places, the Historic Property Data File (3/18/13), the California Register, the California Historical Landmarks, the California Inventory of Historic Resources and the California Points of Historical Interest.

PRIOR CULTURAL RESOURCE INVENTORIES WITHIN THE REQUESTED SEARCH AREA AND A ONE-HALF MILE RADIUS

According to the information in our files, there have been no cultural resource studies conducted within the project area. There have been two (2) studies conducted within the one-half mile radius, TU-01365 and TU-01394. Study locations and their associated report numbers are shown on the project map.

RECORDED AND/OR KNOWN CULTURAL RESOURCES WITHIN THE REQUESTED SEARCH AREA AND A ONE-HALF MILE RADIUS

There is one (1) recorded cultural resource within the project area, P-54-004676. There are two (2) recorded cultural resources within a one-half mile radius, P-54-000316 and P-54-004587. Resource locations and their associated primary numbers are shown on the project map.

(RS# 13-403)

There are no cultural resources within the project area or radius that are listed or are eligible to be listed in the National Register of Historic Places, the California Register, the California Inventory of Historic Resources, The California State Historic Landmarks, or the California Points of Historical Interest.

COMMENTS/RECOMMENDATIONS

Requested documents are enclosed. If you have any questions or need additional information, please contact our office at (661) 654-2289.

Please forward a copy of any resulting reports from this project to the office as soon as possible. Due to the sensitive nature of archaeological site location data, we ask that you do not include resource location maps and resource location descriptions in your report if the report is for public distribution. If you have any questions regarding the results presented herein, please contact the office at the phone number listed above.

The provision of CHRIS Data via this records search response does not in any way constitute public disclosure of records otherwise exempt from disclosure under the California Public Records Act or any other law, including, but not limited to, records related to archeological site information maintained by or on behalf of, or in the possession of, the State of California, Department of Parks and Recreation, State Historic Preservation Officer, Office of Historic Preservation, or the State Historical Resources Commission.

Due to processing delays and other factors, not all of the historical resource reports and resource records that have been submitted to the Office of Historic Preservation are available via this records search. Additional information may be available through the federal, state, and local agencies that produced or paid for historical resource management work in the search area. Additionally, Native American tribes have historical resource information not in the CHRIS Inventory, and you should contact the California Native American Heritage Commission for information on local/regional tribal contacts.

Should you require any additional information for the above referenced project, reference the record search number listed above when making inquiries. Invoices for Information Center services will be sent under separate cover from the California State University, Bakersfield Accounting Office.

Thank you for using the California Historical Resources Information System (CHRIS).

Sincerely,

Celeste M. Thomson
Coordinator

Re: Request for Sacred Lands File Search and Native American Contacts list for the **"McKay Point Reservoir Project;"** located in Tulare County, California

Dear Mr. Armstrong:

A record searches of the NAHC Sacred Lands File **failed to indicate** the presence of Native American traditional cultural place(s) in the project sites submitted, based on the USGS coordinates submitted as part of the 'Area of Potential Effect.'(APE). However, there are Native American cultural resources in close proximity to the APE. Also, the absence of archaeological resources does not preclude their existence. Other data sources for Native American sacred places/sites should also be contacted. A Native American tribe of individual may be the only sources of presence of traditional cultural places or sites.

In the 1985 Appellate Court decision (170 Cal App 3rd 604; *EPIC v. Johnson*), the Court held that the NAHC has jurisdiction and special expertise, as a state agency, over affected Native American resources impacted by proposed projects, including archaeological places of religious significance to Native Americans, and to Native American burial sites.

Attached is a list of Native American tribes, individuals/organization who may have knowledge of cultural resources in or near the project area. As part of the consultation process, the NAHC recommends that local governments and project developers contact the tribal governments and individuals to determine if any cultural places might be impacted by the proposed action. If a response is not received in two weeks of notification the NAHC requests that a follow telephone call be made to ensure that the project information has been received.

If you have any questions or need additional information, please contact me at (916) 373-3715.

Sincerely,

Dave Singleton
Program Analyst

RE: McKay Point Reservoir Project, Tulare County, CA

Mr. Neil Peyron,

Applied EarthWorks, Inc. (Æ) is currently providing cultural resources services to the Tulare Irrigation District (TID), in support of the McKay Point Reservoir Project. On behalf of our clients, we are conducting Native American consultation and performing other tasks related to cultural resources management. The project is subject to the requirements of the California Environmental Quality Act.

TID proposes to build a water storage/regulation facility near the confluence of the St. Johns River and the Lower Kaweah River in Tulare County, California. The project area lies within T18S, R 27E, Sections 3 and 4, as shown on the Woodlake 7.5 USGS quadrangle (see attached map).

A record search has been requested for the Project, and results are pending.

Your name and address were provided to us by the Native American Heritage Commission. If you have information on sacred or special sites in the area or if you have any interest about the project, please call me or send a letter to my attention. Your comments will be included in our cultural resources report. You can contact me during normal business hours (559-229-1856) if you have any questions or need additional information. Thank you.

Sincerely,

Jay B. Lloyd,
Project Administrator

d. UTM: NAD 83, Zone 11; 315441 **mE /** 4029656 **mN**
e. Other Locational Data: From the intersection of Highway 245 and Avenue 332 south of Woodlake, proceed east on Avenue 332 for approximately 1.2 miles to a locked ranch gate. Proceed through the gate and continue on the dirt ranch road for approximately 0.7 miles to the dam over the St. John's River. Proceed north over the dame, and then continue west on the dirt road for approximately 0.8 miles to the fence at the western edge of the project area. Turn north and continue for approximately 0.1 miles to the northwest corner of the property. The resource is located approximately 100 feet southeast of the fencepost at the northwest corner of the property.

***P3a. Description:** AE-2193-2 is a historic debris scatter, and represents the remains of a collapsed wooden structure or device. The remains include lumber and metal hardware scattered across a small area in the northwest corner of a cattle pasture. The majority of the planks were too badly degraded to measure, but those that could be measured were 3.5 inches by 3.5 inches in cross-section, and of unknown length due to decay and breakage. The hardware that held the planks together includes ¾-inch square nuts, round-headed nails, and metal rods of undetermined length (all were partially buried) that terminate in threaded nuts. The threaded rods are consistent with crossroads and indicate that these materials are the remains of a wooden wagon. None of the observed hardware is time diagnostic, but wooden wagons would have been used primarily in the 19th and early 20th centuries.

March 2014

SUMMARY OF FINDINGS

At the request of Sespe Consulting, Inc., on behalf of the Tulare Irrigation District (TID), Applied EarthWorks Inc. (Æ) performed a paleontological resource assessment for the McKay Point Reservoir Project (Project) located in Tulare County, California. The Project proposes to construct a water storage/reregulation facility on 168 acres in Tulare County along the Kaweah River, approximately 3 miles downstream from the Terminus Dam and Lake Kaweah. The study consisted of a museum records search and a comprehensive literature and geologic map review. This report summarizes the methods and results of a paleontological resource assessment and provides Project-specific management recommendations.

This assessment included a comprehensive review of published and unpublished literature and museum collections records maintained by the Natural History Museum of Los Angeles County (LACM) and the University of California Museum of Paleontology (UCMP). The purpose of the literature review and museum records search was to identify the geologic units underlying the Project area and to determine whether or not previously recorded paleontological localities occur either within the Project boundaries or within the same geologic units elsewhere. Using the results of museum records search and literature review, the paleontological resource potential of the Project area was determined in accordance to Society of Vertebrate Paleontology guidelines.

Published geologic mapping indicates that the Project area is immediately underlain by Late Pleistocene Modesto Formation and underlain at depth by the Middle Pleistocene Riverbank Formation. Museum records found no previously recorded paleontological localities directly within Project boundaries; however, two vertebrate fossil localities yielding *Mammuthus* (mammoth) and *Equus* (horse) have been documented near the Project area within the Riverbank Formation. Additionally, the UCMP and LACM records indicate that at least 14 vertebrate fossil specimens from 12 localities have been recovered from within unnamed Pleistocene deposits within Tulare County. Finally, numerous fossil specimens representing plants, mammals, reptiles, and birds have been reported from within the Modesto and Riverbank Formations throughout the Central Valley.

As a result of this study, the geologic units underlying the Project area are determined to have a paleontological resource potential (i.e., sensitivity) ranging from low to high. The Late Pleistocene age Modesto Formation has a high potential to contain intact paleontological resources because it has been proven to yield significant vertebrate fossils in the vicinity of the Project area and elsewhere in the San Joaquin Valley. However, because these deposits are likely overlain by recent fluvial sedimentation at the surface, their paleontological sensitivity is low at the surface and increases with depth. Additionally, the Riverbank Formation has a high paleontological resource potential and underlies the Project area at depth.

The Project area is underlain by undisturbed geologic units with a proven potential to yield significant paleontological resources, and the likelihood of impacting vertebrate fossils during construction is high. Therefore, paleontological resource mitigation monitoring during Project construction is recommended. In addition, prior to the start of construction all field personnel

should receive a worker's environmental training module on paleontological resources. By implementing these mitigation measures during Project development, adverse impacts to paleontological resources can be reduced to a less than significant level pursuant to the requirements of the California Environmental Quality Act.

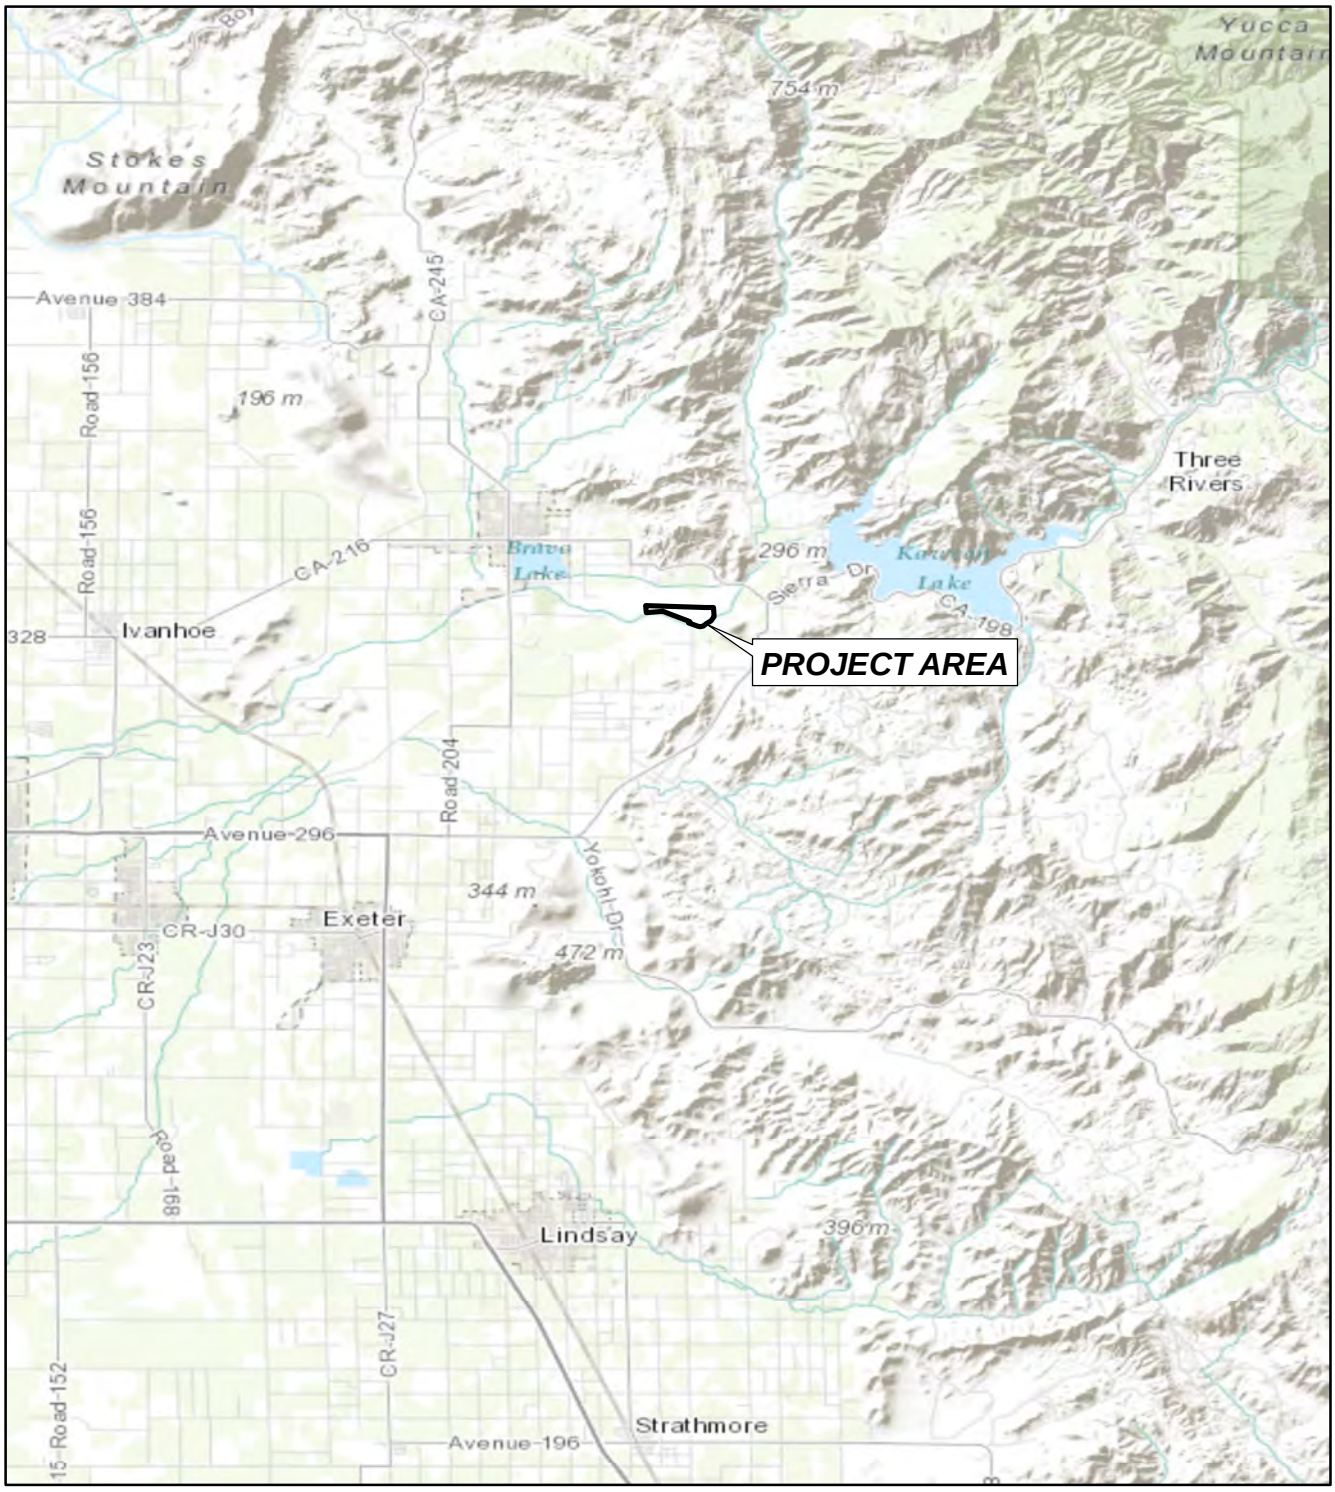
1
INTRODUCTION

At the request of Sespe Consulting, Inc., on behalf of the Tulare Irrigation District (TID), Applied EarthWorks Inc. (*Æ*) performed a paleontological resource assessment for the McKay Point Reservoir Project (Project) approximately 20 miles northeast of Visalia in Tulare County, California (Figure 1-1). The study consisted of a museum records search and a comprehensive literature and geologic map review. This report summarizes the methods and results of the assessment and provides Project-specific management recommendations.

1.1 PROJECT LOCATION AND DESCRIPTION

TID proposes to construct a water storage/reregulation facility (Project) on approximately 168 acres in Tulare County (County). The water storage/reregulation facility will be constructed through the excavation and processing of aggregate (rock, sand, and gravel) by CEMEX, an aggregate mining company under contract with the TID, using existing facilities located adjacent to the Project area. Excavation will reach a maximum depth of 60 feet. The Project area and the existing CEMEX aggregate processing facility are on the north side of the divergence of the Kaweah and St. Johns Rivers near McKay Point (Figure 1-2). TID will be the Lead Agency for purposes of compliance with the California Environmental Quality Act (CEQA). Tulare County will serve as Lead Agency under the Surface Mining and Reclamation Act (SMARA) and, as such, the Project will be required to obtain County approval of a Surface Mining Permit for a SMARA-compliant Reclamation Plan and Financial Assurance Cost Estimate.

1.2 PURPOSE OF INVESTIGATION



The purpose of this paleontological resource assessment is to: (1) identify the geologic units within the Project area, (2) assess their paleontological resource potential (i.e., "sensitivity"), (3) evaluate whether or not the Project has the potential to adversely impact scientifically significant paleontological resources, and (4) provide Project-specific mitigation measures to be implemented during Project development (as necessary). This assessment was performed to satisfy the requirements of the California Environmental Quality Act (CEQA) and was conducted in accordance with professional standards and guidelines set forth by the Society of Vertebrate Paleontology (SVP 2010).

1.3 REPORT ORGANIZATION

This report documents the results of *Æ*'s paleontological resource assessment of the Project area.

- Chapter 1 has introduced the scope of work, identified the Project location, described the Project, and defined the purpose of the investigation;
- Chapter 2 outlines the regulatory framework governing the Project;

- Chapter 3 presents the paleontological resources guidelines and professional standards used for this assessment;
- Chapter 4 presents the methods;
- the geology and paleontology of the Project area is presented in Chapter 5;
- the analysis and results of the assessment are presented in Chapter 6.
- Chapter 7 presents conclusions;
- Management recommendations in Chapter 8; and
- References cited are listed in Chapter 9.

2
REGULATORY FRAMEWORK

Paleontological resources (i.e., fossils) are considered nonrenewable scientific resources because once destroyed, they cannot be replaced. As such, paleontological resources are afforded protection under the various federal, state, and local laws and regulations discussed in this chapter.

2.1 FEDERAL

Paleontological resources are afforded protection under numerous federal laws and regulations, including the National Environmental Policy Act of 1969, the American Antiquities Act of 1906, the Federal Land Policy and Management Act of 1976, Title 43 of the Code of Federal Regulations, and the Paleontological Resources Preservation Act (PRPA). The PRPA was recently enacted as a result of the passage of the Omnibus Public Lands Management Act of 2009 and requires federal land management agencies to manage and protect paleontological resources, affirming the authority of existing policies already in place. Federal laws and regulations would only apply to the Project if it is located on federal lands or if the Project receives federal funding. This Project is not located on federal lands and will not receive federal funding.

2.2 STATE

Paleontological resources cannot be replaced once they are destroyed. Therefore, paleontological resources are considered nonrenewable scientific resources and are protected under the CEQA. Specifically, in Section V(c) of Appendix G of the CEQA Guidelines, the "Environmental Checklist Form," the question is posed: "Will the project directly or indirectly destroy a unique paleontological resource or site or unique geologic feature?" In order to determine the uniqueness of a given paleontological resource, it must first be identified or recovered (i.e., salvaged). Therefore, mitigation of adverse impacts to paleontological resources is mandated by CEQA.

2.3 LOCAL

Tulare County does not have mitigation requirements that specifically address potential adverse impacts to paleontological resources.

2.4 PROFESSIONAL STANDARDS

Absent specific agency guidelines, most professional paleontologists in California adhere to guidelines set forth by SVP in "Standard Procedures for the Assessment and Mitigation of Adverse Impacts to Paleontological Resources" (Society of Vertebrate Paleontology [SVP] 2010). The guidelines establish detailed protocols for the assessment of the paleontological resource potential of a project area and outline measures to mitigate adverse impacts to known or unknown fossil resources during project development. In order to prevent project delays, SVP highly recommends that project developers retain a qualified professional paleontologist in the

advance planning phases of a project to conduct an assessment and to implement paleontological mitigation prior to or during construction, as necessary. A qualified professional paleontologist is defined by SVP as "a practicing scientist who is recognized in the paleontological community as a professional and can demonstrate familiarity and proficiency with paleontology in a stratigraphic context."

Prior to the development phase of a project, SVP provides standard procedures to ensure an adequate paleontological resource assessment. These standard procedures apply to project areas underlain by geologic units determined to have a high, low, and undetermined paleontological sensitivity. The protocols and procedures for a standard paleontological resources assessment include the following elements: (1) literature search, (2) records search, (3) consultation with others, (4) field survey, (5) reporting, (6) agency confirmation, (7) repository agreement, and (8) pre-excavation meeting.

3
PALEONTOLOGICAL RESOURCE ASSESSMENT GUIDELINES

3.1 DEFINITION OF PALEONTOLOGICAL RESOURCES AND SIGNIFICANCE CRITERIA

Paleontological resources are the evidence of once-living organisms as preserved in the rock record. They include both the fossilized remains of ancient plants and animals and the traces thereof (trackways, imprints, burrows, etc.). In general, fossils are considered to be greater than 5,000 years old (older than Middle Holocene) and are typically preserved in sedimentary rocks. Although rare, fossils can also be preserved in volcanic rocks and low-grade metamorphic rocks formed under certain conditions (SVP 2010).

Significant paleontological resources are defined as "identifiable" vertebrate fossils, uncommon invertebrate, plant, and trace fossils that provide taphonomic, taxonomic, phylogenetic, paleoecologic, stratigraphic, or biochronological data (SVP 2010). These data are important because they are used to examine evolutionary relationships, provide insight on the development of and interaction between biological communities, establish time scales for geologic studies, and for many other scientific purposes (Scott and Springer 2003; SVP 2010).

3.2 PROFESSIONAL STANDARDS AND PALEONTOLOGICAL RESOURCE SENSITIVITY

Absent specific agency guidelines, most professional paleontologists in California adhere to guidelines set forth by SVP in "Standard Procedures for the Assessment and Mitigation of Adverse Impacts to Paleontological Resources" (SVP 2010). These guidelines establish detailed protocols for the assessment of the paleontological resource potential (i.e., "sensitivity") of a project area and outline measures to follow in order to mitigate adverse impacts to known or unknown fossil resources during project development. In order to prevent project delays, SVP highly recommends that the owner or developer retain a qualified professional paleontologist in the advance planning phases of a project to conduct an assessment and to implement paleontological mitigation during construction, as necessary.

Using baseline information gathered during a paleontological resource assessment, the paleontological resource potential of the geologic unit(s) (or members thereof) underlying a Project area can be assigned to one of four categories defined by SVP (2010). These categories include high, undetermined, low and no potential. The criteria for each sensitivity classification, and the corresponding mitigation recommendations, are summarized in Table 3-1 below.

If a project area is determined to have high or undetermined potential for paleontological resources following the initial assessment, then SVP recommends that a paleontological resources mitigation plan be developed and implemented during the construction phase of a project. The mitigation plan describes, in detail, when and where paleontological monitoring will take place and establishes communication protocols to be followed in the event that an unanticipated fossil discovery is made during project development. If significant fossil resources

are known to occur within the boundaries of the project and have not been collected, then the plan will outline the procedures to be followed prior to the commencement of construction (i.e., pre-construction salvage efforts or avoidance measures including fencing off a locality). Should microfossils be known to occur in the geologic unit(s) underlying the Project area or suspected to occur, then the plan will describe the methodology for matrix sampling and screening.

Table 3-1
Paleontological Sensitivity Categories

Resource Potential	Criteria	Mitigation Recommendations
No Potential	Rock units that are formed under or exposed to immense heat and pressure, such as high-grade metamorphic rocks and plutonic igneous rocks.	No mitigation required.
Low Potential	Rocks units that have yielded few fossils in the past, based upon review of available literature and museum collections records. Geologic units of low potential also include those that yield fossils only on rare occasion and under unusual circumstances.	Mitigation is not typically required.
Undetermined Potential	In some cases, available literature on a particular geologic unit will be scarce and a determination of whether or not it is fossiliferous or potentially fossiliferous will be difficult to make. Under these circumstances, further study is needed to determine the unit's paleontological resource potential (i.e., field survey).	A field survey is required to further assess the unit's paleontological potential.
High Potential	Geologic units with high potential for paleontological resources are those that have proven to yield vertebrate or significant invertebrate, plant or trace fossils in the past or are likely to contain new vertebrate materials, traces, or trackways. Rock units with high potential also may include those that contain datable organic remains older than late Holocene (e.g., animal nests or middens).	Typically, a field survey as well as onsite construction monitoring will be required. Any significant specimens discovered will need to be prepared, identified, and curated into a museum. A final report documenting the significance of the finds will also be required.

Adapted from SVP (2010).

The paleontological mitigation plan should be prepared by a qualified professional paleontologist and developed using the results of the initial paleontological assessment and survey. Elements of the plan can be adjusted throughout the course of a project as new information is gathered and conditions change, so long as the lead agency is consulted and all parties are in agreement. For example, if after 50 percent of earth disturbing activities have occurred in a particular unit or area, and no fossils whatsoever have been discovered, then the project paleontologist can reduce or eliminate monitoring efforts in that unit or area.

4
METHODS

4.1 LITERATURE REVIEW AND RECORDS SEARCH

Paleontological resources are not found in "soil" but are contained within the geologic deposits or bedrock that underlies the soil layer. Therefore, in order to ascertain whether or not a particular project area has the potential to contain significant fossil resources at the subsurface, it is necessary to review relevant scientific literature and geologic mapping to determine the underlying geology and stratigraphy of the area. Further, to delineate the boundaries of an area of paleontological sensitivity it is necessary to determine the extent of the entire geologic unit, because paleontological sensitivity is not limited to surface exposures of fossil material.

To determine whether or not fossil localities have been previously discovered within the project area or a particular rock unit, a search of pertinent local and regional museum repositories for paleontological localities within and nearby the project area should be performed. For this Project, a museum records search was conducted at the Natural History Museum of Los Angeles County (LACM). The museum records search was supplemented by a review of the University of California Museum of Paleontology's (UCMP) online database, which contains additional paleontological records for Tulare County.

4.2 KEY PERSONNEL

Æ's Paleontology Program Manager Jessica DeBusk served as Senior Paleontologist, requested the museum records search, and provided a quality control (QC) review of this report. Staff Paleontologist Heather Clifford conducted the literature and geologic map review and served as the primary author of this report. DeBusk has more than 10 years of professional experience as a consulting paleontologist and meets the SVP's definition of a qualified professional paleontologist. Geographic Information Systems (GIS) Specialist Michael Mirro produced all graphics.

5
GEOLOGY AND PALEONTOLOGY

5.1 REGIONAL GEOLOGY

The Project area is located on the eastern margin of the San Joaquin Valley within the Great Valley (also referred to as the Central Valley) geomorphic province of California. A geomorphic province is a region of unique topography and geology that is readily distinguished from other regions based on its landforms and diastrophic history (Norris and Webb 1990). The Great Valley is a north-northwest-trending asymmetric structural trough bisected by the Stockton Arch, a structural feature that subdivides the region into the Sacramento Valley in the north and the San Joaquin Valley to the south. The Great Valley is roughly 400 miles long and 50 miles wide and was once covered by marine waters as far back as the Jurassic (201–145 million years ago [Ma]) and into the Paleogene (66–23 Ma). Deposition into the Great Valley began during the Late Jurassic (164 Ma) as the paleo-Sierra Nevada began to rise and deliver eroded sediments to the lowlands. Forearc (i.e., the deep marine region between a volcanic arc and the associated subduction zone) marine and nonmarine shale, sandstone, and conglomerate of the Cretaceous Central Valley Sequence were deposited during this time unconformably on top of the Franciscan Complex of the Coast Range and the Sierran Batholith (Bartow and Nilsen 1990). During the late Mesozoic and much of the Cenozoic (66 Ma to the present), the actively subsiding region persisted as a submerged lowland basin, known as the Great Valley Sea (Harden 1998).

By the Pliocene (5.3–2.6 Ma), most of the marine waters in the Great Valley were drained and brackish and freshwater lakes remained (Weissmann et al. 2005). The present surface of the valley floor is composed of mostly unconsolidated Pleistocene age (2.6 Ma to 11,700 years before present [B.P.]), alluvial sediments associated with the drainage of the glaciated Sierra Nevada, alluvial deposits originating from the Coast Ranges, and recent sediments largely representing the alluvial, flood, and delta plains of the Sacramento and San Joaquin Rivers (Bartow 1991; Matthews and Burnett 1965; Norris and Webb 1990; Weissmann et al. 2005). The east side of the valley in the vicinity of the Project is characterized by a broad plain of low relief consisting of large coalescing alluvial fans (e.g., the Kaweah River Fan) derived from streams flowing from the Sierra Nevada (Weissmann et al. 2005).

5.2 GEOLOGY AND PALEONTOLOGY OF THE PROJECT AREA

Published geologic mapping of the region indicates that the Project area is underlain by the Modesto Formation (Qf) of Pleistocene age (Matthews and Burnett 1965) (Figure 5-1). The Riverbank Formation is exposed in the vicinity of the Project area and likely underlies the Modesto Formation at an unknown depth. The Project area is adjacent to the Kaweah River and is located on a large convex bank immediately north of a meander bend. It is likely, although not explicitly mapped, that the Project area is immediately underlain by recent channel and floodplain deposits of the Kaweah River, which conformably overlie the Modesto Formation. The depth of the recent Kaweah River deposits in the vicinity of the Project area are estimated to be relatively shallow (2–5 feet) due to the degradational nature of the stream and sediment trapping in the upstream Terminus Reservoir Dam (Berryman and Elasser 1966).

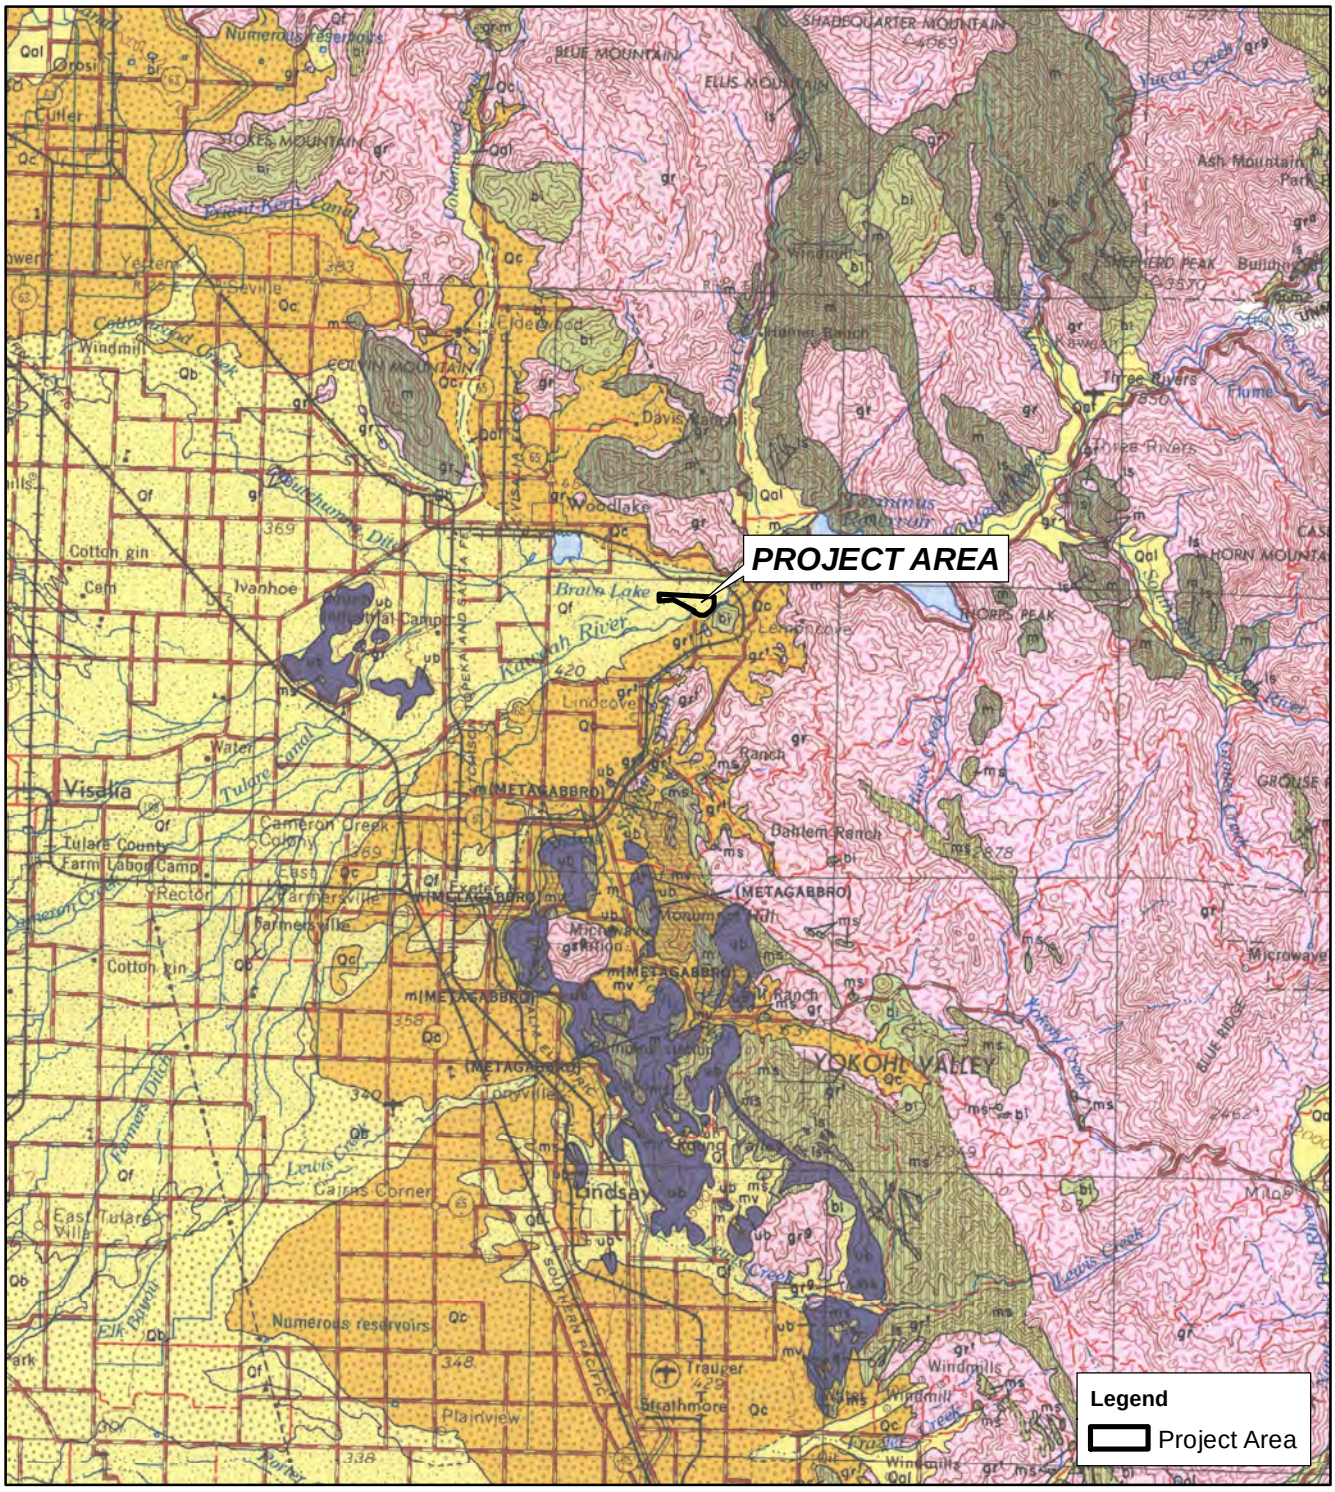

Figure 5-1 Geology in the vicinity of the Project area.

In the vicinity of the Project area, the gently sloping San Joaquin Valley floor rises toward the northeast, reaching an elevation of 600–800 feet above sea level. The local geomorphology is relatively flat but also consists of minor topographic relief derived from flooding and fluvial processes, including terraces and sloughs. In general, the soils are sandy, permeable, and fertile but may consist of hardpan in some areas (Croft and Gordon 1968).

5.2.1 The Modesto Formation

The Modesto Formation is Late Pleistocene in age and consists of poorly indurated fluvial and alluvial deposits and well-developed soils (Davis and Hall 1959; Marchand and Allwardt 1981). The sediments consist of andesitic to arkosic granitic sand, silt, and gravel, which drained from the Sierra Nevada during the Late Pleistocene Wisconsin glaciations (Weissmann et al. 2002). The Modesto Formation extends from the Sacramento River in the north to the Tule River in the south (Matthews and Burnett 1965). It is locally overlain by Holocene alluvial sediments and is unconformably underlain by the middle Pleistocene Riverbank Formation. The Modesto Formation was first described by Davis and Hall (1959) and later redescribed by Marchand (1977) at its type section located at a roadcut near the Mitchell Road Bridge above the Tuolumne River in the town of Ceres, California. Marchand (1977) informally divides the Modesto Formation into a lower and upper member based on topographic expression and the presence of paleosols (i.e., buried soil horizons). The upper member has a maximum thickness of 30 feet and the lower member is up to 70 feet thick (Marchand and Allwardt 1981). The upper member is composed of massive to well-bedded sand, silt, and clay, with subordinate gravel deposits. Where stratification is absent, the sedimentary structures were most likely destroyed by soil development. The lower member is predominately composed of moderately stratified sand and silt deposits, with localized lenticular cross-lamination. The base of lower member of the Modesto Formation is marked by a distinct layer of red clay (Hudson 1960). The total thickness of the Modesto Formation ranges from 50 to 100 feet and its age is estimated to range from 9000 to 42,000 B.P. (Marchand 1977). These depths are characteristic of the Modesto Formation near its type section in the center of the San Joaquin Valley where sediment accumulation has been significant. Adjacent to the Sierran foothills, in the vicinity of the Project area, basement rock is closer to the surface and sediment accumulation is most likely more shallow. Therefore, the thickness of the Modesto Formation in the Project area is unknown, but it is probably less than 50–100 feet thick. Because excavations associated with the Project will be up to 60 feet deep, it is necessary to discuss the underlying Riverbank Formation.

5.2.2 The Riverbank Formation

The Riverbank Formation was deposited in the Middle Pleistocene and consists of granitic sand, silt, and clay primarily derived from the Sierra Nevada (Davis and Hall 1959). In the vicinity of the Project area in Tulare County, the Riverbank Formation is unconformably underlain by the Mesozoic granitic rocks (mapped as “gr” by Matthews and Burnett [1965]). The Riverbank Formation was first described by Davis and Hall (1959) and later redescribed by Marchand and Allwardt (1981) at its type section located on the banks of the Stanislaus River in the town of Riverbank. The Riverbank Formation consists of moderately consolidated deposits of massive to well-bedded silty sand, arkosic sand, pebbly sand, and gravel lenses. Locally, fine sand may exhibit aeolian sorting and coarse sand and gravel may be interbedded with silt and clay deposits (Marchand 1977). These sediments comprise older alluvium, dissected fan, and nonmarine sedimentary deposits in the San Joaquin Valley (Matthews and Burnett 1965; McLeod 2013;

Smith 1964). The thickness of the Riverbank Formation ranges from approximately 50 to 250 feet and it is estimated to range in age from 0.13–0.45 Ma (Marchand and Allwardt 1981).

5.2.3 Paleontology

At least 27 fossil specimens representing plants, mammals, and reptiles have been recovered from the Modesto Formation from various localities throughout the Central Valley (UCMP online database). In 2006, along the San Joaquin River Parkway trail near Friant and Rice Roads in Fresno, a large radius of *Bison* cf. *B. latifrons* was discovered eroding from the side of an outcrop (Dundas et al. 2009). The bison was deposited in the upper member of the Modesto Formation on the San Joaquin River alluvial fan. The bison radius was preserved in a fine-grained clay- and charcoal-rich floodplain deposit approximately 15–30 inches thick. Other terrestrial vertebrate fossils that have been discovered from within the Modesto Formation include *Megalonyx jeffersoni* (Jefferson's ground sloth), *Bison antiquus* (bison), *Mammuthus columbi* (mammoth), *Camelops* (camel), Serpentes (snakes), and Rodentia (rodents) (UCMP online database).

Hundreds of fossil specimens representing plants, mammals, reptiles, and birds have been recovered from the Riverbank Formation from various localities throughout the Central Valley (UCMP online database). During excavations associated with the construction of the Arco Arena in Sacramento, numerous terrestrial vertebrate fossils were discovered from within the Riverbank Formation, including Antilocapridae (antelope*), Bison antiquus* (bison), *Camelops hesternus* (camel), *Canis* cf. *latrans* (coyote), Cervidae (deer), *Mammuthus* (mammoth), *Paramylodon harlani* (Harlan's ground sloth), and *Sciurus* (squirrel). In addition, plant fossils were discovered at the same locality, including the seed of a *Prunus* cf. *ilicifolia* (holly leaf cherry). All fossil specimens were encountered between 13 and 30 feet below the valley surface and represent taxa that are typical of the Late Pleistocene (Hilton et al. 2000). Other paleontological localities within the Riverbank Formation yielded *Equus* (horse) as well as Aves (birds), *Canis dirus* (dire wolf), *Mammuthus columbi* (mammoth), *Neotoma* (packrat), *Orthodon* (blackfish), Proboscidea (elephantoid), *Scapanus latimanus* (broad-footed mole), *Thamnophis* (garter snake), and *Thomomys* (pocket gopher) from throughout the northern and central Great Valley. The depths below ground surface at which these discoveries were made is largely unreported (McLeod 2013; UCMP online database).

6
ANALYSIS AND RESULTS

6.1 MUSEUM RECORDS SEARCH RESULTS

A museum records search of the Project area was conducted by the LACM on December 17, 2013. The museum records search was supplemented by a review of the UCMP's online database, which contains paleontological records for Tulare County. The LACM reports that there are no previously recorded vertebrate fossil localities directly within the Project boundaries; however, museum collections records indicate that at least two vertebrate localities have been recovered nearby from within Riverbank Formation deposits, including a fossilized specimen of *Mammuthus* (mammoth) and *Equus* (horse) (McLeod 2013; Table 6-1). A supplemental review of online museum collections records maintained by the UCMP reveals that at least 12 vertebrate fossil specimens from 10 localities have been recovered from within unnamed Pleistocene deposits in Tulare County. These deposits, similar in age and depositional environment to the Modesto Formation and the Riverbank Formation, have yielded specimens of *Camelops* (camel), *Elephas* (elephant), *Equus* (horse), *Mammuthus columbi* (mammoth), and *Mammut americanum* (mastodon). One of those specimens was recovered from a locality (UCMP V5634) near the South Fork Kaweah River, upstream from the Project area (UCMP online database).

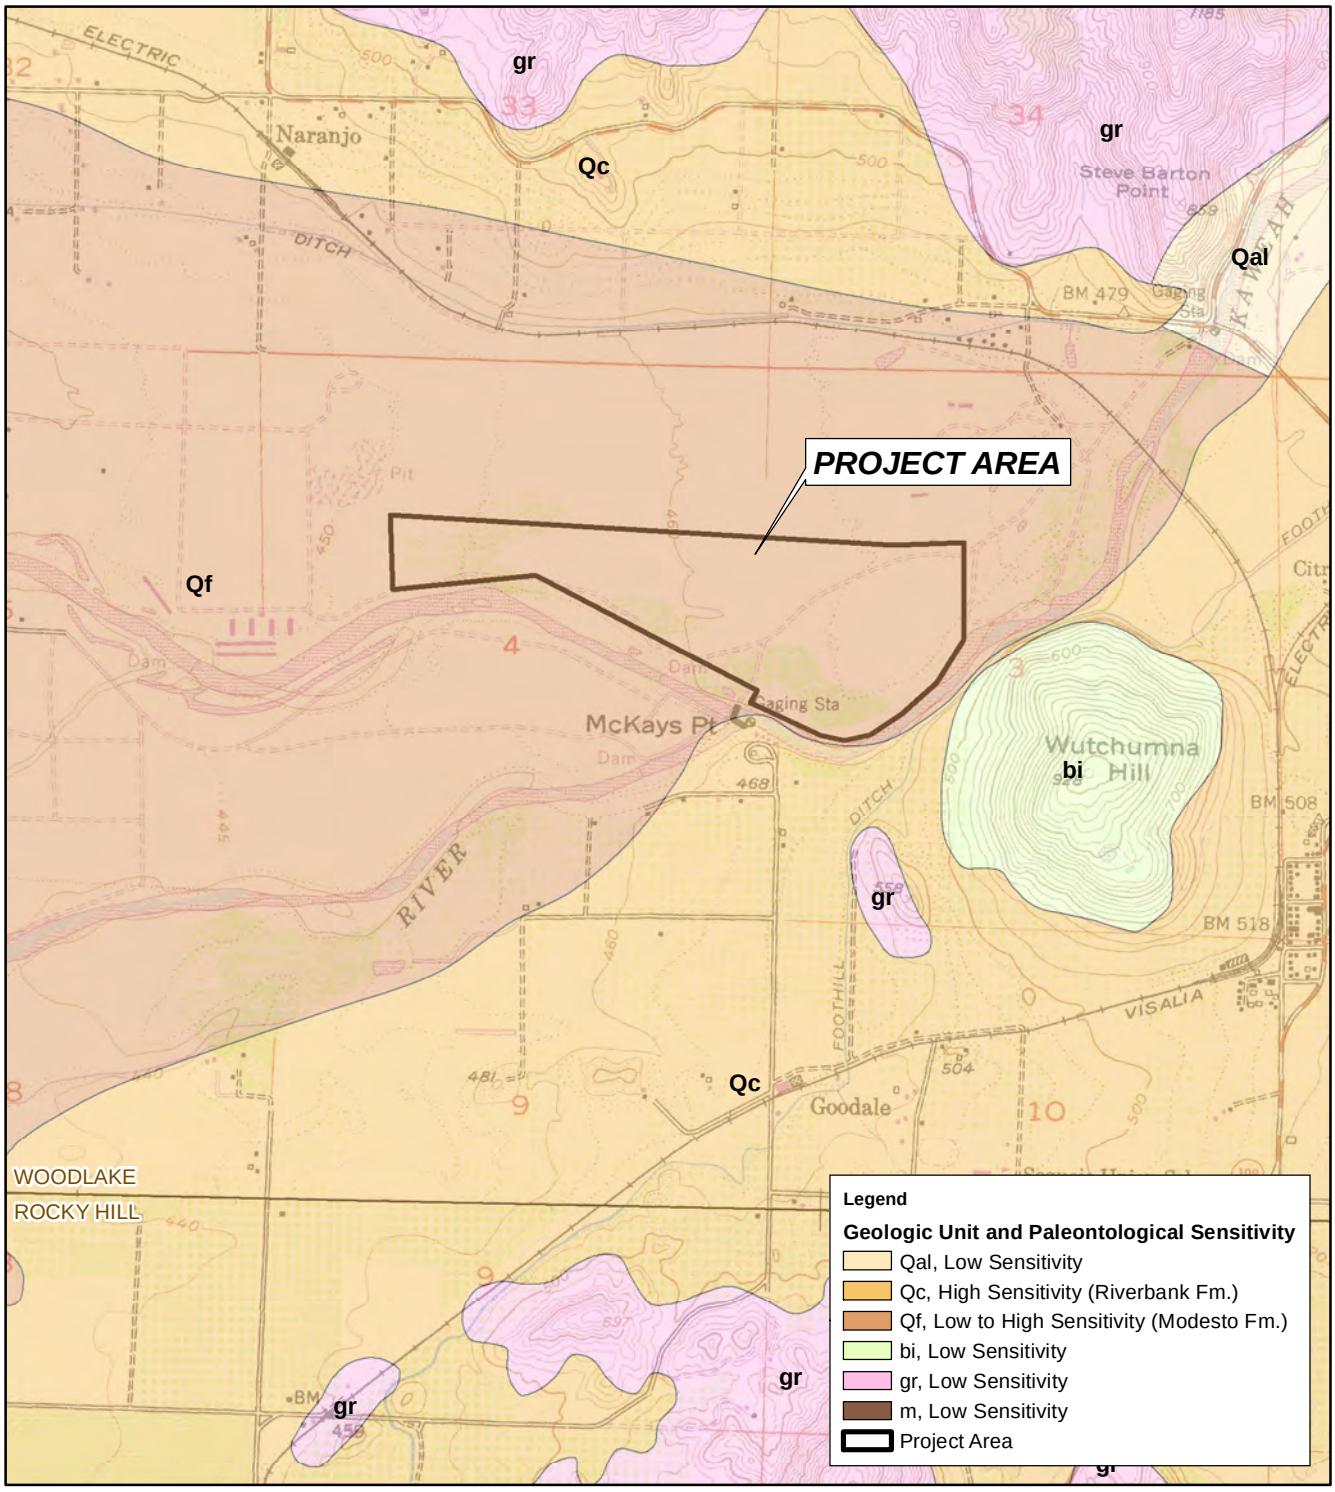

Table 6-1
Vertebrate Localities Reported in the Vicinity of the Project Area[a]

Locality No. and Approximate Location	Geologic Unit	Age	Taxa
LACM 4087; southeast of the Project area, east of Highway 65 and East of Terra Bella	Riverbank Formation	Pleistocene	*Mammuthus* (mammoth)
LACM 1156; south-southwest of the Project area just north of Delano	Riverbank Formation	Pleistocene	*Equus* (horse)

a - McLeod (2013).

6.2 DETERMINATION OF PALEONTOLOGICAL RESOURCE POTENTIAL FOR GEOLOGIC UNITS WITHIN THE PROJECT AREA

Based on the literature review and museum records search results, the geologic units underlying the Project area are determined to have a high paleontological sensitivity in accordance to criteria set forth by SVP (2010). The Pleistocene age Modesto Formation and the Riverbank Formation both have a high potential to contain intact paleontological resources because they have proven to yield significant vertebrate fossils throughout San Joaquin Valley (Figure 6-1). Therefore, further paleontological resource management will be required during Project development as discussed in Chapter 8.

7
CONCLUSION

This assessment is based on the results of a museum records search and review of available geologic and paleontologic literature. Therefore, only fossils that have already been inventoried or collected are available for this analysis. In general, the potential for a given project to result in adverse impacts to paleontological resources is directly proportional to the amount of ground disturbance associated with the project. Due to the substantial excavations planned for the construction of the Project, there is a relatively high potential for an unknown number of paleontological resources to be adversely impacted. However, by implementing the management recommendations outlined in the following chapter, including worker's environmental awareness training and on-site construction monitoring, adverse impacts to paleontological resources can be reduced to a less than significant level pursuant to the requirements of CEQA.

8
MANAGEMENT RECOMMENDATIONS

The following paleontological mitigation measures have been developed in accordance to SVP guidelines and if implemented, will satisfy the requirements of CEQA. These measures have been used by professional paleontologists for many years and have proven to be effective in reducing or eliminating adverse impacts to paleontological resources as a result of private and public development projects throughout California and elsewhere.

8.1 WORKER'S ENVIRONMENTAL AWARENESS TRAINING

Prior to the start of construction, all field personnel will receive a worker's environmental awareness training module on paleontological resources. The training will provide a description of the fossil resources that may be encountered in the Project area, outline steps to follow in the event that a fossil discovery is made, and provide contact information for the Project Paleontologist and onsite monitor(s). The training will be developed by the Project Paleontologist and may be conducted concurrent with other environmental training (e.g., cultural and natural resources awareness training, safety training, etc.). The training may also be videotaped or presented in an informational brochure for future use by field personnel not present at the start of the Project. Provisions in the Project monitoring plan (detailed below) should also provide for periodic "refresher" training of employees to ensure their skills and responsibilities are maintained at the necessary level.

8.2 PALEONTOLOGICAL MITIGATION MONITORING

Prior to the commencement of ground disturbing activities, a qualified professional paleontologist will be retained to prepare and implement a Paleontological Resource Mitigation Plan (PRMP) for the Project. Initially, full-time monitoring will be required in Project areas determined to have a high paleontological sensitivity (i.e., the Modesto Formation [Qf]) during all ground disturbing activities at a depth greater than 5 feet. Part-time monitoring or spot checking may be necessary during very shallow ground disturbances impacting only the uppermost soil layers in order to determine if underlying sensitive geologic deposits are being impacted by construction, and at what depth. If, after 50 percent of the excavations are completed, no fossil resources are encountered, monitoring efforts can be reduced or eliminated at the discretion of the Project Paleontologist. Finally, upon on-site observations, monitoring may also be terminated if the type of excavation, the equipment used, or the lithology of the Project area does not prove to be conducive to fossil preservation.

Monitoring methods will be specified in the PRMP but, in general, will entail the visual inspection of excavated or graded areas and trench sidewalls. In the event that a paleontological resource is discovered, the monitor will have the authority to temporarily divert the construction equipment around the find until it is assessed for scientific significance, and collected.

8.3 FOSSIL PREPARATION, CURATION, AND REPORTING

Upon completion of fieldwork, all significant fossils collected will be prepared in a properly equipped paleontology laboratory to a point ready for curation. Preparation will include the careful removal of excess matrix from fossil materials and stabilizing and repairing specimens, as necessary. Following laboratory work, all fossils specimens will be identified to the lowest taxonomic level, cataloged, analyzed, and delivered to an accredited museum repository for permanent curation and storage. The cost of curation is assessed by the repository and is the responsibility of the Project owner.

At the conclusion of laboratory work and museum curation, a final report will be prepared describing the results of the paleontological mitigation monitoring efforts associated with the Project. The report will include a summary of the field and laboratory methods, an overview of the Project area geology and paleontology, a list of taxa recovered (if any), an analysis of fossils recovered (if any) and their scientific significance, and recommendations. If the monitoring efforts produced fossils, then a copy of the report will also be submitted to the designated museum repository.

RE: Project Notification and Consultation Request Pursuant to CEQA's Assembly Bill (AB) 52 for the McKay Point Reservoir Project (SCH No. 2014011078)

Dear Ms. Kipp,

Pursuant to the provisions of AB 52, as the lead agency under the California Environmental Quality Act (CEQA), the Tulare Irrigation District (TID) hereby extends an invitation to consult on the California Environmental Quality Act (CEQA) review of the McKay Point Reservoir Project (Project) in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American tribal cultural resources and/or tribal cultural places including:

- Native American sanctified cemetery, place of worship, religious or ceremonial site, or sacred shrine; and
- Native American historic, cultural, or sacred site that is listed or may be eligible for listing in the California Register of Historical Resources including historic or prehistoric ruins and any burial ground, archaeological, or historic site.

The proposed Project is located on approximately 500 acres adjacent to the Lower Kaweah River and St. Johns River. In accordance with CEQA (Pub. Resources Code, § 21000 et seq.), the Tulare Irrigation District will be preparing an Environmental Impact Report (EIR) to evaluate the environmental effects associated with the Project. A Notice of Preparation (NOP) under CEQA was published on October 2, 2020 and the distribution included the list of tribes provided by the Native American Heritage Commission (NAHC) at that time. A copy of the current Project Description is included with this notice and request for consultation.

PROJECT INFORMATION/DESCRIPTION

Project Title: McKay Point Reservoir Project

Project Applicant: Project joint owners – Tulare Irrigation District (TID), the Consolidated Peoples Ditch Company (CPDC), and the Visalia and Kaweah Water Company (VKWC).

Assessor's Parcel Number(s): The Project site is comprised of portions of the following Assessor's Parcel Numbers (APN's): 113-070-016-000, 113-080-005-000, 113-080-008-000, 113-090-001-000, 113-100-002-000.

Project Location: Located in Tulare County, California, the Project site lies between and to the south of both Lake Kaweah (2.5 miles northeast of the site) and Bravo Lake (1.5 miles northwest of the site); 1.0 miles northwest of the community of Lemon Cove; and 2.5 miles southeast of the community of Woodlake (Figure 1). The Project site is located approximately 1.0 mile west-southwest of the intersection of State Highways 216 and 198, in Sections 3 and 4, Township 18 South, Range 27 East, Mount Diablo Base and Meridian.

The surrounding land uses in the vicinity of the Project are mining, agricultural, and residential. Mining operations exist to the north, northeast, southwest and west of the Project site, and the areas south and east of the Project site are used for agricultural and, to a limited extent, for rural residential purposes. The Project site has been extensively used and disturbed over the years for cattle grazing.

Project Background: TID is a public agency organized and existing pursuant to Division 11 of the California Water Code. CPDC and VKWC are mutual water companies organized and existing pursuant to Division 3 of the California Corporations Code. The Project Owners are all members of the Kaweah and St. Johns Waters Association (Association), which oversees the surface water rights and diversion operations on the Kaweah River. VKWC is also a mutual water company formed under Section 200 of the California Corporations Code. Together they are the Owners of the Project.

Project Summary: The Owners propose to construct a surface water storage and re-regulation reservoir (the proposed Project) on approximately 200 acres within the 500-acre McKay Point property. The reservoir would be located on the north side of the divergence of the Lower Kaweah River and St. Johns River.

The Project would consist of the following phases: excavation of the site for the reservoir; construction of the reservoir; and operation of the reservoir. The Owners plan to enter into a lease agreement with West Coast Aggregate Supply, Inc. (WCA) to excavate the site to allow for the construction of the reservoir. After the excavation and construction of the reservoir, the McKay Point Reservoir would be used as a surface water storage / re-regulation reservoir. The reservoir would also be used to optimize groundwater recharge within the Owners service areas (Figure 2).

The Project would result in new disturbance to the site. There would be surface disturbance of approximately 134 acres, this includes the proposed perimeter fencing which will be constructed such that it will not disrupt biological resources (i.e., migration routes), perimeter road for reservoir maintenance, and inlet/outlet channels between the rivers and the reservoir. The excavation of the site for construction of the reservoir would be within the approximately 134 acres, covering approximately 110 acres on the surface and approximately 60 feet deep below the existing ground surface (approximately to bedrock). The Project would not extend past the bedrock and no blasting would be required. The Project would include staff education and monitoring of the site to protect cultural, historical, tribal and paleontological resources. These protection measures will be discussed in detail in the Draft EIR.

Discretionary approvals would be required for the Project; therefore, the Project is subject to CEQA. The excavation of the Project site needed to construct the reservoir would require compliance with the State Mining and Reclamation Act (SMARA) and a Reclamation Plan approved by the County of Tulare. TID is the Project Applicant on behalf of the Owners as well as the CEQA Lead Agency.

The Owners' objectives in proposing the Project include the following:

- Capturing and re-regulating water made available to the Owners during flood releases from Lake Kaweah.
- Capturing and re-regulating water entitlements belonging to the Owners released from Lake Kaweah.
- Capturing and re-regulating any other water sources on the Kaweah River that may be made available to the Owners.
- Allowing other entities with water rights on the Kaweah River to capture and/or re-regulate flows when designated by the Owners.
- Allowing other entities to capture and/or re-regulate flows of the Lower Kaweah River and St. Johns River for purposes of storm water runoff and flood prevention with permission of the Owners and Kaweah/St. Johns water rights interests.
- Constructing the reservoir in such a way that revenue can be obtained to offset a portion of the construction and development costs.
- Locating the reservoir adjacent to the Kaweah River to allow for off-stream access to surface water storage, thus minimizing the need for pipelines.

To accomplish these objectives, the Owners propose to construct and operate the Project to:

- Divert and receive water immediately upstream of the divergence of the Lower Kaweah River and St. Johns River, commonly referred to as McKay Point.
- Provide a water storage capacity of approximately 4,600 acre-feet.
- Deliver water back to either the Lower Kaweah River or the St. Johns River, as needed.
- Provide additional storage capacity for storm water layoff and flood prevention.

- Coordinate all such diversions and deliveries to and from the reservoir with the Kaweah Delta Conservation District and the Kaweah and St. Johns River Association.
- Enter into a lease agreement with WCA to excavate the site for the reservoir and process the excavated material into a marketable product (primarily construction grade aggregate). TID would receive revenue from the sale of the excavated material that could be used to offset a portion of the reservoir construction and development costs.

A detailed Project Description is attached to this letter.

Potential Environmental Effects: An EIR would be prepared to evaluate the proposed Project's environmental impacts and analyze Project alternatives. The topic areas anticipated to be analyzed in detail in the EIR include Air Quality, Greenhouse Gas Emissions, Health Risks, Biological Resources, Cultural Resources, Geology and Soil, Hazards and Hazardous Materials, Hydrology and Water Quality, Land Use and Planning, Noise, Tribal Cultural Resources, and Wildfire.

REQUEST FOR CONSULTATION

Pursuant to the provisions of AB 52, as the lead agency under CEQA, the Tulare Irrigation District hereby extends an invitation to consult on the CEQA review of the McKay Point Reservoir Project in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American cultural places and tribal cultural resources.

If your Tribe desires to consult with the Tulare Irrigation District on the review of this Project, please respond in writing within thirty (30) days of receipt of this notification. Written correspondence can be emailed or mailed to the following addresses (email is preferred):

US Post: Maya Rohr
Project Manager
Sespe Consulting, Inc.

RE: Project Notification and Consultation Request Pursuant to CEQA's Assembly Bill (AB) 52 for the McKay Point Reservoir Project (SCH No. 2014011078)

Dear Brandy Kendricks,

Pursuant to the provisions of AB 52, as the lead agency under the California Environmental Quality Act (CEQA), the Tulare Irrigation District (TID) hereby extends an invitation to consult on the California Environmental Quality Act (CEQA) review of the McKay Point Reservoir Project (Project) in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American tribal cultural resources and/or tribal cultural places including:

- Native American sanctified cemetery, place of worship, religious or ceremonial site, or sacred shrine; and
- Native American historic, cultural, or sacred site that is listed or may be eligible for listing in the California Register of Historical Resources including historic or prehistoric ruins and any burial ground, archaeological, or historic site.

The proposed Project is located on approximately 500 acres adjacent to the Lower Kaweah River and St. Johns River. In accordance with CEQA (Pub. Resources Code, § 21000 et seq.), the Tulare Irrigation District will be preparing an Environmental Impact Report (EIR) to evaluate the environmental effects associated with the Project. A Notice of Preparation (NOP) under CEQA was published on October 2, 2020 and the distribution included the list of tribes provided by the Native American Heritage Commission (NAHC) at that time. A copy of the current Project Description is included with this notice and request for consultation.

PROJECT INFORMATION/DESCRIPTION

Project Title: McKay Point Reservoir Project

Project Applicant: Project joint owners – Tulare Irrigation District (TID), the Consolidated Peoples Ditch Company (CPDC), and the Visalia and Kaweah Water Company (VKWC).

Assessor's Parcel Number(s): The Project site is comprised of portions of the following Assessor's Parcel Numbers (APN's): 113-070-016-000, 113-080-005-000, 113-080-008-000, 113-090-001-000, 113-100-002-000.

Project Location: Located in Tulare County, California, the Project site lies between and to the south of both Lake Kaweah (2.5 miles northeast of the site) and Bravo Lake (1.5 miles northwest of the site); 1.0 miles northwest of the community of Lemon Cove; and 2.5 miles southeast of the community of Woodlake (Figure 1). The Project site is located approximately 1.0 mile west-southwest of the intersection of State Highways 216 and 198, in Sections 3 and 4, Township 18 South, Range 27 East, Mount Diablo Base and Meridian.

The surrounding land uses in the vicinity of the Project are mining, agricultural, and residential. Mining operations exist to the north, northeast, southwest and west of the Project site, and the areas south and east of the Project site are used for agricultural and, to a limited extent, for rural residential purposes. The Project site has been extensively used and disturbed over the years for cattle grazing.

Project Background: TID is a public agency organized and existing pursuant to Division 11 of the California Water Code. CPDC and VKWC are mutual water companies organized and existing pursuant to Division 3 of the California Corporations Code. The Project Owners are all members of the Kaweah and St. Johns Waters Association (Association), which oversees the surface water rights and diversion operations on the Kaweah River. VKWC is also a mutual water company formed under Section 200 of the California Corporations Code. Together they are the Owners of the Project.

Project Summary: The Owners propose to construct a surface water storage and re-regulation reservoir (the proposed Project) on approximately 200 acres within the 500-acre McKay Point property. The reservoir would be located on the north side of the divergence of the Lower Kaweah River and St. Johns River.

The Project would consist of the following phases: excavation of the site for the reservoir; construction of the reservoir; and operation of the reservoir. The Owners plan to enter into a lease agreement with West Coast Aggregate Supply, Inc. (WCA) to excavate the site to allow for the construction of the reservoir. After the excavation and construction of the reservoir, the McKay Point Reservoir would be used as a surface water storage / re-regulation reservoir. The reservoir would also be used to optimize groundwater recharge within the Owners service areas (Figure 2).

The Project would result in new disturbance to the site. There would be surface disturbance of approximately 134 acres, this includes the proposed perimeter fencing which will be constructed such that it will not disrupt biological resources (i.e., migration routes), perimeter road for reservoir maintenance, and inlet/outlet channels between the rivers and the reservoir. The excavation of the site for construction of the reservoir would be within the approximately 134 acres, covering approximately 110 acres on the surface and approximately 60 feet deep below the existing ground surface (approximately to bedrock). The Project would not extend past the bedrock and no blasting would be required. The Project would include staff education and monitoring of the site to protect cultural, historical, tribal and paleontological resources. These protection measures will be discussed in detail in the Draft EIR.

Discretionary approvals would be required for the Project; therefore, the Project is subject to CEQA. The excavation of the Project site needed to construct the reservoir would require compliance with the State Mining and Reclamation Act (SMARA) and a Reclamation Plan approved by the County of Tulare. TID is the Project Applicant on behalf of the Owners as well as the CEQA Lead Agency.

The Owners' objectives in proposing the Project include the following:

- Capturing and re-regulating water made available to the Owners during flood releases from Lake Kaweah.
- Capturing and re-regulating water entitlements belonging to the Owners released from Lake Kaweah.
- Capturing and re-regulating any other water sources on the Kaweah River that may be made available to the Owners.
- Allowing other entities with water rights on the Kaweah River to capture and/or re-regulate flows when designated by the Owners.
- Allowing other entities to capture and/or re-regulate flows of the Lower Kaweah River and St. Johns River for purposes of storm water runoff and flood prevention with permission of the Owners and Kaweah/St. Johns water rights interests.
- Constructing the reservoir in such a way that revenue can be obtained to offset a portion of the construction and development costs.
- Locating the reservoir adjacent to the Kaweah River to allow for off-stream access to surface water storage, thus minimizing the need for pipelines.

To accomplish these objectives, the Owners propose to construct and operate the Project to:

- Divert and receive water immediately upstream of the divergence of the Lower Kaweah River and St. Johns River, commonly referred to as McKay Point.
- Provide a water storage capacity of approximately 4,600 acre-feet.
- Deliver water back to either the Lower Kaweah River or the St. Johns River, as needed.
- Provide additional storage capacity for storm water layoff and flood prevention.

- Coordinate all such diversions and deliveries to and from the reservoir with the Kaweah Delta Conservation District and the Kaweah and St. Johns River Association.
- Enter into a lease agreement with WCA to excavate the site for the reservoir and process the excavated material into a marketable product (primarily construction grade aggregate). TID would receive revenue from the sale of the excavated material that could be used to offset a portion of the reservoir construction and development costs.

A detailed Project Description is attached to this letter.

Potential Environmental Effects: An EIR would be prepared to evaluate the proposed Project's environmental impacts and analyze Project alternatives. The topic areas anticipated to be analyzed in detail in the EIR include Air Quality, Greenhouse Gas Emissions, Health Risks, Biological Resources, Cultural Resources, Geology and Soil, Hazards and Hazardous Materials, Hydrology and Water Quality, Land Use and Planning, Noise, Tribal Cultural Resources, and Wildfire.

REQUEST FOR CONSULTATION

Pursuant to the provisions of AB 52, as the lead agency under CEQA, the Tulare Irrigation District hereby extends an invitation to consult on the CEQA review of the McKay Point Reservoir Project in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American cultural places and tribal cultural resources.

If your Tribe desires to consult with the Tulare Irrigation District on the review of this Project, please respond in writing within thirty (30) days of receipt of this notification. Written correspondence can be emailed or mailed to the following addresses (email is preferred):

US Post: Maya Rohr
Project Manager

Project Notification and Tribal Consultation Request Pursuant to AB 52

September 16, 2021

Dunlap Band of Mono Indians
Benjamin Charley Jr., Tribal Chair
PO Box 14
Dunlap, CA 93621

RE: Project Notification and Consultation Request Pursuant to CEQA's Assembly Bill (AB) 52 for the McKay Point Reservoir Project (SCH No. 2014011078)

Dear Benjamin Charley Jr.,

Pursuant to the provisions of AB 52, as the lead agency under the California Environmental Quality Act (CEQA), the Tulare Irrigation District (TID) hereby extends an invitation to consult on the California Environmental Quality Act (CEQA) review of the McKay Point Reservoir Project (Project) in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American tribal cultural resources and/or tribal cultural places including:

- Native American sanctified cemetery, place of worship, religious or ceremonial site, or sacred shrine; and
- Native American historic, cultural, or sacred site that is listed or may be eligible for listing in the California Register of Historical Resources including historic or prehistoric ruins and any burial ground, archaeological, or historic site.

The proposed Project is located on approximately 500 acres adjacent to the Lower Kaweah River and St. Johns River. In accordance with CEQA (Pub. Resources Code, § 21000 et seq.), the Tulare Irrigation District will be preparing an Environmental Impact Report (EIR) to evaluate the environmental effects associated with the Project. A Notice of Preparation (NOP) under CEQA was published on October 2, 2020 and the distribution included the list of tribes provided by the Native American Heritage Commission (NAHC) at that time. A copy of the current Project Description is included with this notice and request for consultation.

PROJECT INFORMATION/DESCRIPTION

Project Title: McKay Point Reservoir Project

Project Applicant: Project joint owners – Tulare Irrigation District (TID), the Consolidated Peoples Ditch Company (CPDC), and the Visalia and Kaweah Water Company (VKWC).

Assessor's Parcel Number(s): The Project site is comprised of portions of the following Assessor's Parcel Numbers (APN's): 113-070-016-000, 113-080-005-000, 113-080-008-000, 113-090-001-000, 113-100-002-000.

Project Location: Located in Tulare County, California, the Project site lies between and to the south of both Lake Kaweah (2.5 miles northeast of the site) and Bravo Lake (1.5 miles northwest of the site); 1.0 miles northwest of the community of Lemon Cove; and 2.5 miles southeast of the community of Woodlake (Figure 1). The Project site is located approximately 1.0 mile west-southwest of the intersection of State Highways 216 and 198, in Sections 3 and 4, Township 18 South, Range 27 East, Mount Diablo Base and Meridian.

The surrounding land uses in the vicinity of the Project are mining, agricultural, and residential. Mining operations exist to the north, northeast, southwest and west of the Project site, and the areas south and east of the Project site are used for agricultural and, to a limited extent, for rural residential purposes. The Project site has been extensively used and disturbed over the years for cattle grazing.

Project Background: TID is a public agency organized and existing pursuant to Division 11 of the California Water Code. CPDC and VKWC are mutual water companies organized and existing pursuant to Division 3 of the California Corporations Code. The Project Owners are all members of the Kaweah and St. Johns Waters Association (Association), which oversees the surface water rights and diversion operations on the Kaweah River. VKWC is also a mutual water company formed under Section 200 of the California Corporations Code. Together they are the Owners of the Project.

Project Summary: The Owners propose to construct a surface water storage and re-regulation reservoir (the proposed Project) on approximately 200 acres within the 500-acre McKay Point property. The reservoir would be located on the north side of the divergence of the Lower Kaweah River and St. Johns River.

The Project would consist of the following phases: excavation of the site for the reservoir; construction of the reservoir; and operation of the reservoir. The Owners plan to enter into a lease agreement with West Coast Aggregate Supply, Inc. (WCA) to excavate the site to allow for the construction of the reservoir. After the excavation and construction of the reservoir, the McKay Point Reservoir would be used as a surface water storage / re-regulation reservoir. The reservoir would also be used to optimize groundwater recharge within the Owners service areas (Figure 2).

The Project would result in new disturbance to the site. There would be surface disturbance of approximately 134 acres, this includes the proposed perimeter fencing which will be constructed such that it will not disrupt biological resources (i.e., migration routes), perimeter road for reservoir maintenance, and inlet/outlet channels between the rivers and the reservoir. The excavation of the site for construction of the reservoir would be within the approximately 134 acres, covering approximately 110 acres on the surface and approximately 60 feet deep below the existing ground surface (approximately to bedrock). The Project would not extend past the bedrock and no blasting would be required. The Project would include staff education and monitoring of the site to protect cultural, historical, tribal and paleontological resources. These protection measures will be discussed in detail in the Draft EIR.

Discretionary approvals would be required for the Project; therefore, the Project is subject to CEQA. The excavation of the Project site needed to construct the reservoir would require compliance with the State Mining and Reclamation Act (SMARA) and a Reclamation Plan approved by the County of Tulare. TID is the Project Applicant on behalf of the Owners as well as the CEQA Lead Agency.

The Owners' objectives in proposing the Project include the following:

- Capturing and re-regulating water made available to the Owners during flood releases from Lake Kaweah.
- Capturing and re-regulating water entitlements belonging to the Owners released from Lake Kaweah.
- Capturing and re-regulating any other water sources on the Kaweah River that may be made available to the Owners.
- Allowing other entities with water rights on the Kaweah River to capture and/or re-regulate flows when designated by the Owners.
- Allowing other entities to capture and/or re-regulate flows of the Lower Kaweah River and St. Johns River for purposes of storm water runoff and flood prevention with permission of the Owners and Kaweah/St. Johns water rights interests.
- Constructing the reservoir in such a way that revenue can be obtained to offset a portion of the construction and development costs.
- Locating the reservoir adjacent to the Kaweah River to allow for off-stream access to surface water storage, thus minimizing the need for pipelines.

To accomplish these objectives, the Owners propose to construct and operate the Project to:

- Divert and receive water immediately upstream of the divergence of the Lower Kaweah River and St. Johns River, commonly referred to as McKay Point.
- Provide a water storage capacity of approximately 4,600 acre-feet.
- Deliver water back to either the Lower Kaweah River or the St. Johns River, as needed.
- Provide additional storage capacity for storm water layoff and flood prevention.

- Coordinate all such diversions and deliveries to and from the reservoir with the Kaweah Delta Conservation District and the Kaweah and St. Johns River Association.
- Enter into a lease agreement with WCA to excavate the site for the reservoir and process the excavated material into a marketable product (primarily construction grade aggregate). TID would receive revenue from the sale of the excavated material that could be used to offset a portion of the reservoir construction and development costs.

A detailed Project Description is attached to this letter.

Potential Environmental Effects: An EIR would be prepared to evaluate the proposed Project's environmental impacts and analyze Project alternatives. The topic areas anticipated to be analyzed in detail in the EIR include Air Quality, Greenhouse Gas Emissions, Health Risks, Biological Resources, Cultural Resources, Geology and Soil, Hazards and Hazardous Materials, Hydrology and Water Quality, Land Use and Planning, Noise, Tribal Cultural Resources, and Wildfire.

REQUEST FOR CONSULTATION

Pursuant to the provisions of AB 52, as the lead agency under CEQA, the Tulare Irrigation District hereby extends an invitation to consult on the CEQA review of the McKay Point Reservoir Project in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American cultural places and tribal cultural resources.

Project Notification and Tribal Consultation Request Pursuant to AB 52

September 16, 2021

Santa Rosa Rancheria Tachi Yokut Tribe
Leo Sisco, Chairperson
PO Box 8
Lemoore, CA 93245

RE: Project Notification and Consultation Request Pursuant to CEQA's Assembly Bill (AB) 52 for the McKay Point Reservoir Project (SCH No. 2014011078)

Dear Leo Sisco,

Pursuant to the provisions of AB 52, as the lead agency under the California Environmental Quality Act (CEQA), the Tulare Irrigation District (TID) hereby extends an invitation to consult on the California Environmental Quality Act (CEQA) review of the McKay Point Reservoir Project (Project) in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American tribal cultural resources and/or tribal cultural places including:

- Native American sanctified cemetery, place of worship, religious or ceremonial site, or sacred shrine; and
- Native American historic, cultural, or sacred site that is listed or may be eligible for listing in the California Register of Historical Resources including historic or prehistoric ruins and any burial ground, archaeological, or historic site.

The proposed Project is located on approximately 500 acres adjacent to the Lower Kaweah River and St. Johns River. In accordance with CEQA (Pub. Resources Code, § 21000 et seq.), the Tulare Irrigation District will be preparing an Environmental Impact Report (EIR) to evaluate the environmental effects associated with the Project. A Notice of Preparation (NOP) under CEQA was published on October 2, 2020 and the distribution included the list of tribes provided by the Native American Heritage Commission (NAHC) at that time. A copy of the current Project Description is included with this notice and request for consultation.

PROJECT INFORMATION/DESCRIPTION

Project Title: McKay Point Reservoir Project

Project Applicant: Project joint owners – Tulare Irrigation District (TID), the Consolidated Peoples Ditch Company (CPDC), and the Visalia and Kaweah Water Company (VKWC).

Assessor's Parcel Number(s): The Project site is comprised of portions of the following Assessor's Parcel Numbers (APN's): 113-070-016-000, 113-080-005-000, 113-080-008-000, 113-090-001-000, 113-100-002-000.

Project Location: Located in Tulare County, California, the Project site lies between and to the south of both Lake Kaweah (2.5 miles northeast of the site) and Bravo Lake (1.5 miles northwest of the site); 1.0 miles northwest of the community of Lemon Cove; and 2.5 miles southeast of the community of Woodlake (Figure 1). The Project site is located approximately 1.0 mile west-southwest of the intersection of State Highways 216 and 198, in Sections 3 and 4, Township 18 South, Range 27 East, Mount Diablo Base and Meridian.

The surrounding land uses in the vicinity of the Project are mining, agricultural, and residential. Mining operations exist to the north, northeast, southwest and west of the Project site, and the areas south and east of the Project site are used for agricultural and, to a limited extent, for rural residential purposes. The Project site has been extensively used and disturbed over the years for cattle grazing.

Project Background: TID is a public agency organized and existing pursuant to Division 11 of the California Water Code. CPDC and VKWC are mutual water companies organized and existing pursuant to Division 3 of the California Corporations Code. The Project Owners are all members of the Kaweah and St. Johns Waters Association (Association), which oversees the surface water rights and diversion operations on the Kaweah River. VKWC is also a mutual water company formed under Section 200 of the California Corporations Code. Together they are the Owners of the Project.

Project Summary: The Owners propose to construct a surface water storage and re-regulation reservoir (the proposed Project) on approximately 200 acres within the 500-acre McKay Point property. The reservoir would be located on the north side of the divergence of the Lower Kaweah River and St. Johns River.

The Project would consist of the following phases: excavation of the site for the reservoir; construction of the reservoir; and operation of the reservoir. The Owners plan to enter into a lease agreement with West Coast Aggregate Supply, Inc. (WCA) to excavate the site to allow for the construction of the reservoir. After the excavation and construction of the reservoir, the McKay Point Reservoir would be used as a surface water storage / re-regulation reservoir. The reservoir would also be used to optimize groundwater recharge within the Owners service areas (Figure 2).

The Project would result in new disturbance to the site. There would be surface disturbance of approximately 134 acres, this includes the proposed perimeter fencing which will be constructed such that it will not disrupt biological resources (i.e., migration routes), perimeter road for reservoir maintenance, and inlet/outlet channels between the rivers and the reservoir. The excavation of the site for construction of the reservoir would be within the approximately 134 acres, covering approximately 110 acres on the surface and approximately 60 feet deep below the existing ground surface (approximately to bedrock). The Project would not extend past the bedrock and no blasting would be required. The Project would include staff education and monitoring of the site to protect cultural, historical, tribal and paleontological resources. These protection measures will be discussed in detail in the Draft EIR.

Discretionary approvals would be required for the Project; therefore, the Project is subject to CEQA. The excavation of the Project site needed to construct the reservoir would require compliance with the State Mining and Reclamation Act (SMARA) and a Reclamation Plan approved by the County of Tulare. TID is the Project Applicant on behalf of the Owners as well as the CEQA Lead Agency.

The Owners' objectives in proposing the Project include the following:

- Capturing and re-regulating water made available to the Owners during flood releases from Lake Kaweah.
- Capturing and re-regulating water entitlements belonging to the Owners released from Lake Kaweah.
- Capturing and re-regulating any other water sources on the Kaweah River that may be made available to the Owners.
- Allowing other entities with water rights on the Kaweah River to capture and/or re-regulate flows when designated by the Owners.
- Allowing other entities to capture and/or re-regulate flows of the Lower Kaweah River and St. Johns River for purposes of storm water runoff and flood prevention with permission of the Owners and Kaweah/St. Johns water rights interests.
- Constructing the reservoir in such a way that revenue can be obtained to offset a portion of the construction and development costs.
- Locating the reservoir adjacent to the Kaweah River to allow for off-stream access to surface water storage, thus minimizing the need for pipelines.

To accomplish these objectives, the Owners propose to construct and operate the Project to:

- Divert and receive water immediately upstream of the divergence of the Lower Kaweah River and St. Johns River, commonly referred to as McKay Point.
- Provide a water storage capacity of approximately 4,600 acre-feet.
- Deliver water back to either the Lower Kaweah River or the St. Johns River, as needed.
- Provide additional storage capacity for storm water layoff and flood prevention.

- Coordinate all such diversions and deliveries to and from the reservoir with the Kaweah Delta Conservation District and the Kaweah and St. Johns River Association.
- Enter into a lease agreement with WCA to excavate the site for the reservoir and process the excavated material into a marketable product (primarily construction grade aggregate). TID would receive revenue from the sale of the excavated material that could be used to offset a portion of the reservoir construction and development costs.

A detailed Project Description is attached to this letter.

Potential Environmental Effects: An EIR would be prepared to evaluate the proposed Project's environmental impacts and analyze Project alternatives. The topic areas anticipated to be analyzed in detail in the EIR include Air Quality, Greenhouse Gas Emissions, Health Risks, Biological Resources, Cultural Resources, Geology and Soil, Hazards and Hazardous Materials, Hydrology and Water Quality, Land Use and Planning, Noise, Tribal Cultural Resources, and Wildfire.

REQUEST FOR CONSULTATION

Pursuant to the provisions of AB 52, as the lead agency under CEQA, the Tulare Irrigation District hereby extends an invitation to consult on the CEQA review of the McKay Point Reservoir Project in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American cultural places and tribal cultural resources.

Project Notification and Tribal Consultation Request Pursuant to AB 52

September 16, 2021

Dunlap Band of Mono Indians
Dirk Charley, Tribal Secretary
5509 E. McKenzie Avenue
Fresno, CA 93727

RE: Project Notification and Consultation Request Pursuant to CEQA's Assembly Bill (AB) 52 for the McKay Point Reservoir Project (SCH No. 2014011078)

Dear Dirk Charley,

Pursuant to the provisions of AB 52, as the lead agency under the California Environmental Quality Act (CEQA), the Tulare Irrigation District (TID) hereby extends an invitation to consult on the California Environmental Quality Act (CEQA) review of the McKay Point Reservoir Project (Project) in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American tribal cultural resources and/or tribal cultural places including:

- Native American sanctified cemetery, place of worship, religious or ceremonial site, or sacred shrine; and
- Native American historic, cultural, or sacred site that is listed or may be eligible for listing in the California Register of Historical Resources including historic or prehistoric ruins and any burial ground, archaeological, or historic site.

The proposed Project is located on approximately 500 acres adjacent to the Lower Kaweah River and St. Johns River. In accordance with CEQA (Pub. Resources Code, § 21000 et seq.), the Tulare Irrigation District will be preparing an Environmental Impact Report (EIR) to evaluate the environmental effects associated with the Project. A Notice of Preparation (NOP) under CEQA was published on October 2, 2020 and the distribution included the list of tribes provided by the Native American Heritage Commission (NAHC) at that time. A copy of the current Project Description is included with this notice and request for consultation.

PROJECT INFORMATION/DESCRIPTION

Project Title: McKay Point Reservoir Project

Project Applicant: Project joint owners – Tulare Irrigation District (TID), the Consolidated Peoples Ditch Company (CPDC), and the Visalia and Kaweah Water Company (VKWC).

Assessor's Parcel Number(s): The Project site is comprised of portions of the following Assessor's Parcel Numbers (APN's): 113-070-016-000, 113-080-005-000, 113-080-008-000, 113-090-001-000, 113-100-002-000.

Project Location: Located in Tulare County, California, the Project site lies between and to the south of both Lake Kaweah (2.5 miles northeast of the site) and Bravo Lake (1.5 miles northwest of the site); 1.0 miles northwest of the community of Lemon Cove; and 2.5 miles southeast of the community of Woodlake (Figure 1). The Project site is located approximately 1.0 mile west-southwest of the intersection of State Highways 216 and 198, in Sections 3 and 4, Township 18 South, Range 27 East, Mount Diablo Base and Meridian.

The surrounding land uses in the vicinity of the Project are mining, agricultural, and residential. Mining operations exist to the north, northeast, southwest and west of the Project site, and the areas south and east of the Project site are used for agricultural and, to a limited extent, for rural residential purposes. The Project site has been extensively used and disturbed over the years for cattle grazing.

Project Background: TID is a public agency organized and existing pursuant to Division 11 of the California Water Code. CPDC and VKWC are mutual water companies organized and existing pursuant to Division 3 of the California Corporations Code. The Project Owners are all members of the Kaweah and St. Johns Waters Association (Association), which oversees the surface water rights and diversion operations on the Kaweah River. VKWC is also a mutual water company formed under Section 200 of the California Corporations Code. Together they are the Owners of the Project.

Project Summary: The Owners propose to construct a surface water storage and re-regulation reservoir (the proposed Project) on approximately 200 acres within the 500-acre McKay Point property. The reservoir would be located on the north side of the divergence of the Lower Kaweah River and St. Johns River.

The Project would consist of the following phases: excavation of the site for the reservoir; construction of the reservoir; and operation of the reservoir. The Owners plan to enter into a lease agreement with West Coast Aggregate Supply, Inc. (WCA) to excavate the site to allow for the construction of the reservoir. After the excavation and construction of the reservoir, the McKay Point Reservoir would be used as a surface water storage / re-regulation reservoir. The reservoir would also be used to optimize groundwater recharge within the Owners service areas (Figure 2).

The Project would result in new disturbance to the site. There would be surface disturbance of approximately 134 acres, this includes the proposed perimeter fencing which will be constructed such that it will not disrupt biological resources (i.e., migration routes), perimeter road for reservoir maintenance, and inlet/outlet channels between the rivers and the reservoir. The excavation of the site for construction of the reservoir would be within the approximately 134 acres, covering approximately 110 acres on the surface and approximately 60 feet deep below the existing ground surface (approximately to bedrock). The Project would not extend past the bedrock and no blasting would be required. The Project would include staff education and monitoring of the site to protect cultural, historical, tribal and paleontological resources. These protection measures will be discussed in detail in the Draft EIR.

Discretionary approvals would be required for the Project; therefore, the Project is subject to CEQA. The excavation of the Project site needed to construct the reservoir would require compliance with the State Mining and Reclamation Act (SMARA) and a Reclamation Plan approved by the County of Tulare. TID is the Project Applicant on behalf of the Owners as well as the CEQA Lead Agency.

The Owners' objectives in proposing the Project include the following:

- Capturing and re-regulating water made available to the Owners during flood releases from Lake Kaweah.
- Capturing and re-regulating water entitlements belonging to the Owners released from Lake Kaweah.
- Capturing and re-regulating any other water sources on the Kaweah River that may be made available to the Owners.
- Allowing other entities with water rights on the Kaweah River to capture and/or re-regulate flows when designated by the Owners.
- Allowing other entities to capture and/or re-regulate flows of the Lower Kaweah River and St. Johns River for purposes of storm water runoff and flood prevention with permission of the Owners and Kaweah/St. Johns water rights interests.
- Constructing the reservoir in such a way that revenue can be obtained to offset a portion of the construction and development costs.
- Locating the reservoir adjacent to the Kaweah River to allow for off-stream access to surface water storage, thus minimizing the need for pipelines.

To accomplish these objectives, the Owners propose to construct and operate the Project to:

- Divert and receive water immediately upstream of the divergence of the Lower Kaweah River and St. Johns River, commonly referred to as McKay Point.
- Provide a water storage capacity of approximately 4,600 acre-feet.
- Deliver water back to either the Lower Kaweah River or the St. Johns River, as needed.
- Provide additional storage capacity for storm water layoff and flood prevention.

- Coordinate all such diversions and deliveries to and from the reservoir with the Kaweah Delta Conservation District and the Kaweah and St. Johns River Association.
- Enter into a lease agreement with WCA to excavate the site for the reservoir and process the excavated material into a marketable product (primarily construction grade aggregate). TID would receive revenue from the sale of the excavated material that could be used to offset a portion of the reservoir construction and development costs.

A detailed Project Description is attached to this letter.

Potential Environmental Effects: An EIR would be prepared to evaluate the proposed Project's environmental impacts and analyze Project alternatives. The topic areas anticipated to be analyzed in detail in the EIR include Air Quality, Greenhouse Gas Emissions, Health Risks, Biological Resources, Cultural Resources, Geology and Soil, Hazards and Hazardous Materials, Hydrology and Water Quality, Land Use and Planning, Noise, Tribal Cultural Resources, and Wildfire.

REQUEST FOR CONSULTATION

Pursuant to the provisions of AB 52, as the lead agency under CEQA, the Tulare Irrigation District hereby extends an invitation to consult on the CEQA review of the McKay Point Reservoir Project in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American cultural places and tribal cultural resources.

If your Tribe desires to consult with the Tulare Irrigation District on the review of this Project, please respond in writing within thirty (30) days of receipt of this notification. Written correspondence can be emailed or mailed to the following addresses (email is preferred):

US Post: Maya Rohr
Project Manager
Sespe Consulting, Inc.
3990 Old Town Avenue, Suite A203
San Diego, CA 92110

Phone: (805) 275-1515

E-mail: mrohr@sespe.com and gstephens@sespe.com (Graham Stephens)

If you need further assistance or have any questions, please feel free to contact Maya Rohr or Graham Stephens by phone at (805) 275-1515.

If the Tulare Irrigation District does not receive a response to this notification, it will be presumed that your Tribe has declined the opportunity to consult on this project pursuant to AB 52.

Project Notification and Tribal Consultation Request Pursuant to AB 52

September 16, 2021

Tubatulabals of Kern Valley
Robert L. Gomez, Jr., Tribal Chairperson
PO Box 226
Lake Isabella, CA 93240

RE: Project Notification and Consultation Request Pursuant to CEQA's Assembly Bill (AB) 52 for the McKay Point Reservoir Project (SCH No. 2014011078)

Dear Robert L. Gomez, Jr.,

Pursuant to the provisions of AB 52, as the lead agency under the California Environmental Quality Act (CEQA), the Tulare Irrigation District (TID) hereby extends an invitation to consult on the California Environmental Quality Act (CEQA) review of the McKay Point Reservoir Project (Project) in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American tribal cultural resources and/or tribal cultural places including:

- Native American sanctified cemetery, place of worship, religious or ceremonial site, or sacred shrine; and
- Native American historic, cultural, or sacred site that is listed or may be eligible for listing in the California Register of Historical Resources including historic or prehistoric ruins and any burial ground, archaeological, or historic site.

The proposed Project is located on approximately 500 acres adjacent to the Lower Kaweah River and St. Johns River. In accordance with CEQA (Pub. Resources Code, § 21000 et seq.), the Tulare Irrigation District will be preparing an Environmental Impact Report (EIR) to evaluate the environmental effects associated with the Project. A Notice of Preparation (NOP) under CEQA was published on October 2, 2020 and the distribution included the list of tribes provided by the Native American Heritage Commission (NAHC) at that time. A copy of the current Project Description is included with this notice and request for consultation.

PROJECT INFORMATION/DESCRIPTION

Project Title: McKay Point Reservoir Project

Project Applicant: Project joint owners – Tulare Irrigation District (TID), the Consolidated Peoples Ditch Company (CPDC), and the Visalia and Kaweah Water Company (VKWC).

Assessor's Parcel Number(s): The Project site is comprised of portions of the following Assessor's Parcel Numbers (APN's): 113-070-016-000, 113-080-005-000, 113-080-008-000, 113-090-001-000, 113-100-002-000.

Project Location: Located in Tulare County, California, the Project site lies between and to the south of both Lake Kaweah (2.5 miles northeast of the site) and Bravo Lake (1.5 miles northwest of the site); 1.0 miles northwest of the community of Lemon Cove; and 2.5 miles southeast of the community of Woodlake (Figure 1). The Project site is located approximately 1.0 mile west-southwest of the intersection of State Highways 216 and 198, in Sections 3 and 4, Township 18 South, Range 27 East, Mount Diablo Base and Meridian.

The surrounding land uses in the vicinity of the Project are mining, agricultural, and residential. Mining operations exist to the north, northeast, southwest and west of the Project site, and the areas south and east of the Project site are used for agricultural and, to a limited extent, for rural residential purposes. The Project site has been extensively used and disturbed over the years for cattle grazing.

Project Background: TID is a public agency organized and existing pursuant to Division 11 of the California Water Code. CPDC and VKWC are mutual water companies organized and existing pursuant to Division 3 of the California Corporations Code. The Project Owners are all members of the Kaweah and St. Johns Waters Association (Association), which oversees the surface water rights and diversion operations on the Kaweah River. VKWC is also a mutual water company formed under Section 200 of the California Corporations Code. Together they are the Owners of the Project.

Project Summary: The Owners propose to construct a surface water storage and re-regulation reservoir (the proposed Project) on approximately 200 acres within the 500-acre McKay Point property. The reservoir would be located on the north side of the divergence of the Lower Kaweah River and St. Johns River.

The Project would consist of the following phases: excavation of the site for the reservoir; construction of the reservoir; and operation of the reservoir. The Owners plan to enter into a lease agreement with West Coast Aggregate Supply, Inc. (WCA) to excavate the site to allow for the construction of the reservoir. After the excavation and construction of the reservoir, the McKay Point Reservoir would be used as a surface water storage / re-regulation reservoir. The reservoir would also be used to optimize groundwater recharge within the Owners service areas (Figure 2).

The Project would result in new disturbance to the site. There would be surface disturbance of approximately 134 acres, this includes the proposed perimeter fencing which will be constructed such that it will not disrupt biological resources (i.e., migration routes), perimeter road for reservoir maintenance, and inlet/outlet channels between the rivers and the reservoir. The excavation of the site for construction of the reservoir would be within the approximately 134 acres, covering approximately 110 acres on the surface and approximately 60 feet deep below the existing ground surface (approximately to bedrock). The Project would not extend past the bedrock and no blasting would be required. The Project would include staff education and monitoring of the site to protect cultural, historical, tribal and paleontological resources. These protection measures will be discussed in detail in the Draft EIR.

Discretionary approvals would be required for the Project; therefore, the Project is subject to CEQA. The excavation of the Project site needed to construct the reservoir would require compliance with the State Mining and Reclamation Act (SMARA) and a Reclamation Plan approved by the County of Tulare. TID is the Project Applicant on behalf of the Owners as well as the CEQA Lead Agency.

The Owners' objectives in proposing the Project include the following:

- Capturing and re-regulating water made available to the Owners during flood releases from Lake Kaweah.
- Capturing and re-regulating water entitlements belonging to the Owners released from Lake Kaweah.
- Capturing and re-regulating any other water sources on the Kaweah River that may be made available to the Owners.
- Allowing other entities with water rights on the Kaweah River to capture and/or re-regulate flows when designated by the Owners.
- Allowing other entities to capture and/or re-regulate flows of the Lower Kaweah River and St. Johns River for purposes of storm water runoff and flood prevention with permission of the Owners and Kaweah/St. Johns water rights interests.
- Constructing the reservoir in such a way that revenue can be obtained to offset a portion of the construction and development costs.
- Locating the reservoir adjacent to the Kaweah River to allow for off-stream access to surface water storage, thus minimizing the need for pipelines.

To accomplish these objectives, the Owners propose to construct and operate the Project to:

- Divert and receive water immediately upstream of the divergence of the Lower Kaweah River and St. Johns River, commonly referred to as McKay Point.
- Provide a water storage capacity of approximately 4,600 acre-feet.
- Deliver water back to either the Lower Kaweah River or the St. Johns River, as needed.
- Provide additional storage capacity for storm water layoff and flood prevention.

- Coordinate all such diversions and deliveries to and from the reservoir with the Kaweah Delta Conservation District and the Kaweah and St. Johns River Association.
- Enter into a lease agreement with WCA to excavate the site for the reservoir and process the excavated material into a marketable product (primarily construction grade aggregate). TID would receive revenue from the sale of the excavated material that could be used to offset a portion of the reservoir construction and development costs.

A detailed Project Description is attached to this letter.

Potential Environmental Effects: An EIR would be prepared to evaluate the proposed Project's environmental impacts and analyze Project alternatives. The topic areas anticipated to be analyzed in detail in the EIR include Air Quality, Greenhouse Gas Emissions, Health Risks, Biological Resources, Cultural Resources, Geology and Soil, Hazards and Hazardous Materials, Hydrology and Water Quality, Land Use and Planning, Noise, Tribal Cultural Resources, and Wildfire.

REQUEST FOR CONSULTATION

Pursuant to the provisions of AB 52, as the lead agency under CEQA, the Tulare Irrigation District hereby extends an invitation to consult on the CEQA review of the McKay Point Reservoir Project in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American cultural places and tribal cultural resources.

If your Tribe desires to consult with the Tulare Irrigation District on the review of this Project, please respond in writing within thirty (30) days of receipt of this notification. Written correspondence can be emailed or mailed to the following addresses (email is preferred):

Project Notification and Tribal Consultation Request Pursuant to AB 52

September 16, 2021

Kern Valley Indian Community – Kawaiisu Tubatulabal
Julie Turner, Secretary
PO Box 1010
Lake Isabella, CA 93240

RE: Project Notification and Consultation Request Pursuant to CEQA's Assembly Bill (AB) 52 for the McKay Point Reservoir Project (SCH No. 2014011078)

Dear Julie Turner,

Pursuant to the provisions of AB 52, as the lead agency under the California Environmental Quality Act (CEQA), the Tulare Irrigation District (TID) hereby extends an invitation to consult on the California Environmental Quality Act (CEQA) review of the McKay Point Reservoir Project (Project) in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American tribal cultural resources and/or tribal cultural places including:

- Native American sanctified cemetery, place of worship, religious or ceremonial site, or sacred shrine; and
- Native American historic, cultural, or sacred site that is listed or may be eligible for listing in the California Register of Historical Resources including historic or prehistoric ruins and any burial ground, archaeological, or historic site.

The proposed Project is located on approximately 500 acres adjacent to the Lower Kaweah River and St. Johns River. In accordance with CEQA (Pub. Resources Code, § 21000 et seq.), the Tulare Irrigation District will be preparing an Environmental Impact Report (EIR) to evaluate the environmental effects associated with the Project. A Notice of Preparation (NOP) under CEQA was published on October 2, 2020 and the distribution included the list of tribes provided by the Native American Heritage Commission (NAHC) at that time. A copy of the current Project Description is included with this notice and request for consultation.

PROJECT INFORMATION/DESCRIPTION

Project Title: McKay Point Reservoir Project

Project Applicant: Project joint owners – Tulare Irrigation District (TID), the Consolidated Peoples Ditch Company (CPDC), and the Visalia and Kaweah Water Company (VKWC).

Assessor's Parcel Number(s): The Project site is comprised of portions of the following Assessor's Parcel Numbers (APN's): 113-070-016-000, 113-080-005-000, 113-080-008-000, 113-090-001-000, 113-100-002-000.

Project Location: Located in Tulare County, California, the Project site lies between and to the south of both Lake Kaweah (2.5 miles northeast of the site) and Bravo Lake (1.5 miles northwest of the site); 1.0 miles northwest of the community of Lemon Cove; and 2.5 miles southeast of the community of Woodlake (Figure 1). The Project site is located approximately 1.0 mile west-southwest of the intersection of State Highways 216 and 198, in Sections 3 and 4, Township 18 South, Range 27 East, Mount Diablo Base and Meridian.

The surrounding land uses in the vicinity of the Project are mining, agricultural, and residential. Mining operations exist to the north, northeast, southwest and west of the Project site, and the areas south and east of the Project site are used for agricultural and, to a limited extent, for rural residential purposes. The Project site has been extensively used and disturbed over the years for cattle grazing.

Project Background: TID is a public agency organized and existing pursuant to Division 11 of the California Water Code. CPDC and VKWC are mutual water companies organized and existing pursuant to Division 3 of the California Corporations Code. The Project Owners are all members of the Kaweah and St. Johns Waters Association (Association), which oversees the surface water rights and diversion operations on the Kaweah River. VKWC is also a mutual water company formed under Section 200 of the California Corporations Code. Together they are the Owners of the Project.

Project Summary: The Owners propose to construct a surface water storage and re-regulation reservoir (the proposed Project) on approximately 200 acres within the 500-acre McKay Point property. The reservoir would be located on the north side of the divergence of the Lower Kaweah River and St. Johns River.

The Project would consist of the following phases: excavation of the site for the reservoir; construction of the reservoir; and operation of the reservoir. The Owners plan to enter into a lease agreement with West Coast Aggregate Supply, Inc. (WCA) to excavate the site to allow for the construction of the reservoir. After the excavation and construction of the reservoir, the McKay Point Reservoir would be used as a surface water storage / re-regulation reservoir. The reservoir would also be used to optimize groundwater recharge within the Owners service areas (Figure 2).

The Project would result in new disturbance to the site. There would be surface disturbance of approximately 134 acres, this includes the proposed perimeter fencing which will be constructed such that it will not disrupt biological resources (i.e., migration routes), perimeter road for reservoir maintenance, and inlet/outlet channels between the rivers and the reservoir. The excavation of the site for construction of the reservoir would be within the approximately 134 acres, covering approximately 110 acres on the surface and approximately 60 feet deep below the existing ground surface (approximately to bedrock). The Project would not extend past the bedrock and no blasting would be required. The Project would include staff education and monitoring of the site to protect cultural, historical, tribal and paleontological resources. These protection measures will be discussed in detail in the Draft EIR.

Discretionary approvals would be required for the Project; therefore, the Project is subject to CEQA. The excavation of the Project site needed to construct the reservoir would require compliance with the State Mining and Reclamation Act (SMARA) and a Reclamation Plan approved by the County of Tulare. TID is the Project Applicant on behalf of the Owners as well as the CEQA Lead Agency.

The Owners' objectives in proposing the Project include the following:

- Capturing and re-regulating water made available to the Owners during flood releases from Lake Kaweah.
- Capturing and re-regulating water entitlements belonging to the Owners released from Lake Kaweah.
- Capturing and re-regulating any other water sources on the Kaweah River that may be made available to the Owners.
- Allowing other entities with water rights on the Kaweah River to capture and/or re-regulate flows when designated by the Owners.
- Allowing other entities to capture and/or re-regulate flows of the Lower Kaweah River and St. Johns River for purposes of storm water runoff and flood prevention with permission of the Owners and Kaweah/St. Johns water rights interests.
- Constructing the reservoir in such a way that revenue can be obtained to offset a portion of the construction and development costs.
- Locating the reservoir adjacent to the Kaweah River to allow for off-stream access to surface water storage, thus minimizing the need for pipelines.

To accomplish these objectives, the Owners propose to construct and operate the Project to:

- Divert and receive water immediately upstream of the divergence of the Lower Kaweah River and St. Johns River, commonly referred to as McKay Point.
- Provide a water storage capacity of approximately 4,600 acre-feet.
- Deliver water back to either the Lower Kaweah River or the St. Johns River, as needed.
- Provide additional storage capacity for storm water layoff and flood prevention.

- Coordinate all such diversions and deliveries to and from the reservoir with the Kaweah Delta Conservation District and the Kaweah and St. Johns River Association.
- Enter into a lease agreement with WCA to excavate the site for the reservoir and process the excavated material into a marketable product (primarily construction grade aggregate). TID would receive revenue from the sale of the excavated material that could be used to offset a portion of the reservoir construction and development costs.

A detailed Project Description is attached to this letter.

Potential Environmental Effects: An EIR would be prepared to evaluate the proposed Project's environmental impacts and analyze Project alternatives. The topic areas anticipated to be analyzed in detail in the EIR include Air Quality, Greenhouse Gas Emissions, Health Risks, Biological Resources, Cultural Resources, Geology and Soil, Hazards and Hazardous Materials, Hydrology and Water Quality, Land Use and Planning, Noise, Tribal Cultural Resources, and Wildfire.

REQUEST FOR CONSULTATION

Pursuant to the provisions of AB 52, as the lead agency under CEQA, the Tulare Irrigation District hereby extends an invitation to consult on the CEQA review of the McKay Point Reservoir Project in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American cultural places and tribal cultural resources.

Project Notification and Tribal Consultation Request Pursuant to AB 52

September 16, 2021

Tule River Indian Tribe
Neil Peyron, Chairperson
PO Box 589
Porterville, CA 93258

RE: Project Notification and Consultation Request Pursuant to CEQA's Assembly Bill (AB) 52 for the McKay Point Reservoir Project (SCH No. 2014011078)

Dear Neil Peyron,

Pursuant to the provisions of AB 52, as the lead agency under the California Environmental Quality Act (CEQA), the Tulare Irrigation District (TID) hereby extends an invitation to consult on the California Environmental Quality Act (CEQA) review of the McKay Point Reservoir Project (Project) in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American tribal cultural resources and/or tribal cultural places including:

- Native American sanctified cemetery, place of worship, religious or ceremonial site, or sacred shrine; and
- Native American historic, cultural, or sacred site that is listed or may be eligible for listing in the California Register of Historical Resources including historic or prehistoric ruins and any burial ground, archaeological, or historic site.

The proposed Project is located on approximately 500 acres adjacent to the Lower Kaweah River and St. Johns River. In accordance with CEQA (Pub. Resources Code, § 21000 et seq.), the Tulare Irrigation District will be preparing an Environmental Impact Report (EIR) to evaluate the environmental effects associated with the Project. A Notice of Preparation (NOP) under CEQA was published on October 2, 2020 and the distribution included the list of tribes provided by the Native American Heritage Commission (NAHC) at that time. A copy of the current Project Description is included with this notice and request for consultation.

PROJECT INFORMATION/DESCRIPTION

Project Title: McKay Point Reservoir Project

Project Applicant: Project joint owners – Tulare Irrigation District (TID), the Consolidated Peoples Ditch Company (CPDC), and the Visalia and Kaweah Water Company (VKWC).

Assessor's Parcel Number(s): The Project site is comprised of portions of the following Assessor's Parcel Numbers (APN's): 113-070-016-000, 113-080-005-000, 113-080-008-000, 113-090-001-000, 113-100-002-000.

Project Location: Located in Tulare County, California, the Project site lies between and to the south of both Lake Kaweah (2.5 miles northeast of the site) and Bravo Lake (1.5 miles northwest of the site); 1.0 miles northwest of the community of Lemon Cove; and 2.5 miles southeast of the community of Woodlake (Figure 1). The Project site is located approximately 1.0 mile west-southwest of the intersection of State Highways 216 and 198, in Sections 3 and 4, Township 18 South, Range 27 East, Mount Diablo Base and Meridian.

The surrounding land uses in the vicinity of the Project are mining, agricultural, and residential. Mining operations exist to the north, northeast, southwest and west of the Project site, and the areas south and east of the Project site are used for agricultural and, to a limited extent, for rural residential purposes. The Project site has been extensively used and disturbed over the years for cattle grazing.

Project Background: TID is a public agency organized and existing pursuant to Division 11 of the California Water Code. CPDC and VKWC are mutual water companies organized and existing pursuant to Division 3 of the California Corporations Code. The Project Owners are all members of the Kaweah and St. Johns Waters Association (Association), which oversees the surface water rights and diversion operations on the Kaweah River. VKWC is also a mutual water company formed under Section 200 of the California Corporations Code. Together they are the Owners of the Project.

Project Summary: The Owners propose to construct a surface water storage and re-regulation reservoir (the proposed Project) on approximately 200 acres within the 500-acre McKay Point property. The reservoir would be located on the north side of the divergence of the Lower Kaweah River and St. Johns River.

The Project would consist of the following phases: excavation of the site for the reservoir; construction of the reservoir; and operation of the reservoir. The Owners plan to enter into a lease agreement with West Coast Aggregate Supply, Inc. (WCA) to excavate the site to allow for the construction of the reservoir. After the excavation and construction of the reservoir, the McKay Point Reservoir would be used as a surface water storage / re-regulation reservoir. The reservoir would also be used to optimize groundwater recharge within the Owners service areas (Figure 2).

The Project would result in new disturbance to the site. There would be surface disturbance of approximately 134 acres, this includes the proposed perimeter fencing which will be constructed such that it will not disrupt biological resources (i.e., migration routes), perimeter road for reservoir maintenance, and inlet/outlet channels between the rivers and the reservoir. The excavation of the site for construction of the reservoir would be within the approximately 134 acres, covering approximately 110 acres on the surface and approximately 60 feet deep below the existing ground surface (approximately to bedrock). The Project would not extend past the bedrock and no blasting would be required. The Project would include staff education and monitoring of the site to protect cultural, historical, tribal and paleontological resources. These protection measures will be discussed in detail in the Draft EIR.

Discretionary approvals would be required for the Project; therefore, the Project is subject to CEQA. The excavation of the Project site needed to construct the reservoir would require compliance with the State Mining and Reclamation Act (SMARA) and a Reclamation Plan approved by the County of Tulare. TID is the Project Applicant on behalf of the Owners as well as the CEQA Lead Agency.

The Owners' objectives in proposing the Project include the following:

- Capturing and re-regulating water made available to the Owners during flood releases from Lake Kaweah.
- Capturing and re-regulating water entitlements belonging to the Owners released from Lake Kaweah.
- Capturing and re-regulating any other water sources on the Kaweah River that may be made available to the Owners.
- Allowing other entities with water rights on the Kaweah River to capture and/or re-regulate flows when designated by the Owners.
- Allowing other entities to capture and/or re-regulate flows of the Lower Kaweah River and St. Johns River for purposes of storm water runoff and flood prevention with permission of the Owners and Kaweah/St. Johns water rights interests.
- Constructing the reservoir in such a way that revenue can be obtained to offset a portion of the construction and development costs.
- Locating the reservoir adjacent to the Kaweah River to allow for off-stream access to surface water storage, thus minimizing the need for pipelines.

To accomplish these objectives, the Owners propose to construct and operate the Project to:

- Divert and receive water immediately upstream of the divergence of the Lower Kaweah River and St. Johns River, commonly referred to as McKay Point.
- Provide a water storage capacity of approximately 4,600 acre-feet.
- Deliver water back to either the Lower Kaweah River or the St. Johns River, as needed.
- Provide additional storage capacity for storm water layoff and flood prevention.

- Coordinate all such diversions and deliveries to and from the reservoir with the Kaweah Delta Conservation District and the Kaweah and St. Johns River Association.
- Enter into a lease agreement with WCA to excavate the site for the reservoir and process the excavated material into a marketable product (primarily construction grade aggregate). TID would receive revenue from the sale of the excavated material that could be used to offset a portion of the reservoir construction and development costs.

A detailed Project Description is attached to this letter.

Potential Environmental Effects: An EIR would be prepared to evaluate the proposed Project's environmental impacts and analyze Project alternatives. The topic areas anticipated to be analyzed in detail in the EIR include Air Quality, Greenhouse Gas Emissions, Health Risks, Biological Resources, Cultural Resources, Geology and Soil, Hazards and Hazardous Materials, Hydrology and Water Quality, Land Use and Planning, Noise, Tribal Cultural Resources, and Wildfire.

REQUEST FOR CONSULTATION

Pursuant to the provisions of AB 52, as the lead agency under CEQA, the Tulare Irrigation District hereby extends an invitation to consult on the CEQA review of the McKay Point Reservoir Project in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American cultural places and tribal cultural resources.

If your Tribe desires to consult with the Tulare Irrigation District on the review of this Project, please respond in writing within thirty (30) days of receipt of this notification. Written correspondence can be emailed or mailed to the following addresses (email is preferred):

Robert Robinson, Chairperson
PO Box 1010
Lake Isabella, CA 93240

RE: Project Notification and Consultation Request Pursuant to CEQA's Assembly Bill (AB) 52 for the McKay Point Reservoir Project (SCH No. 2014011078)

Dear Robert Robinson,

Pursuant to the provisions of AB 52, as the lead agency under the California Environmental Quality Act (CEQA), the Tulare Irrigation District (TID) hereby extends an invitation to consult on the California Environmental Quality Act (CEQA) review of the McKay Point Reservoir Project (Project) in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American tribal cultural resources and/or tribal cultural places including:

- Native American sanctified cemetery, place of worship, religious or ceremonial site, or sacred shrine; and
- Native American historic, cultural, or sacred site that is listed or may be eligible for listing in the California Register of Historical Resources including historic or prehistoric ruins and any burial ground, archaeological, or historic site.

The proposed Project is located on approximately 500 acres adjacent to the Lower Kaweah River and St. Johns River. In accordance with CEQA (Pub. Resources Code, § 21000 et seq.), the Tulare Irrigation District will be preparing an Environmental Impact Report (EIR) to evaluate the environmental effects associated with the Project. A Notice of Preparation (NOP) under CEQA was published on October 2, 2020 and the distribution included the list of tribes provided by the Native American Heritage Commission (NAHC) at that time. A copy of the current Project Description is included with this notice and request for consultation.

PROJECT INFORMATION/DESCRIPTION

Project Title: McKay Point Reservoir Project

Project Applicant: Project joint owners – Tulare Irrigation District (TID), the Consolidated Peoples Ditch Company (CPDC), and the Visalia and Kaweah Water Company (VKWC).

Assessor's Parcel Number(s): The Project site is comprised of portions of the following Assessor's Parcel Numbers (APN's): 113-070-016-000, 113-080-005-000, 113-080-008-000, 113-090-001-000, 113-100-002-000.

Project Location: Located in Tulare County, California, the Project site lies between and to the south of both Lake Kaweah (2.5 miles northeast of the site) and Bravo Lake (1.5 miles northwest of the site); 1.0 miles northwest of the community of Lemon Cove; and 2.5 miles southeast of the community of Woodlake (Figure 1). The Project site is located approximately 1.0 mile west-southwest of the intersection of State Highways 216 and 198, in Sections 3 and 4, Township 18 South, Range 27 East, Mount Diablo Base and Meridian.

The surrounding land uses in the vicinity of the Project are mining, agricultural, and residential. Mining operations exist to the north, northeast, southwest and west of the Project site, and the areas south and east of the Project site are used for agricultural and, to a limited extent, for rural residential purposes. The Project site has been extensively used and disturbed over the years for cattle grazing.

Project Background: TID is a public agency organized and existing pursuant to Division 11 of the California Water Code. CPDC and VKWC are mutual water companies organized and existing pursuant to Division 3 of the California Corporations Code. The Project Owners are all members of the Kaweah and St. Johns Waters Association (Association), which oversees the surface water rights and diversion operations on the Kaweah River. VKWC is also a mutual water company formed under Section 200 of the California Corporations Code. Together they are the Owners of the Project.

Project Summary: The Owners propose to construct a surface water storage and re-regulation reservoir (the proposed Project) on approximately 200 acres within the 500-acre McKay Point property. The reservoir would be located on the north side of the divergence of the Lower Kaweah River and St. Johns River.

The Project would consist of the following phases: excavation of the site for the reservoir; construction of the reservoir; and operation of the reservoir. The Owners plan to enter into a lease agreement with West Coast Aggregate Supply, Inc. (WCA) to excavate the site to allow for the construction of the reservoir. After the excavation and construction of the reservoir, the McKay Point Reservoir would be used as a surface water storage / re-regulation reservoir. The reservoir would also be used to optimize groundwater recharge within the Owners service areas (Figure 2).

The Project would result in new disturbance to the site. There would be surface disturbance of approximately 134 acres, this includes the proposed perimeter fencing which will be constructed such that it will not disrupt biological resources (i.e., migration routes), perimeter road for reservoir maintenance, and inlet/outlet channels between the rivers and the reservoir. The excavation of the site for construction of the reservoir would be within the approximately 134 acres, covering approximately 110 acres on the surface and approximately 60 feet deep below the existing ground surface (approximately to bedrock). The Project would not extend past the bedrock and no blasting would be required. The Project would include staff education and monitoring of the site to protect cultural, historical, tribal and paleontological resources. These protection measures will be discussed in detail in the Draft EIR.

Discretionary approvals would be required for the Project; therefore, the Project is subject to CEQA. The excavation of the Project site needed to construct the reservoir would require compliance with the State Mining and Reclamation Act (SMARA) and a Reclamation Plan approved by the County of Tulare. TID is the Project Applicant on behalf of the Owners as well as the CEQA Lead Agency.

The Owners' objectives in proposing the Project include the following:

- Capturing and re-regulating water made available to the Owners during flood releases from Lake Kaweah.
- Capturing and re-regulating water entitlements belonging to the Owners released from Lake Kaweah.
- Capturing and re-regulating any other water sources on the Kaweah River that may be made available to the Owners.
- Allowing other entities with water rights on the Kaweah River to capture and/or re-regulate flows when designated by the Owners.
- Allowing other entities to capture and/or re-regulate flows of the Lower Kaweah River and St. Johns River for purposes of storm water runoff and flood prevention with permission of the Owners and Kaweah/St. Johns water rights interests.
- Constructing the reservoir in such a way that revenue can be obtained to offset a portion of the construction and development costs.
- Locating the reservoir adjacent to the Kaweah River to allow for off-stream access to surface water storage, thus minimizing the need for pipelines.

To accomplish these objectives, the Owners propose to construct and operate the Project to:

- Divert and receive water immediately upstream of the divergence of the Lower Kaweah River and St. Johns River, commonly referred to as McKay Point.
- Provide a water storage capacity of approximately 4,600 acre-feet.
- Deliver water back to either the Lower Kaweah River or the St. Johns River, as needed.
- Provide additional storage capacity for storm water layoff and flood prevention.

- Coordinate all such diversions and deliveries to and from the reservoir with the Kaweah Delta Conservation District and the Kaweah and St. Johns River Association.
- Enter into a lease agreement with WCA to excavate the site for the reservoir and process the excavated material into a marketable product (primarily construction grade aggregate). TID would receive revenue from the sale of the excavated material that could be used to offset a portion of the reservoir construction and development costs.

A detailed Project Description is attached to this letter.

Potential Environmental Effects: An EIR would be prepared to evaluate the proposed Project's environmental impacts and analyze Project alternatives. The topic areas anticipated to be analyzed in detail in the EIR include Air Quality, Greenhouse Gas Emissions, Health Risks, Biological Resources, Cultural Resources, Geology and Soil, Hazards and Hazardous Materials, Hydrology and Water Quality, Land Use and Planning, Noise, Tribal Cultural Resources, and Wildfire.

REQUEST FOR CONSULTATION

Pursuant to the provisions of AB 52, as the lead agency under CEQA, the Tulare Irrigation District hereby extends an invitation to consult on the CEQA review of the McKay Point Reservoir Project in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American cultural places and tribal cultural resources.

If your Tribe desires to consult with the Tulare Irrigation District on the review of this Project, please respond in writing within thirty (30) days of receipt of this notification. Written correspondence can be emailed or mailed to the following addresses (email is preferred):

US Post: Maya Rohr
Project Manager
Sespe Consulting, Inc.

RE: Project Notification and Consultation Request Pursuant to CEQA's Assembly Bill (AB) 52 for the McKay Point Reservoir Project (SCH No. 2014011078)

Dear Kenneth Woodrow,

Pursuant to the provisions of AB 52, as the lead agency under the California Environmental Quality Act (CEQA), the Tulare Irrigation District (TID) hereby extends an invitation to consult on the California Environmental Quality Act (CEQA) review of the McKay Point Reservoir Project (Project) in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American tribal cultural resources and/or tribal cultural places including:

- Native American sanctified cemetery, place of worship, religious or ceremonial site, or sacred shrine; and
- Native American historic, cultural, or sacred site that is listed or may be eligible for listing in the California Register of Historical Resources including historic or prehistoric ruins and any burial ground, archaeological, or historic site.

The proposed Project is located on approximately 500 acres adjacent to the Lower Kaweah River and St. Johns River. In accordance with CEQA (Pub. Resources Code, § 21000 et seq.), the Tulare Irrigation District will be preparing an Environmental Impact Report (EIR) to evaluate the environmental effects associated with the Project. A Notice of Preparation (NOP) under CEQA was published on October 2, 2020 and the distribution included the list of tribes provided by the Native American Heritage Commission (NAHC) at that time. A copy of the current Project Description is included with this notice and request for consultation.

PROJECT INFORMATION/DESCRIPTION

Project Title: McKay Point Reservoir Project

Project Applicant: Project joint owners – Tulare Irrigation District (TID), the Consolidated Peoples Ditch Company (CPDC), and the Visalia and Kaweah Water Company (VKWC).

Assessor's Parcel Number(s): The Project site is comprised of portions of the following Assessor's Parcel Numbers (APN's): 113-070-016-000, 113-080-005-000, 113-080-008-000, 113-090-001-000, 113-100-002-000.

Project Location: Located in Tulare County, California, the Project site lies between and to the south of both Lake Kaweah (2.5 miles northeast of the site) and Bravo Lake (1.5 miles northwest of the site); 1.0 miles northwest of the community of Lemon Cove; and 2.5 miles southeast of the community of Woodlake (Figure 1). The Project site is located approximately 1.0 mile west-southwest of the intersection of State Highways 216 and 198, in Sections 3 and 4, Township 18 South, Range 27 East, Mount Diablo Base and Meridian.

The surrounding land uses in the vicinity of the Project are mining, agricultural, and residential. Mining operations exist to the north, northeast, southwest and west of the Project site, and the areas south and east of the Project site are used for agricultural and, to a limited extent, for rural residential purposes. The Project site has been extensively used and disturbed over the years for cattle grazing.

Project Background: TID is a public agency organized and existing pursuant to Division 11 of the California Water Code. CPDC and VKWC are mutual water companies organized and existing pursuant to Division 3 of the California Corporations Code. The Project Owners are all members of the Kaweah and St. Johns Waters Association (Association), which oversees the surface water rights and diversion operations on the Kaweah River. VKWC is also a mutual water company formed under Section 200 of the California Corporations Code. Together they are the Owners of the Project.

Project Summary: The Owners propose to construct a surface water storage and re-regulation reservoir (the proposed Project) on approximately 200 acres within the 500-acre McKay Point property. The reservoir would be located on the north side of the divergence of the Lower Kaweah River and St. Johns River.

The Project would consist of the following phases: excavation of the site for the reservoir; construction of the reservoir; and operation of the reservoir. The Owners plan to enter into a lease agreement with West Coast Aggregate Supply, Inc. (WCA) to excavate the site to allow for the construction of the reservoir. After the excavation and construction of the reservoir, the McKay Point Reservoir would be used as a surface water storage / re-regulation reservoir. The reservoir would also be used to optimize groundwater recharge within the Owners service areas (Figure 2).

The Project would result in new disturbance to the site. There would be surface disturbance of approximately 134 acres, this includes the proposed perimeter fencing which will be constructed such that it will not disrupt biological resources (i.e., migration routes), perimeter road for reservoir maintenance, and inlet/outlet channels between the rivers and the reservoir. The excavation of the site for construction of the reservoir would be within the approximately 134 acres, covering approximately 110 acres on the surface and approximately 60 feet deep below the existing ground surface (approximately to bedrock). The Project would not extend past the bedrock and no blasting would be required. The Project would include staff education and monitoring of the site to protect cultural, historical, tribal and paleontological resources. These protection measures will be discussed in detail in the Draft EIR.

Discretionary approvals would be required for the Project; therefore, the Project is subject to CEQA. The excavation of the Project site needed to construct the reservoir would require compliance with the State Mining and Reclamation Act (SMARA) and a Reclamation Plan approved by the County of Tulare. TID is the Project Applicant on behalf of the Owners as well as the CEQA Lead Agency.

The Owners' objectives in proposing the Project include the following:

- Capturing and re-regulating water made available to the Owners during flood releases from Lake Kaweah.
- Capturing and re-regulating water entitlements belonging to the Owners released from Lake Kaweah.
- Capturing and re-regulating any other water sources on the Kaweah River that may be made available to the Owners.
- Allowing other entities with water rights on the Kaweah River to capture and/or re-regulate flows when designated by the Owners.
- Allowing other entities to capture and/or re-regulate flows of the Lower Kaweah River and St. Johns River for purposes of storm water runoff and flood prevention with permission of the Owners and Kaweah/St. Johns water rights interests.
- Constructing the reservoir in such a way that revenue can be obtained to offset a portion of the construction and development costs.
- Locating the reservoir adjacent to the Kaweah River to allow for off-stream access to surface water storage, thus minimizing the need for pipelines.

To accomplish these objectives, the Owners propose to construct and operate the Project to:

- Divert and receive water immediately upstream of the divergence of the Lower Kaweah River and St. Johns River, commonly referred to as McKay Point.
- Provide a water storage capacity of approximately 4,600 acre-feet.
- Deliver water back to either the Lower Kaweah River or the St. Johns River, as needed.
- Provide additional storage capacity for storm water layoff and flood prevention.

- Coordinate all such diversions and deliveries to and from the reservoir with the Kaweah Delta Conservation District and the Kaweah and St. Johns River Association.
- Enter into a lease agreement with WCA to excavate the site for the reservoir and process the excavated material into a marketable product (primarily construction grade aggregate). TID would receive revenue from the sale of the excavated material that could be used to offset a portion of the reservoir construction and development costs.

A detailed Project Description is attached to this letter.

Potential Environmental Effects: An EIR would be prepared to evaluate the proposed Project's environmental impacts and analyze Project alternatives. The topic areas anticipated to be analyzed in detail in the EIR include Air Quality, Greenhouse Gas Emissions, Health Risks, Biological Resources, Cultural Resources, Geology and Soil, Hazards and Hazardous Materials, Hydrology and Water Quality, Land Use and Planning, Noise, Tribal Cultural Resources, and Wildfire.

REQUEST FOR CONSULTATION

Pursuant to the provisions of AB 52, as the lead agency under CEQA, the Tulare Irrigation District hereby extends an invitation to consult on the CEQA review of the McKay Point Reservoir Project in order to assist with identifying and/or preserving and/or mitigating project impacts to Native American cultural places and tribal cultural resources.

If your Tribe desires to consult with the Tulare Irrigation District on the review of this Project, please respond in writing within thirty (30) days of receipt of this notification. Written correspondence can be emailed or mailed to the following addresses (email is preferred):

MANAGEMENT SUMMARY

At the request of Sespe Consulting, Inc., Applied EarthWorks, Inc. (Æ) completed an updated paleontological resource assessment (PRA) for the Tulare Irrigation District's McKay Point Reservoir Project in Tulare County, California (Project). The Project proposes to construct a water storage/reregulation facility on 194 acres in Tulare County along the Kaweah River, approximately 3 miles downstream from the Terminus Dam and Lake Kaweah. This PRA is written in partial satisfaction of requirements of the California Environmental Quality Act (CEQA), and Tulare Irrigation District is the Lead Agency for CEQA compliance.

Æ completed the original PRA for the Project in 2014. Meanwhile, some of the Project plans have been revised. Therefore, the present study addresses the updated Project plans through a new museum records search, comprehensive literature and geologic map reviews, and pedestrian survey. Using the results of museum records search and literature review, Æ determined the paleontological resource potential of the Project in accordance with Society of Vertebrate Paleontology guidelines. This report summarizes the methods and results of the PRA and provides Project-specific management recommendations.

Published geologic maps indicate the late Pleistocene Modesto Formation and underlying middle Pleistocene Riverbank Formation occur within the Project area. Online museum and database records indicate numerous fossil specimens representing plants, mammals, reptiles, and birds from within the Modesto and Riverbank Formations throughout the San Joaquin Valley. These include at least 14 vertebrate fossil specimens from 12 localities within unnamed Pleistocene deposits in Tulare County. Records search results indicate three vertebrate fossil localities yielding *Mammuthus* (mammoth) and *Equus* (horse) within sediments consistent with the Modesto and Riverbank Formations. However, no previously recorded paleontological localities are directly within Project boundaries.

Æ Paleontology Field Monitor Michael George completed a pedestrian field survey of the Project area on January 12, 2021, to confirm the presence/absence of exposed fossils on the ground surface and to evaluate geologic exposures for their potential to yield subsurface fossil material. He did not record any new fossil localities during the survey.

As a result of this study, Æ assigned high paleontological resource potential (i.e., sensitivity) to the Project area because the fossiliferous Modesto and Riverbank Formations mapped near the Project area likely also occur within the Project area at depths as shallow as 7 feet below ground surface (bgs). Significant and intact fossils have been recorded in these geologic units in the vicinity of the Project area and elsewhere in the San Joaquin Valley. Recent fluvial sediments overlying these geologic formations and visible at the present ground surface have low paleontological sensitivity. Therefore, Æ suggests paleontological sensitivity increases with depth within the Project area.

Undisturbed geologic units with a proven potential to yield significant paleontological resources occur at 7 feet bgs in the Project area. Therefore, the potential for impacting significant fossils during ground-disturbing construction activities is high and Æ recommends paleontological

resource mitigation monitoring during Project construction. Æ additionally suggests a Paleontological Resource Mitigation and Monitoring Program for the Project, including, but not limited to, a preconstruction Worker's Environmental Awareness Training module. By implementing these mitigation measures during Project development, adverse impacts to paleontological resources can be reduced to a less than significant level pursuant to the requirements of the CEQA.

1
INTRODUCTION

At the request of Sespe Consulting, Inc., Applied EarthWorks, Inc. (Æ) completed an updated paleontological resource assessment (PRA) for the Tulare Irrigation District's McKay Point Reservoir Project (Project) located approximately 20 miles northeast of the city of Visalia in Tulare County, California (Figure 1-1). This PRA is written in partial satisfaction of requirements of the California Environmental Quality Act (CEQA), and Tulare Irrigation District (TID) is the Lead Agency for CEQA compliance. This report serves as an addendum to the previous PRA for the Project, written by Æ staff in 2014 (Clifford and DeBusk, 2014).

1.1 PROJECT DESCRIPTION

The Project area is in the San Joaquin Valley, on the north side of the divergence of the Kaweah and St. Johns Rivers at McKay Point in Tulare County. The Project area is mapped in Sections 3 and 4 of Township 18 South, Range 27 East, as shown on the Woodlake, California, 7.5-minute U.S. Geological Survey (USGS) topographic quadrangle map (Figure 1-2).

The Project would require discretionary approvals and is therefore subject to the CEQA. The TID is the Project applicant and the CEQA Lead Agency. The TID proposes the excavation, construction, and maintenance and operation of the McKay Point Reservoir (Project) on behalf of the Visalia and Kaweah Water Company and the Consolidated Peoples Ditch Company (Owners). The reservoir would provide surface water storage and reregulation to optimize groundwater recharge within the Owners' service areas.

The Project area consists of 194 acres within the McKay Point property, including excavation of a 110-acre pit extending 60 feet below the ground surface. West Coast Sand and Gravel would be contracted to complete excavation of overburden and transform the aggregate into saleable material offsite. Other construction elements include inflow and outflow channels with reinforced concrete base and riprap, a flow/level control gate, an infiltration gallery made up of on-site ditches, a peripheral fence with access road, an entrance gate, and a generator building. The Project also includes a habitat area adjacent to the reservoir. This area will be preserved and not subjected to any ground-disturbing activity.

1.2 PURPOSE OF INVESTIGATION

This PRA is designed to accomplish several goals: (1) identify the geologic units within the Project area and assess their paleontological resource potential; (2) determine whether the Project has the potential to adversely impact scientifically significant paleontological resources; (3) provide Project-specific management recommendations for paleontological resources, as necessary; and (4) demonstrate compliance with state laws and regulations. The following section describes the ways in which this PRA meets the stated goals.

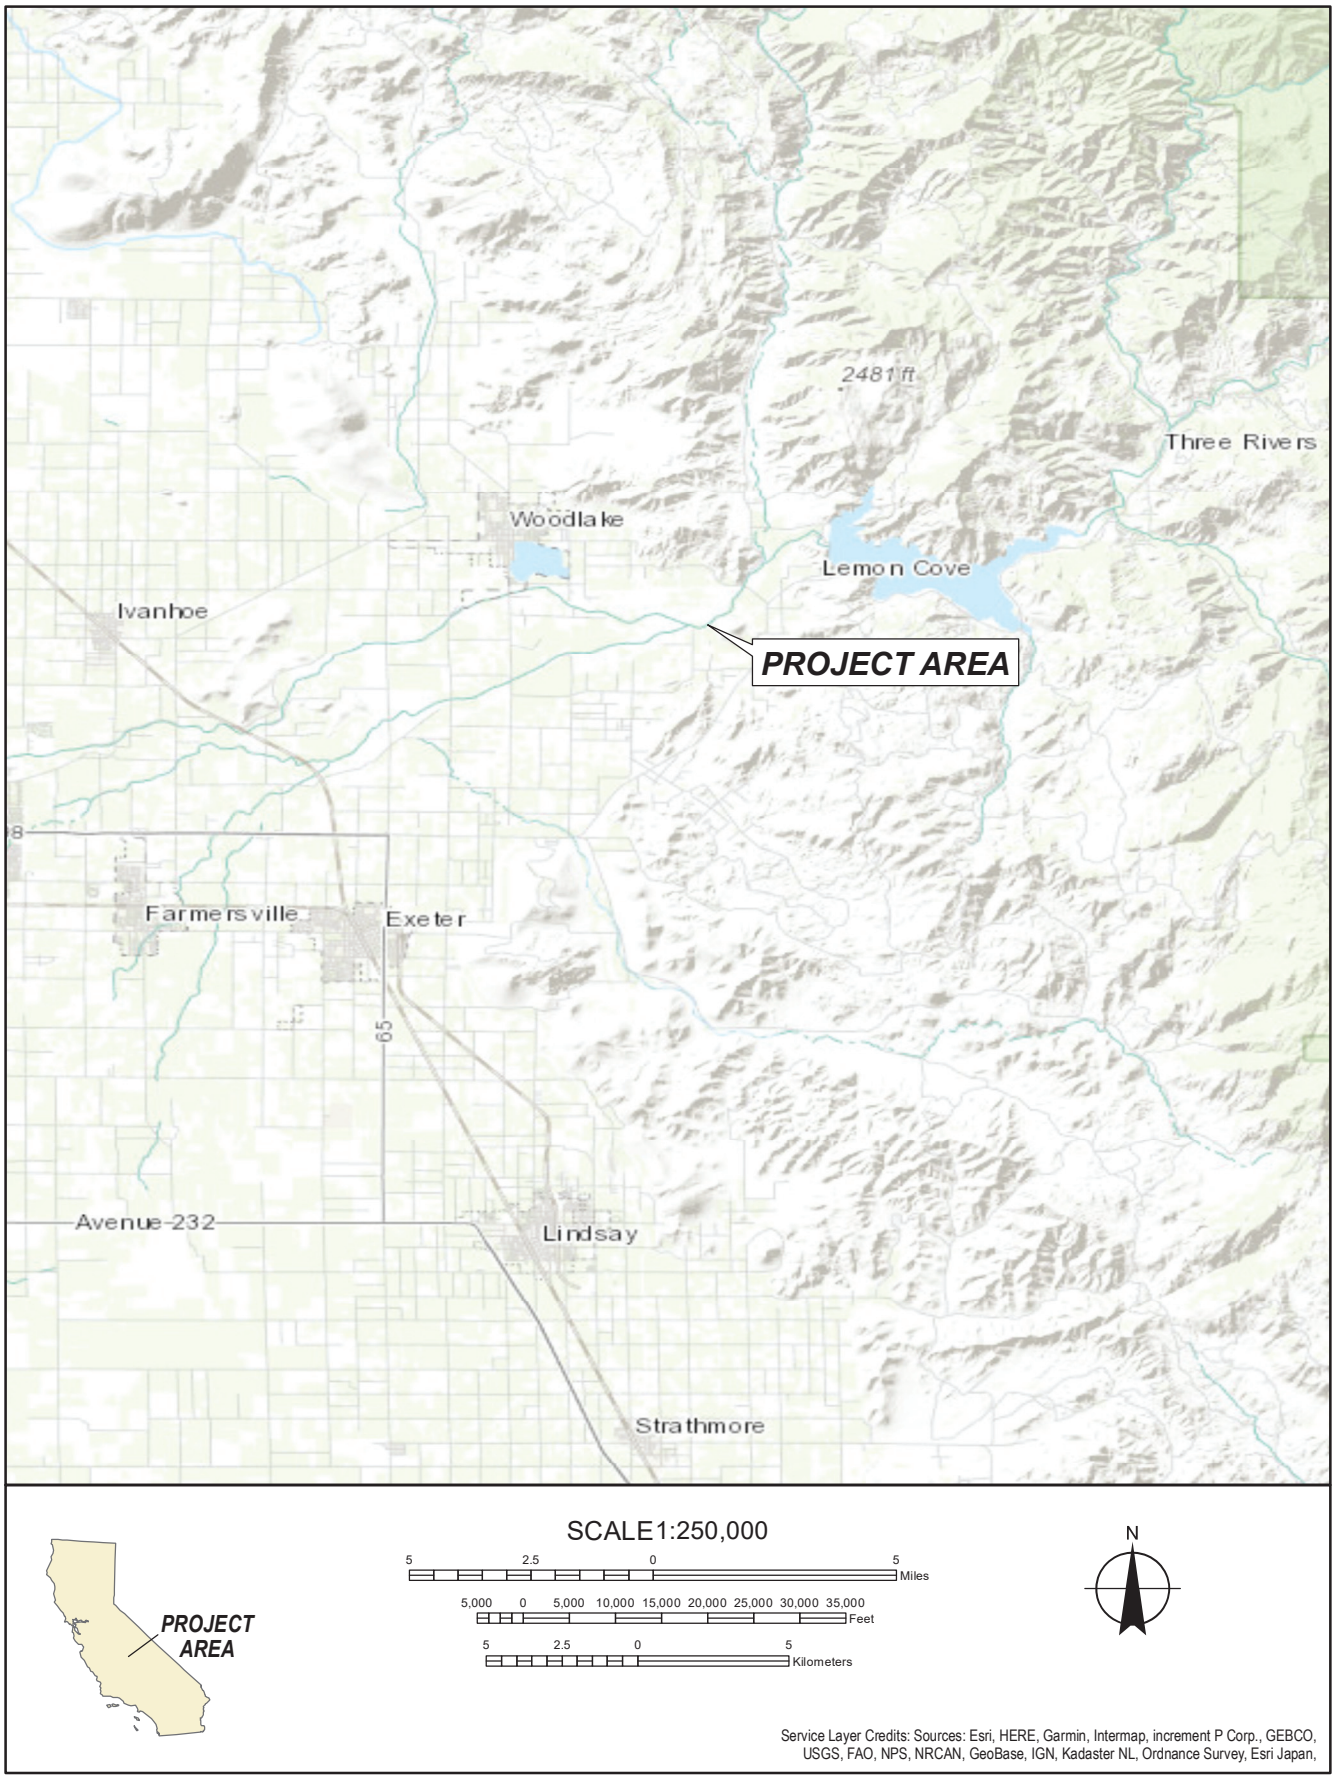

Figure 1-1 Project vicinity in Tulare County, California.

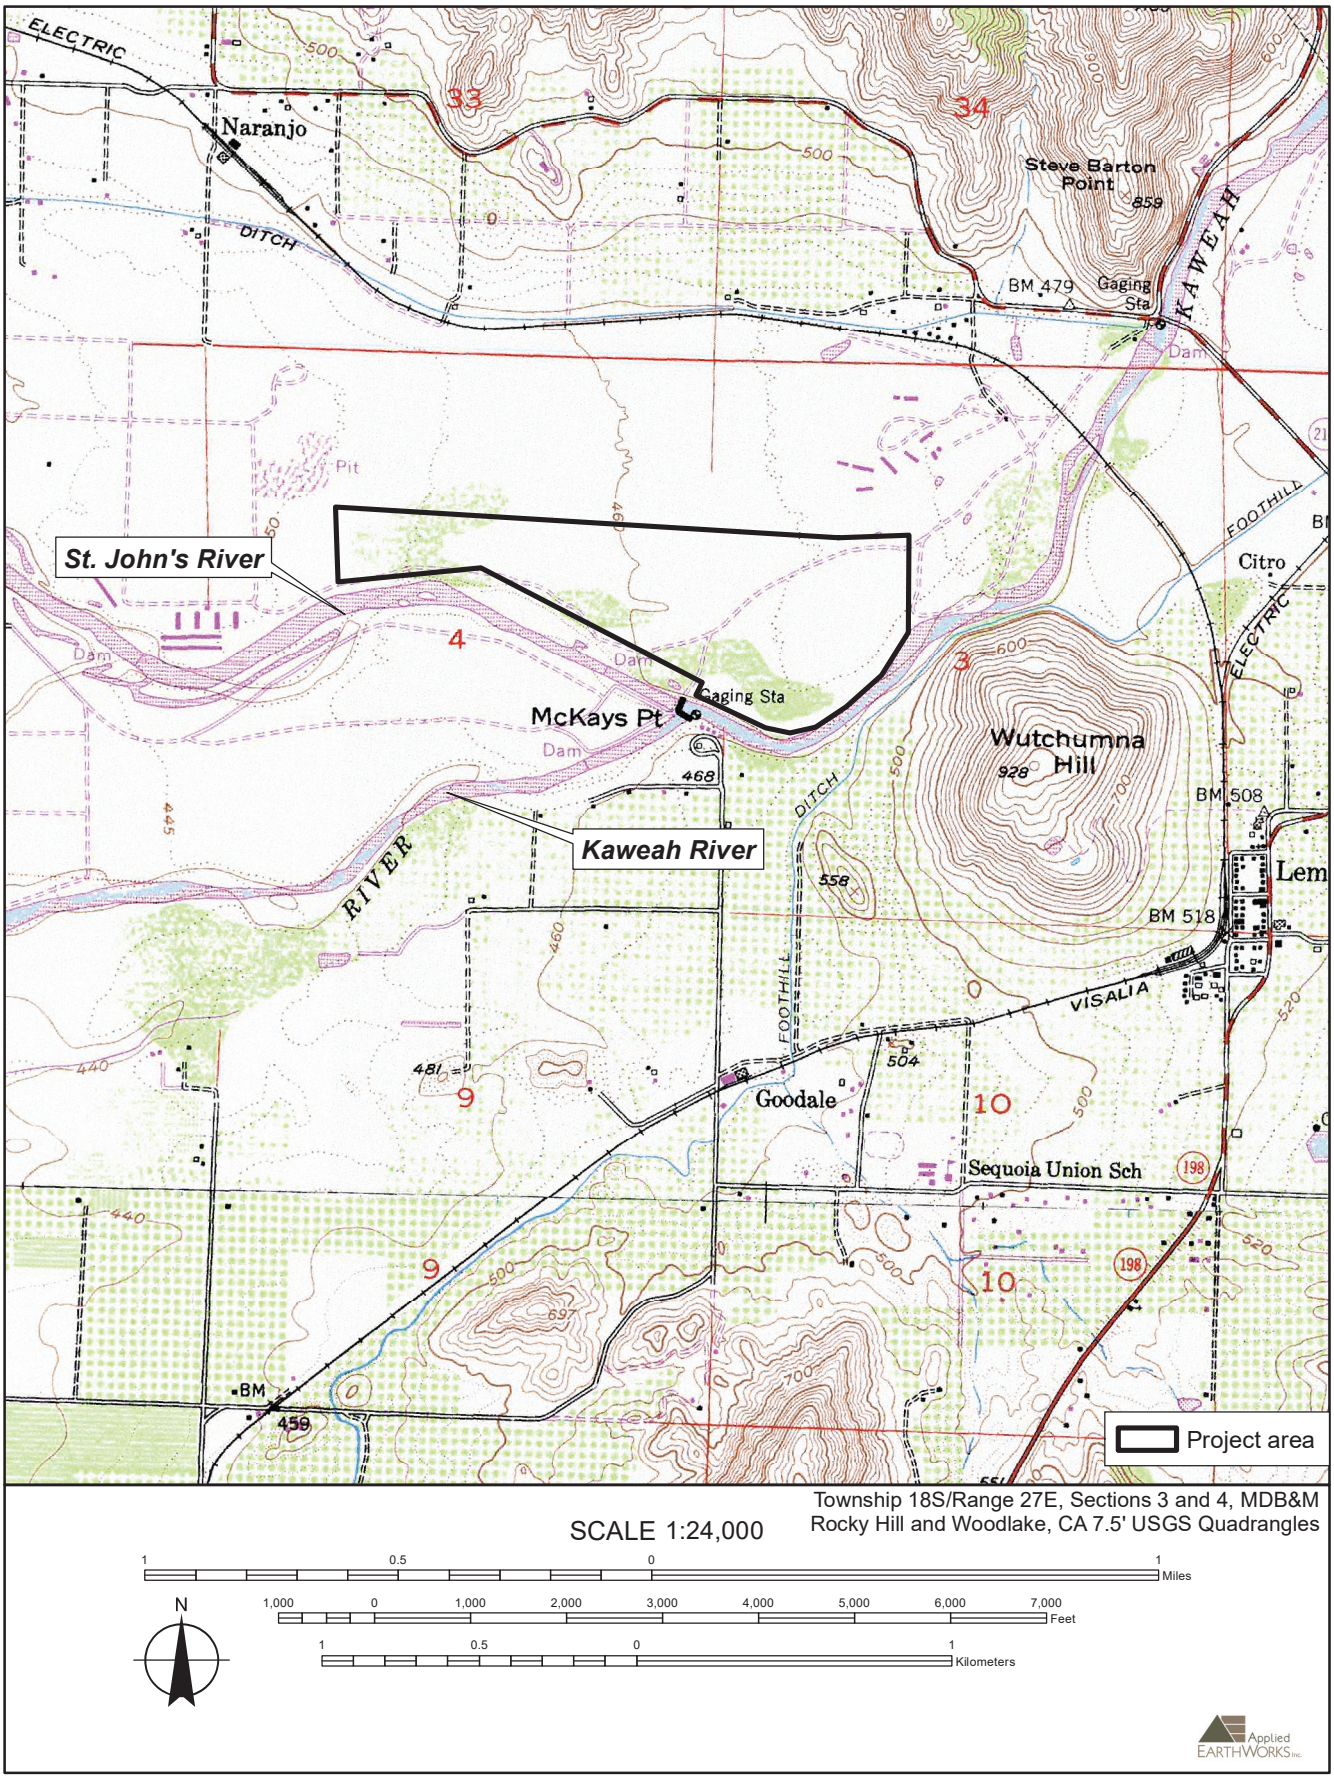

Figure 1-2 Project location map.

1.3 KEY PERSONNEL

The original 2014 study was prepared by Æ's former Paleontology Program Manager Jessica DeBusk and former Staff Paleontologist Heather Clifford. Their credentials were provided in that report and are not repeated herein. For the present study, Æ Paleontology Program Manager Dr. Amy Ollendorf served as the principal investigator for the Project. She oversaw each task required for this PRA, including quality control. Ollendorf qualifies as a principal investigator for paleontology per industry standards (Murphey et al., 2019), although she does not meet Society of Vertebrate Paleontology (SVP) standards. Æ Senior Paleontologist Melissa Macias completed the desktop research, wrote the updated PRA, and created the figures. Paleontological Field Monitor Michael George completed the field survey, with assistance from Macias. Macias meets SVP (2010) and industry standards for qualified professional paleontologist (principal investigator, project paleontologist), and George is a qualified paleontological monitor.

Macias has master's and undergraduate degrees in geology; her master's degree research focused on mammalian paleontology and biogeography. She has over 10 years of experience in geology and paleontology, including the past 5 years in paleontological monitoring, recovery and preparation of fossil remains, laboratory analysis, and report preparation. George has a bachelor's degree in geology and field experience in the San Joaquin Valley. His 6 years of experience in geology and paleontology includes paleontological monitoring and recovery, preparation, and laboratory analysis of fossil remains. Ollendorf has interdisciplinary doctoral and master's degrees involving geology and micropaleontology and an undergraduate degree in geology and anthropology (double major), both of which also focused on paleontological subject matter. Ollendorf has extensive field and laboratory experience in invertebrate and botanical paleontology. Ollendorf also is the principal investigator for paleontology on Æ's 2018–2021 California Statewide Paleontological Resource Use Permit (CA-18-05P). She also is a Registered Professional Archaeologist (RPA 12588) with over 37 years of experience. Qualifications for Æ's key paleontology personnel can be found in Appendix A.

1.4 REPORT ORGANIZATION

Chapter 1 has described the Project, defined the purpose of the investigation, and provided a description of Æ's key personnel for this PRA. Chapter 2 discusses the regulatory framework governing the Project. Chapter 3 presents the paleontological sensitivity criteria and resource guidelines used for this assessment. Chapter 4 provides the methods employed, and Chapter 5 describes the geology and paleontology of the Project area. The results of the desktop studies, field survey, and paleontological sensitivity assessment are presented in Chapter 6. Management recommendations can be found in Chapter 7, and references cited are listed in Chapter 8. Appendix A includes qualifications of key personnel.

2
REGULATORY ENVIRONMENT

Paleontological resources (i.e., fossils) are considered nonrenewable because when they are destroyed, they cannot be replaced. As such, paleontological resources are afforded protection under various federal, state, and local laws. This Project is not subject to federal laws. Consequently, all resources are protected under only state and local laws.

2.1 STATE

California is among the states that protect paleontological resources. CEQA is the legal framework through which this protection is accomplished. Enacted in 1970, CEQA does not directly regulate land uses but instead requires state and local agencies within California to follow a protocol of analysis and public disclosure of environmental impacts of proposed projects and adopt all feasible measures to mitigate those impacts.

2.1.1 California Environmental Quality Act

This Project is subject to Section 15002(a)(3) of the Guidelines for Implementation of CEQA (California Code of Regulations [CCR], Title 14, Chapter 3), which states one of the basic purposes of CEQA is the intention to "prevent significant, avoidable damage to the environment by requiring changes in projects through the use of alternatives or mitigation measures when the governmental agency finds the changes to be feasible." Therefore, CEQA requires detailed studies that analyze the environmental effects of a proposed project.

If a project is determined to have a potential significant environmental effect, the act requires that alternative plans and mitigation measures be considered. Specifically, in Section VII(f) of Appendix G of the CEQA Guidelines, the Environmental Checklist Form poses the question: "Will the project directly or indirectly destroy a unique paleontological resource or site or unique geologic feature?" If paleontological resources are identified as being within the proposed project area, the sponsoring agency must take those resources into consideration when evaluating project effects. The level of consideration may vary with the importance of the resource.

Guidelines for implementation of CEQA are codified in 14 CCR 15000 et seq., which requires state and local public agencies to identify the environmental impacts of proposed discretionary activities or projects, determine if the impacts will be significant, and identify alternatives and mitigation measures that will substantially reduce or eliminate significant impacts to the environment. The various agencies within state government all have their own guidance documents to assist with CEQA compliance. The TID is the government agency responsible for compliance with the CEQA for the Project. The TID relies on Tulare County (County) guidance for the treatment of paleontological resources under the CEQA.

2.2 LOCAL

The County provides guidance for the identification, protection, and preservation of significant paleontological resources. The following section describes all relevant policies, goals, and objectives.

2.2.1 Tulare County

The County specifically addresses paleontological resources under the following policies in Chapter 3: Environmental Analysis of the *Tulare County General Plan* (Tulare County, 2012).

> **ERM Implementation Measure 55B:** In the event that archaeological or paleontological resources are discovered during site excavation, the County shall require that grading and construction work on the project site be suspended until the significance of the features can be determined by a qualified archaeologist or paleontologist. The County will require that a qualified archaeologist/paleontologist make recommendations for measures necessary to protect any site determined to contain or constitute an historical resource, a unique archaeological resource, or a unique paleontological resource or to undertake data recovery, excavation, analysis, and curation of archaeological or paleontological materials. County staff shall consider such recommendations and implement them where they are feasible in light of project design as previously approved by the County.

Although not required prior to construction, the TID opted to proactively contract for the preconstruction PRA in an effort to prepare for the Project's ground-disturbing activities.

3
PALEONTOLOGICAL RESOURCE ASSESSMENT GUIDELINES

Protection of paleontological resources requires assessment of the potential for geologic units to yield significant paleontological resources that could be directly or indirectly impacted or destroyed during Project development. Successful protection also involves the formulation and implementation of appropriate management measures to mitigate impacts.

3.1 DEFINITION OF PALEONTOLOGICAL RESOURCES AND SIGNIFICANCE CRITERIA

Paleontological resources are defined by the Society of Vertebrate Paleontology (SVP, 2010) as fossils and fossiliferous deposits. Fossils are the evidence of once-living organisms as preserved in the rock record. They include both the lithified remains of ancient plants and animals and the traces thereof (trackways, imprints, burrows, etc.). In general, the SVP (2010) considers fossils to be greater than 5,000 years old (older than middle Holocene[1]) and to typically be preserved in sedimentary rocks, although certain volcanic rocks and low-grade metamorphic rocks may be fossiliferous if formed under certain conditions.

Well-preserved and identifiable individual fossils are considered significant paleontological resources if they are a type specimen, rare, a complete specimen, or part of an important diverse fossil assemblage. Of particular importance are fossils found in situ, or undisturbed from their primary geologic context. These fossils are important because they are used to examine evolutionary relationships, provide insight on the development of and interaction between biological communities, establish time scales for geologic studies, and for many other scientific purposes, including investigation into paleoenvironments and paleoclimates (Scott and Springer, 2003; SVP, 2010). Intact and in situ vertebrate fossils are usually assigned a greater significance than other types of fossils as they are comparatively rare. Consequently, more attention tends to be placed on the recovery of vertebrate fossils than other types.

3.2 PROFESSIONAL STANDARDS AND CLASSIFICATION OF PALEONTOLOGICAL RESOURCE SENSITIVITY

Most professional paleontologists in California adhere to the SVP (2010) guidelines, unless others are available. The SVP's guidelines establish detailed protocols for the assessment of the paleontological sensitivity of a project area and outline measures to follow in order to mitigate adverse impacts to known or unknown fossil resources during project development (SVP, 2010).

[1] middle Holocene: extends from 8,200 to 4,200 years ago in the Holocene Epoch of the Quaternary Period, covering approximately the past 11,700 years (Cohen et al., 2021); the Quaternary Period also includes the older Pleistocene Epoch, which lasted from approximately 2.6 million years ago to approximately 11,700 years ago (Cohen et al., 2021).

Baseline information gathered during a paleontological resource assessment is used to assign the paleontological sensitivity of the geologic unit(s) (or members thereof) exposed at or distributed across the ground surface of a project area, in addition to those thought to be beneath a project area at depth. It should be noted that surface geology is not always indicative of subsurface geology or the potential for paleontological resources. For instance, an area whose surface geology is mapped as non-fossiliferous sediments may cover fossil-rich Pleistocene sediments at depth. Also, an area mapped as granite, devoid of fossils, may be covered by fossil-rich Pleistocene sediments. Thus, actual paleontological sensitivity across a project area ultimately can be determined only through a combination of desktop and field efforts.

The SVP provides a classification system to rank a geologic unit's sensitivity or potential for significant paleontological resources. The SVP scale includes High, Undetermined, Low, and No Potential. Geologic units are considered to have a high potential if vertebrates or significant specimens of other fossil types have been recovered anywhere in their extent; or if the units are sedimentary rocks that are temporally or lithologically suitable for the preservation of significant fossils. The criteria for the categories are shown in Table 3-1.

Table 3-1
Paleontological Sensitivity Classifications

SVP Sensitivity/ Potential	Criteria[1]	Mitigation Recommendations[2]
High	Rock units from which vertebrate or significant specimens of other fossil types have been recovered are considered to have a high potential. Rock units with high potential also may include rock units that are temporally or lithologically suitable for the preservation of fossils (e.g., middle Holocene and older, argillaceous and carbonate-rich paleosols, fine-grained marine sandstones, etc.).	Typically, a field survey, mitigation program, and on-site construction monitoring will be required. Any significant specimens discovered during monitoring will need to be prepared, identified, and curated into a museum. A final report documenting the significance of the finds will also be required.
Undetermined	In some cases, available literature on a particular rock unit will be scarce and a determination of whether or not it is fossiliferous or potentially fossiliferous will be difficult to make. Under these circumstances, further study is needed to determine the unit's paleontological resource potential.	A field survey is required to further assess the unit's paleontological potential. The survey may provide data for development of a Paleontological Resource Impact Mitigation Program (PRIMP) prior to construction.
Low	Rocks units from which few fossils have been recovered or are generally unsuitable for preservation of fossils are considered to have a low potential. These units typically yield fossils only on rare occasions and under unusual circumstances (e.g., basalt flows, recent colluvium, etc.).	Mitigation is not typically required; however, if an unanticipated paleontological resource is encountered, a qualified professional paleontologist (Principal Investigator, Project Paleontologist) may need to evaluate the resource to consider mitigation.
No Potential	Rock units that have no potential for paleontological resources are those that are formed under or exposed to immense heat and pressure, such as high-grade metamorphic rocks and plutonic igneous rocks.	No mitigation required.

4
METHODS

This PRA was completed through desktop studies and a field survey. The twofold purpose of the off- and on-site research was: (1) to identify the geologic units in the Project area and immediate vicinity to determine whether previously recorded paleontological localities occur either within the Project area or within the same geologic units elsewhere nearby and (2) to determine the sensitivity of the geologic units in the Project area for their potential to yield paleontological resources.

4.1 LITERATURE REVIEW AND MUSEUM RECORDS SEARCHES

In many areas, the near-surface layers of sediments and sedimentary rocks are broken down and converted to soil (pedogenesis) through chemical and physical weathering processes (Boggs, 2012). During pedogenesis, any fossils preserved within the near-surface layers often are destroyed or rendered unrecognizable. Therefore, intact and identifiable fossils are unlikely to be found in soil. Reviews of relevant geologic maps, regional geological publications, and unpublished reports are necessary to ascertain the geology and stratigraphy of a project area to determine the potential for significant subsurface paleontological resources. The geotechnical report for the Project provided additional information on subsurface geology and sediment types (Lau and Schwartz, 2011).

To supplement the map and literature reviews, Æ requested a search of museum collection records maintained by the Natural History Museum of Los Angeles County (NHMLAC). Æ also completed online searches of two databases readily available to the public—the Paleobiology Database (PBDB) and the database maintained by the University of California Museum of Paleontology (UCMP). In addition, Æ utilized information presented in the previous PRA for the Project (Clifford and DeBusk, 2014).

4.2 FIELD SURVEY

Prior to the field survey, Æ also examined recent aerial photographs of the entire Project area in Google Earth to determine likely locations of geologic outcrops and potential survey routes. Michael George, Æ's paleontological field technician, conducted the field reconnaissance survey for the Project on January 12, 2021. The purpose of the survey was to confirm the presence/absence of exposed fossils on the ground surface and to evaluate geologic exposures for their potential to yield subsurface fossil material. The survey consisted of a combination of close visual inspection and spot-checking to inspect the ground surface for evidence of paleontological resources while using the Arrow 100 Global Positioning System (GPS) antenna and the ArcGIS Collector application to navigate throughout the Project area and collect field data, if needed.

George conducted close visual inspection in portions of the Project area where the ground surface was visible and unobscured by vegetation, excluding the dense trees and bushes in the southeast. He conducted spot-checking for the remainder of the Project area where the ground surface was obscured by vegetation. George kept notes on the geology and sedimentology

encountered and took photographs to document the survey. If he observed any fossils, he field-documented but did not collect them.

5
GEOLOGY AND PALEONTOLOGY

The following sections provide the geological context of the Project area as well as descriptions of the geologic units mapped as surface exposures within the boundaries of the Project area in addition to units exposed nearby and thought to be present in the subsurface. The section also includes any paleontological information reported from the units.

5.1 REGIONAL GEOLOGY

The Project area is on the eastern margin of the San Joaquin Valley within the Great Valley geomorphic province of California. A geomorphic province is a region of unique topography and geology that is readily distinguished from other regions based on its landforms and diastrophic history (Norris and Webb, 1976). The Great Valley is a north-northwest–trending asymmetric structural trough bisected by the Stockton Arch, a structural feature that subdivides the region into the Sacramento Valley in the north and the San Joaquin Valley to the south. The Great Valley is roughly 400 miles long and 50 miles wide and water from the Pacific Ocean covered the trough as far back as the Jurassic (201–145 million years ago [Ma]) and into the Paleogene (66–23 Ma).

Deposition into the Great Valley began during the Late Jurassic (164 Ma) as the paleo-Sierra Nevada began to rise and deliver eroded sediments to the lowlands. Forearc (i.e., the deep marine region between a volcanic arc and the associated subduction zone) marine and nonmarine shale, sandstone, and conglomerate of the Cretaceous Great Valley Sequence were deposited during this time unconformably on top of the Franciscan Complex of the Coast Range and the Sierran Batholith (Bartow and Nilsen, 1990). During the late Mesozoic and much of the Cenozoic (66 Ma to the present), the actively subsiding region persisted as a submerged lowland basin, known as the Great Valley Sea (Bartow, 1991).

By the Pliocene (5.3–2.6 Ma), most of the marine waters in the Great Valley retreated and brackish and freshwater lakes remained (Weissmann et al., 2005). The present surface of the valley floor is composed of mostly unconsolidated Pleistocene age (2.6 Ma to 11,700 years before present [B.P.]), alluvial sediments associated with the drainage of the glaciated Sierra Nevada, alluvial deposits originating from the Coast Ranges, and recent sediments largely representing the alluvial, flood, and delta plains of the Sacramento and San Joaquin Rivers (Matthews and Burnett, 1965; Norris and Webb, 1976; Bartow, 1991; Weissmann et al., 2005). The east side of the valley in the vicinity of the Project is characterized by a broad plain of low relief consisting of large coalescing alluvial fans (e.g., the Kaweah River Fan) derived from streams flowing from the Sierra Nevada (Weissmann et al., 2005).

5.2 GEOLOGY AND PALEONTOLOGY OF THE PROJECT AREA

The Project area has been mapped at various scales:

- **1:500,000:** Generalized Geologic Map and Cross Sections of the San Joaquin Valley, California (Bartow, 1991; and references therein)

- **1:250,000:** Geologic Map of the Hanford-Visalia Area, San Joaquin Valley, California (Croft and Gordon, 1968; and references therein); Geologic Map of California—Fresno Sheet (Matthews and Burnett, 1965; and references therein)

Matthews and Burnett (1965) is part of the *Geologic Atlas of California* series published between 1958 and 1969, which provides the first complete, consistent view of the geology of the state (California Department of Conservation, 2019). These compilations adopt a single set of map symbols to correlate potentially equivalent geologic units by defining the units only by geologic time, rather than by both time and lithology. Consequently, this PRA is based largely on the interpretations of Matthews and Burnett (1965) as the most recent published and most comprehensive map.

Published geologic mapping of the region indicates that the ground surface of the Project area consists of Holocene nonmarine (fluvial) terrace deposits and the Modesto Formation (Qf) of late Pleistocene age (Matthews and Burnett, 1965) (Figure 5-1). The Riverbank Formation (Qc) is exposed directly across the Kaweah River from the Project area and likely underlies the Modesto Formation within the Project area (Matthews and Burnett, 1965).. Due to its low-lying position on the floodplains of the Kaweah and St. John's Rivers, the Project area includes recent channel and overbank fluvial deposits, which conformably overlie the Modesto Formation. The thickness of the recent fluvial deposits is estimated to be 2–5 feet due to the degradational nature of the stream and sediment trapping in the upstream Terminus Reservoir Dam (Berryman and Elasser, 1966).

In the vicinity of the Project area, the gently sloping San Joaquin Valley floor rises toward the northeast, reaching an elevation of 600–800 feet above mean sea level (amsl). Wutchumna Hill peaks at over 900 feet amsl southeast of the Project area on the opposite bank of the Kaweah River. In general, the local geomorphology of the San Joaquin Valley is relatively flat with minor topographic relief derived from flooding and fluvial processes, including terraces and sloughs. In general, the soils are sandy, permeable, and fertile but may consist of hardpan in some areas (Croft and Gordon, 1968).

5.2.1 Modesto Formation (Qf)

The Modesto Formation is late Pleistocene in age and consists of poorly indurated fluvial and alluvial deposits and well-developed soils (Davis and Hall, 1959; Marchand and Allwardt, 1981). The sediments consist of andesitic to arkosic granitic sand, silt, and gravel, which drained from the Sierra Nevada during the late Pleistocene Wisconsin glaciations (Weissmann et al., 2002). The Modesto Formation extends from the Sacramento River in the north to the Tule River in the south (Matthews and Burnett, 1965).

Local deposits of Holocene alluvial sediments cover the Modesto Formation. An unconformable contact marks the boundary between the Modesto Formation and the underlying middle Pleistocene Riverbank Formation. The Modesto Formation was first described by Davis and Hall (1959) and later redescribed by Marchand (1977) at its type section located at a road cut near the Mitchell Road Bridge above the Tuolumne River in the town of Ceres, California.

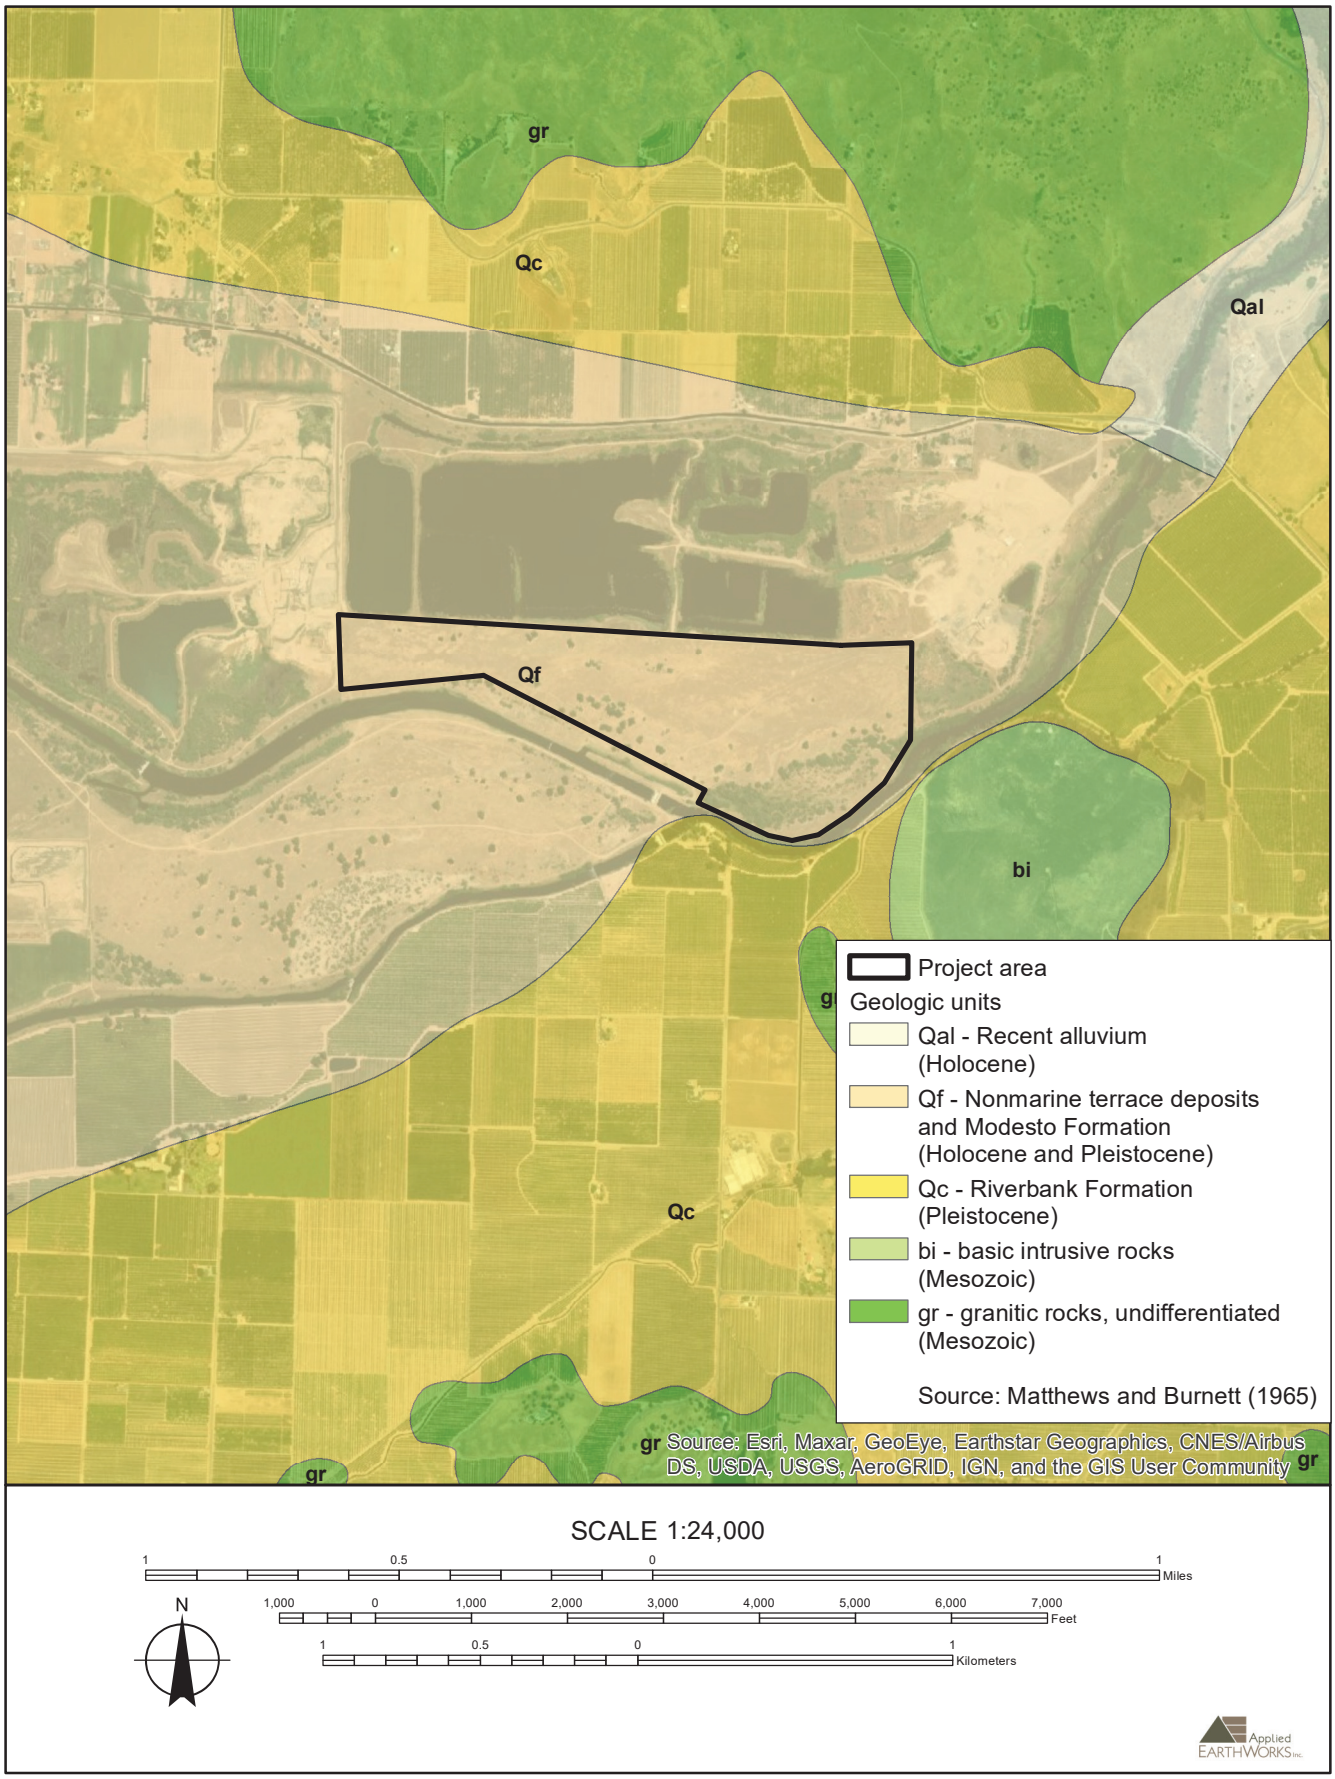

Figure 5-1 Geologic units in the Project area and vicinity.

Marchand (1977) informally divides the Modesto Formation into a lower and upper member based on topographic expression and the presence of paleosols (i.e., buried soil horizons). The upper member has a maximum thickness of 30 feet and the lower member is up to 70 feet thick (Marchand and Allwardt, 1981). The upper member is composed of massive to well-bedded sand, silt, and clay, with subordinate gravel deposits. Where stratification is absent, the sedimentary structures were most likely destroyed by soil development. The lower member is predominately composed of moderately stratified sand and silt deposits, with localized lenticular cross-lamination. Marchand (1977) lists channel deposits, interdistributary and floodplain deposits, colluvium, and eolian sand as facies recognizable within the Modesto Formation. Where exposed, the base of lower member of the Modesto Formation is marked by a distinct layer of red clay (Hudson, 1960).

The total thickness of the Modesto Formation ranges from 50 to 100 feet and its age is estimated to range from 9,000 to 42,000 B.P. (Marchand, 1977). These depths are characteristic of the Modesto Formation near its type section in center of the San Joaquin Valley where sediment accumulation has been significant. Adjacent to the Sierran foothills in the vicinity of the Project area, basement rock is closer to the ground surface and sediment accumulation is thinner than in the center of the valley. Therefore, the underlying fossiliferous Riverbank Formation may be closer to the ground surface (see below).

The Modesto Formation is generally categorized as having high paleontological sensitivity Paleontological details supporting this ranking are provided in the next chapter.

5.2.2 Riverbank Formation (Qc)

The middle Pleistocene Riverbank Formation consists of granitic sand, silt, and clay primarily derived from the Sierra Nevada (Davis and Hall, 1959). In the vicinity of the Project area elsewhere in Tulare County, the Riverbank Formation is unconformably underlain by Mesozoic granitic rocks (mapped as gr by Matthews and Burnett [1965]). Davis and Hall (1959) first described the Riverbank Formation, which was later redescribed by Marchand and Allwardt (1981) at its type section located on the banks of the Stanislaus River in the town of Riverbank.

The Riverbank Formation consists of moderately consolidated deposits of massive to well-bedded silty sand, arkosic sand, pebbly sand, and gravel lenses. Locally, fine sand may exhibit eolian sorting and coarse sand and gravel may be interbedded with silt and clay deposits (Marchand, 1977). These sediments comprise older alluvium, dissected fan, and nonmarine sedimentary deposits in the San Joaquin Valley (Smith, 1964; Matthews and Burnett, 1965). The thickness of the Riverbank Formation ranges from approximately 50 to 250 feet in the San Joaquin Valley and it is estimated to range in age from 130,000–450,000 thousand years (Marchand and Allwardt, 1981).

The Riverbank Formation is generally categorized as having high paleontological sensitivity. The next chapter provides paleontological details supporting this ranking.

5.2.3 Mesozoic Granitic and Basic Intrusive Rocks (gr, bi)

Outcrops of undifferentiated Mesozoic granitic rocks (gr) are present at the surface to the north and east in the Sierran foothills. These include felsic, intermediate, and mafic intrusive rocks

associated with the Sierra Nevada batholith. Wutchumna Hill is composed of mafic (basic) intrusive rocks (bi), specifically hornblende gabbro. These and other associated igneous rocks in the Sierra Nevada batholith have eroded and have been deposited in the surrounding valley floor as the Modesto and Riverbank Formations and associated colluvium adjacent to the Sierran foothills (Matthews and Burnett, 1965).

Per the SVP classification system, intrusive rocks are generally categorized as having no paleontological sensitivity.

6
RESULTS AND ANALYSIS

This chapter reports on the results of the desktop studies and field survey completed for this Project. Paleontological sensitivity rankings also are assigned to the geologic units mapped at the ground surface and likely present at shallow depths within the Project area.

6.1 LITERATURE REVIEW

In the absence of extensive subsurface testing and observation data from a qualified paleontologist, Æ analyzed the results of nonpaleontological investigative drilling of the Project area (Lau and Schwartz, 2011). Findings in the geotechnical report are consistent with the surficial geology as mapped by Matthews and Burnett (1965). Specifically, the ground surface of the Project area is mapped as Modesto Formation by Matthews and Burnett (1965). Additionally, the Mathews and Burnett (1965) map shows ground surface exposures of the Riverbank Formation immediately adjacent to the Project area. This close proximity implies a strong likelihood for the Riverbank Formation at unknown depths within the Project area. The geotechnical data do not specifically name any of the mapped geologic units discussed above; however, the report identifies olive-gray sand and cobbles beginning at 7 feet bgs and yellowish-brown clayey sand beginning at 25 feet bgs in the borings nearest the Kaweah River and 30–35 feet bgs in the borings farther north. The borings indicate granitic bedrock beginning at 70 feet bgs in the eastern half of the Project area. The borings to the west terminated at 90 feet bgs without encountering bedrock (Lau and Schwartz, 2011). The shallower sediments are consistent with the upper member of the Modesto Formation; the deeper sediments may represent the Riverbank Formation.

The UCMP and PBDB online databases list numerous fossil localities from Tulare County. However, these databases specify no localities from the Pleistocene deposits within a 10-mile radius of the Project area.

The UCMP online database lists at least 28 fossil specimens representing plants, mammals, and reptiles from the Modesto Formation from 13 localities throughout the San Joaquin Valley. In 2006, along the San Joaquin River Parkway trail near Friant and Rice Roads in Fresno, Dundas et al. (2009) discovered a large radius of *Bison* cf. *B. latifrons* eroding from an outcrop in the upper member of the Modesto Formation on the San Joaquin River alluvial fan. The bison radius was preserved in a fine-grained clay- and charcoal-rich floodplain deposit approximately 15–30 inches thick. Other terrestrial vertebrate fossils from within the Modesto Formation include *Megalonyx jeffersonii* (Jefferson's ground sloth), *Bison antiquus* (bison), *Mammuthus columbi* (mammoth), *Camelops* (camel), Serpentes (snakes), and Rodentia (rodents) (UCMP online database). The PBDB online database does not list any fossil specimens from the Modesto Formation.

The UCMP and PBDB online databases list hundreds of fossil specimens representing plants, mammals, reptiles, and birds from the Riverbank Formation from various localities throughout the San Joaquin Valley. During excavations associated with the construction of the Arco Arena in

Sacramento, Hilton et al. (2000) discovered numerous terrestrial vertebrate fossils from within the Riverbank Formation, including Antilocapridae (antelope), *Bison antiquus* (bison), *Camelops hesternus* (camel), *Canis* cf. *latrans* (coyote), Cervidae (deer), *Mammuthus* (mammoth), *Paramylodon harlani* (Harlan's ground sloth), and *Sciurus* (squirrel). In addition, they documented plant fossils at the same locality, including the seed of a *Prunus* cf. *ilicifolia* (holly leaf cherry). All fossil specimens were encountered between 13 and 30 feet below the valley surface and represent taxa that are typical of the Late Pleistocene (Hilton et al., 2000).

Other paleontological localities within the Riverbank Formation yielded *Equus* (horse) as well as Aves (birds), *Canis dirus* (dire wolf), *Equus* (horse), *Mammuthus columbi* (mammoth), *Neotoma* (packrat), *Orthodon* (blackfish), Proboscidea (elephantoid), *Scapanus latimanus* (broad-footed mole), *Thamnophis* (garter snake), and *Thomomys* (pocket gopher) from throughout the northern and central Great Valley. The depths below ground surface at which these discoveries were made are largely unreported (Bell, 2020; UCMP online database).

Previous recent paleontological reports were also reviewed for this PRA (Shi and Ollendorf, 2019; Shi and Ollendorf, 2020). These reports acknowledge the fossil-bearing layers within the Modesto and Riverbank Formations are localized and laterally discontinuous (Hilton et al., 2000; Shi and Ollendorf, 2020). In the absence of specific local subsurface paleontological investigations, one can only focus on the paleontological sensitivity of geologic units rather than speculating about the presence or absence of significant paleontological resources within a given Project area.

6.2 MUSEUM RECORDS SEARCHES

The NHMLAC records search listed no fossil localities within the Project area, although they reported several from sedimentary units equivalent to those mapped in and close to the Project area. Table 6-1 summarizes the records search results from the NHMLAC (LACM and CIT collection acronyms).

Table 6-1
Fossil Localities Reported near the Project Area

Locality No.	Geologic Unit	Taxon	Depth	Approximate Distance from Project Area
LACM VP 1156	Unknown Formation (Pleistocene)	*Plessipus* (horse)	45 feet bgs	43 miles
LACM VP 4087	Unknown Formation (Pleistocene)	*Mammuthus* (mammoth)	Unknown	30 miles
LACM 6071	Unknown Formation (Pleistocene)	*Mammuthus* (mammoth)	6 feet bgs	43 miles

Source: Bell (2020).

The NHMLAC search did not yield any fossil localities within the Project area, although several localities are reported from the sedimentary units that occur in or near the Project area, including Quaternary deposits equivalent to the Modesto and Riverbank Formations (Bell, 2020). The nearest of these localities, LACM VP 4087, is approximately 30 miles due south of the Project area. This locality yielded a *Mammuthus* (mammoth) specimen at an unknown depth. Farther to the southeast is LACM VP 6071, approximately 43 miles from the Project area. This locality also

yielded a *Mammuthus* specimen at approximately 6 feet bgs. A third locality to the south-southwest, LACM VP 1156, yielded a specimen of *Plessipus* (horse) at 45 feet bgs. Because of these results, Bell (2020) suggests shallow excavations into Quaternary deposits exposed throughout most of the Project area may well encounter significant fossil remains.

6.3 FIELD RESULTS

Undisturbed sediments were visible throughout the Project area at the time of Æ's field survey (Figure 6-1), with approximately 80 percent ground visibility. Fine- to medium-grained sands with abundant silt are present in much of the Project area. The point bar of the Kaweah River along the southeastern edge of the Project area has abundant river-rounded cobbles present at the surface (Figure 6-2).

Figure 6-1 Project area overview from the northeast corner of the Project area; facing west.

During the survey, George noted small freshwater bivalves along the riverbank on the southwest edge of the Project area. As these were unfossilized, George determined them to be modern and not a paleontological resource. South of the Project area, George documented a stratigraphic profile along the cut bank of the Kaweah River with interbedded gray sand consistent with the upper member of the Modesto Formation (Figure 6-3). These beds were encountered at 2 feet above the modern riverbed and approximately 8 feet below the mean ground surface of the Project area. George did not encounter any paleontological resources during the survey.

Figure 6-2 **Cobbles in point bar of Kaweah River in southeastern portion of Project area; facing east.**

Figure 6-3 **Overview and stratigraphic profile along the Kaweah River channel; facing southeast.**

6.4 DETERMINATION OF PALEONTOLOGICAL RESOURCE POTENTIAL WITHIN THE PROJECT AREA

Using information obtained from the desktop studies and field survey, Æ determined the paleontological resource potential of the geologic units exposed at the ground surface in the Project area. Æ's paleontological sensitivity rankings follow the SVP's (2010) classification system (Table 3-1, Figure 6-4).

Æ notes the Holocene surficial sediments present within the Project area are likely too young to preserve significant fossils and, therefore, are categorized as having low paleontological sensitivity, although sensitivity increases with depth. The underlying late Pleistocene Modesto and Riverbank Formations have a high likelihood of preserving significant paleontological resources. The nearby Mesozoic basic intrusive and granitic bedrock documented at 68 feet bgs in the geotechnical borings has no potential to preserve significant paleontological resources.

TID anticipates that excavation of the reservoir will not exceed 60 feet bgs. Therefore, Æ suggests that the entire Project area has high potential for significant paleontological resources at depths greater than 5 feet bgs.

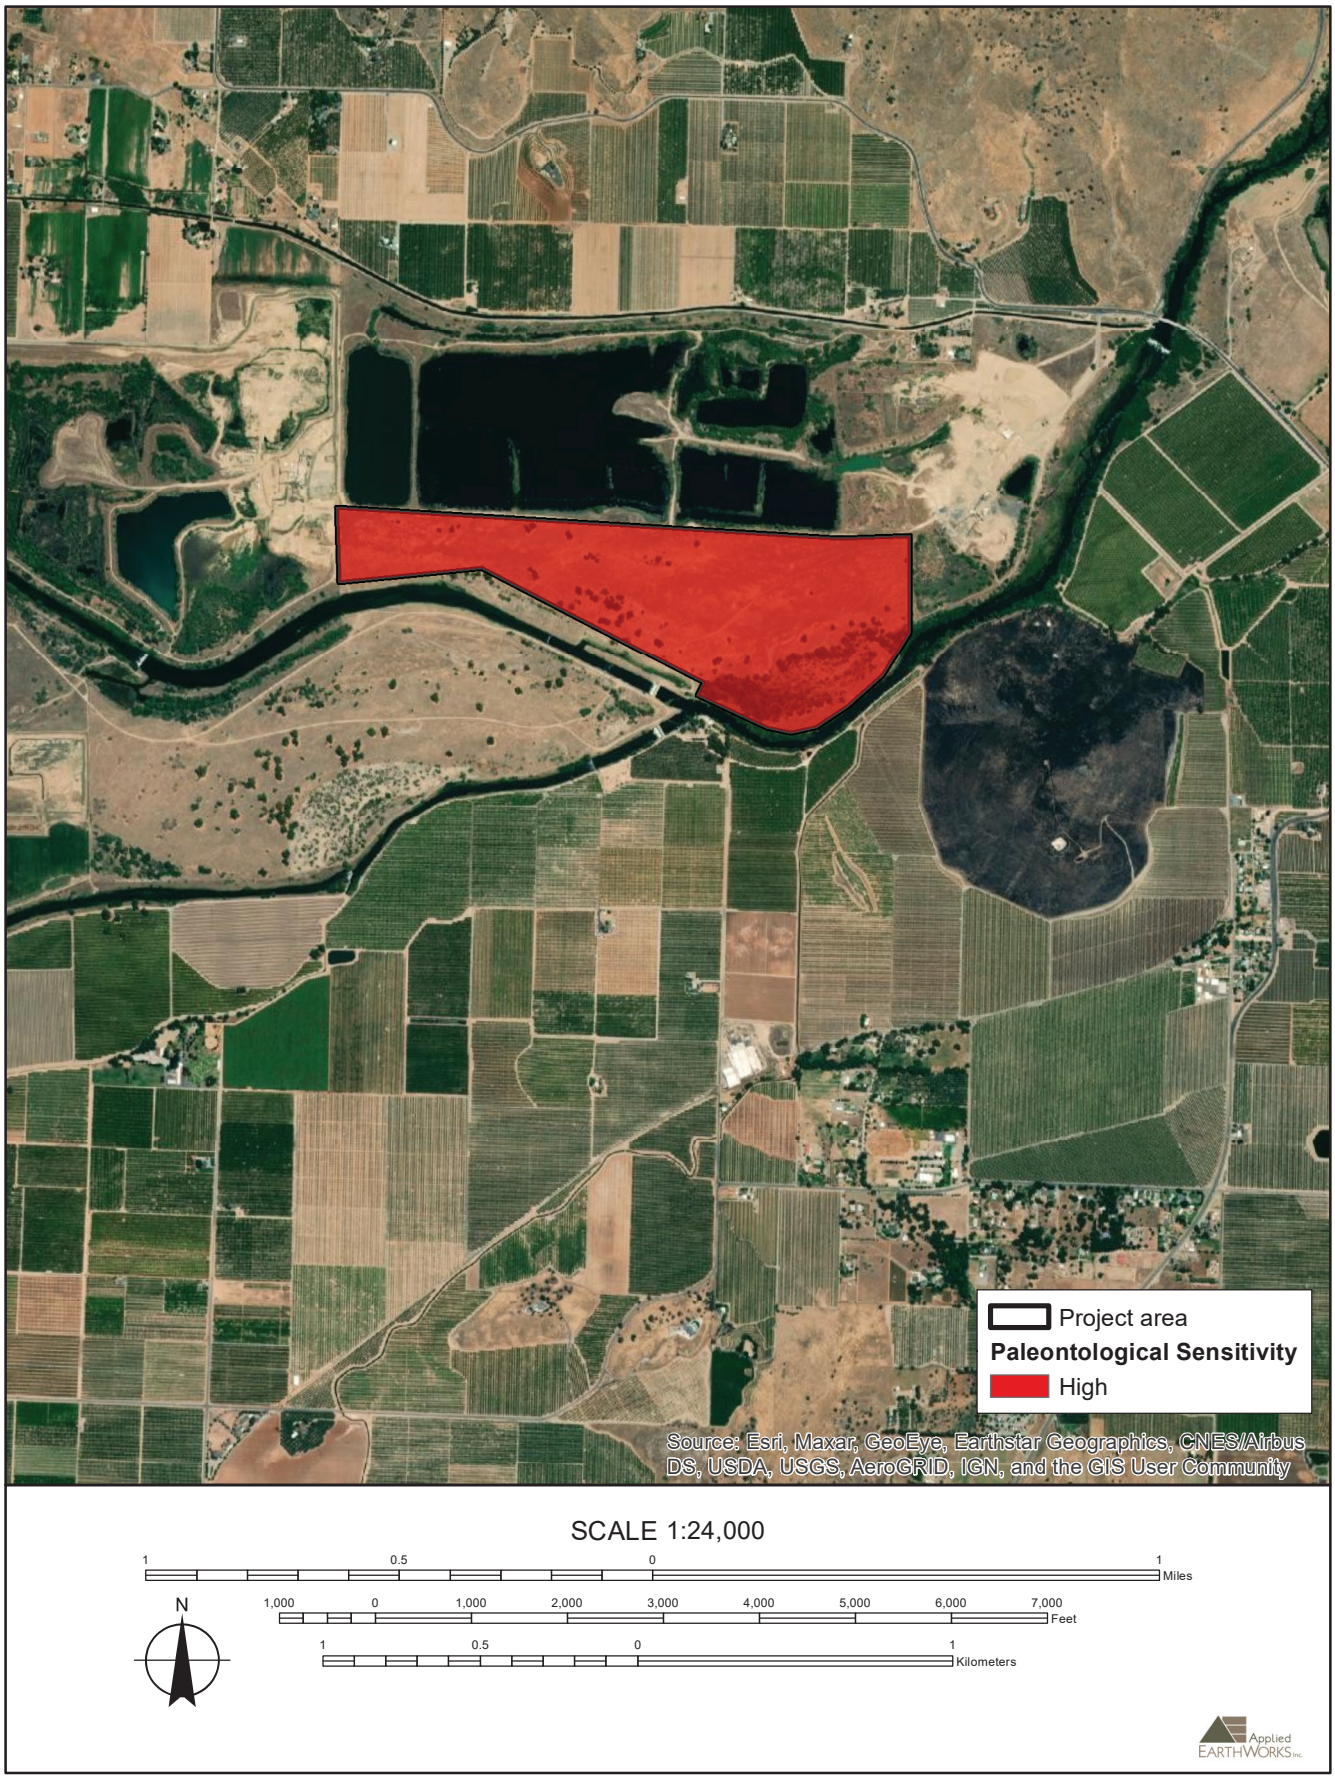

Figure 6-4 Paleontological sensitivity of the Project area.

7
RECOMMENDATIONS

This assessment is based on the results of a museum records search and review of available geologic and paleontological literature. Therefore, only fossils that have already been inventoried or collected are available for this analysis. In general, the potential for a given project to result in adverse impacts to paleontological resources is directly proportional to the amount of ground disturbance associated with the project. Due to the substantial excavations planned for the construction of the project, there is a relatively high potential for an unknown number of paleontological resources to be adversely impacted. However, by implementing management recommendations outlined in this chapter, including worker's environmental awareness training and on-site construction monitoring, adverse impacts to paleontological resources can be reduced to a less than significant level pursuant to the requirements of CEQA.

Æ concludes that Project-related construction activities may impact significant paleontological resources across the entire Project area, especially at depth. Æ's desktop studies and field survey together indicate the paleontological resource potential near the ground surface and to the anticipated maximum depth of excavation is high throughout the Project area (see Table 3-1 for sensitivity classifications). Sources of potentially significant paleontological resources are the Modesto and Riverbank Formations, likely present at depth within the Project area. Therefore, Æ suggests the entire Project area to have high potential for significant paleontological resources at depths greater than 5 feet bgs.

Because of the high paleontological sensitivity of the Project area, Æ recommends a Paleontological Resource Mitigation and Monitoring Program (PRMMP) be prepared by a qualified professional paleontologist as defined by the SVP (2010) and industry standards (Murphey et al., 2019). The PRMMP will assist with compliance with ERM Implementation Measure 55B (Tulare County, 2012) by specifying the steps to be taken to mitigate impacts to paleontological resources, if any are encountered during Project-related ground disturbance. For instance, Worker's Environmental Awareness Program training should be presented to construction personnel prior to the start of any ground disturbance.

A PRMMP also will indicate where construction monitoring will be required for the Project and the frequency of required monitoring (i.e., full-time, spot-checks, etc.). In addition to construction monitoring procedures, a PRMMP also will provide details about fossil collection, analysis, and preparation for permanent curation at an approved repository, such as the NHMLAC or UCMP. Lastly, the PRMMP describes the different reporting standards to be used—monitoring with negative findings versus monitoring resulting in fossil discoveries.

APPENDIX A

Qualifications of Key Personnel

AMY L. OLLENDORF

Managing Principal/Paleontology Program Manager

Education

Postdoctoral Research Associate, 2006–2007, World Heritage Studies, University of Minnesota

Ph.D., Ancient Studies, 1993, University of Minnesota

M.S., Ancient Studies, 1986, University of Minnesota

B.S., Anthropology (with honors) and Geology, 1983, Beloit College

Registrations/Certifications

- Registered Professional Archaeologist 12588
- Licensed Professional Geologist, Minnesota 30084 (6/1998–6/2018, expired)
- Certified Paleontologist and Archaeologist, Orange County (2020–present)
- Paleontology and Cultural Consultant, Riverside County (2018–present)

Professional Experience

- 2018–present, Managing Principal/ Paleontology Program Manager, Applied EarthWorks, Inc.
- 2015–2018 and 2005–2008, President and Senior Project Manager, ALO Environmental Associates LLC
- 2006–2015, Program Manager, Cultural Heritage Planning and Management, AECOM
- 2003–2005, Director, Cultural Resources Management, Peterson Environmental Consulting, Inc.

Summary of Qualifications

Dr. Ollendorf has more than 37 years of experience in cultural heritage, geoarchaeology, paleoecology, paleontology, and environmental compliance at the global, national, tribal, state, and local levels. She meets industry standards for principal investigator in paleontology and she is also Æ's principal investigator on Æ's California statewide Paleontological Resource Use Permit for paleontology from the US Bureau of Land Management (BLM) for 2018–2021.

Dr. Ollendorf has supervised and/or participated in archaeological, historical, architectural history, and paleontological services, tribal negotiations, and agency coordination throughout her career. She also has managed EISs and EAs. Her project experience includes work in 35 states, including Southern California, and other western states, and abroad on a wide range of client projects across many different industry sectors.

During her career, Dr. Ollendorf has written or overseen many hundreds of compliance reports in addition to having published multiple articles in peer-reviewed professional journals and presented to a wide variety of audiences, including professional peers.

Selected Project Experience

Port San Luis Harbor Terrace Project, San Luis Obispo County, California. Paleontology Program Manager (2019–present). Oversaw preparation and completed QA/QC of WEAP training brochure. Will oversee paleontological resource monitoring and reporting for construction for CEQA compliance. Paleontologically sensitive geologic units: Atascadero and Pismo Formations. Working closely with paleontology staff (Chris Shi). Client: RTA Harbor Terrace, LLC for County of San Luis Obispo.

Western San Bernardino County Distribution System Infrastructure Protection Program (DSIPP), San Bernardino County, California. Paleontology Program Manager (2019–present). Overseeing completion of paleontological resource assessment for O&M activities throughout the Programmatic Footprint (74 miles of pipeline, 392 pipeline structures, and approximately 50 miles of patrol roads through 10 cities) as well as within work areas for 13 individual Capital Investment Plan (CIP) projects. Paleontologically sensitive geologic units: Early Holocene or older axial-channel deposits, alluvial fan deposits; Undetermined sensitivity: Miocene-age unnamed fault-bounded conglomerate and sandstone unit. Completing for CEQA compliance (Metropolitan Water District of Southern California). Working closely with paleontology staff (Chris Shi). Client: Dudek.

Professional Experience (continued)

- 2000–2003, Director, Cultural Resources Management, HDR Engineering, Inc.
- 1996–2000, Director, Cultural Resources Management, Braun Intertec Corporation, Inc.
- 1994–1996, Statewide Inventory Coordinator, Minnesota State Historic Preservation Office
- 1993–1994, Staff Archaeologist, Institute for Minnesota Archaeology
- 1991–1993, Independent Contractor—Paleoecology
- 1990, Co-Director, Geoarchaeological Field School, Southern Illinois University, Edwardsville
- 1987–1990, Graduate Research Assistant, Limnological Research Center, University of Minnesota
- 1984–1987, Graduate Research Assistant, Archaeometry Laboratory, University of Minnesota
- 1983–1984, Research Assistant, Crustal Dynamics Project, Geology & Geophysics Branch, NASA Goddard Space Flight Center
- 1987, 1984, Assistant Geoarchaeologist, Tel Miqne Excavations, ASOR-Albright Institute, Jerusalem, Israel
- 1983, Summer Intern, US Bureau of Land Management, Phoenix District, Arizona
- 1983, Teaching Assistant – Evolution of the Earth, Beloit College Geology Department
- 1983, Research Assistant – Palynomorphs (Acritarchs), Beloit College Geology Department

Selected Project Experience (continued)

Improvements to the Avenue 50 and Jackson Street Intersection, City of Indio, Riverside County, California. Paleontology Program Manager (2019–present). Oversaw completion of ground-surface reconnaissance field survey and will provide QA/QC of paleontological technical memorandum for CEQA compliance. Paleontologically sensitive geologic units: Lake Cahuilla beds. Client: Albert A. Webb Associates for County of Riverside.

Replacement of Two Timber Railroad Avenue Bridges near the Community of Whitewater, Riverside County, California. Paleontology Program Manager and Project Manager (2019–present). Oversaw preparation and completed QA/QC of paleontological technical memorandum for replacement of the Railroad Avenue Bridge over Fornat Wash (Bridge Number 56C0099) and the Railroad Avenue Bridge over East Channel Stubbe Wash (Bridge Number 56C0101) within a 4.5-acre Project area. Paleontologically sensitive geologic units: Older Alluvial Deposits, Palm Spring Formation, and Imperial Formation. Completed for NEPA (Caltrans) and CEQA (County) compliance. Worked closely with paleontology staff (Chris Shi). Client: WSP for Caltrans District 8.

Fresno Meat-Rendering Plant, City of Fresno, Fresno County, California. Paleontology Program Manager (2019–present). Overseeing completion of preconstruction paleontological survey of 10 acres and letter report. Paleontologically sensitive geologic units: Pleistocene nonmarine and Quaternary nonmarine alluvial fan deposits. Completing for CEQA compliance (City). Working closely with paleontology staff (Chris Shi). Client: Darling Ingredients, Inc.

Santa Ana River Trail—Phase 6 through Green River Golf Course, Orange-San Bernardino County Line to City of Corona, Riverside County, California. Paleontology Program Manager (2019–present). Overseeing preparation and completing QA/QC of combined paleontological identification report/paleontological evaluation report (PIR/PER) for two possible Santa Ana River Trail (SART) alignments, a short segment linking SART—Phase 5 to SART—Phase 3, and a small staging area. Project included field surveys for paleontological resources. Completing for CEQA compliance (Riverside County Transportation Commission). Working closely with paleontology staff (Chris Shi). Client: Michael Baker International.

Wastewater Collection and Treatment Improvements, Community of Franklin-Beachwood, Merced County, California. Paleontology Program Manager (2019–present). Overseeing preparation and completing QA/QC of paleontological resource identification letter report for the approximately 67-acre project area for CEQA compliance (Franklin County Water District). Paleontologically sensitive geologic units: Riverbank and Modesto Formations. Working closely with paleontology staff (Chris Shi). Client: Quad Knopf, Inc.

Other Paleontological Research

Ph.D. Dissertation

Changing Landscapes in the American Bottom (USA): An Interdisciplinary Investigation with an Emphasis on the Late-Prehistoric and Early-Historic Periods. Advisor: Herbert E. Wright, Jr.

M.S. Thesis

A Study of Phytoliths from Philistine Levels at Tel Miqne (Ekron), Israel. Advisor: George R. Rapp, Jr.

B.S. Theses

The High Diversity of the Mazon Creek Biota: The Result of Excellent Preservation in a Deltaic Environment. Advisor (Geology): Carl Mendelson.

The Role of Man in the Pleistocene Extinction of Large Mammals. Advisor (Anthropology): Daniel Shea.

Selected Project Experience (continued)

Santa Margarita Ranch Agricultural Subdivision Project, San Luis Obispo County, California. Paleontology Program Manager (2019–present). Oversaw preparation and completed QA/QC of paleontological resource impact mitigation program (PRIMP). Will oversee preconstruction worker environmental awareness program (WEAP) training, paleontological resource monitoring, and reporting. Paleontologically sensitive geologic units: Monterey, Santa Margarita, and Paso Robles Formations and older Quaternary alluvium. Completing for CEQA compliance (County). Working closely with paleontology staff (Chris Shi). Client: Kirk Consulting for Santa Margarita Ranch, LLC.

Fairmead Landfill Expansion, City of Chowchilla, Madera County, California. Paleontology Program Manager (2019–present). Overseeing preconstruction WEAP training and construction monitoring over the 23-acre Project area immediately adjacent to the paleontologically diverse Fairmead Locality (Pleistocene, Irvingtonian). Also will oversee post-construction monitoring report. Paleontologically sensitive geologic units: Modesto, Riverbank, and Turlock Lake Formations. Completing for CEQA compliance (County). Working closely with paleontology staff (Chris Shi, Blake Bufford, and Michael George). Client: County of Madera.

Port of Long Beach Master Plan Update, City of Long Beach, Los Angeles County, California. Paleontology Program Manager (2019). Overseeing preparation and providing QA/QC of paleontological resource sections of the Program Environmental Impact Report (PEIR) for the Port Master Plan Update (PMPU) for CEQA compliance. Paleontologically sensitive geologic units: Pleistocene-age sedimentary deposits of the continental shelf and possibly also Late Pleistocene- to Holocene-age young alluvium. Working closely with paleontology staff (Chris Shi). Client: Leidos for Port of Long Beach.

First Street Village Development, Burbank, Los Angeles County, California. Paleontology Program Manager (2019–present). Overseeing pre-construction WEAP training and paleontological resource construction monitoring for CEQA compliance (City). Paleontologically sensitive geologic units: Quaternary alluvium. Working closely with paleontology staff (Chris Shi). Client: First Street Village LLC to City of Burbank.

Bellota-Warnerville 230 kV Reconductoring Project, San Joaquin and Stanislaus Counties, California. Paleontology Program Manager (2019–present). Completed paleontology sections of draft Proponent's Environmental Assessment (PEA); also oversaw preparation and completed QA/QC of field survey and Paleontological Field Survey Report (PFSR) for CEQA compliance for the 23-mile-long project. Paleontologically sensitive geologic units: Modesto, Riverbank, Turlock Lake, Mehrten Formations and possibly also the Laguna Formation. Worked closely with paleontology staff (Chris Shi and Richard Serrano). Client: Stantec for California Public Utilities Commission (CPUC).

Selected Project Experience (continued)

CEMEX Rockfield Modification Project, City of Fresno, Fresno County, California. Paleontology Program Manager (2019–present). Oversaw preparation and completed QA/QC of paleontological technical memorandum for expansion of current aggregate mining and processing operations at quarry and plant sites within a 490.5-acre Project area. Paleontologically sensitive geologic units: Modesto, Riverbank, Turlock Lake, and Tulare Formations. Completed for NEPA and CEQA compliance. Worked closely with paleontology staff (Chris Shi). Client: Buada Associates, Inc. for U.S. Army Corps of Engineers and California Public Utilities Commission (CPUC).

City of Fresno Cannabis Ordinance Environmental Impact Report, Fresno County, California. Paleontology Program Manager (2019–present). Oversaw preparation and completed QA/QC of paleontological technical memorandum to assist with evaluation of the proposed regulation and permitting of commercial cannabis activities with a focus on land-use areas within the City capable of supporting cultivation, distribution, manufacturing, testing, and retail facilities with an 800-foot buffer from other cannabis retailers, schools, daycare centers, and other youth facilities. Paleontologically sensitive geologic units: Modesto, Riverbank, Tulare, and Turlock Lake Formations. Completed for CEQA compliance (City). Worked closely with paleontology staff (Scott Rohlf). Client: Quad Knopf, Inc.

Interstate 10 Eastbound Truck Climbing Lane Improvement Project, City of Yucaipa, San Bernardino County and City of Calimesa, Riverside County, California. Paleontology Program Manager (2019–present). Oversaw preparation and completed QA/QC of paleontological technical memorandum for improvements to a total of 3 miles of existing six-lane eastbound I-10 by adding a truck-climbing lane (TCL) from the 16th Street Overcrossing Bridge to 0.2 mile east of the County Line Road Undercrossing Bridge by paving the existing median. Paleontologically sensitive geologic units: San Timoteo Formation and Pleistocene-age alluvial deposits, and possibly also pre-Pliocene Mill Creek Formation/Potato Sandstone. Completed for NEPA and CEQA compliance (Caltrans and San Bernardino County Transportation Authority). Worked closely with paleontology staff (Chris Shi). Client: HDR.

Pacific Gas and Electric Company (PG&E) Groundwater Remediation, Hinkley, San Bernardino County, California. Paleontology Program Manager and Project Manager (2018–present). Over a multiyear period, completing Release-To-Construction (RTC) project-by-project reviews for cultural and paleontological resource management. Tasks include assessing project areas for sensitivity for cultural and paleontological resources, previously surveyed areas, and recorded locations of cultural resources. Also overseeing cultural and paleontological construction monitoring on a project-by-project basis. Requires project-specific reporting, annual reporting, regular client communication, and coordination with cultural and paleontological staff. Paleontologically sensitive geologic units: Pleistocene alluvium and Middle to Late Pleistocene lacustrine deposits associated with Pluvial Harper Lake. Reports to date include Paleontological Resource Monitoring Report: Installation of Extraction Well 66 (EX-66); Cultural and Paleontological Resources Findings Report: Installation of monitoring Well 44S (SC-MW-44S); and 2018 Annual Report—all co-authored with Chris Shi. Completing for CEQA compliance. Client: Arcadis for PG&E.

Menifee Town Center – Parcels 13, 14, and 15 Development Project, Riverside County, California. Paleontology Program Manager (2018–present). Oversaw preparation and completed QA/QC of PRIMP covering 13-acre project area. Oversaw completion of construction monitoring and will complete QA/QC of final monitoring report. Paleontologically sensitive geologic units: Middle to Late Pleistocene alluvial fan deposits. Worked closely with paleontology staff (Scott Rohlf, Chris Shi, and Aimee Montenegro). Completing for CEQA compliance. Client: Kristoff Commercial Real Estate to City of Menifee.

Sun Lakes Boulevard Realignment, City of Banning, Riverside County, California. Paleontology Program Manager (2019). Edited and approved Constraints Analysis for paleontological resources within the approximately 14-acre project area. Paleontologically sensitive geologic units: Mt. Eden and San Timoteo Formations, and Quaternary alluvial deposits. Worked closely with paleontology staff (Win McLaughlin, Chris Shi). Client: Albert A. Webb Associates, Inc.

Selected Project Experience (continued)

Madera Travel Center at Avenue 17 and Highway 99 Interchange, Madera County, California. Paleontology Program Manager (2018–present). Co-authored draft Paleontological Resource Mitigation Plan (PRMP) for commercial development of approximately 50 acres. Paleontologically sensitive geologic units: Modesto, Riverbank, and Turlock Lake Formations, and possibly also an unnamed Pleistocene nonmarine sedimentary unit. Oversaw WEAP training and overseeing paleontological resource monitoring for construction. Worked closely with paleontology staff (Scott Rohlf, Chris Shi, and Christopher Shea). Completed for CEQA compliance (City). Client: Love's Travel Stops & Country Stores to Madera County.

Highpark Development Project (formerly Ponte Vista) in San Pedro, City of Los Angeles, Los Angeles County, California. Paleontology Program Manager and Project Manager (2018–present). *Æ* provided multiyear paleontological monitoring during construction of 676 homes on 61.5 acres. Paleontologically sensitive geologic units: San Pedro Formation and Palos Verde Sand. By winter 2018, *Æ* paleontological monitors had documented 26 paleontological localities and recovered 27 large vertebrate specimens along with over 4,000 pounds of additional bulk matrix which yielded thousands of scientifically significant invertebrate fossils and more than 25 small-fraction vertebrate specimens. *Æ* has processed the fossil specimens for permanent curation at the Natural History Museum of Los Angeles County and is preparing a final paleontological monitoring report for compliance with the CEQA (City). Final deliverables will be produced and submitted after *Æ* has received a fully executed Deed of Gift Form from the land developer. Oversaw final fossil preparation and providing QA/QC of monitoring report. Working closely with paleontology staff (Chris Shi). Client: Harridge Development Group (formerly iStar Financial).

500 MW Athos Renewable Energy Project, Riverside County, California. Paleontology Program Manager and Project Manager (2018–2019). Overseeing preparation and providing QA/QC of all paleontological resources tasks. For CEQA compliance (County), Project Area on private and state lands consisted of 3,662 acres, including a 11.1-mile-long by 200-foot-wide generation-tie transmission line corridor and access roads. Desktop study included the Project Area plus a 5-mile-wide buffer (Study Area). Paleontologically sensitive geologic units: moderately bedded Pleistocene nonmarine alluvial gravels and sands, reddish paleosols, and Pinto Formation. Supervised completion of paleontological work plan, reconnaissance-level pedestrian field survey for paleontological resources in addition to paleontological observations of geotechnical trenching, Paleontological Identification Report (PIR), and PRIMP. For NEPA compliance, oversaw Paleontology Resource Assessment (PRA), Potential Fossil Yield Classification (PFYC), and BLM Fieldwork Authorization Request for proposed project components on BLM lands. Working closely with paleontology staff (Chris Shi and Scott Rohlf). Client: IP Athos, LLC and Aspen Environmental Group.

Central Coast Oil and Gas Leasing and Development, California. Principal Investigator (2018–2019). Updated paleontology sections of Affected Environment, Environmental Consequences, and References Cited chapters as well as updated the Administrative Record for 7 alternatives covered in the Resource Management Plan Amendment/FEIS on public lands and split mineral estate lands administered by the US Bureau of Land Management (BLM) across approximately 284,000 acres of surface estate and 793,000 acres of federal mineral estate (12 counties). Utilized BLM's Potential Fossil Yield Classification (PFYC) system for 31 paleontologically significant geologic units. Completed for NEPA (BLM) and CEQA compliance (California Department of Conservation, Division of Oil, Gas, and Geothermal Resources for CEQA). Client: Aspen Environmental Group for BLM.

Banning Electric Utility – Ivy Distribution Substation Project, City of Banning, Riverside County, California. Paleontology Program Manager (2019). Oversaw completion and provided QA/QC of paleontological resource constraints memorandum for CEQA compliance. Paleontologically sensitive geologic units: Pleistocene alluvium. Worked closely with paleontology staff (Win McLaughlin and Chris Shi). Client: Albert A. Webb Associates for City of Banning.

Biola University North Dorm Project: Tennis Courts and Wastewater Treatment Area Expansion, City of La Mirada, Los Angeles County, California. Paleontology Program Manager (2019). Oversaw preparation and

Selected Project Experience (continued)

providing QA/QC of paleontological resource monitoring for construction for CEQA compliance. Paleontologically sensitive geologic units: older Quaternary alluvium. Worked closely with paleontology staff (Chris Shi, Aimee Montenegro). Client: Biola University to City of La Mirada.

Rowland Heights Hotel and Plaza Project, Los Angeles County, California. Paleontology Program Manager (2019). Oversaw preparation and completed QA/QC of PRIMP for CEQA compliance. Paleontologically sensitive geologic units: Pleistocene alluvium, Puente/Monterey Formation. Worked closely with paleontology staff (Chris Shi). Client: Envicom for County of Los Angeles.

Rados Heacock Environmental Project, City of Moreno Valley, Riverside County, California. Paleontology Program Manager (2019). Oversaw preparation and completed QA/QC of paleontological technical memorandum for construction of two new industrial buildings on 37.12 acres of vacant land. Paleontologically sensitive Pleistocene-age alluvial deposits are located in the Project area. Completed for CEQA compliance (County). Worked closely with paleontology staff (Scott Rohlf). Client: Albert A. Webb Associates, Inc.

Southern California Logistics Center Project, Victorville, San Bernardino County, California. Paleontology Program Manager (2019). Oversaw preparation and completed QA/QC of PRA and review of the paleontological resource section of the PEIR for the Victorville Airport for CEQA compliance. Paleontologically sensitive geologic units: Pleistocene-age or older alluvial deposits. Worked closely with paleontology staff (Chris Shi). Client: Michael Baker for City of Victorville.

5401 Telegraph Road Parking Structure, City of Commerce, Los Angeles County, California. Paleontology Program Manager (2019). Oversaw preparation and completed QA/QC of WEAP training, and paleontological resource monitoring, and oversaw reporting for CEQA compliance. Paleontologically sensitive geologic units: older Quaternary alluvial deposits, but no paleontological resources were observed during construction monitoring. Worked closely with paleontology staff (Chris Shi, Jorge Mendieta). Client: Parkco Building Company.

Duke Perry Street & Barrett Avenue Project in the City of Perris, Riverside County, California. Paleontology Program Manager (2019). Oversaw preparation and completed QA/QC of paleontological technical memorandum for construct an industrial warehouse and paved parking lot on approximately 7.25 acres. Recommended the creation of a PRIMP since the project area was ranked High B for paleontological sensitivity with nearby Pleistocene vertebrate fossil localities recorded in alluvial deposits similar to those in the Project area. Worked closely with paleontology staff (Chris Shi). Completed for CEQA compliance. Lead agency: City of Perris. Albert A. Webb Associates for Duke Realty. Complete, January 2019.

Cannabis Cultivation Warehouse on Assessor's Parcel 314-160-004, City of Perris, Riverside County, California. Paleontology Program Manager (2019). Oversaw preparation and completed QA/QC of paleontological technical memorandum for development of 0.93 acres of vacant land. Recommended the creation of a PRIMP since the older Quaternary alluvial deposits in the project area are ranked High B for paleontological sensitivity with nearby Pleistocene vertebrate fossil localities recorded in alluvial deposits similar to those in the Project area. Worked closely with paleontology staff (Chris Shi). Completed for CEQA compliance. Client: Richard Park.

LA Water Wheel Project, Los Angeles County, California. Paleontology Program Manager (2019). Oversaw preparation and completed QA/QC of paleontological technical memorandum for the plan to divert waters from the Los Angeles River to irrigate nearby public parks, and will assist City of Los Angeles with Mitigated Negative Declaration (MND) for CEQA compliance. Paleontologically sensitive geologic units: Pleistocene-age alluvial deposits and the Miocene-age Monterey Formation. Client: Ruth Villalobos & Associates for City of Los Angeles.

State Route (SR) 86/Avenue 50 New Interchange Project, City of Coachella, Riverside County, California. Third-Party Senior Reviewer (2018). Reviewed/rewrote Affected Environment, Environmental Consequences, and Avoidance Minimization, and/or Mitigation Measures paleontology chapters and References Cited chapter (of

Selected Project Experience (continued)

the Initial Study/EA written by Michael Baker International). Paleontologically sensitive geologic units: Late Quaternary Period lacustrine deposits associated with ancient Lake Cahuilla. Completed for NEPA, NHPA, Section 4(f), and CEQA compliance. Client: TranSystems Corporation to Caltrans, District 8.

Rose II Residential Development Project, Romoland, Riverside County, California. Paleontology Program Manager (2018). Oversaw preparation and completed QA/QC of PRIMP covering subdivision of 45.6 acres. Paleontologically sensitive geologic units: Middle to Late Pleistocene alluvial fan deposits. Completed for CEQA compliance. Worked closely with paleontology staff (Chris Shi). Client: Pacific Communities Builder, Inc. to County of Riverside.

Sycamore Hills Distribution Center, City of Riverside in Riverside County, California. Paleontology Program Manager (2018). Oversaw preparation and completed QA/QC of Paleontological Resource Assessment covering commercial development of 47.85 acres. No paleontologically sensitive geologic units. Worked closely with paleontology staff (Chris Shi). Completed for CEQA compliance. Client: Ruth Villalobos & Associates, Inc. to County of Riverside.

Temescal Valley Riverside Clinic Investors IV, LLC Project, South of the City of Corona, Riverside County, California. Paleontology Program Manager (2018). Oversaw preparation and completed QA/QC of letter report for paleontological resource mitigation monitoring during construction in the 12.5-acre project area. Paleontologically sensitive geologic units: Vaqueros and Sespe Formations, but no paleontological resources observed during construction monitoring. Worked closely with paleontology staff (Chris Shi). Completed for CEQA compliance. Client: Riverside Clinic Investors IV, LLC to County of Riverside.

39527 Colleen Way Mixed-Use Development Project, City of Temecula, Riverside County, California. Paleontology Program Manager (2018). Oversaw preparation and completed QA/QC of letter report for paleontological resource mitigation monitoring during construction in the 5.3-acre project area. Paleontologically sensitive geologic units: Pauba Formation, but no paleontological resources observed during construction monitoring. Worked closely with paleontology staff (Scott Rohlf and Christopher Shea). Completed for CEQA compliance. Client: Courie Construction to County of Riverside.

Beach Club Development, Thermal, Riverside County, California. Paleontology Program Manager (2018). Oversaw preparation and completed QA/QC of technical memorandum for development of 240 acres of vacant land. Recommended mitigation measures since project area is in High paleontological sensitivity. Paleontologically sensitive geologic units: Late Quaternary Period lacustrine deposits associated with ancient Lake Cahuilla. Worked closely with paleontology staff (Chris Shi and Niranjala Kottachchi). Completed for CEQA compliance. Client: Albert A. Webb Associates to County of Riverside.

500 kV Ten West Link Transmission Connection, Maricopa County, Arizona to Riverside County, California. Paleontology Program Manager and Project Manager (2018). Oversaw preparation and completed QA/QC of PRA for the entire 114-mile-long preferred alignment and alternatives. Utilized BLM's PFYC system. Paleontologically sensitive geologic units: Paleozoic sedimentary rocks, Bouse and Chemehuevi Formations, Bullhead Alluvium and Older Quaternary Alluvium (e.g., Palo Verde Alluvium); and Cenozoic sedimentary rocks have Unknown Potential. Worked closely with paleontology staff (Scott Rohlf, Chris Shi, and Christopher Shea). Completed for NEPA and CEQA compliance. Client: DCR Transmission LLC to BLM and California Public Utilities Commission (CPUC).

Talavera Pipeline Replacement, City of Indio, Riverside County, California. Paleontology Program Manager (2018). Total project length: 5.7 miles. Oversaw preparation and completed QA/QC of paleontological resource technical memorandum for CEQA compliance. Paleontologically sensitive geologic units: Older Quaternary Alluvium. Worked closely with paleontology staff (Scott Rohlf, Christopher Shea, Chris Shi). Client: Albert A. Webb Associates to Coachella Valley Water District.

Blythe Airport Perimeter Fence Project, Riverside County, California. Paleontology Program Manager (2018). Oversaw preparation and completed QA/QC of paleontological resource technical memorandum on

Selected Project Experience (continued)

approximately 700 acres. Paleontologically sensitive geologic units: Late to Middle Pleistocene Old Terrace Deposits, and possibly also Middle to Early Pleistocene Very Old Alluvial Deposits at depth. Worked closely with paleontology staff (Scott Rohlf and Christopher Shea). Completed for NHPA and CEQA compliance. Client: Mead & Hunt to Federal Aviation Administration (FAA) and Riverside County Economic Development Agency.

Madison Avenue Improvements Project, City of Murrieta, Riverside County, California. Paleontology Program Manager (2018). Oversaw preparation and completed QA/QC of the PRA, including identification survey for the Project and Constraints Analysis for the Warm Springs Creek Bridge Crossing for CEQA compliance (City). Paleontologically sensitive geologic units: Young Surficial Deposits, especially pre-Holocene, and Very Old Surficial Deposits, including the Pauba Formation. Worked closely with paleontology staff (Scott Rohlf and Chris Shi). Client: Kleinfelder to City of Murrieta Public Works & Engineering.

Duke Development on the Northwest Corner of Alabama Street & Palmetto Avenue, City of Redlands, San Bernardino County, California. Paleontology Program Manager (2018). Oversaw preparation and completed QA/QC of paleontological resource technical memorandum on approximately 55 acres. Paleontologically sensitive geologic units: Late to Middle Pleistocene alluvial deposits (e.g., Very Old Axial-Channel deposits). Worked closely with paleontology staff (Scott Rohlf and Christopher Shea). Completed for CEQA compliance. Client: Albert A. Webb Associates to County of San Bernardino.

I-10 Monroe Interchange Project, Riverside County, California. Paleontology Program Manager (2018). Oversaw preparation and completed QA/QC of PIR for CEQA compliance. Included paleontological field surveys of two design alternatives over a total of approximately 73 acres. Paleontologically sensitive geologic units: Quaternary, especially pre-Holocene, fluvial deposits and possibly also Lake Cahuilla lacustrine deposits at depth. Worked closely with paleontology staff (Scott Rohlf and Christopher Shea). Client: Michael Baker to Caltrans, District 8.

Water-Main Replacement Project along the San Gorgonio River, City of Banning, Riverside County, California. Paleontology Program Manager (2018). Total project length: 6.5 miles. Oversaw paleontological spot-check monitoring and reporting for water mainline replacement on private lands for CEQA compliance. Paleontologically sensitive geologic units: San Timoteo Formation and Quaternary older alluvium, but no paleontological resources were observed during construction monitoring. Worked closely with paleontology staff (Scott Rohlf and Christopher Shea). Will also oversee full-time monitoring and reporting in high-sensitivity areas on US Forest Service (USFS) lands for compliance with the Omnibus Public Land Management Act. Client: Aspen Environmental Group to City of Banning Public Works Department.

De Anza Sewer Force Main Project, City of San Jacinto, Riverside County, California. Paleontology Program Manager (2018). Total project length: 7,500 linear feet. Oversaw creation of informational brochure for construction-worker sensitivity training for Worker Environmental Awareness Program (WEAP) compliance. Also oversaw coordination and completion of spot-check monitoring. Completed senior review and QA/QC for paleontology mitigation monitoring letter report. Paleontologically sensitive geologic units: older Quaternary deposits, but no paleontological resources were observed during construction monitoring. Worked closely with paleontology staff (Christopher Shea). All completed for CEQA compliance. Client: HELIX to Eastern Municipal Water District.

Sixth Street Park, Arts, River & Connectivity (PARC) Improvements, City of Los Angeles, Los Angeles County, California. Paleontology Program Manager (2018). Completed QA/QC of paleontological resource technical memorandum for CEQA compliance. Paleontologically sensitive geologic units: Middle to Late Pleistocene alluvial deposits, Late Miocene- to Early Pliocene-age Puente Formation, and Early Pliocene- to Early Pleistocene-age Fernando Formation. Worked closely with paleontology staff (Scott Rohlf). Client: GPA Consulting to City of Los Angeles Bureau of Engineering.

Hay Lake and McFarland Parcels Land Exchange, Cook and St. Louis Counties, Minnesota. Principal Investigator (2010). Researched and summarized Existing Conditions of paleontological resources for DEIS. Completed for NEPA compliance. Client: PolyMet Mining to USFS, Superior National Forest.

Selected Project Experience (continued)

Collaborative Research: Deltaic Resilience and the Genesis of Mesopotamian Cities (Iraq) Project. Phytolith Analyst (2014). Completed phytolith analysis and reporting about mudbrick samples from the archaeological site of Ur after overseeing chemical processing. Client: Dr. Jennifer Pournelle, Principal Investigator, University South Carolina Research Foundation.

Geological Background Research for the Naval Industrial Reserve Ordnance Plant (NIROP) Superfund Cleanup Project, City of Fridley, Hennepin County, Minnesota. Staff Geologist (2014). Compiled and examined boring logs and identified stratigraphic contacts for 3D modeling at the 83-acre site located about 700 feet east of the Mississippi River. Research completed for compliance with the US Clean Water Act (CWA). Client: US Navy.

Multiple Projects as Independent Contractor. Paleoecologist (1991–1993). Distinguished the post-contact cultural horizon using pollen analysis for Dr. Daniel Engstrom (University of Minnesota) and Minnesota Pollution Control Agency (MPCA) for projects in Lake St. Croix (MN-WI border) and Duluth-Superior Harbor (MN-WI border). Collected modern pollen samples and made reference slides of Upper Midwest pollen taxa for Dr. Greg McDonald (Cincinnati Museum of Natural History & Science, Ohio). Processed sediment samples from the Island of Madeira and analyzed phytoliths for Dr. Glenn Goodfriend (Carnegie Institution, Washington, D.C.).

Geoarchaeological Field School at Cahokia Mounds State Historic Site (UNESCO World Heritage Site), Collinsville, Illinois. Co-Director (1990). Lectured on paleoecological research and geoarchaeology, led wetland-coring & laboratory activities, participated in remote sensing field and laboratory activities. Co-Director: Dr. Rinita Dalan.

Limnological Research Center, University of Minnesota, Minneapolis. Graduate Research Assistant (1987–1990). Conducted analyses of pollen and other appropriate material from lake-sediment and peat cores. Supervisors: Dr. Herbert Wright, Jr. and Dr. Linda Shane.

Archaeometry Laboratory, University of Minnesota, Duluth. Graduate Research Assistant (1984–1987). Conducted sediment grain-size analyses, processed and identified phytoliths and pollen, assisted in publication, obtained literature about sediment studies, performed various office duties. Supervisor: Dr. George (Rip) Rapp, Jr.

Crustal Dynamics Project, Geology & Geophysics Branch, NASA Goddard Space Flight Center, Greenbelt, Maryland. University of Maryland Research Assistant (1983–1984). Correlated geologic features with satellite magnetic anomalies (MAGSAT) and researched the crustal structure and composition of each feature for Principal Investigator (Dr. Herbert Frey).

Tel Miqne (Ekron) Excavations, American Schools of Oriental Research, Israel. Assistant Geoarchaeologist and Project Archaeologist (1984, 1987). Assisted the Project Geoarchaeologist (Dr. Arlene Rosen) in all phases of field and laboratory studies during spring-summer excavations. **1987 season** involved all phases of grain-size studies, including collection, processing, microscopic analysis, and data analysis; also assisted with on-site geological problems and flotation procedures. **1984 season** involved assistance with wadi stratigraphy studies, on-site geological problems, flotation procedures, and grain-size analyses.

MELISSA K. MACIAS

Senior Paleontologist/Project Manager

Education

M.S., Geosciences, in progress, Fort Hays State University, expected Fall 2020

B.S., Earth Sciences, 2013, University of California, Santa Barbara

A.A., Earth and Planetary Sciences, Santa Barbara City College

Registrations/Certifications

- Certified Paleontologist, Orange County (2016–present)
- Qualified Paleontologist, Riverside County (2019–present)

Professional Experience

- 2020–present, Senior Paleontologist / Project Manager, Applied EarthWorks, Inc.
- 2015–2020, Paleontologist, Psomas
- 2015, Paleontological Monitor, Duke CRM
- 2013–2015, Graduate Teaching Assistant, Fort Hays State University
- 2015, Graduate Curatorial Assistant, Sternberg Museum of Natural History
- 2008–2013, Undergraduate Teaching Assistant, Santa Barbara City College

Other Paleontological Research

M.S. Thesis. *Paleobiogeography of North American Giant Ground Sloths*. Advisor: Dr. Laura Wilson

B.S. Thesis (2013). *Late Pleistocene megafauna localities at Vandenberg Air Force Base.* Advisor: Dr. Andre Wyss

Summary of Qualifications

Melissa Macias has five years of experience with CEQA and NEPA compliance as well as conducting and managing paleontological resource impact assessments. Melissa has worked on paleontological resources impact mitigation programs that have required monitoring of earth-moving activities, recovery and preparation of fossil remains for collections, field personnel supervision, laboratory analysis of paleontological specimens, and final report preparation. In addition to experience in Southern California, Ms. Macias also has paleontology experience in Utah and Montana and extensive geology experience in Utah and Colorado.

Selected Project Experience

Bloomington Business Park Project, San Bernardino County, California. Senior Paleontologist (2020–present). Completed paleontological technical memorandum for Sites 3 and 4. Paleontologically sensitive geologic units: Quaternary older alluvium. Completed for CEQA compliance (County). Working closely with paleontology staff (Chris Shi and Amy Ollendorf). Client: Howard Industrial Partners.

Paleontological Sensitivity GIS Mapping Project. Senior Paleontologist (2020–present). Creating a statewide paleontological sensitivity GIS database using existing geologic maps and Society of Vertebrate Paleontology guidelines. The database will be used to determine baseline sensitivities for current and upcoming projects.

Frank R. Bowerman Landfill Phase VIIIB-1 Landfill Buttress and Liner Project, City of Irvine, Orange County, California. Field Paleontologist (2016–2020). Completed paleontological monitoring of grading and excavation areas and cataloging new fossil localities; screen-washed sediment for small-fraction fossils; prepared jacketed material in the field; and prepared paleontological monitoring report as a condition of environmental mitigation completed for the buttress and liner installation implemented for the existing landfill. Paleontologically sensitive geologic units: Sespe, Vaqueros, Topanga, and Puente Formations. Completed as Psomas employee for CEQA compliance (County). Client: Orange County Waste & Recycling.

Lincoln Bridge Multi-Modal Improvements (LA TOS 27), City of Los Angeles, Los Angeles County, California. Paleontologist (2019–2020). Prepared PIR/PER for the widening of Lincoln Boulevard from Fiji Way to Jefferson Boulevard, including replacement of the Lincoln Boulevard Bridge over Ballona Creek, and replacement of the Culver Boulevard overpass. Paleontologically sensitive geologic units: Quaternary older alluvium. Completed as Psomas employee for CEQA compliance (Caltrans). Client: City of Los Angeles.

Selected Project Experience (continued)

Maywood Mutual Water Company No. 3 Water Quality Improvements, Cities of Maywood, Bell, and Vernon, Los Angeles County, California. Paleontologist (2019). Assisted in the preparation of an IS/MND for proposed rehabilitation of an approximate 450,000-gallon welded steel tank and associated tank appurtenances; replacement of approximately 4,600 feet of pipe segment; numerous valve replacements; and multiple fire hydrant repair and replacements. Supplemental documentation also was created to follow Federal Crosscutter Regulations and California State Water Resources Control Board requirements. Paleontologically sensitive geologic units: Quaternary older alluvium. Completed as Psomas employee for CEQA (Metropolitan Water District of Southern California) compliance. Client: Maywood Mutual Water Company.

Irvine Lake Pipeline Conversion Project, City of Irvine, Orange County, California. Paleontologist (2017–2018). Assisted in the preparation of an IS/MND for the conversion of the northern segment from an untreated water pipeline to a recycled water pipeline. Also provided cross-trained monitoring. Paleontologically sensitive geologic units: Puente Formation. Completed as Psomas employee for CEQA (County) compliance. Client: Irvine Ranch Water District.

La Palma Recharge Basin, City of Anaheim, Orange County, California. Paleontologist (2015–2016). Along with a Native American representative, provided monitoring for grading of the recharge basin. Paleontologically sensitive geologic units: Quaternary older alluvium. Completed as Psomas employee for CEQA compliance (County). Client: Orange County Water District.

Merrill Avenue Brownstones Mixed-Use Development, City of Riverside, Riverside County, California. Paleontologist (2017). Assisted in the preparation of an IS/MND for the proposed mixed-use development with a total floor area of 98,608 SF and consisting of 108 dwelling units and associated amenities and an additional 1,200 SF of retail space to be located on the ground floor. In addition, the Merrill Avenue street section would be modified to provide on-street parking immediately adjacent to the project site. The IS/MND addressed impacts related to noise, vibration, pollutant emissions, and toxic emissions associated with train activity on the tracks north of the site, as well as the traffic impacts from the narrowing of Merrill Avenue and during the holiday season at the Riverside Plaza shopping center to the south. Paleontologically sensitive geologic units: Quaternary older alluvium. Completed as Psomas employee for CEQA (City) compliance. Client: Pelican Communities, LLC.

Eiko's Elephant Graveyard (EEG) Quarry, Vandenberg Air Force Base (AFB), Santa Barbara County, California. Field Crew Chief (2013–present). Completed field and lab work involving fossil specimens of Pleistocene-age giant ground sloths recovered from the quarry. Conducted paleontological research and supervised a crew of students and AFB staff volunteers for the collection of vertebrate fossils, and taphonomic and stratigraphic data. This site was discovered during a 2013 survey of fossil localities. Also gave presentations on this research to multiple groups, including youth scouts and professional scientists. Paleontologically sensitive geologic units: Quaternary older alluvium. Initial work completed as an Undergraduate Honor's Thesis and work ongoing as a volunteer with the Earth and Planetary Sciences Department of Santa Barbara City College. Client: Vandenberg AFB.

Cojo-Jalama Ranches (Bixby Ranch) Project, Unincorporated Santa Barbara County, California. Paleontology Assistant (2013). Assisted with the preparation of an EIR. Duties for this job included field identification of invertebrate and vertebrate fossils and their associated rocks; completion of surveys on remote field sites; and assessment of the paleontological significance of the study area. Melissa also created maps, diagrams, and figures and edited the final report. Paleontologically sensitive geologic units: Quaternary older alluvium, Monterey Formation, Jalama Formation. Project work completed as a RS Gray Consulting employee for CEQA (CA Coastal Commission) compliance. Client: Cojo-Jalama Ranches.

Fort Hays State University, Hays, Kansas. Graduate Teaching Assistant/Curatorial Assistant (2013–2015). Taught introductory, physical, and historical geology lab courses. Also assisted with teaching the summer field geology course, where her duties included maintaining a base camp, driving, and assisting students on geology

Selected Project Experience (continued)

projects in eastern Utah and western Colorado. Also assisted with graphic design of departmental flyers, organized departmental events, worked in the department GIS lab, and tutored students in various geology courses. As a curatorial assistant at Sternberg Museum of Natural History, digitized vertebrate and invertebrate collections databases, cataloged loans, and digitized a specimen loan document database.

MICHAEL GEORGE

Paleontological Field/Lab Technician

Education

B.S., Geology, California State University, Stanislaus, 2018

A.S., Geology, Merced Junior College, 2014

Professional Experience

2019–present, Paleontological Field/Lab Technician, Applied EarthWorks, Inc., Fresno, California

2017-present, Lead Paleontologist/Fossil Collections Manager, Fossil Discovery Center of Madera County, Chowchilla, California

2015-2017 Undergraduate Research Assistant to Dr. Julia Sankey (Paleontologist), Geology Department, CSU, Stanislaus, California

2015-2016, Fossil Preparation Assistant to Dr. Julia Sankey (Paleontologist), Geology Department, CSU, Stanislaus, California

Summary of Qualifications

Mr. George has been trained formally as a geologist who specializes in paleontology. To date, he has completed more than 100 hours of field and laboratory training in the Earth sciences and more than 100 hours of fossil preparation. He has experience measuring stratigraphic sections, describing sedimentary geologic units, creating geologic cross-sections, and writing field reports. He completed a geological field school at California State University (CSU), Stanislaus in 2018 which provided him with experience in field mapping and exposure to the geology of the Central Valley, Sierra Nevada Mountains, Mojave Desert, Peninsular Ranges, and Coast Ranges. Mr. George also has basic knowledge of GPS equipment, ArcGIS v.10.4, and AutoCAD v.16.2.

Project Experience

California High-Speed Rail Construction Package 1, Madera and Fresno Counties, California. Paleontological Field Technician (2020-present). Æ is providing multi-year paleontological monitoring during construction of the 32-mile segment from Avenue 19 in Madera County to East American Avenue in Fresno County. The segment includes 12 grade separations, two viaducts, one tunnel, and a major crossing over the San Joaquin River. Completing paleontological resource monitoring and geologic data collecting during construction. Paleontologically sensitive geologic units: undifferentiated Modesto and post-Modesto Holocene-age sediment; Modesto, Riverbank, Turlock Lake, Tulare, Laguna, and Mehrten Formations; North Merced Gravel; and Pleistocene non-marine sediment. Completing for CEQA compliance (California High-Speed Rail Authority) and NEPA compliance (Federal Railroad Administration). Client: Parsons.

Fairmead Landfill Expansion, City of Chowchilla, Madera County, California. Paleontological Field Technician (2019). Completed paleontological resource monitoring and geologic data collecting during construction for 23-acre landfill expansion. Completed for CEQA compliance (County). Paleontologically sensitive geologic units: Turlock Lake Formation. Client: County of Madera.

Fossil Collection from the Fairmead Landfill Locality at the Fossil Discovery Center of Madera County, City of Chowchilla, Madera County, California. Lead Paleontologist/Fossil Collections Manager (2017-present). Cataloged, prepared, and identified fossils collected during construction of the landfill in 1993.

Investigations in the Turlock Lake Formation near the Town of La Grange, Stanislaus County, California. Undergraduate Research Assistant (2015-2017). Assisted Dr. Julia Sankey (CSU Stanislaus geology faculty) by writing research papers and conducting fossil analysis regarding the flora and fauna of the early Pliocene-age Turlock Lake Formation.

Project Experience (continued)

Fossil Collection from the Fairmead Landfill Locality at the University of California Museum of Paleontology (UCMP), Berkeley, California. Fossil Preparation Assistant (2015-2016). Assisted Dr. Julia Sankey (CSU Stanislaus geology faculty) by completing fossil preparation on various fossils in the UCMP Collection recovered during construction of the landfill in 1993.

1. INTRODUCTION

1.1. BACKGROUND

The Tulare Irrigation District (TID), the Consolidated Peoples Ditch Company (CPDC) and the Visalia & Kaweah Water Company (VKWC) are joint owners (**Owners**) of approximately 500 acres of land adjacent to the Kaweah and St. Johns Rivers in Tulare County, California, commonly referred to as the McKay Point property (**Site**). The Site location is shown in **Figures 1 and 2**.

The Owners propose to develop approximately 200 acres of the total 500-acre McKay Point property on the north side of the divergence of the Kaweah and St. Johns Rivers into a surface water storage and reregulation Reservoir (**Reservoir**).

West Coast Aggregate (WCA) will excavate the Reservoir in accordance with plans and specifications to be developed (**Excavation**). WCA intends to process the resulting aggregate materials (i.e., rock, sand, and gravel) within the Site (**Figures 2 and 3**). WCA would then sell the processed materials.

The Excavation of a pit that will be used for the construction of the reservoir and the Construction / Operation of the Reservoir are the phases collectively referred to as the **Project**. The Reservoir phase of the Project will entail storage and release of surface water only. To minimize groundwater from entering the Excavation and the Reservoir, a subsurface groundwater barrier system (**Slurry Wall**) will be installed around the perimeter to minimize groundwater inflow. While some amount of groundwater inflow will occur during periods when the Reservoir is not full, this inflow will be pumped out and returned to nearby groundwater. The Slurry Wall will also minimize stored water losses from the Reservoir to groundwater when it is full.

The potential impacts of the Project are evaluated from a geotechnical engineering and geology perspective, based on the California Environmental Quality Act (**CEQA**). This report includes an evaluation of impacts related to the Excavation, Reservoir, and Slurry Wall components of the Project. Impact analyses for these elements are based on computer models and other evaluation methods to address the stability of temporary and permanent slopes, dewatering considerations, regional and local geologic conditions, and seismicity.

This report is organized to provide technical input for CEQA document preparation. It includes sections on the environmental setting, general Site conditions, available subsurface information on soils and groundwater, regional and local geology, seismicity, and faulting. The impact of the proposed project on the current conditions are then evaluated, based on our engineering analyses, professional opinions, and our geotechnical engineering related construction know-how. This information is then applied to the proposed development concept and its likely construction scenarios applicable to the different stages of its development. The report concludes by addressing each CEQA significance criteria related to geology and soils. Figures are provided at the end of the report. Further technical details are presented in the Appendices.

DRAFT

1.2. PROJECT OVERVIEW

The overview of the Project and the geology and soils conditions of the Site is based on our review of documents provided by TID (**Applicant**) or their representatives and consultants, as well as publicly available data and reports. The reviewed documents provide information on geotechnical conditions (BSK, 2011) and groundwater conditions (SLR, 2021; Schmidt, 2012; SES, 2012). Information from other documents listed in the References have also been reviewed and evaluated as part of this assessment.

The Owners propose to construct and operate the Reservoir on the north side of the divergence of the Lower Kaweah and St. Johns Rivers near McKay Point in Tulare County, California (**Figures 2 and 3**).

The Reservoir capacity is expected to be 4,600-acre feet. Its depth is expected to range from approximately 60 to 80 feet. The material excavated during construction will consist of resource-grade aggregate and will be processed at the WCA facility to be setup within the excavation area.

The Excavation and the Reservoir will extend vertically below the groundwater levels. The Applicant will implement dry mining methods to recover the aggregate and to create the Reservoir. Dewatering of the excavated area will be conducted, as necessary to allow for dry mining techniques.

Upon completion of the Reservoir excavation, water will be diverted from the Kaweah River and stored in the Reservoir. When completed, the Reservoir will serve as a surface water storage/re-regulation facility.

DRAFT

2. ENVIRONMENTAL SETTING

2.1. REGIONAL SETTING

The Site is in California's Central Valley near the western boundary in the foothills of the Sierra Nevada Geomorphic Province of California. The southern San Joaquin Valley bounds this part of the Sierra Nevada to the west and the Great Basin to the east. The Central Valley is one of the most productive agricultural regions in the world.

This region is underlain by young and old unconsolidated fluvial deposits (sandy and silty gravels, clayey sand and cobbles, and silty and clayey sands) that originated from the nearby Sierra-Nevada Mountains. These moderately to highly permeable silts, sands and gravels generally extend to depths of several hundred feet or more.

The Site vicinity is drained by the Kaweah River and by the St. Johns River, which drain ultimately to the Tulare Lakebed in the southern end of the San Joaquin Valley. In 1962, Lake Kaweah, located upstream from the Site, was created by the construction of Terminus Dam on the Kaweah River. Renovations of this dam in 2004 significantly reduced flooding at the Site and the surrounding area.

2.2. LOCAL SETTING

The Site is currently undeveloped and has been used for cattle grazing under lease arrangements. Most of the Site is vegetated with native grasses. Immediately to the north is CEMEX's Lemon Cove Facility. The Kaweah River Rock aggregate mining and processing facility is located immediately to the west. Adjacent lands to the south and east are used intensively for agricultural and, to a limited extent, for rural residential purposes.

The surface soil at the Site primarily consists of loose, medium-grained sand with occasional gravel and cobbles. Site surface drainage east of the river split is generally to the south and southeast toward the Kaweah River and west of the River split generally to the south and southwest toward the St. Johns River. The Site elevation slopes from approximately 472 feet above mean sea level (msl) at the northeastern end of the property, downward to approximately 454 feet above msl at the southwestern end.

DRAFT

3. BASELINE GEOLOGIC AND SOIL CONDITIONS

3.1. REGIONAL AND LOCAL GEOLOGY

The Central Valley has been formed by millions of years of deposition of Quaternary sediments derived from the uplifted Sierra Nevada and Coast Ranges, which bound the Central Valley on its east and west (**Figure 1**). The Central Valley is an alluvial plain approximately 50 miles wide (E-W) and 400 miles long (N-S). Sediments have been deposited into the Central Valley for the last 160 million years and can be thousands of feet thick in certain areas.

Numerous rivers and streams originating in the higher elevations of the Sierra Nevada, including the Kaweah River, flow westward into the Central Valley, depositing Quaternary alluvial sediments upon which the Site is located (Mathews and Burnett, 1965). This alluvium is underlain by a sequence of marine and continental sedimentary rocks consisting of shale, siltstone, and sandstone and locally granitic rock underlying the alluvium at the Site. Beneath the sedimentary rocks lie an impermeable basement complex of igneous and metamorphic rocks that extend as deep as 13,000 feet bgs. These basement rocks are a subsurface extension of the same rocks that occur in the Sierra Nevada (Faunt et al., 2009). A geologic map of the region is included as **Figure 4**.

The subsurface stratigraphy of the site has been previously explored, evaluated, and reported in several studies, as cited in the References. Excerpts from available documents is reproduced in Appendix A. A total of 6 soil borings were conducted at the Site in November 2011 (BSK, 2011). Based on these borings and hydrogeologic interpretations by Schmidt (2012), the thickness of fluvial sediments within the Reservoir area ranges between approximately 40 and 100 feet bgs. Alluvial deposits at the Site consist of sand that is about 15-20 feet thick. Luhrdorff and Scalmanini (1995) describe these upper alluvial sediments as Younger Alluvium. Below this, cobbles, boulders with sand, silt, and clay are common. These deposits extended to a depth of about 40 feet bgs on the eastern portion of the Site, and to about 100 feet bgs on the western portion. Luhrdorff and Scalmanini (1995) describe these lower alluvial sediments as Older Alluvium.

Geologic cross-sections for the Site have been prepared previously and included in **Attachment A** (Available Subsurface Information). The SLR geologic cross-sections depict a generalized view of the subsurface strata in the E-W and N-S directions across the Site (Attachment A). These generalized depictions are suitable for planning-level studies but are not intended for design, which will require additional subsurface explorations at the Site. The profiles shown are based on information at discrete locations and depths and actual subsurface condition variations across the site will vary. Section 5 of this report describes the subsurface stratigraphy in further detail in terms of engineering characteristics of the materials, for use in slope stability and slurry wall evaluation purposes.

The bedrock encountered is likely Mesozoic granitic rocks of the Sierra-Nevada batholith, which has been mapped as outcrops at higher elevations within about a mile to the north, east, and south of Site. The surrounding hill and outcrop features suggest bedrock could get deeper to the west and southwest, towards the valley. Available borings encountered bedrock in the easterly portion of the site, at approximately 77 ft bgs. In the westerly portion of the site, bedrock was not

encountered within the explored depths of about 90 feet bgs, indicating it would be deeper than that.

Available photos of the bedrock cores indicate hard, granitic rock where it was encountered, as shown in **Figure 5**. Weathered or decomposed bedrock zones and some discontinuous intrusions of clay or clayey sand may also exist. There is an approximate 10- to 15-foot thick mantle of very dense silty, clayey sand overlying the bedrock. This layer generally follows the top of rock, likewise dipping down to the west. Both the bedrock and the overlying mantle of very dense soils are expected to be less pervious than the overlying alluvial materials and therefore provide a good opportunity to key-in a slurry wall to achieve the desired hydraulic barrier.

3.2. GROUNDWATER

Regionally, groundwater flows generally toward the west from the recharge areas of the Sierra Nevada mountains to the center of the valley (SLR, 2021). Groundwater elevations in the region vary from around 460 feet amsl near the Site, to around 250 ft amsl near the City of Visalia (DWR, 2014). Groundwater is pumped extensively in the area for agricultural and urban uses.

The Site is in the Kaweah Subbasin, within the Tulare Lake Hydrologic Region (DWR, 2003). The long-term water level measurements for wells in the immediate Site area indicate relatively stable water levels, with a slight downward trend in recent years. Seasonal water level fluctuations in the Site vicinity have generally varied by less than 20 feet for the last 50 years (Fugro, 2007).

Based on available soil borings within the Site, the depth to groundwater ranges from 7 to 20 feet bgs. Further information on known groundwater levels and trends in and around the vicinity of the Site are provided in the Hydrology Report (SLR, 2021). The groundwater levels will fluctuate over time, with seasonal variations, and other factors.

3.3. FAULTS AND SEISMICITY

The Site is located in an area of relatively moderate seismicity for California. This area is centrally located between two zones of significant seismicity: the Eastern Sierra Seismic Zone, located approximately 50 miles to the east, and the San Andreas Fault Zone located approximately 80 miles to the west. There are no active or potentially active faults within 30 miles of the Site. A map of active faults in the area is provided in **Figure 6**. A list of active faults and their respective distances to the Site is provided in **Table 1**.

The nearest potentially active fault is the Independence Fault located approximately 48 miles east. This fault is part of the Owens Valley Fault Zone which is capable of producing large earthquakes, such as the Owens Valley Earthquake of 1872, which is estimated to have been a magnitude 7.4 event.

DRAFT

Table 1. Active Faults in the Area

Source	Distance (km)		Deterministic Magnitude	Fault Mechanism	Dip Angle
	(km)	(miles)			
Independence	77.0	47.9	7.2	Normal	50
Birch Creek	89.6	55.7	6.6	Normal	50

Note: Data obtained from EZ-FRISK, Source: USGS 2008

Earthquakes on active or potentially active faults, depending on magnitude and distance from the Site, can produce a range of ground-shaking intensities. Although there are no active faults within the immediate vicinity of the Site, distant earthquakes have historically caused strong ground-motion in the Site vicinity. The most significant example is perhaps the aforementioned Owens Valley Earthquake which occurred in March of 1872. The epicenter was approximately 56 miles east of the Site, but this earthquake is estimated to have caused strong (Mercalli Intensity, MM VI) shaking intensities in the area (Hough and Hutton, 2008).

The current state of practice to determine the seismic hazard at a given location is to perform a Probabilistic Seismic Hazard Analysis (PSHA), from which the probability of exceeding a specific ground motion parameter (typically the Peak Ground Acceleration (PGA)) within a time period is calculated. Typically evaluated sets of probability and time-period are seismic events with 10% probability of occurrence in 50 years, and those with 2% probability of occurrence in 50 years. These probabilities correspond to return periods of 475 and 2,475 years respectively. The probability of exceedance of the ground motion parameter is calculated based on the following input parameters:

- Seismic sources that can generate ground shaking at the Site;
- Characteristics of each seismic source: length, rate of ruptures, maximum magnitude, earthquake occurrence;
- The ground motion parameter versus distance attenuation relationships appropriate for each seismic source and Site conditions.

Seismic sources include active and potentially active faults (or fault zones) in the vicinity of the Site. Active faults are those that have experienced displacement within Holocene time (the past

DRAFT

11,000 years) whereas potentially active faults are those that have experienced displacement within Quaternary times (approximately past 1.6 million years).

The United States Geological Survey (USGS) website provides tools that are commonly used to identify the active and potentially active faults that could generate ground shaking at sites located in the United States. These tools are also used to perform the probabilistic seismic hazard analysis to estimate the level of ground shaking a given site may experience. These tools are based on the user defined location coordinates of the site, and a user defined radius of influence selected based on the general level of seismicity of the site. A typical radius used for such evaluations is on the order of 100 km (67 miles).

The peak ground acceleration (PGA) was estimated using the USGS seismic hazard analysis calculator with the following parameters:

- Exceedance Probability of 10% in 50 years (return period of 475 years) and 2% in 50 years (return period of 2,475 years);
- Shear velocity of the deposit over the top 30 m (100 ft) of 450 m/s (1,355 ft/s) corresponding to a sandy gravelly deposit; and
- Latitude and longitude of 36.4° and -119.04° respectively.

The maximum PGAs for the Site were estimated to be 0.1 g for a return period of 475 years and 0.2 g for a return period of 2,475 years. PSHA outputs are included as **Attachment B**. It is noted that these PGA values are not equivalent to the seismic coefficient used in the pseudostatic slope stability analysis. Guidelines for Evaluating and Mitigating Seismic Hazards in California, SP-117 (California Geological Survey, 2008) states PGA should not be used as a pseudostatic coefficient, as that would result in overly conservative factor of safety (FS). The generally accepted value for pseudostatic coefficient is 0.1, with an acceptable FS of the order of 1.1.

The Site may be subjected to moderate to strong shaking based on correlations between PGA and the Modified Mercalli Intensity chart relating perceived shaking to PGA (Trifunac and Brady, 1975), provided by the USGS (**Table 2**).

Table 2. Modified Mercalli Intensity and Peak Ground Acceleration

PERCEIVED SHAKING	NOT FELT	WEAK	LIGHT	MODERATE	STRONG	VERY STRONG	SEVERE	VIOLENT	EXTREME
Potential Damage	None	None	None	Very light	Light	Moderate	Moderate-Heavy	Heavy	Very heavy
Peak Acc (% g)	<0.17	0.17-1.4	1.4-3.9	3.9-9.2	9.2-18	18-34	34-65	65-124	>124

DRAFT

3.4. SOILS AND EROSION

The baseline conditions at the Site is essentially flat, sloping gently downward to the south and west. The Site is undeveloped, so erosion is minimal and there are no known slope failures at the Site. Soil erosion is limited to the relatively steep slopes facing the Kaweah River at the southern portion of the Site, and select portions of the few man-made dirt roads at the Site. Other than these small areas, the Site is almost entirely covered with vegetation.

The upper 5-10 feet of the onsite soil consists of poorly-graded sand with increasing gravel at depth. Below 15 feet, the soil consists of sandy and silty gravel of increasing size and rounded cobbles to approximately 30 to 35 feet bgs. At greater depth, silty clayey sand and silty clay/low plasticity clay are predominant before bedrock is encountered (BSK, 2011).

DRAFT

4. PROJECT SETTING

4.1. INTRODUCTION

The project consists of the following key components / stages of work:

- Installation of a perimeter slurry wall system to reduce water inflow and initial limited excavation until the complete slurry wall system is in service;

- Excavation of the pit that will be used for reservoir with temporary slopes, and production of aggregate;

- Placement of permanent slopes over the excavation slopes, and the construction of the Reservoir.

Each of these project phases are discussed in the following sections. The existing and proposed topography of the Site are shown in **Figure 7**.

4.2. SLURRY WALL AND INITIAL LIMITED EXCAVATION

During the initial limited excavation and material processing stage, an impermeable slurry wall will be constructed around the exaction area to limit the amount of groundwater flow into the excavation as future excavation progresses below the water table. This initial, relatively shallow excavation area is estimated to be approximately sufficient for a 6-month supply of processed material, while the slurry wall is constructed.

The slurry wall will be designed by a qualified professional and constructed by a qualified contractor with experience in installing similar facilities. Construction would include the following facilities:

- A perimeter access road that would also serve as a leveling surface for the construction of the slurry wall. The road would vary in width from approximately 30 to 50 feet and be built on fill up to 8 foot in height.

- An approximately 60- to 90-foot-deep slurry wall surrounding the excavation/Reservoir area. Its actual depth will be determined during design and verified during construction based on subsurface information, to provide the required reduction in groundwater inflow. As shown on **Figure 3**, the slurry wall would be constructed through the perimeter road and capped off with a durable gravel layer

- An approximately 5-foot-deep water infiltration trench along the northern border of the ultimate Reservoir area.

A conceptual layout of the project elements and on-site facilities applicable to this stage of work is shown in **Figure 8**. A typical section showing the Slurry Wall, slope, access road, and the infiltration trench is provided in **Figure 9**.

DRAFT

After completion of the slurry wall, the following facilities would be demobilized from the site:

- Vehicle and equipment parking areas for the slurry wall operations.
- Fill material stockpiles.
- Equipment storage facilities.
- The bentonite slurry mixing pond(s) (see further discussion below on the slurry wall construction activities).
- The slurry wall backfill mixing area, which would be repositioned as the slurry wall construction progresses, to be in close proximity of the segment being excavated.

The general sequence of slurry wall construction activities would include:

- Surface clearing, grading, and filling to create a sufficiently long section of the perimeter road.
- Excavation of the slurry wall trench (**Figure 9**) through the road. Grading of the road would also provide a relatively level surface to install the slurry wall from and contain the slurry. The trench would be excavated to its full depth and then extended in length.
- Filling the trench with a bentonite slurry (bentonite clay and water mix) to support the sides of the excavation and prevent caving of the trench. The bentonite slurry would be pre-mixed in slurry mixing pond(s) and pumped by pipeline into the excavated trench.
- The soils that are excavated from the trench would be placed in a nearby slurry wall backfill mixing area, for use in preparing the backfill. If the excavated materials are unsuitable, they would be hauled to the WCA operations area for processing, as appropriate. If additional suitable materials are needed, they would be obtained from the WCA operations or imported from off-site.
- As the trench is extended in length, backfilling would commence. The backfill mix would be prepared on-site, in the backfill mixing area(s). Backfill would typically include granular soils, mixed with bentonite, cement (if needed according to design), and water, to create a low permeability material of desired engineering properties. The mix design would be established based on various studies and tests which would be conducted during the design phase.
- Once mixed, the backfill would be pushed into the trench by a dozer or equivalent, from the narrow end of the trench at the opposite end of the trench that is being excavated. The backfill materials would form a slope inside the trench and displace the bentonite slurry. The operation would march in a similar manner, going around the perimeter of the Site. The backfill material in the trench would eventually consolidate and form a low permeability wall.

DRAFT

- The length of the slurry wall is approximately 13,400 feet. Its width would be about 3 feet. It could be wider, depending on the design. If the excavation depth is more in some segments of the wall, the trench width and/or the mix design may be adjusted according to design. Generally, using a uniform width and mix design may be preferred.

- As the wall is completed and gravel cap is placed over the top of the backfilled trench, it will form part of the perimeter road as shown in **Figure 9**.

- A safety berm would be constructed along the inside edge of the road, facing the excavation area.

It should be noted the above discussion is for illustration purposes and actual construction techniques will vary based on the approved means and methods the contractor selects, and possible future technology advances in slurry wall construction.

4.3. EXCAVATION

Excavation is expected to proceed over an estimated period of 15 to 23 years, at an average rate of approximately 920,000 gross tons per year of silts, sands, and gravels. This rate will vary in any given year.

Excavation will be done by West Coast Aggregate (WCA). WCA would also receive, stockpile, and recycle concrete construction debris materials. A conceptual depiction of the anticipated WCA operations is shown in **Figure 8** and a longitudinal cross-section of the reservoir excavation progress over time is shown in **Figure 10**.

The excavation equipment, the material processing plant, and the associated settling pond would be located within the pit footprint. Different areas of the excavation pit bottom would be lowered in stages and the process equipment would be relocated as appropriate. As the excavation of the pit is deepened, an access ramp would be constructed in the excavated slope, as shown in **Figure 11**.

The excavated materials would be processed to produce a specified range of granular construction materials for sale. This phase of the project would include the following key facilities:

- A security fence that surrounds the excavation and eventual Reservoir area.

- A controlled access gate along the west side of the excavation area.

- A scale hose near the entrance gate to provide for weighing recycle materials coming into the site and construction materials being shipped from the site.

- A haul truck unloading and loading area.

- Portable crusher and recycle plant.

- Portable diesel fuel tank for on-site refueling (4,000 gallon).

DRAFT

- An aggregated production (wash/screen) plant and a crushing/ recycling plant.
- A stockpile area, or areas.
- A slurry wall
- A settling pond for clarifying/recycling process and wash water for reuse.

As shown on **Figure 7**, the excavations would occur within the footprint of the Project site. The size and depth of the excavated area would vary over time.

The excavation slope will be of the order of 1.5H: 1V (1.5 Horizontal to 1 Vertical), though other gradients and/or benched slope configurations may be developed during design, based on further geotechnical investigations, analyses, and site-specific conditions exposed during excavation. Section 5 of this report addresses the currently estimated safety factors for different scenarios.

The facilities and their layout shown on **Figures 8 or 11** are for illustrative purposes only. WCA and the design team will refine and adjust these elements as necessary, at the start of the excavation phase. All operations facilities would be kept within the excavation/ pit footprint.

During excavation phase, the area would be dewatered by using wells, trenches, or sumps according to field conditions, as described in Section 5.3.2.1. The dewatering system would drawdown the water table to near or below the excavation floor. The groundwater extraction rates would initially be minimal and increase to their maximum, as the excavation is depended to the maximum depth. The planning-level estimates of dewatering rates and other pertinent information are provided in the Hydrology Report (SLR, 2021).

The water extracted to dewater the excavation would be pumped to the northern edge of the excavation and re-injected into a gravel-filled infiltration gallery along and outside of the northern border of the slurry wall as shown on **Figures 8 and 9**.

The estimated material balance from Excavation is as shown in **Table 3**.

Table 3. Estimated Material Balance from Excavation

ITEM	ESTIMATED QUANTITY	REMARKS
Material Generated from Excavation	16.4 million tons (11,049,300 cy)	1.5H:1V Slope
Exported as product	11.5 million tons	
Use for on-site fill	2.4 million tons	3H: 1V Slope
Use for Road Construction	0.1 million tons	
Use for Slurry Wall	0.2 million tons	

DRAFT

Waste and Shrinkage	2.2 million tons	

4.4. RESERVOIR

The final stage of the excavation is the earthwork required to provide suitable conditions for the construction of the Reservoir. The preparation of the pit for the reservoir is referred to as "earthwork". After the excavation phase is finished, including the earthwork for preparation of the reservoir, the reservoir itself will be constructed. These stages are described below:

- Earthwork: Backfilling of the excavation slopes to flatten them from 1.5H: 1V to 3H:1V. This is shown in **Figures 9**, **10 and 11**. The backfill would be of suitable materials that has both sufficient strength and is relatively free draining. It would be constructed from the bottom up in compacted layers of suitable thickness. The Excavation slopes will be benched, and the reservoir slope fill would be keyed into the wedge of native slope materials in front of the Slurry Wall. If needed, additional slanted chimney drain zones can be provided while the slope fill is being placed from the bottom up. **Figure 11** shows the first layer of the backfill being placed along the east side of the excavation.

- Reservoir: The construction of the Reservoir to include the channels, pumps, pipelines, power supply system, and the monitoring system. A conceptual plan of the Reservoir is shown in **Figure 12**.

DRAFT

5. GEOTECHNICAL STABILITY ANALYSIS

5.1. INTRODUCTION

This section describes the geotechnical objectives in order to achieve the desired Excavation and Reservoir performance. It includes a discussion of the initial excavation and final construction of the Reservoir, the design of the excavation, slurry wall and the final Reservoir operational condition. It provides the planning level technical basis to demonstrate the feasibility of the project form a slope stability and the slurry wall cutoff points of view.

5.2. MATERIAL PROPERTIES

Available subsurface information at the site consists of six (6) borings B-1 through B-6, performed by BSK Associates in November 2011. These borings provide descriptions of the subsurface strata, which have been generalized into five strata as described below and used in the slope stability modeling.

5.2.1. MOIST SAND

In the available borings, this light colored, moist, SAND layer generally exists from the ground surface down to depths ranging from 7 to 15 feet below ground surface (bgs). It has a typical thickness of 12 feet. It is expected to have little to no cohesion and is expected to be medium-dense. The bottom of this layer is at or slightly above the groundwater levels noted in the borings.

In the slope stability analysis material layers as depicted in the output figures (slope stability profiles) provided in **Attachment C**, this layer is shown in yellow.

5.2.2. WET SAND, GRAVEL, COBBLES

This is a water-bearing layer of olive-gray colored SAND, GRAVEL, COBBLES, with an approximate thickness ranging from 15 to 25 feet. In the easterly portion of the site (Borings B-3, B-4, B-5, B-6), groundwater was noted at the top of or close to the top of this strata. In the easterly portion of the site (Borings B-1 and B-2), groundwater is noted to gradually dip to the mid-depth or slightly below the mid-depth of this layer. This stratum is also expected to have little or no cohesion, but with higher friction angles than the sandy layer above it, due to the presence of gravel and cobbles.

In the slope stability profiles, this layer is shown in gray.

5.2.3. WET CLAYEY SAND, GRAVEL, COBBLES

The top of this yellow-brown to olive-brown, wet, CLAYEY SAND, GRAVEL, COBBLE layer is generally at approximate elevation 430 feet MSL (Borings B-1 through B-5). It rises to approximate elevation 440 feet MSL near the east end of the site (Boring B-6). The thickness of this layer is of the order of 20 to 50 feet, generally increasing to the west, as the underlying

DRAFT

bedrock and the dense soil mantle over the bedrock dip down to the west. This layer is expected to have both cohesion due to its clay content, and relatively high friction angle due to its sand, gravel, and cobble components.

In the slope stability profiles, this layer is shown in orange.

5.2.4. DENSE SILTY CLAYEY SAND

This layer consists of mixtures of gray, olive-gray, bluish-gray, olive-brown colored SILTY CLAYEY SAND. It is described as moist to dry, indicating that it is a 'tight' formation since it is dry despite being below groundwater. In some zones, the boring logs note hard to very hard drilling. This layer is expected to have a higher strength, with properties of a stiffer cohesive material intermixed with frictional material. This layer generally tends to follow the bedrock surface as a mantle with thickness of 20 feet or more. Towards the west end of the site, bedrock was not encountered at a depth of 90 feet. The thickness of this layer may increase towards the west.

In the slope stability profiles, this layer is shown in purple.

5.2.5. GRANITIC BEDROCK

Dry, granitic bedrock was encountered at its shallowest, at elevation 400 feet MSL or 67 feet bgs in the easterly quadrant of the site (B-4). Based on an approximate extension of the bedrock surface profile to the west, the top of bedrock can be estimated to be in the range of 340 to 360 feet MSL, or 100 to 120 feet bgs, under the westerly portions of the site. Borings B-1 and B-2 in this area did not encounter bedrock withing their maximum exploration depths of 90 feet bgs. For slope stability modeling purposes, bedrock has been assigned a very high strength and is not considered to be an influencing factor in the stability calculations.

In the slope stability profiles, this layer is shown in green.

The man-placed materials related to our analysis include the following:

5.2.6. SLURRY WALL

This is expected to be a low-permeability barrier consisting of either a soil-bentonite mix or a soil-cement-bentonite mix, depending on the design details. Two types of walls have been conceptually evaluated here: one with an approximate equivalent cohesion value of 400 psf, referred to as the 'low strength wall; and another with an approximate equivalent cohesion value of about 2,000 psf, referred to as the 'moderate strength wall'. In practice, an increase in the shear resistance values for the slurry wall would be achieved by adjusting the cement content of the slurry mix.

5.2.7. COMPACTED BACKFILL

Backfill to create the 3 to 1 reservoir slope is expected to consist of excavated on-site materials which will likely be a blend of granular and fine materials obtained from the pit. For stability

DRAFT

purposes, the excavation slope would be benched and the backfill material will be placed against the slope in horizontal lifts. The backfill material would generally be compacted to 90% relative compaction. Based on experience, compacted fill consisting of a blend of granular and fine materials is assumed to have strength parameters of 200 psf cohesion and 33 degrees friction angle.

5.2.8. SUMMARY

The material parameters relevant to the slope stability analysis are listed in **Table 4**.

Laboratory test data is not available but presumed soil strength parameters can reasonably be assigned based on the available descriptions and professional judgement. The values assigned to each generalized strata as well as the future backfill and slurry wall materials are as summarized in **Table 4**. The permeability values listed in Table 4 are the same as those used in the Hydrology Study (SLR, 2021).

During design, additional geotechnical investigations and laboratory testing would be performed to confirm or modify these parameters as appropriate.

Table 4. Material Properties for Slope Stability Analysis

Material	Unit Weight γ (lbs/ft^3)	Cohesion c (psf)	Friction Angle Φ (°)	Permeability (ft/s)
SAND (SP)	115	0	35	5E-05 (1.5E-3)
SAND, GRAVEL, COBBLES (GP)	125	0	38	7E-04 (2E-2)
CLAYEY SAND, GRAVEL, COBBLES (SC/SM)	120	200	36	2E-06 (6E-5)
SILTY CLAYEY SAND (SC/CL)	120	400	28	5E-08 (1.5E-6)
GRANITIC BEDROCK	135	"INFINITE" STRENGTH		3E-06 (9E-5)
SLURRY WALL	130	varies	0	3E-11 9E-10
COMPACTED BACKFILL	120	200	33	2E-06 (6E-5)

DRAFT

5.3. SLOPE STABILITY ANALYSIS

5.3.1. LIMIT EQUILIBRIUM METHOD

Slope stability analysis has been performed using the Slide2 geotechnical software by RocScience. Slide2 is a two-dimensional limit equilibrium slope stability analysis program for estimating the slope Factor of Safety (FS) by various methods of slices. Circular surfaces were used in the analyses to identify the critical failure surface having the lowest FS for each assumed scenario.

5.3.2. EXCAVATION SLOPE STABILITY

This portion of the evaluation pertains only to the Excavation conditions until permanent reservoir slopes are constructed at a shallower gradient. Throughout the duration of excavation, dewatering systems will be in place to allow safe operation inside the pit. This requires a dewatering system capable of maintaining the groundwater water levels at or below the lowest excavation level in the pit, as excavation progresses. This would be accomplished by the combination of the perimeter slurry wall outside and interior dewatering systems inside the pit. The critical slope condition would be at the maximum excavation depth.

The desired excavation slopes would generally be targeted to achieve the steepest safe gradient. For most applications, this would be in the range of 1.5H: 1V to 1H: 1V. Depending on site-specific conditions and the localized variations in the exposed conditions, various measures are then implemented as excavation proceeds. Some of these measures may include varying the slope gradients, using benches, providing additional drainage and dewatering systems, and if needed, installing additional structural support systems.

Our analysis aimed to evaluate the feasibility of the project based on the soil parameters summarized in Section 5.2.8, without relying on additional stabilizing measures such as benches. Further evaluation and verification of these parameters will be undertaken during design and additional safeguards would be implemented during construction to address the specific conditions.

A generally acceptable FS value for temporary excavation slopes is of the order of 1.25. For relatively longer temporary excavation durations involved here, an additional margin may be desirable, though not mandated.

5.3.2.1. Dewatering Scenarios

For the fully excavated condition, the groundwater levels between the toe of the excavation slopes and front of the slurry wall system would depend on the type and location of the dewatering systems to be used, as well as the slurry wall properties, the permeability of the materials beneath the slurry wall, and the base of the excavation. The assumed permeability values based on generalized subsurface material types are as provided in Table 4. The slurry wall configuration is

DRAFT

as shown in the various slope stability outputs. During design and construction, further details and verification would take place.

For our evaluation, the dewatering system effectiveness between the toe of slope and the slurry wall has been assumed in three categories. In all cases, the dewatering would have to bring the groundwater levels to no higher than the toe of slope. For groundwater levels projected under the slope, three different conditions have been presumed. These are shown in the output figures of Attachment C, as part of the different slope stability analysis scenarios. From a typical construction practice point of view, these three dewatering levels may consist of the following methods:

- **Dewatering by Wells:** Groundwater assumed at or below the bottom of the excavation level between the toe of slope and the front of the slurry wall;
- **Dewatering by Continuous Trenches at the Base and Perimeter of the Excavation:** Groundwater assumed to rise from the toe of slope to + 10 feet at the front face of the slurry wall;
- **Dewatering by Intermittent Sumps:** Groundwater assumed to rise from the toe of slope to + 20 feet at the front face of the slurry wall.

The nomenclature used here for differing categories of dewatering aggressiveness is only intended as a descriptive tool, it does not to imply the application of a specific dewatering system. The suitability and the details of any dewatering system would be developed during design and construction.

5.3.2.2. Slope Gradient Scenarios

For each of these three dewatering categories, three different slope gradients have been evaluated, for a total of nine (9) scenarios. The results of these scenarios are briefly described below and summarized in **Table 5.**

- **1.5H: 1V Slope:** The estimated FS for an excavation slope of 1.5H: 1V is satisfactory for each of the dewatering scenarios considered. The FS values range from 1.4 (with trench or sump dewatering) to 1.5 (with well dewatering). A 1H: 1V slope gradient provides an additional margin above the minimum 1.25 FS value for each of the scenarios analyzed.
- **1.25H: 1V Slope:** The estimated FS for an excavation slope of 1.25H: 1V is adequate with trench or sump dewatering. An added margin can be achieved if a more aggressive dewatering well system is used. It may be possible to achieve higher FS values with this slope with other dewatering methods, depending on the results of further explorations, additional field and laboratory tests, and refinements that can be made during design and construction.
- **1H: 1V Slope:** The estimated FS values for an excavation slope of 1H: 1V range from 1.1 (with sump dewatering) to 1.2 (with trench or well dewatering). These findings may vary depending on the results of further studies. Unless additional studies indicate otherwise, a 1H: 1V excavation gradient is not considered to be suitable under the current assumptions.

DRAFT

5.3.2.3. Summary oof Excavation Slope Stability Scenarios

The estimated Factor of Safety (FS) for different excavation slope scenarios is summarized in Table 5.

Table 5. Estimated Factor of Safety for Different Excavation Scenarios

Excavation Slope Gradient	Condition Analyzed		
	Excavation dewatered from toe of slope to slurry wall	Excavation dewatered from toe of slope to +10 feet at slurry wall	Excavation dewatered from toe of slope to +20 feet at slurry wall
1.5H: 1V (33°)	1.5	1.4	1.4
1.25H: 1V (39°)	1.4	1.3	1.3
1H: 1V (45°)	1.2	1.2	1.1

5.3.3. RESERVOIR SLOPE STABILITY

Upon completion of excavation, the cut slopes will be backfilled to a permanent gradient of 3H: 1V to use the facility as a reservoir. The reservoir will be subject to various cycles of filling and emptying. The results of the slope stability analysis for this long-term use condition are summarized in **Table 6.**

The analysis for reservoir slopes have included steady state, rapid drawdown, and seismic (pseudostatic) conditions. A commonly used dynamic slope stability analysis method is pseudostatic analysis. This method applies a simulated equivalent acceleration acting on the mass of a potential slide mass, using limit equilibrium analysis methods. The ground motion parameter used in a Pseudostatic analysis is referred to as the seismic coefficient “k”, which is different than the peak ground acceleration values.

Steady State:

Steady state seepage conditions were incorporated in the model using the groundwater boundary conditions for the final configuration, using the estimated hydraulic conductivities of subsurface layers and the properties of the slurry wall cutoff system.

Rapid Drawdown:

The rapid drawdown conditions are applicable when the reservoir is emptied. Emptying the reservoirs is expected to occur over approximately 2 weeks which would allow some of the water pressure in the slope to dissipate. However, the analyses performed conservatively assumed no pressure dissipation, which is an extreme worst-case condition.

DRAFT

Pseudostatic:

Seismic slope stability has been evaluated by considering an equivalent horizontal ground acceleration corresponding to a pseudostatic seismic coefficient of 0.1.

Table 6. Estimated Factor of Safety for Different Reservoir Conditions

3H:1V Backfill Placed Over	Condition Analyzed		
	Steady State	Rapid Drawdown	Pseudostatic
1.5H: 1V (33°)	1.6	1.3	1.1
1.25H: 1V (39°)	1.6	1.3	1.1
1H: 1V (45°)	1.5	1.3	1.1

The slope stability FS values for each of the permanent condition scenarios are all within their respective acceptable FS values. The rapid drawdown FS value reflects a conservative assumption and actual conditions would likely be higher. There is no significant difference in FS values for a 3H: 1V slope placed on different excavation slope gradients. This is as expected since the overall stability of the permanent slope is largely governed by the wedge of compacted fill placed over the temporary excavation slopes.

5.4. SLURRY WALL STABILITY ANALYSIS

5.4.1. FINITE ELEMENT METHOD

The analysis method aimed to assess the displacements which would develop in the slurry wall as the strength and stiffness parameters of the wall were varied over an expected range that can be achieved. Analysis was carried out using the finite element modelling software RS2, developed by Rocscience. RS2 is a 2D finite element program for soil and rock applications, with the ability to carry out slope stability analysis using the shear strength reduction method.

The developed slope model was meshed using a graded mesh with 6-noded triangles. The boundaries were fixed both in the x and y plane. Groundwater was set at a total head condition of 5 feet bgs. The typical model configuration and output graphics are provided in **Attachment D**.

The limit equilibrium method such as that used in Section 5.3, evaluates the different failure conditions of the slope system, but does not provide information on ground movements within the system. On the other hand, the fine element model evaluates the ground deformations within the system.

DRAFT

The FS value in limit equilibrium is based on the ratio of resisting forces in relation to the sliding forces. In the finite element method, an equivalent FS is obtained by reducing the soil strength until the deformations become excessive and the computation becomes unstable (failure). The ratio of actual soil strength in relation to the reduced strength for failure is called the Strength Reduction Factor (FRS). The FRS and FS values for a given slope would be similar, but not necessarily identical.

5.4.2. MATERIAL PROPERTIES

The basic soil strength parameters are as established in Section 5.2.8 (Table 4). These values were supplemented with elastic properties corresponding to each layer. The expanded soil material properties are as summarized in **Table 7** below.

Table 7. Additional Soil Properties for Finite Element Model (FEM)

GEOTECHNICAL DOMAIN	UNIT WEIGHT (LBS/FT3)	COHESION (PSF)	FRICTION ANGLE (DEGREES)	ELASTIC MODULUS (PSI)	POISSON'S RATIO	HYDRAULIC CONDUCTIVITY FT/SEC (CM/SEC)
SP	115	0	35	3625	0.3	5.25E-5 (1.60E-3)
GP	125	0	38	10877	0.3	7.38E-5 (2.25E-3)
SC/SM	120	200	36	5076	0.3	3.28E-8 (1E-6)
SC/CL	120	400	28	2175	0.25	3.28E-9 (1E-7)
Bedrock	135	Infinite Strength				-

The slurry wall parameters were varied to explore the deformation pattern variations for progressively stronger slurry wall compositions. **Table 8** summarizes the two different slurry wall strength and elastic properties used in the model.

Table 8. Slurry Wall Material Properties for FEM

SLURRY WALL	UNIT WEIGHT (LBS/FT3)	EQUIVALENT COHESION (PSF)	FRICTION ANGLE (DEGREES)	ELASTIC MODULUS (KSI)	POISSON'S RATIO	HYDRAULIC CONDUCTIVITY FT/SEC (CM/SEC)
Low Strength	130	400	0	1.4	0.3	3.28E-10 (1E-8)
Moderate Strength		2000		6.5		

The low strength value (400 psf cohesion) is intended to approximate a typical soil-bentonite mix. Soil-bentonite mix is commonly used in balanced pressure or modest differential-pressure situations. For detailed design purposes, the engineering properties of different slurry wall mix

designs using on-site materials will be established based on specific sampling and testing to be done.

In the case of uneven earth and substantial hydrostatic pressure differentials across a slurry wall, a more robust system may be needed, depending on several factors that will be considered during design. The moderate strength value of approximately 2 ksf cohesion, is intended to represent a soil-cement-bentonite system which is a more robust slurry wall.

5.4.3. SLURRY WALL STABILITY FOR EXCAVATION

In the FEM scenarios studied, the slurry wall and the slope have the same layout as in Section 5.3. The analyses were conducted for a 3-foot-wide slurry wall, located behind the top of the excavated slope. A slope of 1.5H:1V was applied to all Excavation scenarios since this is the most realistic case. The total excavation depth for all scenarios is 76 feet bgs.

The excavation progress in front of the slurry wall was modeled for the interim stages of excavation. The models were staged to simulate the excavation in approximate depth increments of 3.8 feet, representing a typical annual production rate, to reach the total excavation depth of 76 feet in 20 years.

Outputs from the RS2 finite element model for the various scenarios discussed here are provided in Attachment D.

For each scenario, the deflections of the slurry wall were estimated as provided in **Figures 13 and 14**. The strength reduction method was applied to obtain the critical SRF (FS) for each slurry wall strength scenario at the full excavation stage. A summary of the results for the four scenarios are provided in **Table 9.**

Table 9. Summary of FEM Results for Different Slurry Wall Scenarios

SCENARIO	ESTIMATED MAX. DISPLACEMENT (INCHES)	ESTIMATED ANNUAL DISPLACEMENT (INCHES)	SRF (FS)
Low Strength Slurry Wall (400 psf)	5.2	0.3	1.20
Moderate Strength Slurry Wall (2 ksf)	3.8	0.2	1.26

5.4.4. SLURRY WALL STABILITY FOR RESERVOIR

A finite element model analysis was performed for the case of the slurry wall behind the permanent 3H:1V slope of the Reservoir. The input for our analysis is based on the geotechnical characteristics of the materials in the excavation area, that are assessed from available boring logs.

DRAFT

For the conditions analyzed, the slurry wall extends from the ground surface behind the top of the outer slope, down to approximately 10 feet below the bottom of the Reservoir, into the low permeability native materials.

For the completed Reservoir with 3H:1V slopes and empty condition, which is more critical for slope stability, the calculated FS exceeds the generally accepted value of 1.5.

For rapid drawdown conditions which represents emptying of the reservoir without allowing adequate time for dissipation of water from the soil within the slope, the FS exceeds the generally accepted values which range from 1.25 to 1.40.

For pseudostatic (seismic) conditions, the FS exceeds the generally accepted value of 1.1.

Results show that the proposed slopes are sufficiently stable, including during earthquake conditions. The slope and slurry wall deformation analyses that demonstrate that the slopes and slurry wall deformations would be tolerable with adequate safety.

Further analysis during design will establish a suitable slurry wall mix design to provide the desired performance of the system.

The key design aspects of the slurry wall are the mix designs for both the bentonite slurry that is used to support the trench during excavation and for the backfill soil-bentonite mixture that forms the slurry wall. The details of these mixes would be established during the detailed design process discussed below and would incorporate the following essential design bases and criteria.

- The bentonite slurry mix, which is predominantly a bentonite-water mixture is designed to have sufficient viscosity and density to support the trench walls during excavation.
- The soil-bentonite backfill mix is designed to have a low permeability, be sufficiently ductile to adjust to deformations in the excavation slopes, and to resist the hydraulic pressures that will develop behind the wall as the Excavation is dewatered or the Reservoir is emptied.
- A key parameter in the design is to ensure the grain size of the soil materials are sufficiently large so that the water pressure cannot force them to migrate through the adjacent natural soils to prevent what is known as “piping”. Use of a soil-cement-bentonite mix could further improve the resistance to piping.

These types of walls are frequently constructed and therefore there is a sound basis for assessing appropriate mix designs that will meet the above requirements.

5.5. DESIGN AND CONSTRUCTION CONSIDERATIONS

5.5.1. SUBSURFACE INFORMATION

During design, additional boings will be performed to obtain relevant design information. Groundwater and in-situ permeability of the subsurface strata as well as the likely performance of slurry wall mix materials will also be evaluated in the design phase of the project. The slurry wall embedment depth and having an adequate cutoff depth while avoiding excess penetration into

DRAFT

bedrock, will be based on the soil profile variations along the slurry wall alignment. Subsurface investigations, field tests, laboratory tests, and detailed engineering evaluations will be conducted during design.

5.5.2. SLOPES

5.5.2.1. Excavation Slopes

During excavation, the slope gradients and the types and locations of dewatering elements will be adjusted by the Contractor, in consultation with professionals specialized in this type of work. There are many possible variations which would be implemented during construction. Some of these include adjusting the temporary slope gradients and the layout of benches, and the installation of temporary slope stabilization measures.

5.5.2.2. Reservoir Slopes

The permanent 3H:1V slopes will be placed over the temporary excavation slope face. This will involve benching into the Excavation slope and placement of an engineered fill buttress on the slope, in compacted lifts. Appropriate provisions for drainage and scour prevention will be made during design of the permanent Reservoir slopes.

5.5.3. SLURRY WALL

5.5.3.1. Variations in Design:

The evaluations presented in this document demonstrate that the proposed project concept is feasible. There are several variables that can be adjusted during design to achieve the desired performance. For example, a lower strength slurry wall with a greater width can achieve similar results as a higher strength wall with a narrower width. Also, the design parameters can be adjusted for different segments of the wall if the excavation depths or other demands (subsurface condition variations) require such adjustments.

5.5.3.2. Slurry Wall Materials:

The performance of the slurry wall mix materials will be further evaluated during design. The use of Soil-Bentonite (S-B) versus Soil-Cement-Bentonite (S-C-B) will be determined. While S-B wall is less expensive, it is prone to higher levels of differential settlements as well as higher lateral and cyclic deflections under uneven loading patterns. Design will evaluate the wall materials to achieve the desired long-term performance.

The percentage of fines available in the excavated soils will vary with depth and along the wall alignment. Bentonite addition, and if needed, importing borrow soils will help achieve the required hydraulic conductivity of the backfill mix.

A geotechnical investigation program may include evaluation of likely borrow source areas in the project area. A geotechnical laboratory testing program will provide information on the mix design

DRAFT

and its hydraulic conductivity, consolidation, and strength characteristics. Typically, different mix designs would be prepared and tested to meet the desired characteristics. Also, the mix design would attempt to maximize the use of on-site soils.

5.5.3.3. Slurry Trench Stability:

The open excavation trench would be stabilized by using a bentonite slurry. Design and construction will need to address trench stability through the water-bearing gravelly zones in the upper alluvium. In such conditions, the mix design may need to be adjusted and/or other protective measures, such as trench shields, may be needed. When appropriately designed and constructed, gravel intermixed with other finer materials can help reduce the amount of consolidation settlement of the slurry wall.

The bentonite-water slurry material will provide trench stability and caking on the sidewalls. The slurry material properties (viscosity, density, filtration, pH) will be checked during construction at the mixing point and in the trench with a submerged sampler to facilitate sampling from different depths.

5.5.3.4. Construction Quality Control:

A comprehensive construction quality control and testing program would verify that the parameters intended during design are achieved during construction. Items to be checked during construction may include:

- Various properties of the slurry and backfill materials;
- Adjustments to those properties based on conditions encountered;
- Checking, sampling and testing of the advancing backfill slope (gradient, slump, density, fines content, hydraulic conductivity);
- Checking the cleanliness of the trench bottom;
- Noting the amount of consolidation of the slurry backfill materials;
- Performing other observations, tests, collecting monitoring data, and timely use of such information to make adjustments as the work progresses.

Remedial measures (such as topping off consolidated zones) would be implemented based on the monitoring data collected, and other observations.

After construction is completed, event-based monitoring could include inspections and monitoring data evaluations after significant seismic and storm events.

5.5.3.5. Resiliency Considerations:

During Excavation, the slurry wall will be subject to considerable differential hydraulic gradients between the back and the front of the slurry wall. There will be some differential earth pressures due to level ground on one side and slope on the other. There may also be moisture condition variations due to changes in groundwater conditions, seasonal and climatic variations, dewatering patterns, and non-uniform layering with different water retention properties of soils. Such factors can introduce wetting-drying cycles and/or loading-unloading cycles. Under such conditions, it is normal for fissures to develop in the slurry wall. However these are not anticipated to affect the

DRAFT

performance of the Slurry Wall, as it will still be capable of minimizing inflow in conjunction with appropriate dewatering elements.

During permanent use, the permanent slope will provide a substantial buttressing benefit. During permanent use, multiple cycles of filling and emptying of the reservoir as well as the seasonal and climatic factors may introduce some wetting and drying of the slurry wall, but this will be of a much-reduced nature due to the added soil cover in front of the slurry wall. Also, the load-unload cycles will have a much less significant influence on the slurry wall due to the buttressing effect of the fill. The deflection patterns felt at the slurry wall will diminish during permanent use, which is also evidenced by the Finite Element Modelling results.

5.5.3.6. Monitoring and Verification of Wall Performance:

A monitoring program will need to be implemented to check the performance of the completed wall. Monitoring would include groundwater levels at different locations on either side of the slurry wall, as well as the settlement of the slurry wall. Additional monitoring details related to the slurry wall performance would be developed as recommended by the designer.

5.6. CONCLUSION

The project is feasible from a geotechnical point of view. Additional studies will provide the necessary information needed as the project progresses into its design and construction phases.

DRAFT

6. EVALUATION OF POTENTIAL IMPACTS

6.1. CEQA SIGNIFICANCE CRITERIA

Geology and Soils impacts are described in subsequent sections based on an evaluation of geotechnical, geological, and conditions, and consideration of potential changes to ground conditions due to the Project. A geology and soils impact is considered significant if it would result in any of the following, adapted from the CEQA Guidelines:

a) Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:

   i. Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known active fault trace;

   ii. Strong seismic ground shaking;

   iii. Seismic-related ground failure, including liquefaction;

   iv. Landslides.

b) Result in substantial soil erosion or loss of topsoil.

c) Located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse.

d) Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property.

e) Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater.

6.2. IMPACT GS 1 (CRITERION "A"): SEISMIC HAZARDS

The majority of Tulare County is free of the faults noted on the Alquist-Priolo Earthquake Fault Zoning Map. Such faulting is noted only along the eastern-most boundary with Inyo County. As such, there is no known active earthquake fault in or within 30 miles of the Project site. Risks associated with different manifestations of seismic hazards are addressed below.

6.2.1. Fault Rupture (Criterion "A.i")

Earthquake surface rupture is the physical displacement of surface deposits, either laterally or vertically, along a fault trace. Surface rupture is the surface expression of the subsurface fault movement and generally only occurs along or within a few hundred feet of the fault trace that moves during an earthquake. Not all large earthquakes have a surface expression or co-seismic surface rupture (e.g. blind thrust faulting associated with the 1994 Northridge, M_W6.7 earthquake).

DRAFT

The proposed Project is in Tulare County which is not a designated Alquist-Priolo Earthquake Zone (APEZ) as issued in Special Publication 42 by the California Geological Survey (2007). Geographic areas are designed as APEZ if they encompass potentially active or active faults.

A review of the 2014 fault activity map for California shown on **Figure 6** and tabulated on Table 1 indicates that no active faults cross the Site. The closest faults to the Site are the Independence Fault, the Owens Valley Fault Zone, and the San Andreas Fault Zone at least 35 miles from the Site. Because the Site is not located within or near and APEZ, the potential for surface fault rupture at the Site is considered to be insignificant.

6.2.2. Ground Shaking (Criterion "A.ii")

Ground Shaking Intensity:

The estimated ground shaking (acceleration) at the Site does not pose a potentially significant impact because Project's proposed design accounts for the estimated ground acceleration and therefore ground shaking is expected to pose a less than significant impact. The proposed slopes into the quarry are at an inclination of 3:1 (Horizontal to Vertical) corresponding to an angle of 18.5 degrees. The materials at the site range from silty sand to sandy gravel with shear resistance characterized by friction angles which, for that type of material, ranges from 30 to 38 degrees. Stability analyses were carried out for these conditions and the applicable pseudostatic coefficient. The calculated FS values as discussed in Section 5, meet the necessary stability criteria.

Ground Shaking Induced Seiche:

Seismic events can create hazards with their impact on water bodies. One such phenomenon is Tsunami, which would not apply here since the Site is not near the coast. A seiche is a standing wave that can occur in small water bodies such as basins, swimming pools, and lakes as a result of ground shaking. The wave can reduce water levels at one end of the water body and increase the water level on the other, similar to the "sloshing" of water back and forth.

The risk of seiche developing in the proposed reservoir as a result of ground shaking during an earthquake has been evaluated and the results indicate this to be unlikely.

The occurrence of a seiche and the amplitude of the wave are controlled by the natural period of the reservoir and that of the earthquake. If the two periods are similar, resonance can occur, thus amplifying the wave.

The natural period of the reservoir can be calculated using the Merian formula assuming a rectangular basin (USNRC, 2011).

$$\mathrm{T} = \frac{2\,L}{\sqrt{gh}}$$

Where L is the length of the basin, g the acceleration of gravity (32.2 cm/sec^2), and h the depth of water. Combining a representative value of 600 ft as the average width of the basin and a depth of water h of 70 ft, the natural period of the reservoir is estimated to be:

$$T = \frac{(2)(600)}{\sqrt{(32.2)(70)}} = 25\ s$$

This natural period is to be compared to that of the earthquake that may shake the site. The typical range of period for strong ground motion is between 0 and 5.0 seconds, with the dominant period for the site-specific event being on the order of 0.2 second (USGS, http://geohazards.usgs.gov/hazardtool/application.php). Therefore, the difference in period between the reservoir and the design earthquake is two orders of magnitude.

An empirical formula is provided in HAZUS (FEMA, 2003) to estimate the peak wave height of the seiche as:

$$H = \sqrt{\frac{A}{L\,(\pi f)^2}}$$

Where H is peak height, A the acceleration in, g's, f the frequency of the lake, and L the wavelength (5.12/ft^2). Using the PGA calculated for the 2,475 year event of 0.20 g, the maximum wave height a seiche is estimated to be 0.06 cm.

The estimated value of the peak wave for the seiche at the site is extremely low and for practical purposes, insignificant. In addition, the ratio between the reservoir and the natural period of the seismic event that could occur on site indicates that a possible resonance condition is unlikely.

6.2.3. Ground Failure, Liquefaction, Lateral Spreading (Criterion "A.iii")

Soil liquefaction is a condition in which saturated granular soils undergo a substantial loss of strength and deformation due to increased pore pressure resulting from cyclic stress application induced by earthquakes. During liquefaction, the soil becomes sufficiently mobile to permit both horizontal and vertical movements if the soil mass is not confined. Soils most susceptible to liquefaction are sand deposits that are saturated, loose, clean, uniformly-graded, and fine-grained. If liquefaction occurs, foundations resting on or within the liquefiable layer may undergo differential settlement. This will result in reduction of foundation stiffness and capacity. When this occurs, the structure can settle, tip, or even become buoyant and shift upwards. Liquefaction and associated failures could damage foundations, roads, underground cables and pipelines, and disrupt utility service.

Earthquake induced liquefaction typically occurs within the top 50 ft of liquefaction-prone soil, if those soils are saturated. A review of the logs associated with borings advanced at the Site (BSK, 2011) indicates that the water table is at an average depth of 15 ft below grade (Attachment A). The saturated soils below that depth are classified as silty sand to poorly-graded sandy silt and cobbles. While some of the layers are susceptible to liquefaction, the required dewatering will lower the groundwater levels and reduce the risk of liquefaction.

Settlement of the ground surface can be accelerated and accentuated by earthquakes. During an earthquake, settlement can occur as a result of compaction and settling of loose subsurface materials Given the geologic setting of the Site and generally competent materials, seismically-induced settlement is not considered to be a significant hazard.

DRAFT

Seismically induced lateral spreading involves lateral movement of earth materials laying over potentially liquefiable layers. Lateral spreading is characterized by near-vertical cracks with predominantly horizontal movement of the soil mass. Because the potential for liquefaction at the Site is generally considered to be low and groundwater suppression has to be in effect, the potential for lateral spreading is considered to be low. Pseudostatic slope stability analysis indicates adequate slope stability FS.

6.2.4. Seismically Induced Landslides (Criterion "A.iv")

Slope stability under Site baseline conditions does not present a significant hazard. There are currently no significant slopes or other topographic features at the Site that appear susceptible to slope failure. The California Geologic Survey has produced a series of landslide inventory and landslide hazard maps for unstable areas of the State. The Site and the vicinity are not mapped as having pre-existing or future slope stability hazards.

Static and seismic stability of slopes to be created for the Project are addressed in Section 5 and Attachments C and D of this report.

6.3. IMPACT GS 2 (CRITERION "B"): SOIL EROSION OR LOSS OF TOPSOIL

Erosion is the removal of soils and rocks due to natural process such as flow of water and wind. Erosion is expected to occur within the Project site as a result of excavation, but not at the ground surface (i.e., outside the Project perimeter); therefore, ground erosion is considered to be a less than significant impact.

Vegetation and topsoil will be removed during the initial site preparation and excavation the Project site. Topsoil removed will be stockpiled for use in reclamation/revegetation of the Project site, and/or the adjacent CEMEX Lemon Cove Facility site in accordance with the SMARA-approved Reclamation Plan. The reservoir slopes would be designed to include appropriate scour prevention measures.

6.4. IMPACT GS 2 (CRITERION "C"): GROUND INSTABILITY

This CEQA criterion seeks to answer if the Site is located on a geologic unit or soil that is unstable, or that would become unstable as a result of the Project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse. The seismically induced risk of ground instability (liquefaction, lateral spreading) has been addressed in Section 5. Ground instability related to project activities are addressed in this Section. The project is considered feasible and capable of containing such risks by applying proper design and construction practices. Evaluation of different ground instability factors are addressed below.

Stability of Existing Ground Conditions:

There are no known existing geologic conditions or natural slopes that would impact the stability of existing ground conditions.

Stability of Project Slopes:

The Project involves excavation of a reservoir. The anticipated depth of the reservoir is approximately 75 ft with slopes out at 3:1 (Horizontal to Vertical).

A slurry wall will be installed around the perimeter of the pit. The subsoil conditions at the Site were established based on existing onsite soil boring logs and the grain size analyses performed on samples recovered during the drilling operations (BSK, 2011). The subsoil conditions generally consist of sand, sandy gravel, and clayey sand with cobbles. For the purpose of our slope stability evaluation, a representative cross-section was developed and slope stability analyses were performed as discussed in Section 5 of the report. Supporting analysis details are provided in Attachments C and D.

Based on our analysis, the project slopes have adequate FS values.

6.5. IMPACT GS 2 (CRITERION "D"): EXPANSIVE SOILS

The soils in the area are predominately classified as granular materials such as sand, gravel and cobbles, with some silt and occasional clay lenses. None of those soils are subject to expansion when wetted. Therefore, there is no risk to life or property from expansive soils and this hazard is considered less than significant.

6.6. IMPACT GS 2 (CRITERION "E"): SUPPORT OF WASTEWATER SYSTEMS

There are no permanent habitable facilities involved in this Project. Hence, this item is not applicable (N/A).

DRAFT

7. CONCLUSION

As described in previous sections, SLR has conducted a review of baseline and Project related conditions and has evaluated potential Project related impacts relating to Geology and Soils based on CEQA Appendix G criteria. Based on our evaluation, the project is feasible from a geologic and geotechnical engineering point of view. We have identified no significant impacts.

LIMITATIONS

The services described in this work product were performed in accordance with generally accepted professional consulting principles and practices. No other representations or warranties, expressed or implied, are made. These services were performed consistent with our agreement with our client. This work product is intended solely for the use and information of our client unless otherwise noted. Any reliance on this work product by a third party is at such party's sole risk.

Opinions and recommendations contained in this work product are based on conditions that existed at the time the services were performed and are intended only for the client, purposes, locations, time frames, and project parameters indicated. The data reported and the findings, observations, and conclusions expressed are limited by the scope of work. We are not responsible for the impacts of any changes in environmental standards, practices, or regulations after the performance of our services. We do not warrant the accuracy of information supplied by others, or the use of segregated portions of this work product.

The purpose of an environmental assessment is to reasonably evaluate the potential for, or actual impact of, past practices on a given Site area. Subsurface conditions that are not apparent may exist at the Site. Our professional opinions are based in part on interpretation of existing data by others from a limited number of discrete sampling locations. Actual subsurface conditions may vary.

Further explorations are needed for design and construction. The specific future design demands, passage of time, manifestation of latent conditions, or occurrence of future events may change the findings, observations, and conclusions in this work product.

This work product presents professional opinions and findings of a scientific and technical nature. The work product shall not be construed to offer design or construction information, legal opinions or representations as to the requirements of, or the compliance with environmental laws, rules, regulations, or policies of federal, state, or local governmental agencies.

SUBJECT: Geotechnical Engineering Investigation Report
Proposed McKay Point Reservoir Project
Phase 1: Summary of Field Exploration and Boring Logs
Tulare Irrigation District
Tulare County, California

Dear Mr. Merzario:

BSK Associates (BSK) has completed Phase 1 of the geotechnical investigation for the proposed McKay Point Reservoir Project in Tulare County, California. The enclosed report provides a summary of the geotechnical exploration undertaken at the site starting November 16, 2011 and ending November 20, 2011. BSK logged the samples as they were extracted from the ground during coring. We also performed soil and rock classification per ASTM D2487 and ASTM D2488 on the samples in our Bakersfield lab. The information provided in the enclosed report does not address geotechnical parameters for design of the reservoirs. A more thorough exploration with respect to preliminary recommendations for site preparation and for plans and specifications for the reservoir project will be performed in the future.

We appreciate the opportunity to assist you during the design phase of your project and look forward to continuing our relationship on this project through construction. If you have any questions, please contact us.

Respectfully submitted,
BSK ASSOCIATES

GEOTECHNICAL ENGINEERING INVESTIGATION
PROPOSED MCKAY POINT RESERVOIR PROJECT
PHASE 1: SUMMARY OF FIELD EXPLORATION AND BORING LOGS
TULARE IRRIGATION DISTRICT
TULARE COUNTY, CALIFORNIA

1.0 INTRODUCTION

This report presents the results of a Geotechnical Engineering Investigation conducted by BSK Associates (BSK) for the proposed Site located in unincorporated Tulare County, California. The site is located between Lemon Cove and Woodlake as shown on the Site Vicinity Map, Figure A1. This report provides a preliminary geotechnical description of the subsurface conditions at the site. We understand that the locations of the reservoirs as well as the locations of the associated control structures have not yet been determined. Therefore, we do not recommend that the data included in this report be used to generate any kind of geotechnical design parameters. We understand that Phase 2 of this investigation will include a full scale sampling and testing program to determine recommendations for site preparation and geotechnical design parameters for the proposed reservoirs. This report's conclusions and recommendations will not be considered valid unless the Phase 2 of the site investigation is performed by BSK Associates. We recommend that BSK be retained to perform geotechnical review of the design drawings and construction documents throughout the development phase of the reservoir project.

1.1 PLANNED CONSTRUCTION

Based on the information provided by Sespe Consulting Group and Tulare Irrigation District, the proposed reservoirs will be developed to optimize water released during peak power enhancement flows from the Terminus Dam, retain water during periods of high flows, and time releases based on downstream needs. We understand that the site area is approximately 200 acres. The proposed reservoir project includes three reservoirs which will be constructed by excavation. The capacities of the reservoirs range from 700 to 2,500 acre-feet. The proposed depth of the reservoirs is approximately 60 feet below the existing ground surface (bgs).

1.2 PURPOSE AND SCOPE OF SERVICES

The objective of this geotechnical investigation was to characterize the subsurface conditions in the areas of the proposed reservoir areas. The scope of the investigation included a field exploration, laboratory testing, engineering analyses, and preparation of this report.

2.0 FIELD INVESTIGATION AND LABORATORY TESTING

2.1 FIELD EXPLORATION

The field exploration for this investigation was conducted under the oversight of a BSK Staff. Six (6) borings were cored at the site starting on November 16, 2011 and concluding on November 20, 2011. The site was cored using a 600T Full Sonic Truck Sonic Core rig with a 4 inch core barrel using wet and dry coring, as well as high and low frequency vibration and bit rotation speeds. The drilling contractor was Boart Longyear from Upland, California. The borings were cored to depths

ranging from 87 to 93 feet bgs. The locations of the borings are indicated on the Boring Location Map, Figure A2. Details of the field exploration and the boring logs are provided in Appendix A.

2.2 LABORATORY TESTING

Laboratory tests were performed on selected soil samples to evaluate particle size analysis. A description of the laboratory test method and results are presented in Appendix B.

3.0 SITE CONDITIONS

The following sections address the site description, surface and subsurface conditions, and groundwater conditions at the Site. This information is based on BSK's field exploration, and published maps and reports.

3.1 SITE DESCRIPTION AND SURFACE CONDITIONS

The Site is located between Lemon Cove and Woodlake California in Tulare County, California. The site is located in Sections 3 and 4, Township 26 South, Range 20 East. The GPS coordinates for the site location are 36.392° North latitude and -119.046° West longitude. The site is currently an existing cattle pasture. The surface of the site is generally flat with a depression in the southeast "wildlife area". The surface soil at the site primarily consists of loose, medium grained sand with occasional gravel and cobbles. Native grasses and trees are present and they increase in density with proximity to the nearby rivers.

3.2 SUBSURFACE CONDITIONS

Based on the soil boring data, the upper 15 feet of the on-site soil consist of loose clean poorly graded sand with increasing gravel. Below 15 feet, the soil consists of sandy and silty gravel of increasing size and rounded cobbles to approximately 30 to 35 feet bgs. Below 35 feet, particularly on the west side of the site, the soil consists of clayey sand with cobbles. It should be noted that, in the cobble layers, the maximum observed particle size of the cobbles was 4 inches, which is the inside diameter of the core barrel. However, we believe based upon examination of broken cobble fragments in the samples and observation of the surrounding off-site cut-slopes, that the cobble particle size exceeds 4 inches and likely approaches 10 to 16 inches. The cobbles tend to dominate the soil strata at depths ranging from 15 to 65 feet on the west side of the site and 15 to 40 feet on the east side of the site. The depth of the clayey sand with cobbles varied from approximately 65 feet at Boring B-1 to 40 feet at Boring B-4. Below 35 feet on the east side of the side, the soil type was observed to be primarily silty sand with gravel and 3-4 inch cobbles and highly weathered granite silty sand. Below 65 and 40 feet, respectively, the soil consists of multiple layers of silty and clayey sand, highly weathered granite silty sand with gravel, and moderately weathered granite cobbles. At Boring B-4, large unweathered granite boulders were encountered starting at approximately 72 feet. The fracture spacing of the unweathered granite boulders ranged from 4 inches to 3 feet.

The boring logs in Appendix A provide a more detailed description of the materials encountered, including the applicable Unified Soil Classification System symbols.

3.3 GROUNDWATER CONDITIONS

Groundwater was encountered in all of our borings at the site starting on November 16, 2011 and concluding November 20, 2011. Based on field observations of the groundwater conditions at the site, we estimate that the groundwater depth varies from 7 feet bgs at Boring B-6 to 20 feet bgs at Boring B-1.

4.0 LIMITATIONS

The summary submitted in this report is based upon the data obtained from the test borings performed at the locations shown on the Boring Location Map, Figure A2. The report does not reflect variations which may occur between or beyond the borings. The nature and extent of such variations may not become evident until further investigation is initiated. If variations then appear, a re-evaluation of the summary contained in this report will be necessary after performing on-site observations and laboratory testing during future exploration work and noting the characteristics of the variations.

The findings of this report are valid as of the present. However, changes in the conditions of the Site can occur with the passage of time, whether caused by natural processes or the work of man, on this property or adjacent property. In addition, changes in applicable or appropriate standards may occur, whether they result from legislation, governmental policy or the broadening of knowledge.

BSK has prepared this report for the exclusive use of the Client and members of the project design team. The report has been prepared in accordance with generally accepted geotechnical engineering practices which existed in Tulare County at the time the report was written. No other warranties either expressed or implied are made as to the professional advice provided under the terms of BSK's agreement with Client and included in this report.

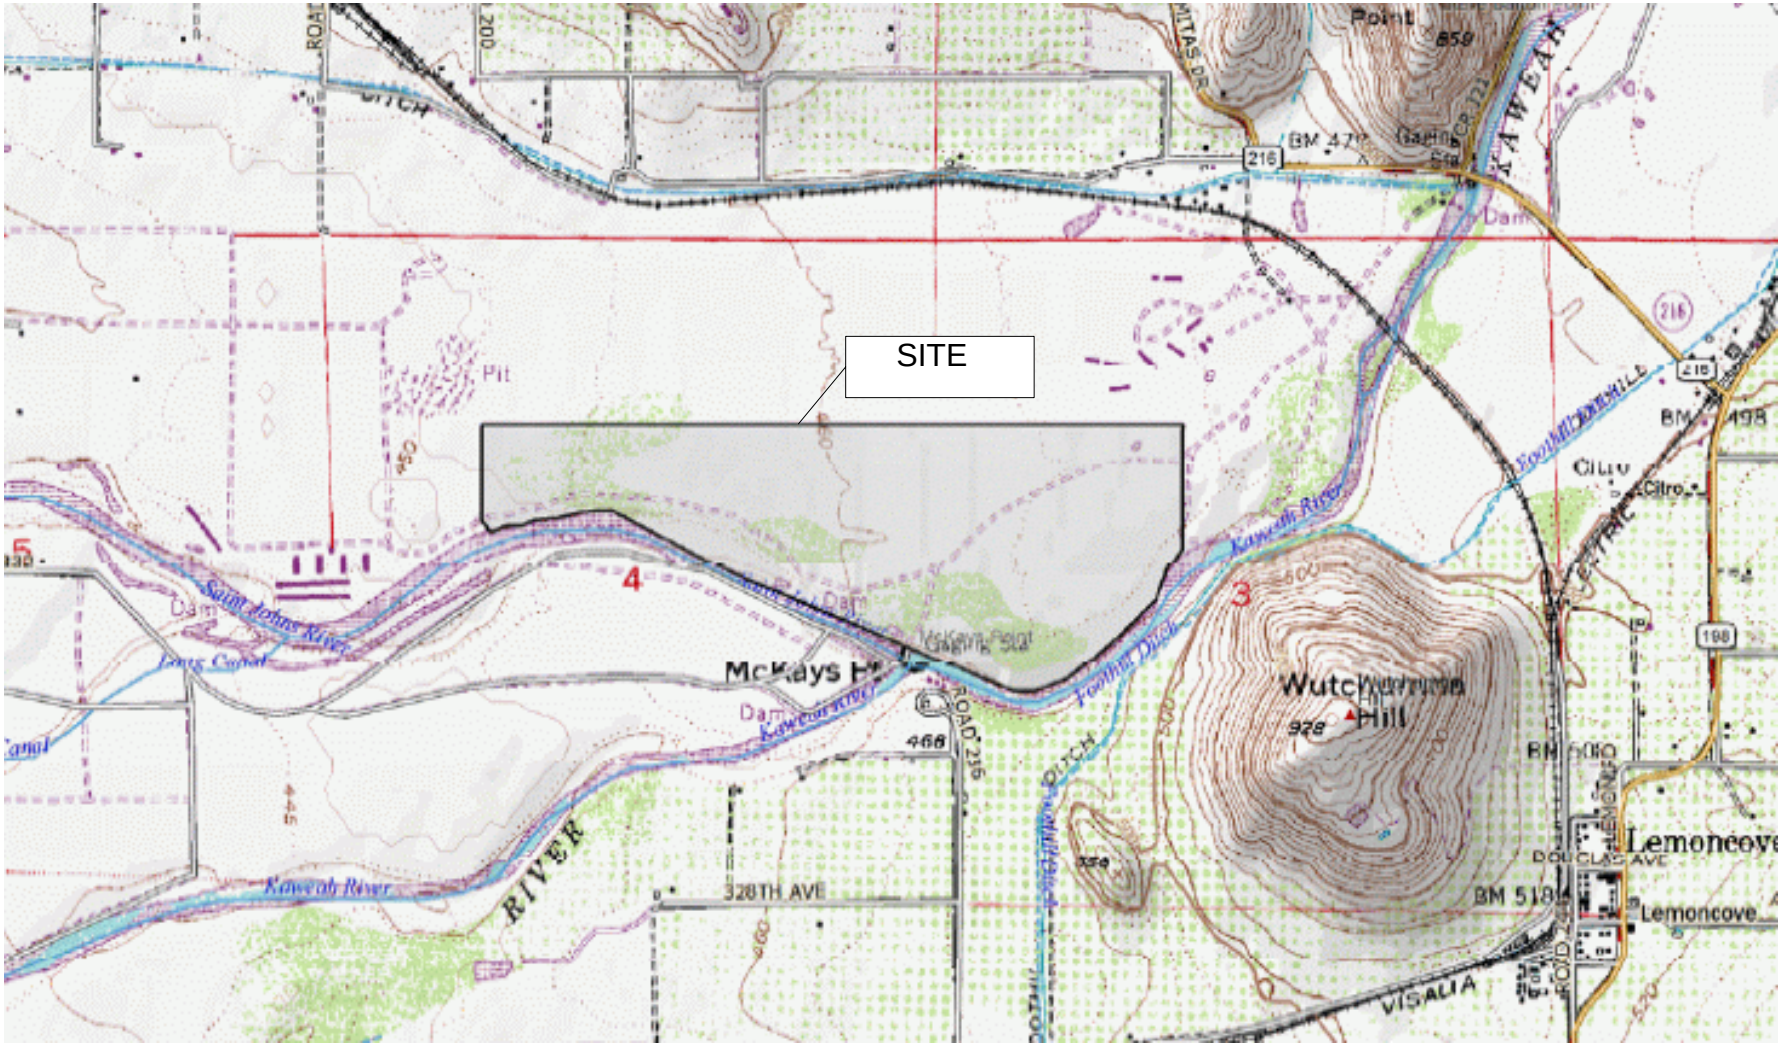
APPENDIX A

Field Exploration



APPENDIX A

FIELD EXPLORATION

The field exploration for this investigation was conducted under the oversight of a BSK Staff. Six (6) borings were cored at the site starting on November 16, 2011 and concluding on November 20, 2011. The site was cored using a 600T Full Sonic Truck Sonic Core rig with a 4 inch core barrel using wet and dry coring, as well as high and low frequency vibration and bit rotation speeds. The drilling contractor was Boart Longyear from Upland, California. The borings were cored to depths ranging from 87 to 93 feet bgs. The locations of the borings are indicated on the Boring Location Map, Figure A2.

The soil materials encountered in the test borings were visually classified in the field, and BSK Staff recorded logs during the drilling and sampling operations. Visual classification of the materials encountered in the test borings was made in general accordance with the Unified Soil Classification System (ASTM D 2488). A soil classification chart is presented herein. Boring logs are presented herein and should be consulted for more details concerning subsurface conditions. Stratification lines were approximated by the field staff based on observations made at the time of drilling, while the actual boundaries between soil types may be gradual and soil conditions may vary at other locations.

Subsurface samples were obtained at the successive depths shown on the boring logs by advancing the sonic core samplers which consisted of a 4-inch inside diameter (I.D.) core barrel sampler. The sampler was advanced using low to high frequency vibration, depending on the material encountered. Water was also added to the system to cool the bit and reduce side friction of the core barrel. The samples were extracted and bagged by the driller and placed in core boxes by BSK Staff. The times, as well as the advancement depths, were recorded for a determination of the penetration rate of the Sonic Core rig during drilling. The penetration rates were observed in the field as an approximate indicator of the strength of the subsurface soil (i.e. fast drilling = loose material, slow drilling = dense material). No formal attempt was made to quantify the relative density of the site soils.

1. INTRODUCTION

1.1. BACKGROUND

This document addresses potential CEQA relevant impacts on hydrology and water quality associated with the Project. Impacts on potential flooding, surface water drainage, groundwater flow, groundwater supply, and water quality are considered.

The hydrology and water quality conditions of the Project were assessed through review of Applicant-submitted documents, existing publicly available data and reports, and field observations. The Applicant has prepared documentation regarding groundwater conditions as presented in *Groundwater Conditions at and in the Vicinity of the Tulare Irrigation District Mackay's Point Project* (Schmidt, 2012) and *McKay Point Project*. Data from other publicly available documents were reviewed and evaluated as part of this assessment.

This document includes a discussion of the general Site conditions including environmental setting, climate, surface-water conditions, and groundwater conditions. The design and the construction stages of the Reservoir are described. Anticipated changes to the baseline conditions due to the Project are also evaluated. Finally, potential impacts to hydrology and water quality are evaluated based on the California Environmental Quality Act (CEQA) Appendix G significance criteria.

1.2. PROJECT OVERVIEW

The Tulare Irrigation District (TID), the Consolidated Peoples Ditch Company (CPDC) and the Visalia & Kaweah Water Company (VKWC) are joint owners (Owners) of approximately 500 acres of land adjacent to the Kaweah and St. Johns Rivers in Tulare County, California, commonly referred to as the McKay Point Project area or Site (Figures 1 and 2). Together, the Owners are the holders of pre-1914 and appropriative water rights on the Kaweah and/or the St. Johns Rivers, and they own storage capacity rights in Lake Kaweah formed by the impoundment of water behind the Terminus Dam.

The Owners are also members of the Kaweah and St. Johns Rivers Association (Association), which oversees the surface water rights and diversion operations on the Kaweah River. The Owners propose to develop approximately 200 acres of the total 500-acre McKay Point property on the north side of the divergence of the Kaweah and St. Johns Rivers into a surface water storage and reregulation reservoir (Reservoir) as shown on Figures 2 and 3. When completed, the Reservoir will serve as a surface water storage/re-regulation facility. The Owners will also use the Reservoir to optimize groundwater recharge in basins within the Kaweah subbasin.

West Coast Aggregate (WCA) will excavate the Reservoir in accordance with plans and specifications to be developed. WCA intends to process the resulting aggregate materials (i.e., rock, sand, and gravel) within the Project Site (Figures 2 and 3). WCA would then sell processed materials such as Portland Cement Concrete (PCC) grade aggregate, used by their customers

DRAFT

offsite to manufacture concrete and asphaltic concrete products. WCA will also recycle concrete construction debris at their facility.

The Reservoir capacity is expected to be 4,600-acre feet. Its depth is expected to range from approximately 60 to 80 feet locally, with a typical average depth of approximately of 75 feet. The material excavated during construction will consist of resource-grade aggregate and will be processed at the WCA facility to be established within the excavation area.

Upon completion of the Reservoir excavation, water will be periodically diverted from the Kaweah River and stored in the Reservoir to achieve the following objectives:

- Store winter runoff and release in summer when required downstream.
- Reduce flood peaks during periods of high flows.
- Store Kaweah River water when the Owners' systems are at capacity so that additional water can be released later to be used for groundwater recharge within the Owners' respective service areas.

The Reservoir will extend vertically below the groundwater levels, and the Applicant will implement dry mining methods to recover the aggregate and to create the Reservoir. Dewatering of the excavated area will be conducted, as necessary to allow for dry mining techniques.

The Reservoir phase of the Project will entail storage and release of surface water only. To minimize groundwater from entering the excavation and the Reservoir, a slurry wall will be installed around the perimeter to decrease groundwater seepage. While some amount of seepage inflow will occur during periods when the Reservoir is not full, this seepage will be pumped out and returned to nearby groundwater. The slurry wall will also minimize stored water losses from the Reservoir to groundwater when it is full.

DRAFT

2. ENVIRONMENTAL SETTING

2.1. REGIONAL SETTING

The Site is in California's Central Valley near the western boundary in the foothills of the Sierra Nevada Geomorphic Province of California (Figure 1). The southern San Joaquin Valley bounds this part of the Sierra Nevada to the west and the Great Basin to the east. The Central Valley is one of the most productive agricultural regions in the world.

The Site vicinity is drained by the Kaweah and St. Johns Rivers, which drain ultimately to the Tulare Lakebed in the southern end of the San Joaquin Valley (Figure 4). In 1962, Lake Kaweah, located upstream from the Site, was created by the construction of Terminus Dam on the Kaweah River. Renovations of this dam in 2004 significantly reduced flooding at the Site and the surrounding area.

The Site is in the eastern portion of Kaweah Sub-basin of the San Joaquin Valley Groundwater Basin. This area is underlain by young and old unconsolidated fluvial deposits (sandy and silty gravels, clayey sand and cobbles, and silty and clayey sands) that originated from the nearby Sierra-Nevada Mountains. These moderately to highly permeable silts, sands and gravels extend to depths of several hundred feet or more.

2.2. LOCAL SETTING

The Site is currently undeveloped and has been used for cattle grazing under lease arrangements. Most of the Site is vegetated with native grasses.

The surface soil at the Site primarily consists of loose, medium-grained sand with occasional gravel and cobbles. Site surface drainage east of the river split is generally to the south and southeast toward the Kaweah River and west of the river split generally to the south and southwest toward the St. Johns River. The Site elevation slopes from approximately 472 feet above mean sea level (msl) at the northeastern end of the property, downward to approximately 454 feet above msl at the southwestern end.

2.3. CLIMATE

2.3.1. CURRENT CONDITIONS

Climate in the Site vicinity is typical of the foothill region of the central valley, with cool rainy winters having a mean daily temperature ranging from 40° to 50° F and hot dry summers when daytime temperatures can exceed 100° F (Table 1). During the summer months, a high-pressure system off the west coast of California prevents precipitation from occurring in the area. During the winter, this high-pressure system is intermittent, allowing Pacific storms to bring rainfall to the foothills. Rainfall increases with elevation in the foothills and the ranges. Most of the precipitation occurs from November through April.

DRAFT

TABLE 1: SITE VICINITY CLIMATE SUMMARY													
	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEP	OCT	NOV	DEC	ANNUAL

Evaporation data from Army Corp of Engineers (2014), Terminus Dam, California, period of record 2001-2007. All other climate data from WRCC (2014), Lemon Cove, California, period of record 1899-2013.													

2.3.2. CLIMATE CHANGE

Based on studies conducted for the Greater Kaweah Groundwater Sustainability Agency (GEI/GSI, 2020) the following changes to the precipitation, evapotranspiration, and runoff in the East Kaweah Basin are projected for 2030 and 2070 respectively. These projections are compared to current, or baseline conditions determined for the period 1981 to 2010.

Precipitation

Annual precipitation is projected to change very little, by approximately 0.5% either up or down. However, the seasonal distribution of precipitation will change with increases projected for Winter and late Summer and decreases in Spring. Specific projected changes are:

- 2030 Precipitation:
  - Annual increase of 0.06 inches or 0.4%
  - Increases in the November to April period; maximum increase in March (0.25 inches or 10%)
  - Decrease in the May through July period; maximum decrease in May (-0.08 inches or -14%)
  - Increase in the August to September period; maximum increase in August (negligible or 9%)
- 2070 Precipitation:
  - Annual decrease of -0.09 inches or -0.6%.
  - Increases in the December to March period; maximum increase in January (0.46 inches or 17%).
  - Decrease in the April through June period; maximum decrease in May (-0.18 inches or -31%).

DRAFT

- Increase in the July to September period; maximum increase in September (0.05 inches or 25%).

Evapotranspiration

Annual evapotranspiration is projected to increase, by approximately 3.2% to 8.2%. Maximum increases are projected to occur in the Winter and Spring periods. Specific projected changes are:

- 2030 Evapotranspiration:
  - Annual increase of 2.1 inches or 3.2% measured as pan evaporation.
  - Maximum relative increases occur in January (0.06 inches or 4.3%) and June (0.35 inches or 3.8%).
- 2070 Evapotranspiration:
  - Annual increase of 5.3 inches or 8.2% as pan evaporation.
  - Maximum relative increases occur in December (0.18 inches or 12.8%) and May (0.58 inches or 8.0%).

Under these conditions it can be expected that the crop demands for water will generally increase in proportion to the increased evapotranspiration estimates; by approximately 3% to 8% over time.

Runoff

Annual runoff is projected to be reduced by approximately -5% by and after 2030. A significant change is projected to occur in the seasonal distribution of runoff. Under current and the projected 2030 conditions the peak inflows occur, and are projected to occur, in May each year, i.e., in mid Spring. By 2070 inflows are predicted to peak in late Winter, two months earlier than March.

Strom Precipitation

As part of California's Fourth Climate Change Assessment, the California Energy Commission sponsored a study of the projected changes to California's precipitation intensity-duration-frequency curves which evaluated how the intensity and frequency of 1-to-7-day precipitation events would change for extreme storms such as the 25-year to 100-year events, compared to those experienced in from 1950 to 1999. The projections were made for the period 2050 to 2099 (50-years). The work was undertaken by the University of California, Irvine (UCI, 2018).

The general conclusions of the study are that extreme precipitation is expected to increase across most cities in California. Climate model simulations under the RCP8.5[1] project that in the future, the frequency of what is currently a 50-year event could double in both Southern and Northern California. This means that areas across California may experience extreme precipitation that is more intense and twice as frequent, relative to historical records.

[1] A Representative Concentration Pathway (RCP) is a greenhouse gas (GHG) concentration trajectory generally adopted by the Intergovernmental Panel on Climate Change (IPCC) for climate change forecasting. The RCPs describe the possible changes in future anthropogenic (i.e., human) GHG emissions. RCP 4.5 is described by the IPCC as an intermediate scenario. Emissions peak occurs around 2040, and then declines. RCP 8.5 emissions continue to rise throughout the 21st century and this pathway is generally taken as the basis for worst-case climate change scenarios.

DRAFT

He closest city to the Project that was analyzed is Fresno. Evaluation of the climate change effect on one-day storm precipitation frequencies for Fresno indicates, for example, that the precipitation values for a return period of 100-years would increase by 14% to 19% for the RCP4.5 and RCP8.5 scenarios respectively for the 50-year future projection period. The current storm precipitation amounts would occur more frequently. For example, the annual probability of occurrence of the current 100-year precipitation which is 1% could be increased to between 1.4% and 1.9% respectively, i.e., this storm event would become nearly twice as likely.

DRAFT

3. BASELINE CONDITIONS

This section contains descriptions of the existing (baseline) Site geologic and hydrologic conditions.

3.1. REGIONAL AND LOCAL GEOLOGY

The Central Valley has been formed by millions of years of deposition of Quaternary sediments derived from the uplifted Sierra Nevada and Coast Ranges, which bound the Central Valley on its east and west sides (Figure 1). The Central Valley is an alluvial plain, approximately 50 miles wide and 400 miles long (north south). Sediments have been deposited into the Central Valley for the last 160 million years and are thousands of feet thick in certain areas.

Numerous rivers and streams originating in the higher elevations of the Sierra Nevada, including the Kaweah River, flow westward into the Central Valley, depositing Quaternary alluvial sediments upon which the Site is located (Mathews and Burnett, 1965). This alluvium is underlain by a sequence of marine and continental sedimentary rocks consisting of shale, siltstone, and sandstone and locally granitic rock. Beneath the sedimentary rocks lie an impermeable basement complex of igneous and metamorphic rocks that extend as deep as 13,000 feet bgs. These basement rocks are a subsurface extension of the same rocks that occur in the Sierra Nevada (Faunt et al., 2009). A geologic map of the region is included as Figure 5

A total of 6 soil borings were conducted at the Site in November 2011 (BSK, 2011). Based on these borings and hydrogeologic interpretations by Schmidt (2012), the thickness of fluvial sediments within the Reservoir area ranges between approximately 40 and 100 feet. Alluvial deposits at the Site consist of sand that is about 15-20 feet thick. Luhrdorff and Scalmanini (1995) describe these sediments as Younger Alluvium. Below this sand interval, cobbles, boulders with sand, clay and silt are common. These deposits extended to a depth of about 40 feet on the eastern portion of the Site, and to about 100 feet on the western portion. Luhrdorff and Scalmanini (1995) describe these sediments as Older Alluvium. Geologic cross-sections for the Site have been prepared by Schmidt (2012) and for this study, which are included in Attachment A.

Weathered bedrock was not encountered in borings on the western portion of the Site but was encountered at approximately 77 ft bgs in two borings drilled at the eastern portion of the Site. The bedrock encountered is likely Mesozoic granitic rocks of the Sierra-Nevada batholith, which has been mapped as outcrops at higher elevations within a few miles to the north, east and south of Site. The weathered bedrock is presumed to underlie the entire Site but is apparently present at various depths (Attachment A). Discontinuous intrusions of clay or clayey sand were also occasionally encountered.

3.2. GROUNDWATER

The shallow aquifer at the Site is composed of the alluvial fan deposits associated with the local rivers. In some areas near the Site where overlying sediments are relatively thin, such as the Lemon Cove and Lindmore areas south of the Site, weathered bedrock forms the predominant aquifer. For example, one Lemon Cove public supply well is screened in the bedrock aquifer.

Most of the groundwater production south of the Kaweah River is from the bedrock interval (Schmidt, 2012).

Regionally, groundwater flows generally toward the west from the recharge areas of the Sierra Nevada mountains to the center of the valley (Figure 6). Groundwater elevations in the region vary from around 460 feet amsl near the Site, to around 250 ft amsl near the City of Visalia (DWR, 2014). Groundwater is pumped in the area for agricultural and urban uses.

The Site is in the Kaweah Subbasin, within the Tulare Lake Hydrologic Region (DWR, 2003). The Site is also near the eastern boundary of the Kaweah Delta Water Conservation District (KDWCD) (District; Figure 7). Approximately 265,000 acres of the district is irrigated for agriculture, and about 45,000 acres is urbanized. Numerous public and private entities within the district boundaries divert water from the river and its distributaries mainly for irrigation. In addition, almost all the land within the KDWCD receives some irrigation water obtained from groundwater, often as a supplement to surface water (Groundwater Sustainability Plan - GWSP, GKGSA, 2020).

KDWCD and surrounding areas have been in long-term groundwater overdraft. The KDWCD wide overdraft for the period 2007 to 2017 was estimated at approximately 78,000 AF/yr. Most of the overdraft occurs in the western portion of the district; not the Project vicinity (GKGSA, 2020).

In January 2020, the Greater Kaweah Sustainability Agency (GKGSA) published its "Groundwater Sustainability Plan" (GWSP). The purpose of the GWSP, is among others, to identify and describe Minimum Thresholds and Measurable Objectives for each monitoring location for each applicable Sustainability Indicator, as required to achieve the Sustainability Goal, and to define and identify Projects and Management Actions proposed by the GKGSA to achieve the Sustainability Goal. The Sustainability Plan area and its jurisdictional boundaries are shown on Figure 8. The Reservoir will be in Hydrogeologic Zone 10 within these boundaries. For this zone, the Minimum Threshold and Measurable Objective groundwater levels have been established for Well KSB-2822 (also referred to as 18S27E05J001M), located between the St. Johns and Kaweah Rivers (Figure 9), as 421 and 420 feet amsl respectively. The levels at KSB-2822 are at the Minimum Threshold and Measurable Objective levels established by the GKGSA).

The shallow aquifer in the Site vicinity is unconfined (Schmidt, 2012) and water levels are significantly higher than the Minimum Threshold and Measurable Objective levels. The long-term water level measurements for wells in the region surrounding the Site indicate stable water levels, except for temporary declines during drought periods (Figure 9). Seasonal water level fluctuations in the Site vicinity have generally varied by less than 20 feet for the last 50 years (Fugro, 2007). Within the Site, approximate water level elevations ranged from 463 feet amsl near the east edge of the Lemon Cove Facility, to just under than 430 feet amsl in the western part of the Site in December 2011 (Figure 10) based on six borings sampled during the site investigation program. The CEMEX excavations located immediately to the north of the Site, have exposed groundwater because of the permitted surface mining on that site. As presented in Attachment B, groundwater level elevations have ranged from about 438 to 443 feet amsl in the area immediately northwest of the Site, to between 456 to 460 feet to the northeast of the Site in the 2008 to 2010 period.

The main source of recharge to the aquifers in the Site area is groundwater flow form the east. Localized groundwater gradients suggests that the St. Johns and Kaweah Rivers lose some of their flow to infiltration, and that these rivers are sources of groundwater recharge. Other sources

DRAFT

of groundwater recharge in the Site vicinity include infiltration of water used for irrigation, and infiltration from local irrigation ditches in the area and from seasonal surface water flow.

3.3. GROUNDWATER WATER QUALITY

Groundwater in the region is generally considered suitable for beneficial uses, including municipal/domestic, industrial, and agricultural purposes except for a few instances that are discussed below. In the project vicinity, groundwater quality is favorable with respect to physical parameters (total dissolved solids, pH, and specific conductivity), and other major constituents related to potability (such as chloride, and sulfate, and nitrate). Groundwater in the project area generally reflects the properties of local surface water runoff, which serves as a replenishment source. While there are localized occurrences of high dissolved minerals or high nitrate levels due to the influence of land use (e.g., infiltration of irrigation tailwater), groundwater generally satisfies Title 22 Drinking Water Standards and is utilized as a drinking water source for municipalities, small community systems, and individual households. High concentrations of iron and manganese are also known to occur in the region, which in some instances may exceed secondary drinking water standards (Luhdorff and Scalmanini, 2004).

Consistent with the regional characteristics, groundwater quality at the project site is characterized by relatively low conductance and is of calcium-bicarbonate to calcium-sodium bicarbonate in composition. Samples collected from monitoring wells completed in the younger alluvium and the older alluvium at the project site had specific conductance values of 120 to 260 mhos/cm and total dissolved solids (TDS) levels of 95 to 170 mg/l (Jones & Stokes, 1998). Calcium and bicarbonate are the predominant cation and anion. Compared with sources to the west, the groundwater in the project area exhibits lower mineralization due to the apparent influences of surface waters in the Kaweah and St. Johns Rivers (Bookman-Edmonston 1972). ·

Several locations surrounding the project vicinity have experienced degraded groundwater quality in the shallower aquifers due to agricultural practices in the area. Examples include the Lemon Cove area, the areas immediately south of Wutchumna Hill and west of the Reservoir, which have elevated levels of nitrate in groundwater, up to approximately 100 mg/L (Schmidt, 2001).

The City of Woodlake has also reported problems with elevated nitrate concentrations and is concerned with any project that may increase degradation (Jones & Stokes, 1998). Other than nitrate, groundwater and surface water in the Site vicinity appear suitable for existing beneficial uses (Fugro, 2007).

3.4. SURFACE WATER

3.4.1. CURRENT CONDITIONS

The east side of the San Joaquin Valley consists of a broad plain formed by coalescing alluvial fans associated with streams draining the western slopes of the Sierra Nevada (Figure 4). The southern end of the San Joaquin Valley is known as the Tulare Basin. The Tulare Basin is hydrologically closed. Instead of flowing to the ocean, streams from the Sierra Nevada flowing into the Tulare Basin terminate at depressions, the largest of which is the Tulare Lakebed.

DRAFT

The primary natural surface water bodies in the Site vicinity are the Kaweah and St. Johns Rivers, which form the eastern and southern Site boundaries. The Kaweah River flows westward from its headwaters in the Sierra Nevada. Along the southern Site perimeter at a location referred to as McKay Point, the Kaweah River diverges into two rivers, forming the St. Johns River and the Lower Kaweah River. Several ponds are located just north of the Site at the adjacent CEMEX operation (Figure 2). A pond is also located on the Kaweah River Rock property to the west of the Site. These ponds consist of exposed groundwater, created by previous mining beneath the groundwater elevation.

Downstream of the Site, the Kaweah River historically branched into 8 or 10 shallow channels that overflowed during high flows, creating marshlands. These shallow channels were later integrated into irrigation canals and ditches for the delivery of irrigation water in support of agriculture irrigation. These channels still carry non-irrigation flow to Tulare Lakebed but only during periods of extraordinary precipitation or snow melt (Figure 4; Army Corps, 1990).

In 1962, Lake Kaweah (the Lake), located approximately 3 miles upstream of the Site, was created by the construction of Terminus Dam (Figure 4). Construction of this dam provided storage of irrigation water and flood protection for downstream areas. The Lake has a capacity of approximately 185,630 AF. Flood control considerations require that, between November and March, a portion of the Lake volume be reserved to store runoff in high rainfall or snowmelt events. Therefore, during a wet year the Lake typically releases most of the water to maintain low levels. In a dry years Lake outflow is typically very low in winter with sporadic increases in response to significant precipitation or snowmelt conditions.

Storage for water supply begins in late winter and releases occur in late spring and early summer. In wetter years, releases may begin in late winter and remain high (above 1,500 to 2,000 cfs) through spring and late summer (EPA, 2005; US Army Corp. 2005, Kaweah, and St. Johns Rivers Association - Water Master Reports though 2007). Water released from the Terminus Dam serves multiple local water districts such as the Tulare Irrigation District (TID) and Kaweah Delta Water Conservation District (KDWCD) as well as several small ditch companies. The dam also discharges water to generate hydroelectricity.

During a typical average year streamflow upstream from McKay Point (gauge Kaweah River at McKay Point) is intermittent for about 8 months during late summer through late winter (September through April (Watermaster Reports). When they occur, flows can typically range up to 1,000 to 2,000 cfs. During June and July flows are more consistent with maximum flows still ranging up to approximately 2,000 cfs or higher (Table 2 below).

DRAFT

TABLE 2: KAWEAH RIVER AT MCKAY POINT – MONTHLY FLOWS – (PERIOD 2001-2020)													
	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEP	OCT	NOV	DEC	ANNUAL
Average (cfs)	313	355	298	314	731	1,359	1,265	525	94	15	61	127	455

Streamflow data from the annual Water Master Reports (Kaweah & St. Johns Rivers Association) for the period of record 2001 to 2020. Year is based on the October to September time frame.										

Flows arriving at McKay point are divided between the St. John and Kaweah Rivers by the McKay Point Structure which consists of two flow control structures, one in the St. Johns and one in the Kaweah River. These water control facilities are owned and operated by the Kaweah Delta Water Conservation District and the Kaweah & St. Johns Rivers Association. Both check structures are located immediately downgradient of McKay Point (Figure 3). The check structures can be closed or opened to control flow rates in the St. Johns and Kaweah Rivers.

Dry Creek flows into the Kaweah between Terminus Dam and McKay Point and is the largest source of runoff below Terminus Dam (Figure 4). Dry Creek flows southward from its headwaters and joins the Kaweah approximately one mile down from Terminus Dam. Water supply diversions begin immediately downstream of the dam through Hawkeye, Lemon Cove, and Foothill Ditches, and flows diverted are less than 10,000 AF/yr. total. Farther downstream, Wutchumna Ditch Company diverts water into Bravo Lake, a 4,000 AF Reservoir (U. S. Army Corps of Engineers, 1990).

DRAFT

Spills from the irrigation systems of the Kaweah and St. Johns Rivers are limited to the above average years as shown by the measured flows in Table 4.

TABLE 4: SPILLAGES FROM THE KAWEAH AND ST. JOHNS RIVER IRRIGATION AREAS MEASURED AT (1) ELK BAYOU BELOW ROAD 96 AND (2) CROSS CREEK AT HIGHWAY 43 TO TULARE LAKE – ANNUAL FLOWS IN AF/YEAR – (PERIOD 2001-2020)

Streamflow data from the annual Water Master Reports (Kaweah & St. Johns Rivers Association) for the period of record 2001 to 2020. Year is based on the October to September time frame.

3.5. FLOODING

Before the Terminus Dam was constructed, extraordinary storm events in December 1955 resulted in an estimated peak flood discharge at McKay Point of 87,000 cfs, which is the largest peak runoff from the Kaweah River watershed in the 20th century. Since the construction of Terminus Dam in 1962, most flooding concerns for areas downstream of the dam were greatly alleviated. For example, the peak average daily inflow to Lake Kaweah during the 1966 flood was 105,000 cfs, whereas the maximum release from the dam was 5,666 cfs. Lake Kaweah is operated with an objective of maintaining a flow of less than 5,500 cfs at McKay Point, which includes flow from undammed tributaries such as Dry Creek. Above this flow rate, flood damage can occur to downstream properties, infrastructure, and municipalities (U. S. Army Corps of Engineers, 1990).

The Terminus Dam height was increased by approximately 21 feet in 2004, which further reduced flooding in the area (U. S. Army Corps of Engineers, 2005). It is estimated that currently the dam provides protection for a design flood event of 50-year return period (FEMA, 2009).

FEMA has prepared a flood hazard map for the area including the Site (Figure 11). FEMA has calculated base flood elevations for the Kaweah and St. Johns Rivers, but only for stretches downstream of McKay Point. The map indicates that the 100-year flood level near the Site along the St. Johns River is approximately 465 feet amsl. During most flooding conditions, major and minor flooding in the area is dissipated by diversions to the network of irrigation ditches, irrigation diversions, channel percolation, and evapotranspiration (U. S. Army Corps of Engineers, 1990).

DRAFT

3.6. SURFACE WATER QUALITY

Surface water near the project Site is generally considered suitable for beneficial uses including municipal, domestic, agricultural and groundwater recharge purposes. Virtually all municipal and industrial water supply in the region is derived from groundwater and surface water is essentially used exclusively for agricultural purposes. As such, the surface water quality is classified as Class I for irrigation by the Department of Water Resources. The water is characterized by relatively low conductance and dissolved solids and is of calcium-bicarbonate to calcium-sodium bicarbonate in composition (Luhdorff & Scalmanini, 2004)

DRAFT

4. PROJECT DISCUSSION

4.1. INTRODUCTION

This section describes the reservoir objectives, includes a discussion of the initial excavation and final construction of the Reservoir, the design of the excavation, slurry wall, and final Reservoir. It provides the water balance analyses for both the excavation and Reservoir operational stages and describes how the reservoir would be operated. The section concludes with an analysis of the water supply and flood control benefits that would be achieved.

4.2. RESERVOIR OBJECTIVES

Once the Reservoir is completed, the Owners will utilize the Reservoir and its facilities to manage their surface water supplies to increase the long-term availability of irrigation supplies, groundwater recharge supplies, and to provide for additional flood flow reductions by temporarily storing high flood waters. Its purpose is to provide multiple benefits including:

- Capturing and re-regulating water made available to the Owners during flood releases from Terminus Dam.
- Capturing and re-regulating water entitlements belonging to the Owners released from Terminus.
- Capturing and re-regulating any other water sources on the Kaweah River, such as Dry Creek, that may be made available to the Owners.
- Allowing other entities with water rights on the Kaweah River to capture and/or re-regulate flows when designated by the Owners.
- Allowing other entities to capture and/or re-regulate flows of the Lower Kaweah River and St. Johns River for purposes of storm water runoff and flood prevention with permission of the Owners and Kaweah/St. Johns water rights interests.
- Effectively extending the Owners' irrigation and/or groundwater recharge season by storing additional Kaweah River water during events in which the Owners' delivery systems are at capacity.

The Reservoir would be constructed in such a way that revenue can be obtained to offset the construction and development costs. Locating the Reservoir adjacent to the Kaweah River allows for easy connection between the river and the Reservoir, thus minimizing the need for pipelines. The elevation of the water surface above McKay Point in the Kaweah River will be used to divert water into the reservoir by gravity.

4.3. RESERVOIR CONSTRUCTION

4.3.1. APPROACH

The proposed Reservoir would occupy a surface area of approximately 130 acres, have an average water depth of 60 to 80 feet, and would have storage capacity of approximately 4,600

DRAFT

acre-feet (Figures 3 and 12). Final side slopes will be approximately 3:1, horizontal: vertical (H:V), to maximize stability and minimize bank erosion from wind, water, and waves. The upper portions of the Reservoir slopes for several feet above and below the full Reservoir water level will be covered with suitable riprap from natural stone sources or processed construction concrete debris to prevent wave action from eroding the surface.

4.3.2. EXCAVATION

Over the estimated approximate 15- to 23-year excavation phase, excavation is expected to proceed at annual rates of up to approximately 920,000 gross tons per year of silts, sands, and gravels, although this rate will likely vary in any given year. The excavation equipment, the material processing plant and associated settling pond would be located within the Reservoir perimeter as shown in Figure 13. Different areas of the excavation bottom would be lowered in stages and the process equipment relocated as appropriate. The excavated materials would be processed to produce a specified range of granular construction materials and sold. The work would be done by WCA. WCA would also receive, stockpile, and recycle concrete construction debris materials.

During the initial excavation and material processing stage, an impermeable slurry wall will be constructed around the exaction area to limit the amount of groundwater flow into the excavation as excavation progresses below the water table.

The WCA excavation phase (Figure 13) would include the following key facilities:

- A security fence that surrounds the excavation and eventual Reservoir area.
- A controlled access gate along the west side of the excavation area.
- A scale hose near the entrance gate to provide for weighing recycle materials coming into the site and construction materials being shipped from the site.
- A haul truck unloading and loading area.
- Portable crusher and recycle plant.
- Portable diesel fuel tank for onsite equipment (4,000 gallon).
- An aggregated production (wash/screen) plant.
- A stockpile area, or areas.
- A slurry wall.
- A settling pond for clarifying/recycling process and wash water for reuse.

As shown on Figure 13 the excavations would occur within the footprint of the total area and be expanded and deepened over time. The initial excavation area shown in Figures 13 and 14, is approximately sufficient for a 6-month supply of processed material. Typically, the side slopes of the excavation will be 1.5 to 1 (Horizontal: Vertical). It should be noted that the layout and facilities shown on the figure are for illustrative purpose and WCA will refine and adjust these as necessary at the start of the excavation program, keeping all the operations within the excavation footprint.

During excavation phase, the area would be dewatered, as needed, by a series of wells constructed within the excavation area to draw down the water table to below the excavation floor. Seepage calculations (Attachment D) indicate these extraction rates would initially be minimal and increase to their maximum as the excavation is deepened to the maximum depth, i.e.

DRAFT

- Initial rate: 0 gpm
- Final rate: approximately 220 gpm

The water extracted to dewater the excavation would be pumped to the northern edge of the excavation and re-injected into a gravel fill infiltration gallery along and outside of the northern border of the slurry wall as shown on Figures 3, 13 and 14. This groundwater pumping would therefore not result in a consumptive loss of water.

The slurry wall will be designed by a qualified professional and constructed by a qualified contractor with experience in installing similar facilities. Construction would include the following facilities:

- A perimeter access road that would also serve as a leveling surface for the construction of the slurry wall. The road would vary in width from approximately 30 to 50 feet and be built on fill up to 8 foot in height.
- An approximately 60- to 80-foot-deep slurry wall surrounding the excavation/Reservoir area. Its actual depth will be determined during design and verified during construction based on subsurface information, to provide the required reduction in groundwater inflow. As shown on Figure 15, the slurry wall would be constructed through the perimeter road and capped off with a durable gravel layer.
- An approximately 5-foot-deep water infiltration trench along the northern border of the ultimate Reservoir area (Figures 15 and 16).

It is anticipated construction would take approximately 6 months and would include the following on-site facilities as shown on Figure 13. After completion of the slurry wall these facilities would be demobilized from the site:

- Vehicle and equipment parking areas.
- A fill material stockpile area.
- Equipment storage area.
- A bentonite slurry mixing pond (see further discussion below on the slurry wall construction activities).
- A slurry wall backfill mixing area that would be moved along with the construction of the slurry wall, so it is always adjacent to the segment being excavated.

The general sequence of slurry wall construction activities would include:

- Surface clearing, grading, and filling to create a sufficiently long section of the perimeter road.
- Excavation of the slurry wall trench (Figure 15) through the road which also provides a relatively level surface to contain the slurry in the excavation. The trench is first excavated to its full depth and then extended in length.
- Filling the trench with a bentonite slurry (bentonite clay and water mix) to support the sides of the excavation and prevent them from collapsing. The bentonite slurry is mixed in the above referenced bentonite slurry mix pond and pumped by pipeline into the excavated trench.
- The excavated soils from the trench are placed in an adjacent prepared slurry wall backfill mixing area for use in preparing the backfill, or if unsuitable for hauling the soil back to the WCA operations for processing as appropriate. The crushed concrete from offsite recycling may also be used as final riprap protection on the Reservoir slopes.

DRAFT

- As the trench is extended in length, backfilling is commenced. This is accomplished by first preparing the backfill material which typically includes granular soils mixed in with bentonite and water to create a low permeability material in the slurry wall backfill mixing area. Either suitable durable excavated granular material will be used, or suitable material will be obtained from the WCA operations or imported from offsite.
- Once mixed, the backfill is pushed into the trench by a dozer, or equivalent, from the narrow end, opposite to the end of the trench that is still being excavated. The backfill material displaces the bentonite slurry in the trench and eventually settles and forms a low permeability wall. The ultimate length of the slurry wall is approximately 13,400 feet and its width is typically 3 feet.
- As the wall is completed and gravel cap is placed over the top of the backfilled trench, it will form part of the perimeter road as shown on Figure 15.
- A road safety berm will also be constructed along the inside of the road facing the excavation area.
- As the excavation of the reservoir is deepened an access ramp as shown on Figure 16 will be constructed in the excavated slope to provide for equipment access.

It should be noted the above discussion is for illustration purposes and actual construction techniques will vary based on the approved means and methods the contractor selects, and possible future technology advances in slurry wall construction.

The longitudinal section through the initial and final excavation is shown on Figure 14. The excavation configuration is relatively shallow compared to its length (horizontal to vertical dimensions are of the order of 100 to 1).

The material balance is as follows:

- Excavated to a 1.5 to 1 slope: 16.4 million tons (11,050,000 cy)
- Use of excavated materials:
  - Exported as product: 11.5 million tons
  - Use for 3 to 1 fill: 2.4 million tons (based on a 75% usability factor)
  - Use for road construction 0.1 million tons
  - Other uses 2.5 million tons

Compared to the above volumes the volume of the slurry wall is much less, at approximately 112,000 cy (0.2 million tons).

4.3.3. RESERVOIR

Construction of the Reservoir would be initiated during the final stages of the excavation and material processing, or if necessary, at a later stage. It would include two major construction activities:

- Backfilling of the excavation slopes to flatten them from 1.5 to 1 to 3.0 to 1. This is shown on Figures 14, 15 and 16. The backfill would be of suitable materials that has both sufficient strength and is relatively free draining. It would be constructed from the bottom up in compacted layers of suitable thickness. Figure 16 shows the first layer of the backfill being placed along the east side of the excavation.

DRAFT

- The second major activity would include construction of the following components (Figure 17):
  - Inflow Channel - controlled by gates
  - Electrically operated slide gates in the Inflow Channel.
  - Inflow Chute – with rip-rap erosion protection.
  - Energy Dissipation Pool - Based upon the drilling logs, it is expected bedrock will be encountered at the proposed final elevation of the Inflow Chute. However, if the excavation does not get down to bedrock, installation of an energy dissipation pool at the base of the Inflow Chute would prevent potential scouring of the excavation slope by water entering the Reservoir.
  - Floating Barge Pump and Discharge Pipeline to deliver into the Kaweah River upstream of the existing McKay Point Structures.
  - Above-Ground Diesel Tank, Generators and Generator Building.
  - Outflow Channel into the St. Johns River.
  - Electrically Operated Weir for the Outflow Channel.
  - Supervisory Control and Data Acquisition (SCADA) equipment would be used to monitor Reservoir levels and conditions, and to operate the Inflow Channel, Outflow Channel, and Floating Barge Pump.

4.4. DESIGN

Conceptual level designs have been completed for the purposes of this report. These are described in the Geology and Soils Technical Study (SLR, 2021), and are at a level of detail that allows for the evaluation of the impacts and benefits associated with the proposed facilities. A brief discussion is also provided of the typical detailed design activities that would be performed before the facilities are constructed.

Conceptual designs of the various reservoir components discussed in Section 4.3.3 above are provided by Provost and Pritchard.

4.5. WATER BALANCE

4.5.1. DURING EXCAVATION

Processing will include both crushing and screening as well as washing. A total water flow rate of up to 1,500 gpm will be required for these processes. The used water will be collected and conveyed to a settling pond in the bottom of the excavation where the washed-out fine material would settle, and the clarified water would be recycled back to the processing plant with the remainder infiltrating back into groundwater under the excavation area. A much smaller amount of makeup water would be required to replace the water lost in the processing and water used for dust control at the Site. This water would be extracted from several wells located within the excavation area, the same wells that are used to dewater the excavation. Estimated makeup water requirements (or consumptive use of water during the construction period) amount to:

DRAFT

- Losses in the processing: 110 AF/year
- Settling pond evaporation: 1 AF/year
- Dust control water: 30 AF/year

  Total: 141 AF/year

The processing will also result in the accumulation of fine silt which collects in the bottom of the settling pond, some of which may be used as a soil amendment onsite in association with revegetation activities, and in construction of safety and slope stabilization berms.

During excavation the groundwater extracted to maintain dry conditions would be pumped back into the infiltration trench so would not represent a consumptive use.

4.5.2. DURING RESERVOIR OPERATIONS

Water balance analyses have been performed to assess how the Reservoir would typically be operated and how much consumptive use is associated with these operations. Water loss would occur form:

- Evaporative loss from the moist surface of the Reservoir when it is maintained in an empty condition.
- Evaporative loss from the Reservoirs surface when it is full, or partially full.

Estimated consumptive use during a year when the reservoir is operating is approximately 200 AF. During years when the reservoir is not used, net evaporation losses range from insignificant for the case where the Reservoir is maintained empty by continuous pumping of the inflowing groundwater into the infiltration trench, to approximately 340 AF for the case when the Reservoir is maintained in a filled condition, thus saving the pumping energy consumption.

4.6. ANTICIPATED RESERVOIR OPERATIONS

4.6.1. INFLOW CHANNEL MANAGEMENT

The Inflow and Outflow Channels will be constructed perpendicular to the Kaweah and St. Johns Rivers (Figures 3 and 17). The Inflow Channel will provide flow into the Reservoir via a reinforced concrete control structure. The control structure would include an approach apron, reinforced concrete floor, flow/level control gates, walls, and a deck on top of the structure. The existing check structures downstream of McKay Point and the proposed inlet gates would control the flow rate into the Reservoir (Provost and Pritchard, 2014).

To divert river water into the Reservoir, when the river water level is higher than that of the Reservoir, the Electrically Operated Weir on the Inflow Channel would be opened. Water would flow by gravity into the Reservoir up to a maximum flow capacity of up to 3,500 cfs and an average of approximately 2,400 cfs as the Reservoir fills up. Upon achieving water level equilibrium between Reservoir and river, the Electrically Operated Weir would be closed. As the level of the river recedes, the Electrically Operated Weir would serve to hold water in the Reservoir.

DRAFT

4.6.2. OUTFLOW CHANNEL MANAGEMENT

Gravity-Flow Water Delivery into The St. Johns River and Kaweah River

The gravity Outflow Channel for the Reservoir is located downstream of the St. John's check structure (Figures 3 and 17). The discharge capacity of the outlet is currently estimated to be approximately 900 cubic feet per second. The outlet could gravity drain up to approximately 1,100-acre feet of the Reservoir into the St. Johns River. A proposed floating pump would empty the remaining 3,500 acre-feet stored in the Reservoir. Discharge capacity of the floating pump is currently estimated to be 160 cubic feet per second and would discharge upstream of McKay's Point allowing for diversions into either the St. Johns or the Lower Kaweah River (Provost and Pritchard, 2014).

When the St. Johns River water level is lower than that of the Reservoir, lowering the Electrically Operated Weir on the Outflow Channel would deliver water by gravity flow into the St. Johns River up to a maximum flow capacity of 900 cfs. The average flow rate will be approximately 350 cfs because the flow rate would reduce gradually to zero as the level of the Reservoir approaches the level of the Outflow Channel.

The Outflow Channel will include a riprap or concrete apron, constructed across the riverbed of the St. Johns River when dry. This apron will prevent the potential scouring effects of the water entering the river.

The Inflow Channel could also be used as an Outflow Channel to deliver releases to the Kaweah River. It also includes riprap protection in the river. When the Kaweah River water level is lower than that of the Reservoir, lowering the Electrically Operated Weir on the Inflow Channel would deliver water by gravity flow into the Kaweah River at a flow capacity of 500 cfs (the Inflow Channel could be used for inflow or outflow). The average flow rate of return will approximate 200 cfs because the flow rate would reduce gradually to zero as the level of the Reservoir approaches the level of the Inflow Channel.

Water delivery in this manner is limited by the amount of water being stored at a level higher than that of the Inflow Channel (i.e., approximately 15 feet of additional storage). Once the level of the Reservoir falls below that of the Inflow Channel, the Floating Barge Pump will be used.

Pumped Water Delivery into The St. Johns and Lower Kaweah River

To release water to the St. Johns River or the Lower Kaweah River when the river water levels are higher than that of the Reservoir, the Floating Barge Pump will pump water from the Reservoir, via the Floating Barge Pump Discharge, into the Kaweah River, upstream of the McKay Point Structure.

DRAFT

4.6.3. RESEVOIR OPERATIONS

The Reservoir would be operated in one of the following modes:

- *Water Conservation Mode* during which excess water would be stored in the Reservoir for later release downstream for irrigation use or groundwater recharge.
- *Flood Control Mode* during which the Reservoir would be used to store flood peaks to alleviate downstream flood damage.
- *Dual Use Mode* during which the Reservoir would be operated either for conservation or flood control.

From mid-April through the end of October, the Reservoir would be in *Water Conservation Mode* for water supply re-regulation. It is anticipated that the Reservoir would fill for the final time with flood water or otherwise storable Owner entitlement. Before the end of the irrigation season the Reservoir would be emptied to meet Owner irrigation demand and would remain empty for the upcoming flood season.

From the beginning of November to the end of January the Reservoir would be in *Flood Control Mode*. Flood peaks resulting from Terminus dam release and flood flows in the unregulated Dry Creek which exceed a stipulated flow rate would be diverted into the Reservoir to decrease downstream flood flows. Further discussion of this control mode is provided in Section 4.6.5 below.

From early February through mid-April approximately, the Reservoir would be in a *Dual Use Mode* which involves the overlapping of two operational drivers: *Flood Control* and Water *Conservation Modes*. During this period the Reservoir would be filled based on the availability of refused floodwater and the need to have an empty Reservoir for flood mitigation given forecasted weather conditions.

The Reservoir could be filled in a few days, depending on the flow in the Kaweah River and would decrease the peak flood flows. The quickest the Reservoir could be completely dewatered would be in approximately 12 days.

4.6.4. WATER SUPPLY BENEFITS (*CONSERVATION MODE* OPERATION)

Tulare Irrigation District (TID) has established a water balance model that simulates the irrigation water system from the outflow from Terminus Dam and Dry Creek down to the spill areas Cross Creek at Highway 43 into Tulare Lake, including supplies from, and exchanges with the Central Valley Project (CVP) and the Friant-Kern Canal, and the demands of the TID and the Consolidated Peoples Ditch Company (CPDC) and the Visalia and Kaweah Water Company (VKWC). The model incorporates the Reservoir operation. This model has been used to illustrate Reservoir operations for the climatic conditions observed for ten years from 2010 to 2019. The results of these simulations are shown in Figures 18A through 18E, and the associated agricultural water gains are summarized in Table 5[2]. These results indicate that the Reservoir benefits occur when the mean annul flow conditions exceed approximately 50% of the long-term mean annual flow, or in 6 out of the 11 years simulated. In these years, it would have benefited agencies to put Kaweah

[2] Note that the year 2017-18 is not plotted in the Figure 18 series since the additional water provided is very small.

DRAFT

water into the Reservoir to be able to take Central Valley Project (CVP) water during events in which Owners' delivery systems were at capacity due to a combination of Kaweah and CVP water and there was surplus CVP water available which had to be refused to avoid additional spill on the Kaweah system.

As shown on Figure 18A for example, the solid red line indicates the period of the *Flood Control Mode*, the dashed red line indicates the duration of the *Dual Use Mode,* and the remaining period corresponds to the *Conservation Mode*. As noted from this figure there were no diversions for flood control purposes. During the *Dual Use* and *Conservation Mode* periods water was transferred into the Reservoir in the April and May, and smaller amounts in June and August as indicated by the green dashed line. This stored water would have been used in May and again in July and August as indicated by the dotted blue line. The corresponding Reservoir volumes are indicated by the solid blue line

TABLE 5 SUMMARY OF ANNUAL AGRICULTURAL BENEFITS

Year	Annual Precipitation at Terminus Reservoir		Annual Runoff of Kaweah River at McKay Point		Agricultural Benefit	
	Inches	% Of Long-Term Mean	Acre Feet	% Of Long-Term Mean	Additional Water Provided for D/S Use (AF)	Number Of Major Water Supply Events
2009-10	18.96	127%	454,670	122%	7,092	2
2010-11	22.38	150%	746,509	201%	6,910	2
2011-12	12.23	82%	200,737	54%	4,600	1
2012-13	6.77	45%	99,523	27%	-	
2013-14	6.15	41%	52,893	14%	-	
2014-15	8.97	60%	43,813	12%	-	
2015-16	18.39	123%	287,178	77%	-	
2016-17	19.89	133%	922,247	248%	5,842	1
2017-18	8.93	60%	202,334	54%	61	1
2018-19	17.33	116%	631,189	170%	11,445	2
AVERAGE ANNUAL	14.94	100%	371,790	371,790	3,595	1.5

The benefits of the *Conservation Mode* operations are expected to increase for climate change scenarios. While the total annual runoff changes are minor (a reduction of up to 5%, Section 2.3.2) the higher seasonal flows are projected to occur earlier in the year likely resulting in increased flood releases from Terminus Dam. With the Reservoir in place these earlier releases could be stored and then used to increase the CVP water by a like amount later in the year. Furthermore, use of the Reservoir will more critical since overall, less runoff will be available, making it more important to reduce any spillage of unused water by storing it in the Reservoir.

4.6.5. FLOOD MANAGEMENT BENEFITS (*FLOOD CONTROL MODE* OPERATIONS)

The Terminus Dam and Kaweah Project is operated so that flows do not exceed 5,500 cfs in the Kaweah at McKay Point to protect the downstream municipalities, rural communities, and agricultural lands in the Tulare Lakebed from flood damage. (USACOE, Revised 2005). Dry Creek is the major uncontrolled tributary to the Kaweah River below Terminus Dam and upstream of the Reservoir. This tributary can produce high magnitude flows that require rapid release changes from the dam if the impact is to be reduced, since there are no flood control measures in place for these flows.

Flood attenuation benefits were assessed by considering the three largest instantaneous flood peak flows that were recorded on Dry Creek between 1960 and 1997. As shown on Table 6, these include:

- December 6, 1966 (peak flow = 14,500 cfs).
- January 25, 1969 (6,070 cfs).
- January 2, 1997 (4,380 cfs).

Operations of Terminus Dam allowed for low release rates on these flood days to compensate for the higher Dry Creek flows as shown by the measured average daily flows in Table 6 (column 3). However even with these reduced discharges the flood peak flows in the Kaweah River at McKay point were still elevated as shown in the 4th column of Table 6, i.e., 4,508, 6,646 and 15,549 cfs respectively. In extremely wet years such as 2017, it would be desirable to have the Reservoir absorb the Dry Creek flows so that Terminus can keep releasing as opposed to reducing releases from Terminus, thereby keeping storage available for flood inflow to Terminus (Watermaster of the Kaweah Delta).

Flood routing simulations were conducted to assess how much the Reservoir, had it been in pace, could have reduced these flood peaks. For these simulations it was assumed that once the Kaweah River at McKay Point flows exceed 2,500 cfs, the excess flows up to the maximum capacity of the inlet to the Reservoir (3,500 cfs[3]) are diverted into the Reservoir. As shown by the results listed in Table 6 (column 5), it would have been possible to reduce the flows to below approximately 3,000 cfs in the river, except for the very large December 1966 flood. Even for this event the flood peak would have been reduced to 12,472 cfs, a reduction of 3,068 cfs.

Figure 19 shows which day of the year the measured annual maximum flood peaks occurred in Dry Creek, and these can be considered to cover the periods during which future large floods may occur and during which the Reservoir could potentially be used for flood control purposes. The solid lines in the chart indicate the approximate starts and finishes to the *Flood Control Mode* period that could be considered. These periods would include:

- November 1 would be the start of the flood control operations during which the Reservoir would exclusively be used for flood control purposes and emptied after each flood storage event in anticipation of the next flood event. The released water could be used for recharge in a variety of basins around TID ranging from several acres to 150 acres in size.
- January 31 would be considered the end of the *Flood Control Mode* period.

[3] This assumes the gates will all be opened to provide for the maximum inflow capacity during a flood event. During normal operations inflow rates would be less.

DRAFT

- February 1 through April 15 would be considered a *Dual Use Mode* period during which water from a projected large flood would be stored in the Reservoir, but after the flood the water would only be released in accordance the which agricultural demand as discussed in Section 4.6.4.

TABLE 6: KAWEAH RIVER AT MCKAY POINT – ANNUAL FLOWS						
HISTORIC FLOOD FLOW DATA				SIMULATED EFFECT OF STORING FLOOD FLOWS ABOVE 2,500 CFS[4] IN RESERVOIR		
DATE	MEASURED INSTANTANEOUS PEAK DRY CREEK FLOW RATE (CFS)	MEASURED AVERAGE SAME DAY DAILY OUTFLOW FROM TERMINUS DAM (CFS)[5]	CALCULATED MAXIMUM INSTANTANEOUS PEAK FLOW IN KAWEAH AT McKAY POINT (CFS)[6]	REDUCED FLOOD FLOWS TO DOWNSTREAM OF RESERVOIR (CFS)[7]	REDUCTION IN KAWEAH RIVER AT McKAY POINT FLOW BY STORING FLOOD WATER IN THE RESERVOIR (CFS)	RESERVOIR STORAGE UNTILIZED (AF)
December 6, 1966	14,500	1,040	15,540	12,472	3,068[8]	4,600
January 25, 1969	6,070	576	6,646	3,146	3,500	2,429
January 2, 1997	4,380	128	4,508	2,628	1,880	939

The flood routing was repeated for the estimated 10-year to 100-year flood peaks at McKay Point developed by FEMA and discussed in Section 3.5 above. The results are provided in Table 7 showing the reductions that could be achieved. It is evident that the Reservoir could reduce flood peaks to below the target 5,500 cfs for flood events up to approximately the one in 50-year event. For larger floods, it would still be possible to reduce the flood peaks, however it would not be possible to meet the 5,500 cfs target at McKay Point.

In conclusion the Reservoir would have the ability to capture some of the floodwater from large floods in Dry Creek, where it would be held until it can be safely returned to the Kaweah and St. Johns rivers for direct use or recharge. The Reservoir has the capacity to reduce flood peak up to approximately the 50-year return period event to below the Target 5,5000 cfs. There would still be a benefit during still larger floods in reducing the peak flow rates.

[4] The 2,500 cfs has been set as a threshold above which water is diverted into the Reservoir. During floods in Dry Creek of this magnitude the flood peaks could be potentially further reduced if necessary.
[5] Based on the difference between the measured average daily flows at "Dry Creek" from "Total Kaweah River at McKay Point" as recorded in the Water Master Reports.
[6] Sum of the measured instantaneous Dry Creek flow and the average daily outflow from the Terminus Dam
[7] Based on flood routing through the Reservoir.
[8] It was not possible to reduce the flood peak by the capacity of the inlet structure because the reservoir was filled with flood water before the actual peak river flow occurred.

TABLE 7 SIMULATED EFFECT OF STORING FLOOD FLOWS ABOVE 2,500 CFS[9] IN RESERVOIR				
DATE	ESTIMATED MAXIMUM INSTANTANEOUS PEAK FLOW IN KAWEAH AT McKAY POINT (CFS)[10]	REDUCED FLOOD FLOWS TO DOWNSTREAM OF RESERVOIR (CFS)	REDUCTION IN KAWEAH RIVER AT McKAY POINT FLOW BY STORING FLOOD WATER IN THE RESERVOIR (CFS)	RESERVOIR STORAGE UNTILIZED (AF)
100-year	18,456	16,706	1,750	4,600
50-year	8,725	5,225	3,500	3,998
10-year	4,400	2,500	1,900	955

Since climate change is expected to result in increased intensities of flood events, more frequent flood events, and earlier arrival of high winter flows. Under these conditions the Reservoir would provide for increased flood control benefits. For example, as discussed in Section 2.3.2, flood peaks for the current frequencies are expected to occur almost twice as often. This would mean that instead of the Reservoir contribution to flood reductions for storms exceeding the 10-year event, it would be more useful and would be able to provide for reductions in flood flows for storms exceeding the 5-year event. This means that over a Project life of 50-year say, instead of the Reservoir being used approximately 5 times, it would be used approximately 10 times.

DRAFT

[9] The 3,500 cfs has been set as a threshold above which water is diverted into the Reservoir. During floods in Dry Creek of this magnitude the flood peaks could be potentially further reduced if necessary.

[10] Based on FEMA estimates

5. POTENTIAL IMPACTS

5.1. CEQA SIGNIFICANCE CRITERIA

Hydrology and water quality impacts are described in subsequent sections based on an evaluation of existing Site surface and groundwater hydrology and water quality conditions, and consideration of Project water consumption and potential changes to surface and groundwater hydrology and quality due to Project ground disturbance and land uses. A hydrology or water quality impact is considered significant if it would result in any of the following, adapted from the CEQA Guidelines, Appendix G:

a) Violate any water quality standards or waste discharge requirements or otherwise substantially degrade surface or groundwater water quality.

b) Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of preexisting nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted).

c) Substantially alter the existing drainage pattern of the Site or area, including through the alteration of the course of a stream or river, in a manner which would result in substantial erosion or siltation on- or off-site.

d) Substantially alter the existing drainage pattern of the Site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or off-Site.

e) Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems, cause flooding on- /or off-Site, or provide substantial additional sources of polluted runoff.

f) Place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map.

g) Place within a 100-year flood hazard area structures which would impede or redirect flood flows.

h) Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding because of the failure of a levee or dam; or

i) Inundation by seiche, tsunami, or mudflow.

Regarding item “f”, the Project does not include the construction of housing. As a result, this criterion has been eliminated from further consideration.

DRAFT

5.2. IMPACT HWQ 1 (CRITERION "a"): THE PROJECT COULD RESULT IN IMPACTS TO WATER QUALITY

The potential for water quality impacts to be caused by the Project due to the use and storage of fuels and chemicals, and possibly due to runoff from the Project Area, is evaluated below.

Any unacceptable impacts due to suspended sediment entrainment in surface water would be prevented by the appropriate engineering measures and regulated under the State Water Resources Control Board's (SWRCB's) General Storm Water Permit. These measures are discussed further below.

5.2.1. USE OF FUELS AND OTHER CHEMICALS FOR EQUIPMENT OPERATION AND MAINTENANCE

The use of hazardous materials during Reservoir construction and operation would mainly include fuels, lubricants, and fluids associated with vehicles and equipment. Hazardous materials used as part of construction operations on onsite equipment and vehicles would primarily include fuels and lubricants. Any spill from vehicles or equipment would likely be small and would be promptly and easily cleaned up and disposed of in accordance with State and County regulations.

During Reservoir excavation and construction, hazardous materials will not be stored onsite. Only minor maintenance of equipment and vehicles would be conducted onsite, and vehicles would be fueled by a mobile fuel truck. These activities would be done within the excavation area (Figure 13) where the receipt, storage, handling, use and disposition of these materials in compliance with the requirements of the approved Business Plan, Hazardous Materials Inventory.

Construction will include the installation of an above-ground diesel storage tank, diesel generators, and a generator building near the Inflow Channel. Except for the fluids stored in or on the vehicles and equipment, and, during operations, one AST containing diesel fuel (see below), hazardous materials will not be stored within the Project site. The AST will be used to operate a floating pump in connection with Reservoir operations and will not be used for fueling of vehicles or equipment. Therefore, dispenser-related spillage will not occur

The AST will be dual walled for leak protection. Filling of the AST will only occur in a designated area underlain by concrete paving or a protected flexible membrane liner to facilitate spill cleanup and to inhibit migration of fuel contaminants into the soil column. The Diesel AST will be managed in accordance with a Spill Prevention, Control and Countermeasure (SPCC) Plan. Storage, transfer, spill avoidance, and spill response procedures will be documented in the SPCC Plan.

The AST will not be in an area predicted to be inundated by a 100-year flood, as described in subsequent sections, and as shown on Figure 11. Therefore, damage of the AST because of flooding is not anticipated.

DRAFT

5.2.2. STORM WATER RUNOFF

The SWRCB (Board) has jurisdiction throughout California. Created by the State Legislature in 1967, the Board protects water quality by setting statewide policy, coordinating, and supporting the Regional Water Board efforts, and reviewing petitions that contest Regional Board actions. Nine Regional Water Quality Control Boards exercise rule making and regulatory activities by basins. Tulare County falls within the jurisdiction of the Central Valley Regional Water Quality Control Board (CVRWQCB). As such, the Project is subject to the requirements of the *Water Quality Control Plan for the Tulare Lake Basin*, revised January 2004.

The SWRCB issued a statewide Industrial General Storm Water Permit (Permit) that applies to all industrial storm water discharges. The SWRCB adopted a new Permit that took effect July 1, 2020.

The Owners will obtain coverage under the Permit, as required. Storm water runoff from the Project Area would be managed through proper implementation of Best Management Practices (BMPs such as sediment and erosion control measures) as described in the Stormwater Pollution Prevention Plan (SWPPP). The primary objective of the SWPPP and BMPs is to ensure that polluted runoff, including runoff containing suspended solids and sediment, does not leave the Site and degrade other water bodies. The SWPPP will contain descriptions of aspects such as potential discharge areas, significant materials, and BMPs. BMPs also include non-structural elements such as employee training, documented operating procedures, and general housekeeping. Compliance with applicable storm water regulations will prevent impacts to water quality.

The Project is designed to divert water from the Kaweah River and store this water for later release downstream for use by irrigation water customers. The Project design incorporates engineering measures such as concrete slabs and riprap to prevent erosion and entrainment of suspended solids at the inlets and outlets to the Reservoir where higher water velocities are expected to occur. The Project will not create large areas of impermeable surfaces and will not result in increased rates of surface runoff. In fact, the Project will serve to capture rainfall, thereby reducing surface runoff compared to baseline conditions. Geologic materials exposed in the Reservoir will consist of natural sediments which do not contain deleterious materials or chemical constituents capable of degrading groundwater. Process water will not be generated or discharged to groundwater or surface water as part of the Project. Therefore, the Project is not expected to produce additional runoff, or convey pollutants to surrounding waterbodies.

During the construction phase, energy dissipaters such as sediment catchment basins or sumps, rock dams, and berms, will reduce erosion, trap sediment, and minimize the potential for off-site transport of pollutants. During the excavation phase of the construction, activities will take place inside the excavation itself, thereby preventing any runoff from these activities from entering the rivers. Operations will minimize the extent of disturbed areas. Discharges of storm water runoff from the Site will decrease. Runoff will be directed into the Reservoir or local detention areas to the extent practical.

The final side slopes for the reservoir will be protected from erosion by wind-wave action by the placement of suitable granular material including riprap to armor these surfaces. The perimeter

DRAFT

road will be graded to direct runoff into the Reservoir or onsite detention areas instead of toward the rivers. Also, the road will continue to be inspected and maintained regularly. Inspections of the road condition and the status of sediment and erosion control measures will be integrated with regular required storm water inspection pursuant to the Permit.

5.2.3. DISCHARGES FROM RESERVOIR COULD CONTAIN SUSPENDED SOLIDS

The Owners may choose to fill the Reservoir during high flow conditions, which may occur in response to periods of extraordinary precipitation. High flow conditions will naturally entrain soil particles from the banks or bottom of the river. As a result, water diverted into the Reservoir may contain elevated concentrations of sediments. Releases from the Reservoir containing excessive sediments could violate the Basin Plan water quality objectives (WQOs), and adversely affect beneficial uses that are designated for the St. John River.

During the time water is stored within the Reservoir, sufficient time will be allowed for settlement of sediments to occur to assure that the discharged water will meet the WQOs with respect to suspended sediment and turbidity.

5.2.4. CONCLUSION

The Project is not expected to cause increased siltation or degrade water quality of surface waters or groundwater, or cause violations of water quality criteria. The Site will be subject to conditions of the SWPPP and SPCC Plan, including provisions for inspections, monitoring, and reporting. The Project involves creation of a Reservoir, which is a topographic depression that will reduce runoff discharges from the Site and vicinity. As a result of proper implementation of sediment and erosion control measures, the Project is not expected to exacerbate the pollutant load of St. Johns or Kaweah Rivers.

Major maintenance of the trucks and equipment will be conducted at approved facilities located outside of the Project area, both during the excavation. construction and operational phases. During the excavation and construction of the Reservoir trucks and equipment will be fueled onsite with mobile fuel trucks within the excavation area. Since the AST will be constructed, operated, and maintained in accordance with applicable regulations, the probability of an onsite spill is minimized. As a result of the factors discussed above, this analysis concludes that the Project would have a less than significant impact on water quality under criterion "a" above.

Level of Significance Before Mitigation: Less than significant
Mitigation Measures: None Required

DRAFT

5.3. IMPACT HWQ2 (b): THE PROJECT COULD IMPACT GROUNDWATER SUPPLIES, GROUNDWATER LEVELS, AND/OR RECHARGE

5.3.1. SLURRY WALL INSTALLATION

As noted above, a slurry wall, installed initially during excavation of the Reservoir, will decrease the flux of groundwater between the Reservoir/excavation and surrounding aquifer. Slurry walls are underground walls made of bentonite (clay) mixtures that are installed to inhibit groundwater flow. In this case, the slurry wall would be installed around the Reservoir perimeter to decrease groundwater seepage flowing into the Reservoir during excavation and construction phases, and to keep the Reservoir in a relatively dry condition when not being used for storage. The slurry wall would be installed from elevations above the groundwater levels and extend upwards into the Reservoir's perimeter berm as needed to contain water stored in the Reservoir above groundwater levels and downwards into natural lower permeability materials as discussed in Section 4.1.

The slurry wall would be a permanent fixture of the Reservoir and would serve as an essential feature to achieve the following:

- Assist in maintaining dewatered storage capacity to receive surface water diversions.
- Keep groundwater out of the Reservoir to minimize aquifer impacts and provide maximum space to receive Kaweah River water; and
- Inhibit losses of surface water stored in the Reservoir to the surrounding aquifer when the Reservoir is full.

It is recognized that even with the slurry wall installed there will be groundwater seepage into the Reservoir from under the slurry wall when the Reservoir is empty and some leakage of stored water to groundwater when the Reservoir is full. How this seepage/leakage is managed is described in Section 4.1 and in the discussion below.

5.3.2. DRY RESERVOIR CONDITIONS

Dry reservoir conditions will exist during construction after slurry wall installation. Dry Reservoir conditions will also exist during Reservoir operations during time periods in which the Owners wish to reserve storage for anticipated dam releases or precipitation events. Under these conditions, the Owners would intend to keep groundwater out of the Reservoir.

The slurry wall will not eliminate flow of groundwater into the Reservoir when the Owners wish to keep it dry. Dewatering will still be required because the bottom of the Reservoir will be at a lower elevation than the surrounding groundwater, creating a hydraulic gradient toward the Reservoir. Therefore, some groundwater seepage into the Reservoir will occur under the slurry wall and is estimated at approximately 220 gpm when the Reservoir is being kept dry (Attachment D). This is the maximum estimated range of groundwater seepage into the Reservoir, which would occur at the end of the excavation and construction phases and is estimated to occur during the entire Reservoir operations phase when the Reservoir is kept empty. At the end of excavation and construction, the bottom of the Reservoir will be approximately 60 - 75 feet below ground surface,

DRAFT

the maximum amount of pit wall will be exposed, and the maximum amount of groundwater head surrounding the Reservoir will be realized.

Reservoir operations do not involve storage of groundwater. Therefore, when dry Reservoir conditions are desired, seepage will be captured in a sump at a designated location within the Reservoir and will pumped back and reintroduced into the local aquifer via an infiltration trench located along the north side of the Reservoir, between the slurry wall and the adjacent CEMEX property. (Figure 12).

As stated above, groundwater in the Site vicinity generally flows toward the northwest (Schmidt, 2012). Based on this gradient, the Kaweah and St. Johns Rivers contribute to groundwater recharge for much of the time, and together with groundwater inflow from the east appear to be primary factors in driving the direction of groundwater flow.

After the slurry wall is installed, the general direction of groundwater flow is not expected to change since it is driven by recharge from the east and from the river channels. This northwest flow is expected to flow around the slurry wall to the north and south. This is not expected to significantly inhibit groundwater flow to areas west or north (downgradient) of the Site because the abundant coarse-grained soils of the alluvium and the fractured rock of the aquifer in the area is expected to accommodate flow around (to the north and south) and underneath the Site (Attachment A).

Groundwater is not expected to significantly mound (accumulate vertically) on the upgradient side of the Site or cause a “shadow” of depressed groundwater levels downgradient of the Site. Parcels located adjacent west of the Site will continue to receive recharge as groundwater flows around the slurry wall.

As stated above, seepage into the excavation will be collected and infiltrated back into to the aquifer, so the seepage will not constitute a loss and is not expected to affect groundwater supplies or levels.

The St. Johns and Kaweah Rivers create a significant hydraulic divide in the groundwater system. In general, any changes occurring on one side of a hydraulic divide are unlikely to affect conditions on the other side. Therefore, it is unlikely that potential groundwater related impacts, if any, would occur at sites located south of the St. Johns River or east of the Kaweah River. Because of the hydraulic divide and because the Project will not affect the fractured rock groundwater unit, groundwater levels in wells south of the Kaweah River such as the Lemon Cove municipal supply well are not expected to be affected by the Project.

The Reservoir, when pumped out, is not expected to impact the Minimum Threshold and Measurable Objective groundwater levels that have been established for Well KSB-2822 (also referred to as 18S27E05J001M), located between the St. Johns and Kaweah Rivers – Figure 9). The modeled changes to the groundwater levels around the outside of the slurry wall are provided in Attachment D which indicates these are insignificant, i.e., less than 3 to 3 feet.

DRAFT

5.3.3. OPERATING RESERVOIR CONDITIONS

An estimated approximately 200 AF/yr. ((approximately 124 gpm as a continuous flow) of net evaporation will occur during a typical year of operation during which the Reservoir remains full or partially full, during the months of May through September and for short periods of days or weeks in the November through January period when used for flood control (se Section 4.5.2). This compares to the additional annual average 3,129 AF of additional agricultural water that would be made available by operating the Reservoir (Section 4.6.3). This evaporation rate amounts to 6% of the added water generated.

On a basin wide scale, the evaporation rate is minimal (less than 0.02%) compared to the 862,000 AF (699,000 AF of which is groundwater) delivered annually for irrigation purposes in the district (Fugro, 2007). Furthermore, since the Reservoir would be frequently emptied (likely 2 or more times per year) this would prevent any buildup of dissolved constituent that may be caused by evaporative concentration.

It is not anticipated that the reservoir will remain in a full condition for an entire year; however, if for some reason this were to occur, the annual evaporative loss is expected to be approximately 340 AF (Section 4.5.2).

During Reservoir operations, when the Reservoir is filled with diverted surface water, the water surface elevation will be up to approximately 460 feet elevation which exceeds the groundwater elevation at several locations within the Reservoir footprint. Although the slurry wall will have been installed to inhibit groundwater flux into and out of the Reservoir, aquifer recharge will occur under full Reservoir conditions because the Reservoir level will be higher than the surrounding groundwater. The recharge rate is expected to be minor due to the presence of the low-permeability slurry wall. The recharge volume depends on how much time the Reservoir water level remains above the groundwater levels in the vicinity. This recharge volume is not further evaluated because it is small and, in any event, constitutes a source of groundwater recharge no more than the recharge from the rivers.

5.3.4. CONSUMPTION WATER USE DURING EXCAVATION AND CONSTRUCTION

During excavation, the amount of water consumption will be relatively minor. As discussed in Section 4.1 it is estimated be approximately 141 AF/year.

Water for these purposes would be obtained from wells installed in the bottom of the excavation. These wells would also be used for maintaining the excavation in a dry enough state for the excavation and processing activities. These consumptive uses from the existing source constitute a minimal impact over baseline conditions. These consumptive uses are not expected to affect groundwater levels or supplies in the Site vicinity.

5.3.5. CONCLUSIONS

Negligible losses to groundwater are anticipated. The slurry wall will be in place, which will form a flow barrier in the alluvial groundwater system. As a result, in the Site area, groundwater flow

DRAFT

directions will change as groundwater flows around the slurry wall through the alluvium and fractured rocks that surround the Site. Groundwater that seeps into the excavation through the slurry wall or through the bottom of the excavation will be collected and re-infiltrated back to the aquifer using infiltration drains. The infiltration gallery will be located north of the excavation, which will minimize changes to the current direction of groundwater flow in this area. Because recharge would not be significantly interrupted and offsite groundwater elevations are not expected to change noticeably, the excavation phase would therefore result in less than significant impacts under criterion “b” above.

Reservoir operations are expected to result in less impact to groundwater than the excavation and construction phases described above. The slurry wall will reduce impacts to groundwater supply by inhibiting groundwater from entering the Reservoir, where it would be subjected to evaporation. Seepage into the Reservoir through the slurry wall during dry-Reservoir periods will be returned to the aquifer. Reservoir operations impacts therefore are considered less than significant under criterion “b”.

Level of Significance Before Mitigation: Less than Significant
Mitigation Measures: None Required

5.4. IMPACT HWQ3 (c): CHANGES TO SITE OR AREA DRAINAGE PATTERNS COULD RESULT IN EROSION OR SILTATION IMPACTS

This section describes an evaluation of the potential for drainage pattern changes to cause erosion or siltation impacts. Drainage system changes associated with the Project include installation and use of the Inlet and Outlet Channel. As described above, the Project involves creation of a topographic depression that will capture precipitation and some storm water runoff. However, there are no identifiable creeks or water bodies that will be disturbed by the Project. The Project will not involve placing structures in the St. Johns or Kaweah River channels. The only changes to the river channels will be placement of riprap at the Inflow and Outflow Channels, and construction of the Inflow and Outflow Channels. The riprap will be placed below the elevation of the surrounding channel, and the Inflow/Outflow Channels will be set back from the main river channels; these structures are designed to avoid impedance of river flows.

To evaluate scouring, SLR reviewed historical aerial photos. Previous aerial photos from the years 1954, 1956, 1969, 1974, 1984, 1989, and 1994 were reviewed to determine if major scouring or changes in morphology of the Kaweah and St. Johns Rivers have historically occurred near the Site. Based on review of these aerial photographs, no significant changes have occurred since the 1954 photograph. Terminus Dam, constructed in 1962, regulates flows and flooding and rapid changes in river morphology and scouring will therefore be minimized.

The potential for scouring to occur during delivery of water from Reservoir to the St. Johns and Kaweah Rivers will be minimized. The Outflow and Inflow Channels would include a riprap and concrete aprons, constructed across the riverbed of the Kaweah River (Figure 3). These aprons will prevent the potential scouring effects of the water being delivered to the rivers. In addition, the aprons will be installed so they do not protrude into the stream, so that they will not affect river flow rates or patterns.

DRAFT

After a flood storage event in the Reservoir, water stored in the upper portion of the Reservoir would be released at flows ranging up to 900 cfs. The erosion protection measured installed in the Reservoir will prevent erosion in the outflow structure and the 900 cfs flow rate is significantly lower than the prior natural flood flows that have occurred in the rive channels and will not result in any changes to the natural erosion patterns in these.

To release water to the St. Johns River or the Kaweah River when the river water levels are higher than that of the Reservoir, a Floating Barge Pump (electrically powered) will pump water from the Reservoir into the Kaweah River, upstream of the McKay Point Structure. The Floating Barge Pump, or series of pumps, would have an approximate maximum flow rate of 160 cfs. Erosion control features will be constructed in the Floating Barge Pump discharge area so that the channel of the Kaweah River is not scoured.

In addition to review of aerial photos, SLR conducted sediment transport modeling using a computer application. The HEC-RAS computer application was utilized to evaluate the potential for sediment transport in the channels of the Kaweah River east of McKay Point, St. Johns River, and the Lower Kaweah River. The potential for sediment transport is dependent on the grain size distribution of channel materials, riverbed gradient, flow rate, and water flow regime. Further details regarding this evaluation are provided in Attachment C.

The sediment transport analysis was conducted based on the average maximum monthly flow of 1,500 cfs. This value consists of the highest average monthly flow rate measured between 2001 and 2007 documented in annual Watermaster reports (Watermaster, 2007). In other words, the flow rate used is considered the higher range of typical flow rates that occur in the Kaweah River in the Site vicinity.

Results of the HEC-RAS sediment transport analysis are presented in Attachment C. These results include profile views of the riverbeds, which illustrate a minimal potential for scour and transport at the flow rate applied.

Based on the results of the analyses the Project is not anticipated to alter the natural flow rates or conditions in the river. During Reservoir operations, flow rates in the St. Johns and Kaweah Rivers will remain within the existing range of typical flow rates that are currently managed through outflows of Terminus Dam. Use of the Reservoir for flood storage may cause flow rates in the Kaweah and St. Johns Rivers to decrease during periods of high precipitation, thereby actually reducing the scour potential.

Aerial photograph review and HEC-RAS sediment transport evaluation both suggest that, under typical conditions, there is insignificant potential for sediment transport in the river channels along the Site southern boundary. Terminus Dam is used extensively to manage flow rates in the rivers, and to avoid flow rates that would result in extensive scouring. The Project does not involve features or facilities that will change these conditions and may reduce flow rates during periods of extraordinary precipitation by providing flood storage. Based on these factors, siltation and erosion impacts associated with the Project are less than significant with respect to criterion “c” above.

Level of Significance Before Mitigation: Less than Significant
Mitigation Measures: None Required

DRAFT

5.5. IMPACT HWQ5 (d): CHANGES TO ON-SITE DRAINAGE PATTERNS, INCLUDING ALTERING THE COURSE OF RIVERS, OR SUBSTANTIALLY INCREASE THE RATE OR AMOUNT OF SURFACE RUNOFF, RESULTING IN FLOODING IMPACTS

Reservoir excavation and construction would not alter the course of rivers. The Project would, however, change onsite drainage patterns because construction of a topographic depression will reduce the amount of storm water runoff flowing out of the Reservoir area. Releases from the Reservoir will not cause river flows to exceed their normal flow rate range and will not cause flooding. In fact, the Reservoir will be used for flood storage, which will decrease river flow rates during periods of extraordinary precipitation. Based on these factors, the Project would not increase the potential for flooding on- or off-site and therefore would not result in significant impacts under criterion “d” above.

Level of Significance Before Mitigation: Less than Significant
Mitigation Measures: None Required

5.6. IMPACT HWQ5 (e): CREATE OR CONTRIBUTE RUNOFF WATER WHICH WOULD EXCEED THE CAPACITY OF EXISTING OR PLANNED STORMWATER DRAINAGE SYSTEMS, CAUSE FLOODING ON- OR OFF - SITE, OR PROVIDE SUBSTANTIAL ADDITIONAL SOURCES OF POLLUTED RUNOFF

Since both during the excavation and Reservoir phases the Project would store any rainfall that falls within the Project area, there would be no increases in flood flows outside of the Project area so the capacity of existing or planned stormwater drainage systems would not be affected. Since stormwater in the Project area would also be collected with either the excavation or Reservoir, there would be no offsite sources of polluted runoff. Discharges from the Reservoir for agricultural purposes would be subject to appropriate water quality standards.

Level of Significance Before Mitigation: Less than Significant
Mitigation Measures: None Required

5.7. IMPACT HWQ4 (g): PLACE HOUSING IN 100-YEAR FLOOD HAZARD AREA, OR STRUCTURES THAT WOULD IMPEDE OR REDIRECT FLOOD FLOWS

The Federal Emergency Management Agency (FEMA) flood map for the area including the Site indicates that the eastern portion of the proposed Reservoir is located within the 100-Year Flood Hazard Zone (Figure 9). FEMA has established base flood elevations for the St. Johns and Lower Kaweah Rivers downstream of McKay Point, but not for the Kaweah River upstream of McKay Point and the portion of the proposed Reservoir within the 100-year Flood Hazard Zone. This

DRAFT

situation is common because FEMA tends to apply its resources to conducting detailed flood mapping in populated areas (such as near the City of Visalia) rather than rural areas.

FEMA's work on the eastern portion of the Site was not conducted in sufficient detail to establish base flood elevations, and it follows that the accuracy of the flood hazard zone presented by FEMA could be improved if flood mapping in greater detail was conducted. Therefore, SLR conducted flood modeling for this area in greater detail to establish base flood elevations, and to delineate the 100-year flood inundation area.

The HEC-RAS hydraulic software package, released by the United States Army Corps of Engineers, was used to simulate the 100-year flood flow at the Kaweah River east of McKay Point. The flow is based upon the raised spillway at the Terminus dam. The peak flow at McKay Point is 18,220 cfs, as calculated by the United States Army Corps of Engineers. Details regarding this flood modeling are included in Attachment C.

The topographic data used for flood modeling consisted of the LiDAR survey conducted for the Tulare and Visalia basin in 2004. These topographic data were part of the same dataset used by FEMA for the flood mapping conducted downstream of McKay Point as documented in FEMA (2009). A total of 12 cross sections, spaced at a maximum of 1,000 feet apart, were created along the length of 7,600 feet east of the McKay Point junction of the Kaweah River. For purposes of model stability, cross sections were interpolated throughout the reach with sections positions at distances no larger than 75 feet apart.

SLR conducted a steady state flow analysis to calculate the based flood elevations for the peak flow of the 100-year flood for the Kaweah River east of McKay Point. The analysis was calibrated to tie into the water surface elevations calculated in the prior analyses conducted by FEMA for stretches of the St. Johns and Kaweah Rivers downstream of McKay Point.

Figure 11 presents the water surface elevations and floodway for the 100-year flood peak flow. Based on SLR's detailed flood modeling evaluation, the floodway for the 100-year flood peak flow will only encroach minimally on the proposed Reservoir footprint. Although the eastern end of proposed Reservoir footprint is in the areas subject to inundation as sated by FEMA, no significant quantities of water will be present in these areas. Therefore, since the Project is not expected to place structures in the 100-year flood hazard zone and is not expected to redirect flood flows this potential impact is considered less than significant under criterion "g".

Level of Significance Before Mitigation: Less than Significant
Mitigation Measures: None Required

5.8. MPACT HWQ6 (h): POTENTIAL IMPACTS OF LEVEE OR DAM FAILURE

This section considers both a levee and dam failure from a facility in the vicinity of the Project, as well as a potential failure of the Project facilities.

Levee or dam failure from a facility in the vicinity of the Project

The Terminus Dam is considered a High Hazard dam where failure or mis-operation could cause loss of human life. It has an Emergency Action Plan (EAP) which describes actions to be taken

to reduce the potential for property damage and loss of life in an area affected by the dam failure of the dam (https://nid.sec.usace.army.mil/#/dams/system/549835/summary). The EAP was last revised on September 19, 2016 and exercised (tested) on October 21, 2020.

A hypothetical failure of the Terminus Dam located upstream of the Project, likely by a dam breach, would result in a flood of released water. In the event of such a failure, the Project would not alter the extent of downstream flooding since it provides no impediment to the dam breach flood wave. Since some of the flood wave would be stored in the reservoir, the Project may slightly reduce the downstream flooding.

Workers at the Project during both the excavation and Reservoir phases would likely be exposed to flooding from a Terminus Dam failure and would need to be made aware of the EAP and be trained to comply with its requirements.

Based on the discussion above, risk associated with the unlikely scenario of a Terminus Dam failure will be minimized by the EAP. Thus, the Project would not result in significant impacts under criterion “h" above.

Potential failure of the Project facilities

The Project involves construction of a perimeter berm that may be as much as approximately 8 feet above surrounding topography in some areas. However, as described in Section 4.7, the Project only includes the placement of a berm at the edge of the predicted area to be inundated by the 100-year flood. In addition, the Project does not involve construction of housing or work areas that will be occupied on a regular basis. As described above, most of the Reservoir operations will be conducted remotely. Construction operations will also be conducted outside of the 100-year flood inundation area. Therefore, the Project is not expected to be affected by a 100-year flood.

The water elevation in the Reservoir may extend above the current natural surface elevation. Water will be withheld in some areas of the Reservoir by a berm that contains a slurry wall. The berm will be designed and constructed, to an appropriate factor of safety, to withhold the hydraulic forces necessary to store surface waters at the desired elevation. Regular inspections of the Reservoir structures and facilities, including the berm, will be conducted. Failures of berms such as the one proposed typically display early signs of an impending failure, such as slumping, appearance of seepage, or settlement, so that corrective actions will be taken by the Owners as appropriate to avoid the failure.

Even if failure occurs, the entire Reservoir volume would not flow out. A maximum of up to approximately 1,000 AF could drain from the Reservoir without pumping, compared to the total Reservoir volume of approximately 4,600 AF. In that unlikely case, the Owners would have multiple response options. The Reservoir level could be quickly lowered in a controlled fashion using the Inlet and/or Outlet Channels. Also, the McKay Point structure immediately downstream could be used to limit the extent to which river levels are raised. Similarly, the additional flow could be accommodated by multiple downstream watercourses, including the Lower Kaweah, St. Johns, and the multiple related irrigation ditches.

DRAFT

Based on the discussion above, the Project is not expected to cause significant loss, injury, or death by dam or dike failure. Thus, the Project would not result in significant impacts under criterion “h" above.

Conclusion

Level of Significance Before Mitigation: Less than Significant
Mitigation Measures: None Required

5.9. IMPACT HWQ7(i): POTENTIAL IMPACTS FROM SEICHE, TSUNAMI, OR MUDFLOW

The Project is not near the coast, so it is not susceptible to inundation by a tsunami. In addition, the Project is surrounded by relatively flat topography, and calculations conducted by SLR suggest that proposed Reservoir slopes are within acceptable factors of safety. Therefore, the Site is not expected to be affected by a mudflow.

A seiche is a standing wave that can occur in small water bodies such as basins, swimming pools, and lakes. The wave can reduce water levels at one end of the water body and increase the water level on the other, like the “sloshing” of water back and forth.

The potential for seismic ground shaking to generate a seiche in the proposed Reservoir was evaluated. The risk associated with a seiche is overtopping of the Reservoir if the amplitude of the wave exceeds the freeboard included in the design by an amount large enough to generate a force that could be detrimental to the facility.

The occurrence of a seiche and the amplitude of the wave are controlled by the natural period of the Reservoir and that of the earthquake. If the two periods are similar, resonance can occur, thus amplifying the wave.

The natural period of the Reservoir can be calculated using the Merian formula assuming a rectangular basin (USNRC, 2011).

$$\mathrm{T} = \frac{2\,L}{\sqrt{gh}}$$

Where L is the length of the basin, g the acceleration of gravity (32.2 cm/sec^2), and h the depth of water. Combining a representative value of 600 ft as the average width of the basin and a depth of water h of 70 ft, the natural period of the Reservoir is estimated to be:

$$T = \frac{(2)(600)}{\sqrt{(32.2)(70)}} = 25\ s$$

This natural period is to be compared to that of the earthquake that may shake the Site. The typical range of period for strong ground motion is between 0 and 5.0 seconds, with the dominant period for the site-specific event being on the order of 0.2 second (USGS, http://geohazards.usgs.gov/hazardtool/application.php). Therefore, the difference in period between the Reservoir and the design earthquake is two orders of magnitude.

DRAFT

An empirical formula is provided in HAZUS (FEMA, 2003) to estimate the peak wave height of the seiche as:

$$H = \sqrt{\frac{A}{L\,(\pi f)^2}}$$

Where H is the peak height, A is the acceleration (in g's), f is the frequency of the lake, and L is the wavelength (5.12/ft^2). Using the PGA calculated for the 2,475-year event of 0.20 g, the maximum wave height of a seiche is estimated to be 0.06 cm.

The estimated value of the peak wave for the seiche at the Site is extremely low and for practical purposes, insignificant. In addition, the ratio between the Reservoir and the natural period of the seismic event that could occur on Site is on the order of 125:1 (25/0.2), which indicates a possible resonance condition is unlikely.

Given the size of the Reservoir and the anticipated earthquake dominant period, resonance will not occur at the Site between the Reservoir and ground shaking, therefore the risk of a damaging seiche is insignificant and any seismic generated wave will be controlled by the design freeboard. Thus, the Project would not result in significant impacts under criterion "i" above.

Level of Significance Before Mitigation: Less than Significant
Mitigation Measures: None Required

DRAFT

6. CONCLUSIONS

As described in previous sections, SLR has conducted a review of baseline and Project related conditions and has evaluated potential Project related impacts relating to Hydrology and Water Quality based on CEQA Appendix G criteria. Based on our evaluation, we have identified no significant impacts.

LIMITATIONS

The services described in this work product were performed in accordance with generally accepted professional consulting principles and practices. No other representations or warranties, expressed or implied, are made. These services were performed consistent with our agreement with our client. This work product is intended solely for the use and information of our client unless otherwise noted. Any reliance on this work product by a third party is at such party's sole risk.

Opinions and recommendations contained in this work product are based on conditions that existed at the time the services were performed and are intended only for the client, purposes, locations, time frames, and project parameters indicated. The data reported and the findings, observations, and conclusions expressed are limited by the scope of work. We are not responsible for the impacts of any changes in environmental standards, practices, or regulations after the performance of our services. We do not warrant the accuracy of information supplied by others, or the use of segregated portions of this work product.

The purpose of an environmental assessment is to reasonably evaluate the potential for, or actual impact of, past practices on a given site area. When performing an environmental assessment, it is understood that a balance must be struck between a reasonable inquiry into the environmental issues and an appropriate level of analysis for each conceivable issue of potential concern. The following paragraphs discuss the assumptions and parameters under which such an opinion is rendered.

No investigation can be thorough enough to exclude the presence of hazardous materials at a given site. If hazardous conditions have not been identified during the assessment, such a finding should not therefore be construed as a guarantee of the absence of such materials on the Site, but rather as the result of the services performed within the scope, practical limitations, and cost of the work performed.

Environmental conditions that are not apparent may exist at the Site. Our professional opinions are based in part on interpretation of data from a limited number of discrete sampling locations and therefore may not be representative of the actual overall Site environmental conditions.

The passage of time, manifestation of latent conditions, or occurrence of future events may require further study at the Site, analysis of the data, and/or reevaluation of the findings, observations, and conclusions in the work product.

This work product presents professional opinions and findings of a scientific and technical nature. The work product shall not be construed to offer legal opinion or representations as to the requirements of, nor the compliance with, environmental laws, rules, regulations, or policies of federal, state, or local governmental agencies.

RIVER ANALYSIS

MCKAY POINT RESERVOIR, CALIFORNIA

1. PURPOSE AND SCOPE

This computation package documents the river analysis conducted for the Kaweah River east of McKay Point at the proposed McKay Point Reservoir Project Site. Maximum 1% flood peak flows were used to calculate the maximum water surface elevation. A sediment transport analysis of the river bottom was conducted under average maximum monthly flow.

2. ANALYSIS

The Federal Emergency Management Agency (FEMA) in 2009 and 2012 created Flood Insurance Rate Maps for the 1% flood (Attachment 1). The maps show the extents of areas subject to inundation, the floodway which can contain the 1% flood flow, and (for some areas) the flood water elevation contours. The extents of areas subject to inundation were calculated by FEMA for the Kaweah River and the St. Johns River only for the Kaweah River and the St. Johns River west of McKay Point. FEMA did not calculate such flood elevations for areas east of McKay Point, as they often tend to devote their resources to areas with larger populations.

The HEC-RAS hydraulic software package, released by the United States Army Corps of Engineers, was used to simulate the 1% flood flow at the Kaweah River east of McKay Point. The flow is based upon the raised spillway at the Terminus dam. The peak flow at McKay Point is 18,220 cfs. The peak flow was calculated by the United States Army Corps of Engineers.

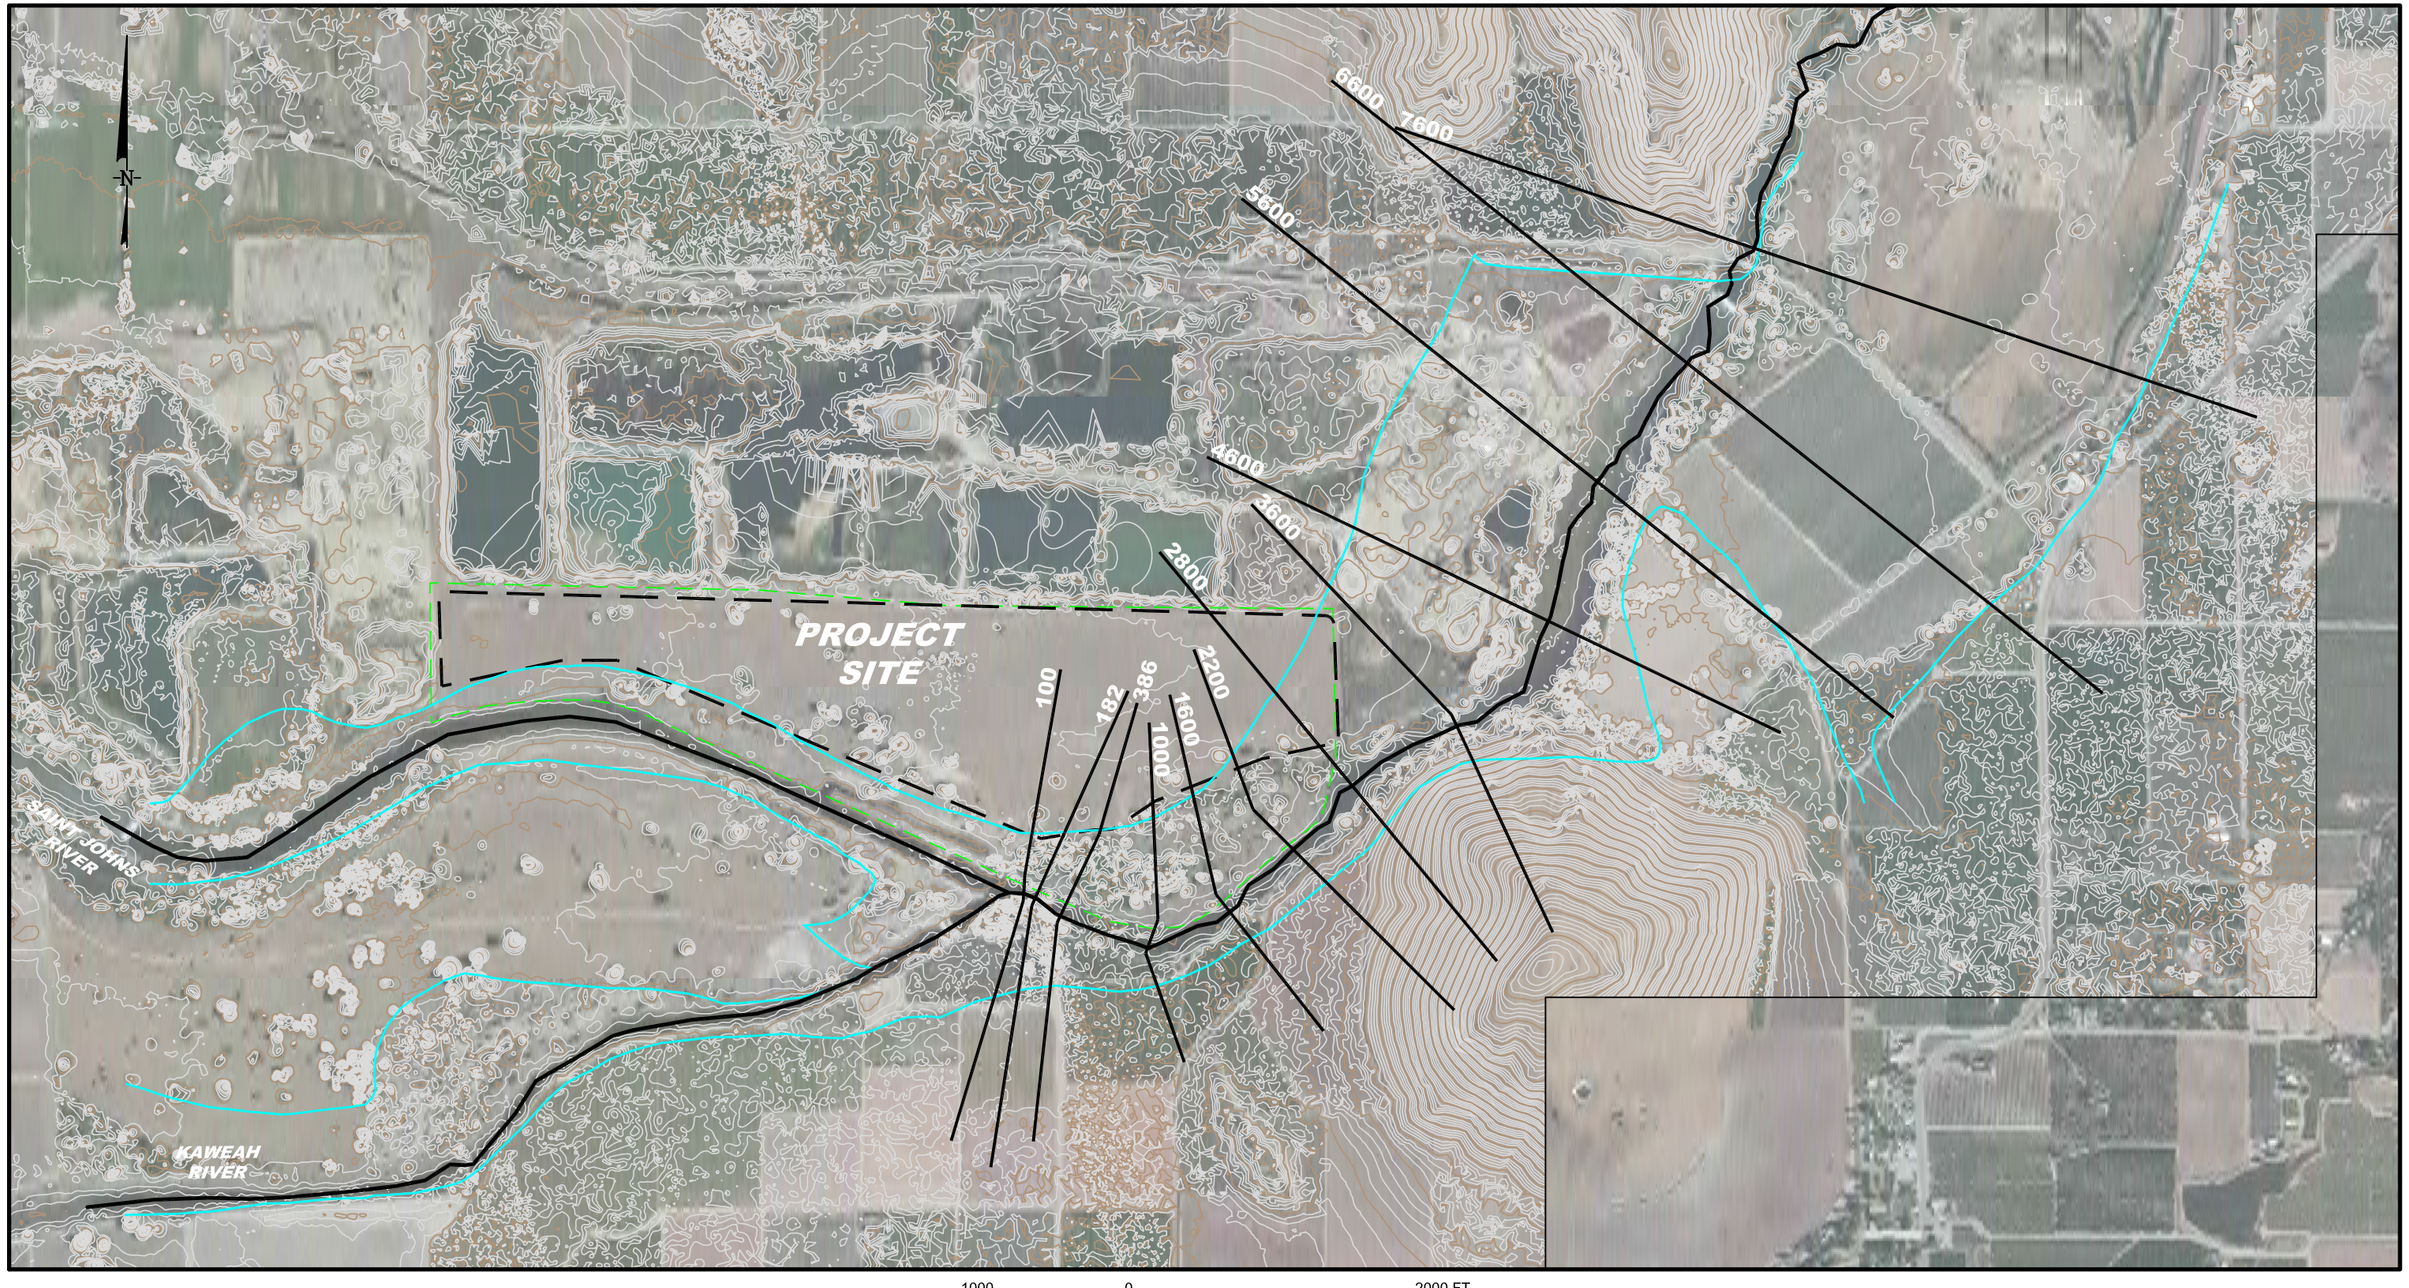
The topographic data used was from the LiDAR survey conducted for the Tulare and Visalia basin in 2004. A total of 12 cross sections, spaced at a maximum of 1,000 feet apart, were created along the length of 7,600 feet east of McKay Point of the Kaweah River. For purposes of model stability, cross sections were interpolated throughout the reach with sections positions at distances no larger than 75 feet apart. See Figure 1 for the HEC-RAS cross section locations.

A steady state flow analysis was conducted to calculate the water surface elevations for the peak flow of the 1% flood for the Kaweah River east of McKay Point. This analysis was calibrated to tie into the water surface elevations calculated in the prior analyses

conducted by FEMA in 2009. Therefore, SLR's river analysis supplements the analyses conducted by FEMA west of McKay Point.

Roughness coefficients (Manning's "n" values) utilized in the flow analysis were based on similar values from the 2009 FEMA analyses for the Lower Kaweah River just downstream of McKay Point. The channel "n" value of 0.035 and the overbank "n" value of 0.05 were used in SLR's river analysis.

3. SUMMARY AND CONCLUSIONS



The results of the HEC-RAS steady-state river analysis pre-project are presented in Attachment 2. The results of the HEC-RAS steady-state river analysis post-project are presented in Attachment 3. Results include a summary table and cross section plots of the 12 cross sections.

Figure 2 presents the post-project water surface elevations and floodway for the 1% flood peak flow. SLR's flood calculation results suggest that the floodway for the 1% flood peak flow will not encroach on the proposed reservoir footprint.

FEMA FLOOD INSURANCE RATE MAPS

NOTES TO USERS

This map is for use in administering the National Flood Insurance Program. It does not necessarily identify all areas subject to flooding, particularly from local drainage sources of small size. The **community map repository** should be consulted for possible updated or additional flood hazard information.

To obtain more detailed information in areas where **Base Flood Elevations** (BFEs) and/or **floodways** have been determined, users are encouraged to consult the Flood Profiles and Floodway Data and/or Summary of Stillwater Elevations tables contained within the Flood Insurance Study (FIS) report that accompanies this FIRM. Users should be aware that BFEs shown on the FIRM represent rounded whole-foot elevations. These BFEs are intended for flood insurance rating purposes only and should not be used as the sole source of flood elevation information. Accordingly, flood elevation data presented in the FIS report should be utilized in conjunction with the FIRM for purposes of construction and/or floodplain management.

Coastal Base Flood Elevations shown on this map apply only landward of 0.0' North American Vertical Datum of 1988 (NAVD 88). Users of this FIRM should be aware that coastal flood elevations are also provided in the Summary of Stillwater Elevations tables in the Flood Insurance Study report for this jurisdiction. Elevations shown in the Summary of Stillwater Elevations tables should be used for construction and/or floodplain management purposes when they are higher than the elevations shown on this FIRM.

Boundaries of the **floodways** were computed at cross sections and interpolated between cross sections. The floodways were based on hydraulic considerations with regard to requirements of the National Flood Insurance Program. Floodway widths and other pertinent floodway data are provided in the Flood Insurance Study report for this jurisdiction.

Certain areas not in Special Flood Hazard Areas may be protected by **flood control structures**. Refer to Section 2.4 "Flood Protection Measures" of the Flood Insurance Study report for information on flood control structures for this jurisdiction.

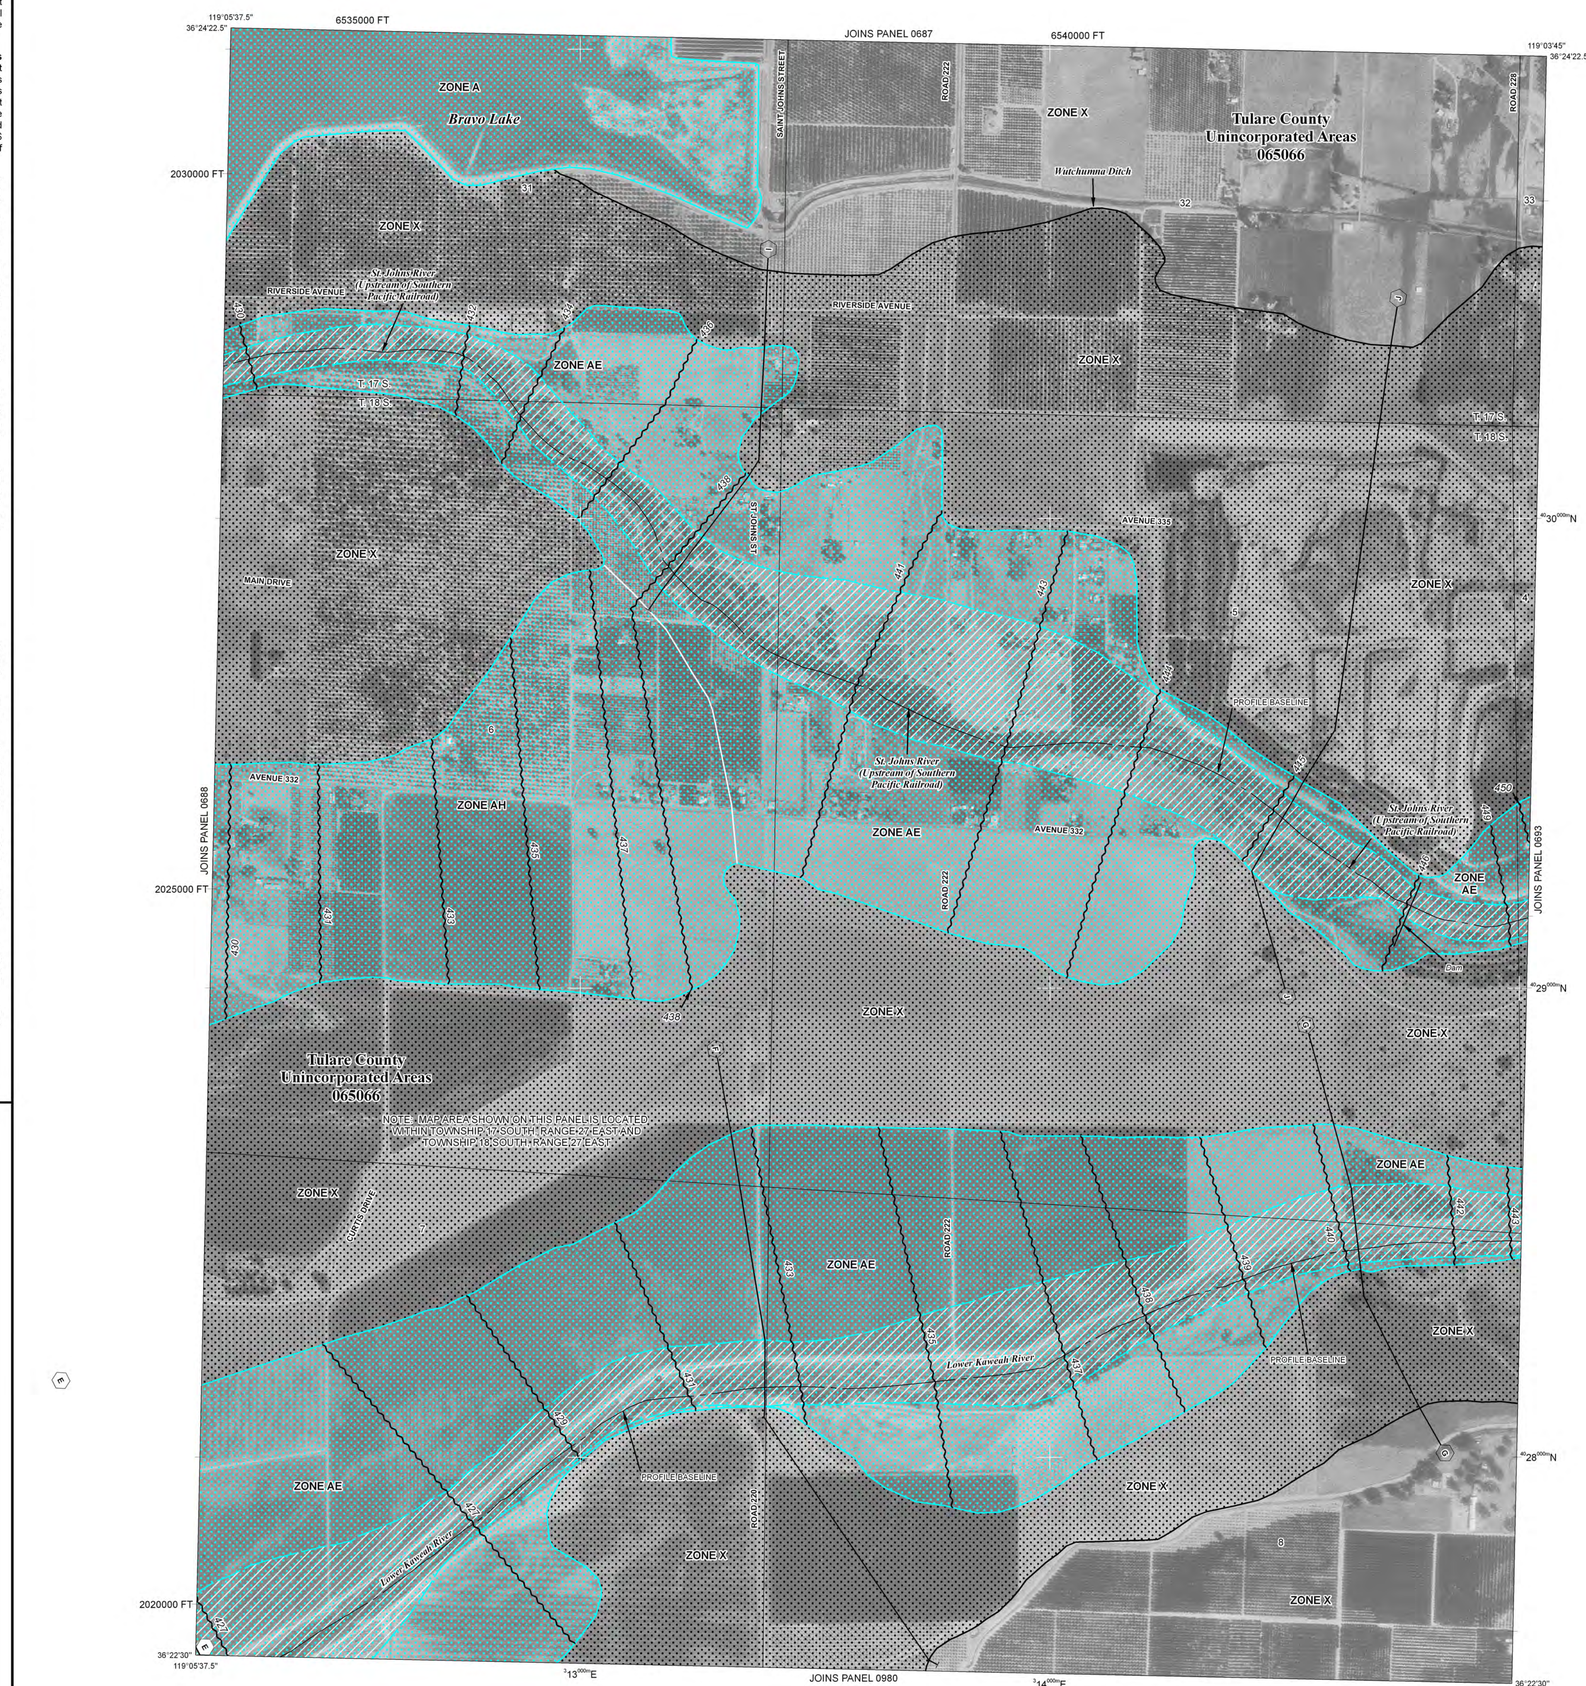
The **projection** used in the preparation of this map was Universal Transverse Mercator (UTM) Zone 11. The **horizontal datum** was NAD 83, GRS80 spheroid. Differences in datum, spheroid, projection or UTM zones used in the production of FIRMs for adjacent jurisdictions may result in slight positional differences in map features across jurisdiction boundaries. These differences do not affect the accuracy of this FIRM.

Flood elevations on this map are referenced to the North American Vertical Datum of 1988. These flood elevations must be compared to structure and ground elevations referenced to the same **vertical datum**. For information regarding conversion between the National Geodetic Vertical Datum of 1929 and the North American Vertical Datum of 1988, visit the National Geodetic Survey website at http://www.ngs.noaa.gov or contact the National Geodetic Survey at the following address:

NGS Information Services
NOAA, N/NGS12
National Geodetic Survey
SSMC-3, #9202
1315 East-West Highway
Silver Spring, Maryland 20910-3282
(301) 713-3242

To obtain current elevation, description, and/or location information for **bench marks** shown on this map, please contact the Information Services Branch of the National Geodetic Survey at **(301) 713-3242**, or visit its website at http://www.ngs.noaa.gov.

Base map information shown on this FIRM was derived from U.S. Geological Survey Digital Orthophoto Quadrangles produced at a scale of 1:12,000 from photography dated 1987 or later.



This map reflects more detailed and up-to-date **stream channel configurations** than those shown on the previous FIRM for this jurisdiction. The floodplains and floodways that were transferred from the previous FIRM may have been adjusted to conform to these new stream channel configurations. As a result, the Flood Profiles and Floodway Data tables in the Flood Insurance Study Report (which contains authoritative hydraulic data) may reflect stream channel distances that differ from what is shown on this map.

Corporate limits shown on this map are based on the best data available at the time of publication. Because changes due to annexations or de-annexations may have occurred after this map was published, map users should contact appropriate community officials to verify current corporate limit locations.

Please refer to the separately printed **Map Index** for an overview map showing the layout of map panels; community map repository addresses; and a Listing of Communities table containing National Flood Insurance Program dates for each community as well as a listing of the panels on which each community is located.

Contact the **FEMA Map Service Center** at 1-800-358-9616 for information on available products associated with this FIRM. Available products may include previously issued Letters of Map Change, a Flood Insurance Study report, and/or digital versions of this map. The FEMA Map Service Center may also be reached by Fax at 1-800-358-9620 and its website at http://msc.fema.gov.

If you have **questions about this map** or questions concerning the National Flood Insurance Program in general, please call **1-877-FEMA MAP** (1-877-336-2627) or visit the FEMA website at http://www.fema.gov.

LEGEND

SPECIAL FLOOD HAZARD AREAS SUBJECT TO INUNDATION BY THE 1% ANNUAL CHANCE FLOOD

The 1% annual flood (100-year flood), also known as the base flood, is the flood that has a 1% chance of being equaled or exceeded in any given year. The Special Flood Hazard Area is the area subject to flooding by the 1% annual chance flood. Areas of Special Flood Hazard include Zones A, AE, AH, AO, AR, A99, V, and VE. The Base Flood Elevation is the water-surface elevation of the 1% annual chance flood.

ZONE A	No Base Flood Elevations determined.
ZONE AE	Base Flood Elevations determined.
ZONE AH	Flood depths of 1 to 3 feet (usually areas of ponding); Base Flood Elevations determined.
ZONE AO	Flood depths of 1 to 3 feet (usually sheet flow on sloping terrain); average depths determined. For areas of alluvial fan flooding, velocities also determined.
ZONE AR	Special Flood Hazard Area formerly protected from the 1% annual chance flood by a flood control system that was subsequently decertified. Zone AR indicates that the former flood control system is being restored to provide protection from the 1% annual chance or greater flood.
ZONE A99	Area to be protected from 1% annual chance flood by a Federal flood protection system under construction; no Base Flood Elevations determined.
ZONE V	Coastal flood zone with velocity hazard (wave action); no Base Flood Elevations determined.
ZONE VE	Coastal flood zone with velocity hazard (wave action); Base Flood Elevations determined.

FLOODWAY AREAS IN ZONE AE

The floodway is the channel of a stream plus any adjacent floodplain areas that must be kept free of encroachment so that the 1% annual chance flood can be carried without substantial increases in flood heights.

OTHER FLOOD AREAS

ZONE X	Areas of 0.2% annual chance flood; areas of 1% annual chance flood with average depths of less than 1 foot or with drainage areas less than 1 square mile; and areas protected by levees from 1% annual chance flood.

OTHER AREAS

ZONE X	Areas determined to be outside the 0.2% annual chance floodplain.
ZONE D	Areas in which flood hazards are undetermined, but possible.

COASTAL BARRIER RESOURCES SYSTEM (CBRS) AREAS

OTHERWISE PROTECTED AREAS (OPAs)

CBRS areas and OPAs are normally located within or adjacent to Special Flood Hazard Areas.

- 1% annual chance floodplain boundary
- 0.2% annual chance floodplain boundary
- Floodway boundary
- Zone D boundary
- CBRS and OPA boundary
- Boundary dividing Special Flood Hazard Area Zones and boundary dividing Special Flood Hazard Areas of different Base Flood Elevations, flood depths or flood velocities.

NOTES TO USERS

This map is for use in administering the National Flood Insurance Program. It does not necessarily identify all areas subject to flooding, particularly from local drainage sources of small size. The **community map repository** should be consulted for possible updated or additional flood hazard information.

To obtain more detailed information in areas where **Base Flood Elevations** (BFEs) and/or **floodways** have been determined, users are encouraged to consult the Flood Profiles and Floodway Data and/or Summary of Stillwater Elevations tables contained within the Flood Insurance Study (FIS) report that accompanies this FIRM. Users should be aware that BFEs shown on the FIRM represent rounded whole-foot elevations. These BFEs are intended for flood insurance rating purposes only and should not be used as the sole source of flood elevation information. Accordingly, flood elevation data presented in the FIS report should be utilized in conjunction with the FIRM for purposes of construction and/or floodplain management.

Coastal Base Flood Elevations shown on this map apply only landward of 0.0' North American Vertical Datum of 1988 (NAVD 88). Users of this FIRM should be aware that coastal flood elevations are also provided in the Summary of Stillwater Elevations tables in the Flood Insurance Study report for this jurisdiction. Elevations shown in the Summary of Stillwater Elevations tables should be used for construction and/or floodplain management purposes when they are higher than the elevations shown on this FIRM.

Boundaries of the **floodways** were computed at cross sections and interpolated between cross sections. The floodways were based on hydraulic considerations with regard to requirements of the National Flood Insurance Program. Floodway widths and other pertinent floodway data are provided in the Flood Insurance Study report for this jurisdiction.

Certain areas not in Special Flood Hazard Areas may be protected by **flood control structures**. Refer to Section 2.4 "Flood Protection Measures" of the Flood Insurance Study report for information on flood control structures for this jurisdiction.

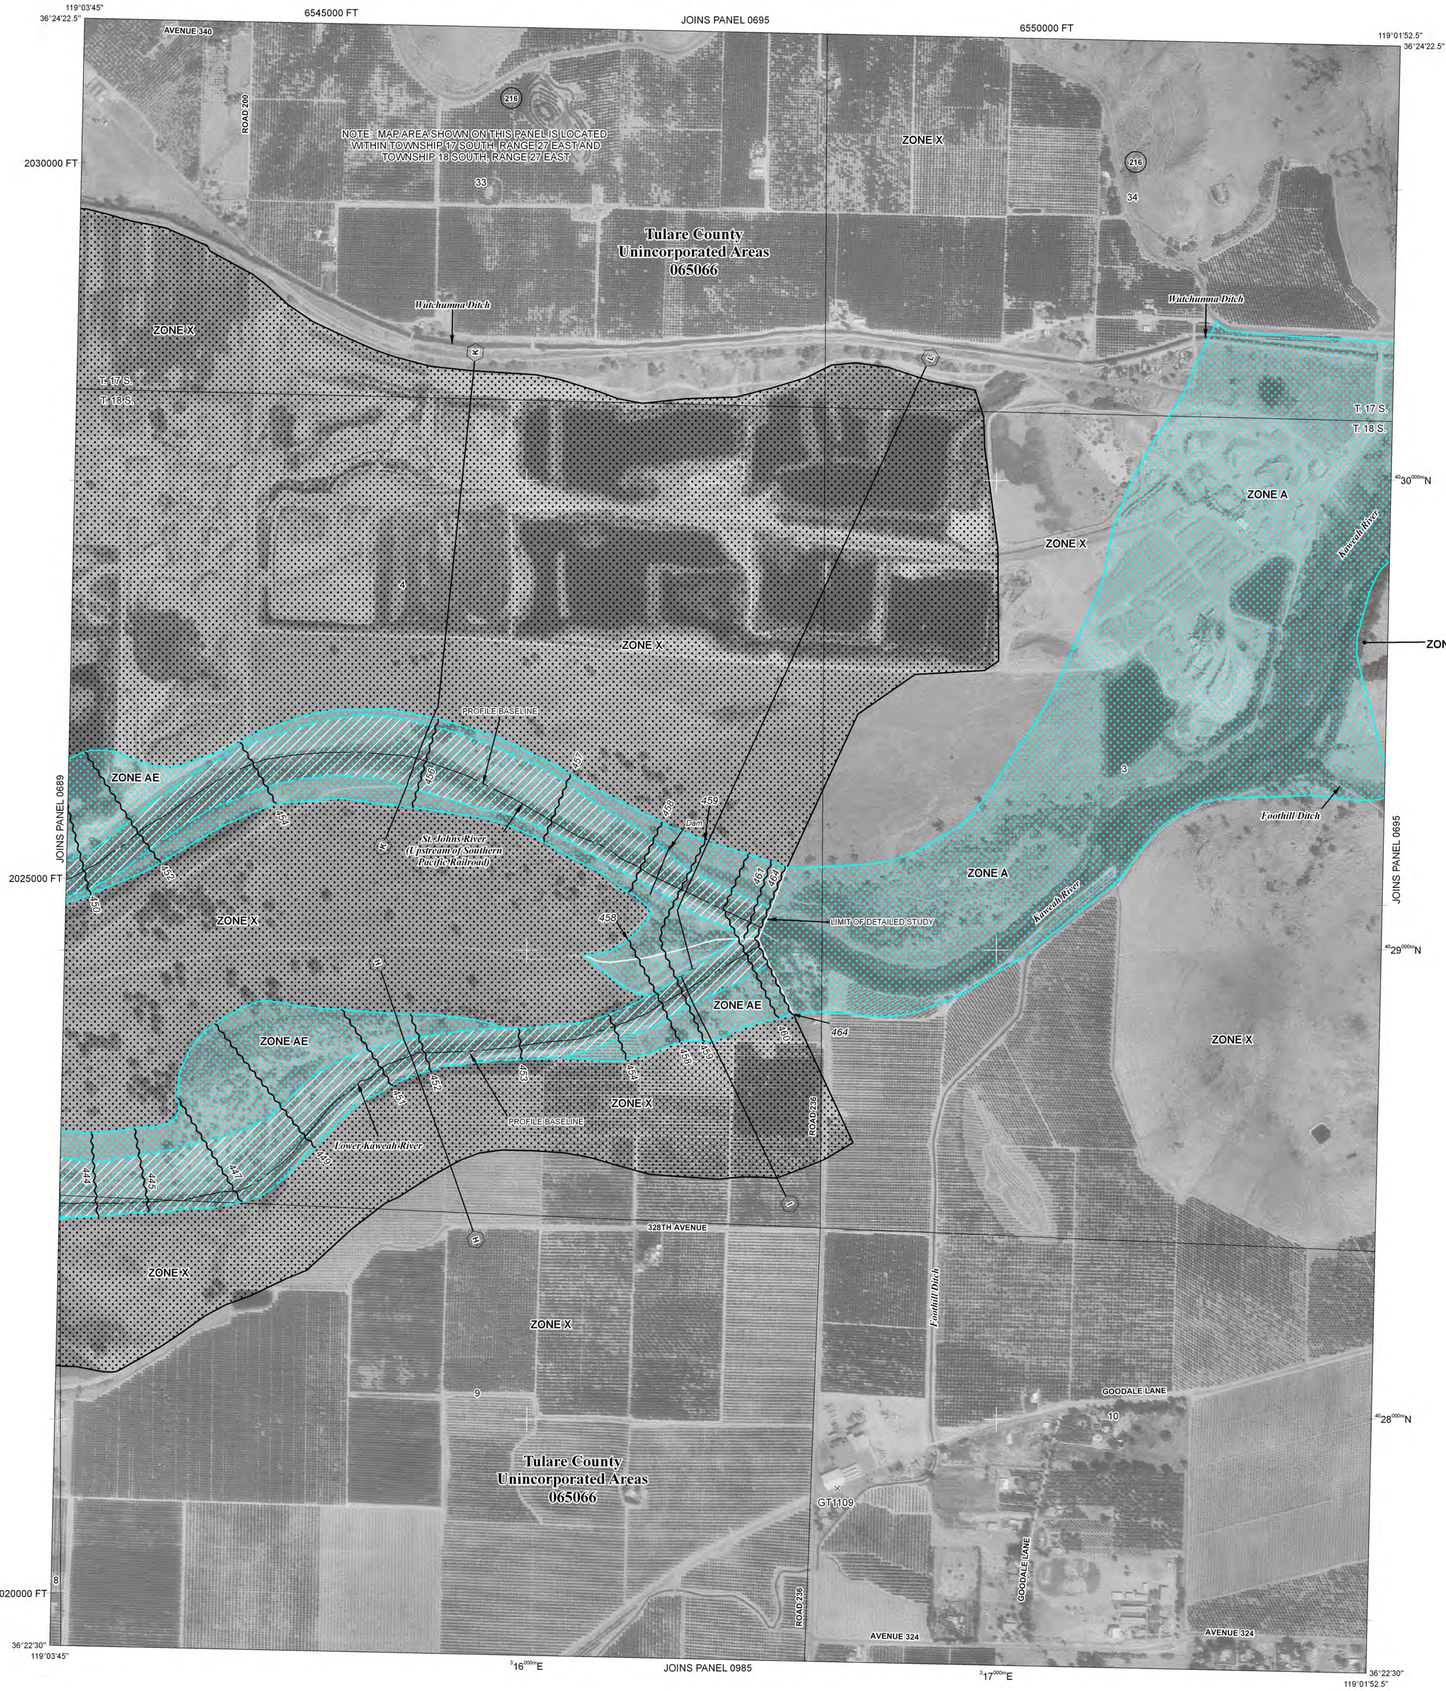
The **projection** used in the preparation of this map was Universal Transverse Mercator (UTM) Zone 11. The **horizontal datum** was NAD 83, GRS80 spheroid. Differences in datum, spheroid, projection or UTM zones used in the production of FIRMs for adjacent jurisdictions may result in slight positional differences in map features across jurisdiction boundaries. These differences do not affect the accuracy of this FIRM.

Flood elevations on this map are referenced to the North American Vertical Datum of 1988. These flood elevations must be compared to structure and ground elevations referenced to the same **vertical datum**. For information regarding conversion between the National Geodetic Vertical Datum of 1929 and the North American Vertical Datum of 1988, visit the National Geodetic Survey website at http://www.ngs.noaa.gov or contact the National Geodetic Survey at the following address:

NGS Information Services
NOAA, N/NGS12
National Geodetic Survey
SSMC-3, #9202
1315 East-West Highway
Silver Spring, Maryland 20910-3282
(301) 713-3242

To obtain current elevation, description, and/or location information for **bench marks** shown on this map, please contact the Information Services Branch of the National Geodetic Survey at **(301) 713-3242**, or visit its website at http://www.ngs.noaa.gov.

Base map information shown on this FIRM was derived from U.S. Geological Survey Digital Orthophoto Quadrangles produced at a scale of 1:12,000 from photography dated 1987 or later.



This map reflects more detailed and up-to-date **stream channel configurations** than those shown on the previous FIRM for this jurisdiction. The floodplains and floodways that were transferred from the previous FIRM may have been adjusted to conform to these new stream channel configurations. As a result, the Flood Profiles and Floodway Data tables in the Flood Insurance Study Report (which contains authoritative hydraulic data) may reflect stream channel distances that differ from what is shown on this map.

Corporate limits shown on this map are based on the best data available at the time of publication. Because changes due to annexations or de-annexations may have occurred after this map was published, map users should contact appropriate community officials to verify current corporate limit locations.

Please refer to the separately printed **Map Index** for an overview map showing the layout of map panels; community map repository addresses; and a Listing of Communities table containing National Flood Insurance Program dates for each community as well as a listing of the panels on which each community is located.

Contact the **FEMA Map Service Center** at 1-800-358-9616 for information on available products associated with this FIRM. Available products may include previously issued Letters of Map Change, a Flood Insurance Study report, and/or digital versions of this map. The FEMA Map Service Center may also be reached by Fax at 1-800-358-9620 and its website at http://msc.fema.gov.

If you have **questions about this map** or questions concerning the National Flood Insurance Program in general, please call **1-877-FEMA MAP** (1-877-336-2627) or visit the FEMA website at http://www.fema.gov.

LEGEND

SPECIAL FLOOD HAZARD AREAS SUBJECT TO INUNDATION BY THE 1% ANNUAL CHANCE FLOOD

The 1% annual flood (100-year flood), also known as the base flood, is the flood that has a 1% chance of being equaled or exceeded in any given year. The Special Flood Hazard Area is the area subject to flooding by the 1% annual chance flood. Areas of Special Flood Hazard include Zones A, AE, AH, AO, AR, A99, V, and VE. The Base Flood Elevation is the water-surface elevation of the 1% annual chance flood.

ZONE A	No Base Flood Elevations determined.
ZONE AE	Base Flood Elevations determined.
ZONE AH	Flood depths of 1 to 3 feet (usually areas of ponding); Base Flood Elevations determined.
ZONE AO	Flood depths of 1 to 3 feet (usually sheet flow on sloping terrain); average depths determined. For areas of alluvial fan flooding, velocities also determined.
ZONE AR	Special Flood Hazard Area formerly protected from the 1% annual chance flood by a flood control system that was subsequently decertified. Zone AR indicates that the former flood control system is being restored to provide protection from the 1% annual chance or greater flood.
ZONE A99	Area to be protected from 1% annual chance flood by a Federal flood protection system under construction; no Base Flood Elevations determined.
ZONE V	Coastal flood zone with velocity hazard (wave action); no Base Flood Elevations determined.
ZONE VE	Coastal flood zone with velocity hazard (wave action); Base Flood Elevations determined.

FLOODWAY AREAS IN ZONE AE

The floodway is the channel of a stream plus any adjacent floodplain areas that must be kept free of encroachment so that the 1% annual chance flood can be carried without substantial increases in flood heights.

NOTES TO USERS

This map is for use in administering the National Flood Insurance Program. It does not necessarily identify all areas subject to flooding, particularly from local drainage sources of small size. The **community map repository** should be consulted for possible updated or additional flood hazard information.

To obtain more detailed information in areas where **Base Flood Elevations** (BFEs) and/or **floodways** have been determined, users are encouraged to consult the Flood Profiles and Floodway Data and/or Summary of Stillwater Elevations tables contained within the Flood Insurance Study (FIS) report that accompanies this FIRM. Users should be aware that BFEs shown on the FIRM represent rounded whole-foot elevations. These BFEs are intended for flood insurance rating purposes only and should not be used as the sole source of flood elevation information. Accordingly, flood elevation data presented in the FIS report should be utilized in conjunction with the FIRM for purposes of construction and/or floodplain management.

Coastal Base Flood Elevations (BFEs) shown on this map apply only landward of 0.0' North American Vertical Datum of 1988 (NAVD 88). Users of this FIRM should be aware that coastal flood elevations are also provided in the Summary of Stillwater Elevations table in the Flood Insurance Study report for this jurisdiction. Elevations shown in the Summary of Stillwater Elevations table should be used for construction and/or floodplain management purposes when they are higher than the elevations shown on this FIRM.

Boundaries of the **floodways** were computed at cross sections and interpolated between cross sections. The floodways were based on hydraulic considerations with regard to requirements of the National Flood Insurance Program. Floodway widths and other pertinent floodway data are provided in the Flood Insurance Study report for this jurisdiction.

Certain areas not in Special Flood Hazard Areas may be protected by **flood control structures**. Refer to Section 2.4 "Flood Protection Measures" of the Flood Insurance Study report for information on flood control structures for this jurisdiction.

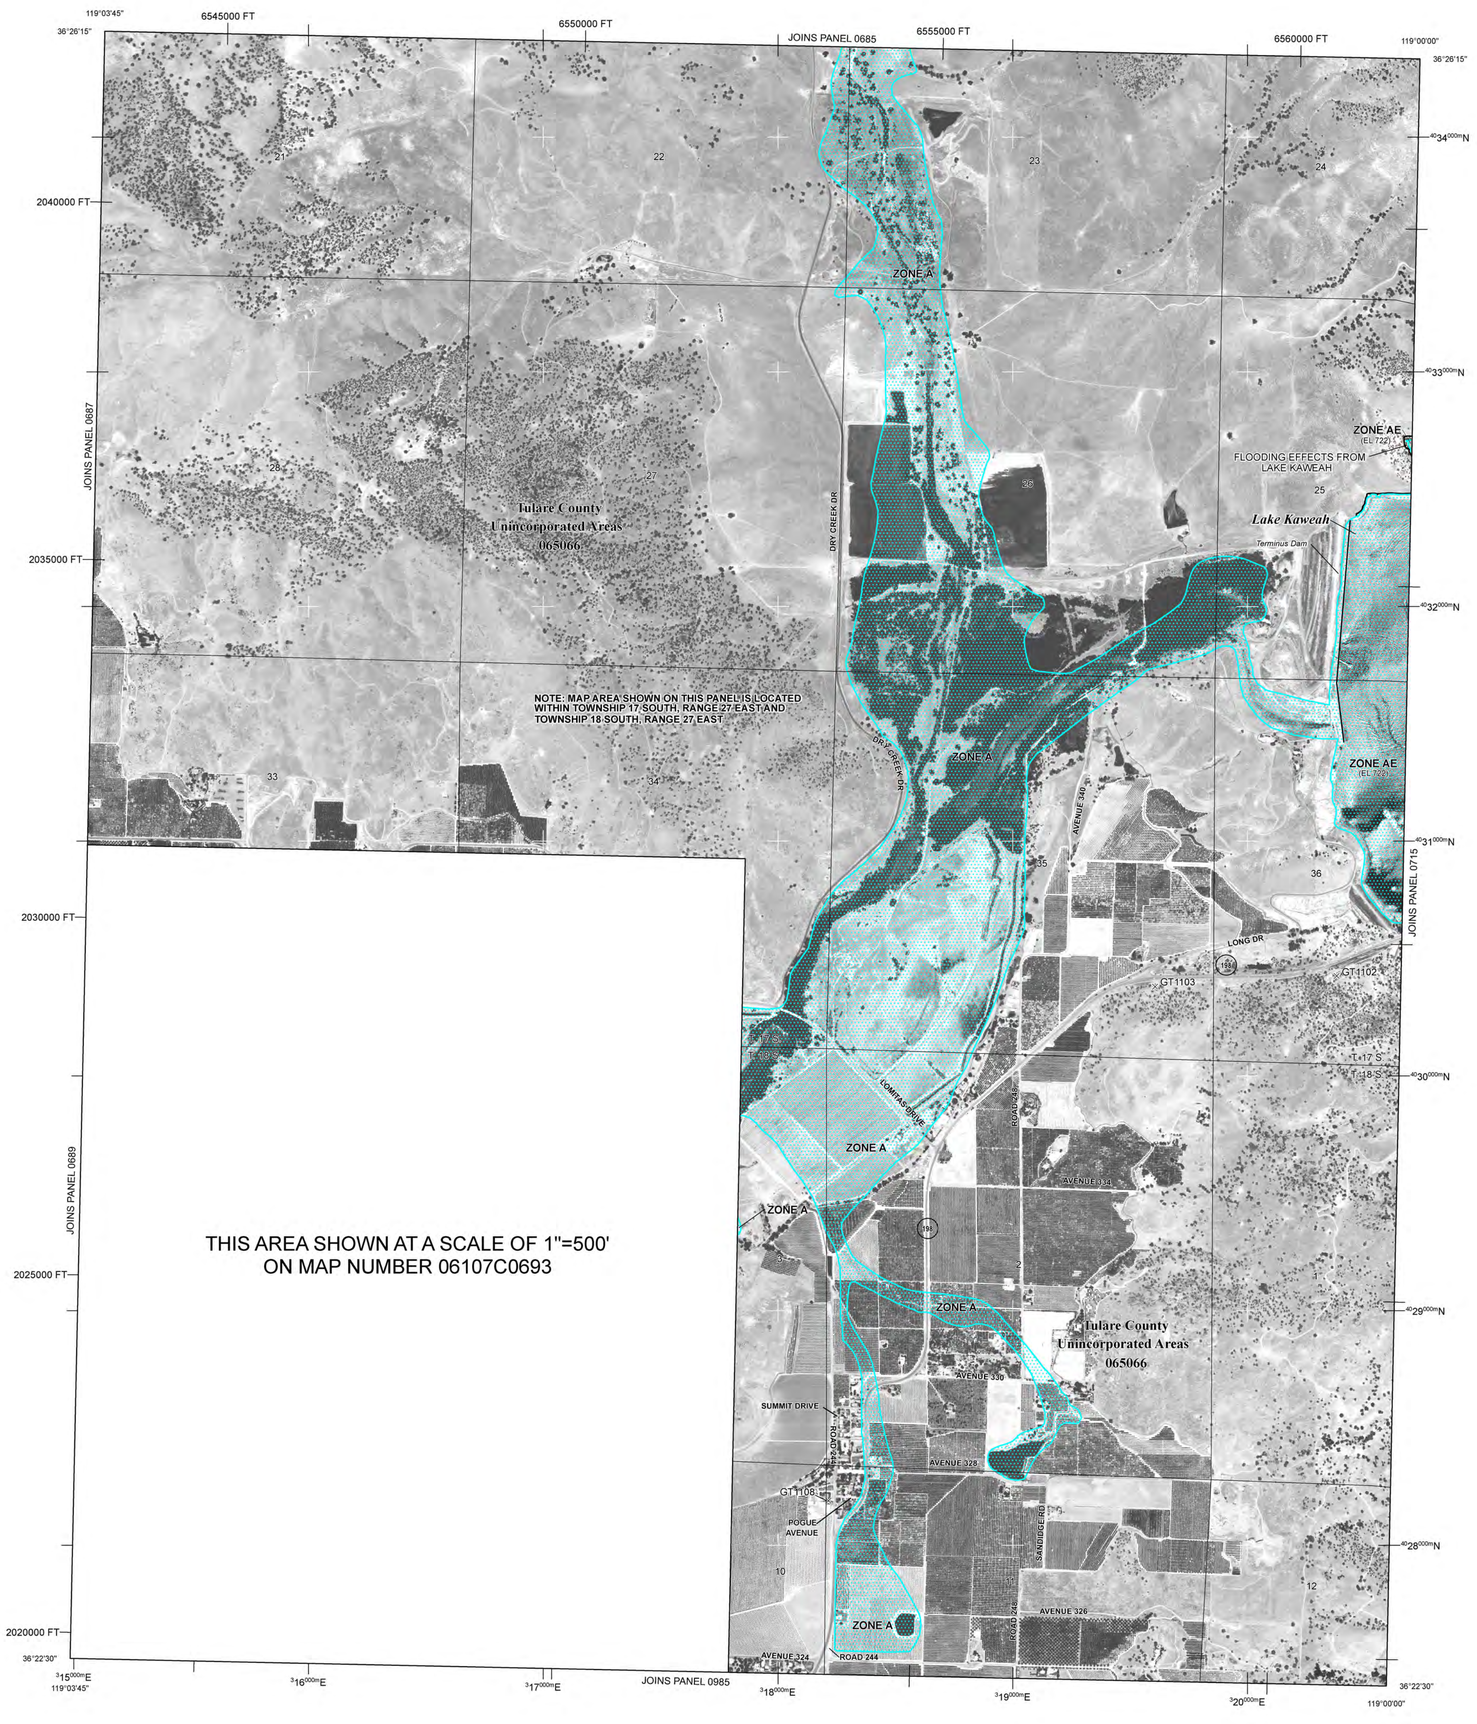
The **projection** used in the preparation of this map was Universal Transverse Mercator zone 11. The **horizontal datum** was NAD83, GRS1980 spheroid. Differences in datum, spheroid, projection or UTM zones used in the production of FIRMs for adjacent jurisdictions may result in slight positional differences in map features across jurisdiction boundaries. These differences do not affect the accuracy of this FIRM.

Flood elevations on this map are referenced to the North American Vertical Datum of 1988. These flood elevations must be compared to structure and ground elevations referenced to the same **vertical datum**. For information regarding conversion between the National Geodetic Vertical Datum of 1929 and the North American Vertical Datum of 1988, visit the National Geodetic Survey website at http://www.ngs.noaa.gov/ or contact the National Geodetic Survey at the following address:

NGS Information Services
NOAA, N/NGS12
National Geodetic Survey
SSMC-3, #9202
1315 East-West Highway
Silver Spring, Maryland 20910-3282
(301) 713-3242

To obtain current elevation, description, and/or location information for **bench marks** shown on this map, please contact the Information Services Branch of the National Geodetic Survey at **(301) 713-3242** or visit its website at http://www.ngs.noaa.gov/.

Base map information shown on this FIRM was derived from U.S. Geological Survey Digital Orthophoto Quadrangles produced at a scale of 1:12,000 from photography dated 1987 or later.



This map reflects more detailed and up-to-date **stream channel configurations** than those shown on the previous FIRM for this jurisdiction. The floodplains and floodways that were transferred from the previous FIRM may have been adjusted to conform to these new stream channel configurations. As a result, the Flood Profiles and Floodway Data tables *in the Flood Insurance Study report (which contains authoritative hydraulic data)* may reflect stream channel distances that differ from what is shown on this map.

Corporate limits shown on this map are based on the best data available at the time of publication. Because changes due to annexations or de-annexations may have occurred after this map was published, map users should contact appropriate community officials to verify current corporate limit locations.

Please refer to the separately printed **Map Index** for an overview map of the county showing the layout of map panels; community map repository addresses; and a Listing of Communities table containing National Flood Insurance Program dates for each community as well as a listing of the panels on which each community is located.

For information and questions about this map, available products associated with this FIRM including historic versions of this FIRM, how to order products or the National Flood Insurance Program in general, please call the FEMA Map Information eXchange at 1-877-FEMA-MAP (1-877-336-2627) or visit the FEMA Map Service Center website at http://msc.fema.gov. Available products may include previously issued Letters of Map Change, a Flood Insurance Study Report, and/or digital versions of this map. Many of these products can be ordered or obtained directly from the website. Users may determine the current map date for each FIRM panel by visiting the FEMA Map Service Center website or by calling the FEMA Map Information eXchange.

The "profile base lines" depicted on this map represent the hydraulic modeling baselines that match the flood profiles in the FIS report. As a result of improved topographic data, the "profile base line", in some cases, may deviate significantly from the channel centerline or appear outside the SFHA.

LEGEND

SPECIAL FLOOD HAZARD AREAS SUBJECT TO INUNDATION BY THE 1% ANNUAL CHANCE FLOOD

The 1% annual chance flood (100-year flood), also known as the base flood, is the flood that has a 1% chance of being equaled or exceeded in any given year. The Special Flood Hazard Area is the area subject to flooding by the 1% annual chance flood. Areas of Special Flood Hazard include Zones A, AE, AH, AO, AR, A99, V, and VE. The Base Flood Elevation is the water-surface elevation of the 1% annual chance flood.

ZONE A	No Base Flood Elevations determined.
ZONE AE	Base Flood Elevations determined.
ZONE AH	Flood depths of 1 to 3 feet (usually areas of ponding); Base Flood Elevations determined.
ZONE AO	Flood depths of 1 to 3 feet (usually sheet flow on sloping terrain); average depths determined. For areas of alluvial fan flooding, velocities also determined.
ZONE AR	Special Flood Hazard Area formerly protected from the 1% annual chance flood by a flood control system that was subsequently decertified. Zone AR indicates that the former flood control system is being restored to provide protection from the 1% annual chance or greater flood.
ZONE A99	Areas to be protected from 1% annual chance flood event by a Federal flood protection system under construction; no Base Flood Elevations determined.
ZONE V	Coastal flood zone with velocity hazard (wave action); no Base Flood Elevations determined.
ZONE VE	Coastal flood zone with velocity hazard (wave action); Base Flood Elevations determined.

FLOODWAY AREAS IN ZONE AE

The floodway is the channel of a stream plus any adjacent floodplain areas that must be kept free of encroachment so that the 1% annual chance flood can be carried without substantial increases in flood heights.

OTHER FLOOD AREAS

ZONE X	Areas of 0.2% annual chance flood; areas of 1% annual chance flood with average depths of less than 1 foot or with drainage areas less than 1 square mile; and areas protected by levees from 1% annual chance flood.

OTHER AREAS

ZONE X	Areas determined to be outside the 0.2% annual chance floodplain.
ZONE D	Areas in which flood hazards are undetermined, but possible.

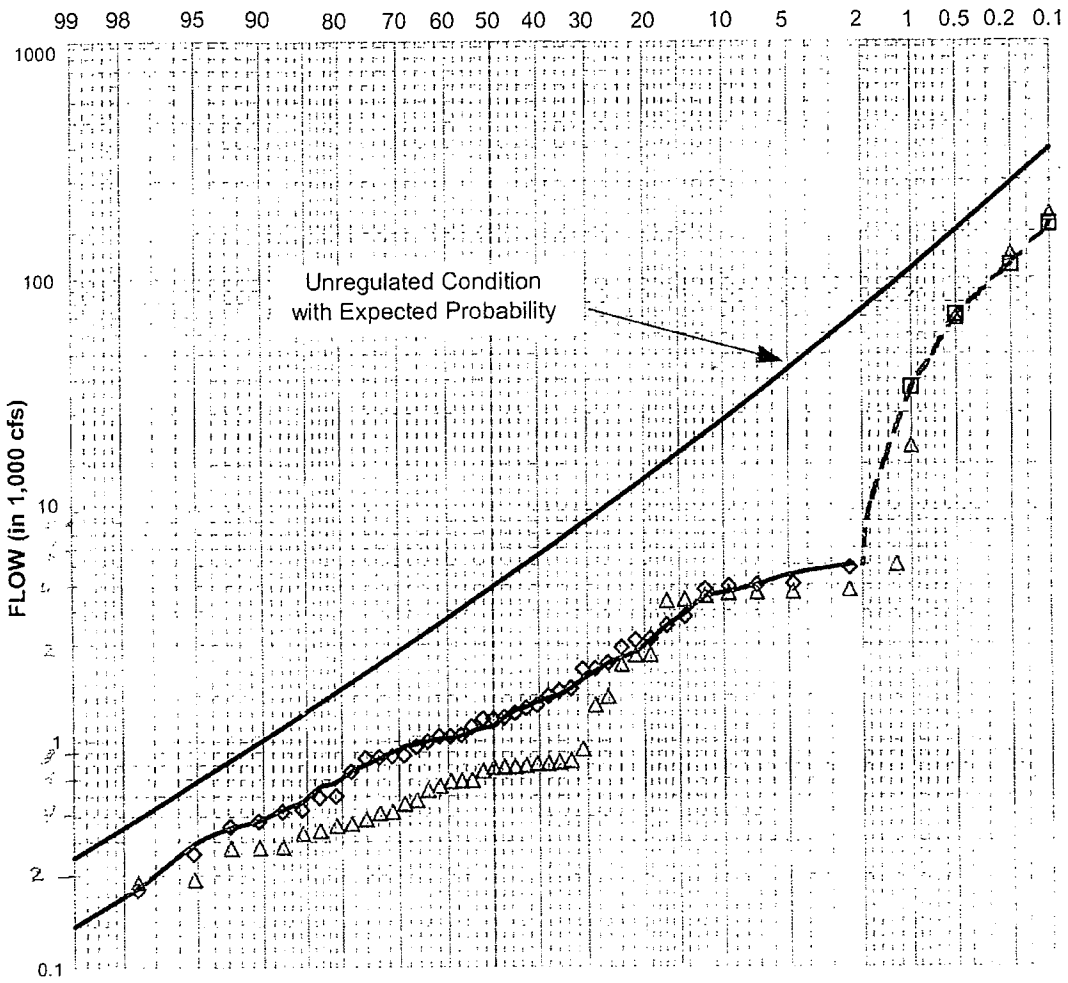
Dear Mr. George:

This is in response to the request to provide the revised flow at McKay Point for the 1% flood. The revised flow is based upon the raise spillway at the dam. The peak release from the reservoir during this event is 17,900 cfs. The peak flow at McKay Point, including local flow from Dry, Mehrtens, and Yokohl Creeks is 18,220 cfs.

Enclosed is the hourly data for the routing along with 2 plots that show the operation and flows.

If you have any questions, please contact Mr. Wayne Johnson at (916) 557-7139.



Sincerely,

Wayne L Johnson FOR

Paul E Pugner, PE

RIVERBED ANALYSIS

Written by: SB Date: 2016 / 06/ 24 (YY MM DD) Reviewed by: TP Date: 2016 / 06/ 24 (YY MM DD)

Client: SESPE Project: McKay Point Reservoir Project No: 117.00981 Task No.: 01

RIVERBED ANALYSIS

MCKAY POINT RESERVOIR, CALIFORNIA

1. PURPOSE AND SCOPE

This attachment documents the riverbed analysis conducted for the Kaweah River and the St. Johns River at the proposed McKay Point Reservoir Project site. The McKay Point Reservoir Project involves the creation of a topographic depression that will capture precipitation and some storm water runoff. The Project will not involve placing structures in the St. Johns or Kaweah River channels and will not alter the course of either river. The only changes to the river channels will be placement of rip rap at the Inflow and Outflow Channels, and construction of the Inflow and Outflow Channels. The rip rap will be placed below the elevation of the main river channels, and the Inflow/Outflow Channels will be set back from the main river channels. These structures are designed to avoid impedance of river flows.

2. ANALYSIS

SLR reviewed historical aerial photos of the riverbeds of the Kaweah and St. Johns Rivers and the surrounding areas. The aerial photos from the years 1954, 1956, 1969, 1974, 1984, 1989, 1994, and 2002 were obtained from Environmental Data Resources, Inc. (EDR, 2014). The aerial photos from the years 2003, 2004, 2005, 2006, 2009, 2010, 2011, 2012, and 2014 were obtained from Google Earth. The photos were reviewed to determine if major scouring or changes to the morphology of the Kaweah and St. Johns Rivers had occurred near the McKay Point Reservoir Project site in the past. The 1954 and 1956 photos show that the size and shape of the river channels varied with the weather conditions and the corresponding flow volumes that occurred at the time. However, starting with the 1969 photo, no significant changes can be observed. Terminus Dam was constructed in 1962, and regulates flows and flooding, and thus river morphology and scouring. Rapid changes in river morphology and scouring have therefore been minimized. Terminus Dam is used extensively to manage flow rates in the rivers and to avoid flow rates that would result in extensive scouring.

3. SUMMARY AND CONCLUSIONS

SLR has conducted a review of historical aerial photographs of the McKay Point Reservoir Project site and the surrounding areas to identify whether the Kaweah and St. Johns Rivers have moved or changed course significantly in the past sixty years. The results of this riverbed analysis are presented in a series of figures in which the 2014 aerial image is overlaid by sketches of the historical outlines of the river channels from the selected years of 1956, 1969,

1974, 1984, 1994, 2002, 2005, and 2014. Based on this evaluation, SLR concludes that the riverbeds of the Kaweah and St. Johns Rivers have not moved significantly since construction of Terminus Dam in 1962.

It is anticipated that during reservoir operations, flow rates in the St. Johns and Kaweah Rivers will remain within the existing range of typical flow rates that are currently managed through outflows of Terminus Dam. Use of the reservoir for flood storage may actually cause flow rates in the Kaweah and St. Johns Rivers to decrease during periods of high precipitation, thereby reducing scour potential. Thus, SLR also concludes that the riverbeds of both the Kaweah and St. Johns Rivers would not move as a result of the McKay Point Reservoir Project.

ATTACHMENT D

SEEPAGE CALCULATIONS

DRAFT

D.1 INTRODUCTION

Seepage calculations were performed to determine the amount of groundwater inflow into the excavated reservoir, both with and without the proposed slurry wall. These analyses were conducted using two methods, i.e.:

- Simplified Two-dimensional (2-D) analyses; and
- A conceptual level Three-dimensional (3-D) analysis as a check on the 2-D modleing and also to assess the likely impacts of the project on the groundwater levels surrounding the Reservoir.

Tw sets of analyses were performed as a check on the range of potential values that could be generated. The details of the modeling work and the results are provided in Sections D.2 and D.3 bellow. The overall key results are as follows:

Table D1-1 Summary of Excavation and Reservoir Inflow Rates

PROJECT STAGE	CONDITIONS	SLURRY WALL	INFILTRATION TRENCH	2-D MODELLING (GPM)	3-D MODELLING (GPM)	RECOMMENDED FOR USE IN ENVIRONMENTAL ANALYSES (GPM)	RATIONAL
Excavation / Reservoir	Final Excavation Empty Reservoir	No	No	0	0	0	
	Initial Excavation Full Reservoir	No	No	659	830	800	Reasonable average value

D.2 TWO DIMENSIONAL ANALYSES

D.2.1 INTRODUCTION

Two geologic cross sections across the reservoir were developed based on the boring logs available and a review of available information about the site. These two geologic cross sections are presented in Attachment A of the Technical Memorandum prepared by SES (SES, 2012). Based on these geologic cross sections and the layout of the reservoir developed by Provost and Pritchard (February 18, 2014), three representative cross sections were developed for seepage analysis. The locations of the three cross sections are shown on Figure D2-1. Each cross section represents the geologic conditions, width of the reservoir, and the hydrogeologic regime in the various areas of the reservoir. The depth of the reservoir at each cross section was taken from the layout developed by Provost and Pritchard.

The seepage analyses consist of evaluating the flow of water into the reservoir during and at the end of excavation. The analyses are performed for the following three scenarios:

1. The first scenario considered construction of the reservoir (i.e. excavation) without a perimeter slurry wall;

2. The second scenario includes a slurry wall installed around the perimeter of the reservoir approximately 50 ft away from the crest of the slopes and extending down to elevation 388 ft above mean sea level (amsl); and

3. The third scenario consists of augmenting scenario two by adding a reinjection/recirculation trench north of the slurry wall to recirculate influent water back into the natural groundwater system.

The seepage analyses presented in this attachment were performed with the finite element programs SEEP/W (GeoStudio, 2012).

D.2.2 REPRESENTATIVE SECTIONS

D.2.2.1 SECTION 1

This section runs north to south and combines the information from geologic cross sections AA' and BB' (Attachment A in SES 2012) with an emphasis on the conditions observed at Boring B-1. Boring B-1 indicates a lack of the bedrock horizon unit that was observed at other boring locations. Consequently, groundwater flow underneath the reservoir will be within the SC/CL layer. Also, this section of the reservoir is triangular rather than trapezoidal.

D.2.2.2 SECTION 2

This section runs north to south and again combines the information from geologic cross sections AA' and BB' with emphasis on the conditions observed at Boring B-2. Boring B-2 indicates a lack of the bedrock horizon unit that was observed at other boring locations. Also, this section of the reservoir was modeled as a trapezoid.

D.2.2.3 SECTION 3

This section again runs from north to south and combines information from geologic cross sections AA' and BB' with an emphasis on the conditions observed at Borings B-3 and B-4. Borings B-3 and B-4 indicate a bedrock horizon existing at the final depth of excavation along with SC/CL and SP lenses. Also, this section of the reservoir was modeled as a trapezoid.

D.2.3 MATERIAL PROPERTIES

The hydraulic conductivities of the different stratigraphic layers were calculated using the results of the geotechnical testing carried out on samples recovered from the borings. A series of grain size analyses (ASTM D422) were performed on samples collected in the borings. The results of these tests were used together with correlations such as those developed by Hazen (1852, 1911), Kozeny (1927) and Carman (1938, 1956) to determine hydraulic conductivities. The details of the analyses are provided in Attachment B of SES (2012). The values estimated by SES were compared to those measured by Fugro (2002) at a nearby site and the values of transmissivity reported by Luhdorff and Scalmanini (1995) for a site west of the project site.

The hydraulic conductivity of the slurry wall is very low and a conductivity value was set based on engineering judgement. The selected hydraulic conductivity of the slurry wall is 3.3×10^{-11} ft/sec (1×10^{-9} cm/s).

The values of isotropic saturated hydraulic conductivities used in the analyses are presented in Table D2-1.

Analyses were performed considering isotropic as well as anisotropic conditions for the alluvium. This is the ratio of the horizontal to the vertical saturated hydraulic conductivity. Both conditions were analyzed as a sensitivity analysis to address the uncertainty in the depositional nature of the alluvium/unconsolidated materials in the upper layers. A coefficient of anisotropy of 5 was used. This coefficient was not applied to the bedrock or the slurry wall.

D.2.4 BOUNDARY CONDITIONS

The boundary conditions for the analysis were established based on the location of the reservoir with respect to the Kaweah River to the south, and the CEMEX ponds (former pits) north of the proposed reservoir.

D.2.4.1 CROSS SECTION 1

This section is the furthest from the Kaweah River at approximately 2,340 ft, and is not affected by its regime. The water table in Boring B-1 was observed at elevation 438 ft amsl. In their report, Luhdorff and Scalmanini have established that the ephemeral nature of the Saint Johns River has no significant effect on the water table in the area. Therefore, the southern boundary condition was set as a constant head of 438 ft amsl at a distance 2,340 ft south of the reservoir. For the northern boundary conditions, the groundwater elevations from Figure 6 of Kenneth Schmidt and Associates (November-December, 2011) were used. The groundwater elevation on the northern boundary was set at an elevation of 438 ft amsl 1000 feet north of the reservoir.

D.2.4.2 CROSS SECTION 2

Groundwater elevations in Borings B-5 and B-2 were used to establish the boundary in terms of total head for the north and south end of this section. The northern boundary condition was set at a constant head of 445 ft amsl at a distance 1000 ft north of the reservoir, and the boundary condition on the south was set as a constant head of 445 ft amsl at a distance 1,780 ft south of the reservoir.

D.2.4.3 CROSS SECTION 3

Section 3 is the most influenced by the Kaweah River. The groundwater elevation in Boring B-6 was used to establish the boundary conditions for the south end of this section and the groundwater elevation Figure 6 of Kenneth Schmidt and Associates was used for the north end of the section. The northern boundary condition was set as a constant head equal to 452 ft amsl at a distance 1000 ft north of the reservoir, whereas the southern boundary condition was set as a constant head of 460 ft amsl at a distance 370 ft south of the reservoir.

D.2.4.4 RADIUS OF INFLUENCE

The radius of influence for the alluvium typical of the area was established in the pump test performed by Luhdorff and Scalmanini. The radius of influence is on the order of 1,000 ft. Consequently, the model's boundary conditions were set at a minimum of 1,000 ft from the edges of the reservoir when applicable. This minimum of 1,000 ft was utilized for the southern boundaries of Sections 1 and 2. However, the southern boundary condition of Section 3 was exempt from the 1,000 ft minimum distance, as the edge of the reservoir is approximately 370 ft from the Kaweah River.

D.2.5 RECIRCULATION / REINJECTION OF INFLUENT GROUNDWATER

Scenario three utilizes an injection/recirculation trench to recirculate all influent water from the excavation back into the natural groundwater system. This injection/recirculation trench was modeled to have dimensions of 3 ft wide by 10 ft deep, and was assigned a material conductivity of $1x10^{-2}$ ft/sec (0.3 cm/sec). The injection/recirculation trench was placed 10 ft north of the slurry wall for scenario three.

As groundwater enters the excavation, it will be pumped into the injection/recirculation trench. The water added to the natural groundwater system from the injection/recirculation trench will consequently increase the flux into the excavation, thus requiring slightly greater pumping into the injection/recirculation trench to keep the excavation unsaturated. Groundwater inflow and required injection/recirculation rates will continue to rise as excavation proceeds, and must be accommodated for.

D.2.6 RESULTS

Analyses were performed for each scenario at each cross section using the representative values of saturated hydraulic conductivity listed in Table D2-1 for each formation assuming either isotropic or anisotropic conditions in the alluvium.

D.2.6.1 FLOWS AT EACH SECTION

The three sections analyzed are shown on Figures D2-2 through D2-4 for scenario one (no slurry wall), D2-5 through D2-7 for the scenario two (slurry wall), and D2-8 through D2-10 for scenario three (slurry wall and reinjection/recirculation). The results in the form of the pressure head and flux into the reservoir are shown on Figures D2-11 through D2-13 for scenario one, D2-14 through D2-16 for scenario 2, and D2-17 through D2-19 for scenario three.

The results for anisotropic conditions are similar, so are not shown herein. The results for isotropic versus anisotropic conditions indicate that the uncertainty in isotropy isn't a determining factor in the results.

The results are presented in Table D2-2 as the flow into the excavation in cubic feet per second (ft^3/s) and gallons per minute (gpm) for each representative section and each scenario analyzed.

D.2.6.2 TOTAL FLOW INTO RESERVOIR

The total flows into the reservoir were evaluated for each scenario by a weighted average of the length of reservoir perimeter best represented by each of the three sections. Those weighting lengths were established based on review of the geologic conditions, width of the reservoir, and the boundary conditions of each section. The lengths of pit modeled by each of the representative cross sections were established as:

- Section 1: 1,600 ft;
- Section 2: 2,200 ft; and
- Section 3: 2,000 ft.

For a total length of 5,800 ft.

The total flows into the reservoir for each scenario are reported in Table D2-3.

Table D2-1: Hydraulic Conductivity Values

LAYER #	SOIL DESCRIPTION	SOIL TYPE	K (cm/s)	K (ft/s)
1	Poorly Graded Sand	SP	$1.6x10^{-3}$	$5.3x10^{-5}$

D.3 THREE DIMENSIONAL ANALYSES

D.3.1 INTRODUCTION

This attachment describes the approach and assumptions used to estimate the seepage inflow rates through numerical and empirical methods. SLR used two methodologies to assess the inflow rates.

Firstly, a systematic groundwater pump and treat (P&T) method for capture zone analysis described by the USEPA was used (USEPA, 2008). The dewatering estimate assumes the groundwater inflows to the excavation can be represented by the saturated thickness and local gradient towards the planned reservoir (Table D3-1). This approach does not include the slurry wall and infiltration trench. However, the method is helpful as a screening tool to perform a basic assessment of the hydrogeologic conditions and as a check on the flow rates expected from the numerical modeling.

Secondly, a steady-state numerical model was developed for the Project to estimate the general groundwater condition around and seepage rate into the planned excavation for the following three scenarios.

1. The first scenario considered the construction of the planned excavation to its maximum depth (i.e., reservoir) without a perimeter slurry wall;

2. The second scenario includes slurry walls installed around the perimeter of the planned maximum excavation; and

3. The third scenario consists of augmenting scenario two by adding a reinjection/recirculation trench north of the slurry wall to recirculate the collected influent water back into the natural groundwater system.

D.3.2 BACKGROUND

The numerical assessment evaluates the anticipated changes to the baseline hydrogeologic conditions resulting from the Project. The source of lithological and hydrogeological data of the evaluation are previous studies conducted on the site, such as Kenneth D. Schmidt and Associates 2012, SLR 2021a, SLR 2021b, and Section D.2 above. Additional data from other publicly available documents were also reviewed and used as part of this assessment.

D.3.3 EXCAVATION DESIGN, SLURRY WALL, AND INFILTRATION TRENCH SETTING

The excavation design has about 5,700 ft length and variable-width ranges from 330 to 1,310 ft Figure 3D-2 and Figure 3D-11 (Provost & Pritchard Consulting Group via email, June 2021). The excavation depth ranges from 370 – 425 ft amsl from the ground surface (about 467 ft, amsl), generally overlying the clay unit and bedrock.

The slurry wall is designed to impede the inflow of water to the planned excavation from all dimensions. A thickness of one foot and hydraulic conductivity equal to that of the clay unit (0.0013 ft/day, or $5x10^{-7}$ cm/sec) was used in the model.

The infiltration trench was set to the north of the slurry wall, and the hydraulic conductivity was equal to that of the gravel (69 ft/da, or 2.5 x 10^{-2} cm/sec).

The existing ponds are represented by surface water that intercepts groundwater flow towards the reservoir. The ponds are treated in the model overlying a highly permeable material extending 10 feet below the local potentiometric surface. The impact of the ponds on the dewatering rate from the excavation was evaluated compared to the results of scenario 2.

D.3.4 METHODOLOGY

The conceptual site model (CSM) provides a framework for understanding site-specific features and physical processes that influence groundwater flow around the planned excavation. The conceptual site model (CSM) aims to organize the field data to simplify the field problem while maintaining its essential characteristics so that the system can be analyzed more readily. Of necessity simplification of site conditions is required when establishing a CSM (Anderson and Woessner, 1992).

A total of seventeen boring logs, six onsite (BSK, 2011), and eleven offsite, boring logs were used to build the CSM (Figure D3-1). The offsite boring logs were collected from the California Department of Water Resources (CA-DWR) website. The lithologic logs were reviewed for their quality, and poorly logged borings were excluded from further consideration. Based on these borings, the thickness of alluvial deposits at the Project site ranges between approximately 60 and 80 feet. The uppermost alluvial deposits at the Project site consist of sand, cobbles, boulders, silt, and clay (Luhdorff and Scalmanini, 1995). The contact between alluvial deposits and bedrock is shallower in the east and gets deeper towards the west (Kenneth D. Schmidt and Associates, 2012).

The CSM formulation involves synthesizing available hydrological, lithological, hydrogeological data contained in various reports. It includes consideration of the

hydrogeologic framework, water budget, and groundwater flow systems. Historical water levels indicate that the groundwater flows from the northeast towards the southwest **(**SLR, 2021b).

Hydrostratigraphic units of the CSM were developed using related strata that control the groundwater flow. There are six major geologic/hydrogeologic units generated from Leapfrog Works (Seequent Limited, 2020, version 4.0.1), consistent with the previous classifications presented in Figure D-2 (also Kenneth D. Schmidt and Associates, 2012; SLR, 2021a). These hydrostratigraphic units were exported from Leapfrog Works and imported into the Groundwater Vistas model grid.

D.3.5 EPA METHOD OF SEEPAGE RATE ESTIMATE

The groundwater inflow rate into the planned excavation was estimated using the following mathematical relationship (USEPA, 2008):

$$Q = K * (b * w) * i * factor$$

Where

Q = extraction rate (cubic feet per day)
K = hydraulic conductivity (ft/day)
b = saturated thickness (ft)
w = excavation width/length in this case (ft)
i = site-wide/regional hydraulic gradient
factor = 1.5 to 2.0, accounting for other contributions to the water in the reservoir, for example, horizontal flow from northeast, vertical flow from another water-bearing zone or ponds, etc.

SLR reviewed site-specific data such as:

- Range of hydraulic conductivities from seepage studies (Section D.2).
- Water levels (SLR, 2021b, CA-WDR's website)
- Site hydraulic gradient (SLR, 2021b, CA-WDR's website)
- Excavation design (surface area, width, depth, side slopes, etc. (SLR, 2021b, Provost & Pritchard Consulting Group via email, June 2021).

Using this information, SLR developed key inputs in Table D3-1, with detailed calculations and results presented in Table D3-3.

Table D3-1 – Key Inputs to the EPA Method of Dewatering Estimates

Excavation Design	
Excavation average depth (ft)	60
Unsaturated thickness around the planned excavation, b (ft)	20 - 25
Saturated thickness around the planned excavation, b (ft)	37 - 52
Length/Width/ of the planned excavation, b (ft)	5,709
Hydraulic properties, gravel (ft/day)	69
Hydraulic gradient (ft/ft) [Average of gradients]	0.012

Note:- The minimum and maximum of the saturated and unsaturated thicknesses are based on borings B1-B6 and all monitoring wells listed in Table D3-4, respectively.

Assumptions inherent to the method include:

- Homogenous, isotropic, confined aquifer of infinite extent;
- Uniform aquifer thickness;
- The saturated zone around the planned excavation represents the aquifer thickness;
- Uniform regional horizontal hydraulic gradient;
- Steady-state flow;
- Negligible vertical gradient;
- No net recharge or net recharge is accounted for in regional hydraulic gradient; and
- No other sources of water were introduced to the aquifer induced by excavation.

D.3.6 NUMERICAL MODEL SEEPAGE RATE ESTIMATE

The CSM is converted into a mathematical model by selecting a code, specifying boundary conditions, grids to represent the geologic formations, employing aquifer parameters, recharge, and discharge zones of the Site. Details of the model development are given below.

D.3.6.1 CODE SELECTION

The numerical model was constructed and calibrated in MODFLOW-USG, a new version of MODFLOW (McDonald and Harbaugh, 1988; Harbaugh, 2005) for unstructured grids (Panday et al., 2013). The modeling environment and pre-/post-processor is Groundwater Vistas version 8.03 (ESI, 2020).

The model cells can take on numerous shapes, such as triangles, octagons, and variable sizes, allowing refinement in areas of interest, i.e., the planned excavation. Unstructured grids do not necessarily require to be arranged on a row, and column bases and cells are linked together regardless of shape. The planned excavation was represented in the domain by “air” zones where high K values (assumed to be 5,000 ft/day) were assigned to let unrestricted water flow into it (Table D3-6). Groundwater Vistas was employed for a pre - and post-processing of input and output data, respectively. It also provides an extensive set of tools for developing, modifying, and calibrating numerical models.

D.3.6.2 MODEL DEVELOPMENT AND INPUT DATA

The three-dimensional geologic model domain was built in Leapfrog Works and exported to the Groundwater Vistas. Historical hydrogeological data were reviewed and processed to represent average conditions (Table D3-4). The model was developed to simulate the steady-state groundwater condition based on the average data of historical water levels. About fifteen monitoring wells, inside and outside the property, were used for calibration. Ten monitoring wells were used as target heads, and the remaining five wells were used to establish General Head Boundary conditions (Table D3-4).

D.3.6.3 MODEL GRID AND BOUNDARY CONDITIONS

No-flow boundaries were assigned to parts of the southern and northern edges of the domain to simulate the general northeast to southwest groundwater flow gradient. These boundaries were set at a sufficient distance from the planned excavation to allow the model to calculate the impact of dewatering the reservoir on groundwater levels surrounding it. General head conditions that allow groundwater flow into and out of the system were set on the northeast and southwest. Water level heads for the General Head Boundaries were set based on the average historical water levels collected from adjacent monitoring wells (Table D3-4). General head conductances were set high enough to permit flow into and out of the system depending on the surrounding heads. A river boundary was specified to imitate the Kaweah River to the south (Figure D3-5).

The model grid consists of 6 layers, 356 columns and 127 rows, with grid spacing ranging from 21 ft to 200 ft and 21 ft to 282 feet for columns and rows, respectively (Figure 3D-1). Finer grid spacing was applied around the planned excavation. The model domain has an active area of 77.7 million sq. ft.

D.3.6.4 AQUIFER PROPERTIES AND RECHARGE

For the steady-state model, the principal aquifer properties are hydraulic conductivities and recharge. The hydraulic conductivities of the major geologic units were determined

by geotechnical testing through grain size analyses (ASTM D422) and Section D.2. Hydraulic conductivity values set for the calibrated model are restricted to be between 95 % to 105 % of the values based on the above geotechnical testing and are presented in Table D3-6.

Recharge flux to the system was estimated from the average precipitation collected from the site vicinity, namely LEMON COVE (LMC). The annual precipitation data summarizes measurements collected from June 2019 to June 2021. The recharge flux applied to the calibrated model is roughly 10 % infiltration of the recharge estimated from LMC (Table D3-2).

Table D3-2. Calibrated Model Recharge

Precipitation Averages (Inches)	
January	2.73
February	2.52
March	2.08
April	1.45
May	0.49
June	0.15
July	0.01

December	2.26
Yearly Precipitation (in)	*14.03*
Recharge flux (ft/day) 20%	*0.000641*
Recharge flux (ft/day) 10%	*0.000320*
Recharge flux (ft/day) in the calibrated model	***0.000285***

D.3.7 MODEL CALIBRATION

Calibration of a numerical groundwater flow model is the process of adjusting model parameters to obtain a reasonable match between field-measured values and model predicted values of heads (groundwater levels) and fluxes (groundwater flows). There are two ways of finding model parameters to achieve calibration (Anderson and Woessner, 2002). (1) Manual trial and error adjustment of parameters and (2) automated parameter estimation. Groundwater Vistas (GV) assists model calibration in three ways (ESI, 2020):

(1) calculation of calibration statistics for a head, drawdown, or flux, (2) automated parameter sensitivity analysis, and (3) automatic model calibration using a nonlinear least-squares technique built into the GV interface or using external inverse models such as PEST (Doherty, 2010). All these methods have been applied to calibrate the steady-state model.

D.3.8 RESULTS

D.3.8.1 RESULTS OF EPA METHOD

The six boring logs and the resulting three-dimensional geologic model demonstrate that gravel and sand dominate the subsurface beneath the planned excavation. The inflow rate was estimated to be 750 (gpm). The estimate was based on calculations with limited site data, and the actual seepage rates may vary. Results are summarized below in Table D3-3.

Table D3-3. Estimation of Extraction Rates

					[1]Scenario 1 - Factor = 1.5		***[2] Scenario 2 - Factor = 2.0***	
Excavation Inflow Estimates	**K[1] (ft/day)**	**b[2] (ft)**	**W[3] (ft)**	**i[4] (ft/ft)**	**Q[5] (ft3/day)**	**Q[5] (gpm)**	**Q[6] (ft3/day)**	**Q[6] (gpm)**
Inflow Rate (Q)	6.9E+01	51.91	5,709	0.0035	108,418	564	144,383	750

Note
1 Scenario 1 represents inflows to the ponds that are coming from the north only.
2 Scenario 2 assumes a small component of inflows from the northeast.
3 The methodology and assumptions are provided in USEPA's "A Systematic Approach for Evaluation of Capture Zones at Pump and Treat Systems", EPA 600/R-08/003, January 2008.

D.3.8.2 RESULTS OF STEADY-STATE NUMERICAL MODEL

3.8.2.1 Calibration Results

The calibration process confirmed that hydraulic conductivities and recharge previously applied for SEEP/W simulation (Section D.2) are still valid. The final calibrated parameters are also within 95 % to 105 % of the previously determined or used to understand the hydrogeologic condition of the Project Site. Locations of targets are provided in Figure D-1. A summary of the calibration steady-state water level targets is provided in Table D3-4.

Table D3-4 Calibrated Water Level Comparison

No.	Target	Easting (UTM, m)	Northing (UTM, m)	Layer	Water Level, Observed (ft, amsl)	Water Level, Modelled (ft, amsl)	Remark

3.8.2.2 Calibration Statistics

Table D3-5 presents a summary of the statistical measures for the steady-state calibration. A Scaled root mean square (SRMS) of less than 10% is desirable and less than 5% preferable. The model's SRMS is about 7.0% (Table D3-5).

Table D3-5 Calibration Statistics

Residual Mean (ft)	-0.47501
Absolute Residual Mean (ft)	1.769329
Residual Std. Deviation (ft)	2.098374
Sum of Squares (ft^2)	46.288088

Chart 3-1 Observed vs. Simulated Groundwater Levels (Steady-State)

3.8.2.3 Calibrated Hydraulic Conductivities

A summary of the final calibrated parameters used for the simulation of the above-mentioned three scenarios is provided in Table D3-6.

Table D3-6 Calibrated Conductivity and Storage Parameters

Parameter	Kx (ft/day)	Ky (ft/day)	Kz (ft/day)
Bedrock	0.3091331	0.3091331	0.00293969
Clay	0.001235	0.001235	0.0013
Silty/Sandy Clay	0.004515	0.004515	0.000371081
Silty/clayey sand	0.139555	0.139555	0.06556124
Gravel	69.3	69.3	6.6
Sand	4.75	4.75	0.5
Air	5000	5000	5000

Table D3-7 Calibrated Recharge Parameters

Parameter	Description	Rate ft/day	% Annual Rainfall
R1	Site-wide	0.000285	10.0%

D.3.8.3 WATER BALANCE

The water balance for the calibrated model is provided in Table D3-8. General Head Boundary comprises most of the total inflows and outflows.

The model is considered to have a good mass balance; flow rates entering and leaving the system are 303 gpm (58,167 ft^3/day) and 302 gpm (58,158 ft^3/day), respectively. The corresponding percent discrepancy is low, 0.02%.

Table D3-8 Summary of Water Balance (steady-state, non-project condition)

	In (ft^3/d)	Out (ft^3/d)
Constant Head	0	0
River	24,634	8,367
General Head	31,477	49,791
Recharge	2,057	0
Total	**58,167**	**58,158**
Discrepancy (In-Out)	8.8 ft3/d	0.02 %

The calibrated model's parameter distribution led to the best overall simulation of the hydrogeologic conditions predicted after the planned excavation placement under the three scenarios mentioned above (Figure 3D-3). Results of the predictive simulations are provided below.

D.3.8.4 RESULTS OF PREDICTIVE MODEL SIMULATION

The results of the predictive models for the three scenarios mentioned above are explained in detail in the following sections.

3.8.4.1 Results of the Frist Scenario- Excavation without Slurry Walls

As the excavation draws more water, the potentiometric surface around the excavation declines progressively to the bottom of the reservoir that ranges from 390 ft amsl to 424 ft amsl. When the resulting potentiometric levels are compared to the natural condition, the drawdown inside the excavation ranges from 43 ft amsl to 65 ft amsl. The shallower water level follows silty/sandy clay or bedrock within the planned reservoir, as the excavation halts at the clay or bedrock units (Figure D3-4).

Figures D3-3 through D3-5 demonstrate the natural condition, project-condition and comparison of the natural (existing) water level with the predicted water level after excavation.

The drain cells, set at 390 ft amsl within the reservoir, quantify the amount of water that needs to be dewatered. The steady-state model estimates the total inflows into the reservoir to be approximately 830 gpm (Table D3-9).

3.8.4.2 Results of the Second Scenario- Excavation with Slurry Walls

The placement of the slurry walls changes the inflow rate into the excavation significantly. When the slurry walls extend to the bottom of layer 2 (~ 378 ft amsl), the barrier diminishes the inflow into the excavation to 70 gpm a reduction of approximately 90% from the previous scenario (Figure D3-6).

To simulate the case where the slurry wall depth is less extensive, the second layer was divided into two and the slurry was set to layer one and half of layer two. It is then assumed, that the slurry wall is installed to a shallower depth, i.e., only through the upper half of layer 2. The inflow increased by two folds compared to the results of scenario two (i.e., from 70 gpm to 160 gpm).

The following figures compare the water level changes caused by excavation with the slurry walls (Figures D3-6 and D3-7).

The model results indicate limited groundwater depression compared to the natural condition. The placement of the reservoir still draws groundwater flow towards it despite the placement of slurry walls. The depression is proportional to the lower inflow rate (160 gpm) and occurs dominantly in layer two. The average depth to the water table in layer one is about 50 % of the thickness of the layer (~22 ft), and thus, a limited decline in the groundwater level. Layer two is fully saturated and experiences an increased decline in groundwater level due to a proportionally higher flow to the reservoir. Overall, the groundwater depression is significantly less when compared to scenario 1. The increased decline in Layer 2 indicates that the pre-excavation upward gradient is reduced. The excavation intercepts the groundwater flow; however, below the bottom of the reservoir, it remains significantly unchanged and is governed by a regional gradient.

3.8.4.3 Results of the Third Scenario- Excavation with Slurry Walls and Infiltration Trench

When scenario two is augmented by the infiltration trench, the estimated inflows into the planned excavation do not change significantly from the estimated rate of scenario two. A limited groundwater mounding is observed in layer one due to about 70 gpm of flux infiltrated through a trench (Figure D3-6 through D3-8). In layer two, like scenario two, depression of groundwater is observed due to the inflow to the excavation.

The results indicate that the slurry wall controls the flow around the excavation (Table D3-9) dominantly.

Table D3-9 Model Mass Balance

Condition	Flux (gpm)	Remarks
Planned Excavation in Layers 1 and 2 [No Slurry Wall]	**Scenario - 1**	Drain cells were set @ 390 ft, amsl, top elevation of L1 ~ 467 ft, amsl, bottom elevation of L2 ~ 380 ft. amsl
	830	
Planned Excavation surrounded by a Slurry wall in Layers 1 and 2 [Scenario 2 with a Slurry wall extended to layer 1 and part of layer 2]	**Scenario - 2**	Drain cells were set @ 390 ft, amsl, top elevation of L1 ~ 467 ft, amsl, bottom elevation of L2 ~ 380 ft. amsl. [Bottom elevation of sublayer 2-1 is ~ 400 ft amsl.]
	70	
	160	
Planned Excavation surrounded by a Slurry wall with Infiltration Trench on the North [Scenario 3 with a Slurry wall extended to layer 1 and part of layer 2]	**Scenario - 3**	Drain cells were set @ 390 ft, amsl, top elevation of L1 ~ 467 ft, amsl, bottom elevation of L2 ~ 380 ft. amsl [Bottom elevation of sublayer 2-1 is ~ 400 ft amsl.]
	74	
	174	

To further characterize inflow for the slurry wall scenario, a different completion depth as assumed. The slurry wall was set to layer one and half of layer two by dividing layer two into two sublayers. The results indicate this would increase the inflows slightly to 160 and 174 gpm respectively (Table D3-93, Figure D-9).

SLR notes that the results of the numerical simulations are based on simplifications of the actual field condition. The actual dewatering rates are expected to be around the approximated inflow rate but may be higher or lower by some amount.

D.3.9 SENSITIVITY ANALYSIS

Sensitivity analyses were conducted to understand how changing some conditions affects the inflow rates to the excavation. The changes made to evaluate the sensitivity of the model are the following.

1. Existing ponds to the North of the Reservoir, which vary in size in the Google Earth historical images, were set as high permeability subsurface material that intercepts groundwater. The “air” zone (5000 ft/day) was assumed up to 10 ft depth below the water level as measured by nearby monitoring wells. Its impact is evaluated by the resulting inflow rate towards the reservoir.
2. In addition, to assess the robustness of the slurry wall in minimizing inflows to the excavation, a simulation was performed assuming a worst-case failure of a segment of the wall, and inflow rates were estimated and compared with the results of scenario two.

D.3.9.1 SENSITIVITY ANALYSES

The following changes were made to analyze the sensitivity of the model to changes in the input parameters.

Existing Ponds to the north of the Reservoir. The pond’s water was treated as surface water intercepting groundwater through artificially high hydraulic conductivity (“air” zone (5000 ft/day)). The subsurface beneath the pond is assumed to be 10 ft below the local water level and is restricted to layer one (Table D3-10). The results indicate the inflows (65 gpm) would be like those with groundwater levels in the area. The slight decrease is due to the slightly differing heads assume in groundwater and the ponds respectively.

Slurry Wall failure. The failure mode analysis assumed that the slurry wall for scenario two was also assumed to fail using two different sizes. Failure of four columns in layers one and two (84 ft by the saturated thickness of layer one and 84 ft by 45 ft in layer two) resulted in an inflow increase by more than two-fold to 190 gpm (Table D3-10). The failure in the wall will occur over an area of 42 feet by 45 feet (i.e., two columns and layer one and half of layer two), the resultant inflows remain the same as scenario 2 (Table D3-10).

Table D3-10 Model Sensitivity Analyses

CONDITION	FLUX (GPM)	REMARKS
Ponds to the North of the Reservoir (Slurry walls set in Layer 1 and Layer 2)	65	The ponds intercept some groundwater flowing towards the reservoir
Slurry walls set in Layer 1 and Layer 2 assumed to fail in bigger section (26 ft by 45 ft)	Scenario - 2 (modified)	
	190	
Slurry walls set in Layer 1 and Layer 2 assumed to fail in smaller section (13 ft by 22.5 ft)	Scenario - 2 (modified)	The small crack does not change the results of Scenario 2.
	70	

3.9.1.1 Model Uncertainties

It is important to understand numerical models have their limitations and the results should be considered approximate at these stage two methods have essentially be applied, i.e. Both 2-D and 3-D analyses to increase the level of confidence in the results. For purposes of these analyses, it is anticipated that during the detailed design process, added field data will be made available and the modeling will be improved.

The calibrated steady-state flow model simulations reasonably match water levels and the groundwater inflow rate estimate through different methods is not significantly different.

Some of the limitations of the modeling work are as follows:

- Site specific lithological, well construction, water level data was limited, and additional data from other publicly available documents were also reviewed and used as presented without further validation.

- The steady-state model represents the general hydrogeologic conditions, and variation of input parameters, water levels and water budget with time is not considered in the numerical simulations.

D.3.10 CONCLUSIONS

The results of the model calibration for the steady-state model reasonably matched water levels and the groundwater flow budget measured or estimated for the site. The total inflows projected using the USEPA (USEPA, 2008) empirical method is not significantly different from the seepage rate estimated numerically. The total flow rates into the reservoir are assessed for each scenario and are reported in Table D3-8.

The results of the numerical simulations are based on simplifications of the actual field condition. The actual dewatering rates are expected to be around the approximated inflow rates but may be higher or lower by some amount.

NOISE IMPACT ASSESSMENT

Tulare Irrigation District
McKay Point Reservoir Project

September 2021

1.0 INTRODUCTION

Sespe Consulting, Inc. ("Sespe") has prepared the following Noise Impact Assessment (NIA) on behalf of the Tulare Irrigation District (TID), to determine noise impacts associated with the development and operation of the proposed McKay Point Reservoir Project ("Project"). The TID, the Consolidated Peoples Ditch Company (CPDC), and the Visalia and Kaweah Water Company (VKWC), collectively referred to as the "Owners", own approximately 500 acres of land adjacent to the Lower Kaweah River and St. Johns River in Tulare County, California, referred to as the McKay Point property. The Owners propose to develop approximately 200 acres within the 500-acre McKay Point property into a surface water storage and re-regulation reservoir. The reservoir would be located on the north side of the divergence of the Lower Kaweah River and St. Johns River, in unincorporated Tulare County (see Figure 1 and Figure 3, Appendix A).

This NIA quantifies the results of background noise monitoring and assesses potential noise impacts associated with the development and operation of the proposed Project on nearby sensitive receptors. Project impacts are presented and compared to applicable noise criteria, and mitigation measures are recommended for receptors where noise impacts were found to be above applicable regulatory thresholds.

TID is currently preparing a Draft Environmental Impact Report (Draft EIR) for the Project, and this NIA will be included as a technical appendix within that document. The TID is the Lead Agency for purposes of administering the requirements of the California Environmental Quality Act (CEQA), and for preparing the Draft and Final EIR.

2.0 PROJECT DESCRIPTION

2.1 Location

The Project site is located in unincorporated Tulare County, on the north side of the divergence of the Lower Kaweah River and St. Johns River. The existing Project site is primarily undeveloped grassland that has historically been used for cattle grazing under lease arrangements. The Project site is bounded by the Lower Kaweah and St. Johns Rivers to the south; an existing aggregate mining and processing facility, known as the Seaborn site, to the west; and, the existing CEMEX Lemon Cove aggregate facility to the north and east. Additionally, various agricultural, residential land uses, including a single-family residence owned by TID, and the Kaweah South Project lies (approximately 1.0 miles away) are located farther south across the Lower Kaweah and St. Johns Rivers. Please see Figure 1 and Figure 2 (Appendix A) which display the McKay Point site and the environmental setting within the immediate vicinity of the Project.

The Project site lies to the south of both Lake Kaweah (approximately 2.5 miles to the northeast) and Bravo Lake (approximately 1.3 miles to the northwest). Nearby communities include the unincorporated community of Lemon Cove (approximately 1.0 miles to the southeast) and the City of Woodlake (approximately 2.5 miles to the northwest). Nearby prominent roadways include State Route 216 (SR-216)/Lomitas Drive (approximately 0.5 miles to the north) and State Route 198 (SR-198)/Sierra Drive (approximately 0.9 miles to the east). Please see Figure 1 through Figure 2 (Appendix A) which shows the regional and local Project site setting.

2.2 Objectives and Benefits

The Project would consist of the following three (3) distinct phases: 1) excavation of the site for the reservoir; 2) construction of the reservoir; and, 3) operation of the reservoir. The Owners intend to enter into a lease agreement with West Coast Aggregate Supply, Inc. (WCA) to excavate the site to allow for the construction of the reservoir. After the excavation phase and construction of the reservoir structures, the McKay Point Reservoir would be used as a surface water storage/re-regulation reservoir. The reservoir would also be used to optimize groundwater recharge within the Owners service areas. Ultimately, once operational, the Owners would utilize the reservoir and its facilities to manage their surface water supplies to increase the long-term availability of irrigation supplies, groundwater recharge supplies, via water re-regulation.

2.3 McKay Point Reservoir Operations/Phases

Before the reservoir can be constructed, the site must first be prepared. The preparation of the site includes the excavation of a pit/basin with sufficient capacity to meet the Owner's needs for water storage. After the pit has been sufficiently excavated and prepared, the reservoir and ancillary structures (e.g., perimeter road, storage tanks, etc.) would then be constructed. Once constructed, the reservoir would be maintained by the Owners and serve as a surface water storage/re-regulation reservoir. As discussed above, the Project would entail the following three (3) discrete phases: 1) Reservoir Excavation; 2) Reservoir Construction; and, 3) Reservoir Operations/Maintenance. The following is a brief discussion of the Project phases, which are individually analyzed within this NIA.

2.3.1 Reservoir Excavation

WCA would excavate the reservoir basin to a depth and surface area sufficient to meet the Project's desired water storage capacity requirements. Specifically, excavation of the Project site would result in an open pit with a surface area of approximately 110 acres and a final depth of approximately 60-feet

below ground surface (bgs). WCA would begin onsite excavation activities at-grade in a single location, and progress downward in that location until the final excavation depth of 60-feet bgs is reached. From there, excavation would then progress at a depth of 60-feet bgs throughout the entirety of the 110-acre Project site, until the pit is fully excavated. It is estimated that approximately 16.5 million gross tons of material will be extracted over an approximately 20-year reservoir excavation phase (may fluctuate depending on market demand). Please see Figure 3 (Appendix A) which shows a schematic of the reservoir and specific design components of the excavation phase.

WCA would process the excavated material onsite using portable processing/wash plant, and at times a portable crushing/recycle plant. Material would be excavated using mobile equipment (e.g., dozers, excavators, etc.) and placed directly into the aggregate processing plant where it would be sized and sorted into marketable products. Due to the type of material to be excavated (i.e., river alluvium), permanent crushing operations will not be required; however, at times WCA may bring a temporary portable crushing/recycle plant onsite to break up oversized pieces of rock prior to screening in the processing/wash plant. The crushing/recycle plant could also be used to recycle used concrete and asphalt brought in from offsite. It is expected the onsite portable crushing/recycle plant would be operated infrequently. Additionally, only one of these two plants (i.e., aggregate processing plant or portable crushing/recycle plant) would be in use at any given time, and the plants would not operate simultaneously. Once processed, marketable materials (e.g., sand, stone, gravel, etc.) would be placed directly into on-road haul trucks by a loader, and delivered to WCA's customers throughout Tulare County. The ingress and egress point for haul trucks and other worker vehicles would be the existing entrance located in the western portion of the Project site, which connects to an existing surface mining facility known as the Seaborn site (see Figure 2, Appendix A). Section 5.1 provides a detailed summary of the onsite equipment required during the reservoir excavation phase.

As discussed above, marketable material excavated/processed at the Project site (i.e., McKay Point) would be transported through the adjacent Seaborn facility for delivery to customers. Sand and gravel (aggregate) mining and processing activities have been conducted at the Seaborn site since the late 1940's. The excavation and storage of aggregate during the reservoir excavation phase of the Project would be coordinated with WCA, such that the historical maximum production rate historically associated with the adjacent Seaborn facility would not be exceeded. Specifically, WCA's annual production rate at the McKay Point site would not exceed production rates (i.e., baseline) of an average of 500,000 tons per year (TPY) and a maximum of 650,000 TPY (these rates were achieved by the Seaborn facility in 2005). Consequently, the number of on-road haul trucks transporting material offsite on public roads to WCA's customers would not increase above baseline levels associated with the Seaborn facility. Similarly, the number of employees and associated work vehicle trips would also not increase, and would most likely decrease, compared to baseline levels. Therefore, noise impacts associate with haul truck activities/traffic, both onsite and on public roadways, was not analyzed in this NIA.

Reservoir excavation operations will occur Monday through Saturday (except holidays), between the hours of 4:30 a.m. (or dawn if later) and 6:00 p.m. (or earlier if sundown). Approximately four (4) to eight (8) daily onsite employees would be required during the reservoir excavation phase, working in two (2) shifts per day; however, this is lower than the seven (7) to twelve (12) employees who historically worked at the adjacent Seaborn facility. Because the hours of operation and number of onsite employees will not increase, and will most likely decrease, compared to historical (i.e., baseline) levels, noise from employee vehicle trips was not analyzed. Reservoir excavation Project phase will generally entail the following activities, which are analyzed in this NIA:

- Mineral resource extraction activities in one (1) phase to develop a reservoir basin. Reservoir excavation/material extraction would occur over an approximate 110-acre area, and reach a maximum depth of 60-feet below natural ground surfaces. The pit design incorporates a final slope configuration of 3:1 (horizontal to vertical).
- Construction and maintenance of onsite roads, including an earthen perimeter access road as shown on Figure 3 (Appendix A).
- Operation of the processing/wash plant (i.e., aggregate plant) to size and sort excavated material. Infrequent use of a portable crushing/recycle plant brought onsite to process oversize and/or imported materials. Processing equipment will generally occur in the bottom of the excavation pit, and the plant(s) will be relocated adjacent to active mining areas as excavation progresses. As discussed previously, only one plant would operate at a given time (i.e., no simultaneous operations).
- Operation of onsite mobile equipment (i.e., haul trucks, loaders, scrapers, water trucks and related equipment) to excavate, and transport materials as needed.
- Conduct all reservoir excavation activities, as described above and herein, on an approximately 110-acre site as shown on Figure 3 (see Appendix A).

Groundwater Management within the Excavation Pit: To prevent groundwater intrusion into the excavation area, a slurry wall will be installed around the perimeter of the pit (see Figure 3, Appendix A) to minimize groundwater seepage into/out of the reservoir basin. The slurry wall(s) will be a below-grade wall that restricts groundwater flow and supports pit walls, using soil-bentonite or cement-bentonite. Additionally, due to the nature of the clay material present at the Project site, a clay liner could also be used as an alternative to a slurry wall, assuming infiltration into the pit can be maintained below 500 gallons per minute (gpm). It is assumed that the slurry wall or clay liner would be installed early in the excavation phase to slow or eliminate groundwater from flowing into the pit. The slurry wall/clay liner would also remain as permanent structure to maintain the reservoir in an empty state as part of the long-term operations (i.e., a full reservoir would have limited water re-regulation value).

Construction of the slurry wall and/or clay liner would be accomplished using the same mobile equipment (loaders, excavators, haul trucks, etc.) and stationary equipment (i.e., processing plant[s]). Additionally, the operational parameters (e.g., operating hours, number of onsite employees, etc.), would remain the same.

2.3.2 Reservoir Facility Construction

Once the reservoir basin is fully excavated and stabilized, construction of the reservoir facilities will commence. The following components/structures, illustrated on Figure 4 (Appendix A), would be constructed or installed during the reservoir construction Project phase:

- Inflow channel and associated electrically operated weir;
- Inflow chute, with an associate energy dissipation pool;
- Floating barge pump (to deliver water upstream to the Kaweah River) and discharge piping;
- Aboveground diesel tank, generators and generator building;
- Outflow channel (deliver water to the St. Johns River) and associated electrically operated weir;
- Access gate(s), as needed; and
- Perimeter berm, perimeter road and truck turnaround (the inflow and outflow channels will pass

under the perimeter road in concrete structures).

The inflow and outflow structures would require some excavation and grading to prepare the site for installation. Specifically, inflow/outflow channel grading would consist of clearing and grubbing of approximately 3 acres, excavation of 20,000 cubic yards of material, and the placement of approximately 9,000 cubic yards of rip-rap to prevent erosion. Construction of the in/out-flow building would consist of finish grading and minor excavation of approximately 600 cubic yards of additional material, and the placement of approximately 1,100 cubic yards of concrete.

During the reservoir construction phase, off-road mobile equipment (e.g., excavators, loaders, water truck, etc.) similar to the equipment required during the reservoir excavation phase will operated onsite; however, at times a cement truck, crane and/or portable generator may also be required. Additionally, no onsite material processing will occur during reservoir construction. Section 5.2 provides a detailed summary of the onsite equipment required during reservoir construction. The number of employees and operating hours would remain unchanged, or possible decrease, compared to the reservoir excavation phase. Please see Figure 4 (Appendix A) which shows the design of the reservoir facilities, and various structures that will be constructed during this Project phase.

2.3.3 Reservoir Operation

Once constructed, the Owners would utilize the McKay Point reservoir and its associated facilities to manage their surface waters to increase the long-term availability of irrigation supplies and groundwater recharge supplies via water re-regulation. As discussed above, the reservoir structures would consist of various check structures on the St. Johns and Lower Kaweah Rivers, each with automated gates. The structures could be operated such that the gates on the St. Johns River side could be raised, therefore shunting more flows down the Lower Kaweah River. Because CPDC, VKWC, and TID hold many of the rights to the waters of the Kaweah River system, water released from the reservoir and shunted into the Lower Kaweah River in this manner would serve CPDC and VKWC customer needs, as well as TID customer needs if necessary.

In a similar manner, the McKay Point Check Structures could be operated such that the gates on the Kaweah River side could be raised, therefore shunting more flows down the St. Johns River. Because TID holds rights to waters of the St. Johns River, water released via the outflow channel would serve TID customer needs. Please see Figure 4 (Appendix A) which shows the final layout of the completed reservoir, including the locations of check structures and related inflow/outflow channels.

During ongoing reservoir operations and management, the Owners would have daily control over the reservoir and related facilities, which include the use of the Supervisory Control and Data Acquisition (SCADA) equipment to monitor and control the facility remotely. SCADA equipment would permit remote monitoring, control, and operations by TID operators from TID's offsite office. In addition, TID operators would have the ability to set the control gates in either a condition of flow control or level control. In flow or level control, the gates would autonomously operate to maintain a desired flow, or a desired elevation, respectively, in the river channels. Through these remote and automated controls, TID’s onsite activities would be limited during the reservoir operations/maintenance phase.

An approximately 10,000-gallon diesel aboveground storage tank (AST), diesel generators, and a generator building near the inflow chute would be installed and used during reservoir operations. The diesel generators would provide power periodically to the floating pump station as needed.

During the ongoing reservoir operations/maintenance phase, TID staff would perform routine onsite inspections to ensure the reservoir is operating properly. The routine onsite maintenance of the Project would be conducted by TID's staff based at their offsite office; therefore, the number of employees routinely driving to the Project site would be minimal, and would be far less than during the previous reservoir excavation and construction phases. Operation and maintenance of the Project would generate only nominal onsite noise and traffic primarily associated with maintenance operations. During the operations and maintenance of the reservoir, there would be limited equipment usage, but equipment could be needed to perform minor grading of the access road and to remove any debris that collects in the bottom of the reservoir. TID estimates that onsite maintenance and related operations using mobile equipment would occur only a few times annually (approximately 1 to 3 days per year).

3.0 EXISTING SETTING

The McKay Point Reservoir Project site is located in unincorporated Tulare County, north of the divergence of the Lower Kaweah and St. Johns Rivers. Existing mining/aggregate operations bound the Project site to the west (Seaborn facility), and to the north and east (CEMEX's Lemon Cove facility). The site is bounded by the Lower Kaweah and St. John's Rivers to the south, with agricultural and rural residential land uses further south across the rivers. Please see Figure 2 (Appendix A) which shows the Project site and surrounding environment.

Though the Project site is located in a generally isolate/undeveloped area. Nearby communities include the community of Lemon Cove (approximately 1.0 mile southeast of the site) and the City of Woodlake (approximately 2.6 miles northwest of the site). As discussed previously, nearby prominent roadways include SR 216/Lomitas Drive (approximately 0.5 miles to the north) and SR 198/Sierra Drive (approximately 0.9 miles to the east). The McKay Point site is accessed via an existing ingress/egress point along the western boundary of the Project site, which connects to the existing Seaborn facility to the west and eventually connects to Road 222. Please see Figure 2 (Appendix A) which shows the layout of the Project site, the access route, and the adjacent environmental setting.

The following sections discuss the existing noise and vibration regulatory and environmental settings applicable to the Project.

3.1 Regulatory Setting & Noise Fundamentals

This section discusses the Project's regulatory setting. Specifically, the Tulare County *General Plan – Noise Element* (Tulare County, 2012) and the Tulare County *Lemon Cove Community Plan 2019* (Tulare County, 2019). Noise and vibration standards from the Federal Highway Administration's (FHWA) *Roadway Construction Noise Model* (Federal Highway Administration, 2006), and applicable guidance from the California Department of Transportation's (Caltrans) are also discussed in this section. Please note, the Tulare County Code (Tulare County, 2020) does not contain any noise ordinances nor does it set specific restrictions related to noise.

3.1.1 Definitions

The following terms are employed in this NIA:

- **Decibel (dB):** A unit division, on a logarithmic scale, whose base is the tenth root of ten, used to represent ratios of quantities proportional to power. In simple terms, if the power is multiplied by a factor of ten, then ten is added to the representation of the power on the decibel scale. If 0 dB represents 1 unit of power, 30 dB represents one thousand units, 60 dB represents one million units, etc.
- **A-Weighted Sound Level (dBA):** Sound pressure level measured using the A-weighting network, a filter which discriminates against low and very high frequencies in a manner similar to the human hearing mechanism at moderate sound levels. The A-weighted sound level is generally used when discussing environmental noise impacts.
- **Maximum Noise Level (L_{max}).** The instantaneous maximum noise level measured during the sample.
- **Equivalent Continuous Noise Level (L_{eq}).** The average noise level over a designated time period. This is often referred to as "equivalent sound level", hence the "eq" subscript. The "equivalence"

is to a sound of constant level that has the same total acoustic energy content.

- **Ambient (i.e., Background) Noise Level:** The current noise level in the vicinity of the proposed Project that results from the combination of all sources, near and far. Please note, ambient noise measurements presented in this NIA include existing noise generated by existing aggregate mining and processing facility adjacent to the McKay Point property (see Section 3.2).
- **Day-Night Average Level (L_{dn} – dBA):** The long-term time average sound level, weighted as follows:
  - Frequency response is filtered using the A-weighting network;
  - Daytime noise (7:00 a.m. – 10:00 p.m.) is not weighted; and
  - Nighttime noise (10:00 p.m. – 7:00 a.m.) is weighted by +10 dB.
- **Community Noise Equivalent Level (CNEL – dBA):** The long-term time average sound level, weighted as follows:
  - Frequency response is filtered using the A-weighting network.
  - Daytime noise (7:00 a.m. to 7:00 p.m.) is not weighted.
  - Evening noise (7:00 p.m. and 10:00 p.m.) is weighted by +5 dB.
  - Nighttime noise (10:00 p.m. and 7:00 a.m.) is weighted by +10 dB.

3.1.2 Characteristics of Noise

Noise is often described as unwanted sound. Sound is defined as any pressure variation in air that the human ear can detect. If the pressure variations occur frequently enough (at least 20 times per second) they can be heard and are called sound. The number of pressure variations per second is called the frequency of sound, and is expressed as cycles per second, called Hertz (Hz).

Measuring sound directly in terms of pressure would require a very large and awkward range of numbers. To avoid this, the decibel scale was devised. The decibel scale uses the hearing threshold (20 micropascals of pressure), as a point of reference, defined as 0 decibels (dB). Other sound pressures are then compared to the reference pressure, and the logarithm is taken to keep the numbers in a practical range. The decibel scale allows a million-fold increase in pressure to be expressed as 120 dB. Another useful aspect of the decibel scale is that changes in decibel levels correspond closely to human perception of relative loudness as presented in Table 1.

The perceived loudness of sound is dependent upon many factors, including sound pressure level and frequency content. However, within the usual range of environmental noise levels, perception of loudness is relatively predictable, and can be approximated by weighing the sound level pressures between 1,000 and 5,000 Hz, which represent the most sensitive frequencies perceived by a healthy human ear and coincidentally the natural frequency range of human speech. This weighting network is referred to as the A-scale. There is a strong correlation between A-weighted sound levels (expressed as dBA) and community response to noise. For this reason, the A-weighted sound level has become the standard tool of environmental noise assessment. All noise levels reported in this NIA are A-weighted. Table 1 provides sound pressure levels of typical noise sources in units of dBA and micropascals (µPa) of pressure.

Community noise is commonly described in terms of the ambient noise level, which is defined as the all-encompassing noise level associated with a given noise environment. A common statistical tool to measure the ambient noise level is the average, or equivalent, sound level (L_{eq}) over a given time period (usually one hour or less). The L_{eq} is also the foundation of both the Day-Night Average Level (L_{dn}) and the

Community Noise Equivalent Level (CNEL) noise descriptors described below, each of which has a strong correlation with community response to noise. The maximum sound level (L_{max}) represents the highest instantaneous noise level recorded over a given time period (usually one hour or less), and can also be utilized to assess community noise impacts.

Table 1 Typical A-Weighted Sound Levels of Common Noise Sources

Loudness Ratio	Micropascals (µPa)	dBA	Description
128	63,245,553	130	Threshold of Pain
64	20,000,000	120	Jet aircraft Take-Off at 100-feet
32	6,324,555	110	Riveting Machine at Operator's Position
16	2,000,000	100	Shotgun at 200-feet
8	632,456	90	Bulldozer at 50-feet
4	200,000	80	Diesel Locomotive at 300-feet
2	63,246	70	Commercial Jet Aircraft Interior During Flight
1	20,000	60	Normal Conversation Speech at 5- to 10-feet
0.5	6,325	50	Open Office Background Level
0.25	2,000	40	Background Level Within a Residence
0.125	632	30	Soft Whisper at 2-feet
0.0625	200	20	Interior of Recording Studio

Sources: (US EPA, 1971) and (Federal Interagency Committee on Noise, 1992).

The Day-Night Average Level (L_{dn}) is based upon the average noise level over a 24-hour day, with a +10 decibel weighting applied to noise occurring during nighttime (10:00 p.m. to 7:00 a.m.) hours. The nighttime penalty is based upon the assumption that people react to nighttime noise exposures as though they were twice as loud as daytime exposures. Because L_{dn} represents a 24-hour average, it tends to smooth out short-term variations in the noise environment. L_{dn} based noise standards are commonly used to assess noise impacts associated with variable noise sources, such as traffic, railroad and aircraft noise. The L_{dn} noise metric forms the basis of the applicable Tulare County General Plan noise criteria described in Section 3.1.6 below.

CNEL is also based upon the average noise level over a 24-hour day, with a +5 decibel weighing applied to noise occurring during evening (7:00 p.m. to 10:00 p.m.) hours and a +10 decibel weighing applied to noise occurring during nighttime (10:00 p.m. to 7:00 a.m.) hours. These additions are made to account for the noise sensitive time periods during the evening and night hours, when people are generally at home and more sensitive to sound.

The maximum sound level (L_{max}) presents the highest instantaneous noise level recorded over a given time period (usually one hour or less). This value is useful as it can reveal short-term, intermittent noise sources (e.g., railroads, aircraft noise) within a noise environment, which would be lost with L_{dn} and CNEL noise descriptors.

3.1.3 Characteristics of Groundborne Vibration

Vibration is like noise in that it involves a source, a transmission path, and a receiver. While vibration is related to noise, it differs in that noise is generally considered to be pressure waves transmitted through air, while vibration is usually associated with transmission through a structure. As with noise, vibration consists of an amplitude and frequency. A person's response to vibration depends on their individual sensitivity as well as the amplitude and frequency of the source. Additionally, damage to structures can occur when exposed to groundborne vibration.

Vibration can be described in terms of acceleration, velocity, or displacement. A common practice is to monitor vibration measures in terms of peak particle velocities (inches/second). Standards pertaining to perception as well as damage to structures have been developed for vibration in terms of peak particle velocity. Although aggregate mining and processing vibration levels are not expected to be significant for this Project due to the relatively large distances between Project equipment (sources) and acoustically sensitive receivers, and the fact that no blasting would occur with this Project, an assessment of mining-related vibration levels is nonetheless addressed.

According to Caltran's *Transportation and Construction Vibration Guidance Manual* (Caltrans, 2020), operation of construction equipment and construction techniques generate ground vibration. Traffic traveling on roadways can also be a source of such vibration. At high enough amplitudes, ground vibration has the potential to damage structures and/or cause cosmetic damage (e.g., crack plaster). Ground vibration can also be a source of annoyance to individuals who live or work close to vibration-generating activities. Traffic, including heavy trucks traveling on a highway, rarely generates vibration amplitudes high enough to cause structural or cosmetic damage.

As vibrations travel outward from the source, they excite the particles of rock and soil through which they pass and cause them to oscillate by a few ten-thousandths to a few thousandths of an inch. Differences in subsurface geologic conditions and distance from the source of vibration would result in different vibration levels characterized by different frequencies and intensities. In all cases, vibration amplitudes would decrease with increasing distance. The maximum rate or velocity of particle movement is the commonly accepted descriptor of the vibration "strength." This is referred to as the peak particle velocity (PPV) and is typically measured in inches per second.

Human response to vibration is difficult to quantify. Vibration can be felt or heard well below the levels that produce any damage to structures. The duration of the event has an effect on human response, as does frequency. Generally, as the duration and vibration frequency increase, the potential for adverse human response increases.

Human and structural response to different vibration levels is influenced by a number of factors, including ground type, distance between source and receptor, duration, and the number of perceived vibration events. Table 2 displays the human response to transient vibration sources (i.e., mining equipment) in terms of particle velocity (PPV) vibration levels.

Table 2 General Human Responses to Transient Vibration Levels

Human Response to Vibration	Peak Vibration Threshold (in./sec. PPV)
Severe	2.0
Strongly perceptible	0.9
Distinctly perceptible	0.24
Barely perceptible	0.035

Source: *Transportation and Construction Vibration Guidance Manual* (Caltrans, 2020).

3.1.4 Federal Standards

The adverse impact of noise was officially recognized by the federal government in the Noise Control Act of 1972 (42 U.S.C. §4901 et seq.), which serves three purposes:

- Establish noise emission standards for interstate commerce.
- Assist state and local abatement efforts.
- Promote noise education and research.

The Federal Office of Noise Abatement and Control (ONAC) was initially tasked with implementing the Noise Control Act. However, the ONAC has since been eliminated, leaving the development of federal noise policies and programs to other federal agencies and interagency committees. For example, the Occupational Safety and Health Administration (OSHA) agency prohibits exposure of workers to excessive sound levels. The Department of Transportation (DOT) assumed a significant role in noise control through its various operating agencies, including the Federal Aviation Administration (FAA), Federal Transit Administration (FTA), and Federal Highway Administration (FHWA).

The FAA regulates noise of aircraft and airports. Surface transportation system noise is regulated by a host of agencies, including the FTA (formerly the Urban Mass Transit Administration). Transit noise is regulated by the FTA, while freeways that are part of the interstate highway system are regulated by the FHWA. Finally, the federal government actively advocates that local jurisdictions use their land use regulatory authority to arrange new development in such a way that "noise sensitive" uses are either prohibited from being sited adjacent to a highway or, alternately that the developments are planned and constructed in such a manner that potential noise impacts are minimized.

Since the Federal government has preempted the setting of standards for noise levels that can be emitted by the transportation sources, the counties and cities are restricted to regulating the noise generated by the transportation system through nuisance abatement ordinances and land use planning.

3.1.5 State Standards

Established in 1973, the California Department of Health Services Office of Noise Control (ONC) was instrumental in developing regulatory tools to control and abate noise for use by local agencies. One significant model is the "Land Use Compatibility for Community Noise Environments Matrix," which allows the local jurisdiction to clearly delineate compatibility of sensitive uses with various incremental levels of noise. This land use compatibility matrix is also referenced within the Tulare County General Plan, specifically under Policy HS-8.6, and presented in Figure 4 (Appendix A).

Article 4 of the California Administrative Code (California Noise Insulation Standards, Title 24, Chapter 1) requires noise insulation in new hotels, motels, apartment houses, and dwellings (other than single-family

detached housing) that prevent interior Day-Night (L_{dn}) or CNEL noise levels from exceeding 45 dBA. When such structures are located within a 60-dBA Day-Night (L_{dn}) or CNEL (or greater) noise contour, an acoustical analysis is required to ensure that interior levels do not exceed the 45-dBA limit. These state-designated noise level limits are consistent with the criteria outlined in the Tulare County General Plan (see Section 3.1.6 below).

Government Code §65302 mandates that the legislative body of each county and city in California adopt a noise element as part of its comprehensive general plan. The local noise element must recognize the land use compatibility guidelines published by the State Department of Health Services. The guidelines rank noise land use compatibility in terms of normally acceptable, conditionally acceptable, normally unacceptable, and clearly unacceptable.

The *Tulare County General Plan – 2030 Update* has an adopted noise element (Chapter 10 – Health and Safety, Section 10.8 – Noise) that outlines various guidelines and requirements related to noise. As discussed above, the Tulare County Code (Tulare County, 2020) does not contain a specific noise ordinance nor does it set specific restrictions related to noise.

3.1.6 County General Plan Noise Policies & Guidelines

The *Tulare County General Plan – 2030 Update*, Noise Element (Section 10.8) has a number of policies related to noise (Tulare County, 2012). General Plan noise policies that apply to the Project are listed below. Please note, the General Plan defines "noise sensitive land use(s)/receptors" to include "residential areas, hospitals, convalescent homes and facilities, schools, and other similar land uses" (Tulare County General Plan, Section 10 – Health and Safety).

HS-8.2 Noise Impact Areas
The County shall designate areas as noise-impacted if exposed to existing or projected noise levels that exceed 60 dB Ldn (or Community Noise Equivalent Level (CNEL)) at the exterior of buildings.

HS-8.3 Noise Sensitive Land Uses
The County shall not approve new noise sensitive uses unless effective mitigation measures are incorporated into the design of such projects to reduce noise levels to 60 dB Ldn (or CNEL) or less within outdoor activity areas and 45 dB Ldn (or CNEL) or less within interior living spaces.

HS-8.4 Airport Noise Contours
The County shall ensure new noise sensitive land uses are located outside the 60 CNEL contour of all public use airports.

HS-8.6 Noise Level Criteria
The County shall ensure noise level criteria applied to land uses other than residential or other noise-sensitive uses are consistent with the recommendations of the California Office of Noise Control (CONC).

Table 10.1: Land Use Compatibility for Community Noise Environments [*see Figure 4, Appendix A*], is provided as a reference concerning the sensitivity of different land uses to their noise environment. It is intended to illustrate the range of noise levels which will allow the full range of activities normally associated with a given land use.

HS-8.7 Inside Noise
The County shall ensure that in instances where the windows and doors must remain closed to achieve the required inside acoustical isolation, mechanical ventilation or air conditioning is provided.

HS-8.8 Adjacent Uses
The County shall not permit development of new industrial, commercial, or other noise-generating land uses if resulting noise levels will exceed 60 dB Ldn (or CNEL) at the boundary of areas designated and zoned for residential or other noise-sensitive uses, unless it is determined to be necessary to promote the public health, safety and welfare of the County.

HS-8.11 Peak Noise Generators
The County shall limit noise generating activities, such as construction, to hours of normal business operation (7 a.m. to 7 p.m.). No peak noise generating activities shall be allowed to occur outside of normal business hours without County approval.

HS-8.13 Noise Analysis
The County shall require a detailed noise impact analysis in areas where current or future exterior noise levels from transportation or stationary sources have the potential to exceed the adopted noise policies of the Health and Safety Element, where there is development of new noise sensitive land uses or the development of potential noise generating land uses near existing sensitive land uses. The noise analysis shall be the responsibility of the project applicant and be prepared by a qualified acoustical engineer (i.e., a Registered Professional Engineer in the State of California, etc.). The analysis shall include recommendations and evidence to establish mitigation that will reduce noise exposure to acceptable levels (such as those referenced in Table 10-1 [*Figure 4, Appendix A*] of the Health and Safety Element).

HS-8.14 Sound Attenuation Features
The County shall require sound attenuation features such as walls, berming, heavy landscaping, between commercial, industrial, and residential uses to reduce noise and vibration impacts.

HS-8.15 Noise Buffering
The County shall require noise buffering or insulation in new development along major streets, highways, and railroad tracks.

HS-8.18 Construction Noise
The County shall seek to limit the potential noise impacts of construction activities by limiting construction activities to the hours of 7 am to 7 pm, Monday through Saturday when construction activities are located near sensitive receptors. No construction shall occur on Sundays or national holidays without a permit from the County to minimize noise impacts associated with development near sensitive receptors.

HS-8.19 Construction Noise Control
The County shall ensure that construction contractors implement best practices guidelines (i.e. berms, screens, etc.) as appropriate and feasible to reduce construction-related noise impacts on surrounding land uses.

3.1.7 Lemon Grove Community Plan – Noise & Vibration Ordinances

Although the Project site is located within unincorporated Tulare County, nearby receptors are located within the Urban Development Boundary (UDB) of the County's *Lemon Grove Community Plan 2019*

(Tulare County, 2019). The Tulare County *Lemon Cove Community Plan 2019* has a number of policies related to noise. The Lemon Cove Community Plan policies, not already listed in the Tulare County *Tulare County General Plan – 2030 Update* (see Section 3.1.6 above), that apply to the Project are listed below.

Goal 2 **Prevent Incompatible Uses Provide designated routes and loading standards that reduce the noise and safety concerns associated with truck traffic.**

Policies and Standards

1. Designate truck routes for use by heavy commercial and industrial traffic. Initially, designated truck routes shall be:
    - State Route 198
2. Design interior street systems for commercial and industrial subdivisions to accommodate the movement of heavy trucks.
3. Restrict heavy duty truck through-traffic in residential areas and plan land uses so that trucks do not need to traverse these areas.
4. Design off-street loading facilities for all new commercial and industrial developments so that they do not face surrounding roadways or residential neighborhoods. Truck backing and maneuvering to access loading areas shall not be permitted on the public road system, except when specifically permitted by the County Engineer.

Goal 9 **Design, construct, and operate the transportation system in a manner that maintains a High level of environmental quality.**

Policies and Standards

1. Control dust and mitigate other environmental impacts during all stages of roadway construction.
2. Protect residents from transportation generated noise hazards. Increased setbacks, walls, landscaped berms, other sound absorbing barriers, or a combination thereof shall be provided along four lane highways in order to protect adjacent noise-sensitive land uses from traffic generated noise impacts. Additionally, noise generators such as commercial, manufacturing, and/or industrial activities shall use these techniques to mitigate exterior noise levels to no more than 60 decibels.
3. Review and monitor proposals for expansion of pipelines for the transport of suitable products and materials, and require mitigation of environmental impacts.
4. Encourage the use of non-polluting vehicles for both public and private uses.
5. Include noise mitigation measures in the design of roadway projects in Lemon Cove.

3.1.8 Vibration Criteria

Tulare County does not have any specific ordinances, policies, criteria or restriction related to groundborne vibration. However, the California Department of Transportation (Caltrans) has developed a set of criteria to assess the potential impacts caused by vibration-generating activities. Table 3 outlines threshold criteria for Project-related vibration impacts on nearby human populations, based on test subjects' responses to transient vibrations in terms of peak particle velocity (PPV) in units of inches per second (in/sec). These criteria form the basis of the groundborne vibration impact analysis in Section 6.1.2.

Table 3 Human Responses to Transient Vibration

PPV (inches/second)	Human Response
2.0	Severe
0.9	Strongly perceptible
0.24	Distinctly perceptible
0.035	Barely perceptible

Source: *Transportation and Construction Vibration Guidance Manual* (Caltrans, 2020).

3.1.9 CEQA Guidelines

The CEQA Guidelines provide threshold criteria that can be used to determine whether a project would result in a significant impact to the environment. These criteria are found in the Environmental Checklist in Appendix G of the CEQA Guidelines. Section 13 of the Environmental Checklist outlines criteria for noise and vibration analysis, and these specific criteria form the basis of the significance thresholds utilized to determine Project impacts. These thresholds are used in this study to determine potential impacts associated with the Project and are discussed further in Section 4.0.

3.2 Environmental Setting

This section describes the noise environment and existing noise sources in and around the Project site, the receptors of concern near the Project site, as well as the ambient noise levels in these areas. For this Project, the local setting and ambient noise levels includes nearby existing mining operations (e.g., Seaborn facility, CEMEX Lemon Cove facility, Kaweah South site, etc.) in the vicinity of the Project site (see Figure 2, Appendix A).

3.2.1 Regional Setting

As discussed previously, the Project site is located in a semi-rural area of unincorporated Tulare County, California, north of the community of Lemon Cove. The existing ambient noise environment experienced by residential receptors closest to the Project site is consistent with that of typical rural areas and consists primarily of natural sounds (wind, birds, insects, etc.), local roadway traffic (e.g., SR-228/Lomitas Drive, SR-198/Sierra Drive, etc.), occasional aircraft over-flights, aggregates mining and processing, and agricultural operations/equipment. Nearby urban centers include the census-designated community of Lemon Cove (1.0 miles to the southeast) and the City of Woodlake (2.5 miles to the northwest); however, urban activities from these nearby communities are generally not audible at the Project site. The closest airports/airstrips are the Woodlake Airport, located approximately 2.4 miles away to the west, and the Exeter Airport, located approximately 11.3 miles away to the southwest. Neither airport has an appreciable influence on noise levels near the Project site, and the site is not located within planning areas and/or designated noise contour areas associated with these airports. Please see Figure 1, Figure 2 and Figure 6 (Appendix A) which show the regional Project setting and the locations of nearby Project site receptors.

3.2.2 Local Vibration Environment

The existing ambient vibration environment in the immediate Project vicinity is extremely low, as would be expected in typical environments with no local sources of vibration. During field visits, Sespe staff could not detect any appreciable groundborne vibrations resulting from adjacent land uses, including the nearby aggregate and agricultural operations. Background vibration levels around the Project perimeter are less

than the threshold of perception.

3.2.3 Local Noise Environment

As discussed above, the existing ambient noise environment is consistent with that of typical semi-rural areas. To quantify the existing ambient (i.e., baseline) noise environment experienced by neighboring receptors closest to the Project site, a total of sixteen (16) short-duration (15-minute) measurements and one (1) long-duration (24-hour) reference noise measurement were collected at ten (10) locations surrounding the Project site on October 21st and 22nd, 2020 (Figure 6, Appendix A). The noise measurements were recorded using two (2) Quest DL SoundPro, Type 2 noise meters (Serial #'s BGI04008, BIJ090010). Noise meters were programmed in "slow" mode, in "A" weighted form, and logging every minute. The microphones were equipped with a windscreen during measurements, and noise meters were calibrated using two (2) Quest QC-10 calibrators (Serial #'s QIB070141, QIJ090052) prior to, and following each, measurement taken. The noise meters and calibrators were calibrated by Engineering Dynamics, Inc., who provided Certificates of Compliance and Calibration for each piece of equipment (Appendix I).

As discussed in Section 3.1.6, noise sensitive land uses (i.e., receptors) are defined as "residential areas, hospitals, convalescent homes and facilities, schools, and other similar land uses" within the Tulare County General Plan (Tulare County, 2012). Per the County noise standards and General Plan criteria, noise impacts to nearby commercial and industrial receptors, specifically the existing Seaborn and CEMEX Lemon Cove aggregate facilities, are not assessed within this NIA. The locations of the baseline noise measurement locations and the corresponding Project site receptors are shown on Figure 6 (Appendix A). The long-duration (i.e., 24-hour) measurement represents both a receptor (R1) and was also utilized as a reference measurement to estimate the Day-Night Average (L_{dn}) noise levels at the other receptor locations where only short-duration measurements were collected. The details of these calculations are presented in Appendix C.

The monitoring locations and associated receptors considered in this NIA are summarized in Table 4. The closest relevant receptor in each direction from the Project site was included. Furthermore, measurements at these closest receptors conservatively account for potentially-affected receptors at locations farther from the Project noise sources. When appropriate, receptors are grouped together and the noise impact at the worst-case portion of the group is determined. See Figure 6 in Appendix A for the locations of the Project site receptors respectively.

Table 4 Summary of Monitoring Locations

Receptor	Duration	Date(s) Measured	Time Start	Time Stop	Description
R1	24-hours	10/21/20 10/22/20	1:29 p.m. ---	--- 1:29 p.m.	Residence owned by TID, south of Project Site.
R2	30-mins	10/21/20 10/22/20	5:29 p.m. 10:52 a.m.	5:44 p.m. 11:07 a.m.	Residence southwest of Project site, along Road 228.
R3	30-mins	10/21/20 10/22/20	5:08 p.m. 11:18 a.m.	5:23 p.m. 11:33 a.m.	Residence southeast of Project site, along Goodale Lane.
R4	30-mins	10/21/20 10/22/20	4:42 p.m. 11:18 a.m.	4:57 p.m. 11:33 a.m.	Residence(s) east of Project site, adjacent to SR-198.

Receptor	Duration	Date(s) Measured	Time Start	Time Stop	Description
R5	30-mins	10/21/20 10/22/20	3:27 p.m. 12:06 p.m.	3:42 p.m. 12:21 p.m.	Residence north/northeast of Project site, along a private dirt road connecting to SR-216.
R6	30-mins	10/21/20 10/22/20	3:27 p.m. 12:06 p.m.	3:42 p.m. 12:21 p.m.	Residence north of Project site, along a private dirt road connecting to SR-216.
R7	30-mins	10/21/20 10/22/20	3:03 p.m. 12:29 p.m.	3:18 p.m. 12:44 p.m.	Residence north of Project site, along a private dirt road connecting to SR-216.
R8	30-mins	10/21/20 10/22/20	2:43 p.m. 12:53 p.m.	2:58 p.m. 1:08 p.m.	Residence northwest of Project site, along Road 228.
R9	30-mins	10/21/20 10/22/20	5:50 p.m. 1:14 p.m.	6:05 p.m. 1:29 p.m.	Residence(s) west of Project site, along Avenue 335 west of the Seaborn facility.
R10	30-mins	10/21/20 10/22/20	10:25 a.m. 1:34 p.m.	10:40 a.m. 1:49 p.m.	Residence west of Project site, along Avenue 332.

Figure 6 (Appendix A) shows the locations described above.

Based on ambient noise measurements taken October 21st and 22nd, 2020, Table 5 presents the existing ambient noise levels experienced at the receptors in the Project site vicinity. Noise from the existing adjacent aggregate operations were captured in these ambient noise levels as the sites were operating while the measurements were taken. Noise measurement logs and additional information regarding the background noise level determination are included in Appendix C. Project site monitoring locations are illustrated on Figure 6 (Appendix A).

Long-term (i.e., 24-hour) measurements consist of daytime, evening and nighttime hours, and reveal average L_{dn}, CNEL, and L_{eq} noise levels. One (1) long-term measurement was collected at Receptor 1 (R1), which is a residence that is owned and rented out by the TID. This receptor is in close proximity to the Project site (approximately 250-feet to the south) but far away from any non-Project related intermittent or high-intensity noise sources (i.e., roads, agricultural and mining operations, etc.), making it generally representative of existing ambient conditions near the Project site. The average hour L_{eq} value from long-term measurements during the applicable measurement periods, as well as the 24-hour L_{dn} and CNEL are presented below in Table 5.

To estimate average Day-Night (L_{dn}) noise levels for receptors where only short-duration (i.e., 15-minute) measurements were collected (i.e., R2 through R10), L_{eq} measurements collected at the long-duration (24-hour) reference location were compared to L_{eq} measurements at each short-duration receptor location(s) during the same time of day to determine the dBA difference between the two points. For example, Receptor R7 measurements (2 measurements, 15 minutes each) collected between 3:03 p.m. and 3:18 p.m. on 10/21/2020 and 12:29 p.m. and 12:44 p.m. on 10/22/2020, when compared to the L_{eq} values collected at the 24-hour reference point during the same time periods show an average noise level difference of +8.0 dBA and +1.8 dBA respectively (average noise difference equates to +4.9 dBA). This difference between the noise levels can be used as a correction factor, which is utilized to estimate the Day-Night (L_{dn}) and CNEL noise levels at Receptors 2 (R2) through 10 (R10). Additional details regarding these calculations are included in Appendix C.

Using this concept, Table 5 and shows the ambient noise levels (L_{eq}, L_{dn} and CNEL) at each receptor. As discussed above, the L_{eq} noise levels represent the measured ambient noise levels at each receptor. While the L_{dn} and CNEL levels at Receptor R1 were measured over a 24-hour period, the L_{dn} and CNEL levels at the remaining receptors were estimated using the appropriate adjustment factors. The nearest noise sensitive receptor to the Project in each direction is included in this assessment. Please see Appendix C which provides more detail regarding ambient noise level measurements and determination.

Table 5 Ambient Noise in Project Site Vicinity (dBA)

Receptor	L_{eq} [A]	Day-Night (L_{dn}) Average [B]
R1	43.8	47.6
R2	44.6	55.9
R3	50.2	59.8
R4	37.8	44.7
R5	56.5	66.2
R6	47.0	53.5
R7	46.3	60.8
R8	41.1	54.3
R9	47.0	47.8
R10	43.8	47.6

Footnotes:

A – L_{eq} values shown represent exterior noise levels at these locations. See Appendix C for more detail.

B – Day-Night (L_{dn}) noise levels at R2 through R10 were calculated by comparing measured daytime values at each of these locations to the measured noise level at the 24-hour reference location during the identical time period. The difference between these values (i.e., correction factor) is then applied to the applicable 24-hour L_{dn} measurements to estimate the appropriate noise levels at each receptor location. Please see Appendix C for more detail.

4.0 SIGNIFICANCE THRESHOLDS

According to the Appendix G Checklist in the CEQA Guidelines (CCR, Title 14, Division 6, Chapter 3, §15000 – 15387), a Project would have a significant effect if any of the following are true:

a) Generation of a substantial temporary or permanent increase in ambient noise levels in the vicinity of the project in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies (see Sections 6.1.1).

b) Generation of excessive groundborne vibration or groundborne noise levels (see Section 6.1.2).

c) For a project located within the vicinity of a private airstrip or an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project expose people residing or working in the project area to excessive noise levels (see Section 6.1.3).

4.1 Tulare County Noise Regulations

As described in Section 3.1.6, Tulare County has adopted various guidelines, requirements and policies related to noise in their General Plan. Tulare County does not have any specific development codes or zoning ordinances related to noise; therefore, the County General Plan criteria represent the only applicable noise thresholds by which Project impacts can be compared. The Tulare County noise thresholds are utilized to address CEQA Checklist item *a)*.

Table 6 presents the applicable unadjusted Project noise thresholds, which are derived from the Tulare County General Plan regulatory standards presented in Section 3.1.6 above.

Table 6 Unadjusted Tulare County Noise Standards

Parameter/Description	Day-Night (L_{dn}) or CNEL Average Noise Limit
Policy HS-8.8: Noise level not to be exceeded at the boundary of areas designated and zoned for residential or other noise-sensitive uses as a result of the Project activities.	60 dB(A)

Source: *Tulare County General Plan – 2030 Update*, Section 10.8 – Noise Element (Tulare County, 2012).

Although not specified within the Tulare County General Plan, generally in cases where the existing ambient noise levels exceed the applicable standards, then the noise level standard would be increased at +3 dBA increments to encompass the ambient noise. This concept corresponds with the concept that a +3 dBA increase or decrease is generally accepted as the minimum perceptible change in noise. Additionally, if ambient noise levels are within ±1 dBA of the applicable significance threshold, the applicable County noise level standards are increased by +3 dBA increments to encompass the ambient (e.g., ambient level of 59.3 dB results in a significance threshold of 62.3 dB rather than 60 dB). Table 7 below presents the applicable Tulare County significance thresholds for each receptor, adjusted as needed to encompass the ambient noise levels presented in Table 5. These noise thresholds are utilized to address CEQA Checklist item *a)* in Section 6.1.1 below. Additional detail regarding these calculations is included in Appendix C.

Table 7 Applicable Tulare County Noise Standards

Receptor	Measured Ambient Noise Level (L_{dn})	Tulare County General Plan Threshold	Adjusted Threshold to Account for Ambient
R1	47.6	60	---
R2	51.7	60	---
R3	59.3	60	62.3
R4	44.7	60	---
R5	57.4	60	60.4
R6	57.4	60	60.4
R7	52.5	60	---
R8	56.0	60	---
R9	51.8	60	---
R10	47.8	60	---

Note: See the calculations/footnotes within Appendix C for more details

4.2 Vibration Significance Thresholds

As discussed in Section 3.1.8, Tulare County does not have any specific standards or criteria related to vibration. Therefore, the Caltrans vibration criteria presented in Section 3.1.8 and Table 3 is utilized to determine the significance of Project vibration impacts. Specifically, the peak particle velocity (PPV) of 0.24 inches per second (in/sec) presented in Table 3, which is considered a "distinctly perceptible" vibration level, is utilized to determine the significance of Project vibration impacts per CEQA Checklist item *b)*.

5.0 METHODOLOGIES

To quantify the noise generated by the Project noise sources (i.e., excavation, construction and reservoir maintenance equipment/structures) reference data was gathered from the Federal Highway Administration's (FHWA) *Roadway Construction Noise Model User Guide* (Federal Highway Administration, 2006) and other relevant sources. The following sections summarize the methodologies, assumptions and reference noise levels utilized in the analyses of each Project phase: 1) Reservoir Excavation; 2) Reservoir Facility Construction; and, 3) Reservoir Operations. Also see Appendix D for more detail.

5.1 Reservoir Excavation

To determine the appropriate sound pressure levels generated during reservoir excavation activities, various noise reference data was utilized. Per information provided by TID and WCA, mobile equipment (e.g., loaders, excavators, haul trucks, etc.) will operate onsite during the reservoir excavation phase to mine and transport material. Mobile equipment source noise average (L_{eq}) and maximum (L_{max}) sound pressure levels were determined using FHWA reference data. Appendix D summarizes the FHWA source noise data utilized to quantify mobile equipment noise levels during reservoir excavation.

In addition to mobile equipment, an aggregate screen/wash plant and, as needed, a mobile crushing/recycle plant (referred to as the processing plants) would also operate onsite during reservoir excavation. Noise levels associated with these plants are based on field measurements collected by Sespe Consulting, Inc. in 2020 from a comparable processing and recycling operation in Otay Mesa, California. In addition to these plants, other ancillary equipment, specifically haul trucks and loaders, were also operating nearby simultaneously when these measurements were collected at the Otay Mesa facility. Therefore, the measured noise levels represent a conservative overestimation of the noise generated by the Project's aggregate screen/wash plant and crush/recycle plant. Appendix D contains additional detail and relevant references for the processing plant noise sources.

Table 8 shows the type and quantity of equipment that would be utilized onsite during the reservoir excavation phase. Usage fraction (%) and maximum sound pressure level (L_{max}) noise data shown for mobile sources are FHWA default values. Source noise calculations in Appendix D provide additional detail.

Table 8 Reservoir Excavation – Reference Equipment Noise Data

Noise Source	L_{max} @ 50-feet (dBA)	Usage (%)	L_{eq} @ 50-feet (dBA)
Mobile Equipment Sources			
Loaders (x4)	80	40%	76
Excavator	85	40%	81
Haul Trucks (x2)	84	40%	80
Water Truck	84	40%	80
Processing Plant(s) Sources			
Aggregate Plant	---	---	84.1
Crushing/Recycle Plant	---	---	84.1

Equipment Sources: Federal Highway Administration (Federal Highway Administration, 2006) and Otay Mesa Noise Study (Sespe Consulting, 2020). See Appendix D for more detail.

Per information provided by WCA, reservoir excavation activities will be limited to Monday through Saturday, between the hours of 4:30 a.m. (or dawn if later) and 6:00 p.m. (or sundown if earlier). Because the County criteria applies to noise impacts over a 24-hour period (i.e., Day-Night [L_{dn}] noise levels), it was assumed that the onsite equipment summarized in Table 8 would operate simultaneously for up to 14-hours in a given day. Additionally, it was conservatively assumed that the equipment would operate at-grade in the onsite locations in closest proximity to each receptor (see Figure 6, Appendix A).

5.1.1 Noise Attenuation due to Excavation Pit Walls

To determined worst-case noise impacts during the initial Project construction phase, it is assumed that the excavation and processing equipment summarized in Table 8 would operate simultaneously at-grade in the onsite location closest to each affected receptor (see Figure 6, Appendix A). Therefore, shielding and noise attenuation due to distance and intervening topography was conservatively not accounted for in the impact calculations. In reality, as the excavation progresses, it's expected that most of the mobile and processing equipment would operate within the pit, which would eventually block line-of-sight between equipment and nearby receptors.

As the excavation pit deepens, significant noise attenuation will be provided by the pit walls as they would sufficiently break line-of-sight between Project excavation noise sources (i.e., mobile equipment and processing plant[s]) and nearby residential receptors. Barrier insertion loss calculations presented in Appendix E show that once reservoir excavation operations reach a depth of 16-feet bgs, assuming equipment is operating within the bottom of the pit, noise levels experienced at nearby receptors would be significantly attenuated (estimated to be a minimum -14.0 dBA reduction at Receptor 1 [R1]). Please see the discussion in Section 6.1.1 below and the calculations in Appendix E for additional detail.

5.2 Reservoir Construction

Once the pit is fully excavated and the basin/slopes stabilized, construction of the reservoir will commence. Specifically, this Project phase will involve construction of the inflow/outflow channels and chutes, installation of the electrically operated weirs and energy dissipation pools, completion of the slurry wall, and installation of other ancillary structures (e.g., perimeter berm/access road, AST tank and related generator/housing structure, etc.).

Per information provided by TID, Table 9 summarizes mobile equipment that will operate onsite during this Project phase. As with excavation, construction of the reservoir is estimated to occur between the hours of 4:30 a.m. (or dawn if later) and 6:00 p.m. (or sundown if earlier). Although much of the reservoir construction activities are expected occur below-grade within the excavation pit, conservatively it is assumed that the equipment presented in Table 9 would operate simultaneously, at-grade in the onsite locations in closest proximity to each receptor (see Figure 6, Appendix A). See Appendix F for the source noise calculations.

Table 9 Reservoir Construction – Reference Equipment Noise Data

Noise Source	L_{max} @ 50-feet (dBA)	Usage (%)	L_{eq} @ 50-feet (dBA)
Mobile Equipment Sources			
Loaders	80	40%	76
Excavator	85	40%	81

Noise Source	L_{max} @ 50-feet (dBA)	Usage (%)	L_{eq} @ 50-feet (dBA)
Backhoe	80	40%	76
Grader	85	40%	81
Trencher	80	40%	76
Compactor	80	20%	73
Crane	85	16%	77
Cement Truck	85	40%	81
Water Truck	84	40%	80
Generator	82	50%	79
Pumps	77	50%	74

Equipment Sources: Federal Highway Administration (Federal Highway Administration, 2006). See Appendix F for more detail.

5.3 Reservoir Operations

Once the reservoir is constructed and fully operational, the Owners would have daily control over operations and management of the reservoir and related facilities, which would primarily involve the use of the equipment to monitor and control the facility remotely. At times, TID staff would also perform routine onsite inspections to ensure the reservoir is operating properly. During the ongoing operations and maintenance of the reservoir, there would be limited equipment usage. For example, equipment may be needed to perform minor grading of the access road or to remove any debris that collects in the bottom of the reservoir. TID estimates that onsite reservoir maintenance using mobile equipment would occur only a few times per year (approximately 1 to 2 days per year).

Mobile equipment summarized in Table 10 would be used onsite annually for intermittent reservoir maintenance operations. Reservoir operations and maintenance activities would be conducted by TID staff during normal working hours, specifically between the hours of 8:00 a.m. and 5:00 p.m.

Table 10 Reservoir Operations/Maintenance – Reference Equipment Noise Data

Noise Source	L_{max} @ 50-feet (dBA)	Usage (%)	L_{eq} @ 50-feet (dBA)
Mobile Equipment Sources			
Loaders	80	40%	76
Grader	85	40%	81
Dump Truck	84	40%	80
Generator	82	50%	79

Equipment Sources: Federal Highway Administration (Federal Highway Administration, 2006). See Appendix G for more detail.

5.4 Project Design Features that Reduce Noise

Consistent with Tulare County General Plan Policies outlined in Section 3.1.6, Numerous design features, best management practices (BMPs), operating practices and other environmental protection measures have been incorporated into the Project to minimize potential impacts on the environment. The environmental protective measures that were considered during this evaluation include, but are not limited to, the following.

1. Blasting would not be used for the proposed operations.

2. No excavation of material would take place within thirty (30) to fifty (50) feet from adjacent property lines (see Figure 3, Appendix A).
3. The processing of aggregate at the Project site has been designed not to exceed the production rates historically achieved at the Seaborn site.

As discussed previously, due to design feature Number 3 listed above, the number of haul trucks and employee vehicles on public roadways would not increase above existing levels as a result of the Project. Therefore, noise impacts resulting transportation sources are not analyzed in this NIA.

6.0 PROJECT-LEVEL IMPACTS & MITIGATION MEASURES

6.1 Impact Assessment

6.1.1 Generation of Noise Levels in Excess of Applicable Standards

Impact Statement

Impact NO-1: *Generation of a substantial temporary or permanent increase in ambient noise levels in the vicinity of the project in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies?* **(Appendix G Threshold Criteria (a))**

Impact Analysis

To address the CEQA Criteria *a)*, the applicable Tulare County General Plan criteria presented in Section 4.1 (also see Table 6 and Table 7) is utilized. The following sections summarize the Project noise impacts determined for each individual Project phase: 1) Reservoir Excavation; 2) Reservoir Facility Construction; and, 3) Reservoir Operations. The predicted change in noise level experience at each receptor as result of Project is quantified and compared to the applicable Tulare County thresholds to determine the significance of Project impacts. Where Project noise levels exceed applicable thresholds, feasible mitigation measures are proposed. Also see the detailed methodology discussion in Section 5.0 and the calculations in Appendices D through G for additional background.

Reservoir Excavation

Table 11 below shows the predicted change in Day-Night (L_{dn}) noise level estimated at each receptor as a result of reservoir excavation operations. As discussed in Section 5.1, it is assumed that the excavation and processing equipment summarized in Table 8 would operate simultaneously at-grade in the onsite location closest to each affected receptor (see Figure 6, Appendix A) to determined worst-case noise impacts during this initial Project phase.

As shown in Table 11 below, worst-case, unmitigated noise levels during reservoir excavation exceed the applicable Tulare County Day-Night (L_{dn}) noise thresholds at Receptors R1, R5 and R6. The calculations in Appendix D provide additional detail. It is also important to note that these exceedances associated with the reservoir excavation operations are expected to be short-term and temporary in nature. Over time, as the excavation pit proceeds to a final depth of approximately 60-feet bgs, equipment noise would be increasingly shielded due to the attenuation provided by the deepening pit walls. Please see Appendix E, which presents calculations and details (e.g., receptor/equipment heights, noise transmission paths, etc.) relating to estimate noise attenuation provided by the excavation pit walls.

Table 11 Reservoir Excavation – Project Noise Impacts/Tulare County Criteria

Receptor	Distance – Source to Receptor (feet)	Project Noise Levels (L_{dn})	Tulare County Threshold (L_{dn})	Significant?	Level of Exceedance (dBA)
R1	465	73.4	60	**Yes**	+13.4
R2	4,978	55.3	60	No	---
R3	3,980	60.6	62.3	No	---
R4	4,190	54.7	60	No	---
R5	2,560	61.0	60.4	**Yes**	+0.6
R6	2,539	61.1	60.4	**Yes**	+0.7

Receptor	Distance – Source to Receptor (feet)	Project Noise Levels (L_{dn})	Tulare County Threshold (L_{dn})	Significant?	Level of Exceedance (dBA)
R7	2,382	60.0	60	No	---
R8	3,262	59.3	60	No	---
R9	4,251	56.1	60	No	---
R10	3,891	55.7	60	No	---

Note: Values shown in **bold** represent a potentially significant impact. See Appendix D for more detail.

Referring to Table 11, noise levels during the Project reservoir excavation phase do not exceed the applicable County noise standards except at Receptors 1 (R1), 5 (R5) and 6 (R6). Please see the mitigation measures presented below.

Level of Significance Before Mitigation

Potentially significant.

Mitigation Measures

As shown in Table 11, at the initial stages of the excavation phase when mobile and processing equipment would be operating at-grade, noise impacts at Receptors R1, R5 and R6 exceed various County Ldn noise standards. As discussed in Section 5.1.1, at an approximate depth of 16-feet bgs, an estimated -16.3 dBA of noise attenuation would result at Receptor 1 (R1). Similar reductions would also be expected at the receptors. Therefore, once reservoir excavation reaches this depth (i.e., 16-feet bgs or lower), and the processing plants are relocated into the pit, Project noise levels would be less than the applicable Tulare County criteria at every receptor, and no additional mitigation measures would be required.

Nevertheless, to ensure noise levels do not exceed these applicable threshold criteria during Project's reservoir excavation operations occurring at 16-feet bgs or higher, control measures sufficient to obtain noise reductions ranging from -13.4 dBA's (i.e., L_{dn} at R1) to -0.6/-0.7 dBA's (L_{dn} at R5 and R6) would need to be implemented. The following discusses potential control measures:

- Because the Tulare County Day-Night (L_{dn}) noise criteria averages noise impacts over an adjusted 24-hour period, Project noise levels can also be controlled by limiting daily operational hours. This is especially true when prohibiting operations between the hours of 10:00 p.m. and 7:00 a.m., as the L_{dn} threshold adds a +10 dBA penalty to Project noise levels generating during those hours.
- As discussed above, the residence located at Receptor 1 (R1) is owned by TID and leased out periodically to tenants. Therefore, TID has the ability to control the occupancy of R1, set the terms of lease agreements, and inform the current occupants of any temporary noise impacts resulting from the Project.

Until the reservoir excavation operations reach a depth of 16-feet bgs and the processing plants are relocated, mitigation measures are required to ensure Project noise levels comply with the applicable Tulare County criteria. As discussed above, one such method would be restricting the operational hours when noise generating activities are occurring. Specifically, if at-grade onsite processing (i.e., screen/wash plant and crush/recycle plant) operations were prohibited between the hours of 4:00 a.m. and 7:00 a.m., noise impacts at affected receptors would be reduced. Table 12 presents the predicted Day-Night (L_{dn}) noise level experienced at each receptor, assuming processing operations were prohibited between the hours of 4:00 a.m. and 7:00 a.m. As discussed above, once excavation reaches a minimum depth of 16-

feet bgs and the processing plants are relocated, the processing operations would not be restricted during these hours.

> ***Mitigation Measure NO-1:*** *Onsite material processing operations occurring at a depth of 16-feet below ground surface or higher shall be prohibited between the hours of 4:00 a.m. and 7:00 a.m.*

Table 12 Reservoir Excavation – Limited Processing Hours of Operation

Receptor	Distance – Source to Receptor (feet)	Project Noise Levels (L_{dn})	Tulare County Threshold (L_{dn})	Significant?
R1	465	**71.6**	**60**	**Yes**
R2	4,978	51.0	60	No
R3	3,980	53.1	62.3	No
R4	4,190	52.5	60	No
R5	2,560	56.7	60.4	No
R6	2,539	56.8	60.4	No
R7	2,382	57.4	60	No
R8	3,262	54.6	60	No
R9	4,251	52.3	60	No
R10	3,891	53.1	60	No

Note: Values shown in **bold** represent a potentially significant impact. See Appendix E for more detail.

As shown in Table 12, even with at-grade onsite processing operations prohibited between the hours of 4:00 a.m. and 7:00 a.m., estimated noise levels experienced at Receptor 1 (R1) still exceed the applicable County L_{dn} threshold by +11.6 dBA's. Therefore, in addition to the provisions outlined above, the following mitigation specific to Receptor 1 (R1) is also proposed. As discussed previously, TID owns and leases the residential receptor located at R1. As with Mitigation Measure NO-1 described above, this additional measure is only necessary if excavation/noise-generating operations are occurring at a depth of 16-feet bgs or higher.

> ***Mitigation Measure NO-2:*** *In order to reduce the noise level at Receptor 1 (R1) to less than the significance threshold, TID must utilize one of the following measures. This mitigation measure can be ceased and no further mitigation will be required, if noise generated equipment operates within the bottom of the excavation pit at a minimum depth of 16-feet below ground surface:*
>
> - *Vacate the residence located at Receptor R1 during reservoir excavation activities; or*
> - *Inform the occupant of Receptor R1 that temporary elevated noise levels may result during initial reservoir excavation activities, and obtain a signed waiver from the tenant indicating that they choose to remain in the house despite the temporary increase in noise levels.*

Through the implementation of Mitigation Measures NO-1 or NO-2, or a combination thereof, reservoir excavation noise sources are expected to have a less than significant impact at nearby receptors with mitigation incorporated.

It is also important to note this analysis was designed to estimate conservative worst-case Project noise impacts at nearby receptors. In reality, when taking into account the shielding or absorption effects from intervening topography/vegetation between source and receptor, as well as the fact that most excavation

and processing operations will not occur simultaneously, near the outermost Project site boundary or within direct line-of-sight of affected receptors (as was assumed in this analysis), noise levels are expected to be less than those calculated within this DEIR. Furthermore, as excavation progresses to a final depth of 60-feet bgs and the pit walls deepen, additional noise attenuation can be assumed.

Level of Significance After Mitigation

Upon implementation of Project design features described in Section 5.4 and adherence to the requirements outlined Mitigation Measure NO-1 and NO-2, Project impacts to nearby receptors during reservoir excavation operations would be **less than significant** with **no additional mitigation required**.

Reservoir Construction

Table 13 below shows the predicted change in Day-Night (L_{dn}) noise level at each receptor during reservoir construction. As with the reservoir excavation analysis, it is conservatively assumed that the reservoir construction equipment summarized in Table 9 would operate simultaneously, at-grade in the onsite location closest to each affected receptor (see Figure 5, Appendix A). Additionally, onsite materials processing, specifically the screen/wash plant and crush/recycle plant, would no longer be required during the reservoir construction phase. As shown in Table 13, worst-case, unmitigated noise levels during onsite reservoir construction activities exceed the applicable Tulare County Day-Night (L_{dn}) noise thresholds at Receptor R1. Because this residence is owned by TID, as discussed above, implementation of Mitigation Measure NO-2 is sufficient to reduce the potential impact to less than significant. The calculations in Appendix F provide additional detail.

Table 13 Reservoir Construction – Project Noise Impacts/Tulare County Criteria

Receptor	Distance – Source to Receptor (feet)	Project Noise Levels (L_{dn})	Tulare County Threshold (L_{dn})	Significant?	Level of Exceedance (dBA)
R1	465	71.9	60	**Yes**	+11.9
R2	4,978	54.5	60	No	---
R3	3,980	60.3	62.3	No	---
R4	4,190	53.4	60	No	---
R5	2,560	60.2	60.4	No	---
R6	2,539	60.3	60.4	No	---
R7	2,382	58.8	60	No	---
R8	3,262	58.5	60	No	---
R9	4,251	55.2	60	No	---
R10	3,891	54.4	60	No	---

Note: Values shown in **bold** represent a potentially significant impact. See Appendix F for more detail.

Level of Significance Before Mitigation

During the reservoir construction phase, the Project would increase ambient noise levels in excess of applicable County standards at Receptors 1 (R1). Therefore, the Project impacts are considered potentially significant.

Mitigation Measures

Upon implementation of Mitigation Measure NO-2 described above, Project impacts to nearby receptors would be less than significant.

Level of Significance After Mitigation

Upon implementation of Project design features described in Section 5.4 and adherence to the requirements outlined Mitigation Measure NO-2, Project impacts to nearby receptors during reservoir construction operations would be **less than significant** with **no additional mitigation required**.

Reservoir Operations/Maintenance

Table 14 below shows the predicted change in Day-Night (L_{dn}) noise level at each receptor during ongoing reservoir operations/routine maintenance. To determined worst-case noise impacts during this Project phase, it is assumed that maintenance equipment listed in Table 10 would operate at-grade in the onsite location closest to each affected receptor. Although onsite reservoir operations/maintenance activities would be very infrequent (approximately 1 to 2 times per year) and would generally not require the use of mobile equipment, conservatively this analysis assumed that all maintenance equipment listed in Table 10 would operate simultaneously for one full day (i.e., 8:00 a.m. to 5:00 p.m.).

As shown in Table 14, worst-case, unmitigated noise levels during reservoir operations/maintenance exceed the applicable Tulare County Day-Night (L_{dn}) noise thresholds at Receptor R1. As discussed above, Receptor R1 is owned by TID; therefore, implementation of Mitigation Measure NO-2 would be sufficient to reduce the potential impact to less than significant. The calculations in Appendix G provide additional detail.

Table 14 Reservoir Operations – Project Noise Impacts/Tulare County Criteria

Receptor	Distance – Source to Receptor (feet)	Project Noise Levels (L_{dn})	Tulare County Threshold (L_{dn})	Significant?	Level of Exceedance (dBA)
R1	465	61.9	60	**Yes**	+1.9
R2	4,978	52.1	60	No	---
R3	3,980	59.4	62.3	No	---
R4	4,190	46.8	60	No	---
R5	2,560	57.8	60.4	No	---
R6	2,539	57.8	60.4	No	---
R7	2,382	53.7	60	No	---
R8	3,262	56.3	60	No	---
R9	4,251	52.3	60	No	---
R10	3,891	49.1	60	No	---

Note: Values shown in **bold** represent a potentially significant impact.

Level of Significance Before Mitigation

During the reservoir operations/maintenance phase, the Project would temporarily increase ambient noise levels in excess of applicable County standards at Receptor 1 (R1). Therefore, the Project impacts are considered potentially significant.

Mitigation Measures

Upon implementation of Mitigation Measure NO-2 described above, Project impacts to nearby receptors would be less than significant.

Level of Significance After Mitigation

Upon implementation of Project design features described in Section 5.4 and adherence to the requirements outlined Mitigation Measure NO-2, Project impacts to nearby receptors during reservoir operations/maintenance activities would be **less than significant** with **no additional mitigation required**.

6.1.2 Generation of Excessive Groundborne Vibration

Impact Statement

Impact NO-2: *Generation of excessive groundborne vibration or groundborne noise levels?* **(Appendix G Threshold Criteria (b))**

Impact Analysis

The Federal Transit Administration's (FTA) *Transit Noise and Vibration Impact Assessment Manual* (Federal Transit Administration, 2018) and Caltrans's *Transportation and Construction Vibration Guidance Manual* (Caltrans, 2020) documents provide guidelines for assessing vibration impacts resulting from construction activities. Table 15 below lists vibration source levels for common types of construction equipment, in terms of peak particle velocity (PPV) in units of inches per second at a distance of 25-feet.

Table 15 Vibration Source Level for Construction Equipment

Equipment	PPV (in/sec) @ 25-feet away
Vibratory Roller	0.210
Large bulldozer	0.089
Caisson drilling	0.089
Loaded trucks	0.076
Jackhammer	0.035
Small bulldozer	0.003
Vibratory Roller	0.210

Source: *Transportation and Construction Vibration Guidance Manual* (Caltrans, 2020), *Transit Noise and Vibration Impact Assessment Manual* (FTA, 2018).

To assess Project vibration impacts at each receptor location, the reference PPV value of 0.089 inches per second (i.e., large bulldozer) is utilized. It is assumed that nothing larger or more powerful than a large bulldozer would operate at the Project site in close proximity to nearby receptors. The distance shown represents the measured distance from the closest boundary of the Project area to the nearest property boundary of each receptor. Using this information, Table 16 summarizes the predicted groundborne vibration impacts resulting from the Project. Significance was determined by comparing the predicted change in groundborne vibration to the applicable Caltrans vibration threshold outlined in Section 4.2.

Table 16 Predicted Project Vibration Levels at Receptors

Receptors	Distance (feet)	Predicted Vibration – PPV (in/sec) [A]	Applicable San Bernardino County Significance Threshold – PPV (in/sec)	Significant?
R1	465	0.0047	≥ 0.035	No
R2	4,978	0.0003	≥ 0.035	No
R3	3,980	0.0003	≥ 0.035	No
R4	4,190	0.0003	≥ 0.035	No
R5	2,560	0.0006	≥ 0.035	No
R6	2,539	0.0006	≥ 0.035	No
R7	2,382	0.0007	≥ 0.035	No
R8	3,262	0.0005	≥ 0.035	No
R9	4,251	0.0003	≥ 0.035	No
R10	3,891	0.0004	≥ 0.035	No

Note: See Appendix H for more detail.
A – The Project vibration levels shown above are considered "barely perceptible" per Caltrans guidance (Caltrans, 2020).

As shown in Table 16, predicted vibration impacts to nearby receptors were well below the applicable Caltrans significance threshold. It should also be noted that predicted vibration impacts at nearby receptors are considered "barely perceptible" per the Caltrans criteria (see Table 3) for human response to groundbourne vibration (i.e., ≤ 0.035 PPV in/sec). Therefore, groundborne vibration impacts to nearby receptors resulting from Project operations are **less than significant** with **no mitigation required**.

Level of Significance Before Mitigation

Less than significant.

Mitigation Measures

None required.

Level of Significance After Mitigation

Not Applicable.

6.1.3 Airport Land Use/Vicinity Analysis

Impact Statement

Impact NO-3: *For a project located within the vicinity of a private airstrip or an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project expose people residing or working in the project area to excessive noise levels?* **(Appendix G Threshold Criteria (c))**

Impact Analysis

The proposed Project site is not located within 2.0 miles of any private or public airports or airstrips, or in an area governed by an airport land use plan. The closest airport/airstrip is Woodlake Airport, located approximately 2.4 miles west of the Project site. Please see Figure 1 which displays the location of this airport in relation to the Project site. Furthermore, the Project does not involve creation of a new noise-sensitive land uses (i.e., residences). Therefore, the Project would have **no impact** related to

airport/airstrip noise levels.

Level of Significance Before Mitigation

No impact.

Mitigation Measures

None required.

Level of Significance After Mitigation

Not Applicable.

7.0 FINDINGS

This Noise Impact Assessment (NIA) finds that:

- Temporary Project impacts during the reservoir excavation and reservoir construction phases are mitigated to the extent feasible and will comply with applicable Tulare County requirements;
- Noise impacts from ongoing reservoir operations/maintenance activities are less than significant at nearby receptors, except for the TID-owned residence at Receptor 1 where impacts have been mitigated to the extent feasible; and
- Project groundborne vibration impacts are less than significant at nearby receptors.

NOTES:

a. EXCAVATION PIT WILL HAVE A FINAL DEPTH OF 60-FEET BELOW GROUND SURFACE, WITH A TOTAL SURFACE AREA OF APPROXIMATELY 110 ACRES. PIT SLOPES WILL NOT EXCEED 3H:1V (HORIZONTAL TO VERTICAL).

b. EARLY IN THE EXCAVATION PHASE, A SLURRY WALL WILL BE INSTALLED AROUND THE PERIMETER OF THE PIT TO PREVENT GROUNDWATER INTRUSION.

c. THE LOCATIONS OF THE WASH/SCREEN PLANT, PORTABLE CRUSH/RECYCLE PLANT, AND ASSOCIATED MATERIAL STOCKPILES ARE APPROXIMATE. THESE WILL BE RELOCATED WITHIN THE EXCAVATION AREA AS MINING PROGRESSES.

d. THERE ARE NO EXISTING ONSITE DRAINAGE OR WATER FEATURES THAT WOULD BE DISTURBED BY EXCAVATION/RECLAMATION ACTIVITIES.

e. SLOPES LOCATED ABOVE THE SLURRY WALL/HIGH-WATER LINE WILL BE VEGETATED TO CONTROL EROSION

f. RIPRAP WILL BE PLACED ON PIT SLOPE AREAS BELOW THE SLURRY WALL TO MINIMIZE EROSION.

g. THERE ARE NO EXISTING PUBLIC ROADS, RAILROADS, OR WATER WELLS WITHIN 500-FEET OF THE SITE.

h. EXISTING SOUTHERN CALIFORNIA EDISON (SCE) POWER LINES RUN ALONG THE NORTHERN PERIMETER OF THE SITE. THE PROPOSED WASH/SCREEN PLANT WILL CONNECT TO THESE EXISTING UTILITIES. NO OTHER UTILITIES (GAS TELEPHONE, WATER, ETC.) EXISTING WITHIN 500-FEET OF THE SITE.

i. DUST WILL BE CONTROLLED THROUGHOUT THE SITE/ON UNPAVED ROADS USING A MOBILE WATER TRUCK.

APPENDIX B

Regulatory References

10.8 Noise

HS-8 To protect County residents and visitors from the harmful effects of excessive noise while promoting the County economic base.

HS-8.1 Economic Base Protection
The County shall protect its economic base by preventing the encroachment of incompatible land uses on known noise-producing industries, railroads, airports, and other sources.

HS-8.2 Noise Impacted Areas
The County shall designate areas as noise-impacted if exposed to existing or projected noise levels that exceed 60 dB Ldn (or Community Noise Equivalent Level (CNEL)) at the exterior of buildings.

HS-8.3 Noise Sensitive Land Uses
The County shall not approve new noise sensitive uses unless effective mitigation measures are incorporated into the design of such projects to reduce noise levels to 60 dB Ldn (or CNEL) or less within outdoor activity areas and 45 dB Ldn (or CNEL) or less within interior living spaces.

HS-8.4 Airport Noise Contours
The County shall ensure new noise sensitive land uses are located outside the 60 CNEL contour of all public use airports.

HS-8.5 State Noise Standards
The County shall enforce the State Noise Insulation Standards (California Administrative Code, Title 24) and Chapter 35 of the Uniform Building Code (UBC). Title 24 requires that interior noise levels not exceed 45 dB Ldn (or CNEL) with the windows and doors closed within new developments of multi-family dwellings, condominiums, hotels, or motels. Where it is not possible to reduce exterior noise levels within an acceptable range the County shall require the application of noise reduction technology to reduce interior noise levels to an acceptable level.

HS-8.6 Noise Level Criteria
The County shall ensure noise level criteria applied to land uses other than residential or other noise-sensitive uses are consistent with the recommendations of the California Office of Noise Control (CONC).

ⓘ *Table 10.1: Land Use Compatibility for Community Noise Environments (see next page), is provided as a reference concerning the sensitivity of different land uses to their noise environment. It is intended to illustrate the range of noise levels which will allow the full range of activities normally associated with a given land use.*

HS-8.7 Inside Noise
The County shall ensure that in instances where the windows and doors must remain closed to achieve the required inside acoustical isolation, mechanical ventilation or air conditioning is provided.

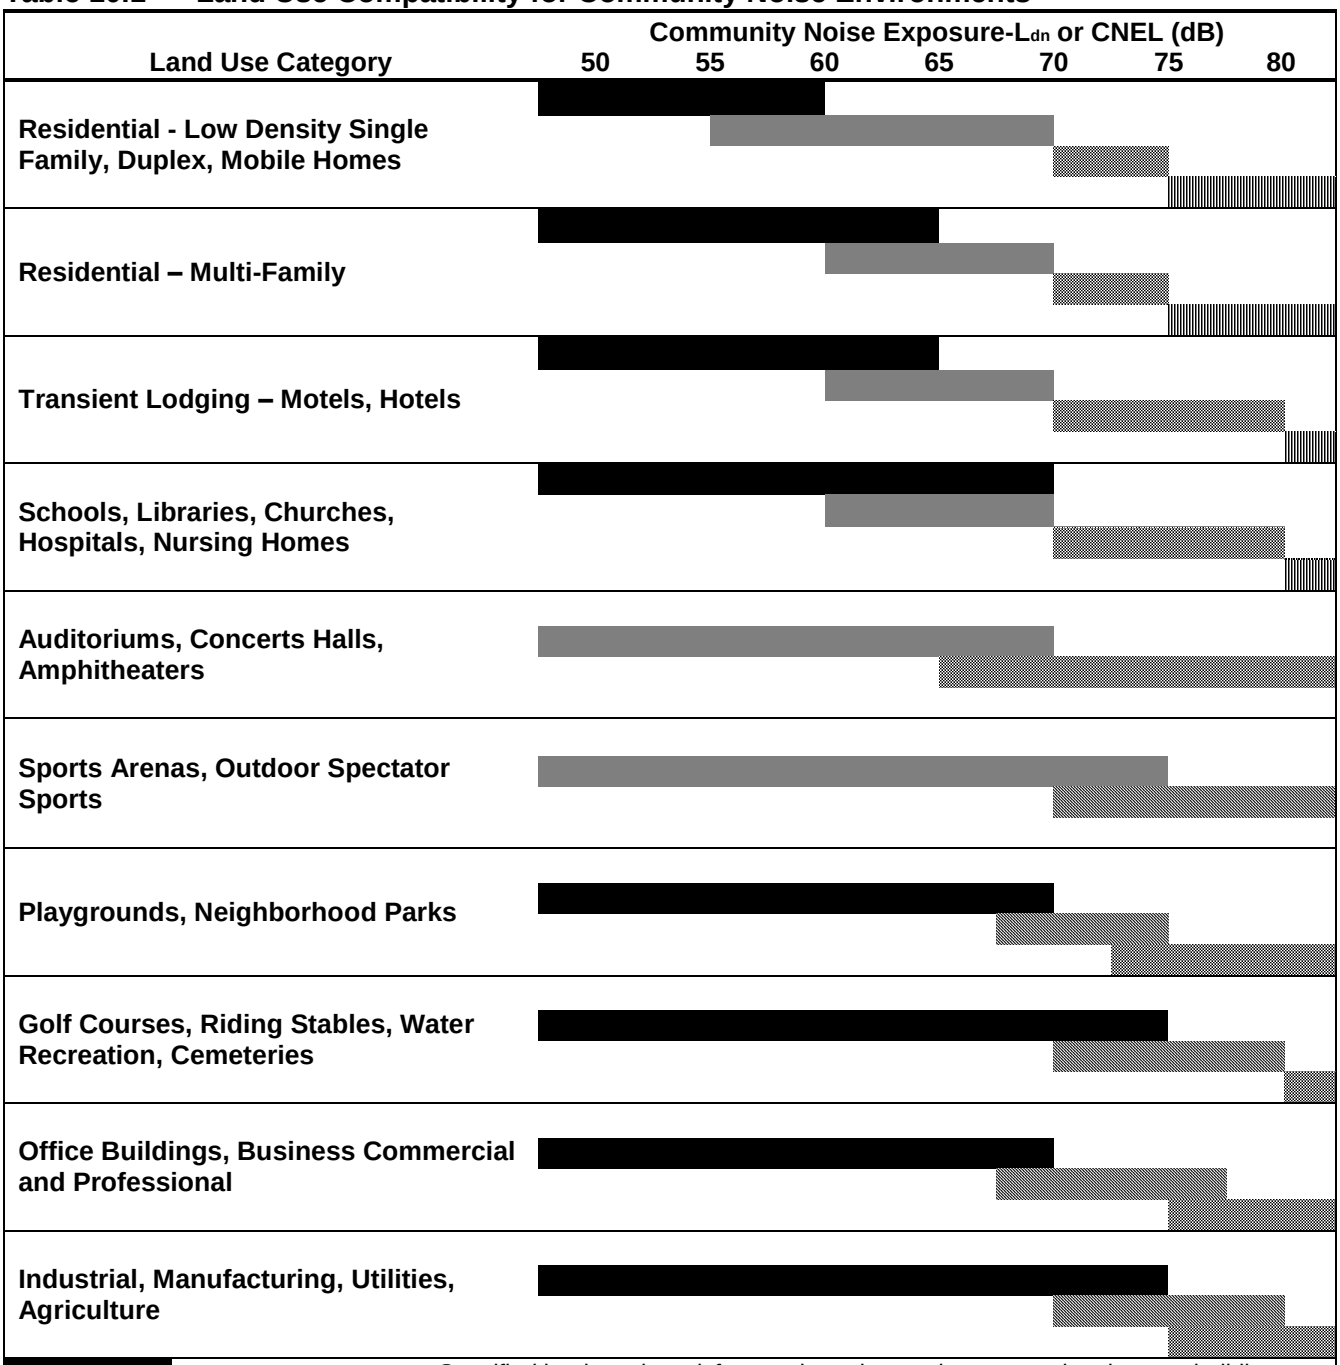
HS-8.8 Adjacent Uses

The County shall not permit development of new industrial, commercial, or other noise-generating land uses if resulting noise levels will exceed 60 dB Ldn (or CNEL) at the boundary of areas designated and zoned for residential or other noise-sensitive uses, unless it is determined to be necessary to promote the public health, safety and welfare of the County.

HS-8.9 County Equipment
The County shall strive to purchase equipment that complies with noise level performance standards set forth in the Health and Safety Element.

HS-8.10 Automobile Noise Enforcement
The County shall encourage the CHP, Sheriff's office, and local police departments to actively enforce existing sections of the California Vehicle Code relating to adequate vehicle mufflers, modified exhaust systems, and other amplified noise.

HS-8.11 Peak Noise Generators
The County shall limit noise generating activities, such as construction, to hours of normal business operation (7 a.m. to 7 p.m.). No peak noise generating activities shall be allowed to occur outside of normal business hours without County approval.



HS-8.12 Foothill and Mountain Noise
For areas designated by Tulare County as being within Foothill and Mountain Planning Areas and outside Foothill Development Corridors, the hourly Leq resulting from the development or new noise-sensitive land uses or new noise-generating sources shall not exceed 50 dB during the day (7:00 a.m.-10:00 p.m.) or 40 dB during the night (10:00 p.m.-7:00 a.m.) when measured at the boundary of areas containing or planned and zoned for residential or other noise-sensitive land uses. For these same areas and under the same circumstances, the maximum A-weighed noise level (Lmax) shall not exceed 70 dB during the day or 60 dB during the night.

HS-8.13 Noise Analysis
The County shall require a detailed noise impact analysis in areas where current or future exterior noise levels from transportation or stationary sources have the potential to exceed the adopted noise policies of the Health and Safety Element, where there is development of new noise sensitive land uses or the development of potential noise generating land uses near existing sensitive land uses. The noise analysis shall be the responsibility of the project applicant and be prepared by a qualified acoustical engineer (i.e., a Registered Professional Engineer in the State of California, etc.). The analysis shall include recommendations and evidence to establish mitigation that will reduce noise exposure to acceptable levels (such as those referenced in Table 10-1 of the Health and Safety Element).

HS-8.14 Sound Attenuation Features
The County shall require sound attenuation features such as walls, berming, heavy landscaping, between commercial, industrial, and residential uses to reduce noise and vibration impacts.

HS-8.15 Noise Buffering
The County shall require noise buffering or insulation in new development along major streets, highways, and railroad tracks.

Table 10.1 Land Use Compatibility for Community Noise Environments

Normally Acceptable	Specified land use is satisfactory, based upon the assumption that any buildings involved are of normal conventional construction, without any special noise insulation requirements.
Conditionally Acceptable	New construction or development should be undertaken only after a detailed analysis of the noise reduction requirements is made and needed noise insulation features are included in the design. Conventional construction, but with closed windows and fresh air supply systems or air conditioning will normally suffice.
Normally Unacceptable	New construction or development should generally be discouraged. If new construction or development does proceed, a detailed analysis of the noise reduction requirements must be made and needed noise insulation features included in the design.
Clearly Unacceptable	New construction or development generally should not be undertaken.

[Source: Figure Noise-1. State Land Use Compatibility Standards for Community Noise Environment: California Governor's Office of Planning and Research, October 2003]

HS-8.16 State Noise Insulation
The County shall enforce the State Noise Insulation Standards (California Administrative Code, Title 24) and Chapter 35 of the Uniform Building Code.

HS-8.17 Coordinate with Caltrans
The County shall work with Caltrans to mitigate noise impacts on sensitive receptors near State roadways, by requiring noise buffering or insulation in new construction.

HS-8.18 Construction Noise
The County shall seek to limit the potential noise impacts of construction activities by limiting construction activities to the hours of 7 am to 7pm, Monday through Saturday when construction activities are located near sensitive receptors. No construction shall occur on Sundays or national holidays without a permit from the County to minimize noise impacts associated with development near sensitive receptors.

HS-8.19 Construction Noise Control
The County shall ensure that construction contractors implement best practices guidelines (i.e. berms, screens, etc.) as appropriate and feasible to reduce construction-related noise-impacts on surrounding land uses.

10.9 Healthy Communities

HS-9	To support healthy lifestyles among residents of Tulare County through the built environment and land use decisions that play an important role in shaping the pattern of community development, in either promoting or discouraging good health for its citizens.

HS-9.1 Healthy Communities
To the maximum extent feasible, the County shall strive through its land use decisions to promote community health and safety for all neighborhoods in the County by encouraging patterns of development that are safe and influence crime prevention, promote a high-quality physical environment and encourage physical activity by means such as sidewalks and walking and biking paths that discourage automobile dependency in existing communities.

HS-9.2 Walkable Communities
The County shall require where feasible, the development of parks, open space, sidewalks and walking and biking paths that promote physical activity and discourage automobile dependency in all future communities.

3.5.1 Barrier Design Goals and Insertion Loss.

The first step in barrier design is to establish the design goals. Design goals may not be limited simply to noise reduction at receivers, but may also include other considerations of safety and maintenance as well. These other considerations are discussed later in Sections 4 through 13.

In this section, the acoustical design goals of noise reduction will be discussed. Acoustical design goals are usually referred to in terms of barrier *Insertion Loss* (IL). IL is defined as the sound level at a given receiver before the construction of a barrier minus the sound level at the same receiver after the construction of the barrier. The construction of a noise barrier usually results in a partial loss of soft-ground attenuation. This is due to the barrier forcing the sound to take a higher path relative to the ground plane. Therefore, barrier IL is the net effect of barrier diffraction, combined with this partial loss of soft-ground attenuation.

Typically, a 5-dB(A) IL can be expected for receivers whose line-of-sight to the roadway is just blocked by the barrier. A general rule-of-thumb is that each additional 1 m of barrier height above line-of-sight blockage will provide about 1.5 dB(A) of additional attenuation (see Figure 13).

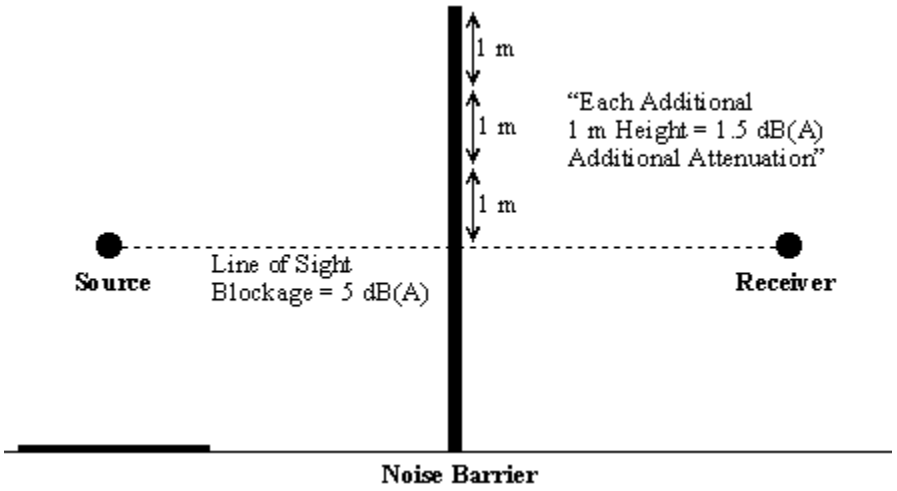

Figure 13. Line-of-sight

Properly-designed noise barriers should attain an IL approaching 10 dB(A), which is equivalent to a perceived halving in loudness for the first row of homes directly behind the barrier. For those residents not directly behind the barrier, a noise reduction of 3 to 5 dB(A) can typically be provided, which is just slightly perceptible to the human ear. Table 4 shows the relationship between barrier IL and design feasibility.

Table 4. Relationship between barrier insertion loss and design feasibility.

Barrier Insertion Loss	Design Feasibility	Reduction in Sound Energy	Relative Reduction in Loudness
5 dB(A)	Simple	68%	Readily perceptible
10 dB(A)	Attainable	90%	Half as loud
15 dB(A)	Very difficult	97%	One-third as loud
20 dB(A)	Nearly impossible	99%	One-fourth as loud

Source: Excerpt from the Federal Highway Administration's *Noise Barrier Design Handbook* (http://www.fhwa.dot.gov/environment/noise/noise_barriers/design_construction/design/design00.cfm)

Table 18. Vibration Source Amplitudes for Construction Equipment

Equipment	Reference PPV at 25 ft. (in/sec)
Vibratory roller	0.210
Large bulldozer	0.089
Caisson drilling	0.089
Loaded trucks	0.076
Jackhammer	0.035
Small bulldozer	0.003
Crack-and-seat operations	2.4

Sources: Federal Transit Administration 2018 (except Hanson 2001 for vibratory rollers) and Caltrans 2000 for crack-and seat-operations.

Using these source levels, vibration from this equipment can be estimated by the following formula:

$$PPV_{Equipment} = PPV_{Ref}\,(25/D)^{n} \quad (in/sec) \qquad (Eq.\ 12)$$

Where:

PPV_{Ref} = *reference PPV at 25 ft.*

D = distance from equipment to the receiver in ft.

n = 1.1 (the value related to the attenuation rate through ground)

The suggested value for "n" is 1.1. Because vibration from this equipment originates primarily near the ground surface, modifying the value of "n" based on soil classification may not necessarily be applicable; however, a higher value of "n" based on site-specific soil conditions could be used for a less-conservative estimation of vibration amplitude. FTA recommends a value of "n" of 1.5 for vibration assessment. Using a value of 1.5 is less conservative than using a value of 1.4 or less (as indicated in Table 17) because it assumes that vibration will attenuate at a greater rate.

7.3 Evaluating Potential Vibration Impacts

As shown in Chapter 6, there is limited consistency between the categorization of effects and damage thresholds; however, it is apparent that damage thresholds for continuous sources are less than those for single-event or transient sources. It is also apparent that the vibration from traffic is continuous and that vibration from a single blasting event is a single transient event; however, many types of construction activities fall between a single event and a continuous source. An impact pile driver, for example, continuously generates single transient events. As a practical matter and based on the nature of available criteria, the criteria can only be reasonably separated into two categories: continuous and transient.

Tulare County Significance Threshold/Criteria Summary

Receptor	Receptor Type	Tulare County - Day-Night (L_{dn}) Threshold		
		Exterior Noise		
		Ambient Day-Night	County Threshold [E]	Adjusted Threshold [F]
Receptor 1 (R1)	Residential	47.6	60	**60**
Receptor 2 (R2)	Residential	51.7	60	**60**
Receptor 3 (R3)	Residential	59.3	60	**62.3**
Receptor 4 (R4)	Residential	44.7	60	**60**
Receptor 5 (R5)	Residential	57.4	60	**60.4**
Receptor 6 (R6)	Residential	57.4	60	**60.4**
Receptor 7 (R7)	Residential	52.5	60	**60**
Receptor 8 (R8)	Residential	56.0	60	**60**
Receptor 9 (R9)	Residential	51.8	60	**60**
Receptor 10 (R10)	Residential	47.8	60	**60**

Footnotes:

A - Please see Figure 6 (Attachment A) which shows the locations of the residential receptors in relation to the Project site.

B - The 24-hour measurement collected at Receptor 1 (R1) is utilized to represent both the noise level experienced at this residential receptor, as well as a reference value to estimate 24-hour Day-Night (L_{dn}) noise levels experienced at the remaining receptors (R2 through R10).

C - For receptors where only short-duration (30-minutes total) measurements were collected (i.e., R2 through R10), a dBA ±change was calculated by comparing measured L_{eq} noise levels at these locations to the noise levels measured at the 24-hour reference location (i.e., R1) during the identical time period(s). The difference between these values (i.e., correction factor) is then applied to the 24-hour Day-Night (L_{dn}) noise level measured at R1 to estimate the appropriate L_{dn} noise levels at the remaining receptors (R2 through R10).

D - Per the Tulare County General Plan, the Day-Night (L_{dn}) average noise level is a long-term (24-hour) average weighted sound level, where a +10 dBA weight is added to noise levels occurring during nighttime hours (10:00 p.m. - 7:00 a.m.). This noise metric is meant to account for the extra annoyance noise impacts caused during the quieter nighttime hours.

E - Values shown represent the applicable Tulare County noise significance threshold, taken from the current General Plan (Tulare County, 2012).

F - Although not specified within the Tulare County guidance documents, generally in cases where the existing ambient noise levels already exceed the applicable standard, the noise standard is increased by +3 dBA increments to encompass the ambient noise. This concept is derived from the fact that a +3 dBA noise level increase is generally accepted as the minimum perceptible change in noise resulting from a source. Additionally, if ambient noise levels are within ±1 dBA of the applicable significance threshold, the applicable County noise level standards are increased by +3 dBA increments to encompass the ambient. Specifically, this concept is applied to Receptors R3, R5 and R6. Because the existing ambient noise already exceeds or is within ±1 dBA of the applicable Day-Night (L_{dn}) threshold, the Project could not feasibly comply with the County standard. Therefore, the ambient L_{dn} noise level +3 dBA is utilized as a the criteria to determine the significance of Project noise impacts at these receptors.

					Processing Plant(s) Noise Level (L_{eq}) - Statistical Average @ 50-feet [C]:		**84.1** dBA

A - Distances (feet) estimated using Google Earth ™.

B - L_{eq}Calc = Selected_L_{eq} - 20*log(D/100). "Selected_L_{eq}" = reference noise level @ 50-feet. D = distance to location/receptor (feet).
Source: Federal Highway Administration's *Roadway Construction Noise Model* (FHWA, 2006).

C - A total of 22 noise measurements (3-minutes each) were collected at 10 locations surrounding the processing/crushing equipment at the Otay Mesa facility on July 27, 2020. Measurements were collected while the processing/crushing equipment was operating at approximately full capacity and within line-of-sight of the noise source(s). Additionally, at least 1 other offroad vehicle was operating nearby within the Otay Mesa site during the noise measurements. By capturing noise from the processing/crushing operation and other offroad vehicle(s) performing unrelated tasks, the measurements overestimate the noise generated by the processing/crushing operations alone. Noise measurements were then statistically combined/averaged to determine an average source noise level (84.1 dBA) at a reference distance of 50-feet.

Reservoir Excavation

Equipment Noise/Noise Levels @ Receptors

Reservoir Excavation - Mobile Equipment				
Equipment	**L_{max} at 50-feet**	**Usage Factor (%) [B]**	**L_{eq} at 50-feet [C]**	**L_{eq} $10^{(Leq/10)}$**

Day-Night (L_{dn}) Noise Level [C]:	**73.4**		**52.8**		**54.9**		**54.3**		**58.6**		**58.6**		**59.2**		**56.5**		**54.2**		**54.9**	

A - Per information provided by West Coast Sand and Gravel (WCSG), reservoir excavation activities will be limited to Monday through Saturday, between the hours of 4:30 a.m. (or dawn if later) and 6:00 p.m. (or sundown if earlier).

B - Please see the previous source noise calculations. Values shown represents the worst-case hourly (L_{eq}) noise level at each receptor resulting from the operation of Project excavation equipment (e.g., processing plant[s], loaders, excavator, haul/water trucks). It was assumed that the onsite equipment would operate at-grade, simultaneously in the Project site location closest to each affected receptor. Please see Figure 5 (Appendix A) which shows the distances analyzed.

C - Because the County criteria applies to noise impacts over a 24-hour period (i.e., Day-Night [L_{dn}] noise levels), it was assumed that the onsite equipment summarized above would operate simultaneously for up to 14-hours (4:00 a.m. - 6:00 p.m.) in a given day. These hourly (L_{eq}) noise levels were then used to estimate the Ldn noise levels at each receptor. Please note, for noise occurring between the hours of 10:00 p.m. and 7:00 a.m., and additional +10 dBA weighting is applied .

Reservoir Excavation - Project Impacts @ Receptors

Reservoir Excavation - Project Noise Levels (L_{dn}) @ Receptors						
Receptor	**Ambient Noise Level [A]**	**Project Noise Level [B]**	**Total Noise Level [C]**	**Tulare County Threshold [D]**	**Significant?**	**Exceedance**
R1	47.6	73.4	73.4	60	**Yes**	13.4
R2	51.7	52.8	55.3	60	No	---
R3	59.3	54.9	60.6	62.3	No	---
R4	44.7	54.3	54.7	60	No	---
R5	57.4	58.6	61.0	60.4	**Yes**	0.6
R6	57.4	58.6	61.1	60.4	**Yes**	0.7
R7	52.5	59.2	60.0	60	No	---
R8	56.0	56.5	59.3	60	No	---
R9	51.8	54.2	56.1	60	No	---
R10	47.8	54.9	55.7	60	No	---

Note: Values shown in **bold** represent an exceedance of the applicable Tulare County Day-Night (L_{dn}) significance threshold.

A - Please see Appendix B for a detailed summary of the ambient noise measurements collected at each Project receptor.

B - Please see the source noise calculations for "Reservoir Excavation" phase presented previously.

C - Values shown represents the total estimated noise level resulting from the operation of Project noise sources (e.g., processing plant[s], mobile equipment, etc.) combined with the measured ambient noise level at each receptor.

D - Significance thresholds shown represent appropriate Tulare County noise thresholds (see Appendix B for more detail). Please note In cases where the existing ambient noise levels already exceed the applicable standard or are within ±1 dBA of the applicable significance threshold, the noise standard is increased by +3 dBA increments to encompass the ambient noise.

APPENDIX E

Insertion Calculations & Mitigated Project Impacts (Reservoir Excavation)

Excavation Pit Insertion Loss Calculations @ R1

Pit Wall Sound Barrier Noise Attenuation

Insertion Loss Calculations @ Receptor 1 (R1)

Insertion Loss (IL) Equation = 5dB + 20log((√2πN)/tanh(√2pN))dB

Source: Center for Transportation Research's *Design Guide for Highway Noise Barriers* (2003)

Caltrans *Technical Noise Supplement* offers the following guidance (Caltrans, 2013):
"Given the same site cross section, distance between source and receiver, and barrier height, a berm allows greater barrier attenuation than the thin screen (wedge), such as a soundwall. In general the actual extra attenuation associated with a berm is somewhere between -1 and -3 dBA."

Fresnel Number (N): $((a + b - \ell)f)/c_0$

Note: Fresnel number (N) is a nondimensional measure of how much farther the sound must travel as a result of the barrier.

ℓ - The original length of the direct path from source to receiver (ft.)
a - Path length from barrier to source (ft.)
b - Path length from barrier to receiver (ft.)
f - Equipment sound frequency in hertz (Hz)
c_0 - Speed of sound propagation in air (approximately 1,100 ft./sec.)

Project Data[B]

ℓ -	707.01	feet	(total distance between excavation/processing equipment and R1 property boundary)
a -	217.15	feet	(direct distance between the top edge of the proposed excavation pit and top of excavation equipment)
b -	490.03	feet	(direct distance between the top edge of the proposed excavation pit and R1 property boundary)
f -	2,000	hertz	(2000 is appropriate for crushing/screening)

Exacation Pit Noise Attenuation @ R1

Excavation Pit Depth (ft.)	Top of Pit to Source (a)	Top of Pit to Receiver (b)	Source to Receiver (c)	Fresnel Number (N)	Estimated Insertion Loss (dB) [A]
8	217.15	490.03	707.01	0.32	11.0
12	217.18	490.08	707.01	0.46	12.2
16	**217.29**	**490.15**	**707.01**	**0.80**	**14.2**

28	218.07	490.56	707.01	2.95	19.7
32	218.47	490.77	707.01	4.06	21.1
36	218.95	491.01	707.01	5.35	22.3

FOOTNOTES:

Note - Reservoir excavation equipment (e.g., processing plant[s], loaders, excavator, haul/water trucks, etc.) height is estimated to be 8-feet. Therefore, line-of-sight between equipment and receivers (e.g., R1) is not broken until the excavation pit reaches a minimum depth of at least 8-feet below ground surface (bgs).

A - Per Caltrans *Technical Noise Supplement* (2013) guidance referenced above, an additional -2 dB of noise attenuation is assumed due to barrier being constructed of "earthen berm" as opposed to a soundwall.

B - Transmission path data presented assumes that receiver (i.e., nearby resident) height is 5-feet above the ground and equipment height is 8-feet above the ground.

Day-Night (L_{dn}) Noise Level:	**71.6**		**51.0**		**53.1**		**52.5**		**56.7**		**56.8**		**57.4**		**54.6**		**52.3**		**53.1**	

A - Per proposed Mitigation Measure NO-1 would limit onsite material processing operations to the hours of 7:00 a.m. and 6:00 p.m., until the excavation reaches a minimum depth of 16-feet below ground surface (bgs), and the processing plant is placed within the pit.
Reservoir excavation activities would not change, and would continue to occur Monday through Saturday, between the hours of 4:30 a.m. (or dawn if later) and 6:00 p.m. (or sundown if earlier).

B - Please see the previous source noise calculations. Values shown represents the mitigated hourly (L_{eq}) noise level at each receptor resulting from the operation of Project excavation equipment (e.g., processing plant[s], loaders, excavator, haul/water trucks).
It was assumed that the onsite equipment would operate at-grade, simultaneously in the Project site location closest to each affected receptor. Please see Figure 5 (Appendix A) which shows the distances analyzed.

C - Because the County criteria applies to noise impacts over a 24-hour period (i.e., Day-Night [L_{dn}] noise levels), it was assumed that the onsite excavation equipment would operate simultaneously for up to 14-hours (4:00 a.m. - 6:00 p.m.) in a given day.
Per proposed Mitigation Measure NO-1, onsite material processing operations would be limited to the hours of 7:00 a.m. and 6:00 p.m., until the excavation reaches a minimum depth of 16-feet below ground surface (bgs)
These hourly (L_{eq}) noise levels were then used to estimate the L_{dn} noise levels at each receptor. Please note, for noise occurring between the hours of 10:00 p.m. and 7:00 a.m., and additional +10 dBA weighting is applied .

Reservoir Excavation - Project Impacts @ Receptors

Mitigation Measure NO-1 (Restrict Onsite Processing Operating Hours)

Reservoir Excavation - Mitigated Project Noise Levels (L_{dn}) @ Receptors						
Receptor	**Ambient Noise Level [A]**	**Project Noise Level [B]**	**Total Noise Level [C]**	**Tulare County Threshold [D]**	**Significant?**	**Exceedance**
R1	47.6	71.6	71.6	60	**Yes**	11.6
R2	51.7	51.0	54.4	60	No	---
R3	59.3	53.1	60.2	62.3	No	---
R4	44.7	52.5	53.1	60	No	---

R8	56.0	54.6	58.4	60	No	---
R9	51.8	52.3	55.1	60	No	---
R10	47.8	53.1	54.2	60	No	---

Note: Values shown in **bold** represent an exceedance of the applicable Tulare County Day-Night (L_{dn}) significance threshold.

A - Please see Appendix B for a detailed summary of the ambient noise measurements collected at each Project receptor.

B - Please see the source noise calculations for "Mitigated Reservoir Excavation" phase presented previously.

C - Values shown represents the total estimated noise level resulting from the operation of Project noise sources (e.g., processing plant[s], mobile equipment, etc.) combined with the measured ambient noise level at each receptor.

D - Significance thresholds shown represent appropriate Tulare County noise thresholds (see Appendix B for more detail). Please note In cases where the existing ambient noise levels already exceed the applicable standard or are within ±1 dBA of the applicable significance threshold, the noise standard is increased by +3 dBA increments to encompass the ambient noise.

APPENDIX F

Source Noise & Project Impacts – Reservoir Construction

Reservoir Construction

Equipment Noise/Noise Levels @ Receptors

Reservoir Construction - Mobile Equipment

APPENDIX H

Vibration Impact Assessment

Vibration Impact Assessment

Reservoir Excavation

Equipment Reference Vibration Source		
Equipment	**Distance (feet)**	**PPV (in/sec)**
Large Bulldozer	25	0.089

Source: *Transportation and Construction Vibration Guidance Manual* (Caltrans, 2020).

Note: Large Bulldozer represents the largest, most powerful vibration source operating onsite. Therefore it is used to calculate worst-case vibration impacts to nearby receivers.

Human Responses to Transient Vibration	
PPV (in/sec)	**Human Response**
2	Severe
0.9	Strongly Perceptible
0.24	Distinctly Perceptible
0.035	Barely Perceptible

Source: *Transportation and Construction Vibration Guidance Manual* (Caltrans, 2020).

Vibration Impact Assessment						
Receptor/Site	**Receiver Type**	**Distance (feet) [B]**	**Predicted Vibration PPV @ Receiver (in/sec) [A]**	**Applicable Caltrans PPV Threshold (in/sec)**	**Significant?**	**Predicted Human Response @ Receptor**
R1	Residential	465	0.0036	≥ 0.035	No	Barely Perceptible
R2	Residential	4,978	0.0003	≥ 0.035	No	Barely Perceptible
R3	Residential	3,980	0.0003	≥ 0.035	No	Barely Perceptible
R4	Residential	4,190	0.0003	≥ 0.035	No	Barely Perceptible
R5	Residential	2,560	0.0005	≥ 0.035	No	Barely Perceptible
R6	Residential	2,539	0.0006	≥ 0.035	No	Barely Perceptible
R7	Residential	2,382	0.0006	≥ 0.035	No	Barely Perceptible
R8	Residential	3,262	0.0004	≥ 0.035	No	Barely Perceptible
R9	Residential	4,251	0.0003	≥ 0.035	No	Barely Perceptible
R10	Residential	3,891	0.0003	≥ 0.035	No	Barely Perceptible

FOOTNOTES:

A - $PPV_{Equipment} = PPV_{Ref} (25/D)^{n}$. PPV_{Ref} = reference PPV @ 25-ft. D = distance from equipment to the receiver in ft. n = 1.1 (the value related to the attenuation rate through ground) Source is the Caltrans *Transportation and Construction Vibration Guidance Manual* (2020).

B - Distances estimated using Google Earth ™. Represents closest distance between active excavation area and the receptor property boundary.

See Figure 6 in Appendix A for more detail.

TRAFFIC ANALYSIS
FOR THE McKAY POINT RESERVOIR PROJECT, TULARE COUNTY, CALIFORNIA

Associated Transportation Engineers (ATE) has prepared the following traffic analysis for the McKay Point Reservoir Project, located in Tulare County, California. The Project site lies south of both Lake Kaweah and Bravo Lake; 1-mile northwest of the community of Lemon Cove and 2.5 miles southeast of the community of Woodlake.

PROJECT DESCRIPTION

The Project includes the excavation, construction and operation of the McKay Point reservoir. The reservoir would serve as a surface water storage/re-regulation reservoir and also to optimize groundwater recharge within the Owners service areas.

West Coast Aggregate (WCA) will excavate the pit required to construct the reservoir in accordance with the Surface Mining and Reclamation Act (SMARA) requirements for surface mining operations. The excavated material will be transported by either a conveyor system or by haul trucks/heavy equipment to the on-site processing plant. Aggregate mining and processing operations have been conducted at the Seaborn site since 1976. The Seaborn site is adjacent to the western boundary of the Project site. The Seaborn site was purchased by the Tulare Irrigation District (TID) in order to gain the necessary ingress and egress needed to excavate the pit for the reservoir. The Project excavation activities would be designed to produce less or not greater than the historical annual maximum production levels (baseline) recorded for the Seaborn operation. Therefore, the Project would not generate new off-site traffic (no increase in baseline on-road truck trips) impacts associated with the processing of the aggregate or the transport of the material to market.

PROJECT-SPECIFIC IMPACT ANALYSIS

The following section evaluates the average daily trips (ADT), AM and PM project-specific impacts related to each phase of McKay Point Reservoir Project compared to the Seaborn site baseline trip generation.

Project Trip Generation

- *Excavation:* During the excavation phase, conservatively it is estimated that 7 to 12 employees would be on-site. The excavation of aggregate could occur between the hours of 4:00 AM and 6:00 PM Monday through Saturday. Excavated material would be processed onsite, using a processing/wash plant and portable crushing/recycle plant. Finished products would be delivered directly from the Project site by WCA, using the existing access road that travels through the adjacent Seaborn site connecting to Road 222 to the west. WCA will transport the processed aggregate to customers via on-road trucks. These employee trips and on-road truck trips would not exceed the baseline activities for the Seaborn site.

- *Construction:* During the construction phase, conservatively it is estimated that 7 to 12 employees would be on-site. The construction activities could occur between the hours of 4:00 AM and 6:00 PM Monday through Saturday. Construction material and equipment would be transported to and from the site by on-road trucks. The employee trips and on-road truck trips during the construction phase would not exceed the baseline activities associated with the Seaborn site. In reality, on average employee and on-road truck trips would be far less than those historically associated with the Seaborn site.

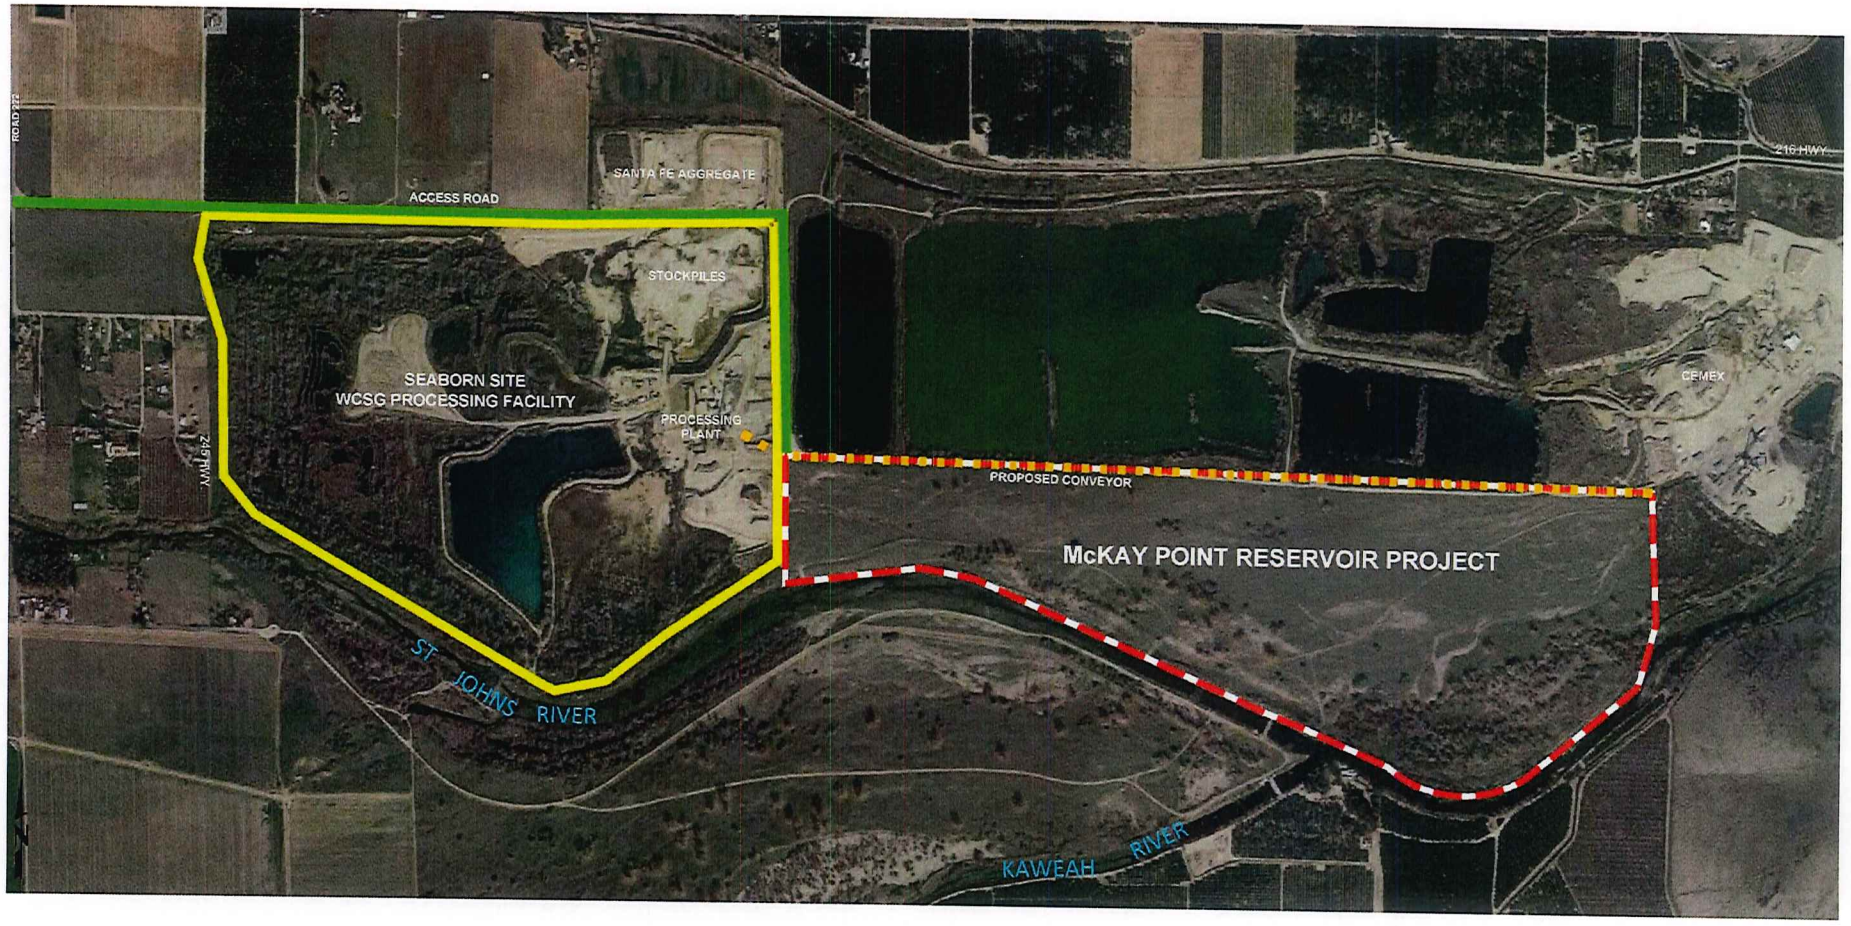
- *Daily Operation:* Operations of the reservoir will primarily be conducted remotely. There will not be employees on-site on a routine basis. Assuming 1-2 daily employees is being conservative since the operation will be controlled remotely from the TID office with only the occasional need for employees on-site for maintenance and inspection reasons.

Table 1
McKay Point Reservoir Project Trip Generation

Development Phase	Number	ADT	AM Peak Hour			PM Peak Hour		
			Trips	Entering	Exiting	Trips	Entering	Exiting
Seaborn Baseline:								
- Employees	12	24	0	0	0	0	0	0
- Truck Loads	160	320	20	10	10	20	10	10
Seaborn Baseline Trip Generation:		344	20	10	10	20	10	10
Excavation:								
- Employees	12	24	0	0	0	0	0	0
- Trucks Loads	160	320	20	10	10	20	10	!0
Excavation Phase Trip Generation:		344	0	10	10	20	10	10
Construction:								
- Employees	12	24	0	0	0	0	0	0
- Truck Loads	160	320	20	10	10	20	10	10
Construction Phase Trip Generation:		344	20	10	10	20	10	10
Daily Operation:								
- Employees	2	4	0	0	0	0	0	0

According to the McKay Point Reservoir Project description, during the excavation phase the Project generates up to 344 daily trips, with up to 20 AM peak hour trips and 20 PM peak hour trips. These Project excavation trips do not exceed the baseline for the Seaborn site. The construction phase of the Project is also anticipated to generate up to 344 daily trips, with up to 20 AM peak hour trips and 20 PM peak hour trips. Neither the Project excavation trips, nor the construction trips exceed the baseline on-road vehicle trips for the Seaborn site. During the daily operational phase, the reservoir will primarily be controlled and operated remotely from the TID office with only the occasional need for employees on-site for maintenance and inspection reasons. Therefore, there will not be employees on-site on a routine basis. Worst-case assuming 1 - 2 daily employees, the Project generates 4 daily trips, with 0 AM peak hour trips and 0 PM peak hour trips. Based on information provided by the applicant, these Project excavation, construction and operational phase on-road vehicle trips do not exceed baseline levels for the Seaborn site. These employee and truck trips are used to determine Project specific traffic impacts.

SUMMARY



The McKay Point Reservoir Project is not expected to generate significant traffic impacts. The project-generated traffic volumes would be consistent with the existing Seaborn baseline scenario.

Subject: Transportation and Vehicle Miles Travelled (VMT) Analysis – McKay Point Reservoir Project

Dear Mr. Fukuda,

This letter is in response to the County of Tulare's (County's) request for a Vehicle Miles Traveled (VMT) analysis, as required by the County Planning Department, for the proposed surface water storage and re-regulation reservoir located on the north side of the divergence of the Lower Kaweah River and St. Johns River. The Tulare Irrigation District (TID), the Consolidated Peoples Ditch Company (CPDC) and the Visalia & Kaweah Water Company (VKWC) are joint owners (Owners) of approximately 500 acres of land adjacent to the Lower Kaweah River and St. Johns River in Tulare County, California, commonly referred to as the McKay Point property. The Owners propose to construct and operate the McKay Point Reservoir on the property (Project). The construction and operation of this reservoir is the Project under review.

The Project would consist of the following phases: excavation of the site for the reservoir; construction of the reservoir; and operation of the reservoir. The Owners would contract with West Coast Aggregate Supply, Inc. (WCA) to excavate the site to allow for the construction of the reservoir. After the excavation and construction of the reservoir, the McKay Point Reservoir would be used as a surface water storage/re-regulation reservoir. The reservoir would also be used to optimize groundwater recharge within the Owners service areas.

Background

The Project site is located in Tulare County, and lies between and to the south of both Lake Kaweah (2.5 miles northeast of the site) and Bravo Lake (1.5 miles northwest of the site); 1.0 miles northwest of the community of Lemon Cove; and 2.5 miles southeast of the community of Woodlake. The Project site is located approximately 1.0 mile west-southwest of the intersection of State Highways 216 and 198.

Historically, the Project site has been used for cattle grazing under lease arrangements. The CEMEX Lemon Cove aggregate facility is immediately to the north, and their Stillwell Aggregate Mine is approximately 1.0 miles to the northeast of the Project site. The Kaweah River Rock aggregate mining and processing facility is located immediately to the west on the Seaborn site, and the Kaweah South Project lies approximately 1.0 mile to the southwest of the Project site.

Excavated and processed materials would be loaded directly on to on-road haul trucks within the Project site. Once loaded, the on-road haul trucks would exit the Project site via the privately owned access road on the

Seaborn site (owned by TID and CPDC) which connects to Road 222. From there the material would be transported to WCA's customers via public roads. The number of on-road haul trucks on public roads associated with WCA's sale of the processed material would not increase from the baseline level of on-road truck traffic (160 trips per day) leaving from TID's access road. The number of on-road haul trucks carrying the processed aggregate as well as the number of on-road trucks needed for the transport of other materials (recycled concrete and asphalt, excess fines, blending materials) being exported or imported to or from the site would not be allowed to exceed the baseline production rate from the previous operations at the Seaborn site (average of 500,000 tons per year [TPY] and a maximum of 650,000 TPY).

The excavation phase of the Project would require only 7 to 12 onsite employees. This would be consistent with the baseline number of employees previously required during the mining and processing activities at the Seaborn site. For evaluation purposes, it is assumed that each employee would make 2 trips per day (inbound and outbound). This would result in a maximum of 24 trips on peak days, assuming all 12 employees are onsite as compared to the 35 employee trips per day during mining and processing activities at the Seaborn site. As a result, the Project would generate only nominal traffic on public roadways, which would not result in a significant increase from baseline operations at the Seaborn site.

Access for employees and service vehicles would be via Road 222 through the Seaborn site to the entrance to the Project site. Note that a single-way trip is referred to as a "trip" and a round trip (going from the WCA facility to their customers and the return trip by the on-road truck back to the facility) is referred to as a "load" (two one-way trips).

Truck Traffic

The California Office of Planning and Research's (OPR's) guidance and Section 15064.3 of the California Environmental Quality Act (CEQA) Guidelines states that "…'vehicle miles traveled' refers to the amount and distance of automobile travel attributable to a project. Neither the Technical Advisory nor CEQA Guidelines Section 15064.3(a) directly address how to analyze transportation impacts associated with changes to goods movement, which is largely carried out by heavy-duty trucks. CEQA Guidelines Section 15064.3(a) specifies that VMT to be analyzed is defined as the amount and distance of *automobile travel* (emphasis added) attributable to a project. The term 'automobile' refers to on-road *passenger vehicles, specifically cars and light trucks* (emphasis added).[1] Senate Bill (SB) 743 is not intended to require the inclusion of heavy-duty truck trips, utility vehicles, or other types of vehicles in the VMT analysis.[2] In the case of trucks (other than light trucks), based on CARB's 2017 Scoping Plan, the State's strategy for the goods movement sector is not in VMT reduction, but in advances in technology [zero-emissions (ZE) and near-zero emissions (NZE) control strategies].[3]

Additionally, as discussed above, because the production rate of marketable aggregate would not increase from baseline, the number of on-road haul trucks transporting product offsite on public roadways would also not be

[2] South Coast coordinated with staff at OPR on January 12, 2021 to confirm how to address heavy-duty freight VMT in CEQA documents. OPR staff identified that the intent of SB 743 was to address passenger vehicle VMT impact and not freight VMT, as cited under CEQA Guidelines Section 15064.3(a). Therefore, lead agencies could exclude freight VMT from transportation VMT impact analyses under CEQA.

increased above existing levels. The Project operations (excavation of the site, construction of the reservoir and reservoir operations) would be managed such that the number of on-road haul trucks, delivery trucks and/or service vehicles would not result in an increase to the baseline. For these reasons, heavy-duty trucks have been excluded from the Project's VMT evaluation.

Vehicle Miles Travelled (VMT) Evaluation

Guidelines for assessing the Project's VMT as part of a transportation impact analysis under CEQA are contained in the "County of Tulare SB 743 Guidelines," dated June 8, 2020. The advisory contains recommendations regarding VMT assessment, significance thresholds and mitigation measures. Under CEQA, lead agencies have the authority to establish their own VMT significance thresholds and analysis methodologies or rely on thresholds and methodologies recommended by other agencies, provided such guidelines are supported by substantial evidence.

The Tulare County advisory provides "screening thresholds" for identifying whether a land use project should be expected to result in a less than significant transportation impact under CEQA. Projects meeting one or more of these criteria would not be required to undergo a detailed VMT analysis. One of the screening thresholds is described as "Small Projects". Small projects are presumed to have a less than significant transportation impact. The County guidelines define a small project to be a project that generates less than 500 trips per day.

The proposed Project would fall within the small project category since the Project is expected to generate 24 daily trips on peak days, which is less than the 500-trip threshold. Therefore, the project would "screen out", and be expected to have less than significant transportation impacts.

In addition, the number of employees required at the site would be less than baseline, thus reducing the number of employee vehicles on public roads. The distance/daily VMTs to and from the site to deliver product to WCA's customers in the region would also not significantly change from the VMT associated with the existing Seaborn operations. Therefore, the Project would not interfere with transportation or result in an increase of local traffic. The routine operation of the reservoir would be conducted remotely from TIDs offsite office and would not result in a significant increase in TID employees.

Please contact me, Maya Rohr, or John Hecht at (805) 275-1515 if you have any questions or require additional information.

Kind regards,

Graham Stephens
