Burrowing owl *Athene cunicularia*	SC, CSSC, VHP	Prefers annual and perennial grasslands, typically with sparse or nonexistent tree or shrub canopies. In California, burrowing owls are found in close association with California ground squirrels; owls use the abandoned burrows of ground squirrels for shelter and nesting. The nesting season as recognized by the CDFW extends from February 1 through August 31. After nesting is completed, adult owls may remain in their nesting burrows or in nearby burrows, or they may migrate; young birds disperse across the landscape from 0.1 to 35 miles from their natal burrows.	**Seismic Retrofit Area: Absent as Breeder.** No suitable nesting habitat is present in the Seismic Retrofit Area, and this species is not currently known to breed anywhere in the vicinity, as the species' South Bay breeding populations have declined and burrowing owls no longer breed (aside from recent Santa Clara Valley Habitat Agency reintroduction efforts) in the Morgan Hill area as they did through the 1990s. Burrowing owls are recorded on Coyote Ridge and in North Coyote Valley in small numbers during the nonbreeding season, and it is possible that an occasional migrant or wintering owl occurs in grassland or riprap around Anderson Dam or in the bed of the drawn-down reservoir. **Conservation Measures Project Area: Low Likelihood of Presence.** No suitable nesting habitat is present in the Conservation Measures Project Area, and this species has not been recorded in these areas. **Expanded Study Area: Low Likelihood of Presence.** The species' South Bay breeding populations have declined and burrowing owls no longer breed in the Morgan Hill or Coyote Valley areas (aside from recent Santa Clara Valley Habitat Agency reintroduction efforts) as they did through the 1990s. Burrowing owls are recorded in North Coyote Valley in small numbers during the nonbreeding season.

Common Name Scientific Name	Regulatory Status	Habitat	Potential for Occurrence in Study Area
Tricolored blackbird *Agelaius tricolor*	ST, VHP	Highly colonial nester that establishes dense breeding colonies in emergent vegetation, grain fields, fallow fields, extensive thickets of blackberry, ruderal vegetation such as mustard or thistle, and occasionally in early-successional riparian habitat. Nesting colonies usually are located near fresh water. Tricolored blackbirds are itinerant nesters, and because their nesting habitat is ephemeral, it is possible for this species to colonize or recolonize an area as suitable breeding habitat becomes available.	**Seismic Retrofit Area: Moderate Likelihood of Presence.** Surveys for tricolored blackbirds and their breeding habitat in the Seismic Retrofit Area have not detected the species, nor any high-quality nesting habitat for it. However, the bed of drawn down Anderson Reservoir has become colonized by fairly extensive stands of bull thistle along San Felipe Creek, upstream from the reservoir's deadpool, and it is possible that tricolored blackbirds could breed in these thistle stands. **Conservation Measures Project Area: Moderate Likelihood of Presence.** Tricolored blackbirds nested at the Ogier Ponds, in the pond immediately northwest of the Model Aircraft Skypark, each year from 1993 to 1998 (Cornell Lab of Ornithology 2022). Although the species is still observed at the Ogier Ponds on occasion, there has been no evidence of breeding since 1998. Nevertheless, suitable nesting habitat is present in emergent vegetation in freshwater marsh at the Ogier Ponds. Although no suitable nesting habitat is present within the footprint of proposed activities at the Coyote Percolation Dam, the wetland mitigation area to the north provides potential nesting habitat. That mitigation site does not provide high-quality nesting habitat, as woody riparian vegetation (e.g., willows) is more extensive than emergent vegetation and is too tall for use by tricolored blackbirds, and even when the site was dominated by emergent vegetation in its earlier years, nesting by tricolored blackbirds was not documented. However, given the extent of freshwater marsh emergent vegetation in that mitigation area, there is at least a low potential for tricolored blackbirds to nest there. This species would not nest or forage in the closed-canopy riparian habitat at the North Channel Reach ~~Extension~~ and Live Oak Restoration Reach areas. **Expanded Study Area: Moderate Likelihood of Presence.** Tricolored blackbirds have nested in several areas along Coyote Creek and in North Coyote Valley, in habitats that could be impacted by changes in groundwater levels during Project construction. Tricolored blackbirds nested at the Coyote Ranch Pond, upstream from Metcalf Road, during several years in the 1980s and 1990s (CNDDB 2022) and in the IBM detention basin along Bailey Avenue in the 1990s. The species has not been documented breeding in North Coyote Valley or along Coyote Creek (aside from the Ogier Ponds) since then, but it is present, often in large numbers, in North Coyote Valley during the nonbreeding season. Potential breeding habitat is still present at Coyote Ranch and in North Coyote Valley, and there is some potential for the species to breed in these areas in the future.
Salt marsh harvest mouse *Reithrodontomys raviventris*	FE, SE, SP	Salt marsh habitat dominated by common pickleweed or alkali bulrush; recent studies have indicated that the species also uses brackish marshes, nontidal managed wetlands, and some adjacent upland habitats (Smith 2019).	**Seismic Retrofit Area: Absent.** Suitable habitat is absent, and the Seismic Retrofit Area is outside the species' range. **Conservation Measures Project Area: Absent.** Suitable habitat is absent, and the Conservation Measures Project Area is outside the species' range. **Expanded Study Area: Present.** This species is present in tidal and nontidal salt marsh, and in some tidal brackish marsh habitat, along Coyote Creek/Coyote Slough from the vicinity of the Coyote Creek Reach 1A waterbird pond to the mouth of Coyote Slough.
Mountain lion, Southern California/Central Coast Evolutionarily Significant Unit *Puma concolor*	SC	Has a large home range size and occurs in a variety of habitats. Natal dens are typically located in remote, rugged terrain far from human activity. May occasionally occur in areas near human development, especially during dispersal.	**Seismic Retrofit Area: High Likelihood of Presence.** Mountain lions are widespread in the Diablo Range, and they have been reported occasionally in the Holiday Lake Estates and Jackson Oaks neighborhoods southeast of Anderson Dam. This species is unlikely to have a primary (i.e., natal) den in the Seismic Retrofit Area due to the high level of human activity there, but mountain lions occur as occasional dispersants and foragers, and the territory of one or more individuals could overlap the Seismic Retrofit Area. **Conservation Measures Project Area: High Likelihood of Presence.** This species is unlikely to have a primary (i.e., natal) den in the Conservation Measures Project Area due to the high level of human activity there, but mountain lions could occur as occasional dispersants and foragers, particularly at the Ogier Ponds, the Live Oak Restoration Reach, and the North Channel Reach ~~Extension~~ Area, and possibly also at the Coyote Percolation Dam. **Expanded Study Area: Present.** Mountain lions are known to occur along Upper Penitencia Creek, where steelhead relocation may occur during Project construction, and they likely also occur as occasional dispersants and foragers in North Coyote Valley.
California Species of Special Concern			
Northern harrier *Circus hudsonius*	CSSC (nesting)	Nests in marshes and moist fields with tall vegetation and sufficient moisture to inhibit accessibility of nest sites to predators. Forages over open areas.	**Seismic Retrofit Area: Absent as Breeder.** No suitable nesting habitat is present in the Seismic Retrofit Area, though this species likely forages in grassland and within the bed of the drawn-down reservoir. **Conservation Measures Project Area: Absent as Breeder.** No suitable nesting habitat is present in the Conservation Measures Project Area, though this species forages in grassland and other open areas at the Ogier Ponds. **Expanded Study Area: Present.** Northern harriers breed in extensive marshes along Coyote Slough. They also forage widely in North Coyote Valley, and it is possible that the species could breed there in moist fields or wetlands.
~~Burrowing owl~~ ~~*Athene cunicularia*~~	~~CSSC~~	~~Prefers annual and perennial grasslands, typically with sparse or nonexistent tree or shrub canopies. In California, burrowing owls are found in close association with California ground squirrels; owls use~~	~~**Seismic Retrofit Area: Absent as Breeder.** No suitable nesting habitat is present in the Seismic Retrofit Area, and this species is not currently known to breed anywhere in the vicinity, as the species' South Bay breeding populations have declined and burrowing owls no longer breed (aside from recent Santa Clara Valley Habitat Agency reintroduction efforts) in the Morgan Hill area as they did through the 1990s. Burrowing owls are recorded in North Coyote Valley in small numbers during the nonbreeding season.~~
Bryant's savannah sparrow *Passerculus sandwichensis alaudinus*	CSSC	Breeds primarily in pickleweed dominant salt marsh and adjacent grassland and ruderal habitat around the edge of San Francisco Bay; very scarce and local breeder in extensive grasslands in the Santa Cruz Mountains	**Seismic Retrofit Area: Absent as Breeder.** This species is not known to breed in the Diablo Range or on the Coyote Valley floor (Rottenborn 2007), and therefore it does not breed in the Seismic Retrofit Area; nonbreeders may forage in the area outside the breeding season. **Conservation Measures Project Area: Absent as Breeder.** This species is not known to breed on the Coyote Valley floor (Rottenborn 2007), and therefore it does not breed in the Conservation Measures Project Area; nonbreeders may forage at the Ogier Ponds outside the breeding season. **Expanded Study Area: Present.** This species breeds in tidal and nontidal salt marsh, brackish marsh, and adjacent levees, grasslands, and ruderal habitat along lower Coyote Creek from the vicinity of the Coyote Creek Reach 1A waterbird pond to the mouth of Coyote Slough.
Alameda song sparrow *Melospiza melodia pusillula*	CSSC	Nests in salt marsh, primarily in marsh gumplant and cordgrass along channels	**Seismic Retrofit Area: Absent.** Suitable habitat is absent, and the Seismic Retrofit Area is outside this subspecies' range. **Conservation Measures Project Area: Absent.** Suitable habitat is absent, and the Conservation Measures Project Area is outside the species' range. **Expanded Study Area: Present.** This species breeds in tidal and nontidal salt marsh, brackish marsh, and immediately adjacent areas along lower Coyote Creek from the vicinity of Newby Island to the mouth of Coyote Slough (San Francisco Bay Bird Observatory 2012).
San Francisco common yellowthroat *Geothlypis trichas sinuosa*	CSSC	Nests in herbaceous vegetation, usually in wetlands or moist floodplains	**Seismic Retrofit Area: Absent.** The Seismic Retrofit Area is outside this subspecies' range. **Conservation Measures Project Area: Absent.** The Conservation Measures Project Area is outside the species' range. **Expanded Study Area: Present.** This species breeds in weedy riparian habitats (including overflow channels); tidal and nontidal freshwater, brackish, and salt marsh; and weedy ruderal habitats with dense vegetation along lower Coyote Creek, from the vicinity of Montague Expressway downstream to the mouth of Coyote Slough (San Francisco Bay Bird Observatory 2012).
Yellow warbler *Setophaga petechia*	CSSC (nesting)	Nests in riparian woodlands	**Seismic Retrofit Area: Present.** Several pairs of yellow warblers breed in mixed riparian woodland and forest within the Seismic Retrofit Area and forage in habitats as well. **Conservation Measures Project Area: Present.** Several pairs of yellow warblers breed in mixed riparian woodland and forest and willow riparian forest and scrub within the Conservation Measures Project Area at the Ogier Ponds, and a pair could breed in mixed riparian woodland and forest near the Coyote Percolation Dam, Live Oak Restoration Reach, and North Channel Reach ~~Extension~~ Area; these birds forage in adjacent habitats as well. **Expanded Study Area: Present.** This species breeds in low numbers in riparian habitats along Coyote Creek from Anderson Dam downstream nearly to the limits of tidal influence, particularly in areas that are not closely hemmed in by urban development. Several pairs likely nest in riparian habitat in North Coyote Valley as well.
Pallid bat *Antrozous pallidus*	CSSC	Forages over many habitats; roosts in caves, rock outcrops, buildings, and hollow trees	**Seismic Retrofit Area: Present.** Since 1998, H. T. Harvey & Associates bat biologist Dave Johnston has been periodically monitoring a maternity colony of pallid bats located in the Cochrane Road barn, near the base of Anderson Dam immediately adjacent to the Seismic Retrofit Area. This barn has supported up to 105 females, which use the roost year-round (including as a maternity roost in spring and summer). Given the presence of these females, an equivalent number of males are likely present in the vicinity, producing a population estimate of approximately 200 or more individuals associated with this roost since monitoring began. The most recent maternity-season surveys of the Cochrane Road barn, in July 2021 and June 2022, produced counts of 75 and 105 individuals, respectively, exiting the barn, while surveys conducted shortly after the maternity season, in September 2019 and September 2022, recorded 64 and 115 individuals, respectively (Valley Water 2019e ~~2019d,~~ 2021d, Dave Johnston, personal observation). Since 1998, seven other pallid bat colonies monitored in Santa Clara County have declined substantially; for example, in 2012, those other colonies collectively supported approximately 35 females, and in 2016, only one of those other colonies was active (supporting only three females). More recently, a colony of 10 to 15 individuals has been detected at the University of California's Blue Oak Ranch Reserve (D. Johnston, personal observation), but the colony in the Cochrane Road barn represents the largest and

Common Name Scientific Name	Regulatory Status	Habitat	Potential for Occurrence in Study Area
			most stable colony of the species known in Santa Clara County, and supports at least half of the known individuals in the county. Pallid bats may also roost in the Seismic Retrofit Area in trees and rock outcrops, and individuals could forage in any open habitat. **Conservation Measures Project Area: May be Present.** Pallid bats could forage in open habitats around the Ogier Ponds, and larger trees at the Ogier Ponds, Live Oak Restoration Reach, and North Channel Reach ~~Extension~~ Area could possibly support roosts. **Expanded Study Area: High Likelihood of Presence.** Pallid bats could roost in larger trees, particularly those with large cavities, along Coyote Creek downstream from Anderson Dam. This species is most likely to occur where large trees with cavities are present near extensive grassland or other open (rather than developed) areas.
Townsend's big-eared bat *Corynorhinus townsendii*	CSSC	Roosts in caves and mine tunnels, and occasionally in deep crevices in trees such as redwoods or in abandoned buildings, in a variety of habitats	**Seismic Retrofit Area: Absent as Breeder.** Townsend's big-eared bat is not known to occur in or very close to the Seismic Retrofit Area (e.g., it has not been recorded at the Cochrane Road barn where pallid bats roost), and aside from that barn, no high-quality roost sites are present in the area. Although this species may forage over the Seismic Retrofit Area infrequently and in low numbers, it does not roost there. **Conservation Measures Project Area: Absent as Breeder.** Townsend's big-eared bat is not known to occur in or very close to the Conservation Measures Project Area, and no high-quality roost sites are present in the area. Although this species may forage over the Conservation Measures Project Area infrequently and in low numbers, it does not roost there. **Expanded Study Area: Absent as Breeder.** Townsend's big-eared bats could occasionally forage over parts of the study area outside the Project Area, in small numbers, but they do not roost or occur frequently in impact areas within the remainder of the study area.
Western red bat *Lasiurus blossevillii*	CSSC	Roosts in foliage in forest or woodlands, especially in or near riparian habitat	**Seismic Retrofit Area: Absent as Breeder.** Individual western red bats occur near the Seismic Retrofit Area in low numbers as migrants and winter residents, but this species does not breed in the South Bay. Individual western red bats may roost in small numbers in the foliage of trees virtually anywhere, but they roost primarily in riparian areas. **Conservation Measures Project Area: Absent as Breeder.** Individual western red bats may roost in small numbers in the foliage of trees, primarily in riparian areas. **Expanded Study Area: Absent as Breeder.** Individual western red bats may roost in small numbers in the foliage of trees, primarily in riparian areas along Coyote Creek and in North Coyote Valley.
Salt marsh wandering shrew *Sorex vagrans halicoetes*	CSSC	Medium to high marsh 6 to 8 feet above sea level with abundant driftwood and common pickleweed	**Seismic Retrofit Area: Absent.** Suitable habitat is absent, and the Seismic Retrofit Area is outside the species' range. **Conservation Measures Project Area: Absent.** Suitable habitat is absent, and the Conservation Measures Project Area is outside the species' range. **Expanded Study Area: Likely Present.** This species is likely present in tidal and nontidal salt marsh along Coyote Creek/Coyote Slough from the vicinity of the Coyote Creek Reach 1A waterbird pond to the mouth of Coyote Slough.
San Francisco dusky-footed woodrat *Neotoma fuscipes annectens*	CSSC	Nests in a variety of habitats including riparian areas, oak woodlands, and scrub	**Seismic Retrofit Area: Present.** The San Francisco dusky-footed woodrat is known to occur throughout much of Santa Clara County, particularly in foothill/mountain areas and along creeks in less heavily urbanized portions of the valley floor (Valley Water 2010b). Surveys of Anderson Dam conducted by Valley Water in 2006 and 2009 detected one woodrat nest at the dam (Valley Water 2012a). Since then, small numbers of woodrat nests have been observed on and around Anderson Dam in coast live oak forest and woodland, mixed serpentine chaparral, northern coastal scrub/Diablan sage scrub, and other land cover types in the Seismic Retrofit Area during preactivity surveys for Project-related geotechnical activities and the FOCP. Most nests have been located in dense scrub, though some have been in trees, and woodrats were detected at rock outcrops on Basalt Hill during camera surveys for ringtails (Valley Water 2017). These surveys have confirmed that woodrat nest densities/numbers at the site are low, even in ostensibly high-quality habitat. **Conservation Measures Project Area: Present.** San Francisco dusky-footed woodrat nests are present at the Ogier Ponds in dense mixed riparian forest and woodland and willow riparian forest and scrub. Nest densities are low, but the species occurs fairly widely. Likely also present at the Live Oak Restoration Reach and North Channel Reach ~~Extension~~ area, and in scattered locations elsewhere along Coyote Creek in the Project area. **Expanded Study Area: Present.** San Francisco dusky-footed woodrat nests are present in riparian habitats along Coyote Creek downstream from Anderson Dam. Though the species is likely absent or present in very low densities in urban areas, some woodrats may be present downstream nearly to the limits of tidal influence (Valley Water 2010b).
American badger *Taxidea taxus*	CSSC	Burrows in grasslands and occasionally in infrequently disked agricultural areas	**Seismic Retrofit Area: Absent as Breeder.** American badgers are expected to disperse through the Seismic Retrofit Area in low numbers, and they likely forage there, but the extensive grasslands preferred by this species are absent from the area, and it would not den within the Seismic Retrofit Area.

Common Name Scientific Name	Regulatory Status	Habitat	Potential for Occurrence in Study Area
			Conservation Measures Project Area: Absent as Breeder. American badgers are expected to disperse through the Ogier Ponds area in low numbers, and they likely forage there, but this species has not been observed at the Ogier Ponds and is unlikely to den there. **Expanded Study Area: Present.** American badgers have been recorded in North Coyote Valley, primarily as roadkills or in adjacent foothills, though they likely disperse through and forage in valley-floor areas as well. They may use riparian habitats in North Coyote Valley and along Coyote Creek from Anderson Dam downstream to the Metcalf Road area for cover.
State Fully Protected Species			
Golden eagle *Aquila chrysaetos*	SP	Breeds on cliffs or in large trees (rarely on electrical towers), forages in open areas	**Seismic Retrofit Area: Present.** Multiple territories are present around Anderson Reservoir. Focused surveys of the area around Anderson Reservoir since 2019 have detected two nesting pairs east of the reservoir (1.7 miles north and 2.4 miles east of the spillway), two additional pairs south/southeast of the southern end of the reservoir, and an additional territory northwest of the reservoir (Valley Water 2020e ~~2020a~~, 2021c ~~2021e~~, 2022a ~~2022b~~). This species forages in grassland, scrub, and the bed of the drawn-down reservoir throughout the Seismic Retrofit Area. **Conservation Measures Project Area: Absent as Breeder.** Golden eagles are occasionally seen flying over the Ogier Ponds, and they could forage in open habitats around the ponds, though they are usually observed high overhead. The species does not nest near the Conservation Measures Project Area, and it would not forage in the closed-canopy riparian habitat at the North Channel Reach ~~Extension~~ and Live Oak Restoration Reach areas. **Expanded Study Area: Present.** Golden Eagles are regularly seen foraging in North Coyote Valley, though not in areas that may be affected by changes in groundwater levels during Seismic Retrofit construction. This species could forage along Coyote Creek from Anderson Dam downstream to the Metcalf Road area, but it does not nest in any areas where it could be affected by Project activities.
White-tailed kite *Elanus leucurus*	SP	Nests in tall shrubs and trees, forages in grasslands, marshes, and ruderal habitats	**Seismic Retrofit Area: Present.** White-tailed kites are present in small numbers around Anderson Dam, being seen most often just outside the Seismic Retrofit Area in the Rosendin portion of Coyote Lake County Park. This species could forage in grassland, scrub, and the bed of the drawn-down reservoir throughout the Seismic Retrofit Area, and small numbers may nest in trees in or near the Seismic Retrofit Area. **Conservation Measures Project Area: Present.** One or two pairs regularly nest around the Ogier Ponds, and the species forages in open habitats all around the pond complex. It is possible that a pair may nest in or near the North Channel Reach ~~Extension~~ and Live Oak Restoration Reach areas. **Expanded Study Area: Present.** White-tailed kites breed and forage in a number of areas in North Coyote Valley and along Coyote Creek downstream from Anderson Dam.
Peregrine falcon *Falco peregrinus*	--* ~~SP~~	Nests on cliffs, tall buildings, and occasionally old nests of other birds on electrical towers, foragers over a variety of open habitats, often near water	**Seismic Retrofit Area: Absent as Breeder.** Although no nesting habitat is present in or near the Seismic Retrofit Area, nonbreeding peregrine falcons occur in the area as occasional foragers, typically around Anderson Reservoir. **Conservation Measures Project Area: Absent as Breeder.** Although no nesting habitat is present in or near the Conservation Measures Project Area, nonbreeding peregrine falcons forage occasionally at the Ogier Ponds and the Coyote Percolation Pond. This species would not forage in the closed-canopy riparian habitat at the North Channel Reach ~~Extension~~ and Live Oak Restoration Reach areas. **Expanded Study Area: Absent as Breeder.** Although no nesting habitat is present, small numbers of nonbreeding peregrine falcons forage in North Coyote Valley and along Coyote Creek downstream from Anderson Dam, often on waterfowl.
Ringtail *Bassariscus astutus*	SP	Boulder fields, talus slopes, rocky outcrops, and woodlands	**Seismic Retrofit Area: Absent as Breeder.** Ringtails may disperse through the Seismic Retrofit Area infrequently and in low numbers, but the species is not expected to den within the Seismic Retrofit Area. Focused camera surveys for ringtails among rock outcrops on Basalt Hill did not detect any individuals (Valley Water 2017). **Conservation Measures Project Area: Absent as Breeder.** Ringtails may disperse through the Ogier Ponds, Live Oak Restoration Reach, and North Channel Reach ~~Extension~~ areas in low numbers, but this species has not been observed in or near these areas and likely does not den there. **Expanded Study Area: Absent as Breeder.** Ringtails have not been recorded in or near North Coyote Valley or along Coyote Creek downstream from Anderson Dam. If they occur in these areas, they likely occur as infrequent dispersants.

Special-status animals considered for potential occurrence in the study area, but determined to be absent by ecologists for purposes of impact assessment because suitable habitat is absent and/or the study area is outside the species' range include western snowy plover (*Charadrius nivosus nivosus*; in the South Bay, this species breeds exclusively, and forages primarily, in managed ponds that will not be affected directly or indirectly by the Project), bank swallow (*Riparia riparia*; absent as a breeder, present only as a scarce migrant), California condor (*Gymnogyps californianus*; not known or expected to occur anywhere in the study area except perhaps during high-altitude flights), willow flycatcher (*Empidonax traillii*; absent as a breeder, present only as an uncommon migrant), least Bell's vireo (*Vireo bellii pusillus*; the species is not known to have bred, even historically, in the study area), San Joaquin kit fox (*Vulpes macrotis mutica*; the species is not known to have occurred, even historically, in the study area, and coast horned lizard (*Phrynosoma blainvillii*; no suitable habitat is present in the study area, and the species is not known or expected to occur there.

Several species are designated as California SSC only when breeding, but they occur in areas where they could be impacted by Project activities only as nonbreeders; these species, which include the Vaux's swift (*Chaetura vauxi*), long-eared owl (*Asio otus*), short-eared owl (*Asio flammeus*), olive-sided flycatcher (*Contopus cooperi*), loggerhead shrike (*Lanius ludovicianus*), grasshopper sparrow (*Ammodramus savannarum*), yellow-breasted chat (*Icteria virens*) are not included in **Table 3.5-5,** because they do not occur in the study area as special-status species.

All other special-status animals that are known to occur, or that could occur, in areas where they may be subject to Project impacts are discussed in **Table 3.5-5**.

3.5.1.5 Wildlife Movement and Habitat Connectivity

Habitat connectivity is vital to animals for maintaining connections between core habitat areas (i.e., larger intact habitat areas where species typically reside). Connectivity helps ensure that genetic diversity is maintained by allowing individuals to disperse and share genes between populations, thereby diminishing the probability of inbreeding depression, and helps to maintain populations, as individuals from larger or more productive populations can disperse to areas where populations are lower. This helps to ensure that populations are more widely dispersed rather than being confined to fewer, more limited areas where disease, large disturbances, such as extensive fires, or random events could cause extirpation (local extinction). Connectivity is especially important in landscapes fragmented by urban development and agricultural activities.

Vegetation communities along streams and rivers often function as environmental corridors; in the study area, Coyote Creek functions as a wildlife movement corridor (ICF 2012). In addition, other natural habitats (e.g., oak woodlands and scrub) and the shorelines of Anderson Reservoir function as pathways for terrestrial wildlife movement that allow animals to move along these areas. A variety of animals, including amphibians, reptiles, mammals, and birds moving in a northwest-southeast direction along the western edge of the Diablo Range foothills move along the edges of Anderson Reservoir. In addition, animals move in an east-west direction across Coyote Valley. The ability of animals to be able to move—either over generations, in the case of less mobile animals, or during long-distance dispersal events for birds, bats, and larger mammals—across Coyote Valley and intermix and breed with genetically unrelated members of the species is important to the maintenance of populations of many species in the Diablo Range and Santa Cruz Mountains. Coyote Valley represents the highest-quality linkage between these two mountain ranges, because the foothills of both ranges come so close together at North

Coyote Valley, and because the mostly undeveloped nature of North Coyote Valley allows wildlife movement with limited impediments.

3.5.2 Regulatory Setting

The preceding *Biological Resources—Fisheries Resources* ~~Aquatic Biological Resources~~ section describes federal, State, and local laws, regulations, and policies relevant to the evaluation of the Project's impacts on aquatic biological resources. Most of those laws, regulations, and policies apply to terrestrial biological resources as well, and those detailed descriptions are not repeated here. This section therefore lists the federal, State, and local laws, regulations, and policies relevant to the evaluation of the Project's impacts on terrestrial biological resources; cross-references the aquatic section as appropriate; provides detailed descriptions of those few laws, regulations, and policies relevant to terrestrial but not aquatic biological resources; and provides a brief summary of the applicability of each law, regulation, and policy to the Project's impacts on terrestrial biological resources.

3.5.2.1 Federal Laws, Regulations, and Policies

Clean Water Act

Section 404, Permits for Fill Placement in Waters of the United States and Wetlands

See Section 3.14, *Water Quality*, ~~See the Aquatic Biological Resources section~~ for a description.

Project applicability: The Project will discharge fill materials into waters of the U.S. for construction of the following Project components: Seismic Retrofit, Ogier Ponds CM, Coyote Percolation Dam CM, North Channel ~~Extension~~ Reach Maintenance and Live Oak Restoration Reach Maintenance ~~CM~~, and Sediment Augmentation Program.

Federal Endangered Species Act

See Section 3.4, *Biological Resources—Fisheries Resources*~~, the Aquatic Biological Resources section~~ for a description.

Project applicability: The Project is anticipated to result in the take of federally listed species and may also impact proposed and candidate species. Terrestrial species protected by ESA are regulated by the USFWS. ESA-listed or proposed species that are considered covered species under the VHP and that may be impacted by the Project are Tiburon paintbrush (*Castilleja affinis* ssp. *neglecta* ~~*Neglecta*~~), Coyote ceanothus (*Ceanothus ferrisiae*), Santa Clara Valley dudleya (*Dudleya abramsii* ssp. *setchellii* ~~*Setchellii*~~), Metcalf Canyon jewel-flower (*Streptanthus glandulosus* ssp. *albidus* ~~*Albidus*~~), Bay checkerspot butterfly (*Euphydryas editha* ~~*wains*~~ *bayensis*), California tiger salamander (*Ambystoma californiense*), California red-legged frog (*Rana draytonii*), and foothill yellow-legged frog (*Rana boylii*). The majority of Project impacts on these species are considered covered activities under the VHP, and incidental take approval for VHP-covered activities' effects on these species is provided via the VHP. Authorization of any incidental take of these species resulting from the limited subset of Project activities that are not covered by the VHP will be provided via Project-specific Section 7 consultation with ~~between~~ FERC/USACE and USFWS. The Project could also result in take of the California Ridgway's rail and salt marsh harvest mouse (*Reithrodontomys raviventris*), federally listed species that occur along lower Coyote Creek near San Francisco Bay. Because these two species are not VHP-covered species, approval of any incidental take of these species resulting from the Project will be provided via Project-specific Section 7 consultation between FERC/USACE and USFWS. The northwestern pond turtle, which is a VHP-covered species, and the monarch butterfly (*Danaus plexippus*), which is not covered by the VHP, are proposed for listing as threatened ~~are candidates for listing~~ under ESA. Valley Water anticipates impacts to these two ~~candidate~~ species as a result of the Project. Consultation between FERC/USACE and USFWS may address these species as well.

Fish and Wildlife Coordination Act

See Section 3.4, *Biological Resources—Fisheries Resources*~~, the Aquatic Biological Resources section~~ for a description.

Project applicability: Consultation between USFWS, CDFW, and other agencies regarding the Project has been occurring through ongoing interagency meetings and technical working group meetings and will continue as necessary, including FERC and USACE consultation with these agencies.

Federal Migratory Bird Treaty Act

The Migratory Bird Treaty Act (MBTA) (16 USC Section 703–712) implements the provisions of treaties between the United States, Great Britain, Mexico, Japan, and Russia, and authorizes the U.S. Secretary of the Interior to protect and regulate take of migratory birds. USFWS administers the MBTA. It establishes seasons and bag limits for hunted species, and renders taking, possession, import, export, transport, sale, purchase, and barter of migratory birds, their occupied nests, and their eggs illegal except where authorized under the terms of a valid federal permit. Activities for which permits may be issued include scientific collecting; falconry and raptor propagation; "special purposes," which include rehabilitation, education, migratory game bird propagation, and miscellaneous other activities; control of depredating birds; taxidermy; and waterfowl sale and disposal. The MBTA protects whole birds, parts of birds, and bird eggs and nests, and it prohibits the possession of all nests of protected bird species whether they are active or inactive. An *active* nest is defined as having eggs or young, as described by the USFWS in its June 14, 2018, memorandum "Destruction and Relocation of Migratory Bird Nest Contents". Nest starts (nests that are under construction and do not yet contain eggs) and inactive nests are not protected from destruction.

More than 800 species of birds are protected under the MBTA. Specific definitions of *migratory bird* are discussed in each of the international treaties; in general, however, species protected under the MBTA are those that migrate to complete different stages of their life history or to take advantage of different habitat opportunities during different seasons.

Project applicability: With the exception of the California quail, which is in a family explicitly excluded from MBTA protection, all native birds in the study area are protected under the MBTA. The Project includes measures to avoid violation of the MBTA by detecting and avoiding impacts to active nests of protected birds.

Federal Bald and Golden Eagle Protection Act

The Bald and Golden Eagle Protection Act (BGEPA) (16 USC Section 668-668d) makes it unlawful to import, export, take, sell, purchase, or barter any bald eagle or golden eagle, or their parts, products, nests, or eggs. Take includes pursuing, shooting, poisoning, wounding, killing, capturing, trapping, collecting, molesting, or disturbance. The Department of the Interior has interpreted BGEPA to authorize issuance of regulations to permit the taking of eagles for various purposes, provided the taking is compatible with the preservation of the bald eagle or the golden eagle.

Project applicability: Seismic Retrofit construction would impact nesting bald eagles (*Haliaeetus leucocephalus*) and golden eagles (*Aquila chrysaetos*). Valley Water has been coordinating with USFWS regarding these impacts and will obtain a BGEPA incidental take permit from USFWS prior to engaging in any Project activities resulting in the take of eagles.

Executive Orders

The actions of federal agencies are guided by Presidential Executive Orders related to environmental protection, including the following:

- Executive Order (EO) 11990 (Wetlands): For projects proposing to affect wetlands, federal agencies must demonstrate that no practicable alternatives exist to avoid or further minimize impacts on wetlands and that all practicable avoidance, mitigation, and/or preservation measures have been incorporated into the project to minimize impacts on wetlands. Federal agencies are required to provide the public opportunity to review proposals for impacts to wetlands.
- EO 11988 (Floodplain Management): For projects that may be in a floodplain, federal agencies are required to evaluate the effects of the action on the floodplain and identify practicable alternatives or measures to avoid impacts associated with the occupancy and modification of the floodplain and to avoid incompatible development in the floodplain.
- EO 13112 (Invasive Species): Federal agencies are required to prevent the introduction of invasive species and not authorize actions that could cause or promote the introduction or spread of invasive species. Federal agencies must identify feasible measures to minimize the risk of harm caused by invasive species.
- EO 13186 (Migratory Birds): Federal agencies are required to evaluate the effects of their actions on migratory birds and to minimize the take of migratory birds through development of procedures for evaluating such take and conservation efforts in coordination with the USFWS.

Project applicability: Project activities would affect wetlands, floodplains, and migratory birds, and may introduce or spread invasive species. FERC and USACE would comply with the Eos applicable to them. Valley Water has been coordinating with federal agencies (i.e., FERC, USFWS, NMFS, and USEPA) during Project planning regarding these issues, and the Project incorporates AMMs related to these issues.

3.5.2.2 State Laws, Regulations, and Policies

Porter-Cologne Water Quality Control Act

See Section 3.14, *Water Quality,* ~~the Aquatic Biological Resources section~~ for a description. Note that AB 2875 of 2024 established a state policy to ensure no net loss, and long-term gains, in the quantity, quality, and permanence of wetlands acreage.

Project applicability: The Project would impact waters of the State during construction of the following Project components: Seismic Retrofit, Ogier Ponds CM, Coyote Percolation Dam CM, North Channel ~~Extension, the~~ Reach and Live Oak Restoration Reach Maintenance ~~CM,~~ and Sediment Augmentation Program. Therefore, Valley Water would obtain a Section 401 Water Quality Certification for the Project from the State Water Board prior to engaging in Project activities affecting waters of the State.

California Endangered Species Act

See Section 3.4, *Biological Resources—Fisheries Resources*~~, the Aquatic Biological Resources section~~ for a description.

Project applicability: The Project would result in the take of State-listed species. Terrestrial species protected by CESA and regulated by CDFW include the VHP-covered California tiger salamander and foothill yellow-legged frog. The majority of Project impacts on these species are considered covered activities under the VHP, and incidental take approval for VHP-covered activities' effects on these species is provided via the VHP. Approval of any incidental take of these species resulting from the limited subset of Project activities that are not covered by the VHP may be sought via Project-specific CESA take authorization.

Several other CESA-listed species may also be impacted by the Project, but take of these species, as defined by CESA, will be avoided. For example, no take of Tiburon paintbrush would result from the Project, and the Project would incorporate measures to avoid take (as defined by CESA) of bald eagle, tricolored blackbird (*Agelaius tricolor*), and Swainson's hawk (*Buteo swainsoni*). The Project could result in impacts on the California Ridgway's rail, California black rail, and salt marsh harvest mouse, CESA-listed species that occur in habitats along lower Coyote Creek near San Francisco Bay. However, because these species are listed as "fully protected" under the Fish and Game Code, take of these species per CESA would be avoided.

The Southern California/Central Coast Evolutionarily Significant Unit of mountain lion (*Puma concolor*) is a candidate for listing under CESA, and this species occurs in the study area, but no take of this species will result from the Project. Crotch's bumble bee (*Bombus crotchii*) is a candidate for listing under CESA. As long as legally protected or unless and until Crotch's bumble bee is added to the VHP as a covered species (at which point any incidental take of the species resulting from the Project would be provided via the VHP), Valley Water will implement the FOCP *Crotch's Bumble Bee Avoidance Plan* (Valley Water 2024a) to avoid take of the species. Measures will also be implemented to avoid take of the state candidate burrowing owl.~~, and it is possible that take of this species could result from the Project. If it is listed under CESA, Valley Water would obtain an Incidental Take Permit authorizing such take.~~

California Native Plant Protection Act

The California Native Plant Protection Act (NPPA) of 1977 (Fish and Game Code Section 1900 to 1913) directed the Fish and Game Commission to use their authority to designate plants as rare or endangered to "preserve, protect, and enhance" these species. Under Section 1901, a species is *endangered* when its prospects for survival and reproduction are in immediate jeopardy from one or more causes. A species is *rare* when, although not threatened with immediate extinction, it exists in such small numbers throughout its range that it could become endangered if its present environment worsens.~~ T).~~ The CDFW maintains a list of federal and State-listed Endangered, Threatened, and Rare Plants of California (see https://nrm.dfg.ca.gov/FileHandler.ashx?DocumentID=109390&inline). Take of rare plants can only be authorized under Title 14 CCR Section 786.9. Take of endangered plants can only be authorized under the provisions of CESA. Various activities are exempt from CNPPA, although take of rare and/or endangered plants as a result of these activities may require other authorization from CDFW under the Fish and Game Code.

Project applicability: The Project would not result in take of any plant species protected by the NPPA.

Fish and Game Code Section 1600 et seq.

See Section 3.4, *Biological Resources—Fisheries Resources*~~, the Aquatic Biological Resources section~~ for a description.

Project applicability: Several Project components would result in impacts to the bed and banks of streams and lakes regulated by CDFW under Fish and Game Code Section 1600 et seq. Valley Water will apply for and obtain a LSAA before impacting CDFW-regulated resources.

Fish and Game Code – Fully Protected Species

California statutes afford fully protected status to a number of specifically identified birds, mammals, reptiles, and amphibians. These species cannot be taken~~, even with an incidental take permit,~~ unless authorized by a NCCP or unless CDFW issues an Incidental Take Permit in accordance with Senate Bill 147 of 2023; that bill authorizes CDFW to issue Incidental Take Permits for implementation of certain types of projects, including maintenance, repair, or improvement projects to critical regional or local water agency infrastructure. See Fish and Game Code Sections 3505, 3511, 4700, 5050, and 5515.

Project applicability: Fully protected species that may be impacted by the Project are bald eagle, golden eagle, California Ridgway's rail, California black rail, salt marsh harvest mouse, white-tailed kite, ~~peregrine falcon (*Falco peregrinus*),~~ and ringtail (*Bassariscus astutus*). The Project incorporates measures to avoid take of these species as defined by the Fish and Game Code. Although the Project meets the criteria for obtaining an Incidental Take Permit for fully protected species per Senate Bill 147, no Incidental Take Permit for fully protected species is expected to be necessary given the implementation of take avoidance measures.

Fish and Game Code Sections 3503, 3513, and 3800

Fish and Game Code sections 3503, 3513, and 3800 (and other sections and subsections) protect native birds, including their nests and eggs, from all forms of take. Disturbance that causes nest abandonment and/or loss of reproductive effort is considered take by the CDFW. Raptors (e.g., eagles, hawks, and owls) and their nests are specifically protected in California under Code Sections 3503.5. Section 3503.5 states that it is "unlawful to take, possess, or destroy any birds in the order Falconiformes or Strigiformes (birds of prey) or to take, possess, or destroy the nest or eggs of any such bird except as otherwise provided by this code or any regulation adopted pursuant thereto."

Project applicability: All native birds in the study area, and some nonnative birds, are protected by these Fish and Game Code sections. The Project includes measures to avoid violation of these Fish and Game Code sections by detecting and avoiding impacts to active nests of protected birds, including indirect impacts that cause nest abandonment and/or loss of reproductive effort.

Fish and Game Code Section 4150

Bats and other nongame mammals are protected by Fish and Game Code Section 4150, which states that all nongame mammals or parts thereof may not be taken or possessed except as provided otherwise in the code or in accordance with regulations adopted by the commission. Activities resulting in mortality of nongame mammals (e.g., destruction of an occupied nonbreeding bat roost, resulting in the death of bats), or disturbance that causes the loss of a maternity colony of bats (resulting in the death of young), may be considered take by the CDFW.

Project applicability: All bats occurring in the study area are protected by Fish and Game Code Section 4150. The Project includes measures to avoid violation of Fish and Game Code Section 4150 by detecting and avoiding injury or mortality to, or disturbance of a maternity colony of, bats.

Natural Community Conservation Planning Act

See Section 3.4, *Biological Resources—Fisheries Resources*~~, the Aquatic Biological Resources section~~ for a description.

Project applicability: The vast majority of Project activities are considered covered activities under the VHP, which is a joint HCP/NCCP. Valley Water would obtain VHP coverage of eligible activities and comply with all applicable VHP conditions.

3.5.2.3 Local Laws, Regulations, and Policies

Santa Clara Valley Habitat Plan

See Section 3.4, *Biological Resources—Fisheries Resources*~~, the Aquatic Biological Resources section~~ for a description.

Project applicability: The vast majority of Project activities are considered covered activities under the VHP. Valley Water would obtain VHP coverage of eligible activities and comply with all applicable VHP conditions.

Safe, Clean Water, and Natural Flood Protection Program (Measure B—the Safe, Clean Water and Natural Flood Protection Program)

The Safe, Clean Water, and Natural Flood Protection Program is designed with five priorities, including: (1) ensure a safe, reliable water supply; (2) reduce toxins, hazards, and contaminants; (3) protect the water supply from earthquakes and natural disasters; (4) restore wildlife habitat and provide open space; and (5) provide flood protection. Valley Water prepares an annual report providing a progress update for each of these program priorities, along with fiscal year accomplishments. This program benefits terrestrial resources through restoration activities, monitoring, and preserving natural lands.

Water Resources Protection Ordinance of the Santa Clara Valley Water District (as amended by Ordinance 081)

The Water Resource Protection Ordinance (as amended by Ordinance 081) was adopted by Valley Water to help implement the Guidelines and Standards for Land Use near Streams (Santa Clara Valley Water Resources Protection Collaborative 2006). The ordinance is intended to protect the water resources managed by Valley Water and provides a set of model guidelines and standards for land use along stream corridors, and it regulates access to and use of Valley Water's facilities and easements. The ordinance specifies the project review and permitting process for projects located within 50 feet of a creek or waterway, or within 50 feet of a Valley Water-owned property or easement. The Water Resources Protection Manual provides guidance for complying with the ordinance. This ordinance protects aquatic habitat and adjacent terrestrial resources and guides land use activities to reduce impacts to aquatic habitats and adjacent terrestrial resources.

Santa Clara County Tree Ordinance

County Code tree ordinance (County Code Division C16) protects protected trees, as defined, on any private or public property in designated areas of the county and which measure over 37.7 inches in circumference (12 inches or more in diameter) measured 4.5 feet above the ground, or which exceed 20 feet in height. Removal of protected trees requires an administrative permit from the County. The permit requires mitigation for removed trees by replacement planting on or offsite at a mitigation ratio determined by the County Planning Department. The County tree ordinance is applicable only to unincorporated areas of the county; within the limits of an incorporated city, it is superseded by that City's tree ordinance, if one exists.

<u>Project applicability</u>: Valley Water is exempt from compliance with the County tree ordinance under either Government Code Sections 53091(d) or (e) (which state that County or City building and zoning ordinances do not apply to the construction of facilities for water storage or transmission), or for nonbuilding and zoning ordinances, under *Hall v. Taft* (1956) 47 Cal. 2d 177,189 (which holds that water districts are exempt from municipal police power regulation). Therefore, Valley Water's removal of ordinance-sized trees would not conflict with the County tree ordinance. Nevertheless, recognizing the importance of protected trees to the County, Valley Water is voluntarily proposing a mitigation measure calling for the planting of replacement trees.

City of Morgan Hill Tree Ordinance

The City of Morgan Hill tree ordinance (Morgan Hill Municipal Code Chapter 12.32) requires a tree removal permit for removal of any tree on any city or private property with a circumference greater than 40 inches or more for nonindigenous species and 18 inches or more for indigenous species measured at 4.5 feet vertically above the ground or immediately below the lowest branch, whichever is lower, and having the inherent capacity of naturally producing one main axis continuing to grow more vigorously than the lateral axes. A tree removal permit is required for removal of trees of any size within a public right-of-way.

To obtain a tree removal permit, the applicant must submit: (1) a site plan, including location, type, and size of trees to be removed; (2) a disposal plan for felled wood (the City prefers composting or mulching over burning land filling); and (3) a letter of justification of tree removal, including a description of the condition of the tree(s), an explanation of why removal of the tree is requested, photographs showing the condition of the tree(s), and any other information pertinent to the request. The applicant also must agree to post a Public Notice for Tree Removal Permit.

Project applicability: The City of Morgan Hill tree ordinance does not apply to Project Area trees that may be removed as part of Project construction, since all trees within Morgan Hill city limits that would be impacted by the Project are located on public property owned by Valley Water. Therefore, Valley Water's removal of ordinance-sized trees would not conflict with the City's tree ordinance.

City of San José Tree Ordinance

The City of San José tree ordinance (San José Municipal Code Chapter 13.32) requires a live tree removal permit for removal of all live trees on private property over 56 inches in circumference, measured at a height of 24 inches above natural grade slope.

To obtain a live tree removal permit, the applicant must submit: (1) a plot plan, including information on the type, size, location and condition of trees to be removed and the location of required replacement trees; (2) photographs which show the entire tree(s); (3) evidence explaining why the tree(s) should be removed; and (4) indication of whether the tree(s) to be removed being used for nesting by birds or other animal species. The applicant also may be required to submit a Certified Arborist's Report. As part of the tree removal permitting process, a public hearing may be held. Public hearing notices are prepared by the Department of Planning, Building and Code Enforcement and mailed to all property owners and residents (adjacent for single-family residences and 300 feet for all others).

Project applicability: The City of San José tree ordinance does not apply to Project Area trees that may be removed as part of Project construction, since all trees within San José city limits are located on public property. Therefore, Valley Water's removal of ordinance-sized trees would not conflict with the City's tree ordinance.

Santa Clara County General Plan

See Section 3.4, *Biological Resources—Fisheries Resources*~~, the Aquatic Biological Resources section~~ for a description.

Project applicability: The County's General Plan goals, policies, and actions have been considered during Project planning as appropriate.

City of Morgan Hill General Plan

See Section 3.4, *Biological Resources—Fisheries Resources*~~, the Aquatic Biological Resources section~~ for a description.

Project applicability: The City of Morgan Hill General Plan goals, policies, and actions have been considered during Project planning as appropriate.

City of San José General Plan

See Section 3.4, *Biological Resources—Fisheries Resources*~~, the Aquatic Biological Resources section~~ for a description.

Project applicability: The City of San José General Plan goals, policies, and actions have been considered during Project planning as appropriate.

3.5.3 Methodology and Approach to Impact Analysis

The following impact analysis evaluates impacts on biological resources that would occur as a result of the following activities:

- Seismic Retrofit Construction Impacts Analysis
- Conservation Measures Construction Impacts Analysis
- Construction Monitoring Impacts Analysis
- Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Monitoring Impacts Analysis, including Post-Construction ADSRP and FAHCE Adaptive Management Impacts Analysis

For each of these four aspects of the Project, impacts were assessed for the Seismic Retrofit Area, the Conservation Measures Project Area, and additional portions of the study area where biological resources could be impacted as described in *Habitat Conditions and Characteristic Species in Other Impact Areas* (i.e., the expanded study area). The analysis of impacts on biological resources is based on the results of the field surveys, habitat assessments, and desktop analyses conducted for biological resources and on the baseline conditions with respect to presence/absence, locations of occurrence, and abundance/extent of biological resources, as well as the life history traits of plants and animals that influence how they may be impacted by Project activities.

Impacts on biological resources were first evaluated to qualitatively describe how Project activities could adversely affect biological resources, and where applicable to quantify impacts in terms of number of individuals of certain species, or the extent of regulated habitat or special-status species habitat that could be impacted. Impacts were assessed relative to baseline conditions. For the purpose of the analysis of Seismic Retrofit and Conservation Measures Project construction impacts on terrestrial biological resources, baseline conditions are the existing conditions present at the time of EIR preparation as modified by FOCP implementation (the Existing Conditions Baseline). The effects of post-construction operations were analyzed relative to both the pre-FOCP baseline (Pre-FERC Order Baseline) and operations that would have occurred in 2035 if Valley Water were to continue operating Anderson Dam as it has done historically rather than with implementation of FAHCE measures as the Project proposes (Future Baseline).

The impact evaluation also considered whether impacts to land cover types would be "temporary" or "permanent." The VHP defines a temporary impact as "direct impacts that alter land cover for less than one year and that allow the disturbed area to recover to pre-Project or ecologically improved conditions within one year (e.g., prescribed burning, construction staging areas) of completing construction." All impacts that alter land cover for more than 1 year or that take more than 1 year, following construction, for recovery to pre-Project or improved conditions are considered by the VHP to be permanent impacts. Because the majority of Project impacts on biological resources are considered covered activities by the VHP, the VHP's definitions of temporary vs. permanent impacts are followed in this section for VHP compliance (where they apply to a land cover type). As a result, the majority of direct, construction-related impacts on land cover types are considered permanent impacts, because the duration of construction activities exceeds the 1-year duration allowed for impacts to be considered temporary. In reality, though, much of the Project Area will be restored to pre-Project or ecologically improved conditions following completion of Project construction; for example, the portions of Anderson Reservoir where construction activities would occur would be restored to their function as a reservoir following construction. As a result, these impacts are not truly long-term impacts, even though they are considered permanent for purposes of VHP compliance and consistency. Project impacts on plants and animals, rather than land cover types, are not considered permanent, for the purposes of this analysis, if the impacts are not long-term (e.g., if they occur only during construction) and they do not result in the loss of a plant or animal; for example, disturbance of animals by noise, equipment, and personnel during construction is not considered a permanent impact even if it lasts throughout the construction period.

The Project is described in the VHP as a covered activity, and the majority of Project activities are covered by the VHP. However, some Project activities are not covered, because they are explicitly excluded from VHP coverage or because they exceed thresholds that the VHP set for coverage. In addition, some impacts of the Project affect species that occur only in areas that are outside the VHP permit area. Project impacts that are not covered by the VHP are as follows:

- Dewatering of Anderson Reservoir for longer than 3.5 years—the Project would require dewatering for up to 4.5 years, so from fall of Year 5 until the reservoir refills during the wet season following Year 6 (approximately 1 year), effects on VHP-covered species of the reservoir's dewatered condition are not covered by the VHP. Activities that would be occurring within the dewatered reservoir in Year 6 include hauling of material from the Packwood Gravel Borrow Pit (PGBP) and Stockpile Area K, placement of small amounts of material in the Reservoir Disposal Area, and restoration of access roads. The reservoir would also be maintained in a dewatered condition for this additional year.
- Relocation of steelhead—Valley Water proposes a number of Conservation Measures to maintain suitable conditions for steelhead in the CWMZ throughout Project construction. However, if water levels become too low or water temperatures too high, so that steelhead relocation is necessary during Project construction, fish would be moved to a more suitable location, which may include lower Coyote Creek near its confluence with Upper Penitencia Creek or Upper Penitencia Creek within Alum Rock Park. Impacts on terrestrial biological resources that may occur during such relocation are not covered by the VHP.

- Differences in dam releases between those covered by the VHP and those that may occur during Project construction ~~and post-construction operations~~—as discussed on page 2-60 and in **Table 2-4** of the VHP, the VHP covers Anderson Dam releases during dewatering for Seismic Retrofit construction up to 550 cfs, the capacity of the current dam outlet, for dewatering during the period November 1 to April 30 and up to 50 cfs for dewatering during the period May 1 to October 31. The VHP describes these maximum releases as being associated with draining the reservoir to dewater it for construction. The VHP indicates that if dewatering flows will exceed those in **Table 2-4** of the VHP, those flows would not be covered by the VHP.

Valley Water intends to adhere to the VHP-covered release requirements when draining Anderson Reservoir for dewatering each year, at the start of the construction season (i.e., around April 15). However, wet season flows through Anderson Dam may be much higher than those discussed in the VHP, as Valley Water needs to avoid having Anderson Reservoir fill during Project construction. Prior to the completion of the Stage 2 Diversion System, flows through the existing 42-inch outlet valve plus the Anderson Dam Tunnel (constructed by the FOCP) could be as high as 2,500 cfs. After the spring of Year 2, the Stage 2 Diversion System would provide additional flow capacity from the reservoir through the diversion system to function as an emergency spillway since the dam embankment would be lowered and the existing spillway would be offline. For the Stage 2 Diversion System, flows could range from 1 cfs to 65 cfs during the dry season, and the combined capacity of all outlets could allow for releases of up to 6,000 cfs during the wet season. The VHP did not explicitly discuss the possibility that flows may exceed those in VHP **Table 2-4** during the construction period, outside actual dewatering events. Therefore, the impacts of such flows on terrestrial biological resources may not be covered by the VHP.

The VHP does not cover impacts to species associated with San Francisco Bay, so any effects of the Project on species associated with baylands habitats would not be covered by the VHP.

Regarding post-construction operational impacts, the VHP intended to cover the FAHCE Program (referred to as the Three Creeks HCP in the VHP), though in 2012 when the VHP was prepared, details of the FAHCE Program were still being developed. Pages 2-55 and 2-56 of the VHP state:

The Three Creeks Conservation Program is still under development by Valley Water; thus, while this Plan provides coverage for covered species that are affected by the activities described below, the discussions of these activities are at a programmatic level. Once the Three Creek HCP Conservation Program has been adopted the range of activities and impacts will be better understood. Therefore, for specific project impacts that cannot be evaluated, coverage under this Plan would be conditioned upon additional review and approval by the Wildlife Agencies (see Section 8.7.3). The covered activities are described to encompass as much of the activities in the Three Creeks HCP Conservation Program as is currently expected to occur.

The description of the Three Creeks HCP in the VHP (page 2-56) includes geomorphic rehabilitation, gravel enhancement, reservoir and recharge reoperation, a supplemental flow program, and a monitoring program. The supplemental flow program described in the VHP (pages 2-82) includes activities such as summer cold water releases, winter base flow releases, pulse flows, and supplemental flows (including water from alternative water sources) that are consistent with those included in the Project. Therefore, the Project's post-construction FAHCE operations are considered VHP-covered activities.

The distinction between whether an activity is or is not covered by the VHP is relevant because the VHP's conservation program was developed so that covered projects complying with VHP conditions would be offsetting their impacts—or their contribution to cumulative impacts—on VHP-covered species and habitats through VHP compliance. Therefore, VHP compliance is considered an integral part of the Project, rather than a mitigation measure, and for many impacts on terrestrial biological resources, no additional mitigation is necessary due to VHP compliance. Impacts that are not covered by the VHP were evaluated to determine whether impacts are significant, and if so whether mitigation measures are necessary to reduce any such impacts to less-than-significant levels.

After qualitative and, where applicable, quantitative analysis of an impact was performed, the impact was then evaluated with the application of Valley Water BMPs (Valley Water 2014c) and any applicable VHP conditions with which the Project would comply, including consideration of the Conservation Measures that would be implemented as a result of Valley Water's payment of VHP impact fees (e.g., population or habitat restoration, acquisition, preservation, and management). For each Project impact on biological resources, **Table 3.5-6** summarizes Valley Water BMPs to be implemented; **Table 3.5-7** summarizes applicable VHP conditions; and **Table 3.5-8** summarizes specific, applicable AMMs related to VHP Conditions 3 (*Maintain Hydrologic Conditions and Protect Water Quality*), 4 (*Stream Avoidance and Minimization for In-Stream Projects*), and 5 (*Avoidance and Minimization Measures for In-Stream Operations and Maintenance*). A determination was then made regarding whether the impact was significant (and thus requires mitigation). For impacts that would remain significant even with implementation of BMPs and compliance with applicable VHP conditions, feasible mitigation measures were identified, and the significance of the impacts was re-evaluated to determine if mitigation measures would reduce impacts to a less-than-significant level.

The following sections provide an overview of the ways in which each of the four Project components evaluated—Seismic Retrofit Construction, construction and implementation of the Conservation Measures, construction monitoring, post-construction operations, maintenance, and FAHCE adaptive management)—could impact terrestrial biological resources. These discussions are provided here to streamline the sections analyzing impacts on individual biological resources (e.g., by minimizing repetition).

3.5.3.1 Seismic Retrofit Construction and Construction Phase Drawdown

Seismic retrofit construction would necessitate considerable modification of existing land cover types at Anderson Dam and in staging, stockpiling, and access areas. This impact assessment assumes that the entire area shown as being within the Seismic Retrofit Area (Proposed Construction Footprint) on **Figure 3.5-2** would be impacted during Project construction. In addition, it is possible that construction activities may need to take place anywhere within the reservoir bed, in the area indicated on **Figure 3.5-2,** as "Anderson Reservoir Boundary (Potential Additional Seismic Retrofit Construction)." Although most of the Seismic Retrofit Area would eventually be restored to pre-Project or ecologically improved conditions after completion of the 7-year construction Project, and truly permanent impacts would therefore be limited, impacts persisting for more than 1 year to all land cover types, except urban-suburban, are considered permanent in accordance with VHP conventions.

Within the Seismic Retrofit Area, it was assumed that virtually all vegetation (including all special-status plants and vegetated habitats/communities) would be removed or substantially disturbed, and conditions for most plants and animals within that area will be lost or degraded. Construction activities would therefore result in the loss of plants and animals within the Seismic Retrofit Area. It was assumed that habitat quality would be very low to negligible within any portions of the Seismic Retrofit Area undergoing active disturbance during the 7-year duration of construction.

Table 3.5-8. Summary of Santa Clara Valley Habitat Plan-Required Aquatic Avoidance and Minimization Measures Related to Conditions 3, 4, and 5 That Are Applicable to Each Project Impact on Biological Resources

ID	Avoidance and Minimization Measure	Terrestrial Biological Resources Impact														
		TERR-1a	TERR-1b	TERR-1c	TERR-1d	TERR-1e	TERR-1f	TERR-1g	TERR-1h	TERR-1i	TERR-1j	TERR-2	TERR-3	TERR-4	TERR-5	TERR-6
General																
1	Minimize potential impacts on covered species most likely to be affected by changes in hydrology and water quality.			x	x	x					x	x	x	x		x
2	Reduce stream pollution by removing pollutants from surface runoff before the polluted surface runoff reaches local streams.			x	x	x					x	x	x	x		x
3	Maintain the current hydrograph and, to the extent possible, restore the hydrograph to more closely resemble predevelopment conditions.			x	x						x	x	x	x		x
6	Activities in the active (i.e., flowing) channel shall be avoided, or AMMs in this table shall be applied.			x	x	x					x	x	x	x		x
7	Personnel shall prevent the accidental release of chemicals, fuels, lubricants, and nonstorm drainage water into channels.			x	x	x					x	x	x			x
8	Spill prevention kits shall always be in close proximity when using hazardous materials (e.g., crew trucks and other logical locations).	x	x	x	x	x	x	x	x	x	x	x	x			x

ID	Avoidance and Minimization Measure	Terrestrial Biological Resources Impact														
		TERR-1a	TERR-1b	TERR-1c	TERR-1d	TERR-1e	TERR-1f	TERR-1g	TERR-1h	TERR-1i	TERR-1j	TERR-2	TERR-3	TERR-4	TERR-5	TERR-6
11	Vehicles shall be washed at approved areas. No washing of vehicles shall occur at job sites.	x	x	x	x							x	x			x
12	No equipment servicing shall be done in the stream channel or immediate floodplain unless equipment cannot be readily relocated.			x	x	x					x	x	x			x
13	Personnel shall use the appropriate equipment for the job that minimizes disturbance to the stream bottom.			x	x	x					x	x	x	x		x
14	If high groundwater is present in a work area, pump it out of the work site carefully to remove sediment prior to the water re-entering a creek.			x	x							x	x			x
15	Implement native aquatic vertebrate relocation plan when ecologically appropriate as determined by a qualified biologist.			x	x											x
17	Install cofferdams both upstream and downstream not more than 100 feet from the extent of the work areas.			x	x							x	x	x		x
18	Small in-channel berms that deflect water to one side of the channel may be constructed of channel material in channels with low flows.			x	x							x	x			x
20	Diversions shall maintain ambient stream flows below the diversion, with no reduction or degradation.			x	x							x	x			x

ID	Avoidance and Minimization Measure	Terrestrial Biological Resources Impact														
		TERR-1a	TERR-1b	TERR-1c	TERR-1d	TERR-1e	TERR-1f	TERR-1g	TERR-1h	TERR-1i	TERR-1j	TERR-2	TERR-3	TERR-4	TERR-5	TERR-6
21	If stream bed design changes are not part of the project, the stream bed shall be returned to as close to pre-project condition as appropriate.			x	x							x	x	x		x
22	Remove all temporary diversion structures and the supportive material no more than 48 hours after work is completed.			x	x							x	x	x		x
23	Temporary fills, such as for access ramps, diversion structures, or cofferdams, shall be completely removed upon finishing the work.			x	x							x	x	x		x
24	To prevent increases in temperature and decreases in dissolved oxygen, properly size bypass pipes or use a low-flow channel.			x	x							x	x			x
25	Diversions shall maintain fish passage under specified project conditions.			x	x									x		x
26	Any sediment removed from a project site shall be stored and transported in a manner that minimizes water quality impacts.			x	x	x						x	x	x		x
29	Existing native vegetation shall be retained by removing as much vegetation as necessary to accommodate the trail clearing width.	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

ID	Avoidance and Minimization Measure	Terrestrial Biological Resources Impact

30	Vegetation control and removal in channels, on stream banks, and along levees and maintenance roads shall be limited.	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
31	When conducting vegetation management, retain as much understory brush and as many trees as feasible.	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
32	The top of the bank shall be protected by leaving vegetation in place to the maximum extent possible.	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
33	Regional Board objectives for temperature change in receiving waters shall not be exceeded.			x	x											x
Project Design																
34	Use the minimum amount of impermeable surface (building footprint, paved driveway, etc.) practicable.	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
35	Use pervious materials, such as gravel or turf pavers, in place of asphalt or concrete to the extent practicable.	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
36	Use flow control structures such as swales, retention/detention areas, and/or cisterns to maintain the existing (pre-project) peak runoff.	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

ID	Avoidance and Minimization Measure	Terrestrial Biological Resources Impact														
		TERR-1a	TERR-1b	TERR-1c	TERR-1d	TERR-1e	TERR-1f	TERR-1g	TERR-1h	TERR-1i	TERR-1j	TERR-2	TERR-3	TERR-4	TERR-5	TERR-6
39	Minimize alterations to existing contours and slopes, including grading the minimum area necessary.	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
40	Maintain native shrubs, trees, and groundcover whenever possible and revegetate disturbed areas with local native or noninvasive plants.	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
42	Use flow-control structures, permeable pavement, cisterns, and other methods to ensure no change in peak runoff.	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
43	Assess site conditions to determine if designs such as bioengineered bank treatments with live vegetation can be successfully used.			x	x							x	x			x
44	Maintain natural stream characteristics, such as riffle-pool sequences, riparian canopy, sinuosity, floodplain, and a natural channel bed.			x	x							x	x	x		x
45	Incorporate free-span bridges that allow for upland habitat under bridges.			x	x					x		x	x	x		x
49	The project or activity must be designed to avoid the removal of riparian vegetation, if feasible.		x	x	x		x	x	x	x	x	x	x	x	x	x
51	All projects shall be conducted in conformance with applicable County and/or city drainage policies.			X	x							x	x			x

ID	Avoidance and Minimization Measure	Terrestrial Biological Resources Impact														
		TERR-1a	TERR-1b	TERR-1c	TERR-1d	TERR-1e	TERR-1f	TERR-1g	TERR-1h	TERR-1i	TERR-1j	TERR-2	TERR-3	TERR-4	TERR-5	TERR-6
52	Adhere to the siting criteria described for the borrow site covered activity (see Chapter 2 for details).	X	x	x	x	x	x	x	x	x		x	x	x	x	x
53	When possible, maintain a vegetated buffer strip between staging or excavation areas and receiving waters.	X	x	x	x		x	x	x	x	x	x	x	x	x	x
54	Outside of the construction footprint, maintain deep pools within stream reaches as refugia for fish and wildlife.			X	x											x
56	Bank stabilization site design shall consider hydraulic effects immediately upstream and downstream of the work area.			X	x							x	x			x
58	Use existing access routes/levee roads to minimize impacts of new construction in special-status species habitats and riparian zones.	X	x	x	x	x	x	x	x	x	x	x	x	x	x	x
61	Minimize ground disturbance to the smallest area feasible.	X	x	x	x	x	x	x	x	x	x	x	x	x	x	x
62	Use existing roads for access and disturbed area for staging as site constraints allow.	X	x	x	x	x	x	x	x	x	x	x	x	x	x	x
63	Prepare and implement sediment erosion control plans.	X	x	x	x	x	x	x	x	x	x	x	x	x	x	x

ID	Avoidance and Minimization Measure	Terrestrial Biological Resources Impact														
		TERR-1a	TERR-1b	TERR-1c	TERR-1d	TERR-1e	TERR-1f	TERR-1g	TERR-1h	TERR-1i	TERR-1j	TERR-2	TERR-3	TERR-4	TERR-5	TERR-6
64	No winter grading shall occur unless approved by City Engineer and specific erosion control measures are incorporated.			X	x							x	x	x		x
65	Control exposed soil by stabilizing slopes (e.g., with erosion control blankets) and protecting channels.	X	x	x	x	x	x	x	x	x	x	x	x	x	x	x
66	Control sediment runoff using sandbag barriers or straw wattles.	X	x	x	x	x	x	x	x	x	x	x	x	x	x	x
67	No stockpiling or placement of erodible materials shall occur in waterways or along areas of natural stormwater flow.	X	x	x	x	x	x	x	x	x	x	x	x	x	x	x
68	Stabilize stockpiled soil with geotextile or plastic covers.	X	x	x	x	x	x	x	x	x	x	x	x	x	x	x
69	Maintain construction activities within a defined project area to reduce the amount of disturbed area.	X	x	x	x	x	x	x	x	x	x	x	x	x	x	x
70	Clear/prepare land which shall be actively under construction in the near term.	X	x	x	x	x	x	x	x	x	x	x	x	x	x	x
71	Preserve existing vegetation to the extent possible.	X	x	x	x	x	x	x	x	x	x	x	x	x	x	x
72	Equipment storage, fueling, and staging areas shall be sited on disturbed areas or nonsensitive habitat outside a stream channel.	X	x	x	x	x	x	x	x	x	x	x	x	x	x	x
73	Avoid wet season construction.			X	x						x	x	x			x

ID	Avoidance and Minimization Measure	Terrestrial Biological Resources Impact														
		TERR-1a	**TERR-1b**	**TERR-1c**	**TERR-1d**	**TERR-1e**	**TERR-1f**	**TERR-1g**	**TERR-1h**	**TERR-1i**	**TERR-1j**	**TERR-2**	**TERR-3**	**TERR-4**	**TERR-5**	**TERR-6**
74	Stabilize site ingress/egress locations.	X	x	x	x	x	x	x	x	x	x	x	x	x		x
75	Dispose of all construction waste in designated areas and prevent stormwater from flowing onto or off these areas.	X	x	x	x	x	x	x	x	x	x	x	x	x		x
76	Prevent spills and clean up spilled materials.	X	x	x	x	x	x	x	x	x	x	x	x	x		x
77	Sweep nearby streets at least once a day.	X	x	x	x						x	x	x			x
78	In-stream projects occurring while the stream is flowing must use appropriate measures to protect water quality and native aquatic species.			X	x						x	x	x	x		x
80	All personnel working in or adjacent to the stream setback shall be trained by a qualified biologist in AMMs.	X	x	x	x	x	x	x	x	x	x	x	x	x	x	x
83	Sediments shall be stored and transported in a manner that minimizes water quality impacts.	X	x	x	x	x	x	x	x	x	x	x	x	x	x	x
84	Appropriate erosion control measures (e.g., fiber rolls, filter fences, vegetative buffer strips) shall be used onsite.	X	x	x	x	x	x	x	x	x	x	x	x	x	x	x
86	Topsoil removed during soil excavation shall be preserved and used as topsoil during revegetation, when necessary.	X	x									x	x			x

Notes:

*These measures are paraphrased from **Table 6-2** of the VHP (as revised via a minor modification dated March 17, 2016, which removed redundant measures) and are required for VHP Conditions 3, 4, and 5. This table indicates which specific AMMs pertain to each identified biological resources impact attributed to implementation of the Project.*

A blank cell indicates that the measure is not applicable to that specific biological resources impact. VHP AMMs that are not applicable to any impact mechanism attributed to implementation of the Project are not included in this table.

Key: AMM = Avoidance and Minimization Measure

In addition, some impacts would occur during construction in portions of the study area outside the immediate footprint of the Seismic Retrofit Area. Mobilization of dust would affect vegetation (including special-status plants, plants used by special-status animals, and plants comprising sensitive natural communities) immediately adjacent to or downwind from areas of earth-moving or equipment/vehicle activity. Dust may coat vegetative and floral surfaces, interfering with normal gas exchange, photosynthesis, or pollination. Drainage patterns may be altered so that areas downslope from construction areas may be subject to reduced or increased runoff; this could result in erosion, or creation of conditions too dry or too wet for certain plant species. Ground disturbance followed by periods of inactivity could improve conditions for colonization by invasive plants. Movement of earth, vegetation, water (e.g., runoff and water used for dust suppression and other construction activities), equipment, vehicles, and personnel could spread invasive plant propagules and pathogens, such as *Phytophthora*. *Phytophthora* could impair the health of plants, spreading through root systems. These invasive plants and pathogens could reduce habitat quality for special-status plants, or directly affect their health, in areas immediately outside the construction footprint.

During Seismic Retrofit construction, Anderson Reservoir would be largely dewatered, so less water would be available for release into Coyote Creek during construction than under Pre-FERC Order and Existing Conditions ~~during FOCP Construction Phase~~ Baseline conditions (i.e., existing conditions as modified by the FOCP). Valley Water would use a combination of bypassed inflow into Anderson Reservoir and imported water released through the CDL and Cross Valley Pipeline Extension to help maintain adequate water in Coyote Creek for fish (in the CWMZ) and groundwater recharge throughout the creek. In this way, Valley Water intends to maintain adequate creek flow to avoid substantial degradation of sensitive habitats due to inadequate water availability related to the Project. This combination of water sources would minimize flow-related impacts on aquatic animals, creek flow for the wetland and riparian habitats along Coyote Creek downstream from the Seismic Retrofit Area, and groundwater levels that support aquatic, wetland, and riparian habitats in North Coyote Valley. Modeling performed by Valley Water predicted that there would be a reduction in groundwater recharge and storage during Seismic Retrofit construction relative to the Pre-FERC Order baseline (when ~~interim seismic~~ restrictions limited reservoir capacity to 51,200 acre-feet but no FERC reservoir drawdown order was in effect); however, with make-up sources of water provided during ongoing construction. Groundwater storage is still predicted to be above Valley Water's 2021 Groundwater Management Plan storage target (Valley Water 2023a). Nevertheless, the impact analyses considered whether degradation of these water-dependent habitats could occur if inadequate water is available during construction, thus resulting in loss or degradation of regulated and sensitive habitats, and reduced habitat extent/quality for special-status species that rely on such habitats. The imported water used to augment creek flows may contain nonnative predatory fish and pathogens that could then affect plants and animals in Coyote Creek. However, imported water is already in use in Coyote Creek, and thus the impact analyses assume that no new nonnative animals or pathogens would be introduced from imported water for the Project.

Changes to the dam's outlets and compliance with FERC's order to leave dam outlets open until completion of ADSRP construction to maintain deadpool may also result in increases in wet weather flows downstream from the dam during construction (Valley Water 2022c ~~2022d~~) relative to Pre-FERC Order Baseline and Existing Conditions Baseline conditions, which for construction-period flows are represented by existing conditions at the time of EIR preparation modified by FOCP implementation. The pre-FOCP Anderson Dam outlet valve has a maximum flow capacity of 500 cfs. The ADTP—a component of the FOCP—would install the Stage 1

Diversion Outlet, which is capable of releases from Anderson Reservoir up to 2,000 cfs (in addition to the existing 500 cfs outlet). Thus, Pre-FERC Order Baseline Conditions allows for releases from the dam of 500 cfs, and Existing Conditions Baseline conditions for Seismic Retrofit construction allow for releases from the dam of up to 2,500 cfs. After the spring of Year 2, the Stage 2 Diversion System would provide additional flow capacity from the reservoir through the diversion system to function as an emergency spillway since the dam embankment would be lowered and the existing spillway would be offline. For the Stage 2 Diversion System, flows could range from 1 cfs to 65 cfs during the dry season, and the combined capacity of all outlets would allow releases of up to 6,000 cfs during the wet season. These flows are described in detail in the *Biological Resources—Fisheries Resources* section of the EIR.

The magnitude of flow, and frequency of flows of a certain magnitude, would depend on rainfall amounts during individual runoff events and Coyote Reservoir releases. Valley Water (2022c ~~2022d~~) predicts higher flows during construction because outlets would be left wide open, so that Anderson Reservoir is not detaining water. At their maximum, such flows could be as high as approximately 6,000 cfs, which represents the maximum capacity of all dam outlets that will be present. However, a 6,000-cfs flow during Seismic Retrofit construction has a very low probability of occurring, as it would represent a 200-year event (with a 0.5 percent likelihood of occurring in any given year). The higher the flow, the lower the probability and frequency of that flow occurring in any given year, so that very high flows, greater than the 10-year or 20-year events, are unlikely during the project construction period, though possible. The 10-year event has a 10 percent likelihood of occurring in any given year, and the 20-year event has a 5 percent likelihood of occurring in any given year.

Higher release rates during the construction period could result in erosion, deposition of sediment (from the reservoir bed and from material eroded from the Coyote Creek bank downstream from Anderson Dam), and scour of riparian vegetation along the creek channel. However, the magnitude of such flows during the construction period would more closely resemble a non-dam (or pre-dam) hydrologic situation more than the existing dam-in-place Pre-FERC Order Baseline or Existing Conditions Baseline condition does, and therefore represent conditions under which the plant and animal communities in and along Coyote Creek downstream from Anderson Dam had experienced historically prior to the dam's construction.

Although large flow events could modify riparian vegetation in the short term, they can also create floodplain inundation and open habitat along the channel edge conducive to germination of riparian vegetation. The dominant riparian trees along Coyote Creek, such as cottonwoods, willows, and sycamores, can become established only in areas that provide bare sediment, with no existing canopy providing shade, close enough to the water table to allow for these species to become established and grow roots that can tap into groundwater. In the absence of high flows and mobilization of sediment there are no suitable areas for riparian tree germination. Existing trees can continue to grow and mature, but the result is a mature, senescent riparian forest that lacks substantive regeneration. It takes the scour of vegetation (to reduce shading) or the creation of new bars or low shelves of bare sediment to create the conditions suitable for cottonwoods and willows to germinate, so that the riparian corridor has trees of a variety of ages. This uneven-aged stand structure creates diverse habitat conditions that helps to support high riparian animal diversity. These effects of higher flows were observed when Anderson Reservoir spilled in February 2017. Riparian trees and shrubs in some areas along Coyote Creek downstream were lost due to scour, but those areas were immediately colonized by cottonwood and willow seedlings, and within a few years, there were dense thickets of riparian shrubs and young trees that provided different microhabitat conditions from the more mature trees farther from the channel, enhancing animal diversity in those areas.

Flooding, scour, and sediment mobilization are also important for the regeneration of California sycamore and sycamore alluvial woodland, a scarce and declining plant community in the region. Although sycamores can thrive with limited summer water and intermittent flows, they become established only under certain conditions. A recent study of the conditions associated with distribution, health, and regeneration of sycamores along upper Coyote Creek and Pacheco Creek determined that sycamores need flood events large enough to either move cobbles or to remove finer sediment overlaying cobbles on floodplain terraces, and to remove any shading overhead, as most of the younger sycamores observed in this study were in areas dominated by herbaceous vegetation and/or in cobbly substrates (San Francisco Estuary Institute-Aquatic Science Center and H. T. Harvey & Associates 2017). High flows that carry seeds, deliver sediment, and inundate floodplains play a key role in sycamore regeneration.

The creek has been largely "starved" of sediment due to the presence of the dam and the accumulation of sediment behind the dam. The insufficient sediment input and the infrequency of high flow events due to the dam's presence have limited natural stream erosion and sedimentation processes and have limited the regeneration of species such as cottonwoods and willows that rely on bare sediment along stream channels for germination. As a result, following potential initial loss of wetland and riparian habitat due to increased construction-period wet season flows, erosion, and sedimentation, flows during the construction period may improve the regeneration of riparian vegetation over the long term and help sustain high-quality habitat conditions.

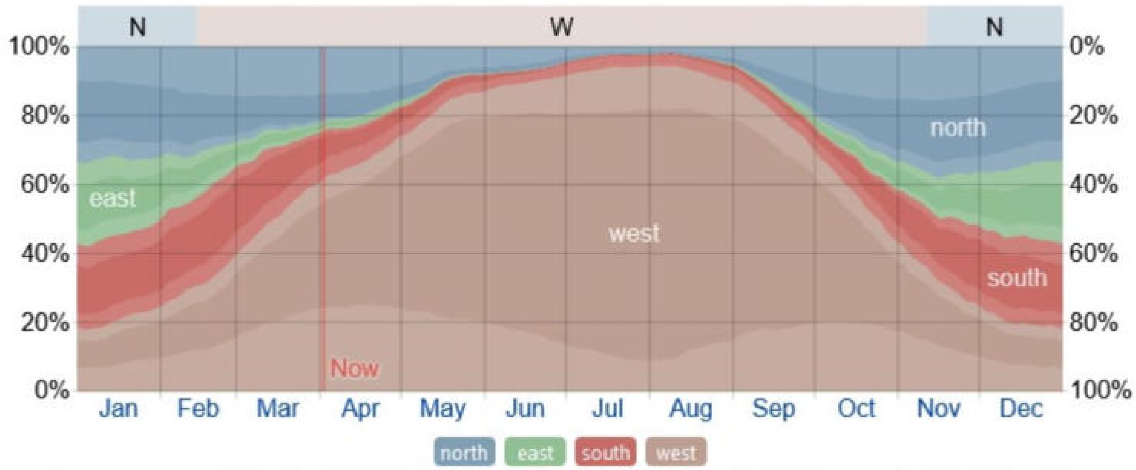
Animals present in and along Coyote Creek downstream from Anderson Dam could be displaced by flows that are higher than Pre-FERC Order Baseline and Existing Conditions Baseline winter flows; as discussed previously, flows during storm events could increase during construction. Because wet season high-flow events will ramp up naturally, individuals close enough to the creek to be affected by high flows are expected to be able to emerge and move to higher ground in response to rising water levels. Such displaced individuals may be subject to increased injury or mortality due to predation attempts.

Considerable sediment has accumulated in the bed of Anderson Reservoir since construction of the dam. When this sediment is covered by water, as under normal conditions when the reservoir is filled, it is not easily eroded. However, when the reservoir has been dewatered, these sediments will be more subject to erosion from rainfall runoff and from the reservoir's tributaries. Because the reservoir's outlets will be left open during the wet season to minimize the amount of water that accumulates in the reservoir bed, considerable sediment is predicted to be mobilized downstream from the dam during the Project. This increase in sediment mobilization will result from both the exposure of sediments under certain flows and the higher flow rates through the dam during construction. Modeling concluded that the maximum sediment mobilization will occur if back-to-back 2-year rainfall events (i.e., events that have a 50 percent likelihood of occurring in any given year), or a single 5-year event (20 percent likelihood of occurring in any given year), were to occur when relatively little water was present in the reservoir (URS ~~AECOM~~ 2021). During those events, flows would be high enough to erode large amounts of sediment from the reservoir (approximately 167,000 tons per event) but not so high as to inundate the reservoir to a higher water level than the bed sediment, which would reduce their erosivity. Sediment transport will result in changes to habitat conditions in and along the

Coyote Creek channel all the way downstream to tidal areas, including deposition of sediment in tidal habitats. However, given that the creek has limited sediment due to the dam and the accumulation of sediment behind the dam, the small amounts of sediment input and the infrequency of high flow events due to the dam's presence have limited natural stream erosion and sedimentation processes and have limited the regeneration of species, such as cottonwoods and willows that rely on bare sediment along stream channels for germination. Mobilization of sediment to Coyote Creek downstream from Anderson Dam will benefit riparian plant species. In addition, such sediment will facilitate accretion of tidal marshes along the lowest tidal reach of Coyote Creek. Such marshes need sediment inputs to be able to maintain suitable elevations for vegetation in the face of sea level rise, and restoration of managed ponds to tidal habitats (e.g., by the South Bay Salt Pond Restoration Project) depends on accretion of sediment in restored tidal habitats to achieve the appropriate elevations for the colonization of marsh vegetation.

Seismic retrofit construction would involve considerable activity of equipment and vehicles that emit nitrogen compounds as a by-product of fuel combustion. Nitrogen deposited on nutrient-poor soils, such as those derived from serpentinite, essentially fertilizes those soils, allowing nonnative grasses and forbs that would not otherwise be able to colonize (at least robustly) those serpentine soils to become established. As a result, nitrogen deposition can remove the competitive advantage that native, special-status, serpentine-associated plants have over nonnative species that are not adapted to dry, shallow, nutrient-poor serpentine soils. The effects of nitrogen deposition occur primarily downwind of the emission source, as wind carries nitrogen from the source to the area where it is deposited (Weiss 1999). In the Anderson Dam area, winds during the primary construction season (April through October) are predominantly from the west or northwest (WeatherSpark 2022; ~~**Figure 3.5-10**~~ **Figure 3.5-11**). Therefore, most of the nitrogen emitted during Project construction activities would be carried toward the east or southeast. Serpentine-associated plants, animals, and communities downwind from construction activities could be affected by deposition of nitrogen emitted by Seismic Retrofit activities, in combination with nitrogen emissions from other regional sources. Assessment of impacts from Project construction-related nitrogen emissions on serpentine communities and species (or more accurately, the Project's contribution to cumulative impacts of nitrogen emissions) therefore take into account the locations of those serpentine resources relative to the Seismic Retrofit Area. Nitrogen deposition resulting from Seismic Retrofit construction is unlikely to have a substantial impact on plants or communities not associated with serpentine, and this impact is thus not assessed for non-serpentine-related species and communities.

Figure 3.5-11. ~~3.5-10~~ Summary of Prevailing Winds in the Morgan Hill Area by Month.



The percentage of hours in which the mean wind direction is from each of the four cardinal wind directions, excluding hours in which the mean wind speed is less than ***1.0 mph****. The lightly tinted areas at the boundaries are the percentage of hours spent in the implied intermediate directions (northeast, southeast, southwest, and northwest).*

Source: WeatherSpark (2022)

The 2020 FERC Order required Valley Water to maintain the Anderson Reservoir surface water no higher than elev. 565 feet effective at the time of the FERC order in February 2020 and draw down the reservoir surface water to elev. deadpool beginning no later than October 1, 2020. It has been suggested by some local residents that this drawdown of Anderson Reservoir facilitated the expansion of feral pigs into residential areas west of the reservoir. In addition to damaging lawns, landscaping, and golf courses, feral pigs can have ecological impacts on sensitive resources by rooting through sensitive habitats, such as wetlands and consuming special-status plants and even special-status animals, possibly including the California red-legged frog, San Francisco dusky-footed woodrat, and others.

There is no evidence that the distribution of feral pigs was affected substantially by the FERC-ordered drawdown, or that dewatering or other effects of the Seismic Retrofit would further facilitate expansion of feral pigs. As discussed under *Invasive Species* above, County Parks has been managing pigs on its lands since 1994 (https://parks.sccgov.org/feral-pigs); this species' populations have been increasing throughout the region over the past several decades, and feral pigs are occurring in more areas, more regularly, and in greater abundance throughout the South Bay as a result, irrespective of the drawdown of Anderson Reservoir. As a result, feral pigs have caused damage to private property and residential neighborhoods throughout the region, including neighborhoods in Almaden Valley, Coyote Valley, Evergreen, Guadalupe Mines, Metcalf, Santa Teresa, and Silver Creek districts of San José in addition to neighborhoods near Anderson Reservoir. Relative to the Pre-FERC Order Baseline and Existing Conditions Baseline, further dewatering of the reservoir during Project construction could possibly make it easier for individual pigs to move from the east side of the reservoir to the west side. However, large numbers of pigs are already present in areas all around the reservoir, and along Coyote Creek downstream from the dam. Because most feral pigs are averse to humans and human activity, the level of activity of construction personnel, vehicles, equipment, and noise in the Seismic Retrofit Area could even encourage pigs to move away from the Seismic Retrofit Area during construction and discourage dispersing pigs from lingering in the Project vicinity. Therefore, the

Seismic Retrofit would not result in a substantial increase in feral pig activity or numbers in or near the Project Area, or in facilitation of pig dispersal into new areas where they are not already present under Existing Conditions Baseline conditions. For this reason, potential impacts of the Project related to feral pig distribution are not discussed further in the EIR impact analyses.

3.5.3.2 Conservation Measures Project Construction and Construction Phase Operation

Most of the Project's Conservation Measures are intended to implement FAHCE Phase 1 nonflow measures and therefore are focused on benefiting steelhead and other fish. These measures would have both adverse and beneficial effects on the terrestrial biological resources addressed in this chapter.

Conservation Measures include normal operation of Coyote Reservoir. Because there would be no change to the operation of Coyote Reservoir, and therefore releases of water into the reach of Coyote Creek between Coyote Dam and the upper end of Anderson Reservoir would continue, no impacts on biological resources, relative to the Pre-FERC Order or Existing Conditions Baseline, would occur in Coyote Reservoir or in the reach of Coyote Creek between reservoirs. Other construction phase FOCP and/or Project Conservation Measures include the bypass of Anderson Reservoir inflow into the Coyote Creek channel downstream from Anderson Dam, supplementation of creek flow within the FCWMZ with imported water (up to 10 cfs of which may be passed through chillers as necessary) released at the upper end of the CWMZ through the CDL, and supplementation of creek flow downstream from the Ogier Ponds through the Cross Valley Pipeline Extension. These releases would help more reaches of Coyote Creek stay wetted, enable recharge of the Coyote Valley and South San José areas throughout the construction period, and support the maintenance of aquatic habitats for wildlife and riparian vegetation. Although imported water may contain nonnative predatory fish and pathogens, imported water is already in use in Coyote Creek, and thus no new nonnative animals or pathogens would be introduced from imported water through the Project.

The Ogier Ponds CM would restore creek flows to approximately 6,500 linear feet of the pre-1997 creek channel along the southwest side of the pond complex and separate the Ogier Ponds from Coyote Creek. This Conservation Measure would result in substantial modifications of existing land cover types within a portion of the Ogier Ponds complex, including fill of existing open water and wetland habitats and removal of wetland and riparian vegetation. As a result, several plant and animal species would be subject to adverse effects during construction. However, this Conservation Measure would also restore and create extensive wetland, aquatic, and riparian habitat, and would provide long-term benefits to many sensitive habitats and animal species.

~~The Anderson Dam Outlet North Channel Extension component involves the extension of the North Channel of Coyote Creek to more effectively connect it to the South Channel, elimination of existing pools that could result in fish stranding, establishment of a sediment injection point for the placement of 500 cy of sediment to enhance fish habitat downstream, and native habitat revegetation. As described for Ogier Ponds activities above, the North Channel Extension and Habitat Enhancements would modify existing land cover types, thus impacting existing aquatic and riparian habitats/vegetation and animal species that use those habitats, during construction, but this measure would create riparian habitat and longer-term benefits to aquatic~~

~~and riparian plant and animal species. The Conservation Measures also include implementation of additional sediment augmentation to enhance spawning gravel in Coyote Creek for steelhead, and to improve fish rearing habitat. This measure could result in minor, temporary impacts on aquatic species such as western pond turtles, but the longer-term, net effect would be an increase in instream habitat diversity, and likely an increase in aquatic invertebrate populations, thus increasing prey for a variety of aquatic and terrestrial animals.~~

The Phase 2 Coyote Percolation Dam CM involves improvements to the dam to enhance fish passage. This measure would impact existing aquatic and riparian habitats/vegetation and animal species that use those habitats during construction, and, while it will benefit fish species, it is unlikely to provide a substantive benefit to terrestrial species or communities in the long-term.

During and after completion of Project construction, Valley Water would continue to maintain the wetland bench, restoration plantings, and flow capacity within the North Channel Reach, as well as the instream habitat enhancements in the Live Oak Restoration Reach, that were implemented as part of the FOCP and FOCP's HMMP. Maintenance would include regular monitoring to ensure the integrity of these reaches, clearing of the channel if flows are compromised, and maintenance of instream habitat structures. This maintenance could result in minor, temporary impacts on aquatic species such as northwestern pond turtles and California red-legged frogs, but the net effect would be the maintenance of the stream, wetland, and riparian restoration performed by the FOCP, thus helping to maintain high-quality habitat.

Implementation of the ~~Live Oak Restoration Reach and~~ Sediment Augmentation Program CM~~s~~ will involve initial placement of 500 cy of coarse sediment and gravel within the Live Oak Restoration Reach, and replenishment every five years of up to 500 cy ~~of couarse sediment and gravel within Coyote Creek in~~ within the Live Oak Restoration Reach and/or ~~near and within~~ the new channel created by the Ogier Ponds creek/pond restoration CM. ~~These~~ This CM~~s~~ will enhance steelhead spawning and rearing habitat, as well as the geomorphic conditions and channel substrate within the Coyote Creek CWMZ. ~~These CMs~~ This CM will benefit the terrestrial habitat and species as described above by periodically introducing sediment into reaches of Coyote Creek deprived of sediment by the ongoing existence of Anderson Dam.

Finally, the Conservation Measures include payment of VHP impact fees, which will be used by the VHA to implement the overall VHP conservation program. The conservation program includes the acquisition, preservation, and management of extensive habitat areas; creation and restoration of wetlands, ponds, and sensitive habitats; and other specific conservation activities focused on enhancement and management of sensitive habitats and VHP-covered species. Payment of VHP impact fees and compliance with other VHP conditions would provide adequate mitigation for the impacts of VHP-covered activities on VHP-covered species. In addition, payment of VHP impact fees would contribute to the conservation of many non-VHP-covered species that occur within the VHP permit area through habitat protection and management.

3.5.3.3 Construction Monitoring

The construction monitoring component of the Project includes measures to monitor the effects of the Project on the environment and reduce those effects through avoidance and minimization of impacts. Construction monitoring includes monitoring of stream flow and water quality; suspended sediment; sediment deposition; and steelhead habitat quality, conditions, migration, migration flows, spawning, and juvenile rearing in Coyote Creek downstream from Anderson Dam. These measures would involve small numbers of people visiting sites throughout the Seismic Retrofit and Conservation Measures Project Areas. Those workers, including their vehicles and equipment, may result in minor, localized, and temporary disturbance of aquatic, wetland, and riparian habitats; vegetation; and special-status species, such as the northwestern pond turtle during monitoring. However, such monitoring would help minimize impacts on biological resources during construction by identifying adverse effects requiring remediation.

Steelhead may need to be moved to Coyote Creek near its confluence with Upper Penitencia Creek and/or the reach of Upper Penitencia Creek in Alum Rock Park. Relocation of steelhead to lower Coyote Creek would not impact non-fish special-status species, as that urban segment of creek does not support such species aside from low densities of northwestern pond turtles. However, Upper Penitencia Creek supports California red-legged frogs and foothill yellow-legged frogs, and relocation of fish could result in increased competition for prey and possibly mobilization of amphibian pathogens or the invasive New Zealand mud snail (*Potamopyrgus antipodarum*), which can reach such high densities as to adversely affect stream productivity and food webs for native species. During dewatering activities, aquatic species (which may include fish, northwestern pond turtles, and native amphibians) would be relocated as necessary to minimize loss of individuals.

Groundwater monitoring would help determine whether flow augmentation using Coyote and Anderson Reservoir bypassed flows and imported water is adequate to maintain groundwater levels, minimizing adverse effects of changes in groundwater levels on aquatic, wetland, and riparian habitats (and associated species) along Coyote Creek downstream from Anderson Dam and in North Coyote Valley. In addition, continued implementation of the Wetland and Riparian Habitat Dryback Monitoring Plan (Valley Water 2020f ~~2020j~~) throughout Seismic Retrofit construction would help identify any adverse effects that creek dryback may be having on these habitats. If any adverse dryback conditions are noted, Valley Water would augment creek flow if feasible, and Valley Water would pay impact fees to compensate for any loss of wetland or riparian habitat that can be attributed to reduced creek flows due to Seismic Retrofit construction.

Implementation of the Invasive Species Monitoring and Control Plan prepared for the FOCP (Valley Water 2020g ~~2020f~~) would continue throughout Project construction. Continued implementation of this plan would result in a net reduction in invasive animals relative to Existing Conditions Baseline conditions, thus reducing the adverse effects of invasives on native reptiles and amphibians. Similarly, Valley Water would develop and implement management and monitoring plans for *Phytophthora*, building upon the *Phytophthora* Pathogen Management Plan and the Post-Project *Phytophthora* Monitoring Plan prepared for the FOCP (Valley Water 2020h, 2021e ~~2021c~~) and lessons learned during the FOCP. This would help protect sensitive plant species and communities from the adverse effects of *Phytophthora* by minimizing the spread of this pathogen.

During Project construction, Valley Water would also continue to implement the plan for monitoring northwestern pond turtles that was developed for the FOCP (Valley Water 2020d ~~2020i~~). Monitoring of northwestern pond turtles along Coyote Creek from Anderson Dam downstream to the Coyote Percolation Pond/Parkway Lakes area, and at the Ogier Ponds, would help determine whether Project construction is causing a substantial decline in this species' abundance. Continued implementation of the Milkweed Survey Plan ~~milkweed monitoring plan~~

prepared for the FOCP (Valley Water 2020i ~~2020g~~), unless and until the monarch butterfly is added to the VHP as a covered species, would also minimize direct impacts on monarch butterflies and their larval host plants. Valley Water would also continue to conduct surveys for several other terrestrial animal species that occur during the FOCP. Such surveys include annual surveys for nesting bald eagles and golden eagles, and annual monitoring surveys at a pallid bat roost near Anderson Dam. In addition, implementation of the FOCP Crotch's Bumble Bee Avoidance Plan (Valley Water 2024a) would continue during Project construction, unless and until the Crotch's bumble bee is added to the VHP as a covered species or is no longer legally protected.

3.5.3.4 Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Adaptive Management

Seismic Retrofit

Post-construction operations and monitoring for the Seismic Retrofit are related primarily to maintenance of Anderson Dam, implementation of flows for the benefit of steelhead, and monitoring of the effectiveness of those flows for steelhead conservation. These Project components include operation of Anderson Dam using the FAHCE operational rule curves to guide the timing and magnitude of flows released from Anderson Dam, storage of imported water in Anderson Reservoir, implementation of new outlet works that allow for releases of cooler water to Coyote Creek, and the Cross Valley Pipeline Extension ~~CVPE~~ outlet south of Ogier Ponds for additional imported water releases.

Due to elimination of DSOD and FERC elevation restrictions on water storage in Anderson Reservoir, water levels in the reservoir will be maintained at higher elevations than Pre-FERC Order Baseline conditions. Because the reservoir will refill following Seismic Retrofit construction, plants such as San Francisco collinsia and Coyote ceanothus seedlings that have expanded into the drawn-down reservoir, as well as other vegetation, will be inundated when Anderson Reservoir refills following Seismic Retrofit completion. Terrestrial animals that have been using the bed of the reservoir under drawdown conditions will be displaced. However, the maximum elevation of water levels will be the same as those prior to DSOD restrictions, and therefore, habitat conditions within the reservoir will simply return to those that were in place for decades prior to enforcement of those restrictions.

The FAHCE rule curves are intended to provide suitable spawning and rearing habitat within the Coyote Creek watershed, providing adequate passage for adult steelhead and salmon to reach suitable spawning and rearing habitat, and for the out-migration of juveniles. The FAHCE rule curves provide winter base flows, pulse flows, and summer base flows to support each life stage, and provide a framework for ramping flows and reservoir operations under low-flow conditions. Winter base flows would be adequate to provide between 5 cfs and 26 cfs of winter base flow at the Madrone stream gage November 1 – April 30 depending on the level of combined storage within Anderson and Coyote Reservoirs, which is primarily determined by local precipitation conditions; spring pulse flows would entail up to two releases of 50 cfs for a period of 5 consecutive days, carried out between February 1 – April 30; and summer base flows would target maintaining a water temperature not to exceed a daily average of 64.4°F (18°C) in the CWMZ, and, after completion of the Ogier Ponds CM, in as much of the FCWMZ as possible. Flows would be ramped up and down to allow aquatic animals to adapt to changing flows.

Post-construction flows based on FAHCE releases were analyzed in comparison to the Pre-FERC Order Baseline, representing the way Valley Water has historically managed Anderson Dam releases, and the WEAP-modeled Future Baseline conditions, representing how Valley Water would likely manage Anderson Dam releases in the absence of FAHCE but accounting for future water demand and imported water availability (Valley Water 2022c ~~2022d~~). In general, FAHCE flows entail slightly lower flow in winter and summer, due to retention of water in the reservoir for spring pulse flows, than conditions under the Pre-FERC Order and Future Baselines, punctuated by the spring pulse flows described above. However, the effects of such changes may differ in different parts of Coyote Creek. As indicated in Figure P-CO.1 of Appendix F (Biological Resources – Fisheries Technical Appendix), FAHCE operations would likely result in lower creek flows than the Pre-FERC Order Baseline and Future Baseline from May through November and lower flow than the Pre-FERC Order Baseline (but similar conditions to the Future Baseline) from late February through April, in the downstream portion of the CWMZ. However, in the upstream portion of the CWMZ, FAHCE operations are expected to produce higher flows from May through October than under the Pre-FERC Order and Future Baselines (see Figure P-CO.2 of Appendix F). Overall, the frequencies of flows of a given magnitude are predicted to be slightly lower under the FAHCE rule curves than the Pre-FERC Order Baseline. FAHCE flows are predicted to be slightly greater than Future Baseline flows. How such changes in flow, relative to the baseline conditions, affect terrestrial biological resources varies by species and habitat. Maintaining cooler temperatures in the CWMZ, relative to baseline conditions, could reduce habitat suitability for northwestern pond turtles and cause them to spend more time basking.

Releases to Coyote Creek during normal dry season operations of Anderson Reservoir would range from 2 to 90 cfs through the bypass pipeline, which would flow to the South Channel of Coyote Creek. During normal wet season operations, the LLOW could release up to 1,540 cfs when the reservoir is full in order to follow the flood risk reduction rule curve. The HLOW would not be operated during normal operating conditions. Instead, it would be used in the event of an emergency to make controlled emergency releases up to 5,300 cfs. As noted above, the differences between post-construction and either Pre-FERC Order or Future Baseline flows would not be so different from historical operations as to result in substantive impacts on terrestrial biological resources.

From October through April, post-construction water temperatures in the CWMZ would not differ from the Pre-FERC Order or Future Baseline (see Figure P-CO.3 and Figure P-CO.4 in Appendix F). In summer, post-construction base flows would target maintaining a water temperature not to exceed a daily average of 64.4°F (18°C) in the CWMZ and, after completion of the Ogier Ponds CM, in as much of the FCWMZ as possible, which would differ from the Pre-FERC Order and Future Baselines. As depicted in Figure P-CO.3 and Figure P-CO.4 in Appendix F, the difference between FAHCE water temperatures and baseline temperatures varies considerably among locations within the CWMZ, and in some locations, differences can be as great as 5-10°F. In most locations, however, the difference would be only 2-4°F.

In addition, Valley Water would maintain all Project-constructed features and facilities to ensure their proper function. Maintenance activities will primarily impact land cover types and areas that have already been subject to Project construction-related impacts, and that are considered permanently impacted for VHP compliance purposes, so additional impacts on biological resources from maintenance would be minimal. Valley Water would maintain the newly retrofitted Anderson Dam and Reservoir per Valley Water's existing DMP. Maintenance of

Anderson Dam facilities was previously evaluated in the Final DMP Program EIR prepared in January 2012 (SCH No. 2011082077; Valley Water 2012). The DMP includes BMPs and mitigation measures to reduce biological resources impacts. For biological resources impacts, the Project's post-construction maintenance activities would not differ substantially from those impacts identified in the DMP EIR. Furthermore, previously identified DMP impacts would not be exacerbated with implementation of the Project.

Conservation Measures

The Conservation Measures focus on improving fish habitat (e.g., Maintenance Activities at the North Channel Reach and Live Oak Restoration Reach and Sediment Augmentation Program gravel augmentation, ~~North Channel Extension,~~ separation of Coyote Creek from Ogier Ponds, fish passage enhancement at the Phase 2 Coyote Percolation Pond). Operations and maintenance of these fish habitat improvements would have minor adverse effects but net benefits on terrestrial biological resources. For the ~~North Channel Extension and~~ Ogier Ponds CM, operations and maintenance would include vegetation management, vegetation restoration, and inspection and repair of the channel, berms, weirs, habitat enhancement, and erosion protection. Maintenance of the North Channel ~~Extension~~, Live Oak Restoration Reach, and ~~the~~ Ogier Ponds Conservation Measure will be covered under the SMP and SMP EIR. Maintenance of ~~for~~ the North Channel Reach ~~Extension and Habitat Enhancement component~~ would further include removal of debris or vegetation from the channel, and possibly dewatering and grading of the channel, if necessary, so that the channel maintains positive drainage (to avoid fish stranding). Maintenance of gravel augmentation would include inspection and placement of additional gravel/sediment in those amounts necessary to replenish 500 cy within Coyote Creek in the Live Oak Restoration or Ogier Ponds reaches.

At the Phase 2 Coyote Percolation Dam CM, maintenance would include periodic removal of sediment, vegetation management, repair of rock slope protection, and replacement of any in-channel bio-engineered habitat enhancements, as needed. Valley Water would maintain the Phase 2 Coyote Percolation Dam ~~r~~per Valley Water's existing DMP. Maintenance of the percolation dam was previously evaluated in the Final DMP Program EIR prepared in January 2012 (SCH No. 2011082077; Valley Water 2012). The DMP includes BMPs and mitigation measures to reduce biological resources impacts. For biological resources impacts, the percolation dam post-construction maintenance activities would not differ substantially from those impacts identified in the DMP EIR. Furthermore, previously identified DMP impacts would not be exacerbated with implementation of the Project.

In general, Conservation Measure components maintenance activities would result in the same types of impacts as described previously for construction activities. However, the magnitude of those impacts would be much lower for maintenance, as repairs and maintenance would be required infrequently and in more limited, localized areas than the initial construction. Furthermore, these activities would be necessary to allow these facilities to continue to operate effectively as described for post-construction operations of Seismic Retrofit and CM components, thereby benefiting aquatic and amphibious species using these facilities.

As discussed for Seismic Retrofit Construction above, there is no expectation that operation or maintenance of Conservation Measures following Project completion will facilitate dispersal of feral pigs into areas where they are not currently present, or in increases in populations of pigs.

Project and FAHCE Adaptive Management

The FAHCE AMP, outlined in Section 6.2 of the FHRP in accordance with the FAHCE *Settlement Agreement* (2003), would guide adaptive management of all post-construction operations and all non-flow fish barrier remediation and habitat restoration Conservation Measures that have met their specified success criteria, as defined through the regulatory permitting process. Based on the FAHCE AMP, a project-specific Project and FAHCE AMP (see Appendix D for details) has been developed in accordance with the framework described in the FAHCE Settlement Agreement and FAHCE Program. Implementation of the Project and FAHCE AMP is designed to satisfy the measurable objectives defined in the FAHCE Settlement Agreement, the FAHCE FHRP, and Appendix D, and to assure the long-term management and effectiveness of ADSRP CMs to benefit steelhead and Chinook salmon.

The Project and FAHCE AMP includes four key elements: measurable objectives, monitoring, adaptive actions, and reporting. The AMP monitoring program is designed to track progress toward achieving the measurable objectives in Coyote Creek. These key elements would be tracked and implemented for all Conservation Measures and all FAHCE measures through the AMP.

The Project and FAHCE AMP consists primarily of monitoring and the determination of what incremental modifications of Project activities need to be made to achieve measurable objectives for fish species. Considerations for adaptive management decision making include inter-annual and seasonal variation in hydrologic conditions, other constraints and limiting factors affecting achievement of the overall management objectives, monitoring results of the actual habitat enhancement measures already implemented, opportunities for improving habitat for other fish, wildlife, and plant species, and more generally, the ecological conditions of the watersheds. Data and analysis from compliance, validation, effectiveness, and long-term trend monitoring, evaluated using measurable objectives, would help determine whether refinements need to be made to post-construction operations reservoir releases, fish passage projects or habitat restoration projects carried out as part of the Project to incrementally improve instream fisheries habitat conditions.

Impacts of monitoring activities on terrestrial biological resources would be minor, and similar to the impacts of construction monitoring. Small numbers of people would be visiting sites throughout the Seismic Retrofit and Conservation Measures Project Areas. Those workers, including their vehicles and equipment, may result in minor, localized, and temporary disturbance to aquatic, wetland, and riparian habitats; vegetation; and special-status species, such as the northwestern pond turtle during monitoring.

Adaptive management measures may refine Anderson Dam flow releases and implemented habitat restoration and fish barrier remediation Conservation Measures when they are not functioning as intended or not meeting measurable FAHCE objectives. Refinements would likely have impacts similar to those discussed for Conservation Measure construction and post-construction operations of Anderson Dam. These are considered here at a programmatic level, because the detailed characteristics, timing, and/or locations of adaptive measures are not known at the time of EIR preparation. Project-specific CEQA review would be undertaken in the future, as necessary, when specific adaptive measures are proposed and necessary details are available.

As described in **Table 2-1** *Project Components*, implementation of a Geomorphic Flows Plan would occur as part of future adaptive management under the Project and FAHCE AMP and will require additional CEQA assessment andregulatory approvals. In general, the geomorphic flows would include infrequent high flows sufficient to scour sediment, erode banks, scour vegetation, and result in channel migration in localized areas, which would maintain and increase both aquatic and riparian habitat complexity, reduce non-native invasive species, and increase benthic macroinvertebrate production, benefitting a variety of mammals, birds, reptiles, amphibians, and invertebrates.

3.5.3.5 Thresholds of Significance

Based on guidance from *CEQA Guidelines* Appendix G, implementation of the Project would have significant impacts on terrestrial biological resources if it were to:

> **TERR-1:** Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFW or USFWS
>
> **TERR-2:** Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by CDFW or USFWS
>
> **TERR-3:** Have a substantial adverse effect on State or federally protected wetlands (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means
>
> **TERR-4:** Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites
>
> **TERR-5:** Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance
>
> **TERR-6:** Conflict with the provisions of an adopted HCP, NCCP, or other approved local, regional, or state HCP

Specifically, the significance criteria used for the analysis of impacts on terrestrial biological resources are:

- Substantial adverse effects on the following categories of terrestrial biological resources:
  - special-status plants
  - special-status invertebrates
  - special-status amphibians
  - northwestern pond turtle
  - bald eagle and golden eagle
  - breeding special-status birds
  - nonbreeding special-status birds
  - pallid bat

  - other special-status mammals
  - special-status species associated with San Francisco Bay
  - riparian habitats or other sensitive natural communities
  - federally regulated or State-regulated wetlands or other jurisdictional waters
- Substantial interference with wildlife movement or use of native wildlife nursery sites
- Any conflict with local policies or ordinances protecting biological resources
- Any conflict with the provisions of an adopted HCP, NCCP, or other approved local, regional, or state HCP

3.5.4 Impact Analysis

***Impact TERR-1: A substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFW or USFWS Service* (Significant and Unavoidable)**

The following impact analysis describes the Project's impacts on special-status species. The analysis is organized by species or groups of species and is based on the information in **Table 3.5-4** and **Table 3.5-5**. Species that are not listed in those tables as occurring in the study area are not analyzed below as they would not be impacted by the Project.

***Impact TERR-1a: Special-Status Plants* (Less than Significant with Mitigation)**

Seismic Retrofit Construction

Surveys have identified four special-status plant species present in the proposed construction footprint of the Seismic Retrofit Area (see **Figure 3.5-2**) under Existing Conditions Baseline conditions: Coyote ceanothus, smooth lessingia, woodland woollythreads, and most beautiful jewel-flower (Valley Water 2012a, 2014a, 2014b, 2021a ~~2021f~~; **Figure 3.5-8** and **Figure 3.5-9**). Mt. Hamilton thistle could possibly occur in the unlined portion of the spillway, though the most recent (2021) survey did not detect the species there. Both Mt. Hamilton thistle and San Francisco collinsia occur in the portion of the reservoir bed where no construction is currently proposed, but where construction activity could possibly occur (see **Figure 3.5-2)**. Two other special-status plants, Santa Clara Valley dudleya and fragrant fritillary, occur close to, but outside, the Seismic Retrofit Area (**Figure 3.5-9**). In addition, portions of the Seismic Retrofit Area have not been surveyed for special-status plants (**Figure 3.5-10**). As a result, there is some potential for smooth lessingia, woodland woollythreads, most beautiful jewel-flower, San Francisco collinsia, and fragrant fritillary, as well as big-scale balsamroot and Loma Prieta hoita (the latter two species are not known from the immediate Project vicinity, but potential habitat is present in the unsurveyed areas), to occur in these unsurveyed areas. Two additional species, Metcalf Canyon jewel-flower and Tiburon paintbrush, are not expected to occur in these unsurveyed areas, but botanists would look for these species during surveys of the unsurveyed areas.

Two additional special-status plants, alkali milk vetch and Point Reyes bird's beak, could occur in tidal marshes of the study area along lower Coyote Creek/Coyote Slough that may be subject to increased flow frequency and magnitude, and sediment deposition, during Seismic Retrofit construction; these two species are addressed with other baylands species in Impact TERR-1j.

Table 3.5-9 indicates the number of individuals of each special-status plant species known to be present in the Seismic Retrofit Area, provided separately for the currently proposed construction footprint and the additional areas in the reservoir bed that could possibly be impacted by construction. For Coyote ceanothus, comprehensive surveys of the entire Seismic Retrofit Area have been conducted, and thus the number indicated in **Table 3.5-9** indicates the number of individuals that would be directly impacted by (i.e., lost to) Project construction. For the other three species listed in **Table 3.5-9**, the number provided in the table represents the minimum number of individuals that may be impacted, as these species, as well as San Francisco collinsia, fragrant fritillary, big-scale balsamroot, and Loma Prieta hoita, could occur in the unsurveyed areas. However, given the limited extent of the unsurveyed areas, the number of individuals of any of these species present in those areas (if any) would be low.

Table 3.5-9. Direct Impacts on Special-Status Plants from Project Construction.

Species	Number of Individuals	
	Currently Proposed Project Footprint	**Potential Additional Project Construction Area**
Coyote ceanothus	2,666	
Smooth lessingia	1,921	
Woodland woollythreads	1,142	
Most beautiful jewel-flower	4	
Mt. Hamilton thistle		840
San Francisco collinsia		3,022

Source: Valley Water 2012a, 2014a, 2014b, <u>2021a</u> ~~2021f~~

Construction activities such as grading, excavation, and placement of new structures and soil stockpiles could impact these special-status plants. Project activities may affect these plants through direct disturbance of vegetation; disturbance, modification, or destruction of habitat and damage to underground root structures. In addition, equipment use, vehicular traffic, and worker foot traffic may result in the injury, mortality, altered growth, or reduced seed set of individual plants. Creation of access routes and staging areas may result in the mechanical or physical removal of vegetation and modification of the seed bank due to grading.

In serpentine habitats, the conservation of topsoil and seed banks after grading would not be able to restore such habitats to similar conditions, because topsoil would become homogenized, mixing the seeds and soils of previously specialized habitat types with more common California annual grassland. Such topsoil and seed banks, if placed in areas that previously supported serpentine habitats, would be unlikely to support the same poor nutrient conditions or the characteristically high proportion of native forbs following grading and restoration.

Movement of earth, vegetation, water (e.g., runoff), equipment, vehicles, and personnel could spread invasive plant propagules and pathogens such as *Phytophthora*. Invasive plants could reduce habitat quality for special-status plants, or directly affect their health, in areas immediately outside the footprint of the Seismic Retrofit Area. *Phytophthora* could impair the health of plants, spreading through root systems and resulting in the loss of individuals. The potential for *Phytophthora* to be spread by Seismic Retrofit construction activities will be reduced via implementation of a Project-specific *Phytophthora* Pathogen Management and Monitoring Plan prepared for the Project prior to the start of work and approved by Valley Water. This plan will be based on those developed for the FOCP (Valley Water 2020h, 2021e ~~2021c~~) and the results of FOCP implementation and *Phytophthora* monitoring, including lessons learned from the FOCP project implementation.

Although all direct impacts on special-status plants are considered permanent, and because the individuals present in the Seismic Retrofit Area could all be lost, it is likely that conditions in some construction areas, such as areas used for construction access north of the spillway, would provide suitable conditions for natural recolonization by some of these species following completion of construction. As a result, some natural recovery of impacted populations would likely occur.

In addition, after Seismic Retrofit construction completion, refilling of Anderson Reservoir to the design capacity would result in the loss of individuals of some species that have colonized areas within the rim of the drawn-down reservoir. For example, Coyote ceanothus, San Francisco collinsia, and smooth lessingia have colonized some areas that are below the current drawn-down level of the reservoir, and those individuals would be lost when the reservoir refills.

The Project would not result in an increase in the reservoir's capacity. Rather, after Seismic Retrofit completion, refilling of the reservoir would simply restore the reservoir and its shoreline to the condition that was present prior to DSOD drawdown requirements. As a result, impacts of the Project on the San Francisco collinsia population resulting from refilling of the reservoir (as opposed to direct impacts during construction, if construction occurs outside the currently proposed construction footprint) would likely reflect a return to pre-2012 conditions. There is natural interannual variability in the size of the collinsia population; therefore, the long-term average size of the population and its extent, from 2011 (when Valley Water began comprehensively mapping and surveying the occurrence) through 2022, would best represent the Existing Conditions Baseline. Based on Valley Water observations and mapping of the population, approximately 90 percent (0.6 acres) of the area that has been occupied by collinsia since 2011 would be inundated when the reservoir is refilled to its maximum design capacity. Wind fetch along the shoreline and resultant erosion of the reservoir bank could have an additional impact on the population, although some moderate slope disturbance may have beneficial effects on the species by uncovering additional seedbank and or/creating new areas for colonization. This impact analysis assumes that approximately 90 percent of the known population (0.6 acres of occupied habitat supporting 3,022 individuals averaged from 2011 to 2022) would be impacted.

Project construction may also impact other special-status plant species outside the construction footprint. Santa Clara Valley dudleya occurs on steep rock outcrops just north of the Seismic Retrofit Area; fragrant fritillary occurs just east of the BHBA; and Mt. Hamilton thistle occurs along the edge of the reservoir northeast of the spillway. These plants are not located in areas where they would be subject to direct, physical impacts, nor would they be affected by gravity-driven mobilization of runoff or sediment. However, dust that could be generated by construction activities may coat vegetative and floral surfaces, interfering with normal gas exchange, photosynthesis, or pollination. Dust mobilization may therefore affect these plants, and *Phytophthora* within dust particles may impact them as well.

Nitrogen emitted by construction vehicles and equipment may impact serpentine-associated special-status plants by fertilizing the soils and allowing nonnative grasses and forbs that would not otherwise be able to colonize (at least robustly) those serpentine soils to become established. Nitrogen emitted from the Seismic Retrofit Area may therefore impact any serpentine-associated special-status plants growing in areas where nitrogen emitted by construction activities is deposited. Such species include Coyote ceanothus, Mt. Hamilton thistle, San Francisco collinsia, smooth lessingia, woodland woollythreads, most beautiful jewel-flower, Santa Clara Valley dudleya, and fragrant fritillary occurring close to or downwind from the construction area. Other serpentine-associated special-status plants, such as Tiburon paintbrush, Metcalf Canyon jewel-flower, and Loma Prieta hoita, may be adversely affected by deposition of nitrogen emitted by construction activities as well. However, known occurrences of those three species are located to the north and northwest of the Seismic Retrofit Area, and prevailing winds during the construction season are primarily from the west and northwest (WeatherSpark 2022). Therefore, the amount of Project construction-related nitrogen deposition on occurrences and habitat of the Tiburon paintbrush, Metcalf Canyon jewel-flower, and Loma Prieta hoita will be low.

Aside from alkali milk vetch and Point Reyes bird's beak, which are addressed with other baylands species in Impact TERR-1j, no special-status plants occur along Coyote Creek downstream from Anderson Dam. Therefore, any increases in flows that occur during Seismic Retrofit construction would have no impact on special-status plants.

In summary, Seismic Retrofit construction would directly impact Coyote ceanothus, smooth lessingia, woodland woollythreads, and most beautiful jewel-flower within the currently proposed construction areas; may impact San Francisco collinsia and Mt. Hamilton thistle directly, especially if construction occurs in portions of the reservoir bed where these species are known to occurs; and may impact Santa Clara Valley dudleya and fragrant fritillary outside the construction areas through the mobilization of dust and *Phytophthora* during construction. Because limited areas of suitable habitat within the construction area have not been surveyed, it is possible that additional individuals of smooth lessingia, woodland woollythreads, most beautiful jewel-flower, San Francisco collinsia, and fragrant fritillary, and possibly big-scale balsamroot and Loma Prieta hoita, may be impacted as well if they are present in the unsurveyed areas.

Conservation Measures Construction

Special-status plants will benefit from Valley Water's payment of VHP impact fees, which contribute to the VHP's conservation program that benefits VHP-covered (and many nonVHP-covered) special-status plants.

Special-status plants are absent from areas directly affected by the proposed Conservation Measures, and therefore no direct impacts of Conservation Measures on special-status plants would occur. However, implementation of Conservation Measures could impact serpentine-associated special-status plants by contributing to the cumulative effects of nitrogen deposition on serpentine habitats supporting these species. In particular, activities associated with the Ogier Ponds CM would involve considerable earth moving. The Ogier Ponds are located immediately west of Coyote Ridge, which supports populations of Tiburon paintbrush, Coyote ceanothus, Mt. Hamilton thistle, smooth lessingia, woodland woollythreads, most beautiful jewel-flower, Metcalf Canyon jewel-flower, Santa Clara Valley dudleya, Loma Prieta hoita, and fragrant fritillary. Nitrogen emitted from earth-moving equipment and vehicles associated with work at the Ogier Ponds could be deposited on occurrences of, and suitable habitat for, those plants by the westerly winds that prevail during the majority of the construction season. Lesser amounts of nitrogen emitted during activities associated with the Coyote Percolation Dam CM ~~and North Channel Extension~~ would also be carried to Coyote Ridge.

Of the plants listed above, occurrences of Loma Prieta hoita, Metcalf Canyon jewel-flower, and fragrant fritillary would be impacted least by nitrogen emissions associated with proposed Conservation Measures, as most or all known occurrences are located northeast or north of the Ogier Ponds, where winds during the construction season would infrequently carry nitrogen emitted from Ogier Ponds activities.

Construction Monitoring Impacts Analysis

Most construction monitoring measures would occur in areas where special-status plants are absent, and therefore have no impact on special-status plants. The only construction monitoring-related activity that could have a substantive effect on special-status plants is the development and implementation of management and monitoring plans for *Phytophthora*. Given the extensive movement of equipment, vehicles, soil, dust, water, and personnel during Project implementation near highly sensitive serpentine plant communities (particularly those immediately north and northeast of the dam), mobilization of *Phytophthora* could result in long-term adverse effects on serpentine communities. Implementation of measures to avoid contaminating serpentine communities with *Phytophthora* are very important, and construction monitoring activities will therefore minimize the potential for other Project components to result in adverse effects on special-status plants.

Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Adaptive Management

Aside from the possible occurrence of special-status plants in tidal marsh along lower Coyote Creek/Coyote Slough, addressed in Impact TERR-1j below, no special-status plants are present along Coyote Creek downstream from Anderson Dam, and therefore, post-construction operations related to flows and releases from the dam and the Cross Valley Pipeline Extension, as well as operation <u>and maintenance</u> of the Ogier Ponds CM ~~and~~ Coyote Percolation Dam CM, <u>and the North Channel Reach and Live Oak Restoration Reach</u> would not impact special-status plants.

Maintenance of Anderson Dam facilities would occur in areas that were already impacted by Seismic Retrofit construction and therefore would not result in any new impacts on special-status plants. However, there is some potential for *Phytophthora* to be mobilized by operations and maintenance activities at Anderson Dam, potentially leading to infection of adjacent occurrences of special-status plants outside the Seismic Retrofit Area.

Maintenance of all Conservation Measures, including sediment augmentation, Ogier Ponds and Coyote Percolation Dam habitat restoration improvements, the Live Oak Restoration Reach, and <u>the</u> North Channel <u>Reach</u> ~~Extension~~, would not occur in areas occupied by, or providing suitable habitat for, special-status plants. Maintenance equipment and vehicles could contribute to cumulative impacts on serpentine-associated, special-status plants through their nitrogen emissions, but otherwise, maintenance of Conservation Measures will not impact special-status plants. Adaptive management activities will affect areas downstream from Anderson Dam that do not support special-status plants and will thus not impact such species.

Significance Conclusion Summary

Implementation of Valley Water BMPs and compliance with applicable VHP conditions would reduce impacts on special-status plants. BMPs applicable to this impact are identified in **Table 3.5-6**. VHP conditions applicable to this impact are provided in **Table 3.5-7**, and VHP-related AMMs are provided in **Table 3.5-8**.

Implementation of BMP AQ-1 will reduce the potential for construction activities to mobilize dust onto special-status plants outside the Project footprint, thus reducing the effects of dust and the potential for *Phytophthora* to be mobilized to special-status plants within that dust. BMPs BI-8 and WQ-9 will avoid competition between invasive plants and special-status plants by requiring local plant species in revegetation. BMPs ~~HM-7,~~ HM-8, HM-9, HM-10, WQ-15, and WQ-16 will minimize the potential for hazardous materials and other pollutants to impact special-status plants, and HM-12 would reduce the potential for fire to affect such plants. BMPs BI-3, WQ-4, WQ-5, and WQ-11 will involve removing temporary fill, establishing appropriate staging and stockpiling areas and construction access areas, and keeping the work site clean, minimizing impacts on special-status plants and avoiding the spread of *Phytophthora* and weeds. BMP BI-4 will minimize impacts of pesticides on nontarget species, such as special-status plants.

Implementation of VHP Conditions 4 and 5 would reduce the potential for and magnitude of impacts on special-status plants through numerous AMMs summarized in **Table 3.5-8**; these AMMs include limiting the footprint of activities, reducing the potential for pollutants to impact plants, avoiding the encouragement of invasive plants, and avoiding erosion and sediment impacts on special-status plants. VHP Condition 7 would entail minimizing ground disturbance and vegetation removal, stabilizing soil to avoid erosion and sedimentation, and revegetating with native plants or other appropriate plants. Conditions 13, 19, and 20 specifically address serpentine-associated special-status plants by requiring surveys to determine where such plants occur, avoidance and minimization of covered species where feasible, and plant salvage when impacts are unavoidable (at the discretion of the SCVHA).

Maintenance of Anderson Dam facilities would occur as part of the DMP and would employ the BMPs and mitigation measures implemented by the DMP to avoid and minimize impacts on sensitive biological resources, such as special-status plants. **DMP Mitigation Measure Vegetation-1** requires periodic botanical surveys, which would identify the locations of special-status plants, thus facilitating their avoidance when maintenance activities are performed (although as noted above, it is unlikely that new plant occurrences will occur within the Seismic Retrofit's impact areas). DMP BMPs BI-10 and BI-11 include measures to minimize impacts to vegetation whenever clearing or trimming is necessary and minimize root impacts. BMP BI-12 entails avoidance of special-status plant species and sensitive natural communities, such as serpentine communities, which support most of the special-status plants in and adjacent to the Seismic Retrofit Area. BMP BI-13 requires use of local ecotypes of native plants and appropriate erosion control seed mixes to avoid impacts from invasive plant species. However, the DMP mitigation measures do not include measures to minimize the potential for introduction or spread of *Phytophthora*, and therefore, there is some potential for *Phytophthora* to be mobilized by operations and maintenance activities at Anderson Dam, potentially leading to infection of adjacent occurrences of special-status plants outside the Seismic Retrofit Area.

Of the 12 special-status plants that could be impacted by the Project, nine—the Coyote ceanothus, Santa Clara Valley dudleya, most beautiful jewel-flower, Metcalf Canyon jewel-flower, Mt. Hamilton thistle, smooth lessingia, Tiburon paintbrush, fragrant fritillary, and Loma Prieta hoita—are VHP-covered species. The SCVHA is considering adding woodland woollythreads as a VHP-covered species during the upcoming VHP amendment. General and serpentine impact fees paid by Valley Water for Project impacts would be used by the SCVHA to offset adverse impacts to the nine VHP-covered plant species (with two caveats discussed below), and to woodland woollythreads if it is added as a VHP-covered species, through the preservation, restoration, and management of populations of, and suitable habitat for, these species.

In addition to payment of fees for preservation, restoration, and management of the VHP-covered plant species, Valley Water is complying with VHP conditions related to Project impacts on Coyote ceanothus through two additional measures. In compliance with a VHP requirement for Valley Water to protect or create a new population of this species within 5 years of Project impacts, an occurrence of Coyote ceanothus on the Baird and Davidson properties, on the west side of Coyote Valley, was recently acquired and protected. The VHP also states that within the 50-year permit term, five populations must be created or protected. To meet the VHP's long-term requirements, Valley Water has begun establishing a new population of Coyote ceanothus on property it owns on Coyote Ridge, north of Anderson Dam. Planting of seedlings and direct seeding in the test plots on Coyote Ridge has been occurring annually since 2015, and these plants are being monitored to determine the success of the site to support a new, functional population of Coyote ceanothus. Based on the results of this initial planting, Valley Water has prepared an occurrence creation plan that summarizes all the research and field efforts (Valley Water 2018b), and this plan is being used to guide a subsequent full-scale planting effort currently underway, with the goal of establishing a viable Coyote ceanothus population on Valley Water's Coyote Ridge property. Plants are being grown via seed collected from the Anderson Dam population in a nursery and planted in accordance with the occurrence creation plan, as modified based on lessons learned from the initial planting effort. Success criteria include whether the population is reproducing and self-sustaining (based on reproduction and survival rates) over time, with minimal active site management. Specific management activities for the long-term health of the population would be described in a subsequent long-term management plan.

The two caveats regarding VHP coverage of impacts on VHP-covered special-status plant species are:

- First, although Tiburon paintbrush is a VHP-covered species, the VHP only covers impacts on this species from management of VHP preserves, and neither of the two populations on Coyote Ridge that could be affected by Project-related nitrogen emissions are located in VHP preserves. Therefore, payment of VHP fees would not necessarily result in conservation of Tiburon paintbrush. Due to the extreme rarity of Tiburon paintbrush, the low number of populations known, and the potential for substantial adverse impacts to this species could occur, this impact would be significant in the absence of mitigation measures. Implementation of **Mitigation Measure TERR-1a(1)** would reduce Project impacts on Tiburon paintbrush to less-than-significant levels by managing invasive plants at two ~~Valley Water's~~ Coyote Ridge populations of Tiburon paintbrush, thereby preventing substantial adverse effects by preventing the Project's nitrogen emissions from benefitting populations of invasive plants that would compete with Tiburon paintbrush at these two ~~Valley Water's~~ populations.

- Second, one non-VHP-covered Project activity could affect special-status plants—maintenance of Anderson Reservoir in a dewatered condition for 1 additional year, beyond the 3.5 years of dewatering authorized by the VHP. During activities in the dewatered bed of the reservoir from late fall/early winter of Year 5 through the fall of Year 6, dust mobilization could adversely affect the health of Coyote ceanothus, Santa Clara Valley dudleya, smooth lessingia, San Francisco collinsia, and Mt. Hamilton thistle in immediately adjacent areas. However, the likelihood and magnitude of any such adverse effects are low. The haul road along the edge of the southern arm of the reservoir would pass near some mature Coyote ceanothus, San Francisco collinsia, and smooth lessingia growing on the edge of the reservoir northeast of the existing boat ramp. However, the haul road that would traverse the edge of the northern arm of the dewatered reservoir, adjacent to the only occurrences of Mt. Hamilton thistle and Santa Clara Valley dudleya near the Seismic Retrofit Area, and near the highest densities of Coyote ceanothus and smooth lessingia located outside of the Project Area, would not be used after Year 5. Therefore, haul routes used in Year 6 would not be located near Mt. Hamilton thistle or Santa Clara Valley dudleya, or near the highest concentrations of ceanothus or dudleya. Implementation of Valley Water's BMPs, including Valley Water BMP AQ-1, will reduce mobilization of dust from Year 6 project activities onto special-status plants by implementing appropriate dust control measures and minimizing vehicular activities immediately adjacent to these plants.

With implementation of BMPs and compliance with VHP conditions and AMMs, there would be no substantial adverse effects on Metcalf Canyon jewel-flower. This species may be affected by deposition of nitrogen emitted by Project activities (particularly those emitted by the Ogier Ponds CM and Coyote Percolation Dam CM construction), but it is not known or expected to occur in areas near Anderson Dam or any of the Conservation Measures where operations and maintenance could adversely affect this species through the introduction or spread of *Phytophthora*. Therefore, impacts on Metcalf Canyon jewel-flower would be less than significant.

Implementation of BMPs and compliance with VHP conditions and AMMs (including payment of fees, establishment of a new Coyote ceanothus population, and completion of special-status plant surveys in the Seismic Retrofit Area by surveying the limited, previously unsurveyed areas) would reduce adverse effects on the VHP-covered Coyote ceanothus, Santa Clara Valley dudleya, most beautiful jewel-flower, Mt. Hamilton thistle, smooth lessingia, and fragrant fritillary, and on the VHP-covered Loma Prieta hoita if it occurs in the unsurveyed areas of the Seismic Retrofit Area; these measures would also reduce impacts on woodland woollythreads, and big-scale balsamroot if it occurs in the unsurveyed areas of the Seismic Retrofit Area. Although woodland woollythreads is not currently a VHP-covered species, the SCVHA is considering adding it as a VHP-covered species during the VHP amendment currently being prepared. Whether this species is explicitly VHP-covered or not, this species and big-scale balsamroot would benefit from the VHP's conservation program. The VHP's vast conservation program would conserve lands that support populations of these species due to its breadth, both geographically and in terms of the diversity of habitat types to be conserved. Therefore, Valley Water's payment of VHP impact fees for the Project would likely contribute to a conservation program that would compensate for any impacts that the Project might have on woodland woollythreads and big-scale balsamroot.

The only remaining significant impact on Coyote ceanothus, Santa Clara Valley dudleya, most beautiful jewel-flower, Mt. Hamilton thistle, smooth lessingia, fragrant fritillary, woodland woollythreads, and, if they occur in the unsurveyed areas of the Seismic Retrofit Area, Loma Prieta hoita and big-scale balsamroot, that would require mitigation is the potential for post-construction operations and maintenance at Anderson Dam to result in substantial adverse effects from the introduction or spread of *Phytophthora*. These plant species occur at or close to Anderson Dam, and such adverse effects could occur, because the AMMs and mitigation measures employed by the DMP do not include measures to minimize *Phytophthora*-related impacts. This would be a substantial adverse effect, and therefore a significant impact. Implementation of **Mitigation Measure TERR-1a(2)** would reduce Project impacts on these species to less-than-significant levels by implementing AMMs during post-construction maintenance at Anderson Dam to reduce the potential for introduction or spread of *Phytophthora*, thereby preventing substantial adverse effects.

San Francisco collinsia is not a VHP-covered species. The Anderson Reservoir rim population of San Francisco collinsia is: (1) recorded by CNDDB as one of four records within the county (CNDDB 2022), (2) the only population in the county with an excellent occurrence rank, and (3) the only county occurrence that has been observed within the last decade, and possibly the only extant occurrence in the county. In recent years, Valley Water has not been able to locate the other documented county populations. The Anderson Reservoir population also represents the most inland population of the species and the only known population in the Diablo Range, emphasizing its ecological importance. San Francisco collinsia is a very rare species, with 35 extant populations known from six California counties (CNPS 2022). Due to the species' rarity and the Anderson Reservoir population's ecological significance as the most inland population of the species and the known population in the Diablo Range, substantial adverse impacts to the Anderson Reservoir population resulting from construction activities~~,~~ and subsequent refilling of the reservoir after Project completion would be a significant impact.

If San Francisco collinsia populations are present within lands added to the VHP Reserve System, and management of those lands helps to enhance and maintain those populations, then Valley Water's payment of VHP impact fees and the resulting contribution of those fees to reserve acquisition and management would compensate for at least some Project impacts on San Francisco collinsia. However, because San Francisco collinsia is so rare and has such a local distribution, it is uncertain that this species would be present in the VHP Reserve System. Therefore, impacts on this species may not be adequately reduced through VHP compliance, and impacts on this species would be significant, because there could be substantial adverse effects. Valley Water would implement **Mitigation Measures TERR-1a(3)** and **TERR-1a(4)** to reduce impacts on San Francisco collinsia to less-than-significant levels by surveying for this species in the previously unsurveyed portions of the Seismic Retrofit Area (to help quantify impacts on the species) and establishing a mitigation population commensurate with the population size and acreage impacted by the Project, thereby preventing substantial adverse effects.

With implementation of **Mitigation Measures TERR-1a(1), TERR-1a(2), TERR-1a(3),** and **TERR-1a(4)**, Project impacts on special-status plants would not be substantial and therefore would be **less than significant**.

Mitigation Measures

TERR-1a(1) Invasive Plant Management at ~~Valley Water's~~ Coyote Ridge Tiburon Paintbrush Populations

Valley Water will offset impacts from Project-related nitrogen deposition on Tiburon paintbrush by ~~performing~~ providing for invasive plant management in and around the two Tiburon paintbrush populations currently known to occur on Coyote Ridge, including the "Paintbrush Hill" population ~~located~~ on Valley Water's Coyote Ridge property and the "Paintbrush Canyon" population on land owned by Waste Management, Inc. Nitrogen deposited on nutrient-poor serpentine soils facilitates the ability of nonnative grasses and forbs to compete with serpentine endemic plants such as Tiburon paintbrush, so invasive plant management would directly address and reduce the impacts of nitrogen deposition. During each year of construction for the Ogier Ponds CM, as well as the year following completion of that CM, Valley Water will perform manual weeding of plants considered to be of moderate or high invasiveness by Cal-IPC (2022) on the Paintbrush Hill population and perform manual weeding or fund weeding at the Paintbrush Canyon population. ~~Such weeding will be performed at least twice during each growing season in which invasive plant management occurs.~~ Weeding may be performed by hand or using hand-held motorized tools (e.g., line trimmers) as long as no impacts to individual Tiburon paintbrush plants would occur. Special care will ~~would~~ be taken to avoid trampling individual Tiburon paintbrush plants, which are quite fragile.

TERR-1a(2) Implementation of Avoidance and Minimization Measures during Post-Construction Maintenance at Anderson Dam and Conservation Measures Facilities to Reduce the Potential for Introduction or Spread of Phytophthora

Valley Water will ~~would~~ develop and implement AMMs to reduce the potential for introduction and spread of *Phytophthora* during post-construction maintenance at Anderson Dam, because the DMP (under which post-construction maintenance would occur) does not include AMMs for this purpose. AMMs will ~~would~~ also be implemented during maintenance of Conservation Measures facilities to reduce the potential for introduction and spread of *Phytophthora* during post-construction maintenance to affect sensitive communities. The AMMs will ~~would~~ include a description of areas that are contaminated with *Phytophthora*; sensitive habitats that are not contaminated with *Phytophthora*; procedures for decontamination of tools, equipment, vehicles, and maintenance personnel clothing and footwear prior to accessing those sensitive habitats; procedures for ensuring that water for irrigation or dust suppression, soil, mulch, plant material, and other materials are free from *Phytophthora* if used in, near, or upslope from sensitive habitats that are not contaminated with *Phytophthora*; decontamination procedures for vehicles, equipment, tools, footwear, and personnel clothing after working in areas contaminated by *Phytophthora*; and other procedures deemed necessary. Details of the BMPs will ~~would~~ be developed following Project completion, as they will ~~would~~ be informed by the results of *Phytophthora* monitoring during, and following completion of, Project construction.

TERR-1a(3) Special-Status Plant Survey in the Previously Unsurveyed Portions of the Seismic Retrofit Area

Valley Water will conduct a survey for special-status plants in the limited portions of the Seismic Retrofit Area that provide potential special-status plant habitat but have not yet been surveyed (see **Figure 3.5-10**). The survey will be conducted according to VHP standards and protocols, by a VHP-approved botanist, and will be floristic in nature so that all potentially occurring special-status plants are detected if present. Multiple site visits will ~~would~~ be necessary to detect all the potentially occurring species by targeting their flowering periods. If any San Francisco collinsia are detected, impacts will be mitigated by adding those detected individuals to the population that will be created by **Mitigation Measure TERR-1a(4)**. If other special-status plants are detected, impacts would be reduced with implementation of **Mitigation Measure TERR-1a(2)**.

TERR-1a(4) ~~Seed Collection and Creation of a New Population of~~ San Francisco Collinsia Conservation Measures

Valley Water will ~~would~~ compensate for impacts on San Francisco collinsia by performing weed management in the existing population during Seismic Retrofit construction; collecting seed from San Francisco collinsia plants at Anderson Reservoir; storing some of the seed in an accredited seed bank; and prepping, seeding, managing, and monitoring suitable habitat at one or more sites outside the Project Area to create one or more new populations of the species. The mitigation will be commensurate with the impacts, targeting at least 0.6 acres of occupied habitat supporting at least 3,022 individuals, based on the average population size and extent between 2011 and 2022, plus any individuals that might be detected in the previously unsurveyed portions of the Seismic Retrofit Area during the survey described in **Mitigation Measure TERR-1a(3)**. Prior to Project implementation, a qualified biologist will ~~would~~ prepare an HMMP that will ~~would~~ include, at a minimum, the following information:

- summary of impacts and proposed mitigation
- description of the location and boundaries of the proposed mitigation site(s) and description of existing site conditions
- description of the mitigation design and any measures to be undertaken to enhance (e.g., through focused management) the mitigation site for San Francisco collinsia, which may include prescribed burning or other habitat management strategies
- identification of an adequate funding mechanism for long-term management of the mitigation site
- description of management and maintenance measures intended to maintain and enhance habitat for San Francisco collinsia (e.g., weed control or fencing maintenance)
- description of germination methods and planting techniques that will be used to introduce the species into the mitigation site, although this information on San Francisco collinsia may not be well known, the related native annual species purple collinsia (*Collinsia heterophylla*) is available commercially and is described as easy to grow, requiring no pre-treatments, and with seeds shallowly sown into loosened topsoil (Everwilde Farms 2022, Swallowtail Garden Seeds 2022)
- description of habitat and species monitoring measures on the mitigation site, including specific, objective performance criteria (e.g., rate of germination and survival to seed-set; at a minimum, performance criteria will ~~would~~ include presence of at least as many

individuals as were impacted within the population by Year 7 of monitoring), monitoring methods, data analysis, reporting requirements, and monitoring schedule; monitoring will ~~would~~ document compliance with each element requiring habitat compensation or management

- a contingency plan for mitigation elements that do not meet performance or final success criteria within described periods. The plan will ~~would~~ include specific triggers for remediation if performance criteria are not met and a description of the process by which remediation of problems within the mitigation site (e.g., presence of noxious weeds) will ~~would~~ occur
- a requirement that Valley Water will ~~would~~ be responsible for monitoring, as specified in the HMMP, for at least 7 years post-construction

Valley Water has already been collecting seed from San Francisco collinsia plants at Anderson Reservoir and has banked this seed at the California Botanic Garden (formerly known as Rancho Santa Ana Botanic Garden) and the University of California, Santa Cruz Arboretum. Given the ease with which another native collinsia species, purple collinsia, can be cultivated and grown as a landscape plant (Everwilde Farms 2022, Swallowtail Garden Seeds 2022), it is likely that growing San Francisco collinsia by seed and establishing a new population to compensate for any affected occurrences is feasible if a suitable introduction site is identified. While some of the seed collected from this population will ~~would~~ be used in the mitigation effort, the remaining seed will ~~would~~ continue to be maintained in permanent conservation storage at the California Botanic Garden.

Although the majority of the collinsia population will be impacted directly when the reservoir is refilled following completion of Seismic Retrofit construction, maintaining a healthy collinsia population until the reservoir refills is important to allow for collection of seed as described above and to maximize the number of individuals that might persist along the shoreline after the reservoir is refilled. During Seismic Retrofit construction, Valley Water will remove weedy vegetation that threatens to outcompete San Francisco collinsia by encroaching into the area occupied by San Francisco collinsia due to the reservoir drawdown. At least once each spring or summer, a qualified botanist will determine which weedy vegetation (which may include both native and nonnative species encroaching into the collinsia population) needs to be removed to maintain suitable habitat conditions for collinsia. That vegetation will be removed under the direction of the qualified botanist.

Impact TERR-1b: Bay Checkerspot Butterfly, Monarch Butterfly, and Crotch's Bumble Bee (Less than Significant)

Seismic Retrofit Construction

Three special-status invertebrates, Bay checkerspot butterfly, monarch butterfly, and Crotch's bumble bee, occur in areas where they could be impacted by Seismic Retrofit construction.

Seismic Retrofit construction may impact Bay checkerspot butterflies in offsite serpentine grasslands in the expanded study area, but it is unlikely to affect individuals, or habitat used regularly by the species, directly. No Bay checkerspot butterflies have been observed in the Project Area during any field surveys, including surveys for adults conducted in the most suitable habitat in April 2014, and high-quality habitat is absent from the Project footprint. No extensive areas of serpentine bunchgrass habitat or of the Bay checkerspot butterfly's larval host plants are present on the site. The Project would result in impacts on 2.6 acres of designated critical habitat for the Bay checkerspot butterfly within designated Critical Habitat Unit 13. However, any small patches of open habitat supporting this species' host plants in the Project area are unsuitable to support a viable breeding population of the Bay checkerspot butterfly due to their small size, isolated locations, locations on south-facing slopes, and other factors. It is possible that an occasional dispersant may visit the site (and possibly nectar), but the Seismic Retrofit Area does not provide suitable habitat to support a subpopulation of the species, and it is unlikely that the species breeds in or immediately adjacent to the Project footprint.

Clearing of vegetation by Project activities could remove larval host plants (though these are unlikely to be used for breeding by the species due to the small and scattered nature of patches of these plants) and nectar sources for occasional adult dispersants, and dust mobilization by Project activities could adversely affect the health of such plants in areas adjacent to grading areas, stockpile areas, and haul roads. However, because Bay checkerspots visit these impact areas very infrequently and in low numbers, if at all, these effects would have little impact on the species. Also, the construction season would only slightly overlap with the adult flight season (e.g., in April), so the effects of dust mobilization on flowers that are in active use by adult Bay checkerspots would be minimal.

Seismic Retrofit construction activities could impact the Bay checkerspot butterfly and its habitat by contributing to the cumulative effects of nitrogen deposition on serpentine grasslands supporting this species. As discussed in Impact TERR-1a, prevailing winds would mobilize most of the nitrogen emissions from construction in the reservoir and around Anderson Dam away from the largest Bay checkerspot populations on Coyote Ridge to the northwest. However, nitrogen emitted by construction equipment and vehicles in the reservoir and around Anderson Dam could be carried to potential Bay checkerspot butterfly habitat on serpentine grasslands to the southeast, on the ridge east of the valley between Anderson Reservoir and Coyote Reservoir. There, Bay checkerspots were observed in serpentine habitat west of Coyote Reservoir, in Harvey Bear Ranch County Park, as recently as 2015 (CNDDB 2022). Thus, nitrogen emitted by Project construction equipment and vehicles could impact Bay checkerspot butterfly individuals and habitat by facilitating growth of invasive plants in the species' habitat.

Seismic Retrofit construction could impact monarch butterflies by removing milkweed, the larval host plant; killing eggs, larvae, or pupae on that milkweed; and removing a variety of flowering plants that serve as adult nectar sources. Milkweed is present in scattered patches on Anderson Dam and around the rim of the reservoir, and grading and clearing for construction would result in the removal of this plant. While milkweed removal would reduce the availability of the larval host plant, this would likely have only limited impacts on South Bay breeding populations of the monarch butterfly. As indicated in **Table 3.5-5**, inspection of approximately 480 clusters of milkweed plants along Coyote Creek between Anderson Dam and the Coyote Creek Golf Course area (including the Ogier Ponds) in May and June 2022, and 100 plants along the rim of Anderson Reservoir in July 2022, detected only two monarch larvae. Thus, although monarch butterflies do breed in the Project vicinity, they are scarce breeders. Rather, monarchs occur in the Seismic Retrofit Area primarily as migrants. Implementation of the milkweed survey plan as part of the Project construction monitoring components would minimize impacts on milkweed and avoid injury or mortality of monarch butterflies that might be using that milkweed. <u>Implementation of the milkweed survey plan would also reduce impacts on the Crotch's bumble</u>

bee, which uses milkweed heavily as a nectar and pollen source(California Bumble Bee Atlas 2024).

Crotch's bumble bee has been recorded once in the Seismic Retrofit Area, foraging on bull thistle in the bed of the drawn-down reservoir. ~~This species' habitat requirements in the county are poorly known; of the nine recent (2019-2022) County records in the iNaturalist (2022) and Bumble Bee Watch (2022) databases, two are from urban areas well removed from relatively natural habitats, and four were observed foraging only on the invasive bull thistle~~ Since 2019, there have been documented occurrences of more than 100 individuals from approximately 20 locations in Santa Clara County (Bumble Bee Watch 2024, iNaturalist 2022, S. Lockwood and S. Rottenborn, pers. obs.), indicating that the species is still extant, and fairly widespread, in the County. This species could occur in scrub, grassland, or other habitats in the Seismic Retrofit Area, both when foraging and possibly when nesting (e.g., in small mammal burrows or rock crevices). Seismic Retrofit construction could destroy subterranean nests and their occupants, clear vegetation that serves as pollen and nectar sources, and affect pollen and nectar sources through dust mobilization or changes in drainage patterns. To the extent that Crotch's bumble bee might breed in the bed of the drawn-down reservoir, refilling of the reservoir following Seismic Retrofit construction could result in the loss of overwintering queens. This species likely occurs in the Seismic Retrofit Area only in low densities (e.g., during a survey of the reservoir bed on July 30, 2022, only one Crotch's bumble bee was seen among 300 or more bumble bees inspected closely), and therefore the number of individuals that could be impacted by Seismic Retrofit construction would be low.

Changes to the dam's outlets may result in increases in flows downstream from the dam during construction. The magnitude of flow, and frequency of flows of a certain magnitude, will depend on rainfall amounts during individual runoff events and Coyote Reservoir releases. Valley Water (2022c ~~2022d~~) predicts higher flows at the 2-, 5-, and 10-year return intervals during construction. At their maximum, such flows could be as high as 6,000 cfs, which represents the maximum capacity of all dam outlets that will be present. However, a 6,000-cfs flow during Seismic Retrofit construction has a very low probability of occurring, as it would represent a 200-year event (with a 0.5 percent likelihood of occurring in any given year). The higher the flow, the lower the probability and frequency of that flow occurring in any given year, so that very high flows, greater than the 10-year or 20-year events, are unlikely during the Project construction period, though possible.

Higher flows would result in erosion, deposition of sediment (from the reservoir bed and from material eroded from the Coyote Creek bank downstream from Anderson Dam), and loss of riparian vegetation along the creek channel. This would not affect the Bay checkerspot butterfly, which does not occur along Coyote Creek downstream from the dam. However, large flow events would modify vegetation along the creek, potentially removing milkweed and nectar/pollen sources for monarch butterfly and Crotch's bumble bee. Conversely, the open ground created by high flows and scour impacts on existing vegetation would be more conducive to the germination of milkweed and flowering plants that provide nectar and pollen for these species. Although there may be a temporal loss of floral resources for these insects as a result of higher flows, increased flows during construction would result in a net enhancement of habitat for these two species.

These elevated flows would be highest during the winter wet season, when monarch butterflies are scarce or absent from Coyote Creek, and when eggs, larvae, or pupae are not present on native milkweed (recent winter breeding by monarchs in the South Bay has been documented, but is associated with cultivated and irrigated, typically, nonnative milkweed rather than milkweed in natural settings that senesces in winter). As a result, any effects of high winter flows on milkweed would not impact individual monarch butterflies. Such high flows could result in the loss of overwintering Crotch's bumble bees, if they are in areas close to Coyote Creek, though it is likely that this species has evolved to select wet season refugia away from areas prone to high flows, so such impacts are unlikely.

Conservation Measures Construction

Special-status invertebrates would benefit from Valley Water's payment of VHP impact fees, which contribute to the VHP's conservation program that benefits VHP-covered (and many non VHP-covered) special-status species. The Bay checkerspot butterfly is a VHP-covered species, and the VHP's conservation program includes actions (i.e., habitat preservation, management, and monitoring) to directly benefit and recover this species. The monarch butterfly and Crotch's bumble bee are not currently VHP-covered species, though the SCVHA is proposing to add both as VHP-covered species during the upcoming VHP amendment. Whether or not these species are formally covered by the VHP, the VHP's conservation program includes the acquisition, enhancement, and management of lands providing suitable habitat (e.g., grasslands, riparian habitats, and other land cover types for monarch butterfly and grassland and scrub habitats for Crotch's bumble bee) that support and benefit these two species as well.

Otherwise, Bay checkerspot butterflies are absent from areas directly affected by the proposed Conservation Measures (including maintenance of the North Channel Reach and Live Oak Restoration Reach), and therefore no direct impacts of Conservation Measures on that species would occur. However, implementation of Conservation Measures could affect the Bay checkerspot and its habitat by contributing to the cumulative effects of nitrogen deposition on serpentine habitats supporting these species. These impacts would occur as described in *Conservation Measures Impacts Analysis* in Impact TERR-1a for special-status plants above.

Implementation of Conservation Measures could impact the monarch butterfly by removing milkweed; killing eggs, larvae, or pupae on that milkweed; and removing flowering plants that serve as adult nectar sources. Milkweed is present in the Ogier Ponds CM Area, and monarch butterflies have been documented breeding in that area. Milkweed is present in a number of areas along Coyote Creek in the Project Area (i.e., from Anderson Dam downstream to Coyote Creek Golf Drive, including the North Channel Reach and Live Oak Restoration Reach), and monarchs are expected to breed along this segment of creek. However, the number of breeding monarchs in the Conservation Measures Project Area is low, and implementation of the milkweed survey plan as part of the Project's construction monitoring components would minimize impacts on milkweed and avoid injury or mortality of monarch butterflies that might be using that milkweed.

It is unknown whether Crotch's bumble bee is present in the Conservation Measures Project Area. However, it is possible that the species could be present, possibly nesting or collecting pollen and nectar from flowering plants. Conservation Measures at the Ogier Ponds and Coyote Percolation Dam CM Areas, and possibly maintenance of the North Channel Reach and Live Oak Restoration Reach, could destroy nests and their occupants and remove pollen and nectar sources. However, the likelihood and magnitude of impacts of Conservation Measures on Crotch's bumble bee is low due to this species' low abundance.

Construction Monitoring

Two construction monitoring-related activities would help to minimize Project impacts on special-status invertebrates. Implementation of the milkweed survey plan as part of the Project's construction monitoring components would minimize impacts on milkweed and avoid injury or mortality of monarch butterflies that might be using that milkweed by taking steps to inspect milkweed for monarch eggs, larvae, or pupae before it is impacted and protecting those life stages if they are found. Because Crotch's bumble bees are known to regularly nectar on milkweed, implementation of the milkweed survey plan would help to minimize impacts on the bumble bee as well. The development and implementation of management and monitoring plans for *Phytophthora* would also reduce impacts on special-status invertebrates by minimizing impacts of Project activities on native plant species and communities from mobilization of *Phytophthora*.

Otherwise, construction monitoring activities are unlikely to have any substantive effect, adverse or beneficial, on the Bay checkerspot butterfly, monarch butterfly, or Crotch's bumble bee. Those activities involve relatively limited field activity by monitoring personnel, and though it is possible that those personnel could trample milkweeds or nectar/pollen sources for these species, or disturb individuals, such impacts would be minor and localized.

Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Adaptive Management

Bay checkerspot butterflies do not occur along Coyote Creek downstream from Anderson Dam, and therefore, post-construction operations of Anderson Dam related to downstream flows, and operations and maintenance of all the Conservation Measures along Coyote Creek downstream from the dam (e.g., Cross Valley Pipeline Extension, Ogier Ponds CM, Coyote Percolation Dam CM, North Channel Reach ~~Extension~~, Live Oak Restoration Reach, and gravel augmentation) would not impact that species. Monarch butterflies do occur along the downstream reach of Coyote Creek, and this species' larval host plant is locally common along the portion of the creek in Coyote Valley, and likely occurs in scattered patches even further downstream. In general, operation of Anderson Dam in accordance with FAHCE rule curves will result in flows predicted to be slightly lower than pre-FOCP flows, though spring pulse flows could be slightly higher for brief periods. Post-construction flows would not differ substantially from Pre-FERC Order Baseline flows in ways that could affect monarch butterflies, Crotch's bumble bees, or their habitats.

Maintenance of facilities at Anderson Dam, the Ogier Ponds CM, Coyote Percolation Dam CM, and the Cross Valley Pipeline Extension would occur in areas that were impacted by Project construction, and such maintenance would not occur in any additional areas occupied by, or providing suitable habitat for, special-status invertebrates. Therefore, such maintenance is not expected to result in impacts on these species above and beyond construction-phase impacts. Maintenance of the North Channel Reach and Live Oak Restoration Reach would involve very limited and localized impacts to maintain habitat enhancements constructed by the FOCP and would therefore have little potential to impact the monarch butterfly and/or Crotch's bumble bee. Maintenance activities could impact habitat for these invertebrates by mobilizing *Phytophthora*, and maintenance equipment and vehicles could contribute to cumulative impacts on the Bay checkerspot butterfly and its habitat through their nitrogen emissions. Adaptive management activities will affect areas downstream from Anderson Dam that do not support the Bay checkerspot butterfly; impacts of adaptive management activities on the monarch butterfly, Crotch's bumble bee, and their habitat would be similar to those resulting from Conservation Measures and post-construction flows.

Significance Conclusion Summary

Implementation of Valley Water BMPs and compliance with applicable VHP conditions would reduce impacts on the Bay checkerspot butterfly, monarch butterfly, and Crotch's bumble bee. BMPs applicable to this impact are identified in **Table 3.5-6**. VHP conditions applicable to this impact are provided in **Table 3.5-7**, and VHP-related AMMs are provided in **Table 3.5-8**.

Implementation of BMP AQ-1 will reduce the potential for construction activities to mobilize dust onto larval host plants, adult nectar sources, and bumble bee pollen sources, thus reducing the effects of dust and the potential for *Phytophthora* to be mobilized within that dust to plants on which these special-status invertebrates rely. BMPs BI-8 and WQ-9 will avoid competition between invasive plants and native plants used by these invertebrates by requiring local plant species in revegetation. BMPs ~~HM-7,~~ HM-8, HM-9, HM-10, WQ-15, and WQ-16 will minimize the potential for hazardous materials and other pollutants to impact native plants and individuals of these special-status invertebrates, and HM-12 would reduce the potential for fire to affect these species and their habitats. BMPs BI-3, WQ-4, WQ-5, and WQ-11 will involve removing temporary fill, establishing appropriate staging and stockpiling areas and construction access areas, and keeping the work sites clean, thus helping to minimize impacts on special-status invertebrates and their habitats, and avoiding the spread of *Phytophthora* and weeds. BMP BI-11 will minimize predator attraction, thus reducing predators of these invertebrates. BMP BI-4 will minimize impacts of pesticides on nontarget species such as special-status invertebrates.

Implementation of VHP Conditions 4 and 5 would reduce the potential for and magnitude of impacts on special-status invertebrates and their habitats through numerous AMMs summarized in **Table 3.5-8**; these AMMs include limiting the footprint of activities, reducing the potential for pollutants to impact these species and their habitats, avoiding the encouragement of invasive plants, and avoiding erosion and sediment impacts on these species' habitats. VHP Condition 7 would entail minimizing ground disturbance and vegetation removal, stabilizing soil to avoid erosion and sedimentation, and revegetating with native plants or other appropriate plants. Condition 13 specifically addresses serpentine-associated special-status species, such as the Bay checkerspot by requiring surveys for adults and avoidance and minimization of impacts to their habitats.

Maintenance of Anderson Dam facilities would occur as part of the DMP and would employ the BMPs and mitigation measures implemented by the DMP to avoid and minimize impacts on sensitive biological resources, such as special-status plants. DMP BMPs BI-10 and BI-11 include measures to minimize impacts to vegetation whenever clearing or trimming is necessary and minimize root impacts. BMP BI-12 entails avoidance of special-status plant species and sensitive natural communities, such as serpentine communities. BMP BI-13 requires use of local ecotypes of native plants and appropriate erosion control seed mixes to avoid impacts from invasive plant species. **DMP Mitigation Measure Wildlife-4** prohibits the use of herbicides that are not excluded from the applicable injunction, thus reducing the potential for herbicides to impact these invertebrates and their habitats.

Of these three invertebrates, only the Bay checkerspot butterfly is a VHP-covered species. All Project activities that could impact this species are covered by the VHP except for the additional year of Anderson Reservoir dewatering. High-quality Bay checkerspot butterfly breeding habitat is located far enough from Anderson Reservoir that no activities occurring in the bed of the dewatered reservoir in Year 6 would adversely affect populations of the species or high-quality habitat as a result of dust mobilization or other means. During activities in the dewatered bed of the reservoir in early spring of Year 6, dust mobilization could adversely affect the health of some plants that may be used as nectar sources by occasional adults that may disperse to the vicinity of the Seismic Retrofit Area. However, the construction season would barely overlap with the adult flight season (e.g., in April), so the effects of dust mobilization on flowers that are in active use by adult Bay checkerspots would be minimal. The haul road along the edge of the northern arm of the dewatered reservoir, closest to the large Bay checkerspot populations on Coyote Ridge (and therefore closest to where any dispersing adult checkerspots are most likely to occur near the Seismic Retrofit Area), would not be used after Year 5. Implementation of Valley Water's BMPs, including Valley Water BMP AQ-1, will further minimize mobilization of dust from Year 6 Project activities onto any Bay checkerspot nectar sources. As a result, activities within the dewatered bed of the reservoir in Year 6 would not result in the loss of any individual Bay checkerspot butterflies or in substantive impacts on this species' habitat. Therefore, with implementation of Valley Water BMPs and compliance with VHP conditions, Project impacts on the Bay checkerspot will not be substantial, and therefore would be **less than significant**.

Implementation of the FOCP *Milkweed Survey Plan* ~~*milkweed survey plan*~~ would avoid and minimize impacts on both the monarch butterfly and Crotch's bumble bee. That plan requires surveys to detect milkweed, avoidance and minimization of impacts to milkweed as feasible, and measures to avoid impacts to individual monarch butterfly eggs, larvae, and pupae if milkweed must be impacted. Implementation of the plan, which will continue unless and until the monarch butterfly is added to the VHP as a covered species, will therefore minimize Project impacts on individual monarch butterflies and on milkweed plants used by both these species. If the Monarch Butterfly is formally added to the VHP as a covered species as is currently proposed, which may occur by 2026, the VHP would then include conservation measures specifically focused on this species. Valley Water would then comply with all VHP conditions concerning the species in lieu of implementing the FOCP *Milkweed Survey Plan*.

Implementation of the FOCP *Crotch's Bumble Bee Avoidance Plan, w*hich would continue unless and until the Crotch's bumble bee is added to the VHP as a covered species or is no longer legally protected, would avoid and minimize impacts on the Crotch's bumble bee. That plan requires surveys to detect Crotch's bumble bees and their nests, avoidance measures if individuals or nests are detected, and measures to minimize impacts to the species' floral resources. Implementation of the FOCP *Crotch's Bumble Bee Avoidance Plan* would therefore minimize impacts on this species. If the Crotch's bumble bee is formally added to the VHP as a covered species as is currently proposed, Valley Water would comply with all VHP conditions concerning that species in lieu of implementing the FOCP *Crotch's Bumble Bee Avoidance Plan*.

Although the monarch butterfly and Crotch's bumble bee are not currently VHP-covered species, the VHP's vast conservation program would conserve lands that support populations of these two species due to its breadth, both geographically and in terms of the diversity of habitat types to be conserved. For example, narrow-leaved milkweed, the primary native larval host plant of the monarch butterfly, is common and widespread in the county, and it occurs on a variety of lands in the VHP's conservation areas. Similarly, Crotch's bumble bee is a generalist forager, using a vast array of flowering plants (Thorp et al. 1983). VHP conservation lands are expected to support Crotch's bumble bee populations, given the geographic spread of recent occurrences in the county, as well as high-quality habitat for the species. Therefore, Valley Water’s payment of VHP impact fees for the Project would contribute to a conservation program that would compensate for any impacts that the Project might have on the monarch butterfly and Crotch's bumble bee, even if these species are not formally added to the VHP as covered species. Thus, with implementation of Valley Water BMPs and compliance with VHP conditions, the Project will not have a substantial adverse effect on the monarch butterfly or Crotch's bumble bee, and Project impacts would be **less than significant**. Further, if the monarch butterfly and/or Crotch’s bumble bee are added to the VHP as covered species, as currently proposed, the VHP would include these species in its conservation program explicitly, thus providing even greater conservation benefits to these species.

Mitigation Measures

No mitigation is required.

Impact TERR-1c: California tiger salamander, California red-legged frog, and foothill yellow-legged frog **(Less than Significant with Mitigation)**

Seismic Retrofit Construction

A known California tiger salamander and California red-legged frog breeding pond (Rosendin Pond) is located 0.3 miles southeast of the Anderson Dam spillway and approximately 500 feet southeast of the proposed BHBA (CNDDB 2022). Because individual California tiger salamanders can disperse distances of up to 1.3 miles (Orloff 2007), California red-legged frogs can disperse up to 2 miles (Bulger et al. 2003), and because other ponds that potentially supporting these species are present in various locations around Anderson Reservoir, there is some potential for dispersing California tiger salamanders and California red-legged frogs to occur virtually anywhere in the Seismic Retrofit Area. Due to the detection of adults in the unlined spillway chute in June 2020, California red-legged frogs may attempt breeding in other waterbodies, such as the spillway chute, the pond below the spillway waterfall, or a pond just outside the Seismic Retrofit Area south of the dam, and it is possible that small numbers could attempt breeding in Coyote Creek below Anderson Dam as well. The abundance of predatory fish and bullfrogs in at least some of these waterbodies (e.g., the unlined spillway chute and Coyote Creek below the dam) would limit breeding success.

All land cover types that occur in such Project Areas, aside from reservoir and urban-suburban, are considered by the VHP as providing potential habitat for these species; the bed of the reservoir is not considered suitable habitat for the purposes of VHP compliance, though when the reservoir is dewatered, salamanders and frogs could disperse into its bed. All impacts to land cover types other than urban-suburban are considered permanent following VHP conventions. However, the Project would not result in the long-term loss of substantial amounts of California tiger salamander or California red-legged frog habitat, as most impact areas would continue to provide habitat similar to Existing Conditions Baseline conditions (i.e., post-FOCP conditions) after Seismic Retrofit construction and associated revegetation is completed.

Seismic Retrofit construction activities would include grading, excavation, and construction of new structures that would result in the loss of California tiger salamander and California red-legged frog foraging, dispersal, and refugial habitat and could result in the loss of individuals.

Construction activities may result in the injury or mortality of individuals as a result of worker foot traffic, equipment use, vehicular traffic, vegetation removal, and earth moving activities. Seasonal movements of these species may be temporarily affected during construction because of disturbance, and substrate vibrations may cause individuals to move out of refugia, exposing them to a greater risk of predation or desiccation. Lighting from nighttime work may spill into areas outside the construction footprint, subjecting individuals to increased risk of predation. Petrochemicals, hydraulic fluids, and solvents that are spilled or leaked from construction vehicles or equipment may kill individuals, although BMPs to control releases of such chemicals make this unlikely. Increases in human concentration and activity in the vicinity of suitable habitat may result in an increase in native and nonnative predators that would be attracted to trash left at the work site and that would prey opportunistically on these species. Movement of construction personnel and equipment within the site, and between onsite and offsite areas, could also spread pathogens such as chytrid fungus and ranavirus, which can impair the health of amphibians. California tiger salamanders and California red-legged frogs could be trapped in pits, trenches, or other depressions excavated during the Project or could be impacted if they take refuge in construction materials that are subsequently moved.

The number of individual California tiger salamanders and California red-legged frogs that could be impacted by construction activities is low given the distance from the nearest breeding ponds to the majority of the work areas and the minimal recorded occurrences of the species on the site. However, it is possible that some individuals would be present within these activity areas when construction occurs and could therefore be lost.

No known breeding habitat currently used by California tiger salamanders or California red-legged frogs would be impacted by Seismic Retrofit construction. Impacts to the unlined spillway chute, the pond below the waterfall, and Coyote Creek would affect potential breeding habitat for the California red-legged frog, though as discussed above, these waterbodies do not provide high-quality breeding habitat due to predator abundance. Because California tiger salamanders and California red-legged frogs do not use reservoirs for foraging or breeding (ICF 2012), these species would not breed in the reservoir during the wet season between Years 1 and 2, so dewatering in the spring of Year 2 would not result in stranding or desiccation of individuals, including eggs or larvae. By the time the reservoir is dewatered in Year 2, the egg-laying season for the species would have been completed, so even if smaller pools of water remain in the reservoir bed after dewatering occurs, they would not attract or be used by California tiger salamanders or California red-legged frogs.

During the wet seasons following Years 2 through 5 of Seismic Retrofit construction, water levels in the reservoir would be lower, because the reservoir’s outlets would be left wide open through the wet season. Depending on the timing and amount of rainfall, it is possible that California tiger salamanders or California red-legged frogs may attempt to breed in the smaller waterbody (or waterbodies, depending on topography and drainage) present in the reservoir bed. Heavy rains that maintain flow through the reservoir bed would discourage salamanders from laying eggs, but if pools without heavy flow form in depressions in the reservoir bed, individuals could lay eggs in those pools. In the spring of Years 3 to 6, when construction in the reservoir bed begins, there is some potential for California tiger salamander or California red-legged frog eggs or larvae to be present in pools in the reservoir. Pumping out the water in those pools, filling pools, or diverting flow that would otherwise have kept pools wet could result in desiccation of eggs or larvae, if present. Petrochemicals, hydraulic fluids, and solvents that are spilled or leaked from construction vehicles or equipment may kill individuals in such pools.

Despite the increased potential for California tiger salamanders and California red-legged frogs to occur in the reservoir bed as a result of dewatering, habitat conditions in the reservoir bed (e.g., along the channels entering the reservoir, in pools that form in depressions, and in the pool behind the cofferdam ~~at ponds behind check dams)~~ are unlikely to be so suitable that large numbers of individuals would occur in areas where they could be impacted by Project activities. Therefore, construction and dewatering within the reservoir would affect relatively few individuals.

Also, it is possible that the dewatered condition of the reservoir could allow California tiger salamanders and California red-legged frogs to disperse across the reservoir during the construction period, something that may not occur under normal conditions when the reservoir is filled. This dispersal may allow exchange of individuals and genes between subpopulations on either side of the reservoir, which can benefit the regional population given that the reservoir impedes such dispersal under normal conditions.

As the reservoir refills during the wet season following Year 6, any California tiger salamanders and California red-legged frogs that may be present in refugia within the reservoir bed would be displaced from their burrows by rising water. Such displacement could expose them temporarily to increased predation risk, desiccation risk, and associated energetic stresses. However, water levels would rise gradually enough that any individuals, who are well adapted to changing hydrologic conditions, would be able to safely disperse to refugia on higher ground. Furthermore, because this refilling would occur primarily during wet-season natural inflow from tributaries, California tiger salamanders and California red-legged frogs would be at less risk of desiccation when leaving burrows, because waters would rise during or closely following rain events, when the ground surface and vegetation are moist and when tiger salamanders would naturally be moving on the surface at night.

During Seismic Retrofit construction, dry season flows in Coyote Creek downstream from Anderson Dam would be maintained via bypass flows released from Coyote Reservoir, supplemented with water released into Coyote Creek through the CDL and Cross Valley Pipeline Extension. Groundwater levels along Coyote Creek or in North Coyote Valley (where California tiger salamanders breed in ponds near the west side of the valley) are not predicted to drop substantially as a result of operations during construction. Modeling performed by Valley Water predicted that there would be a reduction in groundwater recharge and storage during Seismic Retrofit construction relative to 2015 base conditions (when ~~interim seismic~~ restrictions limited reservoir capacity to 51,200 AF); however, groundwater storage is still predicted to be above Valley Water's 2021 Groundwater Management Plan storage target (Valley Water 2023a). Nevertheless, in the event that reduced creek flows resulting from the Project combined with critical drought conditions were to occur and cause a drop in groundwater levels, it is possible that ponds supporting California tiger salamanders in North Coyote Valley could have reduced hydroperiod, which could reduce the breeding success of the species by causing larvae to metamorphose before they have reached a large size, or to be stranded and desiccate in drying ponds. The ponds where California tiger salamanders have been recorded in North Coyote Valley are near the western edge of the valley (H. T. Harvey & Associates 2000d,e,f ~~2000a,d,~~ 2020, 2021), where the influence of Coyote Creek flows is likely much lower than in areas farther east, closer to the creek. No California red-legged frogs are known to breed in North

Coyote Valley; numerous surveys for the species have been performed along Fisher Creek and in ponds in North Coyote Valley, yet the species has not been detected (HTH 2000b,c,e, 2006a,b, 2007a,b, 2020, 2021), and it is possible that the species does not breed there at all. Because Valley Water would be monitoring groundwater levels and dryback effects in North Coyote Valley throughout Seismic Retrofit construction, and would augment creek flows, if necessary, no impacts on habitat for these species in North Coyote Valley are likely to occur.

Construction Phase Existing Conditions Baseline conditions for Seismic Retrofit construction allow for discharges from the dam of up to 2,500 cfs. During Seismic Retrofit construction, the reservoir's outlets would be left open during the wet season to minimize the amount of water that accumulates in the reservoir bed. The magnitude of flow, and frequency of flows of a certain magnitude, will depend on rainfall amounts during individual runoff events and Coyote Reservoir releases. Valley Water (2022c ~~2022d~~) predicts higher flows at the 2-, 5-, and 10-year return intervals during construction. At their maximum, such flows could be as high as 6,000 cfs, which represents the maximum capacity of all dam outlets that will be present. However, a 6,000-cfs flow during Seismic Retrofit construction has a very low probability of occurring, as it would represent a 200-year event (with a 0.5 percent likelihood of occurring in any given year). The higher the flow, the lower the probability and frequency of that flow occurring in any given year, so that very high flows, greater than the 10-year or 20-year events, are unlikely during the Project construction period, though possible.

If California red-legged frogs are present along the creek downstream from the dam, they could be displaced by winter flows that are higher during construction than the Existing Conditions Baseline. Because higher wet season flows would ramp up naturally, individuals close enough to the creek that may be affected by the rising water elevation would be able to emerge and move to higher ground in response to rising water levels. Such displaced individuals may be subject to increased predation risk and desiccation risk. However, the number of individuals that could be present in areas at risk of inundation is low due to the absence of high-quality breeding habitat in areas close to Coyote Creek downstream from the dam. If red-legged frogs were to attempt breeding in Coyote Creek downstream from the dam, high flows could dislodge egg masses or cover them with sediment, though again, the likelihood and frequency of attempted breeding in the creek would be low. These construction-period reservoir operations would more closely follow the natural hydrograph, with higher flows associated with rain events and lower flows during dry conditions, than normal dam operations. These flows during construction (including both drier conditions in summer and some higher-flow events in winter) are similar to the hydrological conditions under which California red-legged frogs evolved, so frogs would be well adapted to such conditions.

There is some possibility that an occasional individual California tiger salamander from nearby breeding areas (e.g., Rosendin Pond) might be present in upland refugia along the banks of Coyote Creek downstream from Anderson Dam, in areas that would be subjected to inundation as a result of higher winter flows during construction. Because higher wet season flows would ramp up naturally, individuals that are in burrows close enough to the creek to be affected by rising water elevations would be able to emerge and move to higher ground in response to rising water levels. Such displaced individuals may be subject to increased predation risk and desiccation risk. However, the number of individuals that could be present in areas at risk of inundation is very low due to the absence of high-quality breeding habitat in areas close to Coyote Creek downstream from the dam.

Considerable sediment has accumulated in the bed of Anderson Reservoir since construction of the dam. When these sediments are covered by water, as under normal conditions when the reservoir is filled, they are not easily eroded. However, when the reservoir has been dewatered, these sediments would be more subject to erosion from rainfall runoff and from the reservoir's tributaries. Because the reservoir's outlets would be left open during the wet season to minimize the amount of water that accumulates in the reservoir bed, considerable sediment is predicted to be mobilized downstream from the dam during Seismic Retrofit construction. This increase in sediment mobilization would result both from the exposed nature of sediments under certain flows and the higher flow rates through the dam during construction. URS ~~AECOM~~ (2021) modeled sediment mobilization under different flow scenarios, concluding that the maximum sediment mobilization would occur if back-to-back 2-year rainfall events (i.e., events that have a 50 percent likelihood of occurring in any given year), or a single 5-year event (20 percent likelihood of occurrence in any given year), were to occur when relatively little water was present in the reservoir. During those events, flows would be high enough to erode large amounts of sediment from the reservoir (approximately 167,000 tons per event) but not so high as to inundate the reservoir level above the sediment bed, which would reduce their erosivity. This mobilized sediment could adversely affect California red-legged frogs by coating or covering egg masses, and increased turbidity could inhibit efficient foraging by larvae. However, very few individuals, egg masses, or larvae (if any) would be affected given that Coyote Creek, below Anderson Dam, does not provide high-quality habitat for the California red-legged frog. Farther downstream, where Coyote Creek flows through urban San José, California red-legged frogs are likely completely absent due to the absence of suitable habitat and the cumulative stressors of the urban environment (e.g., predation, human disturbance, and water-quality impacts).

In addition, flows that occur through the dam during Seismic Retrofit construction may result in erosion of wetland and riparian habitat along Coyote Creek downstream if flow velocity is high enough to erode sediment and scour vegetation. Such habitats provide potential habitat for California red-legged frogs, and all impacts to land cover types other than urban-suburban are considered permanent following VHP conventions. However, while this sedimentation and erosion may have adverse effects on red-legged frog cover for a year or two, until these areas are recolonized by vegetation, the long-term effects on the ecology of Coyote Creek would be beneficial. Sediment supplies to the creek have been modified and reduced due to the historical presence of the dam and the accumulation of sediment behind the dam. The constraints on sediment input to the creek, and limitations on natural erosion and sediment deposition processes downstream from the dam have contributed to limited regeneration of species, such as cottonwoods and willows that rely on bare sediment along stream channels for germination. As a result, following the potential initial loss of wetland and riparian habitat due to increased construction period wet-season flows, erosion, and sedimentation, the bed dynamism and rejuvenated sediment load from potential flows during the construction period could improve the regeneration of riparian vegetation over the long-term and help sustain high-quality habitat conditions.

There are no recent records of the foothill yellow-legged frog from the Project Area. No surveys conducted for the DMP, FOCP, or Project have detected the species at or near Anderson Dam, and surveys for the species have not detected yellow-legged frogs along Coyote Creek either downstream from Anderson Dam or in the reach between Coyote Dam and Anderson Reservoir (Valley Water 2016, 2019b ~~2019c~~; H. T. Harvey & Associates 2019b ~~2019a~~). If individuals were to disperse downstream from known occurrences along Otis Creek, or from historical locations along San Felipe Creek, normal conditions in Anderson Reservoir (i.e., the presence of vast, deep water) would likely prevent this stream-dwelling frog from reaching Anderson Dam. When the reservoir is dewatered during Seismic Retrofit construction, yellow-legged frogs could attempt to disperse into the bed of the reservoir along these tributaries. However, yellow-legged frogs are closely associated with cobbly streams. They would need to travel through a mile or more of stream channel lined with fine sediment that has accumulated in the reservoir bed to reach areas where Project activities would occur. Due to the presumed low sizes (owing to the lack of recent records) of yellow-legged frog populations that occur in areas where they could disperse to the Project Area, coupled with the distance these frogs would need to travel through unsuitable habitat conditions in silt-lined stream channels in the reservoir bed, there is a very low probability that foothill yellow-legged frogs would occur in areas where Project activities would occur within the bed of the dewatered reservoir. Foothill yellow-legged frogs would not reach Anderson Dam itself, or occur along Coyote Creek downstream from the dam.

Because foothill yellow-legged frogs are closely associated with streams, rather than making overland movements like California red-legged frogs, and because the species does not occur in the “reservoir” land cover type, Seismic Retrofit activities would not affect any land cover that is considered suitable for the species, where individuals may occur. For example, although the VHP models Coyote Creek downstream from Anderson Dam as secondary habitat for the species (ICF 2012), yellow-legged frogs have largely disappeared from streams below dams, and this species does not occur in Coyote Creek below Anderson Dam.

Seismic Retrofit construction could affect foothill yellow-legged frogs only in the unlikely event that an individual dispersed downstream into the bed of the dewatered reservoir. If that were to occur, injury or mortality of individuals may occur in the same ways described above for California tiger salamander and California red-legged frog. The number of individual foothill yellow-legged frogs that could be impacted by construction activities is extremely low, and it is possible that none would be adversely affected. No suitable breeding habitat currently used by foothill yellow-legged frogs would be impacted by the Project, and the channels that develop in the bed of the dewatered reservoir would be too silty (rather than cobbly), and contain too little flow, for use by breeding foothill yellow-legged frogs. Therefore, the Project would not affect yellow-legged frog eggs, larvae, or breeding habitat. If any yellow-legged frogs are present in the bed of the reservoir when it refills during the wet season following Year 6, they would disperse upstream to more suitable habitat, and no adverse effects from reservoir refilling would occur.

Conservation Measures Construction

The potential for California red-legged frog occurrence in the Ogier Ponds CM and Coyote Percolation Dam CM Areas is low, as abundant fish and bullfrogs in the Ogier Ponds, the Parkway Lakes, and the Coyote Percolation Pond reduce the potential for maintenance of a viable population in those areas, and US 101 impedes dispersal of individuals from breeding populations east of the highway. However, there is one CNDDB record from Ogier Ponds; a large population is present in a red-legged frog mitigation area on the Kirby Canyon landfill east of US 101, and individuals could occasionally disperse through culverts under the highway to the Ogier Ponds area. In addition, red-legged frogs have been recorded in the culvert carrying the Coyote Canal under US 101, adjacent to Ogier Ponds. Therefore, there is some potential for at least small numbers of individuals to occasionally occur in the Ogier Ponds CM Area. Similarly, few, if any, California red-legged frogs are present in the North Channel Reach or Live Oak Restoration Reach where maintenance of ~~Extension Area or other areas where~~ fish-related habitat enhancements are proposed. Nevertheless, if individual California red-legged frogs are present in these areas, they could be subject to the same types of construction-related impacts described for Seismic Retrofit construction above.

The potential for California tiger salamander occurrence in any of the~~se~~ Conservation Measures Project Areas is extremely low given the absence of suitable breeding ponds and pools that could provide a source for dispersing individuals. At best, a long-distance dispersant might be present along Coyote Creek in the North Channel ~~Extension Area~~ Reach or Live Oak Restoration Reach where maintenance of the habitat enhancements ~~Conservation Measures~~ would be implemented. Such an individual could then be subject to the same types of ~~construction-related~~ impacts, though more limited in scale and duration, described for Project construction above.

Foothill yellow-legged frog is absent from these areas downstream from Anderson Reservoir and would not be impacted by Conservation Measures.

All land cover types that occur in the Conservation Measures Project Area, aside from reservoir and urban-suburban, provide potential habitat for the California red-legged frog and California tiger salamander. Approximately 6.1 acres of new hardscaping is proposed at the Ogier Ponds (maintenance roads, spillway, and outlet) and Coyote Percolation Dam (the roughened ramp), thus resulting in the loss of some suitable habitat. Otherwise, Conservation Measures would not result in the long-term loss of California tiger salamander or California red-legged frog habitat, as most impact areas would continue to provide habitat similar to, or of higher quality than, Existing Conditions Baseline (post-FOCP) conditions after construction of Conservation Measures is completed. Therefore, although impacts modifying VHP land cover types for more than 1 year are considered permanent for VHP compliance purposes, no substantial long-term impacts on habitat of the California tiger salamander or California red-legged frog will result from the Project's Conservation Measures.

Conservation Measures include release of imported water via the CDL and Cross Valley Pipeline Extension, which would help maintain groundwater levels and thus the aquatic, wetland, and riparian habitats along Coyote Creek and in North Coyote Valley that may be used by special-status amphibians.

Special-status amphibians would benefit from Valley Water's payment of VHP impact fees, which contribute to the VHP's conservation program that benefits VHP-covered (and many nonVHP-covered) special-status species. The California tiger salamander, California red-legged frog, and foothill yellow-legged frog are all VHP-covered species, and the VHP's conservation program includes a number of actions, including habitat preservation, restoration, enhancement, and management, to directly benefit and recover these species.

Construction Monitoring

Although California red-legged frogs occur downstream from Anderson Reservoir only infrequently and in low numbers, monitoring of water quality, suspended sediment, and sediment deposition during Project construction would help to reduce impacts from unconstrained flow releases on any individuals present downstream from the reservoir. Invasive species monitoring and control to be implemented during construction would reduce impacts of invasive species, such as bullfrogs and nonnative fish, on California red-legged frogs in the Project Area. However, if any individuals are present in Coyote Creek downstream from the reservoir, they could be disturbed, captured, or possibly subject to electroshock during such construction-related, fisheries-related monitoring. California tiger salamanders would not use the creek itself, downstream from Anderson Reservoir, and thus would not be impacted by instream construction monitoring activities.

If steelhead require relocation from the CWMZ to Upper Penitencia Creek during Project construction, they could be relocated to areas supporting California red-legged frogs and foothill yellow-legged frogs (California tiger salamanders would not be present in fish relocation areas). The physical presence and activity of biologists during fish release and subsequent monitoring may disturb individual frogs. Relocated steelhead could compete with frogs for food, and larger individuals could possibly prey on red-legged frog and yellow-legged frog larvae. However, as described in the Fish Rescue and Relocation Plan (Valley Water and Stillwater Sciences 2020), the number of steelhead relocated to a given area within Upper Penitencia Creek would be low enough that steelhead densities would be within the natural range of variation that has allowed populations of other sensitive species (such as California red-legged frogs and foothill yellow-legged frogs) to persist so that no long-term, population-level impacts of steelhead relocation on red-legged frogs or foothill yellow-legged frogs would occur. Relocation of fish from Coyote Creek to Upper Penitencia Creek, and any follow-up monitoring (e.g., for amphibian diseases or New Zealand mud snails) involves some risk of relocating diseases or invasive species. However, chytrid has previously been recorded in the upper watershed of Upper Penitencia Creek (Padgett-Flohr and Hopkins 2010) and was detected by Valley Water in 2021, during monitoring associated with FOCP fish relocation. Chytrid was detected along Upper Penitencia Creek above the waterfall that serves as a barrier to upstream fish movement, demonstrating the presence of the pathogen is unrelated to fish relocation (Valley Water 2022b ~~2022a~~). The Fish Rescue and Relocation Plan includes measures to minimize the spread of pathogens or invasive aquatic species. If any fish relocations to Upper Penitencia Creek are necessary, then Valley Water would continue to implement the Amphibian Disease and New Zealand Mud Snail Monitoring Plan (Valley Water 2020j ~~2020e~~) throughout the Project.

Designated California red-legged frog critical habitat is present in the reach of Upper Penitencia Creek, where fish relocation may occur. Fish relocation would not modify red-legged frog habitat or the primary constituent elements of designated critical habitat, and with implementation of the measures in the Fish Rescue and Relocation Plan, the impacts of fish relocation on California red-legged frogs in Upper Penitencia Creek would be minimal. Therefore, fish relocation is not likely to adversely affect California red-legged frog critical habitat.

During Project construction, Valley Water would monitor groundwater levels and continue to perform monitoring per the Dryback Monitoring Plan. Results of this monitoring would be used by Valley Water to determine whether creek flows need to be augmented to avoid adverse dryback effects on aquatic, wetland, or riparian habitats that could affect special-status amphibians. Valley Water would compensate for any impacts on wetland, riparian, or aquatic habitat that are detected by dryback monitoring and that can be attributed to reduced creek flows due to Project construction by paying VHP fees for the impacts detected.

Construction monitoring related to *Phytophthora* would help minimize the potential for mobilization or spread of other pathogens, including those (such as ranavirus) affecting amphibians.

Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Adaptive Management

Analysis of the effects of post-construction FAHCE operations on the California tiger salamander, California red-legged frog, and foothill yellow-legged frog was performed relative to the Pre-FERC Order Baseline (2017 conditions) and WEAP-modeled Future Baseline (2035 conditions). As described previously in the general discussion of Project impacts on terrestrial biological resources, flows under the FAHCE rule curves will be generally similar to~~,~~ ~~those under 2017 conditions~~ but possibly slightly lower than the Pre-FERC Order Baseline Conditions, while FAHCE flows are likely to be slightly higher than under the WEAP-modeled Future Baseline. Any increase in flows would be ramped up and down to allow aquatic animals to adapt to changing flows. In general, FAHCE flows may entail slightly lower flows in winter and summer, due to retention of water in the reservoir for spring pulse flows, than either the Pre-FERC Order or Future Baselines, punctuated by the spring pulse flows described above. However, the effects of such changes may differ in different parts of Coyote Creek, as described previously.

Proposed FAHCE flows would have no substantial impact on California red-legged frogs. Very few California red-legged frogs would occur near Coyote Creek downstream from Anderson Dam due to the absence of high-quality breeding habitat near this reach of the creek. Flow ramping would occur to manage changes in the rate of water flow in a slow, stepwise fashion, allowing frogs to move to more sheltered refugia as flow rates are increased. Ramping would occur whenever Valley Water-controlled flows would be increased or decreased by 25 ~~50~~ percent or more from the existing flow condition. High flows may displace an occasional California red-legged frog along Coyote Creek downstream from Anderson Dam, and such changes in effects could impact a red-legged frog egg mass. However, flows high enough to result in such effects will occur very infrequently, and would occur slightly less frequently under post-construction operations than under pre-FOCP conditions. California tiger salamanders are unlikely to be in burrows so close to the creek that they would be adversely affected by spring pulse flows. Any salamanders subjected to such increases would be able to relocate to higher ground, especially if flow increases were great enough that ramping of flows would occur. Foothill yellow-legged frogs are absent from Coyote Creek downstream from Anderson Dam and thus would not be affected by post-construction operations of the dam.

From October through April, post-construction water temperatures in the CWMZ would not differ from the Pre-FERC Order or Future Baselines (see Figure P-CO.3 and Figure P-CO.4 in Appendix F). In summer, post-construction base flows would target maintaining a water temperature not to exceed a daily average of 64.4°F (18°C) in as much of the CWMZ as possible, which would differ from the Pre-FERC Order or Future Baselines. As depicted in Figure P-CO.3 and Figure P-CO.4 in Appendix F, the difference between FAHCE water temperatures and baseline temperatures varies considerably among locations within the CWMZ, and in some locations, differences can be as great as 5-10°F. In most locations, however, the difference would be only 2-4°F. Frogs are affected by water temperature, as larvae develop more rapidly in warmer water than in cool water (Manin and Pandian 1985), and studies suggest that California red-legged frogs in cool, moist regions may spend more time farther from water than frogs in warmer, drier regions (Bulger et al. 2003, Christopher 2004 in USFWS 2022, USFWS 2022). However, California red-legged frogs are also adversely affected by high temperatures, often being found in cooler sites, and warm-water fish are known predators of this species (USFWS 2006). Younger embryos tolerate water temperatures of 48-70°F (9-21°C) (Nussbaum et al. 1983), and areas with higher numbers of California red-legged frog larvae in a San Mateo County study had mean water temperatures of 60-75°F (15-25°C) (USFWS 2002). Another study found that California red-legged frogs were absent from water exceeding 70°F (22°C). Therefore, the target post-construction water temperatures in the CWMZ are well within the range used by California red-legged frogs. Furthermore, this species is unlikely to breed, or even occur, regularly or in numbers, if at all, in the CWMZ due to the abundance of nonnative predators and distance from suitable breeding sites. Therefore, reduced water temperatures resulting from post-construction operations will not have a substantial effect, either adverse or beneficial, on the California red-legged frog. Changes in water temperature will not affect the California tiger salamander, which would not use instream habitat downstream from Anderson Dam, or the foothill yellow-legged frog, which is absent from this reach of Coyote Creek.

Post-construction operations and maintenance of the Ogier Ponds CM, Live Oak Restoration Reach habitat improvements, and North Channel Reach ~~Extension~~ will have little effect on the California red-legged frog, which will occur only occasionally, if at all, in these areas. If any red-legged frogs are present in these areas, they would use the habitats provided by these Conservation Measures. The potential for California tiger salamander occurrence in any of the Conservation Measures areas is extremely low given the absence of suitable breeding ponds and pools that could provide a source for dispersing individuals. At best, an individual dispersing from a distant breeding location might be present along Coyote Creek in the North Channel Reach or Live Oak Restoration Reach where maintenance of habitat enhancements would occur. Operation of these Conservation Measures will have little to no effect on the California tiger salamander and no effect on the ~~or~~ foothill yellow-legged frog, which is ~~are~~ absent from these areas. The Coyote Percolation Dam CM will not impact special-status amphibians, which are not expected to be present in Coyote Creek downstream from the percolation dam.

Maintenance of Anderson Dam facilities would have little effect on California tiger salamanders or California red-legged frogs. It is possible that small numbers of individuals could be killed or injured by maintenance equipment, vehicles, or personnel, or during activities, such as filling and compaction of mammal burrows on the dam face. However, based on the lack of occurrences detected at the dam, and the absence of any individuals detected during the scoping of burrows for amphibians during 4 years of surveys, these species are present infrequently and/or in low numbers. Maintenance of all Conservation Measures, including sediment augmentation, Ogier Ponds and Coyote Percolation Dam habitat restoration improvements, and others, would not occur in areas occupied by, or providing suitable habitat for, the California tiger salamander, and the likelihood/frequency of occurrence by California red-legged frogs in these areas would be low. If a California red-legged frog were present during maintenance of a Conservation Measure, impacts could occur in the ways described above for maintenance of dam facilities.

Adaptive management activities consist primarily of monitoring and potential adaptive management actions. There is a very low potential for field monitoring activities to disturb California red-legged frogs, though if any individuals were present in monitoring locations, they could be disturbed by field personnel. Impacts of adaptive management actions would likely be similar to those resulting from Conservation Measures and post-construction flows.

Foothill yellow-legged frogs would not be impacted by post-construction operations, maintenance, or monitoring, as they are absent from areas affected by these activities.

Significance Conclusion Summary

Project impacts on the foothill yellow-legged frog are unlikely to occur and would not be substantial, and therefore the Project would have a less-than-significant impact on this species.

Implementation of Valley Water BMPs and compliance with applicable VHP conditions would reduce Project impacts on the California tiger salamander and California red-legged frog and reduce any adverse effects on the foothill yellow-legged frog that could occur. BMPs applicable to this impact are identified in **Table 3.5-6**. VHP conditions applicable to this impact are provided in **Table 3.5-7**, and VHP-related AMMs are provided in **Table 3.5-8**.

Implementation of BMPs BI-2, WQ-1, and WQ-2 will reduce impacts on California red-legged frogs by minimizing use of vehicles and equipment in streams. BMPs BI-3, BI-9, WQ-4, WQ-5, and WQ-11 will involve removing temporary fill, restoring channel bottoms, establishing appropriate staging and stockpiling areas and construction access areas, and keeping the work site clean, thus helping to minimize impacts on special-status amphibians and their habitats and avoid the spread of pathogens. BMPs BI-8 and WQ-9 will reduce impacts on special-status amphibian habitat by avoiding competition between invasive plants and native vegetation. BI-10 would avoid entrapment of amphibians in pipes, hoses, trenches, and other locations during construction. BMP BI-11 will minimize predator attraction, thus reducing predators of these amphibians. BMPs ~~HM-7,~~ HM-8, HM-9, HM-10, WQ-3, WQ-6, WQ-15, and WQ-16 will minimize the potential for hazardous materials and other pollutants to impact these amphibians and their habitats, and HM-12 will reduce the potential for fire to affect these species and their habitats. BMP BI-4 will minimize impacts of pesticides on nontarget species, such as special-status amphibians.

Implementation of VHP Conditions 3, 4, 5, 7, 11, and 12 would reduce the potential for and magnitude of impacts on special-status amphibians and their habitats by minimizing impacts on stream, wetland, and pond habitats. These conditions require implementation of numerous AMMs summarized in **Table 3.5-8**; these AMMs include limiting the footprint of activities, reducing the potential for pollutants to impact these species and their habitats, avoiding the encouragement of invasive plants, and avoiding erosion and sediment impacts on these species' habitats. VHP Condition 7 would entail minimizing ground disturbance and vegetation removal, stabilizing soil to avoid erosion and sedimentation, and revegetating with native plants or other appropriate plants.

Maintenance of Anderson Dam facilities would occur as part of the DMP and would employ the BMPs and mitigation measures implemented by the DMP to avoid and minimize impacts on sensitive biological resources, such as special-status amphibians. DMP BMPs BI-10 and BI-11 minimize impacts to vegetation, and **DMP Mitigation Measure Vegetation-6** requires restoration of vegetation that may have been lost due to dryback following dewatering. BMP BI-13 requires use of local ecotypes of native plants and appropriate erosion control seed mixes to avoid impacts to amphibian habitat from invasive plant species. **DMP Mitigation Measure General-3** requires development of a reservoir-specific dewatering plan to minimize impacts on sensitive wildlife during dewatering, specifically including amphibians. BMP BI-2 requires salvage of native aquatic vertebrates from dewatered channels, and **DMP Mitigation Measure Wildlife-1** and BMP WQ-12 require implementation of a flow bypass system for activities that would interrupt flow downstream from the dam. **DMP Mitigation Measure Wildlife-2** restricts vehicle and equipment use in salmonid streams during portions of the year, which would reduce impacts on the occasional California red-legged frog that might occur in Coyote Creek downstream from the dam. **DMP Mitigation Measure Wildlife-4** prohibits the use of herbicides that are not excluded from the applicable injunction, thus reducing the potential for herbicides to impact these amphibians and their habitats. **DMP Mitigation Measure Wildlife-5** reduces the potential for special-status amphibians to be captured in rodent traps, and BMP BI-16 avoids entrapment of sensitive animals in pipes, hoses, holes, and trenches. **Mitigation Measure Wildlife-7** includes a number of AMMs specific to special-status amphibians. **Mitigation Measure Wildlife-8** includes measures to avoid California red-legged frogs and California tiger salamanders during weephole and expansion joint cleaning and repair. BMP BI-17 minimizes the attraction of predators of sensitive species. The DMP also includes a number of BMPs to protect water quality, maintain clean work sites, and reduce erosion, thereby reducing the potential for impacts on special-status amphibians; these include BMPs WQ-4, WQ-5, WQ-7, WQ-10, WQ-14, and WQ-18.

The California tiger salamander, California red-legged frog, and foothill yellow-legged frog are covered by the VHP, and most of the activities that could impact these species (including post-construction operations under FAHCE rule curves) are explicitly VHP-covered. Thus, VHP compliance would ensure that impacts of VHP-covered activities on these species remaining after implementation of BMPs and DMP measures would not be substantial, and therefore would be **less than significant**.

However, the following Project activities are not VHP covered, and their impacts are discussed below:

- The additional year of Anderson Reservoir dewatering could affect California tiger salamanders and California red-legged frogs (though not likely foothill yellow-legged frogs) that may disperse into the reservoir bed and that are then impacted by construction activities due to the reservoir's dewatered condition and could affect eggs or larvae in pools within the reservoir bed. However, habitat conditions in the reservoir bed (e.g., along the channels entering the reservoir, in pools that form in depressions, and in the pool behind the cofferdam ~~at ponds behind check dams~~) would not be so suitable that large numbers of individuals would occur in areas where they could be impacted by Project activities during the additional year of dewatering. Therefore, construction and dewatering within the reservoir during that year would affect relatively few individuals. During this additional year of dewatering, Valley Water would continue to implement all VHP conditions. Although this additional year of dewatering could result in adverse dryback effects on aquatic, wetland, and riparian habitat along Coyote Creek downstream from Anderson Dam and in North Coyote Valley, creek flow augmentation, groundwater monitoring, and dryback monitoring (with additional flow augmentation, and payment of VHP impact fees for impacted wetland and riparian habitat, as necessary) would avoid significant impacts related to dryback effects.

  In addition, to further reduce impacts, Valley Water will implement **Mitigation Measure TERR-1c(1)** to provide additional avoidance and minimization during activities in the dewatered reservoir from the end of the Year 5 construction season through the Year 6 construction season.

- Differences in dam releases between those covered by the VHP and those that may occur during Project construction, although the Project will adhere to the VHP-covered release requirements when draining Anderson Reservoir for dewatering each year, at the start of the construction season (i.e., around April 15), wet-season flows through

Anderson Dam may be much higher than those discussed in the VHP, as Valley Water needs to avoid having Anderson Reservoir fill during Project construction. At their maximum, such flows could be as high as 6,000 cfs, which represents the maximum capacity of all dam outlets that will be present. However, a 6,000-cfs flow during Seismic Retrofit construction has a very low probability of occurring, as it would represent a 200-year event (with a 0.5 percent likelihood of occurring in any given year). The VHP did not explicitly discuss the possibility that flows may exceed those in VHP **Table 2-4** during the construction period, outside of actual dewatering events. Therefore, the impacts of such flows on terrestrial biological resources may not be covered by the VHP.

As discussed above, these increased flows would have little, if any, adverse effect on special-status amphibians, as foothill yellow-legged frogs are absent from Coyote Creek downstream from the dam, and California tiger salamanders and California red-legged frogs would occur in areas where they could be affected by high flows very infrequently and/or in low numbers. These individuals would be able to move out of areas where they could be adversely affected by high flows as the flows ramp up (either intentionally, in the case of post-construction flows, or naturally during rain events, during construction). As a result, the higher flow rates would have little impact, if any, on special-status amphibians.

- Impacts of steelhead relocation to Upper Penitencia Creek are not covered by the VHP. Although these relocations would have little impact on the foothill yellow-legged frog and California red-legged frog (and no impact on the California tiger salamander) with implementation of the measures in the Fish Rescue and Relocation Plan and the Amphibian Disease and New Zealand Mud Snail Monitoring Plan, there is some potential for introduction of diseases or mud snails during those fish relocations; diseases or mud snails could cause substantial adverse effects on foothill yellow-legged frog and California red-legged frog, and this impact would be significant. If fish relocation to Upper Penitencia Creek is necessary, Valley Water will implement **Mitigation Measure TERR-1c(2)** to compensate for any impacts of such relocations on special-status amphibians by removing nonnative species that could adversely affect special-status amphibians from Valley Water-owned properties in the Upper Penitencia Creek watershed.

With implementation of **Mitigation Measures TERR-1c(1)** and **TERR-1c(2)**, Project impacts on the California tiger salamander, California red-legged frog, and foothill yellow-legged frog would not be substantial and therefore would be **less than significant**.

Mitigation Measures

TERR-1c(1) Special-Status Species Avoidance and Minimization Measures During Year 6 Reservoir Dewatering

Valley Water and/or its contractor will implement the following AMMs during Year 6 construction activities (i.e., dewatering; movement of construction personnel, vehicles, and equipment; or storage or stockpiling of equipment or materials) in the dewatered bed of Anderson Reservoir:

- Prior to Year 6 construction activities, Valley Water will obtain approval from USFWS and CDFW of appropriate relocation sites for all life forms of the California tiger salamander, California red-legged frog, ~~and~~ foothill yellow-legged frog, and northwestern pond turtle.

- A qualified biologist approved by USFWS and CDFW (hereafter “approved biologist”) Will conduct a preactivity survey for all life forms of the California tiger salamander, ~~and~~ California red-legged frog, and northwestern pond turtle (as well as the foothill yellow-legged frog, even though it is unlikely to be present) in areas where they could be stranded or desiccated as those pools are pumped out or dry out. Any individuals detected will be moved to USFWS/CDFW-approved relocation sites.
- Within 48 hours prior to the start of construction or other activities within the bed of the reservoir, following dewatering in the spring of Year 6, an approved biologist will conduct a preactivity survey for all life forms of the California tiger salamander, California red-legged frog, ~~and~~ foothill yellow-legged frog, and northwestern pond turtle in areas where they could be subject to impacts from activities in the bed of the reservoir during Year 6 construction. Any individuals detected will be moved to USFWS/CDFW-approved relocation sites.
- Before any heavy equipment stored overnight is moved, a dedicated member of the construction crew trained by an approved biologist will inspect the area underneath and around the equipment to determine that no California tiger salamanders, California red-legged frogs, ~~or~~ foothill yellow-legged frogs, or northwestern pond turtles are present and at risk of being crushed by moving equipment. If an individual of one of these species is present in an area where it could be killed or injured by Project activities, that member of the construction crew will contact the approved biologist, who will capture and relocate the animal to a USFWS/CDFW-approved relocation site.
- An approved biologist will be onsite or on-call during all activities that could result in the take of the California tiger salamander, California red-legged frog, ~~or~~ foothill yellow-legged frog, or northwestern pond turtle to determine that all Conservation Measures are being implemented appropriately and to relocate any individual of these species that needs to be relocated to avoid injury or mortality.
- ~~Pipes diverting water from behind check dams or cofferdams to outlets below Anderson Dam will be completely screened with wire mesh not larger than 5 millimeters, to prevent California tiger salamanders, California red-legged frogs, and foothill yellow-legged frogs from being entrained in outflow pipes. Screens will not be placed directly on the openings of the diversion pipes, to avoid having flow velocities that are too great for small or larval animals. Rather, the screens will be placed farther from the pipe, encircling an area of water just above the entrance to the diversion or formed into a cage around the pipe entrance, so that flow velocities through the screen are not so high as to entrain animals against the screen.~~

TERR-1c(2) Nonnative Species Management in Upper Penitencia Creek Watershed

During each year in which steelhead relocation to Upper Penitencia Creek occurs during Project construction, prior to relocation, Valley Water will perform management of nonnative species that could adversely affect special-status amphibians and reptiles on Valley Water-owned properties in the Upper Penitencia Creek watershed. Such management will include the removal and euthanasia of bullfrogs, nonnative fish, and/or nonnative turtles from selected ponds on Valley Water’s Upper Penitencia Creek watershed properties. Prior to performing annual nonnative species management, Valley Water will provide the USFWS and CDFW a description of the proposed nonnative species management and obtain those agencies' approval of the management activities. Following the implementation of the annual nonnative species management, Valley Water will provide the USFWS and CDFW a brief report summarizing the management actions performed.

***Impact TERR-1d~~: Western~~ Northwestern Pond Turtle* (Less than Significant)**

Seismic Retrofit Construction

Seismic Retrofit construction activities would include grading, excavation, and construction of new structures that would result in the loss of northwestern pond turtle foraging, dispersal, and refugial habitat; this could possibly result in impacts to northwestern pond turtle nests and nesting habitat that may result in the loss of individuals. Construction-related impacts on individuals could occur in the ways described in Impact TERR-1c for special-status amphibians. However, the number of individuals that could be impacted by Seismic Retrofit construction is very low. Although a northwestern pond turtle was recorded in Anderson Reservoir in 2001 (CNDDB 2022), the species is very scarce there, based on the lack of observations during a number of recent surveys and focused monitoring. This species has been recorded in low numbers elsewhere in the Seismic Retrofit Area, namely in a pool below the spillway waterfall and in Coyote Creek immediately downstream from the dam. Therefore, it is possible that some individuals would be present within these activity areas when construction occurs and could therefore be lost.

All land cover types that occur in the Seismic Retrofit Area provide potential habitat for the northwestern pond turtle, and all impacts to land cover types other than urban-suburban are considered permanent following VHP conventions. However, from a biological perspective, Seismic Retrofit construction would not result in the long-term loss of substantial amounts of northwestern pond turtle habitat, as most impact areas would continue to provide habitat similar to, or of higher quality than, Existing Conditions Baseline conditions after Seismic Retrofit construction is completed.

Groundwater levels along Coyote Creek or in North Coyote Valley are not predicted to drop substantially as a result of operations during construction. Modeling performed by Valley Water predicted that there would be a reduction in groundwater recharge and storage during Seismic Retrofit construction relative to 2015 base conditions (when ~~interim seismic~~ restrictions limited reservoir capacity to 51,200 AF); however, groundwater storage is still predicted to be above Valley Water's 2021 Groundwater Management Plan storage target (Valley Water 2023a). Nevertheless, it is possible that fewer pools suitable for this species may be present in the Coyote Creek channel, particularly if drought conditions continue, and that ponds supporting northwestern pond turtles (such as the Ogier Ponds) could have lower water levels or a reduced hydroperiod. This could increase competition among northwestern pond turtles, and between northwestern pond turtles and nonnative red-eared sliders, for food or basking sites. Dryback could also cause northwestern pond turtles to disperse away from their preferred waterbodies, thus exposing them to increased risk of predation or vehicular mortality.

Construction Phase Existing Conditions Baseline conditions for Seismic Retrofit construction allow for discharges from the dam of up to 2,500 cfs. During Seismic Retrofit construction, the reservoir's outlets would be left open during the wet season to minimize the amount of water that accumulates in the reservoir bed. The magnitude of flow, and frequency of flows of a certain magnitude, will depend on rainfall amounts during individual runoff events and Coyote Reservoir releases. Valley Water (2022c ~~2022d~~) predicts higher flows at the 2-, 5-, and 10-year return intervals during construction. At their maximum, such flows could be as high as 6,000 cfs, which represents the maximum capacity of all dam outlets that will be present. However, a 6,000-cfs flow during Seismic Retrofit construction has a very low probability of occurring, as it would represent a 200-year event (with a 0.5 percent likelihood of occurring in any given year). The higher the flow, the lower the probability and frequency of that flow occurring in any given year, so that very high flows, greater than the 10-year or 20-year events, are unlikely during the project construction period, though possible.

~~Western~~ Northwestern pond turtles within Coyote Creek downstream from Anderson Dam could be displaced by winter flows during construction that are higher than Existing Conditions Baseline (post-FOCP) flows. Because wet-season high-flow events would ramp up naturally, individuals close enough to the creek to be affected by high flows would be able to move to higher ground in response to rising water levels, though such displaced individuals may be subject to increased predation risk or vehicular mortality. However, such flows would resemble the natural hydrograph more than the Existing Conditions Baseline conditions do, and therefore represent conditions under which northwestern pond turtles evolved, so turtles should be well adapted to such conditions. Increased sediment mobilization during high flows could affect foraging efficiency by northwestern pond turtles by increasing turbidity, though such effects would be short-lived.

In addition, higher flows that occur through the dam during Seismic Retrofit construction would result in erosion of wetland and riparian habitat along Coyote Creek downstream. As described in Impact TERR-1c, this would result in an initial loss of wetland and riparian habitat followed by considerable regeneration of riparian vegetation that would help sustain high-quality habitat conditions over the long-term. Downed trees in sunlit areas would provide high-quality basking sites for northwestern pond turtles, and thus basking habitat along Coyote Creek would improve as a result of increases in flows during Project construction. Such high flows are unlikely to impact turtle nests; this species has evolved along creeks, which in climates like that in the Project Area involve flashy flows. As a result, turtles nest outside of floodplains where their nests could be impacted by high flows.

Conservation Measures Construction

The Ogier Ponds and the Coyote Percolation Pond, as well as the Parkway Lakes, which are outside the Project area but adjacent to the Coyote Percolation Pond, provide high-quality turtle habitat, with permanent ponding and ample sunlit areas for basking. ~~Western~~ Northwestern pond turtles are known to occur in the Ogier Ponds CM and Coyote Percolation Dam CM Areas. Within the Ogier Ponds complex, the individual ponds used most heavily by northwestern pond turtle, small former borrow pits that are part of a County Parks mitigation site in the southeastern corner of the complex, would not be impacted by the Ogier Ponds CM Project, and therefore the conversion of pond/reservoir land cover types to stream, wetland, and riparian habitats at Ogier Ponds would not result in a substantial loss of pond turtle habitat. Rather, the increase in instream habitat is likely to result in a net improvement in northwestern pond turtle habitat at Ogier Ponds. Young northwestern pond turtles have not been seen during monitoring of Coyote Creek or Ogier Ponds in recent years, and reproductive success is apparently low. Once Ponds 1-4 at Ogier Ponds are no longer in-line with Coyote Creek, following completion of construction of the Ogier Ponds CM, there may be some eutrophication of these ponds during warmer months (Valley Water 2023b). Eutrophication could reduce dissolved oxygen levels within ponds, potentially reducing populations of aquatic prey for northwestern pond turtles. However, eutrophication would not directly affect individual turtles (which do not rely on dissolved oxygen), and whether or not eutrophication occurs is dependent on nutrient loads to the ponds, which may not be high once the creek no longer flows through these ponds. Although grading and construction for Conservation Measures could result in impacts to northwestern pond turtle nests, the majority of grading would occur away from the ponds most heavily used by this species, and therefore the most likely nesting habitat would be avoided.

The Coyote Percolation Dam CM would not result in the loss of high-quality northwestern pond turtle habitat, as the area downstream from the existing percolation dam is not used as heavily as the percolation pond just upstream from the dam. Rather, this Project component may improve the ability of pond turtles to move upstream over the percolation dam without having to exit the creek and risk predation during overland dispersal. Nevertheless, construction activities at Ogier Ponds and Coyote Percolation Dam, as well as ~~Conservation Measures in the~~ maintenance of the North Channel Reach and Live Oak Restoration Reach ~~Extension and other areas where fish-related habitat enhancements are proposed,~~ could impact individual turtles in the same ways that Seismic Retrofit construction could impact them.

Improvement of steelhead rearing habitat at Ogier Ponds would include placement of woody debris in selected areas of Coyote Creek to enhance and restore fluvial processes and channel complexity. This activity would improve habitat conditions for northwestern pond turtles by improving basking habitat.

All land cover types that occur in the Conservation Measures Project Area, aside from urban-suburban, provide potential habitat for the northwestern pond turtle. With the exception of very limited areas of additional hardscaping proposed at the Coyote Percolation Dam, Conservation Measures would not result in the long-term loss of northwestern pond turtle habitat, as most impact areas would continue to provide habitat similar to, or of higher quality than, Existing Conditions Baseline (post-FOCP) conditions after construction of Conservation Measures and revegetation of temporarily impacted areas is completed. Therefore, although impacts modifying VHP land cover types for more than 1 year are considered permanent for VHP compliance purposes, no substantial long-term impacts on habitat of the northwestern pond turtle will result from construction of the Project's Conservation Measures.

Conservation Measures include release of imported water via the CDL and Cross Valley Pipeline Extension, which would help maintain groundwater levels and thus the aquatic, wetland, and riparian habitats along Coyote Creek and in North Coyote Valley used by northwestern pond turtles.

The Conservation Measures include the use of chillers to cool imported water discharged into Coyote Creek via the CDL. ~~Western~~ Northwestern pond turtles may spend more time basking (subjecting them to increased predation risk or lower time for foraging) and have lower growth rates when exposed to colder water (Ernst and Lovich 2009). However, the use of chillers is intended only to reduce temperatures of warm imported water in the CWMZ to levels tolerable for steelhead, and would not result in very cool conditions that could adversely affect turtles.

The northwestern pond turtle would benefit from Valley Water's payment of VHP impact fees, which contribute to the VHP's conservation program that benefits VHP-covered (and many nonVHP-covered) special-status species. The northwestern pond turtle is a VHP-covered species, and the VHP's conservation program includes a number of actions, including habitat preservation, restoration, enhancement, and management, to directly benefit and recover this species.

Construction Monitoring

~~Western~~ Northwestern pond turtles could be disturbed, captured, or possibly subject to electroshocking during such construction-related fisheries monitoring. Invasive species monitoring and control would also be implemented in the Project Area during construction; this would involve removal of any captured nonnative turtles, which would reduce competition (e.g., for high-quality basking sites) between northwestern pond turtles and nonnative turtles, as well as removal of any captured nonnative fish and bullfrogs, which prey on young northwestern pond turtles.

During Project construction, Valley Water would also continue to implement the plan for monitoring northwestern pond turtles that was developed for the FOCP (Valley Water 2020d ~~2020i~~). Although monitoring would not include Anderson Reservoir (which would remain dewatered per the 2020 FERC Order during Seismic Retrofit construction) as it does for the FOCP, monitoring of northwestern pond turtles along Coyote Creek from Anderson Dam downstream to the Coyote Percolation Pond/Parkway Lakes area, and at Ogier Ponds, would help determine whether Project construction is causing a noticeable decline in this species' abundance, potentially encouraging the SCVHA to implement additional measures (e.g., installation of basking structures in portions of Ogier Ponds not being impacted by the Project).

During Project construction, Valley Water would monitor groundwater levels and continue to perform monitoring per the Dryback Monitoring Plan. Results of this monitoring would be used by Valley Water to determine whether creek flows need to be augmented to avoid adverse dryback effects on aquatic, wetland, or riparian habitats. Valley Water would compensate for any impacts on wetland, riparian, or aquatic habitat that are detected by dryback monitoring and that can be attributed to reduced creek flow due to Project construction by paying VHP fees for the impacts detected.

Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Adaptive Management

Analysis of the effects of post-construction FAHCE operations on the northwestern pond turtle was performed relative to the Pre-FERC Order Baseline (2017 conditions) and WEAP-modeled Future Baseline (2035 conditions). As described previously in the general discussion of Project impacts on terrestrial biological resources, flows under the FAHCE rule curves will be generally similar to, ~~those under 2017 conditions~~ but possibly slightly lower than the Pre-FERC Order Baseline Conditions, while FAHCE flows are likely to be slightly higher than under the WEAP-modeled Future Baseline. Any increase in flows would be ramped up and down to allow aquatic animals to adapt to changing flows. In general, FAHCE flows may entail slightly lower flow in winter and summer, due to retention of water in the reservoir for spring pulse flows, than either the Pre-FERC Order Baseline or Future Baseline, punctuated by the spring pulse flows described above. However, the effects of such changes may differ in different parts of Coyote Creek.

FAHCE flows would not change conditions for northwestern pond turtles substantially, relative to pre-FOCP flows, and therefore would not result in substantial impacts to individuals or their habitats. Although spring pulse flows may cause turtles to disperse away from areas with higher flow velocities, such pulse flows would not be very high, and flow ramping would occur to manage changes in the rate of water flow in a slow, stepwise fashion, allowing individuals to move to more sheltered refugia as flow rates are increased. FAHCE operations and other post-construction flows would not impact northwestern pond turtle nests, which would be located above the floodplain.

Seismic Retrofit would enable storage of a deeper, higher volume cold pool, which, in turn, post-construction would enable Valley Water to release cooler water to the CWMZ from Anderson Dam during post-construction FAHCE rule curve operations than currently occurs. Such cool releases, which are described in detail in the special-status amphibian impact assessment above, would occur to benefit steelhead. Reductions in water temperature in the CWMZ could cause northwestern pond turtles to spend more time basking in the CWMZ. However, the improvements to basking habitat resulting from these flows and mobilization of large wood into the channel would offset adverse effects related to water temperature.

Post-construction operations of the Coyote Percolation Dam CM will not result in substantial impacts on northwestern pond turtles, which are adapted to variable flows, being able to move upstream or downstream, and out of the water, in response to changes in flow patterns. Post-construction operations and maintenance of the Ogier Ponds CM, Live Oak Restoration Reach habitat improvements, and North Channel Reach ~~Extension~~ will provide suitable habitat for northwestern pond turtles in Coyote Creek, while continuing to provide suitable habitat in the offline Ogier Ponds. Maintenance of all Conservation Measures would occur in areas that may be occupied by northwestern pond turtles. If a turtle were present during maintenance of a Conservation Measure, impacts could occur, as described above, for maintenance of dam facilities.

Maintenance of Anderson Dam facilities would have little effect on northwestern pond turtles. It is possible that small numbers of individuals could be killed or injured by maintenance equipment, vehicles, or personnel. However, based on the lack of occurrences near the dam, this species would be present infrequently and/or in low numbers.

Adaptive management activities consist primarily of monitoring and adaptive management actions. There is a very low potential for field monitoring activities to disturb northwestern pond turtles. However, if any individuals were present in monitoring locations, they could be disturbed by field personnel. Impacts of adaptive management actions would likely be similar to those resulting from Conservation Measures and post-construction flow. In addition, as described in **Table 2-1** *Project Components*, implementation of a Geomorphic Flows Plan would occur as part of future adaptive management under the Project and FAHCE AMP and will require additional CEQA review and regulatory approvals. In general, the geomorphic flows would include infrequent high flows sufficient to scour sediment, erode banks, scour vegetation, and result in channel migration in localized areas, which would maintain and increase both aquatic and riparian habitat complexity, reduce non-native invasive species, and increase benthic macroinvertebrate production. Geomorphic flows would thus enhance habitat for northwestern pond turtles by providing higher-quality (and likely more numerous) pools and basking habitat.

Significance Conclusion Summary

Implementation of Valley Water BMPs and compliance with applicable VHP conditions would reduce impacts on the northwestern pond turtle. BMPs applicable to this impact are identified in **Table 3.5-6**. VHP conditions applicable to this impact are provided in **Table 3.5-7**, and VHP-related AMMs are provided in **Table 3.5-8**.

Implementation of BMPs BI-2, WQ-1, and WQ-2 will reduce impacts on <u>north</u>western pond turtles by minimizing use of vehicles and equipment in streams. BMPs BI-3, BI-9, WQ-4, WQ-5, and WQ-11 will involve removing temporary fill, restoring channel bottoms, establishing appropriate staging and stockpiling areas and construction access areas, and keeping the work site clean, thus helping to minimize impacts on <u>north</u>western pond turtles and their habitats and avoid the spread of pathogens. BMPs BI-8 and WQ-9 will reduce impacts on <u>north</u>western pond turtle habitat by avoiding competition between invasive plants and native vegetation. BI-10 will avoid entrapment of turtles in pipes, hoses, trenches, and other locations during construction. BMP BI-11 will minimize predator attraction, thus reducing predators of <u>north</u>western pond turtles. BMPs ~~HM-7~~HM-8, HM-9, HM-10, WQ-3, WQ-6, WQ-15, and WQ-16 will minimize the potential for hazardous materials and other pollutants to impact <u>north</u>western pond turtles and their habitats, and HM-12 will reduce the potential for fire to affect this species and its habitats. BMP BI-4 will minimize impacts of pesticides on nontarget species, such as <u>north</u>western pond turtles.

Implementation of VHP Conditions 3, 4, 5, 7, 11, and 12 would reduce the potential for and magnitude of impacts on <u>north</u>western pond turtles and their habitats by minimizing impacts on stream, wetland, and pond habitats. These conditions require implementation of numerous AMMs summarized in **Table 3.5-8**, and include limiting the footprint of activities, reducing the potential for pollutants to impact these species and their habitats, avoiding the encouragement of invasive plants, and avoiding erosion and sediment impacts on this species' habitats. VHP Condition 7 would entail minimizing ground disturbance and vegetation removal, stabilizing soil to avoid erosion and sedimentation, and revegetating with native plants or other appropriate plants.

Maintenance of Anderson Dam facilities would occur as part of the DMP and would employ the BMPs and mitigation measures implemented by the DMP to avoid and minimize impacts on sensitive biological resources such as <u>north</u>western pond turtles. DMP BMPs BI-10 and BI-11 minimize impacts to vegetation, and **DMP Mitigation Measure Vegetation-6** requires restoration of vegetation that may have been lost due to dryback conditions following dewatering. BMP BI-13 requires use of local ecotypes of native plants and appropriate erosion control seed mixes to avoid impacts to pond turtle habitat from invasive plant species. **DMP Mitigation Measure General-3** requires development of a reservoir-specific dewatering plan to minimize impacts on sensitive wildlife during dewatering, specifically including <u>north</u>western pond turtles, and BMP BI-2 requires salvage of native aquatic vertebrates from dewatered channels, and **<u>DMP</u> Mitigation Measure Wildlife-1** and BMP WQ-12 require implementation of a flow bypass system for activities that would interrupt flow downstream from the dam. **DMP Mitigation Measure Wildlife-2** restricts vehicle and equipment use in salmonid streams during portions of the year, which would reduce impacts on <u>north</u>western pond turtles. **DMP Mitigation Measure Wildlife-4** prohibits the use of herbicides that are not excluded from the applicable injunction, thus reducing the potential for herbicides to impact <u>north</u>western pond turtles and their habitats. DMP **Mitigation Measure Wildlife-5** reduces the potential for special-status species to be captured in rodent traps, and BMP BI-16 avoids entrapment of sensitive animals in pipes, hoses, holes, and trenches. **Mitigation Measure Wildlife-7** includes a number of AMMs specific to the protection of <u>north</u>western pond turtles and their habitat. BMP BI-17 minimizes the attraction of predators of sensitive species. The DMP also includes a number of

BMPs to protect water quality, maintain clean work sites, and reduce erosion, thus reducing the potential for impacts on northwestern pond turtles; these include BMPs WQ-4, WQ-5, WQ-7, WQ-10, WQ-14, and WQ-18.

The northwestern pond turtle is covered by the VHP, and most of the activities that could impact this species (including post-construction operations under FAHCE rule curves) are explicitly VHP-covered. Thus, VHP compliance would ensure that impacts of VHP-covered activities remaining after implementation of BMPs and DMP measures on the northwestern pond turtle would not be substantial, and therefore would be **less than significant**.

Following is a discussion of Project activities that are not VHP covered, and why impacts from these activities would not be substantial, and therefore would be less than significant:

- The additional year of Anderson Reservoir dewatering could result in adverse dryback effects on aquatic, wetland, and riparian habitat along Coyote Creek downstream from Anderson Dam and in North Coyote Valley. However, creek flow augmentation, groundwater monitoring, and dryback monitoring (with additional flow augmentation, and payment of VHP impact fees for impacted wetland and riparian habitat, as necessary) would avoid significant impacts related to dryback effects.
- Differences in dam releases between those covered by the VHP and those that may occur during Project construction would occur, although the Project will adhere to the VHP-covered release requirements when draining Anderson Reservoir for dewatering each year. At the start of the construction season (i.e., around April 15), wet-season flows through Anderson Dam may be much higher than those discussed in the VHP, as Valley Water needs to avoid having Anderson Reservoir fill during Project construction. At their maximum, such flows could be as high as 6,000 cfs, which represents the maximum capacity of all dam outlets that will be present. However, a 6,000-cfs flow during Seismic Retrofit construction has a very low probability of occurring, as it would represent a 200-year event (with a 0.5 percent likelihood of occurring in any given year). The VHP did not explicitly discuss the possibility that flows may exceed those in VHP **Table 2-4** during the construction period, outside of actual dewatering events. Therefore, the impacts of such flows on terrestrial biological resources may not be covered by the VHP. However, as discussed above, these increased flows would have little adverse effect on northwestern pond turtles. These individuals would be able to move out of areas where they could be adversely affected by high flows as the flows ramp up (either intentionally, in the case of post-construction flows, or naturally, during rain events and during construction).
- Impacts of steelhead relocation to Upper Penitencia Creek are not covered by the VHP. However, northwestern pond turtles do not occur in high numbers in the reach of Upper Penitencia Creek where steelhead relocation could occur, and therefore steelhead relocation would not result in substantial adverse effects on northwestern pond turtles ~~they would not be adversely affected by such relocation~~.

With implementation of BMPs, DMP measures, and compliance with the VHP, Project impacts on the northwestern pond turtle would be **less than significant**.

Mitigation Measures

No mitigation is required. Nevertheless, northwestern pond turtles would benefit from two mitigation measures described above. Northwestern pond turtles are expected to occur only in low numbers within the dewatered bed of Anderson Reservoir, so there is a low potential for impacts on individuals of this species during the additional, non-VHP-covered year of dewatering, but northwestern pond turtles will be included in the AMMs implemented per Mitigation Measure TERR-1c(1) to further reduce any impacts. In addition, nonnative species management in the Upper Penitencia Creek watershed, as described in Mitigation Measure TERR-1c(2), would benefit northwestern pond turtles in that watershed.

Impact TERR-1e: Bald Eagle and Golden Eagle (Less than Significant with Mitigation)

Seismic Retrofit Construction

Up to two pairs of bald eagles have nested near Anderson Reservoir in recent years. The most recently occupied nests have been located approximately 950 and 995 feet from the nearest area where Seismic Retrofit construction activities are currently proposed in the bed of the reservoir (i.e., within the "Seismic Retrofit [Proposed Construction Footprint]" on **Figure 3.5-2**). However, it is possible that construction activities may need to take place anywhere within the reservoir bed, in the area indicated on **Figure 3.5-2** as "Anderson Reservoir Boundary (Potential Additional Seismic Retrofit Construction)," and these two recently occupied nests are located approximately 250 and 790 feet from the edge of the reservoir. In addition, at least two (and possibly more) golden eagle territories overlap the reservoir, with recently occupied nests located approximately 0.8 and 1 mile from the nearest area where Seismic Retrofit activities are currently proposed in the bed of the reservoir and 0.34 and 0.83 miles from the edge of the reservoir. Because territories of both species overlap the Project area, Seismic Retrofit construction would impact these species. No nest trees would be impacted, as these eagles nest in trees well removed from the edge of the reservoir and well outside of direct impact areas where tree removal would occur. Eagles are not expected to build nests closer to Project activities than they currently do given the high levels of human disturbance associated with ongoing FOCP activities.

Seismic Retrofit construction would impact foraging habitat for these species; the wetted area of the drawn-down reservoir provides foraging habitat for the bald eagle, and both species also forage in the dry bed of the drawn-down reservoir and adjacent grassland habitats. Dewatering of the reservoir and construction activities within the reservoir bed would reduce the availability of foraging habitat for these species during construction. Following completion of construction, foraging habitat for the bald eagle would be enhanced as the reservoir is allowed to refill to a higher post-construction elevation, though refilling of the reservoir would reduce the availability of dry reservoir bed that is likely currently used by foraging golden eagles. In the long-term, though, refilling of the reservoir is unlikely to result in the loss of a golden eagle territory or have an adverse effect on productivity given the extensive grassland foraging habitat available to nesting eagles around the reservoir (including extensive grassland within each territory that has been identified by recent surveys).

During construction, the movement of heavy equipment, vehicles, and personnel within the Seismic Retrofit Area would increase human activity in proximity to existing eagle nests. The USFWS recommends disturbance-free buffers of 0.5 miles for blasting, 330 feet for nonmotorized human activities, and 660 feet for other Project activities near active nests of bald eagles (USFWS 2007), and 1 or 2 miles for blasting activities for active nests of golden eagles (USFWS 2017). Based on 2021-2022 nest locations, both bald eagle nests along the northwest arm of Anderson Reservoir are well over 660 feet from the nearest currently proposed Project activities (haul roads for stockpiling of materials are proposed within the reservoir bed). Each of the two golden eagle nest locations is approximately 2.1 miles from blasting areas at Basalt Hill; while one of these nests is just over a mile from the nearest Project activities in the reservoir bed, one nest is less than the recommended 1 mile from Project activities. USFWS guidelines suggest that buffers may be reduced, in consultation with USFWS, especially if nests are not within line-of-sight of construction activities. Topography interrupts line-of-sight for the golden eagles, and thus, golden eagles at the two current nest locations would not be disturbed by construction activities, or affected by reductions in foraging habitat, to the point that they would abandon their territories. However, because golden eagles fly around extensively while foraging, they would be aware of the construction activity in the reservoir bed, and there is some potential for reduction in productivity at the nest that is 0.8 miles from construction activity.

The analysis in the previous paragraph considers conditions present as of the 2022 breeding season. It is possible that the bald and/or golden eagles that have been nesting near the reservoir in recent years will move closer to or further from the reservoir prior to Seismic Retrofit initiation, that new pairs may nest near the reservoir, and/or that pairs may nest in different locations in different years during the 7-year Project. Also, as noted above, construction may need to occur within the bed of the reservoir in areas other than those currently proposed. As a result, there is some potential for Seismic Retrofit construction to occur within 660 feet of a bald eagle nest, or for golden eagles, or multiple pairs of golden eagles, to nest within the aforementioned, USFWS-recommended buffers. If that occurs, then by the time the construction season starts in mid-April, eagles could have a nest with eggs or young close to the construction area. Construction activities could therefore cause the abandonment of an active nest with eggs or young, or a reduction in productivity (e.g., if disturbance reduces foraging time or efficiency and adults are not able to provide all of their young with food).

Bald eagles establish their territories and build nests as early as December or January, and they may lay eggs as early as January or February. During Seismic Retrofit construction, the reservoir would be maintained at a low-water condition by leaving the outlets open throughout the wet season. Therefore, bald eagles would begin nesting under similar conditions, in terms of reservoir levels, as those that will be present when construction commences in any given year of the Project. Only minimal dewatering may be necessary prior to the start of each year's construction in mid-April, and such dewatering is not expected to reduce foraging habitat or prey availability, relative to levels present when nests are established in January or February, to the extent that it would adversely affect productivity.

Thus, Project construction could result in the abandonment of bald eagle or golden eagle nests and the loss of reproductive success, possibly including loss of eggs or young in nests. These impacts could occur throughout the Project construction period. However, the effects of this relatively short-term impact on regional bald eagle populations would be minor. This species did not historically nest in the county, yet more than 10 (and possibly 15 or more) pairs of bald eagles are currently present in the county, and this species' central California coast breeding numbers have increased considerably in the past 20 years. As a result, the short-term impact on bald eagle breeding and foraging habitat extent and quality at Anderson Reservoir would be minor from the perspective of its effect on regional bald eagle populations. Golden eagle populations have not been increasing regionally, and the loss of golden eagle productivity could have greater population impacts than is the case with bald eagles.

Bald eagles that forage at Anderson Reservoir in winter may use the reservoir in lower numbers and/or less frequently during Seismic Retrofit construction, as the dam's outlets would be left open so that minimal water accumulates behind the dam. However, because wet-season construction would not be occurring within the reservoir bed, some bald eagles would likely continue to forage there during winter. Changes in Coyote Creek flow downstream from Anderson Dam during Seismic Retrofit construction would have little effect, if any, on eagles. Although bald eagles occasionally forage downstream from the dam, they do so infrequently, and no substantial loss or modification of foraging habitat for bald eagles would result from changes in flows during construction.

Conservation Measures Construction

Implementation of Conservation Measures could affect bald eagles. A pair nested, apparently unsuccessfully, near Pond 3 at Ogier Ponds in 2019 (Valley Water 2022a ~~2022b~~). Although the species has not been known or suspected of nesting there since then, bald eagles occasionally forage at Ogier Ponds, especially in the winter season (Cornell Lab of Ornithology 2022). The Ogier Ponds CM Project would result in the conversion of some reservoir, pond, wetland, riparian, and grassland habitat to creek, wetland, and riparian habitat. This activity would not modify foraging habitat for bald eagles to the extent that it would substantially reduce the use of Ogier Ponds by bald eagles. In the event that bald eagles attempt to nest at Ogier Ponds again (e.g., if one of the Anderson Reservoir pairs were to relocate to Ogier Ponds), construction activities during the breeding season may result in the disturbance of nesting eagles, possibly to the point of nest abandonment. The nest tree used in 2019 is located approximately 350 feet from the nearest area of proposed disturbance for the Ogier Ponds CM, and other suitable trees (e.g., eucalyptus trees near the northern corner of Pond 3, where bald eagles have been observed perching) are even farther from Project areas. Bald eagles have not nested near the Coyote Percolation Dam CM, but they do forage at the Parkway Lakes and Coyote Percolation Pond (Cornell Lab of Ornithology 2022), and there is some potential (albeit low) for this species to nest near the Coyote Percolation Dam CM. Construction activities could disturb foraging bald eagles at both the Ogier Ponds CM and Coyote Percolation Dam CM Areas, and there is at least a low potential for nesting bald eagles to be disturbed by construction of these two conservation activities. Bald eagles are unlikely to forage in the North Channel Reach ~~Extension~~ or Live Oak Restoration Reach maintenance areas given the closed canopy of the riparian woodland, and they are also unlikely to nest in these ~~is~~ areas.

Golden eagles are occasionally observed at both the Ogier Ponds CM and Coyote Percolation Dam CM Areas, and elsewhere along Coyote Creek where other Conservation Measures are proposed, though they forage infrequently in those areas (they are typically seen flying high overhead), and they do not nest in or near any of those areas. Construction of Conservation Measures may disturb foraging golden eagles, but the magnitude and likelihood of such an impact is low, and neither project would result in substantial impacts to golden eagle foraging habitat or prey. Conservation Measures include the release of imported water via the CDL and Cross Valley Pipeline Extension, which would help maintain groundwater levels and thus the aquatic, wetland, and riparian habitats along Coyote Creek and in North Coyote Valley that support eagle prey, especially for the bald eagle.

Although neither eagle species is a VHP-covered species, both would benefit from Valley Water's payment of VHP impact fees. The VHP's vast conservation program conserves habitats that provide grassland, scrub, ponds, wetlands, streams, and other foraging habitats, as well as habitats that provide tall trees for nesting, for these two species due to its breadth, both geographically and in terms of the diversity of habitat types to be conserved.

Construction Monitoring

Foraging eagles could be disturbed by personnel conducting construction-related fisheries monitoring. However, any monitoring that benefits fish may benefit the bald eagle, given that fish are an important component of that species' diet.

During Project construction, Valley Water would monitor groundwater levels and continue to perform monitoring per the Dryback Monitoring Plan. Results of this monitoring would be used by Valley Water to determine whether creek flows would need to be augmented to avoid adverse dryback effects on aquatic, wetland, or riparian habitats. Valley Water would compensate for any impacts on wetland, riparian, or aquatic habitat that are detected by dryback monitoring and that can be attributed to reduced creek flow due to Project construction by paying VHP fees for the impacts detected. Such impact fees would contribute to the VHP's conservation program, and although neither eagle species is explicitly covered by the VHP, the conservation program conserves habitats used by both species, as described above. Thus, no substantial adverse effects of reductions in creek flow on foraging habitat or prey for bald eagles would occur.

Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Adaptive Management

Post-construction operations of Anderson Dam would provide for a reservoir that furnishes ample foraging habitat and prey for bald eagles, thus maintaining this important resource for that species. Otherwise, post-construction operations would not result in substantial impacts on bald or golden eagles. Golden eagles do not nest or forage in areas downstream from Anderson Dam that could be affected by post-construction flows, and FAHCE flows would not adversely affect foraging or nesting bald eagles.

Operation of the Ogier Ponds CM and Coyote Percolation Dam CM would provide habitat in Coyote Creek and Coyote Percolation Pond that bald eagles may use for foraging while continuing to maintain suitable bald eagle foraging habitat in the offline Ogier Ponds. Operation and maintenance of the North Channel Reach ~~Extension~~ and Live Oak Restoration Reach Conservation Measures would be unlikely to disturb eagles, which likely do not forage in these closed-canopy areas.

Both species of eagles occasionally forage near the dam, and they could forage near Conservation Measures during maintenance activities. Maintenance and monitoring of both Seismic Retrofit and Conservation Measures, including the noise or activity of maintenance personnel, equipment, or vehicles, could occasionally disturb foraging eagles. However, no operations, maintenance, or monitoring activities would disturb nesting eagles. Adaptive management activities consist primarily of monitoring and potential adaptive management actions. There is a very low potential for field monitoring activities to disturb foraging eagles, though if any individuals were present in monitoring locations, they could be disturbed by field personnel.

Adaptive management activities consist primarily of monitoring and potential adaptive management actions. There is a very low potential for field monitoring activities to disturb bald or golden eagles, though if any individuals were present in monitoring locations, they could be disturbed by field personnel. Impacts of adaptive management actions would likely be similar to those resulting from Conservation Measures and post-construction flows.

Significance Conclusion Summary

Implementation of Valley Water BMPs and compliance with applicable VHP conditions would reduce impacts on the bald eagle and golden eagle. BMPs applicable to this impact are identified in **Table 3.5-6**. VHP conditions applicable to this impact are provided in **Table 3.5-7**, and VHP-related AMMs are provided in **Table 3.5-8**.

Valley Water would implement BMP BI-5 to avoid and minimize impacts on nesting eagles; implementation of this BMP will avoid disturbance of active nests to the point of abandonment by conducting preactivity surveys and maintaining appropriate buffers between Project activities and active nests. BMPs HM-8, HM-9, HM-10, WQ-11, WQ-15, and WQ-16 will minimize the potential for hazardous materials and other pollutants to impact eagles and their prey, and HM-12 will reduce the potential for fire to affect these species and their habitats. BMP WQ-4 limits impacts from staging and stockpiling activities. BMPs BI-8 and WQ-9 will reduce impacts on eagle foraging habitat by avoiding competition between invasive plants and native vegetation. BMP BI-4 will minimize impacts of pesticides on nontarget species such as special-status eagles and their prey.

Implementation of VHP Condition 1 would avoid direct impacts on nesting eagles. VHP conditions 3, 4, 5, 7, and 11 would reduce the potential for and magnitude of impacts on bald eagles and their habitats by minimizing impacts on stream, wetland, and pond habitats. These conditions require implementation of numerous AMMs summarized in **Table 3.5-8**; these AMMs include limiting the footprint of activities, reducing the potential for pollutants to impact these species and their habitats, avoiding the encouragement of invasive plants, and avoiding erosion and sedimentation impacts on this species' habitats. VHP Condition 7 would entail minimizing ground disturbance and vegetation removal, stabilizing soils to avoid erosion and sedimentation, and revegetating with native plants or other appropriate plants.

Maintenance of Anderson Dam facilities would occur as part of the DMP and would employ the BMPs and mitigation measures implemented by the DMP to avoid and minimize impacts on sensitive biological resources, such as bald and golden eagles and their habitats. BMP BI-8 requires preactivity surveys for nesting birds, and **DMP Mitigation Measure Wildlife-10** requires establishment of a disturbance-free buffer around nests of migratory birds, which includes eagles. DMP BMPs BI-10 and BI-11 minimize impacts to vegetation, and **DMP Mitigation Measure Vegetation-6** requires restoration of vegetation that may have been lost due to dryback following dewatering. BMP BI-13 requires use of local ecotypes of native plants and appropriate erosion control seed mixes, which would avoid impacts to eagle foraging habitat from invasive plant species. **DMP Mitigation Measure General-3** requires development of a reservoir-specific dewatering plan to minimize impacts on sensitive wildlife during dewatering. **DMP Mitigation Measures Wildlife-11** and **Water Quality-1** and BMP BI-7 will reduce the potential for eagles to be poisoned by rodents that have ingested pesticide, and **Mitigation Measure Wildlife-4** prohibits the use of herbicides that are not excluded from the applicable injunction.

One pair of golden eagles is currently nesting close enough to proposed Project activities that there is some potential for loss of productivity owing to Project-related disturbance. Based on the current locations of bald eagle nests and currently proposed Project activities, construction would occur far enough from nests (greater than 660 feet) that construction-related disturbance of active nests would not occur. However, it is possible that bald and golden eagles could nest closer to construction activities in future years and/or that construction activities could occur anywhere in the reservoir bed, and construction activities could therefore cause the abandonment of an active nest with eggs or young, or a reduction in productivity (e.g., if disturbance reduces foraging time or efficiency and adults are not able to provide all of their young with food). This would be a substantial short-term adverse effect, even after application of BMPs and VHP Conditions. Implementation of **Mitigation Measure TERR-1e** will reduce Project impacts on these species to less-than-significant levels by implementing AMMs during Seismic Retrofit construction to minimize impacts on nesting eagles.

Long-term effects of the Project on the bald eagle are **less than significant**. The short-term impacts on bald eagle breeding and foraging habitat extent and quality at Anderson Reservoir would be minor from the perspective of its effect on regional bald eagle populations. Furthermore, the Project is necessary to allow Valley Water to continue to operate Anderson Reservoir and to eventually refill it. A larger, refilled reservoir would support greater numbers of pairs of bald eagles, and thus, the Project is necessary to ensure the long-term availability of the reservoir that has attracted nesting bald eagles and to provide suitable habitat for multiple pairs.

Compared to conditions under the Existing Conditions Baseline (existing conditions modified by FOCP implementation) conditions, the more extensive reservoir that will be present once the Project has been completed and Anderson Reservoir is refilled will provide habitat to support additional pairs of bald eagles. Suitable habitat to support golden eagles, in similar abundance to Existing Conditions Baseline conditions, will continue to exist around Anderson Reservoir after Project completion. Therefore, regional eagle populations would not be adversely affected by the Project.

With implementation of **Mitigation Measure TERR-1e**, Project impacts on bald eagles and golden eagles would not be substantial, and therefore would be less than significant. Furthermore, Valley Water would obtain a BGEPA permit from the USFWS to obtain authorization for the loss of any eagle productivity (which would most likely apply to bald eagle, given that this species forages in the reservoir) and would comply with permit conditions, which would further reduce impacts.

Mitigation Measures

TERR-1e Nesting Eagle Avoidance and Minimization Measures

Valley Water and/or its contractor will implement the following avoidance and minimization measures during Seismic Retrofit construction:

- Prior to drawdown of Anderson Reservoir and commencement of work activities within the reservoir bed during each year of construction (which would occur around April 15), Valley Water will perform surveys to identify the locations of active bald and golden eagle nests in areas where they might be disturbed by upcoming construction activities that would occur during the eagle breeding season and post-fledging dependency period for juvenile eagles (January 1 through August 31). Such surveys will focus on areas within 0.5 miles for blasting, 330 feet for nonmotorized human activities, and 660 feet for other project activities for bald eagle nests, and within 2 miles for blasting and 1 mile for other project activities for golden eagle nests.

- To the extent feasible, as determined by Valley Water's Project engineer, based on their assessment of whether alternative locations for Project activities that can maintain the appropriate buffers can be used during construction, construction activities will maintain buffers of 0.5 miles for blasting, 330 feet for nonmotorized human activities, and 660 feet for other project activities for bald eagle nests and 2 miles for blasting and 1 mile for other project activities for golden eagle nests, during the breeding season and post-fledging dependency period for juvenile eagles (January 1 through August 31). These buffers would apply during the courtship and egg-laying phases of the breeding season (January 1 through April 15). After April 15, if a qualified biologist confirms that the eagles did not lay eggs, or that a nest is no longer in use because the nest has failed or young are no longer dependent on adults, the buffers would not be necessary around that nest during that construction season.
- If Valley Water's Project engineer determines that the aforementioned buffers cannot feasibly be maintained around an active nest, as described above:
  - Valley Water will coordinate with CDFW and USFWS to determine whether there are feasible minimization measures that can be implemented to avoid or minimize disturbance of nesting eagles.
  - For nests that can be observed from accessible areas, a ~~A~~ qualified biologist will monitor the eagles' behavior at the nest as work occurs to determine whether there are any specific work activities that would disturb the birds, which may inform the identification of additional minimization measures.

If Valley Water determines that a work activity in the coming year must occur so close to a routinely used eagle nest (i.e., a nest used in the prior 2 years) that there is a high likelihood of nest abandonment once work commences in spring of a given year, Valley Water will coordinate with CDFW and USFWS to determine whether deterring nesting, prior to egg-laying, is appropriate.

Impact TERR-1f: Tricolored Blackbird, Yellow Warbler, White-tailed Kite, Northern Harrier, and Other Breeding Birds (Less than Significant)

Seismic Retrofit Construction

A variety of bird species protected by the MBTA and Fish and Game Code breed, forage, and roost in the Seismic Retrofit Area. These include breeding special-status species, such as the yellow warbler and white-tailed kite, as well as numerous nonspecial-status species. The tricolored blackbird is not known to breed in the Seismic Retrofit Area, but the colonization of portions of the dewatered bed of the reservoir by large patches of bull thistle provides potential habitat that could be used by this species for nesting. The northern harrier (*Circus hudsonius*) does not breed in the Seismic Retrofit Area, but one or two pairs could breed in North Coyote Valley wetlands that may be subject to dryback impacts due to reduced Coyote Creek flow during Seismic Retrofit construction. Northern harrier also breeds in tidal marshes along lower Coyote Creek and so is also discussed in Impact TERR-1j below.

Although birds do not nest in the open water of the reservoir (some species may nest in emergent or floating vegetation) or in most areas mapped as urban-suburban, most of the Seismic Retrofit Area provides potential nesting habitat for protected bird species. Thus, Seismic Retrofit construction would result in the loss of that nesting habitat. Much of that habitat (e.g., most areas that are not within the bed of the reservoir that would be refilled or that would be converted to urban-suburban land cover) would regenerate following the completion of construction and vegetative stabilization of bare soils by Valley Water, and would then be available for use by nesting birds, but some long-term loss of habitat would occur.

The nesting season for most birds breeding in the Seismic Retrofit Area is typically from February 1 through August 31, though some species may begin nesting in January or may have nests that remain active into September. Because construction in the bed of the reservoir and in Coyote Creek must occur during the dry season, the primary construction season would largely overlap the avian breeding season. If birds are actively nesting in or close to construction areas when construction activities occurs, vegetation clearing, grading, and activity of equipment, vehicles, and personnel could, in the absence of BMPs and VHP conditions, result in the physical disturbance or destruction of active nests (including eggs and young) or disturb adults to the point of nest abandonment.

Increased human activity may also affect the behavior of birds, causing them to avoid work areas, and therefore exposing them to increased competition with other birds in the areas to which they have dispersed, and increased levels of predation caused by unfamiliarity with the new area. Increases in human concentration and activity associated with construction in the vicinity of suitable habitat for these species may also result in an increase in native and nonnative predators that would be attracted to trash left in work areas and a reduction in the quality of breeding or foraging habitat caused by the introduction of nonnative vegetation or pathogens such as *Phytophthora*.

Groundwater levels along Coyote Creek or in North Coyote Valley are not predicted to drop substantially as a result of operations during construction. Modeling performed by Valley Water predicted that there would be a reduction in groundwater recharge and storage during Seismic Retrofit construction relative to 2015 base conditions (when ~~interim seismic~~ restrictions limited reservoir capacity to 51,200 AF); however, groundwater storage is still predicted to be above Valley Water’s 2021 Groundwater Management Plan storage target (Valley Water 2023a). Nevertheless, in the event that reduced creek flow combined with drought conditions were to cause a drop in groundwater levels, it is possible that habitats supporting nesting northern harriers, tricolored blackbirds, and yellow warblers, either along Coyote Creek or in North Coyote Valley, could suffer reduced health.

Existing Conditions Baseline conditions for Seismic Retrofit construction allow for discharges from the dam of up to 2,500 cfs. During Seismic Retrofit construction, the reservoir’s outlets would be left open during the wet season to minimize the amount of water that accumulates in the reservoir bed. The magnitude of flow, and frequency of flows of a certain magnitude, will depend on rainfall amounts during individual runoff events and Coyote Reservoir releases. Valley Water (2022c ~~2022d~~) predicts higher flows at the 2-, 5-, and 10-year return intervals during construction. At their maximum, such flows could be as high as 6,000 cfs, though the higher the flow, the lower the probability and frequency of that flow. Therefore, very high flows are highly improbable.

Higher flows during storm events could cause erosion and scour that would result in the loss of some riparian vegetation along the channel that is used by nesting special-status birds, such as yellow warblers, as well as numerous nonspecial-status birds. However, such habitat modifications would produce snags used by many bird species and would allow regeneration of riparian trees such as cottonwoods, willows, and sycamores as described in Impact TERR-1c. Thus, the habitat modifications resulting from such high flows and related inundation of habitat along Coyote Creek would help to rejuvenate the riparian corridor along Coyote Creek and maintain habitat heterogeneity that supports a diverse avian community. Furthermore, high flows and related inundation of riparian habitats would occur primarily outside the nesting season, and therefore would not disturb active nests.

Conservation Measures Construction

Numerous protected bird species breed in the Conservation Measures Project Area, including the Ogier Ponds CM Area, Coyote Percolation Dam CM Area, ~~and Conservation Measures in the~~ <u>Maintenance of the</u> North Channel <u>Reach, and Maintenance Activities at</u> the Live Oak Restoration Reach~~, and other areas where fish-related habitat enhancements are proposed~~. These species include a number of nonspecial-status species in addition to special-status species. The yellow warbler could breed in riparian habitat in and near any of the Conservation Measures; the white-tailed kite could breed in both riparian and adjacent upland habitats, and the tricolored blackbird could breed in more extensive areas of emergent wetland, such as at Ogier Ponds (though the species has not bred there in recent years). The northern harrier forages at Ogier Ponds, though it does not nest there. Impacts on nesting birds resulting from construction of the Conservation Measures could occur in the same ways described above for Seismic Retrofit construction activities.

Conservation Measures include release of imported water via the CDL and Cross Valley Pipeline Extension, which would help maintain groundwater levels and thus the aquatic, wetland, and riparian habitats along Coyote Creek and in North Coyote Valley that are used by numerous species of nesting birds.

Aside from the tricolored blackbird, no bird species impacted by the Project are VHP-covered species. However, numerous species would benefit from Valley Water's payment of VHP impact fees. The VHP's vast conservation program conserves a number of habitat types throughout much of the county, and these habitat types provide nesting and foraging habitat for many bird species, including tricolored blackbird, yellow warbler and white-tailed kite. Thus, due to its breadth, both geographically and in terms of the diversity of habitat types to be conserved, the VHP's conservation program benefits all the bird species potentially impacted by the Project.

Construction Monitoring

Construction monitoring for water quality, fisheries monitoring and fish rescue, aquatic species rescue and relocation, invasive species monitoring and control, and other monitoring efforts during the avian breeding season could result in the disturbance of nesting birds due to the noise and activity of monitoring personnel and equipment. Such impacts would be localized and infrequent.

During construction, Valley Water would monitor groundwater levels and continue to perform monitoring per the Dryback Monitoring Plan. Results of this monitoring would be used by Valley Water to determine whether creek flows need to be augmented to avoid adverse dryback effects on aquatic, wetland, or riparian habitats. Valley Water would compensate for any impacts on wetland, riparian, or aquatic habitat that are detected by dryback monitoring and that can be attributed to reduced creek flow due to Project construction by paying VHP fees for the impacts detected. Thus, no substantial adverse effects of reductions in creek flow on habitat for nesting birds would occur.

Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Adaptive Management

Analysis of the effects of post-construction FAHCE operations on nesting birds was performed relative to the Pre-FERC Order Baseline (2017 conditions) and WEAP-modeled Future Baseline (2035 conditions). FAHCE flows are not expected to result in substantial impacts, either adverse or beneficial, on nesting birds. As described previously in the general discussion of Project impacts on terrestrial biological resources, flows under the FAHCE rule curves will be generally similar to, ~~those under 2017 conditions~~ but possibly slightly lower than the Pre-FERC Order Baseline Conditions, while FAHCE flows are likely to be slightly higher than under the WEAP-modeled Future Baseline. In general, FAHCE flows may entail slightly lower flows in winter and summer, due to retention of water in the reservoir for spring pulse flows, than either the Pre-FERC Order Baseline or Future Baseline, punctuated by the spring pulse flows described above. However, the effects of such changes may differ in different parts of Coyote Creek, as described previously. There is some potential for spring pulse releases to disturb active nests very close to the water's surface (e.g., due to inundation or scour), but the relatively brief nature of these releases, and the fact that these flows would not be particularly high, would minimize the potential for any such impacts. Changes in creek temperature as a result of post-construction operations would not have a substantial effect on nesting birds.

Post-construction operations of the Ogier Ponds CM will provide habitat for nesting birds along the realigned segment of Coyote Creek while maintaining suitable habitat at the offline Ogier Ponds as well. The Coyote Percolation Dam CM will not result in substantial impacts on nesting birds.

Maintenance of Anderson Dam facilities and Conservation Measures, including maintenance of the North Channel Reach and Live Oak Restoration Reach, could disturb active nests of birds, either due to physical impacts to nests that are constructed on structures or in vegetation requiring maintenance or due to disturbance from noise or activity of maintenance personnel and equipment. Adaptive management activities consist primarily of monitoring and potential adaptive management actions. There is some potential for field monitoring activities to disturb nesting birds. Impacts of adaptive management actions would likely be similar to those resulting from Conservation Measures and post-construction flows.

Significance Conclusion Summary

Implementation of Valley Water BMPs and compliance with applicable VHP conditions would reduce impacts on nesting birds, including the northern harrier, tricolored blackbird, yellow warbler, and white-tailed kite. BMPs applicable to this impact are identified in **Table 3.5-6**. VHP conditions applicable to this impact are provided in **Table 3.5-7**, and VHP-related AMMs are provided in **Table 3.5-8**.

Valley Water would implement BMP BI-5 to avoid and minimize impacts on nesting birds; implementation of this BMP will avoid disturbance of active nests to the point of abandonment by conducting preactivity surveys and maintaining appropriate buffers between Project activities and active nests. BMP BI-6, which involves installing nest exclusion materials to prevent birds from nesting in areas where they may be impacted, may also be implemented. BMPs HM-8, HM-9, HM-10, WQ-11, WQ-15, and WQ-16 will minimize the potential for hazardous materials and other pollutants to impact nesting birds and their food sources, and HM-12 will reduce the potential for fire to affect these species and their habitats. BMP WQ-4 limits impacts from staging and stockpiling activities. BMPs BI-8 and WQ-9 will reduce impacts on birds' nesting and foraging habitats by avoiding competition between invasive plants and native vegetation. BMP BI-11 will minimize the attraction of predators that may prey on nesting birds. BMP BI-4 will minimize impacts of pesticides on nontarget species, such as nesting birds and their food sources.

Implementation of VHP Condition 1 would avoid direct impacts on nesting birds. VHP conditions 3, 4, 5, 7, and 11 would reduce the potential for and magnitude of impacts on nesting birds and their habitats by minimizing impacts on stream, wetland, and pond habitats. In particular, these conditions require implementation of numerous AMMs summarized in **Table 3.5-8**; these AMMs include limiting the footprint of activities, reducing the potential for pollutants to impact these species and their habitats, avoiding the encouragement of invasive plants, and avoiding erosion and sediment impacts on these species' habitats. VHP Condition 7 would entail minimizing ground disturbance and vegetation removal, stabilizing soil to avoid erosion and sedimentation, and revegetating with native plants or other appropriate plants.

Maintenance of Anderson Dam facilities would occur as part of the DMP and would employ the BMPs and mitigation measures implemented by the DMP to avoid and minimize impacts on sensitive biological resources, such as nesting birds and their habitats. BMP BI-8 requires preactivity surveys for nesting birds, and **DMP Mitigation Measure Wildlife-10** requires establishment of a disturbance-free buffer around nests of migratory birds. DMP BMPs BI-10 and BI-11 minimize impacts to vegetation, and **DMP Mitigation Measure Vegetation-6** requires restoration of vegetation that may have been lost due to dryback following dewatering. BMP BI-13 requires use of local ecotypes of native plants and appropriate erosion control seed mixes, which would avoid impacts to bird habitat from invasive plant species. **DMP Mitigation Measure General-3** requires development of a reservoir-specific dewatering plan to minimize impacts on sensitive wildlife during dewatering. **DMP Mitigation Measures Wildlife-11** and **Water Quality-1** and BMP BI-7 will reduce the potential for birds of prey to be poisoned by rodents that have ingested pesticide, and **DMP Mitigation Measure Wildlife-4** prohibits the use of herbicides that are not excluded from the applicable injunction.

Of the nesting bird species considered in this impact, only the tricolored blackbird is a VHP-covered species. All Project activities that could impact this species are covered by the VHP except for the additional year of Anderson Reservoir dewatering. By the time Year 6 construction occurs, no suitable nesting habitat for the tricolored blackbird would be present in or near work areas in the bed of the dewatered reservoir, so no direct impacts related to that additional year of dewatering would occur. The additional year of Anderson Reservoir dewatering could result in adverse dryback effects on aquatic, wetland, and riparian habitat along Coyote Creek downstream from Anderson Dam and in North Coyote Valley, where tricolored blackbirds could breed. However, creek flow augmentation, groundwater monitoring, and dryback monitoring (with additional flow augmentation, and payment of VHP impact fees for impacted wetland and riparian habitat, as necessary) would avoid significant impacts on tricolored blackbirds related to dryback effects.

With the exception of the colonial tricolored blackbird, other bird species nesting in areas where they could be impacted by Project activities are present at relatively low densities. Several pairs of the yellow warbler and white-tailed kite, for example, could breed among all the Project's impact areas, and only one or two pairs of northern harriers might nest in North Coyote Valley. Numerous pairs of a wide variety of other bird species nest in the Project's impact areas, though the Project's impacts on the populations of any one species would not be so great as to result in a decline in regional (e.g., South Bay) populations. With implementation of BMPs, particularly BMP BI-5 for nesting birds, and compliance with VHP conditions, impacts on nesting special-status and nonspecial-status birds will not be substantial, and therefore will be **less than significant**. Furthermore, the VHP's vast conservation program would conserve numerous habitats throughout much of the county that support populations of virtually all bird species, including yellow warbler, white tailed kite, and tricolored blackbird, that may be affected by the Project due to the breadth of conserved habitat, both geographically and in terms of the diversity of habitat types. Therefore, Valley Water's payment of VHP impact fees for the Project would contribute to a conservation program that would help to offset impacts on habitat for nesting special-status birds.

Mitigation Measures

No mitigation is required.

Impact TERR-1g: Nonbreeding special-status birds (Less than Significant with Mitigation)

Seismic Retrofit Construction

Several special-status bird species, the Swainson's hawk, burrowing owl, and peregrine falcon, are not known or expected to breed in any areas where they could be impacted by Seismic Retrofit activities, but they could occur there as nonbreeding foragers, particularly during migration and in winter. In the Seismic Retrofit Area, grasslands and the bed of the drawn-down reservoir provide the areas most likely to be used by foraging Swainson's hawks and burrowing owls; peregrine falcons may forage in these same areas, and they may forage on waterbirds on the reservoir as well. Migrant or wintering burrowing owls may roost in California ground squirrel burrows in the Seismic Retrofit Area (most likely in grassland, among riprap on the dam face, or in the bed of the drawn-down reservoir). Due to the scarcity of these species near Anderson Reservoir, the number of individuals that may use the Seismic Retrofit Area for roosting or foraging is very low (likely no more than 1-2 individuals when these species are present at all).

All impacts to land cover types other than urban-suburban are considered permanent following VHP conventions. However, Seismic Retrofit construction would not result in the long-term loss of substantial amounts of grassland foraging habitat for burrowing owls or Swainson's hawk, or riprap that could provide refugia for nonbreeding burrowing owls, and it would result in an increase in reservoir habitat supporting prey and foraging areas for peregrine falcons. Construction activities could disturb foraging individuals of these species, though given the extensive areas of potential foraging habitat, those few individuals that might be foraging in the area could simply move to alternative areas nearby. Burrowing owls could be injured or killed if they are present in burrows when grading occurs, and construction activities could disturb roosting owls to the point of abandonment of their burrows, subjecting them to increased predation risk as they look for alternative burrows.

Groundwater levels along Coyote Creek or in North Coyote Valley are not predicted to drop substantially as a result of operations during construction. Modeling performed by Valley Water predicted that there would be a reduction in groundwater recharge and storage during Seismic Retrofit construction relative to 2015 base conditions (when ~~interim seismic~~ restrictions limited reservoir capacity to 51,200 AF); however, groundwater storage is still predicted to be above Valley Water's 2021 Groundwater Management Plan storage target (Valley Water 2023a). Nevertheless, in the event that reduced creek flow combined with drought conditions were to cause a drop in groundwater levels, any adverse effects of reduced Coyote Creek flow during Project construction on waterbird habitat along Coyote Creek or in North Coyote Valley could reduce prey availability for peregrine falcons, which often forage on waterbirds.

Construction Phase Existing Conditions Baseline conditions for Seismic Retrofit construction allow for discharges from the dam of up to 2,500 cfs. During Seismic Retrofit construction, the reservoir's outlets would be left open during the wet season to minimize the amount of water that accumulates in the reservoir bed. The magnitude of flow, and frequency of flows of a certain magnitude, will depend on rainfall amounts during individual runoff events and Coyote Reservoir releases. Valley Water (2022c ~~2022d~~) predicts higher flows at the 2-, 5-, and 10-year return intervals during construction. At their maximum, such flows could be as high as 6,000 cfs, which represents the maximum capacity of all dam outlets that will be present. However, a 6,000-cfs flow during Seismic Retrofit construction has a very low probability of occurring, as it would represent a 200-year event (with a 0.5 percent likelihood of occurring in any given year). The higher the flow, the lower the probability and frequency of that flow occurring in any given year, so that very high flows, greater than the 10-year or 20-year events, are unlikely during the Project construction period, though possible.

Higher flows during storm events could cause erosion and scour that would result in the modification of potential foraging habitat for peregrine falcons, Swainson's hawks, and burrowing owls along Coyote Creek. However, such habitat is infrequently used by foraging individuals of these species. A nesting pair of Swainson's hawks in North Coyote Valley could occasionally forage along the creek, though that pair has been seen most often foraging in agricultural and grassland habitats away from Coyote Creek. Therefore, effects of high construction-period flows on habitat for foraging special-status birds would not be substantial. Furthermore, high flows and related inundation of habitats along Coyote Creek would occur primarily outside the nesting season, so that it would not affect pairs of these nonbreeding special-status birds nesting outside the Project area and foraging within the Project area.

Conservation Measures Construction

Construction and implementation of proposed Conservation Measures could impact foraging activities of the Swainson's hawk, burrowing owl, and peregrine falcon, and roosting burrowing owls in the same ways as described for Seismic Retrofit Project construction activities above. Although peregrine falcons are occasionally observed at Ogier Ponds and in the Parkway Lakes/Coyote Percolation Pond area, Swainson's hawks and burrowing owls have not been recorded using these areas (Cornell Lab of Ornithology 2022), though they could occur rarely. These species could also occur, infrequently and in low numbers, in ~~areas supporting Conservation Measures in~~ the North Channel Reach and Live Oak Restoration Reach ~~Extension~~

~~Area and other areas~~ where maintenance of fish-related habitat enhancements would occur ~~are proposed~~. Implementation of the Conservation Measures would not result in a substantial reduction in the availability or quality of foraging habitat for these nonbreeding species, or in substantial adverse effects on roosting burrowing owls.

Conservation Measures include releases of imported water via the CDL and Cross Valley Pipeline Extension, which would help maintain groundwater levels and thus the aquatic, wetland, and riparian habitats along Coyote Creek and in North Coyote Valley that may be used by prey of these nonbreeding special-status birds.

The burrowing owl is a VHP-covered species, and the VHP includes a number of conservation activities focused on this species. In addition, the VHP's vast conservation program conserves numerous habitats, including grasslands, wetlands, ponds, and other habitats, that provide roosting and foraging habitat for many bird species, including these three species, due to its breadth, both geographically and in terms of the diversity of habitat types to be conserved. Therefore, payment of VHP fees would contribute to a conservation program that benefits the Swainson's hawk (which is under consideration for inclusion as a VHP-covered species in the upcoming VHP amendment), burrowing owl, and peregrine falcon.

Construction Monitoring

Construction monitoring for water quality, fisheries monitoring and fish rescue, aquatic species rescue and relocation, invasive species monitoring and control, and other monitoring efforts could result in the disturbance of roosting or foraging peregrine falcons, Swainson's hawks, or burrowing owls due to the noise and activity of monitoring personnel and equipment. Such impacts would be localized and infrequent, if they occur at all, due to the scarcity of these three species in areas where construction monitoring would occur.

Peregrine falcons often forage on waterbirds, and thus, any adverse effects of reduced Coyote Creek flow during Project construction on waterbird habitat along Coyote Creek or in North Coyote Valley could reduce prey availability for peregrine falcons. During construction, Valley Water would monitor groundwater levels and continue to perform monitoring per the Dryback Monitoring Plan. Results of this monitoring would be used by Valley Water to determine whether creek flows need to be augmented to avoid adverse dryback effects on aquatic, wetland, or riparian habitats. Valley Water would compensate for any impacts on wetland, riparian, or aquatic habitat that are detected by dryback monitoring and that can be attributed to reduced creek flow due to Project construction by paying VHP fees for the impacts detected. Thus, no substantial adverse effects of reductions in creek flow on peregrine falcon prey availability would occur.

Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Adaptive Management

Analysis of the effects of post-construction FAHCE operations on nonbreeding special-status birds was performed relative to the Pre-FERC Order Baseline (2017 conditions) and WEAP-modeled Future Baseline (2035 conditions). FAHCE flows are not expected to result in substantial impacts, either adverse or beneficial, on such birds. As described previously in the general discussion of Project impacts on terrestrial biological resources, flows under the FAHCE rule curves will be generally similar to~~,~~ ~~those under 2017 conditions~~ but possibly slightly lower than the Pre-FERC Order Baseline Conditions, while FAHCE flows are likely to be slightly higher than under the WEAP-modeled Future Baseline. In general, FAHCE flows may entail slightly lower flow in winter and summer, due to retention of water in the reservoir for spring pulse flows, than either the Pre-FERC Order Baseline or Future Baseline, punctuated by the spring pulse flows described above. Spring pulse releases may temporarily inundate foraging habitat, but such habitat is infrequently used by foraging individuals of these species, no burrowing owl roost sites are expected to be present in areas that might be inundated, and such flows would be relatively brief (and not particularly high, from the perspective of inundation of these bird species' foraging and roosting habitats). Changes in creek temperature as a result of post-construction operations would not have a substantial effect on nonbreeding special-status birds.

Post-construction operations of the Ogier Ponds CM would provide potential foraging habitat and prey for Swainson's hawk and peregrine falcon, and operations of the Coyote Percolation Dam CM would help to maintain suitable foraging habitat and prey for the peregrine falcon at the Coyote Percolation Pond. These species are not likely to use the closed-canopy riparian woodland at the North Channel Reach ~~Extension~~ and Live Oak Restoration Reach.

Maintenance of Anderson Dam facilities and Conservation Measures could disturb foraging individuals of these species, and possibly roosting burrowing owls, due to disturbance from noise or activity of maintenance personnel and equipment. However, these species are not expected to occur frequently near areas where such maintenance will occur, and therefore no substantial disturbance impacts would occur. Adaptive management activities consist primarily of monitoring and potential adaptive management actions. There is some potential for field monitoring activities to disturb foraging or roosting birds, though again, such impacts would occur infrequently (if at all) due to the infrequency with which these species use areas where monitoring would be performed. Impacts of adaptive management actions would likely be similar to those resulting from Conservation Measures and post-construction flows.

Post-construction operations of Anderson Dam would provide for a reservoir that furnishes ample foraging habitat and prey for peregrine falcons. Refilling of the reservoir would reduce foraging habitat for nonbreeding Swainson's hawks and reduce foraging and potential roosting habitat for migrant and wintering burrowing owls. However, foraging habitat of the same or higher quality is abundant in grasslands in the region, and the loss of this foraging habitat would not result in any effects on populations of these species. Although burrowing owls could be using burrows in the reservoir bed when the reservoir refills following construction, those owls would relocate as the water level rises.

Significance Conclusion Summary

Implementation of Valley Water BMPs and compliance with applicable VHP conditions would reduce impacts to foraging and roosting, nonbreeding special-status birds, including the Swainson's hawk, burrowing owl, and peregrine falcon. BMPs applicable to this impact are identified in **Table 3.5-6**. VHP conditions applicable to this impact are provided in **Table 3.5-7**, and VHP-related AMMs are provided in **Table 3.5-8**.

Valley Water would implement BMPs HM-8, HM-9, HM-10, WQ-11, WQ-15, and WQ-16 to minimize the potential for hazardous materials and other pollutants to impact foraging birds and their food sources, and HM-12 would reduce the potential for fire to affect these species' habitats and prey. BMP WQ-4 limits impacts from staging and stockpiling activities. BMPs BI-8 and WQ-9 would reduce impacts on birds' foraging habitats by avoiding competition between invasive plants and native vegetation. BMP BI-11 will minimize the attraction of predators that may prey on birds. BMP BI-4 will minimize impacts of pesticides on nontarget species, such as nonbreeding special-status birds and their prey.

VHP conditions 3, 4, 5, 7, and 11 would reduce the potential for and magnitude of impacts on nonbreeding special-status birds and their habitats by minimizing impacts on stream, wetland, and pond habitats. In particular, these conditions require implementation of numerous AMMs summarized in **Table 3.5-8**; these AMMs include limiting the footprint of activities, reducing the potential for pollutants to impact these species and their habitats, avoiding the encouragement of invasive plants, and avoiding erosion and sediment impacts on these species' habitats. VHP Condition 7 would entail minimizing ground disturbance and vegetation removal, stabilizing soil to avoid erosion and sedimentation, and revegetating with native plants or other appropriate plants.

Maintenance of Anderson Dam facilities would occur as part of the DMP and would employ the BMPs and mitigation measures implemented by the DMP to avoid and minimize impacts on sensitive biological resources, such as nesting birds and their habitats. DMP BMPs BI-10 and BI-11 minimize impacts to vegetation, and **DMP Mitigation Measure Vegetation-6** requires restoration of vegetation that may have been lost due to dryback following dewatering. BMP BI-13 requires use of local ecotypes of native plants and appropriate erosion control seed mixes, which would avoid impacts to bird habitat from invasive plant species. **DMP Mitigation Measures Wildlife-11** and **Water Quality-1** and BMP BI-7 will reduce the potential for birds of prey to be poisoned by rodents that have ingested pesticide, and **DMP Mitigation Measure Wildlife-4** prohibits the use of herbicides that are not excluded from the applicable injunction.

Of the potentially occurring nonbreeding special-status bird species, only the burrowing owl is a VHP-covered species. All Project activities that could impact this species are covered by the VHP, except for the additional year of Anderson Reservoir dewatering. However, by the time Year 6 construction occurs, the bed of the reservoir is likely to be so disturbed that burrowing owls would make little use of it for foraging or roosting.

The foraging and roosting habitat for these nonbreeding special-status birds that would be impacted by Project activities is not known to be used frequently or by large numbers of these species, and the extent of such habitat that would be impacted represents a very small proportion of regionally available habitat. Therefore, impacts on habitat used by these species, aside from burrowing owls, would not be substantial, and therefore would be **less than significant**.

Although no individual Swainson's hawks or peregrine falcons would be impacted, roosting burrowing owls could be injured or killed in burrows within the Project Area. Valley Water's payment of VHP impact fees for the Project would contribute to a conservation program that includes a number of conservation activities focused on the burrowing owl, and that would also benefit the Swainson's hawk and peregrine falcon.

Nevertheless, substantial adverse effects on burrowing owls could occur, and this impact would therefore be significant. Implementation of **Mitigation Measure TERR-1g** would avoid such impacts by identifying the locations of any burrowing owls prior to initiation of Project activities that could impact them and avoiding injury or mortality of those birds. With implementation of **Mitigation Measure TERR-1g**, impacts of the Project on nonbreeding special-status birds are **less than significant**.

Mitigation Measures

TERR-1g Burrowing Owl Impact Avoidance

Although burrowing owls have not been observed breeding in the Project Area, preconstruction surveys will be conducted, regardless of the season, prior to construction in any area providing burrowing owl refugia, as determined by a qualified biologist retained by Valley Water, due to the potential occurrence of migrant, wintering, or dispersing burrowing owls. A qualified biologist will determine whether potential roost sites (e.g., burrows of California ground squirrels, or riprap) ~~is~~ <u>are</u> present in, or within 250 feet of, the work area. If suitable habitat is present within these areas, a preconstruction survey will be performed within 7 days of the start of work activities. If a burrow with signs of burrowing owl presence (e.g., whitewash, pellets, and/or feathers) is observed during the preconstruction survey but no burrowing owl is present, a second survey will be performed within 24 hours prior to the start of work to determine whether burrowing owls are present. The second survey will occur between morning civil twilight and 10:00 a.m., or between 2 hours before sunset and evening civil twilight, to provide the highest detection probability. If no burrowing owls are found during the preconstruction surveys, the work may proceed. If burrowing owls are detected during the surveys and/or during the course of construction activities, the following measures will be implemented.

- If occupied burrows are identified, no new activities (i.e., activities that were not ongoing when the burrow was established) will occur within a 250-foot buffer zone during the nesting season (defined as February 1 to August 31). However, the buffer may be reduced with CDFW and SCVHA approval.
- After the nesting season, work may occur within the 250-foot buffer zone provided:
    - A qualified biologist monitors the owls for at least 3 days prior to construction to determine baseline foraging behavior (i.e., behavior without construction).
    - The same qualified biologist monitors the owls during construction and finds no change in owl foraging behavior in response to construction activities.
    - If there is any change in owl foraging behavior as a result of construction activities, these activities will cease within the 250-foot buffer.
    - If the owls are gone for at least one week, the Project proponent may request approval from the SCVHA that a qualified biologist excavate the usable burrows to prevent owls from re-occupying the site. After the usable burrows are excavated, the buffer zone will be removed, and construction may continue.
    - Monitoring must continue as described above for the nonbreeding season as long as the burrow remains active.
- <u>In the event that passive relocation of burrowing owls from burrows must occur for Project activities to continue, Valley Water will coordinate with the CDFW and SCVHA to determine the appropriate procedures for relocation.</u>

Impact TERR-1h: Pallid Bat (Significant and Unavoidable)

Seismic Retrofit Construction

A maternity colony of the pallid bat has been located just outside of the Seismic Retrofit Area, in the Cochrane Road barn, since 1998. Based on periodic monitoring of this site conducted since

1998, this barn has supported up to 105 females, which use the roost year-round. This colony likely represents the largest and most stable colony of the species known in Santa Clara County. Males associated with this roost likely roost in suitable hollows or crevices within mature trees, and in crevices within rock faces, in the Seismic Retrofit Area.

Seismic Retrofit construction would not result in direct impacts on the Cochrane Road barn; the closest Project activities would be along Cochrane Road 75 feet away. Therefore, Seismic Retrofit construction would not cause any physical disturbance to or modification of the roost. However, given the intensity of construction activities, which would include some nighttime work, and the extent to which foraging habitat on Anderson Dam would be disturbed during construction, it is possible that pallid bats may abandon the roost within the barn while construction is ongoing. The noise associated with construction equipment and generators, and lighting from nighttime activities, may disturb bats as they roost in the barn or forage outside the barn, causing them to avoid foraging or roosting (or to abandon roosts) in areas close to construction activity. Typical buffers recommended between intense construction activity and pallid bat roosts are 90 feet for motor vehicles and foot traffic; 120 feet for heavy equipment; 150 feet for trenching; 250 feet for idling equipment or generators; 250 feet for shielded lighting; and 400 feet for unshielded lighting (H. T. Harvey & Associates 2016, Johnston et al. 2017). While it is possible that some females may tolerate construction occurring only 75 feet away, others may abandon the roost. Therefore, heavy construction activity associated with access along Cochrane Road, coupled with some nighttime work on the dam and the large-scale modification of habitat that would occur during construction, could cause at least some female pallid bats to abandon the roost.

Construction during the maternity season (April 1 to August 31) near maternity roosts may cause mothers to attempt to relocate to new roosts. Some females may find alternative roosts in other buildings, hollows in trees, or crevices in rock outcrops nearby. If females leave the barn roost early in the maternity season (e.g., in April or May), their young may be small enough that the females can carry the young to a new roost. However, if females leave the roost later in the maternity season (e.g., June or July), the young may be too large to carry, and abandonment of young or unsuccessful attempts to relocate young could lead to their mortality.

If pallid bats abandon the Cochrane Road barn roost during construction, they may return to the barn once Seismic Retrofit construction has been completed. However, unless high-quality alternative roost sites are present in the vicinity, the population may decline before the bats can re-occupy the barn due to permanent dispersal of females away from the roost, lower reproductive success by females using inferior roost sites (such as roosts located farther from high-quality foraging habitat), or predation of bats that are unable to find suitable roost sites.

Removal of trees containing large cavities and crevices, and modification of rock outcrops with large crevices, would reduce availability of roosting sites for males, which typically do not roost among the females within the barn. Removal of trees and modification of rock outcrops suitable for use by roosting bats would also remove alternative maternity roost sites, if pallid bats abandon the barn as a result of disturbance by the Seismic Retrofit construction.

When trees, structures, or rock outcrops containing roosting colonies or individual bats are removed or modified, individual bats could also be physically injured, killed, or subjected to physiological stress resulting from being disturbed during torpor. Bats roosting in trees, buildings, or rock outcrops that are to be removed or otherwise disturbed may flush from these areas before they can be injured or killed. However, bats flushed during the daytime could suffer increased predation, resulting in the loss of small numbers of individuals.

During construction, Seismic Retrofit activities would also result in the short-term loss of foraging habitat, such as open grassland areas in which the bats forage, as well as a temporary impact on foraging individuals through the alteration of foraging patterns (e.g., avoidance of work areas because of increased noise and activity levels during Project activities). However, the Project would not result in substantial long-term changes to the availability of foraging habitat after construction is completed and thus would not have a long-term impact on foraging habitat or prey availability.

Existing Conditions Baseline conditions for Seismic Retrofit construction allow for discharges from the dam of up to 2,500 cfs. During Seismic Retrofit construction, the reservoir's outlets would be left open during the wet season to minimize the amount of water that accumulates in the reservoir bed. The magnitude of flow, and frequency of flows of a certain magnitude, will depend on rainfall amounts during individual runoff events and Coyote Reservoir releases. Valley Water (2022c ~~2022d~~) predicts higher flows at the 2, 5, and 10-year return intervals during construction. At their maximum, such flows could be as high as 6,000 cfs, which represents the maximum capacity of all dam outlets that will be present. However, a 6,000-cfs flow during Seismic Retrofit construction has a very low probability of occurring, as it would represent a 200-year event (with a 0.5 percent likelihood of occurring in any given year). The higher the flow, the lower the probability and frequency of that flow occurring in any given year, so that very high flows, greater than the 10-yr or 20-yr events, are unlikely during the project construction period, though possible.

Higher flows during storm events could cause erosion and scour that would result in the loss of some large trees that could provide roosts for pallid bats (although no such roosts are known). However, such flows would occur primarily outside the maternity season, so that they would be unlikely to disturb maternity roosts. As described in Impact TERR-1c, larger flows would enhance the regeneration of riparian trees, including sycamores and cottonwoods that, when mature, could provide cavities large enough to support pallid bat roosts. Erosion and sedimentation resulting from high-flow events would also create more open foraging habitat for pallid bats.

Conservation Measures Construction

Pallid bats are not known to occur in the Conservation Measures Project Area. However, this species could forage in open habitats around the Ogier Ponds CM Area and Coyote Percolation Dam CM Area, and ~~Conservation Measures in~~ where maintenance of the North Channel Reach and ~~the~~ Live Oak Restoration Reach would occur ~~and other areas where fish-related habitat enhancements are proposed~~. Larger trees in these areas could possibly support roosts. If bats are roosting in trees within or near the Conservation Measures Project Area, they could be impacted in the same ways described above for tree roosts in the Seismic Retrofit construction area.

Conservation Measures include releases of imported water via the CDL and Cross Valley Pipeline Extension, which would help maintain groundwater levels and thus the aquatic, wetland, and riparian habitats along Coyote Creek and in North Coyote Valley that may be used by roosting or foraging pallid bats, or that support their prey.

The pallid bat is not a VHP-covered species. However, the VHP's vast conservation program conserves habitats, including forests, woodlands, and grasslands, that provide suitable roosting and foraging habitat for this species due to its breadth, both geographically and in terms of the diversity of habitat types to be conserved. Payment of VHP fees would thus contribute to a conservation program that benefits the pallid bat.

Construction Monitoring

Construction monitoring activities would have little effect, adverse or beneficial, on the pallid bat. To the extent this species might roost in riparian trees along Coyote Creek downstream from Anderson Dam or in North Coyote Valley, or forage in those areas, reduced Coyote Creek flow during Seismic Retrofit construction could affect the health of roost trees or reduce prey availability for pallid bats. During construction, Valley Water would monitor groundwater levels and continue to perform monitoring per the Dryback Monitoring Plan. Results of this monitoring would be used by Valley Water to determine whether creek flows need to be augmented to avoid adverse dryback effects on aquatic, wetland, or riparian habitats. Valley Water would compensate for any impacts on wetland, riparian, or aquatic habitat that are detected by dryback monitoring and that can be attributed to reduced creek flow due to Project construction by paying VHP fees for the impacts detected. Thus, no substantial adverse effects of reductions in creek flow on the pallid bat would occur.

Construction monitoring for water quality, fisheries monitoring and fish rescue, aquatic species rescue and relocation, invasive species monitoring and control, and other monitoring efforts could result in the disturbance of roosting pallid bats due to the noise and activity of monitoring personnel and equipment. However, such impacts would be localized and infrequent, and it is unlikely that bats would be substantially disturbed by such activities.

Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Adaptive Management

Analysis of the effects of post-construction FAHCE operations on pallid bats was performed relative to the Pre-FERC Order Baseline (2017 conditions) and WEAP-modeled Future Baseline (2035 conditions). After Seismic Retrofit construction is completed, refilling of the Anderson Reservoir will result in the inundation of the reservoir bed, which will reduce foraging habitat for pallid bats. However, ample foraging habitat will remain in the vicinity of the Cochrane Road roost site, in the form of grassland and other open habitats around the dam and reservoir. Post-construction operations would not result in substantial impacts on pallid bats' use of the Cochrane Road barn. Water releases from the dam would not affect these roosting bats, and maintenance activities would not occur close enough to the Cochrane Road barn to disturb these bats.

FAHCE flows are not expected to result in substantial impacts, either adverse or beneficial, on pallid bats. Flows under the FAHCE rule curves will be similar to those under 2017 conditions but possibly slightly lower, while FAHCE flows are likely to be slightly higher than under the WEAP-modeled Future Baseline. In general, FAHCE flows may entail slightly lower flow in winter and summer, due to retention of water in the reservoir for spring pulse flows, than either the Pre-FERC Order Baseline or Future Baseline, punctuated by the spring pulse flows described above. Such flows would not affect pallid bats or their roosting or foraging habitats.

Post-construction operations and maintenance of the Ogier Ponds CM and Coyote Percolation Dam CM will not result in substantial impacts on pallid bats. Maintenance of the North Channel Reach ~~Extension~~ and Live Oak Restoration Reach could occasionally disturb roosting individuals, though such effects would be minor, localized, and infrequent, and would not impact large roosts. Maintenance of Anderson Dam facilities could result in increased noise in the vicinity of the Cochrane Road barn, though such impacts would be minor, localized, and infrequent and would not cause abandonment of the roost.

Adaptive management activities consist primarily of monitoring and potential adaptive management actions. Monitoring could result in the disturbance of roosting pallid bats due to the noise and activity of monitoring personnel and equipment. However, such impacts would be localized and infrequent, and it is unlikely that bats would be substantially disturbed by such activities. Impacts of adaptive management actions would likely be similar to those resulting from Conservation Measures and post-construction flows.

Significance Conclusion Summary

Implementation of Valley Water BMPs and compliance with applicable VHP conditions will reduce impacts on the pallid bat. BMPs applicable to this impact are identified in **Table 3.5-6**. VHP conditions applicable to this impact are provided in **Table 3.5-7**, and VHP-related AMMs are provided in **Table 3.5-8**.

Valley Water will implement BMPs HM-8, HM-9, HM-10, WQ-11, WQ-15, and WQ-16 to minimize the potential for hazardous materials and other pollutants to impact pallid bats and their food sources, and HM-12 will reduce the potential for fire to affect this species and its habitats. BMP WQ-4 limits impacts from staging and stockpiling activities. BMPs BI-8 and WQ-9 will reduce impacts on pallid bats' roosting and foraging habitats by avoiding competition between invasive plants and native vegetation. BMP BI-11 will minimize the attraction of predators that may prey on pallid bats. BMP BI-4 will minimize impacts of pesticides on nontarget species such as pallid bats.

Implementation of VHP Conditions 3, 4, 5, 7, and 11 will reduce the potential for and magnitude of impacts on pallid bats, their habitats, and their prey by minimizing impacts on stream, wetland, and pond habitats. These conditions require implementation of numerous AMMs summarized in **Table 3.5-8**; these AMMs include limiting the footprint of activities, reducing the potential for pollutants to impact these species and their habitats, avoiding the encouragement of invasive plants, and avoiding erosion and sediment impacts on this species' habitats. VHP Condition 7 will entail minimizing ground disturbance and vegetation removal, stabilizing soil to avoid erosion and sedimentation and revegetating with native plants or other appropriate plants.

Maintenance of Anderson Dam facilities will occur as part of the DMP and will employ the BMPs and mitigation measures implemented by the DMP to avoid and minimize impacts on sensitive biological resources such as pallid bats and their habitats. DMP BMPs BI-10 and BI-11 minimize impacts to vegetation, and **DMP Mitigation Measure Vegetation-6** requires restoration of vegetation that may have been lost due to dryback following dewatering. BMP BI-13 requires use of local ecotypes of native plants and appropriate erosion control seed mixes, which will avoid impacts to bat habitat from invasive plant species. **DMP Mitigation Measure Wildlife-4** prohibits the use of herbicides that are not excluded from the applicable injunction.

While these measures will reduce Project impacts on pallid bats, they would not eliminate disturbance of roosting pallid bats at the Cochrane Road barn, including during the maternity roost season (April 1 to August 31). The abandonment of the pallid bat maternity roost in the Cochrane Road barn, a substantial decline in the number of bats using that roost as a result of the Project, or the loss of multiple pallid bat individuals within an occupied roost (at any time of year) would be a substantial adverse effect and therefore a significant impact because this species' populations and available habitat are limited locally and regionally. Because the roost within the Cochrane Road barn is the largest and most stable known roost in the county, the loss of, or substantial decline in the number of individuals using, a roost in this barn or elsewhere in the Project vicinity would result in a substantial regional decline in this species' regional populations.

It is likely that currently unknown pallid bat roosts will benefit from the VHP's conservation program, and therefore Valley Water's contribution to that program through payment of impact fees would provide some benefit to pallid bat populations. However, because pallid bat populations in the county have been declining and the Anderson Dam population is the largest and most stable known to occur in the county, contribution to the VHP's conservation program will likely not adequately compensate for adverse impacts on the roosting bats at the Cochrane Road barn. Therefore, impacts on this species will likely not be adequately offset through VHP compliance alone. Project impacts on pallid bats would be substantial, and therefore significant. Valley Water will implement **Mitigation Measures TERR-1h(1)** to **TERR-1h(4)** to reduce impacts on individual pallid bats, the maternity roost site present in the Cochrane Road barn, and the population occupying this roost.

Implementation of **Mitigation Measure TERR-1h(1)** will reduce impacts on the pallid bats using the Cochrane Road barn roost. If adequate buffers are provided around the roost, then the pallid bat colony may persist on the site during and following construction. Implementation of **Mitigation Measure TERR-1h(3)** will further reduce the possibility that pallid bats may abandon the site and will provide further protection to this bat population by minimizing the potential for males and nonbreeding females outside the barn to be injured or killed during Project activities. Valley Water implementation of **Mitigation Measures TERR-1h(1)** and **TERR-1h(3)**, if fully implemented, will minimize the probability of colony abandonment or a substantial reduction in the size of the colony.

If Project activities during the maternity season cannot observe the buffers described in **Mitigation Measure TERR-1h(1)**, and especially if such activities must occur so close to the barn that bats must be evicted, then the risk of colony abandonment (or a substantial reduction in the number of females present in the colony) will be greater. Implementation of **Mitigation Measure TERR-1h(1)**, in conjunction with **Mitigation Measure TERR-1h(2)**, will avoid the abandonment of an active maternity colony during the maternity season. Bats evicted per **Mitigation Measure TERR-1h(2)** may find alternative roost sites; however, given the size of the roost at the Cochrane Road barn, it is unlikely that these bats will find commensurate habitat elsewhere, and the population of pallid bats in the county may be reduced substantially. Implementation of **Mitigation Measure TERR-1h(4)** will compensate for Project impacts if the number of females using available roosts after Project construction (i.e., the alternative roost structures and the barn, if it is not demolished) can be documented to be at least 75 percent of baseline numbers within 3 years following the completion of construction. The baseline for assessing the effectiveness of **Mitigation Measure TERR-1h(4)** is represented by the Existing Conditions Baseline, existing conditions modified by FOCP implementation; therefore, baseline numbers could consist of the most recent maternity-season survey tally (e.g., 105 females documented in June 2022) or the results of another survey conducted by Valley Water immediately after, or closer to the completion of, the FOCP. The standard for determining that **Mitigation Measure TERR-1h(4)** has adequately compensated for Project impacts is set at 75 percent of the population, rather than the entire population, because a reduction in colony size is likely to occur due to the residential development and subsequent loss of foraging habitat that is occurring in the area northwest of the barn, outside the Project Area, and due to inter-annual fluctuations in abundance of pallid bats at this roost site. Because of these fluctuations, and the possibility that pallid bats would return to the barn shortly after construction has been completed, determination of the post-construction number of pallid bats using this roost (and any alternative roost structure provided by Valley Water) would be based on surveys within three years following completion of construction. If pallid bat numbers are documented to be at least 75 percent of baseline numbers (as described previously in this paragraph) during any survey within 3 years following completion of construction, then the impact would be **less than significant**. Nevertheless, the Project could cause the number of females at this site to drop below 75 percent of existing numbers, and a substantial proportion of the regional population would have been affected. No other mitigation would be feasible to reduce this impact, as **Mitigation Measures TERR-1h(1)** to **TERR-1h(4)** represent the only feasible measures to reduce this impact, and because pallid bats are selective about their choice of roost sites, it is unknown whether pallid bats would use any alternative roost site provided under **Mitigation Measure TERR-1h(4)**. Therefore, this impact would be **significant and unavoidable**.

Mitigation Measures

TERR-1h(1) Avoid Disturbance of the Cochrane Road Barn Roost

The most important component of the pallid bat population near Anderson Dam is the offsite Cochrane Road barn in which the maternity colony is located. Measures to avoid and minimize disturbance of bats using the barn could avoid causing the abandonment of this roost. To the extent feasible (as determined by Valley Water’s Project engineer, based on their assessment of whether Project activities can proceed while implementing the appropriate measures during construction), Valley Water will implement the following measures during the maternity season (April 1 to August 31), if bats are using the barn in a given year:

- With the exception of vehicular use of Cochrane Road, Project-related activities, including staging of equipment and laydown of materials, will maintain a buffer from the barn of at least 65 feet for foot traffic; 90 feet for motor vehicles; 120 feet for operation of heavy equipment; 150 feet for trenching; 250 feet for idling equipment or generators; 250 feet for shielded lighting; and 400 feet for unshielded lighting.
- Lighting, both for construction and Project operations, will be directed away from the barn and designed to minimize any increase in lighting around the barn. Examples of design features that may be implemented to minimize lighting increases include shielding of lights, adaptation of light pole arm length and mast height to site-specific conditions, and placing light poles at non-standard intervals.
- All light-emitting diodes (LEDs) or bulbs installed for Project construction or operation will be rated to emit or produce light at or under 2700 Kelvin unless higher-Kelvin lighting is necessary for the particular activity being performed.

Fencing or other appropriate materials shall be placed around the Cochrane Road barn to indicate to construction personnel the limits of the buffers listed above. These measures can be relaxed (e.g., buffers reduced) if a qualified biologist, in consultation with the CDFW, determines that the risk to the colony of evicting the bats (per **Mitigation Measure TERR-1h(2)** below), so that they are not present in the barn during the maternity season, exceeds the risk of allowing Project activities to occur within buffers less than those described above. These measures will also be implemented, to the extent feasible (as determined by Valley Water's Project engineer, based on their assessment of whether Project activities can proceed while implementing the appropriate measures during construction), during the remainder of the year (September 1 to March 31) to avoid causing disturbance to the point that bats abandon the barn roost. Again, a qualified biologist, in consultation with CDFW, may determine that the risk to the colony of evicting the bats (per **Mitigation Measure TERR-1h(2)** below) exceeds the risk of allowing Project activities to occur within buffers smaller than those described above, allowing these measures to be relaxed.

A biological monitor will observe the Cochrane Road barn during initial activities conducted within the buffers described above, and periodically (weekly or more frequently) during Seismic Retrofit construction to determine whether there is any evidence that the colony is being disturbed by construction activities. If the biological monitor observes any such evidence of disturbance, the monitor will notify a qualified biologist who would determine (in consultation with CDFW) whether any feasible measures, such as increased buffers, can be implemented to avoid or reduce disturbance.

TERR-1h(2) Evict Pallid Bats prior to Initiating Maternity-Season Disturbance near the Cochrane Road Barn Roost

If prior to the maternity season it is determined by Valley Water's project engineer that it will not be feasible to maintain the buffers described in **Mitigation Measure TERR-1h(1)**, Valley Water may need to evict the bats roosting in the Cochrane Road barn prior to the maternity season to prevent abandonment of young (e.g., if construction starts during the maternity season) and to provide females with the opportunity to look for alternative, less disturbed roost sites in which to bear young. A qualified biologist retained by Valley Water (in consultation with CDFW) will determine, based on the type and level of disturbance that would occur during the upcoming maternity season, whether it is appropriate for the bats to be evicted or whether the proposed disturbance is of such a minor nature that eviction is unnecessary. In some circumstances, it may be preferable to allow roosting bats to continue using a roost while construction is occurring near the roost site. If it is determined that the risks to bats from eviction (e.g., increased predation or exposure, competition for roost sites, or long-term abandonment of the roost) are greater than the risk of colony abandonment, then the bats will not be evicted.

If the qualified biologist determines that eviction of bats is necessary to avoid abandonment of young, eviction will occur at night to decrease the likelihood of predation (compared to eviction during the day). Eviction will occur between September 1 and March 31, outside the maternity season. For example, if Valley Water and the qualified biologist determine that the Project activities planned for the upcoming maternity season are likely to disturb roosting bats to the point of causing abandonment of an active maternity colony, the bats will be evicted prior to the beginning of that maternity season. Eviction will not occur during long periods of inclement or cold weather (as determined by the qualified biologist) when prey is not available or bats are in torpor. Eviction activities will be planned by and performed under the supervision of a qualified biologist (in consultation with CDFW).

The precise eviction methods will be determined by the qualified biologist to minimize physical alterations of the Cochrane Road barn, recognizing its historical importance. Eviction may occur via removal of some of the boards on the barn to increase airflow through the barn, thereby reducing the suitability of thermal conditions within the roost. Alternatively, one-way doors may be installed in crevices being used for roosting to allow bats to exit the roost at night but not to re-enter. Following eviction, bat exclusion devices may be installed or left in place to prevent bats from taking up occupancy of the structure prior to the onset of the Project activities.

Exclusion devices may be removed after Project activities within the buffers described in **Mitigation Measure TERR-1h(1)** have reached their peak intensity in terms of level of activity of heavy equipment and night lighting, and proximity of those activities to the barn roost. At that point, removal of exclusion devices will allow those bats tolerant of such activities to resume use of the barn, without risk that activities will increase in intensity. Any exclusion devices in place when Project construction has been completed will be removed at that time.

TERR-1h(3) Minimize Impacts on Pallid Bats Roosting Outside the Cochrane Road Barn

Although the Cochrane Road barn is the center of activity for the female pallid bats associated with this roost, males likely roost during the day in smaller groups (or singly) in other locations nearby, and females may day-roost in other locations as well, particularly during the nonbreeding season. In addition, pallid bats could roost in trees outside the Seismic Retrofit Area, such as in the Conservation Measure Project Area. Because pallid bats may use a variety of such nonbreeding day-roosts, it is unknown which roosts may be occupied by pallid bats when Project activities disturb various locations. Therefore, Valley Water will implement measures during construction to minimize the likelihood of injury or mortality of individual pallid bats using roosts other than the Cochrane Road barn.

Prior to removal of any trees greater than 8 inches in diameter at breast height, a qualified biologist retained by Valley Water will inspect trees identified for removal for cavities, ~~or~~ crevices, or deep bark fissures that may be suitable for use by roosting pallid bats. If any trees contain such features, potential for bat presence will be presumed. All suitable roost trees will be ~~identified and~~ removed over a 2-day period under the supervision of a qualified biologist according to the following procedures. On the first day, the trees will be limbed but not entirely removed. In the afternoon, chainsaws will be used to remove tree limbs that do not contain suitable bat roosting habitat (e.g., cavities, crevices, and deep bark fissures); the disturbance and modification of the tree will discourage any bats roosting within from returning to the roost the next morning. On day 2, the rest of the tree with suitable roosting features will ~~can~~ be removed.

Similarly, prior to activities involving physical impacts on rock outcrops providing crevices suitable for roosting pallid bats, a qualified biologist will inspect the outcrops to identify suitable crevices. Depending on the locations and dimensions of the crevices, the qualified biologist will identify the most suitable means of encouraging bats to leave the crevices before rock outcrops are removed or destroyed. Examples of measures may include removal of portions of the outcrop, so that the disturbance and modification of the roost site discourages bats from returning once they have departed the roost; using bright, portable lights to illuminate the crevices, discouraging bats from returning to the crevices once they have exited; or installation of one-way doors in the crevices. Such measures will be implemented under the supervision of a qualified biologist.

Removal of potentially suitable bat roosting trees and eviction of bats from rock outcrops will not occur under unfavorable weather conditions (i.e., when nighttime temperatures are below 45°F or when it is rainy) and will occur outside the April 1-August 31 maternity season unless a qualified biologist surveys the trees or outcrops and determines that no maternity roost is present.

Similar preactivity surveys will be performed prior to any work within 120 feet of potential roost trees or rock outcrops for operation of heavy equipment; 150 feet for trenching; 250 feet for idling equipment or generators; 250 feet for shielded lighting; and 400 feet for unshielded lighting. Such surveys will be conducted by a qualified biologist within 2 weeks prior to the initiation of these activities near mature trees or structures that could provide suitable roost sites. If active pallid bat roosts are detected, the buffers, as described above, will be maintained during the maternity season. Outside the maternity season, the bats will be evicted under the direct supervision of the qualified biologist.

TERR-1h(4) Provide Alternative Pallid Bat Maternity Roost Structures

It is possible that Project disturbance, including construction activity and lighting near the Cochrane Road barn roost, the large-scale (albeit temporary) disturbance of foraging habitat on Anderson Dam, and/or eviction of bats per **Mitigation Measure TERR-1h(2)**, will cause the pallid bats to abandon the barn altogether or to return in reduced numbers. Therefore, if construction cannot comply with the buffers described in **Mitigation Measure TERR-1h(1)**, or if bats are evicted from the barn, Valley Water will provide an alternative bat roost and install it in an appropriate location near the Project Area at least six months prior to the initiation of Project construction or eviction of bats from the barn. A qualified biologist retained by Valley Water will design and determine an appropriate location for an alternative roost structure, based on the location of the original roost, habitat conditions in the vicinity, and areas of Project disturbance. The roost structure may be built to specifications determined by a qualified biologist or may be purchased from an appropriate vendor (although the qualified biologist must determine that the roost is appropriate for pallid bats). The bat roost structure will be installed in a location close to the barn but far enough from planned Project activities that Project construction is unlikely to disturb bats. The design and location of any alternative bat roost will be determined by the qualified biologist in coordination with CDFW.

Valley Water will monitor the alternative roost and the existing Cochrane Road barn for up to 3 years following Seismic Retrofit completion to determine use by bats. This mitigation measure will be deemed successful if at least 79 female pallid bats (or 75 percent of the highest number documented during the maternity season in any year between 2022 and start of construction, if additional monitoring is performed) are observed using a combination of the artificial roost and the barn following Project completion. Monitoring need not continue once this performance standard has been reached, even if 3 years of monitoring have not been completed. If by Year 3, at least 79 female pallid bats have not been recorded using a combination of the alternative roost structure and the barn, a qualified biologist, in consultation with CDFW, will identify alternative roost designs or locations for placement of the roost (or additional roost structures), and Valley Water will monitor the new roost structure(s) for an additional three years (or until the success criterion has been met, whichever occurs first).

Impact TERR-1i: Other special-status mammals (Less than significant)

Seismic Retrofit Construction

This impact analysis addresses special-status mammal species other than the pallid bat, including the San Francisco dusky-footed woodrat, mountain lion, ringtail, American badger, Townsend's big-eared bat, and western red bat.

The San Francisco dusky-footed woodrat nests and forages in all the forested, woodland, and scrub land cover types within the Seismic Retrofit Area. In addition, the species has been detected around boulders and rock outcrops on Basalt Hill and likely resides in crevices there. Seismic retrofit construction would result in the loss of 43.2 acres of suitable habitat for the species. In addition, construction could result in the injury or mortality of individual woodrats and disturbance or destruction of nests and young, leading to increased predation risk on woodrats flushed from nests, as a result of vegetation clearing and operation of equipment. However, the densities of woodrats observed in the Seismic Retrofit Area are low, even in high-quality habitat, based on surveys that have been conducted in that habitat (e.g., preactivity surveys for Project-related geotechnical activities and the FOCP). Therefore, the number of individuals and nests that would be disturbed is very low. Following completion of construction, vegetation in much of the impacted area would regrow over time.

The mountain lion, ringtail, American badger, Townsend's big-eared bat, and western red bat are not known or expected to breed in the Seismic Retrofit Area. However, all five species likely occur in the area as nonbreeders. The Seismic Retrofit Area could be part of the much larger territory of one or more mountain lions or badgers, and these species, as well as ringtails, may disperse into or through, or forage in, the area. Townsend's big-eared bats and western red bats may forage in the area, and small numbers of western red bats could roost in trees in the Seismic Retrofit Area. Virtually all of the land cover types in the Seismic Retrofit Area except reservoir and urban-suburban provide suitable habitat for these species, which may also forage in or over the bed of the drawn-down reservoir.

Seismic retrofit construction could impact all suitable habitat for these species within the Seismic Retrofit Area. Following completion of construction, vegetation in much of the impacted area would regrow over time. Construction would be unlikely to result in injury or mortality of individuals of the mountain lion, ringtail, American badger, or Townsend's big-eared bat, as no high-quality den or roosting habitat is present in the Seismic Retrofit construction area, and any individuals in the construction area would move away from heavy equipment or vehicles before they could be impacted. Western red bats could be roosting in trees when tree removal occurs, though in very low numbers, as this noncolonial species is present in the region only in low numbers during winter and migration; this foliage-roosting bat would also be able to fly away as soon as disturbance of the tree begins, and though daytime flushing of red bats would expose them to increased predation risk, the number of individuals that could be injured or killed as a result of predation attempts caused by Seismic Retrofit construction would be low.

Groundwater levels along Coyote Creek or in North Coyote Valley are not predicted to drop substantially as a result of operations during construction. Modeling performed by Valley Water predicted that there would be a reduction in groundwater recharge and storage during Seismic Retrofit construction relative to 2015 base conditions (when ~~interim seismic~~ restrictions limited reservoir capacity to 51,200 AF); however, groundwater storage is still predicted to be above Valley Water's 2021 Groundwater Management Plan storage target (Valley Water 2023a).

Nevertheless, reduced creek flow combined with drought conditions could result in adverse effects on riparian habitats or other vegetation used by these special-status mammals (e.g., for cover or foraging, and in the case of the woodrat, for nesting). Valley Water would be monitoring groundwater levels and dryback effects in North Coyote Valley throughout Seismic Retrofit construction, and would augment creek flows if necessary; therefore, no impacts on habitat for these special-status mammal species in North Coyote Valley are likely to occur.

Existing Conditions Baseline conditions for Seismic Retrofit construction allow for discharges from the dam of up to 2,500 cfs. During Seismic Retrofit construction, the reservoir's outlets would be left open during the wet season to minimize the amount of water that accumulates in the reservoir bed. The magnitude of flow, and frequency of flows of a certain magnitude, will depend on rainfall amounts during individual runoff events and Coyote Reservoir releases. Valley Water (2022c ~~2022d~~) predicts higher flows at the 2-, 5-, and 10-year return intervals during construction. At their maximum, such flows could be as high as 6,000 cfs, which represents the maximum capacity of all dam outlets that will be present. However, a 6,000-cfs flow during Seismic Retrofit construction has a very low probability of occurring, as it would represent a 200-year event (with a 0.5 percent likelihood of occurring in any given year). The higher the flow, the lower the probability and frequency of that flow occurring in any given year, so that very high flows, greater than the 10-year or 20-year events, are unlikely during the project construction period, though possible.

Higher flows during storm events could inundate riparian habitat supporting woodrat nests, or used by the mountain lion, ringtail, and American badger for cover or foraging, and though these species would be able to move to higher ground in response to rising water levels, they would temporarily lose the use of that habitat, and such displaced individuals would be subject to increased predation risk or vehicular mortality. Woodrat nests could be lost to such inundation. However, such habitat modifications would allow regeneration of riparian trees such as cottonwoods, willows, and sycamores, as described in Impact TERR-1c. Thus, the habitat modifications resulting from such high flows and related inundation of habitat along Coyote Creek would help to rejuvenate the riparian corridor along Coyote Creek and maintain habitat heterogeneity that supports a diverse avian community.

Conservation Measures Construction

San Francisco dusky-footed woodrats also nest at Ogier Ponds and along Coyote Creek downstream from Anderson Dam, such as within the North Channel Reach and Live Oak Restoration Reach maintenance areas ~~Extension Area.~~ In these areas, woodrats nest in dense mixed riparian forest and woodland, willow riparian forest and scrub, and coast live oak forest and woodland. As is the case at Anderson Dam, this species occurs in relatively low densities in these areas. Woodrat nests have not been detected at the Coyote Percolation Dam CM Area but could possibly be present in low numbers. The mountain lion, ringtail, American badger, Townsend's big-eared bat, and western red bat may use habitats at Ogier Ponds and along Coyote Creek downstream from Anderson Dam, such as within the North Channel Reach and Live Oak Restoration Reach maintenance areas ~~Extension Area~~, for dispersal habitat; they are less likely to occur at the Coyote Percolation Dam CM Area due to its more urban surroundings to the west and the presence of US 101 to the east. To the extent that these species are present in (or occasionally use) the areas where Conservation Measures construction will occur, these species and their habitats could be impacted by implementation of Conservation Measures in the same ways described for Seismic Retrofit construction above.

Conservation Measures include release of imported water via the CDL and Cross Valley Pipeline Extension, which would help maintain groundwater levels and thus the aquatic, wetland, and riparian habitats along Coyote Creek and in North Coyote Valley that may be used by these special-status mammals.

None of these mammals is a VHP-covered species, although the mountain lion and American badger are under consideration for inclusion as VHP-covered species in the upcoming VHP amendment. However, the VHP's vast conservation program conserves habitats, including a variety of grassland, scrub, woodland, and forest habitats, that support large populations of woodrats and provide suitable habitat for the other mammal species, due to its breadth, both geographically and in terms of the diversity of habitat types to be conserved. Payment of VHP fees would thus contribute to a conservation program that benefits all these special-status mammals.

Construction Monitoring

Construction monitoring for water quality, fisheries monitoring and fish rescue, aquatic species rescue and relocation, invasive species monitoring and control, and other monitoring efforts could result in the disturbance of woodrats and their nests, as well as individuals of the other mammal species, due to the noise and activity of monitoring personnel and equipment. Such impacts would be localized and infrequent, and they would not result in the loss of woodrat nests or suitable habitat for any of these species.

Reduced Coyote Creek flow during Seismic Retrofit construction could affect the health of riparian habitat that may be used by these species. During Seismic Retrofit construction, Valley Water would monitor groundwater levels and continue to perform monitoring per the Dryback Monitoring Plan. Results of this monitoring would be used by Valley Water to determine whether creek flows need to be augmented to avoid adverse dryback effects on aquatic, wetland, or riparian habitats. Valley Water would compensate for any impacts on wetland, riparian, or aquatic habitat that are detected by dryback monitoring and that can be attributed to reduced creek flow due to Project construction by paying VHP fees for the impacts detected. Thus, no substantial adverse effects of reductions in creek flow on these special-status mammals would occur.

Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Adaptive Management

Analysis of the effects of post-construction FAHCE operations on these special-status mammals was performed relative to the Pre-FERC Order Baseline (2017 conditions) and WEAP-modeled Future Baseline (2035 conditions). FAHCE flows are not expected to result in substantial impacts, either adverse or beneficial, on these mammals. As described previously in the general discussion of Project impacts on terrestrial biological resources, flows under the FAHCE rule curves will be generally similar to, ~~those under 2017 conditions~~ but possibly slightly lower than the Pre-FERC Order Baseline Conditions, while FAHCE flows are likely to be slightly higher than under the WEAP-modeled Future Baseline. In general, FAHCE flows may entail slightly lower flow in winter and summer, due to retention of water in the reservoir for spring pulse flows, than either the Pre-FERC Order Baseline or Future Baseline, punctuated by the spring pulse flows described above. There is some potential for spring pulse releases to disturb woodrat nests, though most nests would be outside/above the areas inundated, and such flows will be relatively brief (and not particularly high, from the perspective of inundation of these mammal species' habitats). Changes in creek temperature as a result of post-construction operations would not have a substantial effect on special-status mammals.

Post-construction operations of the Ogier Ponds CM and Phase 2 Coyote Percolation Dam Project will not result in substantial impacts on these mammals, though the Ogier Ponds CM would provide vegetation that may be used as nesting and foraging habitat by woodrats, roosting habitat by western red bats, and foraging habitat and cover during dispersal by mountain lions, badgers, and ringtails.

Maintenance of Anderson Dam facilities and Conservation Measures, including maintenance of the North Channel Reach and Live Oak Restoration Reach, could disturb woodrat nests, either due to physical impacts to nests that are constructed in vegetation requiring maintenance or due to disturbance from noise or activity of maintenance personnel and equipment. The number of nests likely to be disturbed would be low, however, given the low densities at which woodrat nests occur in these areas under Existing Conditions Baseline conditions and the fact that maintenance will occur in areas that were previously disturbed by construction. Maintenance could result in disturbance of roosting western red bats and foraging or dispersing individuals of any of these special-status mammal species, though such disturbance would occur infrequently and affect few individuals given the scarcity of all these species in the Project Area.

Adaptive management activities consist primarily of monitoring and potential adaptive management actions. There is some potential for field monitoring activities to disturb roosting western red bats and foraging or dispersing individuals of any of these special-status mammal species, though again, such disturbance would occur infrequently and affect few individuals. Impacts of adaptive management actions would likely be similar to those resulting from Conservation Measures and post-construction flows.

Significance Conclusion Summary

Implementation of Valley Water BMPs and compliance with applicable VHP conditions would reduce impacts on the San Francisco dusky-footed woodrat, mountain lion, ringtail, American badger, Townsend's big-eared bat, and western red bat. BMPs applicable to this impact are identified in **Table 3.5-6**. VHP conditions applicable to this impact are provided in **Table 3.5-7**, and VHP-related AMMs are provided in **Table 3.5-8**.

Valley Water will implement BMPs HM-8, HM-9, HM-10, WQ-11, WQ-15, and WQ-16 to minimize the potential for hazardous materials and other pollutants to impact special-status mammals and their food sources, and HM-12 will reduce the potential for fire to affect these species' habitats and food. BMP WQ-4 limits impacts from staging and stockpiling activities. BMPs BI-8 and WQ-9 will reduce impacts on special-status mammal habitats by avoiding competition between invasive plants and native vegetation. BMP BI-11 will minimize the attraction of predators that may prey on these mammals. BMP BI-4 will minimize impacts of pesticides on nontarget species such as nonbreeding mammals and their food sources. BMP BI-10 will avoid entrapment of special-status mammals in pipes, hoses, pits, or trenches during construction.

VHP Conditions 3, 4, 5, 7, and 11 will reduce the potential for and magnitude of impacts on special-status mammals, their habitats, and their food sources by minimizing impacts on stream, wetland, and pond habitats. These conditions require implementation of numerous AMMs summarized in **Table 3.5-8**; these AMMs include limiting the footprint of activities, reducing the potential for pollutants to impact these species and their habitats, avoiding the encouragement of invasive plants, and avoiding erosion and sediment impacts on these species' habitats. VHP Condition 7 will entail minimizing ground disturbance and vegetation removal, stabilizing soils to avoid erosion and sedimentation, and revegetating with native plants or other appropriate plants.

Maintenance of Anderson Dam facilities would occur as part of the DMP and would employ the BMPs and mitigation measures implemented by the DMP to avoid and minimize impacts on sensitive biological resources such as special-status mammals and their habitats. DMP BMPs BI-10 and BI-11 minimize impacts to vegetation, and **DMP Mitigation Measure Vegetation-6** requires restoration of vegetation that may have been lost due to dryback following dewatering. BMP BI-13 requires use of local ecotypes of native plants and appropriate erosion control seed mixes, which would avoid impacts to mammal habitat from invasive plant species. DMP **Mitigation Measures Wildlife-11** and **Water Quality-1** and BMP BI-7 will reduce the potential for predatory mammals to be poisoned by rodents that have ingested pesticide, and **<u>DMP</u> Mitigation Measure Wildlife-4** prohibits the use of herbicides that are not excluded from the applicable injunction.

Based on the low abundance of San Francisco dusky-footed woodrat nests observed in the Project Area, the number of individuals and nests of this species that would be impacted is low. The San Francisco dusky-footed woodrat is regionally common, reaching very high densities in some areas, and therefore the number of individuals that could be affected by the Project represents a very small proportion of the regional populations of this species. As a result, this effect does not reach the threshold for a substantial reduction in this species' regional populations, and the impact on San Francisco dusky-footed woodrat would therefore be less than significant.

The mountain lion, ringtail, American badger, Townsend's big-eared bat, and western red bat would be impacted in very low numbers, and with the exception of possible predation of western red bats flushed during tree removal, it is unlikely that any Project activities would result in injury or mortality of individuals. Furthermore, the Project would not result in substantial long-term impacts on habitat used by these species. Impacts on these species would not be substantial, and therefore would be less than significant.

These special-status mammals would also benefit from the VHP conservation program, to which Valley Water would contribute VHP impact fees for all land cover types that provide suitable habitat within the Project Area. Based on the above analysis, impacts on the San Francisco dusky-footed woodrat, mountain lion, ringtail, American badger, Townsend's big-eared bat, and western red bat would not be substantial, and would be **less than significant**.

Mitigation Measures

No mitigation is required.

Impact TERR-1j: San Francisco Bay special-status species (Less than Significant with Mitigation)

Seismic Retrofit Construction

Two special-status plant species, alkali milk vetch and Point Reyes bird's beak, could occur in tidal marshes of the expanded study area along lower Coyote Creek/Coyote Slough that may be subject to increased flow frequency and magnitude, and sediment deposition, during Seismic Retrofit construction. However, due to the complete lack of any recent records of those species from the Coyote Creek/Coyote Slough area, the probability of their occurrence in these areas is very low. Their potential presence is assumed solely because the tidal areas of the expanded study area have not been thoroughly surveyed for those species.

In addition, a number of special-status animals are known to inhabit tidal and nontidal habitats along lower Coyote Creek and Coyote Slough, which may be subject to increased flow frequency and magnitude and sediment deposition during Seismic Retrofit construction, but are absent from other areas subject to Project impacts. These species are the California Ridgway's rail, California black rail, Alameda song sparrow, San Francisco common yellowthroat, Bryant's savannah sparrow (*Passerculus sandwichensis alaudinus*), salt marsh harvest mouse, and salt marsh wandering shrew (*Sorex vagrans halicoetes*).

Nonbreeding northern harriers forage in the Seismic Retrofit Area and Conservation Measures Project Area, but this species is considered a California SSC only when nesting. It may nest in North Coyote Valley, and it is addressed in Impact TERR-1f above in the context of nonbaylands breeding bird species that may be impacted by the Project. In addition, it nests commonly in tidal marshes along lower Coyote Creek, where it could be affected by increased flow frequency and magnitude, and sediment deposition, during Seismic Retrofit construction.

The California least tern (*Sternula antillarum browni*) also uses baylands habitats, but it would not be present along Coyote Slough during the time of year when Seismic Retrofit-related increases in frequency and magnitude of flows or sediment mobilization would occur (as discussed in **Table 3.5-5**), so it would not be impacted by the Project and is not discussed further.

Aside from the northern harrier (discussed in Impact TERR-1f above), Project activities would have little to no direct impacts on any of these baylands-associated special-status plant or animal species, as they do not breed or forage in or very close to the Seismic Retrofit Area. Even activities that could reduce water quality in Coyote Creek, such as spills of fuel or chemicals during construction, are unlikely to have a substantive effect on tidal marsh species given the dilution that would occur between construction areas and tidal marshes. However, during Seismic Retrofit construction, these species could be impacted by increased frequency and magnitude of flows, effects of such increased flows on the salinity of tidal marshes and tidal marsh vegetation, and deposition of sediment mobilized from the reservoir. During Seismic Retrofit construction, the reservoir's outlets would be left open during the wet season to minimize the amount of water that accumulates in the reservoir bed. The magnitude of flow, and frequency of flows of a certain magnitude, will depend on rainfall amounts during individual runoff events and Coyote Reservoir releases. Valley Water (2022c ~~2022d~~) predicts higher flows at return intervals greater than about the 2-year return interval during construction. At their maximum, such flows could be as high as 6,000 cfs, which represents the maximum capacity of all dam outlets that will be present. However, a 6,000-cfs flow during Seismic Retrofit construction has a very low probability of occurring, as it would represent a 200-year event (with a 0.5 percent likelihood of occurring in any given year). The higher the flow, the lower the probability and frequency of that flow occurring in any given year, so that very high flows, greater than the 10-year or 20-year events, are unlikely during the project construction period, though possible.

Valley Water (2023c ~~2022e~~) modeled potential effects of construction-period flows on tidal habitats along lower Coyote Creek and Coyote Slough in natural habitats. This modeling assumed that higher flows through Anderson Dam, taken from the memo used to compare construction-period flows through the dam with Pre-FERC Order Baseline flows (Valley Water 2022c ~~2022d),~~ would be coupled with tide height equaling mean higher-high water (MHHW) to represent the conditions that would occur if higher flows down Coyote Creek coincided with high tides.

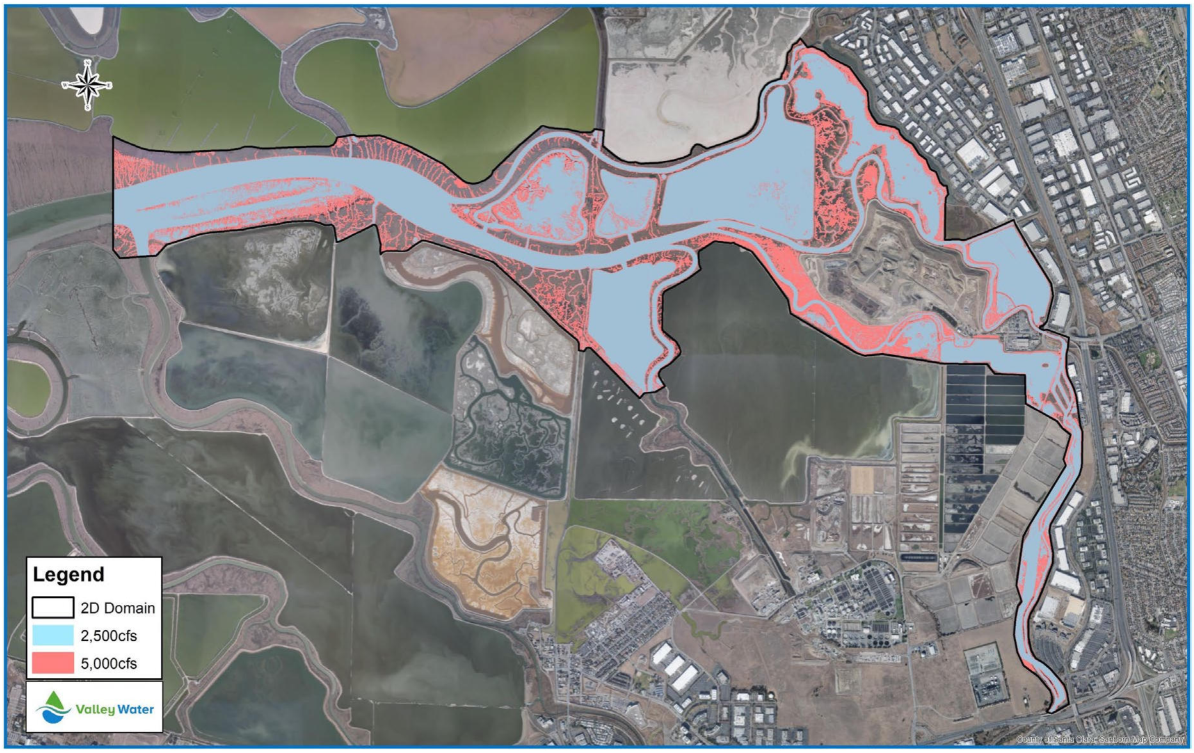
In addition to input of water flowing through Anderson Dam, there are 125 square miles of watershed downstream from Anderson Dam that would contribute water to Coyote Creek that eventually reaches tidal habitats (Valley Water 2023c ~~2022e~~). Storms that result in higher flows through Anderson Dam are likely to cause additional runoff entering Coyote Creek from the rest of the watershed. For example, during a late December 2022 storm, Anderson Dam was releasing water at a rate of 500 cfs, but Coyote Creek flows at CA-237 (just upstream from the uppermost tidal areas) were above 2,000 cfs (USGS). Thus, Anderson Dam contributes only a portion of the water that reaches tidal areas of Coyote Creek; the exact proportion provided by flows through Anderson Dam varies according to variability in rainfall and runoff among locations within the Coyote Creek watershed. For the purposes of the modeling performed for this tidal impact analysis, Valley Water (2023c ~~2022e~~) assumed that 2,000 cfs would be a baseline flow in Coyote creek that would reasonably occur without dam influence. This is based on historic stream gage data (USGS). Valley Water's analysis only considered the effects of flow through Anderson Dam during Seismic Retrofit construction on tidal habitats above the 2,500 cfs flow threshold (Valley Water 2023c ~~2022e~~).

Analyzing flows at 5-, 10-, 20- to 25-, and 50- to 100-year return intervals, Valley Water's modeling predicted that the extent of inundated floodplain (i.e., tidal marsh), beyond post-FOCP baseline conditions, would increase by approximately 68 acres (during the 5-year event) to 155 acres (during the 50- to 100-year event). Predicted acreage of additional inundation was 86 acres during the 10-year event and 121 acres during the 20- to 25-year event. These scenarios represented an increase in inundation ranging from 4.3 to 9.7 percent of the entire tidal floodplain in the expanded study area. Water surface elevation (i.e., depth) was predicted to increase more in the uppermost limits of tidal action, from CA-237 downstream to the confluence of Lower Penitencia Creek with Coyote Creek. Downstream from Lower Penitencia Creek (i.e., in the areas where baylands species could potentially occur), water surface elevation was predicted to increase by approximately 0.15 to 0.75 feet (during the 5-year flow) to 0.4 to 2 feet (during the 50 to 100-year flow), with intermediate increases during the 10- and 20- to 25-year flows.

Figure 3.5-12. ~~3.5-11~~ Modeled inundation change in tidal areas from the construction baseline condition (maximum Coyote Creek prevailing local flow of 2,500 cfs) to 3,500 cfs, representing a 5-year event passed through Anderson Dam during Seismic Retrofit construction.

Source: Valley Water (2022 e)

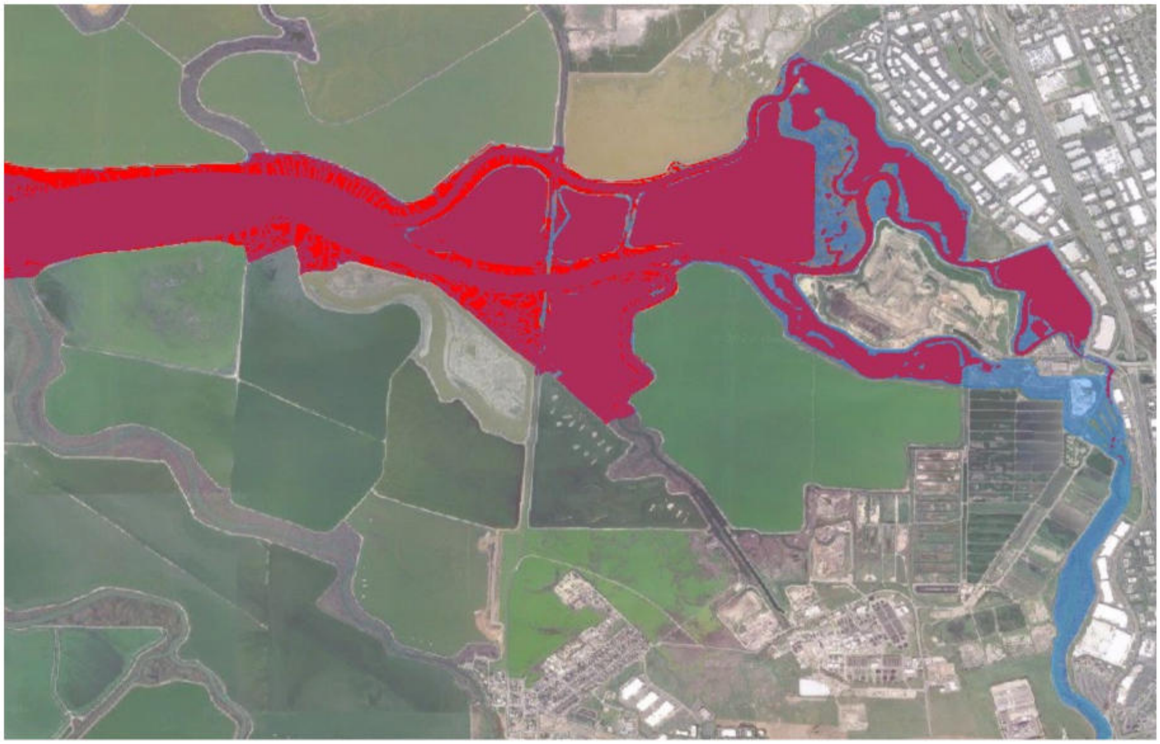
Figure 3.5-13. ~~3.5-12~~ **Modeled inundation change in tidal areas from the construction baseline conditions (maximum Coyote Creek prevailing local flow of 2,500 cfs) to 5,000 cfs, representing a 50- to 100-year event passed through Anderson Dam during Seismic Retrofit construction.**



Source: Valley Water (2022d ~~2022e~~)

To provide a familiar basis for comparison, Valley Water (2023c ~~2022e~~) also modeled inundation resulting from a January 2022 king tide event with no creek flow. This was overlaid with inundation that would occur from a 50-100-year flow passed through Anderson Dam with MHHW and shown in **Figure 3.5-14** ~~**Figure 3.5-13**~~.

Figure 3.5-14. ~~3.5-13~~ Modeled inundation of tidal areas from a January 2022 king tide (red) vs. the inundation from a 50- to 100-year flow event (5,000 cfs) passed through Anderson Dam during Seismic Retrofit construction (blue).



Source: Valley Water (2023c ~~2022e~~)

As indicated in **Figure 3.5-12** ~~**3.5-11**~~ and **Figure 3.5-13** ~~**3.5-12**~~, most of the areas affected by higher flows through Anderson Dam outlets are subtidal and intertidal habitats that are not currently vegetated. Most of the tidal marsh that would be inundated by such flows is located in the upper tidal reaches, such as in the Warm Springs Marshes, South Coyote Slough, and the Reach 1A Bypass area (all around the Newby Island Landfill). Less inundation of tidal marsh would occur farther downstream. Similarly, compared to areas inundated during a recent (January 2022) king tide, the additional areas that would be inundated by a 50- to 100-year event are concentrated in the upper tidal reaches (**Figure 3.5-14** ~~**3.5-13**~~). These marshes that would be inundated by flows from Anderson Dam during storm events support baylands species such as salt marsh harvest mice, salt marsh wandering shrews, California Ridgway's rails, California black rails, Alameda song sparrows, San Francisco common yellowthroats, and Bryant's savannah sparrows. In addition, 50- to 100-year flows would inundate some high-marsh and ecotone habitat further downstream, around the edges of the Island Ponds and along the railroad tracks, that would not be inundated during the king tide analyzed in **Figure 3.5-14** ~~**3.5-13**~~. Thus, 50- to 100-year flows would inundate some habitat used by tidal marsh species to escape rising water levels. Twenty- to 25-year flows would not inundate most of the high marsh and ecotone habitat in these tidal areas.

Seismic Retrofit-related increases in magnitude of flows, and frequency of higher flows, could impact the baylands animal species present along lower Coyote Creek and Coyote Slough. California Ridgway's rails, California black rails, salt marsh harvest mice, and salt marsh wandering shrews may have to move to higher ground or seek refuge in dense vegetation during high-flow events, particularly if they coincide with lunar high tides (e.g., king tides). These animals are particularly susceptible to predation during such events as they are forced to move into more exposed areas and to upland edges. Therefore, increased predation on rails, salt marsh harvest mice, and salt marsh wandering shrews could occur as a result of higher flows through Anderson Dam during Seismic Retrofit construction. Such effects would be greater with larger flows, as more of the tidal marsh would be inundated, yet the probability of such flows decreases with increasing rate of flow. Therefore, more limited areas of marsh would be inundated during the lower, higher-probability flows. Also, these species have evolved with exposure to high water levels from high fluvial flows and tidal flooding. As water levels ramp up, these tidal marsh species would move to higher ground and refugia in vegetation to avoid predation. Some predation would still occur, though (e.g., **Figure 3.5-14** ~~3.5-13~~ shows inundation of some ecotonal, high-tide refugial habitat), and the short-term (construction-period) effects of higher flows could lead to increased predation and loss of individuals of these species. California Ridgway's rail numbers are lower in the upper tidal reaches that would be affected most by higher flows during Seismic Retrofit construction than in lower reaches that would be affected least. Salt marsh harvest mice may breed March to November. Although the species has evolved with exposure to high wet-season flows, and thus it is unlikely to breed in numbers during the wet season, high flows during the period March-November could inundate nests of this species.

The Alameda song sparrow, San Francisco common yellowthroat, and Bryant's savannah sparrow are more mobile than rails or small mammals, being much more willing to seek refuge from high water in vegetated areas outside (upslope from) the marsh. Although these species would be displaced by high water, they would be less susceptible to increased predation risk than the rails or small mammals would be. Northern harriers would not be adversely affected, as they would likely take advantage of high-flow events to hunt for small birds and mammals exposed by high water.

Flows high enough to cause these tidal marsh-associated animals to be exposed to increased predation risk occur infrequently (with the magnitude of the flows inversely proportional to frequency of occurrence), so the likelihood and magnitude of any adverse effect of high flows on these species during the 7-year Seismic Retrofit construction period is not high. Nevertheless, the probability that a 20-year flow event will occur within the 7-year construction period is 30 percent.

Because the California Ridgway's rail, California black rail, Alameda song sparrow, San Francisco common yellowthroat, and Bryant's savannah sparrow have evolved in and near tidal marsh habitats subject to inundation from storm events and king tides, they are unlikely to have active nests in tidal marsh during the winter and early spring period when Seismic Retrofit-related increases in flows are most likely to occur. However, if a mid/late spring storm event were to occur and flows through Anderson Dam were substantially higher than Existing Conditions Baseline conditions, active nests of the California Ridgway's rail, California black rail, Alameda song sparrow, San Francisco common yellowthroat, and Bryant's savannah sparrow could be lost to inundation. Such an event has an extremely low probability, however.

If alkali milk vetch or Point Reyes bird's beak is present in marshes subject to increased frequency and magnitude of flows during Seismic Retrofit construction, individuals could be adversely affected as a result of inundation. However, these species are adapted to some inundation, having evolved in wetlands, and therefore mortality may not occur. Also, these are high-marsh species that would be subjected to inundation at a lower depth, velocity, and duration than areas closer to intertidal habitats. Therefore, it is unlikely that increased inundation as a result of higher flows through Anderson Dam during construction would adversely affect these two plant species.

In summary, the dam's outlets will be managed during Seismic Retrofit construction in such a way as to potentially result in increased frequency, depth, and/or duration of inundation of tidal marsh habitats far downstream from the dam. Such increased inundation would reduce the vegetative cover available to special-status species associated with San Francisco Bay tidal marshes, increasing predation of special-status tidal marsh animals that have to seek out more limited patches of vegetation that is not inundated. Such impacts would be infrequent and would occur only during the construction period.

The potential for increased flows during Seismic Retrofit construction to modify the salinity of water and sediment in tidal marshes, and thus the species composition of tidal marshes, was also assessed. Monitoring bay salinity, the USGS (Schemel 1998) concluded that large storm events can result in reductions in salinity in San Francisco Bay as a result of increased input from local (South Bay) streams and from the Sacramento/San Joaquin River Delta. Monitoring plant communities in South Bay marshes from 1989 to 2012, H. T. Harvey & Associates (2012) documented the dynamic nature of tidal marsh plant associations, with vegetation in certain areas becoming dominated by plant species associated with higher salinity in some years and changing to more brackish species associated with moderate or lower salinity in other years. They concluded that changes in dominant tidal marsh plant species among years is primarily a result of the effects of variability in freshwater runoff on plant species having differing tolerances to salinity. Following years of higher runoff, the extent of brackish-marsh plant species such as alkali bulrush expands at the expense of species associated with higher-salinity marshes such as pickleweed. Following drier years, the reverse occurs. Because the salt marsh harvest mouse and California Ridgway's rail are typically associated with more saline marshes, changes in dominant tidal marsh plant species composition as a result of increased freshwater inputs during Seismic Retrofit construction could potentially degrade habitat quality in marshes along lower Coyote Creek by reducing the extent of salt marsh and increasing the extent of brackish marsh.

However, the Project would not result in a substantial impact on special-status tidal marsh species as a result of the potential for increased freshwater input during construction, for a number of reasons. The most important contribution to salinity in the South Bay, including lower Coyote Creek, comes from input from the Sacramento/San Joaquin Delta (H. T. Harvey & Associates 2012). During wet years and large storm events when flows through Anderson Dam are higher, runoff through the Delta is also expected to be higher, so that the influence of freshwater inputs from Coyote Creek on South Bay salinity will always be lower than the influence from the Delta. The amount of fresh water reaching tidal habitats along lower Coyote Creek would not differ between baseline conditions and conditions during Seismic Retrofit construction; rather, it is the magnitude of flows during storm events that could increase during construction. The total volume of fresh water passing through Anderson Dam and reaching tidal habitats along lower Coyote Creek would depend on the weather, not on dam management during construction.

Special-status tidal marsh species, such as the salt marsh harvest mouse and California Ridgway's rail, are able to use a variety of tidal marsh plant associations, and while these species are most closely associated with marsh dominated by plants associated with higher-salinity marshes, they also use brackish marsh vegetation (H. T. Harvey & Associates 1990, 2007c; Shellhammer et al. 2010; Sustaita et al. 2011; Smith 2019). As a result, changes in the distributions of dominant plants as a result of changes in runoff are unlikely to result in substantial reduction in populations of these tidal marsh animals. Finally, any effects of increased freshwater inputs resulting from management of the dam’s outlets during construction would be short-term impacts, occurring only during, and possibly immediately following, Seismic Retrofit construction. Monitoring of marsh vegetation has documented that plant associations change relatively quickly (e.g., over a year or two) in response to variability in freshwater runoff and salinity, so any minor effects of increased freshwater inputs resulting from Seismic Retrofit construction would not last for more than a year or two following completion of construction. Because all the tidal marsh-associated special-status animals and plants considered in this impact assessment have evolved under conditions in which tidal marsh salinity varies among years based on climatic variability and freshwater inputs from Bay tributaries, none of these species would be impacted substantially by potential short-term changes in freshwater inputs from Coyote Creek during Seismic Retrofit construction.

During Seismic Retrofit construction, sediment that has accumulated in the bed of Anderson Reservoir may be mobilized downstream. When this sediment is covered by reservoir water, as under normal conditions when the reservoir is filled, they are not easily eroded. However, when the reservoir has been dewatered, sediment would be more subject to erosion from rainfall runoff and from the reservoir’s tributaries. Modeling of sediment mobilization under various scenarios of storm events and reservoir water levels by URS ~~AECOM~~ (2021) concluded that maximum sediment mobilization would occur if back-to-back 2-year rainfall events (i.e., events that have a 50 percent likelihood of occurring in any given year), or a single 5-year event (with a 20 percent likelihood of occurring in any given year), were to occur when little water was present in the reservoir and sediments are exposed. During those events, flows would be high enough to erode large amounts of sediment from the reservoir (approximately 167,000 tons per event) but not so high as to fully cover the sediments with water, which would reduce their erosivity. Less sediment would be mobilized during lower-magnitude, more frequent flows, during flows that occur when the reservoir has temporarily filled to contain more water and cover more sediment, or during higher flows that quickly cover sediment in the reservoir with water.

To predict the effects of such sediment mobilization on species using tidal baylands along lower Coyote Creek and Coyote Slough, the modeling efforts also estimated sediment deposition in tidal habitats along lower Coyote Slough. Under normal conditions, average sediment loads carried by the tides in the vicinity of the Island Ponds (approximately midway between the upper limits of tidal action along Coyote Creek and the mouth of Coyote Slough that serves as the lower end of the action area) are approximately 500 tons per tide cycle (or 1,000 tons per day) with peak daily loads of over 2,000 tons per day (over two tide cycles) (URS ~~AECOM~~ 2021). Thus, the tidal marshes, aquatic habitats, and mudflats in the study area are dynamic features, exposed to considerable sediment flux even in the absence of sediment mobilization from Anderson Reservoir. Nevertheless, sediment mobilized from the reservoir and carried to tidal habitats along lower Coyote Creek/Coyote Slough would result in some deposition in these habitats. **Table 3.5-10** provides estimates of the amount of sediment that would be deposited in low intertidal zones (e.g., the lower limits of mudflats) in four locations within the action area under different storm scenarios. The amount of sediment mobilized would be less than any of the predictions in **Table 3.5-10** during storm events of greater frequency and lower magnitude (e.g., 1-year events).

Within tidal habitats at the lowermost end of Coyote Creek and in Coyote Slough, maximum deposition of up to 6.46 inches of sediment in lower intertidal areas near the Warm Springs Wetlands, could occur during a 2-year, double peak storm event that occurs over 4.8 days when the reservoir has been dewatered during Seismic Retrofit construction. The depth of deposition would decrease along an upstream-downstream gradient within the baylands, being very low under all scenarios near the mouth of Coyote Slough. In addition, the depth of deposition would decrease with increasing elevation, so that the upper intertidal zone would experience less deposition than is indicated in **Table 3.5-10**, and deposition would be even less in the high marsh; in other words, sediment deposition in tidal areas is greatest in sloughs and channels providing aquatic, subtidal habitats, and intertidal mudflats, and least in vegetated tidal marsh. Whereas the modeling results assume deposition rates under very low-flow, inactive conditions, the flow velocities associated with events that transport large amounts of sediment downstream would be higher, and actual depths of deposition would therefore be lower because some sediment would continue to be carried downstream. Also, subsequent flows with lower sediment loads would wash some of the deposited sediment away, so that these sediment depths would not represent the magnitude of long-term increases in depth/elevation. Therefore, the depth of sediment actually deposited in vegetated marshes during a given flow event would be lower than indicated in **Table 3.5-10**.

Sediment mobilization during Seismic Retrofit construction provides a means of moving much-needed sediment to marshes. The historical urbanization and the presence of Coyote Dam and Anderson Dam have reduced the volume of sediment that would otherwise have been carried downstream in unmodified conditions. Due to sea level rise, sediment accumulation in marshes is important to help vegetated marshes remain at elevations, relative to a rising sea. Delivering increased sediment to the Bay's marshlands has been identified by several regional agencies as a priority for long-term marsh resilience in light of rising sea levels.

Table 3.5-10. Project Depth of Sediment Deposition (per Event) in Low Intertidal Zones of Quiescent and Slow-Moving Areas in Coyote Creek Estuary

Scenario	**1**	**2**	**3**	**4**	**5**
Flow Condition	2-Year Event	2-Year Event	2 ½-Year Event	2-Year Double Peak	5-Year Event
Reservoir Elevation (feet)	490 ~~488~~	Empty	Empty	467	467
Duration (days)	8.5	4.5	4.0	4.8	5.9
Location	**Projected Depth of Deposition (inches)**				
Warm Springs Wetland	0.28	2.06	0.44	6.46	2.69
Above Island Ponds	0.24	1.59	0.40	5.50	2.31

In addition, the South Bay Salt Ponds Restoration Project is restoring former salt ponds to tidal habitats, yet most ponds are, upon breaching, below elevations that would allow colonization and persistence of marsh vegetation. Sediment deposition is necessary to elevate these marshes to the point that they can be colonized by marsh vegetation. According to the tidal marsh recovery plan (USFWS 2013 ~~2016~~), "The effects of rising sea levels on tidal marshes are dependent upon the relative rate of sea level rise versus rates of sedimentation and accretion of the marsh surface. Unless a balance between sedimentation/accretion and erosion/subsidence is met that equals or exceeds the rate of sea level rise, there will be a net loss of tidal marsh habitat." Thus, by helping to elevate tidal habitats in the lower Coyote Creek/Coyote Slough area, sediment mobilization from Anderson Reservoir would contribute to the establishment of vegetated marshes in breached ponds such as the Island Ponds and Pond A6 and help existing marsh to be maintained in the face of sea level rise, thus helping to maintain suitable habitat for the alkali milk vetch, Point Reyes bird's beak, and baylands-associated animals. However, the extent of sediment mobilization from Anderson Reservoir that reaches tidal marshes is unknown.

If alkali milk vetch or Point Reyes bird's beak is present in marshes subject to increased sediment deposition during Seismic Retrofit construction, individuals could be adversely affected as a result of smothering by sediment. However, as noted in the discussion of inundation above, these species are adapted to some inundation and sediment deposition, having evolved in wetlands, and therefore mortality may not occur. Also, these are high-marsh species that would be subjected to less sediment deposition than areas closer to intertidal habitats. Sediment deposition would have a long-term beneficial effect on these species, if they are present.

Aside from inundation, sediment deposition associated with the Seismic Retrofit construction may have short-term, minor adverse effects and long-term beneficial effects on these baylands animal species. California Ridgway's rails and California black rails forage primarily on invertebrates, though Ridgway's rails may also take small vertebrates (Albertson and Evens 2000). Ridgway's rails feed in higher intertidal areas (e.g., mudflats), usually close to the cover of vegetated marshes, though they forage within marsh vegetation as well, and black rails forage almost exclusively within the cover of vegetation. Sudden deposition of several inches of sediment could reduce foraging efficiency by covering prey, which may adversely affect the prey and reduce their availability by making it harder for rails to reach them. However, because many of the rails' prey are benthic burrowers living in a dynamic environment, these invertebrates are able to adapt to sediment deposition, and no large-scale or long-term reduction in the invertebrates' populations (and therefore food availability for rails) would result from sediment deposition associated with the Seismic Retrofit. Also, the depth of sediment deposition would decrease with increasing elevation; the upper edges of mudflats (where Ridgway's rails typically forage) and tidal sloughs higher in the marsh would experience less deposition than indicated by the values in **Table 3.5-10**, and the higher-marsh areas inhabited by black rails (and salt marsh harvest mice and salt marsh wandering shrews) even less, reducing effects of sediment deposition on these species and their food. Insects, spiders, and other prey available to rails in vegetated marsh, may not be affected at all by sedimentation (e.g., if those prey are on vegetation above the high waters that carry the sediment).

During flow events that deposit sediment, salt marsh harvest mice and salt marsh wandering shrews climb higher into vegetation or move into higher patches, so no individuals would be covered or stuck in deposited sediment. Newly deposited sediment may cover seeds or other plant materials used by mice, or invertebrate prey for voles, on the substrate surface, reducing food availability somewhat. There is no expectation that sediment deposition would kill vegetation used by these bayland animals. Tidal marsh plants are adapted to growing in dynamic depositional environments, so the density and structure of vegetative cover and nesting habitat would not be adversely affected.

As discussed above, sediment deposition would have a long-term beneficial effect on all these special-status, tidal marsh-associated species by contributing to the establishment of vegetated marshes in breached ponds such as the Island Ponds and Pond A6 and help existing marsh to be maintained in the face of sea level rise, thus helping to maintain suitable habitat for these species in the long term.

In addition to inundation and sediment deposition impacts, contaminants in Anderson Reservoir sediments could adversely affect these bayland animal species. Under CWA Section 303(d), Anderson Reservoir is listed as impaired for mercury and polychlorinated biphenyls (PCB) (SWRCB 2017a ~~2018~~). In particular, mercury and PCBs have been found in fish caught in Anderson Reservoir. Neither Anderson Reservoir nor any of its tributaries are identified on the CWA Section 303(d) list as impaired for diazinon (SWRCB 2017a). Diazinon was banned for residential use in 2004 and there is no agricultural source of diazinon near Anderson Reservoir. None of the five samples cited by the SWRCB exceeded regulatory thresholds for listing (SWRCB 2017a), and the Final 303(d) Listing Report includes five samples with no exceedances.

Valley Water (2021f ~~2021a~~) prepared a Mercury, Diazinon, and PCBs Plan describing the potential occurrence of these contaminants in Anderson Reservoir and the means by which their concentrations would be tested during dredging for the FOCP. Monitoring and analysis of these issues were conducted pursuant to that plan in conjunction with implementation of FOCP. In consultation with RWQCB staff, it was determined that no further testing is necessary, nor are any diazinon-specific control measures necessary during the implementation of the FOCP (Valley Water 2021f ~~2021a~~). Composite samples of lake sediments collected in 2019 revealed that the reservoir has low sediment mercury concentrations consistent with natural background and industrial-era atmospheric deposition (SWRCB 2017b). Mercury concentrations in reservoir fish are elevated, likely due to biogeochemical and food web conditions that are conducive to methylmercury production and bioaccumulation (Valley Water 2021f ~~2021a~~). Valley Water's existing mercury data do not indicate that there is a reasonable potential for mercury in Anderson Reservoir sediments to exceed mercury thresholds (Valley Water 2021f ~~2021a~~). Anderson Reservoir is included on the CWA Section 303(d) list as impaired for PCBs in fish (SWRCB 2017a), with four of seven samples from Anderson Reservoir fish exceeding evaluation guidelines. However, sediment PCB concentrations in Anderson Reservoir have never been detected in outflow monitoring from Anderson Reservoir.

Literature indicates that California Ridgway's rail reproductive success can be adversely affected by a variety of contaminants and metals, including mercury and PCBs. When introduced to bird species through the bioweb, these contaminants may occur in the species' eggs in the South Bay (Schwarzbach et al. 2006, Ackerman et al. 2012~~, Casazza et al. 2014~~). Mercury is toxic to rail embryos and has a long biological half-life. Schwarzbach et al. (2006) found high mercury levels and low hatching success (due both to predation and, presumably, mercury) in Ridgway's rail eggs throughout the Estuary. Mercury contamination has also been linked to reduced body condition in Ridgway's rails (Ackerman et al. 2012), suggesting there are detrimental effects on survivorship of adult birds as well. Literature also shows that harvest mice may be affected by mercury and PCBs in the intertidal zone (Clark et al. 1992).

Most of the mercury in tidal areas in the South Bay comes from the Guadalupe River watershed, due to the high concentrations of naturally occurring mercury in the watershed and the amount that has been mobilized from historical mercury mines. Valley Water (2021f ~~2021a~~) determined that concentrations of mercury in Anderson Reservoir sediments are relatively low, particularly in comparison to levels already present in the South Bay due to inputs from the Guadalupe River waters. Similarly, available monitoring data indicate low levels of diazinon and PCBs in sediments and water mobilized from Anderson Reservoir (Valley Water 2021f ~~2021a~~), and removal of fish (which bioaccumulate mercury and PCBs) from Anderson Reservoir when it is drained prior to Seismic Retrofit construction would remove much of these contaminants from the system. Therefore, no substantial adverse effects on the health or reproductive success of special-status, baylands-associated animal species would result from mobilization of sediment and potentially adhered contaminants from Anderson Reservoir.

In summary, sediment mobilization and mobilization of contaminants as a result of Seismic Retrofit construction would not result in substantial adverse effects on species associated with San Francisco Bay tidal marshes. Sediment mobilization would provide a net beneficial effect, although the amount of sediment that would be mobilized during Project construction is unknown.

Conservation Measures Construction

Project Conservation Measures would not impact baylands-associated, special-status species, as no such measures would take place in areas where these species occur; Conservation Measures would not increase inundation of tidal marsh habitats or increased freshwater input to tidal marshes; and Conservation Measures would not cause substantial mobilization of sediments, contaminants, or any other potential stressors to tidal marsh far downstream.

Construction Monitoring

During Seismic Retrofit construction, Valley Water would monitor sedimentation of, and water quality within, Coyote Creek downstream from the dam following the Sediment Monitoring Plan (Horizon Water and Environment 2021). This monitoring would determine whether construction activities are resulting in substantial turbidity impacts; see the *Water Quality* section of this EIR for more detail. Otherwise, Project construction monitoring would not impact baylands-associated, special-status species, as no construction monitoring would take place in areas where these species occur; construction monitoring would not increase inundation of tidal marsh habitats or freshwater input to tidal marshes; and construction monitoring would not cause mobilization of sediments, contaminants, or any other potential stressors to tidal marsh far downstream.

Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Adaptive Management

Analysis of the effects of post-construction FAHCE operations on baylands species was performed relative to the Pre-FERC Order Baseline (2017 conditions) and WEAP-modeled Future Baseline (2035 conditions). FAHCE flows are not expected to result in substantial impacts, either adverse or beneficial, on baylands species. As described previously in the general discussion of

Project impacts on terrestrial biological resources, flows under the FAHCE rule curves will be generally similar to, ~~those under 2017 conditions~~ but possibly slightly lower than the Pre-FERC Order Baseline Conditions, while FAHCE flows are likely to be slightly higher than under the WEAP-modeled Future Baseline. In general, FAHCE flows may entail slightly lower flow in winter and summer, due to retention of water in the reservoir for spring pulse flows, than either the Pre-FERC Order Baseline or Future Baseline, punctuated by the spring pulse flows described above. Spring pulse releases would be of such low magnitude that they would not result in any substantial inundation, even temporarily, of habitat for baylands species; these brief flows would result in very small water surface elevation increases that are well within the normal range of tidal elevations along lower Coyote Creek and Coyote Slough. Similarly, Coyote Creek flow augmentation through the Cross Valley Pipeline Extension would not have substantive impacts on water surface elevations, relative to tidal marsh, in tidal areas because of the limited amount of such flow augmentation. Changes in creek temperature as a result of post-construction operations would not have a substantial effect on baylands species, as these special-status species would not be affected by minor variations in water temperature, and any changes in temperature of water released from the dam are not expected to be manifested in water temperature far downstream in tidal areas.

Valley Water (2022e ~~2022f~~) analyzed the potential effects of proposed FAHCE-related freshwater inputs on salinity in the South San Francisco Bay. Because of the limited magnitude of FAHCE-related flows, Valley Water concluded that the natural range and frequency of freshwater flows experienced by streams such as Coyote Creek would not change, and therefore, the ecological habitats in tidal areas downstream would not be affected substantially by these freshwater inputs. Therefore, operational flows from Anderson Dam following construction would not result in any substantial effects on tidal habitats as a result of changes in salinity.

Maintenance of Seismic Retrofit facilities and Conservation Measures (including maintenance of the North Channel and Live Oak Restoration Reach), and monitoring during adaptive management, would have no substantive impact on tidal marsh species far downstream, as no maintenance or adaptive management monitoring would take place in areas where these species occur; these activities would not increase inundation of tidal marsh habitats or freshwater input to tidal marshes; and these activities would not cause mobilization of sediments, contaminants, or any other potential stressors to tidal marsh habitats. Impacts of adaptive management actions would likely be similar to those resulting from Conservation Measures and post-construction flows.

Significance Conclusion Summary

Implementation of Valley Water BMPs and compliance with applicable VHP conditions would reduce impacts on tidal marsh-associated, special-status species to some extent by reducing impacts to water quality. BMPs applicable to this impact are identified in **Table 3.5-6**. VHP conditions applicable to this impact are provided in **Table 3.5-7**, and VHP-related AMMs are provided in **Table 3.5-8**. None of these species are VHP-covered, and the VHP does not cover activities or habitats in baylands areas along lower Coyote Creek/Coyote Slough.

Implementation of BMPs BI-2, HM-8, HM-9, HM-10, WQ-1, WQ-2, WQ-3, WQ-4, WQ-6, WQ-11, WQ-15, and WQ-16 minimize the potential for hazardous materials and other pollutants to enter Coyote Creek waters and eventually be transported downstream to tidal habitats.

Implementation of VHP Conditions 3, 4, 5, 7, and 11 would reduce the potential for and magnitude of impacts on tidal marsh species and their habitats by minimizing impacts on stream and wetland habitats, and ~~thus~~ by reducing the potential for hazardous materials and other pollutants to enter Coyote Creek waters and eventually be transported downstream to tidal habitats. ~~require implementation of numerous AMMs summarized in the footprint of activities, reducing the potential for pollutants to impact these species and their habitats, avoiding the encouragement of invasive plants, and avoiding erosion and sediment impacts on these species' habitats.~~ VHP Condition 7 would entail minimizing ground disturbance and vegetation removal, stabilizing soils to avoid erosion and sedimentation, and revegetating with native plants or other appropriate plants.

Maintenance of Anderson Dam facilities would occur as part of the DMP and would employ the BMPs and mitigation measures implemented by the DMP to avoid and minimize impacts on sensitive biological resources, such as tidal marsh species. **DMP Mitigation Measure Wildlife-2** restricts vehicle and equipment use in salmonid streams during portions of the year. The DMP also includes a number of other BMPs to protect water quality, maintain clean work sites, and reduce erosion, thus reducing the potential for impacts on special-status amphibians; these include BMPs WQ-4, WQ-5, WQ-7, WQ-10, WQ-14, and WQ-18.

It is unlikely that alkali milk vetch and Point Reyes bird's beak are present in areas that could be affected by Seismic Retrofit-related increases in frequency and magnitude of flow, patterns of freshwater input, and sedimentation, so the Project is unlikely to have adverse effects on these species. Even if they were to be adversely affected, the magnitude of those effects would be low, and the benefits of increased sediment deposition would outweigh the adverse effects. Impacts on these species would not be substantial, and therefore would be **less than significant**.

The California Ridgway's rail, California black rail, northern harrier, Alameda song sparrow, San Francisco common yellowthroat, Bryant's savannah sparrow, salt marsh harvest mouse, and salt marsh wandering shrew are present in areas along lower Coyote Creek/Coyote Slough that would be affected by Seismic Retrofit-related increases in frequency and magnitude of flow and sedimentation. No substantial effects of changes in the patterns of freshwater inputs would result from the Project, for reasons previously discussed. No substantial effects of contaminants or water quality impacts would occur, as Anderson Reservoir is not a substantial source of contaminants. The long-term effects of mobilization of sediment from Anderson Reservoir to tidal marshes on which these species depend would be beneficial. As indicated in the tidal marsh recovery plan, sediment needs to equal the rate of sea level rise for existing marshes to be maintained (USFWS 2013 ~~20166~~), and for new marshes to develop in tidal habitats being restored by the South Bay Salt Ponds Restoration Project, sediment availability needs to be even higher. By helping to elevate tidal habitats in the lower Coyote Creek/Coyote Slough area, sediment mobilization from Anderson Reservoir would contribute to the establishment of vegetated marshes in breached ponds such as the Island Ponds and Pond A6 and help existing marsh to be maintained in the face of sea level rise, thus helping to maintain suitable habitat for these species. However, the amount of sediment that would be mobilized from Anderson Reservoir to tidal marshes during Project construction is unknown, so the degree to which sediment mobilization would benefit tidal marsh species is uncertain.

The Project could also result in adverse effects on these tidal marsh species as a result of displacement of rails, mice, and shrews due to inundation and the associated increased predation risk. These effects would occur infrequently and would only have potential to occur during the 7-year Seismic Retrofit construction period, so such effects would be short-term in nature. Nevertheless, if higher flows during Project construction (i.e., flows exceeding the Existing Conditions Baseline, post-FOCP maximum rate of 2,500 cfs) were to result in increased extent, duration, or depth of inundation of tidal marsh habitat, individuals of these tidal marsh species could be lost as a result of the Project. Given the low population sizes and limited distributions of California Ridgway's rails, California black rails, salt marsh harvest mice, and salt marsh wandering shrews, loss of individuals as a result of Project-related inundation would be a substantial and therefore **significant** impact. Valley Water would implement **Mitigation Measure TERR-1j** to reduce Project impacts on these species by contributing to predator management activities in the South Bay and through high tide refugia enhancement, thereby offsetting increases in predation resulting from the Project. With implementation of **Mitigation Measure TERR-1j**, impacts on tidal Baylands species would not be substantial and therefore would be **less than significant**.

Mitigation Measures

TERR-1j Contribution to Baylands Predator Management and High Tide Refugia Enhancement

Valley Water will contribute funds to be used for predator management and enhancement of vegetation providing high tide refugia in areas where predation of the California Ridgway's rail, California black rail, salt marsh harvest mouse, and/or salt marsh wandering shrew could occur in South San Francisco Bay. For predator management, Valley Water will provide $22,500 in funding (approximately half of the entire 2022 predator management budget for the Don Edwards San Francisco Bay National Wildlife Refuge [Refuge]) for each year during Seismic Retrofit construction in which flows through Anderson Dam exceed 2,500 cfs. Valley Water will develop and implement an agreement with the U.S. Department of Agriculture Animal and Plant Health Inspection Service (APHIS), which performs predator management in coordination with the Refuge. That agreement will specify the funding that Valley Water will provide for ~~predator~~ management of avian and mammalian predators and, generally, how APHIS personnel will use those funds. In any given year, how those funds are spent will be determined by Refuge biologists, who routinely work with APHIS to prioritize predator management needs based on the most pressing predation issues occurring around the Refuge, on special-status species, at that time.

Prior to the start of Seismic Retrofit construction, Valley Water will provide APHIS with $45,000 in funding, representing 2 years of predator management activities. This funding will be provided in advance of impacts from greater than 2,500-cfs flows through the dam actually occurring, and for more than 1 year of predator management, to assist APHIS in planning for its staffing needs to perform the necessary predator management. Subsequently, during each year of Seismic Retrofit construction, Valley Water will monitor whether flows through Anderson Dam exceed 2,500 cfs. If such flows occur in a given calendar year, $22,500 will be debited from the initial payment of $45,000. If flows exceed 2,500 cfs in 2 years during construction, Valley Water will provide another $22,500 payment for another, future year of predator management. Valley Water will continue to make such payments for each year in which flows exceed 2,500 cfs during Seismic Retrofit construction.

For enhancement of high tide refugia, Valley Water will contribute funds to one or more ongoing programs that focus on removal of nonnative marsh vegetation and/or planting or management of native marsh vegetation that provides suitable high tide refugia for species such as the California Ridgway's rail and salt marsh harvest mouse. Examples of programs to which Valley Water might contribute include the San Francisco Bay Sea Lavender Control Program, the Invasive Spartina Project (to which Valley Water might contribute funds for restoration rather than invasive Spartina control), or revegetation efforts performed by Save the Bay or other organizations. Valley Water will contribute $20,000 to such programs for each year in which flows exceed 2,500 cfs during Seismic Retrofit construction.

Impact TERR-2: A substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by CDFW or USFWS (Less than Significant with Mitigation)

Seismic Retrofit Construction

The Seismic Retrofit Area supports five sensitive land cover types/natural plant communities – mixed riparian woodland and forest, coast live oak forest and woodland, foothill pine-oak woodland, and mixed serpentine chaparral. Aquatic and wetland habitats, including the reservoir, pond, perennial stream, intermittent stream, and coastal and valley freshwater marsh land cover types, are also considered sensitive, but they are addressed in detail in Impact TERR-3 rather than here (and mixed riparian woodland and forest is addressed in both impact sections).

Riparian habitats, such as mixed riparian woodland and forest, are important ecologically due to the high biodiversity they support and the ecological functions they perform. Oak woodland habitats, such as coast live oak forest and woodland and foothill pine-oak woodland, also support high numbers of wildlife species and thus are important ecologically. Serpentine communities, such as mixed serpentine chaparral, generally support low species diversity, but the species they do support are often rare due to the limited number of species adapted to life on serpentine soils and the limited distribution of such soils.

Seismic Retrofit construction would directly impact all the mixed riparian woodland and forest, coast live oak forest and woodland, foothill pine-oak woodland, and mixed serpentine chaparral in the Seismic Retrofit Area. Although all direct impacts on these land cover types are considered permanent in accordance with VHP conventions, it is likely that conditions in some construction areas, such as areas used for construction access north of the spillway, would provide suitable conditions for natural recolonization by these land cover types following completion of construction. As a result, some recovery of these impacted communities would occur. **Table 3.5-11** indicates the acreage of each sensitive plant community in the Seismic Retrofit Area, thus representing the maximum extent of each community that could be directly impacted by (i.e., lost to) Seismic Retrofit construction.

Table 3.5-11. Direct Impacts on Sensitive Natural Communities from ~~Construction of~~ Seismic Retrofit Construction

Community	Impact (acres)*
Mixed Riparian Woodland and Forest	1.29 ~~4.14~~
Coast Live Oak Forest and Woodland	10.6 14.3
Foothill Pine-Oak Woodland	11.2
Mixed Serpentine Chaparral	2.5

** In accordance with VHP conventions, acreages are reported to the nearest 0.1 acres except for wetland and riparian land cover types, which are reported to the nearest 0.01 acres.*

Construction activities such as grading, excavation, and placement of new structures and soil stockpiles would impact these land cover types. Project activities would affect these land cover types through direct disturbance and removal of vegetation and through damage to underground root structures. In addition, equipment use, vehicular traffic, and worker foot traffic may result in the injury, mortality, altered growth, or reduced seed set of individual plants within these communities. Creation of access routes and staging areas may result in the mechanical or physical removal of vegetation and modification of the seed bank due to grading. Dust that could be generated by construction activities may coat vegetative and floral surfaces, interfering with normal gas exchange, photosynthesis, or pollination.

In serpentine habitats, the conservation of topsoil and seed banks after grading would not be able to restore such habitats to similar conditions because topsoil would become homogenized, mixing the seeds and soils of previously specialized habitat types with more common California annual grassland. Such topsoil and seed banks, if placed in areas that previously supported serpentine habitats, would be unlikely to support the same poor nutrient conditions or the characteristically high proportion of native forbs following grading and restoration.

Movement of earth, vegetation, water (e.g., runoff), equipment, vehicles, and personnel could spread invasive plant propagules and pathogens such as *Phytophthora*. Invasion of native habitats by nonnatives results in adverse effects on both the native plants being displaced and native animals that would otherwise use those habitats. Because many invasive plants are able to easily colonize recently disturbed areas and/or tolerate repeated disturbance better than many natives, Project construction activities, such as clearing and grading, could create conditions suitable for spreading of invasive plant species. In addition, bare upland soils left after construction of temporary staging areas could encourage growth of weedy species, and mulching or erosion control mixes could include and thus introduce invasive, nonnative plant species. Furthermore, nonnative plant species could temporarily benefit from dewatering associated with the Project. *Phytophthora* could also impair the health of plants, spreading through root systems and resulting in the loss of individuals. *Phytophthora* could impair the health of plants in all these sensitive plant communities and therefore degrade the habitat quality these communities provide. Thus, both invasive plants and *Phytophthora* could impact sensitive communities both within and adjacent to the Seismic Retrofit Area. The potential for *Phytophthora* to be spread by Seismic Retrofit construction activities will be reduced via implementation of a Project-specific *Phytophthora* Pathogen Management and Monitoring Plan prepared for the Project based on those developed for the FOCP (Valley Water 2020h, 2021e ~~2021c~~) and the results of FOCP implementation and *Phytophthora* monitoring.

During Seismic Retrofit construction, dry season flows in Coyote Creek downstream from Anderson Dam would be maintained via bypass flows released from Coyote Reservoir, supplemented with water released into Coyote Creek through the CDL and Cross Valley Pipeline Extension. Groundwater levels along Coyote Creek or in North Coyote Valley are not predicted to drop substantially as a result of operations during construction. Modeling performed by Valley Water predicted that there would be a reduction in groundwater recharge and storage during Seismic Retrofit construction relative to 2015 base conditions (when ~~interim seismic~~ restrictions limited reservoir capacity to 51,200 AF); however, groundwater storage is still predicted to be above Valley Water's 2021 Groundwater Management Plan storage target (Valley Water 2023a). Nevertheless, in the event that reduced creek flow combined with drought conditions were to cause a drop in groundwater levels, riparian habitats could suffer reduced health.

Existing Conditions Baseline conditions for Seismic Retrofit construction allow for discharges from the dam of up to 2,500 cfs. During Seismic Retrofit construction, the reservoir's outlets would be left open during the wet season to minimize the amount of water that accumulates in the reservoir bed. The magnitude of flow, and frequency of flows of a certain magnitude, will depend on rainfall amounts during individual runoff events and Coyote Reservoir releases. Valley Water (2022c ~~2022d~~) predicts higher flows at the 2-, 5-, and 10-year return intervals during construction. At their maximum, such flows could be as high as 6,000 cfs, which represents the maximum capacity of all dam outlets that will be present. However, a 6,000-cfs flow during Seismic Retrofit construction has a very low probability of occurring, as it would represent a 200-year event (with a 0.5 percent likelihood of occurring in any given year). The higher the flow, the lower the probability and frequency of that flow occurring in any given year, so that very high flows, greater than the 10-yr or 20-yr events, are unlikely during the project construction period, though possible. Also, the probability of very high flows (i.e., flows greater than the 10-year/20-year magnitude/frequency) would be lower during construction than under Existing Conditions Baseline conditions because water would not be detained in the reservoir during construction, and therefore the probability of spilling would be lower. Thus, while moderate-sized flows could occur more frequently during construction, very high flows are likely to be less frequent (Valley Water 2022c ~~2022d~~).

Higher flows during storm events could cause erosion and scour that would result in the loss of some riparian vegetation along the channel. However, such habitat modifications would allow regeneration of riparian trees such as cottonwoods, willows, and sycamores, as described in Impact TERR-1c. With the dam's outlets kept wide open during Seismic Retrofit construction, the frequency and magnitude of flows through the dam will more closely resemble natural fluvial conditions that help to maintain riparian vegetation along natural streams. Thus, the habitat modifications resulting from inundation and scour help to rejuvenate the riparian corridor along Coyote Creek and maintain habitat heterogeneity that supports healthy riparian communities.

Deposition of nitrogen emitted by construction vehicles and equipment could impact sensitive serpentine communities, such as mixed serpentine chaparral, by facilitating the growth of nonnative plants that otherwise would be unable to compete with natives. Thus, Seismic Retrofit activities could impact serpentine communities offsite. As discussed in Impact TERR-1a, prevailing winds would mobilize most of the nitrogen emissions from Seismic Retrofit construction away from the most extensive, highest-quality serpentine communities on Coyote Ridge to the northwest. However, nitrogen emitted by construction equipment and vehicles in the reservoir and around Anderson Dam could be carried to serpentine grasslands to the southeast, on the ridge east of the valley between Anderson Reservoir and Coyote Reservoir.

Northern coastal salt marsh, which is absent from the Seismic Retrofit footprint but present in tidal habitats along lower Coyote Creek/Coyote Slough that could be impacted by increased frequency and magnitude flows and sediment mobilized during Seismic Retrofit construction, is also considered a sensitive community by CDFW. Northern coastal salt marsh could be impacted as described in Impact TERR-1j above, with inundation by high flow events and sediment deposition, and possibly increases in the magnitude of freshwater inputs during individual storm events, resulting in minor, temporary adverse effects. However, northern coastal salt marsh is well-adapted to flooding, inundation, and natural variability in freshwater inputs, and as described previously, deposition of sediment mobilized from Anderson Reservoir during Seismic Retrofit construction would provide a net benefit to northern coastal salt marsh by contributing to the establishment of vegetated marshes in breached ponds such as the Island Ponds and Pond A6 and helping existing marsh to be maintained in the face of sea level rise.

Conservation Measures Construction

Sensitive communities within the Conservation Measures Project Area (aside from aquatic and wetland communities addressed in Impact TERR-3 below) include mixed riparian woodland and forest, willow riparian forest and scrub, and coast live oak forest and woodland. These communities would be impacted by construction and implementation of the Ogier Ponds and Coyote Percolation Dam Conservation Measures in the same manner described above for Seismic Retrofit construction. **Table 3.5-12** indicates the acreage of each sensitive natural community in the Conservation Measures Project Area, thus representing the maximum extent of each community that could be directly impacted by (i.e., lost to) construction of Conservation Measures.

Table 3.5-12. Direct Impacts on Sensitive Natural Communities from Construction of Ogier Ponds and Phase 2 Coyote Percolation Dam Conservation Measures

Community			
	Impact (ac)		
	Ogier Ponds CM Area (acres)*	Phase 2 Coyote Percolation Dam CM Area (acres)*	Conservation Measures Total (acres)**
Mixed Riparian Woodland and Forest	4.95	0.20	5.15 ~~7.28~~
Willow Riparian Forest and Scrub	14.35	0	14.35
Coast Live Oak Forest and Woodland	0.7	0	0.7

* *In accordance* with VHP conventions, the area (acreage) of all streams is included in mixed riparian woodland and forest, and acreages are reported to the nearest 0.1 acres except for wetland and riparian land cover types (and except where the acreage is very low, as for coast live oak forest and woodland).

*** The "Total" column summarizes the total acreages within the Ogier Ponds* CM and Coyote Percolation Dam CM Areas. Additional impacts may result from Conservation Measures such as sediment augmentation, as discussed in the text. ~~though the locations and extents of such impact areas are not yet known~~

Key: CM = Conservation Measures

The Sediment Augmentation Program would periodically place sediment downstream of Anderson Dam within the upper portion of the CWMZ and monitor the rate and volume of sediment transport relative to flows. At a minimum, the Sediment Augmentation Program would include the placement of at least 500 cy of sediment within the Live Oak Restoration Reach. Annual sediment deposition and transport monitoring and long term habitat assessment monitoring would be conducted as a part of this CM, and sediment in this reach or the Ogier Ponds CM Restoration Reach will be augmented as necessary. The Ogier Ponds CM will impact 19.3 acres of mixed riparian woodland and forest and willow riparian forest and scrub. However, that Conservation Measure will also include the restoration of riparian habitats. Valley Water predicts that approximately 39.5 acres of riparian habitat, between ordinary high water (i.e., the edge of the realigned creek channel) and the top of bank on either side of the realigned channel, will be restored as part of the Ogier Ponds CM. ~~In addition, riparian habitat will be restored by the North Channel Extension CM.~~ Although there will be a temporal loss of riparian habitat during construction of this ~~these~~ Conservation Measures and maturation of the restored riparian habitat, there will be a net increase in riparian habitat acreage as a result of the~~se~~ Conservation Measures.

Maintenance of the North Channel Reach would include maintaining the constructed wetland bench, maintaining design flow capacity through the North Channel, and replacing restoration plantings, as needed. Maintenance of the Live Oak Restoration Reach habitat would continue to occur to assure continuing fisheries benefits created by the implementation during FOCP of restoration work in that reach. The extent of impacts to sensitive natural communities that would result from maintenance of the North Channel Reach and Live Oak Restoration Reach would depend on the extent of degradation that occurs during ADSRP construction. All impacts resulting from such maintenance would be beneficial, as the purpose of such impacts would be ameliorating any degradation to the habitat enhancements constructed by the FOCP. Because the locations and extent of maintenance activities cannot be known at this time, it is assumed that impacts could occur anywhere within the North Channel Reach and Live Oak Restoration Reach area shown on **Figure 3.5-6**. Conservatively, Valley Water has assumed that up to 10 percent of each type of sensitive natural community within the North Channel Reach and Live Oak Restoration Reach could be impacted by maintenance performed during the ADSRP. **Table 3.5-13** provides the maximum acreage and linear footage (for stream impacts) of each type of sensitive natural community that may be impacted by activities to maintain habitat restored within North Channel Reach and Live Oak Restoration Reach.

Table 3.5-13. Maximum Direct Impacts to Sensitive Natural Communities from Maintenance of the North Channel Reach and Live Oak Restoration Reach

Land Cover Type	Maximum Potential Impact (acres)	Impact (linear feet)[1]
Perennial Stream	0.51	325
Intermittent Stream	0.10	75
Coastal and Valley Freshwater Marsh	0.01	50
Willow Riparian Forest and Scrub	0.02	330

Mixed Riparian Forest and Woodland	0.56	400
Total	**1.20**	**400**

[1] The full linear footage of each land cover type occurring along drainages is provided, even where stream and riparian land covers occur along the same stream segment. However, the total linear footage does not double-count such areas of overlap among land cover types along a drainage.

In addition, implementation of Conservation Measures could impact serpentine communities, including high-quality serpentine communities on Coyote Ridge, by contributing to the cumulative effects of nitrogen deposition on serpentine habitats supporting these species. These impacts would occur as described in *Conservation Measures Impacts Analysis* in Impact TERR-1a for special-status plants.

Conservation measures include release of imported water via the CDL and Cross Valley Pipeline Extension, which would help maintain groundwater levels and thus the riparian habitats along Coyote Creek and in North Coyote Valley. Payment of VHP impact fees would directly contribute to the conservation of all the described sensitive natural communities impacted by the Project, as the VHP's conservation program includes preservation and management targets for all these communities. As discussed for Impact TERR-1j, Project Conservation Measures would not impact northern coastal salt marsh.

Construction Monitoring

During Seismic Retrofit construction, Valley Water would monitor groundwater levels and continue to perform monitoring per the Dryback Monitoring Plan. Results of this monitoring would be used by Valley Water to determine whether creek flows need to be augmented to avoid adverse dryback effects on water-dependent habitats, including riparian land cover types. If early signs of dryback are observed during monitoring, Valley Water would determine whether adaptive management of imported water releases during the construction and reservoir drawdown period could be used to reduce impacts (i.e., increasing release rates of imported water). Valley Water would compensate for any impacts on these habitats that are detected by dryback monitoring that cannot be reduced or reversed through imported water releases, and that can be attributed to reduced creek flow due to Seismic Retrofit construction by paying VHP fees for the impacts detected. Thus, no substantial adverse effects of reductions in creek flow on riparian habitat would occur.

During Seismic Retrofit construction, Valley Water would monitor sedimentation of, and water quality within, Coyote Creek downstream from the dam following the Sediment Monitoring Plan (Horizon Water and Environment 2021). This monitoring would determine whether construction activities are resulting in substantial turbidity impacts; see the *Water Quality* section of this EIR for more detail. However, as noted in the discussion of Seismic Retrofit construction impacts above, increased flows and associated erosion, sediment mobilization, and scour would have a net benefit on riparian plant communities.

Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Adaptive Management

Analysis of the effects of post-construction FAHCE operations on sensitive plant communities was performed relative to the Pre-FERC Order Baseline (2017 conditions) and WEAP-modeled Future Baseline (2035 conditions). As described previously in the general discussion of Project impacts on terrestrial biological resources, flows under the FAHCE rule curves will be generally similar to, ~~those under 2017 conditions~~ but possibly slightly lower than the Pre-FERC Order Baseline Conditions, while FAHCE flows are likely to be slightly higher than under the WEAP-modeled Future Baseline. In general, FAHCE flows may entail slightly lower flow in winter and summer, due to retention of water in the reservoir for spring pulse flows, than either the Pre-FERC Order Baseline or Future Baseline, punctuated by the spring pulse flows described above. However, the effects of such changes may differ in different parts of Coyote Creek, as described previously. No substantial impacts, either adverse or beneficial, of FAHCE flows on riparian plant communities would occur, as even spring pulse flows are not expected to be high enough to result in erosion or scour of riparian vegetation. FAHCE flows will not impact oak-dominated or serpentine plant communities, which are not located in areas that would be affected at all by these flows. Changes in creek temperature as a result of post-construction operations would not impact sensitive plant communities. As discussed for Impact TERR-1j, post-construction operations would not impact northern coastal salt marsh.

Post-construction operations of the Ogier Ponds CM will sustain riparian habitat along the realigned segment of Coyote Creek, though operation of the Coyote Percolation Dam CM or other Conservation Measures will not result in substantial impacts on sensitive habitats.

Maintenance of the North Channel Reach and Live Oak Restoration Reach to assure continuing fisheries benefits created by the implementation during FOCP could potentially impact riparian habitats as described in the Conservation Measures Construction section above.

Following completion of Seismic Retrofit activities, Anderson Reservoir would be allowed to refill to its maximum design capacity. If water levels in the reservoir result in more frequent inundation of plant populations or higher soil moisture levels, the risk of *Phytophthora* infection and disease may become greater than exists under current conditions (Phytosphere Research 2018).

Maintenance of facilities at Anderson Dam would occur in areas that were impacted by Seismic Retrofit construction, and such maintenance would not occur in any additional areas occupied by sensitive natural communities. Maintenance of Conservation Measures could impact riparian habitat via trampling during maintenance access and via vegetation management, though the extent of vegetation that would be subject to pruning or removal would be limited. Seismic Retrofit and Conservation Measures maintenance activities could impact sensitive communities by mobilizing *Phytophthora*, and maintenance equipment and vehicles could contribute to cumulative impacts on serpentine communities through their nitrogen emissions. Maintenance of the Seismic Retrofit would occur as part of the DMP and would employ the AMMs implemented by the DMP to avoid and minimize impacts on sensitive biological resources such as sensitive communities. However, the AMMs employed by the DMP do not include measures to minimize the introduction or spread of *Phytophthora*.

Adaptive management activities consist primarily of monitoring and potential adaptive management actions. During field monitoring, monitoring personnel or equipment could trample vegetation or spread *Phytophthora* in sensitive communities. Impacts of adaptive management actions would likely be similar to those resulting from Conservation Measures and post-construction flows. In addition, as described in **Table 2-1** *Project Components*, implementation of a Geomorphic Flows Plan would occur as part of future adaptive management under the Project and FAHCE AMP and would require additional CEQA review and regulatory approvals. In general, the geomorphic flows would include infrequent high flows sufficient to scour sediment, erode banks, scour vegetation, and result in channel migration in localized areas, which would maintain and increase both aquatic and riparian habitat complexity, reduce non-native invasive species, and increase benthic macroinvertebrate production. Although geomorphic flows may scour some riparian vegetation, they would also provide suitable substrate to allow for the germination of cottonwoods, willows, and other riparian plants, thus allowing the development of multi-aged stands of riparian habitat.

Significance Conclusion Summary

Implementation of Valley Water BMPs and compliance with applicable VHP conditions would reduce impacts on riparian habitats and other sensitive natural communities. BMPs applicable to this impact are identified in **Table 3.5-6**. VHP conditions applicable to this impact are provided in **Table 3.5-7**, and VHP-related AMMs are provided in **Table 3.5-8**.

Implementation of BMP AQ-1 will reduce the potential for construction activities to mobilize dust onto sensitive communities outside the Project footprint, thus reducing the effects of dust and the potential for *Phytophthora* to be mobilized to sensitive communities within that dust. BMPs BI-8 and WQ-9 will avoid competition between invasive plants and native plants by requiring local plant species in revegetation. BMPs ~~HM-7,~~ HM-8, HM-9, HM-10, WQ-2, WQ-3, WQ-6, WQ-15, and WQ-16 will minimize the potential for hazardous materials and other pollutants to impact sensitive communities, and HM-12 would reduce the potential for fire to affect such communities. BMPs BI-3, BI-9, WQ-1, WQ-4, WQ-5, and WQ-11 will involve removing temporary fill, restoring channel bottoms, establishing appropriate staging and stockpiling areas and construction access areas, and keeping the work site clean, thus helping to minimize impacts on sensitive communities and avoid the spread of *Phytophthora* and weeds. BMP BI-4 will minimize impacts of pesticides on nontarget species such as native plants.

Implementation of VHP Conditions 4 and 5 would reduce the potential for and magnitude of impacts on sensitive communities through numerous AMMs summarized in **Table 3.5-8**; these AMMs include limiting the footprint of activities, reducing the potential for pollutants to impact plants and habitats, avoiding the encouragement of invasive plants, and avoiding erosion and sediment impacts on sensitive communities. VHP Condition 7 would entail minimizing ground disturbance and vegetation removal, stabilizing soil to avoid erosion and sedimentation, and revegetating with native plants or other appropriate plants. Conditions 13, 19, and 20 specifically address serpentine communities by requiring surveys to determine where serpentine-associated plants occur, avoidance and minimization of covered species where feasible, and plant salvage when impacts are unavoidable (at the discretion of the SCVHA).

Ongoing maintenance of the North Channel Reach, Live Oak Restoration Reach, and Ogier Ponds CM would occur as part of the SMP and would employ BMPs and mitigation measures required by the SMP to avoid and minimize impacts on sensitive biological resources, such as riparian habitats. Maintenance of Anderson Dam facilities would occur as part of the DMP and would employ the BMPs and mitigation measures implemented by the DMP to avoid and minimize impacts on sensitive biological resources such as riparian and other sensitive habitats. DMP BMPs BI-10 and BI-11 minimize impacts to vegetation, and **DMP Mitigation Measure Vegetation-6** requires restoration of vegetation that may have been lost due to dryback following dewatering. DMP **Mitigation Measure Vegetation-1** requires periodic botanical surveys, which would identify the locations of special-status plants (which are likely in serpentine communities), thus facilitating their avoidance when maintenance activities are performed (although as noted above, it is unlikely that new plant occurrences will occur within the Seismic Retrofit's impact areas). DMP BMPs BI-10 and BI-11 minimize impacts to vegetation. BMP BI-12 entails avoidance of sensitive natural communities such as serpentine communities. BMP BI-13 requires use of local ecotypes of native plants and appropriate erosion control seed mixes to avoid impacts from invasive plant species. **DMP Mitigation Measure Wildlife-1** and BMP WQ-12 require implementation of a flow bypass system for activities that would interrupt flow downstream from the dam. The DMP also includes a number of BMPs to protect water quality, maintain clean work sites, reduce erosion thus reducing the potential for impacts on riparian habitats; these include BMPs WQ-4, WQ-5, WQ-7, WQ-10, WQ-14, and WQ-18. However, the DMP mitigation measures do not include measures to minimize the potential for introduction or spread of *Phytophthora*, and therefore, there is some potential for *Phytophthora* to be mobilized by maintenance activities at Anderson Dam, potentially leading to infection of adjacent sensitive natural communities outside the Seismic Retrofit Area.

The Project will result in permanent impacts on a total of 20.79 ~~25.77~~ acres of mixed riparian woodland and forest and willow riparian forest and scrub, including 1.29 ~~4.14~~ acres from Seismic Retrofit construction and 19.50 ~~21.63~~ acres from Conservation Measures construction. However, approximately 39.5 acres of riparian habitat will be restored as part of the Ogier Ponds CM. Therefore, the Project will result in a net increase in the acreage of riparian woodland, forest, and scrub habitat. This net increase will help to compensate for the temporal loss of riparian functions and services that will occur between the time the existing riparian habitat is impacted and restored riparian habitat is planted and matures. In addition, the restored riparian habitat will have higher ecological functions and services than much of the impacted riparian habitat. For example, much of the impacted riparian habitat at Ogier Ponds consists of narrow stringers of riparian trees along the edges of Ponds 1 and 2, or riparian habitat around Pond 5 that is not in-line with Coyote Creek. In contrast, the riparian habitat that will be restored by the Ogier Ponds CM will include a broad, diverse corridor of riparian habitat that is immediately adjacent to the realigned creek channel and that therefore both benefits the channel (providing shade, woody debris, and organic material to the creek) and receives benefits from the channel (e.g., in the form of insects that hatch in the creek and are then fed on by terrestrial riparian animals). Therefore, the restoration of riparian habitat along the realigned creek channel at Ogier Ponds~~, coupled with riparian restoration at the North Channel Extension,~~ will compensate for Project impacts on riparian habitats.

The Project will permanently impact a total of 15 acres of coast live oak woodland and forest, 11.2 acres of foothill pine-oak woodland, and 2.5 acres of mixed serpentine chaparral, mostly from Seismic Retrofit construction. These land cover types would not be created or restored by the Project (e.g., as part of the Conservation Measures). However, VHP fees to be paid by Valley Water for the Project include specialty fees for mixed riparian woodland and forest, willow riparian forest and scrub, and mixed serpentine chaparral, in addition to general land cover fees. The Project's impact fees would contribute directly to the conservation of sensitive natural communities, including not only these riparian and serpentine communities, but also the coast live oak woodland and forest, and foothill pine-oak woodland, land cover types that will be impacted by the Project. Thus, with VHP compliance, impacts of VHP-covered activities on these sensitive natural communities would be **less than significant**.

Maintenance of the North Channel Reach and Live Oak Restoration Reach during and following Seismic Retrofit construction would impact up to 0.58 acre of mixed riparian forest and woodland and willow riparian forest and scrub. The net effects of this maintenance would be

<u>beneficial, occurring as needed to assure continuing fisheries benefits created by the implementation during FOCP of restoration work in those reaches.</u>

Three Project activities that are not VHP-covered could impact sensitive natural communities:

- The additional year of Anderson Reservoir dewatering could result in adverse dryback effects on riparian habitat along Coyote Creek downstream from Anderson Dam and in North Coyote Valley. However, creek flow augmentation, groundwater monitoring, and dryback monitoring (with additional flow augmentation, and payment of VHP impact fees for impacted wetland and riparian habitat, as necessary) would avoid significant impacts on riparian habitats related to dryback effects. Dust mobilization onto serpentine communities could also occur during this additional year of dewatering, but for reasons discussed in Impact TERR-1a, those impacts would be minimal.
- Differences in dam releases between those covered by the VHP and those that may occur during Project construction, although the Project will adhere to the VHP-covered release requirements when draining Anderson Reservoir for dewatering each year, at the start of the construction season (i.e., around April 15), wet-season flows through Anderson Dam may be much higher than those discussed in the VHP, as Valley Water needs to avoid having Anderson Reservoir fill during Project construction. At their maximum, such flows could be as high as 6,000 cfs, which represents the maximum capacity of all dam outlets that will be present. However, a 6,000-cfs flow during Seismic Retrofit construction has a very low probability of occurring, as it would represent a 200-year event (with a 0.5 percent likelihood of occurring in any given year). The VHP did not explicitly discuss the possibility that flows may exceed those in VHP **Table 2-4** during the construction period, outside of actual dewatering events. Therefore, the impacts of such flows on terrestrial biological resources may not be covered by the VHP.

  As discussed above, higher flows during construction-period storm events could cause erosion and scour that would result in the loss of some riparian vegetation along the Coyote Creek channel. However, such habitat modifications would allow regeneration of riparian trees such as cottonwoods, willows, and sycamores, as described in Impact TERR-1c. Thus, the habitat modifications resulting from higher flows help to rejuvenate the riparian corridor along Coyote Creek and maintain habitat heterogeneity that supports healthy riparian communities, a beneficial impact.
- High flows and sediment mobilized during Seismic Retrofit construction could impact northern coastal salt marsh in tidal areas far downstream from Anderson Dam. The net effect of the Project on this sensitive natural community would be beneficial.

In addition, because riparian habitats are regulated by CDFW under Section 1602 of the Fish and Game Code, and some riparian habitats are also regulated by the RWQCB under the Porter-Cologne Act, Valley Water would obtain all necessary permits from these agencies for impacts to riparian habitats and would comply with permit conditions. Implementation of Valley Water BMPs and DMP mitigation measures and BMPs, as well as compliance with the VHP, would assure that impacts on riparian habitats and other sensitive natural communities would not be substantial and therefore would be less than significant.

However, the DMP mitigation measures do not include measures to minimize the potential for introduction or spread of *Phytophthora*, and no other AMMs or BMPs provide *Phytophthora* minimization measures pertaining to Conservation Measures facilities. Therefore, there is some potential for *Phytophthora* to be mobilized by operations and maintenance activities at Anderson Dam and in the Conservation Measures locations. This could potentially lead to infection of sensitive communities. Implementation of **Mitigation Measure TERR-1a(2)** will reduce Project impacts on sensitive communities to **less-than-significant** levels by implementing AMMs during post-construction maintenance at Anderson Dam and Conservation Measures facilities to reduce the potential for introduction or spread of *Phytophthora*, thereby preventing substantial adverse effects.

Mitigation Measures

TERR-1a(2) Implementation of Avoidance and Minimization Measures during Post-Construction Maintenance at Anderson Dam and Conservation Measures Facilities to Reduce the Potential for Introduction or Spread of Phytophthora

Impact TERR-3: A substantial adverse effect on State or federally protected wetlands through direct removal, filling, hydrological interruption, or other means **(Less than Significant with Mitigation)**

Seismic Retrofit Construction

The Seismic Retrofit Area supports five land cover types—reservoir, pond, perennial stream, intermittent stream, and coastal and valley freshwater marsh—that are regulated by the USACE and SWRCB as jurisdictional waters of the U.S. and waters of the State, respectively, and by CDFW as a part its regulation of alterations in the bed and bank of rivers, creeks and streams, and related fish and wildlife resources. In addition, the SWRCB and CDFW may regulate impacts to mixed riparian woodland and forest, impacts to which are also addressed in Impact TERR-2. While each agency's jurisdiction with respect to these land cover types varies depending on the statute authorizing regulation, the jurisdiction of USACE, CDFW and the SWRCB over surface water features and land cover types overlaps substantially. **Table 3.5-14** ~~**Table 3.5-13**~~ indicates the acreage (and linear footage for applicable land cover types ~~stream impacts~~) of each type of jurisdictional wetlands or other waters of the U.S. or State in the Seismic Retrofit Area, thus representing the maximum extent of each type of jurisdictional habitat type that could be directly impacted by Seismic Retrofit construction.

Table 3.5-14 Table ~~3.5-13~~. Direct Impacts on Potential Jurisdictional Waters (Waters of the U.S., Waters of the State, and CDFW Jurisdictional Waters) from Seismic Retrofit Construction

Land Cover Type	Impact (acres) by Jurisdiction[1]			Impact (linear feet) by Jurisdiction[4]		
	Waters of the U.S.	Waters of the State	CDFW	Waters of the U.S.	Waters of the State	CDFW
Reservoir[2]	357.6	357.6	357.6	43,454 ~~---~~	43,454 ~~---~~	43,454 ~~---~~
Pond	0.19	0.19	0.19	---	---	---
Perennial Stream[3]	0.05 ~~0.73~~	0.05 ~~0.73~~	0.05 ~~0.73~~	120 ~~1,082~~	120 ~~1,082~~	120 ~~1,082~~
Intermittent Stream	0.88 ~~1.02~~	0.88 ~~1.02~~	0.88 ~~1.02~~	668 ~~864~~	668 ~~864~~	668 ~~864~~
Coastal and Valley Freshwater Marsh	0.51 ~~0.52~~	0.51 ~~0.52~~	0.51 ~~0.52~~	613 ~~---~~	613 ~~---~~	613 ~~---~~
Mixed Riparian Woodland and Forest	---	1.29 ~~4.14~~	1.29 ~~4.14~~	---	1,378 ~~---~~	1,378 ~~---~~
Total	**359.23 ~~360.06~~**	**360.52 ~~364.20~~**	**360.52 ~~364.20~~**	**44,855 ~~1,946~~**	**46,233 ~~1,946~~**	**46,233 ~~1,946~~**

Notes:

[1] In accordance with VHP conventions, acreages are reported to the nearest 0.1 acres for the reservoir land cover type and the nearest 0.01 acres for wetland and riparian land cover types.

[2] A total of 357.6 acres of reservoir are present within the currently proposed Seismic Retrofit construction footprint, but some portion of an additional 849.2 acres within the reservoir may also be indirectly impacted by construction activities.

[3] Perennial stream impact does not include approximately 1.3 ~~1.98~~ acres and 1,338 ~~1,674~~ linear feet of perennial stream that will have been impacted by the FOCP but that may also be present prior to the start of, and may therefore be impacted by, Seismic Retrofit construction.

[4] The linear footage of impacts represents the same impact areas as the impact acreage, just with a different metric.

Key: CDFW = California Department of Fish and Wildlife

Since 2012, Anderson Reservoir has been maintained in restricted condition due to DSOD storge elevation safety restrictions. In the fall of 2020, the reservoir was drawn down in compliance with a 2020 FERC order, and the reservoir must be maintained at the deadpool elevation until Seismic Retrofit construction is completed. These restrictions complicated the determination of the Ordinary High Water Mark (OHWM) for the reservoir because under the Existing Conditions Baseline, reservoir levels are lower than they were between 2012 and 2020, and much lower than they were prior to 2012, when the reservoir was operating without elevation restrictions. Per discussions with the USACE regarding the limits of waters of the U.S. in the reservoir during the drawdown, the reservoir land cover type was mapped in all areas below the elevation of the reservoir's rim, which is 627.9 feet, equivalent to the spillway elevation. Thus, for purposes of assessing impacts of the Project on federally and State-protected wetlands and waters, it was assumed that the entire reservoir, below elev. 627.9 feet, represents waters of the U.S., waters of the State, and CDFW jurisdictional waters.

Seismic Retrofit construction activities would result in the placement of fill, and related hydrological interruption, alteration of bed and bank, degradation of water quality, and other direct impacts on the acreages and linear footage of wetlands (coastal and valley freshwater marsh), non-wetland other waters (perennial stream, intermittent stream, pond, and reservoir), and mixed riparian woodland and forest as indicated in **Table 3.5-14** ~~**Table 3.5-13**~~. Seismic Retrofit impacts to wetlands will result entirely from lining the unlined portion of the spillway. Impacts to mixed riparian woodland and forest, perennial stream, and intermittent stream will result primarily from Project activities within the unlined spillway area and portions of the North Channel and South Channel of Coyote Creek that are not included in the North Channel Reach or Live Oak Restoration Reach ~~just downstream from Anderson Dam~~. Impacts to the reservoir will result from a variety of activities within the reservoir, including primarily discharges of fill for reconstruction and reinforcement of the base of the dam (which would result in a larger dam base), stabilization of the dam embankment and reservoir rim, construction of a coffer dam, and placement of spoils excavated from the dam within in-reservoir disposal areas. These types of Seismic Retrofit construction activities will impact areas within the 357.6 acres of reservoir comprising the Seismic Retrofit construction footprint. Other impacts that may result from the placement of fill for Seismic Retrofit construction, such as sedimentation and turbidity in the reservoir and Coyote Creek, and inundation of terrestrial species and their habitats upon refilling the reservoir to an unrestricted elevation, could potentially occur in other portions of the 1,206.8-acre reservoir.

Although impacts to all the jurisdictional land cover types within the Seismic Retrofit Area are considered permanent per VHP conventions, the majority of impacts unrelated to permanent placements of fill would occur only during the approximately 7-year period of Seismic Retrofit construction. These shorter-term impacts would result from drawdown of the reservoir, fill for reinforcement of the dam (in portions of the reservoir that would then be refilled with water); outlet channel construction; temporary access needed for construction of the Project; staging for activities and improvements to be constructed within jurisdictional waters; trampling of wetland vegetation; vegetation removal; and soil compaction from access and equipment, sedimentation and turbidity, and inundation following construction. Following construction, most of these impacted areas would be restored or recover to pre-Project conditions. After restoration or recovery, the long-term net loss of water and wetland habitats from Seismic Retrofit construction – including areas that were previously impacted by FOCP activities but remain as regulated habitats following completion of the FOCP – is limited to 3.0 acres ~~for~~ of reservoir, 0.51 ~~0.52~~ acre ~~for~~ of wetlands, ~~4.14~~ 0.25 acre of mixed riparian forest and woodland ~~acres for woody riparian habitats~~, and 0.55 ~~0.19~~ acre ~~for other waters (i.e.,~~ of pond and stream habitats~~)~~ (see **Table 3.5-16** ~~**Table 3.5-15**~~).

Given the drawn-down condition of Anderson Reservoir for implementation of FOCP, limited areas of temporary vegetated wetlands have formed outside the Project Area in the existing condition along the main creek channels in the upper ends of the reservoir, and at seeps, below the reservoir's OHWM. The Existing Conditions Baseline (i.e., post-FOCP) extent of these wetlands cannot be estimated accurately, as these vegetated wetlands disappear when inundated (as occurred for much of the reservoir bed during December 2022 and January 2023 storms) and regrow under drier conditions, so the extent of these wetlands upon completion of the FOCP will depend on rainfall and inundation over the next year or two. Following completion of dam reconstruction, these vegetated wetland areas would be inundated as the reservoir is refilled. Because water levels in the reservoir would not be higher at completion of the Project than they were prior to the lowering of the reservoir levels starting in 2012, no vegetated wetlands that were present under historical (pre-DSOD-restriction) conditions will be inundated when the reservoir refills. Rather, the reservoir will refill to its historical extent, and wetlands can be expected to re-establish at the post-construction, unrestricted reservoir water elevation.

During Seismic Retrofit construction, Anderson Reservoir would be largely dewatered not just to deadpool, but beginning in Year 2, to a lower elevation, so less water would be available during construction Years 2 to 7 than was available for release into Coyote Creek under Existing Conditions Baseline conditions (i.e., existing conditions as modified by the FOCP construction). Valley Water would use a combination of bypassed inflow into Anderson Reservoir and imported water released through the CDL (and, when necessary, chillers for CDL water) and Cross Valley Pipeline Extension to help maintain adequate water in Coyote Creek for fish (in the CWMZ) and groundwater recharge throughout the creek. In this way, Valley Water intends to maintain adequate creek flow to avoid substantial degradation of sensitive stream, riparian and pond habitats due to inadequate water availability related to ongoing construction of the Project. As a result, groundwater levels along Coyote Creek or in North Coyote Valley, such as groundwater supporting the seasonal wetlands in Laguna Seca, are not predicted to drop substantially as a result of operations during construction. Modeling performed by Valley Water predicted that there would be a reduction in groundwater recharge and storage during Seismic Retrofit construction relative to Pre-FERC Order baseline (when ~~interim seismic~~ restrictions limited reservoir capacity to 51,200 AF); however, barring extreme drought conditions that do not have a substantial probability of occurring during the construction phase, groundwater storage is still predicted to be above Valley Water’s 2021 Groundwater Management Plan storage target (Valley Water 2023a). Nevertheless, in the event that reduced creek flow combined with extreme drought conditions were to occur, the combination would cause a drop in groundwater levels, aquatic, wetland, and riparian habitats could suffer reduced health.

During Seismic Retrofit construction, the reservoir’s outlets would be left open during the wet season to minimize the amount of water that accumulates in the reservoir bed. Existing Conditions Baseline conditions for Seismic Retrofit construction when the Stage 1 Diversion is in place, dam outlets will allow for wet weather releases from the dam of up to 2,500 cfs. When the Stage 2 Diversion is in place, dam outlets will allow for wet weather releases from the dam of up to 6,000 cfs, although such releases have a very low probability of occurring. The magnitude of flow, and frequency of flows of a certain magnitude, will depend on rainfall amounts during individual runoff events and Coyote Reservoir releases. Valley Water (<u>2022c</u> ~~2022d~~) predicts higher flows approximately 2,500 cfs at the 2-, 5-, and 10-year return intervals during construction. At their maximum, such wet weather reservoir outflows could be as high as 6,000 cfs, which represents the maximum capacity of all dam outlets that will be present. However, a 6,000-cfs flow during Seismic Retrofit construction has a very low probability of occurring, as it would represent a 200-year event (with a 0.5 percent likelihood of occurring in any given year). The higher the flow, the lower the probability and frequency of that flow occurring in any given year, so that very high flows, greater than the 10-year or 20-year events, are unlikely during the project construction period, though possible. Also, the probability of very high flows (i.e., flows greater than the 10-year/20-year magnitude/frequency) would be lower during Years 2 to 7 of ADSRP construction than under Existing Conditions Baseline conditions because less water would be detained in the reservoir during construction, and therefore the probability of maximum release would be lower. Thus, while moderate-sized flows could occur more frequently during Years 2 to 7 of Seismic Retrofit construction because outlet capacity increases in Year 2, very high flows are likely to be less frequent (Valley Water 2022c ~~2022d~~).

Higher flows released during storm events in Construction Years 2 to7 could impact mixed riparian woodland and forest, as described in Impact TERR-2. Higher flows during storm events could cause erosion and scour that would result in the loss of some riparian vegetation and instream wetlands along the channel. However, such habitat modifications would allow regeneration of riparian trees such as cottonwoods, willows, and sycamores, as described in Impact TERR-1c, as well as expanded areas for colonization by wetland vegetation at the edges of channels. With the dam’s outlets kept open during Seismic Retrofit Project construction, the frequency and magnitude of flows will more closely resemble natural fluvial conditions that maintain riparian vegetation along natural streams. Thus, the habitat modifications resulting from inundation and scour help to rejuvenate the riparian corridor along Coyote Creek and maintain habitat heterogeneity that supports healthy riparian and wetland communities.

Conservation Measures Construction

The Conservation Measures Project Area supports reservoir, pond, perennial stream, seasonal wetland, and coastal and valley freshwater marsh land cover types that are regulated by the USACE and State as jurisdictional waters of the U.S. and waters of the State, respectively, and as part of the regulation of stream and lake beds and banks by CDFW. In addition, the State may regulate impacts to some mixed riparian woodland and forest and willow riparian forest and scrub as well; impacts to these two riparian land cover types were also addressed in Impact TERR-2. These land cover types would be impacted by the Ogier Ponds CM and the Phase 2 Coyote Percolation Dam CM~~, and Conservation Measures along the North Channel Extension, and other areas where instream habitat improvements such as sediment augmentation in the Live Oak Restoration Reach and other areas of the FCWMZ would occur~~. **Table 3.5-15** ~~**Table 3.5-14**~~ indicates the acreage (and linear footage for stream impacts) of each type of jurisdictional wetlands or other waters of the U.S. or State expected to be impacted by ~~in the Conservation Measures Project Area, thus representing the maximum extent of each type that could be directly impacted by (i.e., lost to)~~ construction of the Ogier Ponds CM and Phase 2 Coyote Percolation Dam CM ~~Conservation Measures~~.

Table 3.5-15~~.~~ ~~Table 3.5-14~~ Direct Impacts on Potential Jurisdictional Waters (Waters of the U.S., Waters of the State, and CDFW Jurisdictional Waters) from ~~Conservation Measures~~ Construction of the Ogier Ponds and Phase 2 Coyote Percolation Pond Conservation Measures

**In accordance with VHP conventions, acreages are reported to the nearest 0.1 acres except for wetland and riparian land cover types.*

*** The full linear footage of each land cover type occurring along drainages is provided, even where stream and riparian land covers occur along the same stream segment. However, the total linear footage does not double-count such areas of overlap among land cover types along a drainage. The linear footage of impacts represents the same impact areas as the impact acreage, just with a different metric.*

~~*Notes:*~~

~~*This table summarizes the total acreages within the Ogier Ponds CM, Coyote Percolation Dam CM, and North Channel Extension Areas. Additional impacts to jurisdictional habitats may result from Conservation Measures such as sediment augmentation, though the locations and extents of such impact areas are not yet known.*~~

Key: CDFW = California Department of Fish and Wildlife

Conservation Measures construction would result in placement of fill and alteration of bed and bank to restore Coyote Creek stream banks through the Ogier Ponds area and ~~place up to 500 cy of gravel and course sediment every 5 years for replenishment of spawning habitat within the FCWMZ,~~ install a roughened ramp to assist fish passage as part of the Phase 2 Coyote Percolation Dam CM. As discussed in Impact TERR-2 above, each gravel augmentation event implemented as part of the Sediment Augmentation Program would involve placement of up to 500 cy of sediment, potentially impacting up to 1,200 square feet (0.03 acre) of riparian habitat and up to 100 ft of linear perennial stream channel. Conservation Measures construction would also result in ~~and widen and lengthen the North Channel Extension ;~~ construction-phase localized hydrological interruption from dewatering; construction-phase degradation of water quality due to releases of sediment or other construction related pollutants during restoration project work; and other potential direct impacts on jurisdictional habitat types. Jurisdictional habitat types that would be affected are wetlands (coastal and valley freshwater marsh and seasonal wetland), non-wetland other waters (perennial stream, reservoir, and pond), and mixed riparian woodland and forest and willow riparian forest and scrub. ~~Because the entire footprints of these Conservation Measures could be impacted during construction, impact acreages for jurisdictional habitat types could total those reported in **Table 3.5-14**.~~ Although impacts to all the jurisdictional land cover types within these Conservation Measures areas are considered permanent per VHP conventions, portions of these impact areas (e.g., ~~intermittent~~

~~stream in the North Channel Extension Area and~~ perennial stream in the Coyote Percolation Dam CM Area) will be impacted only during construction.

All Conservation Measures will be comprised primarily of natural habitat types upon completion and attainment of habitat related success criteria. Upon implementation, the Ogier Ponds CM ~~and North Channel Extension~~ will result in the creation and restoration of jurisdictional habitats. Valley Water predicts that approximately 12.5 acres of perennial stream riverine aquatic and wetland habitat below the OHWM, as well as 39.5 acres of riparian habitat between the OHWM and the top of bank on either side of the realigned channel, will be restored, and 4.5-acres of freshwater marsh wetland will be created in the borrow site near Pond 3 as part of the Ogier Ponds CM. ~~In addition, 0.8 acres of intermittent stream, 0.2 acres of perennial stream and 1.4 acres of riparian habitat adjacent to the OHWM will be restored by the North Channel Extension.~~ Although there will be a temporal loss of riparian habitat during construction of the~~se~~ Conservation Measures, ~~for which VHP permanent impact fees will be paid,~~ implementation of the restoration and creation of habitat types by the CMs and related maturation of the restored riparian and wetland habitat types associated with the CMs will result in a net increase in stream, wetland, and riparian habitat acreage within Coyote Creek, in addition to providing fish habitat improvements and benefits as discussed in the ~~Aquatic Biological Resources~~ Biological Resources—Fisheries Resources section.

Collectively, the Ogier Ponds CM and Phase 2 Coyote Percolation Dam CM~~, and North Channel Extension~~ are intended to improve habitat quality and ecological functions and services, not only for steelhead but also for riparian and wetland animals. Net impacts of Conservation Measures on riparian habitat were discussed in detail in Impact TERR-2 above. Of the approximately 24.67 ~~24.96~~ acres of impacts to aquatic (reservoir, pond, and riverine) and wetland (coastal and valley freshwater marsh and seasonal wetland) land cover types resulting from the Ogier Ponds CM and Phase 2 Coyote Percolation Dam CM ~~these Conservation Measures,~~ 17.2 acres consist of reservoir at Ogier Ponds. At Ogier Ponds, the reservoir land cover type is used by low to moderate numbers of relatively few species of waterbirds, such as ducks, double-crested cormorants, and grebes. Conversion of reservoir to riverine and wetland habitats within the realigned Coyote Creek channel, with fringes of marsh and extensive riparian habitats, will continue to provide habitat for these waterbirds and wetland-associated animals while also increasing the number and diversity of terrestrial animals that will use those areas formerly occupied by reservoir, thus resulting in an increase in ecological functions and services in those areas. This increase in functions and services within 12.5 acres of restored riverine aquatic and 4.5 acres of wetland habitat will offset, and likely improve upon the functions and services currently provided by the 7.47 ~~7.76~~ acres of stream, pond, marsh, and seasonal wetland habitats as well as the 17.2 acres of reservoir that will be impacted by the Ogier Ponds CM and Phase 2 Coyote Percolation Dam CM ~~project~~. Conservation Measures also include release of imported water via the CDL and Cross Valley Pipeline Extension, which would help maintain groundwater levels and thus the aquatic, wetland, and riparian habitats along Coyote Creek and in North Coyote Valley (such as Laguna Seca).

Valley Water's payment of VHP permanent impact fees would include specialty fees for all wetland, other waters, and riparian land cover impacts (except for reservoir impacts) as required by the VHP. Payment of VHP impact fees would directly contribute to the conservation of intermittent and perennial streams, ponds, coastal and valley freshwater marsh, seasonal wetlands, mixed riparian woodland and forest, and willow riparian forest and scrub, as the VHP's conservation program includes preservation and management targets for all of these land cover types. SCVHA and Valley Water will track wetlands mitigation created and conserved with VHP fees in comparison to wetlands impacts to demonstrate the additional offset of wetlands impacts (i.e., from the combination of the Project's Conservation Measures and payment of VHP impact fees). Implementation of the Conservation Measures will provide additional habitat enhancements beyond what is required to offset project impacts. Specifically, the Ogier Ponds CM will include wetland features that would further enhance wetlands functions and values along Coyote Creek.

Table 3.5-16 summarizes the net impacts, in terms of loss and gain, of the Project resulting from construction of the Seismic Retrofit component, the Ogier Ponds CM, and the Phase 2 Coyote Percolation Dam CM.

Table 3.5-16.~~Table 3.5-15~~ Net Impact on Potential Jurisdictional Waters (Waters of the U.S., Waters of the State, and CDFW Jurisdictional Waters) from Construction of the Seismic Retrofit, Ogier Ponds CM, and Phase 2 Coyote Percolation Dam CM ~~and Conservation Measure Construction~~

	Permanent Loss (ac)[1]				Creation/Restoration (ac)	Net Loss/Gain

Notes:

[1] This is expected loss from permanent impacts/fill, and does not necessarily match the VHP definition of "permanent"

[2] Based on the OHWM along the realigned creek, these acres could include riverine and wetland habitat, though most is likely to be non-wetland (riverine).

[3] The total riparian habitat lost as a result of seismic retrofit construction does not include the loss of 0.70 acre that was previously impacted by the FOCP, and for which permanent VHP impact fees were paid.

<u>Implementation of the Sediment Augmentation Program and maintenance of the North Channel Reach and Live Oak Restoration Reach would not result in a net change (i.e., loss or gain) of the area of waters of the U.S., waters of the State, or CDFW-jurisdictional habitats, as these CMs do not replace jurisdictional waters with non-jurisdictional habitats, and they are therefore not included in **Table 3.5-16**. As indicated in **Table 3.5-13**, maintenance of habitat restored within the North Channel Reach and Live Oak Restoration Reach could impact up to 1.20 acres and 400 linear feet of stream, marsh, and riparian habitat. However, such maintenance activities would be beneficial, maintaining the habitat enhancements implemented in these areas by the FOCP.</u>

Construction Monitoring

During Seismic Retrofit construction, Valley Water would monitor groundwater levels and continue to perform monitoring per the Dryback Monitoring Plan. Results of this monitoring would be used by Valley Water to determine whether creek flows need to be augmented to avoid adverse dryback effects on water-dependent habitats, including aquatic, wetland, and riparian land cover types. Valley Water would compensate for any impacts on these habitats that are detected by dryback monitoring and that can be attributed to reduced creek flow due to Seismic Retrofit construction by paying VHP fees for the impacts detected. Thus, no substantial adverse effects of reductions in creek flow on aquatic, wetland, and riparian habitat would occur.

Other construction monitoring measures that would monitor impacts on jurisdictional wetlands and other waters include construction-phase monitoring of water quality, suspended sediment, and sediment deposition in Coyote Creek. These monitoring activities would protect jurisdictional water from adverse effects and would not significantly adversely impact those resources.

Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Adaptive Management

Post-construction, Anderson Reservoir would be allowed to refill to the unrestricted elevation, thus increasing substantially the volume and acreage of waters that are actually held within the reservoir, relative to Pre-FERC Order Baseline and Existing Conditions Baseline (post-FOCP) conditions, both of which are characterized by reservoir storage restrictions that are eliminated upon completion of the Project. However, refilling of the reservoir would simply restore the historical conditions, with respect to type and extent of jurisdictional waters present within the reservoir that were present prior to DSOD restrictions in 2012 and drawdown in 2020 in response to the FERC order.

Analysis of the effects of post-construction FAHCE operations on jurisdictional waters was performed relative to the Pre-FERC Order Baseline and WEAP-modeled Future Baseline. As described previously in the general discussion of Project impacts on terrestrial biological resources, flows under the FAHCE rule curves will be generally similar to those under Pre-FERC Order conditions but possibly slightly lower, while FAHCE flows are likely to be slightly higher than under the Future Baseline. In general, FAHCE flows may entail slightly lower flow in winter and summer, due to retention of water in the reservoir for spring pulse flows, than either the Pre-FERC Order Baseline or Future Baseline, punctuated by the spring pulse flows described above. However, the effects of such changes may differ in different parts of Coyote Creek, as described previously. No substantial impacts, either adverse or beneficial, of FAHCE flows on jurisdictional habitats would occur, as even spring pulse flows are not expected to be high enough to result in erosion or scour of riparian vegetation. Further, post-construction operations would allow for releases that maintain groundwater recharge historical levels and would not adversely affect groundwater-dependent wetland and riparian habitat. As a result, post-construction operations would not adversely affect jurisdictional wetlands, other waters, and riparian habitats.

Post-construction operations of the Ogier Ponds CM will sustain jurisdictional habitats along the realigned segment of Coyote Creek. Operation of the Phase 2 Coyote Percolation Dam CM or other Conservation Measures will not result in substantial impacts on jurisdictional habitats, though maintenance of all Conservation Measures could result in minor, localized, and infrequent impacts to jurisdictional habitats similar in character to, but less severe than those associated with construction.Maintenance of facilities at Anderson Dam would occur in areas that were impacted by Seismic Retrofit construction, and such maintenance would not occur in any additional areas occupied by jurisdictional habitats. Maintenance of the habitat restoration and fish barrier remediation Conservation Measures could impact wetlands, other waters, and riparian habitat, though the extent of impacts would be limited. Seismic Retrofit and Conservation Measures maintenance activities could impact riparian habitats by mobilizing *Phytophthora*, as described in Impact TERR-2. Maintenance of the Seismic Retrofit and Phase 2 Coyote Creek Percolation Dam CM would occur as part of the DMP and would employ the AMMs implemented by the DMP to avoid and minimize impacts on sensitive biological resources, such as sensitive communities. Maintenance of the North Channel Reach ~~Extension~~, Live Oak Restoration Reach, and Ogier Ponds CM would occur as part of the SMP and would employ the AMMS implemented by the SMP to avoid and minimize impacts on sensitive biological resources, such as sensitive communities. However, the AMMs employed by the DMP and SMP do not include measures to minimize the introduction or spread of *Phytophthora*.

Adaptive management activities consist primarily of monitoring and determination by the AMT to adjust post-construction flow operations for Anderson Dam or CMs or revise the design for certain non-flow, fish passage barrier remediation or habit restoration CMs. While field monitoring would not significantly adversely affect jurisdictional resources, monitoring personnel or equipment could trample vegetation or spread *Phytophthora* in riparian habitats. Impacts of adaptive management actions to adjust post-construction flow operations or fish passage barrier and habitat restoration CMs would likely be similar in character to, but less substantial than those resulting from construction of Conservation Measures and implementation of post-construction flows. In addition, as described in **Table 2-1** *Project Components*, implementation of a Geomorphic Flows Plan would occur as part of future adaptive management under the Project and FAHCE AMP, and would require additional CEQA review and regulatory approvals. In general, the geomorphic flows would include infrequent high flows sufficient to scour sediment, erode banks, scour vegetation, and result in channel migration in localized areas, which would maintain and increase both aquatic and riparian habitat complexity, reduce non-native invasive species, and increase benthic macroinvertebrate production. Geomorphic flows would thus help to enhance and maintain diverse, high-quality instream and riparian habitat.

Significance Conclusion Summary

Project Construction

Implementation of Valley Water BMPs, payment of VHP permanent impact specialty habitat fees, and implementation of applicable VHP conditions would offset impacts on federally and State-regulated wetlands, other waters, and riparian habitats. BMPs applicable to this impact are identified in **Table 3.5-6**. VHP conditions applicable to this impact are provided in **Table 3.5-7**, and VHP-related AMMs are provided in **Table 3.5-8**.

Implementation of BMP AQ-1 will reduce the potential for construction activities to mobilize dust onto jurisdictional habitats outside the Project footprint, thus reducing the effects of dust and the potential for *Phytophthora* to be mobilized to jurisdictional habitats within that dust. BMPs BI-8 and WQ-9 will avoid competition between invasive plants and native plants by requiring local plant species in revegetation. BMPs ~~HM-7,~~ HM-8, HM-9, HM-10, WQ-2, WQ-3, WQ-6, WQ-15, and WQ-16 will minimize the potential for hazardous materials and other pollutants to impact wetlands, other waters, and riparian habitats, and HM-12 would reduce the potential for fire to affect such communities. BMPs BI-3, BI-9, WQ-1, WQ-4, WQ-5, and WQ-11 will involve removing temporary fill, restoring channel bottoms, establishing appropriate staging and stockpiling areas and construction access areas, and keeping the work site clean, thus helping to minimize impacts on jurisdictional habitats and avoid the spread of *Phytophthora* and weeds. BMP BI-4 will minimize impacts of pesticides on nontarget species such as native plants.

Implementation of VHP Conditions 4 and 5 would further reduce the potential for and magnitude of impacts on jurisdictional habitats through numerous AMMs summarized in **Table 3.5-8**; these AMMs include limiting the footprint of activities, reducing the potential for pollutants to impact plants and habitats, avoiding the encouragement of invasive plants, and avoiding erosion and sediment impacts on jurisdictional habitats. VHP Condition 7 would entail minimizing ground disturbance and vegetation removal, stabilizing soil to avoid erosion and sedimentation, and revegetating with native plants or other appropriate plants.

Valley Water will pay VHP impact fees for wetlands, other waters, and riparian habitats, which include specialty fees for these important land cover types, as required by the VHP. The Interagency Review Team, including USACE, CDFW, and the RWQCB, have approved the VHP as an In Lieu Fee Program for impacts to water of the United State and waters of the state. The USACE Compensatory Mitigation Rule, which has been incorporated into Subpart J of the Watershed Definition of the Procedures for Discharges of Dredged or Fill Material to Waters of the State (April 2, 2019), require provision of compensatory mitigation in accordance with an approved In Lieu Fee Program where available as a first priority. If insufficient mitigation is available through an approved In Lieu Fee Program, applicants may provide compensatory mitigation that is consistent with such program as permittee-responsible mitigation. The VHP serves as both an approved In Lieu Fee Program, and as a landscape and watershed-level framework for compensatory mitigation for impacts to jurisdictional waters, including waters of the U.S., waters of the State, and CDFW-jurisdictional habitats. The VHP specifically sets biological goals for land cover types that constitute jurisdictional resources. Accordingly, in accordance with state and federal regulations that prioritize mitigation via approved In Lieu Fee Programs, Valley Water will pay permanent impact fees for all land cover types associated with jurisdictional waters that are impacted during construction of the Project, including the Seismic

Retrofit components and (as required by the VHP) the CMs, notwithstanding habitat restoration and creation that is planned as a part of the Project.

In addition to the payment of VHP permanent impact fees as required by the VHP, the implementation of the Conservation Measures more than offsets the Project's net impacts on such habitats (see **Table 3.5-16** ~~**Table 3.15-15**~~). Ecological services and functions associated with the habitat created by the CMs are expected to exceed those provided in the Existing and Pre-FERC Order conditions. Therefore, the Project will result in a net increase in the acreage of riparian, wetland, woodland, forest, and scrub habitat. This net increase, together with the payment of VHP permanent impact fees, will account for the temporal loss of riparian functions and services that will occur between the time the existing riparian habitat is impacted and restored riparian habitat is planted and matures. In addition, the restored riparian and wetlands habitat will have higher ecological functions and services than much of the impacted riparian habitat. For example, much of the impacted riparian habitat at Ogier Ponds consists of narrow stringers of riparian trees along the edges of Ponds 1 and 2, or riparian habitat around Pond 5 that is not in line with Coyote Creek. In contrast, the riparian habitat that will be restored by the Ogier Ponds CM will include a broad, diverse corridor of riparian habitat that is immediately adjacent to the realigned creek channel and that therefore both benefits the channel (providing shade, woody debris, and organic material to the creek) and receives benefits from the channel (e.g., in the form of insects that hatch in the creek and are then fed on by terrestrial riparian animals).

Maintenance of the North Channel Reach and Live Oak Restoration Reach during and following Seismic Retrofit construction would impact up to 0.61 acre of stream and 0.01 acre of coastal and valley freshwater marsh. The net effects of this maintenance would be beneficial, occurring as needed to assure continuing fisheries benefits created by the implementation during FOCP of restoration work in those reaches.

Implementation of Valley Water BMPs, payment of VHP permanent impact specialty habitat fees, and implementation of applicable VHP conditions would offset impacts to a level that is less than significant. BMPs applicable to this impact are identified in **Table 3.5-6**. VHP conditions applicable to this impact are provided in **Table 3.5-7**. VHP-related AMMs are provided in **Table 3.5-8,** and anticipated habitat restoration and creation acreages and linear feet are set forth in **Table 3.5-16** ~~**Table 3.15-15**~~**.**

Because waters of the U.S. are regulated by the USACE under Section 404 of the CWA, waters of the State are regulated by the State under Section 401 of the CWA and under the Porter-Cologne Act, and stream and riparian habitats are regulated by CDFW under Section 1602 of the Fish and Game Code, Valley Water would also obtain all necessary permits from these agencies related to impacts on wetlands and other waters and would comply with permit conditions.

Project Maintenance

Maintenance of Anderson Dam and Phase 2 Coyote Percolation Dam CM facilities would occur as part of the DMP and would employ the BMPs and mitigation measures required by the DMP to avoid and minimize impacts on sensitive biological resources, such as jurisdictional habitats. DMP BMPs BI-10 and BI-11 minimize impacts to vegetation, and **DMP Mitigation Measure Vegetation-6** requires restoration of vegetation that may have been lost due to dryback following dewatering. DMP BMPs BI-10 and BI-11 minimize impacts to vegetation. BMP BI-13 requires use of local ecotypes of native plants and appropriate erosion control seed mixes to avoid impacts from invasive plant species. **DMP Mitigation Measure Wildlife-1** and BMP WQ-12 require implementation of a flow bypass system for activities that would interrupt flow downstream from the dam. The DMP also includes BMPs to protect water quality, maintain clean work sites, reduce erosion thus reducing the potential for impacts on jurisdictional habitats; these include BMPs WQ-4, WQ-5, WQ-7, WQ-10, WQ-14, and WQ-18. However, the DMP mitigation measures do not include measures to minimize the potential for introduction or spread of *Phytophthora*, and therefore, there is some potential for *Phytophthora* to be mobilized by operations and maintenance activities at Anderson Dam, potentially leading to infection of adjacent jurisdictional habitats outside the Seismic Retrofit Area.

Ongoing maintenance ~~Maintenance~~ of the North Channel ~~Extension~~ Reach, Live Oak Restoration Reach, and Ogier Ponds CM would occur as part of the SMP and would employ BMPs and mitigation measures required by the SMP to avoid and minimize impacts on sensitive biological resources, such as jurisdictional habitats. SMP BMPs GEN-1 and GEN-2 limit instream work to periods that limit impacts to jurisdictional habitats; GEN-9 requires identification and avoidance of sensitive natural vegetation communities, which includes wetland and riparian habitats. GEN-16-GEN-27 and GEN-32 would protect jurisdictional habitats for indirect impacts, such as hazardous material spills, during maintenance. GEN-29-GEN-31 require dust control and vehicle maintenance practices that would prevent the introduction and spread of invasive weeds and *Phytophthora*. SMP vegetation management BMPs would also protect jurisdictional habitats during maintenance work from direct impacts, invasive weeds, and fire risks, and post-project restoration BMPs would restore any temporarily impacted jurisdictional habitats.

Implementation of Valley Water BMPs and DMP and SMP mitigation measures and BMPs, and compliance with the VHP, would reduce ongoing impacts associated with maintenance of Anderson Dam and the CMs on federally and State-regulated wetlands and other waters. However, the SMP and DMP mitigation measures do not include measures to minimize the potential for introduction or spread of *Phytophthora*. Therefore, there is some potential for *Phytophthora* to be mobilized by maintenance activities at Anderson Dam and in the Conservation Measures locations. This could potentially lead to degradation of the quality of jurisdictional wetland and riparian habitats due to the adverse effects of *Phytophthora*. Implementation of **Mitigation Measure TERR-1a(2)** will reduce Project impacts on jurisdictional habitats to **less than significant** levels by implementing AMMs during post-construction maintenance at Anderson Dam and Conservation Measures facilities to reduce the potential for introduction or spread of *Phytophthora*, thereby preventing substantial adverse effects.

Project Operation and Adaptive Management

Project flow operations are not expected to affect the quality or extent of federally or State-regulated wetlands, riparian habitat or non-wetland waters, and impacts would be less than significant.

Monitoring activities associated with long-term adaptive management are not expected to adversely affect and would benefit the quality or extent of federally or State-regulated wetlands, riparian habitat or non-wetland waters, and impacts would be less than significant. While adaptive management actions to adjust or modify flow operations or fish barrier remediation and habitat restoration CMs cannot be predicted with certainty at this time, it is expected that adaptive management modifications would be like those associated with post-construction operations and maintenance of Seismic Retrofit components and CMs. Accordingly, those impacts would be less than significant for the same reasons that post-construction operations and Project maintenance activities are concluded to be less than significant.

Mitigation Measures

TERR-1a(2) Implementation of Avoidance and Minimization Measures during Post-Construction Maintenance at Anderson Dam and Conservation Measures Facilities to Reduce the Potential for Introduction or Spread of Phytophthora

Impact TERR-4: Interfere substantially with the movement of any native resident or migratory species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites **(Significant and Unavoidable)**

Seismic Retrofit Construction

Seismic retrofit construction would have both adverse and beneficial effects, all temporary, on wildlife movement. Removal of vegetation providing cover or other resources for animals; construction of fencing to prevent human access into the construction area; grading and excavation; and the disturbance associated with activity by construction vehicles, equipment, and personnel would discourage some animals that would otherwise have moved through the Seismic Retrofit Area from doing so, causing them to avoid this area during construction. Although most construction activities would occur between 6:00 a.m. and ~~5:00~~ 6:00 p.m., tunneling required for the outlet works and concrete construction activities could occur 24 hours/day, 6 days/week. Because some construction may occur at night, when many mammals, reptiles, and amphibians are active, use of the Seismic Retrofit Area by nocturnal animals would be diminished during construction due to disturbance, resulting in a reduction in habitat connectivity through the site during construction.

Because US 101 impedes wildlife movement across Coyote Valley, culverts, road undercrossings, and Coyote Creek crossings are important locations for dispersing animals to be able to move under the highway. The US 101 crossing over Coyote Creek 1.5 miles west of the Seismic Retrofit Area is particularly important for habitat connectivity and wildlife movement because of its large size; many animals are reluctant to move through long, narrow corridors such as culverts, so the large size of the Coyote Creek undercrossing makes it attractive to a variety of animals. Seismic Retrofit activities are far enough from that undercrossing that construction would not result in a substantial reduction in use of that undercrossing by dispersing animals.

Once construction activities are complete, conditions for wildlife movement through and within the Project Area would be the same as Existing Conditions Baseline (post-FOCP) conditions, and there would be no long-term impacts on wildlife dispersal through the Seismic Retrofit Area. Furthermore, sufficient habitat and cover for dispersing animals would remain on the downstream side of the dam, along with sufficient cover within riprap on the upstream side of the dam, following Project completion so that animals would still be able to disperse across the dam even following removal of vegetation during construction.

During Seismic Retrofit construction, dry season flows in Coyote Creek downstream from Anderson Dam would be maintained via bypass flows released from Coyote Reservoir, supplemented with water released into Coyote Creek through the CDL and Cross Valley Pipeline Extension. Groundwater levels along Coyote Creek or in North Coyote Valley are not predicted to drop substantially as a result of operations during construction. Modeling performed by

Valley Water predicted that there would be a reduction in groundwater recharge and storage during Seismic Retrofit construction relative to 2015 base conditions (when ~~interim seismic~~ restrictions limited reservoir capacity to 51,200 AF); however, groundwater storage is still predicted to be above Valley Water's 2021 Groundwater Management Plan storage target (Valley Water 2023a). Nevertheless, in the event that reduced creek flow combined with drought conditions were to cause a drop in groundwater levels, aquatic, wetland, and riparian habitats providing cover and other resources for animals dispersing along the creek could suffer reduced health.

Existing Conditions Baseline conditions for Seismic Retrofit construction allow for discharges from the dam of up to 2,500 cfs. During Seismic Retrofit construction, the reservoir's outlets would be left open during the wet season to minimize the amount of water that accumulates in the reservoir bed. The magnitude of flow, and frequency of flows of a certain magnitude, will depend on rainfall amounts during individual runoff events and Coyote Reservoir releases. Valley Water (2022c ~~2022d~~) predicts higher flows at the 2-, 5-, and 10-year return intervals during construction. At their maximum, such flows could be as high as 6,000 cfs, which represents the maximum capacity of all dam outlets that will be present. However, a 6,000-cfs flow during Seismic Retrofit construction has a very low probability of occurring, as it would represent a 200-year event (with a 0.5 percent likelihood of occurring in any given year). The higher the flow, the lower the probability and frequency of that flow occurring in any given year, so that very high flows, greater than the 10-year or 20-year events, are unlikely during the project construction period, though possible. Also, the probability of very high flows (i.e., flows greater than the 10-year/20-year magnitude/frequency) would be lower during construction than under Existing Conditions Baseline conditions because water would not be detained in the reservoir during construction, and therefore the probability of spilling would be lower. Thus, while moderate-sized flows could occur more frequently during construction, very high flows are likely to be less frequent (Valley Water 2022c ~~2022d~~).

Higher flows during storm events could cause erosion and scour that would result in the loss of some riparian vegetation along the channel that could be used by dispersing animals. However, such habitat modifications and sediment brought into the creek channel by higher frequency and magnitude flows would allow regeneration of riparian trees such as cottonwoods, willows, and sycamores, as described in Impact TERR-1c. Thus, the habitat modifications resulting from higher flows help to rejuvenate the riparian corridor along Coyote Creek and maintain habitat heterogeneity that supports healthy riparian communities for wildlife dispersal. Higher flows could briefly interrupt dispersal events by animals attempting to cross Coyote Creek, though these flows would subside quickly after storm events, because Anderson Dam would not be detaining flows during construction.

Dewatering of the reservoir during Seismic Retrofit construction is likely to improve the ability of some terrestrial animals to move along and across the reservoir. Dewatering would increase the amount of terrestrial habitat and narrow the aquatic impediments to dispersal to the narrow stream channels within the reservoir bed. For some animals with lower mobility, such as reptiles and amphibians, Anderson Reservoir represents a dispersal impediment that makes it difficult for individuals to move between populations on either side of the reservoir, and such dispersal may occur more readily during Seismic Retrofit implementation. For example, the dewatered condition of the reservoir could allow fewer mobile species that do not use reservoir habitat, such as California tiger salamanders, California red-legged frogs, and small mammals, to disperse across the reservoir during the construction period, something that may not occur under normal conditions when the reservoir is filled. This dispersal may allow exchange of individuals and genetic diversity between subpopulations on either side of the reservoir, which can benefit the regional population given that the reservoir impedes such dispersal under normal conditions.

For larger, more mobile animals, such as black-tailed deer, mountain lions, and feral pigs, larger numbers of individuals are already present on both sides of the reservoir, and these larger animals can more easily disperse long distances around the reservoir under post-FOCP or even historical conditions. As a result, dewatering of the reservoir during Seismic Retrofit construction will not have a substantial effect, either adverse or beneficial, on larger mammals. For example, such dewatering will not increase the abundance of feral pigs on either side of the reservoir, as large numbers of pigs are already present and are able to easily disperse east and west across the reservoir under Existing Conditions Baseline conditions.

Numerous animals breed within and around the Seismic Retrofit Area, but with the exception of the pallid bat maternity roost in a barn along Cochrane Road, no particularly important wildlife nursery areas are present in the vicinity or would be impacted by Seismic Retrofit construction. The pallid bat roost would be impacted by construction-related disturbance as described in Impact TERR-1h.

Conservation Measures Construction

The Conservation Measures Project Area includes areas important for wildlife movement on both local and regional scales. As mentioned above, North Coyote Valley provides a critical landscape linkage for animals dispersing between the Santa Cruz Mountains and Diablo Range. To animals dispersing from one side of the valley to the other, or species for which cross-valley gene flow occurs over a period of generations, Coyote Creek and Ogier Ponds provide important habitat areas for cover, foraging areas, and nesting, roosting, or denning sites. The construction of the Ogier Ponds CM would impact habitats used by a variety of animals for dispersing along Coyote Creek, and the removal of vegetation, grading and excavation, and disturbance by construction equipment and personnel would reduce such wildlife movement during construction of that Conservation Measure. However, during construction animals would still be able to move around the construction area (e.g., between the pond complex and US 101) when moving along Coyote Creek. After completion of the creek realignment, animals would be able to move along the realigned section of Coyote Creek at least as easily as they currently do or even more easily. The restored creek channel would likely provide even higher-quality cover and habitat than is currently present. As a result, the Ogier Ponds CM will not result in a long-term impact on wildlife movement.

Other Conservation Measures, such as construction of the Coyote Percolation Dam CM, maintenance ~~Maintenance~~ of the North Channel Reach and Live Oak Restoration Reach, ~~Extension~~ and implementation of the Sediment Augmentation Program, could result in temporary disturbance of wildlife movement during construction/implementation. However, those impacts would be minor, localized, and of short duration.

Construction phase water releases from the reservoir, CDL and Cross Valley Pipeline Extension would help to maintain aquatic, wetland, and riparian habitats along the Coyote Creek channel on which dispersing animals depend for cover and other resources. These water releases will thereby minimize adverse effects of dryback on wildlife movement for animals using the aquatic, wetland, and riparian habitats along Coyote Creek. Payment of VHP impact fees as required by the VHP would directly contribute to the preservation and enhancement of wildlife movement. The VHP's conservation program includes targeted acquisition, enhancement, and management of lands that are important to wildlife movement throughout the region, so Valley Water's payment of impact fees will benefit wildlife movement.

Numerous animals breed within and around the Conservation Measures Project Area, but no particularly important wildlife nursery areas are present near, or would be impacted by, proposed Conservation Measures.

Construction Monitoring

During Seismic Retrofit construction, Valley Water would monitor groundwater levels and continue to perform monitoring per the Dryback Monitoring Plan. Results of this monitoring would be used by Valley Water to determine whether creek flows need to be augmented to avoid adverse dryback effects on water-dependent habitats, including aquatic, wetland, and riparian land cover types. Valley Water would compensate for any impacts on these habitats that are detected by dryback monitoring and that can be attributed to reduced creek flow due to Seismic Retrofit construction by paying VHP fees for the impacts detected. This monitoring would therefore reduce the potential for dryback impacts to affect cover and the use of Coyote Creek habitats by dispersing animals.

Construction monitoring for water quality, fisheries monitoring and fish rescue, aquatic species rescue and relocation, invasive species monitoring and control, and other monitoring efforts could result in the disturbance of dispersing animals due to the noise and activity of monitoring personnel and equipment. Such impacts would be localized and infrequent, and they would not substantially impede wildlife movement.

No particularly important wildlife nursery areas would be impacted by proposed construction monitoring. For example, construction monitoring would not occur close enough to the pallid bat roost in the Cochrane Road barn that monitoring would disturb bats using the roost.

Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Adaptive Management

Post-construction operations would allow Anderson Reservoir to refill. This would reduce the ability of smaller, less mobile animals to move across the bed of the dewatered or drawn-down reservoir, though it would simply be restoring conditions faced by dispersing animals prior to the 2012 DSOD restrictions. Post-construction operations would allow for releases that maintain sufficient water in Coyote Creek downstream to continue to support aquatic, wetland, and riparian habitats, thus facilitating continued use of the Coyote Creek corridor for wildlife movement.

Analysis of the effects of post-construction FAHCE operations on wildlife movement was performed relative to the Pre-FERC Order Baseline (2017 conditions) and WEAP-modeled Future Baseline (2035 conditions). FAHCE flows are not expected to result in substantial impacts, either adverse or beneficial, on wildlife movement. As described previously in the general discussion of Project impacts on terrestrial biological resources, flows under the FAHCE rule curves will be generally similar to~~, those under 2017 conditions~~ but possibly slightly lower than the Pre-FERC Order Baseline Conditions, while FAHCE flows are likely to be slightly higher than under the WEAP-modeled Future Baseline. In general, FAHCE flows may entail slightly lower flow in winter and summer, due to retention of water in the reservoir for spring pulse flows, than either the Pre-FERC Order Baseline or Future Baseline, punctuated by the spring pulse flows described above. There is some potential for spring pulse releases to inundate vegetative cover along Coyote Creek that may be used by dispersing animals. However, such flows will be relatively brief (and not particularly high, from the perspective of inundation of habitat for dispersing animals). Changes in creek temperature because of post-construction operations would not have a substantial effect on wildlife movement.

Maintenance of Anderson Dam facilities and Conservation Measures, including maintenance of the North Channel and Live Oak Restoration Reach, could disturb dispersing animals, either due to physical disturbance of vegetation or due to disturbance from noise or activity of maintenance personnel and equipment. Such maintenance activities would be localized and infrequent and would therefore not substantially impede wildlife movement. Adaptive management activities consist primarily of monitoring and potential adaptive management actions. There is some potential for personnel or equipment involved in field monitoring activities to disturb dispersing animals, though such impacts would be localized and brief. Impacts of adaptive management actions would likely be similar to those resulting from Conservation Measures and post-construction flows.

Post-construction operations, maintenance, and monitoring would have little to no impact on the pallid bat roost in the Cochrane Road barn, as such activities would not occur very close to that barn.

Significance Conclusion Summary

Implementation of Valley Water BMPs and compliance with applicable VHP conditions would reduce impacts on wildlife movement and nursery sites. BMPs applicable to this impact are identified in Table 3.5-6. VHP conditions applicable to this impact are provided in **Table 3.5-7**, and VHP-related AMMs are provided in **Table 3.5-8**.

Valley Water would implement BMPs HM-8, HM-9, HM-10, WQ-11, WQ-15, and WQ-16 to minimize the potential for hazardous materials and other pollutants to impact dispersing animals, as well as pallid bats and their food sources, and HM-12 would reduce the potential for fire to affect these species and their habitats. BMP WQ-4 limits impacts from staging and stockpiling activities. BMPs BI-8 and WQ-9 will reduce impacts on these species' habitats by avoiding competition between invasive plants and native vegetation. BMP BI-11 will minimize the attraction of predators that may prey on dispersing animals and pallid bats. BMP BI-4 will minimize impacts of pesticides on nontarget species. BMP BI-10 will avoid entrapment of animals in pipes, hoses, pits, or trenches during construction.

Implementation of VHP Conditions 3, 4, 5, 7, and 11 would reduce the potential for and magnitude of impacts on dispersing animals, pallid bats, their habitats, and their prey by minimizing impacts on stream, wetland, and pond habitats. These conditions require implementation of numerous AMMs summarized in **Table 3.5-8**; these AMMs include limiting the footprint of activities, reducing the potential for pollutants to impact these species and their habitats, avoiding the encouragement of invasive plants, and avoiding erosion and sediment impacts on this species' habitats. VHP Condition 7 would entail minimizing ground disturbance and vegetation removal, stabilizing soil to avoid erosion and sedimentation, and revegetating with native plants or other appropriate plants.

Maintenance of Anderson Dam facilities would occur as part of the DMP and would employ the BMPs and mitigation measures implemented by the DMP to avoid and minimize impacts on sensitive biological resources, such as pallid bats, dispersing animals, and their habitats. DMP BMPs BI-10 and BI-11 minimize impacts to vegetation, and **DMP Mitigation Measure Vegetation-6** requires restoration of vegetation that may have been lost due to dryback following dewatering. BMP BI-13 requires use of local ecotypes of native plants and appropriate erosion control seed mixes, which would avoid impacts to animals' habitat from invasive plant species. **DMP Mitigation Measure Wildlife-4** prohibits the use of herbicides that are not excluded from the applicable injunction.

Although Project activities may temporarily affect wildlife movement during construction, animals would still be able to move through the Project Area during construction, and no long-term impacts on wildlife movement would result. Post-construction operations, maintenance, and adaptive management would not substantially affect wildlife movement. Thus, the Project would not interfere substantially with wildlife movement and impacts on wildlife movement would therefore be **less than significant**. The VHP conservation program would assemble a Reserve System with landscape linkages and wildlife movement in mind to protect and, where possible, enhance movement pathways on a regional scale. Valley Water's impact fees would thus contribute to the maintenance and improvement of opportunities for movement and genetic exchange of native plants and animals within and between natural communities inside and connecting to areas outside of the VHP Reserve System.

The only regionally important wildlife nursery site in the Project vicinity is the Cochrane Road barn pallid bat maternity roost addressed in Impact TERR-1h. Implementation of **Mitigation Measures TERR-1h(1)** through **TERR-1h(4)** will reduce impacts on that roost, and thus impacts on wildlife nursery sites would be **less than significant**. If pallid bat numbers are documented to be at least 75 percent of baseline numbers (as described in Impact TERR-1h) during any survey within 3 years following completion of construction, then the impact would be **less than significant**. Nevertheless, the Project could cause the number of females at this site to drop below 75 percent of existing numbers, and a substantial proportion of the regional population would have been affected. No other mitigation would be available to reduce this impact, as **Mitigation Measures TERR-1h(1)** to **TERR-1h(4)** represent the only available measures to reduce this impact, and because pallid bats are selective about their choice of roost sites, it is unknown whether pallid bats would use any alternative roost site provided under **Mitigation Measure TERR-1h(4)**. Therefore, this impact on the pallid bat roost, and thus on wildlife nursery sites, would be **significant and unavoidable**.

Mitigation Measures

TERR-1h(1) Avoid Disturbance of the Cochrane Road Barn Roost

TERR-1h(2) Evict Pallid Bats prior to Initiating Maternity-Season Disturbance near the Cochrane Road Barn Roost

TERR-1h(3) Minimize Impacts on Pallid Bats Roosting Outside the Cochrane Road Barn

TERR-1h(4) Provide Alternative Pallid Bat Maternity Roost Structures

Impact TERR-5: Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance (No Impact)

Seismic Retrofit Construction

As noted in the *Regulatory Setting* section above, the County, the City of San José, and the City of Morgan Hill all have tree removal regulations that protect trees of certain types and sizes and require permits before such trees are removed. The number of trees meeting the criteria for protection by those regulations was estimated for each of these three jurisdictions based on a survey of a portion of the Seismic Retrofit Area conducted in 2020 by WCA and estimates of trees in additional impact areas by H. T. Harvey & Associates in 2022 and 2023. Seismic Retrofit construction will necessitate the removal of approximately 290 trees in Morgan Hill that are large enough to meet that City's ordinance size, and approximately 40 trees in San José that meet that City's criteria for ordinance-sized trees. However, as discussed in the *Regulatory Setting* section, the City of San José tree ordinance applies only to private property, and the City of Morgan Hill tree ordinance applies only to private and City property. These ordinances by their terms therefore do not apply to the study area locations on public property where trees would be removed.

In the unincorporated county, Seismic Retrofit construction would result in the removal of approximately 270 ordinance-sized trees, particularly within coast live oak forest and woodland, foothill pine–oak woodland, and mixed riparian woodland and forest land cover types.

Valley Water is exempt from compliance with the County tree ordinance under either Government Code Sections 53091(d) and (e) (which state that County or City building and zoning ordinances do not apply to the construction of facilities for water storage or transmission), or for nonbuilding and zoning ordinances, under *Hall v. Taft* (1956) 47 Cal. 2d 177,189 (which holds that water districts are exempt from municipal police power regulation). Therefore, although the County tree ordinance by its terms would ordinarily apply to the Project, Valley Water's removal of ordinance-sized trees would not conflict with the County tree ordinance, and there would be no impact. Nevertheless, recognizing the importance of protected trees to the County and the terms of the County ordinance, Valley Water has voluntarily proposed **Mitigation Measure AES-1**, calling for the planting of replacement trees removed on County Park land.

Conservation Measures Construction

Conservation Measures such as the Ogier Ponds CM and Coyote Percolation Dam CMs~~, and the North Channel Extension improvements~~ would result in the removal of approximately 40 trees protected by County tree removal regulations. Maintenance of the North Channel Reach and Live Oak Restoration Reach would not necessitate removal of trees in conflict with the County tree ordinance. ~~Although trees within Morgan Hill would be impacted by the North Channel Extension, no~~ No trees on private property or ~~City~~ property of the cities of Morgan Hill or San Jose would be removed.

Valley Water's payment of VHP impact fees would help to offset impacts to trees and oak woodlands, as those fees would contribute to the VHP's conservation program, which includes the conservation, restoration, and management of a number of land cover types supporting trees, including oak woodlands.

Valley Water's removal of ordinance-sized trees would not conflict with the County tree ordinance, and therefore there would be no impact. Nevertheless, recognizing the importance of protected trees to the County, Valley Water has voluntarily proposed **Mitigation Measure AES-1**, calling for the planting of replacement trees removed on County Park land.

Construction Monitoring

No construction monitoring activities would result in removal of trees in conflict with the County tree ordinance.

Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Adaptive Management

Post-construction operations and maintenance of the Seismic Retrofit or the Conservation Measures, including ongoing maintenance of the North Channel Reach and Live Oak Restoration Reach, would not necessitate removal of trees in conflict with the County tree ordinance. Adaptive management activities consist primarily of monitoring and potential adaptive management actions. Monitoring would not remove ordinance-sized trees in the unincorporated county. Impacts of adaptive management actions would likely be similar to those resulting from Conservation Measures and post-construction flows.

Significance Conclusion Summary

Implementation of Valley Water BMPs and compliance with applicable VHP conditions would reduce impacts on regulated trees. BMPs applicable to this impact are identified in **Table 3.5-6**. VHP conditions applicable to this impact are provided in **Table 3.5-7**, and VHP-related AMMs are provided in **Table 3.5-8**.

Valley Water will implement BMP HM-12 to reduce the potential for fire to affect trees, and BMP WQ-9 to reduce impacts on native trees by avoiding competition with invasive plants. Implementation of VHP Conditions 4, 5, and 7 would reduce the potential for and magnitude of impacts on trees by minimizing impacts on riparian habitats. These conditions require implementation of numerous AMMs summarized in **Table 3.5-8**; these AMMs include limiting the footprint of activities, reducing the potential for pollutants to impact vegetation, avoiding the encouragement of invasive plants, and avoiding erosion and sediment impacts on vegetation. VHP Condition 7 would entail minimizing ground disturbance and vegetation removal, stabilizing soil to avoid erosion and sedimentation, and revegetating with native plants or other appropriate plants.

Maintenance of Anderson Dam facilities would occur as part of the DMP and will employ the BMPs and mitigation measures implemented by the DMP to avoid and minimize impacts on sensitive biological resources. DMP BMPs BI-10 and BI-11 minimize impacts to vegetation, and **DMP Mitigation Measure Vegetation-6** requires restoration of vegetation that may have been lost due to dryback following dewatering. BMP BI-13 requires use of local ecotypes of native plants and appropriate erosion control seed mixes. **DMP Mitigation Measure Wildlife-4** prohibits the use of herbicides that are not excluded from the applicable injunction.

Valley Water's payment of VHP impact fees would help to offset impacts to trees, as those fees would contribute to the VHP's conservation program, which includes the conservation, restoration, and management of a number of land cover types supporting trees.

Valley Water's removal of ordinance-sized trees would not conflict with the County tree ordinance, and there would be **no impact**. Nevertheless, recognizing the importance of protected trees to the County, Valley Water has voluntarily proposed **Mitigation Measure AES-1**, calling for the planting of replacement trees removed from County Park land.

Mitigation Measures

No mitigation is required.

Impact TERR-6: Conflict with the provisions of an adopted Habitat Conservation Plan/Natural Community Conservation Plan, or other approved local, regional, or State habitat conservation plan (Less than Significant)

Valley Water is a signatory on one conservation plan: the VHP, which is an HCP and NCCP for terrestrial species and related habitats. As described in *Project Description*, the VHP explicitly included the Project in its list of covered activities, and most impacts of the Project were included in the VHP's analysis of the effects of covered activities. All VHP-covered species that may be affected by the Project are discussed in this Final ~~Draft~~ EIR, including Coyote ceanothus, Mount Hamilton thistle, Santa Clara Valley dudleya, smooth lessingia, Tiburon paintbrush, Metcalf Canyon jewel-flower, most beautiful jewel-flower, Loma Prieta hoita, and fragrant fritillary (Impact TERR-1a); Bay checkerspot butterfly (Impact TERR-1b); California tiger salamander, California red-legged frog, and foothill yellow-legged frog (Impact TERR-1c); northwestern pond turtle (Impact TERR-1d); tricolored blackbird (Impact TERR-1f); and burrowing owl (Impact TERR-1g). Similarly, impacts on sensitive habitats, such as stream, wetland, riparian, and serpentine habitats, for which the VHP requires specific impact fees, are discussed in this Final ~~Draft~~ EIR. Valley Water would apply for VHP coverage for the Project and adhere to all applicable VHP Conditions during Project implementation. Therefore, the Project would not be in conflict with the VHP.

Some impacts of the Project are not covered by the VHP, because they are explicitly excluded from VHP coverage, they exceed thresholds that the VHP set for coverage, or they affect species that occur only in areas that are outside the VHP permit area. Valley Water would address those impacts outside of the context of the VHP (e.g., through its BMPs, additional mitigation measures, and Project-specific consultation with the USFWS and CDFW as necessary), and the inclusion of these non-VHP-covered impacts do not conflict with the VHP. Therefore, this impact is less than significant.

Mitigation Measures

No mitigation is required.

3.5.5 Cumulative Impacts

The geographic study area for wildlife and terrestrial resources encompasses the Coyote Creek watershed downstream of Coyote and Anderson Dams, the Upper Penitencia Creek watershed, and the areas surrounding other relevant Valley Water and non-Valley Water projects and plans in northern Santa Clara County.

This section describes the Project's contribution to cumulative impacts on wildlife and terrestrial resources, as summarized in **Table 3.5-17**.~~**Table 3.15-16**~~

Cumulative impact thresholds for wildlife and terrestrial resources are the same as the impact thresholds presented in Section 3.5.3.5, *Thresholds of Significance*, as listed below.

Table 3.5-17 ~~Table 3.15-16~~. Summary of Project Impact Contribution to Cumulative Impacts on Biological Resources – Wildlife and Terrestrial Resources

Impact	Cumulatively Significant with FOCP?	Cumulatively Significant with other projects?	Incremental Project Contribution	Applicable Project Mitigation	Cumulatively Considerable after Mitigation?
Cumulative Impact TERR-1: Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFW or USFWS	Yes	Yes	CC	TERR-1a(1-4) TERR-1c(1-2) TERR-1e TERR-1g TERR-1h(1-4) TERR-1j	Yes
Cumulative Impact TERR-2: Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by CDFW or USFWS	Yes	Yes	CC	TERR-1a(2)	No
Cumulative Impact TERR-3: Have a substantial adverse effect on State or federally protected wetlands through direct removal, filling, hydrological	Yes	Yes	CC	TERR-1a(2)	No

Impact	Cumulatively Significant with FOCP?	Cumulatively Significant with other projects?	Incremental Project Contribution	Applicable Project Mitigation	Cumulatively Considerable after Mitigation?
interruption, or other means					
Cumulative Impact TERR-4: Interfere substantially with the movement of any native resident or migratory species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites	Yes	Yes	CC	TERR-1h(1-4)	Yes
Cumulative Impact TERR-5: Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance	No	No	NI	AES-1	No
Cumulative Impact TERR-6: Conflict with the provisions of an adopted Habitat Conservation Plan/Natural Community Conservation Plan, or other approved local, regional, or State habitat conservation plan	No	No	NCC	N/A	No

Key: CC = cumulatively considerable; N/A = not applicable; NCC = not cumulatively considerable

***Cumulative Impact TERR-1: Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFW or USFWS* (Cumulatively Considerable)**

Degradation of special-status species habitats and reductions in their diversity are existing concerns in Santa Clara County. Implementation and operation of the Project would impact Coyote ceanothus, smooth lessingia, woodland woollythreads, most beautiful jewel-flower, Mt. Hamilton thistle, and San Francisco collinsia individuals; and, if present within unsurveyed areas, may impact alkali milk vetch, Point Reyes bird's beak, Metcalf Canyon jewel-flower, Santa Clara Valley dudleya, fragrant fritillary, big-scale balsamroot, and Loma Prieta hoita. Further, the movement of earth, vegetation, water (e.g., runoff), equipment, vehicles, and personnel could spread invasive plant propagules and pathogens such as *Phytophthora*, which could degrade vegetation communities and habitat for numerous special-status species. Implementation and operation of the Project entails the potential to impact special-status insects (Bay checkerspot butterfly, monarch butterfly, and Crotch's bumble bee); amphibians (California tiger salamander, California red-legged frog, and foothill yellow-legged frog); <u>north</u>western pond turtle; bald and golden eagles; nonbreeding special-status birds (Swainson's hawk, burrowing owl, and peregrine falcon); pallid bat, other special-status mammals (San Francisco dusky-footed woodrat, mountain lion, ringtail, American badger, Townsend's big-eared bat, and western red bat); and San Francisco Bay special-status species (California Ridgway's rail, California black rail, Alameda song sparrow, San Francisco common yellowthroat, northern harrier, Bryant's savannah sparrow, salt marsh harvest mouse, and salt marsh wandering shrew) individually or in aggregations (e.g., nests, host plants, roosts, overwintering sites).

Cumulative Effects of Project with the FOCP

The FOCP would involve modifications to the existing structures surrounding Anderson Dam and Reservoir which could also impact special-status plants around the reservoir, spread invasive plant propagules and pathogens such as *Phytophthora*, and disturb special-status insects, amphibians, and mammals with construction activity. In particular, FOCP construction activities are near the Cochrane Road barn and large colony of pallid bat, which could cause disruption to the existing pallid bat colony. The construction schedules for FOCP and the Project would not overlap, reducing the potential for cumulative construction-related impacts. Also, the FOCP includes avoidance and minimization measures, and a ~~Habitat Monitoring and Mitigation Plan (~~HMMP~~)~~, designed to minimize impacts special status species and habitats. The cumulative impacts with the Project and FOCP are nevertheless significant, and the Project's contribution is cumulatively considerable.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Many of the reasonably foreseeable future projects, plans, and programs identified in Section 3.0.5, *Approach to Cumulative Impacts*, when combined with impacts of the Project (as described in Section 3.5), could affect terrestrial biological resources, including identified federally or State listed, candidate, sensitive, or special-status species. Some of these future projects, such as the South Bay Salt Ponds Restoration Project, SMP, and FAHCE, would acquire and preserve, create, restore, and/or enhance conditions for some of the terrestrial biological resources that would be impacted by the Project. Also, as discussed in further detail below, the VHP is a Natural Community Conservation Plan (NCCP) and Habitat Conservation Plan (HCP) that contributes to the recovery of listed species and the preservation of natural communities regionally, thus resulting in a net benefit (considering all VHP-covered activities that both impact and benefit species and communities) to these terrestrial biological resources. Thus, some of these future projects, in combination with the VHP, help to reduce or even counteract adverse cumulative impacts. Nevertheless, because some of the future projects, plans, and programs identified in Section 3.0.5, *Approach to Cumulative Impacts*, are not covered by the VHP and do not result in a net benefit to special-status species, the cumulative impact to special-status terrestrial biological resources resulting from the Project in combination with these other probable future projects, plans, and programs within the relevant geographic area would be significant.

Although the Project would directly or indirectly impact special-status species populations or their habitat, many of these impacts would be reduced through adherence to VHP conditions. The Project is covered under the VHP, which is intended to address cumulative impacts on biological resources from foreseeable development over the next 50 years by ensuring that conservation measures adequately offset the impacts of covered activities. Projects that are covered activities under the VHP would mitigate impacts on covered species and their habitats through the VHP's Conservation Program, and implementation of the VHP itself would help to ensure the conservation of these species and their habitats in the region.

As an NCCP, the VHP fulfills the requirements for NCCPs and HCPs, contributing both to the recovery of listed species and the preservation of natural communities at the ecosystem scale. As such, the VHP goes above and beyond addressing project-specific impacts and mitigation by providing a higher level of in-perpetuity conservation of plant and animal species and their habitats at an ecosystem level. The VHP's reserve system provides comprehensive ecosystem conservation for a wide range of natural resources and benefits numerous Santa Clara County plant and animal species (special-status and otherwise) and their habitats. Thus, although permits issued under the VHP name specific species (i.e., "covered species"), which are either listed as threatened or endangered or may be listed in the future during the permit term, the VHP contributes to the conservation of entire communities of common and rare plant and wildlife species and their habitats in Santa Clara County.

Nevertheless, the cumulative impacts of the Project on special status species and their habitat when added to the impacts of other probable future projects are considered significant.

Significance Conclusion Summary

Valley Water would reduce the Project's proportion of impacts on special-status species through payment of VHP impact fees. In addition, implementation of Valley Water BMPs would reduce the potential for dust from construction activities to mobilize *Phytophthora* to special-status species and their habitat; reduce competition between invasive plants and native plants; protect sensitive communities from hazardous materials, pesticides, and other pollutants; and require restoration of staging and stockpiling areas and channel bottoms temporarily affected by construction activities. Compliance with Valley Water BMPs, Valley Water's Dam Safety Program (DMP) MMs, applicable VHP conditions and required AMMs, in addition to payment of VHP fees for covered species, would reduce impacts on special-status species, but some impacts would still be significant and cumulatively considerable pre-mitigation.

Implementation of **Mitigation Measure TERR-1a(1)** would offset impacts from Project-related nitrogen deposition on Tiburon paintbrush by performing invasive plant management in and around two ~~the~~ Tiburon paintbrush populations located on ~~Valley Water's~~ Coyote Ridge ~~property~~. **Mitigation Measure TERR-1a(2)** would reduce the potential for introduction or spread of invasive plants or pathogens, such as *Phytophthora*, thereby preventing substantial adverse effects. **Mitigation Measure TERR-1a(3)** would require Valley Water to conduct additional special-status species surveys in areas not yet surveyed according to VHP standards and protocols. **Mitigation Measure TERR-1a(4)** would compensate for impacts on San Francisco collinsia by collecting seed from San Francisco collinsia plants; storing some of the seed in an accredited seed bank; and creating one or more new populations of the species outside the Project Area. **Mitigation Measure TERR-1c(1)** would require special-status amphibian AMMs during Year 6 construction activities. **Mitigation Measure TERR-1c(2**) would require nonnative species (bullfrogs, nonnative fish, and/or nonnative turtles) management in the Upper Penitencia Creek watershed at selected Valley Water ponds. **Mitigation Measure TERR-1e** would require avoidance of nesting eagles and **Mitigation Measure TERR-1g** would require avoidance of burrowing owls during construction. **Mitigation Measure TERR-1h(1)** through **TERR-1h(4)** would require avoidance, eviction, and establishment of alternative maternity roost structures for pallid bats. **Mitigation Measure TERR-1j** would reduce predation in Don Edwards San Francisco Bay National Wildlife Refuge through contributions to the Baylands Predator Management Program and high tide refugia enhancement. Through implementation of these mitigation measures, the Project's contribution to cumulative impacts on special-status species would **not be cumulatively considerable**, except for the impact to pallid bats when considered in conjunction with the impacts caused by FOCP. Even with the implementation of mitigation measures to reduce the impacts to pallid bats, the Project's seismic retrofit construction would have a **cumulatively considerable** contribution.

Mitigation Measures

TERR-1a(1) *Invasive Plant Management at ~~Valley Water's~~ Coyote Ridge Tiburon Paintbrush Populations*

***Cumulative Impact TERR-2: Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by CDFW or USFWS* (Not Cumulatively Considerable)**

Degradation of riparian habitats and other sensitive natural communities are existing concerns in Santa Clara County, and impacts on riparian habitats are regulated by CDFW and the RWQCB. The Project area supports five sensitive land cover types/natural plant communities – mixed riparian woodland and forest, willow riparian forest and scrub, coast live oak forest and woodland, foothill pine-oak woodland, and mixed serpentine chaparral. Aquatic and wetland habitats are also considered sensitive, but they are addressed in Cumulative Impact TERR-3 (mixed riparian woodland and forest and willow riparian forest and scrub are addressed in both impact sections). The Project would adversely affect riparian habitats and other sensitive natural communities by direct disturbance and removal of vegetation and underground root structures from activities such as grading, excavation, and placement of new structures and soil stockpiles. Impacts to the seedbank as well as disruption to plant growth and reproduction and introduction of pathogens, such as *Phytophthora*, could also result from the Project.

Cumulative Effects of Project with the FOCP

Construction of the Anderson Dam tunnel will directly impact riparian habitat from the construction of the tunnel under the existing dam face, particularly the extension riparian corridor along the Coyote Creek backwater and the old northern channel of Coyote Creek at the FOCP outlet. Project activities related to the Anderson Dam tunnel construction have the potential to directly impact up to 4.07 acres of mixed riparian woodland and forest communities. The Project's construction would have a significant cumulative impact to riparian habitat and other sensitive natural communities when considered together with the FOCP, and the Project's contribution would be cumulatively considerable pre-mitigation.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Many of the reasonably foreseeable future projects, plans, and programs identified in Table 3.0-5, ~~4-2~~ when combined with impacts of the Project's seismic retrofit construction; conservation measure construction; and post-construction operations, maintenance, and adaptive management activities ~~(as described in Section 3.5),~~ could affect riparian habitats and other sensitive natural communities. As discussed for Cumulative Impact TERR-1, some of these future projects, in combination with the VHP, will create, restore, and/or enhance sensitive natural communities, helping to reduce or even counteract adverse cumulative impacts. Nevertheless, because some of the future projects, plans, and programs identified in Table 3.0-5 ~~4-2~~ are not covered by the VHP and do not result in a net benefit to sensitive natural communities, the cumulative impact to riparian habitats and sensitive natural communities resulting from the Project in combination with these other probable future projects, plans, and programs within the Project area and expanded study area would be significant and the Project's contribution is cumulatively considerable without mitigation

Significance Conclusion Summary

Although the Project would result in the loss of 20.59 ~~adversely affect 25.77~~ acres of mixed riparian woodland and forest and willow riparian forest and scrub habitats, these impacts would be reduced through the restoration of 39.5 ~~40.9~~ acres of riparian habitat throughout the Project area, implementation of Valley Water BMPs and adherence to VHP conditions. Valley Water would reduce the Project's proportion of impacts on riparian habitats and other sensitive VHP-covered species through payment of impact fees. Payment of VHP impact fees would contribute to the VHP's conservation program that benefits numerous species, habitats, and natural communities in the region. Implementation of Valley Water BMPs would reduce the potential for dust from construction activities to mobilize invasive plants and pathogens, such as *Phytophthora,* to sensitive communities; reduce competition between invasive plants and native plants; protect sensitive communities from hazardous materials, pesticides, and other pollutants; and require restoration of staging and stockpiling areas and channel bottoms temporarily affected by construction activities. Compliance with applicable VHP conditions and required AMMs, in addition to payment of VHP fees for covered species, would reduce impacts on riparian habitats and other sensitive natural communities, including serpentine communities. Implementation of **Mitigation Measure TERR-1a(2)** would reduce the potential for introduction or spread of invasive plants and pathogens, thereby preventing substantial adverse effects that would otherwise be significant and cumulatively considerable. Through implementation of these measures, as well as **Mitigation Measure TERR-1a(2)** to reduce the introduction or spread of *Phytophthora*, the Project's contribution to cumulative impacts on riparian habitats and other sensitive natural communities would be **not cumulatively considerable**.

Mitigation Measures

TERR-1a(2) *Implementation of Avoidance and Minimization Measures during Post-Construction Maintenance at Anderson Dam and Conservation Measures Facilities to Reduce the Potential for Introduction or Spread of Phytophthora*

Cumulative Impact TERR-3: Have a substantial adverse effect on State or federally protected wetlands through direct removal, filling, hydrological interruption, or other means (Not Cumulatively Considerable)

Loss of wetlands is an ongoing issue in California, including Santa Clara County, primarily due to development pressures and water quality degradation. The Project Area supports six aquatic resource land cover types – reservoir, pond, perennial stream, intermittent stream, seasonal wetland, and coastal and valley freshwater marsh – that are regulated by the USACE and SWRCB as jurisdictional waters of the U.S. and waters of the State, respectively. The Project would result in the permanent impact to 4.16 ~~4.2~~ acres of freshwater marsh from the placement of fill, hydrological interruption, alteration of bed and bank, degradation of water quality, vegetation removal or disturbance, soil compaction, and other direct impacts on wetlands (seasonal wetland and coastal and valley freshwater marsh). The Project would also result in impacts to tidal wetlands and associated species along the lower, tidal reaches of Coyote Creek from occasional high flows. These tidal habitats and species are not covered by the VHP, and the VHP's conservation program therefore does not directly benefit these tidal resources.

Cumulative Effects of Project with the FOCP

FOCP construction activities will result in the placement of fill, hydrological interruption, alteration of bed and bank, degradation of water quality, and other direct adverse effects on wetlands and other waters. Most of these effects would be temporary, resulting from temporary access needed for construction of the Project, staging for activities and improvements to be constructed within jurisdictional waters, trampling of wetland vegetation, vegetation removal, and soil compaction from access and equipment. The Project's seismic retrofit construction would have a significant impact to wetlands and other waters when considered together with the FOCP, and the Project's contribution would be cumulatively considerable pre-mitigation.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Many of the reasonably foreseeable future projects, plans, and programs identified in Table 3.0-5 ~~4-2~~, when combined with impacts of the Project (as described in Section 3.5), could affect jurisdictional waters. Projects impacting jurisdictional waters are expected to reduce their impacts as a result of conditions of permits that would be needed from the many resource agencies that regulate those waters, thus reducing those projects' impacts. Furthermore, as discussed for Cumulative Impact TERR-1, some of these future projects, in combination with the VHP, would create, restore, and/or enhance wetlands, helping to reduce or even counteract adverse cumulative impacts. Nevertheless, because some of the future projects, plans, and programs identified in **Table 3.0-5 ~~4-2~~** are not covered by the VHP and do not result in a net benefit to jurisdictional waters, the cumulative impact to jurisdictional waters resulting from the Project in combination with these other probable future projects, plans, and programs within the study area would be significant.

Significance Conclusion Summary

Although the Project would adversely affect jurisdictional waters through hydrological interruption, bed and bank alteration water quality impacts and other direct impacts as noted above, these impacts would be reduced through the creation of 4.5 acres of emergent freshwater marsh, implementation of Valley Water BMPs and adherence to VHP conditions. Valley Water would mitigate the Project's proportion of impacts on wetlands through payment of impact fees. Payment of VHP impact fees would contribute to the VHP's conservation program that benefits numerous species, habitats, and natural communities in the region. Implementation of **Mitigation Measure TERR-1a(2)** would reduce the potential for introduction or spread of *Phytophthora* that could degrade the quality of jurisdictional waters, thereby preventing substantial adverse effects that would otherwise be significant and cumulatively considerable. Through implementation of these measures, the Project's contribution to cumulative impacts on jurisdictional waters, including state-protected and federally protected wetlands, would **not be cumulatively considerable**.

Mitigation Measures

TERR-1a(2) Implementation of Avoidance and Minimization Measures during Post-Construction Maintenance at Anderson Dam and Conservation Measures Facilities to Reduce the Potential for Introduction or Spread of Phytophthora

***Cumulative Impact TERR-4: Interfere substantially with the movement of any native resident or migratory species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites* (Cumulatively Considerable)**

Because US 101 impedes wildlife movement across Coyote Valley, culverts, road undercrossings, and Coyote Creek crossings are important locations for dispersing animals to be able to move under the highway. Many animals are reluctant to move through long, narrow corridors such as culverts, so the large size of the Coyote Creek undercrossing between the Seismic Retrofit area and the Ogier Ponds makes it attractive to a variety of animals. Construction of the Project has the potential to affect the movement patterns or nursery sites of the following wildlife species: special-status insects (Bay checkerspot butterfly, monarch butterfly, and Crotch's bumble bee); amphibians (California tiger salamander, California red-legged frog, and foothill yellow-legged frog); northwestern pond turtle; bald and golden eagles; nonbreeding special-status birds (Swainson's hawk, burrowing owl, and peregrine falcon); pallid bat, other special-status mammals (San Francisco dusky-footed woodrat, mountain lion, ringtail, American badger, Townsend's big-eared bat, and western red bat); and San Francisco Bay special-status species (California Ridgway's rail, California black rail, Alameda song sparrow, San Francisco common yellowthroat, northern harrier, Bryant's savannah sparrow, salt marsh harvest mouse, and salt marsh wandering shrew).

Although Project activities may temporarily affect wildlife movement during construction, BMPS and VHP conditions would reduce these impacts, animals would still be able to move through the Project Area during construction, and no long-term impacts on wildlife movement would result. Post-construction operations, maintenance, and adaptive management would not substantially affect wildlife movement. Thus, the Project would not interfere substantially with wildlife movement and impacts on wildlife movement would therefore be less than significant with the exception of pallid bat impacts. The VHP conservation program would assemble a Reserve System with landscape linkages and wildlife movement in mind to protect and, where possible, enhance movement pathways on a regional scale. Valley Water's impact fees would thus contribute to the maintenance and improvement of opportunities for movement and genetic exchange of native plants and animals within and between natural communities inside and connecting to areas outside of the VHP Reserve System.

The Project's pallid bat impacts would be significant and unavoidable, even with implementation of **Mitigation Measures TERR-1h(1)** through **TERR-1h(4)**.

Cumulative Effects of Project with the FOCP

A maternity colony of the pallid bat is located just outside of the Seismic Retrofit area, in the Cochrane Road barn, since 1998. This colony likely represents the largest and most stable colony of the species known in Santa Clara County. Noise from the traffic and general construction associated with the FOCP represent a localized increase above its respective baseline, but implementation of the FOCP would not directly impact the barn itself. Given the intensity of Project construction activities, which would include some nighttime work, and the extent to which foraging habitat on Anderson Dam would be disturbed during construction, it is possible that pallid bats may abandon the roost within the barn while construction is ongoing. Unless high-quality alternative roost sites are present in the vicinity, the population may decline before the bats can re-occupy the barn due to permanent dispersal of females away from the roost, or the FOCP may cause lower reproductive success by females using inferior roost sites (such as roosts located farther from high-quality foraging habitat), or predation of bats that are unable to find suitable roost sites. Even though the construction impacts of the FOCP and ADSRP do not overlap, the cumulative impacts created by the Project and FOCP together are significant, and the Project's contribution is cumulatively considerable.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Many of the reasonably foreseeable future projects, plans, and programs identified in **Table 42,** when combined with impacts of the Project (as described in Section 3.5), could affect species movement, wildlife corridors, and nursery sites. Of those projects listed in **Table 42**, the Residential, Commercial, Industrial, and Recreation Area Development could collectively affect the important wildlife movement pathway across Coyote Valley dependent on location, and it would be required to provide mitigation for its wildlife movement impacts. The cumulative impact to species movement resulting from the Project in combination with these other probable future projects, plans, and programs within the study area would be less than significant, except for pallid bat impacts, which would be significant, and for which the Project's contribution is cumulatively considerable.

Significance Conclusion Summary

Implementation of Valley Water BMPs, DMP MMs, and compliance with applicable VHP conditions would reduce impacts on wildlife movement and nursery sites. Implementation of Valley Water BMPs would protect dispersing animals from hazardous materials, pesticides, and other pollutants; reduce competition between invasive plants and native plants; minimize attraction of predators; limit impacts from staging and stockpiling activities; and avoid entrapment of animals during construction. Compliance with applicable VHP conditions and required AMMs, in addition to payment of VHP fees for covered species, would reduce impacts on dispersing animals, pallid bats, their habitats, and their prey. The VHP conservation program would assemble a Reserve System with landscape linkages and wildlife movement in mind to protect and, where possible, enhance movement pathways on a regional scale. While Project activities may temporarily affect wildlife movement during construction, animals would still be able to move through the Project Area during construction, and no long-term impacts on wildlife movement would persist. Post-construction operations, maintenance, and adaptive management would not substantially affect wildlife movement. Therefore, the Project would not substantially interfere with wildlife movement, and its contribution to interference of wildlife movement would **not be cumulatively considerable**, except for pallid bat impacts.

Implementation of BMPs, VHP conditions and AMMs, DMP MMs, and mitigation measures may not be adequate to reduce Project impacts on pallid bat populations to less-than-significant levels. Implementation of **Mitigation Measure TERR-1h(1)** through **TERR-1h(4)** represent the only available measures to reduce this impact. If implementation of **Mitigation Measures TERR-1h(1)** through **TERR-1h(4)** results in the maintenance of a pallid bat maternity roost consisting of at least 75 percent of the baseline population, then the Project would successfully mitigate its impacts on this species' population, and the Project would not have a cumulatively considerable contribution to cumulative impacts on biological resources. If, despite implementation of those mitigation measures, the pallid bat colony is abandoned or reduced substantially, the Project would result in an incremental contribution to this cumulative impact that would be **cumulatively considerable**.

Mitigation Measure

TERR-1h(1) *Avoid Disturbance of the Cochrane Road Barn Roost*

TERR-1h(2) *Evict Pallid Bats prior to Initiating Maternity-Season Disturbance near the Cochrane Road Barn Roost*

TERR-1h(3) *Minimize Impacts on Pallid Bats Roosting Outside the Cochrane Road Barn*

TERR-1h(4) *Provide Alternative Pallid Bat Maternity Roost Structures*

Cumulative Impact TERR-5: Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance **(No Contribution)**

Santa Clara County, the City of San José, and the City of Morgan Hill all have tree removal regulations that protect trees of certain types and sizes and require permits before such trees are removed. However, the San José tree ordinance applies only to private property; the Morgan Hill tree ordinance applies only to private and City property; and Valley Water is exempt from compliance with the County tree ordinance that would ordinarily apply to the Project. Therefore, Valley Water's removal of ordinance-sized trees would not conflict with the County tree ordinance and would not contribute to cumulative impacts to regulated trees. Other probable future projects within the study area would be required to comply with applicable local tree ordinances. Therefore, there would be no cumulative impact.

Implementation of Valley Water BMPs and compliance with applicable VHP conditions would reduce impacts on regulated trees. Implementation of Valley Water BMPs would reduce the potential for fire to affect trees and avoid competition between native trees and invasive plants. VHP conditions would reduce the magnitude of impacts on trees by minimizing impacts on riparian habitats. DMP BMPs and mitigation measures would avoid and minimize impacts on sensitive biological resources. Valley Water's payment of fees to the VHP's conservation program would help to reduce impacts to trees. While the Project would therefore reduce its impacts on regulated trees, the Project would make **no contribution** to cumulative impacts related to local tree ordinances because the Project will not have any impacts that conflict with tree ordinances of Santa Clara County, the City of San José, or the City of Morgan Hill. Nevertheless, recognizing the importance of protected trees to the County, Valley Water has voluntarily proposed **Mitigation Measure AES-1**, calling for the planting of replacement trees in unincorporated Santa Clara County.

Mitigation Measures

AES-1 *Replacement Trees on Santa Clara County Parkland*

***Cumulative Impact TERR-6: Conflict with the provisions of an adopted Habitat Conservation Plan/Natural Community Conservation Plan, or other approved local, regional, or State habitat conservation plan* (Not Cumulatively Considerable)**

Valley Water is a signatory on the VHP, which is an HCP and NCCP for terrestrial species and related habitats. The VHP explicitly included the Project in its list of covered activities, and most impacts of the Project were included in the VHP's analysis of the effects of covered activities. Similarly, Valley Water would pay specific impact fees for impacts on sensitive habitats, such as stream, wetland, riparian, and serpentine habitats. Valley Water would apply for VHP coverage for the Project and adhere to all applicable VHP conditions during Project implementation. Therefore, the Project would not be in conflict with the VHP.

Some impacts of the Project are not covered by the VHP because they are explicitly excluded from VHP coverage, they exceed thresholds that the VHP set for coverage, or they affect species that occur only in areas that are outside the VHP permit area. Valley Water would address those impacts outside of the context of the VHP (e.g., through its BMPs, additional mitigation measures, and Project-specific consultation with the USFWS and CDFW as necessary), and these non-VHP-covered impacts do not conflict with the VHP. Therefore, this impact is less than significant.

Many of the reasonably foreseeable future projects, plans, and programs identified in Table 3.0-5 ~~4-2~~ may be covered by the VHP or involve VHP-covered activities. Permanent VHP impact fees will have been paid by Valley Water for areas that will have been permanently impacted by the FOCP. Consistency with the VHP would be determined on a project-by-project basis, and the applicants for any VHP-covered activities would be obligated to comply with VHP conditions. Therefore, the Project in combination with these other probable future projects, plans, and programs within the study area would not result in a significant cumulative impact relating to VHP consistency. The Project's contribution to cumulative impacts related to consistency with adopted habitat conservation plans would be **not cumulatively considerable.**

Mitigation Measures

No mitigation is required.

3.6 Cultural Resources

This section describes cultural resources in the Project's study area. The regulatory and environmental setting is provided, as well as an analysis of impacts to cultural resources from implementation of the Project. For the purposes of this assessment, cultural resources are defined as early Native American (precontact) and historic-era, or post-contact, archaeological sites, features, and isolated finds; historic-era buildings, structures, and objects; early Native American and historic-era districts and landscapes; and traditional properties of importance to cultural groups. Tribal cultural resources are addressed in Section 3.20*, Tribal Cultural Resources***.**

This section describes existing cultural resources conditions within the Seismic Retrofit and Conservation Measure components study areas. The analyses for Project construction are based on the existing conditions at the time of the EIR preparation as modified by the FOCP implementation, while the analyses for Project operations are based on the Pre-FERC Order Conditions Baseline. The significant impacts that could result from Project implementation and mitigation measures to reduce these impacts to less-than-significant levels are identified and described in this section.

This section relies on the information and findings presented in a series of cultural resources technical reports (see Section 3.6.2 for additional details). These reports detail the methods and results of the cultural resources studies for the Project and associated environmental, ethnographic, and historic background of the Project study area, emphasizing aspects of human occupation. ~~Of these reports, those with no archaeological site location information are provided in Appendix H, while those with archaeological~~ Archaeological site location information ~~are~~ is provided in a confidential Appendix H ~~appendix~~ ~~(not included in this EIR)~~ due to the confidential nature of archaeological site location information, as regulated by applicable state regulations (California Government Code Section 6250 et seq. and Section 6254 et seq. [implementing regulations of the California Public Records Act of 2016]). This confidential appendix is available to qualified individuals upon request to Valley Water. Information on historical resources is included in the Historic Resources Technical Appendix (Appendix I).

3.6.1 Study Area for Cultural Resources

The cultural resources study area for the Project is designed to include all elements of Project construction and operations and to encompass all archaeological and built environment resources that could be impacted, both directly and indirectly, by the Project (**Figure 3.6-1**). This includes all areas covered by the archaeological survey and land parcels identified for potential indirect impacts (on built environment resources); due to the inclusion of entire cultural resource boundaries, the study area is larger than the overall Project Area identified in Section 2, *Project Description*, and **Figure 2.2-2**. For the purpose of the impact analysis, the study area has been broken down into two regions based upon Project impacts: the Seismic Retrofit study area, and the Conservation Measures study area. The Conservation Measures study area has been further split according to each Conservation Measure: Ogier Ponds Geomorphic and Habitat Enhancement (Ogier Ponds CM), Phase 2 Coyote Percolation Dam Fish Passage Enhancements (Phase 2 Coyote Percolation Dam CM), and the Maintenance of the North Channel Reach ~~Extension~~.

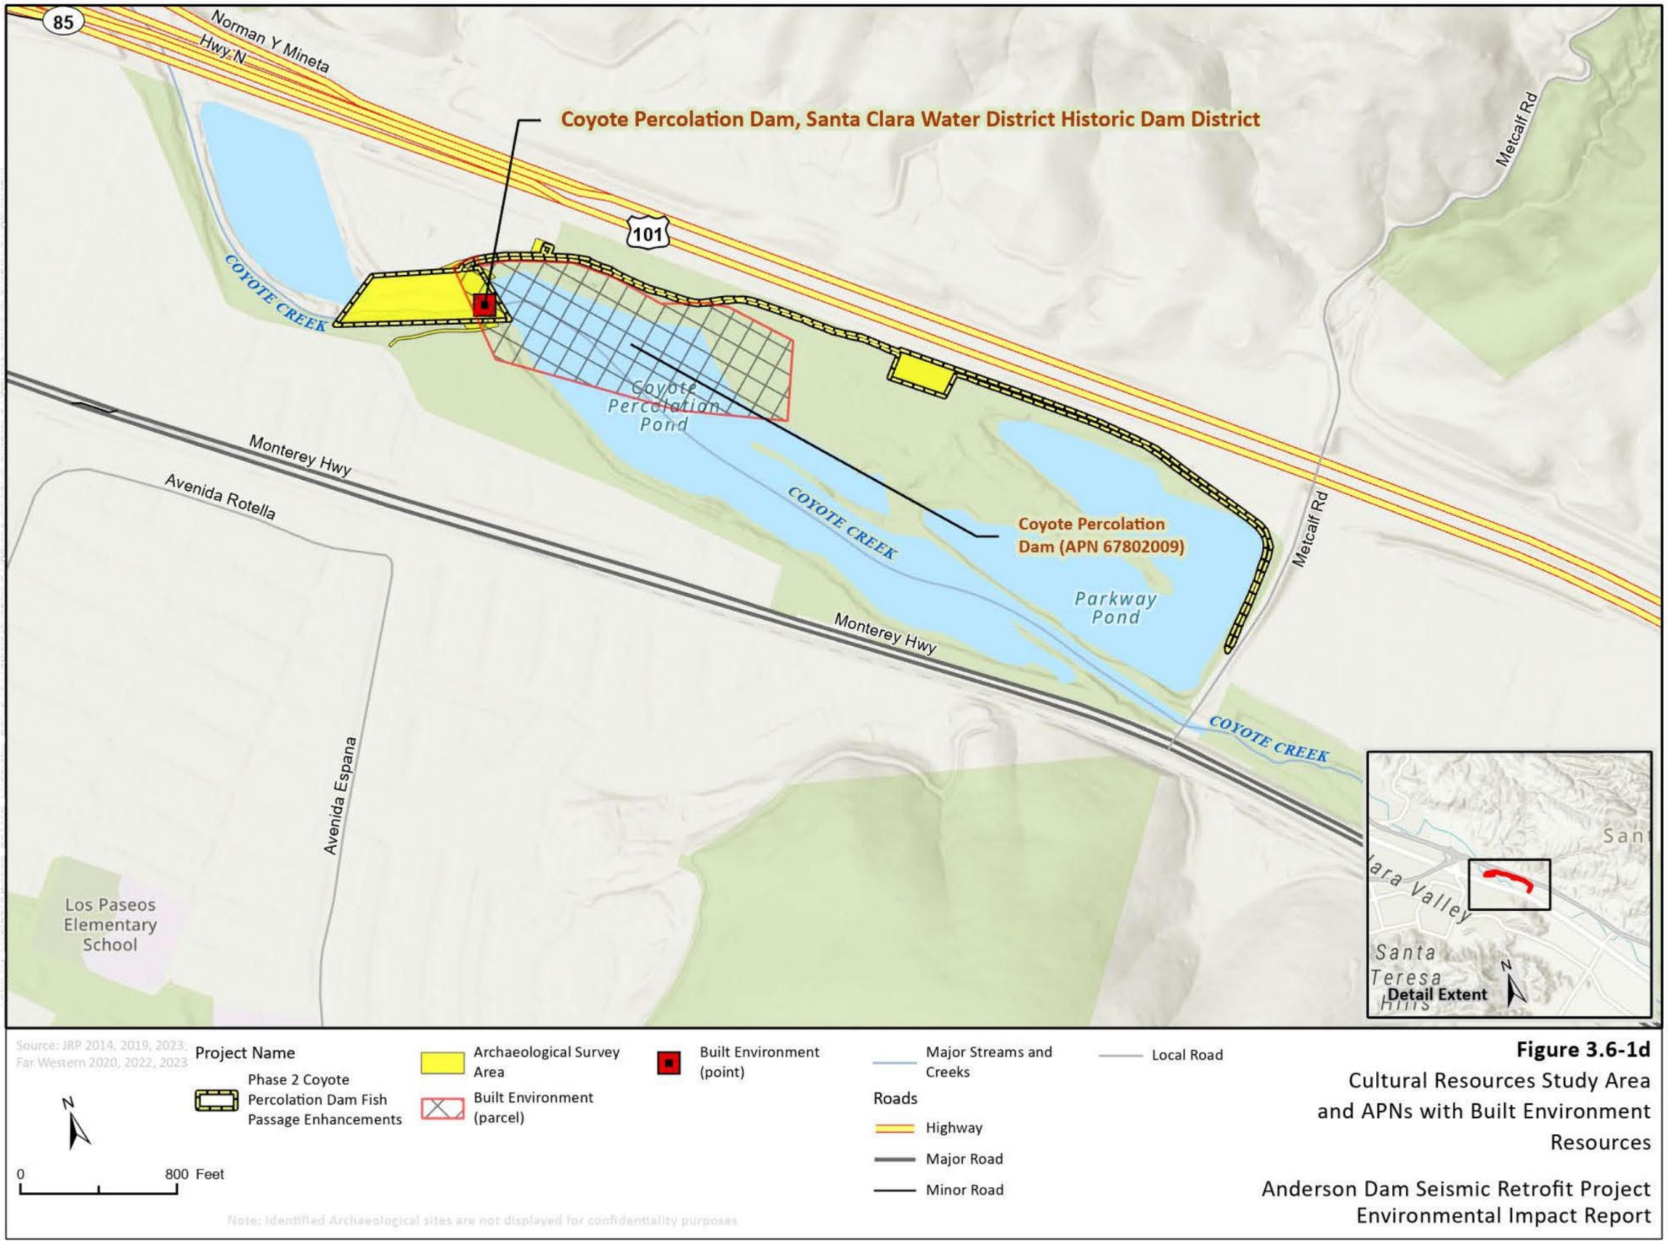

Figure 3.6-1d
Cultural Resources Study Area and APNs with Built Environment Resources

Anderson Dam Seismic Retrofit Project
Environmental Impact Report

The Maintenance Activities at Live Oak Restoration Reach and the Sediment Augmentation Program Conservation Measures, including adaptive management, are not included in the study area, nor in the analysis, as these actions would be contained within Coyote Creek and would not include any ground disturbance that could impact cultural resources. The quarries for sediment, haul roads, and staging areas that would be used to implement the Maintenance Activities at Live Oak Restoration Reach and the Sediment Augmentation Program would also be used for both the construction of the Seismic Retrofit and the Conservation Measures. Therefore, the use of those quarries and haul roads will be analyzed under the relevant Project components. The Seismic Retrofit component study area for cultural resources contains Anderson Reservoir (to the OHWM of elev. 628 feet), all areas of ground-disturbing activities and lands outside the Project Area where activities may cause changes in the character or use of historical resources. Locations outside the Project Area identified in Section 2, *Project Description*, relate to locations subject to archaeological survey for earlier iterations of the Project or aspects of the FOCP, or specifically to built environment resources, in which the study area is expanded to include parcels that are adjacent to construction areas.

The study area for the Seismic Retrofit component covers approximately 1,530 acres, including the reservoir pool, the Anderson Dam, and those portions of the Project Area below the dam, as shown in **Figure 3.6-1**. The vertical study area is 29 feet above the existing dam to accommodate the increased crest height of the dam from 647 feet to 660 feet above mean sea level,[1] and excavation below the existing ground surface that would be required to reach the acceptable foundation to meet design requirements at elev. 370.

The study area acreages associated with individual Conservation Measures include approximately 398 ~~432~~ acres for the Ogier Ponds CM (including the staging area and Barnhart Avenue Stockpiling Area), 2 acres for the Maintenance of the North Channel Reach ~~Extension~~, and approximately 8 acres for the Phase 2 Coyote Percolation Dam CM. In addition, seven parcels adjacent to the Ogier Ponds CM are included in the study area for the Conservation Measures to include potential impacts on built environment resources. Cumulatively, the maximum vertical depth is 12 feet to account for construction of the Ogier Ponds CM.

3.6.2 Environmental Setting

This section describes the methods and results of the cultural resources records search and literature review, pedestrian survey, and Native American consultation used to gather data about the cultural resources identified within the cultural resources study area (**Figure 3.6-1**). These data are fundamental to the analyses undertaken to evaluate the Project's potential to impact cultural resources. This section also includes information on the Native American precontact period, the Native American ethnohistoric period, the historic period within the Project vicinity, and identifies known recorded cultural resources in the study area and vicinity. Information provided in this section is derived or taken directly from the following technical reports prepared in support of the Project (note, confidential appendix H in which they can be found is provided after each reference:

[1] This includes 4 feet of additional height in the central portion of the dam that would taper down to the dam abutments to accommodate post-construction settlement. The average dam height will be at elev. 656 feet above mean sea level (see Section 2.5.4.~~2.5.2~~).

3.6.2.1 Regional Setting

The information in this section is directly derived or extrapolated from the Archaeological Inventory for the Anderson Dam Seismic Retrofit Project, Santa Clara County, California (Scher and Younie 2020) and Archaeological Resources Inventory for the Anderson Dam Seismic Retrofit Project Conservation Measures, Santa Clara County, California (Izzi and Siskin 2023).

Native American Precontact Period

Prior to colonization, Native American populations lived in the Project region for many thousands of years, as demonstrated through the archaeological record. Excavations in the San Francisco Bay region were first undertaken in the early 1900s, mostly with the intent to discover the depth, composition, and contents of the large shell mounds scattered around the bay (Gifford 1916, Nelson 1909, Schenck 1926, Uhle 1907). Later research efforts attempted to build a cultural sequence for the entire region based on changes in artifacts, mortuary practices, and shellfish remains (King 1970, Wallace and Lathrap 1975). The bay region's cultural sequence was incorporated by Beardsley (1948) into the Central California Taxonomic System (CCTS), which included three primary horizons—Early, Middle, and Late—defined largely based on stylistic variation of funerary artifacts. Revisions to the chronology have taken many forms over the years (Fredrickson 1974~~a~~), all generally employing a similar sequence of three periods.

While the CCTS continues to have utility, archaeological periods are today more commonly tied to broad environmental changes that have occurred since the Pleistocene and the end of wide-spread glaciation in North America that enabled populations to move throughout the continent. Environmental change required indigenous populations to adopt strategies for new subsistence regimes that, in turn, influenced cultural practices that are reflected in the material record observed through archaeological study. **Table 3.6-1** summarizes the archaeological record according to geologic time segments.

Table 3.6-1 Characteristics of the San Francisco Bay Chronological Sequence (Adapted from Izzi and Sisken 2023)

General Description	Specific Characteristics	Representative Artifacts
Terminal Pleistocene (13,000–11,700 cal years before present (BP[1])		
▪ Earliest entry into New World along California Coast ▪ No deposits identified in California due to landscape evolution and sea-level rise	▪ Wide-ranging, small bands of mobile hunters of large game ▪ Gatherers	▪ Fluted point
Early Holocene (11,700–8200 cal BP)		
▪ Rare in Bay Area, found in buried alluvial or colluvial contexts	▪ Semi-mobile hunter-gatherers exploiting a wide range of plant and animal foods from marine, lacustrine, and terrestrial contexts	▪ Stemmed points, crescents, and steep-edged formed flake tool ▪ Handstones and millingslabs ▪ Napa obsidian dominates

General Description	Specific Characteristics	Representative Artifacts
Middle Holocene (8200–4200 cal BP)		
▪ Surface and buried deposits ▪ Some substantial residential settlements ▪ Increased populations	▪ A series of buried sites with diverse cultural assemblages and occasional burials ▪ Isolated burials ▪ Long-distance exchange ▪ Longer seasonal occupation	▪ Ground stone (mortar and pestle by 6000 cal BP) ▪ Side-notched dart points ▪ Cobble-based tools ▪ Shell beads (Type N grooved rectangular *Olivella*) ▪ ornaments
Late Holocene (4200–170 cal BP)		
▪ Divided into three periods with subdivisions ▪ Well-documented in Bay Area (200 14C dates) ▪ Upward trends in population and social, political, and economic complexity	▪ Economic intensification territorial circumscription ▪ Active landscape management (e.g., burning) ▪ Limited inter-group violence ▪ Nonegalitarian social structure and status ascription	▪ Bow and arrow after 700 cal BP, Stockton serrated arrow point ▪ Various *Olivella* and *Haliotis* beads

Source: Izzi and Sisken 2023

Notes:

[1]Cal BP: BP means "before present." The "cal" prefix indicates that the dates are the result of radiocarbon calibration using tree ring data. The term "cal BP" means the number of years before 1950 and can be directly compared to calendar years.

Terminal Pleistocene (13,500–11,700 cal BP)

There is general agreement that humans entered the Americas via multiple migrations using both coastal and inland routes (Erlandson et al. 2007). Throughout California, Terminal Pleistocene occupation is infrequently encountered and poorly understood, and most often represented by isolated fluted points (Erlandson et al. 2007, Rondeau et al. 2007, Rosenthal and Fitzgerald 2012) likely related to the Clovis and Folsom Periods of the Great Plains and the Southwest (Haynes 2002). No fluted points or archaeological deposits dated to the Terminal Pleistocene have been documented in the Bay-Delta Area, which is likely explained by sea level rise, coastal erosion, localized subsidence, and the likelihood that initial human populations were small and highly mobile, leaving a faint and widely spaced archeological signature on the landscape.

Early Holocene (11,700–8200 cal BP)

It is typically thought that Early Holocene central California was inhabited by semi-mobile hunter-gatherers exploiting a wide range of plant and animal foods from marine, lacustrine, and terrestrial contexts (Erlandson et al. 2007, Jones et al. 2002, Meyer and Rosenthal 1995, Moratto 2002). Early Holocene assemblages often include stemmed points, crescents, and steep-edged formed flake tools, similar to contemporaneous material in the Great Basin and southern North Coast Ranges (Rosenthal et al. 2007). However, California assemblages are distinguished by the ubiquitous presence of milling tools, such as handstones and milling slabs (Rosenthal and Fitzgerald 2012).

Middle Holocene (8200–4200 cal BP)

More than 60 Bay-Delta Area archaeological sites have produced radiocarbon dates indicating occupation during the Middle Holocene. Both surface and buried deposits are present, including a number of substantial residential settlements. Notably, the Middle Holocene includes a series of buried sites with diverse cultural assemblages and occasional burials. Several isolated human burials have also been found in buried contexts in the northern Santa Clara Valley and along the edge of the bay in the Southwest region and near Coyote Point (Henn et al. 1972; Leventhal 1987; Meyer 2008, 2015; Scher and Meyer 2014). Artifact assemblages are varied and include ground stone (some only with milling slabs and handstones, some with mortars and pestles, and some with both); side-notched dart points; cobble-based chopping, scraping, and pounding implements; and shell beads and ornaments (Fitzgerald 1991 ~~1993~~, Meyer and Rosenthal 1998).

Late Holocene (4200–180 cal BP)

The Late Holocene is very well-documented in the Bay-Delta Area (Milliken et al. 2007). It is generally thought that regional human population increased over the last 4,000 years and there was an upward trend in social, political, and economic complexity, in part reflected by distinct, geographically specific cultural traditions. A number of studies indicate ongoing resource intensification—an increasing reliance on lower-ranked and more costly foods such as smaller species of marine mammals, terrestrial mammals, birds, fish, plants, and possibly dogs (Broughton 1999, 2002; Broughton et al. 2006 ~~2007~~; Byrd et al. 2013; Whitaker and Byrd 2014; Wohlgemuth 1996, 2009 ~~2002~~). Territorial circumscription, active landscape management (e.g., burning), and periodic upswings in inter-group violence are also indicated (Andrushko et al. 2010; Bartelink et al. 2013; Lightfoot et al. 2013a, 2013b; Milliken 2006; Schwitalla et al. 2014). Drawing largely on mortuary remains, a number of scholars have argued that community organization entailed nonegalitarian social structure and ascribed status (Bellifemine 1997, Gould 1975 ~~Fredrickson 1974b~~, Hylkema 2002: 258–261, King 1974, Luby 2004, Milliken et al. 2007). Most suggest that these changes took place near the beginning of the Late Period, although King (1974: 38) and Luby (2004: 18) argue that they developed earlier, during the Middle Period.

Native American Ethnographic Contact Period (180–115 cal BP)

The Santa Clara Valley falls within the territory of Ohlone-speaking Native Americans (Levy 1978). The territory of the Ohlone extended along the Pacific Coast from south of Monterey Bay all the way up the San Francisco Peninsula and inland into the Coast Ranges. The Ohlone territory included the open coast, the littoral zone of the bay, and a variety of inland settings, each with a varied range of resources. Early Spanish colonizers documented exceedingly high-population densities in the San Francisco Bay and Delta area, equaled in California only by the Santa Barbara-area Chumash (Cook and Heizer 1968; Kroeber 1939; Milliken 2006, 2010).

The Ohlone language group (also referred to as Costanoan, from Costanos, Spanish for “coastal people”) is a linguistic subfamily of the Penutian language stock (Bean 1994, Kroeber 1925, Levy 1978, Teixeria 1997). According to early linguists (Milliken et al. 2009), there are six Costanoan languages, each associated with a geographic location and the tribelet(s) that inhabited the locality. Because language and community boundaries are ill-defined, it can be surmised that the Project Area is located at the approximate boundary between two of these languages, San Francisco Bay Costanoan and Awaswas, and is largely within Awaswas territory (Milliken et al.

2009:138). Communities within the upper Coyote Creek watershed are identified at the *Auxentac* and *Matalan* tribelets.

Historical accounts by Spanish explorers and priests traveling through the area indicate that much of the lowlands within Santa Clara Valley consisted of wetland habitat during the spring, with lagoons, large lakes, streams, and rivers containing abundant fish, waterfowl, and associated vegetation. Within this environment, permanent Ohlone villages were established near the coast, the bay, and along river drainages, with temporary camps in prime resource-processing areas. Some tribes occupied a central village, while others had several villages within a few miles of each other. No named villages have been identified by the ethnographic record within the Project Area.

The most common type of housing consisted of hemispherical huts thatched with grasses and rushes (Kroeber 1925: 219). Although village organization is poorly documented, other types of village structures included sweathouses, dance enclosures or plazas, and assembly houses, with sweat houses and menstruation houses situated outside the village. Sacred places on the landscape, such as nearby Mt. Diablo and Brushey Peak, also played an important role in ceremonial activities, such as those of the secret Kuksu society (Kroeber 1932; Loeb 1932, 1933). Burial practices varied within the Ohlone area (in the South Bay) and included destroying or burying items of personal ownership; cremations were more widespread than inhumations in the Chochenyo area (in the East Bay).

For the Ohlone as a whole, the basic unit of political organization was a territory-holding group of one or more associated villages and smaller temporary encampments, often referred to as a tribe or tribelet (Kroeber 1962). These groups were generally considered independent, multi-family, landholding polities of 60 to 400 people (Levy 1978: 487). Milliken (2010) has identified 59 Ohlone tribelets. As noted above, the *Auxentac* and *Matalan* tribelets are associated with the Project Area. Territorial community organization included a chief, who could be a man or woman, although the office was generally inherited via patrilineal descent (Levy 1978: 487). The chief took a leadership role in important tasks such as hosting visitors, leading food procurement expeditions, and representing a tribal council of elders who served as advisors to the villagers. War leaders and shaman also played key roles in each community.

Prior to European contact, the Ohlone were hunters, gatherers, and fisherfolk, similar to other California indigenous peoples. Subsistence activities centered around the seasonal availability of gathered resources. Women gathered hazelnuts, strawberries, blackberries, and soaproot (Palóu 1926:209), and processed acorns into flour. Seeds, an important source of calories, were harvested on the grasslands. Men were observed by the Spanish engaging in both hunting and fishing activities, including communal drives for antelope, deer, elk, quail, rabbits, grasshoppers, and fishing from rafts. The Ohlone practiced burning on an annual basis to ensure an abundance of fall-ripening acorns, seed-bearing annuals, and forage for large game (Crespí 1927, Levy 1978: 491). Domesticated dogs (Harrington 1942) presumably served as companions and camp protectors and may have played an important dietary role when food was scarce (Byrd et al. 2013, Levy 1978: 491).

The Ohlone manufactured a variety of stone tools, including knives, arrow and spear points, handstones and milling slabs, mortars and pestles, net sinkers, anchors, and pipes. Chert was obtained from local quarries, and obsidian was acquired in trade. Balsas (canoes), mats, and baskets were made from tule, cordage, nets, baskets from plant fibers, blankets from sea otter, rabbit, and duck skins. Mortars, both bedrock and portable, were important components of acorn-processing technology. Shell beads were gaming and trading commodities, as well as ornamental items. Trade relations with neighboring villages and groups were well-established. According to Davis (1961: 23), bows, arrows, basketry materials, paints, and feather blankets were procured from the east, while the Ohlone traded mussels, dried abalone, salt, and abalone shells to the neighboring Yokut groups and provided the Sierra Miwok with *Olivella* and abalone shell beads.

The Spanish occupation of the Ohlone area lasted 46 years, from 1776 to 1822. This period involved the establishment of multiple outposts and marked the beginning of Euro-American occupation of the region that intensified over the decades and profoundly altered traditional indigenous lifeways. In January 1777, the first site of Mission Santa Clara was dedicated by the Spaniards, and by the end of the year Spanish settlers had founded the pueblo of San José 3 miles south on the Guadalupe River. This same year, native inhabitants suffered the first of several epidemics, devastating their populations and disrupting precontact lifeways. Spanish occupation of Alta California was the driving force behind tribal disintegration, with native people leaving their villages for the missions where padres controlled their daily lifestyles, work, diet, and religious expression. By 1810, all Ohlone villages had been abandoned (Milliken 1995, 2006). However, small Indian settlements were dispersed throughout the Southern Santa Clara Valley and eastern hill country through much of the Mission Period (Panich and Schneider 2015).

Historic Period Context

Gaspar de Portolá was the first Spanish explorer to enter the Santa Clara Valley, entering from the west along the shoreline of the San Francisco Bay in 1769 after traveling along the Pacific coast through Monterey, Santa Cruz, and San Mateo Counties. Pedro Fages was the next to arrive in 1770, following a similar path to that of Portolá. He returned in 1772 along a route that cut inland from Monterey, passed through the Salinas and San Juan Valleys before continuing north along the eventual route of El Camino Real (US 101), past Morgan Hill (camping on Coyote Creek), and meandered down into the Santa Clara Valley and beyond. All these explorations encountered and interacted with the Ohlone along the way. However, the historic era truly began with the establishment of Mission Santa Clara in 1777, as mentioned above.

Anderson Dam is located in a part of the county first settled in the 1830s, with the establishment of Rancho Refugio de la Laguna Seca, Rancho Ojo de Agua de la Coche, and Rancho San Felipe y Las Animas, primarily used as cattle ranches (Archives and Architecture 2012: 33, City of Morgan Hill 2006 ~~CIRCA 2006~~: 24–26, Dill Design Group 2003: 11–12). Drought in the 1860s propelled wheat cultivation to the forefront of agricultural pursuits in the Santa Clara Valley. Wheat yields began to decline in the 1880s, and dairy and fruit production became the mainstay of Santa Clara Valley agriculture for decades to come (Archives and Architecture 2012: 40–41, 60). This shift to horticulture triggered changing land ownership patterns, as large ranch owners subdivided and sold their land for highly profitable orchard plots (City of Morgan Hill 2006 ~~CIRCA 2006~~: 52–53, Payne 1987: 78).

The earliest communities in the Morgan Hill area began as stage stops along Monterey Road (El Camino Real), including Madrone, which was the primary shipping center for the railroad until a railroad station was established in Morgan Hill in 1893 (City of Morgan Hill 2006 ~~CIRCA 2006~~: 32–33). Fruit dehydrators, and canning and packing plants, were soon built near the Morgan Hill depot (City of Morgan Hill 2006 ~~CIRCA 2006~~: 32–38). Fruit production continued to grow into the twentieth century with orchards extending into the woodlands, oak savannas, and low hills of the Diablo Range. With the introduction of refrigerated rail cars, shipment of fresh fruit also became possible. A 1939 USGS topographic map and the earliest aerial photographs of the study area from 1938/1939 show extensive orchard planting downstream of the dam adjacent to Coyote Creek, as well as in a few areas now inundated beneath the south arm of Anderson Lake. Horticulture remained the principal agricultural industry in the Santa Clara Valley in succeeding decades, with irrigation aided by dam construction and groundwater development projects of Valley Water (City of Morgan Hill 2006 ~~CIRCA 2006~~: 52–53, Payne 1987: 78–79).

Agriculture in the Santa Clara Valley relied on available groundwater. Until around 1900, groundwater levels were sufficiently high that farmers could irrigate with artesian wells. By 1915, increased pumping and drought resulted in a substantial drop in groundwater levels, and by 1930, the groundwater table had dropped to alarming levels (Tibbetts 1934, American Society of Civil Engineers 1977~~: 25~~). Valley Water was established in 1929, and valley leaders and local engineers proposed a system of dams and conservation facilities to aid in recharging the valley's groundwater (~~American Society of Engineers 2003~~, Tibbetts 1936). The original main storage dams were Calero, Almaden, Guadalupe, Vasona, and Stevens Creek, built in 1935, and Coyote Reservoir, finished in 1936. Valley Water built Anderson Dam in 1950 and Lexington Dam in 1952 (McArthur 1981).

Agriculture continued to be the backbone of the Morgan Hill area economy until the 1970s when high-tech firms began locating to the city, and US 101 was built and bypassed the downtown area. The area has become a suburb of San José, triggering the construction of large residential subdivisions east and north of Morgan Hill and their annexation into the city. In recent decades, relatively dense residential development has spread east of Morgan Hill towards the vicinity of Anderson Dam, further altering the once rural and agricultural character of the area (USGS maps, City of Morgan Hill 2006 ~~CIRCA 2006:~~ 36–38).

3.6.2.2 Results of Cultural Resources Studies

Cultural Resources Records Search and Literature Review

Numerous record search requests were submitted to the Northwest Information Center (NWIC) of the California Historical Resources Information System (CHRIS) at Sonoma State University by Far Western between November 2013 and August 2022, as the Project description and preliminary engineering designs were refined. In general, the record search areas comprised the entire Project Area with a 0.25-mile buffer. Subsequent record searches for the Seismic Retrofit component construction area included both 0.5- and 1-mile buffers in order to better understand the cultural resource types within the immediate vicinity of the Project Area. Additionally, at the request of Rincon, the NWIC conducted a records search (#24-0311) in June and September 2024, for the Live Oak Reach Restoration Project and staging areas with a 0.5-mile radius. The record searches conducted in support of the Project are listed in **Table 3.6-2**.

Table 3.6-2. California Historical Resources Information System Record Searches

NWIC File Number	Date Report Received
File No. 13-0537	November 2013
File No. 17-0218	August 2017
File No. 19-0141	July 2019
File No. 19-1183	February 2020
File No. 19-1888	May 2020
File No 20-1331	January 2021
File No. 22-0347	August 2022
File No. 23-1737	June 2024
File No. 24-0311	September 2024

Notes:

NWIC = Northwest Information Center

According to the record search data, a large number of studies have been conducted within the Seismic Retrofit study area and vicinity, primarily downstream of Anderson Dam. These include archaeological field studies (survey and excavation), many of which were linear surveys for pipelines or telecommunication lines, architectural or historic-era studies, and archaeological management or literature research studies (no field component). Despite this high volume of previous studies, large portions of the Seismic Retrofit study area were previously un-surveyed, including some areas downstream of the dam and much of the current shoreline of Anderson Lake. For the Conservation Measures, approximately 50 percent of the Ogier Ponds CM area had been studied, though the staging area for this Conservation Measure had not. Alternately, the study area for the Phase 2 Coyote Percolation Dam CM had been completely surveyed, while none of the area of North Channel Reach ~~Extension~~ had been studied. The number of reports and resources reported by the NWIC record searches for the Seismic Retrofit and Conservation Measures components areas are listed in **Table 3.6-3**.

Table 3.6-3. Record Search Results for the Project Area

Location	Reports	Cultural Resources
Seismic Retrofit		
Seismic Retrofit	5	Total: 5 Precontact: 3 Built Environment: 1 Historic District: 1 (includes built environment resources and a precontact lithic scatter)
Conservation Measures

Key: CM = Conservation Measures

Sixteen (16) ~~Fourteen (14)~~ sites were previously recorded in the Seismic Retrofit study area and records search buffer, including ten ~~eight~~ precontact archaeological sites, one historic-era archaeological site, two multi-component archaeological sites with both precontact and historic-era components (including built environment elements), two individual built environment resources, and one unknown resource. One historic district was also identified. Five ~~Eight~~ of these resources are in the Seismic Retrofit study area. These consist of: three precontact Native American lithic scatters (one with reported burials); one built environment structure; and one historic district. Previously recorded resources within the Seismic Retrofit study area. The five resources within the Seismic Retrofit study area are summarized below and in **Table 3.6-4.**

Two of the precontact sites are on the rim of Anderson Lake (P-43-001090 and P-43-001094[2]), and one (P-43-000364) is downstream of the dam. None of these sites previously had been evaluated for eligibility for listing in the National Register of Historic Places (NRHP) or California Register of Historical Resources (CRHR).

The one built environment structure is Anderson Dam (P-43-004144). Anderson Dam was originally recorded in 2006 and assessed as ineligible for both the NRHP and CRHR, with concurrence from the State Historic Preservation Officer (SHPO) received in 2020 (McMorris and Melvin 2014, 2019).

The historic district is the Rhoades Ranch Historic District (P-43-000171), which consists of the Rhoades House and the Phegley House, as well as a precontact lithic scatter. The Rhoades Ranch Historic District is listed in the NRHP and CRHR, and is a County-designated landmark. The precontact lithic scatter is not listed as a contributing element to the historic district, nor are any portions of the pre-contact archaeological site within the Project Area; therefore, impacts to the precontact archaeological site portion of the district are not further addressed in this EIR.

[2] Numbers P-43-XXXXX reference primary numbers assigned by the regional Information Center of the CHRIS to cultural resources that have been identified and submitted to the Information Center. The numbers are comprised of "P," for primary, followed by a number representative of the county (e.g., 43 means Santa Clara County), followed by the assigned number. Numbers CA-SCL-XXXXX reference numbers, referred to as trinomials, are also assigned by the regional Information Center of the CHRIS to cultural resources that have been identified and submitted to the Information Center. The numbers are comprised of "CA," followed by a number representative of the county (e.g., SCL means Santa Clara County), followed by the assigned number. All resources submitted to the CHRIS receive a "P" number, but not all resources receive a trinomial. For simplification, in the text of this chapter, "P" numbers are used to identify resources; trinomials are included in tables, as appropriate, to provide complete information on the identity of resources. The addition of an "H" to the trinomial indicates the resource is of the historic era.

Table 3.6-4. Record Search Results: Previously Recorded Cultural Resources in the Study Area

Primary Number (P-43-)	Trinomial (CA-SCL-)	Age: Type	Location
Seismic Retrofit Study Area			
004144 ~~N/A~~	N/A	Historic: Built environment—Anderson Dam	At dam
000171	159/H	Multi-component: Rhodes Ranch Historic District—Precontact lithic scatter, Phegley House, Rhodes House, horse barn, water tower, office, equipment building	At downstream base of dam (precontact archaeological site portion not in Project Area)
000364	358	Precontact: Lithic scatter, human remains	At downstream base of dam
001090	727	Precontact: Lithic scatter	Reservoir footprint
001094	731	Precontact: Lithic scatter	Reservoir footprint
Conservation Measures Study Areas			
000176	165	Multi-component: Historic-era refuse; precontact flake and shell	Ogier Ponds
001001	164	Precontact: Lithic scatter and midden	Ogier Ponds
000189	178	Precontact: occupation site with human remains	Phase 2 Coyote Percolation Dam Fish Passage Enhancements
001814	953	Precontact: Buried deposit with flaked/ground stone	Phase 2 Coyote Percolation Dam Fish Passage Enhancements
003559	N/A	Built environment: Coyote Percolation Dam; Santa Clara Valley Water District Dams Historic District	Phase 2 Coyote Percolation Dam Fish Passage Enhancements

Source: ~~JRP~~ McMorris and Melvin 2014, 2019, McMorris and Skow 2023

Notes:

Not all build environment resource evaluations have been submitted to the regional CHRIS and, as a result, they do not have primary numbers. Only resources with archaeological deposits receive trinomials.

Key: N/A = Not Applicable.

The record search for the Conservation Measure study area also yielded information on previously recorded cultural resources for Ogier Ponds and the Phase 2 Coyote Percolation Dam CM study areas; no previously recorded resources were identified for the Maintenance of the North Channel Reach ~~Extension~~ study area. As listed in **Table 3.6-4**, one multi-component site (P-43-000176) and one precontact site (P-43-001001) had been previously recorded within the study area for the Ogier Ponds CM. Two precontact sites, P-43-000189 and P-43-001814, the former a large occupation site with human remains, had previously been recorded within the

Phase 2 Coyote Percolation Dam CM study area. One built environment resource, the Coyote Percolation Dam, which is a contributing element to the Santa Clara Valley Water District Dams Historic District (P-43-003559), is also within the Phase 2 Coyote Percolation Dam CM study area. Two of the previously recorded resources in the Phase 2 Coyote Percolation Dam CM study area, precontact site P-43-000189 and Santa Clara Valley Water District Dams Historic District (P-43-003559), have been determined eligible for the NRHP/CRHR. None of the other previously recorded sites within the CM study area have been evaluated for NRHP/CRHR-eligibility. Although site P-43-001814 has not been formally evaluated for NRHP/CRHR-eligibility, data from the NWIC record search indicated the site was thoroughly destroyed by excavation of one of the ponds within the Ogier Ponds CM; therefore, this resource is considered no longer extant and is not further addressed in this EIR.

Archaeological Pedestrian Survey and Results

The archaeological survey area for Seismic Retrofit component construction encompassed all the elements depicted on **Figure 2.2** *Project Area Map*, including the entire reservoir to the dead pool elevation. Altogether, the archaeological survey area for the Seismic Retrofit component encompassed a total area about 1,530 ~~1,145~~ acres, as shown on **Figure 3.6-1a**. Note that the survey area exceeded the Seismic Retrofit component Project Area in some locations to fully record archaeological sites in response to the needs of the FOCP, which also required archaeological surveys, or to earlier iterations of Project design. As described below, areas of dense vegetation, unsafe areas with steep slopes and excessive mud, and paved or artificially constructed areas, all of which were in the Project study area, were not subject to pedestrian survey.

Far Western conducted initial pedestrian survey in the Seismic Retrofit component Project Area on October 2, 2013, and April 23, 2014, with additional survey in August 2017, and August 2019 (Scher and Izzi 2017, Scher and Younie 2020, Scher et al. 2014). The 2019 work included a survey of the reservoir rim from the high-water level at the time of elev. 578 feet, to the reservoir's maximum operating elevation of 628 feet above mean sea level. A final survey was conducted during the spring and summer of 2020 at the reservoir between 578 feet and the deadpool elevation (Buonasera et al. 2022). All newly identified cultural resources were recorded on standard California Department of Parks and Recreation (DPR) forms. Previously recorded sites within the survey areas were re-located, and original DPR site forms were updated. Site boundaries were defined using surface indicators, such as artifact and feature distributions, or the presence of organic-rich anthropogenic sediments (midden). Site boundaries were mapped with a submeter Global Positioning System. Artifacts and features were mapped, described in detail, and photographed. Isolated finds were recorded and photographed where warranted.

Ground visibility varied considerably throughout the study area, with some areas completely covered with vegetation and others fully exposed. Varied levels of survey were conducted. Intensive pedestrian survey was conducted where feasible, including the majority of accessible portions of the Seismic Retrofit study area (i.e., not inundated beneath the reservoir or on private property without access permission). It consisted of systematic transect coverage at intervals of no more than 60–75 feet, depending on conditions. In some locations, shallow surface scrapes were excavated to improve ground visibility and assist with site boundary definition. Mixed-strategy survey was conducted in areas with limited access due to very steep slopes or dense brush and poison oak. Surveyors covered as much of the area as was practical by surveying the upper and lower edges of steep slopes and gaps in dense vegetation. The

Coyote Creek channel was visually inspected from the top of the creek bank where there was no pedestrian access for crossing. In 2019, approximately 2,000 linear feet of channel through the Live Oak Group Picnic Area, was specifically inspected to satisfy a request made by the Ohlone Indian Tribe, during Native American consultation; water in the creek was high with a fast flow at the time of survey, and creek bank views were limited. No survey occurred in inaccessible areas. This included areas just above the 488-foot water line that were too muddy to safely survey, some overly steep slopes, or where the landscape had already been significantly altered.

Additionally, Rincon conducted a field survey of the Live Oak Reach Restoration project area along with Staging Areas 2, 5, and 6, and the Barnhart Avenue Stockpiling Area, and Communication lines/fiber optic lines area on July 10 and September 9 and 10, 2024. Ground visibility was variable ranging from zero to 100 per cent. No artifacts or cultural soils were identified in the Live Oak Restoration Reach, Staging Areas 5 or 6, Barnhart Avenue Stockpiling Area, or Communication lines/fiber optic lines project areas. One archaeological resource (AD-HS-01) was identified within Staging Area 2 and is a historic-period refuse scatter consisting of glass fragments (colorless, aqua, green and brown), ceramic fragments, and metal flatware dating to the 1940s/1950s. AD-HS-01 measures approximately 70 feet by 30 feet and has a sub-surface component. AD-HS-01 has not been evaluated for the CRHR or NRHP.

The results of the archaeological studies ~~study~~ for the Seismic Retrofit Project Area are depicted in **Table 3.6-5,** which lists all the previously recorded (n=3) and newly recorded (n=13 ~~14~~) archaeological sites in the Seismic Retrofit study area. In addition to the 16 ~~17~~ archaeological sites recorded within the Seismic Retrofit Project Area, 35 isolated artifacts[3] were recorded. The isolates were overwhelmingly comprised of precontact flaked or ground stone tools and were located within the reservoir pool. Six of the isolates recorded in the reservoir were of the historic era, as were the only two isolates located downstream of the dam. While isolated artifacts can be useful for identifying land use patterns, they are rarely considered eligible for the NRHP or CRHR due to their limited data potential. As a result, isolated artifacts will not be considered further in this EIR.

Table 3.6-5. Archaeological Resources in the Seismic Retrofit Study Area*

Resource Identifier	Description	NRHP/CRHR Eligibility	Location	Comments/ Potential Impacts
P-43-001090	Multi-component; lithic scatter, water trough	Not Eval	Reservoir Inundation footprint	In construction zone, within stockpile area. Reservoir fluctuation during Project operations.
P-43-001094	Multi-component Ground and flaked stone scatter, midden, sparse historic-era refuse	E**	Reservoir Inundation footprint	Not in construction zone. Reservoir fluctuation during Project operations.

[3] Isolated finds are defined as three or fewer artifacts within a 270-square-foot (25-square-meter) area. A single artifact, such as a ceramic plate, broken into multiple pieces, constitutes a single artifact.

Resource Identifier	Description	NRHP/CRHR Eligibility	Location	Comments/ Potential Impacts
P-43-004082	Precontact Quarry	NE	Reservoir Inundation footprint	Not in construction zone. Reservoir fluctuation during Project operations.
P-43- 004083	Precontact midden, lithic scatter, human remains	E	Reservoir Inundation footprint	Not in construction zone. Reservoir fluctuation during Project operations.
P-43-004084	Precontact Flaked and ground stone scatter	NE	Reservoir Inundation footprint	Not in construction zone. Reservoir fluctuation during Project operations.
P-43-004085	Multi-component ranching, midden, lithic scatter, human remains	E	Reservoir Inundation footprint	In construction zone, adjacent to stockpile area. Reservoir fluctuation during Project operations.
P-43-004086	Multi-component lithic scatter with two rock clusters, sparse historic-era artifacts	NE	Reservoir Inundation footprint	In construction zone. Reservoir fluctuation during Project operations.
P-43-004087	Historic Refuse deposit	NE	At downstream base of dam	In construction zone, within staging area.
P-43-004089	East Dunne Avenue/Cochrane Bridge abutment	NE	Reservoir Inundation footprint	Not in construction zone. Constructed 1951, demolished 1987.
AD-2022-02	Historic; Structure remnants	Not Eval	Reservoir Inundation footprint	Not in construction zone. Reservoir fluctuation during Project operations.
AD-2022-03	Multi-component; Historic-era and precontact artifacts	Not Eval	Reservoir Inundation footprint	In construction zone, within stockpile area. Reservoir fluctuation during Project operations. May be the Pomeroy Adobe.
AD-2022-04	Precontact; Quarry	Not Eval	Reservoir Inundation footprint	Not in construction zone. Reservoir fluctuation during Project operations.
AD-2022-05	Precontact; Ground stone and flaked lithics	Not Eval	Reservoir Inundation footprint	In construction zone. Reservoir fluctuation during Project operations.

Resource Identifier	Description	NRHP/CRHR Eligibility	Location	Comments/ Potential Impacts
AD-2022-06	Precontact; Quarry	Not Eval	Reservoir Inundation footprint	In construction zone, slight overlap of stockpile area. Reservoir fluctuation during Project operations.
	Anderson Dam Bridge	NE	Encased existing dam	In construction zone. Will be disposed of during construction of replacement dam. Likely constructed 1905 to 1908, decommissioned 1950.
AD-HS-01	Historic-period refuse scatter with glass and ceramic fragments and metal flatware	Not Eval	Staging Area 2	In Staging Area 2

** Shaded rows indicate archaeological sites considered historical resources for the purpose of this EIR.*

*** Site P-43-001094 was originally evaluated as not eligible, but the 2022 study (Buonasera et al. 2022) suggests evaluation should be reconsidered due to discovery of midden deposit.*

Key: CRHR = California Register of Historical Resources; E = Eligible; NE = Not Eligible; Not Eval = Not Evaluated; NRHP = National Register of Historic Places

The complete study areas for the Phase 2 Coyote Percolation Dam CM and Maintenance of the North Channel Reach ~~Extension Conservation Measures~~ were inspected for archaeological resources. All the Ogier Ponds CM area was surveyed with the exception of 21 acres south of Coyote Creek in an area planned for restoration that was not accessible due to high water in the creek. As with the Seismic Retrofit area, all identified cultural resources in the Conservation Measures areas were recorded on DPR forms, and previously recorded sites were visited and recorded with DPR site record updates.

Archaeological survey of the Ogier Ponds CM resulted in the identification and recordation of three new historic-era archaeological resources. Two of the resources (ADKS02 and ADKS03) are within the area of Ogier Ponds CM, and the third (ADKS01) is within the staging area identified for the construction of this Conservation Measure. Of the two previously recorded archaeological sites in the area, one was not observed during the field effort (P-43-001001), and the second was in the area inaccessible to survey (P-43-000176). For the Phase 2 Coyote Percolation Dam CM, the two previously recorded sites (P-43-000189 and P-43-001814[4]) in the study area could not be relocated during the pedestrian survey; no new archaeological resources were identified. Archaeological resources had not previously been recorded in the Maintenance of the North Channel Reach ~~Extension~~ study areas, nor were any identified during the pedestrian survey. **Table 3.6-6** lists all previously recorded and newly identified archaeological resources associated with the Conservation Measure study areas.

[4] Note that it was previously stated that site P-43-001814 had been destroyed. It is, therefore, not listed in **Table 3.6-3**, nor discussed further in this EIR.

Table 3.6-6. Archaeological Resources in the Conservation Measure Study Areas*

Resource Identifier	Description	NRHP/CRHR Eligibility	Conservation Measure	Comments/Potential Impacts
P-43-000176/ CA-SCL-165	Multi-component	Not Eval	Ogier Ponds	Site area not accessible for survey; development of floodplain along Coyote Creek.
P-43-001001/ CA-SCL-164	Precontact	Not Eval	Ogier Ponds	No surface evidence of site during survey; in conservation area but no impacts identified.
ADKS01	Historic: dense and extensive historic-era domestic refuse deposit; 1940s-1950s	Not Eval	Ogier Ponds	Evidence of looting noted; in staging area.
ADKS02	Historic: two concrete foundation slabs and artifact scatter	Not Eval	Ogier Ponds	Near proposed berm.
ADKS03	Historic: 1950s sparse refuse scatter	Not Eval	Ogier Ponds	Adjacent to existing road and trail.
P-43-000189	Precontact with human remains	E	Phase 2 Coyote Percolation Dam	No surface evidence of site during survey; under access road.

Archaeological Trenching and Results

Because a high percentage of identified archaeological sites in the Santa Clara Valley are buried and much of the Project Area downstream of the dam has been rated as high to highest for buried archaeological site sensitivity, a series of backhoe trenches were excavated where Project elements could have an impact on buried archaeological resources (Scher and Younie 2020). Backhoe trenches were also used to explore the presence of buried cultural materials at the recorded location of archaeological resource P-43-000364 within the Seismic Retrofit Project Area, which was not relocated during the pedestrian survey (Scher and Younie 2020). Twenty-two trenches were excavated within the recorded portion of P-43-000364 located north of Cochrane Road and in the Seismic Retrofit construction area.[5] Only one of the backhoe trenches revealed a buried deposit. The identified resource was a historic-era refuse deposit within the previously recorded boundaries of site P-43-000364. The historic refuse site (P-43-004047) was

[5] A total of 31 backhoe trenches were excavated within the downstream portion of the seismic retrofit construction Project study area; however, some of these were in locations that were later excluded from the Project seismic retrofit construction area.

recorded as a separate site from P-43-000364, and because no precontact materials were identified in the area, the boundary of P-43-000364 was redrawn to restrict the site to the south of Cochrane Road and outside of the Project limits. Because the site was determined to be outside of the Project Area, it has been eliminated from further analysis.

Archaeological Site Evaluations

Archaeological site evaluations for NRHP/CRHR eligibility[6] were conducted for eight archaeological sites and one historic-era archaeological feature (Anderson Dam Bridge) within the Seismic Retrofit study area by Far Western in the summer of 2020 (Scher et al. 2022). Far Western prepared research designs to define research issues for both Native American precontact and post-contact sites and historic-era sites prior to implementing the evaluations (Scher and Hyde 2020). Archaeological sites were evaluated by excavating a program of surface transect units (STU) and control units (CU). Archival research was also conducted for the historic-era elements of the multi-component sites, the one historic-era site, and the Anderson Dam Bridge. Note that the Anderson Dam Bridge is encased in the core of the existing Anderson Dam, and because it is buried in soil, it was not evaluated as a built environment resource. The Anderson Dam Bridge was identified and evaluated solely based on archival research. The evaluated resources are listed in **Table 3.6-7**; the resultant NRHP/CRHR eligibility status of each resource is listed in **Table 3.6-2**.

Table 3.6-7. Evaluated Archaeological Resources in Seismic Retrofit Study Area

Resource Identifier	Description	Surface Recording	STUs	CUs	Feature Exposures	Archival Research

Key: H – Historic; M – Multi-component; P – Precontact; CU – Control Unit – 1 by 1 or 2 by 1 meters, excavated in 10-centimeter levels, screened through 1/4-inch or 1/8-inch mesh; STU – Surface Transect Unit – 1 by 0.5 meters, excavated in 20-centimeter levels, screened through 1/4-inch mesh; Feature Exposure – Exposure of a feature identified at the surface, excavated with greater attention to stratigraphy, screened through 1/4-inch or 1/8-inch mesh.

[6] All archaeological sites evaluated for NRHP/CRHR eligibility were also evaluated against the criteria for unique archaeological resources under PRC 21083.2(g). Very rarely do archaeological sites meet these criteria without also being found eligible for the NRHP/CRHR. Such is the case for the Project's evaluated sites; sites found ineligible for the NRHP/CRHR were also determined not to meet the unique archaeological resource criteria. Therefore, for the purposes of this EIR, archaeological sites determined ineligible for the NRHP/CRHR can be assumed to be nonunique archaeological resources pursuant to PRC 21083.2(h) though it may not be explicitly stated in the text.

As previously discussed, one other archaeological site (P-43-000189) in the Phase 2 Coyote Percolation Dam CM area, had previously been evaluated and found eligible for the NRHP/CRHR.

Archaeological Resources Setting Summary

Altogether, ten of the 22 ~~21~~ known archaeological resources within the study areas (Seismic Retrofit and Conservation Measures components) have been evaluated for NRHP/CRHR eligibility, leaving 12 ~~13~~ of the sites unevaluated. These 12 ~~13~~ archaeological sites are considered CEQA-defined historical resources for the purpose of the impact analyses presented in Section 3.6.5, along with the four other sites that have been determined NRHP/CRHR-eligible. Impacts to sites that are determined ineligible, which are not listed in a local register of historic resources and are not unique archeological resources, do not require further consideration under CEQA and therefore, they are not analyzed further.

Built Environment Survey and Results

JRP Historical (JRP) initially conducted a study of built environment resources within the Seismic Retrofit study area in 2014 (McMorris and Melvin 2014); a follow-up study was conducted in 2019 as the Project evolved (McMorris and Melvin 2019). Surveys for the Conservation Measures took place in 2021 and 2023 (McMorris and Skow 2022, 2023). A total of 13 resources were identified, recorded on DPR forms, and analyzed for NRHP/CRHR eligibility. Five of the resources are located in the Seismic Retrofit study area (construction area and immediately adjacent parcels), and eight are in the Conservation Measure study areas (construction area and immediately adjacent parcels). Seven of the resources in the Conservation Measure study areas are in the Ogier Ponds CM study area, and one is in the Phase 2 Coyote Percolation Dam CM study area. Recorded resources (see **Table 3.6-8**) included a variety of structures (residences, out buildings, barns, warehouses) and irrigation features.

Two previously recorded historic districts, the Rhoades Ranch Historic District and the Santa Clara Valley Water District Dams Historic District, are located in the Seismic Retrofit area and the Phase 2 Coyote Percolation Dam CM, respectively. Both historic districts were revisited for the purposes of the EIR, and are the only CEQA-defined built environment historical resources in the Project Area. All of the newly-identified built environment resources were recommended as not eligible for listing in the NRHP/CRHR, and none are listed as significant resources on any local registry; therefore, they will not be analyzed further in this EIR.

Table 3.6-8. Built Environment Resources within the Project Study Areas*

Name or Type of Resource	APN/Address	NRHP/CRHR Eligibility	Description	Direct/Indirect Footprint

Rhoades Ranch Historic District

This historical resource is located at 2290 Cochrane Road (APN 728-34-010), directly downstream of the existing Anderson Dam. The APN parcel containing the Rhoades Ranch Historic District crosses to just north of Cochrane Road for a maximum of 30 feet and, thus, into the Seismic Retrofit construction area (see **Figure 3.6-1b**). This portion of the Project, north of Cochrane Road, is within the construction area of the extant dam and currently contains a parking area for access to the Coyote Creek Trail. The boundary of the Rhoades Ranch Historic District, however, is entirely south and west of Cochrane Road (McMorris and Melvin 2014). The NRHP nomination form, completed in 2012, noted that "[t]he property today is located in a rural environment as it has been since established in the 1860s, although Anderson Dam, built in 1949-1950 is clearly visible to the northeast" (Maggi and Winder 2012). Thus, construction of the extant dam did not impact the characteristics of the Rhoades Ranch Historic District that contributed to its significance. Furthermore, the area has lost some of its rural character, as the area directly west of the property has since been developed as a housing tract.

The Rhoades Ranch Historic District was listed in the NRHP[7] in 2013. It was determined significant under NRHP Criterion A, for its association with agricultural development of the region; NRHP Criterion B, for its association with Harold E. Thomas; and NRHP Criterion C, for distinctive architecture. This ranch was developed in the 1860s during the county's Early American Period as a 248-acre portion of the Rancho La Laguna Seca. La Laguna Seca was established in 1834 when Mexican Governor José Figueroa granted four leagues of land in Coyote Valley to Juan Alvires. During 100 years of agricultural production, this site evolved from a cattle ranch to a horticultural farm where prunes, apricots, and walnuts were grown. By the mid-twentieth century, the site, reduced to its present size, became the location of an experimental strawberry facility where propagation work took place that created many disease-resistant varieties now grown throughout the world. A number of significant people have been involved in this ranch: early owner James F. Phegley, a South County rancher who served on the County's Board of Supervisors, Ira Osborne Rhoades, a railroad purchasing agent who retired to the ranch and became involved in a leadership role in the statewide California Prune and Apricot Growers Association, and Dr. Harold E. Thomas, a plant pathologist who helped found, and was Director of, the nonprofit Strawberry Institute of California.

The property contains two residences that are architecturally significant. The Phegley House is a unique and rare two-story board-wall house (National folk style) that was constructed in the 1860s during California's Early American Period. The Phegley House was renovated during the early-twentieth century but retains its distinctive 1860s character and composition that is expressed through its preserved materials, workmanship, and early National-style construction technology.

The Rhoades house is a distinguished example of Spanish Eclectic architecture for 1917, an innovative design by two important local architects, Andrew Hill Jr. and Howard Higbie. The Rhoades House has changed little since its construction and continues (through its massing and detailing) to illustrate its associations with local architect-designed work.

Harold E. Thomas is known as the "Father of the California Strawberry Industry." Thomas' major contributions were the development of disease-resistant strawberry varieties, which changed the character and scope of strawberry production in California and opened the potential of strawberries as a fresh market fruit. Thomas acquired the property that contains the Rhoades Ranch Historic District in 1945 and established the Strawberry Institute to further his research, which lasted until 1966.

Santa Clara Valley Water District Dams Historic District/Coyote Percolation Dam

The Santa Clara Valley Water District Dams Historic District was evaluated and recommended eligible for the NRHP/CRHR in 2006 (JRP 2006). The Santa Clara Valley Water District Dams Historic District is a discontinuous district that consists of seven dams and appurtenant structures that comprise the original and integral components of the Santa Clara Valley Water Conservation District's system. The dams, which were constructed between 1934 and 1936, included in the district are Coyote Dam, Coyote Percolation Dam, Almaden Dam, Guadalupe Dam, Vasona Dam, Stevens Creek Dam, and Calero Dam. The Santa Clara Valley Water District Dams Historic District was found eligible for listing in the NRHP/CRHR under Criterion A/1 as an

[7] Resources eligible for or listed on the NRHP are automatically eligible for or listed on the CRHR pursuant to PRC 5024.1(d)(1) and CCR 4851(a)(1).

important aspect of the economic development of the Santa Clara Valley. The construction of the seven dams as a unified system provided a steady, reliable, and consistent supply of water for municipal, industrial, and agricultural uses. It was also found eligible under Criterion C/3 as the dams and their associated features can be considered the work of a master, Fred H. Tibbetts. The Coyote Percolation Dam is a contributing element to the Santa Clara Valley Water District Dams Historic District but is not considered an individually eligible resource (McMorris and Skow 2022).

The Coyote Percolation Dam was among the first structures of the historic district to be built. Tibbetts designed the dam in 1932 and it was constructed two years later by Macco Construction Co. It was built with removable flashboards which, when installed, created a pond to hold the natural flow of Coyote Creek at medium river stages that allow for water to percolate into the aquafer. Once Anderson Dam was built upstream and east of Morgan Hill in 1950, the Coyote Percolation Dam also began to serve as storage for Anderson Dam flows when they naturally decrease.

3.6.3 Regulatory Setting

3.6.3.1 Federal Laws, Regulations, and Policies

National Historic Preservation Act

Projects that require federal permits, receive federal funding, or are located on federal lands must comply with 54 USC Section 306108, formally known as Section 106 of the National Historic Preservation Act (NHPA). To comply with Section 106, a federal agency must “take into account the effect of the undertaking on any district, site, building, structure, or object that is included in or eligible for inclusion in the National Register of Historic Places”. The implementing regulations for Section 106 are found in Title 36 CFR, Part 800, as amended (2004).

The implementing regulations of the NHPA require that cultural resources be evaluated for NRHP eligibility if they cannot be avoided by an undertaking or a project. Resources listed or eligible for NRHP listing are called *historic properties*. To determine if a site, district, structure, object, and/or building is significant, the NRHP Criteria for Evaluation are applied. A resource is significant and considered a historic property when it:

- Is associated with events that have made a significant contribution to the broad patterns of our history
- Is associated with the lives of persons significant in our past
- Embodies the distinctive characteristics of a type, period, or method of construction, or that represents the work of a master, or that possesses high artistic values, or that represents a significant and distinguishable entity whose components may lack individual distinction
- Yields, or may be likely to yield, information important in prehistory or history

In addition, 36 CFR Section 60.4 requires that, to be considered significant and historic, resources must also exhibit the quality of significance in American history, architecture, archaeology, engineering, or culture, and must possess integrity of location, design, setting, materials, workmanship, feeling, and association.

FERC would be the lead federal agency for Project Section 106 consultation.

3.6.3.2 State Laws, Regulations, and Policies

California Register of Historical Resources

The CRHR is established in PRC Section 5024.1. The register lists all California properties considered to be significant historical resources, including all properties listed in, or determined to be eligible for listing, in the NRHP. The criteria for listing in the CRHR include resources that:

- Are associated with the events that have made a significant contribution to the broad patterns of California's history and cultural heritage
- Are associated with the lives of persons important in our past
- Embody the distinctive characteristics of a type, period, region, or method of construction, or represent the work of an important creative individual, or possess high artistic values
- Have yielded, or may be likely to yield, information important in prehistory or history

CCR section 4852 sets forth the criteria for eligibility, as well as guidelines for assessing historical integrity and resources that have special considerations.

California Environmental Quality Act

Under CEQA, a project will have a significant effect if it causes a “substantial adverse change” in the significance of an “historical resource.” An “historical resource” is defined as a resource that is (*CEQA Guidelines* Section 15064.5[a]):

- Listed in or determined by the State Historical Resources Commission to be eligible for listing in the CRHR
- Listed in a local register of historic resources
- Determined to be eligible for California Register-listing, based on an historical resource survey meeting defined requirements; or determined by the Lead Agency’s exercise of discretion, based on substantial evidence in the record, to be an historical resource

The *CEQA Guidelines* also provide guidance on how to mitigate significant impacts on historical resources (*CEQA Guidelines* Section 15126.4(b)).

In addition, Section 21083.2 of CEQA (PRC Section 21000 et seq.) requires that the lead agency determine whether a project may have a significant effect on unique archaeological resources. A unique archaeological resource is defined in CEQA as an archaeological artifact, object, or site where it can be clearly demonstrated that there is a high probability that it:

- Contains information needed to answer important scientific research questions, and there is demonstrable public interest in that information
- Has a special or particular quality, such as being the oldest of its type or the best available example of its type
- Is directly associated with a scientifically recognized important prehistoric or historic event or person

Measures to conserve, preserve, or mitigate and avoid significant effects on unique archaeological resources are also provided under CEQA Section 21083.2.

Health and Safety Code Section 7050.5 and Public Resources Code Section 5097.98

Section 7050.5 of the Health and Safety Code requires that construction or excavation be stopped in the vicinity of discovered human remains until the County Coroner can determine whether the remains are those of a Native American. If the remains are determined to be a Native American, the Coroner must then contact the California Native American Heritage Commission (NAHC). When human remains are discovered or recognized in any location other than a dedicated cemetery, no further excavation or disturbance of the site or any nearby area reasonably suspected to overlie adjacent human remains may take place until the County Coroner has been informed and has determined that no investigation of the cause of death is required. If the Coroner determines, or has reason to believe, the remains to be those of a Native American, the Coroner shall contact the NAHC by telephone within 24 hours. If the remains are of Native American origin, the descendants of the deceased Native American(s) may make a recommendation to the landowner or the person responsible for the excavation work for means of treating or disposing of, with appropriate dignity, the human remains and any associated grave goods as provided in PRC Section 5097.98. This excludes instances where the NAHC was unable to identify a descendant, or the descendant failed to make a recommendation within 24 hours after being notified by the commission. Similar procedures are required by *CEQA Guidelines* Section 15064.5(e).

3.6.3.3 Local Laws, Regulations, and Policies

Santa Clara County General Plan

The Santa Clara County General Plan (County 1994) provides a comprehensive approach to identifying and addressing cultural resources (referred to as heritage resources), which is found under the Resource Conservation Element. The General Plan identifies three strategies for protecting heritage resources:

Strategy #1. Inventory and Evaluate Heritage Resources

Strategy #2. Prevent, or Minimize, Adverse Impacts on Heritage Resources

Strategy #3. Restore, Enhance, and Commemorate Resources as Appropriate

The General Plan also acknowledges the challenges for preserving heritage resources in urban settings versus rural settings and provides policies for each setting. There are two General Plan policies that guide implementation of the strategies in rural settings:

R-RC 81: Heritage resources within the rural unincorporated areas of Santa Clara County shall be preserved, restored wherever possible, and commemorated as appropriate for their scientific, cultural, historic and place values.

R-RC 82 The following strategies should provide overall direction to efforts to preserve heritage resources:

1. Inventory and evaluate heritage resources.
2. Prevent, or minimize, adverse impacts on heritage resources.

3. Restore, enhance, and commemorate resources as appropriate.

City of Morgan Hill 2035 General Plan

In lieu of discussing cultural resources in the City of Morgan Hill 2035 General Plan, the City of Morgan Hill address Cultural and Historic Resources under their Healthy Community element. One goal is defined: GOAL HC-8 Historic identity and cultural resources that are preserved for future generations. Of the seven policies listed under the goal, the two listed below are the only ones somewhat applicable to the Project:

- Policy HC-8.4 Tribal Consultation. Consult with Native American tribes that have ancestral ties to Morgan Hill regarding proposed new development projects and land use policy changes.
- Policy HC-8.5 Mitigation. Require that if cultural resources, including tribal, archaeological, or paleontological resources, are uncovered during grading or other on-site excavation activities, construction shall stop until appropriate mitigation is implemented.

Most of the City's regulations for cultural resources are deferred to their Historic Resources Code that is within Section 18.60 of the Municipal Code (City of Morgan Hill 2021). The code is comprehensive but largely emphasizes the protection, restoration, and treatment of historic structures rather than archaeological sites. Section 18.60.090, however, addresses archaeological resources. The City maintains an archaeological sensitivity map and the Municipal Code requires that developers request a record search to determine if known archaeological sites are in or near a proposed development. If a known archaeological site is within or adjacent to a project area, appropriate mitigation measures must be developed. If a known archaeological site is not within or adjacent to a project area, an archaeological survey must be conducted, and the applicant must comply with standard conditions developed by the City. These standard conditions include having an archaeologist present onsite to monitor all ground-disturbing activities and treating any discovered archaeological resources appropriately. If human remains are discovered during construction, the project would comply with all applicable state and federal laws, including California Health and Safety Code Section 7050.5 and *CEQA Guidelines* Section 15064.5(e).

The City has also produced an Historic Context Statement that provides an extensive history of the city (City of Morgan Hill 2006 ~~CIRCA: Historic Property Development 2006~~). The document discusses historic themes and property types to assist in the NRHP/CRHR evaluation of cultural resources recorded within city limits.

Envision San José 2040 General Plan

The City of San José addresses archaeological resources (paired with paleontological resources) under the Environmental Leadership Element of the Envision San José 2040 General Plan (City of San José 2023 ~~2011~~) with the following goal, policies, and actions:

Goal ER-10 – Archaeology and Paleontology

Preserve and conserve archaeologically significant structures, sites, districts and artifacts in order to promote a greater sense of historic awareness and community identity.

Policies – Archaeology and Paleontology

ER-10.1 For proposed development sites that have been identified as archaeologically or paleontologically sensitive, require investigation during the planning process in order to determine whether potentially significant archeological or paleontological information may be affected by the project and then require, if needed, that appropriate mitigation measures be incorporated into the project design.

ER-10.2 Recognizing that Native American human remains may be encountered at unexpected locations, impose a requirement on all development permits and tentative subdivision maps that upon their discovery during construction, development activity will cease until professional archaeological examination confirms whether the burial is human. If the remains are determined to be Native American, applicable state laws shall be enforced.

ER-10.3 Ensure that City, State, and Federal historic preservation laws, regulations, and codes are enforced, including laws related to archaeological and paleontological resources, to ensure the adequate protection of historic and prehistoric resources.

Action – Archaeology and Paleontology

ER-10.4 The City will maintain a file of archaeological and paleontological survey reports by location to make such information is retrievable for research purposes over time.

The Historic Preservation section under the Land Use and Transportation Element of the General Plan, which identifies historic landmarks, historic districts, and conservation districts, emphasizes built environment resources. The City recognizes that “Historic sites and structures provide an educational link to San José’s past and foster a sense of place and community identity for San José. The preservation of appropriate remnants of a city’s past provides multiple benefits important to the health and progress of the city” (City of San José 2023 ~~2020~~, Chapter 6: 19).

3.6.4 Methodology and Approach to Impact Analysis

The impact analysis considers whether implementation of the Project would result in significant impacts to cultural resources pursuant to the applicable significance criteria in Appendix G of the *CEQA Guidelines* (see Section 3.6.3.2). Specifically, the impact analysis considers the effects of Seismic Retrofit Project construction, as well as the effects of Seismic Retrofit Project post-construction operations and maintenance. The analysis also considers the effects of Conservation Measures incorporated into the Project, including both construction and post-construction operations and maintenance. As described in Section 3.0, *Introduction*, the baseline for evaluating Seismic Retrofit and Conservation Measures construction is the existing conditions at the time of the EIR preparation modified by the FOCP implementation. However, for both the Seismic Retrofit and the Conservation Measures components, the baselines for evaluating post-construction operations and maintenance effects include the Pre-FERC Order Conditions Baseline (based on the 2015 WEAP model) which is also described in Section 3.0, *Introduction*.

Construction monitoring impacts are not analyzed, as monitoring is focused on water temperature and quality, groundwater, fisheries, and various other biological species, as discussed in Chapter 2, *Project Description*. Such activities would not cause any ground disturbance or result in direct or indirect adverse impacts to cultural resources under baseline conditions.

Similarly, adaptive management strategies under the FAHCE program are not analyzed, because resources subject to adaptive management are within Coyote Creek and such strategies would largely comprise non-ground-disturbing activities or would be in areas analyzed for other Project components. Geoarchaeological studies (Scher and Younie 2020) for the Project indicated that areas along Coyote Creek where these Conservation Measures would be implemented are not sensitive for buried cultural resources; however, should unknown archaeological materials be uncovered during Conservation Measures components implementation, these would be addressed according to mitigation measures included herein. Should the results of future adaptive management studies lead to infrastructure improvements, these improvements could require additional CEQA assessment and other regulatory approvals, and additional cultural resources studies would take place at that time, as necessary.

3.6.4.1 Seismic Retrofit Construction

This analysis considers the potential direct and indirect impacts on cultural resources that would result from constructing the Seismic Retrofit components, as described in Chapter 2, *Project Description*. Project implementation would require a significant amount of ground-disturbing activities necessary for the construction of the Seismic Retrofit components. While a significant amount of the disturbance would be in locations that have either been previously disturbed (e.g., the spillway) or in places with artificial fill (e.g., the dam), many other locations could affect original ground (e.g., temporary and permanent road construction; preparation for staging, stockpiling, and borrow areas) where surface or subsurface archaeological remains could be located (see Impact CR-2 and Impact CR-3). In some cases, built environment resources could also be affected by Project construction activities (see Impact CR-1). The potential for significantly impacting known and unknown cultural resources within the Seismic Retrofit component of the Project study area is discussed below.

3.6.4.2 Conservation Measures Construction

This impact analysis considers the potential for construction of the Conservation Measures component to cause significant adverse impacts to cultural resources. Conservation Measures that involve construction and/or physical improvements may result in impacts to built environment resources (see Impact CR-1), or surface or buried archaeological resources, including human burials (see Impact CR-2 and Impact CR-3). The location and nature of Conservation Measure components construction activities are considered in the context of known cultural resources and the potential to discover buried cultural resources. The potential for Conservation Measure components construction to result in significant impacts to cultural resources is evaluated. Conservation Measures requiring construction activities that are evaluated in the impact analysis include:

- Ogier Ponds CM
- Maintenance of the North Channel Reach ~~Extension~~
- Phase 2 Coyote Percolation Dam CM

The Maintenance Activities at Live Oak Restoration Reach and Sediment Augmentation Program areas, including adaptive management actions, are not analyzed, as the measure actions would be contained within Coyote Creek and would not include any ground disturbance that could impact cultural resources. Adaptive management actions identified under the FAHCE program are also not addressed as they would not result in any ground-disturbing activities that could impact cultural resources for similar reasons. Should the results of future adaptive management actions lead to infrastructure improvements that require additional CEQA assessment and other regulatory approvals, additional cultural resources analyses would take place, as necessary.

3.6.4.3 Post-Construction Anderson Dam Facilities Operations and Maintenance

This analysis considers the direct and indirect impacts to cultural resources that would result from operational changes proposed for nonemergency flow releases following completion of the FOCP and Anderson Dam facility upgrades and improvements, as described in Chapter 2, *Project Description*. The baseline for evaluating post-construction operation effects for the Seismic Retrofit Project is the Pre-FERC Order Conditions Baseline. Thus, Project operations would impact those sites within the reservoir that would be subject to wave action caused by the fluctuating water levels from reservoir operations and power boating activities. These effects would be primarily to those sites located along the reservoir shoreline (see Impact CR-2). The potential for significantly impacting archaeological resources through Seismic Retrofit Project operations is discussed below.

Additionally, as described in Chapter 2, *Project Description*, Valley Water would maintain the newly retrofitted Anderson Dam and Reservoir per Valley Water's existing DMP. DMP activities were evaluated previously in the DMP Final Program EIR prepared in January 2012 (SCH No. 2007022052 ~~2011082077~~; Valley Water 2012). Dam maintenance activities would be restricted to built environment features that are either newly constructed or have previously been determined ineligible for the NRHP/CRHR and would not impact cultural resources. For these reasons, post-construction dam facility maintenance activities are not discussed further for built environment resources in this section.

3.6.4.4 Post-Construction Conservation Measure Operations and Maintenance

The baseline for evaluating post-construction operation and maintenance effects for the Seismic Retrofit component and Conservation Measures component is the Pre-FERC Order Conditions Baseline. Conservation Measures post-construction operations and maintenance impacts are not addressed, because they would not impact cultural resources once these facilities are constructed. This is because all areas of post-construction operations and maintenance would occur in areas impacted by construction of the Conservation Measure elements, and no ongoing disturbance would be required; therefore, any potential impacts to cultural resources would have occurred at that time.

3.6.4.5 Post-Construction Project and FAHCE Adaptive Management

The Project and FAHCE AMP would guide post-construction adaptive management of Project flow operations and Conservation Measures that have met their specified success criteria, as defined through the regulatory permitting process. As required by the FAHCE AMP framework, the Project and FAHCE AMP includes four key elements: measurable objectives, monitoring, adaptive actions, and reporting. Monitoring and adaptive actions involve physical activities that could have environmental impacts.

The Project and FAHCE AMP monitoring program would inform a selection of adaptive management measures to implement in response to management triggers and includes compliance, validation, effectiveness, and long-term monitoring. Validation, effectiveness, and long-term trend monitoring would build on existing Valley Water monitoring infrastructure (e.g., hydrologic monitoring network), water quality monitoring (e.g., water temperature monitoring network), habitat monitoring (e.g., habitat mapping), and fisheries monitoring (e.g., VAKI Riverwatcher, PIT tag detectors, genetics sampling, electrofishing surveys). Impacts of these monitoring activities are not evaluated in the impact analysis because they are not the types of activities that would reasonably be anticipated to have the potential to impact cultural resources, as they would not include ground-disturbing activities or activities associated with potential alterations to built environment resources.

The Project and FAHCE AMP identifies triggers for adaptive actions to help meet measurable objectives. Adaptive actions for FAHCE flows and imported water storage/releases would include refinements of reservoir releases, which would have impacts and benefits similar to the original FAHCE flows and imported water storage/releases. Adaptive actions for Conservation Measures would generally include minor construction and maintenance actions, whose impacts would be similar but less than those from original Conservation Measure construction. Impacts of these adaptive actions are not evaluated in the impact analysis because, as noted above, such actions would occur within Coyote Creek and largely comprise non-ground-disturbing activities or be in areas analyzed for other Project components. These areas are not sensitive for buried cultural resources; however, should unknown archaeological materials be uncovered during Conservation Measures components implementation, these would be addressed according to mitigation measures included herein.

3.6.4.6 Applicable Best Management Practices and VHP Conditions

There are two ~~is one~~ Valley Water BMPs that are ~~is~~ applicable to the protection of cultural resources, including historical and archaeological resources, and human burials, and that are ~~is~~ described below.

BMP AQ-1: Use Dust Control Measures

The following BAAQMD Dust Control Measures will be implemented:

1. All exposed surfaces (e.g., parking areas, staging areas, soil piles, graded areas, and unpaved access roads) shall be watered two times per day;
2. All haul trucks transporting soil, sand, or other loose material off-site shall be covered;
3. All visible mud or dirt track-out onto adjacent public roads shall be removed using wet power vacuum street sweepers at least once per day. The use of dry power sweeping is prohibited;
4. Water used to wash the various exposed surfaces (e.g., parking areas, staging areas, soil piles, graded areas, etc.) will not be allowed to enter waterways;

5. All vehicle speeds on unpaved roads shall be limited to 15 mph[8];
6. All roadways, driveways, and sidewalks to be paved shall be completed as soon as possible. Building pads shall be laid as soon as possible after grading unless seeding or soil binders are used;
7. Idling times shall be minimized either by shutting equipment off when not in use or reducing the maximum idling time to 5 minutes (as required by the California airborne toxics control measure Title 13, Section 2485 of California Code of Regulations), and this requirement shall be clearly communicated to construction workers (such as verbiage in contracts and clear signage at all access points);
8. All construction equipment shall be maintained and properly tuned in accordance with manufacturer's specifications, and all equipment shall be checked by a certified visible emissions evaluator;
9. Correct tire inflation shall be maintained in accordance with manufacturer's specifications on wheeled equipment and vehicles to prevent excessive rolling resistance; and,
10. Post a publicly visible sign with a telephone number and contact person at the lead agency to address dust complaints; any complaints shall be responded to and take corrective action within 48 hours. In addition, a BAAQMD telephone number with any applicable regulations will be included.

BMP CU-1: Accidental Discovery of Archaeological Artifacts or Burial Remains

If historical or unique archaeological artifacts are accidentally discovered during construction, work in affected areas will be restricted or stopped until proper protocols are met. Work at the location of the find will halt immediately within a 30-foot radius. A "no work" zone will be established utilizing appropriate flagging to delineate the boundary of this zone. A Consulting Archaeologist will visit the discovery site as soon as practicable for identification and evaluation pursuant to Section 21083.2 of the PRC, and Section 15126.4 of the CCR. If the archaeologist determines that the artifact is not significant, construction may resume. If the archaeologist determines that the artifact is significant, the archaeologist will determine if the artifact can be avoided and, if so, will detail avoidance procedures. If the artifact cannot be avoided, the archaeologist will develop an action plan within 48 hours which will include provisions to minimize impacts and, if required, a Data Recovery Plan for recovery of artifacts in accordance with PRC Section 21083.2 and Section 15126.4 of the CEQA Guidelines. If burial finds are accidentally discovered during construction, work in affected areas will be restricted or stopped until proper protocols are met. Upon discovering any burial site as evidenced by human skeletal remains, the County Coroner will be immediately notified. The field crew supervisor will take immediate steps to secure and protect such remains from vandalism during periods when work crews are absent. No further excavation or disturbance within 30 feet of the site or any nearby area reasonably suspected to contain adjacent remains may be made except as authorized by the County Coroner, California NAHC, and/or the County Coordinator of Indian Affairs.

[8] The 15 miles per hour speed limit would apply to all vehicles and equipment only in areas containing naturally occurring asbestos. Outside of these areas, a 25 mile per hour speed limit would be observed for haul trucks on unpaved roads (light duty pick-up trucks would observe the 15 mile per hour limit), such as the in-reservoir access roads to Stockpile Areas K and L. Limiting haul truck speeds to 15 miles per hour on all unpaved access roads would not be feasible to construct the Project interim dam to its full height, as the interim dam at the proposed height could not be reconstructed in a single work season.

There are no relevant VHP conditions that would apply to cultural resources.

3.6.4.7 Thresholds of Significance

For the purposes of this analysis, the Project would result in a significant impact on cultural resources if it would:

- CR-1: Cause a substantial adverse change in the significance of a historical resource
- CR-2: Cause a substantial adverse change in the significance of an archaeological resource
- CR-3: Disturb any human remains

No topics related to cultural resources that are included in the significance criteria listed above were eliminated from further consideration. All relevant topics are analyzed below.

3.6.5 Impact Analysis

***Impact CR-1: Cause a substantial adverse change in the significance of a built environment historical resource* (Less than significant)**

Seismic Retrofit Construction

One built environment resource, the NRHP/CRHR-listed Rhoades Ranch Historic District, is within the Seismic Retrofit component area (**Figure 3.6-1b**). The parcel that contains the Rhoades Ranch Historic District minimally overlaps the Seismic Retrofit area but the boundary of the Rhoades Ranch Historic District is not within the Seismic Retrofit construction area. Therefore, the Project would not result in any direct impacts on the historical resource. Activities related to construction of the Seismic Retrofit component would not be significantly different from those implemented during the construction of the Anderson Dam in the 1950s. Although the Rhoades Ranch Historic District would be subjected to atmospheric and audible elements (i.e., dust and noise), and vibration from construction, these impacts would be temporary and would not significantly alter the elements that contribute to the significance of the historical resource. Similar elements were also present during the construction of the ADTP as part of the FOCP and did not impact the Historic District. Therefore, the construction of the Seismic Retrofit component would have a less-than-significant impact on the Rhoades Ranch Historic District. Additionally, BMP AQ-1 would ensure that dust and air quality management measures are implemented, including implementation of BAAQMD's BMPs for dust suppression, thereby reducing any potential impact on the Historic District from dust related to Project construction.

Conservation Measures Construction

There are no built environment historical resources located within or adjacent to the disturbance areas of the Ogier Ponds CM and Maintenance of the North Channel Reach ~~Extension~~. However, one historical resource, the Santa Clara Valley Water District Dams Historic District (P-43-003559), is within the Phase 2 Coyote Percolation Dam CM area. Through the FOCP, the existing flashboard dam was replaced by an inflatable bladder dam, and mitigation was implemented by Valley Water to document ~~preserve~~ the historical significance ~~of this~~

~~feature~~ to commemorate this historical resource. The mitigation plan was developed in consultation with the SHPO and USACE, in accordance with the FOCP Programmatic Agreement. Therefore, this resource would no longer be extant by the time the Conservation Measure is constructed. Therefore, there will be no impact to this resource.

Significance Conclusion Summary

There are two built environment historical resources that could be impacted by the construction of the Project components: the Rhoades Ranch Historic District and the Santa Clara Valley Water District Dams Historic District. The parcel that contains the Rhoades Ranch Historic District minimally overlaps the Seismic Retrofit area that was previously disturbed by construction of the existing dam. The boundary of the Rhoades Ranch Historic District does not, however, include the Seismic Retrofit construction area, and there would be no direct impact on the historical resource. Atmospheric and audible elements (i.e., dust and noise) from construction would cause some impacts; however, they would be temporary and would not significantly alter the elements that contribute to the significance of the resource.

For Conservation Measure construction, the Ogier Ponds CM area and the Maintenance of the North Channel Reach ~~Extension~~ area contain no built environment resources. The Coyote Percolation Dam, which is a contributing element to the Santa Clara Valley Water District Dams Historic District, is located in the construction limits of the Phase 2 Coyote Percolation Dam CM. However, implementation of this Conservation Measure would have no impact on the dam because, prior to Project implementation, the resource will have been demolished and replaced by an inflatable bladder dam as part of FOCP.

Therefore, the Project will have a **less-than-significant impact** to built environment historical resources, and no mitigation measures are required.

Impact CR-2: Cause a substantial adverse change in the significance of an archaeological resource (Less than significant with mitigation)

Seismic Retrofit Construction

Twelve archaeological resources (P-43-001090, P-43-001094, P-43-004082, P-43-004083, P-43-004084, P-43-004085, P-43-004086, AD-2022-02, AD-2022-03, AD-2022-04, AD-2022-05, AD-2022-06) are located within the reservoir inundation area of the Seismic Retrofit Project Area (**Table 3.6-5** ~~**Table 3.6-2**~~). Three of the resources (P-43-001094, P-43-004083, P-43-004085) have been formally evaluated and determined eligible for the NRHP/CRHR and, thus, are considered historical resources; two of these resources (P-43-004083, P-43-004085) contain midden deposits and human remains, while the third (P-43-001090) is a midden deposit without human remains. Three of the archaeological resources (P-43-004082, P-43-004084, P-43-004086) in the reservoir inundation area of the Seismic Retrofit Project Area have been formally evaluated and determined not eligible for the NRHP/CRHR and, thus, do not qualify as historical resources or unique archaeological resources. The additional six archaeological resources (P-43-001090, AD-2022-02, AD-2022-03, AD-2022-04, AD-2022-05, AD-2022-06) within the reservoir inundation area of the Seismic Retrofit Project Area have not been formally evaluated for NRHP/CRHR-eligibility for the purpose of this analysis, these six resources are considered eligible for listing in the NRHP and CRHR and are, therefore, considered historical resources.

~~Five~~ Six archaeological historical resources (P-43-001094, P-43-004085, AD-2022-03, AD-2022-05, AD-2022-06, AD-HS-01) are in the Seismic Retrofit component construction Project Area[9] and have the potential to be impacted by construction activities, while four archaeological historical resources (P-43-001094, P-43-004083, AD-2022-02, AD-2022-04) within the reservoir inundation area of the Seismic Retrofit Project Area are outside the construction area and would not be impacted by construction activities.

~~Three~~ Four of the six ~~five~~ archaeological historical resources (P-43-001090, AD-2022-03, AD-2022-06, AD-HS-01) in the construction area are in areas identified for stockpiling soil during construction or within a staging area would be directly impacted by the Project. The placement of stockpile areas, which require ground preparation such as grading, on these historical resources, in addition to other related impacts from Seismic Retrofit component construction activities (i.e., access or haul roads), may cause substantial adverse changes to the significance of these resources.

One archaeological historical resource (P-43-004085) is located in the reservoir footprint adjacent to a proposed soil stockpile area that has been designed to avoid the resource; thus, the Project will have no impact on this historical resource. AD-2022-05, while located in the Project construction area, is located outside of any construction-related activities and would not be impacted by the Project.

Not all archaeological sites are visible on the ground surface and can be discovered during construction activities. The entire Seismic Retrofit component would result in a large area of ground disturbance for a duration of 5 years over a large area at the dam site, just downstream of the dam, and within the reservoir, as demonstrated by the list of Seismic Retrofit components found in **Table 2-1** and detailed in Section 2.5. Ground-disturbing activities would include preparation of construction staging/stockpiling/borrow areas and access roads, dam excavation and reconstruction, road realignments, and installation of infrastructure such as pipelines, electric power lines, and fiber optic telecommunication lines. Previously undiscovered archaeological sites, including midden deposits and human burials, may be unearthed during Project construction. BMP CU-1 (Accidental Discovery of Archaeological Artifacts or Burial Remains) would reduce this impact, but the inadvertent discovery of such resources could result in a substantial adverse change in the significance of archaeological resources that could meet the criteria for NRHP/CRHR-eligibility or qualify as unique archeological resources.

Based on the above analysis, impacts to known and undiscovered archaeological resources would be significant. Implementation of **Mitigation Measures CR-1, CR-2,** and **CR-3** would reduce these impacts to archaeological resources during construction activities in the Seismic Retrofit study area. **Mitigation Measure CR-1**, Preconstruction Cultural Resources Awareness Training, will require that construction personnel are made aware of the potential for disturbing archaeological remains and provide training on how to identify archaeological remains if they are uncovered during ground-disturbing activities. Although archaeological and tribal monitors will be present in areas considered sensitive for buried remains, they will not be present at all locations at all times. Application of **Mitigation Measure CR-1** requires that discovered archaeological remains be treated appropriately by construction personnel. **Mitigation Measure CR-2**, Prepare a Data Recovery and Treatment Plan for Historical Resources that cannot be

[9] The Seismic Retrofit construction area within Anderson Reservoir (579 acres) is smaller than the overall Seismic Retrofit Project Area (1142 acres).

Avoided, requires that archaeological historical resources that cannot be avoided by construction are treated according to each site's significant characteristics and according to the requirements of CEQA. **Mitigation Measure CR-3**, Prepare a Monitoring and Unanticipated Discoveries Plan, will provide for archaeological and Native American monitors in areas sensitive for buried cultural deposits to ensure that any materials discovered during construction are treated and evaluated appropriately. The mitigation measure will also detail the protocols to be followed by onsite personnel should buried materials be unearthed. Application of these mitigation measures would therefore reduce impacts in the Seismic Retrofit area to less than significant with mitigation.

Conservation Measures Construction

Five archaeological sites (described in Section 3.6.3.2) considered to be historical resources are present within the Ogier Ponds CM area. Two of the sites (P-43-000176, P-43-001001) are pre-contact Native American sites, and the remaining three sites (ADKS01, ADKS02, ADKS03) are of the post-contact historic era. None of the sites have previously been evaluated for NRHP/CRHR-eligibility and are considered historical resources for the purpose of the EIR. All but one of the sites (P-43-001001), which is outside any areas of planned construction, could be impacted by construction activities for this Conservation Measure, ranging from floodplain development to berm and trail/road development and construction staging. Any of these actions, all of which would require ground disturbance, could cause substantial adverse changes to the significance of these archaeological historical resources.

Two archaeological sites are located within the area of the Phase 2 Coyote Percolation Dam CM. Both sites are precontact deposits; one site (P-43-000189) has been determined eligible for the NRHP/CRHR, while the second site (P-43-001814) has not yet been evaluated for NRHP/CRHR-eligibility, though no surface evidence of either site was observed during archaeological pedestrian surveys and P-43-001814 was previously recorded as being destroyed by construction of the Coyote Percolation Dam and will, thus, not be impacted by Project activities. P-43-000189 is largely recorded outside the Conservation Measure boundary. Furthermore, the portion of the site within the Conservation Measure limits is below an existing access road and will not be further disturbed by construction activities. Because P-43-000189 is buried beneath an access road, there will be a less-than-significant impact on this resource by construction of the Phase 2 Coyote Percolation Dam CM.

Because archaeological resources are not always visible on the ground surface, ground-disturbing construction activities that involve ground disturbance at any of the Conservation Measure sites (Ogier Ponds CM, Phase 2 Coyote Percolation Dam CM, and the Maintenance of the North Channel Reach ~~Extension~~) could uncover cultural resources that meet the criteria for NRHP/CRHR-eligibility or qualify as unique archaeological resources. Examples of such construction activities include, but are not limited to, grading for haul roads and staging areas, excavation and grading for infrastructure construction, and clearing and grubbing of vegetation for channel restoration. BMP CU-1 (Accidental Discovery of Archaeological Artifacts or Burial Remains) would reduce this impact, but the inadvertent discovery of such resources could result in a substantial adverse change in the significance of archaeological resources that could meet the criteria for NRHP/CRHR-eligibility or qualify as unique archeological resources.

Based on the above analysis, impacts to known and undiscovered archaeological resources would be significant. Potential impacts to archaeological historical resources within the Conservation

Measure construction areas would be less than significant with the implementation of **Mitigation Measures CR-1, CR-2,** and **CR-3**. Implementation of **Mitigation Measure CR-1** (Preconstruction Cultural Resources Awareness Training) will require construction crews to receive awareness training for identifying archaeological materials uncovered during ground disturbance. **Mitigation Measure CR-2** (Prepare a Data Recovery and Treatment Plan for Historical Resources that Cannot be Avoided) will require that a Data Recovery and Treatment Plan be prepared for those historical resources that cannot be avoided by construction. **Mitigation Measure CR-3** (Prepare a Monitoring and Unanticipated Discoveries Plan) will require that work stop in the vicinity of any archaeological materials discovered during Project construction, and that a Monitoring and Unanticipated Discoveries Plan will provide protocols for monitoring and treating archaeological deposits discovered during construction. Application of these mitigation measures would therefore reduce impacts in the Conservation Measure area to less than significant with mitigation.

Post-Construction Anderson Dam Facilities Operations

Overall, post-construction operations of the reservoir would be largely similar to the Pre-FERC Order Conditions Baseline, with the addition of FAHCE rule curves and pulse flows and a higher reservoir elevation due to lifting of Pre-FERC Order ~~seismic~~ restrictions. Operations of the reservoir could impact the nine archaeological sites that are considered historical resources within the reservoir inundation area. The initial re-filling of the reservoir and future fluctuating water levels resulting from reservoir operations would cause sheet erosion, shoreline erosion, siltation, and the decomposition of exposed organic remains contained in some archaeological sites. As water levels rise and fall, erosion would also cause artifacts within the soil matrix of archaeological sites to move. The location of the resources within the fluctuation zone would determine how frequently the site is inundated, exposed, or subject to both inundation and exposure on an annual basis. Archaeological sites at higher elevations are inundated only when the reservoir is near capacity, while archaeological sites at lower elevations are exposed when the reservoir is drawn down below normal levels. Archaeological sites at middle elevations are often inundated and exposed during the same year as those at low levels. Archaeological sites containing organic material are highly susceptible to the effects of inundation, exposure, and wave action, whereas sites containing isolated bedrock mortars remain reasonably intact in spite of regular inundation. At lower elevations, some archaeological sites have conceivably been buried under silt accumulating in the reservoir.

The return of recreational power boating to the reservoir would also cause wave action that would similarly impact archaeological sites. This may significantly impact the archaeological historical resources that are known to be within Anderson Reservoir.

All of these actions could cause substantial adverse effects on the significance of historical resources archaeological sites that are located in the reservoir inundation area.

The flow regime in Coyote Creek downstream of Anderson Dam would be modified from the Pre-FERC Order Conditions Baseline but would not result in substantial increases in erosion and related geomorphic processes (See Section 3.8, *Geology and Soils*) that would result in substantial adverse changes to archaeological historical resources. As a result, there would likely be a less-than-significant impact to both known and unknown archaeological resources that are historical resources in the downstream region of the Seismic Retrofit area.

The implementation of a Monitoring and Unanticipated Discoveries Plan prepared under **Mitigation Measure CR-3** will require that archaeological sites that are historical resources within the reservoir fluctuation zone be routinely monitored, and appropriate treatments will be applied, as necessary. Implementation of **Mitigation Measure CR-3** would, thus, reduce impacts to archaeological historical resources caused by Project operations to less than significant with mitigation.

Significance Conclusion Summary

Archaeological resources that have been determined to be eligible for listing for the NRHP/CRHR through formal evaluation, or that have not been formally evaluated but are assumed eligible for the purpose of this analysis, are located in the Project's Seismic Retrofit Project Area, and within the boundaries of the Ogier Ponds CM and the Phase 2 Coyote Percolation Dam CM. Ground disturbance during construction at archaeological resources in both the Seismic Retrofit construction area and the Ogier Ponds CM areas could have significantly impact elements of sites that contribute to their NRHP/CRHR-eligibility.

In addition, even with implementation of BMP CUL-1, undiscovered archaeological historical resources could be significantly impacted by Seismic Retrofit or Conservation Measure construction. Erosion and recreational power boating within Anderson Reservoir related to the operation of the Seismic Retrofit component of the Project could create wave action along the exposed shoreline of the reservoir as the reservoir is refilled after Project completion, during the regular rise and fall of the reservoir due to Project operation and the resumption of recreational boating. These actions may erode archaeological historical resources and displace the artifacts within them.

For these reasons, the Project may cause substantial adverse changes to the significance of both known and undiscovered archaeological resources that are considered historical resources, and, therefore, these impacts are significant. BMP-CUL-1 (Accidental Discovery of Archaeological Artifacts or Burial Remains) will require that work will cease in areas where archaeological materials are discovered during construction until the finds can be analyzed and evaluated for NRHP/CRHR-eligibility, if appropriate, and that any eligible resources will either be avoided or subject to data recovery studies. **Mitigation Measure CR-1** (Preconstruction Cultural Resources Awareness Training) will provide construction workers with awareness training about the nature of archaeological materials that might be discovered during ground disturbing activities and the protocols to be followed, should they be found. **Mitigation Measure CR-2** (Prepare a Data Recovery and Treatment Plan for Historical Resources that cannot be Avoided) will develop and implement a Data Recovery and Treatment Plan for archaeological resources that cannot be avoided. Lastly, **Mitigation Measure CR-3** (Prepare a Monitoring and Unanticipated Discoveries Plan) will require an archaeological and tribal monitor in areas sensitive for cultural resources during Project construction, the monitoring of sensitive areas during Project operations, and will implement protocols of the Monitoring and Unanticipated Discoveries Plan should archaeological materials be discovered. With implementation of these mitigation measures, substantial adverse changes in the significance of an archaeological resource would not occur, and significant impacts to archaeological historical resources within the Project Seismic Retrofit and Conservation Measure areas would be reduced to **less than significant with ~~through~~ mitigation**.

Mitigation Measures

CR-1 Preconstruction Cultural Resources Awareness Training

Valley Water will provide a cultural resources awareness training program to all construction personnel within the various construction areas during earth moving activities throughout the duration of Project construction. The training will be conducted in person, or via a video or PowerPoint presentation to be viewed by all construction personnel involved in ground-disturbing activities prior to working on the Project. The training will be developed and conducted in coordination with a qualified archaeologist who meets the U.S. Secretary of the Interior Professional Qualifications Standards for Archeology, as well as a representative from culturally affiliated California Native American Tribe(s) who have participated in consultations with Valley Water. The program will include relevant information regarding sensitive cultural resources (including human remains and burials), applicable regulations, protocols for avoidance, and consequences of violating state laws and regulations. The worker cultural resources awareness program will also describe appropriate avoidance and minimization measures for resources that have the potential to be located within the Project construction area and will outline what to do and whom to contact if any potential archaeological resources, human remains and burials, or artifacts are encountered. The program will emphasize the requirement of confidentiality and culturally appropriate treatment of any finds of significance to Native Americans, and behaviors consistent with Native American Tribal values.

CR-2 Prepare a Data Recovery and Treatment Plan for Historical Resources that cannot be Avoided

The preferred treatment for impacts to archaeological sites, including those identified as Tribal cultural resources, is avoidance, as directed under *CEQA Guidelines* 15126.4(b)(3)(b)(1) and PRC 21084.3. Valley Water has designed the Project to avoid archaeological sites that are historical resources, where feasible; however, not all archaeological sites could be avoided by design. As a result, a Data Recovery and Treatment Plan will be prepared by a qualified archaeologist who meets the U.S. Secretary of the Interior Professional Qualifications Standards for Archeology, to address impacts to those archaeological historical resources that cannot be avoided by Project construction. The Data Recovery and Treatment Plan will be developed consistent with requirements in PRC Section 21083.2 and Section 15126.4(b) of the *CEQA Guidelines*. The Data Recovery and Treatment Plan will include a research design to identify research questions as the focus of data recovery efforts, as well as detail the field and laboratory methods to address the questions. The Data Recovery and Treatment Plan will also include a specific discussion of the methods and level of effort at each site for data recovery excavations, which are an acceptable form of mitigation under Section 15126.4(b)(3)(c) of the *CEQA Guidelines*. Specific plans for Native American sites will be prepared in consultation with Native American Tribes who participated in EIR Tribal consultation. Valley Water will require that data recovery and treatment be scheduled such that the actions will be completed in advance of construction involving impacted sites. The Data Recovery and Treatment Plan protocols will also be used for addressing accidental discoveries, as discussed in **Mitigation Measure CR-3**.

The Plan will specify that if human remains are discovered, procedures for notification of the County Coroner and for the disposition of Native American human remains under Health and Safety Code Section 7050.5 and PRC Section 5097.5 will be followed.

CR-3 Prepare a Monitoring and Unanticipated Discoveries Plan

Valley Water will prepare a Monitoring and Unanticipated Discoveries Plan in consultation with participating Native American Tribes prior to the initiation of Project construction. The Monitoring and Unanticipated Discoveries Plan will provide that a qualified archaeologist will monitor ground disturbance (e.g., grading, trenching, vegetation clearing and grubbing with a backhoe or other mechanical methods, etc.) in all areas sensitive for archaeological sites, such as those adjacent to Coyote Creek or other water sources. Valley Water will coordinate with participating Native American Tribes to retain a tribal monitor to work in tandem with the archaeological monitor. Monitoring will take place at locations within 50 feet of known archaeological historical resources and at locations identified as cultural resource environmentally sensitive areas in the Plan. Monitoring will also occur in areas identified by the archaeological principal investigator as sensitive for buried archaeological deposits. Protocols for monitoring, such as scheduling, personnel responsibilities, chain of command, and reporting, will be detailed in the Monitoring and Unanticipated Discoveries Plan.

The Monitoring and Unanticipated Discoveries Plan will also address the accidental discovery of archaeological resources and incorporate the guidelines of BMP CU-1(accidental discovery of archaeological artifacts or burial remains), including issuance of a stop work order and establishment of a no work zone in the immediate vicinity of the find. The area of the discovery will be flagged to delineate the boundary of the sensitive zone. If either an archaeological or Tribal monitor are not present at the time of the discovery, a qualified archaeologist, who meets the U.S. Secretary of the Interior Professional Qualifications Standards for Archeology, will visit the discovery site, as soon as practicable for identification and evaluation pursuant to Section 21083.2 of the PRC and Section 15064.5 of the *CEQA Guidelines*. If the archaeologist determines that the archaeological find is not a “historical” or “unique archaeological” resource and thus not significant, construction may resume. If the archaeologist determines that the archaeological find is significant, the archaeologist will determine if the find can be avoided and, if so, will detail avoidance procedures. If the archaeological find cannot be avoided, the archaeologist will develop an Action Plan within 48 hours which will include provisions to minimize impacts and, if required, a Data Recovery and Treatment Plan that will follow the protocols outlined in the Data Recovery and Treatment Plan described in **Mitigation Measure CR-2**.The Plan will specify that if human remains are discovered, procedures for notification of the County Coroner and for the disposition of Native American human remains under Health and Safety Code Section 7050.5 and PRC Section 5097.5 will be followed.

Valley Water will also retain a qualified archaeologist to implement monitoring every five years of the vicinity of the nine archaeological sites that are historical resources within the reservoir fluctuation zone, including the two sites that are known to contain human remains (P-43-004083, P-43-004085). A Data Recovery and Treatment Plan will be prepared for any sites exposed by reservoir fluctuations. The Plan will specify that any remains exposed during reservoir fluctuations will be treated consistent with Health and Safety Code Section 7050.5 and PRC Section 5097.5 procedures, and in accordance with the desires of the culturally affiliated California Native American Tribes. The specifics of the monitoring and treatment protocols will be developed in consultation with participating Tribes and also detailed in the Monitoring and Unanticipated Discoveries Plan.

Impact CR-3: Disturb human remains **(Less than significant with mitigation)**

Seismic Retrofit Construction

Two archaeological sites (P-43-004083, P-43-004085) within the reservoir pool portion of the Seismic Retrofit construction area are known to contain human remains. The two known sites contain midden deposits and were evaluated as NRHP/CRHR-eligible. P-43-004083 is within the reservoir fluctuation zone but outside the delineated construction area and would not be impacted by construction of the dam. P-43-004085 is located directly adjacent to a stockpile area. A third site, P-43-001094, contains a midden deposit and, therefore, may also contain human remains. This site, while in Anderson Reservoir, is outside the construction area and would not be impacted by Seismic Retrofit construction activities.

As previously discussed, archaeological deposits, including human remains, may not be visible on the ground surface. The large amount of earth movement required for the Seismic Retrofit construction element of the Project could uncover unknown locations that contain human burials. Such an inadvertent discovery in the Seismic Retrofit construction area could result in a disturbance of human remains.

BMP CU-1 (Accidental Discovery of Archaeological Artifacts or Burial Remains) would be implemented to require that construction be halted at the specific location in the event that human remains are discovered, and that the County Coroner and NAHC be notified to identify a most likely descendent per PRC Section 5097. **Mitigation Measures CR-1** (Preconstruction Cultural Resources Awareness Training) will provide training for construction workers about how to respectfully treat human remains, if discovered during construction. **Mitigation Measure CR-2** (Prepare a Data Recovery and Treatment Plan for Historical Resources that cannot be Avoided) will outline the treatment of human remains in the Data Recovery and Treatment Plan, while **Mitigation Measure CR-3** (Prepare a Monitoring and Unanticipated Discoveries Plan) will provide clear and detailed protocols, beyond the legislated requirements of PRC Section 5097.98, for addressing discovered human remains in the Monitoring and Unanticipated Discoveries Plan. Both the Data Recovery and Treatment Plan and the Monitoring and Unanticipated Discoveries Plan will include guidance from the California Native American Tribes who have participated in EIR Tribal consultation about how to treat Native American human remains. Mitigation measures will therefore reduce impacts to human remains to less than significant with mitigation.

Conservation Measures Construction

One site, P-43-000189, within the Phase 2 Coyote Percolation Dam CM site is known to contain human remains. A majority of this site is located outside of the Conservation Measure boundary and is underneath US 101, where a number of burials were removed during excavations in the early 1980s to support the construction of the then-new highway alignment (Izzi and Sisken 2023). The portion of the site within the Phase 2 Coyote Percolation Dam CM area is beneath an existing access road. No evidence of human remains, or the site itself, was observed during the archaeological pedestrian survey. The site area would not be disturbed by construction activities, and therefore there would be a less-than-significant impact to known human remains at site P-43-000189 from construction of the Phase 2 Coyote Percolation Dam CM.

Unknown human remains could be uncovered during the course of ground-disturbing construction activities at any of the Conservation Measure locations (Ogier Ponds CM, Phase 2

Coyote Percolation Dam CM, and Maintenance of the North Channel Reach ~~Extension~~). Examples of such construction activities include, but are not limited to, grading for haul roads and staging areas, excavation and grading for infrastructure construction, and clearing and grubbing of vegetation for channel restoration.

Impacts to human remains within the Conservation Measure construction areas would be reduced by implementation of BMP CU-1 (Accidental Discovery of Archaeological Artifacts or Burial Remains). These impacts will be further reduced, to less-than-significant levels, by **Mitigation Measures CR-1** (Preconstruction Cultural Resources Awareness Training), **Mitigation Measure CR-2** (Prepare a Data Recovery and Treatment Plan for Historical Resources that cannot be Avoided), and **Mitigation Measure CR-3** (Prepare a Monitoring and Unanticipated Discoveries Plan). These measures will each require that excavation stop if human remains were discovered and that the County Coroner and NAHC are contacted. In addition, under **Mitigation Measure CR-1**, the construction crew will receive awareness training regarding the respectful treatment of human remains uncovered during ground disturbance. Furthermore, a Data Recovery and Treatment Plan will be prepared and executed under **Mitigation Measure CR-2**, which would detail protocols for treatment of human remains discovered during data recovery. Finally, a Monitoring and Unanticipated Discoveries Plan prepared under **Mitigation Measure CR-3** will provide protocols for monitoring and treating human remains discovered during construction of the Conservation Measures.

Post-Construction Anderson Dam Facilities Operations

Overall, post-construction operations of the reservoir would be largely similar to the Pre-FERC Order Conditions Baseline, with the addition of FAHCE rule curves and pulse flows and a higher reservoir elevation due to lifting of Pre-FERC Order ~~seismic~~ restrictions. The filling of the reservoir and future water level fluctuations could impact the two archaeological sites within the reservoir known to contain human remains (P-43-004083, P-43-004085) and the one archaeological site with midden that has a high potential to contain as-yet undiscovered human remains (P-43-001094). The erosional impacts of fluctuating reservoir levels would generally be similar to the Pre-FERC Order Conditions Baseline, as has been described under Impact CR-2. The return of recreational power boating would also cause wave actions that could cause significant erosion and displacement of exposed human remains.

One site with human remains, P-43-004083, is located at the highest elevations of the fluctuation zone with only a small portion of the site directly within the reservoir pool; thus, the site would be impacted only when the reservoir is at maximum capacity. The second site, P-43-004085, is similarly situated but extends much further into the reservoir pool and would have a greater potential to be exposed to erosion impacts by annually fluctuating water levels and power boating. Site P-43-001094 is fully within the reservoir pool and would also be subject to these operational impacts. As a result, Seismic Retrofit operations could disturb archaeological deposits with known human remains and deposits with a potential to contain human remains.

Furthermore, erosion from reservoir operations, including power boating, could uncover currently buried archaeological sites with unknown human remains that could significantly impact these resources.

No human remains are known to exist along Coyote Creek in the Project Area downstream of Anderson Dam. As a result, there would be no impact to known human remains in the downstream region of the Seismic Retrofit area due to operation of the reservoir. Although the area downstream of Anderson Dam has a high potential for containing buried archaeological resources, changes to the flow regime in Coyote Creek would not result in substantial increases to erosion and related geomorphic processes (See Section 3.8, *Geology and Soils*) after implementation of the FOCP that would result in substantial adverse changes to the significance of human remains. As a result, there would likely be no impact to human remains in the downstream region of the Seismic Retrofit Project Area. The implementation of a Monitoring and Unanticipated Discoveries Plan prepared under **Mitigation Measure CR-3** requires Valley Water to install a program for regular monitoring of sites in the fluctuation zone of the reservoir, which is known to contain human remains, and treat any finds consistent with the protocols detailed in the Monitoring and Unanticipated Discoveries Plan. Should archaeological resources containing human remains be uncovered by erosion through releases of water due to post construction operations of the reservoir as a result, implementation of **Mitigation Measure CR-3** would reduce impacts caused by reservoir operations to human remains to less than significant.

Significance Conclusion Summary

Two archaeological sites with human remains and one with a high potential to contain as-yet unidentified human remains are known to exist within Anderson Reservoir. All three of these sites in the reservoir could be damaged by erosion from fluctuating water levels during Seismic Retrofit operations, as well as by wave action caused by power boating. In addition, both construction activities anywhere in the Seismic Retrofit area and erosion in Anderson Reservoir through Project operations have the potential to uncover sites with burials and significantly impact those resources. Therefore, Project impacts on disturbance of human remains would be significant.

An archaeological site with human remains has also been recorded within the boundaries of the Phase 2 Coyote Percolation Dam CM. However, this site is currently under an access road and construction of this Conservation Measure will not impact the site.

Compliance with Health and Safety Code Section 7050.5 and PRC Section 5097.98 would reduce impacts related to disturbance of human remains.

Mitigation Measure CR-1 (Preconstruction Cultural Resources Awareness Training) will require that workers on the Project are made aware of the extreme sensitivity of exposed human remains and how to treat them appropriately, if encountered. **Mitigation Measure CR-2** (Prepare a Data Recovery and Treatment Plan for Historical Resources that cannot be Avoided) will also require that a Data Recovery and Treatment Plan be implemented for sites that cannot be avoided. Erosion due to fluctuations from the operation of the reservoir cannot be avoided, but application of the **Mitigation Measure CR-3** (Prepare a Monitoring and Unanticipated Discoveries Plan) will monitor erosion at in the vicinity of known sites with the potential for human remains and treat exposed human remains appropriately. These mitigation measures will reduce impacts to disturbing human remains to **less than significant with mitigation**.

Mitigation Measures

CR-1 Preconstruction Cultural Resources Awareness Training

CR-2 Prepare a Data Recovery and Treatment Plan for Historical Resources that cannot be Avoided

CR-3 Prepare a Monitoring and Unanticipated Discoveries Plan

3.6.6 Cumulative Cultural Resources Impacts

The geographic study area for the cumulative impact analysis for Cultural Resources encompasses Project Areas where ground-**Table 3.6-9**.

Cumulative impact thresholds for aesthetics are the same as the impact thresholds presented above in Section 3.6.4.7, *Thresholds of Significance*.

Table 3.6-9. Summary of Project Impact Contribution to Cumulative Aesthetic Impacts

Impact	Cumulatively Considerable with FOCP?	Cumulatively Considerable with other projects?	Incremental Project Contribution	Applicable Project Mitigation	Cumulatively Considerable after Mitigation?
Cumulative Impact CR-1: Cause a substantial adverse change in the significance of a built environment historical resource	No	No	NCC	None	No
Cumulative Impact CR-2: Cause a substantial adverse change in the significance of an archaeological resource	Yes	Yes	CC	MM CR-1 MM CR-2 MM CR-3	No
Cumulative Impact CR-3: Disturb Human Remains	Yes	Yes	CC	MM CR-1 MM CR-2 MM CR-3	No

Key: CC = cumulatively considerable; FOCP = FERC Order Compliance Project; MM = Mitigation Measure; N/A = not applicable; NCC = not cumulatively considerable; S = significant

Cumulative Impact CR-1: Cause a substantial adverse change in the significance of a built environment historical resource **(Not Cumulatively Considerable)**

There are two built environment historic resources that could be impacted by the construction of the Project components. The parcel that contains the Rhoades Ranch Historic District minimally overlaps the Seismic Retrofit. The boundaries of the Rhoades Ranch Historic District are, however, outside the Seismic Retrofit construction area, and there will be no direct impact to the historic resource. The Coyote Percolation Dam, which is a contributing element to the Santa Clara Valley Water District Dams Historic District, is in the construction limits of the Phase 2 Coyote Percolation Dam CM. However, implementation of this Conservation Measure would have no impact to the dam, because, prior to Project implementation, the resource will have been demolished and replaced an inflatable bladder dam as part of FOCP.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if they create impacts in a manner that progressively reduces the significance of the resource.

Cumulative effects of Project with the FOCP

As noted in the analysis, the Project would result in indirect impacts to the Rhoades Ranch Historic District, such as noise and dust. The FOCP also caused similar indirect impacts on the resource and used a staging area on a lot on the opposite side of Cochrane Road similar to the Project. However, these impacts are temporary and would not alter the elements that contribute to the significance of the resource. There would be no cumulative impact when Project impacts are added to FOCP impacts.

Cumulative effects of Project with Probable Future Projects, Programs, and Plans

The Cochrane–Borello Residential Development Project constructed single-family residences on a 122-acre parcel west and south of the Rhoades Ranch Historic District between 2017 and 2021. The Cochrane–Borello parcel had historically been used for agricultural purposes, most recently as orchards. Development of this residential project altered the agricultural setting of the historic district that contributed to the character-defining features of the historical resource.

The Draft EIR for the Cochrane–Borello Project discussed the proximity of the project to the historic district and concluded that the space between the development and the primary buildings of the Rhoades Ranch created a sufficient buffer “to maintain the rural setting of the landmark property” and hence, that project had a less-than-significant impact on the Rhoades Ranch Historic District (City of Morgan Hill 2012~~b~~). This analysis assumed that other elements of the Rhoades Ranch’s agricultural and natural setting would remain following construction of the Cochrane–Borello project. There would be a less-than-significant cumulative impact when Project impacts are added to Cochrane–Borello Project impacts.

Significance Conclusion Summary

Construction of the new dam would not significantly alter the current viewshed of the historical resource and would not alter the physical characteristics of the Rhodes Ranch Historic District such that its historic integrity and ability to convey significance would be diminished. Realignment of Cochrane Road would not impact the parcel. Establishment of a staging area adjacent to the property, but on the opposite side of Cochran Road at Anderson Lake County Park, would likely increase noise and dust levels, but these impacts will be temporary and will not permanently alter the integrity of the site. Overall, the cumulative impact on built environment historic resources would not be significant, and the Project's contribution would be **not cumulatively considerable**.

Mitigation Measures

No mitigation is required.

Cumulative Impact CR-2: Cause a substantial adverse change in the significance of an archaeological resource **(Not Cumulatively Considerable)**

Ground disturbance during construction at the Seismic Retrofit construction area and the Ogier Ponds CM areas could impact elements of sites that contribute to their NRHP/CRHR eligibility. Erosion and recreational power boating within Anderson Reservoir could erode archaeological resources buried along the shoreline of the reservoir. In addition, construction activities and future use of reservoir could expose undiscovered resources.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if they create impacts in a manner that progressively reduces the significance of the resource.

Cumulative effects of Project with the FOCP

The reservoir was drawn down, as part of the FOCP, which could expose archaeological resources and make them vulnerable to damage. The Project would extend the period that the reservoir is drained and exposed resources in the reservoir are vulnerable to loss or damage. This impact is cumulatively significant.

Both projects create similar risks to the loss or destruction of undiscovered archaeological resources through ground disturbance and construction activities that would result in a cumulatively significant impact.

Cumulative effects of Project with Probable Future Projects, Programs, and Plans

Other projects that take place along Coyote Creek, such as the SMP, Coyote Creek Flood Protection Project, and the County Parks Planning Projects and Natural Resource Management, where ground-disturbing activities may take place in or near the creek bed, could result in similar impact to undiscovered archaeological resources as the Project. Cumulative impacts would be significant.

Significance Conclusion Summary

The Project may cause considerable impacts to the significance of both known and undiscovered archaeological resource that are considered historical resources. BMP-CUL-1 (Accidental Discovery of Archaeological Artifacts or Burial Remains) will reduce these impacts by requiring that work will cease in areas where archaeological materials are discovered during construction until the finds can be analyzed and evaluated for NRHP/CRHR-eligibility, if appropriate, and that any eligible resources will either be avoided or subject to data recovery studies.

Mitigation Measure CR-1 (Preconstruction Cultural Resources Awareness Training) will provide construction workers with awareness training about the nature of archaeological materials that might be discovered during ground-disturbing activities and the protocols to be followed, should they be found. **Mitigation Measure CR-2** (Prepare a Data Recovery and Treatment Plan for Historical Resources that cannot be Avoided) will develop and implement a Data Recovery and Treatment Plan for archaeological resources that cannot be avoided. Lastly, **Mitigation Measure CR-3** (Prepare a Monitoring and Unanticipated Discoveries Plan) would require an archaeological and Tribal monitor in areas sensitive for cultural resources during Project construction, the monitoring of sensitive areas during Project operations, and will implement protocols of the Monitoring and Unanticipated Discoveries Plan should archaeological materials be discovered.

Implementation of these mitigation measures would reduce the Project's incremental contribution to cumulative impacts on archaeological resources to **not cumulatively considerable**.

Mitigation Measures

CR-1 Preconstruction Cultural Resources Awareness Training

CR-2 Prepare a Data Recovery and Treatment Plan for Historical Resources that cannot be Avoided

CR-3 Prepare a Monitoring and Unanticipated Discoveries Plan

Cumulative Impact CR-3: Disturb Human Remains (Not Cumulatively Considerable)

Three archaeological sites within the reservoir pool portion of the Seismic Retrofit construction area have the potential to contain human remains. These sites have the potential to be damaged by erosion and fluctuating water levels during operation of the reservoir. A site with human remains is recorded in the boundaries of the Phase 2 Coyote Percolation Dam CM, but this site would not be impacted by the Project.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if they disturb human remains in the same area as the Project.

Cumulative effects of Project with the FOCP

The reservoir was drawn down, as part of the FOCP, which could expose known sites with human remains. The Project would extend the period that the reservoir is drained and exposed resources in the reservoir are vulnerable to loss or damage. This impact is cumulatively considerable.

Both projects create similar risks to the disturbance of undiscovered remains through ground disturbance and construction activities that would result in a cumulatively significant impact.

Cumulative effects of Project with Probable Future Projects, Programs, and Plans

Other projects that take place along Coyote Creek, such as the SMP, Coyote Creek Flood Protection Project, and the County Parks Planning Projects and Natural Resource Management, where ground-disturbing activities may take place in or near the creek bed, could result in similar disturbance to undiscovered remains. The combined impacts of probable future projects and the Project are cumulatively significant.

Significance Conclusion Summary

Cumulative impacts of the Project and other projects on human remains would be significant, the Project's contribution would be cumulatively considerable. **Mitigation Measure CR-1** (Preconstruction Cultural Resources Awareness Training) will require that workers on the Project are made aware of the extreme sensitivity of exposed human remains, and how to treat them appropriately if encountered. **Mitigation Measure CR-2** (Prepare a Data Recovery and Treatment Plan for Historical Resources that cannot be Avoided) would require that a Data Recovery and Treatment Plan be implemented for sites that cannot be avoided. Erosion due to fluctuations from the operation of the reservoir cannot be avoided, but application of the **Mitigation Measure CR-3** (Prepare a Monitoring and Unanticipated Discoveries Plan) will monitor erosion at in the vicinity of known sites with the potential for human remains and treat exposed human remains appropriately.

Implementation of these mitigation measures would reduce the Project's incremental contribution to cumulative impacts on disturbance of human remains to **not cumulatively considerable**.

Mitigation Measures

CR-1 Preconstruction Cultural Resources Awareness Training

CR-2 Prepare a Data Recovery and Treatment Plan for Historical Resources that cannot be Avoided

CR-3 Prepare a Monitoring and Unanticipated Discoveries Plan

3.7 Energy

This section evaluates the Project's impacts related to energy. The discussion included herein evaluates the Project's energy demands; provides input on construction- and operation-related energy use; and considers the Project's size, location, equipment use, and renewable energy features that could be incorporated into the Project.

The study area for energy focuses on the portions of the county, San José, and Morgan Hill that comprise the Project Area, including the construction limits of the Seismic Retrofit and Conservation Measures components.

3.7.1 Environmental Setting

3.7.1.1 Statewide and Regional Setting

Energy is generally transmitted either in the form of electricity, measured in kilowatts (kW) or megawatts (MW), or natural gas measured in British thermal units (BTU), cubic feet, or therms. Fuel, such as gasoline or diesel, is measured in gallons or liters.

With a relatively mild Mediterranean climate and strict energy efficiency and conservation requirements, California has lower energy consumption rates on a per person basis than most other parts of the country.

California relies on a regional power system composed of a diverse mix of natural gas, and renewable, hydroelectric, and nuclear generation resources. Approximately 70 percent of the electrical power needed to meet California's demand is produced in California; the balance, approximately 30 percent, is imported from the Pacific Northwest and the Southwest. In 2021, California's in-state electricity use was derived from natural gas (50 percent), coal (0.2 percent), large hydroelectric resources (6 percent), nuclear sources (9 percent), and renewable resources that include geothermal, biomass, small hydroelectric resources, wind, and solar (35 percent) (California Energy Commission [CEC] 2022a ~~2022b~~).

Electricity and natural gas in California are generally consumed by stationary users, such as residential, commercial, and industrial facilities, whereas petroleum-based fuel is generally consumed by mobile users such as vehicles (U.S. Energy Information Administration [USEIA] 2022a).

Gasoline and Diesel Fuel Generation, Demand, and Use

Fuel is used primarily for powering off-road equipment (construction and operational) and vehicles (commercial trucks and other vehicles). The typical fuel types used are diesel and gasoline.

The Northern California region produced an annual average of 6,138,527,000 ~~thousand~~ gallons of gasoline and 2,363,161,000 ~~thousand~~ gallons of diesel over the 5-year period of 2018-2022 (CEC 2023a ~~2023c~~). The energy consumed by the transportation sector accounts for roughly 85 ~~83~~ percent of California's refined petroleum products (i.e., gasoline and diesel) demand (USEIA 2022b ~~2022d~~). According to the CEC, the state relies on gasoline and diesel fuels for 98 percent of its transportation needs (USEIA 2022a, 2022b ~~2022d~~). In 2022, taxable gasoline sales (including aviation gasoline) in California accounted for approximately 12.5 billion gallons of gasoline (California State Board of Equalization [CBE] 2023a), and taxable diesel fuel sales accounted for approximately 2.8 billion gallons of diesel fuel (CBE 2023b).

The CEC forecasts show that the demand for gasoline in California will range from 12.1 billion to 12.6 billion gallons in 2030, with most of the demand generated by light-duty vehicles. While the models show an increase in light-duty vehicles along with population and income growth over the forecast horizon, total gasoline consumption is expected to decline, primarily due to increasing fuel economy (stemming from federal and state regulations) and gasoline displacement from the increasing market penetration of zero-emission vehicles (ZEV). For diesel, demand is forecast to increase modestly by 2030, following the growth of California's economy, but would be tempered by an increase in fleet fuel economy and market penetration of alternative fuels, most prominently by natural gas in the medium- and heavy-duty vehicle sectors (CEC 2018).

According to the CEC, 2021 sales of gasoline and diesel fuel in the county were 599 million gallons and 50 million gallons, respectively (CEC 2022b~~d~~). Note that the CEC only tracks fuel sales at the retail level, which allows for data to be collected on a county-by-county basis, whereas the CBE tracks all fuel sales, retail and non-retail, but only at the statewide level. Thus, the impact calculations presented in the impact analysis rely on separate data sets for comparison to the county and statewide transportation fuel consumption figures.

Electricity Generation, Demand, and Use

Electricity is used primarily for lighting, equipment, and other uses associated with building, structures, and vehicle operations. Electricity sources range from renewable (hydroelectric, solar, wind, geothermal, biomass) to nonrenewable (natural gas, petroleum, nuclear, coal).

In 2021, total system electric generation for California was 277,764 gigawatt-hours (GWh), up 2 percent from 2020's total generation of 272,576 GWh (CEC 2021a ~~2022b~~). Electricity from non-carbon dioxide (CO_2) emitting electric generation categories (i.e., nuclear, large hydroelectric, and renewable generation) accounted for 49 percent of total in-state generation.

Total system electric generation in California is predicted to increase in coming years. Factors contributing to the projected increase include greater numbers of light duty electric vehicles, increased manufacturing electricity consumption, and decreases in savings from energy efficiency programs as population increases. With regard to total consumption of electricity across all sectors, California consumed 247,250 GWh of electricity in 2021 (USEIA 2022c~~e~~). PG&E provides electrical services to most residential, commercial, industrial, and agricultural consumers in much of Northern California, including the Bay Area. In 2021, PG&E generated and/or procured a total of 33,149 GWh of electricity (PG&E 2022a). PG&E has established contracts and commitments to ensure there is adequate electricity generation and natural gas capacity to meet its current and future energy loads (PG&E 2022b). **Table 3.7-1** shows the mix of sources for PG&E's electrical supply (PG&E 2022c).

Table 3.7-1. PG&E 2021 Power Content Label

Energy Resources	PG&E 2021 Power Mix				(For Comparison)
	Base Plan	50% Solar Choice	100% Solar Choice	Green Saver	2021 California Power Mix
Eligible Renewable[1]	47.7%	70.9%	93.9%	89.9%	33.6%

Notes:

[1] The eligible renewable percentage above does not reflect Renewables Portfolio Standard compliance, which is determined using a different methodology.

[2] Unspecified power is electricity that has been purchased through open market transactions and is not traceable to a specific generation source.

[3] Numbers may not add to 100% due to rounding.

In the county, electric utility companies include PG&E, the City of Palo Alto, and Silicon Valley Power (CEC 2021b ~~2022e~~). The Project site is located within PG&E's electric service area (CEC 2021b ~~2022e~~). Silicon Valley Clean Energy (SVCE) is the official electricity provider for Morgan Hill and Unincorporated Santa Clara County, among other communities (SVCE 2020).

Table 3.7-2 provides a summary of electricity consumption in the county by residential and non-residential uses. **Table 3.7-3** provides a more detailed summary of electricity consumption by PG&E customers, sorted by sector type.

Table 3.7-2. Electricity Consumption in Santa Clara County

	Electricity Consumption by Year (GWh)							
	2014	2015	2016	2017	2018	2019	2020	2021

Notes:

The most recent year of published data is 2021.

Totals may not equal the sum of the parts due to rounding.

Key: GWh = gigawatt hours = 1 million kilowatt hours.

California law requires load-serving entities, such as PG&E, to gradually increase the amount of renewable energy they deliver to their customers to at least 33 percent of their total annual retail sales by 2020, 44 percent by 2024, 52 percent by 2027, 60 percent by 2030, 90 percent by 2035, 95 percent by 2040, and 100 percent by 2045. This program, known as the Renewables Portfolio Standard (RPS), became effective in December 2011, and has since been enhanced with the passage of Senate Bill (SB) 350, SB 100, and SB 1020. Renewable generation resources, for purposes of the RPS program, include bioenergy, small hydroelectric facilities (30 MW or less), wind, solar, and geothermal energy, and in 2021 PG&E obtained almost 50 percent of its electricity from renewable sources (PG&E 2022d).

Natural Gas Use

Natural gas is used primarily for heating and water heating and is typically associated with building operations.

One third of energy consumed in California is natural gas, which is largely imported from other regions (CEC 2019b). Californians consumed 21,728 million therms of natural gas in 2021, which is equal to approximately 2,172,800,000 million BTU (MMBTU) (USEIA 2022d ~~2022f~~). Nearly 31 percent of the natural gas burned in California is used for electricity generation, and most of the remainder is consumed in the residential (21 percent), industrial (34 percent), and commercial (11 percent) sectors.

PG&E provides natural gas service to industrial, large commercial, natural gas-fired electric generation facilities, and residential users that are connected to the gas system throughout much of Northern California, including the Bay Area. In 2021, the total consumption of natural gas in the county was 417 million therms, or 41,728,162 MMBTU (CEC 2022f ~~2022h~~), which was approximately 2 percent of California's total gas consumption.

3.7.1.2 Valley Water and Anderson Dam

Electricity Generation

Valley Water participates in the Power and Water Resources Pooling Authority (PWRPA), which consists of publicly owned electric utilities that coordinate pooling of energy resources and supplement wholesale power purchasing. PWRPA coordinates construction and maintenance of intervening facilities (e.g., transmission and distribution systems, substations, and other infrastructure) and negotiates agreements. Ninety-five (95) percent of Valley Water's purchased electricity is sourced from PWRPA, which enables Valley Water to source carbon-free electricity from utility-scale solar and hydroelectric projects (Valley Water 2021a). Since some of the sources of this carbon-free electricity are based on hydroelectric projects, it is subject to variability, especially during drought conditions. The 2021 Power Content Label for PWRPA is shown in **Table 3.7-4**.

Table 3.7-4. PWRPA 2021 Power Content Label

	PWRPA 2021 Power Mix		(For Comparison)
Energy Resources	**Standard Water Portfolio**	**Zero Carbon Water Portfolio**	**2021 California Power Mix**
Eligible Renewable[1]	11.3%	26.8%	33.6%
Biomass & Biowaste	0.0%	0.0%	2.3%
Geothermal	0.0%	0.0%	4.8%
Eligible Hydroelectric	0.5%	0.2%	1%
Solar	10.8%	26.6%	14.2%
Wind	0.0%	0.0%	11.4%
Coal	0%	0%	3%

Source: PWRPA 2022

Notes:

[1]The eligible renewable percentage above does not reflect Renewables Portfolio Standard compliance, which is determined using a different methodology.

[2]Unspecified power is electricity that has been purchased through open market transactions and is not traceable to a specific generation source.

[3]Numbers may not add to 100% due to rounding.

[4]Water portfolio is the portfolio of energy resources provided by PWRPA to its members to power operations related to water such as pumping, water delivery, etc.

Key: PWRPA = Power and Water Resources Pooling Authority

The Anderson Hydroelectric Facility was constructed in 1987 to generate energy from water released from Anderson Dam through its outlet pipe. The Anderson Hydroelectric Facility consists of two 500-kW Francis turbines and two 470-kW induction generators. ~~The potential capacity of the system is approximately 800 kW.~~ Valley Water entered into a 30-year Qualifying Facilities Power Purchase Agreement (PPA) with PG&E to sell electricity generated from the hydroelectric facility to the utility grid. Valley Water's PPA with PG&E ended in 2018, and in 2019, Valley Water opted into PG&E's Renewable Energy Self-Generation Bill Credit (RESBCT) program. This program allowed generated renewable energy to be credited towards other Valley Water accounts. Prior to opting into RESBCT, the power generated was sold to the grid. Operation of the facility stopped in 2019 and was recommended by Valley Water for decommissioning in January 2021.

Throughout the lifetime of the hydroelectric facility, the facility~~s~~ generated approximately 39,700,000 kWh of renewable energy, valued at approximately $3,000,000 ~~$2,910,000~~, with cost of operations and maintenance totaling $3,450,000 (Valley Water 2021b). The potential capacity of the system is approximately 800 kW. However, the facility has been inactive since 2019 ~~2018~~. Since 2019 ~~2018~~, there have been no plans to reactivate the hydroelectric facility given that nearly all of Valley Water's current energy use if from carbon-free sources at competitive costs; revenues from the hydroelectric facility are expected to continue to decline; and operations and maintenance costs for the facility are expected to continue to rise. Historic electricity generation from this hydroelectric facility is shown in **Table 3.7-5**.

Table 3.7-5. Anderson Hydroelectric Facility Historical Annual Production

Calendar Year	Production (kWh)	Revenue ($)	Value of Energy ($/kWh)
1988	92,500	$6,321	$0.068

Source: Valley Water 2021b

Key: kWh = kilowatt-hour

In 2021, Valley Water staff recommended pursuing FERC decommissioning of the Anderson Hydroelectric Facility as part of the Project due to its aging infrastructure, cost of operations, and maintenance. Valley Water determined that future energy investments are better used in other green energy projects with a better cost-benefit outlook (Valley Water 2021b). The hydroelectric facility primarily supplied electricity for Valley Water's own use from 1988 to 2019 ~~2018~~, which was replaced with other Valley Water owned electricity generation facilities, such as large-scale solar complexes and cooperative agreements with other facilities under PWRPA.

Electricity Use

Valley Water prepared an Energy Audit Report in February 2013 that focused on electrical energy use at key load centers within Valley Water (~~SCVWD~~ Valley Water 2013~~a~~). The audit included a review of energy consumption and production data for 2009, 2010, and 2011, as these years were considered to be representative of typical years and did not include extreme wet or dry years. The Advanced Water Purification Facility was not included in the audit, since it did not start operation until 2013 and did not have any historical operating data. The Advanced Water Purification Facility was estimated to utilize 8 million kWh of electrical energy per year if operated at its intended production capacity. Valley Water's annual average electricity consumption for water treatment plants and pumping plants is shown below in **Table 3.7-6**. As shown in **Table 3.7-6**, annual electricity consumption for Valley Water facilities is 49,605,362 kWh. The Pacheco Pumping Plant utilized the highest amount of electricity among the pumping plants, and the Rinconada Water Treatment Plan utilized the highest amount of electricity among the water treatment plants. The Rinconada Water Treatment Plan utilized the highest amount of electricity because it has treated water pumping, while the Penitencia Water Treatment Plan and Santa Teresa Water Treatment Plan have no booster pumping.

Table 3.7-6. Valley Water Facilities Annual Electricity Consumption

Facility	Annual Average Electricity Consumption (kWh)[1]
Penitencia Water Treatment Plant	1,727,104
Santa Teresa Water Treatment Plant	2,082,826
Rinconada Water Treatment Plant	6,593,342
Pacheco Pumping Plant	30,564,327
Coyote Pumping Plant (Project Power)[2]	3,436,160
Coyote Pumping Plant (PWRPA Power)[3]	259,509
Vasona Pumping Plant	257,170
Non-Process Buildings	4,684,925
Total	**49,605,362**

Source: Valley Water 2013

Notes

[1] The annual average electricity consumption for all Valley Water facilities, except for non-process buildings, is the average annual consumption based on total electricity consumption from 2009 to 2011.

[2] Project power is when pumping raw water from San Luis reservoir to Santa Clara County.

[3] PWRPA power is when pumping raw water to and from Anderson reservoir.

Gasoline and Diesel Use

Valley Water prepared a Liquid Fuels Analysis in February 2013 that assessed Valley Water's mobile equipment use of gasoline and diesel fuel (~~SCVWD~~ Valley Water 2013~~b~~). Valley Water consumed approximately 66,300 gallons of gasoline and 2,100 gallons of diesel in 2012, or 68,700 gallons of gasoline equivalent. Based on the cost of gasoline and diesel, Valley Water spent approximately $212,000 on gasoline and $7,000 on diesel, for a total cost of $219,000.

Natural Gas Use

According to Valley Water's Energy Audit Report, during the three-year period from 2009 to 2011, natural gas represented approximately four percent of total energy costs for Valley Water's water treatments plants and pumping plants. Non-process buildings utilized an average of 96,102 therms of natural gas at an average annual cost of $90,665.

3.7.2 Regulatory Setting

3.7.2.1 Federal Laws, Regulations, and Policies

Federal Vehicle Emissions Standards

In 1975, Congress enacted the Energy Policy and Conservation Act, which established the first fuel economy standards for on-road motor vehicles in the United States. Pursuant to the act, the USEPA and NHTSA are responsible for establishing additional vehicle standards. In August 2012, standards were adopted for model year 2017 through 2025 for passenger cars and light-duty trucks. Notably, the State of California harmonized its vehicle efficiency standards through 2025 with the federal standards through the Advanced Clean Cars Program.

In March 2022, CAFE standards were finalized for model years 2024 through 2026. The final rule establishes standards that require an industry-wide fleet average of approximately 49 miles per gallon (mpg) for passenger cars and light trucks. Current rulemaking is working on establishing (NHTSA 2022):

- standards for model years 2027 and beyond for passenger cars and light trucks
- fuel efficiency standards for model years 2029 and beyond for heavy-duty pickup trucks and vans
- fuel efficiency standards for model years 2030 and beyond for medium and heavy-duty on-highway vehicles and work trucks

Federal Power Act

The FERC has the power to regulate hydroelectric facilities and dams under the Federal Power Act (FPA). The FPA was enacted in 1920 to establish a regulatory framework for the development of hydropower in the United States. FERC's responsibilities include authorizing the construction of hydroelectric facilities and overseeing these facilities' operation and safety.

Energy Policy Act of 2005

The Energy Policy Act of 2005 seeks to reduce reliance on non-renewable energy resources and provide incentives to reduce current demand on these resources. For example, under the Energy Policy Act, consumers and businesses can attain federal tax credits for purchasing fuel-efficient appliances and products. Businesses are eligible for tax credits for buying hybrid vehicles, building energy-efficient buildings, and improving the energy efficiency of commercial buildings. Additionally, tax credits are given for the installation of qualified fuel cells, stationary microturbine power plants, and solar power equipment. The Energy Policy Act of 2005 also established the first renewable fuel volume mandate in the United States. The original Renewable Fuel Standard program required 7.5 billion gallons of renewable fuel to be blended into gasoline by 2012.

Under the Energy Independence and Security Act of 2007, the Renewable Fuel Standard program was expanded to include diesel and to increase the volume of renewable fuel required to be blended into transportation fuel from 9 billion gallons in 2008 to 36 billion gallons by 2022.

USEPA and NHTSA Joint Rulemaking for Vehicle Standards

In April 2010, the USEPA and NHTSA issued a final rulemaking establishing new federal GHG and fuel economy standards for model years 2012 to 2016 passenger cars, light-duty trucks, and medium-duty passenger vehicles. In addition, on August 9, 2011, the USEPA and NHTSA finalized regulations to reduce GHG emissions and improve fuel efficiency of medium- and heavy-duty vehicles, including large pickup trucks and vans, semi-trucks, and all types and sizes of work trucks and buses. In subsequent rulemakings the agencies extended the national program of fuel economy standards to passenger vehicles and light-duty trucks of model years 2017-2025, culminating in fuel economy of 54.5 mpg by model year 2025 (USEPA 2012), as well as to medium- and heavy-duty vehicles of model years 2014-2018, including large pickup trucks and vans, semi-trucks, and all types and sizes of work trucks and buses (USEPA and U.S. Department of Transportation [USDOT] 2011).

The USEPA and NHTSA updated CAFE and GHG emissions standards for passenger cars and light trucks and established new standards, covering model years 2021 through 2026, under the Safer Affordable Fuel Efficient (SAFE) vehicles final rule (SAFE Rule Part Two). This rule, which went into effect on June 29, 2020, rolled back some of the fuel efficiency mandates that had been in effect. SAFE Rule Part Two was judicially challenged, but the litigation has been placed in abeyance while undergoing review by the Biden Administration.

Earlier, in 2019, NHTSA and USEPA had also issued a regulation revoking CCAA's waiver, which had allowed the State to set its own emissions standards, asserting that the waiver was preempted by federal law. On December 21, 2021, NHTSA published its CAFE Preemption Rule, which finalizes its repeal of the SAFE Rule Part One. USEPA rescinded SAFE Rule Part One on March 9, 2022, and reinstated California's authority under the CCAA to implement its own GHG emission standards and ZEV sales mandate.

3.7.2.2 State Laws, Regulations, and Policies

Warren-Alquist Act

The 1975 Warren-Alquist Act established the California Energy Resources Conservation and Development Commission, now known as the CEC. The act established a state policy to reduce wasteful, uneconomical, and unnecessary uses of energy by employing a range of measures.

Integrated Energy Policy

In 2002, the Legislature passed SB 1389, which required the CEC to develop an integrated energy plan biannually for electricity, natural gas, and transportation fuels, for the California Energy Report. The plan calls for the State to assist in the transformation of the transportation system to improve air quality, reduce congestion, and increase the efficient use of fuel supplies with the least environmental and energy costs. To further this policy, the plan identifies a number of strategies, including assistance to public agencies and fleet operators in implementing incentive programs for ZEVs and their infrastructure needs, and encouragement of urban designs that reduce vehicle miles traveled and accommodate pedestrian and bicycle access.

The latest update is the 2022 Update to the Integrated Energy Policy Report (CEC 2023b~~a~~).The 2022 Integrated Energy Policy Report (IEPR) Update identifies actions the State and others can take to ensure a clean, affordable, and reliable energy system. The 2022 IEPR Update covers a broad range of topics, including energy reliability and western electricity integration, decarbonizing the electricity sector, and transportation electrification.

Renewables Portfolio Standard

The State of California adopted standards to increase the percentage of energy from renewable resources that retail sellers of electricity, including investor-owned utilities and community choice aggregators, must provide in their portfolio. The RPS was established in 2002 under SB 1078, accelerated in 2006 under SB 107, and expanded in 2011 under SB 2. The standards are referred to as the RPS. Qualifying renewables under the RPS include bioenergy such as biogas and biomass, small hydroelectric facilities (30 MW or less), wind, solar, and geothermal energy. The California Public Utility Commission (CPUC) and the CEC jointly implement the RPS program.

In November 2008, then-Governor Schwarzenegger signed Executive Order (EO) S-14-08, which expanded the State's RPS to 33 percent renewable power by 2020. In September 2009, then-Governor Schwarzenegger continued California's commitment to the RPS by signing EO S-21-09, which directed the CARB under its AB 32 authority to enact regulations to help the State meet its RPS goal of 33 percent renewable energy by 2020.

Senate Bill 350 - Clean Energy and Pollution Reduction Act (SB 350).

SB 350, also known as the Clean Energy and Pollution Reduction Act of 2015, was enacted on October 7, 2015, and provides a new set of objectives in clean energy, clean air, and pollution reduction by 2030. The objectives include the following:

1. To increase from 33 percent to 50 percent by December 31, 2030, the procurement of California's electricity from renewable sources.

2. To double the energy efficiency savings in electricity and natural gas final end uses of retail customers through energy efficiency and conservation.

100 Percent Clean Energy Act (SB 100)

On September 10, 2018, then-Governor Brown signed SB 100, establishing that 100 percent of all electricity in California must be obtained from renewable and zero-carbon energy resources by December 31, 2045. SB 100 also creates new standards for the RPS goals that were established by SB 350 in 2015. Specifically, the bill increases required energy from renewable sources for both investor owned utilities and publicly owned utilities from 50 percent to 60 percent by 2030. Incrementally, these energy providers are also required to have a renewable energy supply of 33 percent by 2020, 44 percent by 2024, and 52 percent by 2027. The updated RPS goals are considered achievable, since many California energy providers are already meeting or exceeding the RPS goals established by SB 350.

Clean Energy, Jobs, and Affordability Act (SB 1020)

SB 1020, also known as The Clean Energy, Jobs, and Affordability Act of 2022, establishes the requirement that eligible renewable energy resources and zero-carbon resources supply 90 percent of all retail sales of electricity to California end-use customers by December 31, 2035; 95 percent of all retail sales of electricity to California end-use customers by December 31, 2040; 100 percent of all retail sales of electricity to California end-use customers by December 31, 2045; and 100 percent of electricity procured to serve all State agencies by December 31, 2035.

Low Carbon Fuel Standard (Executive Order S-1-07)

The Low Carbon Fuel Standard (LCFS), established in 2007 through EO S-1-07 and administered by CARB, requires producers of petroleum-based fuels to reduce the carbon intensity of their products that started with a 0.25 percent reduction in 2011 and culminated in a 10 percent total reduction in 2020.In September 2018, CARB extended the LCFS program to 2030, making significant changes to the design and implementation of the program, including a doubling of the carbon intensity reduction to 20 percent by 2030.

Petroleum importers, refiners, and wholesalers can either develop their own low carbon fuel products or buy LCFS credits from other companies that develop and sell low carbon alternative fuels, such as biofuels, electricity, natural gas, and hydrogen.

Pavley Alternative Fuel Standards (AB 1007)

AB 1007 (Pavley, Chapter 371, Statutes of 2005) required the CEC to prepare a state plan to increase the use of alternative fuels in California (State Alternative Fuels Plan).The CEC prepared the State Alternative Fuels Plan in partnership with CARB and in consultation with other state, federal, and local agencies. The final State Alternative Fuels Plan, published in December 2007, attempts to achieve an 80 percent reduction in GHG emissions associated with personal modes of transportation, even as California’s population increases.

CARB Emission Standards for In-use Off-road Diesel Vehicles

In 2007, CARB adopted a regulation to reduce DPM and NO_X emissions from in-use, off-road, heavy-duty diesel vehicles in California. The regulation imposes limits on vehicle idling and requires fleets to reduce emissions by retiring, replacing, repowering, or installing exhaust retrofits to older engines. In December 2011, the regulation was amended to modify the compliance dates for performance standards and establish requirements for compliance with verified diesel emission control strategy technologies that reduce PM and/or NO_X emissions. The regulation is in the process of finalizing additional amendments that will require the phase out of the oldest and highest emitting off-road engines and would restrict the addition of vehicles with Tier 3 and Tier 4 interim engines. The rules would be implemented starting in 2024 and would require contracting entities to obtain and retain a fleet's valid Certificate of Reported Compliance prior to awarding a contract or hiring a fleet, mandate the use of R99 or R100 Renewable Diesel for all fleets with some limited exceptions, and provide additional requirements to increase enforceability and provide flexibility for permanent low-use vehicles.

ZEV Executive Orders

In March 2012, then-Governor Brown issued EO B-16-12 establishing a goal of 1.5 million ZEVs on California roads by 2025.In addition to the ZEV goal, the executive order stipulated that by 2015 all major cities in California will have adequate infrastructure and be "zero-emission vehicle ready"; that by 2020 the State will have established adequate infrastructure to support 1 million ZEVs; and that by 2050, virtually all personal transportation in the state will be based on ZEVs, and GHG emissions from the transportation sector will be reduced by 80 percent below 1990 levels.

On January 26, 2018, then-Governor Brown issued EO B-48-18 establishing a goal of 5 million ZEVs on California roads by 2030 and spurred the installation and construction of 250,000 plug-in electric vehicle chargers, including 10,000 direct current fast chargers, and 200 hydrogen refueling stations by 2025.

In September 2020, Governor Newsom signed EO N-79-20, which sets a new State goal that 100 percent of in-state sales of new passenger cars and trucks will be zero-emission by 2035; that 100 percent of medium- and heavy-duty vehicles in the state be zero-emission by 2045 for all operations, where feasible, and by 2035 for drayage trucks; and that 100 percent of off-road vehicles and equipment will be zero emission by 2035, where feasible. This order calls upon state agencies, including CARB, the CEC, the CPUC, the Department of Finance, and others to develop and propose regulations and strategies to achieve these goals.

CARB Clean Cars Programs

The Advanced Clean Cars emissions-control program (referred to as Pavley) was approved by CARB in 2012 pursuant to AB 1493 (CARB 2017a). The program requires a greater number of ZEV models for years 2015 through 2025 to control smog, soot, and GHG emissions. This program includes the Low-Emissions Vehicle regulations to reduce criteria pollutants and GHG emissions from light- and medium-duty vehicles; and the ZEV regulations require manufactures to produce an increasing number of pure ZEV's (meaning battery and fuel cell electric vehicles) with the provision to produce plug-in hybrid electric vehicles between 2018 and 2025.

California recently adopted the new Advanced Clean Car II in August 2022, which dramatically reduces emissions from passenger vehicles for model years 2026 through 2035. Advanced Clean Cars II will require more aggressive tailpipe emission standards for gasoline cars and heavier passenger trucks and require all new vehicles sold by 2035 be ZEVs (CARB 2023).

CARB 2022 California Climate Change Scoping Plan

AB 1279, "The California Climate Crisis Act," was passed on September 16, 2022, and declares the State is to achieve net-zero GHG emissions as soon as possible, but no later than 2045, and will achieve and maintain net-negative GHG emissions thereafter. In addition, the bill states that the State would reduce GHG emissions by 85 percent below 1990 levels no later than 2045. CARB adopted the Final 2022 Scoping Plan in December 2022 as an update to the 2017 Scoping Plan to assess the progress towards the 2030 target, as well as to outline a plan to achieve carbon neutrality no later than 2045. The 2022 Scoping Plan focuses on outcomes needed to achieve carbon neutrality by assessing paths for clean technology, energy deployment, natural and working lands, and others, and is designed to meet the State's long-term climate objectives and support a range of economic, environmental, energy security, environmental justice, and public health priorities (CARB 2022). The 2022 Scoping Plan aims to encourage the build out of renewable energy to displace fossil-fuel fired electrical generation and to electrify energy demand in all sectors.

California Code of Regulations Title 24 (California Building Code)

Updated every three years through a rigorous stakeholder process, Title 24 of the California Code of Regulations requires California buildings and structures to meet strong energy efficiency measures, thereby lowering their energy use. Title 24 contains numerous subparts, including Part 1 (Administrative Code), Part 2 (Building Code), Part 3 (Electrical Code), Part 4 (Mechanical Code), Part 5 (Plumbing Code), Part 6 (Energy Code), Part 8 (Historical Building Code), Part 9 (Fire Code), Part 10 (Existing Building Code), Part 11 (Green Building Standards Code), Part 12 (Referenced Standards Code). The California Building Code is applicable to all development of buildings and structures in California. (Health and Safety Code §§ 17950 and 18938(b).) The regulations receive input from members of industry, as well as the public, with the goal of "[r]educing of wasteful, uneconomic, inefficient, or unnecessary consumption of energy." (Pub. Res. Code § 25402.) These regulations are scrutinized and analyzed for technological and economic feasibility (Pub. Res. Code § 25402(d)) and cost effectiveness (Pub. Res. Code § 25402(b)(2) and (b)(3)).

Part 6 – Building Energy Efficiency Standards

CCR Title 24 Part 6 is the Building Energy Efficiency Standards. This code, originally enacted in 1978, establishes energy-efficiency standards for buildings and structures in order to reduce California's energy demand. The Building Energy Efficiency Standards is updated periodically to incorporate and consider new energy-efficiency technologies and methodologies as they become available. New construction and major renovations must demonstrate their compliance with the current Building Energy Efficiency Standards through submission and approval of a Title 24 Compliance Report to the local building permit review authority and the California Energy Commission.

The 2022 Building Energy Efficiency Standards became effective on January 1, 2023. The Standards focus on four key areas: 1) smart residential photovoltaic systems; 2) updated thermal envelope standards (preventing heat transfer from the interior to exterior and vice versa); 3) residential and nonresidential ventilation requirements; 4) and nonresidential lighting requirements. Under the 2019 Standards, non-residential buildings will be 30 percent more energy-efficient compared to the 2016 Standards.

Part 11 – California Green Building Standards

The California Green Building Standards Code, referred to as CALGreen, was added to CCR Title 24 as Part 11 first in 2009 as a voluntary code, which then became mandatory effective January 1, 2011 (as part of the 2010 CBC). Current CALGreen institutes mandatory minimum environmental performance standards for all ground-up new construction of non-residential and residential structures. It also includes voluntary tiers (I and II) with stricter environmental performance standards for these same categories of residential and non-residential buildings. Local jurisdictions must enforce the minimum mandatory Green Building Standards and may adopt additional amendments for stricter requirements.

Mandatory standards require:

- 20 percent reduction in indoor water use relative to specified baseline levels;
- 50 percent construction/demolition waste diverted from landfills;
- Inspections of energy systems to ensure optimal working efficiency; and
- Low-pollutant emitting exterior and interior finish materials such as paints, carpets, vinyl flooring, and particleboards.

Similar to the compliance reporting procedure for demonstrating Building Energy Efficiency Standards compliance in new buildings and major renovations, compliance with the CALGreen water-reduction requirements must be demonstrated through completion of water use reporting forms for new low-rise residential and non-residential buildings. Buildings must demonstrate a 20 percent reduction in indoor water use by either showing a 20 percent reduction in the overall baseline water use as identified in CALGreen or a reduced per-plumbing-fixture water use rate.

3.7.2.3 Regional and Local Laws, Regulations, and Policies

Valley Water Climate Change Action Plan

Valley Water's Climate Change Action Plan (CCAP) provides goals, strategies, and possible actions to address the ways that Valley Water is vulnerable to climate change impacts in each of Valley Water's mission areas, including water supply, flood protection, ecosystem stewardship, and emergency preparedness (Valley Water 2021a). The CCAP sets seven goals to guide Valley Water's response to climate change, three of which focus on reduction of operational GHG emissions, and four of which focus on climate change resilience and adaptation. Applicable policies from the CCAP to the Project's energy impacts include:

- **Action 1.2.3:** Develop a Valley Water-wide soil management plan to reduce truck hauling trips and encourage more efficient use of sediment/soil/spoils;
- **Action 1.2.7:** Promote fuel-saving policies and protocols such as, when safe, limiting hard braking while driving Valley Water vehicles, etc.
- **Action 1.3.3:** Continue to replace less efficient equipment with more fuel-efficient Class 4 equipment or devices that are powered by renewable energy.
- **Action 1.3.5:** Promote use of renewable energy for Valley Water field monitoring equipment.

- **Action 1.4.1:** Incorporate new energy, water, and fuel efficient technologies into capital project planning and design. Minimize construction-related vehicle miles traveled.
- **Action 1.4.5:** Incorporate process-based geomorphic channel designs into capital projects and utilize natural energy and local materials.
- **Action 2.1.1:** Continue to procure carbon-free and renewable energy from the Power and Water Resources Pooling Authority.
- **Action 2.1.2**: Examine and pursue opportunities to increase renewable energy in Valley Water's energy portfolio, in accordance with the latest Energy Optimization Plan.
- **Action 2.1.3**: Participate in the Community Choice Aggregation Program or other green power purchasing options.
- **Action 2.2.1**: Update or expand the Energy Optimization Plan and other energy efficiency efforts. Regularly track the implementation of this plan and Valley Water's progress towards energy efficiency.
- **Action 2.2.2**: Continue to maintain status as a Certified Green Business. Expand associated energy and water saving measures.
- **Action 2.2.3**: Develop and implement a Valley Water LEED and/or Building Sustainability Policy, building on prior efforts.
- **Action 2.2.4**: Conduct regular energy assessments and encourage use of energy efficient technologies (including at the treatment plants, the Advanced Water Purification Center, and water pumping equipment).
- **Action 2.2.5**: Expand energy efficient lighting systems (e.g.: automatic light shutdowns, motion sensor lights, attaching task lights to timers, install more efficient bulbs).
- **Action 2.2.6**: Set office equipment such as multifunction printers to automatically enter Power Save Mode after inactivity. Switch to secure printing (printers require passwords) rather than individual printers for sensitive documents. Reduce office equipment when possible (such as physical servers).
- **Action 2.2.7**: Promote sustainable workplace behavior (i.e. turning off computers and other devices at night).
- **Action 2.2.8**: Engage in outreach and information sharing at the local, regional, state, and national levels to promote energy efficiency both internally and in the water industry.

Santa Clara County General Plan

The Santa Clara County General Plan (County 1994) contains the following policies relevant to energy:

General Policies

- **Policy C-RC 77**: Energy efficiency and conservation efforts in the transportation, industrial, commercial, residential, agricultural and public sectors shall be encouraged at the local, county (subregional), and regional level.
- **Policy C-RC 78**: The objectives of the state energy plan should be implemented at the local and regional level through an overall strategy consisting of a) reducing transportation energy demand and oil-dependency; b) conserving energy in residential,

commercial, agricultural, and industrial sectors; and c) increasing consumer and general public awareness through education.

Strategy #1: Reduce Transportation Energy Demand and Oil-Dependency

- **Policy C-RC 79:** Energy use and fossil fuel dependency in the transportation sector should be reduced by the following general means: a) growth management policies and implementation to minimize increases in the extent of the urbanized area and to promote balanced, compact urban development; b) land use and development standards which support alternative transportation modes; c) travel demand management (TDM) and transportation system operational efficiency; d) expanded transit service; and e) increased availability and use of alternative fuels.
- **Policy C-RC 80:** Sub-regional/countywide planning for Santa Clara County should place major emphasis on the inter-related goals, strategies, and policies for improving energy efficiency in transportation, air quality, and reducing traffic congestion.

Strategy #2: Conserve Energy in Residential and Other Sectors

- **Policy C-RC 82**: Alternatives to non-renewable energy sources should be encouraged and implemented in the design of new buildings and incorporated in the redesign and reconstruction of older buildings.
- **Policy C-RC 83:** Industrial and agricultural processes should be modified wherever feasible to take advantage of energy savings, to reduce operational costs, and to enhance competitiveness.

The Santa Clara County General Plan's Health Element (County 2015) contains the following policies relevant to energy:

- **Policy HE-G.10**: Conservation. Promote energy conservation and efficiency in homes, businesses, schools, and other infrastructure to reduce energy use and criteria pollutant and greenhouse gas emissions.
- **Policy HE-G.11**: Renewable energy. Encourage renewable energy, such as solar and wind turbines, on commercial, industrial, and residential buildings.
- **Policy HE-G.12**: Energy technologies. Support regional and local initiatives that promote integrated building systems, distributed generation, demand response programs, smart grid infrastructure, energy storage and backup, and electric transportation infrastructure.

Santa Clara County Sustainability Master Plan

The Santa Clara County Sustainability Master Plan (County 2021) contains the following programs relevant to energy:

- **Strategy 1.1. Clean Energy**: The County has set a target of a 100 percent renewable energy system by 2045 which aligns with the State's Policies and Regulations. This strategy will evaluate opportunities to transition gas-powered equipment to electric. It will look to expand and incentivize the installation of solar photovoltaic systems at County sites and private land owners. Evaluate opportunities to expand wind-powered energy generation in the County. The County will also conduct a cost-benefit analysis of energy-related climate solutions.

- **Strategy 1.2 Decarbonization of Buildings and Facilities:** The County has set the target for all new County-owned buildings to meet CALGreen Tier 1 requirements and for large projects to be Leadership in Energy and Environmental Design (LEED) certified. The County will also evaluate strategies and implement pilot projects for zero-net energy retrofits, solar hot water, boiler efficiency measures or biogas procurement that contribute toward County facility decarbonization over the next five years. The County will ensure that the most energy-efficient lighting is installed where the savings will cover the cost of the lighting investments. The County will increase the number of electric vehicle chargers at County facilities and work to decarbonize all healthcare facilities and operations. The County also includes a target to reduce per capita energy use by at least 50 percent. The County will increase the overall energy savings achieved through Bay Area Regional Energy rebate programs.
- **Strategy 1.3. Clean, Safe, and Active Transportation**: The County will ensure that 100 percent of public fleet vehicles are electric, hybrid-electric, or run on alternative fuels where alternatives exist. The County will establish telecommuting policies and targets to reduce greenhouse gas emissions from employee commutes. The County will decrease the percentage of single-occupancy vehicles employee commutes by at least 10 percent below the 2020 Employee Commute Survey levels by calendar year 2022. The County will adopt Complete Streets policies into the General Plan Circulation and Mobility Element by 2024. The County will also adopt a County Active Transportation Plan and identify targets to track progress. Finally, the County will increase the percentage of people age 16 and over who walk, bike, or take public transportation to work.

City of Morgan Hill 2035 General Plan

The City of Morgan Hill General Plan (City of Morgan Hill 2016) contains the following goals, policies, and actions relevant to energy:

Natural Resources and Environment (NRE)

Goal NRE-16: Conservation of energy resources.

Policy NRE-16.1: Energy Standards for New Development. New development, including public buildings, should be designed to exceed State standards for the use of energy.

Policy NRE-16.2: Energy Conservation. Promote energy conservation techniques and energy efficiency in building design, orientation, and construction.

Policy NRE-16.5: Energy Efficiency. Encourage development project designs that protect and improve air quality and minimize direct and indirect air pollutant emissions by including components that promote energy efficiency.

Policy NRE-16.7: Renewable Energy. Encourage new and existing development to incorporate renewable energy generating features, like solar panels and solar hot water heaters.

Envision San José 2040 General Plan

The Envision San José 2040 General Plan (City of San José 2023 ~~2011~~) contains the following policies/actions relevant to energy:

Goal MS-2: Energy Conservation and Renewable Energy Use: Maximize the use of green building practices in new and existing development to maximize energy efficiency and conservation and to maximize the use of renewable energy sources.

> **Policy MS-2.4:** Promote energy efficient construction industry practices.
>
> **Policy MS-14.3**: Consistent with the California Public Utilities Commission's California Long Term Energy Efficiency Strategic Plan, as revised, and when technological advances make it feasible, require all new residential and commercial construction to be designed for zero net energy use.
>
> **Policy MS-14.4**: Implement the City's Green Building Policies so that new construction and rehabilitation of existing buildings fully implements industry best practices, including the use of optimized energy systems, selection of materials and resources, water efficiency, sustainable site selection, passive solar building design, and planting of trees and other landscape materials to reduce energy consumption.

3.7.3 Methodology and Approach to Impact Analysis

This impact analysis considers the potential for the Project to result in the wasteful use of energy or energy resources during Project construction and operation, consistent with PRC 21100(b)(3) and section 15126.2(b) and Appendices F and G of the *CEQA Guidelines*. This section also includes an evaluation of the potential for Project implementation to conflict with or obstruct a State or local plan for renewable energy or energy efficiency, consistent with Appendix G of the *CEQA Guidelines*. The analysis evaluates impacts related to energy that could occur as a result of the following activities:

- Seismic Retrofit Construction
- Conservation Measures Construction
- Construction Monitoring
- Post-Construction Anderson Dam Facilities Operations and Maintenance
- Post-Construction Conservation Measures Operations and Maintenance
- Post-Construction Project and FAHCE Adaptive Management

The analysis includes quantification of electricity, natural gas, gasoline, and diesel fuel that would be required to construct and operate the Project. Energy use includes off-road equipment and on-road mobile sources. Specifically, the analysis provides construction energy use estimates for the Project. Construction energy use estimates and operational energy assumptions are used to determine whether energy use from construction and operation of the Project would be considered wasteful, inefficient, or unnecessary, taking into account available energy supplies and existing use patterns, the Project's energy efficiency features, and compliance with applicable standards and policies aimed to reduce energy consumption.

3.7.3.1 Seismic Retrofit Construction

As described in Section 3.0, *Introduction*, the baseline for evaluating Seismic Retrofit components construction effects is the existing conditions at the time of EIR preparation modified by FOCP implementation (referred to as the existing conditions baseline).

The energy analysis is based on default values in the latest versions the CalEEMod, the CARB's Emission Factor Model version 2021 (EMFAC2021), and the CARB's equipment offroad inventory (OFFROAD2017) (CARB 2017b, 2017c). EMFAC2021 has not been updated for the most recent executive orders, specifically EO N-79-20, which bans the sale of gasoline-powered cars in California by 2035; and AB 1279 of 2022, which sets as a target carbon neutrality in California by 2045. EO N-79-20 and AB 1279 would alter the energy mix in California related to the Project by substantially decreasing fossil fuel usage and increasing electricity usage. Energy consumption estimates for the Project, including fuel and electricity consumption, do not account for the effects of EO N-79-20 and AB 1279 on available energy supplies, which would increase the supply of renewable energy sources in the future. Thus, energy consumption estimates are conservative, since at the time of construction, there would be a greater supply of renewable energy sources available. Accordingly, this energy analysis has been conducted with the most recent tools available at the time of Draft EIR preparation.

Construction Energy Estimates

For the purposes of estimating construction energy, primary construction activities for the Seismic Retrofit component include the following: site mobilization and preparation, including clearing and preparing staging and stockpile areas, reservoir dewatering and cofferdam construction, constructing the temporary water diversion system, dam excavation and fill (including excavation of embankment materials from borrow areas and disposal of excess materials at spoils disposal areas), constructing the new outlet works and spillway, construction of other ancillary facilities, decommissioning the hydroelectric facility, related fisheries improvements, and site restoration. Construction is planned to start in Year 1 and continue for approximately 7 years.

Off-Road Equipment

Off-road equipment is the most significant source of the Project's construction fuel usage. Fuel consumption associated with onsite off-road construction equipment was estimated based on the construction schedule, equipment list, and CARB estimated fuel consumption rate for off-road equipment from the OFFROAD2017 model (CARB 2017a, 2017b). Further details on the construction schedule and equipment list are provided in the Air Quality, Greenhouse Gas, and Health Risk Assessment Technical Report (see Appendix E).

It was conservatively assumed that all off-road equipment would be powered by diesel. Fuel consumption was calculated based on annual CO_2 emissions from construction activities and the USEIA's CO_2 emissions coefficients by fuel type (USEIA 2022e ~~2022g~~). CO_2emissions coefficients for gasoline and diesel are provided in **Table 3.7-7**.

On-Road Vehicles

On-road construction vehicles such as light-duty automobiles, shuttles, and trucks that would be used by workers for commuting to and from the construction site are assumed to be fueled by gasoline; and on-road trucks, such as vendor and haul trucks for demolition debris, soil, and other material hauling, are assumed to be fueled by diesel fuel. Similar to off-road equipment, fuel consumption required for on-road vehicle travel during construction was calculated based on annual CO_2 emissions from worker, vendor, and hauling trips during construction and the USEIA's CO_2 emissions coefficients by fuel type. CO_2emissions coefficients for gasoline and diesel are provided in **Table 3.7-5** ~~**Table 3.7-5**~~ (USEIA 2022e ~~2022g~~).

Table 3.7-7. Carbon Dioxide Emissions Coefficients by Fuel

Fuel Type	Pounds of CO_2 per Gallon
Gasoline[a]	17.87
Diesel[b]	22.46

Source: USEIA 2022e
Notes:
[a] *Emission coefficient is selected for finished motor gasoline, which includes fuel ethanol blended into motor gasoline.*
[b] *Emission coefficient is selected for the diesel and home heating fuel (distillate fuel oil) category.*
Key: CO_2 = Carbon Dioxide

Electricity Use

Construction of the Seismic Retrofit component is expected to use minimal electric equipment. However, electric equipment would be powered by diesel-fueled generators (diesel use is included in the diesel consumption estimates in **Table 3.7-8**) at the construction site, instead of electricity from the local power grid. Therefore, electricity used during the Seismic Retrofit component construction was not quantified.

3.7.3.2 Conservation Measures Construction

As described in Section 3.0, *Introduction*, the baseline for evaluating Conservation Measure components construction effects is the existing conditions at the time of EIR preparation modified by FOCP implementation (existing conditions baseline). Conservation measures requiring construction activities that are evaluated in the impact analysis include:

- Ogier Ponds Conservation Measure
- Maintenance of the North Channel Reach ~~Extension~~
- Maintenance Activities at the Live Oak Restoration Reach
- Sediment Augmentation Program[1]
- Phase 2 Coyote Percolation Dam Conservation Measure

The energy impacts from the construction of the Conservation Measure components were analyzed using the same methodologies as construction of the Seismic Retrofit components.

[1] Energy demand was only quantified for the initial placement of gravel, assumed to occur in Year 8. While energy demand associated with future gravel augmentation is assumed to be minor, its scale, timing, and duration are speculative and energy demand was not quantified.

3.7.3.3 Construction Monitoring

Construction monitoring activities are not considered in the impact analysis, as monitoring would involve data and information collection and assessment and would result in only minor use of energy or energy resources. Thus, construction monitoring is not discussed further in this section.

3.7.3.4 Post-Construction Anderson Dam Facilities Operations and Maintenance

Operation of Anderson Dam following construction of the Seismic Retrofit component would involve implementation of the FAHCE rule curves and pulse flows, which would not change energy consumption compared to the existing conditions baseline. The Anderson Hydroelectric Facility would be removed and would no longer be available to be reactivated and generate electricity. Under existing conditions, the hydroelectric facility has not generated electricity since 2018. As mentioned above, Valley Water discontinued operations of the hydroelectric facility due to the increasing cost of operations and maintenance of the facility (Valley Water 2021b). Given the current, and near future, inability of the hydroelectric facility to provide any meaningful amounts of electricity, the hydroelectric facility is not currently considered as a local or regional energy supplier. Thus, energy supply planning would not consider the hydroelectric facility a source of near-term additional capacity.

As described in Section 3.0, *Introduction*, the baseline for evaluating post-construction operation effects to energy is the existing conditions at the time of EIR preparation modified by FOCP implementation (existing conditions baseline).

Additionally, as described in Chapter 2, *Project Description*, Valley Water would maintain the newly retrofitted Anderson Dam and Reservoir per Valley Water's existing DMP. Maintenance of Anderson Dam facilities was previously evaluated in the Final DMP EIR prepared in January 2012 (SCH No. 2011082077; Valley Water 2012). No new long-term operational sources requiring energy would be added by dam maintenance. Therefore, post-construction dam facility maintenance activities are not discussed further in this section.

3.7.3.5 Post-Construction Conservation Measures Operations and Maintenance

Similar to the operation of the Anderson Dam, post-construction operations and maintenance of the Conservation Measures components would involve minimal activities requiring energy consumption. As described in Chapter 2, Project Description, Valley Water would maintain Coyote Percolation Dam per Valley Water's existing DMP. Maintenance of Coyote Percolation Dam facilities were previously evaluated in the Final DMP EIR prepared in January 2012 (SCH No. 2011082077; Valley Water 2012). No new long-term operational sources requiring energy would be added by the Ogier Ponds CM, Maintenance of the North Channel Reach ~~Extension~~, Maintenance Activities at the Live Oak Restoration Reach, and the Sediment Augmentation Program. However, post-construction operation of the Phase 2 Coyote Percolation Dam CM would include operation of the motorized inflatable bladder dam installed as part of FOCP. As such, only post-construction operation of the Phase 2 Coyote Percolation Dam CM is discussed further in this section.

3.7.3.6 Post-Construction Project and FAHCE Adaptive Management

The FAHCE AMP would guide post-construction adaptive management of Project ~~project~~ flow operations and Conservation Measures that have met their specified success criteria, as defined through the regulatory permitting process. As required by the FAHCE AMP framework, the Project and FAHCE AMP includes four key elements: measurable objectives, monitoring, adaptive actions, and reporting. Monitoring and adaptive actions involve physical activities that could have environmental impacts.

The Project and FAHCE AMP monitoring program would inform a selection of adaptive management measures to implement in response to management triggers, and includes compliance, validation, effectiveness, and long-term monitoring. Validation, effectiveness, and long-term trend monitoring would build on existing Valley Water monitoring infrastructure (e.g., hydrologic monitoring network), water quality monitoring (e.g., water temperature monitoring network), habitat monitoring (e.g., habitat mapping), and fisheries monitoring (e.g., VAKI Riverwatcher, PIT tag detectors, genetics sampling, electrofishing surveys). Impacts of these monitoring activities are not evaluated in the impact analysis because they would result in only minor use of energy or energy resources.

The Project and FAHCE AMP identifies triggers for adaptive actions to help meet measurable objectives. Adaptive actions for FAHCE flows and imported water storage/releases would include refinements of reservoir releases, which would have impacts and benefits similar to the original FAHCE flows and imported water storage/releases. Adaptive actions for Conservation Measures would generally include minor construction and maintenance actions, whose impacts would be similar but less than those from original Conservation Measure construction. Impacts of these adaptive actions are not evaluated in the impact analysis because they would result in only minor use of energy or energy resources.

3.7.3.7 Applicable Best Management Practices and VHP Conditions

The following Valley Water BMP would serve to minimize impacts on energy resources from the Project (refer to Chapter 2, *Project Description*, for the full text of the BMPs):

AQ-1: Use Dust Control Measures

No VHP conditions are applicable to energy.

3.7.3.8 Thresholds of Significance

Significance Criteria

For the purposes of this EIR and pursuant to Appendix G of the *CEQA Guidelines*, the Project would result in a significant impact related to energy use if it would:

(a) result in a significant environmental impact due to wasteful, inefficient, or unnecessary consumption of energy, or wasteful use of energy resources, during Project construction or operation; or

(b) conflict with or obstruct a state or local plan for renewable energy or energy efficiency.

Specific Thresholds of Significance

This EIR applies the following energy thresholds:

Energy Consumption

<u>Construction</u>

The following thresholds are used to evaluate the significance of energy consumption impacts resulting from construction of the Project:

- Construction that would result in the inefficient and wasteful use of energy, especially nonrenewable energy
- Construction that would not incorporate renewable energy and energy efficiency measures.

<u>Operation</u>

The following thresholds are used to evaluate the significance of energy consumption impacts resulting from operation of the Project:

- Utilization of larger amounts of operational energy compared to environmental baseline conditions
- Utilization of larger amounts of operational nonrenewable energy compared to environmental baseline conditions
- Non-incorporation of renewable energy and energy efficiency measures.

Renewable Energy and Energy Efficiency Plan Consistency

<u>Construction and Operation</u>

The following qualitative threshold is used to evaluate the significance of renewable energy and energy efficiency plan consistency impacts resulting from implementation of the Project:

- Construction and operation of buildings, appliances, equipment, and vehicles would not adhere to the renewable energy and energy efficiency targets, standards, and guidance included in California Green Building Standards Code (CALGreen or Title 24 Part 11), California Building Energy Efficiency Standards (Title 24 Part 6), SB 100, Valley Water CCAP, Santa Clara County General Plan, Santa Clara County Sustainability Master Plan, Morgan Hill 2035 General Plan, and Envision San José 2040 General Plan.

3.7.4 Impact Analysis

***Impact ENR-1: Result in a significant environmental impact due to wasteful, inefficient, or unnecessary consumption of energy resources* (Less than significant with Mitigation)**

Construction

Seismic Retrofit Construction

Primary construction activities associated with the Seismic Retrofit construction include demolition, reconstruction of the dam and spillway, alteration of roadway alignments, and excavation related to installation of new outlet works, pipeline alignments, and communication lines. The Seismic Retrofit component would result in a temporary increase of energy consumption during the construction period. Gasoline and diesel consumption for Seismic Retrofit construction is summarized in **Table 3.7-8**. As shown in **Table 3.7-8**, construction of the Seismic Retrofit component is estimated to consume 14,873,000 ~~11,274 thousand~~ gallons of diesel and 665,000 ~~428 thousand~~ gallons of gasoline during the entire construction period lasting approximately 7 years.

Table 3.7-8. Seismic Retrofit Construction Gasoline and Diesel Consumption

Year	Diesel (Thousand Gallons)	Gasoline (Thousand Gallons)
Year 1	331 ~~113~~	95 ~~5~~
Year 2	2,559 ~~2,006~~	80 ~~58~~
Year 3	2,575 ~~2,013~~	104 ~~80~~
Year 4	3,338 ~~2,400~~	126 ~~94~~
Year 5	2,810 ~~2,192~~	126 ~~93~~
Year 6	2,892 ~~2,262~~	92 ~~67~~
Year 7	368 ~~288~~	43 ~~31~~
Total	**14,873 ~~11,274~~**	**665 ~~428~~**

Source: Air Quality, Greenhouse Gas, and Health Risk Assessment Technical Report (see Appendix E).

Seismic Retrofit construction energy usage would be reduced by implementation of **Mitigation Measure AQ-1**, which will require all off-road construction equipment greater than 25 hp and operating for more than 20 hours over the entire duration of construction activities to be equipped with Tier 4 engines and will require all on-road vehicles as well as boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** will also minimize construction equipment idling time and require regular maintenance for all equipment. Seismic Retrofit construction non-renewable energy usage would be reduced by implementation of **Mitigation Measure GHG-1**, which will require use of zero emission construction equipment whenever feasible as well as renewable diesel fuel. Furthermore, the construction contractor will have a financial disincentive to waste fuel used by construction equipment given excess fuel usage reduces profits. Therefore, fuel used during construction would be conserved when feasible.

Energy use during Seismic Retrofit construction would result in increased demand on local and regional supplies of fossil fuel, such as diesel and gasoline. However, as discussed above, implementation of **Mitigation Measures AQ-1 and GHG-1** will reduce energy usage, including non-renewable energy usage, during construction. Additionally, given that the northern California region produced an annual average of 6,138,527,000 ~~thousand~~ gallons of gasoline and 2,363,161,000 ~~thousand~~ gallons of diesel over the 5-year period of 2018-2022, annual Seismic Retrofit construction energy demand is less than 0.01 ~~0.007~~ percent of the region's gasoline production throughput and less than 0.6 ~~0.4~~ percent of the region's diesel production throughput (CEC 2023a ~~2023c~~). Furthermore, the impacts of Seismic Retrofit construction on local and regional fuel supplies would be temporary and not require an increase in fuel production capacity. Similarly, due to the relatively small demand related to gasoline and diesel fuel during Seismic Retrofit construction, there would not be temporary disruptions in local fuel supplies or requirements for additional fuel capacity in the region. Therefore, the impacts of Seismic Retrofit construction with regard to gasoline and diesel demand would be minimal.

Seismic Retrofit construction may potentially consume other forms of energy such as electricity, propane, and compressed natural gas. However, electricity consumed during Seismic Retrofit construction would be generated from on-site diesel generator sets. Any propane and/or compressed natural gas use would be as alternatives to gasoline and diesel consumption. Therefore, Seismic Retrofit construction is also unlikely to cause strain on peak- and base-period demand for electricity and other forms of energy, including natural gas.

Construction of the Seismic Retrofit component would also result in a temporary increase in transportation energy use. Energy use requirements of diesel and gasoline for construction on-road vehicles during Seismic Retrofit construction are included in **Table 3.7-8**.

Finally, Seismic Retrofit construction would utilize fuel-efficient equipment consistent with State and federal regulations and would comply with State measures related to incorporation of renewable energy and energy efficiency measures. Per applicable regulatory requirements of CALGreen, Seismic Retrofit construction activities would comply with construction waste management practices to divert construction and demolition debris from landfills. These practices would result in efficient use of energy and less consumption of non-renewable energy during Seismic Retrofit construction.

For the reasons listed above, construction of the Seismic Retrofit component would not result in the wasteful, inefficient, or unnecessary consumption of energy, especially non-renewable energy. Therefore, the Seismic Retrofit construction impact related to the consumption of energy resources is less than significant with mitigation.

Conservation Measures Construction

Ogier Ponds CM

Primary construction activities associated with the Ogier Ponds CM includes dewatering, placing fill in Ponds 1, 2, 4, and 5, construction of earthen berms, grading of the channel area, and construction of the new spillway and discharge structure. The Ogier Ponds CM would result in a temporary increase of energy consumption during the construction period. Gasoline and diesel consumption for Ogier Ponds CM construction is summarized in **Table 3.7-9**. As shown in **Table 3.7-9**, Ogier Ponds CM construction is estimated to consume 2,788,000 ~~2,660 thousand~~ gallons of diesel and 85,000 ~~83 thousand~~ gallons of gasoline during the construction period.

Table 3.7-9. Ogier Ponds CM Construction Gasoline and Diesel Consumption

Year	Diesel (Thousand Gallons)	Gasoline (Thousand Gallons)
Year 6	1,473 ~~1,394~~	2~~1~~
Year 7	957 ~~908~~	31 ~~30~~
Year 8	359 358	33 32
Total	**2,788 ~~2,660~~**	**85 ~~83~~**

Source: Air Quality, Greenhouse Gas, and Health Risk Assessment Technical Report (see Appendix E).

Ogier Ponds CM construction energy usage would be reduced by implementation of **Mitigation Measure AQ-1**, which would require all construction equipment greater than 25 hp and operating for more than 20 hours over the entire duration of construction activities to be equipped with Tier 4 engines. Implementation of **Mitigation Measure AQ-1** will also minimize construction equipment idling time and require regular maintenance for all equipment. Furthermore, the construction contractor would have a financial disincentive to waste fuel used by construction equipment (i.e., excess fuel usage reduces profits). Therefore, fuel used during construction would be conserved when feasible.

Energy use during Ogier Ponds CM construction would result in increased demand on local and regional supplies of fossil fuel, such as diesel and gasoline. However, as discussed above, implementation of **Mitigation Measures AQ-1 and GHG-1** will reduce energy usage, including non-renewable energy usage, during construction. Additionally, given that the northern California region produced an annual average of 6,138,527,000 ~~thousand~~ gallons of gasoline and 2,363,161,000 ~~thousand~~ gallons of diesel over the 5-year period of 2018-2022, annual Ogier Ponds CM construction demand is less than 0.002 ~~0.001~~ percent of the region's gasoline production throughput and less than 0.12 ~~0.11~~ percent of the region's diesel production throughput (CEC 2023a~~c~~). Additionally, the impacts of Ogier Ponds CM construction on local and regional fuel supplies would be temporary, and would not require an increase in fuel production capacity. Similarly, due to the relatively small demand on gasoline and diesel fuel during Ogier Ponds CM construction, there would not be a temporary disruption in local fuel supplies, or requirements for additional fuel capacity in the region. Therefore, the impacts of Ogier Ponds CM construction on demands for gasoline and diesel would be minimal.

Ogier Ponds CM construction may potentially consume other forms of energy, such as electricity, propane, and natural gas. However, electricity during Ogier Ponds CM construction would be generated from on-site diesel generator sets. Any propane and/or compressed natural gas use would be as alternatives to the gasoline and diesel consumption, discussed above. Therefore, Ogier Ponds CM construction is also unlikely to cause any strain on peak and base period demand for electricity and other forms of energy, including natural gas.

Construction of the Ogier Ponds CM would result in a temporary increase in transportation energy use. Energy use requirements of diesel and gasoline for construction on-road vehicles during Seismic Retrofit construction are included in **Table 3.7-9**.

Finally, Ogier Ponds CM construction would utilize fuel-efficient equipment consistent with State and federal regulations related to incorporation of renewable energy and energy efficiency measures. Per applicable regulatory requirements of CALGreen, Seismic Retrofit construction activities would comply with construction waste management practices to divert construction and demolition debris from landfills. These practices would result in efficient use of energy by Ogier Ponds CM construction.

For the reasons listed above, construction of the Ogier Ponds CM would not result in the wasteful, inefficient, or unnecessary consumption of energy, including non-renewable energy. Therefore, the Ogier Ponds CM construction impact related to the consumption of energy resources is less than significant with mitigation.

Maintenance of the North Channel Reach and Live Oak Restoration Reach Extension

Primary construction activities associated with the Maintenance of the North Channel Reach and Live Oak Restoration Reach ~~Extension~~ include ~~grading,~~ vegetation management, sediment management, and site restoration. Maintenance activities would be minor and intermittent, largely driven by maintenance in response to high flow events or plant mortality. ~~Construction is planned to occur over 2 months during the dry season of Year 1. Additional native vegetation along the North Channel would be planted during Year 7 to enhance the restored North Channel. Construction~~ Maintenance of the North Channel Reach ~~Extension~~ and Live Oak Restoration Reach would involve ~~less~~ limited construction activity and ~~less construction~~ equipment, particularly as compared to ~~than~~ the Seismic Retrofit component or ~~any of the~~ other Conservation Measures (e.g., Ogier Ponds CM), so corresponding energy usage has not been quantified. Given the duration and scale of ~~construction~~ Project activities, Maintenance of the North Channel Reach and Live Oak Restoration Reach ~~Extension, construction~~ would involve negligible energy consumption, including non-renewable energy consumption. Therefore, Maintenance of the North Channel Reach and Live Oak Restoration Reach ~~Extension~~ construction impacts related to the consumption of energy resources is less than significant.

Sediment Augmentation Program

Primary construction activities associated with the Sediment Augmentation Program include access establishment, minor grading, vegetation management, and stockpiling and placement of material. The Sediment Augmentation Program would result in a temporary increase of energy consumption during the construction period. Gasoline and diesel consumption for Sediment Augmentation Program construction is summarized in **Table 3.7-10**. As shown in **Table 3.7-10**, construction of the Sediment Augmentation Program is estimated to consume 200 ~~7,468~~ gallons of diesel and 100 ~~1,569~~ gallons of gasoline during the construction period.

Table 3.7-10. Sediment Augmentation Program Construction Gasoline and Diesel Consumption

Year	Diesel (Thousand Gallons)	Gasoline (Thousand Gallons)
~~Year 2~~	579	123
~~Year 3~~	536	117
~~Year 4~~	~~536~~	~~116~~
~~Year 5~~	~~527~~	~~114~~
~~Year 6~~	524	113
~~Year 7~~	522	112
Year 8	0.2 528	0.1 111

Year	Diesel (Thousand Gallons)	Gasoline (Thousand Gallons)
~~Year 9~~	536	110
~~Year 1~~0	533	110
~~Year 11~~	~~527~~	~~109~~
~~Year 1~~2	523	108
~~Year 1~~3	527	108
~~Year 1~~4	535	107
~~Year 1~~5	535	111
Total	**0.2 ~~7,~~468**	**0.1 ~~1,5~~69**

Source: Air Quality, Greenhouse Gas, and Health Risk Assessment Technical Report (see Appendix E).

While minimal, Sediment Augmentation Program construction energy usage would be reduced by implementation of **Mitigation Measure AQ-1**, which will require all construction equipment greater than 25 hp and operating for more than 20 hours over the entire duration of construction activities to be equipped with Tier 4 engines and would require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** will also minimize construction equipment idling time and require regular maintenance for all equipment. Construction non-renewable energy usage would be reduced by implementation of **Mitigation Measure GHG-1**, which will require use of zero emission construction equipment whenever feasible as well as renewable diesel fuel. Furthermore, the construction contractor would have a financial disincentive to waste fuel used by construction equipment (i.e., excess fuel usage reduces profits). Therefore, fuel used during construction would be conserved when feasible. Energy use during Sediment Augmentation Program construction would result in increased demand on local and regional supplies of fossil fuel, such as diesel and gasoline. However, as discussed above, implementation of **Mitigation Measure AQ-1** will reduce energy usage during construction. Additionally, given that the northern California region produced an annual average of 6,138,527,000 ~~thousand~~ gallons of gasoline and 2,363,161,000 ~~thousand~~ gallons of diesel over the 5-year period of 2018-2022, annual Sediment Augmentation Program construction demand is negligible (less than 0.000002 ~~0.02~~ percent of the region's gasoline production throughput and less than 0.000009 ~~0.3~~ percent of the region's diesel production throughput (CEC 2023a ~~2023c~~)). Additionally, the impacts of Seismic Retrofit construction on local and regional fuel supplies would be temporary, and would not require an increase in fuel production capacity. Similarly, due to the relatively small demand on gasoline and diesel fuel during Sediment Augmentation Program construction, there would not be a temporary disruption in local fuel supplies, or requirements for additional fuel capacity in the region. Therefore, the impacts of Sediment Augmentation Program construction with regard to demand for gasoline and diesel would be minimal.

Sediment Augmentation Program construction may potentially consume other forms of energy, such as electricity, natural gas, and propane. However, as discussed previously, electricity during Sediment Augmentation Program construction would be generated from onsite diesel generator sets. Any propane and/or compressed natural gas use would be as alternatives to the gasoline and diesel consumption, discussed above. Therefore, Sediment Augmentation Program construction is also unlikely to cause any strain on peak and base period demand for electricity and other forms of energy, including natural gas.

Construction of the Sediment Augmentation Program would result in a temporary increase in transportation energy use. Energy use requirements of diesel and gasoline for construction on-road vehicles during Sediment Augmentation Program construction are included in **Table 3.7-10**.

Finally, Sediment Augmentation Program construction would utilize fuel-efficient equipment consistent with State and federal regulations related to incorporation of renewable energy and energy efficiency measures. Per applicable regulatory requirements of CALGreen, Sediment Augmentation Program construction activities would comply with construction waste management practices to divert construction and demolition debris from landfills. These practices would result in efficient use of energy by Sediment Augmentation Program construction.

For the reasons listed above, construction of the Sediment Augmentation Program would not result in the wasteful, inefficient, or unnecessary consumption of energy, including renewable energy. Therefore, the Sediment Augmentation Program construction impact related to the consumption of energy resources is less than significant with mitigation.

Phase 2 Coyote Percolation Dam CM

Primary construction activities associated with the Phase 2 Coyote Percolation Dam CM include construction of haul roads and stockpiling areas, clearing and grubbing, construction of creek bypass, and roughened ramp construction. The Phase 2 Coyote Percolation Dam CM would result in a temporary increase of energy consumption during the construction period. Gasoline and diesel consumption for Phase 2 Coyote Percolation Dam CM construction is summarized in **Table 3.7-11**. As shown in **Table 3.7-11**, Phase 2 Coyote Percolation Dam CM construction is estimated to consume 173,000 ~~108 thousand~~ gallons of diesel and 25,000 ~~23 thousand~~ gallons of gasoline during the construction period.

Table 3.7-11. Phase 2 Coyote Percolation Dam CM Construction Gasoline and Diesel Consumption

Year	Diesel (Thousand Gallons)	Gasoline (Thousand Gallons)
Year 1 ~~4~~	69 ~~29~~	10 ~~7~~
Year 2 ~~5~~	104 ~~79~~	15 ~~16~~
Total –	**173 ~~108~~**	**25 ~~23~~**

Source: Air Quality, Greenhouse Gas, and Health Risk Assessment Technical Report (see Appendix E).

Phase 2 Coyote Percolation Dam CM construction energy usage would be reduced by implementation of **Mitigation Measure AQ-1**, which will require all construction equipment greater than 25 hp and operating for more than 20 hours over the entire duration of construction activities to be equipped with Tier 4 engines and would require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** will also minimize construction equipment idling time and require regular maintenance for all equipment. Construction non-renewable energy usage would be reduced by implementation of **Mitigation Measure GHG-1**, which will require use of zero emission construction equipment whenever feasible as well as renewable diesel fuel. Furthermore, the construction contractor would have a financial disincentive to waste fuel used by construction equipment (i.e., excess fuel usage reduces profits). Therefore, fuel used during construction would be conserved when feasible.

Energy use during Phase 2 Coyote Percolation Dam CM construction would result in increased demand on local and regional supplies of fossil fuel, such as diesel and gasoline. However, as discussed above, implementation of **Mitigation Measure AQ-1** will reduce energy usage during construction. Additionally, given that the northern California region produced an annual average of 6,138,527,000 ~~thousand~~ gallons of gasoline and 2,363,161,000 ~~thousand~~ gallons of diesel over the 5-year period of 2018-2022, annual ~~Seismic Retrofit~~ Phase 2 Coyote Percolation Dam CM construction demand is negligible (less than 0.0004 percent of the region's gasoline production throughput and less than 0.007 ~~0.005~~ percent of the region's diesel production throughput (CEC 2023a ~~2023c~~)). Additionally, the impacts of Phase 2 Coyote Percolation Dam CM construction on local and regional fuel supplies would be temporary~~,~~ and would not require an increase in fuel production capacity. Similarly, due to the relatively small demand on gasoline and diesel fuel during Phase 2 Coyote Percolation Dam CM construction, there would not be a temporary disruption in local fuel supplies, or requirements for additional fuel capacity in the region. Therefore, the impacts of Phase 2 Coyote Percolation Dam CM construction on demands for gasoline and diesel would be minimal.

Phase 2 Coyote Percolation Dam CM construction may potentially consume other forms of energy, such as electricity, natural gas, and propane. However, as discussed previously, electricity during Phase 2 Coyote Percolation Dam CM construction would be generated from onsite diesel generator sets. Any propane and/or compressed natural gas use would be as alternatives to the gasoline and diesel consumption, discussed above. Therefore, Phase 2 Coyote Percolation Dam CM construction is also unlikely to cause any strain on peak and base period demand for electricity and other forms of energy, including natural gas.

Construction of the Phase 2 Coyote Percolation Dam CM would result in a temporary increase in transportation energy use. Energy use requirements of diesel and gasoline for construction on-road vehicles during Phase 2 Coyote Percolation Dam CM construction are included in **Table 3.7-11**.

Finally, Phase 2 Coyote Percolation Dam CM construction would utilize fuel-efficient equipment consistent with State and federal regulations related to incorporation of renewable energy and energy efficiency measures. Per applicable regulatory requirements of CALGreen, Phase 2 Coyote Percolation Dam CM construction activities would comply with construction waste management practices to divert construction and demolition debris from landfills. These practices would result in efficient use of energy by Phase 2 Coyote Percolation Dam CM construction.

For the reasons listed above, construction of the Phase 2 Coyote Percolation Dam CM would not result in the wasteful, inefficient, or unnecessary consumption of energy, including non-renewable energy. Therefore, the Phase 2 Coyote Percolation Dam CM construction impact related to the consumption of energy resources is less than significant with mitigation.

Operations and Maintenance

Post-Construction Anderson Dam Facilities Operations and Maintenance

As discussed in Section 3.7.3, *Methodology and Approach to Impact Analysis*, above, post-construction operations and maintenance of the Anderson Dam Facilities would not change energy consumption or procurement of renewable energy from PWRPA compared to the existing conditions baseline. Operation of this Project component would also incorporate non-renewable energy and energy efficiency measures pursuant to CalGreen and the California Energy Efficiency Standards. In addition, the hydroelectric facility is not considered a local or regional energy supplier, nor would its existing non-operational status change with implementation of the Project. As such, post-construction operations and maintenance of the Anderson Dam Facilities would not result in greater utilization of energy, including non-renewable energy, during operation compared to environmental baseline conditions and, thus, would not result in the wasteful, inefficient, or unnecessary consumption of energy resources. Therefore, the Anderson Dam Facilities Operations and Maintenance operational impact related to the consumption of energy resources is less than significant.

Post-Construction Conservation Measures Operations and Maintenance

Post-construction operations of the Phase 2 Coyote Percolation Dam CM would consume 25.2 kWh annually, while the post-construction operations and maintenance of the Ogier Ponds CM, Maintenance of the North Channel Reach ~~Extension~~, Maintenance Activities at the Live Oak Restoration Reach, and the Sediment Augmentation Program would not require new long-term operational sources requiring energy.

Existing baseline conditions of operation of the Phase 2 Coyote Percolation Dam includes manual removal and replacement of the flashboard dam, which does not require electricity consumption. Post-construction operation of the Phase 2 Coyote Percolation Dam CM is estimated to consume approximately 25.2 kWh of electricity annually through the up to four times annual inflation of the bladder dam installed as part of FOCP. As such, a larger amount of operational energy would be used compared to existing baseline conditions. However, post-construction operation of the Phase 2 Coyote Percolation Dam CM represents less than 0.001 percent of Valley Water's annual electricity consumption (Valley Water 2013). Therefore, post-construction operation of the Phase 2 Coyote Percolation Dam CM would not place a significant demand on electricity supply. Additionally, 95 percent of Valley Water's purchased electricity is procured from PWRPA, which provides Valley Water with carbon-free electricity. Thus, post-construction operation of the Phase 2 Coyote Percolation Dam CM would utilize renewable energy for electricity consumption. As such, post-construction operation of the Phase 2 Coyote Percolation Dam CM would not result in greater utilization of non-renewable energy during operation compared to environmental baseline conditions and, thus, would not result in the wasteful, inefficient, or unnecessary consumption of energy resources. Therefore, the Conservation Measures Operations and Maintenance operational impact related to the consumption of energy resources is less than significant.

Post-Construction Project and FAHCE Adaptive Management

As discussed in Section 3.7.3 ~~3.9.3~~, *Methodology and Approach to Impact Analysis*, above, post-construction Project and FAHCE Adaptive Management would generally include monitoring activities and minor construction and maintenance actions, whose impacts would be similar but less than those from original Conservation Measure construction. It would also involve minor adjustments to FAHCE rule curves. As such, post-construction FAHCE Adaptive Management would result in negligible energy consumption and would not result in greater utilization of non-renewable energy compared to environmental baseline conditions and, thus, and would not result in the wasteful, inefficient, or unnecessary consumption of energy resources. Therefore, the Project and FAHCE Adaptive Management operational impact related to the consumption of energy resources is less than significant.

Significance Conclusion Summary

Construction of the Seismic Retrofit and Conservation Measures components would consume approximately 17,842,000 ~~21,150 thousand~~ gallons of diesel and 780,000 ~~2,103 thousand~~ gallons of gasoline. Energy use during construction of the Seismic Retrofit and Conservation Measures components would result in increased demand on local and regional supplies of fossil fuel, such as diesel and gasoline. However, compared to the northern California region's annual average production of fuel over the 5-year period of 2018-2022, the total annual average energy demand of the Project would be approximately 0.01 ~~0.03~~ percent of the region's gasoline production throughput and approximately 0.75 ~~0.89~~ percent of the region's diesel production throughput (CEC 2023a~~c~~). The impacts of Project construction on local and regional fuel supplies would be temporary and minimal.

Furthermore, implementation of **Mitigation Measures AQ-1** and **GHG-1** would increase the efficiency of energy usage and decrease the amount of non-renewable energy usage during construction. Specifically, implementation of **Mitigation Measure AQ-1** will require all construction equipment greater than 25 hp and operating for more than 20 hours over the entire duration of construction activities to be equipped with Tier 4 engines and would require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** will also minimize construction equipment idling time and require regular maintenance for all equipment. Implementation of **Mitigation Measure GHG-1** will require use of zero emission construction equipment whenever feasible as well as renewable diesel fuel.

Project construction would utilize fuel-efficient equipment consistent with State and federal regulations and would comply with State measures to reduce the inefficient, wasteful, or unnecessary consumption of energy. Per applicable regulatory requirements of CALGreen, Project construction activities would comply with construction waste management practices to divert construction and demolition debris from landfills. These practices would result in efficient use of energy by Project construction.

Post-construction operations and maintenance of the Project would consume a minimal amount of electricity, and the electricity consumed would be sourced from renewable resources. Therefore, because the Project would not result in any wasteful, inefficient, or unnecessary consumption of energy resources, the overall Project impact related to energy consumption is less than significant, and after mitigation to further reduce impacts would be **less than significant with mitigation**.

Table 3.7-12. Overall Project Construction Gasoline and Diesel Consumption

Year	Diesel (Thousand Gallons)	Gasoline (Thousand Gallons)
Year 1	400 ~~113~~	105 ~~5~~
Year 2	2,663 ~~2,58~~5	95 ~~181~~
Year 3	2,575 ~~2,549~~	104 ~~197~~

Mitigation Measures

AQ-1 Implement Construction Criteria Air Pollutants Reduction Measures

GHG-1 Utilize Electrification and Renewable Fuels During Construction

Impact ENR-2: Conflict with or obstruct a state or local plan for renewable energy or energy efficiency **(Less than significant with mitigation)**

Construction

Seismic Retrofit and Conservation Measures Construction

Project construction would utilize fuel-efficient equipment consistent with State and federal regulations and would comply with State measures to reduce the inefficient, wasteful, or unnecessary consumption of energy. The Valley Water CCAP, Santa Clara County General Plan, Santa Clara County Sustainability Master Plan, City of Morgan Hill 2035 General Plan, and Envision San José 2040 General Plan provide renewable energy and energy reduction policies. However, none of these policies are specifically relevant to construction activities outside of encouraging the use of fuel efficient or alternative fuel equipment and vehicles, and reducing transportation energy. Implementation of **Mitigation Measures AQ-1 and GHG-1** would increase the efficiency of energy usage during Project construction, consistent with these policies. Implementation of **Mitigation Measure AQ-1** will require all construction equipment greater than 25 hp and operating for more than 20 hours over the entire duration of construction activities to be equipped with Tier 4 engines and would require all on-road <u>truck</u> engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** will also minimize construction equipment idling time and require regular maintenance for all equipment. Implementation of **Mitigation Measure GHG-1** will require use of zero emission construction equipment whenever feasible as well as renewable diesel fuel. As such, Project construction of buildings and use of equipment and vehicles would adhere to the renewable energy and energy efficiency standards and guidance included in the aforementioned State and local plans. Therefore, the Seismic Retrofit construction and Conservation Measures construction would not conflict with or obstruct a State or local plan for renewable energy or energy efficiency, and the impact would be less than significant with mitigation.

Operations and Maintenance

Post-Construction Anderson Dam Facilities Operations and Maintenance

As discussed in Section 3.7.3, *Methodology and Approach to Impact Analysis*, above, post-construction operations and maintenance of the Anderson Dam Facilities would not substantially change energy consumption compared to the existing conditions baseline. In addition, the hydroelectric facility is not considered a local or regional energy supplier, nor would its existing non-operational status change with implementation of the Project. As such, post-construction operations and maintenance of the Anderson Dam Facilities would result in negligible energy consumption during operational use of equipment and vehicles and adhere to the renewable energy and energy efficiency standards and guidance included in the aforementioned State and local plans. Therefore, post-construction Anderson Dam facilities operations and maintenance would not conflict with or obstruct a State of California or local plan for renewable energy or energy efficiency, and the impact would be less than significant.

Post-Construction Conservation Measures Operations and Maintenance

As discussed under Impact ENR-1 above, post-construction operations of the Phase 2 Coyote Percolation Dam CM would consume 25.2 kWh annually, which would result in more energy consumption for operation of the inflatable bladder dam in comparison to existing baseline conditions. The post-construction operations and maintenance of the Ogier Ponds CM, <u>Maintenance of the</u> North Channel <u>Reach</u> ~~Extension~~, Maintenance Activities at the Live Oak Restoration Reach, and the Sediment Augmentation Program would not require new long-term operational sources requiring energy. Thus, only the Phase 2 Coyote Percolation Dam CM is discussed below in terms of Conservation Measures Operations and Maintenance consistency with plans and regulations for renewable energy and energy efficiency.

<u>Senate Bill 100, 2022 California Green Building Standards, and 2022 California Building Energy Efficiency Standards Consistency</u>

The primary State regulation that aims to increase the production and use of renewable energy is SB 100. SB 100 supports the reduction of GHG emissions from the electricity sector by accelerating the State’s RPS Program and requires electricity providers to increase procurement from eligible renewable energy resources to 33 percent of total retail sales by 2020, 60 percent by 2030, and 100 percent by 2045. Valley Water procures 95 percent of its electricity from PWRPA’s zero carbon profile, which sources electricity from renewable energy sources. Thus, post-construction operation of the Phase 2 Coyote Percolation Dam CM would be powered by renewable energy procured from PWRPA. This exceeds SB 100 requirements, which requires electricity providers to increase procurement from eligible renewable energy resources to 33 percent of total retail sales by 2020, 60 percent by 2030, and 100 percent by 2045. As such, Project operational use of equipment and vehicles would adhere to the renewable energy targets, standards, and guidance included in SB 100. Therefore, post-construction operation of the Phase 2 Coyote Percolation Dam CM would align with the overall intent of SB 100 and be consistent with this State renewable energy plan.

Relevant State regulations that aim to increase energy efficiency include the 2022 California Green Building Standards Code (CALGreen or Title 24 Part 11) and the 2022 California Building Energy Efficiency Standards (Title 24 Part 6). CALGreen (Title 24 Part 11) institutes mandatory minimum environmental performance standards for all ground-up new non-residential and residential structures and major renovations.[2] In addition, the California Building Energy Efficiency Standards (Title 24 Part 6) establishes energy-efficiency standards for residential and non-residential buildings in order to reduce California's energy demand. CCR Title 24 (Parts 6 and 11) is updated periodically to incorporate and consider new energy-efficiency technologies and methodologies as they become available. New structures and major renovations must demonstrate their compliance with the current Building Energy Efficiency Standards and CalGreen through submission and approval of a Title 24 Compliance Report to the local building permit review authority and the CEC. Post-construction operation of the Phase 2 Coyote Percolation Dam CM would be designed to comply with the energy efficiency standards of CALGreen and the California Building Energy Efficiency Standards. Therefore, compliance with these regulations would minimize potential conflicts with these State energy efficiency plans.

Valley Water CCAP Consistency

The CCAP includes goals related to renewable energy and energy efficiency to guide Valley Water's response to climate change. Post-construction operation of the Phase 2 Coyote Percolation Dam CM consistency with the CCAP is discussed in **Table 3.7-13**. As shown therein, post-construction operation of the Phase 2 Coyote Percolation Dam CM related to equipment and vehicle use would be consistent with the renewable energy and energy efficiency goals of the Valley Water CCAP.

Table 3.7-13. Valley Water CCAP Strategies Consistency Analysis

Goals	Action	Description	Project Consistency
Expand Renewable Energy and Improve Energy Efficiency	1.3.3	Continue to replace less efficient equipment with more fuel-efficient Class 4 equipment or devices that are powered by renewable energy.	Consistent. Post-construction operation of the Phase 2 Coyote Percolation Dam CM would replace operations of the existing flashboard dam with a remotely operated bladder dam. Post-construction operation of the Phase 2 Coyote Percolation Dam CM would be powered by renewable energy that Valley Water would procure from PWRPA. Although the bladder dam

[2] Major renovations are defined as changes to the building envelop or changing equipment, including different components and entire systems.

Goals	Action	Description	Project Consistency
			would consume more electricity than the flashboard dam (given the flashboard dam is currently removed and replaced manually), remote operation of the bladder equipment would reduce the number of vehicle trips needed to operate the dam. Thus, this Project component would replace less-fuel-efficient vehicle trips with more fuel-efficient equipment powered by renewable energy.
	1.3.5	Promote use of renewable energy for Valley Water field monitoring equipment.	Consistent. Post-construction operation of the Phase 2 Coyote Percolation Dam CM equipment, including monitoring equipment, use would be powered by renewable energy that Valley Water would procure from PWRPA.

Santa Clara County General Plan, Santa Clara County Sustainability Master Plan, Morgan Hill 2035 General Plan, Envision San José 2040 General Plan Consistency

The Santa Clara County General Plan, Santa Clara County Sustainability Master Plan, City of Morgan Hill 2035 General Plan, and Envision San José 2040 General Plan provide renewable energy and energy reduction policies. However, most of these policies are not relevant to post-construction operation of the Phase 2 Coyote Percolation Dam CM. Post-construction operation of the Phase 2 Coyote Percolation Dam CM consistency with relevant policies is discussed in **Table 3.7-14**. As shown therein, post-construction operation of the Phase 2 Coyote Percolation Dam CM related to equipment and vehicle use would be consistent with the renewable energy and energy efficiency policies of the Santa Clara County General Plan, Santa Clara County Sustainability Master Plan, City of Morgan Hill 2035 General Plan, and Envision San José 2040 General Plan.

Table 3.7-14. Santa Clara County General Plan, Santa Clara County Sustainability Master Plan, Morgan Hill 2035 General Plan, Envision San José 2040 General Plan Policies Consistency Analysis

Policy	Project Consistency
Santa Clara County General Plan	
Policy C-RC 77: Energy efficiency and conservation efforts in the transportation, industrial, commercial, residential, agricultural and public sectors shall be encouraged at the local, county (subregional), and regional level.	Consistent. Post-construction operation of the Phase 2 Coyote Percolation Dam CM would be powered by renewable energy that Valley Water would procure from PWRPA. Additionally, post-construction operation of the Phase 2 Coyote Percolation Dam CM would be designed to comply with the energy efficiency and conservation standards of CALGreen and the California Building Energy Efficiency Standards.

Policy	Project Consistency
Policy HE-G.10: Promote energy conservation and efficiency in homes, businesses, schools, and other infrastructure to reduce energy use and criteria pollutant and greenhouse gas emissions.	Consistent. Post-construction operation of the Phase 2 Coyote Percolation Dam CM would be powered by renewable energy that Valley Water would procure from PWRPA. The use of renewable energy to operate Phase 2 Coyote Percolation Dam CM equipment, rather than the use of non-renewable energy, would promote energy conservation and reduced non-renewable energy use, which in turn would also reduce emissions of criteria air pollutants and GHGs.
Santa Clara County Sustainability Master Plan	
Strategy 1.1. Clean Energy. The County has set a target of a 100 percent renewable energy system by 2045 which aligns with the State's Policies and Regulations. This strategy will evaluate opportunities to transition gas-powered equipment to electric. It will look to expand and incentivize the installation of solar photovoltaic systems at County sites and private land owners. Evaluate opportunities to expand wind-powered energy generation in the County. The County will also conduct a cost-benefit analysis of energy-related climate solutions.	Consistent. Valley Water procures 95 percent of its electricity from PWRPA's zero carbon profile, which sources electricity from renewable energy sources. Thus, post-construction operation of the Phase 2 Coyote Percolation Dam CM would be powered by renewable energy procured from PWRPA and would be consistent with the County's target to reach 100 percent renewable energy by 2045.
City of Morgan Hill 2035 General Plan	
Policy NRE-16.1: Energy Standards for New Development. New development, including public buildings, should be designed to exceed State standards for the use of energy.	Consistent. Post-construction operation of Phase 2 Coyote Percolation Dam CM equipment would be designed to comply with the energy conservation and efficiency standards of CALGreen and the California Building Energy Efficiency Standards that constitute State standards for the use of energy.
Policy NRE-16.2: Energy Conservation. Promote energy conservation techniques and energy efficiency in building design, orientation, and construction.	Consistent. Post-construction operation of Phase 2 Coyote Percolation Dam CM facilities related to the bladder dam would be designed to be comply with the energy conservation techniques and efficiency required by CALGreen and the California Building Energy Efficiency Standards.
Envision San José 2040 General Plan	
Policy MS-14.4: Implement the City's Green Building Policies so that new construction and rehabilitation of existing buildings fully implements industry best practices, including the use of optimized energy systems, selection of materials and resources, water efficiency, sustainable site	Consistent. Post-construction operation of Phase 2 Coyote Percolation Dam CM facilities related to the bladder dam would be designed to be comply with the energy conservation techniques and efficiency required by CALGreen and the California Building Energy Efficiency Standards, which include industry best practices to reduce energy consumption.

Policy	Project Consistency
selection, passive solar building design, and planting of trees and other landscape materials to reduce energy consumption.	

Overall, the Post-Construction Conservation Measures Operations and Maintenance would not conflict with or obstruct State or local plans for renewable energy or energy efficiency, and the impact would be less than significant.

Post-Construction Project and FAHCE Adaptive Management

As discussed in Section 3.7.3 ~~3.9.3~~, *Methodology and Approach to Impact Analysis*, above, post-construction Project and FAHCE Adaptive Management would generally include monitoring activities and minor construction and maintenance actions, whose impacts would be similar but less than those from original Conservation Measure construction. It would also involve minor adjustments to FAHCE rule curves. As such, post-construction Project and FAHCE Adaptive Management would result in negligible energy consumption during equipment and vehicle operation and adhere to the renewable energy and energy efficiency standards and guidance included in the aforementioned State and local plans. Therefore, the Post-Construction Project and FAHCE Adaptive Management would not conflict with or obstruct a State or local plan for renewable energy or energy efficiency, and the impact would be less than significant.

Significance Conclusion Summary

Project construction would be consistent with renewable energy and energy efficiency targets, standards, and guidance included in California Green Building Standards Code (CALGreen or Title 24 Part 11), California Building Energy Efficiency Standards (Title 24 Part 6), SB 100, Valley Water CCAP, Santa Clara County General Plan, Santa Clara County Sustainability Master Plan, Morgan Hill 2035 General Plan, and Envision San José 2040 General Plan with implementation of **Mitigation Measures AQ-1 and GHG-1**. Project operation related to equipment and vehicle energy use would be consistent with these regulations and plans without mitigation. Therefore, Project construction and operation would not conflict with or obstruct a state or local plan for renewable energy or energy efficiency, and overall impacts would be less than significant, and after mitigation to further reduce impacts would be **less than significant with mitigation.**

Mitigation Measures

AQ-1 Implement Construction Criteria Air Pollutants Reduction Measures

GHG-1 Utilize Electrification and Renewable Fuels During Construction

3.7.5 Cumulative Impacts

The cumulative impact study area for energy focuses on the portions of the County, San José, and Morgan Hill that comprise the Project Area, including the construction limits of the Seismic Retrofit and Conservation Measures components.

The approach to the cumulative impacts analysis and list of foreseeable future projects, programs, and plans considered in the cumulative impact analysis is included in Section 3.0.5, *Approach to Cumulative Impacts*.

This section describes the Project's contribution to cumulative energy impacts, as summarized in **Table 3.7-15**. Cumulative impact thresholds for energy are the same as the impact thresholds presented in Section 3.7.3.8 ~~3.9.3.8~~, *Thresholds of Significance*.

Table 3.7-15. Summary of Project Impact Contribution to Cumulative Energy Impacts

Impact	Significant Cumulative Impact with FOCP?	Significant Cumulative Impact with other Projects?	Incremental Project Contribution	Applicable Project Mitigations	Cumulatively Considerable after Mitigation?
Cumulative Impact ENR-1: Result in a significant environmental impact due to wasteful, inefficient, or unnecessary consumption of energy resources	No	Yes	CC	MM AQ-1 MM GHG-1	No
Cumulative Impact ENR-2: Conflict with or obstruct a state or local plan for renewable energy or energy efficiency	No	No	NCC	MM AQ-1 MM GHG-1	No

Key: CC = cumulatively considerable; MM = Mitigation Measure; NCC = not cumulatively considerable

Cumulative Impact ENR-1: Result in a significant environmental impact due to wasteful, inefficient, or unnecessary consumption of energy resources (Not Cumulatively Considerable)

Cumulative Effects of Project with the FOCP

The FOCP would be completed before construction activities for the Project begin; therefore, these two projects would not result in cumulative impacts related to energy usage. There would be no cumulative effect.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Most of the other reasonably foreseeable future projects identified in Section 3.0.5, *Approach to Cumulative Impacts*, would occur within the County. Construction or operation of future projects, programs, and plans could overlap in time with the 8 ~~15~~-year construction schedule that Seismic Retrofit components and Conservation Measures construction would occur.

Cumulative development would increase consumption of energy resources. However, new iterations of the California Building Energy Efficiency Standards and CALGreen would require increasingly more energy efficient appliances and building materials that reduce energy consumption in new development. In addition, vehicle fuel efficiency is anticipated to continue improving through implementation of the existing Pavley Bill regulations under AB 1493. As indicated under Impact ENR-1, Project construction would have a less-than-significant impact with mitigation incorporated related to the wasteful, inefficient, or unnecessary consumption of energy, including non-renewable energy. Implementation of **Mitigation Measure AQ-1** will require all construction equipment greater than 25 hp and operating for more than 20 hours over the entire duration of construction activities to be equipped with Tier 4 engines and will require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** will also minimize construction equipment idling time and require regular maintenance for all equipment. Implementation of **Mitigation Measure GHG-1** will require use of zero emission construction equipment whenever feasible as well as renewable diesel fuel. Project operation would not result in the wasteful, inefficient, and unnecessary consumption of energy resources. Nevertheless, the combined increase in energy consumption from cumulative projects, when added to the Project's impacts could result in a significant cumulative impact related to the wasteful, inefficient, and unnecessary consumption of energy, including non-renewable energy, and the Project's contribution to this impact could be cumulatively considerable. However, **Mitigation Measures AQ-1** and **GHG-1** would reduce the Project's incremental impact so that it would be not cumulatively considerable after mitigation.

Significance Conclusion Summary

Valley Water would reduce Project construction's incremental contribution to cumulative impacts with regard to wasteful, inefficient, and unnecessary consumption of energy, including non-renewable energy, through implementation of **Mitigation Measures AQ-1** and **GHG-2**. Implementation of **Mitigation Measure AQ-1** will require all construction equipment greater than 25 hp and operating for more than 20 hours over the entire duration of construction activities to be equipped with Tier 4 engines and will require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** will also minimize construction equipment idling time and require regular maintenance for all equipment. Implementation of **Mitigation Measure GHG-1** will require use of zero emission construction equipment whenever feasible as well as renewable diesel fuel. With implementation of **Mitigation Measures AQ-1 and GHG-1,** Project construction would not result in the wasteful, inefficient, and unnecessary consumption of energy resources. Project operation would not result in the wasteful, inefficient, and unnecessary consumption of energy resources without mitigation. Nevertheless, the combined increase in energy consumption from cumulative projects would potentially result in a significant cumulative impact related to the wasteful, inefficient, and unnecessary consumption of energy, including non-renewable energy. The Project's contribution to this impact could be cumulatively considerable. However, **Mitigation Measure AQ-1** and **GHG-1** would reduce the Project's incremental impact so that it would be **not cumulatively considerable** after mitigation.

Mitigation Measures

AQ-1 Implement Construction Criteria Air Pollutants Reduction Measures

GHG-1 Utilize Electrification and Renewable Fuels During Construction

Cumulative Impact ENR-2: Conflict with or obstruct a state or local plan for renewable energy or energy efficiency (Not Cumulatively Considerable)

Cumulative Effects of Project with the FOCP

The FOCP would be completed before construction activities for the Project begin; therefore, these two projects would not result in cumulative impacts related to GHG emissions. There would be no cumulative effect.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Most of the other reasonably foreseeable future projects identified in Section 3.0.5, *Approach to Cumulative Impacts*, would occur within the County. Construction or operation of future projects, programs, and plans could overlap in time with the 8 ~~15~~-year construction schedule that Seismic Retrofit components and Conservation Measures construction would occur. Cumulative development construction and operation would increase use of energy, including non-renewable energy. However, future projects, programs, and plans throughout the county are required to adhere to applicable renewable energy and energy efficiency regulations, plans, programs, and policies such as California's RPS, the CARB 2022 Scoping Plan, SB 100, Title 24 (Parts 6 and d), and local county and city standards. As discussed under Impact ENR-2, Project construction would be consistent with the energy-related goals and policies of the Statewide plans and regulations with mitigation. Implementation of **Mitigation Measure AQ-1** will require all construction equipment greater than 25 hp and operating for more than 20 hours over the entire duration of construction activities to be equipped with Tier 4 engines and will require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** will also minimize construction equipment idling time and require regular maintenance for all equipment. Implementation of **Mitigation Measure GHG-1** will require use of zero emission construction equipment whenever feasible as well as renewable diesel fuel. Project operation would not conflict with the energy efficiency and renewable energy-related goals and policies of the Statewide plans and regulations. The Project would not contribute to a significant cumulative impact with respect to consistency with such renewable energy and energy efficiency plans. Therefore, the cumulative impact resulting from the Project in combination with other probable future projects would be cumulatively less than significant, and the Project's contribution would not be cumulatively considerable.

Significance Conclusion Summary

Valley Water would reduce Project construction's incremental contribution to cumulative impacts on consistency with renewable energy and energy efficiency plans through implementation of **Mitigation Measures AQ-1** and **GHG-1**. Implementation of **Mitigation Measure AQ-1** will require all construction equipment greater than 25 hp and operating for more than 20 hours over the entire duration of construction activities to be equipped with Tier 4 engines and will require all on-road truck engines and boats to be year 2010 or newer. Implementation of **Mitigation Measure AQ-1** will also minimize construction equipment idling time and require regular maintenance for all equipment. Implementation of **Mitigation Measure GHG-1** will require use of zero emission construction equipment whenever feasible as well as renewable diesel fuel. With implementation of **Mitigation Measures AQ-1** and **GHG-1,** Project construction would not conflict with any renewable energy and energy efficiency plans. Project operation would also not conflict with any renewable energy and energy efficiency plans. Therefore, the Project's contribution to cumulative impacts on consistency with renewable energy and energy efficiency plans is **not cumulatively considerable.**

3.8 Geology and Soils

This section evaluates Project impacts on the study area that has been defined for geologic hazards and soils resources. The *CEQA Guidelines* significance criteria for geology and soils addresses impacts related to the rupture of a known earthquake fault, strong seismic ground shaking, seismic-related ground failure that includes liquefaction and lateral spreading, landslides, substantial soil erosion or loss of topsoil, unstable geologic units, expansive soils, and paleontological resources.

The study area that was defined to assess impacts related to geology and soils is limited to the Project Area that includes the construction limits of the Seismic Retrofit component and Conservation Measures components (**Figure 2-3** in Chapter 2, *Project Description*), and the total surface and subsurface area within which all Project activities would occur.

Existing conditions, including regional and Project Area geology, soils, geologic and seismic hazards, landslides and other slope instability hazards, and the potential for paleontological resources, are described below. More detailed paleontological resources information can also be found in Appendix P, *Paleontological Resources Impact Assessment*. ~~*for the Anderson Dam Retrofit Project,*~~ ~~and~~ ~~*Post-Paleontological Survey for the Anderson Dam Drawdown to Deadpool Project*~~

Note that the Project does not involve the installation of septic tanks or alternative wastewater disposal systems. Therefore, the capability for soils within the Project Area to support septic tanks or alternative wastewater systems is not discussed in this section.

3.8.1 Environmental Setting

3.8.1.1 Geology

Regional Geology

The Project is located on the southwestern flank of the Diablo Range on the southeastern margin of the Santa Clara Valley, a southward extension of the valley occupied by the San Francisco Bay (URS 2021a). The Santa Clara Valley and surrounding mountain ranges are located within the Coast Range Geomorphic Province of California, which extends from south of the Oregon border to the central coast of California (California Geological Survey [CGS] 2015). This geomorphic province is characterized by mountains that range in elevation from 2,000 to 4,000 feet above mean sea level and sometimes reach elevations as high as 6,000 feet (CGS 2015). The rocks of the Santa Cruz Mountains are being pulled north and west, away from the crustal block defining the Diablo Range on the east (Stoffer and Messina 2002). This northwest relative motion between the Santa Cruz Mountains and the Diablo Range is causing the intervening Santa Clara Valley to drop relative to the surrounding mountain ranges.

Geologic units in the Santa Clara Valley include large alluvial complexes, Cenozoic sedimentary sequences, and varying basement rocks. The basement rocks in the Santa Cruz Mountains, beneath the Santa Clara Valley, and in the Diablo Range, consist of the Franciscan Complex structurally overlain by the Coast Range Ophiolite and Mesozoic marine deposits of the Great Valley Sequence. The Santa Cruz Mountains, Santa Clara Valley, and Diablo Range have been divided into several distinct northwest-southeast trending fault-bounded blocks. Margins of the valley contain large alluvial fan gravel deposits including Miocene and Pliocene volcanics and Pleistocene gravels (Wentworth et al. 1999 ~~1998~~).

Anderson Reservoir and Coyote Creek are within the Coyote Block and the Silver Creek Block and fill the canyon drained by Coyote Creek. The rock units in the Coyote block consist of Jurassic Coast Range ophiolite and overlying Cretaceous and Tertiary strata. In the northernmost part of the block, the Tertiary sequence consists of Eocene mudstone, middle Miocene Claremont Formation, and middle to upper Miocene Briones Formation. In the east-central part of the block, in contrast, the sequence is composed of lower to middle Miocene Temblor sandstone overlain by Claremont Formation. The Coyote Block pinches out to the north where bedding steeply[1] converges with steeply west-dipping reverse faults. A large, northwest-trending, very steeply northeast-dipping linear ridge of silica-carbonate rock is present upstream of the right abutment and spillway. Steeply dipping stream and alluvial fan gravel deposits of the Miocene-Pliocene Silver Creek gravels occur in the eastern sections of the Project area (**Figure 3.8-1**) (Wentworth et al. 1999 ~~1998~~).

The Silver Creek Block is exposed, or visible at ground surface, northeast of the southern Santa Clara Valley. In the Silver Creek Block, Pliocene Silver Creek gravels are faulted between serpentinite and Franciscan mélange or have moved relative to each other as a result of tectonic forces. Structurally interleaved between the basement rocks are tightly folded Jurassic through Tertiary strata, including the Pliocene Silver Creek Gravels. The basement rocks were thrust over these strata along the Silver Creek thrust. In addition to its structural formation, the Silver Creek block contrasts with surrounding blocks in its Tertiary stratigraphy. The locally exposed Miocene rocks in the block are quite different from the Miocene sections in the adjacent Alum Rock, Coyote, and New Almaden blocks, being composed of mica-rich sandstone and 9.3-10.5 mega annum (Ma) andesite and basalt instead of fossiliferous quartz-lithic sandstone, siliceous shale, and polymictic conglomerate. The large volume of Pliocene volcanic rocks is also unique to the Silver Creek block (**Figure 3.8-1**) (Wentworth et al. 1999 ~~1998~~).

Prior to the construction of the Anderson Dam, Coyote Creek drained directly into the Santa Clara Valley, forming a broad alluvial fan. The Pleistocene-age Coyote Creek alluvial fan deposits consist of coarse sand and gravel with local accumulations of middle and late Pleistocene-age vertebrate fossils (Helley and Brabb 1971). The Holocene-age alluvial deposits consist of moderately well sorted fine sand and silt. Gravel beds became more abundant toward fan heads. The Holocene-age deposits locally contain aboriginal artifacts and skeletal remains (Helley and Brabb 1971).

Project Area Geology

Seismic Retrofit Project Area

The rocks underlying the majority of Anderson Dam have been described as Franciscan Complex rocks, including zones of serpentinite, mélange, graywacke sandstone, and local metavolcanics (greenstone, basalt). These rock types generally occur in distinct, northwest-trending zones, and are separated by faults. Specifically, the upstream end of the spillway and the upstream right abutment are underlain by sheared serpentinite. The central part of the embankment and

[1] *Dipping* refers to the angle at which sediments are tilted as a result of tectonic forces.

downstream spillway are underlain by graywacke sandstone and mélange with high shale content, and the southwestern part of the downstream left abutment and downstream end of unlined spillway chute are underlain by metavolcanic rocks and serpentinite (URS 2021a).

The Santa Clara Formation and younger sediments overlie the bedrock beneath and near the embankment and spillway. The Santa Clara Formation consists of poorly sorted conglomerate, sandstone, siltstone, and claystone formed by prehistoric streams (Iwamura 1995). The age of these deposits ranges from approximately 500,000 years to 4 million years (Pliocene to Pleistocene) (URS 2021a). The boundary between the underlying Franciscan Complex and the Santa Clara Formation is an unconformity representing a gap of millions of years in the geologic record. Younger (late Pleistocene to late Holocene) alluvial fans emanate from drainages in the Diablo Range and overlie Mesozoic rocks and Santa Clara Formation sediments along the range front (URS 2021a). The geology in the area surrounding Anderson Dam is shown on **Figure 3.8-2.**

Conservation Measures Project Area

As described above, Coyote Creek historically drained directly into the Santa Clara Valley, forming a broad alluvial fan. Thus, the area downstream of Anderson Dam along Coyote Creek in the vicinity of the Conservation Measure components consists of Holocene- and Pleistocene-age natural floodplain and alluvial fan deposits (refer to **Figure 3.8-2**)**.** The Santa Clara Formation and younger sediments are located in the vicinity of the Conservation Measures. Where younger sediments are exposed at ground surface, Santa Clara Formation is likely to underlie the younger sediments at unknown depth.

3.8.1.2 Soils

Soils are comprised of particles known as sand, silt, and clay with variable amounts of organic matter. Soil types provide site-specific information, such as erosion and runoff potential, and various behaviors that effect structures, such as expansion and settlement. Soils that are primarily sandy are porous and are less stable and more susceptible to seismic hazards, such as liquefaction and erosion. Soils that are primarily clay are close-textured but can be expansive, and susceptible to shrinking and swelling. Finally, soils overlaying steep slopes or soft alluvial geologic units are more susceptible to instability, such as landslides.

Seismic Retrofit Project Area

Native and artificial soils (excluding modern lake sediment) at the Anderson Dam site, particularly in the valley bottom and lower slopes, are generally derived from coarse-grained alluvial deposits or formations (URS 2022). The principal soil types found in the vicinity of the Seismic Retrofit area, based on the Natural Resources Conservation Service (NRCS) soil survey for the eastern Santa Clara area, are characterized by the presence of the following soil units: Altamont clay, Garretson loam, Gilroy clay loam, Hillgate silt loam, Inks stony clay loam, Keefers clay loam, and Montara rocky clay loam (NRCS 2019) (**Figure 3.8-3**). These soil units are classified as being well drained, with bedrock occurring 10 to 36 inches below the surface. The parent material for these soils is residuum from weathered greenstone, basalt, and sandstone formations.

Soils derived from weathered bedrock (i.e., Franciscan Complex, Santa Clara formation) generally have higher amounts of fine-grained material (silt and clay) but are not known to contain clay properties associated with shrink/swell behavior. Review of available online NRCS soil mapping data (URS 2022) for the area around the dam and downstream indicates that the soils outside of the recent Coyote Creek channel, where the alluvium is granular and non-plastic,[2] have plasticity index[3] ranging from about 5 to 25, with most of the soils between 10 and 20, and are therefore not classified as expansive soils (URS 2022). NRCS maps describe the area around the dam and just downstream as having soils with low or moderate shrink/swell qualities (NRCS 2021 ~~2022~~). ~~Additionally, all of the Seismic Retrofit components would be constructed on bedrock foundations or on compacted fill materials that do not exhibit shrink/swell behavior (URS 2022).~~

Undisturbed soil is not found on the dam faces; fill material to create the dam was taken from nearby quarries (Valley Water 2012).

Conservation Measures Project Area

Soils found along Coyote Creek in the vicinity of the Conservation Measures components are typical of those found near water features within historical floodplains. The units are listed below (NRCS 2019). All soils within the conservation measures area have low to moderate expansiveness (NRCS 2021 ~~2022~~).

- Soils in the North Channel Reach ~~Extension~~, Live Oak Restoration Reach, and the Sediment Augmentation and Cold Water Management Zone consist of the Cortina very gravelly loam, Garretson loam, and river wash.
- Soils in the vicinity of Ogier Ponds CM consist primarily of gravelly loams and clay, including Cortina very gravelly loam, river wash, Garretson loam, Yolo silty clay loam, and Hillgate silt loam.
- Soils near the Phase 2 Coyote Percolation Dam CM consist of the Canine creek complex sandy loam and the Cropley clay.

[2] Plastic soils are generally more predominantly of clay and thus are more expansive than non-plastic soils.
[3] Soils with a low plasticity index from 0 to 20 generally are considered to have low expansion potential, whereas soils with a plasticity index over 35 are considered to have high expansion potential (EDT 2018).

Anderson Dam Seismic Retrofit Project
Environmental Impact Report

3.8.1.3 Geologic and Seismic Hazards

Seismic activity in California is concentrated in tectonically active regions, such as the Coast Ranges, the Sierra Nevada Range, and the Cascades Range. There are thousands of mapped faults in the Coast Ranges, including dozens in the county and at least four in the vicinity of the Project area (CDOC 2015). The Santa Clara Valley is part of the San Andreas fault system, which comprises a complex system of primarily northwest-trending, right lateral, strike-slip faults that include the San Andreas, Hayward, and Calaveras faults. Smaller faults in the Project area are potentially connected to these larger faults; specifically, the Coyote Creek Range Front fault could be linked to the Calaveras fault (URS 2021b).

In accordance with the Alquist-Priolo Earthquake Fault Zoning Act of 1972, only faults with evidence of historic or Holocene surface fault rupture are considered active (or Holocene-active) earthquake faults. A fault whose recency of past movement is older than 11,700 years is a pre-Holocene fault. Under DSOD fault categorization, an active fault is one that has ruptured within the last 35,000 years, and a conditionally active fault is one that has ruptured in the Quaternary, but its displacement history during the last 35,000 years is unknown. Some faults in the Project area are active, whether based on the DSOD or the CGS Alquist-Priolo method of classification (see 3.8.2, *Regulatory Setting*, below). **Table 3.8-1** shows the fault names, whether they are considered active under CGS and DSOD, distance and direction from the Project area, and the estimated maximum moment magnitude.

Table 3.8-1. Faults in the Project Area

Fault	CGS (DSOD) Active[a,b]	Distance from Project Area	Direction from Project Area	Maximum Moment Magnitude (Mw)
Coyote Creek Range Front	Undifferentiated Quaternary (conditionally active)	Intersects	Intersects	6.6
Calaveras	Historic (active)	Intersects	Intersects	6.8
Sargent-Berrocal	Historic (active)	10.0	West	6.8
San Andreas	Historic (active)	10.7	West	7.9
Monte-Vista/Shannon	Late Quaternary (conditionally active)	14.7	Northwest	6.8
Hayward	Historic (active)	15.9	Northwest	7.1
San Gregorio	Historic (active)	42.6	West	7.3

Sources: Table 3.8-1USGS 2021~~a~~, URS 2021b, Peterson et al. 1996, DSOD 2018, CGS 2010

Notes:

CGS classifies faults on the basis of surface fault rupture hazard, as follows:

Historic faults that have shown movement within the past 250 years

Holocene faults that have shown movement in the past 11,700 years

Late Quaternary faults that have shown movement between 11,700 and 1.6 million years

Undifferentiated Quaternary faults that have shown movement at an unspecified time during the Quaternary

B DSOD classifies faults on the basis of seismic hazard, as follows:

Active fault – A fault having ruptured within the last 35,000 years

Conditionally active fault – A fault having ruptured in the Quaternary, but its displacement history during the last 35,000 years is unknown.

Inactive fault – Fault inactivity is demonstrated by a fault trace that is consistently overlain by unbroken geologic material older than 35,000 years. A fault that has no indication of Quaternary activity is presumed to be inactive, except in regions of sparse Quaternary cover.

Key: CGS = California Geological Survey; DSOD = Division of Safety of Dams; MW = megawatt

Other faults within the Santa Clara Valley include the Silver Creek fault, the San José fault, the Monte Vista-Shannon fault zone, the Sargent-Berrocal fault, and Calero fault located west of the Project area; Arroyo Aguague fault located to the north; and the Hayward fault zone located to the northwest. In addition, the San Andreas fault zone traverses the Santa Cruz Mountains west of the Santa Clara Valley, and the San Gregorio fault lies west of the San Andreas fault zone. While the Project could experience the effects of movement along any of these faults, due to their location there is no possibility that Project activities could change the risk of tectonic movement and seismic effects. Therefore, these faults are not discussed further.

As described in Chapter 2, *Project Description*, and shown in **Figure 3.8-4**, Anderson Reservoir sits on the Coyote Creek Range fault system. Anderson Dam is located between two faults associated with the Coyote Creek Range fault system; the Coyote Creek Range fault, which passes through the dam and extends to the northwest along Coyote Creek, and the Front Range fault, which extends southeast of the dam (URS 2021b). For purposes of this section and as shown in **Figure 3.8-4**, the Coyote Creek Range fault system is also referred to as the Coyote Creek Front Range fault or Coyote Creek Range fault zone. The Coyote Creek Range fault system and other nearby faults are capable of producing fault offsets on the earthquake-producing fault during a large earthquake that could result in as much as 4 feet of sharp, discrete offset along any of the fault traces (Valley Water 2012). The MCE[4] for the Coyote Creek Front Range fault was identified to be a 6.6-magnitude (M), reverse-oblique event occurring at the dam site which would generate a peak ground acceleration (PGA)[5] of 1.14g[6] at the site (URS 2021b). This PGA equates to extremely intense ground shaking, as shown in **Table 3.8-2**, which presents approximate earthquake magnitudes and average peak accelerations associated with each intensity value.

The Calaveras fault is located approximately 1-mile east of Anderson Dam and traverses across the southeastern leg of the reservoir. The MCE for the Calaveras fault was identified to be a 7.25M, strike-slip event occurring 1.2 miles from the dam site which would generate a PGA of 0.85g at the site (URS 2021b). There is an approximately 16 percent probability that an earthquake with a magnitude greater than 6.7 will occur on the Calaveras fault within the next 30 years (USGS et al. 2015). It is likely that the Coyote Creek Front Range fault and Central Calaveras fault may merge south of the dam at depth and thus are not considered independent seismic sources; movement along the Central Calaveras fault could therefore cause movement along the Coyote Creek Front Range fault (URS 2021b).

[4] MCE refers to the maximum credible earthquake that could occur along a recognized fault under the tectonic framework.

[5] PGA refers to peak ground acceleration of seismically induced ground shaking. It measures the relationship between local ground movement based on earthquake magnitude and the distance of the location where PGA is calculated from the earthquake epicenter.

[6] "g" is gravity at 9.80 meters per second squared, a measure of the estimated acceleration of ground movement.

Seismic Retrofit Project Area

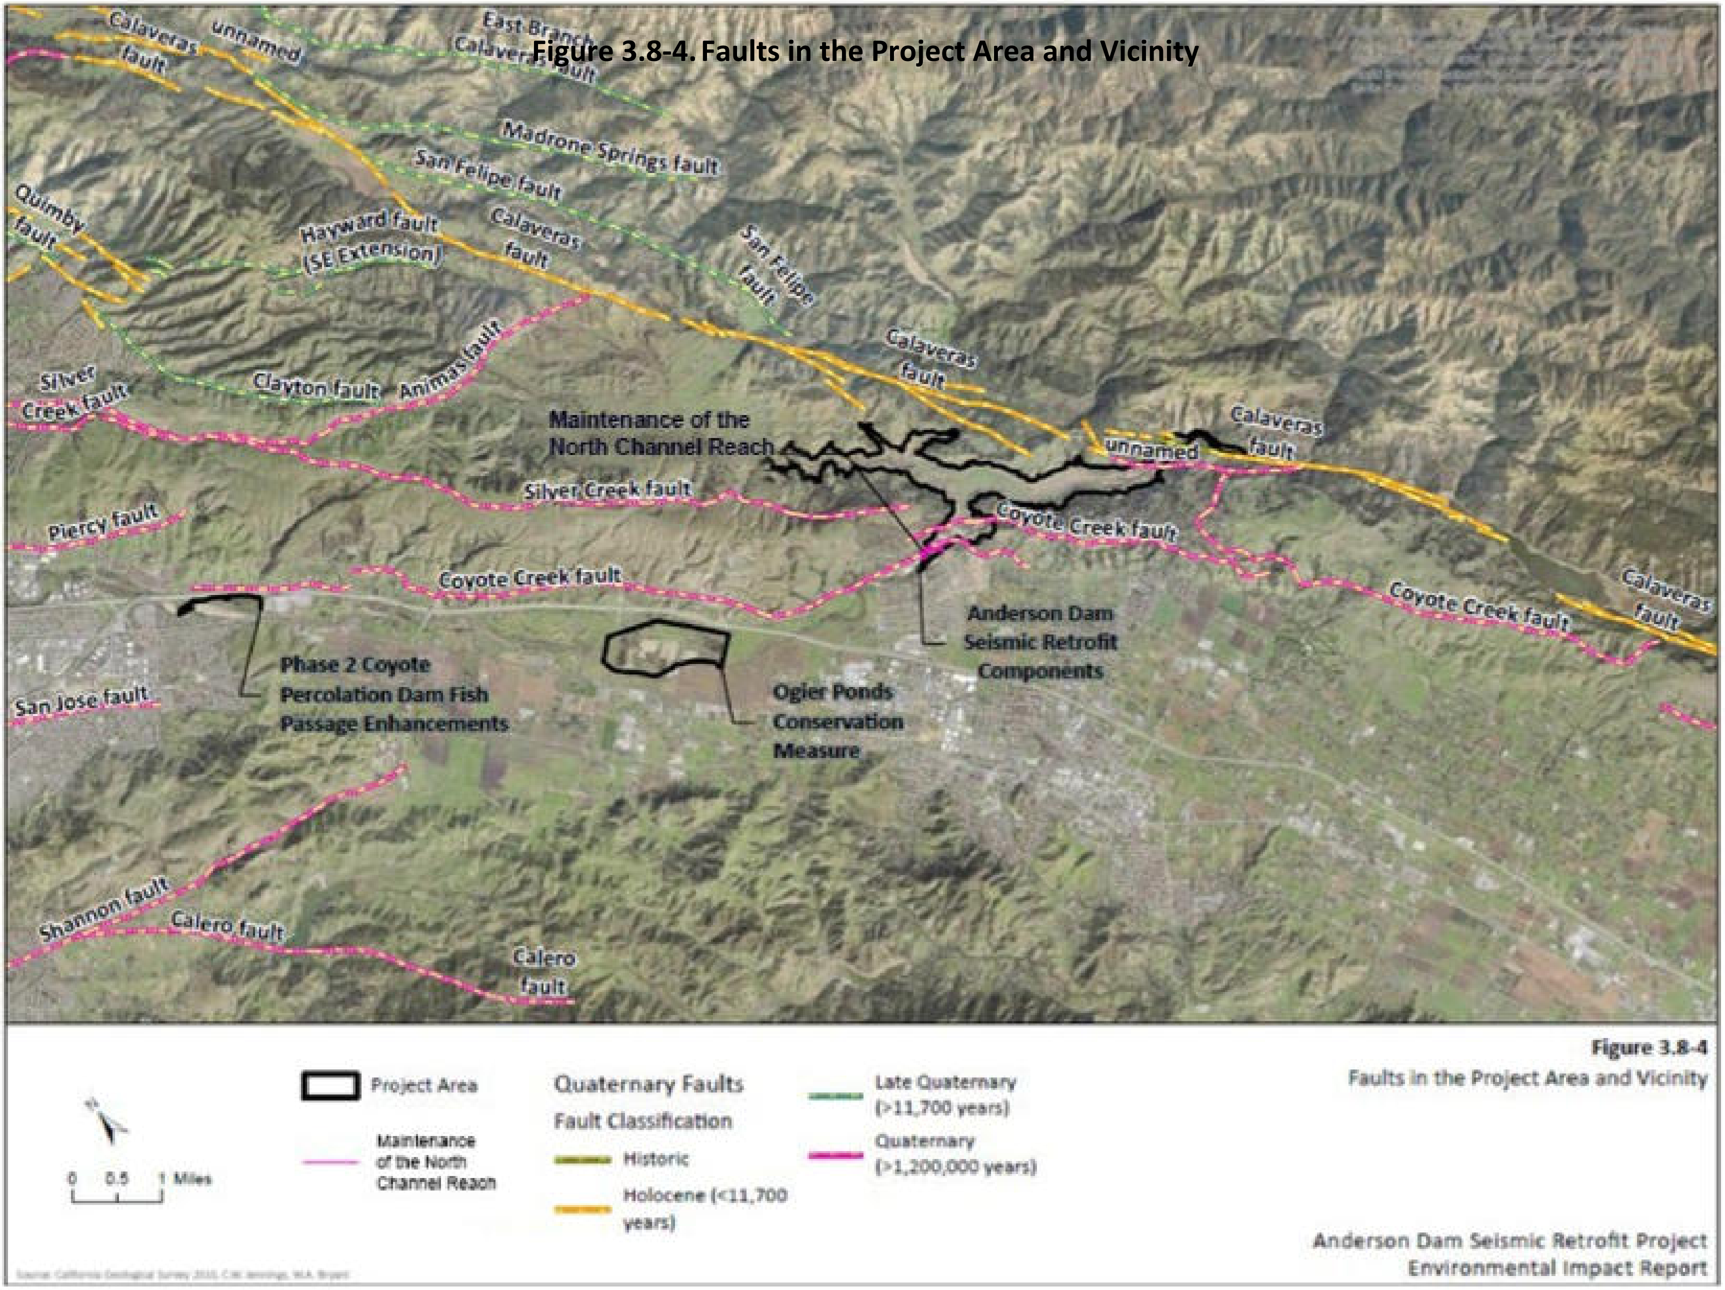
Because the dam is located within a highly active seismic area, dam embankment failure, deformation of the dam, cracking of the dam core and pipe failure, and damage to the existing outlet works and spillway may result either from surface fault rupture or strong ground shaking if a large earthquake occurs on either the Calaveras or Coyote Creek faults. Damage could include dam failure and subsequent downstream flooding. FERC requirements necessitate that the dam be seismically retrofitted to withstand fault rupture and that the spillway be modified to safely pass flood flows. Section 2.3 in Chapter 2, *Project Description*, describes the purpose and objectives of the Project to meet the FERC seismic safety requirements, as well as DSOD and Valley Water public safety requirements.

In addition, movement along the Coyote Creek Range fault or Calaveras fault could cause a seiche, similar to a tsunami but in a confined inland waterbody such as a lake or reservoir.

Conservation Measures Project Area

Downstream of Anderson Dam, the Coyote Creek Range fault zone parallels Coyote Creek. The Coyote Creek Range fault zone is located approximately 0.25- to 0.75-miles east of Coyote Creek near all of the CM components, respectively. Thus, the area downstream of Anderson Dam in the vicinity of the Conservation Measures is also susceptible to fault rupture and strong seismic ground shaking, which could damage any of the CM components and could adversely affect the flood control capacity and/or reduce the ability of fish to move upstream and populate habitat.

Figure 3.8-4. Faults in the Project Area and Vicinity



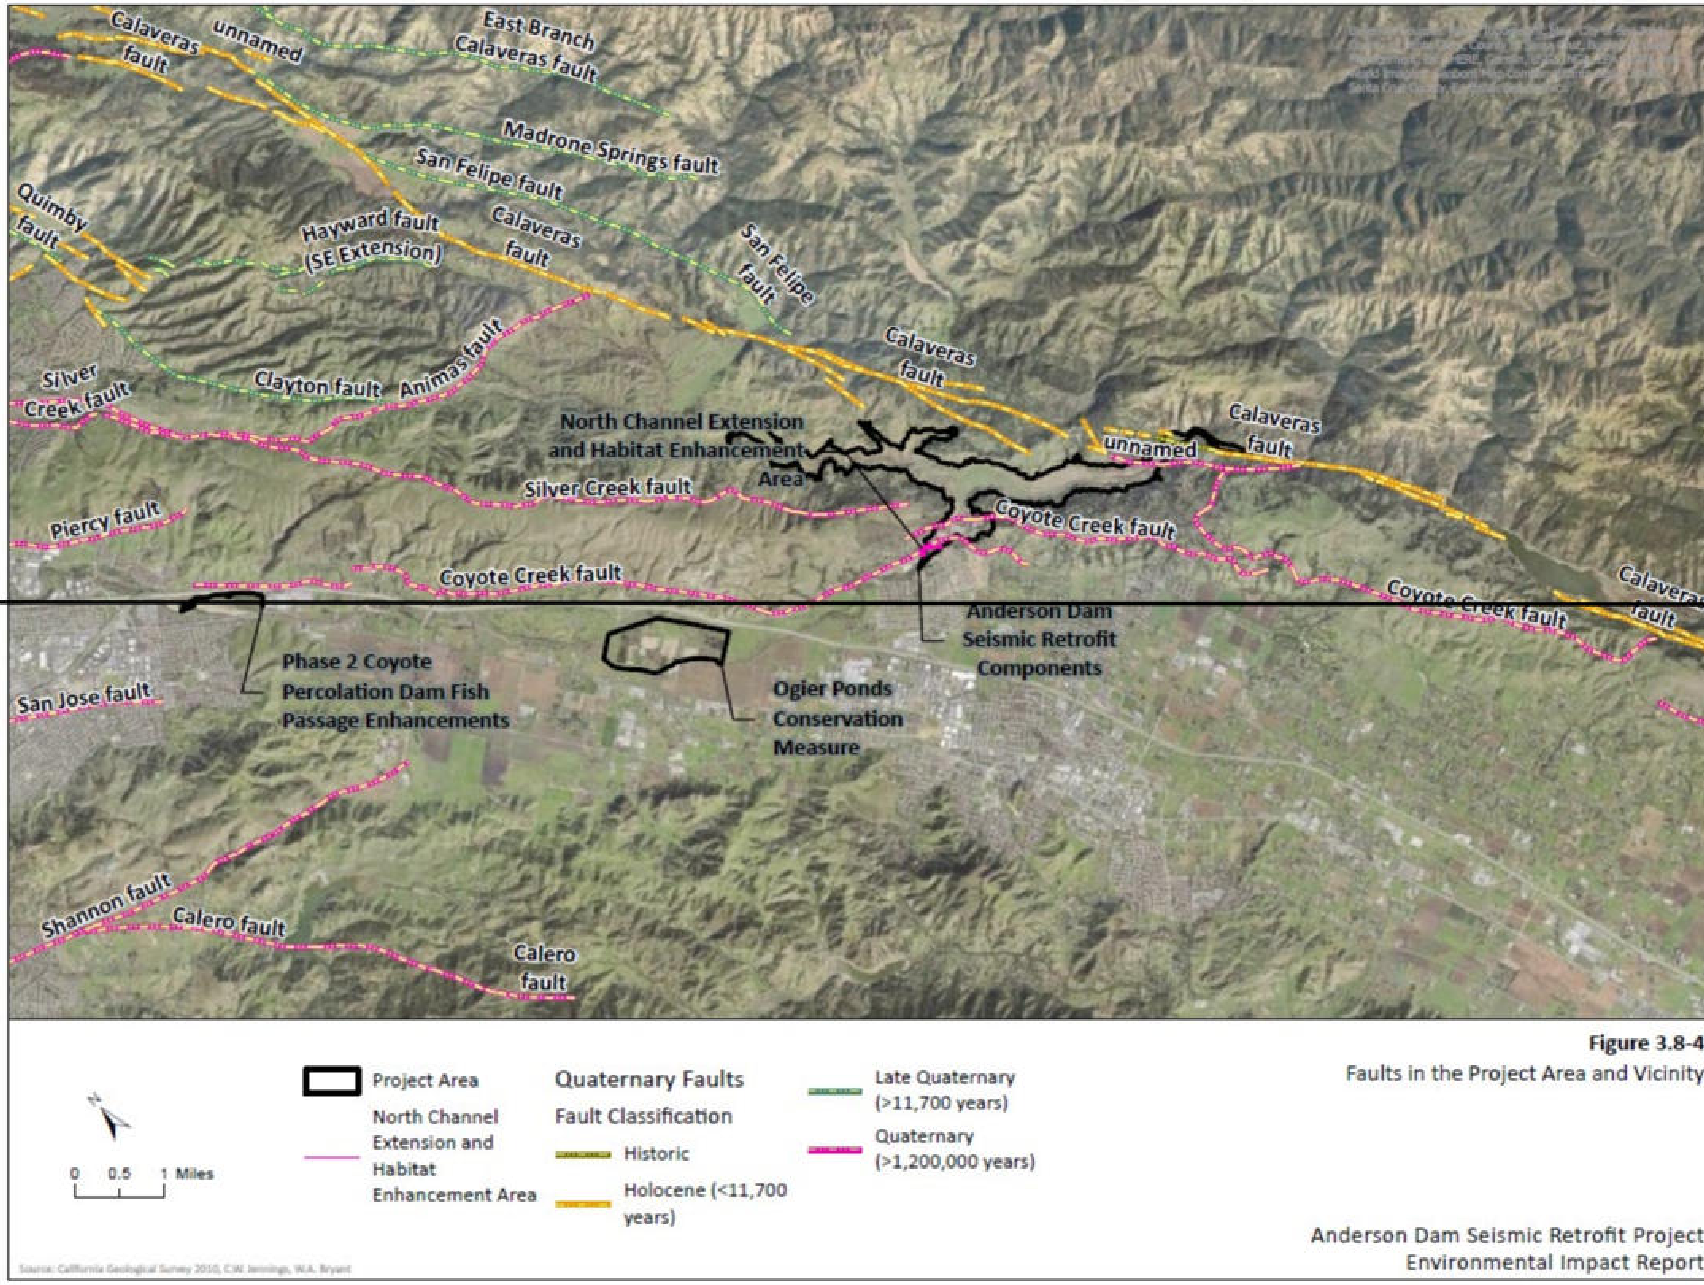


Figure 3.8-4
Faults in the Project Area and Vicinity

Table 3.8-2. Modified Mercalli Scale for Earthquake Intensity

Intensity Value	Intensity Description	Approximate Earthquake Magnitude (Richter)	Average Peak Acceleration
I	Not felt except by a very few persons under especially favorable circumstances	1.0–3.0	< 0.015g
II	Felt only by a few persons at rest, especially on upper floors of buildings. Delicately suspended objects may swing.	3.0-3.9	
III	Felt noticeably indoors, especially on upper floors of buildings, but many people do not recognize it as an earthquake. Standing motor cars may rock slightly, vibration similar to a passing truck.		
IV	During the day felt indoors by many, outdoors by few. At night some awakened. Dishes, windows, doors disturbed; walls make creaking sound. Sensation like heavy truck striking building. Standing automobiles rock noticeably.	4.0-4.9	0.015g-0.02g
V	Felt by nearly everyone, many awakened. Some dishes and windows broken; cracked plaster in a few places; unstable objects overturned. Disturbances of trees, poles, and other tall objects sometimes noticed. Pendulum clocks may stop.		0.03g-0.04g
VI	Felt by all, many frightened and run outdoors. Some heavy furniture moved; a few instances of fallen plaster and damaged chimneys. Damage slight.	5.0-5.9	0.06g-0.07g
VII	Everybody runs outdoors. Damage negligible in buildings of good design and construction; slight to moderate in well-built ordinary structures; considerable in poorly built or badly designed structures; some chimneys broken. Noticed by persons driving cars.		0.10g-0.15g
VIII	Damage slight in specially designed structures; considerable in ordinary substantial buildings with partial collapse; great in poorly built structures. Panel walls thrown out of frame structures. Fall of chimneys, factory stack, columns, monuments, and walls. Heavy furniture overturned. Sand and mud ejected in small amounts. Temporary or permanent changes in well water levels. Persons driving cars disturbed.	6.0-6.9	0.25g-0.30g
IX	Damage considerable in specially designed structures; well-designed frame structures thrown out of plumb; great in substantial buildings, with partial collapse. Buildings shifted off foundations. Ground cracked conspicuously. Underground pipes broken.	7.0 and higher	0.50g-0.55g

Intensity Value	Intensity Description	Approximate Earthquake Magnitude (Richter)	Average Peak Acceleration
X	Some well-built wooden structures destroyed; most masonry and frame structures destroyed with foundations; ground badly cracked. Rails bent. Landslides considerable from riverbanks and steep slopes. Shifted sand and mud. Water splashed, slopped over banks.		0.60g-0.80g
XI	Few, if any, (masonry) structures remain standing. Bridges destroyed. Broad fissures in ground. Underground pipelines completely out of service. Earth slumps and land slips in soft ground. Rails bent greatly.		0.80g-0.90g
XII	Damage total. Waves seen on ground surface. Lines of sight and level distorted. Objects thrown into the air.		>0.90g

3.8.1.4 Landslides and Other Slope Stability Hazards

Landslides

Slope failure and landslides occur when the downhill-driving forces of the native material, principally under the influence of gravity, exceed the resisting forces of the material. The forces triggering landslides can be increased by adding to the weight of the soil or rock mass through saturation during periods of high rainfall or by loading with fill, while forces resisting landslide can be reduced by erosion or grading at the toe of a slope or landslide mass. Zones with low resistance to landslides are often associated with the presence of expansive clay soils and weak bedrock units or structural features susceptible to failure, such as faulted geologic units. Both increasing landslide triggers and decreasing landslide resistance can increase incidence of landslide. Landslides can also be induced by ground shaking from earthquakes and may take several forms, including soil creep, earthflow, slump, debris slide, debris flow, and rockfall.

Seismic Retrofit Project Area

Anderson Dam is located in a mountainous area with steep slopes that are designated as having landslide risk and exhibit landslide activity (**Figure 3.8-5**) (URS 2021c). Landslide hazards are prevalent in mountainous and foothill areas in the Seismic Retrofit vicinity where there are occurrences of unconsolidated alluvium. The California landslide inventory depicts numerous landslides surrounding Anderson Dam and the Anderson Reservoir (CDOC and CGS 2021). In addition, areas along both sides of Anderson Reservoir are within earthquake-induced landslide zones (CGS 2004). Landslide mapping of the reservoir area has been performed by multiple parties over time (Scott 1976, Coyle 1988, Meehan 1988, Wahler 1988, AMEC Geomatrix, Inc. [AMEC] 2009). Landslides have been ongoing in and around Anderson Dam for a long period of time and existed prior to development of the dam in the 1950s (URS 2021c). Weak ground due to faults and historic landslides have made the area susceptible to movement when water is present.

There are multiple existing landslides along the reservoir rim (URS 2021c). Studies of the landslides have described them as being relatively shallow failures with moderate thicknesses of approximately 30 feet, meaning that the soil that moves in these landslides is up to 30 feet deep. These landslides are considered marginally stable and sensitive to fluctuation in groundwater, heavy rainfall, and reservoir fluctuations.

Five major landslides exist along the southern portion of the dam: two on the west side, the Boat Marina Landslide the Hoot Owl Way Landslide, and three on the east side, the East Dunne Landslides (consisting of the East Dunne Avenue Landslide, Northern East Dunne Landslide, and the Woodchopper Landslide) (**Figure 3.8-5**) (URS 2021c). These landslides have a history of movement during previous drawdowns of the reservoir. In the 1986 to 1988 drawdown, movements of up to 1 to 2 feet were observed at the Boat Marina Landslide, with only a small amount near the headscarp. Movements of 1 to 5 vertical feet and 6 to 10 horizontal feet were observed at the Hoot Owl Way Landslide. Little movement was reported near the scarp, although 6- to 12-inch scarps and slumps have been observed since that drawdown. Movements of 18 feet were observed on the East Dunne Avenue Landslide. Movements of up to 1 foot occurred on the Woodchopper Landslide at the headscarp. No movement was recorded at the Northern East Dunne Landslide, although, based on aerial imagery, movement of this landslide has occurred in the past. The Hoot Owl Way Landslide is located immediately below numerous private properties, and the three landslides along East Dunne Avenue all intersect East Dunne Avenue. These landslides, therefore, present risk to existing structures and infrastructure. While these are active landslides, the FOCP included the acquisition and demolition of the identified residences along Hoot Owl Way, and the stabilization of the Boat Marina Landslide (CDFW 2021 ~~2020~~). Stabilization techniques include excavation and re-compaction of disturbed soils, slope grading, and installation of soil nails. Accordingly, it is not expected to move as a result of future disturbance.

In addition, a landslide is present in the left abutment of Anderson Dam near the existing intake structure. This landslide is expected to continue to move periodically; however, it does not pose a risk to the intake structure (URS 2021c). Furthermore, a landslide within the Packwood Gravels Borrow Pit area has been observed (URS 2021d ~~2023~~). The landslide is located in unstable and hummocky terrain,[7] and the area is normally covered by the reservoir. A review of historical photographs indicates that the landslide was not present during original dam construction but was present when the reservoir was drawn down in 1960. Other smaller landslides have been either removed or are not located nearby the existing intake structure (URS 2021c). Other than the Boat Marina Landslide, which has been stabilized, all of these landslides could be activated in the future by heavy precipitation; reservoir fluctuations, including drawdown and refilling; and disturbances to the landslide toe such as construction.

Conservation Measures Project Area

No steep slopes are located within the downstream portion of Coyote Creek near any of the proposed CM components. In addition, this portion of Coyote Creek is not located within an area identified as susceptible to landslides (CGS 2003, 2004) (refer to **Figure 3.8-5**). However, the one CM at the North Channel Reach ~~Extension~~ is located in an area of landslide susceptibility (CGS 2004) (**Figure 3.8-5**).

Liquefaction and Lateral Spreading

Liquefaction is the temporary transformation of saturated and very low cohesion or cohesionless soils into a vicious liquid as a result of ground shaking. Liquefaction may occur in water-saturated sediment during ground shaking caused by moderate to large earthquakes. Liquefied sediment loses strength and may fail, causing damage to any load-bearing features that are located on the liquefiable sediments. The susceptibility of an area to liquefaction is determined largely by its depth to groundwater and the properties of the soil and sediment within and above the groundwater. The sediments most susceptible to liquefaction are saturated, unconsolidated sand and silt within 50 feet of the ground surface.

Of the liquefaction hazards, lateral spreading generally causes the most damage. Lateral spreading is a phenomenon in which large blocks of intact, non-liquefied soil moves downslope on a liquefied substrate of large areal extent. The mass moves toward an unconfined area, such as a descending slope or stream-cut bluff and can occur on slope gradients as gentle as one degree. Drainages and swales between hill slopes are generally filled by unconsolidated

[7] The presence of hummocky terrain can imply landslide movement (URS 2021d ~~2023~~).

alluvium, colluvium, landslide debris, and slope wash, which readily move once an activating event, such as liquefaction, occurs.

There are two aquifers in the southern county: a shallow aquifer and a principal or deep aquifer. Depth to the shallow groundwater table can be as shallow as 5 feet below ground surface (bgs) in the southern county (Valley Water 2010). While depth to groundwater varies seasonally and between years, the shallow aquifer is expected to be relatively close to ground surface. Presence of shallow groundwater would affect likelihood of liquefaction and lateral spreading as well as lateral earth pressure in the Seismic Retrofit area.

Seismic Retrofit Project Area

Liquefiable soil layers of the dam embankment (specifically within the lower finer fill) and alluvium exist beneath both the upstream and downstream slopes of the dam embankment. Because the embankment consists of materials which place a load on underlying sediments, strong seismic ground shaking could result in movement of Project features and materials placed on liquefiable sediments. Any such movement could make the dam unstable following a large earthquake (AMEC 2011, URS 2021a) (**Figure 3.8-5**). Thus, during very strong earthquake shaking, major slumping and cracking of the dam could occur. Subsequently, this could lead to a failure of the dam by either overtopping or piping through large cracks, resulting in an uncontrolled release of reservoir water. Conditions favorable to lateral spreading may be present around the rim of Anderson Reservoir.

Conservation Measures Project Area

The area downstream of the dam along Coyote Creek and in the vicinity of all of the CM components is located in liquefaction seismic hazard zones according to CGS (2015) (refer to **Figure 3.8-5**). All of the CM components are located within areas at risk to liquefaction due to water-saturated sediment. Any Project load-bearing features placed in this area on liquefiable sediments could trigger soil displacement during strong seismic ground shaking. Where no load-bearing features are placed on liquefiable sediments, there is no risk of increasing risk of liquefaction during ground shaking.

Liquefiable soils are located along Coyote Creek in the vicinity of all of the CM components (CGS 2004, 2006; County n.d.), including Ogier Ponds and the Phase 2 Coyote Percolation Dam. These areas are generally flat, but because of the presence of stream banks, lateral spreading could occur if seismic ground shaking causes liquefaction in this area.

3.8.1.5 Paleontological Resources

Paleontological resources are limited, nonrenewable resources of scientific, cultural, and educational value (Far Western 2021). Fossils are any remains, trace, or imprint of past life that have been preserved by natural processes in the rock record. Paleontological resources include both fossils themselves as well as the rocks in which fossils are preserved because the geologic character of the rock record preserves the ecological, geographic, and evolutionary context of past life represented by fossils themselves. Paleontological resources are objects of national significance that are worthy of preservation for the inspiration and interpretive opportunities they offer.

Certain geologic units may contain paleontological resources. Some geologic units are more likely to contain paleontological resources, depending on age, rock type, and depositional environment (Far Western 2021). Paleontological sites indicate that the containing sedimentary rock unit or formation is fossiliferous. The limits of the entire geologic formation, both areal and stratigraphic, therefore define the scope of the paleontological potential in each case. Fossils are often contained within surficial sediments or bedrock and are therefore not observable or detectable unless exposed by erosion or human activity. Geologic units in the Project area are shown in **Figure 3.8-6**.

The geologic record of the Santa Clara Valley region, which includes the Coyote Valley area, dates from the Jurassic Period (approximately 200 to 145.5 million years ago) to the present (Dibblee and Minch 2005a, 2005b). Fossilized Pleistocene vertebrates, dating from approximately 2.6 million to 11,700 years ago, have been discovered in Quaternary deposits (dating from 2.588 million years ago to the present) in the south San Francisco Bay area, which has resulted in paleontological interest in the region (Valley Water 2011, Maguire and Holroyd 2016). Fossil mammal assemblages have also been discovered in Quaternary sediments located along the south San Francisco Bay, all of which have produced fossil elephant, camel, and bison specimens (Maguire and Holroyd 2016).

Table 3.8-3 lists geologic units in the study area and their paleontological sensitivity as determined through the Potential Fossil Yield Classification (PFYC) system described in Section 3.8.2.1, *Federal Laws, Regulations, and Policies* (Far Western 2021, 2023).

Table 3.8-3. Paleontological Sensitivity for Geologic Units in the Study Area

Formation	Symbol	PFYC	Justification
Landslide deposits	Qls	2—Low	Young age (<10,000 years)[a]
Alluvium	Qa	2—Low	Young age (<10,000 years)[a]
Sand and gravel of major stream channels	Qg	2—Low	Young age (<10,000 years)
Santa Clara Formation	QTs	4—High	Known and diverse significant paleontological resources[a,b]
Panoche formation	Kp/Kps	2—Low	Lack of known record[a]
Serpentinite	sp	1—Low	Metamorphic[a]

Formation	Symbol	PFYC	Justification
Greenstone	fg	1—Low	Metamorphic[a]

Seismic Retrofit Project Area

As described in paleontological resources evaluations for the Seismic Retrofit study area (Far Western 2021) and the drawdown area (Far Western 2023) and listed above in **Table 3.8-3**, a geologic unit with high paleontological sensitivity, Santa Clara Formation, occurs in the Seismic Retrofit area. Other geologic units with lower paleontological sensitivity lie adjacent to this formation and in some cases overlie it at an unknown depth. Geologic units in the Seismic Retrofit area include Quaternary alluvium (Qa), Quaternary landslides (Qls), Santa Clara Formation (QTs), Panoche Formation (Kp and KPs), serpentinite (sp), and greenstone (fg) (**Figure 3.8-6**)[8] (Far Western 2021, 2023; Dibblee and Minch 2005a, 2005b).

The Quaternary alluvium and landslide deposits in the Seismic Retrofit area resulted from ongoing erosion activity. Alluvium (i.e., surficial sediments) consists of alluvial gravels, sands, and clays typical of river deposits. Landslide deposits consist of rubble from rock upslope and are common in the area due to the unstable nature of most of the underlying units. Both the landslide deposits and alluvium in the Seismic Retrofit area have a low fossil yield ranking due to their young age (less than 10,000 years) (Far Western 2021).

The Santa Clara Formation, on the other hand, has a record of yielding paleontological resources (Far Western 2021, ~~Axelrod 1944~~, Casteel 1978, Adam et al. 1983, Holland and Allen 2000). The Santa Clara Formation is from the Pliocene to Pleistocene epochs. Geologic units from these epochs, depending on depositional environment, are likely to yield fossils. This deposit is primarily conglomerate but has significant units of sand and clay. The Santa Clara Formation has a high paleontological sensitivity[9] due to the known and diverse significant paleontological resources occurring in this unit (Far Western 2021) (**Table 3.8-3**). While Quaternary landslide deposits generally are too young to yield fossils, as discussed immediately above, a landslide occurring in the Santa Clara Formation could expose significant fossils during downslope movement; however, these would have moved from their original context and would no longer exhibit scientific significance.

The Panoche Formation forms the hills to the east of Anderson Reservoir and consists of marine sediments with layers of well-lithified sandstone; however, these sediments are generally fossil-poor. This formation has a low fossil yield ranking due to the lack of known fossil records (Far Western 2021).

The hills west of Anderson Reservoir are underlain by metamorphic ocean crust (primarily serpentinite and greenstone). Serpentinite consists of hydrothermally metamorphosed and mafic mantle rock of the Coast Range Ophiolite Complex from the late Jurassic to Cretaceous

[8] Figure 3.8-6a through 3.8-6e show geologic units at a higher resolution that Figure 3.8-2.

[9] Methodology for determining paleontological sensitivity or PFYC ranking according to BLM 2016 is described in more detail in Section 3.8.2.1 ~~3.8.1.1~~, *Federal Laws, Regulations, and Policies*.

age. Serpentinite forms blue-green or gray highly fractured rocky outcrops and underlies much of the higher hills. Because it is metamorphosed mantle rocks, fossils are not found in the bedrock but could occur in caves developed on fractures (although none have been reported in this area). Greenstone consists of metamorphosed basalt of the Franciscan Complex and is located in the southwest part of the seismic retrofit area. Similar to serpentinite, because it is metamorphosed volcanic rock, fossils are not expected to occur. These two formations have a low fossil yield ranking based on their metamorphic history (Far Western 2021).

A records search was conducted through the University of California Museum of Paleontology (UCMP) for the Paleontological Resources Impact Assessment (Far Western 2021) for the Seismic Retrofit area and is included in Appendix P. The records search identified 52 fossils consisting of plant and mammal (i.e., bison, mammoths, horses, camelids, sloth, pronghorn, peccary) fossils from Pliocene or Pleistocene deposits from the Santa Clara Formation. Of particular note, an artiodactyl (camelid) tibia was found in Anderson Lake in 1993. In addition, two fossils were discovered around the reservoir rim during an archaeological field survey in 2019 (Far Western 2021, 2023).

All of the named geologic units that have yielded fossils identified in this search are Santa Clara Formation. As described in **Table 3.8-3**, because of this formation's documented history of having yielded vertebrate fossils, this geologic unit is considered to have high paleontological sensitivity (rated 4 in the PFYC methodology from Bureau of Land Management [BLM]).

A surface collecting survey for paleontological resources in the reservoir drawdown area was conducted and reported on by Far Western (2023). Pedestrian surveys of the area below the ordinary high-water mark and above deadpool occurred between September 12 and September 15, 2022. One significant vertebrate bone was collected in the field and prepared in the paleontological laboratory space in Chico, California. The fossil is a nearly complete and large camelid metapodial that is highly silicified. Preliminary identification of the genus is *Camelops*, although further study will be necessary to confirm. Other fossils that were collected during the survey include another camelid metapodial, the rib of an unknown mammal, and a limb bone fragment of a large perissodactyl (e.g., horse or rhinoceros) that was not identifiable. Other non-significant fossils were observed, including bivalve mollusks and fossilized wood.

Conservation Measures Project Area

Geologic units in the Conservation Measures area vary by location of the Conservation Measure footprint. Geologic units underlying Maintenance of the North Channel Reach ~~Extension~~ are Quaternary alluvium (Qa) and Quaternary sand and gravel of major stream channels (Qg) (**Figure 3.8-6c**). Both geologic units are too young to yield fossils. This Conservation Measure is located very near an outcropping of the fossil-yielding Santa Clara Formation (QTs). Geologic units underlying the Ogier Ponds CM are Quaternary alluvium (Qa), Quaternary sand and gravel of major stream channels (Qg), and Santa Clara Formation (QTs) (**Figure 3.8-6d**). Geologic units underlying the Phase 2 Coyote Percolation Dam CM are Quaternary alluvium (Qa) and Quaternary sand and gravel of major stream channels (Qg) (**Figure 3.8-6e**). While Santa Clara Formation (QTs) is located fairly near this conservation measure, none of the construction area is adjacent to this formation.

3.8.2 Regulatory Setting

3.8.2.1 Federal Laws, Regulations, and Policies

Clean Water Act

Activities discharging pollutants from a point source to a water of the United States are subject to the National Pollutant Discharge Elimination System (NPDES) permitting program, as authorized by the CWA, established in 1972. The NPDES permitting program has been delegated to the State of California for implementation through the SWRCB and nine RWQCBs. Under the NPDES program, any construction project that would result in the disturbance of 1 or more acres would require compliance with the state's NPDES Construction General Permit for stormwater discharges associated with the construction activity, discussed in more detail below under *General Permit for Construction Activities*.

National Earthquake Hazards Reduction Act

The United States Congress passed the National Earthquake Hazards Reduction Act in 1977 (Public Law [PL] 95-124, 42 USC 7701 et seq.) to develop a national policy to reduce the risks of earthquakes in the United States. The act was amended in 2004 by PL 101-614, 105-47, 106-503, and 108-360 to reduce the risks to life and property from future earthquakes through the establishment of the National Earthquake Hazards Reduction Program (NEHRP). The goals of the NEHRP are to: (1) develop effective practices and policies for earthquake loss reduction and accelerate their implementation, (2) improve techniques for reducing earthquake vulnerabilities of facilities and systems, (3) improve earthquake hazards identification and risk assessment methods and their use, and (4) improve the understanding of earthquakes and their effects (Federal Emergency Management Agency (FEMA) et al. 2021). FEMA, the National Institute of Standards and Technology (NIST), the National Science Foundation (NSF), and the USGS are the four agencies responsible for managing the NEHRP (FEMA et al. 2021). These four agencies together carry out the NEHRP's mission: to develop, disseminate, and promote knowledge, tools, and practices for earthquake risk reduction—through coordinated, multidisciplinary, interagency partnerships among the NEHRP agencies and their stakeholders—that improve the Nation's earthquake resilience in public safety, economic strength, and national security (FEMA et al. 2021 ~~2009~~).

Potential Fossil Yield Classification

Valley Water has adopted the BLM's PFYC system (2016) for the Project to categorize the potential for a geologic unit to produce scientifically significant fossils. This is determined by rock type, history of the geologic unit in producing significant fossils, and fossil localities recorded from that unit. Paleontological sensitivity is derived from the known fossil data collected from the entire geologic unit, not just from a specific survey. The BLM's PFYC system provides guidance for predicting, assessing, and mitigating impacts to paleontological resources. The PFYC system ranks geologic formations or members on a 1 to 5 scale, with 5 having the highest potential for preserving fossil resources and uses geologic mapping as a predictive tool to identify areas of paleontological sensitivity. This classification does not reflect rare or isolated occurrences of significant fossils or individual localities, only the relative occurrence on a formation or member-wide basis. Any rare occurrences require additional assessment and mitigation if they fall within the area of anticipated impacts. The PFYC system is based on the relative abundance of vertebrate fossils or scientifically significant invertebrate or plant fossils and their sensitivity to adverse impacts.

The following descriptions of paleontological sensitivity class rankings pertinent to this Project ~~project~~ and drawn directly from the BLM Guidelines (2016) are provided below:

Class 1—Very Low. Geologic units that are not likely to contain recognizable paleontological resources. Units assigned to Class 1 typically have one or more of the following characteristics:

- Geologic units are igneous or metamorphic, excluding air-fall and reworked volcanic ash units.
- Geologic Units are Precambrian in age.

Class 2—Low. Geologic units that are not likely to contain paleontological resources. Units assigned to Class 2 typically have one or more of the following characteristics:

- Field surveys have verified that significant paleontological resources are not present or are very rare.
- Units are generally younger than 10,000 years before present.
- Recent aeolian deposits
- Sediments exhibit significant physical and chemical changes (i.e., diagenetic alteration) that make fossil preservation unlikely.

Class 3—Moderate. Sedimentary geologic units where fossil content varies in significance, abundance, and predictable occurrence. Units assigned to Class 3 have some of the following characteristics:

- Marine in origin with sporadic known occurrences of paleontological resources
- Paleontological resources may occur intermittently, but abundance is known to be low.
- Units may contain significant paleontological resources, but these occurrences are widely scattered.
- The potential for an authorized land use to impact a significant paleontological resource is known to be low to moderate.

Class 4—High. Geologic units that are known to contain a high occurrence of paleontological resources. Units assigned to Class 4 typically have the following characteristics:

- Significant paleontological resources have been documented but may vary in occurrence and predictability.
- Surface disturbing activities may adversely affect paleontological resources.
- Rare or uncommon fossils, including nonvertebrate (such as soft body preservation) or unusual plant fossils, may be present.
- Illegal collecting activities may impact some areas.

Class 5–Very High. Highly fossiliferous geologic units that consistently and predictably produce significant paleontological resources. Units assigned to Class 5 have some or all of the following characteristics:

- Significant paleontological resources have been documented and occur consistently.
- Paleontological resources are highly susceptible to adverse impacts from surface disturbing activities.
- Unit is frequently the focus of illegal collecting activities.

Consistent with BLM (2016), Valley Water considers management concerns for paleontological resources in geologic units categorized as Class 4 and Class 5 to be high to very high.

3.8.2.2 State Laws, Regulations, and Policies

Alquist-Priolo Earthquake Fault Zoning Act

The Alquist-Priolo Earthquake Fault Zoning Act (PRC section 2621 et seq.), also known as the Alquist-Priolo Act, was passed in 1972 to mitigate the hazard of surface faulting to structures intended for human occupancy. The act's main purpose is to prevent the construction of buildings used for human occupancy on the surface trace of active faults. The law requires the State Geologist to establish regulatory zones (known as Earthquake Fault Zones) around the surface traces of active faults and to issue appropriate maps depicting those zones. The maps are distributed to all affected cities, counties, and state agencies for their use in planning and controlling new or renovated construction. Before a project can be permitted, cities and counties must require a geologic investigation to demonstrate that proposed buildings would not be constructed across active faults. An evaluation and written report of a specific site must be prepared by a licensed geologist. If an active fault is identified, a structure for human occupancy cannot be placed over the trace of the fault and must be set back from the fault (generally 50 feet) (CDOC 2019a). Under the Alquist-Priolo Fault Zoning Act, an active fault is one that has ruptured in the last 11,000 years.

Seismic Hazards Mapping Act

The Seismic Hazards Mapping Act of 1990 (PRC sections 2690-2699.6) is intended to reduce the threat to public safety resulting from earthquakes. While the Alquist-Priolo Act addresses surface fault rupture, the Seismic Hazards Mapping Act addresses other earthquake-related hazards, including strong ground shaking, liquefaction, and seismically induced landslides. The Seismic Hazards Mapping Act highlights the need to identify and map seismic hazard zones to allow cities and counties to adequately prepare the safety element of their general plans, and to encourage land use management policies and regulations that reduce and mitigate those hazards to protect public health and safety. Cities and counties are required to regulate development within mapped Seismic Hazard Zones (CDOC 2019b).

Surface Mining and Reclamation Act

The Surface Mining and Reclamation Act of 1975 (SMARA) (PRC sections 2710–2719) was enacted to provide a comprehensive surface mining and reclamation policy to ensure that adverse environmental impacts of mining are minimized and that mined lands are reclaimed to a usable condition. Certain land use activities, such as public or private engineering projects, including dams, do not require a permit, based on the Economic Exclusion category presented in the Guidelines for Classification and Designation of Mineral Lands (CDOC 2019c).

Project excavation from borrow areas necessary to construct the Seismic Retrofit is exempt from compliance with SMARA under PRC section 2714(b). This section provides a SMARA exemption for onsite excavation and onsite earthmoving activities that are an integral and necessary part of a construction project and that are undertaken to prepare a site for construction of structures, landscaping, or other land improvements associated with those structures, including the related excavation, grading, compaction, or the creation of fills, road cuts, and embankments, whether or not surplus materials are exported from the site, provided four conditions are met. The Project will meet all four of these conditions, which require approval of permits for the construction project, lead agency CEQA compliance for the construction project, consistency of the construction project with the site general plan or zoning, and timing limitations on export of surplus materials. As discussed in Chapter 2, *Project Description*, the onsite excavation and earthmoving activities are integral and necessary for construction of the Project.

Please note that the same PRC section 2714(b) exemption is also found in the Santa Clara County Zoning Ordinance – section 4.10.370 (Surface Mining).

California Building Code and International Building Code

The State of California mandates minimum standards for building design through the California Building Code (CBC) (CCR Title 24) for geologic and seismic hazards, other than surface faulting, to address seismic safety, earthquake-resistant design, and construction ~~(California Building Standards Commission 2021b).~~ The 2022 CBC was published in July 2022 with an effective date of January 1, 2023 (California Building Standards Commission 2023). The most current and updated version of the CBC is generally adopted by local jurisdictions to guide building construction. The CBC specifies criteria for open excavation, seismic design, and load-bearing capacity directly related to construction in California.

The International Building Code (IBC) (known as the Uniform Building Code prior to 2000) was developed by the International Conference of Building Officials, and is used by most states, including California, as well as local jurisdictions, to set basic standards for the acceptable design of structures and facilities. The IBC provides information on criteria for seismic design, construction, and load-bearing capacity associated with various buildings and other structures and features. Additionally, the IBC identifies design and construction requirements for addressing and mitigating geologic hazards. New construction generally must meet the requirements of the most recent version of the IBC. The IBC was incorporated as part of the CBC, which has been modified for California based on the natural environment of the state that requires more detailed and/or more stringent regulations.

With certain modifications, the County has adopted the 2022 CBC. The County’s modifications and amendments to the 2022 CBC are given in Division C3, Chapter I, Article 2 of the County Ordinance Code. Valley Water’s internal standard is also the 2022 CBC, which is currently used for the design of all Valley Water projects.

Division of Safety of Dams

The DWR, with regulatory power from the California Water Code, delegates dam safety to the DSOD to protect people against loss of life and property from dam failure. DSOD engineers and engineering geologists review and approve plans and specifications for the design of dams and oversee their construction to ensure compliance with the approved plans and specifications. Geologic and seismic reviews include site geology, seismic setting, geologic/geotechnical site investigations, construction material evaluation, and seismic dam stability. In addition, DSOD engineers inspect existing dams on a yearly schedule to ensure they are performing and being maintained in a safe manner.

The DSOD Inspection and Reevaluation Protocols (DSOD 2018) define active, conditionally active, and inactive faults relative to the timeframe in which a fault is documented to have ruptured. An active fault, according to these protocols, ruptured in the last 35,000 years; a conditionally active fault ruptured in the Quaternary, but its displacement during the last 35,000 years is unknown; and an inactive fault is one whose fault trace is consistently overlain by unbroken geologic material older than 35,000 years.

DSOD authority is granted by the California Water Code (Parts 1 and 2 of Division 3, *Dam and Reservoirs*). The DSOD provides oversight to the design, construction, and maintenance of over 1,200 jurisdictional sized dams in California, including the Anderson Reservoir Dam. Jurisdictional dams are dams that are more than 6 feet high and impound 50 acre-feet or more of water, or 25 feet or higher and impound more than 15 acre-feet of water. The jurisdictional height of a dam, as determined by DSOD, is the vertical distance measured from the lowest point at the downstream toe of the dam to its maximum storage elevation, which is typically the spillway crest. The DSOD ensures dam safety by:

- Reviewing and approving dam enlargements, repairs, alterations, and removals to ensure that the dam appurtenant structures are designed to meet minimum requirements.
- Performing independent analyses to understand dam and appurtenant structures performance. These analyses can include structural, hydrologic, hydraulic, and geotechnical evaluations.
- Overseeing construction to ensure work is being done in accordance with the approved plans and specifications.
- Inspecting each dam on an annual basis to ensure it is safe, performing as intended, and is not developing issues. Roughly 1/3 of these inspections include in-depth instrumentation reviews of the dam surveillance network data.
- Periodically reviewing the stability of dams and their major appurtenances in light of improved design approaches and requirements, as well as new findings regarding earthquake hazards and hydrologic estimates in California.

The structural elements of the Project would undergo appropriate and final design-level geotechnical evaluations prior to final design and construction. Implementing the regulatory requirements in the DSOD regulations and ensuring that all structures constructed in compliance with the law is the responsibility of the Project engineers and building officials. The design engineer, as a registered professional with the State of California, is required to comply with the DSOD and local codes while applying standard engineering practice and the appropriate standard of care for the particular region in California, which, in the case of the Project, is Santa Clara County.[10] The California Professional Engineers Act (Building and Professions Code Sections 6700-6799), and the Codes of Professional Conduct, as administered by the California Board of

[10] A geotechnical engineer (GE) specializes in structural behavior of soil and rocks. GEs conduct soil investigations, determine soil and rock characteristics, provide input to structural engineers, and provide recommendations to address problematic soils.

Professional Engineers and Land Surveyors, provides the basis for regulating and enforcing engineering practice in California.

NPDES Construction General Permit

The State of California adopted the Construction General Permit, Order No. 2022-0057-DWQ, effective September 1, 2023. The Construction General Permit regulates construction site stormwater management. Projects that will disturb 1 or more acres of soil, or disturb less than 1 acre, but are part of a larger common plan of development that in total disturbs 1 or more acres, are required to obtain coverage under the Construction General Permit for discharges of stormwater associated with construction activity. The General Permit requires the preparation of a Project-specific SWPPP to minimize any potential stormwater impacts to surface waters (SWRCB 2020). This program is further discussed in Section 3.11, *Hydrology*. Construction activities that are subject to this permit include clearing, grading, and ground disturbance (stockpiling or excavation), but do not include regular maintenance activities performed to restore the original grade of the disturbed area.

Permit applicants are required to submit a Notice of Intent (NOI) to the SWRCB and to prepare a SWPPP. The SWPPP identifies BMPs that must be implemented to reduce construction effects on receiving water quality based on pollutants. BMPs are directed at implementing sediment and erosion control measures, and other measures to control chemical contaminants. The SWPPP must also include descriptions of the BMPs to reduce pollutants in stormwater discharges after all construction phases have been completed at the site (post-construction BMPs). The SWPPP must contain a visual monitoring program, a chemical monitoring program for “nonvisible” pollutants to be implemented if there is a failure of BMPs, and a sediment monitoring plan if the site discharges directly to a waterbody listed on the CWA section 303(d) list of waterbodies impaired for sediment.

Public Resources Code Section 5097.5

PRC section 5097.5 defines a misdemeanor as any unauthorized disturbance or removal of a historic or prehistoric ruin, burial ground, or archaeological or vertebrate paleontological site on public lands,[11] without the express permission of the public agency having jurisdiction over the lands. This protection includes fossilized footprints, inscriptions, or other archaeological, paleontological, or historical features on public land.

3.8.2.3 Regional and Local Laws, Regulations, and Policies

Santa Clara County

Grading Ordinance

The Santa Clara County Grading Ordinances, Title C, Division C12, Chapter III governs grading and drainage for all projects that are subject to its requirements and describes requirements for permits. Section C12-407(a) notes that grading is exempt from the requirements of the ordinance when it is performed by or under the supervision or construction control of a

[11] As used in this section, “public lands” means lands owned by, or under the jurisdiction of, the State, or any City, County, District, Authority, or public corporation, or any agency thereof.

governmental agency, including the County, where that agency has provided written confirmation from an authorized representative of that agency assuming full responsibility for the work. C12-409€ similarly states that drainage projects are exempt from the ordinance's requirements when it concerns the addition of impervious area or drainage alterations by, or under the supervision or construction control of, a governmental agency including the County, where that agency has provided written confirmation from an authorized representative of that agency assuming full responsibility for the work.

General Plan

Geologic Hazards

Book A of the Santa Clara County General Plan (County 1994a), Safety and Noise element, provides strategies, policies, and implementation programs to reduce the risks of natural hazards countywide. Those that are relevant to the Project are listed below.

Strategy #1: Inventory Hazards and Monitor Changing Conditions. Adequate documentation of natural hazard areas such as floodplains, landslide areas, fault traces, and high fire hazard areas is essential for purposes of determining the appropriate densities for general areas and for determining placement of structures such as schools, landfills, and hazardous materials storage facilities.

As new landslide areas and faults are discovered, or as other conditions change, inventories used by local jurisdictions should be updated to provide an adequate basis for decision-making.

> **Policy C-HS 29:** Inventories and mapping of natural hazards should be adequately maintained for use in planning and decision-making.

Strategy #3: Design, Locate and Regulate Development to Avoid or Withstand Hazards. Development which occurs in areas subject to natural hazards must be designed, constructed, and maintained to reduce the threat of hazards to occupants as well as to the community.

> **Policy C-HS 33:** Development in areas of natural hazards should be designed, located, and otherwise regulated to reduce associated risks, by regulating the type, density, and placement of development where it will not: (a) be directly jeopardized by hazards, (b) increase hazard potential, and (c) increase risks to neighboring properties.

Strategy #4: Reduce the Magnitude of the Hazard, If Feasible. One type of measure not specifically related to individual development projects that is intended to reduce the risks of natural hazards is dam reinforcement. Dam reinforcement is important to both an assured water supply and to protect the safety of populations and property downstream of the water impoundments.

> **Policy C-HS 34:** Flood control measures should be considered part of an overall community improvement program and advance the following goals, in addition to flood control: (a) resource conservation, (b) preservation of riparian vegetation and habitat, (c) recreation, and (d) scenic preservation of the county's streams and creeks.
>
> Book B of the Santa Clara County General Plan (Santa Clara County 1994b), Safety and Noise element, provides strategies, policies, and implementation programs to reduce the risks of

natural hazards in rural unincorporated areas. Those that are relevant to the Project are listed below.

Strategy #1: Inventory Hazards and Monitor Changing Conditions. This strategy is the same as presented in Book A, discussed above.

Policy R-HS 6: Inventories and mapping of natural hazards shall be adequately maintained for use in planning and decision-making, including: (a) Relative Seismic Stability Map; (b) Composite Geologic Hazards Map; (c) Soil Creep; (d) Saturated, Unstable Soils; (e) Slope Maps; (f) Flood Hazards Maps; (g) Relative Fire Hazard Rating; (h) Dam Failure Inundation Areas Maps; (i) Airport Safety Zones; and (j) Closed Solid Waste Disposal Sites.

Strategy #3: Design, Locate and Regulate Development to Avoid or Withstand Hazards. The design, construction, and location of development can in many cases significantly reduce the risk associated with some natural hazards.

Policy R-HS 10: In all hazard areas, projects shall be designed and conditioned to avoid placement of structures and improvements where they would: (a) be directly jeopardized by hazards; (b) increase the hazard potential; and/or (c) increase risks to neighboring properties.

Policy R-HS 11: Proposals for General Plan amendments, zone changes, use permits, variances, building site approvals, and all land development applications subject to environmental assessment shall be reviewed for the presence of hazardous conditions, utilizing the best, most up-to-date information available. If a development proposal would require a major investment or addition to public infrastructure in areas subject to high hazards, objective estimates of the probable public costs of maintaining and repairing the infrastructure should be provided to decision-makers.

Policy R-HS 12: Proposals shall be conditioned as necessary to conform with County General Plan policies on public safety. Projects which cannot be conditioned to avoid hazards shall be conditioned to reduce the risks associated with natural hazards to an acceptable level or shall be denied.

Policy R-HS 13: Where needed to adequately assess the hazards of a proposal, the County shall require on-site investigations and analysis by certified professionals.

Policy R-HS 14: Critical structures and infrastructure vital to the public health, safety, and general welfare, such as water supply facilities, other utilities, police and fire stations, and communications facilities, shall not be located in areas subject to significant impacts from geologic or seismic hazards unless there is no feasible alternative site. Projects shall be designed to mitigate any seismic hazards associated with their sites.

Policy R-HS 19: In areas of high potential for activation of landslides, there shall be no avoidable alteration of the land or hydrology which is likely to increase the hazard potential, including: (a) saturation due to drainage or septic systems; (b) removal of vegetative cover; and (c) steepening of slopes or undercutting the base of a slope.

Policy R-HS 20: Lands where soils are in a continually saturated condition should not be used for structural purposes or filled with heavy earth fills due to their inherently weak and unstable nature. Uses requiring septic systems in such areas should not be allowed.

Policy R-HS 21: Proposals involving potential geologic or seismic hazards shall be referred to the County Geologist for review and recommendations.

Paleontological Resources

Book A of the Santa Clara County General Plan (County 1994a), Resource Conservation element, provides strategies, policies, and implementation programs to inventory, preserve, and restore heritage resources countywide. Heritage resources are defined in this element as including paleontological resources. Those that are relevant to the Project are listed below.

Strategy #1: Inventory and Evaluate Heritage Resources. Inventories of heritage resources serve several purposes:

- to document the existence of identified resources and their location;
- to help evaluate the significance, quality, and protective status of the resources;
- to form the basis for recommendations that resources of various kinds be included in state inventories or the National Register of Historic Places;
- to ensure that local decision-makers take heritage resource conservation into account; and
- to publicize and increase awareness of the value of heritage resources.

Inventories may be initiated by formal action, such as the case when surveys are commissioned for an area or jurisdiction. As conditions change, inventories must be updated and maintained. Incidental observations by members of the public as well as by various governmental agencies involved with such work may add to the knowledge base. However, involvement of local historians and architectural historians[12] should be integral to the work of conducting and maintaining adequate resource inventories.

Policy C-RC 51: Inventories of heritage resources should be maintained as the basis for local decision-making regarding such resources.

Strategy #2: Prevent or Minimize Adverse Impacts on Heritage Resources. Preventing losses to heritage resources, given their irreplaceable nature, should take precedence wherever possible over attempts to compensate or minimize the impact. However, when loss or damage to such resources is unavoidable, impacts should be mitigated to the maximum extent possible. Alternatives may be able to preserve some, if not all, of the resource.

Policy C-RC 52: Prevention of unnecessary losses to heritage resources should be ensured as much as possible through adequate ordinances, regulations, and standard review procedures. Mitigation efforts, such as relocation of the resource, should be employed where feasible when projects will have significant adverse impact upon heritage resources.

Book B of the Santa Clara County General Plan (County 1994b), Resource Conservation Element, provides strategies, policies, and implementation programs to inventory, preserve, and restore heritage resources in the rural unincorporated portions of the county. Heritage

12 Although not mentioned specifically in the General Plan, involvement of applicable professionals includes paleontologists for the study of paleontological resources.

resources are defined in this element as including paleontological resources. Those that are relevant to the Project are listed below.

Strategy #1: Inventory and Evaluate Heritage Resources. This strategy is the same as presented in Book A, discussed above.

Policy R-RC 83: The County's Heritage Resources database shall be maintained and used to review private development projects and guide the design of public projects.

Policy R-RC 84: Heritage resource acquisition, preservation, restoration, and interpretation projects eligible for funding with County Parks Charter Funds are identified in the "Santa Clara County Heritage Resources Inventory" adopted by the Board of Supervisors.

Strategy #2: Prevent or Minimize Adverse Impacts on Heritage Resources. This strategy is the same as presented in Book A, discussed above.

Policy R-RC 85: No heritage resource shall knowingly be allowed to be destroyed or lost through a discretionary action (zoning, subdivision site approval, grading permit, building permit, etc.) of the County of Santa Clara unless: (a) the site or resource has been reviewed by experts and the County Historic Heritage Commission and has been found to be of insignificant value; or (b) there is an overriding public benefit from the project and compensating mitigation to offset the loss is made part of the project.

Policy R-RC 86: Projects in areas found to have heritage resources shall be conditioned and designed to avoid loss or degradation of the resources. Where conflict with the resource is unavoidable, mitigation measures that offset the impact may be imposed.

Policy R-RC 88: For projects receiving environmental assessment, expert opinions and field reconnaissance may be required if needed at the applicant's expense to determine the presence, extent, and condition of suspected heritage resources and the likely impact of the project upon the resources.

City of San José

Grading and Drainage Permits

Title 17, Chapter 17.04, Part 6 describes excavation and grading requirements for projects constructed in San José. 17.04.310(A)(8) notes that earthwork entirely within public rights-of-way or easements and/or which is authorized and administered by a public agency is exempt from grading and drainage permits.

Geologic Hazard Ordinance

The purpose of Title 17, Chapter 17.10 is to ensure an appropriate level of review to projects which are located in geologically sensitive areas in order to identify any geologic hazard and impose necessary mitigations before development may be permitted. Geologic conditions change over time, and knowledge about geologic hazards and technology to respond to those hazards is evolving. A certificate of geologic hazard clearance must be received for any discretionary approval for development, grading permit, or building permit.

General Plan

Geologic Hazards

The Envision San José 2040 General Plan (City of San José 2023) contains goals and policies related to seismic hazards and geologic and soils hazards.

Goal EC-3 – Seismic Hazards. Minimize the risk of injury, loss of life, property damage, and community disruption from seismic shaking, fault rupture, ground failure (liquefaction and lateral spreading), earthquake-induced landslides, and other earthquake-induced ground deformation.

Policy EC-3.2 Within seismic hazard zones identified under the Alquist-Priolo Fault Zoning Act, California Seismic Hazards Mapping Act and/or by the City of San José, complete geotechnical and geological investigations and approve development proposals only when the severity of seismic hazards have been evaluated and appropriate mitigation measures are provided as reviewed and approved by the City of San José Geologist. State guidelines for evaluating and mitigating seismic hazards and the City-adopted California Building Code will be followed.

Policy EC-3.5 Locate, design and construct vital public utilities, communication infrastructure, and transportation facilities in a manner that maximizes risk reduction and functionality during and after an earthquake.

Goal EC-4 – Geologic and Soil Hazards. Minimize the risk of injury, loss of life, and property damage from soil and slope instability including landslides, differential settlement, and accelerated erosion.

Policy EC-4.2 Approve development in areas subject to soils and geologic hazards, including un-engineered fill and weak soils and landslide-prone areas, only when the severity of hazards has been evaluated and if shown to be required, appropriate mitigation measures are provided. New development proposed within areas of geologic hazards shall not be endangered by, nor contribute to, the hazardous conditions on the site or on adjoining properties. The City of San José Geologist will review and approve geotechnical and geological investigation reports for projects within these areas as part of the project approval process.

Policy EC-4.3 Locate new public improvements and utilities outside of areas with identified soils and/or geologic hazards (e.g., deep seated landslides in the Special Geologic Hazard Study Area and former landfills) to avoid extraordinary maintenance and operating expenses. Where the location of public improvements and utilities in such areas cannot be avoided, effective mitigation measures will be implemented.

Paleontological Resources

The Envision San José 2040 General Plan (City of San José 2023) contains goals and policies related to paleontological resources.

Goal ER-10 – Archaeology and Paleontology. Preserve and conserve archaeologically significant structures, sites, districts, and artifacts in order to promote a greater sense of historic awareness and community identity.

Policy ER-10.1: For proposed development sites that have been identified as archaeologically or paleontologically sensitive, require investigation during the planning process in order to determine whether potentially significant archeological or paleontological information may be affected by the project and then require, if needed, that appropriate mitigation measures be incorporated into the project design.

Policy ER-10.3: Ensure that City, State, and Federal historic preservation laws, regulations, and codes are enforced, including laws related to archaeological and paleontological resources, to ensure the adequate protection of historic and pre-historic resources.

City of Morgan Hill

Geologic Hazards Ordinance

The purpose of Title 18, Chapter 18.70 includes preventing increases in the potential for loss of life, injury, and property damage caused by geologic hazards in Morgan Hill. No discretionary approval for development, grading permit, or building permit shall be issued for any project located in an area zoned for geologic hazards unless the director has first approved an application for geologic clearance.

General Plan

Geologic Hazards

The City of Morgan Hill 2035 General Plan (City of Morgan Hill 2017) contains goals and policies related to seismic hazards and geologic and soils hazards.

Goal SSI-2 Reduction of potential harm to persons or property from geologic/seismic hazards.

Policy SSI-2.1 Land Use and Geologic Hazards. Limit uses on lands with geologic hazards but allow uses on previously urbanized lands with proper mitigation. Keep development in hazardous areas to a minimum by encouraging low-density, low-intensity uses and the types of uses least disruptive to the soil and vegetative cover. (South County Joint Area Plan 15.02a)

Policy SSI-2.2 Site Preparation for Geologic Stability. On lands with geologic hazards that have already been developed, require mitigation procedures, including geotechnical investigations appropriate for the known or suspected geologic problems.

Policy SSI-2.3 Site Preparation in Hazardous Areas. Require site preparation in hazardous areas to be designed to achieve long-term geologic stability.

Policy SSI-2.4 Code Requirements for Critical Structures. Design and construct critical structures above and beyond the applicable engineering and building standards, where such measures are deemed necessary from available geologic and engineering data. Critical structures are those structures:

a) needed after a disaster (e.g., emergency communications, fire stations, hospitals, bridges and overpasses;

b) whose continued functioning is critical (e.g., major power lines and stations, water lines, and other public utilities); or

c) whose failure might be catastrophic (e.g., large dams).

Policy SSI-2.5 Design of Critical Structures. Design and construct critical structures to resist minor earthquakes without damage, resist moderate earthquakes without structural damage, and resist major earthquakes of the intensity or severity of the strongest experienced in California without collapse.

Policy SSI-2.6 Hillside Development. Protect hillsides and carefully control development on steep slopes. When hillside land is developed, it should be done with minimum disruption of topography and vegetative cover. (South County Joint Area Plan 15.00)

Policy SSI-2.7 Landslides. Prohibit development on known active landslides and limit development in areas where such development might initiate sliding or be affected by sliding on adjacent parcels. (South County Joint Area Plan 15.02c)

Policy SSI-2.8 Runoff and Slope Stability. Prohibit development in areas where increased runoff from the addition of impervious surfaces and drainage would increase the probability of downslope landsliding, or where additional projects would add to the cumulative effect of increased runoff, unless a downslope drainage improvement plan has been approved. (South County Joint Area Plan 15.02d)

Policy SSI-2.9 Geologic Studies. Continue to require geologic and geotechnical studies for development in potentially hazardous areas, such as hillside areas and geotechnical studies for critical facilities in areas with liquefiable soils. The costs for consulting geologists shall be covered by a fee to the developer.

Policy SSI-2.10 Slope Stability. Enforce and maintain strict grading and building regulations to minimize instability of sloping areas and reduce public costs associated with maintaining roads and utilities on unstable slopes. (South County Joint Area Plan 15.12b)

Policy SSI-2.11 Geotechnical Investigations. Require geotechnical investigations on all projects in unstable areas, including areas of expansive soils, prior to construction to ensure that the potential hazards are identified and can be properly mitigated. (South County Joint Area Plan 15.13)

Paleontological Resources

The City of Morgan Hill 2035 General Plan (City of Morgan Hill 2017) contains goals and policies related to paleontological resources.

Goal HC-8 Historic identity and cultural resources that are preserved for future generations.

Policy HC-8.5 Mitigation. Require that if cultural resources, including tribal, archaeological, or paleontological resources, are uncovered during grading or other on-site excavation activities, construction shall stop until appropriate mitigation is implemented.

3.8.3 Methodology and Approach to Impact Analysis

The impact analysis considers whether implementation of the Project would exacerbate existing seismic or geologic hazards, cause significant impacts related to soils, or result in significant adverse impacts to paleontological resources. The analysis evaluates impacts on these resources that would occur as a result of the following activities:

- Seismic Retrofit construction
- Conservation Measure construction
- Construction Monitoring
- Post-construction Anderson Dam facilities and Conservation Measures operations and maintenance
- Post-construction FAHCE adaptive management

The analysis focuses on reasonably foreseeable effects of the Project on existing geologic conditions and paleontological resources based on review of the following resources:

- Geotechnical evaluations including
    a. Anderson Dam Seismic Retrofit Project Naturally Occurring Asbestos and Metals Evaluation Report (URS 2021a)
    b. Embankment basis of design technical memorandum for the Project (URS 2021b)
    c. Anderson Dam Seismic Retrofit Project Landslide Monitoring and Mitigation Plan (URS 2021c)
    d. Miscellaneous geotechnical information for EIR (URS 2022)
    e. Material development and handling technical memorandum for the Project (URS 2021d ~~2023~~)
- Paleontological Resources evaluations included in Appendix P:
    a. Paleontological Resources Impact Assessment for the Anderson Dam Seismic Retrofit Project (Far Western 2021); Post-Paleontological Survey for the Anderson Dam Drawdown to Deadpool Project, Santa Clara County, California (Far Western 2023)
- Results of the desktop evaluations performed using GIS based on data from the following sources:
    a. For information about distance of the Project from seismic sources, CGS's 2010 Fault Activity Map of California (2010)
    b. For soils hazards, soils mapping and evaluation of soil hazards by NRCS (NRCS 2021 ~~2023~~)
    c. For paleontological resources, geologic mapping by Dibblee and Minch (2005a, 2005b)

The analysis considers temporary impacts, or short-term impacts, that may occur during the 7-year construction period, as well as permanent impacts, or impacts considered to be long-term and/or that would result from ongoing facility operations and maintenance.

The direct effects of the Project are described and evaluated according to significance criteria generally derived from Appendix G of the *CEQA Guidelines*, discussed below.

The assessment of impacts for the purposes of this section has been divided into construction related impacts and operation/maintenance related impacts by Project ~~project~~ component, as identified and described in **Table 2-1** of Chapter 2, *Project Description*. Additional information on impact assessment approach by Project ~~project~~ component is provided below.

3.8.3.1 Seismic Retrofit Construction

As described in Section 3.0, *Introduction*, the baseline for evaluating Seismic Retrofit construction effects is the existing conditions following completion of the FOCP upgrades to the existing dam and reservoir facilities (i.e., existing conditions baseline).

3.8.3.2 Conservation Measures Construction

Conservation measures requiring construction activities that are evaluated in the impact analysis include:

- Ogier Ponds CM ~~Geomorphic and Habitat Restoration~~
- Maintenance of the North Channel Reach ~~Extension~~
- Maintenance of Spawning Gravel and Rearing Habitat Improvements in Live Oak Restoration Reach
- Sediment Augmentation Program
- Phase 2 Coyote Percolation Dam CM ~~Fish Passage Enhancements~~

As described in Section 3.0, *Introduction*, the baseline for evaluating conservation measure construction effects is the existing conditions baseline.

3.8.3.3 Construction Monitoring

Construction monitoring activities include data collection to monitor habitat environmental conditions (e.g., water quality; fisheries; fish rescue and relocation; juvenile rearing, migration, and growth; aquatic species rescue and relocation during dewatering; suspended sediment; sediment deposition; groundwater; invasive species; wetland and riparian habitat dryback; phytophthora pathogen; northwestern pond turtle; ~~and~~ milkweed, and other terrestrial animal species), identify any changes to ecological functions and habitat values that have or may result from construction activity, and where feasible, adjust construction activities to prevent or reduce the effect of those changes on the existing conditions baseline, often in compliance with Project regulatory permits. Construction monitoring activities are not considered in the impact analysis, as monitoring would involve data and information collection and assessment and would not result in direct or indirect adverse impacts to geology, soils, and paleontological resources.

Any monitoring response actions that could result in physical impacts would occur as part of the Seismic Retrofit and Conservation Measure components construction addressed above.

3.8.3.4 Post-Construction Anderson Dam Facilities Operations and Maintenance

This analysis considers indirect and direct impacts to geology and soils that could result from operational changes and proposed for nonemergency flow releases following completion of the Seismic Retrofit construction, as described in Chapter 2, *Project Description.* The analysis addresses whether changes to reservoir flow releases could result in soil instability and increased potential for erosion downstream in Coyote Creek. The analysis also considers stochastic modeling output in the ~~Potential Flood Impacts for the Project~~ Hydrology Technical

Appendix ~~Memorandum~~ (Valley Water 2023; Appendix K) for potential impacts to geology, soils, and paleontological resources within the Project area.

As described in Section 3.0, *Introduction*, the baseline for evaluating post-construction operation effects is the Pre FERC-Orders Baseline.

Additionally, as described in Chapter 2, *Project Description*, Valley Water would maintain the newly retrofitted Anderson Dam and Reservoir per Valley Water's existing DMP. Maintenance of Anderson Dam facilities was previously evaluated in the Final DMP EIR prepared in January 2012 (SCH No. 2011082077; Valley Water 2012). The DMP includes measures to reduce impacts related to geology, soils, and paleontological resources during maintenance activities, including impacts associated with earthwork, steep slopes, landslides, and discovery of unknown paleontological resources. The DMP EIR **Mitigation Measures Geology-1, Geology-2, Geology-3,** and **Paleo-1** require recontouring and revegetating temporary access roads and preparing a slope stabilization plan and performance of slope stability analysis, respectively, to reduce potential effects associated with increased erosion and unstable slopes. Impacts related to geology, soils, and paleontological resources associated with Project post-construction maintenance activities would not differ substantially from those impacts identified in the DMP EIR. Furthermore, previously identified DMP impacts would not be exacerbated with implementation of the Project. Therefore, no new impacts would occur as a result of post-construction dam maintenance activities that are not addressed by the DMP EIR. For these reasons, post-construction dam facility maintenance activities are not discussed further in this section.

3.8.3.5 Post-Construction Conservation Measures Operations and Maintenance

Operations and maintenance of the constructed Conservation Measures could include ground-disturbing activities, including placement of sediment into Coyote Creek. However, excavation is not anticipated. Operations and maintenance would also involve management of nonnative species, including the removal of vegetation and subsequent replanting. Accordingly, operations and maintenance of the Conservation Measures would not result in ground-disturbing activities that have the potential to cause significant impacts related to seismic or geologic hazards, increase the potential for erosion, or impact paleontological resources, and these impacts are not discussed further in this section.

Aside from the maintenance of restored and enhanced habitats of the Conservation Measures, which would ensure achieving success criteria during establishment periods designated in Project permits, maintenance of water conveyance infrastructure along Coyote Creek between the Conservation Measures for flood control and groundwater recharge of water released from Anderson Dam would be conducted consistent with existing Valley Water maintenance programs (e.g., SMP, DMP). Because Conservation Measure maintenance would be consistent with existing maintenance programs, no new impacts outside of those already accounted for in the SMP and DMP environmental analyses would result.

Operations and maintenance of Conservation Measures would not cause impacts related to seismic hazards, geologic hazards, or soils, or result in impacts to paleontological resources. Therefore, these topics are not discussed further in this section.

3.8.3.6 Post-Construction Project and FAHCE Adaptive Management

The FAHCE AMP would guide post-construction adaptive management of project flow operations and Conservation Measures that have met their specified success criteria, as defined through the regulatory permitting process. As required by the FAHCE AMP framework, the Project and FAHCE AMP includes four key elements: measurable objectives, monitoring, adaptive actions, and reporting. Monitoring and adaptive actions involve physical activities that could have environmental impacts.

The Project and FAHCE AMP monitoring program would inform selection of adaptive management measures to implement in response to management triggers, and includes compliance, validation, effectiveness, and long-term monitoring. Validation, effectiveness, and long-term trend monitoring would build on existing Valley Water monitoring infrastructure (e.g., hydrologic monitoring network), water quality monitoring (e.g., water temperature monitoring network), habitat monitoring (e.g., habitat mapping), and fisheries monitoring (e.g., VAKI Riverwatcher, PIT tag detectors, genetics sampling, electrofishing surveys). Impacts of these monitoring activities are evaluated in the impact analyses below.

The Project and FAHCE AMP identifies triggers for adaptive actions to help meet measurable objectives. Adaptive actions for FAHCE flows and imported water storage/releases would include refinements of reservoir releases, which would have impacts and benefits similar to the original FAHCE flows and imported water storage/releases. Adaptive actions for Conservation Measures would generally include minor construction and maintenance actions, whose impacts would be similar but less than those from original flow measures and Conservation Measure construction. Impacts of these adaptive actions are evaluated in the impact analyses below. These impacts are considered here at a programmatic level, because the detailed characteristics, timing, and/or locations of the proposed adaptive measures are not known at the time of EIR preparation. Project-specific CEQA review would be undertaken in the future, as necessary, when specific projects are proposed and project-specific details are available.

3.8.3.7 Applicable Best Management Practices and VHP Conditions

As noted in Chapter 2, *Project Description*, Valley Water would incorporate a range of BMPs, including conditions and AMMs from the VHP, to avoid and minimize adverse effects on the environment that could result from the Project. All relevant BMPs and AMMs for the Project are included in Appendix A, *Best Management Practices and Santa Clara Valley Habitat Conservation Plan Conditions, Avoidance and Minimization Measures, and Mitigation Measures* ~~*Incorporated in the Proposed Project*~~. BMPs relevant to geology and soils include the following:

GEN-20: Erosion and Sediment Control Measures – Would reduce the potential for erosion and sedimentation. This BMP describes measures to recover disturbed and exposed soils with seeding or erosion control materials. These measures would capture soil affected by erosion and keep it on the site and out of downslope waterways, where it could affect water quality as well as sedimentation.

GEN-21: Staging and Stockpiling of Materials – Would reduce the potential for erosion. This BMP specifies that staging must occur on surfaces that are either paved or already compacted, stockpiled materials must be hydrologically disconnected from waterways, and stockpiled soils will remain covered during the wet season, among other measures. These measures would ensure that any sediments remain onsite and do migrate to downslope waterways.

AQ-1: Use Dust Control Measures – Would implement dust and air quality management measures, including implementation of BAAQMD’s [Bay Area Air Quality Management District’s] BMPs for dust suppression. Removal of ground cover, including both vegetation and structures, would expose soil to erosive forces. Dust control measures would minimize erosion by requiring exposed surfaces to be watered, limiting vehicle speed and idling times, and planting or paving exposed surfaces as soon as possible, among other measures.

BI-3: Remove Temporary Fill – Would reduce the potential for erosion. Temporary fill materials, because they consist of exposed soil, are vulnerable to erosion. Removing this temporary fill after it has served its purpose would remove the source of erosion.

BI-8: Choose Local Ecotypes of Native Plants and Appropriate Erosion Control Seed Mixes – Would reduce the potential for erosion. Planting and seeding reduce the risk of erosion by replacing ground cover that was removed during construction. Replanting with native plants or erosion control mixes would provide for a stable ground cover that will hold soil in place in the face of erosive forces.

WQ-4: Limit Impacts from Staging and Stockpiling Materials – Would reduce the potential for erosion. Staging can increase the risk of erosion by removing ground cover and disturbing soil, making it more vulnerable to erosive forces. Stockpiling of materials can increase erosion if the stockpiled materials consist of soil. This BMP would limit staging to areas that are already disturbed and where possible compacted or paved and would ensure that stockpiled soils would either be covered or surrounded by properly installed silt fencing or other means of erosion control.

WQ-5: Stabilize Construction Entrances and Exits – Would reduce the potential for erosion. This BMP minimizes the risk of erosion in areas where construction equipment enters and exits the work area by minimizing the distance between the entrance or exit and the work area and by planning work site access to minimize disturbance of water bodies and stream banks.

WQ-9: Use Seeding for Erosion Control, Weed Suppression, and Site Improvement – Would reduce the potential for erosion. Similar to BI-8 discussed above, seeding reduces the risk of erosion by replacing ground cover that was removed during construction. Replanting with native plants or erosion control mixes would provide for a stable ground cover that will hold soil in place in the face of erosive forces.

BANK-1: Bank Stabilization Design to Prevent Erosion Downstream – Would reduce the potential for erosion at streambanks. This BMP would involve planting or placing protective devices such as logs, rock, and flow deflectors at locations where streambanks could be disturbed by Project activities and thus exposed to erosion.

REVEG-1: Seeding – Would reduce the potential for erosion. Similar to BI-8 discussed above, seeding reduces the risk of erosion by replacing ground cover that was removed during construction. Replanting with native plants or erosion control mixes would provide for a stable ground cover that will hold soil in place in the face of erosive forces.

VHP conditions were developed to help covered activities meet regional avoidance and minimization goals. VHP conditions that would apply to geology and soils relate to erosion control, slope stability, and paleontological resources (that could be unearthed through erosion or landslide). VHP conditions that would minimize impacts are the following:

- Condition 3, Maintain Hydrologic Conditions and Protect Water Quality
- Condition 4, Avoidance and Minimization for In-Stream Projects
- Condition 5, Avoidance and Minimization for In-Stream Operations and Maintenance
- Condition 7, Rural Development Design and Construction Requirements
- Condition 8, Implement Avoidance and Minimization Measures for Rural Road Maintenance
- Condition 11, Stream and Riparian Setbacks
- Condition 12, Wetland and Pond Avoidance and Minimization

In addition, VHP AMMs that would apply to geology and soils relate to erosion control, slope stability, and paleontological resources (that could be unearthed through erosion or landslide).

3.8.3.8 Thresholds of Significance

For the purposes of this analysis, the Project would result in a significant effect related to geology and soils if it would:

GEO-1: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving rupture of a known earthquake fault (criterion a.i)

GEO-2: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving strong seismic ground shaking (criterion a.ii)

GEO-3: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving liquefaction (criterion a.iii)

GEO-4: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving landslides (criterion a.iv)

GEO-5: Result in substantial soil erosion or the loss of topsoil (criterion b)

GEO-6: Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse (criterion c)

GEO-7: Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature (criterion f)

3.8.3.9 Issues Dismissed from Further Review

CEQA Guidelines Appendix G also suggests that projects may have a significant effect on geology and soils if the project involves structures located on expansive soils, as defined in **Table 18-1-B** of the Uniform Building Code (criterion d) or if they have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater (criterion e). Because the Project would not be located on expansive soils (refer to discussion in Section 3.8.2.2) or include the installation of septic tanks or alternative wastewater disposal systems, the IS dismissed criteria d and e from further analysis (Appendix B) (Valley Water 2013). These topics are therefore not discussed in this section.

In addition, the erosion analysis in this section focuses on erosion impacts that could lead to future erosion, result in changes to the ground surface, or involve loss of topsoil and does not consider water quality or sedimentation issues. Impacts related to mobilization of particles in sediment deposited during historic operation of the reservoir through the course of Coyote Creek through these sediments would not result in future erosion as defined for this section. This is because, when the reservoir is refilled, these sediments will no longer be subject to erosion through Coyote Creek, because any loss of these sediments would not change the ground surface, and because no topsoil would be affected. Therefore, this impact is not discussed further in this section. Impacts related to downstream water quality and sedimentation are discussed in Section 3.14, *Water Quality* and Section 3.11, *Hydrology*.

3.8.4 Impact Analysis

Impact GEO-1: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving rupture of a known earthquake fault **(Less than Significant)**

Seismic Retrofit Construction

As described above, the Coyote Creek Range fault zone and Calaveras fault are located within the Project Area (**Figure 3.8-4**). The Coyote Creek Range fault traverses the dam face and the Calaveras fault is located 1 mile east of the dam along the east side of the reservoir and traverses across the southeastern leg of Anderson Reservoir. Although both faults are considered active (having surface ruptured in the last 250 years or shown displacement in the last 11,700 years), only the Calaveras fault is delineated as an Alquist-Priolo fault under the Alquist-Priolo Earthquake Fault Zoning Act. However, effects associated with the potential for rupture at both faults are included in this analysis.

The Project could directly or indirectly cause substantial adverse effects related to surface fault rupture if vibration generated by Seismic Retrofit construction would affect local seismicity. Although the Seismic Retrofit Project ~~project~~ component would involve ground disturbing activities such as excavation, tunneling, and blasting within an active fault zone, these proposed excavation methods are not known to have any effect on local seismicity or on-site response to seismic activity, including fault rupture (URS 2022). Furthermore, the location of where rock on either side of a fault is locked, where stress develops, and energy is ultimately released when an earthquake occurs is located in the range of 3.5 to 10 miles bgs. Peak ground accelerations (PGA) during blasting similar to what would occur at the Project area were measured at the Calaveras Dam Replacement Project. The measured PGAs dropped off to near 0 within 350 feet of the blast, which is much shallower than the depth at which the fault is locked. Tunneling and excavation impart lower energy to the ground than blasting activities. Because of the shallow depth to which would not exacerbate fault rupture at the site. Therefore, Seismic Retrofit construction activities would not directly or indirectly exacerbate the effects of a surface fault rupture, reasonably increase the likelihood of an earthquake, or increase the force or magnitude of a surface fault rupture.

While the Coyote Creek Range fault transects the location of Anderson Dam, changes to the dam would not increase load on the fault such that risk of surface fault rupture would increase. In addition, Seismic Retrofit components would be designed to withstand the MCE on the Coyote Creek Front Range and Calaveras faults, such that any offset from surface fault rupture on these faults would not affect dam stability or affect downstream people or structures.

Therefore, construction of Seismic Retrofit components would not exacerbate the effects of a known earthquake fault and accordingly would not directly or indirectly expose people or structures to substantial adverse effects involving the rupture of a known earthquake fault. Therefore, the impact would be less than significant.

Conservation Measures Construction

Earthwork and new structures would be constructed as part of the Ogier Ponds CM, the Phase 2 Coyote Percolation Dam CM, and the Maintenance of the North Channel Reach ~~Extension~~ CM. Although construction of the conservation measures would be exposed to seismic risks including fault rupture from nearby active faults, construction methods would not directly or indirectly exacerbate the effects of rupture (URS 2022). These actions could include ground disturbance, potentially including actions that would involve placing or moving sediment. Any increased load from placed sediment would be too small to increase likelihood of surface fault rupture. Furthermore, as discussed under *Seismic Retrofit Construction* above-ground-disturbing activities involving vibration would not exacerbate fault rupture at the site. Placement of sediments would not increase load on nearby faults and would accordingly not increase likelihood of surface fault rupture. Accordingly, conservation measure construction activities would not increase the likelihood of an earthquake or exacerbate risk of fault rupture and therefore would not directly or indirectly expose people or structures to substantial adverse effects involving the rupture of a known earthquake fault. Therefore, the impact would be less than significant.

Post-Construction Anderson Dam Facilities Operations

Operational changes proposed for nonemergency flow releases would not exacerbate the effects of surface fault rupture of the known earthquake faults.

The Project could not directly or indirectly cause substantial adverse effects related to surface fault rupture because there would be no change in the range of reservoir depths from the Pre-FERC Order Conditions Baseline conditions. Deep reservoirs in seismically active areas can result in reservoir-induced seismicity (RIS). RIS occurs when deep (80 meters or 263 feet) or very deep (deeper than 150 meters or 492 feet) reservoirs are located on or near active faults (USGS 1996). The mechanism is a combination of increased load and increased lubrication on the fault. However, the Project would not increase the depth of the reservoir over the Pre-FERC Order Conditions Baseline and therefore would not exacerbate risk of RIS and according to surface fault rupture.

No earth moving activities would be required, so vibration would not affect the underground locked fault, which is at considerable depth bgs and would not be affected by earth-moving activities. Furthermore, operation of the Anderson Dam would not increase load on or lubrication of the faults by increasing depth of water because there would be no increase in dam capacity compared to the Pre-FERC Order Conditions Baseline. On the contrary, implementation of the Project would increase the seismic safety of the dam and associated infrastructure with respect to surface fault rupture, reducing the likelihood of seismic failure during an earthquake event, resulting in a beneficial impact related to seismic safety. Thus, because operations would not increase the likelihood of an earthquake nor exacerbate risk of fault rupture, post-construction Anderson Dam facilities operations would not directly or indirectly expose people or structures to substantial adverse effects involving the rupture of the known earthquake faults, and the impact would be less than significant.

Post-Construction Project and FAHCE Adaptive Management

The implementation of adaptive actions as part of the Project and FAHCE AMP may include refinements to the timing, frequency, and duration of Anderson Dam flow releases or physical changes in the Coyote Creek watershed such as exotic species removal, replacement riparian planting, or additional sediment augmentation. These actions would occur when conservation measures are not functioning as intended or not meeting measurable objectives.

These actions could include ground disturbance, potentially including actions that would involve placing or moving sediment. Any increased load from placed sediment would be too small to increase the likelihood of surface fault rupture. Similarly, any vibration generated from sediment movement would be too small to affect the underground locked fault. Although these adaptive actions would occur within the Coyote Creek channel and adjacent lands, they would not have the potential to exacerbate the likelihood of fault rupture. Therefore, post-construction FAHCE adaptive management would not increase the likelihood of an earthquake nor exacerbate the likelihood of surface fault rupture and therefore would not directly or indirectly expose people or structures to substantial adverse effects involving the rupture of the known earthquake faults. If necessary, additional CEQA review would be undertaken for any adaptive management that is proposed for the Project that would result in impacts that are not addressed in this EIR. Therefore, the impact would be less than significant.

Significance Conclusion Summary

The Project, including both Seismic Retrofit and Conservation Measure components, is located within a seismically active region. The nearby active Calaveras fault lies just east of Anderson Reservoir and the active Coyote Creek Range fault transects Anderson Dam. However, construction and operation of the Project would not exacerbate the risk of fault rupture that may occur in the vicinity of the Project area. The reservoir is not deep enough to cause RIS, vibrations associated with blasting and tunneling activities would not affect the earth at depths of where the underlying faults are locked (URS 2022), and no Project-related actions would increase the likelihood of seismic activity and associated surface fault rupture. Accordingly, neither construction nor operation of the Project would increase the likelihood of an earthquake or exacerbate the likelihood of surface fault rupture in the Project area or directly or indirectly expose people or structures to substantial adverse effects involving rupture of a known earthquake fault. Therefore, Therefore, the impact would be **less than significant**.

Mitigation Measures

No mitigation measures are required.

***Impact GEO-2: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving strong seismic ground shaking* (Less than Significant)**

Seismic Retrofit Construction

As shown in **Figure 3.8-4**, Anderson Dam is located within a highly seismically active area surrounded by numerous faults. In addition, the Coyote Creek Front Range fault traverses the dam face and the Calaveras fault located a mile east of the dam along the east side of Anderson Reservoir traverses across the southeastern leg of the reservoir within the Project area. Given the quantity of faults and proximity of the faults to the dam, the entire region would be subject to strong seismic ground shaking in the event of an earthquake.

Specifically, a high-magnitude earthquake on either the Coyote Creek Front Range fault or the Calaveras fault would create severe seismic ground shaking at the Project area. As discussed above in Section 3.8.1.3, the MCE for the Coyote Creek Front Range fault was identified to be a 6.6M event that would generate PGA levels of 1.14g at the site (URS 2021a). The MCE on the Calaveras fault was identified to be a 7.25M event that would generate PGA levels of 0.85g at the site (URS 2021a). This PGA level translates to severe perceived intensity with heavy damage (Bolt 1993) (**Table 3.8-2**). Accordingly, whether an MCE event were to occur on the Coyote Creek Front Range fault or the Calaveras fault, severe ground shaking at Anderson Dam would occur during an earthquake on either fault. Seismic effects could also include surface faulting (discussed under Impact GEO-1 above) and deformation (i.e., where rocks bend, twist or fracture). Thus, because these faults are located within the Project area, earthquakes along these two faults were considered in the design of the Project. The Embankment Basis of Design technical memorandum (URS 2021a) evaluates tectonic stresses on materials used for the replacement dam as well as materials underlying and neighboring the dam in order to affirm that the dam as designed would withstand the MCE on either fault.

The Project could directly or indirectly cause substantial adverse effects related to surface fault rupture if vibration generated by Project construction would affect local seismicity. While Seismic Retrofit construction activities, including tunneling and blasting, would be located in areas susceptible to earthquakes, these excavation methods are not known to have any effect on local seismicity or onsite response to seismic activity, including seismic ground shaking (URS 2022). The location of where rock on either side of a fault is locked, where stress develops and energy is ultimately released when an earthquake occurs, is located in the range of 3.5 to 10 miles bgs. Because of the shallow depth to which energy from blasting and tunneling activities extends, those activities during construction would not exacerbate ground shaking at the site. Therefore, the Project would not cause ground shaking or reasonably exacerbate the effects of ground shaking that may occur in the Project Area. The dam embankment, spillway, diversion system, outlet works systems, and permanent roadways and recreation facility modifications would be designed in accordance with existing laws and regulations related to geological and seismic stability. Specifically, the Seismic Retrofit components would be designed in accordance with DSOD and CBC/IBC standards and regulations intended to ensure construction would withstand damage from ground rupture and seismic shaking. Additionally, these facilities would not be used for human occupancy. Because seismic retrofit construction would not exacerbate the effects of seismic ground shaking and would not directly or indirectly expose people or structures to substantial adverse effects involving seismic ground shaking, the impact would be less than significant.

Conservation Measure Construction

Earthwork and new structures would be constructed as part of the Ogier Ponds CM, the Phase 2 Coyote Percolation Dam CM, and Maintenance of the North Channel Reach ~~Extension~~ CM. Although construction of the Conservation Measures would be exposed to seismic risks including strong seismic ground shaking during an earthquake on nearby faults, excavation methods would not directly or indirectly cause or exacerbate the effects of strong seismic ground shaking (URS 2022). These actions could include ground disturbance, potentially including actions that would involve placing or moving sediment. Any increased load from placed sediment would be too small to increase likelihood of surface fault rupture. As discussed under *Seismic Retrofit Construction* above, ground disturbing activities involving vibration would not exacerbate seismic ground shaking at the site. Placement of sediments would not increase load on nearby faults and would accordingly not increase likelihood of surface fault rupture. Accordingly, Conservation Measure construction activities would not exacerbate the effects of seismic ground shaking and therefore would not directly or indirectly expose people or structures to substantial adverse effects involving seismic ground shaking. Therefore, the impact would be less than significant.

Post-Construction Anderson Dam Facilities Operations

Operations (i.e., reservoir filling and flow releases) would not exacerbate the effects of seismic ground shaking as earth moving activities would not be required.

The Project could directly or indirectly cause substantial adverse effects related to seismic ground shaking if the increased depth of the reservoir could result in RIS. RIS occurs when deep (80 meters or 263 feet) or very deep (deeper than 150 meters or 492 feet) reservoirs are located on or near active faults (USGS 1996). However, the Project would not increase the depth of the reservoir over the Pre-FERC Order Conditions Baseline, and therefore would not exacerbate the risk of RIS or strong seismic ground shaking.

Implementation of the Project would increase the seismic safety of the dam with respect to strong seismic ground shaking over the Pre-FERC Order Conditions Baseline, reducing the likelihood of seismic failure during an earthquake event, resulting in a beneficial impact related to seismic safety. Thus, because post-construction Anderson Dam operations would not exacerbate likelihood of seismic ground shaking and therefore would not directly or indirectly expose people or structures to substantial adverse effects involving seismic ground shaking, the impact would be less than significant.

Post-Construction Project and FAHCE Adaptive Management

The implementation of adaptive actions as part of the Project and FAHCE AMP may include refinements to the timing, frequency, and duration of Anderson Dam flow releases or physical changes in the Coyote Creek watershed such as exotic species removal, replacement riparian planting, or additional sediment augmentation. These actions would occur when conservation measures are not functioning as intended or not meeting measurable objectives.

These actions could include ground disturbance, potentially including actions that would involve placing or moving sediment. Any increased load from placed sediment would be too small to increase likelihood of surface fault rupture. Similarly, any vibration generated from sediment movement would be too small to affect the underground locked fault. Although these adaptive actions would occur within the Coyote Creek channel and adjacent lands, they would not exacerbate the likelihood of seismic ground shaking. Therefore, post-construction FAHCE adaptive management would not exacerbate the likelihood of seismic ground shaking and therefore would not directly or indirectly expose people or structures to substantial adverse effects involving seismic ground shaking. If necessary, additional CEQA review would be undertaken for any adaptive management that is proposed for the Project that would result in impacts that are not addressed in this EIR. Therefore, the impact would be less than significant.

Significance Conclusion Summary

The Project, including both Seismic Retrofit and Conservation Measure components, is located within a seismically active region that would experience strong seismic ground shaking during an earthquake. However, construction and operation of the Project would not cause or exacerbate the risk of seismic ground shaking that may occur in the Project area. The reservoir is not deep enough to cause RIS, vibrations associated with blasting and tunneling activities would not affect the earth depths of where the faults are locked (3.5 to10 miles bgs), and no Project-related actions would increase likelihood of seismic activity and associated seismic ground shaking. Construction activities would not have the potential to exacerbate seismic ground shaking at the site. Accordingly, neither construction nor operation of the Project would expose people or structures to substantial adverse effects involving seismic ground shaking. The Seismic Retrofit and Conservation Measures components would not exacerbate the likelihood of seismic ground shaking in the Project Area and therefore would not directly or indirectly expose people or structures to substantial adverse effects involving seismic ground shaking. Therefore, the impact would be **less than significant**.

Mitigation Measures

No mitigation measures are required.

Impact GEO-3: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving liquefaction (Less than Significant)

Seismic Retrofit Construction

Anderson Dam and the majority of work areas needed for Seismic Retrofit construction are situated on Quaternary alluvial and artificial fill in a known liquefaction hazard area in a region that is susceptible to strong seismic ground shaking. As shown in **Figure 3.8-5**, areas immediately downstream of the dam along Coyote Creek are susceptible to liquefaction in response to seismic ground shaking. Accordingly, the presence of liquefiable soil layers in the existing dam embankment and foundation of the dam could result in major slumping and failure of the embankment following a large earthquake (AMEC 2011, URS 2021b). Subsequently, this could lead to a failure of Anderson Dam by either overtopping or piping through large cracks resulting in an uncontrolled release of reservoir water. Placement of the replacement dam materials onto liquefiable soils, failing to remove existing liquefiable soils in the dam embankment, or constructing the dam using soils susceptible to liquefaction could increase likelihood of liquefaction during seismic ground shaking, potentially leading to seismic densification, settlement, and overtopping of the dam. In addition, construction of the Seismic Retrofit components could increase the likelihood of liquefaction of susceptible soils through vibration caused by blasting, which would be used to facilitate tunneling and borrow activities.

Furthermore, the placement of excavated soils that are susceptible to liquefaction could increase the likelihood of liquefaction at the disposal site if structures are placed on these disposed materials. As described in Section 3.8.1.2, *Soils*, soils at and near the dam site have low to moderate risk of liquefaction. While the dam would not substantially increase the load on underlying foundation soils, placement of the new dam materials could nevertheless exacerbate the slight risk of liquefaction. In case of the occurrence of the MCE, liquefaction could cause differential settlement that could cause the dam crest to lower in elevation and lead to overtopping of the dam. Investigations have demonstrated that, during an MCE event, the dam crest could lower by 1.25 to 4.75 feet due to settlement (URS 2021a). Analysis has shown, however, that the freeboard remaining following an earthquake would be sufficient to avoid overtopping the dam, even when the reservoir is full.

In addition, the interim dams constructed to contain water before the final embankment dam is completed could be damaged by seismically induced liquefaction. If this were to occur, the interim dams could be breached or overtopped. Analysis shows that vertical displacement of the interim dams as a result of seismic ground shaking would range from 0.2 to 0.7 feet, which is within the required range of performance to avoid overtopping the dams (URS 2021a).

While the embankment contains liquefiable soils, liquefiable materials in the existing dam would be removed (URS 2021a). The liquefiable materials in the existing embankment dam would be replaced with nonliquefiable earth fill materials that would be capable of withstanding the effects of large earthquake events on the nearby faults (e.g., seismic ground shaking). In addition, the dam would be constructed to minimize conditions that could lead to liquefaction. Specifically, the replacement dam would include special-purpose zones[13] designed to resist liquefaction. The central core, being constructed of clay, would not be susceptible to liquefaction. Although the transition zone surrounding the central core could contain sands that could liquefy if saturated with water, adjacent filter and drain zones would allow any water in the dam to exit the embankment and avoid saturation of transition zone sands. By using properly compacted earth materials and drainage systems, the new dam embankment itself would not be prone to liquefaction (URS 2021a). Furthermore, construction activities associated with the Seismic Retrofit component of Anderson Dam would be conducted in accordance with all relevant provisions of the current DSOD and IBC/CBC standards to minimize effects resulting from dam failure caused by liquefaction.

Although Seismic Retrofit construction activities would include blasting, which has the potential to generate ground motion that could induce liquefaction in the liquefiable soils of the existing dam, ground motion induced by blasting would not induce liquefaction during construction of the seismic retrofit components. The closest blast source to liquefiable materials in the existing embankment would occur as part of the construction of the tunnel, which would occur at least 250 feet away (URS 2022). PGA generated from the ground motions of blasting would substantially decrease within a short distance from the blast source. It is estimated that PGA values would be less than the 100-year level (0.36g) event at a distance of 200 to 250 feet from the blast source. In addition, materials at Anderson Dam would need to be shaken between at least 9 and 12 seconds during a design-level earthquake in order to liquefy, whereas blasting activities would be considerably shorter in duration (i.e., ground motions would last generally

[13] Larger embankment dams are generally *zoned* with fine soils such as silts or clays at the core to hold the water in the reservoir, sand, gravel, or rock fill to provide the stability needed for the embankment (termed *transition zones*), and filters and drains to remove the water to resist seepage (University of California, Davis Civil and Environmental Engineering n.d.).

less than 1 second). Analyses for Anderson Dam with these assumptions have shown that the embankment would be stable after a 100-year level event. Thus, because ground motions would be short in duration, and because blasting activities would occur over 250 feet away from potentially liquefiable materials, blasting during construction would not induce liquefaction within the potentially liquefiable layers of the dam (URS 2022). Furthermore, construction activities associated with the Seismic Retrofit of Anderson Dam would be conducted in accordance with all relevant provisions of the current DSOD and IBC/CBC standards to minimize effects resulting from dam failure caused by liquefaction.

Liquefiable materials from the dam embankment that cannot be reused would be disposed of within the designated Reservoir Disposal Area. The Reservoir Disposal Area would be located on the reservoir bottom (URS 2021d ~~2023~~). Excavated waste materials, including the liquefiable soils removed from the existing dam embankment, would be placed on a prepared multi-layered surface consisting of geotextile, geogrid, and fill on top of reservoir sediment 10 to 24 feet deep. No structure or other load would be placed on these disposed materials. Therefore, any liquefiable soils removed from the existing dam embankment and disposed of would not present an increased risk of liquefaction in the Reservoir Disposal Area.

Construction of the Seismic Retrofit components would also not increase the groundwater table or otherwise increase soil saturation in the area that would increase the potential for liquefaction.

Soils at the site of the Seismic Retrofit components are rated as having low to moderate liquefaction potential, so risk of liquefaction from placement on liquefiable soils is low. Liquefaction caused by an MCE earthquake could cause the dam crest to lower in elevation, but the freeboard remaining following an earthquake would be sufficient to avoid overtopping the dam. Implementation of the Seismic Retrofit component would remove the liquefiable soils from the existing embankment and replace them in a zoned embankment with nonliquefiable soils with good drainage, thereby reducing the potential for dam failure caused by liquefaction. Construction activities such as blasting would not generate strong ground motion close to liquefiable materials that would induce liquefaction in these materials. Disposal of liquefiable soils would not be placed in a location where they would support a new structure. Furthermore, construction activities associated with the Seismic Retrofit component of Anderson Dam would be conducted in accordance with all relevant provisions of the current DSOD and IBC/CBC standards to minimize effects resulting from dam failure caused by liquefaction. Thus, because Seismic Retrofit component construction would not substantially exacerbate the effects of liquefaction and would not directly or indirectly expose people or structures to substantial adverse effects involving liquefaction, the impact would be less than significant.

Conservation Measure Construction

As discussed in Section 3.8.1.4 under *Liquefaction*, areas along Coyote Creek downstream of Anderson Dam are susceptible to liquefaction, including at all Conservation Measure components (CGS 2003, 2004). All of the Conservation Measures involve placement of at least some fill (though expected to be negligible for Maintenance of the North Channel Reach and Live Oak Restoration Reach), including gravels and riprap, on liquefiable soils. Thus, new facilities associated with these Conservation Measure components that add load to these liquefiable sediments could increase likelihood of liquefaction during seismic ground shaking.

Construction of the Ogier Ponds CM would require the import of approximately 450,000 cy of soil materials to completely fill Ponds 1 and 5, partially fill Ponds 2 and 4, expand the floodplain, and create a new overflow bypass levee to reestablish the original Coyote Creek alignment. ~~The North Channel Extension would involve grading of the North Channel through County parks and private property to connect with the confluence of the North and South Channels of Coyote Creek. Construction of the North Channel Extension would consist of grading activities and habitat enhancement.~~ The Sediment Augmentation Program would involve placing approximately 500 ~~55,000~~ cy of suitable sediment in Coyote Creek in the Live Oak Restoration Reach (initially), and in the Live Oak Restoration Reach or Ogier Ponds Reach over time, as determined by monitoring during adaptive management ~~at multiple locations~~. The Phase 2 Coyote Percolation Dam CM at Metcalf Ponds would involve removal of 9,650 ~~3,200~~ cy of cut material and placement of 12,192 ~~8,800~~ cy of large rock and engineered fill. The Live Oak Restoration Area may also include the addition of gravels necessary to sustain steelhead habitat. The area surrounding Coyote Creek consists of liquefiable materials.

For all of the Conservation Measures components, placement of materials on liquefiable soils could result in consolidation and associated subsidence after seismic ground shaking as a result of liquefaction of the foundation soils. While subsidence of foundation soils under pond, floodplain, and instream sediments would not expose people or structures to substantial adverse effects involving liquefaction, liquefaction of foundation soils under the levee and the fish ramp could result in deformation, subsidence, and possibly failure such that water could overtop the structures. Project placement of materials associated with the levee could, therefore, exacerbate the likelihood of liquefaction and thereby directly or indirectly expose people or structures to substantial adverse effects involving liquefaction.

Required compliance with CBC/IBC standards and regulations, which require geotechnical investigations including soils studies as well as measures to minimize geotechnical risks, for all Conservation Measure improvements and structures would reduce the potential for liquefaction-induced effects. Therefore, construction of the Conservation Measures would not substantially exacerbate the effects of liquefaction and would therefore not directly or indirectly expose people or structures to substantial adverse effects involving liquefaction. There, the impact would be less than significant.

Post-Construction Anderson Dam Facilities Operations

Once the Seismic Retrofit construction is complete, all liquefiable soils from the embankment would be removed; therefore, soils inside the embankment would no longer be at risk of failure from liquefaction following an earthquake. The capacity of the reservoir would not increase compared to the Pre-FERC Order Conditions Baseline, so the load on underlying foundation soils caused by water in the reservoir would not increase and exacerbate any existing risk of seismically induced liquefaction. The dam would be larger than the original dam and therefore would increase load on underlying foundation soils; however, a geotechnical evaluation has not identified the risk of liquefaction at the location of soils under the dam. Operations (i.e., reservoir filling and flow releases) would resume, and reservoir releases would continue to flow within Coyote Creek. Flows down Coyote Creek would also not exacerbate the likelihood of liquefaction.

Overall, the Project would reduce potential adverse impacts on people and structures due to dam failure caused by liquefaction by removing liquefiable materials from the existing dam embankment. Thus, because operations would not exacerbate liquefaction and thereby directly or indirectly expose people or structures to adverse effects involving liquefaction, the impact would be less than significant.

Post-Construction Project and FAHCE Adaptive Management

The implementation of adaptive actions as part of the Project and FAHCE AMP may include refinements to the timing, frequency, and duration of Anderson Dam flow releases or physical changes in the Coyote Creek watershed such as exotic species removal, replacement riparian planting, or additional sediment augmentation. These actions would occur when Conservation Measures are not functioning as intended or not meeting measurable objectives. Adaptive actions would occur within the Coyote Creek floodplain. Placement of sediments on liquefiable soils could increase likelihood of liquefaction. However, consequences of liquefaction would include consolidation and potentially subsidence of the underlying soils and would not include damage or injury to structures or people. Therefore, although post-construction FAHCE adaptive management could exacerbate the likelihood of liquefaction, these actions would not directly or indirectly expose people or structures to substantial adverse effects involving liquefaction. If necessary, additional CEQA review would be undertaken for any adaptive management that is proposed for the Project that would result in impacts that are not addressed in this EIR. The impact would be less than significant.

Significance Conclusion Summary

The Seismic Retrofit and Conservation Measure components are located in areas susceptible to liquefaction. Placement of dam materials could increase the load on liquefiable soils, which may densify and settle during an earthquake. However, analysis has shown that such settlement would not cause overtopping of the newly constructed dam. Furthermore, construction of the Seismic Retrofit component would not substantially exacerbate the effects of liquefaction at the Seismic Retrofit Project site because of the zoned construction of the embankment, the short duration of blasting activities, the distance of blasting activities to the potentially liquefiable materials, and disposal of liquefiable waste materials in the middle of the reservoir in an area where no structural load would be placed on top. In addition, construction of the Seismic Retrofit component would remove the liquefiable soils from the existing Anderson Dam embankment, thereby reducing the potential for dam failure caused by liquefaction.

Placement of structures associated with the Conservation Measures on liquefiable soils during construction could exacerbate liquefaction hazards. However, construction of the Project would adhere to DSOD and CBC/IBC standards and regulations as applicable, reducing potential liquefaction risks. Other than Post-Construction FAHCE Adaptive Management, operations associated with the Project would not involve ground disturbance that could exacerbate liquefaction. Post-Construction FAHCE Adaptive Management could involve the placement of sediments in Coyote Creek and Ogier Ponds, but in the unlikely event that impacts are greater than those addressed in this EIR, additional CEQA review would be undertaken. Thus, the Project would not substantially exacerbate the effects of liquefaction and would not directly or indirectly expose people or structures to substantial adverse effects involving liquefaction. The impact would be **less than significant.**

Mitigation Measures

No mitigation measures are required.

Impact GEO-4: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving landslides **(Less than Significant with Mitigation)**

Seismic Retrofit Construction

Anderson Dam is located in a mountainous area with steep slopes susceptible to landslides due to weak ground from faults and historic landslides that predate the reservoir. As shown in **Figure 3.8-5**, areas susceptible to seismically induced landslides surround the reservoir, and five landslide areas exist along the southern portion of Anderson Reservoir on the west and east side; these include the Boat Marina landslide, Hoot Owl Way landslide, and the East Dunne landslides (consisting of the East Dunne Avenue landslide, Woodchopper landslide, and one possible additional slide in the north side of the area).These landslides have a history of movement during previous drawdowns of the reservoir and during months of heavy rainfall. During a recent drawdown, a landslide within the area of the Packwood Gravel Borrow Pit area was also observed (URS 2021d ~~2023~~). Although landslides are a regular occurrence and some of the landslides entered the reservoir water, there is no history of seiches.

Given the existing geologic and soils conditions, landslides are part of the existing conditions that have occurred before this Project and are expected to continue to occur after completion of Project construction activities in the same manner as they do now. Therefore, the only condition that would be changed due to the Project in the Seismic Retrofit construction area would be the construction activities themselves and short-term and temporary drawdown of the reservoir to below deadpool levels during the retrofit of the dam, as analyzed below.

Construction-related activities could increase the risk of landslides. Earth moving activities could disturb the toe of a landslide, removing the buttress that serves to hold the landslide sediments in place. In addition, the reservoir drawdown to below deadpool levels followed by refilling could increase risk of landslides. Much of the reservoir drawdown was achieved as part of the FOCP and is therefore considered as part of the existing conditions baseline. The mechanisms that would cause movement of landslides during drawdown and subsequent refilling include change in pore water pressure conditions and loss of toe support that was provided by the water at the base of the reservoir bank prior to drawdown.

If a landslide were to occur on the west or east side of the reservoir during construction, Valley Water would in most cases leave the landslide in place, as it does now. The only landslides that would be repaired are those that would impact existing improvements. Existing improvements include roads, utilities, structures, fill or cut slopes, and other man-made features. Ground stabilization methods may include removal of slumped or cracked material, placement of engineered fill, slope drainage, retaining walls, slope reinforcement, anchor installation, or other ground stabilization work. Monitoring and potential repair activities would continue through seismic retrofit construction and initial filling of the reservoir. Implementation of **Mitigation Measure GEO-1**, described further below, would reduce impacts to less than significant**.**

During Seismic Retrofit construction, nine stockpile areas would be used for temporary storage and processing of embankment and fill materials. Some of the stockpile areas on the western slope of the reservoir would be located within areas known to be susceptible to landslides. These landslides could be reactivated during construction, affecting personnel and equipment at the stockpile areas during preparation and use.

During construction, soil and earthen material would be removed from the BHBA and PGBP for use in the new dam embankment. To reduce landslides and rock falls from the freshly exposed faces at the BHBA where there are areas of fractured or weathered rock, the slopes would be stabilized with steel-fiber-reinforced shotcrete or steel mesh as described in Chapter 2, *Project Description* (URS 2021d ~~2023~~). Based on performed stability analyses, the slopes at PGBP would remain stable during construction (URS 2021d ~~2023~~).

Construction of all facilities associated with the Seismic Retrofit would be conducted in accordance with all relevant provisions of the current FERC and DSOD standards that reduce risks associated with geologic and slope stability. However, even with compliance with these requirements, construction of the Seismic Retrofit components could increase the risk of landslides, as previously discussed. The impact would be significant. Implementation of **Mitigation Measure GEO-1**, as described further below, will reduce impacts to less than significant with mitigation.

Once constructed, the reservoir levels would return to the pre-existing baseline range of levels prior to safety restrictions by FERC and DSOD. Landslide ground movement may continue to occur but would occur as they had prior to imposed restrictions and would not constitute a change for post-construction conditions.

Conservation Measure Construction

Other than Maintenance of the North Channel Reach ~~Extension~~, the Conservation Measure components downstream of the dam (i.e., Ogier Ponds CM, Sediment Augmentation Program, and Phase 2 Coyote Percolation Dam CM) would not be located within areas identified as susceptible to landslides (CGS 2003, 2004). No steep slopes are located within this portion of the Project Area. Therefore, construction of these Conservation Measures would not exacerbate likelihood of landslide.

The North Channel Reach ~~Extension~~ is located in the vicinity of steep slopes that are identified by CGS as being susceptible to landslide (CGS 2004). A majority of the activities in the North Channel Reach would be limited to minor and intermittent maintenance (e.g., vegetation management). ~~Excavation associated with construction~~ Maintenance of the North Channel Reach would not occur near the foot of this slope~~. Because of the distance from the slope, it is considered~~, and therefore, it is unlikely that maintenance ~~excavation~~ at this site would increase risk of landslide. Accordingly, ~~construction of the~~ Maintenance of the North Channel Reach ~~Extension Conservation Measure~~ would not exacerbate existing landslide hazards in the vicinity and therefore would not directly or indirectly expose people or structures to potential substantial adverse effects involving landslides. Therefore, impact would be less than significant.

Post-Construction Anderson Dam Facilities Operations

Following construction, the pre-existing reservoir capacity would be restored and storage of water would resume similar to conditions prior to ~~seismic~~ restrictions. As noted above in Impact GEO-1 and GEO-2, the depth of the reservoir would not increase, so there would be no increased risk of RIS. Furthermore, although the landslides along the reservoir rim would still exist and could be reactivated by seismic ground shaking, exacerbated by the fluctuation of reservoir storage volumes during normal operations (including during drought conditions), likelihood of seismically induced landslide would be similar to the likelihood during Pre-FERC Order Baseline Conditions. Furthermore, any such landslide would be addressed in accordance with the DMP, as described above. Thus, post-construction operations would not exacerbate existing landslide hazards in the seismic retrofit Project area and therefore would not directly or indirectly expose people or structures to potential substantial adverse effect involving seismically induced landslides. Therefore, this impact would be less than significant.

Post-Construction Project and FAHCE Adaptive Management

The implementation of adaptive actions as part of the Project and FAHCE AMP may include refinements to the timing, frequency, and duration of Anderson Dam flow releases or physical changes in the Coyote Creek watershed, such as exotic species removal, replacement riparian planting, or additional sediment augmentation. These actions would occur when conservation measures are not functioning as intended or not meeting measurable FAHCE objectives. Adaptive actions would occur within the Coyote Creek floodplain downstream of the Anderson Dam. While the Ogier Ponds CM, Sediment Augmentation Program, and Phase 2 Coyote Percolation Dam CM would not be located within areas identified as susceptible to landslides, the North Channel Reach ~~Extension conservation measure~~ is located adjacent to slopes that have been mapped by CGS as susceptible to landslide (CGS 2004). However, no specific excavation or other activity that could affect risk of landslide is proposed as a result of Project and FAHCE adaptive management. Therefore, post-construction Project and FAHCE adaptive management would not exacerbate likelihood of landslide and therefore would not directly or indirectly expose people or structures to potential substantial adverse effects involving landslides. If necessary, additional CEQA review would be undertaken for any adaptive management that is proposed for the Project that would result in impacts that are not addressed in this EIR. Therefore, the impact would be less than significant.

Significance Conclusion Summary

Ground disturbance associated with construction of the seismic retrofit of Anderson Dam, including drawdown of the reservoir, construction of stockpiles near landslides, removal of materials from the BHBA and the PGBP, and refilling of the reservoir could exacerbate likelihood of landslides by destabilizing landslide deposits. All construction activities would be performed in accordance with DSOD, IBC, and CBC standards as applicable. In addition, Valley Water would continue to monitor slope stability and landslide movement through the use of installed survey monuments and satellite reflectors within the reservoir as part of its normal operations.

Although maintenance activities ~~excavation~~ associated with the Maintenance of the North Channel Reach CM ~~Extension conservation measure~~ would occur ~~near~~ in the vicinity of slopes that are mapped by CGS (2004) as susceptible to landslide, all ~~construction~~ maintenance activities would be performed in accordance with IBC and CBC standards as applicable, and the distance of ~~construction~~ maintenance activities from the foot of the slope, and the limited scale of these activities, makes increasing the risk of landslide unlikely.

Operations of the reservoir after completion of the seismic retrofit components would return the reservoir to similar conditions with respect to landslide risk as existed during the Pre-FERC Order Condition Baseline. While landslides could occur during the Project operation period, the seismic retrofit components would not exacerbate likelihood of landslide. Similarly, adaptive management conducted under FAHCE would involve activities near an existing landslide near the North Channel Reach ~~Extension~~ ~~conservation measure~~. However, none of the activities would change the likelihood of landslide occurrence or exacerbate likelihood.

Construction of most of the conservation measures and operation of the Project would not cause landslides or exacerbate existing landslide hazards in the vicinity, and the impact for these aspects of the Project would be less than significant.

However, construction of the Seismic Retrofit components has potential to exacerbate landslide likelihood and thereby expose people or structures to potential substantial adverse effects involving landslides. This impact is significant. Implementation of **Mitigation Measure GEO-1** will reduce impacts to **less than significant with mitigation** by requiring Valley Water to remediate landslides caused by the construction activities and pose risks to private property.

Mitigation Measures

GEO-1 Repair Landslides Caused by Construction Activities

Valley Water will reduce impacts to less than significant with mitigation by requiring Valley Water to monitor the five active landslide areas during the Seismic Retrofit Construction and initial filling of the reservoir. If landslide movement is determined to have been caused by the Seismic Retrofit Construction activities and found to impact existing improvements, then Valley Water will ~~would~~ implement ground stabilization methods to prevent further movement. Existing improvements include roads, utilities, structures, fill or cut slopes, and other man-made features. Ground stabilization methods may include removal of slumped or cracked material, placement of engineered fill, slope drainage, retaining walls, slope reinforcement, anchor installation, or other ground stabilization work.

Impact GEO-5: Result in substantial soil erosion or the loss of topsoil (Less than Significant)

Seismic Retrofit Construction

Erosion can result in multiple effects: loss of growing medium for plants (loss of topsoil), destabilization of the ground surface including slopes and stream banks from mobilization and movement of sediment particles, changes in water quality, and sedimentation. This impact analysis focuses on loss of topsoil and mobilization of sediment particles that could lead to future erosion or result in changes to the ground surface. Impacts related to change in water quality are addressed in Section 3.14, *Water Quality*. Impacts related to sedimentation from increased erosion are addressed in Section 3.11, *Hydrology*.

Excavation and ground-disturbing activities associated with construction of the seismic retrofit could result in soil erosion or the loss of topsoil compared to the existing conditions baseline. Erosion increases when vegetation and other ground covers are moved, subjecting the underlying soil to erosive forces such as wind and water. Construction activities for the seismic retrofit components that would expose soil to erosive forces include clearing and preparing staging and stockpile areas; cofferdam construction; constructing the temporary water diversion system; dam excavation and fill; excavation of borrow materials, establishing new access and haul roads; constructing the new outlet works and spillway; constructing the permanent bladder dam; and use of unpaved access roads. Rain and wind events in areas where these activities would occur could result in erosion of soil into adjacent waterways.

Adhering to applicable BMPs and other erosion-focused measures can reduce erosion during construction. Because the Project occupies an area greater than 1 acre, as described in detail in Section 3.11, *Hydrology*, Valley Water would be required to obtain coverage under the SWRCB's General Permit for Storm Water Discharges Associated with Construction Activity Order 2022-0057-DWQ (Construction General Permit), which would require development and implementation of a SWPPP for out-of-reservoir construction activities. The SWPPP would include measures to control erosion and sedimentation from seismic retrofit construction activities outside of the reservoir. Erosion-control measures included in the SWPPP may include scheduling or limiting activities to certain times of the year (i.e., during the dry season); installing sediment barriers, such as silt fence and fiber rolls along the perimeter of construction areas; and implementing sediment-tracking controls, such as stabilizing entrances to the construction site. Furthermore, adherence to requirements of the applicable BMPs within and outside the reservoir would reduce the potential for erosion by implementing erosion control measures around stockpiled soils and staging areas, stabilizing construction entrances and exits, and removing temporary fill: GEN-20 (Erosion and Sediment Control Measures), GEN-21 (Staging and Stockpiling of Materials), AQ-1 (Use Dust Control Measures), WQ-4 (Limit Impacts from Staging and Stockpiling Materials), WQ-5 (Stabilize Construction Entrances and Exits), and BANK-1 (Bank Stabilization Design to Prevent Erosion Downstream). In addition, adherence to requirements of the following VHP conditions would minimize impacts related to erosion: VHP conditions 3 (Maintain Hydrologic Conditions and Protect Water Quality), 4 (Avoidance and Minimization for In-Stream Projects), and 5 (Avoidance and Minimization for In-Stream Operations and Maintenance). In addition, the Project would adhere to requirements of VHP Conditions and AMMs. Upon completion of construction, any temporary fill other than the cofferdam to be constructed on the floor of Anderson Reservoir would be removed, and site restoration measures would be implemented to return individual sites to preconstruction conditions, as specified in BMPs BI-3 (Remove Temporary Fill), BI-8 (Choose Local Ecotypes of Native Plants and Appropriate Erosion Control Seed Mixes), WQ-9 (Use Seeding for Erosion Control, Weed Suppression, and Site Improvement), and REVEG-1 (Seeding).

In addition to excavation and ground-disturbing activities associated with construction, materials excavated from the existing Anderson Dam embankment and the borrow areas would be stockpiled before use and could be subject to erosive forces. Construction of the seismic retrofit components would reuse embankment and fill materials excavated from the existing Anderson Dam embankment and would augment these materials with additional materials from the BHBA and PGBP to replace the dam embankment. In order to prepare the BHBA for use, topsoil and rock that cannot be used for the dam embankment would be removed and disposed either in the designed Reservoir Disposal Area or hauled to the Ogier Ponds ~~supplemental~~ staging or stockpiling areas for reuse as part of the geomorphic and habitat restoration effort. In addition, approximately 6 to 12 inches of topsoil from the west facing slope of the BHBA would be stripped, stockpiled, and reused during restoration. These excavated materials would be stored at the designated stockpile areas for use in the replacement dam. SWPPP erosion control measures for out-of-reservoir construction activities and applicable ~~,~~ BMPs~~,~~ and VHP conditions listed above within and outside the reservoir would protect the soil stockpiles from storm events and stabilize stockpiles during times of inactivity by revegetation or temporary cover to reduce the potential for substantial soil erosion and loss of soil. Stockpile areas would also be moisture-treated to reduce fugitive dust, as discussed in Chapter 2, *Project Description*.

Furthermore, implementation of BMP AQ-1 (Use Dust Control Measures) would require a variety of measures to reduce fugitive dust during construction, which would also serve to minimize loss of topsoil and reduce erosion (see discussion in Section 3.3, *Air Quality*). The SWPPP erosion control measures for out-of-reservoir construction activities, applicable BMPs listed above, and applicable VHP conditions and AMMs listed above would require implementation of approaches and technologies to retain sediment in place and prevent its movement. Therefore, construction of the seismic retrofit components would not result in substantial soil erosion or loss of topsoil, and this impact would be less than significant.

Conservation Measures Construction

Construction of some of the Conservation Measure components (e.g., Ogier Ponds ~~G~~CM, Phase 2 Coyote Percolation Dam CM, Live Oak Restoration Reach, and Maintenance of the North Channel Reach ~~Extension~~) would disturb the ground through clearing, grubbing, and excavation and expose soil to erosive forces. Construction of these conservation measures involves not only the conservation measures themselves but also temporary access roads and temporary stockpiles. Intense rain or wind events in areas where these activities would occur could result in soil erosion into adjacent waterways. Similar to the seismic retrofit and in compliance with the Construction General Permit, a SWPPP would be required, which would include measures to control erosion and sedimentation from construction activities. Furthermore, adherence to requirements of BMPs GEN-20 (Erosion and Sediment Control Measures), GEN-21 (Staging and Stockpiling of Materials), AQ-1 (Use Dust Control Measures), WQ-4 (Limit Impacts from Staging and Stockpiling Materials), WQ-5 (Stabilize Construction Entrances and Exits), and BANK-1 (Bank Stabilization Design to Prevent Erosion Downstream) will reduce erosion by implementing erosion control measures around stockpiled soils and staging areas and stabilizing construction entrances and exits. Upon completion of construction, any temporary fill would be removed, and site restoration measures would be implemented to return individual sites to pre-construction conditions, as specified in BMPs BI-3 (Remove Temporary Fill), BI-8 (Choose Local Ecotypes of Native Plants and Appropriate Erosion Control Seed Mixes), WQ-9 (Use Seeding for Erosion Control, Weed Suppression, and Site Improvement), and REVEG-1 (Seeding). In addition, the Project would adhere to requirements of VHP conditions 3 (Maintain Hydrologic Conditions and Protect Water Quality), 4 (Avoidance and Minimization for In-Stream Projects), and 5 (Avoidance and Minimization for In-Stream Operations and Maintenance). In addition, the Project would adhere to VHP Conditions and AMMs described in Section 3.8.3.7 ~~3.8.3.8~~.

The Sediment Augmentation Program would involve ~~removing and stockpiling suitable sediment from the exposed reservoir and~~ placing coarse sediment ~~the materials~~ in Coyote Creek at multiple locations between Anderson Dam and Ogier Ponds, initially at the Live Oak restoration reach. Sediment loads would be delivered by trucks, transported on conveyer belts, and placed using standard construction equipment. Each sediment augmentation site would require the establishment of access roads (or use of existing roads and trails) and a means to deliver sediment to channel, which may require some minor grading and/or vegetation removal. Rain and wind events in areas where these activities would occur could result in soil erosion into adjacent waterways. Constructing the access roads would involve ground disturbance in the form of grading and excavation. Using the access roads would compact the soil, leading to increased water velocity, which could in turn increase erosion both on the access roads and in the areas adjacent to the roads. Placement of sediment onto the streambed would not involve ground disturbance. However, it could change the hydraulic characteristics of the stream, potentially changing water velocity at the water's edge and thus increasing erosion of the stream bank. In addition, high flows from Anderson Dam could wash away these added sediments, and movement of the coarse sediments against the streambank could erode the streambank. However, adherence to requirements of the SWPPP, applicable BMPs and applicable VHP conditions and AMMs would ensure that impacts remain less than significant.

In addition, stockpiling suitable sediment for the Sediment Augmentation Program near the augmentation sites could expose this unconsolidated stockpiled material to erosion from rain or wind. SWPPP erosion control measures, BMPs listed above, and VHP conditions and AMMs listed above would protect the stockpiles from storm events and stabilize stockpiles during times of inactivity by revegetation or temporary cover to reduce the potential for substantial soil erosion and loss of soil. Stockpile areas would also be moisture-treated to reduce fugitive dust, as discussed in Chapter 2, *Project Description*. Furthermore, adherence to BMP AQ-1 (Use Dust Control Measures) will require a variety of measures to reduce fugitive dust during construction, which would also serve to minimize loss of topsoil and reduce erosion (see discussion in Section 3.3, *Air Quality*).

With adherence to the requirements of the SWPPP erosion control measures, BMPs listed above, and VHP conditions listed above, Conservation Measures construction would not result in substantial soil erosion or loss of topsoil, and impacts would be less than significant.

Post-Construction Anderson Dam Facilities Operations

Conditions at the dam and reservoir relating to erosion would be largely similar to the Pre-FERC Order Conditions Baseline. Although the downstream slope of the replacement embankment would be steeper than the existing embankment (i.e., 1.9:1 and 2.2:1, as opposed to 2.5:1), it would be well compacted and would not require erosion protection measures on the downstream or upstream side (URS 2021a). In addition, during post-construction dam operations, the reservoir levels would continue to fluctuate depending on seasonal conditions and water demand, leaving in some cases exposed slopes of the reservoir rim that could be subject to erosion. The Project would ~~not~~ increase the height of the dam but not ~~or~~ the capacity of the reservoir, so it is not expected that any new bank area would be disturbed by wave action compared to the Pre-FERC Order Conditions Baseline. Therefore, operations of the reservoir would not result in a large net loss of topsoil or erosion compared to the pre-FERC order conditions baseline at the dam and reservoir.

Operational and peak discharges into Coyote Creek under the Project would generally be higher under the Project than under Pre-FERC Order Conditions Baseline, because maximum capacity for releasing water through the dam would increase from 500 cfs under Pre-FERC Order Conditions Baseline to 6,800 cfs in the future after Project implementation. This would represent a substantial increase in the potential peak releases/flows from the dam; however, very high flows can potentially pass over the spillway during uncontrolled releases under the Pre-FERC Order Conditions Baseline. In addition, under FAHCE, there would be release of “pulse” flows of 50 cfs for 5 days, occurring up to two times from February 1 to April 30.

High flows can increase the potential for erosion downstream, as greater volumes of water traveling at greater velocities would increase the erosive power of the flows. Therefore, these higher discharges could result in increased streambank erosion from increased streamflow compared to Pre-FERC Order Conditions Baseline. However, many of the conservation measures would minimize potential adverse effects associated with peak flows. Reconnecting Coyote Creek to the historic channel through the Ogier Ponds CM would reestablish a more continuous, uninterrupted flow path for creek waters. Planting of native vegetation in areas along the floodplain in this area to create riparian habitat would also serve to reduce erosion along the reach. The North Channel Extension, constructed as part of FOCP, ~~and Habitat Enhancement measure~~ would allow high flows to be split between the north and south channels of Coyote Creek, minimizing water velocity and therefore erosive power. The Sediment Augmentation Program would replenish sediment that a high flow event would remove, as necessary based on monitoring results. Plantings if implemented under the FAHCE Adaptive Management measure would restore lost vegetation and provide ground cover, minimizing future risk of erosion. With operation of the conservation measures, high discharges under Project operation are unlikely to substantially increase streambank erosion within Coyote Creek.

Operation of the individual Conservation Measures even in the absence of high flows would also improve conditions with respect to erosion potential on Coyote Creek. As mentioned in the previous paragraph, the North Channel Extension, constructed as part of FOCP, would allow high flows to be divided between the North Channel and the South Channel of Coyote Creek, lowering both velocity and erosive power. The Sediment Augmentation Program would lower risk of erosion and incision in the creek by replacing and augmenting coarse sediment that would be less likely to mobilize except under higher flows. The disconnection of Ogier Ponds from Coyote Creek would likely be a benefit with respect to hydrology over the longer term. Reconnecting Coyote Creek to the historic channel would reestablish a more continuous, uninterrupted flow path that could increase sediment transport further downstream. Planting of native vegetation in areas along the floodplain in this area to create riparian habitat would also serve to reduce erosion along the reach. Accordingly, the conservation measures are unlikely to increase erosion.

Maintenance activities for Anderson Reservoir and conservation measures during the post-construction period would be relatively minor and would have low potential to result in substantial erosion and siltation on- or offsite. Activities such as repair or replacement of dam components or facilities, vegetation management, debris removal, sediment removal, and related activities for Anderson Reservoir and/or conservation measures could result in some erosion and potential siltation/sedimentation, but these effects would be less than significant with adherence to requirements of applicable BMPs and VHP conditions and AMMs.

Thus, post-construction operations would not result in substantial soil erosion or loss of topsoil, and impacts would be less than significant.

Post-Construction Project and FAHCE Adaptive Management

The implementation of adaptive actions as part of the Project and FAHCE AMP may include refinements to the timing, frequency, and duration of Anderson Dam flow releases or physical changes in the Coyote Creek watershed such as exotic species removal, replacement riparian planting, or additional sediment augmentation. These actions would occur when conservation measures are not functioning as intended or not meeting measurable objectives. Adaptive actions occurring within the Coyote Creek floodplain downstream of the Anderson Dam could result in temporary ground disturbance or restoration treatments, such as invasive plant removals, that could result in erosion or loss of topsoil. Implementation of BMPs GEN-20 (Erosion and Sediment Control Measures), GEN-21 (Staging and Stockpiling of Materials), BI-8 (Choose Local Ecotypes of Native Plants and Appropriate Erosion Control Seed Mixes), WQ-9 (Use Seeding for Erosion Control, Weed Suppression, and Site Improvement), BANK-1 (Bank

Stabilization Design to Prevent Erosion Downstream), and REVEG-1 (Seeding) as well as applicable VHP conditions and AMMs would minimize the potential for adaptive actions to result in substantial soil erosion or loss of topsoil. Furthermore, if necessary, additional CEQA review would be undertaken for any adaptive management that is proposed for the Project that would result in impacts that are not addressed in this EIR. Impacts would be less than significant.

Significance Conclusion Summary

Construction activities associated with Seismic Retrofit and Conservation Measure components, including FAHCE adaptive management actions, would involve ground-disturbing activities that have the potential to disturb soils and increase the potential for erosion and loss of topsoil. Such activities include clearing and preparing staging and stockpile areas; constructing, using, and maintaining stockpiles; excavating materials at borrow sites and conservation measures sites; placing sediment; and constructing and using unpaved roads. Implementation of a SWPPP (in compliance with the Construction General Permit) for out-of reservoir construction activities would require the implementation of measures to control erosion and sedimentation from construction activities. Furthermore, adherence to requirements of applicable BMPs, VHP conditions, and aquatic habitat AMMs will reduce erosion by implementing erosion control measures around stockpiled soils and staging areas, stabilizing construction entrances and exits, removing any temporary fill, restoring the site to its preconstruction condition, and reducing fugitive dust.

Changes in dam releases under future operations would increase the frequency of downstream inundation, which would in turn potentially cause erosion. However, the conservation measures would minimize potential adverse effects associated with peak flows by minimizing water velocity and replenishing sediment lost during high flows. Even in the absence of high flows, conservation measures would improve conditions with respect to erosion potential on Coyote Creek by the same mechanisms. Furthermore, adherence to requirements of applicable BMPs, VHP conditions, and VHP AMMs described will reduce erosion through replanting, enhancing coarse sediments in streams, and protecting and restoring stream banks.

Thus, with adherence to requirements of the SWPPP for out-of-reservoir construction activities, Valley Water, and applicable BMPs, ~~and~~ VHP conditions and AMMs listed above, substantial soil erosion or loss of topsoil resulting from the Project would not occur, and this impact would be **less than significant.** While not required to reduce impacts to less than significant, Mitigation Measure WQ-1 would further reduce these impacts by requiring implementation of a WQMPP for in-reservoir construction activities, which would include evaluation of the water quality monitoring data collected during FOCP implementation and Project construction, and implementation of BMPs to control sediment associated with in-reservoir construction activities to the extent technically feasible and in accordance with regulatory requirements.

Mitigation Measures

No mitigation measures are required.

Impact GEO-6: Located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse (Less than Significant)

While landslides, liquefaction, and lateral spreading can occur without a seismic event, the impacts if these were to occur would be the same. Impacts relative to landslides, liquefaction, and lateral spreading are analyzed under Impact GEO-4 and are not repeated here. Subsidence and collapse are analyzed below.

Seismic Retrofit Construction

Subsidence is typically caused by the extraction of groundwater or crude oil on a large scale. The Project would not include either of these activities.

Excavation associated with construction of the Seismic Retrofit components, including borrow sites, tunnel portals, and tunneling for the HLOWs, would present conditions that could lead to the collapse of excavated walls and the tunnel roof through lateral earth pressures (URS <u>2021c</u> ~~2021e~~). Groundwater at the level of tunnel excavation would increase risk of tunnel collapse. However, standard construction procedures consistent with requirements of the IBC and Occupational Safety and Health Administration (OSHA) require lateral earth pressure designs to be developed and submitted. In addition, the tunnel lining systems would be designed to withstand lateral round pressures. Furthermore, excavation and construction of the tunnel would be subject to DSOD requirements. Accordingly, risk of collapse through lateral earth pressures is low.

During excavation of the dam embankment, tunnels, portals, and borrow areas, unusable materials would be disposed of at the designated Reservoir Disposal Area. Placement of up to 1,150,000 cy of material would have the potential to compress the underlying lake sediment resulting in differential settlement if appropriate methods are not implemented. To reduce the potential for differential settlement to occur, the contractor would be required to cover the entire disposal area with 5 feet of material before starting the next layer. Each successive layer would be placed in 2-foot thicknesses across the entire area so that the lake sediment would consolidate evenly under the weight of the disposed materials. Overall, Seismic Retrofit construction would be conducted in accordance with all relevant provisions of the current DSOD and IBC/CBC standards related to geologic and slope stability to minimize effects resulting from unstable geologic units. Risk of collapse from lateral earth pressure would be managed through adherence to current DSOD and IBC/CBC standards related to geologic and slope stability. Risk of subsidence would not occur because the <u>Project</u> ~~project~~ does not include the withdrawal of groundwater or crude oil. Thus, impacts related to collapse and subsidence would be less than significant.

Conservation Measure Construction

Construction of the Conservation Measures would not require actions that would affect groundwater levels, such as extensive dewatering. While some dewatering would be conducted at Ogier Pond, the volumes and dewatering time would not be sufficient to cause subsidence. Accordingly, subsidence as a result of lowered groundwater levels is not anticipated. The Conservation Measures would not involve excavation that could create unsupported faces that could collapse due to lateral earth pressure. Therefore, operation would not increase risk of collapse. Thus, impacts related to collapse and subsidence would be less than significant.

Post-Construction Anderson Dam Facilities Operations

Operation of the Project would not include the extraction of groundwater or crude oil and subsidence would not occur. Operation of the Project after construction would not involve excavation that could create unsupported faces that could collapse due to lateral earth pressure. Therefore, the operation of the Project would not increase risk of collapse.

Operation of the Project would not increase risk of subsidence or collapse at the Seismic Retrofit components or at the Conservation Measures. Thus, this impact would be less than significant.

Post-Construction Project and FAHCE Adaptive Management

The implementation of adaptive actions as part of the Project and FAHCE AMP may include refinements to the timing, frequency, and duration of Anderson Dam flow releases or physical changes in the Coyote Creek watershed such as exotic species removal, replacement riparian planting, or additional sediment augmentation. These actions would occur when conservation measures are not functioning as intended or not meeting measurable objectives. Adaptive actions occurring within the Coyote Creek floodplain downstream of the Anderson Dam could result in temporary ground disturbance or restoration treatments, such as invasive plant removals. However, these adaptive actions would not change conditions with respect to subsidence or collapse. Due to the mild slopes and because ground disturbance would be limited, implementation of adaptive actions would not exacerbate any instability in underlying geologic units or soil resulting in subsidence or collapse. Furthermore, if necessary, additional CEQA review would be undertaken for any adaptive management that is proposed for the Project that would result in impacts that are not addressed in this EIR. Therefore, the impact would be less than significant.

Significance Conclusion Summary

Anderson Dam is located on unstable ground conditions; soils at the reservoir rim, adjacent to the dam, and downstream of the dam are susceptible to subsidence or collapse, which could lead to a significant impact if the Project exacerbated such instability. Construction of the Project would be conducted in accordance with all relevant provisions of the current DSOD and IBC/CBC standards related to geologic and slope stability to minimize effects resulting from unstable geologic units, which would sufficiently minimize effects. The Seismic Retrofit component construction would not exacerbate any instability in underlying geologic units or soil resulting in subsidence or collapse. Therefore, the impact would be **less than significant**.

Impact GEO-7: Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature (Less than Significant with Mitigation)

A unique geological feature is a discrete and clear geologic feature that has a clear identity distinct from other geologic features (e.g., Grand Canyon, Yellowstone Geysers). None of the geologic units that underlie any of the Project components contain unique geologic features. The geologic units are common and widespread throughout the region. Therefore, there would be no impact related to unique geologic features and are not discussed further.

Seismic Retrofit Construction

As described above in Section 3.8.1.5, the Santa Clara Formation underlying the Project area has a high-fossil yield ranking due to the known and diverse significant paleontological resources occurring in this unit. As identified in the archaeological field study conducted for the Project Paleontological Resources Impact Assessment (Far Western 2021) and the Post-Paleontological Survey for the Anderson Dam Drawdown to Deadpool Project, Santa Clara County, California (Far Western 2023), 52 fossils were previously recorded in the county in the Santa Clara Formation, as well as two significant fossil discoveries around the reservoir rim. As described in Section <u>3.8.1.5</u> ~~3.8.2.5~~, *Paleontological Resources*, Far Western (2023) conducted and reported on a surface collecting survey for paleontological resources in the reservoir drawdown area. Several significant mammalian fossils were retrieved from the Santa Clara Formation and were properly curated consistent with professional standards, fully mitigating for impacts on paleontological resources resulting from reservoir drawdown conducted by the time of the survey (at deadpool).

These discoveries suggest that further reservoir dewatering below deadpool, grading of native sediments, and other ground disturbing activities such as quarrying at the borrow sites associated with Seismic Retrofit construction could uncover further paleontological resources within the underlying Santa Clara Formation. Because Seismic Retrofit construction activities could directly or indirectly destroy such paleontological resources, the Project could result in a significant impact.

Mitigation Measure GEO-3 (Paleontological Construction Monitoring) requires paleontological construction monitoring during excavation in regions underlain by the Santa Clara Formation and other locations with high probability of a discovery. **Mitigation Measure GEO-4** (Paleontological Discoveries Treatment Plan) outlines the appropriate procedures to follow in the event that fossils are discovered. The potential for inadvertently destroying any significant paleontological resources would be reduced through the procedures outlined in the mitigation measures listed above, which provide for the protection, evaluation, and preservation/ documentation of any discovered resources. Thus, the potential for construction of the seismic retrofit to directly or indirectly destroy a unique paleontological resource or site or unique geologic unit would be minimized, and this impact would be less than significant with mitigation.

Conservation Measure Construction

A geologic unit, known to have yielded significant paleontological resources and categorized with paleontological sensitivity 4—High, Santa Clara Formation (QTs), occurs in the conservation measures area.

Construction of the Ogier Ponds CM, <u>Maintenance of</u> the North Channel <u>Reach</u> ~~Extension~~, and <u>Phase 2</u> Coyote Percolation Dam CM would involve excavation associated with creating new stream channels. Excavation for the new and altered stream channels ~~at the Conservation Measures~~ at Ogier Ponds ~~and North Channel Extension~~ have potential to excavate into Santa Clara Formation, depending on precise location and depth of the excavation, with potential to uncover significant paleontological resources. If excavation conducted for the Conservation Measures activities were to directly or indirectly destroy such paleontological resources, the Project would result in a significant impact. Implementation of **Mitigation Measures <u>GEO-2,</u> GEO-3,** <u>and</u> **GEO-4,** ~~and **GEO-5**~~ will provide for a survey for the presence of surface fossils in the Conservation Measures, area as well as the protection, evaluation, and preservation/

documentation of any resources discovered during excavation. The impact would be less than significant with mitigation.

Post-Construction Anderson Dam Facilities Operations

Operations would not involve any excavation or ground-disturbing activities that would impact paleontological resources. However, operational and peak discharges into Coyote Creek under the Project would generally be higher under the Project than under Pre-FERC Order Conditions Baseline because capacity for releasing water through the dam would increase from 500 cfs under Pre-FERC Order Conditions Baseline to a maximum of 6,800 cfs in the future after Project implementation. This would represent a substantial increase in the potential peak releases/flows from the dam; however, very high flows can potentially pass over the spillway during uncontrolled releases under the Pre-FERC Order Conditions Baseline. In addition, under FAHCE, there would be releases of "pulse" flows of 50 cfs for 5 days, occurring up to two times from February 1 – April 30.

Higher flows could increase potential for erosion downstream. Therefore, these higher discharges could result in increased streambank erosion from increased streamflow compared to Pre-FERC Order Conditions Baseline. The erosion could result in unearthing significant paleontological resources if the erosion occurs in Santa Clara Formation. While the resources may not be damaged by erosion, they would be removed from their original context, and therefore their scientific significance could be compromised. However, adherence to requirements of BMPs GEN-20, WQ-9, BI-8, BANK-1, and REVEG-1; VHP conditions 3, 4, and 5; and VHP AMMs will reduce erosion through replanting, enhancing coarse sediments in streams, and protecting and restoring stream banks, thereby limiting risk of damage to paleontological resources through erosion. Furthermore, many of the Conservation Measures would minimize potential adverse effects associated with peak flows as well as improve conditions with respect to erosion during lower flows. Thus, post-construction operations would not directly or indirectly destroy a unique paleontological resource or site or unique geologic unit. The impact would be less than significant.

Post-Construction Project and FAHCE Adaptive Management

The implementation of adaptive actions as part of the Project and FAHCE AMP may include refinements to the timing, frequency, and duration of Anderson Dam flow releases or physical changes in the Coyote Creek Watershed, such as exotic species removal, replacement riparian planting, or additional sediment augmentation. These actions would occur when conservation measures are not functioning as intended or not meeting measurable objectives. Adaptive actions occurring within the Coyote Creek floodplain downstream of the Anderson Dam could result in temporary ground disturbance or restoration treatments, such as invasive plant removals, that involve ground disturbance. Any ground disturbance into Santa Clara Formation or any sufficiently deep ground disturbance into other geologic units near Santa Clara Formation (QTs) could unearth significant paleontological resources. However, no adaptive actions are currently proposed that would involve excavation into this unit or into geological units that are located close to outcroppings of the Santa Clara Formation (QTs).

If necessary, additional CEQA review would be undertaken for any adaptive management that is proposed for the Project that would result in impacts that are not addressed in this EIR. Therefore, the impact would be less than significant.

Significance Conclusion Summary

Excavation and ground-disturbing activities associated with Seismic Retrofit or Conservation Measures construction occurring in regions underlain by the Santa Clara Formation could expose paleontological resources. In addition, higher peak flows released from Anderson Dam during Project operation could increase risk of erosion downstream, which could increase risk of erosion uncovering significant paleontological resources and removing them from the original context, thereby potentially reducing their scientific significance. However, the Conservation Measures would minimize risk of erosion. Furthermore, adherence to requirements of BMPs GEN-20, WQ-9, BI-8, BANK-1, and REVEG-1; VHP conditions 3, 4, and 5; and VHP AMMs will reduce erosion through replanting, enhancing coarse sediments in streams, and protecting and restoring stream banks, thereby limiting risk of damage to paleontological resources through erosion. Because the Project could directly or indirectly destroy such paleontological resources, the Project could result in a significant impact. However, the Project would adhere to conditions 3, 4, and 5; and VHP AMMs, which would reduce erosion through replanting, enhancing coarse sediments in streams, and protecting and restoring stream banks. Reducing erosion would reduce risk of damage to paleontological resources that could be unearthed by erosion. However, even with adherence to BMPs, conditions, and AMMs, this impact could be significant. **Mitigation Measures GEO-2, GEO-3** and **GEO-4~~, and GEO-5~~** will require surveys and monitoring by paleontological monitors and require that the proper procedures to evaluate and protect paleontological resources are followed in the event of a discovery and would reduce impacts to paleontological resources to **less than significant with mitigation**. Operational activities would result in **less-than-significant impacts** to paleontological resources.

Mitigation Measures

GEO-2 Paleontological Initial Survey

Valley Water will require that a trained Paleontological Monitor under the supervision of a qualified Paleontologist (as defined by the BLM 2008) conduct ~~and~~ initial field surveys of the Conservation Measures area prior to any ground-disturbing activities. The qualified paleontologist will meet the Society for Vertebrate Paleontology's criteria for a qualified paleontologist. The initial survey will map the lithologic boundaries and sedimentary facies of the survey area. If any fossils are discovered during surveys, the Paleontological Monitor will recommend that ~~ensure~~ no Project activities will occur within 50 feet of the discovery, and the Qualified Paleontologist will assess the significance of the fossil and to document the discovery.

GEO-3 Paleontological Detailed Survey and Construction Monitoring

Prior to excavation activities, Valley Water will require that a trained Qualified Paleontological Monitor reporting to a Qualified Paleontologist conduct a detailed field survey of the Project area, consistent with recommendations in BLM (2016) to establish the boundaries of the Santa Clara Formation and the surrounding units and provide an estimate on the thickness of the Quaternary alluvium near Santa Clara Formation outcroppings.

A Paleontological Monitor reporting to a Qualified Paleontologist will further be present during excavation activities occurring in the Santa Clara Formation and other locations having a high potential for fossils according to the PFYC (BLM 2016), as identified by the results of the more detailed survey conducted. Depending on the results of the field survey, namely, the likelihood that significant paleontological resources would be uncovered based on depth of excavation and location of ground disturbance, monitoring will either involve constant monitoring (at locations of direct excavation into Santa Clara Formation (QTs) or into other geologic units underlain at excavation depth near Santa Clara Formation) or spot monitoring (at locations of excavation into other geologic units underlain by Santa Clara Formation below that depth of excavation). Monitoring will not be required into geologic units with low or moderate paleontological sensitivity not underlain by a geologic unit with high paleontological sensitivity. Monitoring will also follow protocols outlined in Scott and Springer (2003) and Murphey et al. (2019), with field monitor(s) reporting to a Qualified Paleontologist.

GEO-4 Paleontological Discoveries Treatment Plan

In the event of a fossil discovery, Valley Water and its contractors will require that all work cease within a 50-foot radius of the discovery and that the discovery be protected from further impacts until the qualified Paleontologist assesses the significance of the fossil and documents its discovery. The Paleontologist will make recommendations regarding the fossil's significance. If the paleontologist determines the fossil to be significant (i.e., the fossil can provide significant information about the history of life), the following treatment actions will be implemented as appropriate for the resource.

For each encountered paleontological resource, selected l treatment actions would range from excavation with protective jackets to surface collection to notation only, depending on the value of the resource. The choice of treatment actions will depend on the condition of the fossil, the potential for articulation of separate elements, and the nature of the enclosing sediments. Potential treatment actions include, but are not limited to:

1. Salvage unearthed paleontological resources, including simple excavation of exposed specimens or, if necessary, plaster-jacketing of large and/or fragile specimens or more elaborate quarry excavations of extensive paleontological resources
2. Record stratigraphic and geologic data to provide context for the recovered resources, typically including detailed descriptions of all resource locations and the associated rock types
3. Prepare collected resources for curation
4. Curate, catalog and identify all resources to the lowest taxon possible and document with site records and photographs
5. Transfer resources to an accredited institution (e.g., University of California, Berkeley) for archival storage and/or display
6. Prepare a report that documents the discovery, and steps taken to protect and conserve the discovery

3.8.5 Cumulative Impacts

The geographic study area for the cumulative impact analysis for geology and soils encompasses the future Project areas the southern San Francisco Bay Area that would be susceptible to ground shaking, liquefaction, landslides, topsoil erosion, or destroy a unique paleontological resource.

This section describes the Project's contribution to cumulative geology and soils impacts, as summarized in **Table 3.8-4**.

Table 3.8-4. Summary of Project Contribution to Cumulative Geology and Soils Impacts I

Impact	Cumulatively Significant with FOCP?	Cumulatively Significant with other projects?	Incremental Project Contribution	Applicable Project Mitigation	Cumulatively Considerable after Mitigation?
Cumulative Impact GEO-1: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving rupture of a known earthquake fault	No	No	NCC	None	No
Cumulative Impact GEO-2: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving strong seismic ground shaking	No	No	NCC	None	No
Cumulative Impact GEO-3: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving liquefaction	No	No	NCC	None	No
Cumulative Impact GEO-4: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving landslides	Yes	No	CC	MM GEO-1	No
Cumulative Impact GEO-5: Result in substantial soil erosion or the loss of topsoil	No	No	NCC	None	No
Cumulative Impact GEO-6: Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse	No	No	NCC	None	No
Cumulative Impact GEO-7: Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature	Yes	Yes	CC	MM GEO-2 MM GEO-2 MM GEO-4	No

Cumulative Impact GEO-1: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving rupture of a known earthquake fault **(Not Cumulatively Considerable)**

The nearby active Calaveras fault lies just east of Anderson Reservoir and the active Coyote Creek Range fault transects Anderson Dam. However, construction and operation of the Project would not exacerbate the risk of fault rupture. The reservoir is not deep enough to cause RIS, vibrations associated with blasting and tunneling activities would not affect the earth at depths of where the underlying faults are locked (URS 2022), and no Project-related actions would increase the likelihood of seismic activity and associated surface fault rupture. As the Project would not increase the likelihood of an earthquake or exacerbate the likelihood of surface fault rupture in the Project area it would have no contribution to cumulative effects, and Project impacts would **not be cumulatively considerable.**

Cumulative Impact GEO-2: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving strong seismic ground shaking **(Not Cumulatively Considerable)**

The Project is located within a seismically active region that would experience strong seismic ground shaking during an earthquake. However, construction and operation of the Project would not cause or exacerbate the risk of seismic ground shaking that may occur in the Project area. The reservoir is not deep enough to cause RIS, vibrations associated with blasting and tunneling activities would not affect the earth depths of where the faults are locked, and no Project-related actions would increase likelihood of seismic activity and associated seismic ground shaking. As the Project would not increase the likelihood of seismic ground shaking it would have no contribution to cumulative effects**,** and Project impacts would **not be cumulatively considerable.**

Cumulative Impact GEO-3: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving liquefaction **(Not Cumulatively Considerable)**

The Project is in an area susceptible to liquefaction. Placement of dam materials could increase the load on liquefiable soils, which may densify and settle during an earthquake. Placement of structures associated with the Conservation Measures, namely the levee at Ogier Ponds and the fish ramp at the Coyote Percolation Pond on liquefiable soils could exacerbate liquefaction hazards in those areas.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if they occur in liquifiable soils at or near the Project sites.

Cumulative Effects of Project with the FOCP

FOCP construction of the Anderson Dam tunnel would involve tunneling through rock and other material at low risk of liquefaction and controlled detonations and use of boring equipment would generate groundborne vibration. Although liquefiable soils exist beneath both the upstream and downstream slopes of the dam embankment vibrations tunnel construction would not likely produce earth shaking at a strength sufficient to trigger liquefaction.

As construction activities for the FOCP would occur prior to the start of Project construction, there is no possibility of groundborne vibrations from FOCP related tunneling to affect dam material during or after construction of the Project or Conservation Measure components. Cumulative liquefaction impacts t are not significant with the FOCP and Project together, and the Project's contribution is not cumulatively considerable.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

None of projects listed in Table 3.0-2 would occur in the same area as the rebuild dam, therefore they would not contribute to cumulative liquification impacts at this site.

Certain future projects, such as the SMP and County Parks Planning Projects and Natural Resource Management, could occur in the vicinity as the Ogier levee and fish ramp at the Coyote Percolation Pond. However, these projects would not involve the placement of fills at these Project sites or involve strong ground shaking that could induce liquefaction in saturated soils. Overall, the risk of liquification is not a significant cumulative impact, and the Project’s contribution to the risk of liquefaction would not be cumulatively considerable.

Significance Conclusion Summary

Cumulative liquefaction impacts would not be significant, and the Project’s contribution to the risk of liquefaction would **not be cumulatively considerable**.

Mitigation Measures

None

Cumulative Impact GEO-4: Directly or indirectly cause potential substantial adverse effects, including the risk of loss, injury, or death involving landslides **(Not Cumulatively Considerable)**

Anderson Dam is in a mountainous area with steep slopes susceptible to landslides due to weak ground from faults and historic landslides that predate the reservoir. Ground disturbance associated with construction of the seismic retrofit of Anderson Dam, including drawdown of the reservoir, construction of stockpiles near landslides, removal of materials from the BHBA and the Packwood Gravels Borrow Site, and refilling of the reservoir could exacerbate likelihood of landslide by destabilizing landslide deposits. ~~Excavation associated with~~ Maintenance of the North Channel Reach ~~Extension~~ conservation measure would occur ~~near~~ in the vicinity of slopes that are mapped by California Geological Survey (2004) as susceptible to landslide; however, due to the distance from the foot of the slope, it is unlikely that maintenance at this site would increase risk of landslide.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if they create ground disturbances near the same areas of potential landslide risk as the Project.

Cumulative Effects of Project with the FOCP

The FOCP involved draining Anderson Reservoir to deadpool. Drawing down the reservoir increased the risk of landslides around the rim by exposing unstable and saturated slopes. In addition, tunneling activities generate ground vibrations that could trigger nearby landslides.

Construction activities take place at different times, such that ground borne vibrations during the FOCP would not affect construction or operation of the Project. However, the Project increases the period that the reservoir is drained and thus increases the potential for landslides on the unstable slopes around the reservoir. Given the extended period that the reservoir would be dewatered and various stockpiles in and around the reservoir, the Project and FOCP impacts combined would be cumulatively significant, and the Project's landslide risk contribution would be cumulatively considerable.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

None of projects listed in Table 3.0-2 would occur in the same area as the reservoir, BHBA or North Channel Reach ~~Extension~~, where the Project would have activities near areas with landslide risk, therefore they would not contribute to cumulative landslide impacts at this site. The Project would not have a significant cumulative effect on landslide risk with other future projects.

Significance Conclusion Summary

All Project construction activities would be performed in accordance with DSOD, IBC, and CBC standards as applicable. In addition, Valley Water would continue to monitor slope stability and landslide movement through installed survey monuments and satellite reflectors within the reservoir as part of its normal operations. For the FOCP Valley Water implemented the Anderson Dam Seismic Retrofit Project Landslide Monitoring and Mitigation Plan, Dewatering and Sediment Management Plan, and Slope Stability Plan. All these measures serve to reduce landslide risks by taking action to minimize soil instability and monitoring for signs of land movement, but cumulative landslide risks with the FOCP are nevertheless significant. The Project would implement **Mitigation Measure GEO-1** to reduce the risk of landslides. As such, ~~that~~ the Project's contribution to significant cumulative landslide risks post-mitigation is **not cumulatively considerable**.

Mitigation Measure

GEO-1 Repair Landslides Caused by Construction Activities

Cumulative Impact GEO-5: Result in substantial soil erosion or the loss of topsoil (Not Cumulatively Considerable)

Excavation and ground-disturbing activities associated with construction of the Project could result in soil erosion or the loss of topsoil. Such activities include clearing and preparing staging and stockpile areas; constructing, using, and maintaining stockpiles; excavating materials at borrow sites and conservation measures sites; placing sediment; and constructing and using unpaved roads.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if they create ground disturbances near the same areas as the Project.

Cumulative Effects of Project with the FOCP

Construction of the Anderson Dam tunnel involved creation of temporary gravel roads and the transportation of excavated material from the tunnel site to a stockpile/disposal site, increasing the potential for soil erosion at the reservoir. Both projects create similar impacts to soil erosion in the same areas around the reservoir. However, both projects implement a SWPPP in compliance with the Construction General Permit, and a set of erosion control BMPs (BMPs GEN-20, GEN-21, WQ-4, WQ-5, BI-3, BI-8, WQ-9, AQ-1, BANK-1, and REVEG-1) to minimize erosion around stockpiled soils and staging areas, stabilizing construction entrances and exits, removing any temporary fills, restoring the site to its pre-construction condition, and reducing fugitive dust. With adherence to requirements of the SWPPP and BMPs, substantial soil erosion or loss of topsoil caused by the projects would not cause a significant cumulative impact**.**

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Projects in the same area as the reservoir, Conservation Measure sites, and Coyote Creek include the SMP, Coyote Creek Flood Protection Project, Santa Clara County Parks Planning Projects and Natural Resource Management, as well as development projects in the County where ground disturbing activities could contribute to erosion and the loss of topsoil. All construction projects that disturb more than one acre are subject to the Construction General Permit ~~CGP~~ and the requirements of a SWPPP. Other Valley Water projects, and most other projects, also include a set of erosion control BMPs. With adherence to requirements of the SWPPP and BMPs, substantial soil erosion or loss of topsoil caused by the Project and other probable projects would not cause a significant cumulative impact.

Significance Conclusion Summary

All Project construction activities would be performed in accordance with a SWPPP for out-of-reservoir construction activities and other applicable erosion control BMPs that minimize the potential for erosion and loss of topsoil. Cumulative soil erosion impacts would not be significant, and the Project's contribution to cumulative soil erosion or loss of topsoil is **not cumulatively considerable**. While not required to reduce cumulative impacts to less than significant, Mitigation Measure WQ-1 would further reduce impacts by requiring implementation of a WQMPP for in-reservoir construction activities, which would include evaluation of the water quality monitoring data collected during FOCP implementation and Project construction, and implementation of BMPs to control sediment associated with in-reservoir construction activities to the extent technically feasible and in accordance with regulatory requirements.

Mitigation Measure

None

Cumulative Impact GEO-6: Located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse (Not Cumulatively Considerable)

Anderson Dam is located on unstable ground conditions; soils at the reservoir rim, adjacent to the dam, and downstream of the dam are susceptible to landslides, liquefaction, lateral spreading, settlement, and subsidence. Excavation and construction of new stream channels or other features associated with the Ogier Ponds CM, Maintenance of the North Channel Reach ~~Extension~~, and Phase 2 Coyote Percolation Dam CM into liquefiable soils could increase risk of lateral spreading. Long-term, the Project would stabilize the embankment of Anderson Dam and reduce potential adverse impacts on people and structures due to dam failure caused by unstable geologic conditions.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if they create ground disturbances near the same areas of potential unstable soils as the Project.

Cumulative Effects of Project with the FOCP

FOCP project elements occurred in bedrock with low potential for soil instability. Construction activities take place at different times, such that ground borne vibrations during the FOCP would not affect construction or operation of the Project. Construction of both the FOCP and Project would be in accordance with all relevant provisions of the current DSOD and IBC/CBC standards related to geologic and slope stability to minimize effects resulting from unstable geologic units, which would sufficiently minimize effects. Neither project would exacerbate instability in underlying geologic units or soil resulting in subsidence or collapse. The cumulative impact of the Project and FOCP would be less than significant, and the Project would have a not cumulatively considerable contribution related to unstable soils.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Certain future projects, such as the SMP and County Parks Planning Projects and Natural Resource Management, could occur in the vicinity as the Ogier Ponds CM, North Channel Reach ~~Extension~~, and Phase 2 Coyote Percolation Pond CM. However, these projects would not involve the placement of fills or substantial soil disturbance at these Project sites. Overall, the Project and other probable future projects would not have significant cumulative impact on the risks of soil instability, and the Project's contribution would not be cumulatively considerable.

Significance Conclusion Summary

All Project construction activities would be performed in accordance with DSOD, IBC, and CBC standards as applicable. In addition, Valley Water would continue to monitor slope stability and landslide movement through installed survey monuments and satellite reflectors within the reservoir as part of its normal operations. For the FOCP Valley Water implemented the Reservoir Bank and Rim Stability Mitigation and Monitoring Plan, Dewatering and Sediment Management Plan, and Slope Stability Plan. All these measures serve to reduce soil instability risks by taking action to minimize soil instability. Cumulative impacts are less than significant and the Project's contribution to on- or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse is **not cumulatively considerable**.

Mitigation Measure

No mitigation is required.

Cumulative Impact GEO-7: Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature (Not Cumulatively Considerable)

Santa Clara Valley is known for yielding significant fossils from alluvium (Maguire and Holroyd 2016). In addition, other geologic units of Pleistocene age and older in the county are documented to have yielded significant fossils, including vertebrate fossils. One of these is the

Santa Clara Formation in the Project area known locally as the Packwood Gravels. Excavation and ground-disturbing activities associated with Seismic Retrofit construction occurring in regions underlain by the Santa Clara Formation could expose paleontological resources. In addition, higher peak flows released from Anderson Dam during Project operation could increase risk of erosion downstream, which could increase risk of erosion uncovering significant paleontological resources and removing them from the original context, thereby potentially reducing their scientific significance.

Cumulative projects, plans, and programs could result in incrementally adverse impacts through ground disturbance activities that would disturb geologic units with high paleontological sensitivity in Santa Clara County.

Cumulative Effects of Project with the FOCP

The FOCP lowered the reservoir level to deadpool which exposed extensive swaths of the Santa Clara Formation, potentially revealing new significant paleontological resources. Construction could affect deposits of the Santa Clara Formation in Coyote Creek channel just downstream of the reservoir. The remainder of the Project Area ~~project area~~ is underlain by units that are either too young or of the wrong geological nature to harbor significant fossils.

The Project would maintain the reservoir at a low level for an additional seven years which extends the period that uncovered fossils are exposed to weathering. Construction activities of both projects could impact uncovered paleontological resources through excavation and grading of Project ~~project~~ components. The projects together have a significant cumulative impact and the Project's contribution is cumulatively considerable.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Most of the projects in Table 3.0-2 include ground disturbance, which have potential to affect paleontological resources, depending on whether the project's ground disturbance would be located on geologic units that are documented as having yielded scientifically significant fossils.

Because of the widespread nature of high paleontological sensitivity in Santa Clara County, it is likely that other projects could encounter and potentially damage or destroy paleontological resources during ground disturbance. While widely adopted mitigation is available to mitigate complete any such impact, including preparing a PRMMP, conducting construction worker education, conducting construction monitoring, stopping work in case of discovery of paleontological resources, and curating any significant finds, it is not guaranteed that all ground disturbance into geologic units with high paleontological sensitivity would be mitigated. Accordingly, a significant cumulative impact on paleontological resources exists in the geographic scope for this resource and the Project's contribution to this risk is cumulatively considerable.

Significance Conclusion Summary

Excavation and ground-disturbing activities associated with both the Project and other projects, occurring in regions underlain by the Santa Clara Formation could expose paleontological resources, a significant cumulative impact. The Project would implement **Mitigation Measure GEO-2** (Paleontological Initial Survey), **Mitigation Measure GEO-3** (Paleontological Detailed Survey and Construction Monitoring), and **Mitigation Measure GEO-4** (Paleontological

Discoveries Treatment Plan) that would require a pre-construction survey, construction monitoring, and plan for discovery of resources. These mitigation measures would reduce the contribution of the Project to significant impacts on paleontological resources to a level that is **not cumulatively considerable**.

Mitigation Measure

GEO-2 Paleontological Initial Survey

GEO-3 Paleontological Detailed Survey and Construction Monitoring

GEO-4 Paleontological Discoveries Treatment Plan

3.9 Greenhouse Gas Emissions

This section provides information about applicable regulations related to GHG emissions and climate change, the existing setting, and evaluates GHG impacts of the Project, including emissions generation and consistency with applicable GHG reduction plans and polices. The information in this section is based in part on the ~~Anderson Dam Seismic Retrofit CEQA~~ Air Quality, Greenhouse Gas, and Health Risk Assessment Technical Report, which is included in Appendix E[1].

The study area for GHG emissions focuses on California statewide.

3.9.1 Environmental Setting

3.9.1.1 Greenhouse Gases and Climate Change

Anthropogenic (human-caused) emissions of GHGs are widely accepted in the scientific community as contributing to global climate change. The Intergovernmental Panel on Climate Change (IPCC) was commissioned by the World Meteorological Organization and United Nations Environment Program to assess scientific, technical, and socio-economic information relevant to the understanding of climate change, its potential impacts, and options for adaptation and mitigation. According to *Climate Change 2007: The Physical Science Basis: Summary for Policymakers* (IPCC 2007 ~~2007a~~), there is no doubt that the climate is warming. In 2023, the IPCC issued an updated report, known as the *Sixth Assessment Report* (AR6 Synthesis Report) that summarizes the state of knowledge of climate change, its widespread impacts and risks, and climate change mitigation and adaptation, based on many independent scientific analyses (IPCC 2023).

Climate change is a global problem, and GHGs are global air pollutants, unlike criteria air pollutants (such as ozone precursors) and TACs that are pollutants of regional and local concern, respectively. GHGs include CO_2, methane (CH_4), and N_2O, among other pollutants. Emissions of CO_2 and N_2O are byproducts of stationary- and mobile-related fossil fuel combustion, among other sources. CH_4, a highly potent GHG, results from off-gassing associated with agricultural practices and landfills, and incomplete combustion of fossil fuels among other sources. The impacts from GHGs aside from CO_2 are often converted to carbon dioxide equivalents (CO_2e), a measure of how much global warming a given type and mass of GHG may cause compared to the equivalent amount of CO_2. For California, projected effects from climate change are described in *California's Fourth Climate Change Assessment* (CCCC 2019). Based on projections using climate modeling, temperatures in California are expected to rise between 5.6°F and 8.8°F by above 2000 averages by 2050 (CCCC 2019). The predicted changes in the future climate have been found to affect the natural environment in California in the following ways (CCCC 2012, CCCC 2019):

- Increased wildfire risk
- Adverse effects on native freshwater fish species

[1] Appendix E has been revised in support of this Final EIR.

- Increased ground-level ozone levels and particulate air pollution
- Earlier snowmelt and runoff
- Faster-than-historical sea-level rise and increased coastal flooding
- Impacts on the agricultural industry from population decreases of pollinators and increases of pests and disease

These changes in California's climate and ecosystems are projected to occur as California's population is expected to increase ~~from 40 million in 2020~~ to 42 ~~45~~ million by 2050 (California Department of Finance 2023 ~~2019~~). As the population increases, the demand for water, power, and transportation as well as other commodities and services, will increase correspondingly, resulting in an increase in the amount of anthropogenic GHG emissions anticipated under a "business as usual" scenario.

3.9.1.2 Statewide and Regional GHG Emissions

California Statewide GHG Emissions Generation

GHG emissions emitted in California are attributable to human activities associated with the industrial/manufacturing, utilities, transportation, residential, and agricultural sectors, as well as natural processes. According to CARB, total California GHG emissions were 369.2 MMT CO_2e in 2020 (CARB 2022a). The major source of GHGs in California is associated with transportation, contributing nearly 37 percent of statewide GHG emissions in 2020. The industrial sector is the second largest source, contributing 20 percent of statewide GHG emissions, and the electricity sector accounted for approximately 16 percent (CARB 2022a).

Santa Clara County GHG Emissions Generation

The county follows a similar pattern as the statewide GHG emissions, with the majority of county emissions originating from transportation sources. Transportation accounted for 49 percent of the county's 2017 GHG emissions, followed by commercial and residential (natural gas) and electrical power which accounted for 23 percent and 22 percent of the county's GHG emissions, respectively. Waste, water, and wastewater sources contributed to the remainder of the county's GHG emissions (County 2021). **Table 3.9-1** compares the relative contributions from the key sectors of anthropogenic GHG emissions for the county and the state of California.

Table 3.9-1. Santa Clara County and California GHG Emissions by Sector

	Santa Clara County[a] (2017)		California[b] (2020)	
Economic Sector	**MMT CO_2e**	**Percent**	**MMT CO_2e**	**Percent**
Transportation	5.4	49%	135.8	37%
Industrial		--	73.3	20%
Electric Power[1]	2.4	22%	59.5	16%
Commercial and Residential[2]	2.5	23%	38.7	11%
Agriculture		--	31.6	9%
High Global Warming Potential[3]	--	--	21.3	6%
Recycling and Waste	0.6	5%	8.9	2%

	Santa Clara County[a] (2017)		California[b] (2020)	
Economic Sector	MMT CO_2e	Percent	MMT CO_2e	Percent
Water	0.04	0.3%	--	--
Wastewater	0.01	0.1%	--	--
Total	11.1		396.2	

Sources: a) Santa Clara County 2021, b) CARB 2022b

Notes:

The most recent years of published data are 2017 for Santa Clara County and 2020 for California.

Due to rounding, percent totals do not equal 100% exactly.

[1] Electricity generation includes GHGs attributable to both in-state-generated and imported power.

[2] Commercial and Residential for Santa Clara County includes GHGs attributable to commercial and residential natural gas usage.

[3] Includes emissions from refrigerants and evaporative losses and ozone depleting substances substitute use, which could not be attributed to an individual sector.

Key: MMT CO_2e: million metric tons per year CO_2 equivalent.

3.9.1.3 Valley Water and Anderson Dam

Valley Water GHG Emissions Generation and Offsets

Valley Water has successfully achieved carbon neutrality since 2014 based on their GHG emissions inventory and offsets that are available through 2017. **Table 3.9-2** shows the source of GHG emissions and offset or sequestered emissions for Valley Water from 2015 through 2017 (Valley Water 2021).

Table 3.9-2. Valley Water GHG Emissions Generation and Offsets

CALENDAR YEAR	2015	2016	2017[1]
Emissions in MT of CO_2e[7]	22,200	16,200	15,300
Scope 1: Direct Emissions from District Operations	2,100	2,100	2,400
Scope 2: Emissions from Purchased Electricity	6,300	200	200
Scope 3: Other Emissions	13,800	13,900	12,700
Reduction/Sequestration	24,235	19,135	19,235
1. Water Conservation Program	17,800[2]	13,900[2]	14,400
2. Recycled water	3,400	3,200	2,800
3. Carbon sequestration	500	500	500
4. Green Business Program	2,200	1,200	1,200
5. Energy Optimization Measures	335[3]	335[3]	335
Carbon Neutrality (positive value indicates exceeding neutrality)	2,035	2,935	3,935

Source: Valley Water 2021.

Notes:

[1] This has been updated using reported energy productions and EFs for each corresponding year. Dates beyond 2017 are currently being finalized. Updated greenhouse gas emissions will be brought to the Board regularly through the CCAP implementation process.

[2] Adjusted based on decreases in PG&E EFs as compared to the 3-year averages of CY 2005 to 2007.

[3] The update includes energy Conservation Measures completed in FY 2015 in addition to zero-emission energy production through on site solar and Anderson Hydro. CO_2e indicates the amount of carbon dioxide that has the equivalent global warming impact as other greenhouse gasses. This creates a common unit to measure greenhouse gas emissions regardless of the type of greenhouse gas.

Key: MT CO_2e: metric tons per year CO_2 equivalent.

3.9.2 Regulatory Setting

3.9.2.1 Federal Laws, Regulations, and Policies

Federal Vehicle Emission Standards

In 1975, Congress enacted the Energy Policy and Conservation Act, which established the first fuel economy standards for on-road motor vehicles in the United States. Pursuant to the act, the USEPA and NHTSA are responsible for establishing additional vehicle standards. In August 2012, standards were adopted for model year 2017 through 2025 for passenger cars and light-duty trucks. Notably, the State of California harmonized its vehicle efficiency standards through 2025 with the federal standards through the Advanced Clean Cars Program.

In March 2022, CAFE standards were finalized for model years 2024 through 2026. The final rule establishes standards that require an industry-wide fleet average of approximately 49 mpg for passenger cars and light trucks. Current rulemaking is working on establishing (NHTSA 2022):

- standards for model years 2027 and beyond for passenger cars and light trucks
- fuel efficiency standards for model years 2029 and beyond for heavy-duty pickup trucks and vans
- fuel efficiency standards for model years 2030 and beyond for medium and heavy duty on-highway vehicles and work trucks

3.9.2.2 State Laws, Regulations, and Policies

State of California Executive Orders for GHG Emissions

- ***Executive Order B-55-18.*** On September 10, 2018, Governor Brown signed EO B-55-18, committing California to total, economy-wide carbon neutrality by 2045. EO B-55-18 directs CARB to work with relevant State agencies to develop a framework to implement and track progress toward this goal.

Executive Order N-79-20. In EO N-79-20, Governor Newsom states that “clean renewable fuels play a role as California transitions to a decarbonized transportation sector”. EO N-79-20 directs as follows: “[T]o support the transition away from fossil fuels consistent with the goals established in this Order and California’s goal to achieve carbon neutrality by no later than 2045, the California Environmental Protection Agency and the California Natural Resources Agency, in consultation with other State, local, and federal agencies, shall expedite regulatory processes to repurpose and transition upstream and downstream oil production facilities ...”. The Governor’s Order also directs CARB to “develop and propose strategies to continue the State’s current efforts to reduce the carbon intensity of fuels beyond 2030 with consideration of the full life cycle of carbon.

Assembly Bill 32 and Senate Bill 32 - California Global Warming Solutions Act

In September 2006, Governor Schwarzenegger signed the California Global Warming Solutions Act (AB 32). AB 32 (Health and Safety Code, Division 25.5) establishes regulatory, reporting, and market mechanisms to achieve quantifiable reductions in GHG emissions and establishes a cap on statewide GHG emissions. AB 32 requires that statewide GHG emissions be reduced to 1990 levels by 2020. This reduction will be accomplished by enforcing a statewide cap on GHG emissions that will be phased in starting in 2012. To effectively implement the cap, AB 32 directs CARB to develop and implement regulations to reduce statewide GHG emissions from stationary sources. CARB adopted a Scoping Plan in in 2008, and updated it in 2014, to set the State strategy for achieving AB 32's 2020 GHG reduction target.

In 2016, SB 32 and its companion bill AB 197 amended Health and Safety Code Division 25.5 and established a new GHG reduction target of 40 percent below 1990 levels by 2030 and included provisions to ensure that the benefits of State climate policies reach into disadvantaged communities. CARB adopted an updated Scoping Plan in 2017 to set the state strategy for achieving SB 32's 2030 GHG reduction target.

Assembly Bill 1279 and CARB 2022 California Climate Change Scoping Plan

The Legislature enacted AB 1279, The California Climate Crisis Act, on September 16, 2022. AB 1279 establishes the State policy to achieve net-zero GHG emissions, as soon as possible but no later than 2045, and to achieve and maintain net-negative GHG emissions thereafter. Additionally, AB 1279 mandates that by 2045, statewide anthropogenic GHG emissions are to be reduced at least 85 percent below 1990 levels. SB 1279 also requires CARB to ensure that the Scoping Plan identifies and recommends measures to achieve carbon neutrality, and to identify and implement policies and strategies for CO_2 removal solutions and carbon capture, utilization, and storage technologies.

The 2022 Scoping Plan for Achieving Carbon Neutrality (2022 Scoping Plan, CARB 2022c), adopted by CARB in December 2022, responds to AB 1279, outlining a strategy to achieve the state's climate target of reducing anthropogenic emissions to 85 percent below 1990 levels by 2045 and achieving carbon neutrality by 2045 or earlier. The 2022 Scoping Plan outlines the strategies that the State will implement to achieve carbon neutrality by reducing GHG emissions to meet the anthropogenic target, and by expanding actions to capture and store carbon through the State's natural and working lands and using a variety of mechanical approaches. The major element of the 2022 Scoping Plan is the decarbonization of every sector of the economy, including rapidly moving to zero-emissions transportation for cars, buses, trains, and trucks.

Appendix E of the 2022 Scoping Plan provides guidance for GHG analyses in local agency CEQA documents. The guidance is focused on land use plans and projects, but some of it can also apply to water and infrastructure projects. In particular, Section 3.2.2 generally endorses a net-zero threshold of significance, while noting that it may not be feasible or appropriate for every project. Also, Section 4.1 recommends a "mitigation hierarchy" not found in the *CEQA Guidelines*. CARB recommends prioritizing CEQA GHG mitigation according to a geographic hierarchy includes carbon offsets as an option. Regarding carbon offset credits, Appendix E of the 2022 Scoping Plan recommends that the offsets credits be registered with a recognized and reputable carbon registry in the voluntary market, such as those also used for the Cap-and-Trade Program. However, CARB does not recommend importing all the strict regulatory requirements of the Cap-and-Trade program when determining the adequacy of offset credits used as CEQA mitigation measures. Rather, CARB recommends that offset credits, as well as their GHG mitigation measures, be consistent with more general CEQA and *CEQA Guidelines* requirements for mitigation (e.g., not otherwise required, enforceable, and supported by substantial evidence).

Low Carbon Fuel Standard (Executive Order S-1-07)

The LCFS, established in 2007 through EO S-1-07 and administered by CARB, requires producers of petroleum-based fuels to reduce the carbon intensity of their products that started with a 0.25 percent reduction in 2011 and culminated in a 10 percent total reduction in 2020. In September 2018, CARB extended the LCFS program to 2030, making significant changes to the design and implementation of the program, including a doubling of the carbon intensity reduction to 20 percent by 2030.

Petroleum importers, refiners, and wholesalers can either develop their own low carbon fuel products or buy LCFS credits from other companies that develop and sell low carbon alternative fuels, such as biofuels, electricity, natural gas, and hydrogen.

CARB Clean Cars Programs

The Advanced Clean Cars emissions-control program was approved by CARB in 2012 and is closely associated with the Pavley regulations (CARB 2017a). The program requires a greater number of zero-emission vehicle models for years 2015 through 2025 to control smog, soot, and GHG emissions. This program includes the low-emissions vehicle (LEV) regulations to reduce criteria pollutants and GHG emissions from light- and medium-duty vehicles and the ZEV regulations to require manufactures to produce an increasing number of pure ZEV's (meaning battery and fuel cell electric vehicles) with the provision to produce plug-in hybrid electric vehicles (PHEV) between 2018 and 2025.

California recently adopted the new Advanced Clean Car II in August 2022, which dramatically reduces emissions from passenger vehicles for model years 2026 through 2035. Advanced Clean Cars II would require more aggressive tailpipe emission standards for gasoline cars and heavier passenger trucks and require all new vehicles sold by 2035 be ZEVs (CARB 2023).

CARB Mobile Source Strategy

The Mobile Source Strategy (2016) includes an expansion of the Advanced Clean Cars program and further increases the stringency of GHG emissions for all light-duty vehicles, and 4.2 million zero-emission and plug-in hybrid light-duty vehicles by 2030. It also calls for more stringent GHG requirements for light-duty vehicles beyond 2025 as well as GHG reductions from medium-duty and heavy-duty vehicles and increased deployment of zero-emission trucks primarily for classes 3 through 7 "last mile" delivery trucks in California. Statewide, the Mobile Source Strategy would result in a 45 percent reduction in GHG emissions and a 50 percent reduction in the consumption of petroleum-based fuels. CARB's Mobile Source Strategy includes measures to reduce total light-duty vehicle miles travelled (VMT) by 15 percent compared to business-as-usual in 2050.

In 2004, the CARB adopted an ATCM to Limit Diesel-Fueled Commercial Motor Vehicle Idling in order to reduce public exposure to diesel particulate matter emissions (Title 13 CCR section 2485). The measure applies to diesel-fueled commercial vehicles with gross vehicle weight ratings greater than 10,000 pounds that are licensed to operate on highways, regardless of where they are registered. This measure does not allow diesel-fueled commercial vehicles to idle for more than 5 minutes at any given location. While the goal of this measure is primarily to reduce public health impacts from diesel emissions, compliance with the regulation also results in energy savings in the form of reduced fuel consumption from unnecessary idling.

In addition to limiting exhaust from idling trucks, CARB also promulgated emission standards for off-road diesel construction equipment of greater than 25 hp such as bulldozers, loaders, backhoes and forklifts, as well as many other self-propelled off-road diesel vehicles. The In-Use Off-Road Diesel-Fueled Fleets regulation adopted by CARB on July 26, 2007 aims to reduce emissions through the installation of diesel soot filters and encouraging the retirement, replacement, or repower of older, dirtier engines with newer emission-controlled models (13 CCR section 2449). The compliance schedule requires full implementation by 2023 in all equipment for large and medium fleets and by 2028 for small fleets. Current rulemaking of this regulation anticipated to be finalized in 2023 includes additional updates to ensure fleet compliance by requiring public agencies and prime contractors to verify compliance with these fleet requirements annually and to report non-compliant fleets. In addition, starting in 2024, fleets will be required to use 99 or 100 renewable diesel.

California Renewable Portfolio Standard

The State of California adopted standards to increase the percentage of energy from renewable resources that retail sellers of electricity, including investor-owned utilities and community choice aggregators, must provide in their portfolio. The RPS was established in 2002 under SB 1078, accelerated in 2006 under SB 107, and expanded in 2011 under SB 2. The standards are referred to as the RPS. Qualifying renewables under the RPS include bioenergy such as biogas and biomass, small hydroelectric facilities (30 MW or less), wind, solar, and geothermal energy. The CPUC and the CEC jointly implement the RPS program.

In November 2008, then-Governor Schwarzenegger signed EO S-14-08, which expanded the State's RPS to 33 percent renewable power by 2020. In September 2009, then-Governor Schwarzenegger continued California's commitment to the RPS by signing EO S-21-09, which directed the CARB under its AB 32 authority to enact regulations to help the State meet its RPS goal of 33 percent renewable energy by 2020.

Clean Energy and Pollution Reduction Act (SB 350)

SB 350, also known as the Clean Energy and Pollution Reduction Act of 2015, was enacted on October 7, 2015, and provides a new set of objectives in clean energy, clean air, and pollution reduction by 2030. The objectives include the following:

1. To increase from 33 percent to 50 percent by December 31, 2030, the procurement of California's electricity from renewable sources
2. To double the energy efficiency savings in electricity and natural gas final end uses of retail customers through energy efficiency and conservation

100 Percent Clean Energy Act (SB 100)

On September 10, 2018, then-Governor Brown signed SB 100, establishing that 100 percent of all electricity in California must be obtained from renewable and zero-carbon energy resources by December 31, 2045. SB 100 also creates new standards for the RPS goals that were established by SB 350 in 2015. Specifically, the bill increases required energy from renewable sources for both investor-owned utilities and publicly owned utilities from 50 percent to 60 percent by 2030. Incrementally, these energy providers are also required to have a renewable energy supply of 33 percent by 2020, 44 percent by 2024, and 52 percent by 2027. The updated RPS goals are considered achievable, since many California energy providers are already meeting or exceeding the RPS goals established by SB 350.

Clean Energy, Jobs, and Affordability Act (SB 1020)

SB 1020, also known as The Clean Energy, Jobs, and Affordability Act of 2022, establishes the requirement that eligible renewable energy resources and zero-carbon resources supply 90 percent of all retail sales of electricity to California end-use customers by December 31, 2035; 95 percent of all retail sales of electricity to California end-use customers by December 31, 2040; 100 percent of all retail sales of electricity to California end-use customers by December 31, 2045; and 100 percent of electricity procured to serve all state agencies by December 31, 2035.

ZEV Executive Orders

In March 2012, then-Governor Brown issued EO B-16-12 establishing a goal of 1.5 million ZEVs on California roads by 2025.In addition to the ZEV goal, the executive order stipulated that by 2015 all major cities in California will have adequate infrastructure and be "zero-emission vehicle ready"; that by 2020 the State will have established adequate infrastructure to support 1 million ZEVs; and that by 2050, virtually all personal transportation in the state will be based on ZEVs, and GHG emissions from the transportation sector will be reduced by 80 percent below 1990 levels.

On January 26, 2018, then-Governor Brown issued EO B-48-18 establishing a goal of 5 million ZEVs on California roads by 2030 and spurred the installation and construction of 250,000 plug-in electric vehicle chargers, including 10,000 direct current fast chargers, and 200 hydrogen refueling stations by 2025.

In September 2020, Governor Newsom signed EO N-79-20, which sets a new State goal that 100 percent of in-state sales of new passenger cars and trucks will be zero-emission by 2035; that 100 percent of medium- and heavy-duty vehicles in the state be zero-emission by 2045 for all operations, where feasible, and by 2035 for drayage trucks; and that 100 percent of off-road vehicles and equipment will be zero emission by 2035, where feasible. This order calls upon state agencies, including CARB, the CEC, the CPUC, the Department of Finance, and others to develop and propose regulations and strategies to achieve these goals.

California Cap-and-Trade Program

Initially authorized by the California Global Warming Solutions Act of 2006 (AB 32), and extended through the year 2030 with the passage of AB 398 (2017), the California Cap and Trade Program is a core strategy that the State has used to meet its GHG reduction targets for 2020 and 2030. CARB designed and adopted the California Cap and Trade Program to reduce

GHG emissions from “covered entities” (e.g., electricity generation, petroleum refining, cement production, and large industrial facilities that emit more than 25,000 $MTCO_2e$ per year), setting a firm cap on statewide GHG emissions and employing market mechanisms to achieve reductions. Under the Cap-and-Trade Program, an overall limit is established for GHG emissions from capped sectors. The statewide cap for GHG emissions from the capped sectors commenced in 2013. The cap declines over time. Facilities subject to the Cap-and-Trade permits to emit GHGs. Per the 2022 Scoping Plan Update, the Cap-and-Trade Program would undergo programmatic changes, so that the State can continue to work towards accelerated emissions reductions goals for 2030.

Up to 8 percent of a covered entity’s compliance obligation can be met using carbon offset credits, which are created through the development of projects, such as renewable energy generation or carbon sequestration projects, that achieve a reduction of emissions or an increase in the removal of carbon from the atmosphere from activities not otherwise regulated, covered under the cap, or resulting from government incentives. Offsets are verified reductions of emissions whose ownership can be transferred to others. As required by AB 32, any reduction of GHG emissions used for compliance purposes must be real, permanent, quantifiable, verifiable, enforceable, and additional. Offsets used to meet regulatory requirements must be quantified according to CARB-adopted methodologies, and CARB must adopt a regulation to verify and enforce the reductions. The criteria developed will ensure that the reductions are quantified accurately and are not double counted within the system (CARB 2008 ~~2009b~~).

3.9.2.3 Regional and Local Laws, Regulations, and Policies

Bay Area Air Quality Management District

BAAQMD 2017 Clean Air Plan

BAAQMD and other air districts prepare clean air plans in accordance with the state and federal Clean Air Acts. On April 19, 2017, the BAAQMD Board of Directors adopted the 2017 Clean Air Plan: Spare the Air, Cool the Climate, an update to the 2010 Clean Air Plan. The Clean Air Plan is a comprehensive plan that focuses on the closely-related goals of protecting public health and protecting the climate. The plan lays the groundwork for a long-term effort to reduce GHG emissions to 40 percent below 1990 levels by 2030 and 80 percent below 1990 levels by 2050 (BAAQMD 2017 ~~2017a~~).

The 2017 Clean Air Plan includes a wide range of proposed control measures to reduce combustion-related activities, decrease fossil fuel combustion, improve energy efficiency, and decrease emissions of potent GHGs. The Clean Air Plan contains 85 measures to address reduction of GHG emissions and several criteria air pollutants and air toxics. The control measures are categorized based on the economic sector framework including stationary sources, transportation, energy, buildings, agriculture, natural and working lands, waste management, and water measures.

BAAQMD 2022 CEQA Guidelines

In 2023, BAAQMD adopted its 2022 *CEQA Guidelines*, which updated and superseded prior *BAAQMD 2017 CEQA Guidelines*. (BAAQMD 2022 ~~2023~~). The 2022 *CEQA Guidelines* provide BAAQMD-recommended procedures for evaluating air quality and climate impacts in CEQA documents. The 2022 *CEQA Guidelines* recommend GHG thresholds of significance for land use plans and projects, but do not recommend GHG thresholds of significance directly relevant to the Project (i.e., for large construction projects or for operation of water projects such as dams and reservoirs). Even though the 2022 *CEQA Guidelines* do not set a GHG threshold for construction projects, to minimize GHG and air pollutant emissions, the Guidelines recommend that projects incorporate 18 BMPs for reducing construction emissions listed in **Table 6-1** of the 2022 *CEQA Guidelines*.

BAAQMD's 2022 *CEQA Guidelines* discuss general GHG mitigation approaches for land use plans and projects, and for stationary sources, but do not specifically recommend GHG mitigation measures for large construction projects or water project operations. The Guidelines do, however, refer to California Air Pollution Control Officers Association's (CAPCOA) *Handbook for Analyzing GHG Emissions Reductions, Assessing Climate Vulnerabilities, and Advancing Health and Equity: Designed for Local Governments, Communities, and Project Developers* (CAPCOA 2021) for several examples of construction GHG mitigation measures that should be considered.

Santa Clara County General Plan

The Santa Clara County General Plan's Health Element (2015) contains the following policies relevant to GHGs:

> **Policy HE-G.1:** Air quality environmental review. Continue to utilize and comply with the Air District's project- and plan-level thresholds of significance for air pollutants and GHG emissions.
>
> **Policy HE-G.3:** Fleet upgrades. Promote Air District mobile source measures to reduce emissions by accelerating the replacement of older, dirtier vehicles and equipment, and by expanding the use of zero emission and plug-in vehicles.
>
> **Policy HE-G.4:** Off-road sources. Encourage mobile source emission reduction from off-road equipment such as construction, farming, lawn and garden, and recreational vehicles by retrofitting, retiring, and replacing equipment and by using alternate fuel vehicles.
>
> **Policy HE-G.5**: GHG reduction. Support efforts to reduce GHG emissions from mobile sources, such as reducing vehicle trips, vehicle use, vehicle miles traveled (VMT), vehicle idling, and traffic congestion. These efforts may include improved transit service, better roadway system efficiency, state-of-the-art signal timing and Intelligent Transportation Systems (ITS), transportation demand management, parking and roadway pricing strategies, and growth management measures.

Santa Clara County Sustainability Master Plan

The Santa Clara County Sustainability Master Plan (2021) was created to help the County reduce climate pollution, adapt to global climate change, and enhance natural resources and the environment. The following strategies are relevant to GHG emissions and climate change:

Goal 1: Carbon Neutrality: Become a carbon neutral County that supports a transition to zero waste and zero emissions.

> **Strategy 1.1** Clean Energy: Transition to a zero-emission energy system.

Strategy 1.3 Clean, Safe, and Active Transportation. Expand zero-emission transportation/travel choices and create safe and accessible streets for all users.

Strategy 1.5 Zero Waste. Reduce overall waste generation by supporting the sustainable consumption of resources and diverting or reusing materials.

Strategy 1.6 Carbon Sequestration. Explore and implement practices that sequester carbon, including agricultural practices and urban ecology to help offset greenhouse gas emissions.

Goal 2: Resilient and Prepared County: Increase preparedness and resilience to respond to the shocks and stressors that impact Santa Clara County and the services it provides.

Strategy 2.1 Planning and Assessment. Conduct and continually maintain a multi-hazard risk assessment to understand vulnerabilities across the County and regularly update resilience and climate adaptation plans and policies to address changing hazard risks and potential impacts to the efficient delivery of County services.

Strategy 2.2 Emergency Preparedness and Response. Implement hazard mitigation and climate adaptation strategies to increase preparedness and response and ensure the existing infrastructure/personnel are adequate to meet the existing levels of service while accommodating for future growth.

City of Morgan Hill 2035 General Plan

The City of Morgan Hill General Plan (2017 ~~2016~~) contains the following goals, policies, and actions relevant to GHG emissions:

Natural Resources and Environment (NRE)

Goal NRE-15: An adaptive and resilient community that responds to climate change.

Policy NRE-15.1: GHG Emission Reduction Targets. Maintain a GHG reduction trajectory that is consistent with the GHG reduction targets of Executive Orders B-30-15 (40 percent below 1990 levels by 2030) and S-03-05 (80 percent below 1990 levels by 2050) to ensure the City is consistent with statewide efforts to reduce GHG emissions.

Policy NRE-15.10: VMT Reduction. Continue to work with the Santa Clara Valley Transportation Authority on regional transportation solutions that will reduce vehicle miles traveled and GHG emissions.

Policy NRE-15.11: Green Building. Promote green building practices in new development.

Morgan Hill Climate Action Plan

The City of Morgan Hill adopted its CAP on December 15, 2021, with the main goal of reducing Morgan Hill's net CO_2 emissions in the building and transportation sectors to 35 percent below 2020 baseline levels by 2030 and 100 percent below 2020 baseline levels by 2045. The CAP focuses on the adoption of electric vehicles and the process of decarbonizing existing buildings by reducing the use of fossil fuels. The City's CAP includes the following sub-goals for the transportation and building sectors (City of Morgan Hill 2021):

Transportation Sector

Utilizing a baseline of 2020,

- Install electric vehicle (EV) charging stations for at least 10 percent of available parking spaces in new non-residential projects.

Building Sector

Utilizing a baseline of 2020,

- Transition 95 percent of existing buildings (roughly 14,000) in Morgan Hill to be all-electric by 2045, with additional targets every five years consisting of:
  - 1 percent of existing buildings by 2025
  - 10 percent of existing buildings by 2030
  - 35 percent of existing buildings by 2035
  - 70 percent of existing buildings by 2040

Envision San José 2040 General Plan

The Envision San José 2040 General Plan (2023 ~~2011~~) contains the following policies/actions relevant to GHG emissions:

Goal MS-10: Minimize air pollutant emissions from new and existing development.

Policy MS-10.1: Assess projected air emissions from new development in conformance with BAAQMD CEQA Guidelines and relative to state and federal standards. Identify and implement feasible air emission reduction measures.

Action MS-10.14: Review and evaluate the effectiveness of site design measures, transit incentives, and new transportation technologies and encourage those that most successfully reduce air pollutant emissions.

Action MS-11.8: For new projects that generate truck traffic, require signage which reminds drivers that the State truck idling law limits truck idling to five minutes.

Goal MS-14: Reduce Consumption and Increase Efficiency: Reduce per capita energy consumption by at least 50% compared to 2008 levels by 2022 and maintain or reduce net aggregate energy consumption levels equivalent to the 2022 (Green Vision) level through 2040.

Policy MS-14.3: Consistent with the California Public Utilities Commission's California Long Term Energy Efficiency Strategic Plan, as revised, and when technological advances make it feasible, require all new residential and commercial construction to be designed for zero net energy use.

Policy MS-14.4: Implement the City's Green Building Policies so that new construction and rehabilitation of existing buildings fully implements industry best practices, including the use of optimized energy systems, selection of materials and resources, water efficiency, sustainable site selection, passive solar building design, and planting of trees and other landscape materials to reduce energy consumption.

Climate Smart San José

Climate Smart San José was adopted by the San José City Council in 2018 and is the City's overarching visionary plan to reduce emissions geared toward the Paris Agreement. Climate Smart San José serves as a roadmap to deep carbon reductions aligned with the State's GHG targets set by AB 32, SB 32, and EO S-3-05, as well as the decarbonization goals of the Paris Agreement, while supporting 40 percent growth in the city's population by 2050 and continued economic growth. It employs a people-centered approach, encouraging the entire San José community to join an ambitious campaign to reduce GHG emissions, save water, and improve the community's quality of life, while also promoting economic growth (City of San José 2018). In November 2021, the City Council set a goal of community-wide carbon neutrality by 2030, thereby accelerating Climate Smart. The proposed Pathway to Carbon Neutrality by 2030 was heard by City Council on June 14, 2022, which contains four strategies to achieve carbon neutrality by 2030: move to zero-emission vehicles, reduce the miles travelled in vehicles by at least 20 percent, switch appliances from fossil fuels to electric, and power the community with 100 percent carbon-neutral electricity (City of San José 2022).

Valley Water Climate Change Action Plan

The Valley Water CCAP was adopted in July 2021 (Valley Water 2021). The CCAP contains the following goals and strategies relevant to GHG emissions:

Goal 1: Reduce Direct GHG Emissions (Scope 1).

- Strategy: Reduce GHG emissions associated with Valley Water fleet.
- Strategy: Reduce GHG emissions from trips between Valley Water offices and work sites.
- Strategy: Reduce GHG emissions associated with Valley Water-owned equipment.
- Strategy: Minimize GHG emissions associated with planning, design, construction, operation, and maintenance of capital projects.
- Strategy: Increase GHG sequestration in Valley Water properties and other areas.
- Strategy: Continue to update Valley Water's GHG accounting practices.

Goal 2: Expand Renewable Energy Portfolio and Improve Energy Efficiency (Scope 2).

- Strategy: Continue to support increased renewable energy in the agency's energy portfolio
- Strategy: Continue to improve energy efficiency at agency facilities.

Goal 3: Reduce Indirect GHG Emissions (Scope 3).

- Strategy: Reduce emissions from Valley Water employee commutes.
- Strategy: Reduce waste produced at facilities.
- Strategy: Continue to create and expand other efforts to minimize indirect emissions.

Goal 4: Water Supply Adaptation.

- Strategy: Diversify local water supplies and expand drought-resistant water supply.

- Strategy: Increase flexibility and resilience of water utility operations and assets.

Goal 6: Ecosystem Adaptation in Santa Clara County

- Strategy: Protect and enhance riverine, coastal, and other watershed ecosystems to improve climate change resilience and wildlife habitat.
- Strategy: Develop and expand programs and plans that support more climate-resilient ecosystems.
- Strategy: Expand the availability of data on regional ecosystems to avoid detrimental climate change-related ecosystem impacts.

Goal 7: Emergency Preparedness

- Strategy: Maximize Valley Water's emergency preparedness for climate-related impacts.

Valley Water Greenhouse Gas Reduction Plan

Valley Water is preparing a Greenhouse Gas Reduction Plan (GHGRP) (Valley Water 2024) that is consistent with the framework outlined under the CEQA Guidelines §15183.5 and is anticipated to be adopted in 2025. The GHGRP will provide an inventory of Valley Water's GHG emissions through 2021, a forecast of future GHG emissions, and a list of measures to achieve a goal of net zero emissions by 2045. It will provide specific measures to reduce GHG emissions and metrics to measure progress and will be considered for adoption in a public process following preparation of a CEQA document analyzing potential environmental impacts of the GHGRP.

Although the GHGRP will include an updated Valley Water GHG emissions inventory, forecast, and emissions goal, the GHGRP was still under preparation and had not been considered for adoption at the time that the ADSRP EIR was being prepared.

3.9.3 Methodology and Approach to Impact Analysis

This impact analysis considers whether implementation of the Project would result in significant impacts related to GHG emissions. This section includes an evaluation of GHG emissions generated by the Project and if the Project would conflict with any applicable plan or policy for GHG emission reductions. The analysis evaluates the GHG emissions that would occur as a result of the following activities:

- Seismic Retrofit Construction
- Conservation Measure Construction
- Construction Monitoring
- Post-construction Anderson Dam Facilities Operations and Maintenance
- Post-construction Conservation Measures Operations and Maintenance
- Post-construction Project and FAHCE Adaptive Management

3.9.3.1 Seismic Retrofit Construction

As described in Section 3.0, *Introduction*, the baseline for evaluating the Seismic Retrofit construction effects is the existing conditions at the time of EIR preparation modified by the

FOCP implementation (referred to as the existing conditions baseline). Existing baseline operations for the Project reflect a seismically restricted capacity (e.g., maintenance of the reservoir at deadpool), and flow releases and maintenance activities projected to occur following completion of the FOCP, presently under construction. Similarly, the construction baseline assumes completion of facility upgrades and physical changes associated with the FOCP.

The ~~CEQA~~ Air Quality, Greenhouse Gas, and Health Rise Assessment Technical Report (Ramboll 2024 ~~2023~~) (Appendix E), which supports the GHG emissions assessment in this section, primarily used the methodology from the CalEEMod version 2022.1~~.0~~ to quantify the GHG emissions for the Project. CalEEMod incorporates numerous default assumptions and CARB emission factors for on-road and off-road vehicles. The emission factors for off-road equipment and mobile sources were obtained from the latest versions of CARB's OFFROAD and EMFAC models, respectively. Emissions calculations associated with off-road construction equipment were based on the construction schedule and the type, size, fuel type, tier level, hours of operation and utilization factor for each piece of equipment. For diesel-powered off-road construction equipment, methodologies consistent with CalEEMod were used to estimate emissions. Where Project-specific equipment information was not available, CalEEMod default horsepower was used. Load factors for each piece of equipment were based on default factors from CalEEMod. On-site boat emissions were estimated using emission factors and methodology from CARB's Pleasure Craft Model Database, matched to their respective gasoline-fueled boat classifications. Emissions from on-road construction trips for workers, vendors, and haul trucks were estimated using emissions factors from EMFAC2021. EMFAC2021 incorporates the Pavley Clean Car Standards and the Advanced Clean Cars program.

Project construction activities would be completed using a combination of off-road and portable construction equipment. It was assumed that all construction off-road equipment is diesel powered except for those specified as electric or gasoline powered. Specific construction equipment assumptions for each phase and construction trip assumptions for workers, vendors, and haul trucks are provided in Appendix E.

Electrical equipment for the Seismic Retrofit component consists primarily of ventilation fans and small excavators, as provided by Valley Water. The equipment would make a negligible contribution to overall ~~project~~ Project GHG emissions and thus is not quantified in this EIR.

Seismic Retrofit construction is anticipated to span a 7-year period. The specific construction phasing schedule is provided in Appendix E. Annual GHG emissions were calculated for the Seismic Retrofit component and reported as MT of CO_2e.

3.9.3.2 Conservation Measures Construction

As described in Section 3.0, *Introduction*, the baseline for evaluating Conservation Measure construction effects is the existing conditions at the time of EIR preparation modified by FOCP implementation (i.e., existing conditions baseline). Conservation Measures involving construction activities with a potential to adversely affect GHG emissions that are evaluated in the impact analysis include:

- Ogier Ponds Conservation Measure
- Maintenance of the North Channel Reach ~~Extension~~

- Sediment Augmentation Program
- Phase 2 Coyote Percolation Dam Conservation Measure
- Maintenance of the Live Oak Restoration Reach

The GHG emissions impacts from the construction of the Conservation Measure components were analyzed using the same methodologies as the Seismic Retrofit construction. Construction activities associated with the Ogier Ponds CM would occur from Year 6 through Year 8 ~~9,~~ Sediment Augmentation Program would initially occur following ADSRP construction (Year 8) and would continue throughout the Project and FAHCE AMP[2] ~~from Year 2 through Year 15~~, and Phase 2 Coyote Percolation Dam CM would occur in Year 1 and Year 2 ~~from Year 4 through Year 5~~. Maintenance of ~~The~~ the North Channel Reach ~~Extension~~ and Live Oak Restoration Reach would occur during the Project's entire construction phase (though intermittently). ~~Conservation Measure would occur for two months in Year 1 and Year 7.~~ Due to the short duration, small number of equipment and workers required, and lack of high-emissions activities, impacts from Maintenance of the North Channel Reach and Live Oak Restoration Reach ~~Extension~~ are anticipated to be negligible in absolute terms in comparison to the impacts of the Seismic Retrofit and other Conservation Measures. Thus, a quantitative analysis of these ~~this~~ Conservation Measures was not performed. A detailed construction schedule for the Conservation Measures, specific construction equipment assumptions for the Conservation Measures, and construction trip assumptions for the Conservation Measures for workers, vendors, and haul trucks are provided in Appendix E.

3.9.3.3 Construction Monitoring

Construction Monitoring activities are not included in the impact analysis, as monitoring would involve data and information collection and assessment and would not result in any meaningful amount of GHG emissions. Thus, construction monitoring is not discussed further in this section.

3.9.3.4 Post-Construction Anderson Dam Facilities Operations and Maintenance

Operation of the Anderson Dam following construction of the Project would involve implementation of the FAHCE rule curves and pulse flows, which would not result in additional GHG emissions compared to the existing conditions baseline.[3] In addition, a diesel generator is proposed at the new outlet works, which would replace an existing diesel generator in the same general area, resulting in no net increase of GHG emissions above baseline conditions. Additionally, as described in Chapter 2, *Project Description*, Valley Water would maintain the newly retrofitted Anderson Dam and Reservoir per Valley Water's existing DMP. Maintenance of Anderson Dam facilities was previously evaluated in the Final DMP EIR prepared in January 2012 (SCH No. 2011082077; Valley Water 2012). No new long-term operational sources of GHG emissions would be generated by the Project and no new long-term operational sources requiring energy would be added by dam maintenance; therefore, this EIR quantifies and

[2] GHG emissions were only quantified for the initial placement of gravel, assumed to occur in Year 8. While GHG emissions associated with future gravel augmentation are assumed to be minor, their scale, timing, and duration are speculative and were not quantified.

[3] GHG emissions may be released from reservoirs through the natural decomposition process for organic matter. Methods for quantifying these emissions are still under development, and these emissions are not currently included in state or federal GHG emissions inventories. Any GHG emissions from Anderson Reservoir following refilling would be similar to GHG emissions from historical reservoir operations

evaluates construction emissions but does not quantify future maintenance and operations activities.

3.9.3.5 Post-Construction Conservation Measures Operations and Maintenance

Similar to the operation of the Anderson Dam, post-construction operations and maintenance of the Conservation Measures would involve minimal activities generating GHG emissions. Post-construction operation of the Phase 2 Coyote Percolation Dam would require maximum annual power usage of 25.2 kWh in any given year.[4] Besides post-construction operation of the Phase 2 Coyote Percolation Dam, no new long-term operational sources generating GHG emissions or requiring energy usage would be added by the post-construction Conservation Measure operations and maintenance. As described in Chapter 2, *Project Description*, Valley Water would maintain Coyote Percolation Dam per Valley Water's existing DMP. Maintenance of Coyote Percolation Dam facilities were previously evaluated in the Final DMP EIR prepared in January 2012 (SCH No. 2011082077; Valley Water 2012). Therefore, operations and maintenance of the Conservation Measures components are not quantified in the impact analysis, because they would result in only negligible GHG emissions.

3.9.3.6 Post-Construction Project and FAHCE Adaptive Management

The FAHCE AMP would guide post-construction adaptive management of Project ~~project~~ flow operations and Conservation Measures that have met their specified success criteria, as defined through the regulatory permitting process. As required by the FAHCE AMP framework, the Project and FAHCE AMP includes four key elements: measurable objectives, monitoring, adaptive actions, and reporting. Monitoring and adaptive actions involve physical activities that could have environmental impacts.

The Project and FAHCE AMP monitoring program would inform selection of adaptive management measures to implement in response to management triggers, and includes compliance, validation, effectiveness, and long-term monitoring. Validation, effectiveness, and long-term trend monitoring would build on existing Valley Water monitoring infrastructure (e.g., hydrologic monitoring network), water quality monitoring (e.g., water temperature monitoring network), habitat monitoring (e.g., habitat mapping), and fisheries monitoring (e.g., VAKI Riverwatcher, PIT tag detectors, genetics sampling, electrofishing surveys). Impacts of these monitoring activities are not evaluated in the impact analysis because they would result in only negligible GHG emissions.

The Project and FAHCE AMP identifies triggers for adaptive actions to help meet measurable objectives. Adaptive actions for FAHCE flows and imported water storage/releases would include refinements of reservoir releases, which would have impacts and benefits similar to the original FAHCE flows and imported water storage/releases. Adaptive actions for Conservation Measures would generally include minor construction and maintenance actions, whose impacts would be similar but less than those from original Conservation Measure construction. Impacts

[4] Annual power usage of 25.2 kWh for the Phase 2 Coyote Percolation Dam equates to 0.011 MT of CO_2e which results in a negligible increase in GHG emissions (USEPA 2023).

of these adaptive actions are not evaluated in the impact analysis because they would result in only negligible GHG emissions.

3.9.3.7 Applicable Best Management Practices and VHP Conditions

No Valley Water BMPs or VHP Conditions are applicable to GHG emissions.

3.9.3.8 Thresholds of Significance

Significance Criteria

This EIR considers whether implementation of the Project would result in significant impacts to GHG levels pursuant to the applicable significance criteria in Appendix G of the *CEQA Guidelines* ~~(see Section 3.6.4.5)~~. For the purposes of this EIR, the Project would result in a significant impact related to GHG emissions if it would:

(a) generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment

(b) conflict with an applicable plan, policy, or regulation of an agency adopted for the purpose of reducing the emission of GHGs

Specific Thresholds of Significance

This EIR applies the following GHG thresholds:

GHG Emissions Generation

Construction

For construction-related GHG emissions generation, this EIR uses a net-zero threshold consistent with CARB 2022 Scoping Plan guidance and the State's long-range GHG reduction targets. The net-zero threshold is used to determine whether the Project's construction GHG emissions would result in a significant environmental impact.

Operation

For operational GHG emissions, this EIR uses the following thresholds consistent with BAAQMD 2022 *CEQA Guidelines*. It should be noted that BAAQMD's operational GHG emissions were developed for residential and commercial land use projects and have been modified slightly to apply to the Project's operational GHG emissions considering the type of project. These thresholds are used to determine if the Project's operational GHG emissions would result in a significant environmental impact:

1. Buildings, appliances, and equipment:
   i. The project would include natural gas appliances or natural gas plumbing.
   ii. Project building, appliance, and equipment operation would result in wasteful, inefficient, or unnecessary energy, especially nonrenewable energy, usage as determined by the analysis required under CEQA section 21100(b)(3) and section 15126.2(b) of the *CEQA Guidelines*.

2. Mobile Emissions:
   - The project would generate a substantial change[5] or increase in long-term VMT.

GHG Emissions Reduction Plan Consistency

<u>Construction and Operation</u>

The following qualitative threshold is used to evaluate the significance of GHG emissions reduction plan consistency impacts resulting from implementation of the Project. The Project would have a significant GHG emissions impact if:

- Construction and operation of buildings, appliances, equipment, and vehicles would not adhere to the GHG emissions targets, measures, and guidance included in SB 32, AB 1279, CARB 2022 Scoping Plan, Valley Water CCAP, Morgan Hill 2021 CAP, and Climate Smart San José.

As discussed in the regulatory setting, the BAAQMD 2022 *CEQA Guidelines* do not recommend significance thresholds applicable to large construction projects or operations of water facilities.

3.9.4 Impact Analysis

***Impact GHG-1: Generate greenhouse gas emissions, either directly or indirectly, that may have a significant impact on the environment* (Less than Significant with Mitigation)**

Construction

Construction of the Seismic Retrofit component would generate temporary GHG emissions primarily from use of construction equipment on site, as well as from vehicles transporting construction workers to and from the Project area and heavy-duty haul trucks transporting materials, equipment, and soil.

Seismic Retrofit Construction

Total GHG emissions for Seismic Retrofit construction are shown in **Table 3.9-3**. As shown in **Table 3.9-3**, Seismic Retrofit construction would generate a total of <u>156,171</u> ~~155,555~~ MT of CO_2e over the entire construction duration. This generation of GHG emissions would exceed the net zero threshold for construction GHG emissions. Therefore, Seismic Retrofit construction would generate GHG emissions that may have a significant impact on the environment and impacts would be significant.

However, implementation of **Mitigation Measure GHG-1**, described below, will require Valley Water and/or its construction contractors to use engine electrification and renewable fuels where feasible. **Mitigation Measure AQ-1** would require all on-road <u>truck</u> engines and boats used in construction to be model year 2010 or newer, which would reduce emissions <u>primarily</u> in Year 1 <u>(associated with the improvements in boat engines) and minimally in subsequent years.</u> Implementation of **Mitigation Measure GHG-2**, described below, will require Valley

[5] Substantial change is defined as an incremental change from existing conditions (e.g., from 1-2 percent)

Water to ~~implement carbon offsets~~ offset GHG emissions before construction activities commence each year in an amount sufficient to reduce GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to less-than-significant levels. With implementation of these mitigation measures, Seismic Retrofit construction-related GHG emissions generation impacts would be less than significant.

Source: Appendix E: Table 18, Table 19

Key: MT = metric tons; CO_2e = CO_2 equivalent emissions

Notes:

[1] *This column only reflects implementation of **Mitigation Measure AQ-1**'s requirement that on-road trucks and boat engines used in construction be model year 2010 or newer. As such, this measure primarily ~~only~~ reduces GHG emissions in Year 1, as the reductions associated with boat engines (used only in Year 1) are greatest. Given the type and duration of electrified equipment use is unknown at this time, to be conservative, reductions from **Mitigation Measure GHG-1** are not quantified in this column.*

Conservation Measures

Ogier Ponds CM

Total GHG emissions for Ogier Ponds CM construction are shown in **Table 3.9-4**. As shown in **Table 3.9-4**, Ogier Ponds CM construction would generate 28,813 ~~27,457~~ MT of CO_2e, which would exceed the net zero threshold for construction GHG emissions. Therefore, Ogier Ponds CM construction would generate GHG emissions that may have a significant impact on the environment and impacts would be significant.

However, implementation of **Mitigation Measure GHG-1**, described below, will require Valley Water and/or its construction contractors to use engine electrification (including hybrid equipment) and renewable fuels where feasible. Implementation of **Mitigation Measure GHG-2**, described below, will require Valley Water ~~to implement carbon offsets~~ offset GHG emissions before construction activities commence each year in an amount sufficient to reduce GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to less-than-significant levels. With implementation of these mitigation measures, Ogier Ponds CM construction-related GHG emissions generation impacts would be less than significant.

Table 3.9-4. Ogier Ponds CM Construction GHG Emissions

Construction Year	**Unmitigated Ogier Ponds CM Construction GHG Emissions (MT of CO_2e)**	**Mitigated[1] Ogier Ponds CM Construction GHG Emissions (MT of CO_2e)**	**Net GHG Emissions (MT of CO2e) from Ogier Ponds CM with Implementation of Mitigation Measures GHG-1 and GHG-2**
Year 6	15,042 ~~14,210~~	15,018	0
Year 7	9,897 ~~9,384~~	9,888	0
Year 8	3,873 ~~3,863~~	*3,873*	0

Notes:

*[1] This column only reflects implementation of **Mitigation Measure AQ-1**'s requirement that on-road trucks used in construction be model year 2010 or newer. Given the type and duration of electrified equipment use is unknown at this time, to be conservative, reductions from **Mitigation Measure GHG-1** are not quantified in this column.*

Maintenance of the North Channel Reach ~~Extension~~

Maintenance of the North Channel Reach ~~Extension~~ was not quantified in terms of construction-related GHG emissions. Maintenance of the North Channel Reach ~~Extension~~ would involve minor and intermittent maintenance activities (e.g., maintaining the wetland bench, replacing plantings, etc.) ~~consist of grading over one dry season of Year 1, construction work over two months in Year 1, and planting of native vegetation during Year 7. Work would require a maximum of 20 onsite workers and an average of 10 onsite workers. Construction would require a bulldozer, motor grader, excavator, loader, dump, light trucks, and a water truck.~~ No material movement is expected to occur as part of this conservation measure, and no other high-emissions construction activities, such as grading, would occur. Maintenance of the North Channel Reach ~~Extension construction~~ would generate a minimal amount of GHG emissions. However, any amount of GHG emissions generated would exceed the net-zero threshold for construction GHG emissions. Therefore, Maintenance of the North Channel Reach ~~Extension~~

~~construction~~ would generate GHG emissions that may have a significant impact on the environment and impacts would be significant.

However, implementation of **Mitigation Measure GHG-1**, described below, will require Valley Water and/or its construction contractors to use engine electrification (including hybrid equipment) and renewable fuels where feasible. Implementation of **Mitigation Measure GHG-2**, described below, will require Valley Water to ~~implement carbon offsets~~ offset GHG emissions before construction activities commence each year in an amount sufficient to reduce GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to less-than-significant levels. With implementation of these mitigation measures, Maintenance of the North Channel Reach ~~Extension~~ construction-related GHG emissions generation impacts would be less than significant.

Sediment Augmentation Program

Total GHG emissions for Sediment Augmentation Program construction are shown in **Table 3.9-5**. As shown in **Table 3.9-5**, Sediment Augmentation Program construction would generate 3 ~~89,091~~ MT of CO_2e, which would exceed the net zero threshold for construction GHG emissions. Therefore, Sediment Augmentation Program construction would generate GHG emissions that may have a significant impact on the environment and impacts would be significant.

However, implementation of **Mitigation Measure GHG-1**, described below, will require Valley Water and/or its construction contractors to use engine electrification (including hybrid equipment) and renewable fuels where feasible. Implementation of **Mitigation Measure GHG-2**, described below, will require Valley Water to ~~implement carbon offsets~~ offset GHG emissions before construction activities commence each year in an amount sufficient to reduce GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to less-than-significant levels. With implementation of these mitigation measures, Sediment Augmentation Program construction-related GHG emissions generation impacts would be less than significant.

*[1] This column only reflects implementation of **Mitigation Measure AQ-1**'s requirement that on-road trucks used in construction be model year 2010 or newer. Given the type and duration of electrified equipment use is unknown at this time, to be conservative, reductions from **Mitigation Measure GHG-1** are not quantified in this column.*

Phase 2 Coyote Percolation Dam CM

Total GHG emissions for Phase 2 Coyote Percolation Dam CM construction are shown in **Table 3.9-6**. As shown in **Table 3.9-6**, Phase 2 Coyote Percolation Dam CM construction would generate 1,979 ~~1,287~~ MT of CO_2e, which would exceed the net zero threshold for construction GHG emissions. Therefore, Phase 2 Coyote Percolation Dam CM construction would generate GHG emissions that may have a significant impact on the environment and impacts would be significant.

However, implementation of **Mitigation Measure GHG-1**, described below, will require Valley Water and/or its construction contractors to use engine electrification (including hybrid equipment) and renewable fuels where feasible. Implementation of **Mitigation Measure GHG-2**, described below, will require Valley Water and/or its contractors to ~~implement carbon offsets~~ offset GHG emissions before construction activities commence each year in an amount sufficient to reduce GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to less-than-significant levels. With implementation of these mitigation measures, Phase 2 Coyote Percolation Dam CM construction-related GHG emissions generation impacts would be less than significant.

*[1] This column only reflects implementation of **Mitigation Measure AQ-1**'s requirement that on-road trucks used in construction be model year 2010 or newer. Given the type and duration of electrified equipment use is unknown at this time, to be conservative, reductions from **Mitigation Measure GHG-1** are not quantified in this column.*

Maintenance of the Live Oak Restoration Reach

Maintenance of the Live Oak Restoration Reach was not quantified in terms of construction-related GHG emissions. Maintenance of the Live Oak Restoration Reach would involve minor and intermittent maintenance activities (e.g., placement of gravels and woody debris). No high-emissions construction activities, such as grading, would occur, and the Conservation Measure would generate a minimal amount of GHG emissions. However, any amount of GHG emissions generated would exceed the net-zero threshold for construction GHG emissions. Therefore, Maintenance of the Live Oak Restoration Reach would generate GHG emissions that may have a significant impact on the environment and impacts would be significant.

However, implementation of **Mitigation Measure GHG-1**, described below, will require Valley Water and/or its construction contractors to use engine electrification (including hybrid equipment) and renewable fuels where feasible. Implementation of **Mitigation Measure GHG-2**, described below, will require Valley Water to offset GHG emission before construction activities commence each year in an amount sufficient to reduce GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to less-than-significant levels. With implementation of these mitigation measures, Maintenance of the Live Oak Restoration Reach construction-related GHG emissions generation impacts would be less than significant.

Operations and Maintenance

As discussed in Section 3.9.3, *Methodology and Approach to Impact Analysis*, above, post-construction operations and maintenance of the Anderson Dam Facilities and Conservation Measures, as well as FAHCE Adaptive Management, is not anticipated to utilize any new natural gas in buildings or install any new non-EV charging spaces for maintenance employees or substantially increase operational VMT (see Chapter 3.19, *Transportation*). As such, the Project would result in negligible GHG emissions during operation. Therefore, there would be a less-than-significant Project operational impact related to generation of GHG emissions.

Significance Conclusion Summary

Project Seismic Retrofit construction and Conservation Measures construction would generate approximately 186,966 ~~273,390~~ MT CO_2e of construction GHG emissions, as shown in **Table 3.9-7**. Project operation would result in negligible generation of GHG emissions and would not utilize any new natural gas in buildings or install any new non-EV charging spaces for maintenance employees or substantially increase operational VMT.

Source: Appendix E: Table 52, Table 53

Key: MT = metric tons; CO_2e = CO_2 equivalent emissions

Notes:

[1] *This column only reflects implementation of **Mitigation Measure AQ-1**'s requirement that on-road trucks and boat engines used in construction be model year 2010 or newer. As such, this measure ~~only~~ primarily reduces GHG emissions in Year 1, as the reductions associated with boat engines (used only in Year 1) are greatest. Given the type and duration of electrified equipment use is unknown at this time, to be conservative, reductions from **Mitigation Measure GHG-1** are not quantified in this column.*

Implementation of **Mitigation Measure GHG-1**, described below, will require Valley Water and/or its construction contractors to use engine electrification (including hybrid equipment) and renewable fuels where feasible. **Mitigation Measure AQ-1** would require all on-road truck engines and boats used in construction to be model year 2010 or newer, which would reduce emissions in Year 1. Implementation of **Mitigation Measure GHG-2**, described below, will require Valley Water to ~~purchase carbon offsets~~ offset GHG emissions before construction activities commence each year in an amount sufficient to reduce any GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to less-than-significant levels. With implementation of **Mitigation Measures GHG-1 and GHG-2**, overall Project construction GHG emissions impacts would be **less than significant with mitigation**.

Mitigation Measures

GHG-1 Utilize Electrification and Renewable Fuels During Construction

During Project construction, and including in construction bid specifications, Valley Water will require all construction contractors to use engine electrification (including hybrid equipment) and renewable diesel or biodiesel for on- and off-road construction equipment. Use of electric or hybrid equipment and renewable diesel or biodiesel fuels will be subject to technical and economic feasibility findings by Valley Water as well as availability in the region prior to the commencement of construction activities.

GHG-2 ~~Purchase Carbon Offsets~~ Offset GHG Emissions Prior to and During Construction

Valley Water will offset Project-related construction GHG emissions to achieve no net increase in Project-related construction GHG emissions. Options for offsetting construction-related GHG emissions will include GHG reduction measures or programs related to Valley Water projects and operations as guided by the GHGRP once adopted, and/or the purchase of carbon offsets. Annual estimates of GHG mass emissions (including from maintenance activities at the North Channel and at Live Oak Restoration Reach) will be prepared by a qualified GHG specialist retained by Valley Water throughout the construction period and will be utilized to determine which option(s) to proceed with.

Valley Water will assess opportunities to reduce and/or offset construction-related Project emissions as guided by the GHGRP once it is adopted. Reduction or offset measures from the GHGRP may be applied to the Project to reduce the amount of offsets that must be purchased to achieve net-zero GHG emissions from Project construction as discussed as an additional option below.

As another option, ~~Carbon~~ carbon offsets will be purchased annually to offset GHG emissions for the coming construction year and prior to commencement of construction activities for that 12-month period. Purchased carbon offsets will be based on annual GHG estimates of mass GHG emissions based on **Table 3.9-7** in conjunction with calculated GHG emission reductions resulting from implementation of GHG-1 and/or use of other new GHG-efficient construction equipment technologies that may be available in the future. ~~Annual estimates of GHG mass emissions will be prepared by a qualified GHG specialist retained by Valley Water.~~

Valley Water will prioritize purchase of offsets that are not “otherwise required” (CEQA Guidelines Section 15126.4(c)(3)) using the following preference hierarchy: within the San Francisco Bay Area Air Basin, originating within California, and originating in other states with offset laws at least as strict as California's. However, all offset credits shall meet the following validation criteria as defined by 17 CCR 95802: the offset credits must be real, permanent, quantifiable, verifiable, enforceable, and additional. Offset protocols must also be consistent with CARB requirements under 17 CCR 95972. Offset credits shall be registered with a recognized and reputable carbon registry, e.g., Climate Action Reserve, the American Carbon Registry, or Verra. Annual estimates of GHG emissions and corresponding annual carbon offsets will be reported publicly by Valley Water annually in a publicly-available mitigation monitoring report. The mitigation monitoring report will also include documentation of any revised estimates of GHG emissions pursuant to the first paragraph.

If, based on the mitigation monitoring report, additional GHG offsets are required, they will be purchased at that time. If purchased offsets exceeded the preceding year's emissions, they will be applied to the GHG emissions for the next 12-month period.

Impact GHG-2: Conflict with an applicable plan, policy or regulation adopted for the purpose of reducing the emissions of greenhouse gases **(Less than Significant with Mitigation)**

Construction

Seismic Retrofit Construction and Conservation Measures Construction

Senate Bill 32, Assembly Bill 1279, and 2022 Scoping Plan Consistency

The first State policy on GHG reduction was AB 32, the California Global Warming Solutions Act of 2006, which was followed by SB 32 and AB 1279. The quantitative goal of AB 32 was to reduce GHG emissions to 1990 levels by 2020. According to CARB, California achieved its 2020 GHG emission reduction target in 2016. The goal of SB 32 is to reduce GHG emissions to 40 percent below 1990 levels by 2030. Pursuant to SB 32, the Scoping Plan was created to outline goals and measures for the state to achieve the reductions, the latest iteration of which is the 2022 Scoping Plan. The 2022 Scoping Plan outlines a path to achieving carbon neutrality and reduction of anthropogenic GHG emissions by 85 percent below 1990 levels by 2045 set under AB 1279. The 2022 Scoping Plan focuses on outcomes needed to achieve carbon neutrality by assessing paths for clean technology, energy deployment, natural and working lands, and others, and is designed to meet the State's long-term climate objectives and support a range of economic, environmental, energy security, environmental justice, and public health priorities. As described under Impact GHG-1, Project construction activities related to Seismic Retrofit construction and Conservation Measures construction would implement **Mitigation Measures GHG-1** and **GHG-2. Mitigation Measure GHG-1** will require Valley Water and/or its construction contractors to use engine electrification (including hybrid equipment) and renewable fuels where feasible. Implementation of **Mitigation Measure GHG-2** will require Valley Water to ~~purchase carbon offsets~~ offset GHG emissions before construction activities commence each year in an amount sufficient to reduce GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to a net total of zero. As such, Project construction activities would not conflict with 2022 Scoping Plan goals, since Project construction activities would be carbon neutral with implementation and not conflict with SB 32, AB 1279, and the 2022 Scoping Plan, and after mitigation there would be a less-than-significant construction impact related to GHG emissions generation conflicting with SB 32, AB 1279, and the 2022 Scoping Plan, which were adopted for the purpose of reducing GHG emissions.

Valley Water CCAP Consistency

The Valley Water CCAP provides goals, strategies, and possible actions to address the ways that Valley Water is vulnerable to climate change impacts in each of Valley Water's mission areas, including water supply, flood protection, and ecosystem stewardship (Valley Water 2021b). The CCAP sets seven goals to guide Valley Water's response to climate change. Project construction consistency with the CCAP is demonstrated in **Table 3.9-8**. As shown therein, Project construction would be consistent with and not conflict with the Valley Water CCAP, and there would be a less-than-significant operational impact related to GHG emissions generation conflicting with the Valley Water CCAP, which was adopted for the purpose of reducing GHG emissions.

Table 3.9-8. Valley Water CCAP Strategies Consistency Analysis

Goals	Strategy	Description	Project Consistency
Reduce Direct GHG Emissions	1.1	Reduce GHG emissions associated with the Valley Water fleet.	Consistent. Implementation of **Mitigation Measure GHG-1** will require engine electrification (including hybrid equipment) and use of renewable fuels where feasible. These actions would reduce GHG emissions from Project construction equipment fleet. Additionally, implementation of **Mitigation Measure GHG-2** will require ~~the purchase of offsets to reduce~~ Valley Water to offset GHG emissions associated with the Valley Water fleet used during Project construction activities to net zero.
	1.2	Reduce GHG emissions from trips between Valley Water offices and work sites.	Consistent. Project construction would utilize maintenance routes that are optimized to minimize GHG emissions, encourage efficient use of sediment, and use efficient transportation alternatives. Additionally, implementation of **Mitigation Measure GHG-1** will require engine electrification (including hybrid equipment) and use of renewable fuels where feasible. Furthermore, implementation of **Mitigation Measure GHG-2** will require ~~the purchase of offsets to reduce~~ Valley Water to offset GHG emissions from trips between Valley Water offices and work sites during Project construction activities to net zero.

Goals	Strategy	Description	Project Consistency
	1.4	Minimize GHG emissions associated with planning, design, construction, operation, and maintenance of capital projects.	Consistent. Implementation of **Mitigation Measure GHG-1** will require engine electrification (including hybrid equipment) and use of renewable fuels where feasible. These actions would reduce GHG emissions from Project construction equipment fleet. Additionally, implementation of **Mitigation Measure GHG-2** will require ~~the purchase of offsets to reduce~~ Valley Water to offset GHG emissions from trips between Valley Water offices and work sites during Project construction activities to net zero..
	3.3	Create and expand other efforts to minimize indirect GHG emissions.	Consistent. Implementation of **Mitigation Measure GHG-1** will require engine electrification (including hybrid equipment) and use of renewable fuels where feasible. These actions would contribute to minimizing indirect Project GHG emissions. Additionally, implementation of **Mitigation Measure GHG-2** will require ~~the purchase of offsets to reduce~~ Valley Water to offset GHG emissions from trips between Valley Water offices and work sites during Project construction activities to net zero.

Morgan Hill 2021 Climate Action Plan Consistency

The City of Morgan Hill CAP centers around the main goal of reducing Morgan Hill's net CO_2e emissions in the building and transportation sectors to 35 percent below 2020 baseline levels by 2030 and 100 percent below 2020 baseline levels by 2045. Construction of the Project would generate GHG emissions; however, implementation of **Mitigation Measures GHG-1** and **GHG-2**, described under Impact GHG-1, will ensure that Project construction does not conflict with the CAP's goal. **Mitigation Measure GHG-1** will require Valley Water and/or its contractor to use engine electrification (including hybrid equipment) and renewable fuels where feasible. In addition, **Mitigation Measure GHG-2** will require Valley Water to ~~implement carbon offsets~~ offset GHG emissions before construction activities commence each year in an amount sufficient to reduce GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to net zero. As such, Project construction activities would be consistent with the CAP's main goal to reduce CO_2 emissions to 100 percent below 2020 baseline levels by 2045, since Project construction activities would be carbon neutral with implementation of **Mitigation Measures GHG-1** and **GHG-2**. Therefore, Project construction would be consistent with the Morgan Hill CAP, and after mitigation there would be a less-than-significant construction impact related to GHG emissions generation conflicting with the Morgan Hill CAP, which was adopted for the purpose of reducing GHG emissions.

Climate Smart San José Consistency

Climate Smart San José centers around the goal for San José to be carbon neutral by 2030. Construction of the Project would generate GHG emissions; however, implementation of **Mitigation Measures GHG-1** and **GHG-2**, described under Impact GHG-1, will ensure that Project construction does not conflict with the plan's goal. **Mitigation Measure GHG-1** will require Valley Water and/or its contractor to use engine electrification (including hybrid equipment) and renewable fuels where feasible. In addition, **Mitigation Measure GHG-2** will require Valley Water to ~~implement carbon offsets~~ offset GHG emissions before construction activities commence each year in an amount sufficient to reduce GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to net zero. As such, Project construction activities would be consistent with the Climate Smart San José's goal to achieve carbon neutrality in San José by 2030, since Project construction activities would be carbon neutral with implementation of **Mitigation Measures GHG-1** and **GHG-2**. Therefore, Project construction would be consistent with Climate Smart San José, and there would be a less-than-significant construction impact related to GHG emissions generation conflicting with Climate Smart San José, which was adopted for the purpose of reducing GHG emissions.

Operations and Maintenance

As discussed in Section 3.9.3, *Methodology and Approach to Impact Analysis*, above, post-construction operations and maintenance of the Anderson Dam Facilities and Conservation Measures, as well as FAHCE Adaptive Management, would result in the generation of negligible GHG emissions. As such, the Project would largely comply with and not conflict with SB 32, AB 1279, 2022 Scoping Plan, Valley Water CCAP, Morgan Hill 2021 CAP, and Climate Smart San José. Therefore, there would be a less-than-significant operational impact related to GHG emissions generation conflicting with an applicable plan, policy, or regulation adopted for the purpose of reducing GHG emissions.

Significance Conclusion Summary

Project construction would be consistent with SB 32, AB 1279, the 2022 Scoping Plan, the Valley Water CCAP, the Morgan Hill CAP, and Climate Smart San José with implementation of **Mitigation Measures GHG-1** and **GHG-2**. Project operation would not conflict with these GHG reduction policies and plans without mitigation. Therefore, the Project would not conflict with an applicable plan, policy or regulation adopted for the purpose of reducing GHG emissions, and overall impacts would be **less than significant with mitigation**.

Mitigation Measures

GHG-1 Utilize Electrification and Renewable Fuels During Construction

GHG-2 ~~Purchase Carbon Offsets~~ Offset GHG Emissions Prior to and During Construction

3.9.5 Cumulative Impacts

GHG emissions generation and related global climate change represent cumulative impacts. Specifically, GHG emissions cumulatively contribute to the significant adverse environmental impacts of global climate change. No single project could generate enough GHG emissions to noticeably change the global average temperature; instead, the GHG emissions from past, present, and future projects, plans, and programs and activities have contributed, currently are contributing, and would contribute to global climate change and its associated environmental impacts. In addition, given that the global atmosphere is the overarching cumulative setting with regard to GHG emissions, GHG emissions cumulative impacts are not location specific but rather time specific.

The approach to the cumulative impacts analysis and list of foreseeable future projects, programs, and plans considered in the cumulative impact analysis is included in Section 3.0.5, *Approach to Cumulative Impacts*.

This section describes the Project's contribution to cumulative GHG impacts, as summarized in **Table 3.9-9**. Cumulative impact thresholds for GHG emissions are the same as the impact thresholds presented in Section 3.9.3.8, *Thresholds of Significance*.

Table 3.9-9. Summary of Project Impact Contribution to Cumulative GHG Emissions Impacts

Impact	Significant Cumulative Impact with FOCP?	Significant Cumulative Impact with other Projects?	Incremental Project Contribution	Applicable Project Mitigations	Cumulatively Considerable after Mitigation?
Cumulative Impact GHG-1: Generate greenhouse gas emissions, either directly or indirectly, that may have a significant impact on the environment	Yes	Yes	CC	MM GHG-1 MM GHG-2	No
Cumulative Impact GHG-2: Conflict with an applicable plan, policy or regulation adopted for the purpose of reducing the emissions of greenhouse gases	Yes	Yes	CC	MM GHG-1 MM GHG-2	No

Key: CC = cumulatively considerable; MM = Mitigation Measure; NCC = not cumulatively considerable

***Cumulative Impact GHG-1: Generate greenhouse gas emissions, either directly or indirectly, that may have a significant impact on the environment* (Not Cumulatively Considerable)**

Cumulative Effects of Project with the FOCP

Implementation of the FOCP would generate GHG emissions from off-road construction activity and other sources. The analysis of GHG emissions is cumulative in nature, as emissions affect the accumulation of GHGs in Earth's atmosphere. Projects that fall below thresholds are considered to have a less-than-significant impact, both individually and cumulatively.

As indicated under Impact GHG-1, Project operational GHG impacts would be less than significant. Project construction would have a significant impact pre-mitigation, which would add to FOCP GHG emissions, resulting in a significant cumulative impact. The Project would have a less-than-significant impact with mitigation incorporated related to GHG emissions. Implementation of **Mitigation Measure GHG-1**, described under Impact GHG-1, will require Valley Water and/or its construction contractors to use engine electrification (including hybrid equipment) and renewable fuels where feasible. Implementation of **Mitigation Measure GHG-2**, described under GHG Impact-1, will require Valley Water to ~~implement carbon offsets~~ offset GHG emissions before construction activities commence each year in an amount sufficient to reduce GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to less-than-significant levels. As the Project will meet the net zero thresholds for construction GHG emissions with implementation of **Mitigation Measures GHG-1** and **GHG-2**, the Project will have a less-than-significant impact post-mitigation individually and cumulatively. Therefore, after mitigation the impact resulting from the Project in combination with the FOCP would be not cumulatively considerable.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Most of the other reasonably foreseeable future projects identified in Section 3.0.5, *Approach to Cumulative Impacts*, would occur within the county. Construction or operation of future projects, programs, and plans could overlap in time with the 8 ~~15~~-year construction schedule that Seismic Retrofit components and Conservation Measures construction would occur. Cumulative development would generate GHG emissions from vehicle trips, off-road construction activity, electrical and water use, and other sources. The analysis of GHG emissions is cumulative in nature, as emissions affect the accumulation of GHGs in Earth's atmosphere. Projects that fall below thresholds are considered to have a less-than-significant impact, both individually and cumulatively.

As indicated under Impact GHG-1, Project operational GHG impacts would be less than significant. Project construction would have a significant impact pre-mitigation, which would add to probable future project GHG emissions, resulting in a significant cumulative impact. The Project would have a less-than-significant impact with mitigation incorporated related to GHG emissions. Implementation of **Mitigation Measure GHG-1**, described under Impact GHG-1, will require Valley Water and/or its construction contractors to use engine electrification (including hybrid equipment) and renewable fuels where feasible. Implementation of **Mitigation Measure GHG-2**, described under GHG Impact-1, will require Valley Water to ~~implement carbon offsets~~ offset GHG emissions before construction activities commence each year in an amount sufficient to reduce GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to less-than-significant levels. As the Project will meet the net zero thresholds for construction GHG emissions with implementation of **Mitigation Measures GHG-1** and **GHG-2**, the Project will have a less-than-significant impact individually and cumulatively. Therefore, after mitigation the Project's contribution would be not cumulatively considerable.

Significance Conclusion Summary

The Project would have a significant cumulative GHG impact pre-mitigation, which would add other project GHG emissions, resulting in a significant cumulative impact. Valley Water would reduce the Project's incremental contribution to significant cumulative impacts on construction GHG emissions through implementation of **Mitigation Measures GHG-1** and **GHG-2**. Implementation of **Mitigation Measure GHG-1**, described under Impact GHG-1, will require Valley Water and/or its construction contractors to use engine electrification (including hybrid equipment) and renewable fuels where feasible. Implementation of **Mitigation Measure GHG-2**, described under GHG Impact-1, will require Valley Water and/or its contractors to ~~implement carbon offsets~~ offset GHG emissions before construction activities commence each year in an amount sufficient to reduce GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to less-than-significant levels. Project construction GHG emissions would exceed the net zero threshold for construction GHG emissions without mitigation, and this impact would be a significant and cumulatively considerable impact before mitigation. With implementation of **Mitigation Measures GHG-1** and **GHG-2,** Project construction GHG emissions will not exceed the net zero thresholds for construction emissions. Post-mitigation, the Project's contribution to cumulative impacts on generation of GHG emissions is **not cumulatively considerable.**

Mitigation Measures

GHG-1 Utilize Electrification and Renewable Fuels During Construction

GHG-2 ~~Purchase Carbon Offsets~~ Offset GHG Emissions Prior to and During Construction

Cumulative Impact GHG-2: Conflict with an applicable plan, policy or regulation adopted for the purpose of reducing the emissions of greenhouse gases **(Not Cumulatively Considerable)**

Cumulative Effects of Project with the FOCP

Implementation of the FOCP would generate GHG emissions from off-road construction activity and other sources. The analysis of GHG emissions is cumulative in nature, as emissions affect the accumulation of GHGs in Earth's atmosphere. Projects that fall below thresholds are considered to have a less-than-significant impact, both individually and cumulatively.

As indicated under Impact GHG-1, Project operational GHG impacts would be less than significant. Project construction would have a significant impact pre-mitigation, which would add to FOCP GHG emissions, resulting in a significant cumulative impact. The Project would have a less-than-significant impact with mitigation incorporated related to GHG emissions. Implementation of **Mitigation Measure GHG-1**, described under Impact GHG-1, will require Valley Water and/or its construction contractors to use engine electrification (including hybrid equipment) and renewable fuels where feasible. Implementation of **Mitigation Measure GHG-2**, described under GHG Impact-1, will require Valley Water to ~~implement carbon offsets~~ offset

GHG emissions before construction activities commence each year in an amount sufficient to reduce GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to less-than-significant levels. As the Project will meet the net zero thresholds for construction GHG emissions with implementation of **Mitigation Measures GHG-1** and **GHG-2**, the Project will have a less-than-significant impact individually and cumulatively. Therefore, after mitigation the impact resulting from the Project in combination with the FOCP would not be cumulatively considerable.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Most of the other reasonably foreseeable future projects identified in Section 3.0.5, *Approach to Cumulative Impacts*, would occur within the county. Construction or operation of future projects, programs, and plans could overlap in time with the 8 ~~15~~-year construction schedule that Seismic Retrofit components and Conservation Measures construction would occur. Cumulative development would generate GHG emissions from vehicle trips, electrical and water use, and other sources that could conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing GHG emissions. The analysis of GHG emissions is cumulative in nature, as emissions affect the accumulation of GHGs in Earth's atmosphere. Projects that fall below thresholds are considered to have a less-than-significant impact, both individually and cumulatively. Thus, projects that have a less-than-significant impact would also not conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing GHG emissions.

As indicated under Impact GHG-2, Project operational GHG impacts would be less than significant. Project construction would have a significant impact pre-mitigation, which would add to probable future ~~project~~ Project GHG emissions, resulting in a significant cumulative impact. The Project would have a less-than-significant impact with mitigation incorporated related to conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing GHG emissions. Implementation of **Mitigation Measure GHG-1**, described under Impact GHG-1, will require Valley Water and/or its construction contractors to use engine electrification (including hybrid equipment) and renewable fuels where feasible. Implementation of **Mitigation Measure GHG-2**, described under GHG Impact-1, will require Valley Water to ~~implement carbon offsets~~ offset GHG emissions before construction activities commence each year in an amount sufficient to reduce GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to less-than-significant levels. As the Project would meet the net-zero thresholds for construction GHG emissions with implementation of **Mitigation Measures GHG-1** and **GHG-2**, the Project will not conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing GHG emissions and would have a less-than-significant impact individually and cumulatively. Therefore, after mitigation the impact resulting from the Project in combination with other probable future projects would not be cumulatively considerable.

Significance Conclusion Summary

The Project would have a significant cumulative GHG impact pre-mitigation, which would add other ~~project~~ Project GHG emissions, resulting in a significant cumulative impact. Valley Water would reduce the Project's incremental contribution to significant cumulative impacts on construction GHG emissions and, thus, to conflicts with an applicable plan, policy, or regulation adopted for the purpose of reducing GHG emissions through implementation of **Mitigation Measures GHG-1** and **GHG-2**. Implementation of **Mitigation Measure GHG-1**, described under

Impact GHG-1, will require Valley Water and/or its construction contractors to use engine electrification (including hybrid equipment) and renewable fuels where feasible. Implementation of **Mitigation Measure GHG-2**, described under GHG Impact-1, will require Valley Water to ~~implement carbon offsets~~ offset GHG emissions before construction activities commence each year in an amount sufficient to reduce GHG emissions remaining after implementation of **Mitigation Measure GHG-1** to less-than-significant levels. Project construction GHG emissions would exceed the net-zero threshold for construction GHG emissions without mitigation and would, thus, conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing GHG emissions. This impact would be a significant and cumulatively considerable impact before mitigation. With implementation of **Mitigation Measures GHG-1** and **GHG-2**, Project construction GHG emissions will not exceed the net-zero thresholds for construction emissions and, thus, will not conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing GHG emissions. The Project's contribution to cumulative impacts on generation of GHG emissions and, thus, to conflicts with an applicable plan, policy, or regulation adopted for the purpose of reducing GHG emissions is **not cumulatively considerable.**

3.10 Hazards and Hazardous Materials

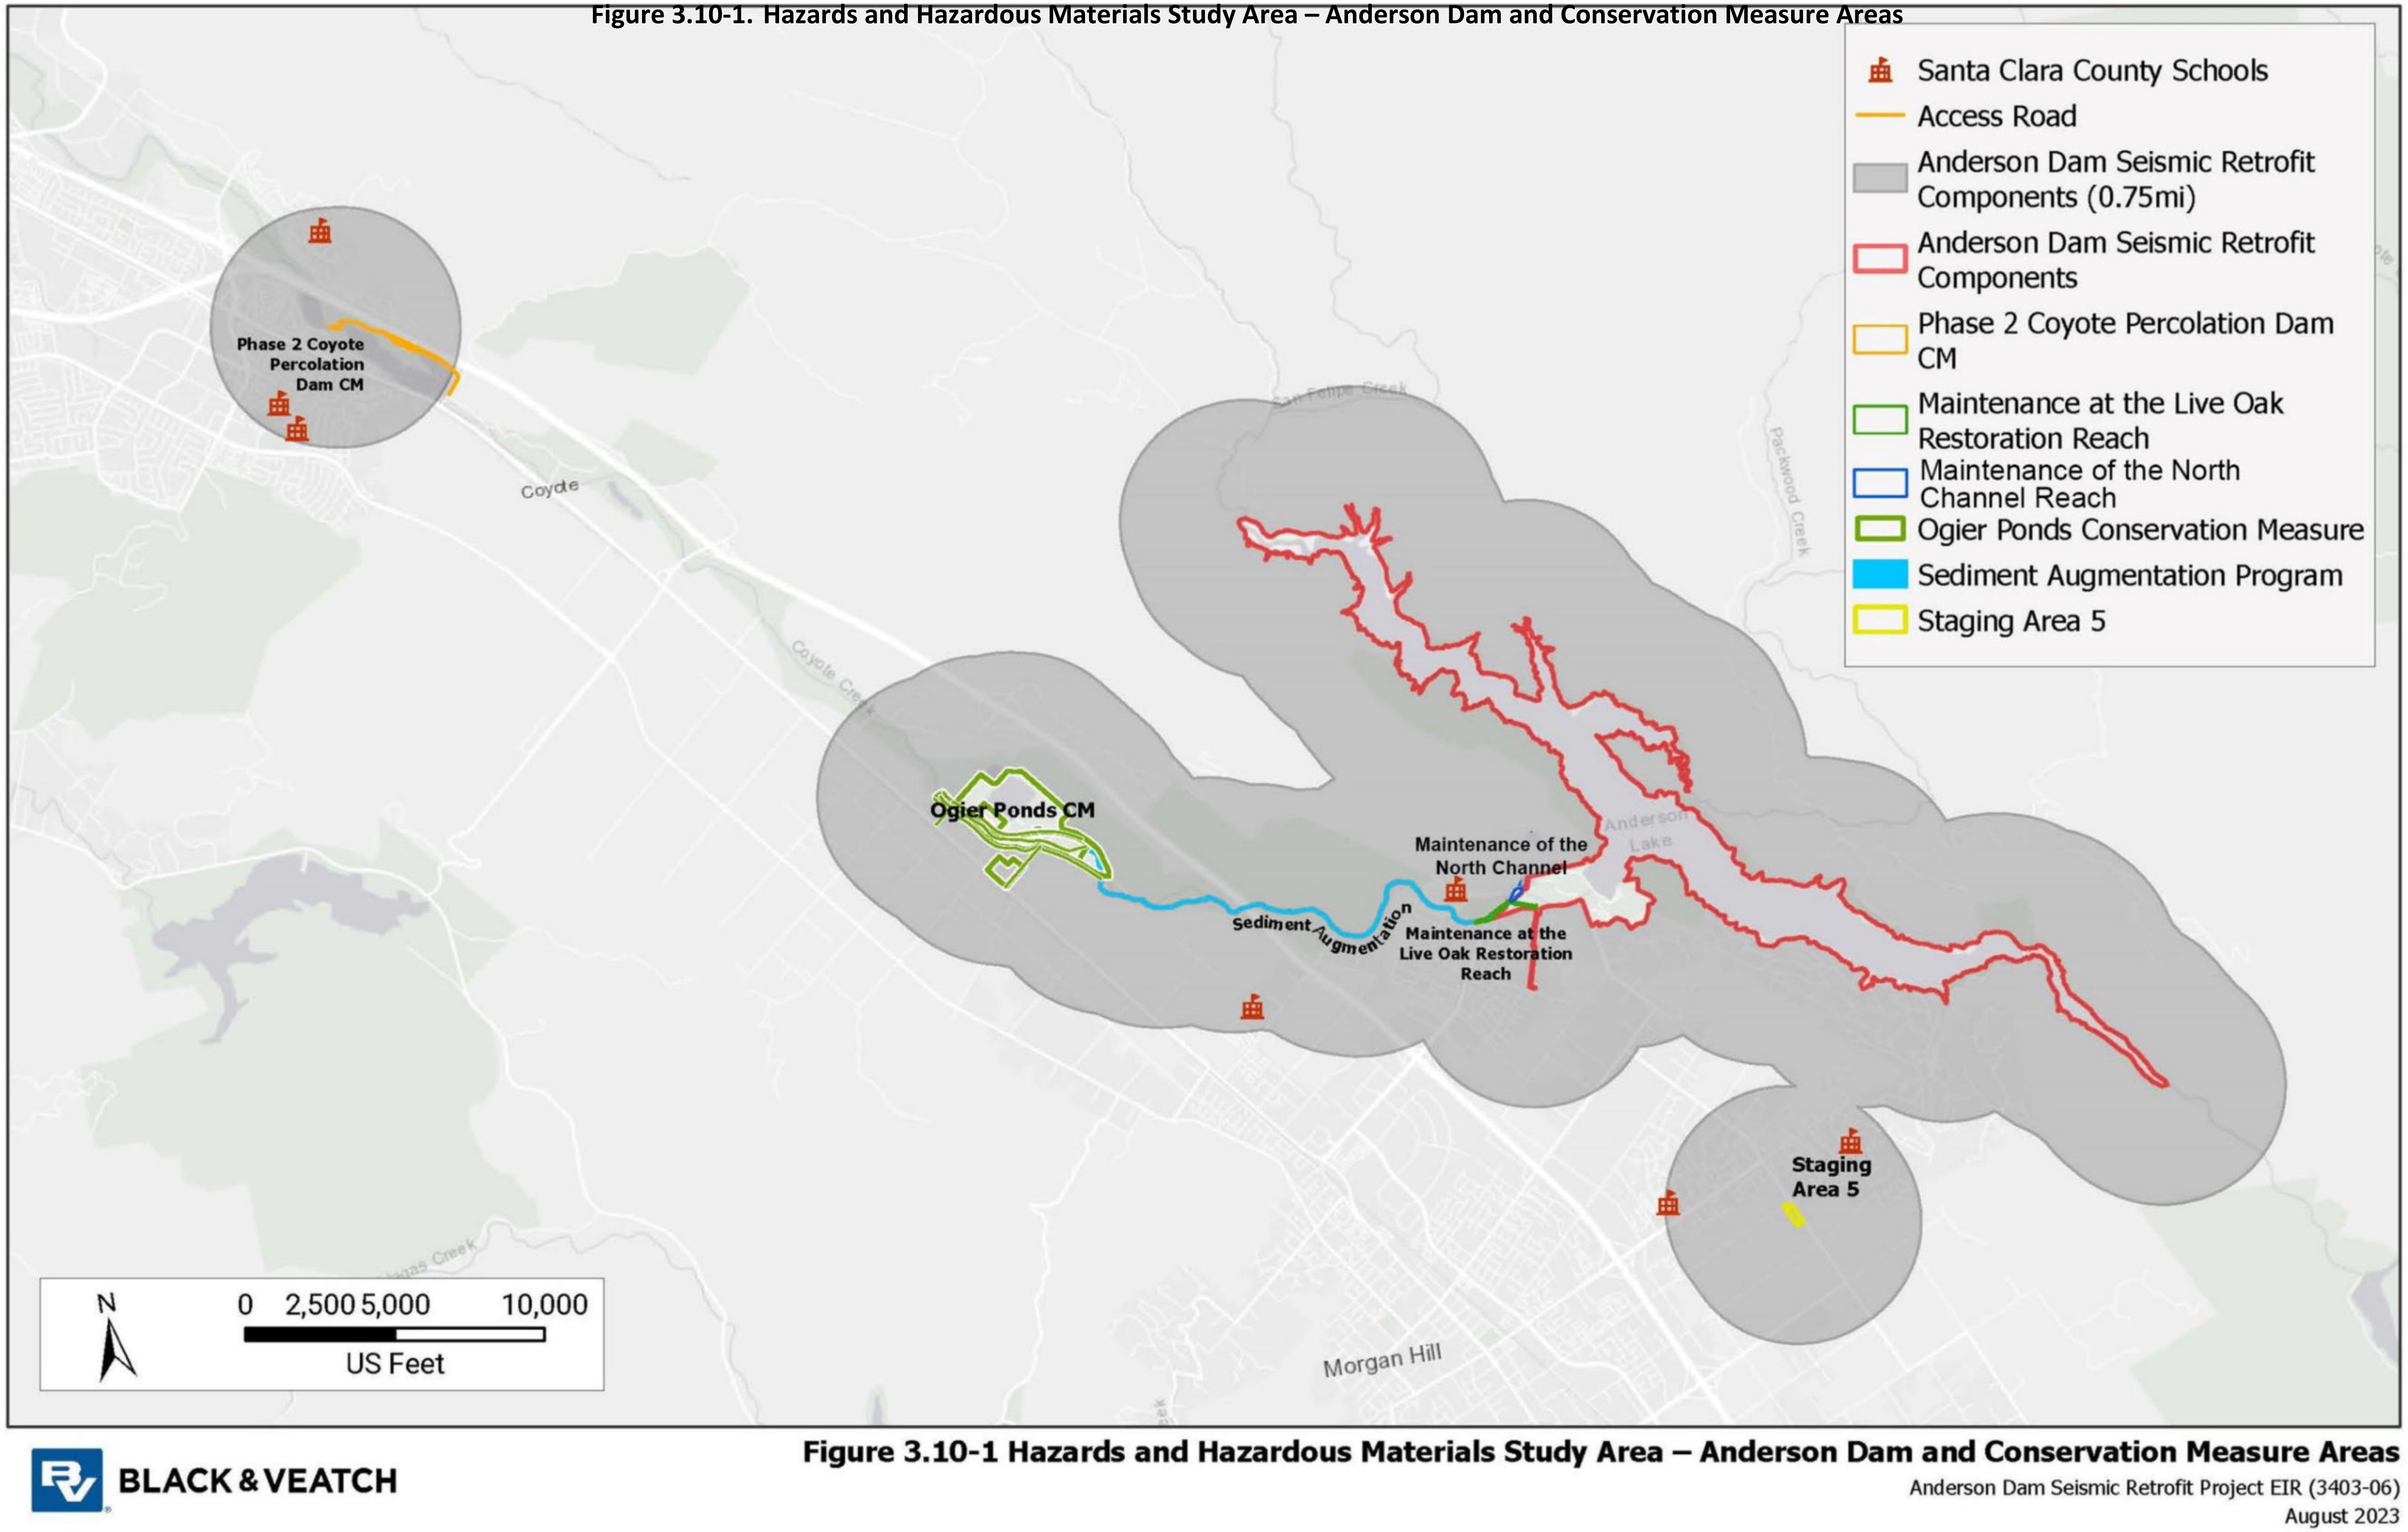
This section evaluates the Project impacts related to hazards and hazardous materials in the study area, as described below. The *CEQA Guidelines* significance criteria for hazards and hazardous materials address impacts related to creating a significant hazard to the public and environment through the routine transport, use, disposal, or the accidental release of hazardous materials, emitting or handling hazardous materials within 0.25 miles of a school or near sensitive uses, being located on a known hazardous materials site, impairing implementation with an adopted emergency response plan or evacuation plan, and exposing people or structures to wildland fires. Additional impacts related to wildland fires are analyzed also in Section 3.22, *Wildfire*, and are not discussed further in this section.

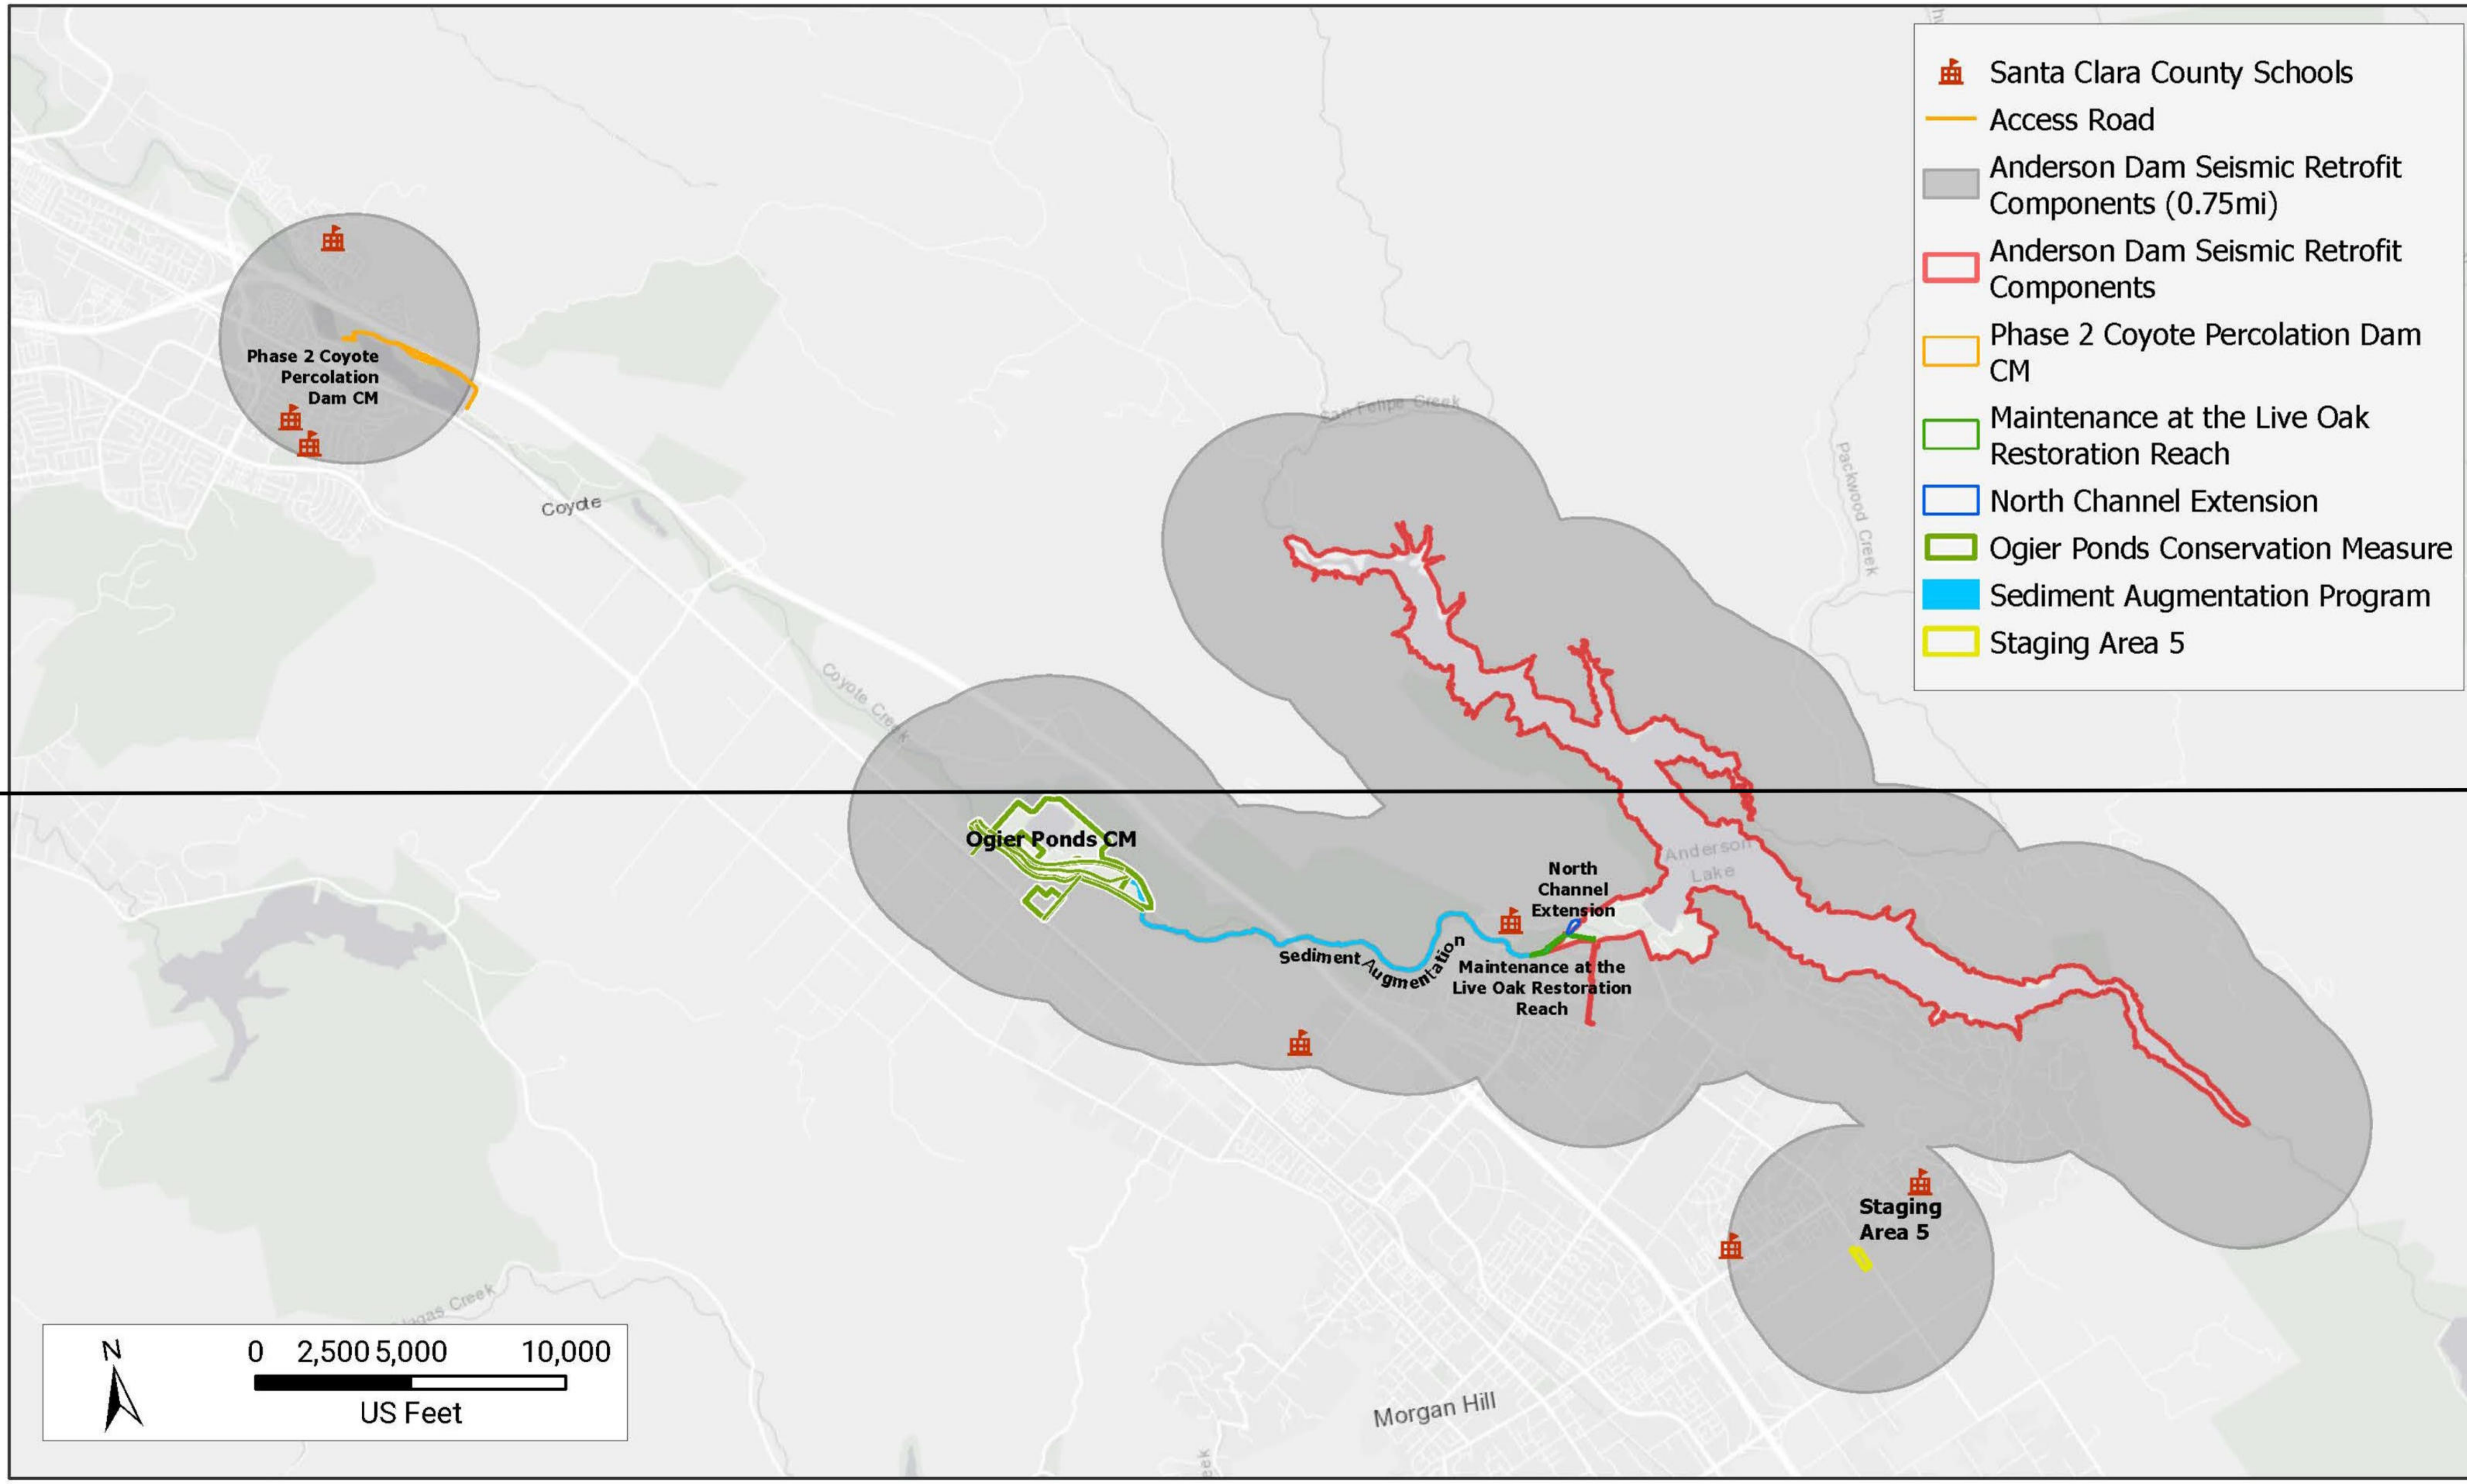
The study area used to assess impacts related to hazards and hazardous materials includes the Project Area that includes the construction limits of all Seismic Retrofit and Conservation Measure components, as well as a 0.75-mile area surrounding these limits (refer to **Figure 3.10-1**).

Note that the Project is not located within an airport land use plan or within 2 miles of a public airport or public use airport. Therefore, impacts related to the use of hazards and hazardous materials within an airport land use planning area, or within 2 miles of an airport, are not analyzed in this section.

This page intentionally left blank.

Figure 3.10-1. Hazards and Hazardous Materials Study Area – Anderson Dam and Conservation Measure Areas





BLACK & VEATCH

Figure 3.10-1 Hazards and Hazardous Materials Study Area – Anderson Dam and Conservation Measure Areas

Anderson Dam Seismic Retrofit Project EIR (3403-06)
August 2023

3.10.1 Environmental Setting

3.10.1.1 Regional Setting and Existing Land Uses

Anderson Dam and Reservoir are located near the junction of Cochrane Road and Coyote Road in the county. The Project Area is located on land owned by Valley Water, the County, and private landowners. Anderson Lake County Park encompasses Anderson Reservoir; thus, the lands surrounding the Project Area are largely used by recreationalists. Existing land uses within and adjacent to the Project Area include agricultural and grazing lands, Coyote Creek, parklands and associated parking areas and hiking trails (Coyote Creek Trail, Serpentine Trail, Lakeview Trail, Rancho Laguna Seca Trail), Anderson Reservoir boat ramp, the Anderson Lake Visitor's Center, the County Justice Training Center, the William F. James Boys Ranch, Ogier Ponds, Coyote Percolation Dam, an orchard, and private residences. A large portion of the Coyote Creek corridor downstream of Anderson Dam is undeveloped open space, interspersed with trails and picnic tables.

3.10.1.2 ~~Figure 3.10-1~~ Schools

Several schools are located on lands around the Project Area within Morgan Hill and San José. None of these schools are located within 0.25 mile of the Project Area. Although not a typical public high school, the William F. James Boys Ranch, which is a juvenile detention facility operated by the County Juvenile Probation Department, houses youth year-round and is located approximately 0.11 miles west of the Project Area near the Live Oak Picnic Area within Anderson County Park. This facility is considered a sensitive use and has been evaluated in the analysis. **Table 3.10-1** lists the schools within the 0.75-miles buffer of the Project Area. These schools are also shown on **Figure 3.10-1**.

Table 3.10-1. Schools Within 0.75 Mile of the Project Area

Proposed Project or Conservation Measure	Nearest School	Location	Proximity (miles)
Anderson Dam	William F. James Boys Ranch	19050 Malaguerra Avenue, Morgan Hill	0.11
<u>Sediment Augmentation Program</u> ~~Ogier Ponds Supplemental Staging Area~~	Ann Sobrato High School	410 Burnett Avenue, Morgan Hill	<u>0.53</u> ~~0.43~~
Phase 2 Coyote Percolation Dam CM	Ledesma Elementary School	1001 Schoolhouse Road, San José	0.50
	Martin Murphy Middle School	141 Avenida España, San José	0.75
	Los Paseos Elementary School	121 Avenida Grande, San José	0.66

Note: Many of the conservation measures involve operational measures or the implementation of monitoring, plans, and/or programs that would not involve construction or the use of hazardous materials. Therefore, only schools within close proximity to Conservation Measure components that involve construction related disturbance are included.

3.10.1.3 Existing Hazardous Materials Sites

The provisions in California Government Code section 65962.5, regulated by CalEPA, are commonly referred to as the “Cortese List.” The list, or a site’s presence on the list, has bearing on the local permitting process and compliance with CEQA. The Cortese List, which includes the resources listed below, was reviewed for sites in the Project Area:

- Hazardous Waste and Substances sites from the California Department of Toxic Substances Control (DTSC) EnviroStor database
- Leaking Underground Storage Tank (LUST) Sites from the SWRCB GeoTracker database
- Solid waste disposal sites identified by the SWRCB with waste constituents above hazardous waste levels outside the waste management unit
- “Active” Cease and Desist Orders and Cleanup and Abatement Orders from SWRCB
- Hazardous waste facilities subject to corrective action identified by DTSC

According to the SWRCB GeoTracker database (SWRCB 2021a) and the DTSC EnviroStor database (DTSC 2021), no hazardous sites or facilities are located within the Project Area.

However, the following three sites are located within 0.75 mile of the Seismic Retrofit component area and associated staging areas, and are shown on **Figure 3.10-2**:

The Estates at San Sebastian – Phase I (located approximately 0.4 mile southwest of Anderson Dam) is listed as a DTSC Voluntary Cleanup site. The site is an agricultural area used for row crops, where onsite soils were determined to be contaminated by organochloride pesticides. The site was listed as a voluntary cleanup site in 2015. Based on assessment by DTSC, the site does not appear to pose a threat to human health or the environment under a residential land use scenario, and DTSC determined that no further action was necessary with respect to investigation and remediation of hazardous substances at the property. The voluntary cleanup agreement was completed in 2016 (SWRCB 2021b).

Borello St. Marks Property (located approximately 0.5 mile west of Anderson Dam) is listed as a DTSC Voluntary Cleanup site. The site is a former agricultural area used for row crops where on-site soils were determined to be contaminated by organochlorine pesticides. The site was listed as a voluntary cleanup site in 2006. Based on assessment by DTSC, the site does not appear to pose a threat to human health or the environment under a residential land use scenario, and DTSC determined that no further action was necessary with respect to investigation and remediation of hazardous substances at the property. The voluntary cleanup agreement was completed in 2006. The same site is listed as an Irrigated Lands Regulatory Programs site (SWRCB 2021c).

Borello Property (located approximately 0.75 mile southwest of Anderson Dam) has two listings; a DTSC Voluntary Cleanup site and a School Cleanup site because the site was selected by the Morgan Hill Unified School District as a future elementary school site. The site was a former agricultural area used for orchards, where onsite soils were determined to be contaminated by toxaphene and dieldrin pesticides. In 2005, the site was remediated to reduce the concentrations of organochlorine pesticides at the agricultural field. However, subsequent investigations in 2014 and early 2016 confirmed that elevated concentrations of dieldrin remain at the site. A Removal Action Workplan (RAW) was approved by DTSC in

November 2017. In November 2020, DTSC approved the Removal Action Completion Report and certified that the site has met the cleanup goals of the RAW (SWRCB 2021d).

Ushiba Property (located approximately 0.9 mile west of Staging Area 5) is listed as a LUST cleanup site. A diesel leak was discovered in 1997 that may have contaminated soil. However, the site was cleaned up and the case was closed in 1997 (SWRCB 2022a).

In addition to the sites identified within 0.75 mile of Seismic Retrofit component area, the SWRCB Geotracker database (SWRCB 2021a) and the DTSC EnviroStor database (DTSC 2021) identified the following 17 sites within 0.75 mile of the Conservation Measures components and associated staging areas, and are shown on **Figure 3.10-2**:

New Morgan Hill High School (located approximately 0.53 mile west of the Sediment Augmentation Program [Coyote Creek] ~~Ogier Ponds Supplemental Staging Area~~) is listed as a DTSC School Cleanup. This site was used historically for agriculture, and elevated levels of chlordane, dieldrin, endrin, lead, arsenic, and cadmium were detected in the soil. Approximately 150 cy of contaminated soil were removed from the site, and the site was certified as clean in 2003 (DTSC 2022).

Colombini Ranch (located approximately 0.69 ~~0.4~~ mile south of the Sediment Augmentation Program [Coyote Creek] ~~Ogier Ponds Supplemental Staging Area~~) is listed as a LUST cleanup site. A gasoline leak was discovered in 1987 that may have contaminated soil. However, the site was cleaned up and the case was closed in 1998 (SWRCB 2022b ~~2022a~~).

Bonner Packing (located approximately 0.11 mile west of Ogier Ponds) is listed as a LUST cleanup site. The site was utilized as a mobile home park, and for agriculture, gravel excavation, fruit packing, and related cold storage. The site contained a 1,000-gallon gasoline UST that contaminated a small amount of soil near the UST. The UST was removed in 1987 and no further remediation work was required. The case was closed in January 1991 (SWRCB 2021e) ~~December 1990 (Valley Water 1990)~~.

Kirby Canyon Landfill (located approximately 0.5 mile east of Ogier Ponds) is a Class III solid waste disposal facility that has been operating since 1986. The landfill is listed as having contaminated groundwater, soil, and surface water with high levels of benzene and toluene. Cleanup activities are ongoing (SWRCB 2022c ~~2022b~~).

Private Residence (Filice Estate Vineyards) (located approximately 0.07 mile west of Ogier Ponds) is listed as a LUST cleanup site. The site was formerly used for agricultural purposes, including vineyards and cherry orchards. The site contained one 350-gallon gasoline UST that contaminated soil near the UST. The UST was removed in 1988 and no further remediation work was required as the UST had no holes or ruptures when removed. The case was closed in December 1989 (Valley Water 1989).

Bonner Packing Parkway Lanes (located approximately 0.22 mile west of Ogier Ponds) is listed as a LUST cleanup site. Soil on the site was reported as contaminated from one gasoline UST. The site was cleaned up and no further remediation onsite was required. The case was closed in January 1991 (SWRCB 2021e).

Kikunaga Nursery (located approximately 0.5 mile west of Ogier Ponds) is listed as a LUST cleanup site. The site was a former nursery that contained one 500-gallon gasoline UST that contaminated soil near the UST. The site was cleaned up and the case was closed in October 1995 (SWRCB 2021f).

Sierra Precast, Inc. (located approximately 0.5 mile southwest of Ogier Ponds) has two listings as a LUST cleanup site. The site was formerly used for agricultural purposes. Contaminated soil was found onsite and three USTs were removed in 1993. Contaminated soil and groundwater used for drinking water supply were also detected onsite beneath a gasoline dispenser pump in 2002. The site was cleaned up and the case was closed in March 2004. Since that time, Valley Water has installed a water supply well at the property (SWRCB 2021g).

Aguilar Trucking (located approximately 0.5 mile southwest of Ogier Ponds) is listed as a LUST cleanup site. A diesel leak was discovered in 1992 that may have contaminated the soil. However, the site was cleaned up and the case has been closed since 1996 (SWRCB 2022d ~~2022c~~).

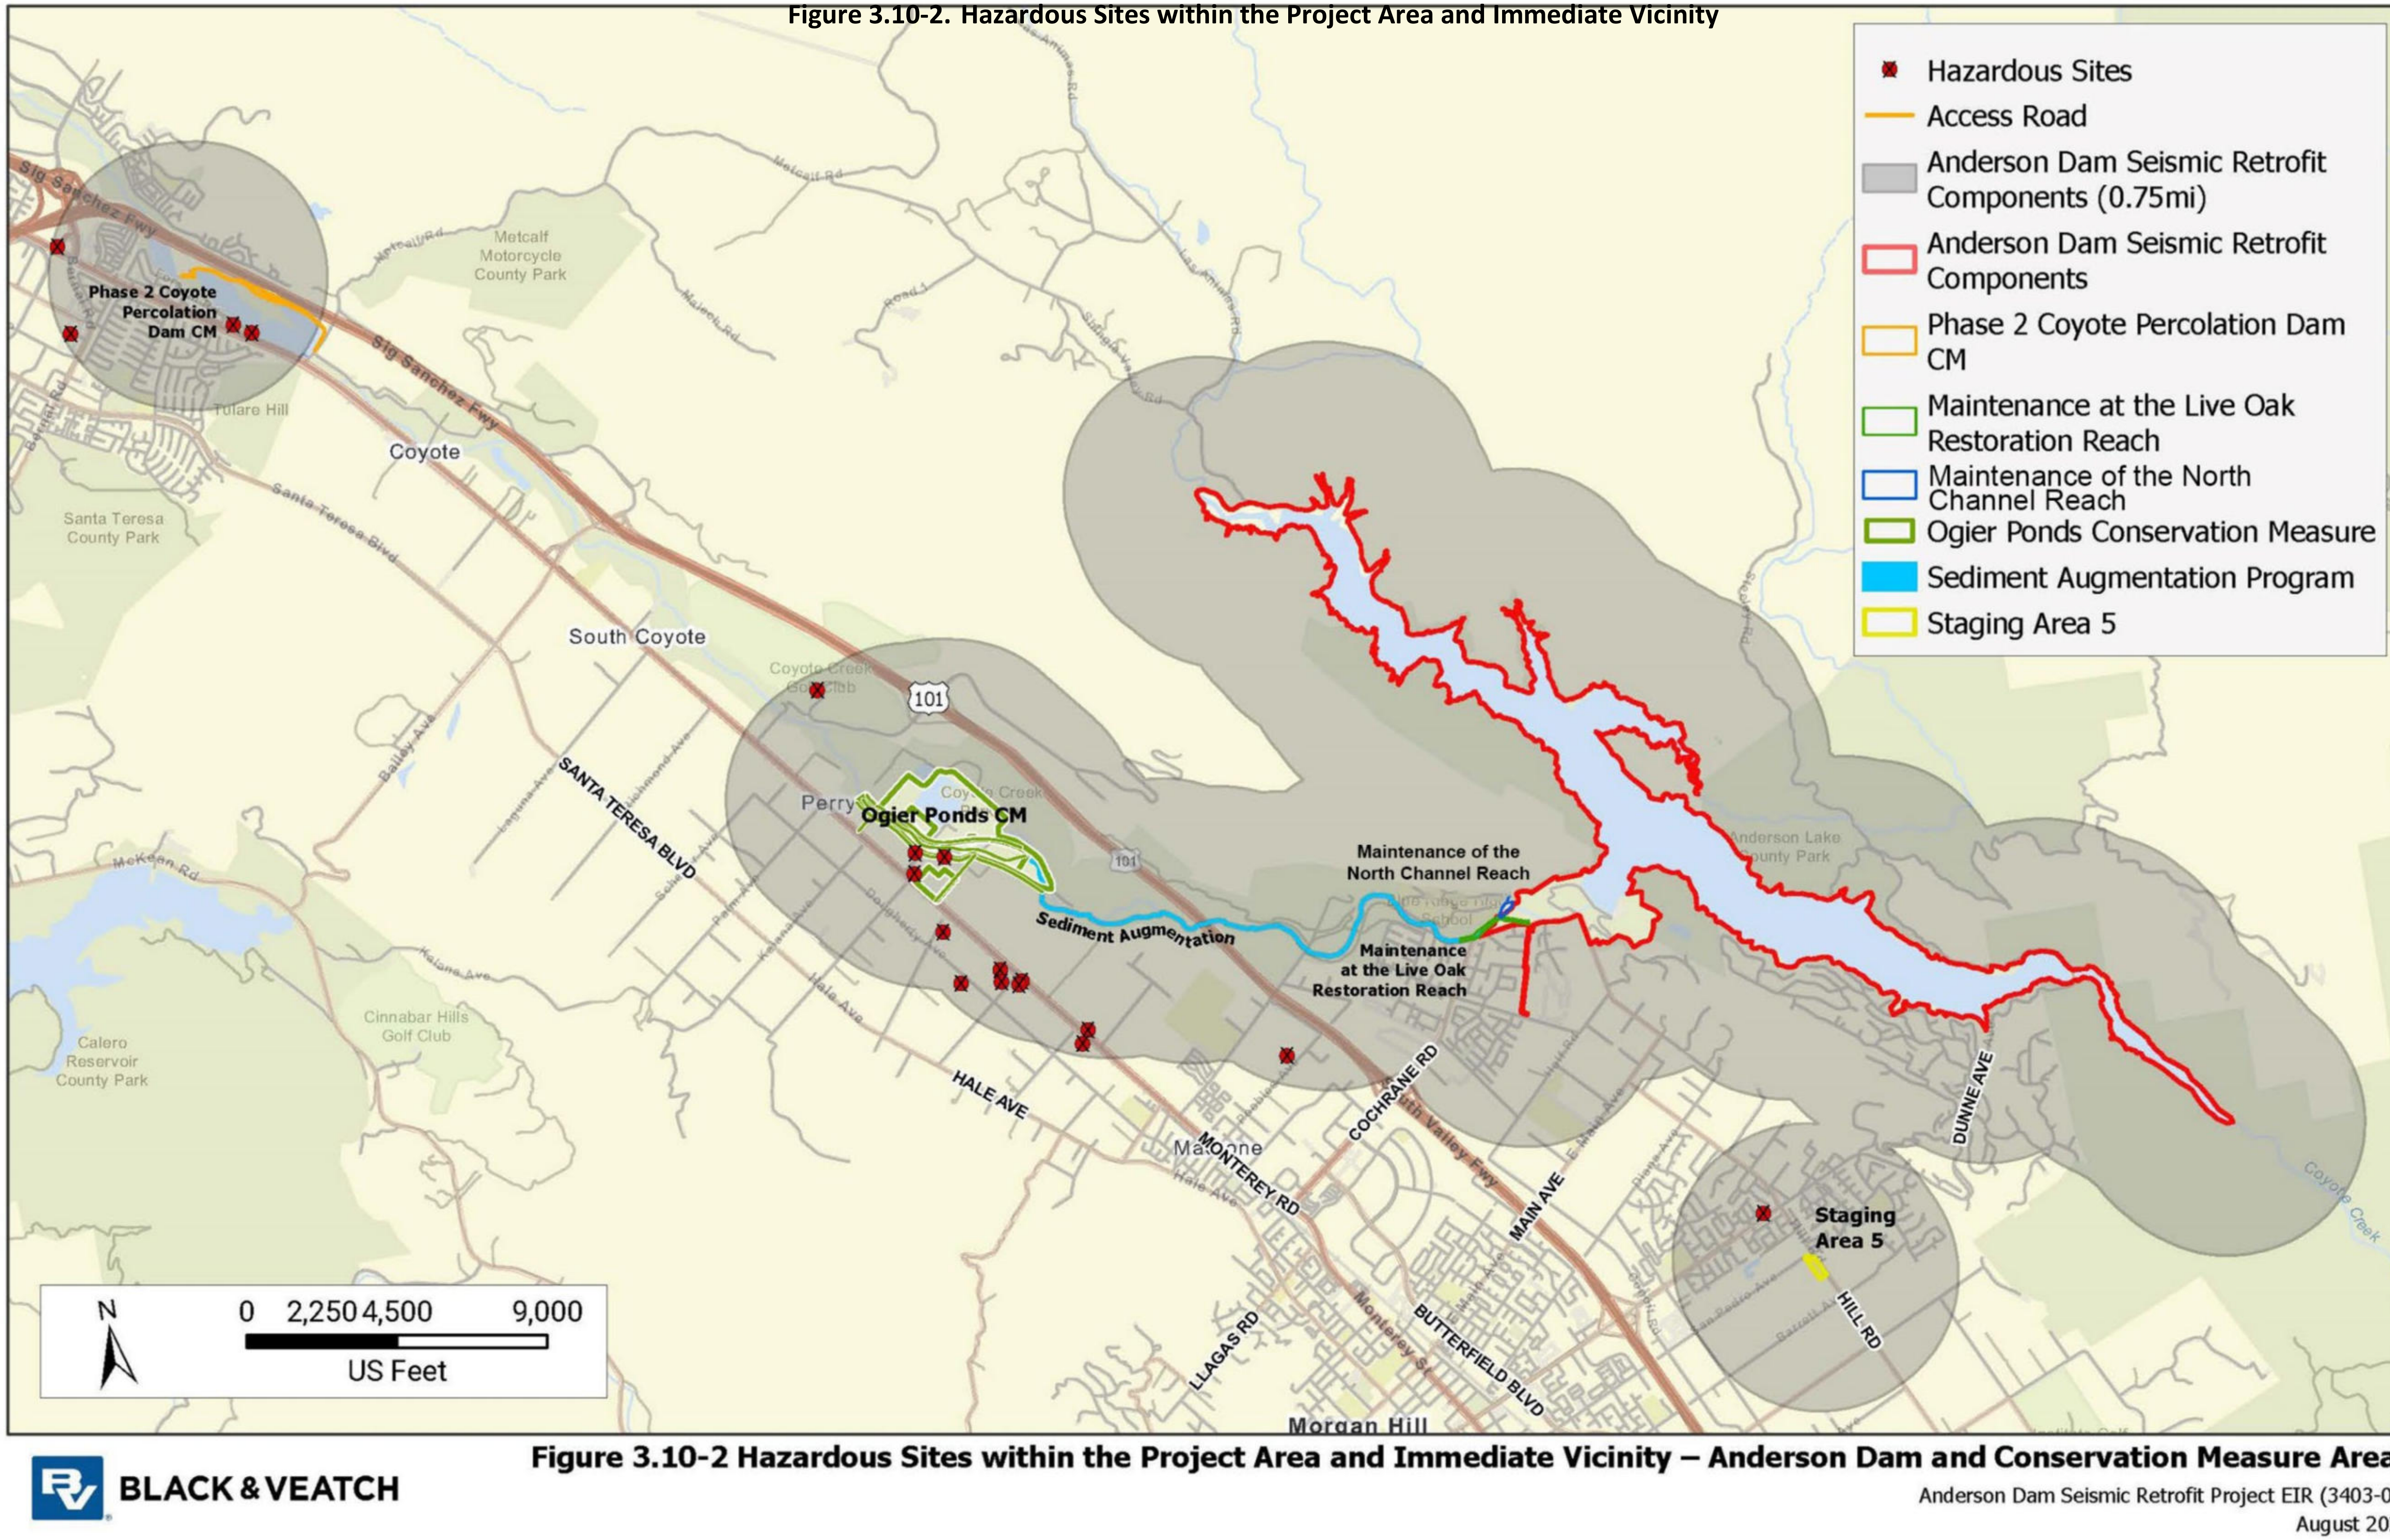

Figure 3.10-2 Hazardous Sites within the Project Area and Immediate Vicinity – Anderson Dam and Conservation Measure Areas

Anderson Dam Seismic Retrofit Project EIR (3403-06)
August 2023

Fujita Farms (located approximately 0.5 mile southwest of Ogier Ponds) is listed as a LUST cleanup site. The site was formerly used for agricultural purposes. Soil was contaminated from two 550-gallon USTs that were removed in 1990; one UST had a pinhole leak. Contamination was localized and was removed during the UST removal. The case was closed in June 1995 (SWRCB 2021h).

Tellez Property (located approximately 0.5 mile southwest of Ogier Ponds) is listed as a LUST cleanup site. The site was formerly used for agricultural purposes. Contaminated soil beneath a 550-gallon UST was detected and the UST was removed in 1988. No further remediation of the site was conducted, and the case was closed in November 1990 (SWRCB 2021i).

Riverside Golf Course (located approximately 0.7 mile northeast of Ogier Ponds) is listed as a LUST cleanup site. The site was formerly a golf course that stored three gasoline USTs. When removed from the site in 1984 and 1990, a hole was detected in one of the USTs. Water used for drinking water could have been potentially contaminated; however, it was determined through further monitoring that no drinking wells were affected. The case was closed in April 2000 (SWRCB 2021j).

Kaufman & Broad-Site #1 (located approximately 0.4 mile southeast of the Coyote Percolation Dam) is listed as a LUST cleanup site. Eight gasoline USTs and contaminated soil were removed in 1998. Contaminated groundwater was also detected onsite. As of July 1999, residual groundwater and soil contamination remained; however, the residual levels do not impact human health or the environment. The case was closed in July 1999 (SWRCB 2021k).

Kaufman & Broad-Site #2 (located approximately 0.5 mile southeast of the Coyote Percolation Dam) is listed as a LUST cleanup site. The site was a former gasoline station that contaminated the soil. All LUSTs were removed with the demolition of the gasoline station in the 1970s. No further remediation was required, and the case was closed in June 1991 (SWRCB 2021l).

PG & E Substation (located approximately 0.9 mile southeast of the Coyote Percolation Dam) is listed as a LUST cleanup site. Petroleum hydrocarbons were released from a 150-gallon UST resulting in contaminated soil onsite. However, the site was cleaned up and the case has been closed since 1993 (SWRCB 2022e ~~2022d~~).

USA Petroleum #832 (located approximately 0.7 mile northwest of the Coyote Percolation Dam) is listed as a LUST cleanup site. This site was used to operate a gasoline and diesel service station since 1994 and contained three 12,000-gallon gasoline USTs. Soil and groundwater samples found contaminated levels of soil and groundwater within the site that may have affected drinking water supplies. Remediation activities took place from 2004 to 2009 and removed methyl tertiary butyl ether (MTBE) and non-methane hydrocarbons from the soil. As of 2010, verification monitoring had not yet been completed (SWRCB 2022f~~e~~).

Fairchild–San José (located approximately 0.7 mile southwest of the Coyote Percolation Dam) is listed as an open cleanup program site. The site was use as a manufacturing site that involved handling, repackaging, and storage of industrial solvents and volatile organic compounds (VOC) that stopped operating in 1983. In 1981, a waste solvent UST failed, releasing hazardous contaminants. VOCs were detected in subsurface soil and groundwater at the site in 1981. The owner has completed a series of remediation activities throughout the 1980s and is currently conducting monitoring. Since 2018, verification monitoring was still being conducted and the case is still considered open. Currently, the site is a retail shopping center with a paved parking lot (SWRCB <u>2022g</u> ~~2022f~~).

3.10.1.4 Previous Hazardous Assessments in the Project Area

Phase I Hazardous Substance Liability Assessments (HSLA) were prepared as part of the acquisition process for three properties located within the Project Area. Five HSLAs were also prepared for five properties located adjacent to the Project Area. A summary of the findings of these reports is provided below.

- A Phase I HSLA (Northgate 2020a) was prepared for a 0.65-acre parcel of vacant land located within Anderson Lake County Park at 2187 Cochrane Road (APN 728-34-020). This parcel was acquired by Valley Water for eventual construction of flood protection banks as part of the Project to protect construction trailers. This site historically consisted of the vacant stream bank and floodplain area adjacent to the historic channel of Coyote Creek before Coyote Creek was rechanneled during construction of the dam in the early 1950s. Serpentine and other ultramafic rock were discovered to be present on the surface of the site during the assessment. These rock types were determined to contain naturally occurring asbestos (NOA) at concentrations greater than 0.25 percent (Mandlekar 2020a).
- A Phase I HSLA (Northgate 2020b) was prepared for portions of the Giancola property located at 2290A Cochrane Road (APN 78-34-010). Valley Water acquired temporary construction easements on this parcel for eventual construction staging and material laydown as part of the Project. This site was historically used for agricultural purposes and thus, residual agricultural chemicals (e.g., pesticides such as DDT-related compounds and metals) could potentially be present in shallow soil at the site. In addition, geologic formations that are sometimes associated with NOA are located on the site; thus, soil onsite could potentially contain NOA (Mandlekar 2020b).
- A Phase I HSLA (Mandlekar 2014) was prepared for the vacant land adjacent to the western portion of Anderson Lake County Park immediately east of Cochrane Road (APN 728-34-016). This parcel was acquired by Valley Water for the Project long-term operations, and for access to the reservoir to support the Project. This parcel currently supports vacant land; however, some chemicals may have been used for maintenance of boats at the offsite boat storage facility west of Cochrane Road (Mandlekar 2014). The assessment found no recognized environmental conditions (REC) onsite but recommended that if any subsurface work is planned at the site that Valley Water prepare a subsurface soil and groundwater sampling and management plan to test soil and groundwater for metals, total petroleum hydrocarbons, and volatile organic compounds.
- A Phase I HSLA (Locus Technologies 2022a) was prepared for two parcels located on Monterey Road (APN 725-05-005 and APN 725-05-066) bordering the western boundary of Ogier Ponds CM and adjacent to the historical channel of Coyote Creek. The two parcels were previously used for agricultural purposes; thus, there is a high likelihood that pesticides were applied onsite that may have contaminated soil. Further investigation is required to test the soils for contamination. The site is currently used by a company that builds fireplaces. Although aboveground storage tanks were present

onsite, they were in clean condition and are not of environmental concern. Valley Water may acquire a fee interest or easement on the property for soil excavation and Coyote Creek improvements associated with the Ogier Ponds ~~Geomorphic and Habitat Restoration~~ CM.

- A Phase I HSLA (Locus Technologies 2022b) was prepared for two parcels located on Monterey Road (APN 725-05-015 and 725-05-016) bordering the western boundary of Ogier Ponds and adjacent to the historical channel of Coyote Creek. The two parcels were previously used for agricultural purposes; thus, there is a high likelihood that pesticides were applied onsite that may have contaminated soil. Further investigation would be required to test the soils for contamination. The site is currently an active ranch with livestock, vegetation, and mobile homes. Valley Water may acquire a fee interest or easement on the property for soil excavation and Coyote Creek improvements associated with the Ogier Ponds ~~Geomorphic and Habitat Restoration~~ CM.
- A Phase I HSLA (Locus Technologies 2022c) was prepared for a 104-acre parcel located in Morgan Hill (APN 725-04-002) at the southern end of Ogier Ponds adjacent to the historical channel of Coyote Creek. The parcel has been used as agricultural land for orchards since 1939; thus, there is a high likelihood that pesticides were and are still applied onsite. The historic and current agricultural land use is considered an environmental concern and further investigation is required to test the soils for contamination. Valley Water may acquire a fee interest or easement on the property for soil excavation and Coyote Creek improvements associated with the Ogier Ponds ~~Geomorphic and Habitat Restoration~~ CM.
- A Phase I HSLA (Locus Technologies 2022d) was prepared for an 11.5-acre commercial property located in Morgan Hill (APN 725-05-014) that borders the western boundary of Ogier Ponds. The parcel was previously used for agricultural purposes; thus, there is a high likelihood that pesticides were applied onsite. The historical agricultural land use is considered an environmental concern and further investigation is required to test the soils for contamination. The site is currently used for commercial purposes including food distribution, construction fencing, and home building services. Valley Water may acquire a fee interest or easement on the property for soil excavation and Coyote Creek improvements associated with the Ogier Ponds ~~Geomorphic and Habitat Restoration~~ CM.
- A Phase I HSLA (Locus Technologies 2022e) was prepared for a residential property owned by Parkway Lakes RV Park located in Morgan Hill (APN 725-05-011) that borders the western boundary of Ogier Ponds. The parcel was previously used for agricultural purposes; thus, there is a high likelihood that pesticides were applied onsite. The historical agricultural land use is considered an environmental concern. The property also has a closed LUST case onsite. Further investigation is required to test the soils for contamination. The site is currently used as a recreational vehicle park. Valley Water may acquire a fee interest or easement on the property for soil excavation and Coyote Creek improvements associated with the Ogier Ponds ~~Geomorphic and Habitat Restoration~~ CM.

3.10.1.5 Naturally Occurring Asbestos

Asbestos is a known carcinogen, and inhalation of asbestos may result in lung cancer or mesothelioma. Exposure and disturbance of rock and soil that contains asbestos can result in the release of fibers to the air and consequent exposure to the public. As noted in Section 3.10.1.2, CARB has identified asbestos as a TAC. NOA is commonly associated with serpentine and ultramafic rock types.

The area located west of Anderson Lake is identified by the State of California as containing ultramafic rock (CDOC 2000) (refer to **Figure 3.10-2**). Ultramafic rock within this area mainly consists of serpentinite, as well as peridotite and gabbro within the Franciscan Complex. NOA is located within most of the Franciscan Formation rock types that underlay the majority of the dam footprint and associated spillway, portals, HLOWs, and tunnels, and the BHBA (URS 2021a). NOA is also located within some rock types associated with the Santa Clara Formation located at the dam and existing spillway, low-level outlet trench, and portal (URS 2021a 2021c). The serpentinite that underlays the dam and spillway foundations and portals, tunnels, and shafts associated with the LLOWs and HLOWs and was found to contain the highest concentration of NOA, ranging from 1 percent to 30 percent (URS 2021b). NOA detected in most of the other Franciscan Complex rock types, and the Santa Clara Formations had concentrations generally lower than 1 to 2 percent (URS 2021b).

Disturbance of soil with greater than 1 percent NOA is considered Class II asbestos work that requires specific training, monitoring, and respiratory protection. Soils with less than 1 percent NOA are not considered asbestos containing material, but protective measures would still be required for soil-disturbing activities (URS 2021b). As described above, serpentine and other ultramafic rock containing NOA at concentrations greater than 0.25 percent were determined to be present within Anderson Lake County Park, located west of the dam at 2187 Cochrane Road (Northgate 2020a). Geologic formations associated with NOA were also detected at the Giancola property located west of the dam, at 2290A Cochrane Road (Northgate 2020b).

In addition, serpentinite can contain chromium, cobalt, nickel, and other metals and elements may be present at elevated concentrations in the Franciscan Complex that may result in air quality concerns if they are disturbed during construction (URS 2021a). A discussion of these metals is included in Section 3.3, *Air Quality*.

3.10.1.6 Valley Fever

Valley Fever—sometimes called “San Joaquin Valley fever” or “desert rheumatism”—is an infection caused by a soil-dwelling fungus (Coccidioides) that, when inhaled, can affect the lungs, causing respiratory symptoms including cough, fever, chest pain, and tiredness. Valley Fever can be contracted as a result of ground disturbing activities and may be common in soil types throughout the Project study area. There are no commercially available tests to detect this fungus in soil. In 2021, Santa Clara County reported 65 cases indicating the fungus that causes Valley Fever was present in Santa Clara County (CDPH 2021).

3.10.2 Regulatory Setting

This section summarizes laws, regulations, and policies pertinent to the evaluation of the Project's impacts related to hazards and hazardous materials.

3.10.2.1 Federal Laws, Regulations, and Policies

Comprehensive Environmental Response, Compensation, and Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), also called the Superfund Act (42 USC section 9601 et seq.), is intended to protect the public and the environment from the effects of prior hazardous waste disposal and new hazardous material spills. Under CERCLA, the USEPA has the authority to seek out the parties responsible for hazardous materials releases, and to assure their cooperation in site remediation (USEPA 2020a). CERCLA also provides federal funding (the "Superfund") for the remediation of hazardous materials contamination. The Superfund Amendments and Reauthorization Act (SARA) of 1986 (PL 99-499) amends some provisions of CERCLA and provides for a Community Right-to-Know program.

The USEPA has the authority to implement CERCLA in all 50 states and all U.S. territories, using a variety of enforcement tools. The identification, monitoring, and remediation of Superfund sites are usually coordinated by state environmental protection and/or waste management agencies.

When potentially responsible parties cannot be identified or located, or when responsible parties fail to act, the USEPA has the authority to remediate abandoned and/or historical sites where hazardous materials contamination is known to exist and to pose a human health hazard.

Pursuant to CERCLA, the USEPA maintains the National Priorities List of uncontrolled or abandoned hazardous waste sites identified for priority remediation under the Superfund program. Sites are identified for listing on the basis of the USEPA's hazard ranking system, or if they meet certain other requirements, such as a designation of one site by a state or territory or if the Agency for Toxic Substances and Disease Registry issues a public health advisory.

Resource Conservation and Recovery Act

The Resource Conservation and Recovery Act (RCRA) (42 USC section 6901 et seq.) was enacted in 1976 as an amendment to the Solid Waste Disposal Act to address the nationwide generation of municipal and industrial solid waste. RCRA gives the USEPA authority to control the generation, transportation, treatment, storage, and disposal of hazardous waste, including underground storage tanks storing hazardous substances. RCRA also establishes a framework for the management of non-hazardous solid wastes (USEPA 2020b). RCRA addresses only active and future facilities; it does not address abandoned or historical sites, which are covered by CERCLA (see preceding section).

RCRA was updated in 1984 by the passage of the federal Hazardous and Solid Waste Amendments (HSWA), which require the gradual phasing out of land disposal of wastes. HSWA also increased the USEPA's enforcement authority, and established more stringent hazardous waste management standards, including a comprehensive underground storage tank program.

Occupational Safety and Health Administration

OSHA is responsible at the federal level for ensuring worker safety. OSHA sets federal standards for implementation of workplace training, exposure limits, and safety procedures for the handling of hazardous substances (as well as other hazards). These standards, codified in 29 CFR Part 1910, address issues that range in scope from walking and working surfaces, to exit routes and emergency planning, to hazardous materials and personal protective equipment (PPE). They include exposure limits for a wide range of specific hazardous materials, as well as requirements that employers provide PPE to their employees wherever it is necessary (29 CFR section 1910.132).

U.S. Department of Transportation Hazardous Materials Transportation Act

The USDOT Hazardous Materials Transportation Act (HMTA) (49 USC Chapter 51) was enacted in 1975 and regulates the interstate transport of hazardous materials and wastes. The HMTA specifies driver training requirements, load labeling procedures, and container design and safety requirements. Transporters of hazardous wastes must also meet the requirements of other statutes, such as the RCRA. The HMTA requires that carriers report accidental releases of hazardous materials to the USDOT as soon as is practicable. Incidents that must be reported include deaths, injuries requiring hospitalization, and property damage exceeding $50,000. The USDOT, the Federal Highway Administration, and the Federal Railroad Administration are the agencies responsible for administering the HMTA. This law may apply to the transportation of hazardous materials to or from the Project Area, if such materials are identified or required as part of Project construction or long-term operations and maintenance activities.

Federal Insecticide, Fungicide, and Rodenticide Act

The Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) (7 USC section 136 et seq.) was enacted in 1947. The purpose of FIFRA is to establish federal jurisdiction over the distribution, sale, and use of pesticides. Key provisions of FIFRA require pesticide applicators to pass a licensing examination for status as "qualified applicators," create a review and registration process for new pesticide products and provide for thorough and understandable labeling that includes instructions for safe use.

3.10.2.2 State Laws, Regulations, and Policies

California Emergency Services Act

Under the Emergency Services Act of 2015, the State of California developed an emergency response plan to coordinate emergency services provided by federal, state, and local agencies. Rapid response to incidents involving hazardous materials or hazardous waste is an important part of the plan, which is administered by the California Office of Emergency Services (Cal OES). This office coordinates the responses of other agencies, including the USEPA, the California Highway Patrol, the nine RWQCBs, the various air quality management districts, and county disaster response offices (Cal OES 2021 ~~2017~~).

Safe Drinking Water and Toxic Enforcement Act of 1986 (Proposition 65)

Proposition 65, officially known as the Safe Drinking Water and Toxic Enforcement Act of 1986, protects the state's drinking water sources from being contaminated with chemicals known to cause cancer, birth defects or other reproductive harm, and requires businesses to inform Californians about exposures to such chemicals. Proposition 65 requires the State to maintain and update a list of chemicals known to the State to cause cancer or reproductive toxicity (OEHHA 2021).

California Occupational Safety and Health Administration Standards

Worker exposure to contaminated soils and vapors, or possibly to contaminated groundwater, is subject to monitoring and personal safety equipment requirements that are established in the California Department of Industrial Relations, Division of Occupational Safety and Health (Cal/OSHA) regulations (CCR Title 8). Workers who are in direct contact with contaminated soil or groundwater are required to perform all activities in accordance with a site-specific health and safety plan, as outlined in Cal/OSHA standards (California Department of Industrial Relations 2021). CRC Title 8 regulations include requirements for Valley fever protection and exposure.

Asbestos Airborne Toxic Control Measure for Construction, Grading, Quarrying, and Surface Mining Operations

The CARB has established the Asbestos ATCM for Construction, Grading, Quarrying, and Surface Mining Operations to minimize the generation of asbestos from earth disturbance or construction activities (17 California Code of Regulations [CCR] Section 93105). The Asbestos ATCM applies to any project that would include sites to be disturbed in a geographic ultramafic rock unit area, or an area where NOA, serpentine, or ultramafic rocks are determined to be present. Under the ATCM, prior to any grading activities at a development site, a geologic analysis is required to determine if serpentine rock is present. If NOA is found at a development site, preparation of an Asbestos Health and Safety Program and an Asbestos Dust Mitigation Plan (ADMP) are required. These plans require approval by the BAAQMD before construction begins.

California Government Code Section 65962.5

California Government Code section 65962.5 requires CalEPA to develop, at least annually, an updated Cortese List (CalEPA 2021). The DTSC is responsible for a portion of the information contained in the Cortese List. Other state and local government agencies, including the State Water Board and the California Integrated Waste Management Board, are required to provide additional hazardous material release information for the Cortese List.

Hazardous Waste Control Act

The Hazardous Waste Control Act of 1972 created the Hazardous Waste Management Program, which is similar to, but more stringent than, the federal program under RCRA. The Hazardous Waste Control Act is implemented by regulations contained in Title 26 of the CCR. These regulations list more than 800 materials that may be hazardous and establishes criteria for their identification, packaging, and disposal. Under the Hazardous Waste Control Act and 26 CCR, hazardous waste generators must complete a manifest that accompanies the waste from the generator to the transporter to the ultimate disposal location. Copies of the manifest must be filed with DTSC.

Motor Vehicle Code

In addition to the RCRA hazardous waste transportation standards, California regulates the transportation of hazardous waste originating or passing through the state. State regulations are contained in the CCR, Title 13, Vehicle Code. Hazardous waste must be regularly removed from generating sites by licensed hazardous waste transporters. Transported materials must be accompanied by hazardous waste manifests.

The California Highway Patrol (CHP) and Caltrans are responsible for enforcing federal and state regulations pertaining to the transport of hazardous materials through California. The CHP enforces materials and hazardous waste labeling and packaging regulations that prevent leakage and spills of material in transit and provides information to cleanup crews in the event of an incident. Vehicle and equipment inspection, shipment preparation, container identification, and shipping documentation are all part of the responsibility of the CHP. The CHP conducts regular inspections of licensed transporters to assure regulatory compliance. The CHP and Caltrans also respond to hazardous materials transportation emergencies. Caltrans has emergency chemical spill identification teams at locations throughout the state.

California Department of Pesticide Regulation, Pesticides and Pest Control Operations

The USEPA has delegated primary authority to the California Department of Pesticide Regulation (CDPR) to enforce federal and state laws pertaining to the proper and safe use of pesticides. County Agricultural Commissioners (CAC) and their staffs are largely responsible for the in-field enforcement of CDPR’s pesticide use regulations in California’s 58 counties. Personnel from CDPR’s headquarters and CDPR field staff provide training, coordination, technical, and legal support to the counties.

Title 3 CCR, Division 6, describes the role of CDPR and provides guidance related to pesticide regulatory programs; pesticides (including pesticide registration and the identification and use of restricted materials); licensing, work requirements, and pesticide-related worker safety during pest control operations; and environmental protection for groundwater, air quality, aquatic and marine environments, surface water, and compost. The CACs, on behalf of CDPR, are responsible for the enforcement of these human health and environmental protections in the field.

California Environmental Protection Agency Unified Program

CalEPA oversees California’s Unified Program which protects Californians from hazardous waste and hazardous materials by ensuring that local regulatory agencies apply statewide standards when permits are issued and conduct inspections and enforcement activities. Specifically, the Unified Program consolidates the administration, permit, inspection, and enforcement activities of the following environmental and emergency management programs: Aboveground Petroleum Storage Act Program, Area Plans for Hazardous Materials Emergencies, California Accidental Release Prevention Program, Hazardous Materials Business Plan Program, Hazardous Material Management Plan and Hazardous Material Inventory Statements (California Fire Code), Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and UST Program.

California Underground Storage Tank Law

The California Underground Storage Tank Law (Title 23 CCR section 2630 or California Health and Safety Code section 25280) establishes requirements for the underground storage of hazardous substances. Title 23 CCR sections 2631 and 2632 specify the design, construction, and monitoring requirements for all new underground storage tanks. Title 23 CCR sections 2633 and 2634 specify alternate design, construction, and monitoring requirements for underground storage tanks installed before January 1, 1997, which only store motor vehicle fuel. Title 23 sections 2635 and 2636 specify requirements for all new underground storage tanks, piping, and secondary containment systems.

California Valley Fever Regulations

Regulations covering Valley Fever are promulgated in CCR, Title 8, *Industrial Relations*, in the sections summarized below.

- Section 3203, Injury and Illness Prevention: This section requires employers to establish and implement a written Injury and Illness Prevention Program (IIPP) that shall identify the person or persons with authority and responsibility for implementing the IIPP, establish a system for ensuring that employees are trained to recognize and comply with safe and healthy work practices, and establish a system for communicating with employees in a form readily understandable by all affected employees on matters relating to occupational safety and health.
- Section 5141, Control of Harmful Exposures: This section requires that harmful exposures shall be prevented by engineering controls whenever feasible. Whenever engineering controls are not feasible or do not achieve full compliance, administrative controls shall be implemented if practicable. Control by respiratory protective equipment shall be used to prevent harmful exposures as follows: (1) during the time period necessary to install or implement feasible engineering controls; (2) where feasible engineering controls and administrative controls fail to achieve full compliance; and (3) in emergencies.
- Section 5144, Respiratory Protection: This section establishes the permissible practice for the use of respiratory protection: (1) In the control of those occupational diseases caused by breathing air contaminated with harmful dusts, fogs, fumes, mists, gases, smokes, sprays, or vapors, the primary objective shall be to prevent atmospheric contamination. This shall be accomplished as far as feasible by accepted engineering control measures. When effective engineering controls are not feasible, or while they are being instituted, appropriate respirators shall be used pursuant to this section. (2) Respirators shall be provided by the employer when such equipment is necessary to protect the health of the employee.

3.10.2.3 Regional and Local Laws, Regulations, and Policies

San Francisco Bay Regional Water Quality Control Board

In 2000, the San Francisco Bay RWQCB first published human health risk-based screening levels (RSL) for over 100 commonly detected contaminants at sites with impacted soil and groundwater. The RSLs were revised in 2003 to become environmental screening levels (ESL), and their scope broadened to include direct exposure screening levels for construction and trench workers, and ecological risks and nuisance/gross contamination concerns (SWRCB 2020). The ESLs are conservative risk-based screening levels initially informed by USEPA Region 9 Preliminary Remediation Goals and CalEPA California Human Health Screening Levels. Although initially developed to regulate water quality for the San Francisco Bay Basin Water Quality Control Plan, the conservative, risk-based ESLs have been adopted by many California regulatory agencies as default screening levels to evaluate risk to human health and the environment.

Bay Area Air Quality Management District

The BAAQMD plans for and regulates air quality in the SFBAAB, including the county, through a comprehensive program of planning, regulation, enforcement, technical innovation, and promotion of the understanding of air quality issues. The BAAQMD responsibilities include the preparation of plans and programs for the attainment of the NAAQS and CAAQS, adoption and enforcement of rules and regulations, and issuance of permits for stationary sources. The BAAQMD also inspects stationary sources, responds to citizen complaints, monitors ambient air quality and meteorological conditions, and implements other programs and regulations required by the Clean Air Act and California Clean Air Act.

Projects located within the SFBAAB are subject to BAAQMD's rules and regulations. Specific rules applicable to the Project and alternatives includes the BAAQMD administration of 17 CCR section 93105: *Asbestos ATCM for Construction, Grading, Quarrying and Surface Mining Operations*. According to the BAAQMD Asbestos ATCM Regulatory Advisory (BAAQMD 2002):

> The ATCM applies to road construction and maintenance, construction and grading operations, and quarries and surface mines when the activity occurs in an area where naturally-occurring asbestos is likely to be found. Areas are subject to the regulation if they are identified on maps published by the Department of Conservation as ultramafic rock units or if the BAAQMD or owner/operator has knowledge of the presence of ultramafic rock, serpentine, or naturally-occurring asbestos on the site. The ATCM also applies if ultramafic rock, serpentine, or asbestos is discovered during any operation or activity.

If the ATCM is found to apply, then (BAAQMD 2002):

> Construction projects that will disturb more than one acre must prepare and obtain district approval for an asbestos dust mitigation plan. The plan must specify how the operation will minimize emissions and must address specific emission sources. Regardless of the size of the disturbance, activities must not result in emissions that are visible crossing the property line.

Exemptions may be granted (BAAQMD 2002):

1) if a geological evaluation demonstrates that ultramafic rock or serpentine is not likely to be found;
2) for road construction and maintenance activities in a remote location; or
3) for the processing of rock from an alluvial deposit.

3.10.3 Methodology and Approach to Impact Analysis

This impact analysis considers whether the construction and operation of the Project would result in significant adverse impacts to the environment as a result of hazards and hazardous materials. The analysis is based on a review of information and data that has been collected within the Project Area and discussed above in Section 3.10.1 *Environmental Setting*. The analysis considers temporary impacts, or short-term impacts that may occur during the 7-year construction period, and permanent impacts, or impacts considered to be long-term and/or those that would result from ongoing operations and maintenance activities.

The direct effects of the Project are described and evaluated according to significance criteria from Appendix G of the *CEQA Guidelines*, discussed below.

The assessment of impacts for the purposes of this section has been divided into construction related impacts and operation related impacts by Project ~~project~~ component, as identified in and described in **Table 2-1** of Chapter 2, *Project Description*. Each Project ~~project~~ component has been analyzed to determine if the construction or operation of that component would create a significant hazard to the public and environment through the routine transport, use of, disposal of, or the accidental release of hazardous materials; emit or handle hazardous materials within 0.25 miles of a school; be located on a hazardous materials site; ~~or~~ impair the implementation of an adopted emergency response plan or evacuation plan; or expose the public to Valley Fever.

The Project would be regulated by the various laws, regulations, and policies summarized above in Section 3.10.2, *Regulatory Setting*. Compliance by the Project with applicable federal, state, and local laws and regulations is assumed in this analysis and local and state agencies would be expected to continue to enforce applicable requirements to the extent that they do so now. Note that compliance with many of the regulations would be a condition of permit approval.

3.10.3.1 Seismic Retrofit Construction

The location and nature of Seismic Retrofit components construction activities are considered in the context of known existing hazardous materials sites, and the proximity of the proposed activities to local schools. The potential for Seismic Retrofit construction activities to result in a significant impact to the environment and public associated with hazards and hazardous materials is evaluated. As described in Section 3.0, *Introduction*, the baseline for evaluating Seismic Retrofit construction effects is the existing conditions following completion of the FOCP upgrades to the existing dam and reservoir facilities. The baseline for review of known locations that support, or have supported, land uses that resulted in hazardous materials being present onsite is based on 2021 data for the Cortese List.

3.10.3.2 Conservation Measures Construction

The potential for Conservation Measures-related construction activities to result in a significant impact to the environment and public associated with hazards and hazardous materials is evaluated. As described in Section 3.0, *Introduction*, the baseline for evaluating impacts related to the construction and operation of conservation measures is the existing conditions following completion of the FOCP upgrades to the existing dam and reservoir facilities. The baseline for the Cortese List is based on review of 2021 data of known locations that support, or have supported, land uses that resulted in hazardous materials being present onsite.

Conservation measures included in the Project and that require construction activities and long-term operation are:

- Ogier Ponds CM

- Maintenance of the North Channel Reach ~~Extension~~
- Maintenance Activities at the Live Oak Restoration Reach
- Sediment Augmentation Program
- Phase 2 Coyote Percolation Dam CM

3.10.3.3 Construction Monitoring

Construction monitoring activities are not considered in the impact analysis, as monitoring would involve data and information collection and assessment, using small numbers of vehicles and equipment These activities would be unlikely to result in significant adverse impacts related to hazards and hazardous materials. Therefore, impacts of construction monitoring are not evaluated further in this section.

3.10.3.4 Post-Construction Anderson Dam Facilities Operations and Maintenance

The potential for operational changes proposed for nonemergency flow releases following the completion of construction of the Seismic Retrofit components to result in a significant impact to the environment and public associated with hazards and hazardous materials is evaluated. As described in Section 3.0, *Introduction*, the baseline for evaluating impacts is existing conditions at the time of EIR preparation modified by FOCP implementation. The newly retrofitted Anderson Dam and associated infrastructure would be maintained per the existing Valley Water DMP. Maintenance of the original Anderson Dam facilities, pre-FOCP improvements, were previously evaluated in the Final DMP Program EIR prepared in January 2012 (SCH No. 2011082077; Valley Water 2012). Impacts related to hazards and hazardous materials associated with the Seismic Retrofit post-construction maintenance activities would not differ substantially from those impacts identified in the DMP EIR and reduced through DMP BMPs. Therefore, no new impacts would occur as a result of post-construction dam maintenance activities, and these activities are not further in this section.

3.10.3.5 Post-Construction Conservation Measures Operations and Maintenance

The Conservation Measures components focus on improving fish habitat (e.g., gravel augmentation, separation of Coyote Creek from Ogier Ponds) and fish passage enhancement. The Conservation Measures components would operate passively, without mechanical or human intervention, and have been planned in accordance with Anderson Dam Reservoir flow releases. While data collection and assessment may indicate that individual Conservation Measures are not meeting success criteria specified for those measures, the modified Conservation Measure actions that would be undertaken to attain the prescribed success criteria would be similar to the original actions and would not result in additional impacts. In the event that modified Conservation Measures would result in additional environmental impacts that are outside of the scope of impacts analyzed in this EIR, additional CEQA review would be undertaken at that time.

Through the implementation of the operations and maintenance phase of the Conservation Measures components in accordance with existing Valley Water maintenance plans, including the SMP, no additional impacts are likely. Therefore, these topics are not discussed further in this section.

3.10.3.6 Post-Construction Project ~~ADSRP~~ and FAHCE Adaptive Management

The Project and FAHCE AMP would guide post-construction adaptive management of Project ~~project~~ flow operations and Conservation Measures that have met their specified success criteria, as defined through the regulatory permitting process. As required by the FAHCE AMP framework, the Project and FAHCEAMP includes four key elements: measurable objectives, monitoring, adaptive actions, and reporting. Monitoring and adaptive actions involve physical activities that could have environmental impacts.

The Project and FAHCE AMP monitoring program would inform selection of adaptive management measures to implement in response to management triggers, and includes compliance, validation, effectiveness, and long-term monitoring. Validation, effectiveness, and long-term trend monitoring would build on existing Valley Water monitoring infrastructure (e.g., hydrologic monitoring network), water quality monitoring (e.g., water temperature monitoring network), habitat monitoring (e.g., habitat mapping), and fisheries monitoring (e.g., VAKI Riverwatcher, PIT tag detectors, genetics sampling, electrofishing surveys). Impacts of these monitoring activities are not evaluated in the impact analysis because they would not involve new ground disturbance or other psychically disruptive activities that would trigger a hazards or hazardous materials impact evaluated in this section. Therefore, monitoring impacts are not discussed further in this section.

The Project and FAHCE AMP identifies triggers for adaptive actions to help meet measurable objectives. Adaptive actions for FAHCE flows and imported water storage/releases would include refinements of reservoir releases, which would have impacts and benefits similar to the original FAHCE flows and imported water storage/releases. Adaptive actions for Conservation Measures would generally include minor construction and maintenance actions, whose impacts would be similar but less than those from original Conservation Measure construction. Impacts of these adaptive actions are not evaluated in the impact analysis because, as implied, the magnitude of the impacts of the Conservation Measures evaluated in this section would be greater than those of the adaptive actions. The BMPs, VHP Conditions, AMMs, and mitigation measures applied to the impacts of the Conservation Measures to achieve a less-than-significant level for hazards and hazardous materials would be at least as adequate, if not more, to achieve the same level of impact or less for the adaptive actions. Therefore, impacts of adaptive management are not discussed further in this section.

3.10.3.7 Applicable Best Management Practices and VHP Conditions

As noted in Chapter 2, *Project Description*, Valley Water would incorporate BMPs, VHP Conditions, and AMMs, to avoid and minimize adverse effects on the environment that may result from the Project. AMMs are project specific measures that have been identified to supplement the standard Valley Water BMPs to minimize impacts from Project construction and implementation. All relevant BMPs, VHP Conditions, and AMMs for the Project are included in Appendix A, *Best Management Practices and Santa Clara Valley Habitat Conservation Plan Conditions, Avoidance and Minimization Measures, and Mitigation Measures.* ~~*Incorporated in the Project.*~~ There are no relevant VHP conditions that would apply to hazards and hazardous materials. BMPs and AMMs that are relevant to hazards and hazardous materials impacts include the following measures:

AQ-1[1]**:** Use Dust Control Measures – would require dust and air quality management measures, including implementation of BAAQMD's BMPs for dust suppression – would reduce impacts on neighboring land uses (e.g., residences and commercial land uses), recreationists that may be in the vicinity of the Project, and workers throughout Project component construction and implementation.

~~**HM-7**: Restrict Vehicle and Equipment Cleaning to Appropriate Locations – would reduce potential hazardous impacts associated with cleaning construction vehicles and equipment by located these activities away from sensitive habitats.~~

HM-8: Ensure Proper Vehicle and Equipment Fueling and Maintenance – would reduce the potential for spills or accidental releases of hazardous materials by locating these activities away from sensitive habitats.

HM-9: Ensure Proper Hazardous Materials Management – would reduce the potential for spills or accidental releases of hazardous materials by following applicable local, state, and federal laws regarding hazardous materials management.

HM-10: Utilize Spill Prevention Measures– would reduce the potential for spills of hazardous materials by requiring spill prevention plans to be developed and implemented during the construction and operation of all Project ~~project~~ components.

HM-13: Avoid Impact from NOA – would reduce potential impacts associated with NOA through the implementation of worker safety measures and dust control.

WQ-6: Limit Impact of Concrete Near Waterways – would reduce potential hazardous impacts related to concrete in waterways by limiting where concrete is mixed away from sensitive habitats.

WQ-17: Manage Sanitary and Septic Waste – would reduce the potential for hazardous waste spillage associated with temporary sanitary facilities through ongoing upkeep of these facilities and limiting the location of sanitary and septic facilities away from sensitive habitats.

TR-1: Incorporate Public Safety Measures – would require fences, barriers, lights, flagging, guards, and signs to ~~will~~ be installed as determined appropriate by the public agency having jurisdiction, to give adequate warning to the public of the construction and of any dangerous condition to be encountered as a result thereof.

[1] BMP AQ-1 includes a requirement that vehicles on unpaved roads observe a 15 mile per hour speed limit. To make this BMP feasible for the Project, this BMP would be modified to allow haul trucks to travel up to 25 miles per hour on unpaved roads, except in areas with naturally occurring asbestos where the 15 miles per hour limit would still apply.

3.10.3.8 Thresholds of Significance

For the purposes of this analysis, the Project would result in a significant effect related to hazards and hazardous materials if it would:

> **HAZ-1:** Create a significant hazard to the public or the environment from the routine transport, use, or disposal of hazardous materials;
>
> **HAZ-2:** Create a significant hazard to the public or the environment through reasonably foreseeable upset or accident conditions involving the release of hazardous materials into the environment;
>
> **HAZ-3**: Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school;
>
> **HAZ-4**: Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would create a significant hazard to the public or the environment;
>
> **HAZ-5**: Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan.

3.10.3.9 Issues Dismissed from Further Review

CEQA Guidelines Appendix G suggests that projects may have a significant effect on hazardous and hazardous materials if the Project is located within an airport land use plan or, where such a plan has not been adopted, the Project is located within two miles of a public airport or public use airport that would result in a safety hazard or cause excessive noise for people residing or working in the Project Area (criterion e). Because the Project Area is not located within an airport land use plan or within 2 miles of a public or private use airport, there would be no impact, and this threshold is dismissed from further environmental evaluation.

CEQA Guidelines Appendix G suggests that projects may have a significant effect on hazardous and hazardous materials if they would expose people or structures to a significant risk of loss, injury, or death involving wildland fires (criterion g). The Project's potential for exposing people or structures to wildland fires is analyzed in Section 3.22, *Wildfire,* under Impact WF-4 (criterion g).

3.10.4 Impact Analysis

***Impact HAZ-1: Create a significant hazard to the public or the environment from the routine transport, use, or disposal of hazardous materials* (Less than Significant)**

Seismic Retrofit Construction

During the construction of the Seismic Retrofit Project components, hazardous materials commonly associated with construction activities (e.g., gasoline, diesel fuel, paints, solvents, hydraulic fluid) would be present and handled onsite, as well as transported to and from the Project Area. These materials would be primarily found within construction equipment but may also be stored onsite at the staging areas, and transported, as necessary, to work areas. The handling of hazardous materials during Seismic Retrofit construction may expose the public to hazardous materials and wastes if adequate precautions are not taken to prevent spills and/or the release of these materials. Adverse human health effects related to hazardous materials exposure may include illness from exposure to toxic substances. Adverse effects to the environment may include the degradation of natural resources.

The Project would comply with all relevant federal, State, and local laws, regulations, and policies designed to minimize hazardous materials impacts to the public and environment. In accordance with OSHA and Cal/OSHA requirements, presented in Section 3.10.2, safety procedures for the handling of hazardous substances would be followed. These include workplace training and safety procedures, emergency planning and evacuation, and the preparation of a site-specific health and safety plan for workers who are in direct contact with contaminated soil or groundwater.

In addition, implementation of the following Valley Water BMPs will further reduce hazardous materials impacts:

- H-7 Restrict Vehicle and Equipment Cleaning to Appropriate Locations - would reduce the potential for exposing the public and the environment to hazardous materials by restricting the washing of vehicles and equipment to occur in approved areas
- HM-8 Ensure Proper Vehicle and Equipment Fueling and Maintenance - ensuring proper vehicle and equipment fueling and maintenance methods are followed
- HM-9 Ensure Proper Hazardous Materials Management - implementing proper handling and storage of hazardous materials measures
- WQ-6 Limit Impact of Concrete Near Waterways - implementing proper concrete curing techniques; and
- WQ-17 Manage Sanitary and Septic Waste - requiring all temporary sanitary facilities provided during construction to be located where overflow spillage would not enter a watercourse directly

When implemented, BMPs HM-8, ~~HM-7 through~~ HM-9, ~~and BMPs~~ WQ-6, and WQ-17 would minimize the Project's generation of hazardous materials and wastes associated with the routing transport, use, and disposal of hazardous materials, and would not create a significant hazard to the public or the environment. This impact would be less than significant.

Conservation Measure Construction

Similar to construction activities associated with the dam seismic retrofit, construction of the conservation measures would involve the routine use, transport, and disposal of hazardous materials and waste such as fuel, paint, or solvents. Such handling and disposal of hazardous materials and waste may create a hazard to the public or the environment if adequate precautions are not taken and a spill were to occur. Through the implementation of Valley Water BMPs HM-8, ~~HM-7 through~~ HM-9, ~~and BMPs~~ WQ-6, and WQ-17, as defined above, the potential for exposing the public and the environment to hazardous materials and wastes would be minimized. Through the implementation of BMPs HM-8, ~~HM-7 through~~ HM-9, ~~and BMPs~~ WQ-6, and WQ-17, conservation measure construction impacts associated with the routine transport, use, and disposal of hazardous materials would not create a significant hazard to the public or the environment. This impact would be less than significant.

Post-construction Anderson Dam Facilities Operations

Through the implementation of the Project, flows would be modified in Coyote Creek as releases from Anderson Dam operations are made consistent with the FACHE operational rule curves. The changes in releases from the dam would not result in changes to the transport, use, or disposal of hazardous materials; fuel use for the generator and periodic painting of structures would resume at pre-Project levels. In addition, with the removal of the Hydroelectric Facility (see Section 2.5.4.13), the net use of fuel and paint would decrease, resulting in a beneficial impact to the public or the environment.

Significance Conclusion Summary

During the construction of the Project's seismic retrofit components, implementation of BMPs HM-8, ~~HM-7 through~~ HM-9, HM-13, WQ-6, and WQ-17 would reduce the potential for the Project to create a hazard to the public and environment through the routine use, transport, and/or disposal of hazardous materials or wastes during construction activities. The Project would also be required to comply with applicable federal, State, and local laws and regulations related to hazardous materials management that would minimize impacts to both the public, including recreators, and construction workers. During operations, the changes in releases from the dam would not result in the transport, use, or disposal of hazardous materials, Therefore, the Project would not create a significant hazard to the public or environment through the routing transport, use, and disposal of hazardous materials and wastes. This impact would be **less than significant.**

Impact HAZ-2: Create a significant hazard to the public or the environment through reasonably foreseeable upset or accident conditions involving the release of hazardous materials (Less than Significant with Mitigation)

Seismic Retrofit Construction

Hazardous materials used during construction of the Seismic Retrofit construction (e.g., gasoline, diesel fuel, paints, solvents, hydraulic fluid) may be released to the environment through the upset or through accidental conditions if adequate precautions are not taken or could release hazardous materials into the environment, such as soil or groundwater contamination from accidental spills or inappropriate disposal practices. Such a release could harm aquatic or terrestrial organisms and pose a hazard to construction workers and/or the public, which would be considered a significant impact.

In order to minimize these potential impacts, the Project would comply with all relevant federal, state, and local laws, regulations, and policies related to hazardous materials, including CERCLA, RCRA, and CCR, designed to minimize impacts of upset or accident conditions. Furthermore, implementation of Valley Water BMPs ~~HM-7~~ HM-8, HM-9, WQ-6 and WQ-17, as discussed above, would minimize the accidental release of hazardous materials. While compliance with existing regulations and implementation of BMPs would reduce impacts, additional measures would be required to reduce impacts to less than significant, as discussed below.

Within the Seismic Retrofit components area, NOA is known to be present within the Franciscan Formation and Santa Clara Formation rock types that underlay the majority of the dam and spillway area ~~(see **Figure 3.10-2**)~~. Although there is no health threat if asbestos fibers in soil and rocks remain undisturbed and do not become airborne, Seismic Retrofit components construction activities would involve excavating serpentinite and other materials containing NOA from the dam and spillway foundations, portals, tunnels, and shafts associated with the outlet works (URS 2021a). These activities could release NOA into the air and may expose the public, including recreators and construction workers to airborne asbestos. Activities that may generate dust emissions that contain NOA include clearing and grading, tunneling, and hauling materials within and offsite (URS 2021d). These activities may expose and create a hazard to the public, including recreators, and construction workers to NOA. In addition, ground disturbing activities could release other hazardous materials into the air (e.g., fungus that causes Valley Fever, as analyzed in Impact HAZ-6). This would be a significant impact.

Compliance with BAAQMD's ATCM for Construction, which requires preparation of an ADMP ~~asbestos dust mitigation plan~~ that specifies how emissions will be minimized and implementation of Valley Water BMP-AQ-1 (Use Dust Control Measures), described in Section 3.3, *Air Quality,* and BMP HM-13 (Avoid Impacts from NOA) would minimize potential impacts from NOA. These requirements would include implementing fugitive dust control measures (e.g., watering disturbed surfaces, covering materials in haul trucks) and worker safety measures when working in areas that support serpentine soils. However, a significant impact may still occur to the public, including recreators and construction workers, when ground-disturbing activities occur in areas that support NOA. An overview of mitigation measures is included below, with a full description provided below under *Mitigation Measures*.

Implementation of **Mitigation Measure HAZ-1** (Construction and Grading Operations Dust Control Measures) requires implementation of dust control measures in all areas potentially containing NOA or other respiratory hazards during construction to reduce the potential for such hazards to become airborne. To minimize potential impacts that may occur through the track-out of materials from work areas to public roadways, **Mitigation Measure HAZ-2** (Track-out Control Measures for Roads from NOA-Containing Areas) and **Mitigation Measure HAZ-3** (Traffic Control Measures within Construction Areas) will be implemented. Additional dust control measures will be implemented for earthmoving and tunneling activities as required by **Mitigation Measure HAZ-4** (Dust Control Measures During Earthmoving Activities) and **Mitigation Measure HAZ-5** (Dust Control Measures During Tunneling Activities). Although excavated materials containing NOA from the portals, tunnels, and structures would be disposed of onsite, disposal of these materials may present a significant impact if they are not appropriately managed and disposed of properly. Implementation of **Mitigation Measure HAZ-6** (Separation of Rock Containing NOA) will require the separation of rock containing NOA from other rock types during construction. This measure will also require the preparation of an excavated materials management plan specifying how excavated rock will be properly classified managed and disposed during construction to minimize adverse impacts. Furthermore, the ADMP would include an air monitoring program for fugitive dust levels and NOA that would verify that mitigation measures and BMPs are effective in areas containing NOA.

Through the implementation of **Mitigation Measures HAZ-1** through **HAZ-6**, impacts related to hazards to the public or the environment through the reasonably foreseeable upset or accident conditions involving the release of hazardous materials would be less than significant with mitigation.

Conservation Measure Construction

Similar to construction activities associated with Seismic Retrofit components, hazardous materials used during construction (e.g., gasoline, diesel fuel, paints, solvents, hydraulic fluid) may be released to the environment through the upset or through accidental conditions if adequate precautions are not taken. Construction activities could also release hazardous materials into the environment, such as soil or groundwater contamination from accidental spills or inappropriate disposal practices. Such a release could harm aquatic or terrestrial organisms and pose a hazard to construction workers and/or the public, which would be considered a significant impact.

In order to minimize these potential impacts, the Project would comply with all relevant federal, State, and local laws, regulations, and policies related to hazardous materials, including CERCLA, RCRA, and CCR, designed to minimize impacts of upset or accident conditions. Furthermore, implementation of Valley Water BMPs ~~HM-7~~ HM-8, HM-9, WQ-6 and WQ-17, as discussed above, would minimize the accidental release of hazardous materials.

Construction of the Conservation Measures would not occur in areas that support Franciscan Formation and Santa Clara Formation rock types that support NOA; ~~(see Figure 3.10 2);~~ therefore, the potential for upset or accident conditions involving exposure to NOA is not likely during construction. Therefore, this impact would be less than significant. Furthermore, the implementation of **Mitigation Measure HAZ-1** (Construction and Grading Operations Dust Control Measures) and **Mitigation Measure HAZ-4** (Dust Control Measures During Earthmoving Activities) would further minimize potential impacts that may occur through earth moving activities. ~~Post-Construction Anderson Dam Facilities Operations~~

Post-Construction Anderson Dam Facilities Operations

Through the implementation of the Project, flows would be modified in Coyote Creek as releases from Anderson Dam operations are made consistent with the FAHCE ~~FHACE~~ operational rule curve. The changes in releases from the dam would not result in reasonably foreseeable upset or accident conditions involving the release of hazardous materials. Therefore, there would be **no impact** to the public or the environment from Anderson Dam operations.

Significance Conclusion Summary

Construction of the Project would comply with all relevant federal, state, and local laws, regulations, and policies designed to minimize hazardous materials impacts, including CERCLA, RCRA, and CCR. Implementation of BMPs HM-8~~7~~ through HM-10, WQ-6, and WQ-17, as discussed above, would further minimize potential impacts to the public or the environment from reasonably foreseeable upset or accident conditions involving the release of hazardous materials. For Seismic Retrofit construction, compliance with BAAQMD's ATCM for Construction, and BMP-AQ-1 and BMP HM-13, would minimize potential impacts from NOA and other respiratory hazards, but they would still be significant. **Mitigation Measures HAZ-1** through **HAZ-6**, as discussed below would further reduce NOA and other respiratory hazards impact such that there would be no significant hazard to the public or the environment through reasonably foreseeable upset or accident conditions. The ADMP would include an air monitoring program for fugitive dust levels and NOA that would verify that mitigation measures and BMPs are effective in areas containing NOA. This impact would therefore be **less than significant with mitigation**.

Mitigation Measures

HAZ-1 Construction and Grading Operations Dust Control Measures.

The Construction Contractor for Seismic Retrofit and Conservation Measure construction will ~~shall~~ be responsible for implementing the following construction and grading operations dust control measures, including in areas containing NOA (as identified in ~~Figure 3.10 2 and~~ the NOA and Metals Evaluation Report [URS 2021c)], consistent with the BAAQMD NOA Technical Advisory Requirements:

- Prior to any ground disturbance, areas to be graded or excavated will ~~shall~~ be kept adequately wet with water to prevent visible emissions from the release of particulate matter into the air.
- Adequately wetted areas will ~~shall~~ produce no visible dust emissions as determined by the Construction Engineer.
- Storage piles will ~~shall~~ be kept adequately wetted, treated with a chemical dust suppressant, or covered when material is not being added to or removed from the pile. Covers, when used, will ~~shall~~ be physically secured and maintained throughout their use.
- Equipment will ~~shall~~ be washed down after use and prior to the equipment moving from the work area onto a paved public road. Wheels will ~~shall~~ be washed prior to moving equipment from construction areas containing NOA to areas that do not contain NOA.
- Haul roads will ~~shall~~ be kept wet while in use on days that trucks drive on the roads. If haul roads are on a disturbed surface, they will ~~shall~~ be kept wet at all times, including days when they are not in use.
- Construction vehicles will ~~shall~~ be limited to 15 miles per hour (mph) or less. Vehicles hauling NOA-containing materials outside NOA-containing areas will ~~shall~~ have loads wetted and/or covered such that no visible emissions are generated and will ~~shall~~ also not exceed 15 mph. Under no circumstances will ~~shall~~ haul trucks be allowed to transport NOA-containing materials in a manner that allows visible particle emissions from either the wheels while traveling over NOA-containing materials or from the load of the truck.
- Suspension of all excavation, grading, and demolition activities will ~~shall~~ be required when wind speeds exceed 20 mph for a minimum of 30 minutes. Wind speeds will ~~shall~~ be monitored using a weather station located onsite with alarms set for this condition, and an automated data recording system. An automated text message will be sent to the Engineer when wind speeds exceed the specified limits. The Engineer will ~~shall~~ enforce suspension of activities, as feasible. The construction manager will ~~shall~~ keep records of time periods where excavation, grading, and demolition activities are suspended due to high wind conditions.
- Work boot wash stations will ~~shall~~ be provided at various locations throughout the site, including at site offices, staging areas, and other locations, as appropriate.

HAZ-2 Track Out Control Measures for Roads from NOA-Containing Areas.

The Construction Contractor for Seismic Retrofit Construction will ~~shall~~ be responsible for implementing the track out prevention and control measures listed below. These measures will ~~shall~~ be implemented to prevent track out from construction areas to public roads.

- Removal of any visible track-out from a paved public road at any location where vehicles exit the work site; this will ~~shall~~ be accomplished using a wet sweeping or a high efficiency particle air (HEPA) filter equipped vacuum device at the end of 10-hour shift or at least one time per day
- Installation will ~~shall~~ require one or more of the following track-out prevention measures:
  - A gravel pad to clean the tires of exiting vehicles
  - A tire shaker
  - A wheel wash system
  - Pavement extending for not less than 50 consecutive feet from the intersection with the paved public road. Any excess water from the wheel wash system will be collected as necessary or used for dust control in NOA-containing areas. Wash water will ~~shall~~ be treated with an oil/water separator prior to use for dust control.

Vehicles that exit the site to a public paved road from unpaved construction areas will ~~shall~~ utilize track-out prevention and control measures will ~~shall~~ include the following:

- Utilization of at least one of the track-out prevention and control measures described above
- Removal of any visible track-out from a paved public road at any location where vehicles exit the work site; this will ~~shall~~ be accomplished using wet sweeping or a HEPA filter or vacuum device equipped with an equivalent particulate filter at the end of each day.

HAZ-3 Traffic Control Measures within NOA-Containing Construction Areas.

The Construction Contractor for Seismic Retrofit Construction will ~~shall~~ be responsible for implementing these traffic control measures. These measures will ~~shall~~ apply to traffic within construction areas containing NOA.

- A maximum vehicle speed limit of 15 mph or less
- One of the following:
  - Paving or maintaining a minimum 3-inch depth gravel cover with a silt content of less than 5 percent and asbestos content of less than 0.25 percent (as determined using an approved bulk test method by the Construction Engineer)
  - Watering road surfaces every 2 hours of active operations or sufficiently often to keep the area adequately wetted
  - Applying chemical dust suppressants consistent with manufacturer's directions and any other permit requirements; or
  - Any other measure deemed as effective as those above and approved by the BAAQMD as part of the ADMP
- Sweeping daily (with water sweepers) all paved access roads, parking areas, and staging areas

HAZ-4 Dust Control Measures During Earthmoving Activities.

The Construction Contractor for Seismic Retrofit and Conservation Measure construction will ~~shall~~ be responsible for implementing one or more of the following dust control measures during earthmoving activities (e.g., pushing of soils, using bulldozers, breaking rock, hauling materials to disposal sites) in areas containing NOA:

- Pre-wetting the ground to the depth of the anticipated cuts, as feasible, and wetting the ground concurrent with excavation;
- Suspending grading operations when winds exceeding 20 miles per hour for more than 30 minutes generate visible dust emissions crossing the limits of work. Limits of work are shown on Project ~~project~~ Plans;~~.~~
- Application of water prior to any land clearing; or
- Any other measure deemed as effective as those above and approved by the BAAQMD as part of the ADMP.

HAZ-5 Dust Control Measures During Tunneling Activities.

The Construction Contractor for Seismic Retrofit construction will ~~shall~~ be responsible for implementing dust control measures during tunneling work. Tunneling work will ~~shall~~ be conducted in a manner that minimizes the potential for the generation of dust, especially if it has the potential to contain asbestos and will ~~shall~~ include the following measures:

- Spraying water on the tunnel and shaft work surfaces, and the materials derived from them, prior to excavation/disturbance and whenever these materials are being excavated or disturbed. Water will ~~shall~~ be applied as frequently as needed in order to avoid the generation of visible dust.
- The use of compressed air for drilling, jack hammering or for any other activity with the potential to disturb NOA will ~~shall~~ be prohibited unless means (e.g., wet suppression, HEPA vacuum dust collection system) are implemented to capture and control all the airborne dust generated by the process, as feasible.
- Whenever rock or soil are being removed using mechanical processes, such as shovels, excavator buckets, hydraulic breakers, water will ~~shall~~ be applied as frequently as needed to avoid the generation of visible dust.

HAZ-6 Separation of Rock Containing NOA.

The Construction Contractor for Seismic Retrofit construction will ~~shall~~ prepare and implement an Excavated Materials Management Plan for Valley Water review and approval prior to construction that specifies how excavated rock will ~~shall~~ be properly classified and managed during construction activities. During construction activities, rock containing NOA will ~~shall~~ be separated from other rock types by following the procedures included in the Excavated Materials Management Plan. The Excavated Materials Management Plan will ~~shall~~ detail the documentation and procedural requirements for tracking soil quality, managing stockpiles, and disposal of soil and debris from excavation including soils containing NOA. Implementation of this plan will ~~shall~~ require the proper disposal of NOA containing material, which would include the covering of trucks transporting soil and rock that contains NOA~~, and the disposal of NOA-containing materials at a licensed disposal facility permitted to accept the waste~~.

***Impact HAZ-3: Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school* (Less than Significant with Mitigation)**

Seismic Retrofit Construction

As described in Section 3.10.1.2, no existing or proposed schools are located within 0.25 mile of the Project Area; however, a juvenile detention facility, William F. James Boys Ranch (Boys Ranch), is located within 0.11 miles of Anderson Dam. Although this facility is not a typical public school, this facility is considered a sensitive receptor for analyzing hazardous impacts that may result from the Project. Based on the location of the facility on private property outside of the Project work area, the handling of hazardous materials would not impact the Boys Ranch. However, the emission of hazardous emissions may result in impacts to the William F. James Boys Ranch during construction related activities associated with Seismic Retrofit elements that would be implemented at the Seismic Retrofit component work area if BMPs and AMMs are not implemented. As discussed under Impact HAZ-1, the Project would comply with all relevant federal, State, and local laws, regulations, and policies designed to minimize hazardous materials, substances, and waste impacts. The Project would also implement the Valley Water BMPs HM-8~~7~~ through HM-10, as discussed above, that would minimize the accidental release of hazardous materials. However, through any ground disturbance there is the potential to discover previously unknown hazardous materials. The Seismic Retrofit component work area is also located in a known area for NOA, as discussed under Impact HAZ-2, and Valley Fever, as discussed in Impact HAZ-6. Project construction activities have the potential to impact the Boys Ranch through the emission of unknown hazardous materials, NOA, or Valley Fever.

Project excavation and grading may encounter soil contamination from past land uses, including agricultural production and boat maintenance. This could expose adjacent land uses, including the Boys Ranch, to the release of hazardous emissions. Although implementation of BMP HM-9 (Ensure Proper Hazardous Materials Management) would include measures for proper handling, storage, and disposal of hazardous materials, if contaminated soil is unexpectedly encountered and appropriate testing is not conducted, a significant impact could result. Implementation of **Mitigation Measure HAZ-7** (Soil Testing and Proper Disposal of Potentially Contaminated Soils) would reduce this impact by requiring soil testing if known or suspected contaminated soil is encountered during construction activities before work activities can continue in the area of discovery. With adherence to **Mitigation Measure HAZ-7**, Project construction activities would not create a significant hazard to the Boys Ranch associated with the emission of hazardous materials. This impact would be less than significant with mitigation.

The release of NOA or the fungus that causes Valley Fever into the air from clearing, earthmoving activities, hauling, and tunneling activities could expose occupants at the Boys Ranch to airborne hazards, such as asbestos or Valley Fever. The exposure of children to asbestos is of particular concern because their longer life expectancy (from the date of exposure) exceeds the latency period for asbestos-related disease. Thus, impacts related to exposure of sensitive receptors to NOA during seismic retrofit construction affecting William F. James Boys Ranch would be significant. For the reasons explained under Impact HAZ-2, implementation of **Mitigation Measures HAZ-1** through **HAZ-6** would reduce construction impacts associated with NOA and other airborne hazards on the William F. James Boys Ranch to less than significant with mitigation. The potential impacts from Valley Fever are discussed below in Impact HAZ-6.

Conservation Measures Construction

None of the Conservation Measures components would be located within 0.25 mile of an existing or proposed school. Therefore, construction of the Conservation Measures components would not emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within 0.25 mile of a school. Therefore, no impact would occur.

Post-Construction Anderson Dam Facilities Operations

Post-construction dam operations pursuant to the FAHCE operational rule curves would not emit hazardous emissions or involve handling hazardous or acutely hazardous materials, substances, or waste. Therefore, no impact would occur.

Significance Conclusion Summary

The Project would comply with all relevant federal, State, and local laws and regulations designed to minimize impacts from hazardous materials management. Implementation of BMPs ~~HM-7~~ HM-8 through HM-10, HM-13, AQ-1 would reduce these impacts, but impacts associated with disturbance of contaminated soils and NOA would still be significant. **Mitigation Measures HAZ-1** through **HAZ-7** would reduce construction impacts on the William F. James Boys Ranch to **less than significant with mitigation.**

Mitigation Measures

HAZ-1 Construction and Grading Operations Dust Control Measures

HAZ-2 Track Out Control Measures for Roads from NOA-Containing Areas

HAZ-3 Traffic Control Measures within NOA-Containing Construction Areas

HAZ-4 Dust Control Measures During Earthmoving Activities

HAZ-5 Dust Control Measures During Tunneling Activities

HAZ-6 *Separation of Rock Containing NOA*

HAZ-7 Soil Testing and Proper Disposal of Potentially Contaminated Soils

In the event that soils suspected of being contaminated (on the basis of visual, olfactory, or other evidence) are exposed during site grading or excavation activities, Valley Water or its Contractor will ~~shall~~ test the excavated soil prior to removal to determine whether hazardous levels of contaminants are present and work will ~~shall~~ stop. The test results will ~~shall~~ be compared against state environmental screening levels (ESLs) from the San Francisco RWQCB for the protection of human health, groundwater quality, and terrestrial receptors. If hazardous levels of contaminants (as defined by federal and State regulations) are present, the materials will ~~shall~~ be taken to a permitted hazardous waste facility. The required handling, storage, and disposal methods will depend on the types and concentrations of chemicals identified in the soil. Any site investigations or remedial actions will ~~shall~~ comply with applicable federal, State, and local hazardous materials and waste laws. The presence of known or suspected contaminated soil will ~~shall~~ require testing and investigation procedures to be supervised by a hazardous materials specialist who meets State and federal regulatory requirements related to handling and disposal of hazardous materials.

Impact HAZ-4: Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would create a significant hazard to the public or the environment (Less than Significant with Mitigation)

Seismic Retrofit Construction

As described in Section 3.10.1.3, the Project Area does not include listed hazardous materials sites (SWRCB 2021a, DTSC 2021). Based on a review of readily available public information for the Project Area, no listed hazardous materials sites or existing hazardous material contamination are present within the Project Area. Although contaminated properties are known to exist within 0.75 miles of the Seismic Retrofit Project Area, cleanup actions for these sites are in progress or have been completed. Furthermore, Seismic Retrofit construction activities would not take place on any of the contaminated properties located within 0.75 miles of the Project.

Nevertheless, there is potential to discover unknown hazardous materials sites within the Seismic Retrofit Project Area involving construction activities. Construction would involve soil excavation and grading, and thus, could encounter soil contamination from past chemical uses, including agricultural and boat maintenance. This would expose construction workers, the public, and the environment to hazards. Although implementation of BMP HM-9 (Ensure Proper Hazardous Materials Management) would include measures for proper handling, storage, and disposal of hazardous materials, if contaminated soil is unexpectedly encountered and appropriate testing is not conducted, a significant impact could result. Implementation of **Mitigation Measure HAZ-7** (Soil Testing and Proper Disposal of Potentially Contaminated Soils) would reduce this impact by requiring soil testing if known or suspected contaminated soil is encountered during construction activities and implementing appropriate disposal actions. With adherence to **Mitigation Measure HAZ-7**, Seismic Retrofit construction would not create a significant hazard to the public or the environment associated with known hazardous materials sites. Impacts would be less than significant with mitigation.

Conservation Measure Construction

As described in Section 3.10.1.3, there are no sites included on the Cortese List located within any of the Conservation Measure Project components areas. However, several closed hazardous material sites are located immediately adjacent to or within 0.75 mile of the Ogier Ponds Conservation Measure and the Phase 2 Coyote Percolation Dam Conservation Measure construction areas. Although the cleanup actions for these sites have been completed, Conservation Measure components construction activities may encounter soil contaminants from the LUST sites or contaminated soils from past agricultural chemical uses. This could expose the public or the environment to significant hazards, resulting in a significant impact. Implementation of BMP HM-9 (Ensure Proper Hazardous Materials Management) would include measures for proper handling, storage, and disposal of hazardous materials, but impacts would be significant. **Mitigation Measure HAZ-7** would reduce this impact by requiring soil testing if known or suspected contaminated soil is encountered during construction activities, and disposal of any contaminated soils consistent with regulatory requirements. Thus, with adherence to **Mitigation Measure HAZ-7**, the Project would not create a significant hazard to the public or the environment associated with known hazardous materials sites. Impacts would be less than significant with mitigation.

Post-Construction Anderson Dam Facilities Operations

Operation activities at the retrofitted dam facilities would not be located on a hazardous materials site. In addition, reservoir level fluctuations associated with post-construction operations would not have the potential to disturb previously unknown contaminated soils as all soils in the reservoir have been previously disturbed. Also, reservoir flow releases do not involve ground disturbing activities. Because operation of the Anderson Dam facilities would not be located on a hazardous site or disturb previously unknown contaminated soils that may expose the public or the environment to significant hazards, no impact would occur.

Significance Conclusion Summary

While no Cortese List sites are located within the Project Area, there are a total of three sites located within 0.75 mile of the Seismic Retrofit construction area and 17 sites located within 0.75 mile of the construction areas for Conservation Measures. Implementation of BMP HM-9 would include measures for proper handling, storage, and disposal of hazardous materials, but impacts would be significant and **Mitigation Measure HAZ-7**, described below would minimize impacts to the public or environment should unknown contaminants or contaminated soil be encountered during construction activities, reducing the impact to less-than-significant levels. As described above, operation of the Project would not result in any effects related to known or unknown hazardous materials sites as operations related activities would not involve ground-disturbing activities. Thus, with implementation of **Mitigation Measure HAZ-7**, the Project would not create a significant hazard to the public or the environment associated with known hazardous materials sites. Therefore, impacts would be **less than significant with mitigation**.

Mitigation Measures

HAZ-7 Soil Testing and Proper Disposal of Potentially Contaminated Soils.

Impact HAZ-5: Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan (Less than Significant with Mitigation)

Seismic Retrofit Construction

Construction of Seismic Retrofit components would involve operation and temporary storage of large construction equipment, transport and storage of construction materials and supplies, and construction worker commute trips to and from the area. Furthermore, the 0.8-mile (4,200-linear-foot) section of Cochrane Road extending between Coyote Road and Malaguerra Avenue (or portions of this segment) would be closed to through traffic for varying durations throughout the construction period. **Figure 3.19-7** ~~**14**~~ (see Section 3.19, *Transportation*) identifies the current traffic routes and Cochrane Road detours and closures during construction. All these activities could disrupt traffic flow and require use of adjacent roads, which could interfere with emergency response or evacuation procedures/plans, which would be a significant impact.

Although the Santa Clara County Emergency Operations Plan (EOP) and City of San José EOP are applicable to the Project, they do not identify any ~~no~~ evacuation routes ~~are identified that are~~ specific to the study area. However, ~~primary~~ emergency evacuation routes ~~are~~ identified along the east side of the reservoir in the Holiday Lake Estates and Jackson Oaks communities~~. in the Holiday Lake Estates and Jackson Oaks Emergency Travel Routes and Temporary Refuge Areas~~

~~(Community Emergency Response Team n.d.) and~~ include East Dunne Avenue, Holiday Drive, and Monterey Road. Local roadways within Holiday Lake Estates and Jackson Oaks that connect to East Dunne Avenue, and therefore ~~which~~ would provide emergency evacuation access as well, are Quail Lane/Copper Hill Drive, Jackson Oaks Drive, ~~and~~ Oak Leaf Drive, and~~.~~ Thomas Grade ~~is identified as a secondary emergency travel route~~ (see **Figure 3.17-1** in Section 3.17, *Public Services*). All evacuation routes are directed west of US 101 (Community Emergency Response Team n.d.). Cochrane Road is the main thoroughfare for the area west of Anderson Dam and provides access to US 101. Additionally, the Project includes construction of temporary access/haul roads that would not serve as evacuation routes to the public, but would allow emergency access to the Project site. Specifically, Las Animas Road and Shingle Valley Road would provide emergency access to the Project site via the constructed Shingle Valley Haul Road. As such, under existing conditions it could be used by emergency vehicles and may be used as an evacuation route by residents in the event of an emergency.

Although most construction vehicles and equipment would be traveling on temporary access roads/haul routes within Anderson Reservoir area and on the dam, construction traffic entering and exiting the construction area could cause short-duration traffic delays or stoppages on surrounding roadways. In addition, Cochrane Road may also be closed or partially closed from Coyote Road to Malaguerra Avenue to through traffic for varying durations during construction. A significant impact would occur if local roadways were to be substantially impacted from construction activities such that they interfered with emergency response and community evacuation routes.

Implementation of BMP TR-1 (Incorporate Public Safety Measures), which requires construction warning signs, safety fencing, and detours would minimize the potential impact, impacts on emergency response and evacuation plans could still be significant.

Implementation of **Mitigation Measure PS-1** (Prepare and Implement Traffic Management Plan) would reduce impacts on emergency response and emergency evacuation plans by requiring the preparation and implementation of a Transportation Management Plan (TMP) and coordination with local and state agencies. The notification and communication requirements of the TMP would require that local emergency managers, such as California Department of Forestry and Fire Protection (CAL FIRE), the Morgan Hill Fire Department, the San José Fire Department, and South Santa Clara Fire Protection District, would be made aware of any traffic management issues and would share that information with first responders. Coordination with these agencies would minimize the impact on evacuation and emergency response access in the event of a wildfire.

Implementation of **Mitigation Measure WF-1** (Reduce Emergency Response and Evacuation Interference during Construction and Develop a Response and Evacuation Strategy [RES] ~~Coordinate with Emergency Response Agencies~~) would further reduce the impact of construction traffic and closure of public roads by requiring coordination with local and State emergency response and fire agencies and require preparation of a RES, which will maintain adequate emergency response and evacuation routes throughout construction of the Project in locations where Project construction substantially interferes with emergency access and evacuation. ~~to identify an alternative temporary refuge area or provide emergency access to the Woodchopper's Flat Picnic Area during Seismic Retrofit construction in the event of an emergency.~~

Therefore, construction for Seismic Retrofit components would not physically interfere with an emergency response plan or emergency evacuation plan with the implementation of BMP-1 and **Mitigation Measures PS-1** and **WF-1**. Impacts would therefore be less than significant with mitigation.

Conservation Measures Construction

Construction of the Conservation Measure components would be similar to those described above for the Seismic Retrofit of the Anderson Dam. Construction of the Conservation Measures components would involve operation and temporary storage of large construction equipment, construction worker trips, and transportation of construction materials that have the potential to disrupt traffic flow along roads adjacent to staging and construction areas required for the Conservation Measures components. The presence of large construction equipment and haul trucks and increased vehicles on the roadways due to construction workers trips could impede movement and access of emergency response vehicles or cause localized congestion, thereby interfering with emergency response and evacuation procedures.

However, as described above, implementation of BMP TR-1 (Incorporate Public Safety Measures), **Mitigation Measure PS-1**, and **Mitigation Measure WF-1** would reduce impacts less than significant with mitigation.

Post-Construction Anderson Dam Facilities Operations

Post-construction releases from Anderson Reservoir into Coyote Creek would conform to FAHCE operating rule curves, as described in Chapter 2, *Project Description*. Operations changes to the reservoir flow releases would not require additional staff at the Anderson Dam facility and would only require minimal employee vehicle trips for routine inspection and maintenance compared to the existing conditions baseline (i.e., existing conditions at the time of EIR preparation modified by FOCP implementation). Furthermore, operations changes would not require the use of equipment that could impede traffic flow or require temporary lane closures. Thus, no operational changes would occur that could result in delays interfering with emergency response and evacuation routes/plans. Therefore, post-construction operations would not impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan. No impact would occur.

Significance Conclusion Summary

During construction of Seismic Retrofit and Conservation Measure components, the presence of large construction equipment and haul trucks and increased vehicles on the roadways due to construction worker trips could impede movement and access of emergency response vehicles or cause localized congestion, thereby interfering with emergency response and evacuation procedures. Implementation of BMP TR-1 ~~and PS-AMM-2~~ will reduce impacts on emergency response and evacuation plans, but they will still be significant. Implementation of **Mitigation Measure PS-1** (Prepare and Implement Traffic Management Plan) would require the preparation and implementation of a TMP and coordination with State and local agencies and, for Seismic Retrofit Construction, **Mitigation Measure WF-1** (Reduce Emergency Response and Evacuation Interference during Construction and Develop a Response and Evacuation Strategy ~~an Emergency Action Plan~~) would require that all emergency response agencies are notified in advance of all lane and road closures and would require that evacuation routes are passable or alternate routes are available to allow residents to evacuate an affected area. These mitigation measures would reduce Seismic Retrofit and Conservation Measure construction impacts on emergency response and evacuation plans to less-than-significant levels. Post-construction operations and FAHCE adaptive management actions would not interfere with traffic flow including emergency response. Thus, impacts related to impairing implementation of or interfering with an adopted emergency response plan or emergency evacuation routes/plans would be **less than significant with mitigation.**

Mitigation Measures

PS-1 Prepare and Implement Traffic Management Plan

WF-1 Reduce Emergency Response and Evacuation Interference during Construction and develop a Response and Evacuation Strategy (RES) a~~n Emergency Action Plan~~

Impact HAZ-6: Create a significant hazard to construction workers or the public through exposure to Valley Fever during Construction Activities **(Less than Significant with Mitigation)**

All Project Components during Construction

As discussed in Section 3.10.1.6, *Valley Fever*, construction activities have the potential to release the soil-dwelling fungus (Coccidioides) that can cause Valley Fever. Such a release could pose a hazard to construction workers and/or the public, which would be a significant impact.

In order to minimize these potential impacts, the Project would comply with all relevant federal, state, and local laws, regulations, and policies related to hazardous materials, including the regulations in CCR Title 8, *Industrial Relations*, ~~d~~ which minimize exposure to California Valley Fever.

As discussed above in Impact HAZ-2, BAAQMD's ATCM for Construction and Valley Water BMP-AQ-1 (Use Dust Control Measures) would be implemented; they would minimize potential impacts from Valley Fever. These requirements would include implementing fugitive dust control measures (e.g., watering disturbed surfaces, covering materials in haul trucks) and worker safety measures when working in areas that may have the fungus that causes Valley Fever. However, a significant impact may still occur to construction workers and the public when ground-disturbing activities occur in areas that have the fungus that causes Valley Fever. As discussed in Impact HAZ-2, the following mitigation measures established to mitigate NOA would also further minimize risks from soil that may contain the fungus that causes Valley Fever:

- **Mitigation Measure HAZ-1** (Construction and Grading Operations Dust Control Measures)
- **Mitigation Measure HAZ-2** (Track-out Control Measures for Roads from NOA-Containing Areas)
- **Mitigation Measure HAZ-3** (Traffic Control Measures within NOA-Containing Construction Areas)
- **Mitigation Measure HAZ-4** (Dust Control Measures During Earthmoving Activities)
- **Mitigation Measure HAZ-5** (Dust Control Measures During Tunneling Activities)

Through the implementation of **Mitigation Measures HAZ-1** through **HAZ-5**, impacts related to hazards to the public or the environment through exposure to Valley Fever will be less than significant with mitigation.

All Project Components During Operations

Once constructed, there would be no further ground disturbing activities from construction equipment and workers, and no potential to disturb soil that may contain the fungus that causes Valley Fever. The recreational activities that occurred before the implementation of the Project would resume at the pre-Project levels and would therefore not constitute a changed condition. Therefore, during operations, there would be **no impact**.

Significance Conclusion Summary

No Valley Fever exposure impacts would occur during Project operations. For Project construction activities, BAAQMD's ATCM for Construction and Valley Water BMP-AQ-1 (Use Dust Control Measures) would minimize potential impacts from Valley Fever exposure. However, a significant impact may still occur to construction workers and the public when ground-disturbing activities occur in areas that have the fungus that causes Valley Fever. **Mitigation Measures HAZ-1** through **HAZ-5** that were established to mitigate NOA would also further minimize risks from soil that may contain the fungus that causes Valley Fever. Through the implementation of **Mitigation Measures HAZ-1** through **HAZ-5**, impacts related to hazards to the public or the environment through exposure to Valley Fever will be **less than significant with mitigation**.

Mitigation Measures

HAZ-1 Construction and Grading Operations Dust Control Measures

HAZ-2 Track Out Control Measures for Roads from NOA-Containing Areas

HAZ-3 Traffic Control Measures within NOA-Containing Construction Areas

HAZ-4 Dust Control Measures During Earthmoving Activities

HAZ-5 Dust Control Measures During Tunneling Activities

3.10.5 Cumulative Impacts

The geographic study area for the cumulative impact analysis for hazards and hazardous materials encompasses the future Project areas where hazards may occur.

This section describes the Project's contribution to cumulative impacts to hazards and hazardous materials, as summarized in **Table 3.10-2**.

Table 3.10-2. Summary of Project Impact Contribution to Cumulative Hazards and Hazardous Materials Impacts

Impact	Cumulatively Significant with FOCP?	Cumulatively Significant with other projects?	Incremental Project Contribution	Applicable Project Mitigation	Cumulatively Considerable after Mitigation?
Cumulative Impact HAZ-1: Create a significant hazard to the public or the environment from the routine transport, use, or disposal of hazardous materials	No	No	NCC	None	No
Cumulative Impact HAZ-2: Create a significant hazard to the public or the environment through reasonably foreseeable upset or accident conditions involving the release of hazardous materials into the environment	Yes	Yes	CC	MM HAZ-1 MM HAZ-2 MM HAZ-3 MM HAZ-4 MM HAZ-5 MM HAZ-6	No
Cumulative Impact HAZ-3: Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school	Yes	Yes	CC	MM HAZ-1 MM HAZ-2 MM HAZ-3 MM HAZ-4 MM HAZ-5 MM HAZ-6 MM HAZ-7	No
Cumulative Impact HAZ-4: Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would create a significant hazard to the public or the environment	Yes	Yes	CC	MM HAZ-7	No
Cumulative Impact HAZ-5: Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan	No	No	NCC	MM PS-1 MM WF-1	No

Impact	Cumulatively Significant with FOCP?	Cumulatively Significant with other projects?	Incremental Project Contribution	Applicable Project Mitigation	Cumulatively Considerable after Mitigation?
Cumulative Impact HAZ-6: Create a significant hazard to construction workers or the public through exposure to Valley Fever during Construction Activities	Yes	Yes	CC	MM HAZ-1 MM HAZ-2 MM HAZ-3 MM HAZ-4 MM HAZ-5	No

Key: CC = cumulatively considerable; MM = Mitigation Measure; N/A = not applicable; NCC = not cumulatively considerable; S = significant

***Cumulative Impact HAZ-1: Create a significant hazard to the public or the environment from the routine transport, use, or disposal of hazardous materials* (Not Cumulatively Considerable)**

During the construction of the Seismic Retrofit and Conservation Measures, hazardous materials commonly associated with construction activities (e.g., gasoline, diesel fuel, paints, solvents, hydraulic fluid) would be present and handled onsite, as well as transported to and from the Project Area. These materials would be primarily found within construction equipment but may also be stored onsite at the staging areas, and transported, as necessary, to work areas.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if they occur at or near the Project sites including Anderson Reservoir and Coyote Creek and involve the handling or transport of hazardous material.

Cumulative Effects of Project with the FOCP

FOCP construction activities would involve the use and transport of similar materials as the Project, although not at the same time. Both projects create a potential hazard to the public and environment. Both projects are required to comply with all relevant federal, state, and local laws, regulations, and policies designed to minimize hazardous materials impacts to the public and environment. In accordance with OSHA and Cal/OSHA requirements, presented in Section 3.10.1 safety procedures for the handling of hazardous substances would be followed. The Project would implement Valley Water BMPs (~~HM-7,~~ HM-8, WQ-6, WQ-17) to minimize the chance of release of hazardous materials. With adherence to requirements of federal, state, and local regulations, and BMPs, cumulative impacts would not be significant, and the Project's contribution to hazards from the use and transport of hazardous materials would not be cumulatively considerable.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Projects in the same area as the reservoir, Conservation Measure sites, and Coyote Creek include the SMP, Coyote Creek Flood Protection Project, Santa Clara County Parks Planning Projects and Natural Resource Management, as well as development projects in the County where the use of large equipment would involve the use and transport of similar materials as the Project. All projects are required to comply with all relevant federal, state, and local laws, regulations, and policies designed to minimize hazardous materials impacts to the public and environment. As discussed above, the Project would also implement BMPs to minimize the chance of release of hazardous materials. With adherence to requirements of federal, state, and local regulations, and BMPs, cumulative impacts would not be significant, and the Project's contribution to hazards from the use and transport of hazardous materials would not be cumulatively considerable.

Significance Conclusion Summary

All Project construction activities would be performed in accordance with applicable state and federal regulations regarding the use, transport, and disposal of hazardous materials. In addition, the Project would implement BMPs to further reduce the potential for release of hazardous materials. With adherence to requirements of federal, state, and local regulations, and BMPs, cumulative impacts would not be significant and the Project's contribution to cumulative hazards to the public and the environment from the routine transport, use, or disposal of hazardous materials is **not cumulatively considerable**.

Mitigation Measure

No mitigation is required.

Cumulative Impact HAZ-2: Create a significant hazard to the public or the environment through reasonably foreseeable upset or accident conditions involving the release of hazardous materials **(Not Cumulatively Considerable)**

Hazardous materials used during construction of the Seismic Retrofit construction (e.g., gasoline, diesel fuel, paints, solvents, hydraulic fluid) may be released to the environment through the upset or through accidental conditions if adequate precautions are not taken. NOA is known to be present within the Franciscan Formation and Santa Clara Formation rock types that underlay much of the dam and spillway area. Construction activities would involve excavating serpentinite and other materials containing NOA from the dam and spillway foundations, portals, tunnels, and shafts associated with the outlet works (URS 2021a) and expose the public, including recreators, and construction workers to airborne asbestos. Activities that may generate dust emissions that contain NOA include clearing and grading, tunneling, and hauling materials within and offsite (URS 2021d).

Cumulative projects, plans, and programs could result in incrementally adverse impacts if they occur at or near the Project sites and involve the potential for the release of hazardous materials.

Cumulative Effects of Project with the FOCP

FOCP construction activities would involve the use of similar materials as the Project, although not at the same time. Both projects create a potential hazard of accidental spill to the environment. Both projects are required to comply with all relevant federal, state, and local laws, regulations, and policies designed to minimize hazardous materials impacts to the public and environment. The Project would implement Valley Water BMPs (~~HM-7,~~ HM-8, WQ-6, WQ-17) to minimize the chance of release of hazardous materials. With adherence to requirements of federal, state, and local regulations, and BMPs, cumulative impacts other than NOA impacts would not be significant, and the Project's contribution to hazards from the use and transport of hazardous materials would not be cumulatively considerable.

FOCP construction activities also occurred in serpentinite materials with the potential to release NOA. The Project would extend the period that public in the area is subject to dust containing NOA, therefore the cumulative NOA impact is significant pre-mitigation and the Project's contribution to airborne NOA is cumulatively considerable.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Projects in the same area as the reservoir, Conservation Measure sites, and Coyote Creek include the SMP, Coyote Creek Flood Protection Project, Santa Clara County Parks Planning Projects and Natural Resource Management, as well as development projects in the County where the use of large equipment would involve the use of similar materials as the Project. All projects are required to comply with all relevant federal, state, and local laws, regulations, and policies designed to minimize hazardous materials impacts to the public and environment. As discussed above, the Project would also implement BMPs to minimize the chance of release of hazardous materials. With adherence to requirements of federal, state, and local regulations, and BMPs, cumulative impacts other than NOA impacts would not be significant, and the Project's contribution to the risk of accidental release of hazards materials would not be cumulatively considerable.

Other projects and activities in the Franciscan Formation and Santa Clara Formation rock types such as Santa Clara County Parks Planning Projects and Natural Resource Management and other Valley Water dam improvement projects could also release dust containing NOA. The impact is significant, and the Project's contribution to this hazard is cumulatively considerable.

Significance Conclusion Summary

All Project construction activities would be performed in accordance with applicable state and federal regulations regarding the use hazardous materials. In addition, the Project would implement BMPs to further reduce the potential for spill of hazardous materials. The Project's contribution to cumulative hazards to the environment from hazardous material releases other than NOA is not Cumulatively Considerable.

For Seismic Retrofit construction, compliance with BAAQMD's ATCM for Construction, and BMP-AQ-1 and BMP HM-13, would minimize potential impacts from NOA. The implementation of **Mitigation Measure HAZ-1** (Construction and Grading Operations Dust Control Measures), **Mitigation Measure HAZ-2** (Track Out Control Measures for Roads from NOA-Containing Areas), **Mitigation Measure HAZ-3** (Traffic Control Measures within NOA-Containing Construction Areas), **Mitigation Measure HAZ-4** (Dust Control Measures During Earthmoving Activities), **Mitigation Measure HAZ-5** (Dust Control Measures During Tunneling Activities), and **Mitigation Measure HAZ-6** (Separation of Rock Containing NOA) would reduce the Project's seismic retrofit construction contribution to significant cumulative NOA impacts to **not cumulatively considerable**

Mitigation Measures

HAZ-1 Construction and Grading Operations Dust Control Measures

HAZ-2 Track Out Control Measures for Roads from NOA-Containing Areas

HAZ-3 Traffic Control Measures within NOA-Containing Construction Areas

HAZ-4 Dust Control Measures During Earthmoving Activities

HAZ-5 Dust Control Measures During Tunneling Activities

HAZ-6 *Separation of Rock Containing NOA*

Cumulative Impact HAZ-3: Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school (Not Cumulatively Considerable)

No existing or proposed schools are located within 0.25 mile of the Project Area; however, a juvenile detention facility, William F. James Boys Ranch (Boys Ranch), is located within 0.11 mile of Anderson Dam. Although this facility is not a typical public school, this facility is considered a sensitive receptor for analyzing hazardous impacts that may result from the Project.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if they occur at or near the Boys Ranch Project and involve the potential for the release of hazardous materials.

Cumulative Effects of Project with the FOCP

FOCP construction activities would involve the use of similar materials as the Project, although not at the same time. Both projects create a potential hazard to the Boys Ranch. Both projects are required to comply with all relevant federal, state, and local laws, regulations, and policies designed to minimize hazardous materials impacts to the public and environment. The Project would implement Valley Water BMP HM-9 to minimize the chance of release of hazardous materials. With adherence to requirements of federal, state, and local regulations, and BMPs, cumulative impacts related to hazards from the use and transport of hazardous materials would not be significant, and the Project's contribution would not be cumulatively considerable**.**

FOCP construction activities also occurred in serpentinite materials with the potential to release NOA. However, the projects occur at different times. The Project would extend the time that the Boys Ranch would be subjected to NOA, therefore hazards from airborne NOA are cumulatively significant and the Project’s seismic retrofit construction is cumulatively considerable.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Projects near the Boys Ranch include the SMP and Santa Clara County Parks Planning Projects and Natural Resource Management, where the use of large equipment would involve the use of similar materials as the Project. All projects are required to comply with all relevant federal, state, and local laws, regulations, and policies designed to minimize hazardous materials impacts to the public and environment. As discussed above, the Project would also implement BMPs to minimize the chance of release of hazardous materials. With adherence to requirements of federal, state, and local regulations, and BMPs, cumulative impacts would not be significant, and the Project’s contribution to the risk to the Boys Ranch would not be cumulatively considerable**.**

The SMP and Santa Clara County Parks Planning Projects and Natural Resource Management projects have the potential to generate dust from Franciscan Formation and Santa Clara Formation rock types that may contain NOA. The release of NOA near the Boys Ranch is cumulatively significant and the Project’s contribution is cumulatively considerable.

Significance Conclusion Summary

All Project construction activities would be performed in accordance with applicable state and federal regulations regarding the use hazardous materials. In addition, the Project would implement BMPs to further reduce the potential for spill of hazardous materials that could impact the Boys Ranch. The Project’s contribution to less-than-significant cumulative hazards to the Boys Ranch from emissions or hazardous materials is Not Cumulatively Considerable.

For Seismic Retrofit construction, compliance with BAAQMD’s ATCM for Construction, and BMP-AQ-1 and BMP HM-13, would minimize potential impacts from NOA. The implementation of **Mitigation Measure HAZ-1** (Construction and Grading Operations Dust Control Measures), **Mitigation Measure HAZ-2** (Track Out Control Measures for Roads from NOA-Containing Areas),

Mitigation Measure HAZ-3 (Traffic Control Measures within NOA-Containing Construction Areas), **Mitigation Measure HAZ-4** (Dust Control Measures During Earthmoving Activities), **Mitigation Measure HAZ-5** (Dust Control Measures During Tunneling Activities), **Mitigation Measure HAZ-6** (Separation of Rock Containing NOA), and **Mitigation Measure HAZ-7** (Soil Testing and Proper Disposal of Potentially Contaminated Soils) would reduce the Project's contribution to significant cumulative NOA exposure cumulative impacts to **not cumulatively considerable**.

Mitigation Measures

HAZ-1 Construction and Grading Operations Dust Control Measures

HAZ-2 Track Out Control Measures for Roads from NOA-Containing Areas

HAZ-3 Traffic Control Measures within NOA-Containing Construction Areas

HAZ-4 Dust Control Measures During Earthmoving Activities

HAZ-5 Dust Control Measures During Tunneling Activities

HAZ-6 Separation of Rock Containing NOA

HAZ-7 Soil Testing and Proper Disposal of Potentially Contaminated Soils

Cumulative Impact HAZ-4: Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would create a significant hazard to the public or the environment **(Not Cumulatively Considerable)**

The Project Area does not include listed hazardous materials sites (SWRCB 2021a, DTSC 2021). Based on a review of readily available public information for the Project Area, no listed hazardous materials sites or existing hazardous material contamination are present within the Project Area. Although contaminated properties are known to exist within 0.75 mile of the Seismic Retrofit Project Area, cleanup actions for these sites are in progress or have been completed. Further, Seismic Retrofit and Conservation Measure construction activities would not take place on any of the contaminated properties located within 0.75 mile of the Project. Nevertheless, there is potential to discover unknown hazardous materials sites within the Project Area involving construction activities. Construction would involve soil excavation and grading, and thus, could encounter soil contamination from past chemical uses, including agricultural and boat maintenance. This would expose construction workers, the public, and the environment to hazards.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if they occur at or near the Project area or Coyote Creek where hazardous materials could be released to the environment.

Cumulative Effects of Project with the FOCP

FOCP construction activities would involve are similar to Project construction activities and both could encounter soil contamination from past chemical uses, including agricultural and boat maintenance. The cumulative impact is significant and the Project's contribution to this risk is cumulatively considerable.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Projects in the same area include the SMP, Coyote Creek Flood Protection Project, Santa Clara County Parks Planning Projects and Natural Resource Management, as well as development projects in the County. Any of these projects could encounter soil contamination from past chemical uses from historic manufacturing or agriculture. The cumulative impact is significant and the Project's contribution to this risk is cumulatively considerable.

Significance Conclusion Summary

Implementation of BMP HM-9 would include measures for proper handling, storage, and disposal of hazardous materials, but impacts would nevertheless be significant. Implementation of **Mitigation Measure HAZ-7** would minimize impacts to the public or environment should unknown contaminants or contaminated soil be encountered during construction activities. With **Mitigation Measure HAZ-7**, the Project's ~~s~~ contribution to significant cumulative impacts related to hazardous materials sites would be **not cumulatively considerable**

Mitigation Measures

HAZ-7 Soil Testing and Proper Disposal of Potentially Contaminated Soils

Cumulative Impact HAZ-5: Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan (Not Cumulatively Considerable)

Construction of Seismic Retrofit and Conservation Measure components would involve operation and temporary storage of large construction equipment, transport and storage of construction materials and supplies, and construction worker commute trips to and from the area, which could impede movement and access of emergency response vehicles or cause localized congestion, thereby interfering with evacuation procedures. Cochrane Road between Coyote Road and Malaguerra Avenue (or portions of this segment) would be closed to through traffic for varying durations throughout the construction period. The Project's impacts on emergency response or evacuation plans would be significant.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if they occur at or near the Project sites and create traffic or congestion on local roadways.

Cumulative Effects of Project with the FOCP

FOCP construction activities also involved large construction equipment, but activities take place at an earlier time. As there is no overlap in construction periods between the projects, there is no possibility for cumulative effects between the projects. The cumulative impact is less than significant.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Projects in the vicinity include the SMP, Santa Clara County Parks Planning Projects and Natural Resource Management activities, as well as development projects in the County could interfere~~nce~~ with emergency response or evacuation plans for various emergencies from additional vehicle trips on local roadways and localized congestion (impacts to emergency evacuation specific to wildland fires is addressed Section 3.22, *Wildfire*). However, these projects would not generate substantial traffic in the same area as the Project. The cumulative impact to adopted emergency response or evacuation plans is less than significant.

Significance Conclusion Summary

The Project would generate traffic and have significant impacts on emergency response or evacuation plans that would be reduced to less than significant levels through implementation of **Mitigation Measures PS-1 and WF-1**. However, there are no other projects that would create a simultaneous significant cumulative impact. The FOCP will be complete by the start of Project construction activities and other projects that may occur at the same time would not be expected to general significant traffic in the Project area that could create greater congestion. The Project's impacts on interference with adopted emergency response plans or emergency evacuation plans is **not cumulatively considerable.**

Mitigation Measures

PS-1 Prepare and Implement Traffic Management Plan.

WF-1 Reduce Emergency Response and Evacuation Interference during Construction and Develop a Response and Evacuation Strategy (RES) ~~Emergency Action Plan~~

Cumulative Impact HAZ-6: Create a significant hazard to construction workers or the public through exposure to Valley Fever during Construction Activities (Not Cumulatively Considerable)

No Valley Fever exposure impacts would occur during Project operations, However, construction of Seismic Retrofit and Conservation Measure components would involve soil disturbance that has the potential to release the soil-dwelling fungus (Coccidioides) that can cause Valley Fever that could pose a hazard to construction workers and/or the public. The Project's impacts relative to Valley Fever exposure would be significant.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if they occur at or near the Project sites and soil-disturbing activities and create fugitive dust.

Cumulative Effects of Project with the FOCP

FOCP construction activities also occur in areas with the potential for Valley Fever exposure. The Project would extend the period that public in the area is subject to Valley Fever. BAAQMD's ATCM for Construction and Valley Water BMP-AQ-1 (Use Dust Control Measures) reduce potential impacts from Valley Fever for both FOCP and the Project Therefore, the cumulative Valley Fever impact is significant pre-mitigation and the Project's contribution to Valley Fever is cumulatively considerable. The Project-specific analysis of Valley Fever relies on **Mitigation Measures HAZ-1 through HAZ-5** to mitigate Valley Fever impacts to less-than-significant levels. With these mitigation measures, the Project's contribution to cumulative impacts would be not cumulatively considerable.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Construction or operation of future projects, programs, and plans could overlap with the 15-year construction schedule that Seismic Retrofit components and Conservation Measures construction would occur. The construction of other probable future projects could generate fugitive dust in addition to that from the Project, potentially exposing workers and the public to Vally Fever.

As discussed above in Impacts HAZ-2 and HAZ-6, BAAQMD's ATCM for Construction and Valley Water BMP-AQ-1 (Use Dust Control Measures) would minimize potential impacts from Valley Fever for the Project, though exposure impacts may still be significant. These requirements include implementing fugitive dust control measures (e.g., watering disturbed surfaces, covering materials in haul trucks) and worker safety measures when working in areas that may have the fungus that causes Valley Fever. The Project-specific analysis of Valley Fever also relies on **Mitigation Measures HAZ-1 through HAZ-5** to mitigate Valley Fever impacts to less-than-significant levels.

Like the Project, it is assumed that probable future projects would comply with regulations in CCR Title 8, *Industrial Relations,* that provide protections from Valley Fever exposure., and with BAAQMD's ATCM for construction. Nevertheless, pre-mitigation, cumulative impacts of the Project and probable future projects combined could be significant, and the Project's contribution would be cumulatively considerable. With implementation of s, **Mitigation Measures HAZ-1 through HAZ-5** the Project's contribution to significant cumulative Valley Fever impacts would be not cumulatively considerable.

Significance Conclusion Summary

The Project would generate fugitive dust through soil disturbing construction activities, which have the potential to release Coccidioides that can cause Valley Fever. The Project's impact would be reduced ~~t~~ through compliance with applicable laws, regulations, and policies, including CCR Title 8; and implementation BAAQMD's ATCM for Construction and Valley Water BMP-AQ-1. The Project's impacts could nevertheless be significant, but reduced to less-than-significant levels by **Mitigation Measures HAZ-1 through HAZ-5**. Pre-mitigation, cumulative impacts of the Project, the FOCP, and probable future projects combined could be significant, and the Project's contribution would be cumulatively considerable. With implementation of **Mitigation Measures HAZ-1 through HAZ-5**, the Project's contribution to Valley Fever exposure impacts is **not cumulatively considerable.**

Mitigation Measures

3.11 Hydrology

This section evaluates Project impacts on hydrological resources within the study area, as defined below. The *CEQA Guidelines* significance criteria for hydrology addresses impacts related to the alteration of drainage patterns in a manner which would result in substantial erosion or siltation, flooding, exceed the capacity of stormwater drainage systems, provide substantial additional sources of polluted runoff, expose people or structures to a significant risk involving flooding, including flooding as a result of dam failure, or risk release of pollutants due to inundation from flood, tsunami, or seiche. *Groundwater Resources* is discussed separately in Section 3.12 and *Water Quality* is discussed in Section 3.14.

The study area used to assess impacts to hydrological resources is Anderson Reservoir, Anderson Dam, Coyote Creek below Anderson Dam, including the tidally inundated portion of lower Coyote Creek and the waters of San Francisco Bay to the confluence with Alviso Slough, the CWMZ, and lands in the immediate vicinity of Anderson Reservoir and Coyote Creek. Upper Penitencia Creek is in the study area; however, the Project would not result in changes to the hydrology of Upper Penitencia Creek, therefore it is not discussed in this section. See **Figure 2-2**.

The analysis of this section is based on key technical memos that are included in Appendix J, K, and L including:

- *Project Construction Operations Technical Memorandum* that defines the FOCP and Project facilities and construction schedule and reservoir operations with the Stage 1 Diversion System and the Stage 2 Diversion System
- *Potential Flood Impacts for Project* that analyzes the frequency and extent of anticipated high flow events during 1) 2017 conditions with ~~seismic~~ restriction, 2) 2023 conditions with the Stage 1 Diversion System, 3) 2028 conditions during construction of the Seismic Retrofit components, and 4) post-Seismic Retrofit with FAHCE+ rule curves
- *Reservoir Drawdown and Operations Plan* that was submitted to FERC establishing how Valley Water would drain the reservoir to deadpool and construct FOCP components
- *Post Project Operations Memo* that defines post Project operation to be implemented upon completion of the Seismic Retrofit components
- *Sediment Deposition in Coyote Creek above Ogier Ponds and Discharge to Estuary that* analyzes the volume and concentration of suspended sediment mobilized from Anderson Reservoir to Coyote Creek during each phase of construction and the locations of sediment deposition in the CWMZ
- *Tidal Floodplain Impacts for Project* that considers flow impacts to the tidal floodplain of Coyote Creek due to Project construction and operation

3.11.1 Environmental Setting

The Project is in the Coyote Creek Watershed, which is the largest watershed in the Santa Clara Basin, encompassing an area of over 320 square miles. Anderson Dam impounds surface runoff from 195 square miles of the Coyote Creek Watershed, which includes inflow from several tributaries and releases from Coyote Reservoir, which is approximately 1.5 miles upstream of Anderson Reservoir. Downstream of Anderson Dam, Coyote Creek flows approximately 37.5

miles north-northwest through many densely urbanized areas in the county, including portions of Morgan Hill, San José, and Milpitas, before ultimately reaching San Francisco Bay. The upstream reaches of Coyote Creek and the watershed that feeds Anderson Dam are largely undeveloped. Surface waters in the Project vicinity are shown in **Figure 3.11-3**.

Please also refer to Section 2.2.2 ~~2.2.1~~, *Regional Area – Coyote Creek Watershed*, within Chapter 2, *Project Description,* for discussion of the regional watershed setting and the primary surface water features in the Project vicinity.

3.11.1.1 Anderson Reservoir

Storage, Releases, and Inflow

Anderson Reservoir is Valley Water's largest reservoir, with a storage capacity of over 89,000 AF. Operations typically involve reservoir water releases for multiple purposes, including water supply, groundwater recharge, flood risk reduction, power generation, downstream aquatic habitat, maintenance, and emergency purposes. While Anderson Reservoir historically operated up to its full capacity, a storage restriction of about 45 feet below the crest of the dam (reducing the storage volume to about 61,000 AF) was voluntarily put into place by Valley Water in 2009 due to the potential seismic deficiencies. Subsequently, Valley Water increased the storage restriction to 55 feet below the dam crest (reducing the allowed storage capacity to 52,553 AF) in response to additional findings during the design phase of the Project (Valley Water 2020a). Currently, water levels are being maintained at dead pool as a result of implementation of the FOCP.

Water stored in Anderson Reservoir comes from within the watershed and from USBR's San Felipe Division of the federal Central Valley Project – specifically, San Luis Reservoir. Imported Central Valley Project and State Water Project water stored in San Luis Reservoir can be transferred and stored in Anderson Reservoir via the SCC and the Anderson Force Main. Water from San Luis Reservoir may also be discharged directly to Coyote Creek via the Coyote Discharge Line near the Anderson Hydroelectric Facility, about 1,300 feet downstream of the toe of the dam. The Anderson Force Main may be used to deliver water from the reservoir to either the Anderson Hydroelectric Facility (which then discharges to Coyote Creek) or to Valley Water raw water distribution system (via the Cross Valley Pipeline). Water released into Coyote Creek recharges the Santa Clara Subbasin (Basin No. 2-9.02) by in-stream percolation in Coyote Creek and at the Coyote Percolation Pond just north of Metcalf Road.

The contributing watersheds to Anderson Reservoir include Coyote Creek above Coyote Dam (i.e., releases from Coyote Reservoir), Las Animas Creek, and other small streams, such as Packwood Creek, that drain directly into Anderson Reservoir (see **Figure 3.11-3**). The watershed's steep slopes descend from a maximum of approximately elev. 3,600 feet above sea level to the Anderson Dam elev. 647 feet at the dam crest. Inflow into the reservoir varies based on the time of year and water year type, as shown in **Table 3.11-1**. Combined inflows from the northern tributaries and from Coyote Reservoir to the south range from 14 AF in a month during a dry year to 37,141 AF in a month during a wet year (Valley Water 2020b).

Table 3.11-1. Estimated Inflow into Anderson Reservoir by Water Year Type

	Reservoir Inflow (AF)		
	Dry Year	**Average Year**	**Wet Year**
Tributary Inflow into Anderson Reservoir (excluding Coyote Reservoir outflows)			
Maximum Monthly Volume	215	2,489	11,070
Minimum Monthly Volume	0	8	129
Inflow into Anderson Reservoir from Coyote Reservoir			
Maximum Monthly Volume	109	3,721	26,071
Minimum Monthly Volume	14	116	472

Source: Valley Water 2020b

Key: AF = acre-feet

Since the dam was constructed in 1950, Anderson Reservoir was dewatered completely in 1961 and 1987 for maintenance and upgrades to the dam. In the past, it has taken about 8 to 10 months to fully dewater the reservoir and a few years for the reservoir to refill.

Sediment

Anderson Reservoir retains all coarse sediment that enters the reservoir. Although some fine sediment is passed through the reservoir, the reservoir is assumed, due to its large size, to have a buffering effect on runoff-induced increases in suspended sediment that would otherwise be translated directly to downstream reaches of Coyote Creek (Valley Water 2020b). During storm-related runoff events, highly turbid water entering Anderson Reservoir mixes with a large volume of stored water, and the suspended sediment concentrations can be diluted before flow is passed downstream of Anderson Dam (Valley Water 2020b). The amount of fine sediment reaching the reservoir's outlet varies depending on particle size, density of sediment in the inflow, amount and rate of inflow, distance traveled through the reservoir, reservoir release operations, and suspended sediment transported during large storms that may reach the outlet at a higher concentration than during smaller storms (Valley Water 2020b). Although some of the suspended sediment settles from the water column in Anderson Reservoir, like other San Francisco Bay Area reservoirs (Kittleson et al. 1996, as cited in Valley Water 2020b), Anderson Reservoir can prevent some of the turbid water from moving quickly through the system and may prolong the release of mildly turbid water to Coyote Creek downstream of Anderson Dam for weeks following a storm (Valley Water 2020b).

Sediment mapping and characterization completed for Anderson Reservoir has indicated that there is an average of about 8 to 20 feet of accumulated fine sediment in the former stream channels in Anderson Reservoir, and 1 to 6 feet on the former terraces adjacent to those historical channels (Valley Water 2020b). This accumulation reflects decades of sediment trapping in the reservoir. The majority of the accumulated sediments consist of cohesive fines described as medium to highly plastic clays. Preliminary estimates indicate that the volume of accumulated sediment in Anderson Reservoir is 2.9 million cy. The volume of sediment above deadpool in the north and south arms of Anderson Reservoir is approximately 1,007,000 and 529,000 cy, respectively (Valley Water 2020c). The volume of sediment below the invert (elev. 450 feet) of the Stage 1 Diversion System is approximately 276,000 cy (Valley Water 2020c).

3.11.1.2 Coyote Reservoir

As described in Chapter 2, *Project Description,* Coyote Reservoir is a smaller reservoir located approximately 1.5 miles upstream from Anderson Reservoir. Coyote Reservoir holds 22,541 AF of water when full and is the second largest reservoir (behind Anderson Reservoir) owned by Valley Water with a surface area of 633 acres. However, a ~~permanent seismic~~ restriction was imposed on Coyote Reservoir by the DSOD in 1992, reducing the storage capacity to 11,843 AF, or 52.5 percent of total capacity (Valley Water 2023a ~~2022a~~). Winter runoff is stored in Coyote Reservoir and released during the dry season. Releases from Coyote Reservoir ultimately flow into Anderson Reservoir.

3.11.1.3 Lower Coyote Creek

Flows

Prior to the drawdown to deadpool as part of the FOCP, flows in Coyote Creek below Anderson Dam are controlled by releases from Anderson Reservoir (including discharges via the hydroelectric facility), and discharge of imported water via the CDL~~, and the hydroelectric facility downstream from the dam~~. USGS streamflow station 11170000 (previously, Valley Water SF82), Coyote Creek near Madrone, California, is the nearest location that measures these releases. The median of daily flows by month, for the water years 2000 through 2019, shows a range of 40-50 cfs in the summer (June to September) and 20-25 cfs in the winter (January to March). Greater summer releases are expected as Valley Water operates to replenish the groundwater subbasin. Large storm events have resulted in creek flows as high as 850 cfs (April 2006), 600 cfs (March 2011), and 7,400 cfs (February 2017) at the Madrone gage with high flows persisting in the channel for as long as 2 weeks (Valley Water 2017).

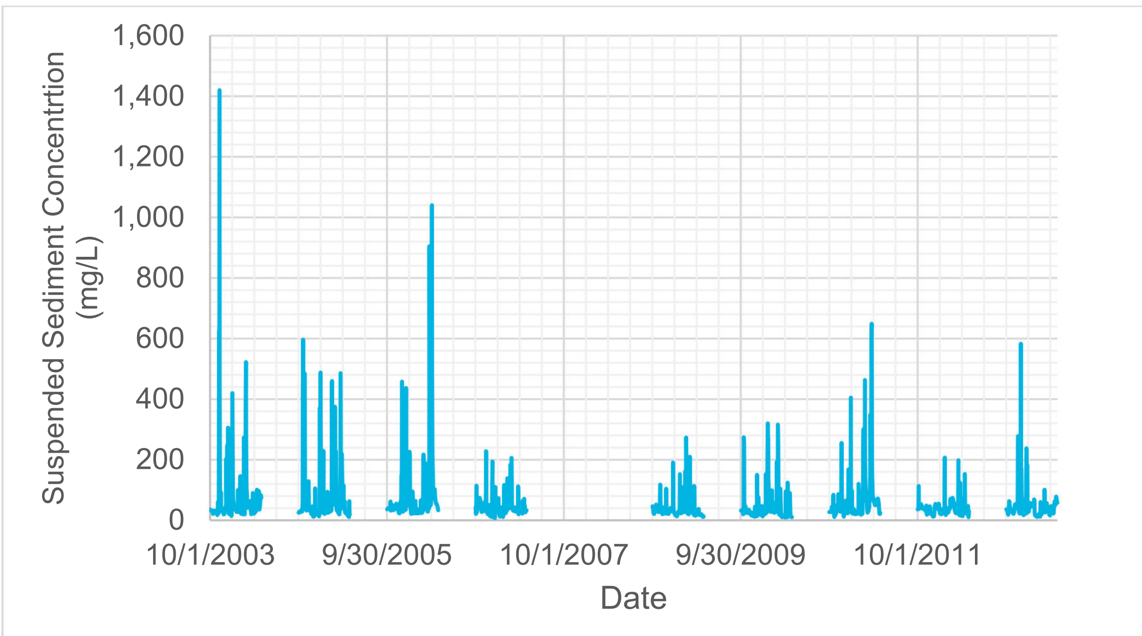
Prior to construction of Anderson Dam, in the early 1900s, Coyote Creek was intermittent in much of the reach below what is now the location of Anderson Dam (FAHCE 2000, SFEI 2006, NMFS 2016a, as cited in Valley Water 2020b). Coyote Creek was likely intermittent from about the location of Ogier Ponds downstream to between Montague Expressway and Berryessa Road, a reach that could be 20 or more miles long, depending on the year (SFEI 2006, as cited in Valley Water 2020b). The intermittent period likely lasted from late spring through early fall (FAHCE 2000, as cited in Valley Water 2020b). Since the construction of Anderson Dam, in 1950, winter flows in Coyote Creek have been attenuated and uncontrolled release events associated with reservoir spilling occur only every 9 years (on average). Due to regulated flows, Coyote Creek is perennial in most years, generally with higher summer flows and lower winter flows than would occur naturally (Valley Water 2020b).

Figure 3.11-4 presents the median of daily flows by month for five Valley Water and USGS stream gages from the reach between Coyote Dam and Anderson Reservoir to Coyote Creek at Highway 237 from Water Years 2000 to 2019. As shown in **Figure 3.11-4**, the median flow stays below 50 cfs for all months of the year at each of the five gage locations. At USGS Station 11170000/Valley Water SF82 (between Anderson Dam and Ogier Ponds, downstream of all outlets), flows are elevated from April to November, which is opposite of the typical or natural hydrograph, owing to releases from storage at Anderson Reservoir and/or imported supplies via the CDL for groundwater recharge. Flows at this location are highest in July (roughly 47 cfs) and August (roughly 48 cfs), which is the peak of summer. Substantial stream loss, due to percolation beneath the stream bed, is evident from **Figure 3.11-4**, as flows downstream (e.g., at SF07 [just upstream of Metcalf Ponds]) are substantially reduced, but follow a similar pattern. The monthly median flow at SF07 peaks in August at roughly 15 cfs. Along Coyote Creek from Anderson Reservoir to San Francisco Bay, water is lost to evapotranspiration and percolation to groundwater, while inflow to Coyote Creek is received from Upper Penitencia Creek, Lower Silver Creek, and other tributaries (refer to **Figure 3.11-3**). Of the 40 to 50 cfs released downstream of Anderson Dam, approximately 8 to 9 cfs is typically recharged to groundwater in the FCWMZ during the summer months (Valley Water 2020b). Additional water in Coyote Creek is lost downstream of Ogier Ponds and in the Coyote Percolation Pond, where substantial infiltration is known to occur.

Suspended Sediment

The USGS collected 10 years of suspended sediment and flow data in Coyote Creek near Milpitas (USGS Gage 11172175), where the gage is located above the tidal zone at the Highway 237 crossing.

Figure 3.11-1. Suspended Sediment Data Collected at Highway 237 at Coyote Creek



Source: AECOM 2021

As shown in **Figure 3.11-1**, peak winter suspended sediment concentrations are generally between 400 and 600 mg/L with some peaks over 1,000 mg/L. Maximum daily loads are generally less than 1,000 tons per day, but there were three events in the record that were greater than 2,000 tons per day (AECOM 2021). The largest storm in the record of USGS data collection at this site occurred in April 2006, in which the storm discharged about 9,000 tons over a period of 2 weeks with a peak daily load of 4,370 tons (AECOM 2021).

More recently, water quality monitoring at five locations along Coyote Creek downstream of Anderson Dam conducted from December 2019 to April 2020 showed total suspended solids (TSS) concentrations from 2.0 mg/L to a maximum of 37.20 mg/L (Valley Water 2021). **Table 3.11-2** shows the TSS measurements at the 5 locations during the study period. The monitoring locations are shown in **Figure 3.11-2**.

Water stored in Anderson Reservoir prevents the turbid inflow from moving quickly through the system. Much of sediment entering the reservoir settles to the bottom; however, the reservoir can also prolong the release of mildly turbid water to Coyote Creek downstream for weeks following a storm. Sediment movement associated with the FOCP is primarily a function of erosion of exposed sediment by inflows to the reservoir as the reservoir is lowered, or during high flow events while the reservoir is lowered.

Table 3.11-2. Total Suspended Solids Monitoring Data, Coyote Creek below Anderson Dam – December 2019 to April 2020

Date	Total Suspended Solids Concentration, mg/L

3.11.1.4 Tsunamis, Seiches, and Flooding

Anderson Dam and Reservoir are located approximately 20 miles inland from the coast at roughly elev. 500 feet above sea level. As such, these facilities are outside of any mapped tsunami hazard zones. The furthest downstream elements of the Project involving construction (Phase 2 Coyote Percolation Dam CM) would be located approximately 20 miles inland from the coast and approximately 21 miles from the San Francisco Bay shoreline. As such, these facilities would also be outside of tsunami hazard zones.

A seiche is a standing wave oscillating in a body of water (NOAA 2021). Seiches are usually limited to partially or fully enclosed basins and are typically caused when strong winds and rapid changes in atmospheric pressure push water from one end of a body of water to the other (NOAA 2021). When the wind stops, the water rebounds to the other side of the enclosed area. The water then continues to oscillate back and forth for hours or even days (NOAA 2021). Seiches can be deadly—for example, in 1844, a 22-foot seiche in Lake Erie breached a 14-foot-high sea wall killing 78 people and damming the ice to the extent that Niagara Falls temporarily stopped flowing (NOAA 2021). To date, no seiches are known to have occurred in Anderson Reservoir.

Flooding has occurred along Coyote Creek in the past, most recently in February 2017 (Valley Water 2017). Other floods events on Coyote Creek occurred in 1911, 1917, 1931, 1958, 1969, 1982, 1983, 1997, and 1998. Valley Water is undertaking two projects to reduce the flood risk along Coyote Creek. The first project, the Coyote Creek Flood Management Measures Project, (CCFMMP) part of the FOCP, which includes floodwalls, a levee, and elevating low-lying residences in reaches that are subject to flood flows, including those that will results from ADTP releases. It was under construction at the time of Draft EIR preparation and is scheduled for completion in 2024. The second project is the Coyote Creek Flood Protection Project (CCFPP), which will further the protection along nine miles of Coyote Creek, between Montague Expressway and Tully Road in San José with the goal of reducing the risk of a flooding during events equivalent to the one experienced in February of 2017. The CCFPP is currently in the design phase and is scheduled for completion by the end of 2027 (Valley Water 2023c).

3.11.2 Regulatory Setting

3.11.2.1 Federal Regulations

Clean Water Act

The CWA is the primary federal law that protects the quality of the nation’s surface waters, including lakes, rivers, and coastal wetlands. CWA section 402 is discussed in this section, as it pertains to stormwater management and hydrology. CWA section 404, which regulates the discharge of dredged and fill materials into waters of the U.S., is also discussed briefly below.” Refer to Section 3.14, *Water Quality*, for discussion of CWA sections 404, 303 and 401.

Section 402, Permits for Stormwater Discharge

CWA section 402 regulates construction related stormwater discharges to surface waters through the NPDES program. The NPDES program is administered by the USEPA. However, in California, the USEPA has delegated authority to the SWRCB; the SWRCB in turn delegates implementation responsibility to the nine RWQCBs (see discussion of the Porter-Cologne Water Quality Control Act in Section 3.14, *Water Quality*).

The NPDES program provides for both general permits (those that cover several similar or related activities) and individual (activity- or project-specific) permits. The General Permit for Construction Activities and Municipal Regional Stormwater Permit are discussed below under State Water Control Board and San Francisco Regional Water Quality Control Board respectively.

Municipal Regional Stormwater NPDES Permit.

Section 404, Permits for Fill Placement in Waters and Wetlands

CWA section 404 regulates the discharge of dredged and fill materials into waters of the U.S., or jurisdictional waters, which include oceans, bays, rivers, streams, lakes, ponds, and wetlands. Before any actions that may discharge dredged or fill material into surface waters or wetlands are carried out, a delineation of jurisdictional waters of the U.S. must be completed, following USACE protocols (USACE 1987), in order to determine whether the project area encompasses wetlands or other waters of the U.S. that qualify for CWA protection. Section 404 permits are discussed in detail in Section 3.14, *Water Quality*.

Federal Energy Regulatory Commission Regulations and Guidelines

Part 12 – Safety of Water Power Projects and Project Works

FERC has regulatory authority over dams which include hydroelectric power generation, such as Anderson Dam. Part 12 of FERC’s regulations (18 CFR Chapter I) includes requirements for reporting of safety-related incidents and maintenance of records, preparation and implementation of emergency action plans, inspection by an independent consultant, development and implementation of quality control programs, installation of warning and safety devices, and testing of spillway gates.

As described in Subpart C, the regulations require preparation of Emergency Action Plans (EAP). Every applicant or licensee must develop an EAP in consultation with appropriate federal, State, and local agencies responsible for public health and safety (18 CFR section 12.20). The EAP must conform to the Guidelines for Preparation of Emergency Action Plans, issued by FERC. In general, EAPs must include: (i) instructions to project operators and attendants and other responsible personnel about the actions they are to take during a project emergency; (ii) detailed plans for notifying potentially affected persons and parties in the event of an emergency; and (iii) procedures for controlling the flow of water, including actions to reduce inflows to reservoirs and outflows from upstream and downstream dams or control structures (18 CFR section 12.22).

The FERC regulations also require regular inspection of hydropower facilities. As stipulated in section 12.32 (Subpart D), the project works of each FERC-licensed dam or facility must be periodically inspected and evaluated by or under the responsibility and direction of at least one independent consultant to identify any actual or potential deficiencies. The inspection must consider specific data and factors related to safety, such as settlement, seepage, seismicity, stability of critical slopes adjacent to reservoir projects works, adequacy of spillways, hydrology, and the quality and adequacy of maintenance, surveillance, and methods of project operations for the protection of public safety (see 18 CFR section 12.35 for full list). Inspections must be conducted every 5 years.

In addition, Part 12 of the FERC regulations contains requirements for quality control, monitoring instrumentation, and warning systems. Under section 12.40, implementation of quality control programs may be required for any construction, repair, or modification work. Section 12.41 requires that in designing a project, a licensee must make adequate provision for installing and maintaining appropriate monitoring instrumentation (e.g., to measure seismic effects or hydrostatic pore pressures) whenever any physical condition that might affect the stability of a project structure has been discovered or is anticipated. Section 12.42 requires that an applicant or licensee install, operate, and maintain any signs, lights, sirens, barriers, or other safety devices that may be necessary to warn the public or fluctuations in flow from the project or otherwise protect the public in the use of project lands and waters. Section 12.44 contains requirements for testing of spillway gates, including that each spillway gate must be tested at least once a year.

Engineering Guidelines for the Evaluation of Hydropower Projects

The *Engineering Guidelines for the Evaluation of Hydropower Projects*, produced by FERC, contain guidelines on dam safety and performance. Chapters 1 and 2 of the *Engineering Guidelines* describe the hazard potential of dams and contain guidelines for evaluating the consequences of dam failure and determining the PMF (FERC 2016 ~~2020~~). Chapter 4 contains information and guidelines on embankment dams, including information for evaluating the potential for liquefaction and overtopping, and guidelines for conducting a seismic stability evaluation. Chapter 6 contains guidelines for developing and implementing EAPs, as required by the regulations described above. Chapter 13 contains more detailed guidelines for evaluating seismic stability and the potential for dam failure from an earthquake. Finally, Chapter 14 contains recommended procedures and criteria for development of a Dam Safety Performance Monitoring Program, which would include a Potential Failure Mode Analysis and a Surveillance and Monitoring Plan (FERC 2016 ~~2020~~).

National Flood Insurance Act of 1968 and Flood Disaster Protection Act of 1973

The National Flood Insurance Act of 1968 (42 USC 4001 et seq.) provides federally backed flood insurance to communities that enact and enforce floodplain regulations. As part of its flood insurance program, the FEMA has developed a Community Rating System, which rewards communities that practice proactive flood management and educational activities above and beyond the minimum requirements of the National Flood Insurance Program (NFIP). The reward is an across-the-board reduction in insurance premiums for residents and businesses in a participating community. The Flood Disaster Protection Act of 1973 (42 USC 4001 et seq.) expanded the NFIP by increasing limits of coverage and by requiring known flood-prone communities to participate in the NFIP.

FEMA Levee Design and Maintenance Regulations

Guidance and criteria for levees included in the NFIP are provided in the FEMA Levee Design and Maintenance Regulations (44 CFR 65.10). Major criteria include freeboard, closure structures, embankment protection, embankment and foundation stability, settlement, interior drainage, and other design criteria. Operation and maintenance requirements are also discussed. Each of these criteria includes specific design guidelines that must be met for the levee to remain in the NFIP.

3.11.2.2 State Regulations

California Department of Water Resources – Division of Safety of Dams

California Water Code

The California Water Code contains statutes related to the supervision of dams, which describe the authority and activity of the DSOD. DSOD is a division of the DWR, which was created following the catastrophic failure of the St. Francis Dam in Southern California in 1928. The DSOD engineers and engineering geologists review and approve plans and specifications for the design of dams and oversee their construction to ensure compliance with the approved plans and specifications. DSOD engineers also inspect dams to ensure adequate performance and maintenance. Since the Oroville Dam spillway failure event in 2017, DSOD has increased its focus on rectifying dam stability issues as quickly as possible, such as those found at Anderson Dam.

Statutes in the Water Code (Division 3. Dams and Reservoirs) of relevance to the Project include:

6101. The department may require owners to keep records of, and to report on, maintenance, operation, staffing, and engineering and geologic investigations and shall issue such rules and regulations and orders as necessary to secure maintenance and operation and to require staffing and engineering and geologic investigations which will safeguard life and property. In addition, the owner of a dam or reservoir or his agent shall fully and promptly advise the department of any sudden or unprecedented flood or unusual or alarming circumstance or occurrence affecting the dam or reservoir.

6102.5.

a) The department shall inspect dams, reservoirs, and appurtenant structures to verify their safety in accordance with the following schedule:

1. A facility that has been determined by the department, pursuant to section 6160, to have a hazard classification of significant, high, or extremely high, shall be inspected at least once per fiscal year.
2. A facility that has been determined by the department, pursuant to section 6160, have a hazard classification of low shall be inspected at least once every two fiscal years.

b) The department shall require owners to perform, at the owner's expense, such work as necessary to disclose information sufficient to enable the department to determine conditions of dams, reservoirs, and critical appurtenant structures regarding their safety and to perform, at the owner's expense, other work necessary to secure maintenance and operation that will safeguard life and property. An inspection pursuant to subdivision (a) shall include, but is not limited to, visual inspection of major features of the dam, including its groins, abutments, and toe areas, the dam's spillway, and the dam's outlet works. The inspection shall also evaluate seepage and instrumentation, and include a review of available geological data and existing geological conditions.

c) An owner of a dam shall operate critical outlet and spillway control features on an annual basis and shall demonstrate their full operability in the presence of the department every three years or as directed by the department.

6110. The department shall immediately employ any remedial means necessary to protect life and property if either: (a) the condition of any dam or reservoir is so dangerous to the safety of life or property as not to permit time for the issuance and enforcement of an order relative to maintenance or operation; or (b) passing or imminent floods threaten the safety of any dam or reservoir.

6111. In applying the remedial means provided for in this article, the department may in emergency do any of the following: (a) lower the water level by releasing water from the reservoir; (b) completely empty the reservoir; or (c) take such other steps as may be essential to safeguard life and property.

6225. Before commencing the repair, alteration, or removal of a dam or reservoir, including the alteration or removal of a dam or reservoir so that it no longer constitutes a dam or reservoir as defined in this part, the owner shall secure the written approval of the department, except as provided in this article.

6226. The application shall give such pertinent information or data concerning the dam or reservoir, or both, as may be required by the department and such information as to other matters appropriate to a thorough consideration of the safety of such a change as may be required by the department.

Outlet Dewatering Requirements

DSOD requires that outlets at major dams have the capacity to draw down the reservoir during an emergency. For reservoirs that impound over 5,000 AF of water, the outlet system should be capable of lowering the maximum storage depth by 10 percent within 7 days and draining its full contents within 90 days (DSOD 2021).

California Department of Fish and Wildlife

Section 1602 – Lake and Streambed Alteration Agreement Program

Under section 1602 of the California Fish and Game Code, CDFW regulates projects that affect the flow, channel, or banks of rivers, streams, and lakes. Section 1602 requires public agencies and private individuals to notify and enter into a streambed or lakebed alteration agreement with CDFW before beginning construction of a project that will substantially divert, obstruct, or change the natural flow or the bed, channel, or bank of any river, stream, or lake, or use materials from a streambed.

Section 1602 contains additional prohibitions against the disposal or deposition of debris, waste, or other material containing crumbled, flaked, or ground pavement where it can pass into any river, stream, or lake. Section 1602 may apply to any work undertaken within the 100-year floodplain of any body of water or its tributaries, including intermittent stream channels. In general, however, it is construed as applying to work within the active floodplain and/or associated riparian habitat of a wash, stream, or lake that provides benefit to fish and wildlife. It typically does not apply to drainages that lack a defined bed and banks, such as swales, or to very small bodies of water and wetlands such as vernal pools.

State Water Quality Control Board

See Section 3.14.2.2 for a discussion of SWRCB authority under the Porter-Cologne Water Quality Control Act.

NPDES General Permit for Construction Activities~~.~~

Most typical construction projects that disturb 1 acre of land or more are required to obtain coverage under the SWRCB's General Permit for Storm Water Discharges Associated with Construction and Land Disturbance Activities (Order 2022-0057-DWQ; "Construction General Permit"; adopted on September 8, 2022, and effective September 1, 2023), which requires the applicant to file a public notice of intent to discharge stormwater and to prepare and implement a SWPPP. The SWPPP must include a site map and a description of the proposed construction activities; demonstrate compliance with relevant local ordinances and regulations; present the BMPs that will be implemented to prevent soil erosion and discharge of sediment and other construction-related pollutants to surface waters; and discuss monitoring that will be conducted to assure ongoing compliance of storm water discharges from the construction site with the Construction General Permit.

The SWPPP must include BMPs to control erosion at the source, such as through minimizing soil disturbance, preserving existing vegetation where feasible, and stabilizing and revegetating disturbed areas as soon as possible after grading or construction activities. Temporary soil stabilization measures/practices that could be utilized include covering disturbed areas with mulch, temporary seeding, soil stabilizers, binders, fiber rolls or blankets, temporary vegetation, and permanent seeding (SWRCB 2022). Additionally, the SWPPP may include sediment control measures, which would be used to capture any soil that becomes eroded. This may include perimeter control measures, such as installing silt fences or placing straw waddles below slopes, sediment basins and active treatment systems to remove sediment prior to storm water releases (SWRCB 2022). Wastewater washout and cleanout areas or structure, secondary containment facilities, hazardous materials spill plans and other hazardous materials control measures to preclude discharge of toxic construction related pollutants in storm water runoff are also typically included in the SWPPP (SWRCB 2022). Permittees are further required to conduct annual monitoring and reporting to ensure that BMPs are correctly implemented and that they are effective in controlling the discharge of construction-related pollutants.

San Francisco Regional Water Quality Control Board

Municipal Regional Stormwater NPDES Permit

The Municipal Regional Stormwater NPDES permit (Order R2-2022-0018) (San Francisco Bay RWQCB 2022) covers municipal stormwater discharges from storm drain systems operated by most Bay Area counties and cities. The permit is applicable to Valley Water, the County, the City of San José, and other cities and storm water management agencies within the county, which have joined together to form the Santa Clara Valley Urban Runoff Pollution Prevention Program. The Municipal Regional Stormwater NPDES permit establishes discharge prohibitions, annual reporting requirements, construction site controls, water quality monitoring, pesticides toxicity control, trash load reductions, and provisions to address existing total maximum daily loads established for the Bay. The continuous monitoring requirements include triggers that indicate the need for further study. The temperature trigger is defined as any of the following:

- MWAT
- 20 percent of instantaneous pH results are < 6.5 or > 8.5
- 20 percent of instantaneous specific conductance results are > 2000 microSiemens, or there is a spike in readings with no obvious natural explanation
- 20 percent of instantaneous dissolved oxygen results are < 7 mg/L in a cold-water fishery stream

When results at one sampling station (e.g., along Coyote Creek) exceed the applicable temperature or dissolved oxygen trigger or demonstrate a spike in temperature or drop in dissolved oxygen with no obvious natural explanation, the Permittees shall identify the sample site as a candidate Stressor/Source Identification (SSID) project. SSID projects are intended to be oriented toward taking action(s) to alleviate stressors and reduce sources of pollutants.

The purposes of the measures included in the Municipal Regional Stormwater NPDES Permit are to control and reduce the levels of pollution in both stormwater and nonstormwater runoff discharges from storm drains into watercourses or features that are waters of the State or waters of the U.S.; gather concentration and loading information for a number of pollutants of concern; and ensure the implementation of appropriate source control, site design, and stormwater treatment measures in new development and redevelopment projects discharge runoff into storm water management systems that concentrate and discharge runoff to jurisdictional waters . The permit was recently amended to refine development categories and low-impact development specifications.

Stormwater runoff that is concentrated within and enters Anderson Reservoir and Coyote Creek through storm water management system outfall pipes and similar facilities is covered under the provisions of the NPDES permit, which include prohibiting certain discharges, such as solid wastes, and discharges that cause or contribute to a violation of any receiving water limitation or applicable water quality standard (San Francisco Bay RWQCB 2022).

3.11.2.3 Local Regulations

Santa Clara Valley Habitat Plan

The VHP (~~County et al.~~ SCVHA 2012) provides coverage for dewatering associated with project construction. The time between the beginning of reservoir dewatering and the time when the reservoir is re-operated according to applicable rule curves is called a dewatering event. The VHP covers dewatering events by Valley Water of up to 2.5 years for implementing a Seismic Retrofit, although it provides an exception for Anderson Reservoir, which the VHP expected would require up to 3.5 years of dewatering. Per the VHP, if the Project were to require a dewatering event of more than 3.5 years, Valley Water would be required to engage in a separate consultation process with the USFWS and CDFW and may be required to provide additional mitigation beyond that required by the VHP.

Valley Water Stream Maintenance Program

Valley Water's SMP (Valley Water 2014) was established to provide an overarching program to remove sediment, invasive vegetation, and trash and debris in the county's waterways to maintain flow capacity. Routine stream maintenance includes activities such as:

- levee safety
- sediment removal
- bank protection
- trash removal
- fence and access repair
- site revegetation maintenance
- tree preservation
- watershed vegetation management

Some of the BMPs created for the SMP are applicable to the Project where activities are similar (for example, sediment removal).

County of Santa Clara General Plan

The County of Santa Clara General Plan (1994) includes the following policies related to hydrology and the Project:

Book A – Resource Conservation

Policy C-RC 16. Seismic safety considerations for new and existing reservoirs should be addressed in order to ensure water supply and public safety in the event of earthquake.

Policy C-RC 19: The strategies for maintaining and improving water quality on a countywide basis, in addition to ongoing point source regulation, should include:

a. effective non-point source pollution control;
b. restoration of wetlands, riparian areas, and other habitats which serve to improve Bay water quality; and
c. comprehensive Watershed Management Plans and "best management practices" (BMPs).

Policy C-RC 20: Adequate safeguards for water resources and habitats should be developed and enforced to avoid or minimize water pollution of various kinds, including:

a. erosion and sedimentation;
b. organic matter and wastes;
c. pesticides and herbicides;
d. effluent from inadequately functioning septic systems;
e. effluent from municipal wastewater treatment plants;
f. chemicals used in industrial and commercial activities and processes;
g. industrial wastewater discharges;
h. hazardous wastes; and
i. non-point source pollution.

Policy C-RC 22: Countywide, compliance should be achieved with the requirements of the [NPDES] permit for discharges into S.F. Bay, and to that end, the Countywide Nonpoint Source Pollution Control Program should receive the full support and participation of each member jurisdiction.

Policy C-RC 23: The countywide Stormwater Management Plan should be routinely reviewed and updated as additional information is collected on the effectiveness of prescribed control measures.

Book B – Resource Conservation

Policy R-RC-13: Sedimentation and erosion shall be minimized through controls over development, including grading, quarrying, vegetation removal, road and bridge construction, and other uses which pose such a threat to water quality.

Policy R-RC 35: Flood control modifications to be made in streams that have substantial existing natural areas should employ flood control designs which enhance riparian resources and avoid to the maximum extent possible significant alteration of the stream, its hydrology, and its environs.

Book B – Safety and Noise

Policy R-HS 19: In areas of high potential for activation of landslides, there shall be no avoidable alteration of the land or hydrology which is likely to increase the hazard potential, including:

a. saturation due to drainage or septic systems;
b. removal of vegetative cover; and
c. steepening of slopes or undercutting the base of a slope.

Coyote Creek Parkway Integrated Resource Management Plan and Master Plan

The Coyote Creek Parkway Integrated Resource Management Plan and Master Plan is designed to balance the long-term resource management of the Coyote Creek Parkway (Parkway) corridor with recreational uses that directly reflect the mission and vision of the SCCPRD. This plan depicts, over a 20-year period, how the Parkway can be managed to provide a quality outdoor recreation experience while also enhancing the habitat for special status species, providing and improving ecological functions of Coyote Creek, including flood protection, and maintaining a riparian forest along Coyote Creek (SCCPRD 2007). Key goals related to this section are listed below.

Goal NRM-1 Restore a functional floodplain along Coyote Creek, to the greatest extent practical, to allow for stable hydro-geomorphic processes beneficial to the preservation of a sustainable riparian habitat corridor

Goal NRM-2 Preserve, and where appropriate, enhance hydrologic connectivity through the creek channel, riparian habitat corridor, and adjacent natural areas

Goal NRM-3 Encourage the Santa Clara Valley Water District's management of the Parkway's creek and ground water resources to maintain and enhance native biodiversity.

Goal NRM-4 Preserve, and where appropriate, enhance a continuous, multi-tiered riparian habitat corridor with dynamic physical processes that promotes native biodiversity and supports threatened and endangered species.

City of Morgan Hill 2023 General Plan

The City of Morgan Hill 2035 General Plan (City of Morgan Hill 2017 ~~2016~~) contains the following goals and policies relevant to hydrology and the Project:

Natural Resources and Environment

Goal NRE-5: Preservation and reclamation of streams and riparian areas as open space.

Policy NRE-5.2: Other Agencies and Environmental Review. Coordinate with jurisdictional agencies, as required, as part of the environmental review process for development projects.

Policy NRE-5.3: Natural State of Streamside and Riparian Areas. Retain natural streamside and riparian areas in their natural state in order to preserve their value as percolation and recharge areas, natural habitat, scenic resources, and recreation corridors, and to stabilize banks. (South County Joint Area Plan 15.08).

Policy NRE-5.5: Flood Control Projects. Where flood control projects are needed to protect existing development, minimize disruption of streams and riparian systems, maintaining slow flow and stable banks through design and other appropriate mitigation measures. (South County Joint Area Plan 15.08)

Policy NRE-5.6: Stream Channel Protection. Protect existing stream channels and riparian vegetation by requiring buffering or landscaped setbacks and storm runoff interception as specified in **Table NRE 1** and consistent with the Santa Clara Valley Habitat Plan.

Table NRE 1 Required Stream Setback Distances

Slope	Category 1 Streams (Water Present Year-Round During Normal Rain Years)		Category 2 Streams (Water Present During the Wet Season Only During Normal Rain Years)
	Inside Urban Service Area	Outside Urban Service Area	Inside/Outside Urban Service Area
0-30%	100 feet	150 feet	35 feet
>30%	150 feet	200 feet	

Safety, Services, and Infrastructure

Goal SSI-5: The least possible damage to persons and property from flooding.

Policy SSI-5.2: Private Development in Flood-Prone Areas. If development is allowed in flood-prone areas, provide flood control facilities or appropriate flood-proofing prior to or in conjunction with development at developers' expense. (South County Joint Area Plan 12.05)

Policy SSI-5.9: Riparian Natural Functions. Restore and maintain the natural functions of riparian corridors, creeks, and channels to reduce flooding, convey stormwater flows, and improve water quality.

Policy SSI-5.10: Development along Reservoirs. Limit development along the shores of reservoirs which can be expected to sustain damage from seismically-induced seiche waves. (South County Joint Area Plan 15.6)

Policy SSI-5.11: New Development in Dam Inundation Areas. Consider risk of dam inundation in new development proposals within the Anderson, Chesbro, and Coyote dam inundation areas.

Goal SSI-6: Adequate, safe, and environmentally responsible drainage and flood control.

Policy SSI-6.1: Flood Control Projects. Minimize disruption of natural riparian areas by flood control projects needed to protect presently existing development by maintaining slow flow and stable banks through design and other appropriate mitigation measures. (South County Joint Area Plan 15.08)

Policy SSI-6.3: Existing and Planned Development. Areas which are developed or planned for development should be protected by the construction of flood control facilities. (South County Joint Area Plan 12.00)

Policy SSI-6.5: Flood Risks. Work with the Santa Clara Valley Water District and other agencies with the responsibility for flood protection to reduce flooding risks in Morgan Hill.

Policy SSI-6.6: Flood Management Design. Encourage flood management designs that respect the natural topography and vegetation of waterways while retaining dynamic flow and functional integrity.

Policy SSI-6.8: Increased Capacity. Encourage increased stormwater and flood management infrastructure capacity in order to accommodate changes in climate, precipitation, and extreme weather events.

Goal SSI-16: Minimized adverse effects on property, natural resources, and ground and surface water quality from stormwater runoff.

Policy SSI-16.2: Drainage System Capacity. Ensure that the level of detention or retention provided on the site of any new development is compatible with the capacity of the regional storm drainage system.

Policy SSI-16.3: Stormwater Management Plans. Require a storm water management plan for each proposed development, to be presented early in the development process and describe the design, implementation, and maintenance of the local drainage facilities. (South County Joint Area Plan 13.03)

Envision San José 2040 General Plan

The Envision San José 2040 General Plan (City of San José <u>2023</u> ~~2011~~) contains the following goals and policies related to hydrology and the Project:

Goal ER-8: Minimize the adverse effects on ground and surface water quality and protect property and natural resources from stormwater runoff generated in the City of San José.

Policy ER-8.1: Manage stormwater runoff in compliance with the City's Post-Construction Urban Runoff (6-29) and Hydromodification Management (8-14) Policies.

Policy ER-8.4: Assess the potential for surface water and groundwater contamination and require appropriate preventative measures when new development is proposed in areas where storm runoff will be directed into creeks upstream from groundwater recharge facilities.

Goal ER-9: Protect water resources because they are vital to the ecological and economic health of the region and its residents.

Policy ER-9.1: In consultation with [SCVWD], other public agencies and the SCVWD's Water Resources Protection Guidelines and Standards (2006 or as amended), restrict or carefully regulate public and private development in streamside areas so as to protect and preserve the health, function and stability of streams and stream corridors.

Goal EC-5: Protect the community from flooding and inundation and preserve the natural attributes of local floodplains and floodways.

Policy EC-5.2: Allow development only when adequate mitigation measures are incorporated into the project design to prevent or minimize siltation of streams, flood protection ponds, and reservoirs.

Policy EC-5.3: Preserve designated floodway areas for non-urban uses.

Policy EC-5.8: Cooperate with the Santa Clara Valley Water District to develop and maintain additional flood protection retention facilities in areas where they are needed or where the design capacity of existing retention facilities cannot be restored.

Policy EC-5.10: Encourage the preservation and restoration of urban creeks and rivers to maintain existing floodplain storage. When in-channel work is proposed, engineering techniques which include the use of plant materials (bio-engineering) are encouraged.

Policy EC-5.11: Where possible, reduce the amount of impervious surfaces as a part of redevelopment and roadway improvements through the selection of materials, site planning, and street design.

Policy IN-3.8: In designing improvements to creeks and rivers, protect adjacent properties from flooding consistent with the best available information and standards from [FEMA] and [DWR]. Incorporate restoration of natural habitat into improvements where feasible.

Santa Clara Valley Water District Water Resources Protection Ordinance

The Water Resources Protection Ordinance was adopted by a Water Resources Protection Collaborative made up of representatives from Valley Water, cities and towns within the county, the Guadalupe-Coyote Resource Conservation District, the San Francisco Bay RWQCB, and various community stakeholder interests. Its purpose is to protect the water resources managed by Valley Water by providing a set of model guidelines and standards for land use along stream corridors and regulating access to and use of Valley Water's facilities and easements (Valley Water 2010). Valley Water uses its *Water Resources Protection Manual* (Valley Water 2006) to administer the Water Resources Protection Ordinance.

Santa Clara Valley Water District Freeboard Standards

Freeboard is a safety factor expressed in feet above a known flood elevation intended to take unknown factors that could contribute to flood heights that are greater than the height calculated for a given size flood. Valley Water's freeboard requirements for flood protection projects and bridge crossings are contained in its *Water Resources Protection Manual* (Valley Water 2006). Valley Water's freeboard requirements are based on a combination of FEMA guidelines, NRCS guidelines, and USACE guidelines. Valley Water's minimum freeboard requirements are shown below in **Table 3.11-3**.

Table 3.11-3. Minimum Freeboard Requirements

Design Water Surface Elevation/Other Considerations	Freeboard Requirements
A. Project design water surface elevation is *above* the natural ground surface. (*including* where levees/floodwalls raise the predicted water surface elevation to above that of the surrounding floodplain)	1. Levees shall have a minimum of 3 feet of freeboard with an additional foot of freeboard required 100 feet of either side of the structures that are within the leveed section of creek or where the flow is constricted such as at bridges. An additional half-foot above the minimum at the upstream end of the levees is also required. To comply, a minimum of 3.5 feet of freeboard should be used within leveed sections and 4 feet within 100 feet of bridges or other constrictions (based on FEMA guidelines).
	2. Floodwalls should use the same freeboard criteria as for levees (Valley Water guideline).
	3. If two-tenths of the specific energy (depth of flow + [$v^2/2g$]) is greater than the freeboard requirement of (1) or (2) above, then the computed value shall be used for freeboard (based on NRCS guidelines).
B. Project design water surface is *below* the natural ground surface. (*excluding* where levees/floodwalls raise the predicted water surface elevation to above that of the surrounding floodplain)	1. One foot of freeboard shall be used for constructed, non-natural channels where large amounts of vegetation are not anticipated in the channel (USACE guideline).
	2. For all channels, if two-tenths of the specific energy is greater than the freeboard requirement of (1) above then the computed values shall be used for freeboard (NRCS guideline).
C. At bridges	1. At new bridges, freeboard shall be the same as in the existing or proposed channel either upstream or downstream whichever is greater. When the bridge structure encroaches into the freeboard area, there shall not be an increase in water surface for bank full flow. The intent is to define a system (bridge and channel) with a uniform level of protection (Valley Water guideline).
	2. Where an existing bridge or culvert can convey the design flow under pressure, it must be structurally sound and must be able to resist the resultant lateral and uplift forces (Valley Water guideline).
D. Other freeboard considerations	1. Evaluate all bridges with debris loads on the piers. Suggest USACE practice of three times pier diameter as blockage.
	2. Freeboard should also contain the flow defined by the 80 percent confidence limit statistical parameter where practical to do so.
	3. All channels with super-critical flow will use sequent (subsequent) depth plus freeboard.
	4. All channels will include freeboard for super-elevation of water surface at curves in addition to requirements specified above.
	5. In areas of the County where there is the possibility of continued land surface subsidence, additional freeboard allowances should be considered.

Source: Valley Water 2006

3.11.3 Methodology and Approach to Impact Analysis

The impact analysis considers the potential impacts on hydrology from the Project pursuant to the applicable significance criteria in Appendix G of the *CEQA Guidelines* (see Section 3.11.3.8). Specifically, the impact analysis considers the effects of Seismic Retrofit ~~construction,~~ and Conservation Measure construction~~,~~ and construction monitoring, and Seismic Retrofit and Conservation Measures post-construction operations, maintenance, ~~and~~ monitoring, and post-construction Project and FAHCE Adaptive Management. With respect to Conservation Measures, the analysis considers the effects of these measures both in terms of reducing the potential adverse effects of the Seismic Retrofit components of the Project on hydrology, as well as in potentially creating any adverse effects of their own.

To the extent possible, quantitative methods are used and effects are discussed quantitatively. However, in many cases, the potential effects cannot be quantified and are discussed in a qualitative manner. The analysis of erosion and sediment transport, in particular, relies on quantitative modeling, as documented in two memorandums *Sediment Transport Modeling Memorandum,* Valley Water 2020c; *Update to April 30, 2021 Memo on Sediment Deposition in Coyote Creek above Ogier Ponds and Discharge to Estuary,* URS 2023), which are included in Appendix K to this EIR. Additionally, the analysis utilizes a technical study of potential flooding impacts (*Potential Flood Impacts for ADSRP Memorandum*, Valley Water 2023b ~~2022b~~), which is also included in Appendix K. Generally, the potential effects of the Project are first discussed without implementation of applicable Valley Water BMPs and compliance with VHP conditions and AMMs (see Section 3.11.3.7) and applicable regulations; then, the analysis considers how implementation of BMPs and compliance with VHP conditions and AMMs and other regulations would reduce those potential adverse effects. If effects remain significant after implementation of BMPs and compliance with VHP conditions and AMMs and other regulations, then mitigation measures are prescribed, if feasible, to reduce those effects to a level that is less than significant.

As discussed further below, separate baselines are used due to the nature of the Project and the different types of effects. Generally, for analyzing construction-related effects, the existing conditions baseline is used, which represents the environmental conditions that exist at the time of EIR preparation modified by the FOCP. Construction effects may also be compared to historical (e.g., prior to 2020 Pre-FERC Order) conditions. For analyzing flow-related operation effects, the Pre-FERC Order baseline is used.

3.11.3.1 Seismic Retrofit Construction

The analysis considers all potential effects of the Seismic Retrofit construction on hydrology. Construction of the Seismic Retrofit components of the Project is planned to occur over a 7-year duration, as described in Chapter 2, and the timing of specific activities with respect to the overall construction schedule is considered in the impact analysis. Of most relevance for the hydrology analysis, Seismic Retrofit construction would include dewatering of the reservoir and the downstream effects of exposing the formerly inundated lake bottom to potential erosion. Seismic Retrofit construction would also include ground disturbance associated with access roads construction, staging areas, borrow areas, stockpile areas, and dam construction work areas. As noted above, the analysis of erosion and sediment transport during Seismic Retrofit construction relied on quantitative studies for the Project, as documented in memorandums

(Valley Water 2020c, URS 2023) included in Appendix K to this EIR. Potential flooding impacts associated with reservoir releases during Seismic Retrofit construction are analyzed utilizing a technical study, as documented in a memorandum (Valley Water 2023b ~~2022b~~), also included in Appendix K. As noted above, the baseline for analysis of impacts from Seismic Retrofit construction is the existing conditions after FOCP baseline.

3.11.3.2 Conservation Measures Construction

The analysis considered the construction of Conservation Measures component is separate from the Seismic Retrofit components of the Project. The Conservation Measures that would be included as part of the Project are described in Chapter 2, *Project Description*, and those involving construction activities are analyzed in this section. These include the following:

- Ogier Ponds CM
- Maintenance of the North Channel Reach ~~Extension~~
- Maintenance of Spawning Gravel and Rearing Habitat Improvements in Live Oak Restoration Reach
- Sediment Augmentation Program
- Phase 2 Coyote Percolation Dam CM

While these Conservation Measures would generally serve to minimize the potential effects of the Project (e.g., on biological resources and groundwater), construction of some of the Conservation Measures could result in impacts as well. The baseline for analysis of impacts from construction of the Conservation Measures is the existing conditions (after FOCP) baseline.

3.11.3.3 Construction Monitoring

The impact analysis also considered the effects of construction monitoring activities with respect to hydrology. The construction monitoring efforts that would be employed during Project construction are listed and described in **Table 2-1** in Chapter 2, *Project Description,* and include a variety of water quality and biological resources monitoring activities. Similar to the Conservation Measure components, construction monitoring activities would generally serve to avoid or reduce potential impacts of the Project on environmental resources. Nevertheless, some monitoring activities themselves could potentially result in impacts of their own and this was analyzed in the section.

3.11.3.4 Post-Construction Anderson Dam Facilities Operations and Maintenance

The analysis considers the potential effects of activities during the post-construction phase of the Project for Anderson Dam facilities. This includes implementation of the updated FAHCE rule curves for operation of Anderson Reservoir, in accordance with the Coyote Creek FHRP pursuant to the FAHCE *Settlement Agreement*, as well as maintenance of Anderson Dam facilities (e.g., outlet works) Maintenance of Anderson Dam facilities would be conducted under the DMP. As part of the evaluation, the analysis considers the potential effects due to the net increase of approximately 2.14 acres of impervious surface as a result of the Project. The analysis of potential flooding impacts uses two technical studies (Valley Water 2023b, 2023c), which are included in Appendix K of this EIR. The baseline for the post-construction effects analysis is the Pre-FERC Order Conditions Baseline.

3.11.3.5 Post-Construction Conservation Measures Operations and Maintenance

The analysis considers the potential effects of activities during the post-construction phase of the Project for the Conservation Measures. This includes operation and maintenance of the Conservation Measures. The baseline for the post-construction effects analysis is the Pre-FERC Order Conditions Baseline.

The Ogier Ponds CM would widen and separate Coyote Creek from the Ogier Ponds by a weir and berms. Eliminating creek flow through the ponds under general conditions via the creek pond separation project is a key element of benefiting steelhead. The spillway structure would be designed to divert flows from the restored channel to the ponds to protect the integrity of the channel when flows exceed 2,000 cfs. Water in the ponds would be generally maintained by groundwater seepage. Creek flows through the ponds would only occur via operation of spillway. High flows would flow into Pond 2 through spillway, then travel through Ponds 3 and 4, until flows exit Pond 4 and flow back into the creek via a culvert that will have fish screens to prevent predation. Monthly inspections would be conducted to monitor water quality in the ponds. Maintenance of Ogier Ponds would include vegetation management, vegetation restoration, and inspection and repair of the berms, weirs, vegetation and habitat enhancement, and erosion protection.

The North Channel Extension, constructed as part of FOCP, would accept most flows discharged from Anderson Reservoir. Maintenance of the North Channel Reach ~~Extension component~~ would include maintenance of the wetland bench, maintenance of the design flow capacity, and replacing restoration plantings. ~~removal of debris or vegetation from the channel, and possibly dewatering and grading the channel, if necessary, so that the channel maintains positive drainage.~~

The sediment augmentation program would include initial placement of 500 cy of sediment at the Live Oak Restoration Reach following Project construction, and continued inspection and placement of additional gravel/sediment, ~~ranging from 5~~ in an amount up to 500 CY every 5 years during adaptive management, as needed to support and maintain steelhead habitat throughout Coyote Creek.

The Phase 2 Coyote Percolation Dam CM would provide improved fish passage over the Coyote Percolation Dam. Within 13 months of completion of the Phase 2 Coyote Percolation Dam design (completion of design anticipated ~~in~~ prior to Year 1 ~~4~~), Valley Water will prepare a Phase 2 Coyote Percolation Dam Operations Plan in coordination with the regulatory agencies. The objectives of the Operations Plan will be to continue to provide sufficient groundwater recharge, while improving conditions for smolt migration. Maintenance would include periodic removal of sediment, vegetation management, repair of rock slope protection, and replacement of any in-channel bio-engineered habitat enhancements, as needed.

Within the Live Oak Reach, maintenance would include vegetation management and replacement of any in-channel bio-engineered habitat enhancements, as needed.

In-stream maintenance activities for the Conservation Measures would be conducted consistent with Valley Water's existing SMP, which includes BMPs and avoidance and minimization measures to minimize potential impacts to water quality.

3.11.3.6 Post-Construction Project and FAHCE Adaptive Management

The FAHCE AMP would guide post-construction adaptive management of project flow operations and Conservation Measures that have met their specified success criteria, as defined through the regulatory permitting process. As required by the FAHCE AMP framework, the Project and FAHCE AMP includes four key elements: measurable objectives, monitoring, adaptive actions, and reporting. Monitoring and adaptive actions involve physical activities that could have environmental impacts.

The Project and FAHCE AMP monitoring program would inform selection of adaptive management measures to implement in response to management triggers, and includes compliance, validation, effectiveness, and long-term monitoring. Validation, effectiveness, and long-term trend monitoring would build on existing Valley Water monitoring infrastructure (e.g., hydrologic monitoring network), water quality monitoring (e.g., water temperature monitoring network), habitat monitoring (e.g., habitat mapping), and fisheries monitoring (e.g., VAKI Riverwatcher, PIT tag detectors, genetics sampling, electrofishing surveys).

The Project and FAHCE AMP identifies triggers for adaptive actions to help meet measurable objectives. Adaptive actions for FAHCE flows and imported water storage/releases would include refinements of reservoir releases, which would have impacts and benefits similar to the original FAHCE flows and imported water storage/releases. Adaptive actions for Conservation Measures would generally include minor construction and maintenance actions, whose impacts would be similar but less than those of the original Conservation Measure construction.

Impacts of AMP monitoring and adaptive actions are considered here at a programmatic level, because the detailed characteristics, timing, and/or locations of the proposed adaptive measures are not known at the time of EIR preparation. Project-specific CEQA review would be undertaken in the future as necessary when specific projects are proposed and project-specific details are available.

3.11.3.7 Applicable Best Management Practices and VHP Conditions

Valley Water BMPs and VHP conditions and AMMs incorporated into the Project are described in Appendix A. Measures applicable to hydrology are listed below and described in the impact discussions as applicable.

- **AQ-1:** Use Dust Control Measures
- ~~**HM-7:** Restrict Vehicle and Equipment Cleaning to Appropriate Locations~~
- **HM-8**: Ensure Proper Vehicle and Equipment Fueling and Maintenance
- **HM-9**: Ensure Proper Hazardous Materials Management
- **HM-10**: Utilize Spill Prevention Measures
- **WQ-1:** Conduct Work from Top of Bank
- **WQ-2:** Evaluate Use of Wheel and Track Mounted Vehicles in Stream Bottoms
- **WQ-4:** Limit Impacts from Staging and Stockpiling Materials

- **WQ-5:** Stabilize Construction Entrances and Exits
- **WQ-8:** Minimize Hardscape in Bank Protection Design
- **WQ-9:** Use Seeding for Erosion Control, Weed Suppression, and Site Improvement
- **WQ-10:** Prevent Scour Downstream of Sediment Removal
- **WQ-11:** Maintain Clean Conditions at Work Sites
- **WQ-16:** Prevent Stormwater Pollution
- **VEG-1**: Minimize Local Erosion Increase from In-channel Vegetation Removal
- **BANK-1**: Bank Stabilization Design to Prevent Erosion Downstream
- **BANK-3:** Bank Stabilization Post-Construction Maintenance
- **REVEG-1**: Seeding

Additionally, the following VHP conditions would serve to minimize impacts on hydrology from the Project ~~(refer to Appendix A for the full text of VHP conditions)~~:

- <u>Condition 3: Maintain Hydrologic Conditions and Protect Water Quality</u>
- <u>Condition 4: Avoidance and Minimization for In-Stream Projects</u>
- <u>Condition 5: Avoidance and Minimization Measures for In-Stream Operations and Maintenance</u>
- <u>Condition 7: Rural Development Design and Construction Requirements</u>
- <u>Condition 11: Stream and Riparian Setbacks</u>
- <u>Condition 12: Wetland and Pond Avoidance and Minimization</u>

<u>Additionally, the following VHP AMMs related to conditions 3, 4, and 5 would serve to minimize impacts on hydrology from the Project:</u>

2: Remove pollutants from surface runoff

4: Reduce the potential for scour at stormwater outlets to streams by controlling the rate of flow into the streams

7: Prevent the accidental release of chemicals, fuels, lubricants, and non-storm drainage water into channels

8: Spill prevention kits shall always be in close proximity when using hazardous materials

9: Personnel shall implement measures to ensure that hazardous materials are properly handled and the quality of water resources is protected by all reasonable means when removing sediments from streams

11: Vehicles shall be washed at approved areas

12: No equipment servicing shall be done in the stream channel or immediate floodplain

13: Personnel shall use the appropriate equipment for the job that minimizes disturbance to the stream bottom

16: When work in a flowing stream is unavoidable, the entire streamflow shall be diverted around the work area by a barrier, except where it has been determined by a qualified biologist that the least environmentally disruptive approach is to work in a flowing stream

17: Install cofferdams both upstream and downstream not more than 100 feet from the extent of the work areas

20: Diversions shall maintain ambient stream flows below the diversion, with no reduction or degradation

21: If stream bed design changes are not part of the project, the stream bed will be returned to as close to pre-project condition as appropriate

22: Remove all temporary diversion structures and the supportive material no more than 48 hours after work is completed

23: Temporary fills, such as for access ramps, diversion structures, or cofferdams, shall be completely removed upon finishing the work

24: To prevent increases in temperature and decreases in dissolved oxygen (DO), properly size bypass pipes or use a low-flow channel.

26: Any sediment removed from a project site shall be stored and transported in a manner that minimizes water quality impacts

30: Vegetation control and removal in channels, on stream banks, and along levees and maintenance roads shall be limited

31: When conducting vegetation management, retain as much understory brush and as many trees as feasible

32: The top of the bank shall be protected by leaving vegetation in place to the maximum extent possible

38: Use flow dissipaters at runoff inlets (e.g., culvert drop-inlets) to reduce the possibility of channel scour at the point of flow entry

39: Minimize alterations to existing contours and slopes, including grading the minimum area necessary

40: Maintain native shrubs, trees, and groundcover whenever possible and revegetate disturbed areas with local native or non-invasive plants

44: Maintain natural stream characteristics, such as riffle-pool sequences, riparian canopy, sinuosity, floodplain, and a natural channel bed

50: If levee reconstruction requires the removal of vegetation that provides habitat value to the adjacent stream (e.g., shading, bank stabilization, food sources, etc.), then the project will include replacement of the vegetation/habitat that was removed during reconstruction unless it is determined to be inappropriate to do so by the relevant resource agencies

51: All projects will be conducted in conformance with applicable County and/or city drainage policies

52: Adhere to the siting criteria described for the borrow site covered activity

53: When possible, maintain a vegetated buffer strip between staging or excavation areas and receiving waters

55: For stream maintenance projects that result in alteration of the stream bed during project implementation, its low-flow channel shall be returned to its approximate prior location with appropriate depth for fish passage without creating a potential future bank erosion problem

56: Bank stabilization site design shall consider hydraulic effects immediately upstream and downstream of the work area

61: Minimize ground disturbance to the smallest area feasible

62: Use existing roads for access and disturbed area for staging as site constraints allow

63: Prepare and implement sediment erosion control plans

64: No winter grading shall occur unless approved by City Engineer and specific erosion control measures are incorporated

65: Control exposed soil by stabilizing slopes (e.g., with erosion control blankets) and protecting channels

66: Control sediment runoff using sandbag barriers or straw wattles

67: No stockpiling or placement of erodible materials shall occur in waterways or along areas of natural stormwater flow

68: Stabilize stockpiled soil with geotextile or plastic covers

69: Maintain construction activities within a defined project area to reduce the amount of disturbed area

70: Clear/prepare land which will be actively under construction in the near term

71: Preserve existing vegetation to the extent possible

72: Equipment storage, fueling, and staging areas will be sited on disturbed areas or non-sensitive habitat outside of a stream channel

73: Avoid wet season construction

74: Stabilize site ingress/egress locations

75: Dispose of all construction waste in designated areas and prevent stormwater from flowing onto or off of these areas

76: Prevent spills and clean up spilled materials

82: Channel bed temporarily disturbed during construction activities will be returned to pre-project or ecologically improved conditions at the end of construction

83: Sediments will be stored and transported in a manner that minimizes water quality impacts. If soil is stockpiled, no runoff will be allowed to flow back to the channel.

84: Appropriate erosion control measures (e.g., fiber rolls, filter fences, vegetative buffer strips) will be used onsite

87: Vehicles operated within and adjacent to streams will be checked and maintained daily to prevent leaks

88: Vehicles and equipment will be parked on pavement, existing roads, and previously disturbed areas

93: When accessing upland areas adjacent to riparian areas or streams, access routes on slopes > 20 percent should generally be avoided

94: Personnel shall use existing access ramps and roads if available

96: Isolate the construction area from flowing water until project materials are installed and erosion protection is in place

97: Erosion control measures shall be in place at all times during construction

100: Potential contaminating materials must be stored in covered storage areas or secondary containment impervious to leaks and spills

102: Immediately after project completion and before close of seasonal work window, stabilize all exposed soil

103: All disturbed soils will be revegetated with native plants and/or grasses or sterile nonnative species

104: Measures will be utilized on site to prevent erosion along streams

108: When reaches require sediment removal, approaches will be considered that may reduce the impacts of the activity. Examples of potential approaches include phasing of removal activities or only removing sediment along one half of the channel bed, allowing the other half to remain relatively undisturbed.

111: If bank failure occurs due to debris blockages, bank repairs will use compacted soil and reseeding with native/sterile nonnative plants

113: The channel bottom shall be re-graded at the end of the work project to as close to original conditions as possible

114: Erosion control methods shall be used as appropriate during all phases of routine maintenance projects to control sediment and minimize water quality impacts.

3.11.3.8 Thresholds of Significance

For the purposes of this EIR, the Project is considered to have a significant impact on hydrology[1] if it would:

- **HYD-1:** Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner which would:
    1. Result in substantial erosion or siltation on- or off-site.
    2. Substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.
    3. Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff.
    4. Impede or redirect flood flows.
- **HYD 2:** Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of dam failure.
- **HYD 3:** In flood hazard, tsunami, or seiche zones, risk release of pollutants due to project inundation.

[1] Note that thresholds from CEQA Guidelines Appendix G related specifically to water quality are addressed in this DEIR in Section 3.14, Water Quality, while thresholds related to groundwater are addressed in Section 3.12, Groundwater.

3.11.4 Impact Analysis

Impact HYD-1: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner ~~matter~~ which would:

i. ***Result in substantial erosion or siltation on- or off-site*** **(Significant and Unavoidable)**

Seismic Retrofit Construction

Construction of the Seismic Retrofit components of the Project could potentially cause substantial erosion or siltation on- or offsite. The different mechanisms, or processes, by which these effects could occur are discussed below.

Reservoir Dewatering and Runoff Through In-Reservoir Areas Not Disturbed During Construction

With Anderson Reservoir at deadpool at the end of the FOCP, it would then be lowered at the start of the Project, flows into the reservoir would be directly passed through downstream to Coyote Creek, capped at the capacity Stage 1 Diversion System (2,500 cfs) for Years 1 and 2 and the Stage 2 Diversion System (6,000 cfs) for Years 3 through 7. During the summer releases of ~~0 to 17~~ 1 to 65 cfs would be made from Coyote Reservoir depending on available storage, which would pass through Anderson Reservoir. Flow through Anderson Reservoir would be supported by imported water discharges to Coyote Creek with the goal of keep the channel wetted through the FCWMZ, which requires releases of approximately ~~8~~ 5 to 10 cfs. In addition, releases would be made from the Cross Valley Pipeline Extension downstream of Ogier Ponds to support in-stream recharge and recharge in Coyote Percolation Pond, and to meet the flow requirement through the Coyote Percolation Pond fish ladder (~~7.5~~ between 2.5 and 25 cfs) and at Edenvale gage (2.5 cfs mean daily flow and 1 cfs minimum flow).

The reservoir dewatering activities during Seismic Retrofit construction would change the drainage patterns by exposing new areas on the bed of the reservoir that had been previously inundated. Following implementation of the FOCP, the reservoir water level would remain at deadpool. During Seismic Retrofit construction, the reservoir water level will be further lowered ~~another 21 feet~~ to elev. 450 ~~467~~ feet during Year 1~~, and then lowered another 17 feet to elev. 450 feet during Year 2~~. Following cofferdam and reservoir bypass pipe construction (occurring in Year 2), the reservoir would be maintained at elev. 450 feet during Years 2 and 3. The reservoir would be filled to elev. 556 feet in Year 4, elev. 556 feet in Year 5, and elev. 657 feet in Year 6. 453 feet during Years 3, 4, 5, and 6. All flows into the reservoir would be discharged through the Stage 2 Diversion System. A pool of water would be held behind the cofferdam (which would have a capacity of 500 AF), but the water level would fluctuate based on inflow and time of year. During the wintertime, or once flows are too high to be accommodated by the bypass pipe, the bypass pipe would be closed and water would flow over the top of the cofferdam and discharge directly to the Stage 2 Diversion System intake structure.

The dewatering of the reservoir will allow runoff water (e.g., generated by precipitation in the watershed upstream of the reservoir during the wet season) to flow over and through deposited sediment in previously inundated areas along the reservoir bed. Though there is some degree of compaction and cohesion in the reservoir sediment beds, once exposed to direct runoff sediment would be susceptible to erosion (displacement and removal) and then transport (conveyance downstream) to Coyote Creek. The ability for runoff to erode and transport the reservoir bed sediments reflects a balance of driving forces, including the force, magnitude, and duration of the runoff, with the resistant forces of the sediment including its mass, texture, and cohesion. Flows that can erode and entrain sediment in the water column will carry the sediment downstream. This will generally apply to finer sediments that are carried in suspension versus larger and coarser grained sediment which would be transported along the bed of the lake as bedload. Most of the sediment deposited in the deadpool storage of the reservoir is considered fine textured and more available to be transported as suspended sediment (Valley Water 2020c).

In addition to making more sediment available to be transported, with the reservoir at deadpool at the end of the FOCP and storage level lowered during the Project, the reservoir would have less buffer to capture sediment. Although coarse sediment would settle in the deadpool, not all fine sediment would have time to settle in the limited storage before passing downstream of the dam. During the Project, when storage is lowered further, the reservoir would have even less ability to capture sediment, and there would be greater possibility of erosion of the exposed reservoir bed, with the likely result of a greater volume of sediment being discharged downstream.

Modeling of reservoir hydrological conditions during Seismic Retrofit construction showed that substantial volumes of sediment could be mobilized and transported downstream during storms that occur while the reservoir is in a dewatered state (Valley Water 2020c). Preliminary FOCP monitoring of suspended sediment concentrations suggests that the modeling slightly overestimated suspended sediment concentrations and therefore adverse suspended sediment impacts described below may be overestimated (Stillwater Sciences 2024). Somewhat counter-intuitively, very large storms may be less problematic with respect to sediment mobilization/transport since a very large runoff event (e.g., greater than 2- or 5-year events) will fill the reservoir, thereby reducing the amount of erosion that occurs from water passing directly over and through exposed sediments in the lakebed. Additionally, while larger, less frequent storms may generate larger amounts of erosion from the upstream watershed and sediment loads into the reservoir, this sediment would likely be deposited in the reservoir pool, which reduces sediment loads and TSS concentrations downstream (Valley Water 2020c). By contrast, smaller storm events may allow runoff flows to pass through the reservoir without filling it, and thereby carry sediment already suspended in the water column from upstream flows or potentially entrain and carry additional fine sediment from the reservoir bed.

Two sediment transport scenarios (numbered Scenarios 3 and 4) were modeled to better understand these processes potentially occurring under the seismic retrofit construction, as documented in the *Sediment Transport Modeling Memorandum* (Valley Water 2020c) (see Appendix K), and summarized in **Table 3.11-4** below:

Table 3.11-4. Reservoir Conditions Considered in Sediment Transport Model

Scenario[1, 2]	Elevation in Reservoir	Outlet	No. of Years
3	450	Existing with ADTP low level restricted to 2,000 cfs	0.25
4	467	Project Diversion	4

Source: Valley Water 2020c

Notes:

[1] Scenarios 1 and 2 pertain specifically to the ADTP (not Project), and thus are not presented here.

[2] Scenario 3 is also used as a proxy for the shoulder seasons during Project when flows up to 1,000 cfs could pass directly into the diversion system at elev. 450 through a diversion extension pipe from upstream of the cofferdam. The diversion extension pipe would be closed in late fall ahead of significant storms and reopened in the spring when the potential for significant storms is past.

Scenario 3 represents the conditions that would exist following complete dewatering (to elev. 450 feet) but before the cofferdam has been constructed. Under this condition, which would only last for approximately 3 months, the reservoir will be drained and there will be no pool of water for suspended sediment to settle in (Valley Water 2020c). The analysis simulated a constant inflow rate plus two storm events (a 2-year event and one-half of the 2-year event) for this scenario. Scenario 4 is expected to last 4 years while the dam excavation and reconstruction is occurring, following cofferdam construction. Under the cofferdam scenario, a small pool will be maintained through each of the four precipitation seasons. Constant inflow and two storm events (2- and 5-year events) were simulated for the cofferdam scenario in Years 3 through 6.

The results of the sediment transport modeling with respect to TSS concentrations released from the reservoir and observed downstream in Coyote Creek are shown in **Table 3.11-5.** With respect to sediment erosion/mobilization within the reservoir, several trends were observed in all the runs (Valley Water 2020c). Most erosion occurred at the beginning of the storm events when the flows were high but before the reservoir level rose to a point high enough to flood the north and south reservoir arms. After the flooding of these areas, there was little erosion because the erodible sediments were inundated by the rising reservoir water level. The TSS concentration in the reservoir then decreased as the sediment settled in the reservoir (Valley Water 2020c).

Table 3.11-5. Peak Total Suspended Solids Results Summary

		Peak Total Suspended Solids Concentrations at Locations Along Coyote Creek (mg/L)				
Scenario	Flow Event	Released from Reservoir	Upstream of Ogier Ponds	Downstream of Metcalf Ponds	Near Upper Penitencia Creek Confluence	At Milpitas
3	Constant Inflow	5,200	4,854	2,383	3,060	2,503
	2-year Inflow	39,140	32,492	18,117	16,055	30,617
	½ of 2-year Inflow	8,308	7,457	4,038	4,060	4,079

Scenario	Flow Event	Peak Total Suspended Solids Concentrations at Locations Along Coyote Creek (mg/L)				
		Released from Reservoir	Upstream of Ogier Ponds	Downstream of Metcalf Ponds	Near Upper Penitencia Creek Confluence	At Milpitas
4	Constant Inflow	290	290	290	87	130
	2-Year Inflow	30,470	26,437	18,145	16,521	16,547
	5-Year Inflow	25,030	13,711	13,711	13,159	13,177

Source: Valley Water 2020c

Key: mg/L = milligrams per liter

As shown in **Table 3.11-5**, the highest TSS levels released from the reservoir (39,140 mg/L) were observed under Scenario 3 during the 2-year storm event inflow. The TSS levels associated with this simulation generally attenuated as one moves downstream as some of the suspended sediment is expected to settle out and deposit into the streambed or in ponds along the flow path, with the exception that TSS concentrations increased back to 30,617 mg/L at Milpitas for Scenario 3, however the reservoir contributions for that peak were estimated to be approximately 18,000 mg/L. TSS levels released from the reservoir were reduced for Scenario 3 under both the constant inflow (5,200 mg/L) and one-half of the 2-year storm event inflow (8,308 mg/L) model runs. The 2-year event inflow simulation also produced the highest TSS levels under Scenario 4. As can be seen in **Table 3.11-5**, during the 2-year event, the peak TSS concentrations were 30,470 mg/L in water released from the reservoir, while the concentrations generally decreased further downstream to 16,521 mg/L near the Upper Penitencia Creek confluence, before increasing slightly to 16,547 mg/L at Milpitas. The TSS concentrations were much lower during the constant inflow model run under Scenario 4 (290 to 87 mg/L), but still quite elevated during the 5-year storm event (25,030 to 13,159 mg/L).

As part of sediment transport modeling, the mass of sediment deposition occurring throughout Coyote Creek was estimated under the different scenarios and storm events/inflow parameters. Most of the sediment would be expected to deposit in the Ogier Ponds (a historical gravel mine) and the Metcalf Ponds (which includes a Valley Water groundwater recharge facility), since the water flow slows down substantially at these locations due to both a reduction in slope and an increase in the channel/pond cross-sectional area. The ability for water to entrain sediment decreases directly with a reduction in velocity. As flow velocity decreases the TSS in the water column would have a chance to settle out and deposit on the pond bottom, very much like the sediments had deposited along the reservoir previously. The results of the sediment deposition modeling for Ogier and Metcalf ponds are shown in **Table 3.11-6**.

Table 3.11-6. Sediment Deposition in Ogier and Metcalf Ponds

Scenario	Flow Conditions	Mass of Deposition (Tons)		Depth of Deposition (Inches)	
		Ogier Ponds	Metcalf Ponds	Ogier Ponds	Metcalf Ponds
3	Constant – 180 cfs	1,164[1]	146[1]	0.1[1]	0.0[1]
	2-year event	27,941	1,160	3.4	0.2
	½ of 2-year event	7,996	1,551	1.0	0.3
4	Constant – 180 cfs	170[1]	1[1]	0.02[1]	<0.01[1]
	2-year event	21,811	1,413	2.6	0.3
	5-year event	27,656	2,450	3.3	0.5

Source: Valley Water 2020c

Notes:

[1] For the constant release scenarios, deposition was calculated as a rate per day.

Key: cfs = cubic feet per second

The greatest amount of sediment deposition is estimated to occur under Scenario 3 during the 2-year storm event at Ogier Ponds (27,941 tons or 3.4 inches). However, this is only slightly greater than what is expected to occur at Ogier Ponds under Scenario 4, the 5-year event (27,656 tons or 3.3 inches). In general, much more sediment would deposit in Ogier Ponds compared to Metcalf Ponds under all scenarios and flow conditions, which makes sense given that the Metcalf Ponds are further downstream from Anderson Dam (10 miles) compared to Ogier Ponds (4 miles).

With respect to the potential for sediment deposition in the reaches of Coyote Creek between the reservoir and Ogier Ponds/Metcalf Ponds, modeling found that there would generally be a net loss in sediment within Coyote Creek below Anderson Dam. These results suggest that the reaches of Coyote Creek downstream of the dam but upstream of Ogier Ponds and Metcalf Ponds do not favor deposition but maintain transport conditions. **Table 3.11-7** shows the results of this analysis.

Table 3.11-7. Erosion and Deposition in Coyote Creek

Scenario	Flow Conditions	Between Anderson Dam and Ogier Ponds			Between Ogier and Metcalf	Between Metcalf and Estuary
		Erosion (tons)	Dep. (tons)	Net Dep. (tons)	Net Dep. (tons)	Net Dep. (tons)
3	Constant – 180 cfs	-183	136	-47	-95	-40
	2-year event	-6,816	4,931	-1,885	-2,768	14,123
	½ of 2-year event	-4,121	3,031	-1,090	-1,992	14,293
4	Constant – 180 cfs	-156	143	-13	-80	10
	2-year event	-6,819	4,959	-1,860	-2,420	14,449
	5-year event	-9,615	6,825	-2,789	-4,746	14,244

Source: URS 2023

As shown in **Table 3.11-7**, in the reach of Coyote Creek between Anderson Dam and Ogier Ponds, rates of erosion are expected to exceed rates of deposition during the flow conditions studied. This results in an overall net loss of sediment for the reach. As described in the *Update to April 30, 2021 Memo on Sediment Deposition in Coyote Creek above Ogier Ponds and Discharge to Estuary* (URS 2023), the Coyote Creek hydraulic and sediment transport model was defined by a series of unevenly spaced channel cross-sections. At each cross-section, hydraulic results (e.g., velocity, depth) and sediment results (e.g., suspended sediment concentration, sediment loads) were calculated (URS 2023). The net erosion and deposition of sediment within a creek reach is calculated as the difference in sediment load passing a section above and below the reach of interest. This method provides the net deposition (or erosion) within the reach though both erosion and deposition could occur at different locations within the reach (URS 2023).

During Seismic Retrofit construction, the rate of erosion in reaches of Coyote Creek downstream of Anderson Dam would be increased due to the higher flows enabled by the Stage 1 Diversion System and Stage 2 Diversion System, relative to the historical outlet capacity. While substantial deposition would occur in Ogier Ponds (refer to **Table 3.11-6**), in the reach between Ogier Ponds and Metcalf Ponds (see **Table 3.11-7**), there would also be a net loss of sediment due to the elevated erosion rates, thereby counteracting the depositional processes. Downstream of Metcalf Ponds, between the ponds and the estuary, net positive deposition can start to be seen in the model. Over 14,000 tons of net sediment deposition would occur in this reach during each of the storm events modeled for Scenarios 3 and 4.

The modeled TSS levels in the reservoir releases and downstream in Coyote Creek (**Table 3.11-5**), as well as the estimated amounts of sediment deposition in Ogier Ponds and Metcalf Ponds (**Table 3.11-6**), are very high relative to historical (Pre-FERC Order) conditions and the existing conditions baseline. As reference, water quality monitoring at five locations along Coyote Creek downstream of Anderson Dam conducted from December 2019 to April 2020 showed TSS concentrations from 2.0 mg/L to a maximum of 37.20 mg/L (Valley Water 2021); refer to **Table 3.11-2** ~~**Table 3.11.-3**~~. Elevated TSS levels would be expected in waterbodies during the wet season following storms (due to erosion in the upstream watershed); however, the elevated levels of suspended sediments predicted under both Scenarios 3 and 4 following storms with moderate return intervals (2-year, one-half 2-year, and 5-year) would be substantially higher than what would be expected baseline conditions. While the chance of a 5-year storm event happening in any given year is 20 percent, the chance of a 5-year event occurring at least once within a 7-year period such as the Seismic Retrofit construction period is roughly 79 percent. The odds are higher for 2-year event or one-half of a 2-year event to occur. The impacts of elevated suspended sediment are also of concern with respect to water quality and biological resources; refer to the respective sections of this EIR (Section 3.4, *Biological Resources – Fisheries Resources,* Section 3.5, *Biological Resources—Wildlife and Terrestrial and Resources,* and Section 3.14, *Water Quality*) for the analysis of impacts to these resources. As detailed in those sections, despite the short-term adverse effects of sediment mobilization and release from Anderson Reservoir during Seismic Retrofit construction, the transport of this sediment downstream to lower Coyote Creek and San Francisco Bay would be beneficial for these downstream ecosystems and habitats and related beneficial uses because the system has historically been deprived of sediment. ~~From~~ However, from the perspective of hydrology, the erosion and sedimentation impact would be significant.

As described in ~~Chapter 2,~~ ~~*Project*~~ *Description* Section 2.7.3, Valley Water would implement a Sediment Deposition Monitoring Plan and a Sediment Monitoring Plan. Monitoring under the Sediment Deposition Monitoring Plan would evaluate available habitat conditions for steelhead and would assess and confirm the anticipated extent of the impacts from in-reservoir sediment mobilized and released during FOCP and Project construction on spawning habitat quantity and quality. ~~to continuously monitor~~ Continuous suspended sediment monitoring under the Sediment Monitoring Plan would be used to assess sediment discharges from Anderson Reservoir through completion of Project construction activities~~, and to monitor the effect of releases carrying suspended sediment to Coyote Creek downstream of the dam~~. The Sediment Monitoring Plan was created as part of the FOCP and would continue to be implemented during the seismic retrofit construction. Monitoring would take place at the Madrone Gage (USGS Station #11170000 [previously Valley Water Station #5082]), Coyote Ranch Road Gage (USGS Station #11170450**)**, Edenvale Gage (USGS Station #11171500), and Highway 237 Gage (USGS Station #11172175). ~~Serpentine Trail Pedestrian Bridge, USGS Station #11170000 (previously Valley Water Station #5082), Coyote Ranch Road, and USGS Gage Station #11172175. The~~ Results of the Sediment Monitoring Plan ~~would use monitoring results~~ and Sediment Deposition Monitoring Plan would be utilized for ongoing assessment of anticipated erosion and deposition within Coyote Creek, Ogier Ponds, and Metcalf Ponds. Assessment of monitoring results would inform post-construction implementation of Conservation Measures, including maintenance of North Channel Reach and Live Oak Restoration Reach, the Ogier Ponds CM, and the Sediment Augmentation Program, to offset ~~to inform adaptive management measures to minimize the~~ discharges of suspended sediment (Valley Water 2021).

~~Thresholds will be established based on the anticipated seasonal baseline targets supported by existing data. When an exceedance is measured, the cause of the exceedance will be investigated. This will involve looking into active construction areas and other construction water quality monitoring, as well as review of real-time data on rim landslide potential to rule that out. Note that the Contractor will be regularly monitoring work areas per their [SWPPP] and construction specific turbidity monitoring requirements. If a turbidity source is found to be related to active construction downstream of the dam and can be isolated, corrective actions may include stormwater BMP repairs, placement of additional stormwater BMPs, or possibly use of baker tanks to settle out turbidity levels. If the turbidity source is dredge and fill activity in the reservoir, treatment options may include temporary work stoppage and rapid assessment and modification to stormwater BMPs and erosion control devices (e.g., turbidity curtains). If no identified source is determined, it will be assumed that the cause is natural. If determined to be natural cause, no further action will be taken. Note that a wide range of turbidity in winter months has been recorded. As a very last resort or in case of emergency, upon consultation and full concurrence with NMFS, the SWRCB, and the San Francisco Bay RWQCB, Valley Water may reduce or shutdown dam releases for a brief, agreed upon period.~~

~~As indicated above, while BMP repairs and other measures would be implemented for sediment discharges where a specific cause/source of the sediment can be identified, if sediment is entrained in reservoir releases as the result of "natural" causes,~~ If mobilization and release of exposed sediment during and following greater than 2- to 5- year storm events are determined to be proximately causing releases that exceed background suspended sediment concentrations, they would need to be controlled in accordance with CWA and Porter-Cologne Water Quality Control Act requirements. However, adaptive management options to prevent sediment from being released from the reservoir are limited, primarily because the FERC 2020

Interim Flood Risk Reduction prohibits storing and settling storm related runoff behind the dam until the retrofit is complete due to the heightened risk to public health and safety. Therefore, methods that rely on runoff detention to reduce sediment in runoff releases cannot be deployed (e.g., sediment curtains, runoff detention, and passive or active treatment to settle sediment out of flow). Also, other conventional erosion controls would be inundated and therefore ineffective. ~~other than temporarily halting reservoir releases (Valley Water 2021). The term “natural” is used in this context to describe that basic hydrologic and geomorphic processes that could erode and transport sediment from the reservoir bed would occur unimpeded during the construction period. Though, the~~

The erosion/sedimentation associated with inflow passing over the previously inundated reservoir areas during Seismic Retrofit construction would not ~~really~~ be entirely “natural,” as it would still be occurring within the footprint of ~~a dam/~~reservoir construction areas, but because the flows and entrained suspended sediment would be unimpeded, the geomorphic processes would resemble ~~a more natural condition than under previous inundation~~ that which occurs when the dam is fully operational. The term “natural” as used here is consistent with its usage in the Sediment Monitoring Plan. Due to the reservoir being dewatered during construction and virtually all inflows being passed through directly to Coyote Creek, this would liberate much of the fine sediment that has accumulated within the reservoir over the years.

It is important to remember that both the existing conditions and Pre-FERC Order Baselines, where vast quantities of sediment are trapped behind Anderson Dam due to decades of accumulation, are “unnatural” in their own right. Since its construction, Anderson Dam has blocked the natural path of sediment from the upstream watershed to the lower reaches of Coyote Creek. Erosion and sedimentation are natural processes, which are important for stream system and ecological health. Indeed, it is at least partly owing to the absence of sediment in stream flows downstream of Anderson Dam (since the sediment is normally trapped behind the dam and not released) that substantial incision and loss of coarse sediment has occurred in the downstream areas. There is a natural balance between erosion and sedimentation that has been upset by the dam. Thus, the Seismic Retrofit construction process, which would alter the dam/reservoir operations during the construction period by maintaining the reservoir in a dewatered state exposing accumulated sediments to mobilization and release, would change the existing “unnatural” detainment of sediment and potentially release a large amount of sediment to the downstream areas exposed by construction activities~~. Regardless, the erosion and sedimentation associated with storm runoff passing over the previously inundated areas would be diffuse and a specific source would not be identifiable—as such, corrective action would not be taken in accordance with the Sediment Monitoring Plan, short of emergency measures in consultation with regulatory agencies (i.e., temporarily halting reservoir releases)~~.

A Sediment Deposition Monitoring Plan would also be implemented during Seismic Retrofit construction, although this plan is more targeted to address impacts to fisheries and spawning habitat. Like the Sediment Monitoring Plan, the Sediment Deposition Monitoring Plan was developed as part of the FOCP and will continue to be implemented during construction of the Seismic Retrofit elements of the Project. The Sediment Deposition Monitoring Plan would evaluate available habitat conditions for steelhead within the Coyote Creek FCWMZ (Valley Water 2020d). This depositional monitoring would be conducted annually and would inform the Sediment Augmentation Program and Maintenance of the Spawning Gravel and Rearing Habitat Improvements at Live Oak Restoration Reach, which would be maintained during the Seismic

Retrofit construction period. As such, spawning gravels and sediment would be placed as needed, potentially on and above newly deposited fine sediments transported from the reservoir, based on the monitoring, thereby minimizing and offsetting potential impacts of the deposition of fine sediments on fish habitat.

Implementation of the Water Quality Sampling Plan and Sediment Monitoring Plan would ~~reduce~~ measure impacts associated with elevated suspended sediment in releases from Anderson Dam during Seismic Retrofit construction~~, with respect to sediment caused by erosion at active construction areas~~. However, since the Water Quality Sampling Plan and Sediment Monitoring Plan would not specify BMPs to address elevated sediment levels due to runoff passing over the previously inundated areas of the reservoir when it is dewatered, it would not ~~account for~~ minimize much of the erosion and sedimentation/siltation that could occur during construction (i.e., the sediment liberated from the reservoir beds during runoff events). As discussed above, and shown in **Table 3.11-5**, substantial quantities of sediment could be discharged from Anderson Reservoir following storms of a certain size during the wet season, even after the cofferdam and Stage 2 Diversion System are constructed (Scenario 4). This includes water with TSS concentrations as high as 39,140 mg/L (Scenario 3, 2-year event) or 30,470 mg/L (Scenario 4, 2-year event) being released from the reservoir, with TSS levels in Coyote Creek above Ogier Ponds still potentially over 25,000 to 30,000 mg/L. Depending on the meteorological conditions that occur during the construction period, these levels could be reached multiple times following multiple storms. It is possible that multiple 2-year or 5-year storms could occur during the construction period (which will include at least four precipitation seasons when the reservoir will be dewatered), along with multiple smaller or larger storms.

These effects from reservoir dewatering would be temporary after storms of a certain size, lasting only the period during which the reservoir would be completely or partially dewatered (Years 2 through 6). Moreover, the reservoir has already been partially dewatered (to deadpool) as part of the FOCP, so elevated risk of erosion and sedimentation due to the reservoir being in a dewatered state is already present to some extent under the post-FOCP conditions baseline. Nevertheless, the greatly accelerated rates of erosion and sediment transport following greater than 2- and 5- year storm events that could be realized through Seismic Retrofit construction (refer to **Table 3.11-5** and **Table 3.11-6**) would be a substantial change from the existing conditions and Pre-FERC Order Baselines and would largely be an adverse short-term effect on ~~to~~ the system, even if some "balancing" of historical sediment deficits may occur and that additional sediment ~~may~~ provides ~~some~~ beneficial impacts to marshes in south San Francisco Bay. Conservation Measures such as the Ogier Ponds CM, Spawning Gravel and Rearing Habitat Improvements at Live Oak Restoration Reach, and the Sediment Augmentation Program would offset and provide long-term beneficial impacts in regard to erosion and sedimentation; however, they would not address the immediate impacts that could occur during construction of the Seismic Retrofit components As a result, this seismic retrofit construction would temporarily cause substantial erosion and siltation, and this impact would be significant.

Meaningful measures to reduce ~~mobilization of~~ lakebed sediment mobilization are limited. For example, measures to stabilize sediment by hydroseeding bare soils in the reservoir would not be feasible throughout the reservoir and would not eliminate the unconsolidated lake sediment that is exposed when the reservoir is drawn down below deadpool and therefore available for mobilization in reservoir releases associated with 2- and 5-year storms ~~available both under the surface soils that would be eroded in larger storms and below the deadpool that would be~~

~~exposed through reservoir lowering as part of the Project~~. Similarly, potential measures to increase sediment settling within the reservoir (i.e. turbidity curtains or managing the reservoir at a higher elevation) would not be feasible during construction. Settling BMPs require stormwater detention prior to release through the Stage 1 or Stage 2 diversion system , but FERC public health and safety interim risk reduction measures mandate that stormwater not be retained behind the dam during construction. Instead ~~because safety measures to pass~~ inflows must be passed as quickly as possible through the diversion system (to keep storage behind the interim dam as low as possible) ~~are required~~ to reduce the risk of the interim dam being overtopped, in order to provide the highest level of public safety available while the dam is under construction.

Runoff Through In-Reservoir Construction Disturbance Areas

Similar to the processes described above, erosion and siltation/sedimentation as a result of Seismic Retrofit construction could occur via runoff passing over or through construction work areas or disturbance areas. First, the various construction/disturbance activities that would occur in the dewatered reservoir, such as access road modification and construction, stockpile and borrow area establishment and utilization, and cofferdam construction, could exacerbate the erosion and sediment transport processes described above. Utilization of these areas would alter the drainage patterns within the area and could contribute additional sources of sediment beyond those predicted via “natural” processes. The linear access roads to be constructed within the reservoir would be more compacted than the existing soils (as required to support heavy equipment and as a result of access road use), which could increase runoff flow velocities and potentially increase erosion in the adjacent areas.

Similarly, utilization of stockpile areas could introduce loose, easily erodible soils to the area, which could exacerbate erosion and sedimentation effects during the wet season. The stockpile areas that would be located within the reservoir would be Stockpile Areas C, D, H, I, J, K, and L, as described in Section 2.5.2.2 within Chapter 2, *Project Description.* These areas would total 132 acres and would be used to stockpile a total of 5,002,300 cy of material. Stockpile Area M is an alternate stockpile area within the southern area of the reservoir, which is 30 acres and could be used to stockpile 1,150,000 cy of material. The stockpiled material would be excavated from the existing dam or from other areas where excess material is generated and, particularly as it dries and prior to reuse, would be susceptible to erosion. Similarly, utilization of the PGBP, located within the reservoir, east of Anderson Dam, would change the land surface due to the excavation of large volumes of material.

Construction of the cofferdam (which would occur during Year 2) would also alter the surface of the formerly-inundated reservoir bottom, by erecting the 300-foot-long, 80-foot-wide dam just upstream of the existing dam work area. Theoretically, the cofferdam could mitigate siltation/sedimentation effects by detaining runoff/inflow from upstream areas and maintaining a small pool in which entrained sediment could settle out prior to discharge of runoff water to Coyote Creek. However, as indicated by the sediment transport modeling (refer to **Table 3.11-5** and **Table 3.11-6**), the cofferdam would only offer relatively limited benefit in this regard, at least following 2- or 5-year storms (see Scenario 4 compared to Scenario 3). Under the “constant inflow” scenario, the cofferdam would be more beneficial in terms of reducing the amount of sediment discharged downstream.

Runoff Through Out-of-Reservoir Construction Disturbance Areas

The construction disturbance areas outside of the existing reservoir footprint would similarly alter drainage patterns, potentially leading to erosion and sedimentation/siltation. These would include the staging areas (of which there would be six); access roads in upland areas; stockpile and borrow areas outside of the reservoir area; and the construction work areas themselves, such as the dam excavation area, spillway and outlet works work areas, areas where trenching will occur for realignment of the AFM and Main Avenue Pipeline, as well as disturbance areas associated with the permanent roadway modifications. With respect to each of these areas where Project construction work would occur, changes to the ground surface, both in terms of slope/elevation and in the compaction or cohesiveness of soils, would have potential to cause or exacerbate any erosion and sedimentation/siltation effects that could occur (e.g., during rainstorms that occur during the construction period). Establishment of staging areas would require removal of vegetative groundcover and debris, grading to create a flat surface, and placement of gravel or a separation fabric over the ground surface, depending on the type of usage. Although no impervious ground surface would be created as part of staging area establishment, these activities (in particular, vegetative groundcover removal) would generally increase runoff flow velocity, thereby increasing potential for erosion and sedimentation/siltation.

Effects associated with the upland stockpile and borrow areas (e.g., BHBA) would be similar to those described above with respect to the in-reservoir areas. Generally, the stockpiling of materials would create opportunities for erosion and subsequent transport of sediment/silt to waterbodies. The stockpiled material is likely to be loose, unconsolidated material without substantial cohesion or resistance to erosive forces, and thus these materials could be washed downgradient to Coyote Creek. By contrast, the depressions or cavities that would be left by the borrow activities would expose underlying soils and materials to potential erosion and offsite transport of sediments/silts. Other construction work areas (e.g., where excavation may occur for construction/installation of Project components) would similarly expose loosened soils that could be susceptible to erosion, and, in some cases, the excavated areas/altered land surface could concentrate flows and thereby exacerbate the erosion issues.

In general, these potential adverse effects would be avoided or reduced either through Project design features, compliance with the Construction General Permit and implementation of the SWPPP for construction activities outside of the reservoir, implementation of applicable Valley Water BMPs and VHP conditions and AMMs, and/or construction monitoring activities. As noted above, the cofferdam installed as part of the Stage 2 Diversion System would have the benefit of detaining sediment/silt that may be entrained in runoff water from upstream areas, as well as maintaining a small pool behind the cofferdam that could allow entrained sediment to settle out. As indicated in **Table 3.11-5**, these benefits would primarily be realized during the constant inflow conditions, as opposed to following large storms. Another Project feature that would reduce potential for siltation downstream in Coyote Creek is the ATS, which would be used to treat stormwater from applicable construction work areas prior to release into Coyote Creek. As described in Chapter 2, *Project Description,* stormwater accumulating in the downstream excavation area of the dam, at spillway and outlet works construction, and at the BHBA would be collected and pumped to an ATS prior to release into Coyote Creek. The ATS would remove sediment, reduce turbidity, and balance pH from these waters. Utilization of the ATS would minimize the adverse impacts to Coyote Creek that could occur from the runoff that passes over/through, and collects in, the construction work areas and other disturbance areas associated with the Seismic Retrofit construction.

Additionally, given that the Project would disturb greater than 1 acre of land, it would be subject to the Construction General Permit. As described in Section 3.11.2, the Construction General Permit requires that the applicant prepare and implement a SWPPP for construction activities outside of the reservoir, which would include BMPs to prevent soil erosion and discharge of sediment and other construction-related pollutants to surface waters. The specific BMPs that would be implemented as part of the SWPPP would be developed at the time of the SWPPP preparation but would include measures to control erosion at the source, such as through minimizing soil disturbance, preserving existing vegetation where feasible, and stabilizing and revegetating disturbed areas as soon as possible after grading or construction activities. Temporary soil stabilization measures/practices that could be utilized include covering disturbed areas with mulch, temporary seeding, soil stabilizers, binders, fiber rolls or blankets, temporary vegetation, and permanent seeding (SWRCB 2009). Additionally, the SWPPP would include sediment control measures, which would be used to capture any soil that becomes eroded. This may include perimeter control measures such as installing silt fences or placing straw waddles below slopes (SWRCB 2009). The SWPPP would need to be prepared by a qualified professional and monitoring would be required during the construction period to ensure that the BMPs achieve the performance standards (e.g., receiving water and effluent limitations) included in the Construction General Permit.

Many of the erosion and sediment control measures that would be included in the SWPPP may also be slated for implementation as part of Valley Water's BMP Handbook or through compliance with applicable VHP conditions and AMMs. A number of Valley Water BMPs would serve to reduce potential for erosion and offsite movement of sediments, such as BMP AQ-1 (Use Dust Control Measures), BMP WQ-4 (Limit Impacts From Staging and Stockpiling Materials), BMP WQ-1 (Conduct Work from Top of Bank), BMP WQ-2 (Evaluate Use of Wheel and Track Mounted Vehicles in Stream Bottoms), BMP WQ-5 (Stabilize Construction Entrances and Exits), BMP WQ-9 (Use Seeding for Erosion Control, Weed Suppression, and Site Improvement), BMP WQ-10 (Prevent Scour Downstream of Sediment Removal), BMP WQ-11 (Maintain Clean Conditions at Work Sites), BMP WQ-16 (Prevent Stormwater Pollution). Similarly, many VHP conditions and AMMs require erosion and sediment control measures that would serve to reduce the potential impacts of seismic retrofit construction, including conditions 3, 4 5, 7, 11, and 12, and AMMs 4, 16, 17, 20, 25, 26, 38, 39, 40, 51, 52, 53, 61, 63, 64, 65, 66, 67, 68, 69, 70, 71, 73, 74, 75, 77, 83, 84, 93, 94, 96, and 97. Refer to Section 3.11.3.7 for descriptions of the applicable BMPs. The full text of the BMPs ~~and AMMs~~ is provided in Appendix A.

As such, whether included in the SWPPP pursuant to the Construction General Permit for out-of-reservoir construction activities, implemented in accordance with Valley Water's BMP Handbook, or in compliance with the VHP, the Seismic Retrofit construction activities would incorporate erosion and sediment control measures to minimize the prospect of substantial erosion and siltation/sedimentation. These measures would assure that the Project's extensive disturbance areas during construction would not cause substantial erosion or siltation, and this impact would be less than significant.

Conservation Measures Construction

Ogier Ponds CM

Construction of the Ogier Ponds CM would alter drainage patterns in the sense that it would change the flow path of the creek, by creating a new section of creek channel at the area of the existing ponds. The new section of creek channel would start at Pond 1 and connect to the pre-1997 channel alignment located west of Ponds 2, 3, 4, and 5, thereby separating Coyote Creek from Ogier Ponds. As described in Chapter 2, construction of the Ogier Ponds CM would require dewatering of the pond areas to be filled (i.e., the entirety of Ponds 1 and 5 and portions of Ponds 2 and 4 ~~5~~), diversion of creek flow around the work area, and control of groundwater to minimize expected seepage into the work areas. Earthen berms would also be constructed to separate the unfilled portions of Pond 2 ~~Ponds 2 and 5~~ from the restored channel, and the new channel area would be cleared of vegetation, excavated and graded.

The construction work within or adjacent to the channel required for construction of the Ogier Ponds CM would have the potential to loosen materials that could be washed downstream, thus contributing to accelerated rates of erosion and sedimentation. Additionally, use of staging and stockpiling areas and mobilization of equipment in upland areas or areas directly adjacent to the creek could contribute sediment-laden runoff to Coyote Creek. As such, the construction activities for the Ogier Ponds CM would have potential to cause erosion and offsite movement of sediments; however, as discussed above in *Runoff Through Construction Disturbance Areas* these effects would be avoided or minimized through implementation of the SWPPP, Valley Water BMPs, and VHP conditions and AMMs.

Maintenance of the North Channel Reach ~~Extension~~

The restoration of the North Channel through the historic creek alignment, which would occur as part of FOCP, would include grading additional channel area to connect it to the South Channel downstream. Maintenance of the North Channel Reach would involve minor and intermittent activities such as maintenance of the wetland bench, restoration plantings, and flow capacity, including replacement of plantings and/or materials that would be required to restore the wetland bench. ~~While the grading and restoration of the channel would reduce potential for erosion over the long-term (e.g., removing deep holes where ponding could occur),~~ As such, there would be limited potential for short-term effects during construction, ~~as~~ though some loosened soils ~~loosened by~~ grading could be eroded and washed downstream. Likewise, vehicle and equipment movement/staging adjacent to the riparian areas could minimally contribute to erosion and discharge of sediment to Coyote Creek. However, as discussed above, these potential adverse effects would be avoided or reduced through implementation of measures included in the SWPPP and in applicable Valley Water BMPs and VHP conditions and AMMs.

Maintenance of Spawning Gravel and Rearing Habitat Improvements in Live Oak Restoration Reach

The spawning gravel and rearing habitat improvements in the Live Oak Restoration Reach that would be conducted as part of the Project, would be done to off-set the potential effects of reservoir dewatering and sediment deposition on spawning and rearing habitat from the FOCP and Project. In this respect, the effects with respect to hydrology would be a net positive.

However, with any work within or near the stream channel, there would be potential during construction to disturb the streambed and/or cause erosion of streambanks, which can subsequently cause silt/sediment to be transported downstream. Implementation of applicable Valley Water BMPs and VHP conditions and AMMs would avoid or reduce these potential adverse effects.

Sediment Augmentation Program

The Sediment Augmentation Program would place sediment in locations of Coyote Creek between Anderson Dam and Ogier Ponds. Sediment augmentation activities would be designed to improve geomorphic processes with respect to steelhead habitat and reduce the legacy channel incision that is typical in Coyote Creek downstream of the dam. ~~The Sediment Augmentation Program would involve removing and stockpiling approximately 55,000 cy of suitable sediment from the exposed sources in the dry Anderson Reservoir lakebed and then delivering sediment loads to various locations in Coyote Creek based on locations most in need as determined by construction phase sediment monitoring and disposition monitoring.~~ The Sediment Augmentation Program would involve initially placing 500 cy of coarse sediment in the Live Restoration Reach following completion of ADSRP construction, and later during adaptive management within the Live Oak Restoration Reach or Ogier Ponds Restoration Reach based on locations most in need of additional sediments, as determined by construction phase sediment monitoring and deposition disposition monitoring. The Live Oak Restoration Reach or Ogier Ponds Restoration Reach would be replenished with up to 500 cy every 5 years based on annual monitoring results.

The potential for impacts during construction would be similar to that described above for the Seismic Retrofit component and other conservation measures. Stockpiling of sediment, if done improperly, would create a pathway for erosion and offsite siltation/sedimentation, while use of trucks and heavy equipment (e.g., for delivery of sediment loads to replenishment sites) could loosen soils and potentially allow for erosion and discharge of fine sediments. Given that it would be implemented over many years, the program may not be subject to the Construction General Permit. Nevertheless, implementation of applicable Valley Water BMPs and VHP conditions and AMMs would substantially reduce potential for erosion and subsequent siltation/sedimentation during construction activities for the program.

Phase 2 Coyote Percolation CM

The Phase 2 Coyote Percolation Dam CM would involve construction of a roughened channel (approximately 500-feet long by 110-feet wide) using engineered streambed materials composed primarily of natural materials (e.g., boulders, cobble, gravel, and sand) placed in such a way as to mimic the configuration of a natural streambed. As described in Chapter 2, construction activities associated with the Phase 2 Coyote Percolation Dam CM would occur during the summer and fall of Years 1 and 2 ~~4 and 5~~ and would include site mobilization, control of flows in Coyote Creek (dewatering), demolition, vegetation clearing, and grubbing, creek material placement and enhancement, roughened ramp construction, and revegetation seeding and planting. Dewatering of the CM area would be implemented through the construction upstream and downstream cofferdams that would be constructed with a bypass feature (pipes) to allow flows to bypass the work area and maintain flows in Coyote Creek throughout Project implementation.

Given the work within the streambed that would be required during construction of the Phase 2 Coyote Percolation Dam CM and operation of construction equipment on adjacent streambanks, there would be similar potential for erosion (i.e., loosening of soils from operation of construction equipment) and subsequent siltation/sedimentation to that discussed above for the Seismic Retrofit component and other conservation measures involving such activities. These effects would be reduced to a less-than-significant level via implementation of Valley Water BMPs and VHP conditions and AMMs. The dewatering required for construction of this conservation measure would expose the base of the pond with previously deposited sediments subject to erosion. As the Coyote Percolation Pond is occasional drained for maintenance in the baseline conditions there would be little potential for erosion and mobilization of sediment above existing conditions. As such, the impacts from dewatering the pond and exposing sediments on the pond bottom as part of this conservation measure would be less than significant.

Construction Monitoring

As described in Chapter 2, *Project Description,* a variety of construction monitoring efforts would be undertaken during the Seismic Retrofit component and Conservation Measure component construction periods. This includes water quality monitoring, fisheries monitoring, *phytophthora* pathogen monitoring, groundwater monitoring, and biological resources monitoring. In general, the monitoring efforts would have limited potential to result in substantial erosion or siltation on- or offsite. Activities such as collecting samples would be conducted on foot and would not involve operation of heavy equipment within the streambed or banks. ~~Setting up fyke nets, electrofishing~~ Electrofishing, installing VAKI Riverwatcher, installing PIT antenna equipment, and related activities could disturb sediments on the streambed or banks, but these impacts would be temporary and very minor. Measures to reduce potential *phytophthora* spread, as identified through the monitoring process, would likely reduce potential for siltation (e.g., hygiene and sanitation measures, such as vehicle and equipment washing). As a result, impacts from construction monitoring activities would be less than significant.

Seismic Retrofit Post-Construction Operations and Maintenance

All these flow scenarios under normal operations are within the flow regimes of the Pre-FERC Order baseline and existing conditions baseline and would not create additional erosion or sedimentation above the baseline conditions. Impacts from future flows would be less than significant.

Higher Flows During Normal Operating Conditions

The Seismic Retrofit components of the Project would greatly increase the capacity of the dam's outlet works and could thus provide the ability to release substantially greater volumes of water, resulting in higher flows downstream in Coyote Creek. As opposed to the dam's outlet works prior to the FOCP, which had a maximum capacity of 500 cfs, outflows from Anderson Reservoir following completion of the Seismic Retrofit would occur in four ways: (1) normal releases, up to 170 cfs to Coyote Creek via the 33-inch bypass pipeline (part of the LLOW); (2) releases up to 1,315 cfs to Coyote Creek through the 78-inch conveyance pipeline (also part of the LLOW, and is the pipeline that facilitates bi-directional transfers of water between Anderson Reservoir the raw water distribution system); (3) releases up to 5,300 cfs from the HLOW; and

(4) uncontrolled releases from the spillway. ~~the Seismic Retrofit would establish new outlet works with a total combined capacity of 6,840 cfs. This would include the LLOW, which would have a maximum capacity of 1,540 cfs, but would operate up to 1,400 cfs under majority of operations. The HLOW would have a capacity of 5,300 cfs and would be used during emergencies that require a DSOD-mandated drawdown of the reservoir (i.e., to respond to an earthquake emergency) (Valley Water 2023d). The new spillway constructed as part of the Seismic Retrofit would be able to safely convey the PMF, which is estimated to be approximately 98,000 cfs, but would be utilized less frequently due to the new larger LLOW.~~ Theoretically, the new dam release facilities constructed as part of the Seismic Retrofit could enable higher flows during operation, which could cause erosion downstream if substantially higher than existing flows.

Releases from Anderson Dam following completion of the Seismic Retrofit components of the Project would be governed by the FAHCE operational rule curves, which would be beneficial for fish. Dam operations under the Pre-FERC Order Conditions Baseline were based on a variety of factors, including water supply, environmental, flood risk, and other considerations. For example, to maintain a wetted Coyote Creek, maximize managed aquifer recharge consistent with the District Act and Sustainable Groundwater Management Act (SGMA), and benefit the environment, a flow requirement of 2.5 cfs at streamflow station 5058 (Edenvale), has been maintained per Valley Water's LSAA with CDFW (Valley Water 2023a ~~2022a~~). Typically, when it is not raining, a total release of 30 to 55 cfs at the base of Anderson Dam is needed to maintain 2.5 cfs at streamflow station 5058, which is approximately 14.8 miles downstream of the dam (Valley Water 2023a ~~2022a~~). The median of daily flows by month at Madrone stream gage (USGS station 11170000), for the water years 2000 through 2019, shows a range of 20-25 cfs in the in the winter (October through April), whereas a range of 40-50 cfs has been observed in the warmer summer season (May through September), when water supply and maintaining groundwater recharge has a higher demand. Total releases at the base of Anderson Dam above 60 cfs are typically more than what is needed to meet water supply and downstream environmental flow requirements, although higher releases may be necessary when recovering from a prolonged drought (Valley Water 2023a ~~2022a~~).

A major difference compared to the Pre-FERC Order Conditions Baseline under FAHCE would be to introduce "pulse" flows during the winter/spring. Under FAHCE, the pulse flows would be 50 cfs for 5 days, occurring up to two times from February 1 – April 30 if storage thresholds are met. Storage-based winter base rule curves would provide releases of 5, 10, 15, 23, and a highest winter base rule curve which would provide for a minimum release of 26 cfs and up to the amount required for recharge and downstream LSAA flow requirements. The revised operating rules under FAHCE would primarily serve to improve conditions for anadromous fish; refer to Section 3.4, *Biological Resources – Fisheries*, for discussion of these largely beneficial effects.

With respect to hydrology and potential impacts related to erosion and siltation/sedimentation, the Pre-FERC Order Conditions Baseline is itself representative of an impacted, "unnatural" system. In this regard, operation of the reservoir over its history has already contributed to changes in the downstream stream morphology. While stream dynamics are complex, this may have included accelerated rates of erosion downstream of the dam due to the "hungry water" effect, whereby flows downstream of a dam that are low in sediment due to deposition above the dam have additional competency to erode and entrain sediment downstream of the dam. As discussed above, the dam would have acted to trap the vast majority of the naturally-transported sediment that was carried in runoff water entering the reservoir from upstream areas, creating the sediment depleted water that is discharged.

With respect to flow magnitude, the dam acted to reduce peak flows that would have occurred following storms under a "natural" hydrological regime. Reservoirs act to store high runoff events and release them under a prolonged low or moderate flow at later times. This results in "shaving off the peak" of the hydrograph and extending the hydrograph out into the future. In practice at Anderson Reservoir, release of winter stored runoff increased summertime flows, resulting in an overall dampening/homogenizing of the flow pattern.

With this context in mind, some undesirable effects (e.g., channel incision) in Coyote Creek downstream of Anderson Dam are part of the Pre-FERC Order Conditions Baseline. The winter baseflows contemplated under FAHCE would not be a significant change relative to the Pre-FERC Order Conditions Baseline; thus, no substantial change to erosion or siltation/sediment is expected as a result. The 50 cfs pulse flows under FAHCE would be higher than typical, baseline operating conditions, where the median of daily flows by month, for the water years 2000 through 2019, at USGS 11170000 range from 20-25 cfs in winter (November through April); however, the pulse flows would be similar to summer flows under the Pre-FERC Order Conditions Baseline. As noted above, releases range from 40-50 cfs in the summertime (May through October). As such, these pulse flows would not be expected to result in substantial additional erosion and siltation/sedimentation relative to that occurring under the Pre-FERC Order Conditions Baseline. Periodic, high flows that might occur due to the new larger LLOW can be beneficial to stream geomorphology (e.g., to prevent excessive encroachment of perennial vegetation and also freshen the stream bed with new features, increasing instream complexity and habitat opportunities). Additionally, as discussed above, relative to the pre-dam state, the pulse flows under FAHCE and the use of the LLOW in response to reaching the FAHCE flood rule curve would be a movement toward the "natural" hydrograph, meaning less dampened and reintroducing some peak flow events.

Imported water would still be used to supplement flows in Coyote Creek for groundwater recharge and habitat benefits. Imported water would mostly be discharged via the CDL (as in existing baseline conditions and Pre-FERC Order baseline), but could also be discharged from the CVPE if the cold-water pool in Anderson Reservoir were limited – in which case cold water would be released from the reservoir to provide flows through the CWMZ at approximately 10 cfs, then additional releases could be made below the CWMZ in the CVPE (at up to 30 cfs) to support full groundwater recharge.

As part of FOCP, Valley Water restored the North Channel of Coyote Creek immediately downstream of Anderson Dam, including extending the limits of this historic creek alignment to reconnect it with the South Channel downstream (historically, all managed dam releases have been discharged directly to the South Channel). This allows high flows to be directed through the restored North Channel, which can accommodate such flows, thus limiting flows within the South Channel and minimizing erosion and flooding of the Live Oak picnic area at this location. Moreover, ~~several~~ conservation measures that would be implemented as part of the Project would serve to minimize any adverse effects associated with operational erosion/sedimentation in Coyote Creek downstream of Anderson Dam. ~~First, as described in Chapter 2, *Project Description,* Valley Water would restore the North Channel of Coyote Creek immediately downstream of Anderson Dam, including extending the limits of this historic creek alignment to~~

~~reconnect it with the South Channel downstream (historically, all managed dam releases have been discharged directly to the South Channel). This would allow high flows to be directed through the restored North Channel, which would be designed to accommodate such flows, thus limiting flows within the South Channel and minimizing erosion and flooding of the Live Oak picnic area at this location. Habitat enhancements in the restored North Channel may also include the establishment of a sediment injection point, per the Sediment Augmentation Program, for the placement of 500 cy of sediment that would be mobilized by high flows for improving downstream substrate conditions. Additionally,~~ Specifically, Valley Water would implement spawning gravel and rearing habitat improvements in the Live Oak Restoration Reach directly downstream of Anderson Dam to address the potential effects of reservoir dewatering and sediment deposition. ~~Each of these aspects/measures~~ This measure would be included in the Sediment Augmentation Program, described below.

To address the effects of coarse sediment loss for steelhead habitat from creek banks and bed incision below Anderson Dam, Valley Water would implement the Sediment Augmentation Program as described above. This would include initial placement of approximately 500 cy of coarse sediment within the Live Oak Restoration Reach following completion of Project construction. ~~removing and stockpiling approximately 55,000 cy of suitable sediment from exposed sources in the dry Anderson Reservoir lakebed between the Dunne Avenue Bridge and the Holiday Estates boat launch staging area throughout the duration of Project construction. The sediment would be placed in Coyote Creek at multiple locations downstream of Anderson Dam through Ogier Ponds from Year 2 through Year 10 of construction, with monitoring and off-hauling continuing through Year 15~~. Over the long-term, ~~approximately~~ up to 500 cy of sediment would be placed in the Live Oak Restoration Reach or within the Ogier Ponds CM restoration reach at least every 5 ~~every 5-7~~ years during the operational phase.

These CMs would help to reduce erosion that could occur due to higher flow releases under operation of the revised dam facilities, as well as ongoing and historical erosion that has occurred immediately downstream of the dam. Replenishment of sediment in these key areas will reduce some of the adverse geomorphic effects that are expected downstream of dams (see the discussion of "hungry water" above). In general, implementation of the FAHCE operational flow regime, along with the CMs included in the Project, would likely lead to an improvement in the health of Coyote Creek sediment conditions relative to the Pre-FERC Order Conditions Baseline. Therefore, impacts would be less than significant.

Peak Flows Associated with Emergency Drawdown or Release Conditions

While the FAHCE rule curves would govern releases the majority of the time during Project operation, the reservoir may need to be lowered quickly during emergency situations, such as responding to a DSOD mandate to draw down the reservoir after an earthquake. This would potentially result in very high flows for short periods of time. The seismic retrofit would greatly increase the capacity of the dam's outlet works, thereby making a quick drawdown of the reservoir's water level possible in an emergency situation. This would comply with DSOD requirements as described in Chapter 2, *Project Description,* to provide a new outlet works at Anderson Reservoir to be capable of lowering the reservoir's maximum storage depth by 10 percent within 7 days and draining its full content within 90 days (DSOD 2018 ~~2017~~). Between the LLOW and HLOW, the reconstructed Anderson Dam would be able to release up to 6,840 cfs. Relative to the dam's maximum discharge capacity via its outlet works of 500 cfs under the Pre-FERC Order Conditions Baseline, this would represent a substantial increase in the potential peak controlled releases/flows from the dam. Under the Pre-FERC Order Conditions Baseline very high flows would pass over the spillway when the reservoir was filled and the volume of water coming into the reservoir was greater than the capacity of the outlet to release water (500 cfs). Under post-construction operations high flows may still pass over the spillway when the reservoir is filled; however, this would be less likely given the ability to release greater volumes of water prior to a large storm (Valley Water 2023b).

Similar to uncontrolled releases observed in the Pre-FERC Order Condition (i.e., 2017 spill event resulted in flows of 7,400 cfs at the Madrone Gage), controlled releases of high flows can increase potential for erosion downstream, as greater volumes of water traveling at greater velocities would increase the erosive power of the flows. Given the infrequency of emergency drawdown scenarios, these effects would also be infrequent and would occur in the context of necessary dam operations for the protection of life and property. In this respect, the effects would be less of a concern, although single, extreme events can cause a large amount of erosion and siltation/sedimentation that can be damaging to the ecosystem. Refer to Impact HYD-1, subsection iv. below for discussion of potential effects related to flooding caused by the higher releases made possible by the seismic retrofit elements of the Project.

Many of the Project features described above would serve to minimize potential adverse effects associated with peak flows in the event of an emergency. For example, the ~~reconstructed North Channel would enable Valley Water to split high flows between the North and South Channels of Coyote Creek, thereby minimizing the concentration of flows and the erosive power. The~~ ongoing sediment augmentation activities, as part of the Sediment Augmentation Program, would ~~also~~ help to replenish sediment that may have been washed out during a high-flow event. As noted above, the existing conditions include very high flows during and after large winter storms that inundate the floodplain and carry large amounts of sediment downstream. Therefore, impacts would be less than significant.

Dam Facility Maintenance

Valley Water would maintain all Project-constructed features and facilities to ensure their proper function. The newly retrofitted Anderson Dam and Reservoir would be maintained under Valley Water's existing DMP. Maintenance of Anderson Dam facilities was previously evaluated in the Final DMP Program EIR prepared in January 2012 (SCH No. 2011082077; Valley Water 2012). The DMP includes BMPs and mitigation measures to minimize water quality impacts. For example, Valley Water would minimize the negative impacts of reservoir dewatering on water quality or sediment quality through implementation of DMP Mitigation Measure General-3, which requires the development a dam-specific reservoir dewatering plan for each dewatering event. BMPs HM-1 and HM-4 through HM-8, and DMP Mitigation Measures Water Quality-1 and Wildlife-4 all deal with minimizing impacts to water quality from herbicides, pesticides, and rodenticides. The Project's post-construction maintenance activities would not differ substantially from those impacts identified in the DMP EIR. Further, previously identified DMP impacts would not be exacerbated with implementation of the Project. Conservation Measure Post Construction Operations and Maintenance

Over the long-term, the CMs included in the Project would generally have positive effects with respect to erosion and siltation/sedimentation. Implementation of the Sediment Augmentation Program would largely counteract the erosion and loss of course sediment that has historically occurred downstream of Anderson Dam, and which may continue to occur during Project operation associated with occasional higher flows. The replacement of course sediment at key locations would be beneficial and may curb further erosion and incision, which are ongoing issues in Coyote Creek. The Phase 2 Coyote Percolation Dam CM, which includes the roughened ramp fishway below the bladder dam (already installed as part of FOCP), would likely reduce the susceptibility of this reach to erosion. Implementation of the Spawning Gravel and Rearing Habitat Improvements at Live Oak Restoration Reach would place spawning gravels and sediment as needed, potentially on and above newly deposited fine sediments transported from the reservoir, based on the monitoring, thereby minimizing potential impacts of the deposition of fine sediments on fish habitat.

Finally, the disconnection of Ogier Ponds from Coyote Creek would likely be a benefit with respect to hydrology over the longer term, as it would aim to restore a natural stream channel with hydrologic connection to flood plains. Under existing conditions, the ponds provide a location for the water flow to slow down substantially, such that sediment can settle out (see sediment deposition modeling in **Table 3.11-6**). Reconnecting Coyote Creek to the historic channel would reestablish a more continuous, uninterrupted flow path that could increase sediment transport further downstream. Planting of native vegetation in areas along the floodplain in this area to create riparian habitat would also serve to reduce erosion along the reach. Therefore, impacts would be less than significant.

Maintenance activities for Conservation Measure facilities have low potential to result in substantial erosion and siltation on- or offsite. Activities such as repair or replacement of new levees at Ogier Ponds and the roughened channel at the Phase 2 Coyote Percolation Dam CM would not result in substantial erosion, although minor erosion could occur like that as discuss above in *Runoff Through Construction Disturbance Areas*. Construction and applicable Valley Water BMPs and VHP conditions and AMMs would be implemented during maintenance activities. Vegetation management, debris removal, sediment removal, and related activities for the North Channel Reach ~~Extension~~, new channel at Ogier Ponds CM, and roughened channel at Phase 2 Coyote Percolation Dam CM could result in some erosion and potential siltation/sedimentation, but these effects would be less than significant given implementation of applicable BMPs and AMMs such as WQ-2 (Evaluate Use of Wheel and Track Mounted Vehicles in Stream Bottoms), WQ-5 (Stabilize Construction Entrances and Exits), WQ-8 (Minimize Hardscape in Bank Protection Design), WQ-9 (Use Seeding for Erosion Control, Weed Suppression), WQ-16 (Prevent Stormwater Pollution and Site Improvement), WQ-10 (Prevent Scour Downstream of Sediment Removal), VEG-1 (Minimize Local Erosion Increase from In-channel Vegetation Removal), BANK-1 (Bank Stabilization Design to Prevent Erosion Downstream), BANK-3 (Bank Stabilization Post-Construction Maintenance), and REVEG-1 (Seeding); and VHP ~~VMP~~ AMMs 21, 22, 23, 24, 30, 31, 32, 50, 55, 56, 62, 82, 102, 103, 104, 108, 111, 113, and 114. These BMPs and AMMs serve to minimize the potential for erosion from maintenance activities in and near Coyote Creek.

Post-Construction Project and FAHCE Adaptive Management

Monitoring activities under the AMP are unlikely to have substantial erosion or siltation impacts (see Construction Monitoring Impact analysis). Similarly, adjustments to FAHCE rule curves or modifications of Conservations Measures are likely to have erosion and siltation impacts similar to but smaller in magnitude than the activities being managed, and impacts would be less than significant.

Significance Conclusion Summary

Construction of the Seismic Retrofit components has the potential to discharge large volumes of sediment following storms of a certain size while the reservoir is dewatered given the exposure of sediments previously inundated on the bottom of Anderson Reservoir, disturbance of soil from in-reservoir construction activities, and the limited capacity to store water behind the coffer dam during construction. This constitutes a significant impact from a hydrology perspective because it would cause substantial temporary erosion and siltation downstream. However, despite the short-term adverse effects of sediment mobilization and release from Anderson Reservoir during Seismic Retrofit construction, the transport of this sediment downstream to Coyote Creek and San Francisco Bay would be beneficial for downstream ecosystems and habitats and related beneficial uses because the system has historically been deprived of sediment. In the long term, these sediment releases, in addition to implementation of Conservation Measures such as the Ogier Ponds CM, Spawning Gravel and Rearing Habitat Improvements at Live Oak Restoration Reach, and the Sediment Augmentation Program, guided by data derived from the Water Quality Sampling Plan, Sediment Monitoring Plan, and the Sediment Deposition Plan, would offset and provide long-term beneficial impacts in regard to erosion and sedimentation; however, they would not address the ~~immediate~~ short-term, acute impacts that could occur during construction of the Seismic Retrofit components following 2 to 5-year or greater storm events.

Mitigation Measure WQ-1 requires implementation of a WQMPP for in-reservoir construction activities, which would include evaluation of the water quality monitoring data collected during FOCP implementation and Project construction, and implementation of BMPs to control sediment and other pollutants associated with in-reservoir construction activities to the extent technically feasible and in accordance with regulatory requirements. While the WQMPP would address in-reservoir construction areas, no additional ~~No~~ feasible mitigation is available to address this impact, given the massive area of the reservoir bottom which would be exposed by the dewatering and amount of accumulated sediment (approximately 2.9 million cy), and the inability to detain water in the reservoir during the construction period due to public health and safety risk. For example, it may be feasible to hydroseed portions of the reservoir bottom, but it would not stabilize enough sediment to reduce the sediment mobilization in a meaningful way and stabilization would not function effectively when inundated by reservoir inflow. Similarly, measures to settle sediments within the reservoir, rather than allowing them to move downstream (turbidity curtains or operating the reservoir at a higher level) would not be feasible during construction because they required detention of reservoir inflows, ~~which of the potential to~~ increases risks of the interim dam being overtopped and is inconsistent with the FERC Interim Risk Reduction Measures. Therefore, the impacts from sedimentation during construction of the Seismic Retrofit components is considered **significant and unavoidable**.

Erosion and sedimentation impacts at out-of-reservoir construction areas would be **less-than-significant** with implementation of the SWPPP, Valley Water BMPs, and VHP conditions and AMMs.

Construction of Conservation Measure components would be **less-than-significant** with respect to erosion and sedimentation because erosion and siltation would not be substantial, given implementation of the SWPPP, Valley Water BMPs, and VHP conditions and AMMs.

Similarly, the post-construction operational and maintenance effects of the Project (e.g., implementation of FAHCE rule curves, emergency drawdown, and Conservation Measures) would be **less than significant,** because erosion and siltation would not be substantially different from Pre-FERC Order conditions.

Similarly, adjustments to FAHCE rule curves or modifications of Conservations Measures during Post-construction FAHCE Adaptive Management are likely to have erosion and siltation impacts similar to but smaller in magnitude than the activities being managed, and impacts would be **less than significant**.

Mitigation Measures

WQ-1 Develop and Implement an In-Reservoir Construction Area Water Quality Monitoring and Protection Plan ~~No mitigation is feasible.~~

ii. Substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or offsite (Less than Significant)

Seismic Retrofit Construction

As discussed under subsection i. above, construction of the Seismic Retrofit components would alter drainage patterns in a number of ways, albeit temporarily, many of which could increase the rate or amount of surface runoff. Perhaps most significantly, construction would involve denuding areas of vegetation to create access or stable surfaces, which reduce the capacity of these areas to absorb water and slow runoff (as well as increasing their susceptibility to erosion). For example, staging areas, access roads, and construction work areas outside of the reservoir may involve some amount of vegetation clearing and grubbing, and grading, which will create surfaces that have less natural material and root systems to slow runoff. Likewise, utilization of such areas by heavy equipment during construction will further compact soils, making the ground surface harder and less conducive to infiltration of water to soil or groundwater. The further dewatering of the reservoir during Seismic Retrofit construction (refer to discussion under subsection i.) could increase the rate of surface runoff (e.g., following storms), but it should not substantially change the total amount of runoff that may occur and collect behind the dam.

In general, the changes to drainage patterns caused by construction activities would not be anticipated to result in flooding on- or offsite. Runoff from construction work areas within the reservoir (e.g., stockpile areas, PGBP, access roads, etc.), as well as many work areas in uplands adjacent to the reservoir, would drain to the collection area behind the cofferdam or interim dam(s). This water could then be discharged via the Stage 2 Diversion System in a controlled manner, which would not result in flooding. Other work areas may drain directly to Coyote Creek; however, the volume of water from these work areas would not be expected to result in overtopping of banks or any other form of flooding on- or offsite. Construction of the Seismic Retrofit would not involve creation of any interim impervious surfaces, as staging areas, access roads, and other types of work area surfaces would not be paved (permanent additions of impervious surface due to the Seismic Retrofit elements of the Project are discussed under *Operations and Maintenance Impacts Analysis* below).

Construction activities would take place in the reservoir April through November and construction and staging areas would be winterized during the wet season to minimize impacts from sedimentation and excess runoff. Additionally, implementation of the SWPPP for out-of-reservoir construction activities, and applicable Valley Water BMPs~~,~~ and VHP conditions and AMMs would serve to reduce the rate and amount of surface runoff from construction disturbance areas. BMPs such as temporary soil stabilization measures/practices (e.g., covering disturbed areas with mulch, temporary seeding, soil stabilizers, binders, fiber rolls or blankets, temporary vegetation, and permanent seeding) reduce potential for erosion, but would also generally slow runoff and encourage infiltration to soil and groundwater. As such, impacts would be less than significant.

Conservation Measures Construction

Several of the Conservation Measure components would alter drainage patterns and the potential for runoff generation during construction, in a manner similar to that described above for the seismic retrofit component. The Ogier Ponds CM would alter drainage patterns via establishment and utilization of access roads, staging and stockpiling areas, and other work areas. These areas would involve vegetation clearing and grubbing, and grading, which would generally increase the rate and volume of surface runoff from the areas, as described above. ~~The~~ Maintenance of the North Channel Reach ~~Extension~~ would only involve minor maintenance activities, and increased surface runoff would be limited ~~similar activities on somewhat of a smaller scale~~. These effects would be minimized through implementation of the SWPPP, Valley Water BMPs, and VHP conditions and AMMs and would not be expected to result in flooding on- or offsite. The runoff from disturbance areas associated with construction of these measures would likely flow into one of the existing ponds or into Coyote Creek, neither of which would pose a threat of flooding.

The maintenance of Spawning Gravel and Rearing Habitat Improvements in the Live Oak Restoration Reach would have limited potential to result in impacts related to increased surface runoff and associated flooding. This conservation measure would be limited to placement of gravel and woody debris and other in-channel improvements within the Live Oak Restoration Reach. There may be some staging and ground-disturbance outside the channel that could potentially increase surface runoff rates and volumes, but these effects would be minimal. Similarly, the Sediment Augmentation Program would involve limited use of staging areas, use/establishment of access roads, and/or other ground-disturbing activities that could potentially increase surface runoff such as to cause on- or offsite flooding.

Construction of the Phase 2 Coyote Percolation Dam CM would utilize an existing 0.8-acres parking area for staging of construction equipment, supplies, and materials, as well as an existing road that provides access to the Coyote Percolation Dam from Metcalf Road. As such, construction of the improvements would not require vegetation clearing and grading of such areas, and would not increase the surface runoff potential of the construction work/disturbance areas above the existing conditions baseline. The actual improvements would be conducted within the channel, which would not affect surface runoff conditions.

Construction related impacts from Conservation Measure components would have a less-than-significant impact on surface runoff that could result in flooding.

Construction Monitoring

None of the construction monitoring activities proposed for implementation as part of the Project would substantially increase the rate or amount of surface runoff such as to potentially result in flooding on- or offsite. The monitoring activities would not require creation of staging areas, access roads, or other types of surfaces or facilities that could alter surface runoff behavior. As such, no impact on flooding from runoff would occur.

Seismic Retrofit Post-Construction Operations and Maintenance

During operations and maintenance, the seismic retrofit components of the Project would alter drainage patterns through permanent additions of impervious surface area. This impervious surface area would increase the rate and amount of surface runoff, although not to a degree to result in any on- or offsite flooding. As described in Chapter 2, *Project Description,* several sections of roadway in the immediate vicinity of Anderson Dam would be widened and/or relocated as part of the Project, resulting in a greater road surface area. In particular, various portions of Coyote Road would be widened resulting in a total of approximately 2.14 acres of additional impervious surface area relative to the Pre-FERC Order Conditions Baseline. Other areas that were disturbed during construction (e.g., access roads, staging areas, stockpile areas, etc.) would be restored to their pre-construction conditions, and as such, would not be expected to exhibit characteristics (e.g., compacted soils) conducive to elevated stormwater runoff over the long term.

In general, impervious surfaces increase the amount of water runoff following storms, as no portion of the precipitation falling on these areas is allowed to infiltrate into the soil and groundwater. Rather, the water flows directly off the surface and at a higher velocity compared to "natural" ground conditions. In the case of the Seismic Retrofit component, the impervious surface that would be added would be due to expansion of existing impervious facilities (e.g., Coyote Road and access roads in the vicinity of Anderson Dam). The impervious surface would not be added to a completely new area that is entirely pervious. Additionally, the existing Coyote Road and nearby access roads are in relatively rural areas with pervious, natural groundcover on each side of the road. The permanent roadway modifications installed as part of the Project would be designed to drain runoff into a stormwater system that would discharge runoff to Coyote Creek in a controlled manner or flow directly to the surrounding pervious lands. As such, this runoff from the widened Coyote Road would be expected to either infiltrate to the soil in surrounding areas or flow to Coyote Creek.

Given these factors, the additional impervious surface that would be created via the Seismic Retrofit components would not substantially alter the Pre-FERC Order Conditions Baseline with respect to runoff that could contribute to flooding. In any situation where there is precipitation heavy enough to result in localized flooding, the roadway improvements would not be considered a primary contributing factor, such that the flooding likely would have occurred regardless. The Project would also comply with the Municipal Regional Stormwater NPDES permit as applicable (refer to Section 3.11.2.2 ~~3.11.1.1~~).

Maintenance of the dam facilities would be done consistent of the DMP, and are covered by the DMP EIR, AMMs, and mitigation measure as discussed in Section i above. Maintenance activities for the Seismic Retrofit components would not create new areas of impervious surface. Certain activities, such as vegetation management activities, could increase surface runoff rates, as vegetation tends to slow runoff and provides greater soil infiltration. To the extent vegetation is thinned or removed, this could increase the rate and amount of surface runoff generated during a precipitation event. However, the volume of additional runoff would be minor and would not contribute to flooding potential.

Effects from additional runoff during operation and maintenance of the Seismic Retrofit components would be less than significant.

Conservation Measures Post-Construction Operations and Maintenance

Once constructed, none of the Conservation Measure components would create any permanent areas of impervious surface. As such, the conservation measure components would not increase the rate or amount of surface runoff over the long-term relative to the pre-FERC Order conditions baseline. Therefore, there would be no potential for increased runoff due to CM operations to potentially result in flooding on- or offsite.

Maintenance and monitoring activities for the Conservation Measures components would not create new areas of impervious surface. Certain activities, such as vegetation management activities, could increase surface runoff rates, as vegetation tends to slow runoff and potentially result in greater soil infiltration. To the extent vegetation is thinned or removed, this could increase the rate and amount of surface runoff generated during a precipitation event. However, the volume of additional runoff would be minor and would not contribute to flooding potential.

The effects from additional runoff during the post-construction operations and maintenance of Conservation Measure components on flooding would not be significant.

Post-Construction Project FAHCE Adaptive Management

AMP monitoring and adaptive management activities would not alter runoff from Project sites because they would not result in surfaces or facilities that could substantially alter surface runoff. As such, no impact from runoff that could cause flooding would occur.

Significance Conclusion Summary

Implementation of the SWPPP for out-of-reservoir construction activities, and applicable Valley Water BMPs~~,~~ and VHP conditions and AMMs, would reduce potential for construction disturbance areas to generate increased surface runoff and associated on- or offsite flooding for the Seismic Retrofit, Ogier Ponds CM, Maintenance of the North Channel Reach ~~Extension~~, and Phase 2 Coyote Percolation Dam CM. The Seismic Retrofit components of the Project would create relatively minor amounts of new impervious surface (widened/expanded existing roadways), which would not result in a significant increase in surface runoff and flooding, whereas the Conservation Measure components would not include any new impervious surfaces. In summary, this impact would be **less than significant**.

Mitigation Measures

No mitigation is required.

iii. Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff (Less than Significant)

Seismic Retrofit Construction

As discussed above, Seismic Retrofit construction would increase potential surface runoff from disturbed/compacted areas within the construction footprint. The dewatering of the reservoir would change runoff patterns, primarily by reducing the inundated area and increasing erosion/sedimentation; however, the runoff from the upstream areas from the dam and the former reservoir bottom will be captured behind the cofferdam and/or directly passed through to Coyote Creek downstream. Similarly, many of the stockpile areas and the PGBP would be located upstream of the dam within the reservoir bottom. While these areas would not create or contribute substantial runoff water, the runoff water that passes through these areas could carry large amounts of suspended sediment. The staging areas located downstream of the dam would increase runoff potential since creation of the staging areas would involve vegetation clearing and grading (refer to discussion under subsection i. above).

The majority of the runoff water from construction disturbance areas, or the water that flows into the reservoir and collects behind the cofferdam/interim dam, would flow to Coyote Creek or infiltrate into surrounding soil. Coyote Creek is a managed stream with flood protection and stormwater drainage functions. Existing constructed stormwater facilities in the reservoir vicinity are limited to roadside ditches along area roads; no piped conveyance systems, retention ponds, or other stormwater facilities exist in immediate proximity to Anderson Reservoir or Coyote Creek downstream of the reservoir (City of Morgan Hill 2017 ~~2016~~, **Figure SSI-10**). Thus, there would be no potential for runoff generated as a result of Seismic Retrofit construction to exceed the capacity of stormwater drainage systems. Any additional flow to Coyote Creek would be marginal compared to the overall flow of the Creek and/or that flow that would have occurred irrespective of the changes brought about by the Seismic Retrofit construction activities.

Due to the use of hazardous materials during construction (e.g., fuel, oil, lubricants, etc. in construction equipment), there would be potential for discharge of polluted runoff if such materials were handled, stored, or disposed of improperly and/or if any accidental releases of such materials were to occur. Seismic Retrofit construction would require use of a wide range of equipment, as listed in **Table 2-3** in Chapter 2, *Project Description,* much of which would involve hazardous materials. The equipment could potentially leak during operation if it is not maintained properly; additionally, hazardous materials could spill during re-fueling or maintenance/servicing activities that may be necessary during the construction period. Hazardous materials stored onsite at staging areas or temporarily at work areas could also spill if proper protocols are not followed and containment provided. These issues are discussed further in Section 3.10, *Hazards and Hazardous Materials*.

Such releases of hazardous materials during Seismic Retrofit construction, if they were to occur, could result in subsequent polluted runoff if the spill materials were not cleaned up prior to a precipitation event. While the spilled hazardous materials may remain in soil or on the ground surface during the dry season, the materials could be mobilized and washed down to receiving waterbodies (e.g., Coyote Creek) during the first rainstorms of the winter season. Without preventative measures, these effects would be considered significant.

Implementation of the SWPPP for out-of-reservoir construction activities, in compliance with the Construction General Permit, along with applicable Valley Water BMPs and VHP conditions and AMMs, would substantially reduce the potential for accidental releases of hazardous materials during Seismic Retrofit construction, as well as the potential for impacts in the event of such releases. The SWPPP would include good housekeeping measures for: construction materials, waste management, vehicle storage and maintenance, landscape materials, and potential pollutant sources (SWRCB 2009). Examples include conducting an inventory of products used, implementing proper storage and containment, and properly cleaning all leaks from equipment and vehicles (SWRCB 2009). While the SWPPP would be prepared prior to construction, consideration of these factors and inclusion of appropriate BMPs for pollutant control would reduce the potential adverse impacts during Seismic Retrofit construction.

The following Valley Water BMPs would reduce potential impacts associated with hazardous materials releases: ~~BMP HM-7 (Restrict Vehicle and Equipment Cleaning to Appropriate Locations),~~ BMP HM-8 (Ensure Proper Vehicle and Equipment Fueling and Maintenance), BMP HM-9 (Ensure Proper Hazardous Materials Management), and BMP HM-10 (Utilize Spill Prevention Measures). These BMPs would include protocols for providing secondary containment for hazardous materials used in the field or stored at staging areas or at work sites, and providing training spill cleanup materials for field personnel, among other measures. Furthermore, compliance with VHP measures, including AMMs 2, 7, 8, 9, 11, 12, 72, 75, 76, 87, 88, and 100, whether implemented independently or incorporated as part of the SWPPP, would reduce potential impacts from hazardous materials during out-of-reservoir construction activities. Implementation of measures included either as part of the SWPPP, Valley Water BMPs, or VHP AMMs, would prevent Seismic Retrofit construction activities from contributing substantial amounts of polluted runoff, and this impact would be less than significant.

Conservation Measures Construction

Construction of Conservation Measure components would have similar impacts to those described above for the Seismic Retrofit components of the Project. Each of the conservation measures involving construction activities would involve similar types of equipment as the Seismic Retrofit component, which would have the potential to leak during construction and/or would require storage or servicing with hazardous materials. Implementation of the SWPPP, and applicable Valley Water BMPs and VHP AMMs, would reduce any potential adverse effects associated with hazardous materials and polluted runoff to a level that is less than significant.

All Conservation Measures would all be located along or adjacent to Coyote Creek and runoff from disturbance/work areas would likely flow directly to the creek (or possibly one of the Ogier Ponds). Although Coyote Creek is not considered a stormwater drainage system, per se, the runoff from CM work areas would not meaningfully affect the capacity of the creek. Therefore, the effects would be less than significant.

Construction Monitoring

None of the construction monitoring processes/activities would increase the rate or amount of surface runoff. The construction monitoring activities would not include impervious surfaces or substantial vegetation removal or grading, which could affect surface runoff behavior. Likewise, the construction monitoring activities would all take place within Anderson Reservoir itself or within or along Coyote Creek; no other existing or planned stormwater drainage systems would be affected. Construction monitoring efforts could potentially use small amounts of hazardous materials (e.g., oil or lubricant needed for monitoring equipment, fuel for vehicles transporting personnel to monitoring sites); however, reasonable care exercised by field personnel would prevent substantial impacts from occurring. As such, effects would be less than significant.

Seismic Retrofit Post-Construction Operations and Maintenance

During the post-construction period, the Seismic Retrofit components of the Project would increase the surface runoff rate and amount to some degree in areas where impervious surface is expanded due to the Project (refer to the discussion under subsection ii.). The Seismic Retrofit components (in particular, the permanent roadway modifications) would increase the amount of impervious surface in the area of the dam by approximately 2.14 acres. However, this would be an incremental change and the majority of the land surface in this area would remain pervious (i.e., water falling on the land as precipitation could infiltrate into the soil and groundwater). The Project would comply with the Municipal Regional Stormwater NPDES permit as applicable (refer to Section 3.11.2.2 ~~3.11.1.1~~). Additionally, no hazardous materials would be stored or used on the site during the post-construction period, except that which may be necessary during maintenance and repair activities. Thus, runoff water from new impervious areas would not include substantial pollutants, which could flow to Coyote Creek or other surrounding areas.

Coyote Creek would not typically be considered a “stormwater drainage system,” although it does serve to convey stormwater from the Project area. Any additional runoff from the expanded impervious surfaces resulting from the Seismic Retrofit component of the Project would not affect stormwater facilities.

Dam maintenance would be subject to the DMP, including its BMPs and mitigation measures. Implementation of applicable Valley Water BMPs and VHP AMMs during maintenance work for the Seismic Retrofit components would prevent substantial impacts from occurring due to releases of hazardous materials and generation of polluted runoff.

Therefore, post-construction impacts from operation and maintenance of Seismic Retrofit components would be less than significant.

Conservation Measures Post-Construction Operations and Maintenance

None of the Conservation Measures would create any permanent areas of impervious surface that would contribute runoff to a stormwater system. Implementation of applicable Valley Water BMPs and VHP AMMs during maintenance work for the Conservation Measure components would prevent substantial impacts from occurring due to releases of hazardous materials and generation of polluted runoff. Therefore, post-construction impacts from operation and maintenance of Conservation Measure components would be less than significant.

Post-Construction Project and FAHCE Adaptive Management

AMP monitoring and adaptive management activities would not alter runoff from Project sites, because they would not result in surfaces or facilities that could alter surface runoff behavior. As such, no impact to stormwater systems would occur.

Significance Conclusion Summary

The seismic retrofit components and CMs would have some potential to generate increased runoff and/or polluted runoff during construction (e.g., due to denuded construction staging and work areas and use, storage, and disposal of hazardous materials); however, implementation of the SWPPP for out-of-reservoir construction activities, and applicable Valley Water BMPs and VHP AMMs would reduce potential impacts to a level that is less than significant. Likewise, while the increased impervious surface area from the Project, and potential use of hazardous materials during maintenance activities, could contribute polluted runoff, implementation of applicable BMPs and AMMs would reduce these effects to less than significant. Adherence to the requirements of the SWPPP for out-of-reservoir construction activities and Valley Water BMPs and VHP AMMs would reduce impacts related to polluted runoff to **less than significant.** While not required to reduce impacts to less than significant, Mitigation Measure WQ-1 would further reduce these impacts by requiring implementation of a WQMPP for in-reservoir construction activities, which would include evaluation of the water quality monitoring data collected during FOCP implementation and Project construction, and implementation of BMPs to control hazardous materials and other pollutants associated with in-reservoir construction activities to the extent technically feasible and in accordance with regulatory requirements. Adaptive management activities would have no potential for impacts. Overall, the Project impact would have **less than significant** impacts to storm drainage system capacity or polluted runoff.

Mitigation Measures

No mitigation is required.

iv. Impede or redirect flood flows (Less than Significant)

Seismic Retrofit Construction

Construction of the Seismic Retrofit components would redirect flood flows through the Stage 1 and 2 Diversion Systems and maintain the reservoir in a dewatered state throughout the anticipated 7-year construction period. The extended dewatering period necessary for Seismic Retrofit construction would alter the behavior of flood flows passing through the dam. Modeling was conducted to help determine the potential effects of Seismic Retrofit construction with respect to flooding, as shown in **Table 3.11-8**. See Appendix K for details on the methodology for and results of the Project flood impacts analysis.

Table 3.11-8. Flow Frequency Analysis

		Stochastic Flows (cfs)			
% Freq.	Return Period	Pre-FERC Order (1)	Post-FOCP (2)	Project Construction (3)	Post-Project FAHCE (4)
0.2	500	18,144	2,500	5,830	16,392
0.5	200	13,512	2,500	5,485	12,143

Source: Valley Water 2023b

Notes:

Scenarios considered: (refer to "Potential Flood Impacts for ADSRP" Appendix K for complete description)

1. **Historic Conditions – ~~Seismic~~ Pre-FERC Order Restrictions ~~(Pre-FERC Order)~~.** This scenario represents operational conditions that existed in 2019 with ~~seismic~~ restrictions for both Anderson and Coyote Dam. Anderson was operated to fully release if its DSOD restriction was exceeded. Coyote Dam was operated with the DSOD restriction established in 1992. ~~to fully release if its DSOD restriction was exceeded, unless Anderson was already above its restriction, at which point Coyote outlet would discharge 5 cfs~~.
2. **Post-FOCP and Project Year 1 – Stage 1 Diversion (Existing Conditions)** This scenario represents operational conditions that are expected to occur after the FOCP is completed. The FOCP includes construction of the ADTP, which is the Stage 1 diversion system during the Project. Coupled with the existing outlet, it is operated to a maximum discharge of 2,500 cfs to maintain deadpool.
3. **Project Construction – Stage 2 Diversion** This scenario represents operational conditions that are expected to exist during the Project, while the emergency spillway is offline. Starting in Year 2, the Stage 2 diversion would release up to 6,000 cfs to maintain the reservoir at deadpool, although the Stage 2 diversion can release up to 6,800 cfs if the reservoir were nearly full.
4. **Post ADSRP (FAHCE Operations) –** This scenario represents the presumed operational conditions after the Project is completed and FAHCE rule curves are enacted. The LLOW, HLOW, and spillway would be functional and the reservoir would be operated at its full storage capacity. Regular reservoir releases would be the FAHCE rule curves.

The modeling shows that the 5-year return period (20 percent annual chance) flow would be elevated under both the Post-FOCP scenario and Project Construction scenario compared to the Pre-FERC Order scenario. As can be seen in **Table 3.11-8**, the 5-year flow would reach 2,500 cfs under the Post-FOCP scenario and 3,369 cfs under the Project Construction scenario, compared to 530 cfs under the Pre-FERC Order scenario. The 20-year return period (5 percent annual chance) or greater, flows under the Post-FOCP, Project Construction and Post-Project scenarios would be reduced compared to the Pre-FERC Order scenario.

All flows would be elevated under the Project Construction scenario relative to the Post-FOCP scenario (i.e., existing conditions baseline). Under the Project Construction scenario, modeled flows would not exceed 5,830 cfs, or the 500-year (0.2 percent annual chance) return period. By contrast, under the Pre-FERC Order scenario (i.e., historic conditions), flows could reach a maximum of 16,535 cfs during an equally unlikely event (a 500-year return period). As reference, some of the most damaging floods in recent history occurred in February 2017, when flows in Coyote Creek below the dam reached roughly 7,400 cfs due to heavy rains and an uncontrolled spill from Anderson Reservoir that lasted for a period of 10 days (Valley Water 2017, 2020b).

Figure 3.11-5 (see end of Section 3.11.5) shows the potential inundation areas associated with flow rates along Coyote Creek up to 7,000 cfs. As shown in **Figure 3.11-5**, there would be moderate potential for flooding impacts along Coyote Creek below roughly 3,000 cfs. At this flow rate, there is limited inundation beyond the immediate Coyote Creek streambanks, except at select locations, such as Watson Park adjacent to US 101, the area of William Street Park/Olinder Park, and Los Lagos Golf Course. At greater flow volumes/rates, additional inundation would occur, with some houses or other structures potentially being threatened; however, wide scale flooding would not occur with flows up to 7,000 cfs, which is inclusive of the maximum flows projected under extreme storm events that could occur during Seismic Retrofit construction. Note that the inundation mapping shown in **Figure 3.11-5** takes into account the flood protection measures that are being implemented as part of FOCP and in advance of Seismic Retrofit construction, as discussed further below.

Given that very high flows have been possible during recent history (refer to Pre-FERC Order scenario in **Table 3.11-8**), potential flooding impacts associated with Seismic Retrofit construction would be reduced compared to both the Pre-FERC Order and Post-FOCP (existing) conditions. The substantially greater capacities of the Stage 1 and 2 Diversion Systems available in the Project Construction conditions relative to the outlet works that existed in the Pre-FERC Order would enable dam operators to pass through more flows during a large storm event without the potential for an uncontrolled spillway release. In this respect, the potential for catastrophic flooding would be reduced.

It is also important to realize that many of the storm events modeled, as presented in **Table 3.11-8**, are exceptionally rare. Thus, the duration of time that the higher flows could be reached and would persist under the different scenarios is low. This duration of flow exceedance is shown in **Table 3.11-9** below.

Table 3.11-9. Duration of Flow Exceedance

Flow Threshold	300	500	1000	1,400	2000	3000	4000	5000	6000	7000
Percentage of Time (1973-2022) above Threshold

Notes:

*Refer to **Table 3.11-8** for description of the scenarios considered.*

As indicated in **Table 3.11-9**, modeling used hydrologic data for a period spanning 49 years (1973-2022) to estimate durations of elevated releases from Anderson Reservoir under the same four scenarios that were used to model peak flows (**Table 3.11-8**). The higher flows possible under the Project Construction scenario, for example, would occur rarely. Above the 4,000 cfs threshold, only 7.1 days were observed during the 49-year study period under the Project Construction scenario, translating to 0.04 percent of the time. The 5,000 cfs threshold was only exceeded for 3.2 days (0.02 percent of the time) under the Project Construction scenario. This was a greater duration of high flows than under the Post-FOCP scenario, where no days were observed when flows exceeded even 3,000 cfs. Relative to the Pre-FERC Order scenario, a greater number of days were observed with flows exceeding 5,000 cfs than under the Project Construction scenario; however, the Pre-FERC Order scenario had more time with flows exceeding the 6,000 and 7,000 cfs thresholds as compared to the Post-FOCP (existing conditions) and Project Construction scenarios.

The modeling shows that moderately high flows (e.g., above 500 or 1,000 cfs) would occur much more frequently under the Post-FOCP and Project Construction scenarios, compared to pre-FERC Order conditions. This is due to the larger capacities of the outlet works under these scenarios and the operational approach of passing through all inflow (i.e., no storage) during the Seismic Retrofit construction period. These more frequent moderately high flows would not result in flooding impacts downstream as Coyote Creek has the capacity to pass at least 3,000 cfs without flooding homes, due to the implementation of FOCP flood management measures as discussed in the Environmental Setting section (3.11.1) (Valley Water 2023a). In addition, as discussed in the Environmental Setting, Valley Water would implement additional flood management measures along Coyote Creek to accommodate even higher controlled flows, known as the Coyote Creek Flood Protection Project, that has been designed to protect communities in San José from storms similar to the 2017 event that causes flooding in residential areas of downtown San José. As mentioned above, the 2017 event was approximated to be a 20-year event (or 5 percent chance of occurring annually) and included flows of about 7,400 cfs passing through the Anderson spillway, which combined with several tributaries downstream. Using the 2017 storm event as the design criteria for the Coyote Creek Flood Protection Project would also provide protection for those same communities when Project Construction flows are made.

Altogether, the modeling shows that the potential for flooding along Coyote Creek would be somewhat elevated during the Seismic Retrofit construction period relative to the Post-FOCP condition. However, the potential flood flows associated with storms during the Seismic Retrofit construction period (Project Construction scenario) would not be anticipated to result in widespread, damaging floods, particularly given implementation of the two phases of the Coyote Creek Flood Protection Project. The potential for flooding would be largely reduced relative to Pre-FERC Order Conditions, when uncontrolled spillway releases could result in very high flows in Coyote Creek during exceptionally large storm events.

Several downstream recreational facilities are already prone to temporary inundation under the Pre-FERC Order Conditions Baseline. In particular, the Coyote Creek Trail is a regional trail that is owned and operated by the Santa Clara County Department of Parks and Recreation (SCCDPR) connects parkland from the Anderson Lake Visitor Center to Hellyer Park via the Coyote Creek Parkway. The Coyote Creek Trail includes several low-flow crossings across Coyote Creek that flood routinely, rendering the trail unavailable to provide a regional connection for bicycle commuters and trail users of other types. SCCDPR has observed that key crossings close at approximately 25 cfs at the Edenvale Gage; this includes a creek crossing that provides the sole access to a picnic area within Hellyer Park. Based on the hydrologic record between 1988 and 2020, streamflow at the Edenvale Gage exceeds 25 cfs approximately 13 percent of the time. This data set is difficult to correlate to Anderson Dam releases that are modeled in **Table 3.11-8** and **Table 3.11-9**, because rates of in channel percolation, evaporation, and stream inputs other than Anderson Reservoir contributions vary widely depending on hydrologic conditions. Depending on conditions, releases from Anderson Reservoir of 55 cfs to 90 cfs could trigger the key low-flow crossings to be closed and historically, those flow rates occurred 13 percent and 4 percent of the time, respectively.

While the Coyote Creek Trail crossings will continue to be periodically closed during Project Construction scenarios, the general trend observed in **Table 3.11-9** shows that releases of 300 cfs will continue to occur routinely, but for shorter periods (8.06 percent in the Pre-FERC Order scenario versus 7.40. percent in the Project Construction scenario) due to the new larger capacity Stage 2 Diversion. However, the maximum geographic extent of inundated parkland would be less under the Project Construction conditions in comparison to the Pre-FERC Order Conditions.

The dam would be essentially out of commission during the 7-year construction period and thus would perform greatly reduced flood protection functions (e.g., catching runoff from upstream areas during large storms through maintenance of an open “flood pool” in the reservoir, nor would it be available to provide water consistently to Coyote Creek making the habitat and groundwater recharge programs completely reliant on imported water releases (see Section 3.4, Biological Resources – Fisheries, for greater discussion). Anderson Dam was never intended or designed as a flood protection facility, but has provided a level of incidental flood protection. The completion of the FOCP has increased the ability to drain the reservoir quicker and has already provided greater flood protection in addition to keeping storage in the reservoir at a greatly reduced level (thus providing greater capacity to hold back large storm events). The modeling indicates flows from very large storms (e.g., 50-year, 100- year and 500-year events) would have reduced peak flows when comparing Pre-FERC Order Conditions to the Project Construction scenario. As a result, impacts from impeding or redirecting flood flows during seismic retrofit construction would be less than significant.

Conservation Measures Construction Impacts Analysis

The Ogier Ponds CM would involve construction of a new channel for Coyote Creek around the ponds. Construction would take place during the dry seasons when flood flows are very unlikely and construction areas would be winterized during the wet season to accommodate high flows. Sediment augmentation and maintenance of the Live Oak habitat enhancement would add gravels to the creek, which would have potential for minor redirections of flood flow; however, the effects of these measures on flood flow would not be substantial. Construction of the Ogier Ponds CM, <u>Maintenance of the</u> North Channel <u>Reach</u> ~~Extension~~, and Phase 2 Coyote Percolation

Dam CM would each involve construction activities within the Coyote Creek Channel. To the extent that construction equipment could be in the channel during high flow events, this could potentially impede the passage of flood flows and/or exacerbate flooding effects. However, in accordance with BMP WQ-1 (Conduct Work from Top of Bank), work activities occurring in the channel would be conducted from the top of bank if access is available and there are flows in the channel. Additionally, in accordance with VHP AMM 73, wet season construction would be avoided.

Thus, it is unlikely that construction equipment associated with the Conservation Measure components would be present in the channel during high flows (which would almost certainly occur during the wet season). Moreover, the degree to which construction equipment or materials in the channel could impede flood flows would likely not be substantial. As seen in **Table 3.11-8** and **Table 3.11-9**, the rates of flow that are possible during Seismic Retrofit construction (Project Construction scenario) associated with storm events are relatively modest compared to the Pre-FERC Order scenario. Additionally, the period and frequency during which very high flows occurred over the 49-year study period was very low. Therefore, impacts from impeding or redirecting flood flows would be less than significant.

Construction Monitoring Impacts Analysis

None of the construction monitoring activities that would be conducted for the Project would include substantial above-ground features or equipment that could greatly impede or redirect flood flows. Many of the construction monitoring efforts, as described in Chapter 2, *Project Description,* would involve field surveys and observations that would be conducted on foot. Some minor equipment may be placed within or adjacent to the stream channel (e.g., PIT antennas and VAKI Riverwatcher units); however, these facilities would not obstruct the flow of Coyote Creek. As a result, no impact would occur.

Seismic Retrofit Post-Construction Operations and Maintenance

During the post-construction period, the flood protection capability of Anderson Dam would be improved relative to the Pre-FERC Order Conditions Baseline, as reservoir storage restrictions would be removed and the new LLOW would be operable. As noted above, Anderson Dam was never intended or designed as a flood protection facility; nevertheless, the reservoir has been operated to provide incidental flood protection to downstream communities, while maintaining water storage at the end of the wet season in April, in accordance with the 1982 Anderson-Coyote Combined Incidental Flood Risk-Reduction Rule Curve (Valley Water 2023a ~~2022a~~). The Anderson-Coyote Combined Incidental Flood Risk-Reduction Rule Curve is based on estimated monthly inflows into the reservoir. During the wet season, when inflows from precipitation events are expected, Valley Water may release water from storage to avoid spilling from the reservoir (Valley Water 2023a ~~2022a~~). This results in no water supply impact since it is anticipated that the water released from storage will be replaced by water from the precipitation event.

Following completion of the Seismic Retrofit construction, the Anderson-Coyote Combined Incidental Flood Risk-Reduction Rule Curve would be implemented, in conjunction with the new reservoir operating rules under FAHCE. As shown in **Figures 2-13 and 2-14** in Chapter 2, *Project Description,* the FAHCE rule curves include an Incidental Flood Risk-Reduction Rule Curve Release stipulation, which requires releases when combined reservoir storage volumes exceed a certain threshold that varies based on the time of year. This maintains a “flood pool” that is reserved for catching runoff from storm events during the rainy season. The threshold for incidental flood risk-reduction releases ranges from roughly 75,000 AF in December to 110,000 AF in May (the point at which it meets the maximum storage capacity of the combined reservoirs, and flood releases are thus no longer necessary). The model results in **Table 3.11-8** and **Table 3.11-9** include a scenario to evaluate post-construction conditions (Post-Project FAHCE), which includes the assumes adherence to the Anderson-Coyote Combined Incidental Flood Risk-Reduction Rule Curve that has been incorporated FAHCE (Appendix D).

Thus, the reconstructed Anderson Dam, in concert with Coyote Dam, would provide at least the same level of flood protection during the post-construction period as under the Pre-FERC Order Conditions Baseline. In fact, the flood protection functions of the dam/reservoir would be improved, since the improvements to the outlet works as part of the Seismic Retrofit components would allow for more rapid drawdown of the reservoir water level in the event of large storms. Specifically, whereas the Pre-FERC Order capacity of Anderson Dam’s outlet works was 500 cfs (under maximum head), the capacity of the LLOW and HLOW following seismic retrofit construction will be approximately 1,480 cfs and 5,300 cfs, respectively, when the reservoir is completely full. However, only releases from the LLOW would be used for normal operation of the FAHCE rule curves, including the Anderson-Coyote Combined Incidental Flood Risk-Reduction Rule Curve, and a more realistic maximum of 1,400 cfs is assumed to be the post-construction maximum for controlled releases. This improved operational ability will allow dam operators to better maintain reservoir levels within the parameters specified in the Anderson-Coyote Combined Incidental Flood Risk-Reduction Rule Curve, and reduce the probability of an uncontrolled spill, which would have the potential for much higher downstream flows.

As shown in **Table 3.11-8**, modeling indicates that maximum flows associated with various storm intensities would be reduced under post-construction conditions (Post-Project FAHCE scenario) compared to the Pre-FERC Order Conditions. Very high flows are still possible under the post-construction conditions; however, these would not be quite as high as under the Pre-FERC Order Conditions Baseline. For example, during a 100-year storm event (1 percent annual chance), flows would reach 8,999 cfs under the Post-Project FAHCE scenario compared to 10,211 cfs under the Pre-FERC Order scenario. During a 500-year event (0.2 percent annual chance), flows would be 16,392 cfs under the Post-Project FAHCE scenario, compared to 18,144 cfs under the Pre-FERC Order scenario. Presumably, this reduction in flood flows under the Post-Project FAHCE scenario is due to the increased LLOW capacity enabling a greater amount water to be released in a controlled fashion prior to a storm's arrival rather than via an uncontrolled spill, although spills could still occur under the future conditions. Given that storms of such intensity are extremely rare, these very high flows did not occur over the duration of modelled flow analysis for the four Project scenarios shown in **Table 3.11-9**, which considered a 49-year period (1973-2022). As such, there were no days (0.0 percent of the time) during which flows exceeded 5,000 cfs under the Post-Project FAHCE scenario, whereas there were 0.9 days (0.01 percent of the time) when flows exceeded 5,000 cfs under the Pre-FERC Order scenario.

The high flows during extreme events under the Post-Project FAHCE scenario could certainly result in extensive flooding and damage along Coyote Creek downstream. As discussed above, the February 2017 floods caused widespread damage when flows in Coyote Creek reached only 7,400 cfs (Valley Water 2017). Albeit, since 2017, flood management measures (e.g., floodwalls, levees, berms, and property elevation/acquisition) have been implemented at key locations to reduce potential impacts from high flows. Nevertheless, given the rarity of these extreme events, and the fact that flooding impacts during Project operation would be reduced relative to baseline (Pre-FERC Order) and post FOCP conditions, the impacts from impeding or redirecting flood flows caused by seismic retrofit operation would be less than significant.

Maintenance of the dam facilities would be done consistent of the DMP, and are covered by the DMP EIR, AMMs, and mitigation measures. While certain activities (e.g., routine maintenance, repair, or replacement of dam parts and facilities) could involve large equipment that may be temporarily located in areas where flows could be impeded (e.g., within stream channel or reservoir area), these activities would take place in the dry season and the scale of these activities would not reasonably result in substantial impedance or redirection of flood flows.

Conservation Measures Post-Construction Operations and Maintenance

Certain Conservation Measure components that would place materials in the channel, such as the Maintenance of Spawning Gravel and Rearing Habitat Improvements in Live Oak Restoration Reach and the larger Sediment Augmentation Program, could increase channel roughness in such a manner to reduce flow velocities resulting in potentially increasing surface water elevations in the channel, and potentially increasing the flooding risk. As described in Chapter 2, *Project Description,* these conservation measures would involve placement of gravel and woody debris in restoration areas within Coyote Creek (the Ogier Ponds CM would also involve planting of native vegetation in floodplain areas, which could slow down flows, while the Phase 2 Coyote Percolation Dam CM would create a roughened fish ramp). These types of channel features tend to slow down flows, which is generally positive for the ecosystem, but can also contribute to flooding concerns. Due to the scale of these activities (affecting just a few relatively small reaches of Coyote Creek), however, the potential adverse effects with respect to flooding downstream would be less than significant.

None of the maintenance activities for the Conservation Measures would substantially impede or redirect flood flows. Additionally, as discussed above, adherence to applicable Valley Water BMPs and VHP <u>conditions and</u> AMMs would avoid work during the wet season and require within-channel work to be done from the top of bank, where possible, thus minimizing potential for impacts.

Certain maintenance activities could improve passage of flood flows, such as vegetation management and sediment removal (e.g., that associated with the Ogier Ponds CM and Phase 2 Coyote Percolation Dam CM). Excessive vegetation growth and sediment accumulation within the channel or floodplain can reduce channel capacity and thereby increase flood risk; thus, the routine maintenance activities proposed as part of the Conservation Measures would minimize this potential impact. None of the monitoring activities during the post-construction period would substantially impede or redirect flood flows.

Post-Construction Project and FAHCE Adaptive Management

AMP monitoring and adaptive management activities would not alter the potential for flooding from Project sites because they would not result in surfaces or facilities that could substantially alter surface runoff behavior. As such, no impact to flooding would occur.

If the changes to the Anderson-Coyote Combined Incidental Flood Risk-Reduction Rule Curve through the adaptive management process are considered in the future, additional evaluations for changes in flood risk impacts would be required.

Significance Conclusion Summary

During construction of the Seismic Retrofit component, there would be increased potential for flooding (i.e., higher flows could occur in Coyote Creek more frequently during storm events) relative to the existing conditions baseline for flows under the 50-year return period; however, this flooding risk would be largely reduced relative to Pre-FERC Order Conditions and would not result in widespread, damaging floods based on the analysis shown in **Figure 3.11-5**. During the post-construction period, flooding risk associated with operation of the dam would be reduced relative to the Pre-FERC Order Conditions Baseline. Several downstream recreational facilities along the Coyote Creek Trail are already prone to temporary inundation under the Pre-FERC Order Conditions Baseline because the trail closes at relatively low flows, approximately 55 cfs to 90 cfs. However, the general trend observed in **Table 3.11-9**, shows that flows less than 1,400 cfs will be more common place (0.08% of the time in Pre-FERC Order scenario versus 1.71% of the time in the Post-Project FAHCE scenario), but overall flood risk releases will occur over a shorter period of time (flows exceeding 300 cfs occurred 8.06 % of the time in the Pre-FERC Order scenario versus the modeled 1.80 % of the time in the Post-Project FAHCE scenario). The maximum geographic extent of disruption of parkland would be less under the Project Construction conditions and the Post-Project FAHCE conditions. Construction, operation, and maintenance of the Seismic Retrofit and Conservation Measures components would not result in substantial impacts related to impedance or redirection of flood flows, and adaptive management also would not result in impacts. Therefore, this impact would be **less than significant**.

Mitigation Measures

No mitigation is required.

Impact HYD-2: Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of dam failure (Less than Significant)

Seismic Retrofit Construction

As discussed under Impact HYD-1, subsection iv., flooding risk during Seismic Retrofit construction would be elevated relative to existing conditions (Post-FOCP scenario); however, the magnitude of flows possible during Seismic Retrofit construction (approximately 6,000 cfs) would not be expected to result in widespread and extremely damaging flooding, although some structures could potentially be threatened during this level of storm event. The potential for catastrophic flooding risk during Seismic Retrofit construction would be substantially reduced compared to Pre-FERC Order Conditions, where flows could reach 18,144 cfs during a 500-year storm. This is due to the reservoir remaining empty during the Seismic Retrofit construction period and flows being passed through the reservoir with the increased capacity of the Stage 1 Diversion System and Stage 2 Diversion System. The modeling shows that there would be no potential for dam overtopping and failure (at least up to a 500-year event) during the Seismic Retrofit construction period. Similar to Impact HYD-1, subsection iv., the effects of Seismic Retrofit with respect to significant risk of loss, injury or death involving flooding would be less than significant.

Another concern with respect to flooding during the Seismic Retrofit construction period is the potential failure of Coyote Dam, which is located approximately 1.5 miles upstream of Anderson

Reservoir. A ~~seismic~~ restriction has been in place for Coyote Reservoir since 1992, limiting storage in this reservoir to 11,843 AF, or 52.5 percent of total capacity (Valley Water 2023a ~~2022a~~). DSOD determined that such a restriction was necessary based on fault rupture concerns at Coyote Dam. ~~given the construction of the dam and proximity to the Calaveras Fault. Should an earthquake occur when Coyote Reservoir is full there is a chance the underlying soils could liquify and/or the dam could otherwise slump allowing water to flow uncontrolled over slumping soils, which would cause additional erosion of dam material and the possibility of the complete loss of the dam.~~ If Coyote Dam were to fail, the downstream effects would be ~~at least partially mitigated~~ reduced by the presence of Anderson Reservoir, which itself has been under a ~~seismic~~ restriction since 2009. During Seismic Retrofit construction, ~~Anderson Dam would be largely out of commission and could be in various states of deconstruction or reconstruction, depending on the point in the construction process. Although interim dams would remain during the wet seasons of the Seismic Retrofit construction period, and these interim dams would be winterized to provide additional reinforcements ahead of the wet season, the interim dams may not be sufficient to contain any natural inflow to Anderson Reservoir along with the very large, one-time flow from failure of Coyote Dam upstream.~~

~~The~~ In addition, the storage restriction on Coyote Reservoir limits the potential effects of severe damage to the dam from an earthquake and the possibility of uncontrolled flows. With restricted capacity the possibility of water overtopping damage caused by an earthquake is nearly completed avoided.

~~Coyote Dam could experience damage at any time during the year, given that the failure risk is principally related to a possible earthquake along the Calaveras Fault, which could strike at any time. From the perspective of the Seismic Retrofit construction process, such a failure during the dry season could potentially be worse since active construction on the dam would likely be underway and the interim dam would not be winterized. However, in this dry season scenario Coyote Reservoir would very likely have storage less than permitted by the seismic restriction. Conversely, if such a failure were to occur during the wet season, it could be exacerbated by elevated inflows to Anderson Reservoir from the upstream watershed, thereby increasing the total volume of water.~~

~~The inundation map for the failure of Coyote Dam (Valley Water 2020f) shows widescale flooding for downstream communities along Coyote Creek and surrounding areas all the way out to the San Francisco Bay. However, the fair weather failure analysis assumes a failure of Coyote Dam at full capacity at the spillway lip without any additional inflow, while flood waters pass through Anderson Dam spillway without any additional failures (Valley Water 2020f). As noted above, however, Coyote Dam is currently subject to a storage restriction of 52.5 percent of capacity, so the mapping does not reflect current conditions. In some respects, the flooding from a failure of Coyote Dam during the Seismic Retrofit construction period would be less severe than that represented by the inundation map since less water would likely be present in both Coyote and Anderson reservoirs at the time of a failure due to the storage restriction in place; but in other respects, the flooding could potentially be worse if the failure were to occur during the period of Seismic Retrofit construction when the Anderson spillway is offline and if the inflow from Coyote Reservoir were to cause an overtopping of the interim dam.~~

In general, the probability of dam failure in any given year is extremely low. Coyote Dam is designated as an extremely high hazard dam by DSOD due to the potential downstream impacts caused by a failure; nevertheless, the dam has stood for 87 years (having been constructed in 1936) and the odds of an earthquake strong enough to cause a catastrophic failure are extremely low in any given year. However, the risk of dam failure for Coyote Dam is present under existing conditions and will continue to exist after Seismic Retrofit construction until a similar Seismic Retrofit Project ~~project~~ is implemented for Coyote Dam. Additionally, the seismic retrofit of Anderson Dam would not exacerbate the risk of failure of Coyote Dam or increase potential downstream flooding compared to existing conditions.

~~Thus, the increment of change for the impacts analysis is the degree to which such a failure would be exacerbated by the state of Anderson Dam during the Seismic Retrofit construction period. As discussed above, this may depend on the specific point in the 7-year construction period during which a failure were to occur, but it is possible that the impacts would be no worse or even better than if Anderson Dam were up and fully operational. For example, if Anderson Reservoir was operational and completely full at the time of a Coyote Dam failure, there would be no storage space within Anderson Reservoir available to catch the inflows; whereas, if Anderson Reservoir was completely empty during Seismic Retrofit construction, there would be some storage space available, even if the dam may be in a partial state of deconstruction/reconstruction. The Seismic Retrofit includes winterization measures to reduce the risk of failure of the interim dam during construction. An ACB-lined spillway would be constructed on the downstream slope of the interim dam to convey some volume of overtopping flow safely past the interim dams as a winterization measure. Sheet pile guide walls installed along the interim dam crests would guide flows into the ACB-lined spillways. Flows from the bottom of the ACB-lined spillways would be conveyed to Coyote Creek through a gabion-lined discharge channel.~~

Based on the above analysis, including the limited duration when Anderson Dam would be under construction, limited probability of an earthquake at a location and magnitude to severely damage Coyote Dam, ~~seismic~~ restrictions limiting storage in Coyote Reservoir, and ~~measures to minimize the risk of interim dam overtopping of~~ available capacity for Anderson Dam to capture and pass flows in the event Coyote Dam failed during construction of the Seismic Retrofit, the risk of loss, injury or death involving flooding from dam failure is considered less than significant.

Conservation Measures Construction

As discussed in Impact HYD-1, subsection iv., several of the Conservation Measure components would involve construction activities within the channel (Coyote Creek). Thus, there could potentially be equipment within or near the channel that could impede or redirect flood flows, potentially exacerbating flooding effects. However, Valley Water BMPs and VHP conditions and AMMs would limit the potential for impacts by requiring that work activities occurring in the channel be conducted from the top of bank if access is available and there are flows in the channel (BMP WQ-1), and that wet season construction be avoided (AMM 73). In this regard, the potential for equipment to be in the channel during a high flow event (which would very likely occur during the wet season, if it were to occur) would be unlikely. As such, the analysis under Impact HYD-1, subsection iv., concluded that impacts related to impedance or redirection of flood flows from CMs construction would be less than significant.

No other aspects of the Conservation Measure components construction process would increase potential for flooding nor expose people or structures to substantial risk of loss from flooding. Similarly, none of the Conservation Measures would increase the likelihood of a dam failure. Theoretically, a failure of Coyote Dam (see discussion above) could occur at the time that construction activities for Conservation Measure components are underway. ~~As such, the presence of construction equipment and materials within or along Coyote Creek could potentially exacerbate the effects of the flooding/inundation caused by the dam failure~~. If Coyote Dam were to fail, the downstream effects would be reduced by the presence of Anderson Reservoir, which itself has been under a seismic restriction since 2009. During Seismic Retrofit construction, each interim reservoir at the end of each construction season has capacity that exceeds the capacity of Coyote Reservoir. However, the likelihood of a dam failure in any given year is extremely low, and the risks posed by Coyote Dam are present under existing conditions. Moreover, construction of the Conservation Measures would not exacerbate risk of failure of Coyote Dam ~~Moreover, the increment of additional impact that could occur as a result of the construction of the Conservation Measure components during such a scenario would be minor in the context of the widespread flooding caused by a dam failure.~~ Therefore, the impacts on the risk of loss, injury or death involving flooding from dam failure would be less than significant.

Construction Monitoring

None of the construction monitoring activities would cause or substantially exacerbate flooding (see discussion under Impact HYD-1, subsection iv.). Furthermore, none of the construction monitoring efforts would cause or substantially exacerbate the effects of a dam failure (e.g., Coyote Dam). No impact would occur.

Seismic Retrofit Post-Construction Operations and Maintenance

The reservoir release rule curves under FAHCE post-construction provide for capacity for storm flows similar to that provided in the Pre-FERC Order Conditions. Releases are based on available storage and none of the release volumes would induce flooding downstream. Pulse flows would require releases of up to 90 cfs while downstream flooding does not occur until approximately 3,000 cfs. The FAHCE rules curves would not expose people or structures to significant risk of loss, injury, or death involving flooding from dam failure.

The long-term effects of the Seismic Retrofit components with respect to flooding and/or inundation due to dam failure would be beneficial relative to the Pre-FERC Order Conditions Baseline, as the Seismic Retrofit components would improve the stability and resilience of the dam structures to earthquake damage and potential failure. As described in Chapter 2, *Project Description,* the Project addresses seismic deficiencies of the dam, specifically providing a stable dam embankment capable of withstanding the MCEs on the Calaveras and Coyote Creek Range Front Faults. In addition to the seismic deficiencies of the dam, presently the spillway lacks the capacity to safely pass the flood flows related to passage of the PMF event and emergency reservoir drawdown; this would be corrected by the Project which would include an improved spillway. The Project would also construct new outlet works (LLOW and HLOW) at the dam that capable of lowering the reservoir's maximum storage depth by 10 percent within 7 days, and draining its full content within 90 days, in accordance with DSOD requirements (DSOD 2018 ~~2017~~). All of these improvements would make it less likely for the dam to fail in the future either due to earthquake faulting/rupture or by overtopping of the dam during the PMF.

The failure of Anderson Dam when at full capacity would result in catastrophic flooding for downstream communities, including the cities of Morgan Hill, San José, and Milpitas. The dam failure inundation map for Anderson Dam (Valley Water 2019) shows flooding depths of over 20 feet in many inhabited areas, with massive flooding hitting Morgan Hill in a matter of minutes. Following the dam failure, flooding would reach San José within about 2 hours and would reach depths of 10 to 20 feet in many densely populated areas of the city (Valley Water 2019). The inundation map considers a fair weather failure scenario whereby the failure is assumed to occur with the dam at full capacity at the spillway lip without any additional inflow (Valley Water 2019). In this respect, the inundation map is not a true representation of the downstream flooding risk during a failure under the Pre-FERC Order Conditions Baseline, as the storage capacity at Anderson Reservoir had been restricted to 52,553 AF (55 feet below the dam crest) during this period, which is substantially less than full capacity. Nevertheless, if a failure were to have occurred during the Pre-FERC Order period, this still would have resulted in substantial, damaging flooding downstream. Like Coyote Dam, DSOD rates Anderson Dam as an extremely high hazard dam due to the potential for downstream impacts.

As such, the Seismic Retrofit components would be a great benefit to the region by reducing the potential for dam failure and the associated devastating impacts. Following construction of the Project, the storage restriction would be lifted, and the reservoir would be returned to full capacity. Although the dam crest would be raised as part of the Project, the spillway elevation would not change, and thus the maximum water surface elevation for storage at the reservoir would not change relative to the Pre-FERC Order Conditions Baseline. As described in Chapter 2, *Project Description,* the Project is expected to decrease the storage capacity at the reservoir somewhat, as the current reservoir capacity of 89,278 AF (which has been reduced compared to historical conditions by approximately 1,790 AF due to sediment accumulation within the reservoir) is expected to be reduced to 88,000 AF following construction. Although a portion of the accumulated sediment would be transported out of the reservoir area during diversion of reservoir inflows around the construction area (thus recovering lost storage), storage would also be lost due to in-reservoir disposal. Thus, the total volume of water that would be stored behind the dam and could potentially be released during a dam failure would not increase and would decrease slightly, in the future following construction of the Project.

As noted under Impact HYD-1, subsection iv., flood management measures have been implemented and planned along Coyote Creek specifically to accommodate an event like the 2017 storm, which will also accommodate the higher flows that would be possible as a result of the Project and expanded outlet works capacity.

Additionally, none of the maintenance activities during the post-construction period would substantially increase the risk of flooding from dam failure. If anything, the proper maintenance of dam components and facilities consistent with the DMP would reduce the potential for dam failure.

Based on the above analysis, the impact of Seismic Retrofit post-construction operations and maintenance on risks of loss, injury, or death caused by flooding due to dam failure would be less than significant.

Conservation Measures Post-Construction Operations and Maintenance

None of the Conservation Measure components that would be implemented as part of the Project would increase the potential for dam failure or substantially increase the potential risk to downstream communities from flooding. As discussed above, certain aspects of the Conservation Measure components could potentially exacerbate flooding (e.g., channel roughening, replenishment of coarse sediment, disconnecting ponds that may serve as detention facilities [Ogier Ponds]); however, other activities to be conducted as part of the Conservation Measure components would serve to reduce flooding potential (e.g., vegetation management along stream banks). Taken together, the effects of the Conservation Measures with respect to flooding would be marginal in the context of the greater Coyote Creek system, including Anderson Dam.

The risk of loss, injury or death involving flooding from dam failure caused by Conservation Measure operations and maintenance would be less than significant.

Post-Construction Project and FAHCE Adaptive Management

AMP monitoring and adaptive management activities would not increase the risk of loss, injury or death involving flooding from dam failure. As such, no impact would occur.

Significance Conclusion Summary

Construction of the Seismic Retrofit components would not directly increase the risk of flooding due to dam failure ~~but could potentially~~ and would not exacerbate the impacts from a failure of Coyote Dam, which is located upstream of Anderson Dam and is also susceptible to seismic risks. The probability of such a dam failure would be low, however, and the risk of Coyote Dam failing was present under the Pre-FERC Order Conditions Baseline. In addition, Anderson Reservoir would have sufficient capacity to capture and pass water released in the event Coyote Dam failed during construction of the Seismic Retrofit, even if Coyote Reservoir was at the full storage capacity.

None of the Conservation Measure components would substantially increase the risk of loss, injury or death involving flooding, including that as a result of dam failure.

Over the long-term, the Project would greatly improve the safety of downstream communities with respect to flooding and dam failure, as it would correct existing deficiencies in Anderson Dam. Similarly, maintenance and monitoring activities during the post-construction period would not increase the risk of flooding. As such, the Project would not cause significant risk of loss, injury or death involving flooding from dam failure, and the impact would therefore be **less than significant.**

Mitigation Measures

No mitigation is required.

Impact HYD 3: In flood hazard, tsunami, or seiche zones, risk release of pollutants due to project inundation (Less than Significant)

As discussed in Section 3.11.2.4 (Tsunamis, Seiches, and Flooding) the Project site is not vulnerable to tsunami or seiche therefore these impacts are not discussed in the analysis below. The risk of release of pollutants due to inundation from flood hazard is discussed below.

Seismic Retrofit Construction

As discussed in HYD 1 and HYD 2, construction of the Seismic Retrofit components would not result in significant impacts to flooding. The only area that would be inundated during construction are part of the bottom of Anderson Reservoir that are typically inundated during normal operations. Construction activities would bring heavy equipment to the reservoir bottom which use hazardous materials (e.g., fuel, oil, lubricants, etc.). There would be potential for discharge of pollutants in areas subject to inundation if such materials were handled, stored, or disposed of improperly and/or if any accidental releases of such materials were to occur. Hazardous materials stored onsite at staging areas or temporarily at work areas could also spill if proper protocols are not followed and containment provided. These impacts are discussed further in Section 3.10, *Hazards and Hazardous Materials*.

Such releases of hazardous materials during construction, if they were to occur, could result in subsequent polluted runoff if the spill materials were not cleaned up prior to future filling of the reservoir. While the spilled hazardous materials may remain in soil or on the ground surface during the construction, the materials could be mobilized to receiving waterbodies (e.g., Coyote Creek) when the reservoir is filled post-construction. Without preventative measures, these effects would be considered significant.

Implementation of the SWPPP for out-of-reservoir construction activities, in compliance with the Construction General Permit, along with applicable Valley Water BMPs and VHP conditions and AMMs, would substantially reduce the potential for accidental releases of hazardous materials and other pollutants during seismic retrofit construction, as well as the potential for impacts in the event of such releases. The SWPPP would need to include good housekeeping measures for: construction materials, waste management, vehicle storage and maintenance, landscape materials, and potential pollutant sources (SWRCB 2009). Examples include conducting an inventory of products used, implementing proper storage and containment, and properly cleaning all leaks from equipment and vehicles (SWRCB 2009). While the SWPPP would be prepared prior to construction, consideration of these factors and inclusion of appropriate BMPs for pollutant control would reduce the potential adverse impacts during seismic retrofit construction.

Additionally, the following Valley Water BMPs would reduce potential impacts associated with hazardous materials releases: ~~BMP HM-7 (Restrict Vehicle and Equipment Cleaning to Appropriate Locations),~~ BMP HM-8 (Ensure Proper Vehicle and Equipment Fueling and Maintenance), BMP HM-9 (Ensure Proper Hazardous Materials Management), and BMP HM-10 (Utilize Spill Prevention Measures). These BMPs would include protocols for providing secondary containment for hazardous materials used in the field or stored at staging areas or at work sites, and providing training spill cleanup materials for field personnel, among other measures. Furthermore, compliance with VHP measures, including AMMs 2, 7, 8, 9, 11, 12, 72, 75, 76, 87, 88, and 100, whether implemented independently or incorporated as part of the SWPPP, would reduce potential impacts from pollutants. Implementation of measures included either as part of the SWPPP for out-of-reservoir construction activities and applicable~~,~~ Valley Water BMPs~~,~~ or VHP conditions and AMMs, would prevent Seismic Retrofit construction activities from releasing pollutants due to inundation, and this impact would be s less than significant.

Conservation Measures Construction

Construction of the Conservation Measures components would have similar impacts to those described for the Seismic Retrofit components. Specifically, the Ogier Ponds CM, Maintenance of the North Channel Reach ~~Extension~~, and Phase 2 Coyote Percolation Dam CM, would bring heavy equipment to areas that are subject to future flooding or inundation. Construction equipment would have the potential to leak during construction and/or would require storage or servicing with hazardous materials. Implementation of the SWPPP, and applicable Valley Water BMPs and VHP conditions and AMMs, would reduce any potential adverse effects associated with hazardous materials and polluted runoff due to inundation to a level that is less than significant.

Construction Monitoring

None of the construction monitoring processes/activities would involve heavy equipment. Construction monitoring efforts could potentially use small amounts of hazardous materials (e.g., oil or lubricant needed for monitoring equipment, fuel for vehicles transporting personnel to monitoring sites); however, routine reasonable care exercised by field personnel would prevent substantial impacts from occurring. As such, effects would be less than significant.

Seismic Retrofit and Conservation Measures Post-Construction Operations and Maintenance

Maintenance of Anderson Reservoir is subject to the DMP, including its BMPs and mitigation measure related to pollutant releases. No hazardous materials would be stored or used on the site during the post-construction period, except that which may be necessary during maintenance and repair activities, which would not be stored in areas that are subject to flooding or inundation. Implementation of applicable Valley Water BMPs and VHP conditions and AMMs during maintenance work for the seismic retrofit components would prevent substantial impacts from occurring due to releases of hazardous materials and generation of pollutants. Therefore, post-construction impacts from operation and maintenance of seismic retrofit components would be less than significant.

Conservation Measures Post-Construction Operations and Maintenance

Normal operations of the Conservation Measure components would not bring pollutants into contact with areas that are subject to flooding. Similar to maintenance of the Seismic Retrofit components, maintenance of Conservation Measure components would be subject to applicable Valley Water BMPs and VHP conditions and AMMs during maintenance work that would prevent substantial impacts from occurring due to releases of hazardous materials and generation of pollutants. Therefore, post-construction impacts from operation and maintenance of Conservation Measure components would be less than significant.

Post-Construction Project and FAHCE Adaptive Management

AMP monitoring activities would have impacts similar to those described for Construction Monitoring. ~~F~~AMP adaptive management actions would have impacts similar to, but less in magnitude, than the measures being adaptively managed. As such, impacts would be less than significant.

Significance Conclusion Summary

The seismic retrofit components and Conservation Measures would have some potential to generate pollutants in areas that are subject to inundation during construction (e.g., use of heavy equipment in construction staging and work areas and use, storage, and disposal of hazardous materials); however, implementation of the SWPPP for out-of-reservoir construction activities and applicable Valley Water BMPs and VHP conditions and AMMs would reduce potential impacts to a level that is **less than significant**. While not required to reduce impacts to less than significant, Mitigation Measure WQ-1 would further reduce these impacts by requiring implementation of a WQMPP for in-reservoir construction activities, which would include evaluation of the water quality monitoring data collected during FOCP implementation and Project construction, and implementation of BMPs to control sediment and other pollutants associated with in-reservoir construction activities to the extent technically feasible and in accordance with regulatory requirements.

Likewise, the potential use of hazardous materials during maintenance activities could contribute pollutants in areas subject to inundation. Implementation of applicable BMPs and AMMs would reduce these effects to **less than significant**.

Overall, this the Project would result in a less than significant risk of pollutant release due to Project ~~project~~ inundation.

Mitigation Measures

No mitigation is required.

3.11.5 Cumulative Impacts

The geographic study area for the cumulative impact analysis for hydrology is Anderson Reservoir and Coyote Creek to San Francisco Bay.

This section describes the Project's contribution to cumulative hydrology impacts, as summarized in **Table 3.11-10**.

Table 3.11-10. Summary of Project Impact Contribution to Cumulative Hydrology Impacts

Impact	Cumulatively Significant with FOCP?	Cumulatively Significant with other projects?	Incremental Project Contribution	Applicable Project Mitigation	Cumulatively Considerable after Mitigation?
Cumulative Impact HYD-1a: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner which would result in substantial erosion or siltation on- or off-site	Yes	Yes	CC	MM WQ-1 ~~None~~	Yes
Cumulative Impact HYD-1b: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner ~~matter~~ which would substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or offsite	No	No	NCC	None	No
Cumulative Impact HYD-1c: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner ~~matter~~ which would create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff	No	No	NCC	None	No
Cumulative Impact HYD-1d: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner matter which would impede or redirect flood flows	No	No	NCC	None	No
Cumulative Impact HYD-2: Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of dam failure	No	No	NCC	None	No
Cumulative Impact HYD-3: In flood hazard, tsunami, or seiche zones, risk release of pollutants due to project inundation	No	No	NCC	None	No

***Cumulative Impact HYD-1a: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner ~~matter~~ which would result in substantial erosion* (Cumulatively Considerable)**

The Project would discharge large volumes of sediment following storms while the reservoir is dewatered given the exposure of sediments previously inundated on the bottom of Anderson Reservoir and the limited capacity to store water behind the coffer dam during construction. Construction and maintenance associated with the various components have the potential to loosen materials that could be washed downstream, thus contributing to accelerated rates of erosion and sedimentation. Additionally, use of staging areas and mobilization of equipment in upland areas or areas directly adjacent to the creek could contribute sediment-laden runoff to Coyote Creek. Conservation Measures such as the Ogier Ponds CM, Spawning Gravel and Rearing Habitat Improvements at Live Oak Restoration Reach, and the Sediment Augmentation Program would provide long-term beneficial impacts to erosion and sedimentation.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if their construction, restoration, or operation also increase the likelihood of erosion to Anderson Reservoir or Coyote Creek.

Cumulative Effects of Project with the FOCP

The FOCP lowered the storage behind Anderson Reservoir to deadpool. This exposed previously inundated sediment that had accumulated behind the dam to erosion as flows from upstream run through the footprint of the reservoir. At the same time, the reduction of stored water reduced the reservoir's ability to settle out sediment being carried down from upstream sources. This may greatly increase the volume of sediments released downstream to Coyote Creek during certain-sized storm events. Construction of new access and haul roads, as well as removal of Coyote Road, during site mobilization involved substantial ground disturbance and operation of heavy equipment. This could result in erosion and subsequent transport/runoff of eroded materials to Anderson Reservoir and Coyote Creek.

Both projects involve construction activities that could increase erosion to Coyote Creek and the Project extends the period that Andreson Reservoir storage is lowered which greatly increases the potential for erosion of the sediments on the bottom of the reservoir. This is a significant cumulative impact even with implementation of a WQMPP for in-reservoir construction areas as required by **Mitigation Measure WQ-1**, and the Project's contribution is cumulatively considerable with the FOCP.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Other projects that could impact erosion in Coyote Creek include the SMP, Coyote Creek Flood Protection Project, Santa Clara County Parks Planning Projects and Natural Resource Management, as well as development projects in the County where ground disturbing activities may take place. These other projects involve construction and maintenance activities that could result in erosion and subsequent transport/runoff of eroded materials.

All construction projects over one acre in size must comply with the Construction General Permit and implementation of a SWPPP which requires erosion control measures and BMPs to avoid and reduce the risk of erosion of materials to adjacent water bodies. The Project, and other Valley Water projects, implement Valley Water erosion control BMPs to further reduce this risk such as: BMP AQ-1 (Use Dust Control Measures), BMP WQ-4 (Limit Impacts From Staging and Stockpiling Materials), BMP WQ-1 (Conduct Work from Top of Bank), BMP WQ-2 (Evaluate Use of Wheel and Track Mounted Vehicles in Stream Bottoms), BMP WQ-5 (Stabilize Construction Entrances and Exits), BMP WQ-9 (Use Seeding for Erosion Control, Weed Suppression, and Site Improvement), BMP WQ-10 (Prevent Scour Downstream of Sediment Removal), BMP WQ-11 (Maintain Clean Conditions at Work Sites), BMP WQ-16 (Prevent Stormwater Pollution). The cumulative effect of general construction activities is not cumulatively considerable with the implementation of a SWPPP and BMPs for work outside of the reservoir.

Construction of the seismic retrofit would add approximately two acres of impervious surface associated with roads and parking lots around Anderson Reservoir. Implementation of the SWPPP, Valley Water BMPs, and VHP conditions and AMMs would reduce surface runoff and associated sedimentation such that the Project with other projects would not result in a cumulatively significant impact.

However, the combination of the Project's and other probable future projects' erosion impacts is cumulatively significant, and Project's contribution of erosion to Coyote Creek from sediments on the bottom of Anderson Reservoir is cumulatively considerable.

Significance Conclusion Summary

The Project, FOCP, and most other probable future projects are over one acre in size and must comply with the Construction General Permit and implementation of a SWPPP or out-of-reservoir construction activities. The Project, and other Valley Water projects, also implement Valley Water erosion control BMPs. The cumulative effect of general construction activities from the Project with the FOCP and other probable future projects is not significant with the implementation of a SWPPP and BMPs and the Project's contribution to these impacts is not cumulatively considerable.

The Project's impact on erosion from the exposure of sediments on the bottom of Anderson Reservoir extends the period that these sediments are vulnerable to erosion during storms. This cumulative impact is significant, and the Project's contribution is cumulatively considerable.

Mitigation Measure WQ-1 requires implementation of a WQMPP for in-reservoir construction activities, which would include evaluation of the water quality monitoring data collected during FOCP implementation and Project construction, and implementation of BMPs to control sediment and other pollutants associated with in-reservoir construction activities to the extent technically feasible and in accordance with regulatory requirements. While the WQMPP would address in-reservoir construction areas, no additional ~~No~~ feasible mitigation is available to address this impact, given the large area of the reservoir bottom which would be exposed by the dewatering and amount of accumulated sediment (approximately 2.9 million cy). For example, it may be feasible to hydroseed portions of the reservoir bottom, but it would not stabilize enough sediment to reduce the sediment mobilization in a meaningful way. Similarly, measures to settle sediments within the reservoir, rather than allowing them to move downstream (turbidity curtains or operating the reservoir at a higher level) would not be feasible during construction because of the potential to increase risks of the interim dam being overtopped. The Project's seismic retrofit construction when added to the impacts of the FOCP and other probable future projects, would cause a significant cumulative impact related to erosion, and the Project's contribution is **cumulatively considerable**.

Mitigation Measures

WQ-1 Develop and Implement an In-Reservoir Construction Area Water Quality Monitoring and Protection Plan.

~~No mitigation is feasible.~~

Cumulative Impact HYD-1b: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner ~~matter~~ which would substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or offsite **(Not Cumulatively Considerable)**

Project construction and maintenance activities would involve denuding areas of vegetation to create access or stable surfaces, which reduce the capacity of these areas to absorb water and slow runoff. Utilization of areas by heavy equipment during construction would compact soils, making the ground surface harder and less conducive to infiltration of water to soil or groundwater. The Seismic Retrofit components of the Project would create relatively minor amounts of new impervious surface (widened/expanded existing roadways).

Cumulative projects, plans, and programs could result in incrementally adverse impacts if their construction, restoration, or operation also increase the likelihood of flooding along Coyote Creek.

Cumulative effects of Project with the FOCP

The FOCP involved similar construction activities as the Project; however, all FOCP impacts would occur prior to the start of Project construction. Because impacts happen at different times there would not be a cumulative effect to the risk of flooding when Project and FOCP impacts are added.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Other projects that could increase flood risk in Coyote Creek include the SMP, Coyote Creek Flood Protection Project, Santa Clara County Parks Planning Projects and Natural Resource Management, as well as development projects in the County where ground disturbing activities and expansion of impervious surface may take place. These other projects involve construction and maintenance activities that create similar impacts as those identified for the Project.

In general, the changes to drainage patterns caused by construction activities from both the Project and other potential projects would not be anticipated to result in flooding on- or off-site. Runoff from construction work areas within the reservoir (e.g., stockpile areas, access roads, etc.), as well as many work areas in uplands adjacent to the reservoir, would drain to the collection area behind the coffer dam or interim dam(s). This water could then be discharged via the Stage 2 Diversion System in a controlled manner, which would not result in flooding. Other work areas may drain directly to Coyote Creek; however, the volume of water from these work areas would not be expected to result in overtopping of banks or any other form of flooding on- or off-site.

Implementation of the SWPPP and Valley Water BMPs would reduce potential for construction disturbance areas outside of the reservoir to generate increased surface runoff and associated on- or off-site flooding for the Project's construction. The flood risk from the Project when added to the impacts of other probable future projects is not cumulatively significant and the Project's contribution to flooding risk is not cumulatively considerable.

Construction of the seismic retrofit would add approximately two acres of impervious surface associated with roads and parking lots around Anderson Reservoir. Implementation of the SWPPP for out-of-reservoir construction activities and applicable~~,~~ Valley Water BMPs~~,~~ and VHP conditions and AMMs would reduce surface runoff such that the Project with other projects would not result in a cumulatively significant impact, and the Project's contribution would not be cumulatively considerable.

Significance Conclusion Summary

The Project and most other probable future projects are over one acre in size and must comply with the Construction General Permit and implementation of a SWPPP for out-of-reservoir construction activities. The Project, and other Valley Water projects, also implement Valley Water erosion control BMPs. The cumulative effect of general construction activities from the Project's construction activities with the FOCP and other probable future projects is not significant, and the Project's contribution is **not cumulatively considerable** with the implementation of a SWPPP and BMPs.

Mitigation Measures

No mitigation is required.

***Cumulative Impact HYD-1c: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner ~~matter~~ which would create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff* (Not Cumulatively Considerable)**

Due to the use of hazardous materials during construction, maintenance, monitoring, and adaptive management activities (e.g., fuel, oil, lubricants, etc. in construction equipment), there would be potential for discharge of polluted runoff if such materials were handled, stored, or disposed of improperly and/or if any accidental releases of such materials were to occur. Project activities would require use of a wide range of equipment, as listed in **Table 2-3** in Chapter 2, *Project Description,* much of which would involve hazardous materials. The equipment could potentially leak during operation if it is not maintained properly; additionally, hazardous materials could spill during re-fueling or maintenance/servicing activities that may be necessary during the construction period. Hazardous materials stored on-site at staging areas or temporarily at work areas could also spill if proper protocols are not followed and containment provided.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if their construction, restoration, or operational also increase the likelihood of polluted runoff to Anderson Reservoir or Coyote Creek.

Cumulative Effects of Project with the FOCP

The FOCP involved similar construction activities as the Project and both projects have the potential to generate polluted runoff.

Implementation of a SWPPP, in compliance with the Construction General Permit, along with applicable Valley Water BMPs, would substantially reduce the potential for accidental releases of hazardous materials during Project activities, as well as the potential for impacts in the event of such releases. The SWPPP <u>for out-of-reservoir construction activities</u> is required to include good housekeeping measures for: construction materials, waste management, vehicle storage and maintenance, landscape materials, and potential pollutant sources (SWRCB 2009). Additionally, the following Valley Water BMPs would reduce potential impacts associated with hazardous materials releases: ~~BMP HM-7 (Restrict Vehicle and Equipment Cleaning to Appropriate Locations),~~ BMP HM-8 (Ensure Proper Vehicle and Equipment Fueling and Maintenance), BMP HM-9 (Ensure Proper Hazardous Materials Management), and BMP HM-10 (Utilize Spill Prevention Measures). These BMPs would include protocols for providing secondary containment for hazardous materials used in the field or stored at staging areas or at work sites, and providing training spill cleanup materials for field personnel, among other measures. The FOCP was also required to prepare and implement a SWPPP and incorporated a similar set of BMPs to avoid the generation of polluted runoff. The impacts of the Project when added to the impacts of the FOCP would not create cumulatively significant impacts on polluted runoff, and the Project's contribution of polluted runoff is not cumulatively considerable with implementation of the SWPPP and Valley Water BMPs.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Other projects that could increase risk of polluted runoff in Coyote Creek include the SMP, Coyote Creek Flood Protection Project, Santa Clara County Parks Planning Projects and Natural Resource Management, as well as development projects in the County where ground disturbing activities and use of heavy equipment may take place. These other projects involve construction and maintenance activities that create similar impacts as those identified for the Project. All potential projects would be required to implement a SWPPP, in compliance with the Construction General Permit to minimize impacts from construction.

The impacts of the Project when added to the impacts of probable future projects would not create cumulatively significant impacts on polluted runoff, and the Project's contribution of polluted runoff is not cumulatively considerable with implementation of the SWPPP and Valley Water BMPs.

Significance Conclusion Summary

The Project, FOCP, and other probable future projects are over one acre in size and must comply with the Construction General Permit and implementation of a SWPPP <u>for out-of-reservoir construction activities</u>. The Project, and other Valley Water projects, also implement Valley Water pollution control BMPs. The cumulative effect of general construction activities with the FOCP and other probable future projects would not be significant, and the Project's contribution is **not cumulatively considerable** with the implementation of a SWPPP and BMPs. While not required to reduce impacts to less than significant, Mitigation Measure WQ-1 would further reduce these impacts by requiring implementation of a WQMPP for in-reservoir construction activities, which would include evaluation of the water quality monitoring data collected during FOCP implementation and Project construction, and implementation of BMPs to control hazardous materials and other pollutants associated with in-reservoir construction activities to the extent technically feasible and in accordance with regulatory requirements.

Mitigation Measures

No mitigation is required.

Cumulative Impact HYD-1d: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river or through the addition of impervious surfaces, in a manner ~~matter~~ which would impede or redirect flood flows (Not Cumulatively Considerable)

During construction of the Seismic Retrofit component, there would be increased potential for flooding (i.e., higher flows could occur in Coyote Creek more frequently during storm events) relative to the existing conditions baseline for flows under the 50-year return period (approximately 4,000cfs – 5,000cfs); however, this flooding risk would be largely reduced relative to Pre-FERC Order Conditions and would not result in widespread, damaging floods based on the analysis shown in **Figure 3.11-5**. During the post-construction period, flooding risk associated with operation of the dam would be reduced relative to the Pre-FERC Order Conditions Baseline.

Cumulative Effects of Project with the FOCP

The FOCP reduced storage in Anderson Reservoir to deadpool, which provided the full reservoir to capture high flows, while the existing outlet is maintained with a maximum capacity of 500 cfs. The FOCP would implement Coyote Creek Flood Management components that would provide long-term flood risk reduction along Coyote Creek. The risk of flooding is low during the FOCP and all FOCP impacts would occur prior to the start of Project construction. Because construction-related hydrology impacts happen at different times, there would not be a cumulative risk of flooding due to impeding or redirecting flood flows when Project and FOCP impacts are added.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Other projects that could increase flood risk in Coyote Creek include the SMP, Coyote Creek Flood Protection Project, Santa Clara County Parks Planning Projects and Natural Resource Management, as well as development projects in the County where ground disturbing activities and expansion of impervious surface may take place. Other projects would be required to comply with applicable Municipal Stormwater NPDES permits that minimize the impact of expanded impervious surfaces on the potential for flooding. The Coyote Creek Flood Protection Project would reduce the long-term risk of flooding along Coyote Creek by making improvements that would allow a storm event similar to the 2017 flood event to be safely passed to San Francisco Bay.

The Project's contribution to flooding risk, which is generally decreased relative to the Pre-FERC Order baseline, would not create cumulatively significant flood risks due to impeding or redirecting flood flows, and the Project's contribution to flood risks is not cumulatively considerable.

Significance Conclusion Summary

The Project, FOCP, and other probable future projects, specifically the Coyote Creek Flood Protection Project have project elements that would reduce flood risk along Coyote Creek. Expansion of impervious surfaces by potential future projects would be required to comply with applicable Municipal Stormwater NPDES permits that minimize the risk of flooding. The cumulative effect of the Project combined with impacts of the FOCP and other probable future projects on impeding or redirecting flood flows is not significant, and the project's contribution is **not cumulatively considerable**.

Mitigation Measures

No mitigation is required.

Cumulative Impact HYD-2: Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of dam failure **(No Cumulative Impact)**

The objective of the Project is to reduce the long-term risk of flooding from dam failure. Construction of the Seismic Retrofit components would not directly increase the risk of flooding ~~due to dam failure but could~~ potentially and would not exacerbate the impacts from a failure of Coyote Dam. ~~Coyote Dam, which is located upstream of Anderson Dam and is also susceptible to seismic risks.~~ If Coyote Dam were to fail, the downstream effects would be reduced by the presence of Anderson Reservoir, which itself has been under a seismic restriction since 2009. During Seismic Retrofit construction, each interim reservoir at the end of each construction season has capacity that exceeds the capacity of Coyote Reservoir.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if their construction, restoration, or operational would increase the risk of flooding along Coyote Creek from dam failure.

Cumulative Effects of Project with the FOCP

The FOCP reduced storage in Anderson Reservoir to deadpool under orders from the FERC to minimize the risk of flooding from dam failure. As the FOCP reduces the risk from dam failure and impacts happen at different times, there would not be a cumulative effect to the risk of flooding when adding Project and FOCP impacts.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

None of projects listed in **Table 3.0-2** would have the potential to increase the risk of dam failure. Future development projects throughout the County that are in the established flood inundation area of Anderson Reservoir increase the risk of loss, injury or death from flooding in the event of dam failure, but the likelihood of dam failure is considered very minor.

The Project would ~~potentially~~ not exacerbate the impacts from a failure of Coyote Dam while Anderson Dam is lowered over three years of the construction period. Coyote Reservoir is under ~~seismic~~ restrictions that reduce the risk of dam failure and Anderson Dam would have capacity to capture and pass flows in the event Coyote Dam failed ~~include winterization measures while the dam is lowered to minimize the risk of failure.~~ Given these factors, the cumulative impact related to dam failure risks is not significant and the Project's contribution to risk from flooding from dam failure is not cumulatively considerable.

Significance Conclusion Summary

Over the long-term, the Project and the FOCP would greatly improve the safety of downstream communities with respect to flooding and dam failure, as it would correct existing deficiencies in Anderson Dam. Similarly, maintenance and monitoring activities during the post-construction period would not increase the risk of flooding. The risk of Coyote Dam failing is present under the Pre-FERC Order Conditions Baseline and is reduced by the FOCP through the draining of Anderson Reservoir to deadpool. Risk of flooding from dam failure increases marginally during construction of the Seismic Retrofit but is minimized through winterization measures in the wet season while the crest of the dam is lowered. Given the very low probability of dam failure, which would require a major earthquake in close proximity to Coyote Reservoir following a wet period that fills the reservoir beyond its capacity to release high flow, the cumulative effect of Project activities when added to impacts of the FOCP and other probable future projects is not significant, and the Project's contribution is **not cumulatively considerable**.

Mitigation Measures

No mitigation is required.

Cumulative Impact HYD-3: In flood hazard, tsunami, or seiche zones, risk release of pollutants due to project inundation (Not Cumulatively Considerable)

As discussed in Section 3.11.1.4 (Tsunamis, Seiches, and Flooding) the Project site is not vulnerable to tsunami or seiche therefore these impacts are not discussed in the analysis below. The risk of release of pollutants due to inundation from flood hazard is discussed.

The seismic retrofit components and Conservation Measures and maintenance and would have some potential to generate pollutants in areas that are subject to inundation during construction (e.g., use of heavy equipment in construction staging and work areas and use, storage, and disposal of hazardous materials)

Cumulative Effects of Project with the FOCP

The FOCP involved similar construction activities as the Project and both projects have the potential to generate pollutants subject to inundation from flooding.

Implementation of a SWPPP for out-of-reservoir construction activities, in compliance with the Construction General Permit, along with applicable Valley Water BMPs, would substantially reduce the potential for accidental releases of hazardous materials during Project activities, as well as the potential for impacts in the event of such releases. The SWPPP is required to include good housekeeping measures for construction materials, waste management, vehicle storage and maintenance, landscape materials, and potential pollutant sources (SWRCB 2009).

Additionally, the following Valley Water BMPs would reduce potential impacts associated with hazardous materials releases: ~~BMP HM-7 (Restrict Vehicle and Equipment Cleaning to Appropriate Locations),~~ BMP HM-8 (Ensure Proper Vehicle and Equipment Fueling and Maintenance), BMP HM-9 (Ensure Proper Hazardous Materials Management), and BMP HM-10 (Utilize Spill Prevention Measures). These BMPs would include protocols for providing secondary containment for hazardous materials used in the field or stored at staging areas or at work sites, and providing training spill cleanup materials for field personnel, among other measures. The FOCP was also required to prepare and implement a SWPPP and incorporated a similar set of BMPs to avoid the generation of polluted runoff. The impacts of the Project when added to the impacts of the FOCP would not create cumulatively significant impacts on polluted runoff, and the Project's contribution of polluted runoff is not cumulatively considerable with implementation of the SWPPP and Valley Water BMPs.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Other projects that could increase risk of polluted runoff in Coyote Creek include the SMP, Coyote Creek Flood Protection Project, Santa Clara County Parks Planning Projects and Natural Resource Management, as well as development projects in the County where ground disturbing activities and use of heavy equipment may take place in or adjacent to Coyote Creek floodplains. These other projects involve construction and maintenance activities that create similar impacts as those identified for the Project. All potential projects would be required to implement a SWPPP in compliance with the Construction General Permit to minimize impacts from construction.

The impacts of the Project when added to the impacts of probable future projects would not create cumulatively significant impacts on polluted runoff, and the Project's contribution of polluted runoff is not cumulatively considerable.

Significance Conclusion Summary

The Project, FOCP, and other probable future projects are over one acre in size and must comply with the Construction General Permit and implementation of a SWPPP for out-of-reservoir construction activities. The Project, and other Valley Water projects, also implement Valley Water pollution control BMPs. The cumulative effect of general construction and maintenance activities with the FOCP and other probable future projects on polluted runoff would not be **cumulatively significant**, and the Project’s contribution is **not cumulatively considerable**. While not required to reduce impacts to less than significant, Mitigation Measure WQ-1 would further reduce these impacts by requiring implementation of a WQMPP for in-reservoir construction activities, which would include evaluation of the water quality monitoring data collected during FOCP implementation and Project construction, and implementation of BMPs to control hazardous materials and other pollutants associated with in-reservoir construction activities to the extent technically feasible and in accordance with regulatory requirements.

3.12 Groundwater Resources

This section describes groundwater resources in the study area, including the area around Anderson Reservoir and downstream underlying Coyote Creek, and discusses the Project's impacts on these resources. The regulatory and environmental setting, which includes a description of applicable regulations and the existing groundwater resources in the study area, are provided as a basis to evaluate impacts. The impact analysis evaluates how the Project could temporarily and permanently impact the existing groundwater resources in and around the study area.

The study area used to assess impacts related to groundwater resources includes the Santa Clara Subbasin, as shown on **Figure 3.12-1**.

3.12.1 Environmental Setting

3.12.1.1 Groundwater Basin Characteristics

The groundwater basin underlying and/or potentially affected by the Project is the Santa Clara Subbasin (DWR Basin 2-9.02), which is a subbasin of the Santa Clara Valley Groundwater Basin (DWR 2004). The Santa Clara Subbasin extends from the northern border of the county to the groundwater divide near Morgan Hill. The subbasin is bounded by the Diablo Range to the east and the Santa Cruz Mountains to the west. The geographic extent of the Santa Clara Subbasin in relation to the Project is shown in **Figure 3.12-5**. As shown in **Figure 3.12-5**, the mapped extent of the subbasin terminates at Anderson Dam (in other words, the subbasin begins on the downstream side of the dam). While Llagas Subbasin is shown on **Figure 3.12-5**, it would not be affected by the Project, so it is not described in this section.

The water-bearing formations of the Santa Clara Subbasin include Pliocene- to Holocene-age continental deposits of unconsolidated to semi-consolidated gravel, sand, silt, and clay (Valley Water 2021). This includes the Santa Clara Formation of Plio-Pleistocene age and the younger alluvium of Pleistocene to Holocene age. The latter of these two units is the most important in the subbasin, as the permeability of the valley alluvium is generally high and principally all large production wells derive their water from the alluvium (DWR 2004). The combined thickness of the water-bearing units exceeds 1,500 feet (Valley Water 2021).

To assist with groundwater management, Valley Water has divided the subbasin into two management areas: the Santa Clara Plain and the Coyote Valley (see **Figure 3.12-1** and **Figure 3.12-5**). The Santa Clara Plain, covering the wide Santa Clara Valley floor and extending to the northern boundary with San Francisco Bay, comprises most of the subbasin. The Coyote Valley area extends from the southern portion of the Santa Clara Valley to the subbasin's southern boundary, north ~~south~~ of Morgan Hill. These two management areas are separated by an area referred to as Coyote Narrows, where the bedrock constricts the Santa Clara Subbasin, forming a hydraulic corridor between the two management areas. The Coyote Valley is mainly composed of thick alluvial sand and gravel deposits with interbedded thin, discontinuous clays (Valley Water 2021).

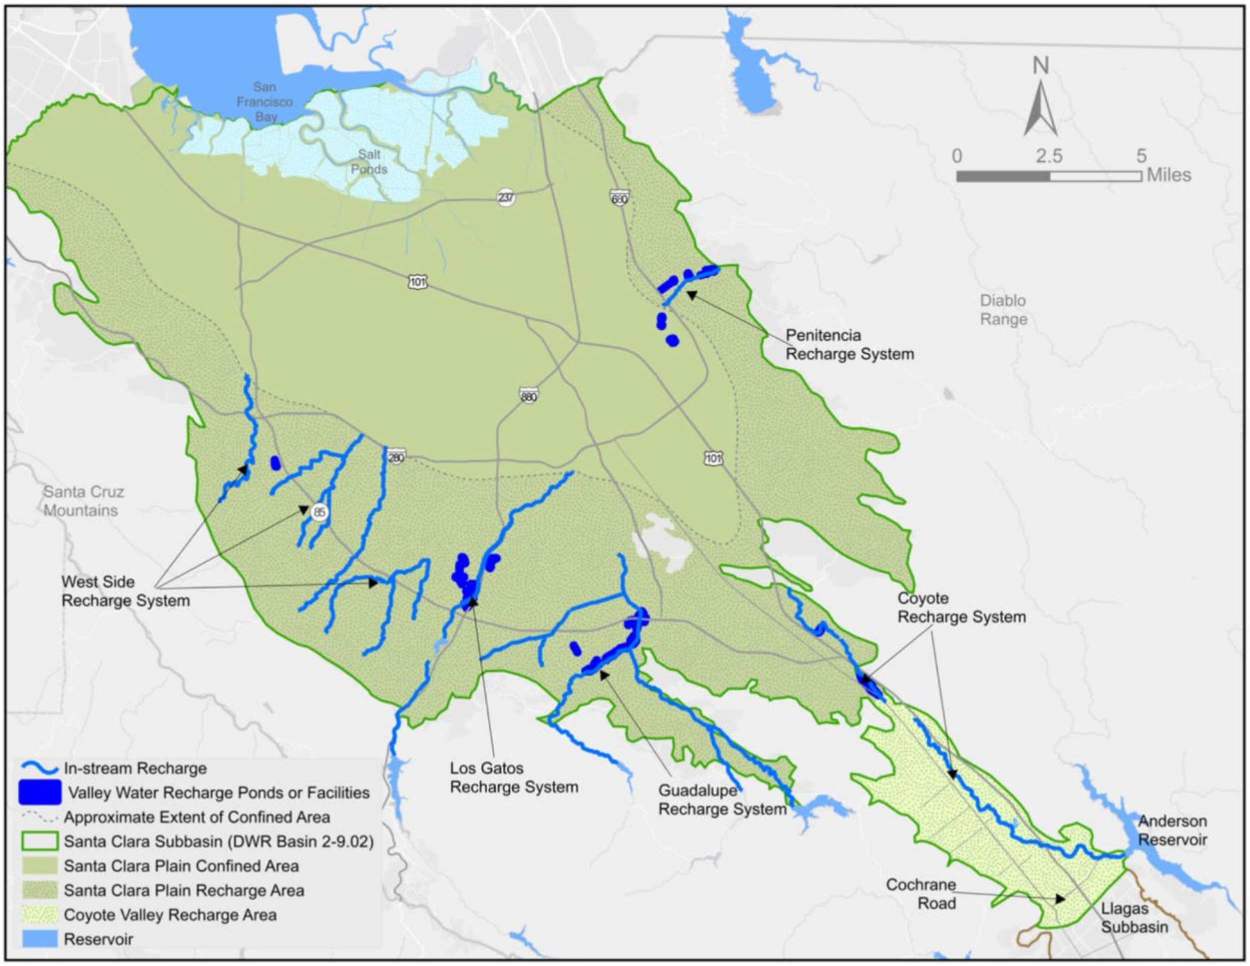
Valley Water estimates the operational storage capacity of the Santa Clara Plain to be 350,000 AF (Valley Water 2021). The operational storage capacity estimation takes into account available pumping capacity, avoidance of land subsidence, and problems associated with high groundwater levels, and is lower than the actual total storage capacity of the subbasin. The operational storage capacity of the Coyote Valley area is estimated to be between 23,000 AF and 33,000 AF (SCVWD 2002, as cited in Valley Water 2021).

3.12.1.2 Groundwater Recharge

Natural groundwater recharge in the Santa Clara Subbasin occurs primarily from the deep percolation of rainfall, natural seepage from creeks, and subsurface inflow from surrounding hills (Valley Water 2021). While the Coyote Valley is unconfined, with generally high lateral and vertical permeability throughout the area, and thereby conducive to recharge operations; a portion of the Santa Clara Plain is confined. The confined area is located in the northcentral portion of the Santa Clara Plain where a laterally extensive, low permeability aquitard restricts the vertical flow of groundwater and contaminants (Valley Water 2021). To augment natural recharge, which is far less than the amount of groundwater pumped, Valley Water has instituted a managed aquifer recharge program. This program accounts for 70 percent of the subbasin recharge, with approximately 60 percent of recharge capacity occurring along stream channels above the aquifer’s unconfined zone and approximately 40 percent occurring at off-stream percolation ponds (Valley Water 2021).

The principal (and only) managed recharge system in Coyote Valley is the Coyote Recharge System, consisting of Coyote Creek supplied via releases from Anderson Reservoir and imported water deliveries (Valley Water 2021). The Coyote Percolation Ponds are located in the Santa Clara Plain near the border with the Coyote Valley (roughly at the Coyote Narrows). Therefore, the Coyote Percolation Ponds and in-stream recharge along the Lower Coyote Creek recharge the Santa Clara Plain and not the Coyote Valley groundwater management area. In-stream recharge operations along the Upper Coyote Creek recharge the Coyote Valley. By contrast, the Santa Clara Plain has multiple recharge facilities, including the West Side Recharge System, Los Gatos Recharge System, Guadalupe Recharge System, and Penitencia Recharge System. **Figure 3.12-1** shows managed recharge facilities in the Santa Clara Subbasin.

Figure 3.12-1. Managed Recharge Facilities in the Santa Clara Subbasin



Source: Valley Water 2021

3.12.1.3 Groundwater Wells, Use, and Water Budget

Numerous groundwater wells are located near the study area and Anderson Reservoir, including about 500 water supply wells within Coyote Valley where groundwater supports over 90 percent of all beneficial use and is the only source of drinking water. Several water retailers operate large groundwater supply wells in the area, including Great Oaks Water Company, the City of San José, and the City of Morgan Hill There are also numerous privately owned wells used for domestic or agricultural purposes. Collectively these wells supply potable water to thousands of people, as well as businesses. Valley Water collects groundwater elevation data at approximately 20 monitoring wells within Coyote Valley.

There are numerous public and private supply wells along Coyote Creek, in particular, downstream of Anderson Dam. These include the wells operated by the City of Morgan Hill and other entities, described above. Several private water production wells are located along the rim of Anderson Reservoir. This area is outside of the Santa Clara Subbasin.

Groundwater pumping in the Coyote Valley area has averaged approximately 11,500 AFY between 2010 and 2019 (Valley Water 2021). In 2019, groundwater pumping in the Coyote Valley area was 11,100 AF (Valley Water 2019). Most of the groundwater pumping (72 percent) in the Coyote Valley area has supported municipal and industrial uses, while 26 percent has supported agriculture, and 2 percent has supported domestic uses (Valley Water 2021). The groundwater pumping in the Santa Clara Plain is even more heavily used (99 percent) for municipal and industrial purposes. From 2010-2019, groundwater pumping in the Santa Clara Plain area averaged 75,500 AFY (Valley Water 2021).

Groundwater pumping and subsurface outflow greatly exceeds natural recharge and subsurface inflow in the Santa Clara Plain and Coyote Valley (**Table 3.12-1**). Without Valley Water's managed recharge operations, there would be about a 50,000 AFY overdraft in the Santa Clara Plain and 13,500 AFY overdraft in Coyote Valley. The managed recharge helps to balance the deficit of inflows and balance the groundwater budget in most years. **Table 3.12-1** shows the water budget for the Santa Clara Plain and Coyote Valley areas from 2010 to 2019. Because of Valley Water's managed recharge operations, the average change in groundwater over that period was about 3,000 AF (increased storage) in the Santa Clara Plain and 0 AF in Coyote Valley (inflows and outflows balanced).

Table 3.12-1. Water Budget for Santa Clara Plain and Coyote Valley (2010-2019)

Water Budget Component	Acre-Feet per Year	
	Santa Clara Plain[1]	**Coyote Valley**
Inflow		
Managed Recharge[2]	53,000	13,500
Natural Recharge[3]	25,000	2,500
Subsurface Inflow[4]	7,500	0
Total Inflow	86,000	16,000
Outflow		
Groundwater Pumping[5]	75,500	11,500
Subsurface Outflow[6]	7,500	4,500

Water Budget Component	Acre-Feet per Year	
	Santa Clara Plain[1]	Coyote Valley
Total Outflow	83,000	16,000
Change in Storage	+3,000	0

Source: Valley Water 2021

Notes:

[1] This analysis is for the Santa Clara Plain principal aquifer.

[2] Managed recharge represents direct replenishment by Valley Water using local and imported water.

[3] For Santa Clara Plain, natural recharge includes the deep percolation of rainfall, natural seepage from creeks, and subsurface inflow from surrounding hills (mountain front recharge). For Coyote Valley, natural recharge includes all uncontrolled recharge, including the deep percolation of rainfall, septic system and/or irrigation return flows, and natural seepage through creeks.

[4] Subsurface inflow represents inflow from adjacent aquifer systems.

[5] Pumping is based on metered pumping volumes (about 94% of pumping for Santa Clara Plain and 91% of pumping for Coyote Valley), or pumping reported by well owners based on a table of average use and/or crop factors.

[6] Subsurface outflow represents outflow to adjacent aquifers in San Mateo County, Alameda County, and beneath San Francisco Bay (for Santa Clara Plain) and outflow to the Santa Clara Plain (for the Coyote Valley).

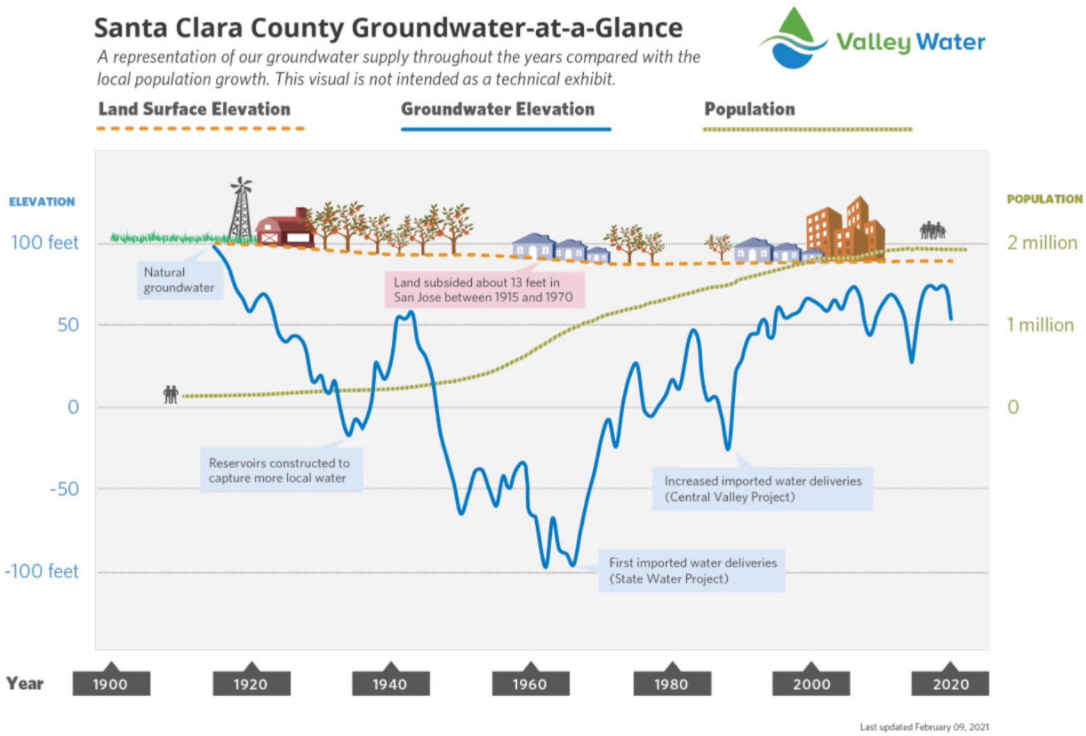
3.12.1.4 Subsidence, Groundwater Levels, and Groundwater Flow

From the early 1900s through the mid-1960s, water level declines from groundwater pumping induced permanent land subsidence in the northern Santa Clara Subbasin. Prior to importation of surface water via the Hetch Hetchy Aqueduct and South Bay Aqueduct and the introduction of the artificial recharge program, water levels declined more than 200 feet in the Santa Clara Valley (DWR 2004). Groundwater levels have generally increased since 1965 as a result of increases in managed recharge and decreases in pumping. **Figure 3.12-2** shows groundwater levels and land subsidence in the county since 1900 in relation to population growth. In 2019, average groundwater elevation in the Coyote Valley area was 277.2 feet, which was up 4.6 feet from 2018, and up 5.4 feet compared to the 5-year average (2015-2019) (DWR 2020). In 2019, average groundwater elevation in the Santa Clara Plain was 90.7 feet, which was down 1.9 feet from 2018, and up 13.2 feet compared to the 5-year average (2015-2019), based on Valley's index well 07S01W25L001 for the Santa Clara Plain (https://gis.valleywater.org/GroundwaterElevations/index.php).

Groundwater movement in the Santa Clara and LLagas Subbasins generally follows topographical and surface water patterns, flowing to the north/northwest toward the interior of the subbasins and eventually to San Francisco Bay (Valley Water 2021). Groundwater also moves toward areas of intense pumping at the local scale. In the Santa Clara Plain, regional groundwater elevations are typically highest near the margins, with elevations decreasing in the subbasin interior (Valley Water 2021). In the Coyote Valley, regional groundwater elevations are typically highest at the groundwater divide near the Llagas Subbasin boundary, with a downward vertical gradient. Generally, throughout the Santa Clara Subbasin, groundwater levels are higher in the spring as compared to the fall due to the lack of precipitation and higher demand in the summer months.

Post-FOCP implementation conditions would result in some adverse groundwater storage impacts that are also anticipated during Project construction. However, normal operations using imported water that is released to Coyote Creek as managed recharge would continue to support and prioritize groundwater recharge to the Coyote Valley groundwater management area to avoid and minimize construction phase impacts.

Figure 3.12-2. Santa Clara County Groundwater History



Source: Valley Water 2021

3.12.1.5 Groundwater Quality

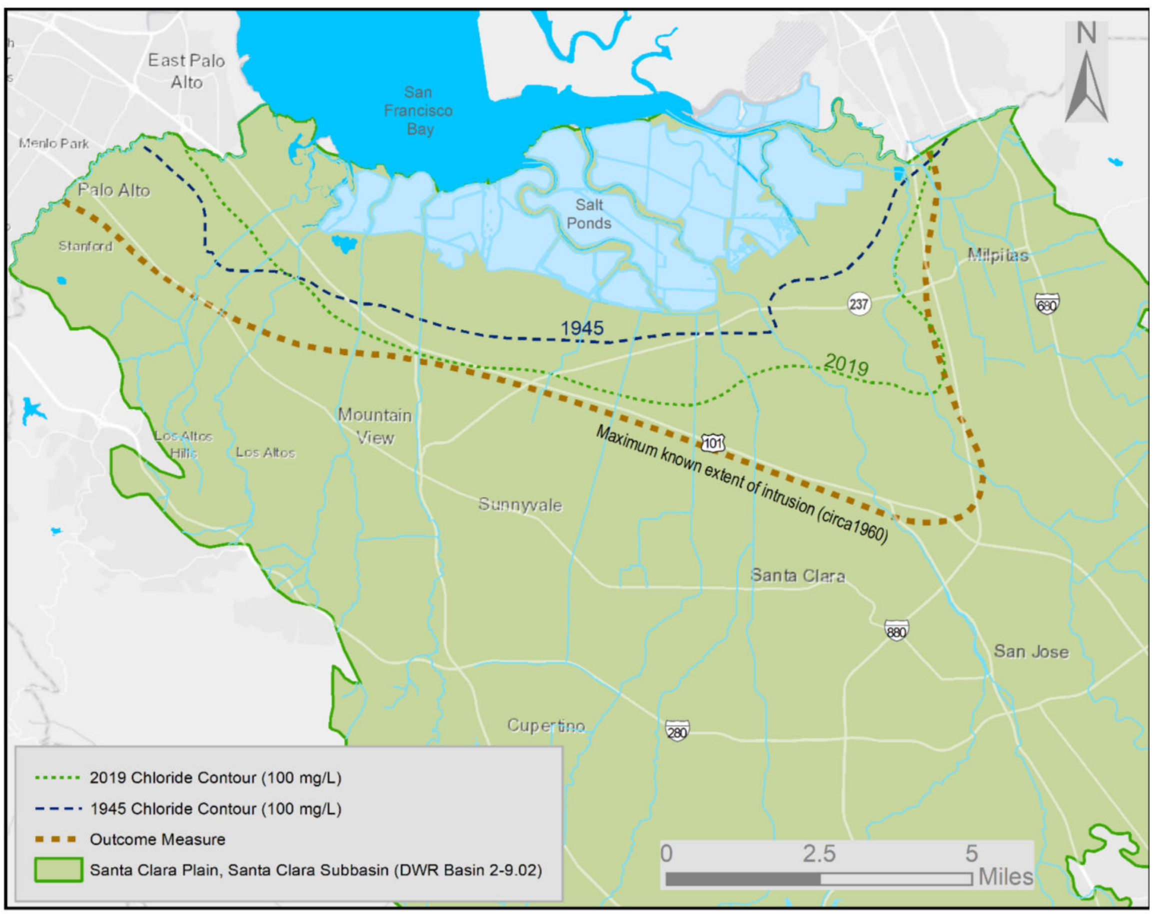
Groundwater in the Santa Clara Subbasin is generally of very good quality, with infrequent detections of water-quality parameters above health-based maximum contaminant levels (MCL) (Valley Water 2021). The Santa Clara Subbasin generally produces groundwater of good quality that does not need treatment beyond disinfection (Valley Water 2021). In 2019, Valley Water collected groundwater samples and analyzed water quality from 254 wells, including 85 dedicated monitoring wells and domestic wells that are sampled each year, 144 domestic wells tested through a voluntary sampling program, and 25 wells located near recycled water irrigation sites (Valley Water 2020). Results showed that groundwater in the Santa Clara and Llagas Subbasins meets drinking water standards in most wells for all parameters tested, with the exception being nitrate, which was found above the MCL in 23 percent of South County water supply wells sampled (primarily in domestic wells) (Valley Water 2020).

Water retailers like Great Oaks Water Company and the City of Morgan Hill closely monitor groundwater quality at individual wells to ensure compliance with federal and State public health standards. Through comprehensive regional groundwater monitoring, Valley Water tracks groundwater conditions and trends, and coordinates with retailers, land use agencies, and regulatory agencies to protect groundwater. Elevated nitrate concentrations from low-density septic systems and agricultural activities is a key concern for groundwater in south Santa Clara County. Furthermore, since groundwater in the Coyote Valley area is largely unconfined and often shallow, the aquifer is extremely sensitive to potential groundwater contamination from human activities at land surface.

In the Santa Clara Plain, closer to the San Francisco Bay, seawater intrusion and elevated chloride concentrations in groundwater have been an issue (Valley Water 2021). Seawater intrusion (also called saltwater intrusion) refers to the temporary or permanent influx of seawater into coastal freshwater aquifers. This is a groundwater management concern, because it can degrade groundwater quality and, if severe enough, result in undesirable conditions that may include limiting groundwater as a water supply for municipal and industrial uses, agriculture, and domestic uses, or degrading groundwater dependent ecosystems (GDE) or infrastructure (Valley Water 2021). Saltwater intrusion in the shallow aquifer zone of the Santa Clara Plain is largely attributed to incursion of water from San Francisco Bay into the tidal reaches of creeks and subsequent transport to shallow groundwater through streambed percolation. **Figure 3.12-3** shows the extent of seawater intrusion in the Santa Clara Plain shallow aquifer zone.

Post-FOCP implementation, groundwater water quality conditions would be similar to those that have been monitored since the 2017 DSOD restriction. These conditions have been monitored on an annual basis in accordance with the Valley Water Groundwater Management Plan and have not varied substantially from historic record (Valley Water 2021).

Figure 3.12-3. Extent of Seawater Intrusion in the Santa Clara Plain Shallow Aquifer Zone



Source: Valley Water 2021

3.12.1.6 Groundwater Dependent Ecosystems

GDEs are defined under SGMA as "ecological communities of species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" (23 CCR Section 351[m]). GDEs in California include a wide range of natural communities, including wetlands, rivers, streams, and estuaries, seeps and springs, and terrestrial vegetation, including deep-rooted plants or plant communities that obtain water from the water table (called phreatophytes) (Valley Water 2021).

Generally, the Santa Clara Subbasin has primarily losing stream reaches that are used in Valley Water's instream managed recharge program where stream water percolates downward through the stream channel and recharges the underlying aquifer (Valley Water 2021). Natural streamflow and operational releases from Valley Water's local reservoirs provide nearly perennial flows during most years in many of the losing stream reaches that were historically ephemeral streams prior to Valley Water's operations (Valley Water 2021). This would typically indicate that the losing stream reaches are disconnected from the regional groundwater table, and thus are not likely interconnected surface water or GDEs. However, based on depth-to-groundwater and other factors, there are a number of likely, transition, and possible GDEs in the Santa Clara Subbasin, as shown in **Figure 3.12-4**.

3.12.2 Regulatory Setting

3.12.2.1 Federal Laws, Regulations, and Policies

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) is intended to protect drinking water and its sources: rivers, lakes, reservoirs, springs, and groundwater wells that serve more than 25 individuals. The goal of the SDWA is to ensure that drinking water is safe for human consumption and will not have adverse health effects on the typical person who drinks water. Under the SDWA, the USEPA has set drinking water standards for chemical, microbiological, radiological, and physical contaminants in its National Primary Drinking Water Regulations (40 CFR Part 141).

3.12.2.2 State Laws, Regulations, and Policies

Porter-Cologne Water Quality Control Act

Refer to Section 3.14, *Water Quality*, for discussion of the Porter-Cologne Act. As described therein, the Porter-Cologne Act requires the RWQCBs to adopt Basin Plans for the protection of surface water and groundwater quality.

Water Quality Control Plan for the San Francisco Bay Basin

The study area is located within the jurisdiction of the San Francisco Bay RWQCB (Region 2). The Water Quality Control Plan for the San Francisco Bay Basin (San Francisco Bay Basin Plan) (San Francisco RWQCB 2019) identifies beneficial uses for surface waters and groundwater within the San Francisco Bay region and establishes narrative and numerical water quality objectives (WQO) to achieve the beneficial uses for those waters. Beneficial uses represent the services and qualities of a waterbody (i.e., the reasons that the waterbody is considered valuable). WQOs reflect the standards necessary to protect and support those beneficial uses. Basin Plan standards are primarily implemented by regulating waste discharges so that WQOs are met.

Table 3.12-2 shows designated beneficial uses of groundwater basins in the study area. Refer to Section 3.14, *Water Quality*, for designated beneficial uses of surface waters in the study area.

Table 3.12-2. Beneficial Uses of Groundwater Basins in the Study Area

Water Body	Beneficial Uses[1]																		
	AGR	MUN	FRSH	GWR	IND	PROC	COMM	SHELL	COLD	EST	MAR	MIGR	RARE	SPWN	WARM	WILD	REC-1	REC-2	NAV
Groundwater Basin (Sub-Basin)																			
Santa Clara Valley (Santa Clara Subbasin -BasinNo. 2-9.02)	E	E			E	E													

Source: San Francisco Bay RWQCB 2019

Notes:

[1] Beneficial Uses are defined as: Agricultural Supply (AGR), Municipal and Domestic Supply (MUN), Freshwater Replenishment (FRSH), Groundwater Recharge (GWR), Industrial Service Supply (IND), Industrial Process Supply (PROC), Ocean, Commercial, and Sport Fishing (COMM), Shellfish Harvesting (SHELL), Cold Freshwater Habitat (COLD), Estuarine Habitat (EST), Marine Habitat (MAR), Fish Migration (MIGR), Preservation of Rare and Endangered Species (RARE), Fish Spawning (SPWN), Warm Freshwater Habitat (WARM), and Wildlife Habitat (WILD), Water Contact Recreation (REC-1), Non-contact Water Recreation (REC-2), Navigation (NAV)

Key: E = existing beneficial use

State Drinking Water Standards

CCR, Title 22, Division 4, Chapter 15 establishes parameters for safe drinking water throughout the state. These drinking water standards are similar to, but in many cases more stringent than, federal standards. Title 22 contains both primary standards, and secondary standards related to aesthetics (taste and odor).

California Statewide Groundwater Elevation Monitoring Basin Prioritization

In 2009, the California State Legislature amended the California Water Code with SBx7-6, which mandates a statewide groundwater elevation monitoring program to track seasonal and long-term trends in groundwater elevations in California. Under this amendment, DWR established the California Statewide Groundwater Elevation Monitoring (CASGEM) program, which established the framework for regular, systematic, and locally managed monitoring in all of California's groundwater basins. The CASGEM program is essential to DWR's ranking all of California's basins by priority: high, medium, low, and very low. DWR's basin prioritization is based on the following factors:

1. Population overlying the basin or subbasin
2. Rate of current and projected growth of the population overlying the basin or subbasin
3. Number of public supply wells that draw from the basin or subbasin
4. Total number of wells that draw from the basin or subbasin
5. Irrigated acreage overlying the basin or subbasin
6. Degree to which persons overlying the basin or subbasin rely on groundwater as their primary source of water

7. Any documented impacts on the groundwater within the basin or subbasin, including overdraft, subsidence, saline intrusion, and other water quality degradation
8. Any other information determined to be relevant by DWR

The Santa Clara Subbasin (2-009.02) underlies the study area. This subbasin is designated as high priority, per CASGEM and DWR's basin prioritization (DWR 2021 ~~2021a~~).

Sustainable Groundwater Management Act

SGMA became law in January 1, 2015, and created a legal and policy framework to manage groundwater sustainably at a local level. SGMA allows local agencies to customize groundwater sustainability plans (GSP) to their regional economic and environmental conditions and needs and establish new governance structures, known as groundwater sustainability agencies (GSA). SGMA requires that GSAs develop GSPs or prescribed alternatives for groundwater basins designated as high and medium priority by DWR. GSPs are intended to facilitate the management of groundwater supply and use in a manner that avoids specific undesirable results. Undesirable results are defined as the following:

- Chronic lowering of groundwater levels (not including overdraft during a drought if a basin is otherwise managed)
- Significant and unreasonable reduction of groundwater storage
- Significant and unreasonable seawater intrusion
- Significant and unreasonable degraded water quality, including the migration of contaminant plumes that impair water supplies
- Significant and unreasonable land subsidence that substantially interferes with surface land uses
- Depletions of interconnected surface water that have significant and unreasonable adverse impacts on beneficial uses of the surface water

GSPs are required to include measurable objectives and minimum thresholds, as well as interim milestones in 5-year increments, to achieve the sustainability goal for the basin for the long-term beneficial uses of groundwater. Additionally, GSPs are required to include components related to groundwater quality monitoring, the monitoring and management of groundwater levels within the basin, mitigation of overdraft, and a description of surface water supply used or available for use for groundwater recharge or in-lieu use.

3.12.2.3 Local Laws, Regulations, and Policies

County of Santa Clara General Plan

The County of Santa Clara General Plan (County 1994 ~~1995~~) includes the following goals and policies related to groundwater and the Project:

Book A – Resource Conservation

Policy C-RC 5: An adequate, high quality water supply for Santa Clara County should be considered essential to the needs of households, business and industry.

Policy C-RC 6: A comprehensive strategy for meeting long term projected demand for water should at a minimum include the following:

a. Continued conservation and increased reclamation;

b. Securing additional sources as supplemental supply;

c. System and local storage capacity improvements; and

d. Drought contingency planning and groundwater basin management programs.

Policy C-RC 7: Countywide land use and growth management planning should be coordinated with overall water supply planning by the SCVWD in order to maximize dependability of long-term water supply resources.

Policy C-RC 17: Drought contingency plans and groundwater basin management programs should be reviewed and updated to prepare for the likelihood of future periods of short-term drought and to minimize:

a. The potential adverse impacts of drought upon households, business, and industry, and

b. The possibility of groundwater overdraft and land subsidence.

Book A – Safety and Noise

Policy C-HS 42: The long-term viability and safety of underground aquifers and groundwater systems countywide shall be protected to highest degree feasible.

Policy C-HS 47: Groundwater quality should be monitored to ensure the long-term integrity of countywide water resources.

Book B – Safety and Noise

Policy R-HS 47: The long-term viability and safety of surface and groundwater supplies countywide shall be protected from contamination to the highest degree feasible.

Policy R-HS 48: To enhance the effectiveness of each agency's efforts to protect local surface and groundwater quality, the County should encourage cooperation between the regional and local water agencies, sharing of information, and appropriate ongoing water quality monitoring efforts.

Book B – South County Joint Area Plan

Policy SC 8.13: In order to provide greater protection of the aquifers which supply drinking water to the South County, special consideration should be given to the management of contaminants (e.g., hazardous materials, sanitary effluents) in groundwater recharge areas where no protective aquitard layer exists.

City of Morgan Hill 2035 General Plan

The City of Morgan Hill 2035 General Plan (City of Morgan Hill 2017 ~~2016~~) contains the following goals and policies related to groundwater resources and the Project:

Natural Resources and Environment

Goal NRE-7: Conservation of water resources.

Goal NRE-8: Protection of water quality from contamination associated with urbanization.

Goal NRE-9: Cooperative efforts to ensure regional water quality.

Policy NRE-9.1: Interjurisdictional Coordination. Maintain close coordination with the following agencies and organizations which share jurisdiction and interest relative to South County's water supply and water quality: the Regional Water Quality Control Boards, Santa Clara Valley Water District, Santa Clara County, City of Gilroy Planning Department, and San Martin Planning Committee. (South County Joint Area Plan 10.02)

Safety, Services, and Infrastructure

Goal SSI-14: High quality water resources, managed effectively.

Policy SSI-14.1: Efficient Water Management. Manage the supply and use of water more efficiently through appropriate means, such as watershed protection, percolation, conservation, and reclamation. (South County Joint Area Plan 7.00)

Policy SSI-14.4: Drought Planning. Encourage water agencies to develop and maintain drought contingency plans, including emergency water connections and related measures to ensure adequate water during drought.

Policy SSI-14.6: Well Pumping. Support cooperation among all jurisdictions and agencies pumping water from wells in order to manage the aquifer to preserve the natural ecology of the region, secure the aquifer's utility as a water resource, and ensure the water's quality. (South County Joint Area Plan 7.04)

Policy SSI-14.7: Water District Programs. Encourage the Santa Clara Valley Water District to continue developing programs to assure effective management of water resources, such as well monitoring, percolation of imported water, reclamation, and conservation. (South County Joint Area Plan 7.07)

Policy SSI-14.8: Sufficient Supply. Ensure that new development does not exceed the water supply. (South County Joint Area Plan 7.08)

Policy SSI-14.9: Well Monitoring. Continue to monitor wells and provide the results to the Santa Clara Valley Water District which would coordinate the data and make it available to all jurisdictions and agencies. (South County Joint Area Plan 8.14)

Goal SSI-16: Minimized adverse effects on property, natural resources, and ground and surface water quality from stormwater runoff.

Envision San José 2040 General Plan

Envision San José 2040 General Plan (City of San José 2023 ~~2011~~) contains the following goals and policies relevant to groundwater resources and the Project:

Goal MS-17: Responsible Management of Water Supply. Demonstrate environmental leadership through responsible and fiscally and environmentally sustainable management of water to restore our environment, enhance our quality of life and provide an adequate water supply to meet the needs of our community now and in the future.

Goal MS-18: Water Conservation. Continuously improve water conservation efforts in order to achieve best in class performance. Double the City's annual water conservation savings by 2040 and achieve half of the Water District's goal for Santa Clara County on an annual basis.

Goal MS-20: Water Quality. Ensure that all water in San Jose is of the highest quality appropriate for its intended use.

Policy MS-20.3: Protect groundwater as a water supply source through flood protection measures and the use of stormwater infiltration practices that protect groundwater quality. In the event percolation facilities are modified for infrastructure projects, replacement percolation capacity will be provided.

Goal ER-8: Stormwater. Minimize the adverse effects on ground and surface water quality and protect property and natural resources from stormwater runoff generated in the City of San José.

Policy ER-8.4: Assess the potential for surface water and groundwater contamination and require appropriate preventative measures when new development is proposed in areas where storm runoff will be directed into creeks upstream from groundwater recharge facilities.

Goal ER-9: Water Resources. Protect water resources because they are vital to the ecological and economic health of the region and its residents.

Policy ER-9.3: Utilize water resources in a manner that does not deplete the supply of surface or groundwater or cause overdrafting of the underground water basin.

Policy ER-9.4: Work with the SCVWD to preserve water quality by establishing appropriate public access and recreational uses on land adjacent to rivers, creeks, wetlands, and other significant water courses.

Policy ER-9.5: Protect groundwater recharge areas, particularly creeks and riparian corridors.

Valley Water Groundwater Management Plan

Valley Water is the GSA for the Santa Clara Subbasin (2-009.02), which underlies the study area. As DWR has designated the Santa Clara Subbasin as a high priority basin (DWR 2021 ~~2021a~~), Valley Water was required to develop a GSP for the subbasin, or submit an Alternative for consideration. Valley Water submitted its 2016 Groundwater Management Plan (GWMP) for the Santa Clara and Llagas Subbasins as an Alternative to a GSP in December 2016. In July 2019, DWR approved the Alternative for both the Santa Clara and Llagas Subbasins, determining that it satisfies the objectives of SGMA (Valley Water 2023). Valley Water submitted its 2021 GWMP to DWR as the periodic evaluation required for the approved Alternative in December 2021 (Valley Water 2023).

Groundwater Management Plan for the Santa Clara and Llagas Subbasins

As noted above, Valley Water's 2016 GWMP was approved by DWR as an Alternative to a GSP, and Valley Water subsequently submitted the 2021 GWMP to DWR in accordance with the periodic evaluation for the approved Alternative. The 2021 GWMP supersedes all previous GWMPs and is the current version in effect. The GWMP describes Valley Water's comprehensive groundwater management framework, including existing and potential actions to achieve basin sustainability goals and ensure continued sustainable groundwater management. The GWMP includes the following sustainability goals related to groundwater supply reliability and protection (Valley Water 2021):

- Manage groundwater to ensure sustainable supplies and avoid land subsidence.
- Aggressively protect groundwater from the threat of contamination.

These goals describe the overall objectives of Valley Water's groundwater management programs. The GWMP then includes basin management strategies to meet the sustainability goals. Many of the strategies have overlapping benefits, acting to improve water supply reliability, minimize subsidence, and protect or improve groundwater quality, as follows (Valley Water 2021):

1. Manage groundwater in conjunction with surface water
2. Implement programs to protect and promote groundwater quality
3. Maintain and develop adequate groundwater models and monitoring networks
4. Work with regulatory and land use agencies to protect recharge areas, promote natural recharge, and prevent groundwater contamination

Finally, the GWMP includes sustainability indicators and outcome measures to gauge performance in meeting the basin sustainability goals, as shown in **Table 3.12-3** below.

Table 3.12-3. Groundwater Management Plan Outcome Measures and Outcome Measure – Lower Thresholds

Sustainability Indicator	Outcome Measure	Outcome Measure – Lower Threshold
Groundwater Storage	Projected end of year groundwater storage is greater than 278,000 AF in the Santa Clara Plain, 5,000 AF in the Coyote Valley, and 17,000 AF in the Llagas Subbasin.	Projected end of year countywide groundwater storage is greater than Stage 5 (150,000 AF) of the Water Shortage Contingency Plan.
Subsidence	Groundwater levels are above subsidence thresholds at the Santa Clara Plain subsidence index wells.	Groundwater levels are above the historical low water levels at the majority of the Santa Clara Subbasin subsidence index wells.
Groundwater Quality	For Santa Clara Subbasin water supply wells, at least 95% meet primary drinking water standards, and at least 90% have stable or decreasing trends for TDS.	At least 70% of water supply wells have stable or decreasing trends for nitrate and TDS.

Sustainability Indicator	Outcome Measure	Outcome Measure – Lower Threshold
Groundwater Quality	For Llagas Subbasin water supply wells, at least 95% meet primary drinking water standards, and at least 90% of wells have stable or decreasing trends for TDS.	At least 70% of water supply wells have stable or decreasing trends for nitrate and TDS.
Seawater Intrusion	In the Santa Clara Subbasin shallow aquifer, the 100 milligram per liter isocontour areas is less than the historical maximum extent area (57 square miles).	In the Santa Clara Subbasin shallow aquifer, the 100 milligram per liter chloride isocontour area is less than 81 square miles, which represents a 1-mile radial buffer of the historical maximum extent area.

Source: Valley Water 2021

Key: AF = acre-feet; TDS = total dissolved solids

Notes: As defined in Valley Water's 2021 Groundwater Management Plan, outcome measures are quantifiable goals to track performance of sustainable management and are functionally equivalent to measurable objectives under SGMA. Outcome measure-lower thresholds are quantifiable values used to define undesirable results and are functionally equivalent to minimum thresholds under SGMA. The outcome measure-lower thresholds account for a reasonable margin of operational flexibility below the outcome measure that accommodates drought, climate change, conjunctive use operations, and other groundwater management activities.

3.12.3 Methodology and Approach to Impact Analysis

The impact analysis considers the potential impacts on groundwater resources from the Project pursuant to the applicable significance criteria in Appendix G of the *CEQA Guidelines* (see Section 3.12.3.8). Specifically, the impacts analysis considers the effects of Seismic Retrofit construction (Section 3.12.3.1), Conservation Measure construction (Section 3.12.3.2), construction monitoring (Section 3.12.3.3), and post-construction Anderson Dam Facilities operations and maintenance, and post-construction Conservation Measure operations and maintenance, (Section 3.12.3.4).

To the extent possible, quantitative methods are used and effects are discussed quantitatively. However, in some cases, the potential effects cannot be quantified and are discussed in a qualitative manner. Generally, the potential effects of the Project are first discussed without implementation of applicable Valley Water BMPs and compliance with VHP conditions (see Section 3.12.3.7) and applicable regulations; then, the analysis considers how implementation of BMPs and compliance with VHP conditions and other regulations would reduce those potential adverse effects. If effects remain significant after implementation of BMPs and compliance with VHP conditions and other regulations, then mitigation measures are prescribed, if feasible, to reduce those effects to a level that is less than significant.

The Project would be regulated by the various laws, regulations, and policies summarized above in Section 3.12.2, *Regulatory Setting*. Compliance by the Project with applicable federal, state, and local laws and regulations is assumed in this analysis and local and state agencies would be expected to continue to enforce applicable requirements to the extent that they do so now. Note that compliance with many of the regulations would be a condition of permit approval.

As discussed further below, separate baselines are used due to the nature of the Project and the different types of effects. Generally, for analyzing construction-related effects except for reduced reservoir releases, the existing conditions baseline is used, which represents the existing conditions at the time of EIR preparation as modified by implementation of the FOCP. For analyzing flow-related construction and operation effects, the Pre-FERC Order Conditions Baseline and/or the future conditions baseline is used.

3.12.3.1 Seismic Retrofit Construction

Seismic Retrofit Construction of the Seismic Retrofit aspects of the Project is planned to occur over a 7-year duration, as described in Chapter 2, and the timing of specific activities with respect to the overall construction schedule is considered in the impact analysis. During the majority of the Seismic Retrofit construction period, the reservoir would be (almost) completely dewatered, which would limit dry season releases to Coyote Creek. The results of a quantitative Water Evaluation and Planning (WEAP) monthly model are used in the analysis as summarized in Appendix J, *Groundwater Technical Memorandum*. The analysis considers implementation of Conservation Measure components and applicable Valley Water BMPs, and compliance with applicable VHP conditions to reduce potential impacts from Seismic Retrofit construction. As noted above, the baseline for analysis of impacts from Seismic Retrofit construction is a Pre-FERC Order (2015) baseline for reduced reservoir releases and the existing conditions baseline for other groundwater impacts.

3.12.3.2 Conservation Measure Construction

The Conservation Measure components that would be included as part of the Project are described in Chapter 2, *Project Description*. Several of the Conservation Measure components would serve to minimize the potential effects of the Seismic Retrofit construction process on groundwater resources (e.g., imported water releases via the CDL and Cross Valley Pipeline Extension). These beneficial effects are considered in the Seismic Retrofit construction analysis. Additionally, the potential for conservation measures involving construction/ground-disturbance to result in adverse effects on groundwater resources is evaluated. These include the following:

- Ogier Ponds CM
- Maintenance of the North Channel Reach ~~Extension~~
- Maintenance Activities of Spawning Gravel and Rearing Habitat Improvements at Live Oak Restoration Reach
- Sediment Augmentation Program
- Phase 2 Coyote Percolation Dam Fish Passage Enhancements

3.12.3.3 Construction Monitoring

Valley Water would implement a wide range of construction monitoring activities during Project construction, including monitoring of stream flow and water quality; suspended sediment; sediment deposition; reptiles and terrestrial animals; and steelhead habitat quality, conditions, migration, migration flows, spawning, and juvenile rearing in Coyote Creek downstream from Anderson Dam. Generally, these measures would involve small numbers of people visiting locations throughout the study area, including potential installation of minor equipment within or adjacent to stream channels. The construction monitoring activities would have no potential to adversely affect groundwater supplies or groundwater recharge, as these activities would not directly use groundwater or involve construction processes (e.g., dewatering) or disturbance (e.g., access roads, staging) that could impact groundwater resources. These activities would be limited to individual field personnel visiting sites, taking samples, and potentially installing minor equipment within or adjacent to the stream channel that would have no potential to impact groundwater. Therefore, no impact would occur and this topic is not discussed further.

3.12.3.4 Post-Construction Anderson Dam Facilities Operations and Maintenance

This analysis considers indirect and direct impacts to groundwater that could result from operational changes and proposed for non-emergency flow releases following the completion of the Seismic Retrofit construction, as described in Chapter 2, *Project Description*. The analysis considers the potential effects of activities during the post-construction phase of the Project for Anderson Dam facilities. This includes implementation of the updated FAHCE rule curves for operation of Anderson Reservoir, in accordance with the Coyote Creek FHRP pursuant to the FAHCE *Settlement Agreement*, as well as maintenance of Anderson Dam facilities (e.g., outlet works) Maintenance of Anderson Dam facilities would be conducted under the DMP. As part of the evaluation, the analysis considers the potential effects on groundwater resources and basins. The analysis addresses whether changes to reservoir flow releases could result in changes to groundwater. As described in Section 3.0, *Introduction*, the baseline for evaluating post-construction operations effects is the Pre-FERC Order.

3.12.3.5 Post-Construction Conservation Measure Operations and Maintenance

The Conservation Measures components focus on improving fish habitat (e.g., gravel augmentation, separation of Coyote Creek from Ogier Ponds) and fish passage enhancement. The Conservation Measures components would operate passively, without mechanical or human intervention, and have been planned in accordance with Anderson Dam Reservoir flow releases. Additionally, as described in Chapter 2, *Project Description*, Valley Water would maintain the newly retrofitted Coyote Percolation Dam per Valley Water's existing DMP. Maintenance of Coyote Percolation Dam was previously evaluated in the Final DMP EIR prepared in January 2012 (SCH No. 2011082077; Valley Water 2012). While data collection and assessment may indicate that individual Conservation Measures are not meeting success criteria specified for those measures, the modified Conservation Measure actions that would be undertaken to attain the prescribed success criteria would be similar to the original actions and would not result in additional impacts. In the event that modified Conservation Measures would result in additional environmental impacts that are outside of the scope of impacts analyzed in this EIR, additional CEQA review would be undertaken at that time.

Through the implementation of the operations and maintenance phase of the Conservation Measures components in accordance with existing Valley Water maintenance plans, including the SMP, no additional impacts are likely. Therefore, these topics are not discussed further in this section.

3.12.3.6 Post-Construction Project and FAHCE Adaptive Management

The FAHCE AMP would guide post-construction adaptive management of Project ~~project~~ flow operations and Conservation Measures that have met their specified success criteria, as defined through the regulatory permitting process. As required by the FAHCE AMP framework, the Project and FAHCE AMP includes four key elements: measurable objectives, monitoring, adaptive actions, and reporting. Monitoring and adaptive actions involve physical activities that could have environmental impacts.

The Project and FAHCE AMP monitoring program would inform selection of adaptive management measures to implement in response to management triggers, and includes compliance, validation, effectiveness, and long-term monitoring. Validation, effectiveness, and long-term trend monitoring would build on existing Valley Water monitoring infrastructure (e.g., hydrologic monitoring network), water quality monitoring (e.g., water temperature monitoring network), habitat monitoring (e.g., habitat mapping), and fisheries monitoring (e.g., VAKI Riverwatcher, PIT tag detectors, genetics sampling, electrofishing surveys). Impacts of these monitoring activities are not evaluated in the impact analysis because monitoring activities in and of themselves would have no impact on groundwater recharge and water quality.

The Project and FAHCE AMP identifies triggers for adaptive actions to help meet measurable objectives. Adaptive actions for FAHCE flows and imported water storage/releases would include refinements of reservoir releases, which would have impacts and benefits similar to the original FAHCE flows and imported water storage/releases. Adaptive actions for Conservation Measures would generally include minor construction and maintenance actions, whose impacts would be similar but less than those from original Conservation Measure construction. Impacts of these adaptive actions are not evaluated in the impact analysis because their groundwater impacts would likely be very minor. ~~e.~~

3.12.3.7 Applicable Best Management Practices and VHP ~~Valley Habitat Plan~~ Conditions

As noted in Chapter 2, *Project Description*, Valley Water would incorporate a range of BMPs, including conditions and AMMs from the VHP, to avoid and minimize adverse effects on the environment that could result from the Project. All relevant BMPs and AMMs for the Project are included in Appendix A, *Best Management Practices and Santa Clara Valley Habitat Conservation Plan Conditions, Avoidance and Minimization Measures, and Mitigation Measures* ~~*Incorporated in the Project*~~*.* BMPs relevant to groundwater include the following:

- **HM-1:** Comply with All Pesticide Application Restrictions and Policies
- **HM-2:** Minimize Use of Pesticides
- **HM-4:** Comply with All Pesticide Usage Requirements
- **HM-5:** Comply with Restrictions on Herbicide Use in Upland Areas
- **HM-6:** Comply with Restrictions on Herbicide Use in Aquatic Areas
- ~~**HM-7:** Restrict Vehicle and Equipment Cleaning to Appropriate Locations and equipment fluids~~
- **HM-8:** Ensure Proper Vehicle and Equipment Fueling and Maintenance
- **HM-9:** Ensure Proper Hazardous Materials Management

- **HM-10:** Utilize Spill Prevention Measures
- **SED**-1: Groundwater Management

Additionally, the following VHP conditions ~~AMMs~~ would serve to minimize impacts on groundwater resources from the Project ~~(refer to Appendix A for the full text of the VHP AMMs)~~:

- Condition 3: Maintain Hydrologic Conditions and Protect Water Quality
- Condition 4: Avoidance and Minimization for In-Stream Projects
- Condition 5: Avoidance and Minimization Measures for In-Stream Operations and Maintenance
- Condition 7: Rural Development Design and Construction Requirements
- Condition 11: Stream and Riparian Setbacks
- Condition 12: Wetland and Pond Avoidance and Minimization

Additionally, the following VHP conditions AMMs related to conditions 3, 4, and 5 would serve to minimize impacts on hydrology from the Project:

- VHP AMM 7: Rural Development Design and Construction Requirements OR Use appropriate erosion and sediment control avoidance and minimization measures to secure the staging and Project Area ~~project area~~ so that sediment runoff is avoided
- VHP AMM 8: Implement Avoidance and Minimization Measures for Rural Road Maintenance OR Protect storm drain inlets and watercourses using appropriate avoidance and minimization measures
- VHP AMM 9: Mulch or revegetate bare soil adjacent to stream channels, or other flow transport paths, to the break-in-slope near those areas
- VHP AMM 11: Stream and Riparian Setbacks
- VHP AMM 12: Wetland and Pond Avoidance and Minimization. OR Dewater active gullies to prevent their enlargement and to reduce their capacity for sediment transport
- VHP AMM 14: Prevent accelerated landsliding by avoiding, minimizing or eliminating future sidecasting on steep or streamside hillslopes
- VHP AMM 72: Equipment storage, fueling and staging areas will be sited on disturbed areas or non-sensitive habitat outside of a stream channel
- VHP AMM 87: Vehicles operated within and adjacent to streams will be checked and maintained daily to prevent leaks
- VHP AMM 88: Vehicles and equipment will be parked on pavement, existing roads, and previously disturbed areas
- VHP AMM 100: Potential contaminating materials must be stored in covered storage areas or secondary containment impervious to leaks and spills

3.12.3.8 Thresholds of Significance

In accordance with Appendix G of the *CEQA Guidelines*, the Project would have a significant effect related to groundwater resources[1] if it would:

GW-1: Substantially decrease groundwater supplies or interfere substantially with groundwater recharge such that the project may impede sustainable groundwater management of the basin

GW-2: Violate groundwater water quality standards or substantially degrade groundwater quality

GW-3: Conflict with or obstruct implementation of the San Francisco Bay Basin Plan groundwater provisions or Valley Water's GWMP

3.12.4 Impact Analysis

***Impact GW-1: Substantially decrease groundwater supplies or interfere substantially with groundwater recharge such that the project may impede sustainable groundwater management of the basin* (Less than Significant with Mitigation)**

Seismic Retrofit Construction

Reduced Reservoir Releases Affecting the Managed Groundwater Basin

As described in Chapter 2, *Project Description,* following implementation of the FOCP, the reservoir water level is currently at deadpool. During Seismic Retrofit construction, the reservoir water level would be further lowered ~~another 21 feet~~ to elev. 450 ~~467~~ feet during Year 1, ~~and then lowered another 17 feet to elev. 450 during Year 2~~. Following cofferdam and reservoir bypass pipe construction (occurring in Year 2), dewatering new flows entering the reservoir would continue to maintain the reservoir at elev. 450 feet during Years 2 and 3. The reservoir would be filled to elev. 556 feet in Year 4, elev. 556 feet in Year 5, and elev. 657 feet in Year 6 ~~453 during Years 3, 4, 5, and 6~~. This ongoing dewatering would occur through the Stage 2 Diversion System. A pool of water would generally be held behind the cofferdam (which would have a capacity of 500 AF), but the water level would fluctuate based on inflow and time of year. During Year 6 of Seismic Retrofit construction, with the approval of applicable dam safety regulatory agencies, the reservoir would be allowed to start filling to prepare for post-construction operations.

Generally, without implementation of the Conservation Measure components, dry season reservoir releases during the Seismic Retrofit construction period would be greatly reduced compared to historical conditions. Whereas historically (e.g., Pre-FERC Order) dry season releases would average roughly 55 cfs when water supplies were available, dry season releases during Seismic Retrofit construction would typically be much lower. During the dry season of Year 1 of construction, flows from the existing outlet structure would be between 1 to 65 ~~5~~ cfs, depending on the releases from Coyote Reservoir. Once the Stage 2 Diversion System is in place (to be installed during Year 2), flows from Anderson Reservoir would range from 1 to 65 cfs

[1] Note that thresholds from CEQA Guidelines Appendix G specifically related to hydrology are addressed in Section 3.11, *Hydrology*, while thresholds related to surface water quality are addressed in Section 3.14, *Water Quality*.

during the dry season, although typically this would be closer to the low end. As indicated above, only roughly 500 AF would be able to be stored behind the cofferdam; and, during the winter/spring, all flows would be bypassed through the diversion structure.

Altogether, this would greatly limit the amount of water that could be released from reservoir for the purpose of groundwater recharge along Coyote Creek. As described in Section 3.12.1, during historical conditions, Anderson Reservoir has played a critical role in supporting groundwater recharge in the Santa Clara Subbasin, in particular in the Coyote Valley management area. Valley Water's managed recharge program, of which Anderson Dam plays an important part, accounts for nearly 70 percent of the subbasin recharge, with approximately 60 percent occurring along stream channels above the aquifer's unconfined zone (Valley Water 2021). **Figure 3.12-1** shows that the Coyote Valley is particularly dependent on instream recharge along Coyote Creek, which is typically supported by releases from Anderson Dam, whereas the Santa Clara Plain management area has a number of other management recharge systems/facilities supporting recharge in this portion of the subbasin. For the period 2010 to 2019, managed recharge in the Coyote Valley averaged 13,500 AFY, whereas natural recharge only averaged 2,500 AFY (Valley Water 2021); refer to **Table 3.12-1**.

Thus, it is reasonable to assume that a prolonged period during which Anderson Dam would be essentially offline (e.g., 7 years throughout the Seismic Retrofit construction) could substantially reduce groundwater supplies and impede sustainable management of the basin. Without the recharge provided via dry season releases from Anderson Dam, groundwater pumping may exceed recharge rates leading to a decline in overall storage in the subbasin (particularly in the Coyote Valley) and potentially lower groundwater levels and increase the risk of subsidence. Depending on hydrologic conditions, a dry year or multiple dry years during the Seismic Retrofit construction period could compound these effects by reducing the amount of natural recharge and potentially increasing pumping demands. While the Seismic Retrofit construction would not actively inhibit natural groundwater recharge, it would disrupt the managed recharge that the region relies upon by keeping the reservoir in a dewatered state and limiting dry season reservoir releases.

As described in Chapter 2, *Project Description,* Valley Water would implement Conservation Measure components to avoid or reduce the potential impacts on groundwater resources during Seismic Retrofit construction. First, Valley Water would maintain normal operation of Coyote Reservoir during the construction period. As it is located approximately 1.5 miles upstream of Anderson Reservoir, releases from Coyote Reservoir are an important component of the overall inflow into Anderson Reservoir, particularly during the dry season. Valley Water aims to maintain a minimum streamflow of 3 to 5 cfs at Gage SF12 (downstream of Coyote Reservoir) through releases from Coyote Reservoir in the spring and summer (when supply is available) and manage storage consistent with the DSOD restriction established in 1992. Full capacity of the Coyote Reservoir outlet would be used when storage in Coyote Reservoir exceeds 11,843 AF, which corresponds to the DSOD restriction on water surface elevation of 758.0 feet in local datum or 760.9 feet in NAVD 88, to reduce storage in Coyote Reservoir to the DSOD-restricted level ~~in the winter to stay within DSOD restrictions (maximum storage is 11,843 AF)~~. The releases from Coyote Reservoir would provide a source of inflow to Anderson Reservoir during the dry summer/fall months, which could then be passed downstream to Coyote Creek where it could percolate through the streambed and/or help fill the Coyote Percolation Pond, where recharge could occur.

Additionally, Valley Water would implement imported water releases from the CDL and Cross Valley Pipeline Extension during the seismic retrofit construction period. Imported water would generally be obtained from San Luis Reservoir via the SCC and would be released into Coyote Creek just below Anderson Dam via the CDL, as well as downstream of Ogier Ponds via the Cross Valley Pipeline Extension. Valley Water would continue to release imported water via the Cross Valley Pipeline Extension, if stream flow from Anderson Dam does not reach the Cross Valley Pipeline Extension outfall and a dryback is present downstream. The amount of flow released from the CDL would depend on the time of year, the temperature, the amount of local water available for release from the reservoir to mix with the imported water, and actual hydrology at the time of the release, with the target of having a minimum flow of 2.5 cfs at the Edenvale streamflow gage (SF5058). Valley Water extended the Cross Valley Pipeline to allow for imported water releases downstream of Ogier Ponds as part of the FOCP; thus, it would be possible to release imported water at this location (approximately 4 miles downstream of Anderson Dam) during seismic retrofit construction. The Cross Valley Pipeline Extension is designed to a maximum flow of 67 cfs, hence it has the capacity of 50 cfs of imported water and up to this amount could potentially be released during the construction period to support groundwater recharge downstream of Ogier Ponds. Valley Water would cease Cross Valley Pipeline Extension releases when flows exceed 65 cfs at streamflow station 5082 and Coyote Creek at Madrone during the adult upstream migration season (December 1 to April 30), unless there is less than 2.5 cfs at streamflow station 5058, Coyote Creek Edenvale. Releasing imported water below Ogier Ponds would ensure that more reaches of Coyote Creek would stay wetted, and would support groundwater recharge of Coyote Valley and South San José areas throughout the construction period. Refer to Section 3.13, *Water Supply*, for discussion of the availability/reliability of imported water during Seismic Retrofit construction.

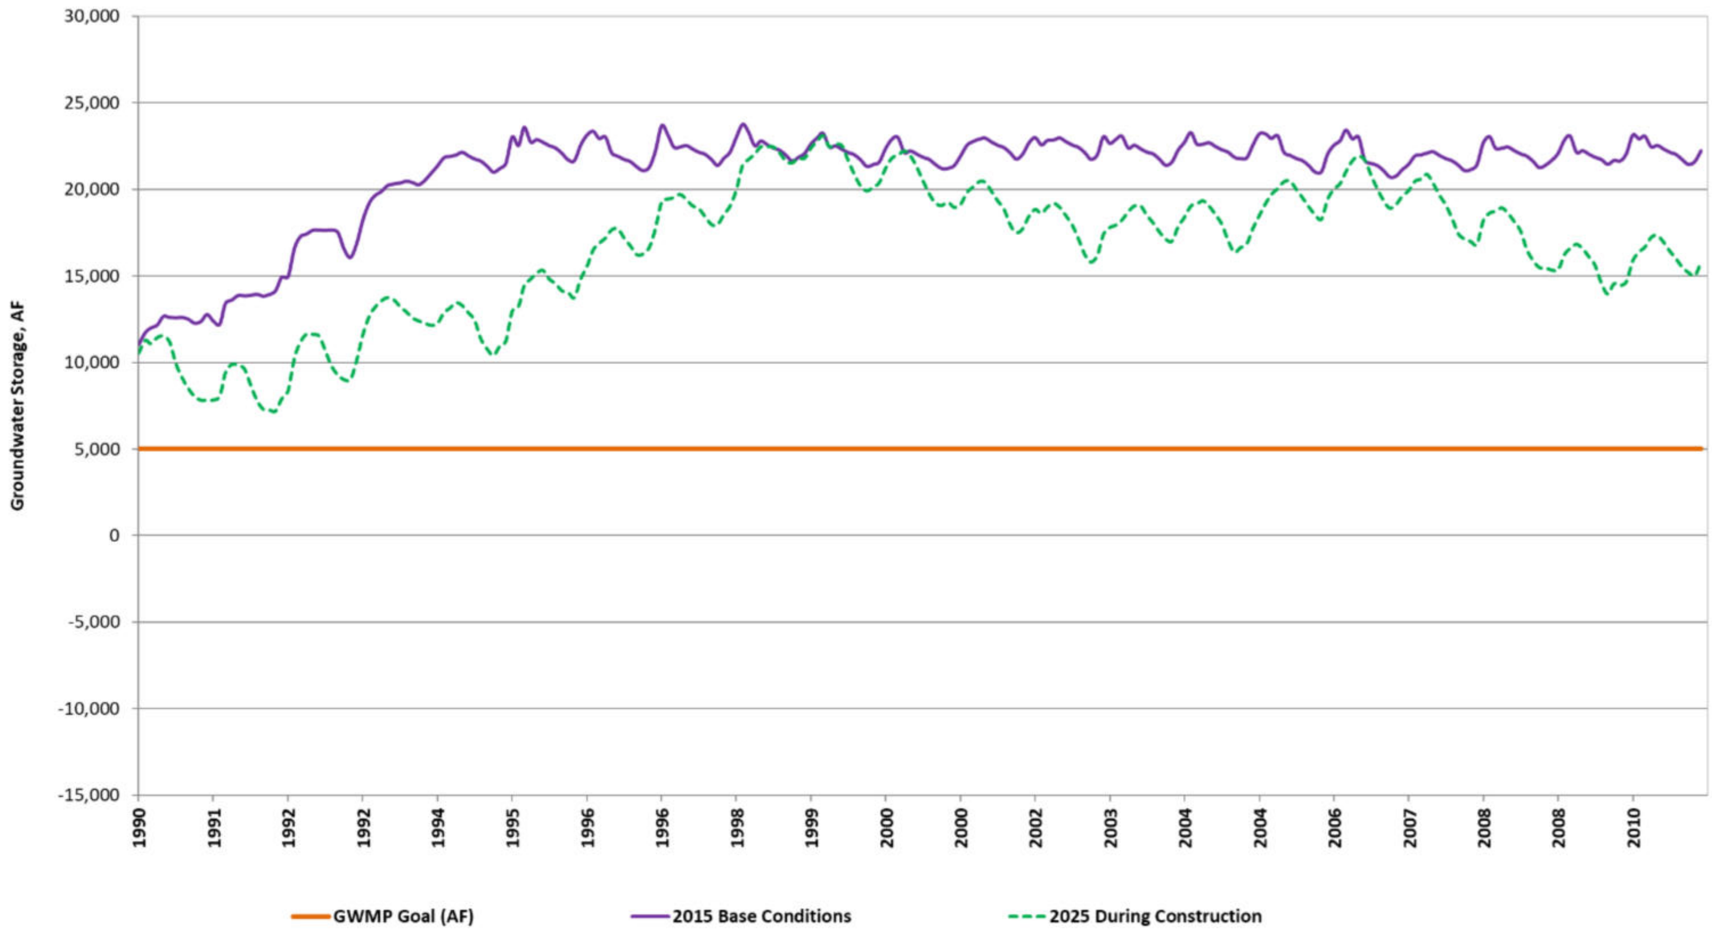
Furthermore, as described in Chapter 2, *Project Description,* Valley Water's Wetland and Riparian Habitat Dryback Monitoring Plan and Groundwater Management Plan would continue to be implemented during the Seismic Retrofit construction period (Valley Water 2020 ~~2020a~~; Valley Water 2021). This includes groundwater level monitoring, mapping of GDEs (e.g., riparian and wetland habitat), and monitoring of groundwater recharge. Groundwater level monitoring would provide real-time assessments for how the Project is impacting groundwater storage sustainability goals and include existing Valley Water programs to monitor groundwater levels, land subsidence, groundwater quality, and surface water. For this effort, Valley Water would utilize its existing network of water level and water quality monitoring wells, including wells installed by Valley Water, existing wells Valley Water has obtained, and privately-owned wells for which Valley Water has secured monitoring access, and supplemental data collected by water retailers to facilitate a comprehensive understanding of groundwater conditions. Based on the results of the monitoring, Valley Water would seek to adjust the imported water releases and/or pursue water use reduction measures to alleviate or correct any identified deficiencies or negative trends in groundwater storage.

Implementation of the Conservation Measure components and monitoring described above would substantially reduce potential impacts on groundwater supplies during Seismic Retrofit construction as a result of dewatering/reduced reservoir releases. Valley Water conducted a modeling exercise to analyze the potential effects of Seismic Retrofit construction on groundwater storage, utilizing the WEAP monthly model in order to be consistent with the FAHCE EIR. The WEAP modeling scenarios are based on 21 years (1990 to 2010) of historical hydrology and demand data provided by Valley Water's Water Supply Planning and Conservation Unit. This historical data includes times of both large rainfall events and drought conditions. The model assumes local supplies are supplemented with imported water during the construction period in accordance with the Conservation Measure components described above. The results of the modeling with respect to Seismic Retrofit construction are shown in **Figure 3.12-6**.

As can be seen in **Figure 3.12-6**, both the "2015 Base Conditions" and "2025 During Construction" scenarios result in total groundwater storage in Coyote Valley that remain above the 5,000 AF storage outcome measure (**Table 3.12-4**) during all years in the study period. The 2015 Base Conditions scenario represents a Pre-FERC Order Baseline, when ~~interim seismic~~ restrictions limited Anderson Reservoir capacity to 51,200 AF. However, the 2015 Base Conditions would logically have better groundwater supply conditions than what would occur under the existing conditions baseline, where reservoir capacity is limited to 3,159 AF (deadpool) following implementation of the FOCP. Using 2015 Base Conditions as a baseline therefore results in a more conservative analysis of Project groundwater impacts. The 2025 During Construction scenario represents conditions during the Seismic Retrofit construction process after the Stage 2 Diversion System has been constructed and put into operational use. As such, the cofferdam will be in place and only a small pool of roughly 500 AF or less may remain during the dry season and limited local supplies would be available for releases to support groundwater recharge; however, the model assumes that imported supplies would be used to augment local supplies in this scenario.

Figure 3.12-6 shows that groundwater supplies would be reduced under the 2025 During Construction scenario as compared to the 2015 Base Conditions scenario, in particular during certain years in the record. For example, one of the largest disparities is in late 1994, when storage under the 2025 During Construction scenario (roughly 10,500 AF) is roughly 10,500 AF lower than under the 2015 Base Conditions scenario (roughly 21,000 AF). The entire period from 1991 to 1998, as well as the periods from roughly 2000 to 2006 and 2007 to 2010, show groundwater storage being lower under the 2025 During Construction scenario relative to the 2015 Base Conditions. By contrast, for brief periods in 1998/1999 and 2006, groundwater storage in Coyote Valley is essentially equal under these two scenarios.

Figure 3.12-6. Coyote Valley Groundwater Storage During the Seismic Retrofit Construction Scenario



Source: Groundwater Technical Memorandum ~~Memo~~ – Appendix J

Groundwater resources along the downstream Santa Clara Plain would not be substantially affected by the seismic retrofit construction since this area of the subbasin (1) begins further downstream along Coyote Creek (approximately 10 miles downstream from Anderson Dam); (2) is much larger than the Coyote Valley management area in terms of area and storage capacity, and (3) has many additional sources of natural and artificial recharge (e.g., West Side Recharge System, Los Gatos Recharge System, Guadalupe Recharge System, and Penitencia Recharge System – refer to **Figure 3.12-1**), (4) and is also conjunctively managed with Valley Water's three water treatment plants. The Coyote Valley and Llagas Subbasin have only a limited hydraulic connection due to a groundwater divide near the boundary. Based on groundwater elevation data, the boundary and groundwater flow direction move slightly north or south depending on the recharge, pumping, and hydrologic conditions. Managed recharge in the northern Llagas Subbasin relies primarily on imported water supplies.

Thus, the Coyote Valley would be the principal groundwater management area that would be affected by the Seismic Retrofit construction process. Given that WEAP modeling shows that the 2025 During Construction scenario would maintain total storage in the Coyote Valley above the 5,000 AF outcome measure during the 21-year study period (1990-2010), the impacts would be less than significant. Although the 2025 During Construction scenario would result in reduced groundwater storage compared to historical conditions (i.e., 2015 Base Conditions scenario), the reduction would be less pronounced compared to the existing conditions baseline. Moreover, the modeling shows that the imported water releases would be sufficient to offset reductions in reservoir storage and releases during the Seismic Retrofit construction period, such as to avoid significant impacts. The study period for the WEAP modeling included a range of hydrologic conditions and water year types, including critically dry and wet periods; thus, the modeling of multiple subsequent dry years occurring during the seismic retrofit construction period shows that significant impacts would still be avoided with respect to sustainable management of the basin since Valley Water plans to have sufficient imported supplies to supplement Coyote Valley recharge. Because groundwater supplies and groundwater recharge would not be substantially decreased such that sustainable management of the basin would be impeded, this impact would be less than significant.

Reservoir Dewatering Affecting Nearby Groundwater Wells

While the reservoir dewatering during the Seismic Retrofit construction period would have potential to impact the managed recharge operations downstream along Coyote Creek (as discussed above), it would also have potential to impact groundwater wells located in close proximity to the reservoir rim. There are a number of water production wells in relatively close proximity to the normal inundation area of Anderson Reservoir, in particular in the Holiday Lake Estates Area and the area along East Dunne Avenue on the eastern shore of the southern portion of the reservoir. Given that Anderson Reservoir was constructed in 1950, all or most of these wells were likely constructed subsequent to the reservoir being in existence. Thus, the groundwater conditions under which the wells were completed may have been influenced by the presence of the reservoir.

Generally, reservoirs raise the groundwater level in the surrounding area, as some of the water stored in the reservoir seeps through the fractures in the surrounding bedrock, potentially affecting water levels in nearby wells that are also screened in the bedrock.

While the characteristics of the subsurface bedrock water-bearing units in the immediate vicinity of Anderson Reservoir are not fully known (this area is outside of the managed Coyote Valley area of the Santa Clara Subbasin), the influence of the reservoir on groundwater levels could extend to the nearby wells. If groundwater levels in the fractured bedrock were to decline at the location of the nearby wells, principally as a result of the dewatered state of the reservoir during the 7-year Seismic Retrofit construction period, this could adversely affect the productivity of these wells, potentially causing the wells to go dry. Groundwater levels from wells screened in bedrock fluctuate from year to year and within the year (typically higher in winter/spring relative to summer/fall) due to hydrologic conditions (e.g., precipitation, runoff, etc.), pumping in nearby wells, and the flowpaths of groundwater in the fractures that supply the wells. Nevertheless, the dewatered reservoir could exert a negative influence on groundwater levels relative to the existing conditions baseline, and in particular, with respect to historical conditions (Pre-FERC Order Conditions). The effects on existing wells in close proximity to the normal (Pre-FERC Order) inundation area of Anderson Reservoir would be significant because groundwater supplies from individual wells may be substantially decreased.

To reduce the potential adverse effects from dewatering during the Seismic Retrofit construction period, Valley Water will implement **Mitigation Measure GW-1**. This measure will require that, for any well(s) in proximity to Anderson Reservoir that go dry during the seismic retrofit construction period and for which Valley Water determines the cause of the well(s) going dry can be attributed to the reduced water level at the reservoir, Valley Water will provide alternative water supplies to the well owner(s) for the duration of the impacts. Implementation of **Mitigation Measure GW-1** will reduce the potential impacts on wells near the dewatered reservoir to a level that is less than significant.

Sediment Deposition in Percolation Ponds

The Seismic Retrofit construction could also impact groundwater due to deposition of fine sediment in the Coyote Percolation Pond along Coyote Creek, potentially resulting in reduced recharge rates of the percolation pond. As described in Section 3.11, *Hydrology*, modeling shows that up to 0.5 inches of sediment deposition could occur in Metcalf Ponds (i.e., the ponds upstream of the Coyote Percolation Dam and just north of Metcalf Road) following a 5-year storm event, while 0.3 inches could accumulate following a 2-year storm event. Most of the sediment that could be deposited in the pond would likely be fine-grained, since it would have been transported in the discharges from Anderson Reservoir.

The fine sediment that could be deposited in the Coyote Percolation Pond could potentially decrease the porosity of the pond bottom (e.g., by filling in interstitial spaces) and thus adversely affect groundwater recharge operations. While similar effects could occur in Ogier Ponds, the effects are not a concern because the Ogier Ponds are not percolation ponds and the site is not suitable for managed groundwater recharge (Valley Water 2018; see further discussion below under *Seismic Retrofit and Conservation Measures Post-Construction Operations, Maintenance, and Monitoring Impacts Analysis*). Continued implementation of Valley Water's existing maintenance program at the Coyote Percolation Pond, which includes discing or removal of accumulated sediment, as needed to maintain recharge/percolation rates, would assure these potential effects on groundwater supplies would be less than significant.

Construction Water Demand

Water needs during the Seismic Retrofit construction process would be met entirely through surface water sources. As described in Chapter 2, *Project Description,* up to 1 cfs of water from the Coyote Reservoir releases would be used for construction activities, including for dust control and wetting of stockpiled materials. This would translate to approximately 646,320 gallons per day or roughly 2 AF per day. Over the course of the entire Seismic Retrofit construction. Given that the water to be used during construction would be obtained from the Coyote Reservoir releases, this would primarily constitute surface water that would inflow to the reservoir either via Coyote Reservoir/Coyote Creek or the several other smaller creeks that feed into the reservoir. No groundwater would contribute to the pool of water retained in Anderson Reservoir during the Seismic Retrofit construction period. Since surface water would be used for construction water, impacts on groundwater supplies would be less than significant.

Other Mechanisms by Which Groundwater Supplies or Recharge Could be Affected During Seismic Retrofit Construction

Apart from the effects of reservoir dewatering and reduced reservoir releases, Seismic Retrofit construction could potentially affect groundwater recharge/supplies via compaction of surfaces (thereby limiting infiltration capacity) and dewatering of nuisance groundwater in work areas. Seismic Retrofit construction would require establishment and use of several temporary impact areas, which would have potential to result in soil compaction and thus limit the ability for infiltration/groundwater recharge in these immediate areas. This would include access roads, which would be located within the reservoir (connecting to stockpile, borrow, and disposal areas) as well as on the upstream and downstream slopes of the dam. Additionally, staging areas (six in total) would be established in upland areas. Preparation of access roads and staging areas would include vegetation removal and grading; staging areas may require placement of gravel or a separation fabric over the ground surface, depending on the type of usage.

Use of these areas during the Seismic Retrofit construction period, including movement of heavy equipment and trucks, would likely compact the soils/surface materials and thus limit the ability of water to pass through to the groundwater table below. In general, these effects would be minor and would not result in a substantial reduction in groundwater supplies and the localized impedance of groundwater recharge would not meaningfully affect overall recharge rates in the subbasin. Given that the temporary disturbance areas would be established within/adjacent to other undeveloped areas, water falling on the access roads or staging areas as precipitation would have the opportunity to run off the compacted areas and infiltrate into the soil at adjacent locations, as it does now.

There would also be some localized dewatering of nuisance groundwater in work/excavation areas that would be required during Seismic Retrofit construction. Particularly in the dam footprint, there would be potential to encounter groundwater in deeper excavations especially. As described in Chapter 2, groundwater that is pumped from the dam footprint throughout construction would be pumped from the site and routed through an ATS in order to remove sediment, reduce turbidity, and balance pH prior to release of the waters into Coyote Creek. The amount of groundwater that would be extracted from dam work areas would be relatively small, and this would not meaningfully affect the regional groundwater supplies or impede sustainable management of the basin. Additionally, any groundwater that is extracted from the dam footprint and then discharged to Coyote Creek (after treatment via the ATS) would have the opportunity to infiltrate back to the groundwater basin via the Coyote Creek streambed or percolation pond.

Significance Conclusion Summary

Therefore, impacts on groundwater supplies from the other mechanisms described above would be **less than significant.**

Conservation Measures Construction

Generally, the Conservation Measure components would have less effects on groundwater storage/supplies and recharge than the Seismic Retrofit construction. While several of the Conservation Measure components (Ogier Ponds CM, Maintenance of the North Channel Reach ~~Extension~~, and Phase 2 Coyote Percolation Dam CM) would require dewatering during construction, this dewatering would be much more localized than that required for Anderson Reservoir and would not substantially affect groundwater recharge. ~~For example, the dewatering required for the North Channel Extension would be limited to the small backwater area at the downstream end of the historic North Channel of Coyote Creek; additionally, this phase of the North Channel Extension construction process would only last approximately 2 months~~.

Ogier Ponds

Construction of the Ogier Ponds Conservation Measure would require more extensive dewatering of the Coyote Creek channel and adjoining portions of Ogier Ponds where construction would occur (all or portions of Ponds 1, 2, 4, and 5 would be dewatered to separate the work areas from the remaining portions of the ponds). Nevertheless, as with each of the Conservation Measure components requiring dewatering during construction, a creek bypass system would be constructed/utilized to maintain flows in Coyote Creek around the work area(s). The Ogier Ponds site is not suitable for groundwater recharge due to limited storage capacity in the vadose zone (Valley Water 2018 – see further discussion below under *Seismic Retrofit and Conservation Measure Post-Construction Operations, Maintenance, and Monitoring Impacts Analysis*); as such, the temporary dewatering of the ponds during construction would not substantially affect groundwater recharge rates in the area (since the ponds do not play a substantial role in groundwater recharge under the existing conditions baseline).

Phase 2 Coyote Percolation Dam

The Phase 2 Coyote Percolation Dam Conservation Measure also would require dewatering during the construction period, as described in Chapter 2, *Project Description,* to isolate the work area and allow for the roughened fish ramp construction. This dewatering effort would also be fairly limited/isolated, as the new roughened channel would extend for a distance of approximately 500 feet. The construction process for this Conservation Measure component would begin in Year 1 ~~5~~, and a portion of the creek including the work area would be dewatered for approximately 6 months. The Coyote Percolation Pond does actively support managed groundwater recharge under the existing conditions baseline; thus, the extent to which construction of the Phase 2 Coyote Percolation Dam Conservation Measure could preclude full utilization of the percolation pond, this could reduce groundwater recharge in this area to some degree over the approximately 18-month construction period (or 6 months during which the work area would be dewatered). However, the effects would be minor and would not substantially affect regional groundwater supplies.

Live Oak Restoration Reach and the Sediment Augmentation Program

Maintenance of Spawning Gravel and Rearing Habitat Improvements in Live Oak Restoration Reach and the Sediment Augmentation Program would have limited potential to adversely affect groundwater supplies or recharge, as these Conservation Measure components would not require dewatering during construction. For these Conservation Measure components, there would be some potential for establishment and use of access roads and staging areas to compact soils and thus limit infiltration capacity; however, these effects would be minor (more so than for the seismic retrofit components) and would not substantially affect regional groundwater supplies. Construction of the Phase 2 Coyote Percolation Dam Conservation Measure would utilize an existing 0.8-acres parking area for staging of equipment and materials and thus would have reduced impacts on groundwater recharge in this regard.

Dewatering

Each of the Conservation Measure components requiring dewatering during construction activities (i.e., Ogier Ponds Conservation Measure, Maintenance of the North Channel Reach ~~Extension~~, and Phase 2 Coyote Percolation Dam CM) would potentially require dewatering of nuisance groundwater that could emerge within the dewatered reaches where construction work activities would occur. This may include installation of pumps and temporary dewatering wells to control the groundwater seepage and nuisance waters throughout the construction process. The groundwater table is known to be shallow along Coyote Creek downstream of Anderson Dam, in particular in the area of Ogier Ponds and the Coyote Percolation Pond, as shown in **Figure 3.12-4**. Generally, the amount of nuisance groundwater that would be extracted during the Conservation Measure construction would be small and would not substantially affect supplies in the subbasin as a whole; thus, it would not impede sustainable management of the basin.

Significance Conclusion Summary

Based on the above analysis, impacts to groundwater supplies and groundwater recharge from Conservation Measures construction would not be substantial, and therefore would be less than significant.

Post-Construction Dam Facilities Operations and Maintenance

Revised Reservoir Operating Criteria

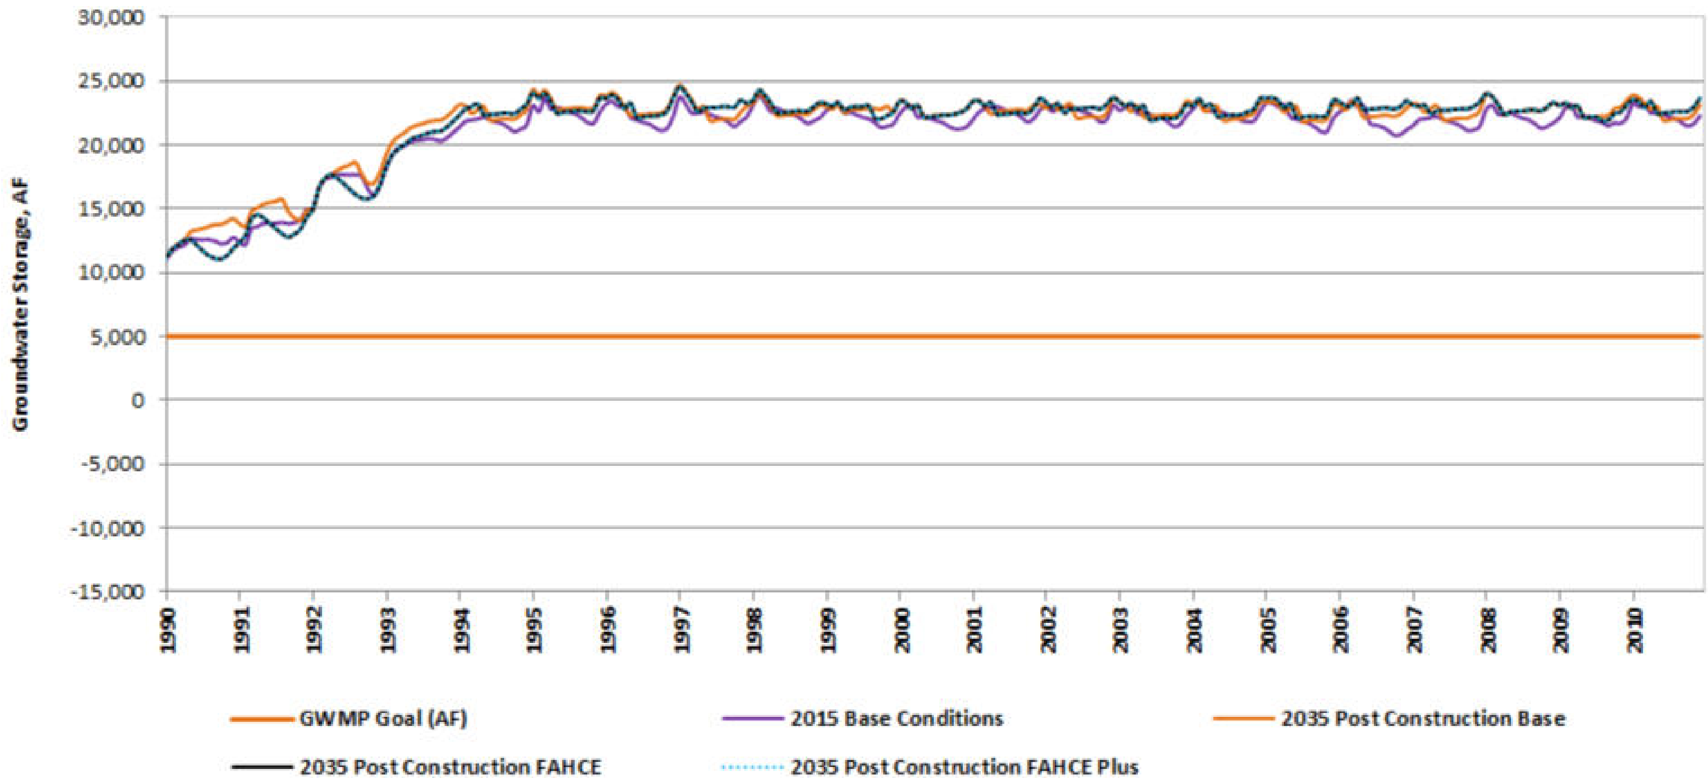
Following construction of the Seismic Retrofit components of the Project, Valley Water would have an improved ability to manage water resources for multiple benefits, including groundwater recharge. The seismic safety restriction that has been in effect (to more or less of a degree) since 2009 would be lifted, allowing Valley Water to utilize the full capacity (roughly 89,000 AF) of Anderson Reservoir. This would enable more water to be stored in the reservoir to support dry season releases for the purpose of groundwater recharge, which supports groundwater storage/supplies in the Santa Clara Subbasin (in particular, the Coyote Valley) and

Llagas Subbasin (to a lesser degree). In this respect, the post-construction operations of Anderson Dam/Reservoir would primarily be beneficial relative to the Pre-FERC Order Baseline.

As part of the Project, Valley Water would implement revised reservoir operating criteria, in accordance with FAHCE. The FAHCE operating tule curves would primarily increase releases from Anderson Reservoir for fish passage and habitat enhancement purposes, in particular with respect to “pulse” flows during the winter/spring, which would entail flows of 50 cfs for 5 days, occurring up to two times from February 1 through April 30. The winter base flows under FAHCE would be 26 cfs if storage is adequate, which would be similar to the Pre-FERC Order Conditions Baseline. In this regard, the FAHCE operational rule curves could potentially decrease the amount of water available for groundwater recharge, since greater amounts of water would be released for environmental or fish passage (i.e., non-groundwater recharge) purposes. Generally, the releases from Anderson Dam are most effective for groundwater recharge when conducted during the dry season, as natural sources of recharge (e.g., precipitation, natural streamflow) are limited during this period. Additionally, the demands on groundwater resources (e.g., pumping) are greater during the dry season. Thus, it is important to retain reservoir storage for use during the dry season. As described in Section 3.13, *Water Supply*, however, the pulse flow releases under FAHCE would be subject to storage criteria that would be protective of dry season storage. This would limit any adverse effects on water supply that could be created by releasing additional water for fish passage purposes.

Based on WEAP modeling conducted by Valley Water staff, the model indicates that groundwater storage would not be substantially affected by the FAHCE operating rules. **Figure 3.12-7** shows the results of the WEAP modeling for the post-construction period. As shown in the figure, the “2035 Post Construction FAHCE” scenario resulted in only slightly reduced groundwater storage in the Coyote Valley for many of the years modeled in relation to the “2035 Post Construction Base” scenario. The 2035 Post Construction FAHCE scenario represents post-construction conditions with Anderson Reservoir being operated in accordance with the FAHCE rules. By contrast, the 2035 Post Construction Base scenario is representative of the future conditions baseline.

Figure 3.12-7. Coyote Valley Groundwater Storage During Post-Construction Operations



Source: Groundwater Technical Memorandum ~~Memo~~ – Appendix J

Generally, as seen in **Figure 3.12-7**, groundwater storage under the 2035 Post Construction FAHCE scenario drops lower than under the 2035 Post Construction Base scenario in certain years (e.g., 1991-1994); however, there are periods (e.g., 1997, 2007) where storage is higher under the 2035 Post Construction FAHCE scenario. Both the 2035 Post Construction FAHCE and 2035 Post Construction Base scenarios generally result in greater groundwater storage in the Coyote Valley (with the exception of certain brief periods) compared to the 2015 Base Conditions scenario, which is not surprising considering the reservoir storage restriction was in place in 2015. The 2015 Base Conditions scenario is representative of the Pre-FERC Order Baseline.

Altogether, while there are slight differences between the modeled scenarios, throughout the study period the differences are minor. For much of the study period (e.g., 1995-2010), the model runs are essentially similar, with groundwater storage in Coyote Valley fluctuating between 20,000 AF and 25,000 AF. As noted above, the WEAP modeling covered a period of 21 years in total (1990-2010), which included both critically dry and wet periods. For all model runs/scenarios, groundwater storage remained well above the 5,000 AF outcome measure for Coyote Valley from Valley Water's GWMP. Therefore, the revised reservoir operating criteria under FAHCE would not result in a substantial reduction in Coyote Valley groundwater supplies or otherwise adversely affect Coyote Valley groundwater storage/recharge such as to impede sustainable management of the basin. The impacts to Coyote Valley groundwater would be less than significant.

Reduced Recharge Due to New or Expanded Impervious Surface

As described in Chapter 2, *Project Description,* the Seismic Retrofit components of the Project would include permanent roadway modifications, including widening of several existing roadways in the dam area and creating a new permanent access road from Cochrane Road to the toe of Anderson Dam. Altogether, new or expanded impervious surface (e.g., asphalt) as a result of the Project would total approximately 2.14 acres (i.e., additional impervious surface relative to existing conditions). The new/expanded impervious surface would generally decrease groundwater recharge relative to the Pre-FERC Order Conditions Baseline, since water falling on these areas as precipitation or running on from adjacent areas would not have the ability to infiltrate into the soil and groundwater below. However, the amount of additional impervious surface would be modest and would be in the context of surrounding pervious lands. As described in Section 3.11, *Hydrology*, stormwater from the roads and other impervious areas in the area of the dam would flow to surrounding areas, where it would have an opportunity to infiltrate to the soil or discharge to Coyote Creek (where it could subsequently percolate to groundwater via the streambed). As such, the additional impervious surface area that would be created by the Project would not substantially affect groundwater recharge rates or otherwise impede sustainable management of the basin.

Post Construction Conservation Measure Operations and Maintenance

Other activities during the post-construction period would have little potential to adversely affect groundwater supplies or recharge. The Conservation Measure components would not use substantial amounts of water during operation and would not create impervious surface. The Ogier Ponds CM would disconnect the existing Ogier Ponds from the flow of Coyote Creek. Valley Water found that the Ogier Ponds site is not suitable for managed groundwater recharge due to limited storage capacity in the vadose zone[2] (Valley Water 2018). In other words, the groundwater table is already very high in the Ogier Ponds area and there is direct hydraulic communication between the shallow groundwater and the ponds, thereby limiting the potential for recharge effectiveness.

Although there is seepage from Ogier Ponds to the shallow groundwater under the Pre-FERC Order Conditions Baseline, there is also inflow to the ponds from the shallow aquifer (Valley Water 2018). The analysis found that disconnection of Ogier Ponds from Coyote Creek would not result in the ponds drying up; but rather that the entire pond-aquifer system is sustained by creek flow through or past the site. Pond levels and surface areas are not strongly affected by whether the creek flows through or around the ponds, but rather by the amount of water flowing in the creek (Valley Water 2018). Pond dry-up would only commence if stream flow dropped for a sustained period below the threshold at which recharge no longer kept up with evaporation and downward leakage (Valley Water 2018). From this, it can be concluded that the Ogier Ponds CM, which would disconnect the ponds from Coyote Creek but create a new segment of Coyote Creek channel adjacent to the ponds, would not substantially reduce groundwater recharge occurring in this area.

Other Conservation Measure components would not substantially change rates of recharge relative to the Pre-FERC Order Conditions Baseline. Following construction of the Phase 2 Coyote Percolation Dam CM, the Coyote Percolation Pond would return to full operation/utilization, and the roughened fish ramp would not affect groundwater recharge that may occur along this reach. The North Channel Extension (completed as part of FOCP) would reconnect the historic Coyote Creek Channel in addition to the constructed South Channel that would remain in place. Flows would be divided between the channels; however, the overall capacity would not change. ~~Therefore, the restored~~ Maintenance of the North Channel Reach would not result in changes to groundwater recharge. The coarse gravel and other materials placed in Coyote Creek associated with the Sediment Augmentation Program and the Maintenance Activities at Live Oak Reach would not substantially affect groundwater recharge/seepage along the streambed; if anything, replacement of fine sediment deposited in the creek would likely improve percolation rates.

Routine maintenance and repair activities (e.g., pursuant to the DMP) during the post-construction period would not affect groundwater supplies or recharge. Likewise, continued monitoring would not impact groundwater resources. As such, overall, impacts would be less than significant.

Significance Conclusion Summary

In summary, Seismic Retrofit construction would not substantially affect groundwater storage/supplies or recharge, as WEAP modeling has shown that groundwater storage in the Coyote Valley would remain above the 5,000 GWMP outcome measure, given implementation of imported water releases in Coyote Creek. The dewatering of Anderson Reservoir during the 7-year Seismic Retrofit construction period could impact nearby wells outside of the groundwater basin/managed aquifer; however, this impact will be reduced to less than significant with implementation of **Mitigation Measure GW-1**. Construction of the Conservation Measure

[2] The vadose zone is the Earth's terrestrial subsurface that extends from the ground surface to the regional groundwater table. The vadose zone includes surface soil, unsaturated subsurface materials, and a transiently inundated capillary fringe.

components will not substantially affect groundwater recharge or impede sustainable management of the basin. Conservation Measure components, maintenance and monitoring) during the post-construction period would improve, or otherwise not substantially adversely affect, groundwater management and conditions. As such, this impact would be **less than significant with mitigation**.

Mitigation Measures

GW-1 Provide Alternative Water Supplies

During the Seismic Retrofit construction period, while Anderson Reservoir is dewatered, Valley Water will provide alternative water supplies to any well owner(s) in proximity to the reservoir (within 0.5-miles) whose well(s) have gone dry or whose water quality has become unacceptable, as a result of the reservoir being maintained in a dewatered state. With the reservoir being dewatered, this could reduce percolation through the reservoir bottom and reduce groundwater levels in the immediately surrounding area. Alternative water supplies will ~~would~~ include water to be supplied by water truck, or via another method, that is treated to an appropriate level for the required use (e.g., drinking water standards, if to be used for domestic purposes).

At the start of construction, Valley Water will establish a contact person and method of contact (phone, email) for members of the public to submit requests for accommodation under this mitigation measure. Valley Water will also establish a system whereby it will evaluate the requests and whether the well(s) have been adversely affected by the reservoir dewatering, or unacceptable water quality. This may include visiting the well owner's property to observe the well(s), comparing groundwater levels and water quality in and around the affected area based on monitoring data, or other methods. Valley Water will make a determination of whether the well(s) has/have gone dry or have unacceptable water quality, as a result of the dewatering—if no other cause can be determined, Valley Water will assume that the reservoir being dewatered will have played a role and alternative water supplies will be provided.

Any alternative water supplies under this mitigation measure will be provided in a quantity and at a frequency to meet the needs of the individual or entity consistent with the existing beneficial uses of the water, and commensurate with the lost production from the well(s). As indicated above, the water will be treated to a level that is appropriate for the intended use. The alternative water supplies will be provided for as long as the well(s) are rendered incapable of production.

Impact GW-2: Violate groundwater water quality standards or substantially degrade groundwater quality **(Less than Significant with Mitigation)**

Seismic Retrofit Construction

Hazardous Materials Releases

As described in Section 3.10, *Hazards and Hazardous Materials*, and Section 3.14, *Water Quality*, much of the construction equipment to be used during Seismic Retrofit construction would contain hazardous materials, such as fuel, oil, lubricants, etc. Trucks used for transport of materials around the site and for disposal at offsite locations would contain similar materials. While the materials would primarily be contained within the equipment, hazardous materials may need to be stored onsite at staging areas and the equipment may need to be serviced/re-fueled in the field or at the staging areas. All of these activities would create potential for hazardous materials to leak from equipment, spill, or otherwise be accidentally released into the environment during Seismic Retrofit construction. If such releases were to occur, the materials could infiltrate into the soil and potentially make its way down to the underlying groundwater aquifer. Hazardous materials spills/releases at staging areas, or other areas within the Seismic Retrofit construction area, could also be washed offsite during subsequent rainstorms where it would then have the opportunity to contaminate groundwater.

As described in Section 3.12.2, the Coyote Valley management area of the Santa Clara Subbasin is entirely unconfined and thus is very vulnerable to groundwater contamination. Since the Coyote Valley is immediately downstream of Anderson Dam, it is of most concern (rather than the Santa Clara Plain, which is further downstream along Coyote Creek) with respect to possible hazardous materials releases during seismic retrofit construction.

Given the susceptibility of the Coyote Valley to contamination, without implementation of preventative measures, the potential hazardous materials releases associated with the seismic retrofit construction activities would be a major concern ~~considered significant.~~ Once groundwater contamination occurs, even isolated substances or plumes, it can be very difficult to fully remove or remediate, and this can compromise the beneficial uses of groundwater, which are dependent on the quality of the water. Designated beneficial uses in the Santa Clara Subbasin from the San Francisco Bay Basin Plan include agricultural supply (AGR), municipal and domestic supply (MUN), industrial service supply (IND), and industrial process supply (PROC) (see **Table 3.12-1**) (San Francisco Bay RWQCB 2019 ~~2017~~).

However, as described in Section 3.14, *Water Quality*, Valley Water would implement a SWPPP for out-of-reservoir construction activities, in accordance with the Construction General Permit, as well as applicable BMPs from its own handbook and VHP conditions and AMMs. The SWPPP for construction activities outside the reservoir would include good housekeeping measures for: construction materials, waste management, vehicle storage and maintenance, landscape materials, and potential pollutant sources (SWRCB 2009). Examples include conducting an inventory of products used, implementing proper storage and containment, and properly cleaning all leaks from equipment and vehicles (SWRCB 2009). Additionally, the following Valley Water BMPs would reduce potential impacts associated with hazardous materials releases: ~~BMP HM-7 (Restrict Vehicle and Equipment Cleaning to Appropriate Locations),~~ BMP HM-8 (Ensure Proper Vehicle and Equipment Fueling and Maintenance), BMP HM-9 (Ensure Proper Hazardous Materials Management), and BMP HM-10 (Utilize Spill Prevention Measures). These BMPs would include protocols for providing secondary containment for hazardous materials used in the field or stored at staging areas or at work sites, and providing training spill cleanup materials for field personnel, among other measures. Furthermore, compliance with VHP measures, including AMMs 7, 8, 9, 11, 12, 72, 75, 76, 87, 88, and 100, whether implemented independently or incorporated as part of the SWPPP, would reduce potential impacts from hazardous materials.

Implementation of the measures included either as part of the SWPPP for out-of-reservoir construction activities and applicable Valley Water BMPs or VHP conditions and AMMs, would reduce the potential for Seismic Retrofit construction activities to result in releases of hazardous materials and subsequent groundwater contamination. As a result, groundwater quality standards would not be violated, and groundwater quality would not be substantially degraded. Impacts would therefore be less than significant.

Pollutants from Blasting Activities

Blasting at the BHBA could involve a range of pollutants including perchlorates and various water-soluble nitrogen-compounds can be released during the use of explosives (California Department of Toxic Substances Control 2005). As described in Chapter 2, *Project Description*, blasting would only be utilized during the excavation of the BHBA. Excavation of BHBA would require drilling and blasting in benches to break up the rock for efficient excavation. Blasting procedures would be developed by a qualified blaster to control noise, air-overpressure, ground vibration, flyrock, and dust. Water would be used before, during, and after the blasting to minimize dust emissions, but not to the point of creating runoff. The risk from perchlorates and other water-soluble nitrogen-compounds is primarily in relation to groundwater. Perchlorate salts are highly soluble in water and sorbs poorly to mineral surfaces and organic material; therefore, it is typically very mobile in groundwater. It is persistent in the environment and at high enough concentrations can affect thyroid gland functions. The release of substantial amounts of perchlorate to the environment where it can dissolve into surrounding surface or groundwater would be significant impact.

Mitigation Measure GW-2 will require that perchlorate-containing explosives are properly handled, cleaned up after use, and properly disposed of such that impacts related to perchlorates entering groundwater, Anderson Reservoir, or Coyote Creek would be minimized.

Reduced Groundwater Levels

As discussed in detail in Impact GW-1, Seismic Retrofit construction would require (nearly) complete dewatering of the reservoir, and that the reservoir remain in such a dewatered state during the majority of the 7-year construction period. This would result in reduced storage in the reservoir compared to the existing conditions baseline, and, in particular, compared to the Pre-FERC Order Conditions. In general, Valley Water would follow an approach of passing through virtually all inflow to the reservoir to Coyote Creek downstream via the Stage 1 Diversion System or Stage 2 Diversion System. This would likely result in higher flows in the creek during the winter/spring, as there would be no flood pool to catch storm runoff flows, but releases from the dam would be substantially reduced during the summer/fall. Anderson Dam releases to Coyote Creek are an important part of Valley Water's managed recharge program, and the creek is the only managed (artificial) recharge facility in the Coyote Valley.

If the dewatering and reduced reservoir releases during Seismic Retrofit construction were to result in substantially lower groundwater levels, this could lead to adverse groundwater quality impacts. One of the consequences of a reduction in groundwater storage (and relatedly, groundwater levels) can be a deterioration of water quality (USGS 2023 ~~2023b~~). One of the principal concerns when groundwater levels decline is the potential for seawater intrusion – and although this has been an issue in the Santa Clara Plain near the San Francisco Bay (refer to **Figure 3.12-3**), it is not a concern in the Coyote Valley due to this area's distance from the Bay. Additionally, groundwater overdraft (potentially brought on by reduced recharge with continued pumping, such as for the seismic retrofit construction) can create new water quality problems or make existing groundwater pollution worse (Moran et al. 2014). As aquifer levels decline, natural and human-made pollutants (e.g., naturally occurring salts and minerals, and human-made pollutants such as nitrate, petroleum products, and synthetic chemicals) can concentrate in the remaining groundwater (Moran et al. 2014).

As described in Impact GW-1, however, Valley Water would increase imported water releases during the Seismic Retrofit construction period to supplement the reduced local supplies. Imported water would be released from the CDL immediately downstream of Anderson Dam, as well as from the Cross Valley Pipeline Extension, which would release water downstream of Ogier Ponds. WEAP modeling conducted by Valley Water shows that increase of the imported water releases should maintain groundwater storage in the Coyote Valley comfortably above the 5,000 AF GWMP outcome measure during the seismic retrofit construction period. This would indicate that substantial reductions in groundwater storage would not occur, meaning that groundwater levels/elevations should also not be substantially affected – thus, groundwater quality impacts caused by reservoir dewatering would not be significant in the Coyote Valley.

The reduction in groundwater levels in the area immediately surrounding Anderson Reservoir (i.e., outside of the mapped aquifer) could adversely affect groundwater quality in this area; however, these effects would be temporary, lasting the duration for which groundwater levels are affected by the dewatered reservoir. Additionally, the impacts on well owners will be reduced through implementation of **Mitigation Measure GW-1**. Therefore, impacts would be less than significant with mitigation.

Other Potential Impacts

No other elements of the Seismic Retrofit construction process would result in substantial impacts on groundwater quality. The release of sediment following storms (e.g., 2-year and 5-year events) associated with the reservoir dewatering would not adversely affect groundwater quality. Although substantial quantities of fine sediment could be released during the Seismic Retrofit construction period, some of which could be deposited within Ogier Ponds and Metcalf Ponds in particular (refer to Section 3.11, *Hydrology*, for detailed discussion), this sediment would not pollute or otherwise adversely affect the groundwater. The sediment suspended in the water column and/or that deposits in the ponds would adsorb to soil particles or otherwise be filtered out as the water percolates to the groundwater aquifer. As such, impacts on groundwater quality for sedimentation would be less than significant.

Conservation Measures Construction

Construction of Conservation Measure components would utilize the same types of hazardous materials contained in construction equipment as the Seismic Retrofit construction. Thus, there would be potential for the same types of impacts (i.e., accidental releases of hazardous materials and subsequent groundwater contamination) as described above the seismic retrofit construction impacts analysis, albeit to a lesser extent.

Given that several of the Conservation Measure components s would be located in areas directly overlying the Coyote Valley management area (whereas the Seismic Retrofit components would largely be just upstream of the mapped groundwater basin), there could be increased potential for contamination from construction activities. For example, the Phase 2 Coyote Percolation Dam CM would be constructed at the existing Coyote Percolation Pond, where managed groundwater recharge operations occur; thus, any releases of hazardous materials at this location could have a direct path to the groundwater aquifer below. Similarly, construction activities within the Coyote Creek channel associated with the Ogier Ponds CM could have elevated potential for groundwater contamination (associated with hazardous materials releases), since water readily percolates through the Coyote Creek streambed to the groundwater table. Construction activities associated with the Sedimentation Augmentation Program, Maintenance of the North Channel Reach ~~Extension~~, and Maintenance at Live Oak Restoration Reach would consist of grading, placement of clean materials in the creek for habitat restoration purposes, and/or maintenance activities. The construction activities associated with these conservation measures would not have elevated potential for groundwater contamination (associated with hazardous materials releases).

As discussed above, compliance with the Construction General Permit, including preparation and implementation of a SWPPP, as well as implementation of Valley Water BMPs and VHP conditions and AMMs, would minimize potential impacts due to hazardous materials releases. This includes BMPs ~~HM-7~~, HM-8, HM-9, and HM-10, which would include protocols for providing secondary containment for hazardous materials used in the field or stored at staging areas or at work sites, and providing training and spill cleanup materials for field personnel, among other measures. Additionally, VHP AMMs 7, 8, 9, 11, 12, 72, 75, 76, 87, and 88 would include a number of measures that would help to protect groundwater quality, such as requiring that spill prevention kits be kept onsite and equipment servicing be performed outside of the stream channel or floodplain, unless the equipment cannot be readily relocated (i.e., pumps, generators). Given implementation of these measures, the impacts on groundwater quality from Conservation Measure components construction would be less than significant.

Post-Construction Anderson Dam Facilities Operations and Maintenance

Over the long term, the Seismic Retrofit components of the Project would be beneficial (or at least not adverse) with respect to groundwater quality. As discussed under Impact GW-1, following the completion of construction, the seismic safety restriction that has been in effect since 2009 would be lifted, allowing Valley Water to utilize the full capacity (roughly 89,000 AF) of Anderson Reservoir. This would enable more water to be stored in the reservoir to support dry season releases for the purpose of groundwater recharge; thus, potentially resulting in better maintenance of groundwater storage/levels in Coyote Valley. As shown in **Figure 3.12-7**, however, these benefits would be modest and could be partially offset by the release of greater quantities of water for fish passage purposes pursuant to FAHCE. The WEAP modeling shows that storage in the Coyote Valley under the 2035 Post Construction FAHCE scenario would be virtually unchanged relative to the future conditions baseline (2035 Post Construction Base) and/or Pre-FERC Order Conditions Baseline (2015 Base Conditions). Thus, reductions in groundwater levels would not cause significant groundwater quality impacts.

Post-Construction Conservation Measures Operations and Maintenance

Post-construction operations of the Conservation Measure components similarly would not significantly impact groundwater quality. Generally, the improvements would operate unattended and the in-stream components would not include any substances or materials that could contaminate groundwater. Routine maintenance of both the Seismic Retrofit components (pursuant to the DMP) and CMs could involve small quantities of hazardous materials (e.g., fuel, oil, pesticides, etc.), which may be utilized in areas where a direct pathway to the groundwater exists, such as within or adjacent to Coyote Creek. Thus, there would be some potential for impacts to groundwater quality to occur, if hazardous materials were to be released or used improperly. However, implementation of Valley Water BMPs, as well as VHP conditions and AMMs, would avoid or reduce these potential impacts to a level that is less than significant. Ongoing monitoring activities would not substantially adversely affect groundwater quality. Therefore, overall, during the post-construction period, groundwater quality impacts would be less than significant.

Significance Conclusion Summary

During Seismic Retrofit construction, implementation of the SWPPP for out-of-reservoir construction activities and applicable Valley Water BMPs and VHP conditions and AMMs would avoid or substantially reduce potential impacts on groundwater quality from accidental releases of hazardous materials, resulting in a **less than significant i**mpact. While not required to reduce impacts to less than significant, Mitigation Measure WQ-1 would further reduce these impacts by requiring implementation of a WQMPP for in-reservoir construction activities, which would include evaluation of the water quality monitoring data collected during FOCP implementation and Project construction, and implementation of BMPs to control hazardous materials and other pollutants associated with in-reservoir construction activities to the extent technically feasible and in accordance with regulatory requirements.

Similarly, implementation of imported water releases (via the CDL and Cross Valley Pipeline Extension) would maintain groundwater levels in the managed aquifer (Coyote Valley) at acceptable levels during Seismic Retrofit construction, thus limiting potential associated impacts on groundwater quality in this area. Reduced groundwater levels in the area immediately surrounding Anderson Reservoir associated with reservoir dewatering could temporarily impact groundwater quality; however, the quality would rebound following reservoir refilling and impacts on specific well owners would be reduced through **Mitigation Measure GW-1**.

Blasting at BHBA could release perchlorates and other water-soluble nitrogen-compounds. With the implementation of **Mitigation Measure GW-2**, and compliance with the General Construction Permit, which requires controls for pollutants from blasting, the impact from blasting activities during Seismic Retrofit component construction would not degrade groundwater quality. The impact would be reduced**.**

Implementation of the SWPPP for out-of-reservoir construction activities and applicable Valley Water BMPs and VHP conditions and AMMs would similarly avoid or reduce impacts due to hazardous materials releases during the Conservation Measure components construction, as well as during routine maintenance activities in the post-construction period for the Conservation Measure components and the Seismic Retrofit components. Monitoring activities (during construction and in the post-construction period) would not substantially affect groundwater quality. Therefore, the Project would not violate groundwater quality standards or substantially degrade groundwater quality, and groundwater quality impacts would be **less than significant with mitigation**.

Mitigation Measures

GW-1 Provide Alternative Water Supplies

GW-2 Perchlorate Best Management Practices

To minimize the risk of perchlorates from explosives Valley Water and/or the contractor will do the following:

- Conduct a thorough assessment of the explosives to be used, identifying perchlorate content and potential alternatives with lower perchlorate levels.
- If more than 500 pounds of solid perchlorate material or 55 gallons of liquid perchlorate material is on-site at any one time, submit to DTSC a one-time notification about their perchlorate materials and related activities.
- Train personnel in proper handling techniques to minimize perchlorate release during explosive loading, assembly, and transportation.
- Store explosives in secure and properly designed magazines to prevent leaks or spills that could lead to perchlorate contamination of the surrounding environment.
- Dispose of perchlorate-containing solid material to either a hazardous waste landfill or a composite-lined portion of a non-hazardous waste landfill.
- Collect and properly dispose any spills of perchlorate products.
- Collected and properly manage any un-ignited explosive material found during the inspection of the site after blasting work.

Impact GW-3: Conflict with or obstruct implementation of the San Francisco Bay Basin Plan groundwater provisions or the District's GWMP **(Less than Significant with Mitigation)**

Seismic Retrofit Construction

As described in Section 3.12.1.2, the San Francisco Bay Basin Plan identifies beneficial uses for surface waters and groundwater within the San Francisco Bay region and establishes narrative and numerical WQOs to achieve the beneficial uses for those waters. **Figure 3.12-2** shows that the following beneficial uses are designated as existing for the Santa Clara Subbasin: AGR, MUN, IND, and PROC (San Francisco Bay RWQCB 2019). Generally, all of these beneficial uses are dependent upon high quality water and the maintenance of existing high quality of groundwater is the primary groundwater objective in the San Francisco Bay Basin Plan (San Francisco Bay RWQCB 2019). Thus, to the extent an aspect of the Project could substantially affect the existing groundwater quality, this would be considered a conflict with the implementation of the San Francisco Bay Basin Plan. It should be noted that the San Francisco Bay Basin Plan applies to all subsurface waters, whether or not those waters meet the classic definition of an aquifer[3] or occur within identified groundwater basins.[4]

[3] Where groundwater occurs in a saturated geologic unit that contains sufficient permeable thickness to yield significant quantities of water to wells and springs, it can be defined as an aquifer.
[4] A groundwater basin is defined as a hydrogeologic unit containing one large aquifer or several connected and interrelated aquifers.

Valley Water's GWMP for the Santa Clara and Llagas Subbasins (Valley Water 2021) describes a comprehensive groundwater management framework, including existing and potential actions to achieve basin sustainability goals and ensure continued sustainable groundwater management. In addition to goals and objectives for protection of groundwater quality, the GWMP includes the goal to "manage groundwater to ensure sustainable supplies and avoid land subsidence" (Valley Water 2021). Specific sustainability indicators and outcome measures from the GWMP are shown in **Table 3.12-3** ~~**Figure 3.12-3.**~~ As discussed above under Impact GW-1, of particular relevance to the Project, the outcome measure with respect to groundwater storage in the Coyote Valley (immediately downstream of Anderson Dam) is projected end of year groundwater storage of greater than 5,000 AF. For the groundwater quality sustainability indicator, the outcome measure for the Santa Clara Subbasin water supply wells is that "at least 95 percent meet primary drinking water standards, and at least 90 percent have stable or decreasing trends for [TDS]" (Valley Water 2021).

As discussed in Impact GW-1 and GW-2, implementation of imported water releases during the seismic retrofit construction process would limit potential impacts on the mapped Coyote Valley basin (i.e., reductions in groundwater storage, potentially also leading to groundwater quality impacts) – refer to **Figure 3.12-6**. In particular, the imported water releases would maintain groundwater storage in the Coyote Valley above the 5,000 AF GWMP outcome measure, based on modeling that accounts for dry years that could occur during the seismic retrofit construction period. This would also avoid substantial impacts on GDEs, such as those located along Coyote Creek near Ogier Ponds and the Coyote Percolation Pond (refer to **Figure 3.12-4**), since groundwater levels would not drop substantially. Maintaining the reservoir in a dewatered state during the construction period would have potential to impact groundwater levels (e.g., due to reduced percolation and hydraulic head) in the area immediately surrounding the reservoir. Although this area is outside of the mapped basin/aquifer, there are several water production wells located there that could be adversely affected, including reductions in water quality or going dry. However, implementation of **Mitigation Measure GW-1** will reduce these potential adverse effects on well owners by providing alternative supplies to individuals or entities whose well(s) are affected.

Additionally, while use of hazardous materials (e.g., contained in construction equipment) during Seismic Retrofit construction could potentially result in impacts on groundwater quality (e.g., if such materials were to leak from the equipment or otherwise be released to the environment); implementation of the SWPPP for out-of-reservoir construction activities and applicable Valley Water BMPs and VHP conditions and AMMs would assure these potential impacts would be less than significant.

Therefore, the seismic retrofit construction process would not conflict with or impair the existing beneficial uses of groundwater in the Santa Clara Subbasin, nor would it conflict with the goals and objectives in the GWMP for protection of groundwater from contamination. Drinking water standards are met for most public supply wells throughout the subbasin without the need for treatment beyond disinfection (Valley Water 2021), and the Seismic Retrofit construction process would not affect the ability for the subbasin to continue to meet these standards, in accordance with GWMP outcome measure.

Overall, given that Seismic Retrofit construction will not (1) substantially affect groundwater storage in the Coyote Valley; (2) adversely affect groundwater well owners in areas immediately surrounding Anderson Reservoir given implementation of **Mitigation Measure GW-1**, or (3) adversely affect groundwater quality with implementation of the SWPPP for out-of-reservoir construction activities and applicable measures – it will not conflict with or obstruct implementation of either the San Francisco Bay Basin Plan or Valley Water's GWMP. As such, impacts would be less than significant with mitigation.

Conservation Measures Construction

Construction of Conservation Measures would have potential to result in similar types of impacts as the seismic retrofit construction, albeit to a lesser extent. Several of the Conservation Measures (i.e., Ogier Ponds Conservation Measure, Maintenance of the North Channel Reach ~~Extension~~, and Phase 2 Coyote Percolation Dam CM) would require localized dewatering during construction; however, this would not substantially adversely affect groundwater supplies, levels, or quality in the subbasin. Likewise, implementation of the SWPPP, Valley Water BMPs, and VHP conditions and AMMs would avoid or reduce potential effects on groundwater quality from use of hazardous materials (e.g., fuel, oil, etc.) during construction. Therefore, given implementation of the applicable measures, Conservation Measures construction would not conflict with or obstruct implementation of the San Francisco Bay Basin Plan or the GWMP. Impacts would be less than significant.

Post-Construction Anderson Dam Facilities Operations and Maintenance

Once the Seismic Retrofit components are constructed, they would provide Valley Water with improved operational flexibility to manage the reservoir for multiple benefits, including groundwater recharge. The ~~seismic~~ restriction in place at Anderson Dam since 2009 will be lifted, allowing Valley Water to utilize the full reservoir capacity (roughly 89,000 AF). Generally, this would have a positive effect on groundwater storage/supplies in the post-construction period and would improve Valley Water's ability to implement its GWMP. However, this may be somewhat counteracted by the need to release more water for fish passage purposes pursuant to FAHCE. WEAP modeling shows that groundwater storage in the Coyote Valley would not change substantially relative to baseline (both the future conditions baseline and Pre-FERC Order Conditions Baseline) with implementation of the Project, including the FAHCE operating rules. Nevertheless, groundwater storage would remain well above the 5,000 AF GWMP outcome measure for the Coyote Valley in the 2035 Post Construction FAHCE scenario; thus, operation of the Project would not conflict with or obstruct implementation of the GWMP.

As operation of the Seismic Retrofit components of the Project (including the FAHCE operating rules) would not result in substantial reductions in groundwater supplies or levels, it would not substantially affect groundwater quality. No other aspects of the Seismic Retrofit operation would substantially affect groundwater quality.

During routine maintenance activities in the post-construction period, use of hazardous materials (e.g., fuel, oil, pesticides, etc.) could create the opportunity for accidental releases of such materials (or improper use) and subsequent impacts on groundwater quality. This would include maintenance of the seismic retrofit components, pursuant to the DMP, as well as maintenance of the Conservation Measures. However, continued implementation of applicable Valley Water BMPs and VHP conditions and AMMs would reduce the potential impacts to a level that is less than significant, such that there would be no impairment of existing groundwater beneficial uses. Monitoring activities during the post-construction period would not adversely affect groundwater.

Therefore, Seismic Retrofit components and Conservation Measures components post-construction operations, maintenance, and monitoring would not conflict with or obstruct implementation of the San Francisco Bay Basin Plan or Valley Water's GWMP. Impacts would be less than significant.

Significance Conclusion Summary

Given implementation of imported water releases (via the CDL and CVP Extension), Seismic Retrofit construction (including reservoir dewatering) would not substantially reduce groundwater supplies in downstream aquifers, including the Coyote Valley. Additionally, with implementation of **Mitigation Measure GW-1**, Seismic Retrofit construction would not substantially affect groundwater well owners in the area immediately surrounding Anderson Reservoir. Use of hazardous materials (e.g., fuel, oil, etc.) during Seismic Retrofit and Conservation Measure construction could potentially impact groundwater quality; however, implementation of the SWPPP for out-of-reservoir construction activities, and applicable Valley Water BMPs and VHP conditions and AMMs would assure these potential impacts would be **less than significant**. While not required to reduce impacts to less than significant, Mitigation Measure WQ-1 would further reduce these impacts by requiring implementation of a WQMPP for in-reservoir construction activities, which would include evaluation of the water quality monitoring data collected during FOCP implementation and Project construction, and implementation of BMPs to control hazardous materials and other pollutants associated with in-reservoir construction activities to the extent technically feasible and in accordance with regulatory requirements.

During the post-construction period, WEAP modeling shows that implementation of FAHCE operating rules would not substantially change groundwater storage in the Coyote Valley, while implementation of applicable measures would avoid or reduce any potential impacts on groundwater quality from use of hazardous materials during routine maintenance of Seismic Retrofit components and Conservation Measure components. Monitoring activities would not adversely affect groundwater. Therefore, overall, with implementation of **Mitigation Measure GW-1**, the Project will not conflict with or obstruct implementation of the San Francisco Bay Basin Plan or Valley Water's GWMP. Therefore, impacts would be **less than significant with mitigation**.

Mitigation Measures

GW-1 Provide Alternative Water Supplies

3.12.5 Cumulative Impacts

The geographic study area for the cumulative impact analysis for Groundwater is the parts of Santa Clara County over the Santa Clara and Llagas Subbasins managed by Valley Water.

This section describes the Project's contribution to cumulative groundwater impacts, as summarized in **Table 3.12-4**.

1 **Table 3.12-4. Summary of Project Impact Contribution to Cumulative Groundwater Impacts**

Impact	Cumulatively Significant with FOCP?	Cumulatively Significant with other projects?	Incremental Project Contribution	Applicable Project Mitigation	Cumulatively Considerable after Mitigation?
Cumulative Impact GW-1: Substantially decrease groundwater supplies or interfere substantially with ground-water recharge such that the project may impede sustainable groundwater management of the basin	Yes	No	CC	MM GW-1	No
Cumulative Impact GW-2: Substantially degrade groundwater quality	Yes	No	CC	MM GW-1 MM GW-2	No
Cumulative Impact GW-3: Conflict with or obstruct implementation of the San Francisco Bay Basin Plan groundwater provisions or the District's GWMP	Yes	No	CC	MM GW-1	No

2 *Key: CC = cumulatively considerable; MM = Mitigation Measure*

Cumulative Impact GW-1: Substantially decrease groundwater supplies or interfere substantially with ground-water recharge such that the project may impede sustainable groundwater management of the basin **(Not Cumulatively Considerable)**

The loss of storage in Anderson Reservoir would greatly limit the amount of water that could be released from the reservoir for the purpose of groundwater recharge along Coyote Creek. As described in Section 3.12.1, Anderson Reservoir plays a critical role in supporting groundwater recharge in the Santa Clara Subbasin. In particular, the Coyote Valley management area is totally groundwater dependent. The dewatering of Anderson Reservoir during the 7-year Seismic Retrofit construction period could impact nearby wells outside of the groundwater basin/managed aquifer.

Seismic Retrofit construction could impact groundwater due to deposition of fine sediment in Coyote Percolation Pond and within Coyote Creek, potentially resulting in reduced recharge rates. As described in Section 3.11, *Hydrology*, modeling shows that up to 0.5 inches of sediment deposition could occur in Metcalf Ponds (i.e., the ponds upstream of the Coyote Percolation Dam) following a 5-year storm event, while 0.3 inches could accumulate following a 2-year storm event. Most of the sediment that could be deposited in the pond would likely be fine-grained, since it would have been transported in the discharges from Anderson Reservoir.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if their construction, restoration, or operation would decrease groundwater supplies or interfere with groundwater recharge in the Santa Clara or LLagas Subbasins such that the sustainable groundwater management of the basin would be impeded.

Cumulative Effects of Project with the FOCP

The FOCP lowered the storage behind Anderson Reservoir to deadpool which reduces available local supplies to be released by the reservoir for groundwater recharge in Coyote Creek and the Coyote Percolation Pond. However, the FOCP also includes the Cross Valley Pipeline Extension and chillers at Anderson Reservoir that increase the flexibility in using imported water for groundwater recharge.

The Project would not substantially affect groundwater storage or recharge. WEAP modeling shows that groundwater storage in the Coyote Valley would remain above the 5,000 GWMP outcome measure, given implementation of imported water releases in Coyote Creek. Groundwater resources along the downstream Santa Clara Plain would not be substantially affected by the seismic retrofit construction since this area of the subbasin (1) begins further downstream along Coyote Creek (approximately 10 miles downstream from Anderson Dam); (2) is much larger than the Coyote Valley management area in terms of area and storage capacity, and (3) has many additional sources of natural and artificial recharge (e.g., West Side Recharge System, Los Gatos Recharge System, Guadalupe Recharge System, and Penitencia Recharge System). Continued implementation of Valley Water's existing maintenance program at the Coyote Percolation Pond, which includes discing or removal of accumulated sediment, as needed to maintain recharge/percolation rates, would assure effects on groundwater supplies are minimized. The impacts of the Project when added to the FOCP's impacts to groundwater supplies within the Valley Water managed groundwater basins are not cumulatively significant, and the Project's contribution is not cumulatively considerable.

The dewatering of Anderson Reservoir during FOCP could impact nearby wells outside of the groundwater basin/managed aquifer, which would be extended by the Project. The Project's impact when added to the FOCP's impact to wells to Anderson Reservoir is cumulatively significant and the Project's contribution is cumulatively considerable.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Other projects that could impact groundwater supplies in Santa Clara County include development projects throughout the County that use groundwater as a source for water supply. New development in the County typically increases the demand for groundwater, although new development is subject to building code requirements that minimize water demand with water efficient water fixtures and landscaping. These projects could also increase impervious surfaces that can reduce natural groundwater recharge that occurs in the confined regions of the Santa Clara and Llagas Groundwater Basins. Other projects would be required to comply with applicable Municipal Stormwater NPDES permits that minimize the impact of expanded impervious surfaces.

The Project would not substantially affect groundwater storage or recharge. WEAP modeling shows that groundwater storage in the Coyote Valley would remain above the 5,000 GWMP outcome measure and groundwater resources in the Santa Clara Plain have many additional sources of natural and artificial recharge. The impact of the Project when added to the impacts of other probable future projects to groundwater supplies within the Valley Water managed groundwater basins is not cumulatively significant, and the Project's contribution is not cumulatively considerable.

There are no known probable future projects in the area around Anderson Reservoir that would rely on groundwater that are not part of the managed groundwater basin. Although the Project would have a significant impact on wells outside of the groundwater basin/managed aquifer adjacent to Anderson Reservoir, this impact would not be cumulatively significant with other probable future projects, and the Project's impacts would not be cumulatively considerable.

Significance Conclusion Summary

The Project's activities would not substantially affect groundwater storage/supplies or recharge, and the increase in population and jobs resulting from new development is accounted for in Valley Water's UWMP. Impacts to groundwater supplies within the Valley Water managed groundwater basins are not cumulatively significant, and the Project's contribution is not cumulatively considerable.

However, the dewatering of Anderson Reservoir during the 7-year Seismic Retrofit construction period, in addition to the four years of FOCP construction, could impact nearby wells outside of the groundwater basin/managed aquifer which would be cumulatively significant, and the Project's contribution would be cumulatively considerable. However, implementing **Mitigation Measure GW-1** (Provide Alternative Water Supplies) would ensure that those with wells impacted by the Project would have an adequate water supply. With mitigation, the Project's contribution to a substantial decrease in groundwater supplies or substantial interference with ground-water recharge such that the project may impede sustainable groundwater management of the basin is **not cumulatively considerable.**

Mitigation Measures

GW-1 Provide Alternative Water Supplies

Cumulative Impact GW-2: Substantially degrade groundwater quality **(Not Cumulatively Considerable)**

Construction equipment to be used during construction and maintenance activities would contain hazardous materials, such as fuel, oil, lubricants, etc. that can degrade groundwater quality if spilled or improperly handled. If the dewatering and reduced reservoir releases construction were to result in substantially lower groundwater levels, this could lead to adverse groundwater quality impacts. One of the consequences of a reduction in groundwater storage can be a deterioration of water quality (USGS 2023 ~~2023b~~). **Mitigation Measure GW-1** (Provide Alternative Water Supplies) would reduce this impact to less than significant levels.

The Project could impact groundwater quality using explosives that contain perchlorate and other nitrogen-based chemicals which could cause groundwater pollution at the Project level. This impact would be significant, but **Mitigation Measure GW-2** (Perchlorate Best Management Practices) would reduce the impact to less-than-significant levels.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if their construction, restoration, or operation could degrade groundwater quality in the Santa Clara or LLagas Subbasins.

Cumulative Effects of Project with the FOCP

The FOCP would have similar impacts from the use of heavy equipment and the use of hazardous materials to groundwater quality. The FOCP lowered the storage behind Anderson Reservoir to deadpool, which reduces available local supplies to be released by the reservoir for groundwater recharge in Coyote Creek and the Coyote Percolation Pond. However, the FOCP also includes the Cross Valley Pipeline Extension and chillers at Anderson Reservoir that increase the flexibility in using imported water for groundwater recharge.

Both projects would comply with the Construction General Permit, including preparation and implementation of a SWPPP, as well as implementation of Valley Water BMPs to minimize potential impacts due to hazardous materials releases. These include BMPs ~~HM-7,~~ HM-8, HM-9, and HM-10, which would include protocols for providing secondary containment for hazardous materials used in the field or stored at staging areas or at work sites and providing training and spill cleanup materials for field personnel, among other measures. With implementation of a SWPPP and BMPs, the impacts of the Project and the FOCP to the degradation of groundwater quality through the release of hazardous materials is not cumulatively significant, and the Project's contribution is not cumulatively considerable.

The Project could impact groundwater quality using explosives that contain perchlorate and other nitrogen-based chemicals which could cause groundwater pollution at the Project level. The FOCP would not ~~could also potentially~~ use explosives in constructing the outlet tunnel that may contain perchlorate or other nitrogen-based chemicals. ~~The cumulative risk to groundwater pollution is significant and the Project's contribution is cumulatively considerable~~.

The dewatering of Anderson Reservoir during FOCP could impact nearby wells outside of the groundwater basin/managed aquifer, which would be extended by the Project. Potentially reducing groundwater levels in wells near Anderson Reservoir could concentrate pollutants that are present and degrade groundwater quality. The impact to the degradation of groundwater quality through a reduction in available groundwater supplies outside of the managed groundwater basin is cumulatively significant with the FOCP and the Project's contribution is cumulatively considerable.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Most projects listed in **Table 3.0-1** involve the use of equipment that use hazardous materials similar to those used by the Project in construction and maintenance activities. All projects would comply with the Construction General Permit, including preparation and implementation of a SWPPP.

Other projects that could impact groundwater supplies in Santa Clara County include development projects throughout the County that use groundwater as a source for water supply. New development in the County typically increases the demand for groundwater, although new development is subject to building code requirements that minimize water demand with water efficient water fixtures and landscaping. These projects could also increase impervious surfaces that can reduce natural groundwater recharge that occurs in the confined regions of the Santa Clara and Llagas Groundwater Basins. Other projects would be required to comply with applicable Municipal Stormwater NPDES permits that minimize the impact of expanded impervious surfaces.

The Project could impact groundwater quality using explosives that contain perchlorate and other nitrogen-based chemicals which could cause groundwater pollution at the Project level. There are no other probable future projects that would have a similar, cumulative impact.

Given the implementation of a SWPPP and BMPs as discussed above with the FOCP, the cumulative impact to groundwater quality within the Valley Water managed groundwater basins is not cumulatively significant with impacts from other probable future projects, and the Project's contribution is not cumulatively considerable.

There are no known probable future projects in the area around Anderson Reservoir that would rely on groundwater that is not part of the managed groundwater basin. The cumulative impact to wells near Anderson Reservoir outside of the groundwater basin/managed aquifer is not cumulatively considerable with other projects.

Significance Conclusion Summary

The Project's activities contribution to the degradation of groundwater quality through the release of hazardous materials with the implementation of a SWPPP <u>for out-of-reservoir construction activities</u> and <u>applicable</u> Valley Water BMPs is not cumulatively significant with impacts from other probable future projects, and the Project's contribution is not cumulatively considerable. <u>While not required to reduce impacts to less than significant, Mitigation Measure WQ-1 would further reduce these impacts by requiring implementation of a WQMPP for in-reservoir construction activities, which would include evaluation of the water quality monitoring data collected during FOCP implementation and Project construction, and implementation of BMPs to control hazardous materials and other pollutants associated with in-reservoir construction activities to the extent technically feasible and in accordance with regulatory requirements</u>.

The Project ~~and FOCP~~ could both pollute groundwater resources through the introduction of perchlorates or other nitrogen-based chemicals by blasting activities. ~~The cumulative impact with FOCP would be significant, and the Project's contribution would be cumulatively considerable~~. Implementation of **Mitigation Measure GW-2** (Perchlorate Best Management Practices) would ensure that risks to groundwater pollution are minimized and the Project's contribution is not **cumulatively considerable**.

The dewatering of Anderson Reservoir during the 7-year Seismic Retrofit construction period in addition to the four years of FOCP construction could impact nearby wells outside of the groundwater basin/managed aquifer. The cumulative impact with FOCP would be significant, and the Project's contribution would be cumulatively considerable. Implementing **Mitigation Measure GW-1** (Provide Alternative Water Supplies) would ensure that those with wells impacted by the Project would have an adequate water supply, preventing degraded groundwater quality from affecting local groundwater supplies. The Project's contribution to impacts that substantially degrade groundwater quality is **not cumulatively considerable.**

Mitigation Measures

GW-1 Provide Alternative Water Supplies

GW-2 Perchlorate Best Management Practices

Cumulative Impact GW-3: Conflict with or obstruct implementation of the San Francisco Bay Basin Plan groundwater provisions or the District's GWMP (Not Cumulatively Considerable)

As described in Section 3.12.2.2, the San Francisco Bay Basin Plan identifies beneficial uses for surface waters and groundwater within the San Francisco Bay region and establishes narrative and numerical WQOs to achieve the beneficial uses for those waters. Valley Water's GWMP for the Santa Clara and Llagas Subbasins (Valley Water 2021) describes a comprehensive groundwater management framework, including existing and potential actions to achieve basin sustainability goals and ensure continued sustainable groundwater management.

As discussed in Impacts GW-1 and GW-2, the reduction in available supplies for groundwater recharge and the use of hazardous material during construction and maintenance could interfere with the beneficial uses identified for groundwater resources in Santa Clara County and achieving the goals of the GWMP.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if their construction, restoration, or operational would interfere with groundwater availability and quality in the Santa Clara or LLagas Subbasins.

Cumulative Effects of Project with the FOCP

The FOCP lowered the storage behind Anderson Reservoir to deadpool, which reduces available local supplies to be released by the reservoir for groundwater recharge in Coyote Creek and the Coyote Percolation Pond. However, the FOCP also includes the Cross Valley Pipeline Extension and chillers at Anderson Reservoir that increase the flexibility in using imported water for groundwater recharge. The FOCP would also have similar impacts from the use of heavy equipment and the use of hazardous materials to groundwater quality.

The Project would not substantially affect groundwater storage or recharge. WEAP modeling shows that groundwater storage in the Coyote Valley would remain above the 5,000 GWMP outcome measure, given implementation of imported water releases in Coyote Creek. Groundwater resources along the downstream Santa Clara Plain would not be substantially affected by the seismic retrofit construction. The impacts of the Project and FOCP together are not cumulatively significant. The cumulative impact of the Project to achieving Basin Plan and GWMP goals is not cumulatively considerable.

The dewatering of Anderson Reservoir during FOCP could impact nearby wells outside of the groundwater basin/managed aquifer, which would be extended by the Project. This is a cumulatively significant impact and the Project's contribution to achieving Basin Plan and GWMP goals is cumulatively considerable.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Other projects that could impact groundwater supplies and quality in Santa Clara County include development projects throughout the County that use groundwater as a source for water supply. New development in the County typically increases the demand for groundwater, although new development is subject to building code requirements that minimize water demand with water efficient water fixtures and landscaping. These projects could also increase impervious surfaces that can reduce natural groundwater recharge that occurs in the confined regions of the Santa Clara and Llagas Groundwater Basins. Other projects would be required to comply with applicable Municipal Stormwater NPDES permits that minimize the impact of expanded impervious surfaces. These other projects also involve the use of equipment that use hazardous materials similar to those used by the Project in construction and maintenance activities. All projects are required to comply with the Construction General Permit, including preparation and implementation of a SWPPP.

The Project would not substantially affect groundwater storage or recharge. WEAP modeling shows that groundwater storage in the Coyote Valley would remain above the 5,000 GWMP outcome measure and groundwater resources in the Santa Clara Plain have many additional sources of natural and artificial recharge. The impacts to groundwater supplies within the Valley Water managed groundwater basins of the Project when added to other probably future projects is not cumulatively significant, and the Project's impacts to groundwater supplies within the Valley Water managed groundwater basins is not cumulatively considerable.

There are no known probable projects in the area around Anderson Reservoir that would rely on groundwater that is not part of the managed groundwater basin. The Project's impact to nearby wells outside of the groundwater basin/managed aquifer is not cumulative with other projects.

Significance Conclusion Summary

Given implementation of imported water releases, Seismic Retrofit construction (including reservoir dewatering) would not substantially reduce groundwater supplies in downstream aquifers, including the Coyote Valley. Additionally, with implementation of **Mitigation Measure GW-1** (Provide Alternative Water Supplies), Seismic Retrofit construction would not substantially affect groundwater well owners in the area immediately surrounding Anderson Reservoir. Use of hazardous materials (e.g., fuel, oil, etc.) construction and maintenance could potentially impact groundwater quality; however, implementation of the SWPPP <u>for out-of-reservoir construction activities</u>, and applicable Valley Water BMPs assure these potential cumulative impacts to achieving Bay Plan and GWMP goals would be not be cumulatively significant with impacts from other probable future projects, and the Project's impacts are **not cumulatively considerable.** While not required to reduce impacts to less than significant, Mitigation Measure WQ-1 would further reduce these impacts by requiring implementation of a WQMPP for in-reservoir construction activities, which would include evaluation of the water quality monitoring data collected during FOCP implementation and Project construction, and implementation of BMPs to control hazardous materials and other pollutants associated with in-reservoir construction activities to the extent technically feasible and in accordance with regulatory requirements.

3.13 Water Supply

This section summarizes the environmental and regulatory setting related to water supply in the context of the Project. The study area for this analysis includes Valley Water's water supply system, with a focus on Anderson Reservoir and Coyote Creek. Since Valley Water receives imported water from San Luis Reservoir, the analysis considers these supplies and the water conveyance facilities that transfer imported water to the county. This section also presents the impact analysis methodology and evaluates the impacts to water supply that may occur as a result of the construction and operation of the Project.

3.13.1 Environmental Setting

3.13.1.1 Water Supplies and Demands

Supplies

About half of the county's water supply currently comes from local sources, and the other half comes from imported water sources. Imported water includes Valley Water's State Water Project and CVP contract supplies, and supplies delivered by the San Francisco Public Utilities Commission (SFPUC) to cities in the northern county. Valley Water currently has 20 appropriative water rights licenses and one filed water right permit with the SWRCB totaling over 227,000 AF of water per year (AFY) (Valley Water 2021a ~~2021~~). However, currently all surface water supplies for Valley Water are constrained by an average of 44,000 AFY because of operating restrictions on local reservoirs for seismic safety (Valley Water 2021b). Water rights are shown in **Figure 3.13-1.**

Valley Water has a contract with the DWR for 100,000 AFY of State Water Project water and a contract with the Bureau of Reclamation for 152,500 AFY of CVP water; however, the actual amount of water allocated under these contracts each year is typically less than these contractual amounts and depends on hydrological and regulatory restrictions. **Table 3.13-1** shows an estimate of future water supplies to Valley Water from each source. Valley Water's basic water supply strategy to compensate for supply variability is to store excess wet year supplies in the groundwater subbasins, local reservoirs, San Luis Reservoir, and the Semitropic Groundwater Storage Bank,[1] and then draw from these stored supplies during dry years to help meet demands. Based on projected demands, and existing and planned sources of supply, Valley Water estimates that it would be able to meet countywide demands through 2045 under normal, a single dry, and 5 consecutive dry year conditions (Valley Water 2021b).

[1] The Semitropic Groundwater Storage Bank is a groundwater banking facility in Kern County that Valley Water invests in. Water is delivered to the bank when surplus supplies are available and withdrawn when supplies are limited.

Table 3.13-1. Valley Water Projected Average Water Supplies (Acre-Feet)

Water Supply[1]	2025	2030[2]	2035	2040	2045
Surface Water	30,000	70,000	185,000	185,000	185,000
Imported Water	130,000	134,000	136,000	139,000	142,000
SFPUC Supply	55,000	56,000	59,000	61,000	63,000
Local Groundwater Storage	140,000	164,000	163,000	162,000	162,000
Out-of-County Storage	75,000	75,000	75,000	70,000	70,000
Recycled Water (non-potable)	16,000	19,000	22,000	26,000	28,000
Total	446,000	518,000	640,000	643,000	650,000

Source: Valley Water 2021b

Notes:

[1] Recycled water, SFPUC supply, and groundwater storage are rounded to the nearest 1,000 AF. All other supplies are rounded to the nearest 5,000 AF. Supplies shown are based on modeled estimates of available supplies. Actual availability during any given year depends on hydrology, groundwater recharge operations and conditions, regulatory requirements, and other factors. Groundwater storage shown assumes groundwater can be drawn down to the severe stage of the WSCP. This does not represent ~~a~~ sustainable long-term groundwater conditions, but these supplies represent water that may be needed to get through a prolonged drought. Imported water allocations are provided by DWR in their Delivery Capability Report 2019, which does not include any projected changes to future regulations nor the hydrologic sequence for the 2012-2016 drought. For comparison, the lowest total annual imported delivery during the 1987-1992 drought in the Delivery Capability Report 2019 dataset is 83,200 AF, while the actual lowest imported delivery during the 2012-2016 drought was 60,320 AF. However, through Valley Water's Monitoring and Assessment Program, Valley Water is conservatively planning for investments by considering severe droughts, such as the 2012-2016 drought, will occur in the future. Projects included in the supply projections include transfer Bethany pipeline (2025); Project and potable reuse (2030; see note 2 below); Guadalupe, Calero, and Almaden Dam seismic retrofits and Pacheco Reservoir Expansion (2035); and an additional 35,000 AF of conservation (to reach Valley Water's goal of 109,000 AF by 2040 with a 1992 baseline).

[2] The surface water supplies jump of 40,000 AF reflects the completion of Project and available runoff to fill Anderson Reservoir; though Project completion is not anticipated until sometime after 2030. ~~However, since the UWMP was prepared, the estimated completion date for Project has been revised to 2032~~.

As shown in **Table 3.13-1**, imported water and local groundwater storage account for the bulk of Valley Water's supplies in the near term; however, surface water supplies increase from 70,000 AFY to 185,000 AFY in 2035. This partly reflects the completion of various Valley Water projects, including the ADSRP, such that Anderson Dam can be brought back online and the reservoir filled to capacity.

Demands

Water use in the county includes domestic, municipal, industrial, and agricultural use. The countywide average 10-year water use for 2001-2019 is 315,532 AFY. However, actual water used changes from year to year and is influenced by a number of factors that include population growth, hydrology, water conservation, drought, and economic conditions. The countywide water use figure represents total use of Valley Water supply, SFPUC supply, and San José Water Company and Stanford University water rights. Largely due to Valley Water's conservation efforts and changing use patterns by the public, overall water use in the county has decreased over the past 15 years despite a 25 percent increase in population (Valley Water 2021b). Actual use of Valley Water's supply in 2020 was estimated at approximately 308,600 AFY (Valley Water 2023a).

Generally, due to increasing retailer demand associated with population growth over time, water demands within the county are projected to increase in the future. However, the projected increase is fairly modest, even out to 2045. The projected countywide demands are shown in **Table 3.13-2**.

Table 3.13-2. Projected Countywide Demand

Land Use	Projected Water Use (Acre-Feet)[1]				
	2025	**2030**	**2035**	**2040**	**2045**
Retailer Demand	288,000	280,000	285,000	290,000	299,000
Agricultural Irrigation	25,000	25,000	25,000	25,000	25,000
Independent Groundwater Pumping	14,000	14,000	14,000	14,000	14,000
Untreated Surface Water	2,000	2,000	2,000	2,000	2,000
Losses	3,000	3,000	3,000	3,000	3,000
Total	330,000	325,000	330,000	335,000	345,000

Notes:

[1] Total numbers are rounded to the nearest 5,000 AF. All other numbers are rounded to the nearest 1,000 AF. The numbers represent countywide demands, which are partially served by the SFPUC, recycled water, and surface water rights held by San José Water Company and Stanford University.

3.13.1.2 Water Supply Infrastructure

To meet countywide needs, Valley Water's water supply and distribution system relies on the following major facilities (Valley Water 2019):

- Ten surface raw water reservoirs, totaling approximately 166,000 AF of reservoir storage capacity
- Five in-stream water supply diversion dams
- 279 miles of natural channels and 44 miles of concrete-lined channels
- 17 miles of raw surface water canals and ditches
- 25 groundwater recharge pond facilities
- 98 miles of controlled in-stream recharge
- 134 miles of raw and treated pipelines
- Three raw water pumping stations
- Three drinking water treatment plants
- One advanced water purification plant

Valley Water's water supply facilities are shown in **Figure 3.13-2** ~~**Figure 3.13-1**~~.

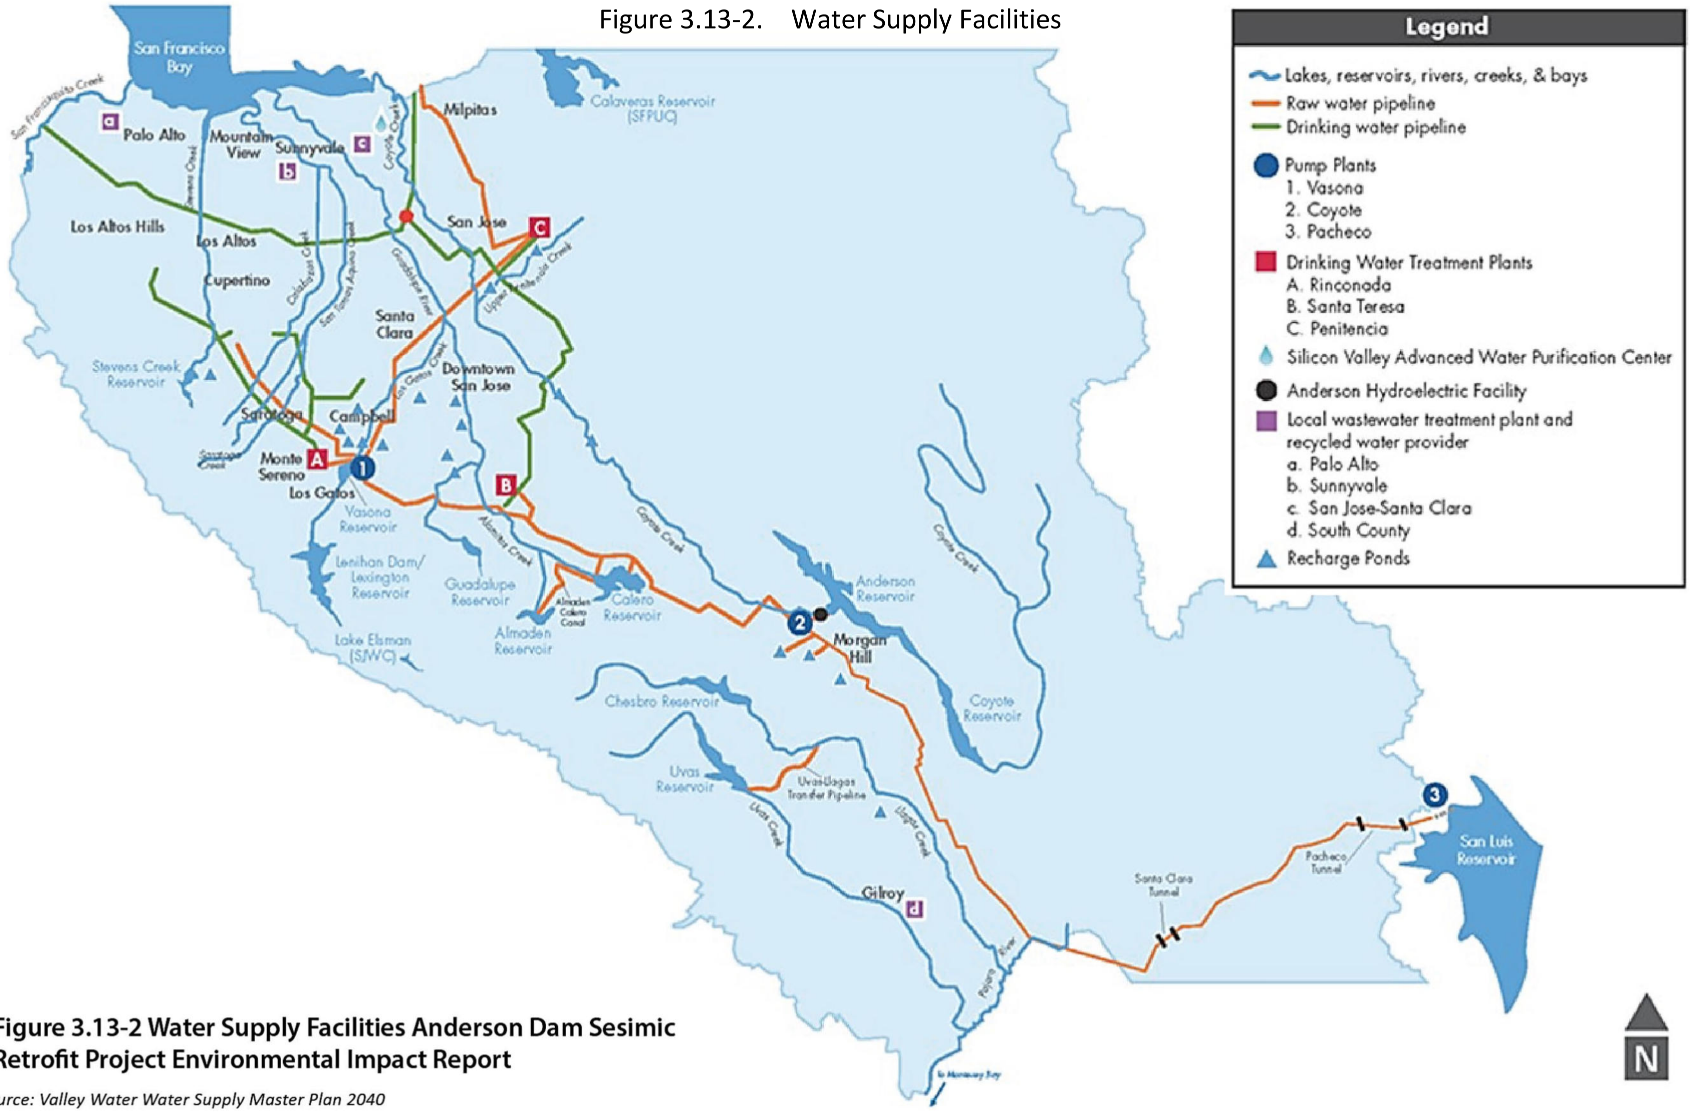
Anderson Dam Seismic Retrofit Project Environmental Impact Report

Figure 3.13-2. Water Supply Facilities



Raw water conveyance relies on streams and constructed infrastructure to distribute local and imported supplies to Valley Water's drinking water treatment plants and groundwater recharge facilities. Valley Water manages these systems to meet multiple objectives, including water supply, flood protection, and stream stewardship. As indicated above, five of Valley Water's dams/reservoirs are under storage restrictions for seismic safety purposes; thus, the full capacity of these facilities is not currently available to Valley Water.

Water supply facilities that are included as part of, or would potentially be affected by, the Project, or are otherwise relevant to the environmental analysis, include Anderson Dam/Reservoir, Coyote Creek, Coyote Percolation Dam/Pond, Cross Valley Pipeline, CDL, SCC, and Anderson Force Main. These facilities are described throughout this EIR, but brief descriptions of the facilities have been provided below. Also, refer to **Figure 3.13-1**.

- **Anderson Dam and Reservoir.** As described in Chapter 2, *Project Description,* Anderson Reservoir is created by Anderson Dam, a 240-foot-high earthen dam constructed in 1950 that measures 1,430-feet long by 900-feet wide. The reservoir can hold over 89,000 AF of water when full, with a surface area of 1,253 acres. This storage capacity is more than all of the other Valley Water surface water reservoirs combined. Storage at Anderson Reservoir is currently restricted to deadpool, or roughly 3,159 AF. Prior to the FERC Order (and even more so, prior to 2009 when seismic storage restrictions limiting storage to 68 percent of capacity first went into effect), Anderson Reservoir was managed to meet regional water supply goals and maximize groundwater recharge. Water from Anderson Reservoir can be released directly to Coyote Creek or used to supply water directly to the raw water distribution system, including deliveries to the water treatment facilities for drinking water supply via the bidirectional Anderson Force Main and Cross Valley Pipeline (see discussion below) (Valley Water 2020a ~~2020~~). Depending on the hydrologic conditions and time of year, a full groundwater recharge program requires 20 to 60 cfs to be released below Anderson Dam in order to meet groundwater supply needs.
- **Coyote Creek.** Coyote Creek is a natural stream that is impounded by Anderson Dam. Upstream of Anderson Reservoir, Coyote Reservoir is also located along Coyote Creek and controls releases/flows along the stretch of Coyote Creek between the two reservoirs. Downstream of Anderson Dam, Coyote Creek flows approximately 37.5 miles north-northwest through many densely urbanized areas in the county, before ultimately reaching San Francisco Bay. Water flowing in Coyote Creek provides in-stream recharge of the Coyote Valley and Santa Clara Plain, which are the two groundwater management areas of the Santa Clara Subbasin.
- **Coyote Percolation Dam and Pond**. The Coyote Percolation Dam is located approximately 10 miles downstream of Anderson Dam and is used by Valley Water to impound water along Coyote Creek for the purposes of managed groundwater recharge. The channel-spanning facility has historically consisted of a flashboard dam (composed of removable steel plates atop a reinforced concrete foundation), rock slope protection, fish ladder, two radial gates, and approximately 40 acres of impoundment. However, as part of the FOCP, Phase 1 improvements offered designs to replace the existing flashboard dam with an inflatable bladder dam and the existing stationary fish ladder panels with adjustable panels to improve fish passage. The improvements to the facility are scheduled for construction in summer 2023. The impoundment behind the Coyote

Percolation Dam is the largest of several ponds also referred to collectively as the Metcalf Ponds.

- **Cross Valley Pipeline.** The Cross Valley Pipeline is a pipeline that transfers water from either Anderson Reservoir, when in operation, or water conveyed from San Luis Reservoir, through pipelines of the San Felipe Division of the federal CVP, to Valley Water's water supply system. The Cross Valley Pipeline begins at the Coyote Pumping Plant in the City of Morgan Hill, runs northwest through the City of Morgan Hill and unincorporated areas of the county, and continues northwest through the Coyote Valley Open Space Preserve and near Cinnabar Hills Golf Club, where the Cross Valley Pipeline ends and the Calero Pipeline begins. The Cross Valley Pipeline and Calero Pipeline together consist of 10.8 miles of 78-inch and 72-inch prestressed concrete cylinder pipes. As part of the FOCP, Valley Water extended the Cross Valley Pipeline to allow for water releases to Coyote Creek downstream of Ogier Ponds.
- **Coyote Discharge Line**. The CDL is used to release imported water from San Luis Reservoir via the SCC (see below) to Coyote Creek approximately 1,200 feet downstream of Anderson Dam. Releases from the CDL are used to augment surface water, primarily to recharge the groundwater supply in the Santa Clara Subbasin (including both the Coyote Valley and Santa Clara Plain groundwater management areas) via infiltration in Coyote Creek and Coyote Percolation Pond.
- **Santa Clara Conduit**. As noted above, the SCC connects to the Cross Valley Pipeline and CDL and is used to transfer water from San Luis Reservoir. The SCC, combined with the Pacheco Conduit, extends many miles from the San Luis Reservoir all the way to the Coyote Pump Station, which is located just southwest of Anderson Reservoir.
- **Anderson Force Main**. The Anderson Force Main is a 54-inch-diameter bi-directional pipeline that enables the release of water to Coyote Creek, transfers raw water to the water treatment plants, and allows the storage of imported water in Anderson Reservoir.

3.13.2 Regulatory Setting

3.13.2.1 Federal

Safe Drinking Water Act

The federal SDWA [42 USC 300(f) et seq.] applies to water supply. See Section 3.12, *Groundwater Resources*, for a full description relevant to the Project.

3.13.2.2 State

Water Rights Permitting Process

Appropriative water rights (Water Code 1200 et seq.) are required for water users who divert water from surface or subterranean streams for use on non-riparian land or use water that would not be there under natural conditions (storing water) on riparian land. The SWRCB issues water rights permits and licenses for these types of diversions.

In May 2015, Valley Water submitted proposed water rights amendments ~~The Project includes several specific proposed water rights changes~~ to the SWRCB to update Valley Water's Coyote Creek water rights ~~permits~~. See Chapter 2, *Project Description*.

California Safe Drinking Water Act

The California SDWA (Health and Safety Code 116270 et seq.) regulates drinking water more rigorously than the federal SDWA. Like the federal SDWA, California requires that primary and secondary MCLs be established for pollutants in drinking water; however, some California MCLs are more protective of health. The SDWA also requires the SWRCB to issue domestic water supply permits to public water systems.

3.13.2.3 Local

Santa Clara Valley Water District Urban Water Management Plan

In accordance with Water Code Sections 10610 to 10656, Valley Water has developed and regularly updated its UWMP to ensure that adequate water supplies are available to meet existing and future water demands during normal, dry, and multiple dry years within its service area. The UWMP is updated every five years as required by DWR. Valley Water's most recently adopted plan, the 2020 UWMP, provides an overall picture of current and future water conditions and management over the next 25 years. The plan documents Valley Water's system, current and projected water supplies, and demands over the next 25 years during normal and drought years. It also includes a water reliability analysis and describes conservation efforts in the county. (Valley Water 2021b).

Santa Clara Valley Water District Water Shortage Contingency Plan

Valley Water's Water Shortage Contingency Plan (WSCP) defines specific triggers that indicate a water supply shortage and allow Valley Water to request the public to implement water use reductions. These shortage contingencies are staged across five levels, where Stage 1 represents no water use restrictions, and Stage 5 equates to greater than 40 percent reductions. The triggers are based on projected end-of-year groundwater storage levels because this reflects the general health of the water supply system.

The WSCP recognizes that Anderson Dam is currently undergoing a seismic retrofit and is not able to provide water storage; and assumed that Anderson Dam's retrofit would be complete in 2030 (construction is now estimated to be complete later than 2030 ~~in 2032~~). As part of WSCP requirements, starting in 2022, Valley Water began preparing and submitting an Annual Water Supply and Demand Assessment to DWR each year. This Annual Assessment provides projected demands through the current year, quantification of available water supplies, and existing infrastructure capabilities and plausible constraints. The Annual Assessment also includes a forecast of water supply conditions assuming the following year has dry conditions, along with recommendations if any water shortage actions are needed (Valley Water 2021a).

Santa Clara Valley Water District Water Supply Master Plan 2040

In November 2019, Valley Water completed its Water Supply Master Plan (WSMP) 2040 (Valley Water 2019), which presents Valley Water's strategy for meeting the county's water supply needs through 2040. As part of the WSMP, the Valley Water Board established the Level of

Service (LOS) goal "to develop water supplies to meet 100 percent of annual water demand during non-drought years and at least 80 percent demand in drought years." To achieve the LOS goal, the WSMP recommends a three-pronged strategy to meet future county-wide demand:

1. Secure existing supplies and infrastructure
2. Increase water conservation and water reuse
3. Optimize the use of existing supplies and infrastructure

Santa Clara Valley Water District Act

The Santa Clara Valley Water District Act (Chapter 1405 of the Statutes of 1951, as amended in 2018) created Valley Water. The act has been amended several times with the latest in 2018. The purposes of this act are to authorize Valley Water to provide comprehensive water management for all beneficial uses and protection from flooding within the county. This Act states that one of the purposes of Valley Water is "to do any and every lawful act necessary to be done that sufficient water may be available for any present or future beneficial use or uses of the lands or inhabitants within the District." To further implement the Santa Clara Valley Water District Act, the Board has developed a mission statement for Valley Water: "The mission of the Santa Clara Valley Water District is to provide Silicon Valley safe, clean water for a healthy life, environment, and economy."

3.13.3 Methodology and Approach to Impact Analysis

The impacts of the Project are described and evaluated according to significance criteria described below. The impact analysis describes impacts on water supply/water rights associated with implementation of the Project. The analysis considers impacts from construction of the Seismic Retrofit components of the Project, as well as construction of Conservation Measures and implementation of Construction Monitoring activities. The analysis also considers longer-term impacts during the post-construction period from operation of the reservoir and Conservation Measures, and ongoing maintenance and monitoring efforts. The analysis considers the extent to which Conservation Measures incorporated into the Project would reduce the adverse effects of the Seismic Retrofit components, as well as how implementation of applicable Valley Water BMPs, VHP conditions, and AMMs would reduce impacts.

The analysis focuses on the effects of the Project as compared with baseline conditions. Separate baselines are used due to the nature of the Project and the different types of effects. For construction of the Seismic Retrofit and Conservation Measures, the baseline conditions are the existing conditions at the time of EIR preparation as modified by implementation of the FOCP (existing conditions baseline). For post-construction operations and maintenance, two baselines are used: the future conditions baseline and Pre-FERC Order Conditions Baseline.

3.13.3.1 Seismic Retrofit Project Construction

Construction-related water supply effects of the Seismic Retrofit component were evaluated by looking at the water needs during construction and comparing that to available water sources for this type of use. Additionally, the analysis considers the extent to which construction activities (e.g., maintaining the reservoir in a dewatered state) could impact Valley Water's overall supplies and ability to meet demands, as well as adversely affect other water right holders in the vicinity.

As part of the Project, Valley Water would augment Anderson Dam releases using other water supply sources so that Coyote Creek would not be dewatered during the construction period. The sources include: 1) winter flows that would typically be collected for storage in Anderson Reservoir would be bypassed, 2) imported water via the CDL, and 3) imported water via the Cross Valley Pipeline Extension. Therefore, impacts to water users downstream of Anderson Dam were evaluated by looking at the availability and reliability of these water sources, as well as analyzing whether the quantity would sufficiently recharge the groundwater supplies in Coyote Valley. Water quality concerns, which could impact water supply, especially for municipal or domestic purposes, are primarily evaluated in Section 3.14, *Water Quality*.

3.13.3.2 Conservation Measures Project Construction

As part of the Project, the Conservation Measures component would include the Ogier Ponds CM, Phase 2 Coyote Percolation Dam CM, Maintenance of the North Channel Reach ~~Extension~~, Maintenance of the Spawning Gravel and Rearing Habitat at Live Oak Reach Restoration Reach, and the Sediment Augmentation Program. While the Conservation Measures are intended to benefit fish habitat, water quality, groundwater recharge, and water supply, their construction could have short-term impacts on water supplies. This analysis considered impacts from disruption of percolation pond operations during construction of measures, using imported water to supplement stream flows during dam construction, construction of the Ogier Ponds CM, and impacts of adding cobble, gravel, and sediment to reaches downstream of the dam.

3.13.3.3 Construction Monitoring

The construction monitoring component of the Project includes a number of measures to monitor the effects of the Project on the environment and reduce those effects through avoidance and minimization of certain impacts. Construction monitoring includes monitoring of stream flow and water quality; suspended sediment; sediment deposition; and steelhead habitat quality, conditions, migration, migration flows, spawning, and juvenile rearing in Coyote Creek downstream from Anderson Dam. These measures would involve small numbers of people visiting locations throughout the Project Area and would be unlikely to result in negative impacts to water supply. However, any adverse effects from construction monitoring activities are evaluated in this section.

3.13.3.4 Post-Construction Anderson Dam Facilities Operations and Maintenance

The post-construction operational water supply effects of the Project were evaluated with regards to the new flow regimes that would be in place due to the FAHCE rule curves. Impacts related to new flow regimes were evaluated by analyzing whether the required reservoir releases would adequately supply downstream water users and sufficiently recharge the groundwater supplies in Coyote Valley, and/or whether there would be any adverse effects on Valley Water's water supplies. Impacts were analyzed by comparisons to the Pre-FERC Order Conditions Baseline and/or future conditions baseline. Maintenance of Anderson Dam facilities would be conducted in accordance with existing Valley Water maintenance programs (e.g., DMP, SMP). BMPs and avoidance and minimization measures associated with these programs would be implemented to minimize potential impacts to water quality (and, by extension, water supply) during maintenance activities.

3.13.3.5 Post-Construction Conservation Measures Operation and Maintenance

The effects related to the operation of Conservation Measures and ongoing maintenance and monitoring activities during the post-construction period were evaluated with respect to water supply. The analysis considered whether the five Conservation Measures described above (Ogier Ponds CM, Phase 2 Coyote Percolation Dam CM, Maintenance of the North Channel Reach ~~Extension~~, Maintenance of the Spawning Gravel and Rearing Habitat at Live Oak Reach Restoration Reach, and the Sediment Augmentation Program) would result in impacts on water supply during the post-construction period. The post-construction impacts analysis used the Pre-FERC Order Conditions Baseline.

3.13.3.6 Post-Construction Project and FAHCE Adaptive Management

The FAHCE AMP would guide post-construction adaptive management of Project ~~project~~ flow operations and Conservation Measures that have met their specified success criteria, as defined through the regulatory permitting process. As required by the FAHCE AMP framework, the Project and FAHCE AMP includes four key elements: measurable objectives, monitoring, adaptive actions, and reporting. Monitoring and adaptive actions involve physical activities that could have environmental impacts.

The Project and FAHCEAMP monitoring program would inform selection of adaptive management measures to implement in response to management triggers, and includes compliance, validation, effectiveness, and long-term monitoring. Validation, effectiveness, and long-term trend monitoring would build on existing Valley Water monitoring infrastructure (e.g., hydrologic monitoring network), water quality monitoring (e.g., water temperature monitoring network), habitat monitoring (e.g., habitat mapping), and fisheries monitoring (e.g., VAKI Riverwatcher, PIT tag detectors, genetics sampling, electrofishing surveys). Water supply impacts of these monitoring activities are not evaluated in the impact analyses below.

The Project and FAHCE AMP identifies triggers for adaptive actions to help meet measurable objectives. Adaptive actions for FAHCE flows and imported water storage/releases would include refinements of reservoir releases, which would have impacts and benefits similar to the original FAHCE flows and imported water storage/releases. Adaptive actions for Conservation Measures would generally include minor construction and maintenance actions, whose impacts would be similar but less than those from original flow measures and Conservation Measure construction. Impacts of these adaptive actions are evaluated in the impact analyses below. These impacts are considered here at a programmatic level, because the detailed characteristics, timing, and/or locations of the proposed adaptive measures are not known at the time of EIR preparation. Project-specific CEQA review would be undertaken in the future, as necessary, when specific projects are proposed and project-specific details are available.

3.13.3.7 Applicable Best Management Practices and VHP Conditions

The BMPs and VHP Conditions and AMMs that would help reduce impacts related to water supply are the same ones that would serve to protect water quality. Therefore, refer to the list of applicable BMPs and VHP Conditions and AMMs provided in Section 3.14, *Water Quality*.

3.13.3.8 Thresholds of Significance

For purposes of this EIR, and consistent with certain thresholds in Appendix G of the *CEQA Guidelines*, the Project would have a significant effect related to water supply if it would:

a) Substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources based on reasonably foreseeable future development during normal, dry, and multiple dry years

b) Require or result in the relocation or construction of new or expanded water facilities, the construction of which could cause significant environmental effects

3.13.4 Impact Analysis

***Impact WS-1: Substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources based on reasonably foreseeable future development during normal, dry, and multiple dry years* (Less than Significant)**

Seismic Retrofit Construction

Reduced Water Supplies and Groundwater Recharge Due to Reservoir Dewatering

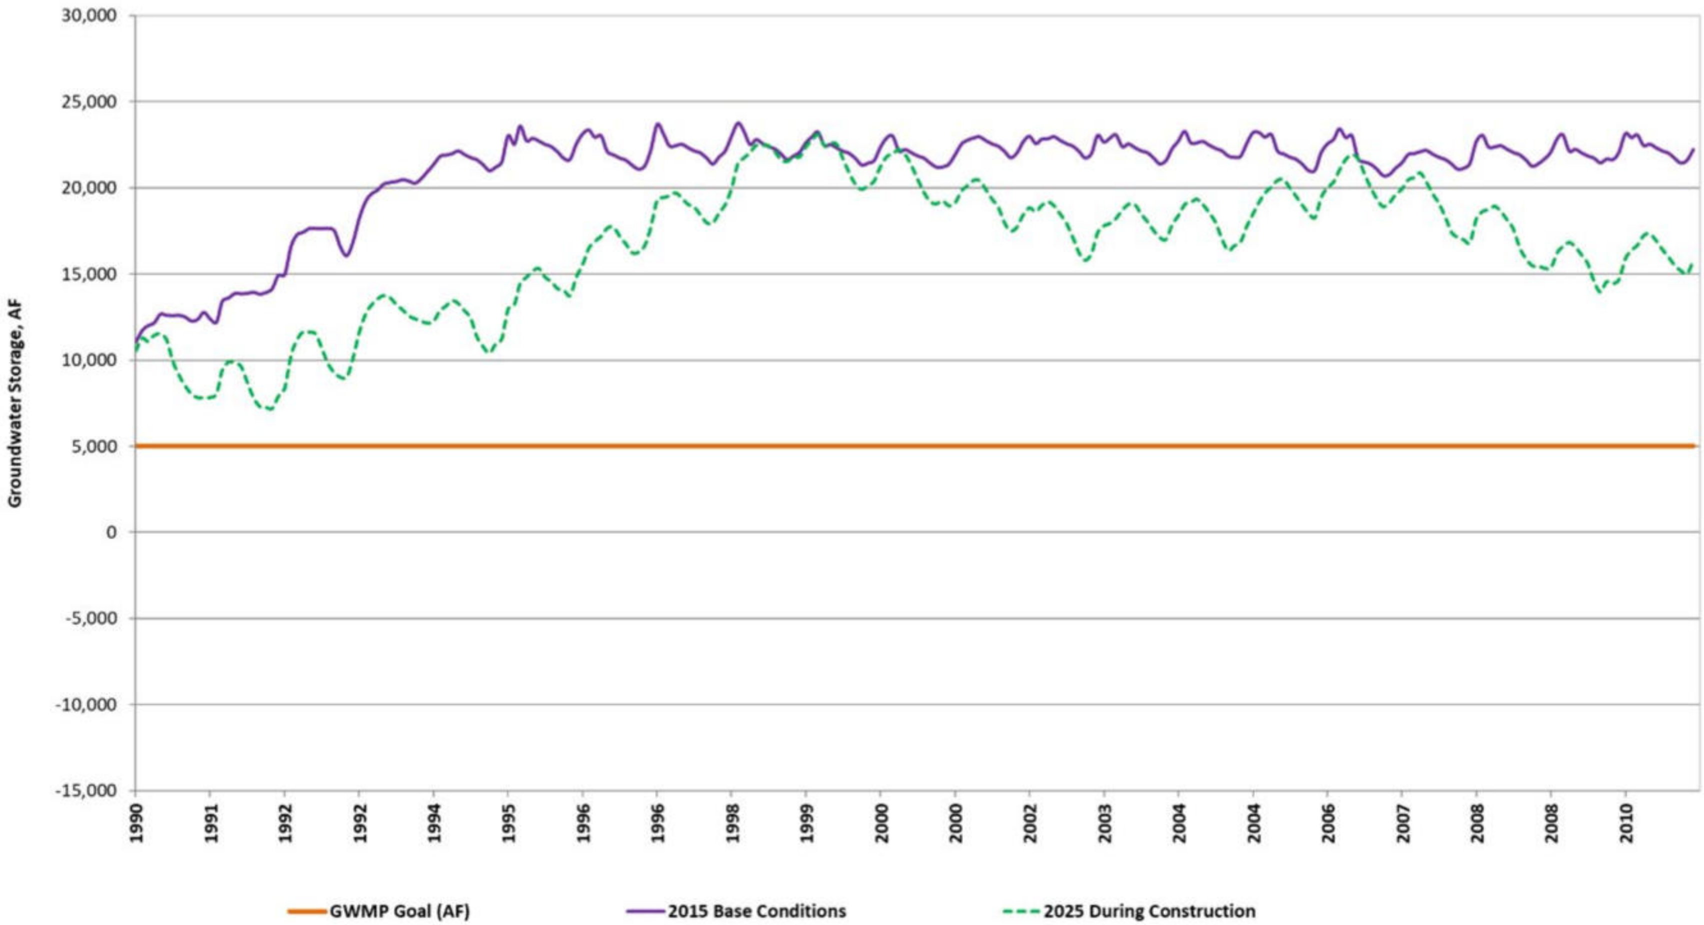
As discussed above, during the Seismic Retrofit component construction, Anderson Reservoir would be almost completely dewatered with refilling of the reservoir likely beginning in Year 6 of construction, but possibly taking multiple years to be completed, depending on hydrologic conditions. As such, the water that is typically stored in the reservoir (over 89,000 AF at full capacity, but just 3,159 AF under baseline, and 52,553 during the Pre-FERC Order period) would be completely unavailable during the Seismic Retrofit component construction period. Normally, prior to the FERC Order taking effect, water in Anderson Reservoir was managed to meet regional water supply goals and maximize recharge. Water from the reservoir could be released directly to Coyote Creek (for recharge purposes, among others) or can be used to supply water directly to the raw water distribution system via the Anderson Force Main and Cross Valley Pipeline.

With respect to Valley Water's overall supplies, the 2020 UWMP accounts for Anderson Reservoir being out of commission until sometime between 2030 and 2035. Therefore, the UWMP, which includes an analysis of the sufficiency of supplies during single-year and multi-year dry periods, accurately reflects the timeline of the Project. As described in Chapter 2, *Project Description,* the Seismic Retrofit component of the Project is estimated to require a 7-year construction duration ~~; thus, assuming a 2025 start date~~, and the reconstructed Anderson Dam would be back online before 2035 ~~in 2032~~. The UWMP projects that Valley Water's supplies would be sufficient in the near term future to meet demands in a short and/or prolonged drought scenario. Again, this accounts for Anderson Reservoir being (almost) completely dewatered and offline for at least the next 9-10 years.

Valley Water would support flows in Coyote Creek throughout the Seismic Retrofit component construction via releases of imported water from the CDL and Cross Valley Pipeline Extension. The CDL discharges immediately downstream of Anderson Dam, while the Cross Valley Pipeline Extension discharges downstream of Ogier Ponds, which are located approximately 4 miles downstream of the dam. Valley Water would continue to release imported water via the Cross Valley Pipeline Extension, if stream flow from Anderson Dam does not reach the Cross Valley Pipeline Extension outfall and a dryback is present downstream. Although the amount of water released from the CDL would depend on a number of factors, the imported water releases, combined with other water sources influencing Coyote Creek flows, would be managed with a target of having a minimum flow of 2.5 cfs at the Edenvale streamflow gage when Coyote Percolation Pond is in operation. The Cross Valley Pipeline Extension is designed to have the capacity to carry 67 ~~50~~ cfs of imported water. Valley Water would cease Cross Valley Pipeline Extension releases when flows exceed 65 cfs at streamflow station 5082 and Coyote Creek at Madrone during the adult upstream migration season (December 1 to April 30), unless there is less than 2.5 cfs at streamflow station 5058, Coyote Creek Edenvale. ~~On average, the facility would deliver about 30 cfs during the dry season and 20 cfs during the wet season to ensure managed recharge in Coyote Creek and the Coyote Percolation Pond~~. Releasing imported water below Ogier Ponds would ensure that more reaches of Coyote Creek would stay wetted, and would support groundwater recharge of Coyote Valley and South San José areas throughout the construction period.

As described in detail in Section 3.12, *Groundwater Resources*, with implementation of the increased imported water releases, WEAP modeling conducted by Valley Water has indicated that no significant impacts would occur to groundwater conditions during the Seismic Retrofit construction period. The During Construction scenario modeled in WEAP shows that some adverse impacts to groundwater (i.e., reduced recharge relative to demands) would occur as a result of the reservoir dewatering and reduced releases during the construction period. However, based on the analysis, which considered hydrologic conditions over a period of 20 years (1990 to 2010), groundwater storage in the Coyote Valley area would remain above 5,000 AF for the entirety of the modeling run (including dry and wet years). **Figure 3.13-3** ~~**Figure 3.13-2**~~ below shows the model results. According to Valley Water's Groundwater Management Plan, the projected end of year groundwater storage outcome measure for the Coyote Valley is 5,000 AF; this outcome measure is the quantifiable goal to track the performance of sustainable groundwater management and is functionally equivalent to a measurable objective under the SGMA. Given that the increased imported water releases that would be implemented during Seismic Retrofit construction would help maintain the Coyote Valley groundwater storage level above the 5,000 AF outcome measure, no significant impacts to groundwater supplies would occur.

Figure 3.13-3 ~~3.13-2~~. Coyote Valley Groundwater Storage During the Seismic Retrofit Construction Scenario



Source: Valley Water 2023b

With respect to the availability of imported water during construction, as indicated in Section 3.13.2, actual allocations of State Water Project and CVP water are based on hydrologic conditions, availability of water supplies after meeting regulations to protect the environment, water quality, and other factors and in dry years can be much lower than contracted values of 100,000 and 152,500 AFY, respectively. In accordance with historical acquisition and use of imported water, adequate imported water would be available to Valley Water during the Seismic Retrofit component construction period to support the increased imported water releases in Coyote Creek. However, if Valley Water's imported water contract supplies are insufficient, Valley Water could attempt to purchase and import water transfer supplies, depending on availability, from other California water rights holders or potentially bring in water stored within Valley Water's share of the Semitropic Groundwater Bank located in Kern County (Valley Water 2023b).

In the unlikely event that Valley Water's regional water supplies run low relative to demands during the Seismic Retrofit component construction period, potentially exacerbated by the unavailability of Anderson Reservoir (Valley Water's largest surface water storage facility), Valley Water would have the ability to issue water use restrictions in accordance with the WSCP. Under Stage 5 (Emergency) water shortage conditions, as indicated by projected end-of-year groundwater storage, Valley Water would request the public and retailers reduce water use by greater than 40 percent (Valley Water 2021a). During less severe water shortage conditions, the requested water reductions would be more limited. Implementation of the WSCP would reduce potential for severe water supply shortages during Seismic Retrofit component construction that could be exacerbated by Anderson Reservoir being offline.

Based on the above analysis, the reduced water supplies during the Seismic Retrofit component construction period due to the reservoir dewatering would not result in substantial water supply impacts. Specifically, the reservoir dewatering effects would not substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources based on reasonably foreseeable future development during normal, dry, and multiple dry years. Therefore, impacts would be less than significant.

Water Needs During Construction

As described in Chapter 2, *Project Description,* up to 1 cfs of water from the Anderson Reservoir deadpool would be used for construction activities during Year 1, including for dust control and wetting of stockpiled materials. For most of the construction period, this water would be obtained by pumping from upstream of the cofferdam. Water during Year 7, and a backup sources of water for Years 1 through 6 would be obtained from the CDL and Main Avenue Pipeline. This translates to approximately 646,320 gallons per day or roughly up to 2 AF per day. Given that Anderson Reservoir would continue to receive inflow from tributaries and Coyote Creek, regulated by releases from Coyote Reservoir, during the construction period, the water that would accumulate behind the cofferdam (up to approximately 500 AF) would be sufficient to supply construction water demands. As described in Chapter 2 (refer to **Table 2-1**), Valley Water would maintain normal operation of Coyote Reservoir throughout the Seismic Retrofit component construction period. This would include the goal of maintaining a minimum streamflow of 3 to 5 cfs at Gage SF12 ~~SF5012~~/USGS station 11169860 (downstream of Coyote Reservoir) through releases from Coyote Reservoir in the spring and summer (when supply is available).

As such, Anderson Reservoir would receive sufficient inflow during the Seismic Retrofit component construction period that would meet the construction water demands. In the event that water is not available from within the reservoir's deadpool, imported water via the CDL could supply the construction effort. As a result, water supply impacts would be less than significant.

Water Quality-Related Effects

As discussed in detail in Section 3.14, *Water Quality* (also refer to Section 3.11, *Hydrology*) construction activities would adversely impact water quality, both within the reservoir and in Coyote Creek. This could include discharge of substantial volumes of sediment from the reservoir, in particular following storms, since the exposed lake sediments would be susceptible to erosion and the runoff water high in suspended sediments would then be discharged to Coyote Creek. This impact is significant and unavoidable from a water quality perspective, since there is no feasible mitigation (short of substantial dredging of accumulated sediments prior to construction, which is considered as an alternative; refer to Chapter 5, *Alternatives*) available to reduce the erosion potential.

Moreover, discharges of sediment and other pollutants could occur during Seismic Retrofit component construction activities due to ground disturbance with heavy construction equipment, runoff from disturbed construction work areas (that are susceptible to erosion), and accidental releases of hazardous materials (e.g., fuel, oil, lubricant, etc. contained in construction equipment). However, implementation of the SWPPP <u>for construction activities outside the reservoir</u> in accordance with the Construction General Permit, as well as applicable Valley Water BMPs and VHP conditions and AMMs, would reduce these water quality impacts to a level that is less than significant. Valley Water BMPs WQ-1, WQ-4, WQ-5, WQ-9, WQ-11, WQ-15, WQ-16, GEN-1, GEN-20, GEN-21, GEN-26, GEN-30, GEN-31, GEN-32, GEN-35, VEG-1, HM-1, HM-2, HM-4, HM-5, HM-6, ~~HM-7~~, HM-8, HM-9, and HM-10, as well as VHP Conditions 3, 4, 5, 7, 11, and 12, and VHP AMMs 2, 7, 8, 9, 11, 12, 66, 67, 68, 72, 75, 76, 84, 87, 88, 97, and 100, would help to limit impacts. Refer to Section 3.14, *Water Quality*, for detailed discussion of these effects.

The adverse water quality effects during the Seismic Retrofit component construction period, in particular those effects that cannot be mitigated (sediment discharges to Coyote Creek associated with reservoir releases), could theoretically impact water supply. For example, the elevated suspended sediment concentrations can make some water unsuitable for various water supply applications (e.g., municipal, domestic, irrigation, etc.). With respect to indirect water supply impacts (e.g., groundwater recharge and subsequent pumping/use), the elevated suspended sediments caused by the Seismic Retrofit component construction would not adversely impact groundwater quality. The suspended sediment would settle out or otherwise adhere to the existing soils and would not percolate to the groundwater aquifer. The measures and BMPs listed above would prevent other pollutants from contaminating the groundwater supply as a result of discharges from the reservoir or construction work areas during the Seismic Retrofit component construction period.

A portion of the sediment suspended and washed out of the reservoir during construction would settle in the Coyote Percolation Pond, which is used to recharge groundwater. As discussed in Section 3.11, *Hydrology*, modeling indicates that up to 0.5 inches of sediment could be deposited in Metcalf Ponds (which include the Coyote Percolation Pond) following a single storm event (5-year event). This is considerably less than is projected to be deposited in Ogier Ponds (which would be disconnected from Coyote Creek as part of the Project and is not considered a recharge facility), but nevertheless, the deposition of fine sediment in the Coyote Percolation Pond could inhibit groundwater recharge if no corrective actions are taken. Monitoring and adaptive management would prevent water supply from being impacted by sediment settling in the percolation pond. This recharge pond already undergoes maintenance including surface discing, vegetation management, and limited sediment removal when necessary as part of an existing Valley Water maintenance program.

Based on the above analysis, water quality-related effects would not substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources based on reasonably foreseeable future development during normal, dry, and multiple dry years. Therefore, impacts would be less than significant.

Significance Conclusion Summary

In summary, Valley Water's overall water supplies would be sufficient to meet demands during the Seismic Retrofit component construction period. Seismic Retrofit construction would not substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources, and this impact would be less than significant.

Conservation Measures Construction

For the reasons discussed above, Valley Water's overall water supplies would be sufficient to meet demands, even accounting for Anderson Reservoir being offline during the Seismic Retrofit component construction period. Construction of the Conservation Measures component would generally not exacerbate any of the effects discussed above with respect to the Seismic Retrofit construction. Several of the Conservation Measures would require localized dewatering of Coyote Creek. Flows would be routed around the work areas, and effects on flows would not be substantial. For example, construction of the Ogier Ponds CM would involve dewatering of a portion of the existing ponds and construction of a creek bypass system to facilitate maintenance of flows throughout construction activities for the new realigned creek channel segment. However, Ogier Ponds do not provide water supply and, therefore, no adverse effects to water supply would occur. Construction of the Phase 2 Coyote Percolation Dam CM may temporarily reduce the use of the percolation pond for recharge purposes, and thus limit the amount of groundwater recharge during the construction period for this Conservation Measure (the measure would be constructed during Years 1 ~~4~~ and 2 ~~5~~). However, these effects would be minor and would not substantially impact Valley Water's ability to meet water demands.

Implementation of the same measures (SWPPP, Valley Water BMPs, and VHP conditions and AMMs) listed above for the Seismic Retrofit component construction would limit the adverse water quality effects from Conservation Measure construction. As such, the construction process would not cause pollution of surface water or groundwater that could thereby limit its suitability for water supply. Therefore, construction of Conservation Measures would not substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources based on reasonably foreseeable future development during normal, dry, and multiple dry years. The water supply impact would be less than significant.

Construction Monitoring

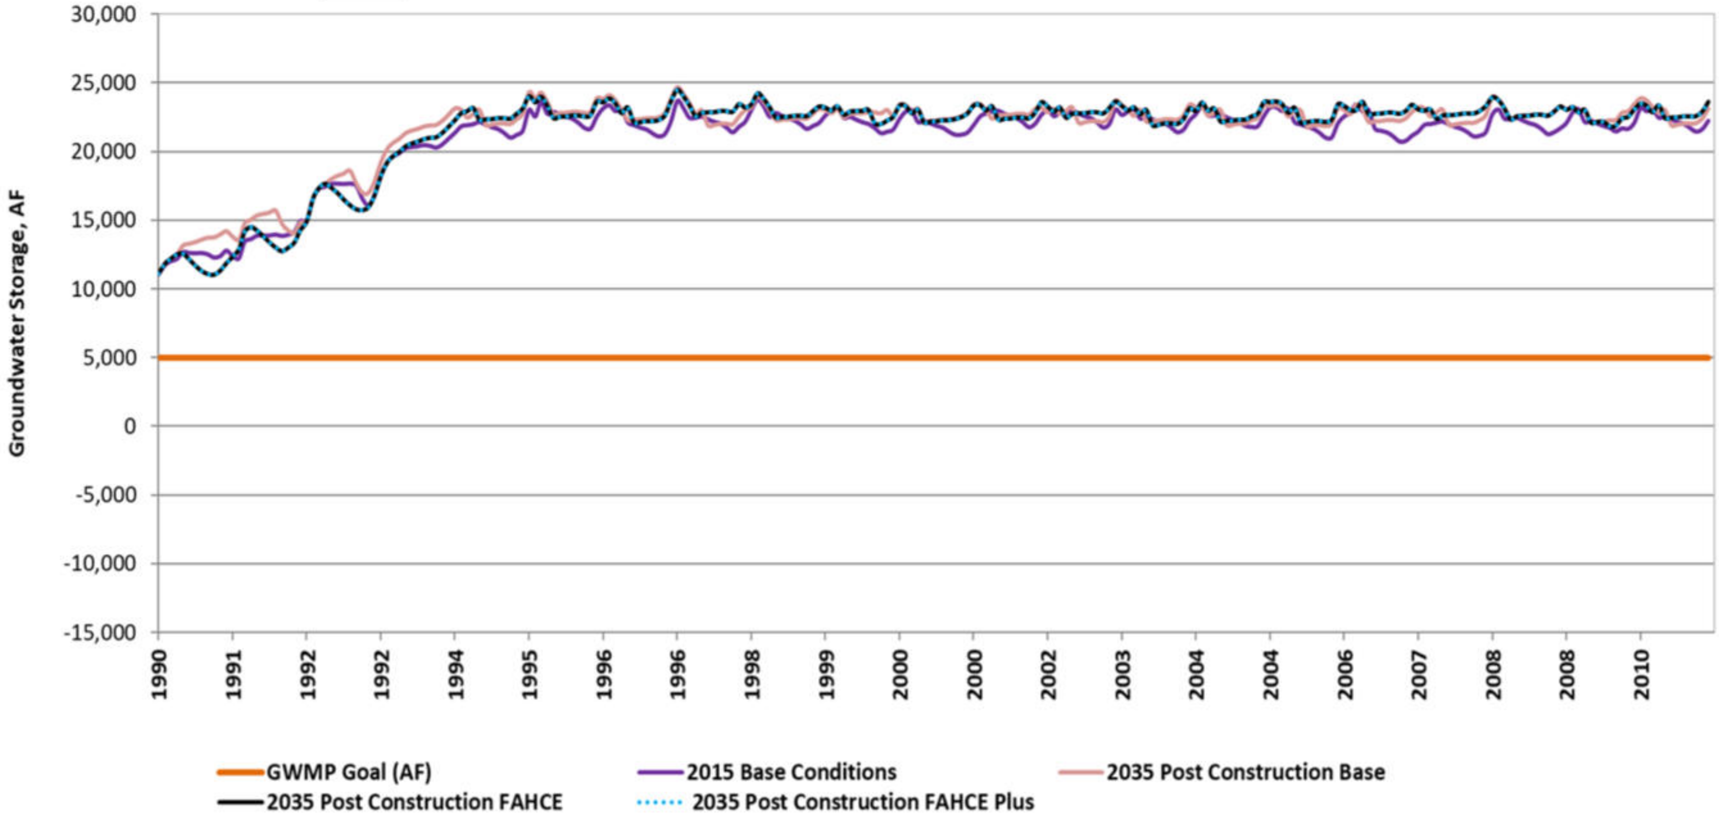
Construction monitoring for water quality, fisheries monitoring and fish rescue, aquatic species rescue and relocation, invasive species monitoring and control, and other monitoring efforts would have little impact on water supplies. Construction monitoring activities would be limited to field personnel traveling to monitoring sites, taking samples, and installing minor equipment within or adjacent to the Coyote Creek channel. Therefore, these activities would not involve substantial water use or activities that could result in substantial contamination of surface water or groundwater. As a result, the construction monitoring activities would not substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources based on reasonably foreseeable future development during normal, dry, and multiple dry years. Impacts would be less than significant.

Post-Construction Anderson Dam Facilities Operations and Maintenance

Once Project construction has been completed, releases from the dam would be made in accordance with the FAHCE operating rule curves. As discussed above, Valley Water's projections in the UWMP indicate that supplies would be sufficient to meet demands into the future, even in single and multiple year dry periods. Starting in 2035, the projections assume that Anderson Reservoir would be back online, which greatly boosts the total available supplies. Although the FAHCE operating rules would allow for greater releases for fish passage and habitat enhancement, the pulse flows are subject to storage criteria which would be protective of dry season storage. This would limit any adverse effects on water supply that could be created by releasing additional water for fish passage purposes.

With respect to groundwater, the post-construction WEAP model run conducted by Valley Water includes scenarios for the 2035 Post Construction Base and 2035 Post Construction FAHCE rule curves. Based on the WEAP monthly model results, no adverse groundwater impacts would occur in the post-construction scenarios. The FAHCE scenario remains consistent with the 2015 Base Condition and 2035 Post Construction Base scenarios. In other words, groundwater recharge and storage in the post-construction period with implementation of FAHCE would not differ substantially from the Pre-FERC Order Conditions Baseline. Likewise, it would not differ markedly from the future conditions baseline. **Figure 3.13-4** ~~**Figure 3.13-3**~~below shows the model results. These model results also show the post-construction scenarios to be above the 5,000 AF outcome measure for Coyote Valley, which is an indicator of sustainability as identified in the Groundwater Management Plan.

Figure 3.13-4 ~~3.13-3~~. Coyote Valley Groundwater Storage During Post-Construction Operations



Source: Valley Water 2023b

Anderson Dam facilities maintenance would include a wide range of activities (e.g., repair or replacement of component parts), as described in Chapter 2, *Project Description.* Generally, none of these activities would use or require large quantities of water. While some localized dewatering could be required to conduct certain maintenance activities, the dewatering would not affect the entirety of Anderson Reservoir for multiple years (as would be required for Seismic Retrofit component construction); thus, any effects on water supply would be much more limited. Certain maintenance activities would involve use of hazardous materials and thus could impact water quality (and consequently, water supply); however, as described in Section 3.13.3.4, Anderson Dam facilities maintenance would be conducted in accordance with the existing DMP and SMP. These programs include BMPs and avoidance and minimization measures that would minimize impacts to water quality and water supply. Thus, post-construction Anderson Dam facilities operations and maintenance would not substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources based on reasonably foreseeable future development during normal, dry, and multiple dry years. Therefore, impacts on waters supplies would be less than significant.

Post-Construction Conservation Measures Operation and Maintenance

Operation and maintenance of the Conservation Measures would not negatively impact water supplies. The Ogier Ponds site is not suitable for groundwater recharge due to limited storage capacity in the vadose zone (Valley Water 2018), so separating Coyote Creek flows from the ponds would not be likely to substantially decrease groundwater infiltration in the area. Operation of the Ogier Ponds CM also would not require substantial water use and would not otherwise adversely affect water supplies. Maintenance activities, such as vegetation management, repair of components (e.g., berms, spillways, fish screens, in-channel bio-engineered habitat enhancements, rock slope protection, and stormwater outfalls), trash removal, inspection and graffiti abatement at floodwalls, access road inspections, and road maintenance, would be conducted in accordance with the Valley Water SMP. This would require implementation of BMPs and avoidance and minimization measures that would be protective of water quality (and thus, water supply).

~~The~~ Maintenance of the North Channel Reach ~~Extension~~ would require minimal operations; like the rest of the Conservation Measures, it would operate unattended and would not consume water in its operation. As described in Chapter 2, *Project Description,* during the post-construction period, Valley Water would maintain ~~monitor~~ the North Channel, including maintaining the constructed wetland bench, maintaining design flow capacity through the North Channel, and replacing restoration plantings, as needed ~~to verify that the channel is maintaining a positive draining channel, and that debris was not accumulating within the channel~~. ~~Maintenance activities that may be required based on inspections/monitoring would include debris and/or vegetation removal, regrading, and localized dewatering (to allow for the regrading).~~ These activities would not substantially affect water supply and would be implemented in accordance with the SMP. Thus, implementation of BMPs and avoidance and minimization measures would prevent substantial effects on water quality from occurring (thus, protecting water supply).

With respect to spawning gravel and the Sediment Augmentation Program, Valley Water would inspect sediment augmentation sites following large flow events to determine if maintenance is required. Maintenance may include placing spawning gravels or sediments within Coyote Creek between Anderson Dam and Ogier Ponds, as well as potentially excavating sediments that have filled or blocked culverts using hand tools or heavy equipment, as determined based on the inspections. Additionally, sediment that has collected in the Coyote Percolation Pond may be excavated using an excavator when the water is drawn down or dewatered. These activities would not substantially affect water supply, as they would not require substantial quantities of water. Since the activities would be conducted in accordance with Valley Water's SMP, it would require implementation of BMPs and avoidance and minimization measures that would minimize impacts on water quality (and thus, water supply). As noted above, the excavation of fine sediment from the Coyote Percolation Pond would improve groundwater recharge operations. In terms of the long-term effects of sediment augmentation activities in other areas of Coyote Creek, given the size, porosity, and permeability of the materials, the addition of supplemental gravel and cobble to creek reaches below the dam would not decrease groundwater infiltration in those reaches. Thus, adverse impacts on water supply would not occur.

Following construction of the Phase 2 Coyote Percolation Dam CM, operation of the Coyote Percolation Pond would not change, and would provide conditions for similar levels of groundwater recharge. Maintenance activities would include the periodic removal of sediment deposited in the roughened channel when it could compromise the channel's conveyance capacity, result in geomorphic instability, or be detrimental to the quality of aquatic habitat (refer to Chapter 2, *Project Description*). This work would be done using hand tools or heavy equipment. Vegetation management would also be required, as well as repair or replacement of roughness elements and in-channel bio-engineered habitat enhancements. These activities would not substantially affect water supply. As explained above for other Conservation Measures, the maintenance activities would be performed in accordance with Valley Water's SMP, which includes BMPs and avoidance and minimization measures to reduce water quality effects (and consequent impacts on water supply).

Altogether, post-construction Conservation Measures operations and maintenance would not substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources based on reasonably foreseeable future development during normal, dry, and multiple dry years. Therefore, water supply impacts would be less than significant.

Post-Construction Project and FAHCE Adaptive Management

Adaptive management measures may refine Anderson Dam flow releases, and augment Conservation Measures when they are not functioning as intended or not meeting measurable objectives. Refinements would likely have impacts similar to those discussed for Conservation Measure construction and post-construction operations of Anderson Dam. The AMP activities would not reasonably include substantial dewatering of Anderson Reservoir or actions that would substantially inhibit or adversely affect groundwater recharge operations. Additionally, the F AMP activities would not require substantial quantities or water. While it is possible that AMP activities could involve heavy equipment operation and use of hazardous materials, which could create an opportunity for water contamination (e.g., accidental releases of such materials) (thus affecting water supply), these impacts could likely be avoided or minimized through implementation of BMPs.

The post-construction adaptive management measures would not substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources based on reasonably foreseeable future development during normal, dry, and multiple dry years. At this programmatic level of analysis, impacts are considered to be less than significant.

Significance Conclusion Summary

Implementation of the Project would allow Valley Water to bring a restricted water storage facility back to its historic capacity. Prior to 2009, when restricted capacities were implemented, Anderson Reservoir had been managed to meet regional water supply goals and maximize groundwater recharge utilizing its full capacity. The primary purpose of this Project ~~project~~ is to seismically retrofit, maintain, and operate Anderson Dam and Reservoir to meet FERC and DSOD safety requirements, thereby allowing Valley Water to maximize water supply and related incidental benefits.

Modeling results indicate that there may be a reduction in groundwater recharge/storage downstream of the dam during construction, but that simulated groundwater storage would remain above the 5,000 AF outcome measure for Coyote Valley. With the increased imported water releases, WEAP modeling has indicated that no significant impacts would occur to groundwater conditions during the Seismic Retrofit construction period. The UWMP, which accounts for Anderson Dam being offline during the Seismic Retrofit component construction period, found that Valley Water's supplies would be sufficient to meet demands in single and multiple dry year scenarios. Project components other than Seismic Retrofit construction would not have substantial impacts on water supplies. Therefore, the Project would not substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources, and this impact would be **less than significant**.

With adherence to the SWPPP for out-of-reservoir construction activities and applicable Valley Water BMPs and VHP conditions and AMMs, water quality-related effects would not substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources based on reasonably foreseeable future development during normal, dry, and multiple dry years. Therefore, impacts would be **less than significant**. While not required to reduce impacts to less than significant, Mitigation Measure WQ-1 would further reduce water quality impacts by requiring implementation of a WQMPP for in-reservoir construction activities, which would include evaluation of the water quality monitoring data collected during FOCP implementation and Project construction, and implementation of BMPs to control sediment and other pollutants associated with in-reservoir construction activities to the extent technically feasible and in accordance with regulatory requirements.

Mitigation Measures

No mitigation is required.

Impact WS-2: Require or result in the relocation or construction of new or expanded water facilities, the construction of which could cause significant environmental effects (Less than Significant with Mitigation)

Seismic Retrofit Construction

As discussed above and in Chapter 2, *Project Description*, in efforts to make Anderson Dam seismically safe, compliant with safety standards, and restore historic capacities, implementation of the Project includes the construction of various water facilities, such as connections to the Anderson Force Main and Main Avenue Pipelines, as well as a temporary cofferdam above Anderson Reservoir. Specifically, the following water supply facilities would be relocated, newly constructed, or expanded as part of the Seismic Retrofit component:

- Anderson Dam embankment, crest, spillway, and outlet works (LLOW and HLOW)
- Stage 2 Diversion System (including cofferdam, extension pipe, and screened intake structure)
- Connections to the existing Anderson Force Main and Main Avenue Pipelines, involving construction of a combined total of 575 feet of new pipeline

The existing hydroelectric facility at Anderson Dam would also be decommissioned, but this would not be considered an expansion or new construction. Although the Stage 2 Diversion System would be constructed as part of the Seismic Retrofit construction process, and would be utilized to facilitate the dam reconstruction activities, it would be decommissioned during Year 6 of construction. As discussed in Chapter 2, *Project Description*, the Project would not expand the capacity of Anderson Reservoir, although the dam would be constructed slightly higher to allow for additional freeboard. The LLOW and HLOW could be considered new, although they are an addition to an existing water supply facility (i.e., Anderson Dam). These new or expanded water facilities are part of the Project, and the impacts related to the construction of each facility are evaluated throughout this DEIR.

As discussed in Impact WS-1 above, in order to construct the Project, up to 1 cfs of water would be necessary. This water would be obtained from the reservoir deadpool. Water would be used for dust control and wetting of stockpiled materials. The construction water demands for the Seismic Retrofit component construction process would be met using existing sources and, thus, no new or expanded water facilities would be needed to supply the construction effort.

With respect to the groundwater impacts of Seismic Retrofit construction (e.g., reduced flows from the dewatered reservoir to support groundwater recharge in Coyote Creek), the modeling conducted by Valley Water (see discussion in Impact WS-1) indicates that no substantial impacts to the groundwater basin would occur during the construction period. With implementation of the increased imported water releases via the CDL and Cross Valley Pipeline Extension, storage in the Coyote Valley area would not drop below the 5,000 AF end-of-year outcome measure. Thus, its groundwater levels (i.e., elevations) would not drop below the normal range. As such, existing wells along Coyote Creek (including those owned and operated by the City of Morgan Hill) would largely not be affected, and there would be no need to construct new or expanded groundwater facilities as a result of the Seismic Retrofit component construction impacts.

The City of Morgan Hill operates 16 municipal groundwater wells throughout the city, including three along Coyote Creek immediately downstream of Anderson Dam at the William F. James Boys Ranch (City of Morgan Hill 2021). The City of Morgan Hill's wells draw water from the Coyote Valley groundwater management area and/or the Llagas Subbasin (City of Morgan Hill 2021); thus, based on the model results shown in **Figure 3.13-3** ~~Figure 3.13-2~~ and the more detailed analysis provided in Section 3.12, *Groundwater Resources*, these wells should not be substantially adversely affected. The groundwater levels for the Coyote Valley would remain above the 5,000 AF outcome measure, while Llagas Subbasin would not be substantially affected by the Seismic Retrofit construction process. Thus, there would be no need for the City of Morgan Hill to construct new or expanded groundwater wells as a result of the Seismic Retrofit component construction.

As discussed in Section 3.12, *Groundwater Resources*, there is potential for small private wells located along the rim of Anderson Reservoir (outside of the managed Coyote Valley aquifer boundary) to be significantly adversely affected by the prolonged dewatering of the reservoir, as this could affect the lateral movement of groundwater and the hydraulic head in the area (potentially affecting the productivity of the wells). However, with implementation of **Mitigation Measure GW-1** (Provide Alternative Water Supplies), which will require provision of alternative water supplies to any individual(s) whose well(s) have run dry or been rendered unproductive as a result of the reservoir dewatering, these effects will not be significant and no new or expanded wells will be constructed as a result of Seismic Retrofit component construction. Given that such alternative water supplies would be provided, as needed, small private well owners would not need to drill new wells or deepen existing wells to address the reduced productivity of their existing wells that could occur due to the reservoir dewatering effects.

Additionally, as detailed in Section 3.12, *Groundwater Resources*, **Mitigation Measure GW-2** (Perchlorate Best Management Practices) will be implemented to avoid or minimize impacts on groundwater wells in the vicinity of Anderson Dam from blasting activities. Blasting would be utilized during Seismic Retrofit component construction at the BHBA, as excavation of the BHBA would require drilling and blasting in benches to break up the rock for efficient excavation. The BHBA is located adjacent to the Anderson Lake County Park boat ramp parking lot; ~~comparing this location to **Figure 3.12-6** shows that~~ there are several water supply wells in relative proximity (the closest being approximately 1,500 feet away) to the BHBA, primarily to the south along Cochrane Road and Barnard Road. There is some potential for blasting activities to result in contamination of groundwater, such as through incomplete combustion of detonators and explosives (New Hampshire Department of Environmental Services 2010); refer to Section 3.12, *Groundwater Resources*, for detailed discussion. If such contamination were to occur as a result of Seismic Retrofit component construction activities, it could result in the need to construct new or expanded water facilities (i.e., wells), which could then result in environmental impacts. However, given implementation of **Mitigation Measure GW-2**, which will require implementation of BMPs for blasting to prevent contamination of groundwater, these effects will not be significant and no new or expanded wells/water facilities will be needed.

Apart from the blasting impacts (which would be minimized via **Mitigation Measure GW-2**), no other Seismic Retrofit component construction activities will result in nitrate contamination (e.g., exacerbation of any existing nitrate problems) or other types of groundwater contamination. Nitrates can get into groundwater from many sources, including fertilizers, manure on the land, and liquid waste discharged from septic tanks (Washington State Department of Ecology 2023). Natural bacteria in soil converts various forms of nitrogen into nitrate, and rain and irrigation can carry nitrate down through the soil into groundwater (Washington State Department of Ecology 2023). As described in Section 3.12, *Groundwater Resources*, groundwater in the Santa Clara Subbasin is generally of very good quality, with infrequent detections of water quality parameters above health-based MCLs (Valley Water 2021c ~~2021~~). Groundwater in the Llagas Subbasin is also generally of good quality. However, nitrate has been found above the MCL in a number of South County water supply wells (23 percent of wells sampled during a 2019 study) (Valley Water 2020b ~~2020~~). The Seismic Retrofit construction process would not involve the use of fertilizers, application of manure, installation of septic tanks, or other activities that could contribute to nitrate contamination of groundwater. Therefore, no other water quality impacts on any existing nearby wells that might require new or expanded wells/water facilities would occur.

With respect to impacts on irrigation water availability during Seismic Retrofit construction, the water sources available to residents in the vicinity of the dam would not be adversely affected. As discussed in Impact WS-1, given increased imported water releases, Seismic Retrofit component construction would not substantially affect the Coyote Valley groundwater management area of the Santa Clara Subbasin. Thus, the water supplies of entities reliant upon groundwater wells in the area (e.g., City of Morgan Hill) should not be substantially affected. For individuals along Coyote Road that may obtain water from private wells, implementation of **Mitigation Measure GW-1** will require that water supplies for such individuals are not disrupted, even if their wells may experience reduced productivity during the construction period. Refer to Section 3.12, *Groundwater Resources*, for more detailed discussion of this issue. As such, water facility impacts related to Cochrane Road vicinity private wells would be less than significant with mitigation.

As such, no new or expanded water facilities would need to be constructed as a result of the Seismic Retrofit construction, apart from the facilities that are part of the Project; impacts of constructing Project water facilities are evaluated throughout the remainder of this EIR. With respect to the impacts related to non-Project water facilities, for the reasons discussed above, the water facility impact is less than significant with mitigation because there would be no construction of new or expanded non-Project water facilities that could cause significant impacts.

Conservation Measures Construction ~~Impacts Analysis~~

Similar to the Seismic Retrofit component, none of the Conservation Measures would require or result in the relocation or construction of new or expanded water facilities, the construction of which could cause significant environmental effects. None of the Conservation Measures would include new habitable development, which may require water supplies; rather, the Conservation Measures would be limited to improvements to portions of Coyote Creek, which generally would not be considered water facilities.

The Ogier Ponds CM would include various infrastructure to manage flows between ponds and to separate flows from the floodplain (e.g., spillways, culverts, berms, weirs, etc.); however, since Ogier Ponds do not provide water supply and are not suitable for groundwater recharge, this infrastructure would not serve any purpose related to water supply. Maintenance of the North Channel Reach ~~Extension~~, Maintenance of Spawning Gravel and Rearing Habitat Improvements in Live Oak Restoration Reach, Sediment Augmentation Program, and Phase 2 Coyote Percolation Dam CM would be limited to modifications and improvements to the Coyote Creek channel itself (e.g., grading of the channel to remove existing deep pools, augmenting gravel/sediment at key locations, creating roughened channel characteristics with bio-engineered elements, etc.), and would not include any new or expanded water supply facilities.

Water demands for construction of the Conservation Measures would be relatively minimal and could be obtained through existing sources/facilities. Therefore, the construction water demands for Conservation Measures would not require or result in the need for new or expanded water facilities.

Several of the Conservation Measures (i.e., Ogier Ponds CM, Maintenance of the North Channel Reach ~~Extension~~, Phase 2 Coyote Percolation Dam CM) would involve localized dewatering; however, as described in Section 3.12, *Groundwater Resources*, this dewatering would not substantially affect regional groundwater supplies (e.g., by reducing recharge) and would not require or result in the construction of new or expanded water facilities, such as groundwater wells. Temporary dewatering wells may be installed during construction of these Conservation Measures (i.e., Ogier Ponds CM, ~~North Channel Extension~~, and Phase 2 Coyote Percolation Dam CM) to manage nuisance groundwater within the dewatered reaches where construction activities would occur; the environmental impacts of these temporary dewatering wells are evaluated throughout this Final ~~DEIR~~ EIR.

Overall, construction of Conservation Measures would not require or result in the relocation or construction of new or expanded water facilities, the construction of which could cause significant environmental impacts. Therefore, water facility impacts would be less than significant.

Construction Monitoring

Construction monitoring for water quality, fisheries monitoring and fish rescue, aquatic species rescue and relocation, invasive species monitoring and control, and other monitoring efforts would have no impact on the need for new or expanded water facilities. As noted above, the construction monitoring activities would be limited to individual field personnel visiting monitoring sites, taking samples, and installing minor equipment within or adjacent to the stream channel. The activities would not require or consume water and no dewatering or other activities would be required that could impact water supply. Therefore, no impact would occur.

Post-Construction Anderson Dam Facilities Operations and Maintenance

The Project would allow Valley Water to use an existing water storage facility to its historic capacity. No new water is being requested as part of the Project, and the Project would not expand the storage capacity of the reservoir. Implementation of the FAHCE flow regime would not require additional water supply, nor would it require any additional water facilities not included in the Project. No aspect of the Project would create additional water demand over the long-term such as to require the construction of new or expanded water facilities.

While dam maintenance activities may require small amounts of water, these water demands could be served through existing, readily available sources. Thus, no new or expanded water facilities would be required. Based on the above analysis, the impact from dam facility operation and maintenance would be less than significant.

Post-Construction Conservation Measures Operation and Maintenance

As discussed above in Impact WS-1, the Conservation Measures (Ogier Ponds CM, Maintenance of the North Channel Reach ~~Extension~~, Maintenance of Spawning Gravel and Rearing Habitat Improvements in Live Oak Restoration Reach, Sediment Augmentation Program, and Phase 2 Coyote Percolation Dam CM) would operate unattended and would not consume water in their operation. None of these Conservation Measures would serve a water supply purpose (although the Phase 2 Coyote Percolation Dam CM would improve fish passage at an existing water supply facility), nor would they involve habitable development that would create a need for water supply. Thus, the operation of the Conservation Measures would not require or result in the relocation or construction of new or expanded water supply facilities, the construction of which could result in significant environmental impacts, and the water facility impact would be less than significant.

Maintenance activities for the Conservation Measures are described above under Impact WS-1, as well as in Chapter 2, *Project Description*; generally, the activities would be limited to vegetation management/debris removal, periodic sediment removal, regrading, localized dewatering, and related actions that would not substantially affect water supply nor require or result in the need to relocate or construct new or expanded water facilities. Any water supply needed during maintenance activities could be met through existing sources. Therefore, water facility impacts would be less than significant.

Post-Construction Project and FAHCE Adaptive Management

Adaptive management measures may refine Anderson Dam flow releases, and augment Conservation Measures when they are not functioning as intended or not meeting measurable objectives. The AMP activities would not reasonably include substantial dewatering of Anderson Reservoir or actions that would substantially inhibit or adversely affect groundwater recharge operations. Additionally, the FAHCE AMP activities would not require substantial quantities or water. As such, the AMP would not require or result in the relocation or construction of new or expanded, the construction of which could cause significant environmental impacts. Therefore, at this programmatic level of analysis, impacts are considered to be less than significant.

Significance Conclusion Summary

The Project itself would include a number of new or expanded water supply facilities, although the proposed modifications modify an existing facility (Anderson Dam) for the purpose of safety and seismic stability. The reservoir capacity would not be expanded. The effects of the Project's water facilities are evaluated throughout the remainder of the EIR, and are thus not repeated here. Although the Seismic Retrofit component construction could adversely affect groundwater recharge/storage to some degree, the effects would not be significant with implementation of increased imported water releases, and no new or expanded well facilities would be constructed as a result.

There is potential for small private wells located along the rim of Anderson Reservoir (outside of the managed Coyote Valley aquifer boundary) to be significantly adversely affected by the prolonged dewatering of the reservoir, as this could affect the lateral movement of groundwater and the hydraulic head in the area (potentially affecting the productivity of the wells). No new or expanded private wells (located along the rim of the reservoir) would be constructed due to water table effects associated with the reservoir remaining in a dewatered state during the construction period, given implementation of **Mitigation Measure GW-1**. Additionally, given implementation of **Mitigation Measure GW-2**, any impacts on groundwater quality from blasting activities will be avoided or minimized, such that new or expanded wells would not need to be constructed. The construction water demands can be met with existing sources and no new or expanded facilities would be needed. Similarly, Project components other than Seismic Retrofit construction would not require new or expanded water facilities. Therefore, the water facility impact would be **less than significant with mitigation.**

Mitigation Measures

GW-1 Provide Alternative Water Supplies

GW-2 Perchlorate Best Management Practices.

3.13.5 Cumulative Impacts

The geographic study area for the cumulative impact analysis for Water Supply is Santa Clara County.

This section describes the Project's contribution to cumulative water supply impacts, as summarized in **Table 3.13-3**.

Table 3.13-3. Summary of Project Impact Contribution to Cumulative Water Supply Impacts

Impact	Cumulatively Significant with FOCP?	Cumulatively Significant with other projects?	Incremental Project Contribution	Applicable Project Mitigation	Cumulatively Considerable after Mitigation?
Cumulative Impact WS-1: Substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources based on reasonably foreseeable future development during normal, dry, and multiple dry years	No	No	NCC	None	No
Cumulative Impact WS-2: Require or result in the relocation or construction of new or expanded water facilities, the construction of which could cause significant environmental effects	Yes	No	CC	MM GW-1 MM GW-2	No

***Cumulative Impact WS-1: Substantially alter or reduce Valley Water's ability to have sufficient water supplies from existing entitlements and resources based on reasonably foreseeable future development during normal, dry, and multiple dry years* (Not Cumulatively Considerable)**

During the Seismic Retrofit component construction, Anderson Reservoir would be almost completely dewatered which would limit supplies available for groundwater recharge and water supply. Once Project construction has been completed, releases from the dam would be made in accordance with the FAHCE operating rule curves. As discussed above, Valley Water's projections in the UWMP indicate that supplies would be sufficient to meet demands into the future, even in single and multiple year dry periods.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if their construction, restoration, or operation would affect Valley Water's ability to have sufficient water supplies from existing entitlements and resources based on reasonably foreseeable future development during normal, dry, and multiple dry years.

Cumulative Effects of Project with the FOCP

The FOCP lowered the storage behind Anderson Reservoir to deadpool, which reduces available local supplies to be released by the reservoir for groundwater recharge in Coyote Creek and the Coyote Percolation Pond. However, the FOCP also includes the Cross Valley Pipeline Extension and chillers at Anderson Reservoir that increase the flexibility in using imported water for groundwater recharge.

The FOCP with the Project extends the period that local supplies would be reduced. However, modeling conducted by Valley Water has indicated that no significant impacts would occur to groundwater and water supply conditions during the Seismic Retrofit construction period. The modeled During Construction scenario shows that some adverse impacts to groundwater (i.e., reduced recharge relative to demands) would occur as a result of the reservoir dewatering and reduced releases during the construction period. However, based on the analysis, which considered hydrologic conditions over a period of 20 years (1990 to 2010), groundwater storage in the Coyote Valley area (the most sensitive area regarding water supply) would remain above 5,000 AF for the entirety of the modeling run. If Valley Water's regional water supplies run low relative to demands during the Seismic Retrofit component construction period, potentially exacerbated by the unavailability of Anderson Reservoir (Valley Water's largest surface water storage facility), Valley Water could issue water use restrictions in accordance with the WSCP.

Implementation of the Project would allow Valley Water to bring a restricted water storage facility back to its historic capacity. Prior to 2009, when restricted capacities were implemented, Anderson Reservoir had been managed to meet regional water supply goals and maximize groundwater recharge utilizing its full capacity. The primary purpose of the Project is to seismically retrofit, maintain, and operate Anderson Dam and Reservoir to meet FERC and DSOD safety requirements, thereby allowing Valley Water to maximize water supply and related incidental benefits.

The impact of the Project with the FOCP on water supplies is not cumulatively significant.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Other projects that could impact water supplies in Santa Clara County include development projects throughout the County. New development in the County typically increases the demand for groundwater, although new development is subject to building code requirements that minimize water demand with water efficient water fixtures and landscaping. Valley Water's overall water supplies to meet future demands during normal, single-year, and multi-year dry periods are analyzed in the 2020 UWMP. The UWMP finds that Valley Water will have sufficient supplies to meet future demand in all year types. The UWMP accounts for new development throughout the County, and Anderson Reservoir being out of commission until sometime between 2030 and 2035, therefore the UWMP accurately reflects the cumulative nature of new development on water supply and the timeline of the Project.

Long-term, the Project would restore storage at Anderson Reservoir, which would support the availability of water in normal, dry, and multiple dry years. In addition, potential future projects in Table 3.01-2 include other reservoir retrofits (at Calero, Almaden, and Guadalupe Reservoirs), all of which would restore available water storage in the County; Pacheco Reservoir Expansion Project and B.F. Sisk Dam Raise and Reservoir Expansion, which would provide new storage for Valley Water; Silicon Valley Purified Water Project, Valley Water Additional Conservation and Stormwater Projects and Programs, and the Countywide Water Reuse Master Plan that would provide new water sources.

The impact of the Project combined with other projects to the availability of water supplies is not cumulatively significant.

Significance Conclusion Summary

Modeling results indicate that there may be a reduction in groundwater recharge and storage downstream of the dam during construction, but that simulated groundwater storage would remain above the 5,000 AF outcome measure for Coyote Valley. With the increased imported water releases, WEAP modeling has indicated that no significant impacts would occur to groundwater conditions during the Seismic Retrofit construction period. The UWMP, which accounts for Anderson Dam being offline during the Seismic Retrofit component construction period and new growth throughout the County, found that Valley Water's supplies would be sufficient to meet demands in single and multiple dry year scenarios. The Project's impact to water supply with the FOCP and other probable future projects are not cumulatively significant, and the Project's contribution is **not cumulatively considerable**.

Mitigation Measures

No mitigation is required.

Cumulative Impact WS-2: Require or result in the relocation or construction of new or expanded water facilities, the construction of which could cause significant environmental effects (Not Cumulatively Considerable)

During the Seismic Retrofit component construction, Anderson Reservoir would be almost completely dewatered, which would limit supplies available for groundwater recharge and water supply.

Cumulative projects, plans, and programs could result in incrementally adverse impacts if their construction, restoration, or operation would affect Santa Clara County's water supply.

Cumulative Effects of Project with the FOCP

The FOCP lowered the storage behind Anderson Reservoir to deadpool, which reduces available local supplies to be released by the reservoir for groundwater recharge in Coyote Creek and the Coyote Percolation Pond. However, the FOCP also includes the Cross Valley Pipeline Extension and chillers at Anderson Reservoir that increase the flexibility in using imported water for groundwater recharge.

The FOCP with the Project extends the period that local supplies would be reduced. However, modeling conducted by Valley Water has indicated that no significant impacts would occur to groundwater and water supply conditions during the Seismic Retrofit construction period.

As discussed in Section 3.12, "Groundwater Resources," there is potential for small private wells located along the rim of Anderson Reservoir (outside of the managed Coyote Valley aquifer boundary) to be significantly adversely affected by the prolonged dewatering of the reservoir, as this could affect the lateral movement of groundwater and the hydraulic head in the area (potentially affecting the productivity of the wells). The impact is cumulatively significant and the Project's contribution to the potential need for new or improved wells around Anderson Reservoir is cumulatively considerable.

The Project could impact groundwater quality using explosives that contain perchlorate and other nitrogen-based chemicals which could cause groundwater pollution at the Project level. The FOCP <u>would not</u> ~~could also potentially~~ use explosives in constructing the outlet tunnel that may contain perchlorate or other nitrogen-based chemicals. ~~The cumulative risk to groundwater pollution is significant and the Project's contribution is cumulatively considerable~~.

Implementation of the Project would allow Valley Water to bring a restricted water storage facility back to its historic capacity. Prior to 2009, when restricted capacities were implemented, Anderson Reservoir had been managed to meet regional water supply goals and maximize groundwater recharge utilizing its full capacity. The primary purpose of the Project is to seismically retrofit, maintain, and operate Anderson Dam and Reservoir to meet FERC and DSOD safety requirements, thereby allowing Valley Water to maximize water supply and related incidental benefits.

The regional impact to the availability of long-term water supplies and need for new or expanded water facilities is not cumulatively considerable with the FOCP.

Cumulative Effects of Project with Probable Future Projects, Programs, and Plans

Other projects that could impact water supplies in Santa Clara County include development projects throughout the County. New development in the County typically increases the demand for groundwater, although new development is subject to building code requirements that minimize water demand with water efficient water fixtures and landscaping. Valley Water's overall water supplies to meet future demands during normal, single-year, and multi-year dry periods are analyzed in the 2020 UWMP. The UWMP finds that Valley Water will have sufficient supplies to meet future demand in all year types. The UWMP accounts for new development throughout the County, and Anderson Reservoir being out of commission until sometime between 2030 and 2035, therefore the UWMP accurately reflects the cumulative nature of new development on water supply and the timeline of the Project.

Long-term, the Project would restore storage at Anderson Reservoir, which would support the availability of water in normal, dry, and multiple dry years. In addition, potential future projects in Table 3.01-2 include other reservoir retrofits (at Calero, Almaden, and Guadalupe Reservoirs), all of which would restore available water storage in the County; Pacheco Reservoir Expansion Project and B.F. Sisk Dam Raise and Reservoir Expansion, which would provide new storage for Valley Water; Silicon Valley Purified Water Project, Valley Water Additional Conservation and Stormwater Projects and Programs, and the Countywide Water Reuse Master Plan that would provide a new water source. These water storage and water supply projects may be needed to address cumulative growth throughout the County and cause significant cumulative impacts; however, the Project's contribution to the need for additional water supplies requiring new or expanded facilities is not cumulatively considerable.

Significance Conclusion Summary

The Project would make Anderson Dam seismically safe, compliant with safety standards, and restore historic storage capacities, which would support water supply in the County.

During construction of the Seismic Retrofit, modeling results indicate that there may be a reduction in groundwater recharge and storage downstream of the dam during construction, but that simulated groundwater storage would remain above the 5,000 AF outcome measure for Coyote Valley. The Project's regional impact to the availability of long-term water supplies and need for new or expanded water facilities is not cumulatively considerable.

There is potential for small private wells located along the rim of Anderson Reservoir (outside of the managed Coyote Valley aquifer boundary) to be significantly adversely affected by the prolonged dewatering of the reservoir, as this could affect the lateral movement of groundwater and the hydraulic head in the area (potentially affecting the productivity of the wells). The impact when added to FOCP impacts is cumulatively significant and the Project's contribution to the potential need for new or improved wells around Anderson Reservoir is cumulatively considerable.

The Project ~~and FOCP~~ could ~~both~~ pollute groundwater resources through the introduction of perchlorates or other nitrogen-based chemicals by blasting activities. <u>The FOCP does not require use of explosives that may contain perchlorate or other nitrogen-based chemicals</u>. ~~The cumulative impact with FOCP would be significant, and the Project's contribution would be cumulatively considerable~~. Implementation of **Mitigation Measure GW-2** (Perchlorate Best Management Practices) would ensure that risks to groundwater pollution are minimized and the Project's contribution is **not cumulatively considerable**.

With the implementation of **Mitigation Measure GW-1** (Provide Alternative Water Supplies), no new or expanded private wells (located along the rim of the reservoir) would be necessary due to water table effects associated with the reservoir remaining in a dewatered state during the FOCP and Project construction period. Additionally, **Mitigation Measure GW-2** (Perchlorate Best Management Practices) will be implemented to avoid or minimize impacts on groundwater wells in the vicinity of Anderson Dam from blasting activities. Post-mitigation, the Project's impacts would **not be cumulatively considerable.**

3.14 Water Quality

This section presents the environmental setting, regulatory setting, and impact analysis, and proposed mitigation measures for the Project's impacts on water quality. Water quality refers to the chemical, physical, and biological characteristics of water. The study area for this analysis includes Anderson Reservoir and all downstream potentially affected surface waters, including Coyote Creek out to South San Francisco Bay. The study area does not include Upper Penitencia Creek or other tributaries downstream of Anderson Reservoir. Fish rescued as part of the Project may be relocated to Upper Penitencia Creek, but this would not adversely affect water quality in Upper Penitencia Creek. Flows from Anderson Reservoir and Coyote Creek cannot flow upstream into tributaries. Additional discussion of water quality or water quality-related information can be found in Section 3.4, *Biological Resources – Fisheries*; Section 3.11, *Hydrology*; Section 3.12, *Groundwater Resources*; Section 3.13, *Water Supply*; Appendix F, *Biological Resources – Fisheries Technical Appendix*; Appendix K, *Hydrology Technical Appendix*; and Appendix L, *Water Quality Technical Memorandum* ~~*Appendix*~~.

3.14.1 Environmental Setting

The Coyote Creek Watershed is the largest watershed in the county, draining approximately 322 square miles, and extending from the urbanized valley floor upward to the natural areas of the Mt. Hamilton range (Valley Water 2021a). Anderson Reservoir has a catchment area of roughly 193 square miles (Valley Water 2020a).

The Project Area includes Anderson Reservoir, Anderson Dam, Ogier Ponds, the Coyote Percolation Dam, and approximately 10 miles of Coyote Creek channel located between Anderson Dam and the downstream edge of the Coyote Percolation Pond where the Phase 2 Coyote Percolation Dam CM would be implemented (**Figure 3.14-1**). The study area includes Coyote Creek downstream to the tidelands area of the Bay. This section provides a summary of information on historic and existing water quality for the impact evaluation conducted for the Project. The information presented is primarily for Pre-FERC Order Baseline Conditions, with occasional references to more recent data.

Flows in Coyote Creek below Anderson Dam are affected by releases from Anderson Reservoir, releases of imported water via the Coyote Discharge Line, and the hydroelectric facility downstream from the dam. USGS streamflow station 11170000 (previously, Valley Water SF82), Coyote Creek near Madrone, California is the nearest location that measures these releases. The median flows by month, for the water years 2000 through 2019, shows a range of 40-50 cfs in the summer (June to September) and 20-25 cfs in the winter (January to March) (Valley Water, 2021c ~~undated 1~~). Greater summer releases reflect Valley Water operations to replenish the groundwater subbasin.

Anderson Reservoir Water and Sediment Quality

Historically (i.e., prior to the drawdown implemented to respond to FERC's February 20, 2020 Order), near-surface temperatures within the reservoir ranged from 10 to 12 °C in winter and 23 to 25 °C in summer (**Table 3.14-1**). Similar values were recorded in 2021 following the drawdown of the reservoir, with temperatures ranging between 9 and 12 °C in January and February and 22 and 24 °C in June and July (Valley Water 2021b ~~2021e~~). Typically, water temperatures in the reservoir stratify seasonally with cooler water toward the bottom, gradually increasing toward the surface during summer and fall. Water temperatures in the reservoir become more uniform top to bottom in winter and early spring (Valley Water, 2021c ~~undated 1~~).

Similar to the temperature conditions in the reservoir noted above, historically prior to implementation of the FERC Order, DO in the reservoir also stratified seasonally in summer and fall. As the reservoir warmed, fair weather conditions reduce reservoir mixing, and DO is used by fish, aquatic plants and algae, and bacteria, anoxic conditions could be created at the reservoir bottom. The stratified conditions supported higher DO levels toward the reservoir surface. DO levels became more uniform with cooler reservoir temperatures and the seasonal mixing of the water column in winter and early spring. Reservoir stratification and oxygen depletion varied based on many factors including water storage, which outlet portal was in use, the rate of outlet portal release, water residence time, fetch, wind, and natural climate fluctuations.

Prior to implementation of the FERC Order near-surface turbidity readings in the reservoir were typically between 1 and 5 NTU but could reach higher levels following large rain events. Some turbidity measurements have been collected within tributary creeks that provide insight into the relationship between influent turbidity and turbidity in the reservoir. Valley Water monitoring data (unpublished) recorded that turbidity in the Las Animas Creek and Packwood Creek tributaries increased to 550 NTU and 210 NTU, respectively, after a March storm event in 2011, whereas turbidity within the reservoir itself was elevated to only about 25 NTU after that storm event, indicating that the reservoir has an overall moderating (settling) effect on natural precipitation related increases in turbidity.

Historically, pH has ranged from 7.4–8.8 in the reservoir, with an average of and averaging approximately 8.1. More recent pH readings have been similar (average of 8.0 for the period of December 1, 2021, to December 15, 2021) (Valley Water 2021c ~~f~~).

Table 3.14-1. Reservoir Near Surface Water Quality Summary, 2004-2019 Averages

Sample Month	Temperature (°C)	Turbidity (NTU)	pH
February	11.2	4.8	8.0
May	18.3	2.5	8.2
August/September	23.8	1.8	8.3
November/December	16.6	48.8	8.1

Source: Valley Water 2021c ~~undated 1~~

~~As noted above, under~~ Under the 2024 CWA Section 303(d) list, water quality in Anderson Reservoir is listed as impaired for mercury and polychlorinated biphenyls (PCBs). Mercury is a naturally occurring trace metal that primarily enters water bodies through geologic or atmospheric sources. Mercury may be present in sediments that have accumulated due to erosion of geologic formations containing mercury, or as a result of significant air deposition over time. PCBs are synthetic organic chemicals that were used for numerous industrial applications until manufacturing was banned in 1979. They are relatively insoluble in water and tend to adsorb to sediments and suspended particulate matter (NCBI 2021, as cited in Valley Water 2021b ~~2021e~~). While Anderson Reservoir is listed as impaired under Section 303(d), mercury and PCBs have not been detected in any near-surface water samples of Anderson Reservoir in recent years (2004-2019) (Valley Water 2021c ~~Undated~~). Additionally, sediment sampling in preparation for and during FOCP construction found that mercury and PCB concentrations in Anderson Reservoir sediments were below sediment screening values for both pollutants (**Table 3.14-2**, Stillwater Sciences 2024).

Figure 3.14-1 Coyote Creek and Anderson Dam Watersheds

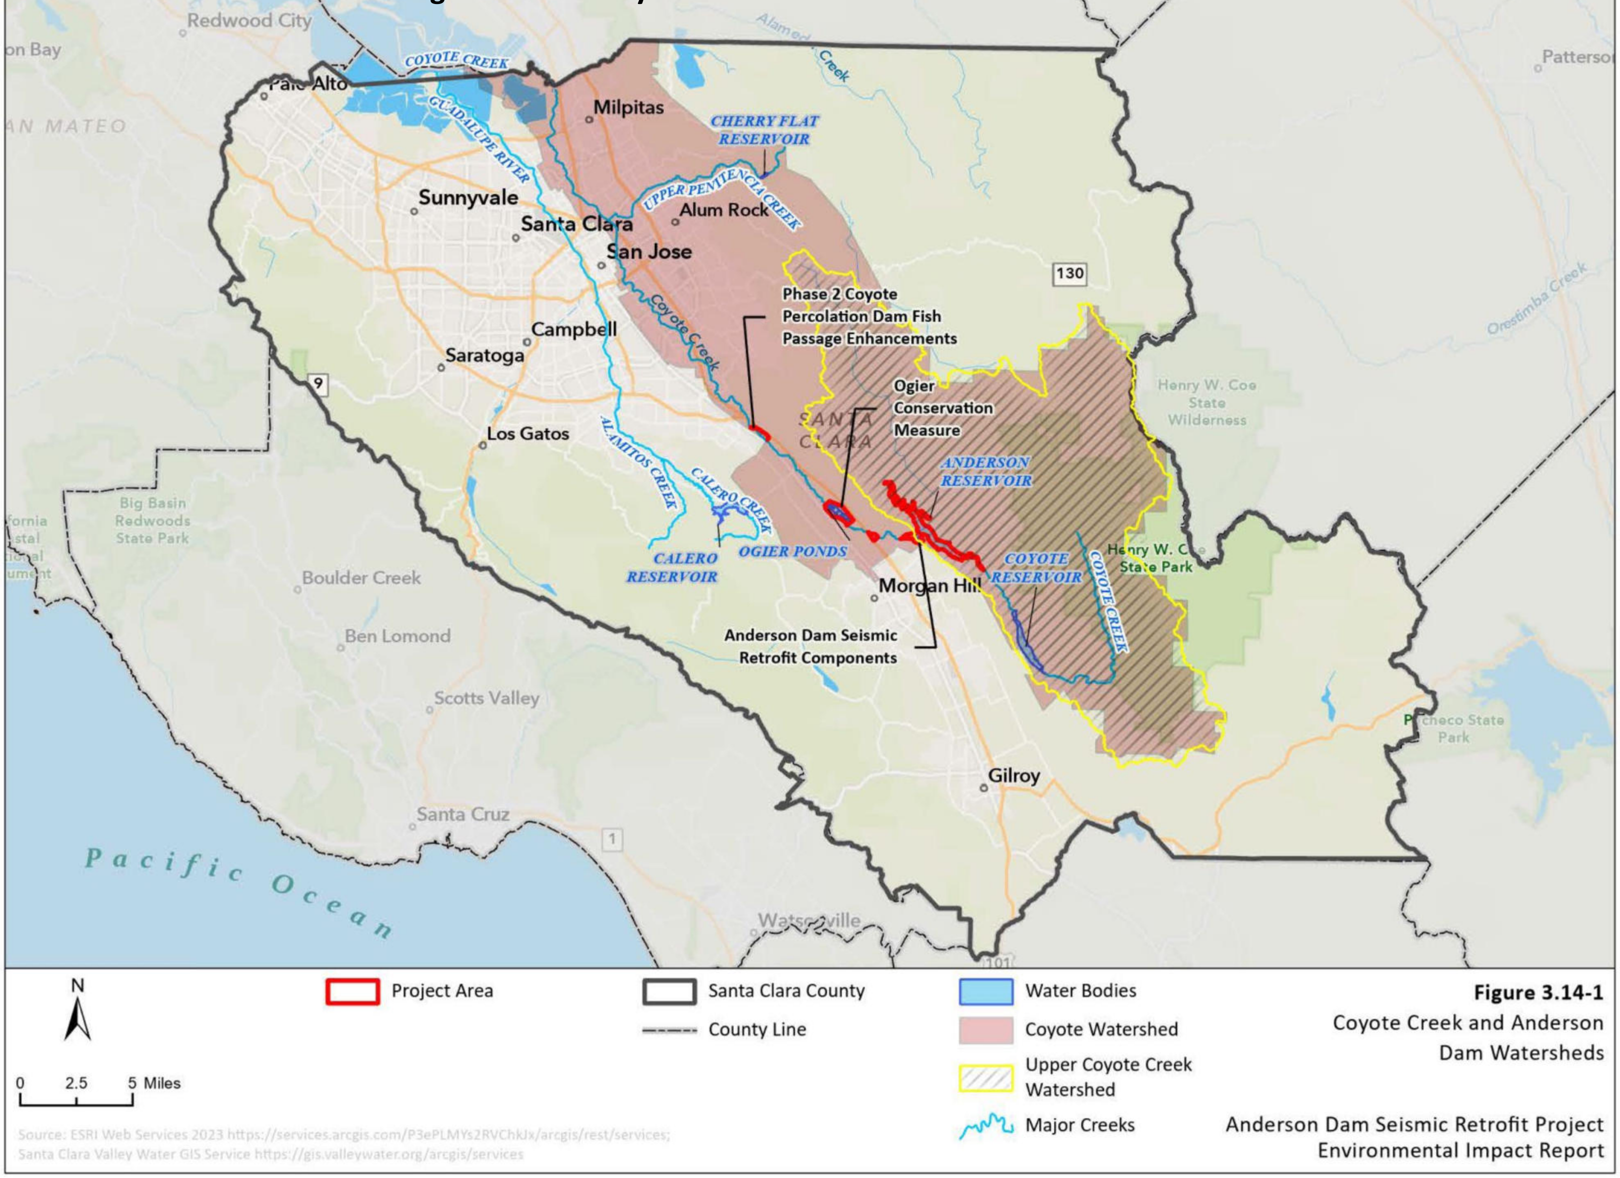

Table 3.14-2 Sediment Quality Screening Values for Mercury and PCBs

Analyte	Weighted Average ~~(µg /kg)~~	Reuse Criteria ~~(µg /kg)~~
Mercury	0.07 (mg /kg)	1.0 (mg /kg)
PCBs	6.3 (µg /kg)	22.7 (µg /kg)

Source: Stillwater Sciences 2024 ~~Valley Water 2023d~~

Key: ~~Mg~~ mg = milligrams; kg = kilograms; µg = micrograms

The source of mercury to Anderson Reservoir is unknown but it is assumed to be naturally occurring in local geology and deposited to the watershed atmospherically (Valley Water 2021b ~~2021e~~). Similarly, the source of PCBs to Anderson Reservoir is unknown (Valley Water 2021b ~~2021e~~). Sediment PCB data ~~are nonexistent~~ for Anderson Reservoir collected as part of the FOCP were below sediment screening values.~~, but~~ In addition, current surface sediment concentrations are assumed to be low, as PCBs have never been detected in outflow from Anderson Reservoir (Valley Water 2021b ~~2021e~~). Sediment samples indicate that PCBs and Mercury are not adhered to reservoir sediments in concentrations that exceed screening values assigned for each constituent that indicate the potential for water quality impact.

Anderson Reservoir is not identified on the 2024 CWA Section 303(d) list as impaired for diazinon (SWRCB 2024). Diazinon was banned for residential use in 2004 and there is no agricultural source of diazinon near Anderson Reservoir. While tributaries to Anderson Reservoir, including Coyote Creek, are impaired for diazinon, none of the five samples collected and tested as required by the FOCP water quality certification exceeded regulatory thresholds for listing diazinon (SWRCB 2024). Available monitoring data indicate low levels of diazinon in sediments and water mobilized from Anderson Reservoir as stated in the *Anderson Dam and Reservoir FERC Order Compliance Project Water Quality Certification Condition 8: Mercury, Diazinon, and PCBs Plan* (Valley Water 2021d). In addition, in consultation with RWQCB staff, it was determined that no further testing is necessary, nor are any diazinon-specific control measures necessary during the implementation of the FOCP.

Coyote Creek Water Quality

Under the 2024 CWA Section 303(d) list, water quality in Coyote Creek is identified as impaired for ~~Diazinon~~ pesticides (diazinon, bifenthrin, cypermethrin, and pyrethroids), toxicity, ~~and~~ trash, dissolved oxygen, and mercury. A study by Santa Clara Valley Urban Runoff Pollution Prevention Program (SCVURPPP) found that over a period of 14 years, sediment toxicity in Coyote Creek has been decreasing and sediment toxicity is generally not present in Coyote Creek (SCVURPPP 2020).

Anderson Reservoir to Ogier Ponds

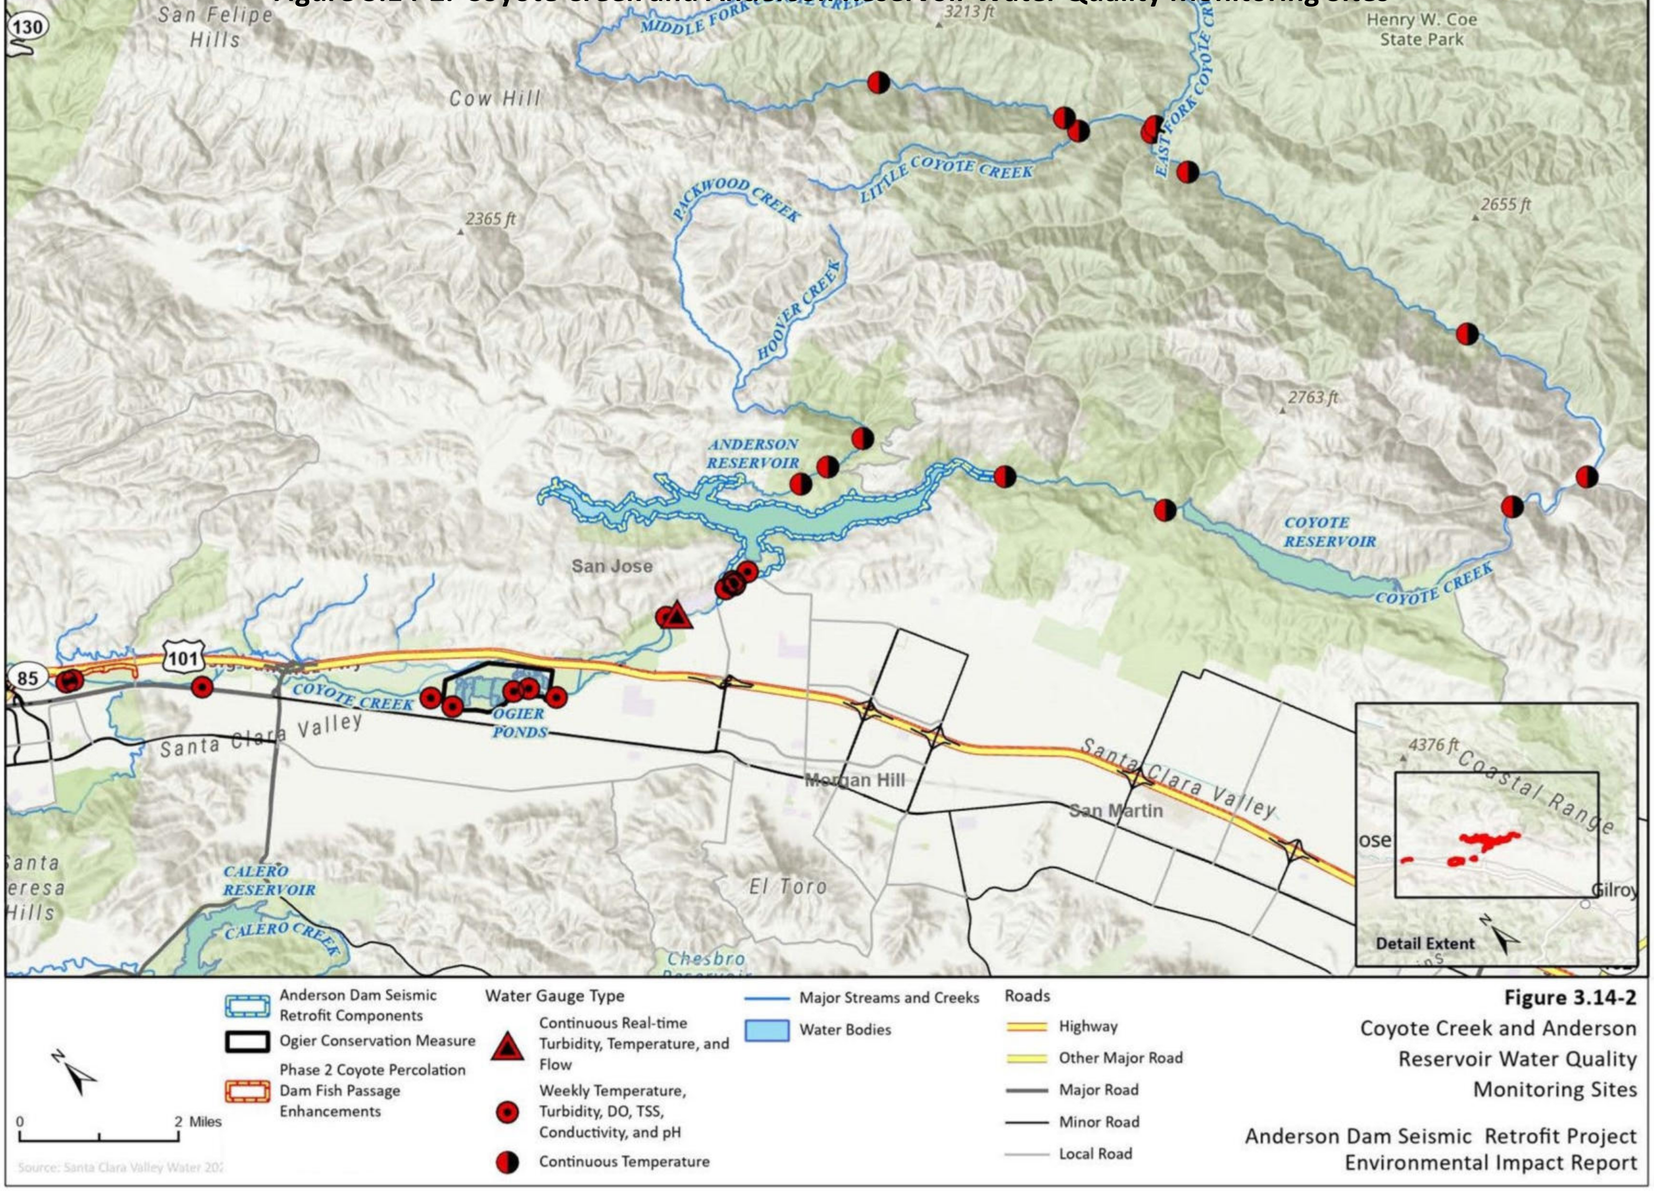
Valley Water has monitored water temperature at multiple sites along Coyote Creek downstream of Anderson Dam for many years. More recently Valley Water has added turbidity, DO, pH, and conductivity to monitoring efforts at some sites (**Figure 3.14-2**). Unpublished temperature data collected by Valley Water in 2005, 2007, 2008, 2009, and, more recently, in 2021, were reviewed for this analysis. Valley Water aggregated and corrected the raw data from these years, as needed, to determine daily average, minimum, and maximum temperatures. The results of these monitoring efforts are summarized below.

Water temperatures in Coyote Creek below Anderson Dam are driven by the volumes of local and imported water used and the elevation of the reservoir cold-water pool in relation to the inlet port being used for releases. From late spring through early fall, water is released from the deep, cold-water pool in Anderson Reservoir to Coyote Creek for groundwater recharge, which also helps maintain cooler water temperatures in the FCWMZ downstream of the dam. Creek temperatures generally fluctuate between 18 °C and 24 °C during the summer and between 8 °C and 12 °C in the winter. Creek temperatures generally peak in July (24 °C) and are coolest in December and January (around 10 °C). In July and August 2021, maximum weekly average temperatures at monitoring sites ranged from 22–25 °C.

Based on a review of available data, Coyote Creek water temperatures in the reach from the dam outlet to the Model Airplane Park (approximately 2.8 miles downstream and within the FCWMZ) appear to be particularly influenced by cooler reservoir discharges from the Anderson Outlet. Downstream of the Model Airplane Park, the channel becomes wider, shallower, and less shaded, and temperatures increase by approximately 2 to 3 °C at the Ogier Ponds and Coyote Creek Golf Course, approximately 4 miles downstream from the dam.

Over that same period, daily mean DO levels at sites between the dam and Ogier Ponds ranged from approximately 6.7 to 9 mg/L. Portions of Coyote Creek can become completely dry during much of the dry season.

Figure 3.14-2. Coyote Creek and Anderson Reservoir Water Quality Monitoring Sites



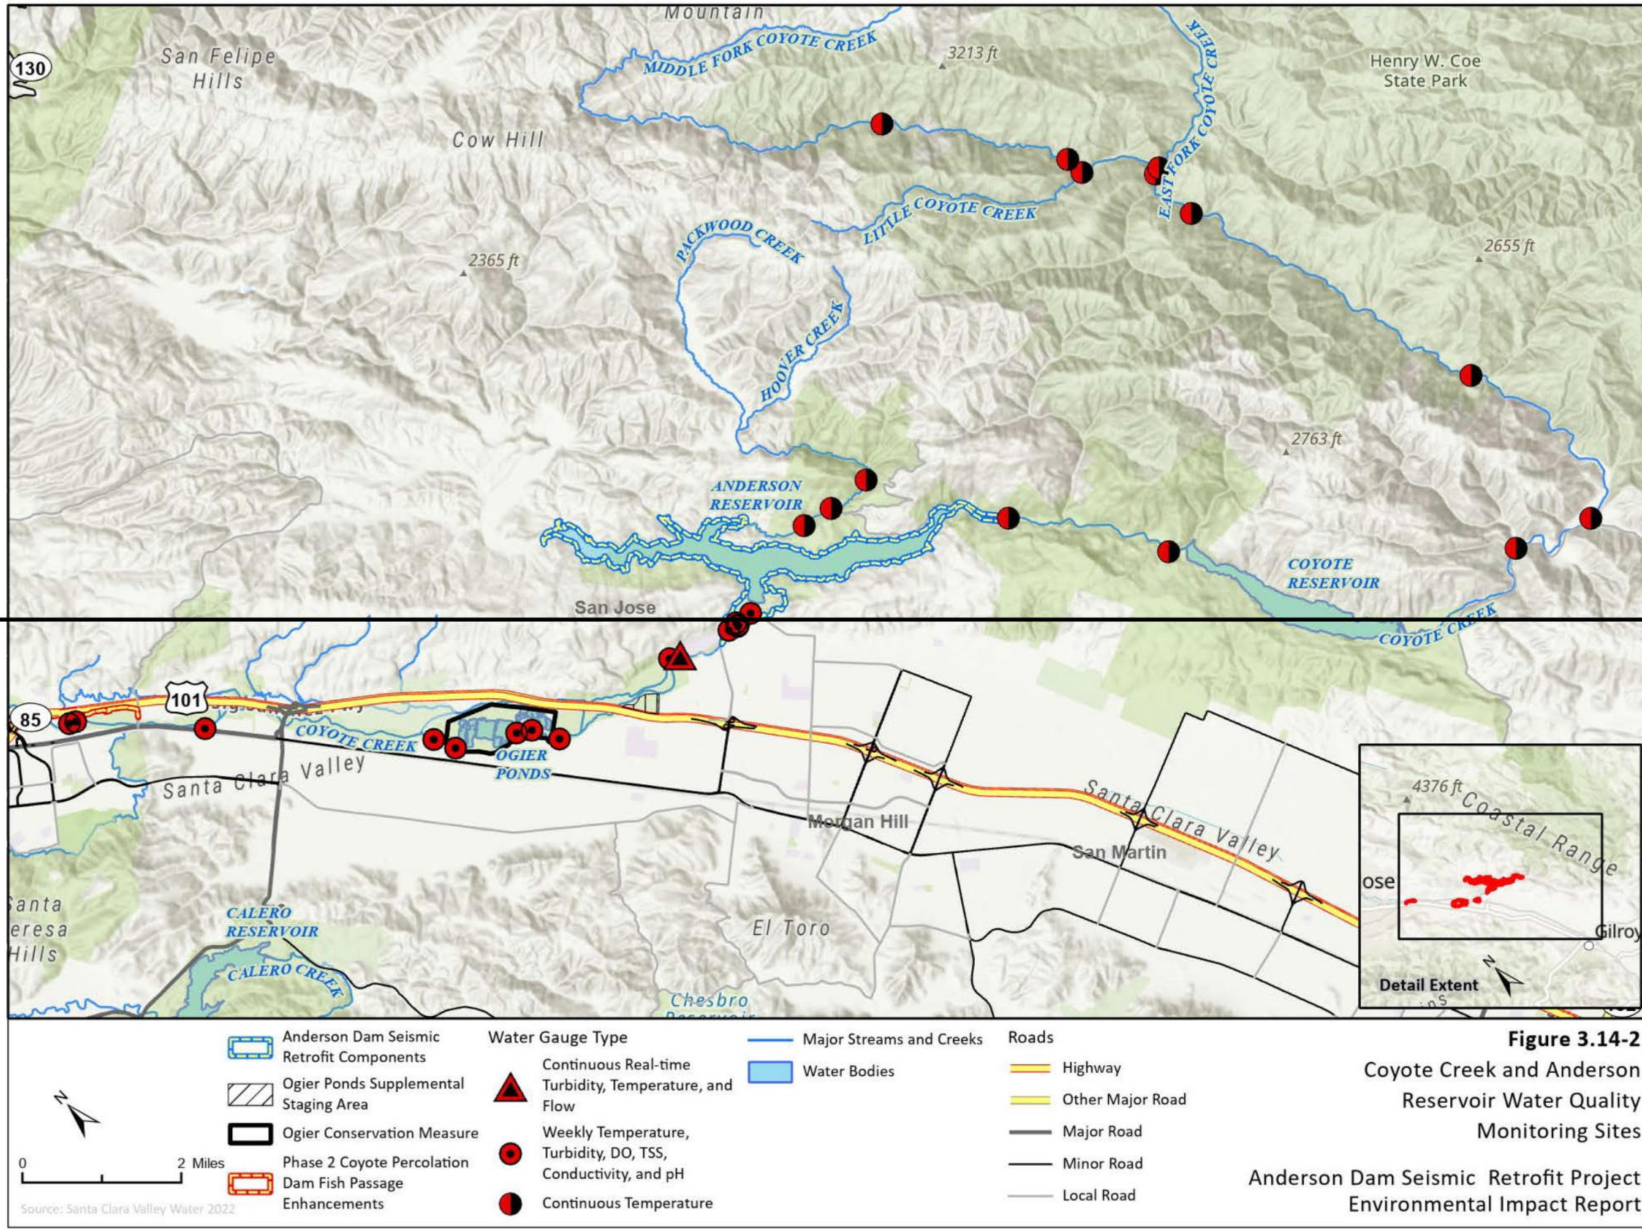


Figure 3.14-2
Coyote Creek and Anderson Reservoir Water Quality Monitoring Sites

Downstream of Ogier Ponds

Recent SCVURPPP annual Urban Creeks Monitoring Reports have presented results from water quality monitoring and sediment sampling on Coyote Creek (SCVURPPP 2018, 2019). In Water Years (WY) 2017 and 2018, general water quality parameters (pH, DO, specific conductance, and temperature) were measured at three stations in lower Coyote Creek (downstream of Ogier Ponds between I-280 and US 101 near Valley Water's COY03) over two 2-week periods in June and September. In 2017, the general water quality parameters were similar among the stations with the exception of DO, which displayed different patterns at the sites. These findings were consistent with SCVURPPP's Coyote Creek Dissolved Oxygen Stressor Source Identification (SSID) Project, which concluded that low gradient channels and high amounts of accumulated organic material in the studied reach cause low DO concentrations.

These sites did not exceed the San Francisco Bay Municipal Regional Stormwater Permit maximum temperature SSID trigger threshold of 24 °C but did exceed the MWAT SSID trigger of 17 °C for two consecutive weeks during both sampling periods for WYs 2017 and 2018.

In both WYs 2017 and 2018, the DO levels in waters designated as having cold freshwater habitat (COLD) beneficial uses (i.e., 7 mg/L) were not met in over 20 percent of the measurements recorded at all three water quality stations in Coyote Creek. The results were similar to the findings from previous studies carried out at the same locations below Ogier Ponds. The low DO concentrations were caused by low gradient channels with high amounts of accumulated organic material.

Values for pH and specific conductivity measured at the three sites in Coyote Creek downstream of Ogier Pond between I-280 and US 101 near Valley Water's COY03) during WYs 2017 and 2018 did not exceed their respective SSUD triggers during either event.

Coyote Creek Estuary and South San Francisco Bay Water Quality

In July 2013, San Francisco Estuary Institute began continuous water quality monitoring for several parameters in San Francisco Bay. DO in the South San Francisco Bay typically ranges from roughly 6 mg/L in the summer to 8.5 or 9 mg/L in the winter months, with levels at Coyote Creek at Alviso Slough dropping as low as 2-3 mg/L in the summer (San Francisco Estuary Institute 2023, San Francisco Bay Nutrients Visualization Tool 2023). Water temperatures in the South San Francisco Bay (at Coyote Creek at Alviso Slough) typically fluctuate between roughly 10 °C in the winter and 24-25 °C in the summer. Turbidity at Coyote Creek at Alviso Slough can fluctuate greatly from about 15 to over 1,000 Formazin Nephelometric Unit (San Francisco Bay Nutrients Visualization Tool 2023).

Imported Water Quality

Imported water <u>from</u> San Luis Reservoir is released Anderson Reservoir and/or Coyote Creek through the CDL to augment groundwater recharge and incidentally improve instream flow volumes and temperatures for fisheries and riparian and groundwater dependent habitat. The imported water comes from San Luis Reservoir, which is part of the Central Valley Project and State Water Project <u>and stores imported water from the San Juaquin-Sacramento Bay Delta</u>. Imported water is sometimes released directly to Coyote Creek through the CDL or at other times is mixed with local water in the reservoir before release, particularly depending upon relative temperature of the reservoir and imported water supplies. Water quality for imported water in San Luis Reservoir is summarized in **Table 3.14-3** below.

Table 3.14-3. San Luis Reservoir Water Quality Summary, 2020-2021 Averages

Sample Month	Temperature (°C)	Turbidity (NTU)	pH
February	14.6	1.0	7.3
May	15.4	1.25	7.4
August	20.3	2.1	8.3
October - December	-	1.7	7.3

3.14.2 Regulatory Setting

3.14.2.1 Federal Laws, Regulations, and Policies

Clean Water Act

The CWA is the primary federal law that protects the quality of the nation's surface waters, including lakes, rivers, and coastal wetlands. The key sections of the CWA that pertain to water quality regulation are sections 303, 401, 402, and 404 (discussed hereunder).

Section 303, Impaired Water Bodies

Under CWA Section 303[d], states are required to identify "impaired water bodies" (those that do not meet established water quality standards), identify the pollutants causing the impairment, establish priority rankings for waters on the list, and develop a schedule for preparing control plans to improve water quality. Following listing, USEPA then approves the state's recommended list of impaired waters or adds and/or removes water bodies to the list. Each RWQCB must update the Section 303[d] list of impaired waters every 2 years. Water bodies on the list have no further assimilative capacity for the identified pollutant, and the Section 303[d] List identifies priorities to develop pollution control plans for each listed water body and pollutant.

The 2024 303(d) list was approved by the SWRCB in March 2024, and partially approved and partially disapproved by the USEPA on December 12, 2024. According to the 2024 303(d) ~~most current~~ list approved by the SWRCB, Anderson Reservoir is listed as impaired for mercury and PCBs, and Coyote Creek is listed as impaired for trash ~~and~~, pesticides (diazinon, bifenthrin, cypermethrin, and pyrethroids), toxicity, dissolved oxygen, and mercury). The South (Lower) San Francisco Bay, to which Coyote Creek drains, is listed as impaired by chlordane, dichlorodiphenyltrichloroethane (DDT), dieldrin, dioxin compounds, furan compounds, invasive species, mercury, PCBs, polycyclic aromatic hydrocarbons (PAHs), toxicity, trash, and selenium from multiple known and unknown sources (SWRCB 2024 ~~2017~~). The USEPA disapproved the omission of Coyote Creek as impaired for benthic community effects and recommended that this impairment be added to the 2024 303(d) list. At the time of preparation of this Final EIR in December 2024, the addition of this impairment to the 303(d) list had not been approved or incorporated into the final 2024 303(d) list. After a 30-day public comment period, the USEPA will transmit the final list of impairments that EPA is adding to the 303(d) list to the SWRCB (USEPA 2024).

The pollution control plans triggered by the CWA Section 303[d] List are called Total Maximum Daily Loads (TMDL). The TMDL is a “pollution budget” designed to restore the health of a polluted body of water. A TMDL is a calculation of the maximum amount of a pollutant that a water body can receive and still meet water quality standards, thereby ensuring the protection of beneficial uses. A TMDL also contains the target reductions needed to meet water quality standards and allocates those reductions among the pollutant sources in the watershed (point sources, non-point sources, and natural sources). The TMDL process quantifies water quality problems, identifies pollutant sources, and recommends pollutant load reductions or control actions needed to restore and protect the beneficial uses of the impaired water body. The calculation of a TMDL includes a margin of safety and considers seasonal variations (40 CFR Section 130.2). TMDLs for ~~the South San Francisco Bay that are relevant to the~~ receiving waters downstream of Anderson Reservoir ~~and Coyote Creek~~ include the San Francisco Bay Mercury TMDL (approved by USEPA in 2008), San Francisco Bay PCBs TMDL (approved by USEPA in 2010), and Diazinon and Pesticide-Related Toxicity in Urban Creeks ~~Dioxin Pesticide Toxicity~~ TMDL (approved by USEPA in 2007).

Project applicability: Project activities would occur within water bodies listed as impaired under Section 303(d), for which TMDLs have been implemented or will be developed.

Section 401, Water Quality Certification

For an applicant of a federal permit or license to conduct any activity that may result in a point source discharge of a pollutant to a water of the United States, Section 401 of the CWA requires the State to issue a certification that the activity will comply with the state’s water quality standards. The state may grant, grant with technical conditions imposed on the project activity, or deny the Section 401 certification.

The discharge of dredged or fill material into waters of the United States, including wetlands, as determined by USACE, is subject to permitting specified under Section 404 of the CWA (Discharges of Dredge or Fill Material), discussed below. A Section 401 water quality certification is required for all Section 404 permitted activities. In California, the SWRCB or its nine RWQCBs issue water quality certifications. The SWRCB or RWQCB is responsible for implementing section 401 in compliance with the CWA and the applicable regional water quality control plan (also known as a basin plan).

Project applicability: Given that the Project would involve, among other activities, the discharge of dredge and fill material into Coyote Creek to seismically retrofit Anderson dam, which is a facility that FERC has exempted from licensing under the Federal Power Act, it will also require issuance of a 401 water quality certification by the SWRCB, which is the water board that has jurisdiction over the project under 23 CCR Section 3855. Projects that require a 404 permit for discharge of dredged and fill materials are also required to obtain a 401 water quality certification.

Section 404, Permits for Fill Placement in Waters and Wetlands

CWA Section 404 regulates the discharge of dredged and fill materials into “waters of the United States,” or jurisdictional waters, which include oceans, bays, rivers, streams, lakes, ponds, and wetlands. Before any actions that may discharge dredged or fill material into surface waters or wetlands are carried out, a delineation of jurisdictional waters of the United States must be completed, following USACE protocols (USACE 1987), in order to determine whether the project area encompasses wetlands or other waters of the United States that qualify for CWA protection.

For actions that will discharge dredged or fill material into waters of the United States, a permit must be obtained from the USACE, unless the activity is exempt from Section 404 regulation (e.g., certain farming and forestry activities).

Under USEPA guidelines, no discharge of dredged or fill material may be permitted if: (1) a practicable alternative exists that is less damaging to the aquatic environment, or (2) the nation’s waters would be significantly degraded (USEPA 2023a). In other words, applicants must first show that steps have been taken to avoid impacts to wetlands, streams and other aquatic resources; that potential impacts have been minimized; and that compensation will be provided for all remaining unavoidable impacts (USEPA 2023a). For most discharges that will have only minimal adverse effects, a general permit may be suitable. General permits are issued on a nationwide, regional, or state basis for particular categories of activities (USEPA 2023a). For proposed activities that have potentially significant impacts, an individual permit is required.

Project applicability: Coyote Creek and Anderson Reservoir would be considered navigable waters, which would be subject to Section 404 and USACE jurisdiction. The Project would involve discharge of dredged and fill materials to such jurisdictional waters, and therefore will require a Section 404 permit from USACE.

Section 402, Permits for Stormwater Discharge

CWA Section 402 regulates discharges of pollutants to surface waters through the NPDES program. The NPDES program is officially administered by the USEPA. However, in California, the USEPA has delegated its authority to the SWRCB; the SWRCB in turn delegates implementation responsibility to the nine RWQCBs, as discussed in Porter-Cologne Water Quality Control Act below. The NPDES program provides for both general permits (those that cover a number of similar or related activities) and individual (activity- or project-specific) permits. Please see below under “State Laws, Regulations, and Policies” for discussion of the Construction General Permit and the Municipal Regional Stormwater NPDES permit, which would be applicable to the Project.

3.14.2.2 State Laws, Policies, and Regulations

Porter-Cologne Water Quality Act

The Porter-Cologne Water Quality Control Act (Porter-Cologne Act) is the primary State regulation governing water quality. The Porter-Cologne Act was passed in 1969, and together with the CWA, provides regulatory guidance to protect water quality and water resources in the state. The Porter-Cologne Act established the SWRCB and divided California into nine regions, each overseen by a RWQCB. The Porter-Cologne Act established regulatory authority over discharges to “waters of the State,” which are defined as “any surface water or groundwater, including saline waters, within the boundaries of the State” (California Water Code, Division 7, Section 13050). More specifically, the SWRCB and its nine RWQCBs have jurisdiction over the beneficial uses and supporting water quality objectives (WQOs~~)~~ assigned by the RWQCB or

SWRCB for various waters of the State. The Porter-Cologne Act also assigned responsibility for implementing CWA sections 303, 401, and 402 within California to the SWRCB and RWQCBs.

The Porter-Cologne Act authorizes the SWRCB to adopt statewide water quality control policies and requires each of the nine RWQCBs to develop and periodically review of regional water quality control plans (basin plans) for the protection of water quality s in each of California's nine regions. Statewide water quality control policies are adopted and maintained by the SWRCB. Regional basin plans are unique to each region and must identify beneficial uses, establish WQOs for the reasonable protection of the beneficial uses, and establish a program of implementation for achieving the WQOs. Basin plans must also comply with Section 303 of the CWA, which requires states to establish their own water quality standards. Basin plans provide the technical basis for the RWQCBs to determine waste discharge requirements, issue CWA Section 402 permits and Section 401 certifications, take enforcement actions, and evaluate grant proposals. In 2024, AB 2875 established a State policy to ensure no net loss, and long-term gains, in the quantity, quality, and permanence of wetlands acreage.

San Francisco Bay Basin Plan

The portions of the county that drain to San Francisco Bay are governed by the San Francisco Bay Basin Plan (San Francisco Bay RWQCB 2019 ~~2023~~). The beneficial uses established in the San Francisco Bay Basin Plan for surface waters in the Project area are shown in **Table 3.14-4**. The Project area is located within the Santa Clara Basin. The Basin Plan also establishes water quality objectives to protect beneficial uses (i.e., WQOs). Key WQOs established in the Basin Plan that apply to the Project are listed below:

- DO in non-tidal waters: Cold water habitat: 7.0 mg/L; Warm water habitat: 5.0 mg/L.
- Temperature: The temperature of any cold or warm freshwater habitat shall not be increased by more than 5°F (2.8°C) above natural receiving water temperature.
- Turbidity: Increases from normal background light penetration or turbidity relatable to waste discharge shall not be greater than 10 percent in areas where natural turbidity is greater than 50 NTU.
- pH: The pH shall not be depressed below 6.5 nor raised above 8.5. This encompasses the pH range usually found in waters within the basin. Controllable water quality factors shall not cause changes greater than 0.5 units in normal ambient pH levels.
- Toxicity: All waters shall be maintained free of toxic substances in concentrations that are lethal to or that produce other detrimental responses in aquatic organisms. Detrimental responses include, but are not limited to, decreased growth rate and decreased reproductive success of resident or indicator species. There shall be no acute or chronic toxicity in ambient waters. Acute toxicity is defined as a median of less than 90 percent survival, or less than 70 percent survival, 10 percent of the time, of test organisms in a 96-hour static or continuous flow test.

Project applicability: The Project would affect Anderson Reservoir, Coyote Creek, Coyote Slough (tidally influenced), and South San Francisco Bay, for which beneficial uses have been designated by San Francisco Bay RWQCB. Thus, the Project would be subject to the San Francisco Bay Basin Plan and the impact analysis (Section 3.14.4) considers the potential for impacts on the applicable beneficial uses.

Table 3.14-4. Beneficial Uses of Surface Water Bodies in the Project Area

Water Body	Beneficial Uses[1]																		
	AGR	MUN	FRSH	GWR	IND	PROC	COMM	SHELL	COLD	EST	MAR	MIGR	RARE	SPWN	WARM	WILD	REC-1	REC-2	NAV
Santa Clara Basin																			
San Francisco Bay South					E		E	E		E		E	E	E		E	E	E	E
Coyote Slough										E			E			E	E	E	
Coyote Creek (nontidal)				E			E		E			E	E	E	E	E	E	E	
Anderson Reservoir		E		E			E		E					E	E	E	E*	E	

Source: San Francisco Bay RWQCB 2019 ~~2023~~

Notes:

[1] Beneficial Uses are defined as: Agricultural Supply (AGR), Cold Freshwater Habitat (COLD), Ocean, Commercial, and Sport Fishing (COMM), Estuarine Habitat (EST), Freshwater Replenishment (FRSH), Groundwater Recharge (GWR), Industrial Service Supply (IND), Marine Habitat (MAR), Fish Migration (MIGR), Municipal and Domestic Supply (MUN), Navigation (NAV), Industrial Process Supply (PRO), Preservation of Rare and Endangered Species (RARE), Water Contact Recreation (REC-1), Non-contact Water Recreation (REC-2), Shellfish Harvesting (SHELL), Fish Spawning (SPWN), Warm Freshwater Habitat (WARM), and Wildlife Habitat (WILD).

[2] E = existing beneficial use, E: Water quality objectives apply; water contact recreation is prohibited or limited to protect public health*

Construction General Permit

Most construction projects that disturb 1 acre of land or more are required to obtain coverage under the SWRCB's General Permit for Storm Water Discharges Associated with Construction and Land Disturbance Activities, (Order 2022-0057-DWQ; adopted on September 8, 2022 and effective September 1, 2023 – "Construction General Permit"), which requires the applicant to file a public notice of intent to discharge stormwater, and to prepare and implement a SWPPP. The SWPPP must include a site map and a description of the proposed construction activities; demonstrate compliance with relevant local ordinances and regulations; and present the BMPs that will be implemented to prevent discharge of pollutants associated with construction activities in storm water and runoff leaving a construction site. For example, BMPs must control soil erosion during construction, discharges of sediment, and discharges of other construction-related pollutants (such as concrete wash water, and heavy equipment fuels and lubricants) to surface waters. The SWPPP must also provide for implementation of visual and water quality sampling-based monitoring for discharges of runoff. The monitoring must be designed and conducted to assure ongoing compliance of storm water and runoff discharges from the construction site with the Construction General Permit.
